Elevation Difference Tolerance <0.0>: 
Use Report Formatter [Yes/<No>]? No will use the standard report window
Reading cell > 49410 Select the drillholes and strata polylines.

Pulldown Menu Location: Drillhole > Reports
Keyboard Command: chreport4
Prerequisite: Drillholes

Pit Channel Samples

Pit/Channel Samples - Import from Text File

This command creates channel samples from comma separated data in a text file. The command starts with a dialog to choose the symbol, symbol size and order of the data columns. Besides the attributes values, the text file must
include the sample northing and easting and a strata identifier of name or elevation. The text file should have comma separated columns of data with each row containing all the data for the sample.

The order of the columns is set in the dialog shown below. To add one of the standard column types, highlight the name from the Available list and click Add. To add a user-defined attribute such as BTU, click the Add Attribute button. Another dialog will appear for entering the attribute name.

Channel Samples can be used as "partial" drillholes or spot samples. They are used in conjunction with the drillholes for modeling.

![Import Channel Samples dialog](image)

**Prompts**

**Import Channel Samples dialog**

**Select Text File dialog**

Created 4 pit/channel samples.

Pulldown Menu Location: Drillhole

Keyboard Command: chansam

**Pit/Channel Samples - Import from CRD File**

This command creates channel samples from points in a coordinate file. Channel samples are strata data points that supplement drillholes. Unlike drillholes, channel samples are not correlated with other strata and are not used for pinch out or conformance. Channel samples represent one strata value such as thickness for strata COAL1. The coordinate file consists of point number, x, y, z data.

The command starts with a dialog to choose the symbol, symbol size and strata attribute name. Then you specify the coordinate file and the range of points to make into channel samples. Similar to drillhole symbols, the channel samples are drawn as the chosen symbol in the CHANNEL layer with the data attached to the symbol. The channel samples can be used in modeling routines such as Strata Isopach Maps or Make Strata Grid Files, by selecting the channel sample symbols along with the drillholes.
Prompts

Import Channel Sample Points dialog
Point numbers to convert: 1-100 or all or *
Point numbers to convert: press Enter
Pulldown Menu Location: Drillhole
Keyboard Command: chansam1

Export Pit/Channel Samples
This command creates a text file of sample data from the selected sample symbols in the drawing. The export file is in the format of Northing, Easting, Description, Strata Name, Attributes. This command is a way to back up the sample data. The export text file can be used to recreate sample symbols using the Import Samples routine.

Prompts

Export Text File to Write Specify a file name
Select samples to export.
Select objects: pick the sample symbols to export
Pulldown Menu Location: Drillhole
Keyboard Command: chansam4

Draw Pit/Channel Sample Text
This command labels the sample data next to the sample symbol. The format and label options are set in the dialog. After selecting the samples to label, the program will read the attribute names from the symbols and prompt at the command line for each one whether to label the attribute.
Prompts

Draw Sample Text dialog
Select samples to label
Select objects: *pick the sample symbols to label*
Label attribute BTU (*<Yes>*/*No*)? *press Enter for Yes*

Pulldown Menu Location: Drillhole
Keyboard Command: chantext

**Place Pit/Channel Sample**

This command creates channel samples at user-specified points and values. The command starts with a dialog to choose the symbol, symbol size, strata name and attribute names. The attribute names to assign are listed in order under the Used list. The Strata Thickness, Bottom Elevation and Top Elevation are the only pre-defined strata attributes. To add one of these attributes to the sample value list, highlight the attribute from the Available list and click Add. All other attributes are user-defined. To add a user-defined attribute, pick the Add Attribute button. Another dialog will appear for entering the attribute name. After filling out the dialog, pick OK. Then you pick the sample positions and enter the sample values at the prompting in the command line. Another option is to use the object snap and select something in the drawing with an elevation, such as a contour. The sample will then use that elevation, thickness or Z value for the sample value.
Prompts

Description «»:
Enter STRATA THICKNESS value: 3.2
Enter STRATA BOTTOM ELEV value: 4598.2
Enter CALCIUM value: 92.4
Pick channel sample location: press Enter
Pulldown Menu Location: Drillhole
Keyboard Command: chansam2

Edit Pit/Channel Sample

This command edits the strata name, attribute name or attribute value of a channel sample. To edit a channel sample, either pick on the symbol after executing the command or simply "double-click" on any sample point. Any changes are saved back to the data attached to the channel sample symbol. The Previous and Next buttons will advance between the different values such as Bottom Elev and Thickness.
Pick channel sample to edit: *pick a channel sample symbol*
Edit Channel Sample Points dialog
Pick channel sample to edit: *press Enter*

Pull-down Menu Location: Drillhole
Keyboard Command: chansam3

**Standard Drillhole Text**

This command draws text for the descriptions, surface elevation, strata names, bed names, thicknesses, attributes, and/or bottom elevations of the selected drillholes. Which values to draw is determined by the selections in the dialog shown below. When bed names are available they may be drawn next to the strata name.

The routine will use Define Strata to determine the full strata name, color and layer name for the strata text. The settings in Define Attribute are used to set the number of decimal places for attributes (i.e. 0 decimals for BTU and 2 decimals for sulfur). If there is no definition, then the text layer and decimals from the Draw Drillhole Text dialog are used.

The layout of the text can also be specified. **Draw attributes on separate lines** will create a new line for each attribute of each strata. Otherwise the attributes of a strata are grouped together on one line and in the **Delimiter** field you can set the text divider such as "/" to use between the values. **Group attributes by strata** will draw all the attributes for a strata together. Otherwise the attributes are grouped by attribute name such as having all sulfur attribute values drawn together.

The **Use Parameter File** option allows you to select a parameter file to filter the drillholes and draw text for only the drillholes that pass the filter. See Define Parameters for more on parameters. The **Draw Strip Ratio** labels the strip ratio for the drillhole from the surface down to the last selected strata. This is a thickness base ratio.

The **Starting Text Position** option allows you to add labels to drillholes with existing labels by shifting the starting text position to an open area. For example, if the drillholes already have two rows of labels, then use a starting text position of three.

**Text Alignment** chooses between drawing the text right justified to the right of the drillhole, center justified above the drillhole or center justified below the drillhole.

**Draw Text At Elevation** creates the labels at the surface elevation of the drillhole. Otherwise, the text is drawn at zero elevation.
Prompts

Draw Drillhole Text Dialog
Select the DrillHoles to label.
Select objects: pick the drillhole symbols
Choose Key Attributes to Draw Optionally choose attributes to label.
Choose Non-Key Attributes to Draw
Drillhole Text Formatter

This routine allows for flexible labeling of any data contained in the drillholes—also known as "posting drillholes." After selecting which drillholes to label, the program prompts whether to process beds. This option will composite the strata by bed name which groups the strata into seams such as bed_top, bed_key, bed_parting and bed_bottom. These composited values are then available for labeling. Without process beds, the strata are reported individually.

The Drillhole Text Format Options dialog is similar to the Drillhole Import routine and other commands in Carlson, where the available options are listed on the left and the used options are added to the right window. All the available strata are listed in the first list box and all the attributes for currently selected strata are listed in the second list box. When the selected available option is added, the next dialog appears for setting the format and location options. The settings can be saved to and recalled from a drillhole text format file.

- **Text Size:** Controls the size of text drawn
- **Text Offset:** Sets the distance from the center of the drillhole to the text
- **Label thickness for missing strata as Zero:** If the seam is not present in a hole, this option will label it as "0.0", otherwise there is no label
- **Prefix layers with drillhole type name:** This adds the Drillhole Type name to the layer as a prefix
- **Skip empty rows:** If a value is not existing in a hole, this option will skip it and go to the next one
- **Overlap labels with same row:** This option, if selected, will start the text at the same location if on the same row
- **Draw text at elevation:** This will draw the text up at elevation of the hole
- **Draw as MTEXT:** Selecting this will group the text as MText (multiline text), otherwise it is separate standard text for each text item.
- **Layer:** Sets the layer for each text line
- **Style:** Sets the text style
- **Color:** Places the text in this color
- **Label Prefix:** Add a prefix to the text, such as BTU: or Thickness:
- **Label Suffix:** Add a suffix such as ft or m
- **Decimals:** Controls the decimals of the values
- **Angle:** Allows to rotate the text, such as straight up, straight down, or 45 degrees etc.
- **Row Position:** Controls the row position counting both up or down from the symbol, based on whether it is set to above or below the symbol
Select the Drillholes to label.
Select objects: *pick the drillholes*
Process beds [<Yes>/No]? *Press Enter for yes.*

Drillhole Text Format Options dialog
Drop-Down Menu Location: Drillhole
Keyboard Command: chtext2

Draw Geologic Column

As the name suggests, this command draws geologic columns for the selected drillholes in both 2D and 3D. There are many options for Draw Geologic Column that are specified in the dialog box. Once you have the settings the way you want, you can save the settings to a geologic column settings file (.geo) that can be loaded later. This settings file allows you to store different schemes of geologic columns. Each setting and option is described separately below.

**Draw...:** The geologic columns can be drawn *In 3D, On 2D Grid or Next to the Drillhole.* For the 3D method, the column is drawn vertically straight down (or at an angle if the Azimuth and Dip are defined for the drillhole) at the X, Y position of the drillhole. This 3D column can be drawn as a cylinder or as flat rectangles as in the 2D grid option except this time in 3D. The settings for 3D are in the 3D Options screen. The *On 2D Grid* option will prompt for a starting position and start drawing the holes in a line from the starting point. When using this option, the next row is active to select the alignment. The *Next to Drillhole* option draws the column on a 2D grid to the right of each drillhole.

**3D Options:** The Column Format has two options to draw in 3D. The cylinder will draw faces that may be rendered in the 3D viewer, while the Rectangle just draws 3D polylines of the drillholes. The Vertical Exaggeration has two options for a starting point, either the Base Elevation entered below, or the Surface. The surface option will scale the
column elevations using the surface elevation as the base point. The base elevation option uses the specified base elevation as the scale reference. The base elevation method is useful for combining the 3D geologic columns with other exaggerated surfaces such as Block Diagram or grid files. For example, you could run Plot 3D Grid Files for a strata elevation grid file with the vertical exaggeration set to 5 : 1 with a base elevation of 500. Then run Draw Geologic Column with the Horizontal Scale as 50 and the Vertical Scale as 10 and the base elevation as 500. To view the 3D columns, use the Viewpoint 3D, Orbit or 3D Viewer Window commands.

Align Horiz by...: For the On 2D Grid method, the location for the geologic columns can be picked individually, lined up or projected. The Individual option will prompt for the location to draw each drillhole. The Line Up option places the geologic columns at an even horizontal interval in the order that the drillholes were selected. For the Line Up method, the Space Scaler field determines the horizontal spacing between the columns. The spacing in drawing units is the Space Scaler multiplied by the Horizontal Scale. The Projected option determines the horizontal alignment by projecting the drillholes onto a polyline and then using the distance along the polyline as the horizontal alignment. Also the Projected option also can draw a surface profile polyline. An offset distance from the horizontal alignment polyline can be set to limit the drillholes selected to just those that fall inside the offset distance. The surface elevations of the geologic columns may not exactly match the surface profile if the drillholes are offset from the alignment polyline.

Space Scaler: When using the Line Up option, this scaler is multiplied by the drawing scale to determine the distance the columns are drawn apart.

Align Vert by...: When using the 2D Grid or Projected options, the geologic columns can be aligned vertically by the real-world elevation, by the surface elevation, or by a strata/bed top or bottom elevation. For example, aligning by the top elevation of strata X would locate all the drillholes such that the top elevation of strata X is drawn in a straight row.
**Draw on Fence Diagram:** The geologic columns can be drawn on a fence diagram. First run the Fence Diagram routine. Then run Geologic Column and choose the Align Horizontally by **Projected** and **Draw on Fence Diagram** options. Also be sure that the horizontal and vertical scales match the fence diagram scale. Then the program will prompt you to select the fence diagram plan-view alignment polyline and the drillholes. Then you pick the lower left grid corner and enter the bottom elevation of the fence diagram grid. The columns should appear on the fence diagram for a visual comparison with the grids that made the fence diagram.

**Strata Name:** This is the strata name that will be used for the above vertical alignment.

**Bed Name:** This is the bed name that will be used for the above vertical alignment.

**From Top Elv and Bottom Elv:** When using the Strata for Align Vert by option, this is the choice for alignment. Either line up the top or bottom elevation of the strata.

**Horizontal Scale:** The Horizontal Scale is the overall drawing scale that many of the options are scaled by. This usually matches the drawing scale set in Drawing Setup.

**Vertical Scale:** The Vertical Scale relative to the Horizontal Scale determines the vertical exaggeration. For example, a Horizontal Scale of 50 and a Vertical Scale of 10 would create 5 to 1 exaggeration. When the Draw Elevation Axis or Draw Depth Axis options are on, the program will draw a vertical elevation and/or depth scale to the left of the geologic column.

**Grid Interval:** The Grid Interval sets the tick mark spacing for the elevation/depth scales. The Grid and Text Intervals can be used as the major and minor axis intervals where the Text Interval in the major and Grid Interval is the minor. The tick mark for the major interval is twice as long. For example, the Text Interval could be 25 and the Grid Interval 5.

**Text Interval:** The text Interval sets the elevation/depth label interval. The Grid and Text Intervals can be used as the major and minor axis intervals where the Text Interval in the major and Grid Interval is the minor. The tick mark for the major interval is twice as long. For example, the Text Interval could be 25 and the Grid Interval 5.

**Draw To Sheets:** This option will work if the options to Draw on 2D, and Align Horizon by individual are set. It draws the individual drillhole on multiple sheets, breaking it by pages set by the scale.

**Draw CESO Sheets:** This option was written for a specific company years ago. It draws the columns on their page form for printing.

**Column Width Scaler:** The Column Width Scaler determines the width of the geologic column by multiplying this value by the Horizontal Scale.

**Text Size Scaler:** The Text Size Scaler sets the text height of the labels by multiplying this field by the Horizontal Scale.

**Hatch Scaler:** The Hatch Scaler is a scaler multiplied by all the hatch scale values when using the Fill By Hatch option.

**Composite Strata to Beds:** This option will composite multiple intervals into one strata by grouping them together by bed name for drawing the column.

**Group Entities:** Selecting this option will draw the drillhole entities as one, as a block in the drawing. If this is off, then all parts of the column are separate entities, such as polylines, hatch and text.

**Offset from Drillhole:** This option is applied when the Draw, Next to Drillhole option is selected. The value is a scaler, and is multiplied with the Horizontal Scale to get the distance.

**Specify Elevation Range - Top Elev / Bottom Elev:** The **Specify Elevation Range** option draws a section of the geologic column within the range of elevations entered to the right. Together with increasing the vertical...
Specify Strata Range - Thickness Roof / Floor: The Specify Strata Range option draws a section of the geologic column within the range of strata. Together with increasing the vertical exaggeration factor, Specify Strata Range can be used to highlight a section of the geologic column. With the strata range option, the program will show a dialog with a list of the strata. You can select multiple strata in this dialog by highlighting the top strata and then picking the bottom strata while holding hold the Shift key. Also for the strata range option, you can specify additional thickness above and below the strata range by using the Thickness Roof and Floor fields. this will add a "roof" and "floor" interval to the column. The Skip to Next will refresh the list of strata by looking at another drillhole with different strata shown.

Draw Bar Graph-Use Red-Blue: The Draw Bar Graph option creates acid-base accounting graphs that are drawn to the right of the geologic column. These graphs are a logarithmic bar graph and a scatter graph. The strata attributes are used as the values for the graphs. The program will prompt for both a key and non-key attribute for the bar graph and the scatter graph. Negative values are drawn to the left on the bar graph and the range of the bar graph is -100 to 100. Values that exceed this range are drawn to the range maximum and then labeled with the real value. The range on the scatter graph is 4 to 8 and values that exceed this range will be drawn off the graph.

Draw Strata Connections: This option will draw lines between the columns to connect the selected strata or beds. This option will display a dialog with a list of strata to choose to connect. Multiple strata can be selected by using the Shift and Ctrl keys while picking the names. The Connect By Bed Name Only option will connect only strata...
that have a matching bed name. Be aware it does not pinch the strata or bed out if it does not appear in a drillhole, it will draw the line right over the hole to the next one. Remove Polyline segment can be used to clean up the drawing.

**Draw Depth Axis:** This option draws a depth grid next to each individual column, or just at the beginning of a row of columns.

**Draw Elev Axis:** This option draws an elevation grid next to each individual column, or just at the beginning of a row of columns.

**No Label:** This option will not label anything next to the columns.

**Label Options:** This button brings up the Label Settings dialog that sets the decimal precision and label prefixes for elevation, thickness and depth. You can also set strata label layer and the grid text layer. The Draw Ferm Codes option will label the ferm code next to the strata name either as the short ferm code name (i.e. "RSS") or as the ferm code full description (i.e. "Red Sandstone"). The ferm codes are defined in the Define Ferm Codes command and the ferm codes are assigned to the strata in the strata attributes. If Ferm codes are used and a corresponding strata attribute is defined, then the ferm hatch pattern, color and layer are used instead.
**Drillhole Options:** This button brings up the Drillhole Label Settings dialog with options whether to label the drillhole northing-easting, drillhole surface elevation, drillhole name and/or drillholes descriptions. There is also an option to label the offset distance from the projection line if the Projection alignment option is used. All of these labels are drawn at the top of the columns, near the collar. You can also set the layer, style and size with scaler, for the drillhole text labels. The drillhole labels can be drawn center justified above the column or to the right of the column.

![Drillhole Label Settings dialog](image)

**Draw as MText:** Using this option will draw the text grouped together as MText (multiline text). Otherwise it comes in as separate entities for each row.

**Label Strata:** This option labels the strata names next to the columns and activates all the labeling options.

**Strata Thickness:** Turn this option on to label the thickness of each interval next to the columns.

**Label Thickness next to Strata Name:** Turn this on to label the thickness on the same line as the name.

**Use Full Strata Name:** This will read the Define Strata settings and label the Full Strata Name found there.

**Label Bed:** This option labels the bed names next to the column. It may be used in addition to the Label Strata Names.

**Bed Thickness:** This will label the bed composite thickness if there are more than one interval of the same bed.

**Label Strata** : To handle crowded strata labels, there are several options for labeling the strata. The **All** option labels all the strata. The **Key-Only** option labels only key strata. The **Bed-Only** option labels only the strata with bed names. The **Fit-Only** option labels only strata with enough thickness to fit the label at the specified label size. The **Selected** option brings up a dialog with a list of strata to choose from.

**Label Strata - Elevations:** This setting will label the top elevation, bottom elevation, or no elevation.

**Label Strata Depths:** This setting will label the top depth, bottom depth, or no depth.

**Label Bed - Elevations:** This setting will label the top elevation, bottom elevation, or no elevation.

**Label Bed Depths:** This setting will label the top depth, bottom depth, or no depth.
**Strata Layer:** This option is active if Strata Layer is set to NonKey Same, or All Same. The layer is entered here. Otherwise, each is drawn in a layer based on strata and bed name. The button next to the window brings up the list of layers to pick from.

**Color Strata by Grade Parameter File:** This option will prompt for the GPF Grade Parameter file. The interval of the drillhole will be colored according to the grade color that is defined in the GPF.

**Layer Strata:** There are three options to set the layers for the entities. Individual will layerize them by the strata names. Non-Key will put just the Nonkey strata on the layer specified above. All Same will put all strata on the layer specified above.

**Fill by:** Solid will fill the columns with a solid fill. Outline will just outline the intervals with no fill or hatch. Hatch will hatch the columns using the predefined hatches in the Define Strata SDF file.

**Use Specific Strata Definitions:** This option will allow for selecting a different Defined Strata file than the one that is set current. Use this option and select a different SDF file for layering, colors and hatching.

**Select Attributes:** If the drillhole has attributes, they can be selected in the Select Attributes window for labeling. They are drawn on the left side of the columns. Key attributes are shown on the left, and Non-Key is on the right side.
A legend for the strata hatch patterns can be created with the Draw Legend function of Define Strata.
Angled Holes:
Carlson will model angled drillholes. There needs to be two attributes added to the drillhole. This is either entered under Drillhole Description to apply the same azimuth and dip to the entire hole, or as a Strata Description if it changes and varies on the way down. The two attributes are SC_AZI and SC_DIP. These represent the Azimuth and Dip of the drillholes. The Azimuth is 0-360 degrees. The Dip is 0-90, with 0 vertically down. Shown below is a 3D view of geologic columns drawn, with the angles shown.

**Prompts**

**Geologic Column Settings dialog**

Select DrillHoles for geologic column.

Select objects: *pick the drillhole symbols*

Select Attributes to Draw dialog

Pick location for geologic column: *pick or enter the bottom center point for the geologic column*

Pulldown Menu Location: Drillhole

Keyboard Command: geocol

---

**Find Drillhole**

This command locates a drillhole by name. The screen is centered around the specified drillhole and a temporary arrow is drawn to it. Be sure that the drawing is not zoomed out too far, as the zoom is not modified, just the panning of the screen to center the drillhole.

---

**Prompts**
Drillhole Inspector

Another inspector command found in Carlson is the Drillhole Inspector. It analyzes the drillholes and displays, in the inspector window, the selected parameters. The first time this command is run, the inspector window (in the top-left) is empty. The user must hit "O" for options to bring up the selection window. The possible parameters to be inspected are selected from the "available" window on the left and added to the "used" window on the right. This routine is very helpful in viewing drillhole data quickly as the cursor is moved across the drawing window, from hole to hole. A dashed arrow is shown in real-time to identify which hole is being inspected.

All drillhole information is available to the list for viewing. This includes such parameters as thickness, elevations, depth, and any user-defined attributes. The "inspector window" in the top-left corner can be moved around the screen by grabbing the title bar at the top and dragging it. The values in the inspector window will change as the cursor is moved over each drillhole. Using the Label option, a label can be posted from available data in the drillhole to a specified insertion point, text size, and alignment.

Prompts
Process beds [Yes/No]? press Enter
Options/<Move pointer near drillhole>: Move cursor over drillholes. Type O to select drillhole options to view. Press Enter to exit.

Pulldown Menu Location: Drillhole
Keyboard Command: chinspect

Apply New Definition
This command allows you to update all drillholes after a change in the drillhole definition file (.CH) is made. The command Define Drillhole creates and modifies the .CH file.

Pulldown Menu Location: Drillhole, Drillhole Utilities
Keyboard Command: chredoall

Change Drillhole Symbol Number
This command will change the actual symbol of the drillhole on screen in the drawing from what was originally placed. The first window that appears is to select the symbol to change to. Click on the symbol desired with the cursor, select the holes to change and the holes are now changed.

Prompts
Symbol Selection Dialog Choose a symbol
Select the Drillholes to change symbol.
Select objects: pick drillhole symbols
Modified 3 drillhole symbols
Pulldown Menu Location: Drillhole
Keyboard Command: chsymbol2

Change Drillhole Symbol Size
This command changes the drillhole symbol size of the selected drillholes to the user-specified size. The diameter of the symbol will be changed to the entered drawing units. Another way to change all the symbols at once, is to change the size in Define Drillhole, then run Apply New Definition.

Prompts
DrillHole symbol size: 50
Select the DrillHoles to resize.
Select objects: pick drillhole symbols
Changed 3 drillhole symbols
Pulldown Menu Location: Drillhole
Keyboard Command: chsymbol

Change Process On/Off Status
This command changes the processing status of the selected drillholes. If the status is off, then they can still appear on screen, but will be ignored for all processing. Drillholes are only used when the status is set to on.

Prompt
Select the Drillholes to set.
Select objects: Specify opposite corner: 42 found
Select objects:
Set processing status [<ON>/OFF]? ON
Modified 42 drillholes.

Pulldown Menu Location: Drillhole
Keyboard Command: chstatus

Change Drillhole Surface Z
This useful command will raise or lower the surface/collar elevation of the selected drillholes either by a surface model file or by an user entered differential. This is necessary when a series of holes have been drilled and surveyed from a local base elevation in the field. Once that benchmark elevation is determined, the selected holes in the drawing can be translated to the appropriate elevation. Older holes located before GPS surveys might not have the correct surface elevation. This will "drape" them onto a surface model file which can be a grid, TIN or FLT file.

Prompts
Select the Drillholes to process.
Select objects: all (to select the drillholes) 190 found
Set elevation by surface model or differential [<Model>/Differential]?
M for Model or Enter if in <>
Reading cell> 251316
Hold strata thickness [<Yes>/No]? y Yes will keep the same thickness of all strata, No will change the thickness of the first strata in the drillhole.
Modified 180 drillholes.
Skipped 10 drillholes already at elevation

OR:
Select the Drillholes to process.
Select objects: pick the drillholes
Enter elevation change: 150. Use a positive value to raise the elevation and a negative value to move down. This example will raise the elevations by 150.
Hold strata thickness [<Yes>/No]? press Enter for Yes If Yes, then the complete stratigraphic column will be moved up or down, keeping the thickness of each the same. If No, then the thickness of the first strata in the hole will be affected; thicker with a positive value as the collar elevation is raised, and thinner if negative.
Modified 15 drillholes.

Pulldown Menu Location: Drillhole
Keyboard Command: chelev

Assign Strata Correlation
This command assigns strata and bed names to intervals in a geologic column view. This is a great tool for a geologist to do the on-screen correlating. Rows of geologic columns can be drawn, and correlated just by "picking" the intervals to connect with lines. Before starting this command, create geologic columns with the Draw Geologic Column command. The Fill option set to Outline Only can make it easier to pick the strata.

While viewing the geologic columns, pick the strata polylines to name on the left or right edge, or they can be selected with a window. Then a dialog appears where you can enter the strata name and an optional bed name. These names are saved back in the drillholes, or in the database. There is an option to connect the strata with the
same names with lines. The one thing it does not do is update the text. The drillholes need to be drawn again to see that update.

**Prompts**

Connect strata with lines (<Yes>/No)? press Enter for Yes  
Select the Strata to name.  
Select objects: pick the strata polylines from the geologic column  
Name Strata Dialog

![Name Strata dialog](image)

Select the Strata to name.  
Select objects: press Enter to end  

**Pulldown Menu Location:** Drillhole in Advanced Mining  
**Keyboard Command:** nmstrata

**Composite Duplicate Strata**

This command will composite all duplicate strata names found within the selected drillholes. To be composited, the strata must have the same bed names, the same key/non-key status and they must be in sequential order without any other strata in between (no partings). There is an option for whether the strata must have the same name. Also, there is an option whether to composite only key or only non-key strata. Since Carlson doesn't model duplicate strata without bed names, this routine can be useful to composite a strata that duplicates itself. The strata qualities will be weight averaged by thickness, giving one value for each attribute.
### Prompts

Select the Drillholes to process.
Select objects: select drillholes to composite duplicate strata
Strata to process [Key/Non-key/<Both>]? press Enter
Require strata name to match [Yes/No]? press Enter
Update 19 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: dupstrata
Prerequisite: Drillholes

### Composite Strata By Beds

This command composites strata within a drillhole based on bed name and key/non-key status. All the non-key strata with a matching bed name that are above the first key strata are composited and assigned the name strata_top. The non-key strata between the key strata are composited as strata_parting. The key strata with a matching bed name are composited as strata_key. The non-key strata below the last key are composited as strata_bottom. This compositing method is the same the StrataCalc uses for processing strata with bed names. The strata qualities will be weight averaged by thickness, giving one value for each attribute.

### Prompts

Select the Drillholes to composite.
Select objects: pick the drillholes to process
Set Strata Key Status

This command processes a given set of drillholes, searches for the information from the selected drillholes and sets key status of each strata with the user-specified name to the required value. This is a much faster way to change key/non-key strata type than going through the Edit Drillhole or Drillhole Datasheet commands. The * wildcard is supported in this command for multiple selections. Bed names can be used as a filter.

Prompts

Select the Drillholes to process.
Select objects: Specify opposite corner: 7 found
Select objects:
Enter name of the strata to modify (wildcards supported): LS*
Enter bed name to limit the selection or press Enter for none:
Set status as [Key/<Non-key>]? K
Modified 7 drillholes.

Fill-in Missing Key as Zero

This command inserts zero thickness key strata when the strata is missing from the geological sequence in the drillhole. This change is permanent to the drillhole, so make sure to have a back up if this is not the desired change. This allows for more control in the pinch out modeling of the drillholes and thickness modeling.

Select the Drillholes to process.
Select objects: Specify opposite corner: 174 found
Modified 12 drillholes.

Add Strata

This routine inserts an interval into the drillholes at either the very top or the very bottom of the selected holes. It is necessary to do this for certain types of geological modeling that have the top or bottom seam disappearing, and not all intervals in the hole have a bed name, such as in this lignite modeling. It "borrows" thickness from either the top or bottom interval, as in this example shown below in the ROCK strata. Some prefer to enter in a 0.1 interval and just call it TOP.
It went from 99 to 98 thick, with the addition of 1 foot of topsoil. This will aid in the modeling of the seam C1 in holes where it does not exist, due to pinch or erosion. This routine should not be used in holes that are drilled in a valley, and the C1 seam is above the collar; it will be modeled with conformance.

**Prompts**

Add strata to top or bottom of drillhole [Top/Bottom]? Top (in this example)
Enter strata name: Topsoil
Enter bed name: Top
Status for strata [Key/Non-key]? N
Enter strata thickness: 1.0
Select the Drillholes to process. Type ALL or select.
Select objects: Specify opposite corner: 22 found
9 were filtered out.
Select objects: press Enter to accept
Updated 13 drillholes:

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: addstrata
Prerequisite: Drillholes

Delete Strata
This command allows you to remove certain strata in multiple drillholes in one step. If strata is removed the thickness of strata removed is added to strata below.

Prompts

Select the Drillholes to process.
Select objects: Specify opposite corner: 20 found
Select objects:
Enter name of the strata to modify (wildcards supported): LS
Enter bed name to limit the selection or press Enter for none:
Modified 20 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: stratadel

Rename Strata
This command allows you to rename a certain strata in multiple drillholes in one step. It prompts for the old strata name and then the new name.

Prompts

Select the Drillholes to process.
Select objects: Specify opposite corner: 20 found
Select objects:
Enter name of the strata to modify (wildcards supported): LS
Enter bed name to limit the selection or press Enter for none:
Enter a new name for the strata: LS1
Modified 20 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: strataren

Reset Invalid Attribute
This command will set the invalid attribute values in the selected drillholes to blank. The range of valid attribute values are set in the Define Attributes command. Any attributes found in the drillholes outside that range are deleted.

Prompts
Select the Drillholes to process.
Select objects: select the drillholes
Modified 309 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: resetattr

Delete Attribute
This routine is a quick and easy way to remove the specified attribute from the drillholes. It will remove the attribute from all the strata in the selected drillholes.

Prompts

Select the Drillholes to process.
Select objects: select drillholes
Enter attribute name to delete: BTU
Modified 219 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: delattr

Rename Attribute
The function of this command is to rename attributes of selected drillholes. This is the only way to globally rename the name of attributes within holes. Be sure to spell the attribute name precisely the way it appears in the holes.

Prompts

Select the Drillholes to process.
Select objects: select the drillholes
Enter old attribute name to rename: CA
Enter new attribute name: CACO3
Modified 35 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: renmattr

Assign Bed Names
This command assigns a bed name for each strata with picked names in a given set of drillholes. The strata list is generated based on drillholes selected enabling user to pick multiple strata to process. Hold the CTRL or SHIFT keys to select multiple strata for bed assignment.
Prompts

Select the DrillHoles for bed assignment:
Select objects: Select Drillholes
Enter name for the bed: C1_BED

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: assignbed

Fill-in Bed Names
For some methods of processing the strata modeling routines, the drillhole set should have either no duplicate strata names or bed names assigned for each strata. When bed names are assigned to the key strata (or just some strata within drillhole), the blanks may be filled-in using this routine. The routine works from the top of the drillhole down until it finds the first strata with a non-empty bed name. That bed name is then applied to all strata with empty bed names above that strata. This procedure is then repeated to the bottom of the hole. For the strata below the last strata with bed name assigned, the last bed name is used.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: fillbed

Remove Bed Names After Last Key
For some methods of modeling, users prefer to remove or delete all of the bed names in a drillhole after the last Key interval. This command will do the entire selection set of drillholes at one time.

Prompts

Select the Drillholes for bed process.
Select objects: Specify opposite corner: 11 found
Select objects:
Updated 7 drillholes
Split Bed

For the selected drillholes, this command provides the ability to manipulate an existing bed at certain elevations or thickness. The bed can be split by changing the key/non-key status or by supplying a new bed name. With a new bed name, the bed will be split into one part with the old name and the other with the new name. The elevation at which to split the bed can be specified as a flat elevation or as a grid file. For the grid file, the split elevation is defined by the grid file at the drillhole location. The thickness method allows you to split off a specified thickness from the top or bottom of the bed or to add a specified thickness from the adjoining strata to the top or bottom of the bed. Besides changing the structure (thickness/elevation) of the bed, this routine will also split the bed qualities. 

One application of this routine would be to use the thickness option to set the top 0.1 of the KEY bed to non-key to model loss at the top of the seam. Another application is to split a large KEY bed into two beds at an elevation grid to model mining the bed in two passes or benches.

Prompts

Split strata method [<Elevation>/Grid/Thickness]? T for Thickness
Select the Drillholes for bed split.
Select objects: pick the drillhole symbols
Enter name of the bed to split: C2
Rename bed or assign key/non-key status [<Name>/Status]? press Enter for Name
Enter new name for the thickness change: C2B
Split from top or bottom [<Top>/Bottom]? press Enter for Top
Add or subtract thickness from bed [<Add>/Subtract]? S for Subtract
Enter thickness (ft): 2

By Elevation:
Split strata method [<Elevation>/Grid/Thickness]? press Enter for Elevation
Select the Drillholes for bed split.
Select objects: Specify opposite corner: 5 found
Select objects:
Enter name of the bed to split: C1
Rename bed or assign key/non-key status [<Name>/Status]? N
Enter new name for the upper part of the bed: C1u
Enter new name for the lower part of the bed: C1L
Enter a split elevation: 2510

Rename Bed

This command replaces the old bed name with a new bed name in a selected set of drillholes.

Prompts

Select the Drillholes for bed renaming.
Select objects: Specify opposite corner: 42 found
Select objects:
Enter OLD name of the bed: C1
Enter NEW name for the bed: C-ONE
Statistical Analysis

This command calculates the minimum, maximum, average, slope, and standard deviation of strata values in drillholes or from grids. These values can be the strata thickness, bottom elevation, or user-defined attributes such as BTU or GRADE. The statistics are calculated from either drillholes or a grid file. With drillholes, the statistics are calculated using the drillhole data points. With PreCalc and grid files, the data points are the grid cells. Using a grid allows you to analyze an area by selecting inclusion and exclusion closed polylines of the area. Grid or drillholes both handle pit names for analyzing multiple areas at once. A grid file of a strata attribute can be created with the Make Strata Grid File or Autorun Strata Grids commands. The Statistical Analysis program starts with the option to use Grid, PreCalc or Drillholes. With the Grid option, the grid file (.grd) to process can be selected individually in the standard file selection dialog. The PreCalc option allows you to select multiple grid files from a Pre-Calculated Grids File (.pre) that stores a series of grid files, as shown by highlighting multiple strata at one time. There are options for histogram and Bin size in the reports, as well as marking the outliers in the drawing for detailed review. The report can be viewed in the standard report viewer, or it can be turned on to use the report formatter.
Prompts

For drillhole statistics:
Calculate statistics from grid file or drillholes (Grid/Precalc/<Drillholes>)? press Enter for drillholes
Ignore zero values (<Yes>/No)? press Enter
Select the DrillHoles for report.
Select objects: select the drillhole symbols
Choose Strata to Process
Calculate THICKNESS statistics for strata X (<Yes>/No)? No
Calculate BOTTOM ELEVATION statistics for strata X (<Yes>/No)? No
Calculate BTU statistics for strata X (<Yes>/No)? Yes
Number of samples from drillhole data = 38 Ignored 34 zero values
Average: 10410.42, Standard deviation: 1371.25
Minimum value: 2305.00, Maximum value: 11147.00
Write report to file (Yes/<No>)? Yes
Enter the file name to write: report.txt
Write report to printer (Yes/<No>)? Yes
Make sure printer is on-line and connected to the printer port.

For grid and PreCalc statistics:
Calculate statistics from grid file or drillholes (Grid/Precalc/<Drillholes>)? Precalc
Use named pit areas (Yes/<No>)? press Enter for No
Reading cell > 2989 Choose grid to process
Extrapolate grid to full grid size (Yes/<No>)? press Enter Answer yes to calculate values outside the limits of the data to the full grid size.
Select the Inclusion perimeter polylines or ENTER for none.
Select objects: option to pick closed polylines
Select the Exclusion perimeter polylines or ENTER for none.
Select objects: option to pick closed polylines
Number of samples from grid data = 612
Average: 10457.55, Standard deviation: 816.20
Minimum value: 3464.57, Maximum value: 11111.71
Pulldown Menu Location: StrataCalc
Keyboard Command: chstats
Prerequisite: Drillholes or grids
Standard Drillhole Report

Standard Drillhole Report retrieves data from the selected drillholes and generates a report in the Standard Report viewer that can be edited, printed and saved to file. For each drillhole, the drillhole location, description, strata names, and attributes are reported. There is an option to split the report for page breaks between holes.

Prompts

Select the DrillHoles for report.
Select objects: select the drillhole symbols
Add page break between drillholes [Yes/<No>]? press Enter for No
Place all strata attributes on one line [Yes/<No>]? press Enter for No
Report strata depth to [Top/<Bottom>]? press Enter for No
Report strata elevation of [Top/<Bottom>]? press Enter for No

Pulldown Menu Location: Drillhole > Reports
Keyboard Command: chreport

Custom Drillhole Report

This command builds custom reports of the drillholes. The main difference between this command and Standard Drillhole Report is that this command loads all drillhole data into the report formatter. The report formatter allows you to choose which fields to report and their layout. The report data can be exported to Excel, to Access or into a comma-delimited file, or just saved or printed as shown.
Prompts

Select the Drillholes for report.
Select objects: *pick the drillholes*
Process beds [Yes/<No>]? press Enter for No Process beds will composite the strata by bed name. Otherwise the strata are reported individually.
Separate field names by strata/bed [Yes/<No>]? press Enter for No This option will add the strata name to each
strata data field which allows you to control the report for the strata data separately by strata name. For example, if there were strata named "COAL1" and "COAL2", then you would have field names of "COAL1_THICK" and "COAL2_THICK". Otherwise, there would be only one strata thickness field named "THICK" which would report the thickness for both COAL1 and COAL2.

**Pulldown Menu Location:** Drillhole > Reports  
**Keyboard Command:** chreport2

---

**Change History Report**

This command creates a report of drillholes that have been modified during the specified time period. The program reads the change history from strata attribute variables called DATE_CHANGED and CHANGED_BY. The Edit Drillhole and Drillhole Data Sheet routines will update these changed attributes using the current date and the AutoCAD login name when any of the strata data is modified. For the report if a drillhole contains a changed strata, there is an option to either print all the strata for that drillhole or just the modified strata. To setup the DATE_CHANGED and CHANGED_BY attribute, run the Define Drillhole command and add these names to the Key strata attributes and Non-Key strata attributes.

---

**Prompts**

Select the DrillHoles for change history report.  
Select objects: pick the drillholes  
Enter Period Start Date or Enter for None (mm/dd/yy): 1/1/95  
Enter Period End Date or Enter for None (mm/dd/yy): 9/9/06  
Include only changed strata in affected drillholes (Yes/No)? Y  

**Pulldown Menu Location:** Drillhole > Reports  
**Keyboard Command:** chhreport  
**Prerequisite:** Drillholes
Duplicate Drillhole Report

This command reports drillholes located at the same easting/northing position. The holes can have different names. The report dialog displays the names, and locations of the problem holes. The command has an option to draw a circle, of specified size, around the holes that are found duplicate. The purpose of this routine is to help clean up the drillhole database by identifying duplicate position drillholes since the modeling can only process one drillhole at any one location. This routine only shows the duplicates and it is up to you to actually decide which duplicate drillholes to remove or move. It does not report two drillholes that have the same name, but are at different locations.

Prompts

Draw circle around duplicate drillholes [Yes/<No>]? Y
Circle radius <100.0>: press Enter for 100
Pulldown Menu Location: Drillhole > Reports
Keyboard Command: dupch
Prerequisite: Drillholes

Drillholes without key strata

This routine will report all selected drillholes that do not contain any Key strata. It also will give the option to draw a circle around those drillholes.

Prompts

Draw circle around no-key drillholes [Yes/<No>]? y
Circle radius <100.0>: 50

Chapter 14. Geology Module
Drillhole Top to Surface Model

This command reports the difference between the selected drillholes and a selected surface model. There is a tolerance that will not include any drillhole within this vertical distance from the surface model.

Prompts

Select the Drillholes for report.
Select objects: all pick the drillholes
Elevation Difference Tolerance <0.0>::
Use Report Formatter [Yes/<No>]? No will use the standard report window
Reading cell > 49410 Select the drillholes and strata polylines.

Bed Composite Report

This command reports the individual strata qualities and the resulting composite qualities of drillholes. The strata are composited by bed name. It is useful for seams that are sampled extensively at many intervals, and even with different strata names. An example hole report is shown. Each individual strata and bed is broken out first, with the
composite values following at the end of the report. The command uses the report formatter, so the output it gives is very customizable.

### Prompts

**Select the Drillholes for report.**

**Select objects:** select the drillholes to process

**Pulldown Menu Location:** Drillhole > Reports

**Keyboard Command:** chreport3

**Chapter 14. Geology Module**
Invalid Strata Report

Routines that process strata such as Fence Diagram or Make Strata Grid File require strata names to be in correct order and these routines refuse to continue if there is a problem with the strata. This command creates a report of drillholes that have strata that are out of order or have duplicate strata names. An arrow is drawn on the screen pointing to the drillholes that have the problem. If the screen is moved or zoomed, the arrows will disappear. This report can be used to identify the drillholes that need to be cleaned up.

Prompts

Select the drillholes and strata polylines.
Select objects: pick the drillholes

Pulldown Menu Location: Drillhole > Reports
Keyboard Command: badch
Prerequisite: Drillholes
Missing Strata Report

This command reports strata from the selected drillholes that are missing in the strata sequence. The strata sequence is determined by reading the strata from all the selected drillholes. When a strata is missing between other strata, this is reported as PINCH OUT. For example with strata A, B, C and a drillhole with A, C, then strata B will be reported as pinch out. If a strata is missing before the first strata in the drillhole, then this strata is reported as ABOVE. For example a drillhole with B, C would report strata A as above. Likewise a strata missing after the last strata in the drillhole is reported as BELOW. For example a drillhole with A, B would report strata C as below. In the report, the estimated bottom strata elevation and thickness for the missing strata is reported based on pinch out and conformance.

Prompts

Report pinch out strata [<Yes>/No]? Y
Report strata above or below drillhole [<Yes>/No]? Y
Select drillholes, channel samples and strata polylines.
Select objects: Specify opposite corner: 13 found
Select objects:
Reading drillhole 13
Finding splits ...
Finding pinch out ...
Calculating seam stacking ...
Drillhole report

PullDown Menu Location: Drillhole > Reports
Keyboard Command: missch
Related Commands: Place Drillholes

Strata Order and Count Report

This command reports all the strata existing in the selected drillholes, in order from top to bottom and the number of drillholes that contain each strata.
Prompts

Select drillholes, channel samples and strata elevation polylines.
Select objects: Select drillholes from the drawing
Pulldown Menu Location: Drillhole > Reports
Keyboard Command: geo_order2

Attribute Validation Report
This command reads the attribute information from the selected drillholes and checks strata attribute values against the minimum and maximum values specified in the attribute definitions. The attribute definitions are created in the Define Attributes command. Any that fall outside the defined range are added to the report.
Attribute Validation report

Prompts

Select the Drillholes for validation report.
Select objects: Specify opposite corner: 13 found
Select objects:
Place all strata attributes on one line [Yes/<No>]? Y
Report strata depth to [Top/<Bottom>]?
Report strata elevation of [Top/<Bottom>]?

Pulldown Menu Location: Drillhole > Reports
Keyboard Command: checkattr
Prerequisite: Drillholes

Define Parameters

This command prepares an attribute parameter definition file (.par file) that defines the attribute names along with an operator and value. The parameter definition files are filters that are applied in the Compliance Drillhole Report, Compliance Areas and Mark Compliance Drillhole commands. The are two types of parameters: Strata and Drillhole. Strata parameters can be THICKNESS, DEPTH, TOP-ELEV, BOTTOM-ELEV, NAME, BED or any of the user-defined strata attributes such as BTU. Drillhole parameters can be NAME, ELEV, DESC, TYPE, XY_QUAL, Z_QUAL or any of the user-defined drillhole attributes such as Driller Name. The TYPE parameter is for the Drillhole Type and it should be referenced by the position number 1-9 and not by name. For example if drillhole type #9 is "Rotary", then in the Value field you should enter 9. Likewise XY_QUAL and Z_QUAL should be referenced by the XY Qualities and Z Qualities position numbers 1-6. Be sure to spell the attributes exactly the same in the parameter list as in the drillholes. The operators are less than, greater than, equal and not equal. When the parameter file is processed the strata attributes are checked with these definitions.

The Strata Name column is optional for assigning a strata name to a parameter. You only need to fill out the Strata Name column if you are analyzing multiple strata at once. For example, you could check THICKNESS on COAL2
strata name and THICKNESS with a different value on COAL3 strata name. If all the parameters apply to the same strata then when you run routines like Mark Compliance Drillholes, there is an option to test the entire drillhole or a specific strata. You can choose the specific strata option and then select a strata to process. Note: You do not fill in the strata name for the first or top parameter. The program will prompt you for the strata to process.

The And/Or field applies between the parameters in the current row and the row above. The Process column allows you to turn off processing for a parameter. Selecting the HELP button on this screen brings up a list of Available Parameters that should be used. This command is CAPS sensitive.
Compliance Drillhole Report

This command reports drillholes from the selected drillholes that meet all the qualities defined in a parameter file. Drillholes that don't meet the parameter file are not reported. There is an option to analyze the entire drillhole or a specific strata. The entire drillhole method will include the drillhole in the report if any of the strata meet the parameter file. The specific strata method checks one strata and includes the drillhole in the report if this strata meets the parameter file. The parameter file consists of strata qualities and values. The qualities can be THICKNESS or any of the user-defined strata attributes such as BTU. Be sure to spell the attributes exactly the same in the parameter list as in the drillholes. Parameter files can be created ahead of time with the Define Parameter command.

Prompts

Parameter Dialog
Process beds [Yes/<No>]? Y
Analyze entire drillhole or specific strata [<Drillhole>/Strata]?
Require all strata to match or any strata [All/<Any>]?
Select the Drillholes to test.

Compliance Drillhole report

Compliance Areas from Grids

This command draws a closed polyline(s) and hatches the area(s) that meet the specified values for multiple grids. It is similar to the Parameter Compliance from Drillholes, but this analyzes grid files instead of drillholes.

The Set Parameters window is for selecting the grid files and specifying the values to use for compliance. The bottom portion is for choosing the layer, color, pattern and scale for the hatch. The area(s) that meet the criteria are then outlined and filled with the hatch pattern. If no inclusion/exclusion perimeter is selected, then the area of the extrapolated grid is hatched to the limits. As can be verified by the prompts, the command contours each of the
grids for the values specified and then creates closed polygons where the values coincide.

Prompts

Contouring elevation 8000.00
Inserted 686 contour vertices.
Reading file > c:\scad2005\USER\epattern.dta for pattern definitions...
Compliance Areas from Drillholes

This command draws a closed polyline(s) and hatches the area(s) that meet the specified values for parameters. It is similar to the Parameter Compliance from Grids, but this analyzes drillholes instead of grids.

The Set Parameters window is for selecting the parameters and values. In this example, two seams BTU are analyzed, so they are both entered in the Strata Name column.

![Set Parameters Window](image)
Prompts

Pulldown Menu Location: Drillhole > Parameter Compliance
Keyboard Command: charea

Mark Compliance Drillholes
This command highlights drillholes that contain a strata that meets the specified parameters. The drillholes are highlighted by drawing a circle around them, changing the drillhole symbol, changing the drillhole type or changing the drillhole layer. There is also an option to create a selection set of the matching drillholes. Then you can use that selection set in any other command that prompts for drillholes by entering P for Previous at the Select Objects: prompt.

The parameters are set in the Define Parameters window. Be sure to spell the attributes exactly the same in the parameter list as in the drillholes. For more details about parameter definitions, see the Define Parameters command.
Prompts

Set Parameters dialog

Process beds [Yes/No]? press Enter This option composites the strata using their bed names into BED_TOP, BED_PARTING, BED_KEY and BED_BOTTOM. For example, you could have several quality samples of a seam broken into strata names CO with bed name A. The process beds option will composite all these samples into A_KEY. Otherwise the parameter filter will test each sample separately.

Analyze entire drillhole or specific strata [<Drillhole>/Strata]? press Enter The Strata option allows you to select which strata to test. Otherwise all the strata in the drillholes are tested. If Strata is chosen, the Choose Strata window appears for selecting.
Require all strata to match or any strata [All/<Any>]? press Enter. The Any option will mark the drillhole if any of the strata match the parameter filter. The All option requires all the strata to match in order to mark the drillhole.

Select the Drillholes to test.
Select objects: pick the drillhole symbols
Drillhole value to change, create selection set or draw circle
[Layer/Symbol/Type/Selection/Member mode/Draw mode/Circle/]? press Enter for Circle
Mark layer name <COREMARK>?: press Enter for layer
Mark size <25.0>: 100 Enter size.
Marked 7 drillholes.

Pulldown Menu Location: Drillhole > Parameter Compliance
Keyboard Command: charea2
Prerequisite: Drillholes

Set Strata by Parameters

This command sets strata values of strata name, bed name or status (key/non-key) based on whether the strata passed the specified parameter filter. The parameter filter can test strata attributes such as thickness and qualities such as MGO. The change defined in the Set Strata by Parameters dialog will be applied to strata in the selected drillholes that passed the parameter filter. Also in the dialog, you can choose between processing all the strata or specific strata selected by strata name. For example, consider an ore seam that is made of several sequential strata with different quality samples of a strata attribute called GRADE. Set Strata by Parameters could be used to set the key/non-key status of these strata based on whether the strata GRADE attribute is greater than 1.5%.

Prompts
Set Strata by Parameters dialog
Define Parameters dialog

Split Bed by Parameters

This command finds the largest portion of a bed such that the composited qualities meet the specified parameter filter. The bed can be split by key/non-key status or by name. With the status method, the bed portion that passes the filter is set key and the rest is set non-key. For the name option, you can specify the bed name for the portion that passes the filter and names for the portions that don't pass.
This command is different from Set Strata by Parameters because this command composites multiple strata to meet
the filter instead of checking each strata individually against the filter. In Split Bed by Parameters, the composited
portion that passes the filter can contain some strata that fail the filter so long as the total composite portion passes.
For example, if the parameter filter is for strata attribute GRADE to be greater the 1.5, then final bed composite
that passes could be made of one strata with GRADE of 1.6 plus part of another strata with GRADE 1.1 such that
the composite GRADE equals 1.5. The strata that make up the bed can be divided into a part that is used in the
composite and part that is discarded. For example in the above case, the strata with the GRADE of 1.1 could be
originally 2 feet thick. Since this strata is below the target GRADE of 1.5, it could be that only 0.7 feet of this strata
could be added to the composite without bringing the composite below 1.5. So the strata would be split at 0.7 feet
with the remaining 1.3 feet not becoming part of the composite.

This command can also account for minimum and maximum mining heights to limit the composite bed thickness.
If there is no portion that meets the filter at the minimum thickness, then the program will find the best portion.
Likewise if the composite that meets the filter exceeds the maximum height, then the program will find the best
portion with the maximum allowed thickness. The thickness interval resolution allows the intervals to be broken up
into as small of units as required. The Find All Matching Zones will not stop at the single best zone, it will separate
the beds into all of the matching zones.

Restrict Mining Zone is an option that defines where the program will start calculating from, either the top or
bottom. For a surface mine, the Top Down would make the most sense, so that the most efficient method of mining
is designed. For underground, it is possible that the Bottom-Up option is preferred, so that extra material will be
left in the roof for support.

Tag Drillholes for Processing

This command sets the processing status of drillholes based on specified parameters. The processing status is set as ON or OFF which is used by Stratacalc routines to determine whether to include the drillhole in processing. Drillholes have processing ON by default. The drillholes that do not match the specified parameters are tagged as processing OFF. The Reset Selected Drillholes option at the start is a way to set the processing status of the selected drillholes to ON and start fresh, with them all set to ON.

Prompts

Reset selected drillholes to processing on status (Yes/<No>)? press Enter

StrataCalc Data Sheet

This command displays geological data for viewing and editing of the processed values in a spreadsheet view. It could be called an interpolator, as it displays the values that the program interpolates and will use for modeling. Each value can be editing and "forced" or user defined values can be used instead of what is found in the drillhole.
or modeled by the program. Each column represents a datapoint, such as a drillhole. The color of each text value
represents the source of the data. This StrataCalc file (*.STC) will then be used for the modeling. Any time the
program prompts "Select Drillholes", if none are selected and Enter is chosen, then the program will ask for the
StrataCalc file. It will use this file and the values in it for the modeling. This is a great tool for controlling the
geology. If a few drillholes are troublesome and not modeling correctly, the user can edit this file to what they
want to use and create a more accurate model. The first window is to choose the source of the data, either the
drillholes on screen, or to load an existing STC file. Then the Data Sheet comes up for viewing and editing.

- **Select Attribute:** The dropdown controls the values to display and edit in the spreadsheet. It will always have
  Thickness, Bottom Elevation and Top Elevation. Any other user defined attributes will also be here for control.

- **Right click to view/change source type:** When placing the pointer on a cell and right clicking the mouse, the
  menu displays the possible sources of the value. The source used is the one with the check mark next to it. The source can be changed by picking a different one, and the color of the text in the cell would then
  change to represent that.
• **Constant Thickness:** If Constant Thickness toggle is ON, then when the user updates the top elevation, the thickness will be kept constant and the bottom elevation will be changed (bot elev = top elev - thick). If the bottom elevation is changed thickness will remain constant and top elevation be changed (top elev = bottom elev + thick). If the toggle is OFF, then if elevation is changed the thickness will also be updated accordingly. (thick = top elev = bot elev)

• **Apply:** This will apply the changes made to the spreadsheet the update the colors and values.

• **Report:** There are three options to see the values in a text report: Report All Data, Report Current Attribute, or Report to HTML. The HTML report takes the current spreadsheet view of the data and puts it into HTML format. The other two reports output to the report formatter.
• **Save/Load to File:** This saves the changes to the STC file, or loads an existing STC file.

• **Read Drillholes:** Choosing this will bring up two options on how the drillholes should be loaded into the spreadsheet. They can either append and merge, or replace the holes if they already exist.

• **Search Drillhole:** To find a drillhole in the spreadsheet, chose this option and enter in the drillhole name. It will scroll to it and highlight the drillhole column of cells.

• **Color Options:** This is a customizable window to set which color the text will be displayed in the spreadsheet. There are seven main sources of the data: Drillhole, Strata Polyline, Channel Samples, Pinchout value, Seam Stacking value, User Defined, and an Invalid Attribute (out of the range of Define Attributes file).
Prompts

chinterp

Calculating seam stacking ...
Processing only strata with beds.
Attribute Definitions missing (this is because the Define Attributes are empty)

Keyboard Command: chinterp

Draw Outcrops

Draw Outcrops generates polylines that represent the outcrops of strata from the selected drillholes. An outcrop is where a strata comes up to the surface. An option from the Outcrop Settings dialog allows the outcrop line to be calculated from where the top of the strata hits the surface or from where the bottom hits. The Draw Outcrop Polyline At Elevation will draw the outcrops as 3D polylines on the surface topography. For example, on a slope, the top of strata outcrop will be higher than the bottom, and on the inside when viewed in plan view. When coming from drillholes, Draw Outcrops calculates the outcrop by creating a grid of the surface and a grid for the strata and then finding the intersection of the two grids. If the strata never breaks through the surface, no outcrop line will be created. The Pre-Calculated model option reads the surface grid and strata grid from a pre-calculated grid file (.pre). This option will show a dialog with a list to choose from of the strata defined in the pre-calculated grid file. If the File option is used, then a Sub-Crop line can be drawn that will prompt for a thickness grid of the strata. The lines can be smoothed and vertices reduced with the settings shown below.
The option to Label Outcrop Contours will label the strata name in the contour line as contour text. The contour text settings window appears for the desired settings to be entered.
Prompts

Calculating grid by inverse distances 2601...
Contouring elevation 0.0
Inserted 136 contour vertices.

Drop-Down Menu Location: StrataCalc
Keyboard Command: outcrop

**Draw Depth Contours**
This command creates contours for the depth between the surface and strata. The surface models for the ground and strata are modeled by grid if coming from the screen entities and drillholes. When using the PreCalculated file, the list of strata appears to select which strata to use. Specify Depth Contour Range allows for a starting and ending contour elevation. There is the option to contour the depth to either the top or the bottom of the strata. Options are at the bottom for smoothing and reducing the contour vertices. This is basically the thickness from the topography to the top or bottom of the strata. This grid could also be made in Grid File Utilities, but this is a quick way to get the contours without gridding first.
Pulldown Menu Location: StrataCalc in Advanced Mining and Mining  
Keyboard Command: depth

Make Strata Grid Files
For each strata in the drillhole, this routine can generate 3D grid files of the strata thickness, top & bottom elevation, and attributes such as calcium, moisture, sulfur, and BTU. The grid files make up the geologic model in StrataCalc. A 3D grid file is a rectangular mesh of grid cells where each grid cell is the same size rectangle. The elevation or Z value of the four grid corners equals the value at those points. For example, consider a grid cell for a 3D grid mesh of strata thickness. The X and Y coordinates of a grid cell could be (0,0), (10,0), (10,15), and (0,15). The z values, which might be 4.5, 4.7, 4.8, and 4.6, represent the strata thickness at the four X and Y coordinates.
Make Strata Grid Files reads the strata data from the drillholes. The strata data is correlated and processed for beds, pinch out and conformance as specified in the Configure -Mining Module. The strata data points are then used with the selected modeling method to calculate the grid. There are 5 methods for modeling: Triangulation, Inverse Distance, Polynomial, Kriging and Least Squares. There is an option to use a parameter file (made with Define Parameters) to filter the strata data points. For example, when creating a thickness grid for the overburden of 6_COAL, you could have a parameter filter of THICKNESS 6_COAL > 1.0. This filter would make the program use only drillholes with 6_COAL greater than 1.0 when calculating the 6_COAL overburden grid. See the Define Parameter File command for more description on parameters.

The routine starts by prompting for the location of the grid files to create. The location can be specified by picking the lower left and upper right corners or by selecting an existing grid file which sets the new grid location and resolution to match the selected existing grid file. Next there is the Make Strata Grid File dialog for choosing the grid cell resolution, modeling method and other parameters.

- **Range of Elevations/Values to Process:** Only values that fall within the range specified by the Low and High will be used in the gridding. Values that fall outside this range will be ignored.
- **Modeling Method:** There are 5 modeling methods available for geologic gridding, with many settings for each method. They are Triangulation, Inverse Distance, Kriging, Polynomial and Linear Least Squares. They are described in more detail below.
- **Use Triangulation Subdivision:** When modeling with triangulation, this option will divide each triangle into 3 or more smaller triangles for smoother modeling.
- **# of cells in X and Y / Total Cells:** The Grid Resolution will determine the number of grid cells in the X and Y directions. Most of the time, the user specifies the Dimensions of Cells. This calculates the number of cells in the X and Y direction. Multiplying the two together gives the Total number of Cells. This number determines the processing speed for other commands such as reserves and GFU. A good rule of thumb is to try and keep the Total Cells less than 500,000. Any number larger than this and most processors will use up all the RAM and go to the hard drive and processor, which can slow it down. There is no limit to the grid size though. Every computer is different, so try a few and see which size works for you at a reasonable processing time, and captures the accuracy you need.
- **Grid Resolution:** This is either the number of cells in the X and Y direction or the Dimensions of a Cell in
the X and Y direction. Unless the ore body is long and narrow, the Dimensions of a Cell should match in the X and Y direction creating square cells. In rare instances, rectangles can better model a long, slender ore body.

- **Label Values of Data Points:** This option will draw a label next to each drillhole indicating what value was used at each drillhole for the gridding. Set a Text Layer and Text Size here. This option is a good way to visualize and check the data points that the program is using.

- **Create Data Points Report:** The Create Data Points Report option is another way to check the data points that are used in gridding. This option will create a report of the gridding data points. This report is displayed in the Standard Report viewer where it can be saved, printed or put on screen.

- **Create Composite Grids:** The Create Composite Grids option allows you to select multiple strata or beds to combine instead of gridding the strata individually. With compositing, the program shows the same strata selection dialog with the list of strata but you can now select multiple strata by picking from the strata list while holding down the Shift or Ctrl keys on the keyboard. For composites you can grid the top elevation which is the highest elevation at each drillhole for the composite, the bottom elevation which is the lowest composite elevation, the thickness which is the sum of the thicknesses for all the composite strata, or composited strata attributes.

- **Use Parameter File:** Turning this option on will use a parameter filter file made in Parameter Compliance.

After the grid options dialog, the program prompts you to select the drillholes and fault lines. After reading in the selected drillholes, there is a Choose a Strata to Process dialog to choose the strata to process from the list. If Create Composite Grids was turned on, then multiple strata may be selected here. The All, Key Only and Non-Key Only are just viewing options to reduce the number of strata in the window if there are a lot, for ease of selection.

Once the strata is selected, another dialog shows the strata values and attributes that are available to grid. These will be thickness, elevations, equations, and any quality attributes that are in the drillholes. Choose a value to grid from the dialog.
Then the program will prompt for the grid file name to create (.GRD). Next the program will process the strata data points to create the grid and the results are stored in a user-specified file name. The grids created by Make Strata Grid File can be used as the geologic model for the PreCalculated Grids Definition file. Also the grids can be used in the grid application routines, in the Civil Design module, such as Plot 3D Grid File, Grid File Utilities and Elevation Difference.

Making Strata Grids with Fault Lines
There is an option to select fault lines in addition to the drillholes. The fault lines should be drawn as 3D polylines with elevations that equal the fault differential. The program will grid with all modeling methods using the fault lines for making strata elevation grids. The 3D fault polylines should be drawn such that the left side of the polyline, relative to the direction of the polyline, is the low side of the fault and the right side is the high side. As each grid corner elevation is calculated, the program checks each drillhole. If the drillhole is on the same side of the fault polyline as the grid corner, then no adjustment is made to the drillhole elevation data. Otherwise the drillhole is projected onto the fault polyline and the polyline value at this point on the polyline is used to adjust the drillhole elevation. For example, if the fault polyline value was 5.0 and the grid corner was on the high side of fault while the drillhole was on the low side, then 5.0 would be added to the drillhole elevation for modeling at that grid corner. If the grid corner was on the low side and the drillhole was on the high side, then 5.0 would be subtracted from the drillhole elevation. Reverse Polyline is a good way to reverse the fault line if it is drawn in the wrong direction.

Triangulation Modeling Method
This method is straight triangulation between the drillholes. Triangulation calculates these values by interpolating on the plane defined by the three points in the triangle that encloses the point. Since triangulation only interpolates, it can only calculate values within the area of the data. Afterwards, an extrapolation routine can then fill in the rest of the grid. This extrapolation uses a safe method that tends to average out the data. There is an option to extrapolation to apply the global trend. This option finds the average slope and direction of the existing data and applies this slope to extrapolating.

Inverse Distance Modeling Method
Inverse distance calculates the grid values by assigning weights to the existing data. The grid values calculated by inverse distance are a weighted average of the existing data. Inverse distance will not carry trends and the calculated grid values will never be higher than the highest existing data point. Likewise the calculated grid values will never be lower than the lowest existing data point. The weights are proportional to the inverse of the distance between the point to be estimated and the existing data point. Closer points are weighted more than points farther away. The inverse distance can be calculated to first, second, or third power which are \(1/d\), \((1/d)^2\), and \((1/d)^3\) respectively. The power can also be any user-specified number such as 2.5. The inverse distance estimate is a weighted average with the individual weights computed as an inverse power of distance as follows:
\[ W_i = \frac{d_i^{-\text{power}}}{\sum d_i^{-\text{power}}} \quad I = 1 \ldots \text{number of samples} \]

where \( W_i \) is the weight computed for each sample \( i \), each \( d_i \) is the distance between the location being estimated and sample \( i \), and \( -\text{power} \) is the inverse distance weighting power.

In Configure under Mining there are several options for controlling inverse distance. The Inverse Distance Search Radius is used for calculating a value at a point such that only drillholes that are within this Search Radius will be used in the calculations. The Inverse Distance Max Samples value limits calculations to the nearest specified number of drillholes to the point. For example, the program will use the nearest 10 drillholes. Inverse distance can also be controlled by quadrants which are divided into northeast, southeast, southwest and northwest. The Min Quadrants setting will use at least this specified number of drillholes from each quadrant as long as there are drillholes in the quadrant within the Search Radius. For instance, a setting of Min Quadrants of one would make the program look for at least one drillhole from each quadrant. The Max Quadrants value limits the number of drillholes used from each quadrant. For example if Max Samples was set to 25 and Max Quadrants was 10, then the total samples would be 25 with no more than 10 of the closest ones from each quadrant.

Elliptical inverse distance modeling method is an option that appears any time the Inverse distance modeling method is chosen. The prompt will appear:

**Use inverse distance to which power [First/Second/Third/Other]?** Second

**Use elliptical inverse distance [Yes/No]?** Yes

**Enter azimuth of anisotrophy:** 45

**Enter anisotropic factor:** 1

**Calculating grid by inverse distances 33880...**

This will produce oval shaped inverse distance "bulls eyes" that will use the 2nd weighting power, with the 1st weighting power applied to an azimuth of 45. This option will appear anywhere the Inverse Distance modeling method is selected, such as isopaching.

**Kriging Modeling Method**

Kriging estimates the grid values by figuring the relationship between all the existing data points and then assigning weights to this data. Kriging finds the best fit linear unbiased estimates for the given data and model. Kriging can carry trends within and beyond the limits of the data and can find new high and low values. You must supply a model that defines the spatial relationship of the data which can be difficult. In fact, Kriging is a very complicated subject and you will need to reference an outside source for a detailed description such as *An Introduction to Applied Geostatistics* by Isaaks and Srivastava. Carlson uses Ordinary Kriging. All the parameters for this Kriging are specified in the dialog shown.
Polynomial Modeling Method
The polynomial method is based off of triangulation. The difference is that instead of directly interpolating within each triangle, the polynomial method creates smooth transitions by using a fifth degree polynomial function that accounts for neighboring triangles. Since polynomial needs adjoining triangles, when there are fewer than five data points, there will be fewer than four triangles and the polynomial method will revert to straight triangulation. The same extrapolation logic for triangulation applies to the polynomial method.

Linear Least Squares Modeling Method
The linear least squares method finds the least squares best fit plane at each grid corner. The least squares routine weights each data point by inverse distance so that closer points are weighted more than points farther away. So the best fit plane varies at different points on the surface. The linear least squares method extrapolates trends very well. A lower inverse distance factor (i.e. 1.0) will weigh the data points more equally which models the trends more globally (sometimes called "global dip"). Likewise a higher inverse distance factor (i.e. 3.0) will weigh the closer data points more heavily which models local trends strongly (sometimes called "local dip"). Least squares will trend and allows for data points that are new highs and lows, that don't appear in the original drillhole/point data. It does produce very nice, smooth contours that honor the data points.

Approximation Base On Smoothing (ABOS) Modeling Method
ABOS is a method for modeling values of irregularly spaced points by using a continuous function with two independent variables. This method is developed and implemented by the developer of SurGe, Miroslav Dressler.

The ABOS method uses very simple mathematical tools - numerical tensioning and smoothing. The tensioning and smoothing are performed so that elements of matrix, which represents surface z-values at nodes of a regular rectangular grid, are repeatedly replaced by the weighted average of selected surrounding elements. The selection of elements involved into weighted average depends on the type of tensioning or smoothing. Despite the fact that the mathematics of the ABOS method is simple, the resulting surface can be modified by a few parameters so that it is comparable with the surface created by sophisticated methods such as Kriging, Radial Basis Functions or Minimum Curvature.

Following dialog window shows ABOS parameters that need to be set in order to run ABOS inside the Carlson.
Differential Smoothing Factor:
This parameter enables to control smoothness of generated surface. The larger value, the sharper interpolation is obtained. Typical values are:
0.00 - 0.30 ... for smooth interpolation
0.40 - 0.60 ... for normal interpolation (default value is 0.50)
0.70 - 1000.0 ... for sharp interpolation

Sharp / smooth model at local extremes can be improved by increasing the differential smoothing factor. The accuracy of generated surface decreases with increase in this factor. The zero value produces most smooth surface.

Target Accuracy:
This parameter specifies how accurate the generated surface has to be. It represents the percentage value of average difference between z - coordinates of input points and generated surface from (Zmax - Zmin), where Zmin is the minimum value and Zmax is the maximum value of the z - coordinates of the input points. If the calculated accuracy ((Average DZ / Zmax - Zmin) * 100) is less than the Target Accuracy, the process of interpolation stops and outputs the target grid.

Degree of Linear Tensioning:
This parameter enables to set the degree of linear tensioning. It can have four values:
1. None - for no linear tensioning
2. Medium - for medium linear tensioning
3. Strong - for strong linear tensioning
4. Full - for full linear tensioning

Chapter 14. Geology Module
It is clear from the following figure of cross-section of a grid surface that the surface is more linear for higher degree of linear tensioning.

**Prompts**

Use position from another file or pick grid position (File/<Pick)? press Enter Using the position of an existing file copies the grid resolution and corner point locations to the new grid files. This is useful if you need to have grid files match exactly. Most of the time, grids should match position in the geologic model.

Pick Lower Left grid corner: enter or pick a point

Pick Upper Right grid corner: enter or pick the second point to define the grid position

Make Strata Grid File dialog box

Set the grid resolution and other options. A higher grid resolution increases the processing time. Also choose the Modeling Method in this dialog.

Select drillholes, channel samples and strata polylines.

Select objects: select the drillhole symbols

Select fault lines or Enter for none.

Select objects: press Enter for none, or select the fault lines

Choose Strata to Process dialog

Choose Attribute to Process dialog

Pulldown Menu Location: StrataCalc

Keyboard Command: chgrid

**Define Strata Grids AutoRun**

This autorun-macro type command stores a list of strata to process, the value to process (thickness, elevation or attribute), the process method, grid file name and location. Then the grids can be automatically recalculated for an updated set of drillholes without specifying all these options again. These processing settings are stored in a file with a .run file extension. All of the items described in Make Strata Grids applies here also.
• Edit/Add: This brings up the Strata Grid window for each grid to create. It contains all of the same functions as Make Strata Grids. From this dialog, pick the Choose Strata to Process. This will show a list of strata from the selected drillholes. At this point you can select multiple strata by holding down the Shift or Ctrl keys while picking with the mouse. For each selected strata, the program will create an entry in the list with a default grid file name of the strata name plus the attribute name. So selecting multiple strata is a quick way to fill out the Auto-Run table.

• Once the Choose Strata window is selected, the Attribute or variable to grid needs to be selected.
• Remove/Clear: These options will remove a row from the window and clear will remove all rows.

• Add Row: This will add a new row to the bottom of the spread view.

• Move Up/Move Down: To move rows up or down, choose these options.

• On/Off: If the row is turned on, it will be processed and the grid written. If this is off, no grid is written.

• Make Grids: Once all the options are set and save, the Make Grids button generates the grids.

• Change Directory: This will direct the macro to write the grids to the new directory specified.
• Column Options: This option allows for customized viewing of which columns to display in the window.

• Load/Save/Save As/Exit: These are typical operations for file management.

• Create Data Points Report: This brings up a report of the drillholes or data points and what was used at each point, and the source of the data.

• Run GFU Macros at Completion: If this is turned on and a file is selected, the Grid File Utility will be run at the completion of the Autorun Grids.

• Warning Report Message: If for some reason, some grids cannot be written, there will be an error message at the end of the processing time.
**Prompts**

Select drillholes and strata elevation polylines.
Select objects: *select the drillhole symbols*

**Auto-Run Grid Files dialog**

Pulldown Menu Location: StrataCalc in Geology
Keyboard Command: chgrid2

---

**Run Strata Grids AutoRun**

This command will run the predefined RUN file for making strata grid files. This allows for easier definition of the Autorun macro, without having to wait for the modeling and drillhole processing time.

The Define Strata Auto-Run is where you build the macro file containing the grids to create. It does not have to create them at that time, it just prepares the file to be run at a later time. It is optional to select the drillholes at the beginning of the Define routine. Just hitting Enter will bring up the input dialog.

Run Strata Grids Auto-Run takes the predefined *.RUN file (from Define Strata Grids Auto-Run) and processes it, creating the grid files. As mentioned above, with the previous version in very large datasets, it sometimes took several hours after defining the Auto-Run, to actually select the Make Grids button. Now with this split into 2 routines, you can simply load up the predefined *.RUN file, select Make Grids and leave it over lunch, or overnight, while the modeling calculates the new grids.

---

**Prompts**

Select the RUN file dialog
Select drillholes and strata elevation polylines.
Select objects: *select the drillhole symbols*

Pulldown Menu Location: StrataCalc
Keyboard Command: chgrid3

---

**Strata Isopach Maps**

For each strata in the drillholes, this routine can generate isopach maps, or isolines of the strata thickness, bottom elevation, and attributes such as moisture, sulfur, and BTU. An isopach map is essentially a contour map of the specified strata values.
At the start, there is an option to isopach from either from Grid File or Drillholes From Screen. The file option will contour from stored grid files. In the screen option, the program reads the strata data from the selected drillholes and builds strata models on-the-fly while applying pinch out and conformance as set in Configure, Mining. With the screen method, there is an option to draw labels next to the drillholes for the data values used for modeling which is helpful to visualize the source data. Then the program shows a list of strata. After selecting a strata to process, the program cycles through all the possible strata values. When one of these values is chosen, the contour options dialog box is activated which allows the contouring parameters for the isopach map to be set.

Smooth Contours Setup: The Low to High slider bar controls the amount of smoothing. This smoothing method is based on the Bezier method. The Apply Outlier Reduction Filter option will remove spikes in the contour polylines that don't follow the general trend of the contour. The Reduce Before Smoothing option applies the Reduce Vertices function on the contour polylines before applying the Bezier smoothing. By reducing before smoothing, the contours will have more freedom to smooth since the Bezier method holds all original polyline vertices and the reduce will result in fewer vertices to hold. The Offset Distance is the maximum distance the contour is allowed to shift when removing vertices during reduce. Smoothing Sub-Division will internally subdivide the grid cells with a quadratic smoothing algorithm to help create smoother contours.

The Hatch Zones option will fill in the area between contours with a hatch pattern and color for that zone. For example, hatch zones will create a thickness isopach map with the 0-2 area in blue, 2-4 in green and 4-6 in red etc. The Polyline topology option will create closed polylines of each contour zone. This can be used for GIS type applications in other modules.

The Draw Drillhole Labels option draws text next to each drillhole with the value that was used for contouring. After creating the contours with this routine, the contours can be labeled and highlighted with the contour embellishment commands in the Contour drop-down of the Contour-DTM module. The first window determines the source of the isopach and the modeling process if from drillholes. Use Triangulation Subdivision will be applied to the modeling with triangulation. This process is documented in the Make Grid command. Create Composite Contours will allow for multiple strata to be selected at once, to create a "total coal" thickness isopach for example.

There are two different dialogs, depending if you are contouring from drillholes or a grid. They are both shown below.
### Choose a Strata to Process

<table>
<thead>

Define Strata Isopach AutoRun

The Define Strata Isopach Auto-Run is for building the macro auto-run file containing the isopachs to create. There is still the option to run the auto-run from here if desired. If there are not any drillholes, for example, you are coming from grids, just hit Enter when prompted to select drillholes.

The first dialog shows the defined isopachs that will be created. There are buttons to Edit, Add and Remove the row. The Sort will sort them in order. Up and Down will move them up or down the list. The On or Off buttons turn them on or off for processing. The Make Isopachs button starts the process and creates the isopach maps. Load and Save/SaveAs will load or create the CTR file. The two entry dialog boxes are slightly different, depending on drillholes or grids.
Following is a description of all the items on the dialog for the Auto-Run Isopach.

- **Processing on**: This needs to be selected to build the isopach. It controls the Process column on the first screen.
- **Strata Name**: This will display the strata name if isopaching from drillholes. If isopaching a grid, then this will be blank.
- **Value to Process**: This is the attribute or item to isopach. It can be an elevation, thickness or any quality attribute. It will be grayed out if isopaching a grid file.
- **Contour Layer**: Enter the layer for the contours.
- **Color**: Choose a color for the contour layer.
- **Contour Interval**: Enter a contour interval. This is for the intermediate contours. Index contours are set below.
- **Smooth Contours**: This toggle will determine if the contours are smoothed. The slide bar controls the smoothing from Low to High.
- **Smoothing Sub-Division Levels**: The smoothing subdivision option will internally subdivide the grid cells with a quadratic smoothing algorithm to help create smoother contours.
- **Reduce Vertices**: This option removes vertices from the contour lines, as long as the contour line does not move more than the Offset Distance from the original location.
- **Drawing File**: There is the option to output each isopach map to its own drawing file. To do this, just select the Choose Drawing File button and enter a drawing name. This name is displayed above the button. If this is not selected, then the isopachs are drawn in the current drawing.
- **Grid File**: The Choose Grid file button is active only if the Modeling Method is set to Grid File. The grid to isopach is displayed above the button.
- **Modeling Method**: There is the option to model the drillholes by Triangulation, Inverse Distance to any power, Kriging, Polynomial and Least Squares. Using a premade grid file is also set here if the drillholes are not used.
- **Draw Index Contours**: Turn this option on to generate the index contours.
- **Set Index Options**: This brings up the Index contour options screen to set the interval, width, layer and color shown below.
• **Label Contours:** This option will label the contours.

• **Set Label Options:** This button will bring up the Contour Label Options screen shown below.

![Contour Label Options](image)

• **Ignore Zero Values:** This option will ignore any zero values for contouring.

• **Range: Min Z and Max Z:** This defines the low and high values that will be contoured. Any values outside of this range will not be contoured.

• **Use Triangulation Subdivision:** When modeling with Triangulation or Polynomial, this will subdivide the triangles into at least 3 smaller triangles for smoother contours.

• **Extrapolate Grid To Full Grid Size:** When modeling with grid files, this option will extrapolate to assign values to any null cells in the grid file.

• **Use Global Trend Extrapolation:** When modeling with Triangulation or Polynomial, this will extrapolate to the edge of the grid limits based on the overall global trend.

• **Set Kriging Parameters:** When modeling the drillholes with Kriging, This button brings up the Kriging Spatial Continuity Model settings screen shown below.
• **Inverse Distance Power:** When modeling the drillholes with Inverse Distance, this is the power that the distance is raised to. It can be any power, including decimals.

• **Elliptical Inverse Distance:** If the ore body is long and narrow, sometimes an elliptical inverse distance modeling method is preferred. This option will allow for two different powers to create an ellipse.

• **Anisotropic Azimuth/Factor:** When using the Elliptical method, this is the azimuth for the second factor, and the second factor power.

**Prompts**

Select drillholes, channel samples and strata polylines or ENTER for None. Select Enter if isopaching only grid files.

**Run Isopach Maps AutoRun**

This command will execute the predefined Auto-Run Isopach CTR file. It will prompt to select the file, inclusion/exclusion boundaries and the drillholes, then go right into generating the isopachs. It skips the Define Auto-Run step.

**Prompts**

Select Inclusion polyline (Enter for none):
Strata Quantities in Series

For each strata in the drillholes, this command can calculate the volume, tonnage, and average attribute values within a specified area. The possible attributes depend on the configuration set in Define Drillhole. For example, attributes might be moisture, sulfur, BTU, etc. After reading in the selected drillholes, Strata Quantities cycles through all the possible quantities for every strata from top to bottom. Only the desired quantities are calculated and the result is printed out in volume, tons and quality.

Strata Quantities calculates from a 3D grid of the values. The grid resolution is specified in a grid resolution dialog box. A higher resolution yields more accurate results, but slows down the routine.

The area for gathering quantities defaults to the limits of the selected surface entities and drillholes. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. Also, in the first selection for surface entities and drillholes, any selected polylines in the PILLARS layer will be made into exclusion areas and polylines in the PERIM layer will be made into inclusion areas. This is useful for getting quantities from drillholes among pillars and perimeters.

Selected Strata Quantities
For each strata in the drillholes, this command can calculate the volume, tonnage, and average attribute values within a specified area. The possible attributes depend on the configuration set in Define Drillhole. For example, attributes might be moisture, sulfur, BTU, etc.

The area for gathering quantities defaults to the limits of the selected surface entities and drillholes. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. Also, in the first selection of drillholes, any selected polylines in the PILLARS layer will automatically be made into exclusion areas and polylines in the PERIM layer will be made into inclusion areas. This is useful for getting quantities from drillholes among pillars and perimeters.

This command is similar to the Strata Quantities in Series command. The difference is that this command does not process the strata in sequence from top to bottom. Also this command does not model the ground surface. Instead Selected Strata Quantities allows you to select the strata to process from the list of available strata. The advantage is that when there are many strata, you don't have to cycle through all the top strata to get down to a specific strata. Since the ground surface is not calculated, the disadvantage of this command is that the outcrop for the selected strata is not automatically calculated. The volume for the selected strata is calculated using the strata thickness and the calculation area. To limit the volume calculations to be inside the outcrop, draw the outcrop as a closed polyline which can then be used as an inclusion perimeter.
Another advantage of this command verses Strata Quantities in Series is that composite quantities can be calculated. Composite quantities allow you to select multiple strata and add their thickness together for the volume report. Also the weighted average of the attributes is calculated.

**AutoRun Strata Quantities**

This command stores a list of strata to process, the value to process (volume or attribute) and the process method. It is the Auto-Run macro of the Selected Strata Quantities command. By clicking the Calculate Quantities button, the quantities for each item in the list can be calculated automatically without specifying all these options again. This routine allows you to save many steps when recalculating volumes for updated drillholes or different inclusion areas. These processing settings are stored in a file with a .VOL file extension.

Define PreCalculated Grids

This command assigns grid files to strata names in sequence. This list of grid files represents the geologic model of the strata. The Make Strata Grid File or Auto-Run Strata Grids commands can be used to create the grids before running this routine. The Pre-Calc grid assignments are stored in a user-specified file name with the .pre file extension. There are two types of Pre-Calc files: elevation and thickness. When creating a new Pre-Calc file, you have the choice between elevation and thickness. Once the Pre-Calc file is created, the type cannot be changed.

For elevation type Pre-Calc files, the grid files define the bottom elevation surface model for the corresponding strata. A grid file for the ground surface model is also assigned in this routine. The surface grid can be created with the Make 3D Grid File routine in the Civil Design module. When the Pre-Calc file is applied in StrataCalc volume calculations, the strata thickness is determined by comparing the current strata bottom elevation grid with previous upper strata or surface grid. Shown below is an elevation example.
With thickness type Pre-Calc files, the grid files represent the thickness for the corresponding strata. A surface grid file is not specified. Without the ground surface elevation grid, the StrataCalc routines cannot find outcrops or adjust the strata thickness for variations on the surface. So the thickness grids that you supply the Pre-Calc file must account for the outcrops and ground surface variations. To account for outcrops, you can set the thickness grids to zero in outcrop areas by using a closed polyline for the outcrop areas and running Grid File Utilities-Set Value with the Use Inclusion Areas option. A thickness PreCalc will not draw proper Fence Diagrams. To account for surface variations, you can make a grid of the ground surface and a bottom elevation grid of the top strata overburden. Then use Grid File Utilities to subtract the top strata elevation grid from the ground surface. The resulting difference grid is the top strata thickness. Shown below is a thickness example.

All these grid files should have the same location and resolution. They can vary for some commands, such as Surface Mine Reserves. To ensure the same grid position, use the File option at the Use position from another file or pick grid position prompt when making the grid files. The pre-calculated grids are specified in the dialog shown below. The surface grid is defined in the top of the dialog. To assign the surface grid, pick the Select Grid File button in the upper right. Next there is a list of the strata names and the corresponding grid files. To add a strata grid assignment, highlight the strata above the one to add and click the Add button. This brings up the next dialog where you enter the strata name and grid file. Besides elevation and thickness grids, attribute grids such as BTU can be assigned to
the strata names. In the Pre-Calculated Grid Definition dialog, click on the Attribute toggle and enter the Attribute Name. The strata in this list should be listed in top to bottom order. If a strata is out of order, highlight the strata in the list and click the Move Up or Move Down button.

The Load Auto-Run button will prompt you to select an Auto-Run Grid Definition File (.run). The program will then read the strata names from this file and build the Pre-Calc Definition list. The Reset Directory button allows you to reassign the grid files directory in case the grid files have move since the Pre-Calc file was created. Select the grid file at the top of the window, usually the first grid on the list. The surface grid will have to be redirected separately. The Extrapolate will extrapolate and save all the grids to remove NULL values. This option will save time in StrataCalc routines that use the Pre-Calc file and extrapolate the grids on-the-fly each time. There is an option to extrapolate by merging or flattening (pancaking) elevation grids with upper strata. The “pancaking” is an option using the Extrapolate function. It will assign the Nulls in a grid the elevation of the strata above. This change is saved to the .GRD file. The other option will just extrapolate the grid elevation out to the grid limits.

The purpose of this routine is to allow you to process stored grids in routines such as Surface or Underground Reserves and Fence Diagram. These commands have a Pre-Calculated Grid option under the modeling methods. Otherwise these routines will read selected drillholes and calculate the strata models on-the-fly. The advantage to pre-calculated grids is that you have more control over the geologic models. After creating the strata grid file, there are many routines that can be used to analyze and modify the grids to make sure that the grids model the strata the way that you want, and even create a mining model from modifying the geologic grids. For example, you can use Plot 3D Grid File, Grid File Utilities and Contour from Grid in the Civil Design module.

Finally, for users with the Ore Module that have created block models, they may be added into the PreCalc for use with the Fence Diagram and Surface Reserves commands. There is an option, next to Elevation or Attribute for Block Model. The procedure here is to build the PreCalc, interval by interval from the top down as usual. Then add in the block model for each interval, or strata that you have. It is just like the other attributes, in that it must have the same name as the strata it is referring to. There are options on the Fence Diagram and Surface Reserves screens to use the hatch fence by block model and to break out quantities by attributes.

**Pulldown Menu Location:** Drillhole
**Keyboard Command:** precalc

### Draw Fault Line

This command creates a 3D polyline that represents a fault line which is used by Fence Diagram in the intersection mode, or in the Make Strata Grid File command. When the fence line crosses the fault line, the strata will shift by the amount of the shift value of the fault line at that point. This command is very similar to Carlson Draw > 3D Polyline command, in addition to elevation for each vertex of the polyline this command prompts for fault shift. This value is the amount of elevation difference from left to right across the fault line in the direction of the line is drawn. Used is also prompted for the dip angle at the beginning, dip angle is same throughout the length of fault.
Prompts

Enter dip angle (degrees) <0.00>: 90
Reading cell > 89823
[Continue/Extend/Follow/Options/<Pick point or point numbers>]: pick a point
Z: 492.29
Enter fault shift <0.00>: 35
[Arc/Distance/Close/Extend/Follow/Undo/<Pick point or point numbers>]: pick a point
Z: 481.30, Hz dist: 1408.86, Slope dist: 1408.90, Slope: -0.8% Ratio: -128.2:1
Enter fault shift <35.00>: press Enter

Z: 456.02, Hz dist: 750.48, Slope dist: 750.48, Slope: -0.1% Ratio: -855.4:1
Enter fault shift <40.00>: 45
[arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter

Pulldown Menu Location: StrataCalc
Keyboard Command: fault

Edit Fault Line
This command is used to edit the fault line drawn using Draw Fault Line Command. It allows to edit each vertex of the fault along with its shift displacement for each vertex and the dip angle of the fault. The fault appears in the graphic window. There are buttons for pan, zoom in/out, rotate and zoom extents. Each line of the spreadsheet may be edited to update the fault line. The Pick button at the end of the row will switch to the plan view where the new location for that point can be selected. The + Add Vertex button will add a point, the X Remove Vertex will delete a point, and the Pick Location will move an existing point.
Prompts

Prerequisite: fault lines drawn using Draw Fault Line

Calculate Fault Shift
This command assigns fault shifts to polylines. The polylines must be drawn ahead of time and they should follow the fault zones. After selecting the polylines to process, the program prompts for drillholes to process. Then select a strata to model. The fault shift is calculated by modeling the strata twice for each polyline. One model excludes the drillholes on the left of the polyline and the other model excludes the drillholes on the right. Then the elevation difference between the two models is used to assign the fault shifts along the polyline.

Prompts

**Draw Heave Zones**

This command creates closed polylines that represent the fault heave zones where the material is broken up and not mineable. These polylines can then be used as exclusion areas in routine like Strata Isopach maps to avoid contours in those areas. They can also be tagged as Strata Limit Polylines for exclusion for volumes and to delete the area in a Fence Diagram.
The command will use either an existing elevation grid file, or it will model from drillholes on screen. If there are multiple seams that are faulted, each one will have a slightly different area along the fault. Shown here is a result of drawing the heave zones. Most zones will run parallel to the faults, with the distance away from the fault based on the displacement of shift of the fault.

Input-Edit Strike-Dip Symbols
This command works in an editor where the strike and dip symbols can be added, deleted or edited in a spreadsheet type editor. There are options for reporting and importing from an external text file to bring the symbols in.

- **Add Symbol (+):** This button brings up the Strike/Dip Symbol window where a new symbol can be edited. There are defaults in the window that can be modified with the data. There are options to label a description, enter the strike and dip, and symbol and text size. The symbol and text layers can be entered here, or picked from a list of layers with the Select button. The Place Symbol button allows for screen picking of the new location for the symbol.

- **Delete Symbol (X):** This button deletes the highlighted row of the selected symbol.

- **Edit Symbol:** This button is similar to the Add button, but the highlighted row symbol appears in the window, allowing for changes that are done in the drawing when the Exit is selected.

- **Report:** This option will bring up the Report Formatter where the symbols are reported. The following data can be reported, such as X, Y, Z, layer, text size, and others.
• **Import:** This option will import the symbols into the drawing from a text file of the formats shown. It is automatic if a header line is used to define the columns, it will find the names and import the data. If there isn't a header line, then each column will have to be defined prior to importing, with the dropdown arrows.

---

**Prompt**

Select all strike-dip symbols.
Select objects: Specify opposite corner: 20 found, 4 groups. (If there are no symbols in the drawing already, just hit "Enter" and the empty window will appear where new symbols can be added or imported).

**Keyboard Command:** EDIT_STRIKEDIP

**Draw Strike-Dip Symbol**

This command draws the standard strike-dip symbol based on user defined input. It has an option for entering and labeling a description. If no description is desired, then leave it blank. The strike and dip entered in the window will orientate the symbol placement. There are settings for symbol and text size, as well as layers.
Keyboard Command: struckedip

Tag Strata Polylines

This command attaches a strata name to a 3D polyline that represents the bottom elevation, top elevation or the thickness of that strata. When modeling the drillholes, each point in these strata polylines is used as an elevation or a thickness data point for the assigned strata. For example, a 3D polyline for the outcrop of a strata could be tagged with the strata name and used in processing for additional model enhancement. If bed names are used, be sure to include the _TOP, _KEY, _PARTING or _BOTTOM extensions to the bed name.

Prompts

Strata name: Seam1
Type of strata polyline [ <Elevation>/Thickness]? press Enter for Elevation
Elevation reference [ <Bottom>/Top]? press Enter for Bottom
Select strata bottom elevation polylines.
Select objects: 1 found

Pulldown Menu Location: Drillhole
Keyboard Command: stratatag
Offset Strata Polylines

This command creates additional strata elevation polylines offset by the strata thickness from a reference/starting strata polyline for elevation. This is useful for manually creating faults where all the seams are offset along the elevation strata polylines. The first prompt is to open or create an offset strata polylines file (*.OSP). The first column is the strata/bed name attached to the strata polyline. The button next to them brings up the list of defined strata. A Reference polyline is one that already exists and this is the one that will be offset from. The thickness to offset the new polylines can either be entered as a value (+/-) or as a thickness grid file. The layer is the layer that the reference polyline is on, and the layer it will draw the new polylines on. The resulting new strata polylines can be used for more accurate modeling elevations.

**Keyboard Command:** offset_strata_pl

Report Strata Polylines

This command generates a report using the Report Formatter containing all the Strata Polylines automatically found in the drawing. It reports the layer, XY of the start and end of the polyline, the tagged strata name and the type (elevation or thickness).

**Keyboard Command:** report_strata_pline
Highlight Strata Polylines

This command simply highlights the named strata polylines in the drawing. A regen of the screen will unselect the polylines.

Prompts

Select the polylines to check.
Select objects: Specify opposite corner: 5 found
Highlighted 3 Strata Polylines. Skipped 2 other polylines.
Pulldown Menu Location: Drillhole in Geology
Keyboard Command: highlight_strata_pl

Identify Strata Polylines

This command simply allows you to pick a polyline and report the strata name, if any, attached to this polyline. These are tagged for use in modeling the bottom elevation or thickness in addition to drillholes.

Prompts

Select strata polyline to identify:
Strata Name: SEAM2 Type: Thickness
Select strata polyline to identify:
Strata Name: SEAM1 Type: Elevation
Select strata polyline to identify: pick one that is not tagged
No strata name assigned to polyline.
Select strata polyline to identify:
Pulldown Menu Location: Drillhole
Keyboard Command: strataid

Untag Strata Polylines

This command removes the strata polyline information and returns the selected polylines to the original status: regular polylines.

Prompts

Select strata polylines to have strata tags removed.
Select objects: 1 found
Pulldown menu location: Drillhole
Keyboard command: stratauntag
Prerequisite: Named strata polylines

Name Limit Polylines

This command assigns strata names to identify polylines as inclusion or exclusion areas for the strata. Strata limits are used to model discontinuities such as glacier washout or volcanic strata. Strata that gradually trend to pinch out should not use strata limits. The pinch out should be modeled using just the drillholes. When assigning the names for strata in the PreCalc file, be sure they are spelled exactly the same here, so they are applied correctly. Also, when
using Limit Polylines with bed names in the drillholes, be sure to add the _TOP, _KEY, _PARTING, OR _BOTTOM to make sure the limits are applied to each bed interval.

Strata limit polylines are used in the StrataCalc routines to indicate where the strata exists. The inclusion and exclusion polylines are used for trimming the contours in Strata Isopach Maps and used to limit volumes in routines like Surface Mine Reserves. Also in areas outside the strata limits, the strata thickness is set to zero and 10000 is added to the strata elevation. This forces the strata up to clip out to the strata above. Also drillholes that are outside the strata limits are ignored for processing that strata. There is a choice to assign all strata names to the limit lines, or Specific strata. If Specific is chosen, then the following dialog appears.

When drawing a Fence Diagram and using Limit Polylines, the strata cutoff occurs exactly at limit the polylines. Shown here is an example of a Fence Diagram, plotted with the plan view for verification. Notice how the limit lines crop the seams in section view precisely at the limit lines. The plan view was placed on top of the fence diagram just with basic AutoCAD drafting tools. Dashed polylines were then drawn with ortho on to illustrate the crops honoring the limit lines exactly. For all StrataCalc routines that use limit polylines, there is a command line message to report when limit polylines are applied.
Another use of Limit Lines is to control the transition from a full seam to where it splits. Limit lines must be drawn for one or both instances. The full seam and the two split seams can both appear in the PreCalc file for volumes and Fence diagram. An example PreCalc is shown here. Notice the C2_KEY splits into C2L_KEY and C2U_KEY. They also split. All of these can exist in the PreCalc, as long as there are limit lines on screen to control where they appear.

The result is a Fence Diagram as shown here, where the limit lines control where the full seam, and its splits appear.
Prompts

Enter strata name to apply (<All>/Name)? UB for strata UB
Select Inclusion perimeter polylines.
Select objects: pick a closed polyline
Select Exclusion perimeter polylines.
Select objects: press Enter
Pulldown Menu Location: StrataCalc

Keyboard Command: minelmt

Report Limit Polylines

This command reports all Strata Limit Polylines that are in the drawing. The report contains the layers, area, XY of the polyline endpoints, and whether it is an inclusion or exclusion limit polyline.

Keyboard Command: report_strata_limit

Highlight Limit Polylines

This command simply highlights the named strata limit polylines in the drawing. A regen of the screen will unselect the polylines.

Prompts

Command: highlight_limit_pl
Select the polylines to check. (select all the polylines of interest)
Select objects: Specify opposite corner: 10 found, 2 groups, 12 total
Highlighted 2 Limit Polylines. Skipped 10 other polylines.
Pulldown Menu Location: StrataCalc in Geology
Identify Limit Polylines

This command reports the strata names assigned to a polyline for strata limits. There is the option to select one and view its name, to pick inside and have it identify which lines enclose that point, or to search the drawing and automatically highlight and report all that it finds. If the hatch option is used, then the hatch window appears where the hatch pattern can be selected for each limit polyline.

Prompts

Pick on a polyline, pick inside or search drawing [<Pick>/Inside/Search]: i
Pick inside limit polyline to identify:
Hatch Current, select Next or Exit [<Hatch>/Exit]: H to hatch
or

Pick on a polyline, pick inside or search drawing [<Pick>/Inside/Search]:
Select mining limit polyline:

Current: Inclusion: C2U C2L IB1
Hatch Current or Exit [<Hatch>/Exit]: e to exit

Pulldown Menu Location: StrataCalc in Geology
Keyboard Command: minelmtl
**UnTag Limit Polylines**

This command removes the strata limit assignments from the selected polylines.

**Prompts**

Select limit polylines to have limit data removed.

*Select objects: pick the limit polylines*

*Pulldown Menu Location: StrataCalc*

*Keyboard Command: rmlimit*

---

**Prepare Variogram Data**

This command writes out the data file for variogram as a *.DAT file. This is the input file for the Calculate Variogram command. First select the strata to process, then select the value or attribute to process.

**Prompts**
**Calculate Variogram**

This command takes the *.DAT file from Prepare Variogram and calculates the variogram data, outputting the Nugget, Sill and Range.

![Variogram Analysis](image)

**Data File:**
The data file appears in the top left corner. If the file is not displayed, chose Select, or double click in the file name window. To start it with a specific file, start it as:

`\path\Csvgram batch-\path\filename`

**Variogram Type:**
The type of variogram to calculate can is shown in the upper left corner. If the datafile has only one variable, the Covariance option in the yellow box will not be enabled. First, select the Head Variable in the yellow box, shown here as Thk m. Then select the type, such as Semivariogram. This should then display the head variables span from low to high. The current types of variograms to choose from is shown below. Details of each method can be found online.

- Semivariogram
• Cross Semivariogram
• Covariance
• Correlogram
• General Relative Semivariogram
• Parwise Relative Semivariogram
• Semivariogram of Logarithms
• Semirodogram
• Seminadogram

Variogram Attributes:

Trimming limits will provide a range selection to process. A value of 0 trimming will delete null values. Set the number of lags and lag separation distance. Lags are the number of intervals, the separation is the distance between the intervals. Normally the Lag Tolerance is Lag Separation Distance divided by 2. OmniDirectional will look in multiple circular groups for pairs. If it is off, then it will look just directional for the pairs. The number of directions, Angle Tolerance and Bandwidth apply to the directional.

Pressing Go will show the plot and show # of pairs in each lag.

Fitting:
Omnidirectional: Click Exponential option beside big circle on the right to begin. Hold down left mouse and drag on the plot to set Range, Sill and Nugget or enter them in the boxes.
Directional Trend: Select the Head Variable, the variogram plots redraw by clicking on the lines on the large directional circle so the 4 angles would be: 0 Azimuth, 135 Azimuth, 90 azimuth and 45 azimuth. The resulting values are displayed above for geostatistical modeling.

**Format:**

Data Files (standard to all Variogram analysis programs)
Line 1 title
Line 2 # of Data Variables (including X and Y)
Line 3 X Variable Name
Line 4 Y Variable Name
Lines 5 to 5+#-3 Other Variable Names
Remaining lines: X Y V1 V2 ... V(#-2)
Variables separated by spaces - pick some negative number for null
Example:
Zone A Data, Big Bean Field
8
X m meters east of origin
Y m meters north of origin
Thk m zone thickness in meters
Por % porosity in percent
Perm md permeability in millidarcies
LogPerm - base 10 log of permeability
LogPermPrd - LogPerm predicted by regression against Por
LogPermRsd - Residual from LogPerm-Por regression
12100 8300 37.1531 14.6515 2.8547 0.4556 0.1357 0.3198
5300 8700 31.4993 14.5093 -999.9999 -999.9999 -999.9999 -999.9999
3500 13900 36.9185 14.0639 -999.9999 -999.9999 -999.9999 -999.9999

2900 900 28.4249 13.1304 0.3897 -0.4093 -0.1674 -0.2419
7900 6700 33.2458 14.5724 -999.9999 -999.9999 -999.9999 -999.9999
.....

**Prompts**

Command: vgramun
Drop-Down Menu Location: StrataCalc in Geology
Keyboard Command: vgramdat

**Surface Mine Reserves**

This command calculates quantities and qualities from drillholes or predefined grid or block models. Strip ratios can also be calculated as the volume of non-key strata divided by the tons of key strata. Key strata are intended to be the target ore, and non-key strata are intended to be the overburden, interburden and parting strata. Within the drillholes or PreCalc file, each strata has a field that specifies whether the strata is key or non-key. Volumes can be stored in the pits for scheduling with this command. There are many options for reserve calculation and they are detailed in order of appearance below.
**Modeling Method:** The surface reserves can be generated on-the-fly from the selected drillholes or read from stored grid files put into a PreCalc file. The on-the-fly modeling method can be either Triangulation, Inverse Distance, Kriging, Polynomial or Linear Least Squares. An explanation of these different methods is found under Make Strata Grid Files. The Block Model option creates a BLK block model file and calculates reserves "on-the-fly". The stored grid file method is the Pre-Calculated option. The Pre-Calculated modeling method uses prepared grid files that represent the bottom elevation or thickness and quality attributes (i.e. BTU) of the strata. The grid files associated with each strata and the ground surface are set in the Define Pre-Calculated Grids command under Drillhole.

**Source of Top Surface Model...:** Surface Mine Reserves works from the top strata down to the bottom. The ground surface is modeled from either the Screen using selected surface entities, the surface grid found in the PreCalc file, a separate grid file (something different than the surface grid in the PreCalc, such as a top of bench grid) or an elevation. This elevation could be the elevation of a flat bench that represents the top of the reserve calculation interval. In the Screen method, the program builds a grid model from the selected entities (contour polylines, points and 3D entities). See the Make 3D Grid File command for a description of creating a grid file. The "Source of Top Surface Model" option sets this ground surface method. Each strata structure is modeled as the bottom elevation of that strata. The strata volume is figured by comparing the strata bottom elevation model with the previous strata. The first strata bottom elevation is compared with the ground surface grid. Each strata grid clips to the grid above so that the strata grid does not rise above the previous grid which includes the ground surface. The result is that the program will find strata outcrops if any.

**Top Elev:** When using the Elevation method in the Source of Top Surface Model, this is the elevation that controls the top of the structure or reserve block. Enter in any elevation.

**Source of Bottom Surface Model...:** Carlson can either calculate quantities straight down from the inclusion polylines ("Cookie-Cutter") or apply side slopes. There are two methods for modeling the side slopes: using a bottom surface grid or highwall slopes (explained below). Without either of these methods, the program will calculate the strata quantities straight down vertically from the inclusion perimeter. In all cases, the strata quantities are limited by the ground surface grid or elevation which effects the top strata and outcrops any other strata. The Strata Model option will calculate down to the lowest grid in the PreCalc, or the lowest grid in the Selected Strata option, if that is used. The Grid File method will go down to this grid for reserve calculations. It can have any number of benches and slopes in it. This method will prompt you for a grid file which should represent the bottom of pit surface including the side slopes. This grid file should have the same position and resolution as the surface grid. Keep in mind that the grid resolution should be small enough to...
model the pit side slopes. For example, a 100 ft grid interval would not work well for modeling side slopes that are 30 ft wide. Instead, use a grid resolution that is smaller than the side slopes width (i.e. 10 ft in this example). There are many routines for preparing the pit bottom grid including the Design Bench Pit routine and Make 3D Grid File. Typically the inclusion perimeters should start from the daylight line where the pit bottom grid intersects the surface grid. The program will calculate the strata quantities between the surface grid or elevation and the pit bottom grids. The last option is Elevation. It allows for entering an elevation to represent the base of the reserve "block". If using Elevation for the Top Surface Model, and Elevation for the Bottom Surface Model, it will calculate the various quantities within the two elevations that could represent benches. Shown below is an example of the Source of Bottom Surface Model as a Grid File.

- **Bottom Elev**: When using the Elevation method in the Source of Bottom Surface Model, this is the elevation that controls the bottom of the structure or reserve block. Enter in any elevation.
- **Use Auto-Run**: This option will prompt for the SMR auto-run file so that all of the benches, strata and elevations are predefined before hand, and all benches can be run at one time and stored in the pits for scheduling and reporting.

- **Output Elevation Grids**: Turning this option on will create grid files for the bottom of each strata found in the drillholes. Each grid needs to be named separately. The command Make Strata Grids is a better way to create these grids.
- **Output Thickness Grids**: Turning this option on will create thickness grids of the strata calculated for the current bench. It will prompt to create an overburden thickness grid, a key thickness grid and a key tons grid (tons/sq ft. or m). These grids will also be stored in the pits, if Store Results in Pits is activated. The difference is that timing using the actual numbers will average the quantities over pit area while the grids will model the thickness within the pit so that timing through a shallow end of the pit will be faster than the deep end. Within Output Thickness Grids, there is an option to divide the bench by thickness. This option will split the non-key volume at the specified thickness into two benches. For example, if you have 50 feet of overburden and one piece of equipment will remove the first 10 feet while a second removes the rest, then set the divide value at 10 feet and it will divide the first overburden into two benches.
- **Use Surface History**: This option will use the series of grids stored in a grid sequence file (.GSQ) for bench volume calculations. The first grid in the file is used as the starting surface grid and the second grid is used as the bottom grid. The program calculates the strata quantities and qualities using these two grids. Then the program repeats this time using the second grid as the surface grid and the third grid as the bottom grid. Again the strata values are calculated using the next two grids. This process repeats until the last pair of grids in the sequence file. The purpose of this routine is to calculate the strata values at different mining stages or benches. These benches are reported separately in the final report. One routine that prepares the grid sequence file is Design Bench Pit. If the Store Results in Pits is selected, these benches are automatically assigned to the pits for timing.
- **Merge Bench Quantities Percent**: This option is active when using the Surface History File. If there are quantities less than the entered tolerance percent, then they are merged into the associated bench. This
eliminates the error where a grid cell is crossing over from one bench to another.

- **Use Highwall Slopes:** This method applies the side slopes on-the-fly. The slopes to use are specified under the Set Slopes button. In this method, the inclusion perimeters should go around the base of the pit. The program will apply the side slopes from the inclusion perimeter up to the surface starting at the elevation of the bottom strata. The daylight perimeter and any bench lines are drawn as 3D polylines. This will only use depths up from the bottom for changing slope, and is used when just reserving for one total bench. If more complex benching is needed, then the Use Surface History is the preferred method, created with Design Bench Pit.

- **Set Slopes:** When using the Highwall Slopes option, this button brings up the Highwall Slopes dialog. Slope can be entered in as Percent or Ratio. The Smooth Slope Transitions is "all or nothing". Using the slopes shown, if the depth was 60, then the entire slope would be 1.5:1. The Slopes in Series option is more for benching. Using the slopes shown below, 0-50 will always be 1:1. Once the depth gets above 50, it will switch to a 1.5:1 and so on. Using Slopes in Series will allow for Repeat Slopes, until it gets up to the surface. There are only 5 different rows available to enter in the slope template.

![Highwall Slopes Dialog](image)

- **Use Drillhole Elevations in Surface:** This option only applies if one of the modeling methods are chosen and not Pre-Calculated. The drillhole surface elevations should be used if they enhance the surface topo, but if they differ from the surface contours or points, then they should not be used.

- **Ignore Zero Elevations:** This option only applies when using the entities on screen to create the surface. Unless the mine is down near sea-level, zero elevations should normally be ignored.

- **Use Triangulation Subdivision:** This option only applies to the modeling methods of Triangulation and Polynomial. It subdivides the triangles to create smoother surfaces and ensure that contours do not cross.

- **Use Global Trend Extrapolation:** This also applies only to Triangulation and Polynomial. This option finds the average slope and direction of the existing data and applies this slope to extrapolating where there is not surface data.

- **Recovery Percent:** This window defines the percentage of Key strata volume that was recovered in mining and to include in the volume and strip ratio reporting. The non-recovered key strata is added to the NonKey volume. The recovery percent in the Surface Mine Reserves dialog applies to all the Key strata. Enter in as 100 or 95.4 or 92, etc.

- **Use Strata Definitions (for Recovery):** To have different recoveries for each Key strata, use Define Strata to create a strata definition for each Key strata with the appropriate recovery percent. Then run Surface Mine Reserves and click on Use Strata Definitions.

- **Use Attribute (for Recovery):** Another recovery method is to have a strata attribute for recovery. This allows for different recovery percents at different drillholes. Then the recovery is modeled for the area. The name of the recovery attribute is specified in the dialog. This attribute will need to appear in the drillholes for modeling on the fly, or in the PreCalc as a strata attribute, with the name spelled as it appears in the Name window to the right.
• **Name (Attribute):** This is the name of the recovery attribute that will be referenced when using the Use Attribute option for recovery percentage.

• **Min Key Thickness To Use:** This option adds key strata to the nonkey strata above, in areas that have thickness less than the specified minimum thickness. Also areas with thickness less than the minimum are not counted in the reported strata area.

• **Use Density Attribute:** The strata density can be defined at different levels from general to specific and the program will use the most specific density that is found for the strata. The most general density setting comes from the current drillhole definition file (.ch) as set with the Define Drillhole command. The next level is the density setting that is stored in each drillhole. To check a drillhole density, use the Edit Drillhole command, the Key density is displayed in the bottom of the dialog. The next level is strata specific density that can be assigned with the Define Strata command. The most specific level of density definition is the "Use Density Attribute" option shown here in Surface Mine Reserves. This option models the strata density using the strata attribute with the user-specified name for density (i.e., "Density"). Not only does this method use the modeled strata density when averaging the strata quantities with other strata, but the modeled density is used within the strata to weight average that strata qualities. For example, if the strata is more dense in one area, then the qualities such as BTU in this area will be weighted more heavily. This can be changed if desired, under Attribute Options in the Report Formatter.

• **Name (Density):** This is the name of the Density attribute that will be referenced when using the Use Density Attribute option for recovery percentage. This must be spelled exactly as it appears in the drillholes or PreCalc file.

• **Min Minable Parting Thickness:** This setting will add the non-key parting quantities with the key quantities when the non-key parting thickness is less than the specified amount. For example, if the Min Minable Parting is set to 0.5, then a non-key strata between two key strata would be combined with the key in areas where the non-key thickness is less than 0.5 feet. In areas where the thickness is greater than 0.5, the non-key quantities are not adjusted. Combining the non-key quantities to the key will add to the total key tons and affect the strip ratio. If the non-key strata has qualities (i.e., ASH, Sulfur), then these non-key qualities will be composited by nonkey tons with the key tons for the portion of non-key that is less than the minimum parting. This will dilute the key qualities.

• **Min Depth To Use:** The Minimum Depth to Use option adds key strata to the overburden in areas that have depth less than the specified minimum depth. For example, if any Key strata are closer than 10 feet to the surface, then they can be considered "weathered" and reported with the NonKey waste material.

• **Which Strata To Include...:** This determines what will be calculated for the reserve. If All is chosen, then all strata in the drillholes or PreCalc file will be calculated and reported. If Selected is chosen, then the next window to appear is where one or multiple strata can be selected. This can be used for multiple reserve runs, selecting different strata to represent each bench.

• **Skip Running Totals:** This option skips the running total quantities and strip ratios for the strata. If it is not selected, then the total for each pit is added to the next for a "running total" quantity. If it is checked, then the pits are totaled separately, and with a grand total at the end of the report.

• **One Row Per Strata:**

• **All Strata on Same Row:** This option puts all the strata quantities and qualities for each pit polyline on one row. This format is best suited for only a few strata and for printing landscape on a page. If it is not selected, then each strata will appear on a separate row.

• **Group Key/NonKey Pairs:**

• **Calculate Strata Qualities:** This toggle will report the average qualities for strata attributes such as BTU and sulfur. Otherwise the program skips calculating qualities to save time. Besides reporting the qualities for each strata individually, the program can also report the total averaged qualities. By default, the qualities are weight averaged by tons which are calculated by using the strata volume and density.

• **Breakout Quantities By Attributes:** This feature works in conjunction with the Block Modeling and Grade Parameter file. Once the BLK file has been created, and the grade parameter file defined, they are used in this reserve routine to calculate the volume of material falling in certain ranges. For example, Surface Reserves will report tons of ore with calcium of 80-90, tons of ore with calcium 90-100, etc.

• **Fixed Non-Key Qualities:** This option will prompt to enter one value for each strata quality found in the drillholes or PreCalc to use for all non-key strata. This option is useful in the case for calculating the composite
key strata qualities when there is key strata dilution from non-key strata due to Min Minable Parting. Prompts will look like:
Non-Key value for BTU: 1000
Non-Key value for MOIST: 35
Non-Key value for SUL: 7
Non-Key value for ASH: 50
Non-Key value for DENSITY <80.00>: 155

- **Use Named Pit Areas:** The area for calculating quantities defaults to the limits of the selected surface entities and drillholes if no inclusion perimeters are selected. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. An unnamed pit polyline will limit the area of calculations. Also, areas can be labeled with site and pit names (i.e. Site 1, Pits 101, 102, ...). Surface Mine Reserves will then calculate the strip ratios and volumes for each site and pit area. To use site and pit names, there are several commands for creating named pit polylines in the Boundary menu of Surface Mining. If this is selected, then it will look just for named pit polylines, ignoring anything else.
- **Store Results In Pits:** This option is available when named pit polylines are used. This option will store the total non-key volume, key volume and key tons and all quality attributes for each pit polyline as extended entity data to the pit polylines. These quantities can then be used by the Surface Equipment Timing command. Besides the quantity and quality values, a Bench number is also stored with the quantities for sequencing each bench. For example, if you have two key and nonkey seams that you are going to mine in two passes, then use the Which Strata to Include: Selected option and choose the first pair of NonKey/Key strata with the Bench# set to 1. Then run Surface Mine Reserves a second time with the second pair of NonKey/Key strata and the Bench# set to 2. The quantities calculated can be stored either as values or as thickness grids for scheduling. The grid option is activated by the Output Thickness Grids option, otherwise it will store the values in the pits. The difference is that timing using the actual numbers will average the quantities over pit area while the grids will model the thickness within the pit so that timing through a shallow end of the pit will be faster than the deep end. Within Output Thickness Grids, there is an option to divide the bench by thickness. This option will split the non-key volume at the specified thickness into two benches. For example, if you have 50 feet of overburden and one piece of equipment will remove the first 10 feet while a second removes the rest, then set the divide value at 10 feet and it will divide the first overburden into two benches.
- **Bench#:** Enter in the Bench number to assign for this "run" of Surface Reserves. Usually Selected Strata is used with this, to select the strata to assign for each bench number reserve run.
- **Use Property Boundaries:** Property boundaries can be used to break up the reserve by owner and property. The commands for laying out property boundaries are in the Boundary menu. Essentially, property boundaries are closed polylines with owner and property ID names. The property polylines do not need to be clipped with the calculation inclusion perimeter or pit polylines. The program will internally clip the properties with the calculation areas and report the amounts by property within each pit area. If a pit or inclusion polyline is not covered by a property, the property name used for these quantities is "unknown". To activate property boundaries, click on the Use Property Boundaries toggle and the program will search and find them automatically.
- **Use Reserve Classification:** Using this option will prompt for an RSV file created with the separate command Reserve Classification under Grids in the Geology Module. This will separate the reserve into Measured, Indicated, Inferred and Hypothetical, based on what is entered in the RSV file.
- **Output Spoil File:** This option gives the option to create a spoil file. There are 3 options, Off, Nonkey Only and All Strata. Normally, the spoil would include just the Nonkey waste material. This creates a spoil placement file (*.SPO) that is used for the timing of the spoil routines under the Spoil Menu of Surface Mining.
- **Strip Ratio Output:** The Draw Contours option will contour the total strip ratios of all the processed strata (NonKey volume : Key tons). The program will create the contours from a grid file of the calculated strip ratio values. If you just want the grid file and not the contours, choose the Grid File toggle and the program will prompt for a grid file name to create.
- **Type of Strip Ratio Output:** There are two methods for making the strip ratio grid and contours. The
Instantaneous option will calculate the strip ratio using the strata thicknesses of the vertical strata column at each grid corner. The Accumulative method will start with the lowest strip ratio in the calculation area and keep adding the next best strip ratio areas, basically an accumulative strip ratio of the selected areas of the mine site. The grid file is assigned the running strip ratio as the program adds these areas.

- **Non-Key Thickness To Add To Key: Above Key/Below Key:** These fields allow you to specify the amount of non-key thickness above and/or below the key strata that will be combined with the key (roof and floor dilution) This amount will be taken from the non-key quantities and added to the key. Similar to the Min Minable Parting Thickness, the non-key quantities will increase the total key tons which affects the strip ratio and key volume mined. Also any non-key strata qualities will be combined by thickness, weighted by NonKey density, and added to the key which dilutes the key qualities. For example, if you estimate that 0.25 feet on average of the overburden is taken with the coal, then you could set the Non-Key to Add to Key for Above to 0.25.

The Report Formatter Options dialog is the final step of the Surface Reserves routine. It is documented elsewhere in the Help manual for more details on its operation.

Keyboard Command: mnttop

Define Surface Mine Auto Run

This command is the setup routine to create the autorun file for batch processing of multiple benches with one run of the Surface Mine Reserves command. Without this predefined autorun file, then the Surface Mine Reserves command needs to be run separately for each bench. With this Autorun file, all benches are predefined by the PreCalc file, a top and bottom Grid or TIN, or an Elevation.

The steps necessary to create or edit the file are detailed below. Choosing Add or Edit will bring up the Edit Auto-Run window. This is where the Bench# is set. The Strata to Process can either be set to one, multiple, or all to define the benches. If coming out of the PreCalc file, then the elevation grids defined in there will define the benches here. Alternately, the benches can be other grid or TIN surfaces, or flat elevations, and they will be intersected by the seams that appear in the PreCalculated grids file.

To utilize this Autorun file, turn on the option in the Surface Mine Reserves window for "Use Auto-Run" as circled below. Once this is on, the program will prompt to select the *.SMA file this command created.

Pull down Menu Location: StrataCalc
Keyboard Command: mnttop_autorun
Prerequisite: Grids and PRE Calculated Grids file, named pits
Underground Mine Reserves

This command calculates quantities and qualities from drillholes or predefined grid or block models. Key strata are intended to be the target ore, and non-key strata are intended to be the overburden, interburden and parting strata. Within the drillholes or PreCalc file, each strata has a field that specifies whether the strata is key or non-key. There are many options for reserve calculation and they are detailed in order of appearance below.

- **Modeling Method:** The reserves can be generated on-the-fly from the selected drillholes or read from stored grid files put into a PreCalc file. The on-the-fly modeling method can be either Triangulation, Inverse Distance, Kriging, Polynomial or Linear Least Squares. An explanation of these different methods is found under Make Strata Grid Files. The stored grid file method is the Pre-Calculated option. The Pre-Calculated modeling method uses prepared grid files that represent the bottom elevation or thickness and quality attributes (i.e. BTU) of the strata. The grid files associated with each strata and the ground surface are set in the Define Pre-Calculated Grids command under Drillhole.

- **Use Triangulation Subdivision:** This option only applies to the modeling methods of Triangulation and Polynomial. It subdivides the triangles to create smoother surfaces and ensure that contours do not cross.

- **Use Global Trend Extrapolation:** This also applies only to Triangulation and Polynomial. This option finds the average slope and direction of the existing data and applies this slope to extrapolating where there is not surface data.

- **Make Thickness Grids:** Turning this option on will create thickness grids of the selected or all strata. It will prompt to create an overburden thickness grid, a key thickness grid and a key tons grid (tons/sq ft. or m).

- **Output Grids for Each Strata:** Turning this option on will create grid files for the bottom of each strata found in the drillholes. Each grid needs to be named separately. The command Make Strata Grids is a better way to create these grids.

- **Report Areas On One Row:** This option puts all the strata quantities and qualities for each inclusion polyline on one row. This format is best suited for only a few strata and for printing landscape on a page. If it is not selected, then each strata will appear on a separate row.

- **Use Property Boundaries:** Property boundaries can be used to break up the reserve by owner and property. The commands for laying out property boundaries are in the Boundary menu. Essentially, property boundaries are closed polylines with owner and property ID names. The property polylines do not need to be clipped with the calculation inclusion perimeter or pit polylines. The program will internally clip the properties.
with the calculation areas and report the amounts by property within each pit area. If a pit or inclusion polyline is not covered by a property, the property name used for these quantities is "unknown". To activate property boundaries, click on the Use Property Boundaries toggle and the program will search and find them automatically.

- **Calculate Strata Qualities**: This toggle will report the average qualities for strata attributes such as BTU and sulfur. Otherwise the program skips calculating qualities to save time. Besides reporting the qualities for each strata individually, the program can also report the total averaged qualities. By default, the qualities are weight averaged by tons which are calculated by using the strata volume and density.

- **Recovery Percent**: This window defines the percentage of Key strata volume that was recovered in mining and to include in the volume and strip ratio reporting. The non-recovered key strata is added to the NonKey volume. The recovery percent in the Reserves dialog applies to all the Key strata. Enter in as 100 or 95.4 or 92, etc.

- **Use Strata Definitions (for Recovery)**: To have different recoveries for each Key strata, use Define Strata to create a strata definition for each Key strata with the appropriate recovery percent. Then run Surface Mine Reserves and click on Use Strata Definitions.

- **Use Attribute (for Recovery)**: Another recovery method is to have a strata attribute for recovery. This allows for different recovery percents at different drillholes. Then the recovery is modeled for the area. The name of the recovery attribute is specified in the dialog. This attribute will need to appear in the drillholes for modeling on the fly, or in the PreCalc as a strata attribute, with the name spelled as it appears in the Name window to the right.

- **Name (Attribute)**: This is the name of the recovery attribute that will be referenced when using the Use Attribute option for recovery percentage.

- **Min Key Thickness To Use**: This option adds key strata to the nonkey strata above, in areas that have thickness less than the specified minimum thickness. Also areas with thickness less than the minimum are not counted in the reported strata area.

- **Min Minable Parting Thickness**: This setting will add the non-key parting quantities with the key quantities when the non-key parting thickness is less than the specified amount. For example, if the Min Minable Parting is set to 0.5, then a non-key strata between two key strata would be combined with the key in areas where the non-key thickness is less than 0.5 feet. In areas where the thickness is greater than 0.5, the non-key quantities are not adjusted. Combining the non-key quantities to the key will add to the total key tons and affect the strip ratio. If the non-key strata has qualities (i.e. ASH, Sulfur), then these non-key qualities will be composited by nonkey tons with the key tons for the portion of non-key that is less than the minimum parting. This will dilute the key qualities.

- **Non-Key Thickness To Add To Key: Above Key/Below Key**: These fields allow you to specify the amount of non-key thickness above and/or below the key strata that will be combined with the key (roof and floor dilution) This amount will be taken from the non-key quantities and added to the key. Similar to the Min Minable Parting Thickness, the non-key quantities will increase the total key tons which affects the strip ratio and key volume mined. Also any non-key strata qualities will be combined by thickness, weighted by NonKey density, and added to the key which dilutes the key qualities. For example, if you estimate that 0.25 feet on average of the overburden is taken with the coal, then you could set the Non-Key to Add to Key for Above to 0.25.

- **Which Strata To Include...**: This determines what will be calculated for the reserve. If All is chosen, then all strata in the drillholes or PreCalc file will be calculated and reported. If Selected is chosen, then the next window to appear is where one or multiple strata can be selected. This can be used for multiple reserve runs, selecting different strata to represent each bench.

- **Use Named Pit Areas**: The area for calculating quantities defaults to the limits of the selected surface entities and drillholes if no inclusion perimeters are selected. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. An unnamed pit polyline will limit the area of calculations. Also, areas can be labeled with site and pit names (i.e. Site 1, Pits 101, 102, ...). Surface Mine Reserves will then calculate the strip ratios and volumes for each site and pit area. To use site and pit names, there are several commands for creating named pit polylines in the Boundary menu of Underground Mining. If this is selected, then it will look just for named pit polylines, ignoring anything else. The Specify Names button will name the polylines from inside this command if they are not already named using commands found under Boundary.
The Report Formatter Options dialog is the final step of the Underground Reserves routine. It is documented elsewhere in the manual for more details on its operation.

### Prompts

**Underground Mine Reserves dialog**
Select surface entities and at least 3 drillholes. (Unless using a PreCalc.)
Select objects: *select the drillhole symbols and surface entities* Surface entities can include points, lines, and polylines.

**Make 3D Grid File**
This command is described in the Civil Design section of the Manual. Please refer to it there.
**Make Top Of Key Grid**

This command analyzes the thicknesses of the Key strata in a PreCalc file and creates a new base of overburden grid based on a minable key thickness entered. It starts at the top Key strata. Anywhere the thickness is less than the value entered, the grid drops down to the to off the next Key strata. This grid can then be added to a mining model PreCalc file for calculating overburden volumes and for scheduling. Shown below is a cross section example of the grid dropping down when the key thickness falls below the entered thickness value.

![Cross Section Example](image)

**Make Nearest Data Point Grid**

This command creates a distance grid file where the value of each grid corner is set to the distance to the nearest data point in a drillhole. This is useful to see the distance between drillholes when planning additional drilling. The grid can be contoured, as shown below, for better analyzing. The grid dimensions are set first, then two dialogs appear to select the strata to grid, and the attribute to grid.
Prompts

Pick Lower Left limit of surface area <1.45355e+006,1.96843e+006>:
Pick Upper Right limit of surface area <1.46712e+006,1.97763e+006>:
Ignore zero values [<Yes>/No]? N
Select drillholes, channel samples and strata polylines.

Calculating seam stacking ...
Writing grid file C: DRAWINGS \ GRIDS \ Nearest Data Points.grd ...
Pulldown Menu Location: StrataCalc
Keyboard Command: distgrid

Grid Inspector

This command reports and labels the value of grids at user-specified points. Up to nine grids can be analyzed at a time. After loading the grids, the program will display each grid value at the current cursor position in real-time as you move the cursor. The values are displayed in a pop-up window that appears in the top left corner, but can be moved around.

The grids to inspect are specified in the dialog shown below. You can either type in the grid file name or pick the Select File button to choose the grid file. To remove a grid from processing, erase the grid file name or pick the Clear button to remove all the grids from the dialog. The Load Pre-Calc button lets you select grid files from the list of grids stored in a Pre-Calculated file (.pre). The Name field is used for labeling the grid values. It will default to the grid name, but may be edited.
When you pick a point or enter coordinates, the program will label the grid values and draw a symbol at the point. The Select Symbols option will prompt you to select symbols from the drawing and the program will label the grid values at each symbol position. For example, you can use this option to quickly label the grid values at each drillhole symbol.

Prompts

Select Symbols/<Enter or pick point>: pick a point
Select Symbols/<Enter or pick point>: press Enter

Pulldown Menu Location: StrataCalc
Keyboard Command: grdvals

Grid History Review

This command will report information on the creation and history of grid files (.GRD) in the selected directory. Such parameters as modeling methods and settings, time and date, grid cell dimensions, file size and even which drillholes used with their values are reported.
There are no prompts in this routine, only three dialog windows that guide you through this informative command. The first window is where you select the directory containing the grids to analyze. Simply highlight that directory and select OK. The program will read all of the grids in that directory and present them in the Grid History Review window. If there are many grids, this might take a minute or two.

The list of grids shown is sorted alphabetically and displays the name, size, time and date, cell size and modeling method for creation. If the grid was made in a version of SurvCADD from CES (this version is from around 1999) and before, then all the information will show "UNKNOWN".

Highlight a grid and selecting the info button will bring up the report window showing yet more information of the highlighted grid. This is where the method and settings, strata, and drillholes with their names, locations and values are reported. The report may be edited here, saved to a file, sent to the printer or placed on screen as AutoCAD text.
Pulldown Menu Location: StrataCalc
Keyboard Command: grdreview

Draw 3D Grid File
This command is described in the Civil Design section of the Carlson Manual. Please refer to it there.

Contour From Grid File
This command is described in the Civil Design section of the manual. Please refer to it there.

One Surface Volumes
This command is described in the Civil Design section of the manual. Please refer to it there.

Two Surface Volumes
This command is described in the Civil Design section of the manual. Please refer to it there.

Grid File Utilities
This command is described in the Civil Design section of the manual. Please refer to it there.

Merge Grid Files
This command is described in the Civil Design section of the manual. Please refer to it there.

Merge Elevation for Zero Thickness
This command merges two elevation grid files and outputs the result to a new grid file. The purpose of this command is to "pancake" together the top and bottom elevation grids for a strata so that the thickness is zero in specified areas. The two input elevation grid files should have the same grid position and resolution. One represents the top of strata elevation and the other represents the bottom elevation. The output grid will have the top grid elevations except in areas of zero thickness where the output grid will have the bottom grid elevations. This output grid can then be used as the new modified top elevation grid. StrataCalc routines will have the same elevation for the top and bottom of the strata in the areas of zero thickness.

After prompting for the grid file names, the program prompts for the inclusion and exclusion polylines. These should be closed polylines where everything inside the inclusion polylines and outside the exclusion polylines has
zero thickness. For example, you can draw a closed polyline for an inclusion area around an area where the strata pinched out, where you want it to be zero, or has already been mined.

Prompts

Select TOP Elevation Grid File dialog
Select BOTTOM Elevation Grid File dialog
Specify New Elevation Grid File dialog
Specify inclusion and exclusion areas for zero thickness.
Select the Inclusion perimeter polylines or ENTER for none:
Select objects: select a closed polyline
Select the Exclusion perimeter polylines or ENTER for none.
Select objects: press Enter

Pulldown Menu Location: StrataCalc
Keyboard Command: mergegrd2

Cleanup Grid Area

This routine takes a grid file and a closed 3D polyline, and combines the two. The elevations of the closed polyline are assigned to the grid elevations. Then the polyline is modeled and the resulting surface is applied to the original grid inside the polyline area. The resulting grid is then saved to a new grid file.

Prompts

Select a perimeter polyline:
Reading cell > 12604
Adding intersections with grid to polyline...
Assigning elevations...
Triangulating...
Setting new grid elevations...
Reading cell > 12604

Pulldown Menu Location: StrataCalc
Keyboard Command: cleanupgrid

Reserve Classification

This command is a one step reserve classification analysis. The purpose of the analysis is to estimate quantities and qualities of the mine reserve, dividing it into various zones based on the distance to the closest drillhole. The reserve estimation is less reliable when the closest drillhole is farther away. Typically the following zones are defined by the following distances:

Measured <1320ft
Indicated >1320ft, <3960ft
Inferred >3960ft, <15840ft
Hypothetical >15840ft

The first prompt is to create a new, or select an existing Reserve Classification file *.RSV.
The next step is to define a strata name to search for in the drillholes selected along with the quality name and name of the grid file to use. The program processes each line in the list, taking into account only drillholes which have strata specified and calculating from the grid quality values for each zone.

**Strata:** This window is to choose a strata or bed name that appears in the drillholes to classify.

**Quality:** This is the quality attribute to analyze, such as thickness, BTU, Calcium, etc.

**Grid:** This is the grid name that has been created from the drillholes. It will compare these modeled values with the occurrences and spacing in the drilling.

**Match Both Strata and Quality:** This will make sure that the quality and strata name both are defined in a drillhole. If just the strata name is there, but no quality sample, then it will not be used as a sample point that is measured.

**Inc/Excl Layer:** These are the layers that the perimeters are drawn in.

**Result Layer Prefix:** This is a prefix it will put in front of the output layer names.

**Draw Polylines:** This will draw the perimeter polylines that contain the hatching for the four classifications.
**Draw Hatch:** This will draw the hatching inside the perimeters and boundaries of classifications.

**Skip Report:** This option just does the CAD graphics and mapping only, not generating the report.

**Assign Pit Names:** This option will give a Pit Name to each perimeter, so it may be used for other volume calculations with commands such as Surface Mine Reserves.

The command uses property lines, or at the least, an inclusion polyline, to define the extent of the area of reserve. Nothing will be calculated if there is no property line or standard inclusion perimeter selected, and the following error will appear.

![Error Message](image)

The owner name associated with the property line will also be reported, making estimation of royalties an easy task. Optionally, the inclusion perimeter may be specified to limit area of calculations.

The results are shown as colored maps layerized by the chosen quality, with color changing based on the corresponding reserve class.

![Map Example](image)

**Prompts**

- **Select Reserve File dialog**
- **Reserve Classification dialog**
- **Select Drillholes to process:** *select drillholes to use in calculations*
- **Select Inclusion polyline:**
- **Report Formatter Dialog**
- **Pulldown Menu Location:** StrataCalc
Keyboard Command: reserve_class

Convert As Determined Qualities
This function calculates strata qualities "as delivered" based on in place qualities. A Pre-calculated grid file with all strata and quality grids specified is required to run the command.

The dialog below shows a typical use of the routine. The strata list displays all the strata defined in the pre-calculated grid file. To calculate "as delivered" qualities of the particular strata pick that strata from the list. Then fill out at least the Moisture field by picking the corresponding quality name from the list or by specifying a value if grid is not present. This allows the program to calculate dry qualities by picking a quality in pull-downs in the lower left corner and specifying an output grid file name in the corresponding dry grid line.

When Ash and BTU fields are filled out, dry Ash, dry BTU and BTU(MAF) grids may also be calculated.

Repeat this procedure for every strata in the list for which dry qualities are to be calculated by the routine. When finished click on the OK button and all the required grids will be generated.

Prompts
Select Pre-Calculated Grids File Dialog
Select a file for Proximate Analysis (the .DIL File Dialog)
Pulldown Menu Location: StrataCalc
Keyboard Command: dilute1

Composite Qualities Analysis
This function calculates quality grids for user-defined composite strata. A Pre-calculated grids file with all strata and quality grids specified is required to run the command.
First you should define a composite strata by specifying which strata it is made of and amounts of strata included in the composite. The amounts are either specified as % of or thickness of the seam. Then specify a quality to weight the other qualities by, picking from the list on the top. Below it define all the qualities to be calculated along with the corresponding output file names. Click on the OK button when done filling in all the information and the grids specified will be calculated.

### Prompts

- **Select Pre-Calculated Grids File Dialog**
- **Select .AVG File Dialog**
- **Pulldown Menu Location:** StrataCalc
- **Keyboard Command:** dilute2

### Blending Weighted Average

This command creates calculates the weighted average for qualities resulting from mixing different materials together. The names of the qualities are user-defined. Up to four weighted qualities can be calculated at once. The quality names are specified in the first row of boxes. For each type of ore to include in the mix, fill out the row as shown below including the name, tons and value for each quality. The name is used in the report. The weighted average is based on the tons of each value. The report is presented in the standard report viewer which can print, file or draw the report.
Calculate Residuals

This command measures the accuracy of the strata grid model based on the residual at each drillhole data point. The residual is calculated by removing the data point and then comparing the grid model calculation at the point with the actual value. Residuals for any strata data value such as thickness, elevation or BTU can be calculated using any modeling method including triangulation, polynomial, Kriging, least squares and inverse distance.

Consider calculating residuals for thickness with five drillholes. For each drillhole, the drillhole is temporarily removed from the model and the thickness calculated at the drillhole position. For example, one drillhole could have a thickness of 5.0. When this drillhole is removed and the four remaining drillhole using inverse distance calculate the thickness at this point, the modeled value could be 5.25. The difference of 0.25 between the actual value 5.0 and
the modeled value 5.25, is the residual.

The first dialog to appear contains some settings on the residual analysis.

- Ignore Zero Data Values: This will ignore any values of 0 that are found in the drillhole. They could be thickness, elevation or any quality attributes. Sometimes they should not be ignored, depending on what is being modeled.
- Use Report Formatter: Turn this option on to see the report with the Report Formatter. If it is off, then the standard report viewer is used.
- Calculate Histogram: The Histogram is a statistical graph of the distribution of a dataset. It shows the number of data samples within a series of value ranges.
- Number of Histogram Bins: The user can set the number of bins for the graph. For example, if a dataset of sulfur has values from 1.0 to 4.0 and the user asks for 3 bins, then the histogram will show the number of samples between 1.0 to 2.0, between 2.0 to 3.0 and between 3.0 to 4.0.
- Mark Outliers: The Mark Outliers option highlights data points that are more than 2 standard deviations from the data set average. This can be useful for flagging possible problem data points.
- Mark Layer: This is the layer of the circle mark drawn around the outlier drillholes.
- Mark Size: This is the size of the mark, or circle drawn around the outlier drillholes.

Chapter 14. Geology Module
For triangulation and polynomial, the residual is not calculated for some points because removing these points shrinks the triangulation area and the point may fall outside the area. Also you need more than three points to calculate residuals with triangulation and polynomial methods.

**Prompts**

Select drillholes, channel samples and strata polylines.
Select objects: Specify opposite corner: 269 found
Select objects:
Reading drillhole 269
Choose modeling method [Triangulation/Inverse dist/Kriging/Polynomial/LeastSq/ABOS]?
Use inverse distance to which power [First/Second/Third/Other]?
Use elliptical inverse distance [Yes/No]?
Calculating grid by inverse distances 4...
Try another modeling method (Yes/No)? No
Calculate BOTTOM ELEVATION residuals for strata 9 (Yes/No)? No
AutoRun Residuals

This command automates running the Calculate Residuals command. For this command, you set up a list of strata names, values and modeling methods. Then all these methods can be run and the results displayed in a formatted report.

This command starts by prompting for the drillholes to process. The list of available strata comes from these selected drillholes. Then a dialog is displayed that has function keys and shows a list of the methods. Use the Add button to append an entry to the list. The Add routine will bring up a dialog for entering a strata name, value and modeling method. To edit an entry in the list, highlight the entry and pick the Edit button.

The Move Up/Down buttons change the order of the selected entry. The Sort button will sort the list by strata name. The On/Off buttons change the processing status of the highlighted entry. The Auto-Run Residuals list can be saved to a file with a .RES extension. The Use Report Formatter option will activate the report formatter for choosing which fields to report. Otherwise the report is in the same format as the Calculate Residuals command. The Summary Report Only option will report only the strata name, method, and overall statistics. Turn this option on or off.
off to get a report of the residuals at each point. Pick the **Calc Residuals** button to process the list. For more description on the various modeling methods, go to Make Strata Grids where they are described.

### Pulldown Menu Location: StrataCalc

**Keyboard Command:** autostat

### Fence Diagram

Fence Diagram produces a profile of the surface and strata along the selected baseline polyline—a geological cross-section. This command is somewhat similar to the command Profile from Surface Model. Fence diagrams are a good way to verify that the geological model is correct—especially when the drillholes are plotted on them with Draw Geologic Column option. The first step is to draw a baseline polyline in plan view from which the fence diagram is created. This polyline can have more than two points and can either go to drillholes or between them. The Fence Diagram can either be drawn on a 2D grid off to the side, or in 3D, and rotated around in 3D. Fence Diagram derives the strata profiles by either gridding, a Precalculated Grids file, or intersection method. There are many options for scale, hatching and labeling. They are explained separately below.
**Draw Fence Diagram: In Real World Coordinates or On a 2-D Grid:** There are two options for choosing the location of the fence diagram. It can be drawn in real world coordinates in 3D, directly below the fence line drawn in plan view. It will have to be rotated on the X axis and spun around on the Z axis to see it. The other option is to draw it off to the side at a user defined spot, in a 2D grid. Similar to the command Draw Profile. Shown here are 3 Fence Diagrams drawn in Real World Coordinates, hatched by strata attribute.

![Image of fence diagrams drawn in real world coordinates](image.png)

**Ignore Zero Elevations:** When using the Grids from Drillholes or Intersection methods, the surface topo will be modeled by anything on screen. Selecting this will ignore anything that has an elevation. This is recommended unless the mine is near sea-level.

**Fence Extraction Method:** The Grids from Drillholes method creates a grid model of each strata found in the drillholes "on-the-fly". The program will prompt for the modeling method to use (ie Triangulation or Inverse Distance). These modeling methods are described in the command Make Strata Grid Files for more details. The Pre-Calculated Grids option will use a pre-defined PreCalc file that contains grids and seam names. The PreCalc is made under Drillhole-Define PreCalc Grids. The Intersection method triangulates the drillholes and then finds the intersection of the triangulation mesh and the polyline. In order to obtain data for the strata with the intersection method, the polyline must have at least one drillhole on each side. It is the only way to see a fault in a fence diagram when using the drillholes. Grids from Drillholes does not honor fault lines.

**Process Multiple Named Fence Polylines:** This option allows you to draw multiple fence diagrams at the same time. The diagrams are stacked vertically. Instead of picking a single fence alignment polyline, you can selected multiple polylines that have been tagged as fence polylines using the Tag Fence Polylines command. Each of the fence diagrams is labeled with the fence name assigned to the tagged fence polylines.

**Vertical Spacer Between Diagrams:** This controls the spacing between the multiple fence diagrams when draw more than one at a time.

**Prompt for Additional Surface to Draw:** This setting will allow for selecting another surface file to draw on the fence diagram. An example could be an open pit with benches design that will be drawn on top of the geology, all at the same time. Up to 10 additional surfaces can be drawn and each one has a separate layer name setting. The program prompts for these surface file names and layers in a separate dialog after picking OK on the main Fence Diagram dialog.

**Use Specific Strata Definitions:** This option will allow for selecting a different Defined Strata file than the one that is set current. Use this option and select a different SDF file for layering, colors and hatching.
• **Horizontal Scale:** This is the horizontal scale that will be used to draw the fence diagram. It usually matches the horizontal scale of the drawing.

• **Vertical Scale:** This is the vertical scale that will be used to draw the fence diagram. It usually matches the vertical scale of the drawing. If it is the same as the horizontal scale, the fence will be drawn at a 1:1, with no vertical exaggeration. To get a 2X vertical exaggeration, the vertical scale must be 1/2 of the horizontal scale such as 50H/25V. The same drawing distance represents 50 horizontally and 25 vertically. So it must be twice as tall vertically to equal 50.

• **Horizontal Axis Grid Interval:** This is how often a grid line and tick mark will appear horizontally along the X-axis.

• **Vertical Axis Grid Interval:** This is how often a grid line and tick mark will appear vertically along the Y-axis.

• **Horizontal Axis Text Interval:** This is how often a text label will be drawn on the fence diagram axis. It does not have to match the Grid Interval, but it can.

• **Vertical Axis Text Interval:** This is how often a text label will be drawn on the fence diagram axis. It does not have to match the Grid Interval, but it can.

• **Starting Station:** This is the station that is labeled at the beginning of the fence diagram horizontal X-axis grid. By default it is set to 0.

• **Axis Text Size Scaler:** This is the scaler that is multiplied by the horizontal scale to determine the text size. It applies to both the X and Y axis.

• **Grid Ticks Only:** This option will just draw tick marks at the set grid interval for both horizontal and vertical axis.

• **Draw Plan View:** The Draw Plan View option will graph the drillhole locations above the fence diagram. For this graph, each drillhole is projected onto the baseline polyline to find the station and offset of the drillhole.

• **Plan Vertical Scale:** This is the scale factor for the Plan View drawn above the fence diagram. It is separate, so that the text and drillholes drawn can be different then the fence diagram scale settings if desired.

• **Station by another reference centerline:** This option will station the horizontal X-axis by a predefined centerline CL file. The centerline file will be prompted for during the routine.

• **Draw Surface Polyline:** This option will draw a new polyline along the surface of the fence diagram. It is required if the fence diagram has a pit in it. The surface polyline will not be continuous across the entire fence if there is a pit, as it is broken by outcropping seams. Routines such as Cut and Place run on Fence Diagrams require the surface polyline extends across the pit, so it has a place to spoil. The other, broken surface polylines can be erased if the continuous one is used.

• **Label Northing-Easting:** This option labels the Northing and Easting coordinates along the bottom of the fence diagram at every vertex on the fence line that is drawn in plan view. An example is shown below.
• **Layer Settings**: Layers of fence diagram polylines contains 3 options for drawing the polylines layers. The first one, Layer by Strata Name, will create a layer for each strata name found in the drillholes or PreCalc. There are settings for a prefix and suffix to add to the strata name for the layers. The second option, NonKey on Same Layer, will draw the Key strata and layerize them by strata name. All of the NonKey strata will be drawn on the Fence layer, or any user defined layer in the dialog box. The last option, All on Same Layer, will draw all the polylines on the defined layer "Fence" that appears in the dialog, or any user defined layer. There are separate layers for the Pit Label, Surface Polyline, Fault Line, Additional Surface, Grid Lines and Grid Text layers.

![Layer Settings](image)

• **Label Pit Lines**: When the Label Pit Polylines option is on, the program will prompt you to select polylines with attached pit/site names. These pit names will be labeled with a vertical line and labeled along the bottom of the fence diagram grid at the position where the fence plan view polyline crosses the pit polylines. This option is useful for dragline design commands such as Cut and Place. When set to Tick Mark, the vertical line is a fixed height. When set to Bottom Strata, the vertical line goes from the grid bottom to the bottom strata line.

• **Draw Geologic Columns**: This option will use the Geologic Column command to draw drillholes directly on the Fence Diagram. If a drillhole is at an angle, the fence diagram will show the geologic column at the angle projected onto the fence polyline.
- **Max Offset:** This is the search distance from the polyline that the drillholes will be used for drawing on the fence. Any drillhole further than this distance from the polyline will not be drawn.

- **Settings (Draw Geologic Columns):** This button brings up the Draw Geologic Columns window where all of the settings may be modified.

- **Draw Faults:** This option will draw the fault line on the fence diagram cross section in the place and at the angle that it crosses the cross section. It draws it just as a polyline on top of the fence diagram. The seams should be faulted already, this is just a graphic representation of the placement and angle of the fault. The buffer offset is a way to clean up the seams in the are of the fault. The program offsets the fault line in fence view left and right by this amount. Then it trims the strata lines at this offset. Then it projects the trimmed strata lines onto the original fault line. The purpose is to trim out the transition zone area of the strata. Typically, this area size is about the same as the grid cell size of the strata model. So a good buffer offset size is to use the grid cell size. Shown here are the grids without the fault drawn on it, cleaning up the grids, and also with the 45 degree fault drawn. Notice the large difference in how the fence is displayed with the Draw Faults on.

- **Hatch Fence:** Turn this option on to hatch the strata in the fence, otherwise leave it off to just draw polylines. The strata hatch patterns are defined in the Define Strata command. If this is selected, then the hatch patterns defined there will be used. If a strata exists that is not defined, it will use the default hatch in Pattern Name.

- **Pattern:** The default hatch pattern is used if there is no pattern defined for that strata. This can be MDST or SOLID, for example.

- **Select Pattern (Hatch):** Selecting this button brings up the pages of geological hatch patterns to choose from.

- **Scaler:** This is the scale factor that is applied to the hatch pattern in the Fence diagram. A factor of 1.00 here will use the default hatch pattern scale factor set with Drawing Setup.

- **Rotate:** The Rotate option for hatching rotates the hatch pattern to best fit the angle of the strata. A hatch pattern can have only one rotation, so rotating will not be effective for a strata with multiple rotations. There is also the Azimuth option in the Define Strata command to rotate the hatch.

- **Clip Intersecting Strata:** This option is useful to check for crossing grid files. It is ON by default. Turning the option off will draw the polylines as they are in the grids or modeled from the drillholes. It is only active if the hatch option is turned off, and the fence is just drawn as polylines. Shown below is an example of the crossing polylines in a Fence Diagram. This means the grids or modeling might be suspect and should be cleaned up.

- **Draw Key Strata Only:** This option will draw and hatch just the Key strata on the fence diagram. The Non-Key intervals found in between the Key will be left as empty gaps.
• **Max Drillhole Offset from Line:** A maximum distance offset from the baseline polyline can be specified to filter out drillholes beyond the area of interest.

• **Hatch Key Strata Only:** This option will just hatch inside the Key strata that are drawn. The NonKey strata will be just polylines, with no hatch inside. Shown here is an example that has just the Key strata hatched, but also the limit lines are used to define the breaks between the splitting seams. Notice the nice, vertical contact from a full seam to a split seam.

• **Hatch By Block Model:** This option will hatch the seams using the GPF Grade Parameter File and the Block Model BLK files. A legend of the grades can be drawn also in the Define Grade Parameter screen. This is a great option to use to show the changing quality not only horizontally, but also vertically in the geology.

• **Hatch By Strata Attribute:** This option is similar to Hatch by Block Model, except there is no Grade Parameter File required. It will look at look at the quality attributes found in the PreCalc, or in the drillholes, and bring up a list. Select an attribute to hatch by. Then a color palette will appear, allowing to set the colors and ranges of the different "zones". This will just change the hatch horizontally across the strata, not vertically as the Block Model does. Shown below is an example of coal seams colored by BTU.
• **Draw Legend:** Use the Draw Legend option to make a legend of the strata hatch patterns and colors. There will be a prompt to pick the location to draw the legend.

• **Legend Scale:** This is the scale factor to size the legend.

• **Bottom Hatch Scaler:** This is the scale factor to use for the strata that appears at the very bottom of the fence diagram. If using a solid, then no scale is applied, but any other hatch pattern will use a scale factor.

• **Auto Scale Hatch Pattern:** This option will auto fit the hatching inside the strata perimeters.

• **Load/Save:** All of the switches and settings can be saved and loaded with these buttons. It creates a FEN file containing all of the settings.

**Prompts**

*Fence Diagram Settings dialog box*

Select polyline to pull fence diagram from: *pick the polyline*

Select surface entities & at least 3 drillholes.

Select objects: *Select the drillhole symbols and surface entities.* Surface entities can include points, lines, and polylines.

Reading points ... 139

Reading drillholes ...

Choose modeling method (<Triangulation>/Inverse dist/Kriging/Polynomial/LeastSq)? *Press Enter*

Bottom elevation of grid <1600.00>: *press Enter to accept default*

Top elevation of grid <2000.00>: *press Enter to accept default*

Pick the lower left corner for the fence diagram: *pick a point in a clear area of the drawing*

Pulldown Menu Location: StrataCalc

Keyboard Command: fence

Prerequisite: Drillholes or Pre-Calculated Grids, and a fence alignment polyline

*Chapter 14. Geology Module* 2528
Quick Fence is very similar to Quick Profile, in that an instant profile appears at the bottom of the screen, displaying the surfaces. This fence alignment can be set by picking points, selecting a centerline file, or selecting a polyline from the screen. A triangle appears in the plan view as the cross hairs are moved along the fence diagram below. This displays where along the fence line the cross hairs are. The slope of the surface, the station and elevation appear dynamically below the buttons. The Adjust Alignment function allows you to drag a horizontal alignment point and update the fence diagram in real-time for quick and efficient grid model verification.

- **Vertical Exaggeration:** This usually starts at "Fit" to size the fence diagram into the window. The other exaggerators, x1, x2, x5 and x10 can be selected to exaggerate it vertically.

- **Drag Action:** The fence image can be modified with either the zoom or pan actions.

- **Grid Ticks Only:** Turning off this box will extend the elevation and stationing tick marks all the way across the fence diagram.

- **Save:** This option will save the surface as a *.PRO profile

- **Draw:** Selecting this will put the fence diagram in the drawing with the Draw Profile command. The result will be similar to Draw Profile with multiple surfaces.

- **Print:** This will print the fence diagram to a PDF file.

- **Adjust Alignment:** This option allows for the fence line on screen to be moved. If the center of the polyline is selected, then the fence line can be moved in any direction, and the seams will dynamically update as the polyline is moved around. If one of the endpoints is selected, then the fence line can be rotated around the other endpoint, or extended to another length. This is a great tool to do a quick check of the geological grids with real time graphic feed back on the model status.

**Prompts**

Select the Precalculated Grids File (*.PRE)
Pick starting point (CL-Centerline,P-Polyline): p if the polyline is drawn on screen
Polyline should have been drawn in direction of increasing stations.
Fence Polylines

There are three commands for managing fence polylines. The fence polylines are used by the Fence Diagram command as the horizontal alignment. You can run Fence Diagram without pre-defined fence polylines and pick the alignment polyline on-the-fly. One advantage with using fence polylines is that you can specify the alignment polyline once and then more easily select the fence polyline in Fence Diagram which is useful if you run Fence Diagram multiple times for the same alignment. Another advantage is that you can use fence polylines to run Fence Diagram on multiple alignments at the same time.

The fence polyline commands are Tag, Untag and Identify. The Tag Fence Polylines command prompts you to pick a polyline and give it a name. This polyline is then flagged as a fence polyline. The Untag Fence Polylines command removes the tags from the selected polylines. The Identify Fence Polylines command reports the name of the fence polyline. For Identify, you can either report the names for the individually picked polylines or have the program search the whole drawing and report the locations and names for any fence polylines.

Prompts

Tag Fence Polylines
Select fence alignment polyline: *pick a polyline*
Fence name <Fence 1>: *West Pit*
Select fence alignment polyline (Enter to end): *press Enter*

Identify Fence Polylines
Pick polylines to check or search drawing [<Pick>/Search]: *S for search*
Fence polyline West Pit at 1645793.98,244010.72, Layer: FENCE
Highlighted 1 fence polylines.

Untag Fence Polylines
Select polylines to remove fence alignment name.
Select objects: *pick the polylines to process*

Block Diagram

Block Diagram creates a 3D cut out of the site with contours and/or grid mesh on top and fence diagrams or solid faces on the sides. The options for gridding and contours are shown in the first dialog box. The second dialog shows the options for the fence diagrams and grid. The strata hatch patterns are defined in the Define Strata command. The default hatch pattern at the bottom of the dialog is used if there is no pattern defined for that strata. In order to process a strata for the fence diagrams, there must be at least one drillhole inside and at least one outside the block diagram box. This command is basically a 3D Fence Diagram, with grid faces or contours on top. All of these options are defined in Make 3D Grid File and Draw Fence Diagram.
Prompts

Pick or enter Lower Left block corner:
Pick or enter Upper Right block corner:
Reading cell > 194032
Pass > 7 Null Z values left > 0
Calling fence
Drawing strata OVERBURDEN
Drawing strata C1
Drawing strata PARTING
Drawing strata C2
Drawing grid text ...
Draw Voroni Diagram

A Voronoi diagram is a special kind of decomposition of a metric space determined by distances to a specified discrete set of objects in the space, or, by a discrete set of points or drillholes. It is useful here to divide the mine area up into polygon linework for the area of influence around drillholes. These are individual polyline segments, not closed polylines.

The first dialog prompts for the layer name for the diagram linework to create. The Process Method chooses between using all the drillholes at data points for the diagram or using only drillholes that have a certain strata and attribute.

When using Strata/Attribute, the next dialog asks for a strata to analyze.
The next dialog prompts for the value to process.

Prompts

Select drillholes, channel samples and strata polylines.
Select objects: Specify opposite corner: 437 found
Reading drillhole 437
Finding splits ...
Processing only strata with beds.
Select closed inclusion polyline: There must be an inclusion polyline selected with this command.

Drop-Down Menu Location: StrataCalc
Keyboard Command: CHVORONOI
Prerequisite: Drillholes
Color Elevation Grid by Strata

This routine colors the 3D grid faces plotted in the drawing. It uses the colors defined by layers, or in the strata definition file and matches the names up with the intervals in the PreCalc. It is very useful for locating the outcrop of strata, or displaying the subcrops of seams to a mining bench grid. This colored grid can then be viewed in 3D and shaded for full visual effect. Shown below is a final pit of a sand and gravel quarry. The grid has been colored by the seams defined in the PreCalc file. There are options to set the subdivision tolerance. 0 will not subdivide the grid cells. A max of 5 will subdivide the grid into very small cells, for example, 50 x 50 grids will subdivide down to 1.5 x 1.5. There is also an option to use the SDF file from Define Strata for the coloring and layers.

Prompts

Select the PreCalc file
Reading cell > 21364
Select 3D Faces to Process... type all or window the faces
Select objects: Specify opposite corner: 18340 found
Use Layers from Strata Definition File [Yes/<No>]? y
Enter Max Subdivision Level (0-5)<3>: 0
Select 3D Faces to Process...
Select objects: Specify opposite corner: 5005 found
Select objects:
Draw Legend [Yes/<No>]? y
Enter Legend Size <25.0>: 
Pick Legend position: pick location for legend
Select objects: Enter to accept

Keyboard Command: strata_color
Pull-down Menu Location: StrataCalc
Prerequisite: Need a 3D Grid plotted in the drawing and a PreCalc containing grids that intersect the plotted grid.

Block Model Menu

The Block Model menu has commands for creating and viewing block models as well as pit optimization.
**Make Block Model**

This is one of the initial commands to begin using the block modeling features of Carlson. It uses similar grid logic, for location and resolution in the X and Y. It will take bed and subdivide it into vertical divisions. This can be applied to stratafied deposits, or ore based geology, where it is not stratafied, such as limestone or copper, gold and silver. In these ore type cases, the strata or bed name could be just rock, or limestone all the way down the hole. It would then look at just the quality being modeled as the variable. The program takes this interval, makes a roof and a floor and divides it up equally into the number of vertical divisions specified, or at an elevation "lift", where the top and bottom elevations are specified, and the block height calculated based on the number of divisions.

The first dialog brings up the Select Bed and Attribute screen. One bed name must be selected, and one or more attributes selected. If there are no Bed names in the drillholes, then select the Model By Strata Names box to use just Strata names.
The next screen, Make Block Model, is for dimension and modeling settings. The number of cells in the X and Y direction are shown at the top. The total number of cells in plan view is shown next. The block height is determined by the Number of Vertical Divisions and Vertical Position settings. There are two options to determine the Vertical Position. The first one is by Fixed Elevations. This will activate the Bottom Z and Top Z windows where the roof and floor for the block model are entered. The Follow Ore Model makes the top and bottom of the block model follow the top and bottom elevations of the bed being processed. The Use Fixed Elevations for Ore Model controls how the attributes are interpolated for the Fixed Elevations mode. When this option is on, the attributes are calculated at the fixed elevations. When this option is off, the attributes are calculated within the elevation range of the bed and then interpolated to fit within the fixed elevations. The Number of Vertical Divisions controls the number of block model data points between the top and bottom of the block model.

Make Block Model uses 3D Inverse Distance, 3D Kriging or Discrete as the modeling method to produce the block model of the quality values. The Prompt Each Attribute will allow for different methods for different grades in the block modeling. For example, Calcium can be modeled with Inversed Distance and Magnesium modeled with Kriging. It will prompt for each before writing the BLK file. The distance weight for the 3D inverse distance is the combination of the X-Y distance and the Z distance. This vertical factor is multiplied by the Z distance. So if there is no special correlation in the deposit for vertical, then the vertical factor should be set to 1. If there is some strata-like correlation based on deposit level, then this vertical factor should be set greater than 1, such as 10. Inverse Distance horizontal weighting factor, and ellipsoid is prompted for at the command line with: "Use inverse distance to which power [First/<Second>/Third/Other]?" and "Use elliptical inverse distance [Yes/<No>]?"

Discrete is a method to model parameters such as color. It will carry one color 1/2 way over to the next drillhole, then switch to the other color. This way, there is now blending of colors, if color1 is a 2 in one drillhole and color2 is a 4 in the next drillhole, it will not blend them to a "3" in the middle. It models 2, and then switches to 4 at the half way point.
After the routine is finished calculating, it creates a *.BLK file. This file can be viewed in a text editor to see what it contains, as shown here. Basically, it shows the roof and floor, the quality attribute name and the file paths of each level of the block qualities.

Keyboard Command: BLKMODEL
Pull-down Menu Location: Block Model
Prerequisite: Drillholes with a bed name, and variable quality values that can be vertically modeled.

Input-Edit Block Model
This command allows for creating the block model from pre-made grids, not using drillholes. It looks uses a grid file for the top and bottom of the ore zone. It then will reference at least one quality grid file for each vertical division. This is useful if the roof and floor grids already exist, and they will be used instead of grids made by other routines, such as Make Block Model. The dialogs are very easy to get around in.
Choosing the Add or Edit button will bring up the Edit Block Attribute window. The attribute name is entered at the top. The user can add up to 500 vertical divisions or grids. Save the block model as a BLK file for plotting and for use in Fence Diagram and Surface Reserves.

**Pulldown Menu Location:** Block Model  
**Keyboard Command:** blkedit  
**Prerequisite:** Grids of at least the roof and floor, and a quality grid

### Import Block Model

This command imports Q-Pit program block models and Vulcan Block Models from ascii files. The first window is used to select the block model to be imported.

**Q-Pit Block Model**

It will prompt for a ascii file to be selected, then create a Carlson BLK file.

**Vulcan Block Model**

This command allows the user to specify the grade parameters. First, select the Vulcan Block Model file and then the Import Vulcan Block Model window pops up. The coordinate columns X, Y and Z must be specified along with at least one other grade parameter. The Add Attribute button can be used to create a new attribute, The Add Skip
button could be used to skip a corresponding column. File types that it currently looks for are ASC, DAT, CSV, and TXT.

Once that is defined, the user is prompted to select the Carlson Block Model (blk) file to save the resulting block model to.

**Pulldown Menu Location:** Block Model

**Keyboard Command:** readblkm

**Prerequisite:** File to import

### Define Grade Parameters

This command creates the attribute file for the block model. It contains the attributes, grade names, prices and the ranges. The Name of the grade may appear on the list more than once, if several options exist to create a certain grade.

Choosing Add or Edit brings up the Edit Grade Parameters screen for up to 50 parameters at once to define a certain grade and color. There are six Operators: $<$, $>$, $<=$, $>=$, $=$, and Not $=$, combined with either AND or OR for defining the grades.
The Draw Legend button places a legend in the drawing as shown here where the grade name is displayed next to the color sample in the legend. The user chooses the legend layer and size. This is useful after color hatching a fence diagram. Drawing the legend next to the fence diagram is a good reference to see the quality of the ore.

**Prompts**

**Pick location for legend**: pick location on screen  
**Layer name for legend** `<LEGEND>`: Enter to select  
**Size for legend** `<20.0>`: Enter or change size  
**Keyboard Command**: DEFATTRF  
**Pull-down Menu Location**: Ore  
**Prerequisite**: Need to run Make, or Input-Edit Block Model first to get the BLK file. Then define the quality/grade parameter values and their color scheme.
Draw Block Model

This draws the block model in the drawing which can be rendered in 3D for visualization with the 3D Viewer Window. There are two options to use grids to limit the top surface and the bottom surface of the blocks to be drawn. This way, if there is a new topography of the pit, it will only draw blocks of the remaining ore. There is an option to use an inclusion perimeter to draw the blocks inside.

The first dialog shows the Grades, the Layer for each grade and whether to draw them or not. The block model is then drawn. It may be viewed in 3D in the drawing to see the various grades, or loaded into the 3D Viewer Window. It detects the block model and prompts to be rendered.
This will give a 3D rendered image of the blocks colored by grade as shown here. Using the Advanced Options of the 3D Viewer Window, colors can be turned on or off to see what is in the center, behind other grades.

The first step is to select the *.BLK file, then select the *.GPF file.

**Prompts**

Keyboard Command: drawblkm
Pull-down Menu Location: Block Model
Prerequisite: Need a *.BLK file and a *.GPF file from Make Block Model, Input-Edit Block Model and Define Grade Parameters.

**Label Block Model**

This command is an automatic way to label the grades of a block model between two surfaces. There are options for symbols, text size, decimal precision and the CAD layer it will be drawn on.

![Label Block Model Dialog Box](image)

The Block Model and Grade Parameters are set first. Then there is the optional Surface Topo and Bottom Limit Surface to contain the labels to just that depth for the labels. This is useful if the blocks within a certain bench height from 1540 down to 1495 elevation are to be labeled. Once OK is selected, there are prompts to select an inclusion and exclusion perimeter. After that is an option to skip over block cells to label. This will create fewer labels based on how many are skipped over.

![Label Block Model Results](image)

**Prompts**
Select the Inclusion perimeter polylines or ENTER for none.
Select objects: 1 found
Select the Exclusion perimeter polylines or ENTER for none.
Number of cell to skip<2>:

Pulldown Menu Location: Block Model
Keyboard Command: label_blkm
Prerequisite: Need a BLK model file and a GPF grade parameter file.

Color Pits by Grade Parameters
This command colors pits by assigned grade color from grade parameters file. It could be useful in identifying the pits with different grades/qualities.

Prompts
Color Pits by Grade Parameters
Select all directioned pit polylines.
Select objects: all
202 found
Select objects: press Enter
Enter bench number to hatch (1-4): 4, enter bench number to be colored
Pull-down Menu Location: Block Model
Keyboard Command: pitcolor
Prerequisite: Grade Parameter File (gpf) and Surface Pits with directions and quantities

Color Elevation Grid by Block Model

This command will color the 3D faces of an elevation grid plotted on screen or of a flat user defined elevation based on the Grade Parameter File or by a single attribute, where the color palette is selected separately.

After selecting the Block model file (*.BLK), the following dialog box prompts for Single or File for the color scheme. Selecting File would use the predefined *.GPF file. Choosing Single leads to the next colorful dialog box to specify the ranges. The Max Subdivision Level allows for a tolerance to subdivide the cells or blocks. Zero (0) will not subdivide them. A maximum of 4 will subdivide them into very small segments. The option to Draw No Grade 3D Faces will leave gaps where the parameters of the block model don't meet any of the grades. There is the option to use On-Screen 3D Faces or to simply enter an elevation to represent the grid.
The result is a colored grid mesh or elevation that can be rendered and viewed in 3D.
Prompts

Reading cell > 4828
Select 3D Faces to Process... type all or window the faces
Select objects: Specify opposite corner: 15779 found, 11552 were filtered out.
Select objects: Enter to accept
Keyboard Command: BLKCOLOR
Pull-down Menu Location: Ore
Prerequisite: Need a *.BLK model file and a grid drawn on screen.

Block Model Inspector
This command displays the from and to depths, and the grade value as the cursor is moved across the block modeled area. The location can be labeled with a left mouse click to put the text in the drawing. This is a quick way to check the model and for labeling maps to give to the field crew showing the depth range and grade. If "Use Surface Topo" option is on, the depth is calculated from the "Surface Grid" and labeled as "Over Burden Name", such as OB. The Use Bottom Limit Surface will contain the model so that it only labels down to it, such as a flat bench elevation, or pit floor grid. If there exists a no-grade zone for certain elevation range this zone is reported as No-Grade zone.
Prompts

Reading cell > 4828
Select symbols/<Enter or pick point>:

Pull down Menu Location: Block Model  
Keyboard Command: blkm_inspector  
Prerequisite: Need a BLK model file and a GPF grade parameter file.
Block Model 3D Viewer

This command is a quick way to view the block model in the 3D Viewer window without having to draw the block model first. Once the viewer is up, the rotation, zoom and rendering are all the same as the 3D Viewer window routine.

Pulldown Menu Location: Block Model
Keyboard Command: blkm_cube
Prerequisite: A BLK model file and a GPF grade parameter file.

Block Model Statistics

This command is used to report data value statistics on each grid or over all statistics within the block model. The user is prompted to select one of the reporting method, Report by Attribute/Quality or Report by Levels/Grids. The reports are generated using report formatter.
Prompts

Select inclusion perimeter polyline (Enter for None): press Enter

Pulldown Menu Location: Block Model
Keyboard Command: blkstats
Prerequisite: Need a BLK model file

Prepare Value Block Model

This command makes a block model that represents the profit of each block. There are two options, to just Enter the Economic Parameters or to Read Grid Parameters File. A 3-D fixed block model is used for computerized optimization techniques. Carlson defines a block model with a block file (*.blk) and top elevation grid file, bottom elevation grid file and grid files with grade parameters for each layer. The block dimensions are dependent on the physical characteristics of the mine, such as pit slopes, dip of deposit and grade variability as well as the equipment used. The center of each block is assigned, based on drill hole data and a numerical technique, a grade representation of the whole block. Carlson uses inverse distance method, 3D Kriging, and discrete method to estimate grades for each block. A block model can be created using the "Make Block Model" (Command: blkmodel) or the Input-Edit Block Model commands from "Ore" menu.

A value block model consists blocks with profit ($/block) values associated with them. These profit values are calculated based on the grade values of the blocks. The command to make value block model starts with a dialog to choose Carlson block model to process. The first dialog is for selecting the Method for Preparing the Value Block Model. The first option, to Enter the Economic Parameters brings up the following window where the final Ore or Metal Price is set in $/lb for all the key ore.
The second option, to Read Grid Parameters File, brings up the following window where price for each grade ($/lb) appears just as it is entered in the Grade Parameters file GPF.
Each of the input parameters are described below:

- **Metal Price ($/lb)**: The price obtained for a lb of final product
- **Ore Mining Cost ($/ton)**: Cost associated with mining a ton of ore
- **Ore Processing Cost ($/ton)**: Cost associated with processing a ton of ore
- **Waste Mining Cost ($/ton)**: Cost associated with mining a ton of waste
- **Metal Treatment Cost ($/lb)**: Cost associated with treatment of a lb of ore
- **% Recovery**: The fraction of contained product recovered during processing
- **lbs/ton (Default=2204.6)**: Factor used to convert tons into lbs, 2204.6 for long ton and 2000 for short ton
- **Ore Tonnage Factor or Sp. Gravity (cubic ft/ton)**: Density of the ore
- **Waste Tonnage Factor (cubic ft/ton)**: Density of the waste
- **Pit Layback Slope (degree)**: Overall slope of the pit highwalls
- **Vertical divisions (# of Benches)**: This is the number of benches allowed for the surface pit

Using the above input values, first the **Net value/lb** for ore is calculated as follows:

\[ n = \text{Netvalue/lb} = (\text{Metal Price} - \text{Treatment cost}) \times \text{recovery/100$/lb} \]

\[ c = \text{ore mining cost} + \text{ore processing cost} + \text{waste mining cost} \]

Then calculate the Cutoff grade: \( x \% \)

\[ (x/100) \times \text{lb/ton} \times n = c \]

And Mill cutoff grade: \( y\% \)

\[ (y/100) \times \text{lb/ton} \times n = (c - \text{Ore processing cost}) \]
Now we already know the block size (height, width and length) so we can calculate its volume \( V = h \times w \times l \) ft\(^3\). And with tonnage factor we can calculate tons/block = \( Tb = \frac{V}{\text{tonnage factor}} \). Then Profit associated with each block is calculated based on its Grade value that is read from GPF file:

For any block
(a) if Grade is less than \(< y\)

- Revenue = 0
- Cost = \( Tb \times \text{Waste Mining Cost} \)
- Profit = Revenue - Cost

(b) if Grade is greater than \(y\) but less than \(x\)

- Revenue = \( Tb \times \left( \frac{\text{ore grade of the block}}{100} \right) \times \left( \text{Metal Price} \times \frac{\text{lb/ton}}{} \right) \)
- Cost = \( Tb \times (\text{Ore Mining Cost} + \text{Ore Processing Cost} + \text{Ore Treatment Cost}) \)
- Profit = Revenue - Cost

(c) if Grade is greater than \(x\)

- Revenue = \( Tb \times \left( \frac{\text{ore grade of the block}}{100} \right) \times \left( \text{Metal Price} \times \frac{\text{lb/ton}}{} \right) \)
- Cost = \( Tb \times (\text{Ore Mining Cost} + \text{Ore Processing Cost} + \text{Ore Treatment Cost}) \)
- Profit = Revenue - Cost

The blocks with positive Profit are treated as profitable block and the profit value associated with each block is saved in new BLK and GRD files. Then the Lerchs Grossmann Algorithm is used on this Economic Value Block Model to calculate the optimum pit. If the grade block model has more than one attribute (grades) then economic parameters are read from gpf file, otherwise economic and physical parameters are entered directly to create the new value block model. A surface grid file is read to create the surface of the new block model. All the blocks that lie between surface grid and top elevation of the grade block model are treated as waste blocks i.e. grade is assigned to zero for those blocks. The number of blocks and size of blocks in the new block model are calculated based on the physical parameters, pit layback slope angle and number of vertical divisions. The block values (grade) for the new block model are estimated using the original block model. Profit (dollars/block) associated with each block is calculated based on its physical and economical parameters. The blocks with positive profit are treated as ore block. The Value Block Model is saved as a new Carlson block model file (*.blk). There are file selection windows to first select the existing block model (BLK file), the surface Topo grid file and the new Value Block Model to write. The final step is to write out the Value Block Model that may be used in other routines, such as Optimized Pit Design. **Keyboard Command:** mkvalblkm **Pull-down Menu Location:** Block Model

**Prerequisite:** Need a BLK model file, a topo grid file and optionally a GPF grade parameter file.

**Optimized Pit Design**

This command uses the Lerchs-Grossmann Algorithm (LGA) to determine the optimized minable pit. Determining the optimum ultimate pit of a mine is the base of mine planning. The optimum ultimate pit of a mine is defined as the "pit shell contour", which is the result of extracting the volume of material that provides the total maximum profit while satisfying the operational requirements of safe wall slopes. The ultimate pit limit gives the shape of the mine at the end of its life. Usually this contour is smoothed to produce the final pit outline. Optimum pit design plays a major role in all stages of the life of an open pit:

- At the feasibility study stage when there is a need to produce a whole-of-life pit design;
- At the operating phase when pits need to be developed to respond to changes in metal prices, costs, ore reserves, and wall slopes; and
- Towards the end of a mine’s life where the final pit design may allow the economic termination of a project.
At all stages there is a need for constant monitoring of the optimum pit, to facilitate the best long-term, medium-term and short-term mine planning and subsequent exploitation of the reserve. The optimum pit and mine planning are dynamic concepts requiring constant review. Thus the pit optimization technique should be regarded as a powerful and necessary management tool. Further, the pit optimization method must be highly efficient to allow for an effective sensitivity analysis. The ultimate pit limit problem has been efficiently solved using the Lerchs-Grossmann graph theoretic algorithm.

**Lerchs-Grossmann Algorithm for ultimate pit design**
Following is a detailed description of the internal workings of the algorithm.

1. Define a cutoff grade for the mine.

2. Consider the physical location of the Blocks.

3. Calculate the average grade value (profit or loss) associated with each block. This is done with the command Prepare Value Block Model.

4. Considering that overlying blocks must be removed before mining the lower blocks, find possible connections of blocks from lower level to upper levels.
   - 1-5 pattern (at least 2 common vertices between lower and upper blocks)
   - 1-9 pattern (at least one common vertex between lower and upper blocks)

5. Imagine a dummy root (X0) connected to all the blocks with arcs and form a tree T0, assign M (profit) to all the arcs.

6. Assign direction to arcs
   - Plus - if arc is directed away from the root.
   - Minus - if arc is directed towards the root. (Note: Initially all the arcs will be in "Plus" direction.)

<table>
<thead>
<tr>
<th>Case</th>
<th>Direction</th>
<th>Profit</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Plus</td>
<td>Positive</td>
<td>Strong</td>
</tr>
<tr>
<td>2</td>
<td>Plus</td>
<td>Null or negative</td>
<td>Weak</td>
</tr>
<tr>
<td>3</td>
<td>Minus</td>
<td>Positive</td>
<td>Weak</td>
</tr>
<tr>
<td>4</td>
<td>Minus</td>
<td>Null or negative</td>
<td>Strong</td>
</tr>
</tbody>
</table>

8. Divide all the arcs into two groups "Y" and "X-Y".
   - "Y" - contain all the arcs labeled "Strong".
   - "X-Y" - contain all the arcs labeled "Weak".

9. Find all possible directed arcs from group "Y" to "X-Y", if there are no possible arcs from group "Y" to "X-Y" the tree has normalized and the blocks belonging to group "Y" will be mined to give maximum profit, else go to next step.

10. Choose any possible arc (Xk, Xl) such that Xk belongs to group "Y", and Xl belongs to group "X-Y". Determine Xm, strong root of Xk connected to dummy root X0.

11. Drop arc (X0, Xl) and connect (Xk, Xl) and construct a new tree Ti.
12. Update weights according to following transformation

- For an edge $e_i$ on the chain $[X_m ....... X_k] = \Rightarrow M_{newi} = M_m - M_{oldi}$
- For edge $(X_k, X_l) M_k = M_m$
- For an edge $e_j$ on the chain $[X_l...........X_p, X_0] = \Rightarrow M_{newj} = M_m+M_{oldj}$

13. Go to step 6 and repeat the procedure again.

This application is developed using a modified version of LGA. Here we consider only two consecutive branches at a time and normalize them and update the weights or values associated with the each node in the grid.

**Ultimate Pit and Cyclic Production Report Generation**

A pre-existing value (profit) block model is selected to process form this command. The block model is processed using Lerchs Grossmann Algorithm (LGA) to find the Ultimate Optimum pit. There are two methods to determine the ultimate pit. The first method will use the LGA For All Levels. This brings up the second dialog box, where the Total number of blocks is displayed. Below that is the Total Volume, and the breakdown of number of Ore Blocks and # of Waste Blocks. There are two output methods here. Save the Ultimate Pit grid, which will prompt for a new BLK file to save out, and save the Bottom Pit Grid, which will prompt for a new grid file to create, of the bottom of pit surface.

![Select Method for Optimum Pit](image1)

LGA-For All Levels takes all the benches into account at the same time and if there exists an optimum pit, it will find it. It takes care of the constraint that the algorithm for two levels uses. As this one is a iterative process it takes a little long to find the optimum pit if we have large block model.

![Optimized Pit Design](image2)

LGA-For Two Levels will bring up the next dialog window.

![Select Method for Optimum Pit](image3)
LGA-For Two Levels considers only TWO BENCHES at a time, starting from top to bottom. Let's say we have 5 benches in our block model, it takes into consideration bench 1 (top bench) and 2 and finds the optimum pit and updates the profit values of them. Then it takes bench 2 (this bench has updated weights or profit values) and 3, and repeats the same steps for the rest of the benches. The main constraint with this algorithm is that if you more than 2 benches of over burden it will not work.

The following items are shown at the top of the dialog. These are calculated using the LGA on the predefined Value Block Model.

- Total number of blocks
- Total Volume (Ore+Waste) (KTons)
- # of Ore Blocks
- # of Waste Blocks
- Number of blocks in the optimum pit
- Total Mineable Reserve (KTons)

The next 6 items are input values used for creating a cycle or schedule report.

- Cycle Target Blocks: This is the number of blocks that can be mined per cycle period.
- Cycle Target Production (KTons): These are the tons that can be produced per cycle period.
- Total Target Blocks: This is the total number of blocks to be mined in all the cycle periods.
- Total Target Production (KTons): These are the total tons to be mined in all the cycle periods.
- Block Tolerance: This is the tolerance allowed per cycle. +/- this many blocks per cycle period.
- Prefix to save Cycle Block Models: Enter the prefix to assign to the output block model.

The final four check boxes are options to create the output files. The Save Ultimate Pit creates an output BLK file. The Save Remainder Pit is the pit left by mining the total targeted blocks, also saved as a BLK file. All cyclic pits (block models) are saved with given prefix and a cyclic production report is generated showing production and economic details of all the cycles. The Bottom pit grid file can only be saved with save ultimate pit and save remainder pit options selected. The Cyclic Report gives the production per cycle defined.

The values of the ULTIMATE PIT BLK file should be the same as it was in the value block model except for the blocks which has to be mined, it assigns NULL value to the blocks that are to be mined, so that we can visualize what the blocks are that are in the group that is to be mined. The rest of the blocks will have either +ve or -ve values based on whether its a Profit Block or Non-Profit block.

Here is an example of a limestone quarry. Consider the two views of the geologic block model. With the lowest grade removed (yellow), the highest grade, green can be seen. After creating the Value Block Model and generating the Ultimate Optimized Pit, these next views show where it can be mined by running the LGA on the Value Block Model. The first shot is of the value block model. Make a new Grade Parameter File to show Profit and Loss. In this case, Red is Loss, and Green is Profit, but there may be numerous intervals. Then use the Block Model Viewer to see the "before and after."
The final shot is of the output grid file representing the ultimate pit. The original contours are shown above the final grid surface for comparison.
Limitations
There are a few limitations that need to be considered when creating the optimum pit at this time. Future releases might look into some of these.

- The variation in mining cost with depth is not considered.
- Only one layback slope angle can be assigned to all the benches.
- On large models, the speed will be very slow.
- It cannot handle a block model with three benches (layers) of overburden or three consecutive waste benches (layers).
- Sometimes algorithm may not converse for desired number of blocks in that case changing block tolerance might help.
- All cycle block models produced cannot be viewed in 3D viewer at the same time.
- The dimensions and starting coordinates should match in surface grid file and rest block model grid files.

Pulldown Menu Location: Block Model
Keyboard Command: bestpit
Prerequisite: Need a value block model

Production By Block Model
The Production By Block Model is intended to organize grids or triangulation files created by the Carlson Software Civil Design or Mining modules into mineable blocks. The software analyzes each block to report the amounts and qualities of each seam contained in the block. During layout, the analyzed blocks may be subdivided along elevations, or along strata intersections. Only the top-most block in a series of stacked blocks is "active" to the software. Once a block is mined, the next layer of blocks becomes available for selection. Once the model is built, the model files may be transferred to any computer, with or without Carlson, to allow mine personnel to query, build mine plans, and/or mark blocks as mined. The following diagram illustrates the concept where the example blocks are shown in bold.
The block size may be determined to represent an economically viable mining volume, a series of bench elevations or any combination of layout. Blocks may be any size and shape with a single set of requirements:

- All blocks stack on top of similarly shaped blocks,
- Blocks are arranged in a series of constant thickness.

1. Setting Up The Pick and Choose Model

The process for analyzing the Block Model is as follows:

- Define the Pits (Separate Mining Areas)
- Define the Carlson grid or TIN files that describe the subsurface for each pit
- Define Admixtures (future enhancement)
- Layout Blocks for each pit
- Build The Model for each pit
- Analyze the model

The menu structure of the software is organized in the same order:
The first step is to give the model a name. That can be accomplished under the File pulldown menu, Set option. Alternatively, the software will ask for the same information if any other button is pressed before setting the model file. The screen will appear as:

Enter the name and location of the model. If you enter a file that does not exist, the software will ask if you want to create a new one.

2. Defining Pits

Pits are simply names of separate mining areas. Each area has its own set of grid files, even though the files are the same throughout the project. All projects must have at least one pit. New models include this pit and assign its name as 'Default'. Press the "Define Pits" button on the main screen to rename, or add pits. The screen will appear as:

Click on a Pit Name in the list. The name will appear in the bottom entry box. It may be edited there. The pit named DEFAULT may not be renamed unless more than one pit exists.

Press the New button to add a name. A box will appear where the name can be entered for the new pit. When pits are renamed in the bottom box, the change is not recorded until you click on another name in the list. The Cancel button will discard all changes made while on the screen.

3. Specify Model
Set the model file, and the pit on the main screen shown here:

This shows where the model is set to X:\425-002\200407\test, and the pit is set to DEFAULT. Press the Specify Model to obtain a page similar to:

The mining model entry is made in the grid or spreadsheet on the dialog. Mining materials (strata) are defined along the top of the spreadsheet, and attributes (qualities) are listed along the left edge. Every material in the block has the opportunity to relate to every quality. Items that do not apply, are simply left blank in the grid.

Grid or triangulation files may be entered as the defining limits and the qualities of the materials in the blocks. The files are NOT required to be of equal spans, or spacing in grids, and do NOT need to be of similar shape in triangulations. They should, however, cover the entire area of the block model. Blocks falling outside the file limits of a particular area will have that particular volume or quality set to nothing (no data.)
The first pit in the list (DEFAULT or to whatever it has been renamed), defines the material(s) and attached quality(s) associated with each material. All materials (strata) and qualities used in each pit must be defined in the first pit, even if they do not exist. Calculations are made on a regular spacing in the limit of the blocks. This calculation spacing is defined by the user in the box 'Common Calculation Spacing.' This box must be filled in on the first pit, before the entry page is saved to the model or the software warns that it is blank.

4. Manual Entry:

- **Adding materials:** Insert a material (strata) by pressing the Insert Strata button. Enter a name in the box and press enter.
- **Adding qualities:** Insert a quality (attribute) by pressing the Add Quality button. Enter a name in the box and press enter.

The example entered here was 'burden' as a strata, and 'MAG' as a quality:

![Model Specification for Pit DEFAULT](image)

5. Entering File Names In The Spreadsheet:

Move the cursor to an appropriate cell in the spreadsheet and double-click the cell with the mouse. Select the file and press OK. The file name will appear in the box. Materials are defined as top and bottom elevations or a series of thickness files. To establish elevations, the first (top most in the model, left most column in the spreadsheet) material is required to have a structure, or elevation file in the box labeled Top Elevation File. The remainder of materials require only a bottom structure or thickness file. **All materials must be defined the same way, bottom elevations, or thickness.** To toggle between elevations and thickness files, double-click the left-most spreadsheet cell, **fourth row down.** The label will change "Bot Elevation File" and "Thickness".

Once the spreadsheet is complete, select the File pulldown, Save and Exit option. **Be careful, as CLOSING THE SCREEN WITH THE X IN THE UPPER RIGHT CORNER OF THE WINDOW, IS EQUIVALENT TO CANCELING THE ENTRY.**

**Options:**

- **Using Scalar Numbers:** If a grid or triangulation file does not exist, and an assume number is to be used, type the number in place of a file. **Note:** If a file exists with the same name as the number, the file will be used. For example entering a scalar of 123, when a file 123.GRD exists, will cause the program to use the file.

- **Grids or Triangulations:** Clicking the option Grids, or Triangulations will limit the list of possible files when selecting a file. Also, if the file selected is a grid file (.GRD extension) and the Grids option is selected, the extension of the file is not shown in the spreadsheet cell. The same holds true for triangulation files.
• **Ultimate Bottom:** If a Grid or Triangulation file exists that defined the bottom of mining, enter the file in the Ultimate Bottom box (double-click for a file list.) All blocks or portions of blocks falling below this bottom will be trimmed to that file, or discarded completely as needed.

• **Common Folder For Files:** Each Pit may refer to a different folder on the hard disk. This folder can be set with the Set button to the right of the 'Common Folder For Files:' label. This will be the default folder to search in file selection. If selected files are in that folder, the folder path will be removed in the spreadsheet display. If a file is selected outside that path, then the full name, including the path will appear. Changing the common folder will change all files to reference that path, if the files exist.

• **Key:** Volumes and Weights are split into two categories, Key and Non-Key. Totals for each material are given during block mining, as well as total weighted values for Key and Non-Key.

• **Density:** All materials are reported as volumes and converted to weights by either a density grid, or scalar. The weights are then used to report weighted averages of the qualities. A zero is allowed, but discouraged to properly weight averages. If no values are available, use the same scalar for each material. The number 1 is acceptable for such a situation.

• **Using A Carlson Precalc File:** A Carlson Precalc file may be used to fill in the spreadsheet. The behavior of the option differs depending on the status. If no materials or qualities have been defined (a new model), all material (strata) in the precalc file will be added. The user may pick all or some of the attribute (qualities) in the file to use in the block model. If materials and/or qualities have been defined (a new model), all materials (strata) and attributes (qualities) in the precalc file that match the names in the block model will be examined by the software. Spreadsheet cells that are blank and match the precalc file, will be filled in.

• **AutoFill Right:** After at least one material has been added to the model, the AutoFill Right button will appear. After filling in file names for the first strata, the AutoFill Right button may be useful. If all files for each strata are named similarly, the software can make some intelligent selections of files. For example see the following example:

![Model Specification For Pit DEFAULT](image)

The model has three strata, ls1, ls2, and ls3. The file name values are entered for ls1, but are blank for ls2 and ls3. The common folder path is set to X:\425-002\model\BATDORF. By placing the cursor in any cell under the ls1 heading, and pressing the AutoFill Right button, the software looks for files that have the 'ls2' where the 'ls1' occurs in the previous files. It repeats the process for each blank cell, under each named strata. Because the files existed in folder X:\425-002\model\BATDORF for this example, the screen now appears as shown below. This example shows the benefit of using consistent naming practices in Carlson.
6. Copying Files From Other Pits

After the model is set up in the first pit, the basics are complete. However, additional pits still need to have reference to appropriate files for those pits. If model files are being entered for a pit other than the first pit, another option is available under the File pulldown menu. It will appear as "Copy From Pit <NAME>" where <NAME> is the name of the first pit in your project. If this button is picked, an exact duplicate is made of the default (first) pit.

If the names of the files are the same as the first pit, but the folder they are in is different, simply copy the first pit files, and change the Common File Folder. If the files exist, they will redisplay. Files that do not exist are shown in red. You may also copy files into the first pit from another block model file if the current model file is newly created. Select the option under the File pulldown, select the database, and the files are filled in.

7. Laying Out Blocks

Block outlines are generally simple a series of boundary lines stacked one on top of the other throughout the reserve. Generally the block height represents a single bench elevation used in the mining. For example, look at the example below of a pit with a ramp, created with the Carlson Process Fill/Cut command, and rendered with the 3D Viewer.
If we look at a plan view of the pit, contoured at the bench elevations, we would see something like the following:

The contour lines at each bench elevation become the limit of blocks we are going to create. Blocks outside those lines are not accessible, and do not require storage in the block model. The software allows each level of stacked blocks to have its own limiting boundary. In the case of a single bench mine, a single boundary line is all that is required.

8. Block Bench Entry:
Set the appropriate pit on the main menu, and press the Layout Benches And Blocks Button. The screen will appear similar to:

The buttons in the top left corner control the zoom level and view by Zooming Out, In, Previous, Extents, Window, and Pan, respectively.

Block definition is divided into two portions. The first option is Definition of Block Base Elevations. The second option is the Definition of Block Boundaries.

Block Elevation boundaries (Benches) can be accomplished by two methods:

**Manual Entry Block Base Elevations**

**Step 1:**
Enter low, high, and spacing (step) values of benches in the upper right boxes. Pressing the Add button places the values in the frame labeled Bench Base Elevations To Use. For example, suppose the bottom of the pits were at elevation 1240 with bench elevations of 40 units extending upwards to the highest bench of 1520. With those values in the appropriate boxes, pressing the Add button results in:
The list of elevations now shows in the Bench Base Elevations To Use frame, sorted highest to lowest. Each has a color attached to help differentiate the boundaries. To enter a single elevation into the list, put the single elevation value in the Hi, and Lo box, with a Step = 1, and press the Add button. As many as required may be entered. The values do NOT need to be equally spaced.

**Step 2:**

Once all the elevations are set for the benches, each must be assigned a limiting boundary line. Click the mouse on one of the elevations. The elevation will turn bold. In the example below, elevation 1520 was selected:

The bottom button in the Bench Base Elevations frame now says "Set 1520 Inclusion Perimeter." Press that button to select the boundary line in AutoCAD. Once selected, the screen will reappear. In this case the outer-most boundary
line from the contours shown earlier was selected and the screen returns:

Repeat Step 2 for Each boundary line until the screen appears similar to:

Note that the selected elevation in the list highlights the appropriate boundary line on the drawing.

**Automatic Entry of Block Base Elevations**

If the limiting lines for each bench are already drawn on a single layer in AutoCAD, and are 3D Polylines, or 2D Polylines with elevations (as drawn by the Process Fill/Cut command, or Contouring routines in Carlson), the software can use them automatically. The button labeled Select Bench Elevs By Layer In DWG accomplishes this task. Pressing that button switches to the AutoCAD drawing and prompts the user to select a single entity. Note: All entities on that AutoCAD layer are examined so the boundary lines should reside on a layer to themselves (no other polylines on the layer). When the selection is made, the following prompt will occur:
Selecting Yes causes all elevations to be added to the list automatically, and the polylines attached. Choosing No causes only the elevations to be added to the list (no boundary lines.) In this case, Yes was selected. Press the Zoom Extents button to see the boundaries.

**Definition of Block Boundaries**

**Regular Blocks**

Block boundaries are defined in with the options in the lower right box on the page. The simplest option is the button "Regular Block From Starting Point And Angle." The option creates rectangular shaped block boundaries based on a selected orientation. When this option is selected, the screen switches to AutoCAD.

- The program prompts: Select One Corner Of A Block, - Inside AutoCAD, select the corner.
- The next prompt is: Select Angle Along Block Face - Use AutoCAD to select the orientation.

The pit layout screen reappears prompting for the length and width of the block faces. The software then draws the blocks on the screen that could possibly be present. The following screen is an example where square blocks were selected:

As the screen above indicates, some of the blocks are outside the perimeter, some are inside, and some are partially in, partially out. This shows the need for some method to decide whether the block is included in the model or not.

The box labeled "Minimum Block % To Include In Calcs" allows the user to enter a threshold for using the block or not. A value of 100 would include only blocks completely inside the perimeter(s) of the elevation benches while a value of 1 would include any block inside or touching the perimeters. Regardless of the value entered, the percentage of each block contained inside the perimeter is stored along with the block model. When the blocks are mined, the percentage is applied to the recoverable volumes and weight.

**Arbitrary Blocks**

The following is the perimeter of the example Inside Of AutoCAD. It has a series of interior lines drawn at pit boundaries (blue ends indicate the grips from selection in the drawing):
The arbitrary block algorithm uses a polygon processor logic to create the polygon block boundaries from primitive lines and polylines.

- **Option1: From Selection Of Lines And Polylines** - This option allows a selection set manually made in AutoCAD.
- **Option2: From Selection Of Lines And Polylines On A Layer** - This option allows a selection set made by selecting a single entity in AutoCAD. The software then gathers all entities on that layer to use for the selection set.

Regardless of the option, the software starts with the prompt:

Coordinate snap is a method to force the selected line segments to intersect, or trim as needed automatically. It helps clean up loosely drawn geometry to create perfectly matched polygon edges. The following demonstrates the affects of coordinate snap:
Any small number is acceptable, depending on the integrity of the primitives selected. If gaps and overhangs occur in the drawing larger than the entered snap, the user is warned. Red circles are also drawn in the AutoCAD drawing where the errors exist to aid in correcting the primitives. Assuming Option 1 is selected, and the lines shown in the last diagram are selected in AutoCAD, the screen will return as:

Depending on the complexity of the geometry, a small amount of time may pass as the software build the polygons.

**Saving The Block Boundaries And Elevation Limits:**
Process To File, and Process And Append To File accomplish the same task, building the block model. Process To File erases any existing definitions of blocks for this pit, rewriting them completely. The Process and Append leaves existing blocks, adding the new ones described in the page. A progress bar appears on the screen to indicate progress. The process run time is completely dependent on the total number of block, total number of elevations
(benches), and the complexity of the geometry. This process of building blocks is required for each pit separately.

9. Building The Model

This section is fully automatic after setting the active pit and pressing the Build Model on the main screen. Optionally, you may use the File pulldown menu >Build All Pit Models. This option runs the model for each pit, one at a time. The routine interpolates each structure and quality file in the model at the common resolution, applies them to each block, and summarizes the block in the model. It is the most computer intensive section of the block model program.

All summaries are kept in the model file itself. For example, if the model is name Test, the summaries are all in the disk file Test.mdb The software also creates a series of model files for each pit. If we had three pits defined, three additional files would be made: Test1.mdl, Test2.mdl, and Test3.mdl. These files can be quite large depending on the detail of the user selections. However, they are quite useful in analyzing the model (next section.) The software uses the files to instantly re-analyze blocks, should you choose to split a block on elevation boundaries.

Updating A Model With New Information

As is generally the case, continuing mining activities yield more and more information. Should additional holes be drilled, or pit samples added to the Carlson model, the user may choose to rebuild the grid or TIN files used by the model. If that is the case, and the changes warrant updating the blocks, building the model is a simple as pressing the Build Model button.

However, this is true only if the model names are unchanged, and the block layouts have not changed. Those changes require re-entry of the applicable data before building the model.

10. Analysis

After the model is built, press the Analyze Model button on the main page. The screen appears similar to this:

```
Using The Screen

- Placing the mouse on the small corner at the lower of the drawing on the left, pressing the left mouse button, and holding it down, sizes the drawing window.
- Placing the mouse between the two spreadsheets shown by blue line above (not on the actual screen), pressing the left mouse button, and holding it down and moving the mouse up-down, sizes the spreadsheet windows heights.
```
• Placing the mouse between at the left of the top spreadsheet shown by blue green above (not on the ac-
tual screen), pressing the left mouse button, and holding it down and moving the mouse left-right, sizes the
spreadsheet windows widths.
• The drawing may overlap the spreadsheet or vice versa. Clicking the mouse in either one cause that section to
be on top.
• The spreadsheets have control bars to slide up-down or right-left in the data.
• Spreadsheet column widths are adjusted by holding down the mouse on the line between columns in the
header section of the sheet and dragging. All columns in both sheets reflect the new column width.

Basic Concepts:

• Blocks are selected in the drawing area.
• Blocks are selected from the top down.
• Selected blocks go into the temporary work area for viewing of data.
• Once satisfied with the temporary data, the data is moved into the current group.
• Groups are simply user defined mining areas of multiple blocks.

Selecting Blocks (Blocks are selected in multiple ways):

• Place the mouse in side the block and left click.
• Hold down the shift key, and the mouse left button. Move the mouse over block. Blocks are selected as the
mouse touches them.
• Use the Select Pulldown > Fence. Draw a polyline on the drawing by subsequent clicks of the mouse. Press
the End Select button after the last point. All blocks touching the polyline are selected.
• Use the Select Pulldown > Window Poly. Draw a polyline on the drawing by subsequent clicks of the mouse.
Press the End Select button after the last point. The polyline is closed automatically. All blocks inside the
polygon are selected.
• Use the Select Pulldown > Crossing Poly. Draw a polyline on the drawing by subsequent clicks of the mouse.
Press the End Select button after the last point. The polyline is closed automatically. All blocks inside or
touching the polygon are selected.

De-Selecting Blocks:

• Place the mouse in side the block, hold down the Ctrl key and click.
• Hold down the Ctrl key, and the mouse left button. Move the mouse over block. Blocks are de-selected as the
mouse touches them.
• Click the mouse in any cell in the temporary work area spreadsheet. Click the Del Block Button. The block
represented by the column of the active cell is removed.

Previewing The Block Data Before Selection:

If a single block is selected with the right mouse key, a detail of the block is displayed as shown here:
As the mouse is moved throughout the block, the detail data is shown in the spreadsheet in the lower left. That data reflect the values where the mouse lays in the block on the drawing. The total block data is shown in the right spreadsheet. The Exit button cancels the selection, and the OK button adds the block to the temporary list. (Optionally the block seams to mine, or the elevation to mine to is set as explained in later sections.)

**Real-Time Block Data Feedback:**
As the mouse is moved the text under the drawing gives basic feedback on the block. The data shows the bottom elevation of the topmost un-mined block the mouse is over. It also shows the group of the last mining that occurred in the block above.

**Optional Real-Time Block Data Feedback:**
By Selecting the Drawing pulldown > Block Realtime On/Off, a small chart appears under the drawing showing the breakdown of the block the mouse is over such as. The values change as the mouse is moved.
Locating Selected Blocks:
After blocks are selected, they may seem difficult to locate. So, the spreadsheet has some special actions that allow you to find a block on the drawing.

- **Option 1:** Place the cursor in row 1 of any block in either spreadsheet. Right-click the mouse. The drawing will shift so that the particular block is centered on the screen.
- **Option 2:** Place the cursor in any row other than 1 of any block in either spreadsheet. Right-click the mouse. The drawing will highlight the block similar to:

The highlight remains on until another block is selected.
Changing Analysis Screen Appearance

- **Manipulating The Spreadsheet Data Visibility:** By default the spreadsheets show all data for all seams. In addition, the total Key data is shown at the top of the spreadsheet, and the total Non-Key data is at the bottom. The left column in the spreadsheet is the total of all blocks in the spreadsheet. The following example shows the layout:

```

The data visibility can be set with the pulldown menu View > Set Quality Visibility. The following grid appears to turn particular data on/off:

![Set Visibilities](image)

- **Lock the Key Data Display:** The Key data can be prevented from scrolling in the spreadsheet with the pulldown menu View > Freeze Key Info.
- **Turning Pit Areas On/Off From Visibility:** The pulldown menu View will contain the name of each Pit. Clicking on the name of each pit will turn the areas on/off in the drawing.
- **Colorizing Blocks:** Blocks can be colored in various ways using the pulldown Menu Drawing > Colorize >
- **By Bench:** Each level of mining is assigned a new color. A legend appears on the right edge of the drawing.
**Best to Worst:** This section shows suitability of mining on a graded scale. The following menu appears:

The left side of the screen allows you to set the number of colors, and the red, green, blue components of the good, bad, and mid-range colors. The right side of the screen allows selection of the qualities to consider. Turning on the checkbox activates that quality in the weighting. The Weight For This Quality box allows the user to weight a particular quality greater or lower than others in the analysis. The value has no application for a single quality. The Hi Numbers Are Good check box allows the user to specify whether the best value of the quality is a high or low number. The following is an example of the result with 2 qualities, equally weighted. Gray blocks are areas with no quality information to weight.
• **By Qualities:** This section shows colors by a primary and optionally a secondary quality. A menu will appear similar to:

The primary quality is selected in the top box. In this case, MGO was selected. Then a series of breaks was entered into the top spreadsheet. The example shows 3, 4, 5, and 9999999. This would equate to zones of: 0-3, 3-4, 4-5, 5 and up. When the cursor is on a particular row, slide the Red, Green And Blue sliders to obtain a color. Double click in the preview color box under the sliders to set that color to that row.

The secondary quality will be used (if included) to set shades of colors between the two primary colors ranges. Set the applicable seams (materials or strata) and press OK. Each block will be displayed in its own color, for the
weighted total of the selected materials.

- **Additional Plan Views:** Additional plan view windows can be opened using the pulldown menu Drawing > New Plan View. The windows are designed to show a single mining elevation level (bench) at a time. The windows float. That is, they disappear behind the main form when it is active, but remain in the task bar and can be brought to the top by clicking there. The bench elevation to show is set in the pulldown at the top. Below is an example where one window shows the blocks at elevation 1440, and the other at 1360. The windows do not update automatically with mining changes (a speed consideration). Use the R button to refresh them.

- **Section View:** A section view window can be opened using the pulldown menu Drawing > Section View. The window is designed to show a single east-west section view. The window floats like the additional plan views. Once the Section view is activated, click the Section button above the main drawing. Click any point on the drawing. Return to the Section view and zoom extents.
Limiting Mining In Blocks:

- **Limiting the Mining of the Block By Elevation:** The second row of the temporary spreadsheet is labeled "Mine To Elev" By default, when a block is picked, this value is set to the bottom elevation of the block. If the value is changed to a value higher than the bottom, the block is reanalyzed and the data updated. Setting it to a value lower than the block has the same affect as mining the entire block.

- **Limiting the Mining of the Block By Material:** Each material (strata) has a check box row in the spreadsheet. If that box is turned off, and the active cell changed, all materials below the one in question are turned off, the block is reanalyzed and the data updated. Similarly, if the cell is turned on, all materials above it are turned on, the block is reanalyzed and the data updated.

- **Limiting the Mining of the Block By Material On the Entire Temporary Spreadsheet:** Double-clicking the left-most (gray) column in any row with check marks, changes all blocks in the temporary spreadsheet at once.

- **Limiting the Mining of the Block By Material Before Selecting:** To mark the strata to be mined before the blocks are selected, use the menu File pulldown, >Set Lowest Mined Strata. Set the lowest strata to mine and press OK. As the blocks are selected, the materials below the strata selected are marked as unmined.

Note: When a block is partially mined, and added to a group, the remainder of the block is still present for selection in the drawing. For example, if we mine two block, one to elevation 1460, and one through the 'Waste' seam. The drawing would appear as:
This text is only visible when the drawing is zoomed to a fairly tight scale. The next time we choose that block, the material mined previously will not be shown, because it has already been removed from the block.

- **Groups:** Groups are named collections of mined blocks. One group is active at a time. The name of the group active is in bold text in the lower spreadsheet. The button about the temporary spreadsheet also will be labeled "Add To Group &lt;Name&gt;" Where name is the group that the temporary blocks will be added to when pressed. To edit the group list, either use the pulldown menu Groups &gt; Add New Group, or simply double-click the name of the group in the lower spreadsheet. A screen will appear:

![Groups Screen](image)

Double-click any title to make the group the current group, and to edit its name in the lower box, or press the new button to add a new group and name it. When the OK button is pressed, the current group data is displayed. When a group is displayed, the drawing zooms to the group limits, and draws a yellow boundary line around the group such as:
• **Editing Block Data:** If a cell is selected in the block, and the Del Block button is pressed, the block will be deleted from the group. The Clear Group button will delete all blocks.

• **Send To Excel:** This button will dump the current group data to Microsoft Excel.

• **Undoing Actions:** Each time a series of blocks is moved from the temporary spreadsheet to a group, a record of the transaction is made in the database. Using the pulldown menu Undo/Erase > Undo command will undo the last transaction record in the database. Using the pulldown menu Undo/Erase > Redo Last Undo will redo what was just undone. However, this is only usable once between transactions. Using the pulldown menu Undo/Erase > Erase Back To A Block # allows you to remove blocks from the mine plan back to the point a single block was added to a group. The block numbers are labeled in the top row of the group spreadsheet.

• **Analysis Reports:** After a series or groups are mined, the summary report can show the totals of each group, and an overall total. Use the pulldown menu Reports > Summary Page to get the totals. An example is shown here:
The check box at the top of each column includes or excludes the column from the total column. (The box must be changed and the cell exited before the totals update). The data can also be exported to Microsoft Excel with the Send to Excel option.

**Pulldown Menu Location:** Block Model  
**Keyboard Command:** csbm

## Case Studies

### Case Study #1: Techniques of Geological Compositing

Two Types of Compositing are described here. (1) Single Seam or Ore Body compositing where the seam has been sampled at various intervals, and (2) Combinations of Several Seams Separated by Interburden.

**1) Single Seam or Ore Body**

Large ore deposits such as limestone and thick beds of coal are often sampled at multiple points within the single ore body or bed. For long-range planning and reserve estimates, it is often desired to obtain the composite quality for the entire mineral deposit within an inclusion perimeter. For short-range planning, the mine engineer needs to know what quality will be obtained in a particular vertical segment of the ore body or seam, also within a defined perimeter.

**Entire Seam Composites** In the first example, a body of ore has been sampled at 3 to 4 points vertically, as seen in the geologic columns. Note in the geologic columns (generated with Draw Geologic Column) that all the ORE has been assigned bed "A". This will "lump" the various ore samples into one "bed". If the bed name is not assigned when the holes are drawn, then this can be accomplished by the commands "Assign Bed Names" or "Fill in Bed Names". Then the command Selected Strata Quantities will produce this report (showing composite A tons) when the A Key strata is chosen singly and the inclusion perimeter is selected. Compositing of the single A bed is automatic.

Note: The program will not composite qualities for a strata name that is repeated, unless there is a bed name grouping them together.
The command Selected Strata Quantities brings up this screen to select the strata or bed to analyze.

Follow these prompts to get the report screen.

CHQUAN2
Select drillholes, channel samples and strata polylines.

Press ENTER to continue.

Vertical Composite Zones
In the next example, a vertical zone of ore has been defined as the upper part of the ore body or "A" bed from 4130 elevation and up. The "floor" of the vertical cut in this case is flat, following the 4130 elevation. This might correspond to a mine plan where the base of the first of two cuts is designed to hit elevation 4130 within the entire pit. The technique required is to divide bed A into two beds. This is done by the command "Split Bed" within Strata/Bed Utilities under Drillhole. The prompting is as follows:

Command: splitbed
Split strata method [<Elevation>/Grid/Thickness]? E

Chapter 14. Geology Module
Select the Drillholes for bed split. Select the holes
Select objects: Specify opposite corner: 3 found
Enter name of the bed to split: A
Rename bed or assign key/non-key status [Name]/[Status]? Name
Enter new name for the upper part of the bed: A Upper
Enter new name for the lower part of the bed: A Lower
Enter a split elevation: 4130

This shows a drillhole before splitting the A seam into an A Upper and A Lower.

Here is the same drillhole, viewed within "Edit Drillhole" after the command "Split Bed". Notice the new Bed Names, A Upper and A Lower.
The result is a new base of A Upper seam. It is important to note that the quality characteristics of the original ore zone have been applied identically to the new ore zones that have been renamed to A Upper and A Lower. The rest of the ore zone, the lower 12.5 feet, has become part of A Lower. If a drillhole does not reach as low as 4130 elevation, then all the ore remains in the A Upper bed and is unaffected. Conversely, if the ore never exceeds elevation 4130 in a particular drillhole, then it is assigned bed A Lower for all the ore sample points. Here is a Fence Diagram showing the two divisions of the bed, at elevation 4130.

Now the command "Selected Strata Quantities" can be run. Ironically, you don't select the "composite" option.
because you want to calculate the A Upper and the A Lower beds distinctly. You select them one at a time from the
dialog box. This leads to the result shown here in the report. Adding the tons calculated here: 3292460 + 2351700 = 5644160 calculated above, when the bed was just A. This is a good check to make sure the quantities match.

Split Bed by Grid File

In the previous example, we chose to split the bed by elevation. If, by contrast, the goal was to leave 5-feet of lower
ore in place to be removed by different equipment, then the vertical demarcation is not a fixed elevation but a grid
file defined as base of ore plus 5 feet. This grid file is made by using "Make Strata Grid Files" to make the base of
ore, then using Grid File Utilities (in the DTM or StrataCalc menu) you would add a value of 5-feet and re-save the
grid file as Oreplus5.grd or some such name. This new file would be used to delineate the split elevation between
the A Upper and A Lower beds.

Advanced Mine Module Techniques

In the above example, the command "Selected Strata Quantities" was used. This is an "on-the-fly" selection approach,
where the drillholes are selected each time the command is run. It does not take advantage of stored grid files in the
Precalculated Grids file (.PRE), which is the essence of the Advanced Mine Module. To apply the above procedures
to the Advanced Mine Module, follow this sequence:

2. Make grid files for the surface, the top of Bed A Upper, the base of Bed A Upper and the base of Bed A Lower.
3. Enter these files in appropriate order (A Upper first, then A Lower) as a stored "Pre-Calc" grid set, using the
   command "Define Pre-Calc Grids" under the Drillhole pulldown.
Then run Surface Mine Reserves, selecting Pre-Calc Grids as the modeling method. You will obtain the same quantities for each bed as reported from the command "Selected Strata Quantities".

The advantage of setting up grid files is that multiple, prenamed pits can be run within Surface Mine Reserves, and the reporting can be formatted and expanded upon at the user's discretion, even dumped to Excel and Access. The various options within Surface Mine Reserves can be fine-tuned, such as recovery percentage, density and dilution. Furthermore, "grand totals" are obtained where the qualities and volumes/tonnages of beds A Upper and Lower are composited back into the total reserve values. (Indeed, this is the exact procedure used for multiple seams with interburden.)
Shown here is a formatted report for the single inclusion polygon representing the pit in our example. Slight differences in values versus "Selected Strata Quantities" is a function of the difference in gridding locations and cell sizes. With stored "pre-calc" grids, quantities and qualities will be fully repeatable.

(2) Combinations of Several Seams Separated by Interburden

In the mining of stratified deposits it is very common to have several seams separated by interburden. Surface mines must consider the composite tonnage, composite strip ratio and composite quality in any reserve study or short-term mining plan. Two main issues come to mind—how deep to mine, and when to mine and remove interburden as if it
were Key. Let's look at a coal deposit example.

How Deep to Surface Mine
Strip ratios change as each lower seam is taken, and quantities of coal increase. The goal is to get as many lower seams as possible, but not so many that interburden thicknesses and strip ratios increase excessively, or quality degrades. Currently, about a 15:1 strip ratio approaches the maximum feasible ratio for cost-effective mining. Higher ratios do occur and will certainly occur if the market price of coal increases. Coals are said to "outcrop" at the surface, with "crop loss" referring to unmineable, "weathered" coal at the hillside edge. Usually the crop loss is around 12 to 15 feet measured vertically from the surface. It is often deeper in valleys or even small hillside ravines and "drains", due to accumulation of debris and erosion. On "points" or ridges, crop loss may be only 10 to 12 feet, particularly in hardrock conditions. The Surface Mine Reserves routine is designed for estimating reserves and includes a built-in crop loss parameter (measured vertically from the surface), appearing as "Min Depth to Use". Here is a graphic representing the crop loss on the side of a hill.

[Image of crop loss on a hillside]

A conservative engineer or geologist would enter 15 feet to obtain a "low-ball" estimate. Someone looking aggressively for all the coal they could possibly obtain might enter 10 or 12 feet for the vertical crop loss. Be aware that with steep 1.5:1 hillside slopes, a 10' vertical crop loss translates to 15' measured horizontally from the hillside. In 3:1, gently sloping terrain, a 10' vertical crop loss translates to 30' measured horizontally from the hillside. If the natural terrain slopes on the order to 2:1 to 3:1 or more, it is reasonable to use a lower vertical crop loss value for "Min Depth to Use". The value used is strictly a judgment call and is ideally based on observations at the mine. There is no option to have a variable crop loss. That is best handled by defining a "Strata Limit Polyline". See the "OutCrops and SubCrops" case study. In many regions, shallow coals will "subcrop" as they hit an alluvial deposit or as it nears the surface and is decomposed due to oxidation and weathering.

Another Example: Getting Composite Qualities
The Surface Mine Reserves command automatically computes composite qualities and strip ratios on all Key strata, providing "Calculate Strata Qualities" is selected in the dialog box (dialog shown earlier above). The low SULFUR and BTU values for OB and IB are not included in the composite quality for SULFUR and BTU. This is because OB and IB are not defined as KEY. When C1 and C2 are imported or placed in the drawing, they are defined as KEY strata. Alternately, the KEY designation can be assigned and changed using the command "Define Strata". Shown is a drillhole example of this dataset, and the composite KEY quality report.
By contrast, composite qualities can also be computed using the command "Selected Strata Quantities", but this routine will composite any selected strata, key or non-key. In our example, if all 4 beds are selected, the composite BTU is only 1245. All of the above calculations were based on screen-selection of the drillholes (not grid files), and use of Triangulation modeling. (Sulfur was not entered for Nonkey beds).
Partings: When to Mine and When to Waste

Drillholes 8 and 10 below have 2.5 and 1.8 feet of interburden, respectively, between coals C1 and C2. It makes sense to take the thin interburden with the coals, even though this will dilute some qualities (and maybe improve others). Surface Mine Reserves has an option called "Min Minable Parting Thickness" designed specifically for this purpose. The effect on qualities is also shown below. This result is obtained automatically by designating 2.0 feet as the "minimum minable parting thickness", meaning that any lesser thickness will not be separated as waste but will be included as coal.
To obtain interburden qualities and to factor them into the composite quality, it was critical that qualities be associated with non-key strata. This is accomplished within the command "Define Drillhole" or a setting on the main Surface Mine Reserves screen for Fixed NonKey Qualities.

In our example, the interburden had a density set at 150 within Define Strata, and had BTU values in the 1000 range, and sulfur in the 0.5 range. The net effect of including the thin interburden was to improve sulfur and degrade BTU. If sulfur under 1.0% is the more critical value in meeting quality requirements, and less BTU is satisfactory, then the user could accept thicker interburden. Compare these quality values with the ones calculated above and see how the SULFUR is lower and the BTU is also lower, but still within spec. Just try several reserve runs to see what the parting thickness cut off can be.

Case Study #2: Outcrop and Subcrop Modeling

This tutorial steps through examples of how to handle outcrop and subcrop conditions on several examples involving ridge top mines as well as sub-cropping reserves. Accurately locating the crop is one of the first things the planner needs for laying out a mine. Carlson automatically detects the location of the crop within the Surface Mine Reserves command. Volumes will never be calculated from above the ground surface. The advantage of the Draw Outcrop routine is that it allows the user to witness where the program is interpreting outcrops and subcrops. It is also useful in establishing a starting perimeter for pit layout. Outcrops are automatically calculated and drawn using Draw Outcrop command under StrataCalc on the fly directly from the drillhole data, or from pre-calculated grids.

For Generating Outcrops Directly from Drillholes ("On the Fly")

- Surface Topography Grid, PreCalc file or Contours
For Generating Subcrops

- Drillholes on the screen
- Surface Topography Grid or Contours
- Drillholes on the screen
- Thickness Grid for Unconsolidated or Weathered Strata just below the surface

![Outcrop Settings](image)

**Outcrop Procedure**

Select Draw Outcrop in the StrataCalc menu. Fill in the Outcrop Settings dialog box. The user can specify the source for surface topography (grid file or screen selection) and what layer to store the outcrop in when it is drawn. The user normally will use the settings as shown in the dialog box below with one exception. The offset distance could be set to 0.1 to 1.0 ft to reduce the vertices in the outcrop when drawn. Otherwise, the polyline for the outcrop will contain an unnecessarily large number of points.

**Command:** `outcrop`

**Select surface entities & at least 3 drillholes**

**Select objects:** Specify opposite corner: 111 found

**Use drillhole surface elevations in surface model [Yes/<No>]?** enter Y if they match the contours, otherwise N

**Reading points ... 79695**

**Ignored 562 points with zero elevation.**

**Ignored 36 duplicate points.**

**Intersections found 80377**

**Pass> 10 Null Z values left> 0**

**Finding splits ...**

**Finding pinch out ...**

**Calculating seam stacking ...**

**Output grids for strata and surface [Yes/<No>]?** enter N; the files may be saved out for other uses. No is the typical response.

**Choose modeling method [Triangulation]/Inverse dist/Kriging/Polynomial/LeastSq]**?

**Apply global trend to strata extrapolation [Yes/<No>]?** enter Y

**Use Triangulation Subdivision [Yes/<No>]?** enter N

**Triangulating points ... 5**

**Assigning grid values> 98400**

**Pass> 282 Null Z values left> 0**

**Contouring elevation 0.0**
**Inserted 348 contour vertices.** Complete the Make Grid File dialog box. The user may select the total number of rows and columns or the grid spacing pattern option. The program creates the grids "on the fly" from the drillhole data.

![Make 3D Grid File dialog box](image)

Select the preferred method. Once the gridding method is selected the Choose Strata dialog box appears. Choose the strata to process. Each strata can be gridded using independent gridding algorithms. If Inverse Distance or Least Squares was selected as the gridding method, when the strata is selected, the user is prompted for the power to be used in the algorithm. Once the power is entered, assuming Inverse Distance or Least Squares is the selected method, the user is prompted for other strata to be processed. The user can select any number of strata to be processed by holding down the CTRL or SHIFT buttons.

![Choose Strata dialog box](image)

Outcrop lines are produced on elevation zero. To raise the outcrop to the surface, use the command 2D to 3D Polyline by Surface Model command under 3D Data in the Carlson Civil. This uses the surface model as the basis for assigning elevation to the outcrop polyline.
Making Fence Diagrams
As a way to verify the location of the outcrop or make a graphic presentation, a fence diagram can be created using the Fence Diagram command under StrataCalc. Fence diagrams are useful for presenting geologic data as well as verifying the proper location of seams and their burden. Shown below is a fence diagram taken from the line drawn from west to east through the outcrops on the hill.

Fence Diagram Procedure and Prompting:

Command: fence
Select polyline to pull fence diagram from: Pick the polyline to get the fence from
Use drillhole surface elevations in surface model [Yes/<No>]? N
Select surface entities and at least 3 drillholes. Select the drillholes and surface contours
Select objects: Specify opposite corner: 112 found
Reading drillhole 5
Finding splits ...
Finding pinch out ...
Calculating seam stacking ...
Ignore zero elevations [<Yes>/No]? Y
Reading points ... 79695
Choose modeling method [<Triangulation>/Inverse dist/Kriging/Polynomial/LeastSq]? I
Use inverse distance to which power [First/<Second>/Third/Other]? S
Use elliptical inverse distance [Yes/<No>]?
Calculating grid by inverse distances 98456...
Bottom elevation of grid <1650.00>: 1400
Pick the lower left corner for the diagram: Pick an open area in the drawing for the lower left corner of the diagram.
Layer Settings button can be used to set layers for the different components of the fence diagram.

Using Surface Reserves to Check the Outcrop Volumes
To prove that Carlson honors the outcrop in its calculations, layout a rectangular polygon that overlaps the outcrop area. If Surface Mine Reserves recognizes the seam crop, then the area of the seam will be less than the area of the perimeter, and the upper seam crop area will be less than the lower seam area. It calculates reserve areas and handles outcrops automatically. Higher surfaces (the topography in this case) are the limiting factors. Volumes will never be calculated above the next surface up.
The area of the perimeter is shown as 3.371 Acres, some of it within the area of coal, and some outside. Run the Surface Mine Reserves command using the perimeter to get the tons and acres of coal. A typical report from the Surface Mine Reserves command under StrataCalc is shown below. Reports are user-defined in the Report Formatting dialog box.

As the report indicates, Carlson recognizes the limits imposed at the outcrop. It successfully truncates the seam at the outcrop and reports the included area between the crop and rectangle. Notice the C1 has less acres than the C2 because it crops out higher on the slope. The C2 shows 2.192 Acres compared to the full 3.371 Acres of the polygon. The Pit Acres are reported as an available option in the Formatter.

In topographic situations similar to the one shown in this example, for coal, the user will have to deduct from the mineable reserves for crop loss. Crop loss sometimes runs 10' to 15' vertically. The coal in this zone is usually oxidized to such an extent that the BTU is so low and the ash is so high, the coal cannot be sold for steam product, and chemistry is so poor that it cannot go for metallurgical product either. Oxidized coal is treated as overburden.

**Using Outcrops for Laying Out Pits**
In the example below, the outcrop was used to define the limits of the surface mining pits. The outcrop defined the limits of mining on each side of the pit. The direction of mining was input as part of the pit layout routine. The
example below shows the Pit Layout By Advance command executed on the closed polylines. First, create a close polyline of the outcrop/mine boundary. Use the command Draw-Boundary Polyline and pick inside the ridge/outcrop lines to get a new interior polyline. You can also use AutoCAD's BPOLY command. Then, draw a direction line down the ridge to assign direction. Pits will be cut perpendicular to this line.

**Pit Names, Labels, and Identify Pit Names**

Since the process of laying out pits using the Pit Layout By Advance option gives the pits a name, a discussion of naming and labeling procedure is helpful at this point. After the pits are drawn, there are two methods to draw the pit name labels. Go to Label Pit Polylines or Pit Label Formatter. Identify Pit Polylines allows the user to see the Pit Names when the labeling option was not selected.

**Subcrop Procedures**

Subcrops occur where the unconsolidated material (could be glacial till or a channel deposit) has eroded out the key seam below the surface. Subcrops differ from pinchouts, in that unlike pinchouts, which can occur anywhere below the surface, lower strata being eroded by the unconsolidated material cause subcrops. Unlike outcrops which can be created "on the fly" from drillhole data, subcrops are calculated from grids. To calculate subcrops, the user must
have the surface grid, thickness grid of the unconsolidated material, and bottom elevations of the strata to test for subcropping. In addition to the gridding algorithms, the user can specify strata limit polylines to override the natural mathematical interpretation of the data. When Carlson calculates the subcrop it starts from the surface and works down through the grids. If an upper grid has a lower elevation lower than that of a lower grid, the elevation of the upper grid is set to the elevation of the lower grid. This leads to a zero thickness in the lower grid, or a subcrop. Select the File option to begin calculating the subcrop. Carlson allows the user to calculate the subcrop from a pre-calculated grid or directly from the drillhole data.

This example was created by making strata grids from the drillholes. Put them in the PreCalc grids file and then generate a Fence Diagram. The outcrop coincides with the outcrop lines in plan view on the hill side. Notice how the glacial till is subcropping the upper coal seam and the parting.

**Strata Limit Polylines** Using the same example for the Subcrops above, we will now create Strata Limit Polylines for both the coal seams and the parting. They must be drawn in plan view, then named with Name Strata Limit Polylines. Strata Limit Polylines must be turned on under Configure, Mining Modules. There are options to use them, and to automatically select them. The orange lines are limit lines. The interior line is an Exclusion for the upper coal seam. The outer line is an Inclusion for the lower coal seam. Volumes will be calculated accordingly with Surface Mine Reserves.
Case Study #3: Techniques Of Gridding

Surface and Underground Reserves are the key routines for developing reserve estimates and qualities and for setting up equipment-based mine scheduling. Along with the Fence Diagram routine, Surface or Underground Reserves will calculate strata elevations and qualities using pre-calculated grids. These grids represent the "mine model". Working from the stored pre-calculated grids is one of the primary advantages of the Advanced Mine Module. Here we will study how to make the grids strategically to build in well-defined subcrops, outcrops, splits, correct strata thicknesses and qualities.

What is the "Pre-Calculated Grids" File?

The Pre-Calculated Grids File can either be an Elevation model, or a Thickness model. The elevation model consists of a grid model of the surface topography as the first and primary grid. Below the surface grid is the bottom elevation grid for each strata under modeled, placed top to bottom in the pre-calculated grids dialog box. As an option only, any number of quality attribute grids (covering such items as sulfur, ash, moisture, etc.) can be associated with the bottom elevation grid of a particular strata. If a strata is called C1, for example, the C1 name is associated with its bottom elevation grid file, and any attribute grid files to go with that seam. A Thickness PreCalc just contains thickness grids, no elevation grids. There is no surface topo grid file defined in a thickness model. Below are typical examples of both types of Pre-Calculated Grids (PreCalc) files.
When naming attributes such as Ash, BTU and Moisture, be sure to attach the attributes to a strata (in this case C1 and C2) which must match the exact spelling of the strata name containing the associated base elevation or thickness grid. Entries, however, are not case sensitive, and are converted to upper case automatically.

**Grid Cell Dimensions**

Drillholes at many mines are often drilled at a spacing of 500 feet or more, making small cell size unnecessary when modeling geologic aspects, especially quality attributes. As a rule of thumb, cell size should be 1/4 the average drillhole spacing between drillholes for most accurate modeling. With some minerals and ores such as quality controlled limestone and clay, drillholes are drilled as close as 50 feet apart. This would suggest the need for a 12.5-foot cell size or less. Surface topography, however, often demand the tightest cell size, because the topography can include steep cliffs, high stream banks and other abruptly changing features, that can be lost or smoothed if cell size is on the order of 100' to 200' spacing. Below are two examples of surfaces. The first surface has gently sloping terrain and widely-spaced contours. This has been gridded at 100'x100', as there is not any sharp features that need to be captured in the grid file. The second set of images shows an open pit with benches, spoil and roads. To accurately capture all of this detail, it is gridded at 10'x10'. It makes a much larger file, but does not smooth the surface, as a larger grid cell size would do. There is no limit, but try to keep the number of total cells in a grid file.
Cell Positions and Dimensions Should Match

Some routines in Carlson require that the grid position and cell size should be identical for all grid files in a PreCalc grid model set (Design Bench Pit is an example). This has also been a requirement, for example, in many Grid File Utilities, such as Merge Grid. To ensure that grids match position and dimension, make the first grid file, then make all additional grid files based on the position of the first grid file. To do this, you select option "F" when prompted: Use position from another file or pick grid position (<Pick>/File)? There are Grid File Utilities to modify grids, such as Change Position, Change Resolution and Match Dimensions.

In Surface and Underground Reserves calculated from a PreCalc, the grids do not need to match. It is common to have a surface topo grid file with a small cell size, such as 10x10. Then the structure grids for elevation or thickness could have a medium cell size, such as 50x50. Finally, quality attribute grids can have an even larger cell size, such as 200x200. This could be due to the fact that not every drillhole has quality sampled, so the spacing of quality holes is much greater than structure data holes, not needing a tight resolution.

Cell Dimensions Versus Number of Cells

Carlson defaults to 50x50 "number of cells" when first installed, meaning that in any grid window position, there will be 50 cells in the X-direction and 50 cells in the Y-direction, unless altered by the user. If the window is longer in the x-direction, then the cells will be longer in their X-dimension than in their Y-dimension, creating rectangular shaped grid cells. By contrast, the user can specify the cell dimension when making grids, leading to a variable number of cell, depending on the size of the grid window. It should be noted that the default itself can be set by the
This is done by selecting Configure, option Surface Settings, which provides the following dialog. Note that at the bottom of the dialog there is the option to set the number of cells or the dimension of the cells to any desired value.

Make Top of Strata Grids by Adding Thickness Grids to Bottom of Strata Grids

The elevation Pre-Calculated Grids File (another name for "the geologic model") is based on having grid files for the bottom and top of all key strata. If you have only the surface grid, and the bottom and top elevation of each Key strata, you are set up for most reserve and scheduling work. Of course, quality grids can be added, and NonKey elevation grids such as base of unconsolidated overburden are valuable. But the point here is that you want bottom and top of Key grids for each seam under consideration. These grids should in most cases be made by making a thickness grid for the strata and adding thickness to base elevation to obtain top of strata grids. There are two settings that should be monitored when doing this type of modeling. Under Settings, Carlson Configure, Mining Settings, be sure that pinch-out is on for modeling thickness. If not, then the seam will never pinch out in cases of zero thickness holes. When modeling elevation grids, it is often helpful that pinchout turned off, because when it pinches out a seam, it sometimes brings that elevation up to the next seam above, to pinch it out. If pinch out is off, it will keep the elevation grid down where it should be, had the seam been there. Add the two grids together to get the roof. Where the seam had zero thickness, the roof will be the same as the floor, and down and the correct elevation. The following example shows this concept, where the middle seam is pinching out in the middle. The middle hole has a zero value for coal thickness. This will bring the coal up to that hole, then pinch it at the hole.
This next example is created from the example where the seam Coal does not exist in the middle hole, not even a zero. This method will pinch the coal 1/2 way between the holes, based on the Pinchout Settings under Carlson Configure, Mining Settings. Most of the time, this is your best guess.

Using slightly different settings, this next Fence Diagram can be obtained.

Two Strata Limit Polylines were drawn around the drillholes, representing crop lines. The interior line is an exclusion limit line. The outer line is an inclusion limit line. The grids were remade, the bottom elevation and the thickness were added together to get the new roof, and here is the result. The seam carries its full thickness to the cropping limit lines, no pinching is taking place.

**Grid File Utilities**

The Grid File Utilities can be accessed from within the Advance Mining Menu by entering GFU, or under StrataCalc - Grid Utilities. It is also located in the DTM pulldown menu of the Contour-DTM module. After entering GFU, you must first choose Select Grid(s) to load a grid file. Within GFU, you can click an option to be prompted for Inclusion/Exclusion perimeter polylines. The grid manipulation will only occur inside or outside these perimeters.
The commands BPoly and Shrinkwrap under Draw are useful tools to generate these perimeters.

Adding One Grid to Another

In order to add grids, select Grid File Utilities (GFU) to bring up the dialog box shown here. Choose Select Grids and load the base elevation of the coal seam, COAL_ELV.GRD. The next step is to select ADD GRID which asks for the grid file to load (COAL_THK.GRD). At this point you would choose SaveAs" and save the result as file COAL_TOP.GRD. If this modeling effort is a one-time process, there is no need to record a macro that allows for automatic re-running of the grid addition. But if the thickness grid or base of coal grid might change due to the addition of more drillholes (or the editing of existing drillholes), then macros can be time-saving devices. To make a macro for our example, you would get to the dialog above by entering GFU as before. The upper right half of the GFU dialog is for macro recording. Choose Record to start the process. You would then chose Select Grids, choosing the Inclusion Perimeters (if applicable). This next window appears for variable and grid name selection. Comments can be entered here for reference.

Then Choose the Add Grid button. The variable B at top is representing the grid file to be loaded. The variable A has already been assigned to the grid file brought up by the option Load Grid. So A is COAL_ELV.GRD (the base of COAL grid). Be sure to select the option "Store the Grid File Name" as shown. Variable B will be the
The Need to Extrapolate

If modeling is done by Inverse Distance, Kriging or Linear Least Squares, the program will automatically extrapolate the grid, filling in values entirely within the limits of the grid location selected at the beginning of the gridding. If the modeling is done by Triangulation or Polynomial, the grid values will only exist within the area of drillholes. There will not be any grid values outside of the data set of drillholes. Thus the area of modeling by Triangulation or Polynomial will always be less than the area of modeling by Inverse Distance, Kriging or Linear Least Squares. This may create a problem in Grid File Utilities where grid addition is involved. Two things can happen. Number one, the program may complete the addition, but in reality grid values have not changed where the base grid file contained null values. Number two, the program may report "Grid files do not match" and refuse to do the grid math operation. To remedy this, choose "Extrapolate" within Grid File Utilities, select the default method, and extrapolate all grids prior to doing grid math. The extrapolate command itself can become part of the macro if record or append is selected. Other routines have the option to extrapolate, such as Grid Inspector, where there is a check-box to Extrapolate Grids. The Reserve commands will always extrapolate the grids upon loading, so it might be better to make sure they are extrapolated to start with. There are two options at the bottom of the Define PreCalc Grids dialog to extrapolate the grids. One method will extrapolate the elevation out, the other will merge with the next upper seam, pinching the thickness to zero.

Reserves from Pre-Calculated Grids

It is always preferable to compute volumes from PreCalc files using the Surface or Underground Mine Reserves. All the care and control that went into making the grid files is then reflected in the improved accuracy and legitimacy of the result. The PreCalc can contain quality attribute grids, and even a Block Model for detailed quality tracking and breakdown. The alternative is to select drillholes directly from the screen (on-the-fly), which builds in uncertainty as to the nature of the modeling.

Choosing a Method of Gridding

Every user is confronted with the issue of what method of gridding (modeling) to choose. Here there is no substitute for experience and verification in the field. We at Carlson Software have noticed that many qualities such as sulfur or calcium are modeled most often by Inverse Distance. Base elevation, in general, appears to be amenable to the logic of Triangulation or Polynomial, much like surface topography, though even here Inverse Distance is often
used. Strata thickness, however, is again more localized and is often best modeled by Inverse Distance or Least Squares. Polynomial surface modeling utilizes Triangulation, so again lends itself to broad, large area influences. When and how to use Kriging is an art in itself. We have found the "power" form of Kriging to model effectively in evenly distributed drillhole data. The following diagram shows the same drillhole data set modeled with 12 different versions of the algorithms. Notice there are some large differences, yet all have their benefits.

**Calculate Residuals**
This command guides the user to select a modeling method. The concept is much like field checking. With field verification, you would pick a location for testing, then measure coal thickness or sulfur or base elevation and check the data against the model. If it is close, your model is good. If the testing is repeated, you can add up all the errors (the residuals) and make a determination of the effectiveness of one model against another. But even without field testing, you can take 25 drillholes and model with 24, then check the error residual at the removed drillhole. You can then repeat this "removal" process across all 25 drillholes, and verify the average residual error and the standard deviation of the residual error. This is exactly what the command Calculate Residuals in the Advanced Mine Module does.
Shown below, for example, is a comparison all the modeling methods exported to Excel. This was done with Auto-Run Residuals, then using the Report Formatter, export to Excel.

In this example, Inverse Distance has the lowest standard deviation and absolute value residual average, making it the better candidate for modeling this drillhole dataset. The command Calculate Residuals will bring up a report that shows every drillhole and what the residual was. It will also create a Histogram, showing the number of residuals within certain ranges. This can be used to look for extreme values and fliers.
Modeling Options

It is important to set the strata modeling options that are in Settings Carlson Configure command under Mining Settings. These setting are used in modeling commands that process strata from drillholes such as Make Strata Grid, Surface Mine and Underground Mine Reserves and Strata Isopach Maps, just to name a few.

The Inverse Distance and Least Squares settings control the data point search radius and the maximum samples which limits calculations to the nearest set of the specified number of data points. Inverse Distance and Least Squares can also be forced to use a minimum and/or maximum number of data points from each quadrant NE, SE,
During strata correlation, the program matches strata with the same name between drillholes. When a strata name is missing in a drillhole, there are three possibilities. Either the program can skip that drillhole for modeling that strata, or the strata pinched out, or the drillhole did not reach the strata and the strata position can be modeled by conformance. The method to use is determined by the Pinch Out and Conformance settings in this dialog. If you turn off Pinch Out, then the program will skip a drillhole with a pinch out case for modeling that strata. Otherwise the missing strata will be given a negative thickness at the drillhole. The thickness is negative so that when modeled with the other positive thickness drillholes, the pinch out or zero thickness position will be somewhere midway between the missing and existing drillholes. The slide bar "Near Zero <-> Non-Zero" controls the amount of the negative thickness. The Near Zero setting will make a smaller negative value which moves the pinch out position closer to the missing strata drillhole. Likewise Non-Zero makes a larger negative value which moves the pinch out position closer to the drillhole with the strata.

For Conformance, turning off conformance will make the program skip a drillhole with a conformance case for modeling that strata. With conformance active, the missing strata position at the partial drillhole will be calculated by modeling the thickness between the missing strata and a marker strata that does exist in the drillhole. This thickness is modeled with inverse distance using drillholes where both strata exist. Then the thickness is added to the marker strata to locate the missing strata in the partial drillhole. Conformance can be set to Seam-Specific which allows only specified strata to be marker strata. Additionally, the specified marker strata will only conform with specified target strata. The marker and target strata names are set in Define Strata.

**Case Study #4: Limestone Block Modeling**

This lesson will step through modeling a limestone quarry using the Carlson block model routines. It goes through the process from start to finish, importing drillholes to final reporting and viewing graphics. Most of these commands are found in the Block Model menu of the Carlson Geology Module.

**Step 1-Import the Drillhole and Face Data**

To import the drillhole data, it is important to create an ASCII file with a repetitive series of columns for the collar x,y,z position, followed by columns for the downhole information. Shown here is an example of the spreadsheet to import.
To import the drillholes, it will need to be in ASCII form, use Excel to save the file in ASCII form with a ".csv" extension.

Answer Y to the question regarding saving the current worksheet. This results in a comma-separated file ASCII, such as this typical example, viewed with Notepad:

```
HOLE #,X,Y,Z,Z Top,Z Bottom,DESCRIPTION
1-03,25158.6200,18332.4000,652.9800,652.98,634.23,Bastard Stone,Bastard Stone
1-03,25158.6200,18332.4000,652.9800,634.06,632.98,Standard Buff, Standard Buff
... (more entries)
```

Notice that this file contains one "header" line consisting of the title, that we can ignore. Next we bring this file into Carlson by using the command Drillhole Import found in the Import/Export Drillhole flyout, underneath the Drillhole pulldown menu.
Before selecting this command, it is a good idea to pre-set the drillhole symbol to be used within the command Define Drillhole, located in the same Drillhole pulldown menu. Note that there is a rather large 25-unit drillhole dimension and have chosen a solid circle symbol, to distinguish the drillholes from the face data (which will use a small, solid square symbol). Also make sure the default Density is set for the ore.

By choosing "Save" in the lower left of the dialog, these settings are saved in the CH file named earlier. Then with the command Drillhole Import, the CH file will set the default symbol format. Now choose Drillhole Import and within this command, choose the Custom Import Formatter.
This window will appear:

Select "No", as they are in one CSV file.

Note that the default answer is "No" and can be selected by pressing Enter. Load the correct ".csv" file containing the ASCII drillhole data. Now organize the right-hand column to correspond to the ASCII file, as shown here:

Note how you can study the data file organization in the "Preview Window". This format can be given a name and saved by pressing the Save button. Note that we have specified "1" header line to skip (skip the title line) at the bottom right of the dialog, and also notice that we have chosen to skip the "Z Top" column, since the bottom elevation defines the strata, measuring down from the top, collar elevation. Press OK to continue. As a result of the import, we now have 7 drillholes in our area of study, as shown below:
Importing Drillholes is a critical process in geologic modeling, so it is important to be familiar with the precise techniques to accomplish this. Carlson offers extremely flexible importing. The drawing with the 7 new drillholes can now be saved with any file name desired.

You have the option to import these drillholes while already in a drawing (such as a topo map of the site), or you can import the drillholes into a blank drawing then insert additional surface features like contours. The Insert command can be found under the Draw pulldown in Carlson. In this case, we'll insert a contour file called Block Model Contours, to obtain the combined drawing below:

![Combined Drawing](image)

To verify contour elevations, and to check whether the top of the drillholes are close to the contour grades of the contours, use Drawing Inspector under the Inquiry pulldown menu. You will notice that all the holes top out at just about the right elevation you would expect based on the nearby contours, the only slight exception being the slightly lower drillhole shown below, where some of the surface could have been removed where the hole was drilled. It's just a few feet low:

![Drillhole Elevation](image)

Note also that if you inspect the blue boundary lines, they, too have elevation. Those lines should be set to zero using the command, "3D Entity to 2D" under Edit. Otherwise, they will impact surface modeling. It's a good idea to turn off the Drawing Inspector when you are not using it. Also, by right clicking with the mouse button when Drawing Inspector is on, you can change what you inspect (layers versus elevations, for example).

**Step 2- Set up Strata Definitions to Colorize the Strata**

This is a one-time process. The Strata Definitions file is used by Draw Geologic Column and by Fence Diagram and by the routines that color and display the block model. It can also impact tonnage calculations, because you can set the strata density within Strata Definitions. The dialog appears as shown below. The asterisk can be used to apply the definition to anything that begins with the letters preceding the asterisk. In this way, Standard Buff with Vertical Seam would be treated as all the other Standard Buff strata in terms of coloring and modeling.
The columns to be shown in the spread sheet can be set using Column Options. The values can be edited with in the spread sheet shown above or by selecting the strata row and using Edit button. You see more settings that can be changed.

Contrast the StandardBuff settings with those for Dirt, which we have colored black and designated "Non-Key", which means it is waste, not a product you are mining.

**Step 3-Draw Geologic Column**

Once you have verified your colors for the strata (again, a one-time process using Strata Definitions), it is valuable to confirm the quality of the drillhole import by drawing the geologic column. One method is to draw the columns next to the drillholes. So choose Draw Geologic Column at the bottom of the Drillhole pulldown menu. Possible settings for the dialog are shown below:
These settings produce the plot shown here:

This is the first indication of the location of the yellow standard buff, as well as the location of silver grey and other colored zones. The location of the black overburden material is also clear in the plot.

**Step 4-Assign a Bed Name to All Strata**

The block modeling routines require that the various strata be organized into beds. You might have a top 80-foot bed and a lower 100-foot bed in large deposits of ore. If you don't want to distinguish beds, just put all the strata into one bed name, like Stone. Note that if a column "Bed Name" was made in the original Excel file, all the strata could be imported with a bed name and you'd be done. You might consider removing the Ztop column in the original spreadsheet, and substituting a Bed column with the name Stone in every entry, then adjusting the custom import to bring it in. But to add Beds "after-the-fact", choose Assign Bed Names with Strata/Bed Utilities under the Drillhole pulldown menu. Select all drillholes and enter "Stone" for the bed name, for example. Enter N for No for "Use Parameter Filter". Then select all strata in the list at right. Highlight and click OK. Done.
**Step 5-Surface Mine Reserves**

You are now ready to get a volume of any material desired. Before you do the command, you will need a closed polyline perimeter. Note in the above graphic plot with contours, we have 3 blue squares, that might be areas of interest for volumes. Each might represent a mining block. But in reality, these are not closed polylines, but are drawn as individual polylines in approximate N-S and E-W directions. To create closed polylines where the zone of interest is "enclosed" by other polylines, a useful command is "Boundary Polyline" under Draw. Choose this command.

Pick all the blue polylines that "bound" the rectangle of interest (or that bound all the rectangles). Do not pick any contours or other polylines. Enter a snap tolerance of 1 (to "bridge" gaps of up to 1 foot). Enter the layer to draw the polylines in (CLAYER would put them in the current layer). Then pick inside, and the closed, rectangular polylines are drawn.

Now run the command Surface Mine Reserves under the Stratacalc pulldown menu. Fill out the dialog as shown, being sure to select "Block Model" method. This selection does an "on-the-fly" block model. The "Pre-Calculated" selection would work from a stored "pre-calc" file, which can be a block model or a strata-based model. Specify the block by elevation, entering the bottom and top of the zone of interest (we did 580 to 620 here).
Also be sure to select "Calculate Strata Qualities" and "Breakout Quantities by Attributes", options near the bottom left of the dialog. After you select all 7 drillholes to model (you can crossing select the entire screen, as only drillholes will be selected and the rest filtered out), you will get this dialog:

You can "Model by Strata Names" or by Color, since the Color attribute is the strata name! Next you can pick any of the strata to report, by selecting them:
If we choose Crawfoot, SilverBuff and StandardBuff, quantities will be calculated for that block. Next you pick the limits of the study area, from lower left (well below and left of the drillholes) to upper right (well above and to the right of the drillholes) and set your gridding resolution. Figure if you have 40' of elevation range, 80 vertical zones will give you about 0.5' per zone for analysis.

![Make Block Model dialog box]

Pick one of the inclusion perimeters, and you are taken to the "Report Formatter" as shown below. Here it is shown as it might appear with a fresh installation of Carlson, completely unformatted.
Move to the right the Silverbuff C.Y., the Standardbuff C.Y. and the Crawfoot C.Y. You can name the format in the upper middle box as Limestone1, so it is a report option available to you in the future (see below):

Click Display in the lower left of the screen, and you get the first report:
Step 6-Reporting in Cubic Feet: Making User-Defined Attributes for Reporting
When configured to "English" units, that is, feet, the program defaults volumes in the form of cubic yards. If you wanted to output cubic feet, then the default output variable for cubic yards needs to be multiplied by 27 to produce cubic feet. The variables "known" to the program can be listed, within the Report Formatter, by clicking the Attribute Options button at the bottom of the screen. A formula must be created for all of the named strata to convert cubic yards to cubic feet. Therefore, to obtain all of the strata in the Report Formatter, it is necessary to re-run Surface Mine Reserves using the same settings in the dialog, but when prompted for Choose Strata, select all of the strata, as shown.
Then when you press OK and complete the gridding process, all of the strata appear in the Report Formatter, either in the left or right column.

The next step is to click the User Attribute button at the bottom of the screen, which then produces the following dialog:

![User Attribute Dialog](image)

A few conversions are provided by default. We will need to add a conversion to Cubic Feet for each strata of interest. To begin, click Add.

![Add Conversion Dialog](image)

For the example of "BastardStone", you simply multiply the "known" variable for BastardStone by 27 to calculate cubic feet. Whatever is filled out for Description is what appears in the report. To see what the program uses as "known" variables, you click "List keys". The variable can be directly selected from this dialog, then the "*27" can
be appended in the equation. Items are listed alphabetically:

Repeat for each of the stone types involved. The pattern is, every time you click Add, click List Keys, choose the next stone of interest (e.g. BED\_CUT), multiply by 27 in the equation, fill out the new "key word" for the cubic feet variable, fill out the full description for reporting and the decimal places, consider whether to Total by Sum, use No Total, etc., then click OK. Repeat for each strata. In order to see "Crawfoot" as a strata, you may need to select a larger number of vertical divisions, to "reveal" the very thin Crawfoot seam and get it in the list. Note that this is a one-time process. The new key variables will always be retained on future work. The final table might appear as shown below:

Next, click OK and return to the Report Formatter. More the generic "Strata" and cubic yard items from the right column back to the left column and move all the desired cubic feet elements over to the right-hand column and save this new format as Limestone2.
Note that using the "User Attrib" button, you can make new elements for reporting, and these elements, like Standard Buff (C.F.), can be used in equations themselves, using their "key word" designation ("STANDARDBUFFCF"). Thus the Report Formatter can be used to produce all sorts of outputs and reports, all deriving from the known elements in the original report. To see results directly in Excel, click the "MS Excel" tab then click Export to Excel at the lower right of the dialog:

This leads to reporting directly in Excel:

Step 7-Viewing the Ore Body Model in 3D
So far, we have produced volumes of material by "on-the-fly" calculations. We have not created a block model of our strata. The block model has only been created internally by the program based on the selection set of drillholes. An official "block model" is made by the command "Make Block Model" at the top of the Block Model pulldown. Select that. Here again, you can make the block model directly from the strata names.

Choose the lower left corner of the grid by the "Pick" method, and using the "end" snap (for endpoint) pick the lower left corner of the site, then the upper right corner of the site, as defined by the rectangular polyline enclosing all contours. Then set the grid resolution as shown below. Since we are dealing with "named" strata that abruptly transition to another form, use the "discrete" method of modeling. Note that for ore bodies, where qualities are typically modeled, "inverse distance" or "Kriging" are more typical modeling methods.
Note also in the dialog above that you can set the vertical position for modeling at fixed elevations or you can follow the ore model. The "follow" method finds the top and bottom of the ore material, then divides the vertical positions as defined, here by 80 divisions. So if the ore material narrowed, then 80 divisions would narrow to a smaller dimension. If you want fixed vertical dimensions, choose "Fixed Elevations". After you click OK, select all strata to process, and name the block model to be created. Also create, for later use, the grade parameter file and "pre-calc" grid model. Click "Yes" to both the options below:

These options occur only when choosing the "Model by Strata Name" option above. Otherwise, you must use a pre-made Grade Parameter File and make the Pre-Calc Grid File by a separate process. The Grade Parameter File
sets the colors (and even pricing) for the named strata or quality zones (in the case of attribute-defined grades). Making the Grade Parameter File this way does not set colors that match the colors set in Strata Definitions. You will need to run the command, "Define Grade Parameters" under the Ore pulldown menu and change the colors to match what were used in Strata Definitions, for consistent viewing, so that the 3D Views match the colors in Draw Geologic Column, for example.

Now run Block Model 3D Viewer under the Ore pulldown, choose the "blk" Block Model File and the "gpf" Grade Parameter File, press "OK" at the Block Model Viewer dialog, then select a perimeter for viewing. You obtain a plot as shown below:

![Block Model 3D Viewer](image)

Note that you can exaggerate the vertical scale, or using the "Advanced" tab, you can switch from rendered view (above) to "Leave as Points" view. If you switch from Rendered to Points viewing, you must Exit the screen view (lower "exit door" icon) then repeat the command. Note that the yellow "Standard Buff" stone shows clearly in the 3D Block View, as does the red Void zone within the upper portion.

**Step 8-Viewing the Ore Body in Profile View (Fence Diagram)**

The process of making the Block Model was critical not only for 3D Viewing but also for the Profile View or "Fence Diagram". The 3D View used the "blk" file but the Fence Diagram command makes use of the "Pre-Calc Grid" or "pre" file as well as the "blk" Block Model File. Now that we have these, from Step 7 above, we can do the Fence Diagram. Before issuing the Fence Diagram command, draw a polyline through the drillholes or across the site that you will pick for the profile view of the strata (stone). Select Fence Diagram under the StrataCalc pulldown menu. Fill out the dialog as shown below:
You could choose to exaggerate the vertical scale by changing the vertical entries to 20 rather than 50 (scale, grid interval and text interval). Then pick the polyline to use for the profile, and the "pre-calc" and the "grade parameter file" as prompted. A typical result is shown below:

Case Study #5: Block Modeling by Quality Attributes

This tutorial takes a set of drillholes and goes through the steps that create the block model. The different grades are defined in the Grade Parameter File. Blocks are drawn and viewed in 3D for analysis. Cross sections are cut through the blocks and volumes by grade are calculated with Surface Mine Reserves. Finally, the Optimized Pit Design is found with the Lerch-Grossman algorithm.

The first step is to import the drillholes and name the beds based on how the seams are to be modeled. This example is a limestone bed with a thin layer of overburden, so there are just two main material types in the drilling, OB and LS are the bed names. The drillholes have already been imported for this example. That process is documented in other documents. There are 16 drillholes in this drawing. The drawing name for this tutorial is Block Modeling.dwg. Shown here are the plan view of the topography and the drillholes, and also the drillhole datasheet to display the drilling data.
This command is used to create the block model from the drillholes. The first selection is to choose the Bed Name to model, and then the quality or qualities. Just one quality attribute may be used, or several at once. In this example, the LS bed and the CaO attribute will be modeled, as shown in this window. It needs a grid file to set the horizontal block sizes, so either pick the position from screen, and put in a dimension for X,Y, or copy an existing grid for positioning. For this one, the Surface Topo.grd can be copied for a position, which is 20x20 in dimension.
The second window sets the block height and modeling method. There are two distinct methods for setting the block height. They can be set to a fixed elevation and size which is independent of the beds, or can follow the top and bottom of the ore model from the drillholes. This creates almost a stratified block model where the elevations of the blocks follow the top and bottom of the ore elevations. This is like a hybrid of both strata and block modeling. If there are not any strata, such as in a gold or copper deposit, then the Fixed Elevations method is preferred. Both methods work the same. If using the Fixed Elevations method, to set the block height, the top and bottom of the model are entered, with the number of samples chosen to set the average block height, which is calculated and displayed at the top. In this screen, if the Number of Vertical Divisions is set to 16, the average block height listed above is 10.9. This should work well with the horizontal size of 20x20, giving an average block size of 20x20x10. This example will use Inverse Distance as the modeling method with a vertical factor of 1. Selecting OK builds all of the blocks and puts them in the BLK file. Choose a name for the BLK file, such as LS_CaO.BLK.

This command defines the grade ranges of the ore. This is what defines the blocks for colors and divisions for cross sections and volumes. There is a Draw Legend button to put it on the map. The price per pound is also defined here for the cost model, and that will be used for the optimized pit design. Also notice that there are 8 blanks for the various Parameters where the combination of the several attribute ranges can define the grade. For example the CaO \( > 90 \) and MgO \( < 15 \) defines the "High-Grade". For this example, just the CaO is defined for the different ranges. If another range is already defined, then the program will just use what is available. That is why just the "\( > \)" option is used below, starting at the highest grade and working down.

Now that the block model is built and the grade ranges are defined, the model can be inspected and viewed in 3D to check it for any problems. If the model is large, it is best to use an inclusion polyline to view just a subset of the entire model. In the Advanced Tab, there is a way to turn the various blocks on and off like layers. Just click on the line to turn on or off and the blocks are removed or added from the screen. This allows 3D views to see what the quality is inside the middle of the blocks. Notice in this example there are just green and blue blocks remaining.
This is not a required step, but is convenient to place the blocks in the drawing permanently. This command will draw the blocks on screen in CAD as nodes or “dots”. These nodes can then be brought into the 3D Viewer window and rendered the same as the Block Model 3D Viewer does. The nice option in this command allows to have a top and bottom limiting surface to crop the blocks. That way if just the blocks on a certain bench want to be viewed, use just the top and bottom grids of that bench, or even the topography, and an inclusion perimeter, to contain the blocks to draw, and ultimately view. After selecting the file, just leave all set to "YES" on the Draw Block Model screen. The nodes and contours drawn in CAD can be viewed with the 3D Viewer Window as seen below.
This step is necessary to combine the block model with the surface topo and any top or bottom elevation surfaces that will make up the entire model. The procedure for strata models is to just add the elevation grids as normal, and then add the BLK block model file to the appropriate interval. Flat elevation grids can be used for this, if it isn't a stratified model that has roofs and floors, like many hard rock metal mines and quarries that aren't stratified.
Now that the entire model is built and checked, a Fence Diagram can be drawn to see the geology and blocks in section view. Fence Diagram has an option to Hatch by Block Model. This can be drawn in two ways. The initial section shows it on a 2D Grid, the second one can be seen in 3D where it draws and hatches the fence in 3D below the line, in Real World Coordinates. Shown below are two fence diagrams from the drawing, on a 2D grid. Notice the coloration of the blocks based on grade of limestone.
There is also an option to draw the Fence Diagrams in 3D using the Real World Coordinates setting. When this is viewed in the 3D Viewer Window along with 3D Geologic Columns, the result is very useful to visualize the geologic deposit as shown below. The Draw Geologic Column command will draw the drillholes as 3D columns, and they can also be colorized by the Grade Parameter File. Notice how the coloration in the drillholes corresponds to the coloration in the fence cross-sections, indicating and good modeling estimation.

The next step is to get the volume and tons of the different grades of limestone with the Surface Mine Reserves. There is one check box to turn on that will report the tons by grade, it is Breakout Quantities by Attributes. This will not only give total tons of the limestone, but also the tons in the various grades. Here is how the window should appear.
Shown here is the report of the data dumped into Excel using the Report Formatter. Notice how the total Key tons match the individual grade tons added up in the yellow cells. This is a good check to make sure all grades are accounted for in the report. Also confirm that each grade's CaO falls in line with the values defined in the Grade Parameter File.

Now to find the optimized final pit of profitable mining, we will run this command to create a value block model, where each block is assigned a cost associated with it. Once this value block model is created, then the Optimized Pit Design can be run. First, select the geologic block model to analyze. This is the file used in the steps above. Then choose either to use the Grade Parameter file, or to Enter the parameters on screen here. For this run, the Economic Parameters will be entered. Select the Surface Topography grid when prompted to do so. It will use this to calculate the overburden on top of the blocks.
Enter in the Economic Parameters. Shown here is a sample of the costs associated with the various mining stages. This writes the value block model, where each block now has a value assigned to it whether it is profitable or not. This file is named Value Block Model.BLK.

Now that the Value Block Model is written, the Optimized Pit Design is run to create the ultimate pit and create the ultimate pit block model. The Value Block Model is now the file to process, and this one is selected first. All options are turned on to create an ultimate pit grid, block model and a report. The block model is just for calculation purposes and contains cost values.

The final report shows that most of the blocks are mineable. Level 1 doesn’t have anything in it that is mineable. The lowest level, 5 is not mineable, though there are blocks in it. The blocks that are not profitable are what is left in the image below. The grid is displayed here, with the Surface 3D Viewer, and colored by elevation. It is easy to make changes in the input parameters and run it again. The cost to mine or process the ore can be modified and the new cost model created to see how it affects the output.
There is an automatic Grade Parameter File written called the Profit and Loss.GPF. This will colorize the blocks in the Value Block Model green if they are profitable, and red if they are not. This final model can also be viewed in 3D and it will resemble the ultimate pit grid file. Shown below is the full model, and then the profitable blocks are removed or "frozen" and just the red, non-profitable blocks remain.
Underground Mining Module
Notes Menu

The commands in the top section of the Notes pulldown menu are for underground mine note entry and surveying. The bottom section contains commands for inserted mine drawing embellishments. The Locate by Bearing and Azimuth are explained in the Survey section of the manual.

Insert Mining Symbols

This routine places icon mining symbols on the drawing. There are 25 symbols to choose from. After selecting a symbol from the pages in the Select option, simply pick a point to place it. A row of that symbol can be placed by picking a destination point, and an interval point. In this case, multiple symbols are placed the specified interval apart along a line from the start to the destination point. There are options for rotating the symbols, to erase existing symbols, layer name and symbol size.
Custom made symbols can be made with the command Edit Mining Symbols Library.

**Prompts**

**Mine Mapping Symbols Dialog**
Choose a symbol.
**Pick Point for Initial Placement:** pick a point
Edit Mining Symbols Library

This routine edits the mining symbols library. New symbols can be added and existing symbols can be edited. This is very similar to editing the points libraries in the Survey module. To add a new symbol, it must be drawn as entities in a dwg. Choose Create Symbol and give it a name. Choose a DWG to save it as, select the item, and pick the insertion point (usually the center). The new symbol should now be on the list in the library.

Prompts

Select objects: select the symbol
Pick Insertion Point For This Symbol: Symbol saved.
Mine Note Defaults

*Enter Coal Thickness at Offsets* activates coal section prompts in the mine note entry routines which creates sections of coal thickness at the offsets. The *Enter Coal and Rock Thickness at Offsets* option prompts for both coal and rock thickness. *Enter Coal Sections at Offsets* is a similar option that creates a complete coal section at the offsets. *Use Centerline Stations instead of Distances* will prompt for a starting station for the entries. Otherwise the starting station is automatically set to zero. The *Prompt for Spad Number* determines whether the program prompts for spad numbers for the entry points. Turning this option off saves a prompt if you are not using spad numbers. *Enter Distances Back From Face* is an option that allows all of the mine note entry routines to post back from the face. Once this option is set, you never need to set it again except to change it. When this option is on, you will be asked for the "Distance to Face" when starting a note entry routine. Also, each routine will display a message stating "Mine Note From Face Option Active". *Create ASCII File During Mine Note Entry* determines whether or not a record of the offset notes is kept in an ASCII file whose default name is OFFSET.DAT. This file is created by mine note entry routines and can be used by AutoMine Connections and Offsets by ASCII File. If this file already exists when a mine note entry routine is started, there is an option to either append the new notes to the existing file or replace the existing file. All these data files are stored in the Carlson data directory such as C:\SC14\DATA\. Since these files are in ASCII format, they can be easily edited with any text editor. Once ASCII File From Notes is set, you never need to set it again except to change it.

```
Mine Note Entry Options

☐ Enter Coal Thickness at Offsets
☐ Enter Coal and Rock Thickness at Offsets
☐ Enter Coal Sections at Offsets
☐ Prompt for Spad Number
☐ Use Centerline Stations instead of Distances
☐ Enter Distances Back From Face
☐ Create ASCII File During Mine Note Entry

OK  Cancel  Help
```

Mine Note Left/Right/Face

*Mine Note Left/Right/Face* is a simple routine for entering offsets. The flow of this routine is very similar to Mine Note from CooRD File. To get started, the routine only requires a starting point and a direction. Then enter a distance up followed by the offsets. The offsets consist of a code immediately before the distance. The codes are L for left, R for right, CL or *L for corner left, and CR or *R for corner right. For example, the offset CL9 means a corner point offset 9 feet to the left.

Corner points identify a corner of a pillar that is across a cross cut. Corner points are drawn as green dots and other points are drawn as red circles. This distinction is made to assist in pillar connection and is important to AutoMine Connections.

If the ASCII File From Notes option is on, this routine also produces a .DAT file which contains a record of the entries. This file is necessary for AutoMine Connections.
Prompts

Enter Offset File Name $\langle$offset.dat$\rangle$: press Enter
Enter/Pick From Station Point: pick or Enter a point
Entry Number: $1$ This is an identification number for the entries that follow. AutoMine Connections groups spad offsets by this number.
Enter/Pick To Station Point (a for azimuth): pick or Enter a point or enter A
Spad Number or $\langle$Enter$\rangle$ for none: $1043$ This number is drawn at the spad.
Flip Spad Text ($Y$/<$N$>)? $N$ This determines the orientation of the spad text.
Enter distance From Station/Spad on Centerline (Enter to end): $25$
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: $L10$ Offsets left $10$.
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: $CR9$ Offsets a corner point right $9$.
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: press Enter
Enter distance From Station/Spad on Centerline (Enter to end): $47$
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: $SL8$ Offsets a corner point left $8$.
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: $R11$ Offsets right $11$.
Offset, U for Undo, or $\langle$Enter$\rangle$ for new centerline distance: press Enter
Enter distance From Station/Spad on Centerline (Enter to end): press Enter

Pulldown Menu Location: Notes
Keyboard Command: note1
Prerequisite: None

Mine Note Auto Left/Right

Mine Note Auto Left/Right is a simple routine for entering offsets. The routine only requires a starting and ending point, and then simply distance up, distance left, and distance right over and over until the end of that entry. Corner points may be specified for left or right offsets by preceding the number with a C or *. Corner points identify a corner of a pillar across a cross cut. Corner points are drawn as green dots, while other points are red circles. This distinction is made to assist in pillar connections and is important for AutoMine Connections.

If the ASCII File From Notes option is on, this routine also produces a .DAT file in the data directory which contains a record of the entries. This file is necessary for AutoMine Connections.

Prompts

Enter Offset File Name $\langle$offset.dat$\rangle$: press Enter
Enter/Pick From Station Point: pick or enter a point
Entry Number: $1$ This is an identification number for the entries that follow. AutoMine Connections groups spad offsets by this number.
Enter/Pick To Station Point (a for azimuth): pick or enter a point or enter A
Spad Number or $\langle$Enter$\rangle$ for none: $1043$ This number is drawn at the spad.
Flip Spad Text ($Y$/<$N$>)? $N$ This determines the orientation of the spad text.
Enter Distance From Station on Centerline (U to Undo, Enter to end): $25$
Enter Left Offset Distance: $C10$ The C specifies a left corner point.
Enter Right Offset Distance: $8$
Pulldown Menu Location: Notes
Keyboard Command: note2
Prerequisite: None

Mine Note From CooRD File

This mine note entry routine is for when the spads are known coordinates or point numbers from a .CRD file. The flow of entering offsets for this routine is very similar to Mine Note Left/Right/Face. First enter the spads point coordinates...
number or coordinates, and specify the azimuth by either entering the number directly or by identifying another point. Then enter a distance up followed by the offsets. Pressing Enter at the offset prompt will back up the routine so that it asks for another distance up. Then, pressing Enter at the distance up prompt will make it ask for the next spad. Finally, pressing Enter to the spad question will exit the routine.

There are two types of offsets points, corner points and regular points. Corner points identify a corner of a pillar that is across a cross cut. Corner points are drawn as green dots and regular points are drawn as red circles. This distinction is made to assist in pillar connection and is important to AutoMine Connections. The offsets have a code immediately before the distance. The codes are L for left, R for right, CL or *L for corner left, and CR or *R for corner right. For example, the offset *R10 means a corner point offset 10 feet to the right.

Prompts

CooRD File Selection Dialog Choose the file that contains the spad point data.
Starting Spad or north & east coord: 1
Azimuth (DDD.MMSS) or P for Pt.-Defined Direction <0.0>: P

Keyboard Command: note3
Prerequisite: None

Mine Note on Centerline
This command is similar to the other Mine Note routines like Mine Note Auto Left/Right. The difference with this routine is that the program does not prompt for offsets left and right. Instead the program only prompts for the distance along the centerline and places the offset points on the centerline (0 offset).

Prompts

Enter Offset File Name <offset.dat>: press Enter
Append File (<Yes>/No)? press Enter
Enter/Pick From Station/Spad point[node on]: pick a point
Entry Number: 1
Enter/Pick To Station point (a for azimuth): A
Azimuth of Heading (DD.MMSS) or p to pick <0.0>: 11
Enter Spad Number or <ENTER> For None: 101
Flip Spad Text (Yes/<No>): press Enter
Enter distance From Station/Spad on centerline (Enter to end): 40
Enter distance From Station/Spad on centerline (Enter to end): 60
Enter distance From Station/Spad on centerline (Enter to end): press Enter
Another Spad (<Yes>/No)? N
Print file containing offset input data (<Yes>/No)? N

Pulldown Menu Location: Notes
Offsets from ASCII File

This command can be used to update a drawing if the offset file is edited outside a Mine Note Entry command or a new drawing is started. Otherwise, the offset dots are drawn only once, while entering them with a Mine Note Entry command.

Offsets from ASCII File draws points that are defined in the specified offset file. The offset file is created by Mine Note Entry commands. In order to draw the points, a SPT99.DWG and a OFFSET.DWG must be in the Carlson Support directory that was set up when the software was installed.

Prompts

Enter the offset file <offset.dat>: Enter a filename. The default directory for this file is the data directory your Carlson Data directory that was created when the software was installed.

Pulldown Menu Location: Notes
Keyboard Command: moffsets
Prerequisite: An offset file created by one of the Mine Note routines

Drawing Embellishments

Mine Map Insert Commands

Here are ten very useful drawing embellishment commands. Add Core Hole, Bench Marks, Bottom Elev Points, Mine Name, Section Name, Stoppings, Escapeways (solid circle), Takeup Date, and N-E Line are straightforward routines that place their corresponding information in the drawing using the standard layer name, color, font, and height. The prompts for all nine inserts, as well as the Revise Bottom Elev Points routine, are listed below.

Prompts
For Add Core Hole:
Enter or pick 'x' and 'y' co-or of corehole location: pick a point
Corehole name: DH-8332
Surface elevation: 2115.30
Bottom of coal seam elevation: 1521
Total coal in inches: 65
Total impurities in inches: 4

For Bench Marks:
[node on] Pick Location Of Benchmark Elevation: pick a point
Enter BM Number: 834
Enter Elevation of BM: 734.65
Additional Text (Enter if none): V18-P
Pick Location For The BM Text: pick a point
Pick Alignment Point For Text: pick a point

For Bottom Elev Points:
Elevation : 1231
Pick pt. for elevation mark 'x' : pick a point
Pick point at beginning of label: pick a point
Pick point for label alignment: pick a point

For Revise Bottom Elev Points:
Select Bottom Elevation Marks & Text to Revise: pick object

For Mine Name:
Company name : Carlson Mining Company
Mine name : Carlson No,1
MSHA I.D. N.O.: 8332
State I.D. N.O. : 21153
Pick point at beginning of label: pick a point
Pick point for label alignment: pick a point

For Section Name:
Degrees of panel azimuth: 90
Minutes of panel azimuth: 00
Seconds of panel azimuth: 32
Panel name : North Mains
Panel I.D. n.o. : 2338
Panel in date : 3/1/05
Panel out date : 4/1/05
Additional notes : 60’x60’ Centers
Pick point at beginning of label: pick a point
Pick point for label alignment: pick a point

For Stoppings:
Pick point for beginning of stopping line orientation: pick a point
Pick point for end of stopping line orientation: pick a point
Pick point to beginning stopping: pick a point
Pick point to end stopping: pick a point

For Escapeways:
Pick pt. for escapeway symbol: pick a point

For Takeup Date:
Takeup date [ mm-dd-yy format ]: 3-1-05
Pick point at beginning of label: pick a point
Pick point for label alignment: pick a point

For N-E Line:
Enter Northing: 5000
Enter Easting: 5000
This will be placed in the drawing at the corresponding northing and easting.

Pulldown Menu Location: Notes
Keyboard Commands: chole, benchmark, botelev, botelev2, mname, sname, stop, xways, tdate, neline.
Prerequisite: None

Works Menu

The Works pulldown menu contains commands for underground mines and is divided into three sections with projections commands at the top, placing pillars and perimeters commands in the middle, and quantity commands at the end.

Basic Projections

Basic Projections will only produce a rectangular grid of projections (not angular). The sequencing begins by choosing a starting point, direction, and distance. Then enter the number of entries and their sizing. After the projection is drawn, stoppings and ventilation arrows may be added. This routine has fewer prompts and is more automatic than Advanced Projections. All projection lines are on distinct layers (PROJECTIONS, PROJSTOPPINGS, PROJVENTARROWS).
Prompts

Start pt. of belt entry: *pick a point* You are automatically placed in intersect and node snap mode.

Pick end pt. of belt entry: *pick a point*

Number of entries on left side: 3

Number on right side: 3

Entry spacing: 60

Crosscut spacing: 60

Plot Outer Rib Line y/<n>: *Y*

Cut Width <20>: press Enter

Offset to starting rib line (e.g. -10,0,<10>): press Enter

Offset to ending rib line (e.g. -10,0,<10>): press Enter

Offset xcuts y/<n>: press Enter

Pick pt. on xcut for beginning of stopping line: *pick a point*

Draw another stopping line <y>/n: press Enter

Pick pt. on xcut for beginning of stopping line: *pick a point*

Draw another stopping line <y>/n: *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point*

Distance between ventilation arrows: 120

<1>ntake or [R]eturn: *I*

Draw ventilation arrows on another entry <y>/n: *Y*
Pick pt. on entry to begin drawing ventilation arrows [nea on]: pick a point
Distance between ventilation arrows: 120
<intake or [R]eturn: R
Draw ventilation arrows on another entry <y>/n: N
Project another panel <y>/n: N
Pulldown Menu Location: Works
Keyboard Command: panel1
Prerequisite: None

Advanced Projections
Advanced Projections is a flexible routine that is an extension of Basic Projections. Besides creating projections this routine can also draw pillars and perimeter by using the Draw Pillars option. Other options include angling the crosscuts, offsetting entries, variable length entries, and different labeling schemes. All projection lines are on distinct layers (PROJECTIONS, PROJSTOOPS, PROJVENTARROWS). The pillars are drawn by default in the PILLARS layer and the perimeter is drawn by default in the PERIM layer.

Prompts
Pick Start Point For Belt: pick a point
Pick End Point For Belt, or <A> For Azi/Dist: A
Enter Azimuth ddd.mmss <>: 90
Enter Distance: 600
How Many Entries Left Of The Belt <0>: 3
How Many Entries Right Of The Belt <0>: 3

Based on the preceding dialog box responses, the following mine layout is created:
To create various entry spacings and lengths choose the Offset Prompt, Entry Spacing Prompt, and/or Entry Length Prompt check boxes.

Panel Settings Dialog
Spacing for Left Entry No. 1 <60.0>: 90
Spacing for Left Entry No. 2 <60.0>: press Enter
Spacing for Left Entry No. 3 <60.0>: press Enter
Spacing for Right Entry No. 1 <60.0>: 90
Spacing for Right Entry No. 2 <60.0>: press Enter
Spacing for Right Entry No. 3 <60.0>: press Enter
Enter Offset For This Heading <0>: press Enter
First Length along Entry: 60
Enter Length along Entry <540.0>: 60
Enter Length along Entry <480.0>: 60
Enter Length along Entry <420.0>: 60
Enter Length along Entry <360.0>: 60
Chapter 15. Underground Mining Module
Note: The length of the panel was shortened for display purposes. The PILLARS and PERIM layers are reserved layer names used in other routines in Carlson. The layer names can be changed here if you have other reasons to do so.

If you want to display the centerlines with the projections and be prompted for ventilation symbols (stoppings and ventilation arrows), then at the Panel Settings dialog box uncheck the Draw Outline and Pillars only checkbox.

The following panel layout is drawn without the ventilation stoppings or arrows.
Then you will see the Stoppings & Ventilation dialog box and upon filling it out you will be prompted as follows:

**Stoppings & Ventilation Dialog**

Pick pt. on xcut for beginning of stopping line: *screen pick*

Draw another stopping line *<y>/n:* *Y*

Pick pt. on xcut for beginning of stopping line: *screen pick*

Draw another stopping line *<y>/n:* *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *screen pick*

Distance between ventilation arrows: 200

*<I>*ntake or [*R]*eturn: *I*

Draw ventilation arrows on another entry *<y>/n:* *Y*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *screen pick*

Distance between ventilation arrows: 200

*<I>*ntake or [*R]*eturn: *R*

Draw ventilation arrows on another entry *<y>/n:* *N*

Upon filling in the prompts, the map will be drawn as shown above.

**Angled Projections**

It is possible to plot projections as centerlines, as pillars with a perimeter, or both. Within the Pillars section of the dialog, if the three dialog items on the left (Draw Pillars, Draw Outline, Pillars/Outline only) are selected, then only pillars and perimeters are drawn. This type of projection is particularly useful to represent the actual mine for purposes of scheduling equipment, using the Underground Mining Module. Here is an example of angled projections, with a "winged" look created by angling only the first 2 of 4 left and right entries:

If all 4 entries left and right are angled (rather than the 2 above), then the entire projection would be in angled form.
Add Rooms

Typical, Default Room Plotting requires that you click on the left-side Draw Pillars, Draw Outline and Pillars/Outline only, as well as click ‘Add Rooms’. A typical 2 left, 2 right standard projection with 120’ longrooms (current default) has the following dialog appearance and plot.

The default angles lean the left rooms to the left and the right rooms to the right at 60 degrees. The crosscut spacing on the longrooms default to $\frac{1}{2}$ the crosscut spacing on the main projections (60 in our case). I have noticed some irregular rooms if you use different crosscut spacing left and right-in that case, it might be better to plot the right side or left side separately. If the Join Perimeter with Center option is not selected, the projections will be in 3 parts: left, center and right. The outer left and right "extents" of the perimeter default to 30’ plus the distance to the center of the left- and right-most entries. In our case, that distance to the far entry is $2 \times 120 = 240$, meaning that the outer punchout is defaulting to 270’ left and right. I can change that addition of 30’ to any other desired number.

Rooms with Stubouts: You can add stub-outs within the main dialog, and the rooms will attach appropriately. In this example, Stub-out L and Stub-out R were set to 30.

Joining with Center Section: The next variation is to join a left or right section to the center (we don't allow joining all 3 at present). This can be done with or without stub-outs. To activate this option, turn on the Join Perimeter with Center option in the Room Dimensions dialog. Shown below is a left section joined to the center with no stubs involved. Below that is a right section joined with the center with stub-outs. The perimeters have been made bold for emphasis.
Rooms with stubouts connected to a standard panel

Changing Angles in the Rooms: Rooms can have a variety of angles for cutting through. To allow variation in angles, turn on the Angle Left Prompt in the Room Dimensions dialog. In this example, we did 60 (the default), then 60 and 60 in 3 entry left room. We did not vary the right condition. The prompting for the angle will remember the last entry, so the second "60" becomes just an "Enter" default on the left side.

Room with stubouts connected to a panel with stubouts

Left room connected to advancing panel
Right room connected to advancing panel

Angled rooms left (3+ X-cuts deep) and angled room right (2+ X-cuts deep)
Notice neither set of rooms were joined to the panel on the advance

Rooms with entry spacing variations

Entry Spacing Prompt: We can also choose to vary the spacing. In the example below, we did 0 left entries and 3
right entries, and we varied the entry spacing prompt on the right (and included stub-outs and Join Perimeter with Center). We entered 100, 140 and 120 for the three entry spacings and obtained the plot shown below:

Plotting Rooms with No Central Projection: This is useful for attaching left and right rooms to an existing mine plot. You pick your "centerline" as normal to get starting, but you answer 0 to both the number of left and right entries. Normally, this would simply exit the routine, but a new prompt asks "Do Longroom (y/n)". Enter "y" and you can place rooms to the left or right. (The program will only do one side or the other in a "no central panel" projection scheme. Repeat the process to add a right side to the left side rooms.) Here is the "look" of a left-side, 3 room section with no central projection:

Perpendicular Rooms and Offset Rooms

If the Room Dimension dialog is completed as shown below, rooms can be drawn at 90 degrees to the main entry, and can be offset as many crosscuts as desired. The offset up is measured by counting the number of room-size crosscuts. So if you have 40x40 rooms coming off 80x80 mains, and want to offset two main-size crosscuts (160 feet to the first rooms), then enter 4 (4×40 is 160) for the number of crosscuts to offset. Here is the result:
Projections & Ventilation

Projections/Ventilation makes heavy use of specification files. Once parameters have been established for a set of projections within a drawing file, you can save those parameters to a specifications file. When changes or additions are necessary, simply erase any undesired projections, load the file, make changes, and process. The specification file contains all the information contained within the dialog, including the projection and ventilation parameters, mandoor and stopping information, even the layer names to use.

These files can reside in any directory (usually the same directory as the drawing), and have the extension (*.PVS). When the program is activated for the first time within a drawing session, it will look for a PVS file with the same name as the drawing, in the drawing's directory, and if found will load it. If a PVS file with the drawing's name is not found, it will look for a file named DEFAULT.PVS in \\PROJECTIONS/VENTILATION subdirectory, and load it.

You can utilize this feature to your advantage by saving the general specifications about a particular drawing in a PVS file with the same name as the drawing. This way, if only the azimuth changed in a set of projections, you could open the drawing, activate Projections/Ventilation, change the azimuth, and process. You can also access the program's dialog box, enter and then store the specifications you would use most often across drawings as DEFAULT.PVS in \\SCAD\LSP subdirectory.

Dialog Control:
When Projections/Ventilation starts, it will display the dialog shown below. All specifications can be entered inside this dialog, and execution of the entity generation process can be initiated as well. Each section of the dialog will be explained in detail in appropriate subsections that follow.
All of Projections/Ventilation's options are accessed easily through this dialog with edit fields for parameters and buttons for each routine available in the program.

**Geometry Specifications:**
Before generating any entities using Projections/Ventilation, you must specify the geometric specifications of base point, azimuth, entries left/right, number of breaks, break and entry length.

**Base Point:** This button is used to specify the base point of the geometric entities. After picking this button, the dialog will temporarily disappear, allowing you full screen access to your drawing, and a prompt will appear at the command line requesting you to select a base point.

Choose the base point by picking or typing in coordinates. You MUST use an object snap (NODE, CENter, or INSertion) if picking the point graphically, to guarantee that the point selected is exactly on the point, spad circle, or insertion point of a point block.

**Azimuth:** This edit field is used to enter the projected azimuth. Enter the value in the format of DDD.MMSS, where the whole number of degrees are followed by a period, then minutes and seconds. If the minutes or seconds are less than ten (10), put a leading zero in front such as 01, 05, etc. If the minutes or seconds are zero, enter two zeros 00 as a place holder, especially for minutes.

**Entries Left:** This edit field is used to enter the number of entries to the left of the base point. A whole number is expected with no decimal points allowed.

**Entries Right:** This edit field is used to enter the number of entries to the right of the base point. A whole number is expected with no decimal points allowed.

**Break Count:** This edit field is used to enter the number of breaks to travel. The number of breaks times the break length will determine the total length of the set of projections. A whole number is expected with no decimal points allowed.

**Break Length:** This edit field is used to enter the length of each individual break. The break length and entry length do not have to be the same.

**Entry Length:** This edit field is used to enter the length (width) of each entry from the base point. The break length and entry length do not have to be the same.

**Projections:**
If the [x] Draw Projection Lines toggle is turned on, the program will create projection lines with cross break lines. These projection lines are drawn as lines, having a bylayer color and linetype, and placed on the layer designated...
in the layer dialog. See the section on layers for more information about changing layers of Projections/Ventilation entities.

Checking the [x] Draw Projection Pillars toggle can be used to simulate mine pillars. The simulated mine pillars will be polylines, having a bylayer color and linetype, and placed on the layer designated in the layer dialog.

**Beltline:**
Checking the [x] Draw Belt toggle will generate a set of parallel lines, centered about the base point, and running the entire length of the projections on the specified azimuth. The beltline will be lines, having a bylayer color and linetype, and placed on the layer designated in the layer dialog.

**Ventilation:**
Ventilation can be generated along with projections by checking the [x] Draw toggle in the ventilation section and supplying a few additional parameters.

**Distance Between Arrows [ ]:** This edit field is used to enter the distance between the sets (rows) of ventilation arrows. The sets will be placed along the entire run of projections.

The entry type list box shown, is used to setup the type of air flow in each of the entries. The program is setup to handle up to thirteen entries, but you can use as few as needed.

The process works by clicking your pointer button on the entries (in the list box) that you wish to change. When clicked they will become highlighted, or if they are already selected they will be un-highlighted. To change the air flow once entries are selected, press the button on the right corresponding to the type of air flow in each entry as Intake, Neutral, Return, or Exclude. If no air flow is to be designated for the entry, choose the Exclude button, which will draw no arrows. There are more entries available and will fit in the list box, therefore you may need to use the down arrow button on the scroll bar to view and change these.

If all items in the list need to be selected, press the Select All button, which highlights all items in the list. Additionally you can press the Clear All button, which un-highlights all items in the list.

Selecting the Symbols button allows customization of the arrows. Any of the mining symbols can be selected here.

![Ventilation Symbols](image)

**Stoppings:**
To generate stoppings while generating projections and ventilation, turn on the [x] Draw toggle in the stoppings
section and enter the headings where they should appear. The program can handle up to three rows of stoppings for split ventilation systems.

Row1-3: These edit fields are used to indicate the heading in which the stopping will be placed. Since stoppings are normally placed halfway between headings, the valid input will usually have a decimal value of (.5). For example, as shown above, if a row of stoppings is to be placed between the 4th and 5th entries, the valid input is 4.5. To exclude a row, set the value to 0.0.

The block inserted can be modified, and is stored as PVSTOPPIN.dwg in the SCAD\SUP subdirectory.

**Mandoors:**
Mandoors can be automatically added to stoppings. Turn on the [x] Draw toggle in the mandoor section and specify the additional parameters below.

Angle: Indicates the rotation angle of the door symbol when placed on the stopping. The default value of 0 should provide the desired results in most cases, but can be changed if needed.

Space: Indicates the distance between doors along the row of stoppings. Usually set to 300 or 500 feet, however any numerical value is acceptable. The program will track the running distance and automatically choose the correct break to place the mandoor in.

Break1: Indicates the break, relative to the Base Point, that the first mandoor should fall into. The program will begin tracking the space (described above), and place additional doors at the designated distance from this first break.

The block inserted can be modified, and is stored as PVMANDOR.dwg in the SCAD\SUP subdirectory.

**Escapeways:**
You can optionally place sets of escapeway symbols. Turn on the [x] Draw toggle in the escapeway section and specify the additional parameters below.

Prime: Indicates the entry number for the primary escapeway. The block is stored as PVESCPRI.dwg. Valid input would be a whole number with no decimal places.

Second: Indicates the entry number for the secondary escapeway. The block is stored as PVESCSEC.dwg. Valid input would be a whole number with no decimal places.

Offset: Indicates the distance to measure back from the row of ventilation symbols for the placement location of the escapeway symbol. Valid input would be a whole number with no decimal places.

The blocks inserted can be modified, and are stored in the SCAD\SUP subdirectory.

**Layer Control:**
Projections/Ventilation always generates the different sections of its geometry (projection lines, pillars, ventilation arrows, stoppings, mandoors, escapeway, and beltline) on separate layers. These layers can be easily changed within the layer dialog and are automatically saved when the specifications are saved. The layers used are self explanatory and are shown below.

![Layer Control Table]

---

Chapter 15. Underground Mining Module 2663
LAYER CONTROL SUB-DIALOG

To access the layer control dialog shown, press the layer button on the main dialog. After making changes to the layers, choose the OK button. If you wish to reject the changes made to the layer names, simply press the Cancel button.

Specification Save:
Projections/Ventilation can store all specifications previously discussed to a file for later recall. To save a set of specifications, choose the Save button from the main dialog. When pressed, a standard file dialog will appear (defaulting to drawing name) allowing you to save the *.PVS file. PVS stands for Projections/Ventilation specification file. When chosen, the default drawing filename will usually be the filename used for the PVS file. Accept this name or enter a new one, changing directories if appropriate. The normal scheme is to have one PVS file per drawing, having the same name as the drawing and stored in the same directory.

Specification Load:
Projections/Ventilation can re-load all specifications previously discussed to a file for later recall. To load a set of specifications, choose the Load button from the main dialog. When pressed, a standard file dialog will appear, allowing you to enter the *.PVS file. The default drawing filename will usually be the filename used for the PVS file. Accept this name or enter a new one, changing directories if appropriate.

Pulldown Menu Location: Works
Keyboard Command: panel3
Prerequisite: None

Rooms
This routine simply draws centerlines for the rooms. First pick two points to define the beginning side of the rooms. Then specify the room dimensions. Finally, enter the distance that the rooms extend from the edge and on which side of the edge to draw the rooms.

Prompts
Start pt. of rooms: pick a point
End pt. of rooms: pick a point
Distance between room entries: 40
Distance between room crosscuts: 40
Room Depth: 200
Rooms on <R>ight or [L]eft side: R

Label Projection Distances

As its name suggests, this routine labels the distances of a segment in a projection. It applies to projections created by Basic Projections or Rooms.

Prompts

Belt entry [ point to point mode ] y/n>: press Enter
Select line to label distance on: pick a projection line

Panel & Room Label Block

Panel Label Block and Room Label Block both draw labels with their corresponding dimensions.

Prompts

For Panel Label Block:
Insertion point: pick a point
Rotation angle: choose a rotation
SECOND DIMENSION <60'>: press Enter
FIRST DIMENSION <60'>: press Enter

For Room Label Block:
Insertion point: pick a point
Rotation angle: choose a rotation
ON ADVANCE OR RETREAT <ADVANCE> : press Enter
SECOND DIMENSION <40'> : press Enter
FIRST DIMENSION <40'> : press Enter

Draw Outline

Draw Outline creates a polyline in the OUTLINE layer out of the points you pick. The only intent of this routine is to draw old mine works.
Draw Perimeter

Draw Perimeter creates a polyline in the PERIM layer out of the points you pick. These points should compose the perimeter of a mine section. It is necessary to end picking points, and by entering C in order to make a closed polyline. The polyline must be closed, or inaccurate tonnages may result. Before using this routine, the points to connect can be placed using one of the Mine Note Entry commands.

Prompts

[node on] First Point: pick a point
Next Point, U to Undo, C to Close: pick a point
Next Point, U to Undo, C to Close: pick a point
Next Point, U to Undo, C to Close: C for close

Pulldown Menu Location: Works
Keyboard Command: oline
Prerequisite: None

Highlight Unclosed Plines

As its name suggests, this function will temporarily highlight polylines that are not closed. The intention of this function is for checking that the pillars and perimeter polylines are closed, since their closure is necessary for...
calculating quantities.

The procedure is to simply select the polylines to check. Then, after highlighting the selected polylines that are unclosed, the routine will pause for user input and then unhighlight the polylines. Thus, no changes are made to the drawing.

A polyline is considered closed if the endpoints are the same or if the closed flag is set. The closed flag can be set when creating a polyline, with the pline command, by using 'C' to close at the end.

**Prompts**

**Select the polylines to check.**

**Select objects:** select polylines

The program then reports either:

**Unclosed polylines are highlighted.**

**Close all or selected polylines (All/ <Selected >) ? press Enter** Look for the highlighted polylines and select the ones to close.

or

**All the selected polylines are closed.**

**Pulldown Menu Location:** Works

**Keyboard Command:** unclosed

**Prerequisite:** Polylines

---

**Chamfer Pillars**

Chamfer Pillars is meant for redrawing existing pillars that are notched at a corner by mine equipment.

Chamfer Pillars is similar to AutoCAD's chamfer expect that AutoCAD's works only on lines and Chamfer Pillars works only on polylines in the PILLARS layer. Chamfering basically creates a new edge that replaces a corner point and extends down each side a specified distance. In order to determine which corner to chamfer, this routine displays the dialog box shown below.

**A 40' x 40' pillar before and after chamfering the upper right 10' and the lower left 20'**

**Prompts**
Chamfer Dialog Box
Select the pillars the chamfer (polylines in the PILLARS layer).
Select objects: Select the pillars

Pulldown Menu Location: Works
Keyboard Command: pillar_chamfer
Prerequisite: Pillar polylines

AutoMine Connections
This command automates the connecting of dots for pillars and perimeters.

AutoMine Connections draws the pillars and perimeter of a mine based on point data in an offset file. This file can be created by one of the Mine Note Entry commands. There are two types of points in this file, corner points and regular points. Corner points, which appear as green dots, identify the first point across a cross cut for both the left and right side of a spad. Regular points are all other points, and are drawn as red circles. Corner points are critical to AutoMine. If a corner point is missing, AutoMine will become offset and the pillars will appear shifted. Each pillar must have exactly two corner points, one on the left and the other on the right. There can be no regular points between the two corner points on the pillar since AutoMine always directly connects the corner points together. For the perimeter, corner points are not important for the left and right faces. At the end face, however, corner points are required in order to identify the cross cut between the perimeter and the farthest pillar.

The order of entry of points in the offset file is significant in several ways. For one, the spads need to be in left to right order in the direction of mining. To do this, the spads can be entered in order, or the spads can be assigned sequential entry numbers. Another reason to assign entry numbers to the spads is to allow appending of the offset file. When reading appended files, AutoMine will group spads according to their entry number. The spads with the same entry number may be entered in any order since AutoMine sorts these spads by the distance along the direction of mining. For example, provided that spad 2 and spad 4 have the same entry number, then spad 2 and spad 4 offsets may be entered either spad 2’s offsets then 4’s or spad 4’s offsets then 2’s. The offsets within each spad, however, are not sorted, but are drawn in order. Consider, for instance, the cut in the left face of the perimeter in the figure below. These points must be entered in the order 1 then 2 then 3 then 4.

AutoMine removes any pillar or perimeter that is already in the drawing at the same location.

After drawing the pillars and perimeter, AutoMine leaves a pick box hanging off the perimeter so that you may connect it with a previous perimeter.

Prompts

**File Selection Dialog Box**
Select a mine note file. This file must contain points in the format described above.

**Next Point, U to Undo, P for Polyline, C to Close:** C

**Pulldown Menu Location:** Works  
**Keyboard Command:** automine  
**Prerequisite:** An offset file created by one of the mine note routines

**Auto-Connect Pillars**
This routine automatically draws pillar polylines by connecting the selected offset points. The points must be offset points created by one of the Mine Note routines such as Mine Note Auto Left/Right. In addition to the points, polylines must be drawn through each crosscut. The routine works by connecting the points such that no connection crosses a crosscut polyline. The crosscut polylines can be drawn individually with the Draw Polyline command or created as projection polylines with the Advanced Projection routine.

To use the routine see the layouts below. The first layout is created using Mine Note Auto Left/Right to locate the offset points. The centerlines were laid out using Advanced projections.
It is a good idea to manually connect the outer offset points manually and let this routine connect the internal points. Using the Polyline command and with the Osnap setting on Nodes, connect the perimeter points and create them in the PERIM layer as shown:

Next, connect the internal points using the Auto-Connect Pillars command. Select the points to be connected and the center lines that separate them. See the results here:
Prompts

Select pillar points and projection lines.
Select objects: select the points and lines

Pulldown Menu Location: Works
Keyboard Command: autopillar
Prerequisite: Offset points and crosscut polylines

Pillar Cut

Pillar Cut serves two purposes relating to final cuts that are made into pillars. It automates the process of drawing cut pillars, and it creates new pillars and perimeters for use in calculating the tonnage removed from the cuts.

The command is run by first choosing a cut pattern, then selecting the pillars to cut, and finally placing the pattern inside a pillar. The pillars must be closed polylines in the PILLARS layer. The cut pattern can contain either open or closed polylines. When an open pattern symbol is placed in a pillar, Mine Pillar Cut calculates the intersections between the pillar and the end segments of the symbol, and fits the pattern into the pillar. With a closed symbol, the cut pattern is clipped against the pillar. There are two effects this placement can have. One is to recreate the pillar with the cuts taken out. The other creates perimeter polylines inside the pillar in the spaces that are cut out.
Open cut patterns will not work if they divide a pillar into two or more separate pillars. Use a closed cut pattern if the pillar will be cut through.

To create custom cut patterns, create polylines in the desired pattern either as closed polylines or open polylines whose end segments will intersect the pillar when extended. Make sure that the polylines are the correct size to fit with a pillar. Then start Pillar Cut as usual and select the User-Defined symbol. It will ask you to select an insertion point, and pick a place in the table to store the new symbol. The next time Mine Pillar Cut is called, the new pattern
should be in the table.

Prompts

Mine Pillar Cut Symbols Dialog
Select a symbol to cut with or select User-Defined to begin the procedure to define your own symbol.

Enter the azimuth for the cuts <0.0>: press Enter This allows the cuts to be rotated when placed.

Cut the pillar or create new perimeter? (<Cut>/Perim) press Enter a string If Cut is selected, the pillar is re-drawn with the cut hacked out. If Perim is selected, perimeter polylines are created inside the pillar in the spaces that are cut out. The removed portion can be hatched with PERIM.

Select mine pillars (polylines in the PILLARS layer).
Select objects: select polylines This creates the set of pillars that may be cut. These pillars must be closed polylines in the PILLARS layer.

Pick a point for the symbol: pick a point This point must be inside one of the selected mine pillars.

Pulldown Menu Location: Works

Keyboard Command: cutsym

Prerequisite: Pillars to cut and drawn as polylines in the PILLARS layer

Boundary Enclosure

This routine is intended to be used in mines that include different leases or property ownerships. If the property is bounded by a polyline, Boundary Enclosure can be called to divide the mine into separate sets of pillars and perimeters. Then other routines such as Quantities by Average Method can use these sets to determine the exact tonnage quantities for that property.

Boundary Enclosure separates the pillars and perimeter of a mine into two sets based on a boundary line. One set consists of pillars and a perimeter from inside the boundary line and the other set consists of pillars and perimeter from outside the boundary line. If a pillar or perimeter crosses the boundary line, it is divided into two or more new polylines. In some cases, part of the new polyline may follow the boundary line. The boundary line must be a closed polyline. The one restriction on the boundary line is that it cannot create a disjoint inside set of pillars and perimeter. Disjoint outside sets may be created.
Prompts

Enter a color (1-7) <No change>: 2 The pillars and perimeter inside the boundary will change to this color.

Select a boundary polyline: pick a polyline If the point where the polyline is picked crosses additional polylines, all polylines will be highlighted. Pick another point on the desired polyline that distinguishes it from the others.

Select mine pillars and perimeter.

Select objects: pick the selection set of pillars and perimeter These pillars and perimeter must be closed polylines in the PILLARS or PERIM layer.

PullDown Menu Location: Works

Keyboard Command: bound

Prerequisite: Pillars drawn as polylines in the PILLARS layer and perimeter drawn as polylines in the PERIM layer

Draw 3D Mine Model

This command takes the 2D series of linework and converts it to a 3D underground representation of the room and pillar mine. It uses the pillars and perimeter polylines and extrudes them to the thickness of the seam that is being mined.

The above starting linework for 3D conversion

This command will extrude the linework to either the thickness from a flat base, or to a roof and floor defined by either elevations or elevation grid files. The input layers are defined so that the program knows what layers to look for. The Output layers are defined for the new 3D faces that are to be drawn in the assigned layers.
Once the 3D faces have been drawn, they can be viewed in the 3D Viewer Window under the View menu. In the Advanced Tab, the Shading Mode can be set to Both so that both the top and bottom of the faces will be rendered. If that is too dark, then it should be left to just Top mode.

### Prompts

**Command:** UG3D

**Pulldown Menu Location:** Underground Module, Works  
**Keyboard Command:** ug3d
Configure Section Info

This procedure allows you to configure the names, abbreviations, and density of the various strata that appear in your underground mine. Also, the appearance of the section is specified by this routine. This information is needed for placing sections on the drawing which in turn are needed for Quantities by Average and Grid Method. If you reconfigure section info of an existing coal section, the sample points placed using the previous section info will become invalid and must be replaced.

The strata of a section can be configured as either individual or composite. With the individual configuration, each strata has its own name and density. With composites, each strata is still named separately but they also are divided into groups that have a group name and density. The principle advantage to composites is that it allows you to enter and list out each strata height and then combine the strata into their corresponding composite category when generating tonnage quantities.

Mine Boundary Enclosure Example

Warning: After Configuring Section Info be sure to save your drawing. This will get AutoCAD to update the section Block information. Otherwise there can be a conflict between the version of the Block settings and the *.SC file which Carlson creates during Configure Section Info.

Prompts

For an Individual Section:
Enter Coal Section Configuration file name <Drawing name.SC>: SECTION1 (Or the name of your choice.)
Mine Name: Enter a name.
Enter Abbreviated Strata Name/<ENTER> to End: C This name is drawn next to the corresponding height when a section is located in the drawing.
Enter The Full Strata Name <C>: Coal This name is used in quantity reports.
Enter Abbreviated Strata Name/<ENTER> to End: B
Enter The Full Strata Name <C>: Bone
Enter Abbreviated Strata Name/<ENTER> to End: R
Enter The Full Strata Name <C>: Rock
Enter Abbreviated Strata Name/<ENTER> to End: press Enter
Enter Individual densities or Composite densities (I/C) <I>: press Enter
Average wt. of C (Coal) [lbs/ft3]: 80
Average wt. of B (Bone) [lbs/ft3]: 150
Average wt. of R (Rock) [lbs/ft3]: 150
Circle the Coal Section (y/<n>)? Y This specifies whether a circle is drawn around the section when it is placed in the drawing.
Plot the Numeric Value Only (y/<n>)? press Enter

Chapter 15. Underground Mining Module
For a composite section:

Enter Coal Section Configuration file name <Drawing_name.SC>: SECTION2 (Or the name of your choice.)

Mine Name: Enter a name.

Enter Abbreviated Strata Name/<ENTER> to End: TC
Enter The Full Strata Name <C>: Top Coal
Enter Abbreviated Strata Name/<ENTER> to End: TR
Enter The Full Strata Name <C>: Top Rock
Enter Abbreviated Strata Name/<ENTER> to End: BC
Enter The Full Strata Name <C>: Bottom Coal
Enter Abbreviated Strata Name/<ENTER> to End: BR
Enter The Full Strata Name <C>: Bottom Rock
Enter Abbreviated Strata Name/<ENTER> to End: press Enter
Enter Individual densities or Composite densities (I/C) <I>: C

Define the Composite Categories:

Enter Composite Category/<ENTER> to END: Coal
Average wt. of COAL [lbs/ft^3]: 80
Enter Composite Category/<ENTER> to END: Rock
Average wt. of ROCK [lbs/ft^3]: 150
Enter Composite Category/<ENTER> to END: press Enter

Assign the strata to a composite category:

Enter Composite Category for Top Coal TC (COAL ROCK): coal
Enter Composite Category for Top Rock TR (COAL ROCK): rock
Enter Composite Category for Bottom Coal BC (COAL ROCK): coal
Enter Composite Category for Bottom Rock TC (COAL ROCK): rock
Circle the Coal Section (y/<n>)? press Enter
Plot the Numeric Value Only (y/<n>)? press Enter
Text Size <6.0>: press Enter
Prompt for entry width (Yes/<No>)? press Enter The entry width value is used in Quantities by Centerlines.
Place Coal Sections

This routine places a block circle and text of measured section information on the drawing. It serves two purposes: to display the sections for plotting, and to calculate tonnage. Carlson reads the location and values of the section from the block circle and not from the text.

For blank thickness entries, the program can either assume a zero thickness or ignore the section point for that strata. Which method to use is defined in Configure.

Prompts

Coal Section Configuration File Dialog
Pick sample point for coal section: pick a point This places a block circle.
Pick Start Point: pick a point This is where the text begins.
Pick Alignment Point: pick a point
Now enter your measurements.
How many Inches of Coal C: 51 Which quantities it asks for here depends of the configuration file.
How many Inches of Rock R: 9

Edit Coal Sections

This routine edits the measured section information already placed on the drawing. To edit this information, pick the section block circle and the text. Then a dialog box will appear which allows you to change the current amounts of that section.

Quantities by Average Method

Quantities by Average Method is one of three commands that calculate tonnages based on coal cross section data. The other routines are Quantities by Grid Method and Quantities by Centerlines. The grid method is more accurate but the average method is faster and requires fewer coal section sample points. The centerline method uses entry row centerlines instead of pillar and perimeter polylines.
Before executing this command, there must be sample coal section points and pillar and perimeter polylines in
the PILLARS and PERIM layers. The pillars and perimeter polylines can be made with the Draw Pillars, Draw
Perimeter, or AutoMine Connection commands, and sample points are placed by the Place Coal Sections command.

The quantities can also be reported by property owner. The property areas are defined by closed polylines with an
attached property name. There are routines in the Boundary menu of the Underground Mining module for assigning
the property names to the polylines. Quantities by Average Method will prompt you to select property polylines. If
you do not select any, then just the total quantities will be reported. Otherwise the quantities are divided between
the properties and reported separately.

Quantities by Average Method generates detailed a report when it is done calculating. The format of the report
method can be Standard text, Column text, or reported with the Report Formatter. Besides this detailed report, the
command Report Tons and Acres gives coal tonnage reports based on data files that Quantities by Average Method
updates. In order to have these data files updated, you must enter beginning and ending dates and an ownership
name when prompted. If this information is entered, Quantities by Average Method will add the current tonnage to
the data file for the specified ownership name. The data files for the mine and panel names will also be updated if
they are specified. The first time a mine or panel data file is accessed, it will ask for the estimated coal reserves.

Hatched drawing with the area summaries for each property boundary
Text Report Example

Report Formatter option

Prompts

Coal Section Configuration File Dialog
Select property polylines or press Enter for none: select the property boundaries
Coal recovery percent <100.00>: press Enter
Which type of selection? [Standard/Cuts]: press Enter
Select pillars, perimeters, and section sample points. Select these carefully so you only choose the pillars inside the perimeters. Section sample points can be selected outside the perimeter, if they contribute to a more accurate answer.
Pick location to draw results or Enter for none: This is where the Area/Pillar Area/Net Area will be posted for the first property boundary.
Pick Alignment Point: This sets the text direction.
Pick location to draw results or Enter for none: This is where the Area/Pillar Area/Net Area will be posted for the second property boundary.
Pick Alignment Point: This sets the text direction.
Another area [Yes/No]? N

Insert as MText or Text [MText/Text]?: press Enter for MText
Update coal tonnage files [Yes/No]? N

Pulldown Menu Location: Works
Keyboard Command: qavg
Prerequisite: Pillars and perimeter polylines and coal sections

Quantities by Grid Method

Quantities by Grid Method is one of two commands that calculate tonnages based on pillars, perimeter and coal cross section data. The other routine is Quantities by Average Method. The average method is faster and requires fewer coal section sample points, but the grid method is more accurate because it creates a 3D model of the strata which finds deviations the averaging misses. Either Triangulation or Inverse Distance methods can be used for the grid model.

Before executing this command, there must be at least three sample coal section points and pillar and perimeter polylines in the PILLARS and PERIM layers. Perimeters may only be used one at a time. The pillars and perimeter polylines can be made with the Draw Pillars, Draw Perimeter, or AutoMine Connection commands, and sample points are placed by the Place Coal Sections command. Also property owner polylines can be used as described in the Quantities by Average Method command.

Quantities by Grid Method generates a detailed report when it is done calculating. Besides this detailed report, Report Tons & Acres gives coal tonnage reports based on data files that Quantities by Grid Method updates. In order to have these data files updated, you must enter beginning and ending dates and an ownership name when prompted. If this information is entered, Quantities by Grid Method will add the current coal tonnage to the data file for the specified ownership name. The data files for the mine and panel names will also be updated if they are specified. The first time a mine or panel data file is accessed, it will ask for the estimated coal reserves. There are three options for reporting, Standard, Column and Formatter.
Prompts

Select the file that defines the coal section sample points.
Coal recovery percent <100.00>: press Enter
Select property polylines or press Enter for none: select property boundaries only
Select pillars, perimeters, & at least 3 coal section points Select these carefully to only include the ones for the calculation. If you select more than you need and the hatching does not look correct, undo and repeat.
Processing cells ...
Another area [Yes/<No>]? If you want to process more than one area and calculate them together select another area. When you have selected all of the areas the program prompts you for the location if the report.
Start point or Center/Middle/Right/?:

Update coal tonnage files [<Yes>/No]? N
Report window

Report Formatter

Pulldown Menu Location: Works
Keyboard Command: qgrid
Prerequisite: At least three coal sections and pillar and perimeter polylines
Quantities by Centerlines

This command calculates strata quantities based on coal sections and polylines along each cut. The coal sections contain the thickness for each strata and the entry width. When defining the coal section format in Coal Section Info, the Entry Width option must be activated.

Before running Quantities by Centerlines, polylines should be drawn along each cut. This routine sums the polyline lengths to find the linear feet of advance. Crossing cut polylines are handled by subtracting one entry width from the length for each crossing. Multiplying the linear feet of advance by the average entry width gives the mined area which is multiplied by the average strata thicknesses to obtain the strata volumes.

Prompts

Coal Section Configuration File
Select the file that defines the coal section sample points.

Pulldown Menu Location: Works
Keyboard Command: qentry
Prerequisite: Coal sections and polylines

Report Tons & Acres

When you run the take-up procedures Quantities by Average, Quantities by Grid, or Quantities by Centerline, at the end of the procedure after the routine has posted the take-up report you are prompted to update the Tonnage Report. The Tonnage Report gives you the option of keeping track of tons for an Owner, Mine, and each Panel for specific periods of time.

Mine Report produces coal tonnage reports for a specified mine, panel, or ownership.

NUMERICAL AVERAGE COAL SECTION METHOD
Individual Stratas Configuration
MINE: LEAF MINED FROM - 3-1-05 TO - 4-1-05
AREA NO. 1 DESCRIPTION:
LINEAR FEET OF ADVANCE: 2005.95
AVERAGE ENTRY WIDTH: 18.20
NET AREA MINED (S.F.): 36508.30 NET ACRES MINED: 0.838
AVERAGE Coal THICKNESS (INCHES): 59.00 (FEET): 4.92
AVERAGE Hard Rock THICKNESS (INCHES): 4.00 (FEET): 0.33
TOTAL MINING HEIGHT (INCHES): 63.00 (FEET): 5.25
AVERAGE Coal WT. (LBS/CU. FT.): 77.00
AVERAGE Hard Rock WT. (LBS/CU. FT.): 104.00
Coal (TONS): 6910.72
Hard Rock (TONS): 632.81
NON-RECOVERABLE COAL (TONS): 0.00 COAL RECOVERY PERCENT: 100.00%
TOTAL TONS : 7543.53 PERCENT COAL BY WT.: 74.06%
COAL ACRE-FEET: 3.196
CAVITY ACRE-FEET: 3.740

Reports are created for a certain time period. If no dates are entered, a report is generated that includes all the known data. Besides reporting the tons mined for the period, Mine and Panel reports also include the total reserves and remaining reserves.
Coal tonnage data is made with the Quantities by Average Method or Quantities by Grid Method commands, and the data is stored in *.MIN, *.PAN, or *.OWN files in the data directory. These files are in a straightforward ASCII format and may be edited by the Inquiry Dropdown > Display Edit File command.

Prompts

**Type of report (Mine, Panel, <Owner>):** Enter a name

**Report Source File selection dialog** The available data files are displayed for selection.

**Enter a beginning date (MM-DD-YY):** enter a date If no date is entered, the earliest date in the data file is used.

**Enter a ending date (MM-DD-YY):** enter a date If no date is entered, the latest date in the data file is used. You can also select the files from the dialog box.

Besides outputting to the screen, the output can be sent to a printer in the PRN slot.
Do another report (Y/<N>): enter Y or N

Pulldown Menu Location: Works
Keyboard Command: mreport
Prerequisite: Quantity report files

**Property Menu**

The Property menu has commands for managing property boundary polylines.
Assign Property Names

In order to evaluate the quantity and/or quality of ore mined on the particular property, Carlson employs the use of closed polylines representing the property boundary. This function is used for assignment and modification of the owner and property ID names to these polylines. The following commands support property lines:

Quantities by Average
Quantities by Grid
Surface Equipment Timing
Surface Production Timing
Underground Timing
Surface Mine Reserves
Reserve Classification

This command simply prompts to select the polyline and type in the owner and ID. Property polylines supersede the Boundary Enclosure command for the purposes of calculation, since the use of property polylines does not require actual subdivision of the mine plan into properties. Instead the subdivision is performed internally "on-the-fly" by the cutting of a given polyline (such as whole mine property or monthly production pit polyline) against an underlying set of property lines.

In its current implementation the use of property lines has the following limitations: property lines should be closed polylines and make sure that they do not overlap other property lines. If a portion of a pit or panel is outside of all property lines, then in the report, the owner will be reported as UNKNOWN.

Prompts

Select property polyline:
Property Owner Name<>: Federal
Property ID<>: #J1267

Pulldown Menu Location: Boundary
Keyboard Command: property_line

Remove Property Data

When property information attached to the polyline is no longer needed, it may be removed by using this command. Multiple polylines may be processed at once.

Pulldown Menu Location: Boundary
Keyboard Command: clearprop
Property Data Report

This command uses the report formatter to create a report showing all property data associated with the selected property lines. They must be linked to the MPD file where all of the property data is stored.

Pulldown Menu Location: Boundary, Property Line Tools
Keyboard Command: reportprops

Setup Property Link

This command creates the link between the property lines in the drawing and the database. The data can come from an XML file, a TXT or CSV file, an XLS file, an Access MDB file, or miscellaneous ODBC data sources.

After choosing which format it is, select the Continue button.
This Access database shows some data entered in for four different properties.

After choosing the source file, this selection window appears if it is from an Access database. Choose the table the data is stored in.
There are then four choices on how to join the data. The first is to empty the existing data set which would delete
the property and ownership line data. The second is to merge the data, using both data sets. The third option is to
append all to the end of the data, and finally, the last option is to append any new data, and merge the common data.
The next Data Merge table displays all of the available fields. Notice in this example, there are two Owners and two
Properties. In this case, the Merge option is the way to go.

Choosing Index Field on the first Owner gives the following result. The data is now merged and ready to be used
for reporting and reserve runs. Any time these property lines are used in reserves, all of this data is available for
reporting. Choose Continue will process the data and return to the command line.
Property Names By Text

This command converts a large number of closed polylines into property lines by using text label placed inside of the polyline. You are prompted to select closed polylines to become property lines and then the program tries to locate a text label inside each closed polyline that has the same layer as that closed polyline. The text is used as the owner name and the property ID is set to blank.

When you have text labels to start with but no closed polylines, use the Boundary Polyline command under Draw menu to create closed polylines from appropriate linework by using the text insertion point.

Identify Property Lines

This command is one of several property line tools available to identify and trouble shoot property lines. To identify a property line, simply click inside the polyline and the name of the owner and property ID will be displayed in the command text window.

Prompts

Pick on or inside of property polyline:
Owner: State
Property: 459a
Pick on or inside of property polyline:
Owner: Jones
Property: 34
**Pulldown Menu Location:** Boundary, Property Line Tools  
**Keyboard Command:** idprop

### Label Property Lines

This command labels property lines in either automatic placement or manual pick modes. When the Automatic mode is selected, the label is placed at the center of the property line.

#### Prompts

Select all property polylines to label:  
Select objects:  
Select label placement method [Pick/<Auto>]? A  
Label text size: 100

**Pulldown Menu Location:** Boundary  
**Keyboard Command:** labelprop

### Find Property Lines

This command locates property lines by matching the user provided search pattern against owner name and property ID of all property lines in the drawing. All matching property lines will be highlighted. The wildcard character (*) can be used in the search pattern.
Show All Property Lines
This function displays all property lines in the drawing either by highlighting them or by using solid fill. The latter option works for detection of the unassigned properties totally surrounded by the other properties. It is also convenient for location of tiny gaps between properties shown in the timing report as small areas with an UNKNOWN owner.

Prompts
Solid-fill the properties [Yes/<No>]? Y

Pulldown Menu Location: Boundary, Property Line Tools
Keyboard Command: showprop
Break Polyline by Property
This command breaks a closed polyline into separate closed perimeters where they cross property lines. This is useful when smaller, individual perimeters are desired for pits or panels.

![Before and After images of polyline division by property]

Prompts
Select polyline to divide by owners:

Pulldown Menu Location: Boundary
Keyboard Command: ownerdivide

Extract Centroid Data
This command is used to convert property information imported from ArcInfo using shape files into property lines. It searches for polyline centroids, extracts the necessary information stored there and attaches it to the property line. This will only work in AutoCAD MAP.

Pulldown Menu Location: Boundary, Property Line Tools
Keyboard Command: import_shape

Underground Menu
The Underground menu has commands for mine layout and timing. The Mining Project Manager command is described in the Geology section of the manual. There are several different methods for placing panels for the mine layout. The differences between these routines is outlined in the chart below.
**Place Panel**
- Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.
- Level of details: Moderate, depends on amount of settings edited.
- Layout speed: Fast.
- Mine plan versatility: Creates a complete mine plan with "tree-like" connectivity, like a "tree-like" connectivity, providing maximum information for timing precedence.
- Main application: Best for laying out a complicated mine plan with multiple units working and numerous unconnected panels.

**Quick Place Panel**
- Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.
- Level of details: Fast.
- Layout speed: Quickest, most streamlined. Very efficient in placing perim with direction.
- Mine plan versatility: Generates mine plan consisting of separate panels with equipment panels with no equipment assigned, already assigned, or not assigned. Correct timing sequencing is user responsibility.
- Main application: Ideal for trial runs on large number of panels, where fast plan creation and extensive modifications are the must.

**Pick & Place Panel**
- Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.
- Level of details: Assumes default panel settings except for name.
- Layout speed: Slowest, but generates timing results as layout progresses.
- Mine plan versatility: Generates mine plan consisting of separate panels with equipment panels with no equipment assigned. Correct timing sequencing is user responsibility.
- Main application: Best for laying out a mine plan with relatively complicated mine plan large number of pan-

**Auto Place Panel By Text**
- Except for extraction options in the beginning all panel settings are default.
- Level of details: Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.
- Layout speed: Quickest, most streamlined. Very efficient in placing perim with direction.
- Mine plan versatility: Generates mine plan consisting of separate panels with equipment panels with no equipment assigned. Correct timing sequencing is user responsibility.
- Main application: Established mine plan with relatively minor modifications in minor modifications in future.

---

Chapter 15. Underground Mining Module
Timing Project Manager

The Timing Project Manager (Surface Project Manager or Underground Project Manager) applies to both surface and underground mining for file organization and selection. All files and most settings and configurations used in the mine scheduling are found in the manager. Each topic is described below in detail.

Settings

- **Coloring Settings**: These settings are from the Report Options screen from the equipment timing command. Defaults can be set here before running the actual schedule. Explanation of this dialog is found in Underground Timing or Surface Equipment Timing. The screen appears as shown here.
**Drawing Event Types:** Drawing events are entities in the drawing at a specific location that will be used for a marker in the schedule as an option for a delay. This event can be used to delay equipment, switch crews, move other equipment, etc. When the schedule crosses over the insertion point of the drawing event (usually text) the event will trigger the delay or effect. The text/drawing entity in the drawing should be inserted to the position where the delay where occur and in the AutoCAD layer defined in the Capture Layer window. The Event Key and description can be used in the reporting of the schedule to create additional reported items.
• **Calendar Event Types:** Calendar events are named events that will determine equipment down time. The default event in the calendar is Manual. The other events are set under the Calendar Event Types and Calendar Event Definition. Calendar events can be any event that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working with crews, using hours, but not mining).

**Equipment**

- **Equipment Set:** The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule.
Add and Edit will bring up the next screen for detailed entry.

The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example.

Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift.
Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only. The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined from given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

Advanced Options:

Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.
Calendars

- New or Existing Calendar: Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.
The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.

• **Date Selection:** The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. There can be up to 4 shifts. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.

• **Event Rule Definition:** This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.

• **Event Entity Filter:** The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/Panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).

• **Shifts:** The number of shifts checked here will display next to each day.

• **Due to/Calendar Events:** The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to"
Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).

- **Repeat for/Label**: This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.

- **Events for Date Selected/All Defined Events**: This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.

- **Rule Report**: This report displays all of the rules defined for down time within the calendar.

- **Year Report**: This reports all days for the selected calendar year.

- **Unit Report**: This reports all equipment and dates defined in the calendar. See example below.
• **SaveAs/Load**: This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

![SaveAs/Load](Image)

**Timing Assignment**

The Timing Assignment allows for setting the current sequence. The Assignment is similar to the TIM file in the timing routines. The equipment used and which panels or pits they are mining are shown. The Set Current button controls which one will be loaded and used. Shown here is both a surface mine and an underground mine example.
Panels

This displays the selected underground panels in the mine plan assignment. An example is shown here.
Attribute Groups

Attribute groups are Pit or Panel Attributes assigned to the pits and panels for timing. When timing the pits or panels, there are additional attributes that will be calculated and reported in addition to the Non-Key and Key quantities. If these are defaults that should be applied to all the panels or pits, then they should be entered here. Any quality values, density, or difficulty attributes can be defined here either just as a value, or as a grid file with varying values. The Reserved Attribute Names window displays the reserved words that will be recognized in the timing routines, and how they should be entered in. Selecting Keyword Help brings up the Reserved Attribute Names.
The Reserved Attribute Names are defined in a little more detail here:

- **THICKNESS**: Key strata thickness: Will report any other thickness values, this is used mostly for underground timing.
- **DENSITY**: Key strata density: Will report Key density, is used mostly in underground timing to calculate the tons. In surface timing, the tons are already in the pits.
- **ROCKTHICK**: Non-key strata thickness: Reports the Non-Key thickness mostly for underground timing.
- **ROCKDENS**: Non-key strata density: Reports the Non-Key density mostly for underground timing.
- **TIMEGRID**: User-defined grid to use for timing: This will be any additional grid the user would like to add for reporting.
- **DIFFICULTY**: Difficulty factor on advance just for underground timing: This will alter the underground equipment rate on advance.
- **RET_DIFF**: Difficulty factor on retreat for underground timing: This will alter the underground equipment rate on retreat.
- **DIFF_BENCH***: Difficulty factor for bench * for surface timing: This will speed up or slow down the equipment as it mines the specified bench. If a value is above 1, such as 1.2, then it will mine 20% slower at that point in the grid, or everywhere if it is set to value. If it is less than 1, such as 0.84, then it will mine 16% faster at that point.
- **XXXX_BENCH***: This is the dominate attribute that is most widely used in this command for surface pits. All quality grids will be defined in this fashion, for each bench. The example above, BTU_BENCH1, is defined
in this way. All quality parameters need to be entered as the NAME_BENCH*.

**Reports**

Some of the reports generated in the scheduling will appear here for other options to report. These are also accessed in the calendar or after a schedule is run.

![Image of Mining Project window]

**Data Links**

This shows the link of the data when it is linked to an external source for reporting.
Define Equipment

This command is for inputting and editing the equipment for scheduling routines. It is accessed only in the Timing Project Manager. The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule. Crews are created in the Calendar section of the Timing Project Manager.
Add and Edit will bring up the next screen for detailed entry.

The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example.
Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift.

Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only.

The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined from given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

**Advanced Options**

Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.
**Pulldown Menu Location:** Surface in Mining  
**Keyboard Command:** editcrews

---

## Equipment Calendar

Note: Equipment Calendar is also located in the Surface Module section.

This command is accessed through the Timing Project Manager under Underground. Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.
The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.

- **Date Selection:** The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.

- **Event Rule Definition:** This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.

- **Event Entity Filter:** The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/Panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).

- **Shifts:** The number of shifts checked here will display next to each day.

- **Due to/Calendar Events:** The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to" window. Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall
move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).

- **Repeat for/Label**: This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.

- **Events for Date Selected/All Defined Events**: This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.

- **Rule Report**: This report displays all of the rules defined for down time within the calendar.

- **Year Report**: This reports all days for the selected calendar year.

- **Unit Report**: This reports all equipment and dates defined in the calendar. See example below.
• **SaveAs/Load:** This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

**Pulldown Menu Location:** Reserves/Timing in Surface Mining and Underground Menu  
**Keyboard Command:** calendar  
**Prerequisite:** Equipment and crews should be defined for the routine to be used in its full capacity

---

### Set Attribute by Grid File

This command assigns an attribute value such as thickness or BTU to a panel or pit area based on the average value from a grid file. The program prompts for the attribute name and the grid file that represents the attribute. Then multiple panel/pit perimeter polylines can be selected and the program calculates the average grid value in each panel/pit polyline and stores this value.

Another method for using grids is to define the attribute as the actual grid file name instead of the average value. Then the timing routines will calculate attribute values for each timing block from the grid value. The advantage to using Set Attribute by Grid File instead of using the grid file is speed.

The Calculate Seam Split Quantities option is for calculating coal and rock thicknesses by analyzing multiple strata elevation grids using minimum and maximum miner heights. When the coal thickness is less than the minimum height, the minimum height is used. The maximum height is used when the coal thickness is greater than the maximum height. A fixed amount of rock thickness that is always taken can be specified. Given the miner height, the program will find when the miner takes main coal seam plus the parting and any of the second coal seam. The average coal and rock thickness for each panel polyline is calculated and stored.

---

*Chapter 15. Underground Mining Module*
Define Panel Attributes

The panel attributes are used in timing calculations and reporting to define coal quantities and qualities within the panel. Any attributes assigned to panel are included in the timing report. The list of attribute names and values is attached to the panel perimeter polyline. There is a number of predefined attributes:

Attribute Defaults to Meaning
THICKNESS 6ft Coal seam thickness
DENSITY 80lb/sq.ft. Coal density
ROCKTHICK 0ft Rock parting or rock to mine
ROCKDENS 150lb/sq.ft. Rock density

The Attribute Groups are accessed in the Timing Project Manager. These and other attributes may be defined and assigned a value to be used as the default. The attributes with no value assigned will be shown in Edit Panel Attributes dialog for the particular panel, but will not be used in the production report.

In order to improve precision of thickness and attribute calculations for the strata, the option is available to specify a grid file name instead of the average value. This allows the program to calculate the desired value on-the-fly based on the calculated perimeter. To use a grid, click on the attribute to change, then select "Grid" in the Value/Grid popup. Then either type the grid file name or select it using the File Select button and store the change using the Update button. Excessive use of grids in calculations will slow down your computations, so use judgment whenever it is necessary to select grids over value.

In order to make the assignment of the Difficulty Factor (to adjust equipment production rate) easier for large number of panels, the attribute named DIFFICULTY may be used instead of modifying every panel data. The corresponding name for retreat mining is RET_DIFF. Both grid and value attribute types are permitted.

These attributes are also used in Quantities by Average and Quantities by Grid functions to calculate qualities associated with the panels.
When you select **Keywords Help** the following dialog with keyword definitions pops up.

<table>

**Keyboard Command:** editpattr

### Assign Panel Attributes

The command allows for selecting multiple panels and assigning a Panel Attribute Group to them all at once. A typical use for this is where there are different sets of attributes used in different panels, such as a continuous miner and a longwall. These two different attribute groups must be defined first, in the Timing Project Manager, then they appear on the dropdown list of Attribute Groups to choose from. Choosing the button next to the group dropdown will bring up the Edit Attributes screen, where changes can be made if needed. Once the group is selected in the dropdown, choose OK and select all the panels to assign that group to.
Prompts

Select panel polylines to have attribute group assigned.
Select objects: 1 found, 14 total
Select objects:
Saving changes to project database...

Pulldown Menu Location: Underground
Keyboard Command: setpanelattr

Edit Panel Attributes

The function edits the panel attributes attached to a panel perimeter polyline. The list of attributes is loaded from a polyline or created anew using the Default Panel Attributes defined. The dialog used is the same dialog as in the Define Panel Attributes function. Edit Panel Attributes allows you to specify a distinct set of attributes for the particular perimeter polyline. This set has precedence over the default one.
Whenever the Edit Panel Attributes function is used to make changes in attributes for the particular panel, a completely separate set of attributes is created and stored for this panel. From that point on, the changes in default panel attributes will not affect this edited panel. To revert these changes and make the panel use the default set of attributes, use the Reset Panel Attributes function.

**Reset Panel Attributes**

Pulldown Menu Location: AdvMine
Keyboard Command: resetpanelattr

**Set Report Defaults**

Report Options. Each item on the dialog box is defined below.
• **Report by period:** This option runs the schedule and breaks the pits into blocks by period, such as month or year. The blocks and outlines are colored by period and displayed in the report. The report can be formatted many ways.

• **Report by equipment:** This option runs the schedule and breaks the pits into blocks by Equipment. The blocks and outlines are colored by equipment and displayed in the report. The report can be formatted many ways.

• **Report Only:** Choosing this option will not draw any blocks or outlines on the map. It will go directly to the Report Formatter for viewing of the data.

• **Draw blocks:** When this option is selected, the periods or equipment will be drawn as blocks of solid fill or any AutoCAD hatch pattern that is chosen.

• **Draw distinct outline:** When this option is selected, the periods or equipment will be drawn as closed polyline outlines.

• **Draw legend:** This option draws a legend and the picked location on the map. The colors are based on period, custom amounts or equipment.

• **Pastel colors:** Choosing this option draws the blocks or outlines in the pastel color region of the AutoCAD palette. It uses colors in the 11, 21, 31, 41 etc. row. If it is not selected, then it will use the brighter, primary colors such as 10, 20, 30, 40, etc.

• **Enforce custom colors:** Selecting this option will use the custom color palette the is setup with the Custom Dates and Colors Table.

• **Custom table: Dates/Colors:** This brings up the Define Ranges screen. This is where a custom date or color table can be set up. The Auto set button will bring up the smaller window for entering the starting line (row number), starting date, how often to repeat, and how long to keep repeating. The Set colors will prompt for a starting color, and the color number increment. The colors are set by picking the color box. The Pattern is the pattern of the hatch in the blocks. The Scale is the size of the hatch patterns if a hatch is used. The Layer is the AutoCAD Layer of the period. Finally, the Label is what each period will be called for reporting and labeling. The example shown here has created a weekly schedule with custom colors. The Clear button wipes out the data for starting over. The tables can be saved and loaded as CDT files. To use this option, choose Enforce Custom Colors or Custom Date Table.
**Custom table: Amounts:** This button brings up the Define Levels window. This is where the amount to target is set for the Custom Amounts option in the report. The amount to target is set in the first column. The next column is the color for the blocks and outlines. The colors are set by picking the color box. The Pattern is the pattern of the hatch in the blocks. The Scale is the size of the hatch patterns if a hatch is used. The Layer is the AutoCAD Layer of the period. Finally, the Label is what each period will be called for reporting and labeling.

![Define Levels](image)

- Define Levels window: This window allows for the customization of the levels in the report. The Amount column sets the amount to target for each period. The Color, Pattern, Scale, Layer, and Label columns provide additional details for each level.
• Change shade color every: This option will change the color/layer of each block or outline. There are 3 choices. Every Period (what is selected below), Year, or 5 Years.

• Block labeling: This pulldown is for setting the labeling options. There are 5 options here. No Block Labels will not draw any labels. Draw Actual Dates will draw the date of each period. Draw Period Names will place the period name in the block that is entered in the custom date table. Use Custom Names draws the names entered in the custom amount table. Use Custom Text Block activates the Add, Edit and Remove buttons. Choosing Add or Edit will bring up the input screen for arranging the text items in the block. First, give the new block a name. Then move items from the left side to the right, in the row desired. The Add Text button allows for custom text for prefix or suffix entry. The Add Attribute adds any attributes that exist in the schedule. Add New Line moves the added item to the next row. If this is not selected, then the next item is added to the same row, with a + as a separator. Remove will move the entire row from the Line definitions.

- Text Size/Text autosize: This will either place all text in the map with the defined size, or autosize it to fit in the block dimension.

- Length-wise labels: This option draws the text parallel with the long axis of the pits. If it is not selected, then the text will be 90 from the long axis.

- Text Style: Enter in an AutoCAD text style for labels.

- Text Block Style: This section is active if the Block labeling is set to Use Custom Text Block. Any premade blocks will appear on the list and may be selected for text orientation.

- Report Period: This is the start and finish date of the report. By default, the program will display the full range from the start date to the final date it needs to finish. Any date range in the middle may be used.

- Skip format prompt: If this option is selected, then after the blocks are drawn, a report will appear that is similar to the last one created. The program will not bring up the report formatter for customizing.

- Sub-divide by properties: If this is selected, the schedule will recognize any named Carlson property lines drawn on the mineplan. In the report, the periods can be further subdivided by property and owner. These are the same property lines that are used in Underground Mine Reserves.

- Output period grids: Choosing this option will create a grid file of the 3D surface at the end of each period. It needs the Surface Grid and the Bottom of Pit Grid. It needs at least the Bench 1 Grid filled in to make the grids. Finally, create a new output grid path with a prefix to create new grids of each pit. A new grid file is then written of each pit and bench. This can be an "ultimate pit" used in other design work. It doesn't have the flexibility of other commands such as Design Bench Pit. It uses a constant highwall slope of around 80 degrees. Disregard for underground mining.

- Period Polylines to Pits: Selecting this option creates and names the outlines as Carlson pits. The names of the pits are the actual period names. This is useful if these period polylines need to be saved and re-run in the Surface Mine Reserves for additional quantities or analysis. Disregard for underground mining.

- 12 months + 8 quarters + years: A schedule run with this option will break down the first year into 12 monthly periods, the next two years into 8, 3 month quarters, and the remaining periods will be full years.

- Show Months of Development: This method will use the starting day and increment by month to the same day. For example, if the starting day is on the 12th of each month, the schedule will be from the 12th to the
12th for each month.

- **Show 1st Days of Months**: This method will use the starting day and increment to the first of each month. For example, if the starting day is on the 12th of the first month, it will go to the end of the first month and then start fresh on the 1st of each month.

- **Show Years of Development**: This method will use the starting day and increment by year to the same day. For example, if the starting day is on June 15th, the schedule will be from June 15th to the next June 15th.

- **Show 1st Days of Years**: This method will use the starting day and increment to the first of each year. For example, if the starting day is on June 15th, it will go to the end of the first year and then start fresh on the 1st of each year.

- **Show Date Range**: This option is used to just display a period as a partial range. Enter a range above in the Report period windows. Then when the sequence is run, only that period will be hatched all in the same color and time.

- **Custom Date Table**: When a custom Date/Colors table is defined, this option must be selected to use it. Custom Dates/Colors are defined above.

- **Custom Amount Table**: When a custom Amount table is defined, this option must be selected to use it. Custom Amounts are defined above.

- **Legend Scale**: If the Draw Legend box is selected, this is the size of the legend. Sizes from 50-100 should appear legible for most mine plans with a dwg scale of 50.

- **Hatch**: This is the hatch that is used for drawing in the blocks if the custom date or amount tables are not used. All hatch patterns appear on the list, the most common one, solid, appears at the top of the list for easy selection.

- **Retreat Hatch**: This is used for underground retreat hatching. This provides the user the opportunity to create a different pattern for second mining than advance. Note that longwalls are treated as mining on the advance.

- **Divide advance/retreat display**: This divides the advance and retreat mining hatches and splits the panel to display both. Note if you use this option it splits all panels regardless of the presence of retreat mining in a panel.

- **Scale**: If a hatch pattern other than Solid is used, this is the scale it will be drawn at. Sometimes trial and error is needed to get the best scale, as different patterns look better at different scales.

- **Layer**: This is the AutoCAD layer that the blocks and outlines will be drawn in, if no other options are used.

- **Layer by year**: The blocks and outlines will be layered by year. The year will appear as a suffix to the layer name.

- **Layer by period**: This option will put each period on its own layer. If there are many periods, it will create many layers which can be a hassle.

- **Of, Sum for whole mine & Stop at last period**: These options are only active when using the Custom Amount Table. The "Of" window is for selecting what is being target for custom amounts. The options are similar to Surface Production Timing: Total Tons, Key Tons, Waste Tons, Total Area, Mined Area, Total Volume, Waste Volume, and User Grid. Sum for whole mine will keep a running total for summation in the report. Stop at Last Period will end the schedule at the last entered row in the Custom Amount Table entered above.

**Pulldown Menu Location**: AdvMine > Underground, Adv Mine > Surface

**Keyboard Command**: set_report

---

**Subdivide Panel**

The simple way to specify different coal qualities and/or other panel properties is to break a large panel into a number of smaller sections. These sections are later associated with a single panel within the Place Panel routine. This routine divides panels into a given number of smaller ones. The slower alternative to this method, giving better precision, is to use grids instead of average values for panel attributes.
Pulldown Menu Location: AdvMine
Keyboard Command: subdivide

Place Panel
The Place Panel function requires a panel perimeter drawn in the PERIM layer. If you draw the panel with Advanced Projections in the Basic Mining Module and use the option to draw the pillars, the program will automatically calculate the extraction ratio (as shown in the example panel on the left). The extraction ratio can be entered into the Edit Section dialog box, if you start with the perimeter only drawn in the PERIM layer (as shown in the example panel outline on the right).

Place Panel Pre-Requisite Linework Options

The underground timing routine operates with a tree-like structure of the panels built using a centerlines network. The new panel may be added or an existing panel (i.e. created using Advanced Projections) may be attached to the existing network of centerlines using this function.
Each panel may consist of a number of sections, where each section is characterized by the uniformity in the section attributes such as owner, coal thickness and qualities, complexity of mining, extraction ratio, azimuth and length. Therefore each panel is represented by a centerline and a set of panel perimeter polylines, one for every section.

Due to the tree-like structure of the Mine Plan, each new panel should branch from the existing panel. This allows for proper timing calculations and data management. The user is prompted for the starting point and direction of each section, with dimensions dependent on the existing perimeter polyline or on user input.

If an existing polyline is used to define the panel, the program evaluates the section length by intersecting the centerline with this polyline. Otherwise the sizes of the section are defined in the Edit Section Dialog. The appearance of the dialog depends on the way the section is defined. Both kinds of dialogs are shown here.

User has a number of options to define a direction of the panel. The following methods are available:

**Perim:** The direction of panel is defined by the direction of the first segment of polyline.

**Text:** Direction is from "branch off" point to insertion point of the text found inside the panel. The text must be in PANELNM layer and it defines panel name.

**Pick:** Direction of the panel is from "branch off" point to pick point.

**Segment:** Direction is defined by user-picked segment of the panel polyline.

**Panel name:** Identifies the panel for Underground Timing.

**Difficulty factor:** Represents the effectiveness of the mining equipment within the section. Values above 1.0 will cause proportional slow down of the production and below 1.0 will speed it up. This value may be specified using difficulty factor grid file by selecting file with Select File button or typing it in instead of the actual value. The run-time difficulty factor will then be evaluated for corresponding area.

**Precedence:** Defines whether development of the section may not start until all listed sections are completed. Precedence is especially important for the longwall sections, since production there is not possible until all headings are completely developed. The listbox shows panels which have to be developed before the section being edited. Since some sections may be defined after the current section, it is advisable to edit precedence later with Edit Panel function. The precedence can be set by either picking from the list, or screen picking.

**Panel start:** Defines fixed start date of the development. This field is optional and is ignored if the actual starting date is later than date specified.

To define attributes for this panel section (such as THICKNESS, DENSITY and etc. as explained in Define Panel Attributes function) select Prompt for coal qualities toggle.

In the case of using an existing perimeter, the extra unknown is Extraction Ratio, whereas in the other case the dimensions of the section and entry/crosscut spacings need to be defined. The extraction ratio will default to value calculated using pre-drawn pillars and panel perimeter.

The **Entry Width** for predefined panel is only used if the section is mined by the piece of equipment with the linear feet of advance production rate specification.
Retreat Extraction: Defined as ratio of area of all coal extracted on retreat to the area of whole panel. Therefore if extra side coal is picked up on retreat this value combined with advance extraction ratio, exceeds 1.0. To simplify estimation Prompt for retreat options may be used to calculate the retreat extraction for given the extraction polyline.

Retreat Difficulty Factor: Similar to Difficulty Factor except it applies on the retreat stage.

Users who are creating an extensive mine plan, may prefer to use a streamlined Quick-Place mode to create layout and later on use Edit Panel Dimensions to modify panel properties.

Prompts

Use Quick-Place mode (Yes/No)? press Enter
Start new Mine Plan (Yes/No)? press Enter Choose Yes to start Mine Plan.
Select an entry to branch from: pick the panel to branch from at desired location
Enter the azimuth for the segment:
Select a panel polyline or press Enter for dialog:
Edit Section Dialog
Enter the azimuth for the segment:
Select a panel polyline or press Enter for dialog:
Edit Section Dialog
Pulldown Menu Location: AdvMine
Keyboard Command: place_panel

Pick & Place Panel

This routine is parallel to the Place Panel and Underground Timing functions. The timing through the panels is performed as soon as the user picks the panel perimeter. The sequence of picking and all the associated parameters necessary for "replay" are stored in the same form as with the Timing routine. That allows you to modify the mine plan, equipment rates and/or calendar and obtain an updated plan without having to redo the sequence.

The routine goes through the following steps:

– Prompt user for next panel to mine in.
– Check if the picked panel is a part of the mine plan already. Then prompts to pick an existing mine plan or to start new mine plan. The existing plan is loaded in and rerun to obtain the information about the availability of the equipment.
– Bring up the dialog and prompt the user for various parameters and the part of the panel to be mined. The proposed mining is previewed along with the dates and tonnages associated with the proposed segment.
– When editing is finished the colored and labeled timing blocks are displayed in the user-defined style and the whole process is repeated for the next panel.

The starting date of mining in the picked polyline depends on three dates: if the optional panel start date is specified and the unit is available this date is used. Otherwise if the unit is tied up within some other panel, the starting date is the date when the unit finished the last panel offset by the specified moving delay. Lastly if the unit has not been used in the mine plan at all, the start date for the panel is the same date as for the whole mine plan.
The portion of the panel to be mined is determined by the selection made:

**Whole perimeter** The panel will be mined to the end of the panel or to the next pin point if present (retreat).

**Distance** Mining will advance a given distance along the centerline past the last mined point. Use of this option on retreat is associated with automatic reassignment of advance development, followed by rerun of timing plan (advance and retreat use the same set of pin points).

**Period** and **To Date** are similar to Distance, since the program will automatically calculate a distance corresponding to given date.

When the **Test** button is used the portion to be mined is highlighted in the drawing and the timing and quantities results are displayed in the dialog.

The amount of time necessary to mine given portion of the panel depends on the following factors:

- Equipment production rate (use Define Equipment to modify)
- Coal and Rock Attributes (Define Panel Attributes, Edit Panel Attributes)
- Difficulty Factor (may be specified as value or grid on per panel basis or using Define Panel Attributes and by placing a text labels on certain layer within the panels)
- Extraction Ratio (pre-calculated based on pillars draw inside the panel, but may be modified) Equipment Calendar assignments.

**Report Options** are the same as these used in Underground and Surface Timing Routines. The final results for the portion laid out during current session are displayed in the user-defined form using the Report Viewer.

The generated mining plan (the system of green centerlines) may be modified and rescheduled using Underground Timing routine.

**Pulldown Menu Location:** UnderGnd

**Keyboard Command:** pick_panel
Auto Place by Text

This is the best method to place many panels fast. The panel is directed by text orientation with centerline going through text insertion point. The text itself becomes a panel name and it has to be in layer PANELNM to be found. User can specify retreat options, difficulty factors and entry width to be used for all panels before running command. To place the text in the panels easily use Draw Sequential Numbers, found under the Draw dropdown menu.

All panels created in one run become a single connected mine plan with no equipment assigned.

When you note the prompts below for entry width you will want to place the "longwall panels" and "room and pillar" works in two steps in order to get the correct advance distances reported. For this example the room and pillar works are on 20ft width, and the longwall width is 1,000 feet. Placing them in two steps will create two mine plans that can be connected using the Connect Mine Plans option.

Chapter 15. Underground Mining Module
Prompts

Assign zero retreat extraction [Yes/No]? Y

Advance difficulty <1.0>: 

Entry width <20.0>: Use the panel width for longwalls, entry width for room and pillar panels.

Pulldown Menu Location: UnderGnd
Keyboard Command: auto_place

Edit Panel

The function is identical to the section definition portion of Place Panel function. It is used to edit properties of the section of the panel after the panel has been completed. The precedence can be set by either picking from the list, or screen picking.

- Panel name: This is a required field.
• **Panel start**: This is an optional field. The Underground Timing routine have an option for start date that usually makes this field unnecessary. This field can delay the start of a panel independently of the plan start date.

• **Easting**: The easting coordinate value of the first picked point when the panel was placed.

• **Northing**: The northing coordinate value of the first picked point when the panel was placed.

• **Azimuth**: The azimuth from the first to the second picked points when the panel was placed.

• **Entry Width**: This is used to calculate face feet/meters of advance. This should be set to the width of the panel when working with longwall panels to get the correct advance down the panel.

• **Prompt for coal qualities**: A check in this box brings up the Define panel Attributes dialog box.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>THICKNESS</td>
<td>5.0000</td>
<td>Value</td>
</tr>
<tr>
<td>DENSITY</td>
<td>88.0000</td>
<td>Value</td>
</tr>
<tr>
<td>ROCKTHICK</td>
<td>0.5000</td>
<td>Value</td>
</tr>
<tr>
<td>ROCKDENS</td>
<td>155.0000</td>
<td>Value</td>
</tr>
</tbody>
</table>

• **Prompt for retreat options**: The following prompts appear that allow for a second polygon that specifies a second area that can be retreat mined separate from the area mined on the advance. This additional polyline must be closed and can be totally contained in the advance polyline, overlap, or be outside. When the polyline overlaps two options exist: the extraction ratio for the area contained in the advance polyline and the area outside of the advance mining polyline.

**Command Line Prompt:**

- Pick a polyline representing a shape of the retreat area:
- Enter the extraction ratio for remaining pillars: .25
- Enter the extraction ratio for COAL outside the panel: 0

• **Retreat Extraction**: Any entry in this box other than the default zero will place a second mining panel that can be scheduled on the retreat back through the panel.

• **Owner**: A single owner's name can be assigned to the panel.

• **Precedence**: This box gives the opportunity to set fixed scheduling relationships. Any panels selected must be completed before this panel can start.
• **Advance Difficulty Factor:** A value or a grid can be used to provide difficulty factor input for advance mining in the panel.
• **Retreat Difficulty Factor:** A second value or grid can be specified for retreat mining independent of the advance mining difficulty rate.

**Pulldown Menu Location:** UnderGnd  
**Keyboard Command:** edit_panel

**Update Edited Panel**

The mining plan created once should undergo changes as mining progresses. The user may modify, replace or erase panel perimeters in correspondence with changes in the existing mine and then use this command to update the mine plan data. Do not modify or erase the remaining linework, since this linework and internal plan data will be updated to match changes in the associated perimeters. This command should also be used every time the panel polyline is moved, replaced or edited for any other reason.

Naturally the mine starting date should be moved forward each time plan is updated, so that timing of the remaining plan remains correct.
Once the panel linework is updated, re-run the Underground Timing updating the plan start.

**Pulldown Menu Location:** UnderGnd  
**Keyboard Command:** update_plan
Recalculate Extraction

When changes are made to the panels that result in a change in the extraction ratio this function must be run to update the extraction ratio in the panels. This also must be run after placing panels using Auto-Place Panels by text. If the text values for extraction are used to input the extraction ratio for advance or retreat extraction ratios this function must be run. Text for the extraction ratio must be put on the CAD layer of EXTRACTION. Two other layer names that will be recognized by this command to update the panels are ATTR_GROUP to assign a certain Panel Attribute Group to certain panels (such as longwall vs. continuous miner), and ENTRY_WIDTH to set that to the value of the text in that layer.

Prompts

Select all panel polylines to have extraction ratio updated:
Select objects: Specify opposite corner: 6 found
Select objects:
Polyline offset amount <0.0>: press Enter
Retreat recovery <1.0>: 0

Panel 5 RIGHT has extraction of 0.48000
Panel 4 RIGHT has extraction of 0.48000
Panel 3 RIGHT has extraction of 0.48000
Panel 2 RIGHT has extraction of 0.48000
Panel 1 RIGHT has extraction of 0.48000
Panel N MAINS has extraction of 0.55000

Pulldown Menu Location: AdvMine
Keyboard Command: redoextract

Find Panel

Use this command to find a panel with a given name in a complex mine plan. Type the name of the panel in at the command prompt and the ghosted dashed arrow will appear in the center of the screen pointing at the requested
The mine plan consists of visible linework and internal data, including cross-references, containing all data necessary for timing. For this reason a simple deletion of the linework of an unwanted panel is not enough for removing all references to it and is likely to corrupt whole mine plan.

Use the Remove Panel command to remove all the linework and clean up internal data related to panel being removed and all its children panels.

In case if user just wants to remove a panel, but keep its children in the mine plan, remove a panel perimeter polyline and then use Update Edited Panel to tell it what that panel is completed.

Connect Mine Plans

Two mine plans which are located in two separate parts of the mine but are sharing the same equipment or just wanted to appear on the same time plan, may be connected into a single mine plan using this command. The only difference between joint mine plan versus conventional one is that mining progresses simultaneously in all connected plans, if equipment use permits that.

The following drawing contains two separate mine plans: Plan A and Plan B.
Plan A panels are shown when the Underground Timing function is selected. (Before connecting)
Panel B panels are shown when the underground timing option is selected and you pick on the Plan B panels.

(Before connecting)

After connecting Plans A & B the list of available panels is composed of both lists.

Pulldown Menu Location: AdvMine
Keyboard Command: connect_plans
Disconnect Mineplans

A mine plan is a group of placed panels on a common list grouped together for scheduling. Disconnect Mine Plans is used to break a mine plan into two or more groups of placed panels. To select a mine plan pick on the green backbone lines of the placed panels.

Prompts

Select a part of the mine plan to be disconnected: select backbone polyline
Select a part of the mine plan to connect to or press Enter to leave disconnected: press Enter

Pulldown Menu Location: AdvMine
Keyboard Command: disconnect.plans

Add Pin Point
Pin Points are used to provide stopping points within a panel. This is similar to, but not exactly the same thing as sub-dividing as panel. Pin Points can be used to sequence mining up to the stopping point for both advance and
retreat mining. Difficulty factors can be changed between pin points by placing the difficulty factor by text on the DIFFICULTY layer to impact the mining rate as well. Units can mine up to a pin point, mine in another panel, and then return to continue mining later. The N_Mains panel below has been broken into 6 parts that can be scheduled with the 5 pin points as shown.

The function Add Pin includes new pin points into the panel as desired.

For the example shown the sequence of advance mining is as the following:

N_MAINS <B:1>
N_MAINS <1:2>
N_MAINS <2:3>
N_MAINS <3:4>
N_MAINS <4:5>
N_MAINS <5:E>

The different pieces may also be assigned to the separate units as well.

The same set of pinpoints is used for both advance and retreat mining with the following naming convention:

Advance
N_MAINS <B:1>
N_MAINS <2:E>

Retreat
MAINS<B:1>
RET MAINS<2:E> RET, so that a section name on retreat is the same as on advance except for suffix the RET.

Prompts

Select a position for pinpoint: pick the desired location on the centerline
Remove Pin Point
The Remove Pin Point command deletes the unwanted pin point from the panel. See Add Pin Point for detailed information on pin points.

Prompts
Click on centerline close to pinpoint to be removed: *pick on the centerline close to unwanted pin point*

Set Current Position
The purpose of this function is to set the current state of the mine development.

When a mine plan is first created, the mine plan is a snapshot of the layout of the mine. As mining progresses some panels are completed, while mining in the others just starting. Whenever the user wants to advance the Starting Date, the mine plan should be adjusted to the mine state on the new date.

Some of the updates can and should be done using Update Edited Panel after corresponding modification, but whenever a panel is going to be retreated, it is impossible to modify panel perimeter to show changes. In this case a current position of the crew within the panel is marked using Set Current Position function.
Prompts

Select a current stage of panel development (Advance/Retreat)?
Click on centerline at current position: pick on the centerline

Pull Down Menu Location: UnderGnd
Keyboard Command: pstart

Panels Report

Panels Report provides a way to report out all of the information stored in the panels in a common mine plan using the report formatter. Select any backbone polyline in a mineplan and the report formatter will appear ready to print the report.
Underground Timing

The diagram above shows the general steps associated with the creation of a mine plan with the Underground Timing routine. Pre-requisites include:

- Creating thickness, density, and quality grids, and/or average values for the total coal and rock to be mined.
- Define the productivity rates of the equipment and operating schedule for each section of equipment.
- The drawing linework has to be prepared on specific layers.
- Panels can be placed using one of, or a combination of, three placing routines: Place Panel, Auto.Place Panel by Text, and/or Pick and Place Panel.
- Several adjustments to the mine plan can be by Adding Pin Points, Recalculating Extraction, Connecting Mine plans, and Editing panels.
The drawing above shows the North Main panel with 5 panels to the right. The panel perimeters are drawn on the PERIM layer. The panels in this example were placed using Pick and Place.

The Mining Project dialog box above shows some of the key files used in the mine timing. Options on the right side become active depending on the items selected on the left side.
The underground timing scheduling dialog box provides options to assign panels to be mined to the equipment, insert delays between panels, input the plan start date, number of shifts/day, and undo the current report. Disregard the bottleneck options for underground mining. The underground timing routine calculates the time needed to complete the assignment, calculates coal quantities and qualities, draws results period by period, and produces a production report. In the order to calculate timing, every panel needs to be assigned to equipment. The left listbox lists the available equipment. Use Add button to create a new equipment or edit to change the definition of the defined one. This list is stored within the mine plan and is different for every plan. The Edit button calls the same dialog as the Define Equipment function.

The middle listbox shows panels currently assigned to the crew highlighted in the left listbox (if any). To assign a panel to the equipment, first click on the equipment name, then on the panel name in the right listbox and at last on the Assign button. Panels are mined in the same order as they appear in the list. To complete mining of all assigned panels successfully the order should not be controversial (i.e. NMAINS <1:2> can not appear before NMAINS <B:1>). To change sequence of mining click on the desired panel name and use Do Earlier or Do Later buttons to change the order. The Remove button removes the highlighted panel from the list of the panels assigned to the current crew and moves it to the right listbox. Use Add Delay button to add delay (for moving of equipment, maintenance or other reason) after highlighted panel. After all panels for first crew has been added click the next crew and repeat until all the panels needed are added.

Screen Pick will allow for selecting the panels graphically on the screen. Each panel is hatched with solid fill to give instant feedback that the panel has been assigned. If pin points are in the panel, it will only hatch up to the next pin point, allowing the panel to be assigned in order as separate entities.
When the assignment is completed click the Calculate button. Check the timing report produced and make sure that all assigned panels have been developed. If the process terminates earlier, the rest of the plan was inaccessible for some sequencing reason. Modify the assignment if needed and click Calculate again. During retreat mining it is possible that a sub-panel will be completed later that the panel itself. If this conflict occurs the calculation algorithm will try to offset start date of the panel itself to get timeout sufficient to resolve the problem. In the case when a problem could not be resolved an alert box with corresponding message will appear.

The time needed to develop a panel is offset by the Extraction Ratio and Difficulty Factor defined in the Edit Panel Dialog, and thickness and density of coal and rock defined by the Edit Panel Attributes function. The presence of qualities in the production report depends on the list of panel attributes and their values defined by the Edit Panel Attributes function.

In cases when the mine plan includes retreat (second) mining, the system will make sure that when the parent panel is mined on retreat, the mining (advance or retreat) in all child panels is completed. If not it tries to offset the starting date of retreat in the parent panel until the timing conflict is resolved. Sometimes it is impossible to do so and program reports the problem to user for manual resolution.

![Image of Report Options dialog box]

**Reporting Options**
• **Report by period** - To draw the development progress period by period and to obtain quantities and qualities report click on this button. The Report options dialog appears prompting for drawing options and period sizing.

• **Report by equipment** - use different colors to distinguish pieces of equipment not periods.

• **Report only** - skip any drawing, just generate a detailed report.

### Period Sizing

The available period sizing options are:

- **12 months + 8 quarters + years** - Display monthly development for one year, followed by quarterly periods for next 2 years and from then yearly periods;

- **Months/Years of Development, 1st Days of Months/Years** - starting from specified period start date display each Month/Year of development, optionally with rounding start date to the first day of the Month/Year.

- **Custom Date Table** - Completely user-defined sequence of periods, with customized dates, colors, layers and hatches.

- **Show date range** - Display a single period as specified by user.

- **Show custom table amounts** - The same purpose as the previous selection, with ability to specify different amounts and drawing attributes for every period. Option *Sum for whole mine* controls whenever equal quality should be mine from whole mine or from the single panel.

### Text Block Labeling Options

- Text labels are usually drawn perpendicularly to panel scaled to fit into the period area. This behavior may be modified by clearing *Text Autosize* option to have fixed text size and/or by selection *Draw labels lengthwise* to change orientation. User may pre-define a custom text style and specify it in *Text Style* field. User is also able to define a completely custom text block to be used for labeling which may have any information present in the report later as well as any extra text to be displayed. Several named label blocks may be defined.

- **Block Labeling** pull-down defines what is displayed as period name in timing block drawn.

- **Draw period names** option uses short one line name for the period,

- **Use custom names** picks up the name from custom date table.

### Hatching Options

- Three different, user-definable hatches are used for advance, retreat and predefined mine history.

- The layer name for the retreat mining is obtained by prefixing "RT-" to advance layer name.

- **Enforce Custom Coloring Table** option allows to use any period sizing in combination with Custom Date Table defining colors, hatches and layers for every particular period.

- **Change Shade Color** pop-up box controls rotation of color depending on the period drawn.

- **Use Pastel Color** enables use of larger number of colors for drawing timing blocks.

### Using Property Boundaries

*Sub-Divide* by properties controls whether system tries to use property lines and do calculations on per property basis.

### Other Output Options

- **Sum For Whole Mine** toggle defines if for period sizing by amount options the amount is a total for a whole mine or just for each panel.
- *Report Polylines to Pits* enables use of drawn period boundaries as "pits" for calculations using Mountain Top Removal.

- *Output Period Grids* - in surface mining stores current surface grid for each period. This grid sequence may then be played back using View 3D GRid History command.

- *Divide Advance/Retreat display* draws advance coloring to the right of centerline and retreat one to the left.

- *Layer by Year/Period* - place coloring for the same year/period on the same layer.

- *Stop at Last Period* - when using custom period table stop timing at last period defined

When the Custom Date Range option is selected date ranges are displayed similar to that above. The colors/dates table shown defines color/layer/label combination for a specific date range. The Auto Set function may be used to fill out the table for repeating period lengths starting at a particular line and to create a complicated setup like 12 months + 4 quarters + years after.
Date ranges can be automatically set with the dialog box above.

If development progress drawn is not satisfactory and the scheduling needs to be adjusted, use *Undo Report* button in Timing dialog to remove drawn report entities. After the dialog is completed, the mining development is shown step by step and then the coal production report is generated. The report format may be modified to suite the particular need and preferred format saved for further use. See Reference Manual for complete description of Report Formatting dialog. There is a progress window displaying the time elapsed and the time remaining for large schedules that require a lot of time.
The Report Formatter has several output options:

- **Report** - This outputs to an ASCII text file viewer and an ASCII text file can be saved or inserted directly into the drawing.
- **MS Excel** - Exports the report directly to an MS Excel spreadsheet.
- **Import/Export** - Has several options to move data in and out of your reports, and you can export to an MS Access mdb file.

**Report**

The Report tab outputs ASCII text reports as shown below:
The above report is an example of an Ascii text report in Non-columnar format.

<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Date Start Year</td>
</tr>
<tr>
<td>------------------</td>
</tr>
<tr>
<td>8/17/2007</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

The above report is an example of a columnar Ascii text report.

Chapter 15. Underground Mining Module
The report above is an example of an Ascii text report in spreadview.

The User Defined Attribute tab leads to a dialog where custom attributes can be created.
The Attribute options opens with a list of the attributes above, providing display and formatting options below.

MS Excel
When the MS Excel tab is open reports can be exported directly to new or existing spreadsheets, beginning on any specified sheet, row and column. There are also options to include totals and text header information in the file. When the options have been specified click on the *Export to Excel* button. The spreadsheet below was exported using this option.
At the Export button under Import/Export tab there are 5 options shown above.

Rpt format reports can be merged together, as shown above. The rpt reports are the reports that can be loaded and viewed even after the underground timing routine is closed.

Prompts
Select any part of mine plan: Pick any centerline in the mine plan

Underground Timing Dialog

Pull-Down Menu Location: AdvMine

Keyboard Command: schedule_mine

Clear Timing Report

Removing the coloring after the timing routines are completed may be a tedious task. This routine removes and erases all text labels and hatching from surface pits and underground panels for a specific bench or mining direction in one step. It is a quick and efficient procedure, even for objects on many layers. Items are permanently removed from the drawing screen. It supports both surface and underground mining.

Prompts

For Underground Timing:
Remove coloring for [Advance/Retreat/<Both>]? 
Select parts of mineplan to have timing coloring removed:

The following drawings show panels with blocks colored and without blocks colored after using Clear Timing Report.
Subsidence Menu

The subsidence routines work with the SDPS (Subsidence Deformation Prediction System) program. SDPS was written by Virginia Tech. Carlson Software is the exclusive reseller for SDPS.

**DXFOUT Mine Plan to SDPS**

This command creates a DXF file to import the mine plan pillars and perimeter to the Subsidence Deformation Prediction System program. The pillars and perimeter polylines created in Carlson with the layers PILLARS and PERIM. The PERIM layer is written to the DXF file as PANELS for SDPS. This routine provides the user the ability to specify the direction the pillar polygons are drawn. SDPS requires the pillars to be drawn in the counter-clockwise direction. For additional information on this procedure, refer to the SDPS manual.
Prompts

**DXF File for SDPS** Enter a file name. The default directory is the SDPS directory defined in Configure.

**Pulldown Menu Location:** Subsidence  
**Keyboard Command:** sdpsout  
**Prerequisite:** Polylines in the PILLARS and PERIM layers and prediction points on the POINTS layer, if prediction points are input.

**Prediction Point Output**

This command draws text at each prediction point of the subsidence, strain and other SDPS deformation output values. From the dialog, click the Select button to choose an SDPS project file. The program then reads the values from all the output .dat files and labels the values next to the prediction points.
**Pulldown Menu Location:** Subsidence  
**Keyboard Command:** sdpsout  
**Prerequisite:** SDPS output files

## Post-Subsidence Contours

This command creates surface contours after accounting for subsidence. The surface is defined by prediction points which are POINT entities with the elevation of the surface. These points are then exported to the Subsidence Deformation Prediction System program which calculates the subsidence at each point. This subsidence output from SDPS is written to a DAT file in the SDPS directory. Post-Subsidence Contours then subtracts the subsidence values from the file from the elevation of the prediction points.
Prompts

Triangulate & Contour dialog
Select the prediction points.
Select objects: *pick the points*
Select SDPS Output file Choose the subsidence output file.

Pulldown Menu Location: Subsidence
Keyboard Command: sdpsectr
Prerequisite: prediction points and subsidence output file

Contour SDPS Output File

This command creates contours of the values in SDPS output DAT files. The output files can represent subsidence, strain and any other SDPS deformation output.
Prompts

Triangulate & Contour dialog
Select SDPS Output file Choose the output file.

Pulldown Menu Location: Subsidence
Prerequisite: SDPS output file
Keyboard Command: sdpsctr2

Draw Subsidence Profile
This command draws a subsidence profile created by Profile Function Formulation in SDPS. The profile data is stored in a .dat file that is created with the Output>Export option in SDPS.
Prompts

Subsidence Profile to Draw Choose the .dat file from SDPS.
Draw Profile dialog You may want to change the vertical scale to a smaller number to exaggerate the vertical.
Bottom elevation of profile grid < -4.0 >: press Enter
Pick Starting point for axis < 5000,5000 >: pick a point in a clear area of the screen

Pulldown Menu Location: Subsidence
Keyboard Command: sdpsprof
Prerequisite: Subsidence output file

Case Studies

Case Study #6: Underground Mine Layout and Timing

**Underground Project Manager**

The Underground Project Manager (MPD) file should be defined before stating with Underground Mine Layout and Timing using the Underground Project Manager command under Underground menu. It allows user to define Equipments, Timing Calendar, Panel Attributes as well as other essential parameters to be used in the timing.

![Mining Project: C:\Carlson2007\Data\Ugsection.mpd](image)

**Mine Layout Options**

Using the Advanced Projections command in the Basic Mining Module, there are several ways the user can generate mine projections. These different techniques will be based upon personal preference and management's direction. Whether or not to include the centerlines, pillars, and perimeters on the map are up to the user. The Advanced Mine Module timing routines require that some information is kept on specific layers. The pillars must be drawn on the PILLARS layer and the perimeter of each section must be drawn on the PERIM layer. These are the defaults set in the Advanced Projections option under the Basic Mine Module.

Choose the Advanced Projections command under Works. The first three prompts are:

1. Starting point of the belt
2. Number of entries to the left of the belt
3. The number of entries to the right of the belt

After responding to the initial prompts the Panel Settings dialog box appears. This dialog box allows the user to specify how the mine projections will be drawn. Several different variations are possible. Entry spacing and length can be varied, separately or together.
A nice feature of Carlson is that it allows the user to draw the rooms on one or both sides of the panel at the same time the panel is drawn. The rooms perimeter on the left or right side can also be joined to the panel perimeter so the timing blocks will match for the panel and the rooms.

In addition to the configuration of the pillars, the user has the option of what to display, pillars, centerlines, perimeter, as well as chamfer, angled blocks, bracketed pillars, stoppings, and ventilation.
As you can see there are several options to present mine projections with Carlson.

Once the panels have been laid out, they have to be "placed", or have extended entity data attached to them, so that they will relate to each other. Carlson has three different methods of placing panels: Place Panel, Pick & Place, and Auto Place by Text. Of these three techniques only Place Panel builds a network topology, or precedence relationship, between the panels as they are placed. With the other two techniques, Pick & Place and Auto Place by Text, there is no relationship built as they place the panels. This allows the user to actually mine through panels that overlay each other, which could be helpful in laying out mining through overlying strata.

**Place Panel**

To place panels, the panels must be previously drawn with the perimeter drawn in the PERIM layer and the pillars, which are optional, drawn in the PILLARS layer. The program subtracts the sum of the areas of the individual pillars in the PILLARS layer from the area of the perimeter drawn in the PERIM layer to calculate the extraction ratio. The extraction ratio is then applied to the perimeter area to calculate the tonnage in the panel.

In the Advanced Mine Module under the Underground dropdown box you will find Place Panel. When the user selects Place Panel the first prompt is:

**Use Quick Place mode (yes/<no>)?**  Quick place mode is an option that lets the user place panels without entering specific information in the panels other then the panel name. It is a way to get the panels placed quickly. If the user has drawn the pillars and does not intend to retreat mine, the Quick Place mode may be the best way to get the panels placed.

If the user chooses the Quick Place mode the following prompts appear:

**Start new mine plan? (yes/<no>)?**  The user will always respond with yes for the first panel. Next, as long as the panels being placed are adjacent, the response is negative. Panels that are part of the same mine plan, but are physically separated can be placed as new mine plans and connected later.

The next prompt is: **Direction of panel is defined by (<Perim>,Text, P1ck, Segment)?**

- **Perim** - The user defines the starting side of the polygon and the direction of mining is perpendicular to the first side of the polygon. If the panel is laid out using the Advanced Projections in the Basic Mining Module the perimeter is automatically drawn to match up with the requirements for the Perim option.
- **Text** - The direction of mining through the polygon can be set by the direction of the text.
• **Pick** - The user chooses two points to set the direction of mining in the reverse order of mining. The first point is picked inside the polygon, the second point is picked on the beginning side of the polygon. The direction is from the beginning side through the first point picked inside the polygon.

• **Segment** - Pick the starting side of the polygon and any side that parallels the direction of mining of the panel.

When the direction of mining has been set. The program prompts for the name of the panel, offering a name that can be accepted or overwritten. When the name is entered, the program draws the green "backbone" line according to the direction of mining and places the name of the panel at the beginning of the line. The user clicks the right button to complete this process for mining straight through a panel.

To mine around a corner the user left picks the mouse button and repeats the above steps for setting the direction.

Once the panel has been placed, the program prompts the user for the entry to branch from. The program is asking for the point along the "backbone" line to start the next panel. Once the user selects the starting point for the next panel the process repeats.

Using the Quick Place mode does not give the user access to the Edit Section Data dialog box during the panel placing process. If the pillars are not drawn when using the Quick Place mode the user will have to return to the Edit Section Data dialog box to enter the extraction ratio after placing the panels. Most users prefer to enter this information when the panel is being placed, so they usually do not use the Quick Place mode.

If the user chooses not to use the Quick Place mode there are two additional panel direction options available: Azimuth and Pick internal point.
**Pick and Place**

Pick and Place places and times the panel as it is placed, drawing the timing blocks when the panel is placed. In addition to timing as it goes, this option allows the user to test the schedule before placing the panel in the mining sequence, providing real-time feedback while scheduling the mine. This technique does not automatically build precedence between panels automatically. Precedence can be added to the panels in the precedence part of the Edit Section Data dialog box. Once all of the individual panels have been placed, the user runs the schedule to get the complete mine timing report.
Similar to Place Panel, Pick & Place Panel has the following options for specifying direction of mining. They are defined above:

- **Perim** (default)
- **Text**
- **Pick**
Once the direction has been set, the Define Timing Step dialog box appears.

- **Panel Name** - is a required field. The program will offer a name which can be overwritten.
- **Panel Start** - is an optional field.
- **Owner** - is an optional field, if filled out indicates the property owner for the entire panel and will be available in production reports.
- **Starting Date** - is not optional for the first panel assigned to any unit. After the first panel this field is optional and will be calculated.
- **Number of shifts** - is a required field, and overwrites the setting in the equipment definition file if the shifts are less than the equipment file.
- **Retreat Recovery** - If recovery is different on retreat than advance it can be inserted here.
- **Entry width** - if no pillars are drawn in the perimeter the default is 20 feet. Otherwise, it is picked up from the pillar layout.
- **Panel Attributes** - can be anything the user wants to use such as; ash, sulfur, btu, etc. The user can use fixed values for these or refer to a grid.
- **Prompt for Retreat Options check box** - if this is checked it indicates the shape of the retreat perimeter differs from the advance perimeter. If checked, a separate set of prompts will appear giving the user the option to specify the shape of the retreat perimeter and extraction ratios for the pillars mined inside and outside the advance perimeter.
- **Advance Difficulty Factor** - the difficulty factor used on the advance can differ from that used on the retreat. Normal difficulty is (1), greater than one reduces productivity, less than one speeds up production. The difficulty factor can be a factor or a grid.
- **Retreat Difficulty Factor** - can be specified separate from the advance rate.
- **Equipment Name** - is selected from the defined equipment list.
- **Advance Extraction Ratio** - the extraction ratio is the sum of the area of the pillars divided by the area of the perimeter. This factor is usually 1.0 for longwall panels, but for continuous miner sections is usually near .50.
- **Retreat Extraction Ratio** - this factor is percentage of the remaining pillars left on the advance. This factor can be up to 100 percent for the remaining pillars, as opposed to a number less than 1 minus the advance extraction ratio.
- **Advance/Retreat radio button** - if the user left clicks in the panel after it has been assigned on the advance to schedule it the radio button will gray out the advance button highlighting retreat button.
- **Portion to mine** - options include:
  - **Whole Perimeter** - to mine the entire perimeter.
  - **Distance** - the distance displayed in the box to the left of the radio button is the distance to the spot where the user left clicked in the perimeter to Pick & Place the panel. This is useful if the user want to know the distance to a point inside the panel. When this option is selected, a pinpoint is placed at the distance selected, allowing the user to schedule other panels.
  - **Moving time (shifts)** - the move time in shifts the panel is delayed prior to starting.
  - **Test** - this option lets the user try the settings and get feedback before applying them.
  - **Report Options** - this button gives the user two reporting options, one for an abbreviated timing report and the other for the full report.
  - **OK** - applies the selection and schedules the panel showing the timing.
  - **Cancel** - breaks out of the procedure and returns the user to the command prompt.

**Auto Place Panel by Text**
The Auto Place Panel by Text command gives the user the ability to place panels by drawing text in the panel perimeters on the PANELNM layer. The requirement for drawing the perimeter in the PERIM layer is the same. The prompts are set out below.

**Command:** `auto_place`

**Assign zero retreat extraction (Yes/<No>)?**

**Advance difficulty <1.0> :**
Panel Attributes
The default panel attributes option lets the user assign attributes by value or grid. Certain key or reserved words are available to the user that Carlson recognizes. Choose the Keywords Help button to see them:

**Define Equipment**

Define Equipment is where the user adds and edits the production rate of the equipment, it can be accessed from Underground Project Manager. Production rates are input for the entire spread or section. This rate can be modified as a function of time, mining height, or strip bench. The Rate/Shift, Hours/Shift, and Rate/Hour back-calculate, allowing the user the ability to fine-tune the production rate. If the toggle to "Define Crews and Units" is on it gives user an ability to define Labor Crews and Units (combination of Crew and Equipment) separately.
The user can specify the minimum and maximum mining heights. Where mining occurs below the minimum mining height out of seam dilution is added to make up the desired minimum height. When the maximum mining height is selected key strata is combined with non-key material where the key strata exceeds the maximum mining height. A cost per hour can be input and it will be multiplied by the hours worked. Maintenance frequency is scheduled in the same units as the Rate/Shift. The delays apply to the entire spread or section in shifts for both Routine and Main Maintenance Frequencies. The recovery factor is designed to be used with elliptical cross-sectioned entries developed with boring machines.

Calendar
The Editing Calendar is a quick and simple way to schedule a production Equipment or Unit (group of a Equipment and Labor Crew working on it). This should be thought of as an equipment, as opposed to a crew scheduling technique. Equipment needs to be added before the calendar is applied. The calendar can be applied to a single unit or all of the equipment. To apply the calendar to several units select the calendar and the unit and Apply the calendar to the unit. Once the calendar is created two different reports can be generated. The first report is the annual unit calendar and the second is a yearly report of what is working and when.
Pin Points
Pin points are break points set in a panel to indicate where the mining temporarily stops to facilitate mining in other areas. When mining resumes in the panel with the pin point it resumes at the pin point. Pin points allow the user to layout fewer panels.

Underground Timing
The Underground Timing option is selected after the panels have been placed, and the equipment and calendar have been defined. Panels are assigned to equipment in the sequence to be mined. Panels can be selected by name from the unassigned list or screen picked. The unassigned panel list can be sorted by name or direction of mining. Delays can be scheduled between panels in days or shifts. The starting date and number of shifts per day are assigned in the designated boxes. Once the run is set up, left click on the Calculate button. Two reporting options are then available. An abbreviated timing report can be viewed or the detailed timing report can be formatted. The user has a wide range of timing options that impact the presentation of the timing map.
Once the report options are selected the map is timed out.
When the report times the map it also develops a report. The report formatter allows the user to customize the report. By moving available variables across to the used variables side in the order from top to bottom the user can set the order in the report. This order also drives the sub-totaling option to create various report styles. The report can be displayed on the screen, printed, made part of the drawing, or exported to Excel or Access. The order set up in the report format from top to bottom is the order in the report from left to right. There is a line editor in the screen display that allows the user to add lines and edit the report prior to printing.

This is an example of exporting the report to a spreadsheet. Totals can be exported to spreadsheets as an option. If totals are exported they show up in bold font. This report can also be imported into the Microsoft Access database for additional reporting options.
Case Study #8, Part 1: Underground Mine Mapping Procedure

Application

Underground mine mapping requires the entry of traverse notes (for the placement of spads), entry of left and right offsets for locating mine pillars and perimeters, connecting the pillars and perimeters, the placing of special mine symbols and strata thickness measurements, and the drafting of projections for future mining. These are all fully covered in the Mining Module of Carlson. The mapping utilities apply primarily to underground coal mines but also to underground limestone, trona and even salt mines. In fact, any mine that creates pillars for roof support.

Procedure

Here's a quick summary of the mine mapping procedure:

1. Enter the traverse notes and plot the spad points.
2. Draw projections.
3. Enter the mine "offset" notes to pillars and perimeter points.
4. Connect up your pillars and perimeters.
5. Add special mine symbols (stoppings, air flow pointers, etc.).

Let's now look at each of these steps in detail.
(1) Entering the Traverse Notes
The most direct method of entering traverse notes begins with Draw/Locate Point in the Points Dropdown and
continues with Locate by Bearing or Locate by Azimuth. You would Enter coordinates or Pick a Point within
Draw/Locate Point. You might choose to enter a specific northing of 1200465.107 and easting of 795091.135. If
this is your first point on the job you will be asked to select an existing or make a new .CRD file (coordinate file).
You would select New and choose a name, typically equal to the name of the drawing. We will call our file MINE.
Then if you select LOCATE BY AZIMUTH under Notes dropdown menu, the program will start at your first point
by default, and allow you to enter an azimuth and distance to the next point, such as 100.1535 (100 degrees 15
minutes 35 seconds), and a distance of 120.09 feet. Press Enter for 0.00 vertical angle and Enter for no Description.
Pressing ENTER will repeat the LOCATE BY AZIMUTH command. Next try defaulting (repeating) the azimuth
by pressing ENTER, and input a distance of 60.05. You obtain a drawing as shown above.

Now, let's enter an elevation for all 3 points. Go to Points, Coordinate File Utilities, Edit-Assign Point. The
following dialog box appears. Enter in the elevation for Point 1, choose next for points 2 and 3. Point 1 elevation is
1016.73, Point 2 is 1016.75 and Point 3 is set to 1017.03.

To enter the additional points. Use the Inverse and Traverse commands from the COGO module in the COGO
dropdown. Make sure Instrument Rod and Height Prompting is turned on Under Point Defaults. This will prompt for the height each time. Go to the COGO menu and turn on Linework. This will draw the lines of the traverse. Now Select Inverse from the COGO menu, or type I at the command line. Here are the next four Traverse point entry values.

**Command:** i, I
**Calculate Bearing & Distance from starting point? Traverse/SideShot/Options/Arc/Pick point or point number: 2**

<table>

Enter Vertical Angle (dd.mmss) <0.0000>: .07
Instrument Height <-1.9500>: -1.78
Rod-Target Height <-2.1400>: -1.85
The following image should appear in the drawing.

(2) Drawing Projections

There are four types of projections: Basic Projections, Advanced Projections, Projections and Ventilation and Rooms. Basic Projections will only produce rectangular projections (not angular). This option, however, has fewer prompts and is more automatic. Let's run Basic Projections.

Start pt. of belt entry: Pick point 4 (You are automatically placed in intersect and node snap mode. All Carlson points have nodes, so you can use the node snap. You can override the pre-set snap by picking the asterisks at the top of the sidebar menu and selecting another choice.)

Command: panel1, PANEL1
Command: (intersect/node on)
Start pt. of belt entry: Pick Point 4 (for point number 4)
<P>ick End Point For Belt or [A] For Azi/Dist: A
Azimuth to end of belt [ddd.mmss]: 10.1535
Distance to end: 540
Number of entries on left side: 1
Number on right side: 2
Entry spacing: 60
Crosscut spacing: 60
Plot Outer Rib Line y/<n>: Y
Cut Width <20>: press Enter
Offset to starting rib line (e.g. -10,0,<10>): press Enter
Offset to ending rib line (e.g. -10,0,<10>): press Enter
Offset xcuts y/<n>: N
Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*
Draw another stopping line *<y>/n: Y* 
Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*
Draw another stopping line *<y>/n: Y* 
Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*
Draw another stopping line *<y>/n: N* 
Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point as shown on figure*
Distance between ventilation arrows: *pick a point as shown on figure*
*<I>ntake or [R]eturn: I*
Draw ventilation arrows on another entry *<y>/n: Y* 
Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point as shown on figure*
Distance between ventilation arrows: *pick a point as shown on figure*
*<I>ntake or [R]eturn: R*
Draw ventilation arrows on another entry *<y>/n: N* 
Project another panel *<y>/n: N* 
You will notice how all projection lines are on distinct layers (PROJECTIONS, PROJSTOPPINGS, PROJVENTARROWS).

With the projection shown, it is easy to illustrate rooms. Select Rooms under the Works dropdown.

**Command:** rooms, ROOMS
Start pt. of rooms: _int of
End pt. of rooms: _endp of
Distance between room entries: 40
Distance between room crosscuts: 40
Room depth: 240
Rooms on <R>ight or [L]eft side: R

While here, let's select Label Proj. Distances.

**Command:** LDIST
**Belt entry (point to point mode)** y/\(<n>/n>: N
**Select line to label distance on:**

Pick as many entry and crosscut lines as desired. This Label Proj. Distances routine applies to Basic Projections and Rooms using the pick line option. The pick option places the distance on the picked line segment. For Advanced Projections, most lines are continuous from the start to the end of the projections, so the point-to-point end-point pick mode must be used. This point-to-point mode must also be used on the belt line (from spad 4), since it is one continuous line.

Now let's label our panel and rooms. Select Panel Label Block.

**Command:** labelplan, LABELPAN
**Insertion point:** Pick anywhere in the open areas.
**Rotation angle:** Pick the rotation angle from the insertion point.

**SECOND DIMENSION** <60'**: press Enter
**FIRST DIMENSION** <60'**: press Enter

Now Select the command: Room Label Block

**Command:** labelrms, LABELRMS
**Insertion point:** Pick an open spot for the center of the label.
**Rotation angle:** Pick the rotation angle from the insertion point.

**ON ADVANCE OR RETREAT** <ADVANCE>: press Enter
**SECOND DIMENSION** <40'**: press Enter
**FIRST DIMENSION** <40'**: press Enter

The final projection option we'll run is Advanced Projections. Select it.

**Command:** panel2, PANEL2 (Intersect/node on)
**Pick Start Point For Belt:** Pick where Pick3 is on the figure below.
**Pick End Point For Belt, or <A> For Azi/Dist:** A
**Enter Azimuth in ddd.mmss** <280.1535>: 280.1535
**Enter Distance:** 360
**How Many Entries Left Of The Belt** <0>: 2
**How Many Entries Right Of The Belt** <0>: 3
Enter Offset For This Heading <0>: press Enter
Enter Offset For This Heading <0>: press Enter
Enter Offset For This Heading <0>: press Enter
Enter Offset For This Heading <0>: press Enter
Enter Offset For This Heading <0>: 20
Use sidebar to select double-dash stoppings.
Pick pt. on xcut for beginning of stopping line: Pick as many xcuts as you would like.
Draw another stopping line <y>/n: Y Use sidebar to select double-dash stoppings.
Pick pt. on xcut for beginning of stopping line:
Draw another stopping line <y>/n: Y Use sidebar to select double-dash stoppings.
Pick pt. on xcut for beginning of stopping line:
Draw another stopping line <y>/n: N
Pick pt. on entry to begin drawing ventilation arrows [nea on]: Pick ventilation arrow location.
Distance between ventilation arrows: Pick interval distance.
<1>ntake or [Return]: I
Draw ventilation arrows on another entry <y>/n: Y
Pick pt. on entry to begin drawing ventilation arrows [nea on]: Pick ventilation arrow location
Distance between ventilation arrows: Pick interval distance
<1>ntake or [R]eturn: R
Draw ventilation arrows on another entry <y>/n: N
Complete the stopping and ventilation options as desired. A plot similar to the one above is obtained. All entries are continuous lines, while crosscuts are individual lines.

(3) Entering the Offset Notes
Since mining operations have different methods for note taking and posting, there are three distinct routines for entering offset notes: Mine Note Left/Right/Face, Mine Note Auto Left/Right, and Mine Note From CRD File. Each of these routines operate with a similar procedure of first choosing a starting point and direction, and then distancing up and offsetting left and right repeatedly. There are also two setup routines. Mine Note From Face Prompt allows the mine note entry routines to post back from the face, and ASCII File From Notes is an option for keeping a record of the offset notes in an ASCII file. All these routines are located in the Notes dropdown menu.

Before we can begin an example, there needs to be some starting points. Select Locate Point and place one point. Then select Locate By Azimuth and place a point at azimuth 100.0000 and distance 60. Repeat Locate By Azimuth with the same values from the second point.

Now we can enter offset notes. Go to Mine Note Auto Left/Right in the Notes dropdown menu.

**Command:** note2

**Enter Offset File Name <offset.dat>:** press Enter

**Append File [<Yes>/No]?** N (This appears only if the file already exists.)

**Tabular Format–Distance L R Hgt– (<y>/n):** Y

**From Station point[(node on):** (795704.0 1.20119e+006) Pick Point 1

**To Station point (A for Azimuth):** A

**Azimuth of Heading (DD.MMSS) or p for pick <0.0>:** 10

**Spad Number, or <ENTER> For None:** press Enter

**Entry Number:** press Enter

**Enter distance from station on centerline (U To Undo, Enter to end):** 10

**Enter left offset distance:** 10

**Enter right offset distance:** press Enter

**Enter distance from station on centerline (U To Undo, Enter to end):** 30

**Enter left offset distance:** C11

**Enter right offset distance:** C10

**Enter distance from station on centerline (U To Undo, Enter to end):** 70

**Enter left offset distance:** 10

**Enter right offset distance:** 9
Enter distance from station on centerline (U To Undo, Enter to end): 88
Enter left offset distance: C10
Enter right offset distance: C10
Enter distance from station on centerline (U To Undo, Enter to end): 110
Enter left offset distance: 10
Enter right offset distance: 9

Enter distance from station on centerline (U To Undo, Enter to end): press Enter

Another Spad [<Yes>/No]? Y
From Station point[node on]: (795763.0 1.20118e+006) pick Point 2
Azimuth of Heading (DD.MMSS) or p for pick <10.0>: press Enter
Spad Number, or <ENTER> For None: press Enter
Entry Number: press Enter

Enter distance from station on centerline (U To Undo, Enter to end): 30
Enter left offset distance: C11
Enter right offset distance: C11
Enter distance from station on centerline (U To Undo, Enter to end): 65
Enter left offset distance: press Enter
Enter right offset distance: 8
Enter distance from station on centerline (U To Undo, Enter to end): 70
Enter left offset distance: 10
Enter right offset distance: 12
Enter distance from station on centerline (U To Undo, Enter to end): 90
Enter left offset distance: C10
Enter right offset distance: C10
Enter distance from station on centerline (U To Undo, Enter to end): press Enter

Another Spad [<Yes>/No]? press Enter
From Station point[node on]: (795822.0 1.20117e+006) pick Point 3
Azimuth of Heading (DD.MMSS) or p for pick <10.0>: press Enter
Spad Number, or <ENTER> For None: press Enter
Entry Number: press Enter

Enter distance from station on centerline (U To Undo, Enter to end): 10
Enter left offset distance: press Enter
Enter right offset distance: 10
Enter distance from station on centerline (U To Undo, Enter to end): 30
Enter left offset distance: C10
Enter right offset distance: C10
Enter distance from station on centerline (U To Undo, Enter to end): 68
Enter left offset distance: press Enter
Enter right offset distance: 9

Enter right offset distance: 20
Enter distance from station on centerline (U To Undo, Enter to end): 90
Enter left offset distance: C10
Enter right offset distance: C10
Enter distance from station on centerline (U To Undo, Enter to end): press Enter

Another Spad [<Yes>/No]? N

Print file containing offset input data [<Yes>/No]? N

This should produce the following layout of points and spads:
(4) Connecting Pillars and Perimeter

Once the offset notes have been entered, the pillars and perimeters can be drawn by connecting the dots. Pillars are created as closed polylines in the PILLARS layer, and perimeters are created as closed polylines in the PERIM layer.

There are two approaches for connecting the dots. One is to manually connect the pillars and perimeters by simply picking each point in order and using C to close at the end. This is done with the Draw Pillars and Draw Perimeter routines in the Works dropdown. The other method is to use AutoMine Connections which automatically connects up the pillars and perimeter. This routine reads a record file from a mine note entry routine and requires that the corner points (the first points across a crosscut) are coded. If you entered the example offset notes in the previous section, then everything is ready for AutoMine Connections. Select it from the Works dropdown and choose the file "offset". After drawing the pillars and perimeter, AutoMine leaves a pick box hanging off the perimeter so that you may connect it with a previous perimeter. In our sample case, just enter 'C' to close the perimeter.

It is important for quantity calculations that these polylines are closed. To make sure your pillars and perimeter are closed polylines, use the Highlight Unclosed Polylines routine in the Works dropdown.
Case Study #8, Part 2: Computing Tonnage and Acreage

Application

Once the mine map is completed using the techniques described in the previous section, quantities of mined mineral and waste rock may be computed, with industry standard reports. The reports will be generated based on the reporting method selected in the Mining Settings under Settings, Carlson Configure dropdown menu.

Procedure

Here's a quick summary of the procedure for computing quantities:

1. Configure the "look" of your coal sections (or other mineral).
2. Locate all coal sections measured in the mines.
3. Compute tonnages by average or modeled grid methods.
4. Draw and compute quantities for pillar cuts on the "retreat".

(1) Configuring the Section Information

Configuring the section information involves assigning each strata a name and a density, and specifying the look of the section for when it is placed in the drawing. This information is stored in a user-specified file and is referenced for locating sections in the drawing and for quantity calculations. If you reconfigure an existing section file, sections placed in the drawing using the previous section file become invalid and must be replaced. The strata in a section can be configured as either individual or composite. With the individual configuration, each strata has its own name and density. With composites, each strata is still named separately but they also are divided into groups that have a group name and density. The principle advantage to composites is that it allows you to enter and list out each strata height and then combine the strata into their corresponding composite category when generating tonnage quantities. First, let's configure an individual section. Select Configure Section Info in the Works dropdown.

Enter Coal Section Configuration Filer Name (MINE.SC)

Mine Name: Round Mountain
Enter Abbreviated Strata Name/<ENTER> to End: C This name is drawn next to the corresponding height when a section is located in the drawing.
Enter The Full Strata Name <C>: Coal This name is used in quantity reports.
Enter Abbreviated Strata Name/<ENTER> to End: B
Enter The Full Strata Name <C>: Bone
Enter Abbreviated Strata Name/<ENTER> to End: R
Enter The Full Strata Name <C>: Rock
Enter Abbreviated Strata Name/<ENTER> to End: press Enter

Enter Individual densities or Composite densities (I/C) <I>: press Enter
Average wt. of C (Coal) [lbs/ft^3]: 80
Average wt. of B (Bone) [lbs/ft^3]: 150
Average wt. of R (Rock) [lbs/ft^3]: 150

Circle the Coal Section (y/<n>)? Y This specifies whether a circle is drawn around the section when it is placed in the drawing.

Plot the Numeric Value Only (y/<n>)? press Enter

Text Size <6.0>: press Enter
Enter thickness in feet or inches [Feet/<Inches>]? I for Inches
Prompt for entry width [Yes/<No>]? Y if Yes Linear Advance will also be reported

The following figure shows how this section will appear in the drawing.

Now let's make a composite section. Select Configure Section Info in the Works dropdown.

Enter Coal Section Configuration Filer Name: SECTION2 Or the name of your choice.
Mine Name: Round Mountain
Enter Abbreviated Strata Name/<ENTER> to End: TC
Enter The Full Strata Name <C>: Top Coal
Enter Abbreviated Strata Name/<ENTER> to End: TR
Enter The Full Strata Name <C>: Top Rock
Enter Abbreviated Strata Name/<ENTER> to End: BC
Enter The Full Strata Name <C>: Bottom Coal
Enter Abbreviated Strata Name/<ENTER> to End: BR
Enter The Full Strata Name <C>: Bottom Rock
Enter Abbreviated Strata Name/<ENTER> to End: press Enter
Enter Individual densities or Composite densities (I/C) <I>: C Define the Composite categories.
Enter Composite Category/<Enter> to END: Coal
Average wt. of COAL [lbs/ft^3]: 80
Enter Composite Category/<Enter> to END: Rock
Average wt. of ROCK [lbs/ft^3]: 150
Enter Composite Category/<Enter> to END: press Enter Assign the strata to a Composite category.
Enter Composite Category for Top Coal TC (COAL ROCK ): coal
Enter Composite Category for Top Rock TR (COAL ROCK ): rock
Enter Composite Category for Bottom Coal BC (COAL ROCK ): coal
Enter Composite Category for Bottom Rock TC (COAL ROCK ): rock
Circle the Coal Section (y/n)? press Enter
Plot the Numeric Value Only (y/n)? press Enter
Text Size <6.0>: press Enter
Enter thickness in feet or inches [Feet/<Inches>]? I for Inches
Prompt for entry width [Yes/<No>]? Y if Yes Linear Advance will also be reported

The following figure shows how this section will appear in the drawing.

(2) Locating Sections
To locate section information measured from the mine, select Place Coal Sections from the Works dropdown. Select the desired section configuration file such as SECTION2 which you defined in the previous section.

Pick sample point for coal section: pick a point on the map. This is the point where the measurements came from.
Pick Start Point: pick another point. This is where the text will be plotted. The text may be placed anywhere you like because the program gets the section measurements from the small circle at the sample point and not from the text.
Pick Alignment Point: pick a point to align the text

Now enter your measurements.

How many inches of Top Coal TC: 30
How many inches of Top Rock TR: 5
How many inches of Bottom Coal BC: 25
How many inches of Bottom Rock BR: 4
Enter the entry width: 20
Enter Another Section (Y/N) <Y>: press Enter

Enter the other section as shown in the next figure.

(3) Compute tonnages by average or modeled grid methods
There are three routines for calculating tonnages: Quantities by Average Method, Quantities by Grid Method and Quantities by Centerline. These methods require section sample points, and pillars and a perimeter defined as closed polylines in the PILLARS and PERIM layers respectively. As its name suggests, the average method uses the
average values from sample section points to compute its quantities. The grid method actually models the values of the sample points over the mined area which results in more accurate tonnages. For now, let's use the average method because it is much faster and requires fewer sample points.

Select Quantities by Average Method in the Works dropdown.

Select a Mining Project Definition (MPD) File or Create a new one
Select the file that defines the section sample points
Specify the Beginning and Ending dates of take-up and Report Format in the dialog below

Select property polylines or press Enter for none: press Enter if no property lines defined, if defined program gets Owner Name from here
Fill in the Following Dialog: if any field is left blank it will not be reported

Select pillars, perimeters, and section sample points.
Select objects: select the pillars, perimeter, and sample points
Pick location to draw results or Enter for none: pick a point above the mine as shown
Another Area (Y/N) <Y>: N
A report would be generated based on the Report Format method. If standard method selected following report would be generated

**Update coal tonnage files (<Y>/N)?**  
This option updates data files for tonnage reports.

Enter a mine name: *Mine*

Enter a panel name: *press Enter for none*

Enter the estimated coal reserves for mine Mine: **300000**

(4) **Draw and compute volumes for pillar cuts on retreat**

One of the final steps in underground mining is cutting into the pillars on the "retreat". The results of these cuts can be quickly drawn on the mine map using the Pillar Cut routine in the Works dropdown. The procedure is simply to pick a cut pattern and then place the pattern inside the pillar to be cut. That’s it. Depending on the selected method, this routine will either redraw the pillar's polyline with the cuts removed, or it will create new perimeter polylines inside the pillar in the cut out spaces. The pillars must be closed polylines in the PILLARS layer. The rotation of the placed pattern will follow the current snap. If the cut pattern you need is not already in the table, you can define your own by first drawing a polyline of your pattern and then selecting the user-defined box in the Pillar Cut symbol table.

After redrawing the cut pillars with Pillar Cut, Quantities by Average Method or Quantities by Grid Method can be used to compute the quantities of the cuts. If the Cut option of Pillar Cut was used, then you will get the total

---

**Carlson Software Edit: C:\Documents and Settings\Nimesh Malav\Application Data\Carlson\Model**

**File Edit Settings**

**NUMERICAL AVERAGE COAL SECTION METHOD**

**MINE: Round Mountain**  

**AREA NO. 1 DESCRIPTION: Jones**

**CAVITY ACRE-FEET:** 1.100
quantities from the area between the pillars plus the pillar cuts. To get the quantities of only the pillar cuts, use the Perim option of Pillar Cut. This will create perimeter polylines inside the pillars. Then use Quantities by Average Method and select all these perimeter polylines. Let’s practice pillar cuts.

Select Pillar Cut from the Works dropdown.

Choose the Cut 14 symbol or the symbol of your choice.

**Perimeter layer <PERIM>: press enter**

Enter the azimuth for the cuts <0.0>: 10.0

Cut the pillar or create new perimeter? (<Cut>/Perim) Perim

Hatch the new perimeter polylines? (Y/<N>): press Enter

Select mine pillars Polyline in the PILLARS layer.

Select objects: select all the pillars

Pick a point for the symbol: pick a point as shown in the figure above

Do another cut [<Yes>/No]? Y

Pick a point for the symbol: pick a point in the other pillars

Pick a point for the symbol: press Enter to exit

Now let's get the quantity mined from the pillar cuts.

Select Quantities by Average Method in the Mining Works dropdown. Choose Section2 or the file that defines the section sample points.
The Cuts "Selection Type" filters out everything except perimeter polylines and sample points. This allows you to select by windowing the area of the pillar cuts. Be sure not to include the main, outside perimeter.

Select objects: select the perimeter polylines and sample points

Pick location to draw results or Enter for none: pick a point above the mine

Another Area (Y/N) <Y>: N

Update coal tonnage files (<Y>/N)? Y This option updates data files for tonnage reports.

Enter a mine name: Mine

Enter a panel name: press Enter for none

Enter the estimated coal reserves for mine Mine: 300000

This creates the following plot.
Boundary Menu

The Boundary menu has commands for managing pit and property polylines. The property polyline commands are described in the Underground Mining section of the manual.

Name Pit Polylines

This command attaches a pit name and site name to closed polylines that are used as inclusion or exclusion perimeters routines like Surface Mine Reserves and Surface Equipment or Production Timing.

Prompts

Label area names [<Yes>/No]? Choose whether or not to label.
Text height <4.00>: press Enter to accept 4 drawing units (ft or m tall) or enter a new text height
Auto place labels in center [<Yes>/No]? press Enter to accept To manually pick the label position, answer No to this prompt.
Prompt for inclusion, exclusion or both [<Inclusion>/Exclusion/Both]? Bfor Both. If you are only choosing inclusion areas, then you can answer Inclusion to this prompt to skip the exclusion polyline prompt and speed up entry. Or you can use Exclusion if you're just going to add exclusion areas to existing inclusion pit areas.
Site name <Site 1>: press Enter to accept Site 1, or type a new site name
Pit name <Pit 1>: press Enter to accept Pit 1, or type a new pit name
Select Inclusion perimeter polylines.
Select objects: pick closed polylines for areas to include in calculations
Select Exclusion perimeter polylines.
Select objects: pick closed polylines for areas to exclude from calculations
Specify another area [<Yes>/No]? press Enter to accept Yes or type N for no If you do specify another area, then the Site Name remains the same, but the Pit Name is automatically incremented by one for efficient naming.

Pulldown Menu Location: Boundary
Keyboard Command: pitname
Prerequisite: Closed polyline
Assign Pit Names By Layer

When the linework is layerized so that each polyline for pits is placed in the separate layer, this routine may be used to assign pit names by layer name. The user is prompted for site name and pit names are derived from the layer names of each polyline selected.

Prompts

Site name <Site 1>: Enter to accept or type in a new site name
Select polylines to set pit name by layer.
Select objects: pick polylines
Pulldown Menu Location: Boundary in the Advanced Mine Module
Keyboard Command: layerpit

Find Pit

This command will find a certain pit on screen. It will zoom to the pit extents and center it. The pit line is also dashed or highlighted to distinguish it from surrounding pits.

Prompts

Enter a name of the pit to find: x-38
Pulldown Menu Location: Boundary
Keyboard Command: findpit

Label Pit/Site Names

This command labels the pit name and site name that are attached to the selected polyline. The Horizontal and Align placement methods will draw the labels in the center of the polyline. The difference is that the horizontal option will draw the label horizontal to the current twist and the Align method will rotate the label to follow the main direction of the pit. The Pick method prompts you for a center point to pick and an alignment for the text.

Prompts

Text height <4.0>: press Enter to accept 4.0, or type in a new text height
Include Site Name in Label [<Yes>/No]? press Enter for yes or type N for no
Label placement method [<Align>/Horizontal/Pick]? press Enter for Align, or type H for horizontal alignment, or P to pick the alignment and location
Select pit polyline to label: pick a polyline
Site Name: Site 1
Pit Name: Pit 1
Pick point for label: pick a point
Pick alignment point: pick a point
Select pit polyline to label: press Enter to end
Pulldown Menu Location: Boundary in the Advanced Mine Module under Label Pit Polylines
Keyboard Command: pitlabel

Pit Label Formatter

This command places text inside each pit, labeling values such as name, quantities and quality. Anything that is stored in the selected pits will be shown under Available. The formatter screen allows for placement of text in the pits by row, selecting a justification, text size and color. The text can either be drawn horizontally or with the Align
option which will orient the text with the long axis of the pit. There must be values stored in the pits and the pits must have direction assigned.

Move items from the left under Available to the right, under Used. The order you add them is the order they will be labeled in the pits. If they are in the wrong order, use the Move Up or Down buttons. Choose a Text Size that is legible for plotting. The Label Thickness For Missing Strata As Zero is shown here as an option, but applies more to the Drillhole Label Formatter. This format may be Saved and Loaded at a later time with the Load and Save buttons.

When choosing add or Edit, the Edit Text Format screen appears. This is to select the layer and color of the text. The text may have a Prefix or Suffix attached. The Decimals can vary by item. The Row Position is important, so text isn't running on top of other text. Finally, choose a Label Alignment for left, center or right justification.
Prompts

Select pit polylines to label.
Select objects: Specify opposite corner: 192 found
Select objects:
Label placement method [Align]/Horizontal]? H

Pulldown Menu Location: Boundary in the Advanced Mine Module under Label Pit Polylines
Keyboard Command: pitlabel2
Prerequisite: There must be quantities assigned to the pits either from Surface Mine Reserves or Import Timing Data. The pits must have direction assigned to be recognized.

Hatch Pits
This command hatches the selected pit areas. A reason to hatch the pits is to visually check that the whole site is covered by pit polylines. In the options dialog, there are settings for the hatch pattern, color, hatch scale and layer name for the hatches to draw.
Prompts

Select pit polylines to hatch.
Select objects: pick pit polylines
Hatch Settings dialog

Pulldown Menu Location: Boundary
Keyboard Command: pithatch
Prerequisite: Pit polylines

Identify Pit Polylines
This command reports the pit name and site name that are attached to the selected polyline at the command line and shows the pit graphically with a yellow solid fill.

Prompts
Pick inside pit polyline to identify (Enter to end): Pick inside a polyline
If you pick on or near a common line, one pit is highlighted and you are prompted to Press N for next selection or Enter to accept current, highlighted pit line. The selected pit line is filled with a solid yellow hatch that erases when the next pit is selected, or the command is finished.

Site Name: Site 1
Pit Name: Pit 1
Select pit polyline to identify: press Enter to end

Pulldown Menu Location: Boundary in the Advanced Mine Module
Keyboard Command: pitid

Remove Pit Names
This command removes the extended entity data of pit/site names from the selected polylines. For example if you are done calculating for an area, you can use this command to clear the pit names from the polylines in the old area so that these polylines are not picked up as pits anymore by routines such as Surface Mine Reserves and the Timing Routines.

Prompts
Select polylines to remove pit names from.
Select objects: pick the polylines
Removed pit names from 11 polylines.

Pulldown Menu Location: Boundary
Keyboard Command: clearpitnm

Pit by Interior Point
This routine is used to create pit polylines from the existing linework by making closed polylines around points picked. The site and pit names are user-specified and the pit name is incremented after each new pit created. This command uses the Boundary Polyline logic, using any linework (open or closed) and searches out from the picked point for the closed perimeter. It draws a new polyline in the selected layer.

Prompts
Label area names (<Yes>/No)? Choose whether or not to label.
Text height <4.00>: Enter to accept or type new text height
Auto place labels in center (<Yes>/No)?
Site name <Site 1>:
Pit name <Pit 1>:
Layer name <0>: Enter to accept or type in new layer name.
Pick point inside pit perimeter: pick inside a loop or linework representing the pit to use as a pit
Specify another area (<Yes>/No)? If yes is selected, then the Pit Name is automatically incremented by one for efficient entry.

Pulldown Menu Location: Boundary in the Advanced Mine Module
Keyboard Command: pickpit

Pit Plines from Mineplan
This command converts lines and polylines that enclose text into Carlson pits, with the text becoming the pit name. It is best used in conjunction with "Sequential Numbers", a command under the "Draw" pulldown menu that allows the user to place text in increasing order. If pits are to be numbered from U10 through U50, Sequential Numbers
places this text with a single pick. The text inside the pits does not need to be in the same layer as the polylines/lines making up the pits. Since the text is selected by the user, care should be taken not to select extraneous text such as contour elevations.

The user should also avoid selecting contours and other polylines not associated with the pits. It should also be noted that this command makes entirely new polylines in a new layer from the source lines and polylines. If "Boundary Polylines" was used to make closed polylines, and Sequential Numbers is used to place text, then "Pit By Interior Text" will make a new set of polylines in a new layer (this time as "official" pit polylines), resulting in two sets of identical closed polylines. You should use "Delete Layer" or other Carlson tools such as "Freeze Layer" to delete or hide the duplicated polylines. The command will handle arcs. But note that "Pit By Interior Text" will make polylines out of any combination of polylines and lines enclosing text, even where the lines are shared by two adjacent pits and no duplicated lines exist.

"Sequential Numbers" and "Pit By Interior Text" work together to make pits. The location of the text containing the pit name can be used to assign the direction of mining. Therefore, the very location picked within "Sequential Numbers" can set the direction of mining across the pit. If "Assign Directions" is selected within the "Surface Mining" options, the sub-option "Text" will utilize the text insertion position and start the mining through the pit from the side closest to the insertion point. Note that "Sequential Numbers" will middle-justify the text used for the pit name. To emphasize the linkage with "Sequential Numbers", the prompting sequence shown below includes the prompting for "Sequential Numbers".

Using "Pit Plines from Mineplan" you don't need to use "Boundary Polylines" in advance to create the closed pit polylines. "Pit By Interior Text" makes the new polylines and associates the pits all in one step. This command is a great time saver to convert old mine plans with just linework (sometimes sloppy) and the pit name inside to Carlson pits used in reserves and timing.

Prompts

[Sequential Numbers]
Text Height <8.0>: 50
Pick point at center of label: pick insertion point for centered text
Pick point for label alignment: pick text alignment point
Number <1>: U10 (or 50 in the second example)
Auto increment labels (Yes/<No>)? Y
Pick point at center of label: pick next point and U11 (or 51) prints
Pick point at center of label: pick next point and U12 (or 52) print, etc.

[Chapter 16. Surface Mining Module] 2807
Site Name for Pits: Site 1
Layer Name for Pits: PITS
Select pit lines, polylines and text.
Enter snap tolerance <0.0>: This is the size of the gap that the routine can handle to "jump" across and create a closed boundary.
Select objects: select the text and linework New pit lines should appear in the selected layer.

Pulldown Menu Location: Boundary
Keyboard Command: minepitlines
Related Commands: Sequential Numbers, Boundary Polylines, Assign Directions

Pit Matrix Layout

The Pit Matrix Layout function will divide a polyline (preferably closed, but not necessary) into surface pits of any arrangement you specify utilizing temporary alignment polylines. The site and pit names are also defined in this routine. This allows for a great deal of imaginative pit configurations and layouts around difficult geometric and individual situations. The routine will insert the specified number of rows and columns of pits in a matrix form directly inside the baselines, and if used, crosslines. The mine boundary will then serve as an inclusion perimeter and create pits in the matrix form only inside of it.

Prompts

Select mine boundaries:
Select TWO baselines: select objects The best pit configurations result from baselines with equal number of vertices.
Select TWO crosslines or hit Enter for none: select objects Similarly with the baselines, the crosslines should have the same number of vertices.

Note: Baselines are required. Crosslines are not. If just long strips of pits are desired, then just use baselines with no crosslines and enter in 1 for number of pits in the Cutting Across Baselines tab. It is also important to note that the order the base and cross lines are selected will determine where the pit naming will begin. The first baseline selected will be where Pit 1 will start, for example. The same applies to cross lines, for sub pit or block labeling. If there are no crosslines used, then the direction the baselines were drawn will affect the naming of the blocks or sub-pits.
Baselines and crosslines can and probably should be drawn directly on top of the boundary to get exact pit sizing starting at the boundary. They are shown off the boundary line here for clarification of what they should look like. The matrix will begin at the base and cross lines, wherever they are drawn.

With the initial linework completed and knowledge of the general dimensions of the layout, the user can use the following options.

**Number of proportional pits:** This will measure the distance between the baselines and divide the pits proportionally, evenly distributing the size of the pits as they are cut along the baselines using the Number of cuts entry. If the Min/Max options are used, Number of cuts will still be applied. For example, if only 10 pits are desired in a certain layout direction, the routine will stop at 10 pits, then a different plan may be applied from there.

**Min/Max Width pits:** Enter in the minimum and maximum pit widths that will be allowed and the routine will stay within that range to fan pits around corners etc. If the min and max are the same, then all pits will be that width.

**Min/Max/Avg Width Pits:** This is very similar to Min/Max Width, except the average value will be the width that it will use unless it has to fan around a corner. Again, if the minimum and maximum and average are the same, say 175, then all pits will be 175 wide.

The Cross Cut by Advance option in the Cutting Across Baselines Tab should be checked if a certain pit or block size is desired, with little flexibility. Everything is grayed out if this is selected and the block sizing will begin at the cross lines.
Labeling Options: Consider the pit and block scenario. A pit is defined by the base lines and broken into blocks by the cross lines. For labeling, enter a Site Name and Pit Prefix. Both base lines and cross lines can have a section separator (here a dash -). The total number of places can be set with Pad Section and Cross-Section Number so that a resulting pit number such as 056 (for 3 places) can be obtained. The starting pit (section) and block (cross-section) numbers are set in their own windows. The increment is set for both pit and block, here the pit is set to 1 and the block is set to 500. The first few pits in this example will be named: W-056-000, W-056-500, W-057-000 and so on. Distinct Fragmented pits will give a unique name to a pit that is broken due to a gap in the boundary. For example, if the long dragline pit is broken by a washout of coal, and this option is checked, then the pit will have two names: Pit 56a and Pit 56b. It automatically uses a, b, c, etc. If it isn't selected, then both will be named Pit 56.
General: The option to include clipped pits (any pit that touches the boundary) is found under the General tab. An example of both options is shown below. The layer of the new pits is set in the Layer box. The pits are assigned direction for timing with the "Assign direction in which sequence?" option. If you imagine looking down the boundary, from the first selected base line to the second, LL will be mining from the left in each pit, to the right. LR will be from the left in the first pit, then back from the right in the second pit etc. RL and RR are just the opposite.
Labeling options allow special separators.

Including pits clipped by boundary

Excluding pits clipped by boundary

<table>
<thead>
<tr>
<th>Site 1</th>

</thead>
<tbody>
<tr>
<td>Pit 026/06</td>
<td>Pit 026/07</td>
</tr>
<tr>
<td>Pit 025/08</td>
<td>Pit 025/07</td>
</tr>
</tbody>
</table>

Labeling options allow special separators.
When geometric layouts for the pits become more complicated, Pit Layout by Matrix will allow the user to design the pits to most any situation presented. It is extremely useful for "fanning" of the pit where corners or varied widths are encountered. This example above shows how a matrix of [10 X 50] can be fit inside a varied boundary such as this angular mine boundary.

**Prompts**

**Select mine boundaries:** select the boundary
**Select objects:** 1 found

**Select TWO baselines:** select the baselines Pay attention to which is selected first for name direction.
**Select objects:** 2 found

**Select TWO crosslines or hit Enter for none:**

**Select objects:**

**Pulldown Menu Location:** Boundary

**Keyboard Command:** cross.pit

**Prerequisite:** The routine requires a polyline boundary for the pits to be designed inside of (better if closed), two baselines, one on each side of the boundary, and optionally, two crosslines to further define the extent of the "sides" of the pits.

**Pit Layout by Advance**

This command creates pits of the desired advance width by intersecting a closed pit polyline and a direction line indicating the direction the pits will be developed. In the first 2 examples below the outcrop has been created as the outer limit of the pit. The first example shows the impact of laying out a straight direction polyline. The direction polyline must enter the pit boundary from outside and exit the boundary to be valid. The program advances along the direction polyline the distance entered for the Cut Advance and intersects for each pit 90 degrees from the direction line. There are two options on where to start the advance. The first is at the end of the direction line and the second is where the direction line intersects the pit boundary. Most of the time the second option is used. The main use for starting the advance at the beginning of the direction line is if all direction lines start at a known...
"station", then all pit blocks will be uniform, named by station and in line with each other.

Example 1 uses a straight directional polyline and was done in 3 sections. Each pit is drawn 90 degrees from it at the desired Cut Advance.

Example 1

Example 2 uses a bent directional polyline to follow the contour of the outcrop. Here it uses a bent polyline to conform to the contour of the outcrop. The direction polyline cannot contain any arcs, however an arc can be initially drawn for the layout and converted to polyline segments using the command Remove Polyline Arcs on the Edit menu. Again, each pit is created by intersecting the direction line at a 90 degree angle. Going around corners will often look better with a smooth line, hugging the inside corner.

Example 2

This third example will go through two iterations of Pit Layout by Advance to first create long strips of pits 175 wide, then break them into blocks that are 500 long, named with the appropriate stationing in the pit name. This is a unique application that is not apparent by just running the command, so a simple case study will follow. Step 1 is to create a mine boundary and draw a direction line through it. Step 2 is the first iteration of Pit Layout by Advance. This example used 175 for the pit width and created long strips of pits with a unique name, such as A-8 and A-9. Step 3 will prepare to break them up into blocks. First, create direction lines through each pit strip. The fastest way to do this is to draw the first direction line through the first strip. Then the ARRAY command will copy that multiple times, placing a direction line down the middle of each pit strip. Running the Pit Layout by Advance will first prompt to select the pit boundaries. Select all of the boundaries at once with a window, fence or by picking. Then it prompts to select the direction lines, select them all at once. In this type of example, the option to start advance at the beginning of the direction lines is chosen. This gives blocks that are named by station along the direction lines. Notice on the south end where the pit strips are not horizontal. Not using the option to calculate from the starting of the advance line will give pit blocks that are offset and not named by station along the direction centerlines. The pit blocks are created and can be labeled with Label Pit Polylines. Notice the pit names and the stationing of the pit blocks incrementing by 500, which is the length of each block.
Prompts

Select all pit polylines.
Select objects: *pick pit polylines*
Select all direction polylines.
Select objects: *pick direction polylines*
Enter Cut Advance: 175
Enter Starting Sub-Pit Number: 1
Enter Sub-Pit Number Increment (1): 1
Calculate the advance from the start of the direction line [Yes/<No>]? *N*
The highlighted pit does not have site and pit names assigned
Enter a site name: *Site 2*
Enter a pit name: *A*
Pulldown Menu Location: Boundary
Keyboard Command: *cutpitadv*
Prerequisite: A direction polyline and a closed pit area polyline.

Pit Layout by Width

This command creates closed polylines that represent pit inclusion areas for Surface Reserves and Timing. The pit polylines are created by advancing a baseline polyline by a fixed pit width. The sides and end of the pit polylines are defined by the minable boundary polyline. This polyline should be open at the end of the baseline polyline.
Be sure to create the baseline polyline longer than the minable boundary so that the program can always find the intersection of the advancing baseline with the minable boundary. There is an option to automatically assign pit and site names to the polylines. The name of the first pit is set in the dialog shown below. The next pits will be named by incrementing the pit name by one. There is an option to prompt for each pit width or use the same width for all the pits.

Prompts

Pit Sizing dialog Set the pit width, layer and names
Select baseline polyline: pick the polyline
Select minable boundary polyline: pick the polyline
Pulldown Menu Location: Boundary
Keyboard Command: pitsz2
Prerequisite: One open polyline boundary and one baseline polyline extending across the boundaries open end.

Pit Layout by Rate

This command creates closed polylines that represent pit inclusion areas for Surface Mine Reserves or the Surface Timing routines. The pit polylines are created by advancing a baseline polyline along a minable boundary. The sides and end of the pit polylines are defined by the minable boundary polyline. This polyline should be open at the end of the baseline polyline. Be sure to create the baseline polyline longer than the minable boundary so that the program can find the intersection of the advancing baseline with the minable boundary. The next pits will be named by incrementing the pit name by one. The baseline polyline is advanced a distance such that the pit volume equals
the target volume.

The surface model is either represented by contours on screen or a grid file. If neither is available, there is an option to Use drillhole surface elevations in surface model. The Ignore zero elevations will ignore anything on screen with no elevation. When modeling from the drillholes, there are 5 modeling methods available, which are defined elsewhere in detail. If a roof and floor grid exist of the strata to target, then use the Grid File option and these two grids will be prompted for. If Triangulation is the selected modeling method, then the options to Use Triangulation Subdivision (defined in Triangulate and Contour) and Use Global Trend Extrapolation (explained in Make Strata Grids) are active. There is the box to create a new layer name for the new pits. If coming from drillholes, there is the option to choose which strata to include. If Selected is checked, then the following Choose Strata box appears. Holding the CTRL or Shift buttons down allow for multiple strata selection. The grid cell size and resolution are set in the Make 3D Grid window, also only if coming from drillholes.

**Pit Layout Parameters**
The cubic yards or meters / hour is set here with the shift hours per day and number of days worked per period. This will calculate the Target Pit Size. In this example, 480,000 CY of OB_TOP strata is the targeted pit size. Turning on the Name Pits box activates the Site and First Pit Name windows. The subsequent pit names will be incremented by one from the starting pit name.
Starting linework
Final pit layout. Notice that the pits get wider to the east as the OB_TOP thins and the pits must be wider to mine 480,000 CY.

**Prompts**

**Pit Sizing dialog**
Select surface entities & at least 3 drillholes
Select objects: select the drillhole symbols and the contour polylines
Select mine boundary polyline: pick the minable boundary
Make Grid dialog Choose a grid resolution.
Use inverse distance to which power (First/Second/Third/Other)? press Enter
Select baseline polyline: pick the baseline polyline
Select minable boundary polyline: pick the minable boundary again

**Pulldown Menu Location:** Boundary in the Advanced Mine Module
**Keyboard Command:** pitsz

**Import Pit Points**
This creates pit polylines using pit names and geometry data stored in a text file. The fields in the text file must be in order of pit name, site name, easting and northing. The fields must be comma delimited. Here’s a sample text file for two pit polylines:

```
PIT 1,SITE 1,243431.6415685746,1646709.1759626027
PIT 1,SITE 1,243480.4441474760,1646852.2833508430
PIT 1,SITE 1,243914.2811566577,1646640.1845039858
PIT 1,SITE 1,243723.9315959779,1646566.2781082289
PIT 2,SITE 1,243480.4441474765,1646852.2833508428
PIT 2,SITE 1,243529.2467263769,1646995.3907390833
PIT 2,SITE 1,243723.9315959779,1646566.2781082289
PIT 2,SITE 1,243914.2811566577,1646640.1845039858
```

**Prompts**

**Input Data File** Select text file to import
**Layer for pits <PITS>:** press Enter
Imported 9 pits.

**Pulldown Menu Location:** Boundary
**Keyboard Command:** importpit2
**Prerequisite:** Text file with pit data

---

**Merge Pits**

This routine takes two adjacent pits or blocks and merges them to create just one. Routines such as Pit Matrix Layout can sometimes leave small irregular shaped pits along complex boundaries. Usually, the user would like to combine or add a small sliver of a pit with an adjacent one so that the volume is reported, but not as its own tiny pit. Pick first in the pit you want to keep, then in the pit you want to remove. A new polyline is drawn around both, representing the new pit with the same name as the first pit you picked inside of. The last step is to simply erase the text of the smaller, deleted pit (if they were labeled). If a pit is selected on or near a line, then the pit is highlighted and you are prompted to hit Enter to accept the pit or press N to highlight the other nearby pit. The volumes are combined if they are stored in the pits as values.

---

**Prompts**

Pick inside 1st pit polyline to merge:
Pick inside 2nd pit polyline to merge:
Created a shrink-wrap polyline successfully.
Done.

If the pick is near a pit line, then the following prompts appear:
Pick inside 1st pit polyline to merge (Enter to end):
Press N for next selection or Enter to accept current:
Pick inside 2nd pit polyline to merge:
Press N for next selection or Enter to accept current:
Created a shrink-wrap polyline successfully.
Done.

Pulldown Menu Location: Boundary
Keyboard Command: mergepit
Prerequisite: Two adjacent Carlson named pits that you want to combine into one pit.

Assign Directions
In order to schedule equipment through pits, pits (which are closed polylines) must have three distinct types of Extended Entity Data (EED, extra information) associated with them. They must have (1) a pit name, (2) NonKey Volume, Key Volume and Key Tons and optionally quality information and (3) direction of mining. The Assign Directions command places the direction of mining into the pit itself, where it is permanently stored along with other aspects of the drawing. Directions can vary by bench. The command prompts to assign the same direction to the Whole pit, or by bench. If doing by bench, the routine must be run separately for each bench.

Assign Directions is found within Boundary in the Carlson Surface Mining. There are six methods employed to assign direction: Automatic, Text, Sequence, Polyline, Bearing and Azimuth. The "automatic" method will mine "longways" across the pit, following the longest axis detected, but may not choose the preferred direction along that axis. The text method finds the side closest to the insertion point of the pit name and will mine from that side perpendicular across the pit away from the text. The sequence method will mine left to right and/or right to left across a series of pits as specified by the user, the polyline method will follow a "direction polyline" across a pit or series of pits and the Bearing or Azimuth method will mine at defined bearing or azimuth angle. Below is the prompting and results obtained with each method:

Prompts

Assign direction using which method [<Auto>/Text/Sequence/Polyline/Bearing/AZimuth]: A or press Enter
Select pit polylines to have direction assigned to:
Select objects: Pick the pits and the direction is assigned as shown below

In this example, the left most pits were given a direction opposite from the remaining pits. For long-term studies or quick estimates using smaller pits, the direction can be considered a moot point, since you will get where you're going to be whether you mined left to right or right to left through an individual pit. But for larger pits or short-term studies, direction is critical. A pit direction can be easily reversed using the Reverse Directions command.

Next we will look at the Text option.

Assign direction using which method [<Auto>/Text/Sequence/Polyline/Bearing/AZimuth]: T
Select pit polylines to have direction assigned to:
Select objects: pick the pits and the required pit text as shown below
The highlighted pit has the direction information assigned already.
Would you like to overwrite this (Yes, None, All): A for All. This prompt only occurs when pits are chosen that already have pit direction. Note that the command "Clear Directions" could be used to remove directions prior to using Assign Directions.

The arrows show the resulting directions. Note that this routine looks for the pit name for the direction, not for the "site" name. (All pits have a two-tiered naming convention: site and pit, which can be re-worked as pit and block or any other two-level form, to adapt to company practices.) In Pit 5, for example, the "Site 1" text is ignored and the "Pit 5" text is used for direction. In Pit 7, the Site 1 text is completely outside the pit, but is irrelevant since only the Pit 7 text is used for direction. If pits were named Pit 1, Block U15A, then the insertion position of "Block U15A" would be used for setting directions.

Next we will look at the Sequence option.

Assign direction using which method [Auto, Text, Sequence, Polyline, Bearing, Azimuth]: S
Select pit polylines to have direction as signed to:
Select objects: select the pits (Don't worry if you also select other polylines. It only finds pits.)
Select a direction polyline.
Select objects: select a polyline that crosses all of the pits This would be the short south to north polyline in our example.
Assign direction in which sequence (LL, LR, RL, RR): LR

In our example, we selected LR, which causes the pits to be mined left to right on the first pit (with respect to the south-to-north direction polyline–imagine yourself standing at the beginning of the polyline looking down it. LL would mine all pits coming from your left. LR would mine from the Left first, then the Right in the next one and so forth. RR and RL are just the opposite.), then right to left on the second pit, then left to right on the third, etc. An entry of LL would cause the pits to be mined from the left side to the right side. An entry of RR, for example, would mine all the pits from right to left. The entry of RL would mine first right to left, then left to right. The sequence method is ideal for assigning direction to a series of long and narrow pits that have not been broken up into small blocks.
If these same pits were each subdivided into 10 or more blocks, or there are many pits that would not be intersected by the sequence polyline, for example, then the following method, direction by polyline, is most appropriate.

Next we will look at the Polyline option.

**Assign direction using which method** [\texttt{<Auto>/Text/Sequence/Polyline/Bearing/AZimuth}]: \texttt{P}

**Select pit polylines to have direction assigned to:**

**Select objects:** select the pits (Don't worry if you also select other polylines. It only finds pits.)

**Select all direction polylines.**

**Select objects:** In the example above, select the single direction polyline.

The polyline-based selection is ideal for contour mines or outer pits in a mountaintop removal situation in Appalachia, or for pits that follow sinuous property lines. Most Midwest and western pit mining is linear, but the polyline technique for setting direction is still applicable. Direction polylines cannot have arcs, so if you've used an arc to draw the polyline, use the command Remove Polyline Arcs on the Edit menu to remove them.

Last we ill look at the Bearing and Azimuth option

**Bearing Option:**

**Assign direction to whole pit or to a specific bench** [\texttt{<Whole>/Bench}]: W or Enter to assign direction to whole pit

**Assign direction using which method** [\texttt{<Auto>/Text/Sequence/Polyline/Bearing/AZimuth}]: B for Bearing

**Select pit polylines to have direction assigned to:**

**Select objects:** select the pits (Don't worry if you also select other polylines. It only finds pits.)

**Enter Bearing (Qdd.mmss):** 145.0000

The highlighted pit has the direction information assigned already.

**Would you like to overwrite this** [\texttt{<No>/Yes/None/All}]: A

The Bearing is entered in the format (Qdd.mmss), the following figure shows the quarter numbers and the angle is calculated clockwise.
Azimuth Option:

Assign direction to whole pit or to a specific bench [<Whole>/Bench]: W or Enter to assign direction to whole pit
Assign direction using which method [<Auto>/Text/Sequence/Polyline/Bearing/AZimuth]: B for Bearing
Select pit polylines to have direction assigned to:
Select objects: select the pits (Don't worry if you also select other polylines. It only finds pits.)
Enter Azimuth (ddd.mmss): 135.0000
The highlighted pit has the direction information assigned already.
Would you like to overwrite this [<No>/Yes/None/All]: A

The Azimuth angle is calculated from the true north.
Pulldown Menu Location: Boundary
Keyboard Command: assign_dir
Related Commands: Display Directions, Reverse Directions, Clear Directions, Create Pit Plines from Mineplan

Display Directions

If directions have been assigned to pits, this command will display the directions. It therefore serves two purposes: (1) to verify that directions have, in fact, been assigned previously, and (2) to review the direction of mining. When pit directions are detected, arrows are displayed as shown below. These direction arrows will disappear with any "Zoom" command such as Pan or Window, and will also disappear if a Redraw or Regen is executed. The direction leaders can be used to draw direction arrow entities in the drawing. The sample drawing is a good demonstration of the use of Assign Direction by Text.

Prompts

Display direction to whole pit or to a specific bench [<Whole>/Bench]: W
Draw directions as leaders or temporary arrows [Leaders/<Arrows>]? L for Leaders or A for Arrows
Select pit polylines to have direction displayed:
Select objects: Pick the pits to review
Pulldown Menu Location: Boundary
Keyboard Command: display_dir
Related Commands: Assign Directions, Reverse Directions, Clear Directions, Create Pit Plines from Mineplan

Reverse Directions
This command reverses the direction of mining within a pit. It is particularly useful in conjunction with the command Assign Directions, <Auto>, since the automatic mode may assign direction to many of the pits opposite from the desired direction. The result is shown below, where the two pit 10s were reversed.

Prompts
Reverse direction to whole pit or to a specific bench [<Whole>/Bench]:
Select pit polylines to have direction reversed:
Select objects:

Clear Directions
This command removes the directions from pits. The Extended Entity Data (EED) designating pit direction is removed from the pit polyline entity. This command has no effect if direction has not been previously assigned to a pit. Keep in mind that it is not necessary to first remove "old" directions before assigning "new" directions. The Assign Direction command will recognize that directions exist and will prompt the user to overwrite the direction for individual pits or for all pits.

Prompts
Clear direction to whole pit or to a specific bench [<Whole>/Bench]:
Select pit polylines to have direction removed:
Select objects: pick the pit polylines This can be done individually or with a window.
Default Pit Attributes

When timing the pits, there are additional attributes that will be calculated and reported in addition to the Non-Key and Key quantities. If these are defaults that should be applied to all the pits, then they should be entered here. It creates a PTA file which may be specified in the Mining Project Manager. Any quality values, density, or difficulty attributes can be defined here either just as a value, or as a grid file with varying values. The Default Pit Attributes window shows what is defined for defaults, the second window, Reserved Attribute Names, displays the reserved words that will be recognized in the timing routines, and how they should be entered in. Selecting Keywords Help brings up the Reserved Attribute Names. Save and Load will create and load the PTA file for future use.

The Reserved Attribute Names are defined in a little more detail here:

- **THICKNESS**: Key strata thickness: Will report any other thickness values, this is used mostly for underground timing.
- **DENSITY**: Key strata density: Will report Key density, is used mostly in underground timing to calculate the tons. In surface timing, the tons are already in the pits.
- **ROCKTHICK**: Non-key strata thickness: Reports the Non-Key thickness mostly for underground timing.
- **ROCKDENS**: Non-key strata density: Reports the Non-Key density mostly for underground timing.
- **TIMEGRID**: User-defined grid to use for timing: This will be any additional grid the user would like to add for reporting.
- **DIFFICULTY**: Difficulty factor on advance just for underground timing: This will alter the underground equipment rate on advance.
- **RET_DIFF**: Difficulty factor on retreat for underground timing: This will alter the underground equipment rate on retreat.
• **DIFF_BENCH**: Difficulty factor for bench * for surface timing: This will speed up or slow down the equipment as it mines the specified bench. If a value is above 1, such as 1.2, then it will mine 20% slower at that point in the grid, or everywhere if it is set to value. If it is less than 1, such as 0.84, then it will mine 16% faster at that point.

• **XXXX_BENCH**: This is the dominate attribute that is most widely used in this command for surface pits. All quality grids will be defined in this fashion, for each bench. The example above, BTU_BENCH1, is defined in this way. All quality parameters need to be entered as the NAME_BENCH*.

**Pulldown Menu Location:** Boundary  
**Keyboard Command:** editpitattr  
**Related Commands:** Edit Pit, Mining Project Manager

---

**Assign Pit Precedence**

This command will automatically reassign the precedence for multi-bench pits. If the pits have been edited or cleared of precedence, this command will restore them to the default setting. Bench 2 will always require that Bench 1 gets mined first. Bench 3 will always require that Bench 2 gets mine first and so forth. This is the default setting that should be there, unless the pits have been edited. This will ensure the benches will not under-mine themselves. This command also detects pit overlap and automatically sets precedence accordingly, if the overlap area is greater than the tolerance area.

**Prompts**

Enter Overlap Area Tolerance (ft^2) <0.0>: Specify the allowed tolerance area
Select pit polylines to process.
Select objects: Specify opposite corner: 3 found
Select objects:
Done.

**Pulldown Menu Location:** Boundary > Pit Timing Quantities  
**Keyboard Command:** pitprec  
**Related Command:** Edit Pit

---

**Clear Pit Precedence**

This command will automatically erase the precedence for multi-bench pits. This is somewhat dangerous, as now Bench 2 can be mined before Bench 1. It is recommended to run Assign Pit Precedence after clearing them, to restore them to the default setting.

**Prompts**

Select pit polylines to process.
Select objects: Specify opposite corner: 6 found
Select objects:
Done.

**Pulldown Menu Location:** Boundary > Pit Timing Quantities  
**Keyboard Command:** clear_pitprec

---

**Clear Pit Bench Quantities**

This command removes all quantity values and grid paths from the selected pits. There is the option to clear all benches at once, or if Specific is selected, then it will prompt to enter a bench number to clear.

**Prompts**
Clear all bench quantities or a specific bench [All/Specific]? A
Select pit polylines to clear.
Select objects: Specify opposite corner: 5 found, 5 total
Select objects:
Cleared 10 bench quantities.

Pulldown Menu Location: Boundary > Pit Timing Quantities
Keyboard Command: clearpit
Related Commands: Edit Pit, Assign Timing Grids, Import Timing Data

**Remove Empty Benches**
This routine looks at all the pits and benches and removes the bench completely from the pit if the volume and/or tons are less than the specified tolerance. This is useful to remove very small quantities that have been stored in pits by mistake, or just from calculations on the edges of the data. Running this command will remove the pit bench with volume below the tolerance, so when running timing routines, the pits won't show up. This is useful for the 3D Pick option in Surface Equipment Timing to remove upper benches that are in the pit, but have no volume assigned.

**Prompts**

Command: emptypit
Key volume tolerance (CY) <0.0>: 100
Non-Key volume tolerance (CY) <0.0>: 100
Key tons tolerance <0.0>: 100
Select pit polylines to remove empty benches.
Select objects: all
7 found
Removed 2 empty benches.

Pulldown Menu Location: Boundary, Pit Timing Quantities
Keyboard Command: emptypit
Prerequisite: Pits with bench quantities assigned

**Assign Pit Attributes**
This command assigns the attributes to the pits that are in the current PTA file defined with the Mining Project Manager. The only reason to do this is if more than one PTA file is being used for different areas of the mine, or the attributes have completely changed, and new ones need to be assigned. These may be verified with the Edit Pit command.

**Prompts**

Enter Bench Number to Assign Qualities To:1
Select pit polylines to have qualities assigned:
Select objects:

Pulldown Menu Location: Boundary > Pit Timing Quantities
Keyboard Command: setpitattr
Related Commands: Default Pit Attributes, Edit Pit
**Reassign Pit Attributes Grids Folder**

This command will reassign the pit attribute grids folders to a new location if they are moved to a new location or computer. It will prompt for the first grid on the list, then reset all to the same location.

![AutoCAD Message](image)

**Prompts**

Select the first grid in the list.

**Drop-Down Menu Location:** Boundary  
**Keyboard Command:** resetpitattr

**Assign Timing Grids**

This command will assign key thickness, non-key thickness and key tonnage grid files to a series of pits or timing blocks. This is an alternate manual way of assigning grids instead of through the Output Thickness Grids option in the Surface Mine Reserves. These grids are associated with a bench number and stored in the pit polylines. This data is used by the Surface Equipment Timing routine, and these three values are required. Optionally attribute quality grids can be assigned here for each bench. You can use the Pit Report or Edit Pit routines to verify which grids are assigned for each bench. The key tonnage grid is tons/square foot or meter. It is easily made with the thickness grid and a density grid in Grid File Utilities. For example: Thickness Grid (feet) x Density (tons/cubic foot) = tons/square ft. The following dialog box allows for interactive entry so all benches can be entered and viewed together as one step. The blue colored text represents required attributes and the black colored text represents optional, user added attributes.

![Assign Timing Grids](image)

**Prompts**

Chapter 16. Surface Mining Module 2830
Assign Timing Grids Dialog Box.
Select pit polylines to assign grids.
Select objects: select polylines with pit/site names

Pulldown Menu Location: Boundary
Keyboard Command: tmgrids
Prerequisite: Key thickness grid, non-key grid, key tons grid, polylines with pit/site names

Reassign Timing Grids Folder
This command reassigns the path of the pit attribute grids stored in the pit perimeters. It is useful when moving the grids folder to a new location, the entire pit attributes do not need to be reassigned, just run this command to point the pit perimeters to the new grid locations. An useful AutoCAD command is XDLIST to view the extended entity data stored within the polyline. This shows the current path of the pit attributes.

Prompts
Select the site/pit perimeter polylines.
Select objects: Specify opposite corner: 10 found
Select objects:
Reset grids for 8 pit perimeters.

Pulldown Menu Location: Boundary > Pit Timing Quantities
Keyboard Command: reset_tmgrids
Related Commands: Default Pit Attributes, Edit Pit

Import Pit Timing Data
This routine imports timing data values into pits from an external text file. The command can bring in the following pre-assigned parameters: Pit Name, Site Name, Key Volume, Key Tons, Non-Key Volume, Difficulty Factor, Start Date and Bench Number, Precedence and other attributes. Also, any user added quality attribute is inserted with the "Add Attribute" button.
The following example is saved as a comma-delimited file (*.csv), which the routine will bring directly in. It imports files with extensions of TXT, CSV, DAT and ASC. Be sure the Site and Pit names are spelled and identified exactly as they appear in the drawing. Shown below is a sample file in Excel. The program will automatically recognize the data that has been exported by the Pit Report command. Changes and additions can be made to the pit report file, and then reimported to attach the data to the pits.

The Formatter Window is very easy to use. Simply dropdown the arrow in the Name row to define what each column is. This will match the data up with the fields in the pits and import the data.

**Pulldown Menu Location:** Boundary, Pit Timing Quantities  
**Keyboard Command:** tmimport  
**Prerequisite:** A pit data file and pits on screen

**Pit Quantities Report**

This command will generate a customized report of all data contained in the pit polylines. It is the compliment of the Import Pit Timing Data command. This command uses the Report Formatter which allows you to customize the report fields layout, and to export the data to a spreadsheet or database. There must be data already assigned to the pit polylines before running this routine.
Prompts

Select the site/pit perimeter polylines.
Select objects: pick the pit polylines
Report Formatter dialog. Choose fields to report then pick Display.

Pulldown Menu Location: Boundary > Pit Report
Keyboard Command: pitreport
Pit Points Report
This command will generate a customized report of the Site Name, Pit Name, Easting, Northing and Elevation of the vertices (corners) of each pit perimeter. This command uses the Report Formatter, so exporting to Excel of Access is seamless.

Prompts
Select the site/pit perimeter polylines.
Select objects: Specify opposite corner: 19 found
Select objects: Report Formatter dialog. Choose fields to report then pick Display.

Pulldown Menu Location: Boundary > Pit Report
Keyboard Command: pitreport2

Edit Pit

Edit Pit allows the user to review and edit the quantities and attributes such as sulfur and BTU stored in each pit. Surface Equipment Timing and Pit Scheduler takes this information and schedules through the pits. This information is placed into pits using commands such as Surface Mine Reserves, Import Timing Data, or Assign Timing Grids. The quantity/quality information in a pit is one of three categories of Extended Entity Data (EED) that can be stored in pits. There is no limit to the amount of data stored here, as it is stored in the Dictionary. The other two are pit name and direction of mining. Edit Pit requires that the user pick inside each pit to review pit data. The pit is shaded yellow for a visual verification of which pit is edited. The command will not proceed if there are not any named, directional pits in the drawing with quantities stored. The program will detect this automatically when the Edit Pit command is selected.

The following values can be edited for a bench: Pit Name, Site Name, OB Volume, Key Volume, Key Tons, Difficulty, Attr. Group, Start Date, Delay, Mineable, Precedence and Attributes. Other values are calculated from these values and pit dimensions. There are two views that can be used to view/edit information about a pit which can be accessed using Tree View and Spread View tabs.

Tree View:
Following dialog shows the tree view for a typical pit. Pit and Site names are shown on the top of the dialog. All benches in the pit are listed in Pit Benches tree view and the information of currently selected bench is shown in Bench Details spread where these can be edited. A separate list box below Pit Benches shows the Precedence for current bench. The Edit and Screen Pick buttons can be used to edit the precedence.
Following dialog shows the spread view for a typical pit. All the benches in selected pit are listed as column headers and associated data are shown below in the spread sheet. Bench precedence is listed in a dropdown list which can be edited using edit button for that bench.

Names and Bench: The Site Name and Pit Name are defined here at the top of the dialog. The Bench Number is displayed. Any of these items may be edited here to save in the pit.

Grids versus Values: There are two methods of storing quantity data in the pits for Surface Equipment Timing. It can either be stored as a value (CY or CM for Volume and Tons or Metric Tons for the Key Tons) or each can be assigned with a grid file. When grids are stored in the pits, the format changes slightly. The OB and Key Volume grids are actually thickness grids of the strata in the bench. The Key Tons grid will be a Tons per Square Foot or Meter. These values or grids are assigned to the pits by 3 methods. The first method is using the Surface Mine Reserves. The option to Store Results in Pits will add the values to the three windows described above. The option to Output Thickness Grids, if checked, will create and store the three grids explained above in the pits. All three grid names will be prompted for at the end of the Surface Mine Reserves routine. This must be performed for each bench needing to be assigned to the pits. The second method to add these quantities to the pits is Import Timing Data. This command will import the Values from a CSV file made with a spreadsheet. These values will be added to the pit as shown in the graphic above, where a value is in all three boxes. The third option, Import Timing Grids, will import the 3 grids mentioned above directly into the pits. All 3 grids will be prompted for. The two Volume grids should be a thickness grid, and the Key Tons grid will be tons/area. This grid can be calculated with the Grid File Utilities (GFU) using thickness and density grids. Now the question arises, why are there two options? Values are used generally for Equipment Timing when the pits or blocks are smaller. Carlson will schedule through the pit at a constant rate until the volume and tons are mined. This is not desired if the pits are very long, or the thickness of the seams varies a lot. That is when the Grid method is preferred. Carlson will schedule through the pit based on the thickness of the grids. If the OB is thinner, it will schedule through the pit faster, and if the OB thickens, the equipment will slow down in that section of the pit. This gives a more accurate representation of the actual mine plan schedule.
Define Pit Attributes versus the Entries in Edit Pit: There is a hierarchy for the use of pit information. In general, like it is for Underground Mining application, the entries in the Default Pit Attributes dialog are surpassed by Pit Attributes specified in Edit Pit routine. However the use of this feature is discouraged since attributes defined this way are stored as a completely separate set of attributes and therefore further changes in the Default Pit Attributes will have no effect on that particular pit. The pit attributes are listed at the end of the Bench Details.

Consider first the qualities. Surface Equipment Timing will honor quality attributes with a name in the form XXXX_BENCH*, where XXXX is a quality name (does not have to be 4 character long) and * is a bench number the quality should be used for. When Carlson runs a calculation for the bench, it evaluates all qualities for that bench and the report puts XXXX part of the attribute name into the report. This way the same quality calculated from different grids for different benches gets reported as a single quality attribute in the report.

Consider next the overburden and key strata quantities. If one or more of these fields are empty then Surface Equipment Timing will try to find pit attributes to use instead. These are defined in Default Pit Attributes also.

ROCKTHICK for OB Volume (C.Y.) as an average non-key thickness value or overburden thickness grid file;
THICKNESS for Key Volume (C.Y.) as an average non-key thickness value or key thickness grid file;
DENSITY for Key Tons as a key strata density or a density grid file.

Following dialog shows the reserved names for attributes, this can be activated using Keyword Help button.
**Difficulty Factor:** The Difficulty Factor will slow down or speed up mining across a pit. A factor of 1.1 means that mining will be slower than the rates set in Define Equipment. A factor of 0.9 means that mining will be faster (precisely 1.0/0.9 or 1.1111 times faster). The difficulty factor used will be 1 if nothing is entered here. If one or two pits present a problem to surface mining (for example, they are near a highway and require time-consuming buffering for environmental reasons), then Edit Pit offers a handy means of applying the higher Difficulty Factor. The user might choose to enter 1.2 or 1.3 directly, to slow those pits down 20 or 30 percent.

If the mining speed is influenced by constantly changing difficulty, the user might resort to sketching out contours to represent the difficulty factor using the command "Digitize Contours". The contours might range from 0.8 to 1.2, in 0.1 intervals. From these contours, a grid file could be generated representing the difficulty. If this grid file is assigned to the attribute DIFF_BENCH* (where * is bench number) within Define Pit Attributes, then this grid value (varying across a given pit) will be applied to all mining and will override any value within Edit Pit.

There is a 3-level hierarchy to the Difficulty Factor. In addition to the entry within Edit Pit and the overriding entry within Define Pit Attributes, there is a higher, overarching concept of layerized DIFF_BENCH* text. If text is found within the pit in the layer DIFF_BENCH* (where * is a bench number), then the real number value of this text (e.g. 0.95) will absolutely control the difficulty used in mining across the pit. As an example, if the text "1.2" appears inside a pit, in layer DIFF_BENCH1, then for first bench the value 1.2 will override the 1.0 that appears in Edit Pit and will also override any grid or value associated with the word DIFF_BENCH1 found in Define Pit Attributes.

**Multiple Benches:** Surface Equipment Timing is bench based timing. It will consider either the tons of key strata in determining the pace of mining or it will consider the volume of overburden and interburden to be removed. If, in reality, different equipment will mine different strata, then accurate timing requires that the mine be divided into benches. These benches are displayed here, in Edit Pit with the Next and Previous buttons. Each bench will have its own quantities and tons assigned, as well as any optional attributes. Precedence will be automatically set so as not to under-mine bench 2 before 1. This two-equipment or bench scenario requires that we have two benches with distinct volumes. This result is obtained by appropriate use of Surface Mine Reserves. To choose different strata for each bench, choose "Selected Strata" under "Which strata to include", and then specify which strata go to Bench 1 and which strata to Bench 2. This requires two separate runs of the Surface Mine Reserves command. The first run would specify the strata in Bench 1 and the second run would specify the strata in Bench 2 (no duplicates!). In short, the key to "benching" are the options "Selected" and "Bench #" within the Surface Mine Reserves dialog box. Benches can also be set with either of the other two import routines, Import Timing Data and Assign Timing Grids.

**Precedence:** Note that the concept of "precedence" comes into play here automatically. The lower bench 2 cannot be mined until the upper bench 1 has been mined. This "upper bench" precedence is automatically assigned by the program. The user has the option to enter a precedence for any given pit by selecting Edit beneath Precedence. The precedence can also be set just by choosing Screen Pick and picking inside a pit to be mined before. If there are more than one bench, the more times it is picked, the subsequent benches are also set to precede in mining.
When "Edit Precedence" is selected, the program displays all pits and benches available. The convention is to put the bench number after the pit name, such as B1 and B2. Edit Pit can also be used to control the order of mining. For example, by using the higher bench on the current and next two pits in the forward direction for precedence for the lower bench 2, the effect would be to always keep the upper bench equipment two full pits in advance of lower bench equipment for a staggered approach.

Starting Date: The starting date can be safely left blank within Edit Pit. However, it may be that equipment scheduling may be subject to permit approval, land purchase, legal consideration, new equipment coming on line, all of which may determine a specific date before a pit could be mined at the earliest. If such a condition applies, a pit starting date can be entered for any given pit. If the equipment reaches that pit prior to the starting date, it will stop and wait until the date arrives before proceeding.

Pulldown Menu Location: Boundary in Surface Mining
Keyboard Command: editpit
Related Commands: Surface Mine Reserves, Define Pit Attributes, Mine Project Definition File

Pit Inspector
This command follows the "inspector" theme found throughout Carlson. Any variable or attribute will be displayed within the inspector window as the cursor is moved from pit to pit. When each pit's information is being displayed, the pit perimeter is dashed to highlight the pit. If a grid is stored in the pit, then just the grid name path is displayed or labeled, not the value. Picking with the mouse inside a pit will bring up the Edit Pit dialog box where changes may be made if necessary. Options will activate the Pit Inspector window to add or edit the items. Label will allow for labeling the Used items on the screen. The text alignment and height is prompted for at the command line.
Prompts

Options/Label/<Pick To Edit>: L (for label)

Pick starting point for label:
Pick label alignment point:
Text height <50.00>:
Options/Label/<Pick To Edit>: O (brings up the settings window again)
Drop-Down Menu Location: Boundary

Keyboard Command: pitinspect

Timing Project Manager

The Timing Project Manager (Surface Project Manager or Underground Project Manager) applies to both surface and underground mining for file organization and selection. All files and most settings and configurations used in the mine scheduling are found in the manager. Each topic is described below in detail.

Settings
• **Coloring Settings:** These settings are from the Report Options screen from the equipment timing command. Defaults can be set here before running the actual schedule. Explanation of this dialog is found in Underground Timing or Surface Equipment Timing. The screen appears as shown here.

![Report Options Screen](image)

- **Attribute Weighting Settings:** This gives the ability to weight average attributes by other attributes, both calculated and internal. Add new lines with the + button. Enter in the Attribute, or pick it from the Keyword Help button. Then dropdown the Weight By Attribute. This will show up in the Report Formatter once the schedule is ran.

![Edit Attribute Weighting Factor](image)

• **Mining Precedence Rules:** This allows for automatic precedence using an user-defined sequence. When using commands such as AutoPlace Panel by Text, it does not set precedence. Using this command makes sure panels do not start before they are exposed or available to be mined. Each rule is shown at the top. Start by choosing the Select button and select two entries that are compared. Then choose which one goes first, if
it is wrong, use the Swap button. Give it a name (optional) and hit Apply. The Preview button will show the order in the lower window.

To use this precedence, turn on the Use Precedence option in the Sequence Window, as seen here and the blocks and panels will reorganize to fit the order.

- **Drawing Event Types:** Drawing events are entities in the drawing at a specific location that will be used for a marker in the schedule as an option for a delay. This event can be used to delay equipment, switch crews, move other equipment, etc. When the schedule crosses over the insertion point of the drawing event (usually text) the event will trigger the delay or effect. The text/drawing entity in the drawing should be inserted to the position where the delay where occur and in the AutoCAD layer defined in the Capture Layer window. The Event Key and description can be used in the reporting of the schedule to create additional reported items.
There are options to set the layer, give it a full description and internal event key name. The Productivity can be set to not working, working (as normal), and not producing (working, but not moving any material). The event delay length is set here by number of shifts. Calendar based will determine if the shift is off in the calendar. If the box is checked, and that shift is off in the calendar already, then it will not take off any more. If it is off, then it will apply to only the next working shift(s) for not working or producing. Additional Units can be used to also set other units off during the same period. For example, if a longwall is down due to a move, then the CM working with it can also be down for the same time. There is also an option to Delay Only Additional Units. This can be used to set one unit down, when a different unit crosses the drawing event. This allows for clever equipment delays and precedence by using different drawing events.

- **Calendar Event Types:** Calendar events are named events that will determine equipment down time. The default event in the calendar is Manual. The other events are set under the Calendar Event Types and Calendar Event Definition. Calendar events can be any event that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working with crews, using hours, but not mining).
Equipment

• Equipment Set: The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule.

Add and Edit will bring up the next screen for detailed entry.
The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example.

Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift.

Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only.

The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined form given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

**Advanced Options:**
Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.
• New or Existing Calendar: Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.

[Diagram of software interface]

The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.
• **Date Selection**: The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. There can be up to 4 shifts. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.

• **Event Rule Definition**: This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.

• **Event Entity Filter**: The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/Panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).

• **Shifts**: The number of shifts checked here will display next to each day.

• **Due to/Calendar Events**: The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to" window. Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).
• **Repeat for/Label**: This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.

• **Events for Date Selected/All Defined Events**: This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.

• **Rule Report**: This report displays all of the rules defined for down time within the calendar.

• **Year Report**: This reports all days for the selected calendar year.

• **Unit Report**: This reports all equipment and dates defined in the calendar. See example below.

• **SaveAs/Load**: This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

### Timing Assignment
The Timing Assignment allows for setting the current sequence. The Assignment is similar to the TIM file in the timing routines. The equipment used and which panels or pits they are mining are shown. The Set Current button controls which one will be loaded and used. Shown here is both a surface mine and an underground mine example.

Panels
Attribute Groups

Attribute groups are Pit or Panel Attributes assigned to the pits and panels for timing. When timing the pits or panels, there are additional attributes that will be calculated and reported in addition to the Non-Key and Key quantities. If these are defaults that should be applied to all the panels or pits, then they should be entered here. Any quality values, density, or difficulty attributes can be defined here either just as a value, or as a grid file with varying values. The Reserved Attribute Names window displays the reserved words that will be recognized in the timing routines, and how they should be entered in. Selecting Keyword Help brings up the Reserved Attribute Names. If the grid name is red, as shown here, then the file cannot be found. They need to be colored black for successful use.
The Reserved Attribute Names are defined in a little more detail here:
• **THICKNESS**: Key strata thickness: Will report any other thickness values, this is used mostly for underground timing.
• **DENSITY**: Key strata density: Will report Key density, is used mostly in underground timing to calculate the tons. In surface timing, the tons are already in the pits.
• **ROCKTHICK**: Non-key strata thickness: Reports the Non-Key thickness mostly for underground timing.
• **ROCKDENS**: Non-key strata density: Reports the Non-Key density mostly for underground timing.
• **TIMEGRID**: User-defined grid to use for timing: This will be any additional grid the user would like to add for reporting.
• **DIFFICULTY**: Difficulty factor on advance just for underground timing: This will alter the underground equipment rate on advance.
• **RET_DIFF**: Difficulty factor on retreat for underground timing: This will alter the underground equipment rate on retreat.
• **DIFF_BENCH**: Difficulty factor for bench for surface timing: This will speed up or slow down the equipment as it mines the specified bench. If a value is above 1, such as 1.2, then it will mine 20% slower at that point in the grid, or everywhere if it is set to value. If it is less than 1, then it will mine faster at that point. Difficulty is calculated by the equation: \( \text{DIFF} = \frac{100}{(100 - \% \text{reduction})} \).
• **XXX_BENCH**: This is the dominate attribute that is most widely used in this command for surface pits. All quality grids will be defined in this fashion, for each bench. The example above, BTU_BENCH1, is defined in this way. All quality parameters need to be entered as the NAME_BENCH*.
• **SURFACE**: This attribute is used for the 3D Pick window to drape the pit blocks onto the ground surface.
• **SURFACE_BENCH**: This attribute defines the bottom elevation grid for each bench. It is used to display the blocks in the 3D Pick window properly, so the benches are represented accurately.
• **TIMING_SPLIT**: This will globally split all blocks that contain both Key and Non-Key material into two blocks that may be scheduled separately, by either the same unit, or different units. The split is into two portions - key and non-key. Entering a non-zero value will cause a split. Additionally three values are supported as pertains to precedence. Enter in one of these values in for the attribute to split it.
  1 = Both OB and KEY needs to be completed to satisfy precedence
  2 = OB portion needs to be completed to satisfy precedence
  3 = KEY portion needs to be completed to satisfy precedence
• **TIMING_SPLIT_BENCH**: This attribute is the same as TIMING_SPLIT, but is only applied to the specified bench number.

### Reports

Some of the reports generated in the scheduling will appear here for other options to report. These are also accessed in the calendar or after a schedule is run.
Data Links

This shows the link of the data when it is linked to an external source for reporting.

Pull-Down Menu Location: Reserves/Timing in Surface Mining and Underground in Underground Mining
Keyboard Command: stime_project or utime_project
Define Equipment

This command is for inputting and editing the equipment for scheduling routines. It is accessed only in the Timing Project Manager. The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule. Crews are created in the Calendar section of the Timing Project Manager.

Add and Edit will bring up the next screen for detailed entry.
The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example.

Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift.

Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only.

The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined form given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

**Advanced Options**
Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.
Equipment Calendar

Note: Equipment Calendar is also located in the Underground Module section.

This command is accessed through the Surface Production Manager under Reserves/Timing. Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.

The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.
• **Date Selection:** The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.

• **Event Rule Definition:** This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.

• **Event Entity Filter:** The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).

• **Shifts:** The number of shifts checked here will display next to each day.

• **Due to/Calendar Events:** The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to" window. Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).
Repeat for/Label: This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.

Events for Date Selected/All Defined Events: This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.

Rule Report: This report displays all of the rules defined for down time within the calendar.

Year Report: This reports all days for the selected calendar year.

Unit Report: This reports all equipment and dates defined in the calendar. See example below.

SaveAs/Load: This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

Pulldown Menu Location: Reserves/Timing in Surface Mining and Underground Menu
Keyboard Command: calendar
Prerequisite: Equipment and crews should be defined for the routine to be used in its full capacity

Set Attribute By Grid File

This command assigns an attribute grid value such as thickness or BTU to a panel or pit area. The program prompts for the attribute name and the grid file that represents the attribute. Then multiple panel/pit perimeter polylines can be selected and the program calculates the average grid value in each panel/pit polyline and stores this value. This command works similar for both surface pits or underground panels. This is the surface pit description.

Another method for using grids is to define the attribute as the actual grid file name instead of the average value. Then the timing routines will calculate attribute values for each timing block from the grid value. The advantage to using Set Attribute by Grid File instead of using the actual grid file is speed. Timing runs a bit slower when reading the grids.

The average value is stored in each pit and can be verified with the Edit Pit command. If the attribute exists there already, it will not overwrite it. Choose the Attributes button and the attribute should be there, as shown in the Edit Pit window. It matches the first BTU value calculated in the example.

Prompts

Pulldown Menu Location: AdvMine
Surface Production Timing

This command is used for production based timing of a mineplan to see the mine progress when defining production by time period. It is sometimes referred to as a pre-scheduler, prior to running Surface Equipment Timing to get an estimate of mine progression. There are 3 steps needed to prepare for Production Timing as shown in the flow chart below. First, the mining model needs to be set up in the PreCalculated Grids file (PRE). This could also be the geologic model. Next, there must be named, Carlson pit poly-lines representing the mine plan. Finally, the pits lines must have direction assigned for mining. Once these 3 items are created, the command may be run. This command does not use highwall angles or laybacks. It loads the mining model and vertically intersects it with the directioned pits to obtain timing blocks.

Make PreCalculated Grid File ——> Create Named Carlson Pits ——> Assign Directions to Pits ——> Surface Production Timing

The first step is to choose the PreCalc file to process. After it is selected, the first dialog box appears for some initial settings. The Key Strata Recovery can be entered in the window with Set Value, or can be set By Strata Definitions, where it will refer to the Strata Definition File created with the Define Strata command. There, each strata can have it's own recovery. The Key Strata Density is set in the same way. Either by entering it here, or as defined in the SDF file. The units are either pounds/cubic foot or kg/cubic meter, depending on US units or metric units in the drawing. Finally, the Source of Bottom Surface Model can be set here. If Strata Model is chosen, then the routine will use all seams from the surface topography down to the lowest strata grid elevation in the PreCalc file. If Grid File is selected, then volumes will only be calculated from the topography down to that bottom surface grid file, which could be a flat bench elevation for example. A file-select window will appear next, to choose the grid if that option is used.

Next, after selecting the pits and the mining project file, the Surface Production Timing window appears as follows.
The first step is to select pits and move them over to the Assignment box on the left with the Assign button. Following is a detailed description of each item in the dialog box.

- **Do Earlier / Do Later**: These buttons move the pits up or down in the Assignment window.

- **Remove, Remove All**: These buttons will move either the selected pit, or all pits from the Assignment window to the Unassigned Pits window.

- **Assign**: This button will move the highlighted pits from the Unassigned window to the Assignment window.

- **Select All**: This is a quick way to highlight all pits in the Unassigned Pits.

- **Inverse sorting**: If this is checked, then the pits will appear in reverse order in the Unassigned Pits window, otherwise they are in alphabetical and numeric order.

- **Screen Pick**: Allows for manual selection of pits in plan view with a cross-hairs. Simply place the cursor in the pits and pick in the order to mine. Hit enter when done. The selected pits should appear in the Assignment window in the order they were picked.

- **Report pits on one row**: This option is for report formatting. If this is checked, the report will have one row per time period and all strata quantities and qualities will follow on that row, each in their own column. If this is not checked, then each strata will be in its own row in the report, with its quality to follow. This is option is usually not selected.

- **Use property boundaries**: There must be named property boundaries on screen for this option. Production timing will automatically detect them and break out the production by owner and property if desired.

- **Draw timing blocks**: One of the main items of output from this command. It draws the periods as blocks of solid fill or any hatch pattern inside the pits in plan view. They are colored by period. As they are being drawn, the direction and progress of the mineplan can be seen for review.

- **Draw distinct outline**: This is very similar to the timing blocks, except that they are just closed polylines with no fill or hatch. They are in their own color, and optionally, layer. They can be used later for further
**Reserve calculations, or to save the mineplan without hatch or fill.**

- **Draw labels:** This option places the period name in the block or outline. It is either the user defined label, or will just use "Period1", "Period2" etc.

- **Text autosize:** If this is selected, the text will be automatically sized to fit the size of the block outline. Otherwise, the text might be too large for some of the smaller blocks.

- **Draw labels length-wise:** Selecting this option orients the text lengthwise to the long axis of the block outline. Otherwise it will be placed horizontally.

- **Text Size:** Enter in the text size for labels. It will use this if Text Autosize is not selected.

- **Text Style:** Enter the AutoCAD Text Style for labels and legend.

- **Draw Legend:** Select this option to draw a legend of the timing blocks showing the color and the name of the period. It will ask to pick the legend position.

- **Legend Scale:** Enter in a legend scale size to size the legend.

- **Layers by Period:** This option will create a new layer for each time period and draw the blocks and outlines in those layers.

- **Production Table Type:** This is a very important setting that needs to be selected for the target material. There are 10 choices to use for production targeting. Most common are Key Tons and Overburden Volume, but others are available. Total Tons converts all strata to tonnages and mines them accordingly. The NonKey density is set in a window that appears as soon as Run is selected. Key Tons are tons of the combined key material, which name is set in Configure /Mining. Waste Tons will combine all NonKey strata, calculate the tons for it and target that tonnage for production. Mined Area will target a defined area in square feet or meters for production. Total Volume will combine all strata, both Key and NonKey and target the total CY or CM. Key Volume or Coal Volume will target the CY or CM of all Key strata in the selected PreCalc file. Waste Volume combines all NonKey strata and targets the CY or CM of them. User Grid will take any grid and target total quantities for production. An example of this would be a power plant that wants to target total BTU. The grid to select would be total BTU/area. Finally, the Overburden Volume will take just the first NonKey strata in the PreCalc and target that, but still report any additional NonKey seams below it.

- **Stop at Last Period:** If this is checked, then the routine will stop after the last period entered in the Production Table. If it is not checked, then it will continue with the last target amount all the way through the
last selected pit polyline.

- **Production Table:** This is the screen to set the production amount and time period or date. The first column is the amount to target. This is what you have selected under Production Table Type. The second column is the color for that period. The next column is the hatch pattern for the block. If it is a hatch pattern other than SOLID, then it must have a scale factor, set in the next column. The AutoCAD Layer is set in the next column and finally, the Label is set in the last column. This can be anything from dates, to owners and areas. If the Labels are left blank, then it will fill in labels such as Period3, Period4, or month or year, etc. The Clear button will clear the entire screen. There are Save and Load buttons for easy retrieval of the CQT files.

![Define Levels](image)

- **Undo:** This will undo a previous run, removing the colored blocks and outlines.

- **Run:** This is the button to start the actual timing and sequencing of the pits. After the Production Table and all the settings are good, then choose Run.

- **Finish:** After the blocks are drawn and the Surface Production Timing window comes back, selecting the Finish button will start the calculations and generate the quantities and qualities in the Report Formatter. Here items are selected to appear in the report and exported to a file, such as Excel or Access.

A finished map with the blocks drawn on it and the corresponding report are shown here. In this example, the amount was set to 225,000, then 250,000 tons. In the report, notice the accuracy of the tons. Most are within a couple of hundred tons.
Pulldown Menu Location: Surface Mine Module - Reserves/Timing
Keyboard Command: calcplan
Prerequisite: Timing pit polylines

Chapter 16. Surface Mining Module 2867
Pit Scheduler

Pit Scheduler is a short-range surface mine scheduling command and is located under Reserves/Timing dropdown menu in Carlson Surface Mining. It displays selected pits in a cross section view with benches and allows user to assign equipments to pit benches by time period. The planner can simply pick on a bench to mine/un-mine it and the updated quantities will appear in the quantity spreadsheet. These quantities can be reported using report formatter at any time.

Interface Components

1. Menu
   The Pit Scheduler has three main dropdown menus.
   a. File Menu
      i. Read Pit Blocks: This command can be used to read in the new pits in the view to work on.
      ii. Report: This command can be used to report the currently assigned quantities.
iii. Export to Bitmap: This command can be used to save the current pit display in to a bitmap file.
iv. Save and Exit: This command saves all the assignment and exits from the Pit Scheduler.
v. Exit: This will exit from the Pit Scheduler without saving any assignments.

b. View Menu
i. Project Manager: This command brings up the Surface Project Manager that can be used to define equipments, timing calendar, and other components to be used in scheduling and to view assignments and loaded pit names.
ii. Settings: This command shows the settings for Pit View, Pit Text and Mining.

- Pit View: These settings can be used to modify the pit display to view it more efficiently. The "Pit Width" and "Pit Separation" can be set for better viewing the pits based on their thickness. The pit width is the width of the pit column and pit separation is the separation between two pit columns. The "Show Pit" allows users to specify the number of pits to view in the current view. If "Zoom selected Pit in plan view" is on as soon as used clicks on a pit it will be highlighted in the AutoCAD drawing plan view and the view will be zoomed in to the current pit. The "Set Common Elevation" option allows pits to be hanged from a common elevation specified in the "Elevation" edit box, if this option is turned off the program looks for the "SURFACE" attribute for the pit and reads the elevation from there.

- Pit Text: The Pit Text settings can be used to display different text in the pit display for a pit column.

- Mine Settings: These settings are used in timing the pits similar to used in Equipment Timing.

c. Tools Menu

i. Clear Assignments: This command clears all the assignments for the current equipment selected in "Equipment" dropdown list. This will allow user to select the assignments for equipment from the beginning.

ii. Clear All Assignments: This command will clear all the assignments for all the equipments and bring the mine to the starting point, and allows user to start the scheduling from the beginning.

2. View Toolbar
3. Pick Mode and Selection Option
a. Pick Mode: is used to set the mode for selection of pit benches. There are three pick modes:
   i. Assignment: This mode is used to assign the current equipment selected in the "Equipment" dropdown list to the selected bench/benches based on the "Selection Option".
   ii. Waste Bench: This mode is used to specify whether a bench will be mined or treated as waste bench. The waste bench quantities will not be added to the quantities as it will not be mined.
   iii. Add Delay: This mode allows user to add delays associated with a bench. If this mode is selected than based on the selection option delay will be added to the bench/benches and mining will be delayed by delay duration. (Look in Surface Equipment Timing for more information on adding delays)

b. Selection Option: is used to apply the pick mode to the benches. There are five selection options user can choose from.
   i. Individual Pit: the pick mode will be applied to the selected bench in selected pit.
   ii. Current View: the pick mode will be applied to the selected bench for all the pits in the current view.
   iii. All Pits: the pick mode will be applied to the selected bench for all the pits loaded in the Pit Scheduler.
   iv. Pits to the Right: the pick mode will be applied to the selected bench for selected pit and to all the pits on right side.
   v. Pits to the Left: the pick mode will be applied to the selected bench for selected pit and to all the pits on left side.

4. Pit Navigation
The Pit Navigation can be used to scroll through the loaded pits. The "Goto" pit allows user to select the starting pit for the view. The Left or Right View scrolls the view to left or right respectively by the number of pits selected in "Show Pits" in the Settings dialog under View Menu. The Move Left or Right scrolls the view by a single pit.

5. Pit Display
The Pit Display shows the pits with benches in a plan view based on the view and text settings. Following figure shows a typical Pit with all text options turned on.
6. Tool-Tip
A Tool-Tip window is shown with the full name of bench (Site-Pit-Bench) and Key and Non-Key thickness when user cursor over a bench.

SITE 1-PIT 5-B1
Key Thick: 0.5
NonKey Thick: 86.0

7. Period & Equipment
a. Period: can be used to view the number of days used and available for the selected equipment. The Period string can be formatted using the Period Formatter dialog or can directly be typed in the edit box. The Period string must be in the specified format. As soon as the user updates the Period and hit enter the ''Days:'' label is updated to show "Used Days/Available Days (Period Days)".

b. Equipment: This dropdown lists all the defined equipments in the Project Manager. The current selected equipment is used for assignments.

8. Quantity Spread
The quantity spread shows the quantities and qualities for the equipment selected in "Equipment" dropdown for each bench it is assigned to. The spread shows Equipment, Bench, Key-Tons, Key-Thickness, Non-Key Thickness, Key Volume, OB Volume, Area, Acres, and Strip Ratio columns followed by the pit attribute values.
9. Elevation
The current elevation of cursor is show on the "Elevation" label. If the "SURFACE" attribute is defined for the pit it will show the actual elevation for that pit and its benches.

10. Right Click Menu
A Right Click menu pops-up when user right click on a Pit Column. This menu lists Edit Pit followed by the full name of benches in that pit. The thickness of a bench can be very small that it becomes hard to pick that bench using left click, in that case right click menu can be used to pick that particular bench. It shows the mined benches with a check mark. The "Edit Pit" command can be used to edit the pit values and attributes. (For more information refer to "Edit Pit" command under Boundary dropdown menu of Carlson Surface Mining).

Pulldown Menu Location: Reserves/Timing in Surface Mining
Keyboard Command: pit scheduler
Prerequisite: Pits with assigned quantities

Surface Equipment Timing
Surface Equipment Timing schedules through surface pits and blocks based on equipment mining rates in accordance with a calendar. The mining rate is typically based on volume of overburden but may also be based on tons of key strata. The calendar is set by the user to indicate when entire days or individual shifts within a day are down for holidays, time off, or other reasons. The pits themselves must contain key strata and overburden information which is placed in them through use of Surface Reserves, Import Timing Grids, or Assign Timing Data. Surface Equipment Timing is distinct from Surface Production Timing by requiring use of quantities or grids stored in the pits, use of a calendar, and defined rates of production for equipment. The Calendar, Equipment and Crews are defined in the Surface Project Manager.

The Project Manager also appears at the start of Equipment Timing. The purpose of the timing project database file is to provide a single place where everything related to the timing project is stored. This includes equipment definitions, reporting settings, pit and panel information and reports produced. This also includes other data such as calendars, equipment options, date and weight tables, text block definitions. Basically everything except for the grid files, which will be referenced. This means that reviewing or even repeating results of a schedule done previously will be much easier if everything including the last results is stored in the same place.

The left side of the dialog has a tree control which displays the categories of items on the top level, with either set of items or actual items underneath. Depending on what is selected on the left, the buttons on the right will reflect the functionality available for the current selection. The sets of items showing in bold reflect the current set when applicable: i.e. the project can have multiple sets of equipment defined, but the one showing in bold is one used in calculations. By double-clicking on the item the Edit function can be executed if applicable. For equipment, the user can edit, add, copy or remove entire sets of equipment. Use the Set Current button to set a particular item current. Equipment can be imported from an older Equipment Definition file or from another project. It can also be exported to another file. A number of different data can be output to an external data source or brought up in the report formatter.
Following is a detailed description of each function on the Surface Timing window and subsequent windows. After that is a step by step procedure for setting up for the Surface Equipment Timing.

- **Add Unit:** Selecting this button will bring up a list of Available Equipment for selecting a unit to add to the Surface Timing window. This must be done first, before assigning pits or blocks.
• **Edit Unit:** This button will go to the Equipment Production Rate window, similar to Define Equipment. Any rate or shift changes made here will be saved to the equipment file.

• **Replace Unit:** This replaces one unit with another.

• **Remove Unit:** This button will remove the high lighted equipment from the list of Equipment Involved. It will still remain in the fleet for future use, just not on the list for the current mine plan.

• **Edit Calendar:** This will bring up the active calendar where any changes and edits can take place.

• **Do Earlier:** This option will move a selected pit/bench up the list in the Assignment window.

• **Do Later:** This option will move a selected pit/bench down the list in the Assignment window.

• **Remove:** This option will move the selected pit/bench from the Assignment window back to the Unassigned window.

• **Remove All:** This option will move all of the pits/benches from the Assignment window back to the Unassigned window.

• **Add Delay:** This inserts a delay in-between the pit blocks. This brings up the same delay setting as found in the Drawing Events.

• **Assign:** This button will move the high lighted pits/benches from the Unassigned window over to the Assignment window.

• **Select:** This is to select the pits and their appropriate benches for assigning. It will highlight them, ready for the Assign. The choices to select are None, All, or by bench number, such as all the Bench2, or the Bench3.

• **Use Precedence:** This gives the ability to adjust sorting of unassigned pits/panels so that precedence is satisfied (violating names are moved down the list until precedence is satisfied)

• **Screen Pick:** Selecting this allows for screen picking of the pits in plan view. Cross-hairs appear, and the command line states: Pick on or inside of pit polyline or Enter to finish:. Pick inside the pits in the order they should be assigned. Picking once assigns the first available bench. Picking again in the same pit, assigns the next bench (if available) immediately after the first one. Hit Enter to get back to the Surface Timing screen, and the pits should be assigned in the order picked on screen.

• **3D Pick:** This option gives a 3D view of the pits and the quantities stored in them. It allows for viewing, rotating and selecting of the pits to be mined in 3D. When a pit and bench is picked, it disappears from the mine plan, revealing the block beneath it. There must be a Pit Attribute called SURFACE with the surface topography grid assigned to it. Rotate the view to see the benches in 3D, select a unit, and start picking the blocks in the order to be mined. The "mode" it is in will determine what the mouse icon is.
Vertical Scale: This dropdown allows a different vertical scale set in the window from 1X to 16X Single Pick / MultiPick. This allows for switching between selecting one pit block at a time, or a range. To select a single pit block, set the mouse to the arrow/pointer, then double click on a pit block to remove and mine it. If there is a range of pit blocks to select, choose the Multi Pick option and using the same arrow pointer, double click on the starting pit block, and then again on the ending pit block of the line of blocks to mine. Keep picking until the end of the string is reached. It will draw a red line from pick to pick. When finished, Right Click the Mouse, and all the blocks crossed by the red line will mine out in the order they were crossed. This will remove and mine that entire range for scheduling. Use Bench Rules: This option will apply the bench rules to benches on top and those are assigned to the equipment selected for each bench in order top to bottom with defined sequence. The Bench Sequencing screen to set this up is shown below.

Zoom button gives the magnifying glass with the +/- to zoom in and out. Rotate button gives the XY icon to tip it on its side, and the Z icon rotates it around the Z axis. Pan button gives the hand and pans around the screen.

The Pick arrow button is the easiest icon to select the pits with. Just move the icon on top of a block and double click with the left mouse button. The name of the pit and bench it is pointing to is shown above the equipment window. The block will disappear and the name will be added to the Assignment list. Any mistakes can be removed with the Remove Button, the green X.

The Shade button renders the pit benches otherwise they are just 3D faces not shaded. The Zoom Extents button returns to plan view, and zoomed to the extents. Turn Benches On/Off button brings up the Set Layers window where unselecting a specific bench will remove it from the 3D image. Each bench color can be set here for better 3D visualization. These color settings can be saved and loaded at a different time. The Mining Rules sets up the precedence on what must be mined in upper benches to get to the desired block below. Bench Sequencing allows the user to setup default equipment for each bench and bench sequencing rules with ability to play back the sequence with the Play arrow >. A mining sequence rule for the top bench can be setup for each bench by setting the offset in North, East, West and South direction where North begins the twist screen angle from the drawing. Use the Twist Screen command first to rotate the blocks if they are not laid out on a N-S-E-W pattern. Once the rule is setup for one bench it could be applied to all the benches with the Set to All. The Upper Bench Offsets control how many blocks must be removed in each direction from the bench above. The Upper Bench
Sequence sets the order of how to mine these blocks.

Once the bench rules are setup, there is an option to select the Bench to draw the advance on the screen by using "Draw" button, this will draw the perimeter for each bench on top, to show how much needs to advance to uncover the underlying bench for the selected pit. The perimeters will be drawn with the selected color for each bench in CAD.

The Chart Settings button brings up the window for selecting the bar chart attributes to display. Everything stored in the pit benches is available to display in the bar charts. When a pit bench block is selected, the tons, volume or quality of the bar charts increases to show the values. This shows a running total of the values as each block is picked and removed to be mined. The ranges for each attribute set the minimum and maximum values for the bars on the chart. So, as an example if 200,000 tons are needed for some short range mine planning, set the Key Tons to 200,000 maximum and then it is easy to see how many blocks are needed to be picked to get to that volume. Or, if a certain quality of Key material is needed, select blocks and monitor the quality to keep it in the desired zone.
- Timing can be run from this window by selecting the Report button. It brings up the window with the finish date, where the Report or the Detailed Report are selected. Choosing Detailed Report brings up the Report Options and runs the schedule, and hatches the pit blocks in the drawing.

- The blue circle with the yellow square in it is the light control, to cast shadows where the light shines from the direction selected.

- The Vertical Scale box changes the scale for better viewing of sites with low relief.

- Screen Entities button will allow for any picking in CAD of 3D entities to show up in the 3D Pick window. Entities such as contours, ramps, roads, pit shells and perimeters can be selected and viewed with the blocks in the 3D Pick window.

- When done, just hit the Exit button (the door with the arrow going out) and you are back to the main Surface Timing sequencer.

The program uses the SURFACE grid as a starting elevation and the thickness of each block is relative to the volume of material assigned to each bench in the pits. Benches with more volume will show up thicker than others with less. The color scheme is based on the bench you are on. For better viewing of complex pits with separate bench polylines in 3D, surface attribute for each bench can be defined with attribute name SURFACE_BENCH# and value equal to the bench bottom elevation grid. If these attributes are defined the program builds the 3d pick view from top-down calculating the thickness on each pit vertex as elevation difference between two consecutive benches.
• **Add Delay of Days/Shifts:** Adding a number in the day or shift window and hitting the Add Delay button will bring up the following windows. Highlight the pit/bench in the Assignment window and the delay will be added below the row that is highlighted.
The Schedule Effect on Delay gives two choices: Schedule delay, where the delay will take affect when the equipment is working. If the calendar has the equipment off at that time, then the program waits until it starts to work again, then schedules the delay. A Calendar delay, where if the calendar has it off already, then that is all it will do. It will not take it off additionally. The Due To option provides Drawing Event Types to choose from. Choose the button with "..." next to the Due To, to open the Drawing Event Types window. To Add or Edit a type, the Capture/Timing Event Definition screen provides names and productivity options. Any where the text drawn in the Capture Layer is encountered in the drawing, the equipment will be delayed by the Event Delay Length in shifts. The Productivity Effect is the result of the delay. Not working is where the equipment is completely down. Working is no change, and Not Producing is where the equipment is in use, but no quantities are being mined.
• **Assigning Bench Specific Events:** If you want an event to associate with a specific bench put the event on the layer with "BENCH##" (## - Bench Number) suffix to layer name. For example if the dragline move event occurs only on the bench 3 the capture layer name would be "DraglineMove_BENCH3", if there isn't any _BENCH## it would apply to all the benches. Also update the Capture Layer name in the event definitions to "DraglineMove_Bench3". This would make sure that drawing event will occur only on the equipments working on Bench3. You can specify other event on specific benches same way.

• **Undo Report:** This option will Undo a previous Surface Timing run. It will delete the blocks or perimeters drawn in the drawing. If a quick change to the plan or equipment is made, it can be re-run very quickly just by hitting Undo Report and then Calculate again.

• **Starting Date:** This must be filled in before selecting Calculate. Use the format that is defined for dates in Configure under Settings. It can be 12/15/2014 (US) or 15/12/2014 (Australia and Europe) etc.

• **Number of Shifts:** This is the number of shifts the program will use in the actual sequencing. Even if 3 shifts are defined for the equipment or in the calendar, and 2 is entered here; it will only use 2 shifts in the timing. It uses the first two, ignoring the third shift in the equipment rate and calendar.

• **Skip Ore (Key Strata) for Timing:** This toggle will determine if the equipment is mining just the NonKey/Overburden material or both the NonKey and Key Material that appears in the pit and bench. For example, a dragline moving overburden should have this checked so that it ignores the coal volume. It will still report the Key volume and tons, but not use it for the schedule.

• **Perform Bottleneck Analysis / Bottleneck Parameters:** Bottleneck analysis is an option in Surface Equipment Timing that lets you limit the total production from several units to a specific level, even if the sum of the units’ production exceeds the set level. To use this method, check the box for Perform Bottleneck Analysis and then set the parameters.

![Bottleneck Analysis Parameters](image)

The Bottleneck Parameters dialog box is found on the Surface Timing dialog under the Bottleneck Params button. The Field Name you specify must match one of the reserved words for volume, tons, or a user-defined attribute. These reserved names can be found in the Edit User Attributes section in the final report if they are not known. The Threshold value is another name for the limit placed on the attribute name. This limitation can be set for specific equipment units, and it can be set for ALL units as well. To set the unit preference order, ADD them to the dialog box to the right under the Equipment Order heading. The order can be changed by highlighting the unit (by selecting it with the left mouse button) and picking the UP or DOWN button to the right.

There are several schemes you can use to determine which units are restricted to meet to required level.
When production capacity exceeds the system's ability to absorb it, some units need to be scaled back. The options available to reduce production include:

1. **Normal Rotation** - alternates in order through the units.
2. **Hold Lead, rotate rest** - operates the primary unit at full capacity and alternates through the rest of the units reducing production.
3. **Hold tail, rotate rest** - opposite of Hold Lead.
4. **Fixed order** - maintains the order of unit preference reducing production, beginning with the tail unit until it is completely down, then reducing the next in preference order until the objective is met.

Example: There are 4 excavators on a job (Units A-D) with a capacity of 3,000 cyds per shift. All of the material must be loaded in trucks and hauled away. There are 6 trucks in the fleet with the ability of hauling 1,000 cyds per shift. Therefore, the trucks in this case are the bottleneck of 6,000 cy/shift, limiting production of the excavators.

Using the fixed order as the restriction scheme, we will limit the tail unit's production every shift that the excess excavator capacity exists. When the schedule is run, it checks the shift capacity for each shift as the program times out the progress. This slows the program down, showing a bottleneck window with the dates counting by, but keeps the production capacity in line with the desired production level. A report is generated showing which unit is reduced and by how much. An example report is shown here.
When the schedule is run and the map is hatched showing the progress, note the additional time periods for Units C and D. This shows Units C & D have been held back while the other units worked at full production. Unit D is not even working in some of the early months. There is a progress bar to show the time elapsed and time remaining for very large mineplans that take a while to run.
The report generated shows the production for a 30 day month at 3 shifts per day at 6,000 cyds per shift equals 540,000 cyds for the month, as in April below.

**Calculate:** This is the button to start the sequencing. Choosing this button will bring up a small window displaying the completion date. Or if the bottleneck parameters are being used, it will display the days counting down and the various Loops it is using in the calculations. There are two report choices shown here. The Report button will bring up the Equipment Report where the following parameters, such as start and finish dates and the days waiting or pit available are displayed. The Detailed Report will go into the Report Options Screen described next. This is the same as the Report button from the initial screen.
• **Report**: Selecting this will go into the Report Options screen. It should only be active if the Calculate button has been selected previously. This is where many settings in the schedule are set, such as the breakdown of the time periods, hatching etc. The Report Options is defined next.

**Report Options.** Each item on the dialog box is defined below.

- **Report by period**: This option runs the schedule and breaks the pits into blocks by period, such as month or year. The blocks and outlines are colored by period and displayed in the report. The report can be formatted...
may ways.

• **Report by equipment**: This option runs the schedule and breaks the pits into blocks by Equipment. The blocks and outlines are colored by equipment and displayed in the report. The report can be formatted may ways.

• **Report Only**: Choosing this option will not draw any blocks or outlines on the map. It will go directly to the Report Formatter for viewing of the data.

• **Draw blocks**: When this option is selected, the periods or equipment will be drawn as blocks of solid fill or any AutoCAD hatch pattern that is chosen.

• **Draw distinct outline**: When this option is selected, the periods or equipment will be drawn as closed polyline outlines.

• **Draw legend**: This option draws a legend and the picked location on the map. The colors are based on period, custom amounts or equipment.

• **Pastel colors**: Choosing this option draws the blocks or outlines in the pastel color region of the AutoCAD palette. It uses colors in the 11, 21, 31, 41 etc. row. If it is not selected, then it will use the brighter, primary colors such as 10, 20, 30, 40, etc.

• **Enforce custom colors**: Selecting this option will use the custom color palette the is setup with the Custom Dates and Colors Table.

• **Custom table: Dates/Colors**: This brings up the Define Ranges screen. This is where a custom date or color table can be set up. The Auto set button will bring up the smaller window for entering the starting line (row number), starting date, how often to repeat, and how long to keep repeating. The Set colors will prompt for a starting color, and the color number increment. The colors are set by picking the color box. The Pattern is the pattern of the hatch in the blocks. The Scale is the size of the hatch patterns if a hatch is used. The Layer is the AutoCAD Layer of the period. Finally, the Label is what each period will be called for reporting and labeling. The example shown here has created a weekly schedule with custom colors. The Clear button wipes out the data for starting over. The tables can be saved and loaded as CDT files. To use this option, choose Enforce Custom Colors or Custom Date Table.
Custom table: Amounts: This button brings up the Define Levels window. This is where the amount to target is set for the Custom Amounts option in the report. The amount to target is set in the first column. The next column is the color for the blocks and outlines. The colors are set by picking the color box. The Pattern is the pattern of the hatch in the blocks. The Scale is the size of the hatch patterns if a hatch is used. The Layer is the AutoCAD Layer of the period. Finally, the Label is what each period will be called for reporting and labeling.
• **Change shade color every:** This option will change the color/layer of each block or outline. There are 3 choices. Every Period (what is selected below), Year, or 5 Years.

• **Block labeling:** This pull-down is for setting the labeling options. There are 5 options here. No Block Labels will not draw any labels. Draw Actual Dates will draw the date of each period. Draw Period Names will place the period name in the block that is entered in the custom date table. Use Custom Names draws the names entered in the custom amount table. Use Custom Text Block activates the Add, Edit and Remove buttons. Choosing Add or Edit will bring up the input screen for arranging the text items in the block. First, give the new block a name. Then move items from the left side to the right, in the row desired. The Add Text button allows for custom text for prefix or suffix entry. The Add Attribute adds any attributes that exist in the schedule. Add New Line moves the added item to the next row. If this is not selected, then the next item is added to the same row, with a + as a separator. Remove will move the entire row from the Line definitions.

![Define a Text Block](image)

• **Text Size/Text autosize:** This will either place all text in the map with the defined size, or autosize it to fit in the block dimension.

• **Length-wise labels:** This option draws the text parallel with the long axis of the pits. If it is not selected, then the text will be 90 from the long axis.

• **Text Style:** Enter in an AutoCAD text style for labels.

• **Text Block Style:** This section is active if the Block labeling is set to Use Custom Text Block. Any premade blocks will appear on the list and may be selected for text orientation.

• **Report Period:** This is the start and finish date of the report. By default, the program will display the full range from the start date to the final date it needs to finish. Any date range in the middle may be used.

• **Skip format prompt:** If this option is selected, then after the blocks are drawn, a report will appear that is similar to the last one created. The program will not bring up the report formatter for customizing.

• **Sub-divide by properties:** If this is selected, the schedule will recognize any named Carlson property lines drawn on the mineplan. In the report, the periods can be further subdivided by property and owner. These are the same property lines that are used in Surface Mine Reserves.

• **Output period grids:** Choosing this option will create a grid file of the 3D surface at the end of each period, such as a month or a year. It needs the Surface Grid and the Bottom of Pit Grid. It needs at least the Bench 1 Grid filled in to make the grids. The Bench Grids will come in automatically from the Pit Attributes, where the SURFACE attribute is defined as the topography, and each benches bottom elevation is defined as SURFACE_BENCH*. If they aren't define in the Pit Attributes as such, then each grid will need to be
selected here. A new output grid path with an Output Grid Prefix is set to create new grids of each period. A new grid file is then written of each period for the pit and bench. This can be an "ultimate pit" used in other design work. It doesn't have the flexibility of other commands such as Design Bench Pit, but it gives a 3D surface of each period mined. It uses a constant highwall slope of around 80 degrees, but varies based on the grid cell size.

• **Period Polylines to Pits:** Selecting this option creates and names the outlines as Carlson pits. The names of the pits are the actual period names. This is useful if these period polylines need to be saved and re-run in the Surface Mine Reserves for additional quantities or analysis.

• **Output Spoil File:** This option creates the SPO file that is used for the timing of the spoil commands found in the Spoil menu. This output contains the nonkey waste for spoil placement and timing.

• **12 months + 8 quarters + years:** A schedule run with this option will break down the first year into 12 monthly periods, the next two years into 8, 3 month quarters, and the remaining periods will be full years.

• **Show Months of Development:** This method will use the starting day and increment by month to the same day. For example, if the starting day is on the 12th of each month, the schedule will be from the 12th to the 12th for each month.

• **Show 1st Days of Months:** This method will use the starting day and increment to the first of each month. For example, if the starting day is on the 12th of the first month, it will go to the end of the first month and then start fresh on the 1st of each month.

• **Show Years of Development:** This method will use the starting day and increment by year to the same day. For example, if the starting day is on June 15th, the schedule will be from June 15th to the next June 15th.

• **Show 1st Days of Years:** This method will use the starting day and increment to the first of each year. For example, if the starting day is on June 15th, it will go to the end of the first year and then start fresh on the 1st of each year.

• **Show Date Range:** This option is used to just display a period as a partial range. Enter a range above in the Report period windows. Then when the sequence is run, only that period will be hatched all in the same color and time.

• **Custom Date Table:** When a custom Date/Colors table is defined, this option must be selected to use it. Custom Dates/Colors are defined above.
Custom Amount Table: When a custom Amount table is defined, this option must be selected to use it. Custom Amounts are defined above.

Legend Scale: If the Draw Legend box is selected, this is the size of the legend. Sizes from 50-100 should appear legible for most mineplans with a dwg scale of 50.

Hatch: This is the hatch that is used for drawing in the blocks if the custom date or amount tables are not used. All hatch patterns appear on the list, the most common one, solid, appears at the top of the list for easy selection.

Retreat Hatch: This is used for underground retreat hatching. Disregard for surface mining.

Divide advance/retreat display: This is used for underground retreat hatching. Disregard for surface mining.

Scale: If a hatch pattern other than Solid is used, this is the scale it will be drawn at. Sometimes trial and error is needed to get the best scale, as different patterns look better at different scales.

Layer: This is the AutoCAD layer that the blocks and outlines will be drawn in, if no other options are used.

Layer by year: The blocks and outlines will be layered by year. The year will appear as a suffix to the layer name.

Layer by period: This option will put each period on its own layer. If there are many periods, it will create many layers which can be a hassle.

Of, Sum for whole mine & Stop at last period: These options are only active when using the Custom Amount Table. The "Of" window is for selecting what is being target for custom amounts. The options are similar to Surface Production Timing: Total Tons, Key Tons, Waste Tons, Total Area, Mined Area, Total Volume, Waste Volume, and User Grid. Sum for whole mine will keep a running total for summation in the report. Stop at Last Period will end the schedule at the last entered row in the Custom Amount Table entered above.

Split Report by Strata Fractions: This option will utilize the tonnage and volume factors stored as pit attributes and report out the volume and tons of each named seam, not just composite Key Tons and Nonkey volume.

Multi-Bench Mining Example Setup:
The defining of equipment, crews and equipment calendar are (potentially) one-time operations. Similarly, the making of the "Pre-Calc Grids" geologic model need be done only once in advance of numerous timing runs. Surface Equipment Timing, also distinct from Surface Production Timing, allows multi-bench mining by use of different equipment or the same equipment mining different benches, with different production rates. Since single-bench mining is a subset of multi-bench mining, this will illustrate the command with a multi-bench example. Surface Mine Reserves is one of three methods to place quantity and quality information into the pits, by bench. This example will use Surface Mine Reserves. If there are two benches, Surface Mine Reserves must be run twice, one time for each bench. The dialog within Surface Mine Reserves should be completed as follows for Bench 1:
The key is to choose "Selected" strata (for benching) as well as "Use Named Pit Areas" and "Store Results in Pits". You should also select "Calculate Strata Qualities" to assign quality information to the pits. If single-bench mining is conducted, you may omit the "Selected" option. Other items in the dialog are set according to user preference.

Note the option "Output Thickness Grids". If this is not selected, total quantity and composited quality information is placed in the pits, and mining across a single pit is proportional. However, if the "Make Thickness Grids" option is selected, mining across the pits picks up the varying of the overburden thickness, coal thickness and quality information. For small pits or "blocks" as they are sometimes called, storage of total information will still lead to reliable results. Thickness grids are recommended for large and long pits, where the thickness will vary. The choice of "Selected" strata requires that the user select which strata will be mined in Bench 1. The following Choose Strata dialog at will appear:
Holding the CTRL or SHIFT key down, will select Overburden and C1 to mine down to the bottom of the first coal (C1). Bench 2 would be comprised of Parting and C2. Following two runs of Surface Mine Reserves, new information has been added to the pits. Pits contain up to three categories of information: pit name (verified by using "Identify Pit Polylines"), pit direction and pit quantities/qualities organized by bench. Pit quantities and qualities are needed only for Surface Equipment Timing, and can be verified using the command "Edit Pit". For example, the information in Edit Pit is shown below. Select the "Attribute" option to reveal the quality attributes.

You will note that Bench 2 has Bench 1 (referred to as TOPO-A-1-B1) as a "precedence" bench. In other words, you cannot mine Bench 2 unless you first mine Bench 1. Lower benches are automatically set to require prior mining of upper benches (The ordering of the mining comes later!). The Pit Attributes show any attributes set by Define Pit Attributes. Some may be seen here.

Assuming that a calendar has been established (multiple calendars can be saved and recalled), and assuming that equipment has been defined, we are now ready for Surface Equipment Timing. After selecting OK on the Mining Project screen, this is how the dialog appears prior to making any selections.
The first step is to "Add Equipment". In our two-bench mine, we will use one piece of equipment for the upper bench (overburden) and different piece of equipment for the lower bench (parting). Technically, separate equipment would probably be used to remove the coal, but in this example, the coal is not included in the schedule quantities, just uncovered reporting. In fact, a 4-bench mine could be set up that considers each of the two coal seams as separate benches. In reality, however, the overburden and parting removal rate will typically govern the overall progress of the mining. When "Add Unit" is selected, the following dialog appears.

Select the equipment and add them one at a time. The draglines used here are defined based on 3, 8 hour shifts (Shift 3 can be ignored if we plan on a 2-shift system). The "Availability" option can be used to de-rate the mining speed in the Edit Equipment. Any of the above items can be revised from within Surface Equipment Timing. The next step is to assign "Dragline" to Bench 1. It is best to Sort by "Bench, Pit" and then Select "Bench 1", using the options at middle right in the Surface Timing Dialog. These leads to the following appearance:
It is also important to note the option "Skip Coal for timing" at the lower right of the dialog box. Here you can base all progress on the NonKey overburden and parting only, on the assumption that the loaders or other equipment digging the coal will "keep pace" with the equipment removing the overburden and interburden. If "Skip Coal for timing" is not selected, the coal volume will be included in the total quantity mined by the equipment. We can add a second piece of equipment, then highlight it within the Surface Timing dialog and assign all the remaining pits to it (Select All or Bench 2, then Assign). Note also that we can add a delay between completing the Bench 1 pit and beginning the Bench 2 pit. Delays are automatically inserted below the highlighted pit, so if a pit is highlighted, a delay will be added below it that can be moved up or down also. There is a prompt to add this as a calendar or schedule delay (described above). Shown below is the assignment for Bench2.
To complete the calculation, fill in the Starting Date (if the default is not correct), then click on Calculate. This leads to a completion date and the option of a unit report or going directly to the Report Options screen. The Unit Report is very instructive because it highlights when equipment has been idled. Our Bench2 dragline is waiting each time for the "slower" Bench1 dragline to complete bench 1 before it can launch into bench 2. The planner could try lower rated equipment, or reverse the assignments of the equipment, or simply re-shuffle the assignments in any desired manner to maximize efficiency. The last step is to choose "Report" when returned to the Surface Timing dialog which brings up the Report Options dialog.

This example will show the first days of months. This leads to the final hatching shown below as bench 1 (the bench 2 layers were frozen for better appearance), as well as the quantity report which can be formatted many different ways and exported to Excel or Access:
Notes and Comments on Equipment Timing:
Equipment Timing can mimic Surface Production Timing through selection of "Custom Amount Table" at the base of the Report Options dialog. This would be an alternative way of getting to custom table amounts, since the equipment is removed from the equation and is therefore irrelevant. This will target tons of coal, yet report out how many dragline hours need to be scheduled to uncover the coal.

If there are multiple seams (both Key and NonKey) assigned to one bench, the program will report a tonnage and volume factor that applies to each strata. This factor can be used in the User Attributes to calculate the tonnage and volume of each separate strata instead of just a composite number of Key and NonKey.

While Surface Production Timing reports total quantities broken out by seams or specific strata, Surface Equipment Timing only reports totals for all key strata (e.g. coal) and overburden. However, Surface Production Timing does
report specific quantities (composited) for each bench. Therefore, our 2-bench mining example will report quantities for Bench 1 (coal C1) and Bench 2 (coal C2). With sufficient benching, the individual strata quantities are retained. For one-bench mining, all multiple strata are composited in the final report.

To practice "what-if" scenarios, use "Undo Report" within the Surface Timing dialog, which will remove the colored hatching, allowing revision of equipment assignments and another practice run.

**Prompts**

Select all pit polylines.

Select objects: *Pick all polylines*

**Pull-Down Menu Location:** Surface Mining menu, under Surface

**Keyboard Command:** timepit

**Related Commands:** Surface Mine Reserves, Assign Directions, Surface Project Manager, Assign Timing Grids, Import Timing Data, Define Pit Attributes

---

**View 3D Surface History**

This command allows you to modify and playback the grid sequence history generated by several Carlson commands. The command initially displays a list of grid files in the sequence. You can add more grids, modify grid colors or change the grids order. When editing is complete, pick the OK button which brings up the playback 3D viewer window.

In the bottom part of the window there is a row of buttons allowing user to move from step to step in a grid sequence. On each step the grid displayed has elevations of the grid assigned for that step and the color of the last grid when the elevation at a particular location changed. For example the unaffected regions will have the color assigned to surface grid.

The row of buttons at right controls the view response to mouse drags and the shading. The zoom button activates zoom mode, where if you hold left mouse button and drag the mouse pointer up or down the picture zooms out or in correspondingly. In the rotate mode, the horizontal drag rotates the X axis (around Y), the vertical drag rotates the Y axis around X. The circular movement along the periphery of the picture rotates picture around the Z axis.

When pan button used, the picture will pan if mouse is dragged with the left button pressed.

The shade button turns the shading of the grid on or off.

This GSQ file can be used in Surface Mine Reserves to automatically calculate the quantities by bench for the pits with highwalls.

**Prompts**

**Grid Sequence File file selection dialog** Choose the .gsq file to update.

---

**Here are a couple of examples:**
Removing the coloring after the timing routines are completed may be a tedious task. This routine removes and erases all text labels and hatching from surface pits and underground panels for a specific bench or mining direction.

**Clear Timing Report**

Removing the coloring after the timing routines are completed may be a tedious task. This routine removes and erases all text labels and hatching from surface pits and underground panels for a specific bench or mining direction.
in one step. It is a quick and efficient procedure, even for objects on many layers. Items are permanently removed from the drawing screen. It supports both surface and underground mining.

Prompts

For Surface Timing:

Enter Bench Number to Remove coloring for (Bench Number/<All>):
Select parts of mineplan to have timing coloring removed:
(Bench Number/<All>): press Enter

Pulldown Menu Location: Surface
Keyboard Command: utime_clear, stime_clear

Haul Fleet Manager

This command manages the haul truck fleet. There are about 20 trucks included with the program by default, and other trucks can be added based on the type used on site. These input values are based on basic fuel and performance comparisons and applied to all trucks in general. Most mining trucks have about the same haul speed, plus or minus 3%-5%, or only a few mph or kph. What does vary is the engine size, road conditions (Effective Grade) and speed. The Effective Grade % is the Actual Grade + Rolling Resistance. The input screen appears as follows.

Resistance data for the highlighted truck appears below, and is in columns for Total Resistance %, Loaded Fuel Duty Cycle %, Loaded Operating Speed, Empty Fuel Duty Cycle % and Empty Operating Speed. Speed will be in mph or kph, and is determined by the setting under the CAD Drawing Settings.
Saved trucks are put into the text format as shown here. Any new trucks can be entered as ASCII text and imported.
The following graph illustrates the relationship between fuel and speed performance, and is how the Resistance Data table is populated. This will allow for user entry of new trucks, if a new truck is added with the green "+" button.

Once the engine size and effective grade is known, the haul speeds and fuel duties for both loaded and empty are derived. This allows for estimating time and net fuel consumption. For example, here is how it is calculated.

Truck Engine = 1491kW
Engine Duty = 100%
Fuel Consumption = 0.25 (l/kW) * 1491 (kW/h) * 100% = 373 (l/h)

The data can be fine tuned with real dispatch information from mining operation.

- Thank you to Peter Nahan of Goldcorp for his suggestions, references and help in developing this command.

**Pull-Down Menu Location:** Reserves/Timing in Surface Mining

**Keyboard Command:** haul_fleet

**Haul Road Manager**

This command builds and links the haul road network, recognizing 3D polylines and adding them to the network. All possible roads must be drawn as 3D polylines in CAD, either draped onto the surface model, or snapped to contours. Individual layers can be used for clarity to see the roads in the manager by color and layer. There aren't any tagged segments to select the first time this command is run, so the preview image will be blank. The segments must be added by picking the green "+" button to bring them into the editor.
• **Preview Window Display:** The upper preview window has four buttons for Pan, Zoom Realtime, Rotate and Zoom Extents.

• **Add Segments:** Selecting the green "+" button will prompt for selecting the 3D polylines in CAD to add to the haul road network. This must be done initially if there are no segments found.

• **Remove Segment:** This green "X" button will remove the highlighted segment from the manager.

• **Pick Segments:** The Select from Screen, Pick Segments button is used to pick already named haul road segments, and add them to the manager. They must be already tagged with the Add Segments for them to be recognized.

• **Split at Grade Break:** Selecting this button will split the haul roads into smaller segments, based on the percent grade tolerance so that each segment is within that slope tolerance. This isn't a requirement, but the idea is to have segments with constant grade as the truck speed is depended on the grade of the road, and this will divide the road into smaller segments if desired. This will also break the 3D polylines into the smaller segments, so it is recommended to Save the drawing as a new name before breaking, so that there is a back up to go back to if necessary. There are two dialogs that appear from this command. It will only break the highlighted segments, so it is easy to control which roads are being divided.

![Split Segment at Grade Break Dialog](image)

![Selected Segment Split Dialog](image)

• **Delay Points:** These are point symbols inserted into the drawing the will trigger a delay event for the specified number of minutes. Examples would be a stop sign at an intersection, or a one lane bridge where trucks have to stop. Any symbol from all of the libraries can be inserted to represent the location. These delays will be accounted for when the trucks pass over that spot.
• **AutoSet**: The AutoSet Segment Parameters based on Grade option colors all the haul roads based on their percent slope. This is an option to graphically see the slope of each road, simply by the color it is drawn in. This will also change the color of the 3D polylines in the plan view. They will stay on their original layers, so they can be set back to color ByLayer if desired. The slope interval was set here to a 1 or 2%, starting at -5%, as an example.

Notice in the image below, that the new colors are set by the percent slope of the road. These colors are now different than the initial image where they were colored by the layer.
Now that the haul roads are defined in the manager, they can be used in the haul road processing commands.

**Pull-Down Menu Location:** Reserves/Timing in Surface Mining  
**Keyboard Command:** haul_roads

**Haul Cycle Analysis**

This command combines the haul routes and the haul fleet and calculates the time and distance of all the possible travel routes. It utilizes the predefined haul road routes, and the trucks from the haul fleet for analysis. The initial prompts are to select the beginning point and ending points for the truck route. These are usually the loading and dumping locations. The order they are selected is not important, as there is an option to define if the truck is starting as loaded or empty. All slopes and distances are taken into account based on the original 3D polylines of the truck routes. This is a very automated routine. Once the starting and ending points are selected, the dialog displays all the possible road routes. They can be sorted by length, segments, time, or any of the column headers by clicking on the header buttons. When each road is highlighted in the spreadsheet below, the route is shown above in the plan view, as bolder, thicker lines. Many different types of reports are generated leading aiding in the haul truck network design.

- **Assign Haul Truck:** The dropdown displays the list of trucks to choose from. Select the truck to analyze and run through the route. The Fleet button will bring up the original dialog where the truck fleet was created, for
• **Truck Starts (Loaded or Empty):** This option determines whether the truck begins the route at the loading or dumping location. This will be used in the route where the direction of travel, and slopes are accounted for either empty or loaded.

• Calculate (Fleet Size or Production): There are two main parameters to solve for, the number of trucks or the tons per hour hauled. Changing this option will make difference on the appearance of the main dialog. The default is Fleet Size, where it will calculate the number of trucks needed to meet the production. Changing this to Production will allow for entry of the number of trucks to use, and then calculate the tons per hour that can be produced/hauling. These changes are shown in red here.

• **Production Rate or Number of Trucks Used:** This input will be what controls the calculated output. Either enter in the tons needed per hour, or the number of trucks that will be used. Everything is linked, so changing the number of trucks will recalculate the production, allowing for fine tuning the planning process.

• **Estimated Queuing Time:** This is the time in seconds for the truck to add to the turn around point for loading or dumping.

• **Minutes per Production Hour:** This is the actual number of minutes per hour that the truck is hauling. Factors such as shift change, breaks and other delays can be accounted for here.

• **Truck Filling Efficiency %:** This is the average percentage of the trucks load capacity. For example, if it is a 100 ton truck, and the filling efficiency is 94%, then each truck will haul 94 tons on average.

• **Truck Availability X Utilization:** Another variable to account for availability and utilization can be entered here. This percentage is multiplied by the minutes per production hour to determine the overall working time.

• **Use Report Formatter:** This option will use the Carlson Report Formatter instead of just the text window. This allows for more custom report building.
• **CAT FPC Reports:** There are 3 types of CAT FPC reports this will create. The ASCII, GPS and Course Reports are shown here with their examples.

CAT FPC ASCII Report Example:

![CAT FPC ASCII Report Example]

CAT FPC GPS Coordinates Report Example:

![CAT FPC GPS Coordinates Report Example]
• **Cycle Report**: This standard report will use the Report Formatter, or the Text Window to display the calculated and entered data.
Prompts

**Delay: Intersection Merge** (will be a pre-named delay name)

[near on] **Pick start point on Haul Road:** select where the truck will begin, usually where it gets loaded at.

[near on] **Pick end point on Haul Road:** select where the truck will end, usually where it unloads/dumps at.

**Pull-Down Menu Location:** Reserves/Timing in Surface Mining

**Keyboard Command:** haul_cycle

**Surface Menu**

The Surface menu has commands for cross section and surface modeling.
Define Dragline Equipment

The description of available draglines is created and edited using this function. While the most important parameters are those which define dragline operational range for the Cut and Place commands, there is a number of others which are used in the 3D dragline modeling. Bucket size is used to calculate a number of cycles needed to transport a given amount of material, which is used to get the time spent on material handling, together with swing speed and calculated average swing angle. Dragline house sizes are used to estimate how the dragline travels within a given area, while maximum speed gives the time required to complete these moves. Finally, if operational cost is specified, the total cost will appear in the final report. The first screen shows the draglines that are defined within the program.

Choosing Add or Edit will bring up the next screen. Notice the Required Sizes section. These must be all filled in. The remaining windows are all optional. Defaults will be used if they are not defined in the 3D Dragline command. Depending on the Drawing Setup, either CY and FT, or CM and M are displayed as the units to enter. Carlson saves this information in the "dragline.dta" file in the USER folder of Carlson. The Save and Load buttons of the main dialog allow you to save and recall the dragline settings to a .DLN file.
The Save and Load buttons allow you to save and recall the dragline settings to a .DLN file.

**Prompts**

**Keyboard Command:** edit_draglines  
**Prerequisite:** None

**3D Dragline**

This command gives a 3D approach to the design and placement of dragline pits. Unless all the seams are perfectly uniform and horizontal, and pits are straight, the usual cross-section dragline modeling with range diagrams will not provide the appropriate level of precision and visualization. This function allows you to specify the cut and spoil areas and watch the ground surface change in 3D. Surface updates are recorded on every step and may be played back later.

The first step is to define the three grid files at the top of the Dragline project window. They are the original topo grid file, the final grid file (create a new grid if one doesn't exist) and the top of the Key strata grid file.

The Dragline parameters section is for choosing the dragline. Then set its Efficiency %, Fill Factor %, Fill time (seconds) and Dump time (seconds). The Slope and Swell factor are set next, in the center of the screen. Slope is...
either set as ratio or percentage. A swell factor of 1.3 gives 30% swell.

Finally, on each step of the sequence, three pre-drawn closed polylines are chosen: a polyline enclosing the area within which dragline is allowed to move, a bottom of cut area polyline (usually the next pit line), and a top of spoil area polyline (usually the previous pit line). The program then offsets the dragline polyline by the maximum reach distance and crops out the portions of cut and spoil polylines within the dragline reach. These modified polylines will be used in calculations. This allows the program to use larger cut and spoil polylines and move only the dragline on each step.

The program then calculates the overburden volume by using surface grid on top, coal top grid on bottom, and the highwall calculated using the cut polyline and given cut slope. The cut polyline is projected onto the bottom grid prior to calculations. The swell factor is then applied to the freshly cut material, while the rehandled material amount is taken as is. If the spoil polyline is a 3D polyline, its profile will be the elevations of the polyline. Otherwise the spoil ridge is considered to be at the same elevation. The spoil polyline is then moved up and down until the amount of the material between the spoil pile and the existing surface matches the given amount. If any dragline parameters are too small to physically mine here, then error messages, are displayed accordingly.

The calculated cut, spoil, rehandle and timing results are then displayed in the dialog. You may then modify the selection of cut, spoil or dragline polylines and proceed to the next step, or use the Stop button to exit. With use of the history file, the scheduling may be restarted from the point it was finished. Surfaces are updated with each step. To get to the next step, simply select then next 3 polylines, change the first two grid names (the top of coal usually remains the same) and choose next. After each step, the report formatter appears, allowing for customized reports of the steps.

Range Diagram
The Range Diagram command is an interactive tool that displays graphics which are dynamically updated when adding or editing values in the spreadsheet text below. This is a quick and easy way to find parameters such as pit width, or to size a dragline to fit the geology. Output includes both drawing the sections in CAD and printing out reports as PDF files, where each step is a separate page. Each option is detailed below.
**Input Parameters**

- **Top Elevation:** Sets the top elevation of the ground surface
- **Pit Width:** Sets the width of the open pit. This could be the previous pass, or a boxcut
- **Spoil Angle:** Sets the angle of repose of the spoil pile
- **Cut Width:** This parameter is the width of the new cut. This is the field that is frequently changed to see what pit widths will work
- **Cut Direction:** This determines whethere the cut is advancing to the right or left in the graphics window. It is just a mirror image of either.

**Dragline and Seam Data**

- **Dragline:** This dropdown displays a list of predefined draglines. These can be added and edited with the separate command Define Dragline Equipment.
- **Reach:** This displays the horizontal reach of the selected dragline. Since it is colored blue, it cannot be edited here.
- **Max Height:** This displays the vertical dumping height of the selected dragline. Since it is colored blue, it cannot be edited here.
- **Max Depth:** This displays the vertical digging depth of the selected dragline. Since it is colored blue, it cannot be edited here.
- **Swing Angle:** This parameter controls the swing of the dragline. Enter in values from 0-90 degrees.
- **Offset from Crest:** This sets the distance for the dragline center pin offset from the crest of the highwall.
- **Strata:** This is the list of strata added to the cross section.
• **Key**: The Key setting controls whether it is waste (NO), and coal (YES).

• **Thickness**: This is where the thickness of each strata or bench is entered. The section will update graphically when a new value is entered.

• **Face Angle**: This setting controls the highwall angle of each strata. It will update graphically with any change here.

• **Swell%**: This is the swell factor of the material as it is moved from in-place to the spoil.

• **Spoil**: This option controls whether to place the waste into the spoil with the dragline. If it is pre-stripped and hauled away, or interburden removed with other equipment, then the setting here would be NO.

• **Key Cut**

  • **Cut**: The Key cut gives the option to split the overburden block into two sections. The choices are None, Left or Right. An image of Left and Right is shown here. This allows for moving the dragline to get more spoil distance.

  **Left Key Cut**

  ![Left Key Cut Diagram](image)

  **Right Key Cut**

  ![Right Key Cut Diagram](image)
• **Width**: The width is entered in to set the horizontal distance of the Key cut.

• **Angle**: This is the angle of the key cut highwall.

• **D/L Offset**: This is the distance for the dragline center-pin from the crest of the highwall. It is usually more than the initial offset defined above.

• **Spoil**: This option determines whether to spoil or not. If it is hauled away by other equipment, then this should be NO. If it is spoiled with the dragline, then it should be YES.

• **Add Dragline (+)**: This option places the dragline on another strata. It can be the same dragline on another pass, or it can be another dragline if there are more than one working in that pit. Additional Draglines or passes show up as different tabs below the spreadsheet. Shown here is the same dragline as dragline2, working on the IB3 seam on another pass deeper in the pit.
- **Remove Dragline (-)**: This takes away the dragline tab that was added to the diagram.

- **Add Strata (+)**: Use this button to add each strata to the diagram, such as OB, Coal or interburden. Once it is added, then pick in the cell to give it the proper name.

- **Remove Strata (-)**: This takes away the strata that was added to the diagram.

- **Move Up or Down**: This moves the selected strata up or down in the section.

**Graphics Window**: The ground surface is color coded. When it is green, then the spoil will fit into the pit and not cover the coal.

- **Pan**: Pans around in the window

- **Zoom**: Zooms in and out in the window

- **Zoom Extents**: Zooms the diagram to fit the entire display window.

- **Settings**: This button brings up the following dialog for settings:
– **Show Current Dragline Only**: This should be on to see the dragline locations with a Key Cut, and also to see the other dragline locations on other passes.

– **Label**: These options will label the angles, distances, thicknesses and strata names in the display window.

**Output**: The output shows up in the lower right. It displays the area of the cuts and fills, as well as dimensions of each step in the section.

**Draw**: This option will draw the steps in CAD as polylines with fill. It will prompt for the starting point in CAD to draw them. Exit the command to see them in CAD. Here is an example of what it draws, their colors and entities.
**Report**: The report button will create a PDF document where each step in the section will be on a separate page. Then at the end, one final page will show all the steps together with the finished section.

**Pulldown Menu Location**: Surface

**Keyboard Command**: ranged

**Prerequisite**: dragline equipment defined
Dozer Push

This command calculates the volume and distance moved for a dozer push from a highwall into a pit. The program also draws closed polylines that represent the cut and fill areas and the path of the dozer. Dozer Push works with a cross-section view of the pit. Before running this routine, you need a polyline that defines the existing ground including the top surface, highwall and pit bottom. A second polyline is optional for the Cut Bench to push along and also optional is one for the bench bottom. The Cut Bench polyline could be the top of coal for example.

The Dozer Push command starts with the dialog box shown here:

- **Horizontal Scale** and **Vertical Scale**: These are the scale factors for the drawing to generate text, symbols, and vertical exaggeration, among other things.

- **Cut Push Percent**: Push Percent is the percent grade the dozer cuts down from the surface. Enter as a percent.

- **Pit Push Percent**: The Pit Push Percent is the percent grade that it will push out into the pit before spilling over to the repose angle. Enter as a percent, positive or negative.

- **Repose Angle**: Repose Angle is the angle that gravity pulls down the fill slope, as it spills over the edge. Enter as an angle.

- **Wedge Angle**: Wedge Angle is angle the dozer will cut down when the Use Wedge Angle option is on. Enter as an angle.

- **Spoil Percent**: Spoil Percent is the percent grade of the spoil pile as the dozer pushes uphill. Enter as a percent (up). When there is not enough room in the pit to fit the cut at the pit push percent, the remainder will get placed by building up a spoil pile at this specified Spoil Percent. The program will prompt for a base point to start building the spoil slope. This point is typically at the top of the coal so that the spoil pile will not overlap the coal and create extra rehandle.
• **Cut Swell Factor:** The Cut Swell Factor is multiplied by the cut to determine the amount of fill. Enter as 1.2 for 20 percent swell.

• **Sequence Number:** This is the sequence step number that is added to the SEQ sequence file for Process Dragline Sequence.

• **Direction to Push:** The dozer must be specified to push to the right or to the left.

• **Define Cut Depth By:** The Polyline Method will prompt to select the Cut Bench Polyline. This is the surface that the dozer will cut down to. The dozer cut will be located by finding the top of the pit and then moving back along the top surface for the Cut Width entered below. The top of the pit is identified by finding the first grade that is greater than or equal to the Push Percent grade. Then the dozer will cut down at the Push Percent until it reaches the bench polyline. The Pick Points method will prompt for the lower left point and the lower right point. The line drawn between them is then set to the cut surface. This controls the cut width, so the value entered below for Cut Width will not be used.

• **Output Step to Sequence File:** Turn this option on to add the step to a new or existing SEQ file. This file is processed with Process Dragline Sequence.

• **Store Step to Report File:** This option will create or append a CUT file that is processed with the command Dragline Section Report.

• **Find Cut/Fill Balance:** The Find Cut/Fill Balance is a special option that finds the offset distance where the cut and fill balance and draws the push polyline. With this option, the bench polyline is not used.

• **Label Push Distances:** This option will label the distance from the centroid of the cut block to the edge of the highwall where the repose angle.

• **Cut Width:** When using the Polyline method to Define the Cut Depth, this is the total width of the push, from the Cut Push distance down to the Cut Polyline, then across the Cut Polyline the remaining distance to get to the entered width.

• **Use Wedge Angle:** With the Wedge Angle option, the cut will begin by starting at the top of pit and moving down at the Wedge Angle for the specified Cut Width. It will continue down at the wedge angle for the specified horizontal width. The Cut Push Percent is not used if the Wedge Angle is used.

This command does one push at a time. To perform multiple cuts, run Dozer Push for each one. For every push, a cut area and fill area are drawn as closed polylines. The ground polyline and bench polyline are also updated to represent the modified surface. The centroids of the cut and fill areas are used to calculate the push distances. During a stage of the dozer push, there might be rehandle where some of the cut area includes previous fill areas. There is an option to deal with rehandle by selecting the closed fill area polylines that were drawn in a previous Dozer Push. The amount of rehandle is reported and the swell factor is not applied to the cut in rehandle. When there is not enough room to drop the push into the pit, the fill needs to be pushed up to a spoil pile. The program automatically detects this case and prompts for the bottom bench polyline for the spoil start. The end of this polyline is where the spoil grade begins.

Shown next are some dozer push examples with the important points labeled.
Prompts

This command handles many stages of the dozer push. Which values to use from the dialog and the prompting depend on the stage of the dozer push.

Select existing grade polyline:
Pick lower Left cut point:
Pick lower Right cut point:
Select fill areas to rehandle (Enter for None).
Select objects:
CUT (bsf): 9182.6 REHANDLE (bsf): 0.0 FILL (lsf): 9182.6
PUSH: 141.4,3.6%
Pick Point for Label (Enter for none):
Select existing grade polyline: pick the ground polyline
Select cut bench polyline: pick the bench polyline
Select fill areas to rehandle (Enter for none)
Select objects: press Enter
Cut: 308.7 Fill 308.7
Pick Point for Label (Enter for none): pick a point
Select existing grade polyline: pick the ground polyline

Pick Point for Label (Enter for none): pick a point
Select existing grade polyline: pick the ground polyline
Select cut bench polyline: pick the bench polyline
Select fill areas to rehandle (Enter for none)
Select objects: pick the rehandle polylines
Select objects: press Enter
Select bottom bench polyline for spoil start: pick the bottom bench polyline
Pick Point for Label (Enter for none): pick a point

Pulldown Menu Location: Surface
Keyboard Command: dozer
Prerequisite: Surface and strata polylines

Draw Dragline Limits
This command draws an outline in profile view of the dragline reach, depth and height limits. The program draws the limits of the dragline as polylines in the current layer. These limit polylines serve as guides in other dragline commands like Cut & Place. Also, these dragline commands will check the dragline limits and report if the dragline limits are exceeded when processing the sequence file. The dragline parameters are set in the Define Dragline Equipment command. Before starting this command, the dragline should be defined in Define Dragline Equipment and the surface where the dragline sits should be drawn as a polyline in profile view. This polyline can be drawn with the Draw Fence Diagram command or the profile commands in the Civil Design module.

The window prompts for the horizontal and vertical scale. This is to determine the vertical exaggeration if any. There is an option to draw an icon of the dragline. Otherwise, the limits are only drawn as polylines. Choose a direction for the boom to be facing, left or right. The draw swing angles option will label the angles along the top of the limit polyline. The Group Dragline Entities will keep it together as a block instead of individual polylines. If the program detects that dragline limits are already in the drawing, then there is an option to erase the existing limits. This option is useful for automatically erasing old limits before drawing the new limits, as the program tracks where the dragline is located to measure the reach. Then pick the surface polyline and where along the polyline the
dragline is located. There is an option to specify the dragline location by picking a reference point such as the top of the highwall and then entering an offset distance from the reference point to the center pin of the dragline (left offset is a negative value).

**Prompts**

**Draw Dragline Limits Dialog**  
**Choose Dragline dialog**  
**Erase old dragline limit polylines [Yes/No]?**  
**Y for Yes if it is in the drawing**  
**Select ground polyline:** pick the polyline  
**Pick reference point (Enter for None):** pick a point  
**Dragline distance from reference:** -50 Negative for left, positive for right.

**Pulldown Menu Location:** Surface in the Mining Module  
**Keyboard Command:** dlimits  
**Prerequisite:** Surface polyline in profile view

**Cut and Place (Spoil Removal)**

This command removes a cut area in cross-section view from a surface polyline and places a spoil pile of this area. Before starting this command, the surface should be drawn as a polyline from left to right. One way to draw the polylines is to use the Fence Diagram routine. In Fence Diagram use the option to draw the polylines as single polylines instead of closed polylines (with no hatching). Also, if there is an existing pit, turn on Draw Surface Polyline to make sure the surface line extends across the pit floor. The Draw Dragline Limits command can optionally be run before Cut & Place to draw an outline of the maximum reach, height and depth of the dragline.

Cut & Place first brings up a dialog for setting the scale. The Horizontal Scale and Vertical Scale are used to determine the vertical exaggeration of the cross-section view. The Cut Swell Factor will be applied to any new cut areas. The Cut Volume Swell Factor is multiplied by the cut area to determine the fill area of the spoil pile. The Top Spoil Width is the flat width at the peak of the spoil pile in feet or meters. The Highwall Angle is used with the Define Cut Area By Points option as the angle from the picked points at the bottom of the cut area up to the surface. There are both left and right windows. The Repose Angle is the angle of the spoil pile. This can vary, as shown later in an extended bench example. All four of the Angles should be entered in as degrees. The Label Areas option will draw text for the cut and fill amounts, prompting you to pick the text locations. Prompt for Snap activates a snap dialog box during the picking phase of the routine. Track Undisturbed Ground Polyline should be turned on to track rehandle, to make sure it is not swollen more than once, and for reporting rehandle quantities. The Sequence Number window is for entering in the step number for the sequence file if the Store Step to Sequence File is being written. The Spoil Placement Method allows for selecting the position of the Left Toe, Right Toe, or the Top of Pile. These locations will be constant when processing the sequence. The Define Cut Area is either by Points, where you select the lower left, then the lower right cut points, or by a pre-drawn closed polyline representing the cut block.
The Store Step to Sequence File will write out a SEQ file for later processing with Process Dragline Sequence. This file should be set to New for step number 1, then set Append/Revise for any further steps from 2 or more. This method will take the one range diagram template and apply it to the entire pit along a centerline. The Store Step to Report File is used if the user is running cut and place on multiple cross-sections. The file should be new for the first Station, then set to Append/Revise for additional stations. These are processed with the Dragline Section Report commands.

When picking points, there is an option to select a strata polyline which will be used as the bottom cutoff for the cut area. Also while picking the points, there is a real-time window that shows the point offset, slope and distance as you move the cursor. Once the point is picked a snap dialog allows you to adjust the picked point. For example, you could use the real-time window to visually pick the right cut point. The actual picked right position could be 201.32 from the left point and then you can the snap dialog to round the position to 200. This adjust point dialog only appears if the Prompt for Snap option is on. You can also specify a reference point by typing ‘R’ for the Reference option at the command prompt. This option will prompt you to pick a reference point in the section. For example you could choose the toe of the existing highwall as the reference point and make the right cut point offset by 10.0.

After choosing the cut area, the spoil pile is placed by picking a point to place the spoil. This point can be either the left toe of slope, right toe of slope or top of pile. After defining the cut and spoil, there is an option to go back
and adjust the cut or spoil points. Select L, R or S for left point, right point or spoil location. Adjusting the cut points will automatically resize the spoil pile-watch it dynamically change. Once everything is set, press Enter to end the routine. The surface profile polyline is redrawn with the cut area removed and the spoil added. The changed segments of the original surface are drawn a different color, usually gray.

The user input for this command can be saved to a sequence file (.SEQ) for the Process Dragline command or a section report file (.CUT) for the Dragline Section Report command. With the sequence file active, the program will prompt for a centerline reference point which is the point in the cross-section view that the centerline for Process Dragline passes through. It needs this point to locate the cross-section horizontally in the plan view relative to the centerline drawn in plan view. If you choose a strata polyline, the program will ask for the strata name of this polyline. The Process Dragline command will then prompt for a grid file that models this strata name. The data that is saved includes the depth and offset of the cut points, the spoil pile offset, and the slopes. Besides specifying the sequence file name to write to, the sequence number is also stored. This number orders the steps in Process Dragline. For the Dragline Section Report, the program will store the station, sequence number, and cut and fill areas.
The Track Undisturbed Ground Polyline option is for calculating rehandle. With this option on, the program will prompt for the existing ground polyline as usual plus an additional undisturbed ground polyline. The undisturbed polyline is the same as the existing ground polyline except that the undisturbed polyline does not have the spoil piles. One way to start this process is just copy the Surface line onto itself, then move one away from the other on one of the ends for ease of selecting for the first cut. After the first cut, it should be easy to select one or the other. Cut & Place will update the undisturbed polyline by removing the cut area and will not add the spoil pile. The program will also report any rehandle using the undisturbed polyline. The swell factor is not applied to the rehandle.

This command will also fill in for some of the Dozer Push shortcomings. If there is a simple extended bench needed, the set one of the spoil slopes to 0 and it will create a flat spoil for that step. Be sure to hit enter when prompted for the top of coal line. The next cut could be a pre-drawn, closed polyline or a series of cuts to remove the material. The lower right cut slope in the case could be the same as the spoil slope to create the left slope of the spoil.

**Prompts**

Prerequisite: Surface polyline in profile view from a Profile or Fence Diagram. Grids of the seams if writing sequence file.

Cut Only (Coal Removal)
This command is similar to Cut & Place. Cut Only removes a cut area in cross-section view from a surface polyline. The difference with Cut & Place is that this command does not place the cut area as a spoil pile. The cut area is just removed from the surface polyline for operations like remove coal. Try to stay away from a 90 degree face on the coal, AutoCAD doesn't like vertical faces (89 is entered below). The Type of Cut chooses between Coal (Key Only) and Prestrip (Non-Key Only). This setting is used in reporting and doesn't effect the rest of the routine. The same prompting and snap dialogs appear here as in the Cut and Place command.
Prompts

Prerequisite: Surface polyline in profile view

Flatten Spoil Top

This command takes a surface polyline drawn with a spoil pile and flattens the top of the spoil pile so that the horizontal distance across the top equals the user-specified distance. It will either push to the left, right or both directions. This step can be stored to a sequence file (.seq) for the Process Dragline Sequence command.
Chapter 16. Surface Mining Module

Before Flatten Spoil Top
Prompts

Select pile to flatten: *pick the surface polyline near the top of the spoil pile*

Pulldown Menu Location: Surface in the Mining Module

Keyboard Command: spoil

Prerequisite: Surface polyline in profile view with spoils

Cast Blast Profile

This command applies a blast profile to a cut area in cross-section view. Before starting this command, the surface should be drawn as a polyline from left to right.

Cast Blast first brings up a dialog where you can set the scale, highwall angle and swell factor. The Horizontal Scale and Vertical Scale are used to determine the vertical exaggeration of the cross-section view. The Highwall Angle is used with the Define Blast Area By Points option as the angle from the picked points at the bottom of the blast area up to the surface. The Cut Volume Swell Factor is multiplied by the cut area to determine the fill area of the spoil pile.

The area to cut can be either a closed polyline or defined by picking the lower left and lower right points. When picking points, there is an option to select a strata polyline which will be used as the bottom cutoff for the blast area. The blast profile can be defined by either a polyline drawn from left to right on the screen or by a Carlson profile (.pro) file. Refer to the Section & Profile module for how to create a profile file.
After placing the blast profile, there is an option to adjust the blast profile points. To adjust a point, pick on the blast profile near the point to modify. This will pick up that point and you can pick a new position. When a point is moved, the program will automatically fit the updated blast profile. Once everything is set, press Enter to end the routine. The surface profile polyline is redrawn with the blast area showing the blast profile. The changed segments of the original surface are drawn in a different color.

The program reports the cut and fill end areas and the cast to final percent which is the percent of the fill area that is in the final spoil area. The cast to final area is defined by the area past the line starting at the toe of cut and going up at the Repose Angle. This starting point can be offset from the toe of cut by using the Spoil Toe Offset field. A negative offset moves to the left and a positive to the right. The Auto Fit Cast To Final option will adjust the blast profile by moving the profile horizontally such that the placed profile balances the cut and fill areas and meets the specified Target Cast to Final percent.
There is an option to save the user input for this command to a sequence file (.seq) for the Process Dragline command and to a section report file (.cut) from the Dragline Section Report command. With the sequence file active, the program will prompt for a centerline reference point which is the point in the cross-section view that the centerline for Process Dragline passes through. If you choose a strata polyline, the program will ask for the strata name of this polyline. The Process Dragline command then prompts for a grid file that models this strata name. Besides specifying the sequence file name to write to, the sequence number is also stored. This number orders the steps in Process Dragline.

**Prompts**

---

**Polyline to Centerline File**

This command is described in the Centerlines section of the manual. Please refer to it there.

**Area To Section Report**

This command stores the area of closed polylines into a section report file (.cut) that is used by the Dragline Section Report command. Along with the area of cut and fill, this command associates a station and sequence number. The station is the distance along the dragline centerline and the sequence number orders the area in the steps at that station. There can be several steps at each station. This command prompts to select a cut area polyline which should be a closed polyline in section view. There is also an option to select a fill polyline. The areas can be assigned a description that is used in the Dragline Section Report.

Dragline Section Report

This command reports the end areas at different stations based on the accumulated stored results of various dragline routines. The report data is read from a section report file (.CUT). The commands that can add to the section report include Cut & Place, Cut Only, Dozer Push, Cast Blast Profile and Area to Section Report.

The report formatter is used to create the section report. This formatter allows you to choose the fields to report and the report layout. The report can also be output to Excel or Access.
Pulldown Menu Location: Surface
Keyboard Command: cutreport
Prerequisite: A section report file (.cut)

**Process Dragline Sequence**

This command applies 2D cross-section dragline steps along a centerline to create a 3D model. The dragline steps are stored in a sequence file (.SEQ file) that can be created by the Cut & Place, Cut Only, Dozer Push, Flatten Spoil Top and Blast Cast commands.

There are two different methods for Process Dragline Sequence. The Multiple Along Centerline method applies the dragline sequence along a centerline for a range of stations. The centerline defines the dragline alignment and the mining surfaces are defined by grid files and/or section files. This method outputs section files, 3D polylines and a volume report. The Single Section Polyline method applies the dragline sequence to one station in cross section view. The dragline position is defined by picking the centerline position in section view and entering the elevation at this point. The mining surfaces are defined by picking polylines for the ground surface and strata in section view. The output is drawn as polylines in section view for this one station.

Each of the steps has a centerline reference point and the control points for the step are relative to this reference point. For example, the top of the spoil pile for Cut & Place could be 75 feet right of the centerline. Process Dragline Sequence runs the steps along the centerline. A centerline file (.CL file) can be created from a polyline with the Polyline to Centerline command.
The existing ground can be modeled by either a grid file (.GRD file) or section file (.SCT file). Process Dragline Sequence works by repeating the 2D cross-section steps for each section along the centerline. When using a grid file surface, the program will prompt for a station interval and will create ground cross-sections at the specified offset left and right of the centerline at this interval before applying the dragline steps. When using a section file surface, the program will apply the dragline steps at the interval of the section file. There is an option to output the results of dragline steps to a section file. Besides outputting the final section results, sections at the end of each step can be saved to section files. The section files of each step are named automatically by adding the step sequence number to the original final section name.

The dragline steps have an option to use a strata polyline which makes the control points relative to the strata. If strata polylines are used, then the Process Dragline will prompt for a grid file that models the strata. For example, you could use a top of coal polyline in the Cut & Place command to define the bottom of the cut area. With the store sequence file (.SEQ) option on, the program will prompt for a name for the polyline and you could enter "coal". This name is stored in the sequence file and when Process Dragline Sequence is run, the program will prompt for you to select the "coal" grid file.

The program creates a report of the volumes for each step in the sequence. The Coal Density field in the dialog is used for calculating the coal tons for the report. The Taper Spoil Sides option adds stations before the first cut and after the last cut to show the repose angle of the ends of the fill spoil piles. There are options to draw 3D polylines of the pits. Draw Pit Polylines creates 3D polylines parallel to the centerline along the dragline control points such as the top of the spoil pile. Draw Cross Section Polylines creates 3D polylines perpendicular to the centerline for each cross section.

**Design Dragline Pit**

This command designs a pit into the existing ground surface using a set of dragline and bench slopes. The dragline slopes are for the portion of the pit excavated by the dragline and the bench slopes represent the truck-shovel excavation. The pit is drawn with 3D polylines and the pit volumes for the dragline and truck-shovel are calculated.

Before running this command, the base of the pit should be drawn as a closed 3D polyline. This pit polyline should also be assigned the elevations for the bottom of the pit. One way to set the elevation is to create a grid file for the bottom of the pit. For example, use Make Strata Grid Files to make a grid of the top of coal elevation. Then use the command 2D to 3D Polyline by Surface Model to convert the pit polyline into a 3D pit polyline with the grid elevations. This 2D to 3D command usually creates more vertices then necessary for Design Dragline Pit. So it is good to run Reduce Polyline Vertices.

Design Dragline Pit starts with the dialog shown below. All slopes are entered as percent. There is an option for two dragline slopes to allow for different slopes in different material, though it will be reported as one volume. The break point between these slopes can be set as either depth or at a grid surface. The grid surface could be a grid file for the transition strata. Next there is a dragline bench width and slope followed by cut and bench slopes. The cut-bench slopes repeat until intersecting the surface. The resulting modified surface can be saved as a grid file (.grd) with the Write Output Grid File option.

![Dragline Pit Parameters](image)

The program works by starting from the base pit polyline and applying the slopes until the surface is reached. The surface is modeled either by a grid file or from the entities on the screen. With the screen option, all 3D entities in the pit area are used to model the existing surface.

If a pit already exists to one side of the current pit, then this existing pit should be part of the surface model. Then the program will intersect the surface right away on this side without creating all the dragline and bench slopes. The Write Output Grid File allows you to save a grid file at the end of the command that represents the surface updated with the new pit. Then you can run Design Dragline Pit for the next pit and use the grid file output from the previous time as the new surface model.

The volume report shows the dragline cut and the truck-shovel cut. The dragline cut includes the volume from the pit base up to the top of Dragline Slope 2. The truck-shovel cut is the remaining volume up to the surface.
Plan view of dragline pit polylines

**Pulldown Menu Location:** Surface  
**Keyboard Command:** minepit

---

**Design Bench Pit**

This command creates pits where the sides are a series of slopes with benches. The side slopes start from a closed polyline. This pit polyline can be either the bottom of the pit and the slopes run up and out to intersect the ground surface, or the pit polyline can represent the top of the pit and the slopes run down and in, to intersect the pit bottom grid. Different slopes can be used for different sides of the pit. The pit is drawn as 3D polylines and the pit volumes are reported.

Before starting this command, the pit perimeter should be drawn as a closed polyline, 2D at zero elevation, or at 3D elevations on a surface. The program also needs triangulation or grid files for the existing ground surface and the bottom of pit surface. Design Bench Pit starts with the dialog shown below to specify these grid file names.
• **Ground Surface:** This is the surface to start the pit at.

• **Pit Bottom:** This is the surface that will represent the bottom of the pit.

• **Write Surface History File:** This output file is a GSQ file that is used for volumes in Surface Mine Reserves which leads up to surface mine timing and scheduling on these volumes, or for 3D Viewing as a movie with View Surface History File command.

• **Round Exterior Corners:** This option will create rounded corners on the outside edges of the pit for a more realistic design. When this is off, the corners are sharp and angular.

• **Write Output Grid File:** This option will create a grid file (GRD) of the design. It includes the original ground surface grid file, with the pits built onto it.

• **Use Elevations From Pit 3D Polyline:** This will use the elevations on the polyline as the start of the design. It will start the pits at the elevations the polylines are drawn at instead of starting at the Pit Bottom Grid for going up, or the topography when going down.

• **Force Bench with Width and Max Depth:**

• **Process Multiple Polylines by Pit Names:** This option is to process multiple pit perimeter polylines all at once. The pit polylines must have pit/site names assigned and the program will process them in the order of their pit names. As each pit polyline is processed, the ground surface is updated with the pit volume removed. Then the next pit will use this updated ground surface. When Process Multiple is active, the **Sequence Method** choose the way to order the pits for processing. The **Pit Name** method processes the pits in alphabetical order. The **Timing File** method uses the pit assignment order from Surface Equipment Timing from the .TIM file.

• **Separate Layers by Pit Names:** This option puts the 3D polyline break lines of each pit on their own separate layer. It takes the Pit Layer, and increments them by -2, -3 etc.

• **Create Road:** This option carves a rough road into the pit design. In the dialog, the road **Direction**, **Road Width** and **Road Slope** % are specified along with a color for the road polylines to create. When this option is active, the program will prompt for a road starting point along the pit perimeter. The cut slopes are shifted
to make room for the road.

- **Slope Direction:** Up will start at the pit bottom and bench up and out to the surface topography. Down will start at the top surface, and bench down and in to the pit bottom.

- **Slope Method:** Projection is a method that projects the 3D polylines down the slope, across the benches. Offset is a method that offsets the horizontal "toe and crest" lines to create the pit shells this way. Both methods will have horizontal and vertical breaklines, but the method they are generated is different. Each method has its benefits and might work better than the other for each unique scenario. If there is a problem with one method, try the other to see if it handles it better.

- **Horizontal & Vertical Interval:** These settings control the distance to draw the 3D breakline polylines. The horizontal interval will run down the slope, and across the bench. The vertical interval will run parallel with the benches. It should be a factor of the bench height if possible, but not required.

- **Min Bench Height:** The bench is not created when the side slope depth is less than the specified amount.

- **Side Layer:** This is the layer of the 3D polylines drawn perpendicular to the benches, and running down slope.

- **Pit Layer:** This layer is applied to the 3D polyline break lines running parallel to the benches.

- **Use Bench Name for Layer Suffix:** This option adds the bench name to the Pit Layer so that each bench can have a unique name which can be useful for having different colors for each bench for visualization or for isolating benches by layer.

- **Draw Side Slope Polylines:** This option chooses whether to draw the 3D polylines running perpendicular to the benches, and down slope.

- **Bench Color:** This puts the bench 3D polylines in the Pit Layer on a different, specified color so they stand out against the slope breaklines.
The next dialog defines the cut and bench slopes. Cut slopes are entered as ratios. The cut depth can be either a fixed depth number or to a grid file. For a grid file, the program will find the intersection of the cut slope with the grid surface and will end the cut slope at this intersection. For example, you could make a grid file for a second coal seam and have the bench occur at this coal seam. After the cut slope, the bench slope and width are used. The cut and bench slopes are applied in order until there is an intersection with the surface. Once you have all the cut slopes defined, you can use the Save button to save these slope settings to a .PIT file. Then these settings can be recalled later with the Load button.

Four different sets of slope schemes can be defined. To define the another slope scheme, select other Slope Group tab. The set of slopes that you are currently editing is indicated by the selected tab. If you define different sets of slopes, then the program will prompt you to pick which sides to apply each set of slopes to. All sides are assumed to be slope type one. So you only have to identify types two, three and/or four. If only one slope group is defined, then you will not be prompted to select any additional sides.

If a pit already exists to one side of the current pit, then this existing pit should be part of the Ground Surface grid file. Then the program will intersect the surface right away on this side without creating all the bench-cut slopes.

Here are a couple of examples of the various settings in Design Bench Pit.

- Offset Method:

- Offset Method with Road in red:
Projection Method:

- Multiple Pits with Offset Method and Viewing the Grid History File in 3D.

Keyboard Command: minepit2

Design Spoil Pile

This command creates a spoil pile at a target volume or elevation. There are a few design methods. The Perimeter Polyline method takes a 3D polyline outline of the top of a spoil pile and adjusts this polyline by either changing the elevation or extending a side to reach a specified volume for the pile. The resulting pile is drawn as 3D polylines showing the side slopes and where the pile ties into the existing surface. The Cone methods take a single point and slope to build a spoil cone. The cone can be sized by either target volume or by height.

For the Perimeter Polyline method, you can choose between Extend Bench and Adjust Elevation. The extend bench option will prompt for a side of the pile to offset. Holding all the other sides with their elevations, the program will offset the selected side until the target volume is reached. For the adjust elevation, the entire pile polyline is moved up or down to obtain the target volume. Before starting this command in Perimeter Polyline mode, you need to draw a closed 3D polyline that represents the top of the pile. The fill slopes will start at this polyline and will run out and down until the slopes intersect the surface model.

![Spoil Parameters dialog box](image)

The Fill Slope can be specified in ratio, percent or degree format. The Pile Layer is for the 3D polylines that this command creates for the spoil. The Write Output Grid File option creates a .grd file of the spoil surface.

As the program runs, it will seem to draw several piles as it tries to find the target volume. The resulting volume will not match exactly the target volume but will be very close. The smaller the grid cell size, the closer it will be. This difference is just to save processing time.
Spoil Pile by Cone method
**Pulldown Menu Location:** Surface  
**Keyboard Command:** spoil2

**Design Fill Surface**

This command creates fill pile where the sides are a series of slopes with benches. The side slopes start from a closed polyline. The perimeter polyline is the toe of the pile, and the slopes will be up and in from the footprint of the pile. Different slopes can be used for different sides of the fill. The fill is drawn as 3D polylines and the fill volumes are reported.

Before starting this command, the perimeter should be drawn as a closed polyline, 2D at zero elevation, or at 3D elevations draped onto a surface. You also need a grid file for the existing ground surface. Design Fill starts with the dialog shown below where you specify the grid file name.

- **Ground Surface:** This is the surface to place the fill pile on. The **Write Output Grid File** allows you to save a grid file at the end of the command that represents the surface updated with the new pit. Then you can run Design Bench Pit for the next pit and use the grid file output from the previous time as the new Ground Surface. The **Round Exterior Corners** option holds the slopes around the corners which makes the benches curve around the corners. Otherwise the side benches stay straight until they meet benches coming from other sides at the corners.
- **Use Elevations From Perimeter 3D Polyline:** This will use the elevations on the polyline as the toe of the fill pile to start the design.
- **Write Output Grid File:** This option will create a grid file (GRD) of the fill. It includes the original ground
surface grid file, with the fill pile built onto it.

- **Round Exterior Corners:** This option will create rounded corners on the outside edges of the pile for a more realistic design. When this is off, the corners are sharp and angular.

- **Horizontal & Vertical Interval:** These settings control the distance to draw the 3D breakline polylines. The horizontal interval will run down the slope, and across the bench. The vertical interval will run parallel with the benches. It should be a factor of the bench height if possible, but not required.

- **Side Layer:** This is the layer of the 3D polylines drawn perpendicular to the benches, and running down slope.

- **Pile Layer:** This layer is applied to the 3D polyline break lines running parallel to the benches.

- **Draw Side Slope Polylines:** This option chooses whether to draw the 3D polylines running perpendicular to the benches, and down slope.

- **Bench Color:** This puts the bench 3D polylines in the Pile Layer on a different, specified color so they stand out against the slope breaklines.

**Fill Slope Format:** The slope angle can be defined in percent, ratio or degrees. This is what is entered in the Fill Slope.

- **Slope Group:** Four different sets of slope schemes can be defined. To define the another slope scheme, select other Slope Group tab. The set of slopes are currently being edited is indicated by the selected tab. If different sets of slopes are defined, then the program will prompt to pick which sides to apply each set of slopes to. All sides are assumed to be slope type one. it is only necessary to select types two, three and/or four. If only one slope group is defined, then it will not prompt to select any additional sides.

- **Fill Slope:** The slope angle can be defined in percent, ratio or degrees. This is what is entered in the Fill Slope.

- **Fill Target:** The target to fill to for each bench can be a flat elevation, a depth above the previous surface or bench, or up to a grid file surface.
• **Depth:** The Depth must be filled in when the target is set to depth.

• **Elevation:** The Elevation must be filled in when the target is set to elevation.
• **Select File:** The file must be selected when the target is set to file.
• **Bench Slope %:** This setting will slope the benches down for drainage if desired. Normal setting for flat bench is 0.

• **Bench Width:** This is the horizontal width for the bench in feet or meters.

• **Bench Name:** This is used for pit design to name the benches for volumes. It does not have much application in the Fill version of this command.

• **Delete:** This deletes one line of data.

• **Insert:** This inserts a blank row to be filled in.
• **Clear:** This clears the entire slope group page, only the current group.

• **Load:** This loads a previously saved PIT file with the template saved.

• **Save:** This saves the template as shown in the window.

• **Preview:** This displays a preview of the current group to show how the cross section of the fill will look.

Shown here is a sample fill design in both plan view and 3D.

The report window appears at the end of the command to display the volume of the fill in CY or CM.

Define Fill/Cut Design

This routine defines the template for the fill or cut sequence of designed pit or fill. Slope, colors, surfaces and boundaries are specified and saved for processing. This is the first step to designing the cut or fill. After this template is defined, then the 3D design is created with the command Process Fill/Cut.
The first window has a File menu dropdown and several options for settings:

**Load:** This loads a previously saved template file. They have the *.RMP extension.

**Save:** This saves the currently defined Fill/Cut template to a *.RMP file.

**Clear:** Choosing Clear will clear all entries in the template. Use this command if the program is producing errors while running and start over. Sometimes remnants of other templates are still being used, and it is best to start over instead of trying to replace the templates.

**Set Snap:** This option determines the level of acceptable rounding of calculated points. Larger snaps reduce excess points, but may collapse the geometry. The default is 0.01 drawing units.

**Colors:** Selecting the Colors button brings up the Colors dialog box. Here you choose a color for the breaklines created for the Road, Slope and Bench.
**Cut or Fill:** This is the determining setting if the program will cut down or fill up from the boundary.

**Horizontal Resolution:** This is the setting for how often a horizontal breakline will be drawn. Breaklines will be drawn closer in corners and intersections, but never larger than this resolution. These are the breaklines that run from the top to the bottom of the slope.

**Vertical Resolution:** This is the setting for how often a vertical breakline will be drawn. These are the breaklines that run around the disturbance area, parallel with the benches. It works well if the vertical resolution is less than the bench height, putting a breakline in between the slopes. It is best if the interval is a factor of the bench height, i.e. 50' benches and 25' vertical resolution. Here a bench is defined as a flat or nearly flat section in the template between two sloping surfaces.

**Force Road Method:** There are two methods by which the stepping is done. A simple method, and the more complex method that is used by the Road option. If you have a very complex boundary that the regular, simple method does not handle well, use this option. It does not place a road unless that is turned on in the next screen. It just uses the road algorithm. There is no reason to use this method for simple cuts or fills. If they look fine, then leave this off. It will run much slower with this option turned on, so leave it off unless you need some more intelligence. If you have a fill with more than one peak, then you will need to leave the Force Road Method off, as it uses the road logic, and draws a road only to the first peak created.

**Boundary:** Selecting this button leads to the Boundary Line dialog box for specifying the perimeter line and the surface or elevations of the line.

**Boundary Line Definitions**
**Select in AutoCAD:** This option will take you to AutoCAD with the pick box active, ready to select the polyline for the perimeter. Sometimes the dialog disappears and you need to select it from down in the Windows bar.

**Read PLN File:** This will prompt for a *.PLN file to use as the perimeter. The PLN file is created with other Carlson routines.

**Min(imum) Line Length:** This setting will break the segments of the polyline into sections of at least this many units (feet or meters) in addition to the actual vertices on the polyline. This is needed for the Select Points for This Template command seen below.

**Same As Last Run:** Selecting this option brings up the perimeter that was used last run. The large preview window displays the perimeter line that will be used, so it is easy to verify.

**Use Values On Boundary Line:** If the selected polyline is 3D, then it will use the elevations of the polyline.

**Model By Triangulation (FLT) File:** Selecting this option will prompt for the FLT file to use for the polyline elevations.

**Model By Grid (GRD) File:** Selecting this option will prompt for the GRD file to use for the polyline elevations. It draws the grid in the background of the preview window as cyan colored cells.

**Use Elevation:** Selecting this option will prompt for the elevation to use for the perimeter. It will be a flat line at this elevation.

**Previous:** Selecting this button takes you back to the main layout screen.

**Process And Continue:** Once the perimeter and source of elevations are chosen, you select Process And Continue to define the templates. This takes you to the next window.

**Slope Design Templates**
This Slope Extends to Elevation: Selecting one of the five options here determines what the slope will go to.

**Elevation:** The fill or the cut will go to this elevation.

**Grid:** The fill or the cut will go to the selected grid file (*.GRD).

**TIN:** The fill or the cut will go to the selected TIN file (*.FLT).

**Min Area:** The fill or the cut will go to an elevation where the area of the top or bottom will not go below this value in square feet or meters.

**Ultimate Slope:** The fill or cut will continue until the maximum height or depth is attained. This gives a peak in a fill or a V shaped pit bottom.

**Next Slope:** Selecting this option will take you to the next slope group. This is shown by the "1 of 1" text in the upper right corner.

**Delete Slope:** Selecting this option deletes the current slope group.

**Add Slope:** Selecting this option adds a new slope group. The templates will be applied to each slope group separately. For example, one set of templates can cut down at a 1:1 to a certain elevation or file-top or rock for example. The next slope group can continue down at a 0.5:1 slope to the bottom.

**Zoom Functions:** There are 6 zoom functions for changing the view in the preview window: Zoom Out, Zoom In, Zoom Previous, Zoom Extents, Zoom Window and Pan.

**Done:** After everything is defined, this option goes back to the previous screen.

**Road On:** Selecting this option will use the road building algorithm and build a road with the entered parameters.

**Width:** Specify a total road width in feet or meters.

**Slope %:** Enter the road slope in percent, i.e., 12.

**Clockwise:** Choosing this makes the road wind clockwise, leaving it blank creates the road winding counterclockwise.

**Select Start Section:** You must select where to begin the road on the preview of the perimeter. The selection must cross the perimeter line as shown above with the short black line on the far right of the perimeter line. Just pick the two points, one on either side of the perimeter, with two left mouse clicks.
**Show Profile:** This option brings up a profile of the ramp, to make sure it does not cross the existing ground perimeter polyline. If it does, it will give an error message as shown below, and the problem area is shown below the two red lines. To fix this, either pick a new ramp starting location, or modify the elevations of the perimeter.

![Ramp Profile Error Message](image)

To fix this problem, the road starting location was moved to the north, and now the road slope line does not cross the boundary profile line.
**Bench Transition Length:** This is the distance the road goes flat across the bench, until it starts up or down again.

**Taper to Bench Inside:** This is the other option if there is not a Bench Transition Length desired. This will "hug" the inside of the bench until the road gets across it.

**Template Design**

**Hold Elevation or Hold Distance:** When making changes in the template, one of the first two columns must remain fixed, either the elevation or the horizontal distance. You select which one will stay, while the other changes if you modify the slope or any other parameter.

**Template Base Elevation:** Enter in a starting elevation if the bench interval desired is above or below what the program is calculating. Normally, benches are created at logical increments of the template, such as 1050, 1100, 1150, etc. If you want benches at 1055, 1105, 1155, etc, then you would enter 5 in the base elevation for example. This value will basically offset your benches up or down this amount.

**Delta Distance, Delta Elevation, H-V Ratio, Slope %, Slope Degrees:** This is the section to enter in the slope and benches. The first five columns may be used, other variables will be calculated if another is modified. The last
two, Total Distance and Total Elevation are locked, and cannot be used. For flat benches, just enter a Delta Distance, with 0 as the Delta Elevation. A preview of the slope group will appear in the preview box. If it does not show up for some reason, you may need to save the RMP file, close the program and restart it. This will reset the template preview window.

**Bench Taper Length:** Enter in the distance for a bench to taper from zero width to the full width.

**Variable Bench Design:** This option will keep the same bench/slope ratio while the bench widens to its full thickness. If the template has a 45 degree slope, 50' high, and a 50' bench, then as the slope increases its height, the bench width will increase at the same ratio/rate. If the bench height to width is always 5:1, then that ratio will always be produced in the widening of the bench.

**Next Template:** Selecting this button brings up the next template defined. If there is only one, the bottom of the window is red, and nothing happens. If you have other templates defined (with the Add Template), then it will scroll through them. Each will have a distinct color to show where they correlate to the perimeter in the preview window. The colors of the template design window and the corresponding line segments of the perimeter are in this order: red, green, cyan, orange, blue, magenta, light green and black.

**Add Template:** This will add a new, empty template to the design. Each new template added will have its own, unique color to keep them organized. The colors are listed just above.

**Select Points For This Template:** After a template is defined, this option defines where on the perimeter, the program will apply this set of slopes and benches. You must pick a starting point and run clockwise to pick the last point. The perimeter line will change color to match the template color. This lets you know where each template is defined. If there is only one template (the initial red one), then the entire perimeter line is red to match it.

**Pulldown Menu Location:** Ore
**Keyboard Command:** rampdesign

**Prerequisite:** A boundary perimeter and a surface. These could either be selected on screen in AutoCAD or saved as files.

---

**Process Fill/Cut Design**

This routine is simply the execution of the Define Fill/Cut. It creates the 3D design of the fill or cut. Some examples are shown below. The process window shows the elevation it is on and the percent done. The benches can be seen drawing in realtime as it calculates each one.
Valley Fill Example

Stockpile with Ramp Example
Benched Pit with Ramp Example

Prompts

No prompting. It processes the current RMP file.

**Pulldown Menu Location:** Ore
**Keyboard Command:** ramp
**Prerequisite:** Need to have run Define Fill/Cut and created a template

Vertical Pit Quantities

This command calculates overburden and strata quantities. The strata thicknesses are defined in coal sections or drillholes. This routine requires a 3D closed polyline with elevations of the top of the seam. This polyline is also used as the perimeter of the pit. The routine calculates a surface model for the top of seam using this 3D polyline. Then a surface model for the ground surface is calculated from the selected surface entities such as points, lines or polylines with elevation (contour polylines). The overburden volume is calculated as the volume between these two surfaces within the 3D polyline. Each strata is modeled and the volume calculated for the area within the 3D polyline.

Prompts

**Coal Section Configuration File**
Select the file that defines the coal section sample points.

**Pick top of coal polyline:** *pick the closed polyline*
Choose the .grd file to update.

**Select surface entities and at least 3 coal sections or drillholes.**
**Select objects:** *pick the entities*

**Make Grid File dialog** Choose a grid resolution

**Beginning date of takeup [format mm-dd-yy]:** 6-1-92

**Ending date of takeup [format mm-dd-yy]:** 6-30-92

These dates used by Report Tons & Acres.

**Ownership/description:** Jones

This is the name of the data file to be updated for Report Tons & Acres.

**Coal recovery percent <100.0>:** 95

**Write column report file (Yes/No)?** press Enter This option creates a file minearea.dat in the data directory with the calculated quantities and other information in a column format.

**Update Grid File**

This command recalculates the surface model in a .grd file by using additional point data along with the original point data. Only .grd files created by the Make Drillhole Grid File command, in StrataCalc, can be used by Update Grid File. Make Drillhole Grid file stores a point file of the original data used to calculate the grid in a file with the same name as the grid file plus the extension .pnt. For example Make Drillhole Grid File will create stratax.grd and stratax.pnt.

The new point data for recalculation can be specified by picking points, entering point numbers that reference stored points in the current coordinate file, or selecting coal sections (from Place Coal Sections). When updating from coal sections, the program will prompt for a grid file that models the top of the coal sections. Since coal sections have thickness values but no Z values, this top of section grid is used to set the coal sections in the real Z axis. The program then updates the grid files that model each of the bottom elevation surfaces of the strata in the coal sections.

The updated grid can be saved in a new .grd file name or overwrite the original grid file by specifying the same file name. The location and resolution of the grid cannot be updated. So the original location and resolution should be made large enough to include any new area of point data to be added by Update Grid File.

**Prompts**

**Update grid from points or coal sections (Points<Sections>)? Points**

The updated grid will be stored in this .grd file.

**Pulldown Menu Location:** Surface

**Keyboard Command:** grdupdate

**Prerequisite:** Grid file created by Make Drillhole Grid File

**Tag Slope Groups**

This command places special symbols on pit polylines to indicate different slope groups to use in Design Bench Pit. The Design Bench Pit command supports up to four separate sets of cut slope definitions to be used on different sides of the pit polyline. Using the symbols from Tag Slope Groups is a way to batch process many pit polylines with separate slope groups. When Design Bench Pit finds symbols from Tag Slope Groups, the program skips the prompting to specify and slope group sides and uses the assignments from the symbols. For each edge in the pit polyline, the program looks for a slope group symbol. If a symbol is not found on a segment, then slope group #1 is used. So only symbols only need to be placed for slope groups 2-4.
The options dialog defines the symbol from the Symbol Library to use for each slope group as well as the symbol size, layer and color. There are a few methods for placing the symbols. The Pick Individually method prompts to a pick point on the pit segment and the symbols are added one pick at a time. The Crossing Line method prompts for two points and places a symbol at each pit polyline intersection along the line between the two points. The Window Area method prompts for a series of points to define the perimeter of an area and a symbol is drawn on the midpoint of all pit segments within this area.

Pulldown Menu Location: Surface
Keyboard Command: tag_slope_groups
Prerequisite: Pit polylines

Dragline Pits
This command calculates the total volume cut from a pit and the volume of a strata cut from the pit. The program requires two closed 3D polylines that represent the top and bottom of the pit. The top surface for volume calculations is modeled by the top polyline and any points in the bottom polyline that are outside the top polyline. Likewise the bottom surface is modeled by the bottom polyline and any points in the top polyline that are outside the bottom polyline. The top and bottom polylines are used as inclusion area polylines to limit volumes to within these polylines.

The program also processes two grid files that define the top and bottom of a strata. This volume is calculated between these two grids. This volume is the amount of strata cut from the pit. The inclusion area for the strata volume is the bottom pit polyline. The program assumes that the strata is entirely above the bottom of the pit and below the top of the pit.

This example shows a pit that is advancing from left to right. The left side of this pit was the edge of the previous pit.
**Prompts**

Select closed polyline of pit Top: *pick a closed polyline*
Select closed polyline of pit Bottom: *pick a closed polyline*

Make Grid File Dialog Choose a grid resolution.
Select Top of Strata Grid Choose .grd file that models the top of the strata.
Select Bottom of Strata Grid Choose .grd file that models the bottom of the strata.

Enter density of strata (lbs/cf): 75

Tons of strata: 14572.97
Strip ratio (C.Y. other/Ton strata): 2.06

Pulldown Menu Location: Surface
Keyboard Command: dragpit

**Regrade Backfill**

This feature applies to the narrow valleys of Appalachia where the goal is to regrade an existing valley fill with benches and specific slopes. Before starting this command you must create grid files (.grd) that represent the existing surface without any fill and the surface with the existing backfill. These grid files can be created with the Make 3D Grid File routine of the Civil Design module.

Regrade Backfill also requires a pre-drawn alignment polyline which defines the shape of the face of the regrade. This polyline must be drawn below the existing backfill and it must be at least long enough to reach across the widest part of the regrade.

To run the routine, specify the two grid files, the alignment polyline, the direction up the valley, the slopes, and the bench dimensions. The program then draws in the regrade as 3D polylines and calculates the cut and fill. To balance the cut and fill, choose the *Adjust parameters and redesign* option.

**Prompts**

Select Existing Surface Grid File
Select Backfill Grid File

Pick existing backfill perimeter polyline: pick a closed polyline that represents the limits of the backfill disturbed area

Pick the regrade alignment polyline: pick a polyline

Pick direction up regrade: pick a point towards the back end of the valley

Enter the vertical lift between benches <50.0>: press Enter

Enter the slope ratio (x:1) <2.0>: press Enter

Enter the bench width <20.0>: press Enter

Enter the bench percent slope <2.0>: press Enter

Enter the top percent slope <2.0>: press Enter This slope is used after the regrade reaches the top of the existing backfill until the end of the regrade.

Example Regrade Backfill Report:

Regrade Backfill Report

Vertical lift between benches: 50.00
Slope percent: 50.00%, slope ratio: 2.00:1
Bench width: 15.00
Bench slope percent: 2.00 slope ratio: 50.00:1
Top slope percent: 2.00 slope ratio: 50.00:1
Total fill: 13105.186 C.Y., 353840.01687 C.F.
Total cut: 13288.257 C.Y., 358782.93357 C.F.

Existing backfill and existing contours
3D view of regrade backfill. Also showing existing contours.

**Pulldown Menu Location:** Surface  
**Keyboard Command:** backfill  
**Prerequisite:** Grid files of the existing surface and existing backfill and an alignment polyline.

## Blast Pattern Layout

This command creates a pattern of points in rows and columns using surface and shot bottom grids and dip direction. The options for this command are set in the dialog. Grid files for the ground surface and drill bottom are required. The Number By Row/Column option will number the holes by the hole row and column. Otherwise the holes are simply numbered sequentially. Up to four descriptions can be assigned to the holes such as pattern name, driller name, etc. The row and column distances can be specified separately. The drilling angle can be set in the Vertical Dip field which is entered as an angle where 0 degrees is straight down and 90 degrees is horizontal. The Dip Direction defines the horizontal orientation of the vertical dip. The row and column directions are entered as bearing angles. You need to figure these angles before running Blast Pattern Layout by using routines such as Inverse or Bearing & 3D Distance. The format is in dd.mmss where the degrees.minutes.seconds are separated by a decimal.

This command can generate a report using the report formatter that lets you choose the fields for the report and the fields layout. The report formatter can also output to Excel and Access. The points can be also be stored to the current coordinate file (.crd). The Preview button shows a preview of the pattern in the drawing so that if something isn't right, it can be adjusted before choosing OK. If the Create Points is turned on, then the points will be drawn in the blast perimeter.
After filling out the dialog, the program prompts for the blast boundary polyline which should be a closed polyline of the blast area. Finally you specify the starting point within this boundary polyline and the program calculates the points.
Prompts

Blast Pattern dialog

Select blast boundary polyline: pick a polyline
Pick starting point: pick a point
**Interval Along Entity**

This command is described in the Survey section of the manual. Please refer to it there.

**Blast Point Report**

This command projects points either from the blast bottom up to the surface at a dip direction or from the surface down to the blast bottom. These points are then reported using the report formatter that lets you customize the fields to report and the layout. Before running this command, you need the ground surface grid file, the blast bottom grid file and points drawn on the screen. While the Blast Pattern Layout routine also can generate a report, this routine is more flexible because it uses all selected points from the screen and is not limited to only pattern points. For example, you could use Blast Pattern Layout to create a grid of points. Then use Interval Along Entity to create points along a polyline that represents the setback line for the first row of holes. You could also use any of the other Carlson point routines to add or remove points. Then once all the points are placed, you can run Blast Point Report.

![Blast Point Report Window](image1)

**Prompts**
Cast Blast Report

This command uses before and after grid files to report blast volumes, swell and cast to final. Before running this command, you need four grid files and an inclusion perimeter. The inclusion perimeter is a closed polyline that follows the back of the cut area and the toe of the previous spoil pile. The first grid file is the original ground surface before the blast. The second grid file is the ground surface after the blast. The third grid file represents the bottom of the pit (design, or bottom of ore). For example, if you are blasting down to the top of ore, this grid should be the top of ore surface. The fourth grid defines the final pit surface including the final cut and spoil pile. This final grid can be created with the Make 3D Grid File command using 3D polylines for the toe of the highwall, toe of the spoil pile and top of the spoil pile.

The program calculates the volume between the original ground grid and the pit bottom grid within the inclusion perimeter. This volume is reported as the Original Volume. The After Blast Volume is the volume between the final ground grid and the pit bottom grid. The difference between the After Blast Volume and Original Volume is reported as the Swell Factor. The After Blast volume that is below the final pit surface is the Cast to Final volume.

Original Surface: C:\scad\DATA\ex.gnd.grd
Final Surface : C:\scadv\DATA\final.grd
Pit Bottom : C:\scad\DATA\coal.grd
Final Spoil : C:\scad\DATA\spoil.grd
Lower left grid corner : 509141.84, 595450.20
Upper right grid corner: 511087.39, 596727.09
X grid resolution: 100, Y grid resolution: 100
X grid cell size: 19.46, Y grid cell size: 12.77

Original Volume: 1602319.50 C.F., 59345.17 C.Y.
After Blast Volume: 2066992.20 C.F., 76555.27 C.Y.
Blast Swell Factor: 1.29
Cast to Final Volume: 144689.22 C.F., 5358.86 C.Y.
Cast to Final: 9.03%

Select the Inclusion perimeter polylines.
Select objects: pick a closed polyline

Pulldown Menu Location: Surface, Blast Pattern
Keyboard Command: blastinfo
Prerequisite: Original, final, pit and spoil grid files. Inclusion perimeter polyline.

Draw Centroid Point
This command draws points at the centroids of the selected polylines. In the section option, the areas need to be closed polylines representing the blocks to calculate the centroids of. This is useful for calculating haul distances and blast distances in section view. When choosing to come from a grid file, it finds the x,y position for the center of mass. Typically this grid would be the difference between existing and design surfaces, represented as a thickness grid. For example, this routine could be used to find the center of mass for a stockpile using a difference grid of the stockpile grid and base grid.

Prompts
Centroid from cross-section or grid file [Section/Grid]? S
Select closed polyline(s).

Output To Reame
Output to Reame creates a file with a .dat extension that is readable by the REAME2004 stability analysis program for cylindrical failure. The REAME program was developed by Dr. Huang of the University of Kentucky and is widely used in coal mine permitting in the state of Kentucky. The linkage has been tested and verified with the REAME2004.

The program is typically used after a final surface profile is laid graphically over an existing ground profile. You then graphically select the profiles to create the REAME input file. The routine not only creates the input file but provides options to draw the failure study region and key coordinates on the actual profile drawing. The only
significant condition to be aware of is that the profiles should rise upwards from left to right in the direction of increasing station.

To run the Reame program after Output to Reame, it is best to copy the .dat file just made into the directory containing REAME.EXE. Then run REAMEINP to revise the .dat file (to change aspect like cohesion, friction angle and unit weight) or REAME to run the stability analysis. It will ask: FILE NAME -? Enter the name with the .dat extension included. The enter 1 to input from file. The analysis is then completed and stored in a file REAME.TXT.

Prompts

Title of Stability Report: Valley Fill No. 1 (Reame expects this title line, so enter something!)
Select Files or Pick from screen (F or <P>): P; press Enter for the Pick option here. The select file option would require that you enter the name of an existing and final .PRO file.
Next a Profile Settings menu comes up, in which it is important verify scales and the correct starting station and elevation.

[Pick Lower Left Grid Corner <0.00,1445.00>: pick where the starting station and starting elevation grid lines intersect] Switch to int snap if that point is not an end point.
Select Final Grade Polyline: pick final grade
Select Lowest Surface Polyline: pick existing grade Phantom lines at right angles representing the proposed study area for stability analysis now appear.
Pick another Surface (y/n): n, Yes for adding more surface polylines to reame input
Minimum Depth (DMIN) for Failure Slice:

Value for C <0>:
Value for Phid <40>:
Value for G <125>:
Note: Lines will not Appear at Right Angles if Vert. Scale is Exaggerated.
Translated Coords: (-10.0 68.9902) (515.0 173.99)
Is Stability Analysis Zone Acceptable (<y>/n):
Plot Stability Analysis Zone Lines (<y>/n):
Label the Zone Line Endpoints (<y>/n):
[Pick Points for Coord. Label (enter to continue): pick any ground line or final grade line vertices or endpoints for coordinate labeling] Each time you will also be asked:
[none] Pick Starting Point for Text: pick a point
Number of divisions along face of slope <4>:
Number of divisions perpendicular to slope <8>: 

Chapter 16. Surface Mining Module 2972
This would lead to 32 radius points from which to test cylindrical failure.

**Pulldown Menu Location:** Surface > Slope Stability  
**Keyboard Command:** reame  
**Prerequisite:** Surface profiles or polylines

---

**Draw Reame File**

The function allows the user to import their existing Reame file and draw it in the drawing. It prompts to select the RME file created in Reame.

**Pulldown Menu Location:** Surface > Slope Stability  
**Keyboard Command:** reameplt  
**Prerequisite:** Stability Reame file

---

**Output to SB-Slope**

The widely accepted and computationally powerful stability analysis package, SB-Slope has very limited functions for data and geometry modification. The procedure outputs the data files in the SB-Slope data format, thus providing powerful interface for geometry editing. The meaning of all data parameters remains the same as in conventional SB-Slope.

The user is prompted with a single dialog defining the majority of necessary parameters, followed by prompts for soil and water polylines, soil properties and finally the parameters of applied loads if any. For each soil type, the program prompts first to pick polylines which denote upper boundary of the soil (multiple polylines may be selected), and then to pick polylines which represent boundary of the soil and are phreatic lines.

Polylines from the second set may appear in the first set as well.

After all soil polylines, the free-water surface is entered if any and then user is prompted for the soil mechanical properties. At last, distributed loads are entered by picking a horizontal line, representing the load support area, and input of the load value.

**Pulldown Menu Location:** Surface > Slope Stability  
**Keyboard Command:** sbslope

---

**Draw SB-Slope File**

The function allows user to import his existing SB-Slope file into the drawing. Segments of the neighbor lines corresponding to the same soil are joined to simplify creation of new SB-Slope data file from the drawing. The following color scheme is used to mark elements of the layout:

- blue = free water surface  
- green = phreatic surface  
- red = places of load application

**Pulldown Menu Location:** Surface > Slope Stability  
**Keyboard Command:** rsbslope
Spoil Menu

Assign Spoil Names

This command attaches a spoil name and site name to closed polylines that are used as inclusion perimeters in the spoil routines like Calculate Spoil Volume and Spoil Placement Timing. This will create them one at a time, and is recommended if there are just a few to name. Other commands will create more advanced layouts of spoil perimeters for designs that require more perimeters.

Prompts

Label area names [Yes]/No? Choose whether or not to label.
Text height <2.78>: press Enter to accept 2.78 drawing units (ft or m tall) or enter a new text height
Auto place labels in center [Yes]/No? press Enter to accept to manually pick the label position, answer No to this prompt.
Select Inclusion perimeter polylines.
Select objects: pick closed polylines for areas to include in calculations
Site name <Site 1>: press Enter to accept Site 1, or type a new site name
Pit name <Pile 1>: press Enter to accept Pile 1, or type a new pit name
Specify another area [Yes]/No? press Enter to accept Yes or type N for no If you do specify another area, then the Site Name remains the same, but the Pile Name is automatically incremented by one for efficient naming.

Keyboard Command: spoilname
Prerequisite: Closed polyline
Pulldown Menu Location: Spoil in Surface Mine Module

Spoil by Interior Point

This routine is used to create spoil polylines from the existing linework by making closed polylines around points picked. The site and spoil names are user-specified and the spoil name is incremented after each new pile perimeter is created. This command uses the Boundary Polyline logic, using any linework (open or closed) and searches out from the picked point for the closed perimeter. It draws a new polyline in the specified layer.
• **Label Area Names**: Choose whether to label the pile perimeters or not

• **Text Height**: Set the text height in feet or meters based on the drawing setup

• **AutoPlace Labels in Center**: Yes to put the text insertion point on the centroid of the perimeter

• **Layer Name**: Select or enter the layer name to draw the perimeter and text

• **Site Name**: Specify a site name to give to all the new pile perimeters

• **Spoil Name**: Specify a name to give the first pile perimeter. Subsequent piles will increment the name by one automatically.

---

**Prompts**

**Pick point inside pile perimeter**: *pick inside a loop or linework representing the pile for the spoil polyline*

**Specify another area (<Yes>/No)?** If yes is selected, then the Pile Name is automatically incremented by one for efficient entry, such as Spoil 2. **Site name <Site 1>:**

**Pit name <Spoil 2>:**

**Pulldown Menu Location**: Spoil in Surface Mine Module

**Keyboard Command**: pickspoil
**Spoil Layout by Width**

This command creates closed polylines that represent spoil placement inclusion areas for the spoil timing routines. The spoil polylines are created by advancing a baseline polyline by a fixed pile width. The sides and end of the pit polylines are defined by the disturbance boundary polyline. This polyline should be open at the end of the baseline polyline. Be sure to create the baseline polyline longer than the overall boundary so that the program can always find the intersection of the advancing baseline with the boundary. There is an option to automatically assign pile and site names to the polylines. The name of the first pile is set in the dialog shown below. The next spoils will be named by incrementing the spoil name by one. There is an option to prompt for each spoil perimeter width or use the same width for all the piles.

![Image of Spoil Layout By Width dialog]

**Prompts**

- **Spoil Layout By Width dialog** Set the spoil width, layer and names
- **Select baseline polyline**: pick the polyline
- **Select spoil boundary polyline**: pick the polyline

*Calculating spoils ...

*Created 7 spoils.

**Pulldown Menu Location**: Spoil  
**Keyboard Command**: spoils

**Prerequisite**: One open polyline boundary and one baseline polyline extending across the boundaries open end.

**Find Spoil Name**

This command will find a certain named spoil polyline on screen. It will zoom to the pile extents and center it. The spoil line is also dashed or highlighted to distinguish it from surrounding polylines.
Prompts

Spoil name to find: pile 4
Site name to find <*>:

Pulldown Menu Location: Boundary
Keyboard Command: find_spoil

Label Spoil Names

This command labels the spoil name and site name that are attached to the selected polyline. Options for layer and text height are provided. The Horizontal and Align placement methods will draw the labels in the center of the polyline. The difference is that the horizontal option will draw the label horizontal to the current twist and the Align method will rotate the label to follow the main direction of the spoil line. The Pick method prompts you for a center point to pick and an alignment for the text.

Prompt

Label Spoil/Site Names Dialog
Remove Spoil Names

This command removes the extended entity data of spoil/site names from the selected polylines. For example if you are done calculating for an area, or you just want to clear and rename them, you can use this command to clear the spoil names from the polylines in the old area so that these polylines are not picked up as spoil perimeters anymore by routines for timing the spoil.

Prompts

Select polylines to remove spoil names from.
Select objects: pick the polylines
Removed pit names from XX polylines.

Clear Spoil Volumes

This command removes all quantity values and grid paths from the selected spoil polylines. There is the option to clear all benches at once, or if Specific is selected, then it will prompt to enter a bench number to clear.

Prompts

Clear all bench quantities or a specific bench [All/ Specific]? A
Select spoil polylines to clear.
Select objects: Specify opposite corner: 5 found, 5 total
Cleared 10 bench quantities.

Merge Spoils

This routine takes two adjacent spoil perimeters and merges them to create just one. Routines such as Spoil Layout by Width can sometimes leave small irregular shaped pits along complex boundaries. It is common to combine or add a small sliver of a spoil perimeter with an adjacent one so that the volume is added to that one. Pick first in the larger spoil that is to be kept, then in the smaller spoil that is to be removed. A new polyline is drawn around both, representing the new spoil with the same name as the first, larger spoil picked inside of. The last step is to simply erase the text of the smaller, deleted spoil (if they were labeled). If a spoil is selected on or near a common line, then the spoil is highlighted it prompts to hit Enter to accept the spoil or press N to highlight the other nearby spoil. The volumes are combined if they are already stored in the spoils as values.

The images below show the before and after of the Merge Spoils command.
Prompts

Pick inside 1st spoil polyline to merge: pick inside perimeter to keep
Pick inside 2nd spoil polyline to merge: pick inside perimeter to remove, and merge with previous
Created a shrink-wrap polyline successfully.
Done.

If the pick is near a common spoil line, then the following prompts appear:
Pick inside 1st spoil polyline to merge (Enter to end):
Press N for next selection or Enter to accept current:
Pick inside 2nd spoil polyline to merge:
Press N for next selection or Enter to accept current:
Created a shrink-wrap polyline successfully.
Done.

Pulldown Menu Location: Spoil
Keyboard Command: mergespoil
Prerequisite: Two adjacent Carlson named spoil perimeters to be combined into one larger spoil perimeter.
Assign Directions

In order to schedule the spoil polylines (which are closed polylines), they must have directions assigned. The Assign Directions command places the direction of spoil placement into the spoil polyline itself, where it is permanently stored along with other aspects of the drawing. Directions can vary by bench. The command prompts to assign the same direction to the Whole spoil polyline, or by bench. If doing by bench, the routine must be run separately for each bench.

Assign Directions is found within the Spoil menu in the Carlson Surface Mining. There are six methods employed to assign direction: Automatic, Text, Sequence, Polyline, Bearing and Azimuth. The "automatic" method will move "longways" across the pile, following the longest axis detected, but may not choose the preferred direction along that axis. The text method finds the side closest to the insertion point of the pile name and will mine from that side perpendicular across the pile away from the text. The sequence method will mine left to right and/or right to left across a series of piles as specified by the user, the polyline method will follow a "direction polyline" across a pile or series of piles and the Bearing or Azimuth method will mine at defined bearing or azimuth angle. Below is the prompting and results obtained with each method:

Prompts

Assign direction using which method [<Auto>/Text/Sequence/Polyline/Bearing/AZimuth]: A or press Enter
Select pile polylines to have direction assigned to:
Select objects: Pick the piles and the direction is assigned as shown below

In this example, it uses the long axis of the pile, and alternates back and forth for direction. It is a quick way to get directions assigned. A pile direction can be easily reversed using the Reverse Directions command.

Next are the prompts for the Text option.

Assign direction using which method [<Auto>/Text/Sequence/Polyline/Bearing/AZimuth]: T
Select pile polylines to have direction assigned to:
Select objects: pick the piles and the required pile text as shown below
The highlighted pile has the direction information assigned already.
Would you like to overwrite this (<No>, Yes, None, All): A for All. This prompt only occurs when piles are chosen that already have pile direction. Note that the command 'Clear Directions' could be used to remove directions prior to using Assign Directions.

The arrows show the resulting directions. Note that this routine looks for the pile name for the direction, not for the "site" name. (All piles have a two-tiered naming convention: site and pile, which can be re-worked as pile and block or any other two-level form, to adapt to company practices.)
Next is the Sequence option.

**Assign direction using which method [Auto]/Text/Sequence/Polyline/Bearing/AZimuth**: $S$

Select pile polylines to have direction assigned to:

**Select objects**: select the piles (Don't worry if you also select other polylines. It only finds piles.)

**Select a direction polyline.**

**Select objects**: select a polyline that crosses all of the piles

**Assign direction in which sequence (LL, LR, RL, RR)**: $LR$

In our example, we selected LR, which causes the piles to be filled left to right on the first pile (with respect to the south-to-north direction polyline–imagine yourself standing at the beginning of the polyline looking down it. LL would fill all piles coming from your left. LR would fill from the Left first, then the Right in the next one and so forth. RR and RL are just the opposite.), then right to left on the second pile, then left to right on the third, etc. An entry of LL would cause the piles to be filled from the left side to the right side. An entry of RR, for example, would fill all the piles from right to left. The entry of RL would fill first right to left, then left to right. The sequence method is ideal for assigning direction to a series of long and narrow piles that have not been broken up into small blocks.

If these same piles were each subdivided into 10 or more blocks, or there are many piles that would not be intersected by the sequence polyline, for example, then the following method, direction by polyline, is most appropriate.

Next is the Polyline option.

**Assign direction using which method [Auto]/Text/Sequence/Polyline/Bearing/AZimuth**: $P$

Select pile polylines to have direction assigned to:

**Select objects**: select the piles

Select all direction polylines.

**Select objects**: In the example above, select the single direction polyline.

The polyline-based selection is ideal for piles that follow sinuous property lines. Direction polylines cannot have arcs, so if you've used an arc to draw the polyline, use the command Remove Polyline Arcs on the Edit menu to remove them.

Lastly, are the Bearing and Azimuth option
Bearing Option:

Assign direction to whole pile or to a specific bench [Whole/Bench]: W or Enter to assign direction to whole pile
Assign direction using which method [Auto/Text/Sequence/Polyline/Bearing/AZimuth]: B for Bearing
Select pile polylines to have direction assigned to:
Select objects: select the piles
Enter Bearing (Qdd.mmss): 145.0000
The highlighted pile has the direction information assigned already.
Would you like to overwrite this [No/Yes/None/All]: A for all

The Bearing is entered in the format (Qdd.mmss), the following figure shows the quarter numbers and the angle is calculated clockwise.

Azimuth Option:

Assign direction to whole pile or to a specific bench [Whole/Bench]: W or Enter to assign direction to whole pile
Assign direction using which method [Auto/Text/Sequence/Polyline/Bearing/AZimuth]: B for Bearing
Select pile polylines to have direction assigned to:
Select objects: select the piles
Enter Azimuth (ddd.mmss): 135.0000
The highlighted pile has the direction information assigned already.
Would you like to overwrite this [No/Yes/None/All]: A

The Azimuth angle is calculated from the true north as 0, rotating clockwise.

Pulldown Menu Location: Spoil
Keyboard Command: spoil_assign_dir
Related Commands: Display Directions, Reverse Directions, Clear Directions, Create pile Plines from Mineplan

Display Directions
If directions have been assigned to spoil polylines, this command will display the directions. It therefore serves two purposes: (1) to verify that directions have, in fact, been assigned previously, and (2) to review the direction
of filling spoils. When pile directions are detected, arrows are displayed as shown below. These direction arrows will disappear with any "Zoom" command such as Pan or Window, and will also disappear if a Redraw or Regen is executed. The direction leaders can be used to draw direction arrow entities in the drawing, with the leader arrow size a prompt option.

Prompts

Display direction to whole pile or to a specific bench [Whole]/Bench: W
Draw directions as leaders or temporary arrows [Leaders/Arrows]? L for Leaders or A for Arrows
Select pile polylines to have direction displayed:
Select objects: Pick the polylines to display
Pulldown Menu Location: Spoil
Keyboard Command: spoil_display_dir
Related Commands: Assign Directions, Reverse Directions, Clear Directions

Reverse Directions

This command reverses the direction of advance within a spoil polyline. It is particularly useful in conjunction with the command Assign Directions, <Auto>, since the automatic mode may assign direction to many of the piles opposite from the desired direction. The result redraws the arrows in the new direction. If Leader arrows were drawn, then they are erased and redrawn in the updated direction.

Prompts

Reverse direction to whole pile or to a specific bench [Whole]/Bench:
Select pile polylines to have direction reversed:
Select objects:
Clear Directions

This command removes the directions from piles. The Extended Entity Data (EED) designating pile direction is removed from the pile polyline entity. This command has no effect if direction has not been previously assigned to a spoil polyline. Keep in mind that it is not necessary to first remove "old" directions before assigning "new" directions. The Assign Direction command will recognize that directions exist and will prompt the user to overwrite the direction for individual piles or for all piles.

Prompts

Clear direction to whole pile or to a specific bench [Whole]/Bench:
Select pile polylines to have direction removed:
Select objects: pick the pile polylines This can be done individually or with a window.

Calculate Spoil Volumes

This command calculates the volume of the spoil based on the selected grid surfaces. There are options to select the Top Fill Surface, Bottom Fill Surface and two optional top and bottom of bench grids. This command needs to be run separately for each bench to calculate the volumes for each one. The volumes are automatically stored in the spoil polylines, ready for the timing process. They can be verified and edited with the command Edit Spoil Volumes.

The following example shows how to store volumes for two benches. The required surfaces are set by picking the top of the pile elevation of 4850, and the bottom of the pile, stacked onto the original Surface Topography grid. Bench 1 will be from the top of pile, also 4850, down to 4825 elevation grid. Bench 2 will then be from 4825 elevation to the bottom surface, the Surface Topography grid.
The Report Formatter window displays the available attributes to report, such as Spoil, Site Name, Bench#, Fill in CF, CY or CM if metric.

The report can be viewed with the Display button, or taken into Excel with the export to Excel option.
Prompts

Select spoil polylines to process.
Select objects: Specify opposite corner: 6 found
Select objects:
Pre-processing grid cells ...

Keyboard Command: calc_spoil
Prerequisite: Closed polylines named as spoil polylines
Pulldown Menu Location: Spoil in Surface Mine Module

Edit Spoil Volumes

This command displays the spoil destination results in a spreadsheet editor. The Site Name, Pile Name, Bench, Volume and Centroid are in individual columns. This is an editor where the data can be reviewed to see what the volumes are. Any changes made here can be used for the spoil timing and reporting.

Prompts

Select spoil polylines to process.
Select objects: Specify opposite corner: 6 found
Select objects:
**Keyboard Command:** edit_spoil  
**Prerequisite:** Closed polylines named as spoil polylines assigned volumes.  
**Pulldown Menu Location:** Spoil in Surface Mine Module

---

**Edit Spoil Source**

This command brings up a table of the Spoil Source that is required for the Spoil Timing commands. This displays where the material to be placed in the spoil polylines will come from. It shows the Site and Pit names to be mined. It also shows the Bench number, period or strata for each bench, full name and volume. If the SPO was created with the Surface Equipment Timing commands, then the Period will be used instead of the Strata Names, and the Mining Period Start and End dates will be correctly assigned. Otherwise, from Surface Mine Reserves, just the Strata Names and their volumes will apply.

This image shows the source of the spoil material calculated with Surface Mine Reserves.

![Image of Spoil Source](image1)

This image shows the Spoil Source calculated on the same pits, but with Surface Mine Reserves, over three benches instead. It shows the Period instead of strata names, and the Mining Period Start and End dates are straight from the Surface Timing command, into the SPO file.

![Image of Spoil Source](image2)

The Apply Swell will swell the calculated volume stored in the SPO file. If it isn't swelled, then it will use the in-place, bank volume. The value is a percentage greater than 1.0. For example, 1.2 is a 20% swell of the spoiled material. Once OK is selected, the volumes should change on screen to a larger, swelled volume.

---

**Chapter 16. Surface Mining Module**
The Report button will bring up the Report Formatter where the requested fields will be reported in the text window, or exported to Excel. Shown here is an example text report.

Keyboard Command: edit_spo
Prerequisite: SPO file from Surface Mine Reserves or Surface Equipment Timing.
Pulldown Menu Location: Spoil in Surface Mine Module

**Spoil Placement Timing**

This command brings all the spoil commands together as final step and performs the timing and scheduling of the spoil placement. The first window is to select a new Spoil Timing Project file, or load an existing one (*.SPD file).
Once the SPD file is named, then the Fleets and production are defined in the next window, if there aren't any in the file already. The green + and X buttons are for adding and deleting the rows. Give each fleet a name and a production per hour, and hours per day worked on average. If a fleet is already saved, it can be loaded with the Load button.

The next step is to load the Spoil Source file (*.SPO) that was created with either Surface Mine Reserves or Surface Equipment Timing.
The Spoil Source editing window will appear next. This gives the opportunity to review the source data and make any final edits before scheduling. The data in the image below came straight out of the Surface Equipment Timing command.

The next screen will be the Spoil Timing Project manager. This shows a tree structure of the project which is comprised of 3 main areas, including the Haul Fleets, Spoil Sources and Spoil Destinations.
After the Spoil Timing Project screen, where all the items can be viewed and edited, clicking OK brings up the Spoil Placement Timing window. This is where all of the assigning and reporting of the schedule is set.

This is the main dialog for sequencing the spoil timing. It is divided into 4 main areas, and they are described with the matching numbers labeled on the image for clarity.
1. **Spoil Source** section shows a list of available spoil sources from the Spoil Source file that was used. They can be edited with the button, and sorted up or down. The procedure is to move them from left to right, in order to be filled by the mining.

2. **Haul Fleet**: This section shows the list of haul fleet units that are defined. Edits can be made here. To set one current, just pick it and keep it highlighted while timing spoil.

3. **Spoil Destination** section is the method to define where the spoil cuts are going. In this example, there are both in pit and out of pit spoil locations. Multiple benches will be displayed with B1, B2, etc.

4. **Calculate** is used to run the timing and get the reports once the spoil sources have been assigned to a destination. Enter in a start date if it is changed. The Shifts/Day displays how many divisions are displayed in the white window below. The gray grid lines are the shifts per month. If only 1 shift per day is selected, then each grid line is a full day.

5. Each period is divided by the red, vertical lines. This example shows months.

6. The dark blue gantt chart bars are the spoil sources. The gray bars are the spoil destination perimeters. Each spoil source has to go somewhere, once that source is used up, then the destinations go to the next source.

Once selecting the Calculate button, the next window determines the type and options for reporting. If any of the report types are set to just periods, then the window will appear like this.
If the Spoil Source File is selected, then the periods set there, created from Surface Equipment Timing, will set the period intervals. This also activates the Use Equipment Timing Grids, which will use the GSQ grid sequence file, and merge that with the spoil surfaces per period.

To select the output grids for the 3D spoil results, the surface topography, final ground surface grid is set here. Also, the top of each bench grid file is set here, for multibench spoil. These grids can be made with Grid File Utilities to set the designs by area or inclusions. For example, the top of Bench 1 could be a combination of the post mining topography for in the pit spoils, and a fill design elsewhere, for out of pit spoiling and dumping.
The program will now prompt for the existing GSQ Grid Sequence file to use. This file contains the advance of just
the pits in the mining sequence. It will now use this file, matching up the periods, and add in the back fill spoiling.
This will represent the full mining progression, showing the advance of the pits, and the following of the spoil and
dumps.

The plan view map is hatched with the color period blocks to illustrate where each spoil is placed in each period.
This creates a new GSQ file, with the name defined above in the Define Surface Grids window. It uses the name define here by default, SpoilGrids. Viewing this file with the View 3D Surface History will show the mining progression with the spoil fills.

Using the Report Formatter can export the report directly into Excel. An example Excel dump is shown here.
Keyboard Command: timespoil
Prerequisite: SPO file from Surface Mine Reserves or Surface Equipment Timing, spoil polylines with direction, and haulage fleet.
Pulldown Menu Location: Spoil in Surface Mine Module

Case Studies

Case Study #5: Surface Timing With Benches

This next tutorial shows how to run Surface Equipment Timing through a series of benches in pits. This example starts with a pit layout mineplan and structure grids. It is assumed that you already know those operations. Then Design Bench Pit is run on the pits, creating output grids and a Grid Sequence File. Next the quantities for each bench will be calculated and stored in the pit polylines. Then the sequence of mining the benches and pits is assigned and run with Surface Equipment Timing.

Creating Pit Polylines

The first step is to sub-divide the overall pit perimeter into smaller pits. In this example, the larger rectangular mine perimeter is subdivided into 5 smaller pits, named Pit-1 through Pit-5. These will be draped onto the bottom of the pit and benches will go up and out from them. The command Pit Layout By Advance was used to lay them out.
Assigning Pit Directions
In order to schedule the equipment through the pits, the direction of mining needs to be assigned to each pit. In this case, the direction of mining for each pit will be from left to right. First draw a direction polyline through the pits from bottom to top. Then run the Assign Directions command and use the Sequence method with the LL option.

Assign direction using which method (<Auto>, Text, Sequence, Polyline): S for Sequence
Select pit polylines to have direction assigned to:
Select objects: select the pit polylines
Select a direction polyline: pick the direction polyline
Assign direction in which sequence (<LL>, LR, RL, RR): LL

The pits now have direction assigned from west to east.

Design Bench Pit
Using the pit perimeters as the inclusion areas, the program will draw the 3D pit shells, output grids and calculate volumes for each pit and bench. Before running Design Bench Pit, you need the pit bottom perimeter polylines and grid files for the ground surface and benches. In the first dialog, specify the ground surface grid and the bottom elevation grid for the last bench. Also be sure the Process Multiple Polylines by Pit Names and Write Surface History. A grid file for each pit and each bench is created, and they are automatically organized in the Grid History File (GSQ).
In the next dialog, you specify the side and bench slopes. The height of the side slopes can be specified by either a depth number or a grid file. In this case we will use grid files as well as by depth. Four different sets of slopes can be applied to different sides of the pit. For this example, the same slopes will be used on all sides. You can use up to 100 benches.

The output will look as such. Each pit is in its own layer and colored differently. In the above view, the pits are laid down on the side, to show the slope to each grid.
Assigning Bench Quantities

The next step is to store quantities in each pit for each bench using the Surface Mine Reserves command. Before running this command, you need to have a Pre-Calc Grid file (.PRE) in addition to the GSQ history file. This is what determines the bench quantities and automatically assigns them to the benches. Use the Define Pre-Calc Grids command to specify the grids as shown below.
Then run Surface Mine Reserves. The dialog shown below appears. Set the modeling method to Pre-Calculated and you can leave it set to Bench 1. Since we are using the GSQ file, all five benches will be assigned automatically. Turn on all the options you see here.

Some important items to make sure are selected are Use Surface History, Use Named Pit Areas, and Store Results in Pits. After clicking OK on the dialog, specify the Pre-Calc file shown above. Next the program prompts for the Grid History File created earlier by the Design Bench Pit routine. The Merge Bench Quantities Percent applies here. If there is some grid “bleeding” where one seam bleeds into another bench due to the grid cell size, then this option will put that material back into the correct bench, as long as the amount is not less than this percentage.
Now the program will calculate the quantities of all the benches for all the pits. A report formatter allows you to optionally print or display the results. The quantities are stored in the pit polylines for scheduling. If you are not using the GSQ file, then you will have to run this for each bench number, with all the same options except set the Bench # to 2 and choose only Bench 2 from the strata list (Selected Strata turned on). Then repeat this command a third time using bench 3 etc. That is what is nice about the GSQ file, it does them all at once, even calculating and assigning the layback slope volume accordingly. Shown next is the pit by pit and bench by bench volume report.

These values are now stored in the pits and can be verified with Edit Pit under Boundary. Click inside any one of the pits to see the values. All benches can be accessed by selecting the bench number in the tree view on the left of the dialog or by selecting the Spread View tab to view data for all benched at a time.

Chapter 16. Surface Mining Module

3001
Surface Project Manager

The Surface Project Manager can be accessed under Reserves/Timing dropdown menu. It allows user to define Equipments, Timing Calendar, Pit Attributes as well as other essential parameters to be used in the timing.
Define Equipment
Select the Edit Set in Project Manager to create an equipment definition to mine the pits. This example will use three shovels. This command shows a list of existing equipment definitions. Choose the Add button and fill out the dialog as shown below for a three shift operation for all shovels. Shovel 1 mines 24000 CY/shift and Shovel 2 and Shovel 3 mines 12000 CY/Shift.
Define Calendar

The next step is to define the calendar. By default, both units are working every day, every shift. It is your job to take off holidays, weekends and maintenance down time.

Surface Equipment Timing

The Surface Equipment Timing command schedules the equipment through the pits. The first dialog shows three list boxes for the equipment, the pits assigned to the equipment and the unassigned pits. The pit benches are listed as site name - pit name - bench number. For example, "Site 1-Pit 1-2" is for bench 2 in pit1. To set the equipment to
use, choose the Add Equip button and select the equipment name defined in the last step.

The sequence of mining the pit benches must be assigned. In this case, we want a 5-step staircase that advances through the pits. By default the pit benches are sorted in the unassigned list by pit number then bench number. To arrange the pit benches in the staircase order, choose the Sort dropdown list and select 5-Bench Staircase. Then pick the Select button followed by the Assign button. This will assign the pit benches to the equipment in staircase order. In this example, just manually select the first pit/bench, and holding the CTRL button down, select every other one. Then hit Assign, assigning them to Shovel1. Then highlight Shovel2, hit Select All, and assign the remaining pits/benches to Shovel2.

Shown above are 6 profiles of the bench pits. They have been manually connected with polylines and the pits and benches are labeled to show the "blocks". This is to illustrate the real bench width in cross section view. The lower graphic shows this profile exaggerated and numbered exactly as each block is going to be sequenced in the 5 bench staircase method. The sequencer automatically sorts them in this order.

The 3D Pick option can be used to graphically select each bench and pit in the order to be mined. It is very useful for short-term scheduling. Just select 3D Pick, rotate it to an useful 3D view and then double click on each block. It will be removed and assigned to the highlighted unit.
When all the pit benches are assigned as shown in the dialog, click the Calculate button. The program will then run the equipment through the pits and report the completion date. Then click the Detailed Report button. This brings up the Report Options button.

In this case, the report period is set to Show 1st Days of Months. This will give a monthly schedule from the first of each month. Following is a report by monthly period. This can be formatted in many ways and exported to Excel.
Case Study #7: Dragline Range Diagrams

This tutorial shows how to design steps of Cast Blast Profile, Dozer Push and Cut & Place in cross section for dragline extended bench and spoil side methods. It then takes this design "template" and applies it to plan view in 3D, extruding it up and down the pit using a centerline file (CL). Other routines we will use include Define Dragline Equipment, Cut Only (coal removal), Draw Dragline limits and Flatten Spoil Top.

Creating Surface and Strata Cross-Sections

The first step is to generate a cross section of the ground surface and desired strata. This can be accomplished with the fence diagram routine, or drawing multiple profiles or sections that represent these surfaces on a grid. If the fence diagram method is used, be sure and turn off hatch fence diagram, and turn on draw strata polylines as single polylines. Otherwise, the strata will be closed polylines and the program won't use them correctly. If the profile crosses an existing, open pit and seams are cropping, be sure to turn on Draw Surface Polyline in Fence Diagram. This will draw a continuous polyline across the entire length of the section, needed for Cut & Place. Shown is a cross-section of an existing pit. In all diagrams, the existing ground polyline will be represented by the thicker, black line.

EXTENDED BENCH EXAMPLE

Cast Blast

The first operation is to simulate the cast blast for creating the extended bench. The generic profile of the blast can be defined as either a Carlson profile (*.pro) or as a polyline drawn on the screen, above the fence diagram. The profile file or polyline must be created before running Cast Blast. For example, you can draw the typical blast profile on the cross-section view. The program will move the polyline up or down to balance the cut and fill areas. First, the program has a dialog box for options.
In this case, the swell factor was set to 1.2, or 20% and the profile by polyline option was used. Then select the ground and top-of-strata polylines. Next pick the blast or cut area, this example used the lower left and lower right cut points. The left point in this case should be at the cut width, and the right point is snapped to the intersection of the top of coal outcropping at the existing ground surface.

After the program places the blast, it prompts the user if there is any vertex on the blast that needs to be moved or changed. Simply pick the position and the line will move to that location. The existing ground surface line has now been changed, and is ready for the next step.

**Dozer Push**

Now the Dozer Push command is used to create the extended bench.
In the dialog box, set the Pit Push Percent to 0%. This will push the material horizontally out into the pit. Turn off Label Push Distances, otherwise it will label the complete surface line. Also set the swell to 1.0 since this material has already had the swell factor applied from the Cast Blast. Choose OK and pick the left and right cut points as shown below. Use the Nearest Snap to pick the right cut point so it connects directly on the existing surface line. The left and right cut points should be selected at the same elevation if the push is to be flat before the pit also. The existing surface polyline has now been updated and is ready for the next operation.

![Diagram showing Dozer Push Settings and cut points](image)

**Define Dragline Equipment**
This routine simply defines the dragline parameters and dimensions for drawing its reach, depth and height on the range diagram. Fill in at least the required size parameters on the left side of the box. Many Companies supplied their dragline parameters and are on the list for easy reference.
**Draw Dragline Limits**

This draws the workable limits of the dragline on the range diagram cross-section. Pick the existing ground polyline and the location that the center of the machine is sitting. A block of three lines is drawn representing the height, digging depth and horizontal reach of the dragline. There is a vertex placed at the intersection of the ground surface, this is the point to pick for moving the block to the next cut. The vertical line above the vertex is the height, and the line below the vertex is the digging depth. These are the limits to stay within when cutting and placing spoil. There is an option to draw a dragline icon, and also to label the swing angles across the top. This allows you to keep the spoil placement within a certain swing angle. There is a prompt to use a reference point. This could be the crest of the highwall. If one is picked, then it prompts for a distance from that reference point to the center pin of the dragline. Negative values will offset it to the left.
Cut and Place
The next step is the Cut & Place command for the dragline work. In the dialog, set the right highwall angle to the repose angle of the spoil. This will ensure the cut and spoil are the same angle. Also set the spoil placement method to Left Toe.
After selecting OK, pick the ground and strata (top) polylines. Next, pick the left cut, right cut and spoil location points as shown. It is very helpful to use the Osnap endpoint and intersection to get the exact points. Notice how the right highwall angle and the spoil match for an accurate representation of the slope. Again, there is no need to swell the material as it has been already swollen from previous operations.

**Cut Only (Coal Removal)**
The final step in this example sequence is the removal of the coal to prepare the new existing ground surface for the next cut/spoil placement. Like Cut and Place, this routine also allows for differing left and right cut slopes. The strata polyline in this case will be the bottom of coal polyline, which will bring the existing ground polyline down to it.

**SPOIL SIDE BENCH EXAMPLE**

**Cast Blast**
The initial cast blast is the same as the extended bench example in the previous pages. Shown is the cross-section after the cast.

**Spoil Side Bench**
The Cut & Place routine will be used to create the spoil side bench in this example. In the dialog box, set the Top Spoil Width to the bench width (in this case, 100 feet). Then choose OK and select the ground polyline and cut...
points as shown. Again, the snap nearest is useful for selecting the right cut point. Do not select a strata polyline, as we are not going down that deep in the cut. To place the spoil, be sure to select either left or right toe for location method, as there is no spoil peak with which to place it. After placing the spoil pile, there is an option to adjust the left and right cut points. Any adjustment of the cut area is automatically reflected in the spoil bench, which allows you to adjust the spoil bench height.

Draw Dragline Limits
The next step is to show the dragline limits when placed on the spoil side bench. Use the same procedure as in the extended bench example. Another option is to create a block drawing of a dragline and insert it into the drawing to represent the correct dimensions. Shown below is a block of a dragline to scale, inserted into the above range diagram.
Cut & Place
The next step is the Cut & Place routine for the dragline pass. In the dialog, set the right highwall angle to the repose angle and set the spoil placement method to Left Toe. Also set the Top Spoil Width back to zero. Then click OK and select the ground and strata polylines. Next, pick the left cut, right cut and spoil pile points as shown. Notice the right cut point is to the right of the coal block to ensure it is uncovered and minimize rehandling. You can use the Osnap-endpoints to get the exact points. To start the spoil pile 20 feet from the spoil side bench, use the distance option and pick the edge of the spoil side bench as the reference. Type in a positive value to offset to the right and negative to offset to the left.

Cut Only (Coal Removal)
As in the previous example, the coal removal is the last step to prepare the existing ground surface for the next cut. The right side cut angle is again set to the same angle as the spoil repose to simulate the spoil down to the bottom of the removed coal block.

Process Dragline Sequence
One thing not mentioned in the previous examples is the saving of each step to a dragline sequence file. The option to store each step in a sequence file is set at the bottom of the dialog boxes. Typically the first step is saved to a New file as sequence step #1, and each subsequent step is appended to that file as #2 and up. The next example will show a simplified two-cut Cut and Place on a fence diagram and then processed with a centerline to generate 3D polylines drawn in plan view and sections. The first step is drawing the fence line and intersecting it with the centerline for laying out the cuts/pits as shown in the diagram below. This intersection will be known in the commands as the centerline reference point. Then draw the fence diagram with the hatching turned off and draw as single polylines turned on. This will provide an existing ground surface with the strata lines below it. It is usually better if there is
Cut & Place
After drawing the dragline limits, the Cut & Place settings need to be set as shown to the right. A 20% swell has been set, and it will be stored to a new step file as shown with sequence number one. This will be a simple box cut for the first sequence. Step two will be the coal removal, and step three will be the next cut and spoil placement. After step three, the sequence file will be processed and turned into 3D polylines and a section file (*.sct). The first step is shown below:
The first prompt after selecting the existing ground surface is to pick the centerline reference point. In this example, it is station 5+00 and it should be "snapped" to at the intersection of the horizontal grid line and the 5+00 tick mark. After selecting the top of strata polyline, you are prompted to enter the name of the strata. This name will be used later in prompting to select that surface grid file. Select the left and right cut points and the spoil location. Notice the two cuts were drawn in by hand to guide the user in the correct location of the cuts. This is sequence step number one.

**Cut Only (Coal Removal)**
Step number two will be the removal of the coal block. The cut angle will be set to 89 degrees on each side to simulate a near vertical face of coal after it is removed. Try to stay away from pure 90 degree slopes, as AutoCAD has difficulty sometimes. The strata line will be the bottom of coal this time, and you will be prompted to specify a name for that surface. (BOC for bottom of coal works) You will also be asked to snap to the centerline reference point (5+00).
Cut & Place

The third and final operation in the sequence will be the second cut with spoil placement into the first cut. Everything is about the same except for the sequence number needs to be set to three, and it should change automatically. Shown is the final result, sort of a template that will be applied now to our centerline (*.CL file) utilizing the surface grids and create a new surface for possible PMT application.
Process Dragline Sequence

If it has not already been done, use the routine Polyline to Centerline File to create the *.CL necessary for the processing of the sequences. The following window will appear, and needs to have at least the first three files set. It will also create an output section file for later manipulation. The Taper Spoil Sides will taper the ends of the spoil gradually down to the existing ground. The draw pit polylines will create new pit/cut polylines to run for scheduling. After selecting OK, you will be prompted for the grids representing the strata named in the previous routines.

Shown below are two 3D views of the cross section lines that were automatically drawn at the specified 100-foot interval. For visual clarification, the 3D polylines were also contoured to begin building the new surface. Notice the pit is only as long as my centerline was drawn. The top image is a rendered image of Triangle Faces that were drawn.

Another nice feature is to draw a 3D dragline and place it in plan view. This dragline shown was simply drawn with AutoCAD 3D faces and moved to the plan view. It gives good presentation material.
Draw Section File
Another step is to draw the section file created in the processing of the sequence. Shown is a partial series of sections created with the Carlson Range Diagram routines.
This section contains a dozen tutorials designed to assist you in learning the Carlson Survey/Civil/Hydro product line. They are:
Lesson 1: Entering a Deed

In this short lesson you will create a simple drawing. You will enter a 6-sided deed, add a title block, bar scale, and north arrow, add a title and certification text, and plot the deed area.

Note that the Esc key will cancel most commands, so if you choose the wrong command or enter something incorrectly and want to start over, just press Esc.

1 Click the icon for Carlson. You may be presented with a Startup Wizard dialog box. If so, click Exit.

2 Under the Settings menu, click Drawing Setup. Set the unit setting to English and the Horizontal Scale to 50. Click OK.

3 Choose Point Defaults from the Points menu, and, in the dialog box, click Elevations off to eliminate the Elevation prompt. Click Descriptions on and also set the point symbol name to symbol 4 (SPT4), which is the round, open circle. Click Automatic Point Numbering on. Click OK.

4 Under the Survey menu, select Enter Deed Description. The following dialog box will appear so you can specify where to store the coordinates:
Select the New tab. Then, for the File Name, type in "Deed". This creates a file called Deed.crd. All Carlson points are stored in files with the "crd" extension, which stands for "coordinates."

Now use the default settings as shown in this dialog box image. Click OK.

The command line is the area below the graphics and to the left. When prompted to "Pick point or point number" at the command line, pick a point in the lower left quadrant of your screen to start the deed plotting. Respond to the command line prompts exactly as shown here:

When you are prompted for a description, enter "Fence Post".

**Exit/Curve/<Bearing (Qdd.mmss)>**: 125.3500

The quadrant (Q) is 1 for Northeast (2 is Southeast, 3 is Southwest and 4 is Northwest). The bearing is 25 degrees,
35 minutes, and 00 seconds. If all digits for the minutes and seconds are entered as shown above, then the deed call will be fully plotted, including the seconds. If only the degrees and minutes were entered, as in 125.35, then the plot would appear as "N 25d 35' E".

Varas/Meters/Poles/Chains/<Distance(ft)>: 200.51
Note that you can enter old deeds in the forms of Poles and Links, Chains and Links and even Varas (a unit of measurement formerly used in the southwestern states of the U.S.).

Enter Point Description <Fence Post>: Iron Pin

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: 189.4321
Varas/Meters/Poles/Chains/<Distance(ft)>: 225.00
Enter Point Description <Iron Pin>: press Enter
Pressing Enter selects the default, which is Iron Pin.

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: C
Tangent-out/<Radius>: 75
Curve direction [Left(-)/<Right(+)>]? press Enter for right
Non-tangent/Reverse-tangent/Bearing/Chord/DeltaAng/Tangent/<Arc Len>: 118.17
If you don't know the arc length, but you know the tangent, you would choose "T" for tangent.

Enter Point Description <Iron Pin>: Concrete Monument

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: 200.0000 (due South)
If you were to enter just 2 (no degrees, minutes, or seconds), then the deed call would be plotted "S 000 E".

Varas/Meters/Poles/Chains/<Distance(ft)>: 178.00
Enter Point Description <Iron Pin>: Fence Post

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: 488.2300
This entry specifies Northwest 88 degrees, 23 minutes.

Varas/Meters/Poles/Chains/<Distance(ft)>: 300.34
Enter Point Description <Concrete Monument>: Fence Post

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: 454.1109
Varas/Meters/Poles/Chains/<Distance(ft)>: 106.93
Enter Point Description <Fence Post>: press Spacebar, then press Enter

Simply pressing Enter uses the default text (Fence Post) again. To avoid drawing the text "Fence Post" twice on the end point, press the spacebar, skip a blank character, and press Enter.

You have now completed the 6-sided figure (including one curve).

Undo/Exit/Curve/<Bearing (Qdd.mmss)>: E

The following results are reported:

Closure error distance> 0.01709  Error Bearing> S 52d5'26'' E
Closure Precision> 1 in 66076.892  Total Distance Traversed> 1128.950

The resulting deed, has a closure of 1:66077. In the initial prompt "Undo/Exit/Curve...", U for Undo would allow you to reenter the previous deed call.

Use the Extents command on the View menu to see the entire area. Then choose Zoom Out under the View menu giving you adequate room for the next step.

5 Under the Settings menu, select Title Block. The dialog you will see is shown here:
The following dialog appears, allowing you to enter the attributes for the Title Block, select OK to go to the next dialog.

Completed the title block entries, as shown above. Select Paper Size B2 (11 x 17), and enter the layer name of BORDER, then choose OK.

You will be prompted for the border location, pick a point in the lower left of the survey. Note that the title line is plotted in large text on the title block. Its length, therefore, should not exceed 15 characters.

Your drawing should look like the example below at this point.
Use the Extents command, found in the View menu, to see the entire working area. If you want to move the border, use the Move command on the Edit menu. Pick the border lines and the title block objects (up to 3 picks total), press Enter (to end object selection), then pick two points representing the vector of the move.

If you want to see a margin around the working area after you use the Extents command, use the Zoom Out command on the View menu. Then use the Window command on the View menu to capture the view and margin you prefer.

If you make a mistake, enter U for undo, or select the back arrow icon that appears at the top of the screen.

6 On the Annotate menu, select Draw North Arrow.

Accept the default north arrow that is shown at the right side of the dialog, click OK, and place it in the upper right of your drawing. Choose Move on the Edit menu (or Enter M for move at the command line) and move it.

7 On the Annotate menu, select Draw Barscale. Accept the defaults, and then pick an insertion point below the north arrow and directly above the “a” in Farmer, and approximately the same distance from both. You can move the bar scale using the Move command on the Edit menu, if you need to do so.

8 On the Draw menu, select Standard within the Text command. Respond to the prompts as shown below:

Specify start point of text or [Justify/Style]: J for justify
Enter an option [Align/Fit/Center/Middle/Right/TL/TC/TR/ML/MC/MR/BL/BC/BR]: C for center justified
Specify center point of text: pick a point near the top-center of the drawing
Specify height <4.00>: 10 Entering 10 makes the title text bigger than the default.
Specify rotation angle of text <E>: E
To enter a certification in the lower-right of the drawing, again select Text > Standard from the Draw menu, or type "dtext" at the command line. If you haven't done anything else, such as Zoom or Pan, you can simply press Enter to repeat the last command. If pressing Enter does not repeat the Text command, press Esc to cancel. Enter Dtext at the command prompt, and respond to the resulting prompts as shown below.

Pick a point above and to the left of the title block for the certification. You don't have to enter L for left-justification. The Dtext command defaults to left-justification every time.

**Height <10.00>:** 4
**Rotation angle <E>:** press Enter

Text: *Surveyor's Certification*

Text: press spacebar, then press Enter

Text: *I do hereby certify that the survey shown hereon is a true and correct representation...*

Text: press spacebar, then press Enter

Text: ________________________________

Text: *Arnold James, PLS #2534*

Text: press Enter twice to end

The following is a closeup of the certification, north arrow, and bar scale that we just entered:

![Certification Closeup Diagram]

9 Enlarge the two title lines ("Farmer Survey" and "Surveyor's Certification") by a factor of 2.0 using the command Text Enlarge/Reduce on the Edit menu, option Text. When prompted for Scaling Multiplier, enter 2. Select both the Farmer Survey text (at the top of the screen, not in the title block) and the Surveyor's Certification text. When asked again to Select Objects, press Enter.

When you are selecting objects, if you select something you don't want, you can enter "R" at the next Select Objects prompt, and remove items from the selection set. If you want to add objects after you have removed an object, enter "A" at the next Select Objects prompt.
10 Make the enlarged Farmer Survey text at the top of the screen bold by changing its font to the *ITALIC* font. From the Edit menu, select Text then select the Change Text Font option.

**Select Objects:** *pick the Farmer Survey Text at the top of the drawing*

**Select Objects:** *press Enter for no more selections*

**Style Name:** *ITALIC*

11 Select the Edit Text command (under the Edit menu, Text option) to change.

S 00d00'00" E to S 00d E. When you are prompted, "Select Text to Edit:" pick the due South bearing text.

The degree symbol is represented as %%d. (If you had typed N 15%%d25'35" E in the Dtext command, Carlson would draw that entry as N15d25'35"E.) Click in the text to the immediate right of the quotation mark and press the Backspace key until the text reads "S 00%%d E.

Click OK. Press Enter to exit the command.

12 Examine the figure shown in Step 8. Notice how the linework travels into the circle that represents point 5. To clip off the linework at the edge of the corner symbols, use the Trim by Point Symbol command on the Points menu, Point Utilities. This command requires that all points be in view, so if you cannot see your entire drawing, use the Extents command on the View menu (sometimes referred to as Zoom Extents). Respond to the following prompts:

**Select Carlson Software point symbols to trim against.**

**Select objects:** *ALL*

Entering "all" at the command line selects everything on the screen. Only the linework crossing into the corner symbols will be trimmed.

**Select objects:** *press Enter*

You can continue to select objects until you press Enter.

The trimming is completed.

13 Prepare for area labeling by selecting the Area Defaults command on the Area/Layout menu. The dialog box shown below appears.

![Area Defaults dialog box](image)

Select the *Sq. Feet* item and click on the Edit button and make the Area Text Size Scaler 0.2 (doubled from the...
default of 0.1). Click OK when complete. Select the Acres item and click on the Edit button. Change the Other Area Labels and Inverse with Area decimal precision to 4 decimal places. Also, make the Area Text Size Scaler 0.2 (doubled from the default of 0.1) as shown below:

You are going to compute the area by point number. You could have chosen the Area by Lines & Arcs command. In that command, you would pick the lines and arcs that make up the figure. But since the closure was 0.017 off (the distance from point 7 to point 1), you would exceed the default Max gap tolerance. Unless you change that tolerance in this dialog box to something larger than 0.017, you would get no result using the Area by Lines & Arcs command. So do not change it for this exercise because you might forget to change it back. Instead, you will compute the area by inversing from 1 through 7 and back to 1. Click OK to exit the Area Defaults dialog box.

14 Select Inverse with Area on the Area/Layout menu. Respond to the prompts as shown below:

Station/<Pick Starting point or point number>: 1
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 2
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 3
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): R
Radius point number or pick point: CEN for center "snap"
Now move the cursor, without picking, to the arc and see how the center snap becomes active. When the radius point is found, pick on the arc.

Curve direction [Left/<Right>]? press Enter for the Right option
Pick End of Arc or point number (U-Undo, Enter to end): 4
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 5
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 6
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 7
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): 1
Pick point or point numbers (R-RadiusPt, U-Undo, Enter to end): press Enter to end

A Standard Report Viewer dialog box showing the Inverse with Area results will appear. Select Exit at the top of the dialog box and respond to the prompts as shown below:

SQ. FEET: 83921.8 SQ. YARDS: 9324.6 SQ. MILES: 0.0
ACRES: 1.9266 PERIMETER: 1129.0

Pick area label centering point (Enter for none): pick a point near the center of the figure, in its interior.
The area units you chose in Area Defaults are labeled on the screen.

Erase Polyline [<Yes>/No]: Y
This erases a polyline that has been drawn over the original lines and arcs. The Inverse with Area command draws this polyline because often you are solving the area from points and want the new linework drawn.

You snapped to the radius point using the "cen" snap. Additional object snaps appear under Aperture-Object Snap command on the Settings menu. Since all plotted points have a node, you could have inversed around this figure by using the "nod" snap for points 1 through 7, and the "cen" snap to capture the radius point. Snaps are typically entered at the keyboard as 3 characters (for example, "int" for intersect and "end" for endpoint).

15 Freeze the point numbers to finish the drawing by choosing Layer Control on the View menu. In the PNTNO row, click the sun icon to change it to a snowflake icon, which freezes the PNTNO layer. Click OK. The point numbers remain in the drawing, waiting to be "thawed", but they are not displayed.
The final drawing is shown here:
This completes the Lesson 1 tutorial: Entering a Deed.

**Lesson 2: Making a Plat**

In this lesson you will draw out a plat of a single lot, using Carlson drafting techniques. You will make the plat from an ASCII file of points named Plat.txt.

1. Click the icon for Carlson. You may be presented with a Startup Wizard dialog box, as shown below:
You will use the Wizard in Lesson 3 to perform a series of commands to begin a drawing. In this lesson, however, you will enter the commands individually, so that you can see what each one does.

If you see the Startup Wizard dialog box, and you don't want to see it again, click the Skip Startup Wizard Next Time option in the dialog box above. Make sure the other settings are as shown above and click Exit.

Another way to turn off the Wizard is to click it off within the Configure > General Settings command, found under the Settings menu. You will open this General Settings dialog box now.

2 On the Settings menu, click Carlson Configure to display the following menu:

Click General Settings to display the dialog box shown here.
The settings in this dialog box, along with the settings in other Configure sub-options, determine default working conditions for Carlson. Turn on Group Point Entities, which groups point elevations, numbers, and descriptions (all aspects of the points) into a single entity for moving, erasing and other commands.

Choose Numeric Only to store points in numeric form. This produces point numbers such as 1, 2, 3, 10 and 11. If you selected Alphanumeric, then you could have point numbers like 1A, 1B, 1C, HUB5, CTRL, SS10, etc. There is a slight speed advantage to working with purely numeric point numbers. The highest numeric point number allowed is 99999. Regardless of format, point numbers are stored in a file that has a .crd extension. There is no limit to the number of points in an alphanumeric coordinate file. In anticipation of Lesson 3, click on the Use Startup Wizard option. Click OK at the bottom of this dialog box.

Now we want to set the data path. Another of the Configure sub-options is Project/Data Folders. Click this option and you will see this dialog box.

Chapter 17. Tutorials
For this lesson, you will keep it simple. Click on Fixed Folder at the top. Notice the Current Data Folder section at the bottom. This specifies where data files, such as .crd files in this case, are to be stored. Set the folder to C:\Carlson Projects\. Click OK. You are now back to the Configure main dialog.

3 Select Drawing Setup from the Configure main dialog box.

3 The scale acts as a multiplier on all text annotation. For example, 100 * Text Plot Size (0.08) = 8 (text height of 8 units). The Text Plot Size is the effective height, in inches, that the text will appear when plotted at the Horizontal Scale (here 100).

Bearings and Distances, Legends, Title Blocks, and Point Symbols will size up or down on the basis of the Horizontal Scale set within Drawing Setup. Set the Horizontal Scale to 25. Then click OK to exit Drawing Setup. Then click Exit to close the Configure dialog box.

If prompted for Drawing Setup Change, click on the Current and Future button.

If you have not already saved your drawing, now is a good time to do it. Use the Save command on the File menu, and call the file Lesson2.dwg.

4 Next, you will import the ASCII file called Plat.txt and store the points in a Coordinate file called Plat.crd. However, since you are in a new drawing, you have not yet set a coordinate file to store the points in. You must have a Carlson coordinate file (.crd) open and established as the container for your points.

So, under the Points menu, select the command Set CooRDinate File to display a dialog box. Click the New tab, as shown here. To the right of File name enter Plat and click Open. You have now created the required .crd file.
You are now ready to import the points. This time, under the Points menu, select Import Text/ASCII File to display the Text/ASCII File Format dialog box, as shown below. Click the Select Text/ASCII Files button and then choose Plat.txt listed on the right. It is found in the default data folder (C:\Carlson Projects). Click Open.

Plat.txt is an ASCII file containing 54 points in the form of Point Number, Northing, Easting, Elevation and Description. The format of the points appears in the Preview Window. The format is: Point (P), Northing (Y), Easting (X), Elevation (Z), Description (D), or, in short, P,Y,X,Z,D. You must match this format in the Coordinate Order. If you don't see P,Y,X,Z,D in the Coordinate Order box, then select that format from the Common Formats option. Or, you can type the list directly into the Coordinate Order box. Make sure that Draw Points is set to Off.

Click OK. The points will be saved and stored in Plat.crd. A confirming dialog appears as follows:
Click OK.

5 Choose the List Points command under the Points menu.

The List Points dialog box will typically default to the full range of points (ALL), which is 1 through 54 in this exercise. You can control the decimal places for the Northing/Easting and the Elevation of the points in the lower portion of the dialog box. Click OK and the settings shown above result in the report exhibited below in the Standard Report Viewer:
Exit the report by selecting the Exit icon at the top of this report viewer box, or by clicking the X in the upper right of the window.

6 Select the *Draw-Locate Points* command on the Points menu to draw the points on the screen.

Enable the *Descriptions* option as shown above. Also in the figure shown above, the current Symbol Name is showing as SPT10, which stands for Survey Point symbol 10. SPT10 is an X, shown in the symbol display window. You can select a different default symbol using the *Point Defaults* command on the Points menu.

In this exercise you will change the Symbol Name to null, or symbol 0, listed as SPT0 (in effect, no symbol). Later, you will add official property corner and utility symbols. Although you are working without a default symbol, there will always be a "dot" or a node at the correct insertion point of each point number.

At the top click Select. You will see the following dialog box:
Note that the scroll bar at the right of this Select Symbol dialog box leads to more pages of symbols. Click the blank SPT0 point symbol option.

When you select a symbol, you automatically return to the Draw-Locate Point dialog box. Click Draw All and the following dialog will display. The Avoid Point Attribute Overlap dialog uses different adjustment methods, such as moving attributes and creating leader lines, to fix conflicts with the point labels. Pick Cancel for now so we can view these conflicts.

Here you have the rather busy drawing shown below:
You will now be using the *Resize Point Attributes* command on the Points menu. Notice how the lower-right corner of the drawing is very congested, with many overlapping point attributes. You can specify a window containing these points and scale them down by a factor of 0.4. For Scaling Multiplier, you will enter 0.4. When you are prompted to Select Carlson Software points, you will enter WP for Window Polygon and make a polygon around the congested area. Press Enter when you have surrounded the points with the polygon as shown below. Here is the command line sequence, along with the responses you will enter, after clicking *Scale Point Attributes*:

**Method for resizing [<Scale>/Absolute]?:** *Scale*

**Scaling Multiplier <0.500>::** *0.4*

**Scale symbols only, point labels only or both [Symbols/Labels/<Both>]?:** press Enter

**Select points from screen, group or by point number [<Screen>/Group/Number]?:** press Enter

**Select Carlson Software points.**

**Select objects:** *wp*

**First polygon point:** *start creating your polygon*

Once this polygon is complete, you are again prompted to select objects. Press Enter. The following shows the
Next, you will prepare for drawing linework by setting the current layer. You should draft linework and symbol work in designated layers. In this example, you will put linework and symbol work in a layer named Final. (You could put property linework in the Final layer and utility linework in the Utility layer, but, for now, you will put all linework and symbols in the layer Final.) To pick the current working layer, select the Layer Control command from the View menu.

Click Final. Click Current. Click OK.

The 2D Polyline command allows you to enter point numbers to draw a line. First, connect portions of the property line. Select the 2D Polyline command on the Draw menu. A dialog box might appear. If it does, accept the defaults and click OK.
Pick point or point numbers: 1
Pick point or point numbers: 8
Press Enter

This creates a polyline. Keep this as a separate polyline because later you will turn this back lot line into a fence line. Now, connect some of the other property lines. Repeat the 2D Polyline command. You can press Enter to repeat the command, or you can select it from the Draw menu. Connect points 8 through 10, and start an arc, by entering as follows:

Pick point or point numbers: 8-10
Pick point or point numbers: a
Radius pt/radius Length/Arc length/Chord/Second pt/Undo: 15
Pick point or point numbers: 1
Press Enter to end the command

This creates the full lot, with the arc coming off point 10 on a tangent. The line from 15 to 1 is not guaranteed to be tangent to the previous arc.

You should have the following linework at this point:
You will now create a fence line on the polyline you drew from points 1 to 8.

Now, choose the Line Types command on the Annotate menu and select the Change Polyline Linetype command. The Line Types command creates polylines that respond as one entity when selected. When the dialog box appears, click Next twice to display the dialog box shown below.

Choose the Fence_S option (the solid fence line).

When prompted to Select Objects, pick the polyline you created from points 1 to 8. Press Enter to end selection.
Notice in the dialog box above that the current Line Type Scaler, governing spacing, should be 0.5 (inches) and the Text (height) Scaler is 0.1. If your settings are different, you may want to Undo (by entering U for undo) the fence line and select the Annotate Defaults command on the Annotate menu, and set these items to match the example.

On the View menu, select the Isolate Layers command, pick the property line, and press Enter. Here is the result:

Next, you will connect up the edge of pavement. On the View menu, select the Restore Layers command to restore your points. Then select the 2D Polyline command under the Draw menu. Again, a dialog box might appear as shown below. If it does, make sure that the options selected are the same. In the future you can choose not to see this box.
Click OK. Proceed as follows to connect up the edge of pavement:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 45-47,49-51
Press Enter at the next prompt to exit the command and create the road. Press Enter one more time. Note how you can separate range entries using a comma.

12 To smooth the edge of the road, select the Polyline Utilities command on the Edit menu, and select Smooth Polylines.

Enter the looping factor (1-10) <5>: press Enter
Enter the offset cutoff <0.05>: press Enter
Reduce polylines before smoothing [Yes/<No>]? press Enter
Select polylines to smooth.
Select objects: pick the edge of road polyline
Select objects: press Enter

13 To offset the smoothed edge-of-road polyline by 24 feet to make the opposite edge of the road, Select the Offset > Standard Offset command on the Edit menu.

Specify offset distance or [Through/Erase/Layer] <Through>: 24
Select object to offset or [Exit/Undo] <Exit>: pick the edge-of-road polyline
Specify point on side to offset or [Exit/Multiple/Undo] <Exit>: pick to the right of the polyline
Select object to offset or [Exit/Undo] <Exit>: press Enter to end the command

Now, select the Isolate Layers command again from the View menu, pick on any of your linework, and only the entities on the picked layers are displayed.

Select the Restore Layers command from the View menu to recover your points. Experiment with the "cadence" of Isolate and Restore Layers. Select Isolate Layers, pick the layers to isolate, and then press Enter twice. Then select Restore Layers.

14 Next, you will draw the shed. Select the 2D Polyline command on the Draw menu. To draw a two-sided shed, connect points 5 through 7 as follows:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 5-7 press Enter twice
This produces the 2-sided building shown here:
Select the 4 Sided Building command on the Survey menu. Turn the 2-sided shed into a 4-sided shed as follows:

**Options/<Pick a line or polyline>: Pick the shed**

Now your 2-sided building looks like this:

---

15 Focus your attention on the area of tightly spaced points with point numbers ranging from 27 to 44. This is the driveway and paving area. In the case of the driveway, assume that the surveyor who collected the points shot in 3-point arcs. They came up to a PC, shot a point on the arc, and finished up at the PT.

On the View menu, select the Window option, and pick a lower left and upper right point that windows the driveway area. If you wish to use the View > Previous command to zoom out, then use View > Window to zoom in again.

Select the 2D Polyline command under the Draw menu, and walk the polyline through the two arcs as follows:

```
[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 27
[Arc/Close/Distance/Extend/Undo/<Pick point or point numbers>]: 28
[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: A
[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: S
Second point or point number: 29
Endpoint or point number: 30
[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: A
Second point or point number: 32
Endpoint or point number: 33
[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: press Enter
```

In the above exercise you started at point 27, went to the PC at point 28 and inserted a 3-point arc through points 29 and 30. You proceeded on a tangent direction to point 31, which was another PC, then completed a 3-point arc through points 32 and 33, and ended. Now, connect up the basketball court area. Select the 2D Polyline command under Draw, or press Enter to repeat the previous command.

```
[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 27
```

---

Chapter 17. Tutorials
Next you will make a building footprint. Points 18 and 19 are two shot corners of a building. Assume that the surveyors taped the main house, going clockwise from point 18, as follows: 10'L, 20'R, 40'L, 20'R, 20'L, 83'L, 60'L, 23'L, 10'R.

You can easily enter these "jogs" in the building using the Extend by Distance command. If you are zoomed in on the driveway, use View > Zoom > Zoom Out, and then View > Pan to focus on the building north of the driveway. Now use the 2D Polyline command on the Draw menu to draw a line from 18 to 19.

**Pick point or point numbers:** 18

**Undo/Arc/Length/<Pick point or point numbers>:** 19, then press Enter twice to end

From the Edit menu, select the Extend > By Distance command.

**Pick line or pline to extend:** pick the building line closer to point 18

This makes the arrow point toward 18 rather than 19. Now you can go clockwise:

**Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help):** L10 (lower case "l" and "r" work also)

**Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help):** R20

**Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help):** L40
Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help): C to close the figure

17 Next, you will complete the linework for the sewer line and the electric utility line. Use the View > Extents command so you can see all your points.

The sewer line runs from points 52 to 53 to 54. Select the 2D Polyline command from the Draw menu. To create the sewer line, enter the following:

[Continue/Extend/Follow/Options/<Pick point or point numbers>:] 52-54, press Enter twice to end

You will next annotate the sewer polyline using the Change Polyl ine Linetype command, but first you must set the default spacing for the annotation. Select the Annotate Defaults command on the Annotate menu. The following dialog box appears.

![Annotate Defaults dialog box]

Change the Line Type Spacing to 1.5 and click OK. This will label "S" on the sewer line every 1.5" at the current scale (1"=50').

To annotate the sewer line with an S, select the Line Types command on the Annotate menu, and then choose Change Polyline Linetype. Within the dialog box, click Next twice, select the Sewer linetype from the list, and then select the sewer polyline that runs next to the road. The polyline will be annotated.

Next, create the electric utility line, which runs from point 3 to point 4 to point 17. Select the 2D Polyline command on the Draw menu.

[Continue/Extend/Follow/Options/<Pick point or point numbers>:] 3
[Arc/C lose/Distance/Extend/Undo/<Pick point or point numbers>:] 4
[Arc/C lose/Distance/Extend/Undo/Line/Undo/<Pick point or point numbers>:] 17
[Arc/C lose/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>:] press Enter twice to end

No points were taken beyond point 17, due to obstructions from the various setups in the field. So you must extend
the polyline from point 17 to beyond the property. Under the Edit menu, choose Extend, then By Distance. Pick on the electric utility polyline near point 17. Then pick beyond the property. Press Enter to end.

Before you annotate the electric utility line, you must offset it 25' on both sides, for a 50' total right-of-way. You will do this using Standard Offset. Select the Offset > Standard Offset command under the Edit menu. Enter the offset distance of 25. Pick the electric utility polyline and then pick to one side for the first offset. Repeat for the other side, by first picking the electric utility polyline, then picking the other side for the offset. Press Enter to end.

Now annotate the central electric line with an E by selecting the Line Types command on the Annotate menu, and then choose Polyline to Special Line. Choose the Electric linetype, which appears on the third page of linetypes. Then select the electric utility polyline to annotate it, and press Enter.

18 Next, make the Property lines bold. Under the Edit menu select Polyline Utilities > Edit Polyline and then select Change Polyline Width.

**New Width <0.0>: 1.5**

**Select objects:** Pick once for the fence line portion and once for the remaining property lines.

**Select objects:** press Enter to end

19 To add color and improve layer management, make a layer for your road and driveway. Select the Layer Control command on the View menu.

Click the New Layer button, and enter the name "Road" for the new layer. Choose the color Cyan by clicking the color square to the right of the layer name. Click OK.

On the View menu, select the Change Layer command.

**Select entities to be changed.**

**Select objects:** Pick all driveway and road entities and press Enter

**Specify new layer [Name/<pick entity>]: N**

This brings up the dialog box shown below. Select ROAD and click OK.

Your linework is now complete and is shown below:
You will add symbols for trees, property corners, manholes and a light pole.

Start with the trees. Points 11, 12, and 20 are oak trees of different sizes, and point 14 is a pine tree. Use symbol 61 for the deciduous oak trees and symbol 53 for the pine tree. On the Draw menu select the Symbols > Insert Symbols command. The following dialog box appears.

Click the Select button, and within the Select Symbol dialog box, use the down arrow at the right to scroll forward to the tree symbols, which are several pages deep. Choose symbol SPT61. You can also choose Trees under the Symbol category field in this dialog. You are returned to the Insert Symbols dialog box.

Set the Erase Existing Symbols option to Yes and then click the Select Layer button and type in TREES in the Layer Name field. This creates a Trees layer if one does not exist. Click OK. For the Symbol Size use 18. A symbol size equal to the diameter of the tree is often effective. Click OK.

Options/Select entities/Enter Coords/<Pick point or point numbers>: 11
Options/Select entities/Enter Coords/<Pick point or point numbers>: 20
Options/Select entities/Enter Coords/<Pick point or point numbers>: press Enter
Place symbol 61 on the larger point 12 at size 24. Press Enter to repeat the last command, or once again select the
Insert Symbols command from the Draw > Symbols menu. Symbol 61 will now be the default. Change the Symbol
Size to 24 and click OK.

Options/Select entities/Enter Coords/<Pick point or point numbers>: 12
Options/Select entities/Enter Coords/<Pick point or point numbers>: press Enter

Place symbol 53 on the larger point 14 at size 8. To do this, press Enter to repeat the last command, or select Insert
Symbols from the Draw > Symbols menu. Select symbol 53 and a Symbol Size of 8. Click OK.

Options/Select entities/Enter Coords/<Pick point or point numbers>: 14
Options/Select entities/Enter Coords/<Pick point or point numbers>: press Enter

Place symbol 5 (representing an iron pin) on points 8-10 and point 15. Repeat Insert Symbols by pressing Enter
to repeat the last command, or again select the Insert Symbols command from the Draw > Symbols menu. Select
symbol 5 (first page) and leave the Symbol Size of 8. Change the layer to FINAL. Click OK.

Options/Select entities/Enter Coords/<Pick point or point numbers>: 8-10,15
Wildcard match of point description <**>: press Enter

This puts symbols on points 8 through 10, as well as point 15.

Options/Select entities/Enter Coords/<Pick point or point numbers>: press Enter

Place a concrete monument (symbol 13) on point 13 on layer FINAL. Keep the Symbol Size of 8. Press Enter to repeat the last command, or select the Insert Symbols command from the Draw > Symbols menu. Select symbol 13.

Options/Select entities/Enter Coords/<Pick point or point numbers>: 13
Options/Select entities/Enter Coords/<Pick point or point numbers>: press Enter

Place a manhole (symbol 34) on the vertices (endpoints) of the sewer line, at points 52 through 54. You could use the above method, but you can also use S for Select entities, and place the symbol automatically at the vertices of the selected entity.

Select the Insert Symbols command from the Draw > Symbols menu. Select symbol 34 from the list. Keep with layer FINAL and Symbol Size 8. Click OK.

Options/Select entities/Enter Coords/<Pick point of point numbers>: S

The following dialog box appears. Click OK.

Select arcs, circles, faces, points, text, lines and polylines.
Select objects: pick the sewer polyline

The symbols are inserted at the three polyline endpoints.
You can reduce clutter by selecting the Freeze Layer command under the View menu, and picking a point number. The points freeze, leaving only linework and symbols. To bring the points back, use the Thaw Layer command under the View menu. The Freeze Layer and Thaw Layer commands go together, just like the Isolate and Restore Layers commands.

Next, you will create (in reduced size) your building dimensions. You can set the building dimension text size for the current work session using the Survey Text Defaults option of the Survey Text command on the Annotate menu. This dialog box appears:

The changes you will make are in the upper-left section "Building Dimensions." Change the Text Size Scaler to 0.04, select Drop Trailing Zeros and change Offset From Line to 0.02.

The Drop Trailing Zeros option will label 17.0' as 17'. To save more space, you could blank the Characters to Append box, but not this time. Enter the name of a new layer for the building text called BTXT, so that building dimensions can be frozen to reduce the clutter even more. It is generally a good strategy to use layers for selective freezing and thawing.

Click OK on the above dialog box. On the Annotate menu, choose the Survey Text > Building Dimensions command. Click on the middle of the bottom segment of the building and then drag the alignment to the right, along the same bottom segment being dimensioned. The resulting label is shown below.
If you had dragged the cursor to the left rather than to the right, with the same near-parallel angle to the line, the 83’ would be drawn below the building rather than above.

Another example is shown below. Select Annotate > Survey Text > Building Dimensions, and click on the left-most segment of the building. Then click roughly perpendicular to the left. This creates a perpendicular, rather than parallel, label as shown below.

Label the rest of the building. Notice that the sides of the building that you are dimensioning are measured in even feet. Because you had selected the Drop Trailing Zeros option when you set your Survey Text Defaults, and you set the Decimal Places default at 0.0, the ".0" is not reflected in the labels:
If you choose the wrong direction while you are labeling, you can exit the command, or you can erase the incorrect dimension by typing E for erase at the command line, or you can enter U for undo to back out your last work. Once the labels are in place, you can type M for the Move command, and move the text to the desired position.

Next, you will label the offset dimension from property lines to two building corners, the SE corner as offset from the south property line, and the SW corner as offset from the west property line. Because of the options you set in the Survey Text Defaults dialog box above, Offset Dimensions will be created on layer DIMENTXT, and they will be horizontal, with arrowheads.

On the Annotate menu select Survey Text > Survey Text Defaults. The dialog previously shown will reappear. Change the Text Size and Arrow Size Scalers to 0.040. Then select Dual Arrows Line and click OK. On the Annotate menu, select the Survey Text > Offset Dimensions command.

Pick Bldg/Object Corner: pick on the SE building corner
Pick Line To Offset From: pick on the South property line (before the arc, near the end of the driveway)

The setback is labeled 43.5'. Note the distance suffix is/was labeled as an apostrophe "'" rather than ft. If you desire an alternate label, re-examine the Characters to Append control of the Survey Text Defaults command.

On the Annotate menu, select Survey Text > Survey Text Defaults. Under Offset Dimension Text change the Text Alignment to Parallel instead of Horizontal. Click OK. Select Annotate > Survey Text > Offset Dimensions command.

Pick Bldg/Object Corner: pick on the SW building corner
Pick Line To Offset From: pick on the West property line (avoid the electric right-of-way line)

Use the Move command to move the 20' text label to the right, so that it is not overwritten by the offset dimension. The result is shown below:
Notice the display, within the above prompts, of the [end on] and [perp] snaps. When Carlson sets a snap for temporary use, it displays the snap within the brackets as shown. A building corner is always an endpoint, so the end snap always applies to the first pick. The offset is the perpendicular distance to the property lines, so the [perp] snap always applies to the second pick. The "per" (perpendicular) snap applies to offsets from arcs as well. In the case of arcs, the "per" snap finds the shortest, radial distance to the arc.

When you enter a snap at the keyboard in response to a "Pick object" request, type only the first 3 letters of the snap, such as "per" or "end". You could use the Offset Dimension command to label the Electric utility right-of-way distance of 50’ total by entering "nea" (for nearest snap) for the first pick, then entering the default "per" snap for the second pick on the other side of the right-of-way.

24 Next, you will add adjoiner ownership text to the property lines. Select the Survey Text Defaults command, under the Annotate menu, and set the Adjoiner Text Justification option to C for centered, and the Text Size Scaler to 0.06. Click OK and then select the Adjoiner Text command on the Annotate > Survey Text menu.

**Pick Line Or Polyline:** *pick the west property line*

**Pick Starting Point:** *pick a centering point west of the property for the adjoiner text*

**Text:** Brian W. and Mary T. Jones

**Text:** D.B. 101, P. 37

**Text:** press Enter twice

This produces parallel, center-justified text on the west side of the property. Repeat the command for the north side. Press Enter to repeat the Adjoiner Text command or select it from the menus.

**Pick Line Or Polyline:** *pick the north property line*

**Pick Starting Point:** *pick a centering point north of the north property line*

**Text:** Stan W. Bosworth

**Text:** D.B. 94, P. 272

**Text:** press Enter twice

The results are shown here:
Next, you will add bearing annotation. Select the Annotate menu, choose Angle/Distance, select the BearingDistance option to place Bearing and Distance above the line.

Define bearing or set text size [Size/Points/<select line or polyline>]: pick the northern property line to the east, or right side

The bearing direction will be labeled towards the picked end, which is northeast.

Define bearing or set text size [Size/Points/<select line or polyline>]: pick the eastern property line closest to the southern endpoint of the line

To label the western property line on the lower (western) side of the line, select the BearingDistance command on the Angle/Distance menu.

Define bearing or set text size [Size/Points/<select line or polyline>]: pick the western property line on the northern portion of the line

To label the southern line segment with a leader, on the Annotate menu select the Annotate with Leader > Brg-Dist with Leader command.

Options/Size/Points/<Select line or polyline>: pick the southern property line segment on the southwest side
Pick point to start leader: pick a point to start and locate the pointed end of the arrowhead
Label Position: pick a point for the label position
Options/Size/Points/<Select line or polyline>: press Enter to end

Next, you will want to annotate the arc in the drawing. The label will consist of four entries: arc length, radius, chord bearing (direction) and chord distance.

From the Annotate menu, select the Annotate Arc > Stack Label Arc command. The Stack Label Arc dialog box appears.
Set the sequence column to 1, 2, 3 and 4 as shown. When you are done with the dialog box, click OK.

**Curve Info [Options/Points/<select arc or polyline>]**: pick the arc

**Pick point for labels**: pick a point to the right to place the label

As the cursor moves, the text "ghosts", allowing you to make the best possible placement decision

**Pick point to start leader at ([Enter] for none)**: pick a point on or near the arc for the arrowhead

**To point**: pick a point near the labels

**Curve Info [Options/Points/<select arc or polyline>]**: press Enter to end

If your arcs/curves appear as "chorded" segments, type REGEN at the command prompt to "regenerate" the arc. Even if an arc shows up on the screen as a group of jagged chords, it will plot as a smooth arc to a printer or plotter.

27 Next, you will label the trees, the shed, and the building using a special leader, for a hand-drafted appearance. Under the Draw menu, select the Leader > Special Leader command.

**Options/Size/Pick Arrow Location**: pick near the southern most corner of the shed

**Text location**: pick slightly down and to the right

**Text**: Shed

**Text**: press Enter twice to end

Repeat the process for all the special leader text items shown in the drawing below. In the case of the 18" Oak trees, create just one leader with text and on the second oak tree, create only the leader and then press Enter when asked for Text. For the best appearance, enter 18"Oak and 24"Oak with no spaces between the characters.

Your drawing should be similar to this one:
28 You can add a North Arrow and Bar Scale by selecting these options under the Annotate menu. When you place the North Arrow, pick your North Arrow symbol, maybe change the scale, and click OK. Then pick an insertion point. You place the Bar Scale by answering the prompts and picking a location. Both the North Arrow and the Bar Scale can be moved to desired locations with the Move command on the Edit menu.

29 Next, you will insert a title block with a border. Select the *Title Block* command from the Settings menu.

Choose paper size A1 (portrait view, 8-1/2 by 11). Click OK. Pick a point below and to the left of the survey in order to locate the lower-left corner of the border outer line. Remember that the title block will be at the bottom, so leave extra room at the bottom.

The following dialog appears, prompting you for the attributes of the title block. Be sure to also click Next in order to enter in more attributes.
Your drawing should resemble the one shown below.

30 Next, you will add a legend. On the Annotate menu, select the Draw Legend command. Choose the New tab, and then Open the default legend name. When the dialog box appears, select Add from Drawing. You will make one pick for each symbol you want to appear in the legend. Select one of the sewer manholes, one of the iron pins, the concrete monument, one oak tree and the pine tree. Press enter. You will then see the symbols that you picked listed.

If you want to change the order of the items in the list, use the Move Up and Move Down buttons, after first selecting
and highlighting the item to be moved. After the list is ordered correctly, highlight one item on the list and click the Edit button to edit the symbol definition.

Edit each symbol definition individually and type the following descriptions in the description box:

SPT5 = "Iron Pin"
SPT34 = "Manhole"
SPT13 = "Concrete Monument"
SPT61 = "Oak Tree"
SPT53 = "Pine Tree"

Below is the symbol definition, with Description, for SPT13.

After you have entered the descriptions for the symbols, choose the Add option from the Legend Definition dialog box and add the Fence Line type to the list by picking the Select Library Linetype command, as shown below:
Save the completed legend which is shown below.

Select the Draw option from the Legend Definitions dialog box. Set the defaults as shown below.
Click OK. Pick a point for the legend at a coordinate location approximately at 5260,4380. Then click Exit.

You may need to move the fence line portion of the legend to fit in the tight space. You also may need to move the previously drawn bar scale. Use the Move command to do this. The following shows the drawing to this point:

If you wish to reset the spacing of the sewer and electric utility annotation, use the LTSCALE box in the Drawing Setup dialog box found under the Settings menu. (The setting is 50 in this example).

Next, you will use Dtext to label the road and Mtext to create a certification block. Zoom in on the area shown below. At the command line, type Dtext.

Specify start point of text or [Justify/Style]: R (for right-justified)
Specify right endpoint of text baseline: pick a point as shown below, just to the left of the leader annotation
Specify height <8.00>: 10
Specify rotation angle of text <E>: pick a point as shown below by the location of the crosshair

Text: Meadow Lane
Text: press Enter

This right-justifies the label Meadow Lane, ending it before it contacts the leader line.

Now you will enter a certification using Mtext. The Mtext command stretches an entire block of text. This command breaks up the lines in the block of text depending on how you edit and adjust the Mtext window. First, use the View > Extents command to view the entire drawing. Then type Mtext at the command line.

Specify first corner: pick a point in the 5660,4980 range
Specify opposite corner or [Height/Justify/Line spacing/Rotation/Style/Width]: pick a point below and to the right of the first, but inside the inside border line

You now see a dialog box that displays all the text heights that you have used in the drawing. Choose the text height of 8. Then type the following into the dialog box:

![Text Formatting dialog box]

Surveyor’s Certification
I do hereby certify that the survey shown hereon was performed under my direction by method of random traverse, and that the error of closure was 1:52544

3 Brad Smith PLS No 11952

The command "wraps" the text when it runs out of space in the Mtext window. Click OK at the upper right to place this text into the drawing.

After the Mtext is plotted, you can click on the text to activate the grips. All 4 corners highlight as grips. When you pick on a grip, you can expand or change the shape of the Mtext rectangle. When you do this the text adjusts automatically, wrapping into more or fewer lines of text based on the size of the MText window. You can also move the entire text block to a new location.

Next, you will define a text style and then add text using that style. On the Draw Menu, choose the Text > Set Style command. The Text Style dialog box appears. Click New, enter Bold in the New Text Style dialog, and click
Create a **Bold Style** consisting of the Arial Black font tilted at a 10° oblique angle, by entering the settings as shown below.

[Image of New Text Style dialog box]

Then click Apply and Close. Now, run the Dtext command by typing Dtext at the command line, and place the text at the top of the drawing as follows:

**Specify start point of text or [Justify/Style]:** pick a point near the northwest corner of the drawing  
**Specify height <10.00>:** 20  
**Specify rotation angle of text <N 54d40'16' E>:** E for due East  
**Text:** William T. Farmer  
**Text:** press Enter twice

33 Next, you will create an area label for the drawing. Select the Area Defaults command, under the Area/Layout menu, and change the Precision for the Acres labels to 2 decimal places.

Select the **Area by Lines & Arcs** command, under the Area/Layout menu. When prompted to Select objects, pick the 2 polylines that taken together, completely enclose the property.

Pick an area labeling centering point for the area label under the William T. Farmer title at the top of the drawing.

34 Next, bring the points back and draw a contour map. To draw the points, use the **Thaw Layer** command under the View menu. If you did not complete this lesson in one sitting, then Carlson won't "remember" what layer to thaw. In that case, select the **Layer Control** command on the View menu, and thaw the PNTS layer by turning the snowflake to a sun symbol.

Go to the Surface menu and select the **Triangulate & Contour** command. Click the Contour tab.
In this Contour tab section, change the contour interval to 1.0. Now click on the Triangulate tab, and then click on Use Inclusion/Exclusion Areas. Press OK and then answer as follows:

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: press Enter
We have no "inclusion" perimeter.

Select the Exclusion perimeter polylines or ENTER for none.
Select objects: select the building and the shed, and then press Enter
Since the building and shed are closed polygons acting as exclusion perimeters, the contours will not pass through them when they are created.

Select the points and breaklines to Triangulate.
Select objects: type ALL and then press Enter twice

The contour map is created. Freeze the points again by using View > Freeze Layer and picking one of the points.

Next, label the contours. From the Surface menu, select the Contour Utilities > Contour Elevation Label. Select OK after matching the settings in the dialog box shown here:
Now pick two points that cross through one or more contours. The contours are automatically labeled using the current text style. You can use the Change Text Font command, part of the Text command in the Edit menu, to change the font to Romans, or to another font, if you wish to.

The Completed Plat is shown here:

If you have not saved your drawing for awhile, now is a good time to do it. Use the Save command on the File menu.

This completes the Lesson 2 tutorial: Making a Plat.
Lesson 3: Field to Finish for Faster Drafting

In this lesson, you will make a plat using field to finish techniques, with the help of the Startup Drawing Wizard.

1 Launch Carlson, or, if you are already in the program, select the File menu, and select New to start a new drawing. Save your existing drawing first, if you'd prefer. If you are asked to use a template, choose carlsonxx.dwt, where xx is the last two digits of the AutoCAD release that you are working with. For example, for AutoCAD 2008, you would select carlson08.dwt.

The first of several Startup Wizard dialog boxes appears. If the Startup Wizard does not appear, then go to the Settings menu, choose Configure and then select General Settings. In the General Settings dialog, click Use Startup Wizard in the upper-left and click OK. Then open a new drawing again.

Once in the Startup Drawing Wizard, click Set at the top of the dialog box, and enter in a new Drawing Name. Since this is Lesson 3, call the new drawing Plat3.

Verify that the other settings match the settings shown above, and click Next. You will see the Startup Wizard Data Files dialog. This dialog box is used to specify where to store data, and the existing point information source. Click the Set button to establish Plat3.crd as the new CRD file name.

Our source is the same file as in Lesson 2, Plat.txt. This is an ASCII file, so select Text/ASCII File for the source of our Point data and click Next. The Import Text/ASCII File dialog box appears. Click the Set button to establish Plat3.crd as the new CRD file name.

In the next dialog box, titled Text File to Read, choose plat.txt from the "Carlson Projects" folder, and then click Open.
The Text/ASCII File Format dialog appears again, and the format of the points appears in the Preview Window, for verification, as shown below. Be sure that to the right of Draw Point, that Draw-Locate Pts is selected. Set the other options as shown. Click OK.

The points are then copied into the file Plat3.crd. If you repeat this exercise, and again use the file name Plat3.crd, you will be asked:

[O]verwrite w/new coordinates, overwrite [A]ll, or use number <55>: A (for all)

In either case, when you correctly complete the process, the following dialog box appears:
Then this Drawing Import Wizard dialog box appears:

Choose the Field to Finish option, and click Next. If you receive a file selection dialog titled Specify Field Code Definition File, choose the file called "Carlson.fld". A dialog box now appears with a warning that some codes have two descriptions.
The command is asking whether these codes are to be treated as two separate descriptions, or as one description that has a space in it. Choose the default (Split all multiple codes) to tell the command that codes with spaces are really two separate descriptions, and click OK.

The Draw Field to Finish dialog box appears. Choose the options as shown here. Then click Additional Draw Options.

This displays a dialog box that provides many additional options, as shown below.
You want to draw all 1 through 54. Make sure the other options are set as shown above. Click OK twice.

*Draw Field to Finish* now draws the points and linework. *Draw Field to Finish* saves you many manual steps. Your plat is shown below:

2 To understand how the above drawing was created, select *Draw Field to Finish* from the Survey menu. If you are prompted about Possible Multiple Codes, accept the default *Split all multiple codes* option and click OK. On the *Draw Field to Finish* dialog box, select the Edit Codes/Points button. This takes you to the Field to Finish dialog box.
The display window shows a list of point codes, such as IP for iron pin and FL for fence line, that are converted to special symbols and linetypes by Draw Field to Finish. For an example of how the codes are used, look at the sewer line running from point 52 to 53 to 54 (the southernmost point), which is based on a field code of MH. Select MH for Manhole as shown above, and then click Edit. The following dialog box is displayed.

MH has several attributes that are used by Draw Field to Finish, based on the settings shown above. Draw Field to Finish places the manhole on layer SEWER, and plots a text description of "MANHOLE" underneath the symbol (Descriptions can be upper or lower case). Click on the Symbol tab and notice that it draws a manhole using the symbol SPT34. From the Linetype tab, it draws a sewer line with the letter S for sewer. When you are done looking
at the MH field code definition dialog, click OK.

Other codes have fewer attributes. LP is set only to draw a symbol and text (Light Pole), but not to draw linework. FL, for fence line, is set to draw linework but not corner symbols or points descriptions. A code's attributes depend on the entries in the Set Linetype, Set Symbol, Description and Entity Type options.

The “Carlson.fld” Field to Finish code table is provided with Carlson Software. This table shows one possible system, but with far too many codes for a field crew to remember. You can make your own table by choosing the Code Table Settings option from the Field to Finish dialog box, then choose the Set button at the top right. Then select the New or the Existing tab from the top of the Specify the Code Definition File dialog box, in order to create or select a different code table (.FLD) file.

Click Exit to dismiss the Field to Finish dialog box.

Use the Layer ID command, located under the Inquiry menu to verify the layers of the various plotted entities. Select Layer ID. Pick on the fence line, the road and the utility line, and notice the different layers (FENCE, EOP, UTILITY). You can also use Drawing Inspector under Inquiry to hover over linework to see their layer. You should study the layers in a drawing before deciding what to freeze and thaw. To reduce clutter on the screen, select the Layer Control command from the View menu (the appearance of this dialog box might vary from that shown below).

Freeze the PNTS layer, the SPOT layer, and the PNTELEV layer by turning the sun into a snowflake. To select multiple layers hold Ctrl, Then click OK.

Now you will do some drawing cleanup. Note that a single property line is drawn from point 8 to 9 to 10 and to 15. The chord from point 10 to 15 should be an arc. You will erase the segment from 9 to 10 and from 10 to 15, so that you can re-draw it, establish the tangent, then draw the arc and finish back at point 1.

From the Edit menu, select the Polyline Utilities > Remove Polyline > Remove Polyline Segment command.

Break polyline at removal or keep continuous [<Break>/Continuous]: press Enter for Break
Select polyline segment to remove: Pick the segment from 9 to 10, then the segment from 10 to 15, then press Enter to end

To draw the correct polyline, use the 2D Polyline command under the Draw menu. If you prefer to type in the command, type 2dp which stands for 2D Polyline. If the Polyline 2D Options dialog box appears, accept the default values and click OK.

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 9
[Arc/Close/Distance/Options/<Pick point or point numbers>]: 10
[Radius pt/radius Length/Arc length/Chord/Distance/<Pick point or point numbers>]: A
[Radius pt/radius Length/Arc length/Chord/Distance/<Pick point or point numbers>]: 15
[Radius pt/radius Length/Arc length/Chord/Distance/<Pick point or point numbers>]: 1
[Radius pt/radius Length/Arc length/Chord/Distance/<Pick point or point numbers>]: press Enter
Use the 4-Sided Building command (found under the Survey menu) you learned in Lesson 2 to create the other two sides of the shed, located in the upper middle of the screen, near point 17. The end result, except the house, is shown below:

5 Much of the text in the above drawing, such as tree sizes and types, the manhole text, and the light pole text, can be used in the final drawing. But some of the text, such as the text plotted for iron pins and poles, can be fully described in the Legend without the redundancy of plotting to the screen. If you use the Erase command to remove the iron pin and pole text, the entire point will be erased because the attributes are grouped with the point. Instead, use the Erase Point Attributes command under the Points menu.

Select attribute(s) to erase (Enter to end): pick the 3 poles and the 4 iron pins and then press Enter when complete

6 Next, you will use Extend by Distance command to create a building. The building will be less complex than the building you created in Lesson 2, but you will use the "t" and "c" options in addition to "l" for left and "r" for right. From the Edit menu, select the Extend > By Distance command.

Pick line or polyline to extend: pick the western side of the small line segment west of the 12" pine and north of the driveway.

"T" or "t" means "total" distance or "to" the distance - so extend "to" 50 feet total.

In Extend by Distance, the "T" option (for total distance) solves the dilemma of making an existing line of unknown length extend to an exact known length.

7 Use the Twist Screen command to better position the plat on the sheet. Not every drawing can be plotted "due North." Sometimes the plat needs to be oriented so that property lines and important features run nearly left-to-right or top-to-bottom on the plotted page. In this drawing, you want the western line from point 8 to point 9 to run left-to-right on a sheet that will be plotted in landscape style (longer left-to-right than top-to-bottom). Under the
View menu, select the *Twist Screen > Line, Polyline or Text* command.

**Pick a line, polyline or text to make horizontal:** _pick the western line_ from point 8 to point 9, closer to point 9

Now the drawing appears as shown below:

![Image of drawing](image)

Notice that the north indicator (referred to as the USCICON, if shown) at the lower left displays the orientation. The benefit of the *Twist Screen* options are that coordinates of points and directions of lines have not changed. In other words, only the orientation of the data on the screen has changed.

8. Now select *Twist Point Attributes*, under the Points menu, to twist the point descriptions and point numbers back to a left-to-right rotation.

**Twist by** [**<Twist screen>/Azimuth/Entity segment/Follow polyline**]? press Enter

**Enter angle relative to current twist screen <0.0>:** press Enter

**Select points from screen, group or by point number** [**<Screen>/Group/Number**]? press Enter

Select Carlson Software points.

Select objects: *ALL*, and then press Enter twice

The points then twist back orthogonal to the screen, reading once again from left-to-right.

9. The remaining descriptions associated with the points can be used in the final drawing, but they should be moved slightly for a better appearance. For example, the tree descriptions would look better if they were not inside the tree canopies.

Under the Points menu, select *Move Point Attributes - Single*. The steps of the command are:

**Select attribute(s) to move (Enter to end):** _pick an attribute to move_

**Displacement:** _pick the new location for the attribute_

**Rotation:** _pick the new orientation for the attribute_ or press Enter to keep the existing orientation

Then the command repeats. Notice how the text "ghosts" as it moves, which helps you place it in the best position. Try to duplicate this result:
10 Because of the earlier *Twist Screen* command, the E’s in the electric utility polyline are upside down. From the Edit menu, select the *Text > Flip Selected Text* command.

**Select the text to flip.**

**Select objects:** pick the upside down E’s individually and then press Enter (see above image)

11 We wish to apply building dimension labels to the exterior of the building created earlier. From the Annotate menu, select the *Survey Text > Survey Text Defaults* command and set the Exterior option as shown below:

Click OK when complete. From the Annotate menu, select the *Survey Text > Building Dimensions* and pick on the house. If the text overwrites the inside corner of the house, use the *Move* command (under the Edit menu, or type M
for Move at the command prompt) and move the 30' dimension beneath the line.

12 To automatically annotate bearings and distance, as well as arcs, select the Auto Annotate command from the Annotate menu. When the dialog box appears, under the Lines tab, select the options you would like to use so that the bearings and distance labels appear as you would like. Then pick the three polylines that fully define the perimeter: the fence line, the polyline containing the arc, and the lower polyline, which is still the western polyline although you have twisted the screen so that it runs along the lower portion of the drawing. Use the Move command to move the bearing and distance labels to avoid overwriting other features.

When you move the lower distance label, 404.90' to the left, you want to move perfectly level to the screen, since this was the line you used to twist the screen, and it runs perfectly left-to-right. To do this, press the function key F8 to activate Ortho. Then pick 404.90' and move it to the left, picking its final position. Repeat this for the S 17°05'38'' E bearing. After you move these items, press F8 again to turn off Ortho. Sometimes you will load a drawing from another client or source, and the Ortho setting has been left on. This may initially confuse you during the Move commands. Press F8 to deactivate Ortho. Notice that F8 works even with Twist Screen active.

13 Auto Annotate may center the arc annotation above and below the arc, which may cause the arc data to overwrite the surveyed edge-of-pavement (EOP) polyline. As needed, you may want to erase the arc annotation, and use the Annotate > Annotate Arc > Label Arc command to better control the placement of the arc annotation.

If needed, erase selected portions of the arc annotation. At the command line, enter E for Erase.

Select objects: enter WP and then press Enter
First polygon point: pick initial point of a polygon
Specify endpoint of line or [Undo]: pick subsequent points as shown and then press Enter twice when the selection set is complete
There is no "close" option for window polygon and crossing polygon selections.

For the new annotation, under the Annotate menu, select the Annotate Arc command, then the Label Arc option. Then select the arc from the screen. The Label Arc Settings dialog box appears:
You want to locate the arc text inside the arc, on positions 1 and 2. Position (Row) 1 is just under the arc, and 2 is under 1. Be sure they are both Inside. Fill out the dialog box as shown above and click OK.

The new arc text might overwrite the 8’’ Pine, so, if it does, use the command Move Point Attributes - Single, in the Points menu, to relocate the 8’’ Pine description.

With the annotations placed in new positions, your drawing should be similar to the one shown below. Move your annotations to match this drawing.

14 To label the area of the lot, first select the Area Defaults command from the Area/Layout menu. Set Sq. Feet (s.f.) to the nearest whole unit (no decimals) with a Text Size of 0.100 and Acres to 2 decimal places with a Text Size
of 0.100. Then click OK to exit the dialog box. Select the *Area by Lines & Arcs* command from the Area/Layout menu, and pick the three polylines individually that define the property perimeter. Press Enter and locate the text to the left of the 12” Pine.

15 Before completing the final formatting of your drawing, you need to do some minor cleanup, using procedures you learned in Lesson 2.

You don’t want point 16, the PL point, to show in the final drawing. Use the *Drawing Inspector* command, under the Inquiry menu, to verify the layer of point 16, which should be MISC. Freeze MISC using the *Freeze Layer* command on the View menu, and pick point 16. Freeze the point numbers using the *Layer Control* command on the View menu, and freeze the layer PNTNO.

16 To insert an A1, 8-1/2 x 11 border and title block, with the orientation landscape (not portrait), select the *Title Block* command from the Settings menu. You will see this dialog box.
Be sure these above selections match your own. Click OK. For the insertion point, select a point at the very lower-left of the screen, so that your drawing plan entities fit inside the border and somewhat nearer to the top. Pick your screen location. You will then be prompted for the attributes of the title block. Fill them in and click OK.

![Edit Attributes dialog box](image)

If you prefer, you can use the *Move* command, pick the title block and two border perimeters, and move them. Never move the drawing, because you will change the coordinates if you do. Move the drawing only if changing the coordinate locations does not matter.

17 From the Annotate menu, select the *Draw Legend* command. Select the Existing tab and choose the .lgd file that you saved in Lesson 2 and click Open. Then select Draw and OK to close out the dialog boxes that follow, and then click Exit.

Pick an upper-left location point in the available space to the lower-left of the plat. If you did not save a legend in Lesson 2 (or you skipped Lesson 2), follow the steps in that lesson. Use the *Resize Point Attributes* command, under the Points menu, and scale up the oak tree symbol in the Legend by a factor of 1.5.

From the Annotate menu, select the *Survey Text > Survey Text Defaults* command. Change the Offset Dimension Text - Text Alignment to Horizontal (it may have been set to Parallel in Lesson 2). Click OK. From the Annotate menu, select the *Survey Text > Offset Dimensions* command and pick the lower right corner of the building, and then the lower-most property line (in the current twist screen position). This labels the offset dimension horizontal to the current twist screen.

From the Annotate menu, select the *Draw North Arrow* command and find and select the north arrow symbol that is shown in the figure below. Change the Symbol Size Scaler, if necessary. Click OK. Then pick an appropriate location and press Enter. Note how the arrow draws due north, respecting the twist screen.

From the Annotate menu, pick the *Draw Barscale* command and pick a location near the lower-left portion of the drawing.

Your drawing should now look similar to this:
18 Select the *Hatch* command from the Draw menu. Select the SOLID pattern from the pull down list, and then click the Add: Select objects button. Pick the house and the shed, and press Enter, then OK.

19 To offset the EOP polyline, first try using the *Standard Offset* command under Edit > Offset, and try offsetting the edge-of-pavement polyline that runs roughly parallel to the sewer line. You will see an error message because that object is a 3D Polyline, created by the *Draw Field to Finish* command.

To offset a 3D Polyline, you must use a command specifically designed to offset 3D Polylines. From the Edit menu,
select the 3D Polyline Utilities > Offset 3D Polyline command. Enter the offset method as Interval, press OK.

![Offset 3D Polyline dialog box]

**Vertical/Horizontal offset amount**: 30
**Percent/Ratio/Vertical offset amount <0>:** press Enter
Select a polyline to offset: pick the EOP polyline
Select side to offset: pick out and away from parcel for the other side of the road

20 Before you add a title to the drawing, create a text style for the title. From the Draw menu, select the Text > Set Style command.

![Text Style dialog box]

Click New and name the style TITLE. Choose the font named *romant.shx* and then change the oblique angle to 10° as shown. Click Apply, and then click Close. Now, to create the title, type Dtext at the command line. Make sure that TITLE is the current text style.

Specify start point of text or [Justify/Style]: C
Specify center point of text: pick a point near the top-right of the screen
Specify height <8.00>: 20
Specify rotation angle of text <E>: pick a point to right of first point with <Ortho on>, dynamically stretch right
Text: Farmer Survey
Text: August 13, 2006
Text: press Enter twice

From the Edit menu, select the Text > Text Enlarge/Reduce command. Enter a Scaling Multiplier of .8 and pick the date you just entered.
21 Verify your drawing scale through the Settings > Drawing Setup command. Your drawing should have a scale of 100 with a Text Plot Size of 0.08. Change the Text Plot Size to 0.06 to shrink the building labels we are about to place. From the Draw menu, select the Leader > Leader with Text command and label the house "2-Story", "Farm House" (2 lines of labeling).

**Options/Size/Pick Arrow Location:** pick near or on the left side of the house

**To point:** pick off to the left

**Next point (Enter to end):** press Enter

**Text:** 2-Story

**Text:** Farm House

**Text:** press Enter

Pick anywhere on the leader. You should see two grip squares (usually blue, referred to as a cool grip), one on the left side and one of the right side. Pick on the right grip nearest the house (it should turn red, referred to as a hot grip). Move your cursor. Note how the arrow moves. Pick again for the new location and note how the arrowhead and leader are now located and angled to your specifications.

22 Select the Triangulate & Contour command from the Surface menu. On the Triangulate tab, turn off Write Triangulation File. The Contour tab of dialog box should be filled out as shown below:

Click on the Selection tab and fill out to match the following:
Click on the Labels tab and match the following dialog:

Click OK.

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: press Enter

Select the Exclusion perimeter polylines or ENTER for none.
Select objects: pick the house and the shed
Since these objects have now been filled, the selection may be a little tricky. We could (actually should) have placed
the solids on their own layer and froze the layer before beginning the contour command. But we can use the fact that Carlson is filtering the objects to get around the problem. When prompted to select the objects, issue the C (for crossing) option and then pick a box that crosses the edge of the filled polylines. Carlson will accept the polyline but reject the fill.

Select the points and breaklines to Triangulate. select a right-to-left window of the property
A right-to-left selection behaves as a crossing, which means that any object that is touched by the window or included inside the window is selected. A left-to-right selection is a window selection, which means that only objects that are fully enclosed by the window are selected.

Select objects: pick Window location
Other corner: pick other location
Select objects: press Enter to end

Pick the coordinate file that contains the points, plat3.crd, and click Open.

Reading points...
Range of Point Numbers to use [<All>/Group]: press Enter
Wildcard match of point description <*>: press Enter

If the triangulation lines and faces were drawn, freeze them now. The final drawing will look similar to this:

This completes the Lesson 3 tutorial: Field to Finish for Faster Drafting.

**Lesson 4: Intersections and Subdivisions**

1 Click the icon to launch Carlson. Once in the program, exit the Startup Wizard if it appears.

2 Once in Carlson, click Open under the File pull down menu. Look for the file Plat4.dwg (this file should be located in the "C:\Carlson Projects" folder) and click on it. When it lights up blue, as shown below, it will appear in the Preview Window at right. It should look like the open-sided property shown here. You search for the file as you typically would in Windows, clicking the yellow "Up one level" button to go to the parent folder of the current folder, or by clicking the adjacent down arrow to find the desired path in the full tree of folder locations.
Now click Open to select and open the file Plat4.dwg.

3 Enter & Assign a Starting point for the Street Centerline. Select Draw-Locate Points, found under the Points pull down, and obtain the dialog shown below:

Click off the prompting and labeling for Descriptions, Elevations and Locate on Real Z Axis (make them blank as shown). Up top, change the symbol to SPT10 by picking Select at the very top of the dialog, and choosing symbol SPT10 from the dialog of symbol choices (not shown here). Also, verify that Automatic Point Numbering is clicked on, that the Starting Point Number is 1, that the layer is PNTS. Match these entries (which are mostly the default conditions) and click Enter and Assign at the lower left.
Prompting will appear at the bottom of the screen. We will enter the starting point as follows:

**Enter North(y):** 4809.17  
**East (x):** 4391.28

The program will recognize that you have not yet started a coordinate file, so click the New tab and enter the File Name as Plat4.crd (which should be the default). If you enter Plat4, you do not need to enter the extension .crd. The program will add extensions automatically. You will see this:

![Coordinate File to Process](image)

Click Open. You will be prompted again:

**Enter North(y):** press Enter (for no more points; we are done)

4 Traverse from PI to PI (to the two endpoints of our centerline). Select Traverse under the COGO menu, or alternately just enter T at the command line. (T is a hot key. Other hot keys are I for Inverse and SS for Sideshot). Reply to the prompts as follows:

**Traverse, Line OFF, RAW FILE OFF**  
**Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <7>:** 1  
**Enter Bearing Angle (dd.mmss) <90.0000>:** 58.1848  
**Points/<Distance>:** 736.73  
**N: 5196.15 E: 5018.19 Z: 0.00**  
**Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <1>:** E (to exit)

You could keep on traversing, but we will stop here to review. You have created point 2, traversing NE from point 1. To review, code 1 is for NE, 2 for SE, 3 for SW, 4 for NW, 5 for Azimuth, 6 for Angle Left, 7 for Angle Right, 8 for Deflection Left and 9 for Deflection Right. This is the standard way that traverses and sideshots are entered in Carlson with a code entry (followed by Enter), then the angle or bearing entry (followed by Enter). Lesson 1: Entering a Deed, presented another method, where the angle and bearing are together in the form of 158.1848. That is a rare form, designed to save keystrokes, and used primarily only in *Enter Deed Description*. Now you have been exposed to both!

5 **Line On/Off.** Click Line On/Off under the COGO menu to turn on simultaneous linework with traversing. This command toggles on and off each time you click it, with the On status indicated by a check mark. Now repeat the Traverse command. Try T for Traverse this time, entered at the command line.

**Traverse, Line ON, RAW FILE OFF**  
**Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <1>:** 2  
**Enter Bearing Angle (dd.mmss) <58.1848>:** 75.0627  
**Points/<Distance>:** 553.69
6 Draw a Polyline from Point 1 to Point 2, and connect the segments with Join Nearest. We could have turned linework with traverse on before we got started, but now we will do it after-the-fact. So choose 2D Polyline under Draw. Some users like to simply type in 2DP at the command line that starts the Polyline command. If the Polyline 2D Options dialog box appears, set the values shown below and click the OK button.

![Polyline 2D Options dialog box]

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 1
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 2
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter (to end)

Now we have two line objects. The first, from point 2 to point 3 is a pure Line. The second, from point 1 to point 2, is a true Polyline (even though it is only one segment long). It is officially a LWPOLYLINE, a lightweight polyline. This can be verified by picking it using the List command under Inquiry. Polylines are linked combinations of one or more line segments that behave as one unit. We encourage use of polylines versus lines because they offset as a unit, will take on a thickness or width, are easier to select and have superior editing capabilities. A line can be turned into a polyline by picking Polyedit under Edit, picking the line, and answering Y to the question "Do you want to turn it into one? <Y>". To join the polyline and line objects into a single polyline, choose the very useful command Join Nearest, found under Edit.
The defaults are good. Just click OK.

**Select lines, arcs and unclosed polylines to join.**

**Select objects:** pick the polyline from 1 to 2 and the line from 2 to 3, and then press Enter for no more

Now, see the grips on the new polyline by picking it with the cursor. See how the whole thing highlights? That is proof that it is joined up as a polyline.

7 Design a Curve with a 500' Radius. Under Draw, pick **Arc** and slide over to **2 Tangents, Radius**.

**Radius of Arc <0.00 >: 500**

[nea] **Pick Point on 1st Tangent Line:** pick on the 1st polyline segment closer to point 2

[nea] **Pick Point on 2nd Tangent Line:** pick on the 2nd polyline segment close to point 2

The arc draws in, and the centerline remains a polyline, now with 3 segments.

8 I for Inverse. Entering I for Inverse, at the command line, is a handy way to get on a point to begin another traverse. Practice inversing. Enter I. Inverse from point 1, then to point 2, then to point 3 then back to 1. But you can also inverse (go to) a snapped position on a line or polyline, such as the midpoint of an arc. Let's do that, because we want to traverse south from the midpoint of the arc. Enter I, for Inverse.

**Calculate Bearing & Distance from starting point?**

**Traverse/SideShot/Options/Arc/Pick point or point number:** MID (for midpoint snap of) select the arc

**Traverse/SideShot/Options/Arc/Pick point or point number:** T (for traverse)

**Traverse, Line ON, RAW FILE OFF**

**Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <2>:** press Enter

**Enter Bearing Angle (dd.mmss) <75.0627 >: 10.11**

**Points/<Distance>: 400**

**Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <2>:** E (to exit traverse)

Notice that you can transition from inverse, to traverse, to sideshot, etc. with these COGO options. We were in inverse, but we did T for traverse, and could have done I for inverse to return to inverse. This cuts down on keystrokes, and adds to the sense of fluidity of the software.

9 Turn a Line into a Polyline with Polyedit. The command **Offsets & Intersections** requires pure polylines, not lines, to execute. So, since we had Line On with the last traverse, we have created a line. To use this in street design, we need to convert it into a polyline. Select **Polyedit** under the Edit pull down menu.
Select polyline or [Multiple]: pick the side road line
Object selected is not a polyline
Do you want to turn it into one? <Y> press Enter
Enter an option [Close/Join/Width/Edit vertex/Fit/Spline/Decurve/Ltype gen/Undo]: press Enter

10 Offsets & Intersections. Under the Area/Layout > Layout Utilities menu, select Offsets & Intersections.

Select all PRIMARY road polylines.
Select objects: press Enter (we will consider both these subdivision streets secondary)
Select all SECONDARY road polylines.
Select objects: pick the main centerline
Select objects: pick the side road
Select objects: press Enter (for no more)

The street intersections are presented in a dynamic dialog as shown above. Try experimenting with different radii under the Secondary Roads column, then clicking Calculate. The streets will re-draw in the upper graphical area. But after experimenting, change the four values under Secondary Roads to those shown (ignore Primary Roads – those don’t apply here), and click Calculate. Then click Finish 2D. Note the drawn-out street intersection.

Now select Drawing Inspector under the Inquiry menu, right click and make sure Layer is checked. Hover over the outside polyline (it is layer ROW). Hover over the next polyline in from the outside (it is layer EOP). For example, if you had clicked off EOP under the Draw column in the above dialog, the edge-of-pavement polyline would not have drawn.

11 Standard Cul-de-Sac. Under Area/Layout > Layout Utilities, select Cul-de-Sacs. You may want to zoom into the area of the bottom center, near point 4. When finished with the procedure below, zoom back out.

Select all offset polylines to end with cul-de-sac.
Select objects: form a crossing selection from right to left across the lower side road, selecting all 5 polylines (ROW-L, EOP-L, CL, EOP-R, ROW-R)
Select objects: press Enter (for no more)
Pick cul-de-sac center projection onto centerline: END (for endpoint snap)
of pick near the endpoint of the centerline of the lower side road near point 4
Make sure the pick is on the centerline polyline, or the routine will say the centerline not found.
This brings up the following dialog:

Again, you can change the Fillet Radius and the Outside Radius on the EOP or ROW, hit Calculate, and check out its effect (don't make the Outside radii too small or it will fail to Calculate if there is no workable solution). Set values as shown above. Then click on Finish 2D.

12 Teardrop Cul-de-Sac. Now select the *Cul-de-Sacs* routine again, under *Area/Layout > Layout Utilities*.

**Select all offset polylines to end with cul-de-sac.**

**Select objects:** *form a crossing selection* pick from right to left across the right main road, selecting all 5 polylines (ROW-L, EOP-L, CL, EOP-R, ROW-R)

**Select objects:** *press Enter* (for no more)

**Pick cul-de-sac center projection onto centerline:** *END (for endpoint snap)*

of pick the endpoint of the centerline of the lower side road near point 3

For a teardrop cul-de-sac, fill out the dialog as follows, then click on Calculate and Finish 2D.
Teardrop cul-de-sacs allow moving vans and other large vehicles more turning room, and have been popular in the Cincinnati area, for instance. Our drawing now appears as shown below, with the exception of the filled reference dots.

13 Let's make a layer called LOTS using Layer Control found under View. It's a good idea to create a layer and set it current before beginning the design process. Select Layer Control and obtain the following dialog:
Click on for New layer. When Layer1 highlights, as shown at bottom of list, type over it with LOTS, then click under the Color column and change the color to Magenta. Then click the (Set) Current button up top to make this layer current. Then click OK to exit the dialog.

The **Lot Layout** routine under Area/Layout works nicely with reasonable polylines that run roughly parallel. Our goal is to make 1-acre lots. Lots of zigs, zags, and jogs in the polylines cause the perpendicular offset logic to fail to find a solution (lots will radiate perpendicular from the front polyline in Lot Layout). Not only should the front and back lines run opposite each other, but they should end at some point before the calculation runs into difficulty with impossible math.

The outer R-O-W polyline currently runs left-to-right, goes around both cul-de-sacs and returns right-to-left in one, connected polyline. We need to break it near where the filled dot is pointing. It should be easy to lay out lots along the upper portion of the subdivision, as long as we stop to break the R-O-W polyline before it turns and runs back through the lower, more complex frontage and back property portions.

Under Edit, select **Break**, and slide over to **At Selected Point**. You will select using the filled dots, shown on the plan above, as references.

**Select Line, Arc, or Polyline at break point:** pick near the filled dot on the outer boundary polyline

Repeat the command for the ROW polyline.

**Select Line, Arc, or Polyline at break point:** pick the far right end of the Teardrop cul-de-sac R-O-W polyline

To prove you have broken the polylines in two, click on the R-O-W polyline on the south side (only the south portion should highlight), then click on the north R-O-W polyline (which we will use as our frontage polyline in the command Lot Layout). Then press the **ESC** key twice, which gets rid of the grips, as does zooming or panning.

14 Select Lot Layout under Area/Layout > Layout Utilities. A dialog appears:
Fill out as shown. In particular, change the Remainder to *Create Separate End Lot* so that we force 1.000 acre lots and don't just get equal lots of some size such as 1.0017 (because the remainder lot that would not fit was added onto all lots).

Making Closed Polylines means that our side lines will be doubled up, each lot sharing a side line. Click OK.

**Select front polyline:** pick north R-O-W

**Select back polyline:** Pick northernmost polyline the back property line

The 1.00 acres lots are laid out as far as is possible. You may get a small lot at the end of the row, which you would erase.

15 Applications of Reverse Polyline. We can get more Lots from Lot Layout, by doing the lower R-O-W at the left side of the drawing, and picking the southern back polyline. Let's try. Select *Lot Layout* under Area/Layout > Layout Utilities. Use same dialog entries. Select the front polyline as the southern edge of the road R-O-W, near the left side of the drawing. Select the back polyline as the southern property line. Oops! Nothing drew. It was unable to calculate. It turns out that the direction of the polyline is important. Run *Inquiry* > *Drawing Inspector* and check on *Polyline Direction*. You will see the southern R-O-W polyline starts way off to the right, so the program was not even considering where we were looking! We need to reverse the direction of the southern R-O-W polyline so it starts on the left side. Select *Reverse Polyline*, found under the Edit pull down, sliding over from *Polyline Utilities*. It prompts:

**Select polyline or line to reverse:** pick the southern R-O-W polyline

The polyline now reverses direction, goes left-to-right, and shows phantom direction lines (which are automatically removed when the command ends). Now repeat the Lot Layout command as outlined in the beginning of Step 15, and we get one new lot out of the exercise, as shown below. If you get a second wedge shaped lot, erase it.
16 Break at Intersection. The lower back property line is still continuous. We can work with it in small pieces rather than as one big polyline. Say we want to break it at the inside corner identified by the arrow above. To do this, select Edit pull down, Break, sliding over to At Intersection. Prompting:

Select Line, Arc, or Polyline to Break: pick the south property line
[app on] Pick Intersection to break at: move the cursor to the intersection point indicated in step 12, look for the INT snap to appear as you approach the exact corner (which is an intersect), then click there

17 Draw a Polyline from the corner indicated by the filled dot to the beginning of the R-O-W arc, also indicated by a filled dot in the previously referenced graphic. Select 2D Polyline under Draw and click on the OK button to dismiss the dialog box if it appears.

Pick point or point numbers: END (type in end for the endpoint snap)
of pick the inner back property corner
Undo/Arc/Length/<Pick point or point numbers>: END (type in end for the endpoint snap)
of Pick the beginning of the Arc (it will show endpt when you get close to the true start of arc)
Undo/+/-/Arc/Clos/Length/<Pick point or point numbers>: press Enter (to end)

18 Area by Interior Point. We have just created a new lot, but the lot is not defined by one, single, closed polyline. If we want to verify its area, however, we can still use the command Area by Interior Point. Select Area by Interior Point under Area/Layout.

Pick point inside area perimeter: pick inside our new lot
SQ. FEET: 40997 SQ. YARDS: 4555.2 SQ. MILES: 0.0
ACRES: 0.94 PERIMETER: 830.5

Pick area label centering point: press Enter here to avoid labeling
Pick point inside area perimeter (Enter to end): press Enter to end the command

The lot is less than one acre. We will set as a goal to extend its lower boundary to the right to obtain one acre. That is accomplished by using the command Hinged Area. But Hinged Area works best if we have a nice, closed polyline for the new lot. We can get one using the command Boundary Polyline.

19 Boundary Polyline. From the Draw menu, select Boundary Polyline.
Enter layer name for boundary polylines <LOTS>:
Enter snap tolerance <0.0001>: select OK
Select polylines.
Select objects: pick all the polylines that surround our new lot and then press Enter
Pick an internal point: pick a point in the Lot interior
Pick an internal point (U-Undo, Enter to end): press Enter
This creates a new closed polyline, in the current, LOTS layer (magenta).

20 Select Hinged Area under Area/Layout > Adjust Areas.
Define area by points or closed polyline [Points/<Linework>]? press Enter (for linework)
Select polyline segment to adjust: pick on the right-side line (make sure you pick the Lot polyline rather than the single polyline vector)
Select hinge point [endp]: pick on the upper right hinge point (see arrow)
Keep existing polyline [Yes/<No>]? N
Area: 40997.20 S.F, 0.9412 Acres
Remainder/Acres/<Enter target area (s.f.)>: A (for acres)
Remainder/SF/<Enter target area (acres)>: 1.0

The new lot draws, as shown below:

21 Next, use the Erase command to remove the segment that is pointed to above with the text Click on This Side.

22 Make two more Lots with polyline command. Instead of using Draw, 2D Polyline, we will use the straight AutoCAD polyline command. At the command line, enter PL.
Specify start point: END (type in the endpoint snap)
of pick the endpoint (which is the lower right corner of the new lot)
Current line-width is 0.00
Specify next point or [Arc/Halfwidth/Length/Undo/Width]: *PER* (type in the perpendicular snap)
to pick on the R-O-W polyline to the right

Specify next point or [Arc/Close/Halfwidth/Length/Undo/Width]: *press Enter* (to end)

Now for the second lot. Referring to the drawing below, repeat the PL command, and answer as follows:

Specify start point: *NEA* (enter the nearest snap)
of pick on the property line anywhere near the circled point 1 (no need to be exact)

Current line-width is 0.00

Specify next point or [Arc/Halfwidth/Length/Undo/Width]: *PER* (type in the perpendicular snap)
to *Pick on the R-O-W polyline near circled point 2*

Specify next point or [Arc/Close/Halfwidth/Length/Undo/Width]: *press ENTER* (to end)

The drawing appears below:

23 **Issue the** *Break at Intersect* command (step 16), and break the back property polyline and the cul-de-sac R-O-W polyline at the intersections with our newly drawn polyline from step 22. Repeat this command, and break the back property polyline at the filled dot to the right of the "Sliding Side Area" label below.

24 **Repeat** *Lot Layout* with the same entries as before. The front and back polylines to select are shown below, along with the results. This gives us two more usable lots.

Next, use the 2D Polyline command to generate a segment (above the "Sliding Side Area" label below) that runs from the ENDpoint of the corner to a point PERpendicular to the R-O-W line. Next, use Boundary Polyline under the Draw menu to create a closed boundary inside it. To do this, select each boundary line in the segment, press Enter twice, pick an interior point, press Enter again.

Erasing the original segment you placed is a little tricky since the newly formed polyline is on top. When two pieces of geometry lie on top of each other, Carlson will take the one created last. Issue the *Erase* command, then hold down the control key while picking the segment above the "Sliding Side Area" label. When the single segment highlights, press enter to erase it, leaving the boundary polyline. Also note you can hold the shift key, place the cursor over object on screen, and press the space bar to cycle through entities in order to erase objects on top of each other.
25 Sliding Side Area. Because we have a small closed polyline, we can investigate another area command, the Sliding Side Area. As shown in the graphic above, we want to slide the north side of the last, smaller lot parallel to its current bearing such that the lot will contain 1.00 acres. Select *Sliding Side Area* under the Area/Layout > Adjust Areas pull down.

**Define area by points or closed polyline [Points/<Linework>]?** press ENTER for Linework

**Select polyline segment to adjust:** *pick the north side of the lot above* (shown here containing the words Sliding Side Area)

**Keep existing polyline [Yes/<No>]?** press ENTER

**Define new line by selected line, another line, angle or points [<Selected>/Line/Angle/Points]?** press ENTER for Selected

**Area:** 20375.31 S.F, 0.4678 Acres

**Remainder/Acres/<Enter target area (s.f.)>:** A (a for acres)

**Remainder/SF/<Enter target area (acres)>:** 1.0

26 Complete the remaining Lots. Using the *2D Polyline* command, under Draw, use endpoint snaps and perpendicular snaps (end and per) to draw the final 3 polylines, shown below marked 1, 2 and 3 for reference.
It may not be the most aesthetic subdivision, but we applied a lot of tools making it. But we're not done. There's some real automation ahead.

**Create Points from Entities.** We have designed a subdivision, in effect, without point numbers. This is the beauty of CAD. But we need to make point numbers in order to stakeout the subdivision. To do this, select *Create Points from Entities*, under COGO. The following dialog appears:

Set the starting point number to 5, verify the dialog as shown, and click OK. A second dialog, covering what entities to capture, appears next. Stick with the default settings and click OK.
28 Number the lots, clockwise from the upper left, using the command *Sequential Numbers*. Under Draw, select *Sequential Numbers*. This dialog appears:

![Sequential Numbers dialog](image)

Click on the *Select* button to select a desired symbol to circumscribe our sequential numbers.

![Select Symbol for Numbers](image)

Choose the circled text and click OK.
Set the *Text* value to **10** and the *Text Size Scaler* to **0.16** as shown. Then click OK.

**Pick point for label position:** *pick near the center of the first upper left lot*

**Pick point for label alignment:** *press F8 for <$Ortho on$>, pick to the right*

Now pick near the center of all of the lots, going clockwise.

When done, and back to the command line, press F8 again to set Ortho off.

The resulting drawing, with point numbers, is shown below:

29 Lot File by Interior Text. Official lot files can be created whenever a lot number or name exists within a lot as the sole text (other text may be present but could be frozen). So we will play it safe and first freeze the point number layer. Before we do, take note of the point number assigned to the NW corner of Lot 10. In our case, it is point 73 (it may be different in your case, depending on how you selected the objects in the command Convert Entities to Points).

Under View, select *Freeze Layer* and pick on one of the point numbers. Now go to the Area/Layout pull down, select *Create Lots* and slide over to select *Lot File by Interior Text*. Supply the *Lot File to Process* value as shown below.
and click the Open button.

A dialog box will appear. Be sure that is says Block Name 1. Click OK.

**Select lot lines, polylines and text.**

**Select objects:** pick the lots and the lot numbers

The Lot File will be created. Before we look at the Lot File, let's finish up and perform area annotation on the upper Lots with the *Area by Interior Point* command.

**NOTE:** If we had not made points at all lot corners using *Convert Entities to Points*, the *Lot File by Interior Text* would create points at the Lot corners. This is the reason for the *Starting Point Number* prompt. If points are found, no new ones are created. Lot files must have points at all the corners.

30 *Area by Interior Point.* Select *Area Defaults* under *Area/Layout*, and remove the *Sq. Feet* entry leaving only the *Acres* item and verify it is set to plot to 3 decimal places and click OK.
Now choose *Area by Interior Point* under the Area/Layout pull down menu and pick inside Lots 10 through 16, as shown below:

![Diagram of a property with lots numbered 10 to 16]

31 Select *Lot File Manager* under Area/Layout, and the Lot Manager dialog appears:
Pick on Lot 10 and click Report. This will lead to the Lot Report dialog box.

Be sure that your setting are as shown above, and then click Lot Report.
This dialog is typical of the many Carlson Standard Report Viewer dialogs. You can click on one or more lines, highlight them and hit the delete key on the keyboard, and these lines will delete. You can edit lines directly in the dialog. You can also save the report to disk with the Save icon shown above. To exit, click the Exit icon. The Lot Manager dialog box returns.

32 The Edit Current option within the Lot Manager dialog box can be used to describe a lot by different point numbers, or to assign a lot to a different block. This is explained here and shown below for reference purposes only.

Under Selection, select a lot to edit. Click Edit Current. You will get this dialog. Note the graphic display in the lower half, which map the Points listed above. If you've opened this dialog box, click Cancel and the Exit on the Lot Manager dialog box.

33 Re-Drawing Lots after Editing Points. Let's assume you actually changed the point numbers that define Lot 10.
That would cause the lot to draw differently. Also, you could simply alter the coordinate values of a point in the current lot file. That would also cause the lot to draw differently. Let's take the latter approach. Remember point 73? In our case, it is the NW corner of lot 10 (your case may be different as stated above). So select Edit Points under the Points pull down menu. A spreadsheet appears. Scroll down to point 73 (or whatever point is your NW corner of Lot 10).

Click on the Northing and edit it to 5050. This is for illustration purposes. In reality, you might be fine-tuning your subdivision design points. As long as the same points define the lots, you are, in effect, making a ready-made new drawing. Now select at the top of the dialog File, then Save and Exit.

**34 Draw the Lot File.** Before we draw the lot file, save your drawing by selecting Save under the File pull down menu. Then choose New, exit the Startup Wizard (if it appears), and go straight to Lot File Manager, found under the Area/Layout pull down menu. Lot Manager provides the tools for drawing lot files to the screen.

Click the Existing tab and select the plat4.lot file and click Open. Select your existing Ploat4.crd file that you created.
earlier. When the Lot Manager dialog appears, choose all Lots by clicking Select All. Then click Draw.

Apply settings required or as image above and click OK to the Draw Lots dialog box. This leads to the Auto-Annotate dialog, shown below. Use the settings shown here. Click OK.
Next comes the Area Defaults dialog, as seen in Step 30. Fill out exactly as shown in Step 30.

Click OK and then Exit. This leads to the plot shown below, created entirely from stored Lot Files, and showing our revision of Lot 10.
This completes the Lesson 4 tutorial: Intersections and Subdivisions.

Lesson 5: SurvNET

This tutorial is divided into two lessons covering the process of reducing and adjusting raw survey data into final adjusted coordinates, using the SurvNET program. The tutorial will describe the reviewing and editing of the raw data prior to the processing of the raw data. Next, the least squares project settings will be described, and then the final report generated from the least squares processing will be reviewed. This tutorial will review both a total station only project, and a project that combines both total station and GPS vectors.

The raw data files associated with this tutorial is located in the Carlson Projects folder, under the installation folder on your computer (example: \Carlson Projects).

Lesson One - Processing an Assumed Coordinate System 2D Total Station Network

1 The easiest way to start the program is to select SurvNET from the Survey menu. This opens the SurvNET window and program. If the SurvNet Start-up dialog box appears, click Cancel.

2 Open an existing project or create a new project. We will open an existing project. Choose Open Project from the File menu. Navigate to the \Carlson Projects folder and open the SurvNetTut01.prj project.
Learning the meaning and implications of the different project settings is the most critical initial step in learning how to use SurvNET. Let's review the different project screens. Choose *Project Settings* from the Settings menu.

**Least Squares Settings**

The Network Least-Squares Settings dialog box is displayed. In this dialog, the different settings required for the Least Squares reduction are available in the different tabbed dialog boxes. When all of the settings are set as desired, press OK to save the changes to the project settings, or press Cancel to return to the raw data editor without saving any project settings. For the purpose of this tutorial, the Coordinate System settings tab should look as follows before proceeding to the next step. To use an assumed coordinate system, the 'Local' Coordinate System needs to be selected, and the 2D, 1D Adjustment Model must be chosen. When using a local coordinate system, the distance units are not important other than for display purposes in the report. Computing elevation factors and performing Geoid modeling is not applicable to assumed datums. Notice that in this example we are not performing a vertical adjustment.
Choose the 'Input Files' tab. This is the section of the Settings dialog box where you define the data files that make up the project. You can have multiple raw files in a single project. The ability for multiple raw files allows flexibility in collecting the data and processing large projects. It is typically easier in a large project to analyze and edit subsets of the total project, before combining all the data for a final adjustment. Notice that since we are working in a local coordinate system and using the 2D,1D Adjustment Model, GPS vectors cannot be incorporated into this project.

NOTE: The sample tutorial project has the input raw file in the default data folder of C: \ Carlson projects. If you have a different data directory, then set the correct data file by highlighting the default file, pick Remove and then pick Add and select SurvNetTut01.rw5 from your data folder.
Choose the Preprocessing tab to review the least squares preprocessing settings. For the purpose of this tutorial, the Preprocessing settings should look as follows before proceeding to the next step. Preprocessing consists of reducing and averaging all the multiple measurements, applying curvature and refraction correction, reducing the measurements to grid if appropriate, and computing unadjusted traverse closures if appropriate. Much of the data validation is performed during the preprocessing step.

For more information on the content of this dialog box section, please review the SurvNET chapter of this manual.

Choose the Standard Errors tab to review the standard error settings. The standard error settings should look as
follows before proceeding to the next step. Standard errors are an estimate of the different errors you would expect to obtain based on the type of equipment and field procedures you used to collect the raw data. For example, if you are using a 5 second theodolite, you could expect the angles to be measured within +/- 5 seconds (Reading error).

For more information on the content of this dialog box, please review the SurvNET chapter of this manual.

8 Choose the Adjustment tab to review the Adjustment settings. The Adjustment settings should look as follows before proceeding to the next step. The Adjustment settings affect how the actual least squares portion of the processing is performed. Additionally, from the screen the user can set whether ALTA reporting is performed.
Choose the Output Options tab to review the output settings. For the purpose of this tutorial, the Output Options settings should look as follows before proceeding to the next step. These settings apply only to the output of data to the report files. These settings do not affect computational precision. Press OK to return to the main SurvNET screen.

General Rules For Collecting Data for Use in Least Squares Adjustments

Least squares is very flexible in terms of how the survey data needs to be collected. Generally speaking, any combination of angles and distances, combined with a minimal amount of control points and azimuths, are needed. This data can be collected in any order. But there needs to be at least some redundancy in the measurements.

Redundant measurements are measurements that are in excess of the minimum number needed to determine the unknown coordinates. Redundancy can be created by including multiple GPS, and other control points, within a network or traverse. Measuring angles and distances to points in the network that have already been located create redundancy. Running additional cut-off traverses, or additional traverses to existing control points, creates redundancy. Following are some general rules and tips in collecting data for least squares reduction.

- Backsights should be to point numbers. Some data collectors allow the user to backsight an azimuth not associated with a point number. SurvNET requires that all backsights be associated with a point number.
- There has to be at least a minimum amount of control. There has to be at least one control point. Additionally, there needs to be either one additional control point or a reference azimuth. Control points can be entered in either the raw data file, or there can be a supplemental control point file containing the control point. Reference azimuths are entered in the raw data file. The control points and azimuths do not need to be for the first points in the raw file. The control points and azimuths can be associated with any point in the network or traverse. The control does not need to be adjacent to each other. It is permissible to have one control point on one side of the project, and a reference azimuth on the other side of the project.
- At least one of the control points needs to be occupied. There may be situations where no control point is ever occupied in the network, but only backsighted. In these situations, a preliminary value for one of the occupied points needs to be computed and entered as a floating point control point.
- Some data collectors do not allow the surveyor to shoot the same point twice using the same point number. SurvNET requires that all measurements to the same point use a single point number. The raw data may need to be edited after it has been downloaded to the office computer to ensure that points are numbered correctly.
• The majority of all problems in processing raw data are related to point number problems. Using the same point number twice to different points, not using the same point number when shooting the same point, misnumbering backsights or foresights, and misnumbering control points are all common problems.
• It is always best to explicitly define the control for the project. A good method is to put all the control for a project into a separate raw file. A big source of problems with new users is a misunderstanding in defining their control for a project.
• Some data collectors may have preliminary unadjusted coordinates included with the raw data. These coordinate records should be removed from the raw file. The only coordinate values that should be in the raw file are the control points.
• When a large project is not processing correctly, it is often useful to divide the project into several raw data files and debug and process each file separately, as it is easier to debug small projects. Once the smaller projects are processing separately, they can be combined for a final combined adjustment.

Reviewing and Editing the Raw data

10 To review or edit the raw data, choose the **Edit Raw Files** command from the Tools menu.

11 If there are problems with the raw data, such as point numbering problems or incorrect rod heights, the raw data can be edited from this dialog. See the section on the raw data editor in the Carlson documentation to learn the details of the editor. Review the following Standard Errors and Control Points section before exiting the raw data editor.
Standard Errors and Control Points

The default standard errors for points are defined in the Standard Errors sheet of the Settings dialog box. There are times when the default values may need to be overridden. For example, the control may be from GPS and the user has differing standard errors for his various GPS points. Or maybe some of the control points were collected with RTK methods, and other GPS points collected with more accurate static GPS methods. Standard error for individual points can be inserted into the raw data file. The following is the menu option used to insert standard errors into the raw file. Notice in the above raw data file that points TR1 and TR100 are the control points for this project. Also, notice there is a standard error record, CSE, preceding the control points.

The CSE record has the character '!' in the N,E,& Z field. The character '!' designates that all following control points will be fixed. Points that are fixed will not be adjusted during the adjustment. Placing a very small standard error on a control point is almost equivalent to fixing the point. Points can also be designated to be floating points by using the '#' character. The only practical use of creating a floating point is if SurvNET cannot compute preliminary coordinates because no control point is occupied. The surveyor can compute a preliminary value for one of the
occupied points, and insert that point as a floating point. The floating point will be adjusted, and no weight will be given to the floating coordinate values.

Standard error records effect all the records that follow the standard error record. To revert the standard errors back to the default values, a CSE record can be inserted containing the '*' character. In the following example, point TR1 has been designated as a fixed point. TR100 has a north standard error of .02 and east standard error of .01. Following the TR100 point record there is a CSE record containing the '*' character. So, if there were any control points further down in the raw data file they would use the default standard errors as set in the project settings dialog box.

</table>

There may be times when non-control standard errors need to be overridden for certain measurements. For example, if fixed tripods were used for backsights and foresights for part of the traverse, and hand-held rods were used for another portion of the traverse, it would be appropriate to have differing 'Rod Ctr' standard errors for the different sections of the raw data.

Standard errors for angles and distances can also be inserted into the raw data file using the Add menu options **Setup Standard Error** and **Measurement Standard Error**. The standard errors set by these inserted records override the default standard errors. In the following example, a setup standard record, SSE record, has been inserted in record 12. The SSE record effects all setup data that follow until another SSE record is inserted. In the following example, the foresight rod centering error is set to .005, the total station centering error is set to .005, the total station measure-up error is set to .005 and the foresight measure-up error is set to .005.
The following is another example where it would be appropriate to insert a measurement standard error record, MSE, into the raw data. If two different total stations with different accuracy specifications were used to collect the data, it would be appropriate to have different standard errors for the different sections of the raw file, depending on which total station was used to collect the data. In the following example, an MSE record has been inserted for record 27. The horizontal pointing and reading error has been changed to 5 seconds, and the vertical pointing and reading error has been changed to 10 seconds. The inserted MSE record will effect all following raw data until another MSE is inserted.

Least Squares Processing

12 After exiting the raw data editor, we are ready to perform the least squares adjustment. From the Process menu, choose the Network Adjustment option.
The least squares adjustment is performed, and the results from the adjustment are displayed. If the solution converged correctly, the report should look similar to the following window. If there were errors or the solution did not converge, an error message dialog will be generated.

If there are errors, you will need to return to the raw data editor to review and edit the raw data. Since the tutorial example should have converged, we will next review the reports generated by the least squares adjustment. There are four windows created by the least squares program during processing. These files include the .err file, which contains any errors or warnings that were generated during processing. The .rpt file is the primary least squares report file summarizing the data and the results from the adjustment. An .out file is created containing a listing of the final coordinates. There is also a Graphics window that is displayed. The graphic window is temporary and useful only for seeing the results of the survey. To bring up the Graphics window, choose under the Window menu the Graphics command, or click the View Graphics icon on the toolbar.

Relative Error Ellipses

Relative error ellipses are a statistical measure of the expected error between two points. Regular error ellipses are
measure of the absolute error of a single point. Some survey accuracy standards such as the ALTA standards state the maximum allowable error between any two points in a survey. Relative error ellipses can give you this information. There is a more detailed ALTA reporting feature in SurvNET. See the manual for additional information on creating an ALTA report.

13 Press the Relative Error Ellipse toolbar icon button, or choose, off of the Tools menu, Relative Error Ellipse. Enter TR3 and TR7 in the From Pt. and To Pt. fields. Press OK to calculate. The dialog box should look as follows.

At the 95% confidence level there should only be around .02 feet of error between points TR3 and TR7. If you need to compute relative error ellipses for sideshots make sure the "Enable sideshots for error ellipse" toggle is set in the Adjustment tab of the Settings/Project dialog box.

**Review of the Least Squares Report**

14 In this section, the different sections of the least squares report are explained. If the Least Squares Report is not already showing, choose the Window menu and select the Least Square Report item. The report viewer has tabs to quickly access different sections of the report.

**Preprocessing and Header Information**

The following excerpt from the report shows the header information and the preprocessing results. The header information consists of the date and time, the input and output file names, the coordinate system, the curvature/refraction setting, maximum iterations, and distance units.

During the preprocessing process, multiple angles are reduced to a single angle and multiple slope distances, vertical angles, HIs, and rod heights are reduced to a single horizontal distance and vertical difference. During this process the horizontal angle, horizontal distance, and vertical difference spreads are computed. If the spreads exceed the tolerance settings from the Settings dialog box, then a warning message is displayed showing the high and low measurement and the difference between the high and low measurement.
The following excerpt from the report shows the unadjusted measurements. Measurements consist of some combination of control X, and Y, horizontal distances, horizontal angles, and azimuth measurements. These measurements consist of a single averaged measurement. For example, if multiple distances were collected between two points during data collection, only the single averaged measurement is used in the least squares adjustment.

Also, standard errors for the measurements are displayed in this section of the report. The standard errors are computed from the standard error setting in the Settings dialog box using error propagation formulas. The standard error of an angle that was measured several times would typically be lower than an angle that was measured only once.

If the data had been adjusted into NAD 83 coordinates both the ground distances and the grid distances would be displayed. The grid, elevation, and combined factor would also be displayed in this section of the report.

Unadjusted Measurements

The next section of the report shows the final adjusted coordinates. Additionally, the computed standard errors of the coordinates are displayed. If this project was reduced to NAD 83, the final latitude and longitudes are also displayed.

Adjusted Coordinates

The next section of the report shows the final adjusted coordinates. Additionally, the computed standard errors of the coordinates are displayed. If this project was reduced to NAD 83, the final latitude and longitudes are also displayed.

Adjusted Measurements

The following section from the report shows the final adjusted measurements. This section is one of the most important sections to review when analyzing the results of the adjustment. In addition to the adjusted measurement, the residual is displayed. The residual is the amount of adjustment applied to the measurement. The residual is computed by subtracting the unadjusted measurement from the adjusted measurement.

The standard deviation of the measurement is also displayed. Ideally, the computed standard deviation and residual and the standard error displayed in the unadjusted measurement would all be of similar magnitude. The standard residual is a measure of the similarity of the residual to the a-priori standard error. The standard residual is the measurement residual divided by the standard error displayed in the unadjusted measurement section. A standard residual greater than 2 is marked with an "*". A high standard residual may be an indication of a blunder. If there are consistently a lot of high standard residuals it may indicate that the original standard errors set in the Settings dialog box were not realistic.

Statistics
The next section displays some statistical measures of the adjustment including the number of iterations needed for the solution to converge, the degrees of freedom of the network, the reference variance, the standard error of unit weight, and the results of a Chi-square test.

The degree of freedom is an indication of how many redundant measurements are in the survey. Degree of freedom is defined as the number of measurements in excess of the number of measurements necessary to solve the network.

The standard error of unit weight relates to the overall adjustment and not to an individual measurement. A value of one indicates that the results of the adjustment are consistent with the prior standard errors. The reference variance is the standard error of unit weight squared.

The chi-square test is a test of the "goodness" of fit of the adjustment. It is not an absolute test of the accuracy of the survey. The a-priori standard errors which are defined in the project settings dialog box or with the SE record in the raw data file are used to determine the weights of the measurements. These standard errors can also be looked at as an estimate of how accurately the measurements were made. The chi-square test merely tests whether the results of the adjusted measurements are consistent with the a priori standard errors. Notice that if you change the project standard errors and then reprocess the survey the results of the chi-square test change, even though the measurements themselves did not change.

In our example the chi-square test failed at the 95% significant level. Our example failed the chi-square test on the low end, 52.6 is less than 60.5. Failing on the low end indicates that our data is actually better than expected compared to our a-priori standard errors. If we were to decrease the pointing and reading standard error in the Settings menu by 5-10 seconds we would probably pass the chi-square. Also notice that if you change the standard errors by only 5-10 seconds and reprocess the data the final coordinates will not change significantly.

### Statistics

Solution converged in 2 iterations  
Degrees of freedom: 84  
Reference variance: 0.63  
Standard error unit weight: 1/0.79  
Failed the Chi-Square test at the 95.00 significance level  
60.540 <= 52.627 <= 111.242

### Sideshots

If the "Enable sideshots for relative error ellipses" is not set in the Adjustment screen of the project settings screen, sideshots are computed separately after the adjustment is completed.

</tbody>
</table>

If the project had valid elevation benchmarks and measured HI's and rod heights the project could have been defined to adjust elevations. When using the 2D/1D least squares model the horizontal and the vertical adjustments are separate least squares adjustment processes. As long as there are redundant vertical measurements the vertical component of the network can also be reduced and adjusted using least squares. In the vertical adjustment, benchmarks are held fixed.

This is the final step in the adjustment. The final adjusted coordinates are now stored in the current project point database and can now be used for mapping and design.

### Lesson Two - Processing a 3D Network With Both Total Station Data and GPS
Vectors

In this lesson we will process a project that contains both GPS vectors and total station measurements.

1. Following is the opening SurvNET window. The first step is to open the project for lesson two. Choose the File > Open Project option. Navigate to the \Carlson projects directory and open the SurvNetTut02 project.

2. Let’s review the project settings. Go to Settings > Project Settings.

In order to process GPS vectors, the coordinate system must be set to 'SPC 1983' with the appropriate state plane zone. The 'Coordinate System Adjustment Model' must be set to the 3D Model. With the 3D model, horizontal units and vertical units must be the same in regards to output and total station raw data. Geoid modeling may or may not be
important depending on the extent of the project and the accuracies required. The most accurate results are typically obtained by using a 'Geoid File' set to GEOID03.

The project raw data is defined from the 'Input Files' settings screen. Notice that the units need to be specified for both the GPS vector data and the total station raw data. Typically, but not always, GPS vectors are in meters while the total station and the final output may need to be in feet. Also make sure that the correct GPS vector format is correct. Some GPS formats are binary and cannot be edited easily. Sometimes it is needed to edit the GPS vectors usually in terms of point numbers.

NOTE: The sample tutorial project has the input raw file in the default folder of C:\Carlson Projects. If you have a different data directory, then set the correct data file by highlighting the default file, pick Delete and then pick Add and select GPSAndTS.cgr (C&G format raw file) from your data folder. Do the same for the GPS Vector files of GPSAndTS1.gps and GPSAndTS2.gps.
Though this tutorial does not cover the topic, it is from this screen that you would define the traverse file needed to compute either GPS loop closures or totals station traverse closure. See the manual for further details.

Notice the standard error settings related to GPS. The GPS instrument centering error can be defined. The vector standard error is a factor that can be used to increase the standard errors as defined in the GPS vector files.
None of the settings in this screen are specific to processing GPS vectors. See the manual for details on the settings in the 'Adjustment' dialog box.

None of the settings in this screen are specific to processing GPS vectors. See the manual for details on the settings in the 'Output' dialog box. Press the OK to return to the main SurvNET dialog box.

2 Following is the main SurvNET window. To process the data chose the Process/Network Adjustment option.
The project should process and converge and the following windows should be displayed.

Let's review sections of the report that are unique to the processing of GPS vectors and the 3D model.

Sta.  N (feet)  E (feet)  X (feet)  Stem N  Stem E  Stem X
---   ------    ------    ------    ------    ------    ------
    1560984.3895 -4796605.1294  4104125.27    0.0000    0.0000    0.0000

Notice that now that we are working with a specific datum, as opposed to an assumed coordinate system that latitude/longitude, state plane coordinates and geocentric coordinates are all displayed.
In the above unadjusted observations section of the report, notice that distances have been converted to mark to mark distances. Note that vertical angles are now treated as measurements in the 3D model. And lastly, notice that the GPS vectors are also displayed. The GPS vectors are displayed as delta X,Y,& Z in the geocentric coordinate system.

In the above adjusted coordinate section of the report, notice that the grid, elevation, and combined factor are displayed with the adjusted geographic coordinates.
In the above adjusted measurements section, the adjusted measurements are shown along with their residuals, standard residuals, and standard deviation.

This completes the Lesson 5 tutorial: SurvNET.

**Lesson 6: Contouring, DTM and Design**

This is the easiest of the tutorials, and could be completed in as little as three minutes. If that is all the time you have, and you have purchased the Civil Design program, do this one first!

1 Click the desktop icon for Carlson and start-up Carlson Software.

2 Once in Carlson, start a new drawing (exit out of the Start Wizard if it appears) and go straight to the Points pulldown menu. Choose Set CooRDinate File. You will then be asked to choose the coordinate file that you want to use. Select Topo.crd as shown here, and click Open.
Now go to *Draw-Locate Points* under the Points pulldown menu. You obtain this dialog:

Choose Symbol 10 by clicking Select at the top of the dialog, then picking Symbol SPT10 from the options that appear. All other settings are default. Verify that you match what appears here. Then click the option Draw All.

The points immediately plot on the screen, and the program zooms to the extents of the points. If you don't see the points, select *Extents* under View. The point plot is shown below:

3 Triangulate & Contour. Be sure you are in the Civil Design program (Pick *Civil Menu* under Settings > Carlson Menus). Under the Surface pulldown menu, pick *Triangulate & Contour*. The following dialog boxes will appear which you should fill out as shown. We'll start with the Contour tab.
In the Contour tab, as shown above, set the contour interval to 5.0, turn on Draw Index Contours and set its interval to 25.0 (index intervals are most often 5 times the standard contour interval). The Contour tab should appear as shown above. Click on the Triangulate tab.

In the Triangulate tab (as shown above), set the Maximum triangle mesh line length values to 300 in all cases. If the goal of the field crew was never to shoot points further apart then 100 feet, then certainly triangulation over 300 feet can be ignored. Click on the Labels tab.
In the Labels tab, we want to label index contours only (so it's not too busy) and do 2 internal labels per contour. This works very well for a valley. It puts a contour label on each side of the valley. Sometimes you may prefer to label a specific length of contour.

Fill the dialogs in as shown, and press OK. Also look at the selection tab at the top and set settings as required or needed.

Select the points and breaklines to Triangulate.
Select objects: ALL (All means select everything visible on the screen)
615 found
Select objects: press ENTER (for no more)

The contours are drawn. Now, choose the command Freeze Layer under the View menu and pick on one of the points (its number or its elevation), and press Enter. The points freeze. Here is the plot so far:
4 Edit Contours. The arrow above points to an area that needs editing. This area is enlarged below. You may want to zoom into this area for the next edit operation, and zoom back out when you are finished.

Choose the command *Edit Contours*. This is found by going to the Surface pulldown menu and choosing *Modify Contours*.

- **Select contour to edit**: *click on the 1460 contour* (leftmost cursor, shown above)
- **Pick intermediate point (Enter to end)**: *click for the new position of the 1460 contour*
- **Pick intermediate point ('U' to Undo, Enter to end)**: *click a 3rd time*
- **Pick intermediate point ('U' to Undo, Enter to end)**: *click a 4th time* (more if desired you are re-drawing the contour, in effect)
- **Pick intermediate point ('U' to Undo, Enter to end)**: *press Enter* before you want to reconnect to the original 1460 as above
- **Pick reconnection point on contour**: *pick on the 1460 contour to reconnect*
- **Select contour to edit**: *continue and edit other contours, as desired or press Enter to end*

The *Edit Contour* command will keep every edited contour (e.g. our 1460 contour) as a single polyline. The edited segment is auto-joined to the before and after segments. Results below:
5 Draw a Polyline across the Valley to represent the Centerline of a dam. Choose the Draw pulldown menu and select 2D Polyline (near the top of the menu). Click the OK button on the Polyline 2D Options dialog box if it appears. This is an enhanced version of the standard polyline command which draws the same polyline entity that you get when you type PL at the command prompt. Try to split the valley with the polyline (see below).

6 Making Grid Files. A grid file can be used for volumes, comparing one grid to another. While we have the original contours visible, we should save a Topo-e grid file (topo-existing). Select Make 3D Grid File under the Surface pulldown menu. Let’s call the original ground grid Topo-e as shown in the dialog here.
Click Save. This leads to another dialog:

Use the settings shown in this above dialog box (plenty accurate for this application). Click OK.

**Pick first grid corner:** *pick to the lower left of the topo area*

**Pick opposite grid corner:** *pick to the upper right of the topo area*

**Select points, lines, polylines and faces to grid from.**

**Select objects:** *ALL (again we can use the all selection)*

**Select objects:** *press Enter (for no more)*

The file Topo.e.grd is then stored.

Tip: Whenever you make Carlson files, such as coordinate files (crd), grid files (grd), and even pond capacity files (cap), they store to disk. When you do an Undo command (U for undo), you undo the graphics, but the files are safely stored and are not undone. Carlson does not like to overdo making files. Make them if you want, but we will
not make any that are not needed. The entire contouring process, above, was completed without making a single new file, for example, though there were options, clicked off by default, to make files.

7 Design Valley Pond. Select \textit{Design Valley Pond} which can be found under Surface > Design Pond.

Pick the top of pond polyline: \textit{pick the polyline as drawn earlier}
Select the grid file Topo-e.grd. Then click Open. If we had no grid file, we could have chosen the screen-select option, and selected all objects.

Pick a point within the pond: \textit{pick upstream (northwesterly) of the polyline}

Enter the outslope ratio \textless 2.0\textgreater : 3
Enter the interior slope ratio \textless 3.0\textgreater : 4

Range of existing elevations along dam top: 1421.43 to 1576.42
Enter the top of dam elevation: 1460

Calculate stage-storage values \textless Yes/No\textgreater ? \textit{y}

Method to specify storage elevations \textless Automatic/Interval/Manual\textgreater ? press Enter

The following report includes earthwork volumes and water storage volumes.
Click the Exit icon to continue forward in the process.

**Output grid file of final pond surface [Yes/No]? Y**

Save the surface, that includes the pond, in the file Topo-d for Topo with dam.

**Write stage-storage to file [Yes/No]? Y**

Save the pond stage-storage curve information to a file (choose any name). Click Save.

**Adjust parameters and redesign pond [Yes/No]? N**

**Retain trimmed polyline segments [Yes/No]? N**

The process is complete. At the command line, enter E for erase and then when it says **Select objects**: pick on the centerline of the dam, then Enter for no more picks, and the centerline will erase.

Tips: The stage-storage curve that you save will plot in the Carlson Hydrology program. It makes a nice, handy plot for report purposes. See Lesson 11 - Hydrology and Watershed Analysis. Also, it's always good to save your drawing periodically.

8 Check it out in 3D. Select the **3D Viewer Window** option, under the View pulldown.

**Select all entities for the scene.**

**Select objects**: ALL (again, we use the all selection)

**Select objects**: press ENTER for no more

This leads to the starter view (a plan view) shown below:
The main trick is to move the X-Axis bar to the left. Avoid the Y-Axis dial for now, and then grip on the Z-Axis dial and move it back and forth relatively fast, or just click on the Z-Axis arrows and watch things move slower. It's like you are in a helicopter over the site. Here's an example:

9 Exit the 3D Viewer. Now choose 3D Polyline by Slope on Surface, found under 3D Data > 3D Polyline Utilities.

Enter the polyline layer <SLOPE_PLINE>: press OK (to accept this)
Now select the grid file. The file is Topo-d.grd.
Limiting length for polyline (Enter for none): press Enter
Pick origin point of 3D polyline: pick a point on the south side of the top of the dam, just before it contacts the ground
Direction of 3D polyline [Up/Down]? D
Direction of 3D polyline facing down slope [Left/Right]? R
Slope format [Percent/Ratio/Degree]: press Enter
Enter design slope percent: 10
Your information should be similar to this:
Horizontal distance: 693.65, Slope distance: 697.12
Vertical drop: 69.41, Avg slope: 10.01%, Max slope: 10.06%

Pick origin point of 3D polyline (Enter to end): press Enter (no more)

This created a smooth, 10% downhill grade 3D polyline, as shown, which we can use to construct a maintenance road up to the dam.

Offset 3D Polyline. This is a Carlson specialty; a high-powered Civil Design feature. In short, you can work in 3D because you can offset and manipulate 3D polylines using Carlson. So Select Offset 3D Polyline, under 3D Data > 3D Polyline Utilities.

press OK to the above dialog
Vertical/Horizontal offset amount>: 30 (for a 30' wide road)
Percent/Ratio/Vertical offset amount <0>: press Enter
Select a polyline to offset: pick our new 3D polyline
Select side to offset: pick into the hill, to the left or SW
Select a polyline to offset (Enter for none): press Enter (for no more)

This creates the other side of the road parallel, but not joined yet. For that we use Join Nearest.

11 Select Join Nearest under the Edit pulldown menu. A dialog appears which you need to fill out as follows:

![Join Nearest Options dialog]

The most important aspect is to click Directly Connect Endpoints, and tolerate the fact that they are 30’ apart by allowing for a Max separation to join of 31. That way, they will join! Click OK.

Select lines, arcs and unclosed polylines to join. pick both sides of the road one at a time, carefully avoiding picking a contour
If both the edge of roads are picked and highlighted, hit Enter to avoid additional selections.
If a contour is picked, press ESC to exit the command and start over, or press R for remove, pick it to remove it from the selection set, then A to Add, and pick again on the road.
Tip: This may be obvious, but when it is difficult to pick what you want, because several objects are nearby or overtop what you want, it pays to do View, Window and zoom in closer, followed by View, Previous after you are done.
We have a road, or at least a sloping pad, seen below:
Pad Template is one of the more diverse and powerful commands in Carlson. We will use it here to make a simple cut and fill slope from our road pad. We will go 0.5:1 in cut, but 1:1 in fill. You might think a 2:1 in fill is better, but remember, our hillside edge of road (the original edge) follows very closely to the hill itself, as designed. If it cantilevers out a few inches, and the natural slope of the ground is 1.5:1 (which it is!), 2:1 will never catch, and we will create big fill areas. So we will go with 1:1 in fill, and get very tiny, quick tie-ins in those few cases where there is any fill at all.

Pick Design Pad Template, a command under the Surface menu. A dialog appears. Use the standard entries, as shown below:

![Design Pad Template dialog](image)

Click OK. Pick two limit points of pad disturbed area. Another dialog appears. Make sure the entries match what is...
Click OK.

**Pick the pad polyline:** *pick the road pad*

**Enter the fill outslope ratio <2.0>:** 1

**Enter the cut outslope ratio <1.0>:** 0.5

**Calculate earthwork volumes [Yes/No]?** Y

A report is produced similar to Valley Pond. Review and Exit it.

**Adjust parameters and redesign pad [Yes/No]?** N

**Write final surface to grid file [Yes/No]?** Y

Store to the file Topo-f, for Topo final.

**Trim existing contours inside pad perimeter [Yes/No]?** Y

**Retain trimmed polyline segments [Yes/No]?** N

**Contour the pad [Yes/No]:** N

Select the 3D Viewer Window option, under the View pulldown to view the drawing now with a road. This completes the Lesson 6 tutorial: Contouring, DTM and Design.

**Lesson 7: Contouring, Break Lines and Stockpiles**

1. Click the desktop icon for Carlson and start-up Carlson Software.

2. Once in Carlson, exit out of the Startup Wizard (if it appears) and click *Open* under the File pulldown menu. Look for the file Mantopo.dwg drawing in the "\Carlson Projects" folder and open it.

3. Select Triangulate & Contour from the Surface pulldown menu (within the Survey module). Click the Contour tab. Let's target contours at a 1-unit interval, and contour the area of points. You will see this dialog:
Make all settings as shown (most of them are the default). We want to make sure that the Contour Interval (top right) is set to 1. Also, be sure to set the Index Interval to 5. Click OK.

**Select the points and breaklines to Triangulate.**

*Select objects:* ALL (All means select everything visible on the screen)

*Select objects:* *press Enter* (for no more)

A dialog box appears. Select Mantopo.crd as your coordinate file. Click Open and the points will be read from the crd file.

**Range of Point Numbers to use [All]/[Group]:** *press Enter* (to accept All)

**Wildcard match of point description <*:** *press Enter*

Contours are drawn, but notice the unacceptable wavy look around the perimeter, an area which is meant to be a ditch.
Type in U for Undo and press Enter until the new contours (at left) disappear and you are back at the command prompt.

4 Field-to-Finish: From within the Survey module (Settings > Carlson Menus > Survey Menu), under the Survey pulldown menu, select Draw Field-to-Finish.

You will be prompted for the CRD file to process. Choose the Existing tab, then select mantopo.crd, which resides in the main Carlson Projects folder, and click Open. The Draw Field to Finish dialog appears.

![Draw Field to Finish dialog](image)

At the lower left of the Draw Field to Finish dialog, click Edit Codes/Points. The Field to Finish dialog appears.
On the left side of the Field to Finish dialog, under the heading Code Table, there is an option called Code Table Settings. Click on it. You will see this dialog:

As you can see at the top of the Code Table Settings dialog, the default Field to Finish code definition (.FLD) file is Carlson.fld. We want to make a new code table because the coordinate file for the field survey includes special coding (17 and 18) for ditch lines and top of banks.

You can react and adjust to whatever a field crew uses by making a new field-to-finish table that can load up the codes right from whatever descriptions were used in the field. To do this, click Set at the upper-right of the Code Table Settings dialog, then choose the New tab (for new file) and you might name it Mantopo, as shown below (noting the "Carlson Projects" folder):
Click Open. You will be taken to the previous dialog.

Notice how "Carlson Projects\Mantopo.fld" is now listed at the top. Click OK. You will return to the main Field to Finish table, completely empty, as shown below:
Now, get a jump start on the table by choosing the option *Code Table by CRD* (located in the lower left of the dialog). Choose *Append* on the subsequent dialog box (shown below).

In this lesson, we only care about code 17 and 18. Select all other codes (the *GROUND* code in this case) and click the *Delete* button to remove that Code from the list. Now select Codes 17 and 18 (by holding the CTRL or SHIFT key down while picking) as shown below.
Pick the *Edit* button under Code Definitions. The Multiple Set dialog appears.

Click the *Entity* button to establish the type of entity that should be drawn for codes 17 and 18 as shown below. Make all settings as shown in this box. We will turn them both into 3D polylines (which will act as break lines or barrier lines for contouring). Accept the 3D Polyline choice by clicking OK, then hit Exit, which will take you back to the Field to Finish dialog.
The last steps are to first save the Field-to-Finish (.FLD) file Mantopo by clicking the Save button. Then click Draw (lower right) to draw the 3D polylines. You will see the following dialog which allows you to control the details of what to draw. Make sure the Lines option is the only entity to be drawn, not points, symbols, or 3D faces. Let’s take a quick look at the Additional Draw Options.

Make sure that the Point Label Settings are set so that you can see the points properly.
Click OK to both dialog boxes. The following drawing is created. All the ditch lines and top of bank lines, because they were coded 17 and 18, are drawn in one quick procedure.

Because the field crew did not use start and stop logic (e.g. appending 7 or some agreed upon code to a description could end a polyline and start another), some polylines connect that should not. In particular, the line near the NW corner is clearly crossing the ditch line. It must be removed. Choose the Edit pulldown, then Polyline Utilities > Remove Polyline > Remove Polyline Segment.

**Break polyline at removal or keep continuous [<Break>/Continuous]**? press Enter
Select polyline segment to remove: select the polyline segment to the right of point 127 indicated by the arrow below.
You will recognize this as a long segment running from point 127 to point 50.
Select polyline segment to remove: press Enter (for no more)

6 Return back up to the Surface Menu, pick *Triangulate & Contour* and use the same Contour settings as before. Then do a right-to-left crossing selection as before (avoiding the stockpile at the lower right). Select the *Mantopo.crd* file again.

**NOTE:** You may be alerted of a crossing breakline scenario located at the northeast corner of the site. Use the *Zoom To* and *Zoom In/Out* buttons to explore the data geometry at this area of the site. As an optional exercise, experiment with the *Draw Field to Finish* > *Edit Codes/Points* > *Edit Points* routine to adjust the location(s) or coding of the offending point(s).

Now we get excellent contours, with a sharply defined ditch. Under View, do *Freeze Layer* and pick on a point. The points will freeze.

Here is the improved drawing, helped out by 3D polylines that were produced by *Draw Field-to-Finish*. 
Delete Layer. Let's say that now you don't want the break lines in the drawing (since they can be easily re-created with Draw Field to Finish). You don't want to even freeze them; you want to fully delete them. There is a command for that under Edit. Pick Erase, sliding over to Erase by Layer. This dialog appears:

If you know the layer names, you can just type them in. If you know where they are but not their names, then click on Select Layers from Screen. If you'd recognize the layer name if you saw it in a list, click Select Layers by Name. Click on Select Layers by Name and pick 17 and 18, then OK twice. Notice the change in the drawing.

Explode. Inserted Drawings should be exploded so you can work with their individual components. From the View pulldown, choose the Window command and window in on the stockpile at the lower right of the drawing. If you type E to Erase, and try to erase any aspect of the stockpile, the whole stockpile will erase with all its features. That is because the Stockpile was another drawing inserted into this drawing. Sometimes other drawings that are inserted are referred to as Blocks. In any case, this stockpile “block” needs to be exploded. Explode just breaks it up into its unit objects which then start to behave normally. Select Explode under Edit and slide over to Standard Explode. Then pick the stockpile. It is now a set of normal objects.

It's also worth noting that while the block has been exploded, it still exists in the drawing as a block definition.
This means that now that it’s exploded it is taking up twice the amount of storage space in the drawing. As such, you should purge the drawing of the unused block, or turn on the explode toggle when inserting one drawing into another. As a basic rule, if it’s a symbol, don’t turn on the explode toggle; if it’s a complete drawing, turn it on.

9 Change Elevations. Let’s assume our stockpile drawing is too high and should be lowered in elevations by 540 units. To best see the effect of this command, bring back the points by selecting Thaw Layer under View. Now select the Edit pulldown, and then Change > Elevations.

Type of elevation change [Absolute/<Differential>/Scale]: D
Positive number increases, negative number decreases elevation.
Elevation difference <0.00>: -540
Ignore zero elevations [<Yes>/No]? press Enter
Change Layer for changed entities [Yes/<No>]: press Enter
Select Entities for Elevation Change.
Select objects: do a lower right pick to upper left pick (automatic crossing) selection around the stockpile
Select objects: press Enter (for no more)

Notice in the drawing below how the points, breaklines and contour polylines have changed in elevation with the exception of the contour text.

Initiate the command List Elevation under the Inquiry pulldown, pick on an index contour, and notice how the elevation has indeed changed. Repeat step 7 and delete the layer CTEXT, so as to remove the 5 index contour elevations, which are no longer accurate.

10 Volumes by Layer. One of the signature commands of Carlson, Volumes by Layer, will produce accurate volumes without making any files. The only prerequisite is that the data for the existing and final surfaces exist in the drawing on separate layers. It is also very important to have an inclusion perimeter to define the limits where the volumes should be calculated. In our example, the original ground will be the 3D polyline connecting points 1 through 15, and everything else above will be the final ground (including the 3D perimeter itself).

Make sure that you are in the Civil module (Settings > Carlson Menus > Civil Menu). Select Volumes by Layers. This command is found under the Surface > Volumes by Grid Surface.

Pick Lower Left limit of surface area: pick below and to the left of the stockpile, but as close as possible to the
stockpile without clipping it in the window
You want to totally include it, but with little wasted margin.
**Pick Upper Right limit of surface area:** *pick above and to the right* of the stockpile

A dialog appears:

We will stick with the defaults, as shown. Notice that we are using 50 grid cells within our window and since our window was not a perfect square, the cell sizes are not whole numbers. In this example it is 6.73 x 5.32. You may have slightly different sizes. Seeing this, if we wanted 5 x 5 cell size, we could click the Dimensions of a Cell option and set the size to 5 x 5. Hundreds or thousands of cells in both directions will increase calculation time. You can experiment with more cells or, if you prefer, smaller cells (which makes more cells). However, you will begin to see diminishing returns in terms of accuracy changes as your cell size continues to shrink. After a while (depending largely on the spacing of the source data), tighter, smaller cell sizes don't add any value to the precision of the calculation. Click OK.

Then pick the layers that define the existing ground (PERIMETER) and the layers that define the final ground (PERIMETER, PNTS, BARRIER, CTR, CTRINDEX).

Then click OK. Notice how the Perimeter layer is common to both. If you want to be a master of volumes, remember this as a mantra: The perimeter should be a 3D polyline in a distinct layer, common to both surfaces. A stockpile is just a special case in that sometimes the 3D perimeter is all you know about the base surface.

When asked to *Select objects*, do a right-to-left (crossing) selection of the entire stockpile area. Lastly, you will be asked for the inclusion perimeter (pick the perimeter polyline) and the exclusion perimeter (none). This leads to a flexible reporting and output dialog:
Elevation Zone Volumes, for example, would produce volumes in any desired increment from the base of the stockpile going up. If the stockpile consists of coal (80 lbs/c.f.), then Report Tons can be clicked on and a Density value entered.

Click OK, and the basic report is produced, as seen below.

Click the Exit icon to return to the command prompt.

11 Stockpile Volumes. Our Stockpile is naturally well-suited for applying the simplest volume command of all Stockpile Volumes. It requires that the 3D perimeter polyline for the stockpile be placed in a layer called Perimeter, which ours is. So let's try it.

Select Calculate Stockpile Volume found under the Surface > the Stockpile/Ponds/Pit Volumes menu.

**Ignore zero elevations [<Yes>/No]? press Enter**
Select stockpile entities and perimeter. crossing select (right-to-left picks) the entire stockpile area. The grid resolution dialog (note that it is still at 50x50) appears again. Click OK. A report is generated.

This completes the Lesson 7 tutorial: Contouring, Break Lines and Stockpiles.

**Lesson 8: A Dozen Tools for Surface Design**

Tool 1 - Draw 2D Polyline
Tool 2 - Draw 3D Polyline
Tool 3 - Offset 3D Polyline
Tool 4 - Join Nearest
Tool 5 - Bench Pond
Tool 6 - Valley Pond
Tool 7 - 3D Polyline by Slope on Surface
Tool 8 - 2D to 3D Polyline by Surface Model
Tool 9 - Input-Edit Profile
Tool 10 - Profile to 3D Polyline
Tool 11 - Design Template
Tool 12 - Design Pad Template

1. Click the desktop icon for Carlson and start-up Carlson Software.
2. Once in Carlson, exit out of the Startup Wizard (if it appears) and click Open under the File pulldown menu. Look for the file example2.dwg drawing in the "\Carlson Projects" folder and open it.
3. Since example2.dwg will also be used multiple times throughout this tutorial, you might want to make a copy so that you don't overwrite the initial drawing. Click Save As in the File menu and choose a different name, such as example2a.dwg.
4. Load the Civil Module by running Settings->Carlson Menus->Civil Menu.
I. Working with Polylines

A. Draw->2D Polyline (Tool 1)

The most basic use of a polyline is for the creation of flat-bottomed pits and flat "building pads" at any desired elevation. See the two polyline examples shown here.

The rectangle was carved out of the map by first doing the Rectang command, and making a rectangular polyline in the SW corner of the map as shown above. Then we did Erase by Closed Polyline, under the Edit pulldown, selecting the rectangular perimeter and checking Erase Outside. The two polylines are drawn by the Rectang command for the pit, and the PL command at an elevation of 0.00 for the pad as shown above (make sure to use the 'Close' option for the final line).

Then, we selected Design Pad Template, found in the Surface pulldown menu. Make sure Source of Target Surface Model is set to Screen Entities and pick OK. We began with the rectangular pit.

Pick Lower Left limit of pad disturbed area: pick the lower left of map
Pick Upper Right limit of pad disturbed area: pick the upper right of entire map
A dialog box appears. Click OK to accept defaults.
Pick the pad polyline: pick the rectangular pit
Enter the fill outslope ratio <2.00>: 1
Enter the cut outslope ratio <1.00>: 1
Enter the pad elevation: 1960 (Elevation of the pit)
Calculate earthwork volumes [<Yes>/No]? press Enter
Review the report, and then Exit from it.
Adjust parameters and redesign pad [Yes/<No>]? press Enter
Write final surface to grid file [Yes/<No>]? press Enter
Trim existing contours inside pad perimeter [Yes/<No>]? Y
Retain trimmed polyline segments [Yes/<No>]? press Enter
Contour the pad [<Yes>/No]? N

We then repeated the above steps for the pad on the right, except this time, we entered 1964 for the pad elevation. The results are shown below, in 2D and 3D views.

B. Draw->3D Polyline (Tool 2)

This is an obvious tool for creating terrains. Before drawing the polyline, try Viewpoint 3D under the View pulldown, and choose a SW viewing angle at 35 degrees above the XY plane to get a view similar to the 3D graphic shown above. In this view, erase the original pad base polyline, which is still at an elevation of 0.00. This will prevent the "nea" snap from finding the 0 elevation base polyline instead of the new, green, pad polyline. Enter Plan at the command prompt, followed by two Enters, to go back to Plan View. Now, we want to draw the polyline as shown below. We recommend the use of Carlson's 3D Polyline, found near the top of the Draw pulldown menu. We want to build a ramp from north to south into the pit. We will "arbitrarily" start at elevation 1978 by "snapping" to the 1978 contour with the "nea" snap (nearest), and then snap to the base of the pit at 1950 with the nearest snap. In the following steps, we will offset this 3D Polyline, connect its ends by Join Nearest, and create a pad template with 2:1 side slopes.
C. Edit->3D Polyline Utilities->Offset 3D Polyline (Tool 3)

After the 3D Polyline is drawn, do the Inquiry command *Angle & Distance*, Linework option, to check the percent slope of the 3D polyline. At approximately 10% grade, it should be "drivable" by haul trucks. Now, use the Edit > Copy > *Standard Copy* command and make a copy of the polyline, placing it to the right. You will want to use the Polar Tracking to ensure that the second 3D Polyline also contacts the base of pit.

D. Edit->Join Nearest (Tool 4)

Now find *Join Nearest* under the Edit pulldown menu. Select Directly Connect Endpoints, and enter a 35 offset tolerance. Pick both 3D polylines to join them, as shown in the graphic.

E. 3D Polyline Closed Perimeter

Now we have a 3D polyline closed perimeter, which can act as a pad. It is advisable to first do a *List* command, under Inquiry, to verify that each pad vertex is non-zero. Now, pick the *Design Pad Template* routine under the Surface menu. We will no longer be asked for a pad elevation, since the program will obtain the variable pad elevation from the vertices of the 3D polyline. Accept the default settings, and pick a window that encompasses the whole pad.

Enter the fill outslope ratio <2.00>: press Enter
Enter the cut outslope ratio <2.00>: press Enter
Calculate earthwork volumes [ <Yes>/No]? press Enter
Review the report, and then Exit from it.
Adjust parameters and redesign pad [Yes/<No>]? press Enter
Write final surface to grid file [Yes/<No>]? press Enter
Trim existing contours inside pad perimeter [Yes/<No>]? Y
Reading the selection set ...
Retain trimmed polyline segments [Yes/<No>]? press Enter
Contour the pad [ <Yes>/No]? N

The 2:1 cut side slopes (fill side slope is irrelevant, since we are in cut) leads to the drawing shown in the graphic.

Note that we are consistently using *Design Pad Template* to trim existing contours and 3D polylines, and to not retain the trimmed portion. We are also consistently selecting not to draw contours. In this manner, we iterate our way to the desired final terrain. We should also note that we are using the standard 50x50 "number" of cells in the Pad Template routine, windowing the entire site each time. More cells or smaller dimensioned cells lead to a finer calculation.

F. One-Sided Pad Template

![Diagram of pad with contours](image-url)
Design Pad Template in the Surface pull-down menu also works with a 2D or 3D polyline that is open and not closed. In this case, the routine will ask for which side to offset (with a closed polyline, it always offsets outward). For example, suppose you were concerned where a pit located along the northeast side of the site would "catch" if it sloped at 2:1 from an elevation varying from 1980 at the north end to 1985 at the south end. To put this 3D Polyline in, select 3D Polyline under the Draw pulldown menu, and choose the prompt for elevation option. Enter the north elevation as 1980 and the south elevation as 1985. Then do Design Pad Template and choose the left side for the offset at 10:1.

The top of the cut did not impact the building pad or the parking lot.

II. Bench Pond (Tool 5)

A. Fully "Incised" Pond

Here we have drawn a closed polyline in the lower right of the drawing, and will set its elevation to the lowest elevation the line crosses (as prompted by the program). This will ensure that the pond is fully incised and does not have any fill slopes. The Design Bench Pond routine is found under the Surface pulldown menu (make sure that you are working in the Civil Menu). It is based on the use of the closed polyline representing the top of the pond. The program cuts a circular pond into the existing terrain.

Unlike Design Pad Template, the Design Bench Pond routine works "inward". The main thing to remember is that if you have roughly 20 feet to the center of the pond, and you want to go downward at 2:1, do not ask for a depth greater than 10 feet. This will cause one side to pass beyond the other, and you will "hourglass" the interior. Another concept to remember is that the program will cut downward from the drawn polyline, which is placed at an elevation representing the water level or top of pond. A separate cut and fill ratio can be applied to the outside of the drawn polyline. If you place the pond fully in cut (fully incised), then one cut ratio would apply to the interior going down to the base of pond, and another would apply to the exterior going up to "daylight". Of course, the same ratio can be entered for both slopes.

B. Partial Fill-Partial Cut Bench Pond

A typical farm pond might have the downhill side in fill and the uphill side in cut. In fill, the flat-topped "bench" might be 10 feet. In cut, the bench would disappear. Cut above water into original ground might be 6:1. Cut below water might be 3:1. Fill could be set at 6:1 and 3:1 below water. In this case, we would remove the top bench in cut. The graphic shown here is a bench pond cut into the top center of the drawing at elevation 1994.
C. Revisit Pad Template by Doing a Diversion Ditch

If you are getting the idea, try this on your own:

Draw a 3D Polyline that will drain the lower right pond into the upper left pond. Do this through use of the *3D Polyline* command, under Draw. Issue the command, and use a "nea" snap maybe one-third down the northwest "slope direction line" in the pond at the lower right of the graphic. Connect using a "nea" snap to a point halfway down the southeast running "slope direction line" in the pond at the upper left of the graphic.

List your 3D polyline to be sure it runs downhill from approximately 1992 to 1989, or thereabouts. We're only after the concept here. Then do *Offset 3D Polyline* four feet either way for base of ditch. Connect the ends up with *Join Nearest*, tolerating 5' separation. Then do *Design Pad Template* at 3:1 side slopes in Cut and Fill. Your result is shown in 3D.

III. Valley Pond

A. Constructing a Valley Dam (Tool 6)

To begin this exercise, reopen the original example2.dwg file. We can "carve out" another portion of our base map by first drawing a "Rectang" in the SW corner of the map as shown below. Then choose *Erase by Closed Polyline*, under the Edit pulldown, selecting the rectangular perimeter and checking Erase Outside. If you'd like, you can freeze the BORDER layer to clean up your drawing. To preserve the original example2.dwg file, do a Save As under a new filename, such as valley1.dwg.

Unlike *Design Bench Pond*, the *Design Valley Pond* routine requires only a polyline axis line for the center of the dam. The polyline can be a 2-point polyline, or it can have several vertices along its length to create a concave or convex dam structure. The main thing is to "overdraw" the axis polyline, make it ride up on the left and right hillside, well beyond the desired top of dam elevation. This allows the routine to look inward and find the extents of the dam.
on each hillside, without doing an artificial extension of the polyline. Just "overdo" the length of the axis line and you are in business.

Another aspect to concentrate on is the desirability to select enough terrain upstream to enable the program to compute the full waterline extents - the limits of the dammed-up water. Without enough upstream terrain in the initial selection set (which acts like a crossing selection), you will not be able to compute the limits of the water surface and the pond stage-storage information.

Our axis polyline runs from approximately 1960 on one side of the valley to 1960 on the other. It crosses the valley at 1931. Let's decide to put the top of dam at 1950 even. We will make the dam 20' wide, with 3:1 downstream and 4:1 upstream slopes. Select Design Valley Pond under Surface > Design Pond. Source of surface model is, as always in this case study, the screen, so create a window around our new polyline, then click somewhere within where the pond will be. Respond to the prompts as shown below.

Source of surface model [File/<Screen>]? press Enter
Pick Lower Left limit of pond disturbed area: pick the lower left location of the valley pond region
Pick Upper Right limit of pond disturbed area: pick the upper right location of the valley pond region
Pick the top of pond polyline: pick the polyline that represent the centerline of the dam
Enter slopes as percent grade or slope ratio [Percent/<Ratio>]? press Enter
Enter the outslope ratio <2.00>: 4
Enter the interior slope ratio <4.00>: 3
Enter the top of dam width <10.0>: 20
Enter the top of dam elevation: 1950
Side Polyline Spacing <10.0>: press Enter
Cut pond interior [Yes/<No>]? press Enter
Calculate stage-storage values [<Yes>/No]? N
Output grid file of final pond surface [Yes/<No>]? press Enter
Adjust parameters and redesign pond [Yes/<No>]? press Enter
Trim existing contours inside pond perimeter [Yes/<No>]? Y
Retain trimmed polyline segments [Yes/<No>]? press Enter
Contour the pond [<Yes>/No]? N

B. 3D Polyline by Slope on Surface (Tool 7)

How would you start at the top of dam (elevation 1950) and build a road running downhill at 6% grade? Or, in general, how would you obtain 3D polylines for roads and diversion ditches that follow the terrain at prescribed grades starting at desired points?

The answer is 3D Polyline by Slope on Surface (located under the 3D Data menu, within the 3D Polyline Utilities pulldown). This routine requires that we make a grid or triangulation file for the terrain. Use the command Make 3D Grid File under the Surface pulldown menu, and store the file as Dam.grd. Under Grid Position/Resolution, select
Screen Pick and specify a 20x20 cell dimension. Draw a window that encompasses the entire drawing, and pick all points and lines. Then run the 3D Polyline by Slope on Surface command and answer the prompts as follows:

**Enter the polyline layer** `<SLOPE_PLINE>`: press Enter
Select Dam_grd as the grid file to use.
**Limiting length for polyline (Enter for none):** press Enter
**Pick origin point of 3D polyline:** pick a starting point on the north side of the dam
**Direction of 3D polyline [Up]/[Down]?** D
**Direction of 3D polyline facing down slope [Left]/[Right]?** R
**Slope format [Percent]/[Ratio]/[Degree]:** press Enter
**Enter design slope percent:** 6
**Pick origin point of 3D polyline (Enter to end):** press Enter

After the new 3D polyline is drawn, offset it into the hill with the Offset 3D Polyline command (under 3D Data > 3D Polyline Utilities). Press Enter for the defaults when prompted, but make sure to use a horizontal offset of 20, and a vertical offset of 0 to define the road. Then join the ends with Join Nearest, and you should obtain the drawing shown here.

Now we want to use Design Pad Template to carve our road into the terrain. In the drawing showing text information at the upper left, we can see that we now have a "pad" for pad template. Because the southern side of the pad follows close to the original ground, it may "cantilever" over into the "air" in a few places based on the resolution of the calculation. It is recommended that the fill ratio used to catch the ground be low, such as 1:1 rather than 2:1, so that short cantilevered sections of the pad, if placed on natural 2:1 terrain, don't "skim" over the ground and create unnecessary fill. For the cut sections, we will use 3:1 to carve the road into the solid hillside. The result can be seen in 3D.
C. 2D to 3D Polyline by Surface Model (Tool 8)

The 3D view above reveals a 3D polyline running up the base of the stream channel in which the pond was built. Such 3D polylines are important in modeling accurate surfaces for pond design, pad templates and volumes in general. For example, if you were to triangulate and contour the valley at 1’ interval (currently the contours are at 4’ interval), you would obtain poor valley contours which "square off" in the valley - if you did not select the 3D Polyline “break line”.

Thus, an important strategy, better yet policy, is to dress up raw contour maps with valley and ridgeline 3D polylines that act as break lines, and restore the true character of the terrain. The best way to make these 3D polylines is to draw 2D polylines in drains and ridges (see the three circled examples) and "drape" them on the terrain. This is done using the 2D to 3D Polyline by Surface Model command, found under the 3D Data pulldown menu. You can use the Dam.grd file that you created earlier.

D. Creative Uses of 2D to 3D Polyline by Surface Model

More than a command to "dress up" contour maps for greater modeling accuracy, the 2D to 3D Polyline by Surface Model command (sometimes called the "drape" command) has unexpected uses. In the example, a strata angling along a pit face creates instability in the upper part of the pit. The goal is to "lay back" the pit at 2:1 above the strata demarcation line, and retain the 1:1 slope below that line (which is drawn as a 2D polyline at the outset, then converted to 3D when draped).
After the 3D Polyline is "draped" on the surface, you should use Change > Elevations under the Edit menu to drop the entire 3D Polyline just a little, such as -0.2. This will ensure it is fully in Cut. Then the Design Pad Template command can be used to perform a one-sided offset at 2:1 in Cut, resulting in the drawing, shown here in 3D view.

E. Input-Edit Profile (Tool 9)

Our next goal is to build a diversion ditch around the dam using Input-Edit Profile. With Osnaps turned off, draw a simple 2D polyline ("PL" command or Carlson's "2DP") that starts on the water side of the valley dam, near the "break line" that was drawn earlier, and curves around the hill to the south and into the drainage below the dam, as shown in the graphic. The syntax for this using the PL command is: pick first point, pick second point to get a tangent (straight section) going, then type A for arc, arc it around the dam, then do L for line and a second L for length, and pick a point that comes off tangent from the arc and ends in the stream bed below the dam. Then press Enter to exit the PL command.

Now we are going to make this 2D polyline a 3D polyline with a prescribed profile. To prepare for this, we do Polyline Info under the Inquiry pulldown menu, and write down the length of the polyline (this will become the length of the profile we enter). This one here is 377.6 feet, which we will round up to 378. We then use List Elevation under the Inquiry pulldown menu, and pick on the 3D "break line" polyline as close as we can to the point where our 2D polyline makes contact. In our example, this elevation is reported as 1929.4 (along with all vertices elevations). We determine ahead of time that we want the first 50 feet of the diversion ditch to be a 1% downhill slope, starting at elevation 1946 (allowing 4 feet of freeboard to the top of the dam at 1950). We are ready for Input-Edit Profile File in the Profiles menu. Call it Ditch.pro, and fill out the profile dialog as shown in the graphic, but with the data that applies to your example.
The order of entry might be 0 and 1946 on the first line, 378 and 1929.4 on the third line, and 50 and slope% of -1 on the second line, completing the profile. Save it, and Quit from the dialog. The one remaining step to get a 3D polyline is to select the command Profile to 3D Polyline under the Profiles pulldown menu. Pick the ditch centerline and apply the newly saved profile to it. Erase the old centerline and you obtain a "yellow" colored 3D polyline centerline.

Use the command Offset 3D Polyline to offset the ditch into the hill 8 feet for an 8’ base (or offset 4’ either way and erase the original centerline). In either case, you have two parallel 3D polylines. Now, do Join Nearest, tolerate 9’ of separation and Directly Connect Endpoints within Join Nearest.

Note how 3D Polyline > Offset 3D Polyline and Join Nearest become a familiar sequence in doing pad template work! Now create a Design Pad Template with a cut slope of 1.5 to 1.

If it is apparent that the diversion ditch was initially drawn too far into the pond area and created fill, as seen in the graphic, then there is the option to re-design or simply to trim off the fill portion. This likewise applies to the portion of the diversion ditch at its terminus downstream. Note that gaps in contours that need to be re-closed can be very quickly fixed with Join Nearest. With the trimming completed, the final design appears in 3D.
F. Profile to 3D Polyline (Tool 10)

Our next topic of discussion will focus on building a curving road from the top of dam to the base of pit using Input-Edit Profile and converting that profile to a 3D Polyline. Looking at the 3D view in the graphic, let's extend the road from the top of dam into the base of the pit, following a uniform grade and entering the pit at right angles on the south side (or right-side, as seen in the graphic). This "word problem" is nothing more than another iteration of Input-Edit Profile File and Profile to 3D Polyline. The first challenge is to draw the 2D polyline using the PL command. We've already learned how to do this and use the second L approach to come off tangent from an arc. We end up with a centerline that might look like the one in the graphic.

Just as before, find the length of the polyline using Polyline Info under the Inquiry menu. We know the profile... it runs from 1950 (the top of dam) down to 1930 in the base of pit. So we go straight to Input-Edit Profile File, perhaps name it Road (Road.pro) and put in a simple two-entry profile as shown in the dialog box display here.
The slope of the road at -3.17 percent is very acceptable for any type of vehicle. So now we choose Profile to 3D Polyline and apply Road.pro to the road centerline. This time we will offset the new 3D polyline 10 feet either side using 3D Polyline Offset, and erase the original middle centerline (or render it harmless for terrain modeling by the command 3D Entity to 2D found under the Edit menu).

This raises an important point: when we select entities from the screen using Design Pad Template, Design Valley Pond and Design Bench Pond, the pad or pond polyline itself is filtered out of the selection set, and it is not used for modeling the original surface.

If we left intact a 3D polyline centerline that was not part of our pad, it would skew the surface model badly. Thus, if we offset left and right for the outside of the road, the middle of the road must go, must be erased, unless we chose the "grid file" option for the original surface. After offsetting 10' either side and erasing the center 3D polyline, we Join Nearest at a 21' tolerance. Then we do Design Pad Template at standard 2:1 slopes.

Here is the final 3D view (you might use Design Pad Template to divert the ditch and not flood the pit!).

IV. Pad Template in Combination with Design Template for Roads, Ditches, and Levees

A. Roads with Ditches and Berms

The limitation of Offset 3D Polyline within Pad Template is that roads cannot easily be given dynamic characteristics: They won't automatically carve in ditches in cut, or build a berm in fill where fill exceeds a certain threshold,
for example.

Since these "intelligent" features exist within the Design Template routine in the Roads menu of the Civil Design module, all we need to do is invoke the "template" option within the Pad Template. Pad Template will then go out and get a Design Template and apply it to the one-sided or closed pad perimeter. To illustrate this, let's first make a centerline that will have cut and fill. Consider the centerline drawn in the graphic.

If we go a uniform grade from the existing road, upward to the ending elevation (which might represent a mining bench), we are "bound" to get cut as we cross the lower point and fill as we cross the second drain. To "guarantee" fill, we will go uphill early and lessen the last portion of the grade, using a vertical curve length of 500 between profile grades. This is another exercise of Polyline Info (for length), verifying start and end grades, and Input-Edit Profile (as shown in the dialog).

With the profile input (named road1.pro), we can select Profile to 3D Polyline and turn yet another 2D polyline into a 3D polyline. The difference now is that we will not offset the 3D polyline to create a closed, looping "pad". We will instead use a template made in Design Template, and apply it to the 3D polyline.

B. Entering a Template in Design Template (Tool 11)

Design Template, located under the Roads menu in the Civil Design module, is icon driven. Create a new template, you may call it Roads1. See this horizontal strip of icon options.
Shown here is a selection of dialogs that illustrate our entry of a 24' wide road (12' either side) at 2% slope, no shoulder, no subgrade, a 3:1 slope for 6' to the base of ditch, a conditional cut upslope, a 3:1 slope in fill, but a 2:1 berm in fill, rising 4 feet, used when fill exceeds 5 feet. To begin with, this small dialog appears when the Grades button, within the Design Template dialog box, is clicked.

Note that when you are putting in a ditch, you need to click "Add Ditch" at the lower-left of the Cut Grades dialog. The conditional cut upslopes mean 4:1 up to 4 feet of fill, 3:1 between 4 and 10 feet of fill and 2:1 above 10 feet of fill.

The Fill Grade dialog looks similar, with two entries for berms (Add Berm is selected twice), one for upslope at 2:1 for 8 feet (which translates to 4 feet vertically) and a second for downslope of 2:1 for 8 feet for the back of berm.
The “typical section” can be drawn using the command *Draw Typical Template* under Roads. This will help you verify the quality of your template. Our template is shown here.

**C. Design Pad Template (Tool 12)**

Now let's use the *Design Pad Template* routine, found in the Surface menu. The dialog box for *Design Pad Template* is filled out as shown.
For the first time, we have selected the "template" option under Design Slope Format.

Finally, here is how the road appears in 3D using the View > Viewpoint 3D command.

This completes the Lesson 8 tutorial: A Dozen Tools for Surface Design.

**Lesson 9: Calculate Volumes By Five Methods**

For this tutorial, we'll be using a sample stockpile drawing and calculating its volume using five distinct techniques.
1. **Stockpile Volumes:** Creates grid surfaces from perimeter polyline and surface entities and calculates volumes in one command

2. **Two Surface Volumes:** Calculates volumes between two grid files

3. **Volumes By Layers:** Creates grid surfaces from existing and design layers and calculates volumes in one command

4. **Volumes By Triangulation:** Calculates volumes between two triangulation files

5. **Calculate Sections Volumes:** Calculates volumes between two section files using volumes by average end areas

Each of these routines has its own advantages. You can choose the routine that best suits your data or run multiple methods as a check of the volumes. The volume reports for each of these routines will vary slightly due to using different types of surface models that have different resolutions. These volume differences should be less than 2%.

A Results Summary of the various volume methodologies is also provided.

If there is a greater difference, try increasing the resolution of the surface models. For grids, make the grid cell size smaller and for sections, make the station interval smaller. If there is still a significant difference, then the cause should be investigated by checking the source data.

**Common Steps**

The following are common preparation steps for all five volume methods.

**Step 1 - Open Drawing and load Civil Module:**

From the File menu, choose Open and select example1.dwg from the Carlson Projects folder (e.g. C:\Carlson Projects\example1.dwg). Then load the Civil Module menu by running Settings->Carlson Menus->Civil Menu.

**Step 2 - Draw Perimeter (the automated process):**

There are several methods for drawing the perimeter polyline. One such method involves using the CRD (or Field to Finish).
The Surface > Stockpile/Pond/Pit Volumes > 3D Poly Perimeter command can draw by point numbers from the coordinate file. If you have the coordinate file for the points, then you can go directly to draw and use the point numbers. In this example, we have only the drawing and no coordinate file. Still, we can easily create a coordinate file from the points in the drawing.

First run Points > Set CooRDinate File, and in the file selection dialog, choose the New tab and enter example1 for the file name. Next run Points > CooRDinate File Utilities and pick Update CRD File From Drawing. Go with all the defaults for this function and when prompted to select objects, enter All. Now the coordinate file has all the points from the drawing. In this example, the perimeter points are sequential. So at the 3D Poly Perimeter command prompt for points, you can enter the point range of 2000-2028 and it's done.

Step 2 - Draw Perimeter (the quick process):

One of the signature commands found in Carlson Software is the Shrink-Wrap Entities found under the Draw menu. This routine is useful in situations where outlying perimeter locations don't share the same point descriptions, aren't sequentially numbered and is used even if the outlying locations are not points! Let's explore this routine by clicking the Draw > Shrink-Wrap Entities command. Set the parameters in the dialog as shown here.

The resultant perimeter should resemble that as shown in the illustration shown in the next discussion item.

Step 2 - Draw Perimeter (the manual process):

We begin by drawing a perimeter polyline using the outermost points of the stockpile. The perimeter polyline limits the volume calculation to the area within the polyline. In this example, the perimeter polyline consists of points 2000 - 2028 with description B-TOE. To pick these points, set your osnap to Node using the Object Snap under the Settings pulldown menu and turn off all the other osnap methods. Then run Draw 3D Polyline.

Pick all the perimeter points one at a time. At the command line, the program will prompt as follows:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: pick point 2000, a B-TOE point
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: pick point 2001, pick the next B-TOE point
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: pick point 2028, pick the last B-TOE point

... [Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: press C to close the perimeter and exit the routine.

After you draw your perimeter polyline, simply return your osnap to none.
Volume Method 1 - Calculate Stockpile Volume

Step 1 - Calculate Stockpile Volume:

The Calculate Stockpile Volume routine is based on a grid surface methodology like Two Surface Volumes discussed below. The difference with this routine is that it builds the grid surfaces within the routine to save time otherwise needed to build the grid files. The fewer steps make this routine faster and easier but it doesn't have options for checking surfaces. Instead the input data entities should be checked before running this routine. Also, Calculate Stockpile Volume only applies to volumes calculations when the volume is all fill.

NOTE: For situations involving a Cut-only scenario (such as a pond or pit), use the Surface > Stockpile/Pond/Pit Volumes > Calculate Pond/Pit Volume command.

Choose Calculate Stockpile Volume from the Surface menu, under Stockpile/Pond/Pit Volumes. The routine starts with prompts at the command line.

Material density lbs/ft\(^3\) (Enter for none): press Enter

This density option applies when you're measuring a stockpile of a material with a known density and you want to report the material tons for the stockpile.

Ignore zero elevations [Yes/No]? press Enter (filters out elevation zero entities)

Select stockpile entities and perimeter.

Select objects: All

Select objects: press Enter

The program looks for a closed 3D polyline on the PERIMETER layer to use as the inclusion perimeter and the base surface model. If this polyline is not found, then the program will prompt to select the perimeter polyline. All the selected entities including the perimeter are used to model the second surface of the stockpile top.

Specify the grid resolution as shown in the dialog below.
Next you have the option to break up your volumes report by a specified interval. In this example, let's do every 5 feet.

The volume report displays.

NOTE: The limits of the grid are determined automatically and shown in the report. For the sake of accuracy, the next two methods will use the grid parameters shown above.

**Volume Method 2 - Two Surface Volumes**

**Step 1 - Make Base Grid Surface:**

Before running *Two Surface Volumes*, we must create the two grid files by using the *Make 3D Grid File*, located under the Surface menu. The first grid file will be for the base of the stockpile. At the file selection Grid File To Create dialog, enter a name of BASE and click Save.
Next, there is a dialog to set the grid parameters. The Low and High elevations are used to filter out elevations outside the range. By default the Low elevation is set to 1 which filters out zero and negative elevations. For the Modeling Method, use the default Triangulation method for surface models. The other methods are primarily for strata geologic models. For Triangulation mode, the Triangulation Only method triangulates all the data points. The Triangulation with Subdivision does the Triangulate step followed by subdividing the large triangles to make a smoother surface. The Intersection Only method interpolates the grid corners from the intersections of the grid lines with the surface linework which applies to making a grid from all contour polylines. The Auto Detect method looks at the source data and chooses Intersection if all the data is linework or uses Triangulation otherwise.

The grid resolution sets the size of the grid cells either by entering the actual size or by the number of cells. Generally, you should use a grid size that is small enough to pick up the changes in the surface. At the same time, the total number of cells should be less than a million depending on your computer memory. In this example, we have 50x50 cells which results in a cell size of 4.82 in X (Easting) and 3.92 in Y (Northing), and this is enough resolution for the data.

Lastly, check the *Screen Pick* option under Set Grid Position, and then click OK.

To select the grid position from the screen, create the rectangular area for the grid surface that completely encloses the stockpile.
Next, examine the prompts below to use for the model. For the base surface, select only the 3D perimeter polyline.

**Pick first grid corner:** *pick the first grid corner as illustrated*

**Pick opposite grid corner:** *pick the second grid corner as illustrated*

**Select points, lines, polylines and faces to grid from.**

**Select objects:** *pick the 3D perimeter polyline (again)*

**Select objects:** 1 found

**Select objects:** press Enter

**Step 2 - Make Final Grid Surface:**

Next, let's create the top of the stockpile surface by repeating *Make 3D Grid File* used in the last step. Choose *Make 3D Grid File* from the menu and enter a grid file name of FINAL in the file selection dialog.

In the dialogue under Set Grid Position, check the *From Another Grid File* method and select BASE.grd as the reference grid position. This file method uses the grid position and resolution from the selected reference grid. For Two Surface Volumes, the two grids to compare should have matching grid positions and resolution.

Then there are a series of command line prompts for the elevation range and modeling method. Press Enter for each of these prompts to go with the defaults. Then for the selection of objects to process, enter All to use the stockpile perimeter plus all the points.

**Select points, lines, polylines and faces to grid from.**

**Select objects:** *All*

**Select objects:** press Enter

**Step 3 - Check Surfaces:**

This step is optional to verify that the surfaces are good by checking for bad elevation data points and that the surfaces follow the data points. There are several routines that can be used to check the surfaces, including Draw 3D Grid File, Surface Inspector and Contour From Grid File. For this example, we will use Draw 3D Grid File and Surface Inspector.

In the Surface menu, under Draw Surface, choose the *Draw 3D Grid File* command. At the Select Grid File dialog, choose FINAL.grd. In the options dialog, go with the settings shown here and pick OK.
With the grid drawn as 3D Faces, run the 3D Viewer Window command in the View menu. At the command line, it will prompt to select the objects to view. Enter All and press Enter.

Select all entities for the scene.
Select objects: *All*
Select objects: *press Enter*

In the 3D Viewer dialog, move the pointer near the center of the graphic and the cursor will change to an X/Y symbol which is the X/Y axis rotation mode. Click down the left mouse button and drag down to rotate the pile to a good
viewing angle. Then move the pointer near the edge of the graphic and the cursor will change to a Z symbol which is the Z axis rotation mode. Click down the left mouse button and drag around to rotate the pile. You can also set the Vertical Scale to 2.0 and choose the Color By Elevation toggle for better viewing of the elevation difference.

The surface looks right in the 3D Viewer. Close the 3D Viewer by choosing the Exit Door button. We don't need the 3D Faces anymore. Let's delete them by running *Erase By Layer* in the Edit menu. Choose the Select Layers From Screen and pick any 3D Face. Then pick the OK button.

![Erase by Layer/Type](image)

The Draw 3D Face check could also be run on the BASE.grd surface using the same procedure as above, but we're going to skip that in this tutorial to save space.

Now, let's check using Surface Inspector. First, use Zoom Window under View to zoom onto the bottom of the pile so that we can easily read the point elevation labels. Then run Surface Inspector from the Surface menu. In the dialog, set BASE.grd and FINAL.grd as the two surfaces to inspect and then pick OK.

![Surface Inspector](image)

Now, move the pointer around the pile and the program reports the elevation of the two surfaces in real-time. Check that the grid elevations match the point elevations reasonably well. Remember that the base elevations are using only the B-TOE points. The elevations won't match exactly with grid surfaces because the grid model is at the resolution...
Step 4 - Two Surface Volumes:

Now that you have your base file and final grid files, to calculate volumes use the Two Grid Surface Volumes command in the Surface menu, under the Volumes By Grid Surface flyout.

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: select the perimeter polyline
Select objects: press Enter
Select the Exclusion perimeter polylines or ENTER for none.
Select objects: press Enter
Select Base Grid File Choose BASE.grd
Select Final Grid File Choose FINAL.grd

Set the Volume Report Options dialog box as shown above and click the OK button. A volume report similar to that shown below is produced. Note that your volume totals may vary slightly due to the orientation of your grid.
Volume Method 3 - Volumes By Layers

Step 1 - Volumes By Layers:

Like the two previous volume methods, Volumes By Layers is based on grid surfaces. Similar to Calculate Stockpile Volume, this routine builds the grid surfaces within the routine to save the steps of running Make 3D Grid file. The difference between this routine and Calculate Stockpile Volume is that Volumes By Layers uses entities on the specified layers for existing and design to build the surfaces and it will calculate both cut and fill volumes.

Choose Volumes By Layers from the Volumes By Grid Surface flyout of the Surface menu. The routine starts with prompts to set the grid area to model. In the same way as the Make 3D Grid File step of Two Surface Volumes, pick two corner points that make a rectangle to enclose the stockpile area.

Pick Lower Left grid corner: pick to the lower left of the stockpile
Pick Upper Right grid corner: pick to the upper right of the stockpile

Next, there is a dialog to set the grid resolution. Again, the same rules for grid resolution apply as described in the Two Surface Volumes step.

In the next dialog, set the layer names for the entities to use for the Existing (Base) and the Final (Design) surfaces. For this example, pick the Select Layers From Screen button under Existing and then select the perimeter polyline. Then pick the Select Layers button under Final and select both the perimeter polyline and the points.
After specifying the layer names, click OK in the dialog. Then the program prompts to select the surface entities to model. For this example, type All and press Enter to process all the entities. The program will sort the entities for modeling of the existing and design surfaces by the layer names.

Next, you specify the inclusion and exclusion perimeters. For the stockpile, pick the perimeter polyline for the inclusion and press Enter for none at the exclusion prompt. The same Volume Report Options dialog then offers the same output options as Two Surface Volumes. Click OK. After this dialog, the report is displayed.

Select surface entities on corresponding layers.
Select objects: All
Select objects: press Enter
Select the Inclusion perimeter polylines or ENTER for none.
Select objects: select the perimeter polyline
Select objects: press Enter
Select the Exclusion perimeter polyline or ENTER for none.
Select objects: press Enter
Volume Report Options dialog Pick OK

Volume Method 4 - Volumes By Triangulation

Step 1 - Triangulate & Contour for Base:
Before running Volumes By Triangulation, we need two triangulation surface files to compare. From the Surface menu, choose Triangulate & Contour which brings up the Triangulate & Contour dialog.

Under the Contour tab, turn off Draw Contours. Actually, drawing the contours at this step can be a good visual check that the surface is right but we’re going to skip it this time. Under the Triangulate tab, turn on Write Triangulation File, Use Inclusion Perimeter and Ignore Zero Elevations. Then pick the Browse button and set the file name as base.tin. When the dialog is set as shown, pick OK.

Next, the program prompts for the inclusion and exclusion perimeters. Choose the perimeter polyline for inclusion and nothing for exclusion. Then you select the entities to triangulate. For the base surface, pick only the perimeter polyline and then press Enter.

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: pick the perimeter polyline
Select objects: press Enter
Select the Exclusion perimeter polylines or ENTER for none.
Select objects: press Enter
Select the points and breaklines to Triangulate.
Select objects: pick the perimeter polyline
Select objects: press Enter

Step 2 - Triangulate & Contour for Stockpile:

To create the second surface, repeat step 1 with a few simple changes. In the Triangulate, choose Browse, and set the file name to FINAL.tin and then pick OK.

For the inclusion and exclusion perimeters, again choose the perimeter polyline for inclusion and nothing for exclusion. At the select objects prompt, enter All and press Enter to use all the points and the perimeter to make the stockpile surface.

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: pick the perimeter polyline
Select objects: press Enter
Select objects: press Enter
Select the Exclusion perimeter polylines or ENTER for none.
Step 3 - Check Surfaces:

Similar to the Check Surfaces step under Two Surface Volumes, this is an optional step to check that the surfaces are correct. Again, there are several routines that we can use. Let's check the surface file directly.

From the View menu, choose the **Surface 3D Viewer** command and open the **FINAL.TIN** file. Just as before in the **3D Viewer Window**, you are able to use the mouse click-and-drag methods to rotate the stockpile into view. Also, set the Vertical Scale to 2.0 and turn on Color By Elevations.

![Surface 3D Viewer](image)

Close the Surface 3D Viewer by choosing the Exit Door button. Notice how we didn't have to draw anything to the screen/drawing to check this surface!

Step 4 - Volumes By Triangulation:

Now that we have our two triangulation files, we can use **Volumes By Triangulation** which performs a TIN to TIN prismatical volume calculation. Of all the volume methods, this one is the most accurate since all the source data points are used in the volume model. **Volumes By Triangulation** is well suited for this example.

Run **Two Triangulation Surface Volumes** from the Surface > Volumes By Triangulation menu. For the Select Existing Surface File dialog, choose BASE.tin. Next, for the Select Final Surface File dialogue, choose FINAL.tin. Click OK. At the prompts for the inclusion and exclusion perimeters, pick the perimeter polyline and press Enter for None for the exclusion. In the Volume Report Options, go with the defaults and pick OK. Then the volumes are calculated and the report is displayed.

**Select Inclusion polylines.**
**Select objects:** pick the perimeter polyline
**Select objects:** press Enter
**Select Exclusion polylines.**
The volume report displays.

Volume Method 5 - Calculate Section Volumes

Step 1 - Draw Centerline/Baseline:

The first step for section volumes is to draw a polyline to use as the centerline for the section alignment. This centerline needs to be drawn so that the perpendicular section lines to the left and right of the centerline have a clear line to reach the perimeter without crossing and re-crossing the perimeter.

Before drawing the polyline, run *Aperture-Object Snap* in the Settings menu, and turn on only the Node snap.

Choose *2D Polyline* under the Draw menu. If the options dialog is shown, make sure that the elevation is set to zero and pick OK. Then at the command line, the program prompts to pick the polyline points.

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: pick point 2027
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick point 2015
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter
Step 2 - Define Section Alignment:

The next step is to define the station interval and left/right offsets for the sections. Choose *Input-Edit Section Alignment* from the Sections menu. In the Specify Section Alignment File dialog, choose the New tab and enter a file name of Vol-Sections.mxs, and click Open. The program then prompts for the centerline. Pick the centerline polyline that we just drew. For the starting station of the centerline prompt, use the default of 0.

*Polyline should have been drawn in direction of increasing stations.*

**CL File/<Select polyline that represents centerline>:** pick the centerline polyline  
**Enter Beginning Station of Alignment <0.00>:** press Enter

Next there is a dialog to set the section parameters. Set values as shown below and then click OK.
Select boundary polyline: pick the perimeter polyline

The program draws temporary lines in the drawing to show the positions of the sections. The next dialog shows a summary of the section alignment. Pick the Save button.

Step 3 - Create Section File for Base:

To create the section file for the stockpile base, run Sections from Grid or Triangulation Surface from the Sections > Create Sections from... menu. When prompted to Choose Grid or Triangulation file to process, open the BASE.tin file created earlier. When prompted to Choose Section Alignment file to process, open the Vol-Sections.mxs file. For the Section File to Write, save a new file called BASE.sct. On the final dialog for Link Sections to Triangulation, choose No.

Step 4 - Create Section File for Stockpile:

Let's follow similar steps to create the FINAL.sct file.

To create the section file for the stockpile itself, run Sections from Grid or Triangulation Surface from the Sections > Create Sections from... menu. When prompted to Choose Grid or Triangulation file to process, open the FINAL.tin file created earlier. When prompted to Choose Section Alignment file to process, open the Vol-Sections.mxs file. For
Step 5 - Check Sections:

Similar to the Check Surfaces steps under Two Surface Volumes and Volumes By Triangulation, we have a couple surface files. Before running the volumes, this is an optional step to check that the surfaces are correct. There are several routines to check sections including Input-Edit Section File, Draw Section File and Section To 3D Polylines.

For this check, run Input-Edit Section File under the Sections menu. For the Section file to process dialog, choose the FINAL.sct file. Next the Input-Edit Section File dialog is displayed. Pick the button labeled 2nd and choose the BASE.sct file. Then highlight station 0+94 (for example) from the Stations List and double click on it or pick the Edit button.

This brings up the Edit Station viewer for station 1+00. Use the Next and Prev buttons to look at other stations. After checking the stations, pick OK to exit Edit Station, and then pick Exit from the main dialog.
Step 6 - Calculate Section Volumes:

Now that we have our two section files, we can use Calculate Section Volumes, which does volumes by the average end-area method which is traditionally accepted for corridor studies.

From the Sections menu, choose Calculate Section Volumes. For the Existing Ground Section File, choose the BASE.sct file. For the Final Ground Section File, choose the FINAL.sct file. In the Calculate Section Volumes option dialog, use the defaults as shown.

Click OK. The volumes are calculated and reported, along with the cut and fill end-areas at each station.
Results Summary

As mentioned earlier, each volume methodology has a particular use and knowing the applications for each method will serve you well. Here is a summary of our results:

<table>
<thead>
<tr>
<th>Method</th>
<th>Fill (c.y.)</th>
<th>Cut (c.y.)</th>
<th>When to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockpile Volumes</td>
<td>2,656.51</td>
<td>-</td>
<td>Quick and approximate Fill-only volumes are sufficient</td>
</tr>
<tr>
<td>Two Surface Volumes</td>
<td>2,656.43</td>
<td>15.21</td>
<td>Large data sets when approximate Cut and Fill volumes are sufficient</td>
</tr>
<tr>
<td>Volumes By Layers</td>
<td>2,656.43</td>
<td>15.21</td>
<td>Quick and for large data sets when approximate Cut and Fill volumes are sufficient</td>

</tbody>
</table>

This completes the Lesson 9 tutorial: Calculate Volumes By Five Methods.

Lesson 10: Basic Road Design with Volumes

1 First we need to open an example drawing supplied with Carlson. Issue the File Open command and choose EXAMPLE2.DWG. It should be in the Carlson Projects folder, and will look like the example (without the curved road).

2 Draw Road Centerline. Issue the Draw > 2D Polyline command and generate the road centerline shown below. If
the Polyline 2D Options dialog box appears, provide the values as shown below and then click OK.

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 1857700,159400

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: D

Enter distance: 310

Define direction method [Cursor/Line/<Angle>]: press Enter

Code: 1-NE 2-SE 3-SW 4-NW 5-AZ 6-AL 7-AR 8-DL 9-DR

Enter angle code (1-9) <7>: 1 (for a northeast bearing)

Enter bearing (dd.mmss): 68.5525

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: A

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: L

Specify radius length: 500

Curve direction [Left/<Right>]: press Enter

[Arc length/Chord length/Delta angle/<End point or point number>]: D

Specify delta angle (ddd.mmss): 76.2405

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: L

<Enter or pick distance>: 1663.2721

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter
3 Polyline to Centerline File. This step will create a centerline file necessary for the final road design routine. We will do the simplest variation, which is simply picking a polyline. There are other methods to design a centerline. They are documented in the manual.

First (if necessary), zoom back to the extents of the plan view, as we will be working with the polyline created above. Go to Polyline to Centerline File command, under Centerline, and name a *.cl file to create.

Polyline should have been drawn in direction of increasing stations.
Select polyline that represents centerline: pick polyline representing the centerline
Centerline station [Reverse/Ending/<Beginning: 0+00>]: enter

<table>
<thead>
<tr>
<th>Station</th>
<th>North(y)</th>
<th>East(x)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.000</td>
<td>159400.000</td>
<td>1857700.000</td>
<td>LI</td>
</tr>
<tr>
<td>310.000</td>
<td>159511.480</td>
<td>1857989.262</td>
<td>PC</td>
</tr>
<tr>
<td>976.728</td>
<td>159329.389</td>
<td>1858580.264</td>
<td>PT</td>
</tr>
<tr>
<td>2640.000</td>
<td>157961.527</td>
<td>1859526.534</td>
<td>LI</td>
</tr>
</tbody>
</table>

Press ENTER to continue. press Enter

4 Profile from Surface Entities. Now we will make a profile file, *.pro. This will be from the centerline shown in the drawing as the line with the curve. Under the Profiles menu choose Create Profile From... then Profile from Surface Entities. This will create a new file. Type in a file name in the dialog and click Save. On the next dialog, we will use the default values and click OK. Pick the centerline, and without hitting enter, select all of the contours. The data is written to file.

NOTE: Common practice is to build a surface model from any and all data that carries an elevation. However, there are several Carlson Create Profile from... routines and we'd like to work with a routine that gets its information "direct from the source" (i.e. the contours themselves).

5 Draw Profile. This will give us a profile view of the contours at our centerline. Under Profiles, go down to Draw Profile and add our new file to open. Click Ok.
The window below will appear as shown. With the horizontal scale set to 50 and the vertical scale set to 5, there will be a 10X vertical exaggeration of the profile. Fill this dialog box it out as shown below and click OK.

Next, there is the Profile Grid Elevation Range dialog. Accept the top and bottom elevations it gives by hitting OK. Pick a spot in the drawing to draw the profile, then view the profile on the grid by zooming as required. Your profile should look similar to this.
NOTE: The "flat spots" shown in this profile are the result of extracting the profile data directly from the contours. Extracting a profile from a surface model is a more common approach in today's computer age.

6 Design Road Profile. Now we will design how the road centerline profile will be, in relation to the existing ground (which is the first profile we have made). This routine will create another Profile file. Under Profiles, go to Design Road Profile, and then Design Road On Profile Grid (this method is suggested for this tutorial).

The following dialog box will appear. Since we followed up the Draw Profile command with this one, it was able to determine proper startup values for the dialog.

Choose OK on this dialog. A new file creation dialog box will appear, asking for an output file name. Enter a name such as DESIGN, and click Save.

Pick Lower Left Grid Corner <0.00,0.00>[endp on]: pick the lower left grid corner of the profile grid

Carlson has endpoint osnap active to make the pick accurate

At this point another dialog will appear in the upper left corner. Initially, it will display only station and elevation. Once a beginning point has been designated, it will also display the relative difference from the last point to the cursor position (illustrated below). This can be an aid in determining acceptable slopes for your design.
Enter a station or pick a point (Enter to End): \textit{END}
of pick the left-most endpoint of the existing ground profile as a tie in point

The following dialog appears. Choose OK to accept the defaults.

![Snap Profile Point](image)

Station of second PVI or pick a point (U,E,D,Help): 1111.01
Percent grade entry/\langle\text{Elevation of PVI}\rangle: 1999.37
Station of next PVI or pick a point (U,E,D,Help): 1911.64
Percent grade entry/\langle\text{Elevation of PVI}\rangle: 2002.66
View table/Unequal/Through pt/Sight dist/K-value/\langle\text{Vert Curve Length}\rangle: 500.00
For Sag with Sight Distance \rangle VC and Vertical Curve \rangle 500.00
Sight Distance \rangle 1000.0, K-value \rangle 306.6
Use these values (\langle Y \rangle/N)? \textit{Y}
Station of next PVI or pick a point (U,E,D,Help): \textit{END}
of pick the far-right endpoint of the existing road as a tie in point

The following dialog appears. Choose OK to accept the defaults.
For Sag with Sight Distance => 1000.00, K-value => 697.0
Use these values (<Y>/N)? Y
Station of next PVI or pick a point (U,E,D,Help): press Enter

At this point the following dialog appears. Change settings to match, and choose OK.

Pick vertical position for VC text: if prompted pick a point above the top of the grid

Carlson will now finish the road design, and your drawing should like the following:
7 Input-Edit Section Alignment. Now we will layout the alignment for our cross-section file. This step gives the section interval, and the offset left and right from our centerline. Under Sections, go to Input-Edit Section Alignment. Choose the New tab, which brings up the dialog to make a new MXS file (multi-xsection file). Type in a new name and click Open. Notice how all files can have the same name in this road design portion, as they all have a unique file extension. So for the organization of various jobs, it is sometimes helpful to have all of the files with the same name.

Polyline should have been drawn in direction of increasing stations.
CL File/<Select polyline that represents centerline>: pick the centerline polyline
Enter Beginning Station of Alignment <0.00>: press Enter

The dialog will appear as shown, enter in the stations and offsets exactly as they appear here. This will give the needed detail for the road design routine.

Choose OK, and another window appears that allows for any station editing or changes. It all looks good here, so hit Save.
The Alignment file is now written. There is now a preview of the section alignment lines shown on the centerline. These are just images, if the drawing is regenerated, they will disappear (they can be drawn permanently if desired).

8 Sections from Surface Entities. Next, we will create the actual section file (*.SCT) from the contours, in combination with the alignment file (*.MXS). Under Sections > Create Sections from..., go to Sections from Surface Entities. We will use the contours and breaklines for surface elevations, as we did with generating the profile. Specify the MXS file that we just created to read for the alignment. Click Open to select it. Then choose a new file name for the section file, and click Open.

We’ll enter in a distance of 1000 feet to add to our MXS limit of 70. This will search farther for contour elevations, then choose OK. Now, select the surface entities which are the contours and the breaklines. Once you are back to the command prompt, you are done with the making of sections.

9 Design Template. Let's design a wide boulevard, 30' of drivable pavement, with curb and gutter on the outside. Whenever a cut is within rock, the cut slope will employ a 0.5:1 slope rather than the typical 2:1 slope. At the top of rock, the cut will revert to 2:1. In fill, the condition will be 3:1 for fill under 6' and 2:1 for fill over 6' in depth. Pavement depths will be 8" of stone and 4" of asphalt.

First, Select Design Template, found under Roads, within the Civil Design module of Carlson. Click on the New tab.
We'll give it the same name as the drawing. Choose Open. A large dialog box appears as shown below. In it, you enter segments of the template, which work outwards from the middle as you add more lanes, curbs and shoulders. We will enter a symmetrical template, with 13.5' pavement sections either side of centerline, connecting to a 2' curb and gutter, with 18" of gutter and 6" of curb. Then we'll add a 6' shoulder.

For the lanes, click the Grades icon. This leads to a child dialog as shown next:
Fill out as shown. It's important to note that a downhill pavement from a crown in the middle is entered as a negative slope. That is, it is 2% heading from centerline outward, regardless of which side of centerline we are speaking of. Slope is in reference to the centerline of the template, and it is independent of the profile grade point. It is also important to enter an ID whenever requested. ID's can be referenced later.

A break point in a shoulder in superelevation could be defined as occurring at EP+3, as opposed to the exact offset distance from centerline. The advantage of EP+3 is that if the road lane width expands (e.g. for a passing lane), but the shoulder always breaks 3 feet beyond edge of pavement, then EP+3 is the only effective way to reference the break point. Now click OK. You'll note that the lanes show up in the preview window at the top.

Next, we will add a curb. Click the Curb icon. Fill out as shown:

It is especially a good idea to match crown – to make the curb match the slope of the last pavement lane (2% above). But if your curb tilts downward more (like 3%), then use a Special Base Slope Type. If it is flat, by all means click on Flat Base. Now click OK. Here's what our screen looks like so far:
Next, we will add a shoulder, going uphill at 4% for 8'. Notice what is happening. You are lit up on the Curb line, so if you add another Grade, it will append after the curb, and add to the back of the curb. If you were to click on the GRADE: 13.500, -2.000%, EP line, then click on GRADES, you would add a second lane before the curb, which is NOT what you want. Now click on GRADES with CURB: CB highlighted. Fill out the dialog as shown:

That's it for the surface! Here's what our screen looks like now: Note as you select the different items as you create them, the viewer window will highlight the selection.
Now we have subgrade and outslopes still to consider. Let's turn our attention to subgrade. Let's think about this: if our pavement is a total of 12'' deep (4'' asphalt, 8'' stone) and our concrete gutter is 6'' deep, then the stone will run 6'' deep under the gutter. Do we want this stone to come back up at the back of the gutter, behind the gutter, or even wrap around back into the gutter, like a layer of bedding that is covered by dirt? The most complex concept is the wrap around, so let's go for it.

Select the Subgrade icon. We'll do two subgrade surfaces: first asphalt, which will run straight out and hit the curb, and then stone, which will run out, go under the curb, and wrap back.

For any sub-grade, we still do the vertical offset as a negative distance (negative meaning down). But follow this concept: we start it out 13 feet from offset 0, and keep going at "Continue Slope" until it hits something (the curb). This won't work if there is nothing to hit. But it will run into the curb. Or if there is a fill slope, downhill 6:1 recovery zone lane, or something to intersect, it will also. This Continue Slope concept works perfectly for shallow asphalts and concretes that will bump into a curb, when extended.
Complete as shown above, and click OK.

Now for the other subgrade: the stone beneath the asphalt. Follow this: if the stone can't Match Surface (note this option under Slope Type), it will start uphill with the shoulder as it passes beyond the curb (it goes out 17'). So it must have a Special Slope Type, the same 2% all the way. The Wrap Height is the vertical rise at the end of the 17', before it wraps back and hits the curb. Select the Subgrade icon again.

Fill out the Sub-Grade Dimensions dialog as shown above and then click OK. Note the preview screen:
We still need to enter the outslope conditions. They are done with the Cut and Fill icons. Fill is easy in our example. Click on Fill.

Just 3 entries total: 3 (for 3:1), 6 (up to 6'), then 2 (for 2:1 over 6'). Click OK. Next, click the icon for Cut.
This is actually easier (in terms of total entries). Just 2 entries do it: 2 (for 2:1 normal cut) and down below, 0.5 (for 0.5:1 cut when in rock). Click OK.

The template is complete, so click Save, and then Exit the dialogue. Now let's prove we have a good template by doing the command Draw Typical Template.

10 Draw Typical Template. The file extension for templates will be tpl. Select Draw Typical Template under the Roads pulldown menu, select Example2.tpl (or as named above), choose Open and the following dialog shown here is displayed:
We have doubled the text scaler to 0.5 for better appearance in this tutorial. Click on Draw, and pick a starting position point. Here is the look of the plotted template.

Drawing Explorer. As more files are created, edited, loaded and reviewed within a work session, the drawing ini file takes note. You can review your active files as you work, or days later, because they save to the ini file that shares the same name as the drawing file. To see the files associated with this tutorial drawing file, select Drawing Explorer by sliding over from Project, under the File menu.
12 Input-Edit Section File. *Input-Edit Section File* has many uses. One of them is to translate or lower the elevations of a file and re-save. If we lower the elevations of our ground sections 8 feet, we can call that the rock line. Rock lines react with templates and profiles to create rock cuts and rock quantities, within the final step, which is called Process Road Design (Step 13). Select *Input-Edit Section File* under the Sections pulldown menu. Under the Existing tab section, select the SCT file you created earlier and click Open.

The next dialog that appears is shown below:
Click the Translate button. The Translate Selections dialog appears. The Ending Station might differ from what is showing here, but it should be close to this value. Make sure the rest of the dialog looks the same as shown below, and click OK.

Now back at the Input-Edit Section File dialog, click SaveAs, and enter a different name, such as Example2-rock, and save the file. Then click Exit.

Input-Edit Section can do much more through the Edit option. In the case of Edit, you would first highlight one station, then click Edit to review and revise it.

13 Process Road Design. This is the routine that weaves everything together. Select Process Road Design, as the lower command under the Roads pulldown in the Civil Design module. Fill out the dialog as shown below. Be sure to select, under Specify Output Files, the Design Section File option and click New. Enter a new file name and Save. Then click OK.
On the next dialog, be sure to click on Triangulate & Contour at the lower left of the dialog.

Now click OK. Here is a partial view of the final report, with itemized quantities:
Click Exit when finished reviewing the report. You will get this command prompt:

**Trim existing contours inside disturbed area [Yes/<No>]? Y**

**Retain trimmed polyline segments [Yes/<No>]? press Enter**

Here is the resulting graphic, in 3D, obtainable by using 3D View Window found under the View pulldown:

This completes the Lesson 10 tutorial: Basic Road Design with Volumes.

**Lesson 11: Road Rehabilitation**

This lesson designs a road rehabilitation project for two lanes of an Interstate highway. The top surface of the existing road has already been milled and the top of the milled surface has been surveyed. The two lanes are crowned in the
center with a typical cross slope of approximately 1%. The design is to add 8” of concrete with a minimum cross slope of 1.56%.

To begin, let's open the project drawing and verify the proper menu configuration is loaded.

1. Open the drawing named `rehab1_tutorial.dwg` installed in the Carlson Projects folder by default.
2. Make sure the Civil menu configuration is loaded. From the Settings menu, click Carlson Menus → Civil Menu.

Our goal in this section is to create an existing ground surface model named `Exist-rd.tin`. For input, there are survey points for the existing base and polylines for the centerline and edges of pavement.

1. From the Surface menu, click Triangulate & Contour and set the values shown in the dialog box below. Of particular note are the following settings:
   - `Write Triangulation File` is enabled with the file name specified.
   - `Use Inclusion/Exclusion Areas` is disabled.
   - `Shrink-Wrap Perimeter Reduction` is set to `Medium`.
   - `Ignore Zero Elevations` is enabled.
2. Click the OK button on the dialog box and follow the prompts below:

**Select the points and breaklines to Triangulate.**

**Select objects:** Type ALL and press Enter.

**Select objects:** press Enter

**Writing Triangulation File:** C: \ Carlson Projects \ Exist-rd.tin

This concludes the creation of an existing surface model of the milled roadway surface.

Our next task will be to create a horizontal centerline from polyline data found in the drawing. Before we complete this task, we'll want to freeze the **BREAKLINE** layer to expose the polylines on the **PROPOSED PAVEMENT** layer.

1. From the View menu, click Freeze Layer and follow the prompts:

**Pick entities on layers to be frozen.**

**Select entities:** Pick one of the pavement edge polylines and press Enter when complete.

**Freezing layer:** BREAKLINE

2. From the Centerline menu, click Polyline To Centerline File to create a CL file from the center polyline in the drawing.

3. Enter a file name of **rehab.cl**, pick the polyline and enter a beginning station of 73258.51.

Now that the horizontal path of the road has been established, the next step will be to generate cross-section information of existing conditions.

1. From the Sections pull-down menu, choose Input-Edit Section Alignment and supply a section alignment name of **rehab.mxs**.

2. At the centerline prompt, type C (for “CL File”) and select the **rehab.cl** file created earlier.

3. For the Alignment Settings, set the Station Interval to 25 and the Left/Right Offset values to 50.
4. Click the OK button and then click the Save button on the next dialog box showing the list of the section stations.

5. Create the actual cross-section data through the Sections → Create Sections From → Sections from Grid or Triangulation Surface command and select:
   - exist-rd.tin as the source of the surface model
   - "Prompt" as the linking method between the surface model and the output section file.
   - Note: With the prompt option, should the definition of the surface model change, you will be prompted if section data should update as well!
   - rehab.mxs as the section alignment
   - exist-rd.sct as the output section file

This completes the generation of the cross-sectional data of the existing, milled road.

Now that we've generated existing cross-section data, our next task will be to create a design template "overlay" for the road surface we wish to construct:

1. From the Roads menu, click Design Template and create a new template file named rehab.tpl.

2. Click the Grades button and indicate the following desired values for the pavement grade surface:
   - -2% Linear Slope
   - 12 feet for the Horizontal Distance
   - EP for an ID of "edge of pavement"

   Click OK to dismiss the Grade Dimensions dialog box.

3. Click the Subgrade button and indicate the following desired values for the subgrade surface:
   - Straight Up for the Intersect Surface option. This instructs the subgrade surface to intersect vertically to the grade surface above.
   - 0 for the horizontal offset distance. This instructs the subgrade surface to start directly under the centerline of the road.
   - -8 inches for the Vertical Offset. This instructs the subgrade to be 8 inches below the grade surface above and will generate the minimum 8" pavement thickness specified earlier in this lesson.
   - EP for the Distance. This instructs the subgrade width to be the same width as the EP (edge-of-pavement) width specified in the Grade Dimensions.

   Note: By using the parametric/variable ID points (e.g. the "EP" code vs the 12' Horizontal Distance, the subgrade width will vary as needed to accommodate the pavement grade width!)
• Concrete for the Material.

4. Click OK when ready to dismiss the Grade Dimensions dialog box. The proposed road template should resemble the following:

![Design Templates](image)

5. That's all that needs to be defined in the template. Click the Save button and then click Exit.

This completes the proposed definition of the new pavement overlay.

The next step is to design the proposed cross-slopes to follow the existing section grades as much as possible.

1. From the Roads menu, click Template Grade Table and create a new Template Grade Table file named `rehabtgt` and specify the `rehab.tpl` created earlier as the template file to process.
2. Highlight the GRADE surface from the Left Surface list and click the Match Slope button and identify the `exist-rd.sct` file as the Section File to Process.
3. For the Match Slope options, specify:
   - 0 for Reference 1st Offset
   - -12 for Reference 2nd Offset
   **Note:** These values sample the existing sections at the offsets specified to get the existing cross slope.
   - -2.25 for the Lowest Slope %
   - -1.56 for the Highest Slope %
   **Note:** These values restrict the design cross-slopes to be within the range specified.
   - 0.5 for the Max Slope Rate of Change Per 100. This restricts how much the design cross-slope can change between stations. For example, with the maximum set to 0.5 and a cross-slope of -2.0% at station 1+00, the cross-slope at station 2+00 must be between -2.5% and -1.5%.
4. After picking OK on this dialog, highlight the right side grade and pick the Match Slope button.
5. Use the same parameters as the left side except use Reference Offsets of 0 and 12 and then pick OK.

6. From the Template Grade Table dialog box, click Save and then click Exit.

This completes the process of generating a Template Grade Table.

The next step is to define the design profile that minimizes quantities while satisfying the design parameters.

1. From the Roads menu, click the Road Rehabilitation Profile command and specify a new file name rehab.pro.
2. For the Centerline, Design Template, Existing Surface and Template Grade Table, choose the files created in the previous steps as shown below:
3. Click the OK on the file selection dialog to get to the Process Options dialog and specify the following values:
   • Leveling for the Rehabilitation Method
   • 0 inches for the Minimum Leveling Thickness
   • 8 inches for the Overlay Thickness (the same as the Subgrade thickness defined in the Design Template).
   • EP for the Template IDs to Rehab (the same as the pavement edge ID defined in the Design Template).
   • 0.5 for Max Profile Slope Rate of Change Per 100 to restrict the rate of profile grade change.
   Note: This setting is similar to the Max Slope Rate of Change Per 100 in Match Slope for Template Grade Table except this one applies to the profile slope instead of the cross-slope.
   • Leave the rest of the settings as the defaults as shown.

4. Click the OK button to process and generate the desired rehab.pro file.

This completes the process of generating a design profile. Adjustments to the profile can be made through the Profiles → Design Road Profile → Input-Edit Road Profile command.

The road design is now ready to be computed.
1. From the Roads menu, initiate the Process Road Design command.
2. Make sure the Centerline, Profile, Design Template, Existing Surface and Template Grade Table options are each utilizing the files created earlier.
3. Click on the Design Section button to create a new file named Final-rd.sct as illustrated below:

4. Click OK when ready to continue.
5. On the Additional Road Design Parameters dialog box, accept the default values and click OK to initiate the processing of the design.

The program reports the quantities per station and totals in a report similar to that shown below:

```
Process Road Design
Template File> C:\Carlson Projects\rehab.tpl
Profile File> C:\Carlson Projects\rehab.pro
Existing Surface File> C:\Carlson Projects\exist-rd.sct
Centerline File> C:\Carlson Projects\rehab.cl
Template Grade Table File> C:\Carlson Projects\rehab.tgt
Design Section Output File> C:\Carlson Projects\Final-rd.sct

Processing 732+58.510 to 816+42.736
Total Cut : 0.001 C.F., 0.000 C.Y.
Total Fill: 12449.816 C.F., 461.104 C.Y.
Cut to Fill Ratio: 0.00
Total Left Subgrade1 - Concrete: 33533.838 C.F., 1241.994 C.Y., 100603.375 S.F., 11178.153 S.Y.
Total Right Subgrade1 - Concrete: 33533.140 C.F., 1241.968 C.Y., 100601.280 S.F., 11177.920 S.Y.
```

**Note:** Be aware of the following important values:
- The **Total Fill** is the amount of extra leveling.
- The **Subgrade Volumes** are the amount of overlay.

This completes an initial process of the design data.

Our next task will be to visually verify the design by generating cross-section plots.

1. From the Sections menu, click Draw Section File. Set the 1st section file to Exist-rd.sct and the 2nd section file to be Final-rd.sct as illustrated below:
2. On the Draw Section File dialog box, set the following values:
   • 10 for the Horizontal Scale value.
   • 5 for the Vertical Scale value.
   • Click the Scan Files to Set Defaults button to "read" the section files specified earlier and retrieve data from them.
   • Vertical Stack for the Type of Plot.
   • Enable the Label Slopes option and then click the Set button to ensure:
     (a) Label Section 1 is enabled.
     (b) Label Section 2 is enabled.

3. Click the OK button and then screen pick a point in a blank area of the drawing.

This station shows the existing surface with slopes ranging from 1.41% left to 0.57% right and the design with slopes 1.56% left and right. Since 1.56% was the minimum design cross slope, the design is steeper than existing and there is some leveling needed between the design overlay and the existing.

The profile elevation for this station was set by the right edge since this was the highest point. There is some extra
leveling fill needed on the left side. This left side slope can be steeper because our design cross-slope range is 1.56% to 2.25%.

Let's continue with additional steps to refine the design!

From the Roads menu, re-run the Road Rehabilitation Profile command again.

1. Use all the same files for the first dialog.
2. On the second dialog, enable the Adjust Template Grade Table toggle and set the Lowest and Highest Slopes and the Max Cross Slope Rate to the same design parameters used during Template Grade Table as shown below:

   ![Adjust Template Grade Table](image)

3. Click the OK button when ready.

Note: The Adjust Template Grade Table option checks the left and right grades while creating the rehabilitation profile and adjusts the slope on the side that is not controlling the profile grade.

From the Roads menu, issue the Process Road Design command again with all the same settings from the previous run.

Process Road Design

Template File> C:\Carlson Projects\rehab.tpl
Profile File> C:\Carlson Projects\rehab.pro
Existing Surface File> C:\Carlson Projects\exist-rd.sct
Centerline File> C:\Carlson Projects\rehab.cl
Template Grade Table File> C:\Carlson Projects\rehab.tgt
Design Section Output File> C:\Carlson Projects\Final-rd.sct

Processing 732+58.510 to 816+42.736
Total Cut : 21.607 C.F., 0.800 C.Y.
Total Fill: 11152.921 C.F., 413.071 C.Y.
Cut to Fill Ratio: 0.00
Total Left Subgrade1 - Concrete: 33533.761 C.F., 1241.991 C.Y., 100603.375 S.F., 11178.153 S.Y.
Total Right Subgrade1 - Concrete: 33533.107 C.F., 1241.967 C.Y., 100601.280 S.F., 11177.920 S.Y.

For this run, the Template Grade Table has been adjusted. In the report, the overlay quantities are the same and the fill quantity for the extra leveling has been reduced as expected. In this case, the Template Grade Adjustment reduced the Total Fill (extra leveling) amount from 461.104 C.Y. to 413.071 C.Y. (about a 10% reduction in needed
leveling material).

From the Sections menu, click Draw Section File command to redraw the sections data again using all the same settings. The only difference in the final section is that the left side is steeper to better match the existing surface.

This concludes this tutorial lesson on roadway rehabilitation.

**Lesson 12: Hydrology and Watershed Analysis**

This lesson will step through some of the more common Hydrology module routines, and design structures based on the analysis of the watershed. To load the Hydrology module, run Settings->Carlson Menus->Hydrology Menu. The drawing file *HydroLesson.dwg* is a nice example to show the features of the Hydrology Module. A surface *hydrolesson.tin* file is needed for these routines, and is supplied also.

Open *HydroLesson.dwg*. After opening the drawing, take a look around at the various layers, and then go to the *3D View Window* under View, to see the change of elevations in the surface.

There are two main drainage areas that we will be looking at: Drainage 1 and Drainage 2. They are labeled in the below graphic. The other drainage areas in this region will be ignored, as they do not drain to the same area we are looking at, the north central low spot.
There are routines for finding these watersheds based on grid or TIN files, but this drawing has the closed polylines already generated. We will walk through some of the steps to gather the slope and area information.

1. Slope Report. Go to View and use Freeze Layer to freeze all contours, which are on two separate layers. Then freeze the Watershed_Perim layer. We will run the following routine twice, once for each watershed. Go to the Surface pulldown menu in the Hydrology module.

From the Surface menu, choose *Slope Report*. Choose the Slope report by area option, which is the default, and you will be prompted for File or Screen. Choose File, and notice that we have the Hydrolesson.tin file, found in the
Carlson Projects folder, to analyze. Open it.

When prompted for the inclusion line, select the closed perimeter line that runs around Drainage 1. Press Enter for none when prompted for the exclusion line. The report window will appear, and the information can be saved to a file, placed on-screen, or simply reviewed here using the Carlson Standard Report Viewer. In this example, we will review the reports in the viewer. Next, analyze and report on the Drainage 2 watershed, again using Hydrolesson.tin. Shown in the following figures are the reports of the two drainage areas.
Notice that the watersheds are similar in size, and have approximately the same average slope. Thaw the layers that you froze earlier.

2 Run Off Tracking. The command *Run Off Tracking* is found under the Watershed pulldown. It will draw a 3D polyline running downhill in the path that a storm event would. It is useful to fine-tune a watershed boundary. If you pick near the boundary line, you can see which direction the water will flow. Shown is an example of the drawing with the runoff tracking lines falling within their respective watersheds.
3D Polyline Flow Values. This is a step to see what the longest flow line data is within the watersheds. It will create a nice report showing the slopes and vertical drop. The 3D polylines in the drawing were created (with runoff tracking and some editing) to represent the longest flow line. This routine reports out the values of the polylines selected. Go to the Watershed pulldown to 3D Polyline Flow Values. The report can be saved for future reference, but also be aware that when you will need to enter in this data, there is a button on the dialog to simply pick the polylines on-screen.

Drainage 1
4 Rainfall Frequency & Amount. This routine will look up rainfall depths based on what storm type and duration is being analyzed. Under Watershed, go to Rainfall Frequency & Amount. We will do the 25 year, 24 hour storm. Let’s assume the area is somewhere in South Dakota, and so we will use the value of 3.52 inches. For customizing this table to suit your needs, there is the user-defined portion in the lower left corner, if you have specific values you always use; they can be entered here for quick retrieval.

5 Sub-Watersheds by Land Use. This is another way to break up the watersheds, based on land use, or varied surface features. We will break up our watersheds into two types of land use. The steep slopes will be treed, and the top
flats will be vegetated with grasses. Go to Sub-Watersheds by Land Use under the Watershed pulldown. The routine will then ask for the watershed boundary, and the two closed polylines that make up the two different areas. Pick the lines as prompted. The two lines are drawn in layer PILLARS so that the program knows how to identify them.

6 Curve Numbers (CN) & Runoff. This is an easy step to get the runoff and volume of the storm based on the CN and acreage. We will do a weighted curve number representing two land use types. We will run this twice, once for each watershed. Go to Curve Numbers (CN) & Runoff under the Watershed pulldown.

First off, Select Areas, and pick the two closed polylines lines just created inside Drainage 1 (the PILLARS layer). They will have two different CN, based on the type of land. The area is brought in automatically, and the CN will have to be typed in, or looked up on the table. For this example, type the information in according to the charts below. After the CN numbers and the areas are in, hit the Calc Runoff button, and the runoff and volume will appear at the bottom. These can be saved in a report, or simply written down for future reference.
Drainage 1
Drainage 2

Time of Concentration (Tc). This is a quick step necessary for ultimately getting the Peak Flow. Under Watershed, go to Time of Concentration (Tc). We will use the SCS method, and the window will look as follows. The CN number should have been brought in from the last routine, but we will have to Select Flow Line from Screen. This will allow for picking the flow line from the map. This routine will also be executed twice to calculate the TC for both drainage areas.
Now, let's see what the peak flow will be in each drainage, based on the previous seven steps. Run Peak Flow->Graphical Method from the Watershed pull-down menu. The drainage area of the last watershed calculated should appear in the Area window. If not, then simply type it in. The Rainfall depth, frequency, CN, and TC also should be there. All we have to do is hit Calculate, and the peak discharge appears at the bottom.
in CFS (cubic feet per second). This routine should be run twice, once for each drainage. Notice that all of these routines have a Report button to keep a running log of all the calculated data.

Drainage 1
9. Detention Pond Sizing. Now we need to see how large the ponds need to be to detain this size of a storm event. Under Structure, go to Detention Pond Sizing > TR-55 Method.

The Peak Inflow Discharge from the last area calculated will appear, as well as the area. In this example, we will allow for a combined maximum 10 CFS to be discharged from the ponds. This means that 5 cfs from each will be our Desired Peak Outflow. Type that in. Hit Calculate, and the Runoff Volume and the Storage Volume will appear at the bottom of the window. In pond number one, we need to store 6.68 acre feet of water. In pond number two, we will need 9.07 acre feet of storage. So now we have a starting point, and we can now create the pond in 3D with.
these sizes.

Drainage 1
Drainage 2

10 Design Valley Pond. We know approximately where we want the two ponds, and have the dam polylines drawn in the drawing already. They are in the top-of-dam layer. If it is frozen then thaw it out now. We will run Design Valley Pond found under the Structure pulldown menu. For pond number one (corresponding to Drainage 1), the values to enter at each prompt are:
Pick the top of dam polyline: pick it
Select Existing Surface dialog: Open the hydrolesson.tin file
Pick a point within the pond: pick a point upstream from the top of dam polyline
Enter the outslope ratio <2.0>: 2
Enter the interior slope ratio <2.0>: 2
Range of existing elevations along dam top: 1075.88 to 1172.06
Enter the top of dam elevation: 1109
Calculate stage-storage values [Yes/No]? Y
Method to specify storage elevations [Automatic/Interval/Manual]? I
Starting elevation <1088.96>: 1088
Elevation interval <2.0>: press Enter
A Valley Pond Report is produced. Review it noting the stage at which our target storage volume is eclipsed and exit out.
Output grid file of final pond surface [Yes/No]? press Enter
Write stage-storage to file [Yes/No]? Y
This will be a *.CAP file, name it pond1.
Adjust parameters and redesign pond [Yes/No]? N
Trim existing contours inside pond perimeter [Yes/No]? N
Contour the pond [Yes/No]? N

You should now have a pond that looks like the one on the left in the following drawing. Repeat the routine for Pond 2, using a top of dam elevation of 1087, and starting at a low of 1065.
Pond Weir Spillway Design. Now let's see what the spillway will need to be for the storage calculated. We will allow 5 CFS of discharge, so what will be the elevations of the spillway? Under Structure, go to *Rectangular Weir Design*. That will bring up the following window:

![Pond Weir Spillway Design Window](image)

Pond 1
Pond 2

The C-factor we will use is about .3. We will allow up to 5 CFS discharge. This will calculate the depth of the weir (if that is what we use, we'll use a drop pipe in 1, and a channel in 2) with the equation shown at the top of the window. Our required storage volume is 6.68 acre-feet for pond one (9.07 acre-feet for pond two). Hit the Apply to Actual Pond and choose the Pond1.cap file. This should give the two elevations shown in the dialog: 1106.73 for top of pool, and 1104.50 for bottom of spillway. This will be our principle spillway. Our emergency spillway will just be assumed to be 1.5 feet higher.

12 Draw Stage-Storage Curve. Now that we have the spillway elevations and a capacity file (*.CAP) for each pond, let's draw the Stage Storage/Area Curve Graphs to get a graphic of the curves with values to follow. Under Structure, go to Stage-Storage, and then slide over to Draw Stage-Storage Curve. Below the following dialog box are the settings to be entered for Pond 1:
Click OK.

**Pick Starting Position:** *pick a spot* in the open drawing

Do the same for Pond 2, with the other elevations from the spillway and top of dam calculated above, and choose to put this on Page Number 2. Your graphs should look like the two pictured.
Drainage 2

13 Drop Pipe Spillway Design. This will give us a stage discharge file that we will add to our structure in the routine of the storm through our ponds. We will only do this in pond 1. Pond 2 will have a channel, which will create a different stage discharge file. Go to the Structure pulldown to Drop Pipe Spillway Design.

We will design one for the flow we need. Enter in the values shown in the window and hit calculate to get near the 5 CFS discharge we are looking for. Hit File to create the discharge file for pond 1.
14 Channel Design (Manning's n) Non-Erodible. This will generate the other stage discharge file for pond 2. Go to the Structure pulldown to Channel - Non-Erodible. Enter in the parameters shown, and create the second STG file, this one for pond 2. It will calculate the depth and the velocity, base on our dimensions entered.

Click Write Stage-Discharge. You will then provide a file name for the new STG file and save it. It will calculate the depth and the velocity, based on our dimensions entered. Enter a depth of 1.5 and a base elevation of 1081.95 for the bottom.

15 Draw Flow Polylines. Now we will look at creating a skeleton structure of our flow lines with these structures placed on them. We will first produce a hydrograph of the two drainages without the ponds, then add the ponds to
the flow polylines and regenerate the hydrographs. We hope to reduce the discharge to a much smaller amount, but over a longer period of time.

Under Watershed > TR-20 Routing, go to Draw Flow Polylines. This will let us pick a point, from high to low. As seen in the diagram, pick from NW to SE. Enter in the three parameters for Drainage 1.

When asked to draw another, select yes, and join it with the first at the bottom right corner, near the endpoint. This will place the text on them and allow for the next step.

16 Hydrograph Development. This routine will run the TR-20 program and generate a hydrograph file that we can draw on screen. Under Watershed > TR-20 Routing, go to Hydrograph Development and select the two Flow Polylines and the text associated with each one.

The routine will run the TR-20 and give a Standard Report Viewer report. There are now some hydrograph files
17 Draw Hydrograph. Under the Watershed pulldown, go to Draw Hydrograph and select the J1ADD.h1. This is the file of both drainages combined.

The scales to be used should be about 1,1,1,5,5,5 and we will draw the grid on the first one, and turn off grid for additional hydrographs. Choose starting time of 0, and an ending time of 80 (the next one will go that long).

18 Locate Structures. The Locate Structures command, located in the Watershed > TR-20 Routing menu, will place a symbol on our flow lines to representing the ponds and spillways. This will create a small triangle at the end of each flow line where they were picked. You will run this on each flow line individually.
Lesson 13: Stormwater Network Design

In this tutorial, we'll layout the structure and pipes for the stormwater drainage and analyze the flow for a portion of a site. We'll use the tools to automatically calculate the drainage and runoff coefficients. These automated methods require setup of a surface and runoff regions. Alternatively, these tools can be skipped in which case the drainage areas and runoff coefficients for the inlets can be entered manually into the sewer network.

Step 1 - Open Drawing

From the File menu, choose Open and select EXAMPLE3.dwg from the Carlson Work folder (e.g. C:\Carlson Projects\EXAMPLE3.dwg).

Step 2 - Make Surface Model

The drawing entities for the design surface that we will use to model drainage have already been prepared. These entities consist of design contours, elevated pad perimeter polylines, spot elevations and 3D polylines for the road centerlines and face of curbs.

To model the drainage, the program can use either triangulation or grid surfaces. For this example, triangulation is used so that the flow can follow the edges of the road. In general, triangulation is needed for surfaces with breaklines and grids are useful for surfaces defined by contours alone.

Run the Triangulate & Contour command from the Surface menu. In the dialog, go to the Contour tab and turn off Draw Contours. Then in the Triangulate tab, turn on Draw Triangulation Faces, Write Triangulation File, Use Inclusion/Exclusion Areas and Ignore Zero Elevations. Pick the Browse button and set the file name as Example3.tin. Then pick OK.
At the command line, the program will prompt for the inclusion and exclusion perimeters. Pick the perimeter polyline for the inclusion and nothing for exclusion. Next, for the select objects to triangulate, type All and press Enter.

Select the Inclusion perimeter polylines or ENTER for none.
Select objects: pick the perimeter polyline
Select objects: press Enter
Select the Exclusion perimeter polylines or ENTER for none.
Select objects: press Enter
Select the points and breaklines to Triangulate.
Select objects: All
Select objects: press Enter

Step 3 - Check Surface

This step is optional to verify that the surface is good by checking for bad elevation data points and that the surface follows the data points.

With the triangulation drawn as 3D Faces, run the 3D Viewer Window command in the View menu. At the command line, it will prompt to select the objects to view. Type All and press Enter.

Select all entities for the scene.
Select objects: All
Select objects: press Enter
In the 3D Viewer dialog, move the pointer near the center of the graphic and the cursor will change to an X/Y symbol which is the X/Y axis rotation mode. Click down the left mouse button and drag down to rotate the site to a good viewing angle. Then move the pointer near the edge of the graphic and the cursor will change to a Z symbol which is the Z axis rotation mode. Click down the left mouse button and drag around to rotate the pile. To fill in the triangulation faces, pick the Shade icon.

You can also choose the Color By Elevation toggle for better viewing of the elevation range.

The surface looks right in the 3D Viewer. The site has a slope from the top road circle down towards the detention ponds at the bottom. Close the 3D Viewer by choosing the Exit Door button. We don't need the 3D Faces anymore. Let's delete them by running Erase By Layer in the Edit menu. Choose the Select Layers From Screen and pick any 3D Face. Then pick the OK button.

**Step 4 - Runoff Coefficients**
This step sets up layers that are assigned Rational Method runoff coefficients and applied to closed polylines on the specified layers. The runoff coefficients are the C-Factors in the Rational Equation \( Q = C \times I \times A \).

Q is flow, I is rainfall intensity and A is area. The runoff polyline areas use region logic where a polyline inside another on the same layer is used as an exclusion. A limitation is that polylines on the same layer must not intersect each other. For polylines on different layers, there can be polylines within other polylines and for any given point; the smallest enclosing polyline is used to determine the runoff coefficient.

In this example, the site perimeter polyline is on the Regions layer, the building pads are on the Pads layer and the edge of pavement polylines are on the Roads layer. All these polylines are already closed polylines. So we're ready to assign the runoff coefficients to the layers. Run Define Watershed Layers in the Watershed menu. Begin with an empty dialog by deleting any existing layers in the table. Select the Add button.

Let's add the road layer first. Use the Select button next to the Layer field and select the layer name ROADS from the list or screen pick a road polyline. Next choose the Library button and select Streets, Asphaltic from the list. Under the Draw Settings, set the Hatch Color to Magenta. When the dialog is set as shown, pick OK.
Repeat the Add function for the Pads layer and set the runoff to Roofs and the color to Red. Again, repeat add for the Regions layer and set the runoff to Unimproved Areas and the color to Green.

From the main dialog, pick the Hatch All which gives a visual check of the runoff coefficient areas. The areas within the buildings are inside both the Region and Pads polylines and the Pads govern because they are the smaller area. Likewise the road areas are governed by the Roads layer and road interior islands are not counted for Roads because the interior Roads polyline acts as an exclusion perimeter. The rest of the area is set to the Regions layer.

With the three layers defined, click OK from the main dialog.

We don't need to keep the runoff hatches. Let's delete them by running Erase By Layer in the Edit menu. Choose the Select Layers From Screen and pick any hatch to get the RUNOFF_HATCH layer. Then pick the OK button.

**Step 5 - Watershed Analysis**

From the Watershed menu, pick Watershed Analysis and when prompted for the surface file, choose Example3.tin. The program dialog docks on the left side of the drawing.

Before processing the watersheds, set the Rainfall to 1 inch. The program uses the runoff volume calculated from the rainfall depth and drainage areas to figure when the runoff is enough for the flow to go through a low point. If the rainfall depth is set to zero, then the flow lines will stop at every low point or dimple in the surface. At this point, we have not defined our storm event to know the actual rainfall depth. If we did get the storm rainfall depth, we could enter it. For now we're just using Watershed Analysis to give a general idea of the watershed areas and runoff flow lines.

First, go to the Draw tab and turn on Fill Watershed Areas, Sink Locations and Pond Areas.

---

*Chapter 17. Tutorials*
Now pick the Draw Watersheds button. Each watershed area is drawn with a closed polyline and solid filled with different colors. Also, for each watershed the sink (lowest point) is drawn with a solid circle symbol. The areas covered by ponding are drawn as solid blue hatches. The depth and size of the pond areas is determined by the runoff volume. In many places, the pond areas are inside the detention pond structures. In a few places, the ponds are at low points in the road which indicate areas that we need to add storm sewer inlets.

To navigate around the watershed display, move the pointer into the graphic view and use the middle button of the wheel mouse, if you have one, to pan and zoom. If you don't have a wheel mouse, then use the top toolbar icons of the Watershed Analysis dialog to zoom and pan. When you are done inspecting the watersheds, pick the back arrow (shown below) next to the Draw Watershed button to erase all the watershed entities.

Next, choose the Runoff Tracking button under the Tools tab.
In the options dialog, choose Major Flow Tracking that draws flow lines only when the drainage area for the flow line is greater than the specified area. Then choose the 2D Polyline type and the Draw Flow Direction Arrow to use a flow linetype with arrows showing the flow direction.

Use the zoom and pan methods to inspect the runoff flow lines. This graphic shows the flow lines coming off the road circle at the top of the site and following the curbs. We're going to leave the runoff flow lines on the drawing to help guide the placement of inlets. Click Exit to end Watershed Analysis.
**Step 6 - Rainfall**

To setup the storm event to apply with this site, run Rainfall Library under the Sewer Network Libraries flyout in the Network menu. This command keeps a list of different storm events that you can use for different locations and requirements. Let's add a storm by picking the New button. There are six types of rainfall definitions. For this example, select the Rainfall Total (TP-40) method. In the New Rainfall dialog for the TP-40 method, fill in a name for the Rainfall ID, the rainfall amounts for the 2 and 100 year storms for 6 and 24 hours, and the average elevation for the site.

You can use the Map button to show the TP-40 rainfall maps for the different storms. And if you pick on the map display, the program will interpolate the rainfall from the maps. In this case, south central CT was picked.
Click OK on the New Rainfall dialog and then pick OK on the Rainfall Library dialog to save the changes.

Step 7 - Set Centerlines

In preparation to align the inlet symbols with the road centerlines, we need to create centerline files (.cl) for the roads. From the Centerline menu of the Civil Design or Survey modules, choose Polyline To Centerline File. In the file selection dialog, enter a name of North.cl. Then enter a starting station of 0, pick the road centerline for the loop road at the top of the site and press Enter at the end of the station list.

Beginning Station <0+00>: press Enter
Polyline should have been drawn in direction of increasing stations.
Select polyline that represents centerline: pick the north loop road centerline
Press ENTER to continue. press Enter

Repeat Polyline To Centerline File. For the file name, enter Main.cl. Enter a starting station of 0 and pick the main road centerline.
Step 8 - Set Sewer Network Files

The storm sewer network structures and pipes are stored in a .SEW file. Once a .SEW file is set as current, the program will continue to automatically use that file. To start a new sewer network, run Set Sewer File under the Sewer Network Setup flyout of the Network menu. In the file selection dialog, choose the New tab and enter a file name of Example3.sew.

The sewer network also works with a current surface model that is used for the default rim elevations, reporting pipe cover and calculating inlet drainage areas. To set the current surface, run the Set Surface File under the Sewer Network Setup flyout of the Network menu. In the file selection dialog, choose our Example3.tin file.

Step 9 - Create Sewer Network Layout

Before starting the layout, set the object snap (osnap) to nearest (nea) to use for locating the inlets along the curb polylines. Under the Settings menu, run Aperture-Object Snap and turn on only the Nearest snap mode.

Now we're ready to layout the inlets and pipes. Let's work on the drainage for the roads of the north loop and the main road and run this flow to an outlet in the central pond.

Run Create Sewer Structure from the Network menu. The first prompt is to select from three methods to locate the inlets. Press Enter to choose the default method of screen pick. Next the inlet location is picked. Decide where to put the inlet. You can look at the runoff flow lines and place the inlet to capture these flows. When you have a place for the inlet, zoom in very close so that you can see the curb line.

**NOTE:** Be sure to pick the bottom, inside curb polyline and not the top of curb. Otherwise, the routine to find the drainage area from the surface model will not capture flow along the curb.

If you have a wheel-mouse, use the wheel to do the zoom in. Otherwise you can use the zoom toolbar or type 'z at the command prompt. After zooming in, pick a point along the curb polyline using the nearest snap to get right on the polyline. In this case, the first inlet will be on the inside curb of the north loop near the intersection as shown with the M1 symbol.
After this first inlet location is picked, the sewer network dialog is docked on the left side of the drawing. Before designing this inlet, pick the Rainfall Library button (Found under Network > Sewer Network Libraries) and select our Rain3. Next choose the Settings button and, on the Design tab, set the Direction to *Upstream To Downstream*, and uncheck the Minimize Pope Sizes in Design option. The Pipe Settings allow you to configure your design parameters. Select the Pipe tab, and change the Minimum Cover and Velocity to 2.0, Maximum Cover and Velocity to 10.0, and the Drop Across Inverts to 0.1. Now select the Display tab, and set the Display Slope In to %. Next select the Drainage tab and pick the Rainfall Library button and pick the rainfall event set in Step 6. Let's go with defaults for the rest. Pick the OK button.
Now let's work on the structure settings. Pick the Library button next to the Structure ID field. This function brings up a list of the available structures as defined in the library. There are three types of structures: box, circular and outfall. You can add your own structures to the library. For this example, use MH3. To check the dimensions for this structure, pick the Edit button. These dimensions are used for hydraulic calculations as well as drawing the structure in the profile and 3D views. Click OK from the Edit dialog and then highlight MH3 from the library list and pick OK.
Next, pick the Library button next to the Inlet field. This function shows the inlets defined in the inlet library. There are four types of inlets: slotted, curb, grate and curb/grate combo. Inlets can also be defined as located on-grade along the road or at a sag location. Like the structure library, you can add to and edit the inlet library. For this inlet, choose the Combo-Grade from the list and pick OK.

Next, pick the Select button next to the Reference CL label, select by Centerline File, and select North.cl for the centerline. This centerline can be used to align the inlet symbol. In the Symbol Rotate field, choose Parallel To CL Up.

The last change for the structure tab is to set the Depth to 5.5. After making these changes, your dialog should match the settings as shown. Pick the Apply button to save the changes and you should see the plan view symbol for the inlet change to a grate symbol.

Now move onto the Drainage tab. Here the drainage area, time of concentration, runoff coefficient and pavement parameters are set for the inlet. You can manually enter in or have the program calculate these values. With the Pick button, you can select a drainage polyline perimeter and the program will calculate the area and the weighted average runoff coefficient from the runoff layers if defined. In this example, use the Calc button to calculate all
the parameters from the surface model. The first time that Calc is called, the program takes time to calculate the triangulation flows. Then the values are filled in and the drainage area is hatched in plan view. The Time To Inlet comes from the max flow line within the drainage area and accounts for the surface slopes along the path. The Runoff Coefficient is calculated as the weighted average of the runoff sub-areas within the drainage using the runoff layers that we defined in the Define Runoff Layers command. Notice how the drainage area for M1 starts from the road high point and follows the crown of the road to the inlet. In the Pavement Parameters section, the Calc button will calculate the Pavement slopes from the surface aligned by the reference CL at the inlet location.

We're done for now with this first inlet. To add the next inlet, pick the Add button from the Structure Actions row. Pick a position along the right side curb polyline of the main road near the intersection as shown here (M2). Again, you may need to zoom in to be sure to snap onto the curb polyline.
Go to the Structure tab for M2 and change the Reference CL to Main.cl. Then go to the Drainage tab and pick Calc which fills out all the drainage values. Next select the Pipe tab. The program lists all the used and available structures for a pipe connection to the current structure. By default, a connection is made to the nearest structure as long as it's within the maximum pipe length as defined under Settings. In the dialog, set the Down Invert to 370.1. Switch back to the Structure tab and set the Invert-Out as 370.0.

To add the next inlet, pick the Add button. Then pick a position along the inside North loop curb polyline to the left of the intersection as shown here (M3).

A pipe is automatically connected to the nearest structure M1. But for this network, we don't want M3 to connect to M1. Instead, we're going to start new branch with M3. So go to the Pipe tab highlight the Upstream Connection list for M1 and pick the Remove button. On the Structure tab for M3, set the depth to 5.5. On the Drainage tab, pick Calc.

Now we're ready for the next inlet. Pick the Add button in the Structure Actions row and screen pick the position along the main road across from M2 as shown here (M4).
This inlet is on the other side of the road and the symbol is rotated the wrong way. To fix this, go to the Structure tab and change the Symbol Rotate to Parallel To CL Down and pick Apply to update the drawing. Also, change the Invert-Out to 371. Next go to the Drainage tab and pick the Calc button. Again the pipe connection defaulted to the nearest structure of M2. Instead we want the connections to go from M3 to M4 to M2. Under the Pipe tab, highlight the Upstream Connection for M2 and pick Remove. Then highlight the Available structure of M3 and pick Add. For the pipe parameters, change the Down Invert to 371.1. Then go back to the Structure tab and set the Invert-Out to 371.0.

To create the pipe from M4 to M2, pick the Edit button in the Structure Actions row. Then pick on the M2 label or symbol to edit M2. From the Pipe tab, highlight M4 from the Available list and pick Add.

Now let's add the next inlet. Pick the Add button in the Structure Actions row and pick a position further down the main road from M4 as shown here (M5).

Under the Structure tab, change the Depth to 4.5 and set Symbol Rotate to Parallel To CL Down. Under the Drainage
tab, pick Calc. Again we want to remove the default pipe connection since M5 will be the start of a new branch. Go to the Pipe tab, highlight the connection listed and pick Remove.

We have one more inlet to add. Pick the Add button and pick along the curb on the other side of the main road from M5. See M6 in the graphic here.

Under the Structure tab, set the Symbol Rotate to Parallel To CL Up to flip the symbol around. Under the Drainage tab, pick Calc. Under the pipe tab, add a connection to M2.

For the last structure, pick the Add button and pick on the 356 contour in the pond to the right of M6.

In the Structure tab, change the Structure Name to Outfall, set the Structure ID to Outfall-Wall1 and change the Depth to 4.0. In the Pipe tab, set the Down Invert to 352.0.

The initial sewer network layout is done. Pick the Close button and if prompted whether to Save Change, choose Yes.

**Step 10 - Flow Analysis**

The network flow can be analyzed in the Edit Sewer Structure and SpreadSheet Sewer Editor commands. For this example, we'll use Edit Sewer Structure. Either choose this command from the Network menu or double-click on any sewer network label. The same docked dialog from Create Sewer Structure is used. Under the Settings button, and the Drainage tab, choose Period of 50 Year and Duration of 24 Hours. Then pick OK to exit Settings.
Next, pick the Analyze button which runs the selected storm event through the system. If any of our design parameters are exceeded as specified under Settings, the program displays a report. Here's the report for our first Analysis run.

Network Design Warnings
1 Pipe Slope: 11.867 %, Max. pipe slope is 10.000 % From OUTFALL, A to M6, A
2 Pipe Velocity: 1.294 ft/s, Min. velocity is 2.000 ft/s From M2, A to M1, A
3 Pipe Velocity: 1.382 ft/s, Min. velocity is 2.000 ft/s From M4, A to M3, A
4 Pipe Velocity: 0.502 ft/s, Min. velocity is 2.000 ft/s From M6, A to M5, A
5 Pipe Velocity: 13.353 ft/s, Max. velocity is 10.000 ft/s From OUTFALL, A to M6, A

Let's take care of warning #1 for the pipe slope. Choose the Edit button on the Structure Actions row and pick the Outfall label or symbol to edit the Outfall structure. To reduce the pipe slope from M6 to Outfall while keeping the upstream pipe slopes, we will create a step-up at M6. Go to the Pipe tab and change the Up Invert to 356.0. This changes the Invert-Out at M6 while holding the Invert-In at M6.

Pick the Analyze button again. The warning report should only have the flow velocity warnings if any. Exit the report if it comes up. The flow velocity warnings can be resolved by resizing pipes and setting inverts which we will do later. Now let's review the flow results from the dialog.

From the Outfall structure, pick the Up button to move up to M6. From the Drainage tab, the flow results are displayed in the Flow Calculation section. The Flow To Inlet is calculated by the Rational Method using the Drainage Area, Time Of Concentration and Runoff Coefficient for this inlet. The Intercepted Flow, Bypassed Flow, Gutter Spread and Gutter Depth are calculated from the inlet dimensions using formulas from HEC-22. These values can be used to determine whether you have the right inlet structure to capture the flow.

Switch to the Pipe tab. The flow, area and cover are displayed for the pipe connection currently highlighted from the Upstream Connections list. The Total Flow is the accumulated flow for the current pipe. The Total Area reports the accumulated drainage areas for all the inlets coming into this pipe. The Min Cover is calculated using the surface model to the top of the pipe.
Switch to the Hydraulic Calc tab which shows a graphic of the pipe structure, ground surface, hydraulic grade line (HGL) and energy grade line (EGL), along with the HGL and EGL elevations, Flow Depth and Flow Velocity at the pipe upstream and downstream connections.

You can go to other structures to check the flow values for them or use the Report Sewer Network to review the values in a report view. For our storm event, many of the pipes can be resized. For example, the 12" pipe from M5 to M6 has only 3" flow depth. To resize the pipes, you can go to the Pipe tab and change the Pipe Size. The program can also automatically size the pipes based on the flow. To size specific pipes, go to the Pipe tab and pick on the Design toggle next to the Pipe Size field. Then run pick the Design button at the top of the dialog and the program will run a flow analysis and set the pipe size for these pipes marked for Design. To have the program size all the pipes, choose Auto Set All Pipe Sizes in the Settings dialog and then pick the Design button.

For this example, let's have the program assign all the pipe sizes. Pick the Settings button. Turn on Auto Set All Pipe Sizes and Minimize Pipe Size In Design. Then pick OK. The pipes are resized to match the flow. Pick on the Pipe and Hydraulic tabs to see the changes. Pipes that can change would change and the different pipe sizes that the program uses are defined in the Pipe Size Library.

After the pipe sizing, there are likely a few lingering flow velocity warnings. Experiment with the flow velocity by adjusting invert elevations of the affected pipe(s) in your network. Pick the Structure Action button of Edit and pick the structure whose invert elevations need to be modified.

Now run Analyze function which should now complete without any warnings. Pick the Apply button to save the results and then pick Close.

**Step 11 - Plan View Labels**

At this point, the sewer network labels are only showing the inlet name and pipe direction arrow. To change the label format, run Plan View Label Settings in the Sewer Network Setup flyout of the Network menu. In the settings dialog, under the Structure Labels tab, Add the Structure Name, Rim Elevation, Invert-In and Invert-Out labels to the Used Labels category. Under the Pipe Labels tab, turn on Label Pipe Length and Label Pipe Size. For Label
Pipe Size, set the Position as Below Pipe. Also set Pipe Direction Label to Parallel Leader and Draw Link Type to Double/Width.

![Network Label Settings dialog](image)

The sewer labels are linked to the sewer network definition so that any change to the sewer network updates the labels. If you want to explicitly update the sewer labels, run the Draw Sewer Network > Plan View command.

When sewer labels overlap other drawing entities, you can use the Move Sewer Labels command. Let's run this command and move the M4 label to the left of the inlet.

![Sewer network](image)

**Step 12 - Draw Sewer Profile**

To create a profile for the sewer network, run the Draw Sewer Network > Profile command from the Network menu. In the options dialog, set the upstream structure to M1 and the downstream to Outfall. Also turn on Draw Pipe Lateral Connections, Draw Hydraulic Grade Line and Draw Design Surface. When the setting match the dialog shown here, pick OK.
Next, select Example3.tin for the Design Surface File To Read file selection dialog. Then the Draw Sewer Profile program is started. In the Draw Sewer Profile dialog, set the Horizontal Scale and Intervals to 50 and the Vertical Scale and Intervals to 10. Then pick OK.

The next dialog prompts for the elevation range for the profile. The elevations default to fit the profile. So just pick OK.
Now there's a prompt to pick the location to draw the profile. First, zoom out to a clear space in the drawing. Then pick the lower left point for the profile. Some of the pipe labels are longer than the pipe segments, and the program prompts whether to draw the labels. Enter Y for yes.

**Pick Starting Point for Grid <0.00,0.00>: pick the lower left profile grid point**

---

**Step 13 - Draw Sewer in 3D**

Next, let's draw the sewer network in 3D. Run the Draw Sewer Network > 3D Faces command in the Network menu. This command draws the structures and pipes as 3D Faces. At the command line, press Enter to use the default layer for the 3D Faces. That's all the prompts for this command.

**Enter the layer name [SWRNET3D]: press Enter**

To view the 3D Faces, run the 3D Viewer Window command from the View menu. At the select objects prompt, type All and press Enter. Then click and drag the mouse to rotate the view to a good viewing angle as described under the Check Surface step. When done inspecting, exit the viewer by picking the Exit Door button.
Step 14 - Report Sewer Network

Finally, let's check out the reports available under the Report Sewer Network command in the Network menu.

In the Sewer Network Report dialog, you can choose which sewer runs to report and the types of reports to produce. The Report Formatter option allows you to customize which fields to include in the reports and supports outputting the reports to MS Excel and databases. There are specific reports for Inlets, Pipes, Structures and Drainage areas. Let's run the Simple Report to get the summary of our system.

Sewer Network File: C:\Carlson Projects\example3.sew
Ground Surface File: C:\Carlson Projects\Example3.tin
Design Method: Peak Discharge Calculation
Hydro Method: Rational Method
Rainfall ID: Rain3 TP-40
Return Period: 50-Year
Duration: 24-Hour
### Lesson 12: Stormwater Network Design

This lesson covers stormwater network design using Carlson Hydrology. The goal of this functionality within Carlson Hydrology is to automatically extract sub-areas needed by HydroCAD for stormwater modeling. There are 3 main considerations to prepare a dataset for extraction:

1. **Watershed (subcatchment) delineation**, with either
   - Longest flow path and average slope information for Curve Number/Lag method, or
   - Tc with sheet, shallow, and channel flow information defined for TR55 method
2. **Delineation of Hydrologic Soil Group (HSG)** with
   - HSG boundaries defined on one layer and
   - HSG labels on another layer
3. **Ground cover delineation**, with
   - Each type of different ground cover area defined as closed polylines on specific layers, corresponding with entries in the hydrocad.rcl library

---

### Lesson 14: Data Extraction for HydroCAD

This lesson covers extracting watershed data for HydroCAD stormwater modeling using Carlson Hydrology. The goal of this functionality within Carlson Hydrology is to automatically extract sub-areas needed by HydroCAD to do its stormwater modeling. There are 3 main considerations to prepare a dataset for extraction:

1. **Watershed (subcatchment) delineation**, with either
   - Longest flow path and average slope information for Curve Number/Lag method, or
   - Tc with sheet, shallow, and channel flow information defined for TR55 method
2. **Delineation of Hydrologic Soil Group (HSG)** with
   - HSG boundaries defined on one layer and
   - HSG labels on another layer
3. **Ground cover delineation**, with
   - Each type of different ground cover area defined as closed polylines on specific layers, corresponding with entries in the hydrocad.rcl library

---

---

### Chapter 17: Tutorials

---

---

---
Layer Based Process

The entire process described herein is essentially a layer based process, meaning that it is the drawing layers that everything is created on that makes the process work. So before going any further, take a look at the dialog box in which those layers are defined. On the HydroCAD menu, pick Define Watershed layers. In this dialog box, pick the Load button and load the hydrocad.rcl file that is in the Settings folder. After loading, make sure the HydroCAD radio button at the top of the screen is selected.

Any layer names in this dialog box can be changed to whatever you like, but the linework created must use the layers you decide on. A helpful trick is to highlight the layers in the list that you think you will need for the project at hand (using the Ctrl key) and then pick the Create Layers button. The layers will be created for you, thereby eliminating the need to type them all in by hand, and also avoiding typos that will cause the data extraction to fail.

The layers in the drawing must match the names in the list exactly.

Now that the layers are established, you can focus on creating the geometry in the drawing.

Watershed/Subcatchment Delineation

If there is a surface (TIN) for the project site, Carlson Hydrology can greatly aid in the process of delineat-
ing watersheds (subcatchments) and determining the longest flow path for each subcatchment. These tasks are accomplished in Hydrology, under the Watershed menu, or the HydroCAD menu, using the Watershed Analysis command.

Pick the surface for the site. Setting up the watershed panel as shown:

will generate:
Once the watersheds and max flow lines are drawn, you can make decisions on them...are there too many, too few...etc...

Tip: to combine several into one, use Draw - Shrink Wrap...use the Bound method, pick a bunch of watersheds, and a new boundary will be drawn around them.
Ultimately, you should be left with a closed polyline for each watershed, and a single 3D polyline within each watershed representing the longest flow path:
The subcatchments will need to be labeled on the correct layer, but this part of the process is essentially complete. These subcatchment delineations can be done using any process desired...looking at the contours, looking at aerial photos, whatever method is most useful and comfortable is fine. It is the end result of linework that delineates the areas that is needed...the method to get them is inconsequential.

**Soils (Hydrologic Soil Group)**

The same statement holds true for HSG delineation. What you'll need, ultimately, from whatever source(s) you start from, is a drawing with the soil groups drawn as polylines, all on one layer, and the HSG types (A, B, C, or D) labeled within the areas on another single, specific layer. The soil areas must be closed, but do not have to be individual specific closed polylines. The software will run a bpoly on each area to "close" it. The soils information can come from a SHP file from NRCS, from a ground soils survey, from digitized plans...it doesn't matter, the only thing necessary is the linework and labels.

![Soils map](image)

**Ground Covers**

Finally, ground covers. In standard use, this term applies only to the ground cover, which is independent of the underlying soil group(s). Neither layer equates to a specific CN value, which can only be determined after we analyze the intersection of these layers. The actual CN value(s) will be assigned by HydroCAD after this analysis is complete.

Once again, with whatever method you like, create closed polylines on the various ground cover layers.
Putting it all together

Now that you've draw all the watershed and site data, we can start to extract the information we need for hydrologic analysis...

On the HydroCAD menu, pick HydroNet Explorer. In the file dialog, pick the New tab and create a new .HYN file.

In the docked dialog, pick the Settings button at the top, with the tools on it. In the Settings dialog box, on the General tab, set the Surface File to your surface.
On the SubCatchment tab, set the Calculation Method to Curve Number/Lag, and clear the box to Process Curve Numbers, as they will be determined in HydroCAD. Pick OK.

You are ready for the data extraction to be performed, and the results exported to HydroCAD. Pick the Update button (the up arrow). Select all the options.

The subcatchments are listed in the HydroNet Explorer. Doubleclicking on any subcatchment name brings up a dialog with its data. Note the same subcatchments now exist in HydroCAD, ready for any further analysis and/or reporting.
The Edit button next to the Area shows all of the sub-area statistics.

Double-clicking a subcatchment in HydroCAD opens the Hydrograph and Summary report windows.
Project reports can also be generated for Nodes, Areas and Soils.
Any changes made in the drawing can instantly update the data in HydroCAD simply by picking the Update button.

Lesson 15: ESRI to Office to Field and Back

This lesson takes an ESRI geodatabase from ArcView into Carlson Survey and then to Carlson SurvCE for data collection. Next the data is taken from SurvCE into Carlson Survey and then back into ArcView.

Step 1 (ESRI Geodatabase to DWG File):

ArcGIS Desktop has a routine to output a geodatabase to a DWG file. The DWG file contains all the information in a single file. It has the graphic geometry, feature definitions and feature attribute data. The feature information is stored in a format defined by ESRI called Mapping Specification for DWG (MSD) using standard DWG entities and dictionary entries. In this tutorial, we're going to use ArcView 9.3 to create the DWG with MSD.

From the ArcToolbox, choose Conversion Tools->To CAD->Export To CAD. If you need to bring up the ArcToolbox, go to the ArcView->Window pull-down menu and pick ArcToolbox.

Next, select the features to export in the Export To CAD dialog. To select a feature, pick the down arrow on the
Input Features first row and pick the feature name from the list. After selecting the features, choose the output file format for either DWG or DXF file and the version. For example, choose DWG_2007. Finally, enter the DWG file name to create and pick OK.

Step 2 (Open Project in Carlson Survey):

Use File->Open in Carlson Survey to open the drawing created by ESRI.

Next, run GIS->GIS Database Settings. The GIS Features File defines the feature names along with their drawing properties and attribute names. Choose the GIS File format and set the file name. For the Output Data Format, choose ESRI MSD.
To verify that the GIS attribute data is in the drawing, run GIS->Input-Edit GIS Data and pick on an entity in the drawing. The attribute data is shown in a spreadsheet editor. This example shows the Roads feature data assigned to a polyline.

![GIS Smart Prompting - Entity has ESRI Map Specs for Drawings (MSD) Data](image)

**Step 3 (Export Project to SurvCE):**

From the GIS Data menu, choose Export GIS Data to SurvCE. This command takes selected data from the drawing and creates the GIS files that SurvCE uses.
For input files:
Coordinate File: Contains the point database with point#, x, y, z and description.
Field-to-Finish Table: Defines the coding for the description field that will be converted into a Feature Code List for SurvCE.
GIS Feature: Defines the feature and attribute names. Using this file is optional and applies in case that the feature definitions contain more features or attributes than the data entities.

For output files:
Feature Code File: This is the SurvCE format file for the description field coding definitions.
GIS Feature: This defines the feature and attribute names. This file is automatically named after the Feature Code File.
GIS Data: This file contains the attribute data. This file is automatically named after the Coordinate File.
Add Missing Points to Coordinate File: This option creates points in the Coordinate File for any selected point entities that aren’t already in the Coordinate File.

After specifying the files, pick OK and the program prompts for the entities from the drawing to export. You can select the entire drawing by entering “all”, or select a subset of the drawing entities. The program will read the GIS data from the selected entities to create the GIS data file (.vtt) for SurvCE.

Now that the project data is converted to SurvCE format, upload the coordinate file, feature code list, GIS feature, GIS data and drawing onto the SurvCE data collector. If you have SurvCE 2.5 or later, then you can use the DWG file format for the drawing. For earlier versions, use the DXF format. Depending on your collector and connections, you can do the upload with either Carlson Survey->Data Collectors->SurvCE, or Windows ActiveSync, or transfer on a data card. For this example, we have spatial.crd, spatial.fcl, spatial.gis, spatial.vtt and spatial.dwg to upload.

**Step 4 (Data Collection in SurvCE):**

First download the data files from the SurvCE data collector to the computer. Get the coordinate file (.crd), GIS data file (.vtt) and drawing files (.dwg or .dxf).

**Step 5 (Download Project from SurvCE):**

This step converts the SurvCE GIS data (.vtt) into the ESRI MSD format for the drawing.

First download the data files from the SurvCE data collector to the computer. Get the coordinate file (.crd), GIS data file (.vtt) and drawing files (.dwg or .dxf). Then open the drawing file and use Points->Set Coordinate
File to set the coordinate file from SurvCE as current.

From the GIS Data menu, choose Import GIS Data from SurvCE. The routine prompts for the GIS Feature Definition file (.gis) to process along with the SurvCE data to combine the feature definitions.

**Step 6 (Load Project into ESRI Geodatabase):**

Save the drawing file in Carlson and then run ArcView. Pick the Add Data button in the Standard toolbar and select the drawing.

![Image of ArcView interface](image)

**Lesson 16: Takeoff Tutorial: CAD File Takeoff From Start To Finish**

Note: Completing these tutorials will alter the drawing files (takeoffdemo1.dwg, takeoffdemo2.dwg, takeoffdemo3.dwg). To run through the tutorials a second time, copy over the original drawing files (.dwg) provided on the CD under "Tutorials". In addition, all demo .flt, .tin, .trg, .ini, .cl, .pro, .lot, .tpl, .bak, .sew, and .tch files need to be deleted from the folder under C:\Carlson Projects. If you have your own drawing files, be sure to only delete files named takeoffdemo1, or takeoffdemo2, and not a file attached to one of your own drawing.

This lesson takes a drawing file from drawing cleanup to volume calculations and surface viewing.

**Step 1 (Start Takeoff):**

Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a "Startup Wizard" dialog and if so, click Exit.
Step 2 (Open Drawing):

From the File menu, choose Open and select takeoffdemo1.dwg from the Carlson Projects folder.

Now we can begin to process this drawing. The main TakeOff commands are listed in processing sequence in the TakeOff pull-down menu. Many of these commands are also grouped as icons in the toolbar shown here.

Step 3 (Drawing Cleanup):
From the File menu, choose Drawing Cleanup. Typically, drawings have lots of drafting fixes that must be done before the surfaces can be modeled. This command will apply the selected cleanup functions on the drawing to help automate the cleanup. Here's a brief description of the most important of these functions:

**Remove Layers With No Entities:** Drawings often have lots of layers. This routine removes layers that have no entities in the drawing so that we don't have to deal with them.

**Join Linework With Same Endpoints:** This routine will take linework that is broken into multiple segments and join them into a single linework entity. For example, it will join together broken segments of a contour polyline into a single polyline.

**Reduce Polyline Vertices:** This routine removes extra vertices from polylines as long as the removing does not shift the polyline more than the specified Offset Cutoff. This will reduce the size and complexity of the drawing.

**Set Elevation Outside Range To Zero:** In case the drawing contains entities that are outside the range of valid elevations for the site, this routine will set them to zero elevation. The program treats zero elevations as "no elevation' and modeling will filter out these zero elevation entities.

For this site, the elevations are around 800. So let's set the Min elevation to 500 and the Max elevation to 1000. The cleanup will set any entities outside this elevation range to zero. With other TakeOff functions, we can later assign proper elevations to any of these zero elevation entities that need to be used in modeling.

Once the Drawing Cleanup options are set as shown, pick OK. When the cleanup is done, the program will show a report of the cleanup results. Pick the Exit button to exit the report viewer.
Step 4 (Layer Surface):

From the TakeOff menu, choose Define Layer Surface/Material/Subgrade. Every entity (line, polyline, point, etc) in the drawing is assigned a layer name. TakeOff uses the entity layer names to define which entities are for the existing ground surface, the design surface or no surface. These surfaces are referred to as the "Target" surfaces. The drawing entities are assigned their target surface by their layer name. For example, if polylines representing design contours are on the layer "Final", then "Final" will be set as a layer for the design surface. For layers of entities that are for neither existing nor design surfaces (such as text labels for street names), the layer target is set to Other.

The Define Layer Surface dialog has three lists of layers: Existing, Design and Other. To switch between lists, pick the tabs at the top of the dialog.

In this drawing, all the contours are for the existing ground surface. In the layer list, all the layers that start with INDEX and INTER are for these contours. So highlight these layers and then choose Move To Existing. To highlight multiple layers at a time, hold down the keyboard Ctrl key while picking with the mouse.
Next move the layer names that start with "PR" (for proposed) to the Design surface by highlighting these layers and choosing Move To Design. Also move the layer "PAD" to design.

Next pick the Save button to save our changes and then pick Exit.

There are more tools for assigning layer surfaces. In the Display menu, you can turn on/off whether to display layer targets by using Existing Drawing, Design Drawing and Other Drawing. Practice turning on/off the Existing, Design and Other Drawing in the Display menu. When only Existing Drawing is on, you should see just the contours. When only Design Drawing is on, you should see just the design polylines and leader labels. When only Other Drawing is on, you should see the entities that are assigned to neither existing nor design.

Some of these layers we do want to assign to existing and design. To better see the entities, zoom in on them using the View->Window command and pick two points that make a window around the entities as shown. Once zoomed in, you can see a text label of "818.70 PAD" which is for the design surface. Labels "817.00", "818.00" and "819.00" are contour labels for the existing contours. There are a few commands in the Inquiry menu to find out the layer names for these entities: List, Layer ID and Drawing Inspector. Let's run the Layer ID command and pick the "818.70 PAD" label. At the Command line, it reports this layer is "—-TX07". Next pick the "818.00" label and it reports this layer is "TEXTS". Now that we know these layer names, we can return the drawing view back by running View->Zoom->Previous and going to the Display menu and checking on Existing Drawing and Design Drawing.
Next run Define Layer/Material/Subgrade and pick the Other tab. Highlight "—TX07" and pick Move To Design. Then highlight "TEXTS" and pick Move To Existing.
Check that your Layer Surfaces match the three lists shown here. Then pick Save and Exit.

**Step 5 (Define Material/SubGrade):**

Besides assigning target surfaces by layer, layers are also used to define material names and subgrades depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface. The polylines used for subgrade depth must
be closed polylines. TakeOff supports nested subgrade polylines for exclusion areas such as islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the area is not part of the subgrade.

First, we need to know the layer names for our subgrades. Go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Then run Inquiry->Layer ID and pick the large pad polyline. It reports that this layer is PAD. Next use Layer ID to pick the curb polyline. It reports that this layer is PR-FC-CURB.

Next we need to make sure that these polylines are closed. In this example, the outside curb polyline is open at the top. To close the polylines, run Edit->Polyline Utilities->Edit Polyline->Close Polylines. Then pick each of the pad and curb polylines and press Enter when done selecting. Here are the Command line prompts:

Select Polylines to set closed.
Select objects: 5 found, 5 total
Select objects: (Press Enter)
5 polylines already closed.
Closed 1 polylines.

Now run Define Layer Target/Material/Subgrade and pick the Design tab. Highlight layer PAD and pick the Edit button. A dialog appears for defining the pad material properties. Check on the Include In Material Report option, enter the Material Name as "Pad", set the first subgrade name to "Pad", and set the Depth as 1. Once the dialog is filled out as shown, pick OK.

Next pick layer PR-FC-CURB and choose Edit. In the Edit Materials dialog, check on Include In Material Report, set the Material Name to "Pavement", set the first subgrade name to "Pavement", and set the Depth to 1.5. Then pick OK.

To save the subgrade changes, pick the Save button on the Define Layer Surfaces dialog. Then choose Exit.
Now let's visually verify the subgrade areas. In the TakeOff menu, run Subgrade Areas->Hatch Subgrade Areas. There is a dialog to select which subgrade to hatch. Choose the Pavement. Then there is a dialog for the hatch pattern and color. Click OK. Then run Hatch Subgrade Areas again. This time choose Pad and set the hatch pattern to Hex with green color. The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. Also note that the smaller pad area is not hatched because this polyline layer is different than the bigger pad polyline. When finished viewing the subgrade areas, run TakeOff->Subgrade Areas->Erase Subgrade Hatches.

Step 6 (Elevate Drawing - 2D to 3D):

TakeOff will model the existing ground and design surfaces based on points, lines and polylines with elevation. It is essential for these drawing entities to have correct elevations in order to get correct surface models. Often the provided drawings will have the drawing entities at elevation of zero with text labels indicating the true elevation. TakeOff has many tools for assigning elevations to these entities.

To help visualize which entities need to be assigned elevation, TakeOff will color entities at zero elevation in grey. As entities get assigned elevation, they return to their original color. This elevation coloring is applied to layers that have been assigned to the existing or design surfaces.

Let's start by working on the existing surface. To isolate the existing entities, go to the Display menu and check on Existing Drawing, uncheck Design Drawing and uncheck Other Drawing. In the Inquiry menu, there are commands for checking elevations. To check the elevation of the contour polylines, run the Inquiry->List Elevation and pick a contour polyline At the command line, it reports the elevation.

Select Entity: pick pad polyline
Elevation: 816.0000
Select Entity (Enter to end): press Enter

In this example, the existing ground surface is defined by just contour polylines and these polylines already have elevation. So there are no changes needed for preparing the existing surface entities. If the contour polylines were at zero elevation, then you could use the Elevate->Assign Contour Elevation commands.
Next let's prepare the design surface. To isolate the design entities, go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Notice that all the design linework is greyed because it is at zero elevation. Run the List Elevation command and pick the main pad polyline. At the command line, it confirms that the elevation is 0.

To set the pad polyline elevation, run Elevate->Set Polyline To Elevation. Enter an elevation of 818.7 (based on the text label). At the Select objects prompt, pick the bigger pad polyline and press Enter.

New Elevation <0.0000>: 818.7
Select Lines, Arcs, Circles or Polylines for elevation change.
Select objects: (pick the pad polyline) 1 found
Select objects: press Enter
LWPOLYLINE
Number of entities changed> 1

Next let's set the elevation of the smaller pad under the main pad. First, use View->Window to zoom in around the smaller pad so that we can read the text label. The label of "17.56" is short for 817.56. In this example, the 800 was dropped from many of the elevation labels to save on label clutter. Run Set Polyline To Elevation again. This time enter an elevation of 817.56 and pick the smaller pad polyline. Then run View->Zoom->Previous to get back to the full view of the site.

Finally, we need to set the elevations for the curb polylines. First, use View->Window to zoom in around some of the curb labels below the smaller pad. Then run Elevate->2D to 3D Polyline->Text With Leader. This command will assign the elevations from the labels to the polylines by following the label leader to find the position on the polyline. For polyline vertices without elevation labels, the elevations will be interpolated from the other labels. Before processing, this routine prompts for samples of the elevation label, the leader and the polylines to convert. Then you can select all the entities in the drawing and the routine will sort the labels, leaders and polyline by the sample layers and assign the elevations.
For this example, pick one of the labels with a "TC" suffix as the elevation text sample. Then pick the leader line for the annotation leader sample. Then pick the curb polyline for the polyline to convert sample. At the Select objects prompt for processing, type "all" to select all the drawing entities and press Enter. For the elevation to add, enter 800 so that labels like "17.81" get assigned as 817.81.

Next a dialog appears for selecting which labels names to use. When Takeoff detects different text labels within the elevation labels, you need to choose which ones to process. In this case, we only want the labels with "TC". So highlight TC, pick Add and then pick OK.
Step 7 (Boundary Polyline):

The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. In this example, there is a closed polyline on the PERIMETER layer. The layer target for this layer is Other. Go to the Display menu and check on Other Drawing so that the perimeter is displayed. Then run TakeOff->Boundary Polyline->Set Boundary Polyline and pick the perimeter polyline. This selected polyline is now set as the boundary polyline for the rest of the TakeOff routines.
Step 8 (Model Existing and Design Surfaces):

To calculate volumes, TakeOff needs two surfaces: existing ground and design. These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to make the models. The drawing entities have been cleaned up, assigned elevations and assigned target surfaces by layer. Making the models is now a one step process. To make the existing ground surface, run TakeOff->Make Existing Ground Surface. The program will process the entities and make the triangulation surface. Then to make the design surface, run TakeOff->Make Design Surface.

Step 9 (3D Drive Simulation):

As a visual check that the design surface modeled correctly, let's run the Tools->3D Drive Simulation command. This routine shows a 3D view of the site and allows you to drive around. This is a good way to check that the surface modeled correctly. We want to make sure that there are no elevation spikes and that the subgrade depths are modeled. To drive the site, choose a View Direction, View Position and Vehicle. Then pick the Run button and use the arrow keys to turn. Pick the Stop button to pause the moving. You can also try the Surface Shading options for different views of the surface. When done with the 3D Drive Simulation, pick the Exit button (Arrow with door image).

Step 10 (Cut/Fill Color Map):

Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as another check that the models are correct. In the Display menu, choose Cut/Fill Color Map. Cut areas are drawn in different shades of red for different depths of cut while fill areas are drawn in blue. To change the resolution of the color blocks, run Display->Display Options and change the Cut/Fill Color Map Subdivisions. This parameter is the number of rows and columns of color blocks to create. To turn off the color map, go to the Display menu and pick Cut/Fill Color Map to uncheck it.
Step 11 (Calculate Volumes):

To calculate volumes, run the TakeOff->Calculate Total Volumes command. There is an options dialog for setting the cut swell factor and fill shrink factor. These values get multiplied into the cut/fill volumes. Set these factors as desired and click OK. Then the routine calculates the volumes and display the report which includes the cut/fill volumes and areas. The report can be printed or saved to a file. Pick the Exit button to exit the report viewer.
Step 12 (Material Quantities):

To report the quantities, run the TakeOff->Material Quantities->Standard Report routine. There is the option to only report selected entities as well as the ability to report material quantities that may extend beyond the boundary polyline.

The report includes the count, length, area and volume for each type of material that was assigned for reporting in the Define Layer Target/Material/Subgrade command. The Material Quantities->Custom Report routine can be used to reporting these values with control of the report format and the option to export to Excel.
Note: Completing these tutorials will alter the drawing files (takeoffdemo1.dwg, takeoffdemo2.dwg, takeoffdemo3.dwg). To run through the tutorials a second time, copy over the original drawing files (.dwg) provided on the CD under "Tutorials". In addition, all demo .flt, .tin, .trg, .ini, .cl, .pro, .lot, .tpl, .bak, .sew, and .tch files need to be deleted from the folder under C:\Carlson Projects. If you have your own drawing files, be sure to only delete files named takeoffdemo1, or takeoffdemo2, and not a file attached to one of your own drawing.

This lesson takes a drawing file from drawing cleanup to volume calculations and surface viewing.

**Step 1 (Start Takeoff):**

Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a "Startup Wizard" dialog and if so, click Exit.

**Step 2 (Open Drawing):**

From the File menu, choose Open and select takeoffdemo1.dwg from the Carlson Projects folder.

Now we can begin to process this drawing. The main TakeOff commands are listed in processing sequence in the TakeOff pull-down menu. Many of these commands are also grouped as icons in the toolbar shown here.
Step 3 (Drawing Cleanup):

From the File menu, choose Drawing Cleanup. Typically, drawings have lots of drafting fixes that must be done before the surfaces can be modeled. This command will apply the selected cleanup functions on the drawing to help automate the cleanup. Here's a brief description of the most important of these functions:

**Remove Layers With No Entities:** Drawings often have lots of layers. This routine removes layers that have no entities in the drawing so that we don't have to deal with them.

**Join Linework With Same Endpoints:** This routine will take linework that is broken into multiple segments and join them into a single linework entity. For example, it will join together broken segments of a contour polyline into a single polyline.

**Reduce Polyline Vertices:** This routine removes extra vertices from polylines as long as the removing does not shift the polyline more than the specified Offset Cutoff. This will reduce the size and complexity of the drawing.

**Set Elevation Outside Range To Zero:** In case the drawing contains entities that are outside the range of valid elevations for the site, this routine will set them to zero elevation. The program treats zero elevations as "no elevation" and modeling will filter out these zero elevation entities.

For this site, the elevations are around 800. So let's set the Min elevation to 500 and the Max elevation to 1000. The cleanup will set any entities outside this elevation range to zero. With other TakeOff functions, we can later assign proper elevations to any of these zero elevation entities that need to be used in modeling.
Once the Drawing Cleanup options are set as shown, pick OK. When the cleanup is done, the program will show a report of the cleanup results. Pick the Exit button to exit the report viewer.

Step 4 (Layer Surface):

From the TakeOff menu, choose Define Layer Surface/Material/Subgrade. Every entity (line, polyline, point, etc) in the drawing is assigned a layer name. TakeOff uses the entity layer names to define which entities are for the existing ground surface, the design surface or no surface. These surfaces are referred to as the "Target" surfaces. The drawing entities are assigned their target surface by their layer name. For example, if polylines representing design contours are on the layer "Final", then "Final" will be set as a layer for the design surface. For layers of entities that are for neither existing nor design surfaces (such as text labels for street names), the layer target is set to Other.

The Define Layer Surface dialog has three lists of layers: Existing, Design and Other. To switch between lists, pick the tabs at the top of the dialog.

In this drawing, all the contours are for the existing ground surface. In the layer list, all the layers that start with
INDEX and INTER are for these contours. So highlight these layers and then choose Move To Existing. To highlight multiple layers at a time, hold down the keyboard Ctrl key while picking with the mouse.

Next move the layer names that start with "PR" (for proposed) to the Design surface by highlighting these layers and choosing Move To Design. Also move the layer "PAD" to design.

Next pick the Save button to save our changes and then pick Exit.

There are more tools for assigning layer surfaces. In the Display menu, you can turn on/off whether to display layer targets by using Existing Drawing, Design Drawing and Other Drawing. For example, when Design Drawing is checked, then picking this menu item will uncheck it and turn off all the layers for the design surface. Likewise, picking Design Drawing when it is unchecked will make it checked and turn on the design surface layers.

Practice turning on/off the Existing, Design and Other Drawing in the Display menu. When only Existing Drawing is on, you should see just the contours. When only Design Drawing is on, you should see just the design polylines and leader labels. When only Other Drawing is on, you should see the entities that are assigned to neither existing nor design.
Some of these layers we do want to assign to existing and design. To better see the entities, zoom in on them using the View->Window command and pick two points that make a window around the entities as shown. Once zoomed in, you can see a text label of "818.70 PAD" which is for the design surface. Labels "817.00", "818.00" and "819.00" are contour labels for the existing contours. There are a few commands in the Inquiry menu to find out the layer names for these entities: List, Layer ID and Drawing Inspector. Let's run the Layer ID command and pick the "818.70 PAD" label. At the Command line, it reports this layer is "TX07". Next pick the "818.00" label and it reports this layer is "TEXTS". Now that we know these layer names, we can return the drawing view back by running View->Zoom->Previous and going to the Display menu and checking on Existing Drawing and Design Drawing.

Next run Define Layer/Material/Subgrade and pick the Other tab. Highlight "TX07" and pick Move To Design. Then highlight "TEXTS" and pick Move To Existing.

Check that your Layer Surfaces match the three lists shown here. Then pick Save and Exit.

**Step 5 (Define Material/SubGrade):**

Besides assigning target surfaces by layer, layers are also used to define material names and subgrades depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface. The polylines used for subgrade depth must be closed polylines. TakeOff supports nested subgrade polylines for exclusion areas such as islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the area is not part of the subgrade.

First, we need to know the layer names for our subgrades. Go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Then run Inquiry->Layer ID and pick the large pad polyline. It reports that this layer is PAD. Next use Layer ID to pick the curb polyline. It reports that this layer is PR-FC-CURB.

Next we need to make sure that these polylines are closed. In this example, the outside curb polyline is open at the top. To close the polylines, run Edit->Polyline Utilities->Edit Polyline->Close Polylines. Then pick each of the pad and curb polylines and press Enter when done selecting. Here are the Command line prompts:

Select Polylines to set closed.
Select objects: 5 found, 5 total
Select objects: (Press Enter)
5 polylines already closed.
Closed 1 polylines.

Now run Define Layer Target/Material/Subgrade and pick the Design tab. Highlight layer PAD and pick the Edit button. A dialog appears for defining the pad material properties. Check on the Include In Material Report option, enter the Material Name as "Pad", set the first subgrade name to "Pad", and set the Depth as 1. Once the dialog is filled out as shown, pick OK.
Next pick layer PR-FC-CURB and choose Edit. In the Edit Materials dialog, check on Include In Material Report, set the Material Name to "Pavement", set the first subgrade name to "Pavement", and set the Depth to 1.5. Then pick OK.

To save the subgrade changes, pick the Save button on the Define Layer Surfaces dialog. Then choose Exit.

Now let's visually verify the subgrade areas. In the TakeOff menu, run Subgrade Areas->Hatch Subgrade Areas. There is a dialog to select which subgrade to hatch. Choose the Pavement. Then there is a dialog for the hatch pattern and color. Click OK. Then run Hatch Subgrade Areas again. This time choose Pad and set the hatch pattern to Hex with green color. The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. Also note that the smaller pad area is not hatched because this polyline layer is different than the bigger pad polyline. When finished viewing the subgrade areas, run TakeOff->Subgrade Areas->Erase Subgrade Hatches.
Step 6 (Elevate Drawing - 2D to 3D):

TakeOff will model the existing ground and design surfaces based on points, lines and polylines with elevation. It is essential for these drawing entities to have correct elevations in order to get correct surface models. Often the provided drawings will have the drawing entities at elevation of zero with text labels indicating the true elevation. TakeOff has many tools for assigning elevations to these entities.

To help visualize which entities need to be assigned elevation, TakeOff will color entities at zero elevation in gray. As entities get assigned elevation, they return to their original color. This elevation coloring is applied to layers that have been assigned to the existing or design surfaces.

Let's start by working on the existing surface. To isolate the existing entities, go to the Display menu and check on Existing Drawing, uncheck Design Drawing and uncheck Other Drawing. In the Inquiry menu, there are commands for checking elevations. To check the elevation of the contour polylines, run the Inquiry->List Elevation and pick a contour polyline At the command line, it reports the elevation.

Select Entity: pick pad polyline
Elevation: 816.0000
Select Entity (Enter to end): press Enter

In this example, the existing ground surface is defined by just contour polylines and these polylines already have elevation. So there are no changes needed for preparing the existing surface entities. If the contour polylines were at zero elevation, then you could use the Elevate->Assign Contour Elevation commands.

Next let's prepare the design surface. To isolate the design entities, go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Notice that all the design linework is grayed because it is at zero elevation. Run the List Elevation command and pick the main pad polyline. At the command line, it confirms that the elevation is 0.

To set the pad polyline elevation, run Elevate->Set Polyline To Elevation. Enter an elevation of 818.7 (based on the text label). At the Select objects prompt, pick the bigger pad polyline and press Enter.

New Elevation <0.0000>: 818.7
Select Lines, Arcs, Circles or Polylines for elevation change.

Select objects: (pick the pad polyline) 1 found
Select objects: press Enter
LWPOLYLINE
Number of entities changed> 1

Next let's set the elevation of the smaller pad under the main pad. First, use View->Window to zoom in around the smaller pad so that we can read the text label. The label of "17.56" is short for 817.56. In this example, the 800 was dropped from many of the elevation labels to save on label clutter. Run Set Polyline To Elevation again. This time enter an elevation of 817.56 and pick the smaller pad polyline. Then run View->Zoom->Previous to get back to the full view of the site.

Finally, we need to set the elevations for the curb polylines. First, use View->Window to zoom in around some of the curb labels below the smaller pad. Then run Elevate->2D to 3D Polyline->Text With Leader. This command will assign the elevations from the labels to the polylines by following the label leader to find the position on the polyline. For polyline vertices without elevation labels, the elevations will be interpolated from the other labels. Before processing, this routine prompts for samples of the elevation label, the leader and the polylines to convert. Then you can select all the entities in the drawing and the routine will sort the labels, leaders and polyline by the sample layers and assign the elevations.
For this example, pick one of the labels with a "TC" suffix as the elevation text sample. Then pick the leader line for the annotation leader sample. Then pick the curb polyline for the polyline to convert sample. At the Select objects prompt for processing, type "all" to select all the drawing entities and press Enter. For the elevation to add, enter 800 so that labels like "17.81" get assigned as 817.81.

Next a dialog appears for selecting which labels names to use. When Takeoff detects different text labels within the elevation labels, you need to choose which ones to process. In this case, we only want the labels with "TC". So highlight TC, pick Add and then pick OK.
Select sample of elevation text: pick label
Select sample of an annotation leader: pick leader line
Select sample of a polyline to convert: pick curb polyline
Select polylines to convert, leaders and elevation labels to process.
Select objects: all
Select objects: press Enter
Joining adjacent polylines...
Reading the selection set ...
Enter elevation to add to label values <0.00>: 800
Pre-processing entity #420 of 420
Processing leader #141
Remaking polyline #4
All the curb polylines now have elevations.
Now run View->Zoom->Previous to return to the full site view. The design polylines should now have colors because the elevations are assigned.

**Step 7 (Boundary Polyline):**

The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. In this example, there is a closed polyline on the PERIMETER layer. The layer target for this layer is Other. Go to the Display menu and check on Other Drawing so that the perimeter is displayed. Then run TakeOff->Boundary Polyline->Set Boundary Polyline and pick the perimeter polyline. This selected polyline is now set as the boundary polyline for the rest of the TakeOff routines.
Step 8 (Model Existing and Design Surfaces):

To calculate volumes, TakeOff needs two surfaces: existing ground and design. These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to make the models. The drawing entities have been cleaned up, assigned elevations and assigned target surfaces by layer. Making the models is now a one step process. To make the existing ground surface, run TakeOff->Make Existing Ground Surface. The program will process the entities and make the triangulation surface. Then to make the design surface, run TakeOff->Make Design Surface.

Step 9 (3D Drive Simulation):

As a visual check that the design surface modeled correctly, let's run the Tools->3D Drive Simulation command. This routine shows a 3D view of the site and allows you to drive around. This is a good way to check that the surface modeled correctly. We want to make sure that there are no elevation spikes and that the subgrade depths are modeled. To drive the site, choose a View Direction, View Position and Vehicle. Then pick the Run button and use the arrow keys to turn. Pick the Stop button to pause the moving. You can also try the Surface Shading options for different views of the surface. When done with the 3D Drive Simulation, pick the Exit button (Arrow with door image).

Step 10 (Cut/Fill Color Map):

Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as another check that the models are correct. In the Display menu, choose Cut/Fill Color Map. Cut areas are drawn in different shades of red for different depths of cut while fill areas are drawn in blue. To change the resolution of the color blocks, run Display->Display Options and change the Cut/Fill Color Map Subdivisions. This parameter is the number of rows and columns of color blocks to create. To turn off the color map, go to the Display menu and pick Cut/Fill Color Map to uncheck it.
Step 11 (Calculate Volumes):

To calculate volumes, run the TakeOff->Calculate Total Volumes command. There is an options dialog for setting the cut swell factor and fill shrink factor. These values get multiplied into the cut/fill volumes. Set these factors as desired and click OK. Then the routine calculates the volumes and display the report which includes the cut/fill volumes and areas. The report can be printed or saved to a file. Pick the Exit button to exit the report viewer.
Step 12 (Material Quantities):

To report the quantities, run the TakeOff->Material Quantities->Standard Report routine. There is the option to only report selected entities as well as the ability to report material quantities that may extend beyond the boundary polyline.

The report includes the count, length, area and volume for each type of material that was assigned for reporting in the Define Layer Target/Material/Subgrade command. The Material Quantities->Custom Report routine can be used to reporting these values with control of the report format and the option to export to Excel.
Lesson 17: Takeoff Tutorial: Drillhole and Strata

This lesson creates and processes drillhole data.

Step 1 (Run Lesson 1 Example):

This drillhole lesson builds on the resulting drawing called takeoffdemo1.dwg from the tutorial lesson 13 (Takeoff Basics). Before continuing with this tutorial, run through and complete this lesson 1 tutorial.

When lesson 13 is done, let's set the display to show only the design entities. In the Display menu, turn off Existing Drawing and Other Drawing and turn on Design Drawing. Then run, View->Zoom->Extents. Now we're ready to add drillholes.

Step 2 (Drillhole/Strata Settings):

From the Drillhole menu, choose Drillhole/Strata Settings. This command sets the drillhole symbol and the default strata names. For this tutorial, we are interested in rock quantities and we need to define two strata: Dirt (material above the rock) and Rock.
Pick the Add button which brings up another dialog that defines a strata. Enter a strata name of "DIRT" and a density of 125 which will be used to calculate tons in the volume report. You can also have a strata specific cut swell factor. The strata can be modeled either by the elevations from the drillholes or by the depth from the existing ground. In this case, we will model by strata elevation. There are also 3 options of modeling methods. Linear Least Squares extrapolates trends and allows for a strata model to create new highs and lows, that don't appear in the original drillhole data. Inverse Distance will not carry trends and the calculated strata model will never be higher or lower than the original drillhole data. Inverse Distance uses a weighted average of the drillhole data. In general, closer drillholes are weighted more than drillhole farther away. Inverse Distance - Power 3 will weigh drillholes less that are further away. Inverse Distance - Power 2 will weigh them more. When the dialog is filled out as shown, pick OK.

Next, pick the Add button again. This time, fill out the dialog with a strata name of "ROCK" and density of 150. Then pick OK.

The Strata Definitions in the main dialog need to be in top to bottom order. To change the order, highlight a strata name and use the Move Up or Move Down buttons. In this case, we want Dirt then Rock. Click OK now from the main dialog.
Step 3 (Input Drillhole Data):

There are two different methods for entering drillhole data into Takeoff: Drillhole Import and Place Drillhole. Drillhole Import reads the drillhole data from a text file. This command supports customizing the sequence of drillhole data fields to match the format of the text file. Place Drillhole creates the drillholes at picked positions in the drawing and enters the data in a dialog. For this tutorial, we will use Place Drillhole.

Run the Drillhole->Place Drillhole command. At the command line, there is a prompt to pick the drillhole location. If you know the coordinates for the drillhole, you can type in the easting,northing instead of picking on the screen. In this case, let's pick a point above the upper right of the main building.

Pick Drillhole Location: *pick a point*
Then there is a dialog for entering the drillhole data. The surface elevation is automatically filled in using the existing ground surface model. The Drillhole Name and Description are optional. The list of strata defaults to the strata defined in Drillhole/Strata Settings. Each strata defaults to a thickness of zero. To set the strata thickness, highlight the strata and pick the Edit button.

For this case, highlight Dirt and pick Edit. This brings up the Edit Strata dialog. The strata position can be defined by thickness, elevation or depth. Setting any one of these fields will update the other fields. For our dirt strata, fill in a thickness of 2 and then pick OK.

![Edit Strata dialog](image)

Next, pick Rock from the strata list and pick Edit. For this example, we only know the depth to the top of rock depth and not the total rock thickness. We will treat all cut below the top of rock as rock strata. So we will set the rock thickness deep enough to be lower than the deepest cut on site. In this case, we will use a rock thickness of 15. So in the Edit Strata dialog for rock, enter a thickness of 15 and then pick OK.

After editing the rock strata, we are returned to the main Edit Drillhole dialog. Pick the Save button.

![Place Drillhole dialog](image)

Now let’s locate two more drillholes using a different method. Return Drillhole/Strata Settings dialog and change Place Drillhole Prompts to Thickness. Also, check on Default Thickness and set it to 15 feet, Press OK.
Now run Place Drillhole again and for the second drillhole, pick a position in the lower parking lot. The command line will prompt you to enter a dirt thickness, type in 1.5 and your drillhole is created. For the third drillhole, pick a position left of the main building. Enter a dirt thickness of 3.0, save, and enter to end the command.

Step 4 (Make Strata Surfaces):

Now that the drillholes are in the drawing, to make the strata triangulation surfaces, run the Drillhole->Make Strata Surfaces command. There are no prompts for this routine. The strata surfaces are modeled from the drillholes and saved with the project. The file names for the strata surfaces use the drawing name plus "-ch#" where the # is the strata sequence number. For this example, the file names will be "takeoffdemo1-ch1" for bottom of dirt and "takeoffdemo1-ch2" for bottom of rock.

Now that the strata surfaces are created, there are several Takeoff routines that will use these surfaces such as:
- Calculate Total Volumes
- Calculate Volumes Inside Perimeter
- Cut/Fill Labels
- Surface Inspector
- Quick Profile
- Trench Network Quantities

Step 5 (Draw Strata Cut Color Map):

From the Drillhole menu, pick Draw Strata Cut Color Map. This command compares the design surface with the strata surface to make a cut color map of the cut depths for the strata. This command is one way to verify that the strata surfaces are modeled correctly.

There is a dialog to select which strata map to draw. Choose Rock and pick OK. Then there is an option to draw a cut depth legend. Pick a position for the legend in the upper left of the site and use the defaults for size and
Step 6 (Calculate Total Volumes):

Run the Takeoff->Calculate Total Volumes command. When strata surfaces are defined, the volume routine will breakout the cut volume into the different strata. The resulting dirt and rock quantities are shown in the report.
This lesson creates and processes drillhole data.

**Step 1 (Run Lesson 1 Example):**

This drillhole lesson builds on the resulting drawing called takeoffdemo1.dwg from the tutorial lesson 13 (Takeoff Basics). Before continuing with this tutorial, run through and complete this lesson 1 tutorial.

When lesson 13 is done, let's set the display to show only the design entities. In the Display menu, turn off Existing Drawing and Other Drawing and turn on Design Drawing. Then run, View->Zoom->Extents. Now we're ready to add drillholes.

**Step 2 (Drillhole/Strata Settings):**

From the Drillhole menu, choose Drillhole/Strata Settings. This command sets the drillhole symbol and the default strata names. For this tutorial, we are interested in rock quantities and we need to define two strata: Dirt (material above the rock) and Rock.
Pick the Add button which brings up another dialog that defines a strata. Enter a strata name of "DIRT" and a density of 125 which will be used to calculate tons in the volume report. You can also have a strata specific cut swell factor. The strata can be modeled either by the elevations from the drillholes or by the depth from the existing ground. In this case, we will model by strata elevation. There are also 3 options of modeling methods. Linear Least Squares extrapolates trends and allows for a strata model to create new highs and lows, that don't appear in the original drillhole data. Inverse Distance will not carry trends and the calculated strata model will never be higher or lower than the original drillhole data. Inverse Distance uses a weighted average of the drillhole data. In general, closer drillholes are weighted more than drillhole farther away. Inverse Distance - Power 3 will weigh drillholes less that are further away. Inverse Distance - Power 2 will weigh them more. When the dialog is filled out as shown, pick OK.

Next, pick the Add button again. This time, fill out the dialog with a strata name of "ROCK" and density of 150. Then pick OK.

The Strata Definitions in the main dialog need to be in top to bottom order. To change the order, highlight a strata name and use the Move Up or Move Down buttons. In this case, we want Dirt then Rock. Click OK now from the main dialog.
Step 3 (Input Drillhole Data):

There are two different methods for entering drillhole data into Takeoff: Drillhole Import and Place Drillhole. Drillhole Import reads the drillhole data from a text file. This command supports customizing the sequence of drillhole data fields to match the format of the text file. Place Drillhole creates the drillholes at picked positions in the drawing and enters the data in a dialog. For this tutorial, we will use Place Drillhole.

Run the Drillhole->Place Drillhole command. At the command line, there is a prompt to pick the drillhole location. If you know the coordinates for the drillhole, you can type in the easting,northing instead of picking on the screen. In this case, let's pick a point above the upper right of the main building.

Pick Drillhole Location: pick a point

Then there is a dialog for entering the drillhole data. The surface elevation is automatically filled in using the existing ground surface model. The Drillhole Name and Description are optional. The list of strata defaults to the strata defined in Drillhole/Strata Settings. Each strata defaults to a thickness of zero. To set the strata thickness, highlight the strata and pick the Edit button.

For this case, highlight Dirt and pick Edit. This brings up the Edit Strata dialog. The strata position can be defined by thickness, elevation or depth. Setting any one of these fields will update the other fields. For our dirt strata, fill in a thickness of 2 and then pick OK.
Next, pick Rock from the strata list and pick Edit. For this example, we only know the depth to the top of rock depth and not the total rock thickness. We will treat all cut below the top of rock as rock strata. So we will set the rock thickness deep enough to be lower than the deepest cut on site. In this case, we will use a rock thickness of 15. So in the Edit Strata dialog for rock, enter a thickness of 15 and then pick OK.

After editing the rock strata, we are returned to the main Edit Drillhole dialog. Pick the Save button.

Now let's locate two more drillholes using a different method. Return Drillhole/Strata Settings dialog and change Place Drillhole Prompts to Thickness. Also, check on Default Thickness and set it to 15 feet. Press OK.

Now run Place Drillhole again and for the second drillhole, pick a position in the lower parking lot. The command line will prompt you to enter a dirt thickness, type in 1.5 and your drillhole is created. For the third drillhole, pick a position left of the main building. Enter a dirt thickness of 3.0, save, and enter to end the command.

**Step 4 (Make Strata Surfaces):**

Now that the drillholes are in the drawing, to make the strata triangulation surfaces, run the Drillhole->Make Strata Surfaces command. There are no prompts for this routine. The strata surfaces are modeled from the drillholes.
and saved with the project. The file names for the strata surfaces use the drawing name plus "-ch#" where the # is the strata sequence number. For this example, the file names will be "takeoffdemo1-ch1" for bottom of dirt and "takeoffdemo1-ch2" for bottom of rock.

Now that the strata surfaces are created, there are several Takeoff routines that will use these surfaces such as:
- Calculate Total Volumes
- Calculate Volumes Inside Perimeter
- Cut/Fill Labels
- Surface Inspector
- Quick Profile
- Trench Network Quantities

**Step 5 (Draw Strata Cut Color Map):**

From the Drillhole menu, pick Draw Strata Cut Color Map. This command compares the design surface with the strata surface to make a cut color map of the cut depths for the strata. This command is one way to verify that the strata surfaces are modeled correctly.

There is a dialog to select which strata map to draw. Choose Rock and pick OK. Then there is an option to draw a cut depth legend. Pick a position for the legend in the upper left of the site and use the defaults for size and zone summary.

![Select Strata To Process](image)

**Step 6 (Calculate Total Volumes):**

Run the Takeoff->Calculate Total Volumes command. When strata surfaces are defined, the volume routine will
breakout the cut volume into the different strata. The resulting dirt and rock quantities are shown in the report.

Lesson 18: Takeoff Tutorial: Trench Network Quantities

This lesson takes a drawing file through the steps of trench network quantities.

Step 1 (Start Takeoff):

Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a "Startup Wizard" dialog and if so, click Exit.

Step 2 (Open Drawing):

From the File menu, choose Open and select Takeoffdemo2.dwg from the Carlson Projects folder.
Step 3 (Make Existing and Design Surfaces):

In order to calculate trench quantities and profiles in this drawing, we need surfaces for the existing ground and design.

First we need to define the layers of the surfaces. Run TakeOff->Define Surface Target/Material/Subgrade. Then from the tab labeled "Other", highlight "EX_CTR" from the layer list, pick "Existing" from the Move To list and pick the Move To button. Next, highlight "RD RF CONT", choose "Design" from the Move To list and pick the Move To button. Now choose the Save and then Exit buttons. This assigned layer "EX_CTR" to the existing ground surface and "RD RF CONT" to the design surface.
Next, let’s set the site perimeter. Run TakeOff->Boundary Polyline->Set Boundary Polyline. At the command line, there is a prompt:
Select boundary polyline:
Pick anywhere along the six sided perimeter polyline in the drawing.

Now, to make the existing ground surface, run TakeOff->Make Existing Ground Surface. Then to make the design surface, run TakeOff->Make Design Surface.

**Step 4 (Input Trench Network Data):**

The trench network data consists of linked structures where each structure has a name, location (x,y), invert-in, invert-out and rim elevation. Each structure link has a pipe size. There are two ways of entering the trench data. When the drawing contains polylines for the trench lines and labels with the trench data, then you can use Input Trench From Polyline. Otherwise, there is the Create Trench Network Structure command which let’s you pick the structure locations and enter the data in a dialog.

Method 1 (Input Trench Line):
In this example, there is trench data already drawn in the drawing. Zoom in around the upper right area of trench line by running View->Zoom->Window and picking two corner points around this area.

Then run Trench->Input Trench Line and an options dialog appears. In this case, our Input Method is from a Polyline. We also want Trench Type as Sewer because there are manhole rim elevations. Also Prompt For Invert-In Elevations is active since this example has a manhole with multiple connections with different invert-ins. And Connected Network is used so that the trench data can be used by the rest of the trench routines. The Individual Profile option will only create a profile (.pro) file. Prompt For Pipe Wall Thickness allows you to enter in the pipe thickness that will be added to the interior pipe size for accurate volume calculations. Fill out the dialog as shown and click OK.

![Input Trench Dialog](image)

The rest of the prompting for this command is on the command line as the program walks through the trench line. For each point in the trench polyline, the program zooms the drawing to that point. The trench data can be picked from labels in the drawing. If the drawing doesn't have labels for the data, then you can enter the values.
Pick a polyline that represents a trench reach: *Pick the trench polyline*

Starting Station of trench reach <0.0>: 0.0

For station 0.00 ...

Enter/<Select text of Manhole ID>: *Pick the DCB 368 label.* (If you had a drawing without a manhole ID label, then type E for Enter and enter the ID)

ID: DCB 368

Undo/Enter/<Select text of Invert-in elevation>: *Pick the I In=174 label.* (Since this is the upstream starting manhole, there really isn't a separate invert-in. So we are using the invert-out).

Invert-In: 174.000

Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=174 label.*

Invert-Out: 174.000

Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=178.75 label.*

Rim: 178.750

For station 201.44 ...

Enter/<Select text of Manhole ID>: *Pick the DCB 367 label.*

ID: DCB 367

Undo/Enter/<Select text of Invert-in elevation>: *Pick the I In=172.85 label.*

Invert-In: 172.850

Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=172.35 label.*

Invert-Out: 172.350

Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=178.5 label.*

Rim: 178.500

Undo/Enter/<Select text of pipe size>: *Pick the 15" HDPE label.*

Pipe Size: 15.0

For station 327.09 ...

Enter/<Select text of Manhole ID>: *Pick the CB 347 label.*

ID: CB 347

Undo/Enter/<Select text of Invert-in elevation>: *Pick the I In=170.540 (CB 367) label.* (This is the invert-in for the connection to the CB 367 structure that this trench line connects to.)

Invert-In: 170.540

Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=166.1 label.*

Invert-Out: 166.100

Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=176.5 label.*

Rim: 176.500

Undo/Enter/<Select text of pipe size>: *Pick the 15" HDPE label.*

Pipe Size: 15.0

Another Polyline [<Yes>/No]? N for no.
That completes this trench run and Takeoff draws its own trench polyline and labels.

Method 2 (Create Trench Network Structure):
The drawing contains another trench polyline and we could use Input Trench Data From Polyline again. Instead for practice, let's use the Create Trench Network Structure method. First we need to zoom to the new trench location. Run View–>Zoom–>Extents and then View–>Zoom–>Window and pick two points for a window around the lower right trench point (CB 349). Then run Trench–>Create Trench Network Structure. At the command line, there is a prompt for how to locate the structure position. Choose Pick. Locate by pick point, point number or station-offset [<Pick>/Number/CL]? Pick

Next, there is a prompt to pick the position. To get the exact end point of the trench polyline, use the end point snap. The end point snap can be turned on by a number of different ways including the Settings–>Object Snap command. In this case, type "end" and then space or enter. This puts the program in end point snap mode. Now move the pointer along the trench polyline until the end point snap icon is at the manhole location and then pick. Pick structure location: end of (pick point)

Now a dialog appears for entering the structure data. Fill in the Structure Name as CB 349, the Rim Elevation as 187.8, the Invert-Out as 178.3, the Structure Width as 4.00 and then pick OK.
All the structures are now created. The last step is to link this new structure to the network. We need to zoom to the next trench location. Run View->Zoom->Extents and then View->Zoom->Window and pick two points for a window around the left trench point (CB 347). Now run Trench->Edit Trench Network Structure and pick either the symbol for CB 347 or the label. Then a dialog appears with the data for CB 347. From the Available list, highlight CB 349 and pick Add. This creates a link from CB 347 to CB 349 and the link data is shown at the bottom of the dialog. Enter the Invert-In as 171 and the Pipe Size as 24. Then pick OK.

![Trench Structure Data dialog](image)

**Step 5 (Input-Edit Trench Template):**

The Trench Template defines the size of the trench for quantities. Run Trench->Input-Edit Trench Template. You are first prompted for a trench template file name. The Trench Template data is stored in a file that has a .tch extension. Choose the New tab, enter a file name like trench1 and then pick Open.

Next, there is a dialog for entering the trench dimensions. The Bottom Offset is the distance from the bottom of the pipe to the bottom of the trench. The Trench Width is the base width of the trench. The Vertical Side Height is the height from the bottom that the side walls are vertical until switching to the cut slope. If the surface is not reached by the vertical side height, then the cut slope is used for the rest of the distance to the surface. Edit Trench Benches allows you to set up to four benches in your trench. Display Sewer Structure allows you to see your pipe or manhole as part of the trench. Note: This is for display purposes only, calculations will be drawn from the pipe size you set in the Trench Network Structure commands. Add Pipe Diameter To Trench Width will increase the size of your trench by the diameter of your different pipe sizes. The Cut Slope can be entered in slope percent, ratio or degree format. The Backfill materials are optional. They can be defined from the top or bottom of the trench. Up to three materials can be entered from the bottom.

Fill out the dialog as shown and pick Save and Exit.
Step 6 (Trench Network Quantities):

To calculate and report the trench quantities, run Trench->Trench Network Quantities. A dialog sets the report options. Check on Calculate All Trenches to get the quantities for the whole network. To get the trench cut volume, check Use Trench Template For Quantities and pick Set Trench Template and pick trench1.tch. Also turn on Report Backfill Volumes to use our backfill material settings from the trench template. Finally, fill out the depth zones in the intervals that you are interested in. In this case, use 15, 20 and 25. The depth zones will be colored in the plain view. Once the dialog is filled out as shown, pick Setup Depth Zones.
Fill out the depth zones in the intervals that you are interested in. In this case, use 15, 20 and 25. The depth zones will be colored in the plain view. Finally, click OK and OK in the main dialog and the report is shown.

The report includes:
- The structure names at the start of each trench run included in the report.
- The trench template dimensions.
- The cut volume.
- The backfill volumes.
- The number of manholes and length of trench within each depth zone.

The depth zones in the plain view with Zone Map Color Legend.
Step 8 (Draw Trench Network Profile):

To draw a profile of the trench line, run the Trench->Draw Trench Network (Profile) command. There is a dialog to select the starting structure for which trench line to process. Choose DCB 368. Also, there are options whether to draw the existing ground, design surface and strata surfaces if available. You can also choose the profile direction to go upstream or downstream. The Save To Profile File will create a profile (.pro) file for the trench. Fill out the dialog as shown and pick OK.

![Draw Trench Network](image.png)

Next the Draw Profile dialog appears. Set the Horizontal Scale and intervals to 50 and the Vertical Scale and intervals to 25. This will make for two to one vertical exaggeration for the profile. Click OK.
Next, there are prompts at the command line for the profile grid elevations and profile location. Bottom Elevation of Profile Grid <150.0>: Press Enter
Top Elevation of Profile Grid <200.0>: Press Enter
Pick Starting Point for Grid <409458.0, 207303.0>: Pick a point in a blank area off to the side of the drawing.

There is a final command line prompt for whether to use the manhole elevations. Enter Yes which will use the rim elevations defined in our trench network.

Use manhole elevations from profile [Yes/No]? Y for yes.

The profile shows the existing ground at the top, then the design surface and then the trench.

This lesson takes a drawing file through the steps of trench network quantities.

**Step 1 (Start Takeoff):**

Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a
"Startup Wizard" dialog and if so, click Exit.

Step 2 (Open Drawing):

From the File menu, choose Open and select Takeoffdemo2.dwg from the Carlson Projects folder.

Step 3 (Make Existing and Design Surfaces):

In order to calculate trench quantities and profiles in this drawing, we need surfaces for the existing ground and design.

First we need to define the layers of the surfaces. Run TakeOff->Define Surface Target/Material/Subgrade. Then from the tab labeled "Other", highlight "EX_CTR" from the layer list, pick "Existing" from the Move To list and pick the Move To button. Next, highlight "RD RF CONT", choose "Design" from the Move To list and pick the Move To button. Now choose the Save and then Exit buttons. This assigned layer "EX_CTR" to the existing ground surface and "RD RF CONT" to the design surface.
Next, let's set the site perimeter. Run TakeOff->Boundary Polyline->Set Boundary Polyline. At the command line, there is a prompt:
Select boundary polyline:
Pick anywhere along the six sided perimeter polyline in the drawing.

Now, to make the existing ground surface, run TakeOff->Make Existing Ground Surface. Then to make the design surface, run TakeOff->Make Design Surface.

**Step 4 (Input Trench Network Data):**

The trench network data consists of linked structures where each structure has a name, location (x,y), invert-in, invert-out and rim elevation. Each structure link has a pipe size. There are two ways of entering the trench data. When the drawing contains polylines for the trench lines and labels with the trench data, then you can use Input Trench From Polyline. Otherwise, there is the Create Trench Network Structure command which let's you pick the structure locations and enter the data in a dialog.

Method 1 (Input Trench Line):
In this example, there is trench data already drawn in the drawing. Zoom in around the upper right area of trench line by running View->Zoom->Window and picking two corner points around this area.

Then run Trench->Input Trench Line and an options dialog appears. In this case, our Input Method is from a Polyline. We also want Trench Type as Sewer because there are manhole rim elevations. Also Prompt For Invert-In Elevations is active since this example has a manhole with multiple connections with different invert-ins. And Connected Network is used so that the trench data can be used by the rest of the trench routines. The Individual Profile option will only create a profile (.pro) file. Prompt For Pipe Wall Thickness allows you to enter in the pipe thickness that will be added to the interior pipe size for accurate volume calculations. Fill out the dialog as shown and click OK.
The rest of the prompting for this command is on the command line as the program walks through the trench line. For each point in the trench polyline, the program zooms the drawing to that point. The trench data can be picked from labels in the drawing. If the drawing doesn’t have labels for the data, then you can enter the values.

Pick a polyline that represents a trench reach: *Pick the trench polyline*
Starting Station of trench reach <0.0>: 0.0
For station 0.00 ...
Enter/<Select text of Manhole ID>: *Pick the DCB 368 label.* (If you had a drawing without a manhole ID label, then type E for Enter and enter the ID)
ID: DCB 368
Undo/Enter/<Select text of Invert-in elevation>: *Pick the I Out=174 label.* (Since this is the upstream starting manhole, there really isn’t a separate invert-in. So we are using the invert-out).
Invert-In: 174.000
Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=174 label.*
Invert-Out: 174.000
Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=178.75 label.*
Rim: 178.750
For station 201.44 ...
Enter/<Select text of Manhole ID>: *Pick the DCB 367 label.*
ID: DCB 367
Undo/Enter/<Select text of Invert-in elevation>: *Pick the I In=172.85 label.*
Invert-In: 172.850
Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=172.35 label.*
Invert-Out: 172.350
Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=178.5 label.*
Rim: 178.500
Undo/Enter/<Select text of pipe size>: *Pick the 15” HDPE label.*
Pipe Size: 15.0
For station 327.09 ...
Enter/<Select text of Manhole ID>: *Pick the CB 347 label.*
ID: CB 347
Undo/Enter/<Select text of Invert-in elevation>: *Pick the I In=170.540 (CB 367) label.* (This is the invert-in for the connection to the CB 367 structure that this trench line connects to.)
Invert-In: 170.540
Undo/Enter/<Select text of Invert-out elevation>: *Pick the I Out=166.1 label.*
Invert-Out: 166.100
Undo/Enter/<Select text of manhole rim elevation>: *Pick the R=176.5 label.*
Rim: 176.500
Undo/Enter/<Select text of pipe size>: *Pick the 15” HDPE label.*
Pipe Size: 15.0
Another Polyline [<Yes>/No]? N for no.

That completes this trench run and Takeoff draws its own trench polyline and labels.

Method 2 (Create Trench Network Structure):
The drawing contains another trench polyline and we could use Input Trench Data From Polyline again. Instead for practice, let's use the Create Trench Network Structure method. First we need to zoom to the new trench location. Run View->Zoom->Extents and then View->Zoom->Window and pick two points for a window around the lower right trench point (CB 349). Then run Trench->Create Trench Network Structure. At the command line, there is a prompt for how to locate the structure position. Choose Pick.
Locate by pick point, point number or station-offset [<Pick>/Number/CL]? *Pick*

![Pick Point](image)

Next, there is a prompt to pick the position. To get the exact end point of the trench polyline, use the end point snap. The end point snap can be turned on by a number of different ways including the Settings->Object Snap command. In this case, type "end" and then space or enter. This puts the program in end point snap mode. Now move the pointer along the trench polyline until the end point snap icon is at the manhole location and then pick.
Pick structure location: *end of (pick point)*
Now a dialog appears for entering the structure data. Fill in the Structure Name as CB 349, the Rim Elevation as 187.8, the Invert-Out as 178.3, the Structure Width as 4.00 and then pick OK.

All the structures are now created. The last step is to link this new structure to the network. We need to zoom to the next trench location. Run View→Zoom→Extents and then View→Zoom→Window and pick two points for a window around the left trench point (CB 347). Now run Trench→Edit Trench Network Structure and pick either the symbol for CB 347 or the label. Then a dialog appears with the data for CB 347. From the Available list, highlight CB 349 and pick Add. This creates a link from CB 347 to CB 349 and the link data is shown at the bottom of the dialog. Enter the Invert-In as 171 and the Pipe Size as 24. Then pick OK.
Step 5 (Input-Edit Trench Template):

The Trench Template defines the size of the trench for quantities. Run Trench->Input-Edit Trench Template. You are first prompted for a trench template file name. The Trench Template data is stored in a file that has a .tch extension. Choose the New tab, enter a file name like trench1 and then pick Open.

Next, there is a dialog for entering the trench dimensions. The Bottom Offset is the distance from the bottom of the pipe to the bottom of the trench. The Trench Width is the base width of the trench. The Vertical Side Height is the height from the bottom that the side walls are vertical until switching to the cut slope. If the surface is not reached by the vertical side height, then the cut slope is used for the rest of the distance to the surface. Edit Trench Benches allows you to set up to four benches in your trench. Display Sewer Structure allows you to see your pipe or manhole as part of the trench. Note: This is for display purposes only, calculations will be drawn from the pipe size you set in the Trench Network Structure commands. Add Pipe Diameter To Trench Width will increase the size of your trench by the diameter of your different pipe sizes. The Cut Slope can be entered in slope percent, ratio or degree format. The Backfill materials are optional. They can be defined from the top or bottom of the trench. Up to three materials can be entered from the bottom.

Fill out the dialog as shown and pick Save and Exit.
Step 6 (Trench Network Quantities):

To calculate and report the trench quantities, run Trench->Trench Network Quantities. A dialog sets the report options. Check on Calculate All Trenches to get the quantities for the whole network. To get the trench cut volume, check Use Trench Template For Quantities and pick Set Trench Template and pick trench1.tch. Also turn on Report Backfill Volumes to use our backfill material settings from the trench template. Finally, fill out the depth zones in the intervals that you are interested in. In this case, use 15, 20 and 25. The depth zones will be colored in the plain view. Once the dialog is filled out as shown, pick Setup Depth Zones.
Fill out the depth zones in the intervals that you are interested in. In this case, use 15, 20 and 25. The depth zones will be colored in the plain view. Finally, click OK and OK in the main dialog and the report is shown.

The report includes:
- The structure names at the start of each trench run included in the report.
- The trench template dimensions.
- The cut volume.
- The backfill volumes.
- The number of manholes and length of trench within each depth zone.
Step 7 (Draw Trench Network Profile):

To draw a profile of the trench line, run the Trench->Draw Trench Network (Profile) command. There is a dialog to select the starting structure for which trench line to process. Choose DCB 368. Also, there are options whether to draw the existing ground, design surface and strata surfaces if available. You can also choose the profile direction to go upstream or downstream. The Save To Profile File will create a profile (.pro) file for the trench. Fill out the dialog as shown and pick OK.

Next the Draw Profile dialog appears. Set the Horizontal Scale and intervals to 50 and the Vertical Scale and intervals to 25. This will make for two to one vertical exaggeration for the profile. Click OK.
Next, there is a dialog to prompt for the profile grid elevations. Pick OK to accept the defaults. Then there is a command line prompt for the profile location.

Pick Starting Point for Grid <409458.0, 207303.0>: *Pick a point in a blank area off to the side of the drawing.*

There is a final command line prompt for whether to use the manhole elevations. Enter Yes which will use the rim elevations defined in our trench network.

Use manhole elevations from profile [Yes/No]? Y for yes.

The profile shows the existing ground at the top, then the design surface and then the trench.

Lesson 19: Takeoff Tutorial: Digitizing

This lesson transfers a paper plan into Carlson Takeoff.

Step 1 (Setup):

To digitize in Carlson Takeoff, you need to install the Wintab digitizer driver. See Digitizer Setup in the manual if
you have not installed or have problems with the Wintab driver. If Wintab is installed, then make sure your drawing board is on and take the paper plan provided with the manual and place it on your drawing board.  

Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a "Startup Wizard" dialog similar to the one shown below, if so click New.

![Startup Wizard](image)

If a Startup Wizard did not appear, then under File menu, select New to start a new drawing. You will be prompted for a template to use. Templates determine the default settings for your drawing. For this tutorial, select site.dwt or carlson.dwt and click Open.

![Select template](image)
Next, the New Drawing Wizard appears for setting the drawing name. Click on the Set button at the top dialog. In the file selection dialog, enter the file name of "digitize" and pick the Save button. Then Exit the New Drawing Wizard. From here, a Data Files dialog appears where no changes are needed. Pick the Exit button.

![New Drawing Wizard](image)

**Step 2 (Tablet Calibration):**

To start things off, you need to set the coordinate system for the paper plan by running the Calibrate command under Digitize menu and sub-menu Tablet. Calibration is required to let the program know the orientation and scale of the paper plan.

![Tablet Calibration](image)

There are two different Calibration Methods: Known Reference Points and Drawing Scale with New Reference Points. Known Reference Points allows you to enter in the coordinates of two marked points on the paper plan. This method applies when you know the coordinates of at least two points on the paper plans. Drawing Scale with New Reference Points allows you to setup a coordinate system for the plans by entering the plan scale and picking any two points from the paper plan with the digitizer puck.

In this case, we will use Drawing Scale with New Reference Points. First, enter in the Drawing Scale listed on the paper plan. On this drawing, the scale is 1:40, so enter in 40. Use the default coordinates for Point 1 and click OK. Now Carlson Takeoff will prompt you for your First and Second Reference points. Generally, you want to pick to points on the drawing that you can find and use again in case you need to recalibrate. Also, the further away the points are from each other, the more accurate the coordinate system will be. With the digitizer puck, pick...
on the icon in the lower left and upper right of the drawing for the two Reference Points. The first point is assigned the coordinates of 1000,1000 from the dialog and the second point is assigned coordinates to match with the plan scale. From now on, all of your points will be in relation to these two points.

Step 3 (Digitizing Existing Contours):

We will now digitize the existing contours. Under the Digitize menu, click on Existing and then go to Contour Polyline, and this dialog will appear. Enter in a Layer Name of XCONT and select OK. Note: your Elevation Interval should match the intervals marked on your paper drawing. In this drawing, the interval is the same as the default of 1.00.

The rest of the prompting occurs at the command line and starts with the contour elevation. Find the lowest elevation for the existing contours labeled in bottom right corner of the paper plan zoomed in on below. In this example, the lowest elevation is 624 feet. The elevation can be entered either with the digitizer puck keys or with the computer keyboard. The layout of the digitizer keys is set in Digitizing Settings->Puck Layout. Press Enter after you have entered in 624. You want to enter in the lowest contour so that as Carlson Takeoff adds the Elevation Interval, it is from lowest to highest.
Next, you will see the following prompt:

**Sketch[0]/Exit[A]/Pick the first point:**

There are two different ways to digitize: in Pick Mode or Sketch Mode. You can switch between them at anytime. In this tutorial we will run through how to do both. For now, type in [0] and press enter to get into Sketch Mode. In Sketch Mode, you will be prompted to Pick and drag. The point you pick is the starting point of a contour. Drag is asking you to follow that contour with the digitizer puck on the paper plan. Click a second time when you have traced the entire contour and have reached the end of the contour. You will then be prompted as follows:

**Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end):**

Type in [B] for Undo if you made a mistake and need to sketch part of the contour again. [A] will close the contour, and [0] will switch you into Pick Mode. We still have more existing contours to digitize, so press Enter to end and answer yes to the Digitize Another Contour prompt. Takeoff will prompt you to verify the elevation. Remember, we set the Elevation Interval to one, so the default elevation for your next contour line is 625, press Enter. Now, pick the endpoint of the next contour and trace it in the same manner as the previous contour.

Now let's try Pick Mode. Say yes to digitize another contour and check to see if the default elevation corresponds with the contour your about to digitize. If not, simply type in the correct number in the command line. Next, pick [0] to get into Pick Mode. In Pick Mode, you do not have to trace the contour. Rather, pick with the digitizer puck to create points that will make up the contour. Note: Less picks are needed on fairly straight segments. Conversely, more picks will give you a more accurate contour. Press Enter when you have reach the end of the contour. Repeat this until you have digitized all of the existing contours you want to have in Takeoff (see below).
Step 4 (Digitizing the Design):

Now we will digitize the building and curb linework of the Design Surface using the Digitize 2D Polyline and 3D Polyline commands. Besides drawing the linework positions, we will also assign layer names to the linework that we will use later to identify the types of linework. In this example, there are no design contours, only the design building and curb linework and spot elevations.

Let's begin by digitizing the main building. Under Digitize, check on Design and go to 2D Polyline. 2D Polyline is used to digitize linework entities with one elevation. Toggle off the check box Use current drawing layer and name the layer NEW BUILD. Toggle on the Prompt For Polyline Elevation option. Then click OK.

At the command line, enter in the building elevation of 634.41 found labeled in the middle of the building and press Enter. Then pick the points that define the building outline. Start in the upper left corner and pick at every corner around the building. When you have picked around the entire building, type in [A] for close to finish digitizing the building.
Enter polyline elevation <0.00>: 634.41

First point: pick a building point

Close[A]/Undo[B]/Osnap[.]./Pick next point (Enter to end): pick ========= This lesson transfers a paper plan into Carlson Takeoff.

**Step 1 (Setup):**

To digitize in Carlson Takeoff, you need to install the Wintab digitizer driver. See Digitizer Setup in the manual if you have not installed or have problems with the Wintab driver. If Wintab is installed, then make sure your drawing board is on and take the paper plan provided with the manual and place it on your drawing board. Click the icon for Takeoff on your desktop or from the toolbar to launch the program. You may be presented with a "Startup Wizard" dialog similar to the one shown below, if so click New.

If a Startup Wizard did not appear, then under File menu, select New to start a new drawing. You will be prompted for a template to use. Templates determine the default settings for your drawing. For this tutorial, select site.dwt and click Open.
Next, the New Drawing Wizard appears for setting the drawing name. Click on the Set button at the top dialog. In the file selection dialog, enter the file name of "digitize" and pick the Save button. Then Exit the New Drawing Wizard. From here, a Data Files dialog appears where no changes are needed. Pick the Exit button.

Step 2 (Tablet Calibration):

To start things off, you need to set the coordinate system for the paper plan by running the Calibrate command under Digitize menu and sub-menu Tablet. Calibration is required to let the program know the orientation and scale of the paper plan.
There are two different Calibration Methods: Known Reference Points and Drawing Scale with New Reference Points. Known Reference Points allows you to enter in the coordinates of two marked points on the paper plan. This method applies when you know the coordinates of at least two points on the paper plans. Drawing Scale with New Reference Points allows you to setup a coordinate system for the plans by entering the plan scale and picking any two points from the paper plan with the digitizer puck.

In this case, we will use Drawing Scale with New Reference Points. First, enter in the Drawing Scale listed on the paper plan. On this drawing, the scale is 1:40, so enter in 40. Use the default coordinates for Point 1 and click OK. Now Carlson Takeoff will prompt you for your First and Second Reference points. Generally, you want to pick to points on the drawing that you can find and use again in case you need to recalibrate. Also, the further away the points are from each other, the more accurate the coordinate system will be. With the digitizer puck, pick on the icon in the lower left and upper right of the drawing for the two Reference Points. The first point is assigned the coordinates of 1000,1000 from the dialog and the second point is assigned coordinates to match with the plan scale. From now on, all of your points will be in relation to these two points.
Step 3 (Digitizing Existing Contours):

We will now digitize the existing contours. Under the Digitize menu, click on Existing and then go to Contour Polyline, and this dialog will appear. Enter in a Layer Name of XCONT and select OK. Note: your Elevation Interval should match the intervals marked on your paper drawing. In this drawing, the interval is the same as the default of 1.00.

The rest of the prompting occurs at the command line and starts with the contour elevation. Find the lowest elevation for the existing contours labeled in bottom right corner of the paper plan zoomed in on below. In this example, the lowest elevation is 624 feet. The elevation can be entered either with the digitizer puck keys or with the computer keyboard. The layout of the digitizer keys is set in Digitizing Settings->Puck Layout. Press Enter after you have entered in 624. You want to enter in the lowest contour so that as Carlson Takeoff adds the Elevation Interval, it is from lowest to highest.
Next, you will see the following prompt:

**Sketch[0]/Exit[A]/Pick the first point:**

There are two different ways to digitize: in Pick Mode or Sketch Mode. You can switch between them at anytime. In this tutorial we will run through how to do both. For now, type in [0] and press enter to get into Sketch Mode. In Sketch Mode, you will be prompted to Pick and drag. The point you pick is the starting point of a contour. Drag is asking you to follow that contour with the digitizer puck on the paper plan. Click a second time when you have traced the entire contour and have reached the end of the contour. You will then be prompted as follows:

**Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end):**

Type in [B] for Undo if you made a mistake and need to sketch part of the contour again. [A] will close the contour, and [0] will switch you into Pick Mode. We still have more existing contours to digitize, so press Enter to end and answer yes to the Digitize Another Contour prompt. Takeoff will prompt you to verify the elevation. Remember, we set the Elevation Interval to one, so the default elevation for your next contour line is 625, press Enter. Now, pick the endpoint of the next contour and trace it in the same manner as the previous contour.

Now let's try Pick Mode. Say yes to digitize another contour and check to see if the default elevation corresponds with the contour your about to digitize. If not, simply type in the correct number in the command line. Next, pick [0] to get into Pick Mode. In Pick Mode, you do not have to trace the contour. Rather, pick with the digitizer puck to create points that will make up the contour. Note: Less picks are needed on fairly straight segments. Conversely, more picks will give you a more accurate contour. Press Enter when you have reach the end of the contour. Repeat this until you have digitized all of the existing contours you want to have in Takeoff (see below).
Step 4 (Digitizing the Design):

Now we will digitize the building and curb linework of the Design Surface using the Digitize 2D Polyline and 3D Polyline commands. Besides drawing the linework positions, we will also assign layer names to the linework that we will use later to identify the types of linework. In this example, there are no design contours, only the design building and curb linework and spot elevations.

Let's begin by digitizing the main building. Under Digitize, check on Design and go to 2D Polyline. 2D Polyline is used to digitize linework entities with one elevation. Toggle off the check box Use current drawing layer and name the layer NEW_BUILD. Toggle on the Prompt For Polyline Elevation option. Then click OK.

At the command line, enter in the building elevation of 634.41 found labeled in the middle of the building and press Enter. Then pick the points that define the building outline. Start in the upper left corner and pick at every corner around the building. When you have picked around the entire building, type in [A] for close to finish digitizing the building.
Enter polyline elevation <0.00>: 634.41
First point: pick a building point
Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick >>>>>>>> 1.8 the next building point
Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick the <<<<<< Lesson_13_Digitizing.html last building point
Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): A to close

Digitize Another NEW_BUILD Polyline [Yes(A)/<No(B)>]? B for No

Notice that the parking lot linework consists of different elevation levels. To digitize entities with more than one elevation, go to Digitize and select 3D Polyline from the pull-down menu. Make sure that the Prompt For Polyline Elevation option is on, the Use current drawing layer toggle is off and name the layer NEW EDGE ASPH.

Let's start by digitizing the parking lot starting from the zoomed in section below. The edge of asphalt is the inside line. The parking lot elevation labels have been shortened on the paper plan. For example, they read 35.37 and 35.12, when the actual elevations are 635.37 and 635.12. Enter in 600 as the Elevation Adder, then click OK.
Click on the point with the digitizer puck where the 35.37 elevation label points to in the upper left corner of the parking lot. When prompted for Elevation enter in 35.37. Pick below the first point where the linework starts to curve. We do not have an elevation for this point, but we can interpolate the elevation from the two points around it using the interpolate option. Type in I for interpolate or hit the A button on the Puck. Next pick the middle point of the curve and again use Interpolate for the elevation. Next pick the end of the curve at the 35.12 label and enter in the elevation 35.12. Continue digitizing for the rest of the edge of asphalt linework. Digitize each point where there is an elevation label and each point where the curb line changes direction.

The first prompts should resemble these:

**First point:** pick first point (at 35.37 label)

Interpolate[A]/screen Pick/<Elevation[B]><0.00>: 35.37

Z: 635.37

Close[A]/Undo[B]/Osnap[.]Pick next point (Enter to end): pick next point (start of curve)

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: pick next point (middle of curve)

This point elevation will be interpolated upon completion.

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: pick next point (end of curve, at 35.12 label)

This point elevation will be interpolated upon completion.

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: 35.12 (Enter)
To check the elevations of the interpolated points go to List under the Inquiry menu and click on the poly-line you just created and press Enter. A text window will appear showing you the layer name, coordinates, and elevation of each point. To return to the main graphic screen, press F2.

Use the 3D Polyline command to digitize the rest of the parking lot as seen below.

![Diagram of parking lot](image)

**Step 5 (Area):**

Now that we have digitized the Design Surface, let's check the Area of certain sections. Select Area under the Digitize Menu and match the below dialog.

![Digitize Areas dialog](image)

To approximate the area of the main building, pick the points of the building outline.

**Command:** `dig_area`

**Pick starting point:** Pick points as close to the building design linework as you can
Digitize Another Area [<Yes(A)>/No(B)]? B

When finished with the building points, press Enter to end. Then answer no for no more areas. Takeoff will then display an Area report similar to the one shown below.

Step 6 (Spot Elevations):

In our paper drawing, we have two spot elevations labeled 32.57 and 32.41 shown in the bottom left below.
To digitize these elevations, we can use the Spot Elevation command under the Digitize menu. Fill out the Spot Elevation dialog as shown and pick OK.

In the paper plan, find and click on the spot elevations with the puck. When prompted, enter in their corresponding elevations of 632.57 and 632.41.

**Step 7 (Boundary Polyline):**

The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. Under the digitize menu, check on Other and then select Perimeter. Type in PERIMETER as the layer name. Now digitize around the bold, outside line shown below.
Say No to the prompt: **Digitize Another PERIMETER Polyline [Yes(A)/No(B)]?**

Now run Tools->Boundary Polyline->Set Boundary Polyline and pick the perimeter polyline. This selected polyline is now set as the boundary polyline for the rest of the Takeoff routines.

**Step 8 (Layer Targets):**

From the Tools menu, choose Define Layer Target/Material/Subgrade. Every entity (line, polyline, point, etc) in the drawing is assigned a layer name. Takeoff uses the entity layer names to define which entities are for the existing ground surface, the design surface or no surface. These surfaces are referred to as the "Target" surfaces. The drawing entities are assigned their target surface by their layer name. For example, if polylines representing design contours are on the layer "NEW", then "NEW" will be set as a layer for the design surface. For layers of entities that are for neither existing nor design surfaces (such as text labels for street names), the layer target is set to Other.

The Define Layer Targets dialog has three lists of layers: Existing, Design and Other. To switch between lists, pick the tabs at the top of the dialog. We have already defined the layers for their correct targets. We did this by check on Existing, Design, or Other in the pull-down menu.

Check that your Layer Targets resemble the three lists shown here. If a layer is out of place, highlight it, and hit the "Move To" button after selecting the correct target to send it to. After reviewing, pick Save and Exit.
### Chapter 17. Tutorials

#### Define Layer Targets

<table>
<thead>
<tr>
<th>Layer</th>

<tr>
<td>NEW EDGE</td>
<td>NO</td>
</tr>
<tr>
<td>ASPH</td>
<td>NO</td>
</tr>
<tr>
<td>NEW_BUILD</td>
<td>NO</td>
</tr>
</tbody>
</table>

- **Existing**
- **Design**
- **Other**
Now that the layer targets are defined, there are several commands that can be applied. In the Display menu, you can turn on/off whether to display layer targets by using Existing Drawing, Design Drawing and Other Drawing, or by right-clicking with your mouse.

Practice turning on/off the Existing, Design and Other Drawing in the Display menu. When only Existing Drawing is on, you should see just the contours. When only Design Drawing is on, you should see just the design polylines and leader labels. When only Other Drawing is on, you should see the entities that are assigned to neither existing nor design.

Step 9 (Define Material/SubGrade):

Besides assigning target surfaces by layer, layers are also used to define material names and subgrade depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface. The polylines used for subgrade depth must be closed polylines. Takeoff supports nested subgrade polylines for exclusion areas such as islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the
area is not part of the subgrade.

First, let's confirm the layer names for our subgrades. Go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Then run Inquiry->Layer ID and pick the large pad polyline. It reports that this layer is NEW BUILD. Next use Layer ID to pick the curb polyline. It reports that this layer is NEW EDGE ASPH.

Now run Define Layer Target/Material/Subgrade and pick the Design tab. Highlight layer NEW BUILD and pick the Edit button. A dialog appears for defining the pad material properties. Check on the Include In Material Report option, enter the Material Name as "Pad", set the first subgrade name to "Pad", and set the Depth as 1. Once the dialog is filled out as shown, pick OK.

Next pick layer NEW EDGE ASPH and choose Edit. In the Edit Materials dialog, check on Include In Material Report, set the Material Name to "Pavement", set the first subgrade name to "Pavement", and set the Depth to 1.5. Then pick OK.
To save the subgrade changes, pick the Save button on the Define Layer Targets dialog. Then choose Exit.

Now let's visually verify the subgrade areas. In the TakeOff menu, run Subgrade Areas->Hatch Subgrade Areas. There is a dialog to select which subgrade to hatch. Choose the Pavement. Then there is a dialog for the hatch pattern and color. Change the color to green and click OK. Then run Hatch Subgrade Areas again. This time choose Pad and set the hatch pattern to Hex with blue color. The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. When finished viewing the subgrade areas, run TakeOff->Subgrade Areas->Erase Subgrade Hatches.
Step 10 (Model Existing and Design Surfaces):

To calculate volumes, Takeoff needs two surfaces: existing ground and design. These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to make the models. To make the existing ground surface, run Tools->Make Existing Ground Surface. The program will process the entities and make the triangulation surface. Then to make the design surface, run Tools->Make Design Surface.

Step 11 (Cut/Fill Color Map):

Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as a check that the models are correct. In the Display menu, choose Cut/Fill Color Map. Cut areas are drawn in different shades of red for different depths of cut while fill areas are drawn in blue. To change the resolution of the color blocks, run Display->Display Options and change the Cut/Fill Color Map Subdivisions. This parameter is the number of rows and columns of color blocks to create. You can also draw a legend for the Color Map by going to Draw, Cut/Fill Map Legend. Pick a point on your drawing to locate the legend and press Enter. To turn off the color map, go to the Display menu and pick Cut/Fill Color Map to uncheck it.

Step 12 (Calculate Volumes):

To calculate volumes, run the TakeOff->Calculate Total Volumes command. There is an options dialog for setting the cut swell factor and fill shrink factor. These values get multiplied into the cut/fill volumes. Set these factors as desired and click OK. Then the routine calculates the volumes and display the report which includes the cut/fill volumes and areas. The report can be printed or saved to a file. Pick the Exit button to exit the report viewer.
Step 13 (Material Quantities):

To report the material quantities, run the TakeOff->Material Quantities->Standard Report routine. The report includes the count, length, area and volume for each type of material that was assigned for reporting in the Define Layer Target/Material/Subgrade command. The Material Quantities->Custom Report routine can be used to reporting these values with control of the report format and the option to export to Excel.
Close[A]/Undo[B]/Osnaps/./Pick next point (Enter to end): A to close

Digitize Another NEW_BUILD Polyline [Yes(A)/<No(B)>]? B for No

Notice that the parking lot linework consists of different elevation levels. To digitize entities with more than one elevation, go to Digitize and select 3D Polyline from the pull-down menu. Make sure that the Prompt For Polyline Elevation option is on, the Use current drawing layer toggle is off and name the layer NEW EDGE ASPH.

Let's start by digitizing the parking lot starting from the zoomed in section below. The edge of asphalt is the inside line. The parking lot elevation labels have been shortened on the paper plan. For example, they read 35.37 and 35.12, when the actual elevations are 635.37 and 635.12. Enter in 600 as the Elevation Adder, then click OK.
Click on the point with the digitizer puck where the 35.37 elevation label points to in the upper left corner of the parking lot. When prompted for Elevation enter in 35.37. Pick below the first point where the linework starts to curve. We do not have an elevation for this point, but we can interpolate the elevation from the two points around it using the interpolate option. Type in I for interpolate or hit the A button on the Puck. Next pick the middle point of the curve and again use Interpolate for the elevation. Next pick the end of the curve at the 35.12 label and enter in the elevation 35.12. Continue digitizing for the rest of the edge of asphalt linework. Digitize each point where there is an elevation label and each point where the curb line changes direction.

The first prompts should resemble these:

**First point:** pick first point (at 35.37 label)
**Interpolate[A]/screen Pick/<Elevation[B]> <0.00>: 35.37

**Z: 635.37**

**Close[A]/Undo[B]/Osnaps./Pick next point (Enter to end):** pick next point (start of curve)
**Slope/Ratio/Interpolate[A]/Degree/screen Pick/<Elevation[B]> <635.37>:** Press the [A] button on the Puck for Interpolate

**Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnaps./Next point or elevation<Interpolate>:** pick next point (middle of curve)
This point elevation will be interpolated upon completion.

**Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnaps./Next point or elevation<Interpolate>:** pick next point (end of curve, at 35.12 label)
This point elevation will be interpolated upon completion.

**Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnaps./Next point or elevation<Interpolate>: 35.12 (Enter)**

To check the elevations of the interpolated points go to List under the Inquiry menu and click on the polyline you just created and press Enter. A text window will appear showing you the layer name, coordinates, and elevation of each point. To return to the main graphic screen, press F2.
Use the 3D Polyline command to digitize the rest of the parking lot as seen below.

**Step 5 (Area):**

Now that we have digitized the Design Surface, let's check the Area of certain sections. Select Area under the Digitize Menu and match the below dialog.

To approximate the area of the main building, pick the points of the building outline.

**Command:** *dig_area*  
**Pick starting point:** *Pick points as close to the building design linework as you can*  
**Undo [B]**/Pick next point (Enter to end):  
**Undo [B]**/Pick next point (Enter to end):  
**Undo [B]**/Pick next point (Enter to end):  
**Undo [B]**/Pick next point (Enter to end):  
**Undo [B]**/Pick next point (Enter to end):
When finished with the building points, press Enter to end. Then answer no for no more areas. Takeoff will then display an Area report similar to the one shown below.

![Area Report](image)

**Step 6 (Spot Elevations):**

In our paper drawing, we have two spot elevations labeled 32.57 and 32.41 shown in the bottom left below.

![Spot Elevations](image)

To digitize these elevations, we can use the Spot Elevation command under the Digitize menu. Fill out the Spot
Elevation dialog as shown and pick OK.

In the paper plan, find and click on the spot elevations with the puck. When prompted, enter in their corresponding elevations of 632.57 and 632.41.

**Step 7 (Boundary Polyline):**

The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. Under the digitize menu, check on Other and then select Perimeter. Type in PERIMETER as the layer name. Now digitize around the bold, outside line shown below.

Say No to the prompt: **Digitize Another PERIMETER Polyline [Yes(A)/<No(B)>]??**

Now run Tools->Boundary Polyline->Set Boundary Polyline and pick the perimeter polyline. This selected polyline is now set as the boundary polyline for the rest of the Takeoff routines.
Step 8 (Layer Targets):

From the Tools menu, choose Define Layer Target/Material/Subgrade. Every entity (line, polyline, point, etc) in the drawing is assigned a layer name. Takeoff uses the entity layer names to define which entities are for the existing ground surface, the design surface or no surface. These surfaces are referred to as the "Target" surfaces. The drawing entities are assigned their target surface by their layer name. For example, if polylines representing design contours are on the layer "NEW", then "NEW" will be set as a layer for the design surface. For layers of entities that are for neither existing nor design surfaces (such as text labels for street names), the layer target is set to Other.

The Define Layer Targets dialog has three lists of layers: Existing, Design and Other. To switch between lists, pick the tabs at the top of the dialog. We have already defined the layers for their correct targets. We did this by check on Existing, Design, or Other in the pull-down menu.

Check that your Layer Targets resemble the three lists shown here. If a layer is out of place, highlight it, and hit the "Move To" button after selecting the correct target to send it to. After reviewing, pick Save and Exit.
Now that the layer targets are defined, there are several commands that can be applied. In the Display menu, you can turn on/off whether to display layer targets by using Existing Drawing, Design Drawing and Other Drawing, or by right-clicking with your mouse. For example, when Design Drawing is checked, then picking this menu item will uncheck it and turn off all the layers for the design surface. Likewise, picking Design Drawing when it is unchecked will make it checked and turn on the design surface layers.

Practice turning on/off the Existing, Design and Other Drawing in the Display menu. When only Existing Drawing is on, you should see just the contours. When only Design Drawing is on, you should see just the design polylines...
and leader labels. When only Other Drawing is on, you should see the entities that are assigned to neither existing nor design.

---

**Step 9 (Define Material/SubGrade):**

Besides assigning target surfaces by layer, layers are also used to define material names and subgrade depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface. The polylines used for subgrade depth must be closed polylines. Takeoff supports nested subgrade polylines for exclusion areas such as islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the area is not part of the subgrade.

First, let's confirm the layer names for our subgrades. Go to the Display menu and check on Design Drawing, uncheck Existing Drawing and uncheck Other Drawing. Then run Inquiry->Layer ID and pick the large pad polyline. It reports that this layer is NEW BUILD. Next use Layer ID to pick the curb polyline. It reports that this layer is NEW EDGE ASPH.

Now run Define Layer Target/Material/Subgrade and pick the Design tab. Highlight layer NEW BUILD and pick the Edit button. A dialog appears for defining the pad material properties. Check on the Include In Material Report option, enter the Material Name as "Pad", set the first subgrade name to "Pad", and set the Depth as 1. Once the dialog is filled out as shown, pick OK.
Next pick layer NEW EDGE ASPH and choose Edit. In the Edit Materials dialog, check on Include In Material Report, set the Material Name to "Pavement", set the first subgrade name to "Pavement", and set the Depth to 1.5. Then pick OK.

To save the subgrade changes, pick the Save button on the Define Layer Targets dialog. Then choose Exit.

Now let's visually verify the subgrade areas. In the TakeOff menu, run Subgrade Areas->Hatch Subgrade Areas. There is a dialog to select which subgrade to hatch. Choose the Pavement. Then there is a dialog for the hatch pattern and color. Change the color to green and click OK. Then run Hatch Subgrade Areas again. This time choose
Pad and set the hatch pattern to Hex with blue color. The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. When finished viewing the subgrade areas, run TakeOff- Subgrade Areas Erase Subgrade Hatches.

**Step 10 (Model Existing and Design Surfaces):**

To calculate volumes, Takeoff needs two surfaces: existing ground and design. These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to make the models. To make the existing ground surface, run Tools- Make Existing Ground Surface. The program will process the entities and make the triangulation surface. Then to make the design surface, run Tools- Make Design Surface.

**Step 11 (Cut/Fill Color Map):**

Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as a check that the models are correct. In the Display menu, choose Cut/Fill Color Map. Cut areas are drawn in different shades of red for different depths of cut while fill areas are drawn in blue. To change the resolution of the color blocks, run Display- Display Options and change the Cut/Fill Color Map Subdivisions. This parameter is the number of rows and columns of color blocks to create. You can also draw a legend for the Color Map by going to Draw, Cut/Fill Map Legend. Pick a point on your drawing to locate the legend and press Enter. To turn off the color map, go to the Display menu and pick Cut/Fill Color Map to uncheck it.
Step 12 (Calculate Volumes):

To calculate volumes, run the TakeOff->Calculate Total Volumes command. There is an options dialog for setting the cut swell factor and fill shrink factor. These values get multiplied into the cut/fill volumes. Set these factors as desired and click OK. Then the routine calculates the volumes and display the report which includes the cut/fill volumes and areas. The report can be printed or saved to a file. Pick the Exit button to exit the report viewer.
Step 13 (Material Quantities):

To report the material quantities, run the TakeOff->Material Quantities->Standard Report routine. The report includes the count, length, area and volume for each type of material that was assigned for reporting in the Define Layer Target/Material/Subgrade command. The Material Quantities->Custom Report routine can be used to reporting these values with control of the report format and the option to export to Excel.

Lesson 20: Takeoff Tutorial: PDF Section Import

This lesson imports cross sections from a PDF into Carlson .SCT format. PDF files can contain different types of data. Some PDF's contain linework vectors and others have images. For linework data, the program brings the linework into the drawing. For images, the program can either insert the image into the drawing or run a raster-to-vector conversion process to create linework in the drawing. In this first example, the PDF file contains linework.

To begin, run the Import PDF File command in the Tools->Import/Export menu. This command requires you have the program ghostscript installed. For instructions on installing ghostscript, see the Import PDF File portion of this
The program starts by selecting the PDF file to import. Then there is an options dialog. Turn on the Use Colors, Join Nearest and Reduce Vertices options as shown. Then pick Insert Linework.

Then the program reads the PDF file to determine the number of pages and let's you select the range to import.

Next, the program prompts for a point to place the linework from the PDF into the drawing. Pick a point in a blank area of the drawing. Then enter the rotation angle. In this case, enter 90 for the rotation. Finally, enter the scale. At this point, we don't know the scale. So enter 1 and we will scale later.

Pick point to insert PDF: pick a point
Specify rotation angle <0.0>: 90
Specify scale <1.0>: press Enter

The next step is to scale the drawing to match the scale of the section sheets. From the Edit menu, choose Scale Wizard. Use the Screen Pick option to set the scale factor. This routine prompts to pick two points from the drawing and then enter the correct distance between these two points. Pick two points with a known distance such as two points on the section grid. It's best to pick two points that are far apart to reduce errors with screen picking precision. For this example, pick at offset 0 and at offset 40 on the section grid as shown. Enter the target distance of 40.
In this example, the section lines for the existing and design surfaces have a gap at the center median. In order to have sections for both the left and right sides of the road, these separate section lines need to be connected. Run the Join Nearest command from the Edit menu. Set the max separation to 5 to have enough to span the gap. Fill out the rest of the options as shown. Then pick the existing and design section lines on the left and right sides.
Now that the drawing has the section lines, run Create Sections from Polylines on Section Grids. In the options dialog, set the horizontal and vertical scales to match the section grid. The ratio between horizontal and vertical scales is used to determine the vertical exaggeration. Set the .sct file name for the first section for the existing ground. Turn on the option to create a second section and set the file name for the design surface. Then pick OK.

The program then prompts for the station to create and the grid elevation. Then pick the section grid point at the zero offset and that elevation. Then pick the existing and design surfaces. Repeat this input for the other stations.

Exit/Pick text/<Station <0.00>>: 1880
Pick point at starting elevation and zero offset of section ([Enter] for none): pick the section grid for station 1+880 at offset 0 and elevation 0
Select station 1880.00 1st section polyline: pick the existing ground line
Select station 1880.00 2nd section polyline: pick the design surface line
Exit/Pick text/<Station <1882.00>>: 1900
Pick point at starting elevation and zero offset of section ([Enter] for none): pick the section grid for station 1+900 at offset 0 and elevation 5
Select station 1900.00 1st section polyline: pick the existing ground line
Select station 1900.00 2nd section polyline: pick the design surface line
Exit/Pick text/\(\text{Station} <1902.00>\): E for exit

There are several ways to verify the section data. Use Draw Section File to plot the sections and compare to the original PDF. Use Section Report to print out the station, offset and elevation section data. Use Input-Edit Section File to show a graphic preview of the sections along with a spreadsheet of the values. The dialog here shows the Input-Edit Section file screen for both the existing and design surfaces.

This lesson imports cross sections from a PDF into Carlson .SCT format. PDF files can contain different types of data. Some PDF's contain linework vectors and others have images. For linework data, the program brings the linework into the drawing. For images, the program can either insert the image into the drawing or run a raster-to-vector conversion process to create linework in the drawing. In this first example, the PDF file contains linework.

To begin, run the Import PDF File command in the Tools->Import/Export menu. This command requires you have the program ghostscript installed. For instructions on installing ghostscript, see the Import PDF File portion of this manual. The program starts by selecting the PDF file to import. Then there is an options dialog. Turn on the Use Colors, Join Nearest and Reduce Vertices options as shown. Then pick Insert Linework.
Then the program reads the PDF file to determine the number of pages and let's you select the range to import.

Next, the program prompts for a point to place the linework from the PDF into the drawing. Pick a point in a blank area of the drawing. Then enter the rotation angle. In this case, enter 90 for the rotation. Finally, enter the scale. At this point, we don't know the scale. So enter 1 and we will scale later.

**Pick point to insert PDF:** *pick a point*

**Specify rotation angle <0.0>:** 90

**Specify scale <1.0>:** press Enter

The next step is to scale the drawing to match the scale of the section sheets. From the Edit menu, choose 2D Scale. Use the Screen Pick option to set the scale factor. This routine prompts to pick two points from the drawing and then enter the correct distance between these two points. Pick two points with a known distance such as two points on the section grid. It's best to pick two points that are far apart to reduce errors with screen picking precision. For this example, pick at offset 0 and at offset 40 on the section grid as shown. Enter the target distance of 40.

**Calculate Scale Factor:**

- Drawing distance is 15.730.
- Enter target distance:
  - 40
  - OK
In this example, the section lines for the existing and design surfaces have a gap at the center median. In order to have sections for both the left and right sides of the road, these separate section lines need to be connected. Run the Join Nearest command from the Edit menu. Set the max separation to 5 to have enough to span the gap. Fill out the rest of the options as shown. Then pick the existing and design section lines on the left and right sides.
Now that the drawing has the section lines, run Create Sections from Polylines on Section Grids. In the options dialog, set the horizontal and vertical scales to match the section grid. The ratio between horizontal and vertical scales is used to determine the vertical exaggeration. Set the .sct file name for the first section for the existing ground. Turn on the option to create a second section and set the file name for the design surface. Then pick OK.

The program then prompts for the station to create and the grid elevation. Then pick the section grid point at the zero offset and that elevation. Then pick the existing and design surfaces. Repeat this input for the other stations.

Exit/Pick text/<Station <0.00>>: 1880
Exit/Pick text/<Starting elevation of grid <100.00>>: 0
Pick point at starting elevation and zero offset of section ([Enter] for none): pick the section grid for station 1+880 at offset 0 and elevation 0
Select station 1880.00 1st section polyline: pick the existing ground line
Select station 1880.00 2nd section polyline: pick the design surface line
Exit/Pick text/<Station <1882.00>>: 1900
Exit/Pick text/<Starting elevation of grid <0.00>>: 5
Pick point at starting elevation and zero offset of section ([Enter] for none): pick the section grid for station 1+900 at offset 0 and elevation 5
Select station 1900.00 1st section polyline: pick the existing ground line
Select station 1900.00 2nd section polyline: pick the design surface line
Exit/Pick text/<Station <1902.00>>: E for exit

There are several ways to verify the section data. Use Draw Section File to plot the sections and compare to the original PDF. Use Section Report to print out the station, offset and elevation section data. Use Input-Edit Section File to show a graphic preview of the sections along with a spreadsheet of the values. The dialog here shows the Input-Edit Section file screen for both the existing and design surfaces.
1.2

Chapter 17. Tutorials

3381
Introduction

Carlson Civil Suite encompasses all of the functionality of Survey, Site Grading, Road Design, Hydrology and GIS, along with a comprehensive set of drafting and annotation tools. Carlson Civil Suite runs atop any installed AutoCAD executable, running as plain AutoCAD, or found within Map, Land Desktop or Civil 3D as well as IntelliCAD.

Evolved from the Carlson SurvCADD product line, first introduced in 1989, Carlson Civil Suite introduces several brand new state of the art tools, including a dynamic road design program called Road Network, and a dynamic storm drain design program called HydroNet. While these functions automatically respond to design changes, adjusting sections, profiles, and grading, Carlson Civil Suite accomplishes this automation without introducing custom objects, so sharing drawings with others is not an issue.

Carlson Civil Suite continues the Carlson Software tradition of unlimited free tech support, so when needed, help is always a free phone call away, and also introduces the newest support technology in the form of an online, web-based reference manual, complete with demonstration and training movies.

Data File Types and Storage

Carlson Civil has a similarity to Land Desktop in the use of external files to store design data, but differs significantly in that in Carlson Civil the naming and placement of these files is determined by the user, not the software. Carlson Civil offers three distinct methods of file storage, the choice is up to the end user. Carlson Civil data files can either be placed in a single location, known as a data folder, placed with the drawing they are associated with, or placed in a user-defined folder structure. The placement of files within that structure is also totally user-defined, based on the assignment of file types (extensions) to folders.
File types used by Carlson Civil include:

- .crd - Point data, coordinate file
- .rw5 - raw survey data, contains all observations
- .cl - centerline, describes a 2D alignment
- .tin - Surface, newer format, more efficient than .flt in most cases, especially for machine control
- .flt - Surface, original format
- .grd - Surface grid file, used for volumes
- .cfg - Stores configuration settings
- .fld - Field to Finish file, stores rules for inserting symbols for points (LDT Description Key functionality) and automated linework functionality (Autodesk Survey Figures equivalent)
- .lot - Lot file, stores parcel geometry
- .adf - Annotation Default file
- .pro - Profile file
- .mxs - Section Alignment file
- .grp - Point Group definitions
- .rdn - Roadway Networks
- .sct - Road Sections
Settings

Carlson Civil uses several techniques to store settings. There are three main categories of settings: Drawing Setup settings, such as drawing scale and units, Command-specific settings, such as the layer to draw contours on, and Generic control settings, such as whether to link drawing points to the external coordinate file (.CRD).

Drawing Setup settings are stored directly within the drawing files (.DWG). Carlson Civil also creates a file for each drawing using the drawing name with a (.INI) file extension. This file stores a list of all of the design files that are used or created from within the drawing, such as centerline files (.CL), profile files, (.PRO), etc.

Command-specific settings are stored within a set of files with (.INI) file extensions, with the command name as a filename, such as roadnet.ini, or mapcheck.ini. These are typically stored in the \USER folder, and are created as the commands are first accessed.

Generic control settings are stored within a special (.INI) file named Carlson.ini. When new drawings are created, this file is read to set these type of generic controls.

Drawing Setup settings can be accessed directly from the Settings menu, or through the Configure command. If the Drawing Setup dialog is accessed through the Configure command, when exiting the main Configure dialog, the user is prompted whether to save changes to Current and Future drawings, or Future drawings only. Current and Future saves the Drawing Setup settings to the current drawing internally, and updates the Carlson.ini file, while the choice of Future Only does not affect the current drawing, only the Carlson.ini file, and therefore any new drawings created. To change Drawing Setup settings for only the current drawing, do not go through Configure, but use the Drawing Setup command directly off of the Settings menu.

Command-specific settings are accessed when the commands are actually run. The settings displayed are being read from the command's own specific (.INI) file, and any changes made are written to the same files. This way the commands automatically recall the settings that were used for the previous run. Alternatively, the Configure command can be used to access command-specific settings.

The Configure command provides access to a dialog box with 12 buttons, each leading to settings for specific aspects of the software. Changes made within any of these are also automatically saved to the corresponding command (.INI) file, or to the Carlson.ini file in the case of generic settings. The Configure command also provides a Save and Load functionality, utilizing configuration files (.CFG). Saving a configuration file (.CFG) saves all settings currently stored in all of the command-specific (.INI) files, and the Carlson.ini file. Loading a configuration file (.CFG) sets all settings within all these files.
Survey

The complete range of Survey functionality is contained within the Carlson Civil, and is also available in the Carlson Survey program. This includes communication with data collectors, editing and processing of raw survey data, including traverse adjustment, and Field to Finish, which controls the generation of point symbols and linework.

Land Desktop uses Description Keys for point-based symbol insertion, and Autodesk Survey uses Figure notation for the generation of linework. Autodesk requires field coding to produce linework, and the processing of that information takes place when the raw file (.fbk) is Imported. Carlson inserts symbols and linework with one function.
known as Field to Finish (F2F), and performs this task using the point descriptions from the coordinate file, not the raw observations file. So linework can actually be generated from any set of points, even if no field coding has taken place. However, the addition of field coding can certainly make the generation of linework more precise. Carlson Civil can use LDT Description Key file to start a Field to Finish Code File.

Carlson Civil also has powerful functions to Enter Deeds to draw linework, and a Deed Reader which reads a text file of a deed and extracts the data needed to define and draw the deed in the drawing.
Carlson Civil also has a sidebar COGO function called Visual COGO to enter Traverse, Sideshot and other survey data.
Points and Point Groups

This use of point data in Carlson Civil revolves around the use of .crd files, also known as coordinate files.

Carlson Civil supports the creation of Point Groups similar to LDT and applies them in many applications, such as using them to create surfaces, editing and listing. Carlson Civil stores Point Group definitions are associated individually to each .crd file.
Surfaces and Contours

In Carlson Civil, Surfaces can be written out as external files, but a lot of design and computations involving surfaces can also be accomplished directly within the drawing without writing out external files. Triangulation surfaces can be written out as .tin or .flt and grid surfaces as .grd files. When an external file is generated, a named Surface is also stored in the drawing. This named Surface is accessed through the Surface Manager, where it can be edited.

The main Carlson Civil command for working with Surfaces is called Triangulate and Contour. It is a single dialog box with four tabs, and covers the entire process of specifying the general settings to generate the Surface, creating Contours, generating Labels, and specifying the data source(s) for the Surface.
In Carlson Civil, Contours are generated as regular AutoCAD Polylines. Contours can be generated and automatically labeled simultaneously, or labeled after they are generated. Labels can be generated with wipeouts to hide the contour beneath them, and can also be slid along the contour to easily change their location.

The Triangulation Surface Manager has tools to edit, add and remove data points and breaklines and update the triangulation dynamically. It also allows you to change the display properties for the triangulation, contours and labels.

The TIN Utilities function provides a powerful set of editing tools.
Line and Curve Labeling

Carlson Civil refers to the process of labeling lines and curves as Annotation. Lines and curves can be labeled in a dynamic or static mode, depending on the label settings.

There is also a powerful set of tools to check for and correct overlapping labels.
Volumes

There are several ways to generate volumetric calculations within Carlson Civil. Volumes By Layers, Volumes by Triangulation, Calculate Section Volumes and Two Surface Volumes (Grid volumes).

Volumes by Layers is potentially the quickest method. It needs no existing data files and creates no files in the process. You simply specify which layers to use for each of the 2 surfaces.

Volumes by Triangulation uses two triangulated surface files as the source of the data. These files are created through the Triangulate and Contour command. You can choose to create contours in the drawing when you create the TIN files, or just create the files without generating contours.

Calculate Section Volumes calculates volumes by end areas from two cross section files.

The Two Surface Volumes method uses two predefined Surface files as the data source for the calculations.

Once calculated, you can generate Cut and Fill Color Maps, Cut and Fill Centroids, and Cut and Fill Labels to illustrate the volumes.

Alignments

Horizontal Alignments in Carlson Civil are known as Centerlines. They are stored in .cl files. They can be created and edited through the Input-Edit Centerline File command. Polylines can be drawn first and then used to define Centerlines. Once defined as a centerline, double-clicking on the polyline invokes the Input-Edit dialog box.
Profiles

Profiles are stored within .pro files, with user-defined names. Existing Ground/Surface Profiles and Proposed Finished Grade/Design Profiles both use this filetype. Multiple .pro files can be drawn on the same Profile Grid.

There are several different routines for creating profiles including Profiles From Triangulation Files, Profile From Surface Entities and Profile From Points On Centerline. Before using these profile creation routines, the horizontal alignment needs to be created as a centerline file or polyline. The Quick Profile routine can be used to create profiles in one step.
When using Process Road Design or RoadNet, the existing ground Profile can be generated automatically as part of the process, simply by specifying the Surface to use, and so is not a separate prerequisite. The Proposed Finish Grade Profile can then be added in the editor, and the Roadway processed, all without ever drawing anything in the drawing itself. The more traditional LDT approach of generating an existing ground Profile in the drawing and then adding a proposed finish grade Profile by drawing on it in the drawing is also an option.

**Roadway Cross Sections**

Roadway Cross Sections are based on Cross Section Alignments (.mxs files) that are defined by the Input-Edit Section Alignment command to set the station interval and max offsets left and right. Similar to profile creation, there are several routines to create sections including Sections From Triangulation, Sections From Surface Entities and Sections From Points. The Process Road Design and RoadNet commands can create final sections.

Once section files (.sct) are created, the Input-Edit Section File command allows you to review and edit the section data. Also the Draw Section File and Section Report commands can be used.
Roadway Templates

Roadway Templates are created within the Design Template dialog box. They are stored as .tpl files, and can be applied to any road design. Templates are used in Process Road Design, Road Network and within the Input-Edit Road Profile dialog.

The Design Template defines the road grades, subgrades, curb, superelevation break points and cut/fill slope treatments.
Design Control

The idea of Design Control in LDT exists in Carlson Civil in a number of places.
• Template Control - Templates are assigned to centerlines either in the Process Road Design dialog box, or in the Input-Edit Road Profile dialog.
• Slope Control - In Carlson Civil, side slopes are actually part of the Template definition.
• Ditches - Ditches are defined within the Design Template as part of the cut/fill treatment.

Transitions - There are four methods to work with Transitions in Carlson Civil.

The first is called a Template Series, in which multiple Templates are assigned to a single Centerline at different stations. Next is a Template transition, in which a single Template is assigned to the entire Centerline and the user edits it at different stations. Next is a Template Point Centerline, in which a secondary Centerline is defined and attached to a point on the Template for specific horizontal control, such as a lane widening. Last is a Template Point Profile, in which an additional Profile is defined and attached to a point on the Template for specific vertical control, like the flow line of a ditch.

Superelevations - The template breakpoints for superelevation pivots are defined within Design Template. The stations for the superelevation transitions are set in the Input-Edit Superelevation command.

**Roadway Intersections**

One of the very exciting features of Carlson Civil is the use of Roadway Networks. These are sets of centerlines that are aware of each other and clean up at intersections, horizontally and vertically.
Cul-de-sacs

Cul-de-sacs are handled elegantly with the Road Network. Cul-de-sacs can be easily added to any roadway, and designed at a very detailed level, including a profile for the circumference.
Grading

Carlson Civil includes a variety of tools to accomplish the task of grading, including point commands, 3D polylines commands, contour commands and a grading mechanism known as a Pad Template, which is essentially the equivalent of an LDT Grading Object. Pad Templates provide some significant improvements, however, such as the ability to have a separate surface for the area inside the "pad", which moves horizontally and vertically with edits to the pad, and the ability to use a template for the side slopes, so they can project complex grading designs.

LandXML Data Transfer

Transfer of data between LDT and Carlson Civil can be accomplished in several ways, depending on the type of data in question, but the best overall method is the use of LandXML files.

Pipes

Pipe Profiles can be designed and edited in the Input-Edit Profile dialog, and then drafted in the drawing. In Hydrology, Pipe Networks can be created, which are dynamic and "intelligent", and so automatically respond to design changes.

Lots

Carlson Civil includes a set of tools for lot layout and lot design. Defined lots can be stored in a lot file (.lot). Another way to define a set of Lots automatically is with the Lot by Enclosed Text command, which searches for closed areas with enclosed text, and creates lots out of them, using the enclosed text for the lot name/number. Defined Lots can be accessed and edited through the Lot Editor.
In LDT, as part of drawing setup, a set of text styles is created based on information contained in a file with a .STP file extension, most commonly used is the LEROY.STP. These text styles all have fixed heights assigned to them.
based on the current horizontal scale set in the drawing. If the horizontal scale is changed, the heights of the text styles are all changed.

In Carlson Civil, each of the various commands that involve annotation set the text style to be used and the desired height for the text, using a "scaler", which is multiplied by the current drawing scale. The AutoCAD text style should be set with a height of zero.

**North Rotation**

Carlson Civil does not support the concept of a secondary UCS to define and store North, as is done with LDT North Rotation. Instead, Carlson Civil relies on the use of DVIEW Twist to reorient North, and contains a thorough set of tools to work with that command. Any LDT drawings that are going to be brought into Carlson Civil should first have their LDT Base Point and North Rotation checked. If they are not all zeros, they should all be set to 0, have all points inserted to the drawing, and all linework moved and rotated to the location of the points.

**Drawing Cleanup**

If you're not running Carlson Civil on top of Map, or even if you are, Carlson Civil includes an awesome Drawing Cleanup function to find and resolve a wide range of common drawing problems.
Programming Interfaces
LSP Functions

Overview

Many of the Carlson functions and program environment settings are defined in LSP. These functions and variables are available for you to use in your own LSP routines.

The following is a list of useful functions:

scad_getfiled - file selection dialog

The following is a list of useful variables:

lsppdir$ - Carlson LSP folder where program files are located (string)
tmpdir$ - current project data folder (string)
psname - Carlson Support folder (string)
sv:sm - horizontal scale (real)
sv:vs - vertical scale (real)
sv:ts - text size scaler (real)
sv:ps - symbol size scaler (real)
is_metric - english/metric mode (0=english, 1=metric)
crdfile - current coordinate file (string)

scad_getfiled

Runs a file selection dialog. The function returns a string of the selected file name

Usage: (scad_getfiled title folder extension mode)

title - A string for the dialog title
folder - A string for the initial default folder
extension - A string for the file type extension
mode - An integer for the selection mode (0 = existing file, 1 = new file)

Example: (setq file_name (scad_getfiled ''Pick Surface To Process'' tmpdir$ ''tin'' 0))

Coordinate API

Overview

We have created a Lisp file, CrdAPI.FAS, that contains some simple and easy-to-use functions for accessing, modifying, drawing and selecting any type of coordinate file that Carlson Software supports. The CrdAPI.FAS file is located in the Carlson LSP folder. This collection of functions can help you write your own tools. We call this toolkit the Coordinate File Application Programming Interface, or CRD API.

This document describes the Lisp interface of the CRD API.
Supported Types of Coordinate Files

The following enumerated variables are available for specifying the different types of coordinate files that are supported by the CRD API.

;;; Coordinate File format number

(setq
  enCrdTypeUnrecognized -2 ; file exists but is not a recognized type.
  enCrdInvalid -1 ; not a valid type - used in creating new files.
  enCrdSurvCADDNumeric 0 ; Carlson original; point name is numeric. Extension 'crd'.
  enCrdSurvCADDAlpha 1 ; Carlson sequel; point names can be alphanumeric. Extension 'crd'.
  enCrdMemory 2 ; NOT YET IMPLEMENTED.
  enCrdCgAlpha 3 ; C&G alphanumeric. Extension 'cgc'.
  enCrdCgNumeric 4 ; C&G numeric. Extension 'crd'.
  enCrdSimplicity 5 ; Simplicity 'Sight Survey'. Extension is 'zak'.
  enCrdLDD 6 ; Land Desktop Development. Filename is 'points.mdb'.
  enCrdCivil3D 7 ; Civil 3D; point name is numeric.
  enCrdSQLite 8 ; Carlson SQLite. Extension 'crdb'.
)

Working with Points in Coordinate Files

The following functions are for working with Crd Point structures.

Internally, the Crd Point looks like the following list.

(name desc x y z)

To allow for expansions and changes of the Crd Point in the future, please use only the following Crd Point functions for setting and accessing Crd Points.

CrdPointInit

A Crd Point structure will be returned that can be passed into CrdAddPoint, etc. name and desc must both be strings.

(defun CrdPointInit( x y z name desc)
  (list name desc x y z)
)

CrdPointSetName

Sets the name of the Crd Point structure. The Crd Point is returned.

(defun CrdPointSetName( point name)
  (cons name (cdr point))
)

CrdPointGetName

Gets the name of the Crd Point structure.

(defun CrdPointGetName( point)
  (car point)
)
CrdPointSetDesc
Sets the description of the Crd Point structure. The Crd Point is returned.
(defun CrdPointSetDesc( point desc)
  (cons (car point) (cons desc (cddr point)))
)

CrdPointGetDesc
Gets the description of the Crd Point structure.
(defun CrdPointGetDesc( point)
  (cadr point)
)

CrdPointSetXYZ
Sets the x, y, z values of the Crd Point structure given a list of (x y z). The Crd Point is returned.
(defun CrdPointSetXYZ( point xyz)
  (append (list (car point) (cadr point)) xyz)
)

CrdPointGetXYZ
Gets the x, y, z values of the Crd Point structure as a list of (x y z).
(defun CrdPointGetXYZ( point)
  (cddr point)
)

Working with the Coordinate File

The following functions are for working with coordinate files.

CrdOpen
Opens a coordinate file with the given filename. Only one coordinate file can be open at a time through the Lisp interface. If CrdOpen is called twice, the first crd file is closed automatically.

filename  – The file name of the coordinate file with required extension (.crd, .cgc, .mdb).
bOverwrite – If 1 (integer), then any existing file of the same name will be destroyed. Use nil to select default value which is 0.
crdType  – See enCrdType above. This specifies the type of CRD file to create if the given name does not already exist. Use nil to select the default value which is enCrdSurvCADDAlpha.
Returns 1 (integer) if successful and 0 if there was some kind of failure. Call CrdGetLastError() to get the text message of the error.
(defun CrdOpen( filename bOverwrite crdType)
  (cf:crdapi ''CrdOpen'' filename bOverwrite crdType)
)

CrdClose
Closes the current Crd file, if it is open.
(defun CrdClose()
  (cf:crdapi ''CrdClose'')
)

CrdAddPoint
Adds the given Crd Point to the current open Crd File, overwriting any point with the same name that may already exist. Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to get text message of error.
(defun CrdAddPoint( point)
CrdBegin
Starts a traversal of all the points of the Crd File by resetting internal state so that CrdNext will start from beginning of file.

range – if not nil, then it must be a Carlson-style string of point names suggested by the following examples: "1-5,6,12-19" or "all". If nil, that is the same as all. The points will be returned on successive calls to CrdNext() in the order listed in the range.

(defun CrdBegin( range)
  (cf:crdapi 'CrdBegin'' range)
)

CrdNext
Gets the next point in the Crd File. Returns a Crd Point if successful and nil if there are no more points or some other failure.

(defun CrdNext()
  (cf:crdapi 'CrdNext'))

CrdGetPoint
Gets the named point from the current open Crd File. A Crd Point is returned if successful and nil is returned if the point could not be found. Call CrdGetLastError() to get text message of error.

(defun CrdGetPoint( name)
  (cf:crdapi 'CrdGetPoint'' name)
)

CrdRemovePoint
Removes the named point from the current open Crd File. Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to get text message of error.

(defun CrdRemovePoint( name)
  (cf:crdapi 'CrdRemovePoint'' name)
)

CrdRemovePoints
Removes the given range of points (a string) from the current open Crd File. For example, the range could be "1-5,7,10-12".

(defun CrdRemovePoints( range)
  (cf:crdapi 'CrdRemovePoints'' range)
)

CrdTestPointName
Returns nil if the point name is valid for the current Crd type. Otherwise, returns an error string describing the error.

(defun CrdTestPointName( name)
  (cf:crdapi 'CrdTestPointName'' name)
)

CrdTestPoint
Returns nil if the Crd Point is valid for the current Crd type. Otherwise, returns an error string describing the error.

(defun CrdTestPoint( point)
  (cf:crdapi 'CrdTestPoint'' point)
)

CrdGetLastError
Returns the error string of the result of the last operation.
(defun CrdGetLastError()
  (cf:crdapi 'CrdGetLastError))
}

CrdDeleteFile
Deletes the data file(s) underlying the Crd File and closes the Crd File. May not work if the original filename was
not a full path including drive letter. Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to
get text message of error.
(defun CrdDeleteFile()
  (cf:crdapi 'CrdDeleteFile))
}

GetCrdType
Returns the crd type of the current open Crd File.
(defun GetCrdType()
  (cf:crdapi 'GetCrdType))
}

GetCrdTypeName
Returns the official name of the given crd type.
(defun GetCrdTypeName(enCRDType)
  (cf:crdapi 'GetCrdTypeName enCRDType))
)

CrdDraw
Accepts an argument list to indicate a set of points to be drawn, which at a minimum takes the form '(['Points'
' '<points designator>']].
(defun CrdDraw(arglist)
  (eval (append '(cf:crdapi 'CrdDraw') arglist)))
)

The syntax for additional optional parameters which may be included in arglist (indicated by "[]") is as fol-
llows:
(CrdDraw '(''Points' ' '<points designator>''
[''SymbolName' ' '<symbol block name>''
[''SymbolXScale' ' '<X scale>]
[''SymbolYScale' ' '<Y scale>]
[''SymbolRotation' ' '<symbol rotation in AUNITS>''
[''SymbolLayer' ' '<symbol layer name>''
[''BlockName' ' '<attribute block name>''
[''BlockXScale' ' '<X scale>]
[''BlockYScale' ' '<Y scale>]
[''BlockRotation' ' '<attribute block rotation in AUNITS>''
[''BlockNameLayer' ' '<layer for point name>''
[''BlockElevationLayer' ' '<layer for point elevation>''
[''BlockDescriptionLayer' ' '<layer for point description>''
[''PointLayer' ' '<layer for POINT>''])
)

CrdSelect
Accepts an argument list to indicate a set of points to be selected, which at a minimum takes the form nil to select
all points.
The syntax for additional optional parameters which may be included in arglist (indicated by "[]") is as follows:

(CrdSelect '( ; Select all points in drawing
[''Points'' ''<points designator>'']) ; Select all points in <point
designator>
[''Prompt'' ''<prompt for points>'']) ; Interactive (spatial) select points in drawing
[''P0'' point ''P1'' point] ; Select all points in window having corners P0,P1
)

Note that all optional parameters within "[]" are mutually exclusive. The function returns the selected points as a list of points, each of which is itself a sublist indicating the point identifier and its associated drawing entity name.

Example Code

;;;; Examples on how to use.
(CrdOpen "junk2.crd" nil nil)
(princ (strcat "Created a file of type: " (GetCrdTypeName (GetCrdType)) "\n"))

; create a couple of points in memory.
; This first point is at coordinate 100,101,10.5 and has the point name
; of 1012 and the description of IP.
(setq point1 (CrdPointInit 100 101 10.5 ''1012'' ''IP''))
(setq point2 point1)
(setq point2 (CrdPointSetXYZ point2 '(105 101 10.5)))
(setq point2 (CrdPointSetName point2 ''3''))
(setq point3 (CrdPointSetName point2 ''7''))

; adding a point and checking for errors.
(setq bSuccess (CrdAddPoint point1))
(if (= bSuccess 0)
(princ (strcat "Error on point " (CrdPointGetName point1) ": "
(CrdGetLastError)) "\n")

; adding points without checking for errors.
(CrdAddPoint point2)
(CrdAddPoint point3)

; now print out the points 1 through 5
(princ "Listing the point names.\n")
(CrdBegin "1-5") ; nil or "all" would select all the points.
(while (setq point (CrdNext))
(princ (strcat (CrdPointGetName point) " " (CrdPointGetDesc point) "\n"))
)
;
; Drawing points.
; Draw all points in the drawing using defaults. Argument list '<<Points''
'"'<points designator>'') is required as a minimum.
(CrdDraw '<<Points'' 'ALL''))

; Syntax for additional optional parameters indicated by '[]' is as follows:
; (CrdDraw '<<Points'' '<points designator>'
; ["SymbolName'' '<symbol block name>'"
; ["SymbolXScale' <X scale>
; ["SymbolYScale' <Y scale>
; ["SymbolRotation'' '<symbol rotation in AUNITS>'"
; ["SymbolLayer'' '<symbol layer name>'"
; ["BlockName'' '<attribute block name>'"
; ["BlockXScale' <X scale>
; ["BlockYScale' <Y scale>
; ["BlockRotation'' '<attribute block rotation in AUNITS>'"
; ["BlockNameLayer'' '<layer for point name>'"
; ["BlockElevationLayer'' '<layer for point elevation>'"
; ["BlockDescriptionLayer'' '<layer for point description>'"
; ["PointLayer'' '<layer for POINT>''])

; Selecting points.
; Select all points in the drawing
(CrdSelect nil)

; Select all points in window
(CrdSelect '<<P0'' (setq p0 (getpoint 'First Corner: ')) 'P1'
(getcorner p0 'Opposite corner: '))

; Syntax for additional optional parameters indicated by '[]' is as follows.
; (CrdSelect '<<Points'' '<points designator>'') ; Select all points in
<point designator>
["Prompt'' '<prompt for points>'"] ; Interactive (spatial) select points
in drawing
["P0'' point 'P1'' point] ; Select all points in window
; All parameters within [] are optional and are mutually exclusive.

(CrdDeleteFile) ;the only proper way to delete the file(s). C&G uses two
files, for example.
(CrdClose) ;not necessary because of CrdDeleteFile, but doesn't hurt.
(princ ''---the end---\n'')

**DTM API**

**Overview**

A lot of functionality of Carlson triangulation and TIN file manipulation is now available from LISP for the advanced users to use in their routines. This part of the Carlson interface is called DTM API.

API supports the older FLT file format, which stores only edge information, and the new TIN format, which is a binary format containing all the structure of triangulation and therefore is faster to load and takes less space.
The file extension controls which file type is being created.

The functionality of DTM API is implemented in TRI4.ARX. It would be the responsibility of the caller to make sure that this file gets loaded by adding this line at the beginning:

```
(scload (strcat lspdir$ ''tri4''))
```

The ARX should never be unloaded by the caller.

The following is a list of currently supported functions (it can be obtained at any time by calling `(cf:dtm_api)`:

- **create_tin** - create a TIN from selection set
- **draw_tin** - draws a TIN as 3DFACEs;
- **tri_volume** - produce volume report from 1 or 2 TINs
- **tri_change** - modify tin using inc/exc and operators
- **tri_contour** - contour tin using inc/exc and ini file with settings
- **tri_profile** - creates a profile of the TIN along a centerline
- **tri_diff** - produce a difference TIN from two TINs
- **tin_combine** - produce a combined TIN performing a specified operation to elevation
- **tri_store_regions** - create and store TIN difference
- **tri_apply_region** - apply a specific region revision
- **tri_forget_region** - forget all region revisions
- **surface_util** - routines for tin surface manager
- **load_tin** - loads TIN into memory for tin_z function
- **unload_tin** - unloads the current TIN from memory
- **tin_z** - returns the z at the specified x,y for the current TIN set by load_tin

### create_tin

Creates TIN from a given selection set, optionally using inside/outside logic.

**Usage:**

```
(cf:dtm_api 'create_tin' entities_ss inclusion_ss exclusion_ss regions_ss file_name options)
```

- **entities_ss** - Selection set of all entities to be used for triangulation. Currently supported are point, line, arc, polyline, insert, circle, 3Dface, solids, text, and mtext.
- **inclusion_ss** - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.
- **exclusion_ss** - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.
- **regions_ss** - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).
- **file_name** - Full path of file to be created. Extension controls a type of TIN file created.
- **options** - Optional. String containing one or more of the following keywords, space separated:
  - **ignore_zero** - Ignore zero elevation data points.
  - **view_error_log** - In case of warnings during triangulation, bring up the report at the end.
  - **densify** - Perform ridge/valley detection and improve triangulation as needed.

### draw_tin

Draws TIN file at a given layer as 3DFACEs.
Usage: \texttt{(cf:dtm\_api 'draw\_tin' file\_name layer\_name is\_road)}

\textit{file\_name} - Full path of file to be loaded.
\textit{layer\_name} - Layer name to use. If does not yet exist, new layer will be created. Color of entities is set to \texttt{BYLAYER}.
\textit{is\_road} - Optional. If set to 1 and route follows completion of Process Road Design feature it will turn on road coloring.

\textbf{tri\_volume}

Calculates volume of the TIN within a given polyline, optionally with report generated.

Usage: \texttt{(cf:dtm\_api 'tri\_volume' inclusion\_ss exclusion\_ss regions\_ss filename filename2|elevation is\_report is\_silent)}

Return values: If successful, the function returns a list with 4 real values: cut, fill, cut area, and fill area. The volume is in cubic ft or meters and area is in square ft or meters, depending on the configuration.

\textit{inclusion\_ss} - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.
\textit{exclusion\_ss} - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.
\textit{regions\_ss} - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).
\textit{filename} - Full path of main TIN file to be used.
\textit{filename2} - Full path of secondary TIN file to be used. If used, two surface volumes will be calculated between the first and second TINs.
\textit{elevation} - Reference elevation passed as real value. If this option is used, one surface volume will be calculated between the first TIN and this reference elevation.
\textit{is\_report} - 0/1. Specifies whether to bring up the report with calculation results.
\textit{is\_silent} - 0/1. If 0 value is supplied the routine will provide no output at the command line and no progress indicators.

\textbf{tri\_change}

Change TIN file using specified optional inclusion polylines and using one of the possible math operations. For all operations but "embed" the inclusion/exclusion polylines are offset a 0.1 so that a reasonably sharp wall could be produced by modifications.

Usage: \texttt{(cf:dtm\_api 'tri\_change' inclusion\_ss exclusion\_ss regions\_ss filename operation value)}

\textit{inclusion\_ss} - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.
\textit{exclusion\_ss} - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.
\textit{regions\_ss} - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).
\textit{filename} - Full path of main TIN file to be modified.
\textit{operation} - keywords describing what operation is to be performed on the TIN:
add - Add a value to elevation of inside nodes.
scale - Scale elevation of inside nodes by the value.
set - Set elevation of inside nodes to the value specified.
perp - Sets elevation of nodes as if TIN is offset by value along normal at the point. The node is not moved horizontally, just elevation is adjusted.
nil - Removes inside nodes. No value is needed.
embed - No change of elevations, but the inclusion polyline is still added to TIN.

**tri_contour**

Contours TIN file as defined by INI file and inclusion polylines

**Usage:**

```scheme
(cf:dtm_api '"tri_contour"' inclusion_ss exclusion_ss regions_ss tin_filename ini_filename)
```

- `inclusion_ss` - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.
- `exclusion_ss` - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.
- `regions_ss` - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).
- `tin_filename` - Full path of main TIN file to be used.
- `ini_filename` - Full path of INI file defining how contouring is performed. For list of values, check tri4.ini in USER folder which stores values used in Triangulate and Contour function.

**tri_profile**

Creates a profile of the TIN along a centerline

**Usage:**

```scheme
(cf:dtm_api '"tri_profile"' tin_filename cl_filename pro_filename)
```

**Return values:** If successful, the function returns 1, otherwise nil.

- `tin_filename` - Full path of main TIN file to be used.
- `cl_filename` - Full path of centerline (.cl) file to be used.
- `pro_filename` - Full path of the profile file to be created.

**tri_diff**

Calculates difference between two TIN files and creates combined TIN with elevation being the difference of elevations. TINs do not have to match perfectly - face intersections will be performed. Inclusion logic will be applied if needed.

**Usage:**

```scheme
(cf:dtm_api '"tri_diff"' inclusion_ss exclusion_ss regions_ss filename1 filename2 diff_filename)
```

- `inclusion_ss` - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.
- `exclusion_ss` - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.
regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename1, filename2 - Full path to TIN files to be used. Second TIN is subtracted from first one.

diff_filename - Full path of differential TIN file to be created.

**tin_combine**

Combines two TINs into one while applying one of the specified operations. First two TINs are combined into one intersecting all faces which need to be intersected and then elevations are assigned as specified.

Usage: 

```lisp
(cf:dtm_api "tin_combine" inclusion_ss exclusion_ss regions_ss filename1 filename2 merged_filename operation)
```

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename1, filename2 - Full path to TIN files to be used.

merged_filename - Full path to the file where results are stored.

operation - Keywords describing the operation to perform. The following operations are supported:

keep - The elevations of first TIN are used.

copy - Elevations of second TIN are used.

min - Lesser of two elevations is used.

max - Greater of two elevations is used.

join - Points inside are given elevations of first TIN, outside - second one.

**tri_store_regions**

Evaluates "before" and "after" TIN and stores "affected" area as a region with two revisions "0" and "1". The regions then can be applied as needed using other commands. This functionality only works with binary .TIN files.

Usage: 

```lisp
(cf:dtm_api "tri_store_regions" filename1 filename2 mark_name filename3)
```

filename1, filename2 - Full path to TIN files to be used.

mark_name - String label for region to be used.

filename3 - Full path to TIN files to be Save As. If omitted, the file specified by filename1 will be replaced with resulting file.

**tri_apply_region**

Applies a specific pre-stored region revision, so that when TIN file is used it has that revision of the region in use.

Usage: 

```lisp
(cf:dtm_api "tri_apply_region" filename mark_name revision)
```

filename1 - Full path to TIN file to be modified.

mark_name - String label for region to be used.
**revision** - Integer. Optional ID of revision to apply. If omitted, the latest revision of the region is used.

### tri_forget_region

Removes any knowledge of a specific pre-stored region revision from TIN file. Optionally remove triangles found in the region from the TIN.

Usage: `(cf:dtm_api 'tri_forget_region' filename mark_name remove_first)`

- **filename** - Full path to TIN file to be modified.
- **mark_name** - String label for region to be used.
- **remove_first** - 0/1. Optional flag indicating whether region triangles should be removed, leaving a hole in the TIN.

### surface_util

Utilities for dealing with surfaces stored in the drawing.

Usage: `(cf:dtm_api 'surface_util' filename operation)`

- **filename** - Full path to TIN file to be modified.
- **operation** - Keywords describing the operation to perform. The following operations are supported:
  - **check** - Check if TIN is used in one of the surfaces. Returns 0 or 1 depending on outcome.
  - **process** - Apply current surface parameters to TIN file. This function should be used to update surface in the drawing after TIN has been modified.

### load_tin

Loads a TIN into memory for use with the tin_z function.

Usage: `(cf:dtm_api 'load_tin' file_name)`

- **file_name** - Full path of file to be loaded.

### unload_tin

Unloads the current TIN from memory.

Usage: `(cf:dtm_api 'unload_tin'`)

### tin_z

Calculates the elevation of the TIN at the specified x,y location. The TIN to process must be already loaded by the load_tin command. The calculated elevation is returned to LSP on success. A nil is returned to LSP if the command arguments are invalid, a TIN is not loaded or the point is off the surface.

Usage: `(setq elev (cf:dtm_api 'tin_z' point))`

- **point** - List of doubles in x,y format
Examples:

Calculate TIN Elevation at Point

(scload (strcat lspdir$ "tri4"))
(setq file_name (scad_getfiled "Select TIN to Process" "" "tin" 0))
(cf:dtm_api "load_tin" file_name)
(setq pnt (getpoint "\nPick point:"))
(setq elev (cf:dtm_api "tin_z" pnt))
(cf:dtm_api "unload_tin")

Road API

Overview

The Road API is a collection of functions for centerline location and road design calculations. These functions are available from LISP for advanced users to use in their own routines.

The functionality of Road API is implemented in the Carlson EWORKS.ARX program file. This ARX program file must be loaded before calling the Road API functions. Use the following LSP code to load the ARX:

(scload (strcat lspdir$ 'eworks'))

The following is a list of currently supported functions (it can be obtained at any time by calling (cf:road_api):

cl_location_at_pt - calculates the station-offset and centerline position from a specified centerline and point
cl_location_at_sta - calculates the point and vectors for a specified station on a centerline
cl_sta_range - returns the stat and end stations for the specified centerline
profile_z - calculates the profile elevation for the specified station on the profile
profile_sta_range - returns the start and end station for the specified profile
road_z - calculates the road design elevation for the specified point and design files

cl_location_at_pt

Given a centerline file name and a point, this function calculates the station-offset and the projected location of the point along the centerline. On success, the function returns a list of the station, offset and projected centerline point. On failure, the function returns nil.

Usage: (cf:road_api "'cl_location_at_pt'" file_name point is_rr)

file_name - Full path of the centerline file to process (string).
point - Coordinates (x,y) of the point to process (list of reals).
is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

cl_location_at_sta

Given a centerline file name and a station, this function calculates the point on the centerline at the specified station along with the vectors for the tangent and normal of the centerline at that station. On success, the function returns a
list of the point on centerline, the tangent vector and the normal vector. On failure, the function returns nil.

Usage: `(cf:road_api ''cl_location_at_sta'' file_name station is_rr)`

file_name - Full path of the centerline file to process (string).
station - Target station to process (real).
is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

c_l_s_t_a_ r_a_n_g_e

This function simply return the starting and ending stations for the specified centerline. On success, the function returns a list of the starting station and the ending station as reals. On failure, the function returns nil.

Usage: `(cf:road_api ''cl_sta_range'' file_name is_rr)`

file_name - Full path of the centerline file to process (string).
is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

p_r_o_f_i_l_e_z

Given a profile file name and a station, this function calculates the elevation on the profile at the specified station. On success, the function returns the elevation. On failure, the function returns nil.

Usage: `(cf:road_api ''profile_z'' file_name station)`

file_name - Full path of the profile file to process (string).
station - Target station on profile (real).

p_r_o_f_i_l_e_s_t_a_ r_a_n_g_e

This function simply returns the starting and ending stations for the specified profile. On success, the function returns a list of the starting and ending stations as reals. On failure, the function returns nil.

Usage: `(cf:road_api ''profile_sta_range'' file_name)`

file_name - Full path of the profile file to process (string).

r_o_a_d_z

This function calculates elevation of a road design at the specified point. The road design is defined by the design files names. The centerline, profile and template files are required. The other design files are optional. On success, the function returns the elevation. On failure, the function returns nil.

Usage: `(cf:road_api ''road_z'' point cl_file pro_file tpl_file sup_file tpt_file tpc_file tpp_file)`
point - Coordinates (x,y) of the point to process (list of reals).
cl_file - Full path of the centerline file (string).
pro_file - Full path of the profile file (string).
tpl_file - Full path of the template file (string).
sup_file - Full path of the superelevation file (string).
tpt_file - Full path of the template transition file (string).
tpc_file - Full path of the template point centerline file (string).
tpp_file - Full path of the template point profile file (string).

3D Viewer API

Overview

It is now possible to call 3d viewer from LISP for the advanced users to use in their routines.

The functionality of 3D Viewer API is implemented in CUBE.ARX. It would be the responsibility of the caller to make sure that this file gets loaded by adding this line at the beginning:

```lisp
(scload (strcat lspdir$ ''cube''))
```

Displaying a selection set of entities

Prompts the user for a selection set and displays it in a 3d viewer window

Usage: `(cf:sc3dview)

Loading a surface file into 3D viewer

Loads the surface given as grid (.GRD) or triangulation (.FLT or .TIN) file.

Usage: `(cf:sc3dview file_name)
