This command converts the strata data in coal sections into drillhole format. Coal sections are created in the Works pull-down menu of the Standard Mining Module and consist of strata names with thicknesses. Drillholes consist of a surface elevation and strata with top and bottom elevations. Since coal sections contain no real world elevation, the program needs two elevations to assign Z values to make the drillholes. The two elevations are the surface elevation and the top of section elevation. These elevations can be entered for each drillhole or calculated from a surface model defined in a grid file. The top of section elevation represents the top elevation of the first strata in the section. The top and bottom strata elevations for the drillhole are calculated using the top of section elevation and the thicknesses.

The program also prompts for the strata names to use in the drillhole in case the drillhole names differ from the coal sections names. For example, consider this coal section:

C-7
R-3
C-54

In order to avoid duplicate strata names in the drillholes, the two coal section strata named *C* could be named *Coal 1* and *Coal 2* for the drillholes.

Prompts

Drillhole Configuration File Dialog

Choose a drillhole configuration file (*.ch).

Coal Section Configuration File Dialog

Choose a coal section configuration file (*.sc).

Select coal sections.

Select objects: *pick coal section symbols*

Select Surface Grid

Optionally choose a grid file that models the surface elevation. The drillhole surface elevation will be derived from this grid file. Choose Cancel if there is no surface grid and the program will prompt for the surface elevations.

Select Top of Section Grid

Optionally choose a grid file that models the elevation of the top of the first strata in the coal section. Choose Cancel if there is no top of strata grid and the program will prompt for the coal section elevations.

Enter strata name for section coal <COAL>: *press Enter*

Is strata COAL key or non-key (<Non-key>/Key)? *Key*

Enter strata name for section rock <ROCK>: *press Enter*

Enter DrillHole name: *15-A*

Enter DrillHole description: *press Enter*

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: chconvert

Reassign Database File

This command will prompt for the new database file that contains the geologic data of the drillholes on screen.

Prompts

Select the Drillholes to reassign database file.

Select objects: Specify opposite corner: 216 found

Select objects:

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: chsetmdb

Audit Database File

This command will prompt for the database file to audit. The audit removes strata records that reference a drillhole that doesn't exist and removes attribute records that reference a strata that doesn't exist.

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: audit_cdb

Convert Drillholes to External Database/Convert Drillholes to Drawing Data

These commands perform a quick and easy two-way conversion from/to internal (DWG) or external (MDB) storage of drillhole data. This is used in converting the drillholes from one format to another. Before running either of these commands, the desired setting whether to use the external database or not must be set in the current drillhole configuration file (*.ch). There are no prompts, just processing time. Verify the conversion with an Edit Drillhole. The method of storage is listed on the screen.

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: chpts

Export Drillholes

This command exports drillhole data to one of three formats: Simple, Full, and Custom. The Simple export contains minimal data about the drillholes, while the full report contains all drillhole data (both will be written to a .txt or .csv file). The custom option will allow you to choose which drillhole data to export. For more information regarding the Custom option, see the Custom Drillhole Report command.

Prompts

Choose text file to create

Drillhole export file format (Simple/<Complete>)? *press Enter*

Select the Drillholes to export.

Select objects: *pick the drillholes*

Writing file c:\drawings\data\drillhole.txt

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: chexport

Drillholes to Points

This command creates points in the current coordinate file (.CRD) for the strata data from the selected drillholes. The current coordinate file can be set with the Set Coordinate File command under Points. The x,y position for the point comes from the drillhole position. The z value can be the strata elevation, thickness or attribute. The points can be drawn on the screen in addition to being stored to the CRD file. There is an option to create composite values from multiple strata. The drillhole name can be used as the point number or the description of the points. If the drillhole is not used as the point description, then there is a prompt to specify the point descriptions.

Prompts

Select drillholes and strata elevation polylines.

Select objects: *pick the drillholes*

Plot the points (<Yes>/No)? *N for No*

Create composite points (Yes/<No>)? *press Enter for No*

Use drillhole names for [Point#/Desc/<None>]? *press Enter for None*

Choose a Strata to Process dialog

Choose Value to Process dialog

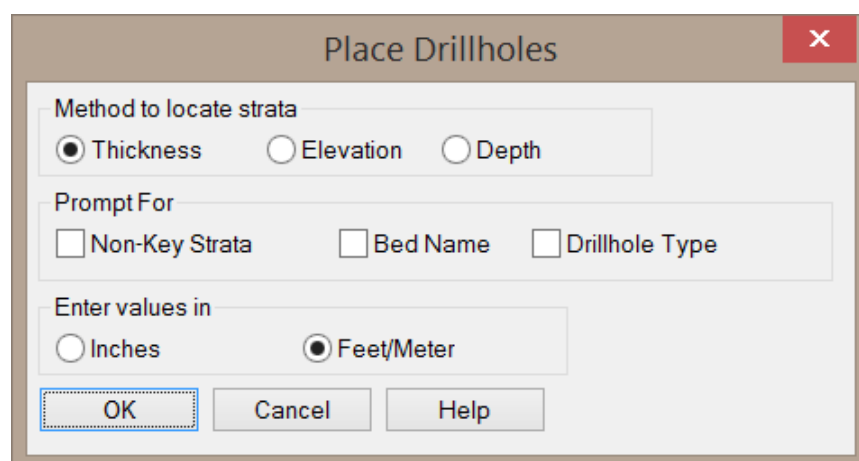

Description for points <C2_KEY_BTU>: *press Enter*

Pulldown Menu Location: Drillhole

Keyboard Command: chpts

Place Drillholes

This command generates drillholes in the drawing one at a time with a series of command line prompts. If the drillhole data is available in digital format, it is quicker to import the information with the Drillhole Import command. When the command is executed, the below dialog will appear.

Method to Locate Strata: This option determines which prompt you will receive to define the limits of each strata.

Prompt for: When these options are enabled, you will receive additional prompts when entering drillhole information.

Non-Key Strata: When this option is disabled, you will be prompted to enter information only for key strata. In this scenario, you will be prompted to enter the thickness and bottom depth/elevation of the key strata, with non-key strata filling in the gaps between the key strata. The non-key strata will be named automatically. For example, a key strata named "Strata A" will be overlain by a non-key strata named "Strata A.OB". When this option is enabled, you will be prompted to enter information for both key and non-key strata, and you will be able to assign a specific name to the non-key layers.

Bed Name: When this option is enabled, you will be prompted to enter a Bed Name for each strata. Bed names are used to group strata together.

Drillhole Type: When this option is enabled, you will be prompted to set a drillhole type. This controls appearance of the drillhole symbol, which can be configured in the Define Lookup Database command.

Enter Values in: This option sets the units of the length values being entered.

After clicking **OB**, you will receive a series of command line prompt. You will first specify the X and Y location of the drillhole followed by the surface elevation and drillhole description. If drillhole definition includes additional descriptions you will be prompted for values, these values are optional, so you may press Enter to continue. After entering this drillhole header information, a loop for entering the strata from top to bottom begins. If an undefined strata name is entered, there is an option to define that strata from there (see Define Strata for more on strata definitions). When all the strata are entered, press Enter to exit the loop. This draws the drillhole in the drawing as an INSERT entity in the current DRILLHOLE layer with all the data attached. From there, another drillhole can be entered or the routine can be exited by pressing Enter. At any time in this routine, entering 'Undo' backs up the prompting sequence.

Prompts

File Selection Dialog

Choose a drillhole configuration file.

Enter or Pick Drillhole x,y location (Enter to End): 5000,5000

Enter Drillhole surface elevation ('U' to Undo): 890.3

Enter Drillhole description ('Undo' to Undo): CH-11 This field is optional.

From here begins a loop to enter the strata in top to bottom order.

Enter strata name (Enter to End, 'Undo' to Undo): OV

Strata OV is a Non-Key strata. OV was found in the strata definitions as a Non-Key strata.

Enter bottom elevation of OV ('U' to Undo): 883.7

Now enter the Non-Key attribute values for the attributes defined by Define Drillhole.

Enter value for OV attribute ACID ('U' to Undo): 1

Enter value for OV attribute BASE ('U' to Undo): 2

Enter strata name (Enter to End, 'Undo' to Undo): C

Strata C is undefined? Define now (<Yes>/No)? No Defining strata C is optional.

Is C a Key or Non-Key strata (Key/<Non-Key>/Undo)? Key All must be set as either Key or Non-Key.

Enter bottom elevation of C ('U' to Undo): 879.7

Now enter the Key attribute values.

Enter value for C attribute BTU ('U' to Undo): 10000

Enter strata name (Enter to End, 'Undo' to Undo): *press Enter* if C is the last strata in the drillhole. Otherwise enter the next strata name.

Enter or Pick Drillhole x,y location (Enter to End): *press Enter to exit* Or specify another location for the next drillhole.

Pulldown Menu Location: Drillhole

Keyboard Command: chplace

Spot Drillholes

This command creates drillholes from existing drillholes and surface entities or from a predefined Geologic Model file. You supply the x,y coordinate for the new drillhole and the routine will calculate the surface elevation and the strata elevations and attribute values based on the other drillholes and surface entities or the grids in the Geologic Model. This feature is useful for providing drillers with an estimate of the geologic column drilling exploration holes.

Prompts

Keyboard Command: chspot

Edit Drillhole

Edit Drillhole is a dialog based editor for viewing and editing drillhole data one hole at a time. The Edit Drillhole dialog lists the strata/bed layers, drillhole header information, and a graphical representation of the drillhole itself. The main dialog is shown below.

Each strata layer in the hole is listed as a separate row in the main table. These strata layers, along with the graphical representation of the hole, are color-coded according to the current strata definition file (from Drillhole Pulldown Menu > Define Strata) by default, but may also be colored according to a grade parameters file (from Block Model Pulldown Menu > Define Grade Parameters) by clicking the **Color Strata By** pulldown menu. When the Color Strata By option is set to 'Grade', you will be prompted for a Grade Parameters File, after which the strata layers will be colored according to the grade set in that file. An example is shown below, wherein the strata layers are colored according to their concentration of calcium oxide.

Strata Name	Depth	Bottom Elv	Thickness	Key	Bed Name	Qual	Edited
1 OVERBURDEN	1.00	1543.57	1.00	<input type="checkbox"/>	OB	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Color Strata By Grade

Selecting multiple strata in the list (by clicking and dragging in the list or by holding CTRL while clicking strata) will display a summary of the selected strata in blue text below the list, as shown in the above image.

To edit a strata, highlight the strata in the list, and then click the **Edit** button, or simply double-click the strata in the list. Edits may also be made by single-clicking a value and typing in the new value. Note that when a strata or quality is manually edited, the **Edited** checkbox will be checked.

To insert new strata, highlight the strata below the desired location and click the **Insert Above** button.

To add a new strata to the end of the list click the **Append to Bottom** button.

Strata are removed by highlighting the strata and clicking the **Remove** button.

The **Adjustment Method** controls how strata will react to a change in thickness, elevation, or depth of another strata. If the **Adjust Bottom Elevations** option is selected, the thickness of all strata will be held constant as the change is applied. For example, if the thickness of the strata layer in row 1 is changed from 1 to 5, then the thicknesses of all strata below it will be held constant while the bottom elevation of each will decrease by 4. If the **Adjust Next Thickness** option is selected, elevations will be held constant while the thickness of the next strata is adjusted. For example, if the thickness of the strata layer in row 1 is changed from 1 to 5, then the thickness of the strata layer in row 2 will change from 9 to 5; no other strata layers will be affected.

When Strata are edited or added, the Edit Strata dialog appears as shown below. This dialog allows editing of information specific to the selected strata layer.

	Name	Value
1	CAO	30.750
2	MGD	21.470
3	SID2	0.084
4	AL2O3	0.033
5	FE2O3	0.056
6	S	0.008
7		
8		
9		
10		
11		
12		
13		
14		
15		
16		

The left side of the Edit Strata dialog lists all strata in the hole. Selecting one of the strata from this list will allow you to edit that strata. The fields at the top of this dialog include the Strata Name, Bed Name, Strata Thickness, Bottom Elevation of the Strata, the Depth to the bottom elevation of the strata from the top of the hole, and the strata's key status (key or non-key). Each of these fields may be edited.

The **Select** button next to the Strata Name will allow you to assign the name by picking from a list of names the Strata Definition File. Similarly, the **Select** button next to the Bed Name field will let you select the bed name from the Bed Names Table in the Lookup Database file.

The table shown on this dialog lists all attributes specific to the selected strata. Attributes and their corresponding values may be entered/edited by simply clicking the field and typing.

The **Return** button will save any changes made to the strata and return to the main Edit Strata dialog.

The list of attributes may be sorted by clicking the Name or Value header at the top of the spreadsheet.

The right side of the Edit Drillhole dialog shows a graphical representation of the drillhole. Each strata layer will be colored according to the option selected in the **Color Strata By** pulldown menu. Hovering the mouse cursor over any strata layer will display the depth to the bottom of that strata layer from the top of the hole.

The window showing the graphical representation of the drillhole allows for zooming and panning to more easily inspect strata layers. Panning is done by holding down the mouse wheel while moving the mouse. Zooming is done by scrolling the mouse wheel, or by using the **Zoom In**, **Zoom Out**, or **Zoom Extents** buttons.

The Drillhole Header information is listed in the bottom half of the Edit Drillhole dialog. This includes the drillhole description, name, northing coordinate, easting coordinate, processing status, surface elevation, drillhole type, X-Y quality, Z quality, density, and drillhole attribute fields.

Above the drillhole header information is the drillhole **Source**. If the drillhole information is stored in the drawing itself (as is most common), the source will be 'Current Drawing with EED (Extended Entity Data) Data'. If the drillhole information is stored in an external database, the database directory will be listed as the source. Any changes made to the drillhole will update the EED/database after clicking **Save**.

The **Description** is a simple description of the hole for notes, comments, etc.

The **Name** is the drillhole identifier.

The **Processing ON** checkbox determines if the hole is used when making Strata Grid Files. If this box is unchecked, the drillhole information will not be used to make Strata Grid Files.

The **Northing** and **Easting** list the Y and X coordinates of the drillhole, respectively.

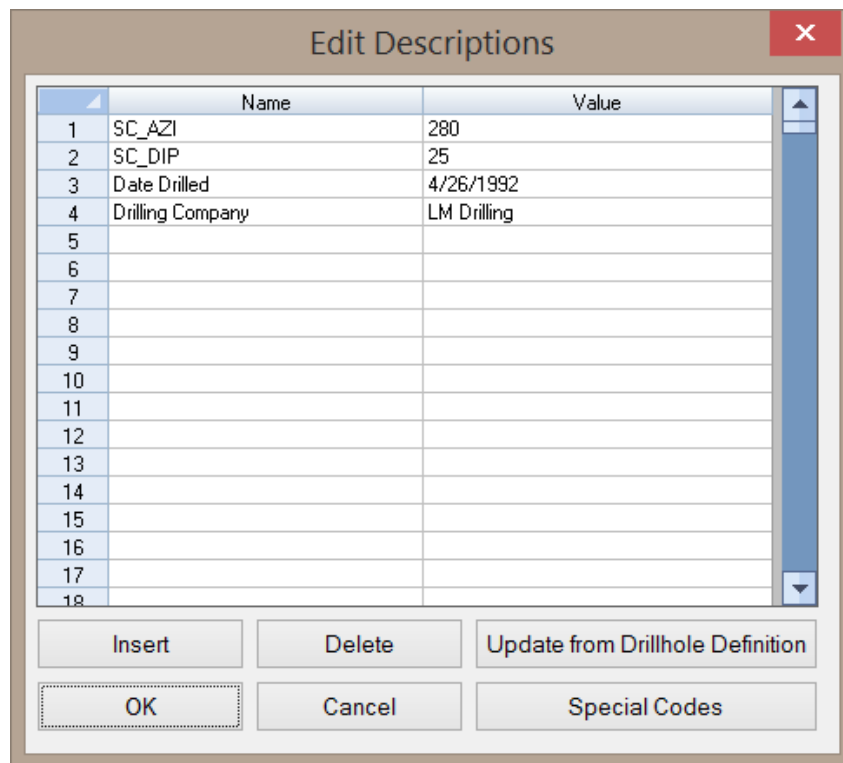

The **Surface Elevation** lists the elevation at the top of the hole. The **Set** button next to this field will set the hole elevation according to a .grd or .tin surface file.

The **Drillhole Type** will change the appearance of the hole according to the settings in the Drillhole Lookup Database command. These settings determine the drillhole, layer, symbol, color, etc.

The **X-Y Quality** and **Z Quality** are simple notes that tell how the drillhole X-Y coordinates and surface elevation were measured, respectively. Default options include Unknown, Total Station, GPS, USGS Quad, Picked off Map, and Tape Measured. Additional options may be added via the Drillhole Lookup Database command.

The **Density** sets the default density for strata in either lbs/ft³ or kg/m³ depending on the unit system selected under Settings Pulldown Menu > Drawing Setup. Note that density may be applied to individual strata/beds as user-defined attribute.

The **Attribute Fields** section lists attributes that apply to the drillhole itself rather than to specific strata, such as date drilled, driller's name, etc. Clicking the **Edit Attributes** button will open a new dialog, as shown below.

This dialog allows you to type in custom attributes that apply to the entire drillhole. Rows may be inserted or deleted with the **Insert** and **Delete** buttons. The **Update from Drillhole Definition** button will add any attributes listed in the drillhole definition file (from Drillhole Pulldown Menu > Define Drillhole).

Four optional, special attributes are also available, and may be set by clicking the **Special Codes** button. These attributes are:

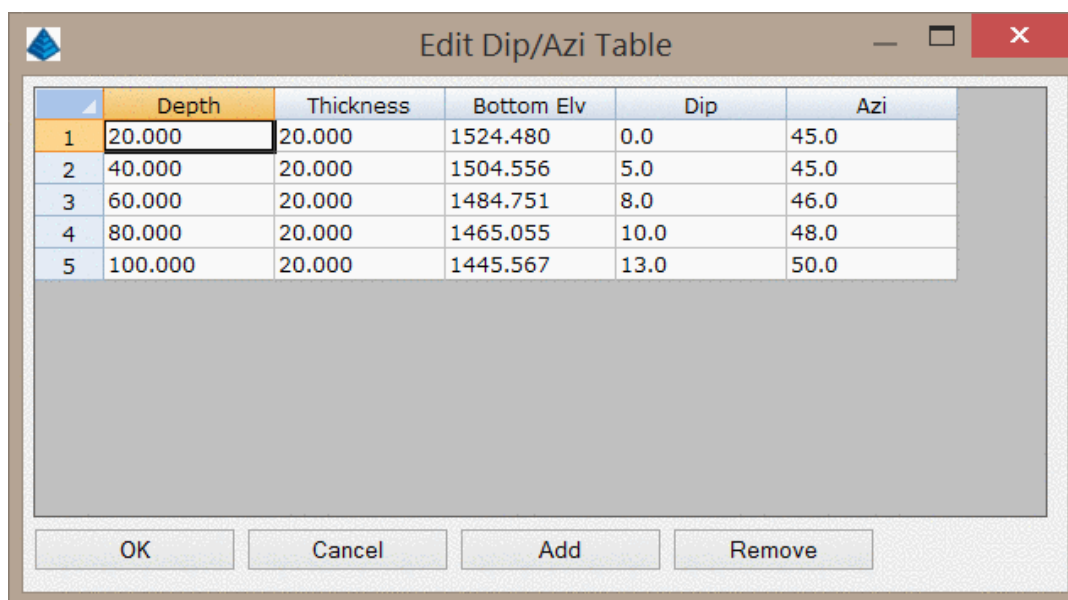

- SC_AZI or AZI: For dipping holes, this value sets the azimuth of the dip direction (0 is directed north, 90 is east, etc.)
- SC_DIP or DIP: For dipping holes, this value sets the angle (in degrees) of the hole. By default, a dip angle of 0 relates to a vertical hole, but this may be modified within Carlson Configure > Mining Settings.
- BELOW: This code is used when a strata is known to exist below the extents of the drillhole. The BELOW code is followed by the depth from the bottom of the hole to the top of the strata. The strata name is listed as the value for this code. For example, consider a strata, "Rock" that is known to exist 20' below the bottom of the hole. In this case, the attribute name is "BELOW20" and the value is "Rock".
- FAULTED: This code is used to skip pinchout and conformance for this drillhole.

Drillhole Dip and Azimuth is controlled by a hierarchy of options, listed below. If Option 1 is detected, the other two will be ignored. If Option 1 is not detected, then Option 2 will be used. If Option 2 is not detected, then Option 3 will be used. If none of these options are detected, the program will assume a vertical drillhole.

1. DIP/AZI Table
2. Strata DIP/AZI attributes
3. Drillhole DIP/AZI attributes

The DIP/AZI Table, shown below, allows the dip of the drillhole to vary on an interval that does not match the strata

samples. This information can be imported with the Import Dip/Azimuth command.

	Depth	Thickness	Bottom Elv	Dip	Azi
1	20.000	20.000	1524.480	0.0	45.0
2	40.000	20.000	1504.556	5.0	45.0
3	60.000	20.000	1484.751	8.0	46.0
4	80.000	20.000	1465.055	10.0	48.0
5	100.000	20.000	1445.567	13.0	50.0

Select Drillhole to edit [\langle Pick \rangle /Name]: pick a hole or type "N" and then type in a name. A double-click with the cross-hairs on a drillhole will also execute this command, but only on the edge of the symbol, not the center where the grip is.

Pulldown Menu Location: Drillhole

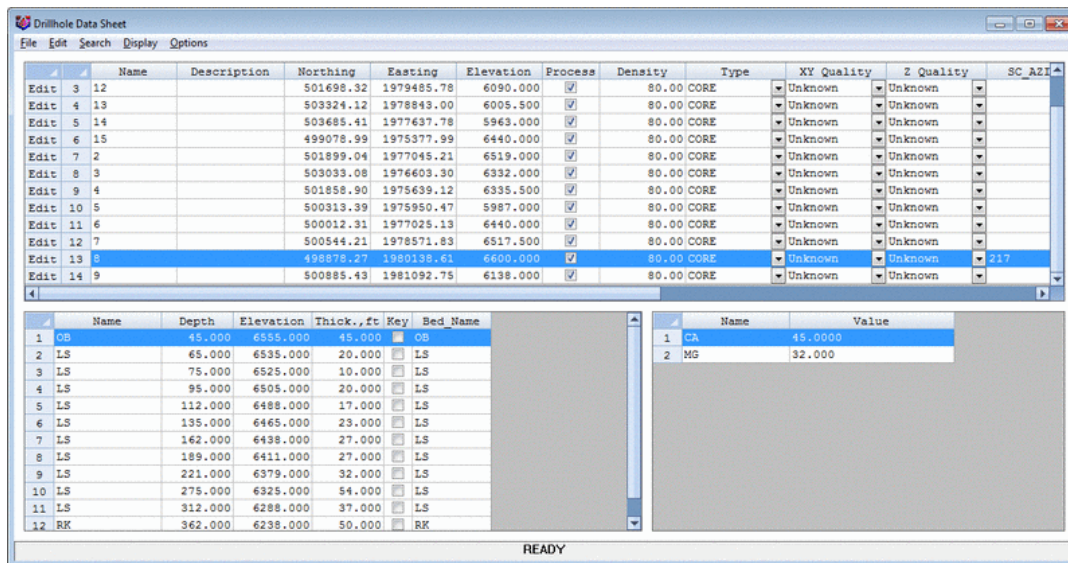

Keyboard Command: chedit

Drillhole Data Sheet

This function allows you to edit data multiple drillholes in a spreadsheet environment. The editor consists of three inter-linked spreadsheets: drillhole data, seam data and attribute data. The strata information corresponds to the currently selected drillhole in drillhole spreadsheet and in-turn the attribute spreadsheet shows data for the highlighted strata. The information changed in the editor will be saved into drawing or the external database on the exit. There is a prompt whether to save changes when exiting.

In any of the spreadsheets, additional entries may be created by moving down from the lowest line of the spreadsheet. The newly created entry needs to be filled in before another one may be created or before saving the spreadsheet. The *Del* key removes the highlighted line from spreadsheet. Drillholes deleted from spreadsheet do not get deleted from the drawing, but all changes made to the deleted drillhole are lost. The *Ins* key inserts an entry above the highlighted one, which is especially handy when you need to insert strata. The *Tab* key switches between spreadsheets. If an entry is invalid or a compulsory field has not been defined the cursor will stay in that field and a message will display in the bottom line of the editor. The incomplete entry should be finished or deleted before proceeding. Changes between Key and Non-key type of strata may change the set of strata attributes. Therefore the values of some attributes will be lost in the transition.

Using the Edit button next to each drillhole name brings up the Edit Drillhole screen, defined elsewhere in the Help manual.

The appearance of the editor may be modified by hiding unwanted columns using Display pulldown and rows may be hidden by selecting unwanted rows and selecting Edit-Hide. To show rows again select rows above and below and pick Edit-Show. The Options pulldown contains options for units selection and the method of elevation adjustment. These options are saved on the exit, so that next time the editor resets to these defaults.

Prompts

Select Drillhole Configuration File (this prompt appears once. Use Set Drillhole Definition to change current Drillhole Definition)

Select Drillholes: *pick Drillholes to load into editor.*

Pulldown Menu Location: Drillhole

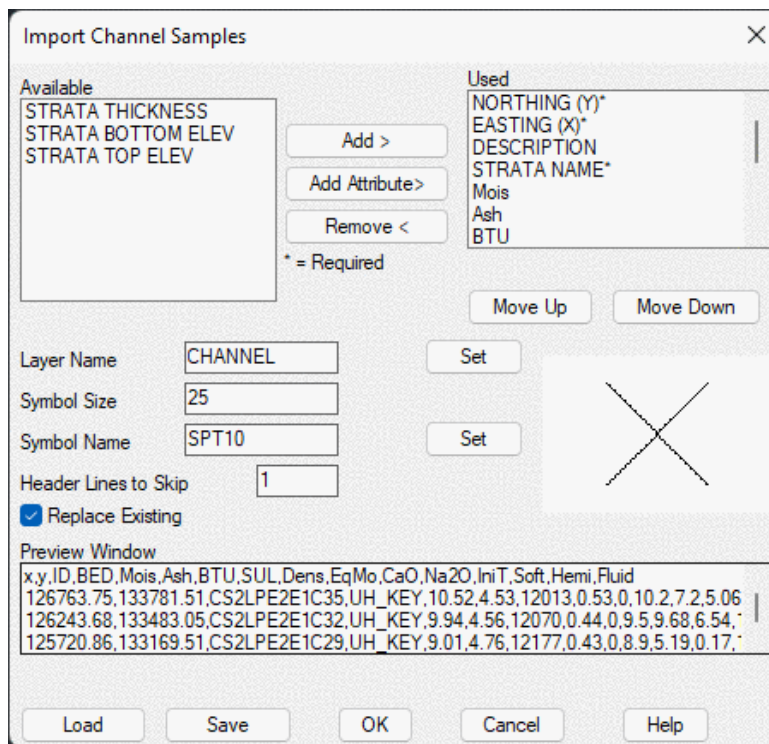

Keyboard Command: spread

Pit/Channel Samples - Import from Text File

This command creates channel samples from comma separated data in a text file. The command starts with a dialog to choose the symbol, symbol size and order of the data columns. Besides the attributes values, the text file must include the sample northing and easting and a strata identifier of name or elevation. The text file should have comma separated columns of data with each row containing all the data for the sample.

The order of the columns is set in the dialog shown below. To add one of the standard column types, highlight the name from the Available list and click Add. To add a user-defined attribute such as BTU, click the Add Attribute button. Another dialog will appear for entering the attribute name.

Channel Samples can be used as "partial" drillholes or spot samples. They are used in conjunction with the drillholes for modeling.

The option to **Replace Existing** will ensure that channel samples are not duplicated when imported. In order for a channel sample to be considered a duplicate, it must match all of the below criteria when compared to channel samples that currently exist in the drawing. If any

- Same X-Y coordinates
- Same Strata name
- Same Description
- Contains at least one of the same attribute (BTU, ASH, etc.)

Prompts

Import Channel Samples dialog

Select Text File dialog

Created 4 pit/channel samples.

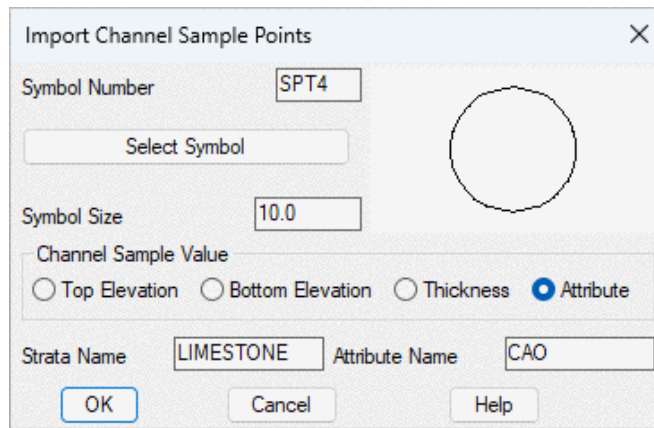

Pulldown Menu Location: Drillhole

Keyboard Command: chansam

Pit/Channel Samples - Import from CRD File

This command creates channel samples from points in a coordinate file. Channel samples are strata data points that supplement drillholes. Channel samples represent one strata value such as thickness for strata COAL1. The coordinate file consists of point number, x, y, z data.

The command starts with a dialog to choose the symbol, symbol size and strata attribute name. Then you specify the coordinate file and the range of points to make into channel samples. Similar to drillhole symbols, the channel samples are drawn as the chosen symbol in the CHANNEL layer with the data attached to the symbol. The channel samples can be used in modeling routines such as Strata Isopach Maps or Make Strata Grid Files, by selecting the channel sample symbols along with the drillholes.

Prompts

Import Channel Sample Points dialog

Point numbers to convert: *1-100 or all or **

Point numbers to convert: *press Enter*

Pulldown Menu Location: Drillhole

Keyboard Command: chansam1

Pit/Channel Samples - Import from Coal Section

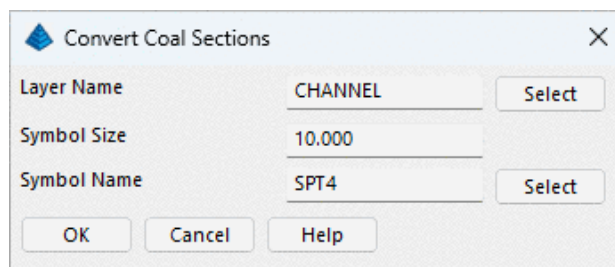

This command converts the strata data in coal sections into thickness channel samples. Coal sections are created in the Works pull-down menu of the Standard Mining Module and consist of strata names with thicknesses.

The program prompts for the strata names to use in the channel samples in case the strata names differ from the coal sections names. For example, consider this coal section:

C-7
R-3
C-54

In order to avoid duplicate strata names in the channel samples, the two coal section strata named *C* could be named *Coal1* and *Coal2* for the channel samples.

The program has settings for the layer, symbol block drawing name and symbol size for the channel sample symbols to create.

Prompts

Coal Section Configuration File Dialog

Choose a coal section configuration file (*.sc).

Select coal sections.

Select objects: *pick coal section symbols*

Create channel samples for section COAL [**<Yes>/No**]? *press Enter*

Enter strata name for section coal **<COAL>**: *press Enter*

Enter channel sample description **<COAL SECTION>**: *press Enter*

Pulldown Menu Location: Drillhole > Pit/Channel Samples

Keyboard Command: chconvert2

Export Pit/Channel Samples

This command creates a text file of sample data from the selected sample symbols in the drawing. The export file is in the format of Northing, Easting, Description, Strata Name, Attributes. This command is a way to backup the sample data. The export text file can be used to recreate sample symbols using the Import Samples routine.

Prompts

Export Text File to Write Specify a file name

Select samples to export.

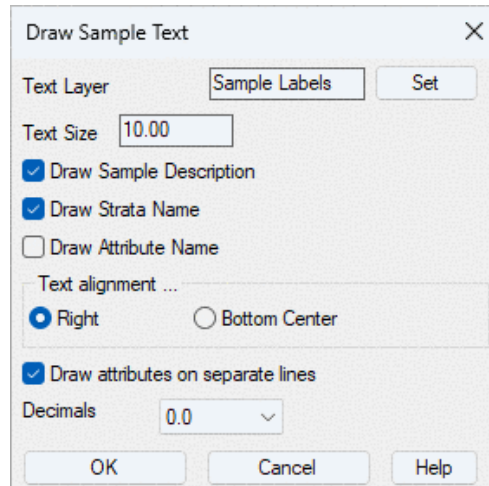

Select objects: *pick the sample symbols to export*

Pulldown Menu Location: Drillhole

Keyboard Command: chansam4

Draw Pit/Channel Sample Text

This command labels the sample data next to the sample symbol. The format and label options are set in the dialog. After selecting the samples to label, the program will read the attribute names from the symbols and prompt at the command line for each one whether to label the attribute.

```
Sample1  
SEAM2  
STRATA THICKNESS: 3.2  
STRATA BOTTOM ELEV: 4567.9  
CALCIUM: 92.1
```

Prompts

Select samples to label

Select objects: *pick the sample symbols to label*

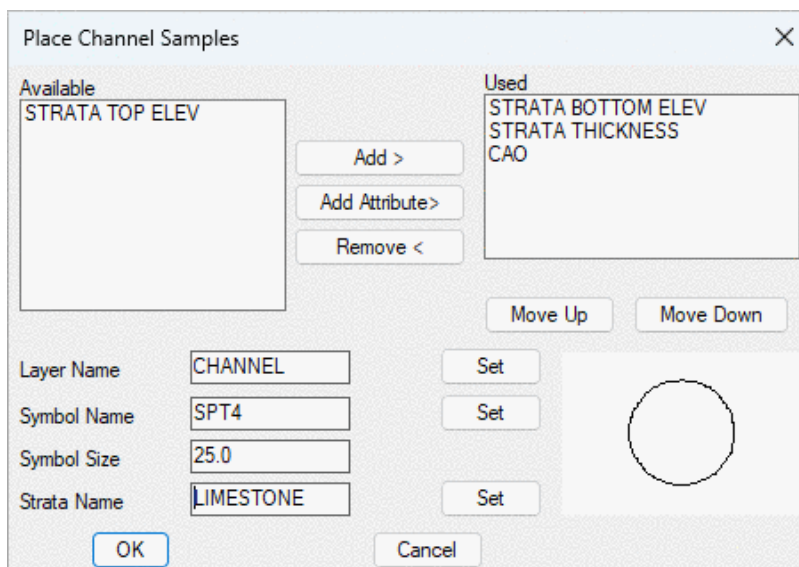

Label attribute BTU (<Yes>/No)? *press Enter for Yes*

Pulldown Menu Location: Drillhole

Keyboard Command: chantext

Place Pit/Channel Sample

This command creates channel samples at user-specified points and values. The command starts with a dialog to choose the symbol, symbol size, strata name and attribute names. The attribute names to assign are listed in order under the Used list. The Strata Thickness, Bottom Elevation and Top Elevation are the only pre-defined strata attributes. To add one of these attributes to the sample value list, highlight the attribute from the Available list and click Add. All other attributes are user-defined. To add a user-defined attribute, pick the Add Attribute button. Another dialog will appear for entering the attribute name. After filling out the dialog, pick OK. Then you pick the sample positions and enter the sample values at the prompting in the command line. Another option is to use the object snap and select something in the drawing with an elevation, such as a contour. The sample will then use that elevation, thickness or Z value for the sample value.

Prompts

Description <>:

Enter STRATA THICKNESS value: 3.2

Enter STRATA BOTTOM ELEV value: 4598.2

Enter CALCIUM value: 92.4

Pick channel sample location: *press Enter*

Pulldown Menu Location: Drillhole

Keyboard Command: chansam2

Edit Pit/Channel Sample

This command edits the strata name, attribute name or attribute value of a channel sample. To edit a channel sample, Either pick on the symbol after executing the command or simply "double-click" on any sample point. Any changes are saved back to the data attached to the channel sample symbol. Each sample must include a strata name, but all other attributes (including description, elevations, and thickness) are optional.

Standard Drillhole Text

This command draws text for the descriptions, surface elevation, strata names, bed names, thicknesses, attributes, and/or bottom elevations of the selected drillholes. Which values to draw is determined by the selections in the dialog shown below. When bed names are available they may be drawn next to the strata name.

Text Layer: This option controls the layer that will be used for the text labels. If the **Use Drillhole Layer** option is selected, text labels will be drawn on the same layer as the drillhole symbol. Note that strata layers may also be set according to the "Layer Text by Strata" option.

Text Size: This option controls the size of the text labels.

Decimals: This option controls the number of decimal places in the values. If the strata attributes are defined in Define Attributes, the number of decimal places to report will respect the attribute definition file.

Draw ____: These check boxes control which attributes of the drillhole will be labeled. These labels are self-explanatory, but a few notes on these options are provided below.

- **Coordinates:** Listed as X,Y
- **Strip Ratio:** calculated for the entire drillhole. The units for this ratio can be defined in Carlson Configure (Mining Settings). The density values used for determining stripping ratio will be pulled from the Strata Definition File (if these density values are not found, standard densities of 80 lbs/ft³ will be used for key material, and 150 lbs/ft³ for nonkey material).
- **Process Beds:** When this option is used, Bed naming conventions will be used in place of the strata names in the drillholes. More information on Bed naming conventions can be found in Carlson Configure (Mining Settings).

Use MText: This option will draw the label using an MTEXT entity instead of a standard TEXT entity.

Draw Strata Elevation/Thickness/Depth: These options control how the elevation/thickness/depth labels will be drawn.

Starting Text Position: This option sets the row to start the text labels. By increasing this value, you can add additional labels without overlapping previous labels. For example, if the drillholes already have two rows of labels, then use a starting text position of three.

Text Offset: This option sets the distance from the center of the drillhole symbol to draw the first text label. It is recommended that this value be set to half the diameter of the drillhole radius to prevent the labels from overlapping the symbol.

Which Strata to Include: This option determines which strata will be labeled. If the "Selected" option is chosen, you will be prompted to select the strata to label. If the "Composite" option is chosen, you will be prompted to select the strata to label, but all selected strata will be grouped as if they were a single strata.

Text Alignment: This option determines the placement of the labels relative to the drillhole symbol (right justified, center justified above the drillhole, center justified below the drillhole).

Use Parameter File: This option allows you to select a parameter file to filter the drillholes and draw text for only the drillholes that pass the filter. See Define Parameters for more on parameters.

Ignore Zero Value Attributes: This option will prevent attributes with a value of zero from being labeled.

Draw Attributes on Separate Lines: This option will create a new line for each attribute of each strata, otherwise the attributes of a strata are grouped together on one line, but separated by the **Delimiter** field.

Group attributes by strata: This option will draw all the attributes for a strata together. Otherwise the attributes are grouped by attribute name such as having all sulfur attribute values drawn together.

Layer Text by Strata: When this option is enabled, the layers used for each label will be set according to the layers defined in the Strata Definition File.

Draw Text At Elevation: **This option** creates the labels at the surface elevation of the drillhole. Otherwise, the text is drawn at zero elevation.

Keyboard Command: chtext

Drillhole Text Formatter

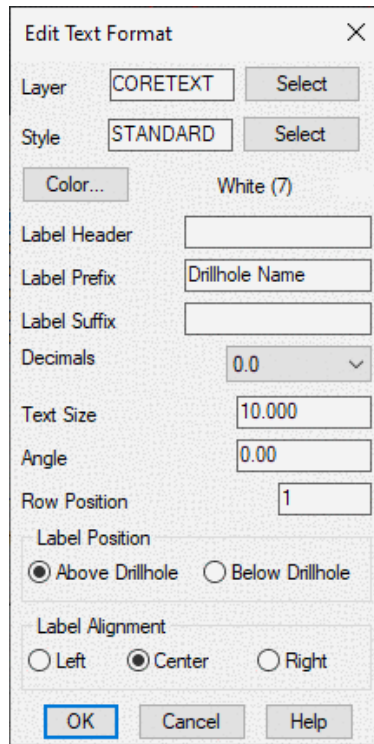

This routine allows for flexible labeling of any data contained in the drillholes- also known as "posting drillholes." After selecting which drillholes to label, the program prompts whether to process beds. If beds are processed, the strata will be composited by bed name into groups such as bed_top, bed_key, bed_parting, and bed_bottom for labeling. If beds are not processed, only the strata names will be used for labeling.

The Drillhole Text Format Options dialog, shown below, allows you to select the information to label. The full list of available information is shown on the left of the dialog, while the "Used" column on the right lists the information that will be labeled. The leftmost column lists the Drillhole, the Strata/Beds, and the Equations (if applicable). Selecting one of these groups will show the specific attributes that can be labeled in the middle column. These attributes can be added to the "Used Column" by double-clicking the attribute, or by highlighting the attribute and clicking the green right-arrow between the "Available" and "Used" columns.

- **Text Offset:** Sets the distance from the center of the drillhole to the text. To avoid overlapping the text with the drillhole symbol, it is recommended to set this value greater than or equal to the radius of the drillhole symbol.
- **Label thickness for missing strata as Zero:** This option will label missing strata with a thickness of zero. This option will also affect Equations in that null values will be treated as zeros. For example, if an Equation adds the thickness of Strata A and B, but a drillhole does not contain Strata B, the Equation will simply report the thickness of Strata A. When this option is disabled, Equations will not be evaluated when a strata is missing.
- **Prefix layers with drillhole type name:** This option prefixes the label layers with the drillhole type name. For example, if the Drillhole is tagged as Rotary hole and the labels are set to draw on layer "Label", this option would draw the labels on the layer "Rotary-Label".
- **Skip empty rows:** When no labels are drawn on a row, this option will slide the other labels up or down to fill in the missing row.
- **Overlap labels with same row:** This option will allow text labels to overlap if they are set to draw on the same row.
- **Draw as MTEXT:** Selecting this will group the text as MText (multiline text), otherwise it is separate standard text for each text item.
- **Use Table:** This option will use a table entity for labels on similar rows, or for labels representing repeating strata. For example, if 5 intervals of the same strata exist in the drillhole, the table entity will have 5 rows of data. Note that table entities may be drawn with or without grid lines.
- **Color By Grade Parameter File:** This option prompts for a Grade Parameter File to set the color of the labels based on the grade of each strata.
- **Draw text at elevation:** This will draw the labels at the same elevation as the drillhole collar.
- **Filter Null Attributes:** When enabled, this option will not draw labels for attributes with specific values/strings used as "null" markers.

When an attribute is added to the "Used" column, the below dialog will appear to control the settings of that attribute label. This dialog can also be accessed by double-clicking an attribute in the "Used" column or by highlighting an attribute and clicking the pen icon between the "Available" and "Used" Columns.

- **Layer:** Sets the layer for each label
- **Style:** Sets the text style
- **Color:** Sets the text color
- **Label Header:** This header text will be inserted on the row above the label. When drawing multiple labels for a strata type, this head can be used to group the labels together, as shown in the below image. In this example, the first Thickness label has been assigned a label header called "OB" while the second thickness label has been assigned a label header called "C1". It is important to note that the Elevations labels should not be assigned label headers.

- **Label Prefix:** Sets a prefix to the text. In the above image, the prefixes of "Bottom Elev: " and "Thick (ft)" have been assigned
- **Label Suffix:** Add a suffix to the text
- **Text Size:** Sets the size of text
- **Decimals:** Sets the number of decimals to display in the value
- **Angle:** Sets the rotation angle of the text
- **Row Position:** Sets the row position for the text. Row 1 will be closest to the drillhole symbol, Row 2 will be further away from the symbol, etc. The rows are counted either up or down from the symbol based on the **Label Position**.
- **Label Position:** Determines if the text is drawn above or below the drillhole symbol
- **Label Alignment:** This option aligns the text with the center of the drillhole symbol, or off to the side of the drillhole.

Select the Drillholes to label.

Select objects: *pick the drillholes*

Process beds [**<Yes>/No**]? *Press Enter for yes.*

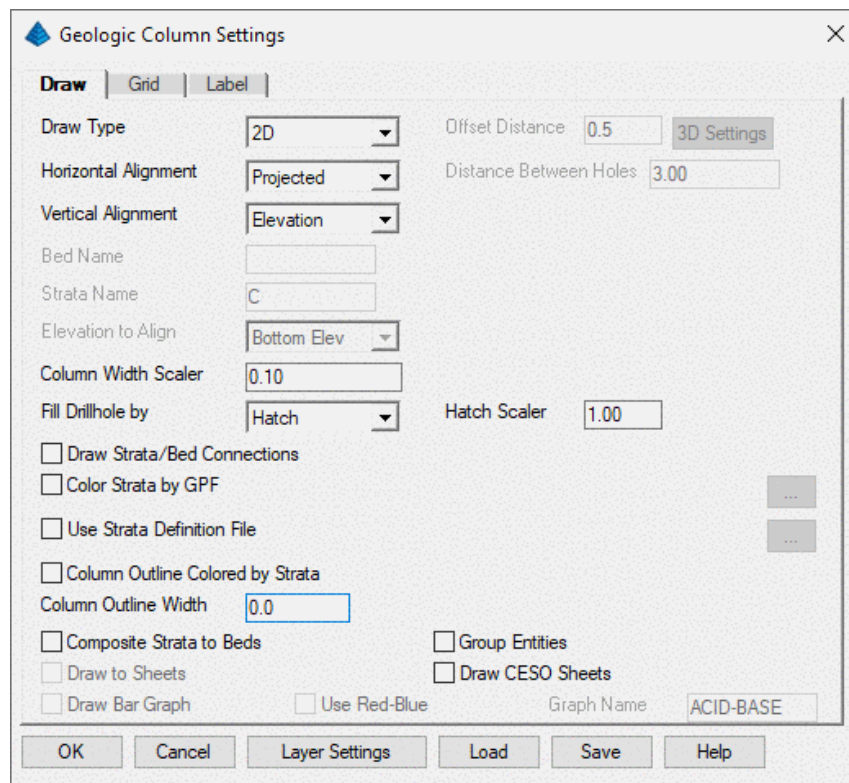

Drillhole Text Format Options dialog

Drop-Down Menu Location: Drillhole

Keyboard Command: chtext2

Draw Geologic Column

As the name suggests, this command draws geologic columns for selected drillholes. All of these settings may be saved to a geologic column settings file (.gcl). Notice that the dialog is divided into three tabs: Draw Settings, Grid Settings, and Label Settings.

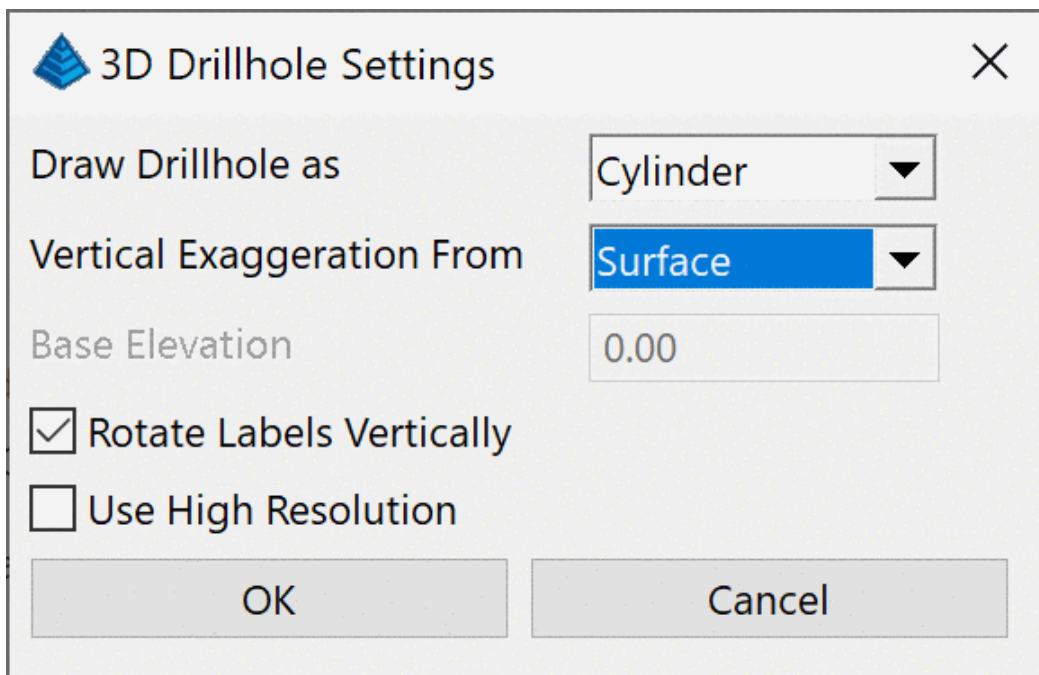

Draw Type: The geologic columns can be drawn in *3D*, *2D* or *Next to Drillhole*.

- The *3D* option will draw the columns in true 3D space.
- The *2D* option will draw a cross-sectional view of the columns in a user defined location.
- The *Next to Drillhole* option will draw a cross-sectional view of the columns next to the true drillhole locations.

Offset Distance This value is only applied when the Draw Type is set to the *Next to Drillhole* option. This value sets the distance between the drillhole symbol and the column. It is important to note that this distance is multiplied by the Horizontal Scale value on the Grid tab to set the actual offset distance.

Distance Between Holes This value is only applied when the Draw Type is set to the *2D* option and the Horizontal Alignment is set to the *Line Up* option. For more details please see the description of the *Line Up* option below.

3D Settings: This button is only active when the Draw Type is set to the *3D* option. These settings control how the drillhole will be drawn in 3D space. When selected, the below dialog will appear.

Draw Drillhole as: This option controls how the column will be drawn. An example of each option is shown below as viewed in the 3D Viewer Window

- The *Cylinder* option will draw the column as 3D faces.
- The *Rectangle* option will draw the column as flat 3D polylines (this essentially draws a 2D column rotated into 3D space)
- The *Line* option will draw a single 3D polyline to represent each column.

Vertical Exaggeration From: This option controls how 3D columns will be drawn when vertical exaggeration is applied.

When the *Base Elevation* options is used, the column will be scaled, but the **Base Elevation** value (entered immediately below this option) will be held at the true elevation, even if the column does not intersect this elevation. When the *Surface* option is used, the column will be scaled, but the top of the hole will be held at the true elevation. For example, consider a drillhole with a collar elevation of 100 and a bottom elevation of 60 to be drawn with a 2X vertical exaggeration. If the *Surface* option is used, the top of the column will be drawn at elevation 100 and the bottom of the column will be drawn at elevation 20. If the *Base Elevation* option is used with a Base Elevation of 0, the top of the hole will be drawn at elevation 200 and the bottom of the hole will be drawn at elevation 120.

Rotate Labels Vertical: When selected, this option will draw all 3D text labels oriented in the vertical direction. When this option is not selected, 3D text labels will be oriented in plan view.

Use High Resolution: When selected, this option will draw the 3D drillhole in High Resolution.

Horizontal Alignment: This option is only available when the Draw Type is set to the *2D* option. Three methods are available for Horizontal Alignment.

- The *Individual* option will prompt you to select the location to draw each individual column.
 - The *Line Up* option will space the columns equal distances apart from one another, regardless of the true distance between the holes. The space between the columns is the product of the **Distance Between Holes** multiplied by the Horizontal Scale on the Grid tab.
 - The *Projected* option will space the columns by projecting them onto a cross-sectional alignment polyline.
- Both the *Line Up* and *Projected* options require that an alignment polyline be drawn through or near the columns of interest prior to the command. After clicking OK on the main dialog, you will be prompted to select this polyline, as well as the "maximum drillhole distance from alignment polyline" to filter out distant holes. Any drillholes outside of this range will not be drawn, even if they are selected.

Vertical Alignment: When Horizontal Alignment option is set to the *Line Up* or *Projected* options, the geologic columns may be aligned vertically in one of three ways.

- The *Elevation* option will draw the columns according to their true elevations.
- The *Surface* option will draw the columns so that all collar elevations are aligned. This allows a horizontal line to be drawn across the top of all the columns. With this option, an elevation axis will be drawn through each column for individual inspection.
- The *Strata* option will draw the columns so that a specific strata/bed is aligned across the columns. This would allow a horizontal line to be drawn through the top/bottom elevation of the strata/bed in all holes. With this option, an elevation axis will be drawn through each column for individual inspection. This option also requires a text string for either the **Strata Name** or **Bed Name** fields. The **Elevation to Align** dropdown list controls if the strata/bed will be aligned according to the top or the bottom elevation.

Column Width Scaler: This value, relative to the Horizontal Scale, determines the width of the geologic column. For example, a Column Width Scaler of 0.15 and a Horizontal Scale of 100 will produce a column with a width of 15 drawing units.

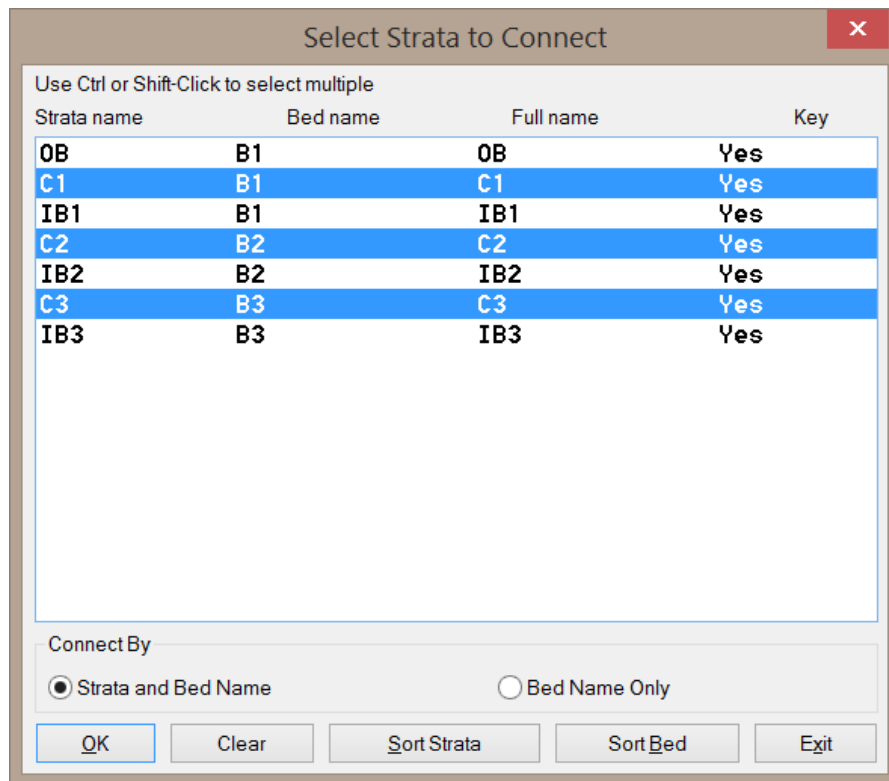

Fill Drillhole by: This option determines the hatch pattern for each strata.

- If the *Outline Only* option is selection, no hatch pattern will be drawn.
- If the *Hatch* option is selected, the strata will be filled with the hatch specified in the Strata Definition File. If a strata is not found in the Strata Definition File, the strata will be hatched with the ANSI31 pattern.
- If the *Solid Fill* option is selected, all strata will be hatch with the SOLID hatch pattern.

Hatch Scaler: This value is only used when the *Fill Drillhole by Hatch* option is selected. This value, relative to the hatch scales in the current Strata Definition File, determines the hatch scale of each strata's hatch pattern. For example, a Hatch Scaler of 5 and a strata with a defined hatch scale of 2 will produce a hatch pattern with a scale of

10. If a strata is not found in the Strata Definition File, the Hatch Scaler will be multiplied by a value of 5 to set the hatch scale of the strata.

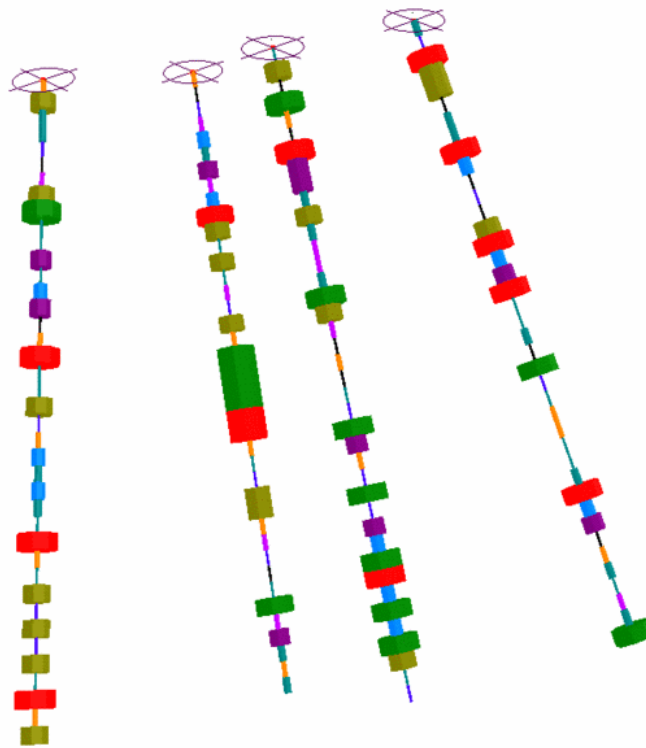

Draw Strata Connections: This option is not available when the *Align Horiz by Individual* option is selected. This option will draw polylines connecting similar strata between columns. Note that if a strata or bed pinches out between columns, this pinchout will not be drawn. After clicking OK on the dialog, you will be prompted for the strata to connect, as shown below.

Connect By: This option will determine if connections are drawn according to Strata Names or Bed Names. If the *Strata and Bed Name* option is selected, connections will be drawn for individual strata layers. If the *Bed Names Only* option is selected, connections will only be drawn for the top and bottom of each bed - individual strata connections will not be drawn.

Sort Strata: This button will sort the list alphabetically by Strata Name.

Sort Bed: This button will sort the list alphabetically by Bed Name. **Color Strata by GPF:** This option will color each strata according to a Grade Parameters File (GPF). You may select a GPF by clicking the ellipsis button to the right of the option. When the drillhole is drawn in 3D, the strata width will be scaled according to the *Geologic Column Scaler* defined for each grade in the Grade Parameters File. This allows for more visual interpretation of high-grade and low-grade sections of the column, as shown below.

Use Strata Definitions: This option allows the use of a Strata Definition File (which controls layering, colors, hatching, etc.) other than the one currently set in the Mining Project Settings. The ellipsis button will prompt you for this Strata Definition File.

Column Outline Colored by Strata: When this option is enabled, the outline of the drillhole will be colored the same as the hatch color. When this option is disabled, the drillhole will be outlined with a white/black line.

Column Outline Width: This value sets the thickness for the column outline.

Composite Strata to Beds: This option will composite strata together by Bed Name where applicable. In order to use this option, both the Strata Name and the Bed Name must be defined in the Strata Definition File.

Group Entities: This option will draw each column as a group of entities (not to be confused with a block entity).

Draw To Sheets: This option is only available if the Horizontal Alignment option is set to *Individual*. This will draw the individual drillholes on multiple sheets, breaking the page as necessary.

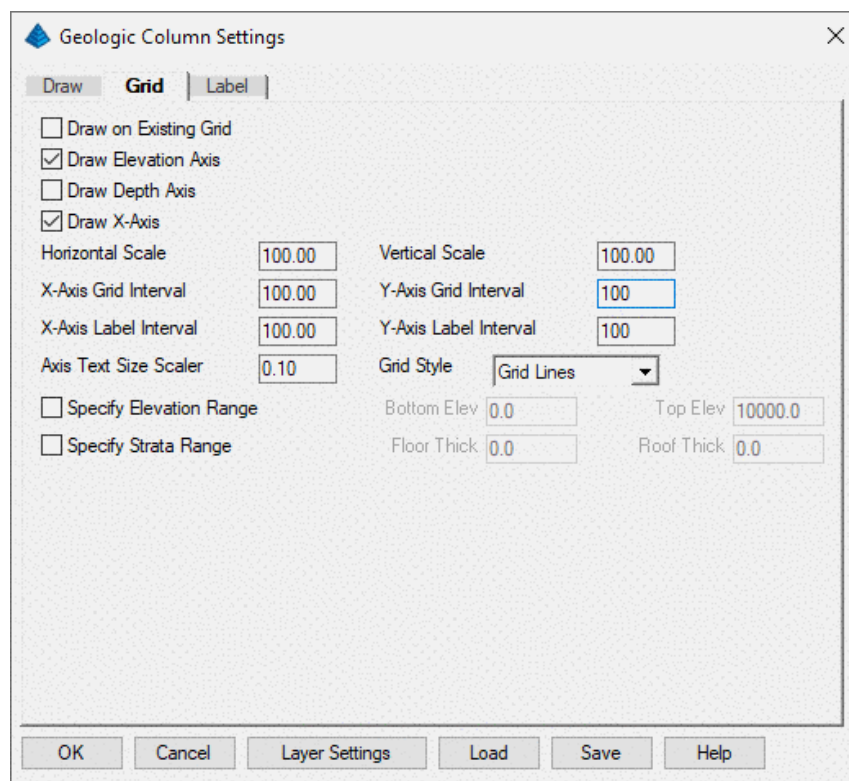

Draw CESO Sheets: This option is similar to the Draw to Sheets option, but is formatted specifically for a particular Carlson user. Unlike the Draw to Sheets option, this option will add header information to the sheets.

Draw Bar Graph: This option is only available when the Draw Type is set to the 2D option. An example Bar Graph as shown below. The graph is intended for acid-base accounting, but any drillhole attribute may be used. The graph is logarithmic, ranging in value from -100 to 100. Any values outside of this range will be drawn at the maximum value and a label will be drawn to indicate the true value. In addition to the Bar Graph, a Scatter Graph may also be drawn. This graph ranges in value from 4 to 10. Any values outside of this range will be drawn off the graph

Use Red-Blue: This option will draw the Bar Graph with only red or blue hatches when selected. Red hatches are used for negative values and blue hatches are used for positive values.

Graph Name: This text string is the title of Bar Graph, which will be drawn below the X-axis values. An example

of a geologic column with a bar graph is shown below.

Draw on Existing Grid: This option is only available when the Horizontal Alignment option is set to *Projected*. This option will draw the drillholes on a pre-existing cross section grid. When this option is selected, you will be prompted to select the bottom left corner of the section and enter the bottom elevation. This ensures the columns are drawn at the correct elevations on the section.

Draw Elevation Axis: This option will draw an elevation axis (vertical line) next to the columns.

Draw Depth Axis: This option will draw a depth axis (vertical line) next to the columns. When this axis is drawn next to a 3D drillhole, the axis will follow the dip of the hole rather than always being drawn as a vertical line.

Draw X-Axis: This option will draw a stationing axis (horizontal line) between drillholes when the Horizontal Alignment option is set to the *Line Up* or *Projected* methods.

Horizontal Scale: This value sets the overall drawing scale that many other options in the dialog reference for scaling. This allows you to quickly change the size the geologic columns with a single value.

Vertical Scale: This value, relative to the Horizontal Scale, determines the vertical exaggeration. For example, a Horizontal Scale of 50 and a Vertical Scale of 10 will produce a 5X vertical exaggeration.

X/Y-Axis Grid Interval: This value sets the grid line spacing for the X and Y axes. For example, a Y-Axis Grid Interval of 25 will draw a tick/grid line every 25 ft/m of elevation change.

X/Y-Axis Label Interval: This value sets the text intervals for the X and Y axes. For example, a Y-Axis Label Interval of 100 will draw an elevation/depth label every 100 ft/m of elevation change.

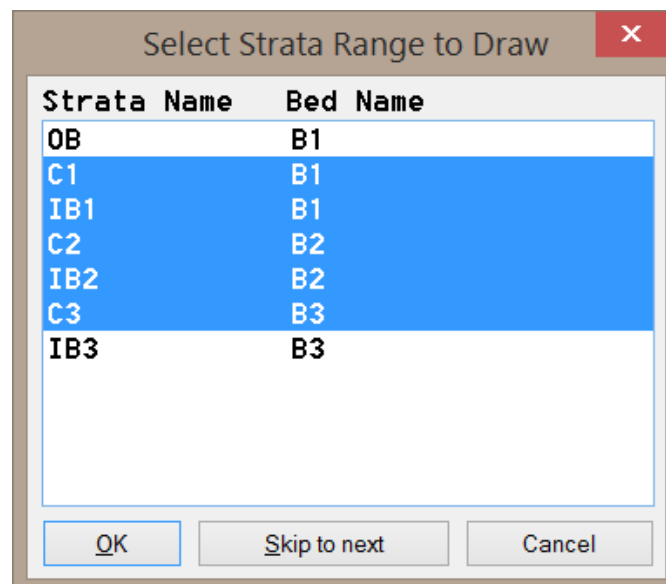

Axis Text Size Scaler: This value, relative to the Horizontal Scale, determines the text height of the elevation/depth/stationing labels. For example, an Axis Text Size Scaler of 0.15 and a Horizontal Scale of 100 will produce text labels with a height of 15 drawing units.

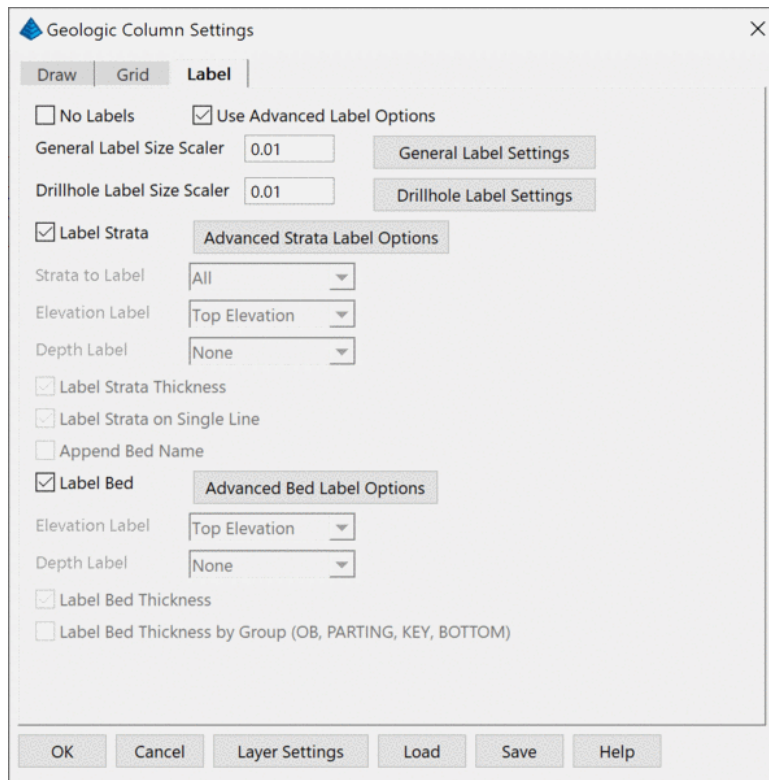

Grid Style: This option controls how the grid will be drawn.

- The *Grid Lines* option will draw a true grid with lines spanning the appropriate axes.
- The *Ticks Only* option will draw the grid axes, but instead of full lines spanning the axes, small tick marks will be placed along each axis.
- The *Ticks and Dots* option will draw tick marks along each axis, as well as points where true grid lines would intersect.

Specify Elevation Range: This option will draw the columns only between a range of elevations, set by the **Top Elev** and **Bottom Elev** values.

Specify Strata Range: This option will draw only a specific range of strata in the columns. After clicking OK on the dialog, you will be prompted for the strata to draw, as shown below. If not all strata are shown in this dialog, clicking *Skip to Next* will scan another hole for strata layers. Portions of strata above/below the selected strata can also be drawn according to the **Roof Thick** and **Floor Thick** values, respectively.

No Labels: This option will turn off labeling for the column and will also ghost out all labeling options in the dialog.

Use Advanced Label Options: This option will turn off all standard labeling options and will activate Advanced Strata and Bed Options.

General Label Size Scaler: This value, relative to the Horizontal Scale, set the text size labels for strata/bed/attribute labels.

General Label Settings: This button will open the below dialog, which controls many of the details of the column labels for strata/bed/attributes.

Draw Labels as: This option controls the type of text that is used for labels.

- The *DText* option will use a standard text entity for labels.
- The *MText* option will use MText (multi-line text) entities for labels.
- The *MLeader* option will use Multileader entities for labels, which are simply MText entities attached to a leader line.

Label Style: This text string sets the text style for the labels. The **Set** button may be used to select a pre-existing text style. Text styles may be edited via the `STYLE` command.

Use Full Strata Name: This option will use the Full Strata Names found in the Strata Definition File for strata labels.

Attributes on Single Line: This option will place all attributes for a single strata on one row rather than placing each attribute on an individual row. Not available if Advanced Label options are used.

Draw Label Leaders: This option will draw red leader lines from the column to the strata label and attribute labels. Labels will sometimes be shifted away from the column to avoid overlaps. Without these leader lines, the labels may be difficult to match up with the strata they relate to. Not available if Advanced Label options are used.

Draw Ferm Codes: This option will label each strata with its Ferm Code in addition to the true strata name (according to the Ferm Code definition file). If the **Ferm Label** option is set to *Code*, then the actual Ferm Code will be used. If the **Ferm Label** option is set to *Full Description*, then the full Ferm Code description will be listed rather than the Ferm Code itself.

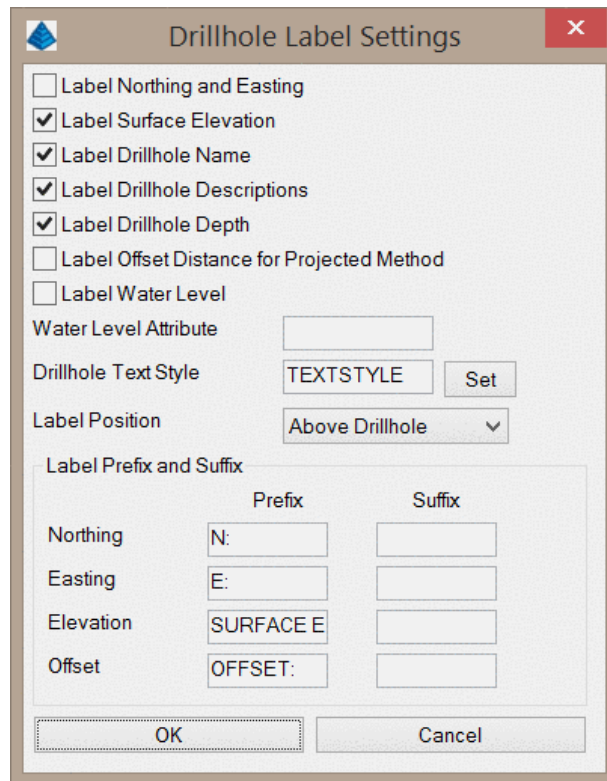

Label by Grade Parameters: This option will add the Grade Name to the label, according to a Grade Parameters File. If this option is set to *Left* the Grade Name will be listed with the attribute label. If the option is set to *Right*, the label will be listed with the strata label.

Elevation/Thickness/Depth Decimals: These options control the number of decimals to display for elevation, thickness, and depth labels, respectively. Not available if Advanced Label options are used.

Elevation/Thickness/Depth Prefix: These text strings set the prefix for elevation/thickness/depth labels, respectively. Not available if Advanced Label options are used.

General Label Size Scaler: This value, relative to the Horizontal Scale, set the text size labels for labels relating to the drillhole itself (such as the collar elevation, northing, easting, etc.)

Drillhole Label Settings: This button will open the below dialog, which controls many of the labels relating to the drillhole itself (rather than labels relating to strata within the drillhole).

Label Northing and Easting: This option will draw a label of the Northing and Easting coordinates for each column.

Label Surface Elevation: This option will draw a label of the Surface Elevation for each column.

Label Drillhole Name: This option will draw a label of the Drillhole Name for each column.

Label Drillhole Descriptions: This option will draw a label of the Drillhole Description for each column.

Label Drillhole Depth: This option will draw a label of the maximum depth for each column.

Label Offset For Projected Method: This option is only applied when the Horizontal Alignment is set to the *Projected* option. This option will draw a label indicating the perpendicular distance from the column to the alignment polyline.

Label Water Level: This option will draw a label of the water table elevation in the column. When this option is selected, the **Water Level Attribute** must match the name of the water level attribute defined in the drillhole. Note that the water level is an attribute of the drillhole itself; it should not be listed as an attribute of a particular strata.

Drillhole Text Style: This text string will set the text style for the drillhole label. The **Set** button may be used to select a pre-existing text style. Text styles may be edited via the STYLE command.

Label Position: This option determines where the drillhole label is drawn.

- If the *Above Drillhole* option is selected, the label will be center justified above the column.
- If the *On Side* option is selected, the label will be drawn to the right of the column.

Northing Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Northing coordinate.

Easting Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Easting coordinate.

Elevation Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Surface Elevation.

Offset Prefix/Suffix: This option will only be applied when the Horizontal Alignment is set to the *Projected* option. These two text strings will set the prefix and suffix for the label of the column Offset from the fence alignment polyline.

Standard Strata/Bed Label Options

Label Strata: This option will draw labels for each strata found in the column. All strata label options will be ghosted when this option is not selected.

Strata to Label: This option will determine which strata are labeled.

- The *All* option will label all strata.
- The *Key-Only* option will only label key strata.
- The *Selected* option will prompt you to select the strata to label.
- The *Fit-Only* option will only draw a label if the strata is thick enough to place a label without having to adjust the label position to avoid overlaps.
- The *Bed-Only* option will only label strata with bed names.

Elevation Label: This option determines which elevation will be labeled for each strata.

- If the *None* option is selected, no elevation label will be drawn.
- If the *Top Elevation* option is selected, the top elevation of each strata will be labeled.
- If the *Bottom Elevation* option is selected, the bottom elevation of each strata will be labeled.

Depth Label: This option determines which depth will be labeled for each strata.

- If the *None* option is selected, no depth label will be drawn.
- If the *Top Depth* option is selected, the depth to the top of each strata will be labeled.
- If the *Bottom Depth* option is selected, the depth to the bottom of each strata will be labeled.

Label Strata Thickness: This option will draw a label for the thickness of each strata.

Label Strata On Single Line: This option will place all strata labels on a single row rather than placing each label on an individual row.

Append Bed Name: This option will label the Bed Name in addition to the Strata Name for each strata in the column.

Label Bed: This option will draw a label for the bed name of each strata. All bed label options will be ghosted when this option is not selected.

Bed Elevation Label: This option determines which elevation will be labeled for each bed.

- If the *None* option is selected, no elevation label will be drawn.
- If the *Top Elevation* option is selected, the top elevation of each bed will be labeled.
- If the *Bottom Elevation* option is selected, the bottom elevation of each bed will be labeled.

Bed Depth Label: This option determines which depth will be labeled for each bed.

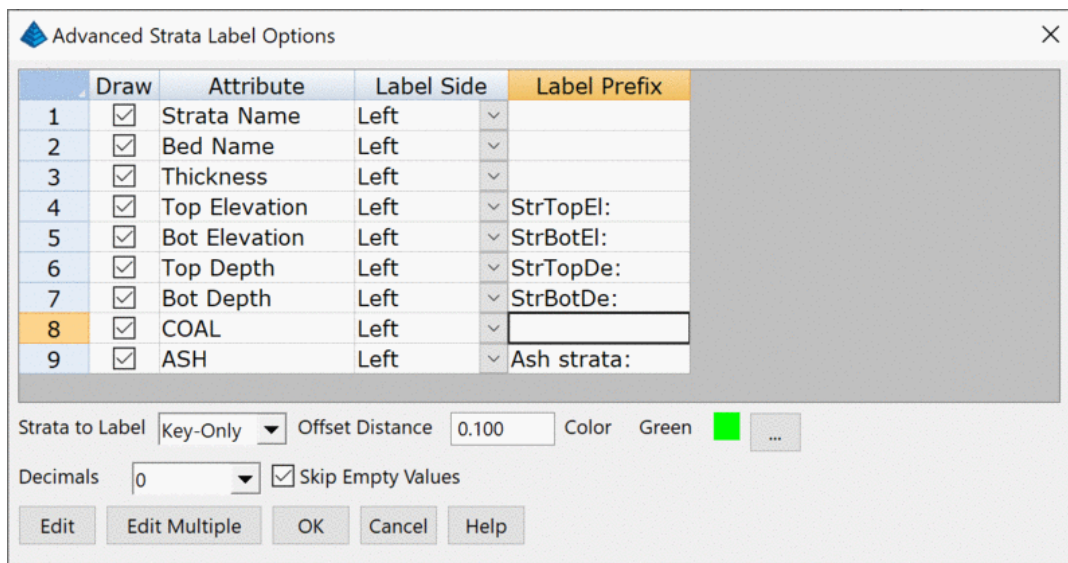

- If the *None* option is selected, no depth label will be drawn.
- If the *Top Depth* option is selected, the depth to the top of each bed will be labeled.
- If the *Bottom Depth* option is selected, the depth to the bottom of each bed will be labeled.

Label Bed Thickness: This option will draw a label for the thickness of each bed.

Label Bed Thickness by Group (OB, PARTING, KEY, BOTTOM): This option will draw a label for each of the four bed groups.

Advanced Strata/Bed Label Options

Advanced Strata Label Options are available when "Use Advanced Label Options" and "Label Strata" are checked.

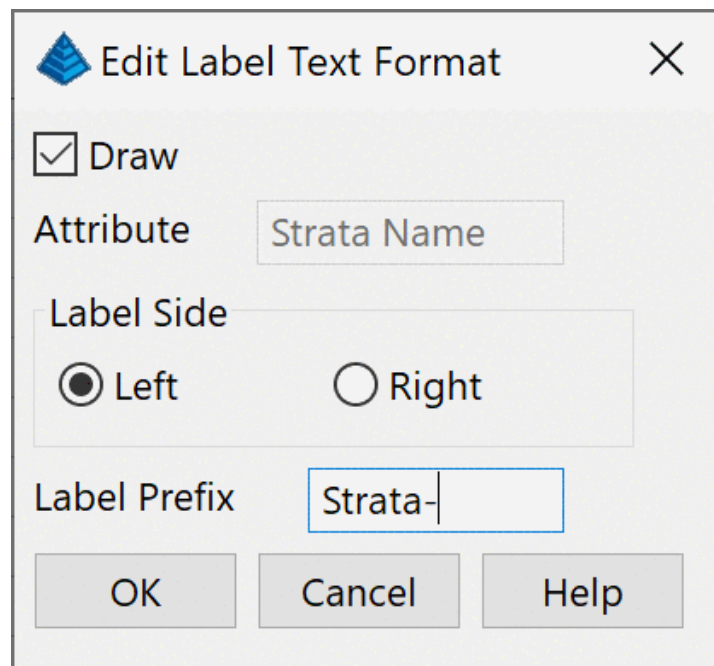

Draw determines which Strata Attribute will be labeled.

Attribute column shows all available Strata Attributes for labeling. Custom attributes such as ASH are read from the selected drillholes.

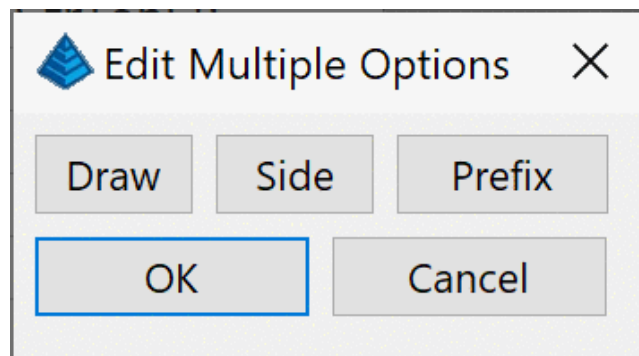

Label Side determines a label side relative to the geologic column for each Strata Attribute.

Label Prefix will set the prefix for the label.

Each Attribute Label can be edited in a separate window by picking the **Edit** button.

To edit label options for multiple Attributes such as the Draw, Side, Prefix highlight multiple rows in the spreadsheet by picking with the Ctrl and/or Shift keys, and then pick the **Edit Multiple** button.

Strata to Label: This option will determine which strata are labeled.

- The *All* option will label all strata.
- The *Key-Only* option will only label key strata.
- The *Selected* option will prompt you to select the strata to label.
- The *Fit-Only* option will only draw a label if the strata is thick enough to place a label without having to adjust the label position to avoid overlaps.
- The *Bed-Only* option will only label strata with bed names.

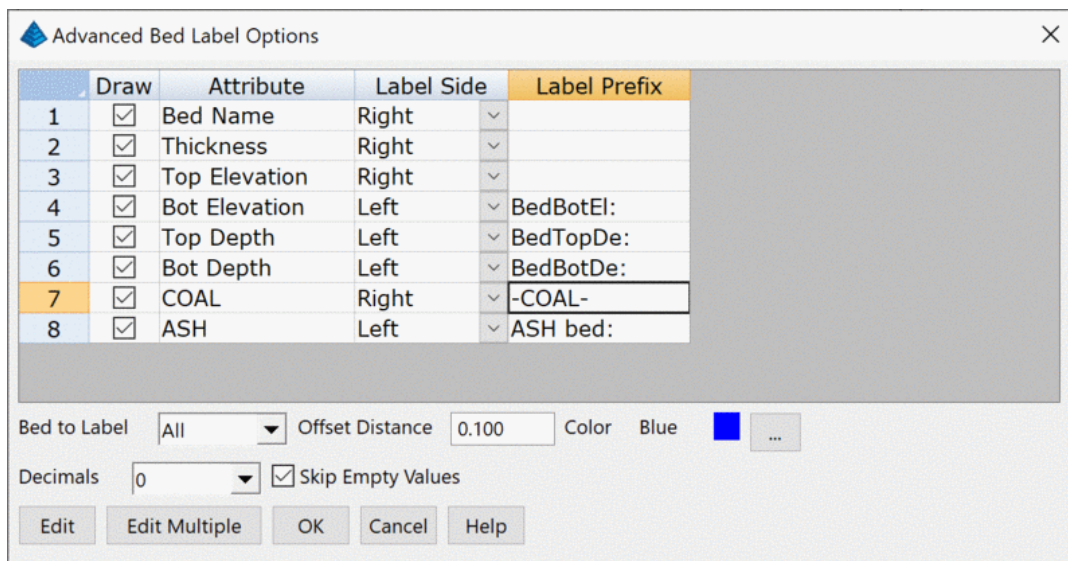

Offset Distance: This value, relative to the Horizontal Scale, set the distance between labels and the geologic column.

Color determines a color for all strata labels.

Decimals controls the number of decimals to display for all strata attributes.

Skip Empty Values will skip all attributes with no value.

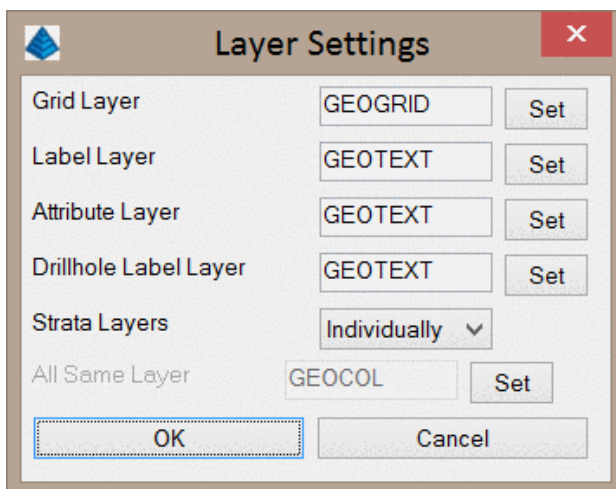

Advanced Bed Label Options are available when "Use Advanced Label Options" and "Label Bed" are checked.

All options described above for the Advanced Strata Label Options dialog are applicable to the Advanced Bed Label Options. The only difference is that **Bed to Label** has fewer options compared to **Strata to Label**:

- The *All* option will label all beds.
- The *Selected* option will prompt you to select the bed to label.
- The *Fit-Only* option will only draw a label if the bed is thick enough to place a label without having to adjust the label position to avoid overlaps.

Clicking the **Layer Settings** button will display the below dialog.

Grid Layer: This text string sets the CAD Layer of the grid linework. The **Set** button can be used to select a pre-existing CAD Layer.

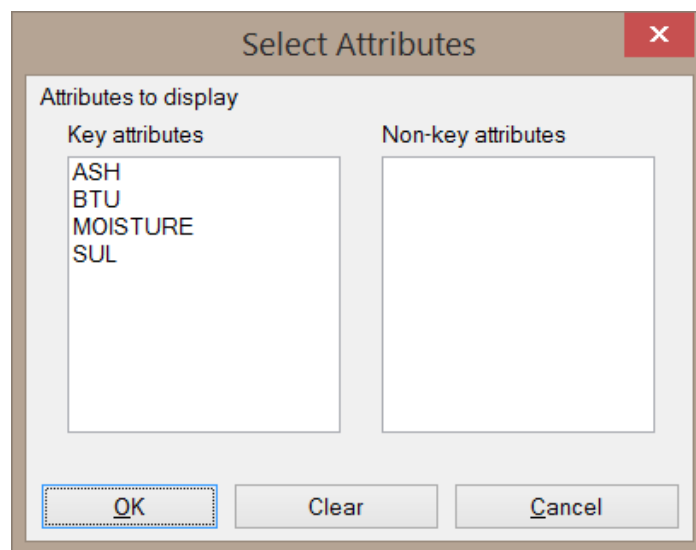

Label Layer: This text string sets the CAD Layer for most label entities, such as the elevation, depth, station, and strata. The **Set** button may be used to select a pre-existing CAD Layer.

Attribute Layer: This text string sets the CAD Layer for attribute labels entities. The **Set** button may be used to select a pre-existing CAD Layer.

Drillhole Label Layer: This text string will set the CAD Layer for the drillhole label. The **Set** button may be used to select a pre-existing CAD Layer.

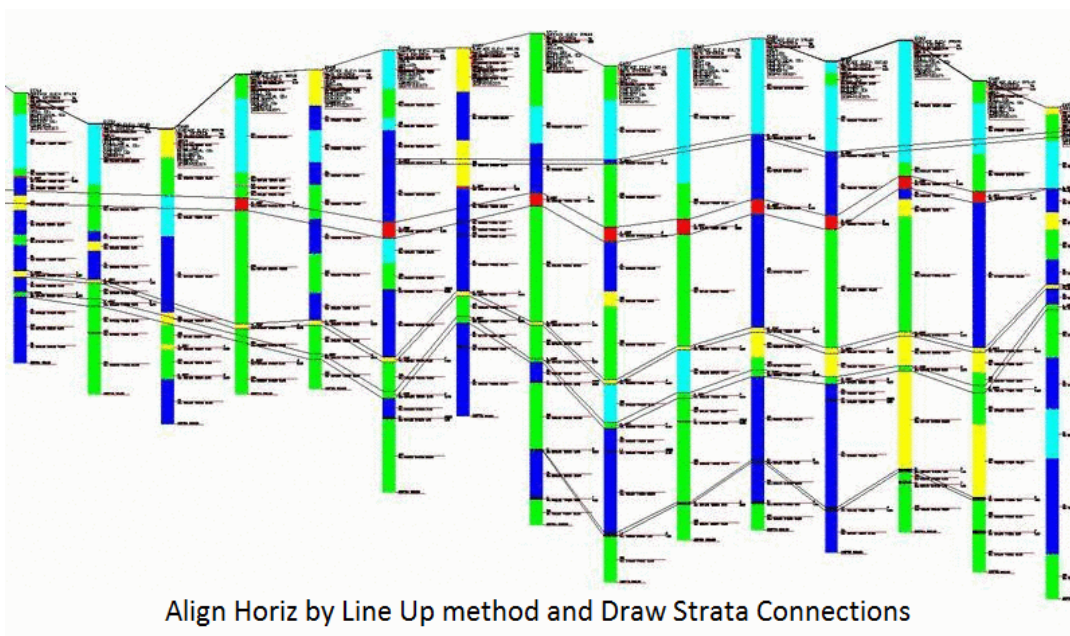

Strata Layers: This option will determine which CAD Layers are used for each strata in the column. If the *Individually* option is used, each strata will be drawn on the CAD Layer specified in the Strata Definition File. If the strata is not found in the Strata Definition File, each strata will be drawn on a CAD Layer matching the name of the strata. If the *Non-Key Same* option is used, all key strata will be drawn as if the *Individually* option were selected and all non-key strata will be drawn on the CAD Layer specified just to the right of this option. The ellipse button may be used to select a pre-existing CAD Layer. If the *All Same* option is selected, all strata will be drawn on the CAD Layer specified just to the right of this option. The ellipsis button may be used to select a pre-existing CAD Layer.

Select Attributes: If Standard Label Options are used, after clicking okay on the main dialog, you may be prompted for any additional settings in the command line. If you have chosen to draw strata/bed labels, you will see the below dialog, which allows you to choose which attributes to label. You may select multiple attributes by holding the CTRL or SHIFT keys while selecting attributes. To clear the selection of attributes, click the **Clear** button.

Select Attributes to Draw dialog (if standard label options are used)

Pick location for geologic column: *pick or enter the bottom center point for the geologic column*

Pulldown Menu Location: Drillhole

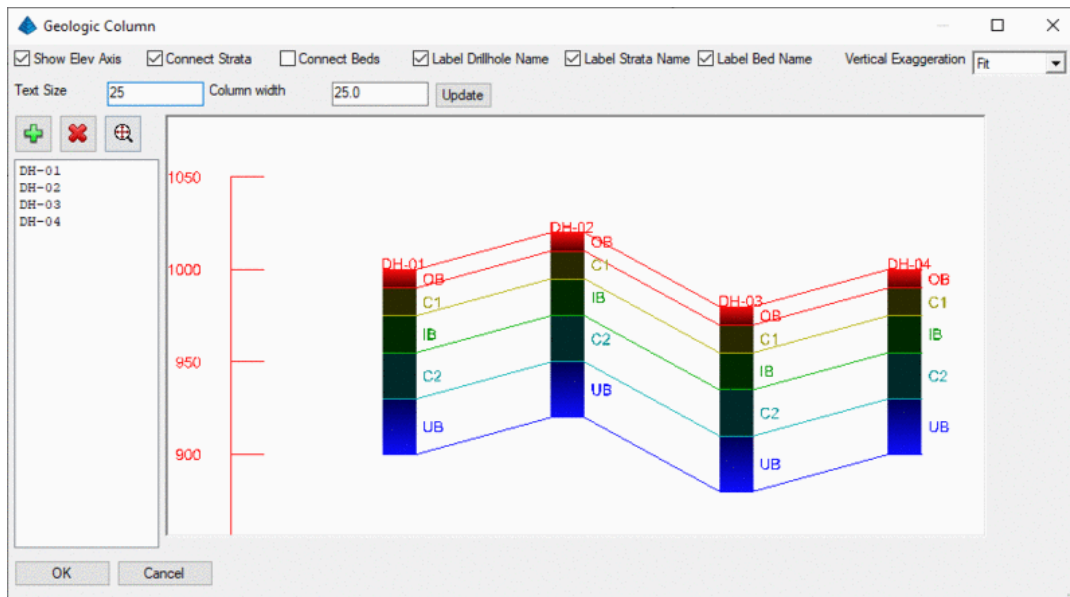

Keyboard Command: geocol

Quick Geologic Column

This command displays a section of drillholes as geological columns that are connected by a polyline fence line. This is an useful command to do quick views of correlations, depths and elevations of drillholes in a section, fence view. Before running this command, there needs to be a polyline drawn to the drillholes that are to be displayed. The seams colors are specified in the Define Strata command prior to running this command. There are options to Show Elevation Axis on the left, to Connect Strata and Beds, to Label Drillhole Name, and to Label Strata Names and Bed Names. The Vertical Exaggeration has an option to fit them to the window, or set the scale.

The green plus icon and the x icon may be used to add or remove drillholes from the view, respectively. The magnifying glass icon may be used to change the zoom of the window so that all drillholes are visible.

The **Text Size** and **Column Width** values will modify the appearance of the drillholes in the graphic view.

Prompts

Select Fence alignment polyline: (select the polyline drawn to the holes)

Maximum drillhole distance from alignment polyline <100.0>: (this is the distance it will search from the line to include the holes in the section)

Select Drillholes for geologic column. (select with a window or pick)

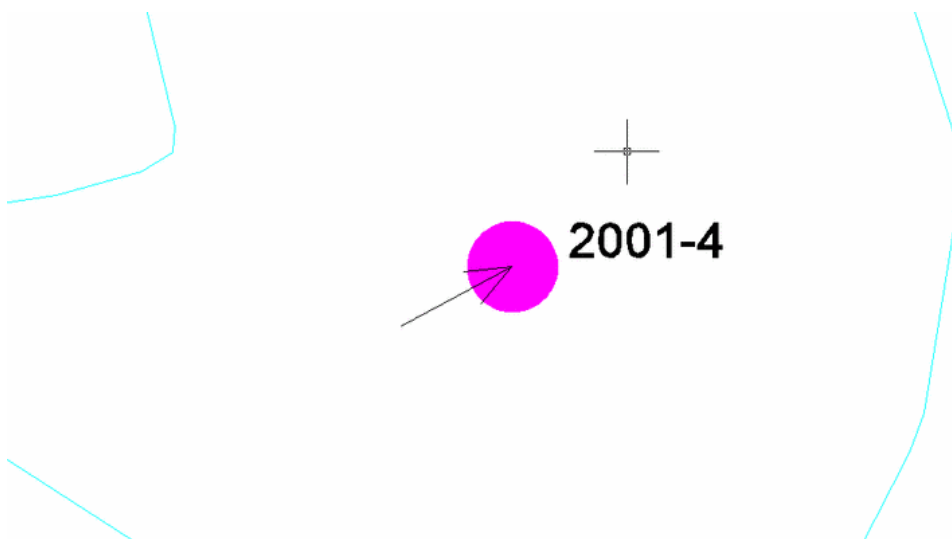

Select objects: Specify opposite corner: 6 found

Pulldown Menu Location: Drillhole

Keyboard Command: qgeocol

Find Drillhole

This command locates a drillhole by name. The screen is centered around the specified drillhole and a temporary arrow is drawn to it. Be sure that the drawing is not zoomed out too far, as the zoom is not modified, just the panning of the screen to center the drillhole.

Prompts

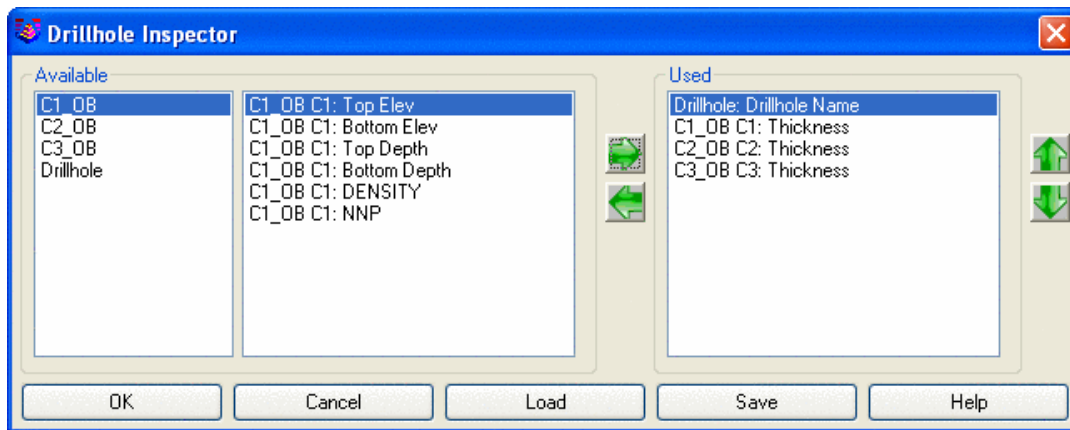

Enter drillhole name to find: 2001-4

Pulldown Menu Location: Drillhole

Keyboard Command: chfind

Drillhole Inspector

Another inspector command found in Carlson is the Drillhole Inspector. It analyzes the drillholes and displays, in the inspector window, the selected parameters. The first time this command is run, the inspector window (in the top left) is empty. The user must hit "O" for options to bring up the selection window. The possible parameters to be inspected are selected from the "available" window on the left and added to the "used" window on the right. This routine is very helpful in viewing drillhole data quickly as the cursor is moved across the drawing window, from hole to hole. A dashed arrow is shown in real-time to identify which hole is being inspected.

All drillhole information is available to the list for viewing. This includes such parameters as thickness, elevations, depth, and any user defined attributes. The "inspector window" in the top-left corner can be moved around the screen by grabbing the title bar at the top and dragging it. The values in the inspector window will change as the cursor is moved over each drillhole. Using the Label option, a label can be posted from available data in the drillhole to a specified insertion point, text size, and alignment.

Prompts

Process beds [Yes/<No>]? press Enter

Options/<Move pointer near drillhole>: Move cursor over drillholes. Type O to select drillhole options to view. Press Enter to exit.

Pulldown Menu Location: Drillhole

Keyboard Command: chinspect

Select Drillholes By Filter

This command creates a predefined selection set of drillholes by filtering them by any available field. The query is defined by either an And/Or. The field names are selected by the dropdown. These items are defined with the command Define Lookup Database, and also include all standard fields of a drillhole, such as name. Inclusion and Exclusion perimeters can also be used to aid in the filter. These are set in the upper right corner by selecting the perimeters. The SQL Query appears in the middle window. After choosing the Execute button, the drillholes that meet the criteria show up in the spreadsheet window below. To utilize these drillholes after the query, Save the query and hit OK. Then, at the command line in CAD, when prompted to "Select Objects" enter P (for Previous, or Predefined selection) and it will only use those holes for the operation.

AND/OR	FIELD NAME	OPERATOR	VALUE
- AND	NAME	LIKE	639*
- AND	DH_TYPE	=	CORE

SQL Query

```
SELECT * FROM DRILLHOLE WHERE  
[NAME] LIKE '639*' AND [DH_TYPE] = 'CORE'
```

Prompts

Built selection of 22 drillholes.

To use type 'P' at Select objects: prompt.

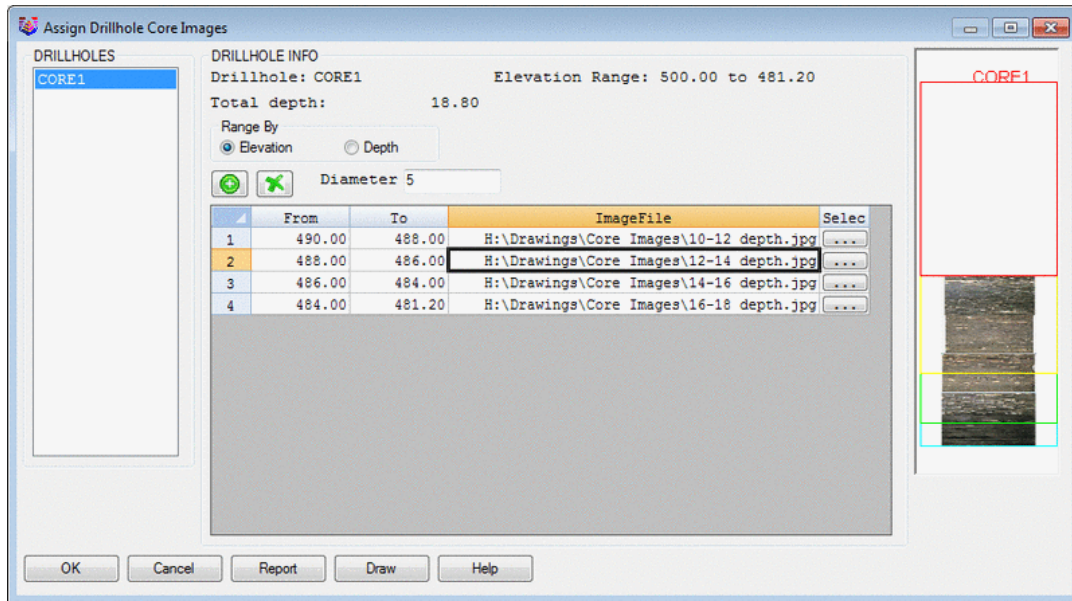

Command:

Pulldown Menu Location: Drillhole

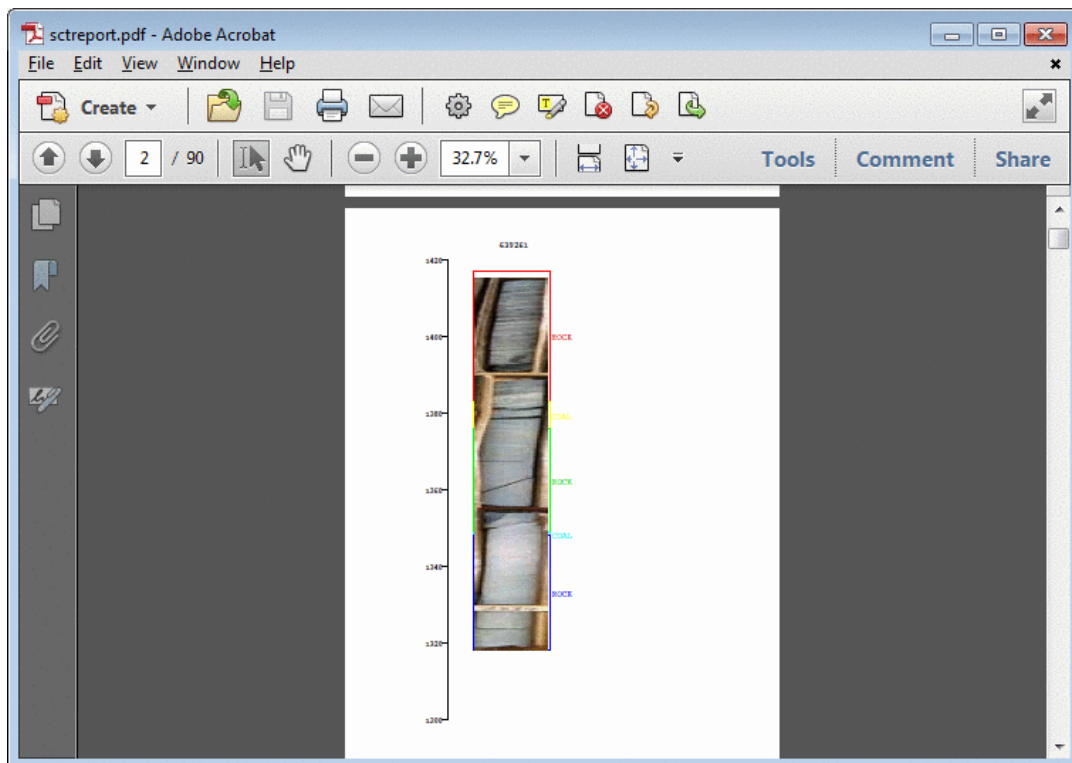

Keyboard Command:

Drillhole Core Images

This routine uses images taken of cores and links them to depths in the holes for reporting and viewing in the drawing. The command will read both JPG and BMP files. In the assignment dialog the drillholes are listed on the left side. The highlighted hole shows up as a column on the right. The intervals for each photo are added to the middle section. Selecting the green + button adds a line in the window. The From and To Elev must be set for each image interval. For each line, use the Select button on the right to find the image file for each interval. As each is entered, the core image shows up on the right in the column for each interval. The Diameter controls how wide the column appears on the right.

Reports are generated of all the holes on the list with the Report button. An example appears here.

The Draw option will place the hole in CAD, and an example of that is shown here.

Prompts

Select drillholes to assign core images.

Select objects: *pick the drillholes*

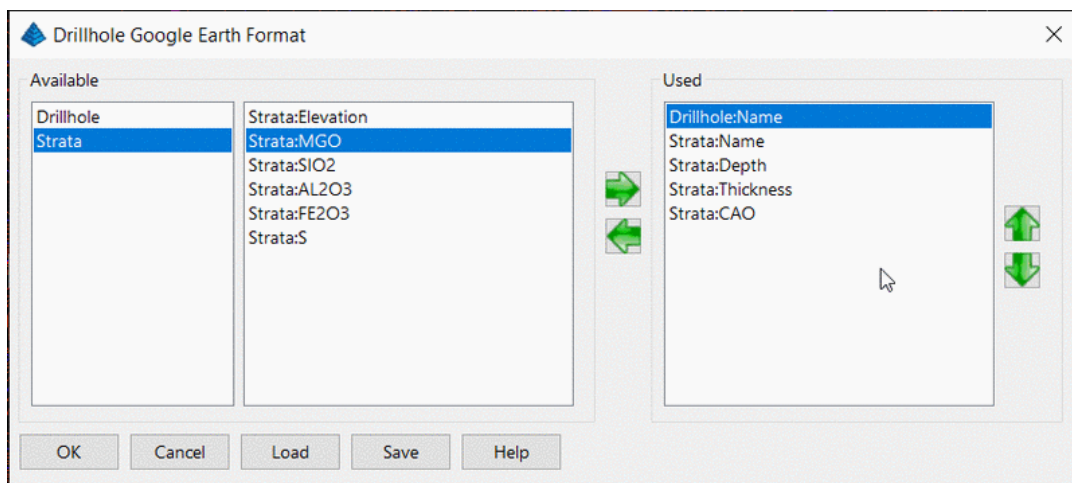

Drillhole Core Image Dialog

Drop-Down Menu Location: Drillhole, Drillhole Utilities

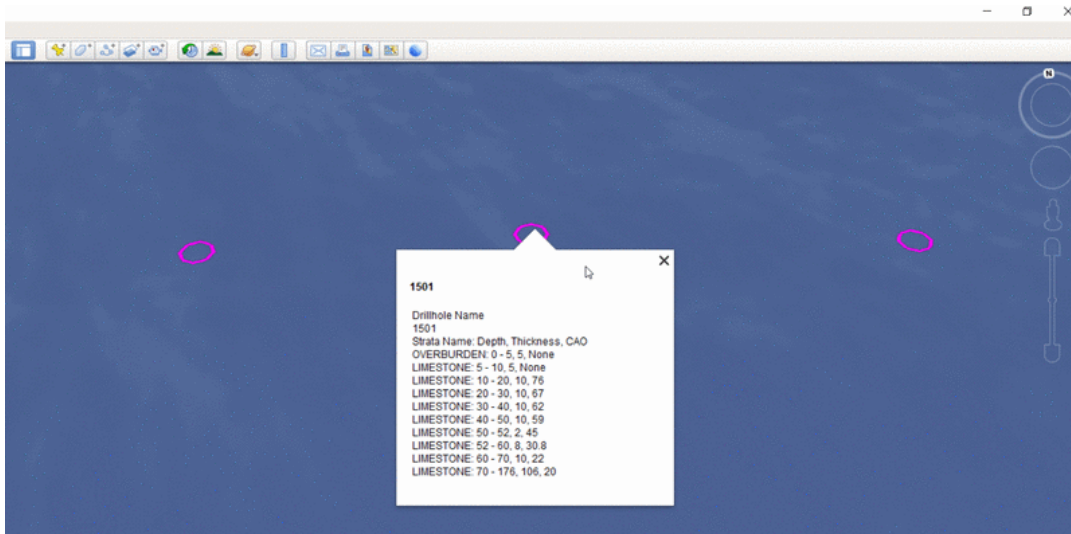

Keyboard Command: dhimage

Set Google Earth Drillhole Tags

This command sets selected fields of drillholes to be exported with the KML/KMZ data for display in Google Earth. Fields such as drillhole name, depth, thickness or any quality data may be tagged for export to Google Earth.

Select the fields from either the Drillhole or Strata section. Move them to the right in the order to be viewed in Google Earth. Then click OK. Once this command has been run, then the data is ready to export with the drillhole symbols to Google Earth. This is a separate command under **File > Export > Export Google Earth File**. Select the drillholes to export, and the symbols will appear georeferenced in Google Earth. The data can be verified with a pick on the drillhole symbol to review, and will appear similar to what is shown here.

Prompts

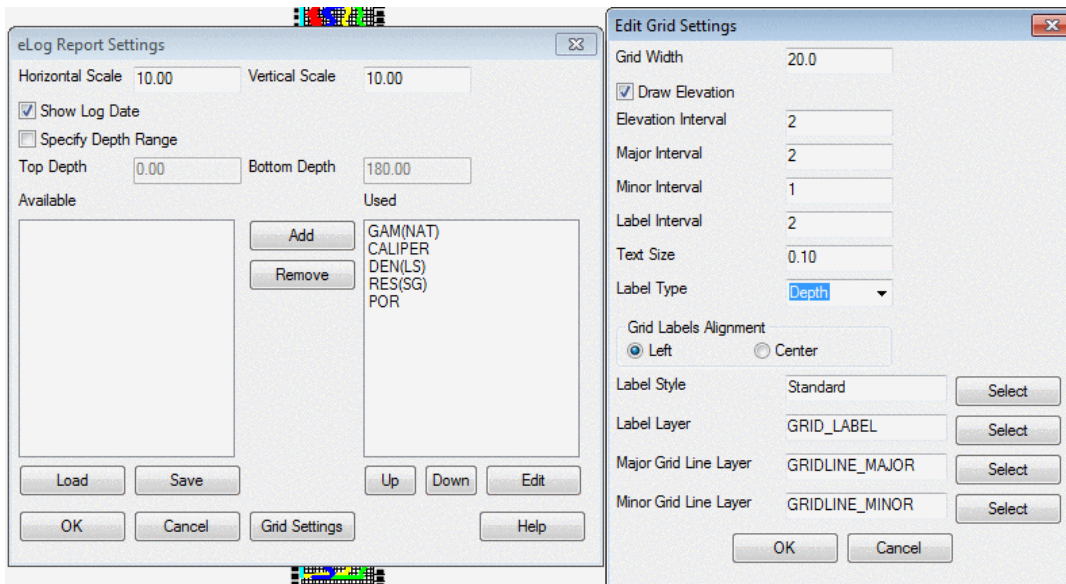

Select Drillholes, then dialog appears

Pull-down Menu Location: Drillhole > Drillhole Utilities

Keyboard Command: tagkmlch

Draw eLogs

This command takes a standard LAS file and draws the eLog data in CAD as linework, ready for analysis and plotting. It can be drawn next to an existing geologic column, or drawn by itself. LAS files are standard formats of electronic logs. The header data can vary, but the program reads through it and automatically find the Gamma, Caliper, Density, Resistivity and Por. The Automatic Mode draws the eLog next to existing geologic columns draw by the Draw Geologic Column command. For the Automatic Mode, there are settings for how far to draw the eLog to the left or right of the geologic columns, and for the folder with the LAS files. The program will match drillhole names in the drawing with the LAS file names in this folder.

Here is a sample LAS file format. The header data might be different for other files, but the program should recognize the columns either way.

Enter strata thickness: *1.0*

Select the Drillholes to process. Type ALL or select.

Updated 13 drillholes:

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: addstrata

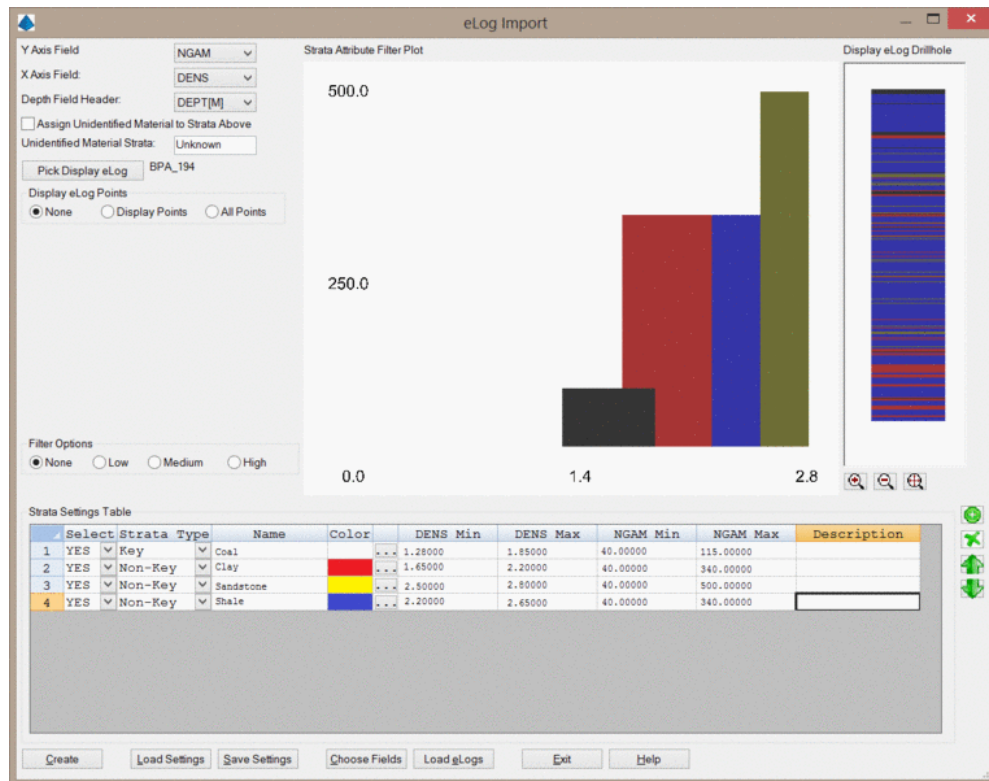

Prerequisite: Drillholes

Create Drillhole From eLog

This command will create drillholes from electronic logs of gamma ray and density readings that vary with depth (although other attributes may also be used for strata classification). These eLog files have an .las file extension,

which should not be confused with point cloud scans that sometimes use the same file extension. It is important to note that gamma/density surveys can vary greatly by equipment, and input settings will likely need to be calibrated to the equipment and project.

When the command is executed, the below dialog will appear.

To create a drillhole from an .las file, the following steps should be taken:

1. Click **Choose Fields** to setup the strata classification table
2. Populate the strata classification table
3. Click **Load eLog** to import .las files
4. Click **Create** to place the drillholes in the drawing

Y-Axis/X-Axis Field: These dropdown menus set the attributes to display on each axis of the strata classification chart shown in the middle of the dialog. The dropdown menus will only be populated after selecting fields with the **Choose Fields** button. These fields only affect the visualization of the strata classification table and do not affect how the strata are actually classified.

Depth Field Header: This dropdown menu sets the attribute to use for the Depth of the drillhole.

Assign Unidentified Material to Strata Above: This checkbox controls the classification of strata that do not fit into the strata classification table. When this option is enabled, unidentified strata will be assigned to the strata

above it. When this option is disabled, unidentified strata will be assigned a name according to the **Unidentifiable Strata Name** field.

Unidentifiable Strata Name: This field sets the name for strata that do not fit into the strata classification table.

Pick Display eLog: This button allows you to select an eLog file to use with the data preview. When multiple files are being imported at once, it can be useful to select a few different files to ensure the strata classification is applied correctly. When you click the Choose Fields button, the eLog file you use will be automatically selected for this option.

Display eLog Points: This option allows you to sample points on the graph area. Displaying these points allows you to quickly check where your eLog data fits into the strata classification you have defined.

The *None* option will not display data points.

The *Display Points* option will display points for the current eLog only (set via the **Pick Display eLog** button).

The *All* option will display points for all eLog files found in the **Load eLogs** list.

Filter Options: These options will filter the .las file to remove noise in the gamma/density readings. If the strata classification changes in an unrealistic manner, filtering the data may correct the problem.

The *None* option will not filter the input data.

The *Low*, *Medium*, and *High* options will filter the data more and more aggressively. When these filters are used, it is recommended to thoroughly check the output for accuracy.

The strata classification table is the spreadsheet at the bottom of the dialog. This table classifies each section of the drillhole to a strata according to min/max values of the density, gamma readings, and other attributes. This table should only be modified after selecting fields with the **Choose Fields** button. Strata may be added, removed, and sorted using the green icons to the right of the table. Here it is important to note that strata listed higher in the table will take precedence over strata on lower rows. In other words, if a section of the drillhole matches the criteria for multiple strata, it will be assigned to the first strata listed in the classification table. This concept is visualized in the classification chart. For example, in the above image, there is some overlap between the criteria for Coal and for Clay. Since Coal is listed at the top of the classification table, the black box in the chart representing Coal is drawn over the red box representing Clay.

Select: This column controls if the strata is used for classification. If this option is set to No, the respective strata will not appear in the drillhole.

Strata Type: This option allows you to define each strata layer as Key or Non-Key.

Name: This column sets the name for each strata.

Color: This column sets the color for each strata in the classification chart. This color is not used for any other purpose. Colors may be set by clicking the ellipse button to the right of this column.

Attribute Min/Max: These columns will be set according to the fields found in the .las file. Each column sets a bounding value for the strata. In the example shown in the above image, strata to be classified as Coal must have a density between 1.28 and 1.85 (note that these values are actually expressed as specific gravity) and a gamma reading between 40 and 115.

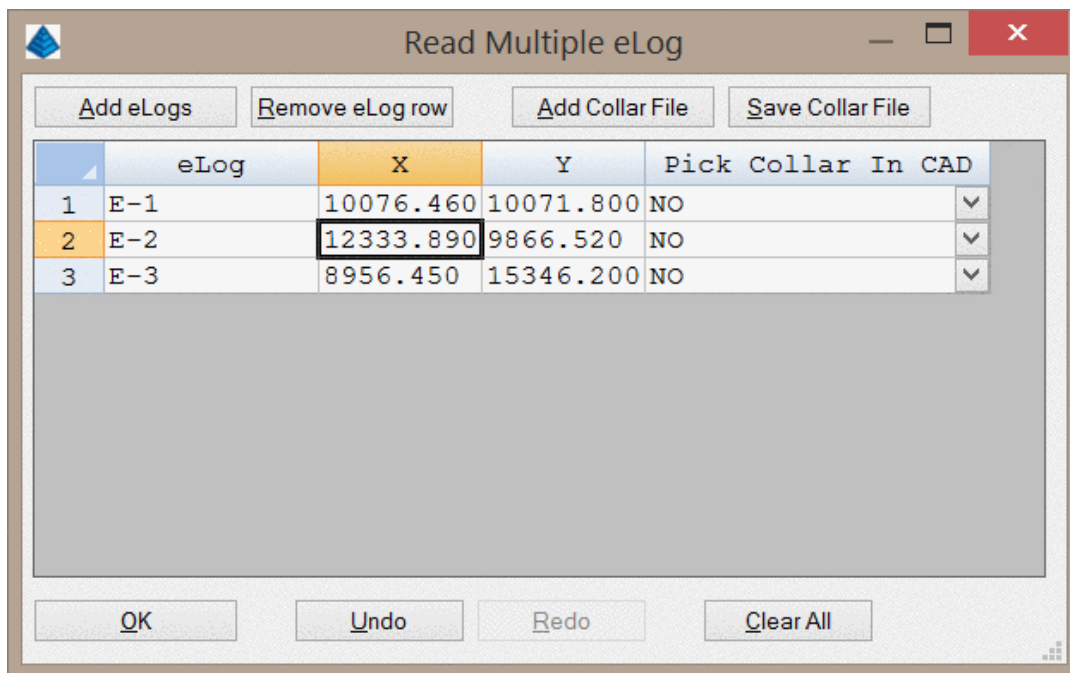

Description: This optional column can be used as a descriptor of the strata. This description will not be stored in the drillhole, however.

Create: This button will create a drillhole from the current .las file. When clicked, you will be prompted to select a location for the drillhole.

Load/Save Settings: These options will load/save settings to a .gd file.

Choose Fields: This button will prompt you for an .las file. The attribute headers found in the .las file will be added to the strata classification table.

Load eLog: This button will prompt you for one or more .las files. When clicked, the below dialog will appear.

Add eLogs: This button allows you to select .las files to add to the list.

Remove eLog row: This button will remove the currently selected eLog file from the list.

Add Collar File: This button allows you to import the coordinates of the eLogs from a text file. The format of this file should simply list the eLog name, the X coordinate, and the Y coordinate.

Save Collar File: This button allows you to save the current collar coordinates to an external text file.

Pick Collar in CAD: This option allows you to ignore the listed XY coordinates and allows you to instead pick the location of the collar for each drillhole in the CAD window.

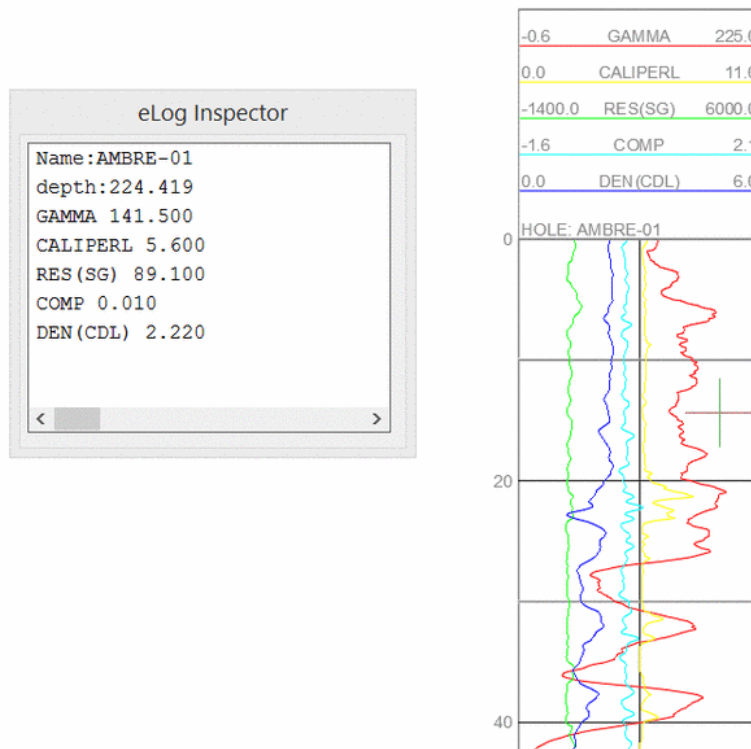

Pulldown Menu Location: Geology Module > Drillhole Pulldown Menu > Drillhole Utilities

Keyboard Command: eLog_import

Inspect eLog

This command is used to quickly display eLog attributes. This requires an eLog to have already been drawn on-screen via the Draw eLog command.

When active, a window will appear as shown below. As the cursor is moved over an eLog, the attributes of that eLog will be displayed in the window. Even if an attribute has not been drawn on the eLog, the attribute will still be displayed in the window.

Pulldown Menu Location: Drillhole > Drillhole Utilities

Keyboard Command: elog_inspect

Apply New Definition

This command allows you to update all drillholes after a change in the drillhole definition file (.CH) is made. The command Define Drillhole creates and modifies the .CH file.

Pulldown Menu Location: Drillhole, Drillhole Utilities

Keyboard Command: chredoall

Change Drillhole Symbol Number

This command will change the actual symbol of the drillhole on screen in the drawing from what was originally placed. The first window that appears is to select the symbol to change to. Click on the symbol desired with the cursor, select the holes to change and the holes are now changed.

Prompts

Symbol Selection Dialog *Choose a symbol*

Select the Drillholes to change symbol.

Select objects: *pick drillhole symbols*

Modified 3 drillhole symbols

Pulldown Menu Location: Drillhole

Keyboard Command: chsymbol2

Change Drillhole Symbol Size

This command changes the drillhole symbol size of the selected drillholes to the user-specified size. The diameter of the symbol will be changed to the entered drawing units. Another way to change all the symbols at once, is to change the size in Define Drillhole, then run Apply New Definition.

Prompts

DrillHole symbol size: *50*

Select the DrillHoles to resize.

Select objects: *pick drillhole symbols*

Changed 3 drillhole symbols

Pulldown Menu Location: Drillhole

Keyboard Command: chsymbol

Change Process On/Off Status

This command changes the processing status of the selected drillholes. If the status is off, then they can still appear on screen, but will be ignored for all processing. Drillholes are only used when the status is set to on.

Prompt

Select the Drillholes to set.

Select objects: Specify opposite corner: 42 found

Select objects:

Set processing status [<ON>/OFF]? *ON*

Modified 42 drillholes.

Pulldown Menu Location: Drillhole

Keyboard Command: chstatus

Change Drillhole Surface Z

This useful command will raise or lower the surface/collar elevation of the selected drillholes either by a surface model file or by an user entered differential. This is necessary when a series of holes have been drilled and surveyed from a local base elevation in the field. Once that bench mark elevation is determined, the selected holes in the drawing can be translated to the appropriate elevation. Older holes located before GPS surveys might not have the correct surface elevation. This will "drape" them onto a surface model file which can be a grid, TIN or FLT file.

Prompts

Select the Drillholes to process.

Select objects: all (to select the drillholes) 190 found

Set elevation by surface model or differential [<Model>/Differential]?

M for Model or Enter if in <>

Reading cell> 251316

Hold strata thickness [<Yes>/No]? y Yes will keep the same thickness of all strata, No will change the thickness of the first strata in the drillhole.

Modified 180 drillholes.

Skipped 10 drillholes already at elevation

OR:

Select the Drillholes to process.

Select objects: pick the drillholes

Enter elevation change: 150. Use a positive value to raise the elevation and a negative value to move down. This example will raise the elevations by 150.

Hold strata thickness [<Yes>/No]? press Enter for Yes If Yes, then the complete stratigraphic column will be moved up or down, keeping the thickness of each the same. If No, then the thickness of the first strata in the hole will be affected; thicker with a positive value as the collar elevation is raised, and thinner if negative.

Modified 15 drillholes.

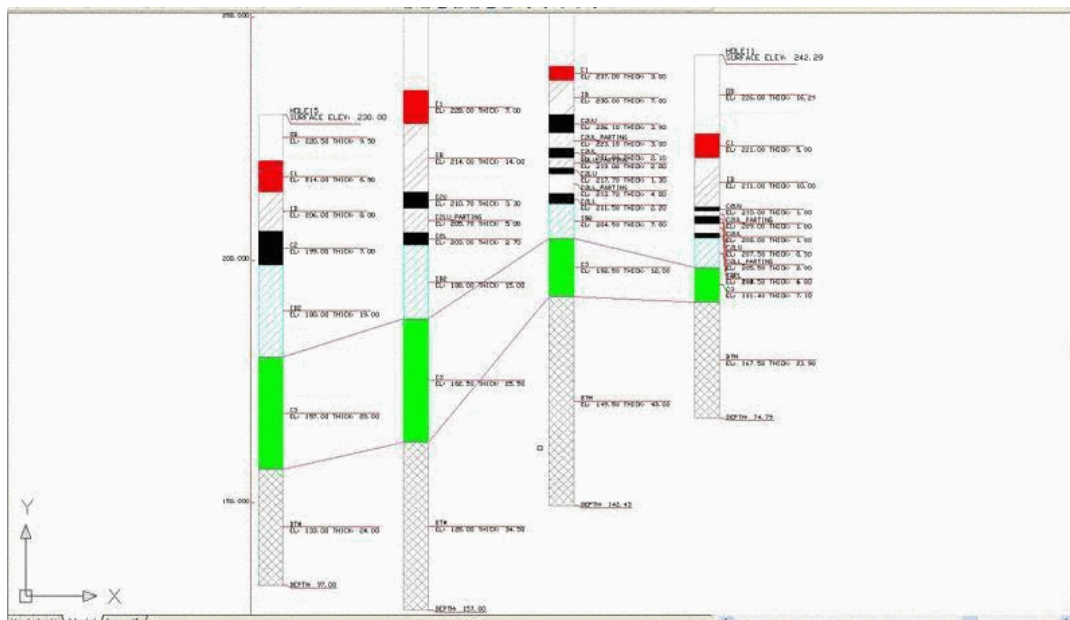

Pulldown Menu Location: Drillhole

Keyboard Command: chelev

Assign Strata Correlation

This command assigns strata and bed names to intervals in a geologic column view. This is a great tool for a geologist to do the on-screen correlating. Rows of geologic columns can be drawn, and correlated just by "picking" the intervals to connect with lines. Before starting this command, create geologic columns with the Draw Geologic Column command. The Fill option set to Outline Only can make it easier to pick the strata.

While viewing the geologic columns, pick the strata polylines to name on the left or right edge, or they can be selected with a window. Then a dialog appears where you can enter the strata name and an optional bed name. These names are saved back in the drillholes, or in the database. There is an option to connect the strata with the same names with lines. The one thing it does not do is update the text. The drillholes need to be drawn again to see that update.

Prompts

Connect strata with lines (<Yes>/<No>)? press Enter for Yes

Select the Strata to name.

Select objects: pick the strata polylines from the geologic column

Name Strata Dialog

Select the Strata to name.

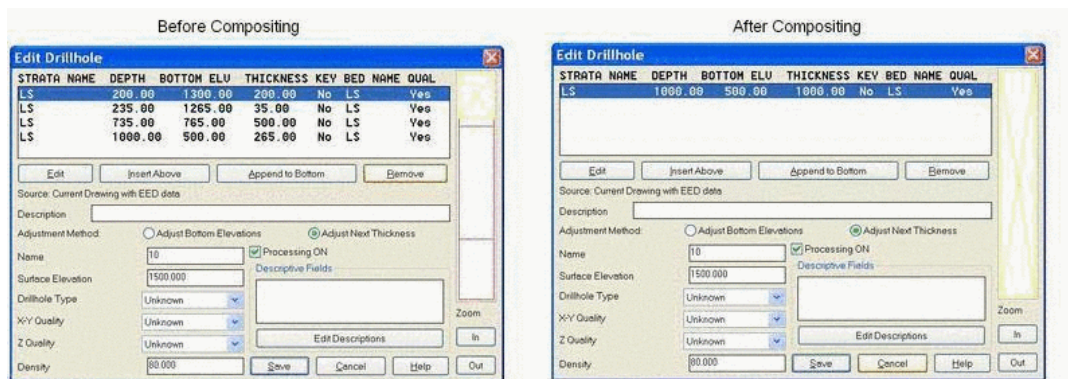

Select objects: press Enter to end

Pulldown Menu Location: Drillhole in Advanced Mining

Keyboard Command: nmstrata

Composite Duplicate Strata

This command will composite all duplicate strata names found within the selected drillholes. To be composited, the strata must have the same bed names, the same key/non-key status and they must be in sequential order without any other strata in between (no partings). There is an option for whether the strata must have the same name. Also, there is an option whether to composite only key or only non-key strata. Since Carlson doesn't model duplicate strata without bed names, this routine can be useful to composite a strata that duplicates itself. The strata qualities will be weight averaged by thickness, giving one value for each attribute.

Prompts

Select the Drillholes to process.

Select objects: select drillholes to composite duplicate strata

Strata to process [Key/Non-key/<Both>]? press Enter

Require strata name to match [<Yes>/<No>]? press Enter

Update 19 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: dupstrata

Prerequisite: Drillholes

Composite Strata By Beds

This command composites strata within a drillhole based on bed name and key/non-key status. All the non-key strata with a matching bed name that are above the first key strata are composited and assigned the name `strata_top`. The non-key strata between the key strata are composited as `strata_parting`. The key strata with a matching bed name are composited as `strata_key`. The non-key strata below the last key are composited as `strata_bottom`. This compositing method is the same the StrataCalc uses for processing strata with bed names. The strata qualities will be weight averaged by thickness, giving one value for each attribute.

Before Composite Strata By Beds

Strata name	Bed name	Key	Thick	Bot	Elev
ROCK	C1	NO	67.00	1684.12	
ROCK	C1	NO	1.00	1683.12	
COAL	C1	YES	1.50	1681.62	
ROCK	C1	NO	0.25	1681.37	
COAL	C1	YES	0.25	1681.12	
COAL	C1	YES	2.00	1679.12	
ROCK	C1	NO	1.00	1678.12	

After Composite Strata By Beds

Strata name	Bed name	Key	Thick	Bot	Elev
C1.TOP	C1	NO	68.00	1683.12	
C1.PARTING	C1	NO	0.25	1682.87	
C1.KEY	C1	YES	3.75	1679.12	
C1.BOTTOM	C1	NO	1.00	1678.12	

Prompts

Select the Drillholes to composite.

Select objects: *pick the drillholes to process*

Pulldown Menu Location: Drillhole-> Strata/Bed Utilities

Keyboard Command: `compstrata`

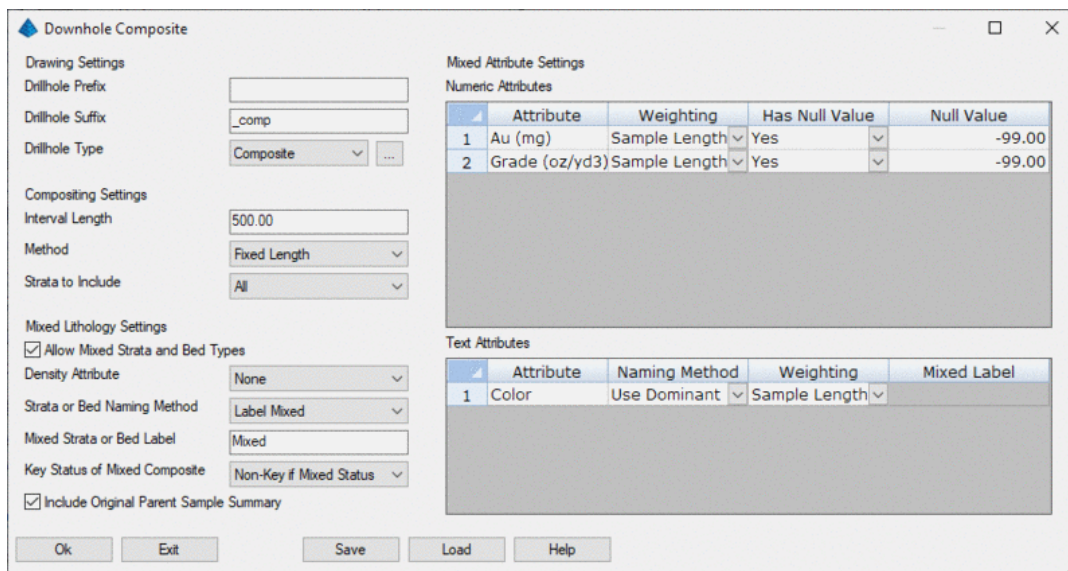

Prerequisite: Drillholes

Composite Strata By Interval

The purpose of compositing strata is to create regularized samples and control bias for geostatistical modeling. For example, one drilling campaign may have sampled strata on a 10' interval, while another drilling campaign sampled on a 3' interval. Using a mix of the two in modeling would lead to distinct zones of higher and lower grade variability purely due to the measurement length. Compositing the 3' to 10' would remove this measurement bias.

It is important to note that this command will create new drillhole entities rather than modifying the original drillholes. This allows you to run other commands with either the original drillholes or the composited drillholes to compare results.

When the command is first executed, you will be prompted to select the drillholes to modify. The below dialog will then appear.

Drillhole Prefix/Suffix: These settings will apply a prefix/suffix to the names of the composited drillholes.

Drillhole Type: This setting controls the Drillhole Type of the composited drillholes. It is important to note that this option will not allow you to select a Drillhole Type in use by the selected drillholes - you must select a new drillhole type. Drillhole Types may be modified by clicking the ellipsis button. More information regarding Drillhole Types is found in the Drillhole Lookup Database documentation.

Interval Length: This value sets the sample length for the new composites. If the **Method** is set to Fixed Length, the program will start at the top of the drillhole and create composites of this exact length moving downward. Any remaining length will be retained as a shorter sample. If the **Method** is set to Best Fit, the program will divide the drillhole into equal lengths that are as close to the specified **Interval Length** as possible.

Strata to Include: This option controls which Strata will be considered for compositing. When using the Selected option, you will be prompted to select the strata in a separate dialog.

Allow Mixed Strata and Bed Types: This option determines if compositing will occur across strata/bed boundaries. When enabled, other settings related to mixing strata/bed types will be made active.

Density Attribute: This option sets the density attribute used for attribute weighting. This option is only required when samples are attributes are weighted by Sample Weight (as opposed to Sample Length)

Strata or Bed Naming Method: This option determines the resulting strata/bed name when composites cross strata/bed boundaries.

The Use Dominant option will retain the name of the longest/heaviest sample contributing to the composite. For example if a 10' composite is created from 7' of Strata A and 3' of Strata B, the resulting composite strata name will be A.

The Concatenate option will concatenate the strata names contributing to composite. For example, if a 10' composite is created from 3' of Strata A, 3' of Strata B, and 4' of Strata C, the resulting composite strata name will be A.B.C.

The Label Mixed option will not retain any of the original strata names when more than one strata contributes to the composite, but will instead label the resulting strata according to the name entered for the **Mixed Strata or Bed Label**.

It is important to note that the Strata Names and Bed Names are considered separately. If a composite is created from 3 samples of Strata A with varying Bed Names, only the Bed Name will be subject to change. Alternatively, if a composite is created from 3 samples with 3 different Strata names but the same Bed Name, only the Strata Name will be subject to change.

Key Status of Mixed Composite: This option controls the key status of the resulting composite strata.

The Use Dominant option will retain the key status of the longest/heaviest strata contributing to the composite.

The Key if Mixed Status will set all Mixed composites as key.
 The Non-Key if Mixed Status will set all Mixed composites as non-key.

Include Original Parent Sample Summary: When enabled, the composited strata will contain additional strata attributes indicating the strata attribute values from the contributing strata.

Numeric Attributes: This spreadsheet will list all numeric strata attributes found in the selected drillholes. Strata attributes may be averaged by the **Weighting** column (Sample Length or Sample Weight). If the strata attributes contain a specific value for null values, this value may be specified in the **Null Value** column when the **Has Null Value** column is set to Yes.

Text Attributes: This spreadsheet will list all text strata attributes found in the selected drillholes. If the **Naming Method** is set to Dominant, only the value of the longest/heaviest contributing strata will be retained in the composite, based on the option selected in the **Weighting** column. If the **Naming Method** is set to Concatenate, the resulting text value will be a concatenation of the contributing text values. If the **Naming Method** is set to Label Mixed, the resulting text value will be set according to the **Mixed Label** column.

An example drillhole before and after compositing on a 5' Fixed Length is shown below.

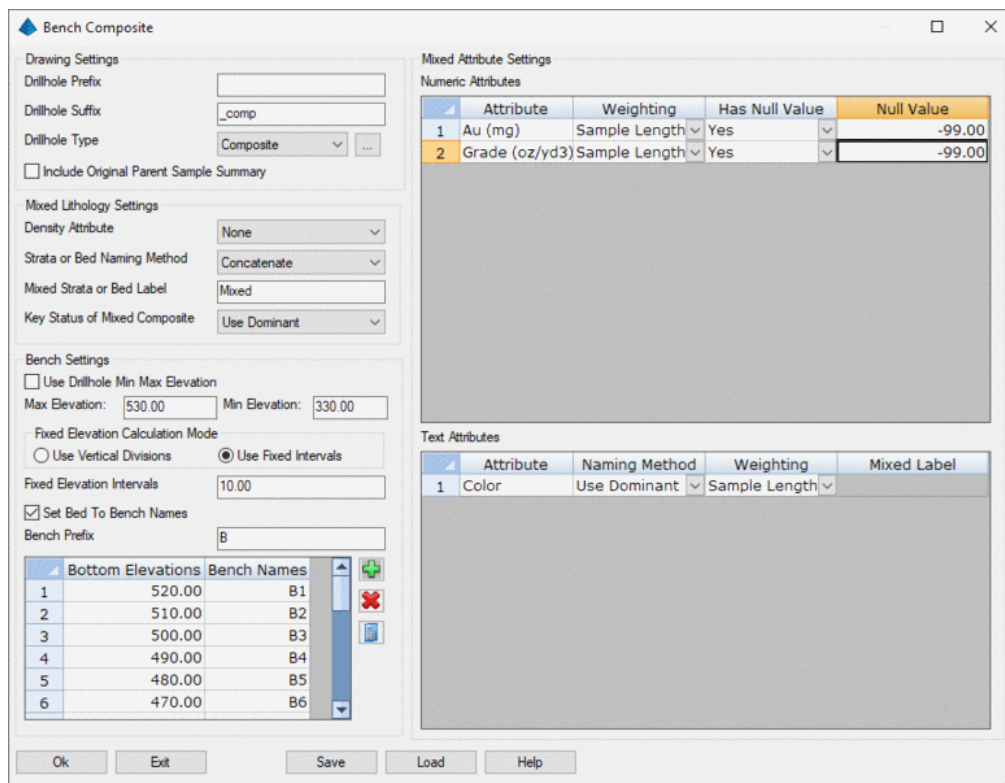

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: compdownhole

Composite Strata by Elevation

The purpose of compositing strata is to create regularized samples and control bias for geostatistical modeling. For example, one drilling campaign may have sampled strata on a 10' interval, while another drilling campaign sampled on a 3' interval. Using a mix of the two in modeling would lead to distinct zones of higher and lower grade variability purely due to the measurement length. Compositing the 3' to 10' would remove this measurement bias.

It is important to note that this command will create new drillhole entities rather than modifying the original drillholes. This allows you to run other commands with either the original drillholes or the composited drillholes to compare results.

When the command is first executed, you will be prompted to select the drillholes to modify. The below dialog will then appear.

Drillhole Prefix/Suffix: These settings will apply a prefix/suffix to the names of the composited drillholes.

Drillhole Type: This setting controls the Drillhole Type of the composited drillholes. It is important to note that this option will not allow you to select a Drillhole Type in use by the selected drillholes - you must select a new drillhole type. Drillhole Types may be modified by clicking the ellipsis button. More information regarding Drillhole Types is found in the Drillhole Lookup Database documentation.

Include Original Parent Sample Summary: When enabled, the composited strata will contain additional strata attributes indicating the strata attribute values from the contributing strata.

Density Attribute: This option sets the density attribute used for attribute weighting. This option is only required when samples are attributes are weighted by Sample Weight (as opposed to Sample Length)

Strata or Bed Naming Method: This option determines the resulting strata/bed name when composites cross strata/bed boundaries.

The Use Dominant option will retain the name of the longest/heaviest sample contributing to the composite. For example if a 10' composite is created from 7' of Strata A and 3' of Strata B, the resulting composite strata name will be A.

The Concatenate option will concatenate the strata names contributing to composite. For example, if a 10' composite is created from 3' of Strata A, 3' of Strata B, and 4' of Strata C, the resulting composite strata name will be ABC.

The Label Mixed option will not retain any of the original strata names when more than one strata contributes to the composite, but will instead label the resulting strata according to the name entered for the **Mixed Strata or Bed Label**.

It is important to note that the Strata Names and Bed Names are considered separately. If a composite is created from 3 samples of Strata A with varying Bed Names, only the Bed Name will be subject to change. Alternatively, if a composite is created from 3 samples with 3 different Strata names but the same Bed Name, only the Strata Name will be subject to change.

It is also important to note that the **Set Bed To Bench Names** option will override any naming convention applied to the Bed Names.

Key Status of Mixed Composite: This option controls the key status of the resulting composite strata.

The Use Dominant option will retain the key status of the longest/heaviest strata contributing to the composite.

The Key if Mixed Status will set all Mixed composites as key.
 The Non-Key if Mixed Status will set all Mixed composites as non-key.

Use Drillhole Min/Max Elevation: When enabled, this option will automatically set the **Max Elevation** and **Min Elevation** values according to the max/min values detected from the selected option . When disabled, you will be able to set the **Max Elevation** and **Min Elevation** values manually.

Fixed Elevation Calculation Mode: This option controls how the Bottom Elevations will be automatically calculated. The Use Vertical Divisions option will allow you to specify the **Number of Vertical Divisions** to set between the **Max Elevation** and **Min Elevation**. The Use Fixed Intervals will allow you to enter the **Fixed Elevation Intervals** value to set the Bottom Elevations for each Interval. To apply each option, you may click the calculator icon to the right of the spreadsheet.

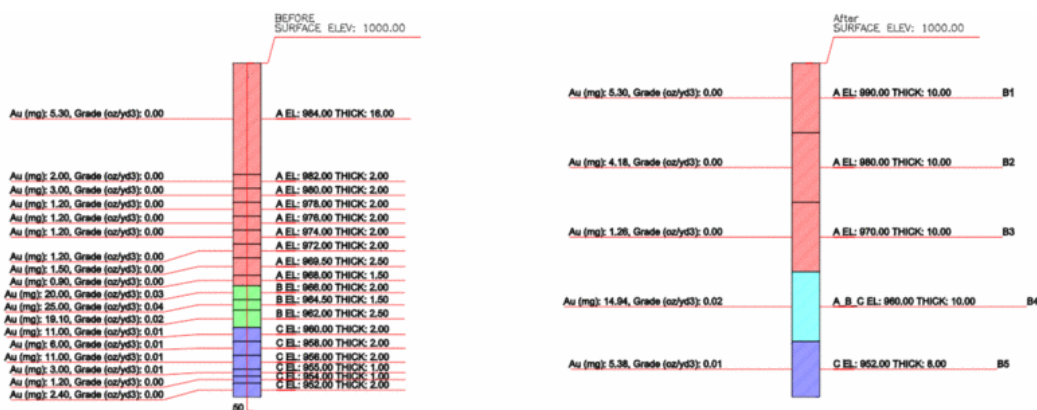

Set Bed to Bench Names: This option will overwrite all new bed names according to the **Bench Names** column of the spreadsheet. When intervals are automatically calculated by clicking the calculator icon, the bench names will be generated in increasing order from top to bottom. You may specify a **Bench Prefix** if desired.

The + and X icons next to the spreadsheet allow you to add or remove rows. This is useful if you need to add a Bottom Elevation that is not automatically calculated for you. It is important to note that Bottom Elevations must be listed in decreasing order from Top to Bottom. If this convention is not met, the out-of-order cells will be highlighted with a red fill.

Numeric Attributes: This spreadsheet will list all numeric strata attributes found in the selected drillholes. Strata attributes may be averaged by the **Weighting** column (Sample Length or Sample Weight). If the strata attributes contain a specific value for null values, this value may be specified in the **Null Value** column when the **Has Null Value** column is set to Yes.

Text Attributes: This spreadsheet will list all text strata attributes found in the selected drillholes. If the **Naming Method** is set to Dominant, only the value of the longest/heaviest contributing strata will be retained in the composite, based on the option selected in the **Weighting** column. If the **Naming Method** is set to Concatenate, the resulting text value will be a concatenation of the contributing text values. If the **Naming Method** is set to Label Mixed, the resulting text value will be set according to the **Mixed Label** column.

An example before and after compositing on 10' intervals from elevation 1000' to elevation 950' is shown below. Note that the strata names have been concatenated while the bed names have been set according to the bench name.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: compbench

Set Strata Key Status

This command processes a given set of drillholes, searches for the information from the selected drillholes and sets key status of each strata with the user-specified name to the required value. This is a much faster way to change key/non-key strata type than going through the Edit Drillhole or Drillhole Datasheet commands. The * wildcard is supported in this command for multiple selections. Bed names can be used as a filter.

Prompts

Select the Drillholes to process.

Select objects: Specify opposite corner: 7 found

Select objects:

Enter name of the strata to modify (wildcards supported): LS*

Enter bed name to limit the selection or press Enter for none:

Set status as [Key/<Non-key>]? K

Modified 7 drillholes.

Pulldown Menu Location: Drillhole, Strata/Bed Utilities

Keyboard Command: stratakey

Fill-in Missing Key as Zero

This command inserts zero thickness key strata when the strata is missing from the geological sequence in the drillhole. This change is permanent to the drillhole, so make sure to have a backup if this is not the desired change. This allows for more control in the pinch out modeling of the drillholes and thickness modeling.

Select the Drillholes to process.

Select objects: Specify opposite corner: 174 found

Modified 12 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities in Geology

Keyboard Command: fillstrata

Add Strata

This routine inserts an interval into the drillholes at either the very top or the very bottom of the selected holes. It is necessary to do this for certain types of geological modeling that have the top or bottom seam disappearing, and not all intervals in the hole have a bed name, such as in this lignite modeling. It "borrows" thickness from either the top or bottom interval, as in this example shown below in the ROCK strata. Some prefer to enter in a 0.1 interval and just call it TOP.

Edit Drillhole

STRATA NAME	DEPTH	BOTTOM ELU	THICKNESS	KEY	BED NAME	QUAL
ROCK	99.00	4818.17	99.00	No		No
COAL	102.00	4815.17	3.00	Yes	C1	No
ROCK	131.40	4785.77	29.40	No		No

It went from 99 to 98 thick, with the addition of 1 foot of topsoil. This will aid in the modeling of the seam C1 in holes where it does not exist, due to pinch or erosion. This routine should not be used in holes that are drilled in a valley, and the C1 seam is above the collar; it will be modeled with conformance.

Prompts

Add strata to top or bottom of drillhole [<Top>/Bottom]? *Top* (in this example)

Enter strata name: *Topsoil*

Enter bed name: *Top*

Status for strata [<Key>/Non-key]? *N*

Enter strata thickness: *1.0*

Select the Drillholes to process. Type ALL or select.

Select objects: Specify opposite corner: 22 found

9 were filtered out.

Select objects: *press Enter to accept*

Updated 13 drillholes:

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: addstrata

Prerequisite: Drillholes

Delete Strata

This command allows you to remove certain strata in multiple drillholes in one step. If strata is removed the thickness of strata removed is added to strata below.

Prompts

Select the Drillholes to process.

Select objects: Specify opposite corner: 20 found

Select objects:

Enter name of the strata to modify (wildcards supported): *LS*

Enter bed name to limit the selection or press Enter for none:

Modified 20 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: stratadel

Rename Strata

This command allows you to rename a certain strata in multiple drillholes in one step. It prompts for the old strata name and then the new name.

Prompts

Select the Drillholes to process.

Select objects: Specify opposite corner: 20 found

Select objects:

Enter name of the strata to modify (wildcards supported): *LS*

Enter bed name to limit the selection or press Enter for none:

Enter a new name for the strata: *LS1*

Modified 20 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: strataren

Reset Invalid Attribute

This command will set the invalid attribute values in the selected drillholes to blank. The range of valid attribute values are set in the Define Attributes command. Any attributes found in the drillholes outside that range are deleted.

Prompts

Select the Drillholes to process.
Select objects: *select the drillholes*
Modified 309 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: resetattr

Delete Attribute

This routine is a quick and easy way to remove the specified attribute from the drillholes. It will remove the attribute from all the strata in the selected drillholes.

Prompts

Select the Drillholes to process.
Select objects: *select drillholes*
Enter attribute name to delete: *BTU*
Modified 219 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: delattr

Rename Attribute

The function of this command is to rename attributes of selected drillholes. This is the only way to globally rename the name of attributes within holes. Be sure to spell the attribute name precisely the way it appears in the holes.

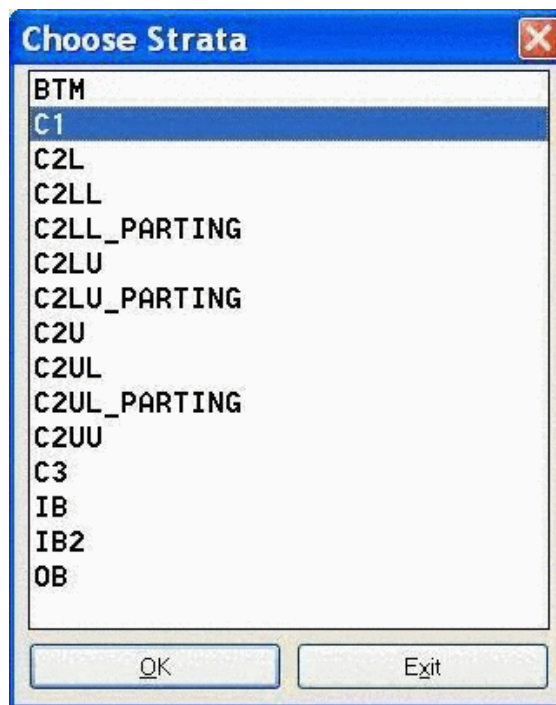

Prompts

Select the Drillholes to process.
Select objects: *select the drillholes*
Enter old attribute name to rename: *CA*
Enter new attribute name: *CAC03*
Modified 35 drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities
Keyboard Command: renmattr

Assign Bed Names

This command assigns a bed name for each strata with picked names in a given set of drillholes. The strata list is generated based on drillholes selected enabling user to pick multiple strata to process. Hold the CTRL or SHIFT keys to select multiple strata for bed assignment.

Prompts

Select the DrillHoles for bed assignment:

Select objects: *Select Drillholes*

Enter name for the bed: *C1_BED*

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: assignbed

Fill-in Bed Names

For some methods of processing the strata modeling routines, the drillhole set should have either no duplicate strata names or bed names assigned for each strata. When bed names are assigned to the key strata (or just some strata within drillhole), the blanks may be filled-in using this routine. The routine works from the top of the drillhole down until it finds the first strata with a non-empty bed name. That bed name is then applied to all strata with empty bed names above that strata. This procedure is then repeated to the bottom of the hole. For the strata below the last strata with bed name assigned, the last bed name is used.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: fillbed

Remove All Non-Key Bed Names

This command sets the bed name to blank for all non-key strata in the selected drillholes.

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: remove_all_nk_bed

Prerequisite: Drillholes in drawing

Remove Bed Names After Last Key

For some methods of modeling, users prefer to remove or delete all of the bed names in a drillhole after the last Key interval. This command will do the entire selection set of drillholes at one time.

Prompts

Select the Drillholes for bed process.

Select objects: Specify opposite corner: 11 found

Select objects:

Updated 7 drillholes

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: remove_last_nk_bed

Split Bed

For the selected drillholes, this command provides the ability to manipulate an existing bed at certain elevations or thickness. The bed can be split by changing the key/non-key status or by supplying a new bed name. With a new bed name, the bed will be split into one part with the old name and the other with the new name. The elevation at which to split the bed can be specified as a flat elevation or as a grid file. For the grid file, the split elevation is defined by the grid file at the drillhole location. The thickness method allows you to split off a specified thickness from the top or bottom of the bed or to add a specified thickness from the adjoining strata to the top or bottom of the bed. Besides changing the structure (thickness/elevation) of the bed, this routine will also split the bed qualities.

One application of this routine would be to use the thickness option to set the top 0.1 of the KEY bed to non-key to model loss at the top of the seam. Another application is to split a large KEY bed into two beds at an elevation grid to model mining the bed in two passes or benches.

Prompts

Split strata method [<Elevation>/Grid/Thickness]? *T for Thickness*

Select the Drillholes for bed split.

Select objects: *pick the drillhole symbols*

Enter name of the bed to split: *C2*

Rename bed or assign key/non-key status [<Name>/Status]? *press Enter for Name*

Enter new name for the thickness change: *C2B*

Split from top or bottom [<Top>/Bottom]? *press Enter for Top*

Add or subtract thickness from bed [<Add>/Subtract]? *S for Subtract*

Enter thickness (ft): *2*

By Elevation:

Split strata method [<Elevation>/Grid/Thickness]? *press Enter for Elevation*

Select the Drillholes for bed split.

Select objects: Specify opposite corner: 5 found

Select objects:

Enter name of the bed to split: *C1*

Rename bed or assign key/non-key status [<Name>/Status]? *N*

Enter new name for the upper part of the bed: *C1u*

Enter new name for the lower part of the bed: *C1L*

Enter a split elevation: *2510*

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: splitbed

Rename Bed

This command replaces the old bed name with a new bed name in a selected set of drillholes.

Prompts

Select the Drillholes for bed renaming.

Select objects: Specify opposite corner: 42 found

Select objects:

Enter OLD name of the bed: C1

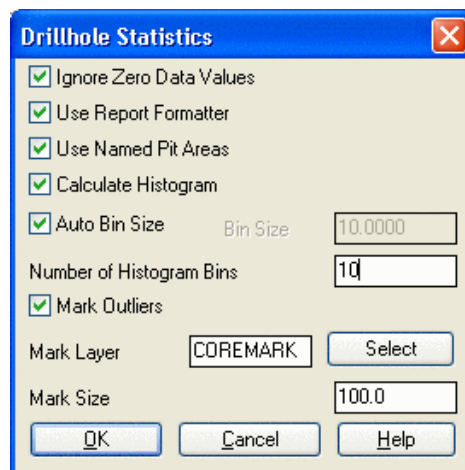

Enter NEW name for the bed: C-ONE

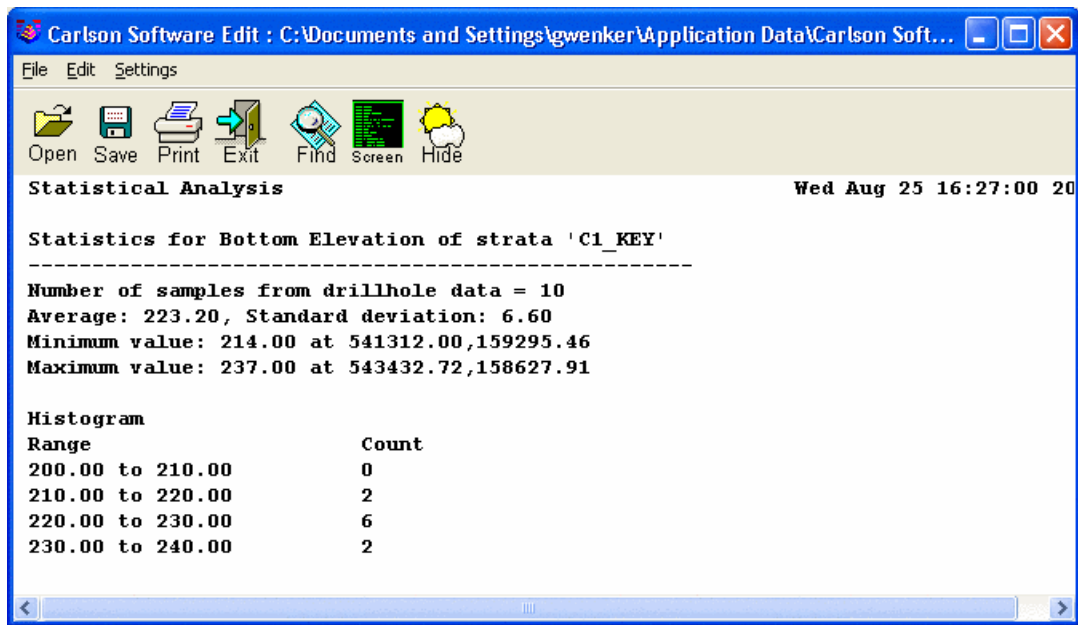

Pulldown Menu Location: Drillhole > Strata/Bed Utilities

Keyboard Command: renamedbed

Statistical Analysis

This command calculates the minimum, maximum, average, slope, and standard deviation of strata values in drillholes or from grids. These values can be the strata thickness, bottom elevation, or user-defined attributes such as BTU or GRADE. The statistics are calculated from either drillholes or a grid file. With drillholes, the statistics are calculated using the drillhole data points. With Geologic Model and grid files, the data points are the grid cells. Using a grid allows you to analyze an area by selecting inclusion and exclusion closed polylines of the area. Grid or drillholes both handle pit names for analyzing multiple areas at once. A grid file of a strata attribute can be created with the Make Strata Grid File or Autorun Strata Grids commands. The Statistical Analysis program starts with the option to use Grid, Geologic Model or Drillholes. With the Grid option, the grid file (.grd) to process can be selected individually in the standard file selection dialog. The Geologic Model option allows you to select multiple grid files from a Geologic Model File (.pre) that stores a series of grid files, as shown by highlighting multiple strata at one time. There are options for histogram and Bin size in the reports, as well as marking the outliers in the drawing for detailed review. The report can be viewed in the standard report viewer, or it can be turned on to use the report formatter.

Prompts

For drillhole statistics:

Calculate statistics from grid file or drillholes (Grid/Model/<Drillholes>)? *press Enter for drillholes*

Ignore zero values (<Yes>/No)? *press Enter*

Select the DrillHoles for report.

Select objects: *select the drillhole symbols*

Choose Strata to Process

Calculate THICKNESS statistics for strata X (<Yes>/No)? *No*

Calculate BOTTOM ELEVATION statistics for strata X (<Yes>/No)? *No*

Calculate BTU statistics for strata X (<Yes>/No)? *Yes*

Number of samples from drillhole data = 38 Ignored 34 zero values

Average: 10410.42, Standard deviation: 1371.25

Minimum value: 2305.00, Maximum value: 11147.00

Write report to file (Yes/<No>)? *Yes*

Enter the file name to write: *report.txt*

Write report to printer (Yes/<No>)? *Yes*

Make sure printer is on-line and connected to the printer port.

For grid and Geologic Model statistics:

Calculate statistics from grid file or drillholes (Grid/Model/<Drillholes>)? *Model*

Use named pit areas (Yes/<No>)? *press Enter for No*

Reading cell> 2989 Choose grid to process

Extrapolate grid to full grid size (Yes/<No>)? *press Enter Answer yes to calculate values outside the limits of the data to the full grid size.*

Select the Inclusion perimeter polylines or ENTER for none.

Select objects: *option to pick closed polylines*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *option to pick closed polylines*

Number of samples from grid data = 612

Average: 10457.55, Standard deviation: 816.20

Minimum value: 3464.57, Maximum value: 11111.71

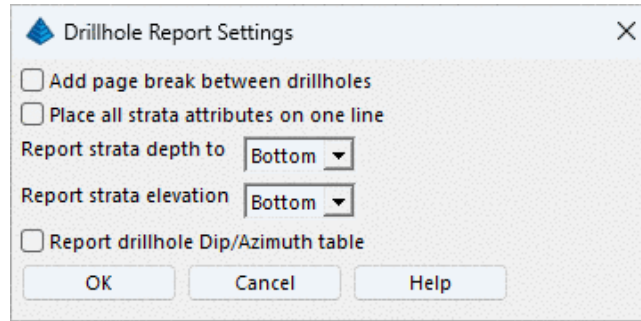

Pulldown Menu Location: StrataCalc

Keyboard Command: chstats

Prerequisite: Drillholes or grids

Standard Drillhole Report

Standard Drillhole Report retrieves data from the selected drillholes and generates a report in the Standard Report viewer that can be edited, printed and saved to file. For each drillhole, the drillhole location, description, strata names, and attributes are reported. When the command is executed, the below dialog will appear.

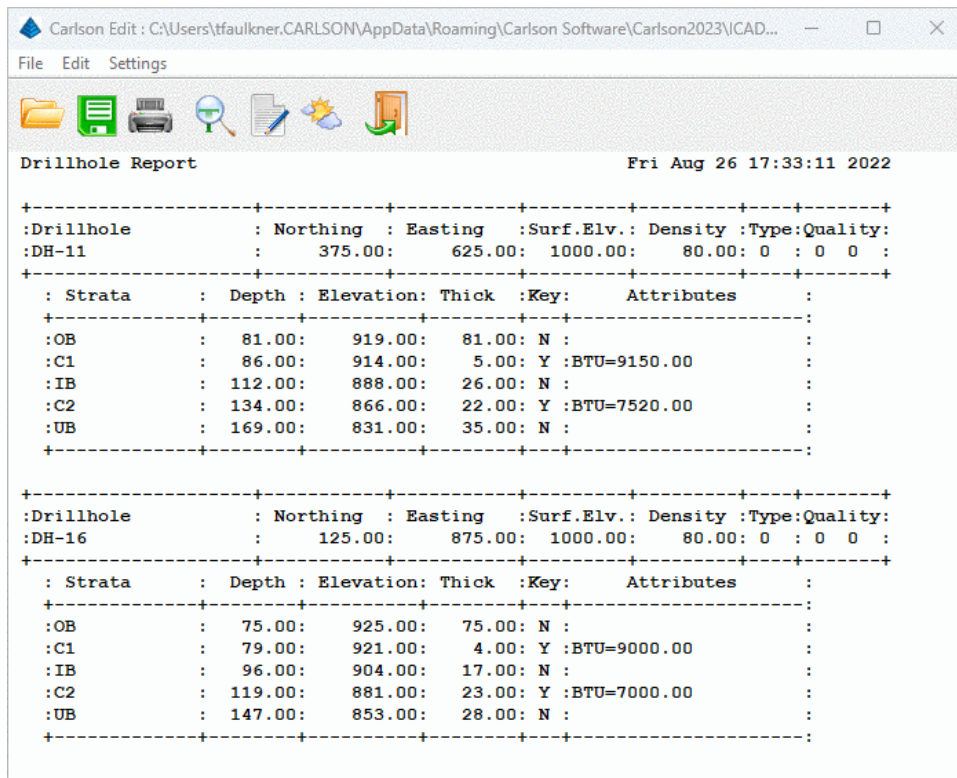

Add page break between drillholes: This option will add a significant spacer between the individual drillholes in the report.

Place all strata attributes on one row: This option will report all attributes on a single row. When disabled, attributes will appear on separate rows.

Report strata depth/elevation to: These options will control if the top or bottom depth/elevation is reported for each strata.

Report drillhole Dip/Azimuth table: This option will include the dip/azimuth table (dip and azimuth reported by varying depth) for the drillholes. Note that drillholes will not include this information by default.

Prompts

Select the DrillHoles for report.

Select objects: *select the drillhole symbols*

Add page break between drillholes [Yes/<No>]? *press Enter for No*

Place all strata attributes on one line [Yes/<No>]? *press Enter for No*

Report strata depth to [Top/<Bottom>]? *press Enter for Bottom*

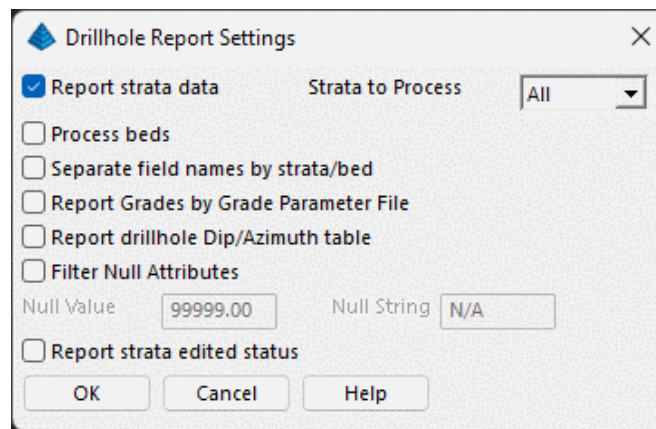

Report strata elevation of [Top/<Bottom>]? *press Enter for Bottom*

Pulldown Menu Location: Drillhole > Reports

Keyboard Command: chreport

Custom Drillhole Report

This command builds custom reports of the drillholes via the Report Formatter. The main difference between this command and Standard Drillhole Report is that this command loads all drillhole data into the Report Formatter. The Report Formatter allows you to choose which fields to report and their layout. The report data can be exported to Excel, to Access or into a comma-delimited file, or just saved or printed as shown.

Report strata data will include the strata values in the report. Otherwise only the drillhole header data will be included in the report.

Strata to Process determines if all strata or specific strata are included in the report.

Process beds will composite the strata by bed name. Otherwise the strata are reported individually.

Separate field names by strata/bed will add the strata name to each strata data field which allows you to control the report for the strata data separately by strata name. For example, if there were strata named "COAL1" and "COAL2", then you would have field names of "COAL1_THICK" and "COAL2_THICK". Otherwise, there would be only one strata thickness field named "THICK" which would report the thickness for both COAL1 and COAL2. When this option is enabled, all of the drillhole information will be reported on a single row (as opposed to using a new row for each strata layer).

Report Grades by Grade Parameter File will prompt for a GPF file to check and report the grade name for each strata.

Report drillhole Dip/Azimuth table will include the strata/dip table in the report. Note that this one of multiple options with which dip may be defined. If Dip is defined as a Strata attribute or a Drillhole attribute, this option will not impact the exporting of those attributes.

Filter Null Attributes will filter out values that match the **Null Value** or **Null String** option.

Report strata edited status will export an additional attribute that indicates if the drillhole value has been modified from its original value.

Prompts

Drillhole Report Settings dialog

Select the Drillholes for report.

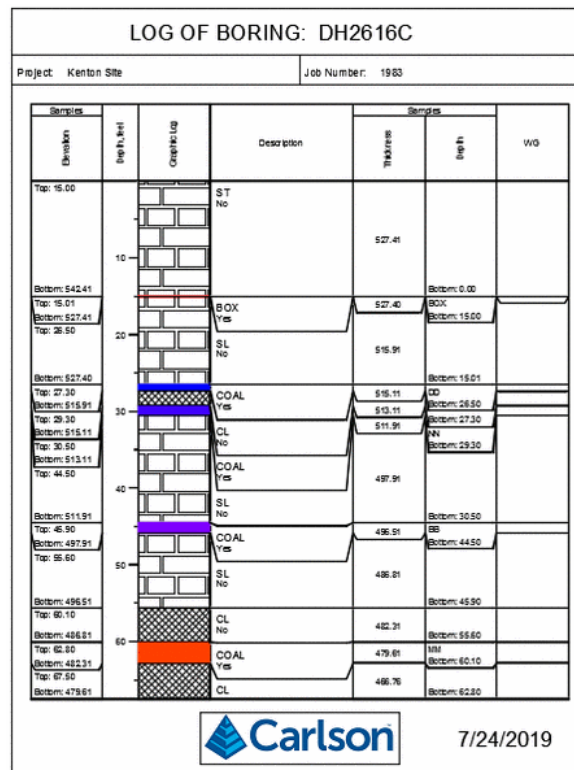

Select objects: *pick the drillholes*

Pulldown Menu Location: Drillhole > Reports

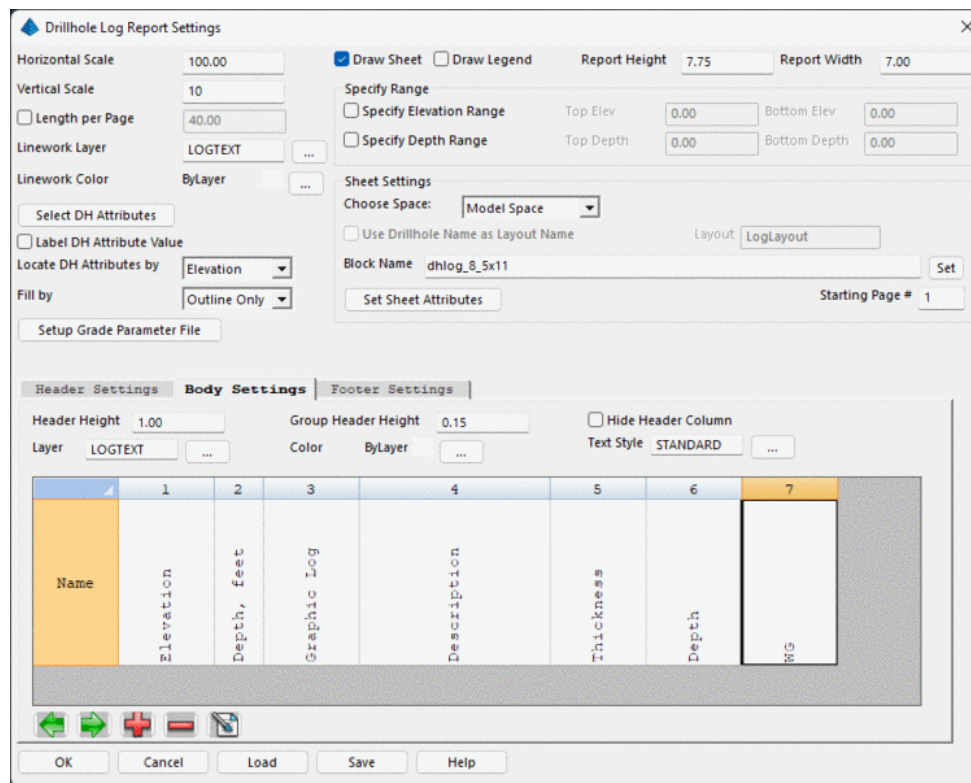

Keyboard Command: chreport2

Graphic Drillhole Report

This command creates a graphic drillhole log of the selected drillholes. It displays drillhole data such as depth, thickness, geological hatch patterns, and any attributes in the drillhole. An example report is shown below.

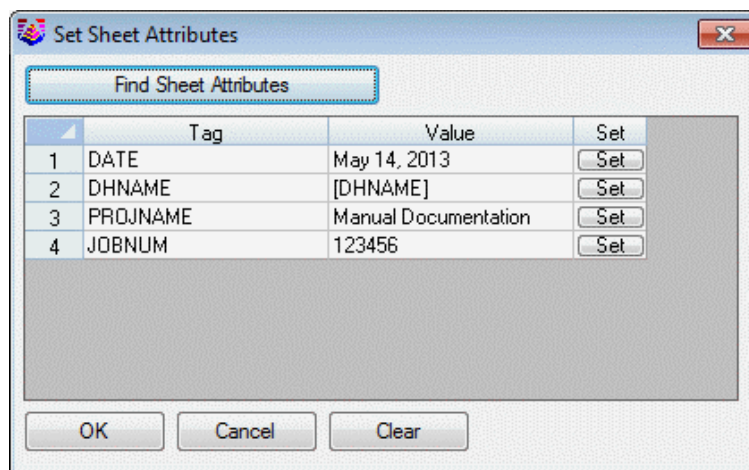

When the command is executed, you will be prompted to select the drillholes to report. This can be done by selecting drillholes on the screen, by entering the drillhole name, or by selecting the drillholes from a list. After selecting the drillhole to label, the below dialog will appear.

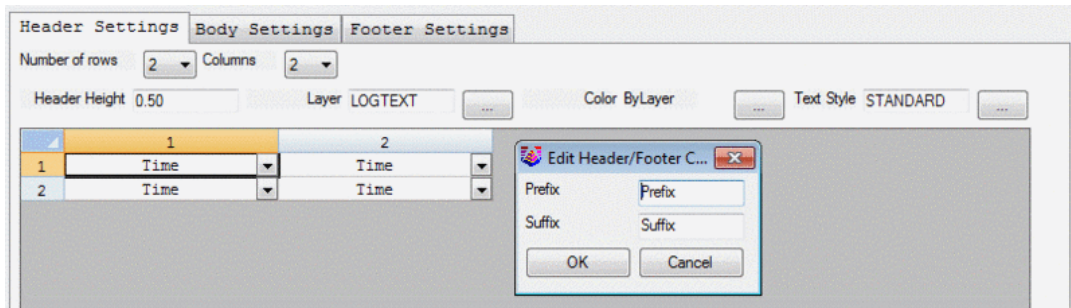

- **Horizontal Scale:** Sets the scale of the drawing. This usually matches the Horizontal Scale found in Drawing Setup, but not always.
- **Vertical Scale:** Controls the vertical exaggeration of the plot. If this value is less than the Horizontal Scale, then it will be vertically exaggerated. For example H100:V50 will be a 2:1, or 2X vertical exaggeration.
- **Length Per Page:** This option allows you to specify the length of the drillhole to display on the page. When enabled, the Vertical Scale will be automatically adjusted so that the desired hole length is displayed on the page.
- **Linework Layer:** This setting controls the layer that the linework is drawn for the boundaries, rows and columns.
- **Linework Color:** This sets the color of the linework.
- **Select DH Attributes:** The list of available drillhole attributes comes from the Define Lookup Database command from the Drillhole Attributes table. Besides defining the attribute names, the Lookup Database also defines the label size, color and layer for the attributes. The values for the attributes come from the drillholes under the Drillhole Attributes.
- **Label DH Attribute Value:** This option will add labels for the selected drillhole attributes.
- **Label DH Attributes by:** Controls whether to label the drillhole value on the Scale Bar and position the drillhole value as a depth or elevation.
- **Fill By:** This controls how to draw the strata in the graphics log. The graphic log can be filled with a hatch pattern, a solid fill, or can simply show the outline of the drill sample.
- **Setup Grade Parameter File:** This option uses a Grade Parameter File (.GPF) for the report. You can choose to color the graphic log or the data labels by the grade colors. There is also an option to label the grade name in the description field.
- **Draw Sheet:** This option draws the entire sheet for the report, including the title, project. Turning it off will turn off the Sheet Settings section, and it will just draw the main rows and columns of the log in the drawing.

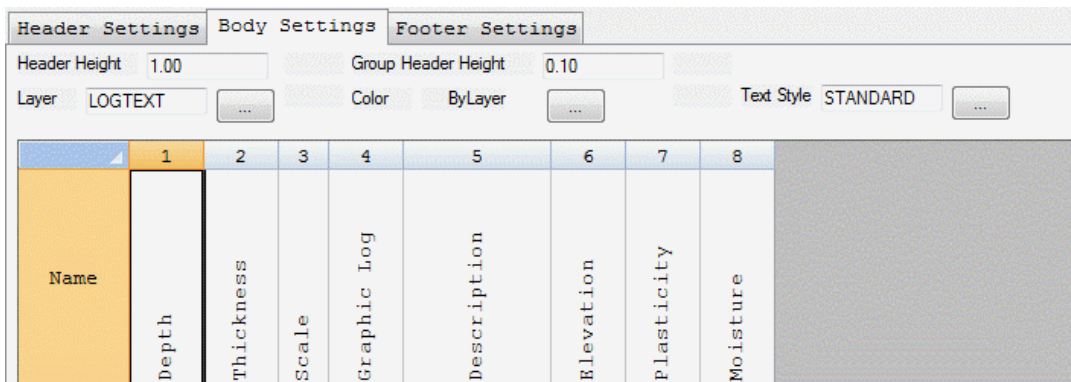

- **Draw Legend:** This option draws a legend of the strata names and hatch patterns.
- **Report Height/Width:** These parameters set the overall dimensions of the report. For use with the provided 8.5x11 sheet, these values should be set to 7.75 and 7.00, respectively.
- **Specify Elevation/Depth Range:** These options allow you to report only a portion of the drillhole, based on a range of elevations or depths. If both of these options are disabled, the entire drillhole will be reported.
- **Choose Space:** There are 3 options for drawing this report. Paper Space, Model Space and PDF. Paper Space will create a new Layout tab, using the name in the Layout Name window. Model Space will draw the plot in the working drawing, where picked. PDF will write the report out to its own PDF file.
- **Use Drillhole Name as Layout Name:** When using the Paper Space option, this option will use the drillhole name for the names of the Layout Tabs.
- **Layout Name:** When using the Paper Space option, this sets the name of the new Layout Tabs.
- **Block Name/Set:** This window sets the dwg drawing block of the sheet to use for the report. A template called dhlog_8_5x11.dwg is provided in the directory C:\Users\USERNAME\AppData\Roaming\Carlson Software\Carlson20XX\XX\SUP. This can be edited to customize how the block will appear in the report, with company logos, legends, etc.
- **Starting Page:** This sets the starting page of the reports for inclusion into existing documents.
- **Set Sheet Attributes:** This sets the topics for the header data in the report. For custom reports, set the project name and job number here. These are read from the Project and Job Number in the Drawing Setup command. They can also be overwritten here with a custom name. The Find Sheet Attributes searches the holes to populate this list of available items, such as Drillhole Attributes. To add custom drillhole attributes, an Attribute definition must be added to the sheet template. The tag of the Attribute Definition must match the tag shown in the below dialog. Once the Attribute Definition has been added, you may use this dialog to match the tag to a Drillhole Attribute. For example, you may add an Attribute Definition of "TD" to the sheet, which ties to the "Total Depth" Drillhole Attribute. To simplify this process, it is recommended to start with the provided dhlog_8_5x11.dwg file, copy and rename Attribute Definitions as desired, then saving the sheet template to a new file. Alternatively, Drillhole Attributes may be added to the report using the **Header/Footer Settings**, discussed below.

- **Header/Footer Settings:** These options prepare the Header format for the report. To add rows and columns, use the Number of rows and Columns pulldowns to set them. Then for each cell, drop them down to choose the field to display in the header. To set a Prefix or Suffix, choose the appropriate cell and choose the Cell Settings button.

- **Body Settings:** These options control how the main body of the report will appear. Rows and columns, header and group heights are set here.

- **Header Height:** This value sets the height of the header label. For longer header names, this value should be increased to ensure the labels do not overlap the borders.
- **Group Header Height:** This values set the height of the Group Header name. Each column name can be assigned a Group Header name. When two adjacent columns share the same Group Header name, an additional label will be added to the Header name. In the below example, the Ash, BTU, and Sulfur all share a Group Header Name of "Quality".

Description	Depth	Quality		
		ASH	BTU	Sulfur

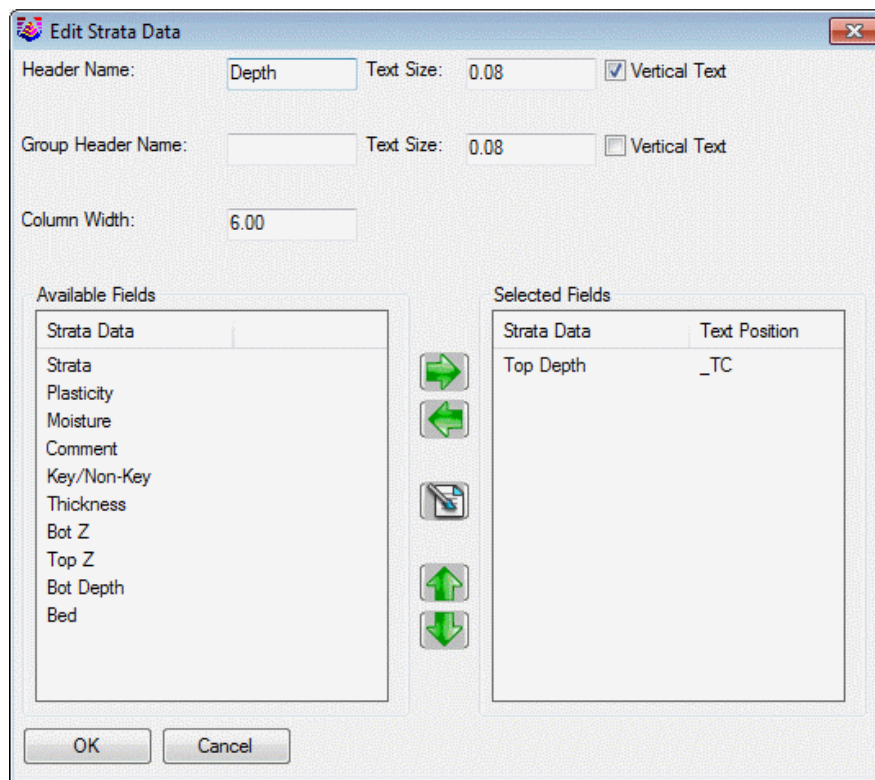

- **Hide Header Column:** When enabled, the gridlines for the column headers will not be drawn.
- **Layer:** This sets the layer for the report.
- **Color:** This sets the color of the report.
- **Text Style:** This sets the text style for the report.
- **Icons:** The arrow/plus/minus icons can be used to reorganize the order of the columns, or to add and remove columns. The pen-and-paper icon allows you to edit column properties.

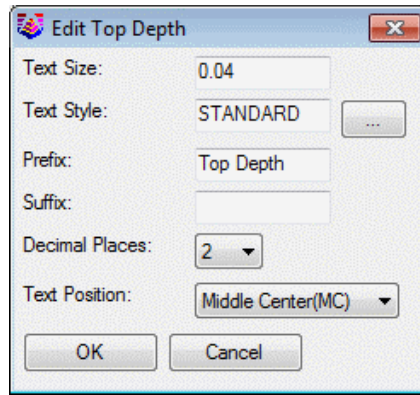

When a new column is added, the below dialog will appear. This allows you to add either Strata Date (thicknesses, qualities, etc.), a graphic log (visual representation of the drillhole), or a scale (to show elevation or depth).

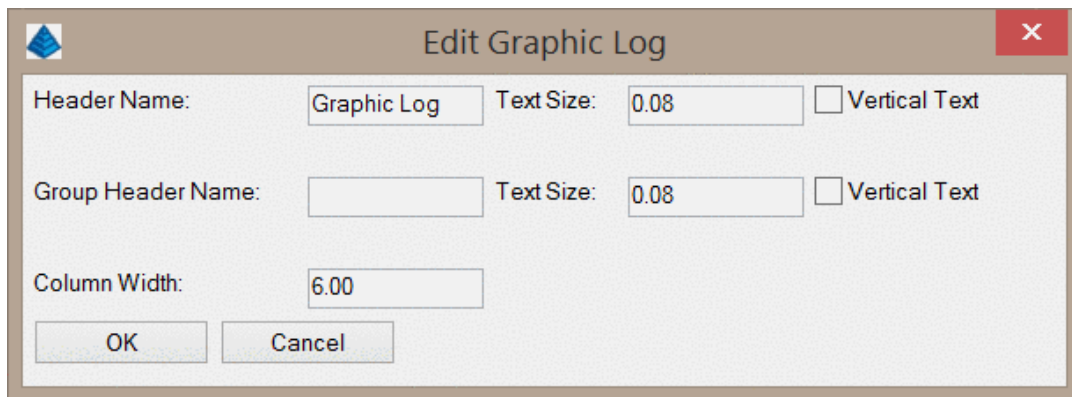

When Strata Data is selected, the below dialog will appear. Here you can add Header Names, Group Header Names, and the Fields to be included in the report. To add fields, move items from the available fields on the left to the right, under selected fields. The green arrows move them in all four directions. The middle, Edit button allows for editing the Selected Field. This is where the text size for the data in the columns is set, as well as the centering in the fields.

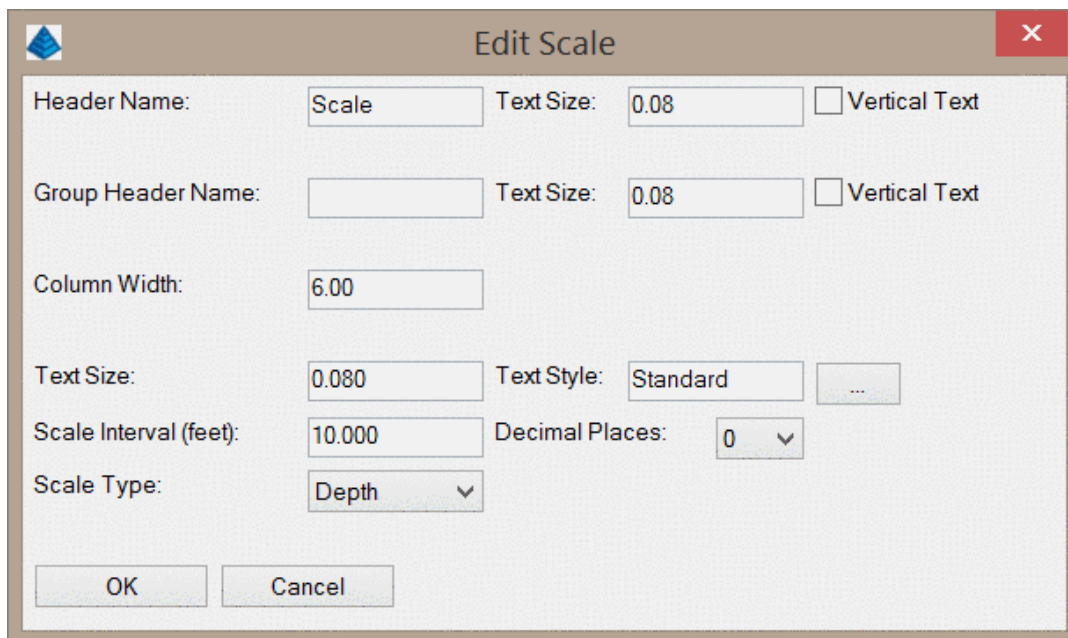

The middle Edit button allows for editing the Selected Field. This is where the text size for the data in the columns is set, along with the positioning, decimal places, etc.

When a Graphic Scale is added, the below dialog will appear. This is similar to adding Strata Data, but fewer settings are available.

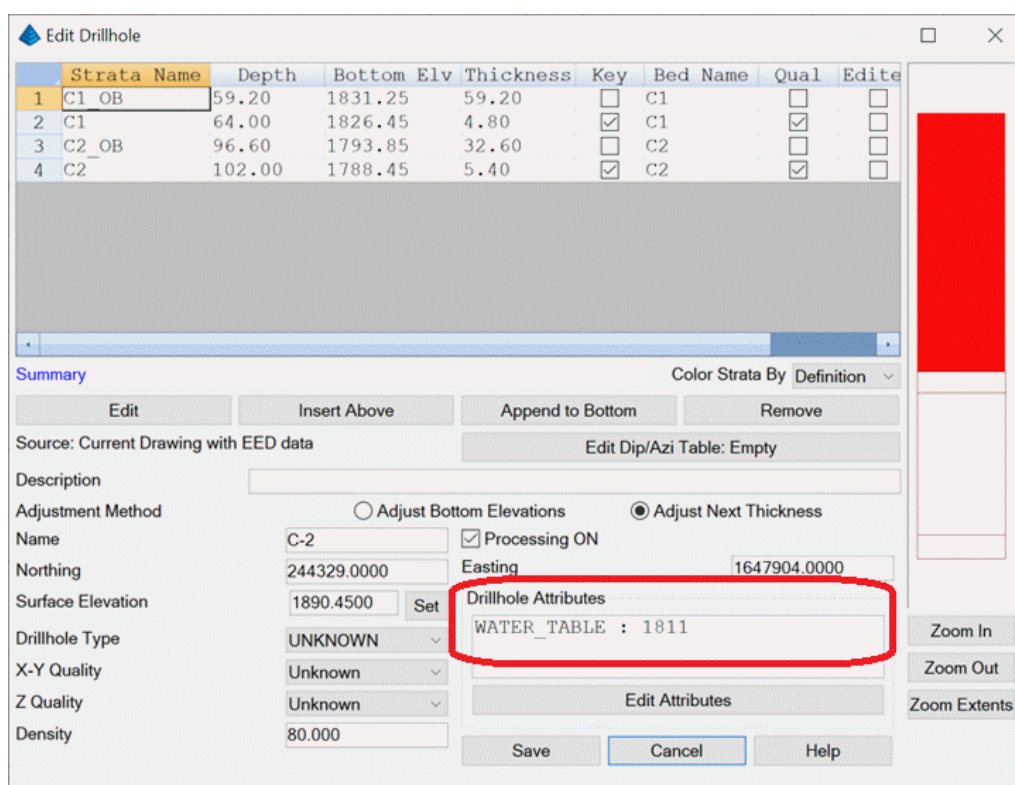

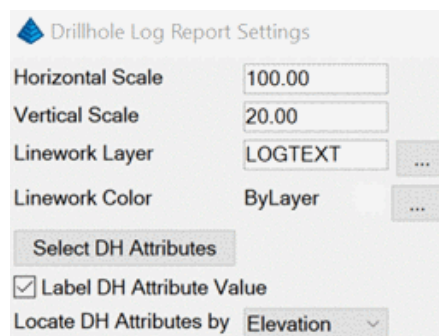

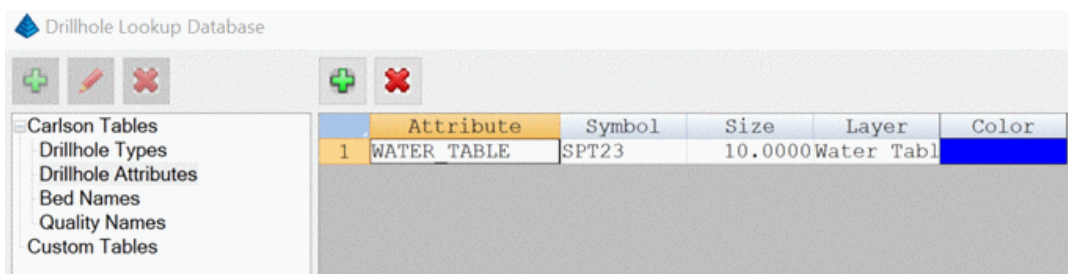

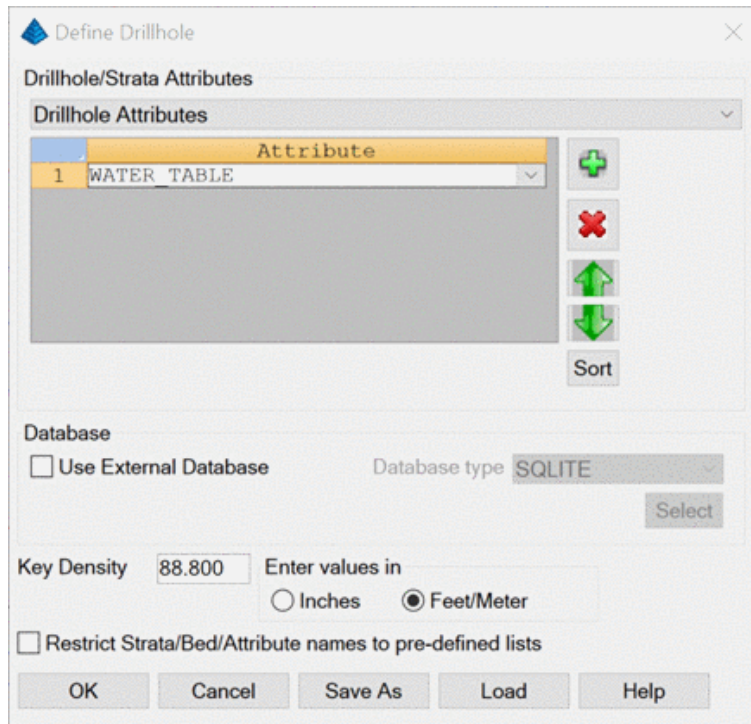

When a Scale is added, the below dialog will appear. Here you can specify the interval of the scale, the scale type, etc.

After all of the settings are defined, hitting OK will prompt for the location to draw the report. Based on the Choose Space setting, it will either go to Model Space, Paper Space Layout, or a PDF file.

To label the water table, the drillholes need an attribute named WATER_TABLE. Define Drillhole needs a drillhole attribute named WATER_TABLE and Define Lookup Database needs a drillhole attribute named WATER_TABLE with the symbol, size, color and layer to use for the report. Then in the dialog for Graphic Drillhole Report, pick on Select DH Attributes and select WATER_TABLE and turn on Label DH Attribute Value and Locate DH Attributes By.

Change History Report

This command creates a report of drillholes that have been modified during the specified time period. The program reads the change history from strata attribute variables called DATE_CHANGED and CHANGED_BY. The Edit Drillhole and Drillhole Data Sheet routines will update these changed attributes using the current date and the AutoCAD login name when any of the strata data is modified. For the report if a drillhole contains a changed strata, there is an option to either print all the strata for that drillhole or just the modified strata. To setup the DATE_CHANGED and CHANGED_BY attribute, run the Define Drillhole command and add these names to the Key strata attributes and Non-Key strata attributes.

Enter Period Start Date or Enter for None (mm/dd/yy): 1/1/95

Enter Period End Date or Enter for None (mm/dd/yy): 9/9/06

Include only changed strata in affected drillholes (Yes/<No>)? Y

Pulldown Menu Location: Drillhole > Reports

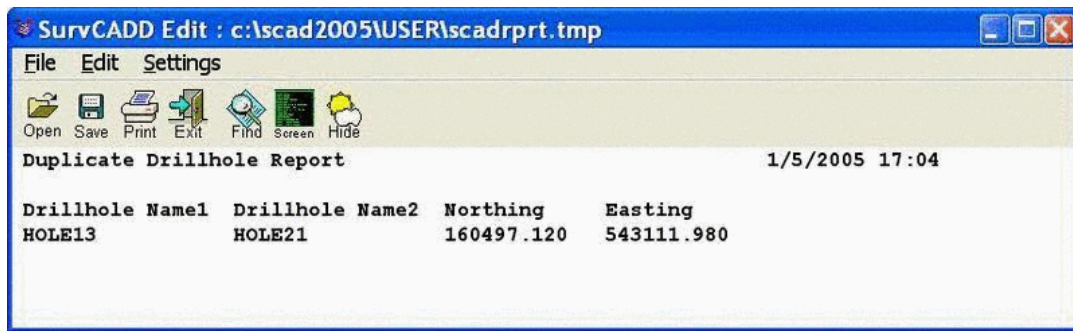

Keyboard Command: chhreport

Prerequisite: Drillholes

Duplicate Drillhole Report

This command reports drillholes located at the same easting/northing position. The holes can have different names. The report dialog displays the names, and locations of the problem holes. The command has an option to draw a circle, of specified size, around the holes that are found duplicate. The purpose of this routine is to help clean up the drillhole database by identifying duplicate position drillholes since the modeling can only process one drillhole at any one location. This routine only shows the duplicates and it is up to you to actually decide which duplicate

drillholes to remove or move. It does not report two drillholes that have the same name, but are at different locations.

Prompts

Draw circle around duplicate drillholes [Yes/<No>]? Y

Circle radius <100.0>: press Enter for 100

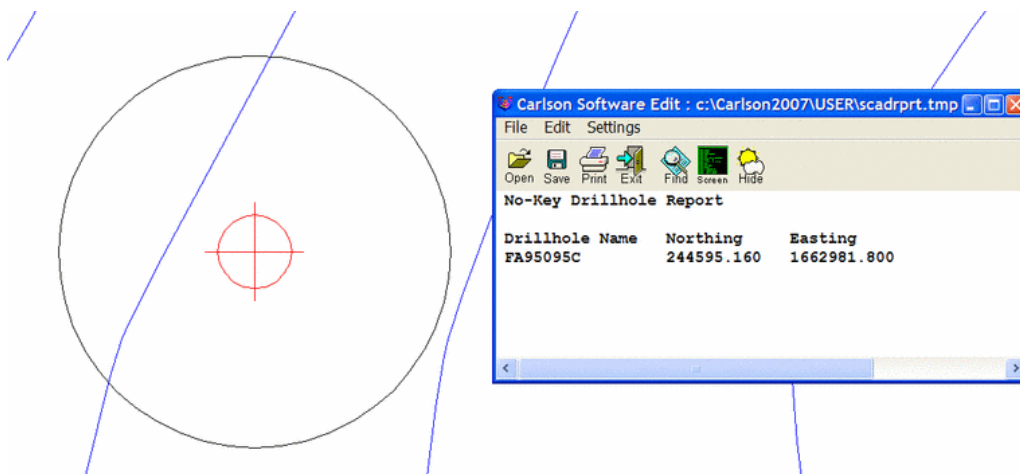

Pulldown Menu Location: Drillhole > Reports

Keyboard Command: dupch

Prerequisite: Drillholes

Drillholes Without Key Strata

This routine will report all selected drillholes that do not contain any Key strata. It also will give the option to draw a circle around those drillholes.

Prompts

Draw circle around no-key drillholes [Yes/<No>]? y

Circle radius <100.0>: 50

Drop-Down Menu Location: Drillhole

Keyboard Command: nokeych

Key Strata Missing Bed

This command reports any drillholes that have key strata with a blank bed name. There is an option to draw a circle around drillholes with missing bed names as a way to highlight them in the drawing.

Pulldown Menu Location: Drillhole > Reports

Keyboard Command: missbed

Prerequisite: Drillholes in drawing

Compare Strata To Model

This command compares drillhole data to grid models. Drillhole values that differ from the grid model by more than the specified Difference Tolerance are reported. The program can create a standard format report or the Use Report Formatter option can be used for custom reports or outputs to different formats like Excel. The purpose of this command is to check that the grid models match the source drillhole data.

After selecting the drillholes to process, you choose which strata process and then which value to process including thickness, elevation or attribute. Then select the grid model to compare with and the program generates the report.

Prompts

Bed Composite Report

This command reports the individual strata qualities and the resulting composite qualities of drillholes. The strata are composited by bed name. It is useful for seams that are sampled extensively at many intervals, and even with different strata names. An example hole report is shown. Each individual strata and bed is broken out first, with the composite values following at the end of the report. The command uses the report formatter, so the output it gives is very customizable.

Invalid Strata Report

Routines that process strata such as Fence Diagram or Make Strata Grid File require strata names to be in correct order and these routines refuse to continue if there is a problem with the strata. This command creates a report of drillholes that have strata that are out of order or have duplicate strata names. An arrow is drawn on the screen pointing to the drillholes that have the problem. If the screen is moved or zoomed, the arrows will disappear. This report can be used to identify the drillholes that need to be cleaned up.

Missing Strata Report

This command reports strata from the selected drillholes that are missing in the strata sequence. The strata sequence is determined by reading the strata from all the selected drillholes. When a strata is missing between other strata, this is reported as PINCH OUT. For example with strata A,B,C and a drillhole with A,C, then strata B will be reported as pinch out. If a strata is missing before the first strata in the drillhole, then this strata is reported as ABOVE. For example a drillhole with B,C would report strata A as above. Likewise a strata missing after the last strata in the drillhole is reported as BELOW. For example a drillhole with A,B would report strata C as below. In the report, the estimated bottom strata elevation and thickness for the missing strata is reported based on pinch out and conformance.

Strata	Drillhole	Northing	Easting	Elevation	Thickness	Description
C2L	HOLE12	157773.4	543049.5	203.0	0.00	Pinch Out

Define Parameters

This command prepares an attribute parameter definition file (.par file) that defines the attribute names along with an operator and value. The parameter definition files are filters that are applied in the Compliance Drillhole Report, Compliance Areas and Mark Compliance Drillhole commands, allowing you to report, select, and modify drillholes that match the criteria. When the command is executed, the below dialog will appear.

Notes on specific attributes are provided below. It is important to note that you may use asterisks (*) as wildcard characters. This command is case-sensitive.

Strata Parameters

- **Thickness:** Thickness of the sample in the drillhole
- **Depth:** Bottom depth of the sample in the drillhole
- **Top-Elev:** Top elevation of the sample in the drillhole
- **Bottom-Elev:** Bottom elevation of the sample in the drillhole
- **Name:** The name of the strata or the bed group. It is important to note that this can be used as an alternative to the Strata Name column of the main dialog. For example, the below configurations of tests will yield the same result. It is important to note that if you use this Name parameter rather than using the Strata Name column, the program will prompt you at the command line if the parameter tests must pass for all strata or if passing for a single strata will suffice.

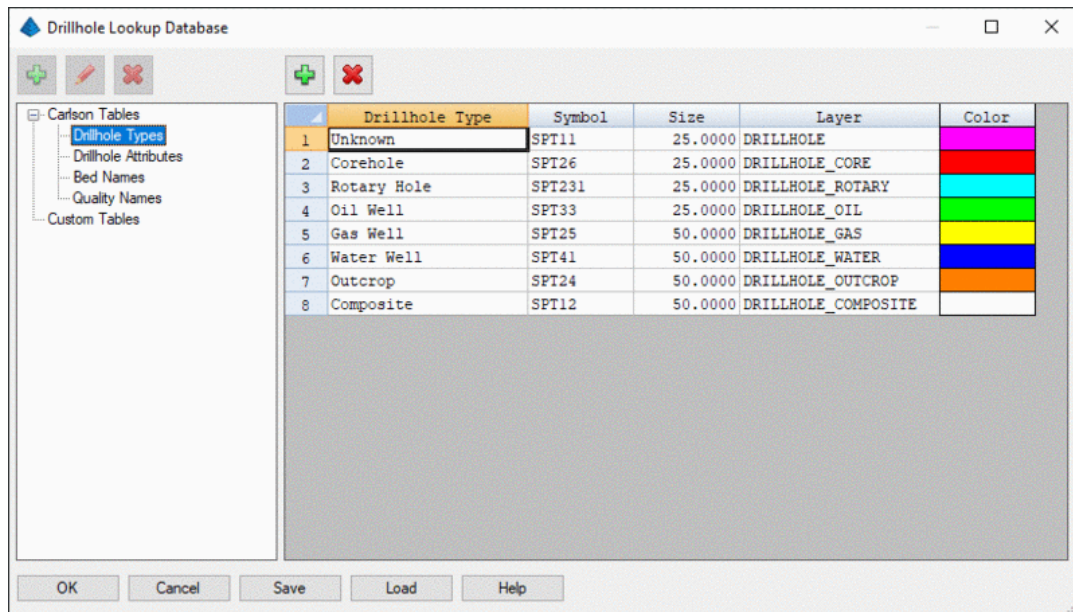

- **Bed:** The bed name of the strata. This will allow you to restrict the test to a strata name that might repeat to a specific bed. For example, if you have many samples with a strata name of "Coal" distributed across three different beds, you could add this BED parameter to restrict the tests to only check Bed "A".
- **Key:** The Key/Nonkey status of the strata. A value of 1 relates to a key strata, whereas a value of 0 relates to a nonkey strata.
- **Contain:** This is used to check for existence of a strata name in a drillhole. This allows you to check for the existence of a strata name. Note that this check is very similar to using a NAME parameter check.

Drillhole Parameters

- **Name:** The name of the drillhole. You may use asterisks (*) as wildcard characters to select all drillholes with a similar prefix/suffix

- **Elev:** The surface elevation of the drillhole.
- **Type:** The integer value relating to the type of the drillhole as defined in the Drillhole Lookup Database command. You should not refer to the drillhole type by name. For example, if you have defined drillhole Type 2 as a "Corehole", you should check for a value of "2" rather than the name "Corehole".

- **Desc:** The text description of the drillhole.
- **XY_Qual** and **Z_Qual:** The integer value relating to the XY or Z Quality (method of measurement of the drillhole coordinates) as defined in the Drillhole Lookup Database command. You should not refer to the Quality by name. For example, if you have defined the Quality of 3 as "GPS", you should check for a value of "3" rather than the name "GPS".

The Strata Name column is optional for assigning a strata name to a parameter. You only need to fill out the Strata Name column if you are analyzing multiple strata at once. For example, you could check THICKNESS on COAL2 strata name and THICKNESS with a different value on COAL3 strata name. If all the parameters apply to the same strata then when you run routines like Mark Compliance Drillholes, there is an option to test the entire drillhole or a specific strata. You can choose the specific strata option and then select a strata to process. Note: You do not fill in the strata name for the first or top parameter. The program will prompt you for the strata to process.

The And/Or field applies between the parameters in the current row and the row above. The Process column allows you to turn off processing for a parameter.

Pulldown Menu Location: Drillhole > Parameter Compliance

Keyboard Command: pardef

Compliance Drillhole Report

This command reports drillholes from the selected drillholes that meet all the qualities defined in a parameter file. Drillholes that don't meet the parameter file are not reported. There are three main prompts you may receive after

defining the parameters.

1) Process beds [Yes/<No>]?

This option determines if the program will read the strata names exactly as they exist in the drillhole, or if they will be regrouped by the bed names. This is very important if you are trying to test a parameter on a single strata sample, or a composite bed group. For example, suppose you have multiple thin samples of strata in a single bed, and you want to check for drillholes where the total bed thickness is greater than 5 ft. If you do not enter a YES for the Process Beds option, the program would only analyze the thickness of each individual strata in the bed, as opposed to checking the full bed thickness.

It is also important to note that when answering YES to this prompt, the strata names will not be considered, but rather, the regrouped bed name. For example if the strata name is "COAL", the Bed Name is "A", and the Key status is KEY, then the regrouped name would be "A_KEY". In this scenario, checking for the existence of COAL when you enter Yes to this prompt would yield no results. For more information on the regrouped names, see the Bed Name Suffixes section of Carlson Configure > Mining Settings.

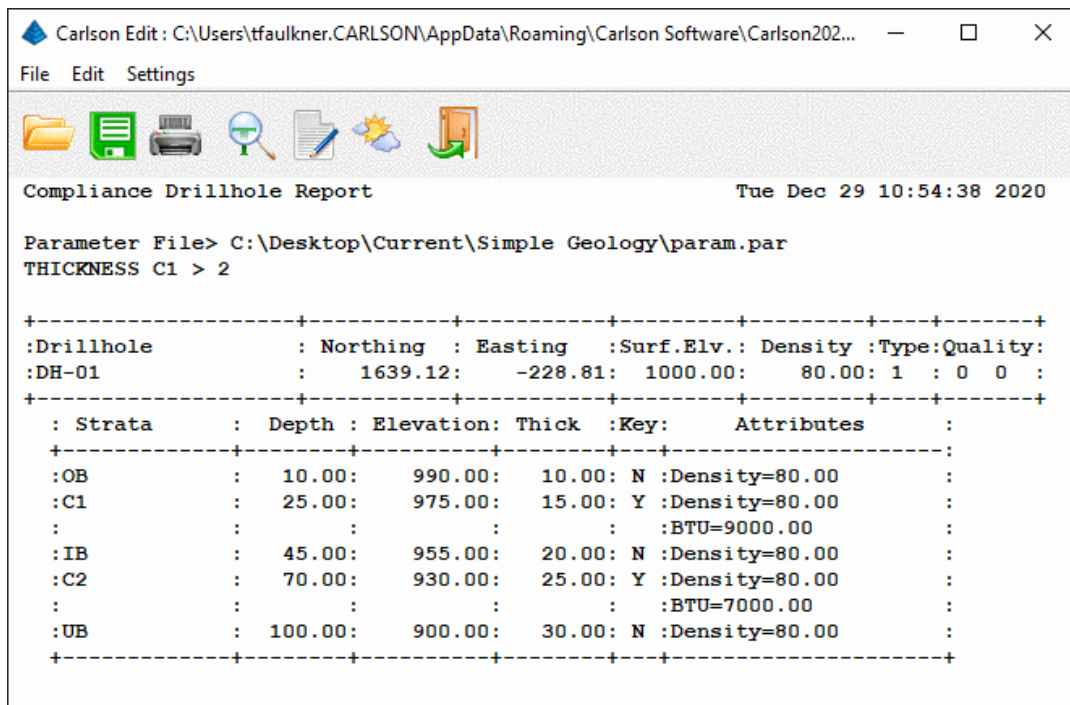

2) Analyze entire drillhole or specific strata [<Drillhole>/Strata]?

The entire drillhole method will include the drillhole in the report if any of the strata meet the parameter file. The specific strata method checks only the selected strata and includes the drillhole in the report if the strata meets the parameter file. When using the Strata option, a dialog will appear with the list of available strata layers.

3) Require all strata to match or any strata [All/<Any>]?

This option will only appear if a Strata Name has not been specified in the Parameter File. With this option, you can specify if all strata that are checked must pass the tests of the .par file, or if only one strata must pass the tests.

After these prompts, a text report will be displayed that shows a list of all of the drillholes passing the tests specified in the .par file. It is important to note that the entire drillhole will be reported, and not simply the strata that were tested.

Compliance Drillhole report

Pulldown Menu Location: Drillhole > Parameter Compliance

Keyboard Command: charea3

Prerequisite: Drillholes

Compliance Areas from Grids

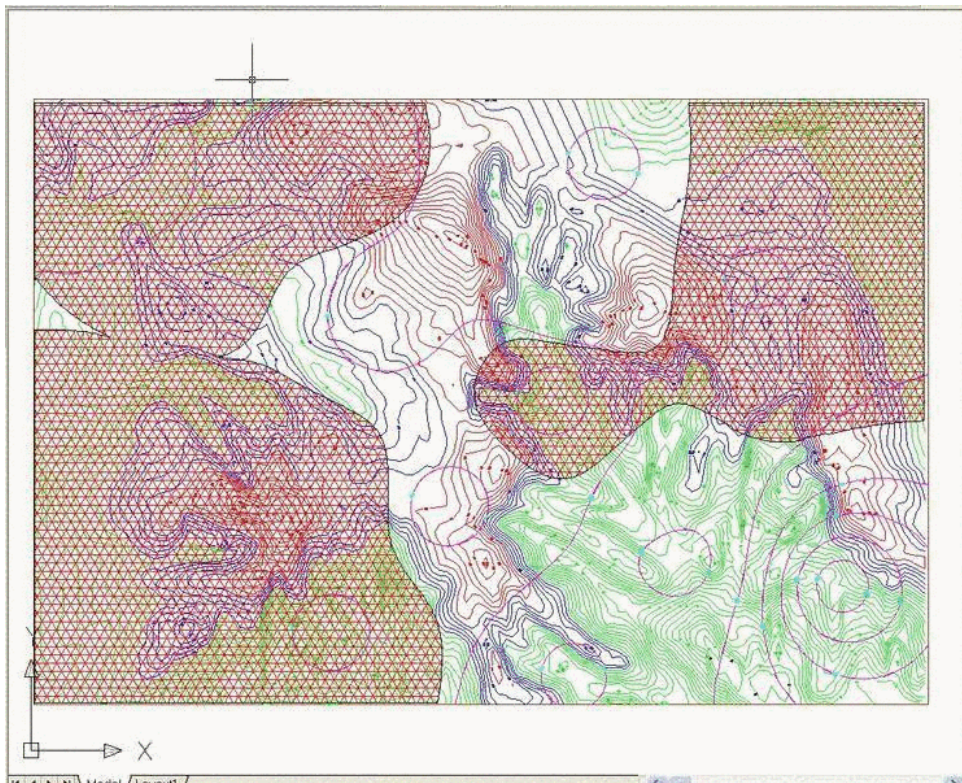

This command draws a closed polyline(s) and hatches the area(s) that meet the specified values for multiple grids. It is similar to the Parameter Compliance from Drillholes, but this analyzes grid files instead of drillholes.

The Set Parameters window is for selecting the grid files and specifying the values to use for compliance. The bottom portion is for choosing the layer, color, pattern and scale for the hatch. The area(s) that meet the criteria are then outlined and filled with the hatch pattern. If no inclusion/exclusion perimeter is selected, then the area of the extrapolated grid is hatched to the limits. As can be verified by the prompts, the command contours each of the grids for the values specified and then creates closed polygons where the values coincide.

Mark Compliance Drillholes

This command highlights drillholes that contain a strata that meets the specified parameters. The drillholes are highlighted by drawing a circle around them, changing the drillhole symbol, changing the drillhole type or changing the drillhole layer. There is also an option to create a selection set of the matching drillholes. Then you can use that selection set in any other command that prompts for drillholes by entering P for Previous at the Select Objects: prompt.

The parameters are set in the Define Parameters window. Be sure to spell the attributes exactly the same in the parameter list as in the drillholes. For more details about parameter definitions, see the Define Parameters command.

Prompts

Set Parameters dialog

Process beds [Yes/<No>]? *press Enter* This option composites the strata using their bed names into BED.TOP, BED.PARTING, BED.KEY and BED.BOTTOM. For example, you could have several quality samples of a seam broken into strata names CO with bed name A. The process beds option will composite all these samples into A.KEY. Otherwise the parameter filter will test each sample separately.

Analyze entire drillhole or specific strata [<Drillhole>/<Strata>]? *press Enter* The Strata option allows you to select which strata to test. Otherwise all the strata in the drillholes are tested. If Strata is chosen, the Choose Strata window appears for selecting.

Require all strata to match or any strata [All/<Any>]? *press Enter* The Any option will mark the drillhole if any of the strata match the parameter filter. The All option requires all the strata to match in order to mark the drillhole.

Select the Drillholes to test.

Set Strata by Parameters

This command sets strata values of strata name, bed name or status (key/non-key) based on whether the strata passed the specified parameter filter. The parameter filter can test strata attributes such as thickness and qualities such as MGO. The change defined in the Set Strata by Parameters dialog will be apply to strata in the selected drillholes that passed the parameter filter. Also in the dialog, you can choose between processing all the strata or specific strata selected by strata name. For example, consider an ore seam that is made of several sequential strata with different quality samples of a strata attribute called GRADE. Set Strata by Parameters could be used to set the key/non-key

status of these strata based on whether the strata GRADE attribute is greater than 1.5%.

Keyboard Command: strata_param

Split Bed by Parameters

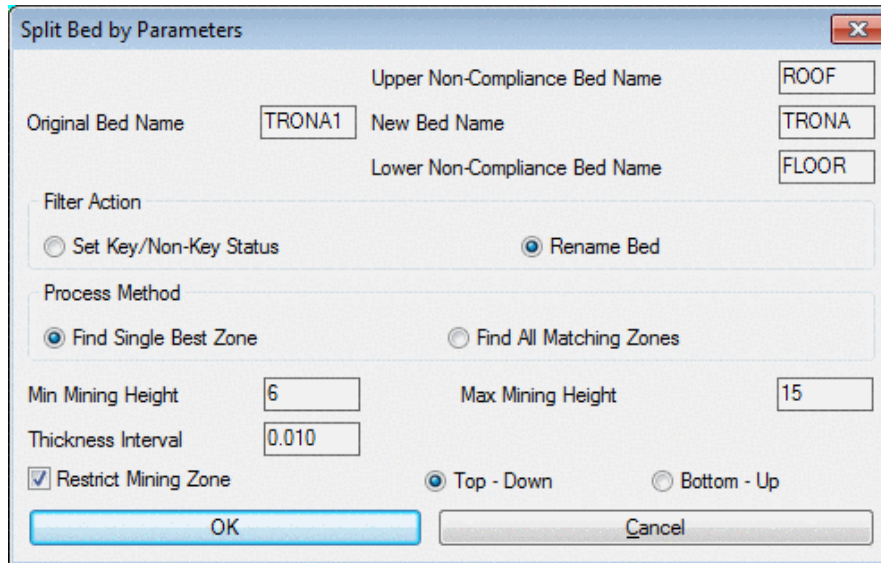

This command finds the largest portion of a bed such that the composited qualities meet the specified parameter filter. The bed can be split by key/non-key status or by name. With the status method, the bed portion that passes the filter is set key and the rest is set non-key. For the name option, you can specify the bed name for the portion that passes the filter and names for the portions that don't pass.

This command is different from Set Strata by Parameters because this command composites multiple strata to meet the filter instead of checking each strata individually against the filter. In Split Bed by Parameters, the composited portion that passes the filter can contain some strata that fail the filter so long as the total composite portion passes. For example, if the parameter filter is for strata attribute GRADE to be greater than 1.5, then final bed composite that passes could be made of one strata with GRADE of 1.6 plus part of another strata with GRADE 1.1 such that the composite GRADE equals 1.5. The strata that make up the bed can be divided into a part that is used in the composite and part that is discarded. For example in the above case, the strata with the GRADE of 1.1 could be originally 2 feet thick. Since this strata is below the target GRADE of 1.5, it could be that only 0.7 feet of this strata could be added to the composite without bringing the composite below 1.5. So the strata would be split at 0.7 feet with the remaining 1.3 feet not becoming part of the composite.

This command can also account for minimum and maximum mining heights to limit the composite bed thickness. If there is no portion that meets the filter at the minimum thickness, then the program will find the best portion. Likewise if the composite that meets the filter exceeds the maximum height, then the program will find the best portion with the maximum allowed thickness. The thickness interval resolution allows the intervals to be broken up into as small of units as required. The Find All Matching Zones will not stop at the single best zone, it will separate the beds into all of the matching zones.

Restrict Mining Zone is an option that defines where the program will start calculating from, either the top or bottom. For a surface mine, the Top Down would make the most sense, so that the most efficient method of mining

is designed. For underground, it is possible that the Bottom-Up option is preferred, so that extra material will be left in the roof for support.

StrataCalc Menu

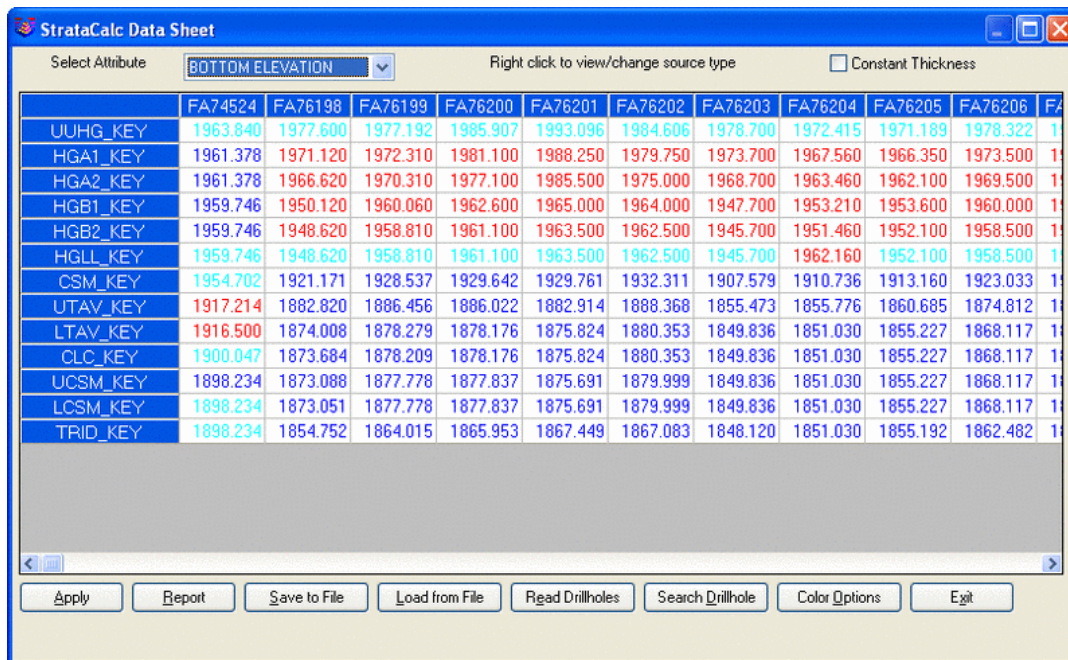

The StrataCalc pull-down menu has commands for creating and processing strata models.

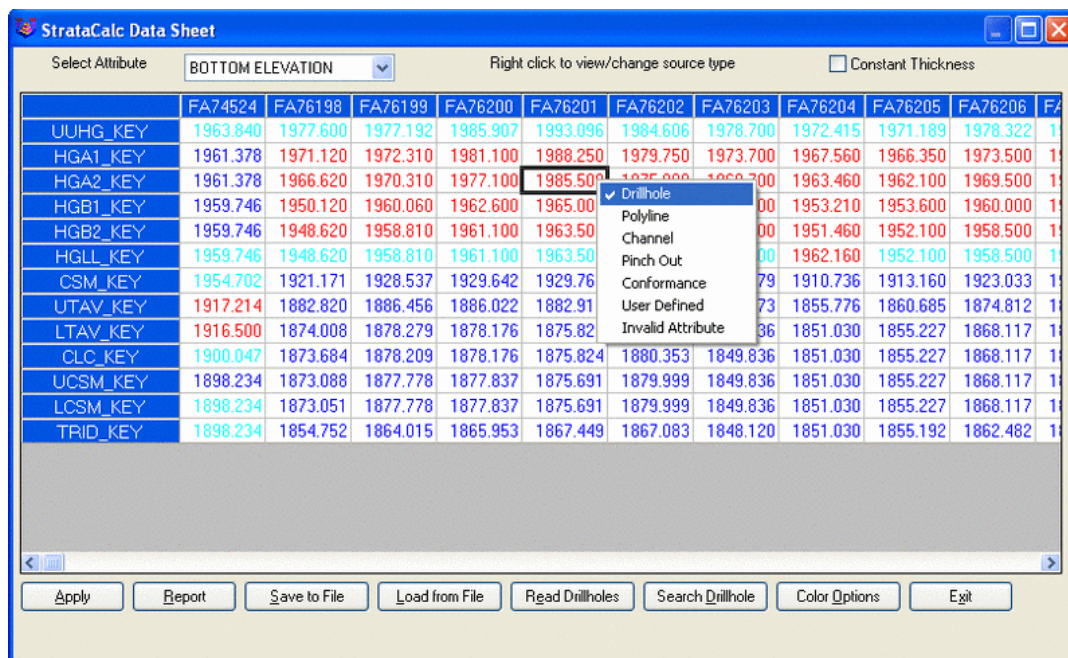

StrataCalc Data Sheet

This command displays geological data for viewing and editing of the processed values in a spreadsheet view. It could be called an interpolator, as it displays the values that the program interpolates and will use for modeling. Each value can be editing and "forced" or user defined values can be used instead of what is found in the drillhole, or modeled by the program. Each column represents a datapoint, such as a drillhole. The color of each text value represents the source of the data. This StrataCalc file (*.STC) will then be used for the modeling. Any time the program prompts "Select Drillholes", if none are selected and Enter is chosen, then the program will ask for the StrataCalc file. It will use this file and the values in it for the modeling. This is a great tool for controlling the geology. If a few drillholes are troublesome and not modeling correctly, the user can edit this file to what they want to use and create a more accurate model. The first window is to choose the source of the data, either the drillholes on screen, or to load an existing STC file. Then the Data Sheet comes up for viewing and editing.

- **Select Attribute:** The dropdown controls the values to display and edit in the spreadsheet. It will always have Thickness, Bottom Elevation and Top Elevation. Any other user defined attributes will also be here for control.
- **Right click to view/change source type:** When placing the pointer on a cell and right clicking the mouse, the menu displays the possible sources of the value. The source used is the one with the check mark next to it. The source can be changed by picking a different one, and the color of the text in the cell would then change to represent that.

- **Constant Thickness:** If Constant Thickness toggle is ON, then when the user updates the top elevation, the thickness will be kept constant and the bottom elevation will be changed (bot elev = top elev - thick). If the bottom elevation is changed thickness will remain constant and top elevation be changed (top elev = bottom elev + thick). If the toggle is OFF, then if elevation is changed the thickness will also be updated accordingly. (thick = top elev = bot elev)
- **Apply:** This will apply the changes made to the spreadsheet the update the colors and values.

- **Report:** There are three options to see the values in a text report: Report All Data, Report Current Attribute, or Report to HTML. The HTML report takes the current spreadsheet view of the data and puts it into HTML format. The other two reports output to the report formatter.

DRILLHOLE REPORT

Keyboard Command: chinterp

Draw Outcrops

Draw Outcrops generates polylines that represent the outcrops of strata from the selected drillholes. An outcrop is where a strata comes up to the surface. An option from the Outcrop Settings dialog allows the outcrop line to be calculated from where the top of the strata hits the surface or from where the bottom hits. The Draw Outcrop Polyline At Elevation will draw the outcrops as 3D polylines on the surface topography. For example, on a slope, the top of strata outcrop will be higher than the bottom, and on the inside when viewed in plan view. When coming from drillholes, Draw Outcrops calculates the outcrop by creating a grid of the surface and a grid for the strata and then finding the intersection of the two grids. If the strata never breaks through the surface, no outcrop line will be created. The Geologic Model option reads the surface grid and strata grid from a Geologic Model file (.pre). This option will show a dialog with a list to choose from of the strata defined in the Geologic Model file. If the File option is used, then a Sub-Crop line can be drawn that will prompt for a thickness grid of the strata. The lines can be smoothed and vertices reduced with the settings shown below.

The option to Label Outcrop Contours will label the strata name in the contour line as contour text. The contour text settings window appears for the desired settings to be entered.

Keyboard Command: outcrop

Draw Depth Contours

This command creates contours for the depth between the surface and strata. The surface models for the ground and strata are modeled by grid if coming from the screen entities and drillholes. When using the Geologic or Mining Model file, the list of strata appears to select which strata to use. Specify Depth Contour Range allows for a starting and ending contour elevation. There is the option to contour the depth to either the top or the bottom of the strata. Options are at the bottom for smoothing and reducing the contour vertices. This is basically the thickness from the topography to the top or bottom of the strata. This grid could also be made in Grid File Utilities, but this is a quick way to get the contours without gridding first.

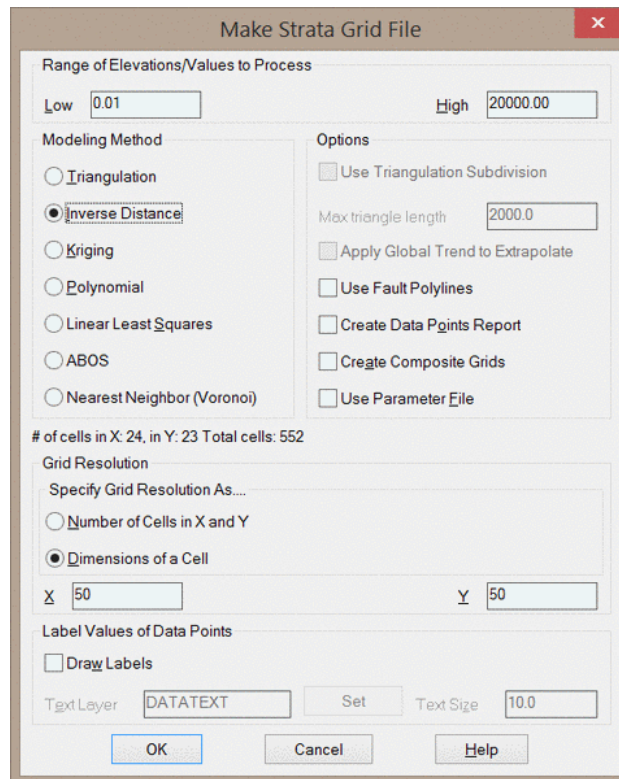

Pulldown Menu Location: StrataCalc in Advanced Mining and Mining
Keyboard Command: depth

Make Strata Grid Files

For each strata in the drillhole, this routine can generate 3D grid files of the strata thickness, top & bottom elevation, and attributes such as calcium, moisture, sulfur, and BTU. The grid files make up the geologic model in StrataCalc. A 3D grid file is a rectangular mesh of grid cells where each grid cell is the same size rectangle. The elevation or Z value of the four grid corners equals the value at those points. For example, consider a grid cell for a 3D grid mesh of strata thickness. The X and Y coordinates of a grid cell could be (0,0), (10,0), (10,15), and (0,15). The z values, which might be 4.5, 4.7, 4.8, and 4.6, represent the strata thickness at the four X and Y coordinates.

Make Strata Grid Files reads the strata data from the drillholes. The strata data is correlated and processed for beds, pinch out and conformance as specified in Carlson Configure. The strata data points are then used with the selected modeling method to calculate the grid. There is an option to use a parameter file (made with Define Parameters) to filter the strata data points. For example, when creating a thickness grid for the overburden of 6_COAL, you could have a parameter filter of THICKNESS 6_COAL > 1.0. This filter would make the program use only drillholes with 6_COAL greater than 1.0 when calculating the 6_COAL overburden grid. See the Define Parameter File command for more description on parameters.

The routine starts by prompting for the location of the grid files to create. The location can be specified by picking the lower left and upper right corners or by selecting an existing grid file which sets the new grid location and resolution to match the selected existing grid file. Next there is the Make Strata Grid File dialog for choosing the grid cell resolution, modeling method and other parameters.

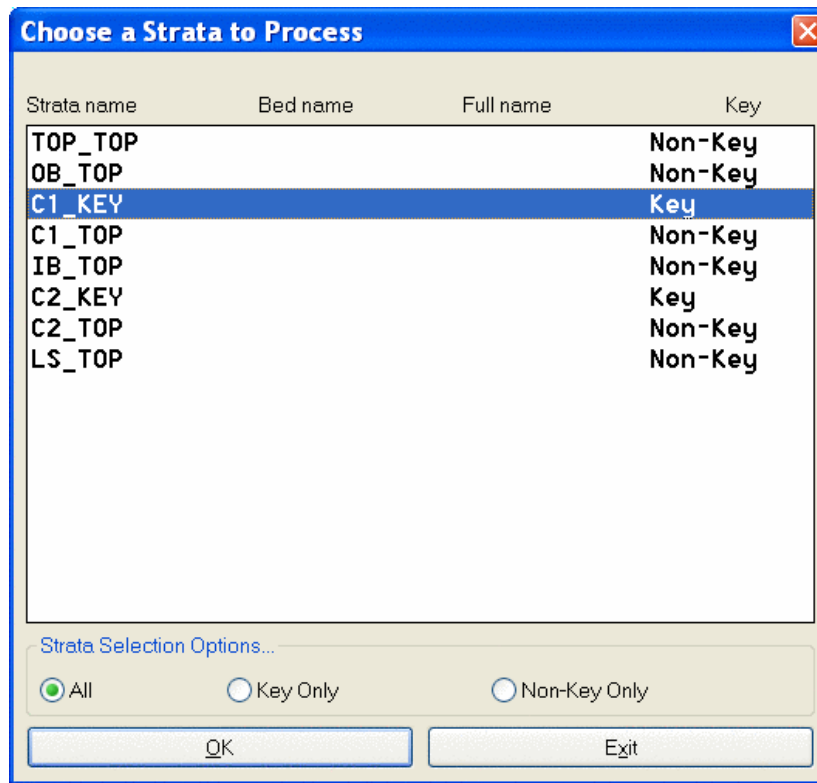

- **Range of Elevations/Values to Process:** Only values that fall within the range specified by the Low and High will be used to make the grid. Values that fall outside this range will be ignored.
- **Modeling Method:** There are multiple modeling methods available for geologic gridding, with many settings for each method. Each method is described in more detail below.
- **Use Triangulation Subdivision:** When modeling with triangulation, this option will divide each triangle into 3 or more smaller triangles for smoother modeling.
- **Max Triangle Length:** This value sets the maximum distance between data points to model when using the triangulation method. If data points are further than this distance from one another, the grid will be modeled with null values.
- **Apply Global Trend to Extrapolate:** When using the triangulation modeling method, values will only be modeled between data points - no extrapolation will be applied. When this option is enabled, however, the grid will be extrapolated to the full extents of the grid file.
- **Use Fault Polylines:** This option will prompt you to select fault lines to apply shifts to elevation grids. For more information regarding faults, see the Edit Fault Line documentation.
- **Create Data Points Report:** The Create Data Points Report option is another way to check the data points

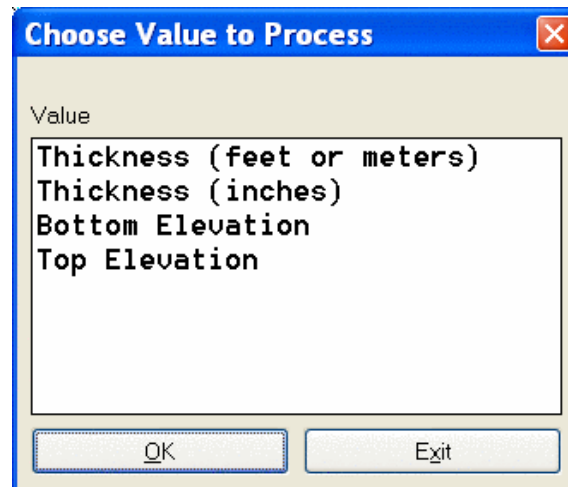

that are used in gridding. This option will create a report of the gridding data points. This report is displayed in the Standard Report viewer where it can be saved, printed or drawn on screen.

- **Create Composite Grids:** The Create Composite Grids option allows you to select multiple strata or beds to combine instead of gridding the strata individually. With compositing, the program shows the same strata selection dialog with the list of strata but you can now select multiple strata by picking from the strata list while holding down the Shift or Ctrl keys on the keyboard. For composites you can grid the top elevation which is the highest elevation at each drillhole for the composite, the bottom elevation which is the lowest composite elevation, the thickness which is the sum of the thicknesses for all the composite strata, or composited strata attributes.
- **Use Parameter File:** Turning this option on will use a parameter filter file made in the Define Parameters command.
- **Grid Resolution:** This option controls the resolution of the grid, that is, it determine the dimensions of each grid cell, as well as the total number of cells in the grid. As these options are updated, a preview of the cell dimension and number of cells will be displayed above this option. It is also important to note that there is a tradeoff between a higher grid resolution and processing time. It is recommended to keep the total number of cells at less than 1,000,000 per grid, but some computers may be able to process more data.
 - **Number of Cells in X and Y:** This option allows you set the total number of cells in the X and Y directions. For example, setting both of these values to 10 will create a grid will 100 cells. When using this option the dimensions of the cells will be automatically calculated based on the extents of the grid and the number of cells specified.
 - **Dimensions of a Cell:** This option allows you to set the dimensions of the cells. It is important to note that extents of the grid are fixed at this point, and that it may not be possible to use the exact dimensions specified here. However, the cells will be made to match these values as closely as possible.
- **Label Values of Data Points:** This option will draw a label next to each drillhole indicating what value was used at each drillhole for the gridding. The **Text Layer** and **Text Size** may be defined.. This option is a good way to visualize and check the data points that the program is using.

After the grid options dialog, the program prompts you to select the drillholes and fault lines. After reading in the selected drillholes, there is a Choose a Strata to Process dialog to choose the strata to process from the list. If Create Composite Grids was turned on, then multiple strata may be selected here. The All, Key Only and Non-Key Only are just viewing options to reduce the number of strata in the window if there are a lot, for ease of selection.

Once the strata is selected, another dialog shows the strata values and attributes that are available to grid. These will be thickness, elevations, equations, and any quality attributes that are in the drillholes. Choose a value to grid from the dialog.

Then the program will prompt for the grid file name to create (.GRD). Next the program will process the strata data points to create the grid and the results are stored in a user-specified file name. The grids created by Make Strata Grid File can be used as the geologic model for the Geologic or Mining Model file. Also the grids can be used in the grid application routines, in the Civil Design module, such as Plot 3D Grid File, Grid File Utilities and Elevation Difference.

Making Strata Grids with Fault Lines

There is an option to select fault lines in addition to the drillholes. The fault lines should be drawn as 3D polylines with elevations that equal the fault differential. The program will grid with all modeling methods using the fault lines for making strata elevation grids. The 3D fault polylines should be drawn such that the left side of the polyline, relative to the direction of the polyline, is the low side of the fault and the right side is the high side. As each grid corner elevation is calculated, the program checks each drillhole. If the drillhole is on the same side of the fault polyline as the grid corner, then no adjustment is made to the drillhole elevation data. Otherwise the drillhole is

projected onto the fault polyline and the polyline value at this point on the polyline is used to adjust the drillhole elevation. For example, if the fault polyline value was 5.0 and the grid corner was on the high side of fault while the drillhole was on the low side, then 5.0 would be *added* to the drillhole elevation for modeling at that grid corner. If the grid corner was on the low side and the drillhole was on the high side, then 5.0 would be *subtracted* from the drillhole elevation. Reverse Polyline is a good way to reverse the fault line if it is drawn in the wrong direction.

Triangulation Modeling Method

This method is straight triangulation between the drillholes. Triangulation calculates these values by interpolating on the plane defined by the three points in the triangle that encloses the point. Since triangulation only interpolates, it can only calculate values within the area of the data. Afterwards, an extrapolation routine can then fill in the rest of the grid. This extrapolation uses a safe method that tends to average out the data. There is an option to extrapolation to apply the global trend. This option finds the average slope and direction of the existing data and applies this slope to extrapolating.

Inverse Distance Modeling Method

Inverse distance calculates the grid values by assigning weights to the existing data. The grid values calculated by inverse distance are a weighted average of the existing data. Inverse distance will not carry trends and the calculated grid values will never be higher than the highest existing data point. Likewise the calculated grid values will never be lower than the lowest existing data point. The weights are proportional to the inverse of the distance between the point to be estimated and the existing data point. Closer points are weighted more than points farther away. The inverse distance can be calculated to first, second, or third power which are $(1/d)$, $(1/d^2)$, and $(1/d^3)$ respectively. The power can also be any user-specified number such as 2.5. The inverse distance estimate is a weighted average with the individual weights computed as an inverse power of distance as follows:

$$W_i = \frac{d_i^{-\text{power}}}{\sum d_i^{-\text{power}}} \quad I = 1 \dots \text{number of samples}$$

where W_i is the weight computed for each sample i , each d_i is the distance between the location being estimated and sample i , and $-\text{power}$ is the inverse distance weighting power.

In Configure under Mining there are several options for controlling inverse distance. The Inverse Distance Search Radius is used for calculating a value at a point such that only drillholes that are within this Search Radius will be used in the calculations. The Inverse Distance Max Samples value limits calculations to the nearest specified number of drillholes to the point. For example, the program will use the nearest 10 drillholes. Inverse distance can also be controlled by quadrants which are divided into northeast, southeast, southwest and northwest. The Min Quadrants setting will use at least this specified number of drillholes from each quadrant as long as there are drillholes in the quadrant within the Search Radius. For instance, a setting of Min Quadrants of one would make the program look for at least one drillhole from each quadrant. The Max Quadrants value limits the number of drillholes used from each quadrant. For example if Max Samples was set to 25 and Max Quadrants was 10, then the total samples would be 25 with no more than 10 of the closest ones from each quadrant.

Elliptical inverse distance modeling method is an option that appears any time the Inverse distance modeling method is chosen. Elliptical inverse distance modeling will produce oval shaped model "bulls eyes" that are aligned by the specified azimuth of anisotropy. The specified factor is used to increase the weight of data samples that line up more closely with the azimuth at the model point. Data samples that exactly line up with the azimuth apply the full factor. Data samples that are perpendicular with the azimuth apply zero extra weight. Data samples at an angle between the azimuth and perpendicular apply a proportional adjustment. The specified factor is adjusted by azimuth is then added with one and then multiplied by the data sample weight. For example, using a factor of 1 and a data sample that matches the azimuth to the model point, this sample will get weighted double; $(1 + 1) * \text{weight}$. When using a factor of 2 and a data sample that matches the azimuth, the sample will get weighted triple; $(1 + 2) * \text{weight}$. The prompts will appear:

Use inverse distance to which power [First/<Second>/Third/Other]? *Second*

Use elliptical inverse distance [Yes/<No>]? Yes

Enter azimuth of anisotropy: 45

Enter anisotropic factor: 1

With these values of azimuth 45 and factor of 1, data samples that are NE/SW of the model points will get double weight (1+1), data samples that are NW/SE will get no extra weight, and data samples at in between angles will get a proportional extra weight.

Kriging Modeling Method

Kriging estimates the grid values by figuring the relationship between all the existing data points and then assigning weights to this data. Kriging finds the best fit linear unbiased estimates for the given data and model. Kriging can carry trends within and beyond the limits of the data and can find new high and low values. You must supply a model that defines the spatial relationship of the data which can be difficult. In fact, Kriging is a very complicated subject and you will need to reference an outside source for a detailed description such as *An Introduction to Applied Geostatistics* by Isaaks and Srivastava. Carlson uses Ordinary Kriging. All the parameters for this Kriging are specified in the dialog shown.

Kriging Spatial Continuity Model

Kriging Model Type

Spherical

Exponential

Gaussian

Power

Linear

Nugget Effect: 0.05

Range (a parameter): 2000.00

Scale (c parameter): 40.00

Azimuth of Anisotropy: 0.00

Anisotropy Ratio: 1.00

Search Radius: 4000.00

Max Points to Use for Kriging (1-25): 10

OK Cancel Help

Polynomial Modeling Method

The polynomial method is based off of triangulation. The difference is that instead of directly interpolating within each triangle, the polynomial method creates smooth transitions by using a fifth degree polynomial function that accounts for neighboring triangles. Since polynomial needs adjoining triangles, when there are fewer than five data points, there will be fewer than four triangles and the polynomial method will revert to straight triangulation. The same extrapolation logic for triangulation applies to the polynomial method.

Linear Least Squares Modeling Method

The linear least squares method finds the least squares best fit plane at each grid corner. The least squares routine weights each data point by inverse distance so that closer points are weighted more than points farther away. So the best fit plane varies at different points on the surface. The linear least squares method extrapolates trends very well. A lower inverse distance factor (i.e. 1.0) will weigh the data points more equally which models the trends more globally (sometimes called "global dip"). Likewise a higher inverse distance factor (i.e. 3.0) will weigh the closer data points more heavily which models local trends strongly (sometimes called "local dip"). Least squares

will trend and allows for data points that are new highs and lows, that don't appear in the original drillhole/point data. It does produce very nice, smooth contours that honor the data points.

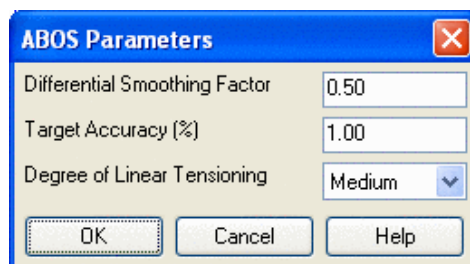

Approximation Base On Smoothing (ABOS) Modeling Method

ABOS is a method for modeling values of irregularly spaced points by using a continuous function with two independent variables. This method is developed and implemented by the developer of SurGe, Miroslav Dressler.

The ABOS method uses very simple mathematical tools - numerical tensioning and smoothing. The tensioning and smoothing are performed so that elements of matrix, which represents surface z-values at nodes of a regular rectangular grid, are repeatedly replaced by the weighted average of selected surrounding elements. The selection of elements involved into weighted average depends on the type of tensioning or smoothing.

Despite the fact that the mathematics of the ABOS method is simple, the resulting surface can be modified by a few parameters so that it is comparable with the surface created by sophisticated methods such as Kriging, Radial Basis Functions or Minimum Curvature.

Following dialog window shows ABOS parameters that need to be set in order to run ABOS inside the Carlson.

Differential Smoothing Factor:

This parameter enables to control smoothness of generated surface. The larger value, the sharper interpolation is obtained. Typical values are:

0.00 - 0.30 ... for smooth interpolation

0.40 - 0.60 ... for normal interpolation (default value is 0.50)

0.70 - 1000.0 ... for sharp interpolation

Sharp / smooth model at local extremes can be improved by increasing the differential smoothing factor. The accuracy of generated surface decreases with increase in this factor. The zero value produces most smooth surface.

Target Accuracy:

This parameter specifies how accurate the generated surface has to be. It represents the percentage value of average difference between z - coordinates of input points and generated surface from $(Z_{max} - Z_{min})$, where Z_{min} is the minimum value and Z_{max} is the maximum value of the z - coordinates of the input points. If the calculated accuracy $(Average\ DZ / (Z_{max} - Z_{min}) * 100)$ is less than the Target Accuracy, the process of interpolation stops and outputs the target grid.

Degree of Linear Tensioning:

This parameter enables to set the degree of linear tensioning. It can have four values:

1. None - for no linear tensioning
2. Medium - for medium linear tensioning
3. Strong - for strong linear tensioning
4. Full - for full linear tensioning

It is clear from the following figure of cross-section of a grid surface that the surface is more linear for higher degree of linear tensioning.

Nearest Neighbor (Voronoi) Modeling Method

The Nearest Neighbor method (also known as the Voronoi method) finds the nearest data point at each grid corner and assigns the grid corner to this data point. This method does not interpolate or extrapolate. Each grid corner is simply assigned the value of the nearest data point.

Prompts

Use position from another file or pick grid position (File/<Pick)? *press Enter* Using the position of an existing file copies the grid resolution and corner point locations to the new grid files. This is useful if you need to have grid files match exactly. Most of the time, grids should match position in the geologic model.

Pick Lower Left grid corner: *enter or pick a point*

Pick Upper Right grid corner: *enter or pick the second point to define the grid position*

Make Strata Grid File dialog box

Set the grid resolution and other options. A higher grid resolution increases the processing time. Also choose the Modeling Method in this dialog.

Select drillholes, channel samples and strata polylines.

Select objects: *select the drillhole symbols*

Select fault lines or Enter for none.

Select objects: *press Enter for none, or select the fault lines*

Choose Strata to Process dialog

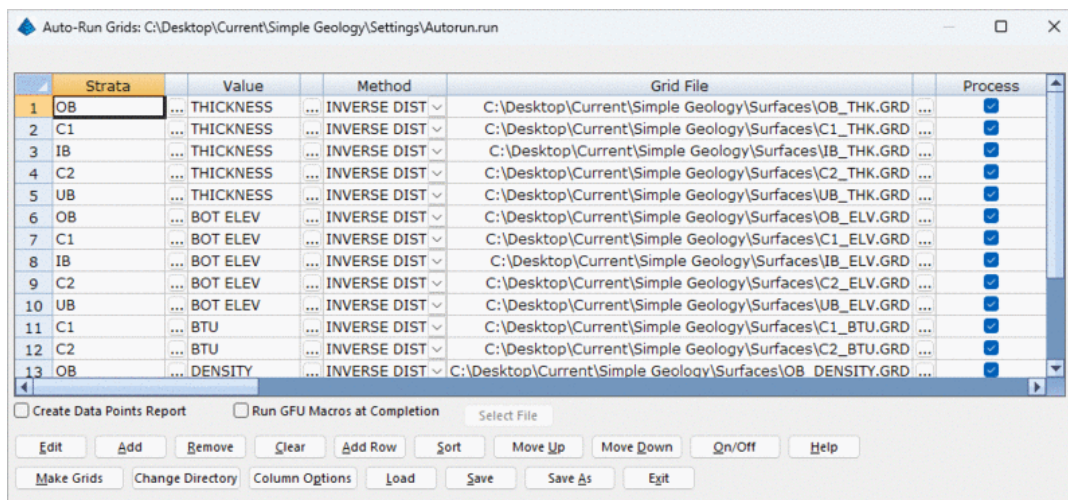

Choose Attribute to Process dialog

Pulldown Menu Location: StrataCalc

Keyboard Command: chgrid

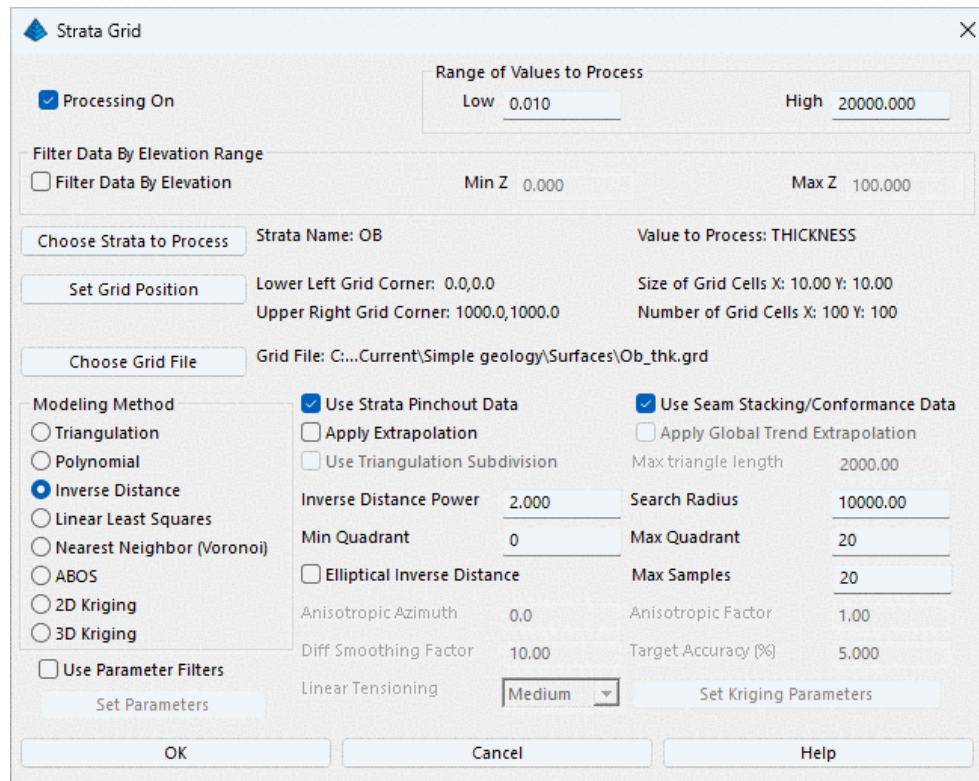

Define Strata Grids AutoRun

This command creates multiple strata grids from drillhole data at one time. This method is much faster than creating the grids one at a time with the Make Strata Grids command, especially when inputs change and the strata grids need to be recalculated quickly. Note that this command will create a .run (or a .runx) file, which can be used with the Run Strata Grids Auto-Run command rather than redefining the auto-run each time the grids need to be remade. Many of the settings in this command are the same as in the Make Strata Grids command, and will therefore not be discussed here. When the command is first executed, you will be prompted to select fault lines, drillholes, and inclusion/exclusion areas. It is important to note that if you select an inclusion area for this command, the program will only simply update grids inside the boundary - the entire grid will not be recreated. To ensure that the grids are populated with the latest available data, an inclusion boundary should not be selected.

This dialog lists the strata grids to be made with each grid listed on a separate row. Changes to each grid can be made in the spreadsheet or with the use of the Edit button.

Edit/Add: These buttons will open the below dialog which modifies parameters for the grid file. Recall that many of the below settings are discussed in the description of the Make Strata Grids command, and are not detailed here.

Processing On: This checkbox controls if the grid file will be created when the **Make Grids** button is clicked. If the grids take a long time to process and only some grids need to be processed, you can toggle this option to avoid making every grid file.

Range of Elevations/Values to Output: Only values that fall within the range specified by the **Low** and **High** fields will be used to make the grid. Values that fall outside this range will be ignored.

Filter Data By Elevation: This option will filter data points outside of the **Min Z** and **Max Z** range. Note that this is not the same as the Range of elevations/values to output. This option would allow you to limit the calculation to ignore the value because of its elevation, even though the attribute value may be valid. For example, suppose an attribute has a value of 10 and the sample exists at elevation 300. You could set the **Max Z** to a value of 250, which would prevent this attribute from being used.

Choose Strata to Process: This button will allow you to select the strata/bed and attribute to model in the grid file. The primary difference between selecting strata in the Make Strata Grids command and selecting strata here is that this command allows you to select multiple strata/beds at the same time. However, you may only create one attribute for the selected strata. For example, if you select five strata to model, you will not be able to select the elevation and the thickness attribute at the same time. Instead, you will have to define the five elevation grids and then repeat the process to define the five thickness grids. Also, when multiple strata are selected, you will only be able to select attributes that those strata have in common.

When selecting multiple strata, you will also be prompted if the strata should be composited or if separate grids

should be made for each strata layer. When strata attributes are composited into a single grid file, the attribute will be weighted by the thickness of the strata. Attributes that require averaging based on the weight of the material should be composited using Grid File Utilities.

After selecting the strata and attributes to model, you will be returned to the above dialog to set additional parameters for the grid(s). The attribute to be modeled and the first strata selected will be shown to the left of the Choose Strata to Process button.

Set Grid Position: This button will set the dimensions and extents of the grid cells. After setting the grid position once, all other grids in the autorun file will default to use the same position and cell sizes.

Choose Grid File: This button will set the name of the grid file. The program will automatically name grids with the following format: "Strata_Attribute.grd". For example, a file named "Overburden_Elv.grd" represents the bottom elevation of the Overburden strata. The below attribute names are used by default:

1. _ELV - this suffix is used for bottom elevation grids
2. _EL2 - this suffix is used for top elevation grids
3. _THK - this suffix is used for thickness grids
4. User-defined attributes will list the full attribute name in the grid file name

Use Pinchout Data/Use Seam Stacking/Conformance Data: These checkboxes control if pinchout and conformance logic will be applied to the grid file. However, this logic will only be applied if it is also enabled under Settings Pulldown Menu > Carlson Configure > Mining Settings. This allows you to quickly enable and disable pinchout and conformance data for select grids.

Modeling Method: Most of these methods are discussed in the section of the help manual corresponding to the Make Strata Grids command. However, the 3D kriging option is discussed in the Make Block Model command.

Apply Extrapolation: This option will extrapolate the grids where null values exist due to an inadequate search radius or inherent limitations by the modeling method. When a value is extrapolated, the data point at the edge of calculated values will be carried into the uncalculated area. This prevents continuation of slopes in the grids, as shown below.

Use Global Extrapolation: This option extrapolates the grids where null values exist, but unlike the Apply Extrapolation option, this option will search for localized slopes in the grid file and attempt to carry the slopes into the uncalculated area. This is shown in the below image.

Max Triangle Length: This value sets the maximum triangle length for the Triangulation and Polynomial modeling methods.

Search Radius: This value sets the maximum search radius for data points. For example, if this value is set to 10,000, any data points beyond 10,000 ft/meters from a given grid node will not be used to estimate the value of that grid node. This concept is shown in the below image.

Max Samples: This value sets the maximum number of data points to use to estimate the value at a grid node. If this value is set to 20, only the 20 data points nearest the grid node being calculated will be used.

Min/Max Quadrant: When the program calculates the value of a grid node, the area around the grid node is divided into four quadrants, as shown below. These Min/Max Quadrant values set the minimum/maximum number of data points to use from each quadrant. This concept is shown in the below image. If the Min Quadrant value is set to 5, a value will only be assigned to the grid node if at least 5 data points are found within all four quadrants. If the Max Quadrant value is set to 20, only the nearest 20 data points in each quadrant will be used for estimation.

Use Parameter Filter: This option will filter data points according to parameters as set in the Define Parameters command. The parameters may be set by clicking the **Set Parameters** button.

Remove: This button will remove the currently selected row from the spreadsheet.

Clear: This button will clear all data from the spreadsheet.

Add Row: This button will create a blank row in the spreadsheet. This can be useful when slightly modifying a row, as you can select an entire row, copy the contents with CTRL+C, paste the contents into the blank row with CTRL+V, and then make the necessary modifications.

Sort: This button will sort the grids alphabetically by strata name. Note that the order in which the grids are listed does not actually have an effect on the grids.

Move Up/Down: These buttons will move the currently selected row up/down in the list.

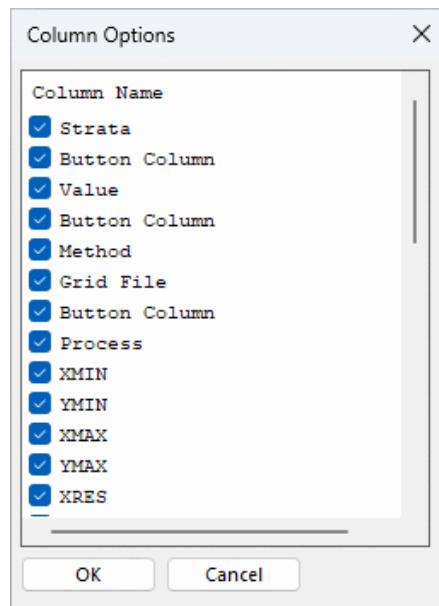

On/Off: This button will toggle the Processing status of the currently selected row(s). Note that the Processing

status controls if the grid is actually created when the Make Grids button is clicked.

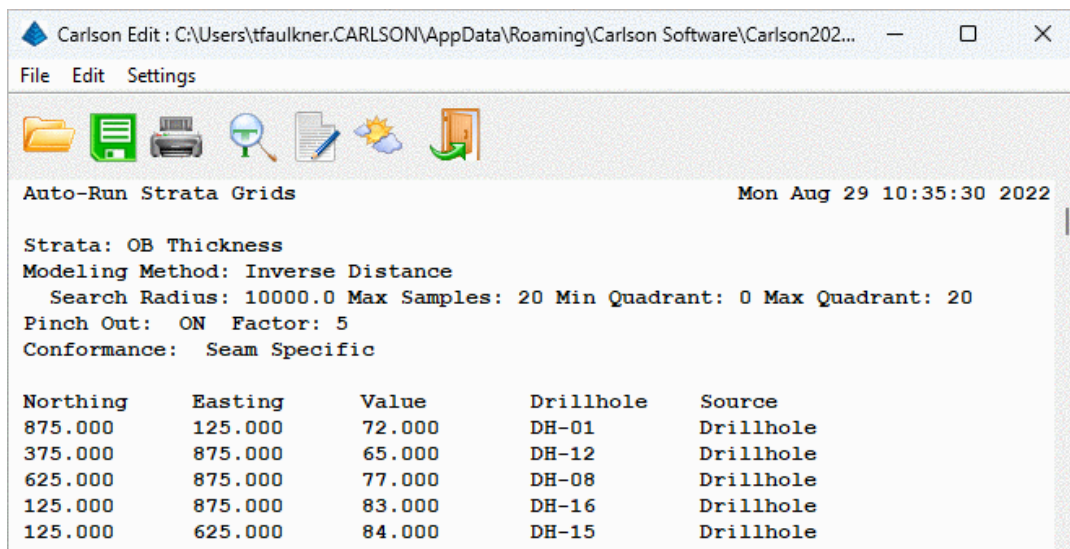

Make Grids: This button will create the grids listed in the spreadsheet.

Change Directory: This button will allow you to set the folder location for the grid files.

Column Options: This button will open the below dialog, which controls which columns are shown in the spreadsheet.

Create Data Points Report: When enabled, this option will output a text report of the data points that were used to create each grid file, as shown below.

Run GFU Macros at Completion: This option will run a Grid File Utilities macro (.gfu file) after making the grids. This file can be made with the Grid File Utilities command. This allows you to quickly customize grid files after they have been generated. When this option is enabled, you will need to click the **Select File** button to select the .gfu file.

Prompts

Select drillholes and strata elevation polylines.

Select objects: *select the drillhole symbols*

Auto-Run Grid Files dialog

Pulldown Menu Location: StrataCalc in Geology

Keyboard Command: chgrid2

Run Strata Grids AutoRun

This command will run the predefined RUN file for making strata grid files. This allows for easier definition of the Autorun macro, without having to wait for the modeling and drillhole processing time.

The Define Strata Auto-Run is where you build the macro file containing the grids to create. It does not have to create them at that time, it just prepares the file to be run at a later time. It is optional to select the drillholes at the beginning of the Define routine. Just hitting Enter will bring up the input dialog.

Run Strata Grids Auto-Run takes the predefined *.RUN file (from Define Strata Grids Auto-Run) and processes it, creating the grid files. As mentioned above, with the previous version in very large datasets, it sometimes took several hours after defining the Auto-Run, to actually select the Make Grids button. Now with this split into 2 routines, you can simply load up the predefined *.RUN file, select Make Grids and leave it over lunch, or overnight, while the modeling calculates the new grids.

Prompts

Select the RUN file dialog

Select drillholes and strata elevation polylines.

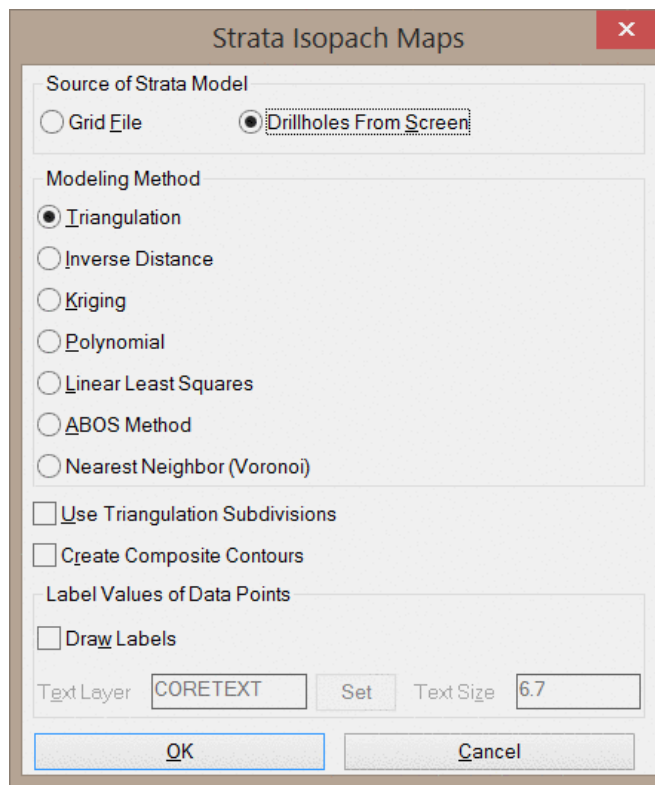

Select objects: *select the drillhole symbols*

Pulldown Menu Location: StrataCalc

Keyboard Command: chgrid3

Strata Isopach Maps

This command will create contours of various strata attributes, either directly from the drillhole data or from existing grid files. When the command is executed, the below dialog will appear.

Source of Strata Model: This option determines the source of the contour information.

The **Grid File** option will use an existing grid file to create the contours. When this option is used, the command is no different than the Contour from Grid File command.

The **Drillhole from Screen** option will use the drillholes in the drawing to create a temporary grid file and contour from that grid. When this option is used, the prompts will be similar to that of the Make Strata Grid Files command, followed by the Contour from Grid File command.

See the above links for explanations of each routine.

Prompts

Select drillholes, channel samples and strata polylines.

Select objects: *pick the drillholes*

Reading drillhole 19

Finding splits ...

Finding pinch out ...

Calculating seam stacking ...

Select the Inclusion perimeter polylines or ENTER for none.

Select the Exclusion perimeter polylines or ENTER for none.

Create composite contours [Yes/<No>]? n

Triangulating points ... 19

Assigning grid values> 33800

Inserted 336 contour vertices.

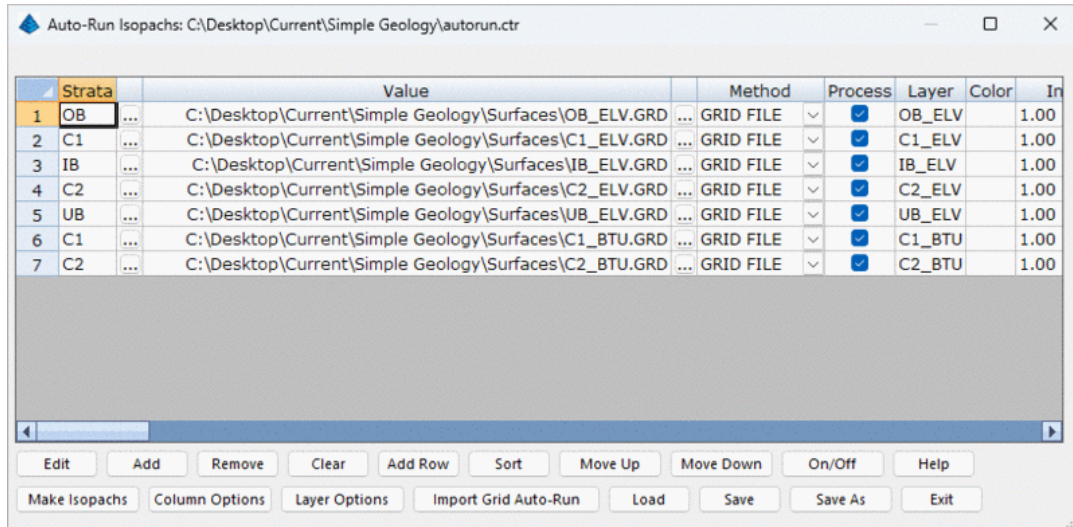

Pulldown Menu Location: StrataCalc

Keyboard Command: chiso

Prerequisite: Drillholes

Define Strata Isopach AutoRun

This command will create a list of contour maps to create. Contours may be extracted from existing grid files, or they can be generated directly from drillhole data. When the command is executed, you will be prompted to select drillholes (you do not have to select drillholes if you would prefer to use existing grids) and inclusion/exclusion perimeters. After this, the below dialog will appear.

Edit: Edits an existing entry in the list.

Add: Adds a new entry to the list.

Remove: Removes an entry from the list.

Clear: Removes all entries from the list.

Add Row: Adds a blank row to the list

Sort: Sort the list in alphabetical order by Strata Name.

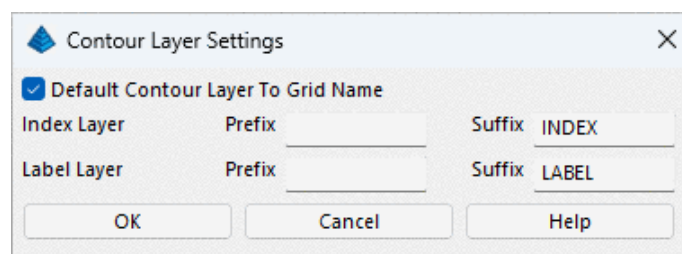

Move Up/Down: Moves the selected entry up/down in the list

On/Off: Changes the Processing status of the entry. When turned off, the entry will not be calculated.

Make Isopachs: Creates the contour maps.

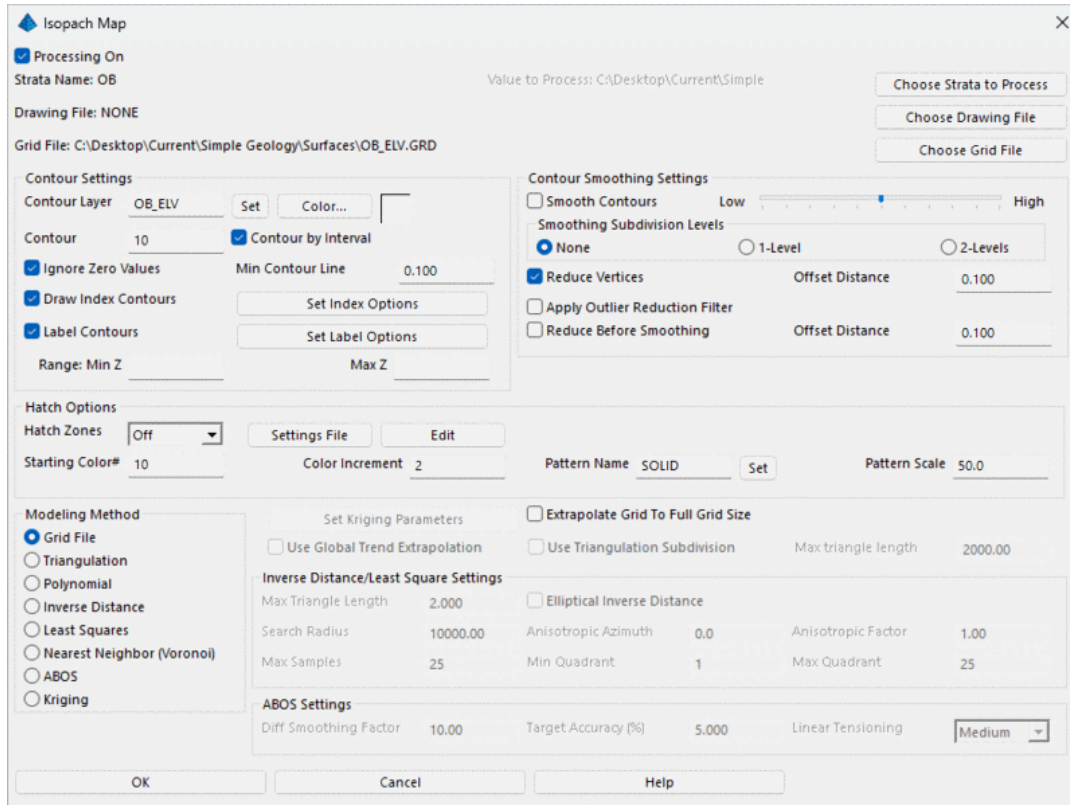

Column Options: Allows you to toggle the visibility of each column in the main dialog.

Layer Options: Opens the below dialog to control automatic layer naming. With this dialog, you can automatically set the contour layer to match the grid/strata names, as well as set prefixes/suffixes for the index contours and labels.

Import Grid Auto-Run: This option will load in a list of grids created from the Define Strata Grids Auto-Run command. When loading one of these files, it is important to note that generic settings will be applied to each grid in the list. It will be important to edit each entry to use appropriate contour intervals, colors, etc.

When you add/edit an entry, the below dialog will appear.

- **Processing on:** This options controls if the contour map will be generated or not.
- **Strata Name:** This will display the strata name if isopaching from drillholes. If isopaching a grid, then this will be blank. You may select a new strata with the Choose Strata to Process button.
- **Drawing File:** This option allows you to export the contour map to a new drawing file by clicking the Choose Drawing File button. If not specified, the contour map will be drawn in the current drawing.
- **Grid File:** This option will specify the grid file to extract the contours from. This option will only be enabled if the **Modeling Method** is set to Grid File.

The Contour Settings, Contour Smoothing Settings, and Hatch Options are described in the Contour from Grid File command.

The Modeling Method and associated settings are described in the Define Strata Grids AutoRun command.

Prompts

Smooth Contours

This command has options for applying smoothing to polylines. Select the radio button for the smoothing option you want to apply. If you use Quadratic B-Spline type smoothing or Cubic B-Spline type smoothing, the *Spline Segments* AutoCAD system variable is relevant. The Curve Fit option provides the least smoothing, and the Cubic B-Spline option applies the most. Another effective way of smoothing is by creating the contours from rectangular meshes using various grid resolutions. Increase the smoothing by lowering the grid resolution and decrease by raising the grid resolution. The Bezier option provides an incremental type of smoothing. The Linetype Generation option turns on the *Ltype Gen* flag for the selected polylines. For more information on this option and the spline smoothing options, look up the *PEDIT* command in the AutoCAD Reference Manual. After selecting the *OK*

button the routine will prompt for needed values.

Bezier smoothing is also embedded in many of the routines that create contours. Bezier smoothing applies the Bezier smoothing algorithm to polylines. This smoothing technique has two advantages over Spline or Curve Fit smoothing. One is that a Bezier smoothed polyline will pass through all of the vertices in the original polyline, while a Spline smoothed polyline only curves towards the original vertices and can pull away from vertices at sharp corners. Hitting all the original vertices can be an important feature in contour maps for maintaining the exact location of the contours. Another benefit of Bezier smoothing is the ability to control the looping and vertex factors. A higher looping factor increases the curving effect. Use this setting with some care, as too high a looping factor may cause nearby contour lines to cross after the smoothing has been applied.

Vertex reduction can also be applied along with the smoothing. This avoids having to create smoothed polylines with numerous vertices and then having to reduce these vertices in a second step. Be sure not to make the cutoff offset for reduction too high or you can negate or even reverse the smoothing effect. One disadvantage to Bezier smoothing is that it cannot be decurved like the other smoothing techniques.

Prompts

Enter the looping factor (1-10) <5>: *press Enter* This determines the extent of curving. 1- least curvy, 10 - most curvy.

Enter the offset cutoff <0.05>: *press Enter* This value is the maximum shift distance for vertices reduction. A higher value removes more vertices.

Select polylines to smooth.

Select objects: *pick polylines*

Before Smoothing

After Smoothing

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: Smooth

Prerequisite: Create Contour lines to smooth

Reduce Contour Vertices

Contouring and smoothing often creates an explosion in file size due to the many vertices it adds to the individual contour polylines. Fortunately, many of these vertices are very close together, some of which can be removed with no visible effect on the contour polylines themselves. *Reduce Contours Vertices* can reduce the total number of vertices up to 90%. This has the benefits of a smaller drawing file, faster drawing loading, and faster regens.

This command removes vertices in a polyline that are within a user specified offset cutoff. The algorithm looks at three vertices at a time, and calculates the distance between the second point and the line from the first to the third point. If this distance is less than the user specified cutoff, the second point is removed. In theory, reducing the polyline vertices should not shift the polyline more than the user's cutoff distance. The default for this cutoff is one tenth of a foot. Increasing the cutoff will remove more vertices while decreasing it will more closely preserve the original contour line. When combining vertex reduction with smoothing, it is suggested to smooth before reducing, although it can be done the other way around.

Prompts

Enter the offset cutoff <0.1>: .3

Select polylines to reduce. *select polylines*

Select objects: *press Enter* to conclude selection

Processed polylines: 1

Total number of vertices: 1125

Number of vertices removed: 939

Before Vertex Reduction

After Vertex Reduction

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: reduce

Prerequisite: Polylines (contours) with vertices to reduce

Edit Contours

This command revises a segment of a contour polyline. Begin by picking a point on the contour where you want to start editing. Then pick new points for the polyline. When finished picking new points, press Enter and then pick a point on the contour to connect with the new points. The polyline segment between the start and end points is then replaced with the new points.

If there is a triangulation file associated with the contours, then the command prompts for whether to update the triangulation surface file to match the contour edits. When this option is used, data points are added to the triangulation surface along the edited contour segment to make the triangulation surface match the contour line. Existing triangulation source data is retained. So the updated triangulation is the combination of the original source data and the additional points from Edit Contours. One way to get a triangulation surface associated with the contours is to use the Triangulate & Contour command with both Write Triangulation File and Draw Contours

options active.

Note: If the triangulation association is not used, then this routine has no effect on the actual triangulation or grid surface model file that the contours may have been drawn from. It only revises the drawn contour or polyline on the screen. If the contours are later regenerated from this file, the edits will be discarded.

Prompts

Select contour to edit: *pick the contour polyline at the place to start editing*

Pick intermediate point (Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *press Enter*

Pick reconnection point on contour: *pick the contour polyline at the place to join*

Edit this contour by picking new points

Contour with segment replaced with new points

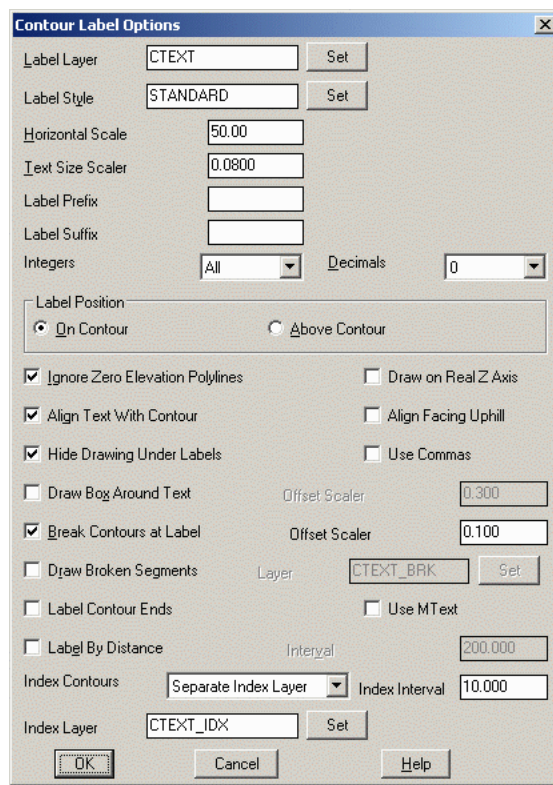

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: editctr

Prerequisite: Polylines with elevation (contour polylines)

Contour Elevation Label

This command can be used to simultaneously create elevation labels on a group of contour polylines at elevation. First the command starts with a dialog with the label options. Then to place the labels, pick two points crossing the contour polylines at the desired label location. The program will find all the contour polylines that intersect the picked line (defined by the two picked points) and will place labels at the intersection point of each contour. A second crossing line can be initiated immediately, so multiple areas can be quickly labeled while remaining in the command. Alternatively, you can type P for Polyline at the Command prompt and select a polyline. Then the program finds all the intersections between the selected polyline and the contours and places labels at these intersections. The actual "z" elevation of the contour line determines the label value.

Label Layer specifies layer name for the contour labels that will be created.

Label Style specifies the text style to be used for labels.

Horizontal Scale is used in conjunction with the Text Size Scaler to determine unit height of the contour labels.

Text Size Scaler is a scaler that will be multiplied by the horizontal scale to set the actual text height of the labels in AutoCAD units.

Integers controls how many digits to label to the left of the decimal. For example, if all contours are in the 5000's, then setting for three digits would label the 5280 contour as 280.

Decimals sets the decimal precision for the labels to be created.

Label Position determines the label position in relation to the contour polyline.

- **On Contour** centers the label on the contour line.
- **Above Contour** places the label above the contour line. If this option is used, the options for Break Contours at Label and Draw Broken Segments become inactive.

Ignore Zero Elevation Polylines enables the routine to filter out all entities with an elevation of zero.

Hide Drawing Under Labels activates a text wipeout feature that will create the appearance of trimmed segments at the contour label, even though the contour line is still fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels, yet the contour lines themselves remain contiguous. This feature will also hide other entities that are in the immediate vicinity of the contour label.

Align Facing Uphill makes the label parallel to the contour and flips the label so that it reads facing uphill. Otherwise, the labels are made to face up relative to the current screen view. When this option is on, the program prompts for a triangulation surface file that should match the surface the contours represent.

Use Commas adds a comma into the labels for the thousands place such as "5,000" instead of "5000".

When **Align Text with Contour** is checked, contour elevation labels will be rotated to align with their respective contour lines.

When **Break Contours at Label** is checked, the contour lines will be broken and trimmed at the label location for label visibility.

When **Draw Broken Segments** is checked, segments of contours that are broken out for label visibility will be redrawn as independent segments. Specify the layer for these broken segments in the box to the right of this toggle.

Label Contour Ends creates labels off the ends of the contours.

Label By Distance places the labels by distance along the contour. The user is not prompted for screen picks of contour crossing when this option is used.

- **Interval** sets the distance interval to be used between labels on each contour.

When **Draw Box Around Text** is checked, a rectangle will be drawn around the elevation labels. The Offset Scaler controls the size of the rectangle.

The **Draw On Real Z Axis** chooses between creating the text entities at the elevations of the contours or at zero elevation.

The **Use MText** chooses between creating MText and DText label entities.

Index Contours: Label All will label both index and intermediate contours with the same settings. Label Index Only labels only the index contours. Separate Index Layer will label both index and intermediate contours with the index labels on a different layer.

Prompts

Contour Label Options Dialog Opens Select the desired options and press OK.

Define a line which slices the contours at the desired label locations.

Pick 1st point (P-Polyline, Enter to end): *pick a point*

Pick 2nd point: *pick a point*

By selecting two points the contour lines that cross the line defined by the two points are labeled.

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: gclabel

Prerequisite: polylines with elevation (contour polylines)

Move Label Along Contour

This command slides an existing contour label along a contour, maintaining its alignment with the contour. After moving the label, you can type F for Flip at the Command prompt to rotate the label orientation by 180. The label must have originally been created with the *Break Contours at Label* option *Off*. If the option to *Hide Drawing Under Labels* was used when the label was created, the wipeout will move with the label when using this command.

In addition to moving a label, an existing label can be copied and placed at a new position along the contour by using the Copy option at the first prompt.

Prompts

Copy/<Select contour label to move>: *Pick label*

Pick new contour label position: *Move mouse to relocate label*

Flip last/<Select contour label to move (Enter to end)>: *press Enter*

Prerequisite: generated contour labels

Flip Contour Labels-Text

This command individually rotates each of the selected text entities by 180 degrees.

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: fliptext

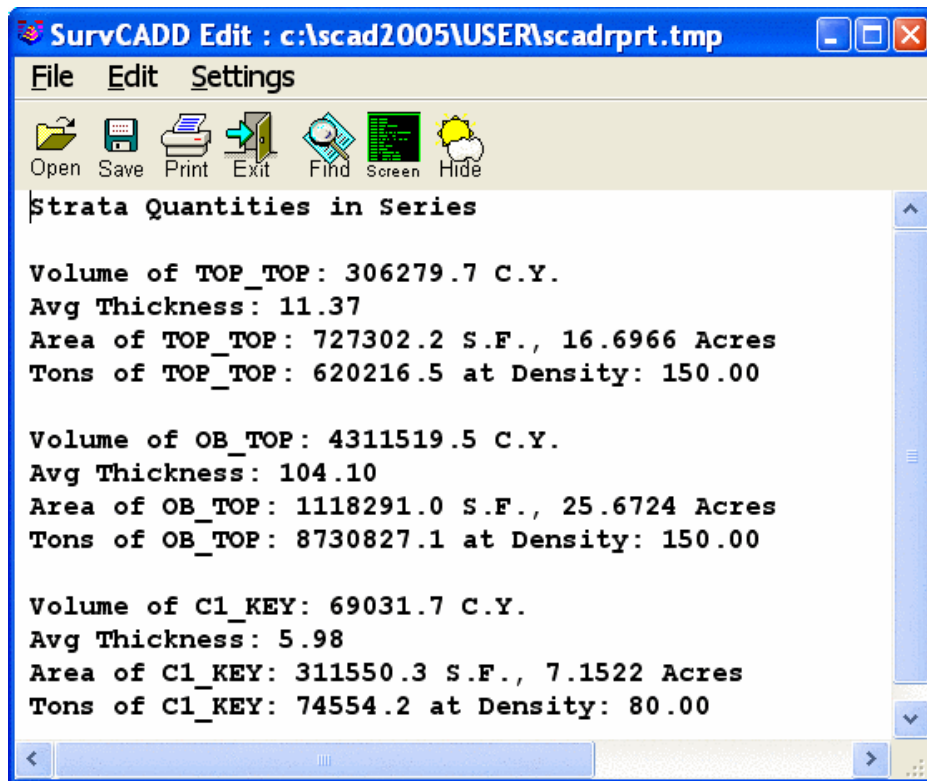

Prerequisite: Text labels on contours

Strata Quantities in Series

For each strata in the drillholes, this command can calculate the volume, tonnage, and average attribute values within a specified area. The possible attributes depend on the configuration set in Define Drillhole. For example, attributes might be moisture, sulfur, BTU, etc. After reading in the selected drillholes, Strata Quantities cycles through all the possible quantities for every strata from top to bottom. Only the desired quantities are calculated and the result is printed out in volume, tons and quality.

Strata Quantities calculates from a 3D grid of the values. The grid resolution is specified in a grid resolution dialog box. A higher resolution yields more accurate results, but slows down the routine.

The area for gathering quantities defaults to the limits of the selected surface entities and drillholes. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. Also, in the first selection for surface entities and drillholes, any selected polylines in the PILLARS layer will be made into exclusion areas and polylines in the PERIM layer will be made into inclusion areas. This is useful for getting quantities from drillholes among pillars and perimeters.

Selected Strata Quantities

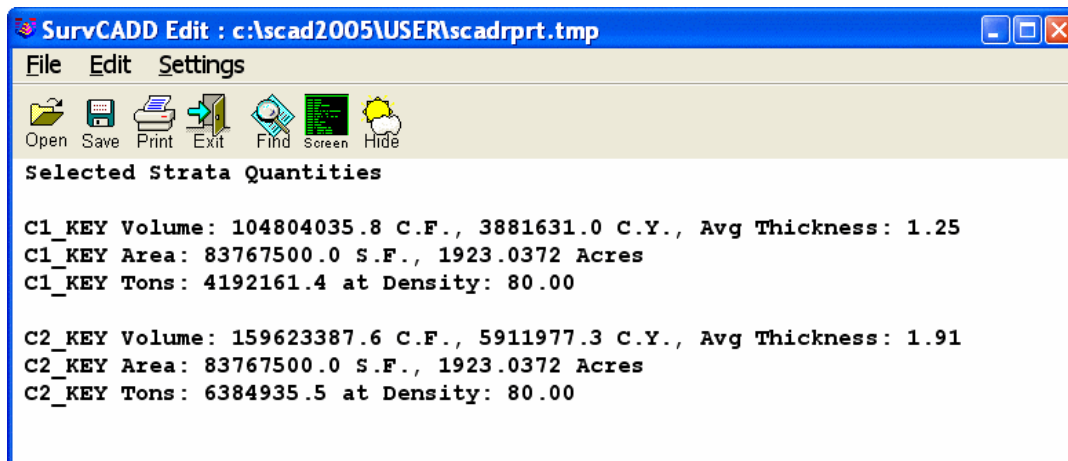

For each strata in the drillholes, this command can calculate the volume, tonnage, and average attribute values within a specified area. The possible attributes depend on the configuration set in Define Drillhole. For example, attributes might be moisture, sulfur, BTU, etc.

The area for gathering quantities defaults to the limits of the selected surface entities and drillholes. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. Also, in the first selection of drillholes, any selected polylines in the PILLARS layer will automatically be made into exclusion areas and polylines in the PERIM layer will be made into inclusion areas. This is useful for getting quantities from drillholes among pillars and perimeters.

This command is similar to the Strata Quantities in Series command. The difference is that this command does not process the strata in sequence from top to bottom. Also this command does not model the ground surface. Instead Selected Strata Quantities allows you to select the strata to process from the list of available strata. The advantage is that when there are many strata, you don't have to cycle through all the top strata to get down to a specific strata. Since the ground surface is not calculated, the disadvantage of this command is that the outcrop for the selected strata is not automatically calculated. The volume for the selected strata is calculated using the strata thickness and the calculation area. To limit the volume calculations to be inside the outcrop, draw the outcrop as a closed polyline which can then be used as an inclusion perimeter.

Another advantage of this command versus Strata Quantities in Series is that composite quantities can be calculated. Composite quantities allow you to select multiple strata and add their thickness together for the volume report. Also the weighted average of the attributes is calculated.

Define Geologic Model

This command assigns grid files to strata names in sequence. This list of grid files represents the geologic model of the strata. The Make Strata Grid File or Auto-Run Strata Grids commands can be used to create the grids before running this routine. The Geologic Model grid assignments are stored in a user-specified file name with the .pre file extension. There are two types of Geologic Model files: elevation and thickness. When creating a new Geologic Model file, you have the choice between elevation and thickness. Once the Geologic Model file is created, the type cannot be changed.

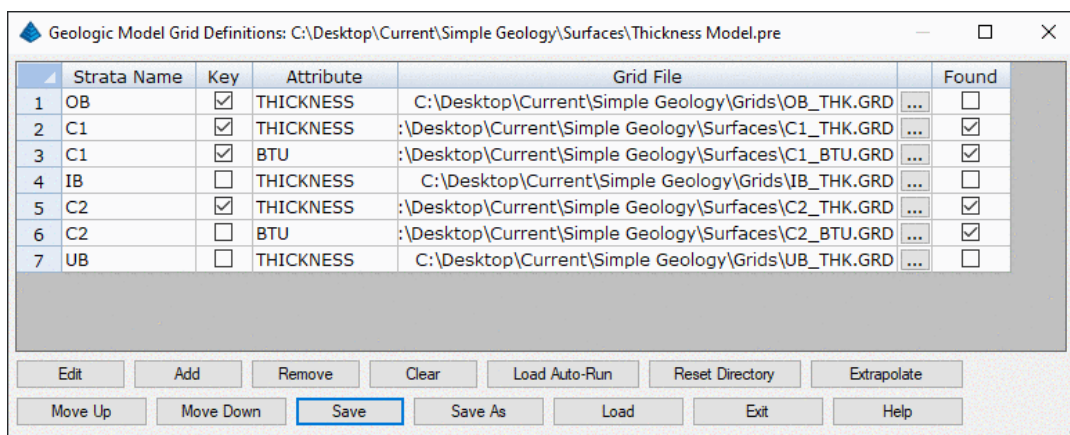

For elevation type Geologic Model files, the grid files define the bottom elevation surface model for the corresponding strata. A grid file for the ground surface model is also assigned in this routine. The surface file can be either a grid or a TIN file, but all other surfaces in the model must be grids. When the Geologic Model file is applied in StrataCalc volume calculations, the strata thickness is determined by comparing the current strata bottom elevation grid with previous upper strata or surface grid. Shown below is an elevation example. Note that these surfaces use a top-down dominance, meaning that if an upper surface (such as the topo) cuts down below a lower grid, the

lower grid will cease to exist in that area. In this way, you can model outcrops without having to modify the strata elevation grids to match the topo.

With thickness type Geologic Model files, the grid files represent the thickness for the corresponding strata. A surface grid file is not specified, and a flat surface is assumed. Without the ground surface elevation grid, the StrataCalc routines cannot find outcrops or adjust the strata thickness for variations on the surface. So the thickness grids that you supply the Geologic Model file must account for the outcrops and ground surface variations. To account for outcrops, you can set the thickness grids to zero in outcrop areas by using a closed polyline for the outcrop areas and running Grid File Utilities-Set Value with the Use Inclusion Areas option. A thickness model will not draw proper Fence Diagrams. To account for surface variations, you can make a grid of the ground surface and a bottom elevation grid of the top strata overburden. Then use Grid File Utilities to subtract the top strata elevation grid from the ground surface. The resulting difference grid is the top strata thickness. Shown below is a thickness example.

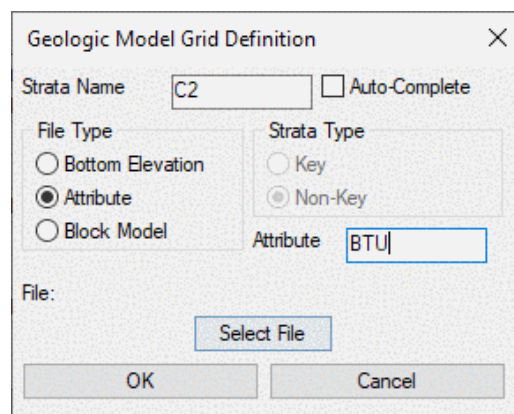

All these grid files should have the same location and resolution, though they can vary for some commands, such as Surface Mine Reserves. When grids have differing sizes/resolutions, the grids will be automatically resized to a common size/location, which can increase processing time. The resolution of the topo grid will be retained when these corrections are applied, effectively allowing one to model the topography with a higher resolution than the strata grids.

The model grids are specified in the dialog shown below. The surface grid is defined in the top of the dialog. To

assign the surface grid, pick the Select Grid File button in the upper right. Next there is a list of the strata names and the corresponding grid files. To add a strata grid, click the **Add** button. This brings up the below dialog where you enter the strata name and grid file. If you have multiple grids related to a single strata type (such as an elevation and an attribute), the Strata Name for all of those grids should use the exact same Strata Name.

Besides elevation and thickness grids, attribute grids such as BTU can be assigned to the strata names. In the Geologic Model Grid Definition dialog, click on the Attribute toggle and enter the Attribute Name. The strata in this list should be listed in top to bottom order. If a strata is out of order, highlight the strata in the list and click the **Move Up** or **Move Down** button.

The **Auto-Complete** option looks for patterns in the existing grids to fill out grids for another strata. For Auto-Complete, the strata name format must have an underscore with the name on the left and the type on the right such as "C1.KEY" with "C1" as the name and "KEY" as the type. For example, if the list of grids already has grids for strata C1.KEY of C1.bottom.grd and C1.BTU.grd, then when adding a new strata named C2.KEY, the Auto-Complete will look for C2.bottom.grd and C2.BTU.grd and automatically add these to the list.

The **Load Auto-Run** button will prompt you to select an Auto-Run Grid Definition File (.run). The program will then read the strata names from this file and build the Geologic Model Definition list. The **Reset Directory** button allows you to reassign the grid files directory in case the grid files have move since the Geologic Model file was created. Select the grid file at the top of the window, usually the first grid on the list. The surface grid will have to be redirected separately. The **Extrapolate** button will extrapolate and save all the grids to remove NULL values. This option will save time in StrataCalc routines that use the Geologic Model file and extrapolate the grids on-the-fly each time. There is an option to extrapolate by merging or flattening (pancaking) elevation grids with upper strata. The "pancaking" is an option using the Extrapolate function. It will assign the Nulls in a grid the elevation of the strata above. This change is saved to the .GRD file. The other option will just extrapolate the grid elevation out to the grid limits.

The purpose of this routine is to allow you to process stored grids in routines such as Surface or Underground Reserves and Fence Diagram. These commands have a Geologic Model option under the modeling methods. Otherwise these routines will read selected drillholes and calculate the strata models on-the-fly. The advantage to the Geologic Model is that you have more control over each of the geologic model grids. After creating the strata grid file, there are many routines that can be used to analyze and modify the grids to make sure that the grids model the strata the way that you want, and even create a mining model from modifying the geologic grids. For example, you can use Plot 3D Grid File, Grid File Utilities and Contour from Grid in the Civil Design module.

Finally, for users with the Ore Module that have created block models, they may be added into the Geologic Model for use with the Fence Diagram and Surface Reserves commands. There is an option, next to Elevation or Attribute for Block Model. The procedure here is to build the Geologic Model, interval by interval from the top down as usual. Then add in the block model for each interval, or strata that you have. It is just like the other attributes, in that it must have the same name as the strata it is referring to. There are options on the Fence Diagram and Surface Reserves screens to use the hatch fence by block model and to break out quantities by attributes.

Keyboard Command: precalc

Define Mining Model

This command creates a Mining Model file (.mmd) which stores a sequence of strata elevation grids along with strata attribute grids and a ground surface grid. The Define Mining Model works the same as the Define Geologic Model. See the Define Geologic Model section of the manual for a description of the functions.

The difference with the Mining Model is that the strata elevation grids are already for any adjustments including recovery, minimum key thickness to mine, minimum depth to mine, minimum separatable parting thickness and non-key thickness to add to the key. The Mining Model can be used in commands like Surface Mine Reserves and the program can directly process the strata elevation grids without having to apply those adjustments as it needs to for a Geologic Model.

Pull down Menu Location: StrataCalc

Keyboard Command: defmine

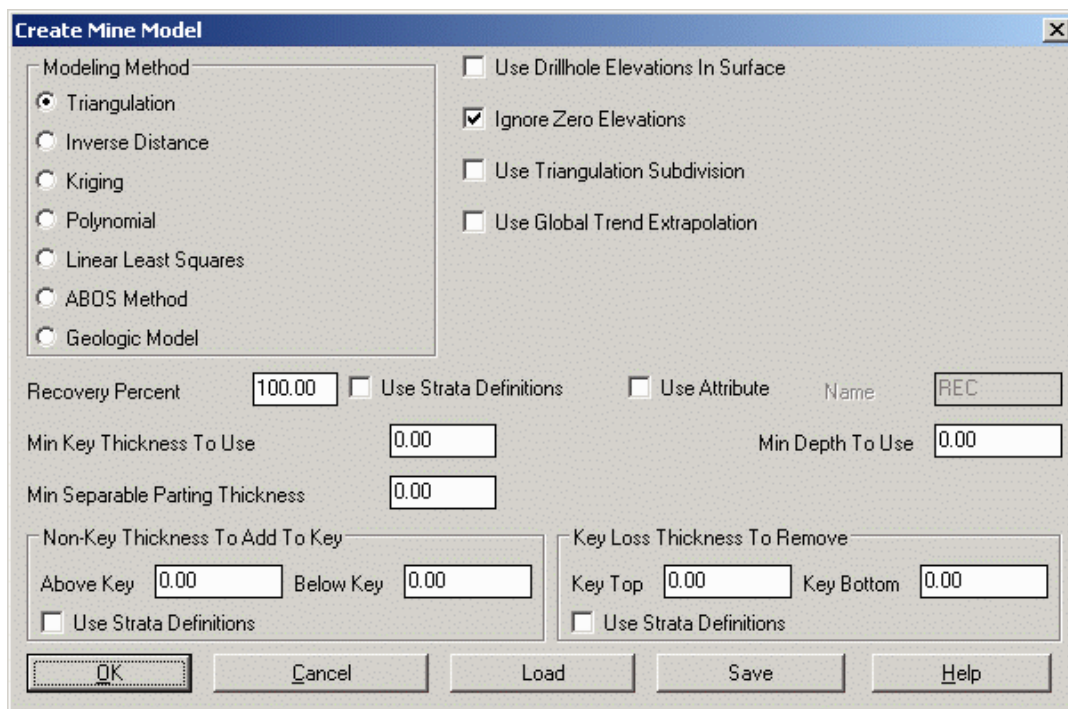

Prerequisite: grid files

Geologic To Mining Model

This command creates a Mining Model file (.mmd) by modeling drillholes or processing a Geologic Model. The Mining Model adjusts the strata elevations for recovery, minimum key thickness to mine, minimum depth to mine, minimum separatable parting thickness, key loss thickness to remove and non-key thickness to add to the key.

The input of the strata grids and the adjustments to create the Mining Model are a similar process to the Surface Mine Reserves command. See the Surface Mine Reserves section of the manual for a description of the input strata grids and the adjustments.

There are a couple key advantages of applying the strata elevation adjustments and saving them to the Mining Model. One purpose is to save time when processing the model in Surface Mine Reserves because the program does not need to take time to apply the adjustments each time the model is run. Another advantage is the mining model can be inspected with various grid tools such as Grid Inspector to verify that the adjustments are applied correctly.

Pull down Menu Location: StrataCalc

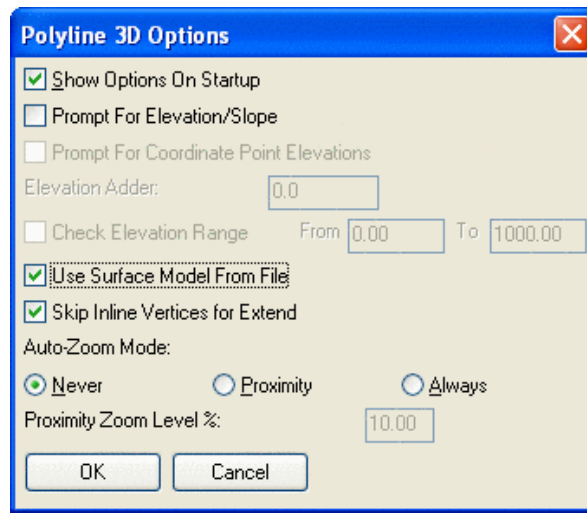

Keyboard Command: minemod

Draw Fault Line

This command creates a 3D polyline that represents a fault line which is used by *Fence Diagram* in the intersection mode, or in the Make Strata Grid File command. This command is very similar to Carlson Draw > 3D Polyline command. In addition to elevation for each vertex of the polyline this command prompts for fault shift. This shift value is the amount of elevation difference from left to right across the fault line in the direction of the line is drawn. Note that a positive shift amount means that the right side of the fault line is lower than the left. Used is also prompted for the dip angle at the beginning, dip angle is same throughout the length of fault.

The fault line defines a fault surface starting at the elevations of the fault line and extending up and down by the dip angle. When a strata surface crosses the fault surface, the strata will shift by the amount of the shift value of the fault line at that point.

Prompts

Enter dip angle (degrees) <0.00>: 90

Keyboard Command: fault

Import Fault Line

This command creates fault polylines by reading data from a text file. Each row in the file is for a fault vertex. The data must include the X, Y and Z position plus the fault shift amount and dip angle. There is also an optional Description field which can be used when there are multiple faults in the same file. Use the End Fault Description as the description in the text file on the last point in the fault to identify where the fault ends and the next fault will start.

After selecting the text file to import, there is a dialog to define the format of the text file followed by a dialog for the End Fault Description and layer for the fault polylines to create.

Prompts

Prerequisite: Text file

Pulldown Menu Location: StrataCalc > Faults

Keyboard Command: import_fault

Edit Fault Line

This command is used to edit tagged fence polylines. When the command is executed, the below dialog will appear.

In this dialog, each vertex of the fault polyline is listed on a separate row. The coordinates, dip angle, and vertical shift associated with each vertex are also listed. A preview of the fault polyline is shown in the graphic window

with a highlight on the currently selected vertex.

Easting/Northing columns: These values list the X/Y coordinates of the fault polyline vertex.

Elevation(Z) column: These values list the elevation of the fault at the vertex. The elevation from row 6 in the above is set to 975. Notice that this is shown in the below diagram with the fault passing through this elevation.

Dip(deg) column: These values list the dip angle of the fault at the vertex. The dip angle is measured from the horizontal direction. The dip angle from row 6 in the above example is set to 50 degrees. This is shown in the below diagram.

Shift column: These values list the vertical shift of the fault. When looking down the direction of the fault polyline, this value is the vertical shift when crossing from the left to the right side of the fault. Note that a positive shift amount means that the right side of the fault is lower than the left. The fault shift in the above example is set to 100'. This is shown in the below diagram.

Pick: This button will allow you to screen-pick a new X-Y location for the fault vertex.

Reduce Vertices: This button removes extra points from the fault without moving the fault position more than the specified cutoff tolerance.

Interpolate: This button interpolates shift values. This way you can fill out shifts at a few key points and have this Interpolate function fill in the rest of the shift values.

Priority Order: This option controls the order that the faults are processing. Priority 1 faults will be processed first, with lower priority faults being processed after.

The green + button to the right of the spreadsheet view will add a new vertex to the fault polyline.

The green X button will remove the currently selected vertex from the fault polyline.

The cursor button will move an the currently selected vertex to a new X-Y location.

The last button in the list will reduce the number of polyline vertices according to a offset cutoff amount. When used, this function will remove any vertices that will allow the polyline to move by less than the offset cutoff. Using the default value of 0.1 will prevent the fault polyline from moving more than 0.1 ft (or meters).

Prompts

Calculate Fault Shift

This command assigns fault shifts to polylines. The polylines must be drawn ahead of time and they should follow the fault zones. After selecting the polylines to process, the program prompts for drillholes to process. Then select a strata to model. The fault shift is calculated by modeling the strata twice for each polyline. One model excludes the drillholes on the left of the polyline and the other model excludes the drillholes on the right. The modeling uses the inverse distance method. Then the elevation difference between the two models is used to assign the fault shifts along the polyline.

Prompts

Select fault lines.

Select objects: *pick polylines to assign fault shift to*

Select drillholes, channel samples and strata polylines.

Select objects: *pick entities to model*

Choose Strata To Process dialog

Draw Heave Zones

This command creates closed polylines that represent the fault heave zones where the material is broken up and not mineable. These polylines can then be used as exclusion areas in routine like Strata Isopach maps to avoid contours in those areas. They can also be tagged as Strata Limit Polylinies for exclusion for volumes and to delete the area in a Fence Diagram.

The command will use either an existing elevation grid file, or it will model from drillholes on screen. If there are multiple seams that are faulted, each one will have a slightly different area along the fault. Shown here is a result of drawing the heave zones. Most zones will run parallel to the faults, with the distance away from the fault based on

the displacement or shift of the fault.

Prompts

Here are the prompts when using the drillholes.

Trim Isopach Within Fault Zone

This command trims isopach polylines in fault zones which applies when the isopachs are unreliable within the fault zones. The program prompts to pick one isopach polyline which is used to get the layer name of the isopach polyline. Then the program automatically selects all the polylines on that layer for processing. Next the program prompts for the fault zone width. The program automatically searches the drawing for all the fault polylines and trims the isopach polylines in areas within this fault zone width of the fault polylines.

Prompts

Select sample of isopach polyline to trim: *pick a polyline*

Fault zone width <10.0>: *press Enter*

Prerequisite: Fault polyline and isopach polylines

Pulldown Menu Location: StrataCalc > Faults

Keyboard Command: trim_fault

Apply Faults to Grid

This command is used to offset the grid values of an existing strata elevation grid file to adjust for faults. The program saves a new grid file with the values offset based on the fault lines drawn with the Draw Fault Line command. There are two methods. The Separate Grids For Each Side of Fault method applies for both regular faults and reverse faults where the strata are folded over top of themselves within the fault zone. In both cases, the strata can be modeled separately for each side of the fault. The Adjust Grid Across Fault applies when the strata can be modeled with the same grid for the whole site. This method adjusts the grid in the fault zone.

Before running Apply Faults to Grid for this method, setup the faults and strata grids as follows:

1. Draw a fault polyline with the dip angle and elevation difference set using the Draw Fault Line command.
2. Draw a closed polyline around the area on the high side of the fault.
3. Create strata grids like usual. Make separate strata grids for the high and low sides.
4. Create a surface topo grid (only necessary for reverse faults)

When using this method, you will be prompted with the below dialog

Reverse Fault: Folded

With this method, the program prompts for the fault polyline and high side polyline from steps 1,2 and the grids from steps 3,4. The processing for the high side strata grids is slightly different than the low side because the way

the program goes about embedding the fault surface to the strata surfaces. For the high side, you specify one strata grid at a time. For the low side, you specify the top and bottom strata grids (ie A1_TOP.grd and A1_KEY.grd).

Continuous Strata Surface

With this method the program prompts for the fault polyline, the high side inclusion polyline, and the high/low-side grids (no topo is needed). This will join the two grids and the fault surface into a single grid file as shown below.

The above image shows the fault surface in blue, the high side of the grid in red, and the low side of the grid in orange. The below image shows how these three surfaces will be joined together.

The Fault Influence Distance is the offset distance away from the fault lines that will be used to transition from the original grid to the faulted values.

This is the grid before applying the faults

This is the grid after applying the faults

Prompts

Fault Influence distance <500.00>: 150 *Enter in distance to use.*

Select fault lines:

Select objects: *Select the fault lines*

Updating grid with faults 190000...

Pull down Menu Location: StrataCalc > Faults

Keyboard Command: apply_faults

Prerequisite: fault lines drawn using Draw Fault Line and a grid file

Remove Faults From Grid

This command creates a strata elevation grid file (.grd) with faulting removed by adjusting an existing strata elevation grid with faults and selecting fault lines from the drawing to process. The purpose of this routine is to check that the fault lines are defined correctly. When the fault lines are in the right places with the right shift amounts, then the resulting grid model from this routine should be smooth without shifting from faulting. The Fault Influence Distance is how far to the sides of the fault lines that the program will adjust the grid.

Prompts

Grid File to Process *Choose input strata elevation grid*

Fault Influence distance <500.00>: 100

Select fault lines.

Select objects: *pick fault lines*

Output Grid To Write *Choose strata elevation grid file name to create*

Pulldown Menu Location: StrataCalc

Keyboard Command: remove_faults

Prerequisite: strata elevation grid and faults

Make Unfaulted Strata Grid

This command creates a strata elevation grid file (.grd) from selected drillholes and faults in the same way as the Make Strata Grid File command. The difference with this command is that it applies at fault adjustments in reverse. The purpose of this routine is to check that the fault lines are defined correctly. When the fault lines are in the right places with the right shift amounts, then the resulting grid model from this routine should be smooth without shifting from faulting.

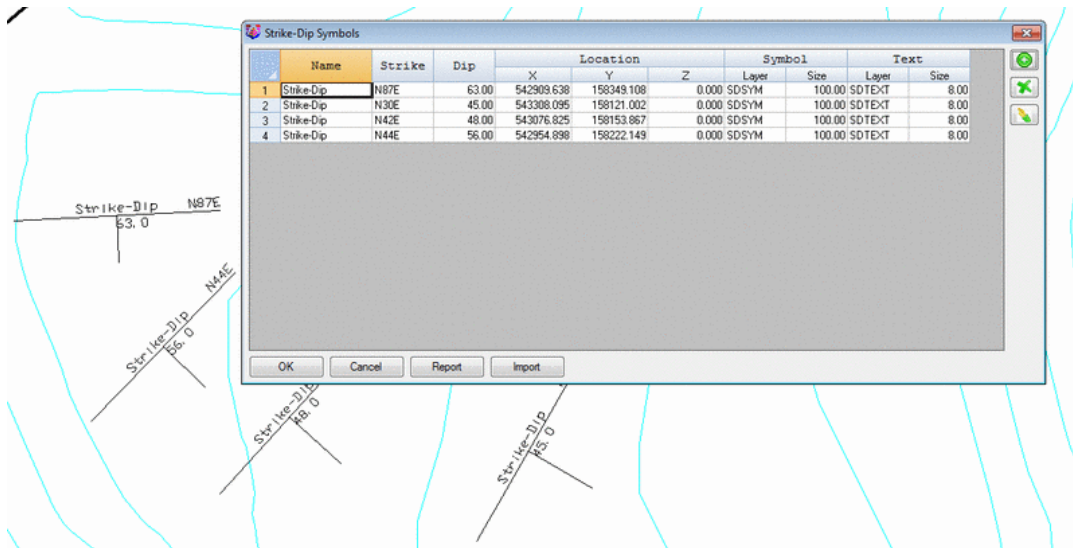

Pulldown Menu Location: StrataCalc

Keyboard Command: unfault_grid

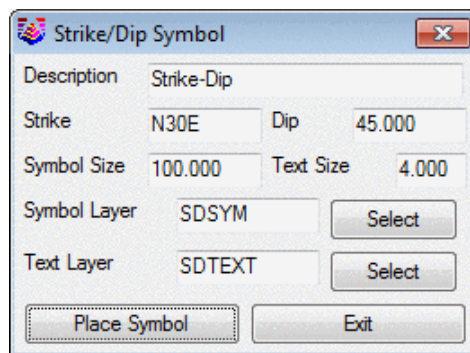

Prerequisite: drillholes and faults

Strike-Dip Symbol Editor

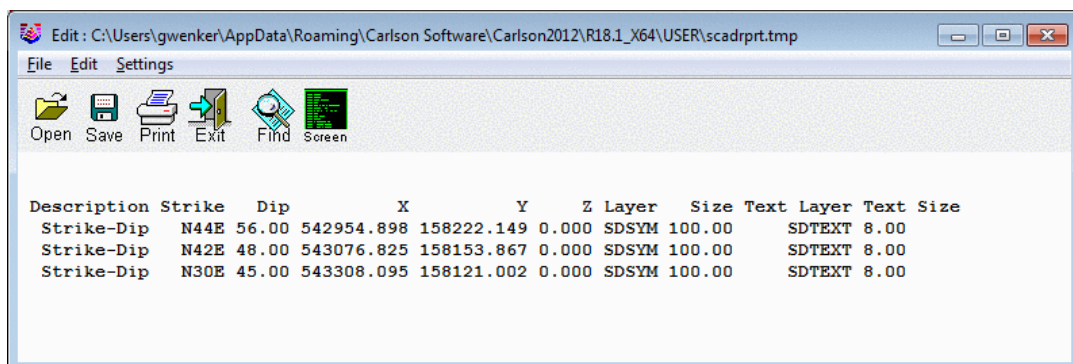

This command works in an editor where the strike and dip symbols can be added, deleted or edited in a spreadsheet type editor. There are options for reporting and importing from an external text file to bring the symbols in.

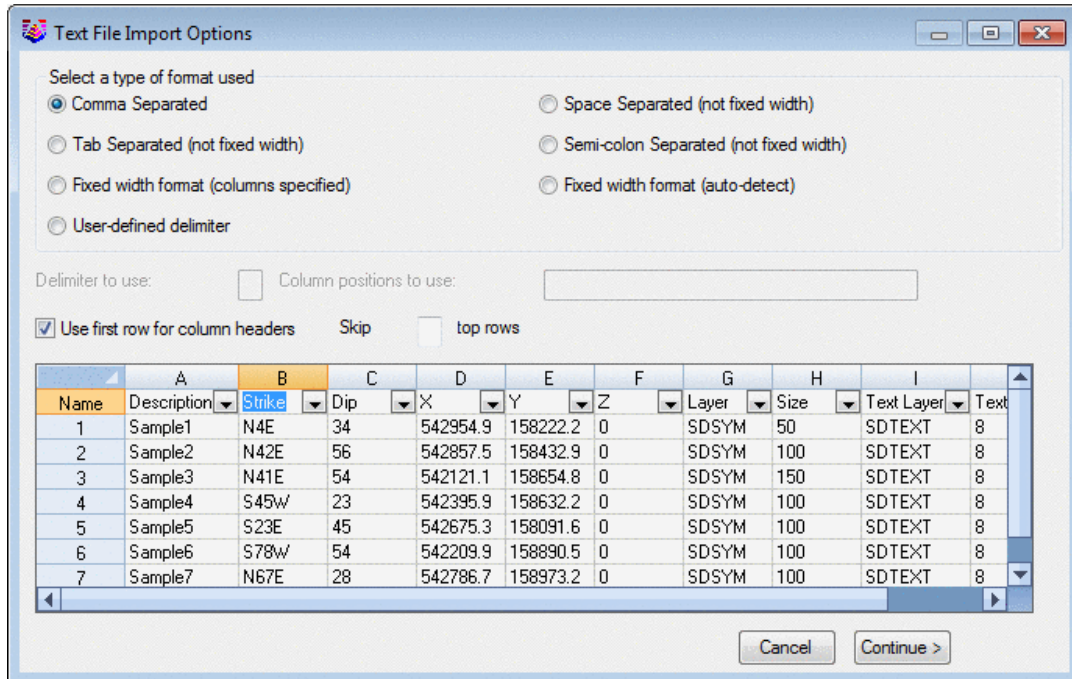

- **Add Symbol (+):** This button brings up the Strike/Dip Symbol window where a new symbol can be edited. There are defaults in the window that can be modified with the data. There are options to label a description, enter the strike and dip, and symbol and text size. The symbol and text layers can be entered here, or picked from a list of layers with the Select button. The Place Symbol button allows for screen picking of the new location for the symbol.

- **Delete Symbol (X):** This button deletes the highlighted row of the selected symbol.
- **Edit Symbol:** This button is similar to the Add button, but the highlighted row symbol appears in the window, allowing for changes that are done in the drawing when the Exit is selected.
- **Report:** This option will bring up the Report Formatter where the symbols are reported. The following data can be reported, such as X, Y, Z, layer, text size, and others.

- **Import:** This option will import the symbols into the drawing from a text file of the formats shown. It is automatic if a header line is used to define the columns, it will find the names and import the data. If there isn't a header line, then each column will have to be defined prior to importing, with the dropdown arrows.

Prompt

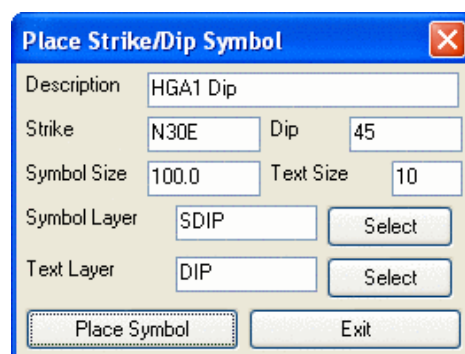

Select all strike-dip symbols.

Select objects: Specify opposite corner: 20 found, 4 groups. (If there are no symbols in the drawing already, just hit "Enter" and the empty window will appear where new symbols can be added or imported).

Keyboard Command: EDIT_STRIKEDIP

Draw Strike-Dip Symbol

This command draws the standard strike-dip symbol based on user defined input. It has an option for entering and labeling a description. If no description is desired, then leave it blank. The strike and dip entered in the window will orientate the symbol placement. There are settings for symbol and text size, as well as layers.

Keyboard Command: `strikedip`

Tag Strata Polylines

This command attaches a strata name to a 3D polyline that represents the bottom elevation, top elevation or the thickness of that strata. When modeling the drillholes, each point in these strata polylines is used as an elevation or a thickness data point for the assigned strata. For example, a 3D polyline for the outcrop of a strata could be tagged with the strata name and used in processing for additional model enhancement. If bed names are used, be sure to include the `_TOP`, `_KEY`, `_PARTING` or `_BOTTOM` extensions to the bed name.

Prompts

Strata name: `Seam1`

Type of strata polyline [`<Elevation>/Thickness`]? *press Enter for Elevation*

Elevation reference [`<Bottom>/Top`]? *press Enter for Bottom*

Select strata bottom elevation polylines.

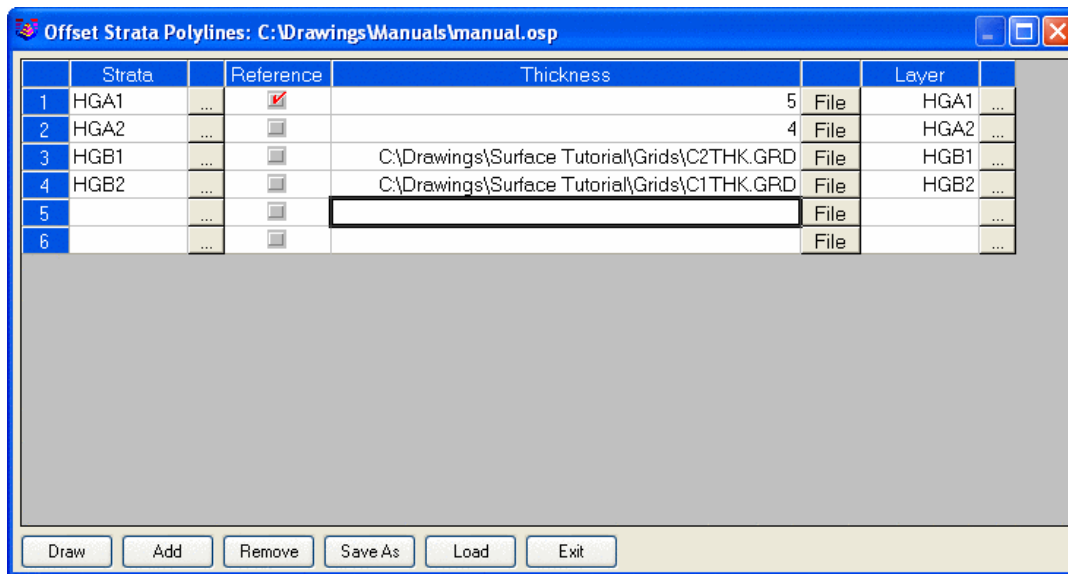

Select objects: 1 found

Pulldown Menu Location: Drillhole

Keyboard Command: `stratatag`

Offset Strata Polylines

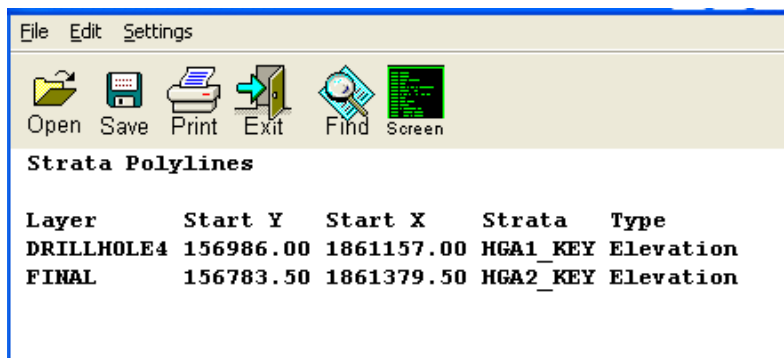

This command creates additional strata elevation polylines offset by the strata thickness from a reference/starting strata polyline for elevation. This is useful for manually creating faults where all the seams are offset along the elevation strata polylines. The first prompt is to open or create an offset strata polylines file (*.OSP). The first column is the strata/bed name attached to the strata polyline. The button next to them brings up the list of defined strata. A Reference polyline is one that already exists and this is the one that will be offset from. The thickness to offset the new polylines can either be entered as a value (+/-) or as a thickness grid file. The layer is the layer that the reference polyline is on, and the layer it will draw the new polylines on. The resulting new strata polylines can be used for more accurate modeling elevations.

Keyboard Command: offset_strata_pl

Report Strata Polyline

This command generates a report using the Report Formatter containing all the Strata Polyline automatically found in the drawing. It reports the layer, XY of the start and end of the polyline, the tagged strata name and the type (elevation or thickness).

Keyboard Command: report_strata_pline

Highlight Strata Polyline

This command simply highlights the named strata polylines in the drawing. A regen of the screen will unselect the polylines.

Prompts

Select the polylines to check.

Select objects: Specify opposite corner: 5 found

Highlighted 3 Strata Polyline. Skipped 2 other polyline.

Pulldown Menu Location: Drillhole in Geology

Keyboard Command: highlight_strata_pl

Identify Strata Polylines

This command simply allows you to pick a polyline and report the strata name, if any, attached to this polyline. These are tagged for use in modeling the bottom elevation or thickness in addition to drillholes.

Prompts

Select strata polyline to identify:

Strata Name: SEAM2 Type: Thickness

Select strata polyline to identify:

Strata Name: SEAM1 Type: Elevation

Select strata polyline to identify: *pick one that is not tagged*

No strata name assigned to polyline.

Select strata polyline to identify:

Pulldown Menu Location: Drillhole

Keyboard Command: strataid

Untag Strata Polylines

This command removes the strata polyline information and returns the selected polylines to the original status: regular polylines.

Prompts

Select strata polylines to have strata tags removed.

Select objects: 1 found

Pulldown menu location: Drillhole

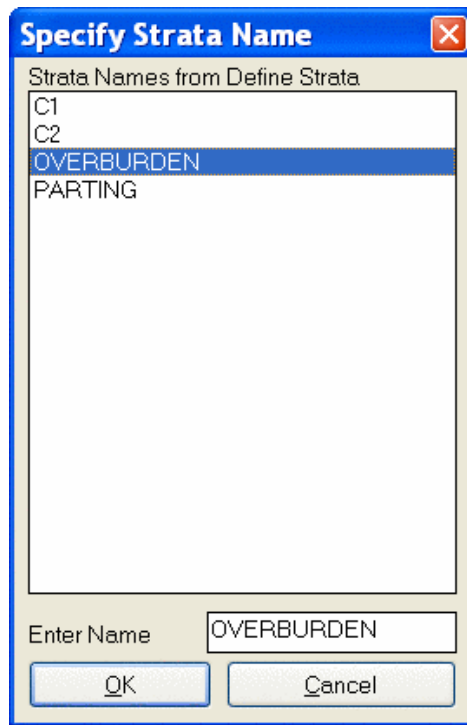

Keyboard command: stratauntag

Prerequisite: Named strata polylines

Name Limit Polylines

This command assigns strata names to identify polylines as inclusion or exclusion areas for the strata. Strata limits are used to model discontinuities such as glacier washout or volcanic strata. Strata that gradually trend to pinch out should not use strata limits. The pinch out should be modeled using just the drillholes. When assigning the names for strata in the Geologic Model file, be sure they are spelled exactly the same here, so they are applied correctly. Also, when using Limit Polylines with bed names in the drillholes, be sure to add the `_TOP`, `_KEY`, `_PARTING`, OR `_BOTTOM` to make sure the limits are applied to each bed interval.

Strata limit polylines are used in the Stratacalc routines to indicate where the strata exists. The inclusion and exclusion polylines are used for trimming the contours in Strata Isopach Maps and used to limit volumes in routines like Surface Mine Reserves. Also in areas outside the strata limits, the strata thickness is set to zero and 10000 is added to the strata elevation. This forces the strata up to clip out to the strata above. Also drillholes that are outside the strata limits are ignored for processing that strata. There is a choice to assign all strata names to the limit lines, or Specific strata. If Specific is chosen, then the following dialog appears.

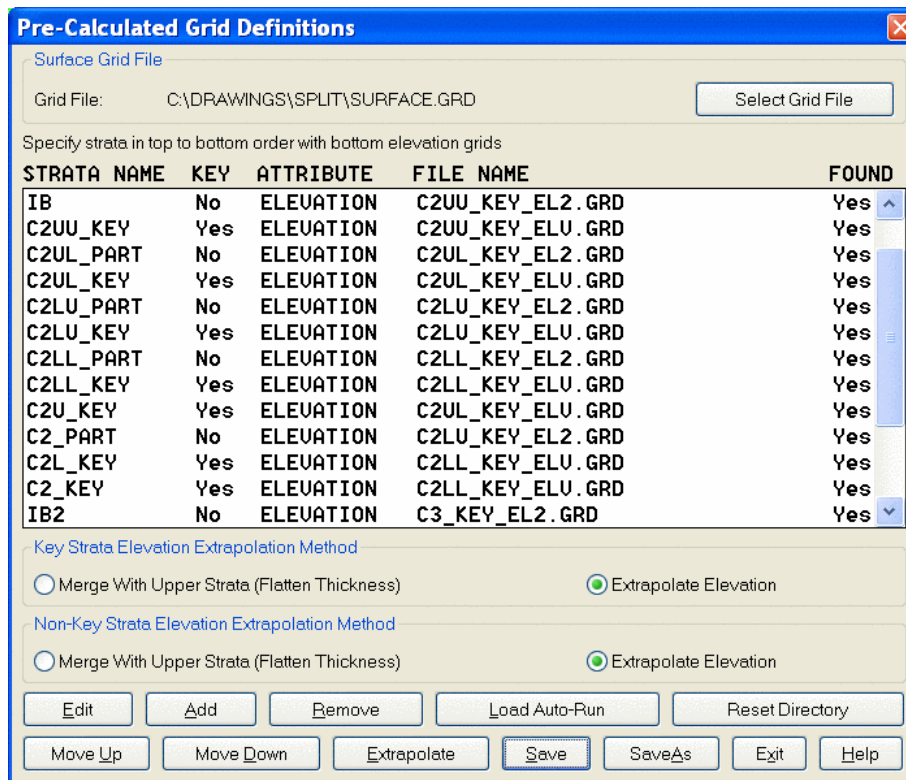

When drawing a Fence Diagram and using Limit Polylines, the strata cutoff occurs exactly at limit the polylines. Shown here is an example of a Fence Diagram, plotted with the plan view for verification. Notice how the limit lines crop the seams in section view precisely at the limit lines. The plan view was placed on top of the fence diagram just with basic AutoCAD drafting tools. Dashed polylines were then drawn with ortho on to illustrate the crops honoring the limit lines exactly. For all StrataCalc routines that use limit polylines, there is a command line message to report when limit polylines are applied.

Another use of Limit Lines is to control the transition from a full seam to where it splits. Limit lines must be drawn for one or both instances. The full seam and the two split seams can both appear in the Geologic Model file for volumes and Fence diagram. An example Geologic Model is shown here. Notice the C2_KEY splits into C2L_KEY

and C2U_KEY. They also split. All of these can exist in the Geologic Model, as long as there are limit lines on screen to control where they appear.

The result is a Fence Diagram as shown here, where the limit lines control where the full seam, and its splits appear.

Prompts

Enter strata name to apply (<All>/Name)? UB for strata UB

Select Inclusion perimeter polylines.

Select objects: *pick a closed polyline*

Select Exclusion perimeter polylines.

Select objects: *press Enter*

Pulldown Menu Location: StrataCalc

Keyboard Command: minelmt

Report Limit Polylines

This command reports all Strata Limit Polylines that are in the drawing. The report contains the layers, area, XY of the polyline endpoints, and whether it is an inclusion or exclusion limit polyline.

Layer	Area SF	Area Acres	Start Y	Start X	Inclusion	Exclusion

Keyboard Command: report_strata_limit

Highlight Limit Polyline

This command simply highlights the named strata limit polylines in the drawing. A regen of the screen will unselect the polylines.

Prompts

Command: highlight_limit_pl

Select the polylines to check. (*select all the polylines of interest*)

Select objects: Specify opposite corner: **10 found, 2 groups, 12 total**

Highlighted 2 Limit Polyline. Skipped 10 other polyline.

Pulldown Menu Location: StrataCalc in Geology

Keyboard Command: highlight_limit_pl

Identify Limit Polyline

This command reports the strata names assigned to a polyline for strata limits. There is the option to select one and view its name, to pick inside and have it identify which lines enclose that point, or to search the drawing and automatically highlight and report all that it finds. If the hatch option is used, then the hatch window appears where the hatch pattern can be selected for each limit polyline.

Prompts

Pick on a polyline, pick inside or search drawing [**<Pick>/Inside/Search**]: *i*

Pick inside limit polyline to identify:

Hatch Current, select Next or Exit [**<Hatch>/Exit**]: *H to hatch*

or

Pick on a polyline, pick inside or search drawing [**<Pick>/Inside/Search**]:

Select mining limit polyline:

Current: Inclusion: C2U C2L IB1

Hatch Current or Exit [**<Hatch>/Exit**]: *e to exit*

Pull-down Menu Location: StrataCalc in Geology

Keyboard Command: minelmtl

UnTag Limit Polylines

This command removes the strata limit assignments from the selected polylines.

Prompts

Select limit polylines to have limit data removed.

Select objects: *pick the limit polylines*

Pull-down Menu Location: StrataCalc

Keyboard Command: rmlimit

Define Washing Curve

Coal washing is accomplished by one of two major processes, by density separation or by froth flotation. This density curve will be applied to all the attributes, and save to a StrataCalc Datasheet STC file, so that the selected float level density of attributes can be gridded and saved in the geologic model. Define Washing Curve is a prerequisite for Apply Wash to define the wash curve for the desired density interval, attributes, and their values. The data is entered here to define the minimum and maximum float levels, the interval for the density. The total mass of the sample is shown in the total material field. All attributes are custom entered based on what is in the sample report. This algorithm assigns each strata/bed interval value to a washing file, saved out as a *.WASH file.

Units	Float	Mass	Inherent	Ash	Volatile	Fixed	Calorific	Total
	Kg/m3	Kg	%(ad)	%(ad)	%(ad)	%(ad)	MJ/kg	%(ad)
Total Material		1.2800	2.2203	34.3625	20.2891	43.1281	19.6049	0.9196
Float 1	1.5000	0.2200	2.5000	15.1000	32.2000	50.2000	27.5000	1.7800
Float 2	1.5500	0.1100	2.2000	23.2000	25.0000	49.6000	24.9000	0.0670
Float 3	1.6000	0.0900	2.2000	26.5000	21.0000	50.3000	22.5600	0.7600
Float 4	1.6500	0.0800	2.3000	28.5000	19.4000	49.8000	20.7700	0.3800
Float 5	1.7000	0.1600	2.4000	32.8000	17.7000	47.1000	20.0100	0.4400
Float 6	1.7500	0.2000	2.3000	38.3000	16.5000	42.9000	17.6100	0.5500
Float 7	1.8000	0.1300	2.1000	42.2000	15.9000	39.8000	16.3500	0.3800
Sink	1.8000	0.2900	1.9000	51.9000	15.5000	30.7000	12.9800	1.5500

The Units are custom defined by the user and can be lbs/ft3 or Kg/m3. The mass can be custom defined to Kg, pounds, or anything the user wants. The Float Density is a specific gravity or relative density. The Sink is the material that is higher than the density, and sinks to the bottom. The attributes in the columns are the values of each, when washed to the density, removing any heavy waste rock.

Data Mode: The Data Mode setting determines the way the weight and attributes are entered for each density. Fractional shows just that percentage for each density, while Cumulative displays the totals increase as the density increases. This must be set to match the source data.

Material Source: Selecting a drillhole graphically is optional, but is useful in going through each drillhole's strata/bed entry and finding the best fit between wash file raw material, and drillhole strata/bed values. Preselecting the drillhole will limit the scope of the best-fit search within that drillhole. If the drill hole is not selected, each strata/bed interval will be checked against every wash file to find the best fit. This is why preselecting the Source Drillhole is an optional input but does give the potential of speeding up the process. The output summary from Apply Wash shows the wash file and drillhole strata/bed match up, and the associated fitting error, a lower number indicates closer match between raw and drillhole values.

Testing Source: These fields are used to identify the Lab Name, ID# and Date of the sample. This is saved in the WASH file for later reporting and review.

Add Float Level: This adds a new row to insert a new density.

Add Attribute: This adds a new column for a new attribute. The name will be incremental, such as "Attribute5".

Edit Attribute Title: This option will rename the newly added attribute to the desired name.

Delete Float: This removes the selected row of the selected density.

Delete Attribute: This removes the selected attribute column.

Clear Data: This option deletes all the rows and columns of float levels and attributes for starting over.

Save/SaveAs/Load: This command creates a *.WASH file that is then used for Apply Wash. Each seam sample is saved as its own wash file. The format is comma delimited and is shown here. This format could also be edited or created in Excel, if the user prefers.

Define Washing Curve Dialog

Drop-Down Menu Location: StrataCalc ->Wash Filter->Define Washing Curve

Keyboard Command: definewash

Apply Wash

This command takes the wash curve files and runs them through the washing process to report the results either at a specified density, or with certain targets defined to calculate the density to wash the product to. These results can be saved as a *.STC Stratacalc file that may then be used with Make Strata Grid or AutoRun Strata Grids to make grids of these washed attribute values, and add them to the geologic model for mine quantities and reserves.

	Target	Active
Min Density	1.510	1.550
Max Density	1.790	1.750
Number of Float Levels	2	5
Number of Files	4	3

Wash File Settings

- **Min / Max Density:** The density range is entered here. Target is what the user wants for low and high, and Active is what is found in the data.
- **Number of Float Levels:** These are the steps or intervals of the density ranges, such as 1.5, 1.55, 1.6, 1.65 etc. There must be at least two float rows, so that a line can be interpreted between the two points on the

graph/curve.

- **Number of Files:** This shows the number of WASH files that were selected and read in. Target shows the actual files that were selected, Active shows the number that contain usable, complete data.
- **Target and Active:** The Target column displays what the user has defined, the Active displays what the program can use, that has complete data.
- **Select:** This button brings up the file selection dialog to select the *.WASH files that were created with Define Washing Curve command. One or multiple files may be selected with CTRL or SHIFT.
- **Missing:** If more than one WASH file is selected, then this Missing button is active. This displays any attributes that are missing from the samples or drillholes. These samples will not be used in the wash analysis, as all attributes must be in all sample points for the proper results. If some attributes are missing, the window appears as follows.

Input Lithology		
	Attribute	Raw Avg
1	ASH CONTENT	28.83
2	CALORIFIC VALUE	21.43
3	INHERENT MOISTURE	1.86
4	TOTAL SULPHUR	.80

Select
Loaded 25

Input Lithology

- **Attribute:** These are the attributes found in the drillhole, stratacalc file, and wash file to be used for the washing results.
- **Raw Average:** This displays the raw average values of all the samples from all the drillholes and lithology intervals.
- **Select:** Even though drillholes were selected at the start of the command, this option allows for adding or reselecting different drillholes for the analysis. The Loaded number refers to the total number of intervals that are used for the analysis, this could be more than the total drillholes.

Wash Density Options

- **Maximize Yield / Fixed:** These two options determine the calculation method. Maximize Yield will require the attribute Targets sections filled out, and the program will calculate and report the density to meet the desired attribute targets. The Fixed Density method will calculate and report the attribute results if the material is to be washed to this specific density.
- **Fixed Wash Density:** This density is what will be washed to with the Fixed option set above.
- **Calculate:** After selecting the density options, and if the targets are filled out for Maximize Yield, then selecting this button will display the results in the bottom sections, and will be ready to report the results.

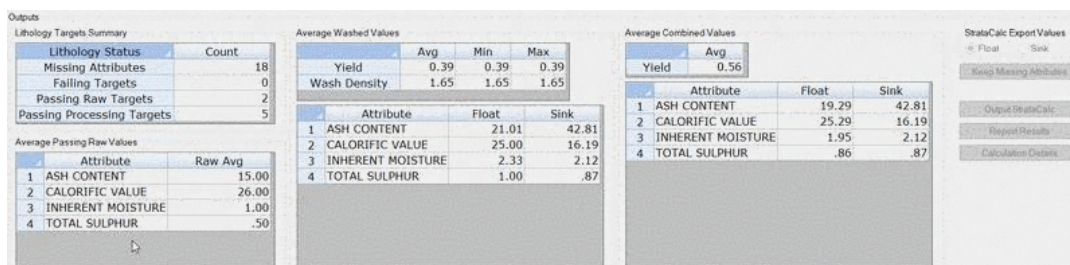

The targets are only used when the Maximize Yield option in the Wash Density Options is used. All three target fields have an Add and Delete Target for the attribute rows. Each target can be saved out as a separate file, with a TRGT file extension.

Raw Targets: The raw targets are first analyzed to see if these conditions are met using the raw material without any washing. If the material passes and meets these targets, then there is no need to wash, and the material is not processed and will be used as is, or raw. The unprocessed material is acceptable and will be used without washing.

Processing Targets - Float Targets: These attribute targets are the quality of material that is desired from the result of washing. Entering the minimum or maximum values of the attributes determines what density the material needs to be washed to for float.

Processing Targets - Sink Targets: This is the target of the sink material, usually waste rock. If the attribute target is used here (not required if targets are set for float), then both the float and sink targets must be met for the material to be washed and pass.

Lithology Targets Summary: The total number in the count should add up to the total number of Loaded Input Lithology samples.

- **Missing Attributes:** Displays the number of samples that were missing at least one of the attributes, so the wash analysis could not be performed on it.
- **Failing Attributes:** Displays the number of samples that failed to meet the attribute targets, so washing was not applied to them.
- **Passing Raw Targets:** Displays the number of samples that met the attribute targets without even needing to be washed.
- **Passing Processing Targets:** Displays the number of samples that did meet the attribute targets and were properly washed and output to the results for modeling.

Average Passing Raw Values: If the Raw material attributes meet and pass the targets, this window displays the average values in raw, unwashed state.

Average Washed Values

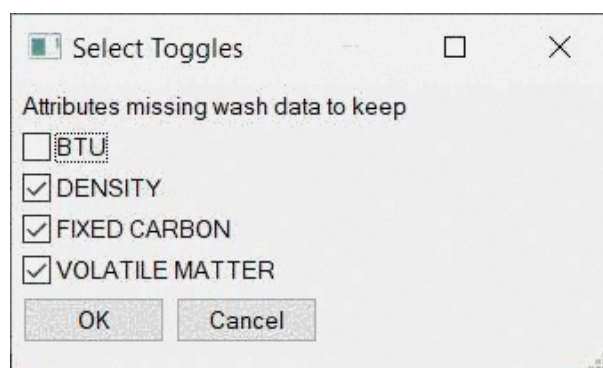

- **Yield:** This displays the percentage of total material meeting and passing the attribute targets when washed to the Wash Density.
- **Wash Density:** This is the density either calculated based on the desired attribute targets, or it is the user entered density to determine the attribute values at that density.
- **Attribute Float / Sink:** These are the average values of all the washed, float and sink material when the material is washed to the specified density meeting the targets.

Average Combined Values

- **Yield:** This reports the total percent yield of both the Raw and Washed (passing Float) of the material.
- **Attribute Float / Sink:** This displays the combined average of both the Raw and Washed (Float) material attributes.

StrataCalc Export Values: This is to select whether to save the attributes out as the Float or Sink values.

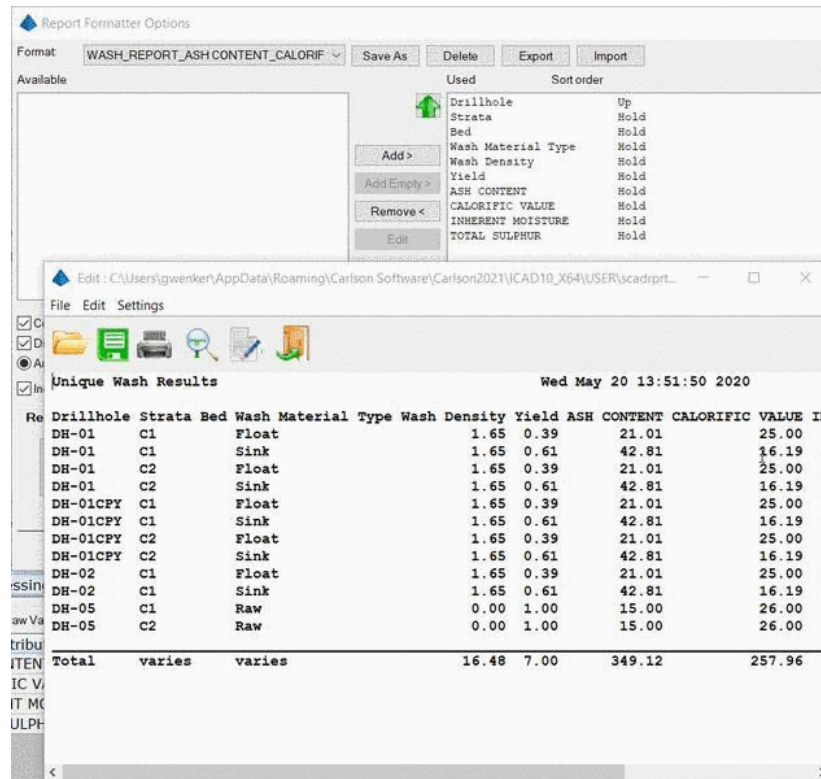

Keep Missing Attributes: Selecting this option gives the option to keep and report any attributes that exist in the drillholes but were not defined or used for any washing analysis. Deselecting any will not include the attribute in the output.

Output StratCalc: In order to make a geologic model of the washed attributes, the values at the selected /

calculated density need to be saved out to a StrataCalc STC file. This file can be viewed and edited with the separate command StrataCalc Datasheet. When the user is prompted to select drillholes or StrataCalc file, this STC file can be the source of the datapoints for the modeling.

Report Results: The Report Formatter will contain the calculated results and allow for custom viewing in many formats such as TXT, HTML or Excel. The washed Float and Sink attribute values for each drillhole, seam and sample point are displayed in the report. The Yield of the Float and Sink totals 1.0. Raw quality values are also included in this report that did not require washing.

Calculation Details: This report shows all the calculation details, attributes used and missing or not used, targets, and the calculations used. This report is a good reference to use as a backup or document the exact washed attribute calculation. Each drillhole and sample interval is listed, including the WASH file that is used for the calculations.

Save Settings/Load Settings: This command creates a *.AWASH file saves all the entered settings for this command.

Prompts

Command: C:APPLYWASH

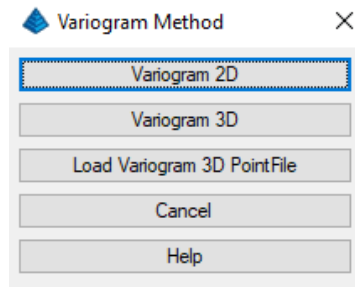

Apply Wash Dialog

Drop-Down Menu Location: StrataCalc ->Wash Filter->Apply Wash

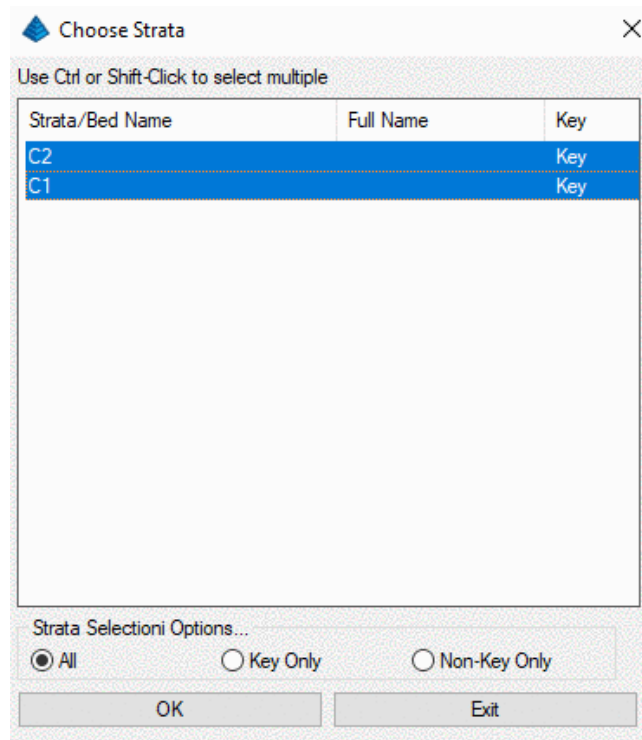

Keyboard Command: applywash

Calculate Variogram

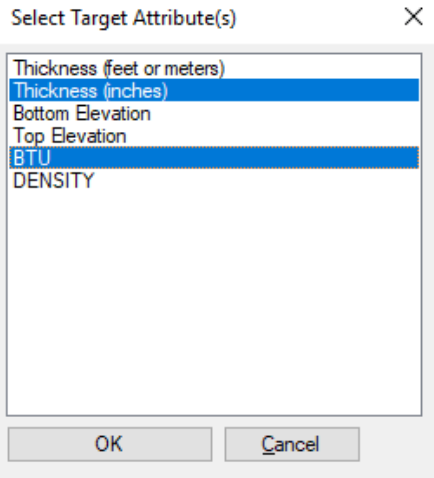

This command takes the selected drillholes and calculates the variogram data, outputting the Nugget, Sill and Range. These parameters are entered into the Carlson Kriging dialogs for gridding and block modeling. Variograms may be 2D or 3D. When the command is first activated, you will be prompted to select the variogram type, as shown below. Selecting Load Variogram3D point file will skip the drillhole, Strata/Bed, and attribute selection steps, and load a "DAT" point file directly and go into the 3D variogram dialogue.

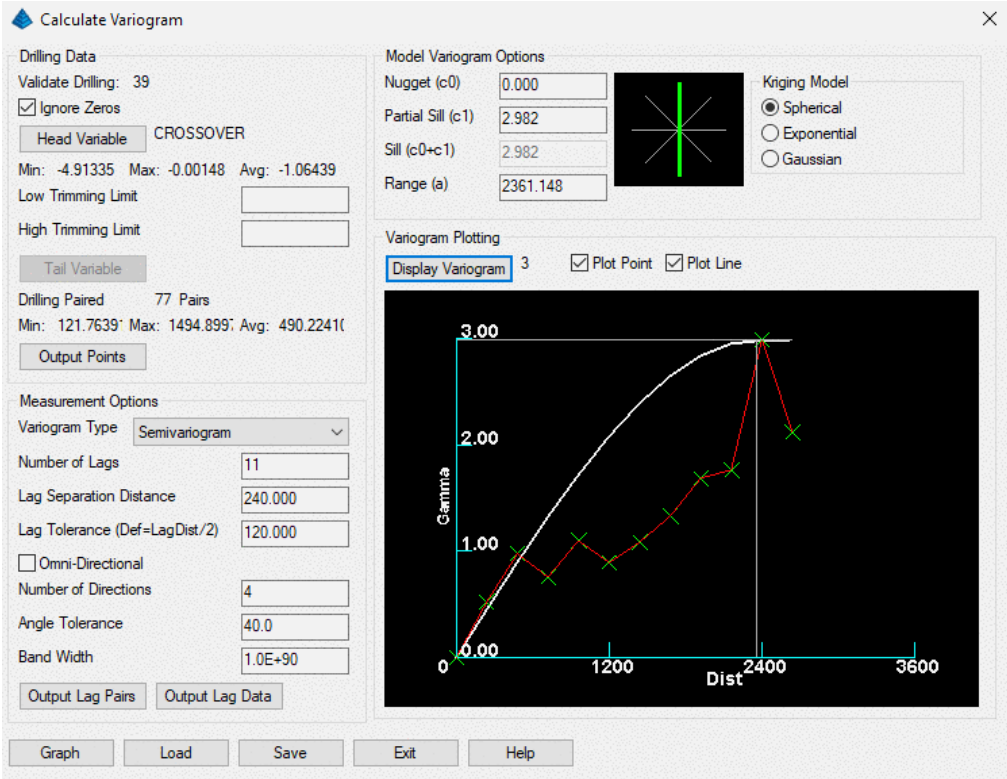

After selecting the variogram type, you will be prompted to select the drillholes, channel samples, and strata polylines to use for variogram calculation. You will then be prompted to select a strata to process, as shown below.

After selecting the strata to process, you will be prompted to select a value or values to process, as shown below.

The 2D variogram window is shown below.

Drilling Data:

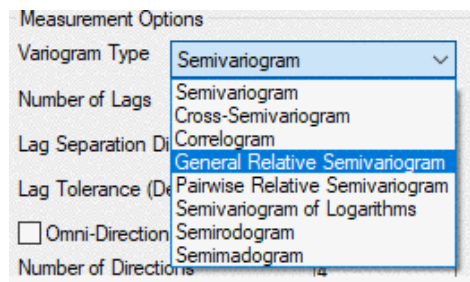

This section covers the base data points and attributes which are being used in the analysis.

- **Head Variable:** Lists the variable that is analyzed.
- **Tail Variable:** Lists secondary the variable that is analyzed for Cross Semivariogram and Correlogram.
- **Ignore Zeros:** Ignores any zero values in the drilling.
- **Validate Drilling:** Lists the number of holes used.
- **Min/Max/Average:** Lists the minimum, maximum and average values of the sample points.
- **Low and High Trimming Limit:** Trimming limits will provide a range selection to process. A value of 0 trimming will delete null values.
- **Drilling Paired Dist.:** This shows the number of found pairs in the drillholes.
- **Min/Max/Avg:** This is the distance between all sampled pairs of drillholes.
- **Output Points:** Outputs a ".csv" file of the points in the analysis for verification and further analysis..

Measurement Options:

This bottom left section of the dialogue covers the several options for the measured variogram

The type of Variogram Type button is a dropdown with the following options.

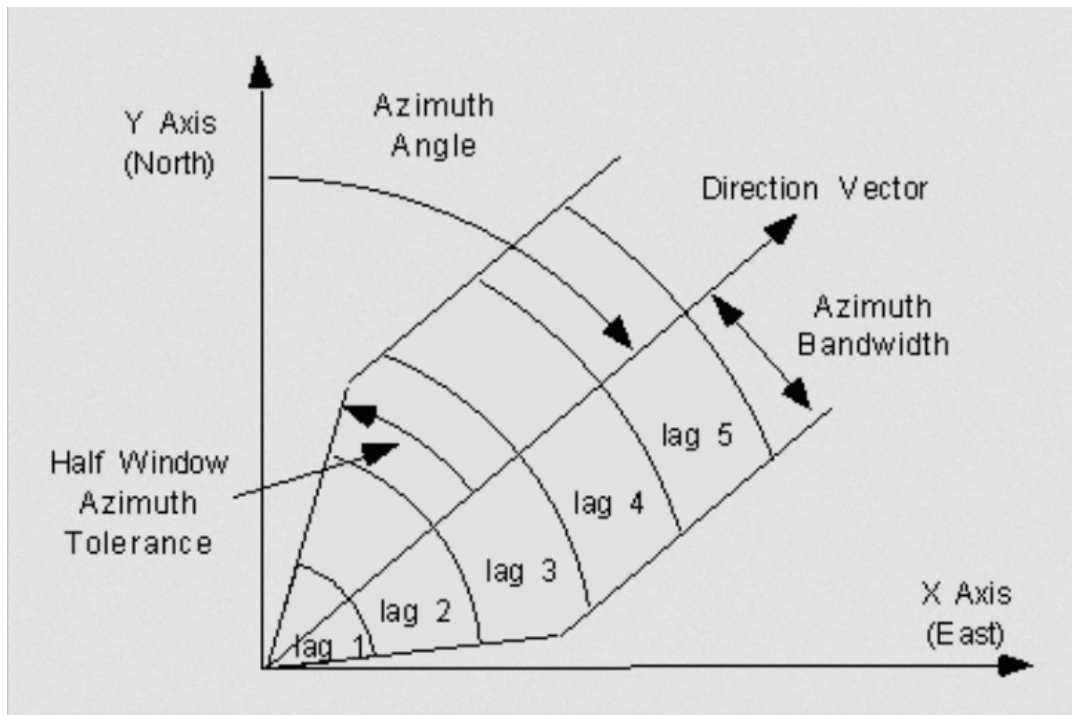

- Semivariogram
- Cross Semivariogram
- Correlogram
- General Relative Semivariogram
- Parwise Relative Semivariogram
- Semivariogram of Logarithms
- Semirodogram
- Seminadogram

The Cross Semivariogram and Correlogram calculate the relationship between two different attribute types and distance. To calculate them a tail variable will have to be selected.

Variogram Measurement Attributes:

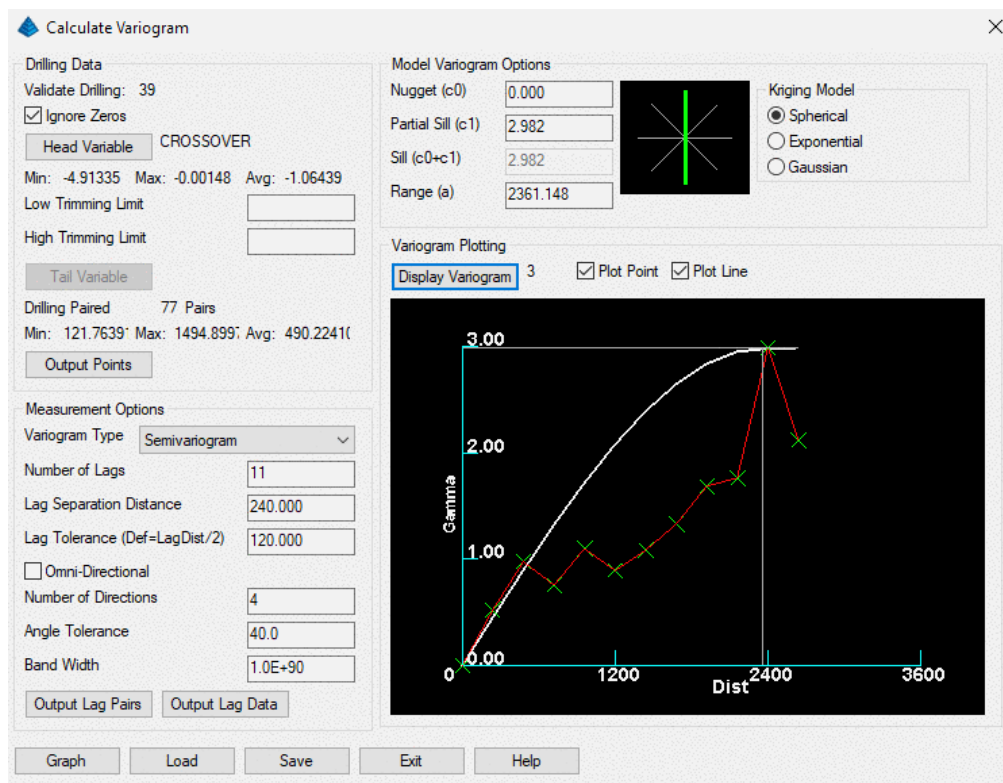

- **Number of Lags:** Set the number of lags, or pairs to model.
- **Lag Separation Distance:** Distance between the pairs. The distance between the lags should be set to the minimum drilling paired distance.
- **Lag Tolerance:** Lag Tolerance is Lag Separation Distance divided by 2.
- **Omni-Directional:** Omni-Directional will look in multiple circular groups for pairs. If it is off, then it will look just directional for the pairs.
- **Number of Directions:** Directions it will look for pairs
- **Angle Tolerance:** angle to stay under for looking for pairs.
- **Band Width:** How wide to look for the pairs.
- **Output Lag Pairs:**
- **Load/Save:** Saves the variogram data as a VIO file that can be loaded later.

Pressing Graph will show the plot as a red line and the points as green X. They can be turned on or off to display in the window. The curve must then be fit to the red line manually with left mouse by double clicking to locate the values.

Fitting:

Omni-Directional: Click Exponential option beside big circle on the right to begin. Left click left mouse and drag on the plot to set Range, Sill and Nugget or enter them in the boxes to update the curve. To move the Nugget, left click on the far left side, at the beginning of the curve.

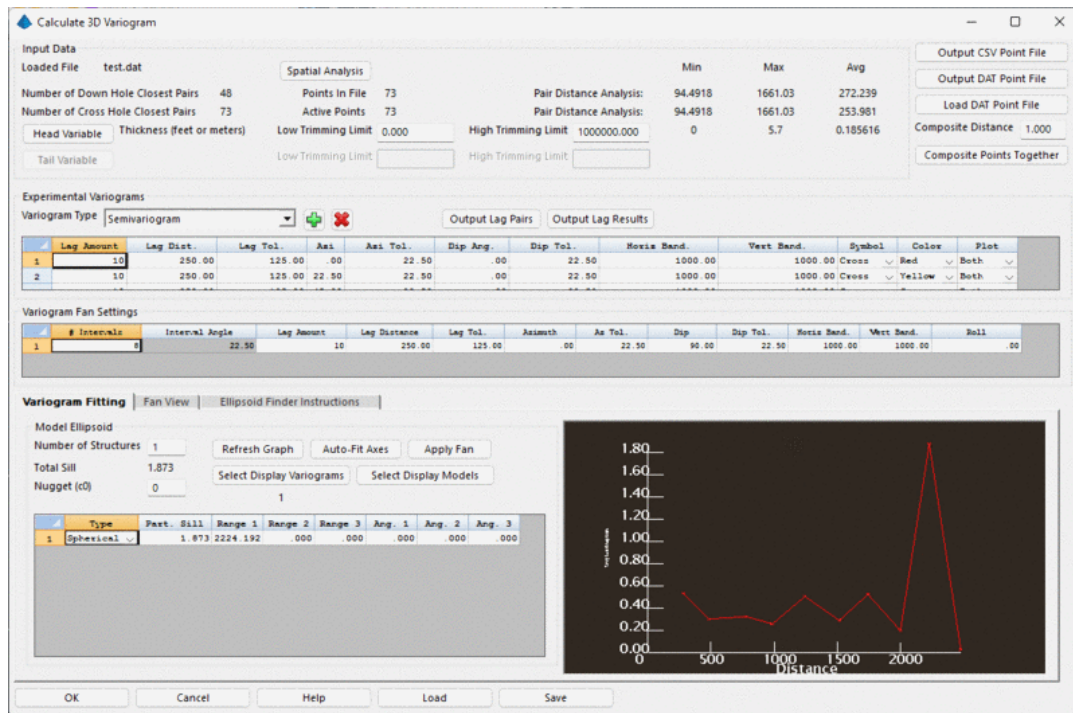

Directional Trend: The variogram plots redraw by clicking on the lines on the large directional window at the top, with the green line, so the 4 angles would be: 0 Azimuth, 135 Azimuth, 90 azimuth and 45 azimuth. The resulting values are displayed above for geostatistical modeling.

The nugget, sill and range are labeled here, for a spherical model:

The 3D variogram is shown below. It calculates a 3D ellipsoid of anisotropy which is used in 3d Kriging by following the steps in "Ellipsoid Finder Instructions Tab".

Input Data:

This section of the dialog deals with the input data, summarizing, and manipulating it.

- **Loaded File:** Informs user the file which has been loaded or whether using the selected data from CAD.
- **Points in File:** The number of data points in the file. Each point does not hold all of the selected attributes.
- **Active Points:** The number of data points which have both the head and tail variable.
- **Closest Pairs:** Gives data on each points closest neighbor. This information helps select the lag distance and decide whether compositing is necessary
- **Spatial Analysis:** This button will scan the sample data and generate summary values which are used to selected values for the Experimental Variogram.
- **Low Trimming Limit:** This value sets the minimum attribute value to consider for the variogram.
- **Maximum Trimming Limit:** This value sets the maximum attribute value to consider for the variogram.
- **Head Variable:** This is the active value for all variogram types, and it can be changed
- **Tail Variable:** This second variable used in Correlogram and Cross Semivariogram analysis

The following items are utility for saving, loading, and manipulating the input data points

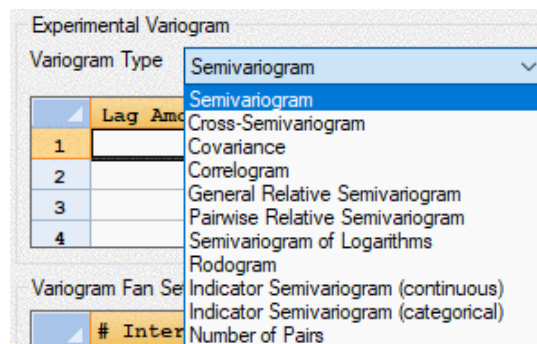

- **Output CSV Point File:** Gives data on each points closest neighbor. This information helps select the lag distance and decide whether compositing is necessary

- **Output DAT Point File:** This button will scan the sample data and generate summary values which are used to selected values for the Experimental Variogram.
- **Load DAT Point File:** This will load a dat file into the model. Useful for saving work from point compositing. Only selected Head and Tail variables will be saved
- **Composite Distance:**The distance which points should be combined together. When compositing points values are averaged together. Compositing is done by selecting "Composite points Together" button.

Experimental Variogram:

This section deals with specifying the settings which to measure directional variograms and how they should be displayed.

- **Variogram Type:** The Variogram types include all of the options of 2D as well as including a plot of the number of pairs. This isn't a variogram type, but instead a shows the number of pairs used to determine the value of each lag, which makes validating data easier.

- **Output Lag Pairs:** This will output a csv file with a list of each lag pair and their associated directional variogram information and the data values.
- **Output Lag Results:** This will output a csv file with the resulting values for each lag bin which can be used to store the results of past experiments.
- **Variogram Table:** Each row represents a measured variogram with controllable direction and direction measurement tolerances. How each variogram is displayed can also be controlled with Symbol, Color, and Plot options.

Variogram Fan Settings:

This section deals with laying out a set of variograms in a plane. The Azimuth and Dip define the first direction of the plane normal and the roll describes the spin of the variogram fan. It is suggested to try apply the fan with Azimuth at 0, Dip at 90, and Roll at 0 and then vary the Roll values to see the changes in experimental variograms.

Model Ellipsoid items deal with fitting a model variogram, and the three directional variograms needed for a 3d Kriging.

Experimental Variograms are not automatically updated for each change in the Variogram Fan Settings. This can allow for custom settings per Experimental Variogram. Select "Apply Fan" to apply to create a set of Experimental Variograms according the the Variogram Fan settings.

The Variogram Fan Settings and Experimental variogram directions are automatically set during the Ellipsoid finder steps, so no further adjustments beyond lag distance settings or direction interval are recommended.

Variogram Fitting:

This section deals with displaying the results of Experimental Variograms and creating the model variograms which are used by 3D Kriging.

The display parameters can refresh for the graph to show adjustments in experimental variogram and adjust which experimental variograms are being displayed.

The Model ellipsoid section deals with setting the values of the modeled variogram and each item is described below

- **Select Display Models:** Specify which or none of the model variograms are being displayed, only Experimental Variograms 1, 2, 3 can be modeled and they are associated with the Major, Minor, and Intermediate Axis of Anisotropy respectively
- **Auto Fit Axes:** This will automatically set the nugget, sill and ranges for all 3 axes according to a single structure model. This uses a max variography point fitting technique, final judgement and adjustment according to statistical judgement is recommended.
- **Number of Structures:** The number of unique variography regions. Each structure is associated with one row of the Model Ellipsoid table
- **Total Sill:** The sum total of each structure's sill and the nugget effect
- **Nugget Effect:** The expected variation at zero distance, a stand in for the inherent variation of the rock mass
- **Range:** The distance at which the model variogram reaches the specified sill value
- **Angle:** These describe the orientation of the Model Ellipsoid. Angle 1 describes the Azimuth, Angle 2 describes the dip, and Angle3 describes the roll. These values do not affect the plot of the model ellipsoid, but the Kriging analysis. It is not suggest to change them once set by the Ellipsoid Finder

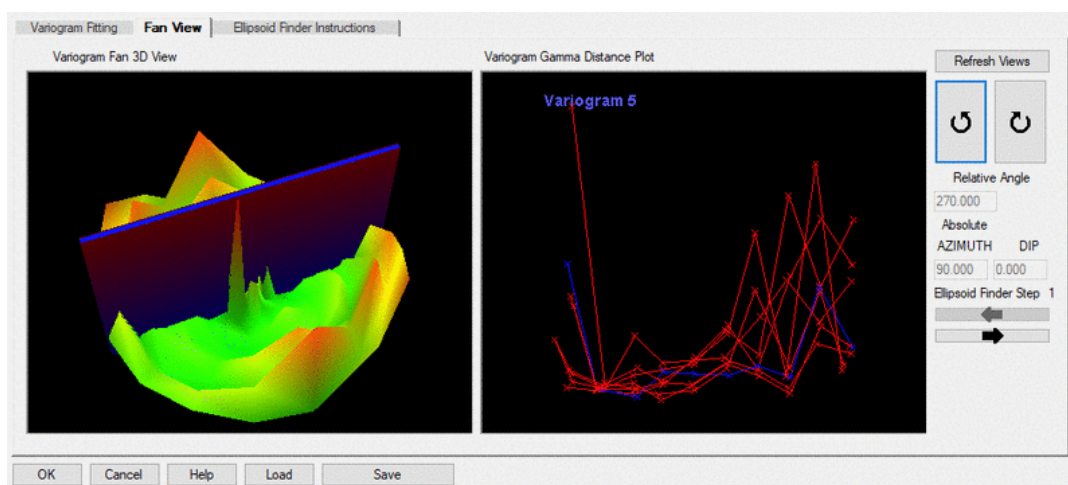

Fan View:

This section deals with visualizing the variography in 3D and 2D plot forms to assist in the selection of minimum or maximum directional variance. Following the steps

Fan View:

This section deals with visualizing the variography and selecting the minimum or maximum directional variance for the Ellipsoid Finder. The Variogram Fan 3D view shows the variography in the z axis, along the variogram fan the X, Y axis. The adjustable plane is the indicator of the selected direction. The "Variogram Gamma Distance Plot" is the same plot which is in Variogram Fitting but with all of the variograms showing. The selected variogram is labeled and shown in blue.

Selecting the rotational arrows switches the target Experimental variogram. Selecting the left right arrows applies the selected variogram direction, updates the Variogram Fan and Experimental Variograms.

Ellipsoid Finder Instructions:

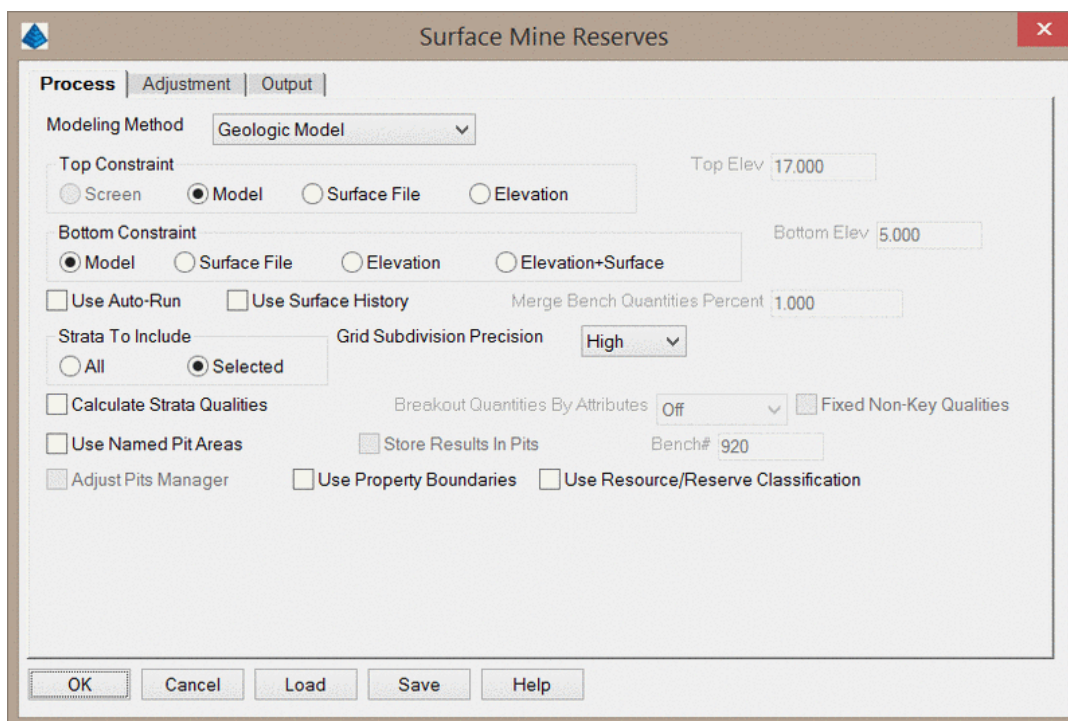

This section gives instructions and tips on calculating the Ellipsoid of Anisotropy. Selecting the left right arrows applies the selected variogram direction. The prompted minimum and maximum directions of variance must be selected in the "Fan View" tab. Once all the directions are found the Sill and Range values must be selected in the "Variogram Fitting" tab. Selecting the "Save" button will save the Modeled ellipsoid of anisotropy and "Load" will bring back previously saved

Pulldown Menu Location: StrataCalc

Keyboard Command: vgramrun

Surface Mine Reserves

This command calculates quantities and qualities directly from drillholes or from predefined Geologic/Mining Models. Additional outputs include stripping ratio contours, composite thickness grids, and more. The dialog is divided into three tabs - Process, Adjustment, and Output - as shown below. It is important to note that if an option is grayed out (not editable) it will not affect the calculations. Some options cannot be used together, and so the unnecessary options will be grayed out to avoid confusion.

Modeling Method: This dropdown menu sets the modeling method to be used for calculations.

The first seven options (Triangulation, Inverse Distance, Kriging, Polynomial, Linear Least Squares, ABOS Method, and Nearest Neighbor) will calculate the reserves from drillholes, strata polylines, and pit/channel samples using the selected modeling method. This option will create grids for calculations, but the grids will not be saved. For more information, see the section of the help manual corresponding to the Make Strata Grids command.

The Block Model option will also calculate the reserves from drillholes, strata polylines, and pit/channel samples by first creating a block model. This block model will not be saved.

The Geologic Model and Mining Model options will calculate the reserves from pre-calculated grid files stored in a .pre or .mmd file. It is highly recommended that you use either a Geologic Model or Mining Model for calculating reserves, as the other options will need to generate grids on-the-fly every time the command is run. Using a Geologic/Mining Model will greatly increase calculation time and reproducibility of the results.

The only difference between a Geologic Model and a Mining Model is the file extension (however, a Mining Model must be based on elevation grids whereas a Geologic Model may be based on elevations or thickness grids). The distinction is made purely for organizational purposes in that the Geologic Model can be used to represent the true geology while the Mining Model can be used to represent the strata as they will be mined. For example, some strata layers may need to be composited in the Mining Model. For more information on creating Geologic/Mining Models, see the sections of the help manual corresponding to the Define Geologic Model, Define Mining Model, and Geologic to Mining Model commands.

Here it is important to note that this command will temporarily extrapolate grid files in the Geologic/Mining Model. This replaces all null values with the nearest known data point. These changes are not saved to the .grd file itself however. When grids are extrapolated, you will receive a notification of which grids were temporarily modified for the calculation. This can increase the amount of time required to complete the calculation, and for this reason, it is recommended that you manually extrapolate grid files using either Grid File Utilities, or the Extrapolate function in Define Geologic Model. When the program automatically extrapolates surface, it will hold the values at the edge of the grid and extrapolate horizontally. An example of a surface file with null values, and the resulting grid that would be temporarily created for this calculation is shown below.

Top Constraint: This option sets the upper limit for the reserve calculation. All calculations will be based on a layering of strata grids. This upper limit will omit any strata information that may exist above it. Four options are available for use:

The Screen option will prompt you for 3D entities (usually elevation contours) to create a grid file. This grid file will not be saved, however.

The Model option will use the surface file specified in the Geologic/Mining Model.

The Surface File option will prompt you for an existing grid or TIN file.

The Elevation option will use a flat elevation as set in the **Top Elev** field.

Bottom Constraint: This option sets the lower limit for the reserve calculation. This lower limit will omit any strata information that may exist below it. Four options are available for use:

The Strata Model option will use the bottom-most elevation grid file specified in the Geologic/Mining Model.

The Surface File option will prompt you for an existing grid or TIN file. This is most commonly used when calculating the reserves within a pit shell.

The Elevation option will use a flat elevation as set in the **Bottom Elev** field.

The Elevation+Surface option will allow you to define both an elevation and a surface file to limit the calculation. For example, you can constraint the calculation with a pit shell surface, but also with a bench elevation.

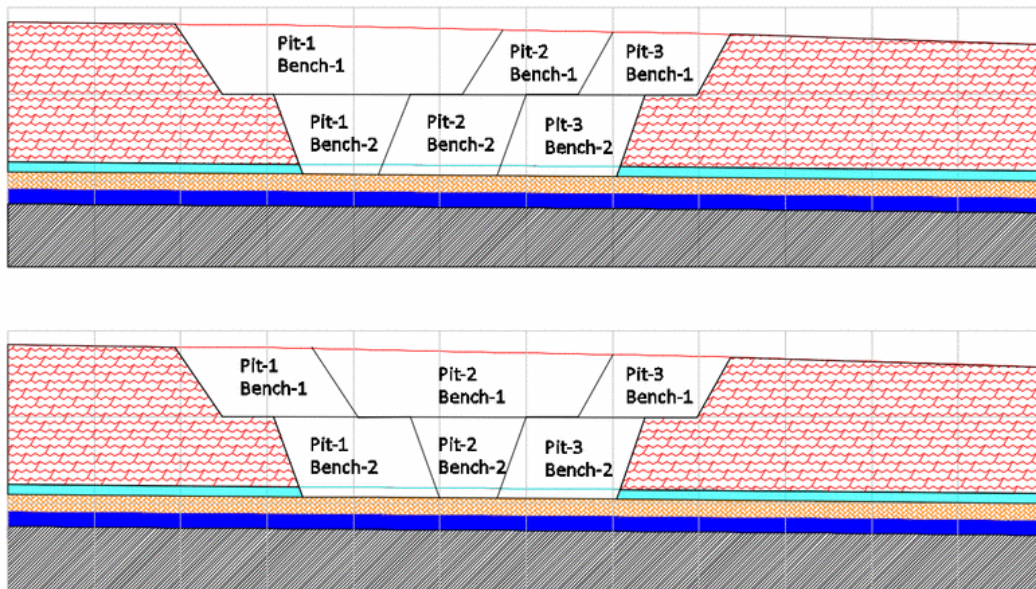

Top Elev and Bottom Elev: These fields will set the elevation limits for the reserve calculation.

Whenever selecting the upper and lower limits of the reserve calculation, it is important to visualize the options you are selecting. The below illustrations show some of the ways that the upper and lower limits can be used to constrain the calculation.

Use Auto-Run: This option will allow you to divide the reserves into benches according to a Surface Mine Reserves Autorun file (.sma file). Dividing reserves into separate benches is useful when using the Store Results in Pits option as it allows for more selective mining with the Surface Equipment Timing command. If this option is not used, results can still be stored in pits, but all data will be stored on a single bench. For more information, see the section of the help manual corresponding to the Define Surface Mine Auto-Run command.

Use Surface History: This option will calculate reserves according to a Surface History file (.gsq file). This file is essentially a list of grid or TIN files and can be created manually or with the Design Bench Pit command. When this option is used, reserves will be divided according to the volumes between the surface files (i.e. the first volume is calculated between the first and second surface file, the second volume is calculated between the second and third surface file, etc.). The below images show an example of how the reserves will be divided into three pits and two benches using a surface history file. The ordering of the surfaces in the Surface History file will have a significant impact on the calculations as it determines the cut angles to be used. For example, the first image shown below cuts out Pit 1 first, whereas the second image cuts out Pit 2 first. For more information on the Surface History file, see the section of the help manual corresponding to the View 3D Surface History command.

Merge Bench Quantities Percent: This option is only available when using a Surface History File. When active, this value is used as a tolerance for reporting volumes. For example, if this value is set to 1%, any volumes less than 1% of the total bench volume will be merged into the previous bench.

Strata to Include: This option determines which strata layers will be calculated for the Report. If the Selected option is chosen, you will be prompted with a dialog for which strata to include. If you are not using the Auto-Run option, the Selected option can be useful for storing specific strata layers onto a bench.

Grid Subdivision Precision: This option controls how grid cells will be subdivided along angled borders for more precise calculations. For the most accurate results, use the High option. Using the Low option will decrease accuracy in exchange for improved calculation time. For grid volume calculations, the program subdivides grid cells that cross a boundary. This setting controls how many times the cell is subdivided. Subdividing more increases the volume accuracy but takes longer. The default for this setting is High. It only makes sense to set it to Low when you're in a hurry and you've got a huge model and a lots of pits. Otherwise, the routine should be fast anyway that you might as well use High and get full precision.

Calculate Strata Qualities: This option controls if strata qualities will be calculated. These are the user defined attributes such as BTU, Ash, Moisture, etc. Non-user defined attributes such as thickness, area, etc. will always be calculated. When qualities are merged for reporting, by default they will be weight averaged according to the strata volume and density. Here it is important to note that the weight averaging of attributes will not account for null values. For example, if Strata A has a Moisture attribute of 0.3, but Strata B does not have a Moisture attribute

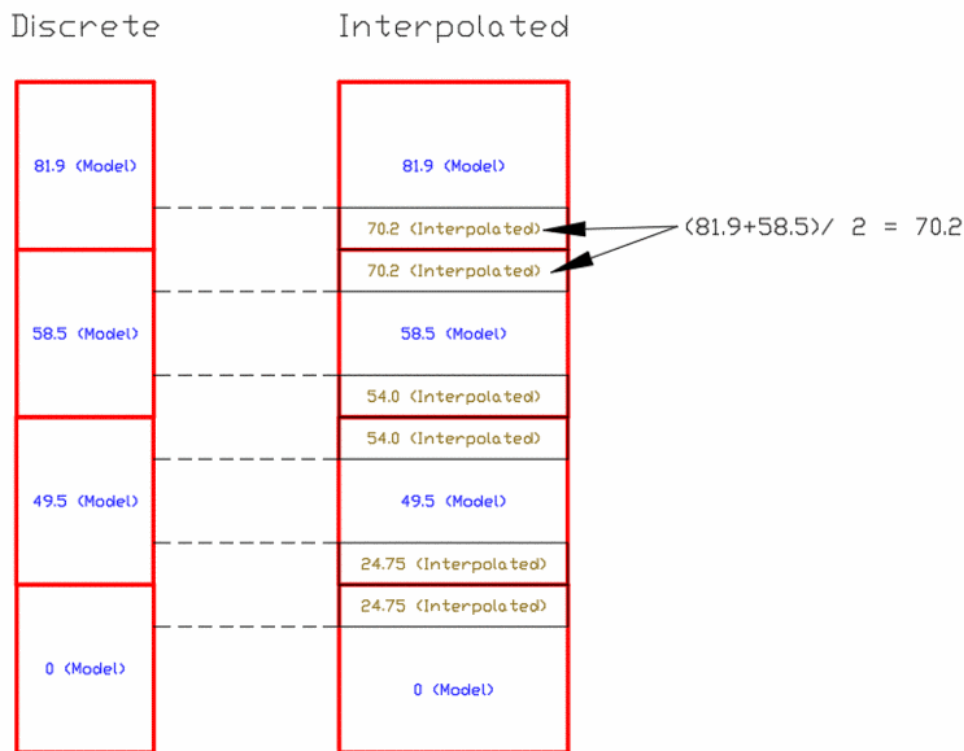

defined, then the combined Moisture content for the two stratum will be 0.3. To properly weight attributes, it is necessary to define an attribute value for each strata. Besides reporting the averaged quality, the program also reports the minimum and maximum quality values. When qualities have not been defined for all strata, you may find the Fixed Non-Key Qualities option useful.

Breakout Quantities by Attributes: This option can only be used when a .blk file is used (either generated on-the-fly from drillholes or when it is stored in a Geologic/Mining Model). When enabled, you will be prompted for a Grade Parameter File (.gpf file) which defines the various grades of the material. This option will report the quantities of material according to this file. For example, if the .gpf file relating to a limestone project defines Grade A material as having 90-100% Calcium, Grade B as having 80-90% Calcium, etc., then the report will calculate the tonnage, volume, and average Calcium content for each grade individually.

The Off option will not breakout quantities by attribute. You will not be prompted for a .gpf file with this option. The Interpolated option will actually interpolate block values between data points, thus allowing for variation of grade within each block.

The Discrete option will treat block values as discrete for the entire block. This prevents any variation of grade within individual blocks.

A comparison of the Discrete and Interpolated options is shown below. Notice that in the Discrete method, each red block is homogeneous. There is no variation of quality within the block. For the interpolated option, however, each red block is subdivided. Half of the block retains the modeled value, while the upper and lower fourth of each block is a calculated average.

Fixed Non-Key Qualities: This option will prompt you to enter a fixed value for each strata attribute found in the drillholes or in the Geologic/Mining Model. These values will be used for all non-key strata. This option is useful for properly weighting attributes due to dilution with non-key material. For example if you have defined an attribute for Sulfur content in your key strata, but not your non-key strata, this option will allow you to quickly assign a Sulfur value to the non-key material for attribute weighting. Using this option for proper attribute weighting is faster than modifying the drillholes or Geologic/Mining Model with these attributes. Here it is important to note that if a non-key strata attribute has been defined in the Geologic/Mining Model, this option will overwrite that value.

Use Named Pit Areas: This option will restrict the calculation to use only closed polylines that have been tagged as pits. Polylines may be tagged as pits using one of the various pit tagging commands in the Surface Mining Module > Boundary Pulldown Menu. These commands include Name Pit Polylines, Assign Pit Names By Layer, Pit by Interior Point, Pit by Interior Text, Pit Matrix Layout, Pit Layout by Advance, Pit Layout by Width, and Pit Layout by Rate. When this option is used, reserves will be split into their respective pits. When this option is not used, you may still use pit polylines (or other, untagged polylines) as inclusion areas, but the reserves will not be divided by pit.

Store Results in Pits: This option is only available when the Use Named Pit Areas option is used. This option will store the total non-key volume, key volume, key tons and all quality attributes in the pit polyline as extended entity data. These quantities and attributes can then be used by the Surface Equipment Timing command. Besides the quantity and attribute values, a Bench number is also stored with the quantities for sequencing each bench. Here it is useful to note that all the material stored on a single bench must be mined together. If two types of material are to be mined separately, they should be placed on separate benches with the Use Auto-Run option or by repeating the Surface Mine Reserves command and incrementing the Bench Number while selecting specific strata.

Rather than storing discrete values in the pits, the non-key volume, key volume, and key tonnage may be stored in the pits as grid files. If the Output Thickness Grids option on the Output tab is used, these three values will be stored in the pits as grids rather than discrete values. Note that you may also store grids in the pits with the Surface Mining Module > Boundary Pulldown Menu > Pit Timing Quantities > Assign Timing Grids command. When this command is run, the grids will overwrite the discrete values.

Bench #: This value will set the bench number for storing results in pit polylines. Note that any reserves calculated will be stored together on this bench number. Note that benches must be integer values - alphanumeric bench numbers are not supported.

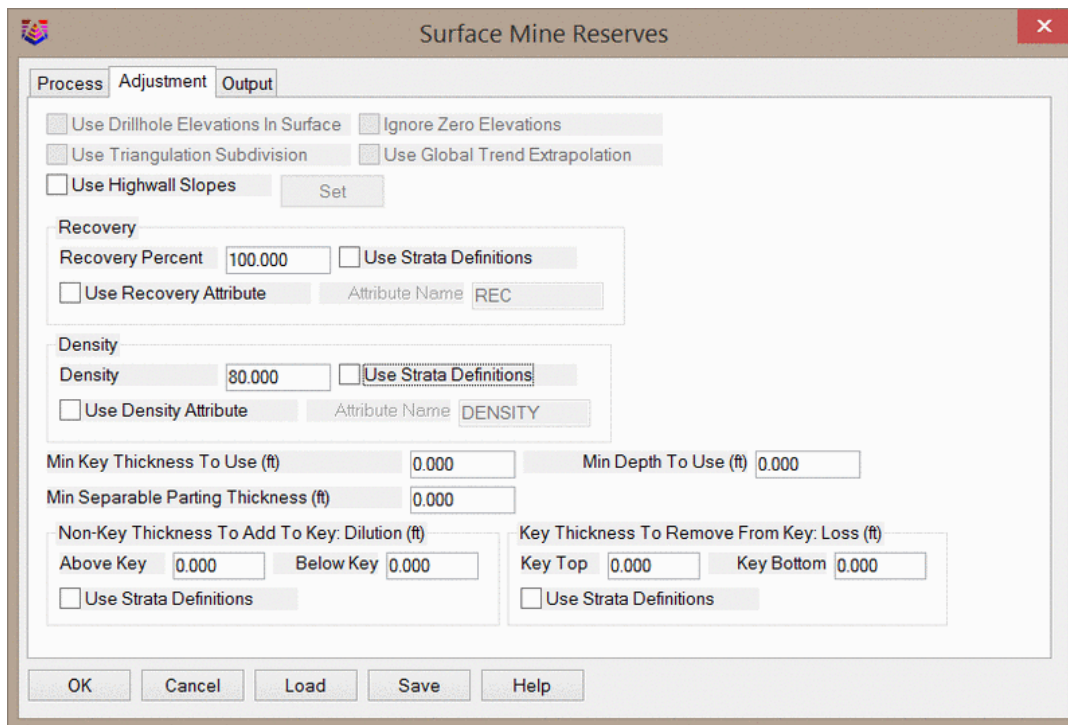

Adjust Pits Manager: This option will allow you to adjust the pit boundaries after the calculation is complete, then reprocess to check the updated results. This can be useful when trying to target a specific volume/tonnage to store in a pit. When this option is enabled, the below Pits Manager dialog will be docked to the bottom of the screen. You can then modify the pit polylines with standard CAD commands (move, grip edit, etc.). Clicking the Process button will then rerun the calculation and display the results. Clicking the Report button will send the results to the Report Formatter. Clicking the Exit button will close the Pits Manager without generating a report.

Process	Pit	Strata	Pit Area S.F.	Total C.Y.	COAL Tons	BTU
Report	Pit 1	C1_TOP	410462.8	1242447.5		
	Pit 1	C1_KEY	410462.8	101102.0	120109.2	12007.713
	Pit 1	C2_TOP	410462.8	325767.2		
	Pit 1	C2_KEY	410462.8	91401.2	108584.6	11492.317
Exit	Pit 2	C1_TOP	233272.6	961928.5		

Use Property Boundaries: This option will divide the reserves according to Property Boundaries, which are closed polylines that have been tagged using the Assign Property Names or Property Names by Text command (available in Surface Mining Module > Boundary Pulldown Menu and Underground Mining Module > Property Pulldown Menu). As long as an inclusion polyline is selected, these property boundaries will be automatically selected when the calculation is performed, even if the property boundaries are on a frozen layer. If an area lies outside of a tagged property boundary, the reported field for Owner will simply say "Unknown" rather than using one of the tagged owner names. It is important to note that "island" property boundaries are supported - for example, if Property A is completely inside of Property B, the program will not double-count the volume/tonnage in Property A.

Use Reserve Classification: This option will divide the reserves according to a Reserve Classification file (.rsv

file) into Measured, Indicated, Inferred, and Hypothetical categories. This file can be generated with the Geology Module > Grids Pulldown Menu > Reserve Classification command. When this option is used, the Report Formatter will include a new attribute called "Reserve Class."

Use Drillhole Elevations in Surface: When calculating the reserves directly from drillholes, this option determines if the drillhole collar elevations will be used to generate the topographic surface.

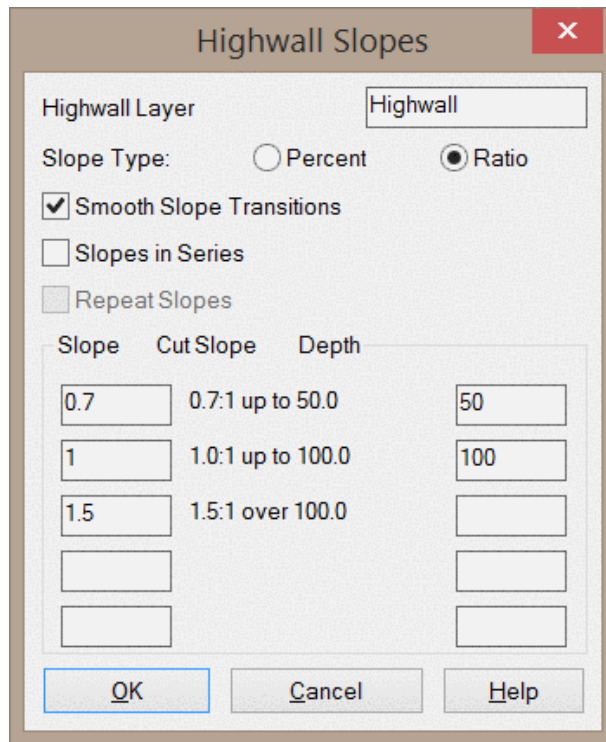

Ignore Zero Elevations: When calculating reserves directly from drillholes, this option will determine if entities at zero elevation will be used to generate the topographic surface. Generally, this option is useful in that it allows you to broadly select entities in the drawing without manually filtering out zero elevation entities.

Use Triangulation Subdivision: This option only applies when using the Triangulation or Polynomial modeling methods to calculate reserves directly from drillholes. When enabled, this option will subdivide triangles to create smoother surfaces.

Use Global Trend Extrapolation: This option only applies when using the Triangulation or Polynomial modeling methods to calculate reserves directly from drillholes. When enabled, this option finds the average slope and direction of the interpolated data and applies this slope to extrapolate to the full extents of the grid.

Use Highwall Slopes: This option will apply highwall slopes to the inclusion polylines to simulate a more realistically shaped pit. This option is limited in that the inclusion polylines selected for reserve calculation must represent the toe of the highwall. This option will project highwalls upwards until it reaches the topography. This option does not account for benches, and so more complex calculations will need to be made using a Surface History File generated from the Design Bench Pit command.

Set (Slopes): This button will open the dialog shown below, which controls the highwall slopes to use.

Highwall Layer: This field sets the layer to use for the highwall linework. This linework will be drawn as a 3D polyline where the highwall projection meets the surface.

Slope Type: This option controls if the highwall slope is expressed as a percent or as a ratio.

Smooth Slope Transitions: This option will gradually transition between slope angles as depth increases around the pit. In the above example, the pit will have an overall slope ratio of 1.0 where the cut depth is between 50 and 100', and a slope ratio of 1.5 for cut depths greater than 100'. In areas where the cut depth is exactly 100', this option will smoothly transition from a slope ratio of 1.0 to 1.5 rather than abruptly changing the slope angle.

Slope in Series: This option will use all slope angles specified in the dialog. Using the above dialog as an example, the cut angle from 0-50 feet (or meters) will always be a 0.7 ratio. After this first 50 feet (or meters) of cut, the slope will be a 1.0 ratio for the next 50 feet (or meters). Any remaining cut will use a 1.5 ratio.

Repeat Slopes: This option will repeat the slopes with specified depths until the projection meets the surface topography. In the above example, the program will repeat cut ratios of 0.7 and 1.0 until it reaches the surface. Since no cut depth has been specified for the 1.5 cut ratio, this slope angle will not be used with this option.

Recovery Percent: This value will set the overall recovery percent for key strata. This is applied after adjustments for non-key dilution and key loss. The volume of material that is not recovered will be reported as non-key material.

Use Strata Definitions: This option will use the recovery percent specified in the current Strata Definition file. This allows you to set a recovery for each strata individually.

Use Recovery Attribute: This option will set the recovery percent according to an attribute defined in the drillholes or in the Geologic/Mining Model. This allows you to use a grid file to set the recovery percent, thus allowing the recovery of each strata to vary.

Attribute Name: This field sets the recovery attribute name to search for in the drillholes or Geologic/Mining Model. This attribute name must exactly match the attribute in the drillholes/model, or else the recovery percent will not be applied.

Density: This value sets the density to use for all strata. Density is always expressed in lbs/ft³ or kg/m³.

Use Strata Definitions: This option will use the density specified in the current Strata Definition file. This allows you to set a density for each strata individually.

Use Density Attribute: This option will set the density according to an attribute in the drillholes or in the Geologic/Mining Model. This allows you to use a grid file to set the density, thus allowing for a varying density within each individual strata.

Attribute Name: This field sets the attribute name to use for density in the drillholes or Geologic/Mining Model. This attribute name must exactly match the attribute in the drillholes/model, or else the density will not be applied.

Min Key Thickness to Use: This value sets a minimum key thickness for reporting. Any areas where the key strata is less thick than this value, the strata will be reported as non-key discard material.

Min Depth to Use: This value sets a minimum depth of cover for key strata for reporting. Any areas of key strata that have less than the specified thickness of cover will be reported as non-key discard material. An example use of this option is accounting for oxidized coal that is (or is close to) outcropping.

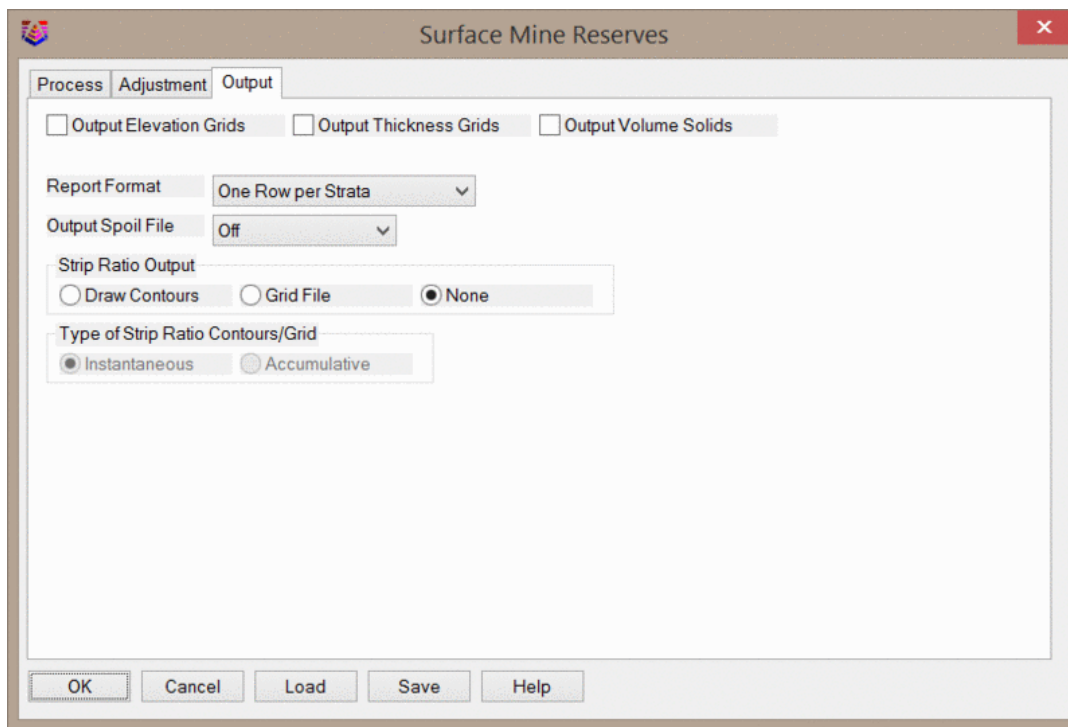

Min Separable Parting Thickness: This value will be used as a tolerance for calculating volume of non-key material between key strata based on thickness. For example, if this value is set to 0.5, any non-key material sandwiched between key strata that is less than 0.5 feet (or meters) thick will be reported as key material. Areas where the non-key strata is greater than 0.5 thick will not be affected.

Non-Key Thickness To Add To Key (Dilution): Above Key/Below Key: These values set the amount of non-key thickness above/below each key strata that will be mined with the key strata. This diluted non-key material will not be mixed with the key strata, but will instead be reported as another key strata layer. The final report, however, can be formatted to account for the dilution of strata qualities. Note that dilution will be accounted for determining the Stripping Ratio in the final report and in grid/contour output.

Use Strata Definitions: This option will use the Dilution values set in the Strata Definition File. This allows you to set the Dilution for each strata individually.

Key Thickness To Remove From Key (Loss): Above Key/Below Key: These values specify the amount of key thickness above/below the key strata that will be subtracted from the key. This amount will be subtracted from the key quantities and reported as non-key material. Note that loss will be accounted for determining the Stripping Ratio in the final report and in grid/contour output.

Use Strata Definitions: This option will use the Loss values set in the Strata Definition File. This allows you to set the Loss for each strata individually.

Output Elevation Grids: This option will create grid files for the bottom elevation of each strata. Each grid will need to be named separately, and so it is recommended to instead use the Strata Grids Autorun to make these grids quickly.

Output Thickness Grids: This option will create composite grid files for the total key thickness, non-key thickness, and key tonnage (expressed in tons/sq ft or tonnes/sq m). Each grid file will need to be named separately. Note that when the option to Store Results in Pits is used, these grids will be referenced in the pit polylines. When this option is used, you will also be prompted to Divide Bench by Thickness. This division will create three more grid files that represent the divided thickness.

Output Volume Solids: This option will create solids of the mined bench according to the pit names. These solids will be automatically saved in a PIT_MODEL folder as .mdl files. This PIT_MODEL folder will be automatically created in the current project folder.

Report Format: This option controls the format of the report.

The One Row per Strata option will report each strata layer on a separate row. This default option is the most commonly used report format.

The All Strata on Same Row option will report all strata layers on a single row. This creates many extra columns for the report, but allows for easier comparison of pit volumes.

The Group Key/Non-Key Pairs option will place overburden strata on the same row as the key strata. This option searches for similar naming in the strata names. For example, the strata COAL_KEY and COAL_OB will be grouped together due to the similarity of the strata names.

Output Spoil File: This option allows you to create a Spoil Source File (.spo file) for use with the Spoil Placement Timing command. This file includes the volume and centroid location of waste material to be placed in spoil piles.

The Off option will not create a Spoil Source File.

The Non-Key Only will only include non-key strata in the Spoil Source File.

The All Strata option will include all strata in the Spoil Source File.

Strip Ratio Output: This option allows you to output stripping ratio as contours or a grid file. The units of stripping ratio will default to (yd³ waste)/(ton key) or (m³ waste)/(tonne key), but different units may be selected in Carlson Configure.

The None option will not output the stripping ratio as contours or a grid file. Note that when this option is used, the stripping ratio will still be calculated in the final report.

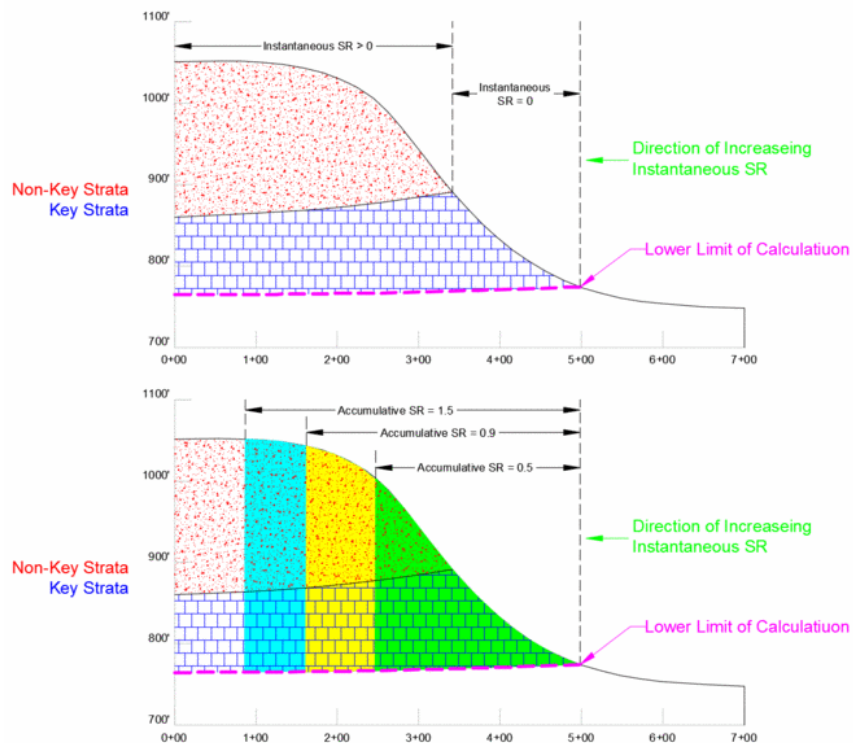

The Draw Contours option will output contour lines of the stripping ratio. This option will use settings similar to those used in the Contour from Grid File command.

The Grid File option will create a grid file that represents the stripping ratio.

Type of Strip Ratio Contours/Grid: This option controls how the stripping ratio is expressed when it is output to contours or a grid file

The Instantaneous option will calculate the stripping ratio for each individual grid node. This stripping ratio will account for all non-key and all key material within the calculation limits - any non-key material existing below the last key strata will also be used for the calculation of the stripping ratio. When the reserves are divided into benches, the stripping ratio will be reported by-bench.

The Accumulative option is intended for use in situations where the key strata outcrops and is relatively flat. The below images illustrate the way this form of stripping ratio is calculated based on direction. The program will first determine the lowest Instantaneous stripping ratio in the calculation area. The program will then determine in which direction the stripping ratio increases the least. If mining were to start in the area of lowest stripping ratio and then move one grid node in the direction of least increasing stripping ratio, the Accumulative stripping ratio would be based on all key and non-key strata between the start point and the next grid node location. In other words, imagine that mining starts at the outcrop of the key material. As mining progresses into the hillside, the accumulative stripping ratio is the overall stripping ratio of all material mined up to the current position.

There are some situations in which a stripping ratio cannot be calculated, as shown in the below illustration.

For areas in which neither waste or key material are included, the stripping ratio will be undefined - if a stripping ratio grid is created, it will be null in this area.

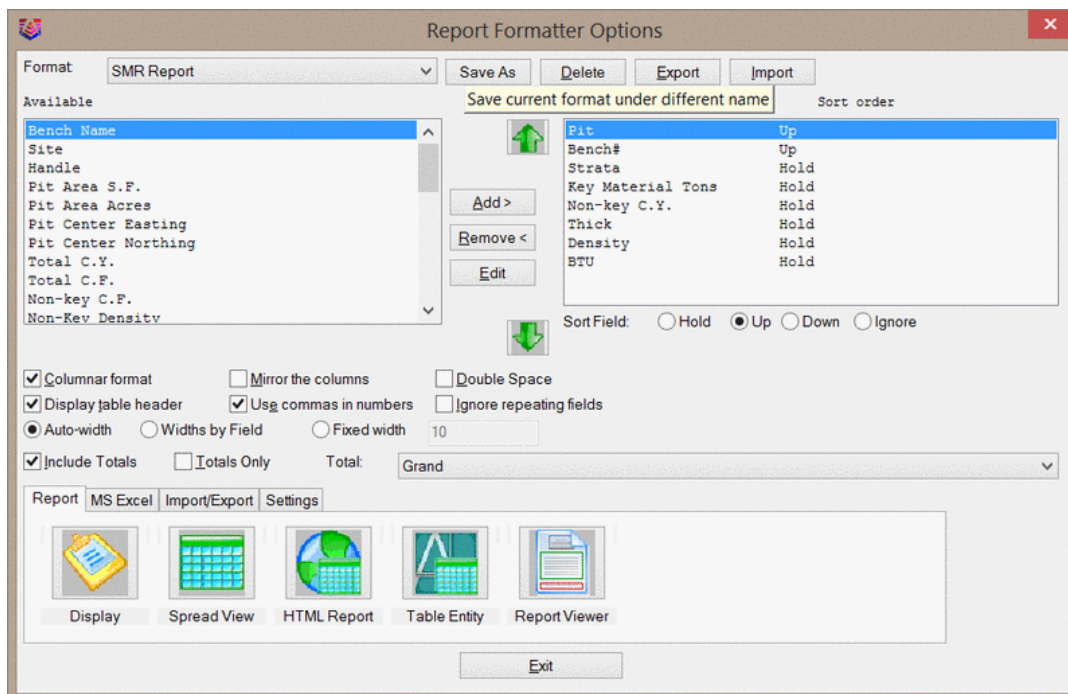

For areas in which only waste material is included, the stripping ratio will also be undefined- if a stripping ratio grid is created, it will be null in this area.

For areas in which no waste material is included, the stripping ratio will be zero.

For areas in which waste material is included, but only a very small portion of key material is included, the stripping ratio can approach an undefined value, which may appear as spikes in the stripping ratio grid file. This is normal for areas with a very small amount of key material. However, the stripping ratio output grid will not exceed a value of 1000. Spikes in the stripping ratio grid can be further filtered with Grid File Utilities.

The Report Formatter displays all information calculated with this command, as shown below. For general information on using the Report Formatter, see the corresponding of the help manual.

Here it is important to note that when a parent seam has been configured to split into two child seams according to the strata definition file, the program will automatically report the splits. For example, if seam A splits into B and C, the program will report tonnage for seam A where it exists as a parent as well as seams B and C where they exist as child seams.

As an additional means of dividing reserves, Cut Sets defined by the GIS Module > GIS Tools Pulldown Menu > Polygon Processor command will be considered when the reserves are calculated. If a Cut Set has been defined for wetland areas with a name of "Wetlands", an additional reporting field will be available in the report format called PP_Wetland. This will show the amount of strata inside the wetland area. Any strata outside the wetland area will be reported separately.

The report formatter will include two forms of stripping ratio: "Strip Ratio" and "Strip Ratio Accumulative". The latter term should not be confused with the Accumulative Stripping Ratio for the stripping ratio grid/contour output. Consider four strata layers: A, B, C, and D where stratum A and C are non-key while stratum B and D are key. When these four stratum are calculated on a single bench, the report will include a "Strip Ratio" and "Strip Ratio Accumulative" for stratum B and D. Both attributes reported for strata B report the stripping ratio as if only strata A and B were mined. The "Strip Ratio" for strata D will report the stripping ratio as if only strata C and D were mined. The "Strip Ratio Accumulative" reported for strata D will report the stripping ratio as if all strata above it were also mined (stratum A and B will be included). The below image is an illustration of this concept.

Miscellaneous note on block models: When the program detects a Geologic Model containing one or more Block Models (.blk files), the thickness of the strata containing the block model will be compared to the thickness of the block model itself. Recall that each strata in a Geologic Model is defined by the difference between two elevation grids (or a thickness grid). Also, a block model will be defined with upper and lower limits (also two elevation grids). If the strata thickness is greater than the block model thickness, the program will extend the block model thickness an extra half-block height on the top and bottom of the model.

Carlson block models will always have top/bottom layers of blocks with half the height of other blocks (for more information on this, see the section of the help manual corresponding to the Make Block Model command). To account for the full block size, surface mine reserves applies the above logic. The idea is that whenever the true strata thickness is thicker than the block model thickness, the extra top/bottom block height needs to be accounted for.

Two types of thickness values can be reported for each strata: Thick Geologic and Thick Mined. Thick Geologic is the full Geologic Thickness, as if no constraints were applied to the model. Thick Mined, however, reports the thickness will all constraints applied (such as a pit shell that only cuts through a portion of the strata). When reporting Pit Volumes, it is recommended to report Thick Mined, as it will reflect the thickness extracted only within the pit shell. It is worth mentioning that when average thickness is calculated, an area-based weight is applied rather than a volume-based weighting.

Two types of areas are included in the report: Area and Pit Area. The Pit Area is the area of the inclusion line used for the report. The Area, however, is not a measurement, but rather a calculation based on the volume and the full Geologic Thickness. The Area is calculated as Volume divided by Thick Geologic.

Define Surface Mine Auto Run

This command is the setup routine to create the autorun file for batch processing of multiple benches with one run of the Surface Mine Reserves command. Without this predefined autorun file, then the Surface Mine Reserves command needs to be run separately for each bench. With this Autorun file, all benches are predefined by the Geologic Model file, a top and bottom Grid or TIN, or an Elevation.

The steps necessary to create or edit the file are detailed below. Choosing Add or Edit will bring up the Edit Auto-Run window. This is where the Bench# is set. The Strata to Process can either be set to one, multiple, or all to define the benches. If coming out of the Geologic Model file, then the elevation grids defined in there will define the benches here. Alternately, the benches can be other grid or TIN surfaces, or flat elevations, and they will be intersected by the seams that appear in the Geologic Model file.

To utilize this Autorun file, turn on the option in the Surface Mine Reserves window for "Use Auto-Run" as circled below. Once this is on, the program will prompt to select the *.SMA file this command created.

Underground Mine Reserves

This command calculates quantities and qualities from drillholes or a predefined Geologic Model. This command is very similar to Surface Mine Reserves, but is simplified for underground application. There are many options for reserve calculation and they are detailed in order of appearance below.

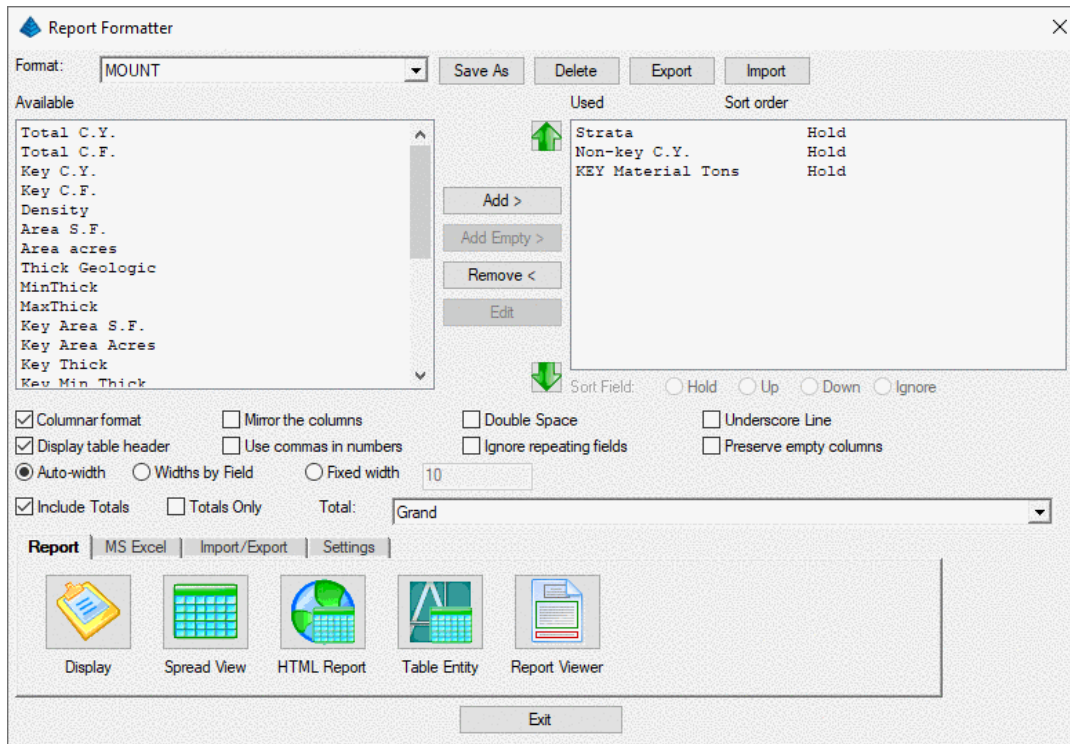

The screenshot shows the 'Underground Mine Reserves' dialog box. The 'Modeling Method' section has 'Triangulation' selected. The 'Recovery Percent' is set to 100.00. The 'Min Key Thickness to Use' and 'Min Separable Parting Thickness' are both set to 0.00. The 'Non-Key Thickness to Add to Key' section has 'Above Key' and 'Below Key' both set to 0.00. The 'Which strata to include ...' section has 'All' selected. The 'Use Attributes' checkbox is checked, and the 'Attribute Name' is set to 'REC'. The 'Specify Names' button is visible next to the 'Use Named Pit Areas' checkbox.

- **Modeling Method:** The reserves can be generated on-the-fly from the selected drillholes or read from stored grid files put into a Geologic Model file. On-the-fly calculation of reserves is generally NOT recommended, as this provides no method of visually inspecting the model for geologic accuracy. Instead, users are encouraged to first create a Geologic Model file and calculate reserves from the model. Nonetheless, on-the-fly calculations can be done for quick checks on estimated volume, but these results should not be reported unless the model has been verified visually with contours, cross sections, and visual inspection of the 3D grid files. Using the Triangulation, Inverse Distance, Kriging, Polynomial, Linear Least Squares, ABOS Method, or Nearest Neighbor option will calculate reserves on-the-fly. Using either the Geologic Model or Mining Model options will calculate reserves from an existing model.
- **Use Triangulation Subdivision:** This option only applies to the modeling methods of Triangulation and Polynomial. It subdivides the triangles to create smoother surfaces and ensure that contours do not cross.
- **Use Global Trend Extrapolation:** This also applies only to Triangulation and Polynomial. This option finds the average slope and direction of the existing data and applies this slope to extrapolating where there is not surface data.
- **Make Thickness Grids:** Turning this option on will create thickness grids of the selected or all strata. It will prompt to create an overburden thickness grid, a key thickness grid and a key tons grid (tons/sq ft. or m).
- **Output Grids for Each Strata:** Turning this option on will create grid files for the bottom of each strata found in the drillholes. However, it is recommended that strata grids are instead made with the Strata Grids Autorun command for easier review and repeat-ability of the grids.

- **Report Areas On One Row:** This option puts all the strata quantities and qualities for each inclusion polyline on one row. This format is best suited for only a few strata and for printing landscape on a page. If it is not selected, then each strata will appear on a separate row.
- **Use Property Boundaries:** Property boundaries can be used to break up the reserve by owner and property. The commands for laying out property boundaries are in the Boundary menu. Essentially, property boundaries are closed polylines with owner and property ID names. The property polylines do not need to be clipped with the calculation inclusion perimeter or pit polylines. The program will internally clip the properties with the calculation areas and report the amounts by property within each pit area. If a pit or inclusion polyline is not covered by a property, the property name used for these quantities is "unknown". When this option is enabled, the program will automatically detect the property boundaries.
- **Calculate Strata Qualities:** This toggle will report the average qualities for strata attributes such as BTU and sulfur. Otherwise the program skips calculating qualities to save time. Besides reporting the qualities for each strata individually, the program can also report the total averaged qualities. By default, the qualities are weight averaged by tons which are calculated by using the strata volume and density.
- **Recovery Percent:** This window defines the percentage of Key strata volume that was recovered in mining and to include in the volume and strip ratio reporting. The non-recovered key strata is added to the NonKey volume. The recovery percent in the Reserves dialog applies to all the Key strata. These values should be entered as percentages rather than decimals (e.g. "100" for total recovery as opposed to "1").
- **Use Strata Definitions (for Recovery):** When enabled, this option will check the current Strata Definition file for recovery values rather than using a constant recovery value for all key strata.
- **Use Attribute (for Recovery):** Another When enabled, this option will check the Geologic Model (or drillholes) for a recovery attribute grid. This allows the program to vary the recovery by area and strata rather than simply applying a constant value to the entire area. When enabled, the **Attribute Name** will need to perfectly match the recovery attribute found in the Geologic Model or the Drillholes (if the attribute in the model/drillholes is "REC", enter the exact same name in this text box).
- **Min Key Thickness To Use:** This option adds key strata to the nonkey strata above, in areas that have thickness less than the specified minimum thickness. Also areas with thickness less than the minimum are not counted in the reported strata area.
- **Min Separable Parting Thickness:** This setting will add the non-key parting quantities with the key quantities when the non-key parting thickness is less than the specified amount. For example, if the Min Separable Parting is set to 0.5, then a non-key strata between two key strata would be combined with the key in areas where the non-key thickness is less than 0.5 feet. In areas where the thickness is greater than 0.5, the non-key quantities are not adjusted. Combining the non-key quantities to the key will add to the total key tons and affect the strip ratio. If the non-key strata has qualities (i.e. ASH, Sulfur), then these non-key qualities will be composited by nonkey tons with the key tons for the portion of non-key that is less than the minimum parting. This will dilute the key qualities.
- **Non-Key Thickness To Add To Key: Above Key/Below Key:** These fields allow you to specify the amount of non-key thickness above and/or below the key strata that will be combined with the key (roof and floor dilution) This amount will be taken from the non-key quantities and added to the key. Similar to the Min Separable Parting Thickness, the non-key quantities will increase the total key tons which affects the strip ratio and key volume mined. Also any non-key strata qualities will be combined by thickness, weighted by NonKey density, and added to the key which dilutes the key qualities. For example, if you estimate that 0.25 feet on average of the overburden is taken with the coal, then you could set the Non-Key to Add to Key for Above to 0.25.
- **Which Strata To Include...:** This determines what will be calculated for the reserve. If All is chosen, then all strata in the drillholes or Geologic Model file will be calculated and reported. If Selected is chosen, then the next window to appear is where one or multiple strata can be selected. This can be used for multiple reserve runs, selecting different strata to represent each bench.

- **Use Named Pit Areas:** The area for calculating quantities defaults to the limits of the selected surface entities and drillholes if no inclusion perimeters are selected. To control the calculation area, multiple closed polylines for areas to include and/or exclude can be selected. An unnamed pit polyline will limit the area of calculations. Also, areas can be labeled with site and pit names (i.e. Site 1, Pits 101, 102, ...). Surface Mine Reserves will then calculate the strip ratios and volumes for each site and pit area. To use site and pit names, there are several commands for creating named pit polylines in the Boundary menu of Underground Mining. If this is selected, then it will look just for named pit polylines, ignoring anything else. The Specify Names button will name the polylines from inside this command if they are not already named using commands found under Boundary.

The Report Formatter Options dialog is the final step of the Underground Reserves routine. It is documented elsewhere in the manual for more details on its operation.

Blending Weighted Average

This command calculates the weighted average for qualities resulting from mixing different materials together. The names of the qualities are user-defined. Up to four weighted qualities can be calculated at once. The quality names are specified in the first row of boxes. For each type of ore to include in the mix, fill out the row as shown below including the name, tons and value for each quality. The name is used in the report. The weighted average is based on the tons of each value. The report is presented in the standard report viewer which can print, file or draw the report.

Name	Tons	Quality 1	Quality 2	Quality 3	Quality 4
North Pit	500000	10000	5	4.1	29.5
South Pit	300000	8500	2.4	8	32.5
East Pit	600000	9000	4	7	31
West Pit	100000	11000	2	3.8	29

Name	Total Tons	BTU	Sulfur	Ash	Moisture
North Pi	500000.00	10000.00	5.00	4.10	29.50
South Pi	300000.00	8500.00	2.40	8.00	32.50
East Pit	600000.00	9000.00	4.00	7.00	31.00
West Pit	100000.00	11000.00	2.00	3.80	29.00
Weighted Average:		9366.67	3.88	6.02	30.67

Calculate Residuals

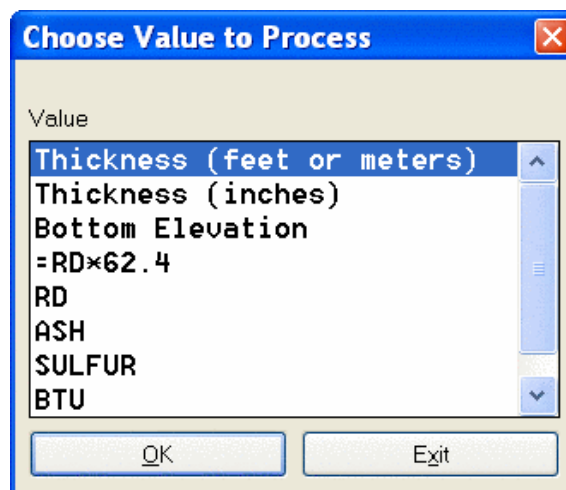

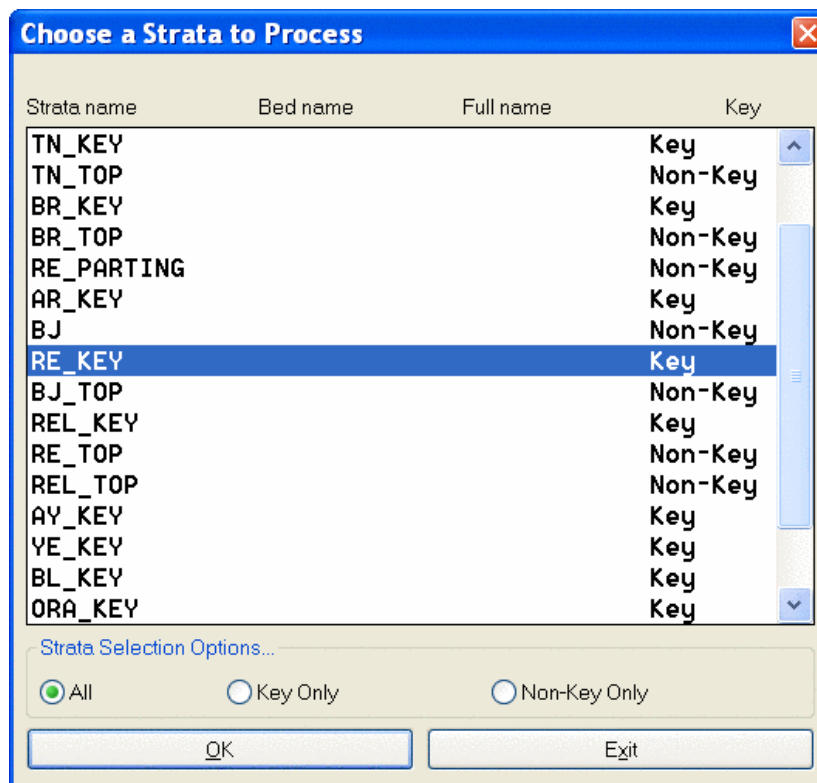

This command measures the accuracy of the strata grid model based on the residual at each drillhole data point. The residual is calculated by removing the data point and then comparing the grid model calculation at the point with the actual value. Residuals for any strata data value such as thickness, elevation or BTU can be calculated using any modeling method including triangulation, polynomial, Kriging, least squares and inverse distance.

Consider calculating residuals for thickness with five drillholes. For each drillhole, the drillhole is temporarily removed from the model and the thickness calculated at the drillhole position. For example, one drillhole could have a thickness of 5.0. When this drillhole is removed and the four remaining drillhole using inverse distance calculate the thickness at this point, the modeled value could be 5.25. The difference of 0.25 between the actual value 5.0 and the modeled value 5.25, is the residual.

The first dialog to appear contains some settings on the residual analysis.

- **Ignore Zero Data Values:** This will ignore any values of 0 that are found in the drillhole. They could be thickness, elevation or any quality attributes. Sometimes they should not be ignored, depending on what is being modeled.
- **Use Report Formatter:** Turn this option on to see the report with the Report Formatter. If it is off, then the standard report viewer is used.
- **Calculate Histogram:** The Histogram is a statistical graph of the distribution of a dataset. It shows the number of data samples within a series of value ranges.
- **Number of Histogram Bins:** The user can set the number of bins for the graph. For example, if a dataset of sulfur has values from 1.0 to 4.0 and the user asks for 3 bins, then the histogram will show the number of samples between 1.0 to 2.0, between 2.0 to 3.0 and between 3.0 to 4.0.
- **Mark Outliers:** The Mark Outliers option highlights data points that are more than 2 standard deviations from the data set average. This can be useful for flagging possible problem data points.
- **Mark Layer:** This is the layer of the circle mark drawn around the outlier drillholes.
- **Mark Size:** This is the size of the mark, or circle drawn around the outlier drillholes.

For triangulation and polynomial, the residual is not calculated for some points because removing these points shrinks the triangulation area and the point may fall outside the area. Also you need more than three points to calculate residuals with triangulation and polynomial methods.

AutoRun Residuals

This command automates running the Calculate Residuals command. For this command, you set up a list of strata names, values and modeling methods. Then all these methods can be run at the same time and the results displayed in a formatted report.

When the command is first executed, you will be prompted to select the drillholes, channel samples, and strata polylines that will be used for modeling. The above dialog will then appear.

Summary Report Only: Creates a simplified report rather than including the details on the residual that is calculated for each data point.

Use Report Formatter: Sends the report to the Report Formatter rather than using the predefined text format.

Calculate Histogram: Categorizes the residual values into histogram bins. The bins may be automatically set with the **Auto Bin Size** and **Number of Histogram Bins** options, or you may set an absolute **Bin Size**

Edit: Edits an existing entry in the list.

Add: Adds a new entry to the list.

Remove: Removes an entry from the list.

Clear: Removes all entries from the list.

Add Row: Adds a blank row to the list

Sort: Sort the list in alphabetical order by Strata Name.

Move Up/Down: Moves the selected entry up/down in the list

On/Off: Changes the Processing status of the entry. When turned off, the entry will not be calculated.

Calc Residuals: Calculates the residuals for each entry in the list, creating the final report.

Column Options: Allows you to toggle the visibility of each column in the main dialog.

When a new entry is added to the list, the below dialog will appear.

OK Cancel Help

The settings found in this dialog are very similar to those found in the Strata Grids Autorun command, and are not discussed in depth here. The **Output Residual Grid File** option will create a grid file from the residual values. This provides a visual means of inspecting the residual values rather than only viewing a text report. Note that when the residual grid is made, the Triangulation method will be used to connect the residual values. After picking the settings for the modeling method, you may click **OK** to add the entry to the list.

An example of the final report is shown below. Often, the most meaningful value is the Absolute Value Residual Average. A lower value indicates that the modeling method was able to very accurately predict the value in an unknown area, whereas a higher value indicates a less accurate modeling method. This is only one means of determining the applicability of the modeling method however. Some modeling methods may not be able to use all of the available data for calculating the residual value, which should be considered when picking a modeling method. The contours of the modeled surfaces should also be considered to ensure correct results. Every data set is different, and there is no universal "best" modeling method or settings that can be blindly applied to any data set.

Fence Diagram

Fence Diagram produces a profile of the surface and strata along the selected baseline polyline—a geological cross-section. Fence diagrams are a good way to verify that the geological model is correct—especially when the drillholes are plotted on them with Draw Geologic Column command. The first step is to draw a baseline polyline in plan view from which the fence diagram is created. This polyline can have more than two points. There are three tabs on this dialog, detailed below.

Fence Type: This option determines if the fence will be drawn in 2D at a user-specified location, or in 3D in real world coordinates.

Source: This option determines the source of the fence.

The *Intersection* method builds a model on-the-fly by triangulating the drillholes and then finding the intersection of the triangulation mesh and the fence polyline. In order to obtain data for the strata with the intersection method, the polyline must have at least one drillhole on each side. It is the only way to see a fault in a fence diagram when using the drillholes.

The *Grids from Drillholes* option builds a model on-the-fly. When this option is used, you will be prompted to select drillholes to build the model, as well as your modeling parameters. This option is only recommended for quick inspection of how the model will appear, but it is not generally recommended as some geologic modeling options cannot be applied with this method, such as accounting for faults.

The *Geologic/Mining Model* option is the most common method, as it pulls the geologic information from an existing Geologic or Mining model file (.pre or .mmd). This is the recommended method for drawing most fence diagrams.

Max Drillhole Offset: This option is only available when the Source is set to the *Grids from Drillholes* option. This value sets a search radius for drillholes. Any drillholes further than this distance from the polyline will not be used for building the geologic model.

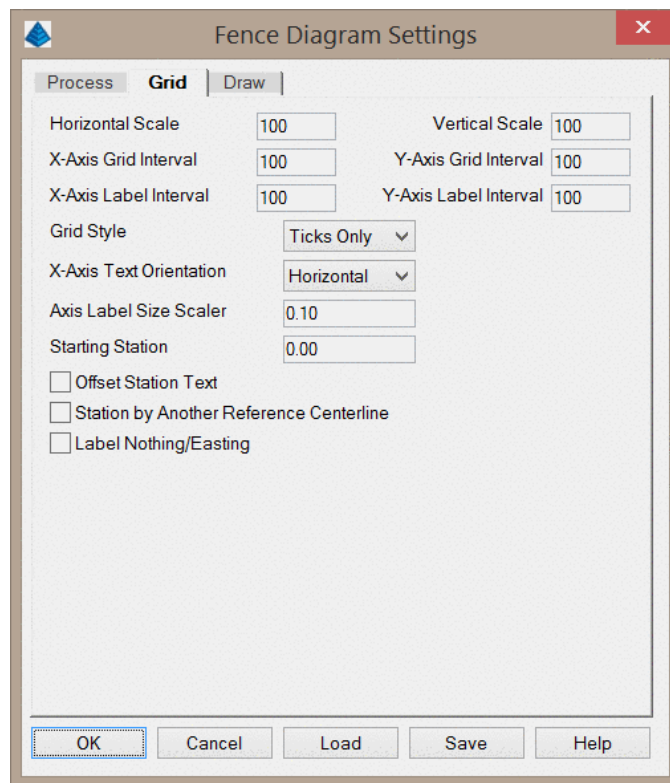

Ignore Zero Elevations: This option is only available when the Source is set to the *Grids from Drillholes* option. When creating a surface topo for the model, this option will disregard any entities at zero elevation.

Process Multiple Fence Polylines: This option allows you to draw multiple fence diagrams at the same time. Instead of picking a single fence alignment polyline, you can select multiple polylines that have been tagged using the Tag Fence Polylines command. Each of the fence diagrams will be labeled accordingly.

Vertical Spacer Between Diagrams: This value controls the spacing between fence diagrams when more than one are drawn at a time. This value is multiplied by the Horizontal Scale and the Fence Label Text Size Scaler to determine the true drawing distance between the diagrams.

Fence Label Text Size Scaler: This value controls the size of the fence labels when drawing more than one at a time (that is, the labels identifying Fence 1, Fence 2, etc.). This value multiplied by the Horizontal Scale sets the actual text size for the labels.

Sort Order: This option determines if the fences will be stacked upwards or downwards when more than one are drawn at a time.

Horizontal Scale: This value sets the overall drawing scale that many other options in the dialog reference for scaling. This allows you to quickly change the size the geologic columns with a single value.

Vertical Scale: This value, relative to the Horizontal Scale, determines the vertical exaggeration. For example, a Horizontal Scale of 50 and a Vertical Scale of 10 will produce a 5X vertical exaggeration.

X/Y-Axis Grid Interval: This value sets the grid line spacing for the X and Y axes. For example, a Y-Axis Grid Interval of 25 will draw a tick/grid line every 25 ft/m of elevation change.

X/Y-Axis Label Interval: This value sets the text intervals for the X and Y axes. For example, a Y-Axis Label Interval of 100 will draw an elevation/depth label every 100 ft/m of elevation change.

Grid Style: This option controls how the grid will be drawn.

The *Grid Lines* option will draw a true grid with lines spanning the appropriate axes.

The *Ticks Only* option will draw the grid axes, but instead of full lines spanning the axes, small tick marks will be placed along each axis.

X-Axis Text Orientation: This option controls the rotation of the stationing labels on the X-axis.

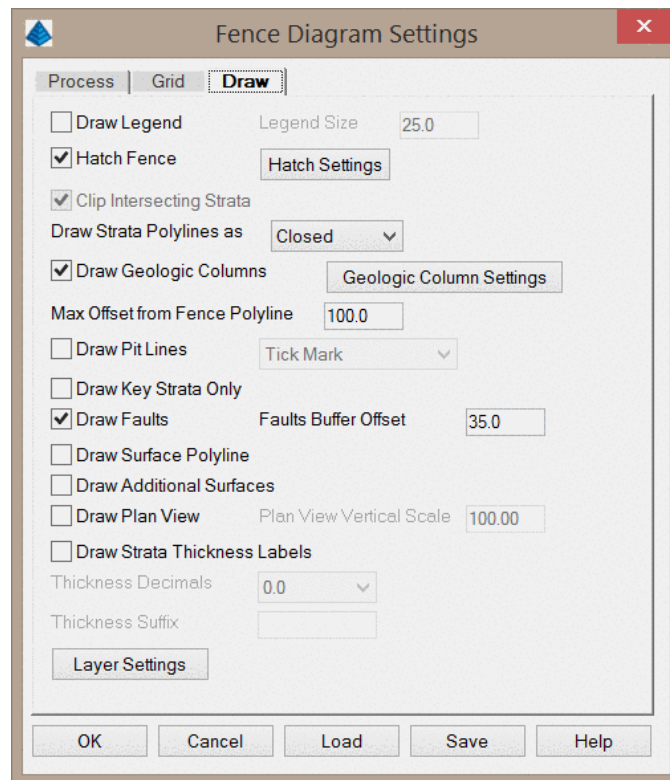

Axis Label Size Scaler: This value, relative to the Horizontal Scale, determines the text height of the elevation/depth/stationing labels. For example, an Axis Text Size Scaler of 0.15 and a Horizontal Scale of 100 will produce text labels with a height of 15 drawing units.

Starting Station: This is the station that is labeled at the beginning of the fence diagram horizontal X-axis grid. By default it is set to 0.

Offset Station Text: Offsets the station labels below the horizontal axis of the grid.

Station By Another Reference Centerline: This option will station the horizontal X-axis by a predefined centerline CL file. The centerline file will be prompted for after clicking OK.

Label Northing/Easting: This option labels the Northing and Easting coordinates along the bottom of the fence diagram at every vertex on the fence line that is drawn in plan view. An example is shown below.

Group Entities: This option creates a CAD Group from all the entities created by Fence Diagram. Then you can select the single group to get all the entities which makes commands like Move easier to move the fence diagram in the drawing.

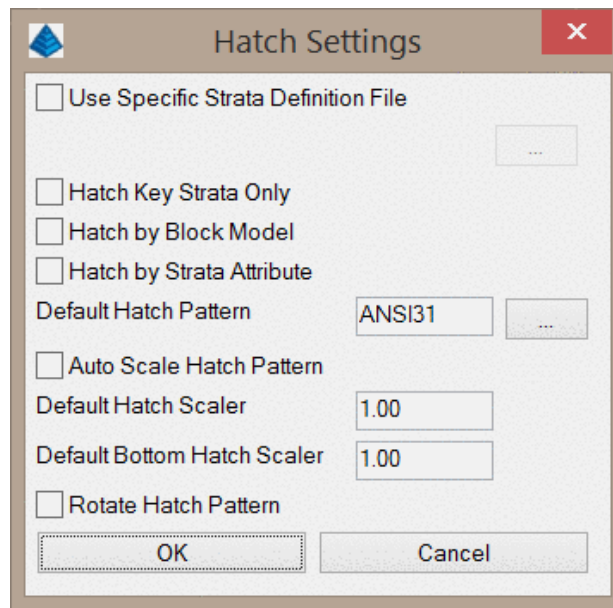

Draw Legend: This option draws a legend of the strata hatch patterns and colors. You will be prompted to pick the location for the legend after clicking OK.

Legend Size: This values sets the size of the legend.

Hatch Fence: This option will hatch in the strata layers in the fence. If this option is disabled, only polylines will be drawn. The strata hatch patterns are defined in the Define Strata command. If a strata exists that is not defined, it

will use a default hatch pattern.

Hatch Settings: This button will display the below dialog.

Use Specific Strata Definition File: This option will draw the strata hatch patterns using a strata definition file other than the current strata definition file. When enabled, you can select the strata definition file by clicking the ellipsis button.

Hatch Key Strata Only: This option will just hatch Key strata that are drawn. The Non-Key strata will be left as polylines with no hatch inside. Shown here is an example that has just the Key strata hatched.

Hatch by Block Model: This option will hatch the seams using a Grade Parameter File. This option requires a block model to be stored in the Geologic Model to define the quality of the strata. An example is shown below.

Hatch by Strata Attribute: This option is similar to Hatch by Block Model, except there is no Grade Parameter File required. It will look at the quality attributes found in the Geologic Model, or in the drillholes, and bring up a list. You will be able to select an attribute to hatch by, and then a color palette will appear, allowing you to specify the colors and ranges for the quality zones. This will just change the hatch horizontally across the strata, not vertically as the Block Model does. Shown below is an example of coal seams colored by BTU.

Default Hatch Pattern: This option sets the hatch pattern for strata layers that are not defined in the Strata Definition file.

Auto Scale Hatch Pattern: This option will auto fit the hatching inside the strata perimeters.

Default Hatch Scaler: This value sets the hatch pattern scale for default hatch patterns. The scale of the hatch pattern will equal this value multiplied by the Horizontal Scale.

Bottom Hatch Scaler: This value sets the hatch pattern scale for the portion of the fence diagram below the last strata layer. The scale of the hatch pattern will equal this value multiplied by the Horizontal Scale.

Rotate Hatch Pattern: This option rotates hatch patterns to best fit the angle of the strata. A hatch pattern can have only one rotation, so rotating will not be effective for a strata with multiple rotations. Rather than use this automated

method for setting the hatch rotation, the rotation for each hatch can also be set in the Strata Definition file.

Clip Intersecting Strata: This option will automatically clip strata layers that cross one another, with the upper grids clipping out the lower grids. This will display the strata layers as they will be interpreted for volume calculations. If this option is disabled, the strata layers will not clip one another. The below image shows two strata layers that clip one another. Note that this option cannot be used when hatch patterns are used.

Draw Strata Polylines as: This option determines if the strata layers are drawn as closed polylines, or as single, open polylines. It is recommended to use the *Single* option when drawing cross sections for use with the Range Diagram commands in the Surface Mining module.

Draw Geologic Columns: This option will draw the drillholes on the Fence Diagram. When this option is enabled, you can click the Geologic Column Settings button to show settings associated with drawing the drillholes. These are the same settings included in the Draw Geologic Column command.

Max Offset from Fence Polyline: This option sets the search distance from the fence alignment polyline. Any drillholes beyond this distance will not be drawn on the fence diagram.

Draw Pit Lines: When this option is enabled, the program will prompt you to select pit polylines. These pit polylines will be labeled with a vertical line and labeled along the bottom of the fence diagram grid at the position where the fence plan view polyline crosses the pit polylines. This option is useful for dragline design commands such as Cut and Place. The dropdown list to the right of this option controls if the vertical line is set to a fixed height (Tick Mark option), or if the vertical line extends from the grid bottom to the bottom strata (To Bottom Strata option).

Draw Key Strata Only: This option will only draw the Key strata on the fence diagram. The Non-Key intervals found in between the Key will be drawn, but not be labeled individually.

Draw Faults: This option will draw the fault line in the location and at the angle that it crosses the cross section. Although grid files may be modeled with a fault, this option ensures that the representation of the fault is sharp. The below image shows a fence diagram without this option (above) and with this option (below). The program uses the **Faults Buffer Offset** value to clip the strata. The fault line will be offset by this amount and the strata within the offset will be redrawn to remove the noise of the grid behavior near the fault. It is recommended to set the Faults Buffer Offset value to be at least 1.5 times the strata grid cell size.

Draw Surface Polyline: This option will draw a new polyline along the surface of the fence diagram. This is particularly helpful for show the true surface topography when there are outcrops, as this new polyline is guaranteed to run along the full length of the cross section. This is necessary for the Range Diagram commands found in the surface Mining module.

Draw Additional Surfaces: This setting will allow you to show additional surface files on the cross section that are not part of the geologic model. A prime example is the water table, which may traverse multiple strata types. When this option is used, you will be prompted to select the surfaces to draw after clicking OK.

Draw Plan View: This option will graph the drillhole locations above the fence diagram. For this graph, each drillhole is projected onto the baseline polyline to find the station and offset of the drillhole. This option is available when the Fence Diagram Source is set to Grids From Drillholes.

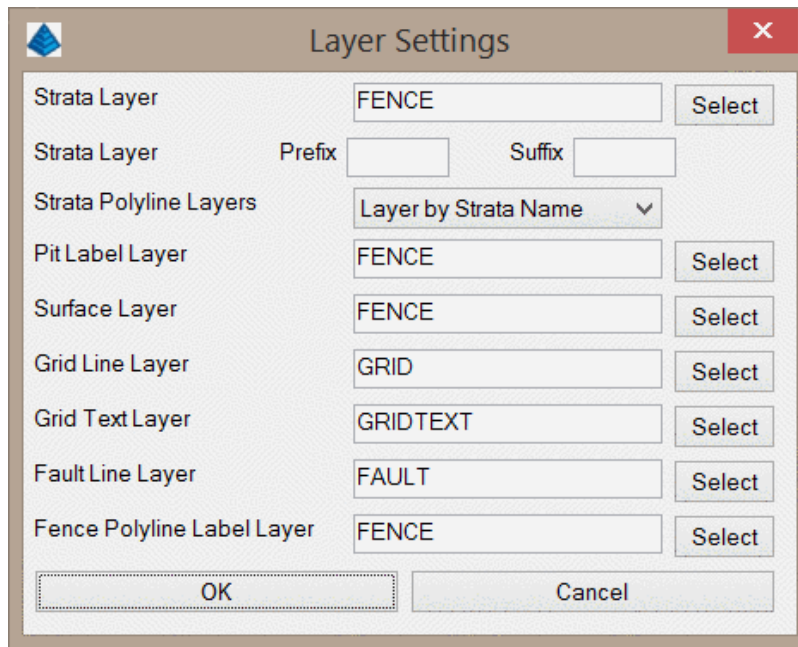

Plan View Vertical Scale: This value sets the scale factor for the Plan View drawn above the fence diagram.

Label Strata Thickness: This option adds a label for the strata thickness along the fence. When this option is used you may specify the number of decimals to display with the **Thickness Decimals** dropdown list, and you may also add a suffix to the labels with the **Thickness Suffix** text box.

Layer Settings: This button displays the below dialog to set the layers for the different portions of the dia-

gram.

The image shows a 'Layer Settings' dialog box with a title bar containing a blue diamond icon and a red close button. The dialog contains several rows of settings, each with a label, a text input field, and a 'Select' button. The settings are: 'Strata Layer' (FENCE), 'Strata Layer Prefix' (empty) and 'Suffix' (empty), 'Strata Polyline Layers' (Layer by Strata Name), 'Pit Label Layer' (FENCE), 'Surface Layer' (FENCE), 'Grid Line Layer' (GRID), 'Grid Text Layer' (GRIDTEXT), 'Fault Line Layer' (FAULT), and 'Fence Polyline Label Layer' (FENCE). At the bottom are 'OK' and 'Cancel' buttons.

Setting	Value	Action
Strata Layer	FENCE	Select
Strata Layer Prefix		
Strata Layer Suffix		
Strata Polyline Layers	Layer by Strata Name	
Pit Label Layer	FENCE	Select
Surface Layer	FENCE	Select
Grid Line Layer	GRID	Select
Grid Text Layer	GRIDTEXT	Select
Fault Line Layer	FAULT	Select
Fence Polyline Label Layer	FENCE	Select

Strata Layer: This value sets the layer the area of the diagram below the last strata layer (the portion of the cross section that has not been modeled as part of the geology). You may also set a **Prefix** and **Suffix** for this layer name.

Strata Polyline Layers: This option controls the layering for the strata polylines.

The *Layer by Strata Name* option will put each strata on a separate layer as defined in the strata definition file. If a strata definition file is not used, the layer for each strata will simply be the name of the strata.

The *All on Same Layer* option will put all strata polylines on the same layer, defined by the **Strata Layer** option.

The *Non-Key on Same Layer* option will place all of the Non-key strata on the same layer, while the Key strata will be placed on their own layers.

Hatch Block Model Layers: This settings allows adding the grade name to the hatch layer as a prefix or suffix.

Pit Label Layer: This option controls the layer for the Pit Labels that are drawn as a result of the **Draw Pit Lines** option.

Surface Layer: This option controls the layer of the surface polyline that is drawn as a result of the **Draw Surface Polyline** option.

Grid Line/Text Layer: These options control the layers of the grid lines and grid labels.

Fault Line Layer: This option controls the layer of the fault polyline drawn as a result of the **Draw Faults** option.

Additional Surface Layer: This option sets the for any additional surface polylines when the Draw Additional Surfaces option is used from the Draw tab.

Fence Polyline Label Layer: This option controls the layer of the labels for the fence name when multiple

fences are drawn at once (e.g. Fence 1, Fence 2, etc.)

Prompts

Reading drillholes ...

Choose modeling method (<Triangulation>/Inverse dist/Kriging/Polynomial/LeastSq)? *Press Enter*

Bottom elevation of grid <1600.00>: *press Enter to accept default*

Top elevation of grid <2000.00>: *press Enter to accept default*

Pick the lower left corner for the fence diagram: *pick a point in a clear area of the drawing*

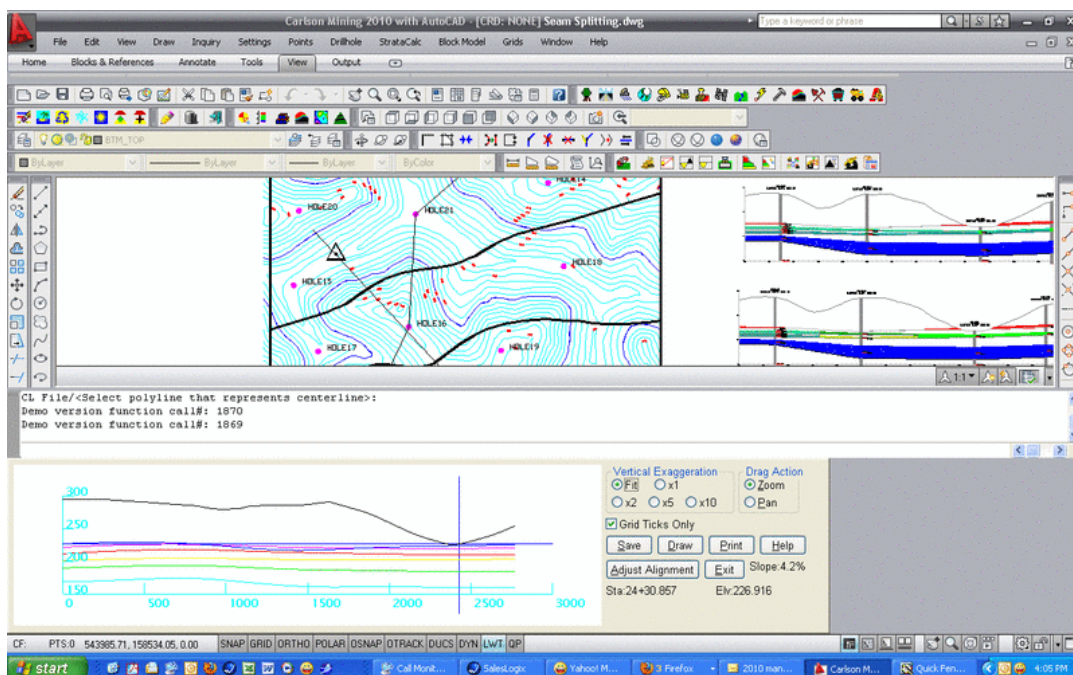

Pulldown Menu Location: StrataCalc

Keyboard Command: fence

Prerequisite: Drillholes or Geologic Model, and a fence alignment polyline

Quick Fence

Quick Fence is very similar to Quick Profile, in that an instant profile appears at the bottom of the screen, displaying the surfaces. This fence alignment can be set by picking points, selecting a centerline file, or selecting a polyline from the screen. A triangle appears in the plan view as the cross hairs are moved along the fence diagram below. This displays where along the fence line the cross hairs are. The slope of the surface, the station and elevation appear dynamically below the buttons. The Adjust Alignment function allows you to drag a horizontal alignment point and update the fence diagram in real-time for quick and efficient grid model verification. It is important to note that this command can only be used with Elevation-based geologic model files. Thickness-based geologic models cannot be used.

- **Vertical Exaggeration:** This usually starts at "Fit" to size the fence diagram into the window. The other

exaggerators, x1, x2, x5 and x10 can be selected to exaggerate it vertically.

- **Drag Action:** The fence image can be modified with either the zoom or pan actions.
- **Grid Ticks Only:** Turning off this box will extend the elevation and stationing tick marks all the way across the fence diagram.
- **Save:** This option will save the surface as a *.PRO profile
- **Draw:** Selecting this will put the fence diagram in the drawing with the Draw Profile command. The result will be similar to Draw Profile with multiple surfaces.
- **Print:** This will print the fence diagram to a PDF file.
- **Adjust Alignment:** This option allows for the fence line on screen to be moved. If the center of the polyline is selected, then the fence line can be moved in any direction, and the seams will dynamically update as the polyline is moved around. If one of the endpoints is selected, then the fence line can be rotated around the other endpoint, or extended to another length. This is a great tool to do a quick check of the geological grids with real-time graphic feedback on the model status.

Prompts

Select the Geologic Model File (*.PRE)

Pick starting point (CL-Centerline,P-Polyline): *p if the polyline is drawn on screen*

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: *select the polyline*

Drop-Down Menu Location: under StrataCalc

Keyboard Command: qfence

Fence Polylines

There are four commands for managing fence polylines. The fence polylines are used by the Fence Diagram command as the horizontal alignment. You can run Fence Diagram without pre-defined fence polylines and pick the alignment polyline on-the-fly. One advantage with using fence polylines is that you can specify the alignment polyline once and then more easily select the fence polyline in Fence Diagram which is useful if you run Fence Diagram multiple times for the same alignment. Another advantage is that you can use fence polylines to run Fence Diagram on multiple alignments at the same time.

The fence polyline commands are **Tag**, **Untag**, **Label** and **Identify**.

The Tag Fence Polylines command prompts you to pick a polyline and give it a name. This polyline is then flagged as a fence polyline.

The Untag Fence Polylines command removes the tags from the selected polylines.

The Label Fence Polylines command creates a text label of the fence name in plan view at the start of the fence polyline. This label is created in the current layer. All the fence polylines in the drawing get labeled.

The Identify Fence Polylines command reports the name of the fence polyline. For Identify, you can either report the names for the individually picked polylines or have the program search the whole drawing and report the locations and names for any fence polylines.

Prompts

Tag Fence Polylines

Select fence alignment polyline: *pick a polyline*

Fence name <Fence 1>: *West Pit*

Prerequisite: None

Block Diagram

Block Diagram creates a 3D cut out of the site with contours and/or grid mesh on top and fence diagrams or solid faces on the sides. The options for gridding and contours are shown in the first dialog box. The second dialog shows the options for the fence diagrams and grid. The strata hatch patterns are defined in the Define Strata command. The default hatch pattern at the bottom of the dialog is used if there is no pattern defined for that strata. In order to process a strata for the fence diagrams, there must be at least one drillhole inside and at least one outside the block diagram box. This command is basically a 3D Fence Diagram, with grid faces or contours on top. All of these options are defined in Make 3D Grid File and Draw Fence Diagram.

Voronoi Diagram

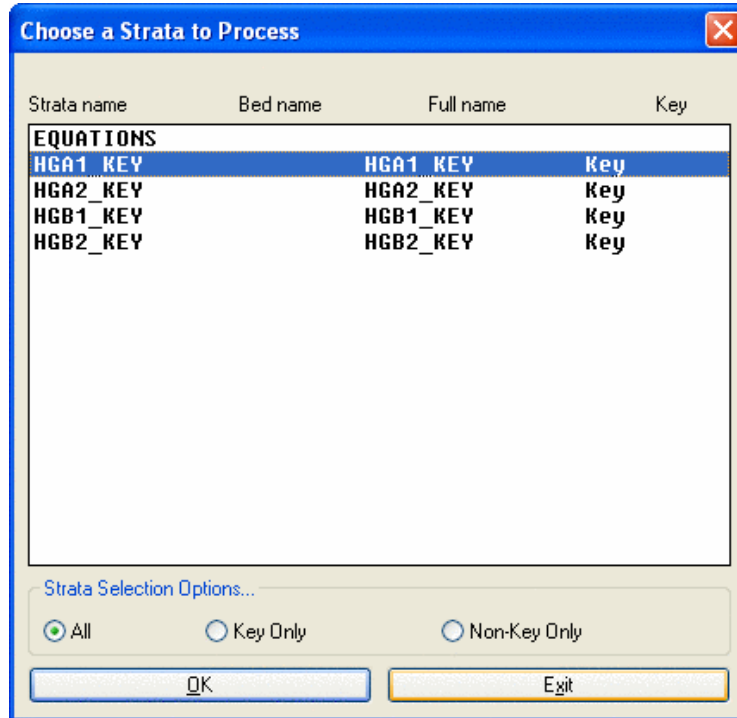

A Voronoi diagram is a special kind of decomposition of a space determined by distances to a specified discrete set of objects in the space, or by a discrete set of points or drillholes. It is useful here to divide the mine area up into polygon linework for the area of influence around drillholes. These are individual polyline segments, not closed polylines.

The first dialog prompts whether to use drillholes or simple CAD points for the input.

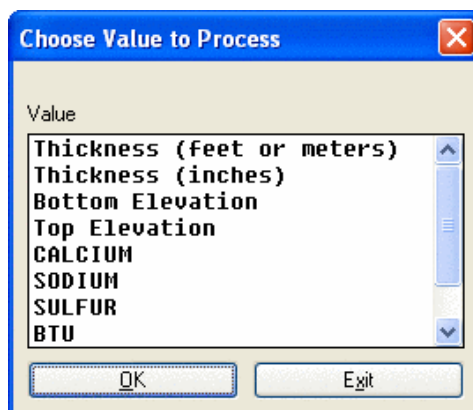

The next dialog prompts for the layer name for the diagram linework to create. The Process Method chooses between using all the drillholes at data points for the diagram or using only drillholes that have a certain strata and attribute.

When using Strata/Attribute, the next dialog asks for a strata to analyze.

The next dialog prompts for the value to process.

Prompts

Select drillholes, channel samples and strata polylines.

Geologic Model Viewer

This command loads the strata elevation models from a geologic model (PRE) into the 3D Viewer.

Pull down Menu Location: StrataCalc

Keyboard Command: view_geology

Prerequisite: Geologic Model file

Color Elev Grid by Strata

This routine colors the 3D grid faces plotted in the drawing. It uses the colors defined by layers, or in the strata definition file and matches the names up with the intervals in the Geologic Model. It is very useful for locating the outcrop of strata, or displaying the subcrops of seams to a mining bench grid. This colored grid can then be viewed in 3D and shaded for full visual effect. Shown below is a final pit of a sand and gravel quarry. The grid has been colored by the seams defined in the Geologic Model file. There are options to set the subdivision tolerance. 0 will not subdivide the grid cells. A max of 5 will subdivide the grid into very small cells, for example, 50 x 50 grids will

subdivide down to 1.5 x 1.5. There is also an option to use the SDF file from Define Strata for the coloring and layers.

Prompts

Select the Geologic Model file

Prerequisite: Need a 3D Grid plotted in the drawing and a Geologic Model containing grids that intersect the plotted grid.

Block Model Menu

The Block Model menu has commands for creating and viewing block models as well as pit optimization.

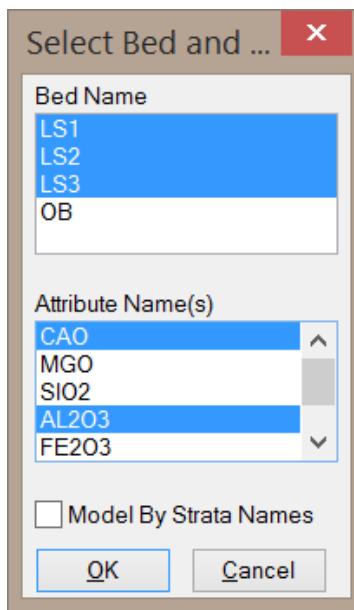

Make Block Model

This command will create a Block Model (.blk file) from drillholes and channel samples. A .blk file is simply a list of .grd files that model the variation of some attribute across a bed (e.g. calcium, magnesium, etc.) or across strata types. Because the block models are represented by a collection of grid files, there are some points that should be noted:

1. The number of blocks in a vertical column for any given X-Y location is constant throughout the model. This allows for variation in block height as the number of vertical divisions is held constant while the upper and lower extents of the block model may vary.
2. Sub-blocking is not currently supported.
3. All attributes must be represented with number. Alphanumeric attributes are not supported.
4. Block models are not a replacement for a Geologic Model, but rather a supplement to it. A Geologic Model may contain multiple block models to describe the variation of some quality of the strata/bed.

When the command is first executed, you will be prompted to select drillholes and channel samples to use. After selecting these entities, the below dialog will appear.

Bed Name: This list will only be populated by beds with attributes. Note that bed names represent a collection of strata. When a block model is created from a bed, there will be no distinction of strata types - all blocks will be treated as being a part of a single bed. In the above example, four beds with quality attributes have been detected: LS and OB. You may select multiple beds for the block model, but it is important to note that the block model will not keep track of the bed name in the blocks.

Attribute Name(s): This list shows the attributes detected within the selected bed. You may include multiple attributes in a single block model by clicking and dragging within the list or by holding the CTRL key while selecting attributes.

Model By Strata Names: This option will create the block model from selected strata names. This option will tag each block in the model as having a different Strata Index number. For example, Limestone blocks may be tagged with a 1, Clay blocks may be tagged with a 2, Overburden blocks may be tagged with a 3, etc. This allows you to distinguish between strata types in the block model rather than treating all blocks as a part of a single bed. You may still model the variation of some attribute throughout the model when this option is selected.

This option will prompt you to create a Grade Parameter File (.gpf file) that defines each Strata Index number. It is recommended to do this as it is the only place to keep track of the strata types in the block model.

This option will also prompt you to create a Geologic Model. This Geologic Model will be listed as having a single strata with a block model added to define the variation in the qualities. When modeling by strata names, the block model actually defines the various types of strata, so it is not necessary to define multiple strata layers in the Geologic Model.

After selecting the options on the above dialog, you will be prompted to select the horizontal extents of the block model by picking X-Y locations on the screen or by referencing the location of an existing grid file. After following these prompts and setting the horizontal extents of the block model, the below dialog will appear.

Specify Horizontal Resolution As...: This option determines how the size of the cells are defined. The Number of Cells in X and Y option will use the **X** and **Y** fields to set the number of cells in the horizontal plane. With this option, the dimensions of the cells will be calculated rather than manually set. The Dimensions of a Cell option will set the cell dimensions using the **X** and **Y** fields. If you opt to set the horizontal extents according to an existing grid file, this dialog will not allow you to set the size of the cells in the X and Y directions.

Vertical Position: This option will define the upper and lower bounds of the block model. The Fixed Elevations option will use flat elevations as specified by the **Bottom Z** and **Top Z** fields. The Follow Ore Model option will create grid files to define the upper and lower extents of the selected bed. With the Follow Ore Model option, the **Block Model Method** will determine how the grids are made.

Crop No Grade: This option is only available when using the Follow Ore Model option. When enabled, you will be prompted for a Grade Parameter File (.gpf file) which defines the various grades of material. When making the upper and lower limits of the block model, these grids will only extend to portions of the bed that have been defined within the Grade Parameter File. In other words, any blocks with values not defined in the Grade Parameter File will be cropped out.

Crop Block by Estimated Strata/Bed: This option is only used when the Vertical Position is set to Fixed Elevation. When this option is off, the blocks will be populated with values at all elevations between the Top and Bottom Z. When this option is on, only some blocks will be populated with block values. The program will create top and bottom elevation grids that follow the ore layer, and any blocks outside of this elevation range will not be populated with values. To ensure that all blocks are populated with values, this option should be disabled.

Number of Vertical Divisions: This option controls the number of blocks per x-y location in the model. If this value is set to 5, a total of 6 blocks will be present in each column of the block model. Here it is important to note that the height of each block will depend on the upper and lower limits of the model. If these limits are set at flat elevations, then the block height will not vary with location. If these limits follow the ore model, it is very likely that the block height will vary with location.

It is also important to note that the top and bottom block of each column will be half the height of the other blocks. This can be seen in the image at the bottom of this article. When calculating reserves with the Surface Mine Reserves command, the program can apply logic to account for the missing half-blocks at the top and bottom of the block model. For more information on this logic, see the section of the help manual corresponding to the Surface Mine Reserves command (subsection "Report Formatter and Miscellaneous Notes").

Block Model Method: This option determines which modeling method is used to create the block model.

1. The Nearest Neighbor method will use the nearest-neighbor method of assigning block values. No interpolation will be applied, but instead the block will take on the attribute value of the nearest sample point.
2. The Kriging method will assign block values based on a variogram. It is recommended to first calculate these variogram parameters using the Geology Module > StrataCalc Pulldown Menu > Calculate Variogram command. When this option is used, you will be prompted with the below dialog.

Minimum: This value sets the minimum attribute value to process when creating the block model.

Maximum: This value sets the maximum attribute value to process when creating the block model.

Min Points to Use: This value sets the minimum number of sample points to use when assigning values to each block in the model.

Max Points to Use: This value sets the maximum number of sample points to use when assigning values to each block in the model.

Search Radius X, Y, Z: These three values set the search radius of points to use when creating each block in the model. These values will determine the maximum distance of influence of each data point used to create the model.

On the right side of the dialog are the variogram parameters. These values may be loaded from a previously calculated variogram using the Load Model button. Detailed information on each of these parameters is provided in the section of the help manual relating to the Calculate Variogram command.

3. The Inverse Distance method will use inverse distance weighting to assign block values. When this option is used, you will be prompted to set the weighting factor and if you would like to use elliptical weighting.
4. The Prompt Each Attribute option will allow you to set the Block Model Method for each attribute in the block model. For example, you can use the Inverse Distance method to model one attribute the Kriging method to model another.

For details about each modeling method, see the section of the help manual corresponding to the Make Strata Grids command.

Vertical Weight Factor: When using the Inverse Distance method as the modeling method, the Vertical Weight Factor can be used to modify the degree of vertical trending in the deposit. It should be noted that this value is not the same as the distance weighting power. When this value is set to 1.0, the model will be calculated using normal inverse distance weighting. When this value is greater than 1.0, the vertical distances between the blocks and the drillhole samples will be exaggerated by the Vertical Weight Factor to allow for more vertical variation in the model. When this value is less than 1.0, vertical variation in the model will decrease. The below diagram and table demonstrates how various Vertical Weight Factors will impact the relative weight of each sample on the resulting block value. In this example, an inverse distance weighting power of 2 is used for all calculations.

In the above example, there are 4 quality samples in the black drillhole. The example block lies 55' away from the drillhole at a centroid elevation of 100. Each of these 4 samples will be weighted to determine the actual value of the block. The table to the right shows how increasing the Vertical Weight Factor will impact the weight of each sample on the block value. Notice that as the Vertical Weight Factor increases, the weight of Sample 1 on the block value increases significantly, while the weight of Sample 4 on the block decreases significantly. This means that for a higher Vertical Weight Factor, a block's value will more closely resemble that of samples at elevations similar to the block.

The below images show how a block model can vary simply by modifying the Vertical Weighting Factor. Three values are used for comparison: 0.1, 1, and 10. Notice how the Vertical Weight Factor of 10 creates horizontal trending between the data points, whereas the other two model have decreasing degrees of horizontal trending. Note that when the Vertical Weight Factor is set to a low value of 0.1, there is almost no variation in the qualities in the vertical direction.

Vertical Weight
Factor = 10

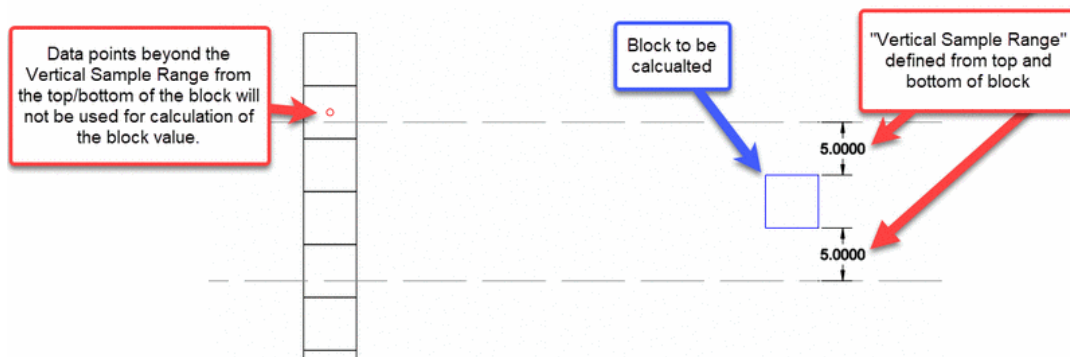

Vertical Weight
Factor = 1

Vertical Weight
Factor = 0.1

Vertical Sample Range: This option allows you to limit the vertical distance the program will search for data points when calculating block values. The below image is a visual explanation of this option. It is important to note that this Vertical Sample Range is checked as each individual block in the model is calculated. For each block level, the program finds sample points from the drillhole within the block level elevation range plus this Vertical Sample Range. When this setting is set to zero, the program creates a single composite data point at each drillhole for each block level.

Horizontal Search Radius: This value sets the search radius for the Inverse Distance modeling method. When the program is calculating the value of a block, any sample points further than this distance from the block centroid will be ignored.

After entering the additional prompts, you will be prompted to give the block model (.blk file) a name. All grids that are created in addition to the .blk file will be named similarly. For example, if the block model is named "Limestone", 5 vertical divisions have been set, and the block model represents the Calcium attribute, then the below files will be created.

Limestone.blk

Limestone-top.grd
 Limestone-bot.grd
 Limestone-Calcium0.grd
 Limestone-Calcium1.grd
 Limestone-Calcium2.grd
 Limestone-Calcium3.grd
 Limestone-Calcium4.grd
 Limestone-Calcium5.grd

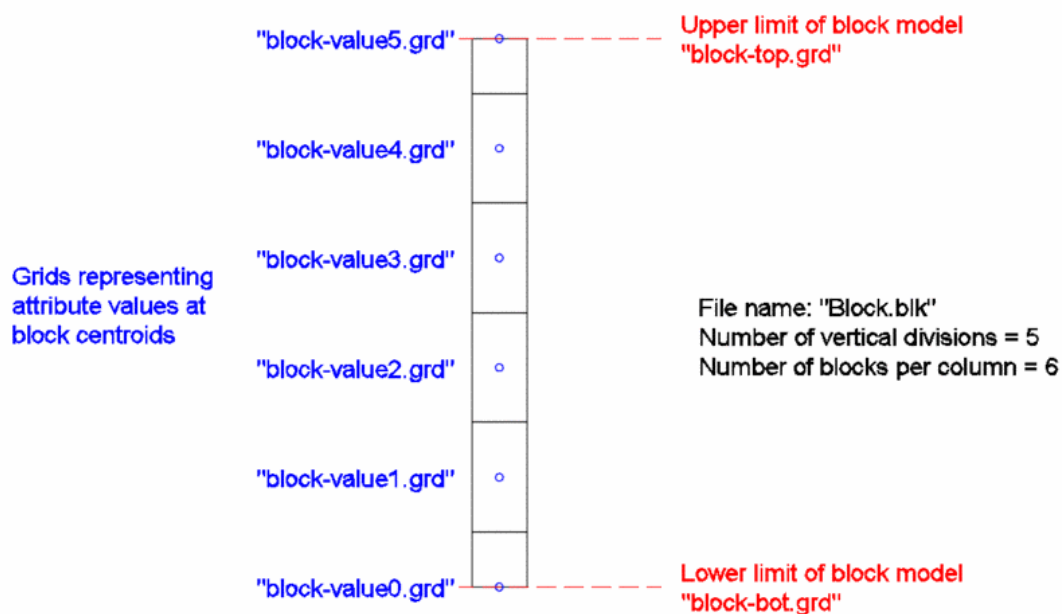

The "Limestone-top.grd" file represents the elevations of the upper limit of the block model.

The "Limestone-bot.grd" file represents the elevations of the lower limit of the block model.

The "Limestone-Calcium*.grd" (where * is a number) files represent the calcium content for each block level. Note that when 5 vertical divisions have been specified, 6 attribute grids will be created. The attribute grid ending with a "0" represents the calcium content for the lower-most block in each x-y location of the block model. The attribute grid ending with a "5" represents the calcium content for the 6th block from the bottom in each x-y location of the block model.

If more than one attribute is modeled, an additional set of grids will be created for each attribute using a similar naming convention.

The below image shows the side view of a column of blocks with grid files labeled in their respective positions.

Keyboard Command: BLKMODEL

Pull-down Menu Location: Geology Module > Block Model

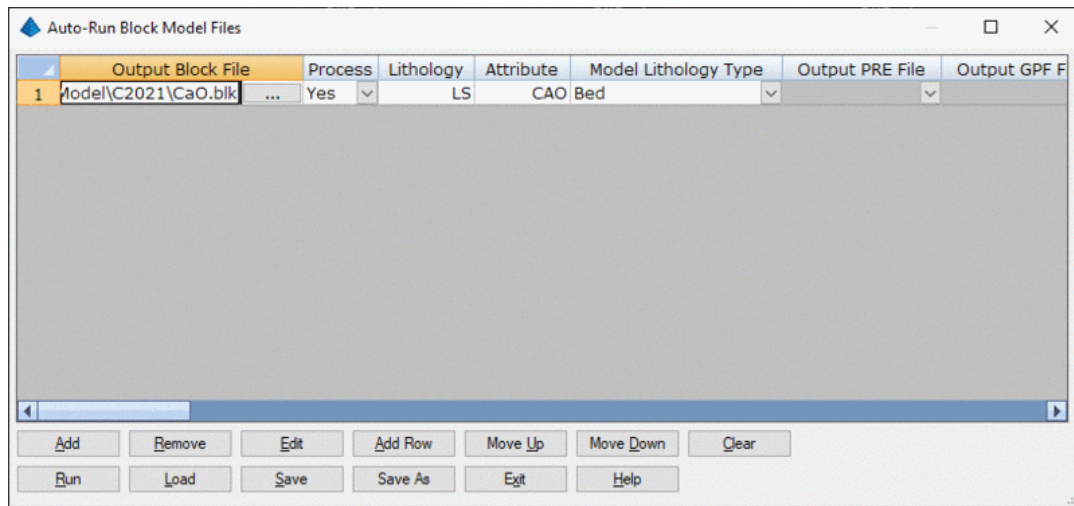

Prerequisite: Drillholes with a bed name, and variable quality values that can be vertically modeled.

Define Block Model Auto-Run

This command will allow you to define one or more block model files to create. This command is simple a macro-form of the Make Block Model command. The advantage of using an Auto-Run is that all settings are saved in a single file. This allows you to quickly recreate block models when input data files change. This also makes it possible to review the settings that were used to create a block model, ensuring new models are consistent with previous work.

When the command is executed, you will be prompted to select the drillhole to use for the calculation. After

selecting the holes, the below dialog will be displayed.

A new block model may be added to the list by clicking the **Add** button. When this button is selected, you will see many of the same settings found in the Make Block Model command. Each setting is explained below, but there are additional settings explained in the Make Block Model command documentation.

You may **Remove** or **Edit** files with the respective buttons. Individual settings may be modified directly in the spreadsheet of the main dialog.

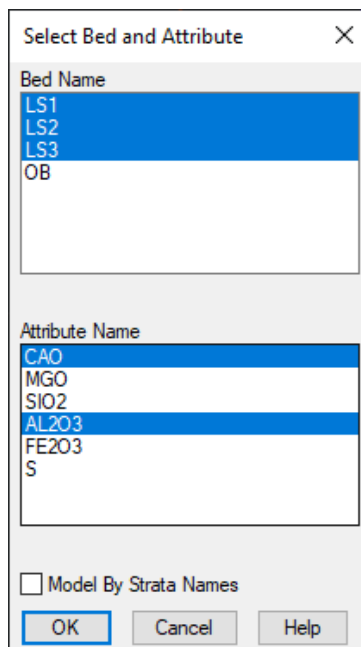

Clicking the **Add Row** button will copy the currently selected block model, but the settings should be reviewed to ensure each model has a unique file name.

Clicking the **Move Up/Down** buttons will move the selected block model up/down in the list. This will change the order in which the block models are calculated.

Clicking the **Clear** button will delete all rows from the spreadsheet.

Clicking the **Run** button will generate the block model(s) in the list. The block model files will not be generated prior to clicking this button. Note that any files that have the **Process** column set to "No" will not be created.

When a new block model is added to the list, you will first be prompted to set the filename. After this, the below dialog will appear.

Bed Name: This list will only be populated by beds with attributes. Note that bed names represent a collection of strata. When a block model is created from a bed, there will be no distinction of strata types unless the **Model by Strata Name** option is enabled. In the above example, four beds with quality attributes have been detected: OB and three distinct groups of LS. You may select multiple beds for the block model, but it is important to note that the block model will not keep track of the bed name in the blocks. Only data points from the selected bed will be used for block estimation. If more than one bed is selected, there will be no distinction between the source of the data (in the above example, the program will mix LS1, LS2, and LS3 data points).

Attribute Name(s): This list shows the attributes detected within the selected bed. You may include multiple attributes in a single block model by clicking and dragging within the list or by holding the CTRL key while selecting attributes.

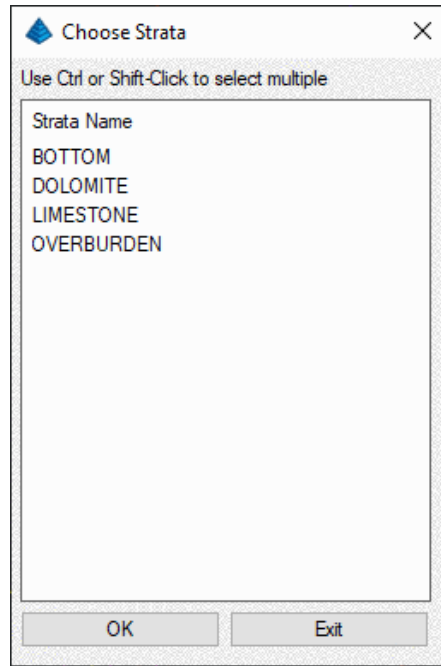

Model By Strata Names: This option will create the block model from selected strata names (strata will be selected on the following dialog). Note that Bed Names do not have to be listed in order to model by Strata Names. This option will tag each block in the model as having a different Strata Index number. For example, Limestone blocks may be tagged with a 1, Clay blocks may be tagged with a 2, Overburden blocks may be tagged with a 3, etc. This allows you to distinguish between strata types in the block model rather than simply grouping all blocks as part of the same bed. You may still model quality attributes in the model when this option is selected.

This option will automatically create a Grade Parameter File (.gpf file) that defines each Strata Index number. It is recommended to do this as it is the only place to keep track of the strata types in the block model. Note that the Grade Parameter File will have the same name as the Block Model, but will have a .gpf file extension.

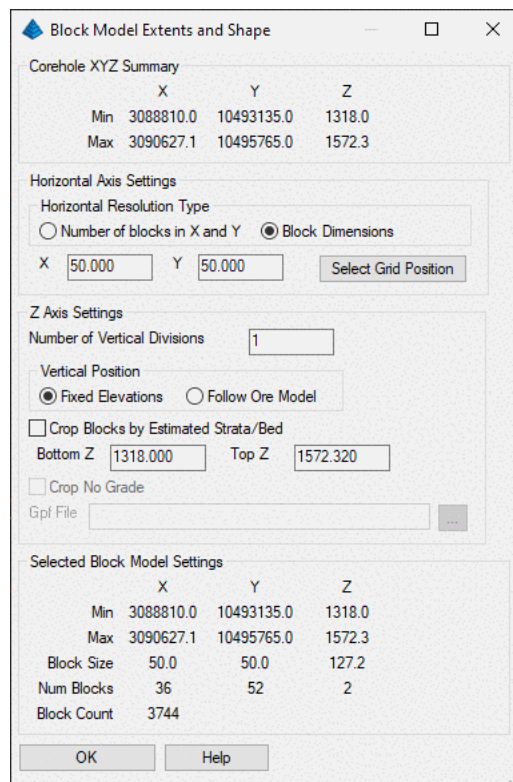

This option will also automatically create a Geologic Model. This Geologic Model will include a single layer with a block model added to define the variation in the qualities. When modeling by strata names, the block model actually defines the various types of strata, so it is not necessary to define multiple strata layers in the Geologic Model. Note that the Geologic Model will have the same name as the Block Model, but will have a .pre file extension.

When this option is enabled, the below dialog will appear after clicking OK. This dialog allows you to select the strata types to include in the block model. It is important to note that strata layers not selected will not

be considered when the block model is created. For this reason, it is recommended to select all strata types in this list.

After clicking OK, the below dialog will appear.

Corehole XYZ Summary: This table lists the minimum and maximum extents of the XYZ coordinates of

the data points to be used for creating the block model. Note that this is not the same as the actual extents of the block model.

Horizontal Resolution Type: This option determines how the horizontal size of the blocks are defined. The *Number of Block in X and Y* option will use the **X** and **Y** fields to set the number of blocks in the horizontal plane. With this option, the dimensions of the cells will be calculated rather than manually set. The *Block Dimensions* option will set the block dimensions using the **X** and **Y** fields as the actual dimensions.

The XY extents of the block model may be set by clicking the **Select Grid Position** button. When this button is clicked, you will be prompted to select the corner extents of the block model.

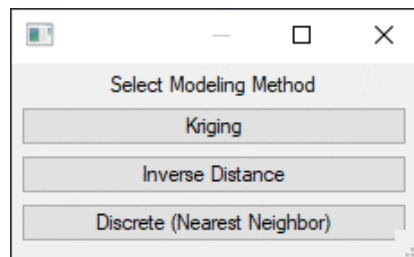

Vertical Position: This option will define the upper and lower bounds of the block model. The *Fixed Elevations* option will use flat elevations as specified by the **Bottom Z** and **Top Z** fields. The *Follow Ore Model* option will create grid files to define the upper and lower extents of the selected bed.

Crop Block by Estimated Strata/Bed: This option is only used when the Vertical Position is set to Fixed Elevation. When this option is off, the blocks will be populated with values at all elevations between the Top and Bottom Z. When this option is on, only some blocks will be populated with block values. The program will create top and bottom elevation grids that follow the ore layer, and any blocks outside of this elevation range will not be populated with values. To ensure that all blocks are populated with values, this option should be disabled.

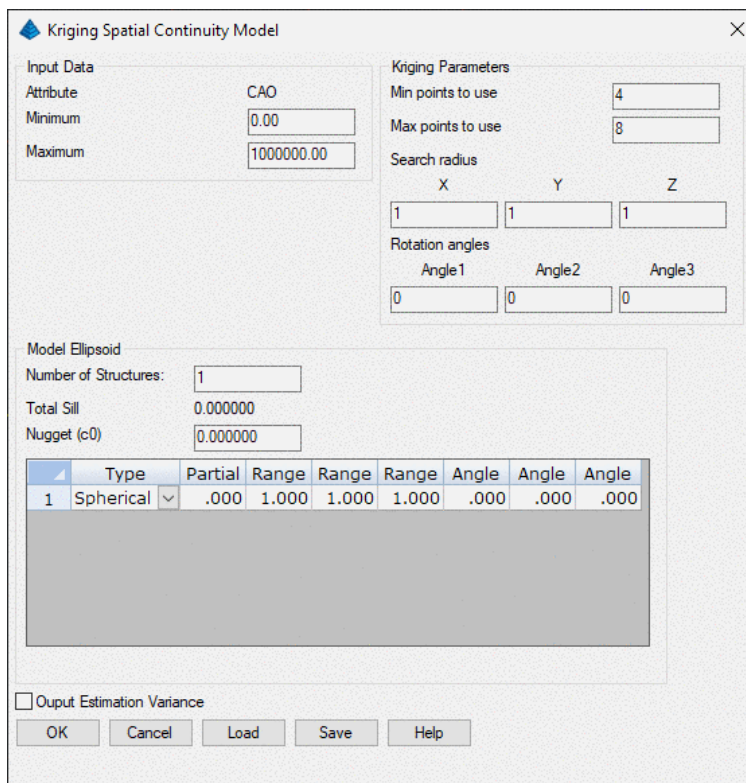

Crop No Grade: This option is only available when using the Follow Ore Model option. When enabled, you will be able to specify a Grade Parameter File (.gpf file) to define the various grades of material. When making the upper and lower limits of the block model, these grids will only extend to portions of the bed that have been defined within the Grade Parameter File. In other words, any blocks with values not defined in the Grade Parameter File will be cropped out.

Selected Block Model Settings: This table lists various information about the extent of the block model to be created. Note that changing settings such as the Top/Bottom Z will cause this table to update.

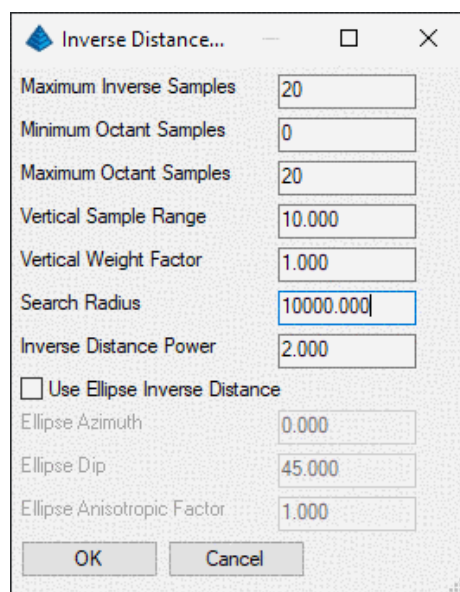

After clicking OK, the below dialog will appear.

1. The **Discrete (Nearest Neighbor)** method will use the nearest data point to of assign block values. No interpolation will be applied, but instead the block will take on the attribute value of the nearest sample point.
2. The **Kriging** method will assign block values based on a variogram. It is recommended to first calculate these variogram parameters using the Geology Module > StrataCalc Pulldown Menu > Calculate Variogram command. When this option is used, you will be prompted with the below dialog to set the kriging parameters.

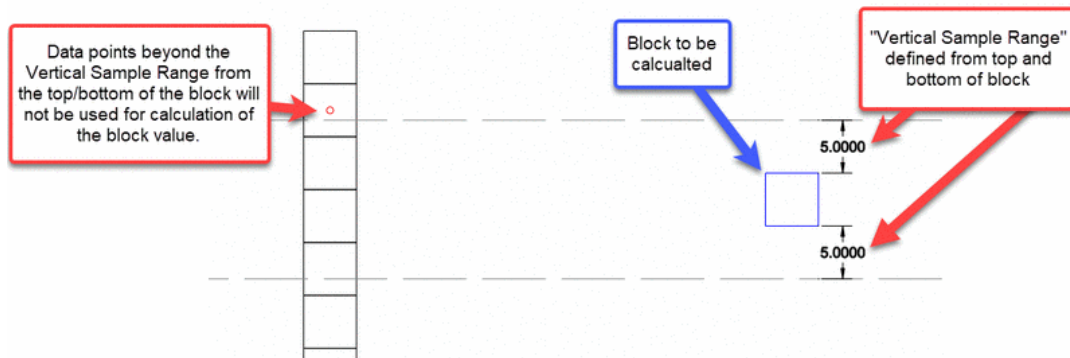

1. The **Inverse Distance** method will use inverse distance weighting to assign block values. When this option is used, the below dialog will be displayed.

Maximum Inverse Samples: Sets the maximum number of data points to use when calculating the value of each block. The points nearest each block will be used for the calculation.

Minimum/Maximum Octant Samples: Sets the minimum/maximum number of data points to be used in each octant around the block to calculate the block value. If the program cannot detect the minimum number of data points in each octant, the block value will not be calculated.

Vertical Sample Range: This option allows you to limit the vertical distance the program will search for data points when calculating block values. The below image is a visual explanation of this option with a Vertical Sample Range of 5. It is important to note that this Vertical Sample Range is checked as each individual block in the model is calculated.

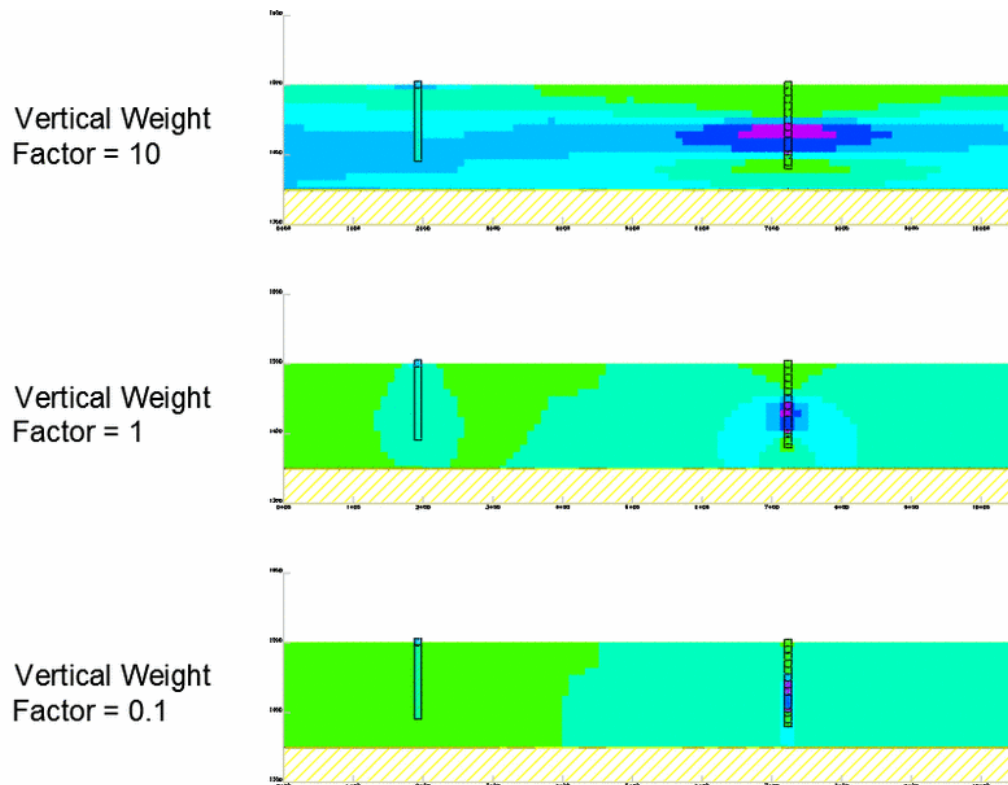

Vertical Weight Factor: When using the Inverse Distance method as the modeling method, the Vertical Weight Factor can be used to modify the degree of vertical trending in the deposit. It should be noted that this value is not the same as the distance weighting power. When this value is set to 1.0, the model will be calculated using normal inverse distance weighting. When this value is greater than 1.0, the vertical distances between the blocks and the drillhole samples will be exaggerated by the Vertical Weight Factor to allow for more vertical variation in the model. When this value is less than 1.0, vertical variation in the model will decrease. The below diagram and table demonstrates how various Vertical Weight Factors will impact the relative weight of each sample on the resulting block value. In this example, an inverse distance weighting power of 2 is used for all calculations.

In the above example, there are 4 quality samples in the black drillhole. The example block lies 55' away from the drillhole at a centroid elevation of 100. Each of these 4 samples will be weighted to determine the actual value of the block. The table to the right shows how increasing the Vertical Weight Factor will impact the weight of each sample on the block value. Notice that as the Vertical Weight Factor increases, the weight of Sample 1 on the block value increases significantly, while the weight of Sample 4 on the block decreases significantly. This means that for a higher Vertical Weight Factor, a block's value will more closely resemble that of samples at elevations similar to the block.

The below images show how a block model can vary simply by modifying the Vertical Weighting Factor. Three values are used for comparison: 0.1, 1, and 10. Notice how the Vertical Weight Factor of 10 creates horizontal

trending between the data points, whereas the other two model have decreasing degrees of horizontal trending. Note that when the Vertical Weight Factor is set to a low value of 0.1, there is almost no variation in the qualities in the vertical direction.

Search Radius: This value sets the search radius for the Inverse Distance modeling method. When the program is calculating the value of a block, any sample points further than this distance from the block centroid will be ignored.

Inverse Distance Power: Sets the weighting power for the inverse distance function. For more information on the Inverse Distance algorithm, see the Make Strata Grid File command documentation.

Use Ellipse Inverse Distance: This option will allow you to introduce a directional trend in the data. For example, if the data values tend to trend in a north-south direction (with more variation in the east-west direction), you may use an elliptical weighting factor.

Ellipse Azimuth: Sets the azimuth for the more heavily weighted data. For example, if data is expected to trend heavily in the north-south direction, an azimuth of zero should be used.

Ellipse Dip: Applies a dip to the anisotropic ellipse.

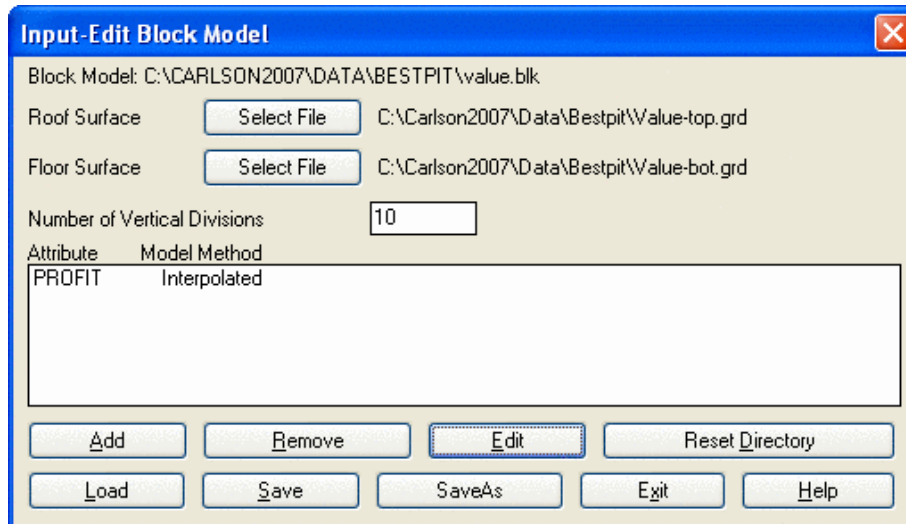

Ellipse Anisotropic Factor: The specified factor is used to increase the weight of data samples that line up more closely with the azimuth. Data samples that exactly line up with the azimuth apply additional weight, whereas data samples that are perpendicular with the azimuth apply zero extra weight. Data samples at an angle between the azimuth and perpendicular apply a proportional adjustment. The specified factor is adjusted by the azimuth and is then added with one and then multiplied by the data sample weight. For example, using an isotropic factor of 1 and a data sample that matches the azimuth to the model point, this sample will get double weighted; $(1 + 1) * \text{weight}$. When using a factor of 2 and a data sample that matches the azimuth, the sample will get triple weighted; $(1 + 2) * \text{weight}$.

Keyboard Command: BLKMODELAUTO

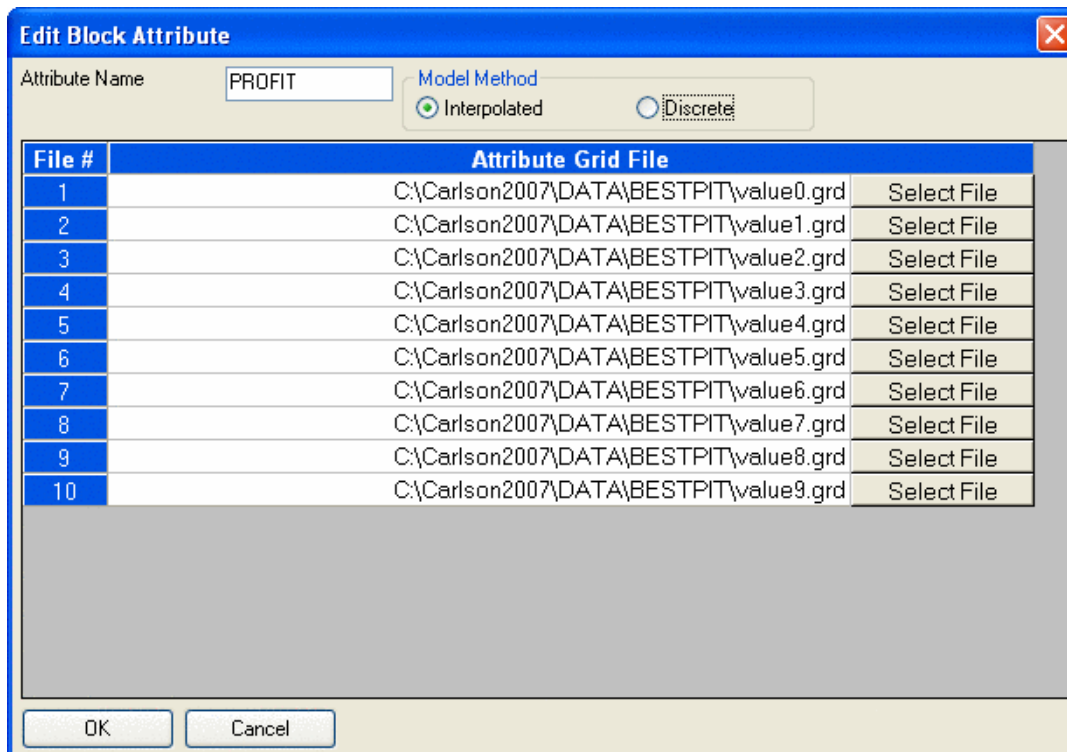

Pull-down Menu Location: Geology Module > Block Model

Block Model Editor

This command allows for creating the block model from pre-made grids, not using drillholes. It looks uses a grid file for the top and bottom of the ore zone. It then will reference at least one quality grid file for each vertical division. This is useful if the roof and floor grids already exist, and they will be used instead of grids made by other routines, such as Make Block Model. The dialogs are very easy to get around in.

Choosing the Add or Edit button will bring up the Edit Block Attribute window. The attribute name is entered at the top. The user can add up to 500 vertical divisions or grids. Save the block model as a BLK file for plotting and for use in Fence Diagram and Surface Reserves.

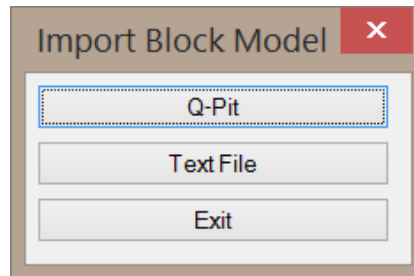

Pulldown Menu Location: Block Model

Keyboard Command: blkedit

Prerequisite: Grids of at least the roof and floor, and a quality grid

Import Block Model

This command imports block models from other programs into a Carlson .blk file. You can import from a Q-Pit file, or from a generic ASCII file from a variety of other programs such as Vulcan, Surpac, Leapfrog, etc. When you start the command, the below dialog will appear.

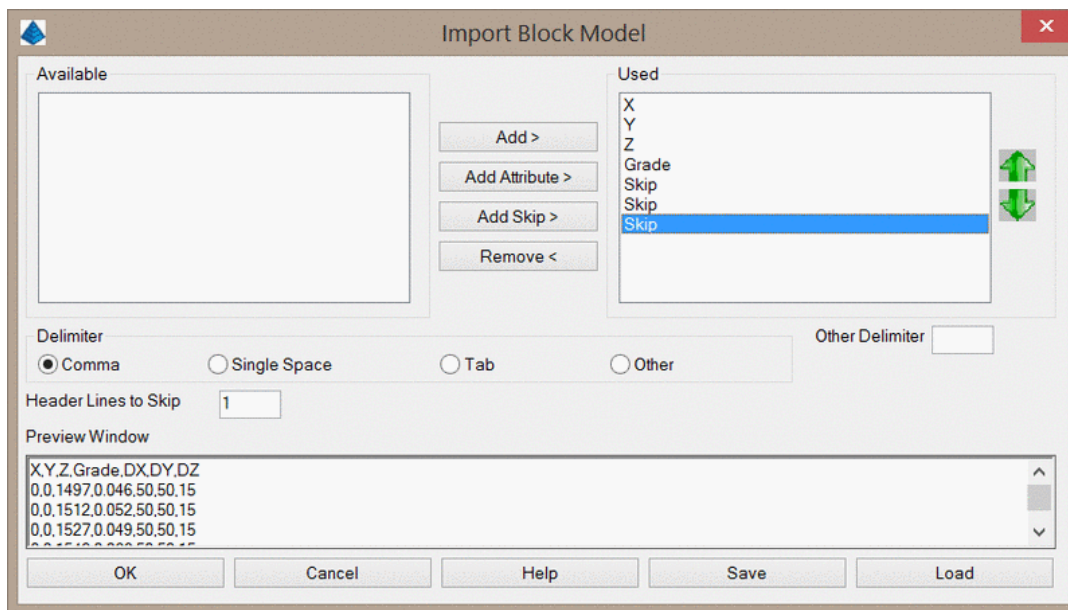

Q-Pit Block Model

This is an automated routine for the Q-Pit file format. After selecting the Q-Pit file, a Carlson .blk file will be created.

Text File

This method allows you to import a generic ASCII text file of the block model. The below dialog will appear, allowing you to define each attribute in the text file. The Available list will include the X,Y, and Z attributes (representing the X,Y, and Z coordinates of the centroid of each block), but you may add additional attributes by clicking the **Add Attribute** button. Only attributes in the Used list will be imported into the block model. You may move attributes between the Available and Used lists by double-clicking the attribute, or by using the **Add** and **Remove** buttons. Attributes should be ordered in this list as they appear in the ASCII file from left to right (the first column of the file should be the first row of the Used list, the second column of the file should be the second row of the Used list, etc.). The Preview at the bottom of the dialog shows the first few lines of the ASCII file to help guide you as you re-order the attributes in the Used list. You may skip over attributes in the file by clicking the **Add Skip** button and ordering the SKIP attribute appropriately.

The X,Y, and Z fields must be used to specify the centroid of each block. You must also specify at least one quality attribute. Other attributes such as dX, dY, dZ which are commonly included in block model exports are not required for this command.

Delimiter: This option specifies the text character that separates the columns of the file. This is most commonly a comma, but other delimiters may be used as well.

Header Lines to Skip: This option allows you specify the number of header lines in the text file. In the above example, there is one header line that must be skipped over.

Null Value: This option is a value in the text file to treat as a null or "no value". For example, 99999.

Please note that Carlson block models do not currently support sub-blocking, mega-blocking, or rotated block models. If you attempt to import a sub-blocked block model, the smallest block size will be applied to all blocks, which can drastically increase the number of blocks that are created in the .blk file. If you attempt to import a rotated block model, the block centroids will still be used, but the program will not be able to detect the true size of each block and will often create a large number of smaller blocks instead.

Pulldown Menu Location: Block Model

Keyboard Command: readblkm

Prerequisite: File to import

Export Block Model

This command writes a comma separated text file (CSV) of block model data. Each row in the file represents the XYZ coordinates of the block centroid, the sizes of the blocks along each axis, and the attribute values. An example is shown below.

	A	B	C	D	E	F	G
1	X	Y	Z	dX	dY	dZ	Grade
2	10000	10000	200	50	50	2	89
3	10000	10000	202	50	50	2	82
4	10000	10000	204	50	50	2	89
5	10000	10000	206	50	50	2	86

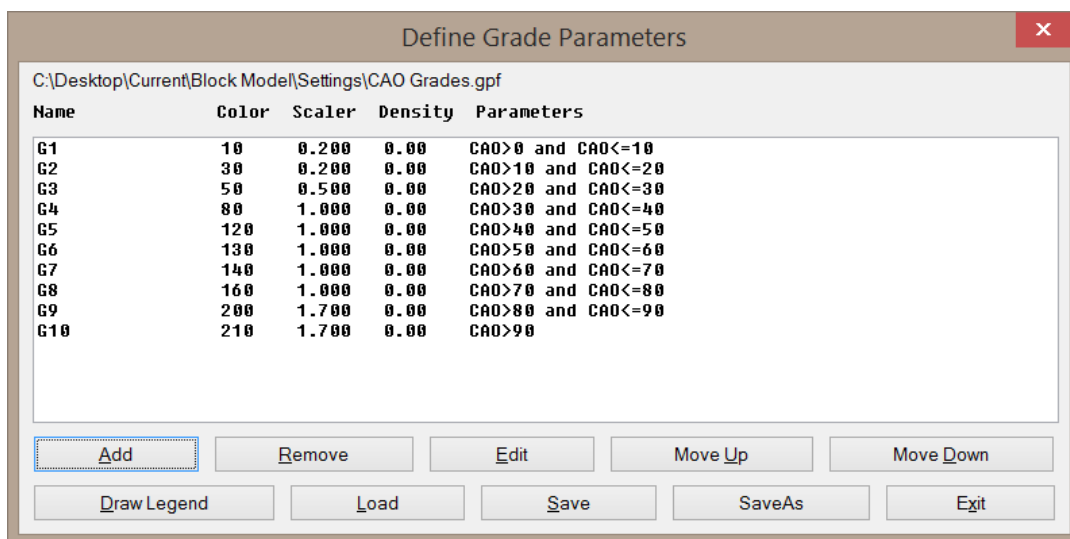

Pulldown Menu Location: Block Model

Keyboard Command: writeblkm

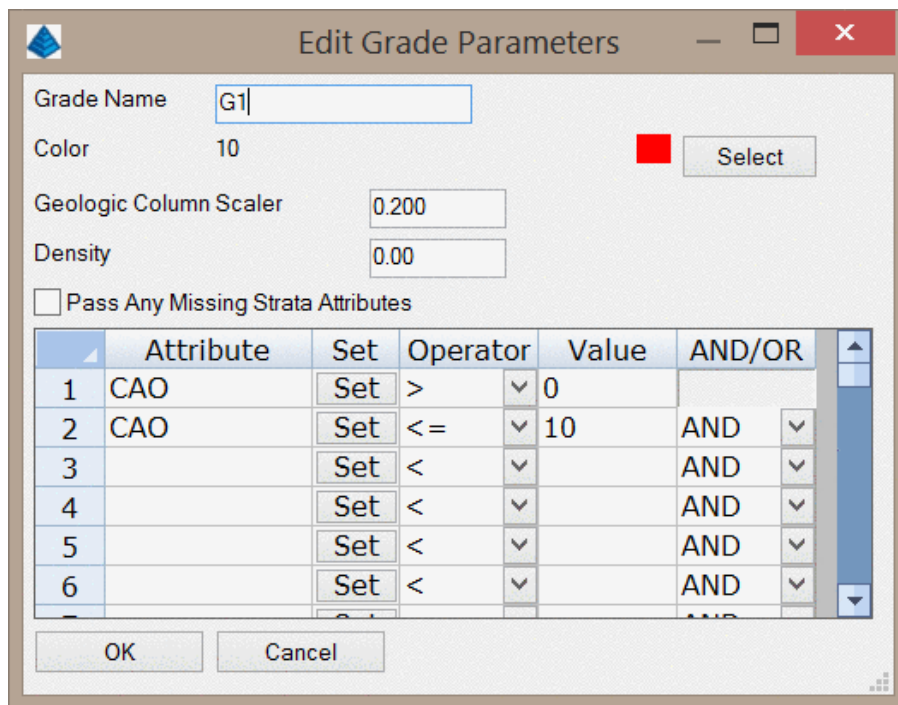

Prerequisite: File to import

Define Grade Parameters

This command creates the grade parameter definitions for use with block models. This assigns each block to a category based on the attribute values to be used for block model viewing and reserve reporting. When the command is executed, you will be prompted to create a new file or open an existing file. After creating/selecting a file, the below dialog will appear. Note that the below example has been populated with ten grade definitions based on CAO percentage.

Clicking **Add** or **Edit** will open the Edit Grade Parameters dialog (shown below).

Grade Name: This text field sets the name of grade. The Grade Name will be displayed in the Block Model 3D viewer and in reserve reports. Grade Names may be used more than once if needed, but it is important to note that duplicate grade names will be reported only once.

The Name of the grade may appear on the list more than once, if several options exist to create a certain grade.

Color: This option sets the display color of the blocks.

Geologic Column Scaler: This value controls the width of the Geologic Column in the Draw Geologic Column command. Changing this value allows you emphasize certain grades by making them smaller or larger. Increasing this value will increase the width of the geologic column.

Density: This value controls the density of the blocks when calculating tonnage with Surface Mine Reserves and Underground Mine Reserves.

Pass Any Missing Strata Attributes: This checkbox determines how missing block values are used for categorization. For example, suppose a grade is based on both CAO and MGO content. With this option enabled, blocks that are missing MGO values can still be considered for grade classification. With this option disabled, blocks without MGO values will not be considered for grade classification.

The spreadsheet in this dialog controls the definitions of the grade. Grades may be defined with up to 50 attribute "tests", where each row of the spreadsheet represents a different test. Each row must contain an attribute name, an operator, and a value. The attribute name must perfectly match the attribute names found in the block model, otherwise an error occur. Attribute names may be entered manually, or by clicking the **Set** button. It is important to note that the **Set** button will only pull attribute names from the Attribute Definition File. An Attribute Definition File is not required to create this file, but if no Attribute Definition File is found, there will be no attribute names to choose from.

There are six Operators available for each test, shown below. It is recommended that each attribute be defined with

an upper and a lower bound when appropriate. For example, grades that are defined by CAO values between 20 to 30 percent should have a lower bound of 20 percent and an upper bound of 30 percent.

- "<" Less Than
- ">" Greater Than
- "<=" Less Than or Equal To
- ">=" Greater Than or Equal To
- "=" Equal To
- "Not =" Not Equal To

Tests may be compounded with AND or OR relationships. For example, a WASTE grade could be defined as failing to have a passing CAO value OR a passing MGO value.

The **Move Up/Down** buttons control the order of the grade definitions. When the program analyzes a block model, the first grade in the list will be checked first. Any blocks assigned to this grade will not be considered for any other grade classification. Thus, the ordering of the grades can be used to your advantage when hierarchical tests are required.

The **Draw Legend** button places a legend in the drawing as shown here where the grade name is displayed next to the color sample in the legend. The user chooses the legend layer and size. This is useful after color hatching a fence diagram. Drawing the legend next to the fence diagram is a good reference to see the quality of the ore.

Prompts

Pick location for legend: pick location on screen

Layer name for legend <LEGEND>: Enter to select

Size for legend <20.0>: Enter or change size

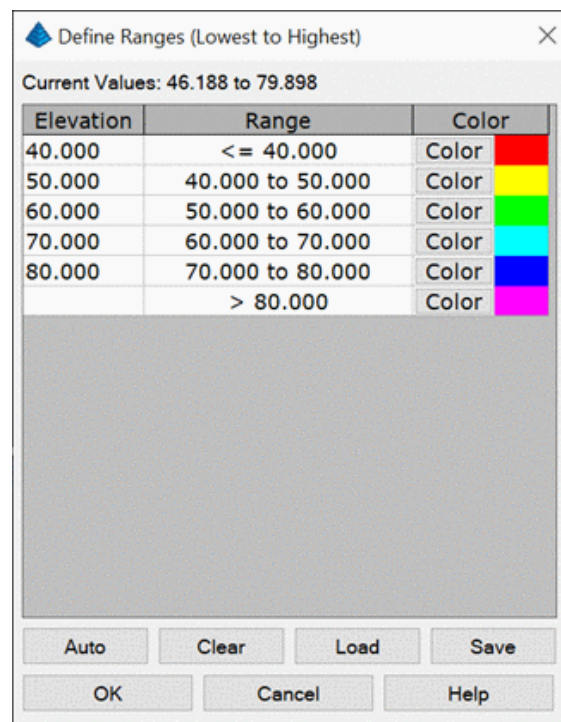

Keyboard Command: DEFATTRF

Pull-down Menu Location: Ore

Prerequisite: Need to run Make Block Model, or Block Model Editor first to get the BLK file. Then define the quality/grade parameter values and their color scheme.

Grade Parameters By Attribute Range

This command creates a grade parameter file for a range of attribute values stored in a block model. The command starts by selecting a block model to process. Then select an attribute from the block model. The program reads the values of the attribute in the block model and display the minimum and maximum values in the Define Ranges dialog. Enter the range values from lowest to highest. You can also use the Auto button to fill out the ranges and colors by an increment. After the Define Ranges dialog, the program prompts for the grade parameter file (GPF) to create. The grades are named by the range values. If you want to edit the grade names, run the Define Grade Parameters command

Keyboard Command: blk_attr_gpf

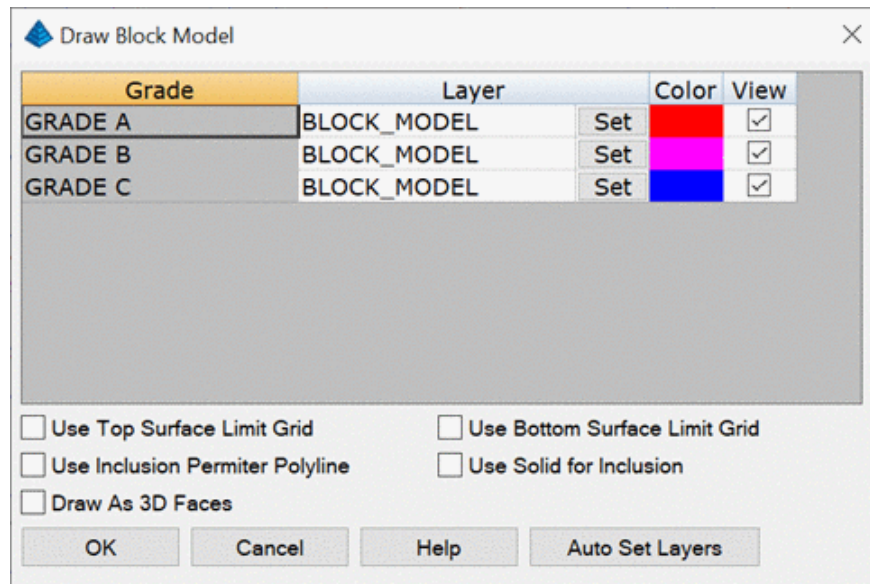

Pull-down Menu Location: Block Model

Prerequisite: Block model (blk)

Draw Block Model

This command draws a block model in the CAD drawing. Once in the CAD drawing, the blocks can be viewed with the 3D Viewer Window or by orbiting the drawing itself. When the command is executed, you will be prompted to select a .blk file and a grade parameter file (.gpf file - controls coloring of the blocks). After selecting these files, the

below dialog will appear.

Spreadsheet: In the spreadsheet you can customize the properties of the grades including the layer name, color and whether to draw.

Use Top/Bottom Surface Limit Grid: These toggles allow you select constraining elevation grids. Any blocks with a centroid above/below these elevation grids will not be drawn.

Use Inclusion Perimeter Polyline: When enabled, you will be prompted to select an inclusion polyline. Any blocks with a centroid outside this polyline will not be drawn.

Use Solid for Inclusion: When enabled, you will be prompted to select a solid (.mdl file). Only blocks with centroids inside of this solid will be drawn.

Draw as 3D Faces: When enabled, all six sides of the blocks will be drawn as 3D faces. When this option is disabled, the blocks will be drawn as points. Drawing the blocks as points will reduce the demand on your computer's hardware, thus allowing for quicker camera movements.

Auto Set Layers: This function sets the layer name by the grade names with a specified prefix and suffix.

After clicking **OK**, the block model will be drawn in CAD, as shown below.

Drawn as Points

Drawn as 3D Faces

Even though the blocks may be drawn as points, these points will be rendered as full blocks if loaded into the 3D Viewer Window. When the blocks are drawn as 3D faces, you may wish to modify the SHADEMODE variable to toggle between a wireframe view and a shaded view.

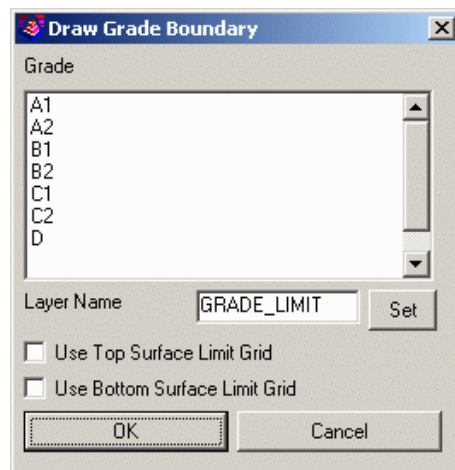

Keyboard Command: drawblkm

Pull-down Menu Location: Block Model

Prerequisite: Need a *.BLK file and a *.GPF file from Make Block Model, Block Model Editor and Define Grade Parameters.

Draw Grade Boundary

This command draws polylines along the boundary of areas of a block model that contain a specified grade. The grades are defined in a Grade Parameter file (GPF). After selecting the block model and grade parameter files, there is a dialog to choose the target grade to process and the layer for the boundary polylines to create. There are options to limit the top and bottom of the block model to check for the target grade. Any sample in a column of the block model that has the target grade and is within the top and bottom limits will make the location of that column count as an area for containing the target grade. So the grade boundaries mark areas that have at least some of the target grade while these areas might also have some other grades.

Prompts

Block Model To Process file selection

Grade Parameter File To Process file selection

Draw Grade Boundary dialog

Pulldown Menu Location: Block Model

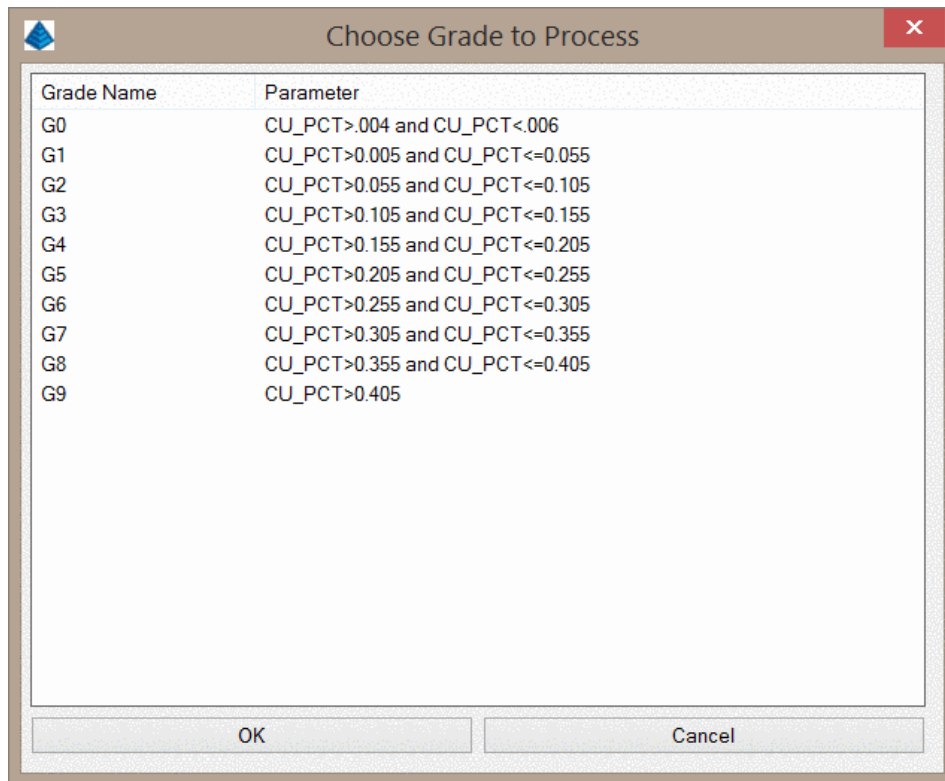

Keyboard Command: draw_grade_limit

Prerequisite: A BLK model file and a GPF grade parameter file

Make Grade Solid Model

This command will create solids (.mdl files) of blocks in a block model matching a specific grade. The inputs are simply a block model and a grade parameter file, and the output is a solid (.mdl file).

When the command executes, you will be prompted to select an existing block model (.blk file) and a grade parameter file (.gpf file). After selecting these files, the below dialog will appear, listing all of the grades.

Here you may select a grade to create a solid. After clicking OK, you will be prompted to specify an .mdl file to create. The below image shows an example Grade in a block model (left) and the corresponding solid that is created using this command (right). Notice how the original block model shows the individual blocks, while the solid does not.

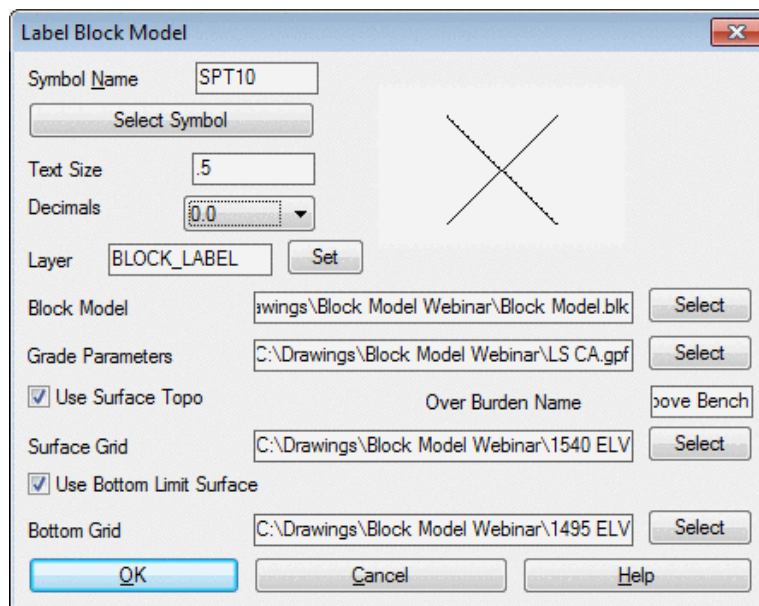

Block Model File
Grade Parameter File
Select Grade to Create Solid
Solid to Create

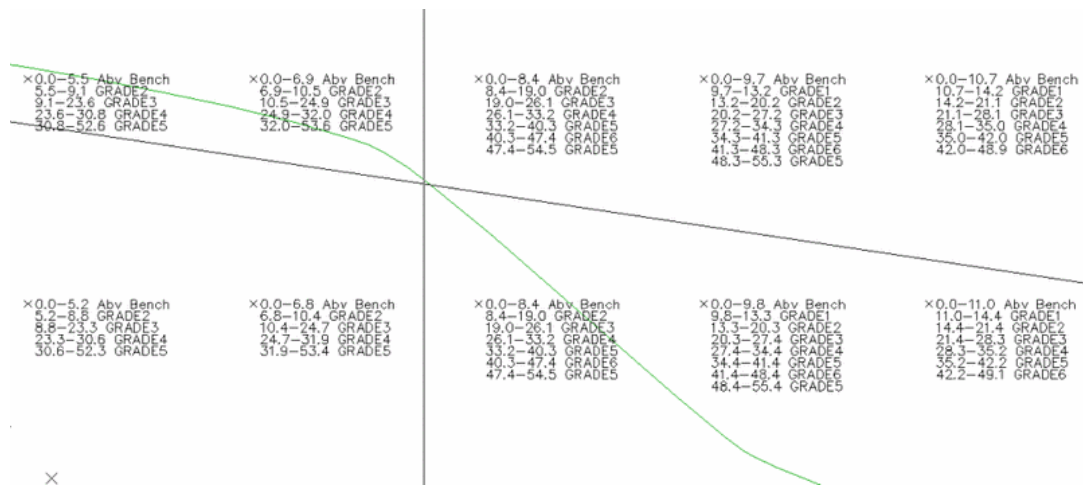

Pulldown Menu Location: Block Model
Keyboard Command: BLK_TO_SOLID
Prerequisite: Block Model and Grade Parameter File

Label Block Model

This command is an automatic way to label the grades of a block model between two surfaces. There are options for symbols, text size, decimal precision and the CAD layer it will be drawn on.

The Block Model and Grade Parameters are set first. Then there is the optional Surface Topo and Bottom Limit Surface to contain the labels to just that depth for the labels. This is useful if the blocks within a certain bench height from 1540 down to 1495 elevation are to be labeled. Once OK is selected, there are prompts to select an inclusion and exclusion perimeter. After that is an option to skip over block cells to label. This will create fewer labels based on how many are skipped over.

Prompts

Select the Inclusion perimeter polylines or ENTER for none.

Select objects: *pick polyline*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *press Enter*

Number of cell to skip <2>: *press Enter*

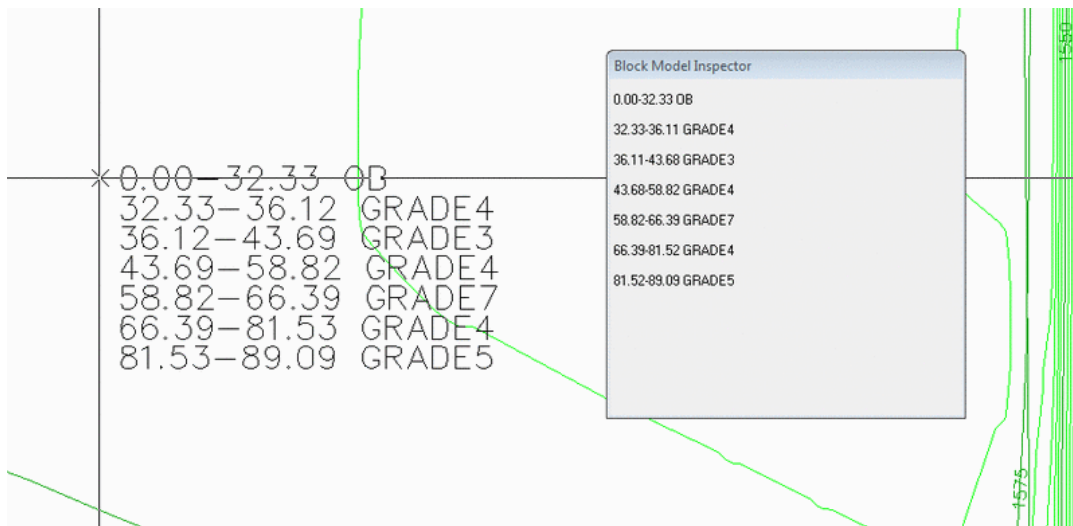

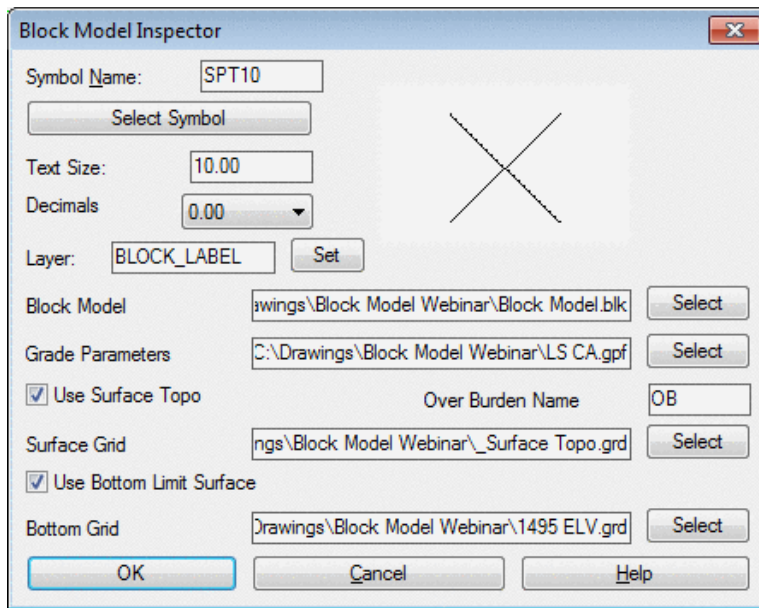

Pulldown Menu Location: Block Model

Keyboard Command: label.blkm

Prerequisite: Need a BLK model file and a GPF grade parameter file.

Block Model Inspector

This command displays the from and to depths, and the grade value as the cursor is moved across the block modeled area. The location can be labeled with a left mouse click to put the text in the drawing. This is a quick way to check the model and for labeling maps to give to the field crew showing the depth range and grade. If "Use Surface Topo" option is on, the depth is calculated from the "Surface Grid" and labeled as "Over Burden Name", such as OB. The Use Bottom Limit Surface will contain the model so that it only labels down to it, such as a flat bench elevation, or pit floor grid. If there exists a no-grade zone for certain elevation range this zone is reported as No-Grade zone.

Φ 0.00-17.70 OB
 17.70-18.17 GRADE_B
 18.17-19.11 GRADE_A
 19.11-21.46 GRADE_B

Prompts

Reading cell> 4828

Select symbols/<Enter or pick point>:

Pulldown Menu Location: Block Model

Keyboard Command: blkm_inspector

Prerequisite: Need a BLK model file and a GPF grade parameter file.

Compare Drillholes to Block Model

This command reports differences between strata attribute values from selected drillholes and attribute values from a block model. This command is a way to check how closely a block model matches the drillhole data. For each strata attribute value, the program compares to the block model at the strata position. The resulting values are reported using the Report Formatter.

Prompts

Block Model To Process file selection

Select drillholes.

Select objects: *pick the drillholes*

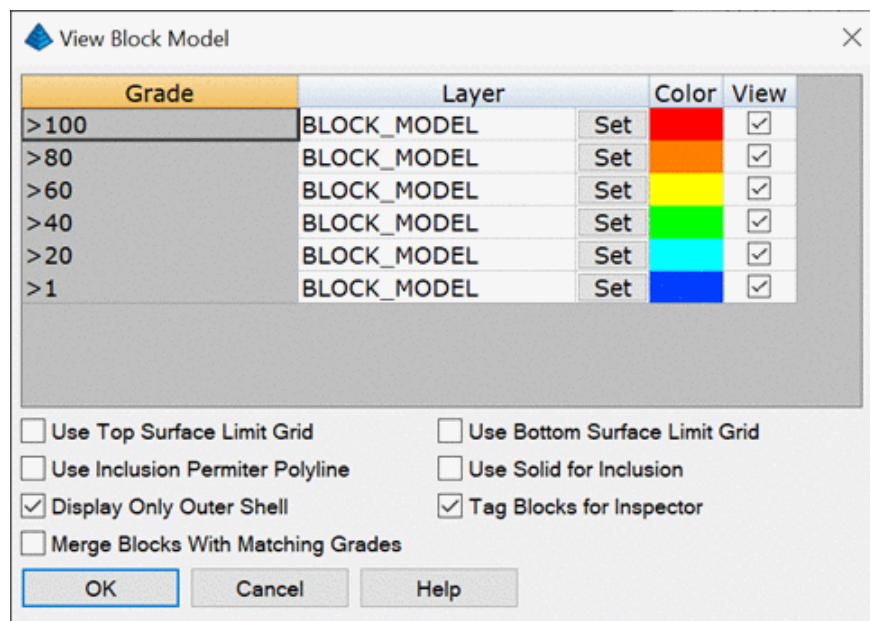

Pulldown Menu Location: Block Model

Keyboard Command: blkm_compare

Prerequisite: A BLK model file and drillholes

Block Model 3D Viewer

This command allows you to view a block model in the 3D viewer window directly from the .blk file. When the command is executed, you will be prompted to select a .blk file and a grade parameter file (.gpf file - controls coloring of the blocks). After selecting these files, the below dialog will appear.

Spreadsheet: In the spreadsheet you can customize the properties of the grades including the layer name, color and whether to view.

Use Top/Bottom Surface Limit Grid: These toggles allow you select constraining elevation grids. Any blocks with a centroid above/below these elevation grids will not be drawn in the 3D Viewer.

Use Inclusion Perimeter Polyline: When enabled, you will be prompted to select an inclusion polyline. Any blocks with a centroid outside this polyline will not be drawn in the 3D Viewer.

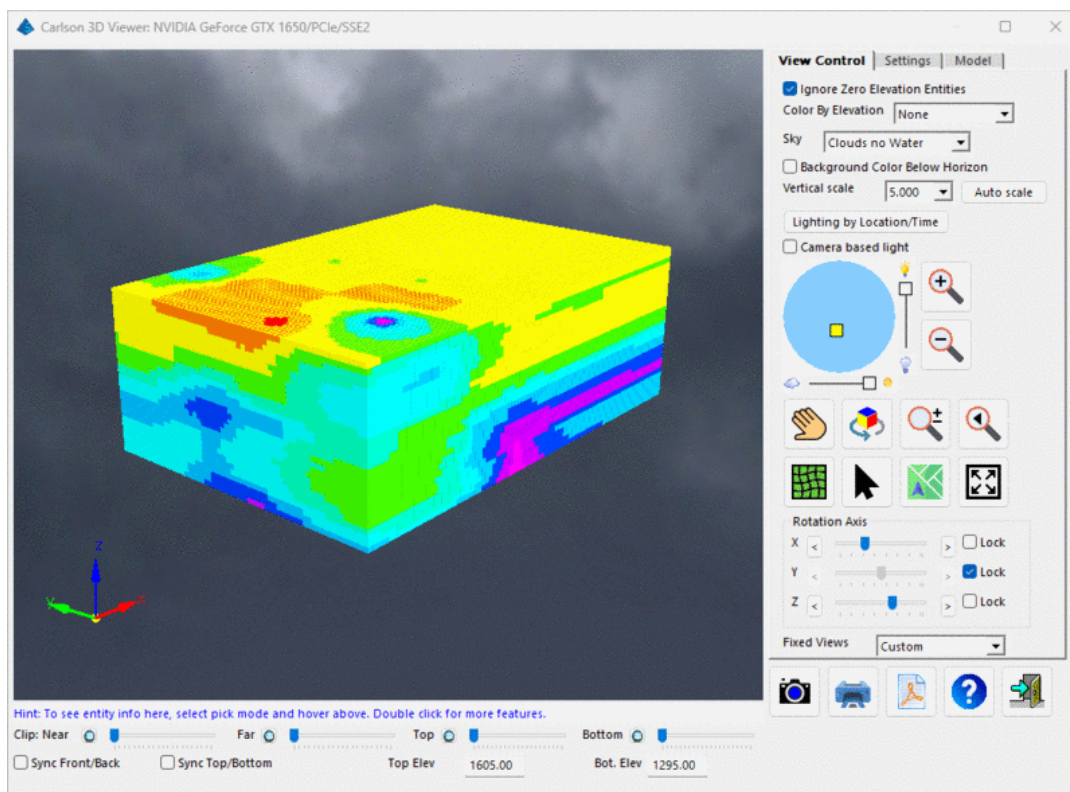

Use Solid for Inclusion: When enabled, you will be prompted to select a solid (.mdl file). Only blocks with centroids inside of this solid will be drawn.

Display Only Outer Shell: This option renders only the blocks that border a different grade or border the sides of the model. Otherwise, all the blocks are rendered.

Tag Blocks for Inspector: This option stores data of the block dimensions and grade in each block. Then in the 3D Viewer, you can pick the pointer mode and the viewer reports these values as you move the cursor over a block. Turning this option off speeds up loading.

Merge Blocks With Matching Grades: This option combines vertically neighboring blocks with the same grade which speeds up processing and viewing a bit.

After selecting these settings and clicking OK, the 3D Viewer window will be displayed as shown below. All controls for this dialog are discussed in the 3D Viewer Window section of the help manual. However, one additional control is specific to this command. The **Auto Scale** button will modify the Vertical Scale to make block viewing easier. This is especially useful for blocks that cover a large area, but do not span a relatively large depth.

You may view additional block models at the same time by picking the Model tab, right-click on Block Models and pick Add Block Model. Also from the Model tab, you may add surface models or CAD entities to the scene.

You may change the coloring of the blocks by right-clicking "Block Model" on the Model tab. The below dialog will be displayed.

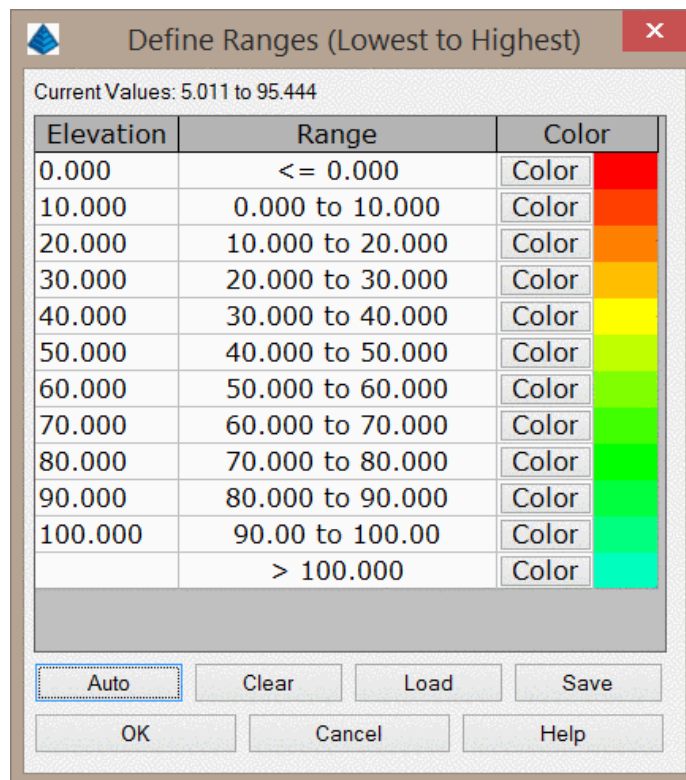

Select Another File: This option will prompt you to select a new Grade Parameter File to recolor the block model.

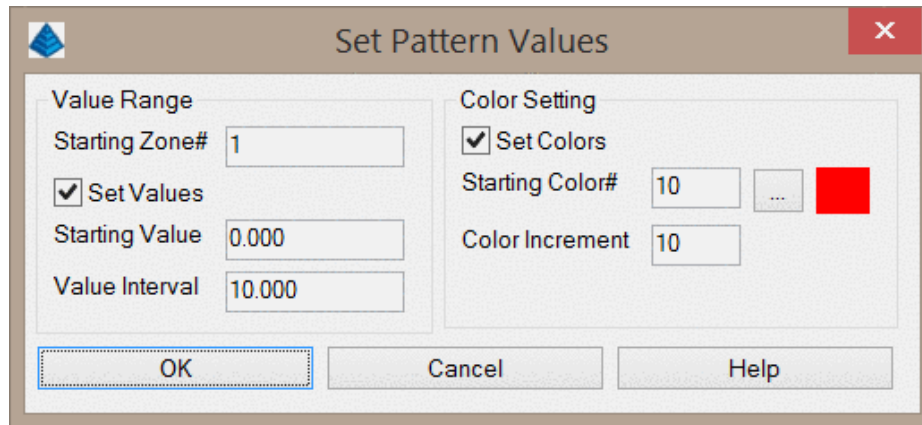

Color by Attribute: This option will allow you to recolor the blocks by defining the attribute values and colors on-the-fly. This is a simplified version of a Grade Parameter File, with the restriction that coloring can only be based on a single attribute. Clicking this option will display the below dialog, which will prompt you to select the attribute of interest.

The next dialog that appears is shown below. Here you can define the range of values and the color for that range.

The **Auto** button can be used to quickly create the ranges using a constant interval. This dialog is shown below.

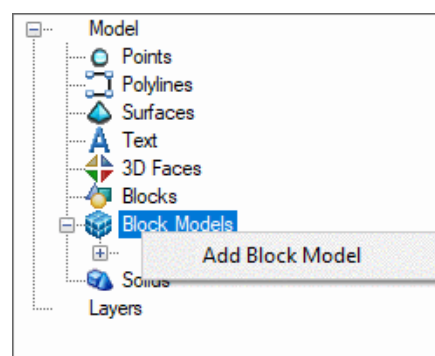

Starting Zone: This value sets the first row to modify. If several rows have already been defined and do not need to be modified, set this value to the next undefined row.

Set Values: This option will modify the values of the rows. If the values have already been set and do not need to be changed, this option should be disabled. When enabled, the Starting Row value will be set to the **Starting Value**. Each row after will increment by the **Value Increment**.

Set Colors: This option will modify the colors of the rows. If the colors have already been set and do not need to be changed, this option should be disabled. When enabled, the Starting Row color will be set to the **Starting Color #**. Each row after will increment by the **Color Increment**. The color values may be viewed by clicking the ellipse button to the right of the **Starting Color**.

It is worth noting that you can load more than one block model into the 3D Viewer. After loading the first block model, you can right-click on the Block Model branch to load a second model.

Grade View Controls: On the Model tab, you can list the block and all the grades. From this list, you can turn grades on/off for viewing by double-clicking on the grade name, or by right-clicking and choosing Thaw Layer or Freeze Layer. Also with right-click, you can set the grade as transparent.

Pulldown Menu Location: Block Model

Keyboard Command: cube_blk

Prerequisite: A BLK model file and a GPF grade parameter file.

Block Model Statistics

This command is used to report data value statistics on each grid or overall statistics within the block model. The user is prompted to select one of the reporting method, Report by Attribute/Quality, Report by Grade Parameters or Report by Levels/Grids. The reports are generated using the Report Formatter. There is an option to select an inclusion perimeter to limit the report to an area. Otherwise the report will cover the whole block model.

The Report By Attribute/Quality reports statistics for all the samples of each attribute in the block model. Here's an example:

Name	Samples	Min Value	Max Value	Avg Value	Variance	Std Dev
SIO2	143820	3.07	71.12	26.88	61.25	7.83
CAO	143820	4.03	53.31	34.78	47.13	6.86

The Report By Levels/Grids reports statistics for each attribute grid at each level in the block model. The attribute names in the report have the level sequence number as a suffix. The grid levels are numbered from 1 at the bottom and going up. Besides the statistics on the attribute values, the report also has statistics on the elevation and depth for each level. Here's an example portion of a report:

Name	Samples	Min Value	Max Value	Average Value	Std Dev	Avg Top Z	Avg Bot Z	Avg Depth
CAO[1]	1410	21.42	43.78	35.67	3.91	47.93	47.43	101.67
CAO[2]	1410	20.96	43.71	35.67	3.99	49.92	48.93	100.17
CAO[3]	1410	20.59	43.82	35.67	4.06	50.92	49.92	99.18
CAO[4]	1410	20.37	43.88	35.68	4.14	51.92	50.92	98.18

For Report By Grade Parameters the program prompts for a Grade Parameter File (gpf) and reports the number of blocks for each grade along with the min, max and average values of the attributes for each grade. With this report, besides using an inclusion perimeter to limit the blocks to report, you can also use a solid model (MDL) or top or bottom surface grids.

Grade	Samples	% of Total	GOLD Min	GOLD Max	GOLD Avg
>100	1	0.0	103.84	103.84	103.84
>80	1	0.0	80.48	80.48	80.48
>60	11	0.0	60.65	76.21	67.33
>40	89	0.2	40.26	59.21	48.11
>20	390	1.0	20.02	39.90	27.15

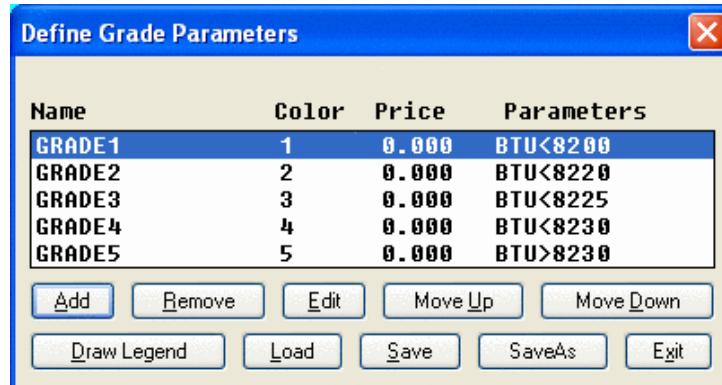

Pulldown Menu Location: Block Model

Keyboard Command: blkstats

Prerequisite: .BLK model file

Color Pits by Grade Parameters

This command colors pits by assigned grade color from grade parameters file. It could be useful in identifying the pits with different grades/qualities.

Prompts

Color Pits by Grade Parameters

Select all directioned pit polylines.

Select objects: *all*

202 found

Select objects: *press Enter*

Enter bench number to hatch (1-4): *4, enter bench number to be colored*

Pull-down Menu Location: Block Model

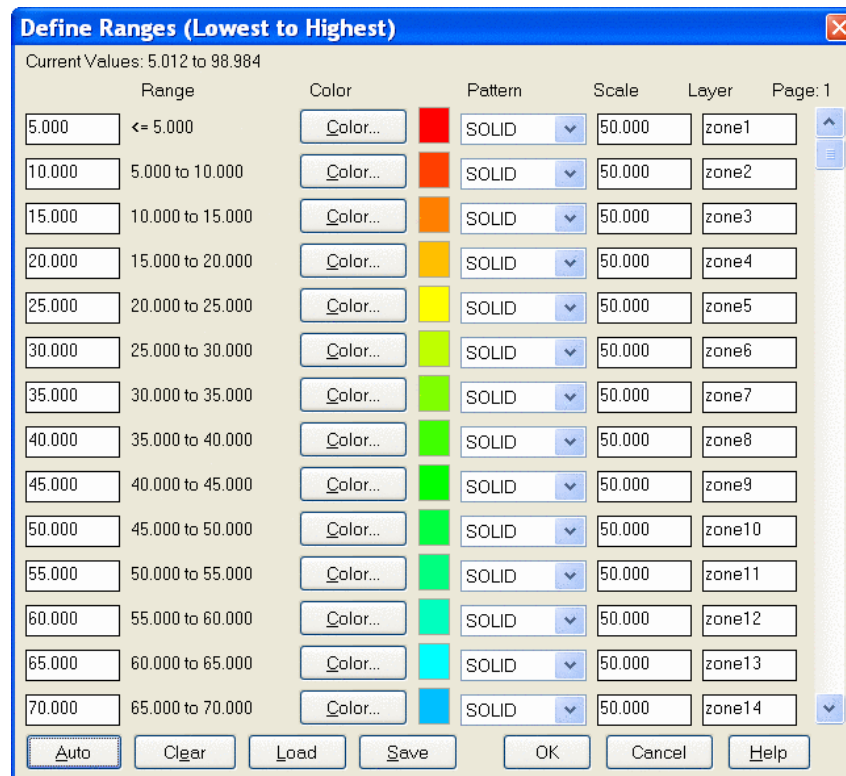

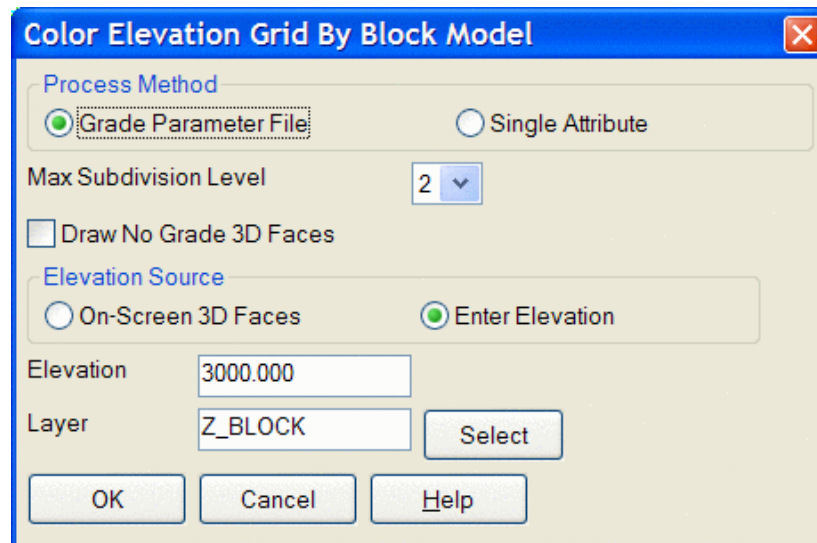

Keyboard Command: pitcolor

Prerequisite: Grade Parameter File (gpf) and Surface Pits with directions and quantities

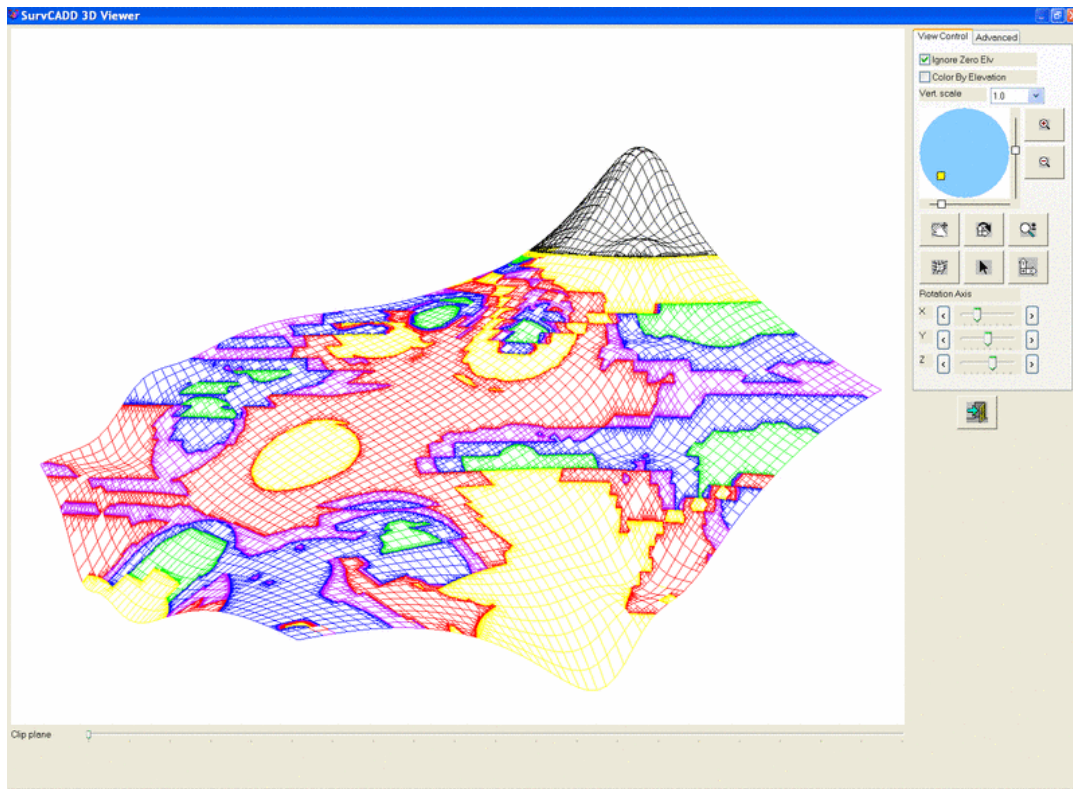

Color Elev Grid by Block Model

This command will color the 3D faces of an elevation grid plotted on screen or of a flat user defined elevation based on the Grade Parameter File or by a single attribute, where the color palette is selected separately.

After selecting the Block model file (*.BLK), the following dialog box prompts for Single or File for the color scheme. Selecting File would use the predefined *.GPF file. Choosing Single leads to the next colorful dialog box to specify the ranges. The Max Subdivision Level allows for a tolerance to subdivide the cells or blocks. Zero (0) will not subdivide them. A maximum of 4 will subdivide them into very small segments. The option to Draw No Grade 3D Faces will leave gaps where the parameters of the block model don't meet any of the grades. There is the option to use On-Screen 3D Faces or to simply enter an elevation to represent the grid.

The result is a colored grid mesh or elevation that can be rendered and viewed in 3D.

Prompts

Reading cell > 4828

Select 3D Faces to Process... type all or window the faces

Select objects: Specify opposite corner: 15779 found, 11552 were filtered out.

Select objects: Enter to accept

Keyboard Command: BLKCOLOR

Pull-down Menu Location: Ore

Prerequisite: Need a *.BLK model file and a grid drawn on screen.

Crop Block Model

This command creates a new block model that is cropped from an input block model. When a block model is larger than needed, this command can be used to make a smaller block model that is faster to process and easier to manage.

After selecting the input and output block models, there is a dialog for selecting the methods to crop. The Use Top Surface Limit Grid applies a grid surface to remove all block cells above this grid. Likewise, the Use Bottom Strata Limit Grid removes all block cells below the grid surface. The Use Inclusion Perimeter Polyline removes block cells that are outside the closed polyline perimeter. The Use Solid for Inclusion removes block cells that are outside the solid model.

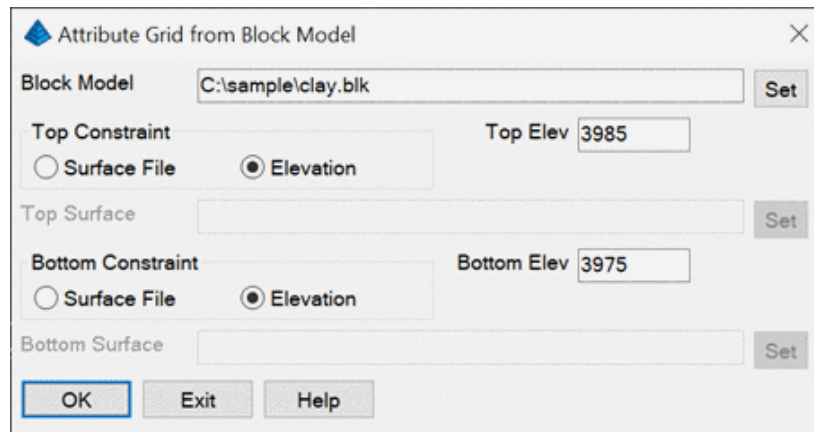

Keyboard Command: crop_blk

Pull-down Menu Location: Block Model

Prerequisite: Block model (blk)

Attribute Grid from Block Model

This command creates strata attribute grids by carving out the attribute data from a block model. The strata attribute grid values are calculated from block model values between a bottom and top constraints. These constraints can be defined either by a grid surface file or a fixed elevation. After selecting the block model to process and the constraints, there is a dialog to choose the attribute to extract and the file name for the attribute grid to create.

Keyboard Command: blk_attr_grd

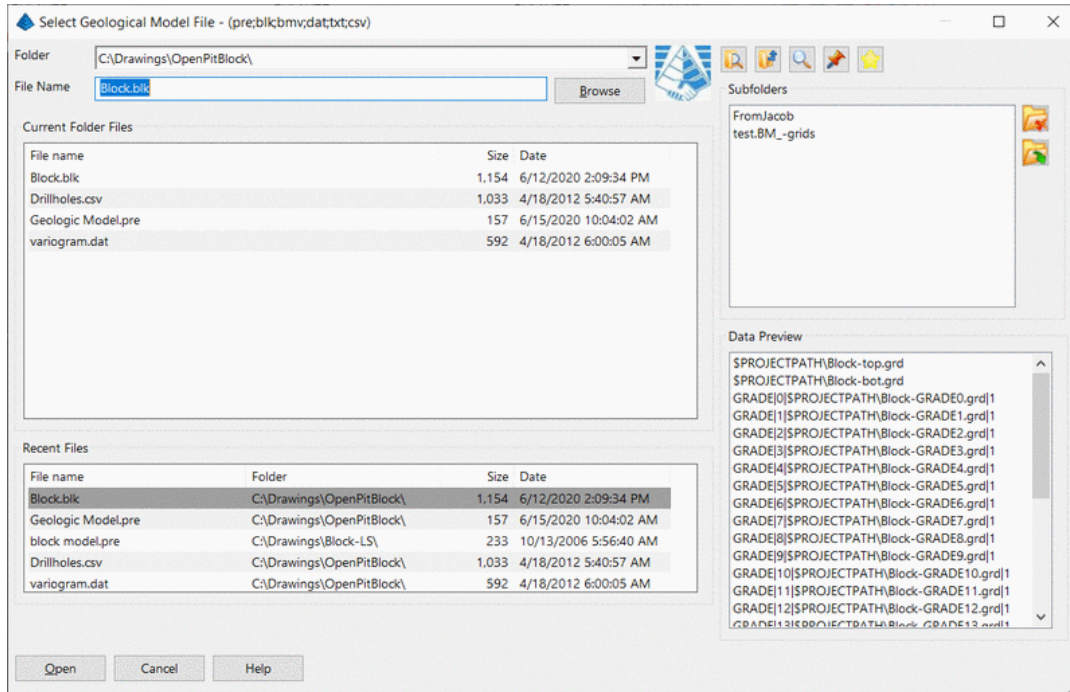

Pull-down Menu Location: Block Model

Prerequisite: Block model (blk)

Prepare Value Block Model

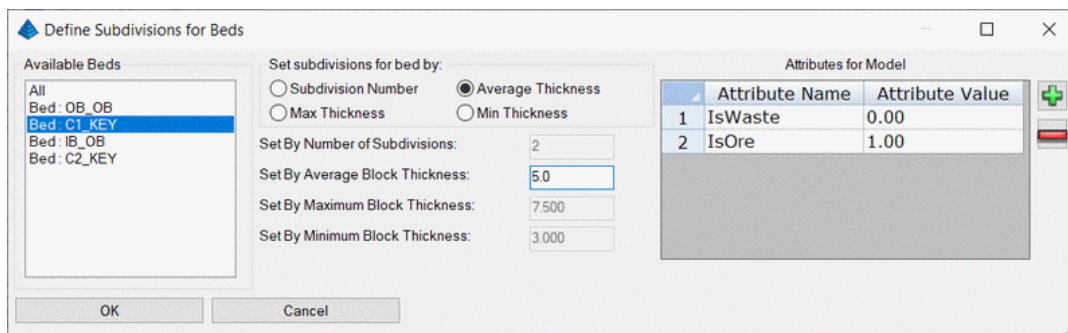

This command creates a block model that represents the economic value of each block. The value block model can be generated from multiple .blk files, a Geologic Model (.pre file), or from an existing .BMV file. The blocks loaded into this command can be modified with user-defined equations to determine the value of each block. The value block model may then be used with the Optimized Pit Design command.

When the command is started, the following dialog will appear.

This command will recognize and use both BLK and PRE files, as well as existing BMV files. To load in .blk files, there should be no gaps between the elevation limits of these block models. The ordering of these files is not important, as they will be sorted automatically according to the elevation limits of each .blk file.

To use a grid based stratified geologic model saved as a .pre file to generate the blocks, select the .PRE file to use. This option will convert a stratified, grid based Geologic Model into a single BMV block model by specifying a number of vertical divisions to apply to each strata/bed. This is basically making a BLK file of each strata/bed in the PRE file. Each seam subdivisions should be set depending on their thickness. This is what determines the block height for each seam. When this option is selected, and the .pre file is chosen, the following dialog will appear.

Available Beds: This column will list all of the strata/beds in the .pre file that are not already defined with a .blk file. Selecting one of these beds allows for defining the subdivisions for that bed. Alternatively, the subdivisions for all beds may be set at once with ALL.

Set Subdivisions for bed by: This option controls how each bed will be vertically subdivided to create a block model. Hit the ENTER button after entering any value, to update the field.

Subdivision Number: This option will subdivide the bed by the number specified. For example, if this value is set to 2, then the resulting block model of the bed will consist of 3 blocks per vertical column. Note that this value must be greater than or equal to 2.

Set By Average Block Thickness: This option will set the number of subdivisions in order to achieve the specified average block thickness. For example, if this value is set to 10, the bed will be subdivided so that the average block thickness of the resulting model will be as close to 10 as possible.

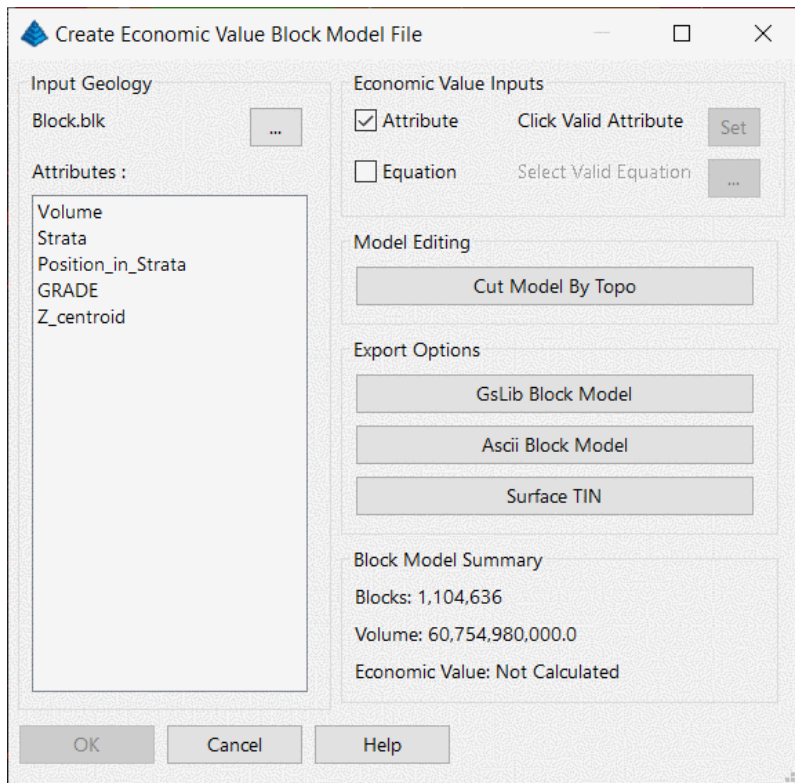

Set By Maximum Block Thickness: This option will set the number of subdivisions in order to achieve the specified maximum block thickness. For example, if this value is set to 10, then the bed will be subdivided so that no blocks in the resulting model have a thickness greater than 10.

Set By Minimum Block Thickness: This option will set the number of subdivisions in order to achieve the specified minimum block thickness. For example, if this value is set to 10, then the bed will be subdivided so that no blocks in the resulting model have a thickness less than 10.

Attributes for Model: This spreadsheet defines new attributes to add to each block in the model, for later use in equations. These attributes can be set to single values, but can be modified when calculating the value of each block later in the command. At least one attribute must be defined for each bed.

Selecting an existing .BMV file. Note that .BMV files are exported from this command, so this option will reload one of these and do additional calculation.

After selecting one of these options, the below dialog will appear.

Any attributes from the input files will be listed on the left side of the dialog. These attributes may be used when writing equations to define the value of each block. Note that when these attributes are referenced, it refers to the value of each block individually - these are not average values for the block model as a whole. In addition to the attributes from input, four additional attributes will always be generated: Z_centroid, Volume, Strata, and Position in Strata.

The Z_centroid attribute is the elevation of each block's centroid. This attribute is useful to calculate the increased mining cost at lower elevations or depths.

The Volume attribute is the volume of each block, as measured in cubic feet or cubic meters.

The Strata attribute is the strata index number. A value of 0 relates to the upper-most strata in the model, a value of 1 relates to the strata below strata 0, etc. If there is just one block model BLK file, then there will be just the one strata index of 0.

The Position in Strata attribute is the block number counted up from the bottom of the model. For example, the lowest block in the bed will be block 1, the next block up will be block 2, etc.

Economic Value Inputs:

Attribute: Click Valid Attribute will set the currently selected/highlighted attribute as the economic value for each block in the value block model. This is an alternative to calculating the block values from a set of equations. Note that this does not modify the input files - you will be prompted to save the updated model as a .BM file after clicking OK.

Define Equations: This option brings up the equation editor (.db3 file). Additional information about this function is provided below.

Model Editing:

Cut Model by Topo: Selecting this option will bring up a dialog to select a grid file. There will be an option to remove blocks found above/below this elevation

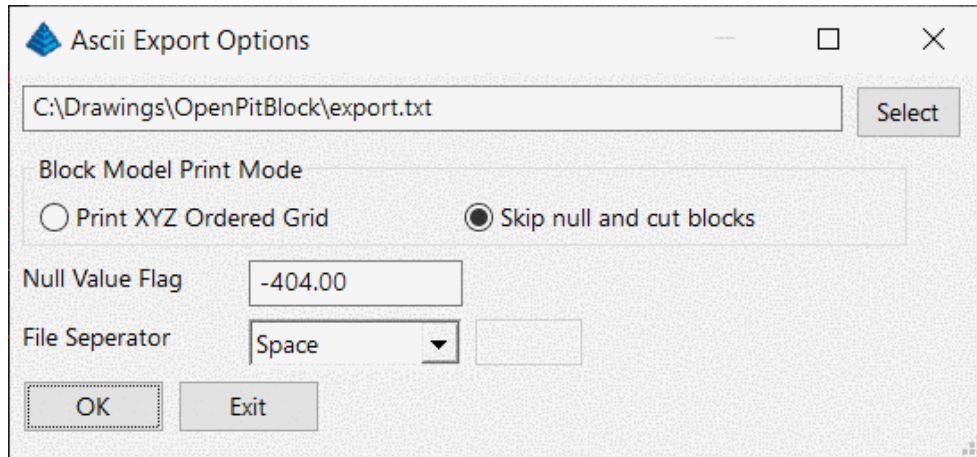

grid.

Export Options:

GsLib File: This button will export the value block model to a .txt file in a GsLib format. Details may be found at www.gslib.com.

ASCII Block Model: This option will output a text file of the block model in xyz format as seen here.

Surface TIN: This button will create a .tin file of the surface of the value block model. Note that this surface will have a block-like appearance and will therefore differ from the original upper limit of the input .blk files.

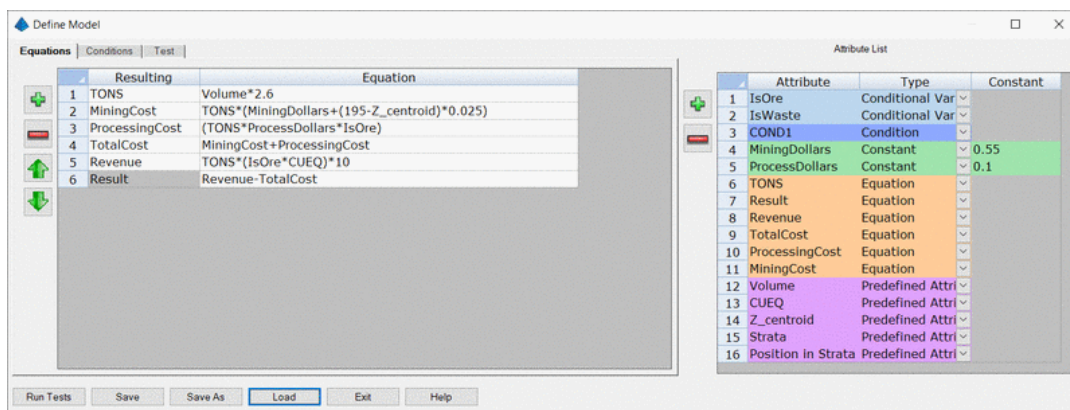

Block Model Summary: These values display basic information about the value block model.

Total Blocks: The total number of blocks in the value block model. Null blocks are not considered in this counter.

Total Volume: The sum of the volume of all blocks in the model.

Total Economic Value: The sum of the economic value of all blocks in the model. This value will not be populated until the equations have been applied to the blocks or until an attribute has been set as the block economic value.

After clicking the Define Equations button, the following dialog will appear. After filling out the tabs with the desired design parameters, save this table to a .db3 file. Choose Exit to return to the previous dialog to calculate the value block model.

The dialog will first appear with only one Equation and Predefined attributes. All other equations, constants, conditions, etc. must be manually added.

Attribute List

The right side of the dialog lists all attributes. Add or remove attributes with the two +/- icons shown to the left of the list. Attributes may be one of five types, with each type showing with a unique color for visual organization.

1. Predefined attributes are attributes that have been found in the input .blk file(s).
2. Equations are attributes that will be calculated when the value block model is created.
3. Constants are attributes that have a non-changing value.
4. Conditions are logical tests that determine which variables to use. For example, a condition may be defined that sets the processing cost for a block based on grade.
5. Conditional Variables are used as a result when Conditions are checked. For example, when setting the processing cost of a block based on grade, the processing cost is the Conditional Variable.

When adding an attribute, the below dialog will appear. This is to assign the attribute a name and set the attribute type, as well as any other relevant options.

Attribute Name	Set Attribute Type	Equation
TONS	Predefined Attribute Equation Constant Condition Conditional Variable	Volume*2.6 Constant Value Condition Expression

Attributes may be renamed by clicking inside the cell of interest and typing a new name. When the name of an attribute is modified, the change will be reflected in the Equations and Conditions tabs on the left side of the dialog. The condition type may be changed by selecting an option from the drop-down menu in the Type column.

Equations Tab

The Equations tab will display all defined equations in a spreadsheet view.

The Resulting Attribute column lists the attribute being calculated by the Equation column. For example, if there is a Resulting Attribute named "Tons", the result of the equation column will be assigned to this "Tons" attribute.

The Equation column is used to write the equation for the attribute being calculated. For example, to calculate the "Tons" for each block, the equation could simply read "Volume*Density". This can be read as "Tons equals Volume multiplied by Density", where Volume and Density are other defined attributes. Equations will be calculated in from top to bottom by row, and therefore equations may reference the results from previously calculated equations. For example, the equation on the row 2 of the equation spreadsheet may reference the result from row 1, but it cannot reference the result from row 3.

The Output to File column controls if the attribute is output to the resulting .bm file. By default, attributes will not be saved to the .bm file. If the .bm file is to be used with the Optimized Pit Design command, only the economic value of each block should be output to the .bm file.

One equation, "Result", will always be defined and output to the .bm file. This equation should always define the value of each block and should always be output to the .bm file.

The below operations and the corresponding symbol are supported in the equation column:

1. Addition "+"
2. Subtraction "-"
3. Multiplication "*"
4. Division "/"
5. Grouping of terms "(" and ")"

Conditions Tab

The conditions tab will display all conditions in a spreadsheet view as shown below.

Condition Name	Condition Expression	True	False	Evaluate Before
1 COND1	Fe>20	COND2 IsWash=,IsOre= None IsWash=0,IsOre=0	None IsWash=0,IsOre=0	Result,Revenue,Process
2 COND2	Al>2.5	None IsOre=,IsWaste= None IsOre=0,IsWaste=0	None IsOre=0,IsWaste=0	Result,Revenue

Condition Name column lists the conditions in the order they were created. These cells are not editable.

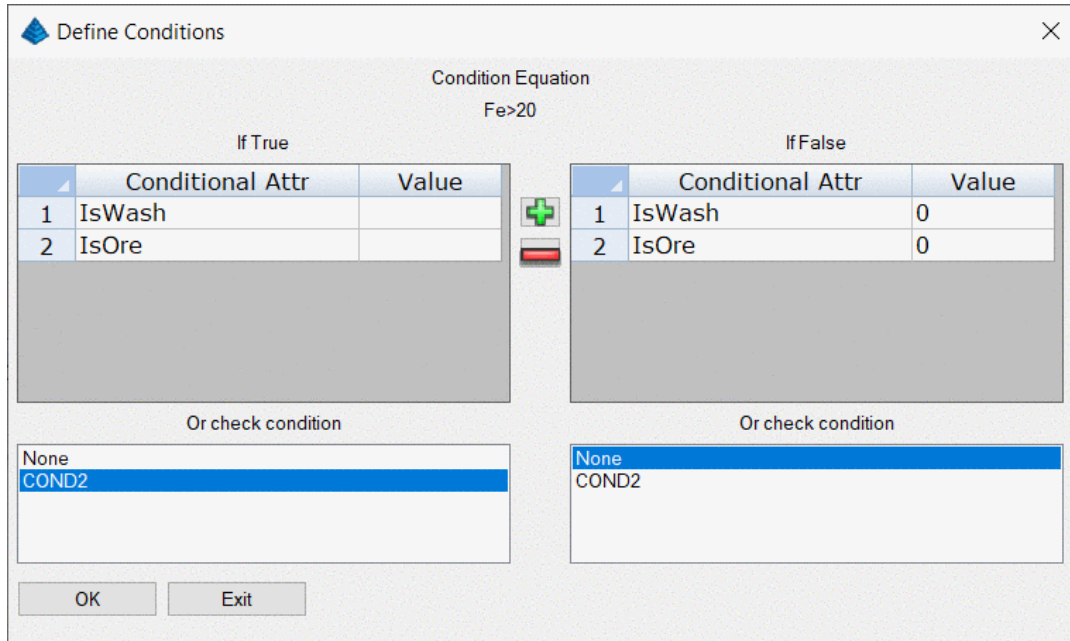

Condition Expression column is the logical test. In the above example, the first logical test checks if the block has an Iron content greater than 20%.

True column lists the actions to take if the logical test is found to be true. At least two actions will be shown, separated by a vertical pipe. The first action tells the program which condition to evaluate next. The second action actually sets values to the Conditional Variables. In the above example, if a block is found to have an Iron content greater than 20%, the program will check Condition #2, but no Conditional Variable values will be assigned based

on this test alone. If Condition #2 is found to be true, the program will not check another condition, but will assign the attributes "IsWash" and "IsOre" values of 1. This is similar to a nested "if" statement.

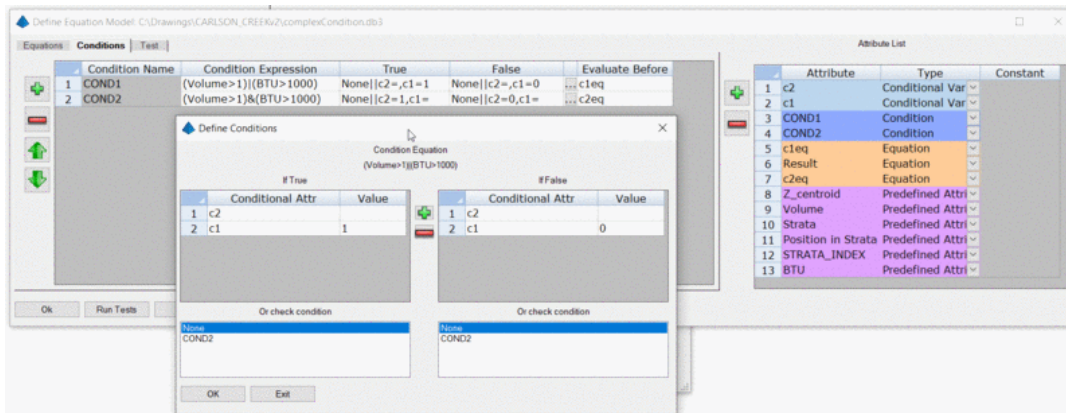

False column lists the action to take if the condition is found to be false. This follows the same format as the True column. In the above example, if a block is found to have an iron content less than or equal to 20%, then no other condition is evaluated and the "IsWash" and "IsOre" conditional variables are assigned a value of 0.

Clicking inside a cell of the True or False columns, or selecting the button next to them will bring up the following dialog.

This dialog sets values for the Conditional Variables based on the logic of the Condition. The two tables list Conditional Variables that will be affected by this Condition (IsWash and IsOre in this case). If the program needs to check another Condition rather than assign values to Conditional Variables as a result of this test, then select the appropriate Condition to check below this Table. Conditional Variables may be added/removed from this list using the appropriate icons between the two tables.

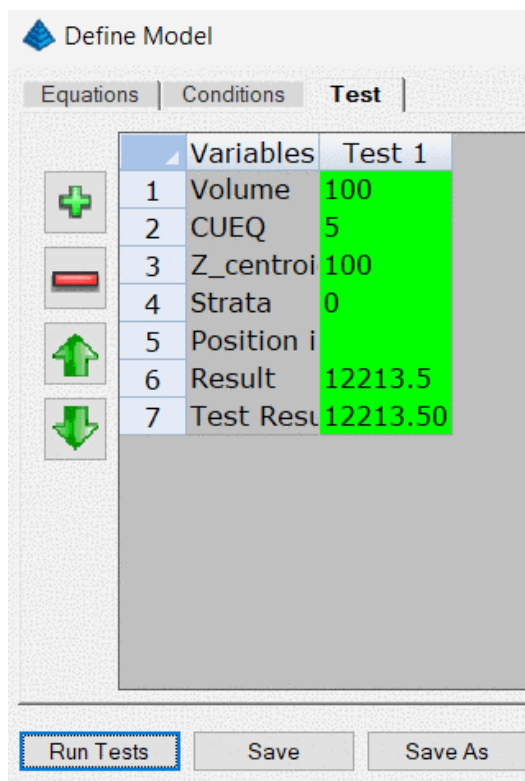

Evaluate Before column lists the equations in which the conditions need to be evaluated before. In the above example, the conditions will be evaluated before the Revenue and Result and Processing Cost equations are calculated. Here is an example of more advanced conditions separated by "and" & and "or" — in the Condition Expression field:

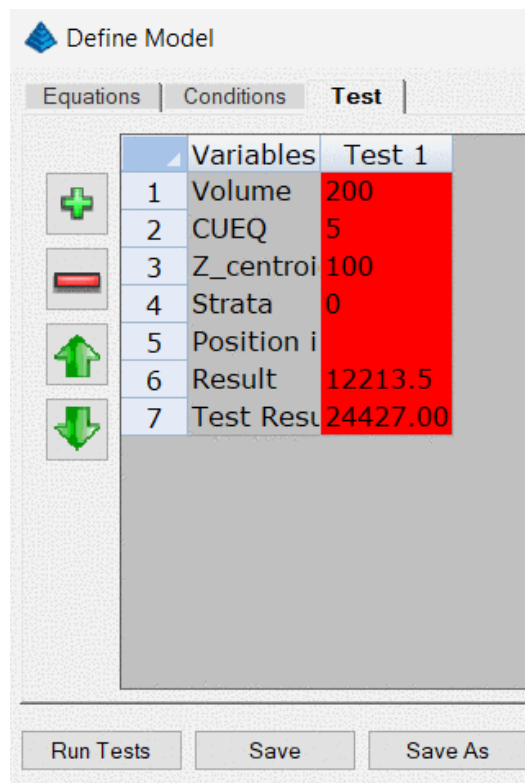

Test Tab

The Test tab displays all defined attributes in a simple spreadsheet. The purpose of this tab is to define example values for each attribute, along with an expected result. Enter in example values and the calculated result, to see if the test of the equations calculates the same result. After defining one or more tests and saving the .db3 file, then click the **Run Tests** button to check the actual RESULT output against the expected, user entered output RESULT. If the Test Result matches the expected result, the cells will be highlighted in green, as shown below. If the values do not match, the cells will be highlighted in red.

Result Passes the Test Result Fails the Test

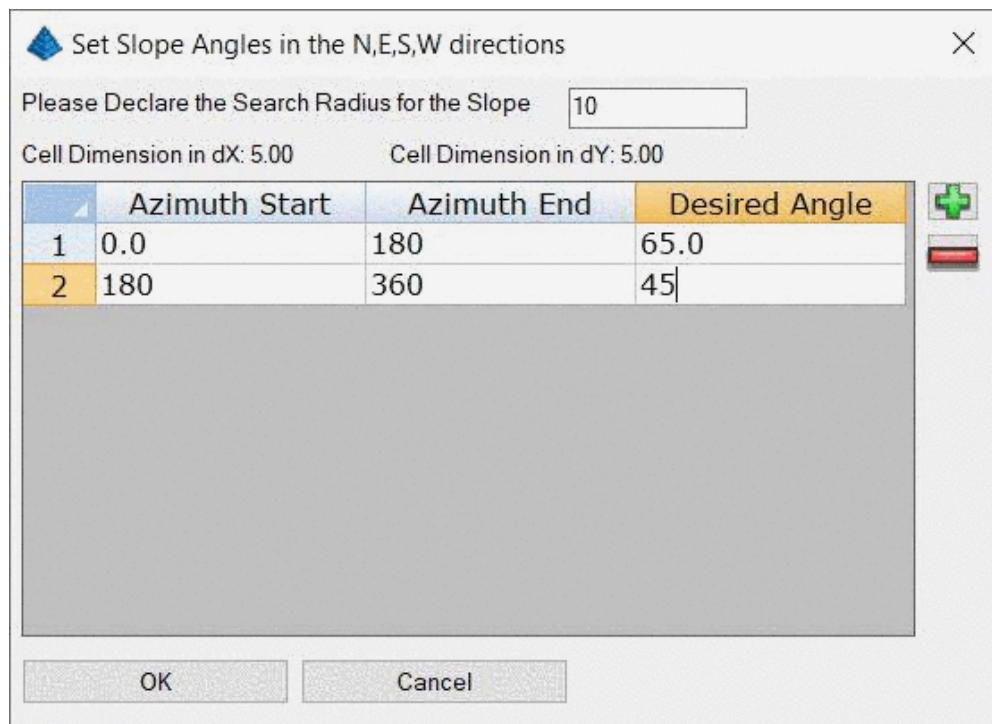

Keyboard Command: mkvalblk **Pull-down Menu Location:** Geology Module > Block Model

Prerequisite: Must have an existing BLK file

Optimized Pit Design

This command uses a max flow algorithm to determine the ultimate mineable economic pit. This is an automated routine with very few prompts. When the command is started, the first prompt is for a value block model (*.BM file). This file is created from the Prepare Value Block Model command which must be run before the Optimized Pit Design to create this file. After selecting the value block model file, the first dialog will then appear to set the slope angles on the various sides of the ultimate pit.

Azimuth and Desired Angle: The Azimuths are defined with 0 to the North, 90 to the East and 180 to the South. The desired slope angles set in the dialog are measured in degrees from the horizontal direction.

After setting these angles, and selecting OK, the program will create a .TIN file of the optimum pit. The surface uses the blocks in full to create the slopes, which can look like benches if the blocks are made at the proper size in the original block model. This TIN file can then be viewed in 3D, contoured, or used to create linework for other pit design routines, such as Design Bench Pit.

The command line displays text after the command stating the monetary value and the volume of the total blocks.

Command: bestpit

The total size is 135x78x62 blocks.

Inserting points...

Inserted 42,120 points

FINISHED with total monetary value of 640,326.91, and a total volume of 410,250.0 cubic units from 3300 Total Blocks

The below image shows a simple block model with the topography file.

The below image shows the same block model with the optimized pit shell .tin file. The TIN file is clipped in the front, to see into the blocks better.

Here is an image of the same block model on a Fence Diagram, with the optimum pit design surfaced drawn as an additional surface. This illustrates the surface combined with the ore, showing the optimum pit in relation to the ore. In this case, the ore is represented by the green and blue blocks, while red and orange is waste.

This image shows a transparent final pit surface in 3D on top of the block model used to calculate it. The irregular appearance of the top of this surface represents the top of the block model itself.

Shown here is another example of multiple optimum pit design TIN files shown with a block model. A fence diagram was also drawn to visualize the pit depth for each design. This was run 3 times, with three different revenue calculations to see the result of the pit at various currency amounts. This command is very easy to run "what if" scenarios with different ore market values to determine the pit design.

The above examples are shown with regular block models. This command can also be used to find the pit design for stratified deposits, such as this dipping coal seam model. The PRE file was used as the input files for Prepare Value Block Model. This will show how deep to follow the dipping seams and still remain profitable. Different revenue amounts may be entered to create different designs showing the mining depth based on varying revenue of the ore. Shown here are geological cross section Fence Diagrams, with the additional surface of the Optimum Pit drawn on top to see the depth to mine to. To the right are the associated pit designs, based on two

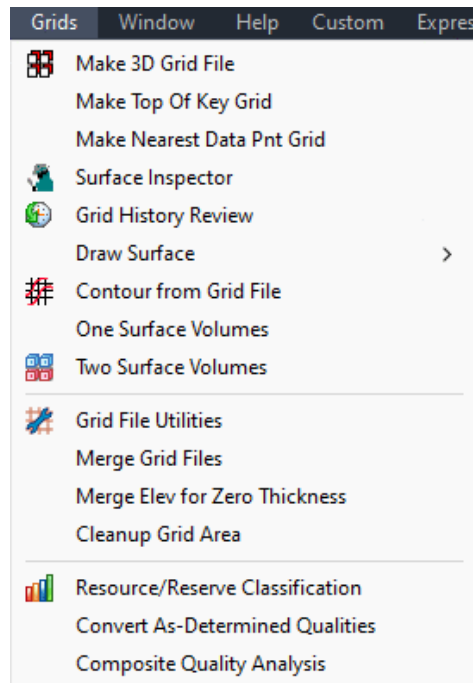

dollar amounts for the coal/ore.

Grids Menu

The Grids menu has commands for creating, editing, and visualizing grid files.

Make 3D Grid File

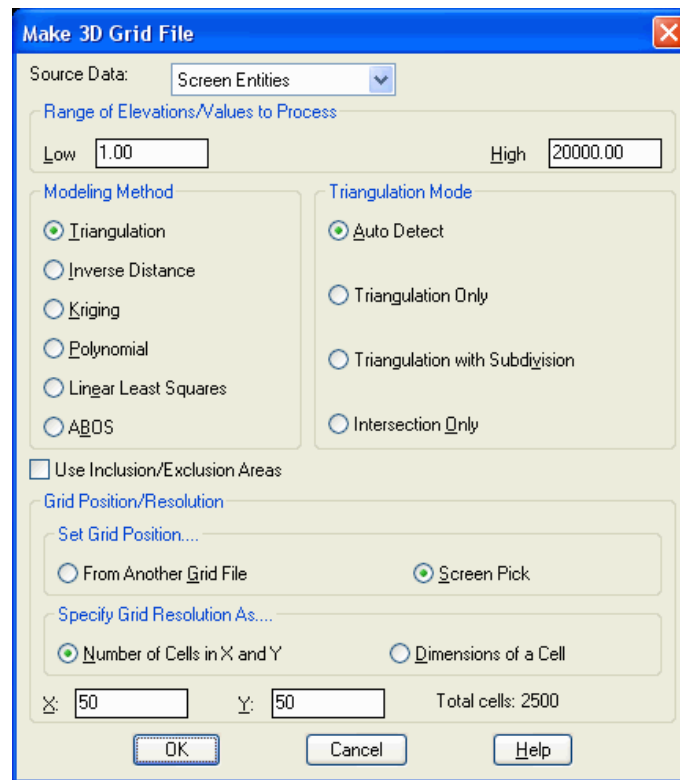

This command creates a grid (.GRD) file which serves as a surface model for use in many of the other Surface routines. The program internally makes a triangular network of the data points (if *Triangulation* is selected as the modeling method) and then interpolates the elevation values of a rectangular grid at the specified grid resolution. Data points can be either points, inserts, lines, or polylines. Lines and polylines are treated as breaklines in the triangulation.

Gridding as a means of modeling surface features is generally less favorable than triangulating as the surface is defined only at the intersection of the grid lines. This can lead to inaccuracies around local features such as ditches or curb lines, since the grid resolution must be small enough to adequately capture the changes in these local regions. Contrast this with Triangulated Networks which carry all this information at every point along the features. Gridding can, however, be useful for modeling large sites in general trends such as watershed analyses and large-scale volume computations.

Grid superimposed over triangulated features

The grid location is specified by first picking a lower left corner and then an upper right corner. The screen cannot be twisted when this is done because grids always run north-south and east-west.

The dialog box sets the range of elevations to process, modeling method and grid resolution. Each of these items is described below.

- **Source Data:** This option selects the type of data to use for gridding. The Screen Entities option processes selected 3D entities from the drawing including points, lines, polylines, 3D faces and inserts. The Coordinate File and Text File options read point data from the selected file. These methods are useful for large datasets that would take extra memory and time to draw as points in the drawing. For the Text File, the program will prompt for the order of the fields and the delimiter. The Triangulation File option will interpolate the grid elevations from the selected triangulation surface.
- **Range of Elevations/Values to Process:** Entities with elevations or values outside the range to process are ignored and will not be used for the gridding.
- **Modeling Method:** The modeling method almost always should be triangulation for surface topographic grid files. Polynomial, inverse distance, kriging and linear least squares apply to random data points for surfaces like underground features, usually sourced by such methods as drillholes, data tables, etc.
- **Triangulation Mode:** When using Triangulation and Polynomial methods, There are four triangulation modes: AutoDetect, Triangulation Only, Intersection with Triangulation and Intersection Only.
 - **Auto Detect** method automatically chooses between the Triangulation Only and Intersection with Triangulation methods. If the selected surface entities are primarily made of polylines, then the Intersection with Triangulation method is used. Otherwise the Triangulation Only method is used.
 - **Triangulation Only** method builds a triangulation surface out of all the selected points, lines and polylines. All lines and polylines are treated as breaklines. Grid node elevations are calculated based on the triangulation.
 - **Triangulation with Subdivision** method uses the subdivisional surfaces modeling method. This option causes each triangle in the triangulation surface model to be subdivided into an average of three smaller triangles per subdivision generation. This gives a much smoother surface model, where instead of one

triangle, there are now three or more.

- **Intersection Only** method goes directly to the Steepest Intersection method using the selected lines and polylines. The Steepest Intersection method is used to assign the grid node elevations from the linework of the triangulation lines and the selected lines and polylines. The triangulation step is skipped and any selected point data is not used. This method can be used for making grids out of polylines such as a contour map as long as the surface is defined just by contour polylines without needing spot elevation points. Skipping the triangulation step makes this method a lot faster especially for large files.
- **Use Inclusion/Exclusion Areas:** This option will prompt for inclusion and/or exclusion perimeter polylines and will only assign grid cell elevations within these areas and leave the rest of the grid cells as Null.
- **Grid Resolution:** The grid resolution is specified by either the number of grid cells or by the size for each grid cell. It is usually best to set the Dimensions of a Cell to a known size, and the program will calculate the "number of cells in X and Y." While the program can handle really large grids with no limit, a general rule of thumb is to keep the total number of grids cells under 500,000 (about 700 by 700 cells) to limit the processing time. The grid location and resolution can also be specified by using the position/resolution from an existing grid file. In this case, the location and resolution of the new grid will match those of the selected grid file which is useful for routines that require two grid files with identical locations and resolutions.

No elevations are calculated on grid cells that extend beyond the extent of the data. The figure shows an example of how the grid is calculated to the limits of the data points. Extrapolation can be used to calculate elevations for the grid cells that are beyond the data limits. When there are grid cells with no elevation in a grid (.GRD) file, many routines will prompt *Extrapolate grid to full grid size?* Extrapolation fills in all the grid cells. The method to extrapolate uses a safe calculation that tends to average out or level the extrapolated values. So extrapolated grid areas are not as accurate as grid areas within the limits of the data. *Grid File Utilities* can be used to apply and save extrapolation to a grid file. The *Plot 3D Grid* command can then draw the grid file so that you can see the extrapolation.

A Carlson grid (.GRD) file has the following format:

Line 1 is the lower left Y coordinate
Line 2 is the lower left X coordinate
Line 3 is the upper right Y coordinate
Line 4 is the upper right X coordinate
Line 5 is the X direction grid resolution
Line 6 is the Y direction grid resolution

The rest of the lines are the Z values of the grid intersects starting from the lower left moving in the left to right direction and ending at the upper right. If the intersect has no value, the letter 'N' is saved instead of the Z value for Null values. An example is shown in the Display-Edit Report dialog.

Cell#	East (x)	North (y)	Elev (
18	4436.21	4639.60	92.58
19	4490.26	4639.60	94.46
20	4544.32	4639.60	94.80
21	4598.38	4639.60	94.62
22	4652.43	4639.60	92.48
69	4436.21	4688.90	92.79
70	4490.26	4688.90	95.29
71	4544.32	4688.90	95.95
72	4598.38	4688.90	96.42
73	4652.43	4688.90	95.46
74	4706.49	4688.90	94.25
119	4382.15	4738.19	89.69
120	4436.21	4738.19	93.14

Gridding from Contour Maps

A grid file can be created from contours represented as polylines with elevation. The program calculates the elevation of each grid corner by looking for contour intersections in eight directions (N, S, E, W, NE, SE, SW, NW) and then interpolating the elevation between the two steepest intersections.

To accurately model the surface, it might be necessary to add entities in addition to the contour polylines. For one, spot elevation points can be added for the high and low points. Otherwise the grid model might plateau at the last contour. Also 3D breaklines need to be added on long narrow ridge and valley contours because in these areas the program will find the same contour when it looks for intersections in the eight directions. When all eight intersections are the same contour, the interpolated grid elevation equals the contour elevation instead of rising up the ridge or dipping in the valley. The 3D breaklines force interpolation along the ridge or valley. To draw these polylines, set the OSNAP to *Nearest* and run the *3D Polyline* command. Then draw the polyline by picking the contour polylines where the breakline crosses them. Another way to quickly create breaklines is to first draw 2D polylines. Then convert these polylines into 3D polylines with the *Screen* option in the *2D to 3D Polyline by Surface Model* command found on the 3Dpoly menu. There is also an automatic way to draw these breaklines. Under 3D Data, use the command: *Create Ridge polylines from Contours*.

Make Top Of Key Grid

This command analyzes the thicknesses of the Key strata in a Geologic Model file and creates a new base of overburden grid based on a minable key thickness entered. It starts at the top Key strata. Anywhere the thickness is less than the value entered, the grid drops down to the top of the next Key strata. This grid can then be added to a mining model Geologic Model file for calculating overburden volumes and for scheduling. Shown below is a cross section example of the grid dropping down when the key thickness falls below the entered thickness value.

Surface Inspector

This command allows you to report and optionally label elevations for selected surface files. You can simultaneously analyze multiple surface files. Surface files can be either triangulation (.flt or .tin) files, grid (.grd) files, or any combination thereof. The following dialog opens when the command is initiated.

Symbol Name sets the symbol name to be plotted. Click **Select** to select the symbol from the symbol library.

Layer Name set the layer to use for the text labels.

Text Size sets the actual size (not scale factor) of the text label placed in the drawing. The **Use MText** controls whether to create the labels as MText or regular Text entities.

Turn the **Draw at Surface Elevation** toggle ON if you want the symbol to be located at the actual elevation of the surface.

The **Extrapolate Grids** option automatically extrapolates any unassigned grid nodes for grid surfaces.

Report Slope displays the slope of the surface along with the elevation.

Report Station/Offset prompts for a centerline and reports the station and offset in addition to the surface elevations.

When there are two surface files, the **Report Elevation Difference** option will add a third report field for the cut/fill between these two surfaces.

Name denotes the name that will be plotted when you label the elevation. The default value is the same as the name of the surface file, but you can change it.

Decimals individually sets the decimal elevation precision for each selected surface.

For **File**, either type in the surface name to use or press the **Select** button to choose the surface file from a browse window.

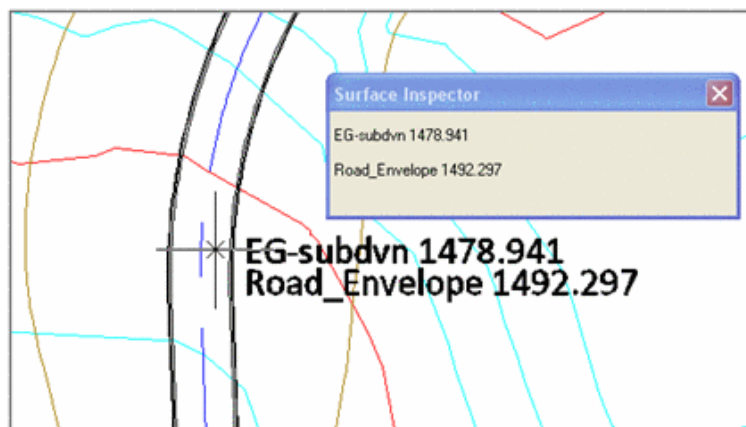

Load Model allows you to select grid files from a list of grids stored in a Geologic or Mining Model file. These files can be created in the Carlson Mining module.

Clear: Clears all values.

Load: Loads a Surface Inspector File (.SIF).

Save: Saves all settings to a Surface Inspector File (.SIF).

After you fill out the dialog box, click OK. Surface Inspector will load the surfaces and begin showing you real-time elevations for each surface as you move the cursor on the screen. If you pick a point or enter coordinates, the elevation will be labeled along with the surface name and selected symbol as shown below.

Pulldown Menu Location: Surface

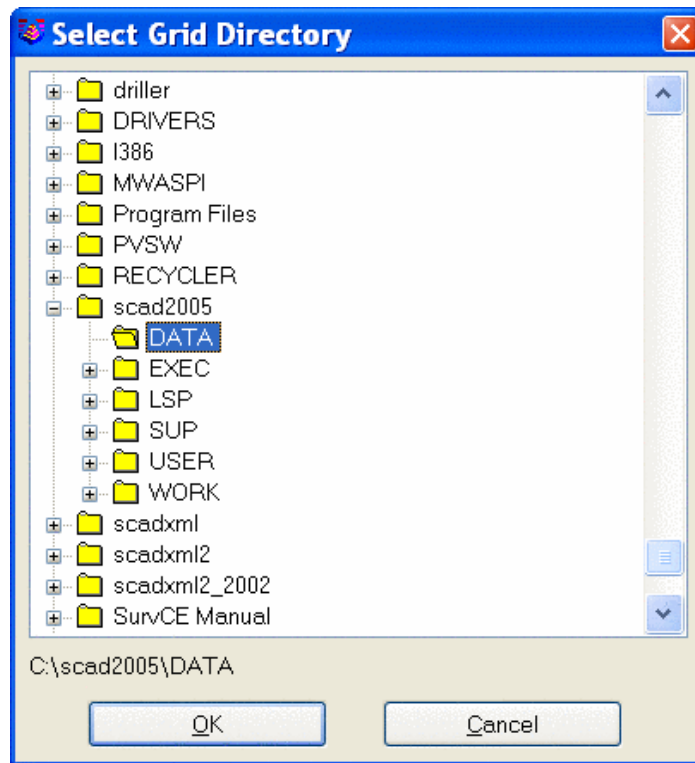

Keyboard Command: surfvals

Prerequisite: Surface Model(s)

Grid History Review

This command will report information on the creation and history of grid files (.GRD) in the selected directory. Such parameters as modeling methods and settings, time and date, grid cell dimensions, file size and even which drillholes used with their values are reported.

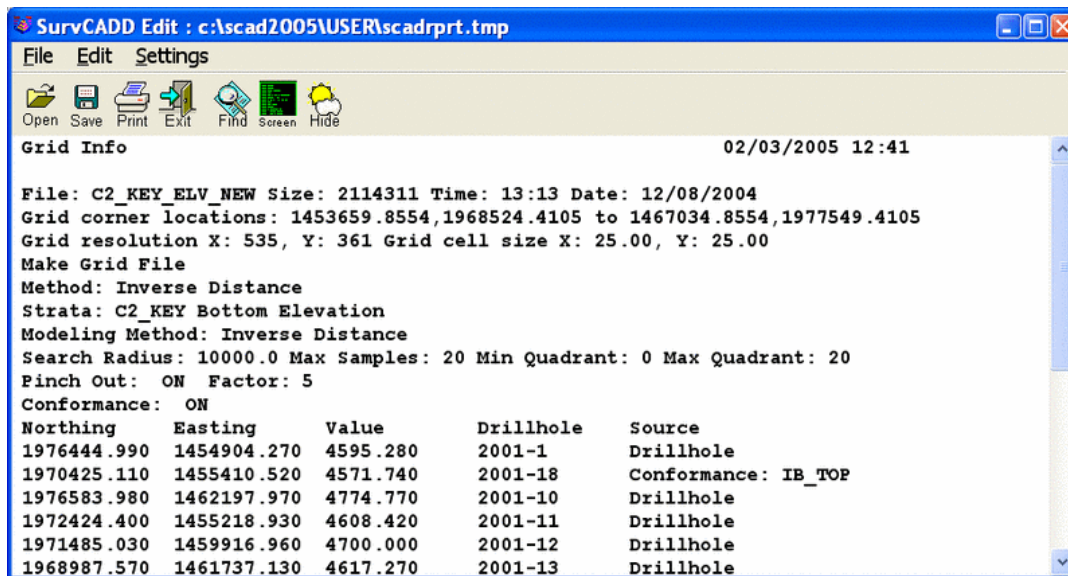

There are no prompts in this routine, only three dialog windows that guide you through this informative command. The first window is where you select the directory containing the grids to analyze. Simply highlight that directory and select OK. The program will read all of the grids in that directory and present them in the Grid History Review window. If there are many grids, this might take a minute or two.

The list of grids shown is sorted alphabetically and displays the name, size, time and date, cell size and modeling method for creation. If the grid was made in a version of SurvCADD from CES (this version is from around 1999) and before, then all the information will show "UNKNOWN".

NAME	SIZE	TIME	DATE	CELL-SIZE	METHOD	
C2_KEY_BTU	2114152	14:05	08/04/2004	25.0	25.0	Inverse Dist
C2_KEY_EL2	2114413	14:05	08/04/2004	25.0	25.0	Inverse Dist
C2_KEY_ELU	2114261	14:05	08/04/2004	25.0	25.0	Inverse Dist
C2_KEY_ELU_NEW	2114311	13:13	12/08/2004	25.0	25.0	GFU
C2_KEY_MOISTUR	1725655	14:05	08/04/2004	25.0	25.0	Inverse Dist
C2_KEY_SUL	1532540	14:05	08/04/2004	25.0	25.0	Inverse Dist
COAL_B1	582220	13:37	02/01/2005	25.0	25.0	Unknown
DL PIT	2054644	20:14	12/08/2004	25.0	25.0	Unknown
FADF	2054054	11:53	12/20/2004	25.0	25.0	Unknown
FADF_1	2054037	11:53	12/20/2004	25.0	25.0	Unknown
FADF_2	2054065	11:53	12/20/2004	25.0	25.0	Unknown
FADF_3	2053984	11:53	12/20/2004	25.0	25.0	Unknown
FADF_4	2053996	11:53	12/20/2004	25.0	25.0	Unknown

Highlight a grid and selecting the info button will bring up the report window showing yet more information of the highlighted grid. This is where the method and settings, strata, and drillholes with their names, locations and values are reported. The report may be edited here, saved to a file, sent to the printer or placed on screen as AutoCAD text.

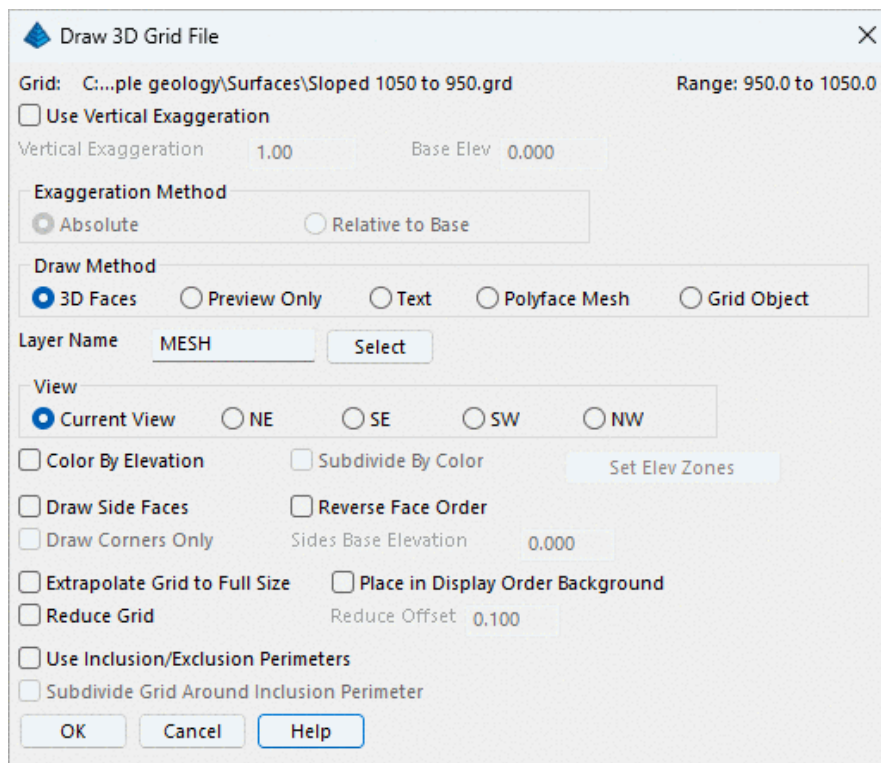

Pulldown Menu Location: StrataCalc
Keyboard Command: grdreview

Draw 3D Grid File

This command draws the 3D grid mesh of the chosen grid (.GRD) file. Each grid cell can be drawn as a Surface Object, 3D Face entities, Polyface mesh, Text or temporary lines. 3D Faces and Polyface Meshes can be viewed/used in the following commands: *3D Viewer Window*, *Viewpoint 3D*, *Hide*, *Shade*, *3D Surface FlyOver*, and *Slope Zone Analysis*.

The Surface Object is a custom object for displaying the grid in the drawing. This custom object also supports the EndPoint snap. The main advantage of the Surface Object is with displaying large grid files because the Surface Object is more efficient than drawing individual 3D Faces. The Surface Object requires Carlson to be loaded to display.

If **Use Vertical Exaggeration** is checked, grid elevations are multiplied by the value specified.

Exaggeration Method specifies whether to use an *Absolute* exaggeration method or *Relative to Base*, which uses the specified base elevation.

Specify the type of entities to draw in **Draw Method**. 3D Faces are described above. The Preview Only option draws the grid using temporary vectors. This method provides a much faster way to view the grid. However these temporary vectors are erased when the viewport is modified. This means as soon as you execute zoom, redraw, regen or plot, this grid will disappear. You can quickly redraw the grid by typing in VG for View Grid at the command prompt. Polyface Mesh is similar to 3D Faces except it is a single entity. The Text option will label the grid elevation at the grid corner. The text is placed center justified over the grid corner. To reduce clutter, there is an option to skip rows and columns.

Specify the layer for the grid entities in **Layer Name**.

Specify the initial viewing direction in **View**.

When **Color by Elevation** is checked, the grid will be colored based on a table of user-defined elevation ranges and the assigned colors. There is also an option to subdivide the grid cells at the color zone transitions, similar to the Elevation Zone Analysis command. Click the Set Elev Zones button to define ranges and colors.

When **Draw Side Faces** is checked, the program will draw vertical faces around the perimeter of the grid. The side faces will be drawn vertically from the grid perimeter to the Sides Base Elevation. You may optionally specify the Sides Base Elevation, it defaults to 0.00.

When checked, **Reverse Face Order** changes the direction of the points for a grid cell from clockwise to counter-clockwise. The order applies to shading the grid cell in 3D render viewers such as the *3D Viewer Window* command. The grid cell will only appear shaded when viewing the grid cell from the clockwise side. Viewing from the other side will show a wire frame. The default is to show the shaded side from the top-down view. This option allows you to draw the grid so that the underside of the grid is shaded.

When checked, **Draw Corners Only** will draw the side lines only at the grid corners. Otherwise side lines are drawn down each perimeter grid cell.

When checked, **Extrapolate Grid to Full Size** draws the entire rectangular surface of the grid.

When **Use Inclusion/Exclusion Perimeters** is checked, it allows you to select inclusion and exclusion areas. Only grid cells inside the inclusion polylines will be drawn. Grid cells inside the exclusion polylines will not be drawn.

When checked, **Subdivide Grid Around Inclusion Perimeter** subdivides grid cells that are partially inside and outside the perimeter into smaller resolution grid cells.

Drawn grid file using inclusion perimeter and side faces option
viewed with Viewpoint 3D

Pulldown Menu Location: Surface >> Draw Surface

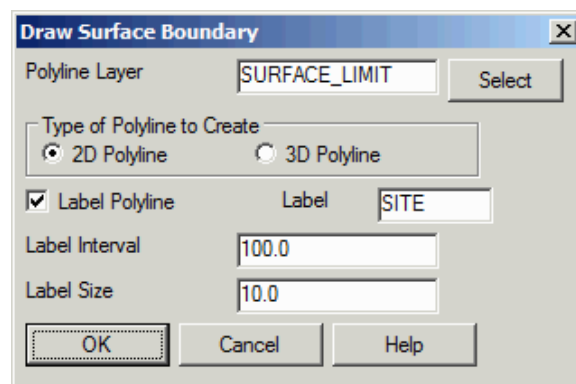

Keyboard Command: plotgrid

Prerequisite: a grid (.GRD) File

Draw Surface Boundary

This command draws the exterior perimeter of a triangulation or grid surface as a polyline. This is a simple way to show the size, shape and location of a surface without adding a lot of drawing entities and file size to the drawing.

The program prompts for the layer of the polyline to create and the type of polyline. A 2D polyline is drawn at zero elevation. A 3D polyline uses the surface elevations. There is an option for Label Polyline which adds text labels along the polyline with the specified name, size and interval. This label can be helpful to identify different surface boundaries.

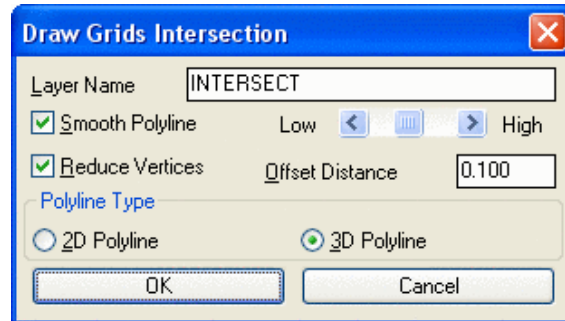

Pulldown Menu Location: Surface >> Draw Surface

Keyboard Command: grdlimit

Prerequisite: a surface file (.GRD, .TIN, .FLT)

Draw Surface Intersection

This command draws a 2D or 3D polyline at the intersection of two surfaces. In addition to this choice, the dialog also allows for the specification of the layer to draw the polylines on, whether or not to smooth them, and whether or not to reduce vertices.

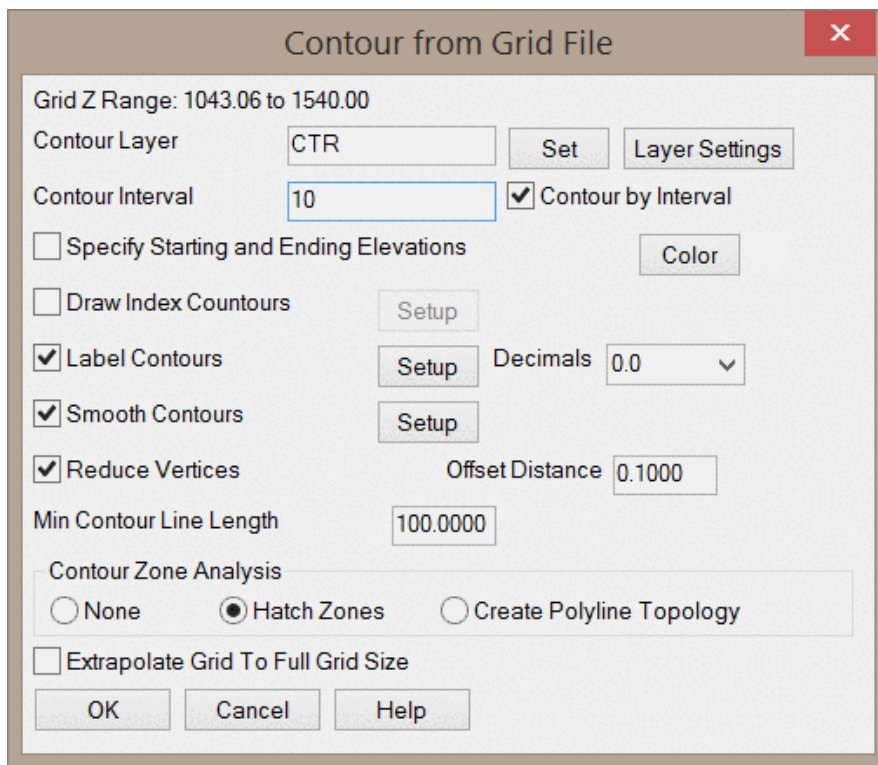

Pulldown Menu Location: Surface >> Draw Surface

Keyboard Command: grdcross

Prerequisite: two surface files (.GRD, .TIN, .FLT)

Contour From Grid File

This command creates contours from a grid file. Contouring from a grid employs a different method than from a triangulation network and generally produces contours that loop more. The grid has data points at a regular interval while the triangulation has edges for every point and breakline in the surface. The smoothness of the contours depends a great deal upon the grid resolution. When the command is executed, you will be prompted to select inclusion/exclusion perimeter polylines to limit the contours to certain areas. If no perimeter polylines are selected, the entire grid will be contoured. After selecting a grid file to contour, the below dialog will appear.

Grid Z Range: This text displays the current range of Z values in the grid file to help you determine the optimal Contour Interval/Values.

Contour Layer: This sets the layer for the contours. You may select an existing layer by clicking the **Set** button.

Layer Settings: This button will open the below dialog, which controls default naming for layers of the various linework.

Default Contour Layer To Grid Name: When enabled, this toggle will automatically set the **Contour Layer** to match the grid name. For example, a grid named "Topo.grd" would default to draw contours on the "Topo" layer. The Prefix and Suffix are combined with the grid name. For example, a grid named "Topo.grd" with a prefix of "Contour" would create a layer of "Contour.Topo".

Prefix Hatch Layers With Contour Layer: When enabled, this toggle will use the **Contour Layer** as a prefix for all of the hatch layers. For example, if the first hatch zone is set to be drawn on the "Zone 1" layer and the Contour Layer is set to "CTR", the actual layer name of the hatch will be "CTR Zone 1".

Set Index/Label Layers by Contour Layer: When enabled, this option will automatically set the **Index Layer** and the **Text Layer** to be the same as the **Contour Layer**. However, you may also specify a prefix or suffix for each layer. For example, if the Contour Layer is set to "CTR" and the Index Layer Suffix is set to " Index", then the index contours will be drawn on the "CTR Index" layer. It is important to note that this option only sets these layer names when the command is first executed or when the above dialog is opened, meaning that you may still override these layer names if you wish.

Contour Interval/Values: This value is dependent on the **Contour by Interval** toggle.

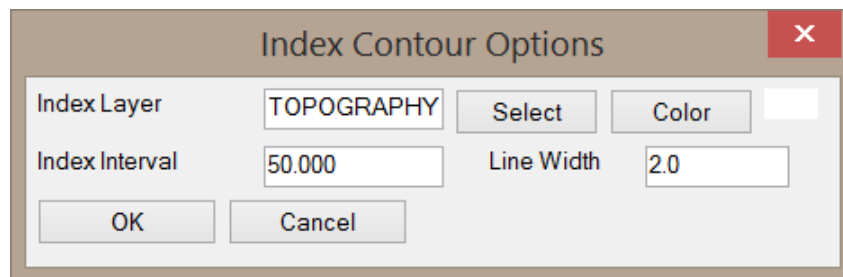

When the toggle is enabled, this value will set the interval for the contours. For example a value of 2 will draw contours along the grid values of 2, 4, 6, 8, etc. The first value contoured will be the first value divisible by that contour value. For example, if an interval of 3 is selected for a grid that ranges from 5 to 20, the first contour will be drawn at a value of 6.

When the toggle is disabled, this value(s) will set the specific value(s) to contour. For example, if a value of 10 is selected, only one contour will be drawn where the grid has a value of 10. Multiple contours may be drawn by entering values separated by spaces. For example, entering "10 12 16" into this text box will draw contours at values of 10, 12, and 16.

Specify Starting and Ending Elevations: When enabled, this toggle will prompt you to enter the starting and ending values to contour. For example, if the grid ranges in values from 0 to 100, you can use this option to only draw contours for values ranging from 30 to 60.

Color: This button will open the color palette, where you can select the color for the contours. Please note that this does not set the color of index contours.

Draw Index Contours: When enabled, this option will draw some contours differently than the main contours. You can control the setup of the index contours by clicking the **Setup** button to the right of this toggle. When clicked, the below dialog will appear.

Index Layer: This sets the layer for the index contours. You may select an existing layer by clicking the **Select** button.

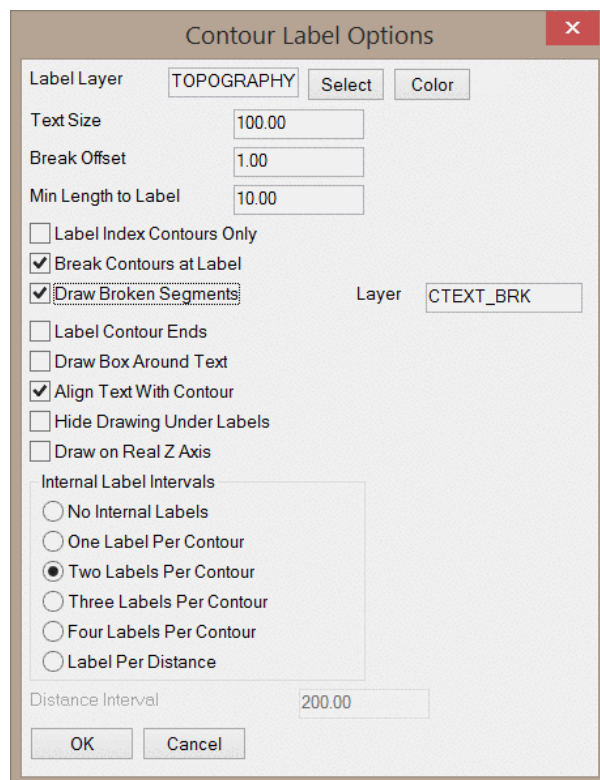

Color: This button will open the color palette, where you can select the color for the index contours. Please note that this does not set the color of non-index contours.

Index Interval: This value sets the interval of the index contours. This value will default to be the **Contour Interval** multiplied by 5.

Line Width: This value sets the width of the index contours. The non-index contours will have a line

width of 0 by default.

Label Contour Lines: When enabled, this toggle will add labels to the contours. The number of decimals in the labels is controlled by the **Decimals** dropdown list. You can control the setup of the labels by clicking the Setup button to the right of this toggle. When clicked, the below dialog will appear.

Label Layer: This sets the layer for the labels. You may select an existing layer by clicking the **Select** button.

Color: This button will open the color palette, where you can select the color for the index contours. Please note that this does not set the color of non-index contours.

Text Size: This value sets the height of the text in drawing units.

Break Offset: This value sets the distance between the end of the trimmed contour and the start/end of the text. This value is only used when the **Break Contours at Label** toggle is enabled.

Min Length to Label: This value sets the minimum length of contours to be labeled. For example, if this value is set to 10, a contour with a length of 5 will not be labeled.

Label Index Contours Only: When enabled, this toggle will only add labels to index contours.

Use MText: Sets whether to create the labels as Text or MText entities.

Break Contours at Label: When enabled, this toggle will break the contour line near the label, making it easier to read the labels.

Draw Broken Segments: When enabled, this toggle will draw the broken segments of the contour (the por-

tion of the contour under the labels). These segments will be drawn on the layer specified to the right of this toggle.

Label Contour Ends: When enabled, this toggle will draw additional labels at the ends of contours. This option will not draw additional labels on contours draw as closed polylines.

Draw Box Around Text: When enabled, this toggle will draw a box around the text labels.

Align Text with Contour: When enabled, this toggle will align the label with the contour itself. When disabled, labels will be aligned horizontally.

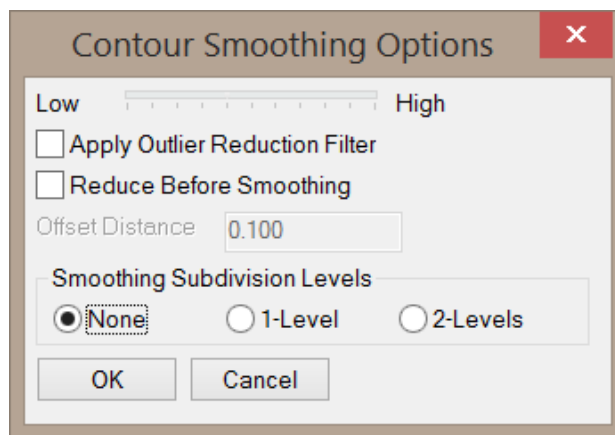

Hide Drawing Under Labels: When enabled, a WIPEOUT entity will be draw around the labels, hiding the contour and any other linework underneath it. This option has the same visual effect as breaking the contour at the label, but allows you to retain a continuous contour.

Draw on Real Z Axis: When enabled, labels will be drawn at the same elevation as the contour. When disabled, labels will be drawn at zero elevation.

--- **Labels Per Contour:** These radio buttons set the number of labels to draw on each contour.

Label Per Distance: This radio button will draw a contour label on a regular interval along the contour, set by the **Distance Interval** value.

Smooth Contours: When enabled, the contours will be smoothed to reduce sharp edges. You can control the smoothing options by clicking the **Setup** button to the right of this toggle. When clicked, the below dialog will appear.

Low-High Slider Bar: This slider bar controls the degree of smoothing. This is based on Bezier smoothing, which holds all the original points calculated from the grid and only smooths between the calculated points.

Apply Outlier Reduction Filter: When enabled, this toggle will remove spikes in the contours that don't follow the general trend direction.

Reduce Before Smoothing: When enabled, this toggle will apply the Reduce Vertices function to the contours before smoothing. The **Offset Distance** is the maximum distance the contour is allowed to move when removing vertices.

Smoothing Subdivision Levels: This option will internally subdivide the grid cells with a quadratic smoothing algorithm to help create smoother contours.

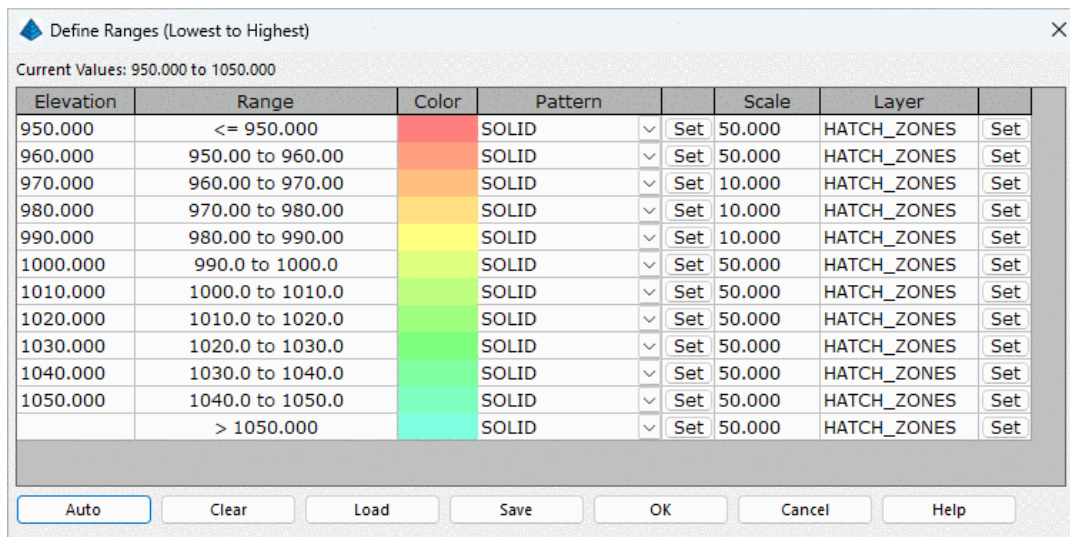

Reduce Vertices: When enabled, this toggle will apply the Reduce Vertices function to the contours. The **Offset Distance** is the maximum distance the contour is allowed to move when removing vertices.

Min Contour Line Length: This values sets the minimum length required for contours to be drawn. For example, if this value is set to 100, a contour with a length of 50 will not be drawn. This filter helps to prevent drawing relatively insignificant contours.

Contour Zone Analysis: This option controls how the contour zones will be drawn. A zone is simply the space between two contour lines.

None: The contour zone boundaries will not be drawn. Only the contours themselves will be drawn.

Hatch Zones: This option will draw the contour zone boundaries and hatch them according to the below dialog. When this option is selected, you will be prompted to pick a location to draw a legend. It is recommended that you select an inclusion boundary when using this option even if you are contouring the entire grid.

The above dialog controls the appearance of the hatch zones. A description of each column is given below. Note that you may need to scroll down to other pages to view all of the contour zones.

Elevation: Sets the maximum contour value for the zone.

Range: Displays the range of values included in the zone.

Color: Sets the hatch color for the zone.

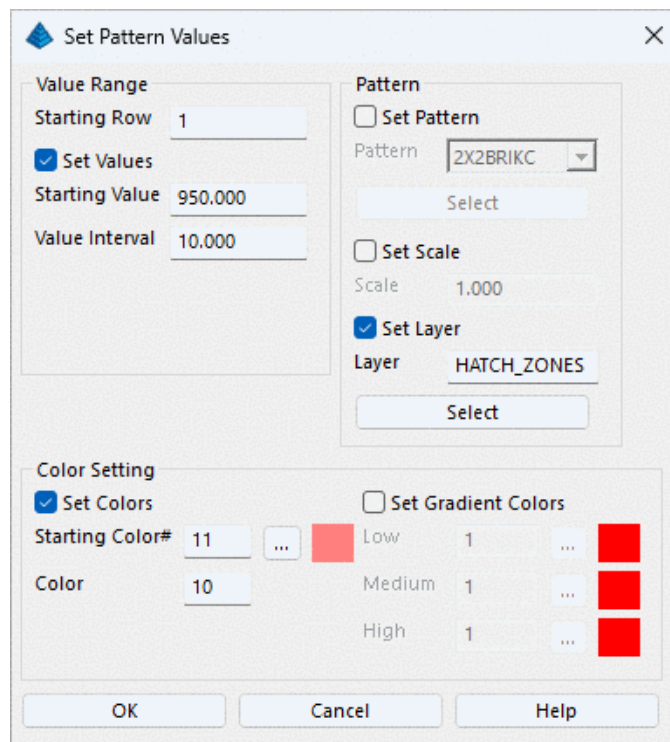

Pattern: Sets the hatch pattern for the zone.

Scale: Sets the hatch pattern scale for the zone.

Layer: Sets the layer for the hatch pattern.

Clear: This button will clear all settings in the dialog.

Auto: This button will display the below dialog, which will let you automatically populate each hatch zone with various properties.

Starting Zone: This value sets the first zone to be modified. If this value is set to 1, all zones in the dialog will be modified. You can toggle the various options on this dialog to only modify certain properties of each zone, however.

Set Values: When enabled, the values of each zone will be modified. The **Starting Value** sets the value of the first zone selected. That value will increment by the **Value Interval** value.

Set Colors: When enabled, the colors of each zone will be modified. There are two ways to set the colors of the zones, controlled by the **Set Gradient Colors** option.

When **Set Gradient Colors** is disabled, the colors for each zone will be defined by a **Starting Color #** and a **Color Increment**. The Starting Color # relates to a color in the CAD color palette. The Color Increment sets the color for the next zone. For example, if the Starting Color # is 10 and the Color Increment is 2, the second contour zone will use color 12. The default values of 10 and 10 will create a rainbow color gradient. Similarly, a Starting Color # of 11 and a Color Increment of 10 will produce a lighter shade of the rainbow gradient. It can be difficult to create other color gradients with this system, but the other method of setting color allows for easier selection of other gradients.

When **Set Gradient Colors** is enabled, you will be able to set color gradients by selecting a **Low**, **Medium**, and **High** color value. All intermediate colors will be selected automatically. It should be noted that this command can only use the colors from the CAD color palette, which includes 255 colors. As a result, attempting to use this option with a large number of hatch zones may result in some hatch zones using the same color.

Set Pattern: When enabled, the pattern for each zone will be set to the selected hatch pattern.

Set Scale: When enabled, the hatch pattern scale for each zone will be set to the **Scale** value.

Set Layer: When enabled, the layer for each zone will be set to the **Layer** value. You may select an existing layer by clicking the **Select** button.

Create Polyline Topology: This option will draw the contour zone boundaries, but will not hatch them. This option will add an extra label in the zone boundary to indicate the range of grid values in that zone. This can

be useful for GIS applications in other modules.

Extrapolate Grid to Full Grid Size: This option will extend the contour lines to the rectangular limits of the grid when values are left as null. Note that this will not modify the grid file itself.

Prompts

Select the Inclusion perimeter polylines or ENTER for none.

Select objects: *pick a closed polyline for the contour boundary if any*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *pick a closed polyline for the area to exclude*

Setting color ranges using "Hatch Zones" option

Pulldown Menu Location: Surface >> Contour from...

Keyboard Command: cntgrd

Prerequisite: A grid file

One Surface Volumes

This command calculates the cut and fill volumes between the surface modeled by one grid (.GRD) file and a constant elevation or value. This is the same as *Two Grid Surface Volumes* except that the second surface is a flat plane at a constant elevation instead of a 3D grid surface. Please refer to that section for additional details. If the grid contains grid cells that have no elevations, you have the option to extrapolate elevations from the grid cells with elevations. When you choose not to extrapolate, no volume is calculated for these grid cells. There are also options

to specify inclusion and exclusion areas. When inclusion areas are specified, only the volume within this inclusion area is calculated. Volumes within an exclusion area are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to using this command.

Note: the volume comparison of this routine uses the selected grid file as the *base* surface, and the target elevation plane as the *final* surface, so be aware that if your target elevation is set primarily below the surface defined by the grid file, it will report as cut, when in reality you may be filling above the target elevation plane to reach the defined surface.

Prompts

Select the Inclusion perimeter polylines or ENTER for none:

Select objects: *press Enter*

Select the Exclusion perimeter polylines or ENTER for none:

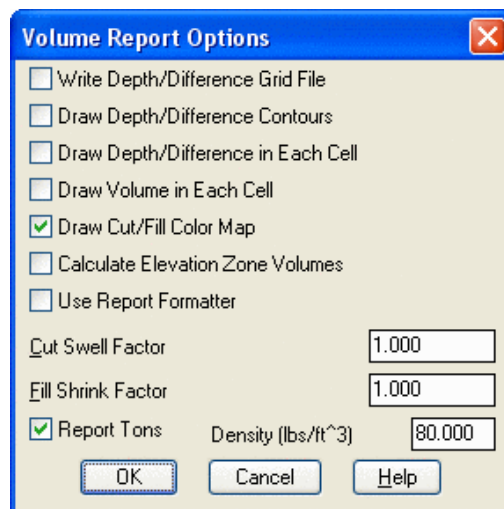

Select objects: *press Enter*

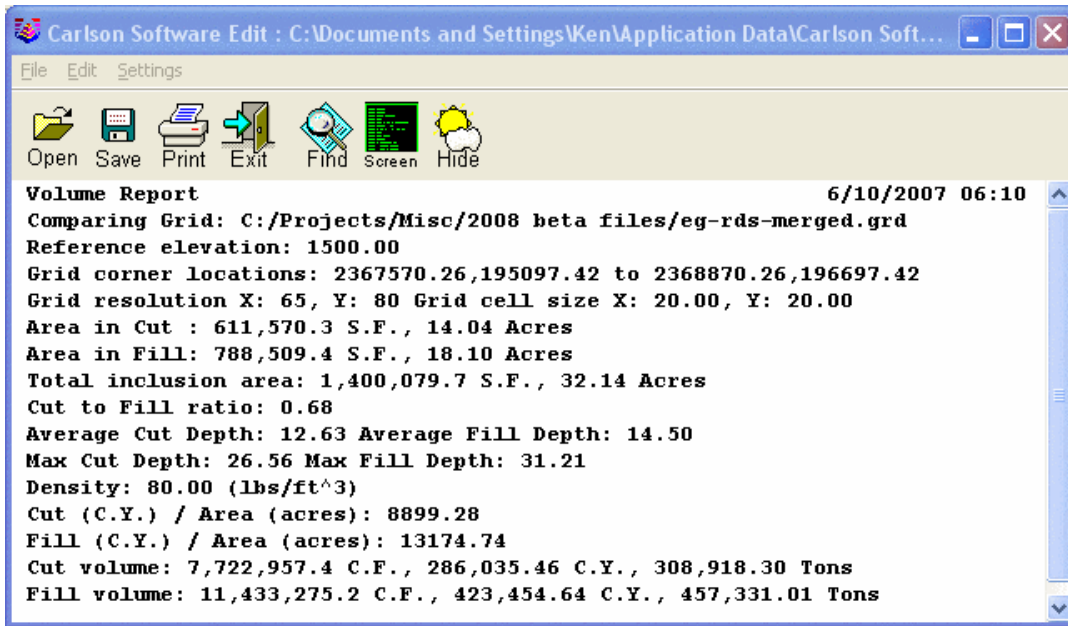

Specify Grid File Selection Dialog Choose a grid (.GRD) file to process.

Extrapolate grid to full grid size (Yes/<No>)? *press Enter* If you enter Yes to this prompt, surface elevations will be computed for any grid cells that have null elevations.

Enter the base elevation: *1500* This defines the second surface.

Volume Report Options Dialog

Pulldown Menu Location: Surface >> Volumes By Grid Surfaces

Keyboard Command: volcalc1

Prerequisite: A grid (.GRD) file

Two Surface Volumes

Two Grid Surface Volumes calculates the cut and fill volumes between two surfaces modeled by grid (.GRD) files. These two grid files must have the same location and resolution. To create the grid files, use the *Make 3D Grid File* routine. When creating the second grid file, choose *Use position of another file* and select the first grid file. Using the position of the first grid file sets the location and resolution of second grid to match the first.

There are several other routines that calculate volumes based on grid files. Grid based volumes can be calculated by *One Grid Surface Volumes*, *Volumes by Layer*, *Stockpile Volumes*, and *Pond/Pit Volumes*. These routines have special prompting and calculate the grid surfaces and volume in one step.

Volumes by Two Surface Volumes has three steps:

1. Creating the first grid file with *Make 3D Grid File*
2. Creating the second grid file with *Make 3D Grid File*
3. Running *Two Grid Surface Volumes*

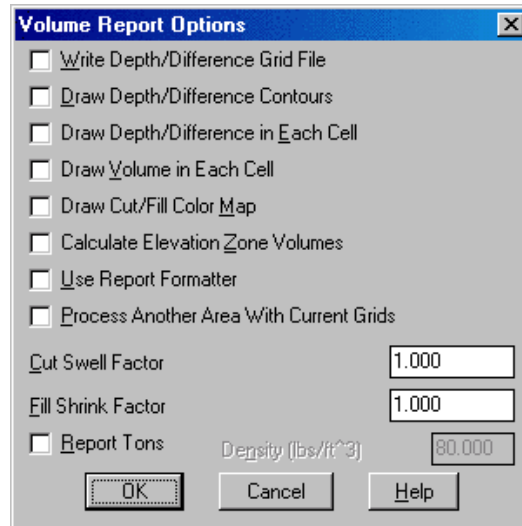

One advantage to this command is that you have more output options to help analyze volumes.

Besides grid based volumes, volumes can also be calculated between triangulation surfaces using the *Volumes by Triangulation* commands. Cross section end area is another volume method that is used by the *Calculate Sections Volume* command in the Civil Design module.

There are also options to specify inclusion and exclusion areas. When inclusion areas are specified, only the volume within this inclusion area is calculated. **Important:** Whenever possible you should use a polyline that represents the limits of disturbed area as the inclusion perimeter. Volumes within an exclusion area are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to calling this routine.

If the grid contains grid cells that have no elevations, you have the option to extrapolate elevations from the grid cells with elevations. When you choose not to extrapolate, no volume is calculated for the grid cells left without elevations. In general, extrapolation is not very accurate and should be avoided whenever possible. Sometimes you may get small amounts of cut in stockpiles that should only be fill, or small amounts of fill in pits that should only

be cut. These extraneous quantities are due to extrapolation at the border and should be small enough to be ignored. When inclusion or exclusion polylines are used, the program will automatically extrapolate the grids. In addition to writing a volume report to the file, printer or screen, there are several volume report options.

Write Difference Grid File creates a grid (.GRD) file of the elevation difference of the two grid files.

Draw Difference Contours creates a contour map of the difference or depth between the two grid files.

Draw Elevation Difference in Each Cell plots the elevation difference at the grid corners which is the same as the Elevation Difference routine.

Draw Volume in Each Cell plots the calculated volume for each grid cell and is an excellent way to verify the volume calculation. If a cell contains both cut and fill, both values will be plotted.

Calculate Elevation Zone Volumes calculates the cut and fill between different elevation ranges.

Draw Cut/Fill Color Map fills each grid cell with different shades based on the average cut or fill in the cell. Red shades are used for cut and blue for fill. There is an option to draw a color legend. You can subdivide the grid cells at zone transitions. Also, there is an option to control the zone intervals and range.

Use Report Formatter allows you to customize the report by choosing the fields to report and their order. Also the report formatter can be used to output the report data to Microsoft® Excel or Microsoft® Access.

Process Another Area with Current Grids runs Two Surface Volumes again using the same grid files but different inclusion/exclusion polylines. This option saves the step of reloading the grid files to calculate volumes from the same grids for multiple areas.

The **Cut Swell Factor** value is multiplied by the cut volume in the report.

The **Fill Swell Factor** value is multiplied by the fill volume in the report.

Report Tons allows you to enter the material density and the program will report the cut and fill tons in addition to volume.

Given two accurate grid (.GRD) files, this routine will calculate accurate volumes. To verify the volume calculation, it is a good idea to check the grid (.GRD) files either by drawing them with *Draw Surface >> Draw 3D Grid File* and viewing them with *the 3D Viewer* or by contouring the grids with the *Contour Grid File* command.

Existing surface

Final surface contours with a closed polyline

Contours from the Draw Depth/Difference Contours option. Cut contours are red, fill contours are blue, daylight contours are green. This is a good way to check that both surfaces are modeled correctly and to verify the volumes.

Sample Two Surface Volumes report:

This shows a grid drawn by *Plot 3D Grid File* and volume values drawn by the Draw Volume in Each Cell option of the Two Surface Volumes routine. Cut appears as negative and fill as positive. Notice that cells bordering cut and fill regions contain a little of both.

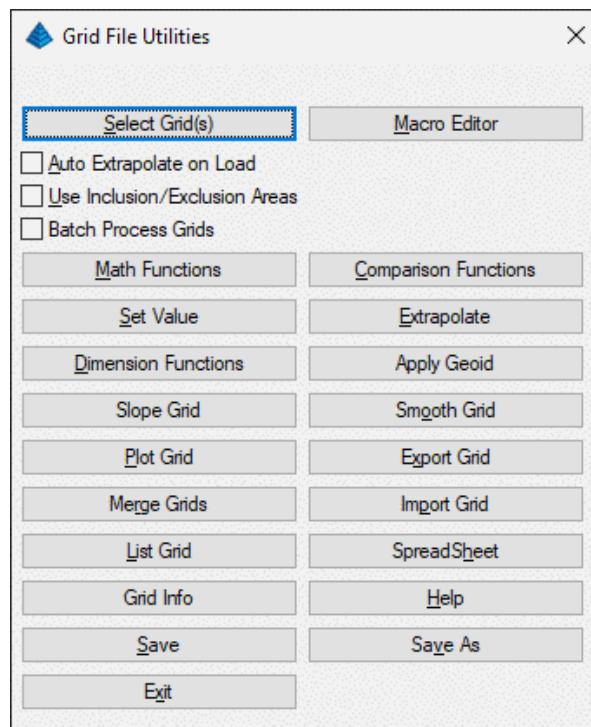

Pulldown Menu Location: Surface >> Volumes By Grid Surfaces

Keyboard Command: volcalc2

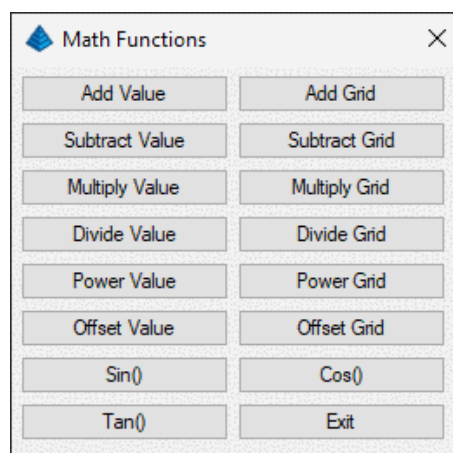

Prerequisite: Two grid files

Grid File Utilities

This command is used to modify and create grid files. The modifications can be done manually on a single grid, on multiple grids in a batch mode, or saved and rerun using the grid macros created with the macro editor. To modify manually, start by picking the Select Grid(s) button. There is an option to use inclusion and exclusion polylines to only modify the grid within/outside these perimeters. With this option active, the program will prompt for inclusion and exclusion polylines when a function is selected. Only grid cells inside the inclusion polylines will be modified. Grid cells inside the exclusion polylines will not be modified. If no inclusion and exclusion polylines are selected, then the entire grid will be modified. Each function is described below.

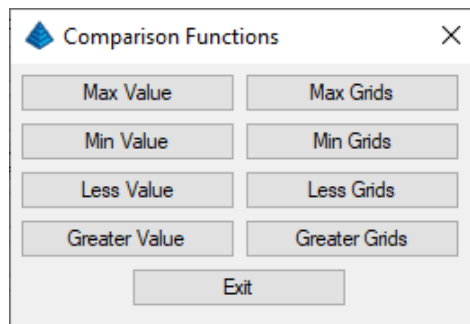

- **Select Grid(s):** This is the first step to load a grid. Usually a grid needs to be loaded before running a function. If Batch Process Grids is turned on, then multiple grids may be selected while holding down the Shift or CTRL buttons.
- **Auto Extrapolate On Load:** This will extrapolate values for any null or empty values in the grid as the grid is loaded.
- **Use Inclusion/Exclusion Areas:** If this is turned on, then the GFU function will only be applied within the selected inclusion polyline and outside the selected exclusion polyline.
- **Batch Process Grids:** When this option is turned on, GFU functions can be executed on many grids at once. It is recommended to move the grids to a backup directory, or create a copy of them, as the grids are over-written with the same name. The functions that cannot be batched are: Plot Grid, Merge Grid, List Grid, Import Grid, and Spreadsheet.
- **Math Functions:**

- **Add Value:** Adds an entered value to the grid values. (GridA + X)
- **Add Grid:** Adds one grid to another grid. (GridA + GridB)
- **Subtract Value:** Subtracts an entered value from the grid values. (GridA - X)
- **Subtract Grid:** Subtracts one grid from another grid. (GridA - GridB)
- **Multiply Value:** Multiplies the grid values by an entered value. (GridA * X)
- **Multiply Grid:** Multiplies the grid values by another grid. (GridA * GridB)
- **Divide Value:** Divides the grid values by an entered value. (GridA / X)
- **Divide Grid:** Divides the grid values by another grid. (GridA / GridB)
- **Power Value:** Raises the grid values to the specified power. (GridA ^X)
- **Power Grid:** Raises the grid values to another grid for the "power". (GridA ^GridB)
- **Offset Value:** Offsets the grid elevations perpendicular to the grid surface. Use a negative value to offset down.
- **Tan(), Sin() and Cos():** Applies these functions to the grid values which need to be in decimal degrees. (tan(GridA), sin(GridA), cos(GridA))

- **Comparison Functions:**

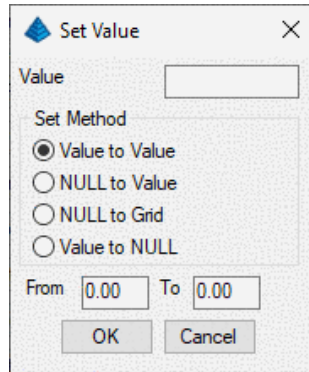

- **Max Value:** Compares a grid and a value and takes the Maximum value of either. This is a way to stop a grid from going negative, below zero.
- **Max Grids:** Compares a grid with another grid and takes the Maximum (higher) value of either.
- **Min Value:** Compares a grid and a value and takes the Minimum value of either. This is a good way to cap a grid off at a certain value so it never goes higher than the specified value.
- **Min Grids:** Compares a grid with another grid and takes the Minimum (lesser) value of either.
- **Less Value:** Asks for a value to compare and a value to assign and uses the following logic:
If GridA < compare_value then GridA = assign_value, otherwise no change
- **Less Grids:** Asks for a grid to compare and a grid to assign and uses the following logic:
If GridA < compare_GridB then GridA = GridC, otherwise no change
- **Greater Value:** Asks for a value to compare and a value to assign and uses the following logic:
If GridA > compare_value then GridA = assign_value, otherwise no change
- **Greater Grids:** Asks for a grid to compare and a grid to assign and uses the following logic:
If GridA > compare_GridB then GridA = GridC, otherwise no change

- **Set Value:** assigns the grid elevations to the user-specified value. Using inclusion and exclusion perimeters are usually required for this command. For example by using Set Value with the inclusion perimeter option,

you could set the grid values to 0.0 within the inclusion polyline for a strata thickness grid. The four options are:

- Value to Value will set all values to one value
- Null to Value will set all Nulls to one value
- Null to Grid will set all Nulls to another specified grid

- Value to Null will set all values to Null.

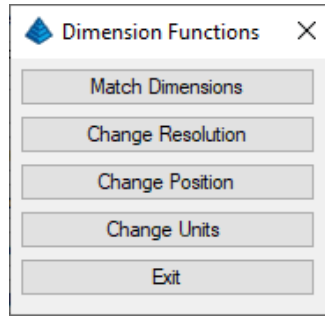

- **Extrapolate:** This function will assign values to null grid nodes by one of four methods. Global Trend finds the average slope and slope direction from the existing grid elevations and applies this slope to calculate the missing elevations. Average method calculates a grid elevation as the average of its nearest neighbors. This will create a very flat extrapolation. Projected method extends the trend at the edge (as opposed to finding an average slope of the entire surface like the Global option). Combined method uses a combination of both the Average and Projected methods.

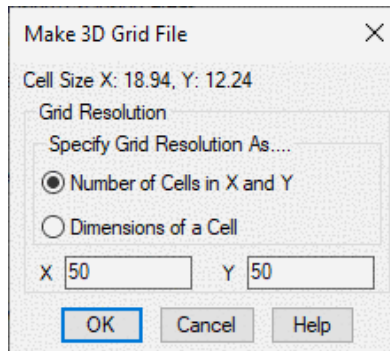

An example extrapolation of a surface using each method is shown below in 3D and in a profile view. The Original surface (brown color) is an example valley that only contains data in the center of the grid.

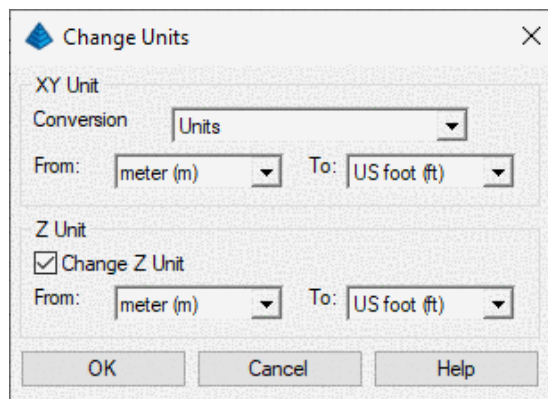

- **Dimension Functions:**

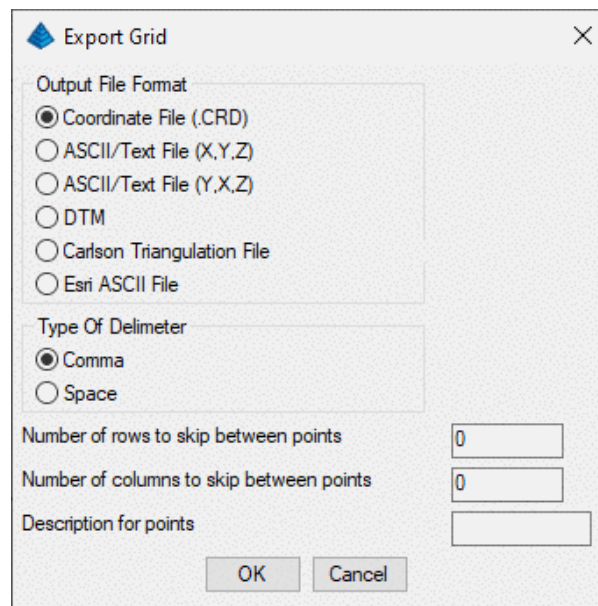

- **Match Dimensions:** Sets the grid position and resolution to match another grid file. The program will prompt for a grid file to get the position from. Certain commands require grids match position and resolution. Running this command will ensure grids will match.
- **Change Position:** This lets you change the lower left and upper right corners of the grid file. For example, you can use this routine to localize a grid file if you have a large grid for the entire site but are currently working on a smaller area. If the new position covers area outside the original position, any grid cells in this area will be assigned a null value. Otherwise the program uses the original grid values for the new grid position.
- **Change Resolution:** This changes the grid resolution (number or dimensions of grid cells). The program uses the original grid values for calculating the grid values at the new resolution. Enter a new value for X and Y number of cells or dimensions of cells.

- **Change Units:** Scales the grid X/Y and/or Z values to switch units such as meters to feet.

- **Apply Geoid:** Adjusts the grid elevations by the selected geoid. To use this function, the grid projection must be defined in the Settings > Drawing Setup command.
- **Slope Grid:** Converts a grid of elevations to a grid of slope values expressed as a percentage.
- **Smooth Grid:** This function has three smoothing method. The **Least-Squares** method applies a moving least-squares algorithm to adjust the grid elevations. The **Eliminate Spikes** method adjusts grid nodes with elevations too different (spikes) from neighbors within the **Search Radius**. The **Search Scaler** is used to identify spikes to adjust by using this scaler multiplied by the standard deviation of the grid values within the search radius. The **Interpolate Radius** is used to select the grid values for recalculating the grid value at the spike. **Quadratic Smoothing** uses neighboring nodes to adjust each grid node. This routine can be used to refine a grid so that the contours from the Contour from Grid routine appear smoother. Typically this adjustment is relatively small. To get more smoothing, run the routine more times.
- **Plot Grid:** This runs the Draw 3D Grid command.
- **Export Grid:** There are several choices for export options: Carlson Coordinate File (CRD), ASCII text as XYZ, ASCII text as YXZ, DTM, Digital Elevation Model (DEM), TIF, Carlson Triangulation (TIN) and Esri (ASC). There are two options for the ASCII delimiter, either a comma or a space. There is an option to skip a number of rows and columns between the exported points. When exporting into the Carlson CRD file, the description for the points is set at the bottom.

Export to DTM writes the current grid file to a DTM format text file. The format of this file is the following:

DTM 1.0 Header Line

test.dtm Name of file

51 Number of cells in X direction

51 Number of cells in Y direction

79442.4697 Lower left grid corner Y coordinate

14899.0326 Lower left grid corner X coordinate

0.0 Lower left grid corner Z coordinate

11.5618 Dimension of cell in X direction

7.0639 Dimension of cell in Y direction

1581.2612 Grid cell values starting from lower left, moving from left to right

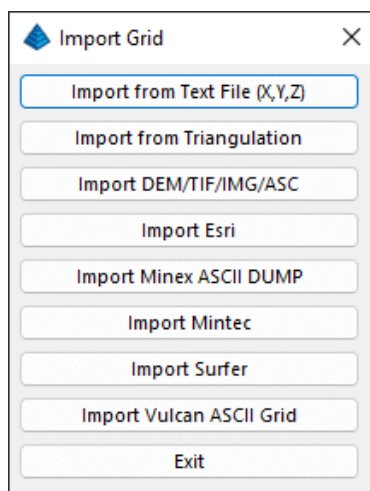

1580.8879

1580.3257

etc...

- **Merge Grids:** creates a grid file by merging together two existing grid files, grid1 and grid2. The current grid is grid1 and the program will prompt for a second grid. These two grids must overlap with the same location and resolution. The inclusion and exclusion perimeters apply to grid2 such that the merged grid will consist of grid2 cells within the inclusion perimeters and outside the exclusion perimeters and grid1 cells everywhere else. The result is stored in the current grid.
- **Import Grid:** There are several formats that may be imported.
 - Text File (ASCII): This function allows for various formats. The data can be comma or space separated or in fixed width columns.
 - Carlson Triangulation (TIN, FLT)
 - Digital Elevation Model (.DEM, .TIF .IMG or .ASC) such as from the USGS (US Geological Survey)
 - Esri (ADF)
 - Minex ASCII DUMP (ASC, CSV)

 - Mintec
 - Surfer (GRD both ASCII and Binary)
 - Vulcan ASCII Grid (ASC, CSV)

Import from Text File (X, Y, Z) creates a grid file from X Y Z data in any text file. There does not need to be a current grid file loaded since this routine will create a grid file. The text file should consist of one X Y Z coordinate per row with the first coordinate being the lower left grid corner and the last coordinate as the upper right grid corner. There are options for space or comma separated coordinates and for the order of the coordinates as either row (left to right) or column (bottom to top). The prompting will be as follows:

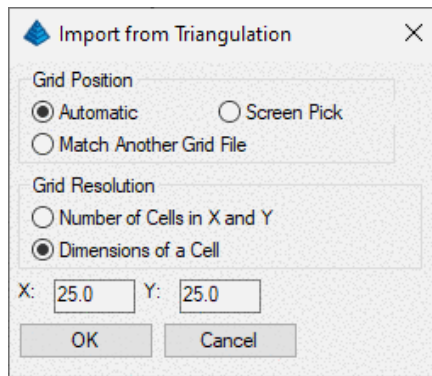

Separation type [<Space>/Comma/FixedWidth]?

Column number for X coordinate <1>:

Column number for Y coordinate <2>:

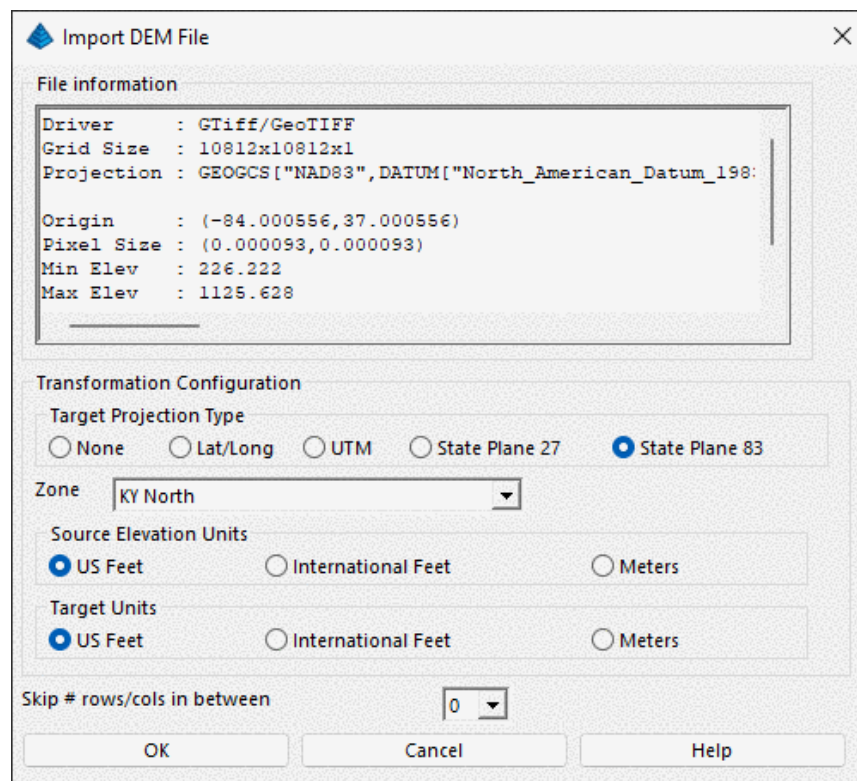

Column number for Z value <3>:

Import from Triangulation prompts user to select a tin or flt file and allows user to adjust grid position and resolution. The grid file is created with the same name in the same directory as the selected tin/flt file.

Import DEM/ESRI prompts the user to select a DEM, ADF, or ASCII ESRI grid file to be imported. The ESRI grid files can be created from ArcMap using the Raster To ASCII tool. If the file format is recognized, the program reads, and displays information about the source projection of the DEM/ADF/ESRI file, and allows the user to define a target projection for transforming the grid to a local coordinate system. the Source Elevation Units define the units of the Z values if they cannot be automatically detected. The Target Units will set the units for the X, Y, and Z values of the new grid. Note that if the Source Elevation Units and the Target Units use different units, the Z values will be scaled accordingly.

The "Skip every # rows/cols" option allows the user to reduce the size of the imported grid file. In the case of a DEM/ESRI files each pixel of elevation information of the DEM/ADF image data is interpreted as representing an elevated point located in the center of that pixel (not multiple points located on the edges of that pixel). In contrast, the "Import DEM/ADF File Dialog" will output the "Origin" of the DEM/ADF file in terms of the raster pixel extents. The output grid file is created with the same name in the same directory as selected DEM/ADF/ESRI file.

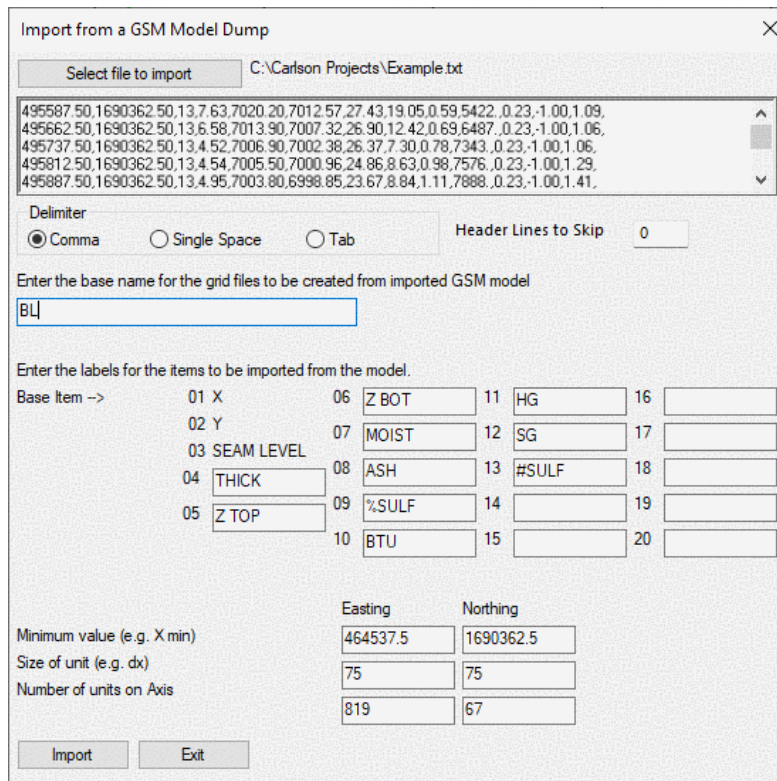

Import Minex ASCII DUMP allows user to import multiple Minex ASCII grids from a single .asc or .csv file. The imported grids will be automatically named according to the header information in the .asc/.csv file. An example

File Format is provided below.

```
; origin      3051045.00    952377.25
; extent      5375.50      4042.63

3051052.50    953929.75    949.10    936.10
```

Import Mintec allows user to import Mintec GSM Model Dump as grd files. User is prompted to select GSM Model Dump (txt) file, which is then processed to determine minimum northing, easting (lower left corner), resolution and size of the grid. First three columns of the GSM model dump must represent the X, Y and SEAM LEVEL respectively, a base name for the grid files is specified along with name of the quality that each column represents. User can define up to 17 qualities. When the import button is pressed all the imported grids are created with the name "BASE NAME-SEAM LEVEL-BASE ITEM.grd" in the same directory as source dump file.

Import Surfer prompts to select a grd file from Surfer program and creates a grd file.

- **List Grid:** displays a list of the northing, easting and elevation of each grid corner. There is an option to Include NULL values in the list. A grid node will have no value, or a Null value (listed as None) if the grid node was outside the limits of the data during Make 3D Grid File.

Carlson Software Edit : C:\Users\Tfaulkner.CARLSON\...

File Edit Settings

Cell#	East (x)	North (y)	Elev (z)

- **Grid Info:** This function displays information about the grid file. It is a form of Grid Statistics. The items it

displays are shown in the report below:

Macro Editor: The Macro Command Recorder allows you to create a script for grid modification and save these steps to a .gfu file. These macros can be rerun to repeat grid modifications when the source grids are modified, thus saving time on tedious manipulation. Macros can also be reviewed for accuracy, whereas manual manipulation of grid files cannot be checked with as much detail. When writing a macro, you essentially perform the normal grid manipulations using the functions on the left of the dialog. Although the prompts will be slightly different than manual manipulation, the steps will be automatically added to the text window. You can then copy/paste the text as needed to speed up the macro-writing process.

Quick notes on the macro editor:

- You may enter the script manually (typing each variable, function, etc), or you may use the function buttons on the left. Some functions are more easily written manually compared to using the function dialogs on the left.
- Function templates may be inserted using the "Template to Insert" droplist on the left. Using these templates, you can see an example of the syntax for each function.
- You may add comments to the script to allow for easier review. Comments are simply preceded by a semi-colon (;). With the exception of the PERIM, INCLU, and EXCLU functions, any text following a semi-colon will be seen as a comment (the program will not attempt to read it upon execution of the script)
- Most all function follow a syntax of RESULT=FUNCTION. For example, to evaluate the result of adding Grids A and B together to create Grid C, the function would be written as C=A+B.
- When a variable is first defined, the variable will take on the grid dimensions (cell size and lateral extent) of the right side of the equal sign. For Example, consider an example in which variable A is defined as a grid and B is not yet defined. If you write the equation B = A + 5, then variable B will cover the same lateral extent and will use the same grid cell size as variable A.

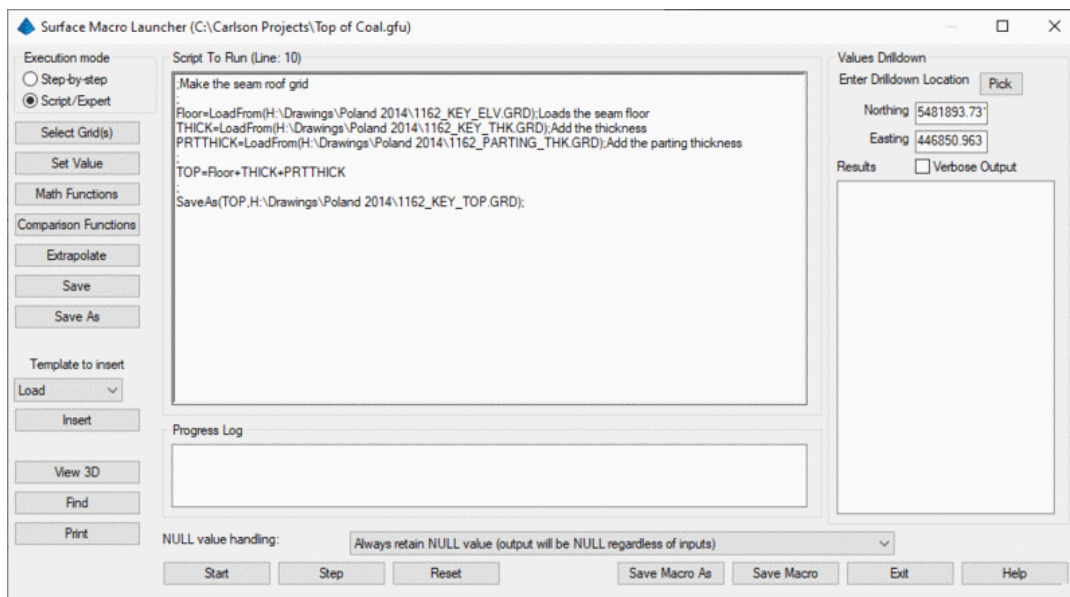

If two grid variables do not use the same grid dimensions, they can still be compared (note that this is not possible with manual manipulation of the grids). For example, if Grid A and Grid B cover only partially overlap, the equation B = A + 5 will allow Grid B to retain it's original dimensions, but it will only be updated where it overlaps A. In this way, you can avoid the intermediate step of settings grids to the same location/cell

size in order to compare them.

- When using the functions on the left side of the dialog (Math Functions, Comparison Functions, etc), you will sometimes be able to select existing grid variables from a dropdown list. In order for this list to be populated with the existing grid variables, you must first Start the macro, otherwise the program will not display the existing grid variables.
- When adding a step that involves another grid file, there are three options for storing this grid into the script. Use Grid Variable will use the grid assigned to the Grid Variable Name. Prompt for Grid File Name will bring up a grid file selection dialog each time the macro is run. Store the Grid File Name will save the specific grid file name into the macro.

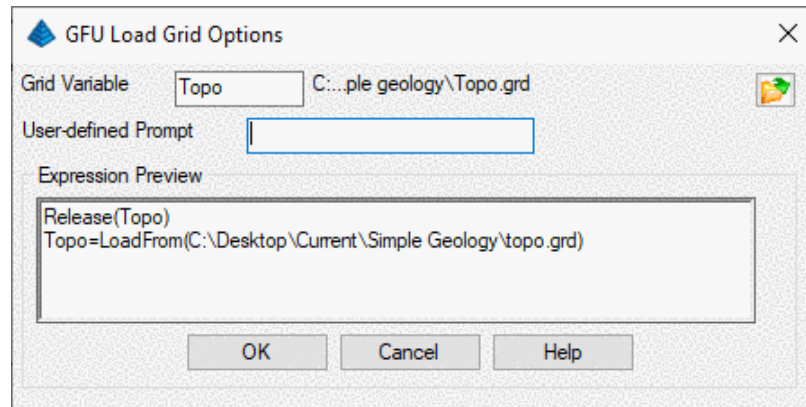

Surface Macro Launcher Details

The Surface Macro Launcher displays the GFU file name in the upper menu bar. This is an editor, and you can use basic functions like CTRL-X, CTRL-C & CTRL-V for cut, copy, & paste. GFU files also can be edited easily in any text editor, such as Notepad, WordPad or K-Edit. If there are any errors in the GFU during its execution, they will be displayed in the error log section when the macro runs. The Values Drilldown on the right side of the dialog allows you to inspect the calculations/grid variables at an actual Northing-Easting location, which is especially useful for checking that the results are correct. You may screen-pick a location by clicking the Pick button, or you may manually enter the Northing and Easting coordinates. As the macro runs, each variable will be display in the text readout below these options. If the Verbose Output option is disabled, only a summary of the grid variables will be displayed, with each variable updating as the macro runs. If the Verbose Output option is enabled, the results from each line of the macro will be displayed in the text readout.

- **Step-by-Step:** This execution mode is a simpler method and is intended to be executed immediately. It is similar to the previous windows simple "button pushing" to execute a function. These two modes have completely different dialogs when the functions are selected.
- **Script/Expert:** This mode stores the history and is a replayable history of the operations. It contains all of the higher level features and options, and is for the users who want to program it manually.

- **Select Grids:** In the Step-by-Step mode, the File Open dialog appears to select the file. In Script/Expert mode, the following dialog initially appears to add the expression to the macro for replaying. This function releases a variable if it is previously defined, and loads a grid file and assigns a variable to it. Another option is to enter an User-defined Prompt instructing the user on which grid to select at the time the macro is run. The dialog appears as shown. The preview shows how it will look when inserted into the macro.

- **Set Value:** This function sets the grid to new values based on the selected options. The Step-by-Step method has the following Set Functions shown in the first image below. The Expert method functions are shown in the second image. The expression #1 can either be set to a Value/Expression or to a New Grid file. The operation type contains four options of Set Value.

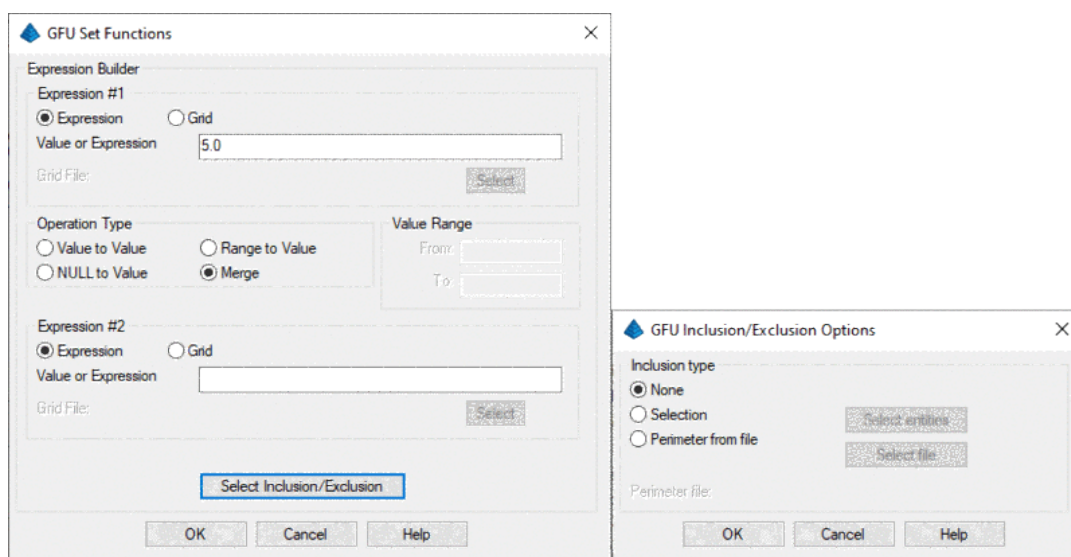

Value to Value (A=B for each point of A, sets the value to the value of B, Expr#1))

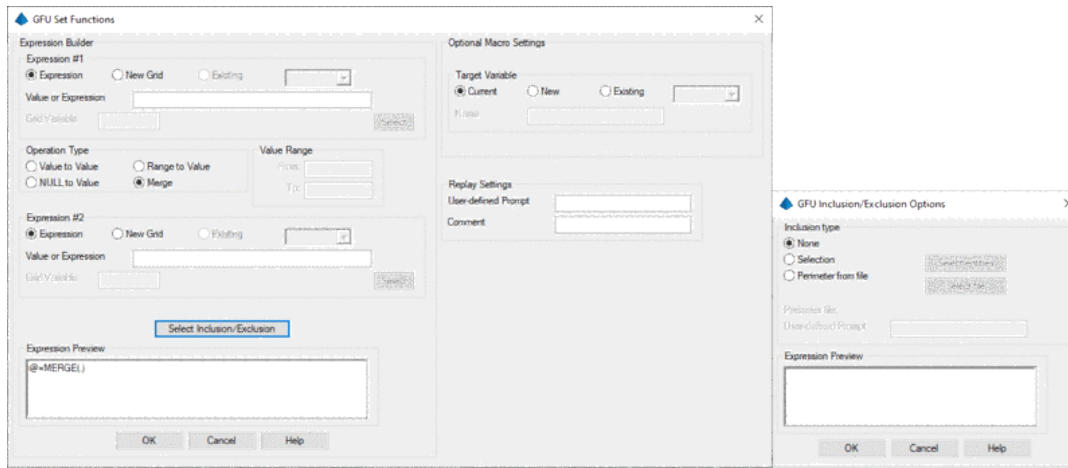

Null to Value (C=SET_NULL (A,B), For each point of C, sets the value to the value of A (Expr#1) if defined and the value of B (Expr#2) otherwise)

Range to Value (A=CHANGE_RANGE(B,C,D,E), for each point of A, if value of B (Expr#1) is between C and D, sets the value to value of E (Expr#2) or Null if not specified)

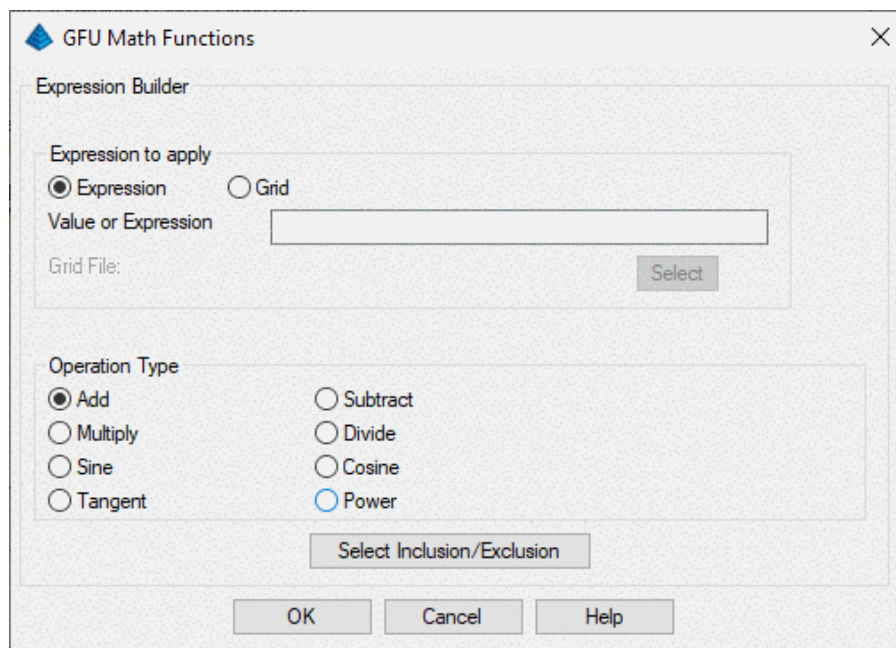

Merge (C=MERGE(A,B), for each point of C, sets the value to the value of B (Expr#2) if defined and the value of A (Expr#1) otherwise). Expression#2 is what the value will be set to, or to a new grid.

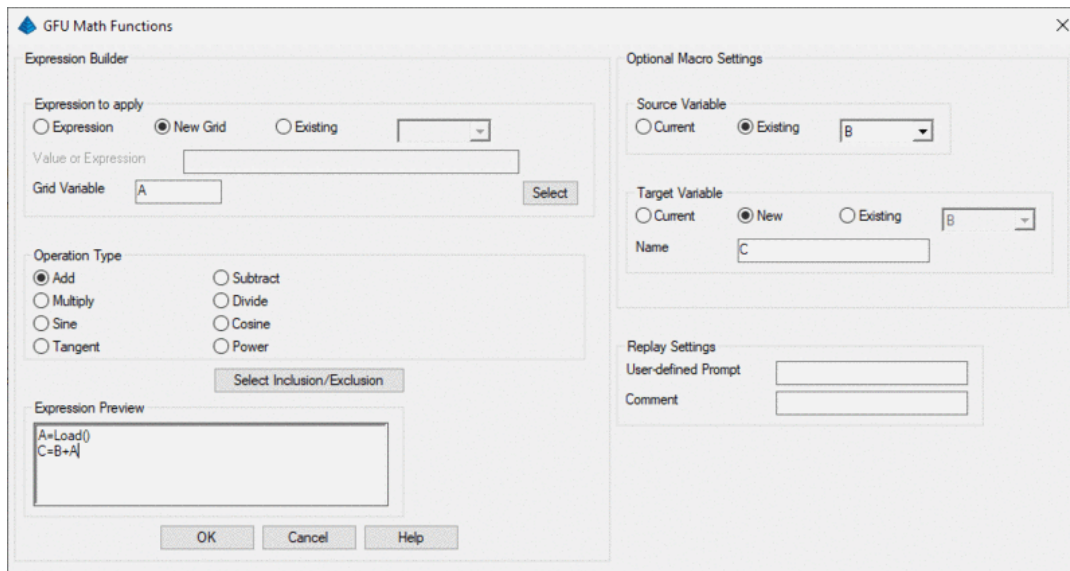

The Select Inclusion/Exclusion options can be set to None, Selection (manually select polyline), or a PLN polyline file. Note that PLN files may be created with the Export Polyline File command. The preview of the expression appears in the expert mode. These two modes appear the same in all the various functions. To set a grid to NULL, where the values fall within a range, use the following format: A=CHANGE_RANGE_VALUE(A,lowrange,highrange,NULL)

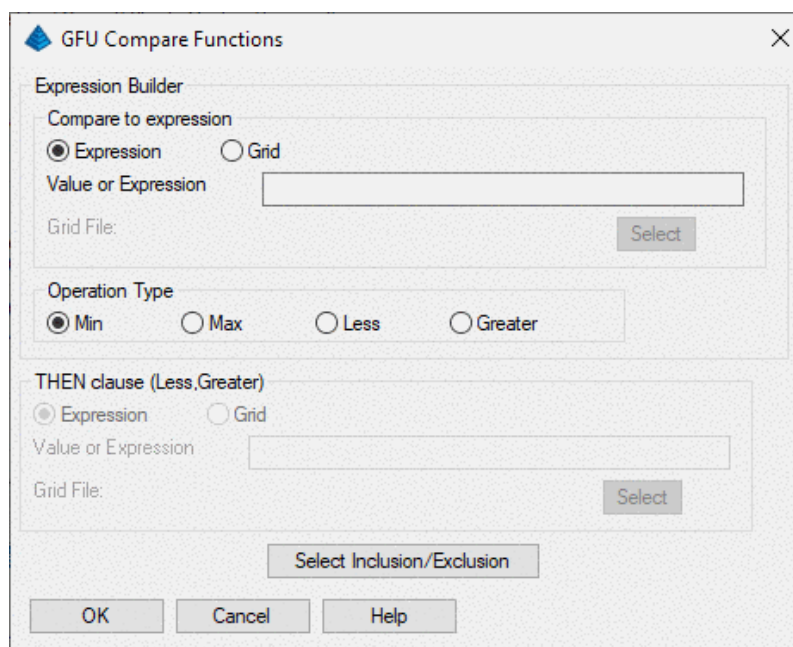

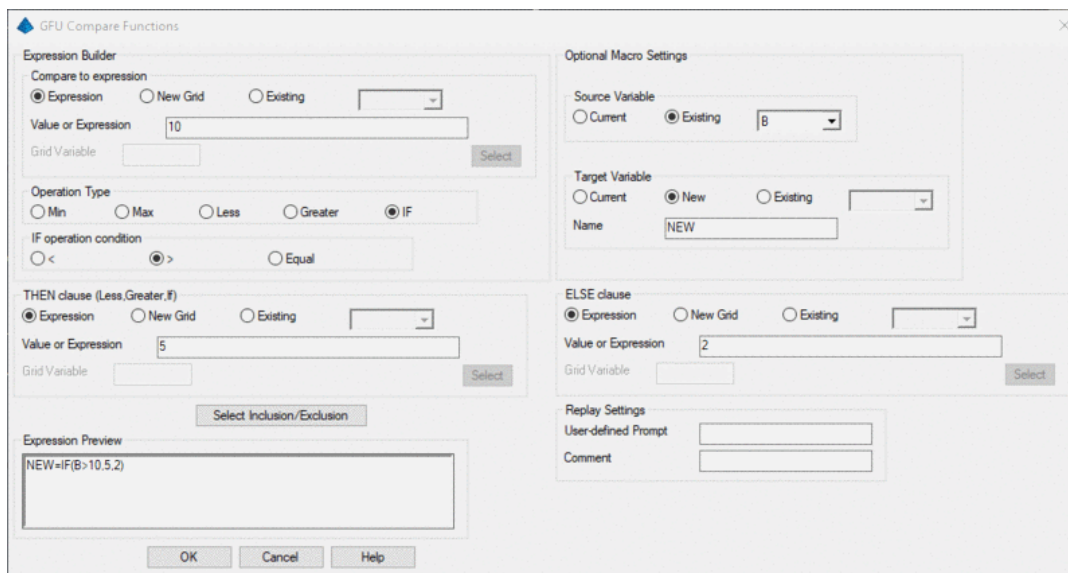

- Math Functions:** These functions apply the mathematical operations selected to the loaded grid. The Step-by-Step mode dialog is shown first, followed by the Script/Expert mode. The operations are Add, Subtract, Multiply, Divide, Sine, Cosine, and Power function.

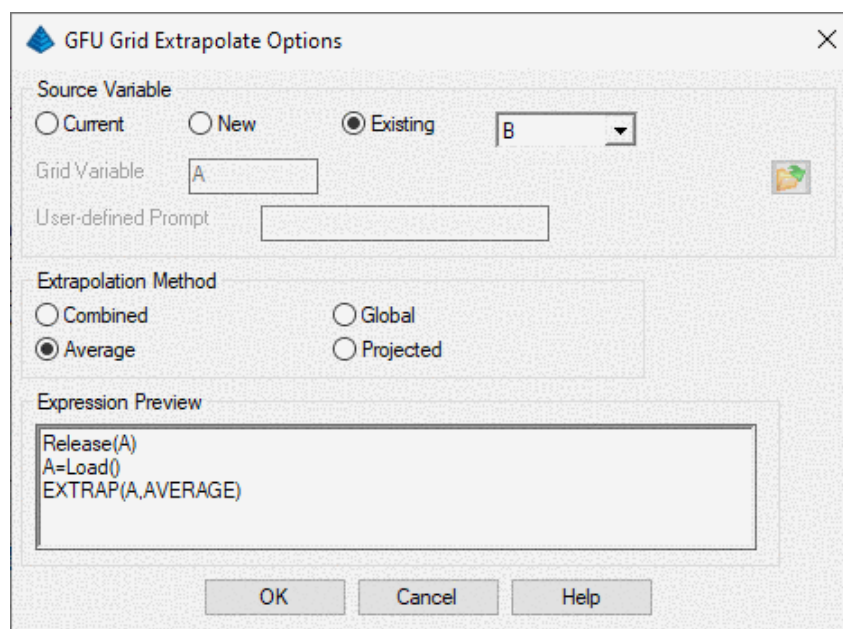

- Comparison Functions:** The Step-by-Step mode uses the Min, Max, Less, and Greater commands for grid editing. This is shown below in the first dialog. The second one shows the Script/Expert dialog that also contains the If Statement functions. The IF statement is the standard format of IF This, Then This, Else This. The Preview shows how it will appear in the GFU syntax.

- **Extrapolate:** This function uses the four methods described above to extrapolate the grid to fill in any Null values. Details on each extrapolation method are provided above.

- **Save/Save As:** These commands add the syntax of saving to the macro. The variable can be the existing, or set to a new one here.

- **Template to insert:** This option allows for easy insertion of the syntax for the following functions.

- **Nested Submacros:** It is possible to define a macro for a certain function, and then call that macro and apply it to other variables in either the same macro, or in a different macro. Here are 3 examples of Submacros.

Submacro in the same macro that calls it. There are two submacros defined at the top, and then they are both called at the bottom, THICK2 and THICK.

```

SUBMACRO THICK()
A1=LOADFROM($PROJECTPATH\one.grd)
B1=LOADFROM($PROJECTPATH\two.grd)
C1=A1+B1;
SAVEAS(C1,$PROJECTPATH\three.grd)
END SUBMACRO
;
SUBMACRO THICK2(A,B,D)
C=A+B;
SAVEAS(C,D);
END SUBMACRO
;
A1=LOADFROM($PROJECTPATH\one.grd);
B1=LOADFROM($PROJECTPATH\two.grd);

```

```
THICK2(a1,B1,$PROJECTPATH\three_b.grd);
THICK()
```

Submacro in a different macro that calls it. The first step is to define the submacros in their own gfu, this one contains THICK and THICK2 and is saved as mymacros.gfu.

```
SUBMACRO THICK()
A1=LOADFROM(C:\downloads\one.grd);
B1=LOADFROM(C:\downloads\two.grd);
C1=A1+B1;
SAVEAS(C1,C:\downloads\three.grd);
END SUBMACRO;
;_____
SUBMACRO THICK2(A,B,D)
C=A+B;
SAVEAS(C,D);
END SUBMACRO;
```

INCLUDE: To include a previously defined macro in another macro, the INCLUDE function is used. Once mymacros.gfu is created, then it can be loaded (with INCLUDE) and referenced in another, separate GFU macro.

```
INCLUDE($PROJECTPATH\mymacros.gfu);

A1=LOADFROM($PROJECTPATH\one.grd);
B1=LOADFROM($PROJECTPATH\two.grd);
THICK2(a1,B1,$PROJECTPATH\three_b.grd);
THICK();
```

Here is an example, with comments, where the bottom elevation and the thickness are added together to get the roof, for 6 seams. The Submacro is defined by the equation just once. Then it is called and used 6 times at the bottom of the macro.

```
;Add the Floor and Thickness to get the seam Roof.
;Coal seams to apply this to are: C1,C2,C3,C4,C5,C6
;_____
;LOAD THE GRIDS INTO MEMORY
;
C1_KEY_ELV=LOADFROM(C:\Carlson Projects\C1_KEY_ELV.GRD)
C1_KEY_THK=LOADFROM(C:\Carlson Projects\C1_KEY_THK.GRD)
C2_KEY_ELV=LOADFROM(C:\Carlson Projects\C2_KEY_ELV.GRD)
C2_KEY_THK=LOADFROM(C:\Carlson Projects\C2_KEY_THK.GRD)
C3_KEY_ELV=LOADFROM(C:\Carlson Projects\C3_KEY_ELV.GRD)
C3_KEY_THK=LOADFROM(C:\Carlson Projects\C3_KEY_THK.GRD)
C4_KEY_ELV=LOADFROM(C:\Carlson Projects\C4_KEY_ELV.GRD)
C4_KEY_THK=LOADFROM(C:\Carlson Projects\C4_KEY_THK.GRD)
C5_KEY_ELV=LOADFROM(C:\Carlson Projects\C5_KEY_ELV.GRD)
C5_KEY_THK=LOADFROM(C:\Carlson Projects\C5_KEY_THK.GRD)
C6_KEY_ELV=LOADFROM(C:\Carlson Projects\C6_KEY_ELV.GRD)
C6_KEY_THK=LOADFROM(C:\Carlson Projects\C6_KEY_THK.GRD)
;_____
;DEFINE THE SUBMACRO EQUATION
;
```

SUBMACRO ROOF(X,Y,Z)

TOP=X+Y

SAVEAS(TOP,Z)

END SUBMACRO

;
; _____

ROOF(C1_KEY_ELV,C1_KEY_THK,C:\Carlson Projects\C1_KEY_TOP.grd)

ROOF(C2_KEY_ELV,C2_KEY_THK,C:\Carlson Projects\C2_KEY_TOP.grd)

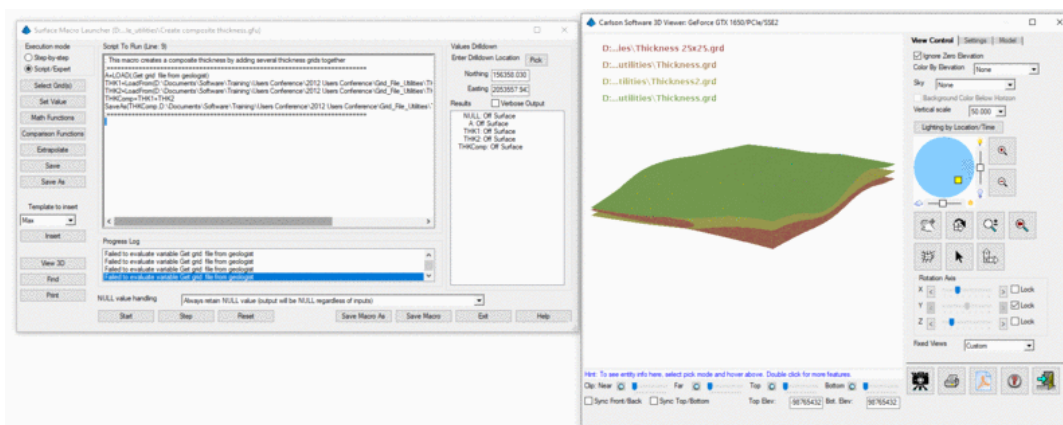

ROOF(C3_KEY_ELV,C3_KEY_THK,C:\Carlson Projects\C3_KEY_TOP.grd)

ROOF(C4_KEY_ELV,C4_KEY_THK,C:\Carlson Projects\C4_KEY_TOP.grd)

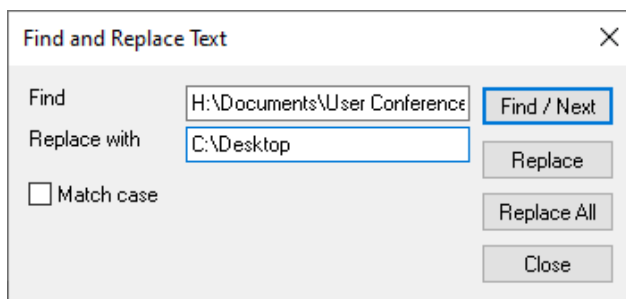

ROOF(C5_KEY_ELV,C5_KEY_THK,C:\Carlson Projects\C5_KEY_TOP.grd)

ROOF(C6_KEY_ELV,C6_KEY_THK,C:\Carlson Projects\C6_KEY_TOP.grd)

- **View 3D:** Using this option brings up the 3D Surface Viewer that steps through live all of the grids and displays them in 3D. This can be left open and moved to the side, or to another monitor to see all the surfaces and how they are modified, in a 3D view.

- **Find:** This is a Find, or Find and Replace to search the GFU text and make edits. It is useful if a file path has changed and all need to be reset to somewhere else.

- **Print:** There are two options for printing. The Script Window prints out the entire GFU syntax. The Results Window prints out

- **NULL Value Handling:** This option determines how null values will be handled in the grid calculations. The "Always retain NULL Value (output will be NULL Regardless of inputs)" option will force any calculations with NULL inputs to create a NULL output. The "Treat NULL as 0.0 if one or more inputs are non-NULL";

Retain NULL if all inputs are NULL)" option will replace null values with zeros for calculations, but will retain null values in the output if all inputs are null.

- **Start/Step/Reset:** These buttons allow for individual stepping through the macro. It will advance only one line at a time with the Step. Start will run the entire macro. Reset will begin back at the beginning.
- **Save Macro As/Save Macro:** This saves the GFU macro either as its original name, or as a new name with Save As.
- **Values Drilldown:** The Values Drilldown is a good method for error checking on the macro. Use the Pick button to select a spot in plan view to fill in the Northing and Easting boxes. Then when the GFU is executed, the results of each line will be displayed. The Verbose Output will show the value of each line L1, L2, etc., instead of overwriting the variable each time it is encountered.

Variables

Variables in the GFU can be any keywords providing meaningful identification of the data loaded. A variable can be either just a value or constant; or most commonly a surface (Grid or TIN). Individual macro lines typically have one of the following forms:

Variable1=Variable2

Variable1=Expression

Variable1=Function(Expression1,Expression2)

Whenever new variable name is encountered on the left side of the equation, the new variable will be created. The program will use its knowledge of the right side of equation to define a type of the new variable. For example:

A=1.0 Variable A will be just a value

A=LoadFrom(abc.grd) Variable A is a grid loaded from file

B=A Variable B is same variable type as A

B=(1+C+A)/D Variable B will be 1+C+A, all divided by D. C and D will need to be defined somewhere before this line in the GFU.

Important!: Once a variable is defined, its type (like grid location and resolution) does not change. Therefore, for the existing variable A, the following expression:

A=Min(B,C)

is interpreted in the following way: for every point of the existing surface A calculate values of surface B and C and use the smaller of the two values to set new value of point elevation on surface A.

The following operators may be used in the expressions:

+, -, *, / - regular arithmetic operators

<, >, =, ! (not) - logic operators

— (or), & (and) - binary operators

Changing the scope of the equation

The scope of any line of the script can be modified by adding one of the following inclusion/exclusion operators:

A=Min(B,C);INCLU(handle_here) - will use AutoCAD entity with specified handle for the inclusion

A=Min(B,C);EXCLU(handle_here) - will use AutoCAD entity with specified handle for the exclusion

A=Min(B,C);PERIM() - will prompt for inclusion/exclusion at run-time

A=Min(B,C);PERIM(file_name) - will use specified file with inclusions/exclusions

Multiple inclusions or exclusions can be appended in this manner. Only points of target surface (A) passing inclusion/exclusion filter will be evaluated.

For custom, user define prompting, the following text should be used:

PERIM(,Prompt goes here) for user defined interactive inclusion and exclusion selection in CAD

The following script functions are currently defined:

Macro functions (performing operations on the entire surface at once)

- LOAD() Prompt user for the file to load. Returns a variable.
- LOAD(,Prompt goes here) for user defined prompting
- LOADFROM(string) Load surface from file. Grids (GRD) and TINs (FLT, TIN) are supported. Returns a variable.
- SAVE(Variable) Saves surface back to original file.
- SAVEAS(Variable,FileName) Saves surface into a file with given name.
- RELEASE(Variable) Releases memory used by a surface and undefines it for further use.
- EXTRAP(Variable[,Type])

Micro functions (taking effect on point by point basis as controlled by left side of the equation) Expressions can be complex ones with variables, value and functions

- MAX(Expression1,Expression2) Sets value to larger of two expressions evaluated.
- MIN(Expression1,Expression2) Sets value to smaller of two expressions evaluated.
- LESS(Expression1,Expression2,Expression3) If result of Expression1 is less than Expression2 then result is Expression3. Otherwise the source point is not changed. If Expression3 is not specified value is set to NULL.
- GREATER(Expression1,Expression2,Expression3) If result of Expression1 is greater than Expression2 then result is Expression3. Otherwise the source point is not changed. If Expression3 is not specified value is set to NULL.
- IF(Expression1,Expression2,Expression3) If Expression1 (can be logic expression like $(A+B)>C$ or $A=B$ or $A!B$ 'not equal') not 0 then result is Expression2, otherwise it is Expression3.
- POW(Expression1,Expression2) Result is value of Expression1 in power of Expression2
- MERGE(Expression1,Expression2) If Expression2 is valid at a point, then result is that value, otherwise it is value of Expression1
- SET_NULL(Expression1,Expression2) If Expression1 is valid at a point, then result is that value, otherwise it is value of Expression2
- CHANGE_RANGE_VALUE(Expression1, Range1, Range2, Expression2) If Expression1 is a valid point and its value is greater than equal to Range1 and less than equal to Range2, then result is Expression2. If Expression2 is not specified value is set to NULL.
- TIN_INTERSECT(Expression1,Expression2) Expects both Expression 1 and Expression 2 to be TIN's. This will add vertices to Expression 1 where Expression 2 has vertices. In this way, one TIN can be made to have vertices at the same XY locations as another TIN. Note that this function does not need to be preceded by "Variable=".

Here is an example of a complex IF statement used for coal recovery based on thickness of the seam:

```
COALTHK=LoadFrom(C:\Carlson Projects\Grids\C40_THK.GRD);
ROM_COAL=COALTHK
ROM_COAL=if((COALTHK<2)—(COALTHK=2),COALTHK - (COALTHK * 0.50),ROM_COAL)
ROM_COAL=if(((COALTHK<4)—(COALTHK=4))&(COALTHK>2),COALTHK      -      (COALTHK      *
0.10),ROM_COAL)
ROM_COAL=if((COALTHK<7)&(COALTHK>4),COALTHK - (COALTHK * 0.075),COALTHK - (COALTHK
* 0.05))
SaveAs(ROM_COAL, C:\Carlson Projects\Grids\C40_ROM_THK.GRD)
```

Pulldown Menu Location: Surface and Grids

Keyboard Command: GFU

Prerequisite: Make a grid (.GRD) file with the *Make 3D Grid File* command.

Merge Grid Files

This command creates a grid file by merging together two existing grid files, grid1 and grid2. The current grid is grid1 and the program will prompt for a second grid. These two grids must overlap with the same location and resolution. The inclusion and exclusion perimeters apply to grid2 such that the merged grid will consist of grid2 cells within the inclusion perimeters and outside the exclusion perimeters and grid1 cells everywhere else. The result is stored in the current grid.

No elevations are calculated on grid cells that extend beyond the extent of the data. Extrapolation can be used to calculate elevations for the grid cells that are beyond the data limits. The prompt *Extrapolate grid to full grid size?* shows when there are grid cells with no elevation in a grid (.GRD) file. Extrapolation fills in all the grid cells. The method to extrapolate uses a safe calculation that tends to average out or level the extrapolated values. So extrapolated grid areas are not as accurate as grid areas within the limits of the data.

Prompts

Merged Grid File to Write Dialog (*new file select dialog*)

Pulldown Menu Location: Surface >> Modify Grid File

Keyboard Command: mergegrid

Prerequisite: Two grid (.GRD) files

Merge Elevation for Zero Thickness

This command merges two elevation grid files and outputs the result to a new grid file. The purpose of this command is to "pancake" together the top and bottom elevation grids for a strata so that the thickness is zero in specified areas. The two input elevation grid files should have the same grid position and resolution. One represents the top of strata elevation and the other represents the bottom elevation. The output grid will have the top grid elevations except in areas of zero thickness where the output grid will have the bottom grid elevations. This output grid can then be used as the new modified top elevation grid. StrataCalc routines will have the same elevation for the top and bottom of the strata in the areas of zero thickness.

After prompting for the grid file names, the program prompts for the inclusion and exclusion polylines. These should be closed polylines where everything inside the inclusion polylines and outside the exclusion polylines has zero thickness. For example, you can draw a closed polyline for an inclusion area around an area where the strata pinched out, where you want it to be zero, or has already been mined.

Prompts

Select TOP Elevation Grid File dialog

Select BOTTOM Elevation Grid File dialog

Specify New Elevation Grid File dialog

Specify inclusion and exclusion areas for zero thickness.

Select the Inclusion perimeter polylines or ENTER for none:

Select objects: *select a closed polyline*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *press Enter*

Pulldown Menu Location: StrataCalc

Keyboard Command: mergegrid2

Cleanup Grid Area

This routine takes a grid file and a closed 3D polyline, and combines the two. The elevations of the closed polyline are assigned to the grid elevations. Then the polyline is modeled and the resulting surface is applied to the original grid inside the polyline area. The resulting grid is then saved to a new grid file.

Prompts

Select a perimeter polyline:

Resource-Reserve Classification

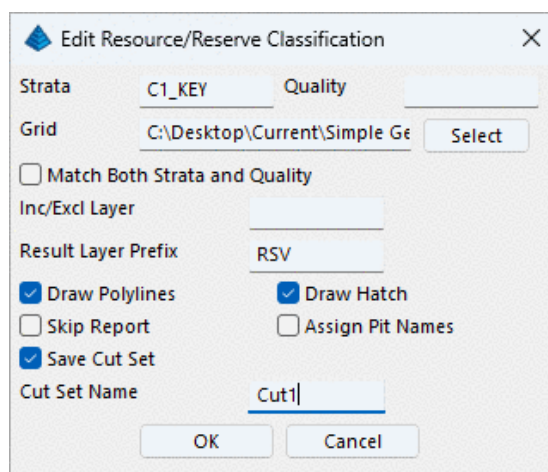

The Resource/Reserve Classification command provides a report based on the area of each zone. The tonnage associated with each zone (Measured, Indicated, Inferred, and Hypothetical) can then be calculated using the Surface Mine Reserves command (found in either the Geology or Surface Mining module). The four classification zones were previously been based off of the following distances from a drillhole, but please note that it is **not** appropriate to blindly assign classification based on these distances under standard reporting requirements such as

- Measured: $x < 1320$ ft (1/4 mile)
- Indicated: $1320 \text{ ft} < x < 3960$ ft (1/4 mile to 3/4 mile)
- Inferred: $3960 \text{ ft} < x < 15840$ ft (3/4 mile to 3 miles)
- Hypothetical: $x > 15840$ (3 miles)

After creating a .rsv file, the below dialog will appear. Here you can add new strata layer to the list.

When adding a new strata to the list, the below dialog will appear.

- **Strata:** This sets the name of the strata to analyze. Note that this must perfectly match the strata/bed name in the drillhole. When using bed names, it is important to include the Bed Name and the grouping suffix. For

example, the above example shows the name that must be entered for the Key portion of the C1 bed (C1_KEY).

- **Quality:** This is the quality attribute to analyze, such as thickness, BTU, etc. It is not required to enter a value for this field.
- **Grid:** This is the grid name that has been created from the drillholes. It will compare these modeled values with the occurrences and spacing in the drilling.
- **Match Both Strata and Quality:** This will make sure that the quality and strata name both are defined in a drillhole. If just the strata name is there, but no quality sample, then it will not be used as a sample point that is measured.
- **Inc/Excl Layer:** These are the layers that the perimeters are drawn in.
- **Result Layer Prefix:** This is a prefix to add in front of the output layer names. The program will create layer names such as "_A_MEASURED" and "_B_INDICATED". If the prefix is set to "RSV", then the resulting layers would be "RSV_A_MEASURED" and "RSV_B_INDICATED".
- **Draw Polyline:** This will draw the perimeter polylines that contain the hatching for the four classifications.
- **Draw Hatch:** This will draw the hatching inside the perimeters and boundaries of classifications.
- **Skip Report:** This option just will only generate CAD graphics and mapping only - the report will not be generated for this strata when this option is enabled.
- **Assign Pit Names:** This option will give a Pit Name to each perimeter, so it may be used for other volume calculations with commands such as Surface Mine Reserves.
- **Save Cut Set:** This option will create a named cut set for the boundaries, which may be used with Surface Mine Reserves or the Timing commands to further divide volumes/tonnage into relevant categories. Note that when using Surface Mine Reserves or the Timing commands, you must enable the relevant options to report by Property Boundaries in order to use the cut set.

After adding strata to the list and clicking OK, you will be prompted to select drillholes and inclusion boundaries. If no boundaries are selected, the program will automatically use polylines tagged as property boundaries. If no inclusion boundaries are selected, and no property boundaries exist, the command will exit and the below message will appear.

The results are shown as colored maps layered by the chosen quality, with color changing based on the corresponding reserve class.

An example report is show below:

Convert As Determined Qualities

This function calculates strata qualities "as delivered" based on in place qualities. A Geologic Model file with all strata and quality grids specified is required to run the command.

The dialog below shows a typical use of the routine. The strata list displays all the strata defined in the Geologic Model file. To calculate "as delivered" qualities of the particular strata pick that strata from the list. Then fill out at least the Moisture field by picking the corresponding quality name from the list or by specifying a value if grid is not present. This allows the program to calculate dry qualities by picking a quality in pull-downs in the lower left corner and specifying an output grid file name in the corresponding dry grid line.

When Ash and BTU fields are filled out, dry Ash, dry BTU and BTU(MAF) grids may also be calculated.

Repeat this procedure for every strata in the list for which dry qualities are to be calculated by the routine. When finished click on the OK button and all the required grids will be generated.

Prompts

Composite Qualities Analysis

This function calculates quality grids for user-defined composite strata. A Geologic Model file with all strata and quality grids specified is required to run the command.

First you should define a composite strata by specifying which strata it is made of and amounts of strata included in the composite. The amounts are either specified as % of or thickness of the seam. Then specify a quality to weight

the other qualities by, picking from the list on the top. Below it define all the qualities to be calculated along with the corresponding output file names. Click on the OK button when done filling in all the information and the grids specified will be calculated.

Case Studies

Case Study #1: Techniques of Geological Compositing

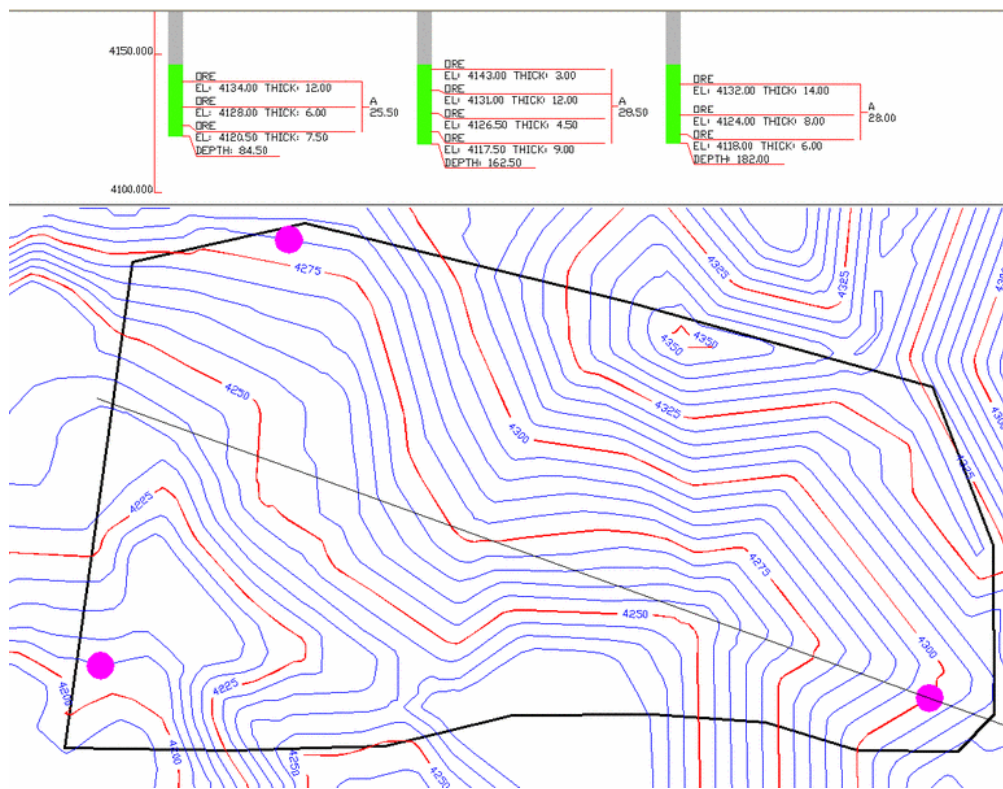

Two Types of Compositing are described here. (1) Single Seam or Ore Body compositing where the seam has been sampled at various intervals, and (2) Combinations of Several Seams Separated by Interburden.

(1) Single Seam or Ore Body

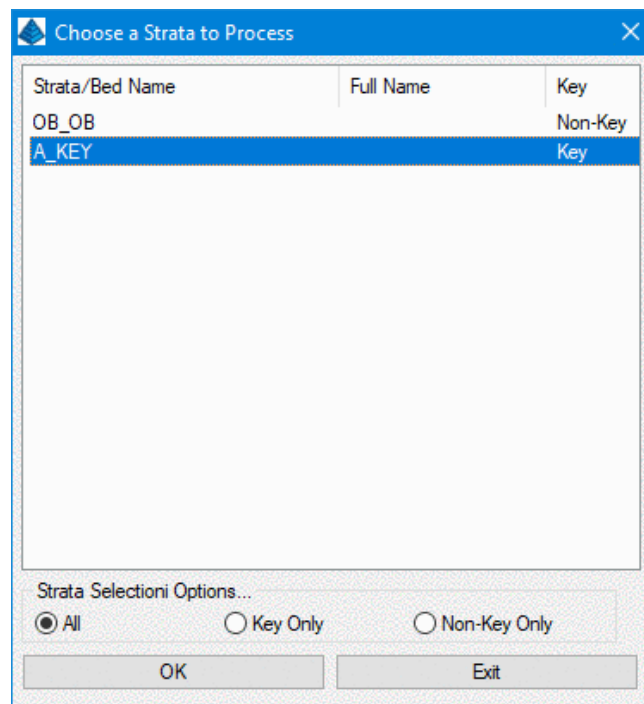

Large ore deposits such as limestone and thick beds of coal are often sampled at multiple points within the single ore body or bed. For long-range planning and reserve estimates, it is often desired to obtain the composite quality for the entire mineral deposit within an inclusion perimeter. For short-range planning, the mine engineer needs to know what quality will be obtained in a particular vertical segment of the ore body or seam, also within a defined perimeter.

Entire Seam Composites In the first example, a body of ore has been sampled at 3 to 4 points vertically, as seen in the geologic columns. Note in the geologic columns (generated with the Draw Geologic Column command) that all the ORE has been assigned bed "A". This will "lump" the various ore samples into one "bed". If the bed name is not assigned when the holes are drawn, this can be accomplished by the commands "Assign Bed Names" or "Fill in Bed Names". The Selected Strata Quantities command will then produce the below report (showing composite A tons) when the A.Key strata is chosen singly and the inclusion perimeter is selected. Compositing of the single A bed is automatic.

Note: The program will not composite qualities for a strata name that is repeated, unless there is a bed name grouping them together.

The command Selected Strata Quantities brings up this screen to select the strata or bed to analyze.

Follow these prompts to get the report screen.

Vertical Composite Zones

In the next example, a vertical zone of ore has been defined as the upper part of the ore body or "A" bed from 4130 elevation and up. The "floor" of the vertical cut in this case is flat, following the 4130 elevation. This might correspond to a mine plan where the base of the first of two cuts is designed to hit elevation 4130 within the entire pit. The technique required is to divide bed A into two beds. This is done by the command "Split Bed" within Strata/Bed Utilities under Drillhole. The prompting is as follows:

Command: splitbed

Split strata method [<Elevation>/Grid/Thickness]? E

Select the Drillholes for bed split. *Select the holes*

Select objects: Specify opposite corner: 3 found

Enter name of the bed to split: A

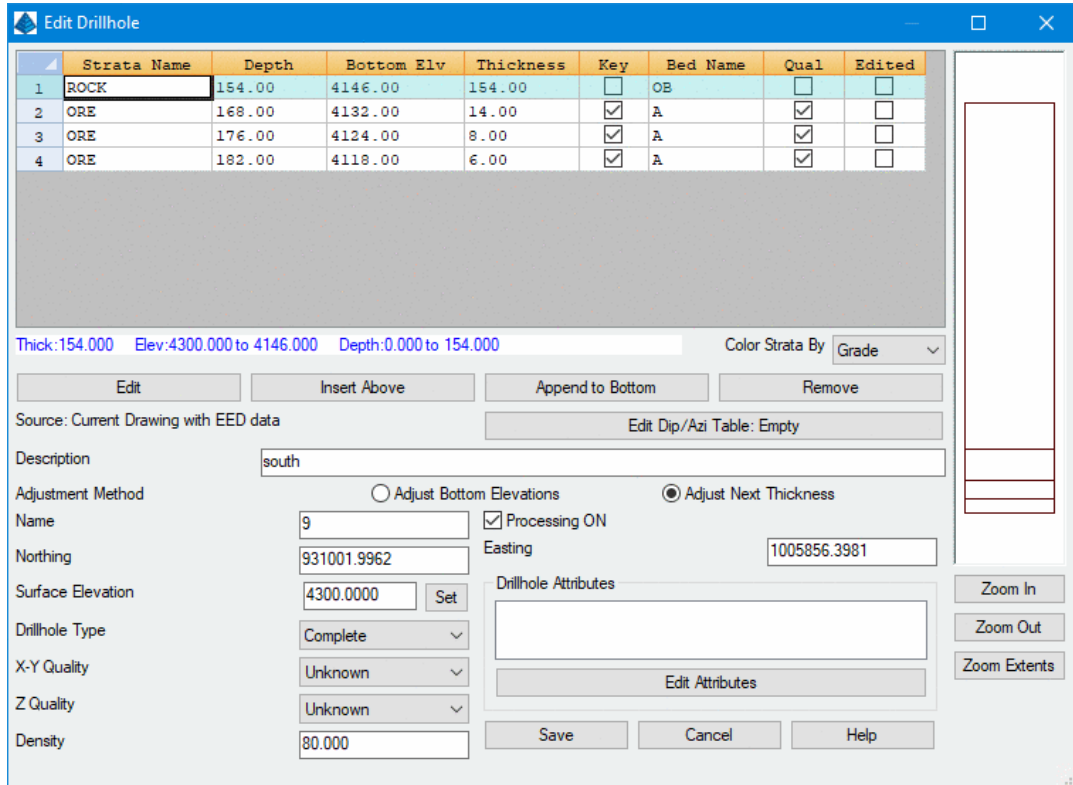

Rename bed or assign key/non-key status [<Name>/Status]? Name

Enter new name for the upper part of the bed: A_Upper

Enter new name for the lower part of the bed: A_Lower

Enter a split elevation: 4130

This shows a drillhole before splitting the A seam into an A Upper and A Lower.

Here is the same drillhole, viewed within "Edit Drillhole" after the command "Split Bed". Notice the new Bed Names, A Upper and A Lower.

Strata Name	Depth	Bottom Elv	Thickness	Key	Bed Name	Qual	Edited
1 ROCK	154.00	4146.00	154.00	<input type="checkbox"/>	OB	<input type="checkbox"/>	<input type="checkbox"/>
2 ORE	168.00	4132.00	14.00	<input checked="" type="checkbox"/>	A UPPER	<input checked="" type="checkbox"/>	<input type="checkbox"/>
3 ORE	170.00	4130.00	2.00	<input checked="" type="checkbox"/>	A UPPER	<input checked="" type="checkbox"/>	<input type="checkbox"/>
4 ORE	176.00	4124.00	6.00	<input checked="" type="checkbox"/>	A LOWER	<input checked="" type="checkbox"/>	<input type="checkbox"/>
5 ORE	182.00	4118.00	6.00	<input checked="" type="checkbox"/>	A LOWER	<input checked="" type="checkbox"/>	<input type="checkbox"/>

Thick:14.000 Elev:4146.000 to 4132.000 Depth:154.000 to 168.000 Color Strata By Grade

Source: Current Drawing with EED data

Description: south

Adjustment Method: Adjust Bottom Elevations Adjust Next Thickness

Name: 9 Processing ON

Northing: 931001.9962 Easting: 1005856.3981

Surface Elevation: 4300.0000

Drillhole Type: Complete

X-Y Quality: Unknown

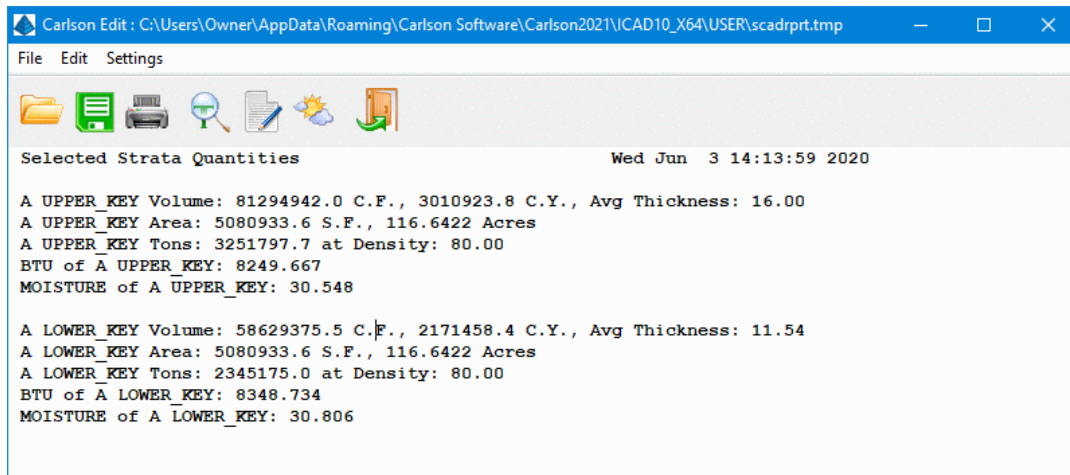

Z Quality: Unknown

Density: 80.000

The result is a new base of A Upper seam. It is important to note that the quality characteristics of the original ore zone have been applied identically to the new ore zones that have been renamed to A Upper and A Lower. The rest of the ore zone, the lower 12.5 feet, has become part of A Lower. If a drillhole does not reach as low as 4130 elevation, then all the ore remains in the A Upper bed and is unaffected. Conversely, if the ore never exceeds elevation 4130 in a particular drillhole, then it is assigned bed A Lower for all the ore sample points. Here is a Fence Diagram showing the two divisions of the bed, at elevation 4130.

Now the command "Selected Strata Quantities" can be run. There is now no need to select the "composite" option because you want to calculate the A Upper and the A Lower beds distinctly. You select them one at a time from the dialog box. This leads to the result shown here in the report. Adding the tons calculated here: 3251797.7+ 2345175.0 = 5596972.7 calculated above, when the bed was just A. This is a good check to make sure the quantities match.

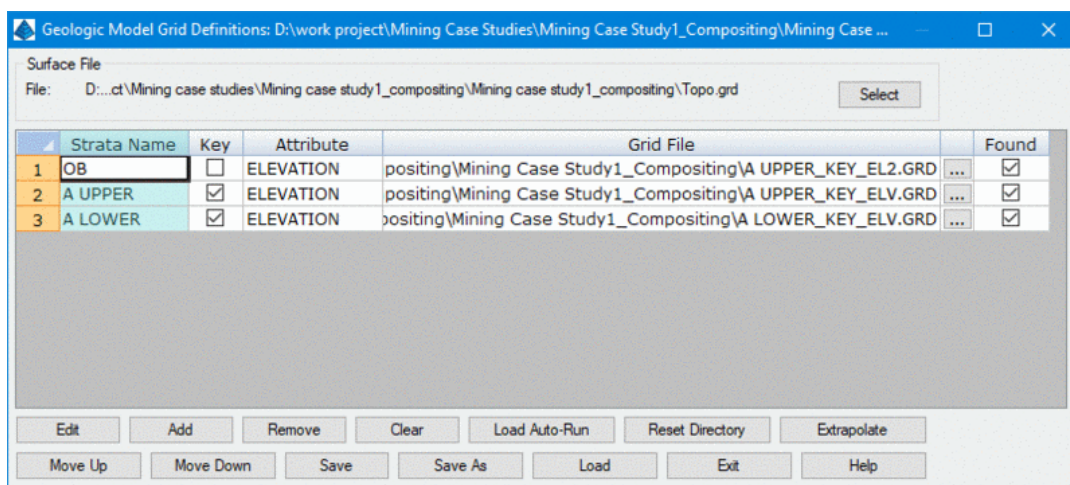

Split Bed by Grid File

In the previous example, we chose to split the bed by elevation. If, by contrast, the goal was to leave 5-feet of lower ore in place to be removed by different equipment, then the vertical demarcation is not a fixed elevation but a grid file defined as base of ore plus 5 feet. This grid file is made by using "Make Strata Grid Files" to make the base of ore, then using Grid File Utilities (in the Grids Pulldown Menu) you would add a value of 5-feet and re-save the grid file as Oreplus5.grd or some such name. This new file would be used to delineate the split elevation between the A Upper and A Lower beds.

Alternative Techniques

In the above example, the command "Selected Strata Quantities" was used. This is an "on-the-fly" selection approach, where the drillholes are selected each time the command is run. It does not take advantage of stored grid files in the Geologic Model file (.PRE), which is generally preferred. To apply the above procedures, follow this sequence:

1. Establish Bed A Upper and Bed A Lower using Split Bed.
2. Make grid files for the surface, the top of Bed A Upper, the base of Bed A Upper and the base of Bed A Lower.
3. Enter these files in appropriate order (A Upper first, then A Lower) as a stored Geologic Model grid set, using the command "Define Geologic Model" under the StrataCalc pulldown.

Then run Surface Mine Reserves, selecting Geologic Model as the modeling method. You will obtain the same quantities for each bed as reported from the command "Selected Strata Quantities".

The advantage of setting up grid files is that multiple, pre-named pits can be run within Surface Mine Reserves, and the reporting can be formatted and expanded upon at the user's discretion, and even exported to Excel or Access. The various options within Surface Mine Reserves can be fine-tuned, such as recovery percentage, density, and dilution. Furthermore, "grand totals" are obtained where the qualities and volumes/tonnages of beds A Upper and Lower are composited back into the total reserve values. (Indeed, this is the exact procedure used for multiple seams with interburden.)

Shown here is a formatted report for the single inclusion polygon representing the pit in our example. Slight differences in values versus "Selected Strata Quantities" is a function of the difference in gridding locations and cell sizes. With stored Geologic Model grids, quantities and qualities will be fully repeatable.

(2) Combinations of Several Seams Separated by Interburden

In the mining of stratified deposits, it is very common to have several seams separated by interburden. Surface mines must consider the composite tonnage, composite strip ratio, and composite quality in any reserve study or short-term mining plan. Two main issues come to mind; how deep to mine, and when to mine while removing interburden as if it were Key. Let's look at a coal deposit example.

How Deep to Surface Mine

Strip ratios change as each lower seam is taken, and quantities of coal increase. The goal is to get as many lower seams as possible, but not so many that interburden thicknesses and strip ratios increase excessively, or quality degrades. Currently, about a 15:1 strip ratio approaches the maximum feasible ratio for cost-effective mining. Higher ratios do occur and will certainly occur if the market price of coal increases. Coals are said to "outcrop" at the surface, with "crop loss" referring to unmineable, "weathered" coal at the hillside edge. Usually the crop loss is around 12 to 15 feet measured vertically from the surface. It is often deeper in valleys or even small hillside ravines

and "drains", due to accumulation of debris and erosion. On "points" or ridges, crop loss may be only 10 to 12 feet, particularly in hardrock conditions. The Surface Mine Reserves routine is designed for estimating reserves and includes a built-in crop loss parameter (measured vertically from the surface), appearing as "Min Depth to Use". Here is a graphic representing the crop loss on the side of a hill.

A conservative engineer or geologist would enter 15 feet to obtain a "low-ball" estimate. Someone looking aggressively for all the coal they could possibly obtain might enter 10 or 12 feet for the vertical crop loss. Be aware that with steep 1.5:1 hillside slopes, a 10' vertical crop loss translates to 15' measured horizontally from the hillside. In 3:1, gently sloping terrain, a 10' vertical crop loss translates to 30' measured horizontally from the hillside. If the natural terrain slopes on the order to 2:1 to 3:1 or more, it is reasonable to use a lower vertical crop loss value for "Min Depth to Use". The value used is strictly a judgment call and is ideally based on observations at the mine. There is no option to have a variable crop loss. That is best handled by defining a "Strata Limit Polyline". See the "OutCrops and SubCrops" case study for more information. In many regions, shallow coals will "subcrop" as they hit an alluvial deposit or as it nears the surface and is decomposed due to oxidation and weathering.

Another Example: Getting Composite Qualities

The Surface Mine Reserves command automatically computes composite qualities and strip ratios on all Key strata, provided "Calculate Strata Qualities" is selected in the dialog box (dialog shown earlier above). The low SULFUR and BTU values for OB and IB are not included in the composite quality for SULFUR and BTU. This is because OB and IB are not defined as KEY. When C1 and C2 are imported or placed in the drawing, they are defined as KEY strata. Alternately, the KEY designation can be assigned and changed using the command "Define Strata". Shown below is a drillhole example of this dataset, and the composite KEY quality report.

Edit Drillhole

	Strata Name	Depth	Bottom Elv	Thickness	Key	Bed Name	Qual	Edited

Surface Mine Reserves Mon Jun 08 04:43:06 2020

Geologic Model: D:\work project\Mining Case Studies\Mining Case Study1_Compositing\TEST.pre

Key strata recovery: 100.00%

Minimum depth to use: 0.00 ft

Minimum key thickness to use: 0.00 ft

Minimum separable parting thickness to use: 0.00 ft

Non-Key thickness Above key to add to key: 0.00 ft

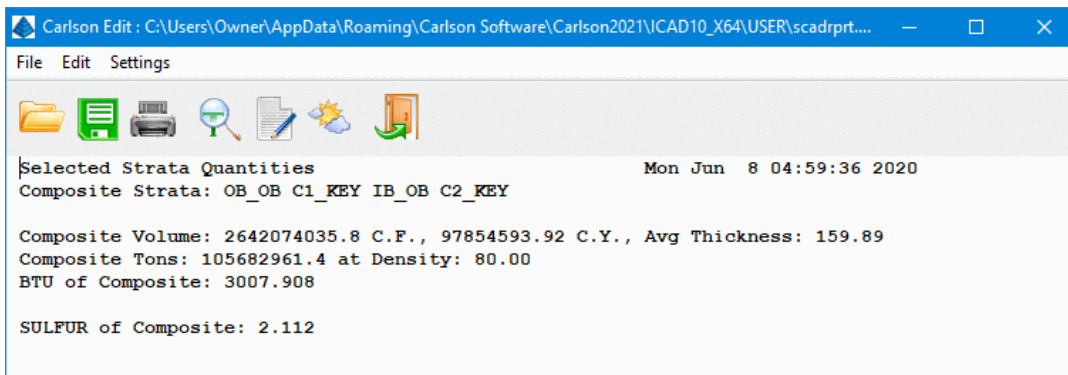

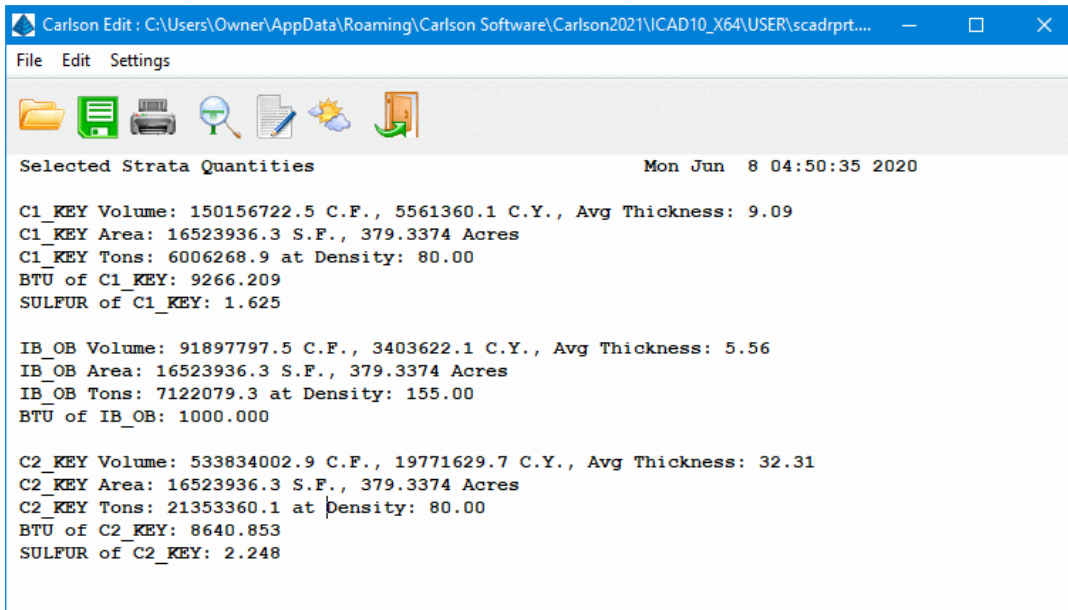

Non-Key thickness Below key to add to key: 0.00 ft

Key top thickness to remove from key: 0.00 ft

Key bottom thickness to remove from key: 0.00 ft

Strata	COAL	Tons	Non-key	C.Y.	Thick	Strip	Ratio	Density	SULFUR	BTU
OB_TOP		69,163,753.9	112.98							
C1_KEY	6,010,514.5		9.09		11.5	80.00	1.625	9,266.074		
IB_TOP		3,406,305.1	5.56							
C2_KEY	21,366,338.9		32.32		0.2	80.00	2.248	8,640.475		
Total	27,376,853.4	72,570,059.0	159.95		2.7	80.00	2.111	8,777.823		

By contrast, composite qualities can also be computed using the command "Selected Strata Quantities", but this routine will composite any selected strata, key or non-key. In our example, if all 4 beds are selected, the composite BTU is only 3008. All of the above calculations were based on screen-selection of the drillholes (not grid files), and use of Triangulation modeling. (Sulfur was not entered for Nonkey beds).

Partings: When to Mine and When to Waste

Drillholes 8 and 10 below have 2.5 and 1.8 feet of interburden, respectively, between coals C1 and C2. It makes sense to take the thin interburden with the coals, even though this will dilute some qualities (and maybe improve others). Surface Mine Reserves has an option called "Min Movable Parting Thickness" designed specifically for this purpose. The effect on qualities is also shown below. This result is obtained automatically by designating 2.0 feet as the "minimum movable parting thickness", meaning that any lesser thickness will not be separated as waste but will be included as coal.

To obtain interburden qualities and to factor them in to the composite quality, it was critical that qualities be associated with non-key strata. This is accomplished within the command "Define Drillhole" or a setting on the main Surface Mine Reserves screen for Fixed NonKey Qualities.

File Edit Settings

Surface Mine Reserves Mon Jun 08 05:06:41 2020

Geologic Model: D:\work project\Mining Case Studies\Mining Case Study1_Compositing\TEST.pre
 Key strata recovery: 100.00%

 Key bottom thickness to remove from key: 0.00 ft

Strata	Non-Key Tons	Non-Key BTU	Non-Key SULFUR	COAL Tons	Thick Strip	Ratio	Density	SULFUR	BTU Non-Key	Density
OB_TOP	140,056,601.6	1,000.000	0.500		112.98					150.00
C1_KEY				6,010,514.5	9.09	11.5	80.00	1.625	9,266.074	
IB_TOP	3,441,521.5	1,000.000	0.500		1.80					150.00
IB_TOP (Min Parting)				3,456,246.3			150.00	0.500	1,000.000	
C2_KEY				21,366,338.9	32.32	0.1	80.00	2.248	8,640.475	
Total	143,498,123.2	1,000.000	0.500	30,833,099.7	156.19	2.3	87.85	1.930	7,905.966	150.00

In our example, the interburden had a density set at 150 within Define Strata, and had BTU values in the 1000 range, and sulfur in the 0.5 range. The net effect of including the thin interburden was to improve sulfur and degrade BTU. If sulfur under 1.0% is the more critical value in meeting quality requirements, and less BTU is satisfactory, then the user could accept thicker interburden. Compare these quality values with the ones calculated above and see how the SULFUR is lower and the BTU is also lower, but still within spec. Just try several reserve runs to see what the parting thickness cut off can be.

Case Study #2: Outcrop and Subcrop Modeling

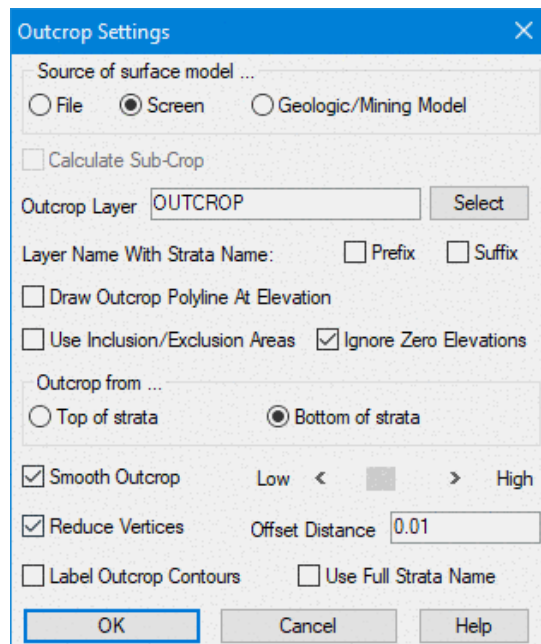

This tutorial steps through examples of how to handle outcrop and subcrop conditions on several examples involving ridge top mines as well as sub-cropping seams. Accurately locating the crop is one of the first things the planner needs for laying out a mine. Carlson automatically detects the location of the crop within the Surface Mine Reserves command. Volumes will never be calculated from above the ground surface. The advantage of the Draw Outcrops routine is that it allows the user to witness where the program is interpreting outcrops and subcrops. It is also useful in establishing a starting perimeter for pit layout. Outcrops are automatically calculated and drawn using Draw Outcrops command under StrataCalc on the fly directly from the drillhole data, or from Geologic Model grids.

For Generating Outcrops Directly from Drillholes ("On the Fly")

- Surface Topography Grid, Geologic Model file or Contours
- Drillholes on the screen

For Generating Subcrops

- Surface Topography Grid or Contours
- Drillholes on the screen
- Thickness Grid for *Unconsolidated* or *Weathered Strata* just below the surface

Outcrop Procedure

Select Draw Outcrops in the StrataCalc menu. Fill in the Outcrop Settings dialog box. The user can specify the source for surface topography (grid file or screen selection) and what layer to store the outcrop in when it is drawn. The user normally will use the settings as shown in the dialog box below with one exception. The offset distance could be set from 0.01 to 1.0 ft to reduce the vertices in the outcrop when drawn. Otherwise, the polyline for the outcrop will contain an unnecessarily large number of points.

Command: outcrop

Select surface entities & at least 3 drillholes

Select objects: Specify opposite corner: 111 found

Use drillhole surface elevations in surface model [Yes/<No>]? Y if they match the contours, otherwise N

Reading points ... 79695

Ignored 562 points with zero elevation.

Ignored 36 duplicate points.

Intersections found 80377

Pass> 10 Null Z values left> 0

Finding splits ...

Finding pinch out ...

Calculating seam stacking ...

Output grids for strata and surface [Yes/<No>]? N The files may be saved out for other uses. No is the typical response.

Choose modeling method [<Triangulation>/Inverse dist/Kriging/Polynomial/LeastSq]? T

Apply global trend to strata extrapolation [Yes/<No>]? Y

Use Triangulation Subdivision [Yes/<No>]? N

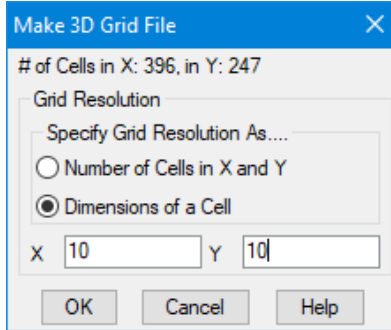

Triangulating points ... 5

Assigning grid values> 98400

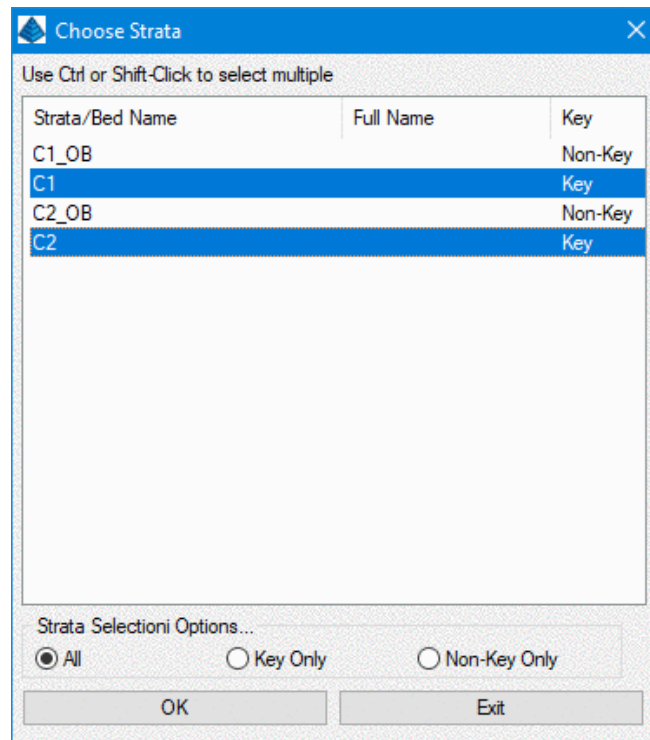

Pass> 282 Null Z values left> 0

Contouring elevation 0.0

Inserted 348 contour vertices. Complete the **Make Grid File** dialog box. The user may select the total number of rows and columns or the grid spacing pattern option. The program creates the grids "on the fly" from the drillhole data.

Select the preferred method. Once the gridding method is selected the **Choose Strata** dialog box appears. Choose the strata to process. Each strata can be gridded using independent gridding algorithms. If Inverse Distance or Least Squares was selected as the gridding method, when the strata is selected, the prompt is for the power to be used in the algorithm. Once the power is entered, assuming Inverse Distance or Least Squares is the selected method, then select the strata to be processed. Any number of strata may be selected to be processed by holding down the CTRL or SHIFT buttons.

Outcrop lines are produced on elevation zero by default. The outcrop polyline can be drawn on the surface file with the option to Draw Outcrop Polyline at Elevation.

Making Fence Diagrams

As a way to verify the location of the outcrop or make a graphic presentation of a geologic cross section, a fence diagram can be created using the Fence Diagram command under StrataCalc. Fence diagrams are useful for presenting geologic data as well as verifying the depths of seams and thickness of burden. Shown below is a fence diagram taken from the line drawn from west to east through the outcrops on the hill.

Fence Diagram Procedure and Prompting:

Command: fence

Select polyline to pull fence diagram from: *Pick the polyline to get the fence from*

Use drillhole surface elevations in surface model [Yes/<No>]? *N*

Select surface entities and at least 3 drillholes. *Select the drillholes and surface contours*

Select objects: Specify opposite corner: 112 found

Reading drillhole 5

Finding splits ...

Finding pinch out ...

Calculating seam stacking ...

Ignore zero elevations [<Yes>/No]? *Y*

Reading points ... 79695

Choose modeling method [<Triangulation>/Inverse dist/Kriging/Polynomial/LeastSq]? *I* Choose a modeling method you prefer.

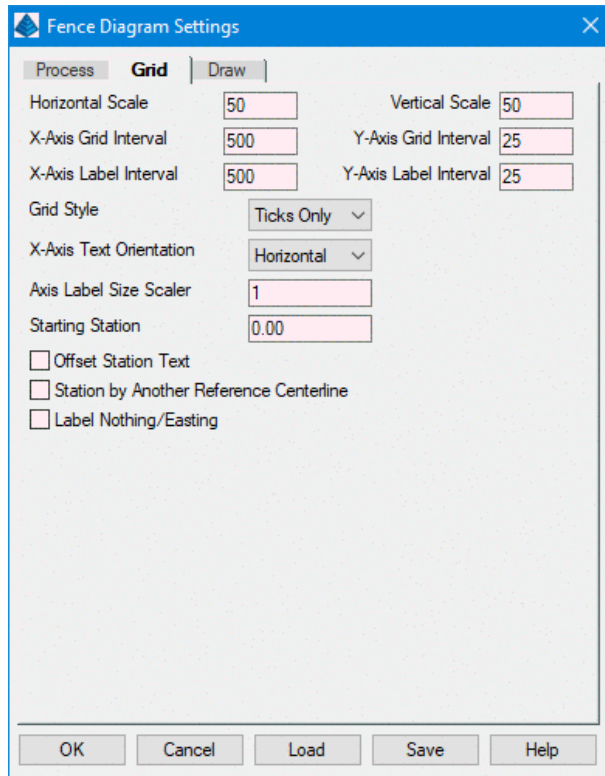

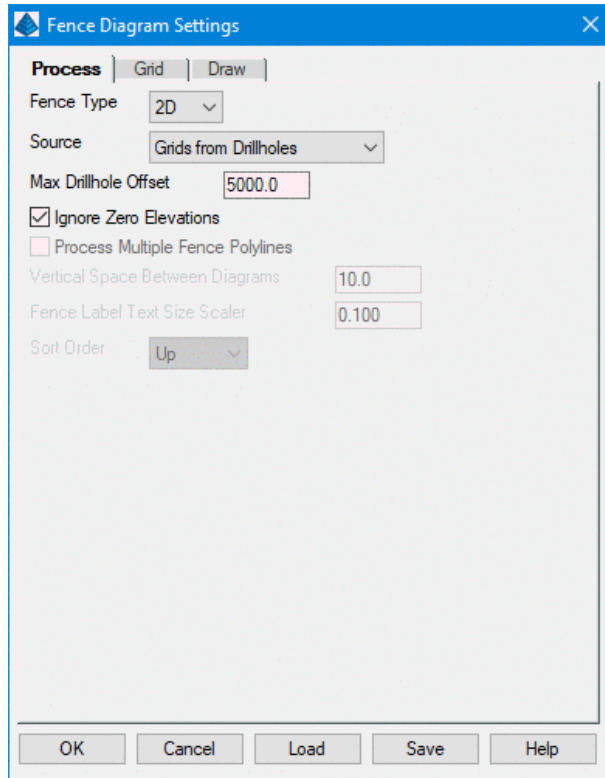

Use inverse distance to which power [First/<Second>/Third/Other]? *S*

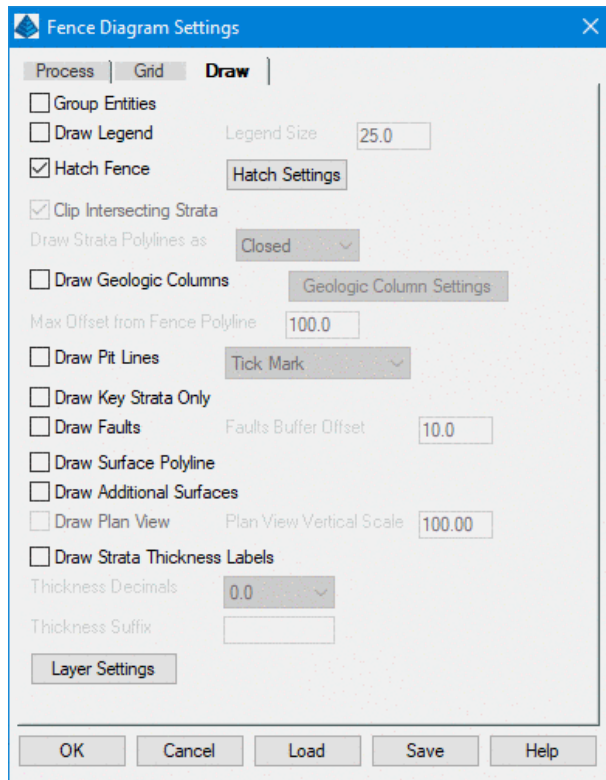

Use elliptical inverse distance [Yes/<No>]?

Calculating grid by inverse distances 98456...

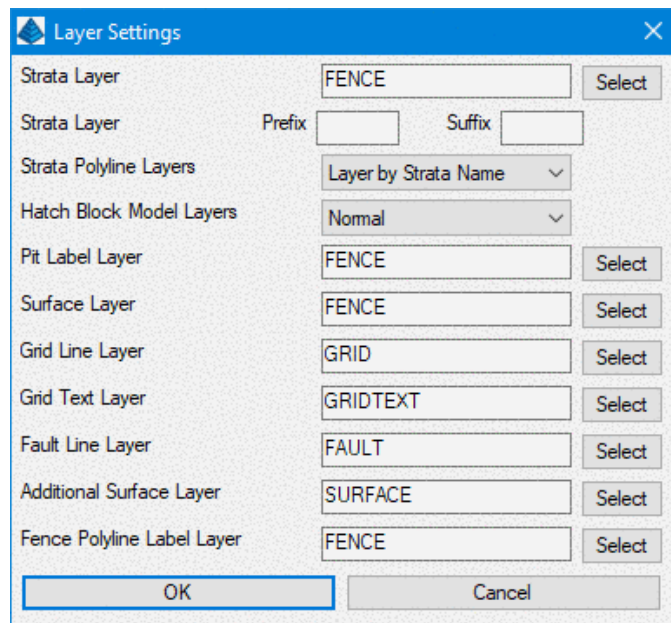

Bottom elevation of grid <1650.00>: 1400

Pick the lower left corner for the diagram: Pick an open area in the drawing for the lower left corner of the diagram.

Layer Settings button can be used to set layers for the different components of the fence diagram.

Using Surface Reserves to Check the Outcrop Volumes

To prove that Carlson honors the outcrop in its calculations, layout a rectangular polygon that overlaps the outcrop area. If Surface Mine Reserves recognizes the seam crop, then the area of the seam will be less than the area of the perimeter, and the upper seam crop area will be less than the lower seam area. It calculates reserve areas and handles outcrops automatically. Higher surfaces (the topography in this case) are the limiting factors. Volumes will never be calculated above the next surface up.

The area of the perimeter is shown as 3.371 Acres, some of it within the area of coal, and some outside. Run the Surface Mine Reserves command using the perimeter to get the tons and acres of coal. A typical report from the Surface Mine Reserves command under StrataCalc is shown below. Reports are user-defined in the Report Formatting dialog box.

Surface Mine Reserves Tue Jun 09 09:22:37 2020

Geologic Model: D:\work project\Mining Case Studies\Mining Case Study 2_Outcrops\NEW.pre
 Key strata recovery: 100.00%
 Minimum depth to use: 0.00 ft
 Minimum key thickness to use: 0.00 ft
 Minimum separable parting thickness to use: 2.00 ft
 Non-Key thickness Above key to add to key: 0.00 ft
 Non-Key thickness Below key to add to key: 0.00 ft
 Key top thickness to remove from key: 0.00 ft
 Key bottom thickness to remove from key: 0.00 ft

Strata	Non-key	C.Y.	Thick	COAL	Tons	Strip	Ratio	Area	acres	Pit	Area	Acres
C1_OB	166,287.6	63.98							1.611			3.371
C1		4.87	14,641.9			11.4			1.724			3.371
C2_OB	61,092.0	18.07							2.096			3.371
C2		6.18	23,904.6			2.6			2.221			3.371
Total	227,379.6	93.10	38,546.5			5.9						

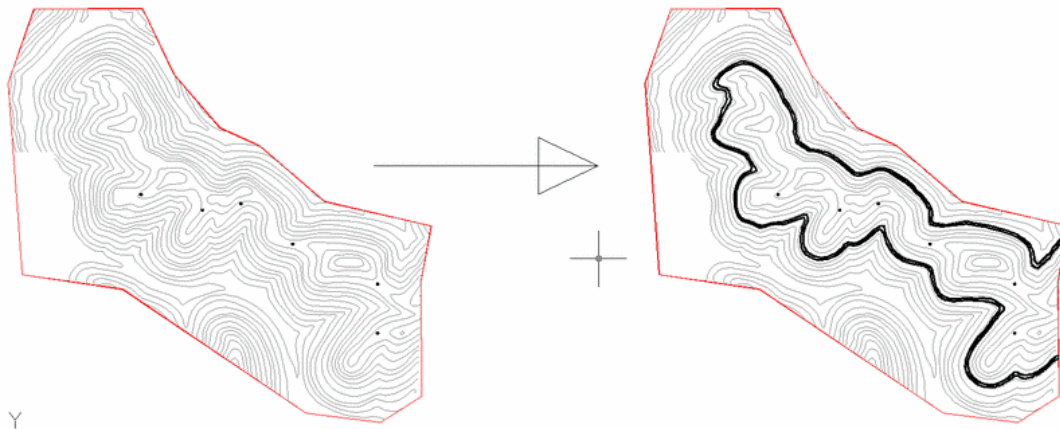

As the report indicates, Carlson recognizes the limits imposed at the outcrop. It properly truncates the seam at the outcrop and reports the included area between the crop and rectangle. Notice the C1 has less acres than the C2 because it crops out higher on the slope. the C2 shows 2.221 Acres compared to the full 3.371 Acres of the polygon. The Pit Acres are reported as an available option in the Report Formatter.

In topographic situations similar to the one shown in this example, for coal, the user will have to deduct from the mineable reserves for crop loss. Crop loss sometimes runs 10' to 15' vertically. The coal in this zone is usually oxidized to such an extent that the BTU is so low and the ash is so high, the coal cannot be sold for steam product,

and chemistry is so poor that it cannot go for metallurgical product either. Oxidized coal is treated as overburden.

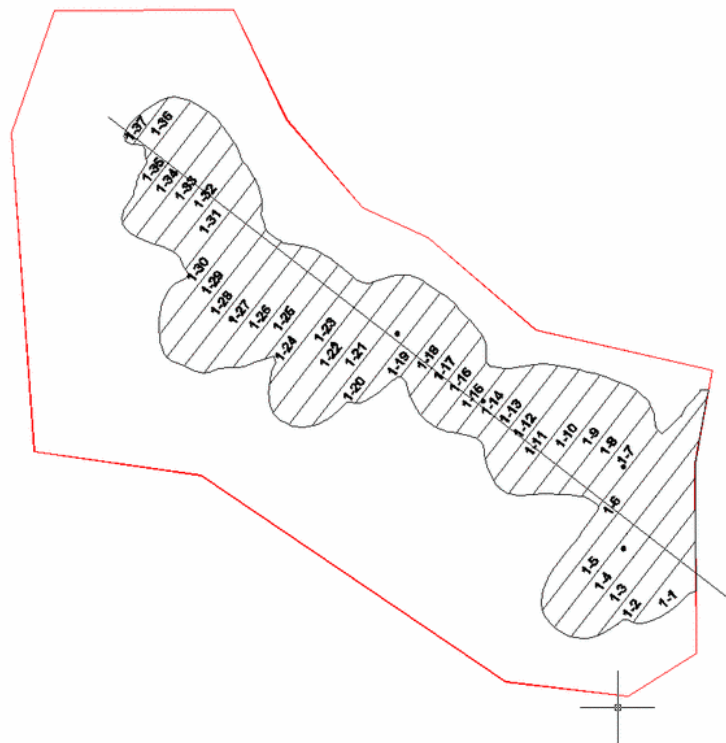

Using Outcrops for Laying Out Pits

In the example below, the outcrop was used to define the limits of the surface mining pits. The outcrop defined the limits of mining on each side of the pit. The direction of mining was input as part of the pit layout routine. The example below shows the Pit Layout By Advance command executed on the closed polylines. First, create a close polyline of the outcrop/mine boundary. Use the command Draw-Boundary Polyline and pick inside the ridge/outcrop lines to get a new interior polyline. You can also use AutoCAD's BPOLY command. Then, draw a direction line down the ridge to assign direction. Pits will be cut perpendicular to this line.

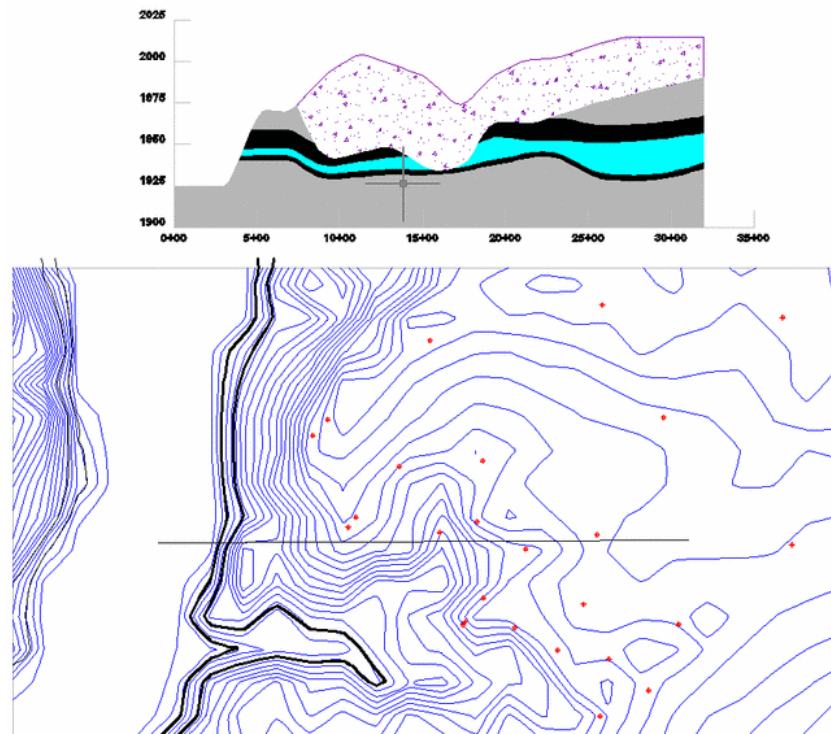

Pit Names, Labels, and Identify Pit Names

Since the process of laying out pits using the Pit Layout By Advance option gives the pits a name, a discussion of naming and labeling procedure is helpful at this point. After the pits are drawn, there are two methods to draw the pit name labels. Go to Label Pit Polylines or Pit Label Formatter. Identify Pit Polylines allows the user to see the Pit Names when the labeling option was not selected.

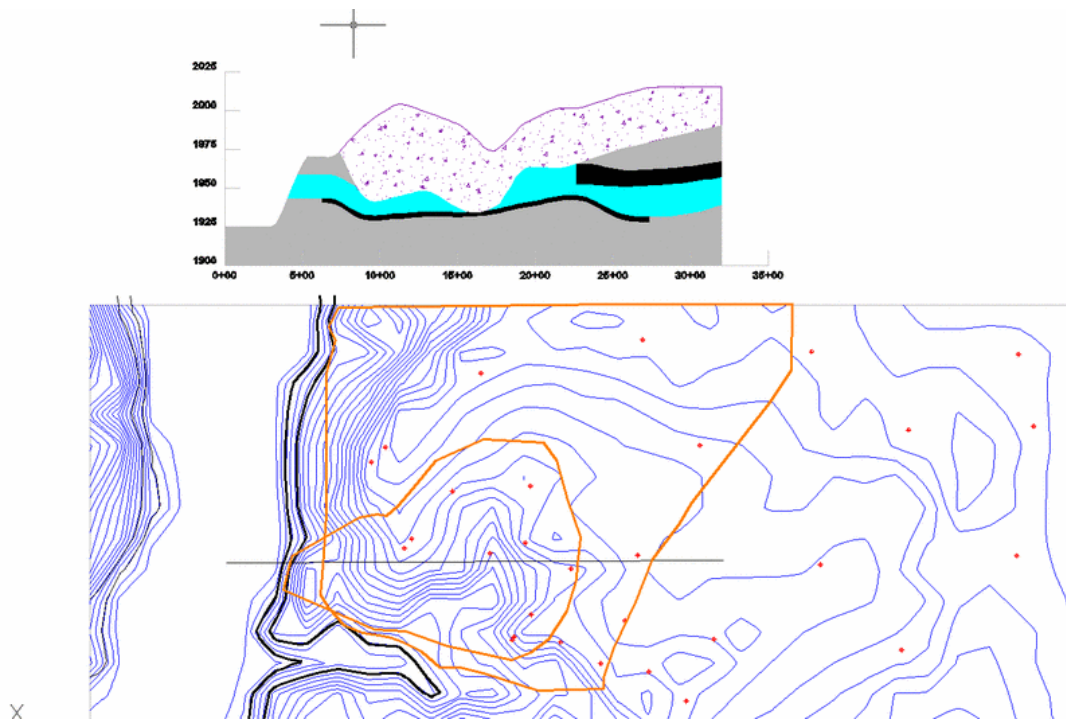

Subcrop Procedures

Subcrops occur where the unconsolidated material (could be glacial till or a channel deposit) has eroded out the key seam below the surface. Subcrops differ from pinchouts, in that unlike pinchouts, which can occur anywhere below the surface, lower strata being eroded by the unconsolidated material cause subcrops. Unlike outcrops which can be created "on the fly" from drillhole data, subcrops are calculated from grids. To calculate subcrops, the user must have the surface grid, thickness grid of the unconsolidated material, and bottom elevations of the strata to test for subcropping. In addition to the gridding algorithms, the user can specify strata limit polylines to override the natural mathematical interpretation of the data. When Carlson calculates the subcrop it starts from the surface and works down through the grids. If an upper grid has a lower elevation lower than that of a lower grid, the elevation of the upper grid is set to the elevation of the lower grid. This leads to a zero thickness in the lower grid, or a subcrop. Select the File option to begin calculating the subcrop. Carlson allows the user to calculate the subcrop from a Geologic Model grid or directly from the drillhole data.

This example was created by making strata grids from the drillholes. Put them in the Geologic Model grids file and then generate a Fence Diagram. The outcrop coincides with the outcrop lines in plan view on the hill side. Notice how the glacial till is subcropping the upper coal seam and the parting.

Strata Limit Polylines Using the same example for the Subcrops above, we will now create Strata Limit Polylines for both the coal seams and the parting. They must be drawn in plan view, then named with Name Strata Limit Polylines. Strata Limit Polylines must be turned on under Setting, Carlson Configure, Mining Modules. There are options to use them, and to also automatically select them. The orange lines are limit lines. The interior line is an Exclusion for the upper coal seam. The outer line is an Inclusion for the lower coal seam. Volumes will be calculated accordingly with Surface Mine Reserves.

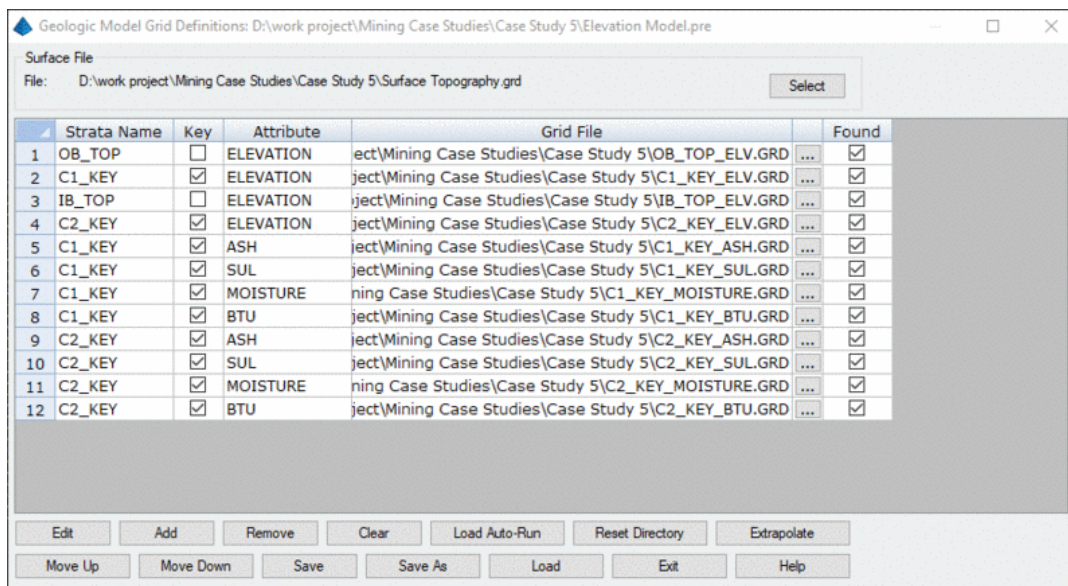

Case Study #3: Techniques Of Gridding

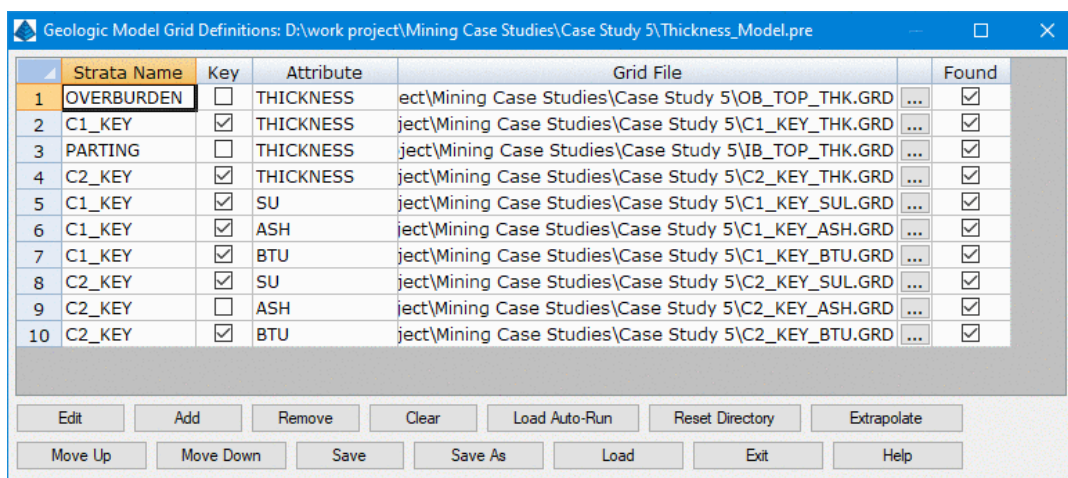

Surface and Underground Reserves are the key routines for developing reserve estimates and qualities and for setting up equipment-based mine scheduling. Along with the Fence Diagram routine, Surface or Underground Reserves will calculate strata elevations and qualities using Geologic Model grids. These grids represent the "mine model". Here we will study how to make the grids strategically to build in well-defined subcrops, outcrops, splits, correct strata thicknesses, and qualities.

What is the "Geologic Model" File?

The Geologic Model File can either be an Elevation model or a Thickness model. The elevation model consists of a grid model of the surface topography as the first and primary grid. Below the surface grid is the bottom elevation grid for each strata to be modeled, ordered top to bottom in the Geologic Model grids dialog box. Any number of quality attribute grids (covering such items as sulfur, ash, moisture, etc.) can be associated with the bottom elevation grid of a particular strata, though they are not required. If a strata is called C1, for example, the C1 name is associated with its bottom elevation grid file, and any attribute grid files should refer to the same Strata name. A Thickness Geologic Model just contains thickness grids (no elevation grids). There is no surface topo grid file defined in a thickness model. Below are typical examples of both types of Geologic Model files.

Geologic Model Elevation Model

Geologic Model Thickness Model

When naming attributes such as Ash, BTU and Moisture, be sure to attach the attributes to a strata (in this case C1 and C2) which must match the exact spelling of the strata name containing the associated base elevation or thickness grid. These names are not case sensitive, and are converted to upper case automatically.

Grid Cell Dimensions

Drillholes at many mines are often drilled at a spacing of 500 feet or more, making small cell size unnecessary when modeling geologic aspects, especially quality attributes. As a rule of thumb, cell size should be 1/4 the average drillhole spacing between drillholes for most accurate modeling. With some minerals and ores such as quality controlled limestone and clay, drillholes are drilled as close as 50 feet apart. This would suggest the need for a 12.5-foot cell size or less. Surface topography, however, often demand the tightest cell size, because the topography can include steep cliffs, high stream banks and other abruptly changing features, that can be lost or smoothed if cell size is on the order of 100' to 200' spacing. Below are two examples of surfaces. The first surface has gently sloping terrain and widely-spaced contours. This has been gridded at 100'x100', as there are no sharp features that need to be captured in the grid file. The second set of images shows an open pit with benches, spoil and roads. To accurately capture all of this detail, a grid size of 10'x10' is more appropriate. It makes a much larger file, but does not over-smooth the surface, as a larger grid cell size would do. There is no limit, but try to keep the number of total cells in a grid file less than one million total cells. It will run much faster if each grid file is less than one half of a million grid cells.

Cell Positions and Dimensions Should Match

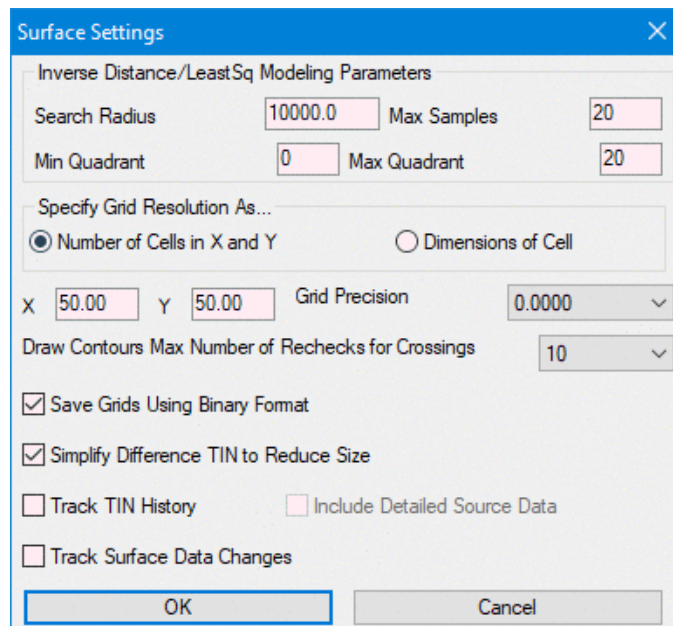

Some routines in Carlson require that the grid position and cell size should be identical for all grid files in a Geologic Model grid model set (Design Bench Pit is an example). To ensure that grids match position and dimension, make the first grid file, then make all additional grid files based on the position of the first grid file. To do this, you select option "F" when prompted: Use position from another file or pick grid position (<Pick>/File)? There are Grid File Utilities to modify grids, such as Change Position, Change Resolution and Match Dimensions.

In Surface and Underground Reserves calculated from a Geologic Model, the grids do not need to match. It is common to have a surface topo grid file with a small cell size, such as 10x10. Then the structure grids for elevation or thickness could have a medium cell size, such as 50x50. Finally, quality attribute grids can have an even larger cell size, such as 200x200. This could be due to the fact that not every drillhole has quality sampled, so the spacing of quality holes is much greater than structure data holes, not needing a tight resolution. Here it is important to note that when volumes are calculated, the elevation and quality grids will be temporarily resized to match the topography (note that the grids themselves will not be permanently modified).

Cell Dimensions Versus Number of Cells

Carlson defaults to 50x50 "number of cells" when first installed, meaning that in any grid window position, there will be 50 cells in the X-direction and 50 cells in the Y-direction, unless altered by the user. If the window is longer in the x-direction, then the cells will be longer in their X-dimension than in their Y-dimension, creating rectangular shaped grid cells. By contrast, the user can specify the cell dimension when making grids, leading to a variable number of cell, depending on the size of the grid window. It should be noted that the default itself can be set by

the user. This is done by selecting Carlson Configure under the Settings Pulldown Menu > Surface Settings, which provides the following dialog. Note that at the bottom of the dialog there is the option to set the number of cells or the dimension of the cells to any desired value.

Make Top of Strata Grids by Adding Thickness Grids to Bottom of Strata Grids

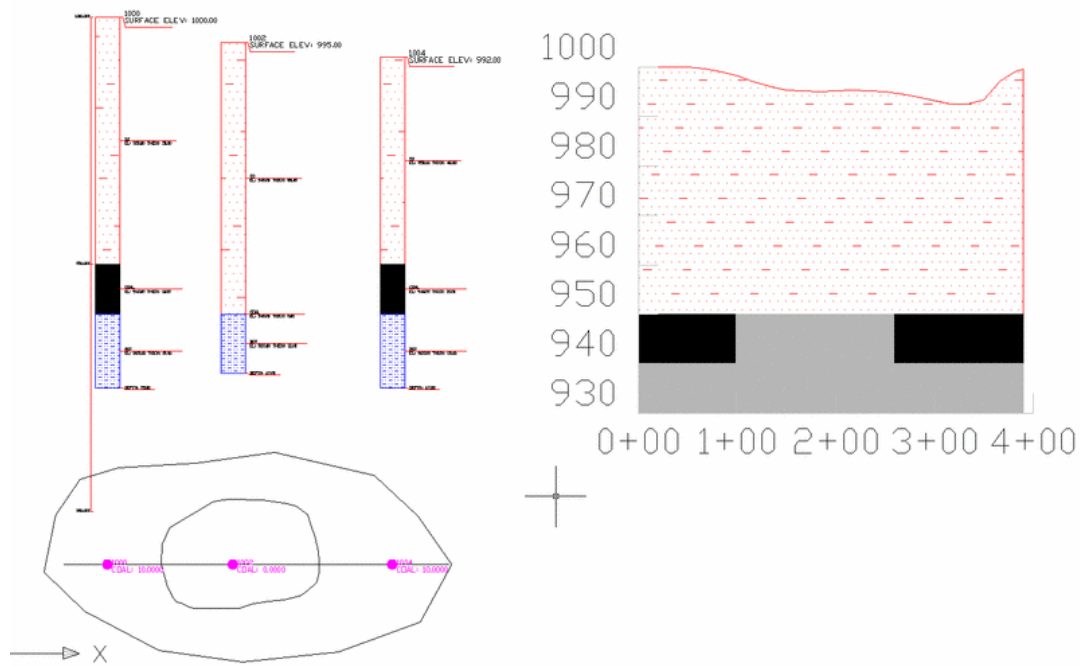

The elevation Geologic Model File is based on having grid files for the bottom and top of all key strata. If you have only the surface grid, and the bottom and top elevation of each Key strata, you are set up for most reserve and scheduling work. Of course, quality grids can be added, and NonKey elevation grids such as base of unconsolidated overburden are valuable. But the point here is that you want bottom and top of Key grids for each seam under consideration. These grids should in most cases be made by making a thickness grid for the strata and adding thickness to base elevation to obtain top of strata grids. There are two settings that should be monitored when doing this type of modeling. Under Settings > Carlson Configure > Mining Settings, be sure that pinch-out is on for modeling thickness. If not, then the seam will never pinch out in cases of zero thickness holes. When modeling elevation grids, it is often helpful that pinchout turned off, because when it pinches out a seam, it sometimes brings that elevation up to the next seam above, to pinch it out. If pinch out is off, it will keep the elevation grid down where it should be, had the seam been there. Add the two grids together to get the roof. Where the seam had zero thickness, the roof will be the same as the floor, and down and the correct elevation. The following example shows this concept, where the middle seam is pinching out in the middle. The middle hole has a zero value for coal thickness. This will bring the coal up to that hole, then pinch it at the hole.

This next example is created from the example where the Coal seam does not exist in the middle hole, not even a zero. This method will pinch the coal 1/2 way between the holes, based on the Pinchout Settings under Carlson Configure > Mining Settings. Most of the time, this is your best guess.

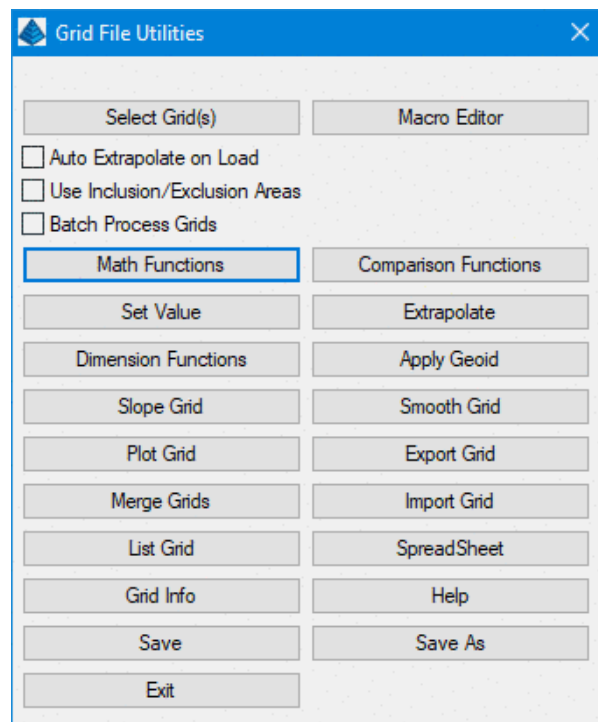

Using slightly different settings, this next Fence Diagram can be obtained.

Two Strata Limit Polylines were drawn around the drillholes, representing crop lines. The interior line is an exclusion limit line. The outer line is an inclusion limit line. The grids were remade, the bottom elevation and the thickness were added together to get the new roof, and here is the result. The seam carries its full thickness to the cropping limit lines, no pinching is taking place.

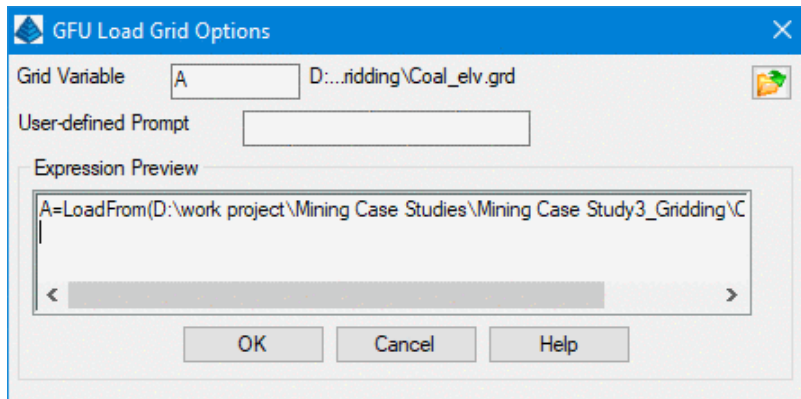

Grid File Utilities

The Grid File Utilities can be accessed from within the Geology Module by entering GFU in the command line, or under the Grids Pulldown Menu > Grid File Utilities. It is also located in the Surface Pulldown Menu of the Civil Module. After starting the command, you must first choose Select Grid(s) to load a grid file. Within GFU, you can click an option to be prompted for Inclusion/Exclusion perimeter polylines. The grid manipulation will only occur inside or outside these perimeters. The commands BPoly and Shrinkwrap under the Draw Pulldown Menu are useful tools to generate these perimeters.

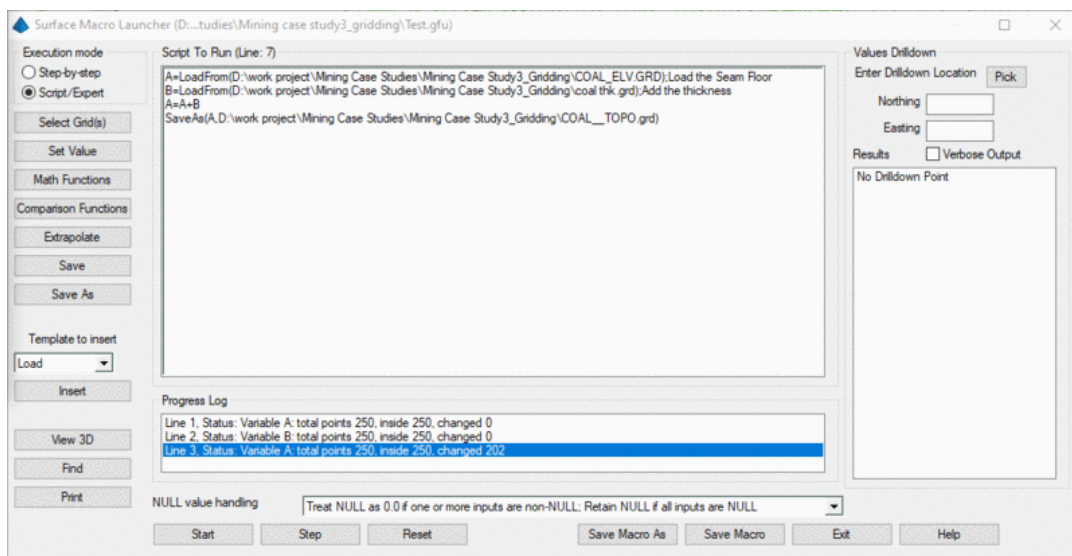

Adding One Grid to Another

In order to add grids, select Grid File Utilities (GFU) to bring up the dialog box shown above. Choose Select Grids and load the base elevation of the coal seam, COAL_ELV.GRD. The next step is to select Math Functions > ADD GRID which asks for the grid file to load (COAL_THK.GRD). At this point you would choose "SaveAs" and save the result as "COAL_TOP.GRD". If this modeling effort is a one-time process, there is no need to save a macro that allows for automatic re-running of the grid addition. However, if the thickness grid or base of coal grid might change due to the addition of more drillholes (or the editing of existing drillholes), then macros can be time-saving devices. To make a macro for our example, you would get to the dialog above by entering GFU as before and clicking the Macro Editor button. First, create a new GFU file for future Auto-Run. Then Choose the Select Grid button. The upper right button in GFU Load Grid Options allow user to choose grid file.

The Grid Variable "A" at the top represents the grid file to be loaded. So A is COAL_ELV.GRD (the base of COAL grid). Repeat loading the second grid and use Grid Variable B for the COAL_THK.GRD thickness grid. Next click Save As, same as above. Now select Start to run the macro. Note that you may manually modify the text in the macro as needed. Comments can be added by typing ";" at the beginning of the comment. For example, the below line will load a grid file, but will recognize the end of the line as a comment rather than part of the actual macro.
A=LoadFrom(D:\work project\Mining Case Studies\Mining Case Study3_Gridding\COAL_ELV.GRD);Load the Seam Floor

The Need to Extrapolate

Some modeling methods (Inverse Distance, Kriging, Linear Least Squares, Nearest Neighbor, and ABOS) will automatically extrapolate the grid, filling in values entirely within the limits of the grid location. If the modeling is

done by Triangulation or Polynomial, the grid values will only exist within the area of the data points - everything beyond the data points will be empty. Thus the area of modeling by Triangulation or Polynomial will always be less than the area of modeling by any other method. This may create a problem in Grid File Utilities where grid addition is involved. Two things can happen. Number one, the program may complete the addition, but in reality grid values have not changed where the base grid file contained null values. Number two, the program may report "Grid files do not match" and refuse to do the grid math operation. To remedy this, choose "Extrapolate" within Grid File Utilities, select the default method, and extrapolate all grids prior to doing grid math. The extrapolate command itself can become part of the macro if record or append is selected. Other routines have the option to extrapolate, such as Grid Inspector, where there is a check-box to Extrapolate Grids. The Reserve commands will always extrapolate the grids upon loading, so it is generally preferred to make sure they are extrapolated to start with. There are two options at the bottom of the Define Geologic Model dialog to extrapolate the grids. One method will extrapolate the elevation out, the other will merge with the next upper seam, pinching the thickness to zero.

Reserves from Geologic Model Grids

It is always preferable to compute volumes from Geologic Model files using the Surface or Underground Mine Reserves. All the care and control that went into making the grid files is then reflected in the improved accuracy and legitimacy of the result. The Geologic Model can contain quality attribute grids, and even a Block Model for detailed quality tracking and breakdown. The alternative is to select drillholes directly from the screen (on-the-fly), which builds in uncertainty as to the nature of the modeling.

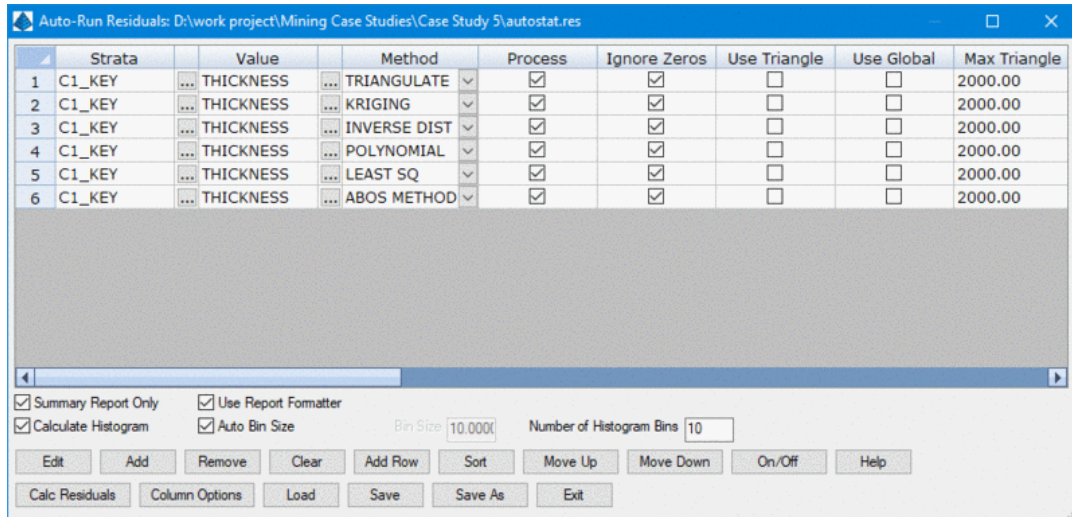

Choosing a Method of Gridding

Every user is confronted with the issue of what gridding algorithm to choose. Here there is no substitute for experience and verification in the field. We at Carlson Software have noticed that many qualities such as sulfur or calcium are modeled most often by Inverse Distance. Base elevation, in general, appears to be amenable to the logic of Triangulation or Polynomial, much like surface topography, though even here Inverse Distance is often used. Strata thickness, however, is again more localized and is often best modeled by Inverse Distance or Least Squares. Polynomial surface modeling utilizes Triangulation, so again lends itself to broad, large area influences. When and how to use Kriging is an art in itself. We have found the "power" form of Kriging to model effectively in evenly distributed drillhole data. The following diagram shows the same drillhole data set modeled with 12 different versions of the algorithms. Notice there are some large differences, yet all have their benefits.

Calculate Residuals

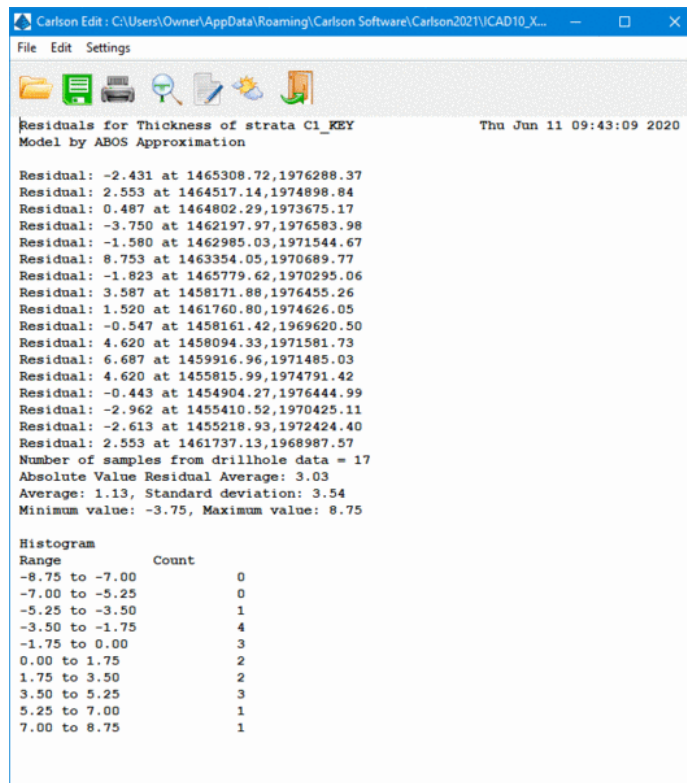

This command guides the user to select a modeling method. The concept is much like field checking. With field verification, you would pick a location for testing, then measure coal thickness or sulfur or base elevation and check the data against the model. If it is close, your model is good. If the testing is repeated, you can add up all the errors (the residuals) and make a determination of the effectiveness of one model against another. But even without field testing, you can take 25 drillholes and model with 24, then check the error residual at the removed drillhole. You can then repeat this "removal" process across all 25 drillholes, and verify the average residual error and the standard deviation of the residual error. This is exactly what the command Calculate Residuals does.

Shown below, for example, is a comparison all the modeling methods exported to Excel. This was done with Auto-Run Residuals command.

	A	B	C	D	E	F	G	H	I	J
1	Strata	Value	Model	Std Deviation	Samples	Absolute Value Residual Average	Avg	Min	Max	
2	C1_KEY	Thickness	Triangulation	4.62	9	4.46	2.37	-8.48	9.11	
3	C1_KEY	Thickness	Kriging	0.00	0	0.00	0.00	0.00	0.00	
4	C1_KEY	Thickness	Inv Dist 2.00 Pwr	4.03	17	3.47	-0.48	-7.00	8.84	
5	C1_KEY	Thickness	Polynomial	4.72	9	3.73	1.13	-8.93	9.58	
6	C1_KEY	Thickness	LeastSq	5.18	17	4.48	-0.94	-11.09	9.70	
7	C1_KEY	Thickness	ABOS	3.54	17	3.03	1.13	-3.75	8.75	
8										
9										

In this example, ABOS has the lowest standard deviation and absolute value residual average, making it a stronger candidate for modeling this drillhole dataset. The command Calculate Residuals will bring up a report that shows every drillhole and what the residual was. It will also create a Histogram, showing the number of residuals within certain ranges. This can be used to look for extreme values and fliers. However, it important to note that even though a gridding method may have the most favorable residual average, the contours and cross sections for that method should still be analyzed for accuracy.

Modeling Options

It is important to set the strata modeling options that are in Settings Carlson Configure command under Mining Settings. These settings are used in modeling commands that process strata from drillholes such as Make Strata Grid, Surface Mine and Underground Mine Reserves, and Strata Isopach Maps, just to name a few.

The Inverse Distance and Least Squares settings control the data point search radius and the maximum samples which limits calculations to the nearest set of the specified number of data points. Inverse Distance and Least Squares can also be forced to use a minimum and/or maximum number of data points from each quadrant NE, SE,

SW and NW. These inverse distance settings are used whenever modeling by inverse distance.

During strata correlation, the program matches strata with the same name between drillholes. When a strata name is missing in a drillhole, there are three possibilities. Either the program can skip that drillhole for modeling that strata, the strata pinched out, or the drillhole did not reach the strata and the strata position can be modeled by conformance. The method to use is determined by the Pinch Out and Conformance settings in this dialog.

If you turn off Pinch Out, then the program will skip a drillhole with a pinch out case for modeling that strata. Otherwise the missing strata will be given a negative thickness at the drillhole. The thickness is negative so that when modeled with the other positive thickness drillholes, the pinch out or zero thickness position will be somewhere midway between the missing and existing drillholes. The slide bar "Near Zero <-> Non-Zero" controls the amount of the negative thickness. The Near Zero setting will make a smaller negative value which moves the pinch out position closer to the missing strata drillhole. Likewise Non-Zero makes a larger negative value which moves the pinch out position closer to the drillhole with the strata.

For Conformance, turning off conformance will make the program skip a drillhole with a conformance case for modeling that strata. With conformance active, the missing strata position at the partial drillhole will be calculated by modeling the thickness between the missing strata and a marker strata that does exist in the drillhole. This thickness is modeled with inverse distance using drillholes where both strata exist. Then the thickness is added to the marker strata to locate the missing strata in the partial drillhole. Conformance can be set to Seam-Specific which allows only specified strata to be marker strata. Additionally, the specified marker strata will only conform with specified target strata. The marker and target strata names are set in Define Strata.

Case Study #4: Limestone Block Modeling

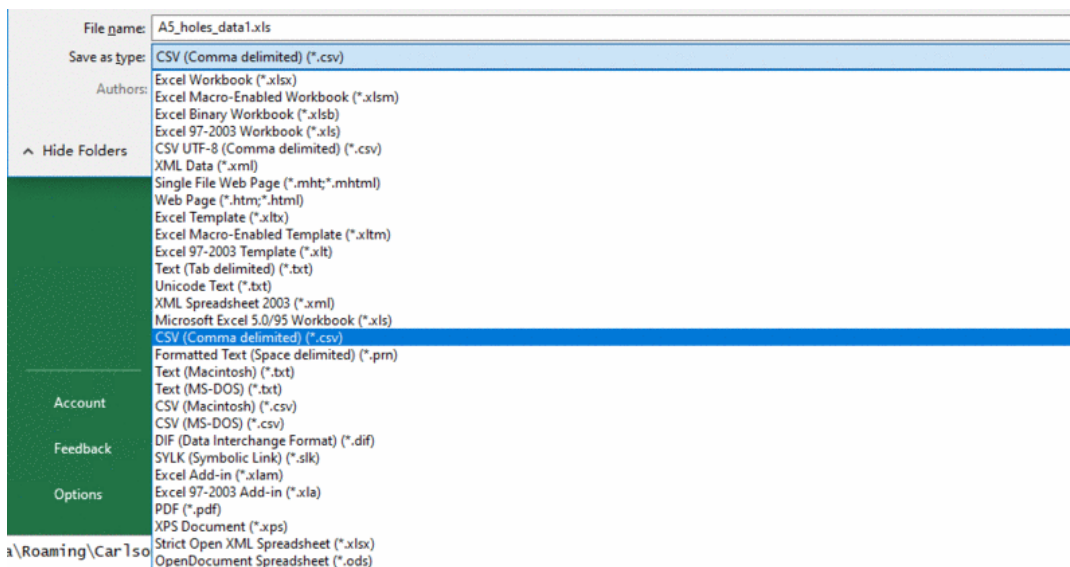

This lesson will step through modeling a limestone quarry using the Carlson block model routines. It goes through the process from start to finish, importing drillholes to final reporting and viewing graphics. Most of these commands are found in the Block Model menu of the Carlson Geology Module.

Step 1-Import the Drillhole and Face Data

To import the drillhole data, it is important to create an ASCII file with a repetitive series of columns for the collar x,y,z position, followed by columns for the downhole information. Shown here is an example of the spreadsheet to import.

	A	B	C	D	E	F	G	H
1	HOLE #	X	Y	Z	Z Top	Z Bottom	DESCRIPTION	Attribute (Color)
2	H-1-04	24463.27	18245.63	676.63	676.63	658.28	Dirt	Dirt
3	H-1-04	24463.27	18245.63	676.63	658.28	651.53	Bastard Stone	Bastard Stone
4	H-1-04	24463.27	18245.63	676.63	651.53	649.24	Void	Void
5	H-1-04	24463.27	18245.63	676.63	649.24	616.82	Bastard Stone	Bastard Stone

28	H-1-04	24463.27	18245.63	676.63	587.52	585.77	Standard Buff	Standard Buff
29	H-1-04	24463.27	18245.63	676.63	585.77	580.35	Silver Buff	Silver Buff

To import the drillholes, it will need to be in ASCII form, use Excel to save the file in ASCII form with a ".csv" extension.

Answer Y to the question regarding saving the current worksheet. This results in a comma-separated file ASCII, such as this typical example, viewed with Notepad:

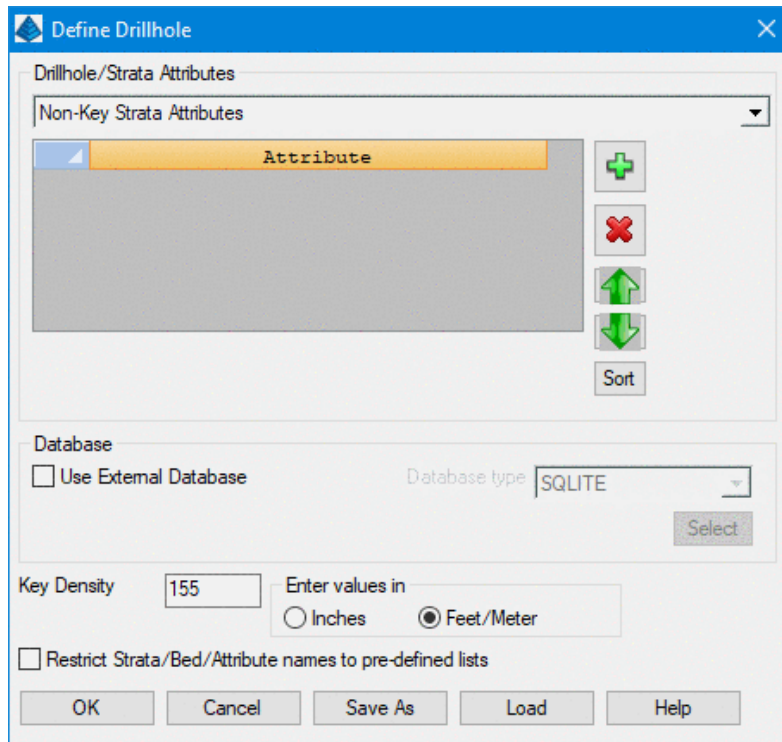

```

HOLE #,X,Y,Z,Z Top,Z Bottom,DESCRIPTION
1-03,25158.6200,18332.4000,652.9800,652.98,634.23,Bastard Stone,Bastard Stone
1-03,25158.6200,18332.4000,652.9800,634.23,634.06,Bed, Bed
1-03,25158.6200,18332.4000,652.9800,634.06,632.98,Standard Buff, Standard Buff

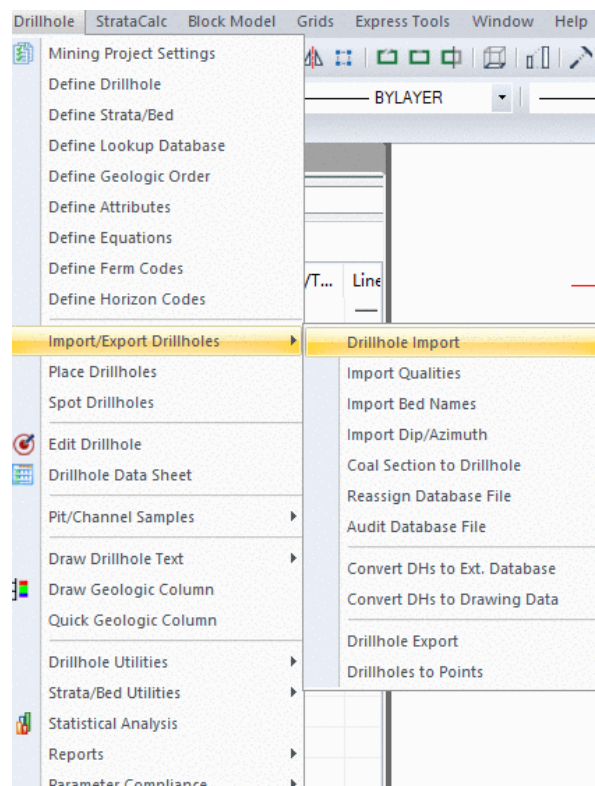

```

Notice that this file contains one "header" line consisting of the title, that we can ignore.

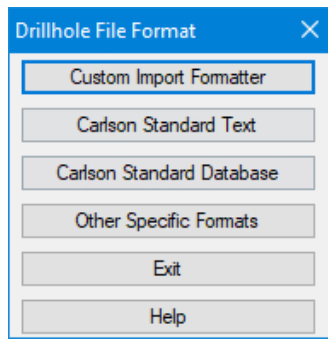

Before importing the drillhole, you will need to create a .CH file via the Drillhole Pulldown Menu > Define Drillhole. Here you only need to specify the default density for key material (note that there are other methods of defining density that will overrule this setting).

Next we bring this file into Carlson by using the command Drillhole Import found in the Import/Export Drillhole flyout, underneath the Drillhole pulldown menu.

Within this command, choose the Custom Import Formatter.

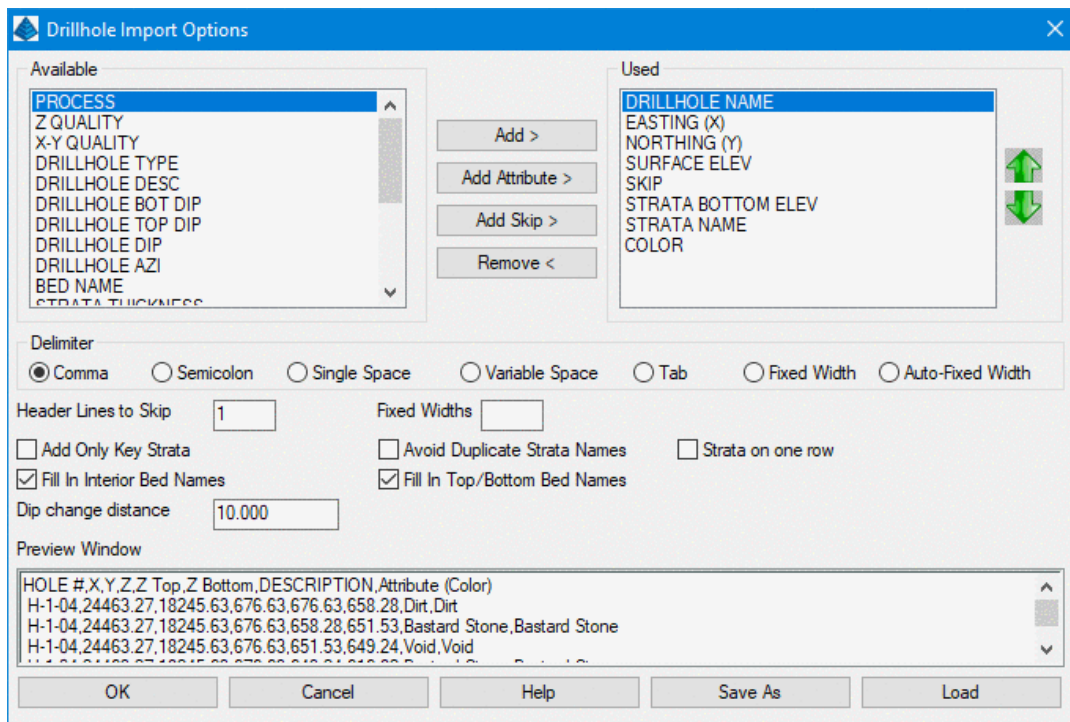

This window will appear:

Select "No", as all the data is in one CSV file.

Note that the default answer is "No" and can be selected by pressing Enter. Load the correct ".csv" file containing the ASCII drillhole data. Now organize the right-hand column to correspond to the ASCII file, as shown here:

Note how you can study the data file organization in the "Preview Window". This format can be given a name and saved by pressing the Save button. Note that we have specified "1" header line to skip (skip the title line), and also notice that we have chosen to skip the "Z Top" column, since the bottom elevation defines the strata, measuring down from the top, collar elevation. Press OK to continue. As a result of the import, we now have 7 drillholes in our area of study, as shown below:

Importing Drillholes is a critical process in geologic modeling, so it is important to be familiar with the precise techniques to accomplish this. Carlson offers extremely flexible importing. The drawing with the 7 new drillholes can now be saved with any file name desired.

You have the option to import these drillholes while already in a drawing (such as a topo map of the site), or you can import the drillholes into a blank drawing then insert additional surface features like contours. The Insert command can be found under the Draw pulldown in Carlson. In this case, we'll insert a contour file called Block Model Contours, to obtain the combined drawing below:

To verify contour elevations, and to check whether the top of the drillholes are close to the contour grades of the contours, use Drawing Inspector under the Inquiry pulldown menu. You will notice that all the holes top out at just about the right elevation you would expect based on the nearby contours, the only slight exception being the slightly lower drillhole shown below, where some of the surface could have been removed where the hole was drilled. It's just a few feet low:

Note also that if you inspect the blue boundary lines, they, too have elevation. Those lines should be set to zero using the command, "3D Entity to 2D" under Edit. Otherwise, they will impact surface modeling. It's a good idea to turn off the Drawing Inspector when you are not using it. Also, by right clicking with the mouse button when Drawing Inspector is on, you can change what you inspect (layers versus elevations, for example).

Step 2-Set up Strata Definitions to Colorize the Strata

This is a one-time process. The Strata Definitions file is used by Draw Geologic Column, Fence Diagram, and by the routines that color and display the block model. It can also impact tonnage calculations, because you can set the strata density within Strata Definitions. The dialog appears as shown below. The asterisk can be used to apply the definition to anything that begins with the letters preceding the asterisk. In this way, Standard Buff with Vertical Seam would be treated as all the other Standard Buff strata in terms of coloring and modeling.

Strata/Bed Name	Full Name	Key	Color	Hatch	Hatch Scale	Density	Layer	Draw Legend
1 STANDARDBUFF*	Standard Buff	<input checked="" type="checkbox"/>	Yellow	SOLID	25.00	BY_DRILLHOLE	Standard Buff	<input checked="" type="checkbox"/>
2 STANDARDGREY*	Standard Grey	<input checked="" type="checkbox"/>	Grey	SOLID	25.00	BY_DRILLHOLE	Standard Grey	<input checked="" type="checkbox"/>
3 SILVERBUFF*	Silver Buff	<input checked="" type="checkbox"/>	Light Green	SOLID	25.00	BY_DRILLHOLE	Silver Buff	<input checked="" type="checkbox"/>
4 RUSTICBUFF*	Rustic Buff	<input checked="" type="checkbox"/>	Orange	SOLID	25.00	BY_DRILLHOLE	Rustic Buff	<input checked="" type="checkbox"/>
5 CRAWFOOT*	Crawfoot	<input checked="" type="checkbox"/>	Blue	SOLID	25.00	BY_DRILLHOLE	Crawfoot	<input checked="" type="checkbox"/>
6 RUSTICGREY*	Rustic Grey	<input checked="" type="checkbox"/>	Dark Blue	SOLID	25.00	BY_DRILLHOLE	Rustic Grey	<input checked="" type="checkbox"/>
7 DIRT	DIRT	<input type="checkbox"/>	Brown	SOLID	25.00	BY_DRILLHOLE	Dirt	<input checked="" type="checkbox"/>
8 VOID	VOID	<input type="checkbox"/>	Red	AR-RROOF	25.00	BY_DRILLHOLE	VOID	<input checked="" type="checkbox"/>
9 BASTARDSTONE*	Bastard Stone	<input type="checkbox"/>	Black	SOLID	25.00	BY_DRILLHOLE	BS	<input checked="" type="checkbox"/>
10 OLDGOTHICBUFF*	Old Gothic Buff	<input type="checkbox"/>	Yellow	BEDCHT	25.00	BY_DRILLHOLE	OGB	<input checked="" type="checkbox"/>
11 OLDGOTHICGREY*	Old Gothic Grey	<input type="checkbox"/>	Grey	BEDCHT	25.00	BY_DRILLHOLE	OGG	<input checked="" type="checkbox"/>
12 BED	BED	<input type="checkbox"/>	Black	SOLID	25.00	BY_DRILLHOLE	BED	<input checked="" type="checkbox"/>
13 RUSTICSILVER*	Rustic Silver Buff	<input checked="" type="checkbox"/>	Blue	SOLID	25.00	BY_DRILLHOLE	RSB	<input checked="" type="checkbox"/>
14 VARIEGATED*	Variagated	<input checked="" type="checkbox"/>	Cyan	SOLID	25.00	155.00	VG	<input checked="" type="checkbox"/>
15 CRAWFOOT		<input type="checkbox"/>	Cyan	ZIGZAG	25.00	BY_DRILLHOLE	crawfoot	<input checked="" type="checkbox"/>

The columns to be shown in the spread sheet can be set using Column Options. The values can be edited with in the spread sheet shown above or by selecting the strata row and using Edit button.

The screenshot shows the 'Strata Definition' dialog box for a strata named 'STANDARDBUFF'. The 'Strata Name' is 'STANDARDBUFF', 'Full Name' is 'Standard Buff', and 'Layer' is 'Standard Buff'. The 'Hatch Name' is 'SOLID', 'Hatch Scale' is '25.00', and 'Hatch Azimuth' is '90°0'0"'. The 'Type of strata' is set to 'Key' (radio button selected). The 'Recovery Percent' is '100.00'. The 'Non-Key Thickness To Add To Key (Dilution)' is '0.00' for both 'Above Key' and 'Below Key'. The 'Key Thickness To Remove From Key (Loss)' is '0.00' for both 'Key Top' and 'Key Bottom'. The 'Use for modeling (pinch out/conformance)' checkbox is checked. The 'Use as seam-specific conformance marker' checkbox is unchecked. The 'Marker Priority Level' is '1'. The 'Strata Split Names' are empty. The 'Additional Attributes' section has 'Attr. Name' empty and 'Update', 'Add', and 'Remove' buttons. The 'OK' and 'Cancel' buttons are at the bottom.

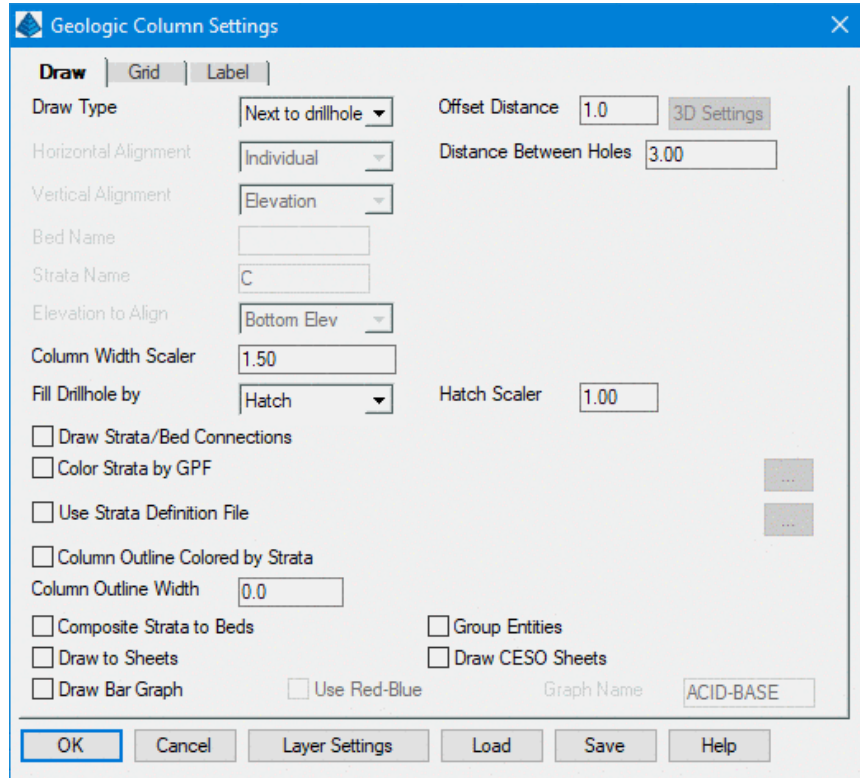

Contrast the StandardBuff settings with those for Dirt, which we have colored black and designated "Non-Key", which means it is waste, not a product you are mining to sell.

The screenshot shows the 'Strata Definition' dialog box for a strata named 'DIRT'. The 'Strata Name' is 'DIRT', 'Full Name' is 'DIRT', and 'Layer' is 'Dirt'. The 'Hatch Name' is 'SOLID', 'Hatch Scale' is '25.00', and 'Hatch Azimuth' is '90°0'0"'. The 'Type of strata' is set to 'Non-key' (radio button selected). The 'Recovery Percent' is '100.00'. The 'Non-Key Thickness To Add To Key (Dilution)' is '0.00' for both 'Above Key' and 'Below Key'. The 'Key Thickness To Remove From Key (Loss)' is '0.00' for both 'Key Top' and 'Key Bottom'. The 'Use for modeling (pinch out/conformance)' checkbox is checked. The 'Use as seam-specific conformance marker' checkbox is unchecked. The 'Marker Priority Level' is '1'. The 'Strata Split Names' are empty. The 'Additional Attributes' section has 'Attr. Name' empty and 'Update', 'Add', and 'Remove' buttons. The 'OK' and 'Cancel' buttons are at the bottom.

Step 3-Draw Geologic Column

Once you have verified your colors for the strata (again, a one-time process using Strata Definitions), it is valuable to confirm the quality of the drillhole import by drawing the geologic column. One method is to draw the columns next to the drillholes. Choose Draw Geologic Column at the bottom of the Drillhole pulldown menu. Possible settings

for the dialog are shown below:

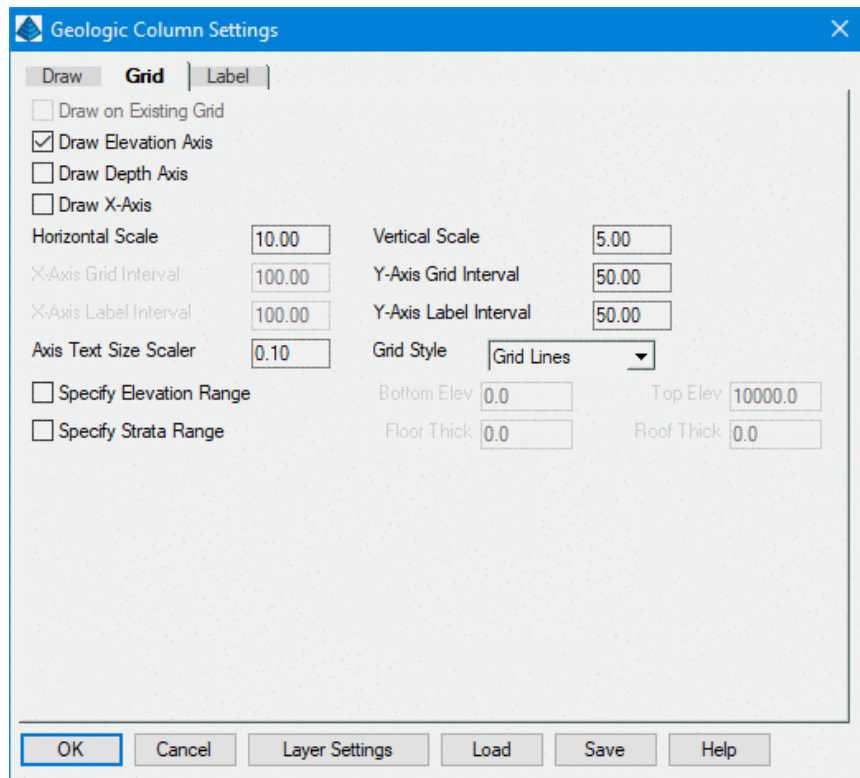

Geologic Column Settings

These settings produce the plot shown here:

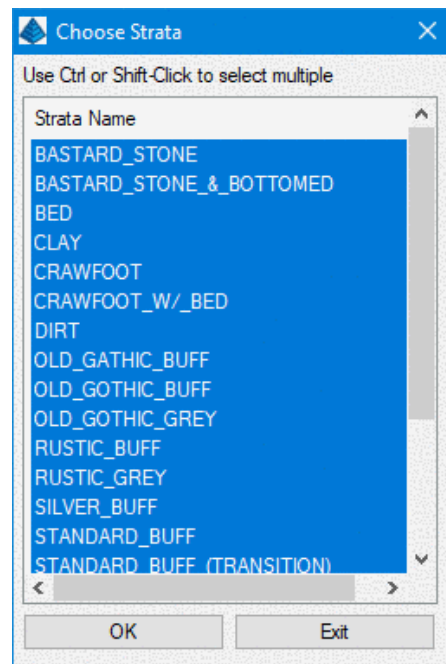

This is the first indication of the location of the yellow standard buff, as well as the location of silver grey and other colored zones. The location of the black overburden material is also clear in the plot.

Step 4-Assign a Bed Name to All Strata

The block modeling routines require that the various strata be organized into beds. You might have a top 80-foot bed and a lower 100-foot bed in large deposits of ore. If you don't want to distinguish beds, just put all the strata into one bed name, like Stone. Note that if a column "Bed Name" was made in the original Excel file, all the

strata could be imported with a bed name without the need for modification. To add Beds "after-the-fact", choose Drillhole Pulldown Menu > Strata/Bed Utilities > Assign Bed Names. Select all drillholes and enter "Stone" for the bed name, for example. Enter N for No when prompted for "Use Parameter Filter?". Then select all strata in the list at right. Highlight and click OK.

Step 5-Surface Mine Reserves

You are now ready to get a volume of any material desired. Before you do the command, you will need a closed polyline perimeter. Note in the above graphic plot with contours, we have 3 blue squares that might be areas of interest for volumes. Each might represent a mining block. But in reality, these are not closed polylines, but are drawn as individual polylines in approximate N-S and E-W directions. To create closed polylines where the zone of interest is "enclosed" by other polylines, a useful command is "Boundary Polyline" under the Draw Pulldown Menu. Choose this command.

Pick all the blue polylines that "bound" the rectangle of interest (or that bound all the rectangles). Do not pick any contours or other polylines. Enter a snap tolerance of 1 (to "bridge" gaps of up to 1 foot). Enter the layer to draw the polylines in (CLAYER would put them in the current layer). Then pick inside, and the closed, rectangular polylines are drawn.

Now run the command Surface Mine Reserves under the Stratacalc Pulldown Menu. Fill out the dialog as shown, being sure to select the "Block Model" method. This selection does an "on-the-fly" block model. The Geologic Model selection would work from a stored Geologic Model file, which can be a block model or a strata-based model. Specify the block by elevation, entering the bottom and top of the zone of interest (we did 580 to 620 here).

Surface Mine Reserves

Process | Adjustment | Output

OK Cancel Load Save Help

Also be sure to select "Calculate Strata Qualities" and "Breakout Quantities by Attributes", options near the bottom left of the dialog on the Process tab. After you select all 7 drillholes to model, you will get this dialog:

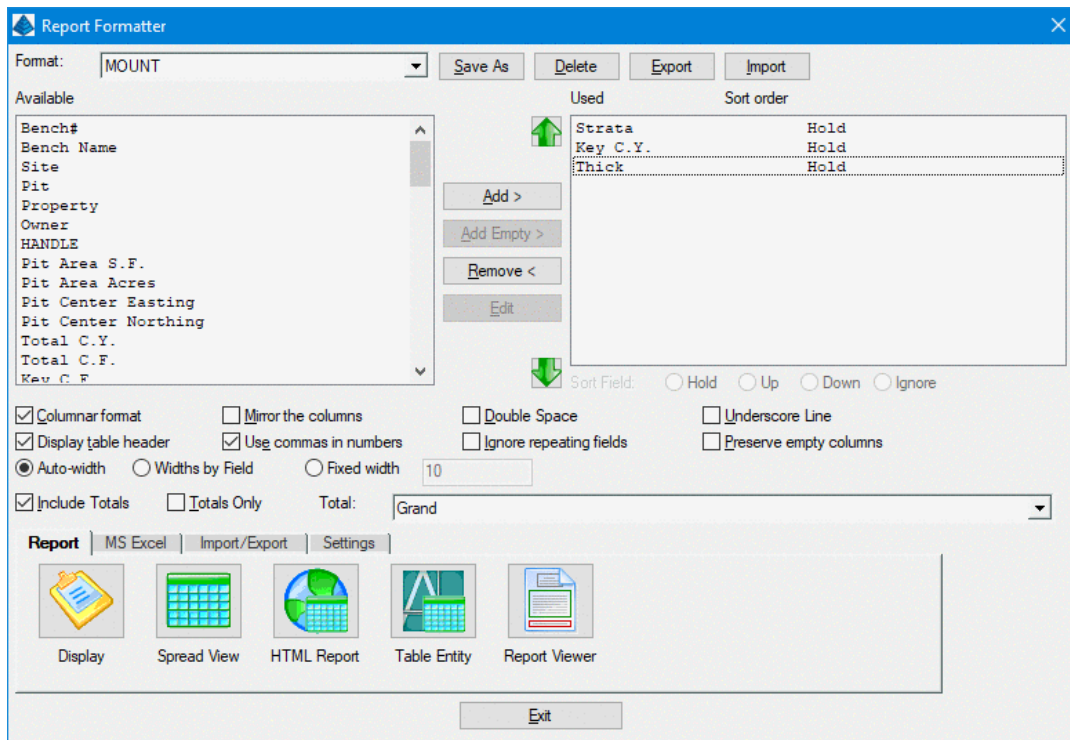

Here we are only interested in modeling the Strata Names, as the color attribute cannot be mathematically modeled (with the exception of the Strata Name, only numeric values may be modeled). Next you can pick any of the strata to report by selecting them:

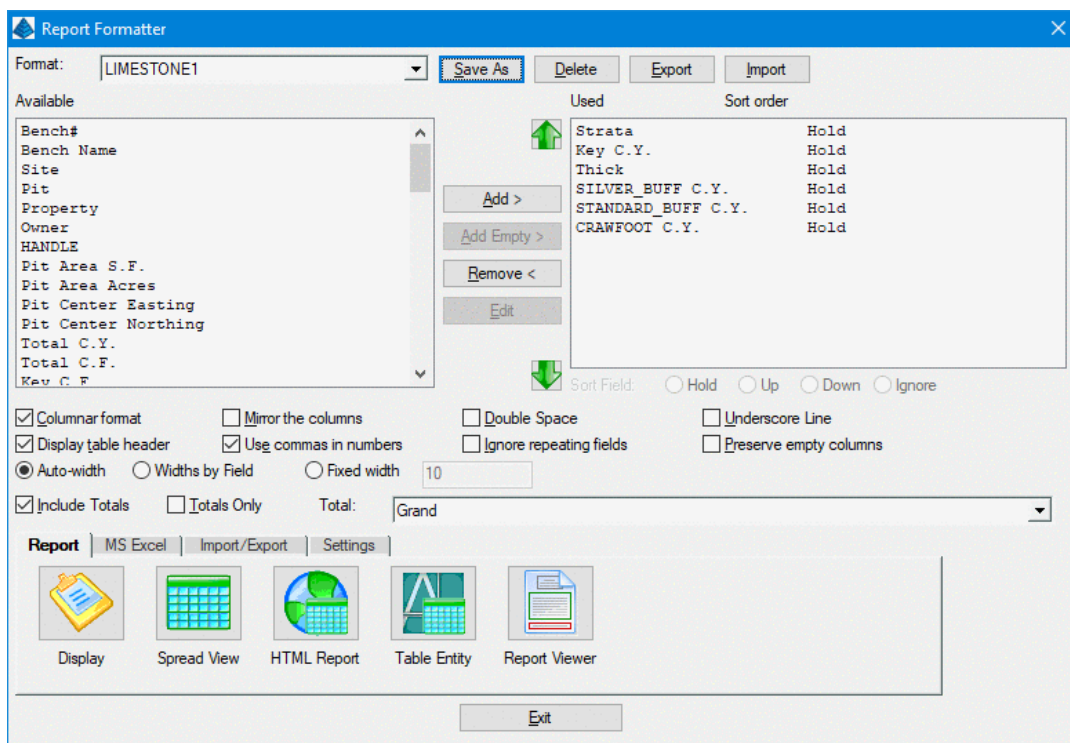

If we choose Crawfoot, SilverBuff and StandardBuff, quantities will be calculated for that block. Next you pick the limits of the study area, from lower left (well below and left of the drillholes) to upper right (well above and to the right of the drillholes) and set your gridding resolution. For example, if you have 40' of elevation range, 80 vertical zones will give you about 0.5' per zone for analysis.

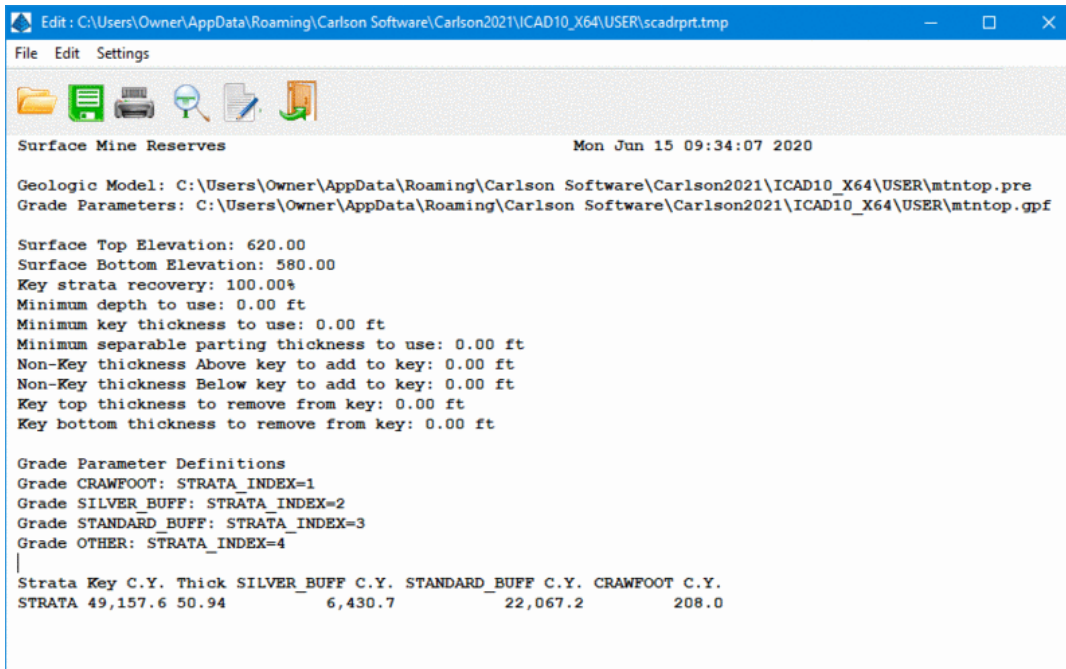

Pick one of the inclusion perimeters, and you are taken to the "Report Formatter" as shown below. Here it is shown as it might appear with a fresh installation of Carlson, completely unformatted.

Move to the right the Silverbuff C.Y., the Standardbuff C.Y. and the Crawfoot C.Y. You can name the format in the upper middle box as Limestone1, so it is a report option available to you in the future (see below):

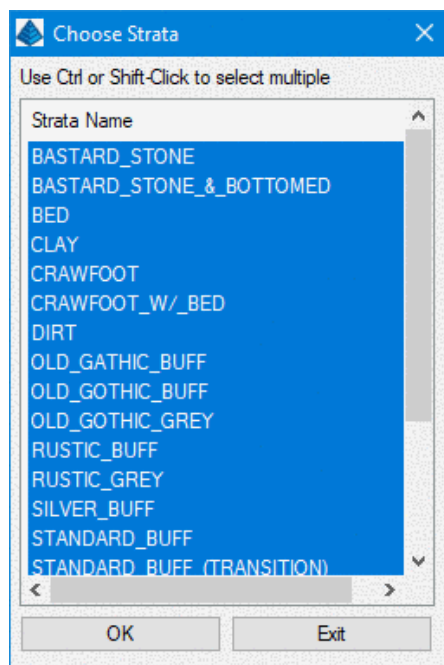

Click Display in the lower left of the screen, and you get the first report:

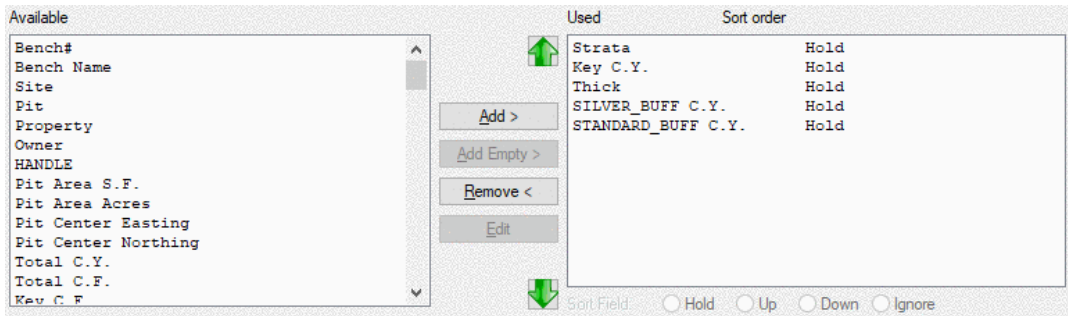

Step 6-Reporting in Cubic Meter: Making User-Defined Attributes for Reporting

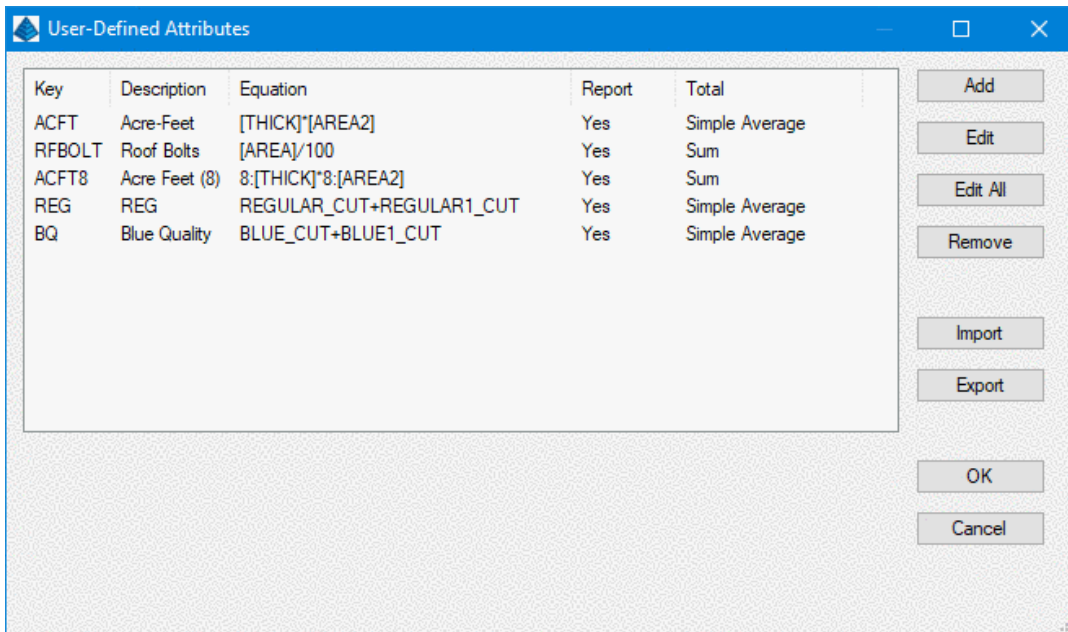

When configured to "English" units, that is, feet, the program defaults volumes in the form of cubic yards. If you wanted to also output cubic meters, then the default output variable for cubic yards needs to be multiplied by 0.765 to produce cubic meter. The variables "known" to the program can be listed within the Report Formatter by clicking the Attribute Options button at the bottom of the screen. A formula must be created for all of the named strata to convert cubic yards to cubic meter. Therefore, to obtain all of the strata in the Report Formatter, it is necessary to re-run Surface Mine Reserves using the same settings in the dialog, but when prompted for Choose Strata, select all of the strata, as shown.

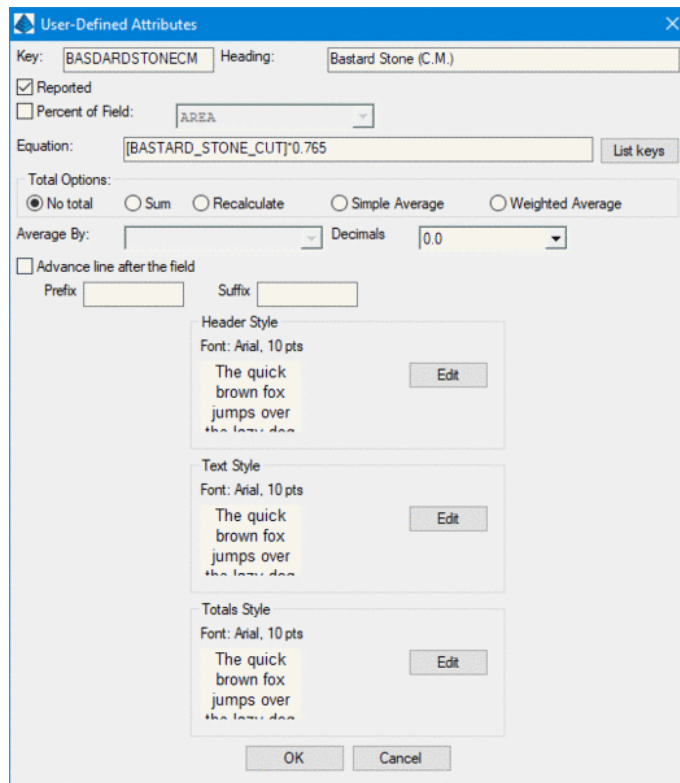

Then when you press OK and complete the gridding process, all of the strata appear in the Report Formatter, either in the left or right column.

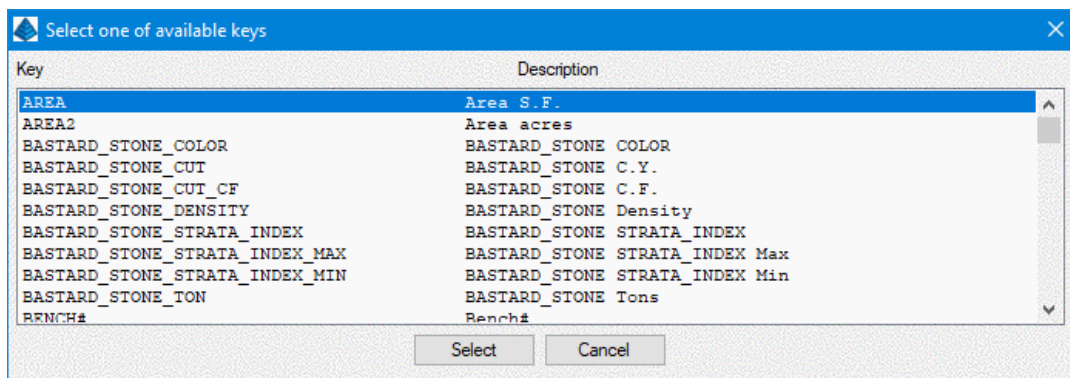

The next step is to click the User Attribute button at the bottom of the screen, which then produces the following dialog:

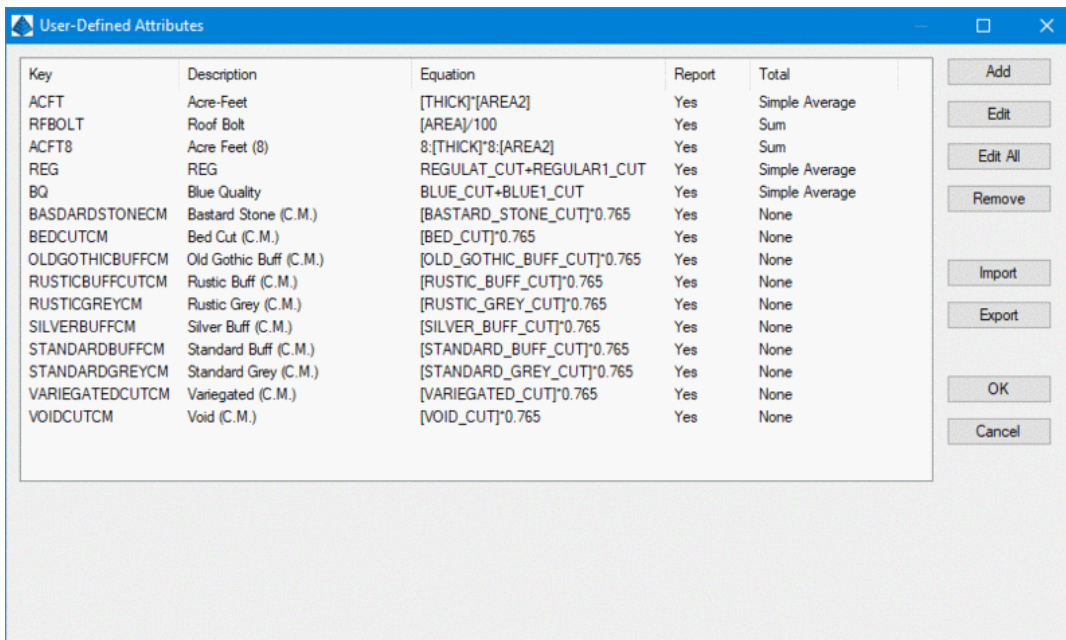

A few conversions are provided by default. We will need to add a conversion to cubic meters for each strata of interest. To begin, click Add.

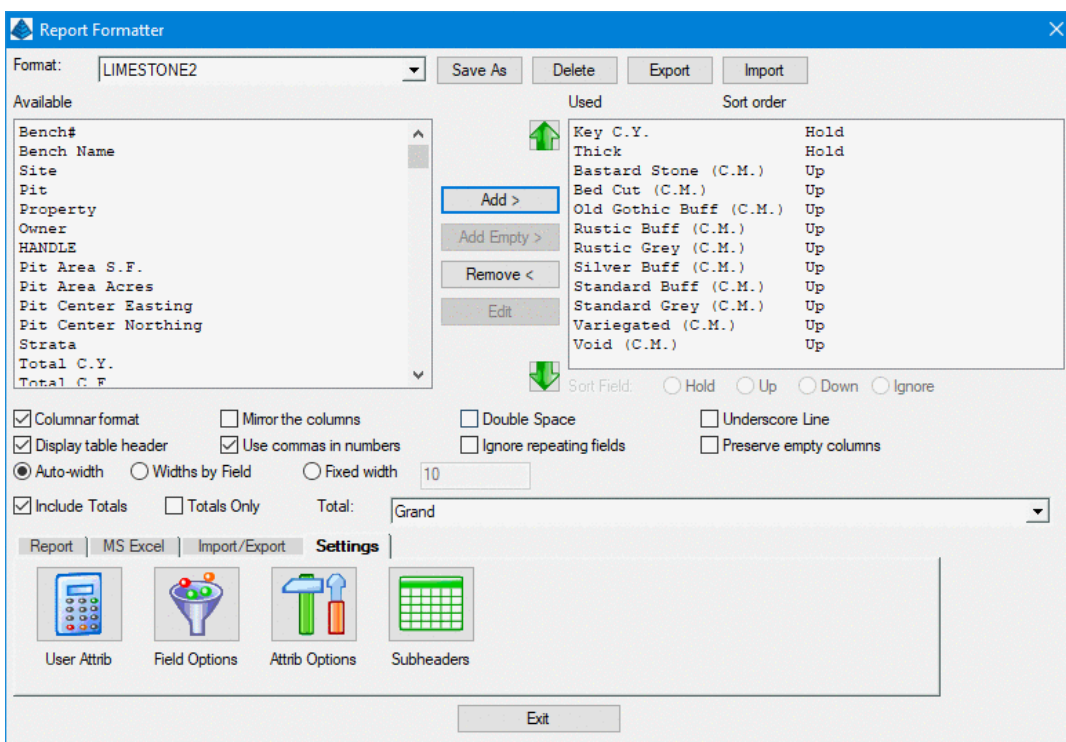

For the example of "BastardStone", you simply multiply the "known" variable for BastardStone by 0.765 to calculate cubic meters. Whatever is filled out for Description is what appears in the report. To see what the program uses as "known" variables, you click "List keys". The variable can be directly selected from this dialog, then the "*0.765" can be appended in the equation. Items are listed alphabetically:

Repeat for each of the stone types involved. The pattern is, every time you click Add, click List Keys, choose the next stone of interest (e.g. BED_CUT), multiply by 0.765 in the equation, fill out the new "key word" for the cubic meter variable, fill out the full description for reporting and the decimal places, consider whether to Total by Sum, use No Total, etc., then click OK. Repeat for each strata. In order to see "Crawfoot" as a strata, you may need to select a larger number of vertical divisions, to "reveal" the very thin Crawfoot seam and get it in the list. Note that this is a one-time process. The new key variables will always be retained on future work. The final table might appear as shown below:

Next, click OK and return to the Report Formatter. Move the generic "Strata" and cubic yard items from the right column back to the left column and move all the desired cubic meter elements over to the right-hand column and save this new format as Limestone2.

Note that using the "User Attrib" button, you can make new elements for reporting, and these elements, like Standard Buff (C.F.), can be used in equations themselves, using their "key word" designation ("STANDARDBUFFCF"). Thus the Report Formatter can be used to produce all sorts of outputs and reports, all deriving from the known elements in the original report. To see results directly in Excel, click the "MS Excel" tab then click Export to Excel at the lower right of the dialog:

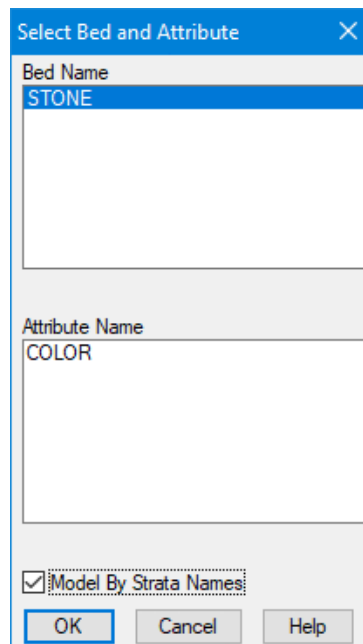

This leads to reporting directly in Excel:

	A	B	C	D	E	F	G	H	I	J	K	L
1	Key C.Y. Thick	Bastard Stone (C.M.)	Bed Cut (C.M.)	Old Gothic Buff (C.M.)	Rustic Buff (C.M.)	Rustic Grey (C.M.)	Silver Buff (C.M.)	Standard Buff (C.M.)	Standard Grey (C.M.)	Variegated (C.M.)	Void (C.M.)	
2	58,907.4	64.34	6,696.2	467.7	3,726.1	6,902.4	1,405.3	5,088.2	15,690.8	3,145.5	402.2	876.3

Step 7-Viewing the Ore Body Model in 3D

So far, we have produced volumes of material by "on-the-fly" calculations. We have not created a block model of our strata. The block model has only been created internally by the program based on the selection set of drillholes. An official "block model" is made by the command "Make Block Model" at the top of the Block Model pulldown. Select that. Here again, you can make the block model directly from the strata names.

Choose the lower left corner of the grid by the "Pick" method, and using the "end" snap (for endpoint) pick the lower left corner of the site, then the upper right corner of the site, as defined by the rectangular polyline enclosing all contours. Then set the grid resolution as shown below. Since we are dealing with "named" strata that abruptly transition to another form, use the "discrete" method of modeling. Note that for ore bodies, where qualities are typically modeled, "inverse distance" or "Kriging" are more typical modeling methods.

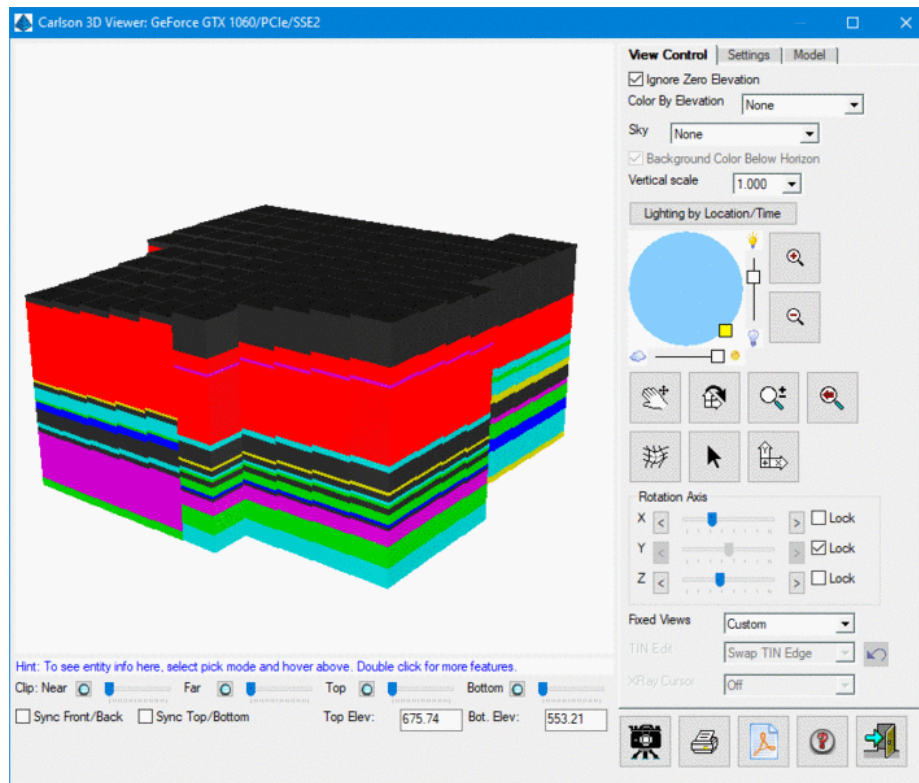

Note also in the dialog above that you can set the vertical position for modeling at fixed elevations or you can follow the ore model. The "follow" method finds the top and bottom of the ore material, then divides the vertical positions as defined, here by 80 divisions. So if the ore material narrowed, then 80 divisions would narrow to a smaller dimension. If you want fixed vertical dimensions, choose "Fixed Elevations". After you click OK, select all strata to process, and name the block model to be created. Also create, for later use, the grade parameter file and Geologic Model grid model. Click "Yes" to both the options below:

These options occur only when choosing the "Model by Strata Name" option above. Otherwise, you must use a pre-made Grade Parameter File and make the Geologic Model file by a separate process. The Grade Parameter File sets the colors (and even pricing) for the named strata or quality zones (in the case of attribute-defined grades). Making the Grade Parameter File this way does not set colors that match the colors set in Strata Definitions. You will need to run the command, "Define Grade Parameters" under the Ore pulldown menu and change the colors to match what were used in Strata Definitions, for consistent viewing, so that the 3D Views match the colors in Draw Geologic Column, for example.

Now run Block Model 3D Viewer under the Block Model pulldown, choose the "blk" Block Model File and the "gpf" Grade Parameter File, press "OK" at the Block Model Viewer dialog, then select a perimeter for viewing. You obtain a plot as shown below:

Note that you can exaggerate the vertical scale, or using the "Settings" tab, you can switch from rendered view (above) to "Leave as Points" view. Note that the yellow "Standard Buff" stone shows clearly in the 3D Block View, as does the red Void zone within the upper portion.

Step 8-Viewing the Ore Body in Profile View (Fence Diagram)

The process of making the Block Model was critical not only for 3D Viewing but also for the Profile View or "Fence Diagram". The 3D View used the "blk" file but the Fence Diagram command makes use of the "Geologic Model" or "pre" file as well as the "blk" Block Model File. Now that we have these, from Step 7 above, we can do the Fence Diagram. Before issuing the Fence Diagram command, draw a polyline through the drillholes or across the site that you will pick for the profile view of the strata (stone). Select Fence Diagram under the StrataCalc pulldown menu. Fill out the dialog as shown below:

Fence Diagram Settings

You could choose to exaggerate the vertical scale by changing the vertical entries to 20 rather than 50 (scale, grid interval and text interval). Then pick the polyline to use for the profile, and the "Geologic Model" and the "grade parameter file" as prompted. A typical result is shown below:

Case Study #5: Block Modeling by Quality Attributes

This tutorial takes a set of drillholes and goes through the steps that create the block model. The different grades are defined in the Grade Parameter File. Blocks are drawn and viewed in 3D for analysis. Cross sections are cut through the blocks and volumes by grade are calculated with Surface Mine Reserves. Finally, the Optimized Pit Design is found with the Lerch-Grossman algorithm.

The first step is to import the drillholes and name the beds based on how the seams are to be modeled. This example is a limestone bed with a thin layer of overburden, so there are just two main material types in the drilling, OB and LS are the bed names. The drillholes have already been imported for this example. That process is documented in other documents. There are 16 drillholes in this drawing. The drawing name for this tutorial is *Block Modeling.dwg*. Shown here are the plan view of the topography and the drillholes, and also the drillhole datasheet to display the drilling data.

Drillhole Data Sheet

5	FE2O3	0.061
6	S	0.032

READY

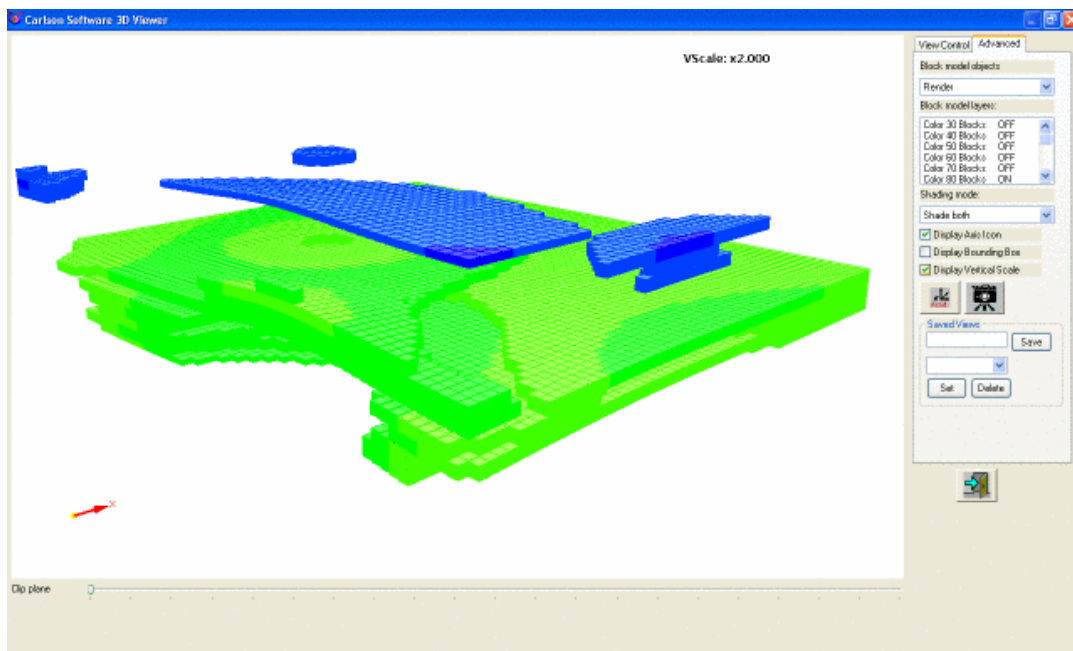

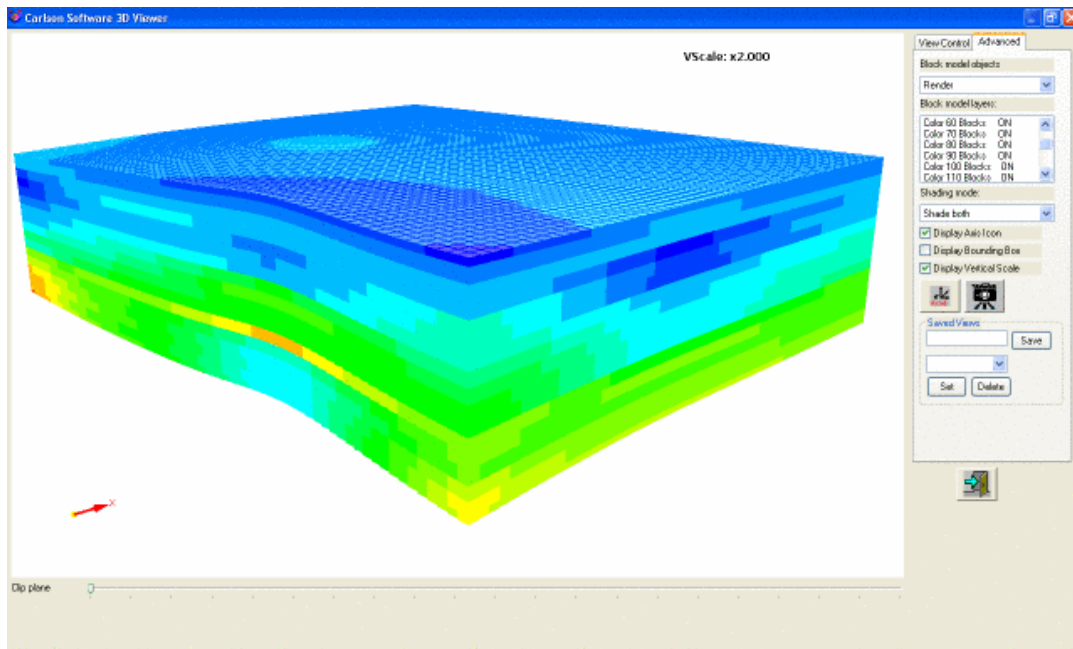

This command is used to create the block model from the drillholes. The first selection is to choose the Bed Name to model, and then the quality or qualities. Just one quality attribute may be used, or several at once. In this example, the LS bed and the CaO attribute will be modeled, as shown in this window. It needs a grid file to set the horizontal block sizes, so either pick the position from screen, and put in a dimension for X,Y, or copy an existing grid for positioning. For this one, the *Surface Topo.grd* can be copied for a position, which is 20x20 in dimension.

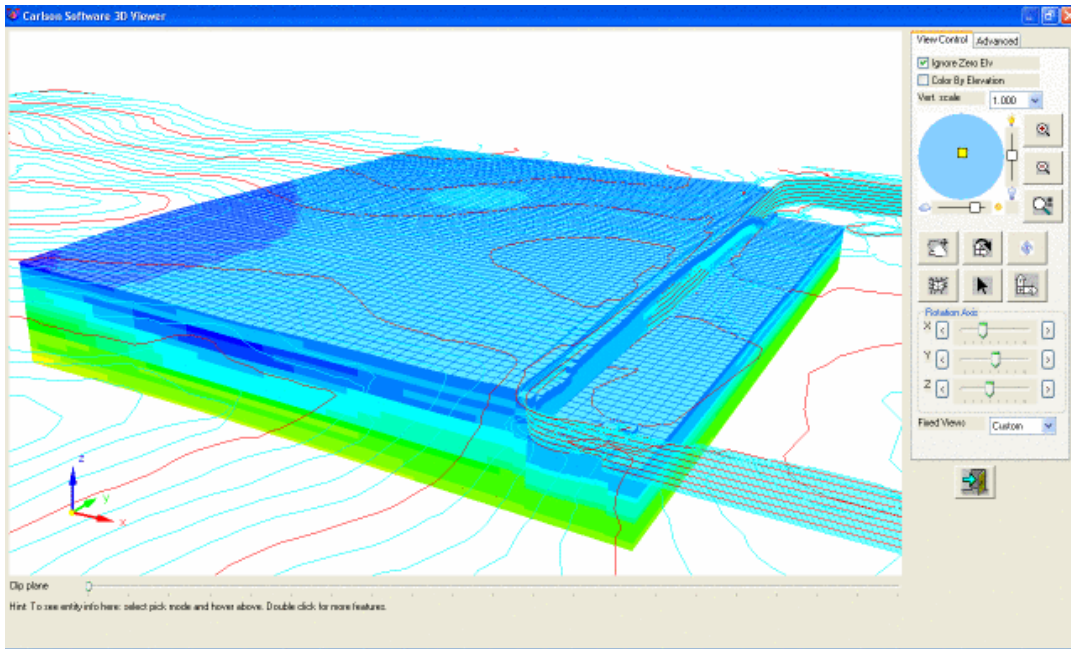

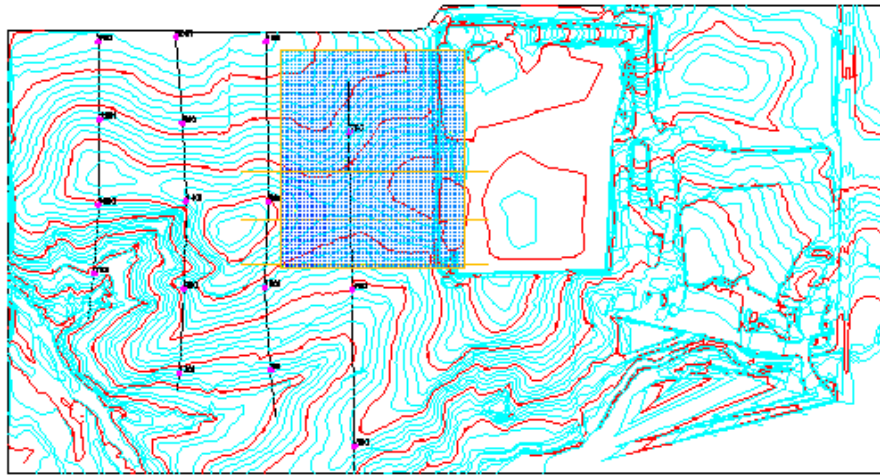

The second window sets the block height and modeling method. There are two distinct methods for setting the block height. They can be set to a fixed elevation and size which is independent of the beds, or can follow the top and bottom of the ore model from the drillholes. This creates almost a stratified block model where the elevations of the blocks follow the top and bottom of the ore elevations. This is like a hybrid of both strata and block modeling. If there are not any strata, such as in a gold or copper deposit, then the Fixed Elevations method is preferred. Both methods work the same. If using the Fixed Elevations method, to set the block height, the top and bottom of the model are entered, with the number of samples chosen to set the average block height, which is calculated and displayed at the top. In this screen, if the Number of Vertical Divisions is set to 16, the average block height listed above is 10.9. This should work well with the horizontal size of 20x20, giving an average block size of 20x20x10. This example will use Inverse Distance as the modeling method with a vertical factor of 1. Selecting OK builds all of the blocks and puts them in the BLK file. Choose a name for the BLK file, such as LS.CaO.BLK.

This command defines the grade ranges of the ore. This is what defines the blocks for colors and divisions for cross sections and volumes. There is a Draw Legend button to put it on the map. The price per pound is also defined here for the cost model, and that will be used for the optimized pit design. Also notice that there are 8 blanks for the various Parameters where the combination of the several attribute ranges can define the grade. For example the CaO > 90 and MgO < 15 defines the "High-Grade". For this example, just the CaO is defined for the different ranges. If another range is already defined, then the program will just use what is available. That is why just the ">" option is used below, starting at the highest grade and working down.

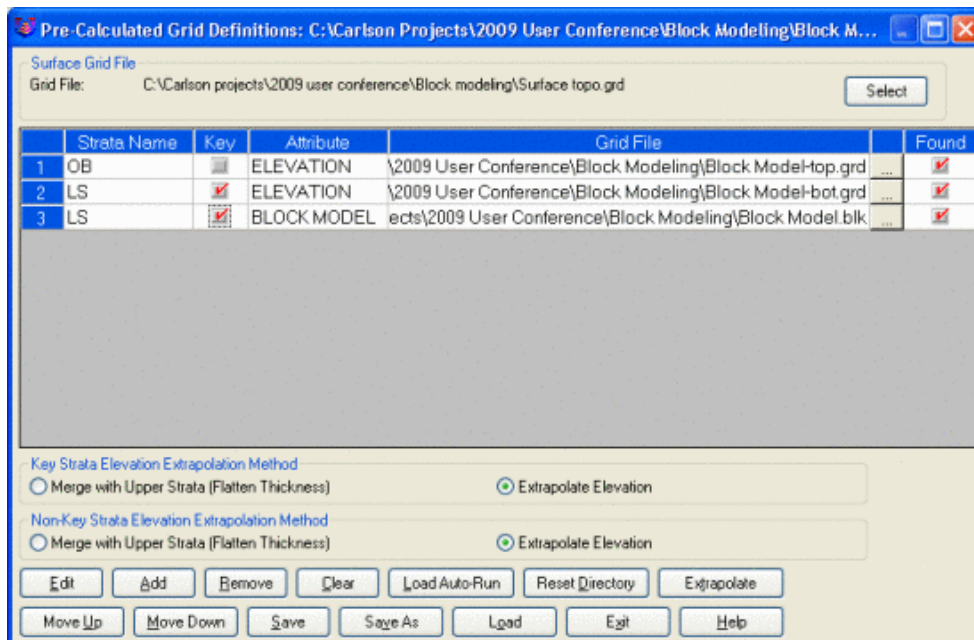

Now that the block model is built and the grade ranges are defined, the model can be inspected and viewed in 3D to check it for any problems. If the model is large, it is best to use an inclusion polyline to view just a subset of the entire model. In the Advanced Tab, there is a way to turn the various blocks on and off like layers. Just click on the line to turn on or off and the blocks are removed or added from the screen. This allows 3D views to see what the quality is inside the middle of the blocks. Notice in this example there are just green and blue blocks remaining.

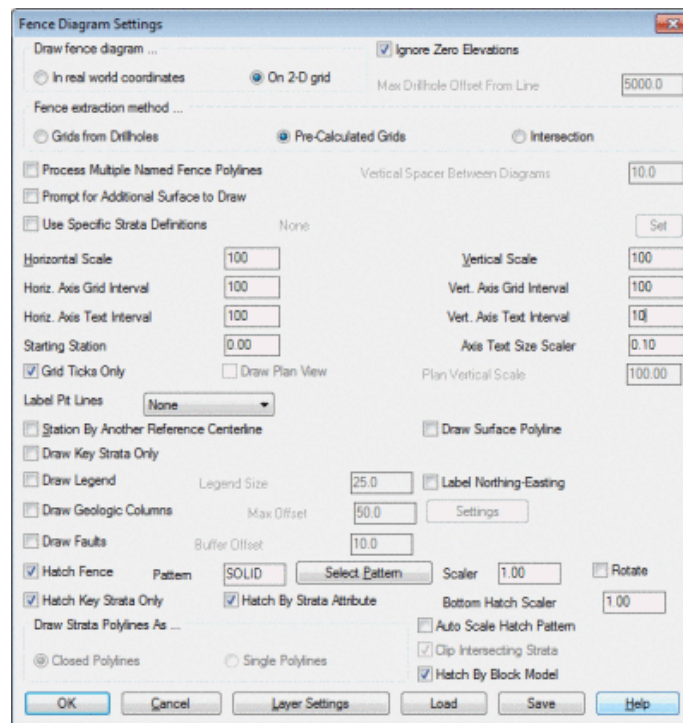

This is not a required step, but is convenient to place the blocks in the drawing permanently. This command will draw the blocks on screen in CAD as nodes or "dots". These nodes can then be brought into the 3D Viewer window and rendered the same as the Block Model 3D Viewer does. The nice option in this command allows to have a top and bottom limiting surface to crop the blocks. That way if just the blocks on a certain bench want to be viewed, use just the top and bottom grids of that bench, or even the topography, and an inclusion perimeter, to contain the blocks to draw, and ultimately view. After selecting the file, just leave all set to "YES" on the Draw Block Model screen. The nodes and contours drawn in CAD can be viewed with the 3D Viewer Window as seen below.

This step is necessary to combine the block model with the surface topo and any top or bottom elevation surfaces that will make up the entire model. The procedure for strata models is to just add the elevation grids as normal, and then add the BLK block model file to the appropriate interval. Flat elevation grids can be used for this, if it isn't a stratified model that has roofs and floors, like many hard rock metal mines and quarries that aren't stratified.

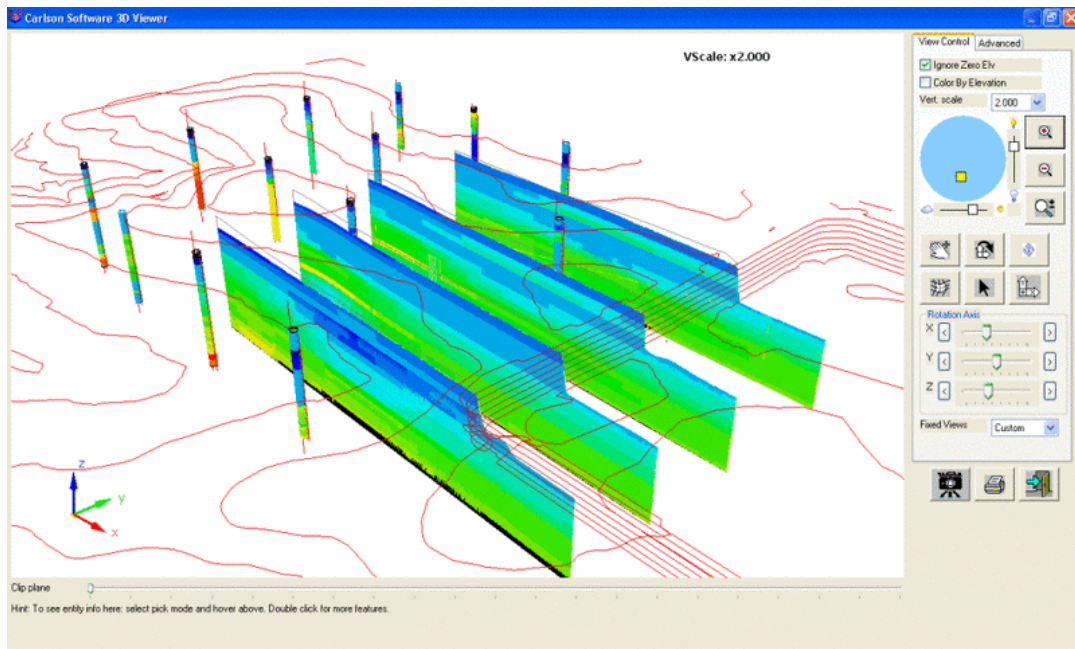

Now that the entire model is built and checked, a Fence Diagram can be drawn to see the geology and blocks in section view. Fence Diagram has an option to Hatch by Block Model. This can be drawn in two ways. The initial section shows it on a 2D Grid, the second one can be seen in 3D where it draws and hatches the fence in 3D below the line, in Real World Coordinates. Shown below are two fence diagrams from the drawing, on a 2D grid. Notice the coloration of the blocks based on grade of limestone.

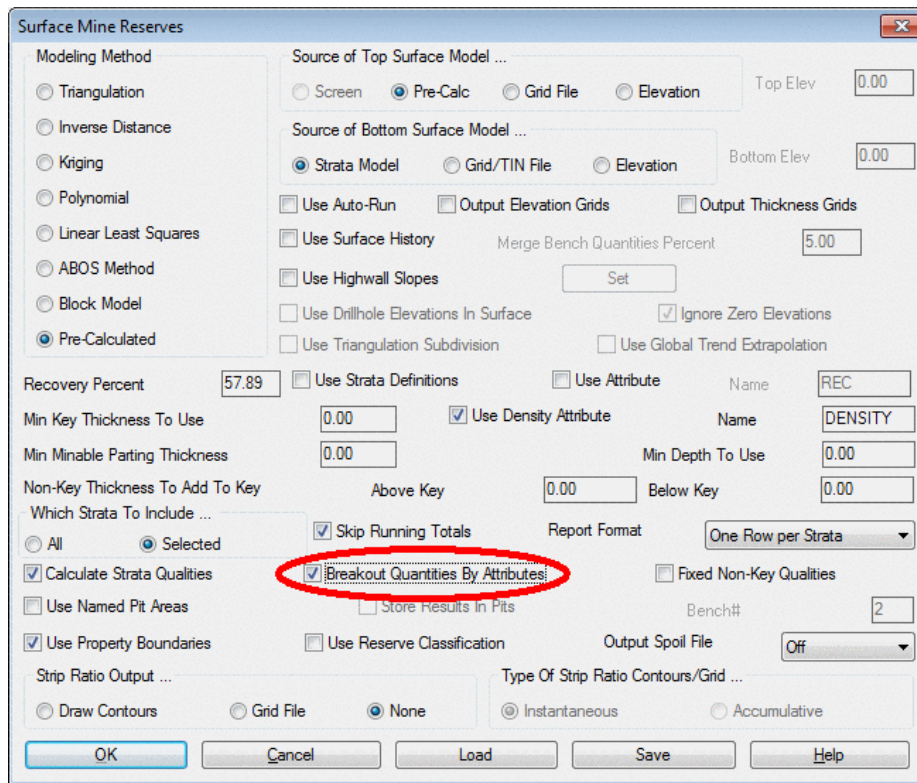

There is also an option to draw the Fence Diagrams in 3D using the Real World Coordinates setting. When this is viewed in the 3D Viewer Window along with 3D Geologic Columns, the result is very useful to visualize the geologic deposit as shown below. The Draw Geologic Column command will draw the drillholes as 3D columns, and they can also be colored by the Grade Parameter File. Notice how the coloration in the drillholes corresponds to the coloration in the fence cross-sections, indicating a good modeling estimation.

The next step is to get the volume and tons of the different grades of limestone with the Surface Mine Reserves. There is one check box to turn on that will report the tons by grade, it is Breakout Quantities by Attributes. This will not only give total tons of the limestone, but also the tons in the various grades. Here is how the window should appear.

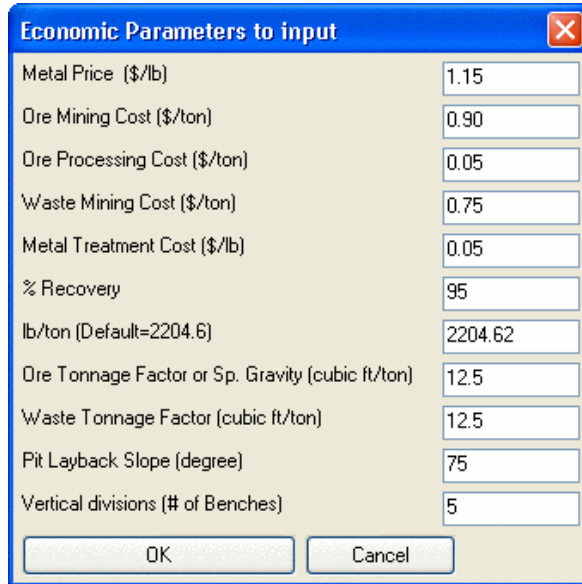

Shown here is the report of the data dumped into Excel using the Report Formatter. Notice how the total Key tons match the individual grade tons added up in the yellow cells. This is a good check to make sure all grades are accounted for in the report. Also confirm that each grade's CaO falls in line with the values defined in the Grade Parameter File.

Pit	Strata	KEY Tons	Waste C.Y.	Thickness	CAO	GRADE3 Tons	GRADE4 Tons	GRADE5 Tons	GRADE6 Tons	GRADE7 Tons	GRADE8 Tons	GRADE9 Tons	GRADE10 Tons
Pit 1 OB			590211.6	11.3									
Pit 1 LS		21197945.2		164.1	46.045	146.2	12406.6	59750.0	253154.6	1060902.4	3945035.3	2172383.6	107092
Pit 1 varies		21197945.2	590211.6		46.045	146.2	12406.6	59750.0	253154.6	1060902.4	3945035.3	2172383.6	107092
		21197945.2	Total from individual grades										
						GRADE3 CAO	GRADE4 CAO	GRADE5 CAO	GRADE6 CAO	GRADE7 CAO	GRADE8 CAO	GRADE9 CAO	GRADE10 CAO
						85.69	81.47	76.86	71.94	67.07	62.41	57.79	52
						85.69	81.47	76.86	71.94	67.07	62.41	57.79	52

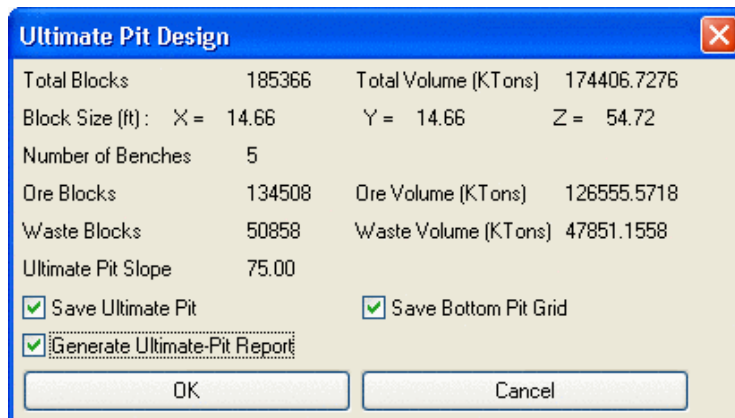

Now to find the optimized final pit of profitable mining, we will run this command to create a value block model, where each block is assigned a cost associated with it. Once this value block model is created, then the Optimized Pit Design can be run. First, select the geologic block model to analyze. This is the file used in the steps above. Then choose either to use the Grade Parameter file, or to Enter the parameters on screen here. For this run, the Economic Parameters will be entered. Select the Surface Topography grid when prompted to do so. It will use this to calculate the overburden on top of the blocks.

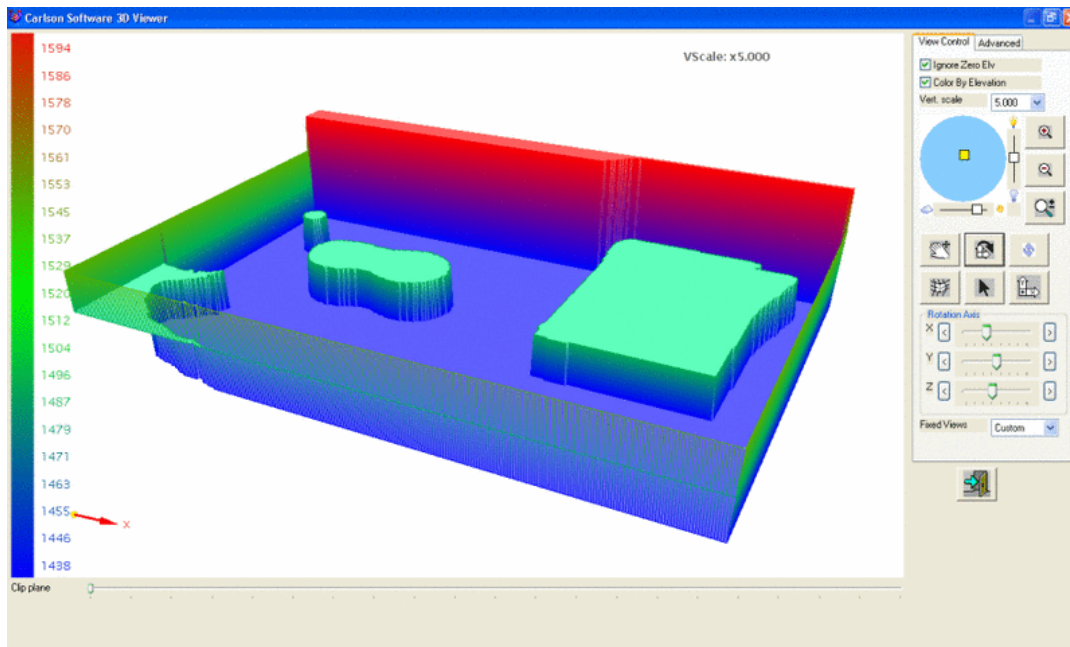

Enter in the Economic Parameters. Shown here is a sample of the costs associated with the various mining stages. This writes the value block model, where each block now has a value assigned to it whether it is profitable or not. This file is named Value Block Model.BLK.

Now that the Value Block Model is written, the Optimized Pit Design is run to create the ultimate pit and create the ultimate pit block model. The Value Block Model is now the file to process, and this one is selected first. All options are turned on to create an ultimate pit grid, block model and a report. The block model is just for calculation purposes and contains cost values.

The final report shows that most of the blocks are mineable. Level 1 doesn't have anything in it that is mineable. The lowest level, 5 is not mineable, though there are blocks in it. The blocks that are not profitable are what is left in the image below. The grid is displayed here, with the Surface 3D Viewer, and colored by elevation. It is easy to make changes in the input parameters and run it again. The cost to mine or process the ore can be modified and the new cost model created to see how it affects the output.

Ultimate Pit Report

=====
 Total Number of Blocks : 185366
 Total Tons in the block model (KTons) : 174406.7276
 Total Number of Ore Blocks : 134508
 Total Number of Waste Blocks : 50858
 Number of Blocks in optimum pit : 132866
 Total mineable reserve (KTons) : 125010.6507

NOTE: All Volume in KTons
 All costs & profit are in (1000*\$)

Level	Total Blocks	Ore Blocks	Waste Blocks	Mineable Blocks	Profit
1	0	0	0	0	0.0000
2	39035	39035	0	39035	29342813.5889
3	48777	48777	0	48270	46463974.9888
4	48777	46696	2081	45561	59158782.2902
5	48777	0	48777	0	0.0000

There is an automatic Grade Parameter File written called the Profit and Loss.GPF. This will colorize the blocks in the Value Block Model green if they are profitable, and red if they are not. This final model can also be viewed in 3D and it will resemble the ultimate pit grid file. Shown below is the full model, and then the profitable blocks are removed or "frozen" and just the red, non-profitable blocks remain.

Underground Mining Module

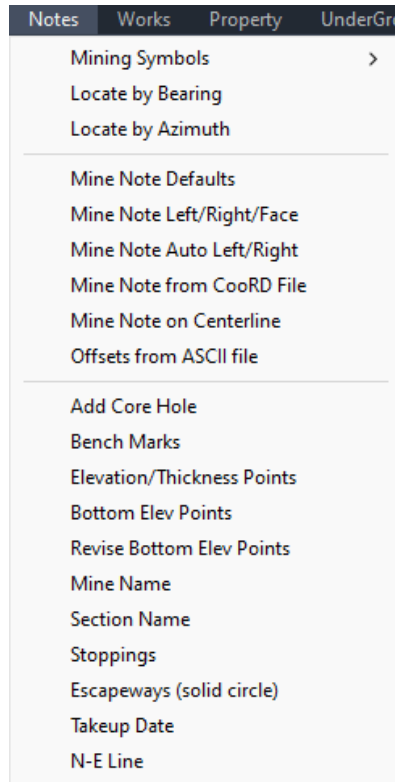

16

The Underground Mining Module consists of various commands for planning and scheduling an underground mining operation. Major features include panel layout, mine mapping, solid modeling/analysis, and mine scheduling. Commands are accessible from the Notes, Works, Property, Underground, Solid, and Subsidence pulldown menus.

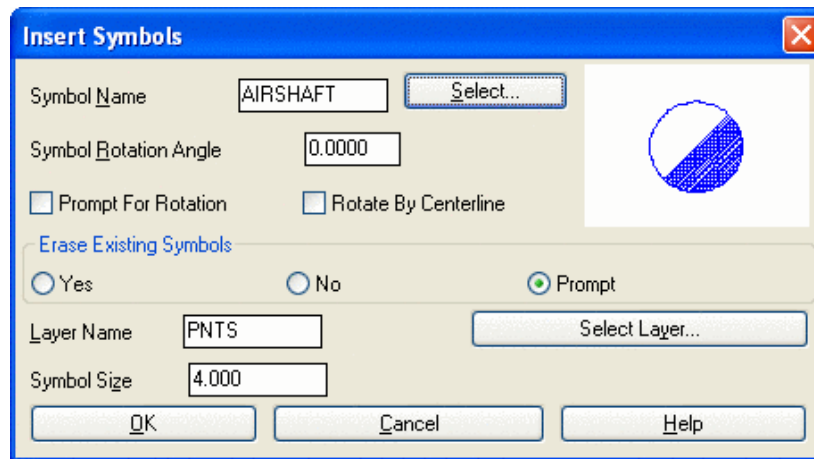

Notes Menu

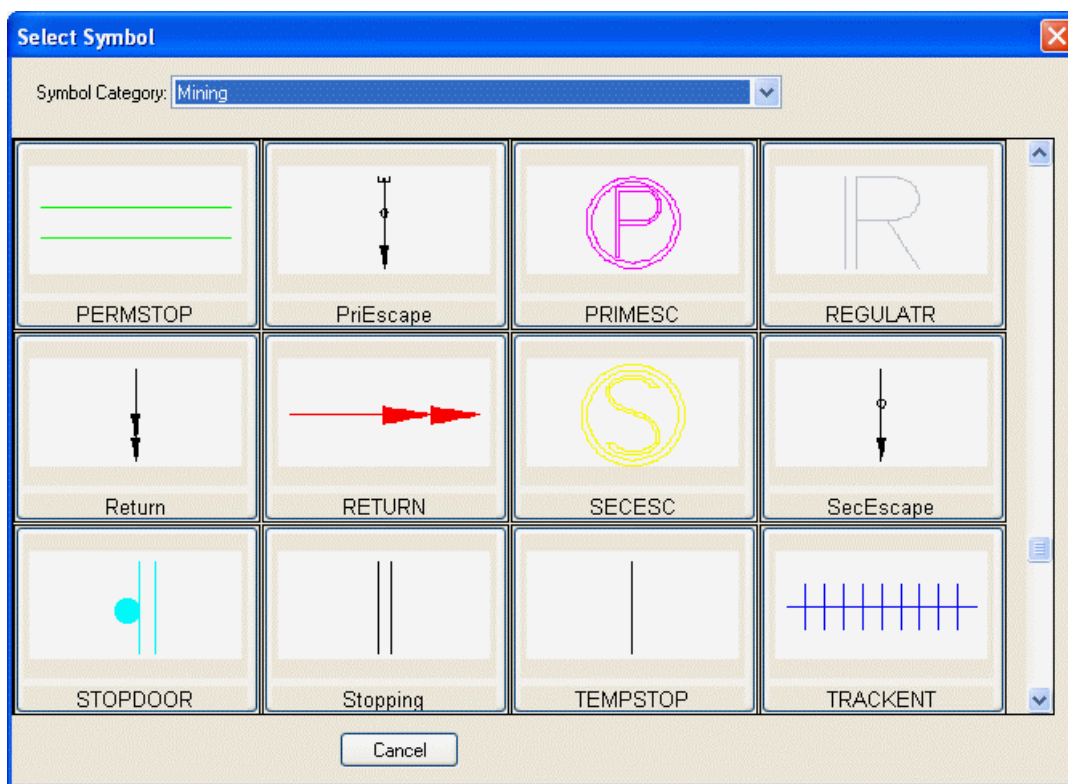

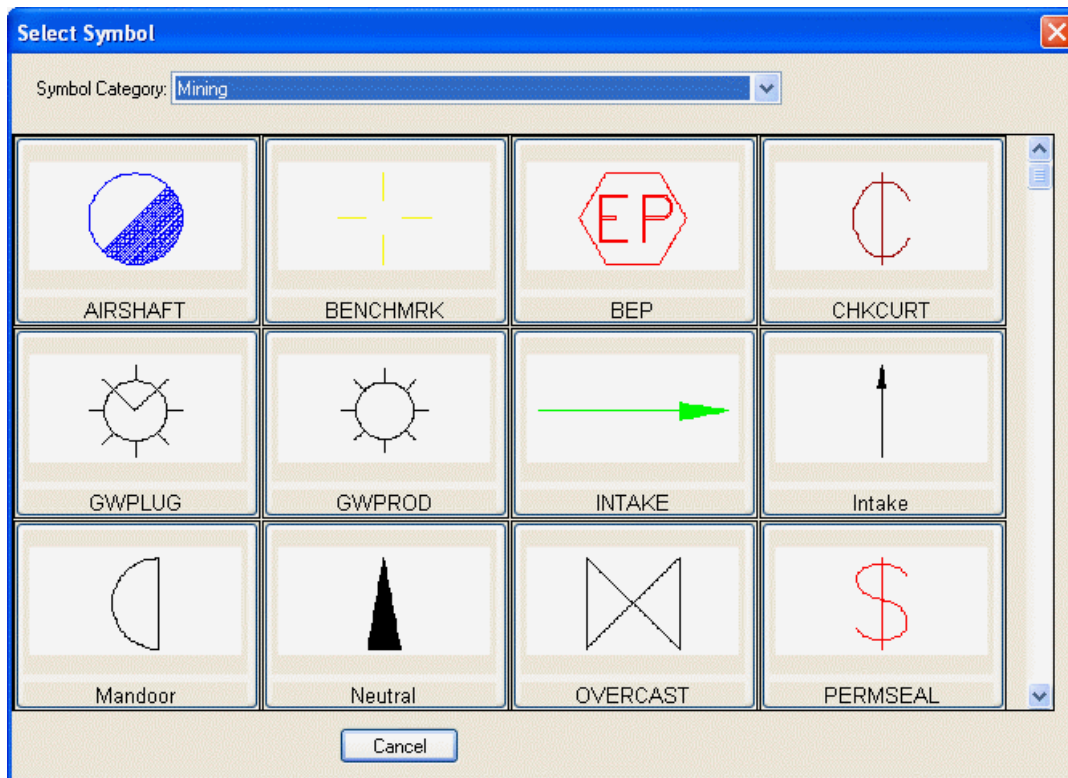

The commands in the top section of the Notes pulldown menu are for underground mine note entry and surveying. The bottom section contains commands for inserted mine drawing embellishments.

Insert Mining Symbols

This routine places icon mining symbols on the drawing. There are 25 symbols to choose from. After selecting a symbol from the pages in the Select option, simply pick a point to place it. A row of that symbol can be placed by picking a destination point, and an interval point. In this case, multiple symbols are placed the specified interval apart along a line from the start to the destination point. There are options for rotating the symbols, to erase existing symbols, layer name and symbol size.

Custom made symbols can be made with the command Edit Mining Symbols Library.

Prompts

Mine Mapping Symbols Dialog

Choose a symbol.

Pick Point for Initial Placement: *pick a point*

Pick Destination Point, or <Enter> For Single Placement: *press Enter*

Rotation angle <E>: *press Enter*

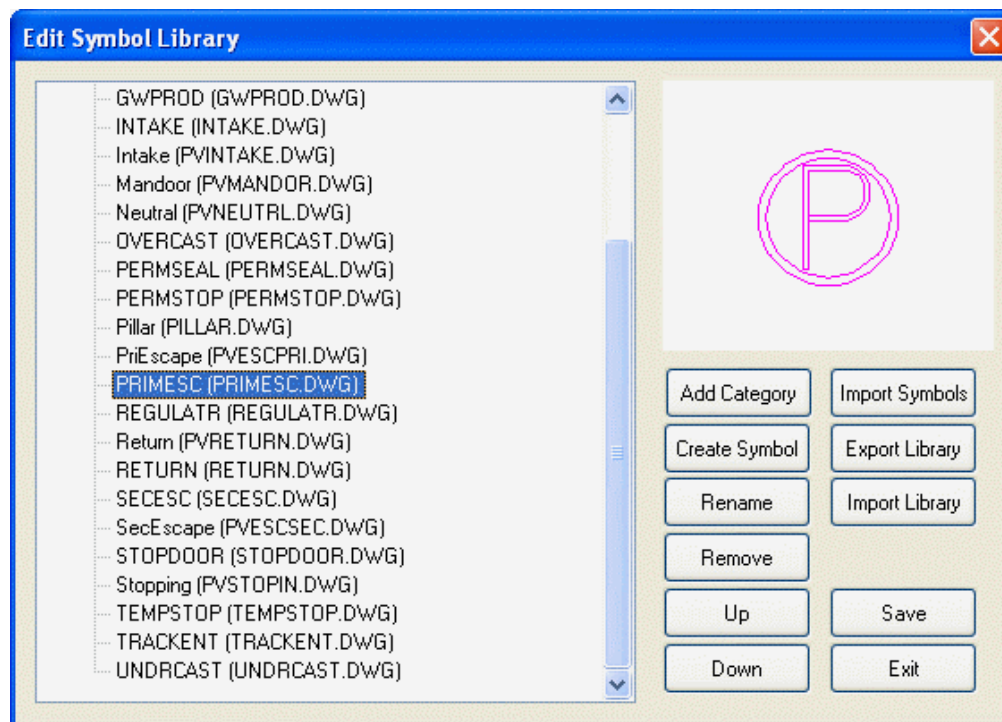

Pulldown Menu Location: Notes

Keyboard Command: ptsym2

Prerequisite: None

Edit Mining Symbols Library

This routine edits the mining symbols library. New symbols can be added and existing symbols can be edited. This is very similar to editing the points libraries in the Survey module. To add a new symbol, it must be drawn as entities in a dwg. Choose Create Symbol and give it a name. Choose a DWG to save it as, select the item, and pick the insertion point (usually the center). The new symbol should now be on the list in the library.

Prompts

Select objects: *select the symbol*

Pick Insertion Point For This Symbol: Symbol saved.

Pulldown Menu Location: Notes
Keyboard Command: editminesym
Prerequisite: None

Locate by Bearing

This command locates points by bearing and distance. Additionally, the AutoCAD text screen provides the horizontal distance and coordinates.

Prompts

[Enter] to use preview point or Select occupied point ?

Pick point/<point Number>: 24

PointNo.	Northing (Y)	Easting (X)	Elev (Z)	Description
24	4922.37	4544.81	0.00	

Enter Bearing (Qdd.mmss) <277.1259>: 435.2317

Enter or pick Distance <104.39>: 200

Enter Vertical Angle (dd.mmss) <0.0000>: Enter

Pulldown Menu Location: COGO > Locate by Bearing-Ang

Keyboard Command: locbrg2, lg

Prerequisite: None

Locate by Azimuth

This command locates points by azimuth and distance. The AutoCAD text screen provides the horizontal distance and coordinates.

Prompts

[Enter] to use preview point/ or Select occupied point ?

Pick point/<point Number>: *_endp of (pick a point)*

Enter Azimuth (ddd.mmss) <22.5632>: 277.1259

Enter or pick Distance <40.32>: 104.39

Enter Vertical Angle (dd.mmss) <0.0000>: Enter

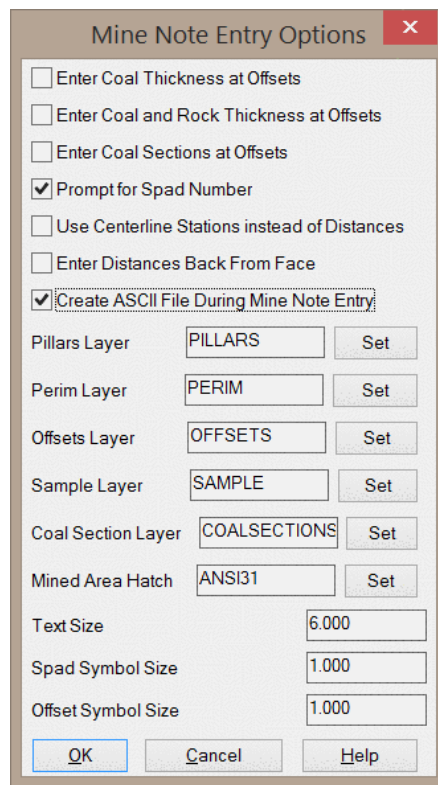

Pulldown Menu Location: COGO > Locate by Bearing-Ang

Keyboard Command: locazi2, az

Prerequisite: None

Mine Note Defaults

These options will toggle various prompts when entering Mine Notes. You can also set the layers for various linework needed for geologic modeling and mine planning.

Enter Coal Thickness at Offsets: This option activates coal section prompts in the mine note entry routines which creates sections of coal thickness at the offsets.

Enter Coal and Rock Thickness at Offsets: This option prompts for both coal and rock thickness.

Enter Coal Sections at Offsets: This option creates a complete coal section at the offsets.

Use Centerline Stations instead of Distances: This option will prompt for a starting station for the entries. Otherwise the starting station is automatically set to zero.

Prompt for Spad Number: This option determines whether the program prompts for spad numbers for the entry points. Turning this option off saves a prompt if you are not using spad numbers.

Enter Distances Back From Face: This option allows all of the mine note entry routines to post back from the face. Once this option is set, you never need to set it again except to change it. When this option is on, you will be asked for the "Distance to Face" when starting a note entry routine. Also, each routine will display a message stating "Mine Note From Face Option Active".

Create ASCII File During Mine Note Entry: This option determines whether or not a record of the offset notes is kept in an ASCII file whose default name is OFFSET.DAT. This file is created by mine note entry routines and can be used by AutoMine Connections and Offsets by ASCII File. If this file already exists when a mine note entry routine is started, there is an option to either append the new notes to the existing file or replace the existing file. All these data files are stored in the Carlson data directory such as C:\SC14\DATA\. Since these files are in ASCII format, they can be easily edited with any text editor. Once ASCII File From Notes is set, you never need to set it again except to change it.

Pillars Layer: This option sets the layer for pillar linework. If pillars are not drawn on this layer, they will not be recognized in many commands such as Place Panel or Recalculate Extraction.

Perim Layer: This option sets the layer for panel perimeters.

Offsets Layer: This option sets the layer for mine notes at offsets.

Sample Layer: This option sets the layer for the location of coal sections. This does not set the layer for text of the coal section.

Coal Section Layer: This option sets the layer for coal sections, including the text and the optional circle around the text. This does not set the layer for the actual location of the coal section.

Mined Area Hatch: This option sets the hatch pattern for mined out areas. This hatch pattern will be drawn with the Quantities by Avg/Grid/Centerlines commands.

Text Size: This option sets the default text size for coal section and mine note labels.

Spad/Offset Symbol Size: This option sets the default size for spad and offset symbols.

Pulldown Menu Location: Notes

Keyboard Command: mconfig

Prerequisite: None

Mine Note Left/Right/Face

Mine Note Left/Right/Face is a simple routine for entering offsets. The flow of this routine is very similar to Mine Note from CoorD File. To get started, the routine only requires a starting point and a direction. Then enter a distance up followed by the offsets. The offsets consist of a code immediately before the distance. The codes are L for left, R for right, CL or *L for corner left, and CR or *R for corner right. For example, the offset CL9 means a corner point offset 9 feet to the left.

Corner points identify a corner of a pillar that is across a cross cut. Corner points are drawn as green dots and other points are drawn as red circles. This distinction is made to assist in pillar connection and is important to AutoMine Connections.

If the ASCII File From Notes option is on, this routine also produces a .DAT file which contains a record of the entries. This file is necessary for AutoMine Connections.

Prompts

Enter Offset File Name <offset.dat>: *press Enter*

Enter/Pick From Station Point: *pick or Enter a point*

Entry Number: *1* This is an identification number for the entries that follow. AutoMine Connections groups spad offsets by this number.

Enter/Pick To Station Point (a for azimuth): *pick or Enter a point or enter A*

Spad Number or <Enter> for none: *1043* This number is drawn at the spad.

Flip Spad Text (Y/<N>)? *N* This determines the orientation of the spad text.

Enter distance From Station/Spad on Centerline (Enter to end): *25*

Offset, U for Undo, or [Enter]for new centerline distance: *L10* Offsets left 10.

Offset, U for Undo, or [Enter]for new centerline distance: *CR9* Offsets a corner point right 9.

Offset, U for Undo, or [Enter]for new centerline distance: *press Enter*

Enter distance From Station/Spad on Centerline (Enter to end): *47*

Offset, U for Undo, or [Enter]for new centerline distance: *L8 Offsets a corner point left 8.

Offset, U for Undo, or [Enter]for new centerline distance: R11 Offsets right 11.

Offset, U for Undo, or [Enter]for new centerline distance: *press Enter*

Enter distance From Station/Spad on Centerline (Enter to end): *press Enter*

Pulldown Menu Location: Notes

Keyboard Command: note1

Prerequisite: None

Mine Note Auto Left/Right

Mine Note Auto Left/Right is a simple routine for entering offsets. The routine only requires a starting and ending point, and then simply distance up, distance left, and distance right over and over until the end of that entry. Corner points may be specified for left or right offsets by preceding the number with a C or *. Corner points identify a corner of a pillar across a cross cut. Corner points are drawn as green dots, while other points are red circles. This distinction is made to assist in pillar connections and is important for AutoMine Connections.

If the ASCII File From Notes option is on, this routine also produces a .DAT file in the data directory which contains a record of the entries. This file is necessary for AutoMine Connections.

Prompts

Enter Offset File Name <offset.dat>: *press Enter*

Enter/Pick From Station Point: *pick or enter a point*

Entry Number: 1 This is an identification number for the entries that follow. AutoMine Connections groups spad offsets by this number.

Enter/Pick To Station Point (a for azimuth): *pick or enter a point or enter A*

Spad Number or <Enter> for none: 1043 This number is drawn at the spad.

Flip Spad Text (Y/<N>)? N This determines the orientation of the spad text.

Enter Distance From Station on Centerline (U to Undo, Enter to end): 25

Enter Left Offset Distance: C10 The C specifies a left corner point.

Enter Right Offset Distance: 8

Pulldown Menu Location: Notes

Keyboard Command: note2

Prerequisite: None

Mine Note From CoORD File

This mine note entry routine is for when the spads are known coordinates or point numbers from a .CRD file. The flow of entering offsets for this routine is very similar to Mine Note Left/Right/Face. First enter the spads point number or coordinates, and specify the azimuth by either entering the number directly or by identifying another point. Then enter a distance up followed by the offsets. Pressing Enter at the offset prompt will back up the routine so that it asks for another distance up. Then, pressing Enter at the distance up prompt will make it ask for the next spad. Finally, pressing Enter to the spad question will exit the routine.

There are two types of offsets points, corner points and regular points. Corner points identify a corner of a pillar that is across a cross cut. Corner points are drawn as green dots and regular points are drawn as red circles. This distinction is made to assist in pillar connection and is important to AutoMine Connections. The offsets have a code immediately before the distance. The codes are L for left, R for right, CL or *L for corner left, and CR or *R for corner right. For example, the offset *R10 means a corner point offset 10 feet to the right.

Prompts

CoORD File Selection Dialog Choose the file that contains the spad point data.

Starting Spad or north & east coord: *1*
Azimuth (DDD.MMSS) or P for Pt.-Defined Direction <0.0>: *P*
Directional Spad or north & east coord: *3*
Distance or 'enter' for new Spad No.: *15*
Offset or 'enter' for new Distance: *L10*
Offset or 'enter' for new Distance: *CR10*
Offset or 'enter' for new Distance: *press Enter*
Distance or 'enter' for new Spad No.: *17*
Offset or 'enter' for new Distance: *CL10*
Offset or 'enter' for new Distance: *press Enter*
Distance or 'enter' for new Distance: *press Enter*
Next Spad No. or north & east coords or 'enter' to exit: *press Enter*
Print file containing offset input data (<y>/n): *n*

Pulldown Menu Location: Notes

Prerequisite: None

Mine Note on Centerline

This command is similar to the other Mine Note routines like Mine Note Auto Left/Right. The difference with this routine is that the program does not prompt for offsets left and right. Instead the program only prompts for the distance along the centerline and places the offset points on the centerline (0 offset).

Prompts

Enter Offset File Name <offset.dat>: *press Enter*
Append File (<Yes>/No)? *press Enter*
Enter/Pick From Station/Spad point[node on]: *pick a point*
Entry Number: *1*
Enter/Pick To Station point (a for azimuth): *A*
Azimuth of Heading (DD.MMSS) or p to pick <0.0>: *11*
Enter Spad Number or <ENTER> For None: *101*
Flip Spad Text (Yes/<No>)? *press Enter*
Enter distance From Station/Spad on centerline (Enter to end): *40*
Enter distance From Station/Spad on centerline (Enter to end): *60*
Enter distance From Station/Spad on centerline (Enter to end): *press Enter*
Another Spad (<Yes>/No)? *N*
Print file containing offset input data (<Yes>/No)? *N*

Pulldown Menu Location: Notes
Keyboard Command: note4
Prerequisite: None

Offsets from ASCII File

This command can be used to update a drawing if the offset file is edited outside a Mine Note Entry command or a new drawing is started. Otherwise, the offset dots are drawn only once, while entering them with a Mine Note Entry command.

Offsets from ASCII File draws points that are defined in the specified offset file. The offset file is created by Mine Note Entry commands. In order to draw the points, a SPT99.DWG and a OFFSET.DWG must be in the Carlson Support directory that was set up when the software was installed.

Prompts

Enter the offset file <offset.dat>: Enter a filename.

The default directory for this file is the data directory your Carlson Data directory that was created when the software was installed.

Pulldown Menu Location: Notes

Keyboard Command: moffsets

Prerequisite: An offset file created by one of the Mine Note routines

Elevation-Thickness Points

This command is very similar to the Bottom Elev Points command (BOTELEV), but in addition to drawing symbols and text labels for the bottom elevation of the strata, the thickness and top elevation of the strata will also be labeled. When the command is executed, the below dialog will appear.

Calculate	Value	Label Prefix	Label Suffix	Text Layer	Symbol Layer
<input checked="" type="radio"/> Top	100.0	Top	'	MinePoint - Top	MinePoint - Top X
<input type="radio"/> Thickness	10.0	Thk	'	MinePoint - Thk	MinePoint - Thk X
<input type="radio"/> Bottom	90.0	Bot	'	MinePoint - Bot	MinePoint - Bot X

Text Size: 10.0 Rotation Angle (deg): 45 Pick Decimals: 0.00

OK Cancel

Calculate: This option controls which values will be entered and which value will be calculated. If this option is set to "Top", then the value for the Top Elevation will be automatically calculated based on the values for the Thickness and the Bottom Elevation.

Value: These are the values that will be labeled.

Label Prefix/Suffix: These fields control the label prefixes and suffixes, as shown in the below image.

Text/Symbol Layer: These fields set the layers for the symbols and the labels.

Text Size: This value sets the text size for the labels. All three labels will be the same size.

Rotation Angle (deg): This value sets the rotation angle (in degrees) of the labels and the symbols. Clicking the **Pick** button will prompt you to pick two points on the screen to set the rotation angle.

Decimals: This dropdown list controls the number of decimals to label.

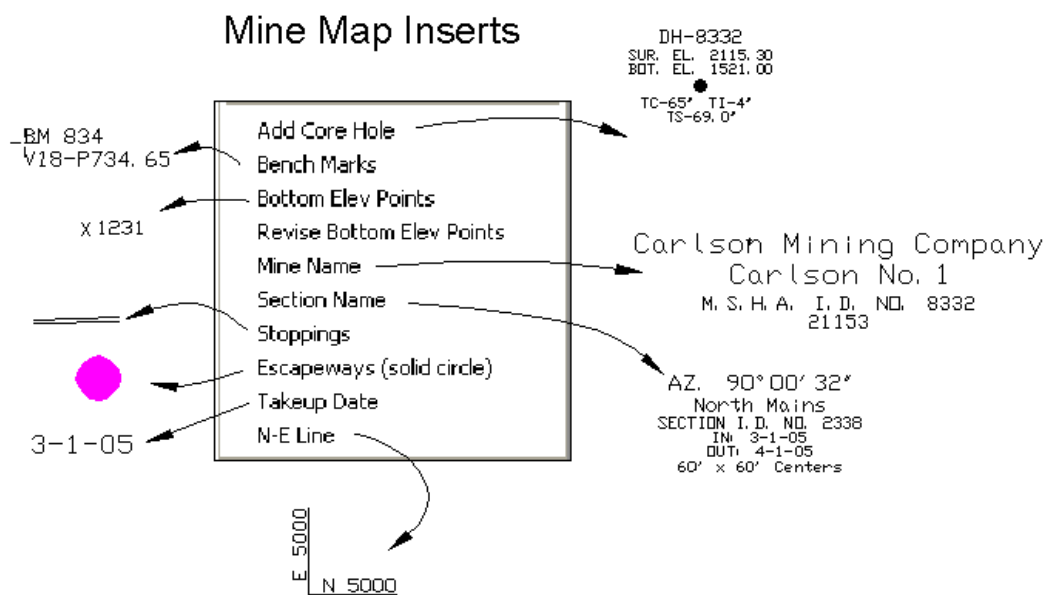

The below image shows the symbols and text that will be drawn using the settings shown in the above dialog.

Top 100.00'
 Thk 10.00'
 Bot 90.00'

Pulldown Menu Location: Notes
Keyboard Command: minepoints

Mine Map Insert Commands

Here are ten very useful drawing embellishment commands. Add Core Hole, Bench Marks, Bottom Elev Points, Mine Name, Section Name, Stoppings, Escapeways (solid circle), Takeup Date, and N-E Line are straight forward routines that place their corresponding information in the drawing using the standard layer name, color, font and height. The prompts for all nine inserts, as well as the Revise Bottom Elev Points routine, are listed below.

Prompts

For Add Core Hole:
Enter or pick 'x' and 'y' co-or of corehole location: *pick a point*
Corehole name: *DH-8332*

Surface elevation: 2115.30
Bottom of coal seam elevation: 1521
Total coal in inches: 65
Total impurities in inches: 4

For Bench Marks:

[node on] Pick Location Of Benchmark Elevation: *pick a point*
Enter BM Number: 834
Enter Elevation of BM: 734.65
Additional Text (Enter if none): V18-P
Pick Location For The BM Text: *pick a point*
Pick Alignment Point For Text: *pick a point*

For Bottom Elev Points:

Elevation : 1231
Pick pt. for elevation mark 'x' : *pick a point*
Pick point at beginning of label: *pick a point*
Pick point for label alignment: *pick a point*

For Revise Bottom Elev Points:

Select Bottom Elevation Marks & Text to Revise: *pick object*

For Mine Name:

Company name : *Carlson Mining Company*
Mine name : *Carlson No,1*
MSHA I.D. N.O.: 8332
State I.D. N.O. : 21153
Pick point at beginning of label: *pick a point*
Pick point for label alignment: *pick a point*

For Section Name:

Degrees of panel azimuth: 90
Minutes of panel azimuth: 00
Seconds of panel azimuth: 32
Panel name : *North Mains*
Panel I.D. n.o. : 2338
Panel in date : 3/1/05
Panel out date : 4/1/05
Additional notes : *60'x60' Centers*
Pick point at beginning of label: *pick a point*
Pick point for label alignment: *pick a point*

For Stoppings:

Pick point for beginning of stopping line orientation: *pick a point*
Pick point for end of stopping line orientation: *pick a point*
Pick point to beginning stopping: *pick a point*
Pick point to end stopping: *pick a point*

For Escapeways:

Pick pt. for escapeway symbol: *pick a point*

For Takeup Date:

Takeup date [mm-dd-yy format]: 3-1-05
Pick point at beginning of label: *pick a point*
Pick point for label alignment: *pick a point*

For N-E Line:

Enter Northing: 5000

Enter Easting : 5000

This will be placed in the drawing at the corresponding northing and easting.

Pulldown Menu Location: Notes

Keyboard Command: chole, benchmark, botelev, botelev2, mname, sname, stop, xways, tdate, neline.

Prerequisite: None

Dynamic Blocks and Tool Palettes

The included dynamic blocks were created for use as Underground Mining symbols; they follow in most part, the requirements from the State of West Virginia guidelines. Other symbols may be found at the West Virginia website <http://www.wvminesafety.org/minemaps.htm>, in the downloadable PDF file and also in the book titled *Mine Mapping & Layout*, by W. Randolph Williams. Only underground mining map symbols and some SCSR Emergency Plan symbols will be released as part of the Carlson Underground Mining Module, version 2015. Dynamic Blocks and Tool Palettes only exist in AutoCAD. They are not found in the IntelliCAD engine of Carlson. Future releases of blocks may consist of CO systems, AC and DC Power, and the Tracking system.

All of the blocks may not work for everyone, based on regional requirements. Blocks and Tool Pallets are readily editable so they can adapt to any desired format. Any existing block can be converted into a dynamic block. All blocks should be placed into one drawing, in the AutoCAD layer 0 to establish mapping standards for blocks and layers for all users in a company.

Dynamic Blocks were first introduced in AutoCAD 2006. Their benefit is they can be edited without exploding them. You can even manipulate the block appearance during or after inserting it into a drawing.

Traditional blocks:

- Multiple steps to place and align
- Design changes require erasing and reinserting or exploding, edit and redefining

Dynamic blocks:

- Automatically align to nearby geometry
- Cycle between multiple insertion points
- Change visibility of geometry to streamline design changes
- Geometry can be edited within a block without exploding it

Dynamic blocks are extremely useful in that they can adapt to the current needs of your design. Blocks representing stoppings or any mining symbols are easily made as dynamic blocks. Dynamic blocks can fill the need for multiple blocks. All blocks will be consistent throughout a company.

Tool palettes are used to manage a block library. Tool palettes provide a consistent interface to insert consistent blocks into all drawings. Tool palettes allow the ability to maintain the blocks in one drawing on a network, so every user reading that drawing is updated instantly. All changes to the blocks should be made in this one drawing. Carlson provides a standard AutoCAD drawing with several mining dynamic blocks. The blocks in this drawing are general standards, and do not imply these symbols will comply with your regional and government agencies. But the blocks are easy to edit so they do comply. The user will need to create a new Tool Palette, and then use the Design Center to drag and drop the blocks from this drawing into the new Tool Palette. Details on this procedure are below.

This document covers the following topics regarding Dynamic Blocks and Tool Palettes

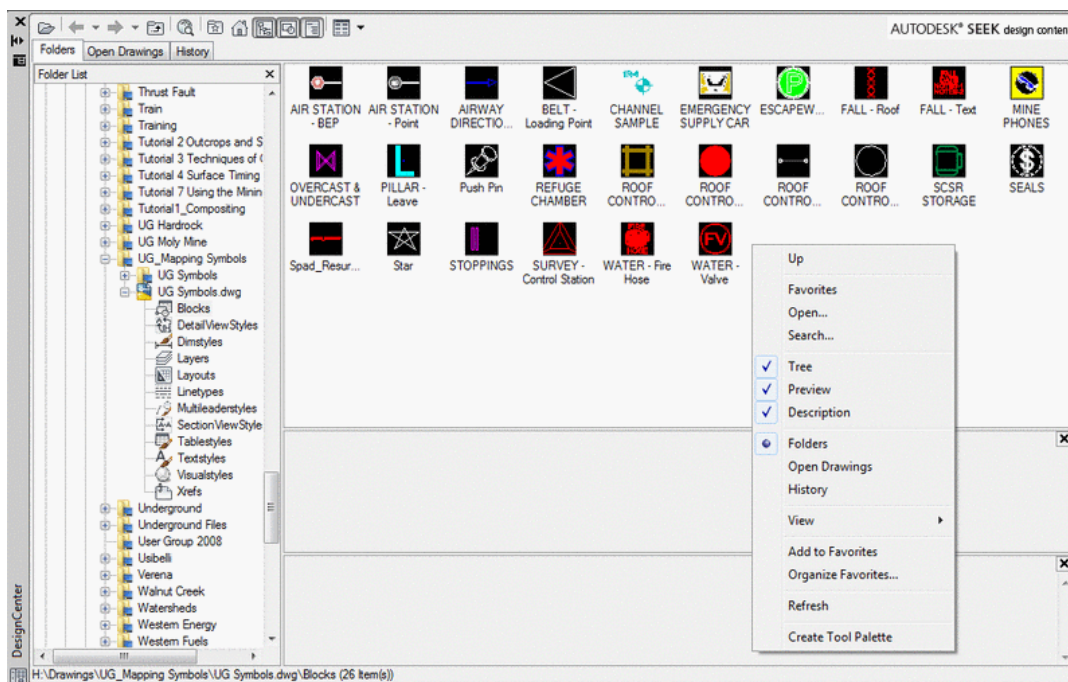

- Tool Palettes

- Creating Dynamic Blocks and Editing
- Standards of blocks and layers
- Design Center
- Revising the blocks
- Updating the drawing
- Reporting information about the Dynamic Blocks in the drawing: Command `_eatttext`

Creating a Tool Palette

To use the included library of underground mining symbols, the steps to create a Tool Palette containing them are as follows. There are two main methods to create a Tool Palette.

1. Use the Tool Palette shortcut menu to create a new, empty palette. This is found by right-clicking anywhere on the tool palette itself, and choosing New Palette. Enter a name for it, such as *UG Symbols* and then add the blocks to it as defined below. The Design Center is the preferred method to add the provided blocks into the new Tool Palette.
2. Use a DesignCenter shortcut menu to create a Tool Palette tab with predetermined content. The DesignCenter button is found in the AutoCAD Standard toolbar or by typing `_adcenter`. Right Click in a blank area of the DesignCenter and Select "Create Tool Palette of Blocks" or "Create Tool Palette". Then hold down "Shift" key and Select the blocks to add to the Tool Palette.

Methods for Adding Tools to the New or Existing Tool Palette. Tools can be added to a new or existing Tool Palette using several methods.

- Drag tools from the drawing space to the palette. Tools include geometric objects, dimensions, fills, blocks, xrefs, raster images, and tables. Others could be lights, cameras, visual styles, and materials (not available in AutoCAD LT).
- **Drag drawings, blocks, and hatches from DesignCenter to the Tool Palette. Drawings that are added to a tool palette are added to the palette.**
- Drag palettes from the Customize. Type `Customize` at the command line to bring it up.

- Drag commands from the Command List pane on the Customize User Interface (CUI) Editor and drop them into a Tool Palette.
- Cut/Copy and Paste tools from one Tool Palette to another.

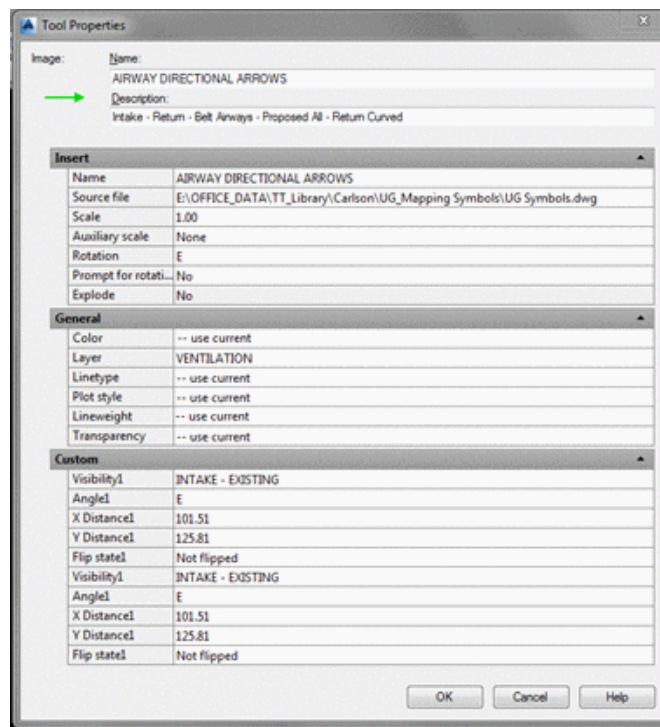

Here is what the new Tool Palette should look like after the Dynamic Blocks are imported.

Customizing the Tool Palette

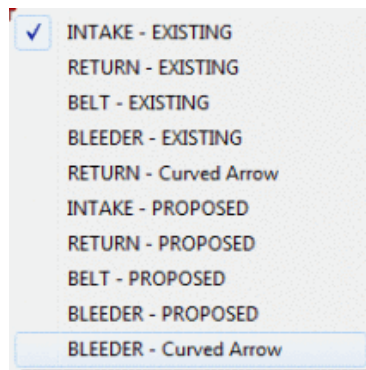

Once a Tool Palette is created, it can be modified and customized by the following methods.

- Rearrange the tools by dragging or sorting them.
- Add text and separator lines.
- Move a Tool Palette tab up and down the list of tabs by using the shortcut menu or Customize dialog box.
- Delete Tool Palettes that you no longer need. (Tool Palettes that are deleted are lost unless they are first saved by exporting them to a file.)
- Set the path to the Tool Palette files location on the Files tab in the AutoCAD Options dialog box. This path can be to a shared network location.
- Associate a customizable Tool Palette group with each panel on the ribbon.
- Change a Tool Palette's read-only status in the palettes folder where they are stored. If a Tool Palette is set to be read-only, a lock icon is displayed in a lower corner of the Tool Palette. This indicates that it cannot be modified beyond changing its display settings and rearranging the icons.
- Tool Properties: How to modify the properties and images of single tools.
- On the Tool Palette, right-click a Symbol/Tool and Select Properties.
- In the Tool Properties dialog box, update or edit the settings.
- Different settings can be used for different tools.

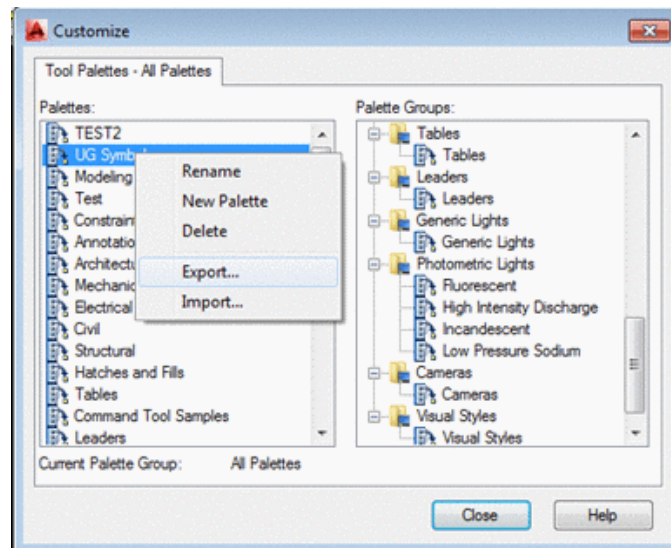

Details of the Tool Properties dialog are listed below.

- **Image Name:** This is the name of the block.
- **Description:** This is a description describing what the block may do.
- **Insert Name:** Block name.
- **Source file:** This is the drawing where all of the Tool Palettes symbols are stored, preferably on the server for others to use for standards. It should be a protected drawing so that users are not able to modify this drawing.
- **Scale:** Default as to what size the Block was drawn at. This can be changed as needed.
- **Layer:** Assigned Layer
- **Custom:** In this case it is only showing the Visibility in the Block.

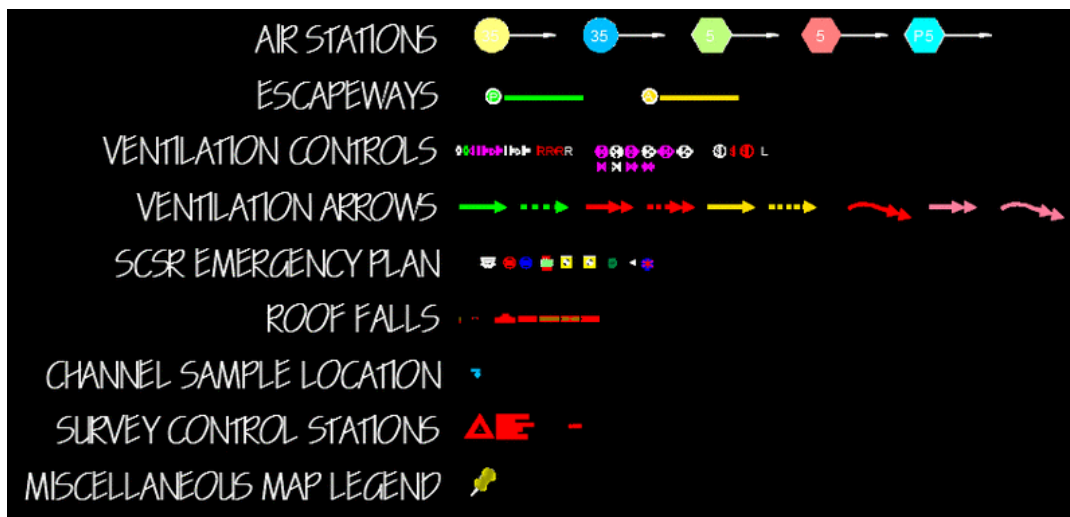

If the Dynamic Blocks are modified in the protected source drawing, such as scale, color or linetype, this revision will change every other drawing that has used it. It may be necessary to do the following to force the change. First, On the Tool Palette Select the tool or Dynamic Block and right-click and Select "Redefine". If these changes are going to be pushed out to all the users then it is necessary to export the Tool Palette and the users will need to re-import the Tool Palette with the changes. That steps to do this are shown below.

- **Exporting a Custom Edited Tool Palette:** To first export a Tool Palette to be shared, first right-click on the Left Side of the Tool Palette or a blank spot inside the Tool Palette and select "Customize Palettes". In the Customize dialog box, to export a Tool Palette, select under Palettes with a right-click on a Tool Palette name and select Export. In the Export Palette dialog box, specify a file name and location and then pick Save. This creates a New Folder with the name of the Tool Palette. A folder for the images is created under it and contains images for the tools. If there is an existing XTP already there, then it can be overwritten.

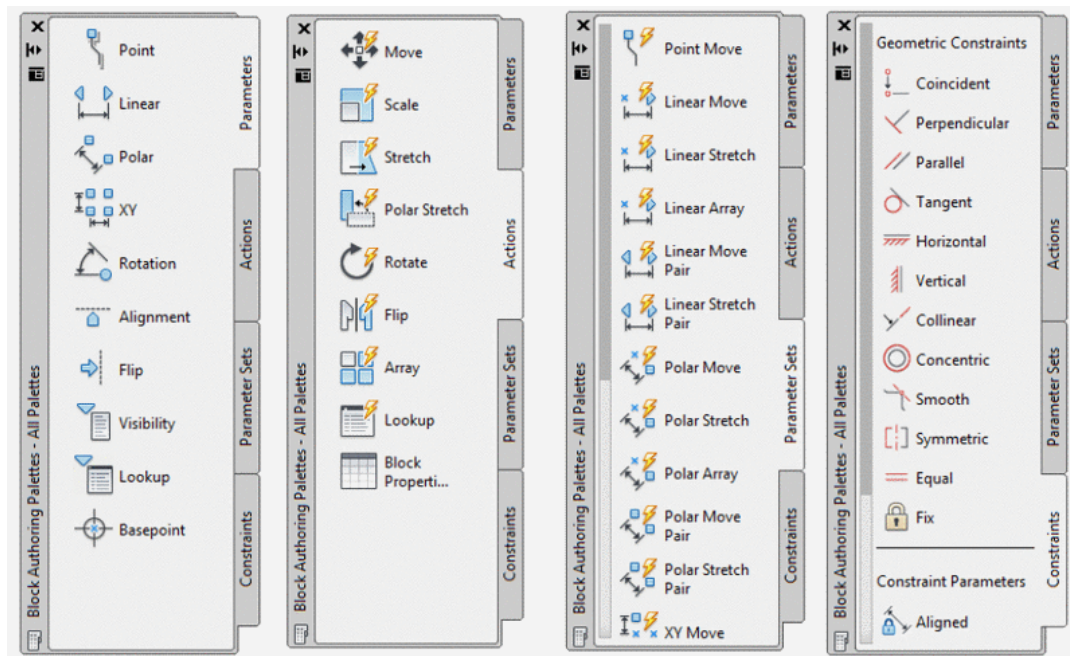

- **Importing a Tool Palette:** This is very similar to Export. Right-click on the Left Side of the Tool Palette or a blank spot inside the Tool Palette. Choose "Customize Palettes". In the Customize dialog box, select Import a tool palette under palettes, right-click on a tool palette name and select Import. In the Import Palette dialog box, specify a file name and location. Click Open.

Here is an image of the source drawing provided by Carlson showing some of the available Dynamic Blocks. User's are allowed to add to it with additional custom Dynamic Blocks, and then include them on the Tool Palette.

Dynamic Block Editing

The AutoCAD ribbon for Blocks is shown here. It appears after picking or selecting a Dynamic Block that is inserted into the dwg, or in the source drawing. To insert a Dynamic Block, turn on the Tool Palettes and just drag and drop a symbol in the drawing. The Authoring Palettes, Parameters and Actions tabs are the functions being used in the Underground Symbols library of blocks.

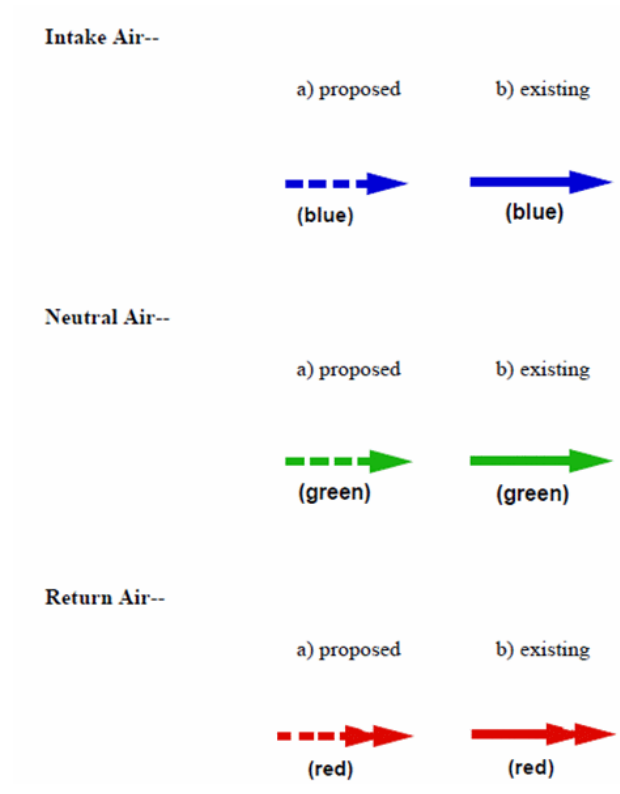

The Parameter Sets and the Constraints, are not covered in this document. For example, the Constraints tab could be used for the Aligned method to place a door or window in an architectural drawing with rules of placing a window in the center of the wall, and the door placed 6 inches from a perpendicular wall.

P	Alignment								
A	Visibility								
R	Basepoint								
A	Point								
M	Linear								
E	Polar								
T	XY								
E	Rotation								
R	Flip								
S	Lookup								
		Move	Stretch	Scale	Array	Polar Stretch	Rotate	Flip	Lookup
		ACTIONS							

Parameters and Action work together to provide the editing capability of Dynamic Blocks. Regular blocks could only have a "Basepoint" parameter. The matrix is a quick reference to determine the appropriate action for each parameter.

Once the Dynamic Block is inserted, pick on it to activate the blue grips. They allow for the editing and orientation

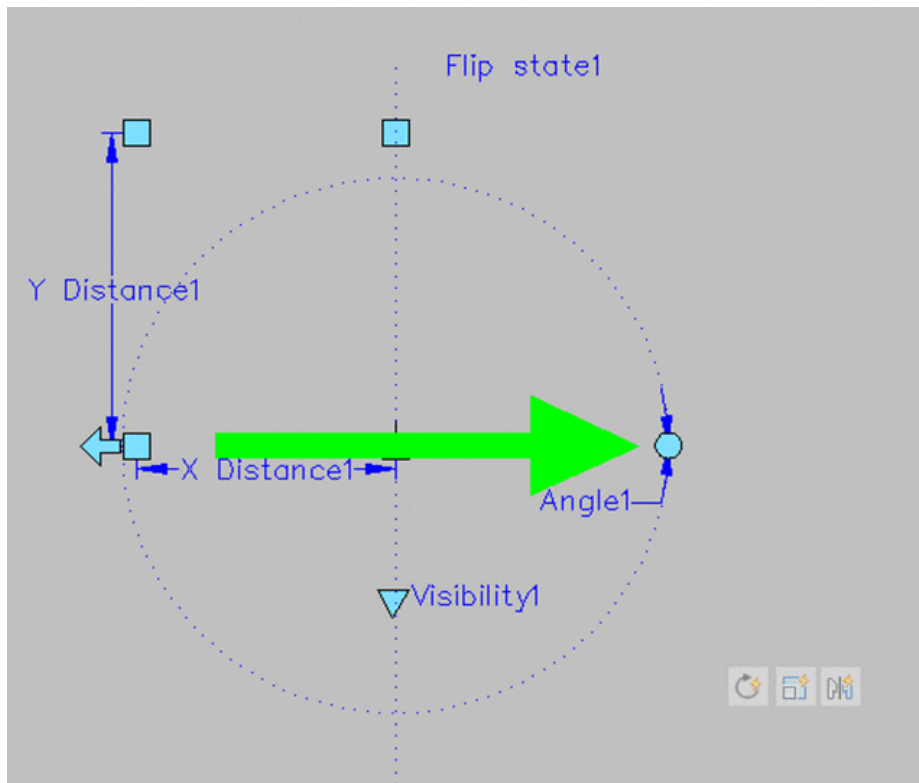

of the block. Picking the down arrow for Visibility1 brings up a list of other blocks and appearances. Here is an example showing ventilation arrows as Dynamic Blocks:

When drawing ventilation arrows, some MSHA districts will not use Neutral Air. They require it to be Belt Air. Some would recommend that the color of the arrows match the reflector underground, or some may require that the double arrow represents the Intake Air instead of the Return Air. Dynamic Blocks allow for editing of colors and arrow heads so they comply.

Dynamic Block Creation and Editing

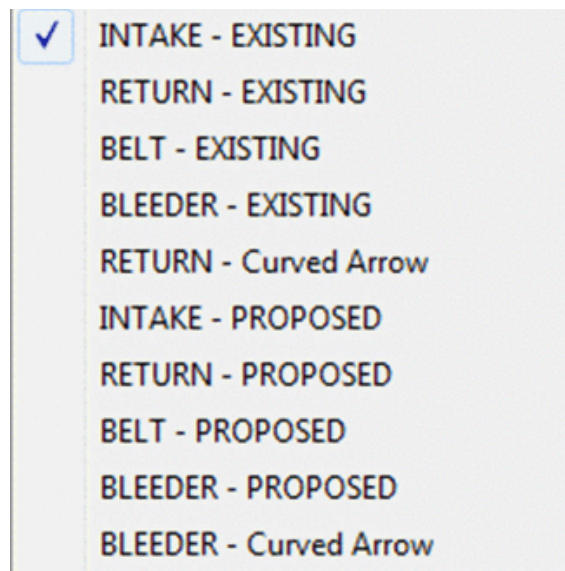

To see the editing features, select the inserted Dynamic Block to show the blue grips and icons. To see the image shown here, right click on a Dynamic Block in the tool palette, and select Block Editor.

1. Visibility1:

- Intake - Existing
- Return - Existing
- Belt - Existing
- Bleeder - Existing
- Return - Curved Arrow
- Intake - Proposed
- Return - Proposed
- Belt - Proposed
- Bleeder - Curved Arrow

Picking on the Visibility1 downward ∇ will bring up the list of visibilities, or types of arrows in this case. This one block can be used for any of the above visibility states in the drawing.

2. Flip state1: Flips the direction of the symbol 180 degrees.

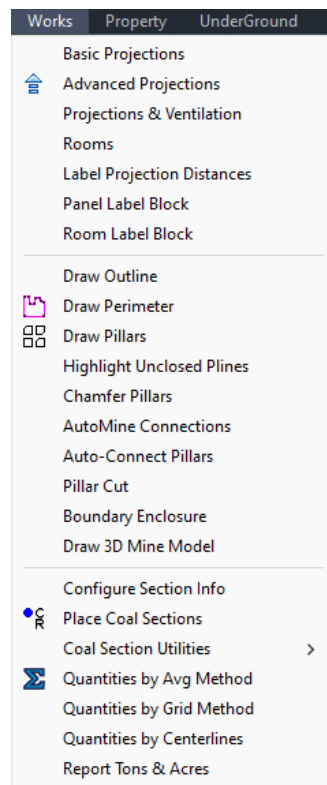

3.X and Y Distance1: Scales and sizes the symbol.

4.Angle1: Rotates the symbol.

All of the above actions are done with the mouse control. As more "Actions" icons are added to the block, they can be moved to any position around the symbol. Other editing icons are for Rotate, Scale and Flip.

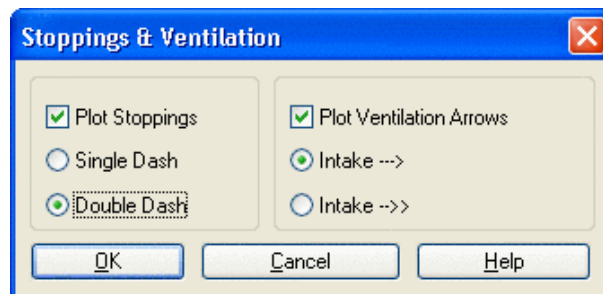

Works Menu

The Works pulldown menu contains commands for underground mines and is divided into three sections with projections commands at the top, placing pillars and perimeters commands in the middle, and quantity commands at the end.

Basic Projections

Basic Projections will only produce a rectangular grid of projections (not angular). The sequencing begins by choosing a starting point, direction, and distance. Then enter the number of entries and their sizing. After the projection is drawn, stoppings and ventilation arrows may be added. This routine has fewer prompts and is more automatic than Advanced Projections. All projection lines are on distinct layers (PROJECTIONS, PROJSTOPPING, PROJVENTARROWS).

Prompts

Start pt. of belt entry: *pick a point* You are automatically placed in intersect and node snap mode.

<P>ick End Point For Belt or [A] For Azi/Dist: *Enter*

Pick end pt. of belt entry: *pick a point*

Number of entries on left side: *3*

Number on right side: *3*

Entry spacing: *60*

Crosscut spacing: *60*

Plot Outer Rib Line y/<n>: *Y*

Cut Width <20>: *press Enter*

Offset to starting rib line (e.g. -10,0,<10>): *press Enter*

Offset to ending rib line (e.g. -10,0,<10>): *press Enter*

Offset xcuts y/<n>: *press Enter*

Pick pt. on xcut for beginning of stopping line: *pick a point*

Draw another stopping line <y>/n: *press Enter*

Pick pt. on xcut for beginning of stopping line: *pick a point*

Draw another stopping line <y>/n: *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point*

Distance between ventilation arrows: *120*

<I>nake or [R]eturn: *I*

Draw ventilation arrows on another entry <y>/n: *Y*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point*

Distance between ventilation arrows: *120*

<I>nake or [R]eturn: *R*

Draw ventilation arrows on another entry <y>/n: *N*

Project another panel <y>/n: *N*

Pulldown Menu Location: *Works*

Keyboard Command: *panell*

Prerequisite: *None*

Advanced Projections

Advanced Projections is a flexible routine that is an extension of Basic Projections. Besides creating projections this routine can also draw pillars and perimeter by using the Draw Pillars option. Other options include angling the crosscuts, offsetting entries, variable length entries, and different labeling schemes. All projection lines are on distinct layers with defaults of PROJECTIONS, PROJSTOPPINGS, PROJVENTARROWS. The pillars are drawn by default in the PILLARS layer and the perimeter is drawn by default in the PERIM layer.

Prompts

Pick Start Point For Belt: *pick a point*

Pick End Point For Belt, or <A> For Azi/Dist: *A*

Enter Azimuth ddd.mmss <>: *90*

Enter Distance: *600*

How Many Entries Left Of The Belt <0>: *3*

How Many Entries Right Of The Belt <0>: *3*

The screenshot shows the 'Panel Settings' dialog box with the following configurations:

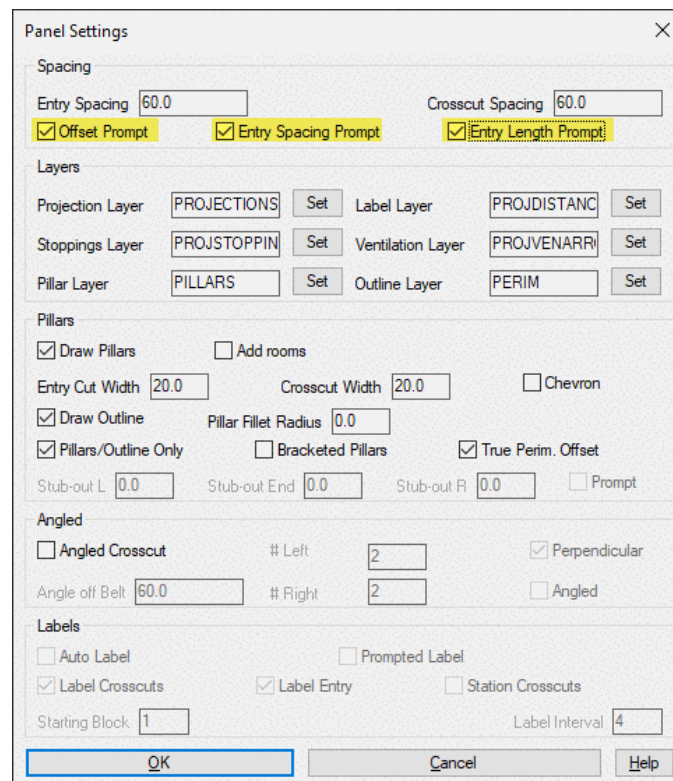

- Spacing:** Entry Spacing: 60.0, Crosscut Spacing: 60.0. Offset Prompt, Entry Spacing Prompt, Entry Length Prompt.
- Layers:** Projection Layer: PROJECTIONS, Label Layer: PROJDISTANC, Stoppings Layer: PROJSTOPPIN, Ventilation Layer: PROJVENARR, Pillar Layer: PILLARS, Outline Layer: PERIM.
- Pillars:** Draw Pillars, Add rooms. Entry Cut Width: 20.0, Crosscut Width: 20.0, Chevron. Draw Outline, Pillar Fillet Radius: 0.0. Pillars/Outline Only, Bracketed Pillars, True Perim. Offset. Stub-out L: 0.0, Stub-out End: 0.0, Stub-out R: 0.0, Prompt.
- Angled:** Angled Crosscut, # Left: 2, Perpendicular. Angle off Belt: 60.0, # Right: 2, Angled.
- Labels:** Auto Label, Prompted Label. Label Crosscuts, Label Entry, Station Crosscuts. Starting Block: 1, Label Interval: 4.

Buttons: OK, Cancel, Help.

Based on the preceding dialog box responses, the following mine layout is created:

To create various entry spacings and lengths choose the Offset Prompt, Entry Spacing Prompt, and/or Entry Length Prompt check boxes.

Panel Settings Dialog

Advanced Projections showing variable entry spacing and offset prompts

Note: The length of the panel was shortened for display purposes. The PILLARS and PERIM layers are reserved layer names used in other routines in Carlson. The layer names can be changed here if you have other reasons to do so.

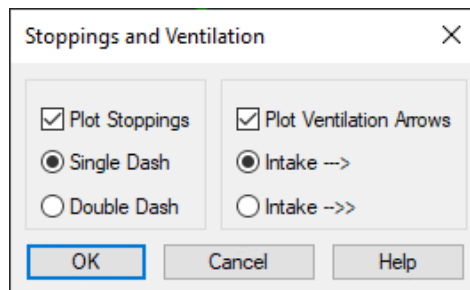

If you want to display the centerlines with the projections and be prompted for ventilation symbols (stoppings and ventilation arrows), then at the Panel Settings dialog box uncheck the Draw Outline and Pillars only checkbox.

The following panel layout is drawn without the ventilation stoppings or arrows.

Then you will see the Stoppings & Ventilation dialog box and upon filling it out you will be prompted as follows:

Stoppings & Ventilation Dialog

Pick pt. on xcut for beginning of stopping line: *screen pick*

Draw another stopping line <y>/n: *Y*

Pick pt. on xcut for beginning of stopping line: *screen pick*

Draw another stopping line <y>/n: *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *screen pick*

Distance between ventilation arrows: *200*

<I>ntake or [R]eturn: *I*

Draw ventilation arrows on another entry <y>/n: *Y*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *screen pick*

Distance between ventilation arrows: *200*

<I>ntake or [R]eturn: *R*

Draw ventilation arrows on another entry <y>/n: *N*

Upon filling in the prompts, the map will be drawn as shown above.

Angled Projections

It is possible to plot projections as centerlines, as pillars with a perimeter, or both. Within the Pillars section of the dialog, if the three dialog items on the left (Draw Pillars, Draw Outline, Pillars/Outline only) are selected, then only pillars and perimeters are drawn. This type of projection is particularly useful to represent the actual mine for purposes of scheduling equipment, using the Underground Mining Module. Here is an example of angled projections, with a "winged" look created by angling only the first 2 of 4 left and right entries:

If all 4 entries left and right are angled (rather than the 2 above), then the entire projection would be in angled form.

Add Rooms

Typical, Default Room Plotting requires that you click on the left-side Draw Pillars, Draw Outline and Pillars/Outline only, as well as click 'Add Rooms'. A typical 2 left, 2 right standard projection with 120' longrooms (current default) has the following dialog appearance and plot.

The default angles lean the left rooms to the left and the right rooms to the right at 60 degrees. The crosscut spacing on the longrooms default to 1/2 the crosscut spacing on the main projections (60 in our case). I have noticed some irregular rooms if you use different crosscut spacing left and right. In that case, it might be better to plot the right side or left side separately. If the Join Perimeter with Center option is not selected, the projections will be in 3 parts: left, center and right. The outer left and right "extents" of the perimeter default to 30' plus the distance to the center of the left- and right-most entries. In our case, that distance to the far entry is $2 \times 120 = 240$, meaning that the outer punchout is defaulting to 270' left and right. I can change that addition of 30' to any other desired number.

Rooms with Stubouts: You can add stub-outs within the main dialog, and the rooms will attach appropriately. In this example, Stub-out L and Stub-out R were set to 30.

Joining with Center Section: The next variation is to join a left or right section to the center (we don't allow joining all 3 at present). This can be done with or without stub-outs. To activate this option, turn on the Join Perimeter with Center option in the Room Dimensions dialog. Shown below is a left section joined to the center with no stubs involved. Below that is a right section joined with the center with stub-outs. The perimeters have been made bold for emphasis.

Rooms with stubouts connected to a standard panel

Changing Angles in the Rooms: Rooms can have a variety of angles for cutting through. To allow variation in angles, turn on the Angle Left Prompt in the Room Dimensions dialog. In this example, we did .60 (the default), then 60 and 60 in 3 entry left room. We did not vary the right condition. The prompting for the angle will remember the last entry, so the second "60" becomes just an "Enter" default on the left side.

Room with stubouts connected to a panel with stubouts

Left room connected to advancing panel

Right room connected to advancing panel

Angled rooms left (3+ X-cuts deep) and angled room right (2+ X-cuts deep)
 Notice neither set of rooms were joined to the panel on the advance

Rooms with entry spacing variations

Entry Spacing Prompt: We can also choose to vary the spacing. In the example below, we did 0 left entries and 3 right entries, and we varied the entry spacing prompt on the right (and included stub-outs and Join Perimeter with Center). We entered 100, 140 and 120 for the three entry spacings and obtained the plot shown below:

Plotting Rooms with No Central Projection: This is useful for attaching left and right rooms to an existing mine plot. You pick your "centerline" as normal to get starting, but you answer 0 to both the number of left and right entries. Normally, this would simply exit the routine, but a new prompt asks "Do Longroom (y/n)". Enter "y" and you can place rooms to the left or right. (The program will only do one side or the other in a "no central panel" projection scheme. Repeat the process to add a right side to the left side rooms.) Here is the "look" of a left-side, 3 room section with no central projection:

Perpendicular Rooms and Offset Rooms

If the Room Dimension dialog is completed as shown below, rooms can be drawn at 90 degrees to the main entry, and can be offset as many crosscuts as desired. The offset up is measured by counting the number of room-size crosscuts. So if you have 40x40 rooms coming off 80x80 mains, and want to offset two main-size crosscuts (160 feet to the first rooms), then enter 4 (4*40 is 160) for the number of crosscuts to offset. Here is the result:

Room Dimensions

No. of Entries Left <input type="text" value="2"/>	No. of Entries Right <input type="text" value="2"/>

Prerequisite: None

Projections & Ventilation

Projections/Ventilation makes heavy use of specification files. Once parameters have been established for a set of projections within a drawing file, you can save those parameters to a specifications file. When changes or additions are necessary, simply erase any undesired projections, load the file, make changes, and process. The specification file contains all the information contained within the dialog, including the projection and ventilation parameters, mandoor and stopping information, even the layer names to use.

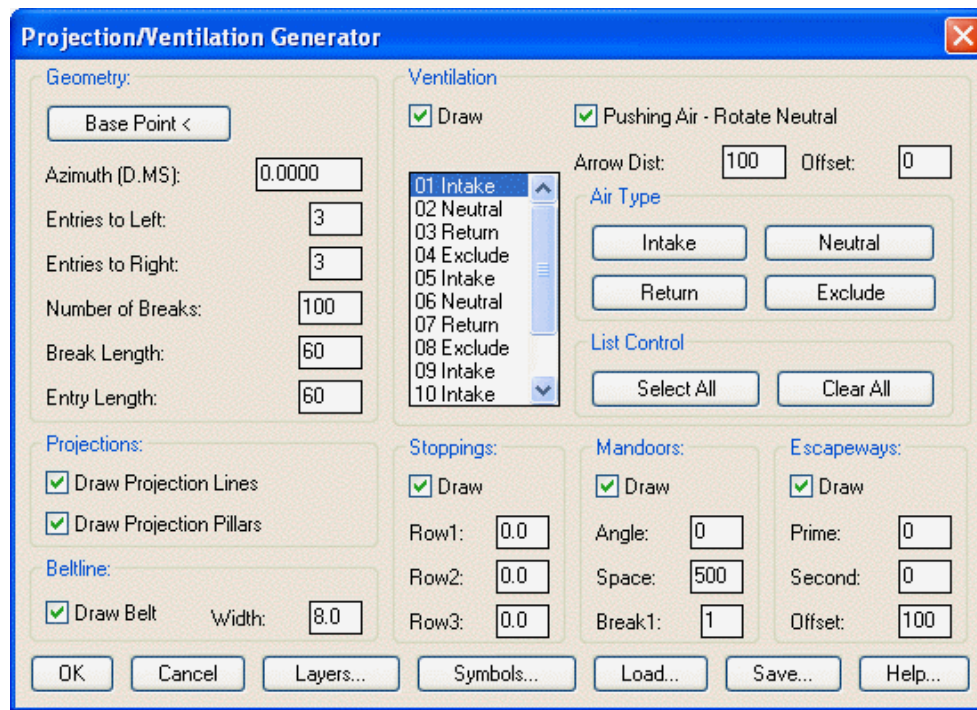

These files can reside in any directory (usually the same directory as the drawing), and have the extension (*.PVS). When the program is activated for the first time within a drawing session, it will look for a PVS file with the same name as the drawing, in the drawing's directory, and if found will load it. If a PVS file with the drawing's name is not found, it will look for a file named DEFAULT.PVS in \PROJECTIONS/VENTILATION subdirectory, and load it.

You can utilize this feature to your advantage by saving the general specifications about a particular drawing in a PVS file with the same name as the drawing. This way, if only the azimuth changed in a set of projections, you could open

the drawing, activate Projections/Ventilation, change the azimuth, and process. You can also access the program's dialog box, enter and then store the specifications you would use most often across drawings as DEFAULT.PVS in \SCAD\LSP subdirectory.

Dialog Control:

When Projections/Ventilation starts, it will display the dialog shown below. All specifications can be entered inside this dialog, and execution of the entity generation process can be initiated as well. Each section of the dialog will be explained in detail in appropriate subsections that follow.

All of Projections/Ventilation's options are accessed easily through this dialog with edit fields for parameters and buttons for each routine available in the program.

Geometry Specifications:

Before generating any entities using Projections/Ventilation, you must specify the geometric specifications of base point, azimuth, entries left/right, number of breaks, break and entry length.

Base Point: This button is used to specify the base point of the geometric entities. After picking this button, the dialog will temporarily disappear, allowing you full screen access to your drawing, and a prompt will appear at the command line requesting you to select a base point.

Choose the base point by picking or typing in coordinates. You MUST use an object snap (NODE, CENTER, or INSERTION) if picking the point graphically, to guarantee that the point selected is exactly on the point, spad circle, or insertion point of a point block.

Azimuth: This edit field is used to enter the projected azimuth. Enter the value in the format of DDD.MMSS, where the whole number of degrees are followed by a period, then minutes and seconds. If the minutes or seconds are less than ten (10), put a leading zero in front such as 01, 05, etc. If the minutes or seconds are zero, enter two zeros 00 as a place holder, especially for minutes.

Entries Left: This edit field is used to enter the number of entries to the left of the base point. A whole number is expected with no decimal points allowed.

Entries Right: This edit field is used to enter the number of entries to the right of the base point. A whole number is expected with no decimal points allowed.

Break Count: This edit field is used to enter the number of breaks to travel. The number of breaks times the break length will determine the total length of the set of projections. A whole number is expected with no decimal points

allowed.

Break Length: This edit field is used to enter the length of each individual break. The break length and entry length do not have to be the same.

Entry Length: This edit field is used to enter the length (width) of each entry from the base point. The break length and entry length do not have to be the same.

Projections:

If the **[x] Draw Projection** Lines toggle is turned on, the program will create projection lines with cross break lines. These projection lines are drawn as lines, having a bylayer color and linetype, and placed on the layer designated in the layer dialog. See the section on layers for more information about changing layers of Projections/Ventilation entities.

Checking the **[x] Draw Projection Pillars** toggle can be used to simulate mine pillars. The simulated mine pillars will be polylines, having a bylayer color and linetype, and placed on the layer designated in the layer dialog.

Beltline:

Checking the **[x] Draw Belt** toggle will generate a set of parallel lines, centered about the base point, and running the entire length of the projections on the specified azimuth. The beltline will be lines, having a bylayer color and linetype, and placed on the layer designated in the layer dialog

Ventilation:

Ventilation can be generated along with projections by checking the **[x] Draw toggle** in the ventilation section and supplying a few additional parameters.

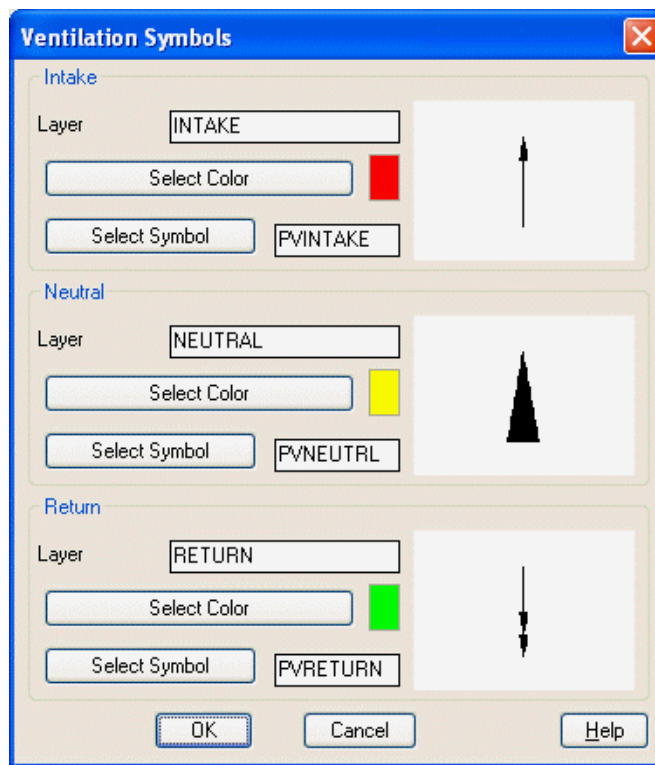

Distance Between Arrows []: This edit field is used to enter the distance between the sets (rows) of ventilation arrows. The sets will be placed along the entire run of projections.

The entry type list box shown, is used to setup the type of air flow in each of the entries. The program is setup to handle up to thirteen entries, but you can use as few as needed.

The process works by clicking your pointer button on the entries (in the list box) that you wish to change. When clicked they will become highlighted, or if they are already selected they will be un-highlighted. To change the air flow once entries are selected, press the button on the right corresponding to the type of air flow in each entry as Intake, Neutral, Return, or Exclude. If no air flow is to be designated for the entry, choose the Exclude button, which will draw no arrows. There are more entries available and will fit in the list box, therefore you may need to use the down arrow button on the scroll bar to view and change these.

If all items in the list need to be selected, press the Select All button, which highlights all items in the list. Additionally you can press the Clear All button, which un-highlights all items in the list.

Selecting the Symbols button allows customization of the arrows. Any of the mining symbols can be selected here.

Stoppings:

To generate stoppings while generating projections and ventilation, turn on the [x] **Draw toggle** in the stoppings section and enter the headings where they should appear. The program can handle up to three rows of stoppings for split ventilation systems.

Row 1-3: These edit fields are used to indicate the heading in which the stopping will be placed. Since stoppings are normally placed halfway between headings, the valid input will usually have a decimal value of (.5). For example, as shown above, if a row of stoppings is to be placed between the 4th and 5th entries, the valid input is 4.5. To exclude a row, set the value to 0.0.

The block inserted can be modified, and is stored as PVSTOPPIN.dwg in the SCAD\SUP subdirectory.

Mandoors:

Mandoors can be automatically added to stoppings. Turn on the [x] **Draw toggle** in the mandoor section and specify the additional parameters below.

Angle: Indicates the rotation angle of the door symbol when placed on the stopping. The default value of 0 should provide the desired results in most cases, but can be changed if needed.

Space: Indicates the distance between doors along the row of stoppings. Usually set to 300 or 500 feet, however any numerical value is acceptable. The program will track the running distance and automatically choose the correct break to place the mandoor in.

Break 1: Indicates the break, relative to the Base Point, that the first mandoor should fall into. The program will begin tracking the space (described above), and place additional doors at the designated distance from this first break.

The block inserted can be modified, and is stored as PVMANDOR.dwg in the SCAD\SUP subdirectory.

Escapeways:

You can optionally place sets of escapeway symbols. Turn on the [x] **Draw toggle** in the escapeway section and specify the additional parameters below.

Prime: Indicates the entry number for the primary escapeway. The block is stored as PVESCPRI.dwg. Valid input would be a whole number with no decimal places.

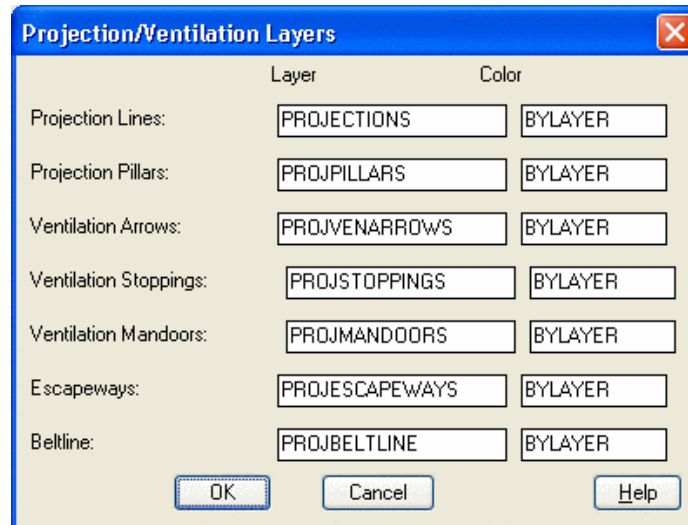

Second: Indicates the entry number for the secondary escapeway. The block is stored as PVESCSEC.dwg. Valid input would be a whole number with no decimal places.

Offset: Indicates the distance to measure back from the row of ventilation symbols for the placement location of the escapeway symbol. Valid input would be a whole number with no decimal places.

The blocks inserted can be modified, and are stored in the SCAD\SUP subdirectory.

Layer Control:

Projections/Ventilation always generates the different sections of its geometry (projection lines, pillars, ventilation arrows, stoppings, manddoors, escapeway, and beltline) on separate layers. These layers can be easily changed within the layer dialog and are automatically saved when the specifications are saved. The layers used are self-explanatory and are shown below.

LAYER CONTROL SUB-DIALOG

To access the layer control dialog shown, press the layer button on the main dialog. After making changes to the layers, choose the OK button. If you wish to reject the changes made to the layer names, simply press the Cancel button.

Specification Save:

Projections/Ventilation can store all specifications previously discussed to a file for later recall. To save a set of specifications, choose the Save button from the main dialog. When pressed, a standard file dialog will appear (defaulting to drawing name) allowing you to save the *.PVS file. PVS stands for Projections/Ventilation specification file. When chosen, the default drawing filename will usually be the filename used for the PVS file. Accept this name or enter a new one, changing directories if appropriate. The normal scheme is to have one PVS file per drawing, having the same name as the drawing and stored in the same directory.

Specification Load:

Projections/Ventilation can re-load all specifications previously discussed to a file for later recall. To load a set of specifications, choose the Load button from the main dialog. When pressed, a standard file dialog will appear, allowing you to enter the *.PVS file. The default drawing filename will usually be the filename used for the PVS file. Accept this name or enter a new one, changing directories if appropriate.

Keyboard Command: pillars

Prerequisite: None

Highlight Unclosed Plines

As its name suggests, this function will temporarily highlight polylines that are not closed. The intention of this function is for checking that the pillars and perimeter polylines are closed, since their closure is necessary for calculating quantities.

The procedure is to simply select the polylines to check. Then, after highlighting the selected polylines that are unclosed, the routine will pause for user input and then unhighlight the polylines. Thus, no changes are made to the drawing.

A polyline is considered closed if the endpoints are the same or if the closed flag is set. The closed flag can be set when creating a polyline, with the pline command, by using 'C' to close at the end.

Prompts

Select the polylines to check.

Select objects: *select polylines*

The program then reports either:

Unclosed polylines are highlighted.

Close all or selected polylines (All/<Selected>)? *press Enter* Look for the highlighted polylines and select the ones to close.

or

All the selected polylines are closed.

Pulldown Menu Location: Works

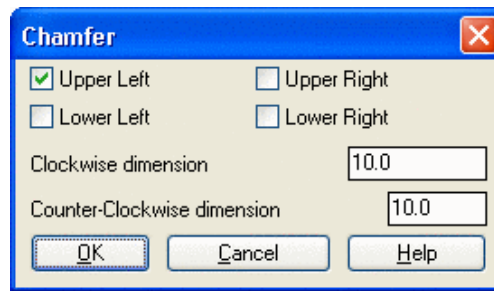

Keyboard Command: unclosed

Prerequisite: Polylines

Chamfer Pillars

Chamfer Pillars is meant for redrawing existing pillars that are notched at a corner by mine equipment.

Chamfer Pillars is similar to AutoCAD's chamfer except that AutoCAD's works only on lines and Chamfer Pillars works only on polylines in the PILLARS layer. Chamfering basically creates a new edge that replaces a corner point and extends down each side a specified distance. In order to determine which corner to chamfer, this routine displays the dialog box shown below.

Chamfer Pillars dialog box

A 40' x 40' pillar before and after chamfering the upper right 10' and the lower left 20'

Prompts

Chamfer Dialog Box

Select the pillars the chamfer (polylines in the PILLARS layer).

Select objects: *Select the pillars*

Pulldown Menu Location: Works

Keyboard Command: pillar_chamfer

Prerequisite: Pillar polylines

AutoMine Connections

This command automates the connecting of dots for pillars and perimeters.

AutoMine Connections draws the pillars and perimeter of a mine based on point data in an offset file. This file can be created by one of the Mine Note Entry commands. There are two types of points in this file, corner points and regular points. Corner points, which appear as green dots, identify the first point across a cross cut for both the left and right side of a spad. Regular points are all other points, and are drawn as red circles. Corner points are critical to AutoMine. If a corner point is missing, AutoMine will become offset and the pillars will appear shifted. Each pillar must have exactly two corner points, one on the left and the other on the right. There can be no regular points between the two corner points on the pillar since AutoMine always directly connects the corner points together. For the perimeter, corner points are not important for the left and right faces. At the end face, however, corner points are required in order to identify the cross cut between the perimeter and the farthest pillar.

The order of entry of points in the offset file is significant in several ways. For one, the spads need to be in left to right order in the direction of mining. To do this, the spads can be entered in order, or the spads can be assigned sequential entry numbers. Another reason to assign entry numbers to the spads is to allow appending of the offset file. When reading appended files, AutoMine will group spads according to their entry number. The spads with the same entry number may be entered in any order since AutoMine sorts these spads by the distance along the direction of mining. For example, provided that spad 2 and spad 4 have the same entry number, then spad 2 and spad 4 offsets

may be entered either spad 2's offsets then 4's or spad 4's offsets then 2's. The offsets within each spad, however, are not sorted, but are drawn in order. Consider, for instance, the cut in the left face of the perimeter in the figure below. These points must be entered in the order 1 then 2 then 3 then 4.

AutoMine removes any pillar or perimeter that is already in the drawing at the same location.

After drawing the pillars and perimeter, AutoMine leaves a pick box hanging off the perimeter so that you may connect it with a previous perimeter.

File Selection Dialog Box

Select a mine note file. This file must contain points in the format described above.

Next Point, U to Undo, P for Polyline, C to Close: C

Pulldown Menu Location: Works

Keyboard Command: automine

Prerequisite: An offset file created by one of the mine note routines

Auto-Connect Pillars

This routine automatically draws pillar polylines by connecting the selected offset points. The points must be offset points created by one of the Mine Note routines such as Mine Note Auto Left/Right. In addition to the points, polylines must be drawn through each crosscut. The routine works by connecting the points such that no connection crosses a crosscut polyline. The crosscut polylines can be drawn individually with the Draw Polyline command or created as projection polylines with the Advanced Projection routine.

To use the routine see the layouts below. The first layout is created using Mine Note Auto Left/Right to locate the offset points. The centerlines were laid out using Advanced projections.

It is a good idea to manually connect the outer offset points manually and let this routine connect the internal points. Using the Polyline command and with the Osnap setting on Nodes, connect the perimeter points and create them in the PERIM layer as shown:

Next, connect the internal points using the Auto-Connect Pillars command. Select the points to be connected and the center lines that separate them. See the results here:

Prompts

Select pillar points and projection lines.

Select objects: *select the points and lines*

Pulldown Menu Location: Works

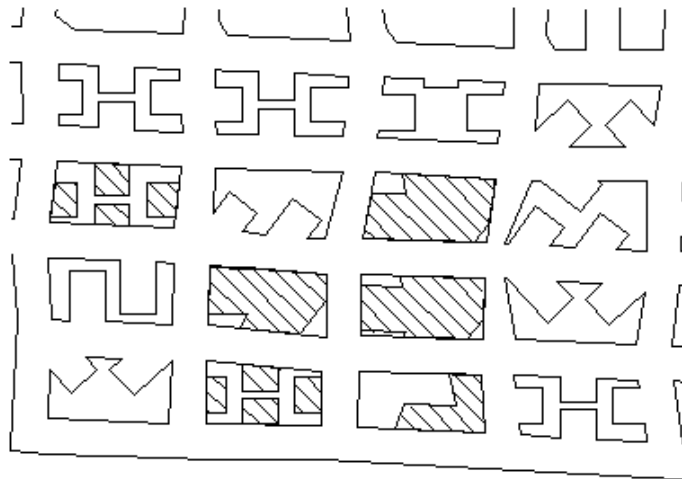

Keyboard Command: autopillar

Prerequisite: Offset points and crosscut polylines

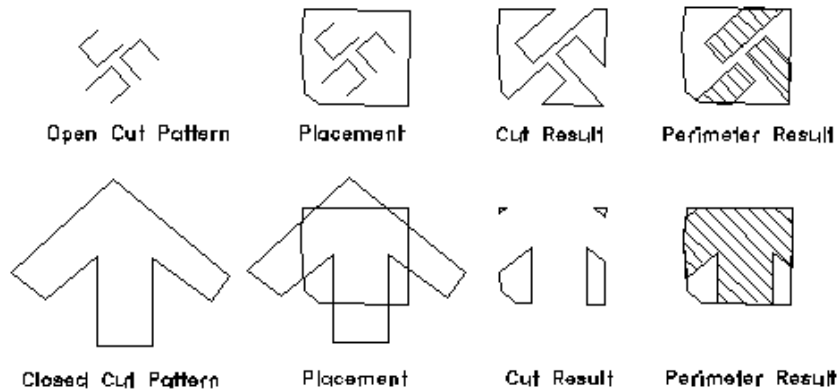

Pillar Cut

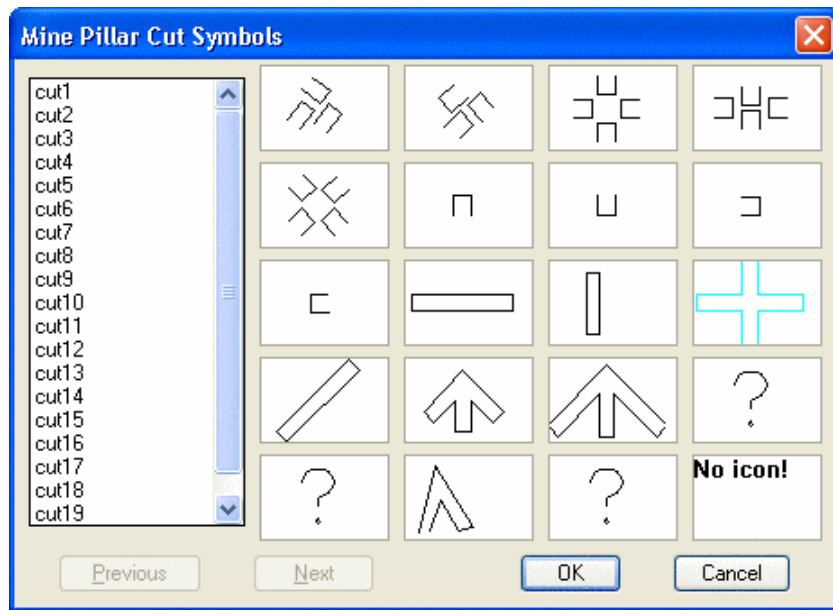

Pillar Cut serves two purposes relating to final cuts that are made into pillars. It automates the process of drawing cut pillars, and it creates new pillars and perimeters for use in calculating the tonnage removed from the cuts.

The command is run by first choosing a cut pattern, then selecting the pillars to cut, and finally placing the pattern inside a pillar. The pillars must be closed polylines in the PILLARS layer. The cut pattern can contain either open or closed polylines. When an open pattern symbol is placed in a pillar, Mine Pillar Cut calculates the intersections between the pillar and the end segments of the symbol, and fits the pattern into the pillar. With a closed symbol, the cut pattern is clipped against the pillar. There are two effects this placement can have. One is to recreate the pillar with the cuts taken out. The other creates perimeter polylines inside the pillar in the spaces that are cut out.

Example of Mine Pillar Cuts

Open cut patterns will not work if they divide a pillar into two or more separate pillars. Use a closed cut pattern if the pillar will be cut through.

To create custom cut patterns, create polylines in the desired pattern either as closed polylines or open polylines whose end segments will intersect the pillar when extended. Make sure that the polylines are the correct size to fit with a pillar. Then start Pillar Cut as usual and select the User-Defined symbol. It will ask you to select an insertion point, and pick a place in the table to store the new symbol. The next time Mine Pillar Cut is called, the new pattern should be in the table.

Prompts

Mine Pillar Cut Symbols Dialog

Select a symbol to cut with or select User-Defined to begin the procedure to define your own symbol.

Enter the azimuth for the cuts <0.0>: *press Enter* This allows the cuts to be rotated when placed.

Cut the pillar or create new perimeter? (<Cut>/Perim) *press Enter a string* If Cut is selected, the pillar is re-drawn with the cut hacked out. If Perim is selected, perimeter polylines are created inside the pillar in the spaces that are cut out. The removed portion can be hatched with PERIM.

Select mine pillars (polylines in the PILLARS layer).

Select objects: *select polylines* This creates the set of pillars that may be cut. These pillars must be closed polylines in the PILLARS layer.

Pick a point for the symbol: *pick a point* This point must be inside one of the selected mine pillars.

Pulldown Menu Location: Works

Keyboard Command: cutsym

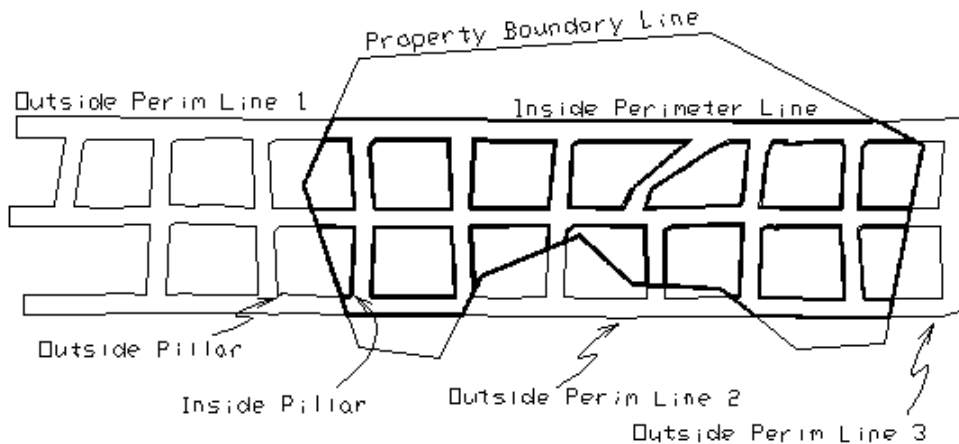

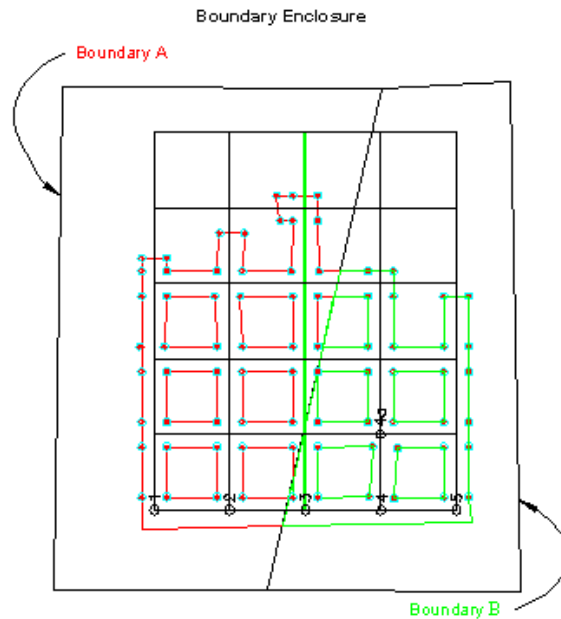

Prerequisite: Pillars to cut and drawn as polylines in the PILLARS layer

Boundary Enclosure

This routine is intended to be used in mines that include different leases or property ownerships. If the property is bounded by a polyline, Boundary Enclosure can be called to divide the mine into separate sets of pillars and perimeters. Then other routines such as Quantities by Average Method can use these sets to determine the exact tonnage quantities for that property.

Boundary Enclosure separates the pillars and perimeter of a mine into two sets based on a boundary line. One set consists of pillars and a perimeter from inside the boundary line and the other set consists of pillars and perimeter from outside the boundary line. If a pillar or perimeter crosses the boundary line, it is divided into two or more new polylines. In some cases, part of the new polyline may follow the boundary line. The boundary line must be a

closed polyline. The one restriction on the boundary line is that it cannot create a disjoint inside set of pillars and perimeter. Disjoint outside sets may be created.

Prompts

Enter a color (1-7) <No change>: 2 The pillars and perimeter inside the boundary will change to this color.

Select a boundary polyline: *pick a polyline* If the point where the polyline is picked crosses additional polylines, all polylines will be highlighted. Pick another point on the desired polyline that distinguishes it from the others.

Select mine pillars and perimeter.

Select objects: *pick the selection set of pillars and perimeter* These pillars and perimeter must be closed polylines in the PILLARS or PERIM layer.

Pulldown Menu Location: Works

Keyboard Command: bound

Prerequisite: Pillars drawn as polylines in the PILLARS layer and perimeter drawn as polylines in the PERIM layer

Draw 3D Mine Model

This command takes the 2D series of linework and converts it to a 3D underground representation of the room and pillar mine. It uses the pillars and perimeter polylines and extrudes them to the thickness of the seam that is being mined.

The above starting linework for 3D conversion

This command will extrude the linework to either the thickness from a flat base, or to a roof and floor defined by either fixed elevations, coal sections, or elevation grid files as set by the **Mine Height Method** in the dialog. The input layers are defined so that the program knows what layers to look for. For the Draw 3D Faces option, the Output Layers are defined for the new 3D faces that are to be drawn in the assigned layers. The Output Solid Model option creates an MDL file.

Configure Section Info

This command configures the names, abbreviations, and density of the various strata that appear in your underground mine. Also, the appearance of the section is specified by this routine. This information is needed for placing sections on the drawing which in turn are needed for Quantities by Average and Grid Method. If you reconfigure section info of an existing coal section, the sample points placed using the previous section info will become invalid and must be replaced.

The strata of a section can be configured as either individual or composite. With the individual configuration, each strata has its own name and density. With composites, each strata is still named separately but they also are divided into groups that have a group name and density. The principle advantage to composites is that it allows you to enter and list out each strata height and then combine the strata into their corresponding composite category when generating tonnage quantities.

This command creates a block drawing for the coal section with block attributes for each strata. The default folder for this .dwg file is your current SUP support folder which works fine for an individual user of the section info. To share the coal section with others, both the section .sc file and block .dwg file should be stored on a shared network folder. The location of the block .dwg file is stored inside the .sc file.

If you have a drawing with existing coal sections but don't still have the associated .SC file, then you can use this

command to recreate the .SC file. Near the beginning of the command prompting, answer Yes to the *Select existing coal section for strata names* prompt. Then the program will prompt to pick an existing coal section and will read the strata names from this section. The program still needs to prompt for the full strata names, densities and some format options.

Warning: After Configuring Section Info be sure to save your drawing. This will get AutoCAD to update the section Block information. Otherwise there can be a conflict between the version of the Block settings and the *.SC file which Carlson creates during Configure Section Info.

Prompts

For an Individual Section:

Enter Coal Section Configuration file name <Drawing_name.SC>: *SECTION1* (Or the name of your choice.)

Mine Name: Enter a name.

Select existing coal section for strata names [Yes/<No>]? *press Enter*

Enter Abbreviated Strata Name/<ENTER> to End: *C* This name is drawn next to the corresponding height when a section is located in the drawing.

Enter The Full Strata Name <C>: *Coal* This name is used in quantity reports.

Enter Abbreviated Strata Name/<ENTER> to End: *B*

Enter The Full Strata Name <C>: *Bone*

Enter Abbreviated Strata Name/<ENTER> to End: *R*

Enter The Full Strata Name <C>: *Rock*

Enter Abbreviated Strata Name/<ENTER> to End: *press Enter*

Enter Individual densities or Composite densities (I/C) <I>: *press Enter*

Average wt. of C (Coal) [lbs/ft³]: *80*

Average wt. of B (Bone) [lbs/ft³]: *150*

Average wt. of R (Rock) [lbs/ft³]: *150*

Circle the Coal Section (y/<n>)? *Y* This specifies whether a circle is drawn around the section when it is placed in the drawing.

Coal Section Block To Write Specify dwg file name

Sample Coal Sections

Sample Coal Sections

Pulldown Menu Location: Works

Keyboard Command: csconfig

Prerequisite: None

Place Coal Sections

This routine places a block circle and text of measured section information on the drawing. It serves two purposes: to display the sections for plotting, and to calculate tonnage. Carlson reads the location and values of the section from the block circle and not from the text.

For blank thickness entries, the program can either assume a zero thickness or ignore the section point for that strata. Which method to use is defined in Configure .

Prompts

Coal Section Configuration File Dialog

Pick sample point for coal section: *pick a point* This places a block circle.

Pick Start Point: *pick a point* This is where the text begins.

Pick Alignment Point: *pick a point*

Now enter your measurements.

How many Inches of Coal C: *51* Which quantities it asks for here depends of the configuration file.

How many Inches of Rock R: *9*

Pulldown Menu Location: Works

Keyboard Command: pcs

Prerequisite: A coal section configuration file

Edit Coal Sections

This routine edits the measured section information already placed on the drawing. To edit this information, pick the section block circle and the text. Then a dialog box will appear which allows you to change the current amounts of that section.

Pulldown Menu Location: Works

Keyboard Command: ecs

Prerequisite: A coal section placed in the drawing

Import Coal Sections From Text File

This command creates coal sections by reading data from a text file. The format of the text file must be northing, easting, thickness and strata name separated by commas. This is the format that the Export Coal Sections To Text File command creates.

Pulldown Menu Location: Works > Coal Section Utilities

Keyboard Command: importcs

Prerequisite: Text file to import and Coal Section definition file (.sc)

Export Coal Sections To Text File

This command creates a text file with the coal section data from the selected coal sections. The program first prompts for the text file name to write. Then the Coal Section Configuration file (.sc) is set. The last step is to select the coal section blocks from the drawing. Then the text file is written.

The format of the text file is northing, easting, thickness, and strata name. The values are comma separated and there is one record per line.

Prompts

Coal Sections Text File To Export

Coal Sections Configuration File

Select coal sections.

Select objects: *pick coal sections*

Pulldown Menu Location: Works > Coal Section Utilities

Keyboard Command: exportcs

Prerequisite: Coal sections

Quantities by Avg Method

Quantities by Average Method is one of three commands that calculate tonnages based on coal cross section data. The other routines are Quantities by Grid Method and Quantities by Centerlines. The grid method is more accurate but the average method is faster and requires fewer coal section sample points. The centerline method uses entry row centerlines instead of pillar and perimeter polylines.

Before executing this command, there must be sample coal section points and pillar and perimeter polylines in the PILLARS and PERIM layers. The pillars and perimeter polylines can be made with the Draw Pillars, Draw Perimeter, or AutoMine Connection commands, and sample points are placed by the Place Coal Sections command.

The quantities can also be reported by property owner. The property areas are defined by closed polylines with an attached property name. There are routines in the Boundary menu of the Underground Mining module for assigning the property names to the polylines. Quantities by Average Method will prompt you to select property polylines. If you do not select any, then just the total quantities will be reported. Otherwise the quantities are divided between the properties and reported separately.

Quantities by Average Method generates detailed a report when it is done calculating. The format of the report method can be Standard text, Column text, or reported with the Report Formatter. Besides this detailed report, the command Report Tons and Acres gives coal tonnage reports based on data files that Quantities by Average Method updates. In order to have these data files updated, you must enter beginning and ending dates and an ownership name when prompted. If this information is entered, Quantities by Average Method will add the current tonnage to the data file for the specified ownership name. The data files for the mine and panel names will also be updated if they are specified. The first time a mine or panel data file is accessed, it will ask for the estimated coal reserves.

Layer for text <REPORT_TXT>: *You can set any layer for the text report.*

Insert as MText or Text [<MText>/Text]?: *press Enter for MText*

Update coal tonnage files [<Yes>/No]? *N*

Pulldown Menu Location: Works

Keyboard Command: qavg

Prerequisite: Pillars and perimeter polylines and coal sections

Quantities by Grid Method

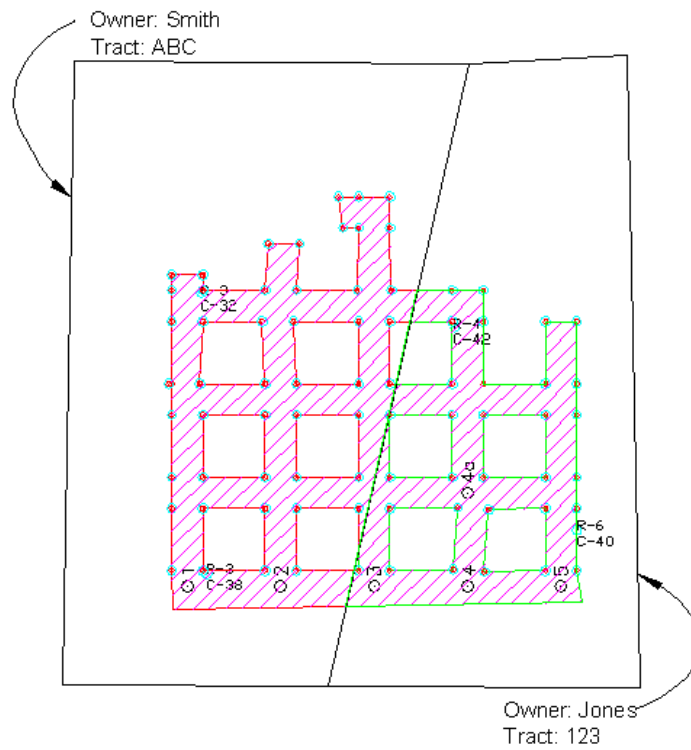

Quantities by Grid Method is one of two commands that calculate tonnages based on pillars, perimeter and coal cross section data. The other routine is Quantities by Average Method. The average method is faster and requires fewer coal section sample points, but the grid method is more accurate because it creates a 3D model of the strata which finds deviations the averaging misses. Either Triangulation or Inverse Distance methods can be used for the grid model.

Before executing this command, there must be at least three sample coal section points and pillar and perimeter polylines in the PILLARS and PERIM layers. Perimeters may only be used one at a time. The pillars and perimeter polylines can be made with the Draw Pillars, Draw Perimeter, or AutoMine Connection commands, and sample points are placed by the Place Coal Sections command. Also property owner polylines can be used as described in the Quantities by Average Method command.

Quantities by Grid Method generates a detailed report when it is done calculating. Besides this detailed report, Report Tons & Acres gives coal tonnage reports based on data files that Quantities by Grid Method updates. In order to have these data files updated, you must enter beginning and ending dates and an ownership name when prompted. If this information is entered, Quantities by Grid Method will add the current coal tonnage to the data file for the specified ownership name. The data files for the mine and panel names will also be updated if they are specified. The first time a mine or panel data file is accessed, it will ask for the estimated coal reserves. There are three options for reporting, Standard, Column and Formatter.

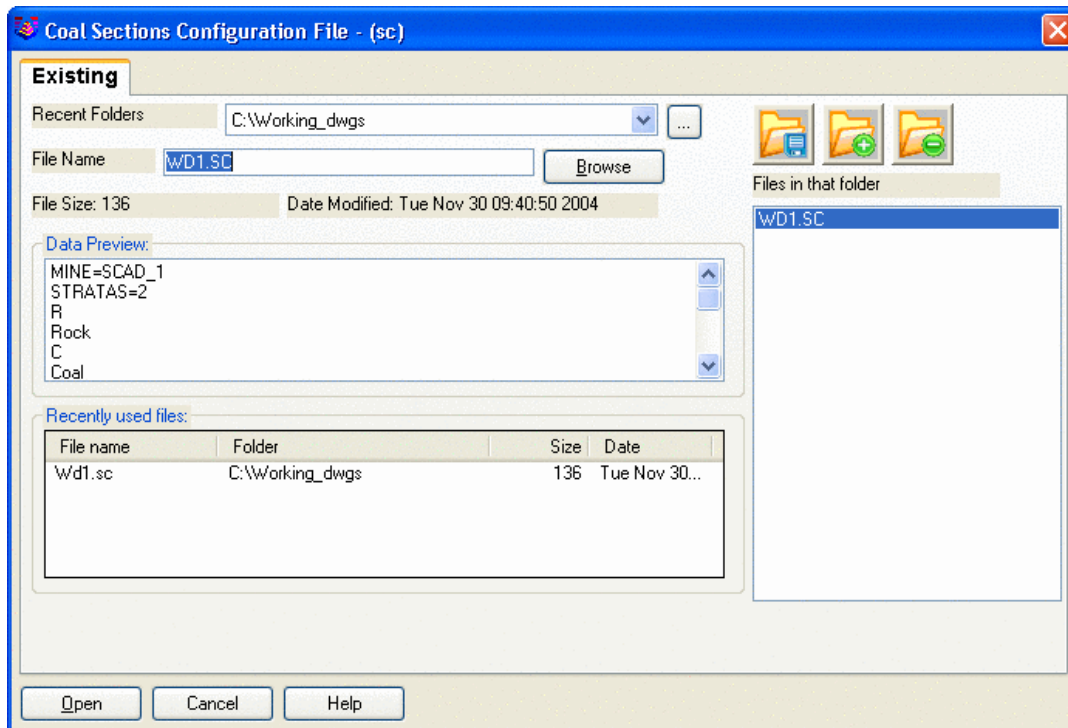

The screenshot shows a dialog box titled "Quantities by Grid Method". It contains the following fields and options:

- SC File: C:\sample\leaf.sc
- Grid Modeling Method: Triangulation, Inverse Distance
- Automatic Grid Size, Grid Cell Size: 10.0
- Beginning date of takeup (mm/dd/yyyy): 4/1/2012 (with a "Select" button)
- End date of takeup (mm/dd/yyyy): 4/30/2012 (with a "Select" button)
- Report Method: Standard, Column, Formatter
- Select Property Polyines
- Buttons: OK, Cancel

Prompts

Select the file that defines the coal section sample points.

Coal recovery percent <100.00>: *press Enter*

Select property polylines or press Enter for none: *select property boundaries only*

Select pillars, perimeters, & at least 3 coal section points Select these carefully to only include the ones for the calculation. If you select more than you need and the hatching does not look correct, undo and repeat.

Processing cells ...

Another area [Yes/<No>]? If you want to process more than one area and calculate them together select another area. When you have selected all of the areas the program prompts you for the location if the report.

Start point or Center/Middle/Right/?:

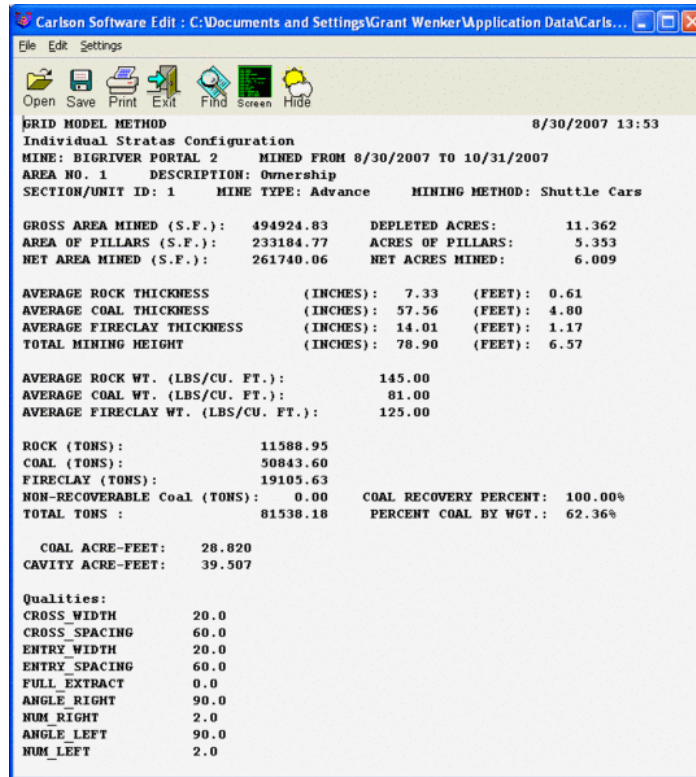

Height <6.00>: 10

Rotation angle <90d0'0">: *press Enter*

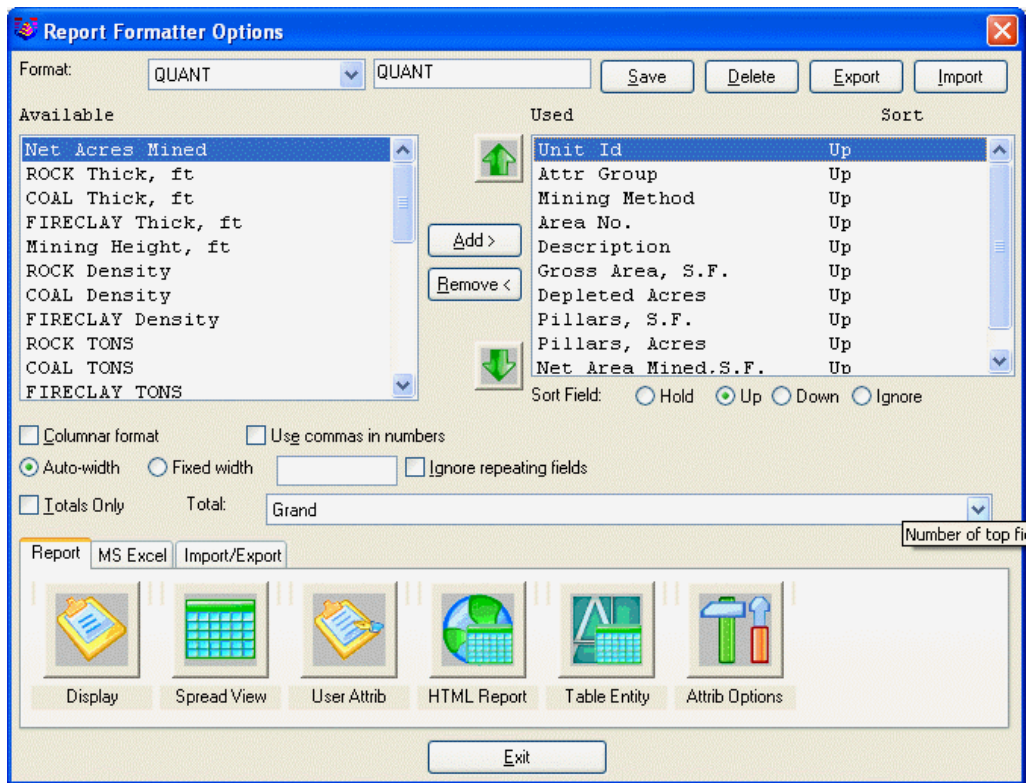

Layer for text <REPORT_TXT>: *press Enter* You can assign a new layer name if you choose.

Insert as MText or Text [<MText>/Text]?: *press Enter*

Update coal tonnage files [<Yes>/No]?: *N*

Report window

Report Formatter

Pulldown Menu Location: Works

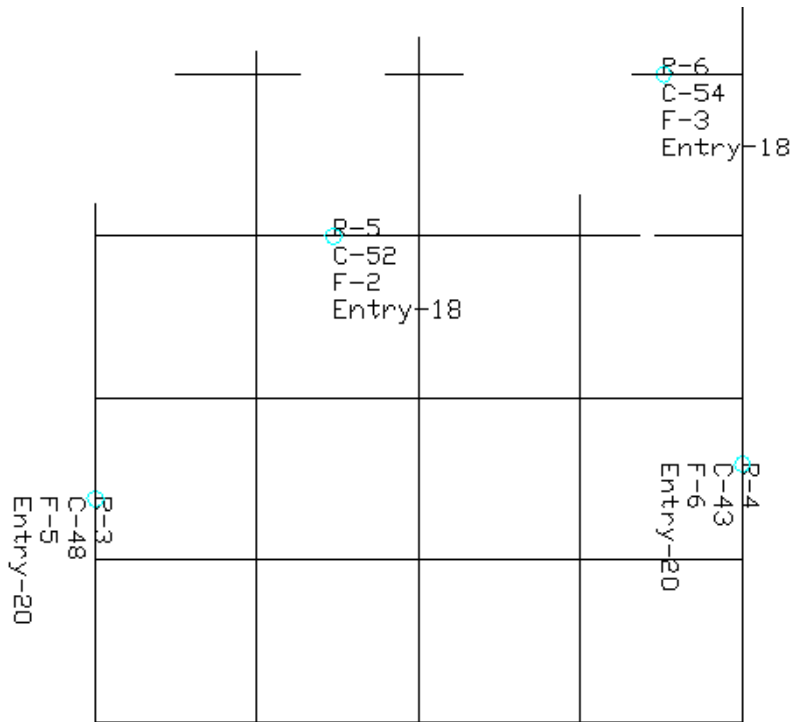

Keyboard Command: qgrid

Prerequisite: At least three coal sections and pillar and perimeter polylines

Quantities by Centerlines

This command calculates strata quantities based on coal sections and polylines along each cut. The coal sections contain the thickness for each strata and the entry width. When defining the coal section format in Coal Section Info, the Entry Width option must be activated.

Before running Quantities by Centerlines, polylines should be drawn along each cut. This routine sums the polyline lengths to find the linear feet of advance. Crossing cut polylines are handled by subtracting one entry width from the length for each crossing. Multiplying the linear feet of advance by the average entry width gives the mined area which is multiplied by the average strata thicknesses to obtain the strata volumes.

Prompts

Coal Section Configuration File

Select the file that defines the coal section sample points.

Beginning date of takeup [format mm-dd-yy] <3-1-05>: *press Enter*

Ending date of takeup [format mm-dd-yy] <4-1-05>: *press Enter*

Report Tons & Acres

When you run the take-up procedures Quantities by Average, Quantities by Grid, or Quantities by Centerline, at the end of the procedure after the routine has posted the take-up report you are prompted to update the Tonnage Report. The Tonnage Report gives you the option of keeping track of tons for an Owner, Mine, and each Panel for specific periods of time.

Mine Report produces coal tonnage reports for a specified mine, panel, or ownership.

NUMERICAL AVERAGE COAL SECTION METHOD

Reports are created for a certain time period. If no dates are entered, a report is generated that includes all the known data. Besides reporting the tons mined for the period, Mine and Panel reports also include the total reserves and remaining reserves.

Coal tonnage data is made with the Quantities by Average Method or Quantities by Grid Method commands, and the data is stored in *.MIN, *.PAN, or *.OWN files in the data directory. These files are in a straightforward ASCII format and may be edited by the Inquiry Dropdown > Display Edit File command.

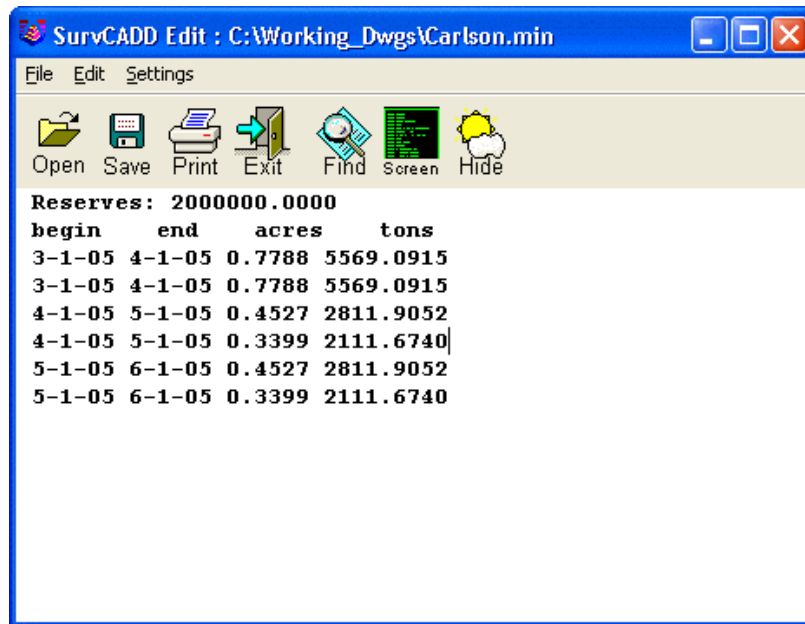

Prompts

Type of report (Mine, Panel, <Owner>): *Enter a name*

Report Source File selection dialog The available data files are displayed for selection.

Enter a beginning date (MM-DD-YY): *enter a date* If no date is entered, the earliest date in the data file is used.

Enter an ending date (MM-DD-YY): *enter a date* If no date is entered, the latest date in the data file is used. You can also select the files from the dialog box.

Pulldown Menu Location: Works

Keyboard Command: mreport

Prerequisite: Quantity report files

Property Menu

The Property menu has commands for managing property boundary polylines.

Assign Property Names

In order to evaluate the quantity and/or quality of ore mined on the particular property, Carlson employs the use of closed polylines representing the property boundary. This function is used for assignment and modification of the owner and property ID names to these polylines. The following commands support property lines:

Quantities by Average
Quantities by Grid
Surface Equipment Timing
Surface Production Timing
Underground Timing
Surface Mine Reserves
Reserve Classification

This command simply prompts to select the polyline and type in the owner and ID. Property polylines supersede the Boundary Enclosure command for the purposes of calculation, since the use of property polylines does not require actual subdivision of the mine plan into properties. Instead the subdivision is performed internally "on-the-fly" by the cutting of a given polyline (such as whole mine property or monthly production pit polyline) against an underlying set of property lines.

In its current implementation the use of property lines has the following limitations: property lines should be closed polylines and make sure that they do not overlap other property lines. If a portion of a pit or panel is outside of all property lines, then in the report, the owner will be reported as UNKNOWN.

Prompts

Select property polyline:

Property Owner Name<>: *Federal*

Property ID<>: *#J1267*

Pulldown Menu Location: Boundary

Keyboard Command: property_line

Remove Property Data

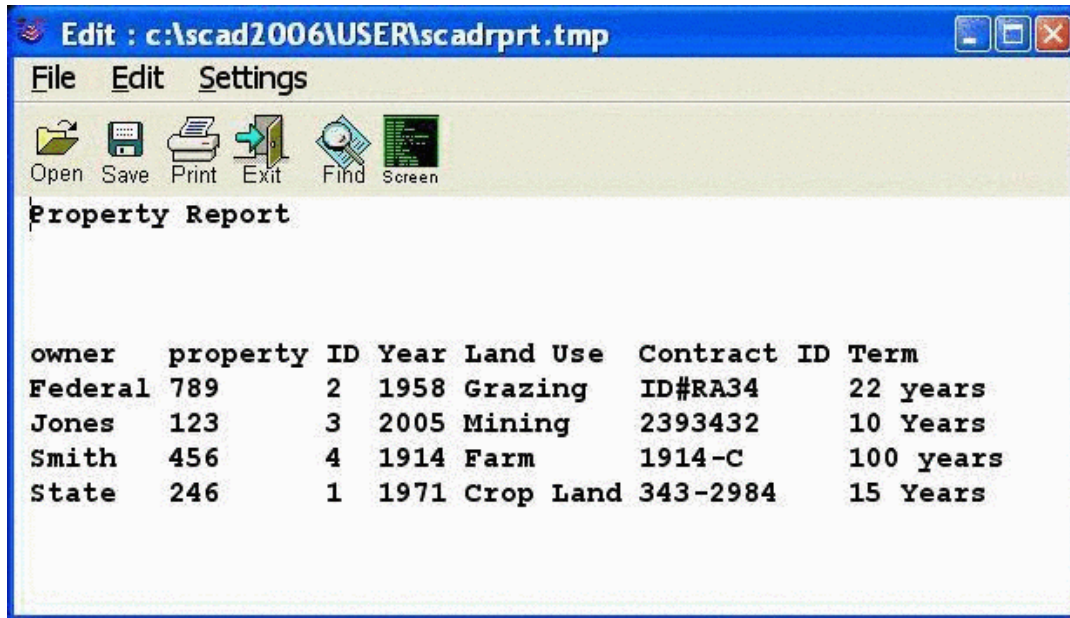

When property information attached to the polyline is no longer needed, it may be removed by using this command. Multiple polylines may be processed at once.

Pulldown Menu Location: Boundary

Keyboard Command: clearprop

Property Data Report

This command uses the report formatter to create a report showing all property data associated with the selected property lines. They must be linked to the MPD file where all of the property data is stored.

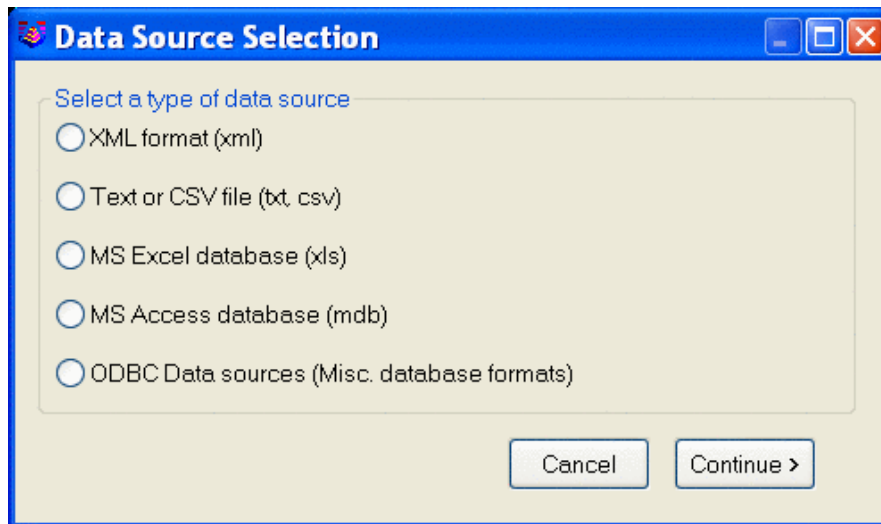

Pulldown Menu Location: Boundary, Property Line Tools

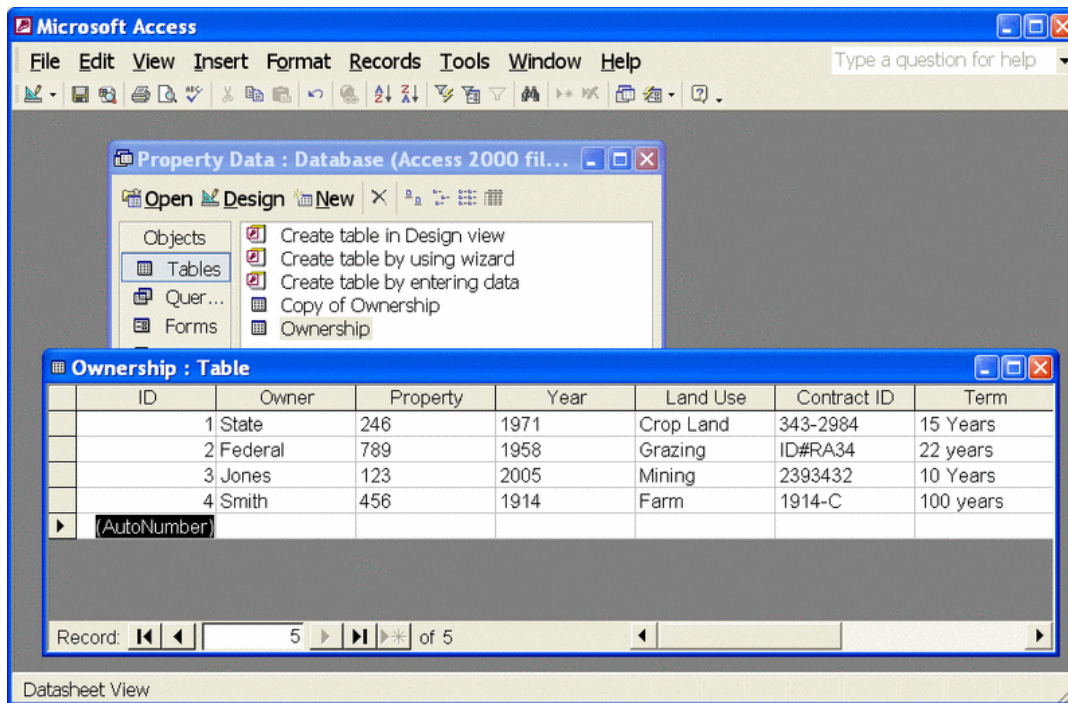

Keyboard Command: reportprops

Setup Property Link

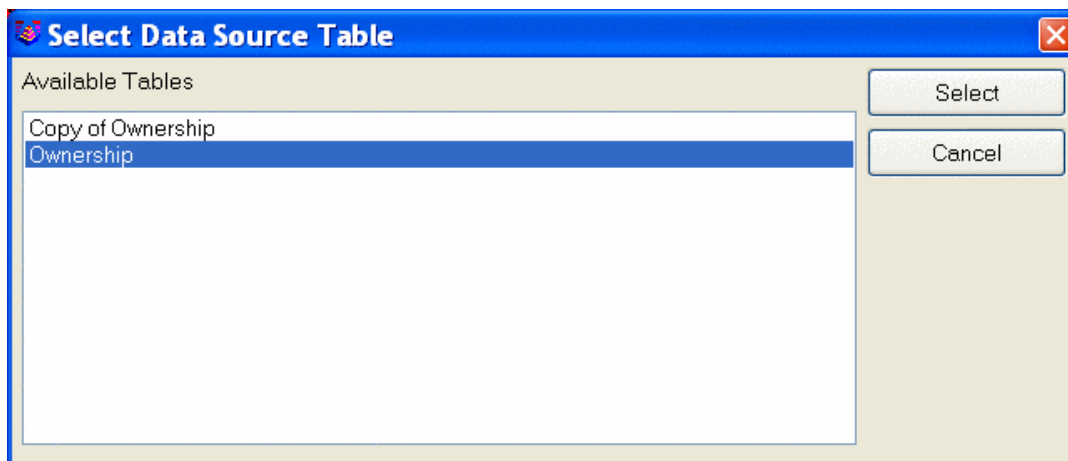

This command creates the link between the property lines in the drawing and the database. The data can come from an XML file, a TXT or CSV file, an XLS file, an Access MDB file, or miscellaneous ODBC data sources.

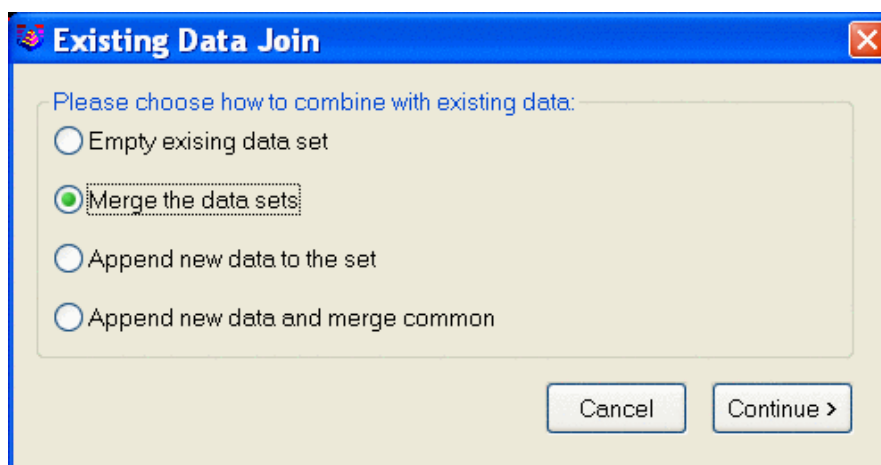

After choosing which format it is, select the Continue button.

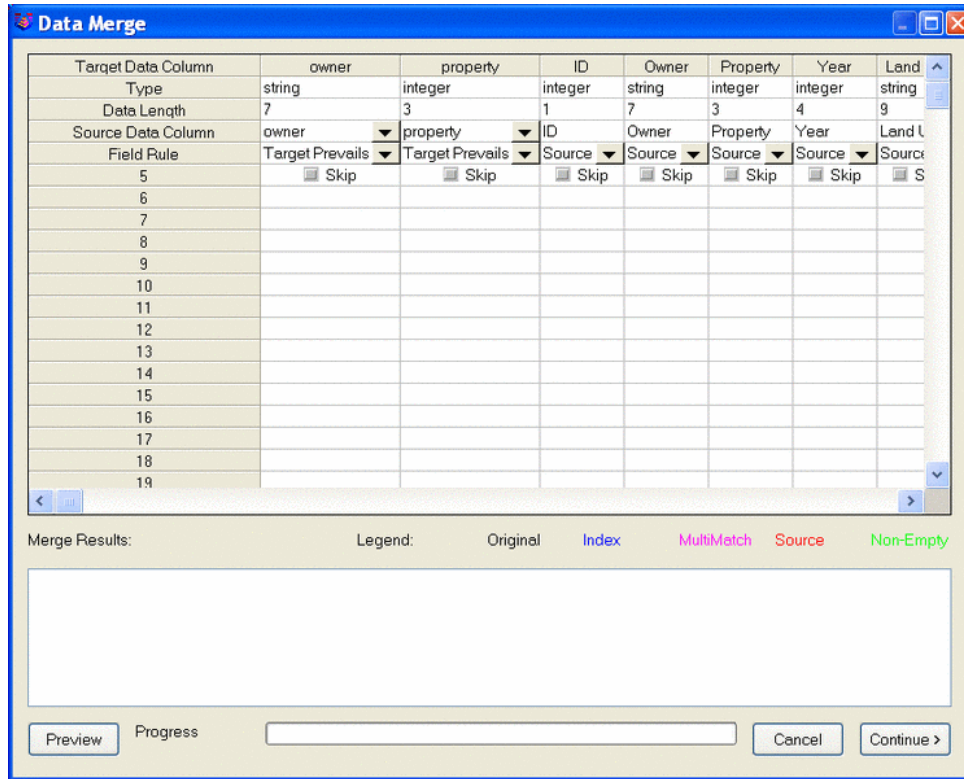

This Access database shows some data entered in for four different properties.

After choosing the source file, this selection window appears if it is from an Access database. Choose the table the data is stored in.

There are then four choices on how to join the data. The first is to empty the existing data set which would delete the property and ownership line data. The second is to merge the data, using both data sets. The third option is to append all to the end of the data, and finally, the last option is to append any new data, and merge the common data. The next Data Merge table displays all of the available fields. Notice in this example, there are two Owners and two Properties. In this case, the Merge option is the way to go.

Choosing Index Field on the first Owner gives the following result. The data is now merged and ready to be used for reporting and reserve runs. Any time these property lines are used in reserves, all of this data is available for reporting. Choose Continue will process the data and return to the command line.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: setuppropdblclick

Property Names By Text

This command converts a large number of closed polylines into property lines by using text label placed inside of the polyline. You are prompted to select closed polylines to become property lines and then the program tries to locate a text label inside each closed polyline that has the same layer as that closed polyline. The text is used as the owner name and the property ID is set to blank.

When you have text labels to start with but no closed polylines, use the Boundary Polyline command under Draw menu to create closed polylines from appropriate linework by using the text insertion point.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: grabprop

Identify Property Lines

This command is one of several property line tools available to identify and trouble shoot property lines. To identify a property line, simply click inside the polyline and the name of the owner and property ID will be displayed in the command text window.

Prompts

Pick on or inside of property polyline:

Owner: State

Property: 459a

Pick on or inside of property polyline:

Owner: Jones

Property: 34

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: idprop

Label Property Lines

This command labels property lines in the drawing. The dialog contains option set the label layer and text size in feet or meters. There are options to label the owner, ID or both. When the Automatic mode is selected, the label is placed at the center of the property line. If the placement method is Pick, then each property line text location will need to be prompted for.

Prompts

Select all property polylines to label:

Select objects:

Dialog Box.

Pulldown Menu Location: Boundary in Surface Mining and Underground Mining Modules

Keyboard Command: labelprop

Find Property Lines

This command locates property lines by matching the user provided search pattern against owner name and property ID of all property lines in the drawing. All matching property lines will be highlighted. The wildcard character (*) can be used in the search pattern.

Pulldown Menu Location: Boundary, Property Line tools

Keyboard Command: findprop

Show All Property Lines

This function displays all property lines in the drawing either by highlighting them or by using solid fill. The latter option works for detection of the unassigned properties totally surrounded by the other properties. It is also convenient for location of tiny gaps between properties shown in the timing report as small areas with an UNKNOWN owner.

Prompts

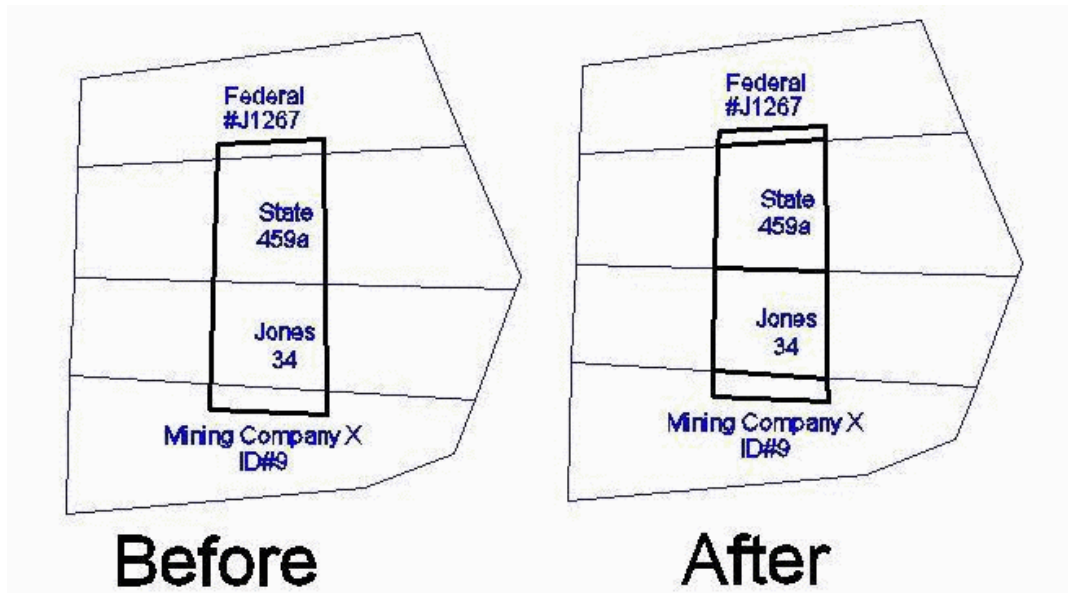

Solid-fill the properties [Yes/<No>]? Y

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: showprop

Break Polyline by Property

This command breaks a closed polyline into separate closed perimeters where they cross property lines. This is useful when smaller, individual perimeters are desired for pits or panels.

Prompts

Select polyline to divide by owners:

Pulldown Menu Location: Boundary

Keyboard Command: ownerdivide

Check Property Polyline Overlaps

This command checks whether property polylines overlap each other. Properties should never overlap since this would lead to extra volumes with the quantities in the overlap area getting reported twice. The program reports any overlaps at the command line.

Prompts

Select pit polylines to check.

Select objects: *pick the polylines*

Found 0 overlaps between 56 properties

Pulldown Menu Location: Boundary > Property Line Tools

Keyboard Command: propcheck

Prerequisite: property polylines

Extract Centroid Data

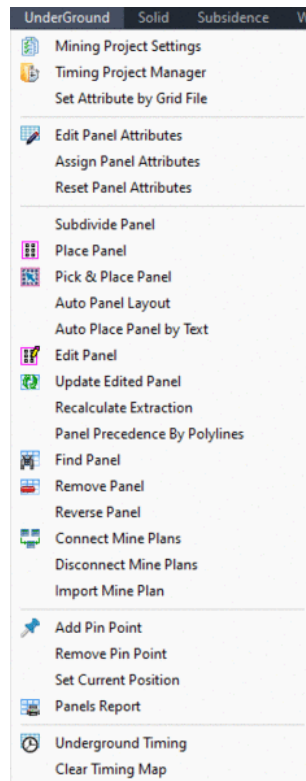

This command is used to convert property information imported from ArcInfo using shape files into property lines. It searches for polyline centroids, extracts the necessary information stored there and attaches it to the property line. This will only work in AutoCAD MAP.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: import_shape

Underground Menu

The Underground menu has commands for mine layout and timing. The Mining Project Manager command is described in the Geology section of the manual. There are several different methods for placing panels for the mine layout. The differences between these routines is outlined in the chart below.

	Place Panel	Quick Place Panel	Pick & Place Panel	Auto Place Panel By Text
Level of details	Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.	Assumes default settings except for every panel during mine layout.	Provides the high level of detail, allowing user to specify every setting for every panel during mine layout.	Except for extraction in the beginning all panel settings are default.
Layout speed	Moderate, depends on amount of settings edited.	Fast.	Slowest, but generates progress.	Quickest, most streamlined results as layout progresses. Very efficient in placing perim with direction.

Mine plan versatility	Creates a complete mine plan with "tree-like" connectivity, providing maximum information for timing precedence.	Creates a complete mine plan with "tree-like" connectivity, providing maximum information for timing precedence.	Generates mine plan consisting of separate panels with equipment already assigned. May be edited and replayed. Correct timing sequencing is user responsibility.
Main application	Established mine plan with relatively minor modifications in future.	Established mine plan with relatively minor modifications in future.	Best for laying out a complicated mine plan with multiple units working and numerous unconnected panels. Ideal for trial runs on large number of panels, where fast creation and extensive modifications are the must.

Mining Project Settings

This command sets the current file names used for several Carlson definition files. For example, this command assigns the Drillhole Configuration file (.ch file) to be used for drillhole placement in other routines such as Place Drillhole and Drillhole Data Sheet. The Mining Project Manager lets you set up different groups of definitions. For example, if you work with two mines, then you can have two sets of strata definitions (strata1.sdf and strata2.sdf), two sets of attribute definitions (attrib1.atr and attrib2.atr), etc. When switching between the projects, you can load the .mpj file to instantly update all of your relevant settings.

Whenever a command is executed that creates one of the below files, it will be automatically added to the Mining Project Manager. However, you can also specify the file names directly from this command.

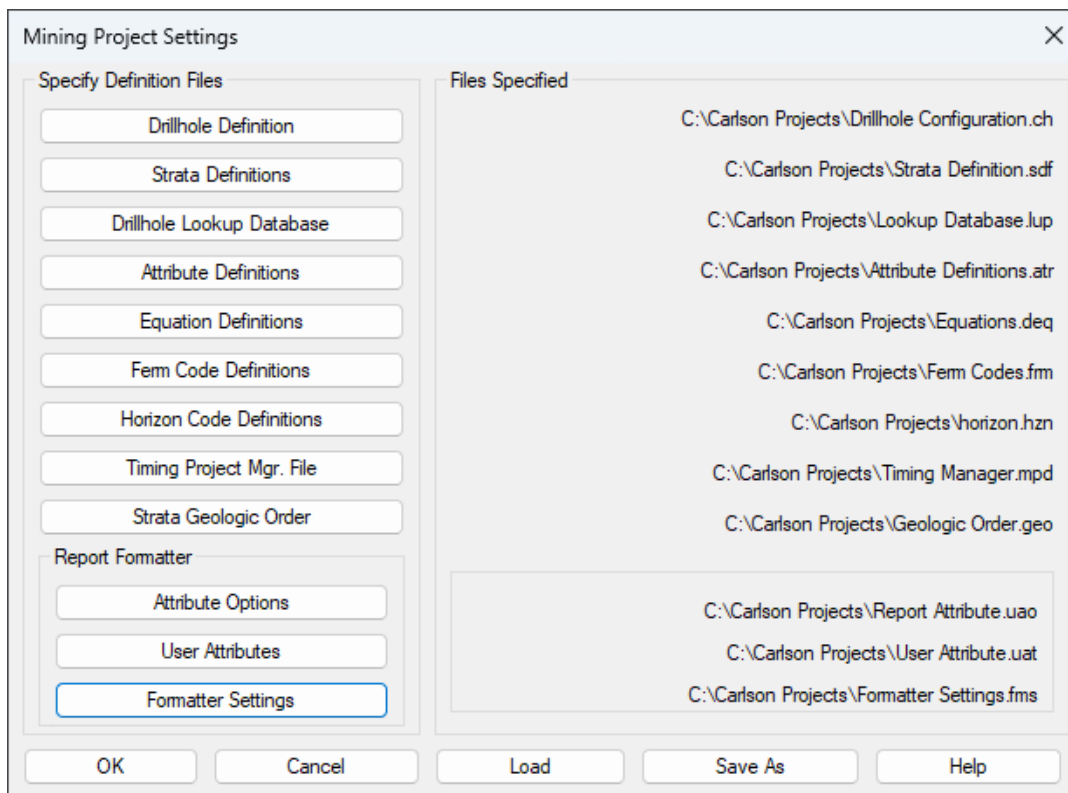

All the file names in Mining Project Manager are saved with the drawing in the drawing .INI file. You can also save this set of file names to a mining project file (.mpj) by picking the Save button. The Load button will then recall the set of file names from the selected .MPJ file.

Following is a list of commands that will create the files shown in the Mining Project Manager. The extensions of the files are shown in the dialog window below.

1. Drillhole Definition: Define Drillhole
2. Strata Definitions: Define Strata/Bed
3. Drillhole Lookup Database: Define Lookup Database

4. Attribute Definitions: Define Attributes
5. Equation Definitions: Define Equations
6. Ferm Code Definitions: Define Ferm Codes
7. Horizon Code Definitions: Define Horizon Codes
8. Timing Project Mgr. File: Underground Timing, Surface Equipment Timing, Solids Timing

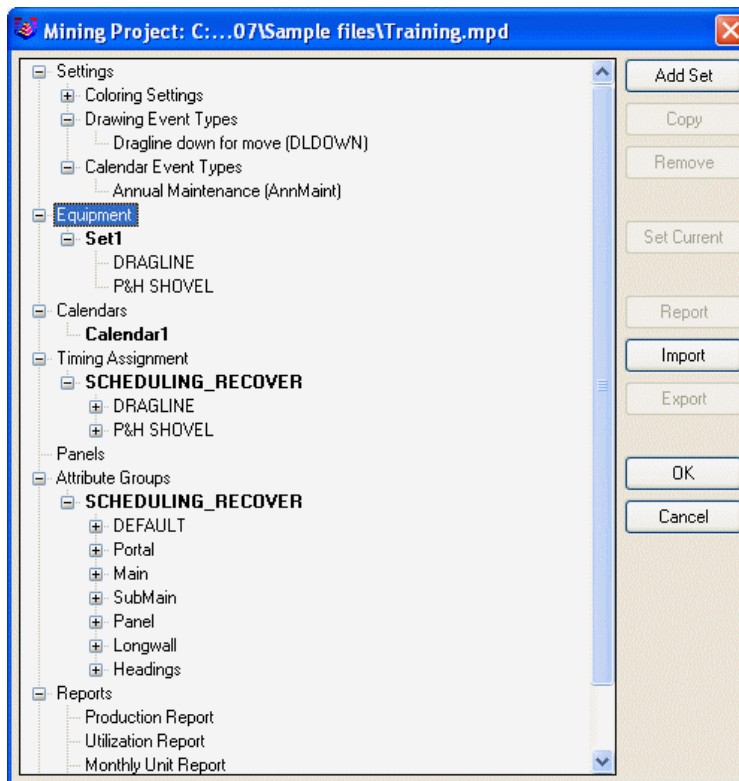

9. Strata Geologic Order: Define Geologic Order
10. Attribute Options: In the Report Formatter, Attribute Options
11. User Attributes: In the Report Formatter, User Attributes.
12. Formatter Settings: In the Report Formatter, Export

Pulldown Menu Location: Drillhole
Keyboard Command: mproject

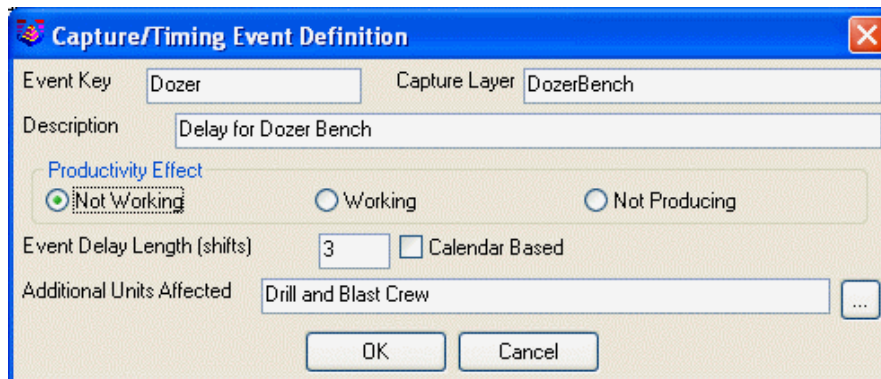

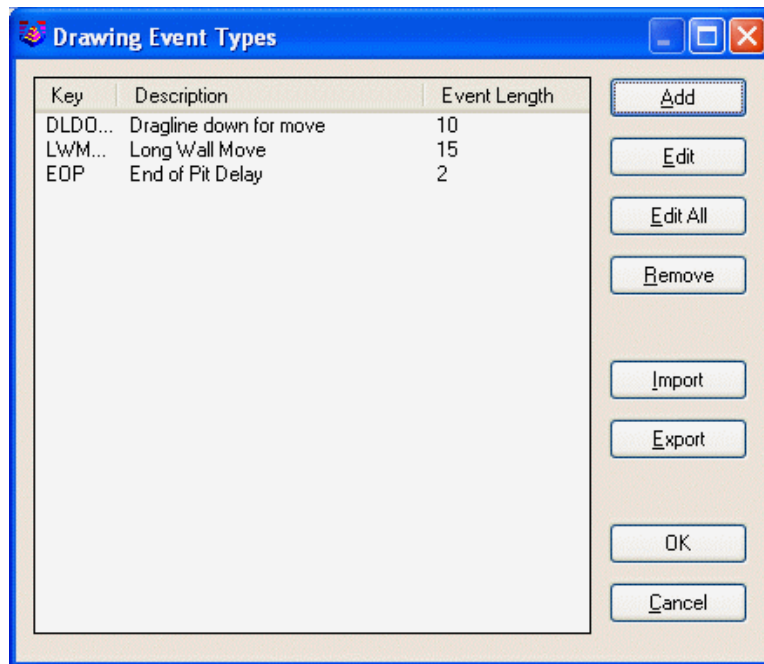

Timing Project Manager

The Timing Project Manager (Surface Project Manager or Underground Project Manager) applies to both surface and underground mining for file organization and selection. All files and most settings and configurations used in the mine scheduling are found in the manager. Each topic is described below in detail. Note that some topics listed below may refer to panels for Underground Timing or Pits for Surface Equipment Timing.

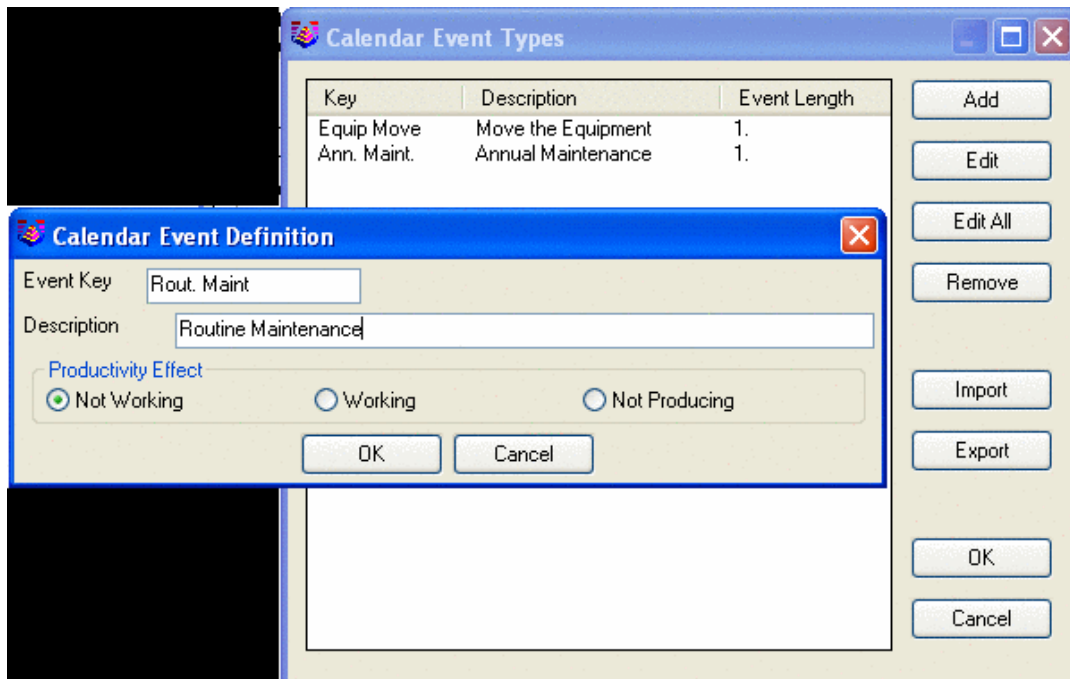

Settings

- Coloring Settings:** These settings are from the Report Options screen from the equipment timing command. Defaults can be set here before running the actual schedule. Explanation of this dialog is found in Underground Timing or Surface Equipment Timing.
- Drawing Event Types:** Drawing events are entities in the drawing at a specific location that will be used for a marker in the schedule as an option for a delay. This event can be used to delay equipment, switch crews, move other equipment, etc. When the schedule crosses over the insertion point of the drawing event (usually text) the event will trigger the delay or effect. The text/drawing entity in the drawing should be inserted to the position where the delay where occur and in the AutoCAD layer defined in the Capture Layer window. The Event Key and description can be used in the reporting of the schedule to create additional reported items.

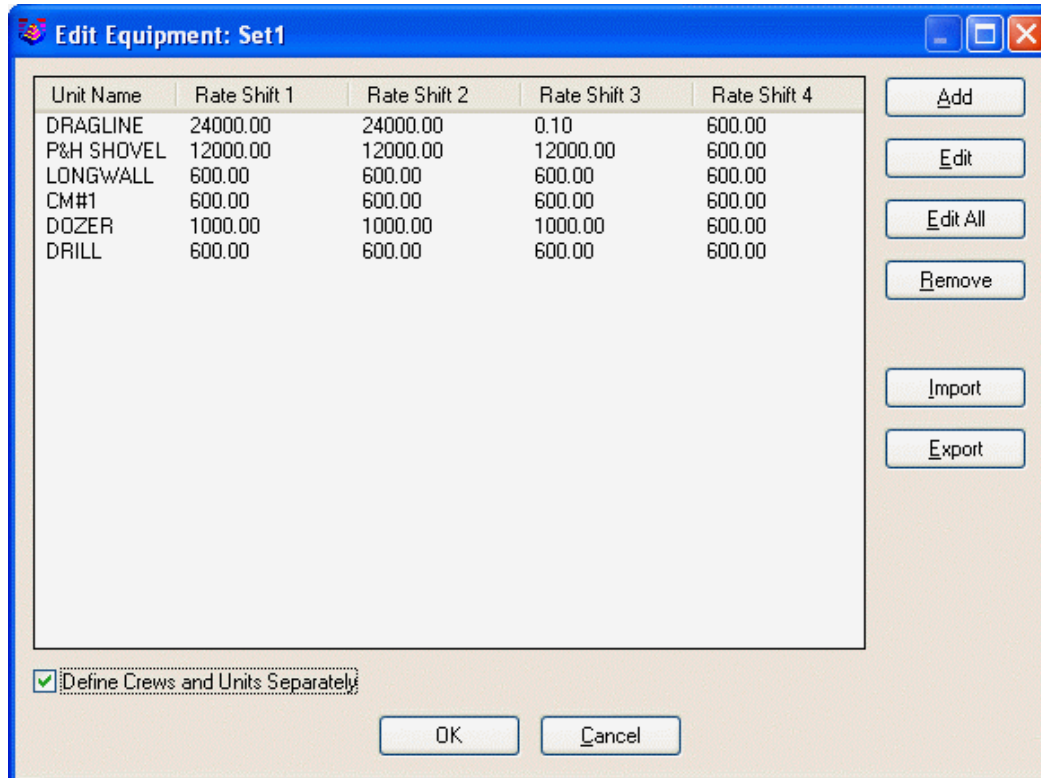

- Calendar Event Types:**Calendar events are named events that will determine equipment down time. The default event in the calendar is Manual. The other events are set under the Calendar Event Types and Calendar Event Definition. Calendar events can be any event that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working with crews, using hours, but not mining).

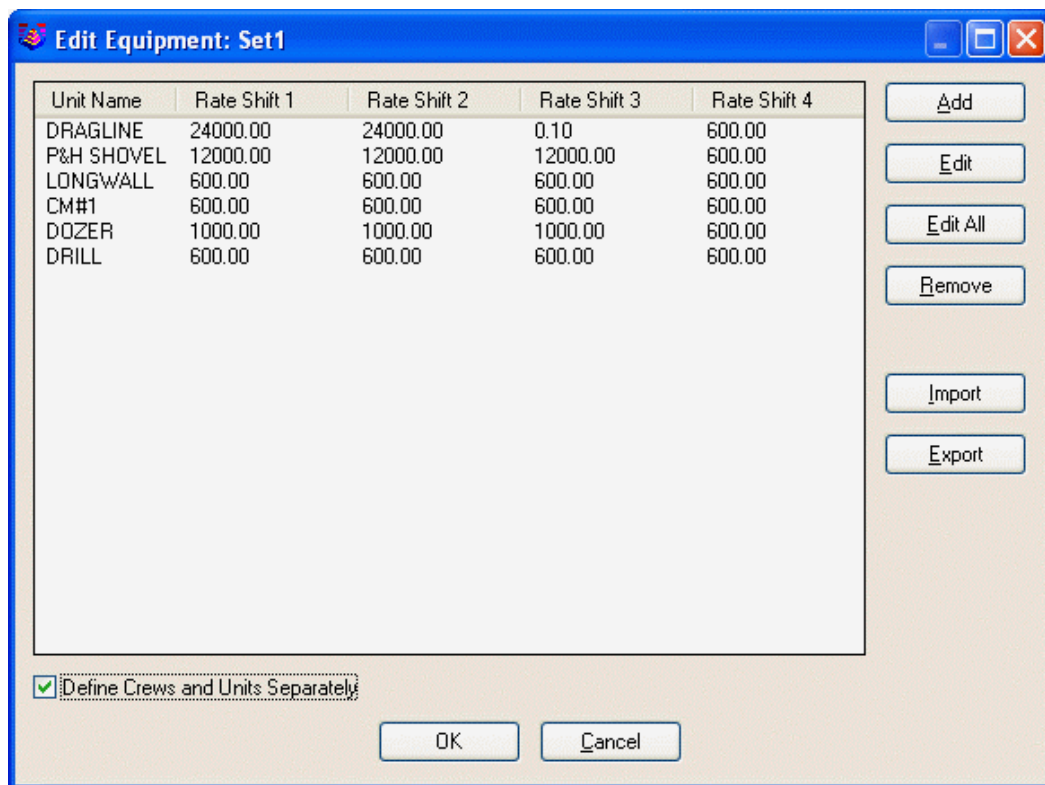

Equipment

- **Equipment Set:** The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule.

Add and Edit will bring up the next screen for detailed entry.

The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example. Linear Feet of Advance is calculated as the area extracted divided by the entry width assigned to the panels. Note that this calculation can be skewed if the entry width varies, or if the pillar dimensions vary.

$$\text{Linear Ft Advance} = \text{Pillar Area} * \text{Extraction Ratio} / \text{Entry Width}$$

Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift. Rates may also be specified in the drawing itself by placing a piece of text on the RATE layer. The value in the text should represent the rate per hour. Note that a piece of text on the RATE layer will temporarily override the normal rate specified on this dialog.

Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only. The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined from given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.

Calendars

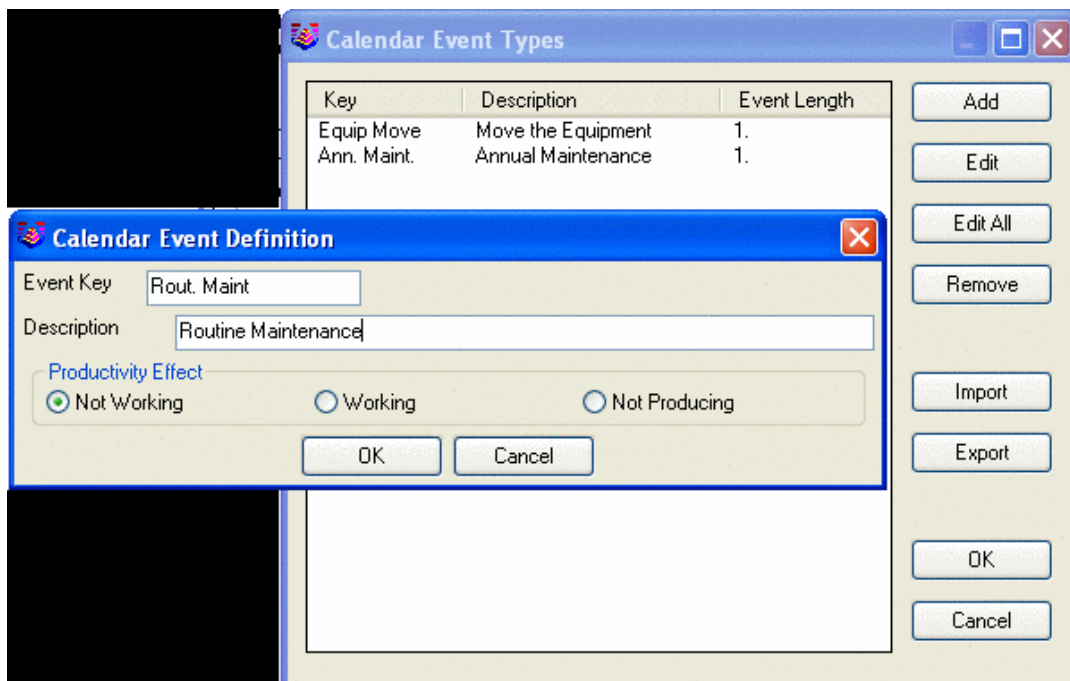

- New or Existing Calendar: Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.

The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.

- **Date Selection:** The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. There can be up to 4 shifts. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.
- **Event Rule Definition:** This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.
- **Event Entity Filter:** The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/Panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).
- **Shifts:** The number of shifts checked here will display next to each day.
- **Due to/Calendar Events:** The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to" window. Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).

- **Repeat for/Label:** This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.
- **Events for Date Selected/All Defined Events:** This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.
- **Rule Report:** This report displays all of the rules defined for down time within the calendar.

- **Year Report:** This reports all days for the selected calendar year.
- **Unit Report:** This reports all equipment and dates defined in the calendar. See example below.

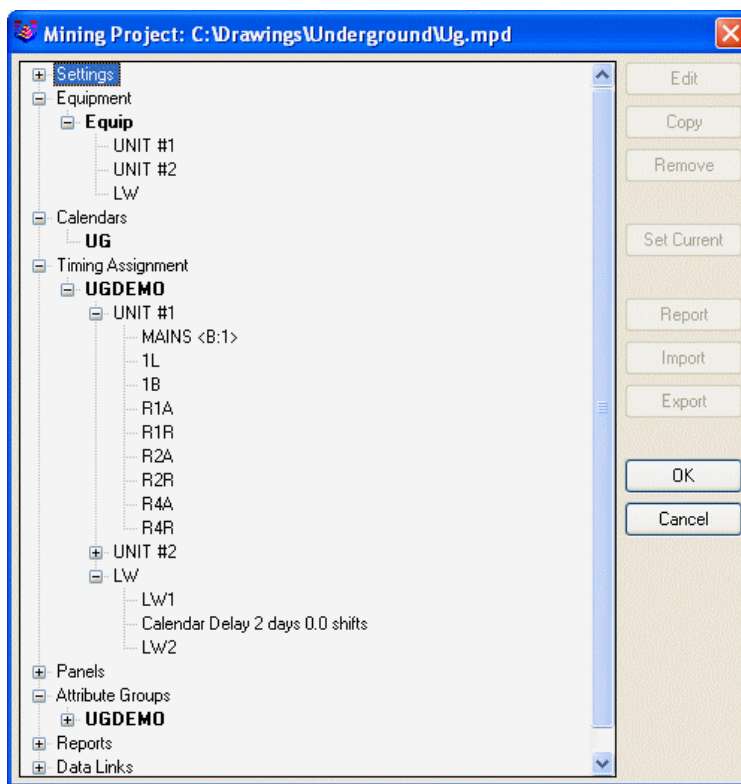

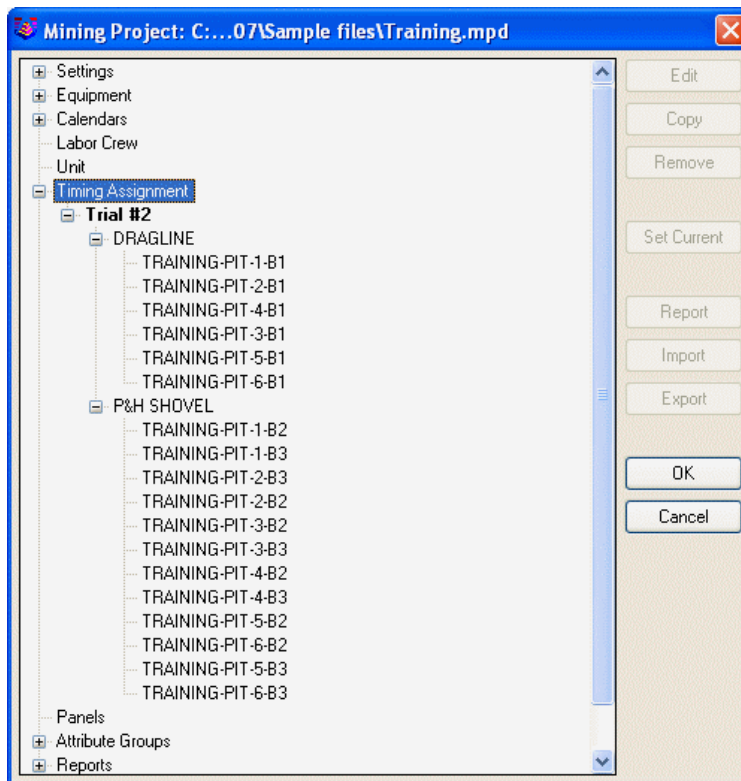

Unit	Month	Year	Operating days	Days	Weekdays	Worked	Saturdays	Worked	Sundays	Worked	Calendar days	Work shifts	Hours

- **SaveAs/Load:** This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

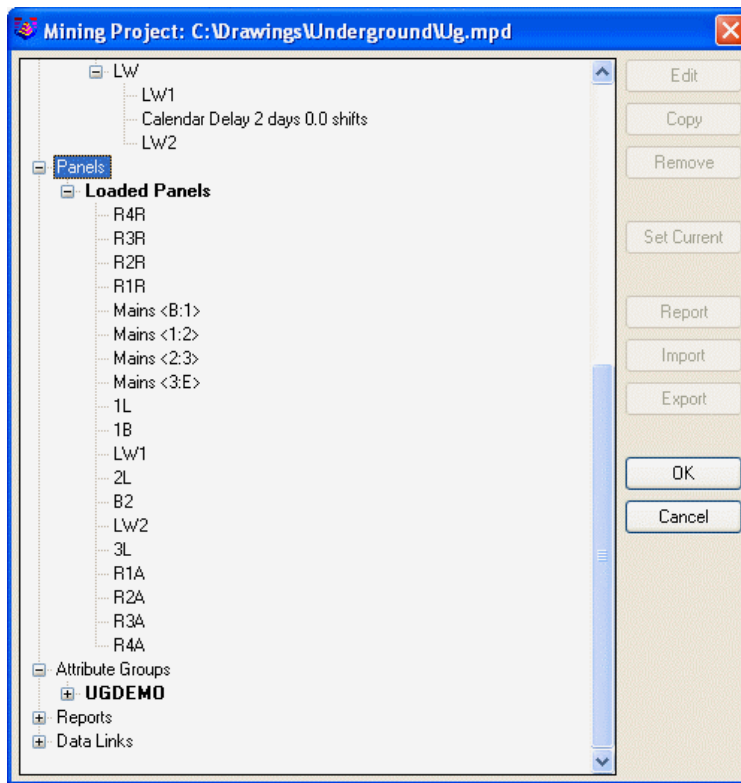

Timing Assignment

The Timing Assignment allows for setting the current sequence. The Assignment is similar to the TIM file in the timing routines. The equipment used and which panels or pits they are mining are shown. The Set Current button controls which one will be loaded and used. Shown here is both a surface mine and an underground mine example.

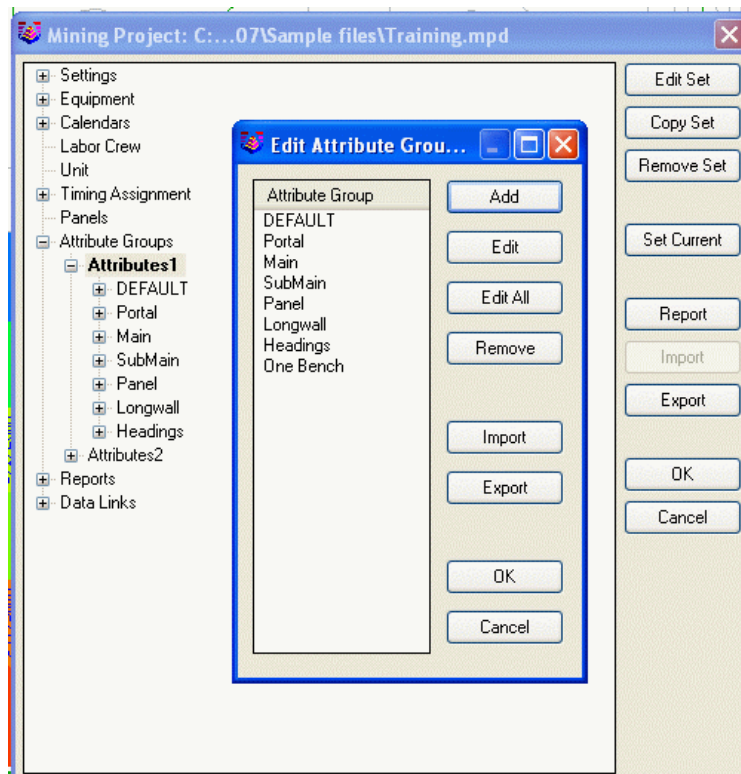

Panels

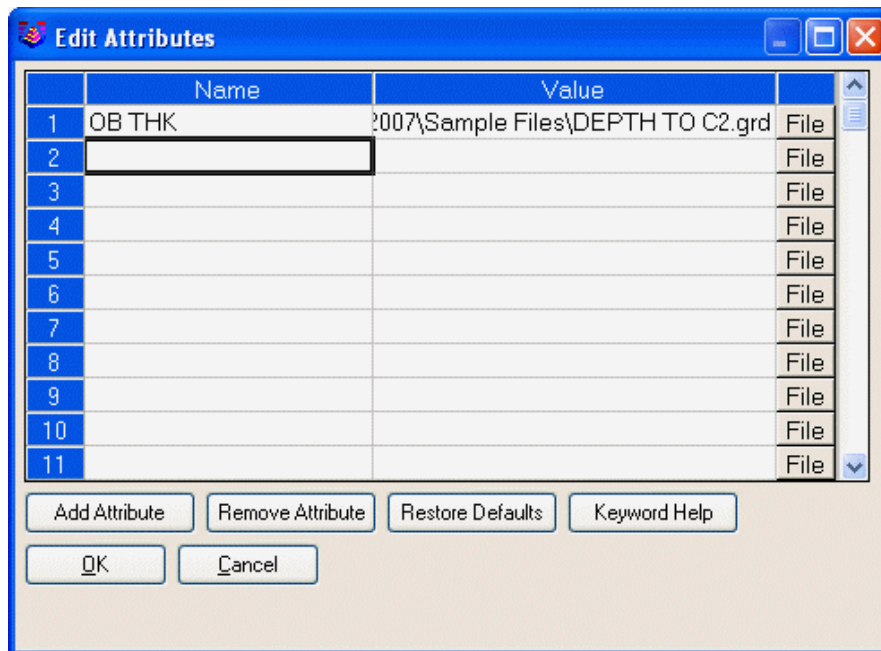

This displays the selected underground panels in the mine plan assignment. An example is shown here.

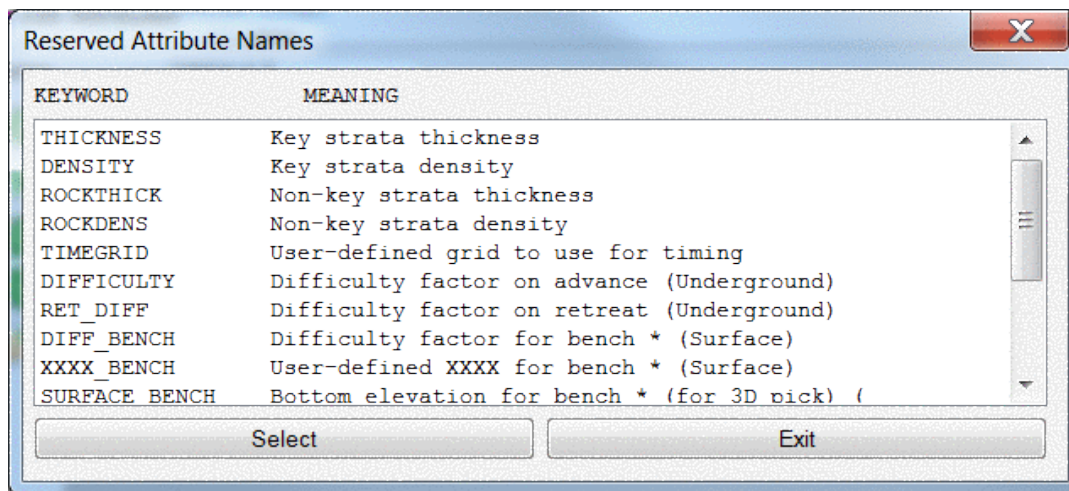

Attribute Groups

Attribute groups are Pit or Panel Attributes assigned to the pits and panels for timing. When timing the pits or panels, there are additional attributes that will be calculated and reported in addition to the Non-Key and Key quantities. If these are defaults that should be applied to all the panels or pits, then they should be entered here. Any quality values, density, or difficulty attributes can be defined here either just as a value, or as a grid file with varying values. The Reserved Attribute Names window displays the reserved words that will be recognized in the timing routines, and how they should be entered in. Selecting Keyword Help brings up the Reserved Attribute Names.

The Reserved Attribute Names are defined in a little more detail here:

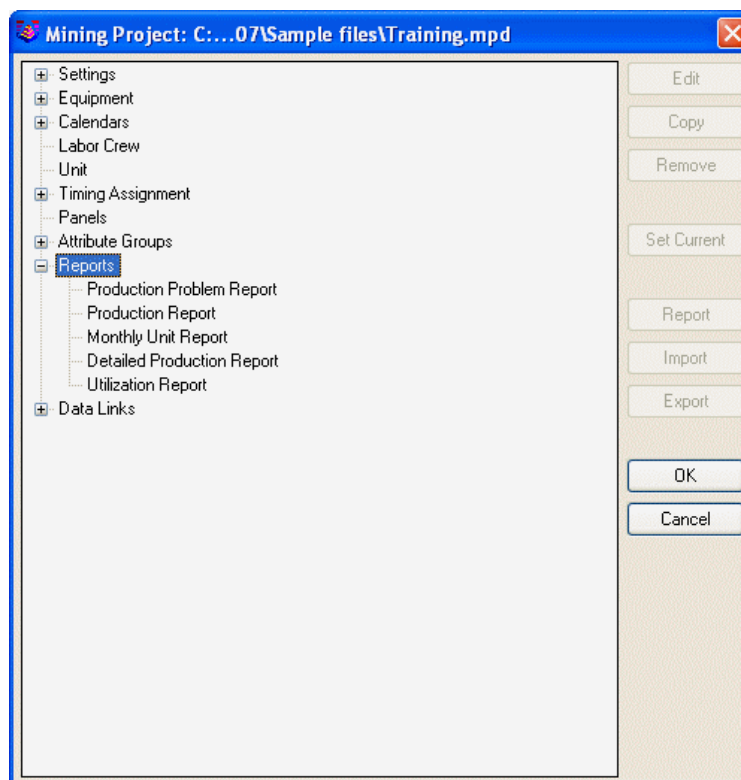

- **THICKNESS:** Key strata thickness: Will report any other thickness values, this is used mostly for underground timing.
- **DENSITY:** Key strata density: Will report Key density, is used mostly in underground timing to calculate the tons. In surface timing, the tons are already in the pits.
- **ROCKTHICK:** Non-key strata thickness: Reports the Non-Key thickness mostly for underground timing.
- **ROCKDENS:** Non-key strata density: Reports the Non-Key density mostly for underground timing.
- **TIMEGRID:** User-defined grid to use for timing: This will be any additional grid the user would like to add for reporting.
- **DIFICULTY:** Difficulty factor on advance just for underground timing: This will alter the underground equipment rate on advance.
- **RET_DIFF:** Difficulty factor on retreat for underground timing: This will alter the underground equipment rate on retreat.
- **DIFF_BENCH:** Difficulty factor for bench * for surface timing: This will speed up or slow down the equipment as it mines the specified bench. If a value is above 1, such as 1.2, then it will mine 20% slower at that

- point in the grid, or everywhere if it is set to value. If it is less than 1, such as 0.84, then it will mine 16% faster at that point.
- XXXX_BENCH: This is any other attribute that will be reported out for a specific bench in the Surface Timing routines. All quality grids will be defined in this fashion, for each bench. Examples would be BTU_BENCH or Rehandle CY. All quality parameters need to be entered as the NAME_BENCH*.
 - SURFACE_BENCH: This is the bottom elevation grid for each bench. They are used in Surface Equipment Timing in the 3D Pick window so that the mine pit blocks are draped onto the actual elevation surfaces.
 - SURFACE: This is the surface topography elevation grid. It is used in Surface Equipment Timing in the 3D Pick window so that the mine pit blocks are draped onto the actual elevation topo.
 - TIMING_SPLIT: This will globally split all blocks that contain both Key and Nonkey material into two blocks that may be scheduled separately, by either the same unit, or different units. The split is into two portions - key and non-key. Entering a non-zero value will cause a split. Additionally three values are supported as pertains to precedence. Enter in one of these values in for the attribute to split it.
 - 1 = Both OB and KEY needs to be completed to satisfy precedence
 - 2 = OB portion needs to be completed to satisfy precedence
 - 3 = KEY portion needs to be completed to satisfy precedence
 - TIMING_SPLIT_BEN: This attribute is the same as TIMING_SPLIT, but is only applied to the specified bench number.
 - RET_THICK: This attribute is applied to Underground Timing. The retreat mining Key thickness grid can be different than the advance Key thickness grid.
 - RET_ROCKTHICK: This attribute is applied to Underground Timing. The retreat mining NonKey Rock thickness grid can be different than the advance Rock thickness grid.

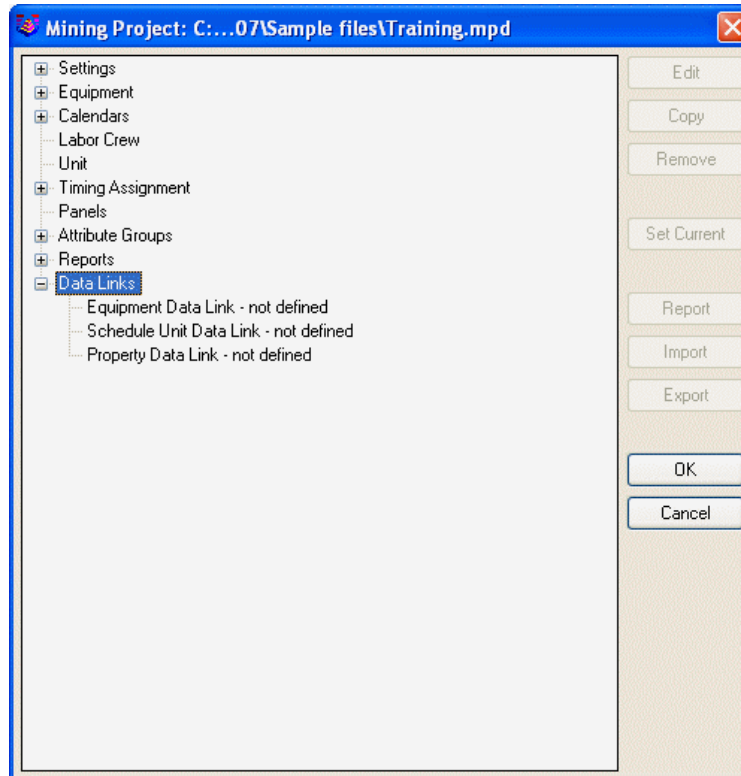

Reports

Some of the reports generated in the scheduling will appear here for other options to report. These are also accessed in the calendar or after a schedule is run.

Data Links

This shows the link of the data when it is linked to an external source for reporting.

Skip Past Report Archiving in Project Database: By default, all reports generated with timing commands will be saved in a backup of the Timing Project Manager as an .mrd file (the file name will be the same as the .mpd file, just with a different extension). If many reports are generated, this archive can become quite large, and may even slow down processing time when running the timing command. When this option is enabled, no reports will be archived, preventing potential slow-down from large .mrd files. It is recommended to enable this option when you have no need for old timing reports.

Pull-Down Menu Location: Reserves/Timing in Surface Mining and Underground in Underground Mining
Keyboard Command: stime_project or utime_project

Set Attribute by Grid File

This command assigns an attribute value such as thickness or BTU to a panel or pit area based on the average value from a grid file. The program prompts for the attribute name and the grid file that represents the attribute. Then multiple panel/pit perimeter polylines can be selected and the program calculates the average grid value in each panel/pit polyline and stores this value.

Another method for using grids is to define the attribute as the actual grid file name instead of the average value. Then the timing routines will calculate attribute values for each timing block from the grid value. The advantage to using Set Attribute by Grid File instead of using the grid file is speed.

The Calculate Seam Split Quantities option is for calculating coal and rock thicknesses by analyzing multiple strata elevation grids using minimum and maximum miner heights. When the coal thickness is less than the minimum height, the minimum height is used. The maximum height is used when the coal thickness is greater than the maximum height. A fixed amount of rock thickness that is always taken can be specified. Given the miner height,

the program will find when the miner takes main coal seam plus the parting and any of the second coal seam. The average coal and rock thickness for each panel polyline is calculated and stored.

Prompts

Type of polylines (<Underground>/Surface)? *press Enter*

Calculate seam split quantities (Yes/<No>)? *press Enter*

Attribute Name: *BTU*

Select Grid File dialog

Select panel polylines.

Select objects: *pick the panel perimeter polylines*

Pulldown Menu Location: AdvMine

Keyboard Command: gridattr

Edit Panel Attributes

The function edits the panel attributes attached to a panel perimeter polyline. The list of attributes is loaded from a polyline or created anew using the Default Panel Attributes defined. The dialog used is the same dialog as in the Define Panel Attributes function. Edit Panel Attributes allows you to specify a distinct set of attributes for the particular perimeter polyline. This set has precedence over the default one.

Edit Section Data

Panel name: LW1 Panel start: []

Keyboard Command: editpanel

Assign Panel Attributes

The command allows for selecting multiple panels and assigning a Panel Attribute Group to them all at once. A typical use for this is where there are different sets of attributes used in different panels, such as a continuous miner and a longwall. These two different attribute groups must be defined first, in the Timing Project Manager, then they appear on the dropdown list of Attribute Groups to choose from. Choosing the button next to the group dropdown will bring up the Edit Attributes screen, where changes can be made if needed. Once the group is selected in the dropdown, choose OK and select all the panels to assign that group to.

Prompts

Select panel polylines to have attribute group assigned.

Select objects: 1 found, 14 total

Select objects:

Saving changes to project database...

Pulldown Menu Location: Underground

Keyboard Command: setpanelattr

Reset Panel Attributes

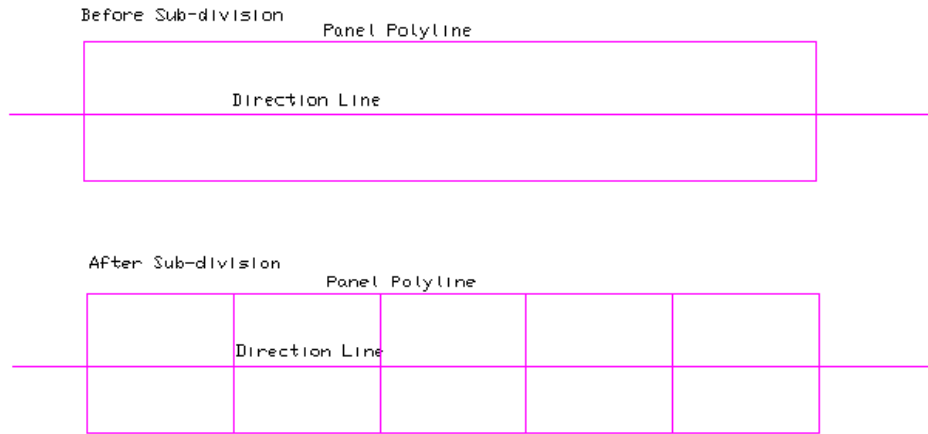

Whenever the Edit Panel Attributes function is used to make changes in attributes for the particular panel, a completely separate set of attributes is created and stored for this panel. From that point on, the changes in default panel attributes will not affect this edited panel. To revert these changes and make the panel use the default set of attributes, use the Reset Panel Attributes function.

Pulldown Menu Location: AdvMine

Keyboard Command: resetpanelattr

Subdivide Panel

The simple way to specify different coal qualities and/or other panel properties is to break a large panel into a number of smaller sections. These sections are later associated with a single panel within the Place Panel routine. This routine divides panels into a given number of smaller ones. The slower alternative to this method, giving better precision, is to use grids instead of average values for panel attributes.

Note: Panel is NOT placed yet, just sub-divided into 5 equal parts along the direction Polyline.

Pulldown Menu Location: AdvMine
Keyboard Command: subdivide

Place Panel

The Place Panel function requires a panel perimeter drawn in the PERIM layer. If you draw the panel with Advanced Projections in the Basic Mining Module and use the option to draw the pillars, the program will automatically calculate the extraction ratio (as shown in the example panel on the left). The extraction ratio can be entered into the Edit Section dialog box, if you start with the perimeter only drawn in the PERIM layer (as shown in the example panel outline on the right).

Place Panel Pre-Requisite Linework Options

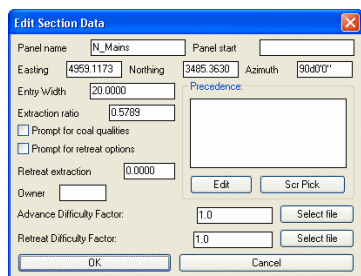

The underground timing routine operates with a tree-like structure of the panels built using a centerlines network. The new panel may be added or an existing panel (i.e. created using Advanced Projections) may be attached to the existing network of centerlines using this function.

Each panel may consist of a number of sections, where each section is characterized by the uniformity in the section

attributes such as owner, coal thickness and qualities, complexity of mining, extraction ratio, azimuth and length. Therefore each panel is represented by a centerline and a set of panel perimeter polylines, one for every section.

Due to the tree-like structure of the Mine Plan, each new panel should branch from the existing panel. This allows for proper timing calculations and data management. The user is prompted for the starting point and direction of each section, with dimensions dependent on the existing perimeter polyline or on user input.

If an existing polyline is used to define the panel, the program evaluates the section length by intersecting the centerline with this polyline. Otherwise the sizes of the section are defined in the Edit Section Dialog. The appearance of the dialog depends on the way the section is defined. Both kinds of dialogs are shown here.

Dialog for pre-drawn panel

Dialog for panel defined on the fly

User has a number of options to define a direction of the panel. The following methods are available:

Perim: The direction of panel is defined by the direction of the first segment of polyline.

Text: Direction is from "branch off" point to insertion point of the text found inside the panel. The text must be in PANELNM layer and it defines panel name.

Pick: Direction of the panel is from "branch off" point to pick point.

Segment: Direction is defined by user-picked segment of the panel polyline.

Panel name: Identifies the panel for Underground Timing.

Difficulty factor: Represents the effectiveness of the mining equipment within the section. Values above 1.0 will cause a proportional slowdown of the production and below 1.0 will speed it up. This value may be specified using difficulty factor grid file by selecting file with *Select File* button or typing it in instead of the actual value. The run-time difficulty factor will then be evaluated for corresponding area.

Precedence: Defines whether development of the section may not start until all listed sections are completed. Precedence is especially important for the longwall sections, since production there is not possible until all headings are completely developed. The listbox shows panels which have to be developed before the section being edited. Since some sections may be defined after the current section, it is advisable to edit precedence later with Edit Panel function. The precedence can be set by either picking from the list, or screen picking.

Panel start: Defines fixed start date of the development. This field is optional and is ignored if the actual starting date is later than date specified.

To define attributes for this panel section (such as THICKNESS, DENSITY and etc. as explained in Define Panel Attributes function) select **Prompt for coal qualities** toggle.

In the case of using an existing perimeter, the extra unknown is **Extraction Ratio**, whereas in the other case the dimensions of the section and entry/crosscut spacings need to be defined. The extraction ratio will default to value calculated using pre-drawn pillars and panel perimeter.

The **Entry Width** for predefined panel is only used if the section is mined by the piece of equipment with the linear feet of advance production rate specification.

Retreat Extraction: Defined as ratio of area of all coal extracted on retreat to the area of whole panel. Therefore if extra side coal is picked up on retreat this value combined with advance extraction ratio, exceeds 1.0. To simplify

estimation **Prompt for retreat options** may be used to calculate the retreat extraction for given the extraction polyline.

Retreat Difficulty Factor: Similar to Difficulty Factor except it applies on the retreat stage.

Users who are creating an extensive mine plan, may prefer to use a streamlined Quick-Place mode to create layout and later on use Edit Panel Dimensions to modify panel properties.

Prompts

Use Quick-Place mode (Yes/<No>)? *press Enter*

Start new Mine Plan (Yes/<No>)? *press Enter* Choose Yes to start Mine Plan.

Select an entry to branch from: *pick the panel to branch from at desired location*

Enter the azimuth for the segment:

Select a panel polyline or press Enter for dialog:

Edit Section Dialog

Enter the azimuth for the segment:

Select a panel polyline or press Enter for dialog:

Edit Section Dialog

Pulldown Menu Location: AdvMine

Keyboard Command: place_panel

Pick & Place Panel

This routine is parallel to the Place Panel and Underground Timing functions. The timing through the panels is performed as soon as the user picks the panel perimeter. The sequence of picking and all the associated parameters necessary for "replay" are stored in the same form as with the Timing routine. That allows you to modify the mine plan, equipment rates and/or calendar and obtain an updated plan without having to redo the sequence.

The routine goes through the following steps:

- Prompt user for next panel to mine in.
- Check if the picked panel is a part of the mine plan already. Then prompts to pick an existing mine plan or to start new mine plan. The existing plan is loaded in and rerun to obtain the information about the availability of the equipment.
- Bring up the dialog and prompt the user for various parameters and the part of the panel to be mined. The proposed mining is previewed along with the dates and tonnages associated with the proposed segment.
- When editing is finished the colored and labeled timing blocks are displayed in the user-defined style and the whole process is repeated for the next panel.

The starting date of mining in the picked polyline depends on three dates: if the optional panel start date is specified and the unit is available this date is used. Otherwise if the unit is tied up within some other panel, the starting date is the date when the unit finished the last panel offset by the specified moving delay. Lastly if the unit has not been used in the mine plan at all, the start date for the panel is the same date as for the whole mine plan.

Test Report Options OK Cancel

Date Start	03/03/00
Date Finish	04/08/00
Crew	CM#1
Panel Name	99RT
Coal (tons)	32735.560000
Rock (tons)	11159.850000
Area mined	252199.999998
Linear adv.	7439.900000
Difficulty	1.000000
Density	80.000000

The portion of the panel to be mined is determined by the selection made:

Whole perimeter The panel will be mined to the end of the panel or to the next pin point if present (retreat).

Distance Mining will advance a given distance along the centerline past the last mined point. A pin point will be added at the end of new segment. Use of this option on retreat is associated with automatic reassignment of advance development, followed by rerun of timing plan (advance and retreat use the same set of pin points).

Period and **To Date** are similar to Distance, since the program will automatically calculate a distance corresponding to given date.

When the **Test** button is used the portion to be mined is highlighted in the drawing and the timing and quantities results are displayed in the dialog.

The amount of time necessary to mine given portion of the panel depends on the following factors:

Equipment production rate (use Define Equipment to modify)

Coal and Rock Attributes (Define Panel Attributes, Edit Panel Attributes)

Difficulty Factor (may be specified as value or grid on per panel basis or using Define Panel Attributes and by placing a text labels on certain layer within the panels)

Extraction Ratio (pre-calculated based on pillars draw inside the panel, but may be modified) Equipment Calendar assignments.

Report Options are the same as these used in Underground and Surface Timing Routines. The final results for the portion laid out during current session are displayed in the user-defined form using the Report Viewer.

The generated mining plan (the system of green centerlines) may be modified and rescheduled using Underground Timing routine.

Pulldown Menu Location: UnderGnd

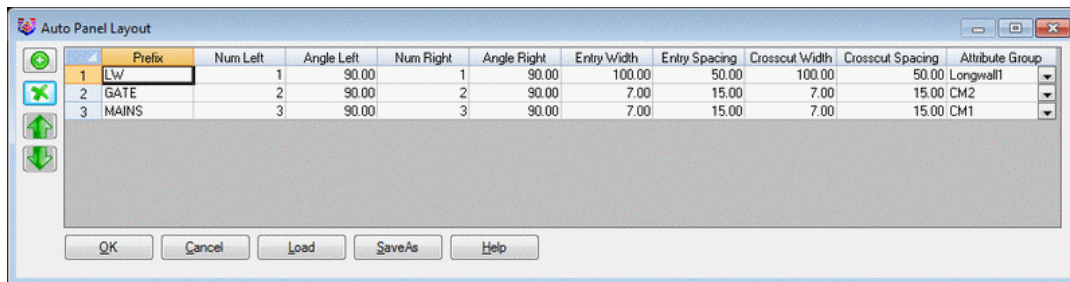

Keyboard Command: pick_panel

Auto Panel Layout

This command takes center lines and text in the drawing, and creates named underground panels based on the names, offset distances, and outer perimeter. The prerequisites are the center lines and text for each panel, and they must be drawn on the proper layers. The center lines need to be on the layer MINEPLAN, and the text needs to be on the layer PANELNM.

Starting the command brings up the following dialog. Shown here are examples on three prefixes that will be used on these lines and text. The prefixes listed must be in the PANELNM text in the drawing, to match up the layout. The width and spacing (shown here in metric) are used to draw the panel perimeters and assign the names. The layout of the center lines in the MINEPLAN layer is the tricky part that takes some time to calculate and draw them correctly offset, to allow for the panels to draw around them. Keep in mind the barriers, and spacing between panels needs to be accounted for too. The Attribute Group will automatically assign these Panel Attributes from the MPD timing file to the specified panels when the panels are drawn.

After choosing OK, the boundary polyline is prompted for. This is necessary to clip or stop the panels as they approach the boundary.

Prompts

Select boundary polylines or press Enter for none:

Select objects: 1 found

Select panel center lines (MINEPLAN layer):

Select objects: Specify opposite corner: 16 found

Select panel names (PANELNM layer):

Select objects: Specify opposite corner: 16 found

16 panels created.

The resulting panels are shown here, and only extend up to the boundary polyline that represents the mining limits for the panels.

Pulldown Menu Location: Underground

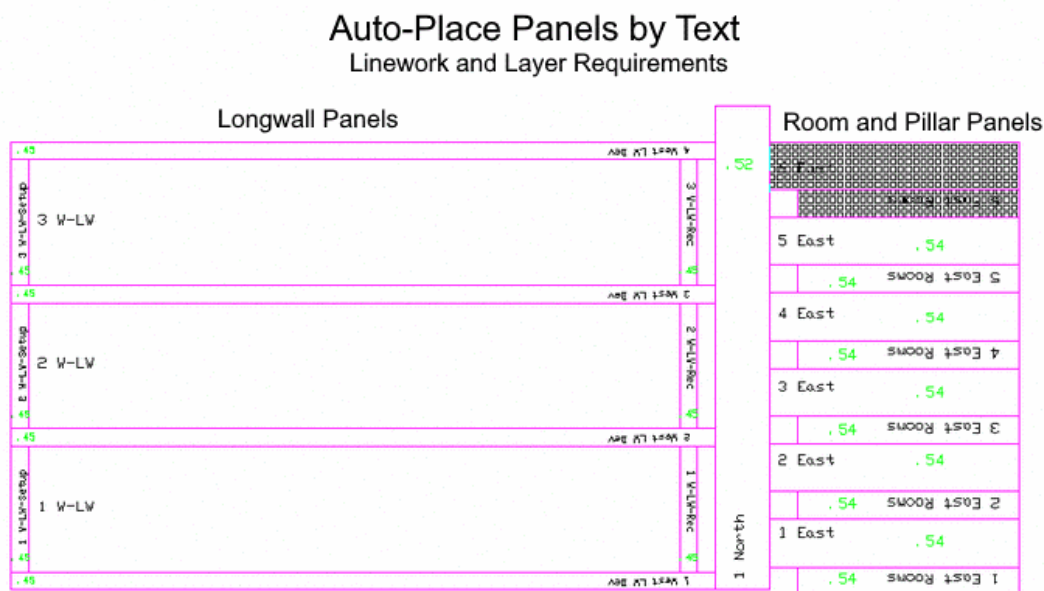

Keyboard Command: auto_panel

Related Commands: Place Panel, Pick and Place, Auto Place Panel by Text

Auto Place Panel by Text

This is the best method to place many panels fast. The panel is directed by text orientation with centerline going through text insertion point. The text itself becomes a panel name and it has to be in layer PANELNM to be found. User can specify retreat options, difficulty factors and entry width to be used for all panels before running command. To place the text in the panels easily use Draw Sequential Numbers, found under the Draw dropdown menu.

All panels created in one run become a single connected mine plan with no equipment assigned.

Required Input

Perimeter on PERIM Layer

Panel name on PANELNM Layer

The linework must be closed polylines. Each panel must have its own closed polyline (including longwall panels). The layer names do not have to be written in all caps. The text insert points must be inside the panel polylines.

Optional Input

*Advance Extraction Ratio on EXTRACTION Layer

*Retreat Extraction Ratio on RET_EXTRACT Layer

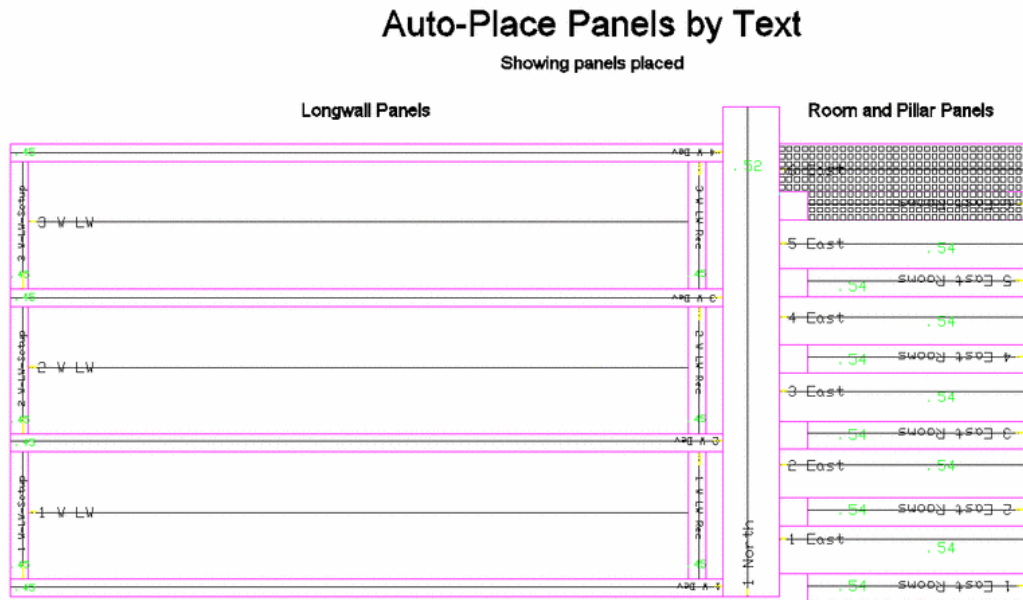

**Advance Difficulty Factor on DIFFICULTY Layer

**Retreat Difficulty Factor on RET_DIFF Layer

*The Extraction Ratio is not updated from the text on the EXTRACTION layer until running the Recalculate Extraction command on the Underground Pulldown Menu. There can only be one Extraction Ratio in a panel. Note that the Extraction Ratio will be automatically calculated if the pillars are drawn.

**There can be more than one Difficulty and Retreat Difficulty Factor per panel if the text is separated by Pin Points.

When you note the prompts below for entry width you will want to place the "longwall panels" and "room and pillar" works in two steps in order to get the correct advance distances reported. For this example the room and pillar works are on 20ft width, and the longwall width is 1,000 feet. Placing them in two steps will create two mine plans that can be connected using the Connect Mine Plans option.

Prompts

Assign zero retreat extraction [Yes/<No>]? Y

Advance difficulty <1.0> :

Entry width <20.0> : Use the panel width for longwalls, entry width for room and pillar panels.

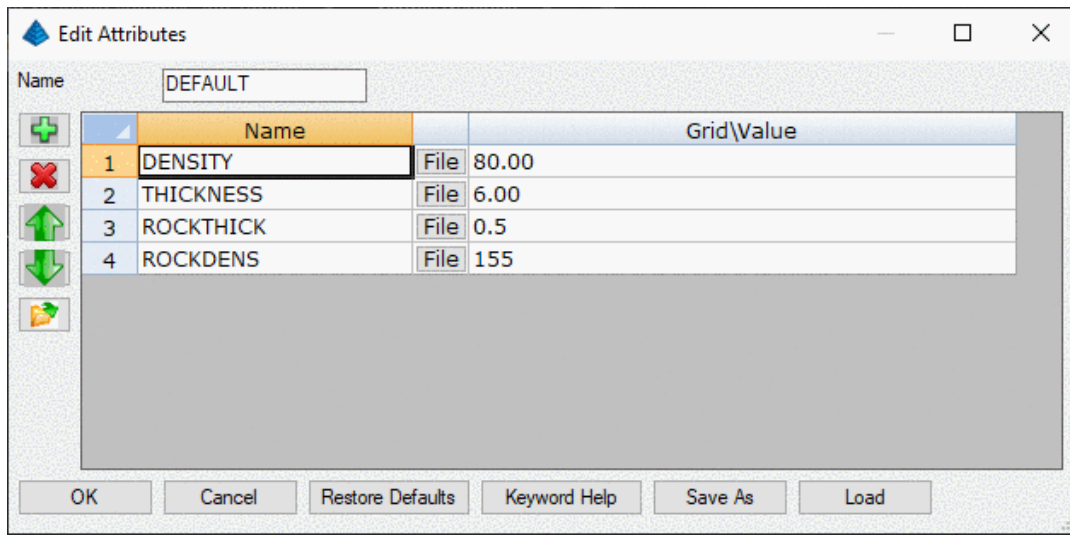

Pulldown Menu Location: UnderGround

Keyboard Command: auto_place

Edit Panel

The function is identical to the section definition portion of Place Panel function. It is used to edit properties of the section of the panel after the panel has been completed. The precedence can be set by either picking from the list, or screen picking.

- **Attribute Group:** Specifies the attribute group for the panel. Attribute groups may be configured in the Timing Project Manager.
- **Panel name:** This is a required field.
- **Panel start:** This is an optional field. The Underground Timing routine have an option for start date that usually makes this field unnecessary. This field can delay the start of a panel independently of the plan start date.
- **Easting:** The easting coordinate value of the first picked point when the panel was placed.
- **Northing:** The northing coordinate value of the first picked point when the panel was placed.
- **Azimuth:** The azimuth from the first to the second picked points when the panel was placed.
- **Entry Width:** This is used to calculate face feet/meters of advance. This should be set to the width of the panel when working with longwall panels to get the correct advance down the panel. With regards to the scheduling/timing command, this value has a direct impact on the linear feet of advance for the panel. Note that the linear feet of advance accounts for the length of all cross cuts and entries in the panel. The linear feet of advance for a panel is calculated as the Mined Area divided by the Entry Width. For a panel covering 60,000 sq ft, an extraction ration of 0.6, and an entry width of 20, the linear feet of advance in the panel would be calculated as $(60,000 * 0.6) / 20 = 1800$. Please note that this calculation assumes that all pillars in panel have similar dimensions).
- **Prompt for coal qualities:** A check in this box brings up the Define panel Attributes dialog box after clicking OK in the main dialog. This is the same dialog that is displayed when defining attribute groups in the Timing Project Manager.

- **Prompt for retreat options:** This option will allow you to select an inclusion polyline for the retreat area of the panel. When this option is enabled, you will receive three command line prompts after clicking OK in the main dialog. An example panel with a separate retreat polyline is shown below.

Pick a polyline representing a shape of the retreat area: *During this prompt, you may select an inclusion polyline for the retreat area of the panel.*

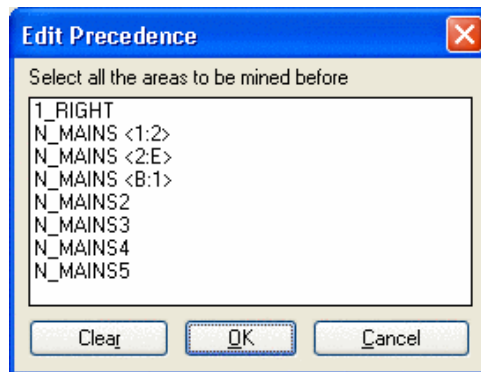

Enter the extraction ratio for remaining pillars: *The value entered here defines the portion of the pillars that will be mined. For example, if the pillar will be entirely mined out, enter a value of 1. If only half of the pillar will be mined, enter a value of 0.5.*

Enter the extraction ratio for KEY outside the panel: *The value entered here defines the extraction ratio for the portion of the retreat panel outside of the main panel area. If all of the key material in this area will be removed, enter a value of 1. If half of the material in this area will be mined, enter a value of 0.5.*

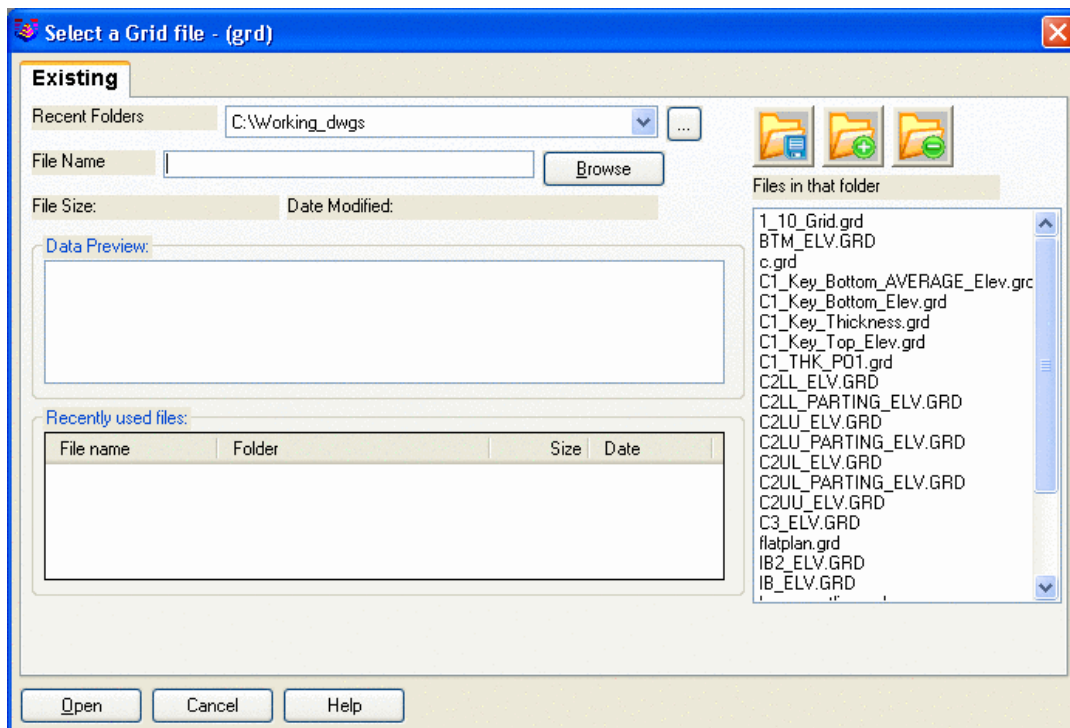

In the below example, we have a panel with an area 60,000 ft². The orange polyline represents the retreat area (10 of the 15 pillars will be retreat mined, and a portion of the rib will also be retreat mined). When prompted for the retreat options, the orange polyline is selected. The extraction ratio for the remaining pillars was set to 0.8 (meaning 80% of the pillars will be mined), and the extraction ratio for Key outside the panel area is was set to 0.6. The table below the dialog shows the effective pillar area to be mined and the effective outside area to be mined. These areas combined give the total retreat area to be mined, which is then divided by the Panel Area to give the Retreat Extraction Ratio.

Area of ten pillars inside retreat polyline, ft ²	16,000	Panel Area, ft ²	60,000
Extraction Ratio for Remaining Pillars	0.80	Retreat Area Mined, ft ²	19,520
Pillar Area mined, ft ²	12,800	Retreat Extraction Ratio	0.3253
Area outside Panel, ft ²	11,200		
Extraction Ratio for Key Outside the Panel	0.60		
Area mined outside panel, ft ²	6,720		

- **Retreat Extraction:** This value represents the area of the panel to be mined on retreat. This is the retreat area divided by the panel area.
- **Owner:** A single owner's name can be assigned to the panel.
- **Level Layer Suffix:** This is only needed when multi-level mining is to be used. Entering "_LEVEL2" for this field would tell the program that this panel is part of the second level.
- **Precedence:** This box gives the opportunity to set fixed scheduling relationships. Any panels selected must be completed before this panel can start.

- **Advance Difficulty Factor:** A value or a grid can be used to provide difficulty factor input for advance mining in the panel.
- **Retreat Difficulty Factor:** A second value or grid can be specified for retreat mining independent of the advance mining difficulty rate.

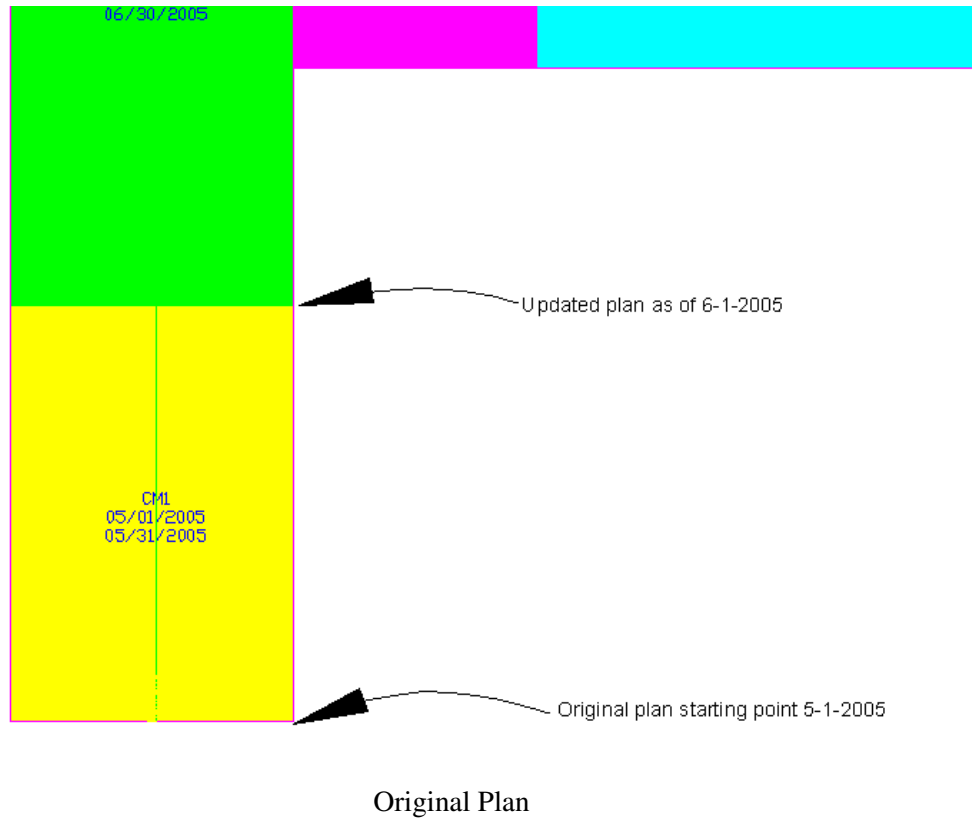

Pulldown Menu Location: UnderGround

Keyboard Command: edit_panel

Update Edited Panel

The mining plan created once should undergo changes as mining progresses. The user may modify, replace or erase panel perimeters in correspondence with changes in the existing mine and then use this command to update the mine plan data. Do not modify or erase the remaining linework, since this linework and internal plan data will be updated to match changes in the associated perimeters. This command should also be used every time the panel polyline is moved, replaced or edited for any other reason.

Naturally the mine starting date should be moved forward each time plan is updated, so that timing of the remaining plan remains correct.

Highlight grips

Drag grips

Updated panel

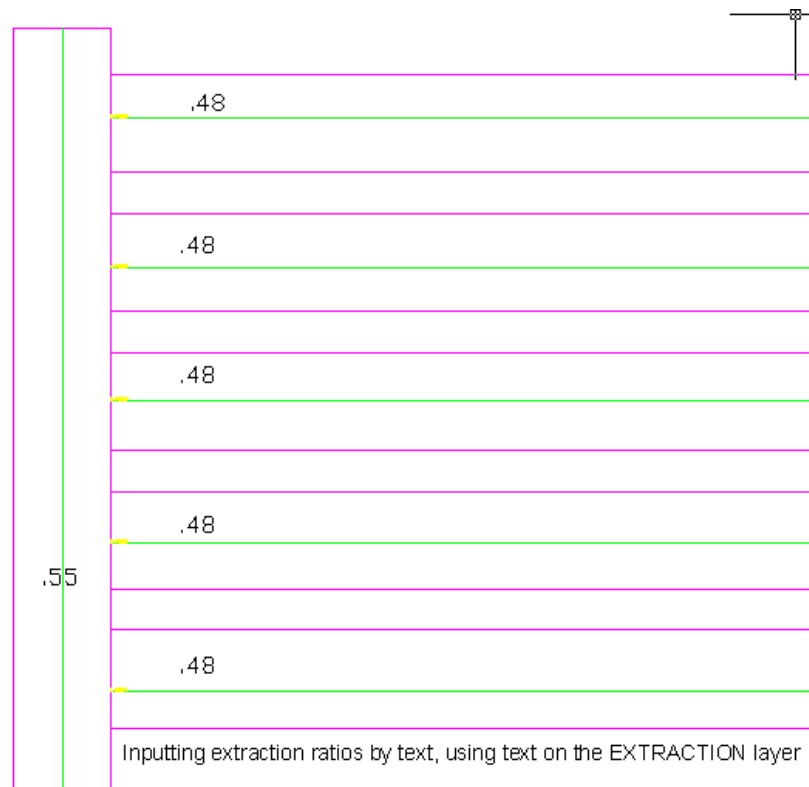

Once the panel linework is updated, re-run the Underground Timing updating the plan start.

Pulldown Menu Location: UnderGnd

Keyboard Command: update_plan

Recalculate Extraction

When changes are made to the panels that result in a change in the extraction ratio this function must be run to update the extraction ratio in the panels. This also must be run after placing panels using Auto-Place Panels by text. If the text values for extraction are used to input the extraction ratio for advance or retreat extraction ratios this function must be run. Text for the extraction ratio must be put on the CAD layer of EXTRACTION. Two other layer names that will be recognized by this command to update the panels are ATTR_GROUP to assign a certain Panel Attribute Group to certain panels (such as longwall vs. continuous miner), and ENTRY_WIDTH to set that to the value of the text in that layer.

Prompts

Select all panel polylines to have extraction ratio updated:

Select objects: Specify opposite corner: 6 found

Select objects:

Polyline offset amount <0.0>: *press Enter*

Retreat recovery <1.0>: 0

Panel 5 RIGHT has extraction of 0.48000

Panel 4 RIGHT has extraction of 0.48000

Panel 3 RIGHT has extraction of 0.48000

Panel 2 RIGHT has extraction of 0.48000

Panel 1 RIGHT has extraction of 0.48000

Panel N_MAINS has extraction of 0.55000

Pulldown Menu Location: AdvMine

Keyboard Command: redoextract

Panel Precedence By Polylines

This command allows you to quickly assign precedence to mine panels by drafting directional polylines which indicate the direction of precedence. Before the command is executed, a polyline must be drawn on the PRECEDENCE layer. The vertices of the polyline must exist inside the panels, as shown below. It is important to note that a vertex must exist inside each panel perimeter (a polyline with 2 vertices will only modify 2 panels, even if it crosses multiple panels).

When the command is executed, you will be prompted to select the panels to modify, followed by the Precedence polylines. You will then be prompted if the precedence panel is Advance or Retreat, followed by a prompt to assign the precedence rule to the Advance or the Retreat of the target panel.

An example Setup is show below. In all three cases, the Main Panel must be mined before R1, R2, and R3.

The resulting Precedence rule for Panel R3 is shown below. In this example, we assigned the Advance of panel R3 <3:E> as a precedence rule to the Advance of Panel R1.

Pulldown Menu Location: Underground

Keyboard Command: pl2panelprec

Prerequisite: Mine Panels and directional polyline(s) on the PRECEDENCE layer

Find Panel

Use this command to find a panel with a given name in a complex mine plan. Type the name of the panel in at the command prompt and the ghosted dashed arrow will appear in the center of the screen pointing at the requested panel.

Pulldown Menu Location: AdvMine

Keyboard Command: find_panel

Remove Panel

The mine plan consists of visible linework and internal data, including cross-references, containing all data necessary for timing. For this reason a simple deletion of the linework of an unwanted panel is not enough for removing all references to it and is likely to corrupt whole mine plan.

Use the Remove Panel command to remove all the linework and clean up internal data related to panel being removed and all its children panels.

In case if user just wants to remove a panel, but keep its children in the mine plan, remove a panel perimeter polyline and then use Update Edited Panel to tell it what that panel is completed.

Pulldown Menu Location: AdvMine

Keyboard Command: delete_panel

Reverse Panel

This command reverses the direction of mining within a panel. The panel must still be mined from the other end after it is exposed, otherwise that could introduce a problem with the mining sequence.

Prompts

Select a part of the mine plan to be reversed:

Select objects:

Pulldown Menu Location: Underground

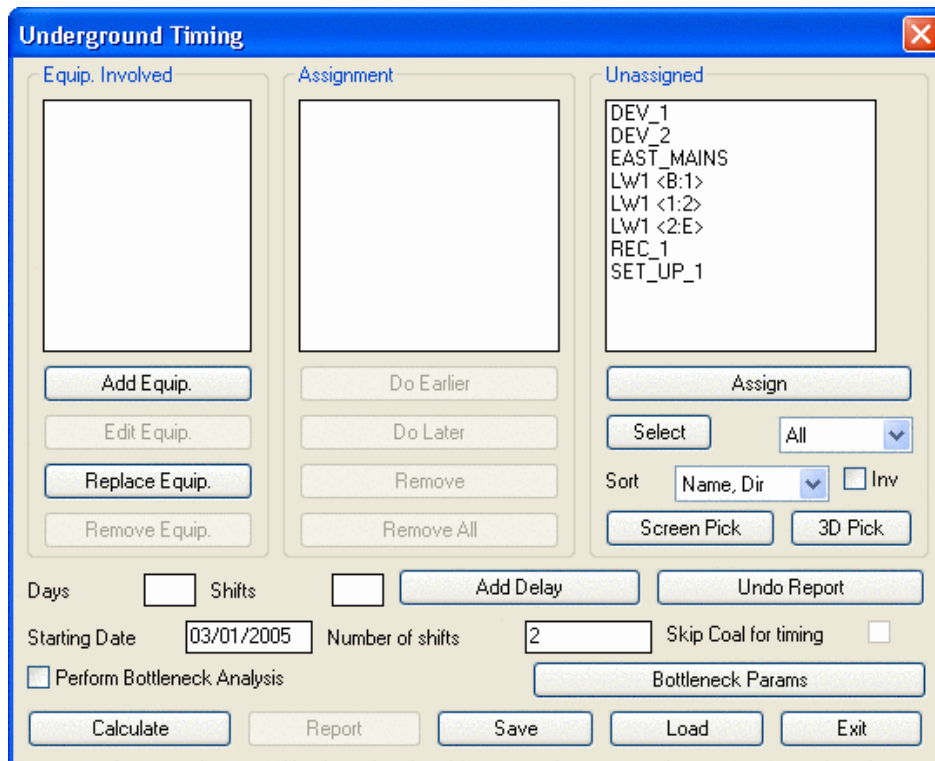

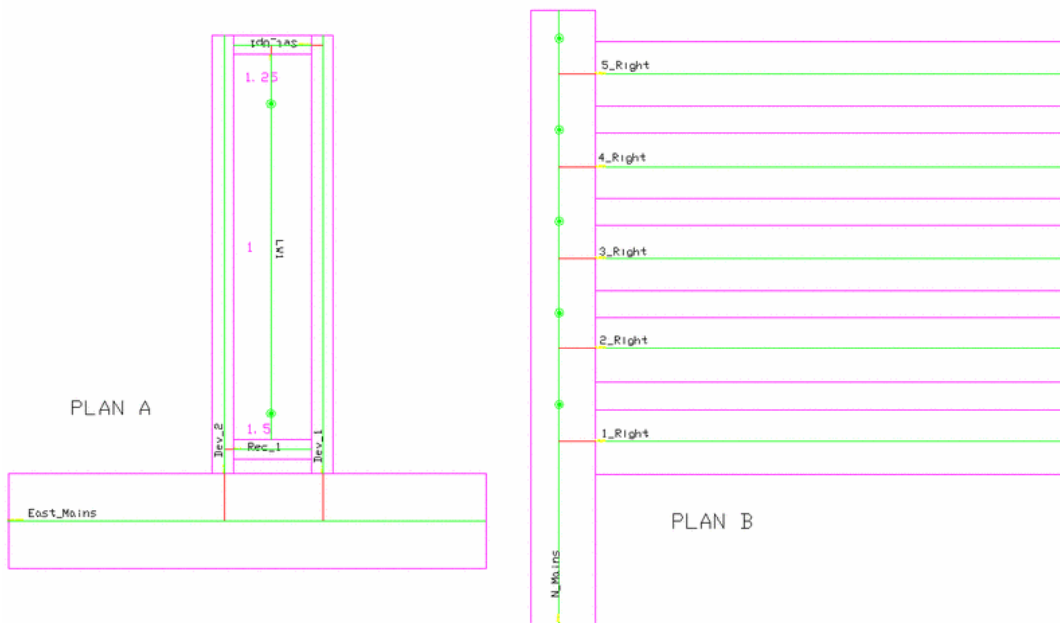

Keyboard Command: reverse_panel

Related Commands: Edit Panel, Remove Panel, Update Edited Panel

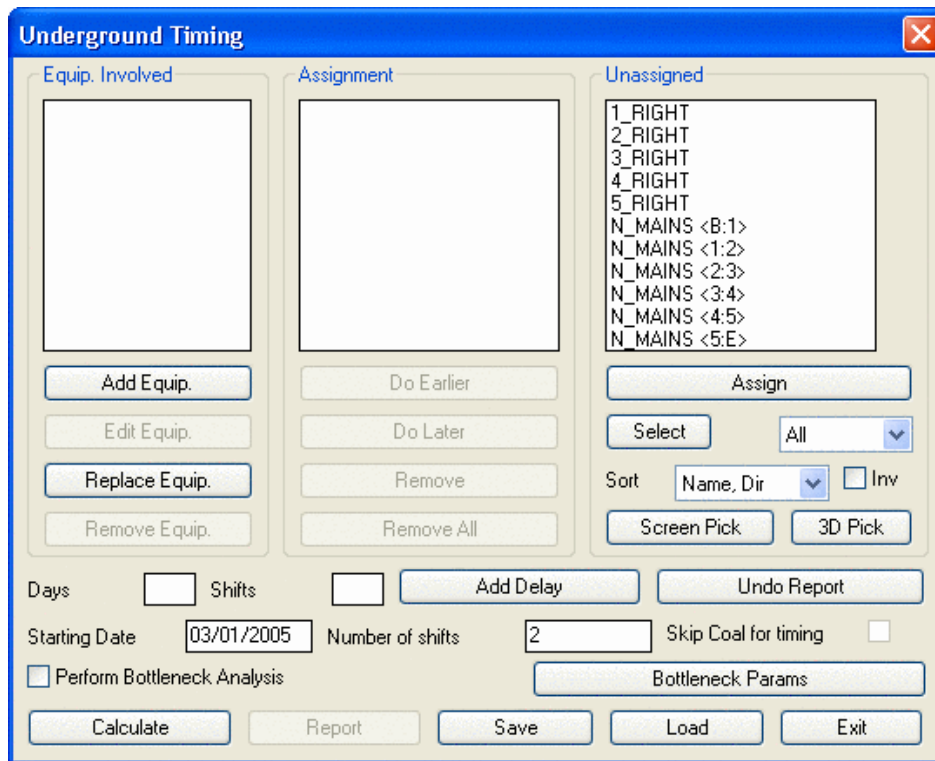

Connect Mine Plans

Two mine plans which are located in two separate parts of the mine but are sharing the same equipment or just wanted to appear on the same time plan, may be connected into a single mine plan using this command. The only difference between joint mine plan versus conventional one is that mining progresses simultaneously in all connected plans, if equipment use permits that.

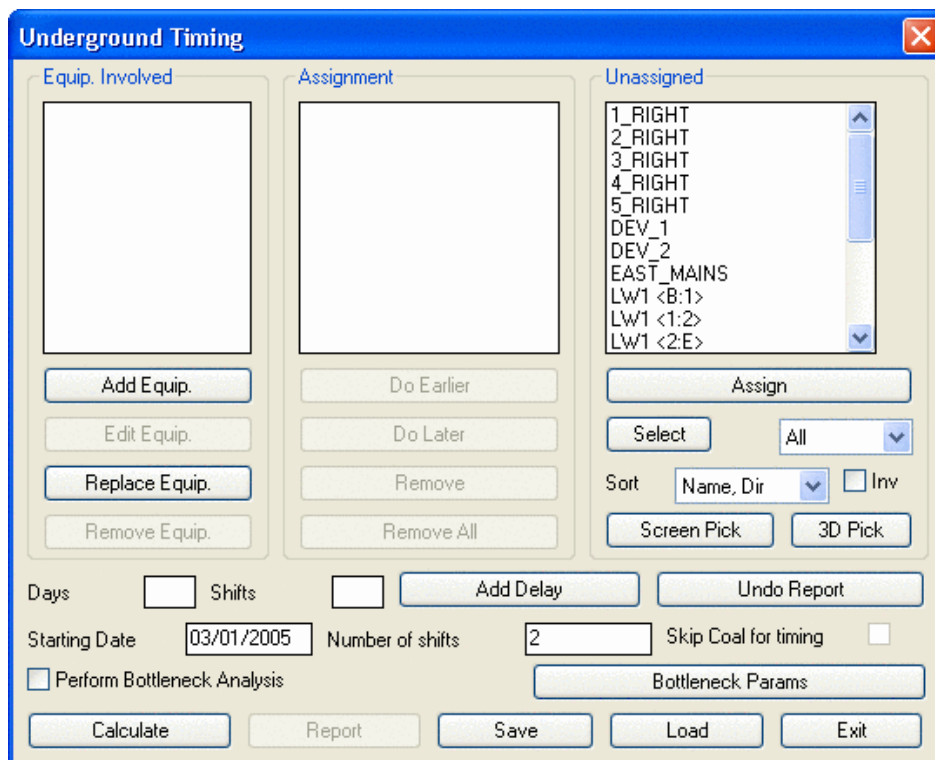

The following drawing contains two separate mine plans: Plan A and Plan B.

Plan A panels are shown when the Underground Timing function is selected. (Before connecting)

Panel B panels are shown when the underground timing option is selected and you pick on the Plan B panels.
(Before connecting)

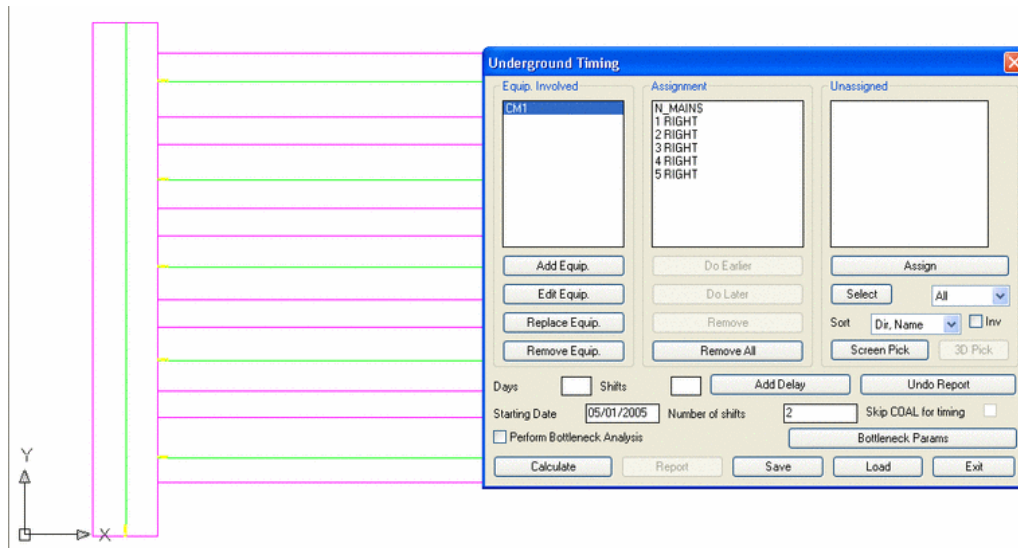

After connecting Plans A & B the list of available panels is composed of both lists.

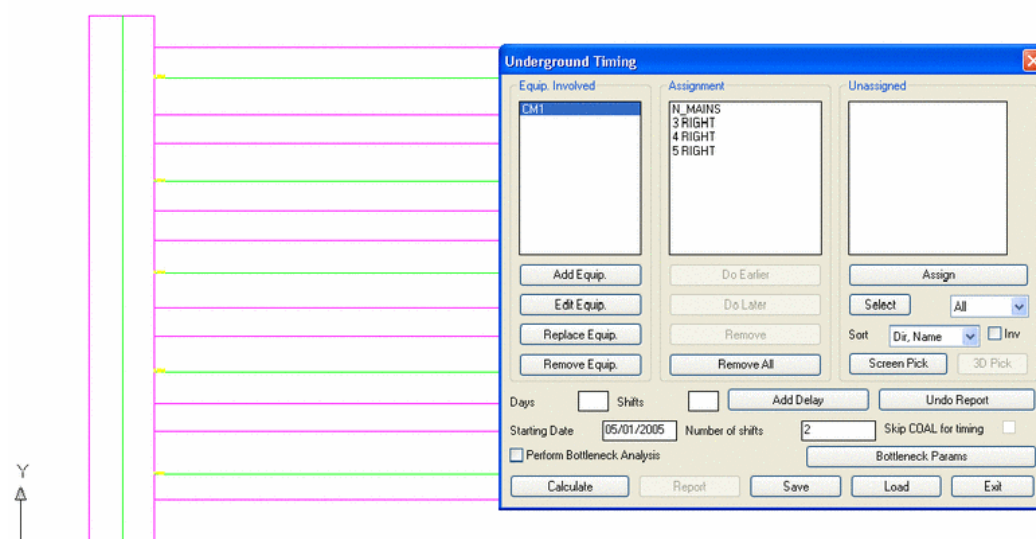

Pulldown Menu Location: AdvMine
Keyboard Command: connect_plans

Disconnect Mineplans

A mine plan is a group of placed panels on a common list grouped together for scheduling. Disconnect Mine Plans is used to break a mine plan into two or more groups of placed panels. To select a mine plan pick on the green backbone lines of the placed panels.

After disconnecting 1 Right and 2 Right panels

List after disconnecting 1 Right and 2 Right

Prompts

Select a part of the mine plan to be disconnected: *select backbone polyline*

Select a part of the mine plan to connect to or press Enter to leave disconnected: *press Enter*

Pulldown Menu Location: AdvMine

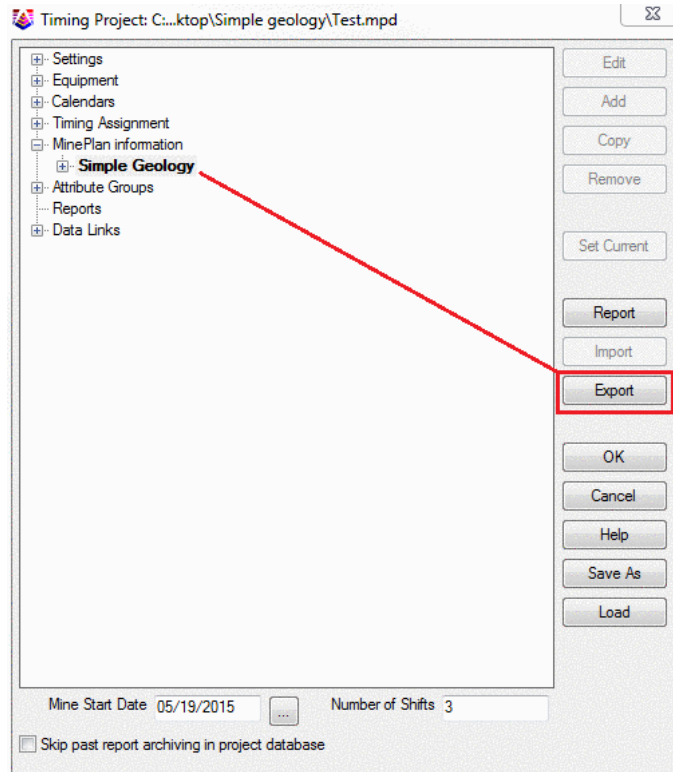

Keyboard Command: disconnect_plans

Import Mine Plan

This command allows you to import an Underground Mine Plan into a drawing. The Mine Plan includes panel perimeters, panel names, panel centerlines, and section data. This command can be used to transfer planning

information between drawings to evaluate multiple mining scenarios.

The Mine Plan is created when you create the mining panels and assign them to a piece of equipment in the Underground Mine Timing command. The Mine Plan can be saved as a .ppi file via the Timing Project Manager. To save this file, open the Timing Project Manager (Underground Pulldown Menu > Timing Project Manager). Then select the Mine Plan under the Mine Plan Information Menu. You can then click **Export** to save the Mine Plan as a .ppi file.

To import a Mine Plan, click Underground Pulldown Menu > Import Mine Plan. Here you can select a .ppi file to import into the drawing. Once the file has been imported, the basic linework of the Mine Plan will be drawn. The below figure shows a simple Mine Plan that has been imported into a new drawing. Notice that the panel perimeters, names, and belt lines have all been imported.

Once the Mine Plan has been imported, you can use the Edit Panel command to inspect the Section Data relating to the panels.

Pulldown Menu Location: Underground Mining/Underground

Keyboard Command: import_plan

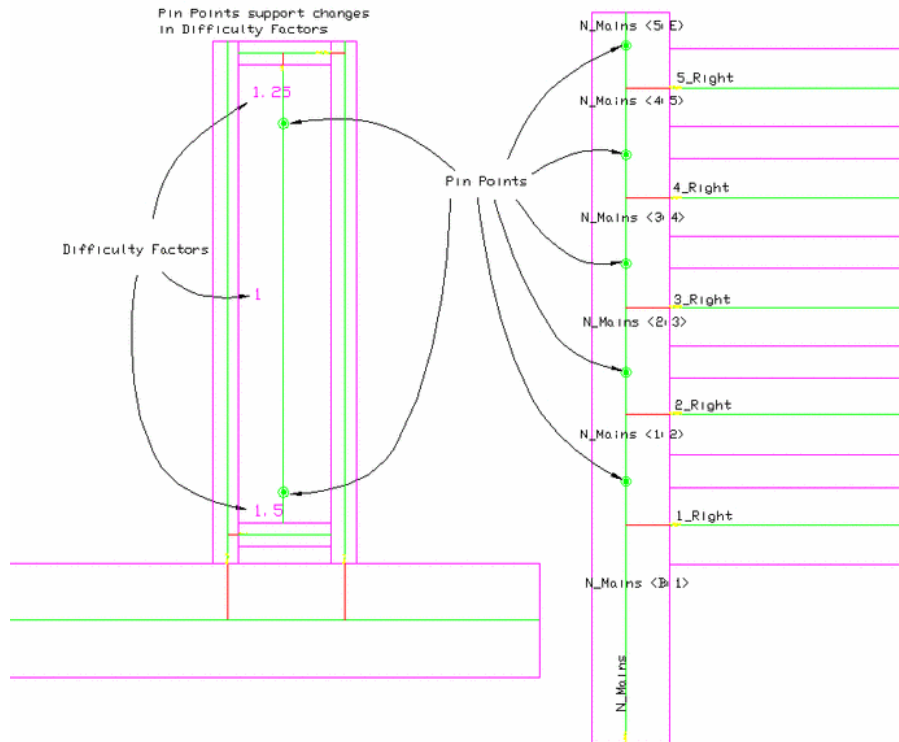

Prerequisite: PPI file previously saved

Add Pin Point

Pin Points are used to provide stopping points within a panel. This is similar to, but not exactly the same thing as sub-dividing as panel. Pin Points can be used to sequence mining up to the stopping point for both advance and

retreat mining. Difficulty factors can be changed between pin points by placing the difficulty factor by text on the DIFFICULTY layer to impact the mining rate as well. Units can mine up to a pin point, mine in another panel, and then return to continue mining later. The N_Mains panel below has been broken into 6 parts that can be scheduled with the 5 pin points as shown.

The function Add Pin includes new pin points into the panel as desired.

For the example shown the sequence of advance mining is as the following:

```
N_MAINS <B:1>
N_MAINS <1:2>
N_MAINS <2:3>
N_MAINS <3:4>
N_MAINS <4:5>
N_MAINS <5:E>
```

The different pieces may also be assigned to the separate units as well.

The same set of pinpoints is used for both advance and retreat mining with the following naming convention:

Advance

```
N_MAINS <B:1>
N_MAINS <2:E>
```

Retreat

```
MAINS<B:1>
RET MAINS<2:E> RET, so that a section name on retreat is the same as on advance except for suffix the RET.
```

Prompts

Pick pinpoint or Enter distance or Define size[<Pick>/Enter/Size]: Whenever this prompt is displayed, you can click directly on a mine panel to place a pin point. This will continue until you select a new command line

option or press ESC to exit the command.

Pick pinpoint or Enter distance or Define size[<Pick>/Enter/Size]:E *This option will let you select a single mine panel and enter distances down the length of the panel to place a pinpoint*

Select mine panel:

Enter distance from starting point:100 *Places a pinpoint at exactly 100 ft (or meters) from the start of the panel*

Enter distance from starting point:200 *Places a pinpoint at exactly 100 ft (or meters) from the start of the panel*

Enter distance from starting point: *Press ESC to return to the main prompt*

Pick pinpoint or Enter distance or Define size[<Pick>/Enter/Size]:S *Allows you to change the size of any new pinpoints created*

Pinpoint size <50.00>: 25 *Sets the size of the pinpoints to 25*

Pulldown Menu Location: Underground

Keyboard Command: addpin

Remove Pin Point

The Remove Pin Point command deletes the unwanted pin point from the panel. See Add Pin Point for detailed information on pin points.

Prompts

Click on centerline close to pinpoint to be removed: *pick on the centerline close to unwanted pin point*

Pulldown Menu Location: AdvMine

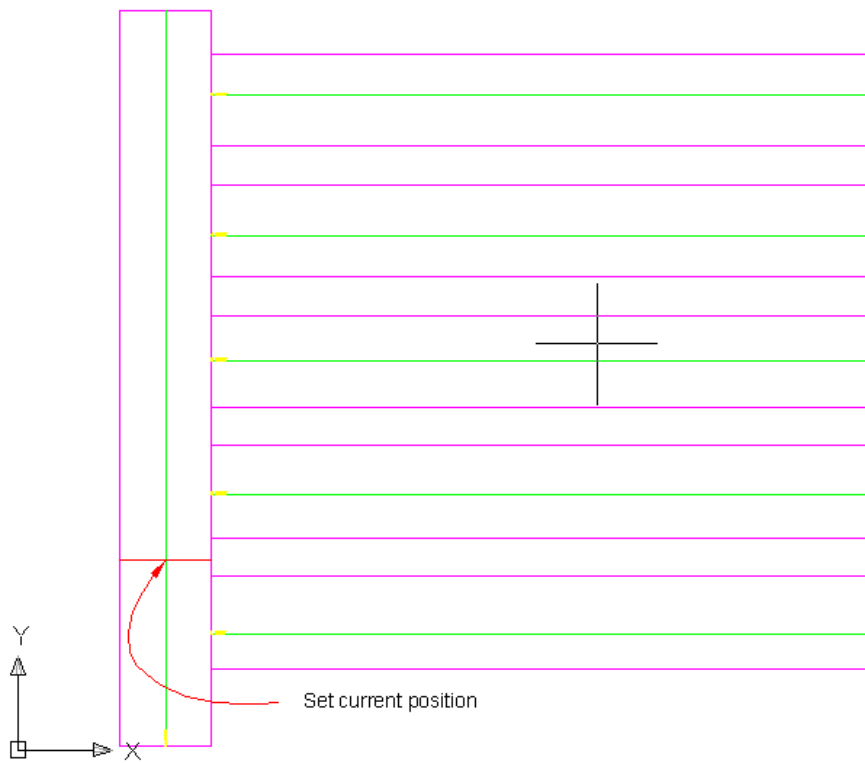

Keyboard Command: delpin

Set Current Position

The purpose of this function is to set the current state of the mine development.

When a mine plan is first created, the mine plan is a snapshot of the layout of the mine. As mining progresses some panels are completed, while mining in the others just starting. Whenever the user wants to advance the Starting Date, the mine plan should be adjusted to the mine state on the new date.

Some of the updates can and should be done using Update Edited Panel after corresponding modification, but whenever a panel is going to be retreated, it is impossible to modify panel perimeter to show changes. In this case a current position of the crew within the panel is marked using Set Current Position function.

Prompts

Select a current stage of panel development (<Advance>/Retreat)?

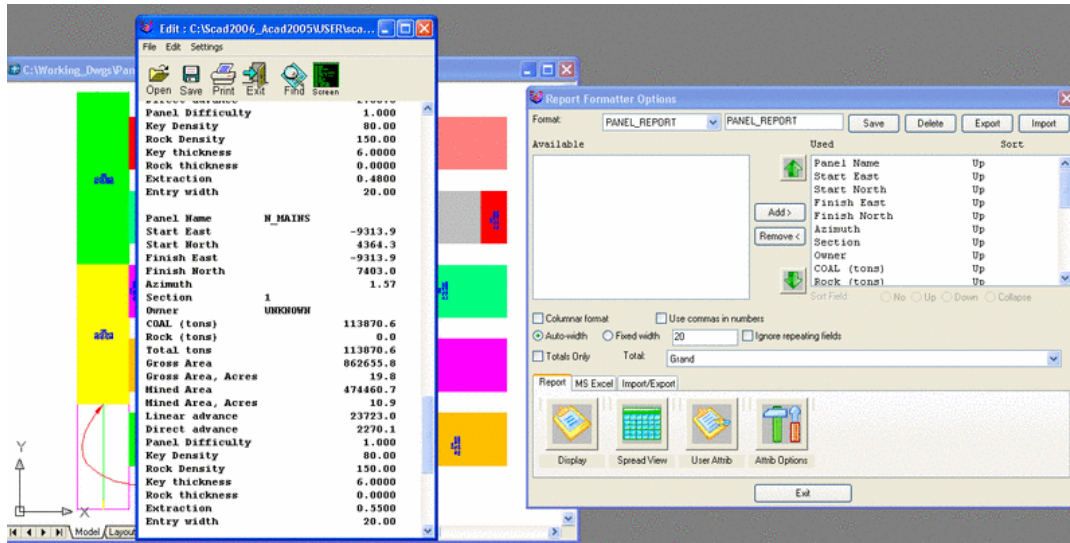

Click on centerline at current position: *pick on the centerline*

Pulldown Menu Location: UnderGnd

Keyboard Command: pstart

Panels Report

Panels Report provides a way to report out all of the information stored in the panels in a common mine plan using the report formatter. Select any backbone polyline in a mineplan and the report formatter will appear ready to print the report.

Pulldown Menu Location: AdvMine
Keyboard Command: panels_report

Underground Timing

The diagram above shows the general steps associated with the creation of a mine plan with the Underground Timing routine. Prerequisites include:

- Creating thickness, density, and quality grids, and/or average values for the total coal and rock to be mined.
- Defining the productivity rates of the equipment and operating schedule for each section of equipment in the Timing Project Manager.
- Preparing the mine linework on specific layers (see below).
- Converting linework into panels with one of four commands: Place Panel, Auto-Place Panel by Text, Auto Panel Layout, and/or Pick and Place Panel.
- Adjusting the mine plan by adding Pin Points, Recalculating Extraction, Connecting Mine plans, and Editing panels.

A complete list of the reserved layer names used in the timing command is below. Linework and/or text on these layers will play a specific role in the timing.

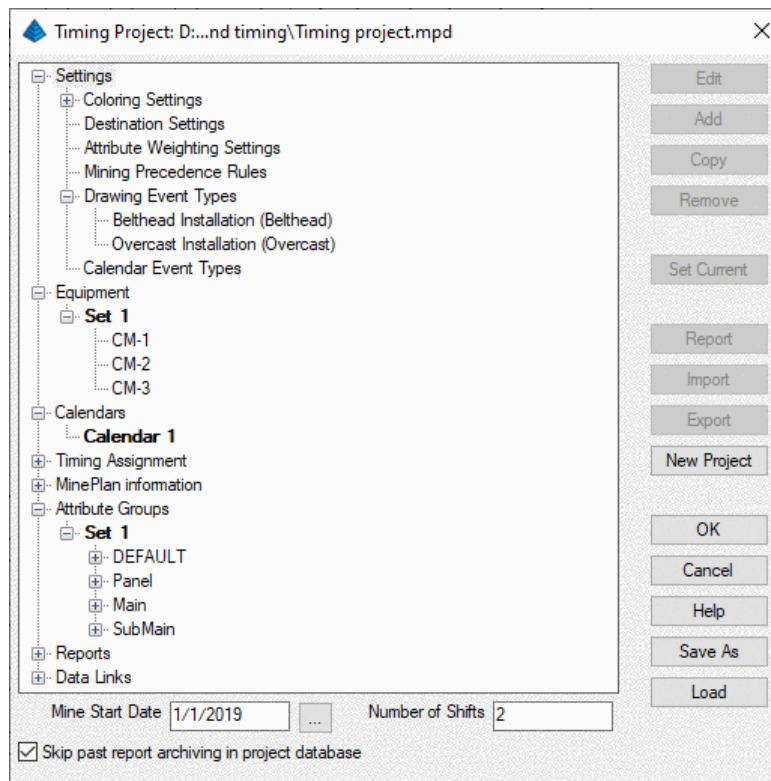

Layer	Data Type	Description
ATTR_GROUP	Text	Assigns Attribute Group for the panel when using Auto-Place Panel by Text and Recalculate Extraction commands
DIFFICULTY	Text	Assigns panel difficulty factor during Underground Timing command (value is read during timing calculation)
ENTRY_WIDTH	Text	Assigns Entry Width for the panel when using Auto-Place Panel by Text and Recalculate Extraction commands

EXTRACTION	Text	Assigns extraction ratio for the panel when using Auto-Place Panel by Text and Recalculate Extraction commands
MINEPLAN	Linework/symbols	Displays Pin Points and panel centerlines when panels have been created - This linework is automatically generated; users do not need to manually create this linework
MINEPLTX	Text	Displays panel names when panels have been created - This text is automatically generated; users do not need to manually create this text
PANELNM	Text	Assigns the panel name when using the Auto-Place Panel by Text command
PERIM	Linework	Defines the panel perimeter - Note that these must be closed polylines
PILLARS	Linework	Defines pillars in the panel - Note that these must be closed polylines
PRECEDENCE	Linework	Assigns precedence rules when using the Panel Precedence by Polylines command
PROJECTIONS	Linework	Displays entry and crosscut projections when using the Basic Projections or Advanced Projections commands
RET_DIFF	Text	Assigns the panel difficulty factor during Underground Timing for retreat mining (value is read during timing calculation)
RET_EXTRACT	Text	Assigns extraction ratio for retreat mining the panel when using Auto-Place Panel by Text and Recalculate Extraction commands

An example mine layout is shown below.

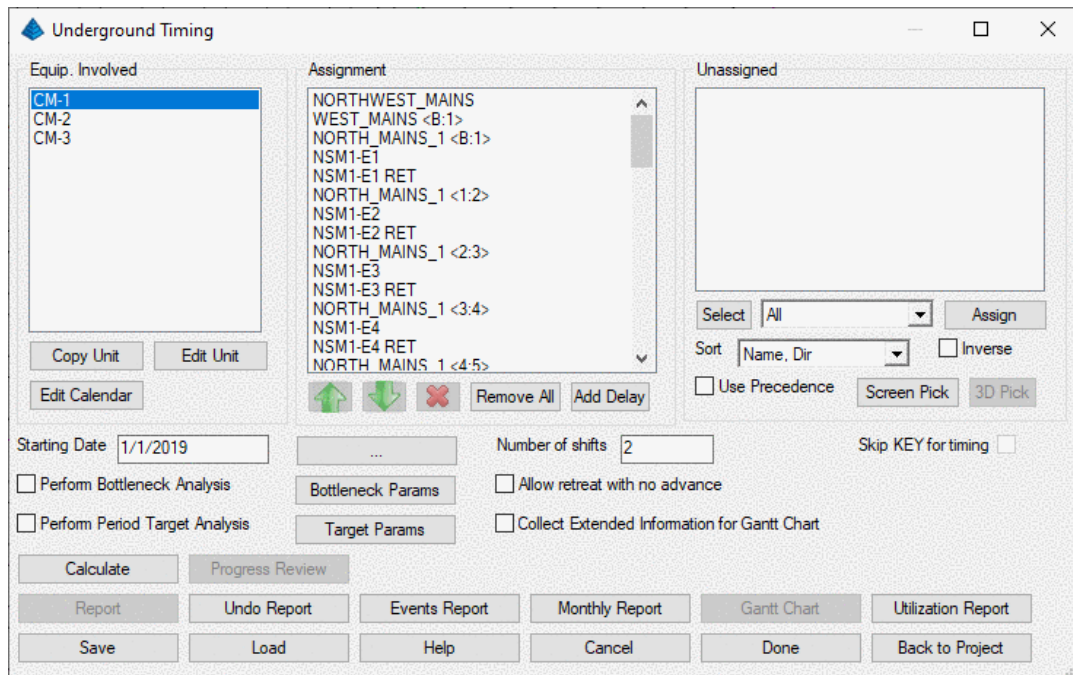

When the command is executed, you will be prompted to select a part of the mine plan. The Timing Project Manager, shown below, will then appear. Here you can define equipment, calendars, attribute groups, and more. For more information on the Timing Project Manager, see the corresponding section of the help manual.

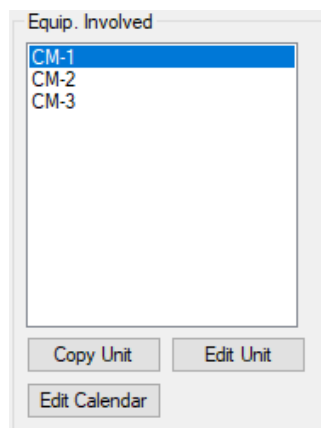

After ensuring all settings are correct in the Timing Project Manager, you can click OK to move on to the assignment dialog, shown below. The primary purpose of this dialog to move panels from the Unassigned Column to the

Assignment column in the order in which they will be extracted. Each piece of equipment has its own assignment list.

The Equip. Involved Column lists all pieces of equipment to be used for the mine scheduling. Panels must be assigned to a specific piece of equipment in order to be mined.

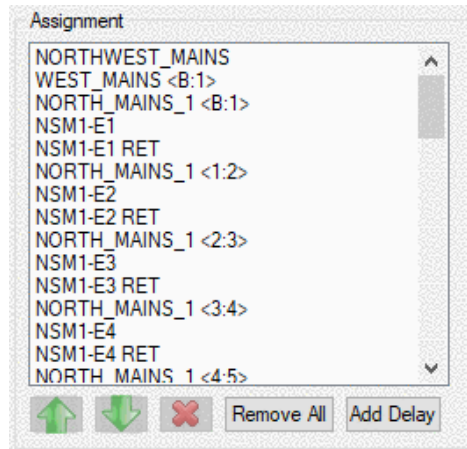

Copy Unit: This button will create a copy of the currently select unit.

Edit Unit: This button will allow you to edit the specifications of the currently selected equipment. More information on defining equipment specifications is available in the Timing Project Manager section of the help manual.

Edit Calendar: This button will allow you to edit the current work calendar. More information on defining the work calendar is available in the Timing Project Manager section of the help manual.

The Assignment Column lists the panels assigned to the currently selected equipment. Selecting a different unit will update this column with the list of panels assigned to that unit. This column lists panels in the order that they will be mined, with panels at the top of the list being mined first. Once panels have been assigned to the various equipment, the assignments can be saved to a .tim or a .csv file. Both can be edited with a simple text editing program such as Notepad, but the .tim format is not as user-friendly as the .csv format. When exported to a .csv, you can very easily editing the timing assignments in Microsoft Excel, then load the timing assignments back into the Underground Timing dialog. In the .csv format, the first column is the equipment name and the second column is the panel name. The assignments will be retained between calculations of the timing, but it is highly recommended to save your timing assignments to an external file.

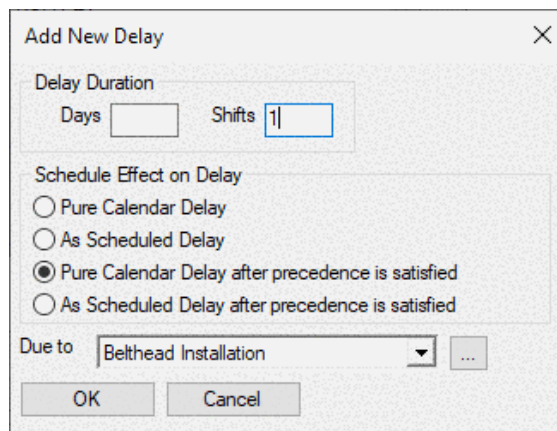

The green **Up/Down Arrow Icons** will move the currently selected panel(s) upward or down in the list, causing it to be mined earlier or later in the sequence.

The red **X icon** will remove the currently selected panel(s) from the list, allowing it to be re-assigned to another piece of equipment.

Remove All: This button will remove all assignments from the currently selected unit.

Add Delay: This button will open the dialog shown below, which controls how delays are handled. A delay will appear in the Assignment Column as if it were another panel to be mined, and may be moved up or down in the sequence.

Delay Duration: These values control how long the delay lasts. In the above example, the equipment will be delayed for a full shift. Note that partial shift delays are allowed.

Pure Calendar Delay: This option will not force a delay. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay: This option will force a delay even if the equipment already has scheduled downtime when the delay is encountered. The delay will wait until the scheduled downtime is complete, then the delay will be applied.

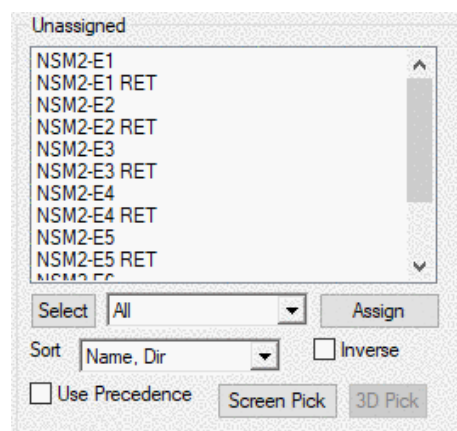

Pure Calendar Delay after precedence is satisfied: This is similar to a Pure Calendar Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the scenario shown in the below table. Equipment E1 is scheduled to mine Panel A and Panel C. Equipment E2 is scheduled to mine Panel B and Panel D. A precedence rule has been created that does not allow Panel D to be mined until Panel A is complete. A delay of this type is placed on Equipment E2 after Panel B. In this scenario, the finish date of Panel A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay after precedence is satisfied: This option is similar to an As Scheduled Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the below scenario. Equipment E1 is scheduled to mine Panel A and Panel C. Equipment E2 is scheduled to mine Panel B and Panel D. A precedence rule has been created that does not allow Panel D to be mined until Panel A is complete. A delay of this type is placed on Equipment E2 after Panel B. In this scenario, the finish date of Panel A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime, the delay will be applied in addition to this downtime.

Due To: This dropdown menu lists the Drawing Event delays defined in the Timing Project Manager. The ellipsis button will allow you to define a new Drawing Event.

Equipment	E1	E2
Assignment	Panel A	Panel B
Sequence	Panel C	Delay
		Panel D (Precedence Rule: Panel A)

The Unassigned Column lists all panels that have not yet been assigned to a piece of equipment.

Assign: This button will assign the selected panel(s) to the selected piece of equipment.

Select: This button will select all panels according to the drop-down menu to the right of this button. If the drop-down menu is set to NONE, all panels will be unselected. If the drop-down menu is set to ALL, all panels will be selected. If the drop-down menu is set to Advance or Retreat, all panels of that type will be selected.

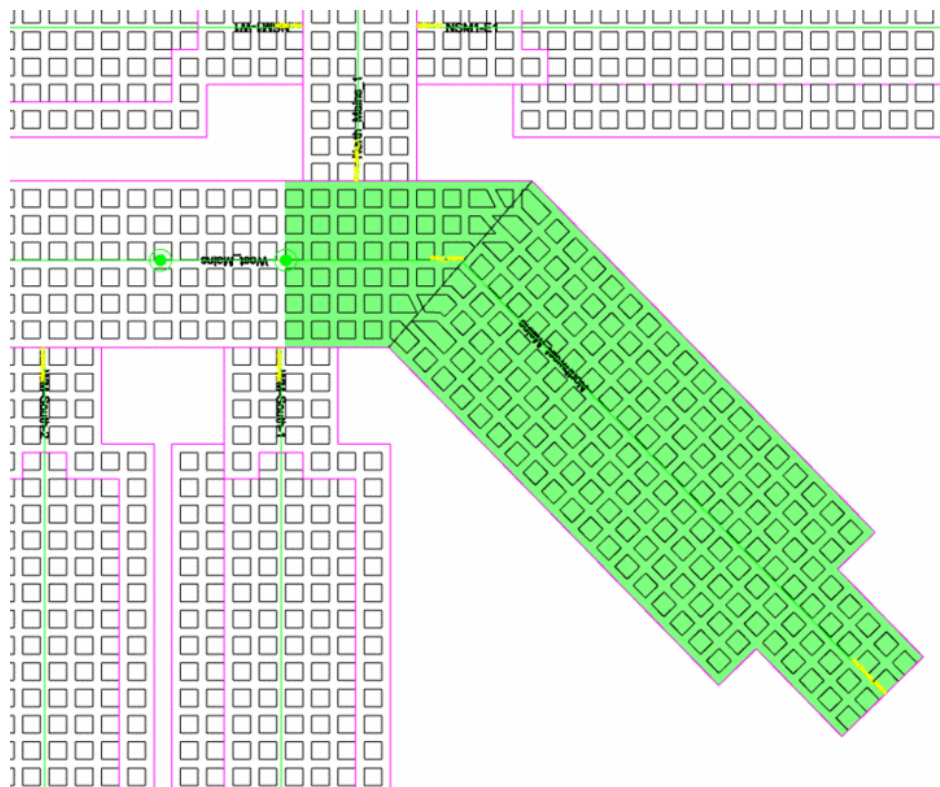

Sort: This drop-down list will sort the panels in the list.

- Name, Dir: This option will sort the list by panel name, then by direction. For example, if you have retreat panels, they will be listed immediately after the advance heading (notice how the RET panels immediately follow the non-RET panels in the image above).
- Dir, Name: This option will sort the list by direction, then by name. This will simply group all of the advance panels together, and all of the RET panels will be grouped as well.

Inverse: This checkbox will invert the sorting order of the Unassigned Column.

Use Precedence: This checkbox will ensure that precedence is satisfied in the list. For example if Panel1 is assigned to precede Panel2, toggling this option on will reorder the list so that Panel1 is listed before Panel22.

Screen Pick: This button will allow you to sequence the panels by selecting them in the drawing. When activated, the Underground Timing Dialog will disappear and the drawing area will be visible. The command line will prompt you to click inside the panel to assign to the currently selected piece of equipment. Panels that have already been assigned to a piece of equipment will be filled with a transparent color. Pressing ENTER after selecting the panels will return to the Equipment Timing dialog. An example of the Screen Pick method of selection is shown below. The green filled panels have already been assigned to a piece of equipment. If pin points are in the panel, it will only hatch up to the next pin point, allowing the panel to be assigned in order as separate entities.

3D Pick: This option is not available in the Underground Timing command - it is only available in the Surface Equipment Timing command.

Additional scheduling options are shown below.

Starting Date: This value sets the date to begin mining operations. The ellipsis button to the right of this field will open a small calendar to assist in date selection. By default, this value will be set the Mine Start Date set in the Timing Project Manager.

Number of Shifts: This value will set the number of working shifts in a day.

Skip COAL (Key Material) for timing: This checkbox controls if key material is used for the timing or not. When this option is on, the key material (be it coal or some other resource) will not be included in the scheduling. Instead, it will be assumed that all key material will be mined quickly enough so that it never delays the removal of waste material.

Perform Bottleneck Analysis and Bottleneck Params: This option is intended for use in the Surface Equipment Timing command, and is therefore not discussed here.

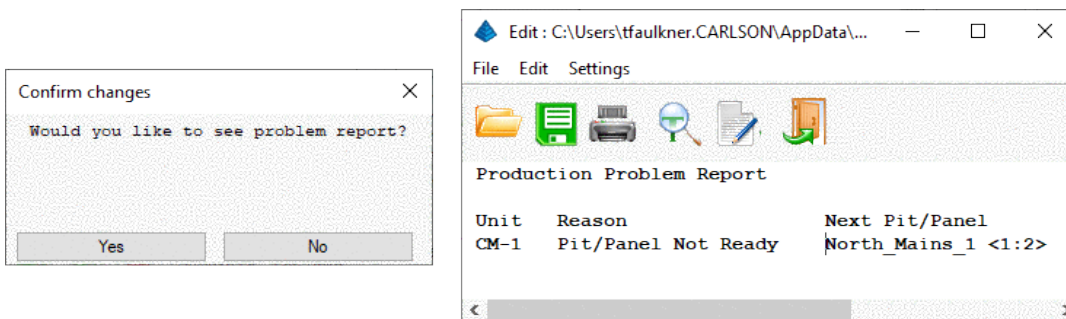

Perform Period Target Analysis and Target Params: This option is intended for use in the Surface Equipment Timing command, and is therefore not discussed here.

Allow Retreat with No Advance: This option allows retreat panels to be mined without first mining the advance panels. This can be useful if it is more advantageous to simply refer to a panel as retreat, even though it is only going to be mined through once.

Collect Extended Information for Gantt Chart: When enabled this option will allow the Gantt Chart to include extra information such as the tonnage, quality, etc.

Calculate: This button will calculate the mine schedule. In cases when the mine plan includes retreat (second) mining, the system will make sure that when the parent panel is mined on retreat, the mining (advance or retreat) in all child panels is completed. If not it tries to offset the starting date of retreat in the parent panel until the timing conflict is resolved. Sometimes it is impossible to do so and the program reports the problem to the user for manual resolution.

If any errors are encountered, the below dialog (left) will appear. The problem report generated will appear similar to below (right). In this example, a precedence rule has been violated for the CM1 equipment. Here, the North_Mains_1 <1:2> panel has violated a precedence rule. This will require an edit to the assignment order for proper timing.

If no problems are encountered, the schedule will be calculated and the below dialog will appear.

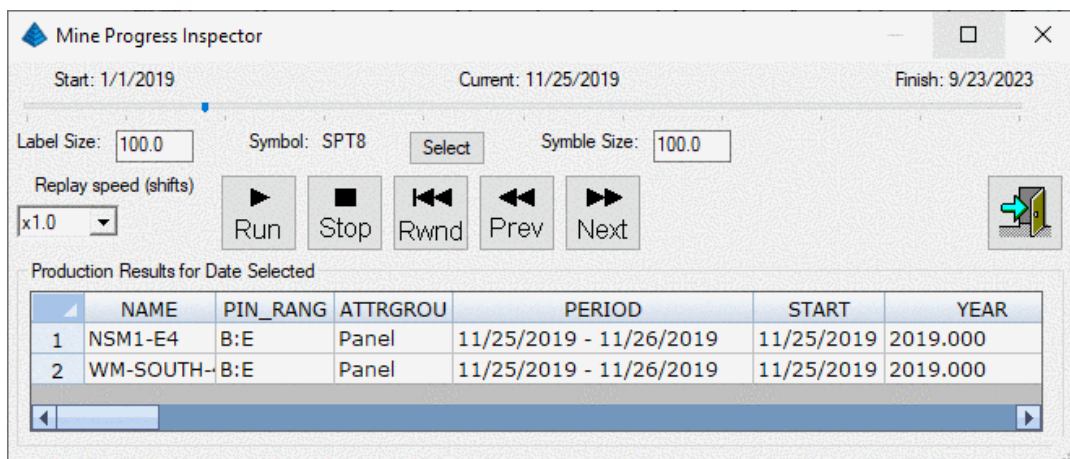

Report: This button will generate a very simple report as shown below. Note that this report does not include information about the amount of material mined. The Days Waiting in this report refer to the number of days in which a panel is waiting to be excavated due to precedence rules, or due to a scheduled delay.

Unit	Days waiting	Panel name	Pinpoints	Sections	Sect. 1 finish	Days Operating	days	Weekdays	Worked	Saturdays
CM-1	0.0	NORTH_MAINS_1	B:1	1	3/26/2019	7.8	9.46	8.46		
CM-1	0.0	NORTH_MAINS_1	1:2	1	5/31/2019	6.9	6.89	5.89		
CM-1	0.0	NORTH_MAINS_1	2:3	1	8/8/2019	7.1	7.06	6.06		
CM-1	0.0	NORTH_MAINS_1	3:4	1	10/15/2019	7.1	7.11	6.11		
CM-1	0.0	NORTH_MAINS_1	4:5	1	12/25/2019	8.8	9.79	8.79		
CM-1	0.0	NORTH_MAINS_1	5:6	1	3/25/2020	8.5	8.46	7.46		
CM-1	0.0	NORTH_MAINS_1	6:7	1	6/4/2020	6.8	6.82	6.82		
CM-1	0.0	NORTH_MAINS_1	7:8	1	8/11/2020	6.8	6.85	6.29		
CM-1	0.0	NORTH_MAINS_1	8:E	1	10/14/2020	5.0	4.99	3.99		
CM-1	0.0	NORTHWEST_MAINS	B:E	1	2/13/2019	29.7	33.22	30.22		
CM-1	0.0	NSM1-E1	B:E	1	5/7/2019	33.0	32.97	29.97		
CM-1	0.0	NSM1-E1 RET	B:E	1	5/23/2019	13.5	13.47	12.47		
CM-1	0.0	NSM1-E2	B:E	1	7/12/2019	33.0	32.97	29.97		

Detailed Report: This button will generate a more detailed report, including information such as the amount of material mined, quality of material, downtime, etc. This report is discussed in more detail later in this help document.

Progress Review: This button will open the Progress Inspector shown below. The Progress Inspector will only be generated with information after the mine schedule has been calculated.

The Progress Inspector allows you to step through the day-by-day schedule of each piece of equipment. The slider bar at the top of the window may be used to cycle through the dates quickly. Various information about each piece of equipment is shown in the spreadsheet view. As you progress through each day with the below controls, a symbol and label will appear on the drawing to indicate the location of the equipment. The size of the labels/symbols may be set with the **Label Size** and **Symbol Size**. A different symbol may be selected by clicking the **Select** button.

Run: This button steps through the overall mine progression day-by-day. You may modify the playback speed by changing the **Replay speed** option.

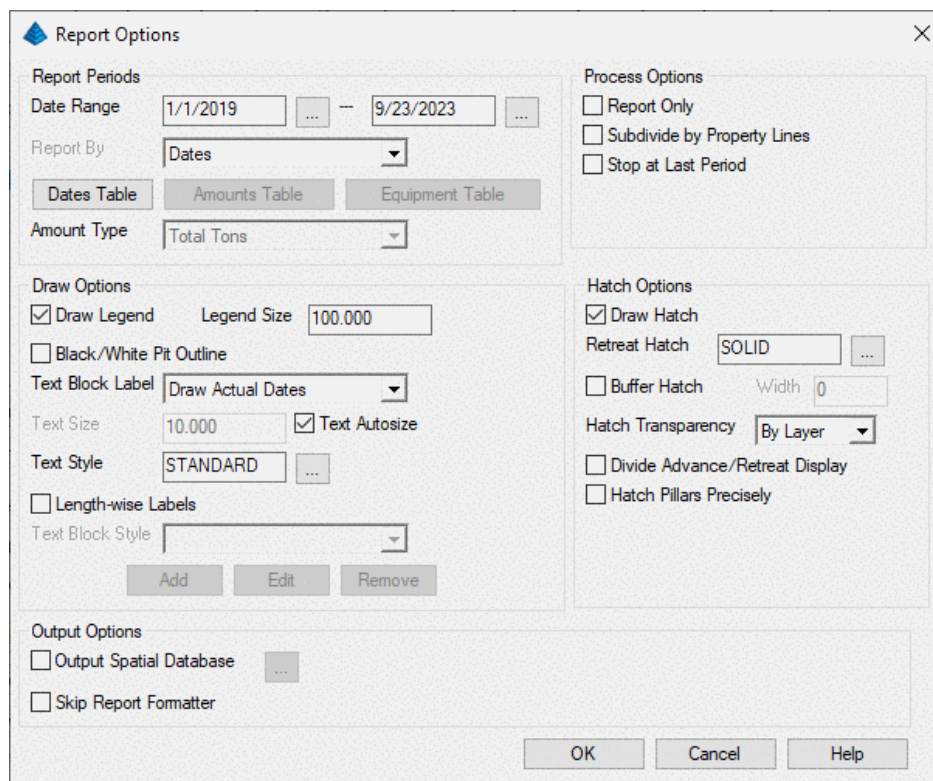

Stop: This button stops the action of the Run button.

Rwnd: This button returns the inspector to the first working day of the schedule.

Prev: This button steps to the previous day in the mine schedule.

Next: This button steps to the next day in the mine schedule.

Report: This button is only available after calculating the mine schedule. This button will open the Detailed Report dialog. This is the same dialog that will appear after selecting the Detailed Report option after clicking the Calculate button.

Date Range: This option will set this range of dates to report.

Report by: This drop list will determine how the timing map is generated.

If the *Dates* option is selected, the timing map will be colored by date ranges.

If the *Amounts* option is selected, the timing map will be colored by amount intervals.
 If the *Equipment* option is selected, the timing map will be colored by equipment.

Dates Table: This button will open the Dates Table, shown below, which is used to define the various time periods used for reporting.

	End Date	Range	Color	Pattern	Scale	Layer	Label
1	2/1/2028	< 2/1/2028	Red	SOLID	Set	250.0 MINETM	Set
2	3/1/2028	2/1/2028 - 3/1/2028	Dark Red	SOLID	Set	250.0 MINETM	Set
3	4/1/2028	3/1/2028 - 4/1/2028	Red-Orange	SOLID	Set	250.0 MINETM	Set
4	5/1/2028	4/1/2028 - 5/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
5	6/1/2028	5/1/2028 - 6/1/2028	Light Orange	SOLID	Set	250.0 MINETM	Set
6	7/1/2028	6/1/2028 - 7/1/2028	Yellow-Orange	SOLID	Set	250.0 MINETM	Set
7	8/1/2028	7/1/2028 - 8/1/2028	Yellow	SOLID	Set	250.0 MINETM	Set
8	9/1/2028	8/1/2028 - 9/1/2028	Light Yellow	SOLID	Set	250.0 MINETM	Set
9	10/1/2028	9/1/2028 - 10/1/2028	Light Green	SOLID	Set	250.0 MINETM	Set
10	11/1/2028	10/1/2028 - 11/1/2028	Green	SOLID	Set	250.0 MINETM	Set
11	12/1/2028	11/1/2028 - 12/1/2028	Dark Green	SOLID	Set	250.0 MINETM	Set
12	1/1/2029	12/1/2028 - 1/1/2029	Light Green	SOLID	Set	250.0 MINETM	Set
13	2/1/2029	1/1/2029 - 2/1/2029	Green	SOLID	Set	250.0 MINETM	Set
14	3/1/2029	2/1/2029 - 3/1/2029	Dark Green	SOLID	Set	250.0 MINETM	Set
15	4/1/2029	3/1/2029 - 4/1/2029	Light Green	SOLID	Set	250.0 MINETM	Set
16	5/1/2029	4/1/2029 - 5/1/2029	Yellow-Green	SOLID	Set	250.0 MINETM	Set

The above dialog can be used to create custom time periods to show in the timing map. The green and red icons at the top of the dialog will add and delete rows of information.

End Date: This column sets the ending date of the period.

Range: This column is automatically generated, and simply identifies the Date Range for the period. Dates may be preceded by > or < to mark indefinite time periods.

Color: This column sets the color of the time period. Double clicking one of these cells will open the CAD color palette.

Pattern: This column sets the hatch pattern for the timing blocks.

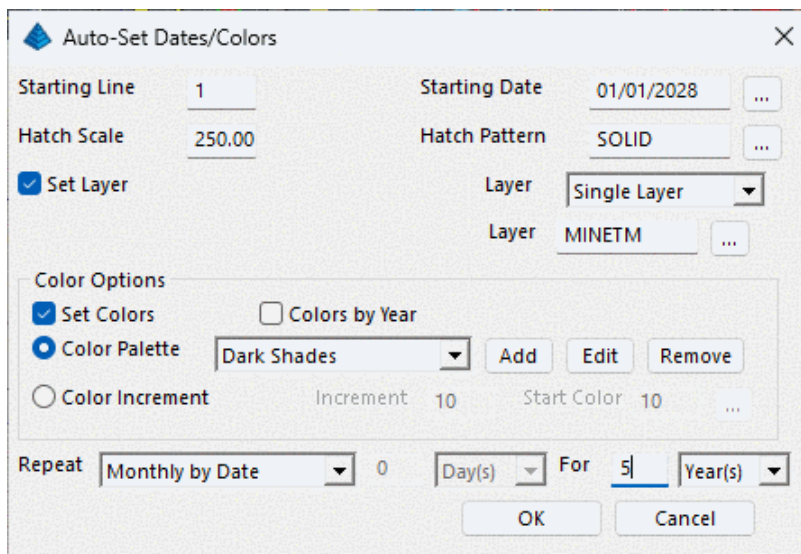

Scale: This column sets the scale of the hatch pattern.

Layer: This column sets the CAD layer on which to draw the timing block.

Label: This column sets a custom label for the timing block.

Clear: This button will clear the table of all information.

Auto Set: This button will open the below dialog, which allows for quick population of the Custom Dates table.

Starting Line: This value will set the row to begin the automatic population of the Custom Date table.

Starting Date: This is the Date From that will be used on the Starting Line. The ellipsis button will open a small calendar to assist in date selection.

Hatch Scale: This value will set the hatch scale for the new time periods.

Hatch Pattern: This field will set the hatch pattern for the new time periods. The ellipsis button will open the list of available hatch patterns.

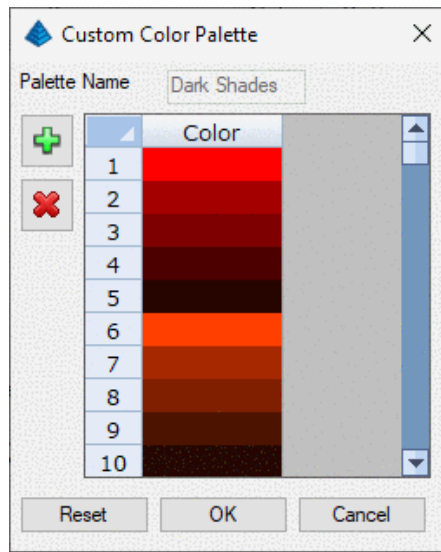

Set Layer: This option will overwrite the Layer names when enabled.

Layer by: This drop list determines how the layers will be populated. If the *Single Layer* option is selected, all layers will be the same, according to the **Layer** text box. If the *Year* option is selected, the layer will be set by the year of the time period.

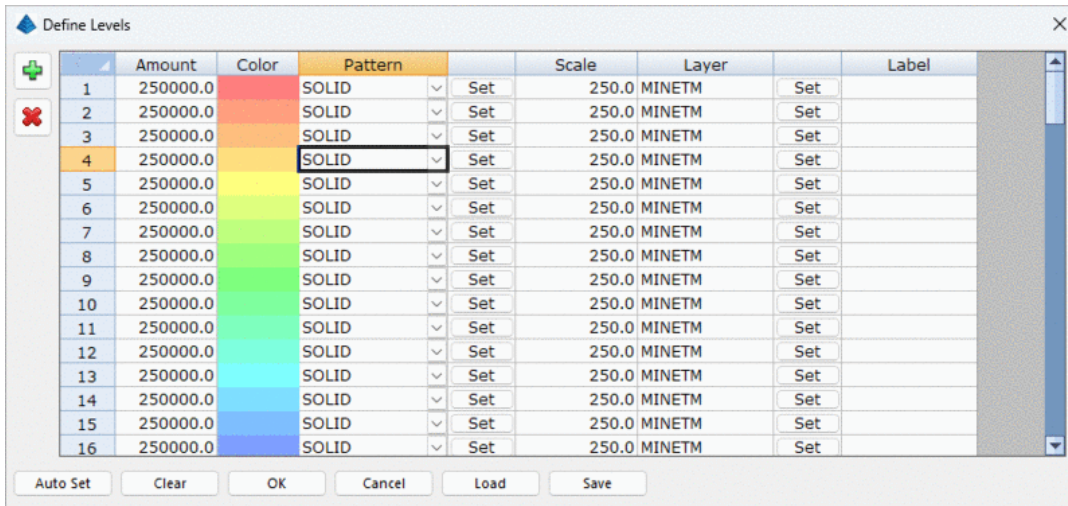

Set Colors: This option will set custom colors for the new time periods. There are two options for setting colors - by using a Color Palette, or by using a Color Increment.

Colors by Year: When this option is enabled, the colors will only increment when the starting date for a row changes. This option is handy for drawing timing maps that have the same color for an entire year, but generate the report on a monthly basis.

Color Palette: This option will use a predefined color palette to color the time periods. When the end of the palette is reached, the colors will start over. Palettes may be added, edited or removed using the corresponding buttons. An example color palette is shown below. Colors may be added or removed from the palette by clicking the Plus or X icons, and colors may be modified by double-clicking them. Any of the predefined palettes may not have their name modified. If you modify the colors in a predefined palette, you may click the **Reset** button to return to the default colors.

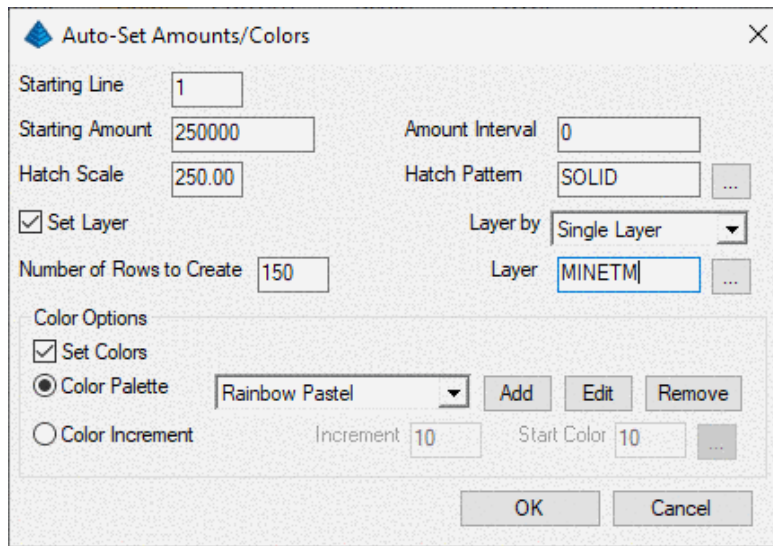

Amounts Table: This button will open the Amounts Table, shown below, which is used to define the various amount intervals used for reporting.

The above dialog is very similar to the Custom Dates table previously discussed. The primary difference is that the dates are replaced with the **Amounts** column. These values may represent one of the following values to be mined, set according to the **Amount Type**:

- Total Tons
- Key Material Tons
- Waste Tons
- Total Area
- Mined Area
- Total Volume
- Key Material Volume
- Waste Volume
- User Grid

Auto Set: This button will open the below dialog, which is very similar to the Auto Set dialog used in the Custom Dates table, as previously discussed. This dialog differs in that amounts are specified rather than dates, and the periods are set to repeat for a set number of times, rather than being based on the dates.

Equipment Table: This button will open the Equipment Table, shown below, which is used to set the colors for each piece of equipment to be reported. This is like a simplified version of the Dates Table and Amounts Table. Here there is no option to set a report period - only the color, hatch, layer, and label for each piece of equipment.

	Equipment	Color	Pattern	Scale	Layer	Label
1	CM-1	Red	SOLID	100	MINETM	CM1
2	CM-2	Yellow	SOLID	100	MINETM	CM2
3	CM-3	Green	SOLID	100	MINETM	CM3

Report Only: This option will not create a timing map; only the mine schedule will be reported. When selected, many other options on the dialog will be ghosted out. This runs much faster than creating a timing map.

Subdivide by Property Lines: This option will sub-divide the report by property owner.

Stop at last period: This option is only available when the Custom Amount Table report option is selected. This option will end the schedule at the last entered user row in the Custom Amount Table.

Draw Legend: This option will draw a color legend of the timing map. The **Legend Size** can be used to make the legend larger or smaller.

Black/White Panel Outline: This option will draw the boundaries of the timing periods with a white/black color as opposed to matching the color of the hatch.

Text Block Label: This drop list will determine how the labels are drawn in the timing map.

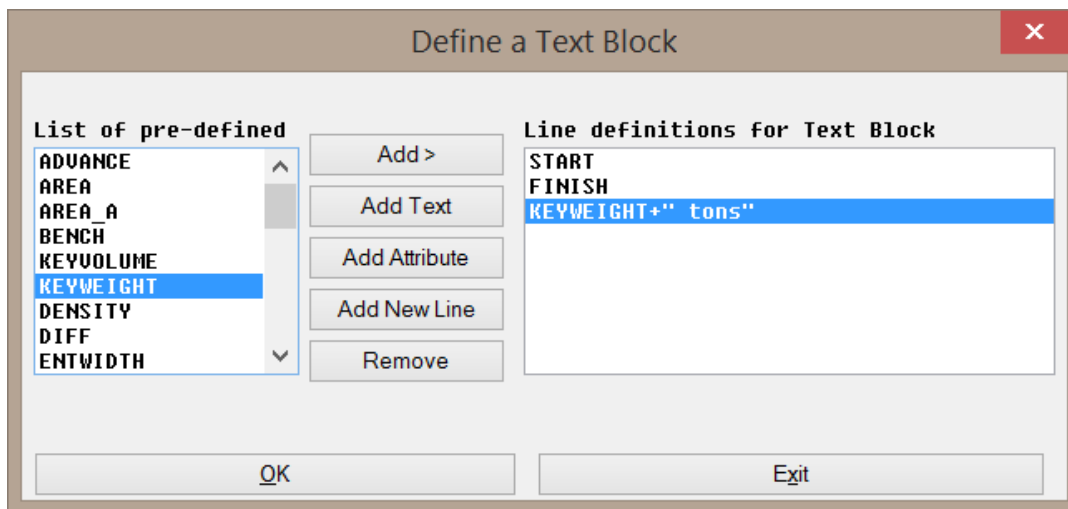

The *No Block Labels* option will not draw labels.

The *Draw Actual Dates* option will label the starting and ending date of each period.

The *Draw Period Names* option will draw labels defined in the Custom Date Table.

The *Use Custom Names* option will draw labels defined in the Custom Amount Table.

The *Use Custom Text Block* option will draw labels according to the below dialog. When selected, the **Text Block Style**, **Add**, **Edit**, and **Remove** buttons will become available. The Text Block Style dropdown list will list all available text block labels. The Add button will create a new text block. The Edit button will edit the currently selected text block. The Remove button will remove the currently selected text block.

The left side of the above dialog contains pre-defined keys that may be used in the labels. The right side of the dialog shows how the text block label will appear.

Add: This button will add the selected attribute to the current line. Multiple attributes may be added to a single line.

Add Text: This button will add custom text to the current line. In the above example, "tons" has been added as a suffix to the KEYWEIGHT attribute.

Add Attribute: This button will add any attribute that is not defined in the pre-defined list. This attribute name must match an attribute available in the final text report.

Add New Line: This button will create a new line in the text block. In the above example, three lines have been created.

Remove: This button will remove the selected line from the text block.

Text Size: This value will set the text size of the block labels.

Text Autosize: This option will automatically size the text of the block labels.

Text Style: This option will set the text style to use for the period labels. The **Select** button will allow you to select one of the existing text styles.

Length-wise labels: This option will rotate the block labels in line with the mining direction of each panel. If not selected, labels will be drawn perpendicular to the mining direction.

Draw Hatch: This option will create boundaries for the timing periods and fill them in with the specified hatch pattern/color.

Retreat Hatch: This option sets the hatch pattern for the retreat hatches. The ellipsis button to the right of this option will open a list of available hatch patterns.

Buffer Hatch/Width: This option will not hatch in the full period, but will instead create a thick boundary of a specified width. The width determines the offset from the perimeter. An example of a Buffer Hatch is shown below.

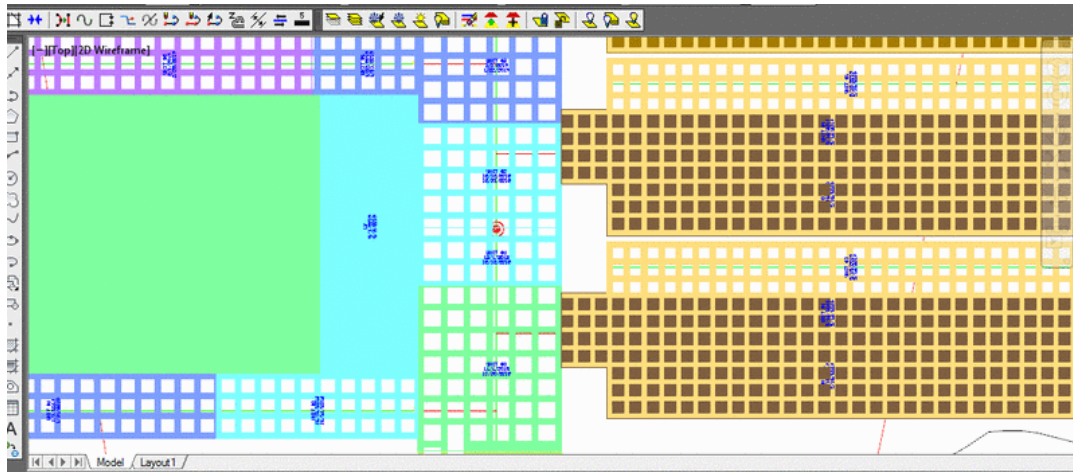

Hatch Transparency: When using the SOLID hatch, this setting controls the transparency of the hatch. The range is from 10%-90%. This allows for viewing the entities behind the hatch. An example of transparent hatches is shown below. Note that if transparency is not used, you would not be able to see the pillars and projection lines behind the hatches.

Divide advance/retreat display: This option will divide the hatches for advance and retreat hatches down the length of the panel. Advance hatches will be drawn on the right of centerline and retreat hatches will be drawn

on the left.

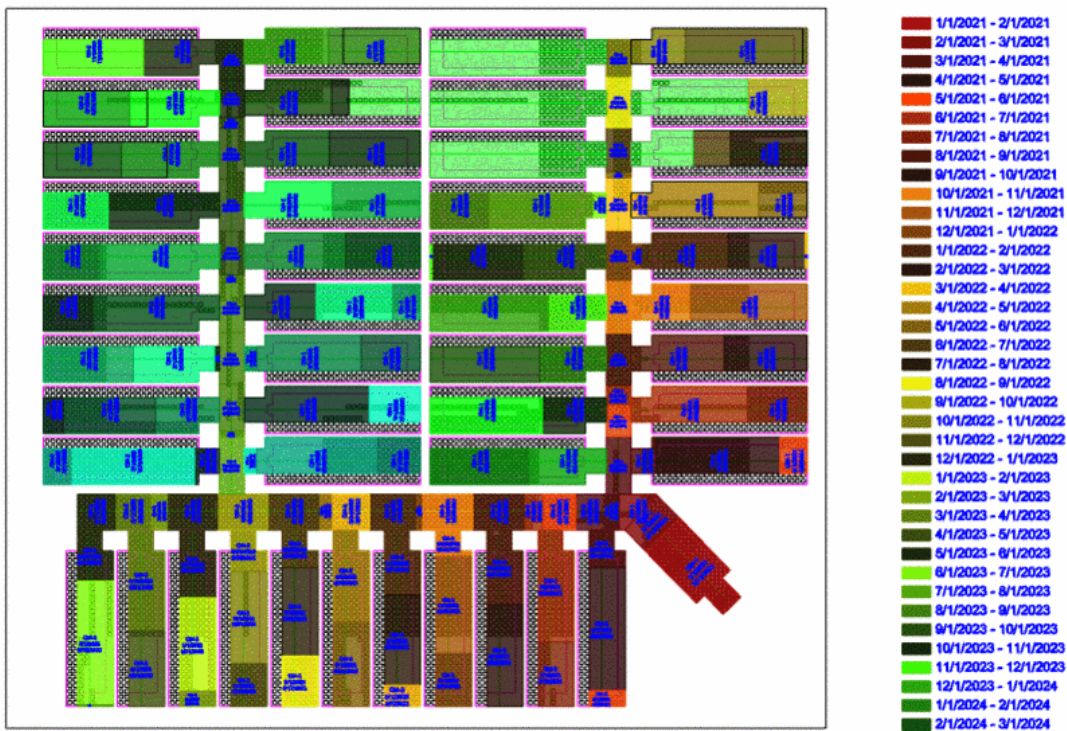

Hatch pillars precisely: Hatches just the entries on the advance, leaving the pillars open. Then if there is retreat mining, the pillars are hatched separately as they are retreat mined.

Output Spatial Database: This option will output the report information to an SQLITE database. The database will retain the coordinate system of the drawing for linkage with GIS software packages. You may specify the file by clicking the ellipsis button to the right of the checkbox.

Skip Report Formatter: This option will skip the report formatter. Rather than customizing the format of the report, the information will be automatically sent to a text file preview.

Examples of a timing map and a generated text report are shown below. Note that there are MANY ways that a timing map and report may be formatted. The Report Formatter is used to generate the text report, but this dialog is not discussed at length here.

5/1/2021 - 6/1/2021	5/6/2021	5/22/2021	CM-2	WM-SOUTH-1 RET	69360.292	0.000	14361.410

There are many attributes available in this report. Most of these attributes are self explanatory, but some are not as clear. The below definitions are therefore provided.

- **Difficulty Factor:** This mining rate factor represents the difficulty of mining a specific area. A value of 1.0 means that mining progresses at a normal rate. This value is the product of the Equipment Difficulty and the Location Difficulty.
- **Equipment Difficulty:** This value is the product of the optional difficulty rates set in the equipment definitions. This can include
 - Date Difficulty
 - Thickness Difficulty
 - Bench Difficulty (Surface Mining Module only)
- **Location Difficulty:** This value is a difficulty factor determined by a hierarchy of the following three options. If the high priority item is detected, it will be used instead of the other two options. If the high priority option

is not detected, the medium priority item will be used. If neither of these items are detected, the low priority item will be used. The low priority item defaults to a value of 1.0, so if no location difficulty is defined, the mining rate will not be affected.

- Highest priority: text in the drawing on the DIFFICULTY layer
 - Medium priority: DIFFICULTY attribute value/grid in the Timing Project Manager Attribute Groups
 - Lowest priority: Difficulty value assigned to the specific panel (set with the EDIT_PANEL command)
- Calendar Days: Actual period length between start date and end date (allows for partial days). Note that a day is not necessarily a 24 hour period, but is instead defined by the equipment definition. For example a piece of equipment working two 8-hour shifts means that one calendar day is equivalent to 16 hours.
 - Operating days: Scheduled shifts divided by number of shifts per day (as defined in equipment definition)
 - Days: Scheduled Hours divided by day length in hours (as defined in equipment definition). Note that if all shifts are the same length, this attribute will be the same as the Operating Days.
 - Weekdays Worked: Shifts scheduled on weekdays divided by number of shifts per day
 - Saturdays Worked: Shifts scheduled on Saturdays divided by number of shifts per day
 - Sundays Worked: Shifts scheduled on Sundays divided by number of shifts per day
 - Days Waiting: Number of days equipment cannot work due to a precedence rule
 - Work Shifts: Number of scheduled work shifts. A shift that is not scheduled to work (due to a Calendar Delay) will not contribute to this value.
 - Hours Scheduled: Number of hours equipment is scheduled to work (this includes Hours Utilized, Hours Delayed, and Hours Available)
 - Hours Down: Number of hours equipment is not scheduled to work (due to downtime scheduled on the calendar)
 - Hours Utilized: Number of hours equipment is actually working
 - Hours Delayed: Number of hours equipment is delayed due to a Drawing Event or Scheduled Delay (note, this is not the same as Hours Down caused by a Calendar Delay). Note that a Scheduled Delay will appear on the Assignment List for each piece of equipment
 - Hours Available: Number of hours is scheduled to work, but is neither being utilized nor is it actually delayed. If a piece of equipment encounters a delay during the middle of the shift, the partial shift time remaining will be counted as Hours Available (the delay will be applied to the next shift)

The below image helps visualize the organization of the different definitions of Hours.

Hours in a day	Hours Scheduled	Hours Utilized
		Hours Delayed
	Hours Available	
	Hours Down	

Undo Report: This button will delete a previous timing map and clear the calculated schedule. This allows for quick what-if analysis of the scheduling.

Events Report: This button will display the Events Report, which lists all Drawing Events encountered during the mine schedule. Drawing Events are discussed in more detail in the Timing Project Manager. This report is only available after a Detailed Report has been generated. An example of the Events Report is shown below.

Events Report Wed Dec 30 11:55:49 2020

Event Key	Event Layer	Description	Period	Unit	Pit/Panel Name
Belthead	Belthead	Belthead Installation	1/1/2021 - 2/1/2021	CM-1	NORTHWEST_MAINS
Belthead	Belthead	Belthead Installation	2/1/2021 - 3/1/2021	CM-1	NORTHWEST_MAINS
Belthead	Belthead	Belthead Installation	2/1/2021 - 3/1/2021	CM-1	WEST_MAINS <B:1>
Belthead	Belthead	Belthead Installation	3/1/2021 - 4/1/2021	CM-1	NORTH_MAINS_1 <B:1>
Belthead	Belthead	Belthead Installation	3/1/2021 - 4/1/2021	CM-2	WEST_MAINS <1:2>

Monthly Report: This button will generate a monthly report, similar to the Detailed Report, but with less information available and without the ability to set custom time periods for reporting. An example of the Monthly Report is shown below.

Monthly Unit Report Wed Dec 30 11:57:08 2020

Unit	Month	Year	Operating days	Days Weekdays Worked	Saturdays Worked	Sundays Worked	Calendar days
CM-1	January	2021	23.00	23.00	20.00	3.00	31.00
CM-1	February	2021	22.00	22.00	20.00	2.00	28.00
CM-1	March	2021	25.00	25.00	23.00	2.00	31.00
CM-1	April	2021	24.00	24.00	22.00	2.00	30.00
CM-1	May	2021	23.00	23.00	21.00	2.00	31.00
CM-1	June	2021	24.00	24.00	22.00	2.00	30.00

Gantt Chart: This button will generate a Gantt chart of the mine schedule. This button is only available after calculating the mine schedule. For more information, see the Gantt Chart section of the help manual.

Utilization Report: This button will generate a Utilization Report of the mine schedule. This report lists each shift for each piece of equipment. Scheduled delays will be reported as such. An example of the Utilization Report is shown below.

Event Date	Shift	Year (start)	Month/Year	Unit	Equipment	Type	Calendar Rule
1/1/2021	1	2021	01/2021	CM-1	CM-1	Scheduled down	New Years Day
1/1/2021	2	2021	01/2021	CM-1	CM-1	Scheduled down	New Years Day
1/1/2021	1	2021	01/2021	CM-2	CM-2	Scheduled down	New Years Day
1/1/2021	2	2021	01/2021	CM-2	CM-2	Scheduled down	New Years Day
1/1/2021	1	2021	01/2021	CM-3	CM-3	Scheduled down	New Years Day
1/1/2021	2	2021	01/2021	CM-3	CM-3	Scheduled down	New Years Day
1/2/2021	2	2021	01/2021	CM-1	CM-1	DELAY	
1/2/2021	1	2021	01/2021	CM-1	CM-1	UTILIZATION	
1/2/2021	1	2021	01/2021	CM-2	CM-2	AVAILABLE	

Back to Project: This button will return to the Timing Project Manager window.

If a mine has multiple levels with similar panels stacked above one another, a special set of layer names must be used when creating the panels to allow for the distinction between levels. The key to distinguishing mining levels is setting the linework on the correct layer names, which must use a suffix similar to '_LEVELX'. For example, the mine plan in the below figure has three levels. The linework for the first level includes the following layers: MINEPLTX, PILLARS_LEVELX, MINEPLAN, and PERIM_LEVELX. When these panels were made using the Auto Place Panel by Text, the panel name was on a layer named PANELNM_LEVEL1 and the panel perimeter was on a layer named PERIM_LEVEL1. Levels 2 and 3 were made in a similar fashion, but with the respective level name as the suffix for each layer. Although it isn't necessary, the linework for each level in the below image has been drawn at a specific elevation to allow for further visual inspection by the 3DORBIT command.

After the panels have been created, you may also inspect the mining level via the Edit Panel command, which will allow you to enter the Level Layer Suffix, as outlined in red below.

Prompts

Select any part of mine plan: *Pick any centerline in the mine plan*
Underground Timing Dialog

Pull-Down Menu Location: Underground

Keyboard Command: schedule_mine

Clear Timing Map

Removing the coloring after the timing routines are completed may be a tedious task. This routine removes and erases all text labels and hatching from surface pits and underground panels for a specific bench or mining direction in one step. It is a quick and efficient procedure, even for objects on many layers. Items are permanently removed from the drawing screen. It supports both surface and underground mining.

Prompts

For Underground Timing:

Remove coloring for [Advance/Retreat/<Both>]?

Select parts of mineplan to have timing coloring removed:

The following drawings show panels with blocks colored and without blocks colored after using Clear Timing Report.

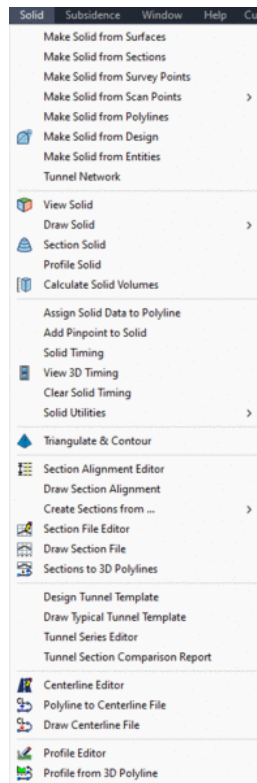

Pulldown Menu Location: Underground

Keyboard Command: utime_clear

Solid Menu

The top portion of the Solid menu has commands specific to the Underground Mining module and are explained in this chapter. The bottom portion of the menu has commands for cross sections and centerlines which are explained in the Civil module of the manual.

Make Solid From Surfaces

This command creates a solid model using TIN surfaces for the roof and floor plus perimeter polylines. This method for creating a solid model applies when there are survey points on the roof, floor and walls.

The TIN surfaces can be prepared with routines like Triangulate & Contour in the Civil module. In Triangulate & Contour to build the roof surface, turn on the option to Write Triangulation File and select the roof points. Then repeat Triangulate & Contour to build the floor surface by selecting the floor points.

The perimeter polylines represent the walls of the solid and can be either 2D or 3D polylines. For 3D, the polylines should have elevations between the floor and roof. If there are survey points on the walls, these can be connected into 3D polylines by using commands like Draw 3D Polyline. Multiple 3D polylines can be used to create the solid model. 3D polylines that are inside other 3D polylines are used as exclusion areas for the solid model and create holes in the model. To build the solid model, the program connects the 3D polylines to the roof and floor surfaces.

For 2D perimeters, the polyline is used to crop the top and bottom surfaces. The solid is built by then connecting the top and bottom surfaces.

3D rib polyline and survey points

3D view of solid model

Prompts

Top Surface To Read *Select TIN file*

Bottom Surface To Read *Select TIN file*

Select rib polylines.

Select objects: *pick 3d polyline(s)*

Solid File To Write *Select MDL file*

Example Workflow

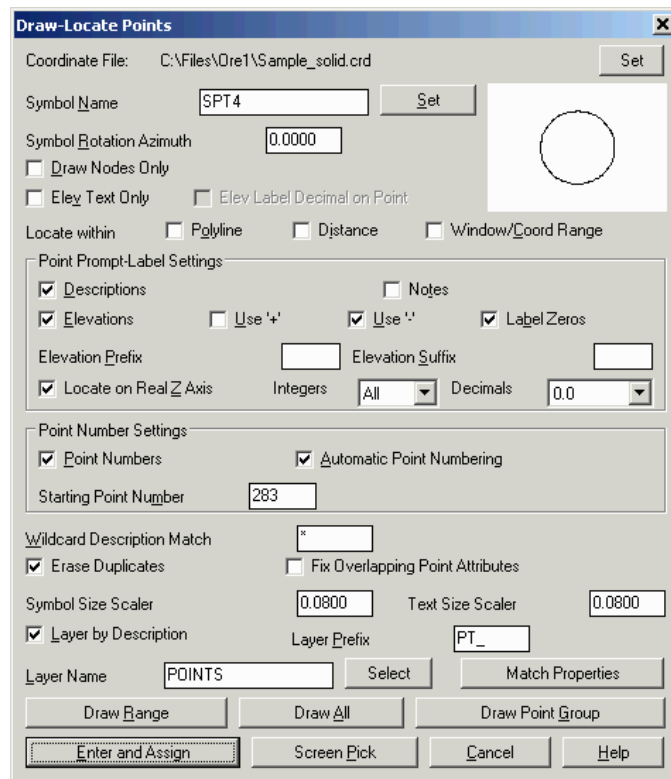

This example uses survey point data to build the solid by creating the rib 3D polyline and top and bottom surfaces.

Step 1: Import Points

From a new drawing, run **Points > Set Coordinate File** and select a coordinate file named sample_solid.crd from the Carlson Projects folder.

To have the points drawn at a good size, run **Settings > Drawing Setup** and set the Horizontal Scale to 10 and the units to English.

Next run **Points > Draw/Locate Points** and turn on the option to **Layer By Description** and then pick **Draw All**. In this example, the points have different description codes to identify roof, floor and rib points.

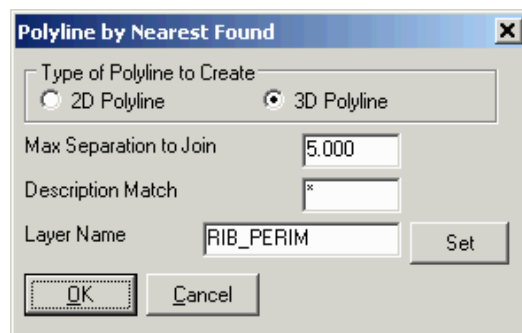

Step 2: Draw Rib 3D Perimeter Polyline

There are two codes of "R" and "P" for points on the perimeter. To view only the perimeter points, run **View > Isolate Layers** and pick on a point with a "R" description and a point with a "P" description.

Next run **Draw > Polyline > Polyline By Nearest Found**. Set the type to 3D Polyline, the max separation to 5 and the layer to RIB_PERIM.

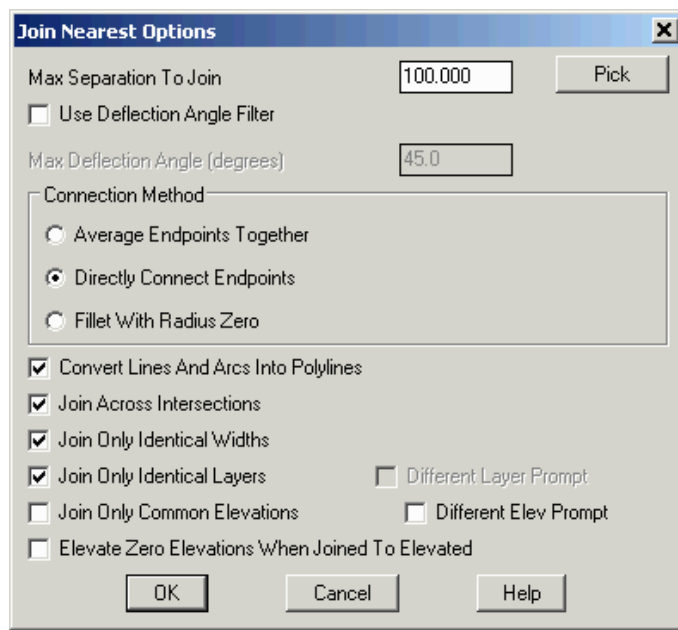

Then choose the Screen selection mode and then select all the points.

Select point from screen or by point number [<Screen>/Number]? *press Enter*

Select points.

Select objects: *all*

The Polyline By Nearest Found connected the points except for the large gaps. To create a single closed polyline and span these gaps, run **Edit > Join Nearest**. Set the max separation to 100 and the method as Directly Connect Endpoints.

Then select all the polylines to be connected.

Select lines, arcs and unclosed polylines to join.

Select objects: *all*

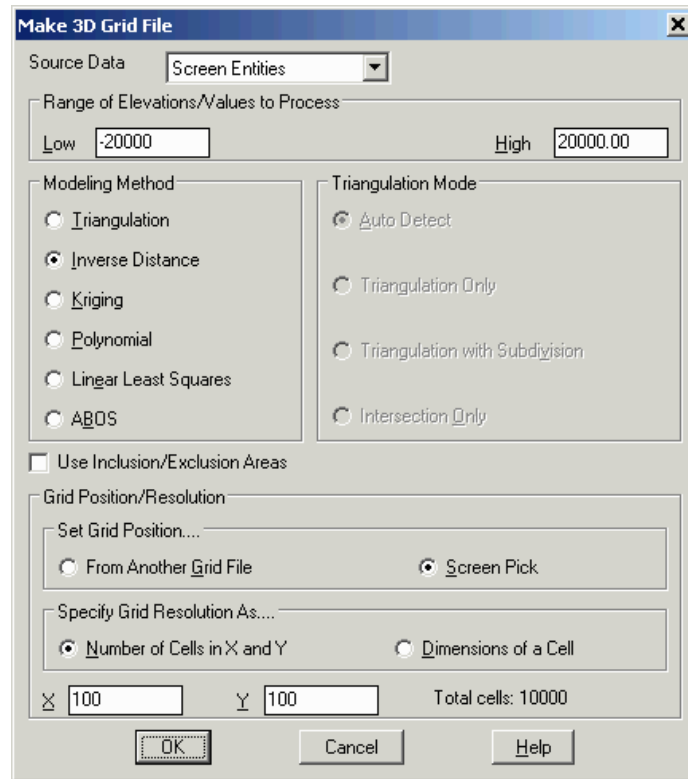

Step 3: Draw Top and Bottom Perimeter Polylines

To use for building the top and bottom surfaces, the next step is to create top and bottom 3D perimeter polylines. First, turn all the points back on by running **View > Restore Layers**.

The bottom points have a description of "S". Run **View > Isolate Layers** and pick on a "S" point.

To elevate the perimeter polyline at the bottom surface, a grid file is a good way to extrapolate the bottom points to

cover the perimeter. Run the **Surface > Make 3D Grid File** command from the Civil module. Set the file name as bottom.grd. In the options dialog, set the method as Inverse Distance and the grid position as Screen Pick.

For the grid corners, pick a large window around the points to generously make an area large enough to cover the perimeter.

Pick first grid corner: *pick the lower left point*

Pick opposite grid corner: *pick the upper right point*

Select points, lines, polylines and faces to grid from.

Select objects: *all*

Reading points ... 29

Use inverse distance to which power [First/<Second>/Third/Other]? *press Enter*

Use elliptical inverse distance [Yes/<No>]? *press Enter*

Now that we have this bottom surface, we can create a bottom 3D perimeter polyline. Turn on all the layers again by running **View > Restore Layers**. Then run **3D Data > 2D to 3D Polyline > By Surface Model** from the Civil model. Choose the bottom.grd as the surface to process. Pick the rib polyline as the polylines to convert. Be sure to answer YES to the Keep Existing Polyline prompt. Set the layer to BOT_PERIM.

Select polylines to convert.

Select objects: *pick the rib polyline*

Use current polyline elevations as vertical offset from surface [Yes/<No>]? *press Enter*

Keep existing polylines [Yes/<No>]? *Y*

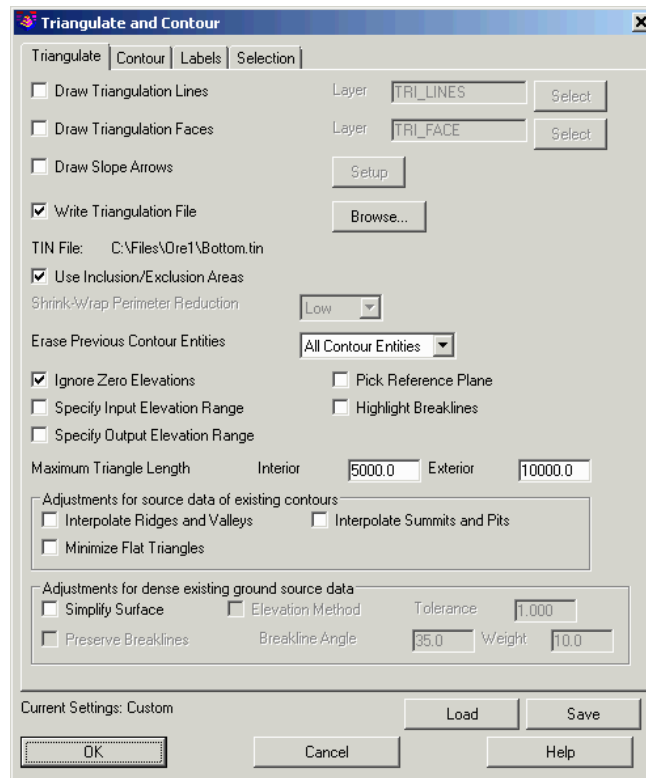

The bottom perimeter polyline is done. Now let's create the top perimeter polyline using the same procedure. Run **View > Isolate Layers** and pick on a point with a "B" description. Run **Surface > Make 3D Grid File** again and use the same inputs except create a grid called top.grd. Then turn the layers back on by running **View > Restore Layers**. Next run **3D Data > 2D to 3D Polyline > By Surface Model** and pick the rib polyline as the polyline to convert, answer YES to the Keep Existing Polyline and set the layer to TOP_PERIM.

Step 4: Create Top and Bottom Surfaces

The data is prepared and now the surfaces can be created. Let's build the bottom surface first. Since the perimeter polyline for rib, top and bottom are on top of each other, it is tricky to select them individually. Run **View > Layer Control** and freeze the layers for RIB_PERIM and TOP_PERIM. Then run **View > Isolate Layers** and pick on a "S" point and the bottom perimeter polyline.

Next run Surface > Triangulate & Contour. On the Triangulate tab, turn on Write Triangulation File and set the file to bottom.tin. Also, turn on Use Inclusion/Exclusion Areas. On the Contour tab, turn off Draw Contours.

Pick OK on the dialog. Then select the perimeter polyline for the Inclusion perimeter. For the Exclusion perimeter prompt, press Enter for none. Then for the select points prompt, type ALL.

Select Inclusion perimeter polylines or ENTER for none.

Select objects: *pick perimeter polyline*

Select Exclusion perimeter polylines or ENTER for none.

Select objects: *press Enter*

Select points and breaklines to Triangulate.

Select objects: *all*

The bottom surface is all done. Now let's create the top surface. Run View > Restore Layers. Then run View >

Layer Control to thaw the TOP_PERIM layer and freeze the BOT_PERIM and RIB_PERIM layers. Then Run View > Isolate Layers and pick on a "B" point as well as the perimeter polyline.

Then run Surface > Triangulate & Contour. Set the TIN file to write as top.tin and then pick OK. At the command line, select the perimeter polyline as the Inclusion and select all for the points to triangulate.

Step 5: Create Solid Model

We need to view the rib perimeter polyline for creating the solid. Run **View > Layer Control** to thaw the RIB_PERIM layer and freeze the TOP_PERIM and BOT_PERIM layers.

Finally, run **Solid > Make Solid From Surfaces**. Select the top and bottom surfaces created in step 4 and the rib polyline created in step 2. Then specify the solid model file name to create.

Top Surface To Read *Select TOP.TIN file*

Bottom Surface To Read *Select BOTTOM.TIN file*

Select rib polylines.

Select objects: *pick rib polyline*

Solid File To Write *Enter a file name*

Pulldown Menu Location: Solid

Keyboard Command: make_solid

Prerequisite: 3d perimeter polyline and two surface files

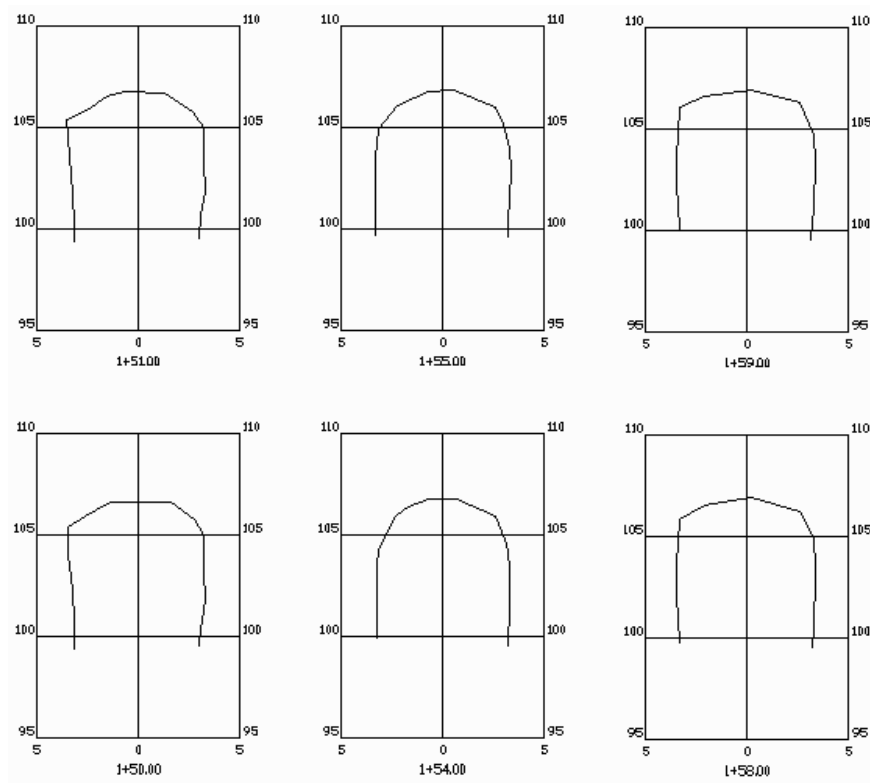

Make Solid From Sections

This command creates a solid model using cross sections and a centerline alignment. For example, tunnel cross sections can be used for this method.

The cross sections can be prepared with the Create Sections routines in the Solid menu. There are also routines to prepare the centerline file in the Solid menu.

The settings dialog has an option to Merge With Existing Solid for merging the solid model for the new cross section data with an existing solid model. This option applies to combining data for intersection tunnels. The Merge Tolerance is the distance for replacing the previous solid model data points with the new data points.

To build the solid model, the program connects the data between the cross section stations and caps the solid model at the ends.

Prerequisite: cross sections and centerline files

Make Solid From Survey Points

This command creates a solid model from survey points on the roof and floor plus a 3D perimeter polyline. This method applies to input data of relatively few data points compared to a point cloud. All the data points must be on the roof or floor and not the sides. The roof and floor points must be drawn on separate layers that the program prompts for in the options dialog.

The solid is built by modeling a surface from the roof points and a separate solid from the floor points. The surfaces are trimmed by the perimeter polyline and then stitched together with the perimeter polyline to make a watertight solid. The resulting solid is stored to the specified MDL file.

In the example shown here, points 1 to 6 are on the ROOF layer and points 7 to 12 are on the FLOOR layer. The perimeter polyline is shown in 3D between these points.

Make Solid From Points By Poisson

This command creates a solid model from a collection of x,y,z points by using the Poisson method. The points need to cover all sides of the surface (top, bottom, left, right, front, back). The Poisson method is a 3D surface

reconstruction algorithm employed to rebuild 3D surfaces from point samples. The screened Poisson formulation considers all the points at once, without resorting to heuristic spatial partitioning or blending, and is therefore highly resilient to data noise. Since the input for this routine uses points in the drawing, the difficulty of CAD to handle a very large number of points limits the number of points this routine can process. This function is also available in the Point Clouds module which stores the data outside of CAD and can process more input points.

The program prompts for CAD point entities in the drawing as the input for the model. Next the program has a dialog for the processing options.

The solid model is designed to follow the source points but does not exactly pass through each point. The options in the dialog control how well the model fits the points and has options for reviewing how well the model fits.

Tolerance: Indicates how much noise is expected in the point data. This setting helps remove outlier points. If the resulting surface is too spikey, adjust this value higher.

Precision: Controls pre-processing calculations. A smaller value results in a tighter solid.

Range: Controls how far the model looks for connecting points. If the solid does not span over expected gap areas, raise this value higher. If the solid spans over unexpected areas, lower the value.

Tightness: Controls the density of the triangles. The higher the value, the smaller the triangles of the resulting solid.

Report Residuals: Reports the residual distances between the source points and the solid model.

Draw Projection Lines: Draws lines from the source points to the solid model.

Smooth points before triangulation: This option applies a moving least-squares smoothing to the points to reduce noise. The Save Sparse Points controls whether to save sparse points which would be thrown out with point smoothing. If points do not have at least 3 neighboring points within the search radius they are discarded. This setting will preserve them.

Make Solid From Points By Sections

This command creates a solid model from a collection of x,y,z points by creating cross sections from the points and then stitching the sections together.

Here is an example of an underground cavity with data points all around: top, bottom and sides. One way to model this case is to set the Model Type to Closed, Triangulate Ends to 3D TIN and Section Alignment to Vertical.

Plan view of data points

Resulting 3D Solid colored by normal and showing edges

Here is an example of a tunnel with points at a section interval. For this case, use the CAD Orbit command to rotate the CAD view so that you're looking down the tunnel. Then in this command, set the Section Interval to match the data, Model Type as Closed, Section Alignment as Current 3D View and Triangulate Ends as None.

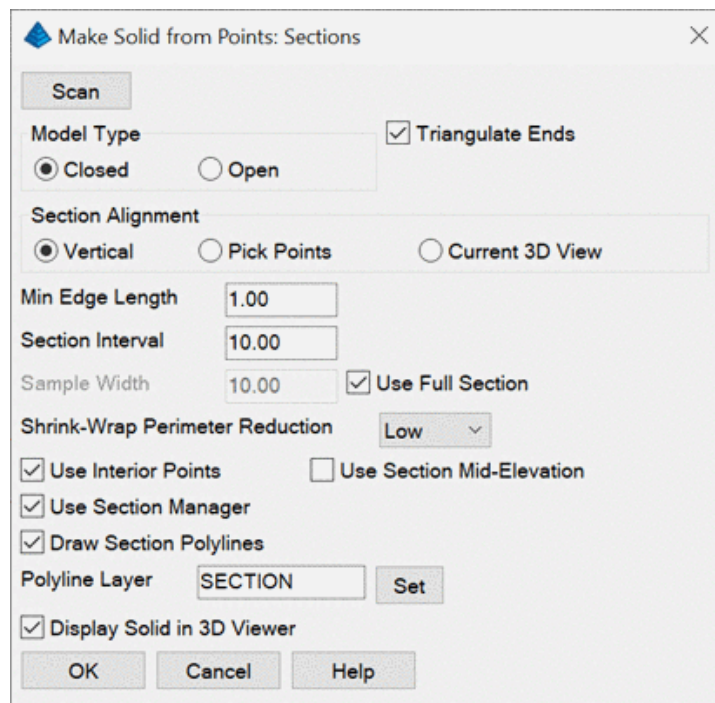

CAD 3D View from Orbit aligned with tunnel

Resulting 3D Solid

colored by normal and showing edges

Scan: Reads the input points to find the min and max elevations which are reported at the top of the dialog.

Model Type: Controls whether to create a watertight closed solid such as an underground cavity, or create an open surface solid such as a cliff face. For a Closed model, the points need to cover all sides of the surface (top, bottom, left, right, front, back).

Triangulate Ends: Controls whether to triangulate and cap off the end sections. The By Section method triangulates the section end polylines. The 3D TIN method triangulates all the end points. The None method leaves the ends open such as for a tunnel.

Section Alignment: Sets how to section the points. It is important to align the sections with the data to get good sections. For example, with a tunnel the alignment should go along the length of the tunnel so that the sections are

like slicing a carrot into discs. The Vertical method slices by elevation range. The Pick Points method prompts for two points and uses the 3D line between these points for the alignment. The Current 3D View method uses the CAD view. This way you can use the CAD 3D view commands to line up a good view for the points.

Min Edge Length: Sets the minimum length of a triangle edge in the solid. When there are several points closer than this distance to each other, some of these points will be left out of the solid model.

Section Interval: Sets the distance between sections along the alignment. This distance needs to be big enough to ensure that plenty of points are used for each section, and the distance needs to be small enough to create enough sections to model the solid.

Sample Width/Use Full Section: Controls whether to use all the data points between sections or limit the data points to the specified distance from the section line.

Shrink-Wrap Perimeter Reduction: The program triangulates the points for each section and uses the boundary of this triangulation for the section. This option controls how much to tighten this boundary polyline by removing long edges.

Use Interior Points: This option shrink-wraps the interior points and then finds the median with the outer shrink-wrap to create the section polyline.

Use Section Mid-Elevation: Controls whether the section lines use the individual elevations of the data points or the same average elevation for the section.

Use Section Manager: This option shows the generated sections in an editor for making changes before building the model. See the Edit Solid topic for more information on this feature.

Draw Section Polylines: This option draws 3D polylines for the sections on the specified layer.

Display Solid in 3D Viewer: This option will automatically run the 3D Viewer for the resulting solid at the end of the command.

Prerequisite: points

Make Solid From Points By 3D Triangulation (Projection)

This command creates a solid model from a collection of x,y,z points using the projection or "greedy" 3D triangulation method. The points need to cover all sides of the surface (top, bottom, left, right, front, back).

Number of points for normal estimate: For each point, the program calculates the normal using the specified number of neighboring points.

Max number of points for triangulation: The number of points to consider when connecting each point. More points should increase accuracy, but increase run time.

Maximum edge length of surface triangle: Sets the maximum distance for 3D triangulation to connect points.

Minimum angle: The minimum acceptable interior angle of a triangle which is used to make up the triangulated mesh.

Maximum angle: The maximum acceptable interior angle of a triangle which is used to make up the triangulated mesh.

Filter points that are too close: Sets the minimum length of a triangle edge in the solid. When there are several points closer than this distance to each other, some of these points will be left out of the solid model.

Smooth Input Points: This option applies a moving least-squares smoothing to the points to reduce noise which can help a lot with calculating the normals and improving the triangulation. The Save Sparse Points controls whether to save sparse points which would be thrown out with point smoothing. If points do not have at least 3 neighboring points within the search radius they are discarded. This setting will preserve them.

Remove interior points: Runs a routine to remove the interior points of the data set. The routine checks that points fall within a triangulated mesh of varying triangle sizes. Using smaller triangles should capture more detailed exterior surfaces, but are prone to labeling interior points as exterior points. Larger triangles will capture less surface detail but are more likely to drop interior points. The triangle size is set by "Minimum edge of triangle".

Consider neighbor triangles surface angle: Whether to limit the rotation between neighboring triangles on the mesh surface. Considering it will limit the possible rotation angle to user-specified setting in degrees. 0 would require a totally flat surface, 90 degrees would allow for a cube surface.

Heal holes in triangulation: triangulates across small holes in the solid that remain after the 3D triangulation so that the final surface is watertight.

Prompts

Prerequisite: points

Make Solid From Points By 3D Triangulation (Tunnel)

This command creates a solid model from a collection of x,y,z points and an alignment polyline using the 3D triangulation. The points need to cover all sides of the surface (top, bottom, left, right). The alignment polyline needs to be a 3D polyline that goes through the center of the points for the entire length.

Min Edge Length: Sets the minimum length of a triangle edge in the solid. When there are several points closer than this distance to each other, some of these points will be left out of the solid model.

Max Edge Length: Sets the maximum distance for 3D triangulation to connect points.

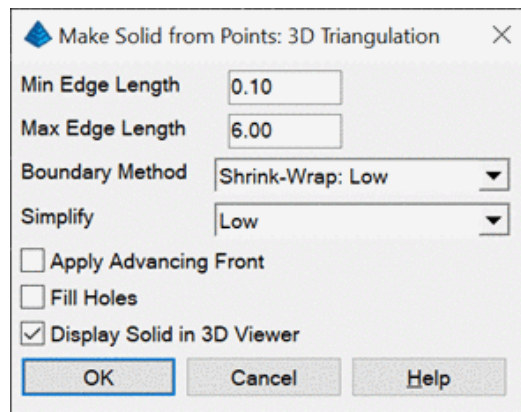

Boundary Method: controls how tightly the solid model wraps around the perimeter points.

Simplify: removes points that cause steep triangles.

Apply Advancing Front: expands the solid by adding triangles to unconnected edges.

Fill Holes: triangulates across small holes in the solid.

Display Solid in 3D Viewer: automatically runs the View Solid command with the model results.

This example of a tunnel shows the input points in CAD along with the alignment polyline along the center of the train tracks and then the resulting solid model viewed with color by normal.

Make Solid From Points By 3D Triangulation (Advancing Front)

This command creates a solid model from a collection of x,y,z points using the "advancing front" 3D triangulation method. The points need to cover all sides of the surface (top, bottom, left, right, front, back).

Min Edge Length: Sets the minimum length of a triangle edge in the solid. When there are several points closer than this distance to each other, some of these points will be left out of the solid model.

Max Edge Length: Sets the maximum distance for 3D triangulation to connect points.

The rest of these options apply to expanding and improving the solid after the 3D triangulation has connected all the points that it can.

Extrapolate Across Gaps: looks for large gaps in the input data and uses a Poisson model points to fill in those gaps.

Remove Dangles: removes triangles that are not connected to the majority of the solid model.

Apply Advancing Front: expands the solid by adding triangles to unconnected edges.

Fill Holes: triangulates across small holes in the solid.

Make Solid From Design

This command creates a solid model using a tunnel template, centerline and profile. The tunnel template defines the cross section. The centerline defines the horizontal alignment and the profile define the vertical alignment. Using the design files, the program creates a cross section for the solid at the specified station interval along the alignments.

Before running this command, the design files must already be created. The tunnel template is created with the Design Tunnel Template command. The centerline can be created by many commands including Centerline Editor. The profile can be created by many commands including Profile Editor.

Use 3D Polyline For Alignment: prompts for a 3D polyline for the horizontal and vertical alignment instead of using centerline and profile files.

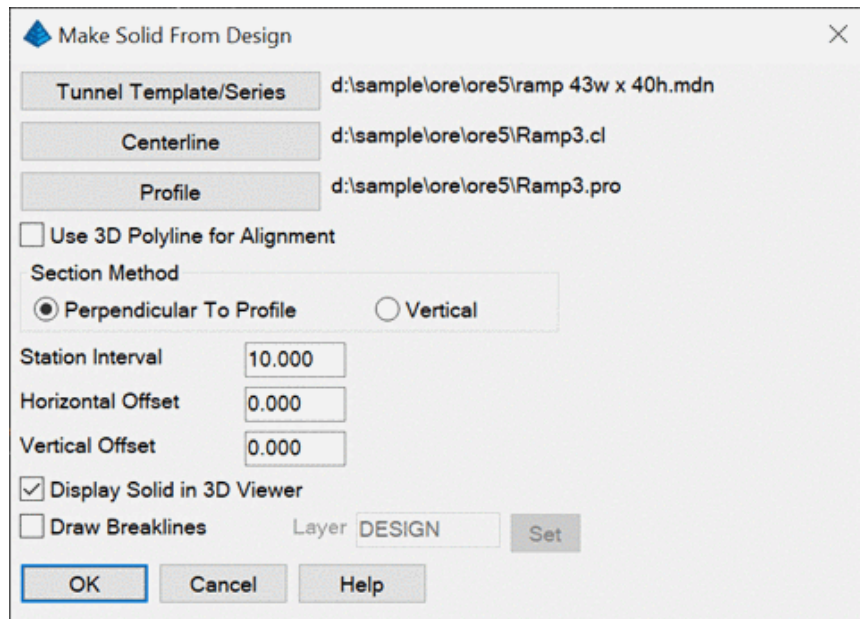

Section Method: controls whether to create the tunnel sections perpendicular to the profile slope or vertical.

Station Interval: sets the interval to create tunnel sections along the alignment.

Horizontal and Vertical Offset: shifts the tunnel template from the alignment such as for a circular template with the profile in the center.

Display Solid in 3D Viewer: automatically runs the View Solid command with the design results.

Draw Breaklines: creates 3D polylines for sections of the design at the station interval.

Make Solid From Entities

This command creates a .mdl graphics files from selected 3D faces. These graphic files are used in 3D viewing commands like 3D Drive Simulation. The Settings > 3D Model Library manages these graphics files. The .mdl file is also used for Solids in the Underground Mining module.

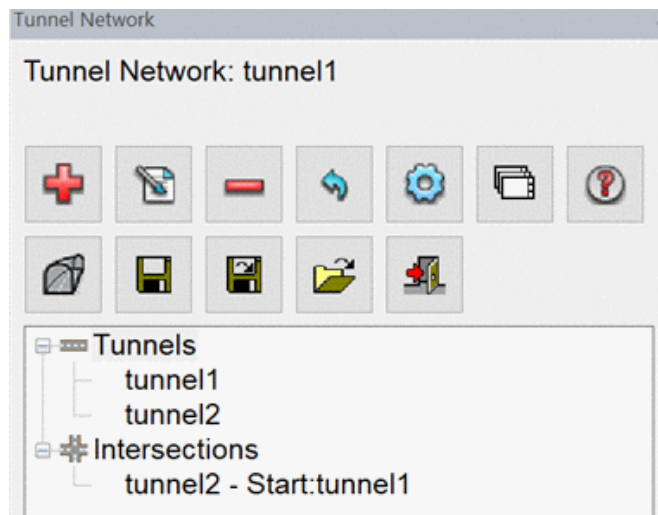

Pulldown Menu Location: Solid

Keyboard Command: dwg2mdl

Prerequisite: 3D faces

Tunnel Network

This command creates a solid model of one or more tunnels. Each tunnel is defined by a centerline, profile and cross section template. This design method is the same as the Make Solid From Design command. The additional ability of Tunnel Network is to process multiple tunnels together. This command automatically finds intersections for tunnel centerlines. At each intersection, the program has controls for how to connect the tunnels.

All the model data is stored in a .TNET file and the program starts by prompting for the TNET file to process. Then the Tunnel Network dialog docks on the side of the screen. The top row of functions are:

Add: To add another tunnel to the model.

Edit: To edit the highlighted tunnel or intersection.

Remove: To remove the highlighted tunnel from the model.

Reset: To reset the highlighted intersection to defaults.

Settings: Tunnel Network settings.

New: Create a new TNET model.

Help: Carlson Manual.

The second row of functions are:

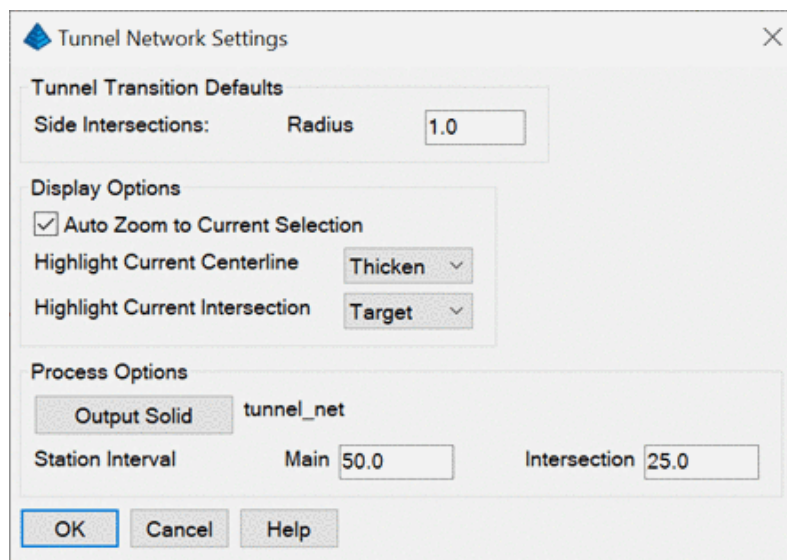

Process: Run the model and create the MDL solid.

Save: Save the current settings to the TNET file.

SaveAs: Save to another TNET file.

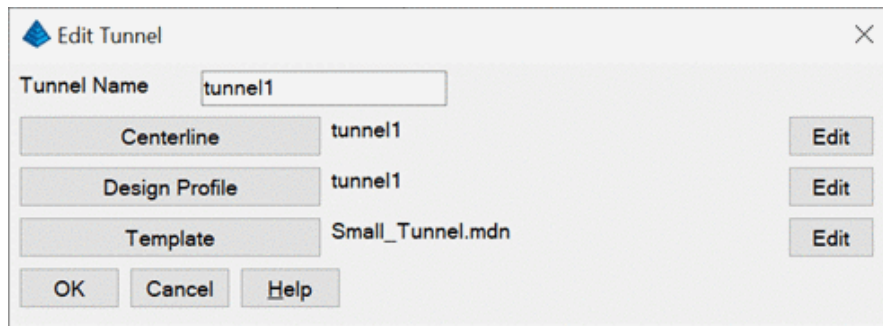

Load: Load another TNET file.

Exit: Close the Tunnel Network program.

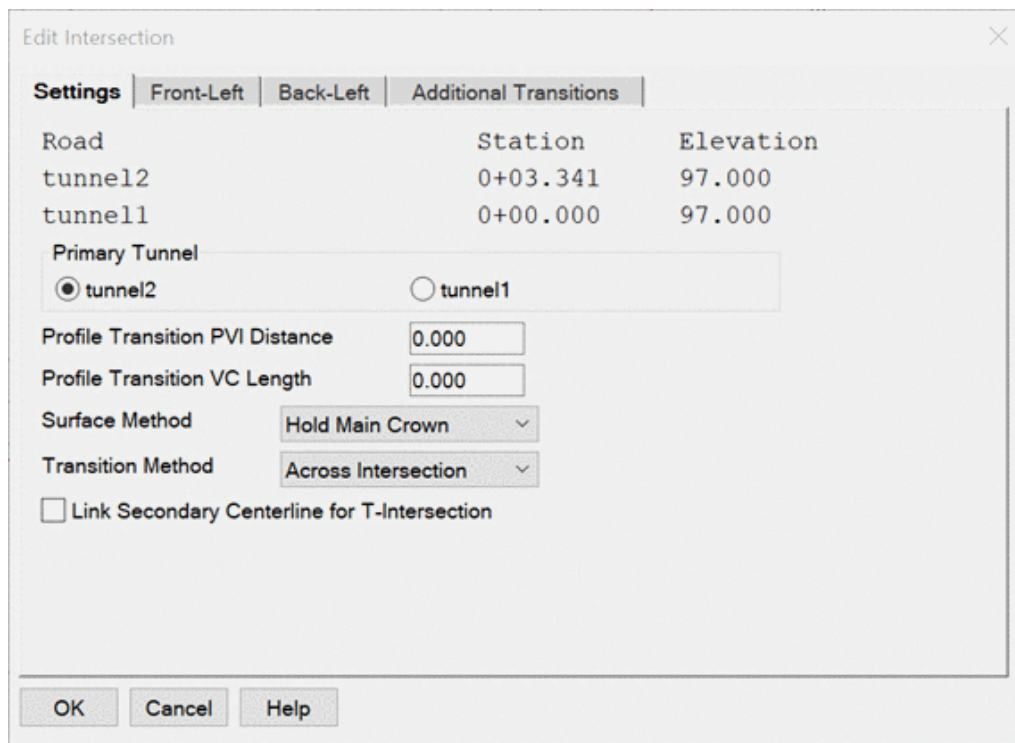

In Tunnel Network Settings, the **Radius** is the default to use for the sides of the tunnels at intersections. The **Display Options** control how to highlight tunnel items in the drawing when they are selected from the Tunnel Network project tree dialog. **Output Solid** sets the name of the MDL to create. The **Station Intervals** control when

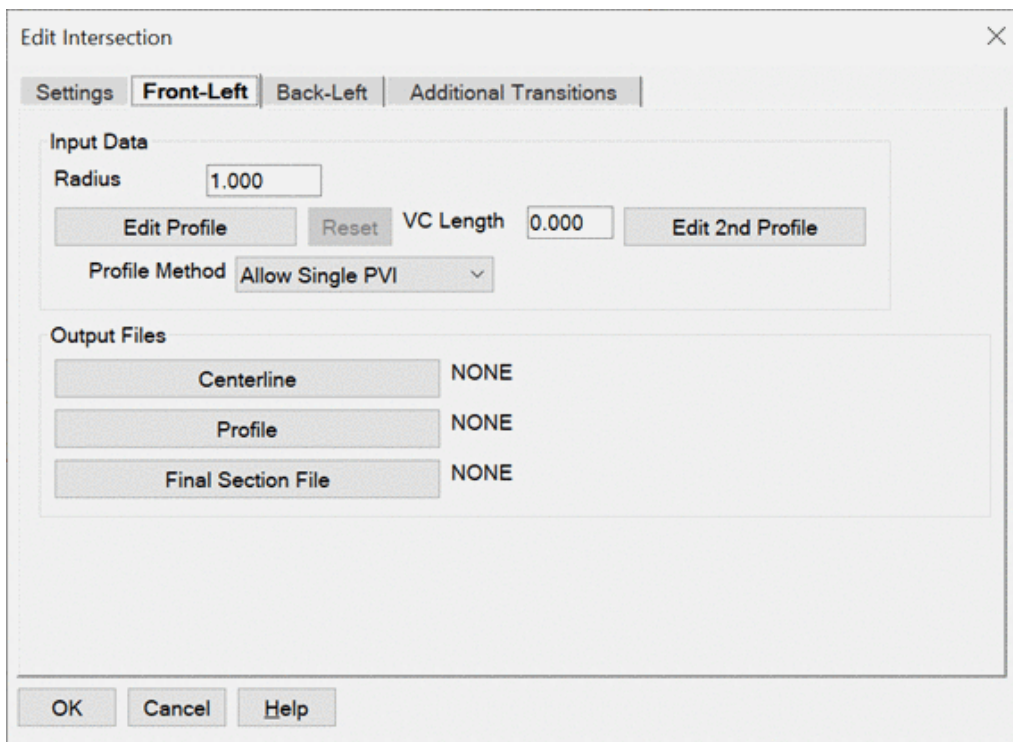

to create sections along the alignment in the model.

When you add or edit a tunnel, there's a dialog to set the **Tunnel Name**. Each tunnel needs a unique name. The **Centerline** defines the horizontal alignment. The **Profile** defines the vertical alignment. The **Template** defines the tunnel cross section. Besides editing these files within Tunnel Network, there are separate commands for these such as Centerline Editor and Profile Editor.

For each intersection, the program calculates the centerline stations and elevation at the intersection. The Primary Tunnel setting controls which profile is held at the intersection. The other profile will be set to match the primary tunnel. There are settings to control the profile transition of the secondary tunnel.

For each corner of the intersection, there are separate tabs for the settings specific to that corner. Each corner is named relative to the primary tunnel direction. For example, Front-Left is the corner along the primary tunnel before entering the intersection and on the left side. The Radius is the fillet radius to transition the outer tunnel side at the intersection. There are setting to control the profile in the corner transition.

When you add tunnels to the model, you can pick the centerline polyline from the drawing and assign a CL file name.

Pick the Process button to build the solid. Then you can use other solids functions such as View Solid.

Pulldown Menu Location: Solid

Keyboard Command: tunnelnet

Prerequisite: solid model file

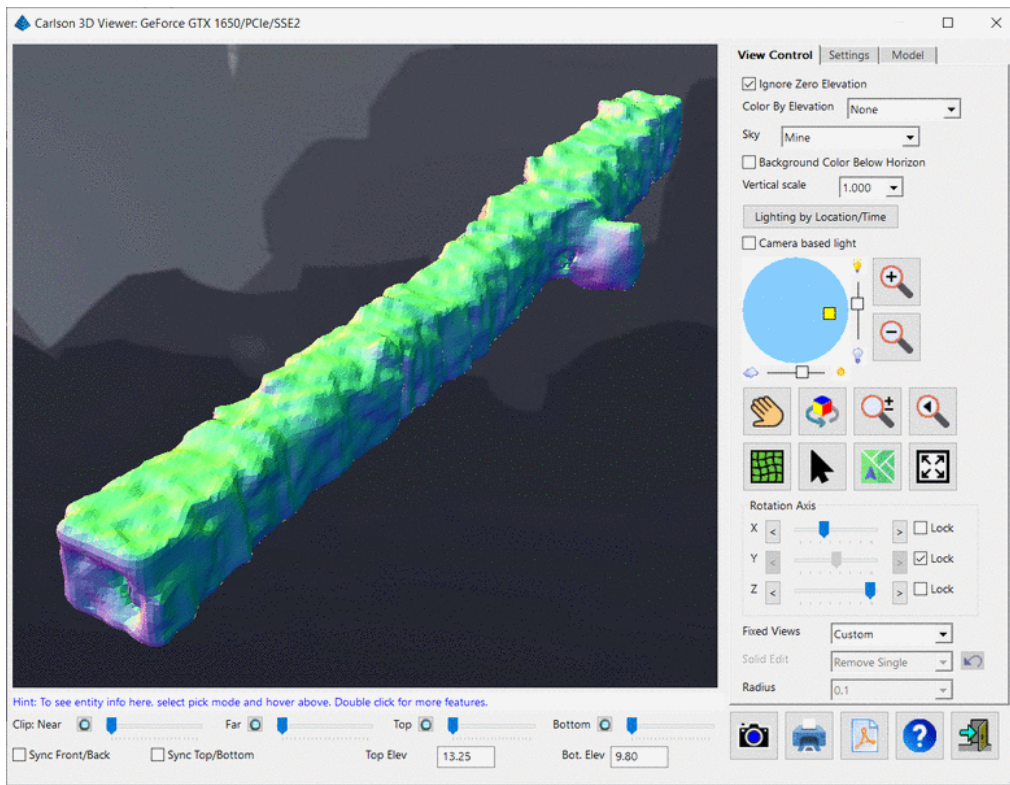

View Solid

This command shows a solid model in the 3D Viewer Window. See the 3D Viewer Window section of the manual for a description of the viewer functions.

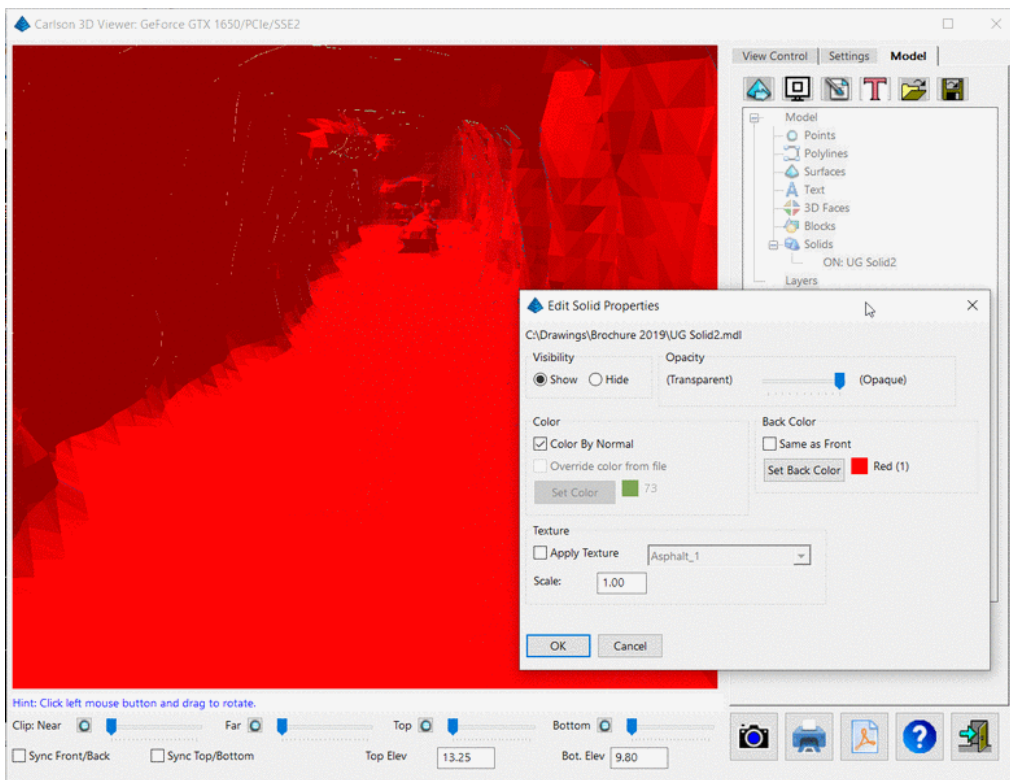

Solid Edit is an extra feature of View Solid that isn't part of the regular 3D Viewer command. To use the Solid

Edit, switch to the Pick Mode by picking this button: The Solid Edit has functions to remove faces from the solid which can be used to clean up a solid. Removing faces will leave holes in the solid. To make the solid watertight and fill in the holes, you can run the Heal Solid command after View Solid. There are two modes to the remove functions. The Remove Single removes only the face that is picked. The Remove Radius removes all faces from the pick point that are within the specified radius.

On the Edit Solid Properties found in the Model tab, there are options to color by Normal, Apply Texture, and to set the Back Color of the faces to a different color than the front. This allows for different color viewing when viewed from the inside of the solid, as seen here.

Pulldown Menu Location: Solid
Keyboard Command: view_solid
Prerequisite: solid model .mdl file

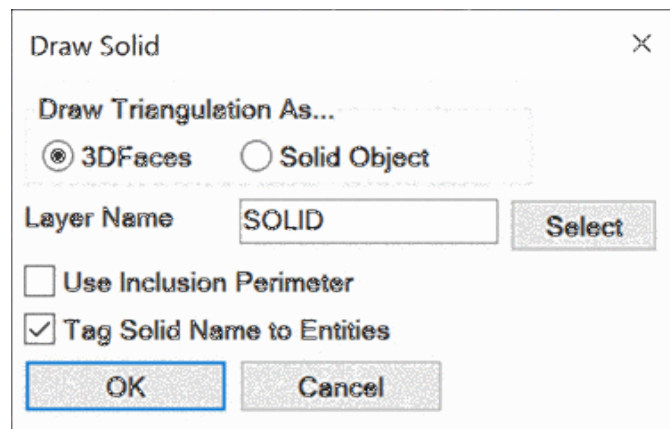

Draw Solid 3D Faces

This command draws a 3D Model from an MDL file as a 3DSolid entity. After selecting the MDL file, the program creates the 3DSolid in the current layer. In AutoCAD, a Solid Entity will be drawn, whereas a Polyface Mesh entity will be drawn in IntelliCAD.

Pulldown Menu Location: Solid
Keyboard Command: mdl2solid
Prerequisite: MDL file

Draw 3D Solid

This command draws a solid model as 3D Faces. The Tag Solid Name To Entities adds XData to the 3D faces with the name of the solid model file that is used by the ID Solid command. To view the solid entities in 3D, use commands like View > 3D Viewer Window.

The Surface Object is a custom object for displaying the solid in the drawing. This custom object also supports the EndPoint snap. The main advantage of the Surface Object is with displaying large solids because the Surface Object is more efficient than drawing individual 3D Faces. The Surface Object requires Carlson to be loaded to display.

Section Solid

This command creates a cross section of a solid. The cross section is either drawn as a 3D polyline or stored to a SCT file and assigned to a station. Use commands like Draw Section File to view the cross section SCT file.

The section alignment can be defined by **MXS File** for creating sections for multiple stations. Use the **Pick Points** method for a single section. With this single section, the program prompts for two points to define the alignment for the cross section. The **Elevation Values** and **Elevation Interval** methods create horizontal sections of the solid which is like contouring the solid. The **3D Polyline** methods create sections that are perpendicular to the slope of the 3D polyline. The Pick method prompts for stations along the polyline for the sections. The Interval method creates sections at a specified station interval.

The solid model can be defined by a Carlson 3D Model file (MDL) or by 3D Solid entities in the drawing.

Assign Solid Data To Polyline

This command links 3D polylines to design solids (.mdl files) in preparation for the Solid Timing command. When the command is executed, the below dialog will be displayed.

Name: Here you can assign a name to the polyline/solid. This name will be displayed in the Solid Timing command. Note that the name does not need to match the filename for the solid (.mdl file).

Polyline: Clicking the **Pick** button will allow you to select a polyline. Note that only one polyline may be selected. Solids/polylines with pinpoints via the Assign Pinpoint to Solid command.

Solid: Clicking the **Select** button will allow you to select a .mdl file that represents the solid to be mined. Note that the polyline selected must be adjacent to or contained within the solid.

Precedence: Precedence rules may be applied to the solid to ensure timing is not calculated in an illogical or impossible progression. Any solids listed in the Precedence list will be mined prior to the current solid.

Other solids may be added to the list by clicking the green plus icon.

Solids may be removed from the list by clicking the red X icon.

All solids may be removed from the list by clicking the Clear button.

Solids may also be added to the list by clicking the Screen Pick button. With this method, you will be able to select polylines from the drawing area rather than picking the names from a list.

Pulldown Menu Location: Solid

Keyboard Command: ASSIGNPLYSOLID

Add Pinpoint To Solid

This command will add a pinpoint to solid's polyline. Pinpoints are used to subdivide solids for assignment in the Solid Timing command. Pinpoints will appear on the 3D polyline as a sphere, as shown below.

Command: addpinsolid

Select solid polyline: *Here the user will need to select the 3D polyline to add the pinpoint.*

Pick pinpoint or Enter distance or Define size[<Pick>/Enter/Size]:? S *Using the Size option will allow you to change the size of the pinpoint symbol.*

Pinpoint sphere diameter size <10.00>: 15

Pick pinpoint or Enter distance or Define size[<Pick>/Enter/Size]:? P *Using the Pick option will allow you manually select the location of the pinpoint. Using the Enter option will allow you to set the location of the pinpoint by entering the distance from the start of the polyline.*

Pick point on selected polyline: *The Nearest Snap will be activated and you will be able to pick a location on the polyline. The command will end after picking a location.*

Pulldown Location: Solid

Keyboard Command: ADDPINSOLID

Prerequisite: A Polyline with a solid assigned (see Assign Solid to Polyline command)

Solid Timing

The Solid Timing command schedules through designed solids (.mdl files) to generate a 3D timing model and a detailed report. Each solid is mined by a single piece of equipment according to a working calendar. As the schedule is calculated, the solids will be compared against a Geologic Model to determine the quality of the material being extracted. The below documentation follows this outline:

1. Required Setup
2. Mine Solid Timing Dialog
3. Reporting Options

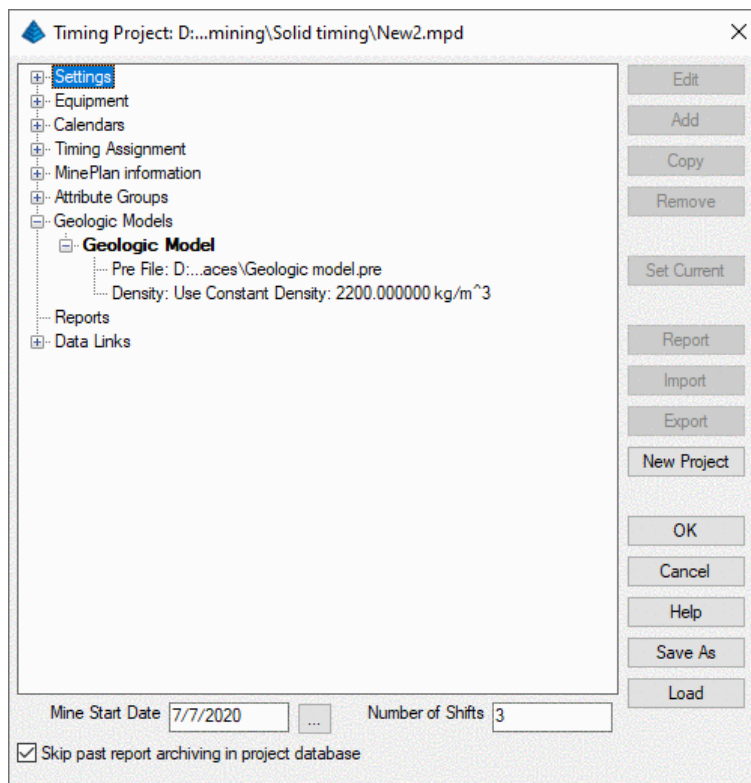

Before the Solid Timing may be executed, proper setup is required. At a bare minimum, this includes drafting polylines that represent the direction/location of the solids, assigning solids to the polylines, and populating the Timing Project Manager.

Polylines may be drafted using any tools you like. The polylines should be contained within or exist along the edge of the solid to be mined. For example, the polyline may represent the geometric centroid of the solid, or they may represent a corner point on the the template of the solid. An example set of polylines is shown below.

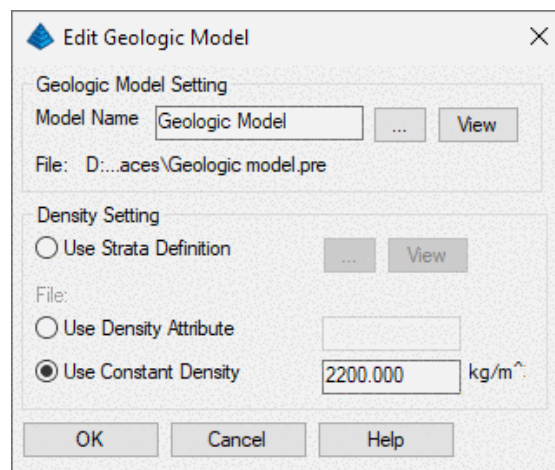

Once the polylines have been drafted, you can assign design solids (.mdl files) to them with the Assign Solid to Polyline command. Note that design solids may be created with a variety of commands found on the Solid Pulldown Menu.

Once the polylines and solids have been defined, you may execute the command. You will first be prompted to define a Timing Project Manager file (.mpd file). This file is described at length here, but has been slightly modified for the application of Solid Timing. Unlike the Surface Equipment Timing and Underground Timing command, the Solid Timing command calculates volumes/qualities directly from a Geologic Model (.pre file) as the timing is executed. Attribute groups are not required, but are still available. An example of the Timing Project manager is shown below.

Note that the Geologic Model branch of the Timing Project Manager is unique to the Solid Timing command. This branch is discussed below, but all other branches of this file are discussed here. It is important to note that in order to calculate the timing, the Equipment, Calendar, and Start Date must be defined. A Geologic Model may be added by double-clicking the Geologic Model branch or by selecting the Branch and clicking the Add Set button. When defining a Geologic Model, the below dialog will appear.

Model Name: The Geologic Model may be assigned any name. You may select a .pre file by clicking the ellipsis button. Once selected, you may view/modify the .pre file by clicking the View button.

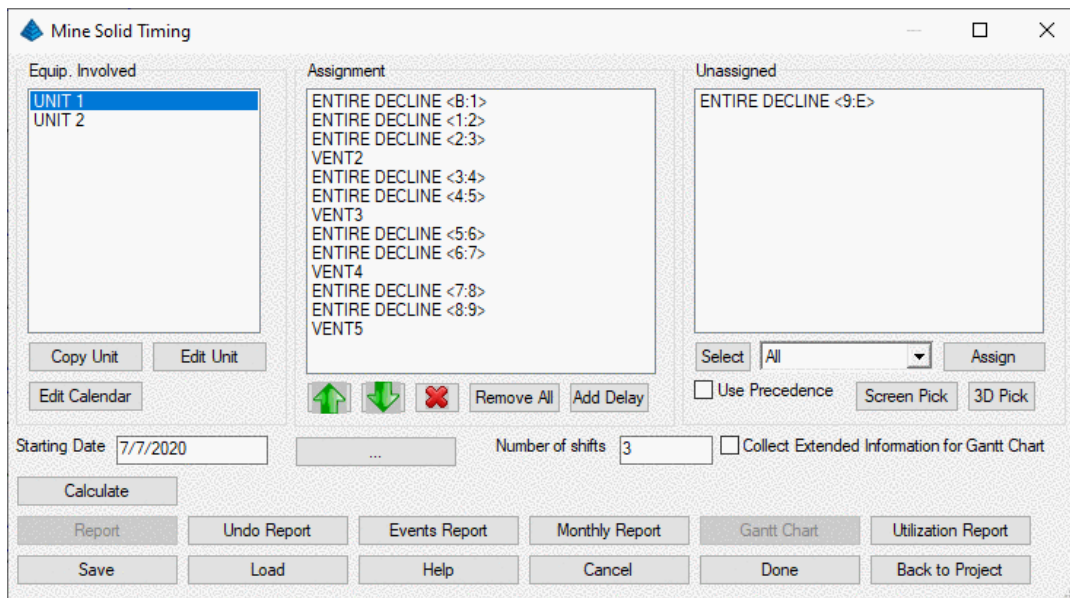

Density Setting: There are three options to specify the density of the materials defined in the Geologic Model.

The **Use Strata Definition** option will read density values from the Strata Definition file (.sdf file). Any strata types

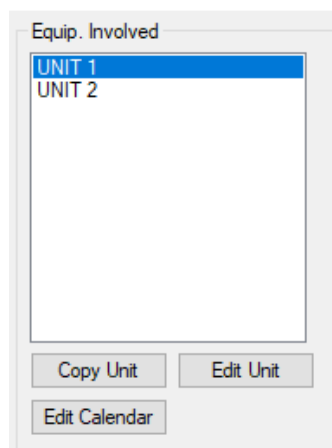

found in the Geologic Model that are not also defined in the Strata Definition will be assigned a default density value. The Strata Definition file may be selected by clicking the ellipsis button and viewed/modified by clicking the View button.

The **Use Density Attribute** will use an attribute found within the Geologic Model to define the density for each strata type. A benefit to this option is that each strata's density may vary across the property. Note that when using this option, you will need to enter the name of the Density attribute exactly as it appears in the Geologic Model. If no density attribute is found when this option is selected, the strata layers will be assigned a default density value.

The **Use Constant Density** option will assign a single density value to all strata types found in the Geologic Model. Once the Timing Project Manager has been defined, you will be prompted to select all of the polylines/solids to use in the timing command. After these entities are selected, the below dialog will appear. This dialog controls the sequencing of the timing. Each section of this dialog is described below.

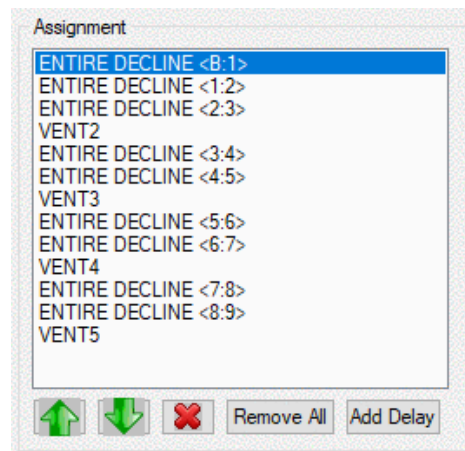

The Equip. Involved column will be automatically populated with equipment from the Timing Project Manager. You may create copies of equipment or edit the equipment definitions with the **Copy Unit** and **Edit Unit** buttons. The **Edit Calendar** button will allow you to modify the current calendar.

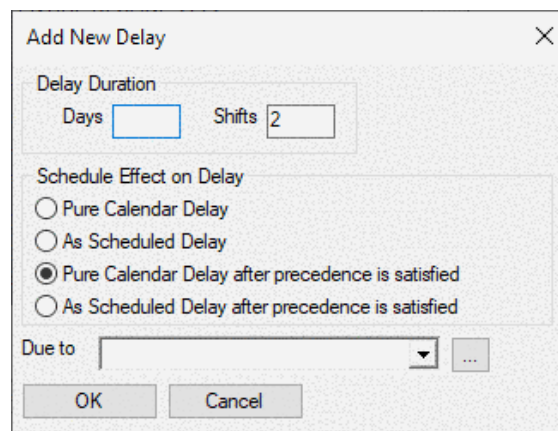

The Assignment Column lists the solids assigned to the currently selected equipment. Selecting a different

unit will update this column with the list of solids assigned to that unit. This column lists solids in the order that they will be mined, with solids at the top of the list being mined first. Solids may be moved up/down in the list by selecting them and clicking the respective **green arrow** icon. Solids may be removed from the list by selecting the solid and clicking the **red X** icon. All solids may be removed from the list by clicking the **Remove All** button.

Delays may be added to the assignment column by clicking the **Add Delay** button. Delays will be added to the assignment column as if they were another solid to be mined. When adding a delay, the below dialog will appear.

Delay Duration: These values control how long the delay lasts. In the above example, the equipment will be delayed for a full shift. Note that partial shift delays are allowed.

Pure Calendar Delay: This option will not force a delay. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay: This option will force a delay even if the equipment already has scheduled downtime when the delay is encountered. The delay will wait until the scheduled downtime is complete, then the delay will be applied.

Pure Calendar Delay after precedence is satisfied: This is similar to a Pure Calendar Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the scenario shown in the below

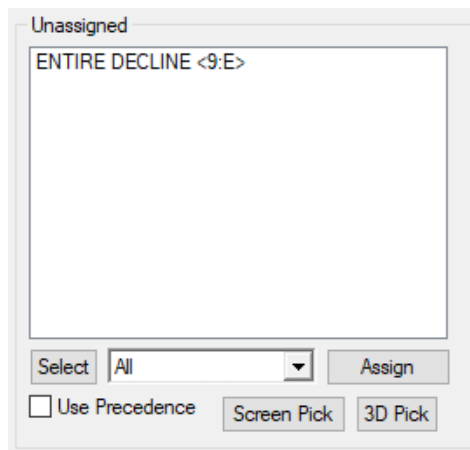

table. Equipment E1 is scheduled to mine Pit A and Pit C. Equipment E2 is scheduled to mine Pit B and Pit D. A precedence rule has been created that does not allow Pit D to be mined until Pit A is complete. A delay of this type is placed on Equipment E2 after Pit B. In this scenario, the finish date of Pit A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay after precedence is satisfied: This option is similar to an As Scheduled Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the below scenario. Equipment E1 is scheduled to mine Pit A and Pit C. Equipment E2 is scheduled to mine Pit B and Pit D. A precedence rule has been created that does not allow Pit D to be mined until Pit A is complete. A delay of this type is placed on Equipment E2 after Pit B. In this scenario, the finish date of Pit A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime, the delay will be applied in addition to this downtime.

Due To: This dropdown menu lists the Drawing Event delays defined in the Timing Project Manager. The ellipse button will allow you to define a new Drawing Event.

Equipment	E1	E2
Assignment Sequence	Pit A	Pit B
	Pit C	Delay
		Pit D (Precedence rule: Pit A)

The Unassigned Column lists all solids that have not yet been assigned to a piece of equipment.

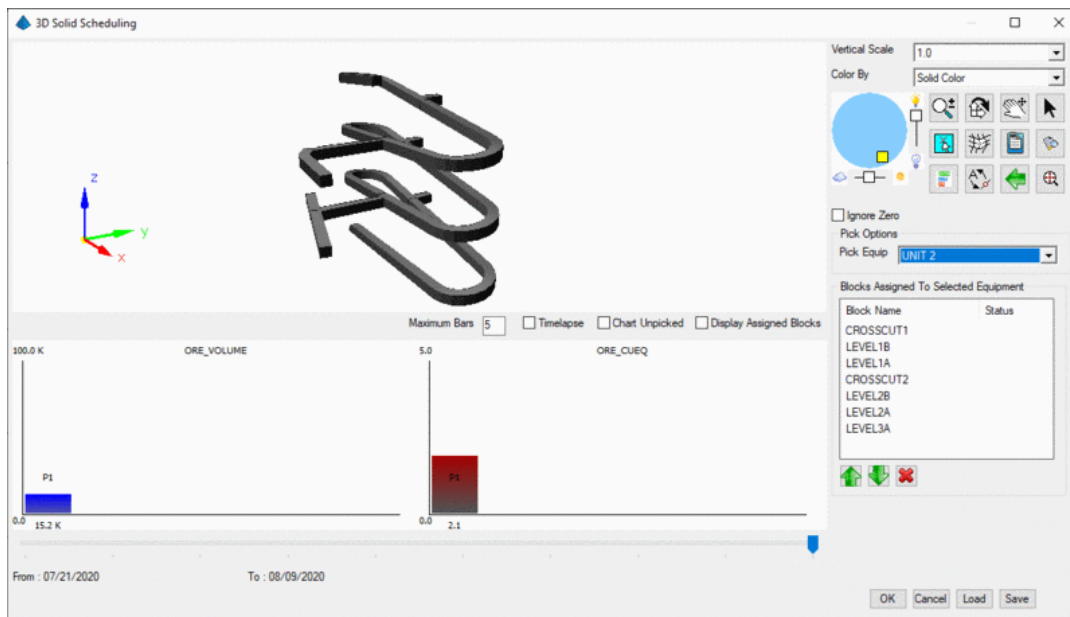

Assign: This button will assign the selected solid(s) to the selected piece of equipment. Solids may also be selected by double-clicking the name in the list.

Select: This button will select the solids according to the drop-down menu to the right of this button. If the drop-down menu is set to NONE, all solids will be unselected. If the drop-down menu is set to ALL, all solids will be selected.

Use Precedence: This checkbox will ensure that precedence is satisfied in the list. For example if Pit1-B1 is assigned to precede Pit1-B2, toggling this option on will reorder the list so that Pit1-B1 is listed before Pit1-B2.

Screen Pick: This button will allow you to sequence the solids by selecting them in the drawing. When activated, the Surface Equipment Timing Dialog will disappear and the drawing area will be visible. The command line will prompt you to click the polyline solid to assign to the currently selected piece of equipment. This option allows you to visually select the solids rather than picking them from a list.

3D Pick: This button will open a new window, as shown below, to show a 3D view of the available solids and the volumes/qualities associated with them. This interactive window allows you to sequence solids in an interactive 3D environment.

Vertical Scale: This value controls the vertical exaggeration of the graphics window.

Color By: This drop-down list controls how benches are colored in the graphics window.

The *Solid Color* option will color each solid with a single color.

The *Normal* option will color each face of the solid according the direction it faces. This adds a more vibrant color variation to the solids.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display.

Switches to Dynamic Zoom mode. Click and drag to zoom in and out.

Switches to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switches to Pan mode. Click and drag to pan.

Switches to Pick mode. Double click a solid to assign it to the currently selected piece of equipment.

Prompts you to select linework such as contours or 3D faces to add to the 3D viewer window. This linework can be used to identify reference points in the drawing to assist in selection.

Toggle shading of Solids and 3D Faces.

Exits the 3D Pick window, calculates the amount of time required to mine the assigned solids, and generates a report. This function is discussed later in this section of the help manual.

Displays a detailed report of the current timing assignment. This is similar to the standard Report function, but provides more detailed information and does not attempt to create a timing map. An example report is shown below.

Task	Date	Eq. name	Start date	Finish date	Days	Pls.
1	PRESTRIP FL	0 AREA 1-9/27/2016	10/2/2016			
2	DRAGLINE	5 0 AREA 1-9/27/2016	10/7/2016			
3	LOADER	12 0 AREA 1-9/27/2016	10/9/2016			
4	PRESTRIP FL	0 AREA 1-9/27/2016	10/7/2016		5.0	
5	DRAGLINE	0 AREA 1-9/27/2016	10/12/2016		-6	
6	LOADER	0 AREA 1-9/27/2016	10/18/2016		-3	
7	PRESTRIP FL	0 AREA 1-9/27/2016	10/9/2016		10.2	
8	DRAGLINE	0 AREA 1-9/27/2016	10/17/2016		3.2	
9	LOADER	0 AREA 1-9/27/2016	10/29/2016		-8	
10	PRESTRIP FL	0 AREA 1-9/27/2016	10/12/2016		12.4	
11	DRAGLINE	0 AREA 1-9/27/2016	10/9/2016		8.2	
12	LOADER	0 AREA 1-9/27/2016	10/29/2016		-7	
13	PRESTRIP FL	0 AREA 1-9/27/2016	10/9/2016		18.8	
14	DRAGLINE	0 AREA 1-9/27/2016	10/29/2016		4.0	
15	LOADER	0 AREA 1-9/27/2016	11/9/2016		1.0	
16	PRESTRIP FL	0 AREA 1-9/27/2016	10/8/2016		22.0	

The calculator icon at the top left of the screen will recalculate the timing results of the currently assigned solids. This allows additional solids to be added/removed from the assigned equipment and then quickly recalculate the impact on the scheduling.

The slider bar at the top of dialog represents the timeline of the mining progression. Clicking-and-dragging the slider will update the displayed information.

The spreadsheet report will display solids to be mined in the currently selected time period.

Controls the information displayed on the bar charts. When clicked the below dialog will appear.

This dialog contains two columns: Available and Used. Only items in the Used column will be shown in the bar chart area below the 3D Pick graphics window. Items may be moved between the two columns by selecting the item and clicking one of the green arrows between the two columns. To the right of the Used column are four icons. The green arrows can be used to move the selected item up and down in the list. The red pencil can be used to edit the selected item as described below. The blue reset icon will clear out all used attributes and return them to the available column.

The attribute listed in the Available column will be automatically generated based off the Geologic Model. The volume, tonnage, and qualities for each strata type will be available.

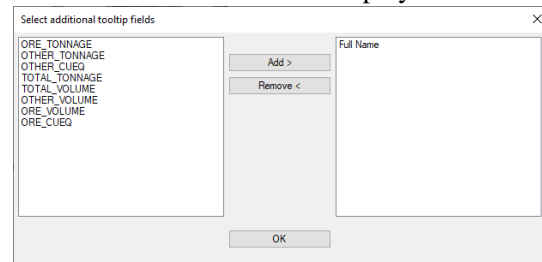

You can use the Create/Edit/Delete Equation buttons to manage equations. These equations can be used to represent values that are not actually in the Geologic Model, but are rather a combination of other values. More information on defining equations is provided here.

When an item is first moved to the Used column, the below dialog will appear to control that item's appearance on the chart, including minimum value to display, maximum value to display, and color. You can also define the method used for calculating the total of the value. For example, values such as volume can be totaled as a Sum, whereas values such as quality can be a Weighted Average that is weighted by the Volume of each solid. You can also enable the Targets, which are simply horizontal lines displayed on the bar charts to represent threshold values.

Controls the attributes that are displayed in the tooltip when the cursor is hovering over a bench. Attributes in the left column will not be displayed.

Undoes the last selection in the 3D pick window.

Zooms to the extents of the items shown in the 3D window.

Ignore zero elev: This option will toggle the visibility of surface features at zero elevation in the graphics window.

Pick Equipment: This drop-down list includes all equipment that have been added to the main Surface Equipment Timing dialog. Solids will be assigned to the selected equipment.

Blocks Assigned to Selected Equipment: This list shows all solids that have been assigned to the selected equipment. The solids are listed in the order they will be mined. The green arrows below the list will move the currently selected solid up and down in the list. The red X will remove the selected solid from the list and make it available for assignment to another piece of equipment.

Maximum Bars: This value controls the maximum number of periods (and thus, the number of vertical bars) that may be shown in each chart when the Timelapse option is enabled.

Timelapse: This checkbox will create a new period each time a solid is selected, thus adding another bar to the charts. Once the maximum number of periods is displayed, older periods will be removed from the charts.

Chart Unpicked: This option will reset the charts and only show information pertaining to solids that have not yet been assigned to a piece of equipment.

Display Assigned Blocks: This option will display solids that have already been assigned to a piece of equipment.

Period Slider Bar: The slider bar below the charts is only available when the Timelapse option is disabled. This slider bar allows you to control how many solids are represented in the last vertical bar of the charts. For example, if the slider bar is moved to the right end of the bar, all assigned solids will be represented in the bar chart. If the slider bar is moved closer further to the left, fewer solids will be represented in the bar chart.

These options at the bottom of the Mine Solid Timing dialog control the various reporting options.

Starting Date: This value sets the date to begin mining operations. The ellipsis button to the right of this field will open a small calendar to assist in date selection. By default, this value will be set the Mine Start Date set in the Timing Project Manager.

Number of Shifts: This value will set the number of working shifts in a day.

Collect Extended Information for Gantt Chart: When enabled, this option will allow the Gantt Chart to include extra information such as the pit volume, quality, etc.

Calculate: This button will calculate the mine schedule. If any errors are encountered, the below dialog (left) will appear. The problem report generated will appear similar to below (right). In this example, a precedence rule has been violated for the Unit 1. Entire Decline <1:2> cannot be mined until Entire Decline <B:1> has been mined. This will require an edit to the assignment order.

If no problems are encountered, the schedule will be calculated and the below dialog will appear.

Report: This button will generate a very simple report as shown below. Note that this report does not include information about the amount of material mined.

Unit	Days waiting	Solid name	Start date	Finish date
UNIT 1	0.0	ENTIRE DECLINE	7/7/2020	7/11/2020
UNIT 1	0.0	ENTIRE DECLINE	7/11/2020	7/16/2020
UNIT 1	0.0	ENTIRE DECLINE	7/16/2020	7/20/2020
UNIT 1	0.0	ENTIRE DECLINE	7/20/2020	7/25/2020
UNIT 1	0.0	ENTIRE DECLINE	7/25/2020	7/29/2020
UNIT 1	0.0	ENTIRE DECLINE	7/29/2020	8/3/2020
UNIT 1	0.0	ENTIRE DECLINE	8/3/2020	8/6/2020
UNIT 1	0.0	ENTIRE DECLINE	8/6/2020	8/12/2020
UNIT 1	0.0	ENTIRE DECLINE	8/12/2020	8/15/2020
UNIT 1	0.0	VENT2	7/20/2020	7/20/2020
UNIT 1	0.0	VENT3	7/29/2020	7/29/2020
UNIT 1	0.0	VENT4	8/6/2020	8/6/2020
UNIT 1	0.0	VENT5	8/15/2020	8/16/2020
UNIT 2	0.0	LEVEL1A	7/17/2020	7/23/2020

Detailed Report: This button will generate a more detailed report, including information such as the amount of material mined, quality of material, downtime, etc. This report is discussed in more detail later in this help document.

Report: This button (directly below the Calculate button) is only available after calculating the mine schedule. This button will open the Detailed Report dialog. This is the same dialog that will appear after selecting the Detailed Report option after clicking the Calculate button. The Detailed Report is described later in this help document.

Undo Report: This button will delete a previous timing map and clear the calculated schedule. This allows for quick what-if analysis of the scheduling.

Events Report: This button will display the Events Report, which lists all Drawing Events encountered during the mine schedule. Drawing Events are discussed in more detail in the Timing Project Manager. This report is only available after a Detailed Report has been generated.

Monthly Report: This button will generate a monthly report, similar to the Detailed Report, but with less information available and without the ability to set custom time periods for reporting. An example of the Monthly Report is shown below.

Unit	Month	Year	Operating days	Days Weekdays	Worked Saturdays	Worked Sundays	Calendar days	Work shifts	Hour
UNIT 1	July	2020	31.00	31.00	23.00	4.00	31.00	93.00	
UNIT 1	August	2020	31.00	31.00	21.00	5.00	31.00	93.00	
UNIT 2	July	2020	31.00	31.00	23.00	4.00	31.00	93.00	
UNIT 2	August	2020	31.00	31.00	21.00	5.00	31.00	93.00	
Total varies			124.00	124.00	88.00	18.00	124.00	372.00	

Gantt Chart: This button will generate a Gantt chart of the mine schedule. This button is only available after calculating the mine schedule. For more information, see the Gantt Chart section of the help manual.

Utilization Report: This button will generate a Utilization Report of the mine schedule. This report lists each shift for each piece of equipment. Scheduled delays will be reported as such. An example of the Utilization Report is shown below.

Event Date	Shift	Year (start)	Month/Year	Equipment	Shift Hours	Pit	Type	Util. Ratio
7/7/2020	1	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00
7/7/2020	2	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00
7/7/2020	3	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00
7/7/2020	1	2020	07/2020	UNIT 2	8		AVAILABLE	
7/7/2020	2	2020	07/2020	UNIT 2	8		AVAILABLE	
7/7/2020	3	2020	07/2020	UNIT 2	8		AVAILABLE	
7/8/2020	1	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00
7/8/2020	2	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00
7/8/2020	3	2020	07/2020	UNIT 1	8	ENTIRE DECLINE <B:1>	UTILIZATION	1.00

Back to Project: This button will return to the Timing Project Manager window.

Detailed Reporting: When a Detailed Report is generated, the below dialog will appear.

Report by: This drop list will determine how the timing map is generated.

If the *Dates* option is selected, the timing map will be colored by date ranges.

If the *Amounts* option is selected, the timing map will be colored by amount intervals.

If the *Equipment* option is selected, the timing map will be colored by equipment.

Dates Table: This button will open the Dates Table, shown below, which is used to define the various time periods used for reporting.

	End Date	Range	Color	Pattern	Scale	Layer	Label
1	2/1/2028	< 2/1/2028	Red	SOLID	Set	250.0 MINETM	Set
2	3/1/2028	2/1/2028 - 3/1/2028	Dark Red	SOLID	Set	250.0 MINETM	Set
3	4/1/2028	3/1/2028 - 4/1/2028	Red-Orange	SOLID	Set	250.0 MINETM	Set
4	5/1/2028	4/1/2028 - 5/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
5	6/1/2028	5/1/2028 - 6/1/2028	Light Orange	SOLID	Set	250.0 MINETM	Set
6	7/1/2028	6/1/2028 - 7/1/2028	Yellow-Orange	SOLID	Set	250.0 MINETM	Set
7	8/1/2028	7/1/2028 - 8/1/2028	Yellow	SOLID	Set	250.0 MINETM	Set
8	9/1/2028	8/1/2028 - 9/1/2028	Light Yellow	SOLID	Set	250.0 MINETM	Set
9	10/1/2028	9/1/2028 - 10/1/2028	Light Green	SOLID	Set	250.0 MINETM	Set
10	11/1/2028	10/1/2028 - 11/1/2028	Green	SOLID	Set	250.0 MINETM	Set
11	12/1/2028	11/1/2028 - 12/1/2028	Dark Green	SOLID	Set	250.0 MINETM	Set
12	1/1/2029	12/1/2028 - 1/1/2029	Light Green	SOLID	Set	250.0 MINETM	Set
13	2/1/2029	1/1/2029 - 2/1/2029	Green	SOLID	Set	250.0 MINETM	Set
14	3/1/2029	2/1/2029 - 3/1/2029	Dark Green	SOLID	Set	250.0 MINETM	Set
15	4/1/2029	3/1/2029 - 4/1/2029	Light Green	SOLID	Set	250.0 MINETM	Set
16	5/1/2029	4/1/2029 - 5/1/2029	Yellow-Green	SOLID	Set	250.0 MINETM	Set

The above dialog can be used to create custom time periods to show in the timing map. The icons at the top left of the dialog will add and delete rows of information.

End Date: This column displays the end date for the row of information.

Range: This column sets the date range of the period. Dates may be preceded by > or < to mark indefinite time periods.

Color: This column sets the color of the time period. Double clicking one of these cells will open the CAD color palette.

Pattern: This column sets the hatch pattern for the timing blocks.

Scale: This column sets the scale of the hatch pattern.

Layer: This column sets the CAD layer on which to draw the timing block.

Label: This column sets a custom label for the timing block.

Clear: This button will clear the table of all information.

Auto Set: This button will open the below dialog, which allows for quick population of the Custom Dates table.

Starting Line: This value will set the row to begin the automatic population of the Custom Date table.

Starting Date: This is the Date From that will be used on the Starting Line. The ellipse button will open a small calendar to assist in date selection.

Hatch Scale: This value will set the hatch scale for the new time periods.

Hatch Pattern: This field will set the hatch pattern for the new time periods. The ellipse button will open the list of available hatch patterns.

Set Same Layer: This option will place all new time periods on the same layer, which is set just to the right of this checkbox. The ellipse button will open the list of existing CAD layers.

Set Colors: This option will set custom colors for the new time periods. The colors are referenced in the CAD color palette, and are numbered 1 through 255.

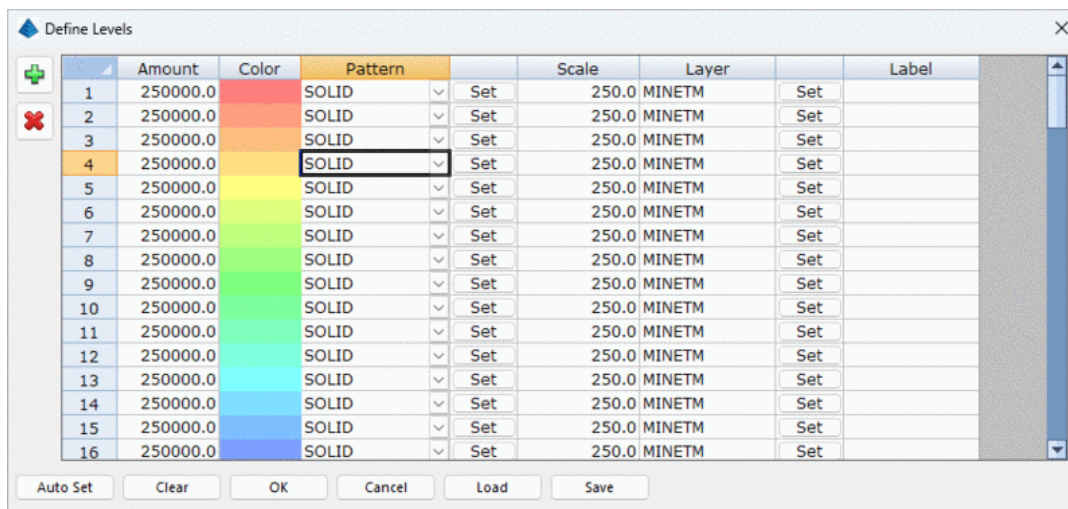

Colors by Year: When this option is enabled, the colors will only increment when the starting date for a row changes. This option is handy for drawing timing maps that have the same color for an entire year, but generate the report on a monthly basis.

Color Increment: This value sets the increment of colors to use for coloring. For example, a value of 10 will increment through colors 10, 20, 30, etc.

Start Color: This value sets the color to use on the Starting Row.

Repeat: This option will determine the length of the time periods. Selecting the *Every* option will allow you to set a custom length for the time periods. The number of time periods to create is set below this dropdown list.

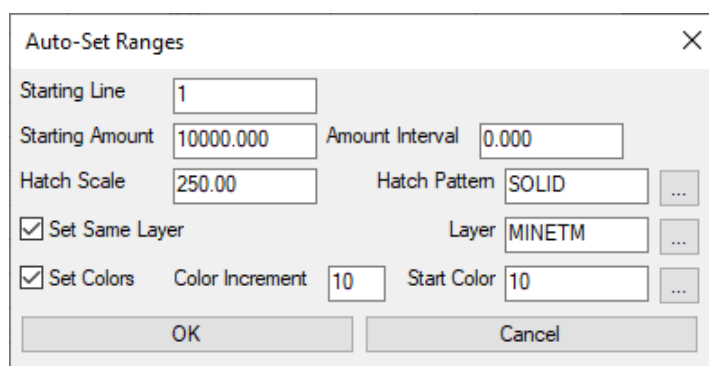

Amounts: This button will open the below dialog, which controls another method of custom coloring of the timing map.

The above dialog is very similar to the Custom Dates table previously discussed. The only difference is that the dates are replaced with the **Amounts** column. These values may represent one of the following values to be mined:

- Total Tons
- Key Material Tons
- Waste Tons
- Total Area
- Mined Area
- Total Volume
- Key Material Volume
- Waste Volume
- User Grid

Auto Set: This button will open the below dialog, which is very similar to the Auto Set dialog used in the Custom Dates table, as previously discussed. This dialog differs in that amounts are specified rather than dates, and the periods cannot be defined to repeat for a specific number of times.

Equipment: This button will open the Equipment Table, shown below, which is used to set the colors for each piece of equipment to be reported. This is like a simplified version of the Dates Table and Amounts Table. Here there is no option to set a report period - only the color, hatch, layer, and label for each piece of equipment.

	Equipment	Color	Pattern	Scale	Layer	Label
1	CM-1	Red	SOLID	100	MINETM	CM1
2	CM-2	Yellow	SOLID	100	MINETM	CM2
3	CM-3	Green	SOLID	100	MINETM	CM3

Draw Period Solids: This option will draw the timing solids in the drawing window. The solids will be colored according to the Report By option previously discussed.

Solid Transparency: This dropdown list will determine the transparency of the timing solids that are drawn in the drawing window.

Draw Legend: This option will draw a color legend of the timing map.

Legend Scale: This option will set the text size of the timing map legend.

Solid Labeling: This dropdown list will determine how the labels are drawn in the timing map.

The *No Block Labels* option will not draw labels.

The *Draw Actual Dates* option will label the starting and ending date of each period.

The *Draw Period Names* option will draw labels defined in the Custom Date Table.

The *Use Custom Names* option will draw labels defined in the Custom Amount Table.

The *Use Custom Text Block* option will draw labels according to the below dialog. When selected, the **Text Block Style**, **Add**, **Edit**, and **Remove** buttons will become available. The Text Block Style dropdown list will list all available text block labels. The Add button will create a new text block. The Edit button will edit the currently selected text block. The Remove button will remove the currently selected text block.

List of pre-defined keys	Buttons	Line definitions for Text Block
ENTWIDTH	<input type="button" value="Add >"/> <input type="button" value="Add Text"/> <input type="button" value="Add Attribute"/> <input type="button" value="Add New Line"/> <input type="button" value="Remove"/>	EQUIPMENT
EQUIPMENT		START
EXTRACT		FINISH
FINISH		
MAREA		
NAME		
OWNER		
PERIOD		
PROPERTY		
RADVANCE		
RECOVER		
BACKPENS		

The left side of the above dialog contains pre-defined keys that may be used in the labels. The right side of the dialog shows how the text block label will appear.

Add: This button will add the selected attribute to the current line. Multiple attributes may be added to a single line.

Add Text: This button will add custom text to the current line. In the above example, "tons" has been added as a suffix to the KEYWEIGHT attribute.

Add Attribute: This button will add any attribute that is not defined in the pre-defined list. This attribute name must match an attribute available in the final text report.

Add New Line: This button will create a new line in the text block. In the above example, three lines have been created.

Remove: This button will remove the selected line from the text block.

Text Size: This value will set the text size of the block labels.

Text Autosize: This option will automatically size the text of the block labels. The text size will vary, as it will be set to 1/6 of the length of the block (e.g. a block that is 600 units long will create a text height of 100 units).

Text Style: This option will set the text style to use for the period labels. The **Select** button will allow you to select one of the existing text styles.

Length-wise labels: This option will rotate the block labels in line with the mining direction of each bench. If not selected, labels will be drawn perpendicular to the mining direction.

Report Only: This option will not create a timing map; only the mine schedule will be reported. When selected, many other options on the dialog will be ghosted out.

Output Timing Viewer File: This option will output a Timing Viewer File of the mine progression. This is a 3D playback that may be controlled with a timeline. You may specify the file name and location by clicking the ellipse button. More information on the Timing Viewer File is available [here](#).

An example report and timing map is shown below.

File Edit Settings

KEY production report Tue Jul 21 17:25:20 2020

Period	Equipment	Date Start	Date Finish	Year	(start)	KEY (Tons)	Non-Key (Tons)
7/7/2020 - 8/7/2020	UNIT 1	7/7/2020	8/1/2020	2020		7512.9	
7/7/2020 - 8/7/2020	UNIT 1	8/1/2020	8/6/2020	2020		1787.1	
7/7/2020 - 8/7/2020	UNIT 2	8/1/2020	8/2/2020	2020		549.9	
7/7/2020 - 8/7/2020	UNIT 2	8/3/2020	8/6/2020	2020		1237.2	
8/7/2020 - 9/7/2020	UNIT 1	8/7/2020	9/2/2020	2020		7927.0	
8/7/2020 - 9/7/2020	UNIT 2	8/7/2020	8/29/2020	2020		6785.4	
8/7/2020 - 9/7/2020	UNIT 2	9/2/2020	9/6/2020	2020		1346.0	
8/7/2020 - 9/7/2020	UNIT 1	9/2/2020	9/6/2020	2020		1373.0	
9/7/2020 - 10/7/2020	UNIT 2	9/7/2020	9/7/2020	2020		166.5	
9/7/2020 - 10/7/2020	UNIT 1	9/7/2020	9/24/2020	2020		5325.5	
9/7/2020 - 10/7/2020	UNIT 2	9/7/2020	10/6/2020	2020		8860.5	
9/7/2020 - 10/7/2020	UNIT 1	9/25/2020	9/26/2020	2020		549.9	
9/7/2020 - 10/7/2020	UNIT 1	9/26/2020	10/6/2020	2020		3124.6	
10/7/2020 - 11/7/2020	UNIT 2	10/7/2020	10/15/2020	2020		2407.1	
10/7/2020 - 11/7/2020	UNIT 1	10/7/2020	10/26/2020	2020		5836.8	
10/7/2020 - 11/7/2020	UNIT 2	10/15/2020	10/21/2020	2020		2062.5	

There are many attributes available in this report. Most of these attributes are self explanatory, but some are not as clear. The below definitions are therefore provided.

- Calendar Days: Actual period length rounded up (to account for partial days)
- Operating days: Actual period length rounded up, minus days that do not have at least one working shift
- Days: Scheduled Hours divided by Shift Length
- Weekdays Worked: Weekdays with at least a portion of shift worked

- Saturdays Worked: Saturdays with a least a portion of a shift worked
- Sundays Worked: Sundays with a least a portion of a shift worked
- Days Waiting: Number of days equipment cannot work due to a precedence rule
- Work Shifts: Number of shifts when production took place
- Hours Scheduled: Number of hours equipment is scheduled to work (this includes Hours Utilized, Hours Delayed, and Hours Available)
- Hours Down: Number of hours equipment is not scheduled to work (due to downtime scheduled on the calendar)
- Hours Utilized: Number of hours equipment is actually working
- Hours Delayed: Number of hours equipment is delayed due to a Drawing Event or Scheduled Delay (note, this is not the same as Hours Down)
- Hours Available: Number of hours is scheduled to work, but is neither being utilized nor is it actually delayed. If a piece of equipment encounters a delay during the middle of the shift, the partial shift time remaining will be counted as Hours Available (the delay will be applied to the next shift)

The below image helps visualize the organization of the different definitions of Hours.

Hours in a day	Hours Scheduled	Hours Utilized
		Hours Delayed
		Hours Available
	Hours Down	

Pulldown Location: Solid

Keyboard Command: UGMINESCHEDULE

View 3D Timing

This command will open a .tv file to playback the progression of the mine. This file can be created from Surface Equipment Timing, Spoil Placement Timing, and Haul Cycle Analysis.

When the command is executed, you will be prompted to select a TIN file representing the topography at the end of the mine life. You will then be prompted to select a .tv file to view, after which the below dialog will appear. It is important to note that in order to view a .tv file, the linework for the spoil piles, haul routes, and the period polylines (output from Surface Equipment Timing as Pits) must be present in the drawing.

Vertical Scale: This value sets the vertical exaggeration for the 3D view.

Show Axis: This toggle controls the display of the X-Y-Z Axis icon in the lower left corner of the 3D view.

Show Solid Name: This toggle controls the display of labels above each solid. Names will only be displayed for solids that are being moved during the current time period.

Show Vehicle Name: This toggle controls the display of labels above each piece of equipment.

Play by: This option controls the playback of the 3D View. The *Pit* option will increment the time period based on when each pit is completely mined out. The *Spoil* option will increment the time period based on when a spoil polyline is completely filled.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display.

Switch to Dynamic Zoom mode. Click and drag to zoom in and out.

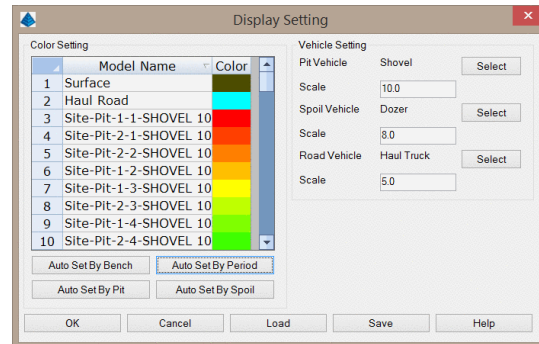

Switch to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switch to Pan mode. Click and drag to pan.

Toggle shading of 3D Faces and Surfaces.

Controls coloring and appearance of 3D symbols. When clicked, the below dialog will appear.

The spreadsheet shown in this dialog lists the name and color of each feature in the 3D window. You can automatically color the solids using one of the Auto Set By... buttons.

Auto Set By Bench: This option will color pits and spoil piles by bench number. For example, all instances of bench 1 will be red, all instances of bench 2 will be orange, etc.

Auto Set By Period: This option will color pits and spoil piles by the time period in which they are modified. For example, all material moved in the first month will be red, all material moved in the second month will be orange, etc.

Auto Set By Pit: This option will color pits and spoil piles by the pit. For example, all material from the first pit mined will be red, all material from the second pit mined will be orange, etc.

Auto Set By Spoil: This option will color pits and spoil piles by the spoil pile. For example, all material that is placed in the first spoil pile will be red, all material placed in the second spoil pile will be orange, etc. All of these buttons will display a similar dialog, shown below.

In this dialog, you can set a **Starting Color #** and a **Color Increment** according to the CAD color palette. The default option of a Starting Color # of 10 and a Color Increment of 10 will produce a rainbow gradient. A Starting Color # of 11 and a Color Increment of 10 will produce a lighter shade of a rainbow gradient.

The **Vehicle Settings** allow you to set different 3D models for the pit equipment, the haulage equipment, and the spoil equipment. The **Select** button will open the 3D Model Library, which includes several pieces of mining equipment. The **Scale** value controls the size of the model in the 3D view.

Takes a screenshot of the 3D Viewer. Several different image file formats are supported including bmp, png, jpg, xpm and gif. The image resolution and color depth may be set with this option.

Switches to Inspection mode. In this mode, hovering the cursor over a solid will display the name of the solid.

Outputs the current time period as a TIN file. With this command, you can progress through the timeline to key points in the mine life and export a surface model.

Exit the command.

Starts playback of the mine timeline.

Stops playback.

Steps back one time period.

Steps forward one time period.

Resets the playback to the beginning of the timeline.

The slider bar shows the current position in the timeline. You can manually click-and-drag the slider bar to progress through the timeline.

Pulldown Menu Location: Reserves/Timing
Keyboard Command: tvviewer

Clear Solid Timing

This command will remove 3D faces and labels generated by the Solid Timing command.

Drop-Down Menu Location: Solid
Keyboard Command: mtime_clear

Import File To Solid

This command creates a solid model in .MDL file format from other solid formats including .STL, STLA, .OBJ, .DXF, .SKP (SketchUp) and .TIN (Carlson Triangulation).

Prompts

Input File To Read *Pick the file to import*
Solid File To Write *Enter MDL file to output*

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: import2mdl

Prerequisite: file to import

Export Solid

These commands output a solid model in .MDL file format to other solid formats including .STL, .OBJ and .TXT. The .STL and .OBJ are industry standard formats. The .TXT outputs the points from the solid as space separated X Y Z. The .TXT has options to output the normal vectors at each point and the triangle indices for the three points for each triangle.

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: mdl2stl, mdl2obj, mdl2txt

Prerequisite: Solid MDL file

Smooth Points

This command using a moving least squares method to modify the position of points to make a smoother data set. For each point, the program calculates a least-squares surface using the point plus neighboring points. The Search Radius controls how many points to process when smoothing a point. The Save Sparse Points controls whether to save sparse points which would be thrown out with point smoothing. If points do not have at least 3 neighboring points within the search radius they are discarded. This setting will preserve them.

Prompts

Select points to process.

Select objects: *pick the points to process*

Smooth Points dialog

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: smooth_pts

Prerequisite: point entities

Reduce Points

This command erases point entities in the drawing for any points that are under the specified minimum distance of other points. This command is a way to remove extra points from a laser scan that is more dense than needed for solid modeling.

Prompts

Min distance: 1.0

Select points to process.

Select objects: *pick the points to process*

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: ptreduce

Prerequisite: point entities

Erase Isolated Points

This command removes points without a specified number of neighbors within a distance. This command is a way to remove isolated points from a laser scan that are from noise or don't belong in the model.

Prompts

Select points to process.

Select objects: *pick the points to process*

Search radius <1.0>: *press Enter*

Min neighbor count <3>: *press Enter*

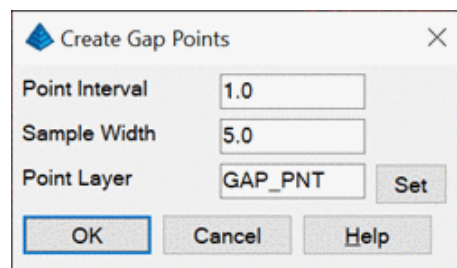

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: ptisolate

Prerequisite: point entities

Create Gap Points

This command creates points to fill a void in a point cloud such as the opening of a tunnel where there are no points from the scanner. The program prompts for three points around the perimeter of the void area. These points are used to define a 3D plane and the new points are created on this 3D plane. In the dialog, the Point Interval is the distance between the new points to create. The Sample Width is the distance from the 3D plane that the program uses to search for existing points to define the perimeter of the void area. The Point Layer is used for the new points.

The example graphic shows the existing points in red and the new gap points in white.

Prompts

Create Gap Points dialog

Pick 1st alignment point: *pick point*

Pick 2nd alignment point: *pick point*

Pick 3rd alignment point: *pick point*

Select points to process.

Select objects: *pick the existing points around the void area*

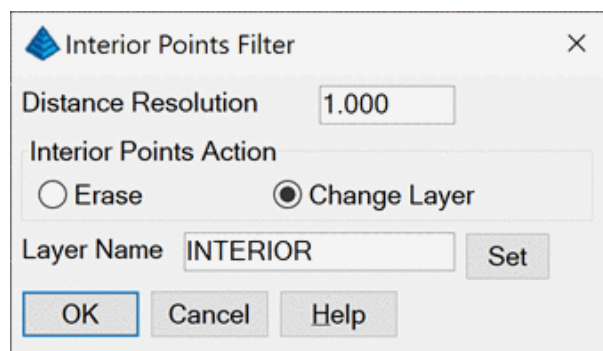

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: gap_pts

Prerequisite: points

Interior Points Filter

This command removes wayward interior points in a tunnel or cavity point cloud such as people or equipment picked up in a scan. The routine checks that points fall within a triangulated mesh of varying triangle sizes. Using smaller triangles should capture more detailed exterior surfaces, but are prone to labeling interior points as exterior points. Larger triangles will capture less surface detail but are more likely to drop interior points. The triangle size is set by Distance Resolution. The dialog has options to either erase the interior points or change their layer.

Prompts

Interior Points Filter dialog

Select points to process.

Select objects: *pick the points to process*

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: interior_pts

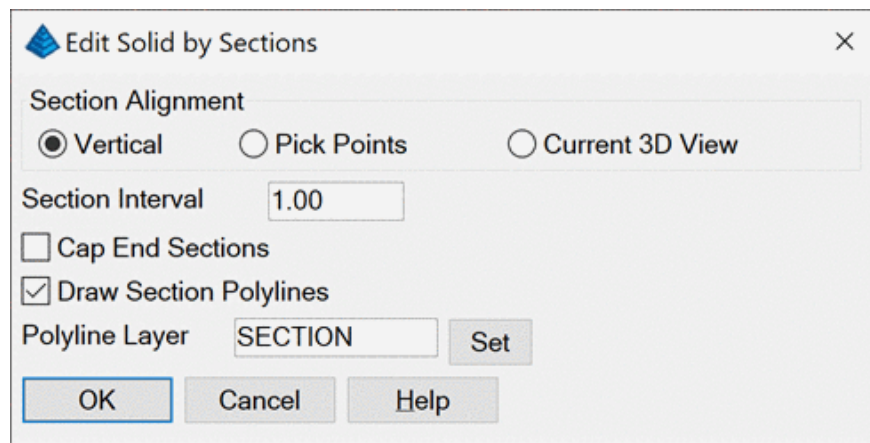

Prerequisite: point entities

Edit Solid

This command edits a solid model (.MDL) by using cross sections. This command is a way to review the solid model in sections and make edits to the sections to correct the model such as for removing nobs.

After selecting the solid model to process and choosing the options in the dialog, the Section Manager dialog docks on the side of the drawing. The Section Manager dialog shows all the cross sections in a graphic window. You can choose the current section by using the Top, Bottom, Up, Down buttons. The current section is highlighted in white. Besides showing the section in the Section Manager graphics windows, the section is also drawn in the drawing window as a polyline. Use the Edit button to edit the current section polyline in the drawing. The edit starts by picking a point on the polyline to begin recreating. Then pick new points for the section polyline. To complete the edit, press Enter at the prompt for new points and then pick a reconnection point on the existing polyline. The Show Adjacent option highlights the section above and below the current section in green and red which helps visualize how the current section transitions to its neighbors. The Delete function removes the current section from the model. When you pick OK on the Section Manager, the program rebuilds the solid model from the sections and prompts for a new MDL file to save the modified model.

Section Alignment: Sets how to section the model. It is important to align the sections with the model to get good sections. For example, with a tunnel the alignment should go along the length of the tunnel so that the sections are like slicing a carrot into discs. The Vertical method slices by elevation range. The Pick Points method prompts for two points and uses the 3D line between these points for the alignment. The Current 3D View method uses the CAD view. This way you can use the CAD 3D view commands to line up a good view for the points.

Section Interval: Sets the distance between sections along the alignment. This distance needs to be big enough to ensure that plenty of points are used for each section, and the distance needs to be small enough to create enough sections to model the solid.

Cap End Sections: This option ends the model at the end cross sections like the model getting sliced at the end sections. Otherwise, the program uses all the model data points at the ends and make a 3D triangulation for the model ends.

Draw Section Polylines: This option draws 3D polylines for the sections on the specified layer.

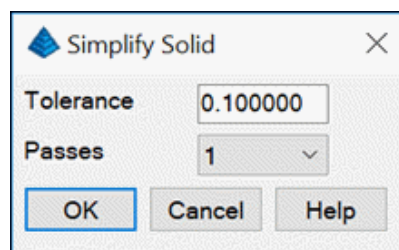

Pulldown Menu Location: Solid

Keyboard Command: edit_solid

Prerequisite: solid model

Simplify Solid

This command reduces the data points in a solid model using the quadric method. The **Tolerance** is the maximum distance the solid is allowed to shift. The program checks all the points in the solid model whether the point can be removed without changing the solid more than the tolerance. After checking all the points and removing points under the tolerance, the program can make another check of the points depending on the **Passes** setting.

Prompts

Solid File To Read: *pick an MDL file*

Simplify Solid dialog: *choose settings*

Solid File To Save: *specify output file*

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: simplify_solid

Prerequisite: Solid file (MDL)

Heal Solid

This command will heal solids by filling holes, making the solid watertight.

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: heal_solid

Remove Solid Dangles

This command removes triangles that are not connected to the majority of the solid model.

Prompts

Solid File To Read: *pick an MDL file*

Solid File To Save: *specify output file*

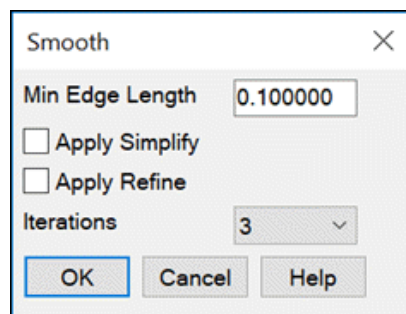

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: solid_dangles

Prerequisite: Solid File (MDL)

Smooth Solid

This command smooths the solid by adding points using the Laplacian method. The Min Edge Length prevents adding points that result in a triangle edge smaller than this value. The Apply Simplify option removes points which can give the solid more freedom to smooth. The Apply Refine option adds points to make the triangles more uniform which can improve the smoothing. These Simplify and Refine options are applied before the smoothing. The Iterations is the number of times the smoothing is applied to the solid.

Prompts

Solid File To Read: *pick an MDL file*

Smooth Solid dialog: *choose settings*

Select inclusion perimeter polyline (Enter for None): *press Enter*

Solid File To Save: *specify output file*

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: smooth_solid

Prerequisite: Solid file (MDL)

Clean Solid

This command removes duplicate points and rebuilds the solid. Points closer than the Distance Tolerance are removed.

Prompts

Solid File To Read: *pick an MDL file*

Clean Solid dialog: *choose settings*

Solid File To Save: *specify output file*

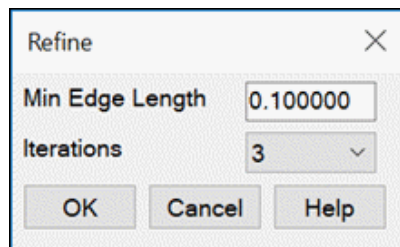

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: clean_solid

Prerequisite: Solid file (MDL)

Refine Solid

This command adds points to the solid to make more uniform triangles. The Min Edge Length prevents adding points that result in a triangle edge smaller than this value. The Iterations is the number of times for the program to check the solid triangles.

Prompts

Solid File To Read: *pick an MDL file*

Refine Solid dialog: *choose settings*

Solid File To Save: *specify output file*

Pulldown Menu Location: Solid> Solid Utilities

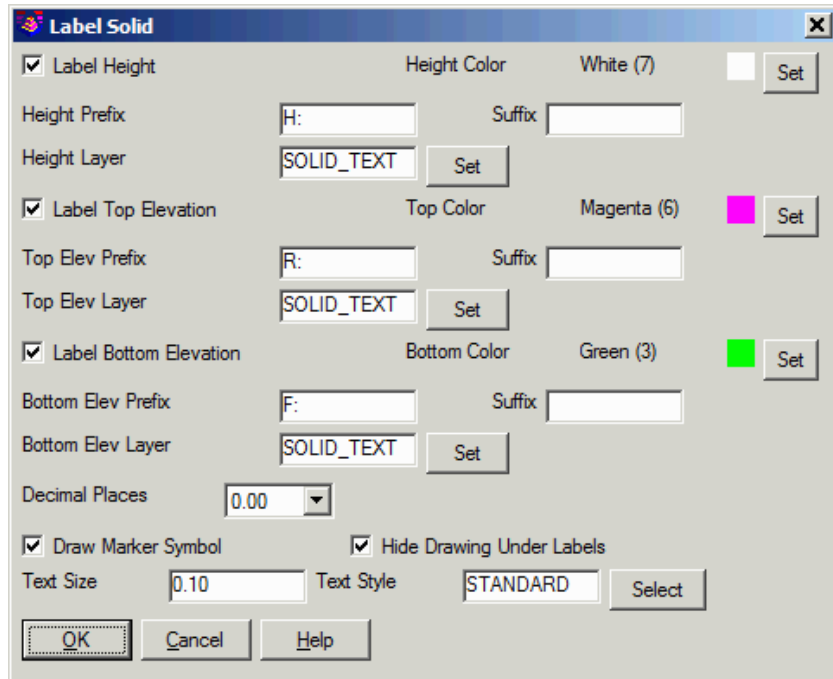

Keyboard Command: refine_solid

Prerequisite: Solid file (MDL)

Label Solid

This command draws labels at picked points for the solid model data. The available labels are the solid model height, top elevation and bottom elevation. For each label, there are controls for the prefix, suffix, color and layer. There are settings that apply to all the labels for the decimal places, size and style. The Draw Marker Symbol option places a symbol at the picked point. The Hide Drawing Under Labels option creates a wipeout under the labels.

× **H:19.84**
R:-558.52
F:-578.36

Prompts

Label Solid options dialog

Solid File To Read *Select MDL file*

Pulldown Menu Location: Solid

Keyboard Command: label_solid

Prerequisite: solid model file

Report Offset Point To Solid

This command calculates the shortest perpendicular distance of a point to the solid. The points can be either individually picked on the screen or read from the vertices of selected entities. The report includes the distance, coordinates of the point and nearest position on the solid, the normal vector from the point to the solid and whether the point is inside or outside the solid.

Prompts

Solid File To Read: *pick an MDL file*

Add from selected entities or pick points [Select/<Pick>]? *press Enter*

Pick point: *screen pick 3D point*

Pick point (Enter to end): *press Enter*

Report Formatter *Choose fields for your report*

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: solid_pt_report

Prerequisite: solid model entities

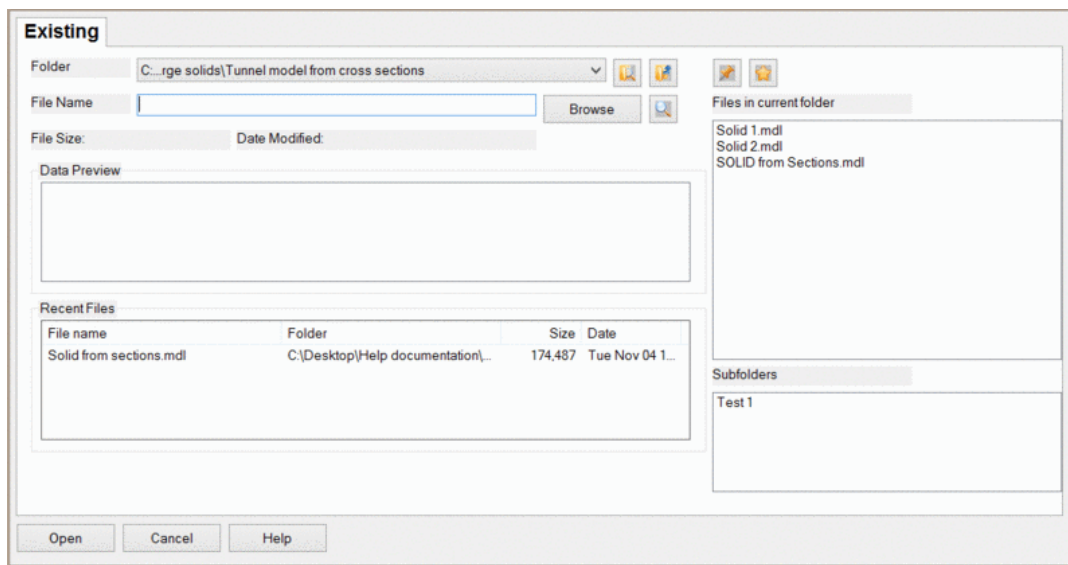

Merge Solids

This command allow you to merge two intersecting/touching solids into a single .mdl file. This command will allow you to select two .mdl files to merge. When prompted, you may assign a name to the merged .mdl file.

The below picture shows two solids, viewed separately.

When the command is executed, the below dialog will appear. The first dialog will prompt for the first .mdl file to load. The second dialog will prompt for the .mdl file to merge with the first.

Keyboard command: merge_solids

Prerequisite: Solid MDL files to merge

Combine Solids

This command puts all the triangles from two solid models into a combined solid model.

Prompts

Select First Solid: *pick an MDL file*
Select Second Solid: *pick an MDL file*
Solid File To Write: *specify output file*

Pulldown Menu Location: Solid> Solid Utilities
Keyboard Command: combine_solids
Prerequisite: 2 MDL files

Add Points To Solid

This command add more points to an existing solid. The points can be either individually picked on the screen or read from the vertices of selected entities. The program finds the nearest position on the solid to the new point and then stitches the point into the solid.

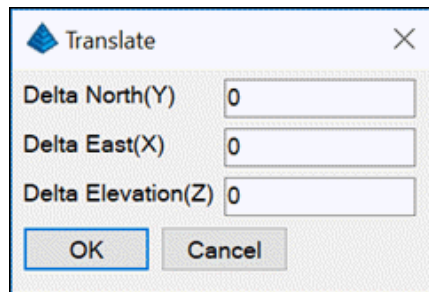

Prompts

Solid File To Read: *pick an MDL file*
Add from selected entities or pick points [Select/<Pick>]? *press Enter*
Pick point: *screen pick 3D point*
Pick point (Enter to end): *press Enter*
Solid File To Write: *pick an MDL file for output*

Pulldown Menu Location: Solid> Solid Utilities
Keyboard Command: add_solid
Prerequisite: Solid file (MDL)

Translate Solid

This command moves a solid by the specified amounts in X, Y and Z.

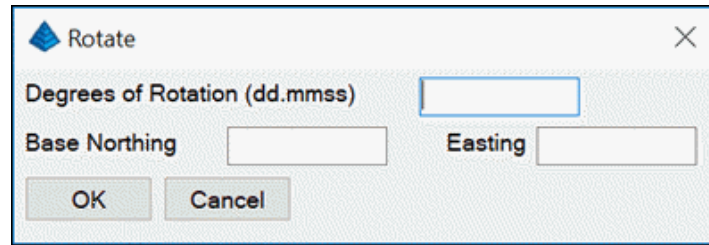

Prompts

Solid File To Read: *pick an MDL file*
Translate dialog: *choose settings*
Solid File To Save: *specify output file*

Pulldown Menu Location: Solid> Solid Utilities
Keyboard Command: translate_solid
Prerequisite: Solid file (MDL)

Rotate Solid

This command rotates a solid in X,Y around the Z axis. The Base coordinate is the pivot point for the rotation.

Prompts

Solid File To Read: *pick an MDL file*

Rotate dialog: *choose settings*

Solid File To Save: *specify output file*

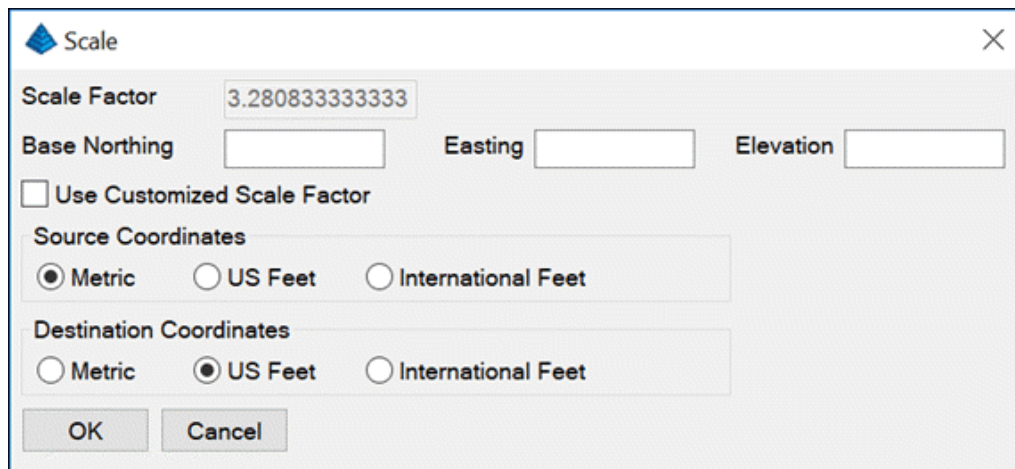

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: rotate_solid

Prerequisite: Solid file (MDL)

Scale Solid

This command scales the points in a solid model. The scale factor can be a custom amount or use a factor to scale between meter and feet units. The Base coordinate can be used to scale the difference between the Base coordinate and the solid points.

Prompts

Solid File To Read: *pick an MDL file*

Scale dialog: *choose settings*

Solid File To Save: *specify output file*

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: scale_solid

Prerequisite: Solid file (MDL)

Flip Solid Order

This command changes the order between clockwise and counter-clockwise of the three points that define each triangle in a solid model. The order of the triangle points determines which sides of the triangle are front and back. The order is important for 3D Viewing and volume calculations. This routine has two methods. The Auto method looks at the direction of the majority of the triangles and flips any triangles going the opposite of the majority direction. The Flip method reverses the direction for all the triangles.

Prompts

Solid File To Read: *pick an MDL file*

Solid File To Save: *specify output file*

Flip Solid Order dialog: *choose settings*

Pulldown Menu Location: Solid > Solid Utilities

Keyboard Command: order_solid

Prerequisite: Solid File (MDL)

Intersect Solids

This command draws 3D polylines along where two solids intersect each other.

Prompts

1st Solid File To Read: *pick an MDL file*

2nd Solid File To Read: *pick an MDL file*

Intersect Solid dialog: *choose layer*

Pulldown Menu Location: Solid> Solid Utilities

Keyboard Command: intersect_solids

Prerequisite: Solid files (MDL)

Trim Solid

This command trims a solid model by either a closed polyline or station range along an alignment polyline. The resulting trimmed solid is saved to a new MDL file. This command is a way to carve out a subset solid.

For the closed polyline method, the polyline should be entirely inside the limits of the solid.

For the alignment method, the centerline polyline should be a 3D polyline that goes along the full length of the solid. This method applies to solids of tunnels. The program prompts for the starting and ending stations along the polyline. The solid is sliced at these stations and then combined with the original solid faces between these stations to create the new solid.

Prompts

Solid File to Read *Select a .mdl file*
Select trim perimeter polyline: *pick a closed polyline*
Solid File to Write *Specify a .mdl file*

Pulldown Menu Location: Solids
Keyboard Command: trim_solid
Prerequisite: 3D Model file (.mdl) and closed polyline

Color Solid

This command assigns either a color or texture to a solid model file (.MDL). This command prompts for the solid model file and then the color or texture to assign.

Pulldown Menu Location: Solid > Solid Utilities
Keyboard Command: color_solid
Prerequisite: MDL file

Solid Information

This command reports the number of points and faces in a solid model along with the coordinate range.

Prompts

Solid File To Read: *pick an MDL file*
Solid: C:\sample\ore2\ball7.mdl
Min X,Y,Z: 22917.942,15537.403,8670.132
Max X,Y,Z: 23125.785,15671.585,8985.034
Number of Points: 3,436 Faces: 6,906

Pulldown Menu Location: Solid > Solid Utilities
Keyboard Command: solid_stats
Prerequisite: Solid File (MDL)

ID Solid

This command prompts to pick any solid 3D face and then reports the source solid model file. Use the Draw Solid command with the Tag Solid Name option to create 3D faces for this routine.

Prompts

Select solid: *pick a solid 3D Face*
Solid Name: RAMP2
Select solid ([Enter] to End): *press Enter*

Pulldown Menu Location: Solid
Keyboard Command: id_solid
Prerequisite: solid model entities

Triangulate & Contour

At the heart of nearly every land design project is at least one terrain model. These models go by several names and one of the most common is that of a "TIN" or Triangulated Irregular Network; another common name is that of a "DTM" or Digital Terrain Model. Since accurate representations of a surface model are significantly important to most land development projects, having a thorough understanding of the Triangulate & Contour controls is very important.

Surface models are generally comprised of combinations of the following general data types:

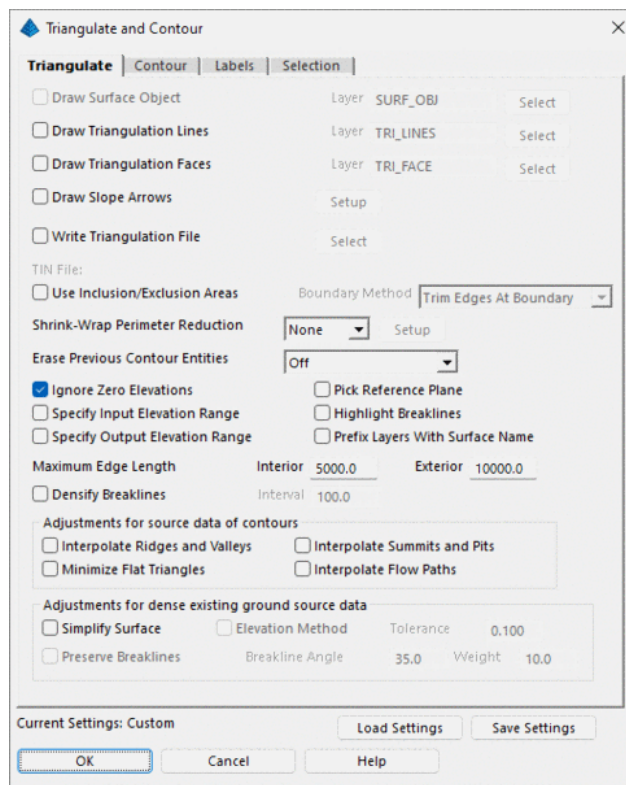

- Points - Most surface models are comprised of points whose coordinates (x,y,z) contribute to the formation of triangular planes that connect three points that are in close proximity to one another. Within Carlson, most points come from the Draw Field to Finish command and/or the Draw-Locate Points command. Points can be selectively filtered from the triangulation engine through the use of the Tag Non-Surface Points command.
- Breaklines - Breaklines (or "fault lines") are used to control the connection sequence between four points which results in two triangles. Common uses of breaklines include ravines, ditches, berms and other areas where distinct grade discontinuity occurs. The "leg" of a triangle can travel along a breakline but cannot cross the breakline. Breaklines must be in the form of 3D polylines or simple lines whose vertices or endpoints define a valid "Z" elevation. A common problem related to breaklines is when two breaklines cross one another in 3D space. In these situations, an impasse results and will result in a "crossing breakline" report. Within Carlson, most breaklines come from the Draw Field to Finish command and/or the 3D Polyline command. Breaklines fall into one of two general categories:
 - "Soft" breaklines - Unless otherwise specified, all breaklines are considered "soft" breakline. The nature of soft breaklines allows a degree of contour smoothing across the breakline itself resulting in a "weathered-" or natural-looking contour.
 - "Hard" breaklines - Breaklines tagged as "hard" breaklines prevent contour smoothing through the breakline. Hard breaklines are generally used to represent man-made terrain breaks that commonly occur during excavation and construction. Breaklines can be changed to hard breaklines through the use of the Tag Hard Breaklines command.

Breaklines and other triangulate-able entities can be selectively filtered from the triangulation engine through the use of the Tag Non-Surface Entities command.

- Inclusions - Inclusions (or "boundaries") are used to identify the entities that can be used for triangulation and multiple inclusion regions can be selected for a given surface model. Entities that fall outside of an inclusion boundary and are not otherwise bound by a different inclusion boundary are ignored by the triangulation engine. Inclusion regions must be in the form of a closed 2D or 3D polylines. Within Carlson, most inclusion polylines come from the Shrinkwrap Entities command.
- Exclusions - Exclusions (or "void regions") are the antithesis of Inclusions and are used to prevent triangulation from occurring between points that are bound by an Inclusion region. Common uses of exclusion regions include building footprints and free-standing water limits (*e.g.* ponds). Entities that fall inside an exclusion region are ignored by the triangulation engine. Exclusion regions must be in the form of a closed 2D or 3D polylines. Within Carlson, most exclusion polylines come from the Boundary Polyline command and/or the 3D Polyline command.

Carlson provides a programming interface for these file types and also offers a third file type (*.GRD) for the representation of terrain data. See the Notes section for additional details.

The **Triangulate** tab provides options and settings that control the creation and analysis of the TIN itself.

Draw Surface Object: This option draws the triangulation faces as a Carlson Surface Object.

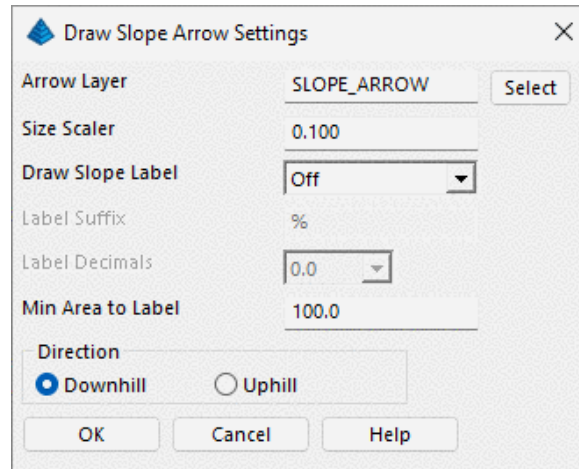

Draw Triangulation Lines: When enabled, the program will draw the triangulation using simple line entities at the appropriate elevation(s). Use the **Select** button or specify the layer for these lines.

Draw Triangulation Faces: When enabled, the program will draw the triangulation using a collection of 3D Face entities. These 3D Faces can then be used rendering routines such as *HIDE* and *SHADE* or in Carlson routines such as 3D Viewer Window, 3D Surface Fly-Over and Slope Zone Analysis. Use the **Select** button or specify the layer for these 3D Faces.

Draw Slope Arrows: When enabled, slope arrows are created within the triangles indicating the downhill dip direction as illustrated below.

Clicking the **Setup** button yields the Draw Slope Arrow Settings dialog box.

Arrow Layer: Indicate the layer to which the slope arrows are to be placed.

Size Scaler: Indicate a positive, non-zero value for the scale factor that should be applied to the slope arrows.

Draw Slope Label: When enabled, the slope value (expressed as a percentage or a ratio) of the triangle is labeled onto the slope arrow. Specify the desired unit suffix (e.g. "%") to apply to the end of the numerical value that is calculated from the TIN triangle(s).

Label Decimals: Indicate the amount of precision that is to be displayed on the slope label.

Min Area to Label: Indicate the smallest allowable triangle size that can be used for the slope percentage labels.

Write Triangulation File: When enabled (strongly suggested), an external surface model file is created which can subsequently be used for volume calculations, the creation of profiles, cross-sections and graded pads. Carlson currently provides two file types to store the DTM data created by the Triangulate & Contour routine:

1. *.TIN - The TIN file format is the default and preferred file format due to its compact file size and organizational efficiency. The Carlson TIN format is governed by Carlson and is in a binary (non-human readable) format.
2. *.FLT - The FLT file format is a legacy ASCII-based (human-readable) file format and is used in some older machine control applications.

Use Inclusion/Exclusion Areas: When enabled, the program will prompt you for inclusion and exclusion polylines and prevents the use of the Shrink-Wrap Perimeter Reduction option. These are used to further control the area of activity for triangulation and contouring. The inclusion and exclusion polylines must be closed polylines and when used, must be drawn before using *Triangulate & Contour*. It is suggested that the height of the **Command:** line display must be set to show at least two lines so that the additional prompts can be easily viewed. Refer to the Notes section for additional information on Inclusion/Exclusion polyline selections.

Boundary Method: This option controls whether edges that cross the inclusion or exclusion perimeter are trimmed or removed. Use the Remove option if you don't want the triangulation to interpolate across the perimeters. Use the Trim option if you want the triangulation to fill the area up to the perimeter.

Shrink-Wrap Perimeter Reduction: This option produces an inferred Inclusion region around the data to be selected and mimics the results of the Shrinkwrap Entities command. Under the Setup, there is an option to draw the shrink-wrap perimeter polyline on a specified layer.

Erase Previous Contour Entities: In the event that a TIN needs to be recreated and Carlson-produced contours are in the drawing, three options exist that allow you to control whether or not the contour data should be removed from the drawing:

- **Off** - All existing Carlson-generated contours are left intact in the drawing. If these contours satisfy all of the triangulation requirements, they can be utilized by the Triangulation algorithm.
- **Current Surface** - Only the Carlson-generated contours that are associated with the active Triangulation file are removed from the drawing.
- **All Contour Entities** - All Carlson-generated contours are removed from the drawing, regardless of the surface model that created them.

Ignore Zero Elevations: When enabled, this option will filter out all data points and entities at an elevation of zero from the triangulation data set.

Pick Reference Plane: When enabled, this option allows you to contour an overhang or cliff by changing the reference plane to a side view. The reference plane can be specified by using the *View>Viewpoint 3D>View* command (see the AutoCAD/IntelliCAD Help menu for additional details) or by specifying three data points on the cliff (two along the bottom and one at the top).

Specify Input/Output Elevation Range: If you would like to manually set the range over which to contour, select either or both of the aforementioned toggles. One controls the triangulation of the source data and the other for the contour output. The program will automatically contour from the lowest elevation in the data set up to the highest at the increment specified in Contour Interval.

Highlight Breaklines: When enabled, this routine highlights breaklines in the triangulation network by drawing the triangulation lines along breaklines in yellow.

Prefix Layers With Surface Name: This option applies when using Write Triangulation File. The file name is added as a prefix to all the layers created during Triangulate and Contour as a way for layer management to organize all the contouring layers for a surface file.

Maximum Edge Length: Two bounds are provided to limit the length of the "legs" within a triangulation network. Based on the available data, if the edge length of a triangle exceeds the respective bound, the triangle will not be formed:

- **Exterior:** This value applies to triangulation lines around the perimeter of the triangulation area.
- **Interior:** This value applies all the other triangulation lines. Generally you would have the Exterior value larger than the Interior value.

Densify Breaklines: This option subdivides linework segments for the input data so that the maximum length of the segments is the specified Interval. This option is similar to the Densify Polyline Vertices command except that the entities are not modified in the drawing. Having shorter breakline segments is often helpful for holding the breaklines in the TIN and making more regularly sized triangles.

Minimize Flat Triangles: When enabled, this toggle instructs the triangulation "engine" to iterate through the triangulation permutations to minimize the occurrence of "flat" (or more precisely, horizontal) triangles. Flat triangles often occur when creating surface models from contour data. In this scenario, the often used Delaunay triangulation algorithm may produce unrealistic results. The Minimize Flat Triangle option will perform additional permutations of the triangulation network through the use of the Surface Manager > Swap Edge routine in an attempt to maximize the number of "sloped" triangles. Another option that produces similar results is the Interpolate Ridges and Valleys option.

Before: Surface made from an existing contour map with Minimize Flat Triangles disabled.

After: The same surface with Minimize Flat Triangles enabled. Note the better defined ravine and ridge definitions.

Difference: A Cut/Fill Color Map showing the regions of significant triangulation difference between the "Before" scenario and the "After" scenario of "Minimize Flat Triangles."

Interpolate Ridges and Valleys: The purpose of this option is to avoid flat areas by better defining surface ridges and valleys. When enabled, this option inserts breaklines into the drawing which are subsequently used in the triangulation process in an attempt to minimize flat, horizontal triangles.

Interpolate Summits and Pits: When enabled, this option creates additional triangulation in a summit or pit situation to more accurately represent existing ground conditions from a surface model created from contour entities. Since the tops of hills and the bottom of pits are often not shown on existing ground contour maps, this option often helps improve the accuracy of existing terrain conditions.

Interpolate Flow Paths: this function generates 3D data polylines from a contour map that approximate the downhill flow of water through valleys. These polylines are then used when creating a triangulation and can improve the it in these valley regions by giving more definition to these areas. The polylines are created by looking for "sharp" or angled regions of the contours, and then connecting these regions with a smooth curve.

Simplify Surface: When enabled, this option reduces the digital size of a surface without significantly compromising the integrity or accuracy of the surface itself. The most common application to enable this option is when using very large datasets, such as smoothed contours. Its use is less applicable to design surfaces or surfaces based on surveyed points, but it can still be utilized.

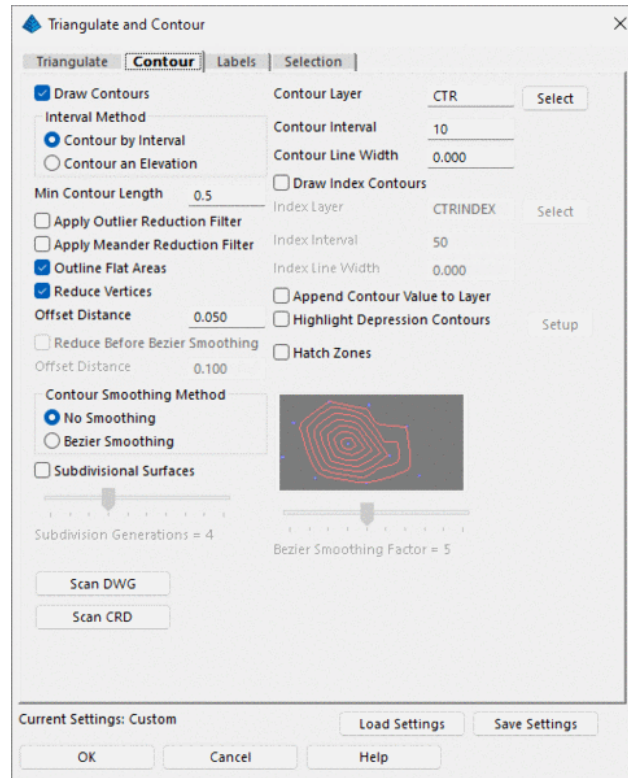

Elevation Method: When enabled, this option reduces the size of the surface file by analyzing the difference in elevation between each vertex of the TIN and the vertices directly surrounding it, assigning a numerical weight or value to each vertex. If it is determined that the calculated weight for a particular vertex is less than the *Tolerance* factor, the vertex is a candidate for removal. The number of vertices removed is directly proportional to the *Tolerance* factor, so the higher the *Tolerance* factor, the more vertices are removed and vice versa.

Preserve Breaklines: When enabled, this option analyzes the TIN by focusing on the edges; calculating the angular difference between adjacent triangular faces. If the angular difference between edges is greater than the specified *Breakline Angle*, it is considered to be a breakline, and it is preserved. If its angular difference is determined to be below the *Breakline Angle*, it becomes a candidate for removal. In that case, the *Weight* factor is applied to the corresponding vertex, adjusting its original value. If the resulting value is still below the *Tolerance*, it is then removed. The number of vertices removed is inversely proportional to the *Weight* factor, so the greater the *Weight* factor. The fewer vertices that are removed, the lower the *Weight* factor, the more vertices that are removed.

A good rule-of-thumb that can be used when deciding whether or not to use these options is:

- If the surface contains no man-made features, use *Simplify Surface* option (with or without the *Elevation Method* option).

- If the surface contains man-made features, such as roads, use both *Simplify Surface* and *Preserve Breaklines*.

Draw Contours: When enabled, the program will draw contour lines using the designated settings after triangulation process is complete. Otherwise, only the designated Triangulation operations are performed. If this option is disabled and contours are subsequently desired, use the Contours from TIN File command.

Interval Method: Indicate the desired elevation(s) for contours to be drawn:

- **Contour by Interval:** Specify the desired interval (*e.g.* every 2 feet) into the *Contour Interval* field.
- **Contour an Elevation:** Specify a desired elevation (*e.g.* a floodplain elevation or other unique elevation of interest) and set the desired value into the *Contour Interval* field.

Contour Layer/Index Layer: Specify the layer to which the contours/index contours are to be drawn.

Contour Interval/Index Interval: Specify the interval to which the contours/index contours are to be drawn. When contouring an elevation, you can enter multiple space-separated values to draw multiple contours. For example, entering "5 8 14" into this field would draw contours at elevations, 5, 8, and 14.

Contour Line Width/Index Line Width: Specify the line width to be applied to the contours/index contours.

Draw Index Contours: When enabled, index (or "major") contours will be created with independent characteristics from the regular contours.

Min Contour Length: Specify the minimum linear threshold that should be used to draw contours.

Apply Outlier Reduction Filter: When enabled, this option attempts to remove "the jaggies" which tend to occur along long, thin triangles.

Apply Meander Reduction Filter: This option smooths contours by removing back-tracking.

Outline Flat Areas: This option will outline flat areas of the surface. This is particularly useful for showing catch-benches that have been designed into a steeply angled portion of the surface. In the below image, a the 700'

contour line is drawn on both sides of the catch bench. If the Outline Flat Areas option were disabled, only one side of the catch bench would be drawn.

Reduce Vertices: When enabled, this option removes extra vertices from the contours using the *Offset Distance* value. The Offset Distance is the maximum amount that the polyline can move horizontally when removing a point. The result of this action is often a significant reduction in vertex locations along the contour resulting in a more efficiently-sized and compact drawing file.

Offset Distance: Specify the maximum allowable distance for shifting the original contour line in order to reduce vertices. The reduced contour will shift no more than this value, at any point, away from the original contour line. A lower value will decrease the number of vertices removed and keep the contour line closer to the original. A higher value will remove more vertices and allows the contour to shift further from the original location.

Reduce Before Bezier Smoothing: When enabled, this option removes extra vertices from the contours before they undergo Bezier Smoothing using the *Offset Distance* value. The Offset Distance is the maximum amount that the polyline can move horizontally when removing a point. Removing points before smoothing gives the Bezier smoothing more freedom to make the contour curvy.

Contour Smoothing Method: Indicate the desired amount of smoothing (often used for existing, natural ground conditions to simulate a "weathered terrain" effect) that should be applied to the contours:

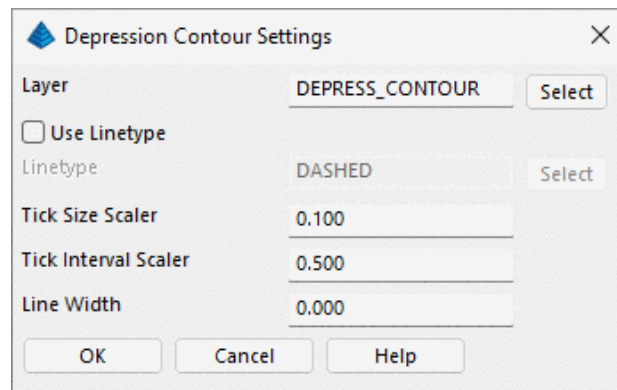

- **No Smoothing:** This option is often used for proposed, man-made surface considerations where the terrain has been shaped with earth-moving equipment. For applications where a "nature-emulated" man-made terrain is desired, refer to the Carlson Natural Regrade documentation.
- **Bezier Smoothing Factor:** This option holds all the contour points calculated from the triangulation and only smooths between the calculated points.
- **Polynomial Smoothing:** This option applies a fifth degree polynomial equation through the contour data points for a smooth transition between the triangulation faces.

Subdivisional Surfaces: When enabled, adjust the horizontal slider to indicate the degree of triangular subdivisions. This causes each triangle in the triangulation surface model to be subdivided into $(x + 1)^2$ triangles, where $x = \text{Subdivision Generations}$. The mathematically generated sub-triangle vertices are raised or lowered to provide smoother contours. More generations increase the smoothness of the contours but incur increased processing time.

Although this algorithm does not produce "crossing contours," it can result in undesired contours in terrain scenarios such as where graded slopes abruptly transition to nearly horizontal slopes (e.g. the sides and bottom of a detention pond).

Bezier Smoothing Factor: Adjust the horizontal slider to obtain a preview of how much smoothing can be expected at each setting. Sliding the bar to the left results in a lower setting which have less looping or less freedom to curve between contour line points. Likewise, moving the slider to the right results in a setting that increases the looping effect. Note that too much smoothing applied in some situations can result in crossing contours.

Highlight Depression Contours: Depression contours are the lowest elevation closed contours that are surrounded by higher closed contours. This option highlights depression contours by either using a separate linetype or by drawing tick marks along the contour. Use the *Setup* button to get this dialog of settings for depression contours.

Linetype: Set the CAD linetype to use for depression contours.

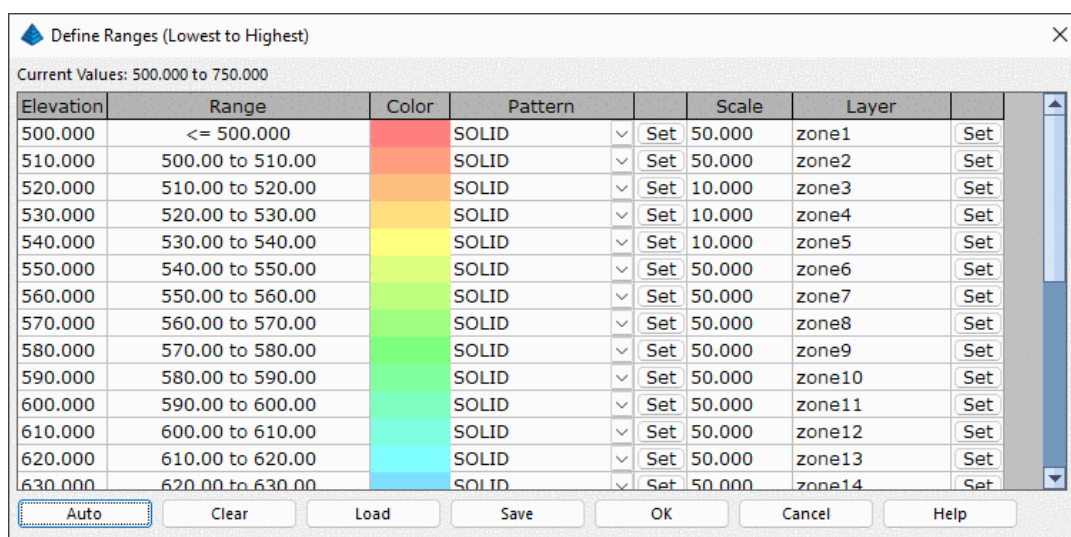

Layer: Specify the layer to which the depression contours are to be drawn.

Tick Size Scaler: Indicate the relative scale factor that should be applied to the depression ticks.

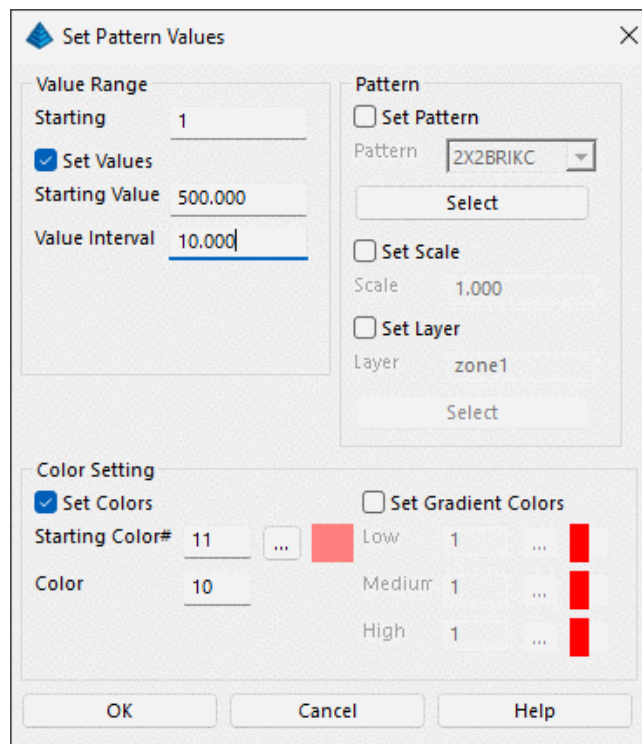

Tick Interval Scaler: Indicate the desired interval scaler which controls the spacing of the depression ticks.

Line Width: Specify the line width to be applied to the depression contours.

Hatch Zones: When enabled, this option will create hatching between the contours based on elevation zones. The following dialog will open allowing the user to specify the hatch type and color for each elevation zone. The entire elevation range of selected data is displayed under Current Values.

Auto: Opens the following dialog, allowing for automatic configuration of the range of elevations in each zone, assigning of colors and hatch patterns, and the scale.

Starting Zone: Sets the zone with which to begin the application of the setting defined in this dialog. For Instance, if the Starting Zone was set to 10, the settings definitions applied here wouldn't affect Zones 1-9, but would start at Zone 10.

Set Values: Enables the Starting Value and Value Interval fields, which allow the user to specify the starting elevation for the given zone and set the zone increment.

Starting Value: Sets the elevation of the beginning zone to define.

Value Interval: Sets the elevation increment for subsequent zones.

Set Pattern: Sets the hatch pattern for the defined zones.

Set Scale: Enables the Scale option.

Scale: Sets the scale for the selected hatch pattern.

Set Colors: Modifies the colors in the table using either Starting Color and Color Increment, or the Gradient option.

Starting Color: Sets the starting color number based on the standard CAD color chart.

Color Increment: Sets the color number to increase for subsequent zones. So if the increment was set to 5, and the starting color was 60, the next color would be 65, 70, and so on.

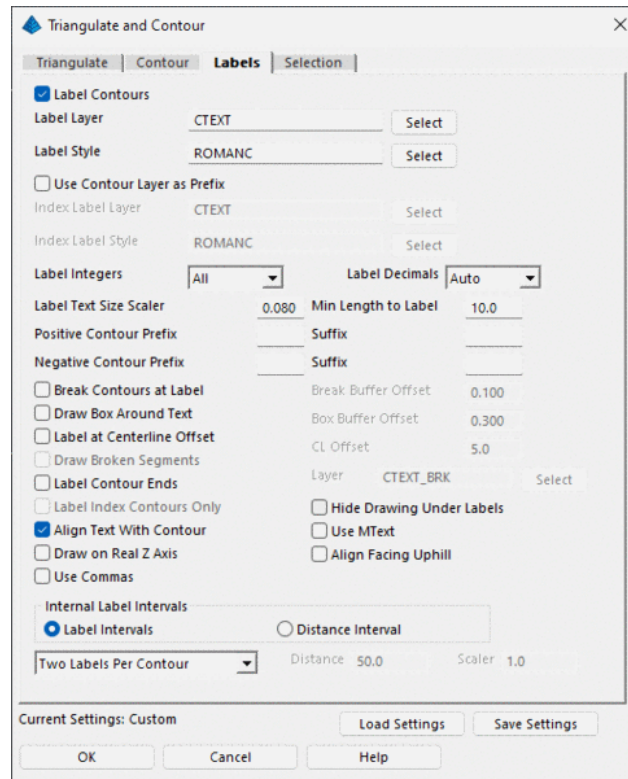

Set Gradient Colors: Sets the colors according to **Low**, **Medium**, and **High** colors. Note that the program will use the Index Colors (total of 256 color options) when setting gradients, which can result in duplicated colors if there are many entries in the table. This option is best used when there are only a small number of hatch zones.

Clear: Clears the all of the Elevation fields in the dialog.

Load: Loads previous settings from a saved .pat file.

Save: Saves the current setting configuration to a .pat file.

Scan DWG/Scan CRD : These buttons report the elevation range which can help with choosing the contour interval.

Label Contours: When enabled, contours will be labeled based on the settings below. If this option is disabled and further contour annotation is desired, utilize the Contour Elevation Label command.

Label Layer: Specify the layer name for intermediate contour labels. To only label index contours, enable the Label Index Contours Only option.

Label Style: Specify the text style that will be used for the contour label text.

Use Contour Layer as Prefix: This option adds the Contour Layer name to the Label Layer name.

Index Label Layer: Specify the layer name for index contour labels.

Index Label Style: Specify the text style that will be used for the index contour label text.

Label Integers controls how many digits to label to the left of the decimal. For example, if all contours are in the 5000's, then setting for three digits would label the 5280 contour as 280.

Label Decimals: Specify the amount of precision to display on the contour labels.

Label Text Size Scaler: Specify a relative text size scale factor to be applied to the label(s).

Min Length to Label: Specify the desired minimum length of contours that should be annotated. In other words, Contours whose length is less than the value will not be labeled.

Positive/Negative Contour Prefix: Indicate a desired string of prefix text (*e.g.* Elev=) that is to precede the positive and/or negative contour elevations, respectively.

Positive/Negative Contour Suffix: Indicate a desired string of suffix text that is to follow the positive and/or negative contour elevations, respectively.

Break Contours at Label: When enabled, the contour lines will be broken and trimmed at the label location for label visibility. As an alternative to physically placing a gap into the contour, consider using the Hide Drawing Under Labels option.

Break Buffer Offset: Specify the offset distance which determines the gap between the end of the trimmed contour line and the beginning or ending of the text.

Draw Box Around Text: When enabled, a rectangle is drawn around the contour elevation labels.

Box Buffer Offset: Specify the offset distance which determines the gap between the box and the beginning or ending of the text.

Label At Centerline Offset: When creating contours and subsequent plan sheets for roads, enable this option to position the labels at a fixed offset from a centerline. The program automatically uses any polylines in the drawing that are tagged as centerlines. To check whether a polyline is a centerline, use the Centerline ID command. To create a centerline polyline from a centerline file, use the Draw Centerline File command.

Draw Broken Segments: When enabled, the segments of contours that have been broken out for label visibility will be redrawn as independent segments. To join these segments back into the contour, use the Join Nearest command.

Layer: Specify the layer that is to receive the newly drawn broken segments.

Label Contour Ends: When enabled, the ends of "open" contours will be labeled.

Label Index Contours Only: When enabled, only the index contours are labeled. This option is active only when Draw Index Contours has been selected in the Contour tab.

Hide Drawing Under Labels: When enabled, a "Wipeout" entity is placed with the annotation label that will create the appearance of trimmed segments at the contour label, even though the contour line is still fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels yet the contour lines themselves remain contiguous. This feature will also hide other entities that are in the immediate vicinity of the contour label.

Align Text with Contour: When enabled, the contour elevation labels will be rotated to align with their respective contour lines.

Use MText: When enabled, contour labels are created using the MText entity type. Otherwise, the standard DText entity type is used.

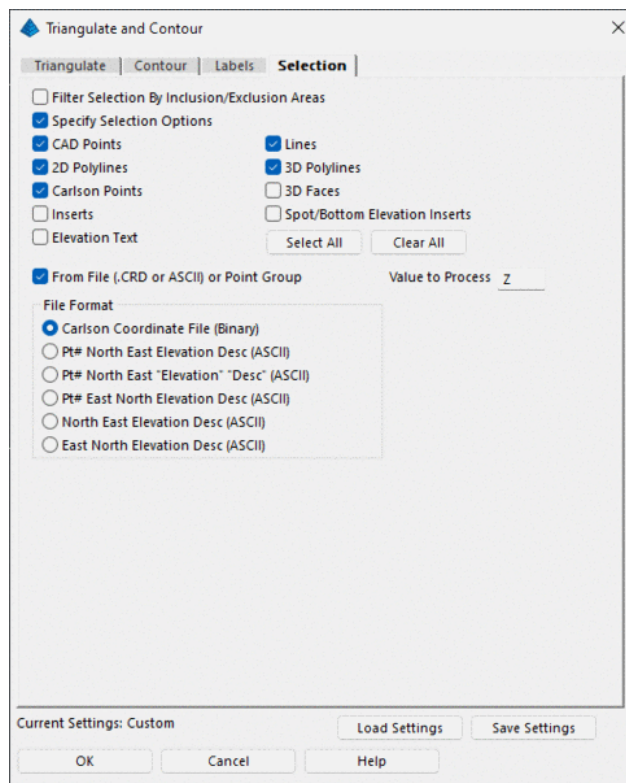

Draw On Real Z Axis: When enabled, the contour labels are placed at the same "Z" (elevation) value of the contour itself. When disabled, the contour labels are placed at a "Z" (elevation) value of 0 (zero).

Align Facing Uphill: When enabled, the contour elevation labels will still be rotated to align with their respective contour lines, but the labels will be placed in such a manner that the top of the text label will always be toward the uphill side of the contour.

Use Commas adds a comma into the labels for the thousands place such as "5,000" instead of "5000".

Internal Label Intervals: Indicate the desired method for contour labels within the contour itself:

- **Label Intervals:** This option will label each contour with a set number of labels.
- **Distance Interval:** This option allows you to specify an interval distance between labels. The distance can be set in drawing units or as a scaler that is multiplied by the drawing horizontal scale.

Filter Selection By Inclusion/Exclusion Areas: This option filters out selected entities from the triangulation that are outside the surface area defined by the inclusion/exclusion perimeter polylines. Otherwise, all the selected entities are used for triangulation and then the triangulation is trimmed at the inclusion/exclusion perimeters. Whether to prompt for inclusion/exclusion perimeters is specified on the Triangulate Tab.

Specify Selection Options: When enabled, indicate the type(s) of entities that are to be used during the triangulation process. This is an excellent method of "filtering out" unwanted entity types or enabling the use of desired entity types.

CAD Points, Lines, 2D Polylines, 3D Polylines, 3DFaces, Elevation Text and Inserts (blocks) are standard CAD entities types.

Carlson Point Inserts refer to Carlson points (such as those placed with the Draw Field to Finish command or which utilize the Carlson "SRVNO*" family of blocks with point number, elevation, and description attributes).

Spot/Bottom Elevation Inserts include text entities that start with 'X'.

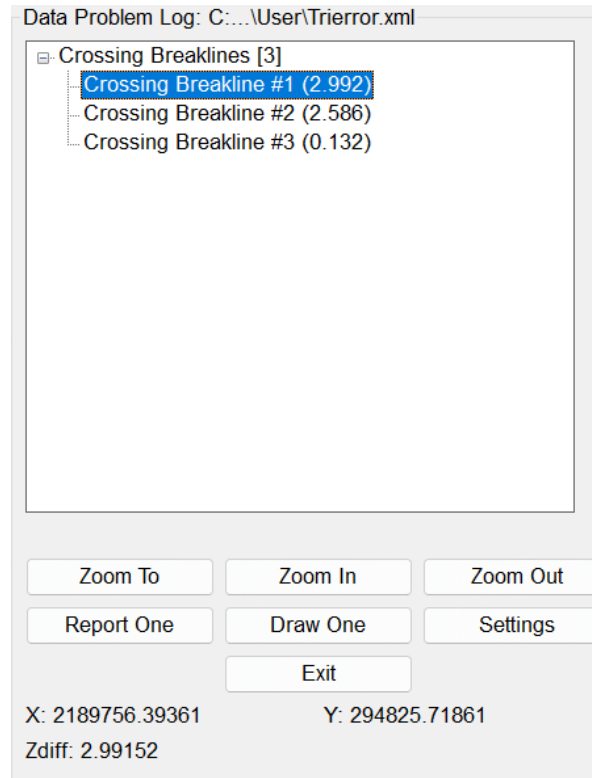

From File: When enabled, allows you to triangulate from the points in an external coordinate (.CRD) or ASCII file. This option also provides access to the use of Point Groups as a data source.

An *Error Log* is generated if the triangulation routine finds vertical conflicts between breaklines or other surface entities and displays the conflicts in a "docked dialog box." Three types of conflicts are reported (each conflict type is listed into its own category):

1. Crossing Breaklines - Indicates the common X,Y location of two breaklines that do not share a common "Z" elevation.
2. Vertical Edges - Indicates that two entities or vertexes of differing elevations have the same x-y location, thus forming a vertical plane to another point.
3. Breakline T-Intersections - Indicates that a third entity is abutting another entity, but the second entity doesn't have a vertex at the point of intersection.

Click the "+" sign beside a category to display the individual conflicts within that category and click the "-" sign

to collapse the list. When a line item error is selected, a highlighted arrow is temporarily placed in the drawing to indicate the exact location of the specific conflict. Zoom functionality allows the user to more closely inspect the specific problem area, and if needed a marker can be drawn or a report generated for an individual conflict or conflicts.

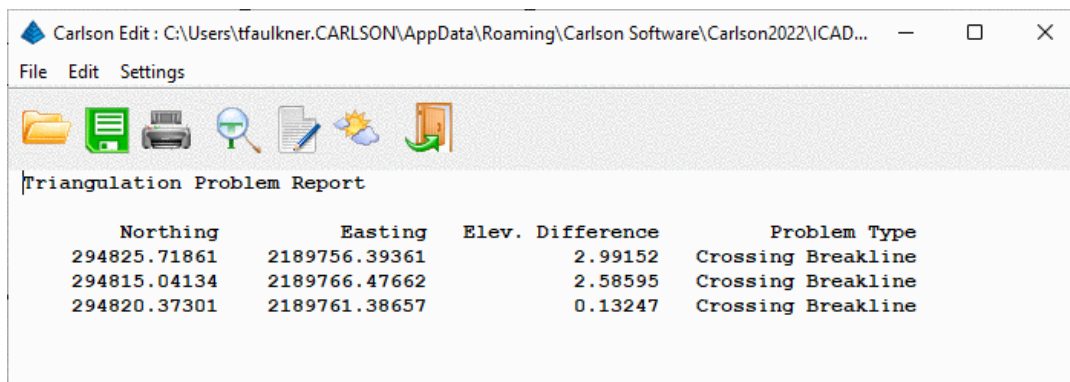

Zoom To: Centers the display on the location of the error without affecting the zoom resolution.

Zoom In: Increases the ability to see detail.

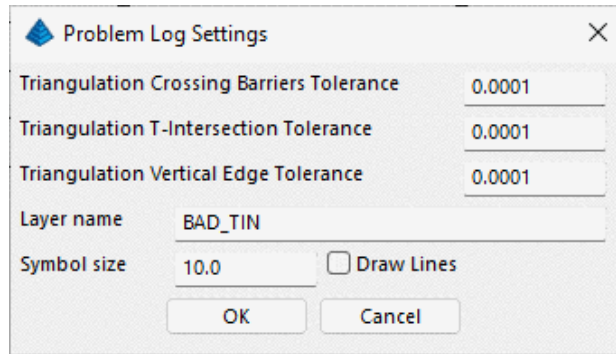

Zoom Out: Decreases the ability to see detail.

Report One/All: This option toggles between "One" and "All" depending whether a single line item conflict or an entire category is selected from the error log. An error report is generated listing the x-y position and the elevation difference of the entities in conflict.

Draw One/All: This option toggles between One and All depending whether a single conflict or a category is selected from the list. This option draws an "X" symbol at each selected conflict.

Settings: Indicate the desired configuration settings for the error log:

Tolerances: Indicate the lowest elevation difference threshold that should be reported for Crossing Breaklines, Vertical Edges and Breakline T-Intersections, respectively.

Layer Name: Specify the layer name for the "X" entities drawn with *Draw One/All* option. This also sets the layer name for the *Draw Lines* option.

In the case of crossing polylines, *Draw Lines* will trace over the polylines responsible for the conflict.

Symbol Size: Specify the size of the "X" symbol that is drawn to delineate the selected errors. This will determine the actual size of the symbol in the drawing. This value is not multiplied by the horizontal drawing scale.

Note:

- When selecting Inclusion/Exclusion polylines, you may select any number of Inclusion polylines and any number of Exclusion polylines. Selecting multiple Inclusion polylines results in "islands" of terrain data within a given TIN file.
- If *Triangulate & Contour* reports zero points found and fails to do anything when you're using Carlson points, then those points are probably located at zero elevation. To fix this problem, make sure that Carlson Point Inserts is toggled on in the Selection tab. This will enable *Triangulate & Contour* to read the elevation from the elevation attribute of the point.
- For those experienced in programming, Carlson offers a DTM API (Application Programming Interface) which provides functions that can be used to access and manipulate information stored within a DTM file.
- In surface situations where a series of rectangular grid cells are desired, explore the Make 3D Grid File command.

Prompts

The following are the most often encountered prompts:

Select the Inclusion perimeter polylines or ENTER for none.

Select entities: Select the desired closed polylines that form the bounding inclusion area(s) of the surface model and press Enter when complete.

Select the Exclusion perimeter polylines or ENTER for none.

Select entities: Select the desired closed polylines that form the regions(s) of the surface model where triangulation should not occur and press Enter when complete.

Select the points and breaklines to Triangulate.

Select entities: Select the desired entities from CAD using standard CAD selection methods and press Enter when complete.

Pull-down Menu Location(s): Surface (Survey, Civil, Hydro, Construction, Field, Natural Regrade), Takeoff > Surface Tools

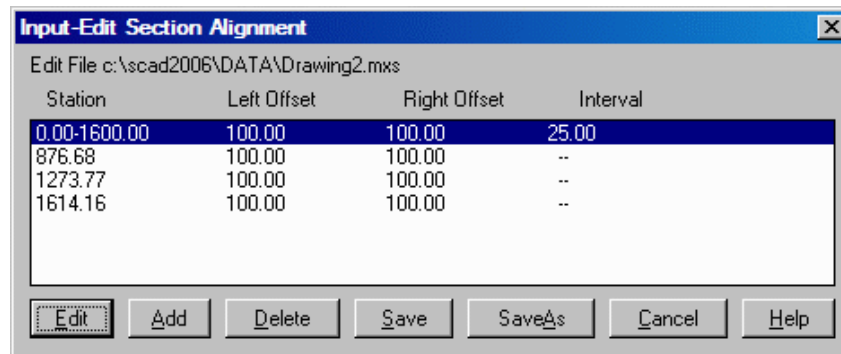

Keyboard Command: tri

Prerequisite: 3D entities in the drawing (defined by the Selection Tab) and/or an external point file

Section Alignment Editor

This command will create or append to a section alignment file which is stored as a Multiple Cross Sections (.MXS) file. This file contains the coordinates that define the center and endpoints of section lines and is a requirement of many section commands such as *Sections from Surface Entities* and *Sections to 3D Polyline*. The section alignment defines the stations along a centerline and how far left and right to create cross sections. This routine starts by asking for a new or existing .MXS file name. Then the centerline is specified by either by choosing a centerline file (.CL file) or selecting a polyline that represents the centerline. Next, the program prompts for the starting station of the centerline. If this is a new section alignment, the Make MXS File Settings dialog appears.

The Section Alignment Editor dialog lists all the section stations and offsets in the alignment of an existing .MXS file.

Dialog if using an existing .MXS file

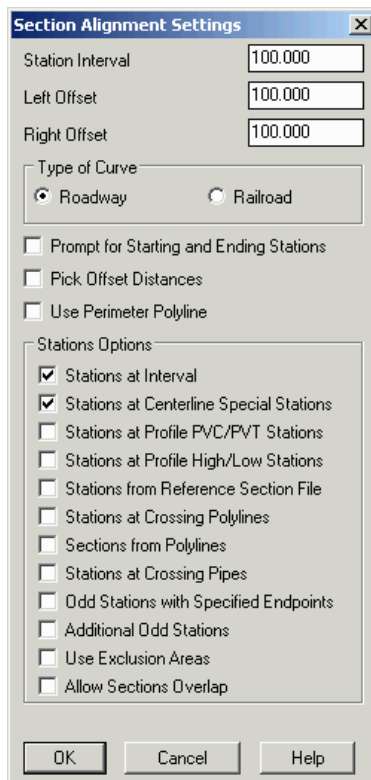

Edit: Allows you to edit the currently highlighted row.

Add: Allows you to add more sections by displaying the Make MXS File Settings dialog (shown below).

Delete: Deletes the currently highlighted row.

Save: Saves the MXS file, exits this dialog and draws the section alignment on the screen using temporary vectors (yellow for left offsets, magenta for right offsets). Any viewport change such as *Redraw* or *Zoom* will cause these vectors to disappear. The draw the section lines with Line entities, use the *Draw Section Alignment* command.

SaveAs: Saves a new MXS file with a user-specified name.

Dialog used for a new section alignment

Station Interval: Enter the station interval for sections.

Right Offset: Enter the width for the sections, right of the centerline. Not available if Pick Offset Distances is checked.

Left Offset: Enter the width for the sections, left of the centerline. Not available if Pick Offset Distances is checked.

Type of Curve: Specify either Roadway or Railroad curve to account for the differences in stationing curves.

Prompt for Starting and Ending Stations: This option allows you to specify the range of stations to process. Otherwise the program will use the full station range of the centerline.

Pick Offset Distances: Allows you to specify the offsets by using the distance between two picked points in the drawing.

Use Perimeter Polyline: Allows you to specify a closed polyline that will be used as the limit of the cross sections. The offsets will be contained within this closed polyline.

Station By Another Reference Centerline: Prompts for a separate CL to use for stationing. The program sets for station to store for the section alignment by locating the position of the original station on the section alignment centerline and then finding the station of this position along the reference centerline.

Stations at Interval: Creates cross sections at the specified interval such as every 25 feet. If the Prompt for Starting and Ending Stations is on, then the program will apply the station interval to the user-specified range of stations. Otherwise the station interval is used along the entire centerline.

Stations at Centerline Special Stations: Creates cross sections at every transition point in the centerline such as the PC, PT, spiral points and end points.

Stations at Profile PVC/PVT Stations: Creates cross sections at profile vertical curve transitions stations. When active, the program will prompt for the profile to process.

Stations at Profile High/Low Stations: Creates cross sections at profile vertical curve high and/or low stations. When active, the program will prompt for the profile to process.

Stations from Reference Section File: Creates cross sections at stations contained in the reference section file. When active, the program will prompt for the section file to process.

Stations at Crossing Polylines: Allows you to select polylines that cross the centerline and creates cross sections at the intersections of these polylines with the centerline.

Sections from Polyline: This method prompts to select polylines that define the section alignments. This method is handy when the section alignments have multiple bends such as for HEC-RAS.

Stations at Crossing Pipes: This method creates cross sections at the stations where pipes intersect.

Odd Stations with Specified Endpoints: Creates cross sections at stations that are entered or at picked points along the centerline. This option also allows you to pick the left and right offset points which do not have to be perpendicular to the centerline.

Additional Odd Stations: Creates cross sections at the specified stations but the offsets are always perpendicular to the centerline with the user-defined default offset distances.

Use Exclusion Areas: This option prompts for selecting closed polylines to use as exclusion areas which are areas to skip for the section surface. The stations and offsets for the exclusion areas are stored in the section alignment file. Then routines like Calculate Section Volumes and Draw Sections will skip over these areas and not calculate volumes or draw section lines in these areas.

Allow Sections Overlap: On the inside of a centerline curve, section lines will cross when the section length is longer than the radius. This option controls whether to shorten the section lines on the inside of the curve or to keep the regular length and let the section lines cross.

Prompts

Specify an MXS file dialog Choose new or existing.

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: *pick centerline*

Enter Beginning Station of Alignment <0.00>: *press Enter*

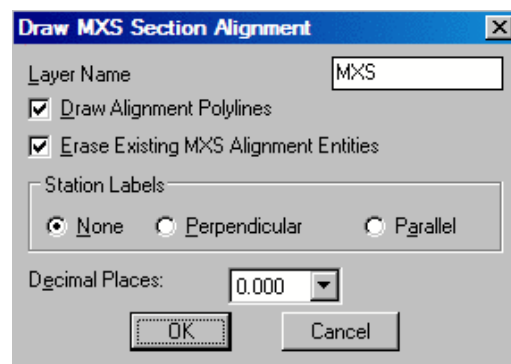

Pulldown Menu Location: Sections

Keyboard Command: editmxs

Prerequisite: A polyline centerline or a centerline .CL file

Draw Section Alignment

This command will draw the location of the cross sections contained in an existing .MXS file. The cross sections stations can also be labeled Perpendicular or Parallel. The main purpose of this routine is to allow you to graphically view the location of the cross sections.

A drawn .MXS file along with the centerline

Pulldown Menu Location: Sections

Keyboard Command: drawmxs

Prerequisite: An existing .MXS file

Sections from Grid or Triangulation Surface

This command creates a cross section file (.SCT file) from a surface model that is defined by a 3D rectangular grid file (.GRD file) or a triangulation file (.FLT, .TIN). The grid file can be created in the Civil Design module with the *Make 3D Grid File* routine. The triangulation file can be created with the Write Triangulation File option in the *Triangulate & Contour* command. This command also requires a Section Alignment (.MXS) file to define the alignment and stations of the sections. The number of section points created is displayed at the end of the routine.

When using a triangulation file, there is an option for whether to link the sections to the triangulation. With the link, the section file will get updated in case the triangulation file is updated. When the link option is set to Auto, the update is done automatically. When the link option is set to Prompt, the program will prompt with a dialog for whether to update the sections when a triangulation change is detected.

Prompts

Choose Grid or Triangulation File to process *choose existing .GRD, .FLT, or .TIN file*

Choose MXS File to Process *choose existing .MXS*

Choose Section file to write *enter new file name*

Found 1410 section points.

Pulldown Menu Location: Sections

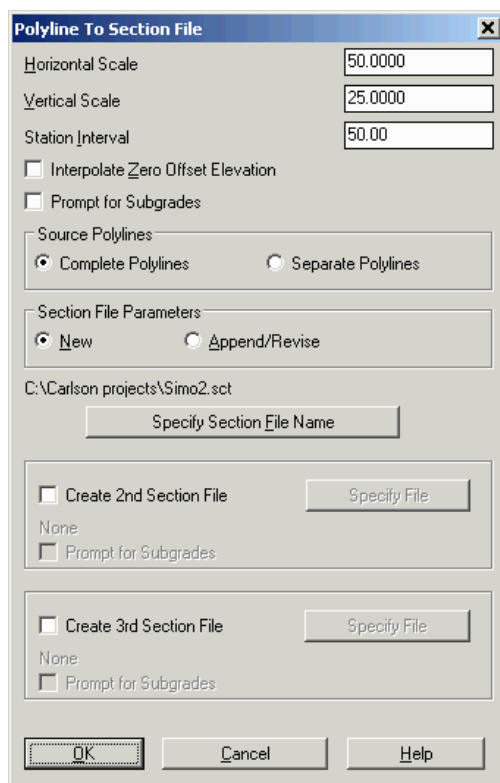

Keyboard Command: sctgrid

Prerequisite: Grid (.GRD) or triangulation (.FLT or .TIN) file, and a cross sections .MXS alignment file

Sections from Polylines

This command allows the user to select a polyline that represents a section in cross section view and writes it to a .SCT file. This can be useful for revising sections or for defining a new one. For example, let's say you have extracted sections from a surface model of the existing ground on a site, and have plotted them using the *Draw Section File* command. Next, the *Polyline by Slope Ratio* command is used to draw the proposed or final grade sections. Now use this command to send the sections to a Section file and compute the earthworks using the *Calculate Sections*

Volume command. After selecting the command, the Polyline to Section File dialog appears.

The first time this command is selected, the output Section file is set to the same name as the current drawing. Select the Specify Section File Name button to specify a different name. The Station Interval edit box allows you to specify the amount that the default station number will be incremented as the station prompt shown below appears. The Interpolate Zero Offset toggle, if on, causes the program to output the elevation of the zero offset to the output .SCT file. A second and a third section file can be specified to process three sections at a time for each station. This allows you to handle both existing and final grades at once. The Prompt for Subgrades option will prompt for selecting subgrade polylines after the surface polyline for that section. For Source Polyline, the Complete Polyline method works with a single polyline that completely define the section for the station. The Separate Polyline methods allows you to select multiple polylines per section in case the section polylines are broken up into separate polyline entities. After selecting the OK button, the prompts below appear.

Prompts

Exit/Pick text/ <Station <0.00>>: *press Enter*

Exit/Pick text/ <Starting elevation of grid <100.00>> 440 This supplies the drawing coordinate to translate the grid from.

[int on] Pick point at starting elevation and zero offset of section ([Enter] for none): *press Enter*

Select station 0.00 1st section polyline: *select a polyline*

Select station 0.00 2nd section polyline: *select another polyline*

Exit/Pick text/ <Station <0.00>>: *E*

Pulldown Menu Location: Sections

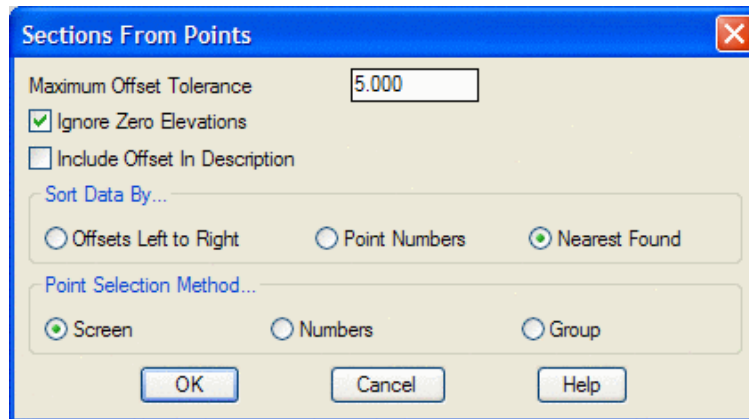

Keyboard Command: scfpl

Prerequisite: Plot the section or profile to write to the .SCT file.

Sections from Points

This command creates an .SCT file from Carlson points in the drawing. An .MXS file is needed to define the centerline and the stations of the cross sections. The offsets for the cross section points are derived from the perpendicular distance between the centerline and the Carlson points. The cross section elevations come directly from the elevations of the points. In order to be included in a cross section, a Carlson point must be within the offset tolerance distance of the cross section line.

The order that the points within the Offset Tolerance at each station are used will of course determine the shape of the cross section. There are three ways for the collected points to be sorted. The Offsets Left to Right option sorts by the distance of each point from the CL. The Point Numbers option ignores that data, and instead sorts the points by their numbers. The Nearest Found option ignores both distance from the CL and point numbers and instead checks the horizontal and vertical proximity of the points to each other and sorts them based on this data. A powerful application of this method would be a survey of a tunnel where the points collected at each station were collected in a random order.

Prompts

Choose MXS File to Process *select file*

Choose SCT file to Append/Write *select file*

Enter the maximum offset tolerance <1.0>: *press Enter*

Ignore Zero Elevations (<Yes>/No)? *press Enter* This option filters out all Carlson points that have a zero elevation.

Select points along the sections.

Select objects: *pick the Carlson points*

Carlson points for use in creating Section file

Pulldown Menu Location: Sections

Keyboard Command: scpts

Prerequisite: Carlson points and an .MXS file

Section File Editor

This program can be used to enter or edit data stored in a section file (.SCT file), including a real-time graphic window in the Edit mode. The section data consists of stations, offsets, elevations and descriptions. This command also has utilities for translating the offsets and elevations, deleting stations from the file, intersecting the outslopes of one section file with another, combining multiple occurrences of the same station and sorting the stations, offsets and elevations.

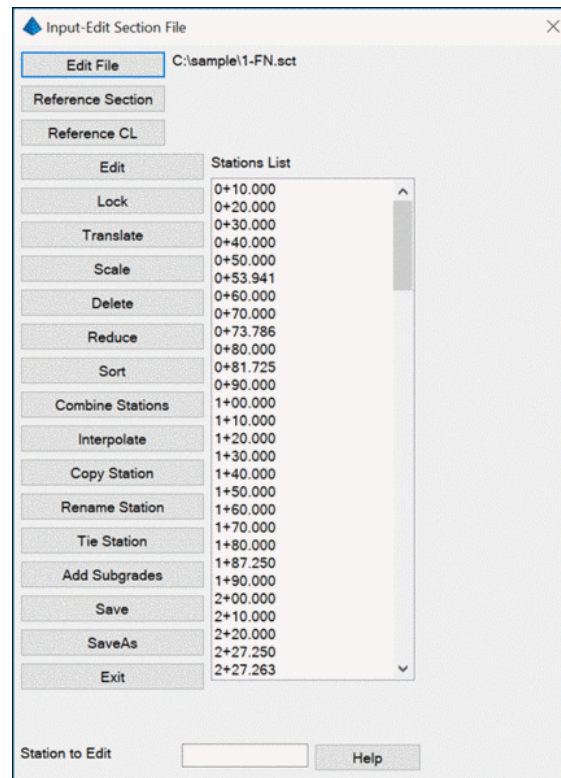

While editing the section file, a second section file can be used as reference. To choose this file, pick the **Reference Section** button. For example, when editing the proposed section file, you can reference and view the ground section file as the second file. Besides showing the reference section in the graphic preview, the program also reports the end areas while editing a section station. Also, the reference section can be used to tie to the catch point. Another option is to set a **Reference CL** which is used to adjust the stations when the centerline has station equations.

The program begins by prompting for a New or Existing section .SCT file to process. The Section file to process dialog appears, allowing you to specify the file that you want to operate on. Use the New option to create a new file. Use the Existing option to edit the offsets and elevations for station/sections that you have already created, or append new stations to a file. The program defaults to a section file with the same name as the drawing or a name that you specified using another section command. You also can choose a 2nd existing .SCT file to reference. After specifying the file name(s), the program displays any stations currently in the file, in the Stations List of the Section File dialog box.

Alternately, when sections are drawn in the drawing, you can double-click on a section polyline to launch Section File for the .SCT file associated with the section polyline.

If you specified a new file, the Stations List box will be blank. To edit and display the offset and elevation data at a station, you can double click on the station in the Stations List box, or input the station in the Station to Edit edit box at the bottom of the dialog. To add a station to a new file or existing file, you must enter the station in the Station to

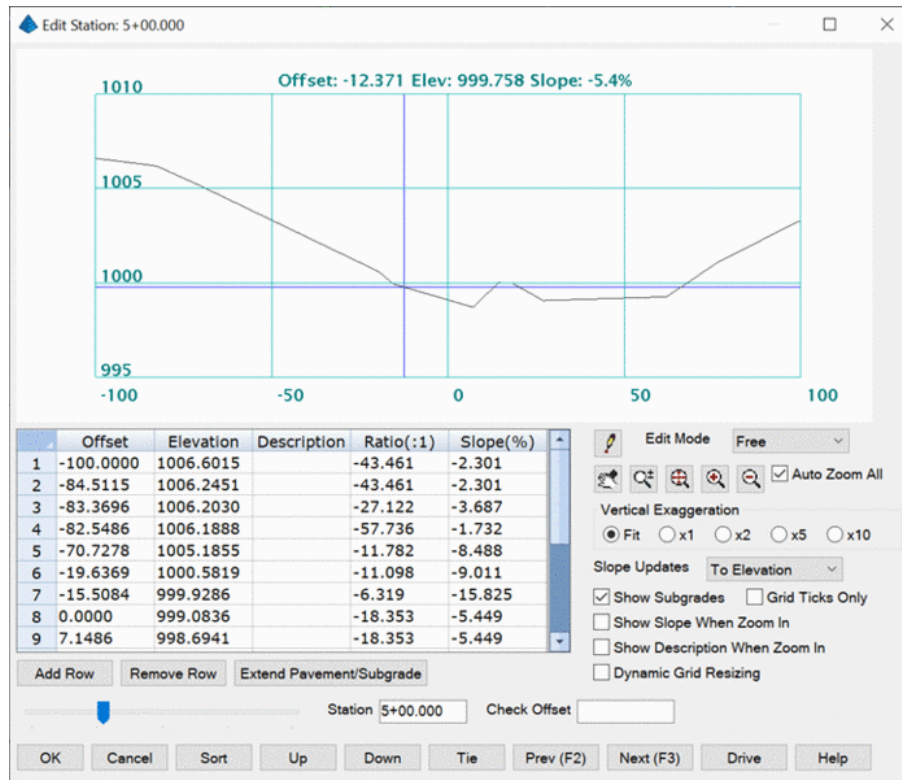

Edit edit box. Stations will present in accordance with the Section-Profile settings in Configure under the Settings pulldown menu (eg. 10+00, 1+000, 1000).

Edit: Opens the Edit Station dialog which shows a graphic of the section on top, a list of the offset-elevation points in the middle, and the function buttons on the bottom. To add an offset point, type in the offset, elevation and optional description in the spreadsheet. Left offsets are entered as negative numbers. You can enter the slope or ratio from the last point and the program will calculate the elevation. To edit an offset point, highlight the point from the list and then edit the values in the Offset, Elev and Desc columns. The highlighted point will be marked by an X in the graphic screen. The Sort button will sort the list of offsets from lowest to highest, left to right. It is recommended that you Sort offsets before doing the Tie command, so that the left-most and right-most offsets appear first and last in the offset list. The Up button will move the highlighted offset point up in the list. Likewise the Down button moves the highlighted offset point down in the list. Prev (F2) and Next (F3) buttons move through the stations and allow you to review and edit stations in forward or reverse order. The scroll bar can also be used to quickly move through stations and then zero in with Prev (F2) or Next (F3). When you edit a slope value in the spreadsheet, then the Slope Updates setting controls which elevation value to update for the section segment.

The section data can be edited directly in the spreadsheet or graphically by picking the Edit Point button with the pencil icon.  To edit graphically, use the click-n-drag method. Start by picking the Edit Point button and then pick the section point to edit in the graphic preview and hold the mouse button down and then drag the mouse to the new position and then release the mouse button. The **Edit Mode** setting governs the click-n-drag operation. The **Free** mode allows the section point to be moved anywhere. There **Hold Slope** modes maintain the slope and moves the point along these slopes. The **Hold Offset** allows changing the section point elevation only. The **Hold Elevation** allows changing the point offset only.

When a Reference Section is set in the main dialog, the Edit Station spreadsheet has a column for Depth. This Depth is the elevation different to the reference section. You can edit the depths to change the elevations for the section.

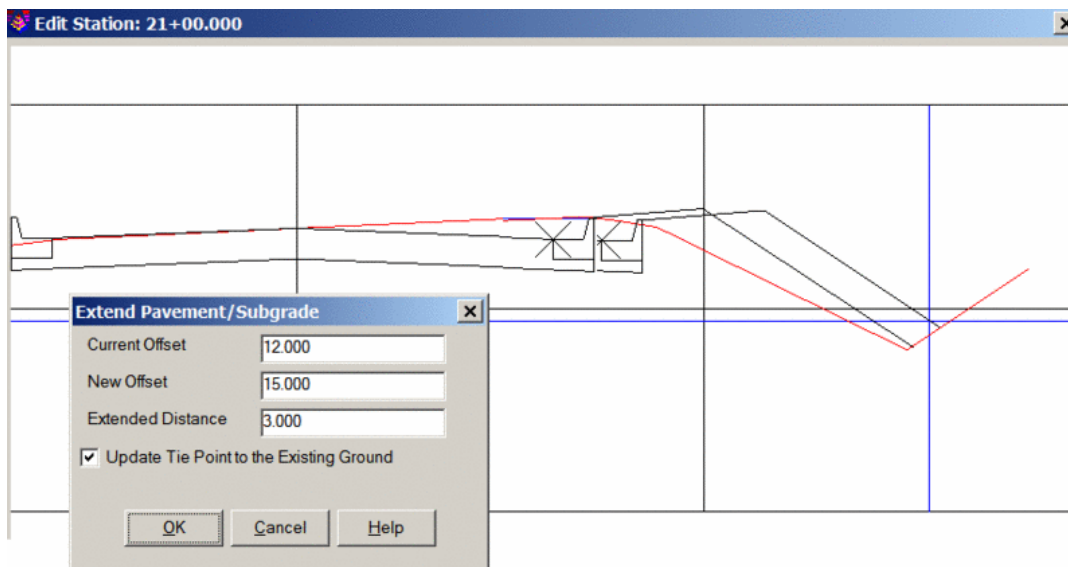

The **Add Row** button inserts an offset line above the currently highlighted row. The **Remove Row** button erases the highlighted offset and elevation from the list. After inputting or editing press the **OK** button to return to the Stations List dialog and keep any changes you have made. Select the **Cancel** button if you want to cancel changes made to the current station.

A real-time report of offset-elevation-slope now displays in the top of the graphic as you move the cursor across the section in the graphic window. The screen defaults to zoom mode where holding down the right-mouse button zooms in and out. You can also switch to pan mode. There are buttons for zoom extents, zoom in and zoom out. If your mouse has a scroll button, you can hold it down to pan and scroll it to zoom in and out. You can also set the **Vertical Exaggeration** ranging from 1X to 10X and including "Fit". **Show Subgrades** has the ability to tie a subgrade into the surface. **Grid Ticks Only** just shows the left and bottom axis lines of the grid with grid tick marks along the axes. With **Auto Zoom All** turned off, you can hold the same view position as you click **Next** and **Previous** and move through the list of stations. The **Description** is used in Draw Section File command to label under the station value and used in the Section Report command. The **Check Offset** field calculates an elevation based on an entered offset.

Extend Pavement/Subgrade allows you to move a surface point and shift, in parallel, the associated subgrades and tie points. One application, shown below, is to extend a shoulder point and re-computer the TIE point, all in one clean operation:

Another application of Extend Pavement/Subgrade is to move the curb position and all associated subgrades. The "inside" curb point is at 12.00 units from centerline. If the pavement is extended from 12 to 15 at this station, use of this feature will extend the subgrades, maintain all slopes and re-compute the TIE point, as shown below:

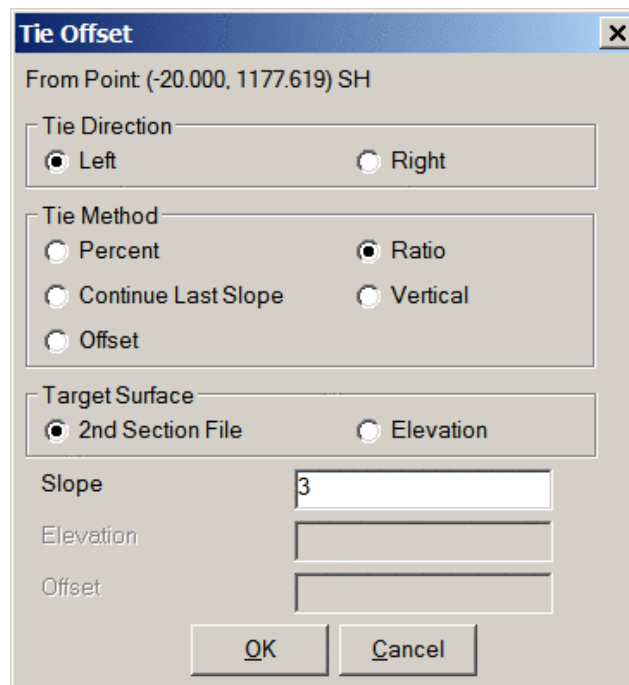

Drive (Edit Station): This function scrolls through the sections at the rate of speed specified by the user in the Speed window. The Drive View options determine whether the sections are displayed using the full width of the graphic window or centered in the window. The combination of Full Grid Range and Auto Zoom All allows the sections to rise and fall with the centerline elevations, as if you were driving an actual road. With Auto Zoom All off, and Full Grid Range on, the grid itself moves up and down at the current position of the first section, as you drive. Focus View On Offset Range allows the user to set the left and right viewing limits of the sections. Section data beyond the specified limits is not displayed.

Elevation Field (Edit Station): Equations (+, -, *, /) can be entered to calculate or adjust an elevation. For instance, to subtract 1.25' from elevation 1926.18, simply enter 1926.18-1.25 and press enter. The new elevation will be calculated and displayed in the viewer window.

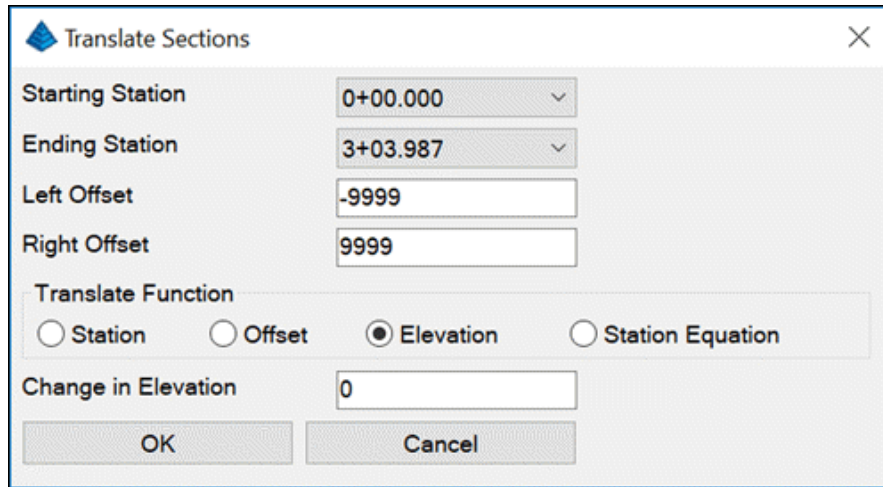

Tie (Edit Station): The Tie button allows you to tie the left and right surface points of the 1st section file into the 2nd section file. It is used for classic outslope intersects from final grade to existing grade. The dialog layout includes an option to tie the section to a specified elevation, in addition to a surface (second section file). A left or right tie direction can also be selected. If a point has been tied in from SH for shoulder at offset -20 at 3:1, a new offset with the description "TIE" is created. If you try another outslope such as 4:1 from the same SH shoulder point, a new "TIE" point is created and the old TIE point is removed automatically.

Lock: This function will tag the section file as locked so that no routine can automatically overwrite this file. If a routine attempts to overwrite this section file, the program will stop, report that the file is locked and prompt whether to override the lock.

Translate: Allows you to add or subtract a distance from the offsets to adjust or shift the centerline. You can also adjust the elevations up or down. When using this option, you can choose the range of stations to operate on (starting and ending stations) and the values to adjust the offsets and elevations. If, for example, you want to shift the centerline, but not the elevations, enter the plus or minus amount you want to translate, and when prompted

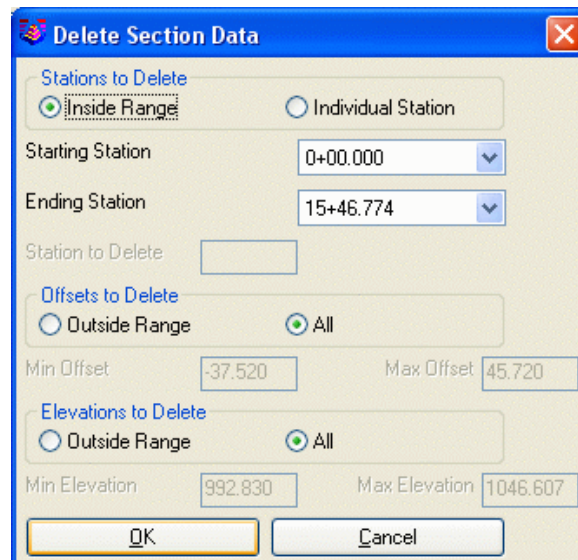

for the elevation enter zero. The Station Equation function removes the station equation adjustments to the station values in order to set the station values to the true centerline distances. To use the Station Equation function, a Reference CL must be set on the main dialog. For elevations, there is an option to use a profile to define the amount of elevation change as the difference between the profile elevation and the section elevation at the zero offset.

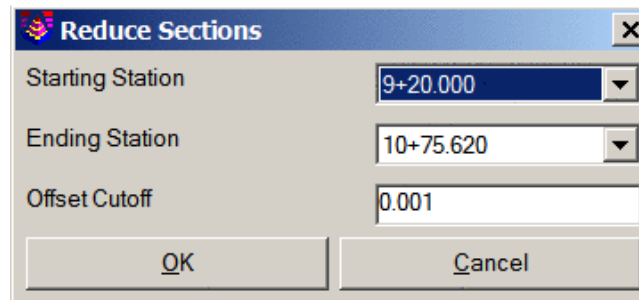

Scale: Allows you to scale the station, offsets and/or elevations by the specified scale factor. This function can be used to convert between English and metric units.

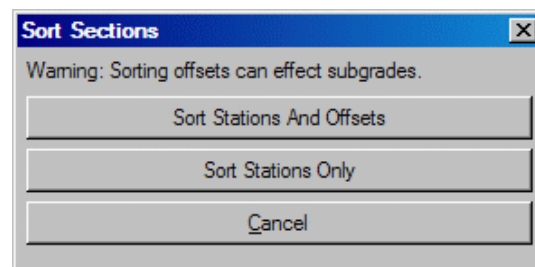

Delete: Allows you to remove a station or range of stations from the Stations List. You can delete a range of stations or an individual station. Also there are options to delete all the data for the selected stations or filter to delete only data that is outside an offset or elevation range. Since the station editor data is stored in memory, if you accidentally delete a range, Quit the editor without saving the stations to disk. Then recall the original file.

Reduce: Allows you to remove offsets from a range of stations by removing vertices in the offsets that are virtually in a straight line. Using an offset cutoff, meaning no offset and elevation moves more than the entered amount (eg. 0.01), excessive numbers of vertices can be eliminated. The command is similar to Reduce Vertices when applied to the plan view.

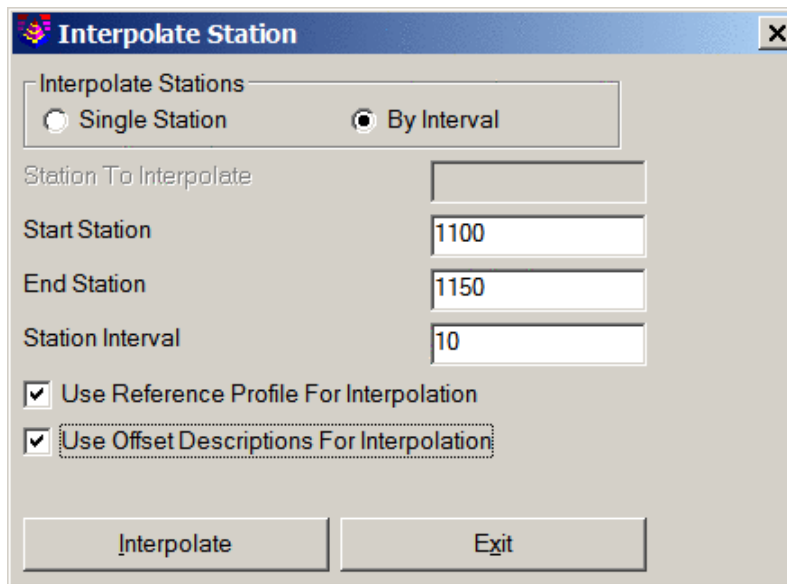

Sort: Allows you to sort the station numbers into ascending order, and sort the offsets and elevations in the individual station records (offsets are sorted from left to right). When sections are derived from the *Sections from Surface Entities* command they are already sorted, but when sections are digitized or input manually they occur in the order that you digitized them. So, for proper plotting and earthworks, you may want to run the Sort option before processing.

Combine Stations: Used to bring together in one record slot multiple occurrences of the same station number. This can occur when using the Digitize Sections (XSec) command and the section that you are digitizing has match/break lines which forces you to digitize the station in two or more parts.

Interpolate: Allows you to add or overwrite a station between two stations or projecting forward from two stations. You can choose to interpolate a single station or an interval of stations. Specify the two known stations in the Start Station and End Station edit boxes, as well as the interval if using the interval method. The program will do straight line, mathematical interpolations, adding offsets to the interpolated stations to match the totality of offsets in the starting and ending stations. However, if the offsets have descriptions, you can choose to interpolate by description and the program will interpolate by description (eg. EP at 12 on Station 1100 and EP at 15 at station 1150 would lead to EP at 12.6 at 1110). There is also an option to reference a profile, so if station 1100 and 1150 were on either side of a high point at 1125, the interpolated offsets would respect the profile as well as the starting and ending station. Use of this command is often critical to creating accurate digital terrain models of sites for machine control. Select the OK button to execute the function with the current settings or select the Cancel button to abort the process.

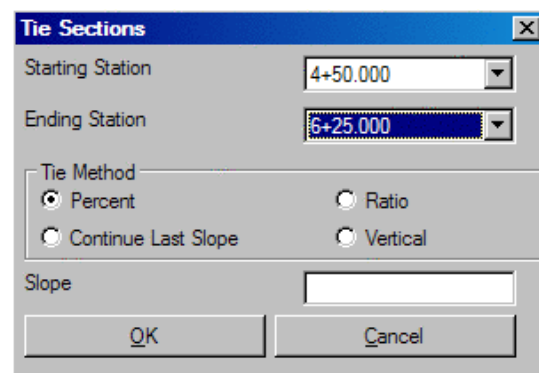

Copy Station: Allows you to copy a station that already exists to a new or existing station number. Choose the existing From Station using the edit pulldown box, then enter the new station number in the To Station edit box. Select the OK button to execute the function with the current settings, or select the Cancel button to abort the process.

Rename Station: Allows you to change the value of a station. In the dialog, select the existing station from the list and enter in the new station value.

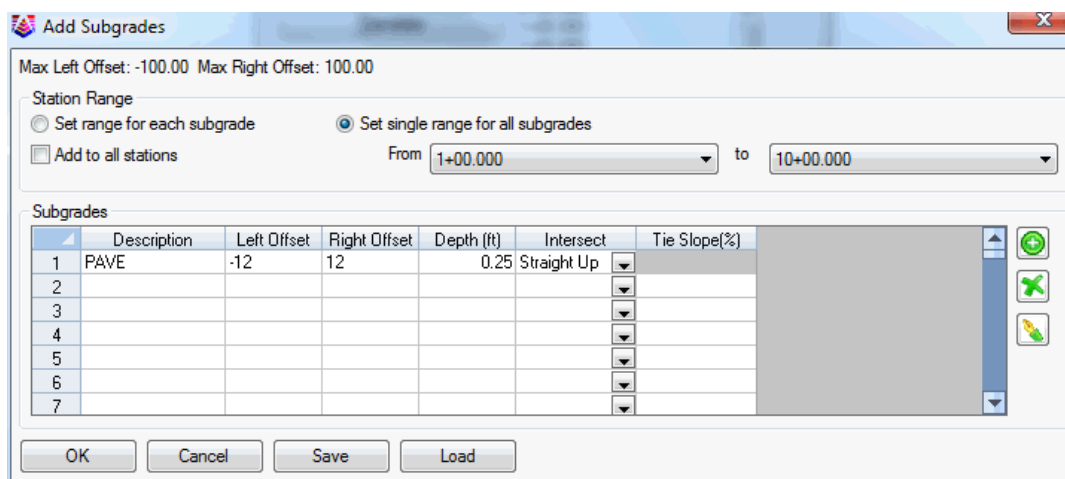

Tie Station: Allows you to tie the outslopes into the reference second section file. This routine first brings up a dialog to specify the range of stations to process. It includes a line to set the slope to tie with. The program will start from the left most offset and use this slope to find the intersection with the reference section file. Then the intersection from the right most offset is calculated with this slope. These intersection points are the tie points. The slope can be defined by percent, ratio, continue the last slope, and vertical.

Add Subgrades: Adds subgrades to the sections with specified depths and offsets. You can add multiple subgrades at a time by filling in the spreadsheet. Each row of the spreadsheet is for a separate subgrade. Each subgrade definition takes a description, left and right offsets, depth and intersection method of either straight up or at a specified slope. The subgrades are added by referencing the existing surface elevation and dropping down the specified depth. The center of the subgrade always drops down vertically. The outside of the subgrade ties in by the specified intersection method. The station range to add the subgrades can be the same of all the subgrades or

specified separately for each subgrade.

Save: Saves the currently loaded section file.

SaveAs: Allows you to save the currently loaded section file as a different file.

Exit: Allows you to exit from the section editor and return to the drawing editor. The program will warn you to save to a file if you have made changes.

Pulldown Menu Location: Sections

Keyboard Command: scted

Prerequisite: None

Draw Section File

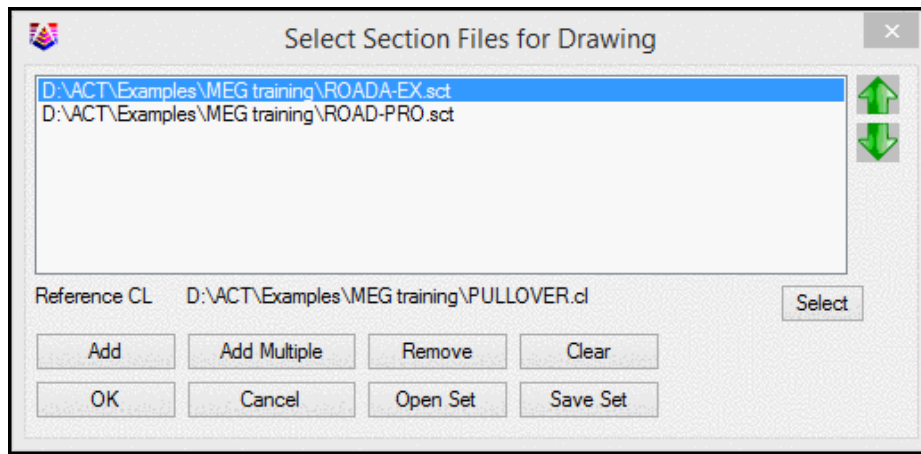

This command generates plots of cross-section data which can be used to further iterate the corridor design or used for construction documentation. The Section files drawn with this command can be created by several methods including the Section File Editor, Digitize Sections, any commands under the Create Sections from... menu, Process Road Design or Road Network commands.

For metric-based projects, please refer to the Drawing Metric Section Sheets section of this document.

The Draw Section File routine will call two primary dialog boxes:

- The first is the Section Files for Drawing dialog box that allows you to specify the Section files (.sct) to be drawn and some general sheet and layer settings.
- The second is the Draw Section File dialog box that allows you to specify various scale, layout and labeling settings.

If the *Type of Plot* option in the Draw Section File dialog box is set to "Sheet," a third Section File Sheet Drafting Parameters dialog will be displayed which provides detailed sheet layout settings.

Add: Specify an unlimited number of Section (.sct) files to plot

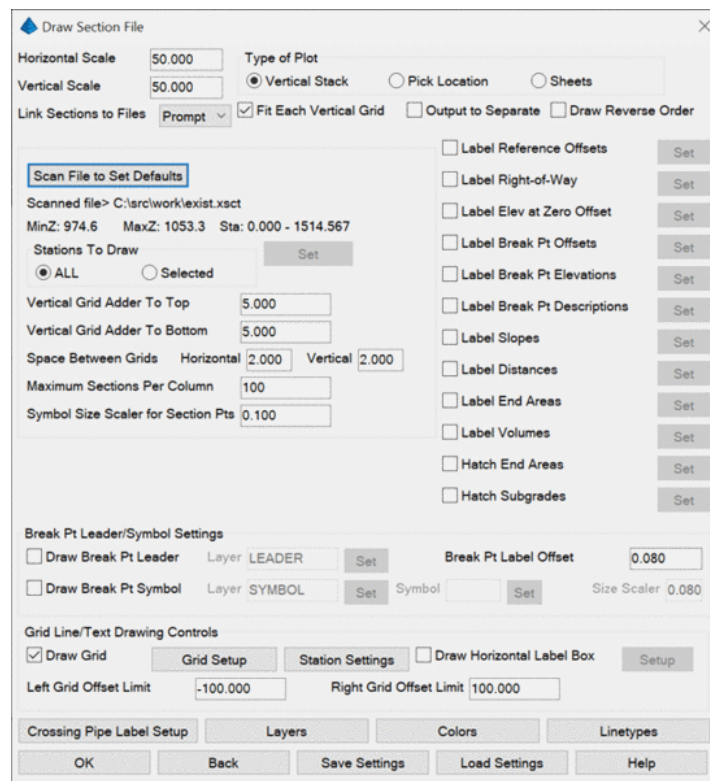

Add Multiple: Add multiple files to plot with a single selection

Remove: Highlight and remove any section file from the selection set

Clear: Clear the selection set (remove all files).

Open Set: Open a preset selection of cross sections(.XST file)

Save Set: Save the current selection set as an .XST file

After specifying the Section Files (.sct) the Draw Section File dialog box opens:

Horizontal Scale: Specify the horizontal scale.

Vertical Scale: Specify the vertical scale. The vertical scale relative to the horizontal scale determines the vertical exaggeration factor.

Link Sections to Files: This setting controls the linkage of the plotted sections to the actual section (.sct) file(s), determining how changes to the file affect the plotted sections.

Type of Plot: Specify the type of Plot you wish to create.

- **Vertical Stack:** Stacks all the cross sections in a vertical row or rows. The cross sections will be drawn in model space and will automatically stack with regard to the parameters set.
- **Pick Location:** allows the user to manually select a location in model space for each individual section.
- **Sheets:** draws the cross sections in either model space or paper space with regard to the settings in the Section File Sheet Drafting Parameters dialog box. When you pick OK on this main dialog, the Sheet Drafting Parameters dialog box appears allowing you to specify all the settings for sheet plotting.

Section File Sheet Drafting Parameters

Choose Space: Indicate whether sheets are to be drawn to **Paper** Space (also known as a Layout) or to **Model** Space. When drawing to Model Space, the Display In Paper Space option will draw the sections in model space and then create layouts with viewports to show the sections.

Layout Name: Indicate the name of the layout to which the first sheet should be drawn.

Use Template Layout: This option allows you to use a layout that exists in the current drawing as the template for layouts created by the command. This option only works for paper space sheet creation.

Add Layout Name To File For Drawing Output: When the Output To Separate Drawing option is active from the

main settings dialog, this option creates separate drawing files for each sheet by appending the layout name to the drawing name.

Tile Sheets: Enabling this option places all sheets in the specified Layout Name. The result is a vertical stack of sheets in the layout. Disabling this option allows additional layouts to be created each containing one sheet. As additional layouts are created, the name of each successive layout is incremented by a value of 1.

Plot at 1:1: Enabling this option draws the sections so that one unit horizontally in the section is equivalent to one plotted unit. The ratio of the Horizontal Scale:Vertical Scale determines the amount of vertical exaggeration.

Block Name: Specify the drawing name that will be inserted for each sheet. The default is SCTSHT1 which is included with Carlson Software and is located in the `%AppData%\Carlson Software\...\Sup\` folder. You can use this or use a sheet block of your own design. The block should be drawn at a 1:1 scale since the program inserts it using the Horizontal Scale setting from the previous dialog. Click the **Set** button to browse/navigate to an alternate drawing file.

Set Sheet Attributes: For grid sheet block names that utilize attributes (useful for items such as sheet numbers, drawn date, drawn by, job name, *etc*), use this command to provide attribute values that will be placed for each sheet block:

Find Sheet Attributes: This routine will scan the Block Name for any attribute definitions and return them to the dialog box so values can be established for each attribute.

Starting Page #: Indicate the starting page number to be applied to the plots through the use of the Set Sheet Attributes command.

Scan Block for Width/Height: Use this routine to scan the specified Block Name for its width and height. These values are populated into the Sheet Width and Sheet Height controls.

Sheet Grid Interval: Indicate the spacing between the grid lines in the sheet block. The routine will not draw the grid lines and uses this information to control the placement of each section onto the sheet.

Vertical Space Between Sheets: Indicate the amount of space that should be placed between sheets when the Tile Sheets option is enabled.

Rows of Sections

Per Sheet: Specify the maximum number of sections that can be stacked on top of each other on a sheet.

Space Between: Specify how much space will be placed between the top of the last section plotted and the bottom of the next section. For U.S. Customary based units, a value of 1 would be a good starting value.

Columns of Sections

Per Sheet: Specify how many columns of sections can be placed on each sheet.

Space Between: Specify the distance between the left edge of one section column edge and the right edge of the next column. This will generally be the area where elevation labels and station circle annotation will be placed. For U.S. Customary based units, a value of 2 would be a good starting value.

Label Grid Zero Offset: Enable this toggle if the zero offset location of each section should be labeled on each section.

Column Order: Controls the station order of the sections for going top to bottom, or bottom to top.

Offset for 1st Section

Horizontal Offset: Specify how far from left edge of the sheet the first section will be placed on to the section sheet. The block SCTSHT1 has a 1" left margin.

Vertical Offset: Specify how far from bottom edge of the sheet the first section will be placed on to the section sheet. The block SCTSHT1 has a 1/2" bottom margin.

Preview: This button allows you to get an approximate idea of what the initial sheet will look like based on the current settings.

Back: This button allows you to return focus to the main dialog and make changes to any previous settings or cancel the routine.

Save Settings: This button allows you to save all the parameters settings to a file so you can easily recall them for another project.

- **Off:** A linkage between the SCT file and the graphical section entities is not formed; you will need to manually re-create section sheets after section design changes.
- **Prompt:** You will be asked whether or not to update the plotted sections when the underlying SCT file is changed.
- **Auto:** The plotted sections will automatically update when the underlying SCT file changes.

Fit Each Vertical Grid: When checked, the grid bottom elevation and grid height are set automatically and you may specify values to add to the top and bottom of each grid (see Vertical Grid Adder to Top and Vertical Grid Adder to Bottom). When not checked, you specify the elevation of the grid bottom and the grid height through the Grid Bottom Elevation and Grid Vertical Height controls, respectively.

Output to Separate Drawing: When checked, this option will prompt for a New drawing name and location into which all cross sections will be drawn. When using the Vertical Stack method, the program will prompt for whether to output all the sections to the same drawing or create a separate drawing for each station.

Draw Reverse Order: When checked, this option will draw the cross sections in the order of the highest numbered station to the lowest.

Scan File to Set Defaults: This button allows the program to set the minimum and maximum parameters. If you choose this option, the program will automatically set the range of stations, vertical spacing distance, right and left grid distances and starting/datum elevation. This option writes a file called "sectsort.tmp" that is read and used to set the defaults the next time you use the program. Therefore, if you are selecting a different .SCT file to plot you should use this option to update the .TMP file.

Stations to Draw: Select eight All or Selected to specify the range of stations from the file which will be drawn.

- **All:** When selected the program will draw all of the stations in the file.
- **Selected:** This option will allow the user to specify exactly which stations will be drawn via the Set dialog box.

Interval: Specify the interval of stations to draw. For example, perhaps you sampled every 25 feet with the Sections from Surface Model command for more accurate quantities but only want to plot 50 foot stations. ALL is the default value for this field.

Range: Specify a range of stations to include

Vertical Grid Adder to Top: Specify the distance that will be added to the highest elevation of the section for the sheets and pick location options. This option is only available when Fit Each Vertical Grid is checked ON.

Vertical Grid Adder to Bottom: Specify the distance that will be subtracted from the lowest elevation of the section for the sheets and pick location options. This option is only available when Fit Each Vertical Grid is checked ON.

Grid Bottom Elevation: Specify actual bottom elevation for each section grid. This option is only available when Fit Each Vertical Grid is checked OFF.

Vertical Grid Height: Specify actual grid height for each section grid. This option is only available when Fit Each Vertical Grid is checked OFF.

Space Between Grids: Specify the **Horizontal** and **Vertical** distance between the sections when they are drawn when the Vertical Stack option is specified.

Maximum Sections Per Column: Sets the maximum number of sections allowed per column when the Vertical Stack option is specified.

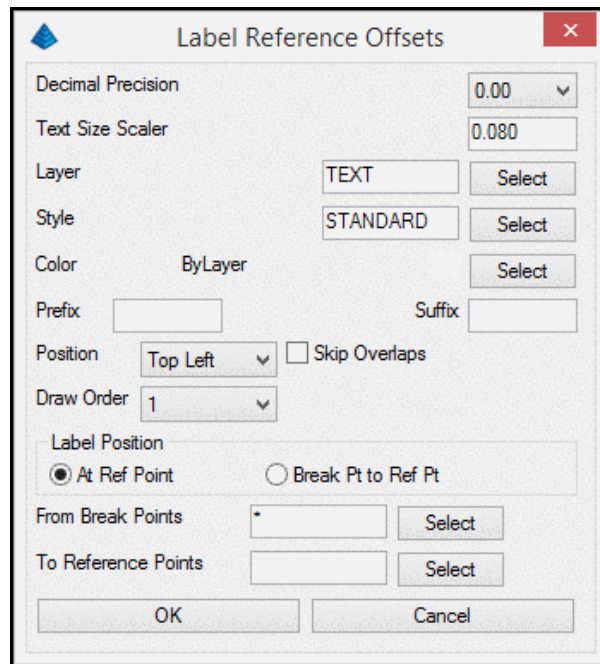

Symbol Size Scaler for Section Pts: Sets the scale as a multiplier of the overall drawing scale for the section points to be drawn.

Label Reference Offsets: When enabled, the offset from selected break points of one section file relative to the position(s) of selected points from another section file can be labeled onto the plots.

Specify which section(s) to draw

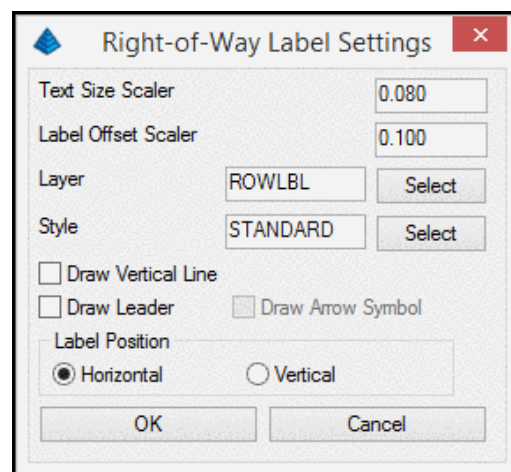

Set: Opens the dialog box for to set the display precision, text size scaler, layer, text style, color, prefix, suffix, position and draw order for these labels.

From Break Points: allows a user based filter to specify break points

To Reference Points: allows the user to control which offsets to label by specifying the reference points from a template (TPL) file.

Label Right of Way: When enabled, this option will label Right of Way points as defined using the Section Points from Right of Way command. Press the **Set** button to the right of this toggle to set the text size and label offset scalers, layer and text style settings.

Draw Vertical Line: Places a vertical line, from top to bottom, through the Right-of-Way point.

Draw Leader/Draw Arrow Symbol: When enabled, a short vertical line is drawn, with or without, the arrowhead through the Right-of-Way point.

Label Position: Indicate the desired orientation of the "ROW" text label.

Label Elev at Zero Offset: Will label the section elevation at offset zero.

Specify which section(s) to draw

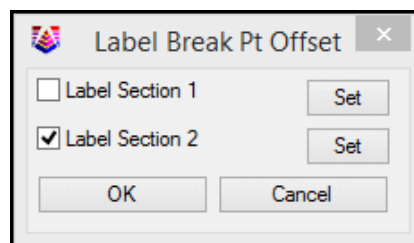

Vertical Offset from: sets the location of the Label relative to the grid or section.

Vertical Offset: controls the offset distance for the label.

Set: opens the dialog box for to set the display precision, text size scaler, prefix, suffix, color and layer for these labels. The Draw Leader option can be set to None, Diagonal or Vertical.

Label Break Pt Offsets: Select the Section(s) to be included in the labeling parameters

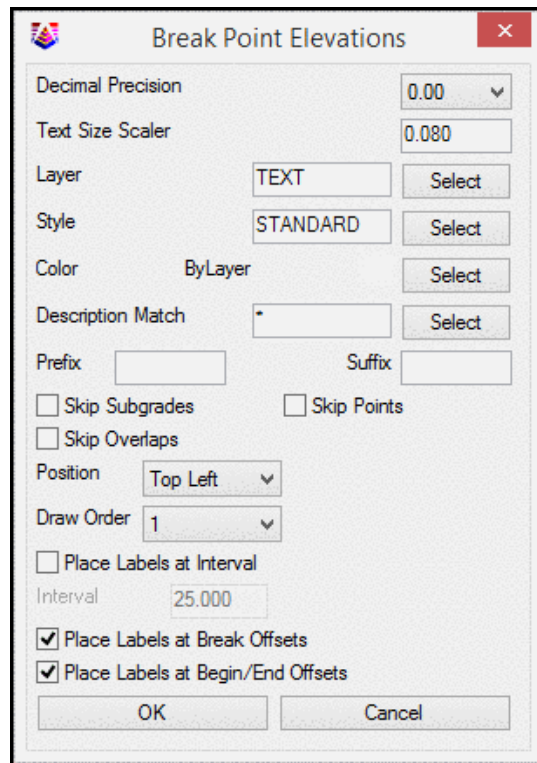

Set: Opens the dialog box for to set the display precision, text size scaler, layer, text style, color, prefix, suffix, and position for these labels. In addition the label position and draw order can be selected.

Label Break Pt Elevations: Select the Section(s) to be included in the labeling parameters.

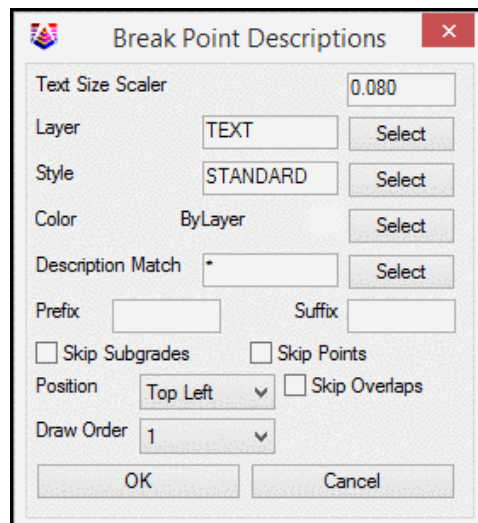

Set: Opens the dialog box to set display precision, text size scaler, Layer, style, color, prefix, suffix, position and draw order for these labels. The Description Match is a way to filter which section points to label. There are also options to toggle whether or not to place labels at the break offsets or Beginning and ending offsets.

Label Break Pt Descriptions: Select the Section(s) to be included in the labeling parameters.

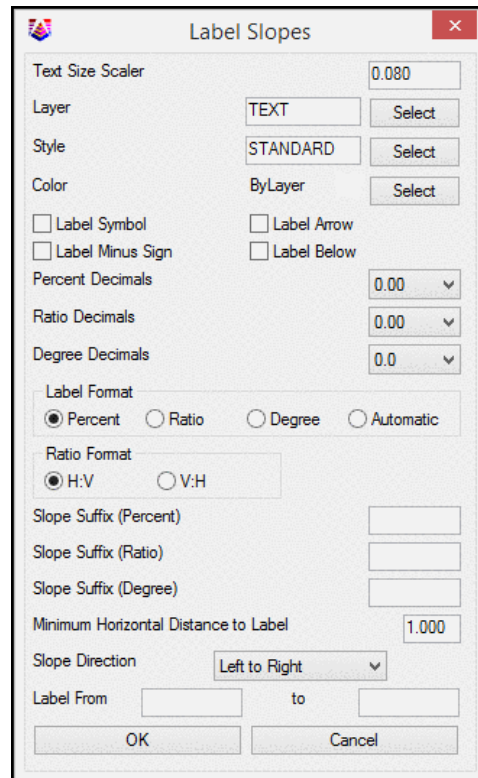

Set: opens the dialog box to set the text size scaler, layer, style, color, prefix, suffix, position and draw order for these labels. The Description Match is a way to filter which section points to label.

Label Slopes: Select the Section(s) to be included in the labeling parameters.

Set: Opens the dialog box to set the text size scaler, layer, style and color for these labels.

Label Symbol: places the % symbol after the slope label

Label Arrow: draws a slope direction arrow next to the label.

Label Minus Sign: places a - in front of negative slope values.

Label Below: places the label below the section line.

Label Format: controls which format the slopes will be labeled in.

Ration Format: Sets either *horizontal to vertical* or *vertical to horizontal* format

Slope suffix (Percent): creates a suffix to the slope label when using the Percent Label Format.

Slope suffix (Ratio): creates a suffix to the slope label when using the Ratio Label Format.

Slope suffix (Degree): creates a suffix to the slope label when using the Degree Label Format.

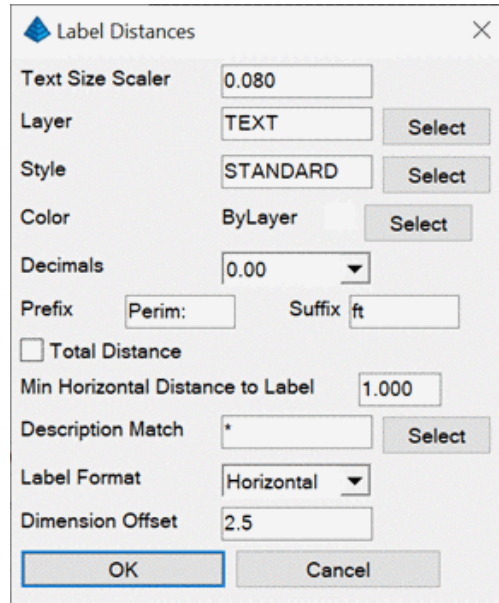

Minimum Horizontal Distance to Label: sets the minimum value of a segment length to label.

Slope Direction: can either be set *left to right* or *right to left*.

Label From: specifies the portions of the section to label a slope. for example, you could specify to only label the

slope between the SW (sidewalk) and SH (shoulder) ID points as defined in the Template file (.tpl) that was used to generate your Section file (.sct).

Label Distances: This option labels the horizontal distances between offset points. There are separate Label Distances settings for each section file. On the first dialog, toggle which section file you want to label distances. Choose the Set button to control the settings for that station. The settings dialog has settings for the distance label size, layer, style, color, decimals and suffix. The **Total Distance** option chooses between labeling just the total distance of the section or individual section segments. The **Description Match** is a way to control which section offset points to label. The **Min Horizontal Distance To Label** setting is a way to filter out short section segments and only label the longer segments. The **Label Format** sets whether to label the distances as a CAD dimension or as regular text rotated by the section slope or horizontal. The **Dimension Offset** controls the vertical distance between the section segment and the label.

Label End Areas: Will label cut and fill end areas on each section. The end areas are either between two sections (existing and design) or with a single section that creates a closed loop like for a tunnel. This dialog box sets the Decimal Precision, text size scaler, layer, style and color of the labels.

The dialog box 'End Area Settings' contains the following fields and options:

- Decimal Precision: 0.0
- Text Size Scaler: 0.080
- Layer: ENDAREA (with Select button)
- Style: STANDARD (with Select button)
- Color: ByLayer (with Select button)
- Cut: Prefix Cut, Suffix
- Fill: Prefix Fill, Suffix
- Skip Zero Labels
- Auto-Center On Section
- Offset: Horizontal 0.000, Vertical 0.000
- Vertical offset from: Top, Bottom
- Use Table
- Title Header: End Areas, Append Station
- Name Header: Material, Value Header: SF
- Include Elevation
- Ground Header: Ground, Final Header: Final
- Include Subgrades
- Subgrade 1: Asphalt, Subgrade 2: Gravel
- Subgrade 3: , Subgrade 4:
- Subgrade 5: , Subgrade 6:
- Buttons: OK, Cancel

Use Table: this option will create a table of the cut/fill values on each section.

Title Header: labels the table with this header. **Append Station** adds the station to the title header.

Cut and Fill label prefix and suffix: allows user defined prefix and suffix added to the label

Auto-Center On Section: this option will center the table or label next to the drawn cross section.

Skip Zero Labels: this option will not label cut or fill values of zero.

Include Elevation: this option will include the centerline elevations in the table. The Ground and Final Headers are user defined.

Include Subgrades: labels the end areas of the subgrades with settings for the names of up to 6 subgrades.

Offset Horizontal and Vertical: manually controls the placement of the table or label.

Vertical offset from: specifies where the offset dimensions are to be referenced to.

End Areas	
Material	SF
Cut	387.5
Fill	0.0
Asphalt	2.4
Gravel	8.0
Stone	6.7

Label Volumes: Will label cut and fill volumes on each section. The volumes are measured between the current station and previous station. There are settings to control the format and placement of the labels. This dialog box sets the Decimal Precision, text size scaler, layer, style and color of the labels.

Use Table: option will create a table of the cut/fill values on each section.

Cut and Fill label prefix and suffix: allows user defined prefix and suffix added to the label.

Include elevation: when enabled, this option will include the centerline elevations in the table. The Ground and Final Headers are user defined.

Auto-Center On Section: this option will center the table or label next to the drawn cross section.

Offset Horizontal and Vertical: manually controls the placement of the table or label.

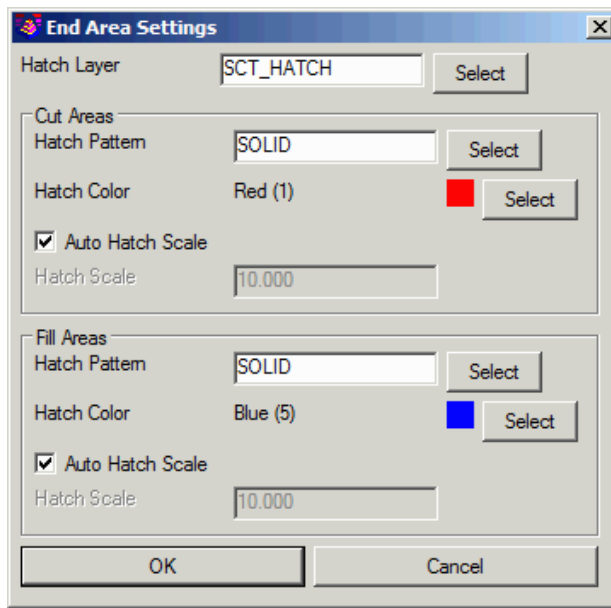

Vertical offset from: specifies where the offset dimensions are to be referenced to.

Label Running total Volumes: will label the accumulative total volumes with each station.

Use all the section stations: chooses between using all the section stations to calculate volumes or only the stations being drawn.

Hatch Subgrades: This option hatches the subgrade areas of design section using the section points with descriptions starting with SUBGRADE. There are settings for up to four different hatch patterns.

Hatch End Areas: This option hatches the cut/fill areas between the first and second section files. The program treats the first section as existing and the second as design for determining cut verses fill. There are separate hatch pattern, color and scale settings for cut and fill.

Draw Break Pt Leader: Enable this option to include a leader with the Label Break Pt Offsets, Label Break Pt Elevations or Label Break Pt Descriptions options. Click the **Set** button to specify the desired layer for the leader.

Note:

- When redrawing sections, the program retains any custom edits to label and leader positions.

Draw Break Pt Symbol: Enable this option to include a symbol with the Label Break Pt Offsets, Label Break Pt Elevations or Label Break Pt Descriptions options. Click the **Set** button (to the immediate right of the Layer control) to specify the desired layer for the symbol. Click the **Set** button (to the immediate right of the Symbol control) to specify the desired symbol and indicated the desired Size Scalar.

Break Pt Label Offset: Indicate the desired offset amount from the surface break point to its label.

Draw Grid: When enabled each cross section is drawn on a grid. The **Grid Setup** is used to customize how the grid will be drawn.

Main Grid Lines: Sets the Layer, Linetype and Color for the Major Grid Lines as set below

Intermediate Grid Lines: Sets the Layer, Linetype and Color for the Intermediate Grid Lines. (Those not defined as major)

Elevation Text: this section contains controls for setting the elevation Precision, text Size Scaler, Offset Scaler, Layer, text Style, and color, prefix and suffix for the elevation labels.

Offset Text: this section contains controls for setting the offset Precision, text Size Scaler, Offset Scaler, Layer, text Style, and color, prefix and suffix for the offset labels.

Label Elevations Left Side Only: when enabled, elevations will be labeled on the left side of the sections only.

Vertical Justification: this sets the justification of the elevation text.

Place Label Offsets: **Top** will place the labels at the top of the grid, **Bottom** will place along the bottom of the grid and **None** skips drawing the offset labels.

Grid Spacing: sets the horizontal and vertical spacing for the grid lines as well as the horizontal and vertical Major Grid lines the offset text (grid spacing) and the elevation text.

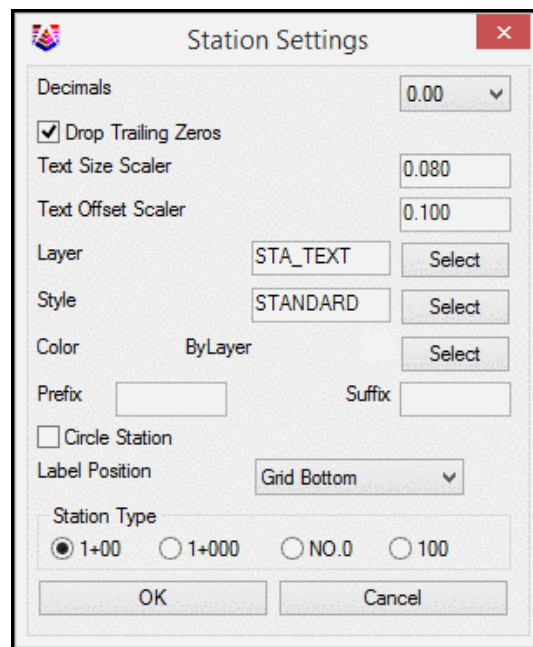

Label Scale: when enabled will label the horizontal and vertical scale.

Grid Style: sets the type of grid lines to be drawn. Grid Lines, Ticks Only, Ticks and Dots, Ticks and Checks, Text Only, Grid Lines and Dots, or Grid Lines Below 1st Section. This last option trims the grid lines by the first section so that the grid lines are drawn only below the section.

Draw Elevation Bar: places the elevations on a bar offset from the grid at a user defined location.

Label Vertical Axis: draws a label vertically along the vertical axis.

The **Station Settings** button displays another dialog box for the station label settings including decimal places, size, layer, style, color, prefix, suffix, format type and position. When the section file has descriptions assigned to the sections, the descriptions are labeled under the station position value. The **Circle Station** option will draw a circle around the station label.

Draw Horizontal Label Box: Enabling this option will draw a table with desired labeling above or below each cross-section. By picking the **Set** button to the right, you can choose the data to be placed in the table. The Elevation, Offset and Description of each point on the cross section can be added to the table. If more than one Section file (.sct) is being drawn on the cross-section, you will also have the option of displaying the elevation difference between sections.

Box Placement: Chooses between drawing the label box above or below the section grid.

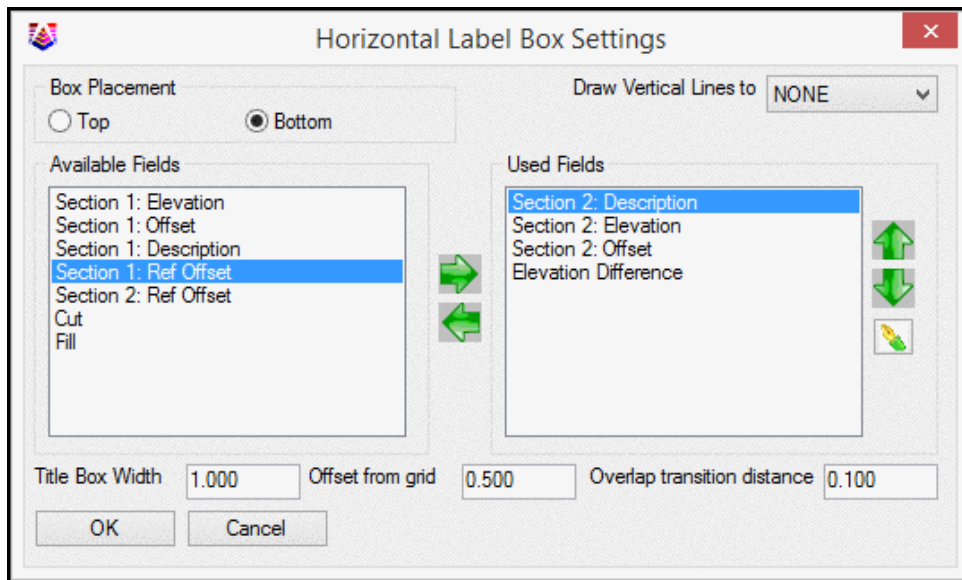

Draw Vertical Line: Sets drawing a vertical line from the section data point to the specified row in horizontal label box.

Title Box Width: Sets the size for the field name in the label box.

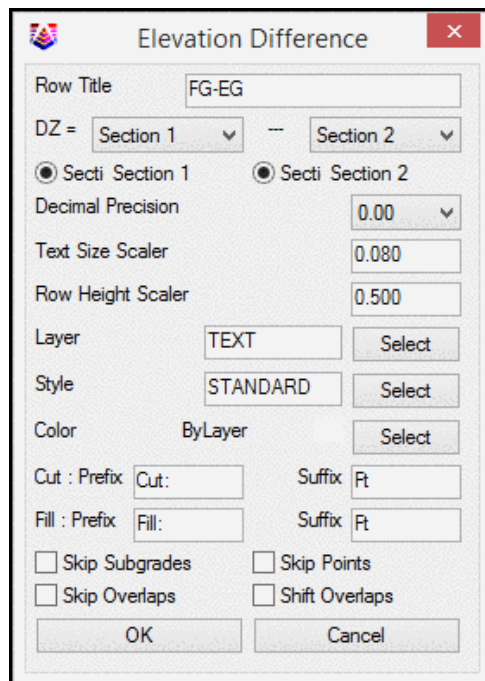

Offset From Grid: Controls the separation distance between the section grid and the label box.

Overlap Transition Distance: When drawing vertical lines and the labels are shifted to prevent overlap, this setting controls the length of the line for shifting over.

Label Elevation at Interval of Top Section: When labeling multiple values such as elevations for different sections, this option uses the stations from the section points of the top section as the stations to label for all the sections.

In the *Draw Horizontal Label Box* dialog, select from the **Available Fields** in the list on the left to populate the list of **Used Fields** on the right side. Once an item has been moved to the list of **Used Fields**, you can double-click on the Field to change settings and format for each Field. An example of the **Elevation Difference** option is shown below:

The **Row Title** for each field can be edited from the default to show a descriptive title. The **DZ** value in the Elevation Difference settings dialog allows you to specify which Section's elevations are to be subtracted from the other. This setting is critical to return the correct cut and fill depth values. In all field settings boxes, you have the ability to skip surface points in order to make the data more legible.

Place Labels at Interval: This option creates labels at the specified offset interval.

Place Labels at Break Offsets: This option creates labels at each section point.

Skip Subgrades: Enable this option to skip all subgrades as may have been defined in Design Template files (.tpl).

Skip Points: Enable this option to skip points in the Section file (.sct) that were created using any of the **Create Section Points...** commands.

Skip Overlaps: Enabling this option will cause any overlapping text in the table to be skipped. Having this option enabled will disable the Shift Overlaps option.

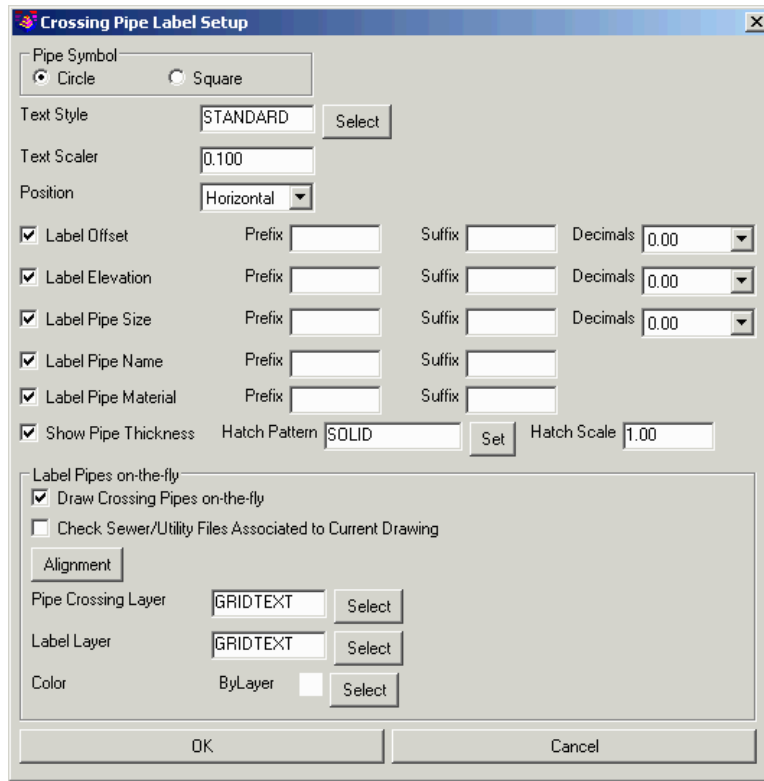

Shift Overlaps: Enabling this option will shift any text in the table to the right so that it does not overlap preceding text.

A sample cross-section with **Horizontal Label Box** is shown below:

EG : Elevation	284.92	285.42	285.48	285.08	284.70	284.42	283.37	283.07	282.70
EG : Offset	-100.00	-66.78	-58.61	-36.29	-1.24	21.45	55.51	72.66	100.00

Crossing Pipe Label Setup

Pipe Symbol: Choose whether to show the Pipe Crossing symbol as a circle or a square. When the sections are drawn with vertical exaggeration by different horizontal and vertical scales, then the circles or squares will be stretched into ellipses or rectangles.

Text Style and Text Scaler: Specify the text style and size of Pipe Crossing labels.

Position: Chooses between creating horizontal or vertical labels.

Label Offset, Label Elevation, Label Pipe Size, Label Pipe Name, Label Pipe Material: Enable any or all of these options to label the distance left or right off the alignment (Label Offset), the invert elevation, pipe size and pipe name of each crossing pipe. Use the optional settings for specifying "Prefix" or "Suffix" text and use Decimals to set precision for each label.

Show Pipe Thickness draws the pipe thickness around the crossing symbols using the specified hatch.

Draw Pipe Crossings on-the-fly: Enable this option to have Crossing Pipes that have been created using a Sewer Network file (.sew) or Draw Pipe 3D Polyline command drawn in cross sections. It is not necessary to enable this option if Pipe Crossings have been saved to a Section file (.sct) using the Section Points from Pipes command.

Check Sewer/Utility Files Associated to Current Drawing: This option looks for crossings with the pipes in .sew and .util files for the current drawing. To review and edit which files are in the current drawing, use the File > Drawing Explorer command. The program will show a list of files to choose from for checking.

Alignment: Pick this button to select either a Centerline file (.cl) or Section Alignment file (.mxs) to scan for Crossing Pipes.

Layer and Color: These settings specify the layer and color of the Pipe Crossing symbol.

Prompts

If the Pick Location option was specified, the program scans the station data and determines the minimum and maximum elevations, and proposes a datum elevation. If you have pre-plotted a grid sheet and want to reference another local grid coordinate, then change the datum elevation appropriately. The Pick Location type of plotting has the following prompts:

Station> 25.000 Min Elev> 1055.301 Max Elev> 1057.068

Change datum elev/<Select point that represents 0 offset elev 1050.0>: Pick a point

Station> 50.000 Min Elev> 1055.557 Max Elev> 1057.324

Change datum elev/<Select point that represents 0 offset elev 1050.0>: Pick a point

The program continues to prompt until the last station in the range specified is drawn. You can use the Cancel function (the *Esc* key) to stop plotting, if necessary.

If the Sheets option was specified with Model space as the destination, you can choose where to insert the sheet(s):

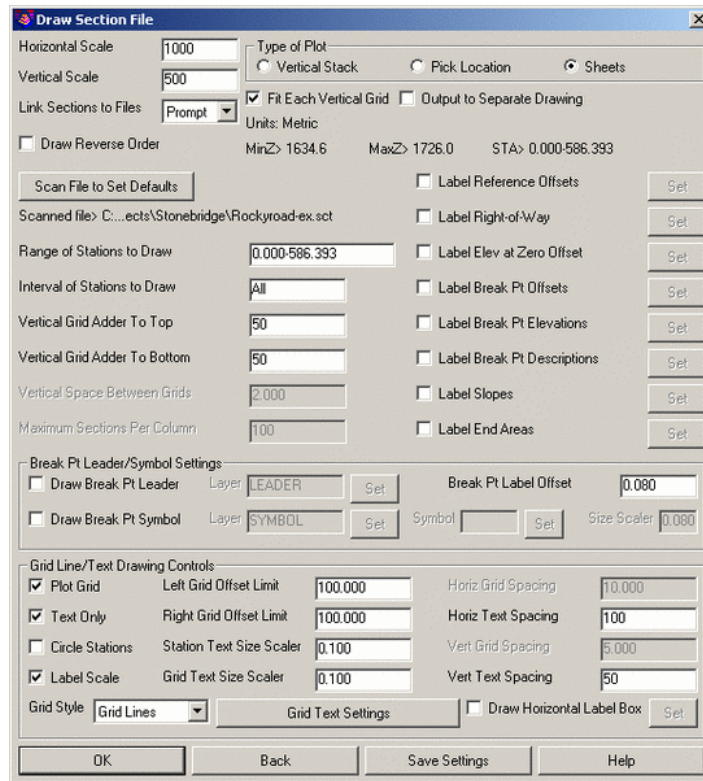

Select Starting Point for Row of Sheets <0.0,0.0>: Pick a point or press Enter to accept the default value specified

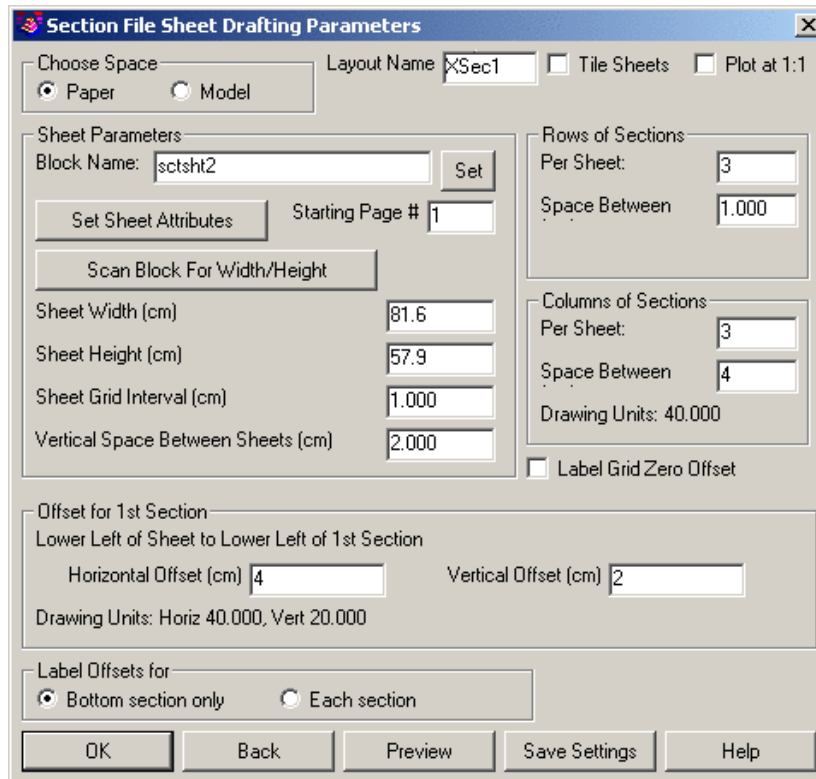

Sheet Sample

Drawing Metric Section Sheets

First, be sure that you are set to metric mode in Drawing Setup under the Settings menu. For our example, assume a 1:1000 horizontal scale. Once set, issue the Draw Section File command and click OK to reach the second dialog. There is a different block name for metric sections called schsht2.dwg which is located in the **%App-Data%\Carlson Software\...\Sup** folder. Begin by setting the parameters for the second dialog as shown.

Second dialog with metric settings

Third dialog with metric settings

Adjust settings as needed to achieve the desired look/layout.

For sections that make a closed loop such as for tunnels, the Label Volumes, Label End Areas and Hatch End Areas will use the difference between the sections. When you have one section for the tunnel design and another section

for the actual, these features will show the over cut and under cut amounts.

Pulldown Menu Location(s): Civil > Sections, Field > Roads

Keyboard Command: drawsct

Prerequisite: A Section (.sct) file

Sections to 3D Polylines

This command creates 3D polylines from a section (.SCT) file. Besides the section file, a centerline polyline, centerline file or section alignment (.MXS) file must be specified to define the plan view location of the 3D polylines. The elevations for the 3D polylines come from the section file. These 3D polylines can then be used by other Carlson routines to create surface models.

In the options, dialog set the range of stations to draw and the Layer Name for the 3D polylines.

The **Draw Method** has four options:

Cross Section: The 3D polylines are drawn as cross-sections perpendicular to the centerline at each station.

Offsets By Description: The 3D polylines are drawn parallel to the centerline by connecting section points when the same description. To use this method, the SCT file must have descriptions on the section points. For example, if the section file has descriptions for each section point then you can draw 3D polylines for EP, SHD, TIE, etc.

Offsets By Value: The 3D polylines are drawn parallel to the centerline at a specified offset value.

Offsets By Sequence: The 3D polylines are drawn parallel to the centerline by connecting section points by their sequence in the section file. For example, a 3D polyline will connect all the 1st section points, another 3D polyline will connect all the 2nd section points, etc. This method requires the sections to have the same number of data points for each station.

Water Level Profile: This method draws two 3D polylines for the left and right banks of a waterway. The section file represents the cross sections of the waterway. The program also prompts for a profile of the water level. At each section, the program gets the water elevation at that station from the water profile and finds the offset on the section for the left and right banks.

Description for Layer: This option uses the section point descriptions in the layer names for the 3D polylines when using the Offsets By Description method.

Draw perimeter of sections: This option will connect all the left most offsets and right most offsets together with a 3D polyline.

Alignment Method: Chooses how to define the horizontal alignment.

Type of Curves: This option chooses between roadway and railroad methods for stationing along curves.

Prompts

Choose Section File to Process Select the .sct file

Sections to 3D Polylines dialog Choose your settings

Select centerline polyline: *pick the polyline*

Enter the centerline starting station <0.0>: *press Enter*

Use reference profile to interpolate between sections [<Yes>/No]? *N for no.* This option will prompt for a profile to use for interpolating elevations along the 3D polylines between the section stations. This improves the accuracy when the profile goes through vertical curves. Without the profile, the 3D polyline elevations will be straightline interpolated between the sections.

Draw all template ids or specific ids and offsets [All/<Specific>]? *press Enter for Specific*

Enter Offset or Description to draw: *EP*

Pulldown Menu Location: Sections > Section Utilities

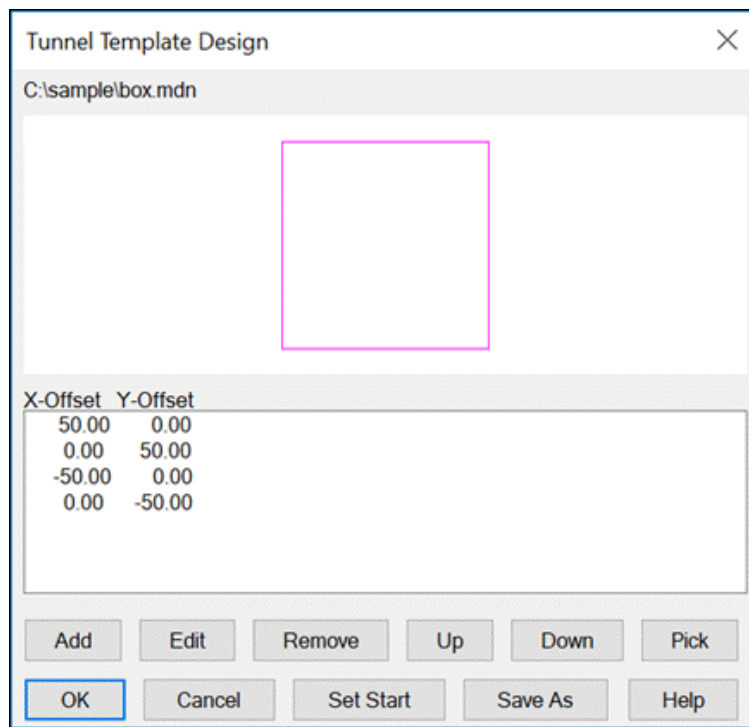

Keyboard Command: scto3dp

Prerequisite: A section (.SCT) file

Design Tunnel Template

This command defines a template to use with the Make Solid From Design command. The template defines the closed cross section for the tunnel. The dialog shows a graphic preview and list of segments. Each segment consists of an offset in X and Y (horizontal and vertical). Use the Add, Edit, Remove, Up and Down buttons to modify the list of segments. The tunnel template definition is stored in a .MDN file.

The template can also be created by first drawing a polyline perimeter and then use the Pick function in this dialog. The program will then use the dimensions of the polyline segments for the template. The starting point of the polyline is used as the alignment point for the tunnel centerline and profile. To change the starting point, highlight the row for the starting segment and pick the Set Start button.

Pulldown Menu Location: Solid

Keyboard Command: tunnel_template

Prerequisite: None

Draw Typical Tunnel Template

This command draws a tunnel template created by the Design Tunnel Template command. The program prompts for the tunnel template file (.MDN), layer name and position in the drawing. Then the tunnel template is drawn as a polyline.

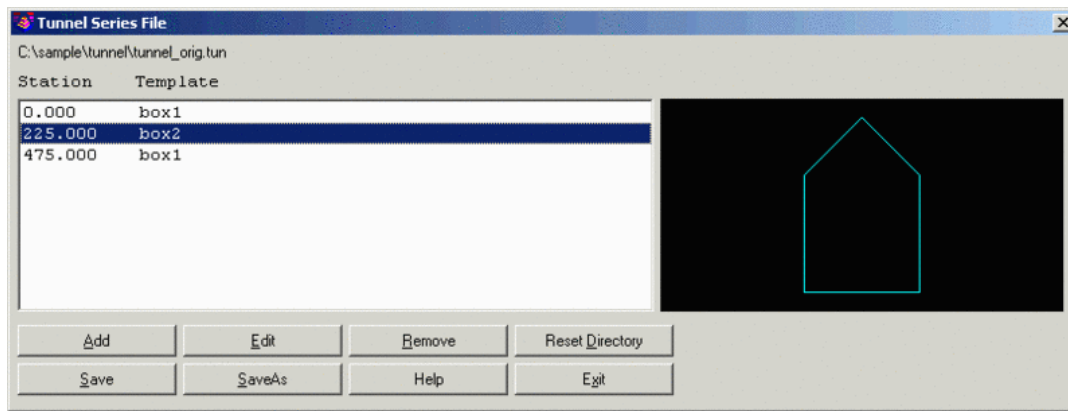

Pulldown Menu Location: Solid

Keyboard Command: draw_tunnel_mdn

Prerequisite: A tunnel template .MDN file

Tunnel Series Editor

This command defines a sequence of tunnel templates to use in the Make Solid From Design command. The tunnel series applies when the tunnel transitions along the alignment. For each tunnel cross section with different dimensions, use Design Tunnel Template to create a .mdn file. Then for the tunnel series, choose the tunnel templates in sequence and assign stations for switching between the templates. In the example dialog, the design starts with template box1, then switches to box2 at station 225 and then switches to box1 at station 475 for the rest of the design. The tunnel series data is stored in a .tun file.

Pulldown Menu Location: Solids
Keyboard Command: tunnel_series
Prerequisite: .mdn files

Tunnel Section Comparison Report

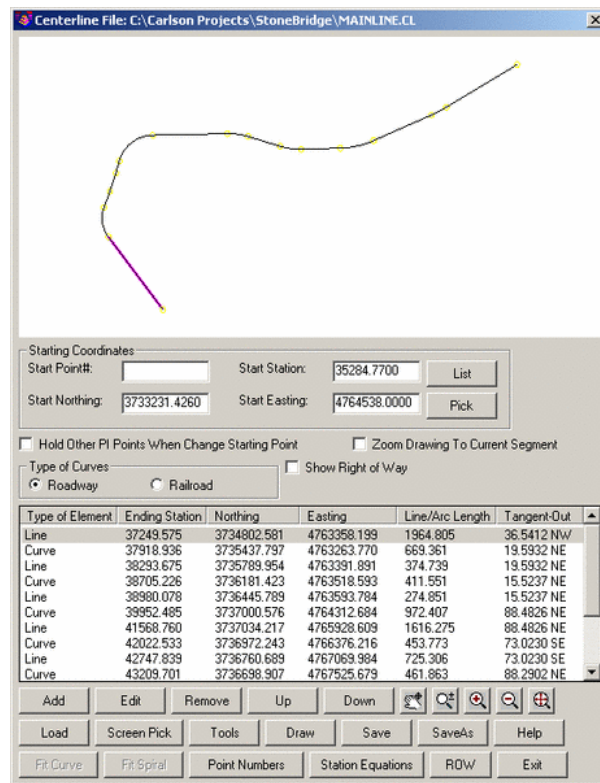

This command calculates the different between two tunnel sections and can be used to compare design sections with as-built sections. The tunnel sections need to make a closed loop. The report includes the end areas and volumes for each section. For the comparison, the report includes the over cut and under cut end areas and volumes. Over cut is area from the 2nd section file that goes outside the 1st section file. Under cut is area from the 1st section file that goes outside the 2nd section file.

Pulldown Menu Location: Solid
Keyboard Command: tunnel_sct
Prerequisite: Two section files (.sct)

Centerline Editor

This command can be used to input a new centerline or edit an existing centerline (.CL) file. It is a dialog-based alternative to Design Centerline and has the advantage of accepting whatever information you have on your centerlines (coordinates, stationing, length of tangents and arcs, *etc*). For creating a new centerline, it is ideal for entering data straight from highway design plans. For editing, this command allows you to change any of the geometric properties of any of the elements of the centerline (lines, curves, spiral-only and symmetrical spiral-curve-spiral elements), including the starting coordinates and station.

Starting this command launches the Centerline Editor main dialog box. To edit an existing Centerline, you can either pick the Load button and pick the .CL file, or pick the Screen Pick button and pick the polyline in the drawing that represents the Centerline. The Centerline is then displayed in the graphics window of the dialog box. The highlighted segment in the text window is also highlighted in the graphics window.

Drag Action (Zoom and Pan): In the graphics window, hold the left mouse button down and move mouse to Pan, roll the wheel to Zoom.

Zoom Drawing To Current Segment: This option zooms the drawing graphics to center on the centerline segment currently highlighted in the dialog.

Hold Other PI Points When Change Starting Point: With this option active, all the existing PI's are held when the starting coordinate is moved. Otherwise, all the PI's are moved by the same amount that the starting point is moved.

Show Right of Way: This option shows any ROW's defined in the centerline in the graphic preview window.

Type of Curves: This setting chooses between roadway and railroad definitions for curve lengths.

Add: Adds a new element after the highlighted element. Prompts you for the type of the element to be added, Line, Curve, Spiral-Only or Spiral-Curve-Spiral.

Edit: Allows you to edit the highlighted segment.

Remove: Removes the highlighted element from the centerline.

Up/Down: Moves elements in the table Up and Down in the list. For example, if this centerline ended with a tangential line from the last curve, then was followed by a non-tangential line at 45d NE, moving the last element up would create a line at 45d after the curve (non-tangential), and the formerly tangential line will remain tangential and therefore continue at NE 45d.

Load: Loads an existing centerline (.CL) file for review or editing. After loading a centerline, the listbox in the dialog shows a list of all the elements in the centerline, identifying them as either a line, curve, spiral only or full spiral-curve-spiral element and reporting the ending station, northing and easting of the element.

Screen Pick: Allows user to pick a CL off the screen in the drawing to load into the editor.

Tools > Reverse: Reverses direction of Centerline.

Tools > Rotate: Rotates the centerline by the specified rotation angle and around the specified pivot point.

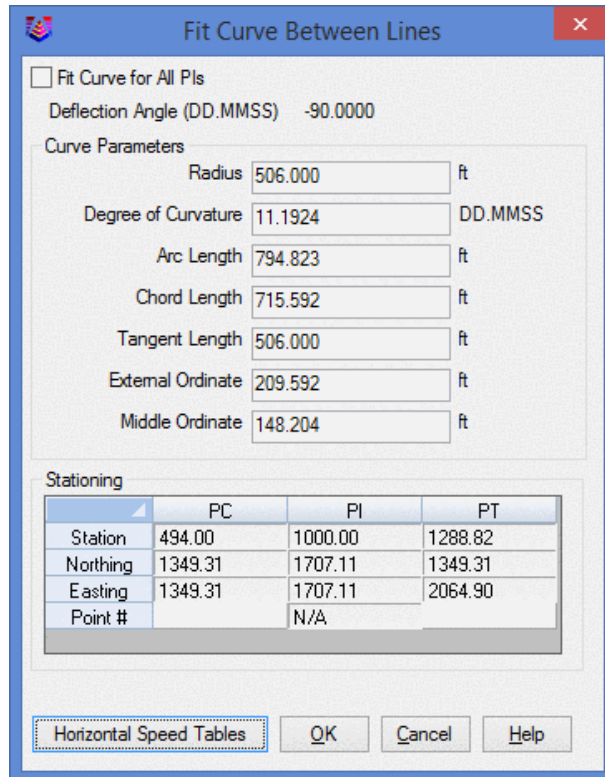

Tools > Scale: Scales the centerline which can be used for changing units between metric and English.

Draw: This button draws the centerline in the drawing on the specified layer.

Save: Saves the currently loaded centerline to a file, or will prompt you for a name if no name has been set.

SaveAs: Prompts you for a file name for the saved file.

Fit Curve: Fits a circular curve element into the centerline after the line element that is currently selected. When all the elements are lines, the program allows you to fit curve for all PIs. The program checks if the radius fits all PIs and will prompt the maximum radius that works for all PIs if the current radius is too big. The Horizontal Speed Tables allows you to pick a speed and a super elevation rate to the minimum radius.

The dialog box titled "Fit Curve Between Lines" contains the following elements:

- Fit Curve for All PIs
- Deflection Angle (DD.MMSS) -90.0000
- Curve Parameters section with input fields:
 - Radius: 506.000 ft
 - Degree of Curvature: 11.1924 DD.MMSS
 - Arc Length: 794.823 ft
 - Chord Length: 715.592 ft
 - Tangent Length: 506.000 ft
 - External Ordinate: 209.592 ft
 - Middle Ordinate: 148.204 ft
- Stationing table:

	PC	PI	PT
Station	494.00	1000.00	1288.82
Northing	1349.31	1707.11	1349.31
Easting	1349.31	1707.11	2064.90
Point #		N/A	

Buttons at the bottom: Horizontal Speed Tables (highlighted), OK, Cancel, Help.

Fit Spiral: Fits a spiral curve element into the centerline after the line element that is currently selected.

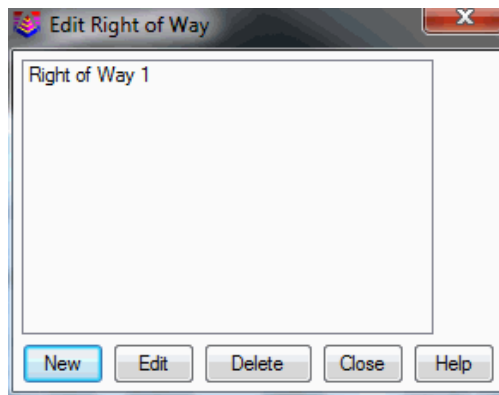

Point Numbers: This will create Carlson points along the elements of the centerline and store them to the current CRD file. The new points will be numbered in sequence beginning with the first available point number in the CRD file.

Station Equations: At any number of locations on a centerline, you can set the back station and forward station for the re-stationing of the centerline. The station equation dialog appears below:

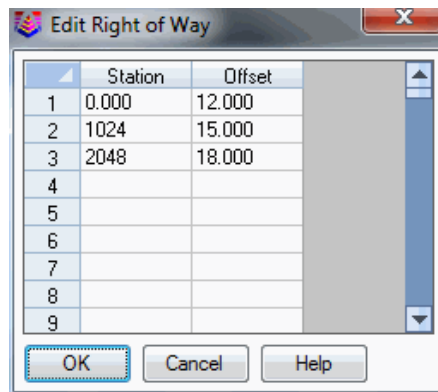

If the Station Back is lower than the Station Ahead, then a "gap" is inserted in the centerline, where the stations jump forward. If the Station Ahead is less than the Station Back, then an overlap occurs, where the common station range is repeated.

ROW: This function edits the right-of-way definitions associated with the centerline. There can be multiple ROW's assigned to the centerline for left and right sides as well as multiple on the same side. The function first shows a list of ROW's for the centerline where you can add, edit or delete.

When you add or edit a ROW, there is a second dialog for entering the stations and offsets that define the ROW relative to the centerline. Use negative offsets for left and positive for right.

Alternatively, the **Enter Right of Way** and **Polyline to Right of Way** commands are other ways to define the ROW's for a centerline.

Exit: Exits this routine, prompting to save changes if necessary.

The dialog for every type of element shows the point ID, the northing, easting and station of the start point of the

element. It then allows the user to modify or define the parameters specific to the type of element. The following are some of the things to remember about data entry in the centerline editor. These are valid for lines, curves and spirals.

- Wherever length of the element is to be entered, entering an expression of the type $123.5 - 93.7$ would evaluate the difference of the values. This is particularly convenient where only the stations of the start and end points of the element are known.
- When the station is specified, the program takes the length of the element as the difference between the station of the start point of the element and the station specified.
- All bearings should be specified by entering the angle between 0 and 90 degrees (in dd.mmss format) and selecting the quadrant.
- When entering the delta angle of a curve, only the absolute value (between 0 and 360 degrees) is to be entered. The direction of the curve is to be explicitly set as right or left, the default being left. All angles are entered in (dd.mmss) format.
- Point numbers, when used, access their coordinates in the current .CRD file. If the point number specified has no coordinates stored in the coordinate file, the point number is remembered for that particular location (say the radius point of a curve or the SC point of a spiral). Then, when the .CL file is saved, the program creates points for that location and stores them to the .CRD file with the specified point number.

The dialog for a Line allows the user to specify the line primarily by its length or station and its bearing. The line can also be defined by its end point number or its coordinates. The bearing of a line can be changed if the Tangential to the Previous Element toggle is not checked. By default, any line which follows a curve element is defaulted to be tangential to it. To use a bearing different than that of the previous element, uncheck this toggle and enter the bearing.

The dialog for the Curve allows the user to define the curve primarily by its radius and delta angle or arc length. The other parameters of the curve that can be edited are the bearing of tangent-out and the "Station to", which also defines the arc length. The curve can also be specified by entering the coordinates or point numbers of its end point (PT) and the radius point. Another way to specify the curve would be to enter the chord length or PT point station and chord bearing. If the central PI point and a point on the forward tangent are known, then the curve can be defined by entering both of these points and at least one other property of the curve (like radius, arc length, delta angle). The point on the forward tangent can be any point that defines the tangent out direction including the next PI point. If only the central PI point is known, then the tangent-out can be entered by bearing instead of by forward tangent point. Central PI and forward tangent points are not displayed from the .CL file. They have to be entered by the user and are valid only for that particular edit session; that is, they are not remembered the next time the file is loaded. Curves are assumed to be tangent to the last element unless the Tangential to the Previous Element checkbox is cleared.

The Curve Edit Mode option defines how the curve is accepted in the centerline. If the Hold PC point is checked on, the radius is taken as fixed and the delta angle of the curve is calculated based on some additional parameter. Hence, the extent of the curve is unlimited. However, if the Hold PI points option is checked on, the bearing of tangent-out of the curve is taken as fixed and the radius is calculated based on some other parameter. In this case, the curve is completely restricted within the central PI point and the bearing of tangent out. Hence, when the Hold PI points option is checked on, the above parameters should also be defined to carry out the calculations.

The dialog for the Spiral-Curve-Spiral element allows the user to define the spiral by entering either the various parameters of the spiral (like the angles and lengths) or the coordinates or point numbers of its defining points: the TS (Tangent-to-Spiral), SC (Spiral-to-Curve), Radius point, CS (Curve-to-Spiral), ST (Spiral-to-Tangent) and end point (optional). While defining the spiral by its geometric properties, the program will accept the data even if the information for the simple curve is given with zero spiral lengths. In this method, however, the central PI point of the spiral MUST be specified (that is, it is always in Hold PI Points mode). The tangent out can be defined by entering bearing or by specifying a point on the forward tangent. This forward tangent point can be the next PI coordinates. The direction of the spiral-in and spiral-out elements would be the same as the direction of the simple curve (left or right). The Spiral Definition setting chooses between Arc definition for clothoid spirals and Chord for 10-chord spirals.

The spiral can be defined by several different parameters and the order that you enter data into the spiral dialog can

be important. There are two main sequences for entering data. The method to use depends on the spiral data that you have. The first method is to enter the radius of the simple curve, the spiral in and out lengths, the tangent bearing out and the PI station. The second method is to make a Line segment coming up to the TS (tangent to spiral) point. This Line segment should be added before creating the Spiral element. Then with the Spiral In point set to the TS point, enter the radius of the simple curve, the spiral in and out lengths, the curve direction (left or right) and the arc length of the simple curve. Then the rest of the spiral points will be calculated.

The Spiral Only element allows for flexible transitions from curve to spiral to curve or line to spiral to curve or between any combination of curve and line elements. The Spiral-Curve-Spiral element, for example, can be entered as Line, Spiral Only, Curve, Spiral Only and Line, producing the same results. You can spiral from tangent to curve, curve to tangent and curve of one radius to curve of another radius. You can also spiral from one endpoint to another endpoint. To define the spiral by sweep angle, use the Delta Angle field. To define the spiral by length, use the Spiral Length field. To define the spiral by end point, fill in the min and max radius fields and then enter either the End Point Pnt# or coordinates and the program will calculate the radius and spiral length to fit that point.

Pulldown Menu Location(s): Centerline (Survey, Civil), Roads (Construction, Takeoff)

Keyboard Command: ccredit

Prerequisite: None

Polyline to Centerline File

This command writes a centerline (.CL) file from a polyline in the direction the polyline was drawn. The Northing and Easting for each vertex of the polyline is written to the centerline file and each arc in the polyline becomes a circular curve. After selecting the polyline, the program shows the direction by drawing temporary arrows along the polyline. To reverse the direction of the polyline, there is a keyword option R for Reverse at the Command line. Also, the Reverse Polyline command can be used to switch the direction of a polyline.

For stationing the centerline, there is a Command line prompt for entering the station at the beginning of the polyline and then using the polyline segment lengths for the rest of the centerline stations. Alternatively, there is a keyword option E for Ending to specify the station at the end of the polyline and then back calculating the centerline stations to the beginning using the polyline lengths. Also, the keyword P for Point prompts to pick a reference point along the polyline and enter the station at this reference point.

In addition to being used as roadway/corridor "baselines," a .CL file can also be used as the horizontal control for a Template Point Centerline.

Note: To convert lines and/or arcs into a polyline, use the Entities to Polylines command or the Join Nearest command

Prompts

Centerline file to Write dialog *Enter the .CL file name to create*

Centerline station [Reverse/Ending/Point/<Beginning: 0+00>]: *Press Enter to accept the default station value specified or Type in the beginning station then press Enter*

Select polyline that represents centerline: *Pick the polyline that represents your centerline*

Pulldown Menu Location(s): Civil > Centerline, Survey > Centerline, Field > Roads

Keyboard Command: cpline

Prerequisite: A polyline drawn in the direction of increasing station values

Draw Centerline File

This command reads a centerline (.CL) file and plots it as a 2D polyline in the drawing at the proper coordinates.

Centerline Layer is the layer name for the polyline to be drawn upon. The **Set** button can be used if you desire to select an existing layer from the current active drawing.

Draw PI Lines draws the straight line segments entering and exiting the PI. The length of the lines is controlled by entering a numerical value in the **PI Lines Length** option.

Label Centerline option draws station labels using a .STA settings file created by the Save Settings function in the Station Polyline/Centerline command.

Clear clears the current .STA file selection

When you click **<OK>**, you are prompted for the file name of the centerline(s) to plot. You can select single centerline (.cl) files individually or, by holding down the **Shift** or **Ctrl** keys, select multiple files at once. All centerline files are drawn with the same settings entered in the above dialog box.

The .CL file can be made with the following commands on the Design menu: *Polyline to CL File*, *Centerline Editor* or *Design Centerline*. Drawing the centerline file is a way to check the .CL file data graphically for correctness. If a spiral exists in the .CL file, the spiral will be represented by polyline segments.

Prompts

Draw Centerline Options dialog

Centerline File to Draw file selection dialog Select the .CL file name(s) to read and plot. Use the CTRL and/or SHIFT keys to select multiple Centerline file(s).

Pulldown Menu Location: Centerline

Keyboard Command: cl2pline

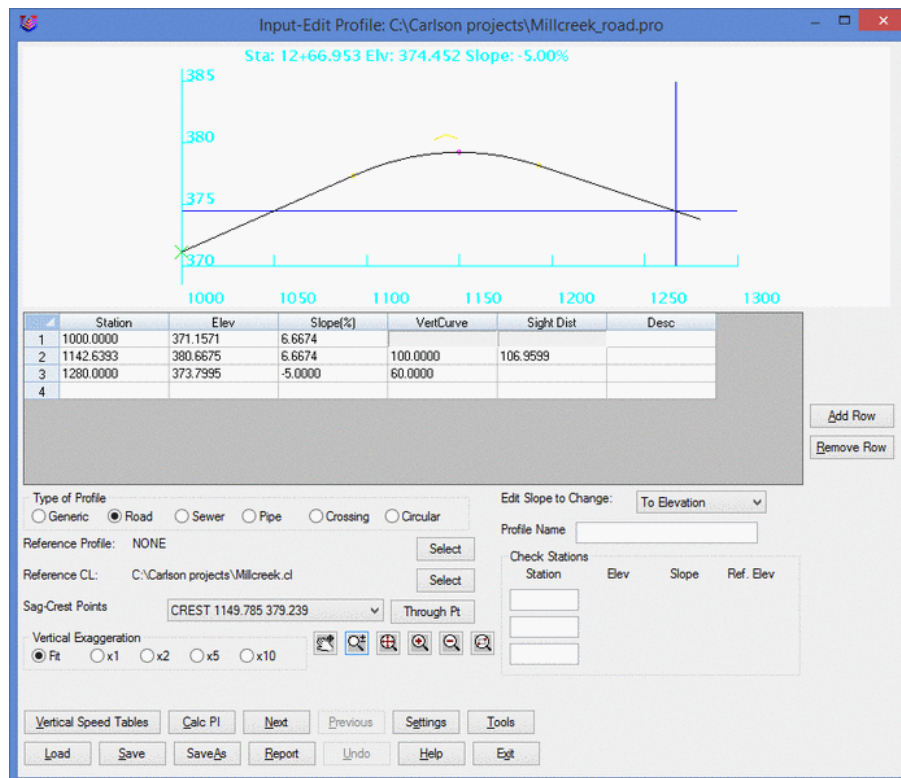

Prerequisite: a centerline file

Profile Editor

Similar to the Road Profile Editor command, this command features a spreadsheet type editor and handles a variety of profile (.PRO) configurations. Besides editing a profile, this routine can be used to just view the contents of a profile.

The command starts by prompting for the profile file to edit. Alternately, you can run Profile Editor by double-clicking on a profile polyline that is drawn on a profile grid.

The opening dialog below shows the layout of this editor. At the top of the dialog, you can dynamically see the profile and vary its appearance by using zoom and pan. The station, elevation and slopes are also shown at the lower left of the dialog which update/track with the movement of the cursor. There are between five and nine possible data fields in a profile depending on the type of profile that has been selected.

Profile Name: This name is optional and often used when multiple profiles are stored in a profile (.PRO) file and graphically generated using the Draw Profile command.

Add Row: Adds a new row into the profile after the current row.

Remove Row: Removes the current row.

Type of Profile: There are 6 types of .pro files and the spreadsheet columns will change to match the data fields for the selected profile type:

- *Generic* - Generic profiles have station, elevation and description fields.
- *Road* - Road profiles include the Generic controls and adds a vertical curve field. For an asymmetrical vertical curve, enter the left and right side values separated by a dash in the spreadsheet cell. For example, a 200' vertical curve with 50' to the left of PVI and 150' to the right would be entered as "50-150".

- *Sewer* - Sewer profiles include the Generic controls and adds step up, pipe size, pipe thickness, manhole elevation and manhole ID fields.
- *Pipe* - Pipe profiles include the Generic controls and adds a pipe size field.
- *Crossing* - Crossing profiles are for pipe crossings along the centerline. Besides station and elevation, the crossing data points also have the pipe size. The crossing elevation is for the bottom elevation of the pipe. The crossing profile data points are not connected.
- *Circular* - Circular profiles are the same as Road profiles except the vertical curve is circular instead of parabolic.

Edit Slope To Change: This setting controls which field to update when the slope is modified in the spreadsheet.

Reference Profile: Selects a reference profile and displays it in the profile graphic view. Also a Depth column is added to the spreadsheet which you can edit to set the profile elevation by depth from the reference profile.

Reference CL: Selects a reference centerline which is used for station equations.

Sag-Crest Points: When editing a road profile, its sag/crest points are shown here.

Through Pt: This button lets user to make the road profile pass through a certain point.

Vertical Exaggeration: Changes the look of the profile.

Edit Slope to Change: When edit the slope value, you can choose a value to change from the following selection: the next elevation, the previous elevation, the next station or the previous station.

Check Stations: Reports profile information at the specified stations. The Check Stations are not stored in the profile; they are merely used as a design/analysis tool for viewing the elevations at certain stations while adjusting the profile data. The **Offset** and **Slope** adjust the profile elevation and report the elevation at the offset.

Speed Tables: This button is enabled only when you edit a road profile. Please refer to the documentation on Road Profile Editor for the information on Vertical Speed Tables.

Next: Used for navigation when editing a .PRO file containing multiple profiles, loads the next profile.

Previous: Used for navigation when editing a .PRO file containing multiple profiles, loads the previous profile.

Load: Used for loading another, existing .PRO file for editing.

Save: Saves the profile using the current profile file name. The current profile file name is displayed in the top title bar of the dialog box.

SaveAs: Allows you to save the profile under a different profile file name.

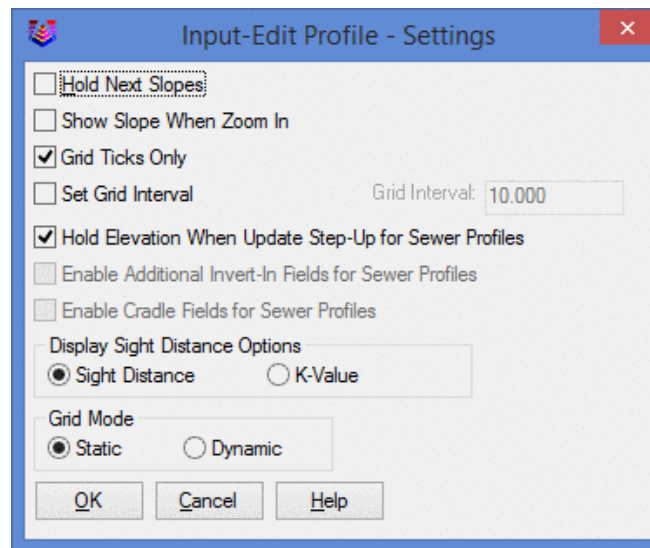

Calc PI: This function calculates a station/elevation point given two existing station/elevation points and slopes from them. The values are entered in this dialog. When you pick Calculate, the program finds the intersection of the grade lines. Then pick OK and the calculated PVI is added to the profile.

Calculate Intersection Point	
Intersection at Station: 1630.000 Elevation: 997.200	
Starting Station	790
Starting Elevation	993
Forward Station	1850
Forward Elevation	999.4
Slope From Starting Position to PI (percent)	0.5
Slope From Forward Position to PI (percent)	-1.0
<input type="button" value="Calculate"/> <input type="button" value="OK"/> <input type="button" value="Cancel"/>	

Report: Creates a report of current profile.

Undo: Reverts the last action in the editor.

Settings: Opens the settings dialog.

Hold Next Slopes: When editing a profile elevation, this option will maintain all the slopes after the edit point by adjusting the elevations. Otherwise, the elevations for the rest of the profile points are held and the slope from the edit profile point to the next profile point is adjusted.

Show Slope When Zoom In: This option allows to display the slopes on the long enough profile segments when zoom in.

Grid Ticks Only: Toggles between displaying the grid and grid ticks in the graphic box.

Set Grid Interval: This option allows you to control the elevation grid spacing in the graphic preview. When this option is off, the program automatically figures the elevation grid interval.

Hold Elevation When Update Step-Up for Sewer Profiles: Toggles between holding the elevation or the pipe slope

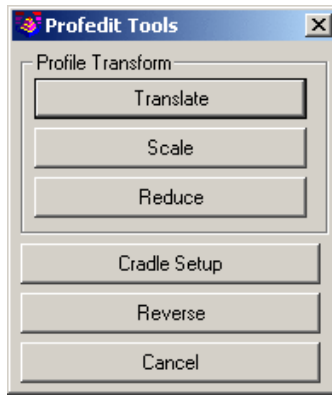

Enable Additional Invert-In Fields for Sewer Profiles: When editing a sewer profile, this option allows you to display an extra invert-in column for in-coming pipes. The invert-in elevations are separated by commas.

Enable Cradle Fields for Sewer Profiles: When editing a sewer profile, this option allows to display cradle above and cradle below columns.

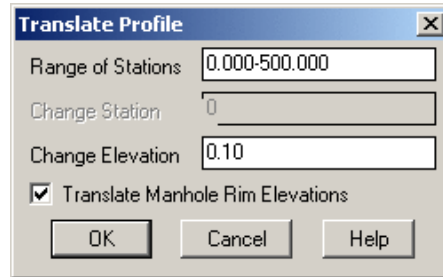

Display Sight Distance Options: Display either K-Value or Sight Distance in the fifth column for road profiles.

Grid Mode: The **Dynamic** option will update the grid interval labels when you zoom in or out of the profile image. The **Static** option will keep the grid interval labels static.

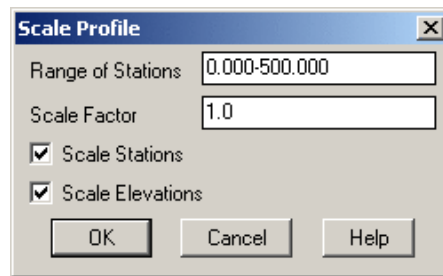

Tools: Opens the Tools dialog.

Translate: Globally adds or subtracts value to stations and/or elevations within the specified range of stations. while Scale will apply the specified scale factor to stations and/or elevations within the specified range of stations.

Scale: Applies the specified scale factor to stations and/or elevations within the specified range of stations.

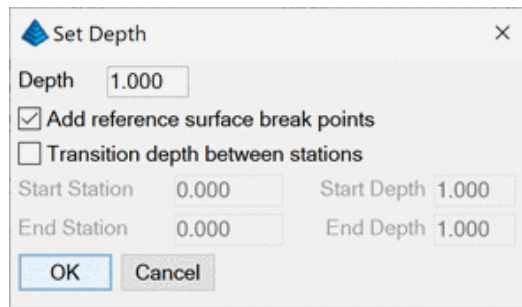

Reduce: Reduces the profile points by the Offset Cutoff value.

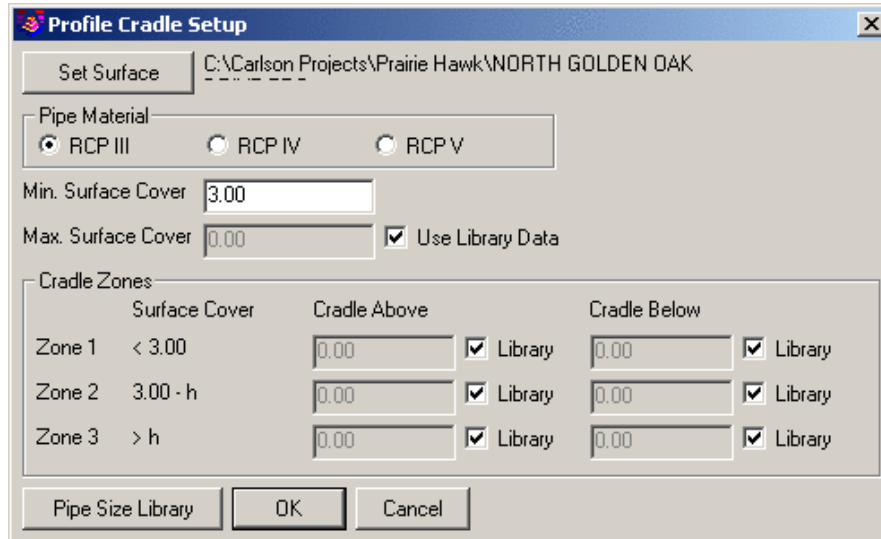

Reverse: Reverses the direction of the stationing for the profile.

Set Depth: When using a Reference Profile, this function sets the profile elevations by a specified depth from the reference profile.

Cradle Setup: Sets up the cradles for sewer profiles. The cradle parameters are different with different pipe sizes and are defined in the Pipe Size Library. You can either use library data or specify new values here.

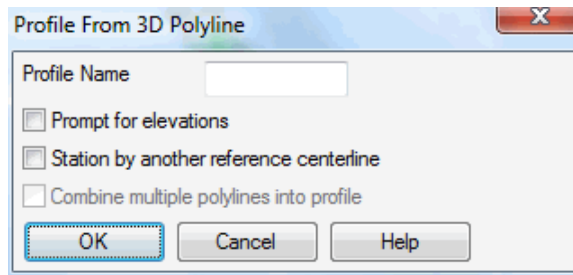

Pulldown Menu Location: Profiles

Keyboard Command: profedit

Prerequisite: None

Profile from 3D Polyline

To create a profile (.PRO), Profile from 3D Polyline uses X-Y distances between the points of a 3D polyline for sequential stations and the Z values at these points for profile elevations. In the options dialog, Profile Name is an optional description for the profile. The Prompt For Elevations option will prompt for the elevation at each polyline vertex to use for the profile instead of using the polyline elevations. The Station By Another Reference Centerline method locates the station for each polyline vertex along a reference centerline and uses this reference station instead of the polyline distance for the profile stationing. The reference centerline can be defined by another polyline or centerline file (.CL). When using the reference centerline, the Combine Multiple Polylines Into Profile option allows you to select multiple 3D polylines and put the data into a single profile. For example, you can use these two options to create a profile of curb elevations with road centerline stationing by selecting multiple 3D curb polylines and the road centerline as the stationing reference.

After the options dialog, the program prompts for the .PRO file to create and then the 3D polyline to process.

Prompts

Profile From 3D Polyline dialog

Profile File to Write dialog Specify a profile file name to create

Select polyline to profile: *pick a 3D polyline*

Created 72 data points for profile C:\sample\abc.pro

The new profile is then stored.

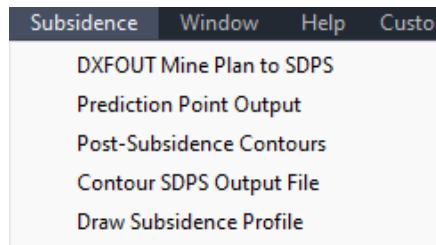

Pulldown Menu Location: Profiles

Keyboard Command: pro3dpl

Prerequisite: A 3D polyline

Subsidence Menu

The subsidence routines work with the SDPS (Subsidence Deformation Prediction System) program. SDPS was written by Virginia Tech. Carlson Software is the exclusive reseller for SDPS.

DXFOUT Mine Plan to SDPS

This command creates a DXF file to import the mine plan pillars and perimeter to the Subsidence Deformation Prediction System program. The pillars and perimeter polylines created in Carlson with the layers PILLARS and PERIM. The PERIM layer is written to the DXF file as PANELS for SDPS. This routine provides the user the ability to specify the direction the pillar polygons are drawn. SDPS requires the pillars to be drawn in the counter-clockwise direction. For additional information on this procedure, refer to the SDPS manual.

Prompts

DXF File for SDPS Enter a file name. The default directory is the SDPS directory defined in Configure .

Pulldown Menu Location: Subsidence

Keyboard Command: sdpsout

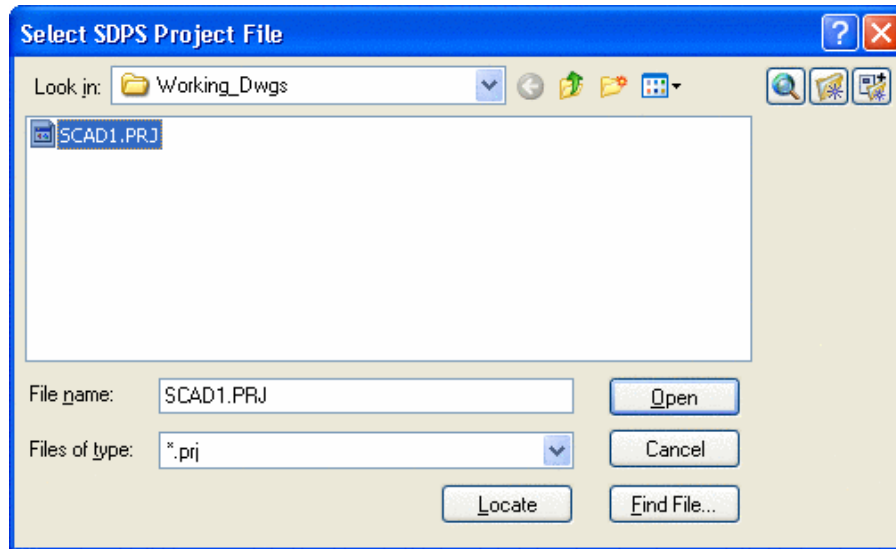

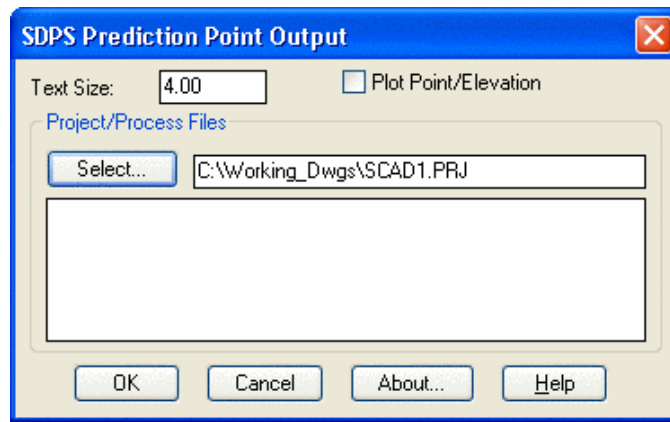

Prerequisite: Polylines in the PILLARS and PERIM layers and prediction points on the POINTS layer, if prediction points are input.

Prediction Point Output

This command draws text at each prediction point of the subsidence, strain and other SDPS deformation output values. From the dialog, click the Select button to choose an SDPS project file. The program then reads the values from all the output .dat files and labels the values next to the prediction points.

Prediction Point Text Output

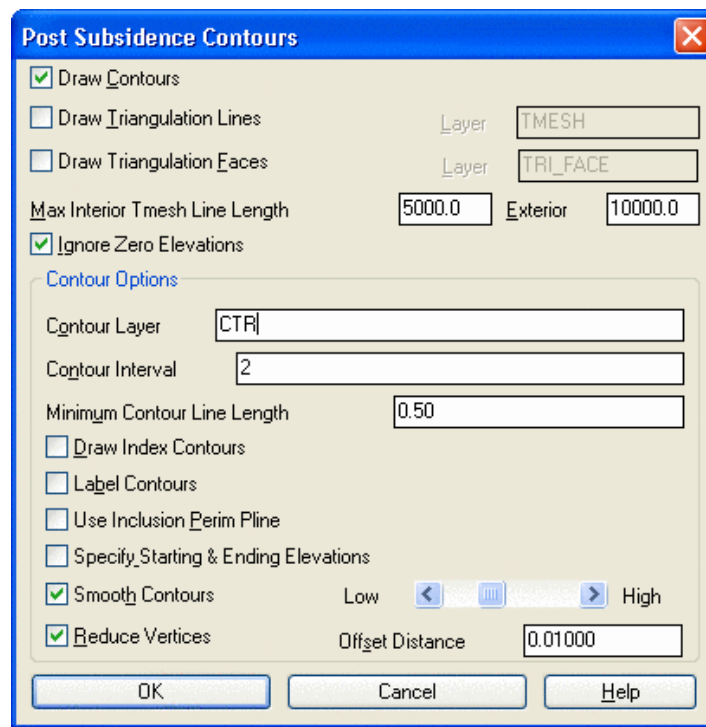

Pulldown Menu Location: Subsidence

Keyboard Command: sdpsout

Prerequisite: SDPS output files

Post-Subsidence Contours

This command creates surface contours after accounting for subsidence. The surface is defined by prediction points which are POINT entities with the elevation of the surface. These points are then exported to the Subsidence Deformation Prediction System program which calculates the subsidence at each point. This subsidence output from SDPS is written to a DAT file in the SDPS directory. Post-Subsidence Contours then subtracts the subsidence values from the file from the elevation of the prediction points.

Prompts

Triangulate & Contour dialog

Select the prediction points.

Select objects: *pick the points*

Select SDPS Output file Choose the subsidence output file.

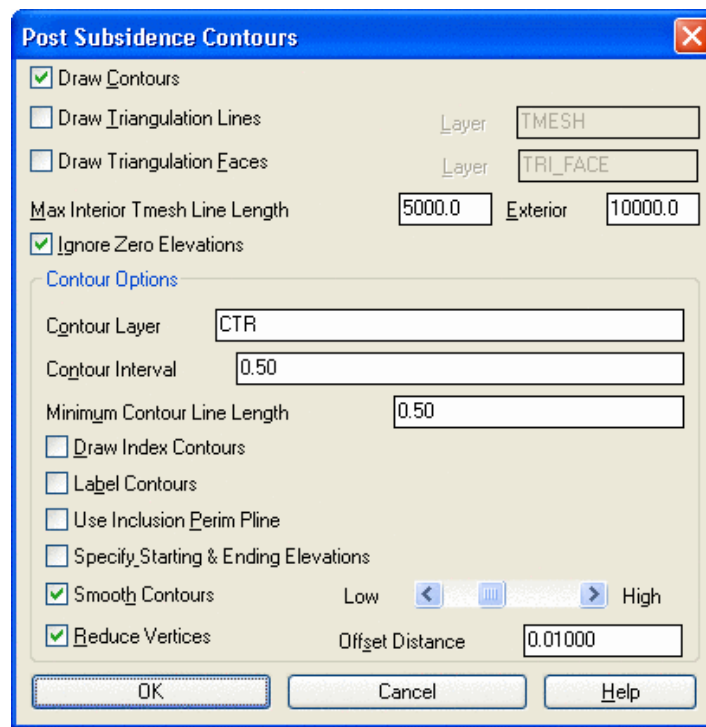

Pulldown Menu Location: Subsidence

Keyboard Command: sdpstr

Prerequisite: prediction points and subsidence output file

Contour SDPS Output File

This command creates contours of the values in SDPS output DAT files. The output files can represent subsidence, strain and any other SDPS deformation output.

Contours of subsidence ".dat" file

Prompts

Triangulate & Contour dialog

Select SDPS Output file Choose the output file.

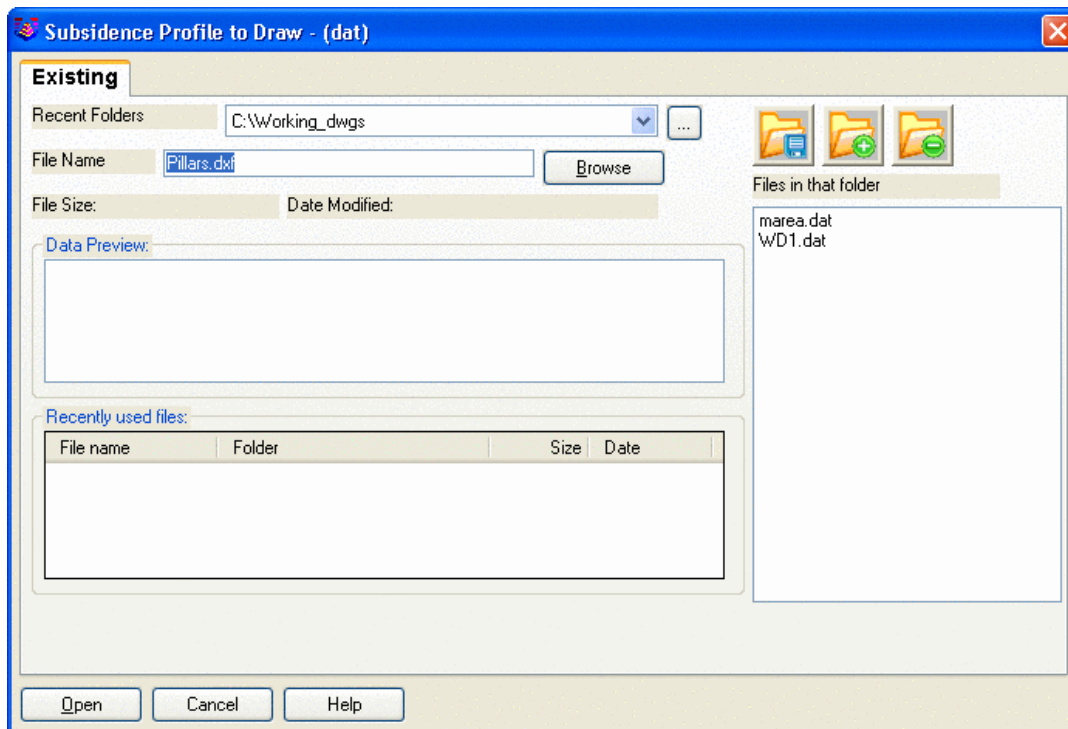

Pulldown Menu Location: Subsidence

Prerequisite: SDPS output file

Keyboard Command: sdpctr2

Draw Subsidence Profile

This command draws a subsidence profile created by Profile Function Formulation in SDPS. The profile data is stored in a .dat file that is created with the Output>Export option in SDPS.

Prompts

Subsidence Profile to Draw Choose the .dat file from SDPS.

Draw Profile dialog You may want to change the vertical scale to a smaller number to exaggerate the vertical.

Bottom elevation of profile grid <-4.0>: *press Enter*

Pick Starting point for axis <5000,5000>: *pick a point in a clear area of the screen*

Pulldown Menu Location: Subsidence

Keyboard Command: sdpsprof

Prerequisite: Subsidence output file

Case Studies

Case Study #6: Underground Mine Layout and Timing

Underground Project Manager

(Underground Mining module > Underground pull-down menu > Timing Project Manager Command)

The Underground Timing Project Manager (MPD) file should be defined before starting with Underground Mine Layout and Timing using the Underground Timing Project Manager command under Underground menu. It allows user to define Equipment, Timing Calendar, Panel Attributes as well as other essential parameters to be used in the timing.

Mine Layout Options

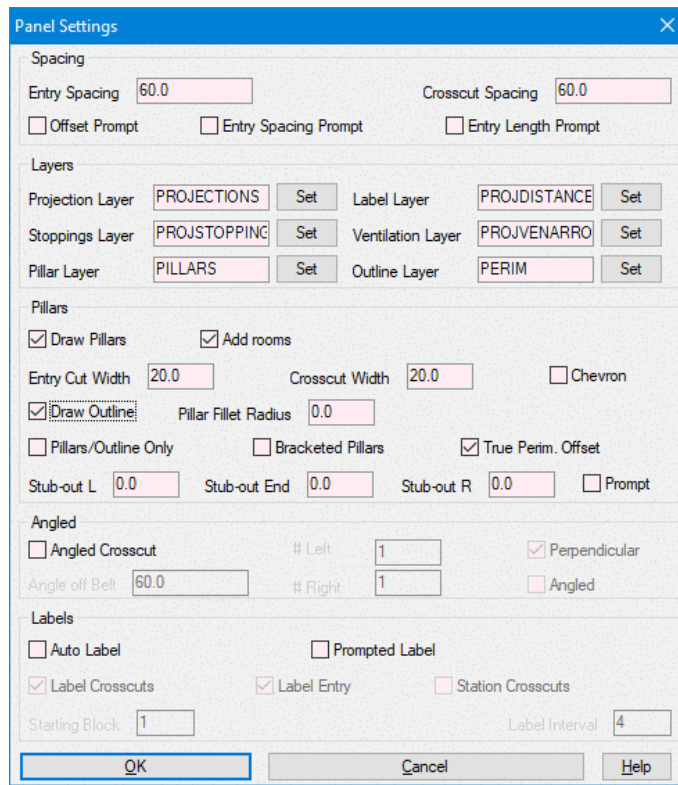

Using the Advanced Projections command in the Underground Mining Module, there are several ways the user can generate mine projections. These different techniques will be based upon personal preference and management's direction. Whether or not to include the centerlines, pillars, and perimeters on the map are up to the user. The Underground Mining Module timing routines require that some information is kept on specific layers. The pillars must be drawn on the PILLARS layer and the perimeter of each section must be drawn on the PERIM layer. These are the defaults set in the Advanced Projections option under the Underground Mining Module.

Choose the Advanced Projections command under Works. The first three prompts are:

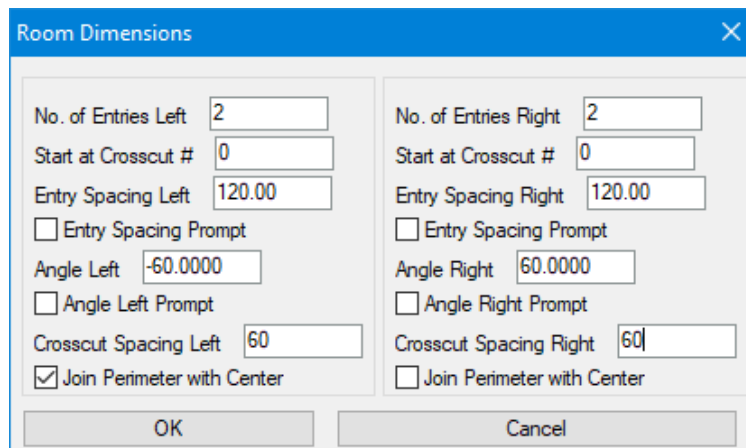

(Underground Mining module > Works pull-down menu > Advance Projections Command)

1. Starting point of the belt
2. Number of entries to the left of the belt
3. The number of entries to the right of the belt

After responding to the initial prompts the Panel Settings dialog box appears. This dialog box allows the user to specify how the mine projections will be drawn. Several different variations are possible. Entry spacing and length can be varied, separately or together.

A nice feature is drawing the rooms on one or both sides of the panel at the same time the panel is drawn. The rooms perimeter on the left or right side can also be joined to the panel perimeter so the timing blocks will match for the panel and the rooms. Join perimeter with center can only be selected once because Carlson doesn't allow you to join all 3 rooms and entry panels together.

In addition to the configuration of the pillars, the user has the option of what to display, pillars, centerlines, perimeter, as well as chamfer, angled blocks, bracketed pillars, stoppings, and ventilation.

Mine Layout Options

As you can see there are several options to present mine projections. Below is the mine projection with angled room and stub-outs created with above dialogues. The stub-out is automatically added when rooms are created.

Once the panels have been laid out, they have to be "placed", or have extended entity data attached to them, so that they will relate to each other. Carlson has three different methods of placing panels: Place Panel, Pick & Place, and Auto Place by Text. Of these three techniques only Place Panel builds a network topology, or precedence relationship, between the panels as they are placed. With the other two techniques, Pick & Place and Auto Place by Text, there is no relationship built as they place the panels. This allows the user to actually mine through panels that overlay each other, which could be helpful in laying out the mine through overlying strata.

Place Panel

(Underground Mining module > Underground pull-down menu > Place Panel Command)

To place panels, the panels must be previously drawn with the perimeter drawn in the PERIM layer and the pillars, which are optional, drawn in the PILLARS layer. The program subtracts the sum of the areas of the individual pillars in the PILLARS layer from the area of the perimeter drawn in the PERIM layer to calculate the extraction

ratio. The extraction ratio is then applied to the perimeter area to calculate the tonnage in the panel.

When the user selects Place Panel the first prompt is:

Use Quick Place mode (yes/<no>)? Quick place mode is an option that lets the user place panels without entering specific information in the panels other than the panel name. It is a way to get the panels placed quickly. If the user has drawn the pillars and does not intend to retreat mine, the Quick Place mode may be the best way to get the panels placed.

If the user chooses the Quick Place mode the following prompts appear:

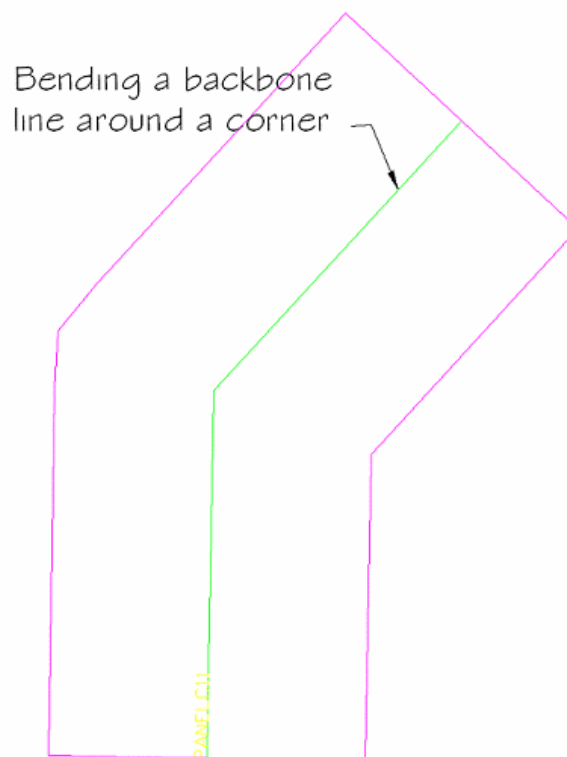

Start new mine plan? (yes/<no>)? The user will always respond with yes for the first panel. Next, as long as the panels being placed are adjacent, the response is negative. Panels that are part of the same mine plan, but are physically separated can be placed as new mine plans and connected later.

The next prompt is: **Direction of panel is defined by (<Perim>,Text, Pick, Segment)?**

- **Perim** - The user defines the starting side of the polygon and the direction of mining is perpendicular to the first side of the polygon. If the panel is laid out using the Advanced Projections in the Underground Mining Module the perimeter is automatically drawn to match up with the requirements for the Perim option.
- **Text** - The direction of mining through the polygon can be set by the direction of the text.
- **Pick** - The user chooses two points to set the direction of mining in the reverse order of mining. The first point is picked inside the polygon, the second point is picked on the beginning side of the polygon. The direction is from the beginning side through the first point picked inside the polygon.
- **Segment** - Pick the starting side of the polygon and any side that parallels the direction of mining of the panel.

When the direction of mining has been set. The program prompts for the name of the panel, offering a name that can be accepted or overwritten. When the name is entered, the program draws the green "backbone" line according to the direction of mining and places the name of the panel at the beginning of the line. The user clicks the right button to complete this process for mining straight through a panel.

To mine around a corner the user left picks the mouse button and repeats the above steps for setting the direction.

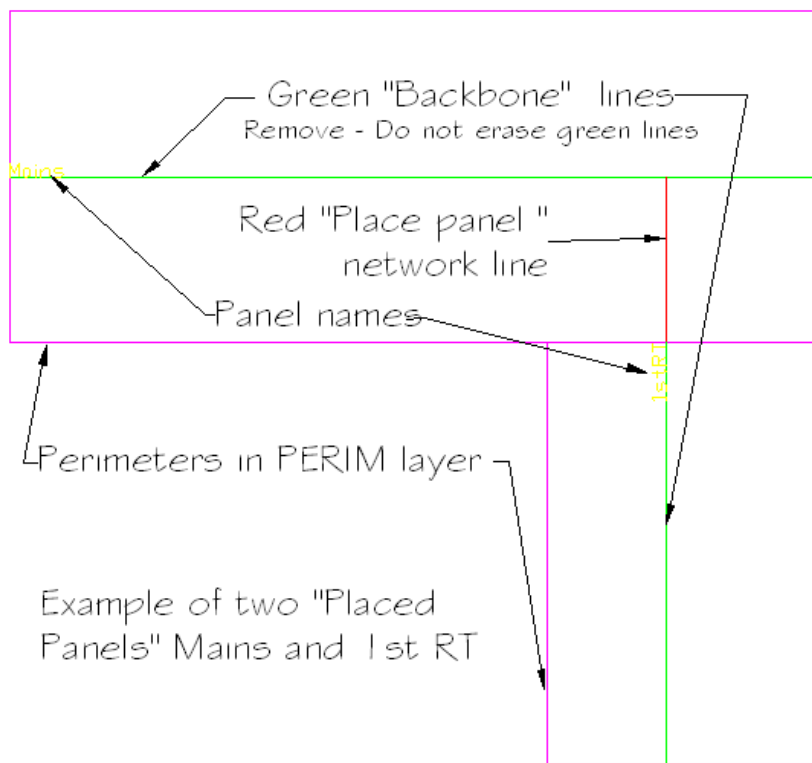

Once the panel has been placed, the program prompts the user for the entry to branch from. The program is asking for the point along the "backbone" line to start the next panel. Once the user selects the starting point for the next panel the process repeats.

Using the Quick Place mode does not give the user access to the Edit Section Data dialog box during the panel placing process. If the pillars are not drawn when using the Quick Place mode the user will have to return to the Edit Section Data dialog box to enter the extraction ratio after placing the panels. Most users prefer to enter this information when the panel is being placed, so they usually do not use the Quick Place mode.

If the user chooses not to use the Quick Place mode there are two additional panel direction options available: Azimuth and Pick internal point.

The screenshot shows the 'Edit Section Data' dialog box with the following fields and values:

- Attr. Group: DEFAULT
- Panel name: ANEL635
- Panel start: [Empty]
- Easting: 3621.1986
- Northing: 5020.1703
- Azimuth: 89°22'38"

- Retreat Difficulty Factor: 1.0
- Buttons: Select file, Select file
- Buttons: Difficulty Calculator, OK, Cancel

Pick and Place

(Underground Mining module > Underground pull-down menu > Pick and Place Panel Command)

Pick and Place places and times the panel as it is placed, drawing the timing blocks when the panel is placed. In addition to timing as it goes, this option allows the user to test the schedule before placing the panel in the mining sequence, providing real time feedback while scheduling the mine. This technique does not automatically build precedence between panels automatically. Precedence can be added to the panels in the precedence part of the Edit Section Data dialog box. Once all of the individual panels have been placed, the user runs the schedule to get the complete mine timing report.

Similar to Place Panel, Pick & Place Panel has the following options for specifying direction of mining. They are defined above:

- **Perim (default)**
- **Text**
- **Pick**
- **Auto**
- **Segment**

Once the direction has been set, the Define Timing Step dialog box appears.

- **Panel Name** - is a required field. The program will offer a name which can be overwritten.
- **Panel Start** - Is an optional field
- **Owner** - is an optional field, if filled out indicates the property owner for the entire panel and will be available in production reports.
- **Starting Date** - is not optional for the first panel assigned to any unit. After the first panel this field is optional and will be calculated.
- **Number of shifts** - is a required field, and overwrites the setting in the equipment definition file if the shifts are less than the equipment file.
- **Retreat Recovery** - If recovery is different on retreat than advance it can be inserted here.
- **Entry width** - if no pillars are drawn in the perimeter the default is 20 feet. Otherwise, it is picked up from the pillar layout.
- **Panel Attributes** - can be anything the user wants to use such as; ash, sulfur, btu, etc. The user can use fixed values for these or refer to a grid.
- **Prompt for Retreat Options check box** - if this is checked it indicates the shape of the retreat perimeter differs from the advance perimeter. If checked, a separate set of prompts will appear giving the user the option to specify the shape of the retreat perimeter and extraction ratios for the pillars mined inside and outside the advance perimeter.
- **Advance Difficulty Factor** - the difficulty factor used on the advance can differ from that used on the retreat. Normal difficulty is (1), greater than one reduces productivity, less than one speeds up production. The difficulty factor can be a factor or a grid.
- **Retreat Difficulty Factor** - can be specified separate from the advance rate.

- **Equipment Name** - is selected from the defined equipment list.
- **Advance Extraction Ratio** -the extraction ratio is the sum of the mined out area outside the pillars divided by the area of the perimeter. This factor is usually 1.0 for longwall panels, but for continuous miner sections is usually near .50.
- **Retreat Extraction Ratio** - this factor is percentage of the remaining pillars left on the advance. This factor can be up to 100 percent for the remaining pillars, as opposed to a number less than 1 minus the advance extraction ratio.
- **Advance/Retreat radio button** - if the user left clicks in the panel after it has been assigned on the advance to schedule it the radio button will gray out the advance button highlighting retreat button.
- **Portion to mine** - options include:
 - **Whole Perimeter** - to mine the entire perimeter.
 - **Distance** - the distance displayed in the box to the left of the radio button is the distance to the spot where the user left clicked in the perimeter to Pick & Place the panel. This is useful if the user want to know the distance to a point inside the panel. When this option is selected, a pinpoint is placed at the distance selected, allowing the user to schedule other panels.
 - **Moving time (shifts)** - the move time in shifts the panel is delayed prior to starting.
 - **Test** - this option lets the user try the settings and get feedback before applying them.
 - **Report Options** - this button gives the user two reporting options, one for an abbreviated timing report and the other for the full report.
 - **OK** - applies the selection and schedules the panel showing the timing.
 - **Cancel** - breaks out of the procedure and returns the user to the command prompt.

Auto Place Panel by Text

(Underground Mining module > Underground pull-down menu > Auto Place Panel by Text Command)

The Auto Place Panel by Text command gives the user the ability to place panels by drawing text in the panel perimeters on the PANELNM layer. The requirement for drawing the perimeter in the PERIM layer is the same. The prompts are set out below.

Command: auto_place

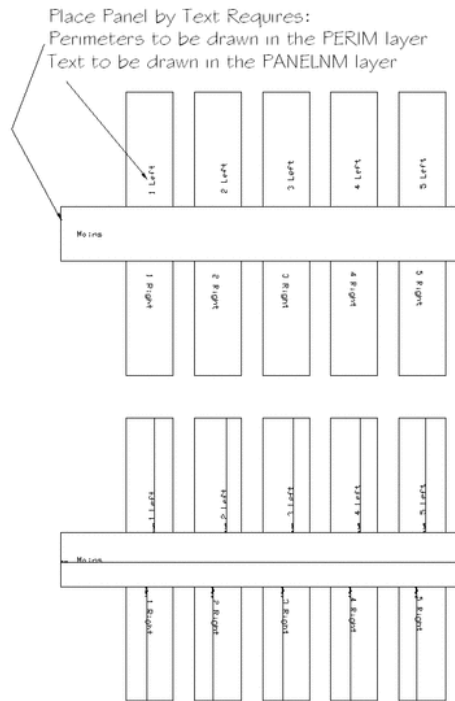

Assign zero retreat extraction (Yes/<No>)?

Advance difficulty <1.0> :

Retreat difficulty <1.0> :

Retreat recovery ratio for remaining pillars <1.0> :

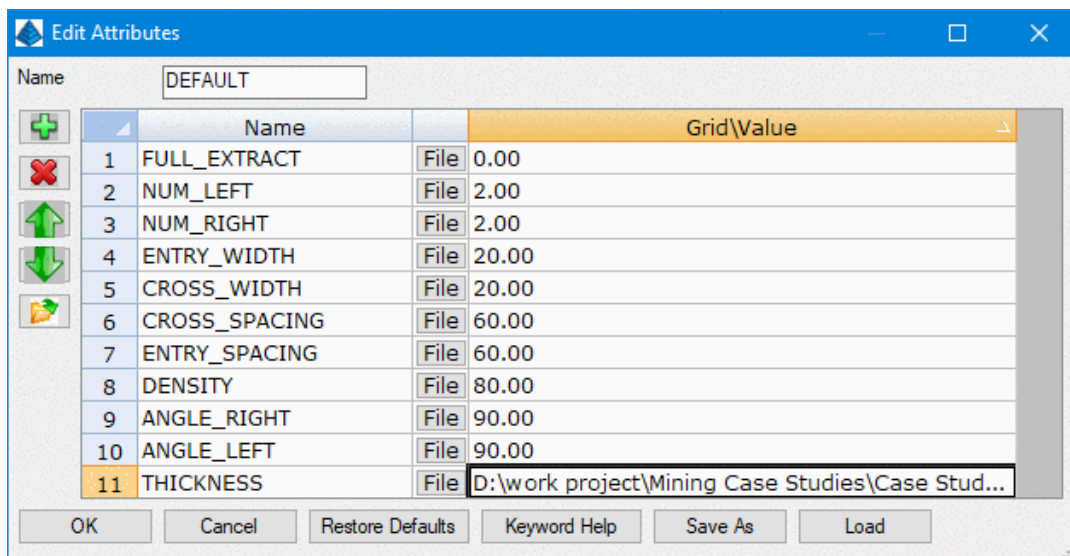

Entry width <20.0> :

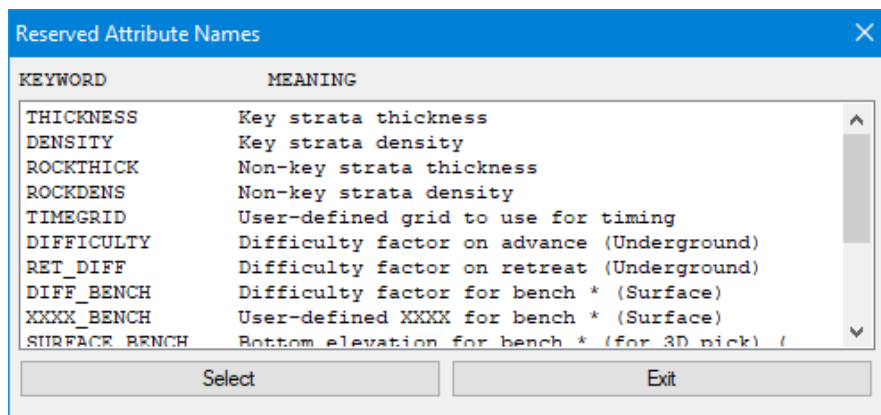

Panel Attributes

(Underground Mining module > Underground pull-down menu > Edit Panel Attributes Command)

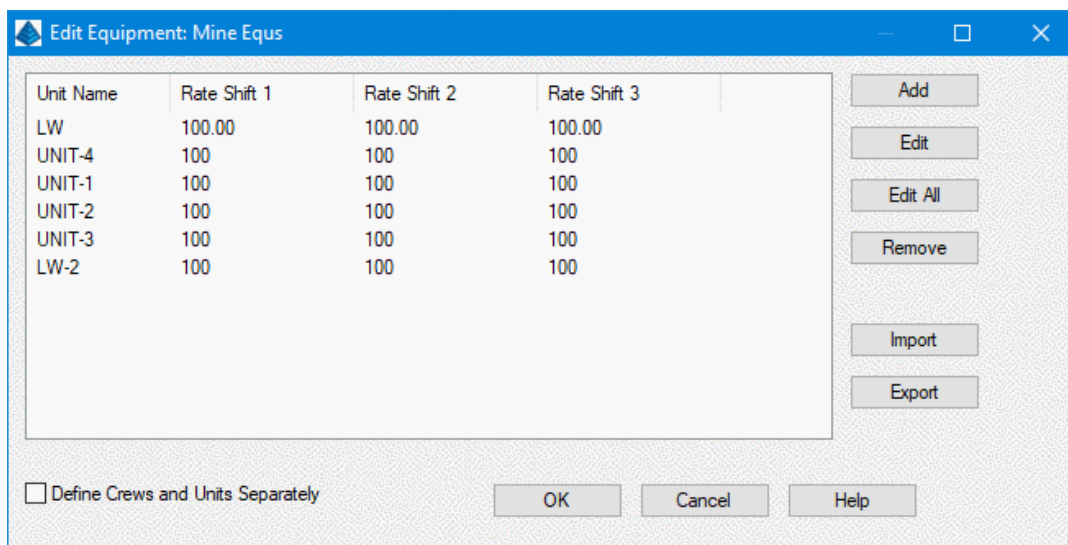

The default panel attributes option lets the user assign attributes by value or grid. Certain key or reserved words are available to the user that Carlson recognizes. Choose the Keywords Help button to see them:

Define Equipment

Define Equipment is where the user adds and edits the production rate of the equipment, it can be accessed from Underground Project Manager. Production rates are input for the entire spread or section. This rate can be modified as a function of time, mining height, or strip bench. The Rate/Shift, Hours/Shift, and Rate/Hour back-calculate, allowing the user the ability to fine tune the production rate. If the toggle to "Define Crews and Units" is on it gives user an ability to define Labor Crews and Units (combination of Crew and Equipment) separately.

Equipment Production Rate

Name:

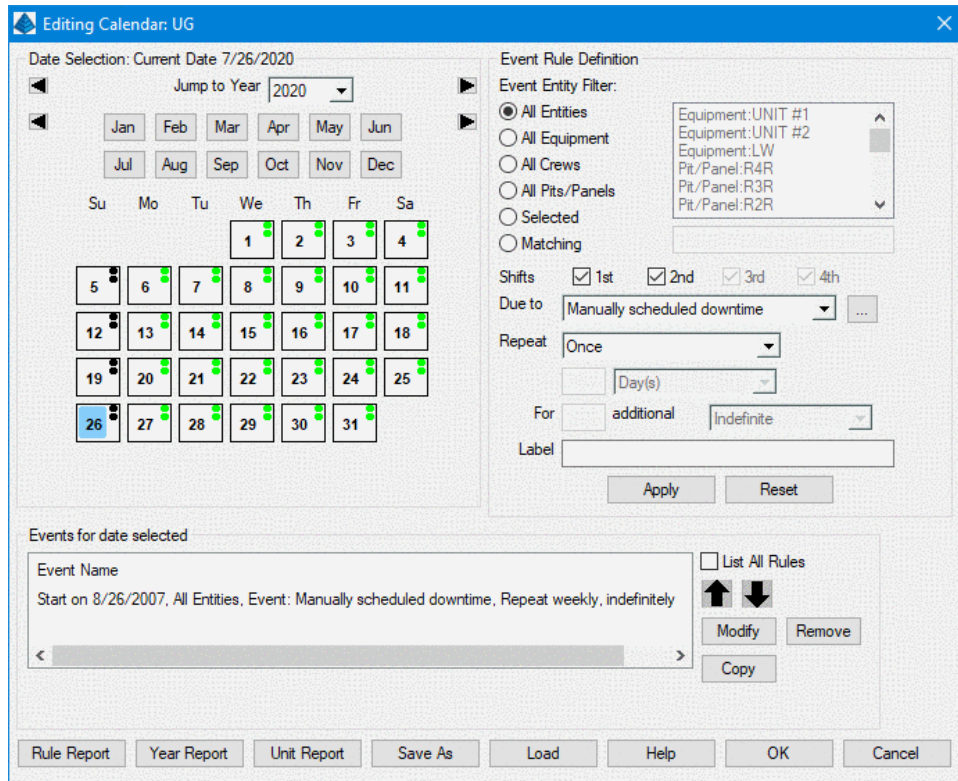

Unit of Production
 Tons Distance Cubic yards Linear ft of Advance

	Shift 1	Shift 2	Shift 3	Shift 4
Advance Rate/shift	<input type="text" value="140.00"/>	<input type="text" value="140.00"/>	<input type="text" value="140.00"/>	<input type="text" value="600.00"/>
Retreat Rate/shift	<input type="text" value="100.00"/>	<input type="text" value="100.00"/>	<input type="text" value="100.00"/>	<input type="text" value="600.00"/>
Hours/shift	<input type="text" value="8.00"/>	<input type="text" value="8.00"/>	<input type="text" value="8.00"/>	<input type="text" value="8.00"/>
Advance Rate/hour	<input type="text" value="17.50"/>	<input type="text" value="17.50"/>	<input type="text" value="17.50"/>	<input type="text" value="75.00"/>
Retreat Rate/hour	<input type="text" value="12.50"/>	<input type="text" value="12.50"/>	<input type="text" value="12.50"/>	<input type="text" value="75.00"/>
Availability	<input type="text" value="1.000"/>	<input type="text" value="1.000"/>	<input type="text" value="1.000"/>	<input type="text" value="1.000"/>
Advance Min. Height	<input type="text" value="7.00"/>	Advance Max. Height		<input type="text" value="9.50"/>
Retreat Min. Height	<input type="text" value="7.00"/>	Retreat Max. Height		<input type="text" value="9.50"/>
Main Maintenance Freq.	<input type="text" value="6500.00"/>	Delay		<input type="text" value="2.00"/> shifts
Routine Maintenance	<input type="text" value="2500.00"/>	Delay		<input type="text" value="5.00"/> shifts
Extraction factor	<input type="text" value="1.0000"/>	Cost per hour		<input type="text" value="0.00"/>

The user can specify the minimum and maximum mining heights. Where mining occurs below the minimum mining height, out of seam dilution is added to make up the desired minimum height. When the maximum mining height is selected key strata is combined with non-key material where the key strata exceeds the maximum mining height. A cost per hour can be input and it will be multiplied by the hours worked. Maintenance frequency is scheduled in the same units as the Rate/Shift. The delays apply to the entire spread or section in shifts for both Routine and Main Maintenance Frequencies. The recovery factor is designed to be used with elliptical cross-sectioned entries developed with boring machines.

Calendar

The Editing Calendar is a quick and simple way to schedule a production Equipment or Unit (group of a Equipment and Labor Crew working on it). This should be thought of as an equipment, as opposed to a crew scheduling technique. Equipment needs to be added before the calendar is applied. The calendar can be applied to a single unit or all of the equipment. To apply the calendar to several units select the calendar and the unit and Apply the calendar to the unit. Once the calendar is created two different reports can be generated. The first report is the annual unit calendar and the second is a yearly report of what is working and when.

Pin Points

(Underground Mining module > Underground pull-down menu > Add Pin Point Command)

Pin points are break points set in a panel to indicate where the mining temporarily stops to facilitate mining in other areas. When mining resumes in the panel with the pin point it resumes at the pin point. Pin points allow the user to layout fewer panels.

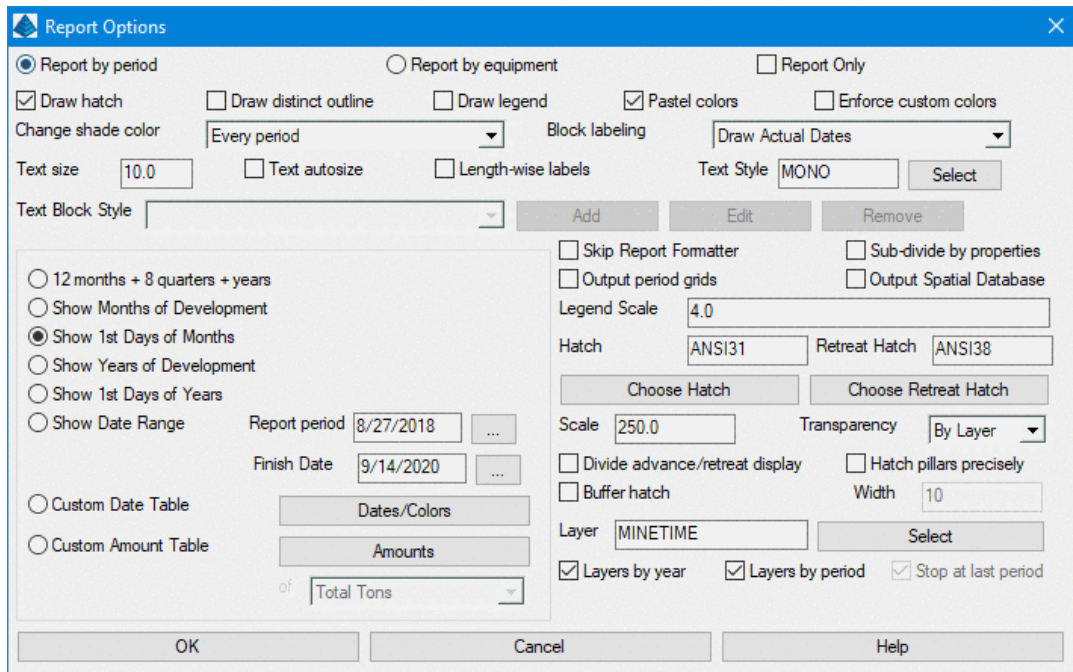

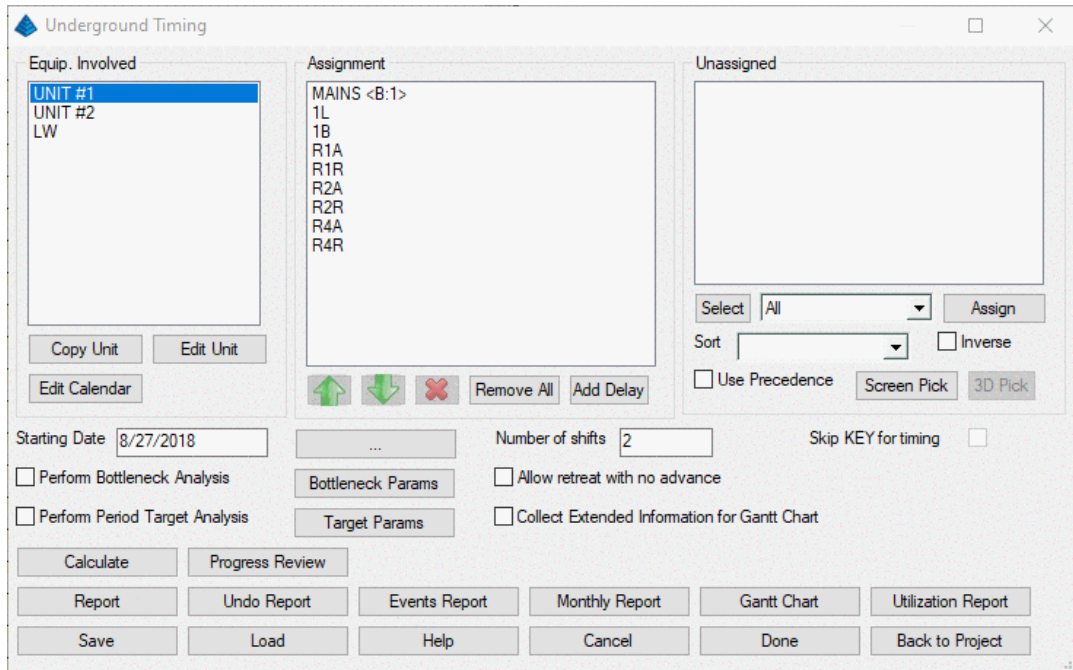

Underground Timing

(Underground Mining module > Underground pull-down menu > Underground Timing Command)

The Underground Timing option is selected after the panels have been placed, and the equipment and calendar have been defined. Panels are assigned to equipment in the sequence to be mined. Panels can be selected by name from the unassigned list or screen picked. The unassigned panel list can be sorted by name or direction of mining. Delays can be scheduled between panels in days or shifts. The starting date and number of shifts per day are assigned in the designated boxes. Once the run is set up, left click on the Calculate button. Two reporting options are then available. An abbreviated timing report can be viewed or the detailed timing report can be formatted. The user has a wide

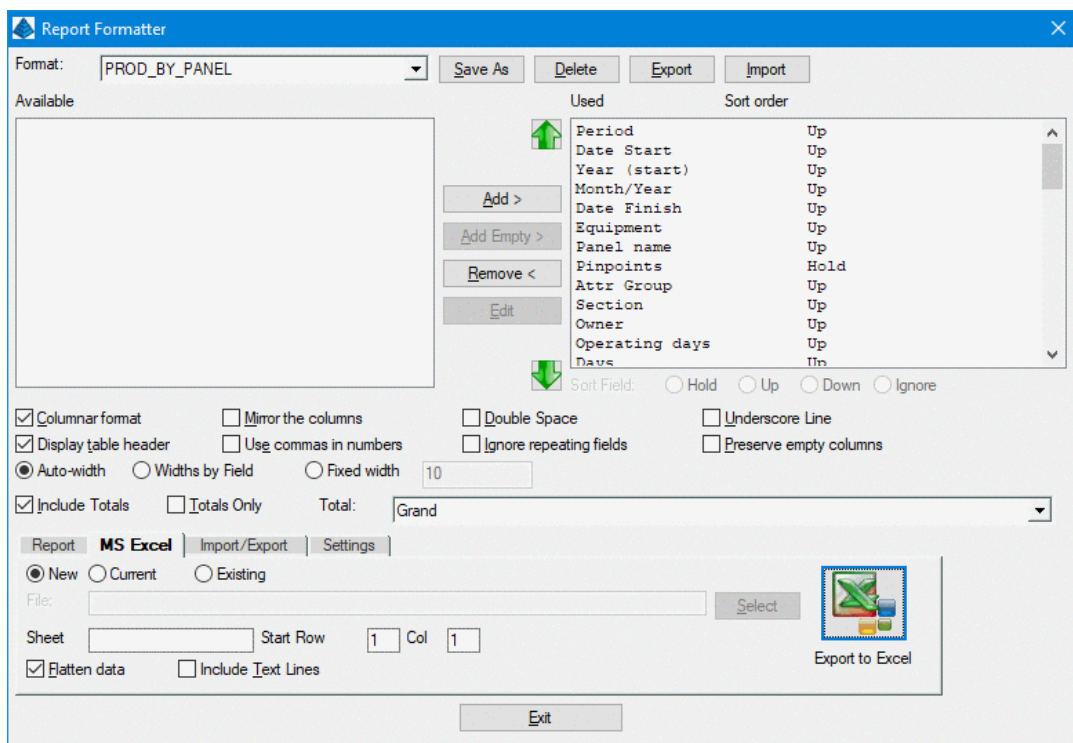

range of timing options that impact the presentation of the timing map.

Once the report options are selected the map is timed out.

When the report times the map it also develops a report. The report formatter allows the user to customize the report. By moving available variables across to the used variables side in the order from top to bottom the user can set the order in the report. This order also drives the sub-totaling option to create various report styles. The report can be displayed on the screen, printed, made part of the drawing, or exported to Excel or Access. The order set up in the report format from top to bottom is the order in the report from left to right. There is a line editor in the screen display that allows the user to add lines and edit the report prior to printing.

This is an example of exporting the report to a spreadsheet. Totals can be exported to spreadsheets as an option. If totals are exported they show up in bold font. This report can also be imported into the Microsoft Access database for additional reporting options.

Period	Date Start	Year (start)	Month/Year	Date Finish	Equipment	Panel name	Pinpoints	Attr Group	Section	Owner	Operating days	Da

=====

Case Study #8, Part 1: Underground Mine Mapping Procedure

Application

Underground mine mapping requires the entry of traverse notes (for the placement of spads), entry of left and right offsets for locating mine pillars and perimeters, connecting the pillars and perimeters, the placing of special mine symbols and strata thickness measurements, and the drafting of projections for future mining. These are all fully covered in the Mining Module of Carlson. The mapping utilities apply primarily to underground coal mines but also to underground limestone, trona and even salt mines. In fact, any mine that creates pillars for roof support.

Procedure

Here's a quick summary of the mine mapping procedure:

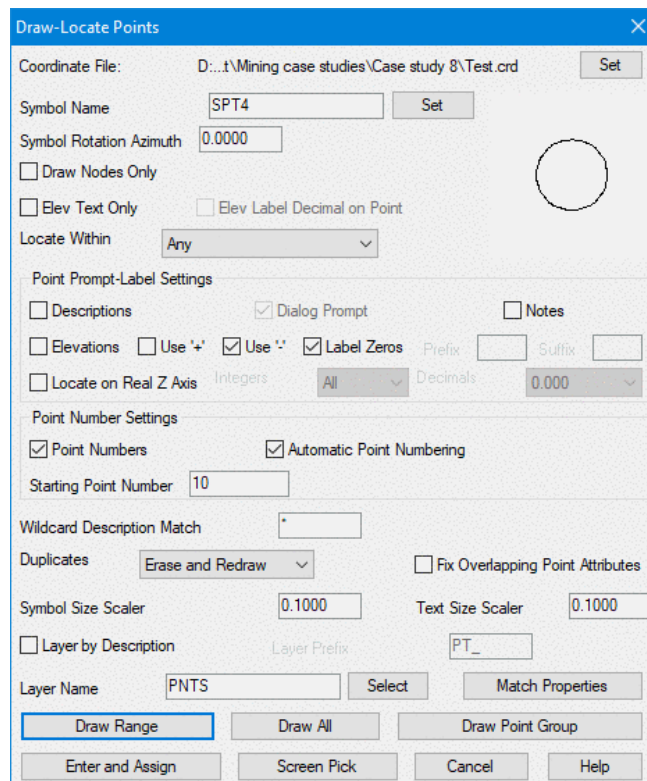

1. Enter the traverse notes and plot the spad points.
2. Draw projections.
3. Enter the mine "offset" notes to pillars and perimeter points.
4. Connect up your pillars and perimeters.
5. Add special mine symbols (stoppings, air flow pointers, etc.).

Let's now look at each of these steps in detail.

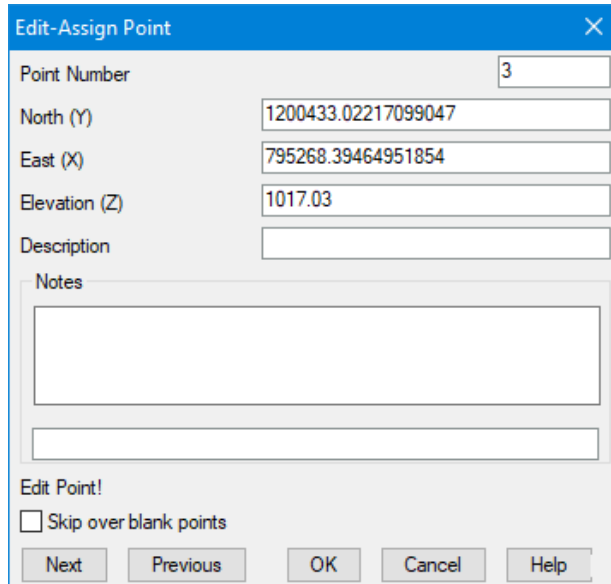

(1) Entering the Traverse Notes

The most direct method of entering traverse notes begins with Draw-Locate Point in the Points Dropdown and continues with Locate by Bearing or Locate by Azimuth. You would Enter coordinates or Pick a Point within Draw/Locate Point. You might choose to enter a specific northing of 1200465.107 and easting of 795091.135. If this is your first point on the job you will be asked to select an existing or make a new .CRD file (coordinate file). You would select New and choose a name, typically equal to the name of the drawing. We will call our file MINE or TEST.

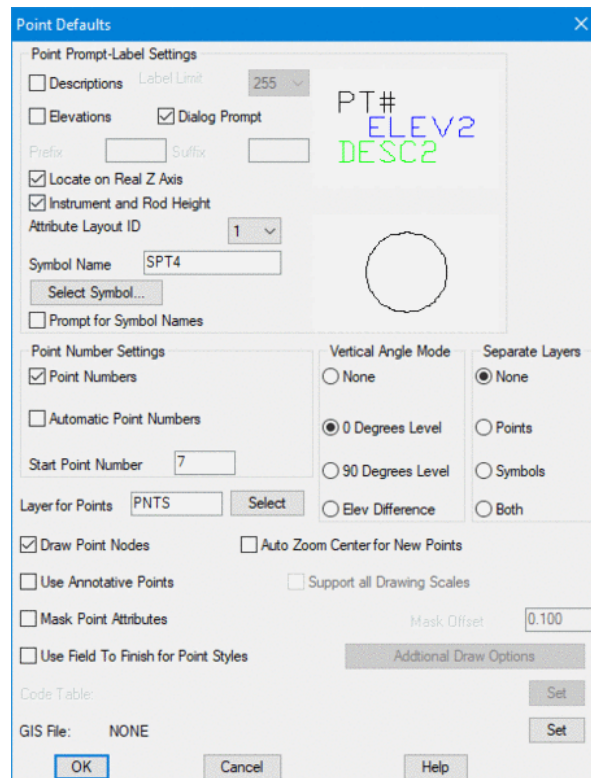

Then if you select LOCATE BY AZIMUTH under the Underground Mining Module > Notes dropdown menu, the program will start at your first point by default, and allow you to enter an azimuth and distance to the next point, such as 100.1535 (100 degrees 15 minutes 35 seconds), and a distance of 120.09 feet. Pressing ENTER will repeat the LOCATE BY AZIMUTH command. Next try defaulting (repeating) the azimuth by pressing ENTER, and input a distance of 60.05. You obtain a drawing as shown above.

Now, let's enter an elevation for all 3 points. Go to Points, Coordinate File Utilities, Edit-Assign Point. The following dialog box appears. Enter in the elevation for Point 1, choose next for points 2 and 3. Point1 elevation is 1016.73, Point 2 is 1016.75 and Point 3 is set to 1017.03.

To enter the additional points. Use the Inverse and Traverse commands from the COGO pulldown in the Survey module.

NOTE:Make sure Instrument Rod and Height Prompting is turned on under Points Pulldown Menu > Point Defaults. This will prompt for the height each time. Next, go to the Survey Module > COGO Pulldown menu and turn on Linework which is "Lines On/Off". This will draw the lines of the traverse. Now Select Inverse from the COGO menu, or type "I" at the command line. Also turn off Automatic Point Numbers for manual naming the points. The point default setting is shown below.

Here are the next four Traverse point entry values.

Command: i, I

Calculate Bearing & Distance from starting point? Traverse/SideShot/Options/Arc/Pick point or point number: 2

PointNo.	Northing(Y)	Easting(X)	Elev(Z)	Description
2	1200443.7177	795209.3048	1016.7500	

Traverse/SideShot/Options/Arc/Pick point or point number: T

Traverse, Line OFF, RAW FILE OFF

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <7>: 5 for Azimuth

Enter Azimuth (ddd.mmss) <280.1535>: 280.1535

Points/<Distance>: 60.03

Vertical Angle Type (0-3) <2>: 1 (0=None, 1=Vertical(0d level), 2=Zenith(90d level), 3=Elevation Difference)

Enter Vertical Angle (dd.mmss) <0.0000>: 54

Instrument Height <-2.7000>: -2.7 Use negatives to come down from the roof.

Rod-Target Height <-1.9000>: -1.9

Hz Distance > 60.0226

Enter Point Number <4>: press Enter

PointNo.	Northing(Y)	Easting(X)	Elev(Z)	Description
4	1200454.4084	795150.2420	1016.8929	

(next point)

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <5>: press Enter

Enter Azimuth (ddd.mmss) <280.1535>: 10.135

Points/<Distance>: 59.98

Enter Vertical Angle (dd.mmss) <0.0000>: -.425

Instrument Height <-2.7000>: -2.3

Rod-Target Height <-1.9000>: -2.1

Hz Distance > 59.9753

Enter Point Description <>: press Enter for none

Enter Point Number <5>: press Enter

PointNo.	Northing(Y)	Easting(X)	Elev(Z)	Description
5	1200513.4302	795160.8942	1015.9456	

(next point)

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <5>: press Enter

Enter Azimuth (ddd.mmss) <10.135>: 280.1535

Points/<Distance>: 60.02

Enter Vertical Angle (dd.mmss) <0.0000>: .23

Instrument Height <-2.3000>: -1.95

Rod-Target Height <-2.1000>: -2.14

Hz Distance > 60.0187

Enter Point Number <6>: press Enter

PointNo.	Northing(Y)	Easting(X)	Elev(Z)	Description
6	1200524.1201	795101.8352	1016.5372	

(next point)

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <5>: press Enter

Enter Azimuth (ddd.mmss) <280.1535>: 190.1535

Points/<Distance>: 60.01

Enter Vertical Angle (dd.mmss) <0.0000>: .07

Instrument Height <-1.9500>: -1.78

Rod-Target Height <-2.1400>: -1.85

Hz Distance > 60.0099

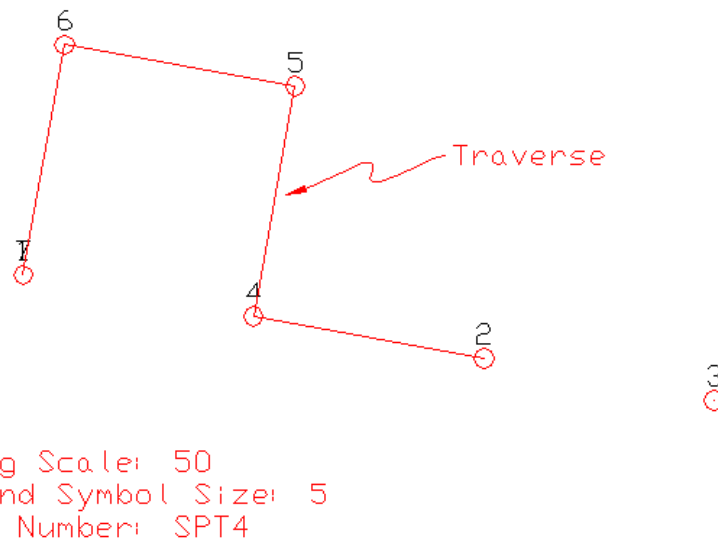

Enter Point Number <7>: *press Enter*

PointNo. Northing(Y) Easting(X) Elev(Z) Description

7 1200465.0698 795091.1468 1016.7293

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <5>: *press Exit to end*

The following image should appear in the drawing.

(2) Drawing Projections

(Underground Mining module > Works pull-down menu > Basic Projections Command)

There are four types of projections: Basic Projections, Advanced Projections, Projections and Ventilation, and Rooms. Basic Projections will only produce rectangular projections (not angular). This option, however, has fewer prompts and is more automatic. Let's run Basic Projections.

Start pt. of belt entry: *Pick point 4* (You are automatically placed in intersect and node snap mode. All Carlson points have nodes, so you can use the node snap. You can override the pre-set snap by picking the asterisks at the top of the sidebar menu and selecting another choice.)

Command: *panell1, PANEL1*

Command: (intersect/node on)

Start pt. of belt entry: *Pick Point 4* (for point number 4)

<P>ick End Point For Belt or [A] For Azi/Dist: *A*

Azimuth to end of belt [ddd.mmss]: *10.1535*

Distance to end: *540*

Number of entries on left side: *1*

Number on right side: *2*

Entry spacing: *60*

Crosscut spacing: *60*

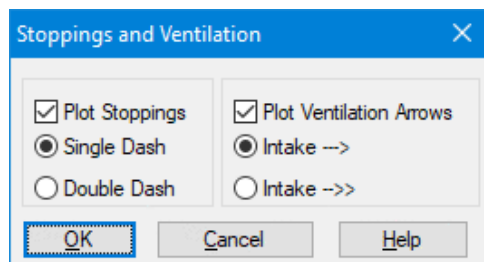

Plot Outer Rib Line y/<n>: *Y*

Cut Width <20>: *press Enter*

Offset to starting rib line (e.g. -10,0,<10>): *press Enter*

Offset to ending rib line (e.g. -10,0,<10>): *press Enter*

Offset xcuts y/<n>: *N*

Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*

Draw another stopping line <y>/n: *Y*

Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*

Draw another stopping line <y>/n: *Y*

Pick pt. on xcut for beginning of stopping line: *pick a point as shown on figure*

Draw another stopping line <y>/n: *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point as shown on figure*

Distance between ventilation arrows: *pick a point as shown on figure*

<I>ntake or [R]eturn: *I*

Draw ventilation arrows on another entry <y>/n: *Y*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: *pick a point as shown on figure*

Distance between ventilation arrows: *pick a point as shown on figure*

<I>ntake or [R]eturn: *R*

Draw ventilation arrows on another entry <y>/n: *N*

Project another panel <y>/n: *N*

You will notice how all projection lines are on distinct layers (PROJECTIONS, PROJSTOPPINGS, PROJVENTARROWS).

With the projection shown, it is easy to illustrate rooms. Select Rooms under the Works dropdown.

Command: rooms, ROOMS

Start pt. of rooms: *pick point 1*

End pt. of rooms: *pick point 3*

Distance between room entries: 40
Distance between room crosscuts: 40
Room depth: 240
Rooms on <R>ight or [L]eft side: R

While here, let's select Label Proj. Distances.

Command: LDIST

Belt entry (point to point mode) y/<n>: N

Select line to label distance on:

Pick as many entry and crosscut lines as desired. This Label Proj. Distances routine applies to Basic Projections and Rooms using the pick line option. The pick option places the distance on the picked line segment. For Advanced Projections, most lines are continuous from the start to the end of the projections, so the point-to-point end-point pick mode must be used. This point-to-point mode must also be used on the belt line (from spad 4), since it is one continuous line.

Now let's label our panel and rooms. Select Panel Label Block.

Command: labelplan, LABELPAN

Insertion point: Pick anywhere in the open areas.

Rotation angle: Pick the rotation angle from the insertion point.

SECOND DIMENSION <60'>: *press Enter*

FIRST DIMENSION <60'>: *press Enter*

Now Select the command: Room Label Block

Command: labelrms, LABELRMS

Insertion point: Pick an open spot for the center of the label.

Rotation angle: Pick the rotation angle from the insertion point.

ON ADVANCE OR RETREAT <ADVANCE>: *press Enter*

SECOND DIMENSION <40'>: *press Enter*

FIRST DIMENSION <40'>: *press Enter*

The final projection option we'll run is Advanced Projections. Select it.

Command: panel2, PANEL2 (**Intersect/node on**)

Pick Start Point For Belt: Pick where Pick3 is on the figure below.

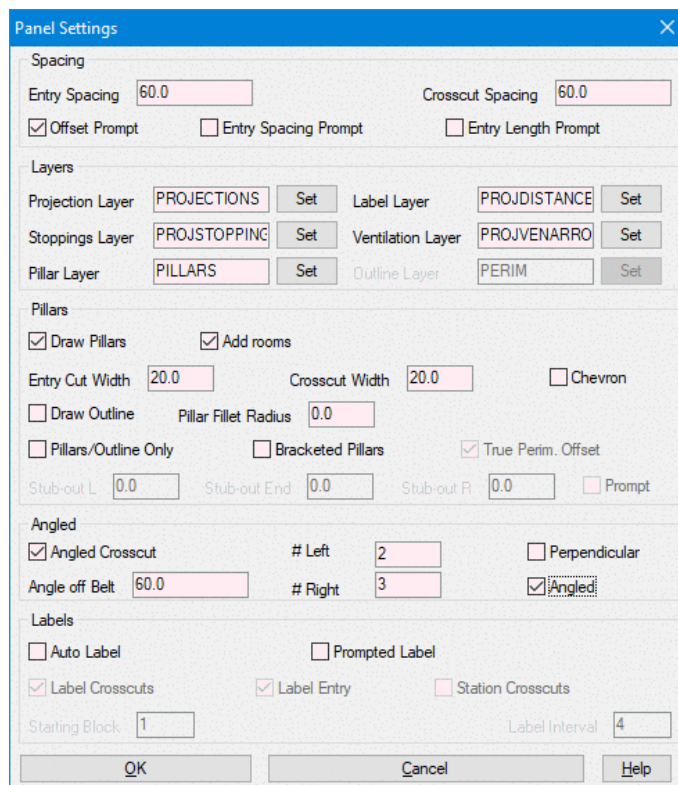

Pick End Point For Belt, or <A> For Azi/Dist: A

Enter Azimuth in ddd.mmss <280.1535>: 280.1535

Enter Distance: 360

How Many Entries Left Of The Belt <0>: 2

How Many Entries Right Of The Belt <0>: 3

Enter Offset For This Heading <0>: *press Enter*

Enter Offset For This Heading <0>: *press Enter*

Enter Offset For This Heading <0>: *press Enter*

Enter Offset For This Heading <0>: *press Enter*

Enter Offset For This Heading <0>: *20*

Use sidebar to select single-dash stoppings.

Pick pt. on xcut for beginning of stopping line: Pick as many xcuts as you would like.

Draw another stopping line <y>/n: *Y* Use sidebar to select single-dash stoppings.

Pick pt. on xcut for beginning of stopping line:

Draw another stopping line <y>/n: *Y* Use sidebar to single select -dash stoppings.

Pick pt. on xcut for beginning of stopping line:

Draw another stopping line <y>/n: *N*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: Pick ventilation arrow location.

Distance between ventilation arrows: Pick interval distance.

<I>ntake or **[R]**eturn: *I*

Draw ventilation arrows on another entry <y>/n: *Y*

Pick pt. on entry to begin drawing ventilation arrows [nea on]: Pick ventilation arrow location

Distance between ventilation arrows: Pick interval distance

<I>ntake or **[R]**eturn: *R*

Draw ventilation arrows on another entry <y>/n: *N*

Complete the stopping and ventilation options as desired. A plot similar to the one above is obtained. All entries are continuous lines, while crosscuts are individual lines.

(3) Entering the Offset Notes

Since mining operations have different methods for note taking and posting, there are three distinct routines for entering offset notes: Mine Note Left/Right/Face, Mine Note Auto Left/Right, and Mine Note From CRD File. Each of these routines operate with a similar procedure of first choosing a starting point and direction, and then distancing up and offsetting left and right repeatedly. There are also two setup routines. Mine Note From Face Prompt allows the mine note entry routines to post back from the face, and ASCII File From Notes is an option for keeping a record of the offset notes in an ASCII file. All these routines are located in the Notes dropdown menu.

Before we can begin an example, there needs to be some starting points. Select Locate Point and place one point. Then select Locate By Azimuth and place a point at azimuth 100.0000 and distance 60. Repeat Locate By Azimuth with the same values from the second point.

Now we can enter offset notes. Go to Mine Note Auto Left/Right in the Notes dropdown menu.

Command: note2

Enter Offset File Name <offset.dat>: *press Enter*

Append File [<Yes>/No]? *N* (This appears only if the file already exists.)

Tabular Format–Distance L R Hgt– (<y>/n): *Y*

From Station point[node on]: (795704.0 1.20119e+006) *Pick Point 1*

To Station point (A for Azimuth): *A*

(4) Connecting Pillars and Perimeter

Once the offset notes have been entered, the pillars and perimeters can be drawn by connecting the dots. Pillars are created as closed polylines in the PILLARS layer, and perimeters are created as closed polylines in the PERIM layer.

There are two approaches for connecting the dots. One is to manually connect the pillars and perimeters by simply picking each point in order and using C to close at the end. This is done with the Draw Pillars and Draw Perimeter routines in the Works dropdown. The other method is to use AutoMine Connections which automatically connects up the pillars and perimeter. This routine reads a record file from a mine note entry routine and requires that the corner points (the first points across a crosscut) are coded. If you entered the example offset notes in the previous section, then everything is ready for AutoMine Connections. Select it from the Works dropdown and choose the file "offset". After drawing the pillars and perimeter, AutoMine leaves a pick box hanging off the perimeter so that you may connect it with a previous perimeter. In our sample case, just enter 'C' to close the perimeter.

It is important for quantity calculations that these polylines are closed. To make sure your pillars and perimeter are closed polylines, use the Highlight Unclosed Polyline routine in the Works dropdown.

Case Study #8, Part 2: Computing Tonnage and Acreage

Application

Once the mine map is completed using the techniques described in the previous section, quantities of mined mineral and waste rock may be computed, with industry standard reports. The reports will be generated based on the reporting method selected under the Settings Pulldown Menu > Carlson Configure > Mining Settings.

Procedure

Here's a quick summary of the procedure for computing quantities:

1. Configure the "look" of your coal sections (or other mineral).
2. Locate all coal sections measured in the mines.
3. Compute tonnages by average or modeled grid methods.
4. Draw and compute quantities for pillar cuts on the "retreat".

(1) Configuring the Section Information

Configuring the section information involves assigning each strata a name and a density, and specifying the look of the section for when it is placed in the drawing. This information is stored in a user-specified file and is referenced for locating sections in the drawing and for quantity calculations. If you reconfigure an existing section file, sections placed in the drawing using the previous section file become invalid and must be replaced. The strata in a section can be configured as either individual or composite. With the individual configuration, each strata has its own name and density. With composites, each strata is still named separately but they also are divided into groups that have a group name and density. The principle advantage to composites is that it allows you to enter and list out each strata height and then combine the strata into their corresponding composite category when generating tonnage quantities. First, let's configure an individual section. Select Configure Section Info in the Works dropdown from underground mining module.

Enter Section Configuration Filer Name (MINE.SC)

Mine Name: *Round Mountain*

Enter Abbreviated Strata Name/<ENTER> to End: *C* This name is drawn next to the corresponding height when a section is located in the drawing.

Enter The Full Strata Name <C>: *Coal* This name is used in quantity reports.

Enter Abbreviated Strata Name/<ENTER> to End: *B*

Enter The Full Strata Name <C>: *Bone*

Enter Abbreviated Strata Name/<ENTER> to End: *R*

Enter The Full Strata Name <C>: *Rock*

Enter Abbreviated Strata Name/<ENTER> to End: *press Enter*

Enter Individual densities or Composite densities (I/C) <I>: *press Enter*

Average wt. of C (Coal) [lbs/ft³]: *80*

Average wt. of B (Bone) [lbs/ft³]: *150*

Average wt. of R (Rock) [lbs/ft³]: *150*

Circle the Coal Section (y/<n>)? *Y* This specifies whether a circle is drawn around the section when it is placed in the drawing.

Plot the Numeric Value Only (y/<n>)? *press Enter*

Text Size <6.0>: *press Enter*

Enter thickness in feet or inches [Feet/<Inches>]? *I for Inches*

Prompt for entry width [Yes/<No>]? *Y if Yes Linear Advance will also be reported*

The following figure shows how this section will appear in the drawing.

Now let's make a composite section. Select Configure Section Info in the Works dropdown.

Enter Coal Section Configuration Filer Name: *SECTION2* Or the name of your choice.

Mine Name: *Round Mountain*

Enter Abbreviated Strata Name/<ENTER> to End: *TC*

Enter The Full Strata Name <C>: *Top Coal*

Enter Abbreviated Strata Name/<ENTER> to End: *TR*

Enter The Full Strata Name <C>: *Top Rock*

Enter Abbreviated Strata Name/<ENTER> to End: *BC*

Enter The Full Strata Name <C>: *Bottom Coal*

Enter Abbreviated Strata Name/<ENTER> to End: *BR*

Enter The Full Strata Name <C>: *Bottom Rock*

Enter Abbreviated Strata Name/<ENTER> to End: *press Enter*

Enter Individual densities or Composite densities (I/C) <I>: *C* Define the Composite categories.

Enter Composite Category/<Enter> to END: *Coal*

Average wt. of COAL [lbs/ft³]: *80*

Enter Composite Category/<Enter> to END: *Rock*

Average wt. of ROCK [lbs/ft³]: *150*

Enter Composite Category/<Enter> to END: *press Enter* Assign the strata to a Composite category.

Enter Composite Category for Top Coal TC (COAL ROCK): *coal*

Enter Composite Category for Top Rock TR (COAL ROCK): *rock*

Enter Composite Category for Bottom Coal BC (COAL ROCK): *coal*

Enter Composite Category for Bottom Rock TC (COAL ROCK): *rock*
Circle the Coal Section (y/<n>)? *press Enter*
Plot the Numeric Value Only (y/<n>)? *press Enter*
Text Size <6.0>: *press Enter*
Enter thickness in feet or inches [Feet/<Inches>]? *I for Inches*
Prompt for entry width [Yes/<No>]? *Y if Yes Linear Advance will also be reported*

The following figure shows how this section will appear in the drawing.

```

O
TC-30
TR-5
BC-25
BR-4

```

(2) Locating Sections

To locate section information measured from the mine, select Place Coal Sections from the Works dropdown. Select the desired section configuration file such as SECTION2 which you defined in the previous section.

Pick sample point for coal section: *pick a point on the map.* This is the point where the measurements came from.

Pick Start Point: *pick another point.* This is where the text will be plotted. The text may be placed anywhere you like because the program gets the section measurements from the small circle at the sample point and not from the text.

Pick Alignment Point: *pick a point to align the text*

Now enter your measurements.

How many inches of Top Coal TC: *30*

How many inches of Top Rock TR: *5*

How many inches of Bottom Coal BC: *25*

How many inches of Bottom Rock BR: *4*

Enter the entry width: *20*

Enter Another Section (Y/N) <Y>: *press Enter*

Enter the other section as shown in the next figure.

Placing a section

(3) Compute tonnages by average or modeled grid methods

There are three routines for calculating tonnages: Quantities by Average Method, Quantities by Grid Method and Quantities by Centerline. These methods require section sample points, and pillars and a perimeter defined as closed

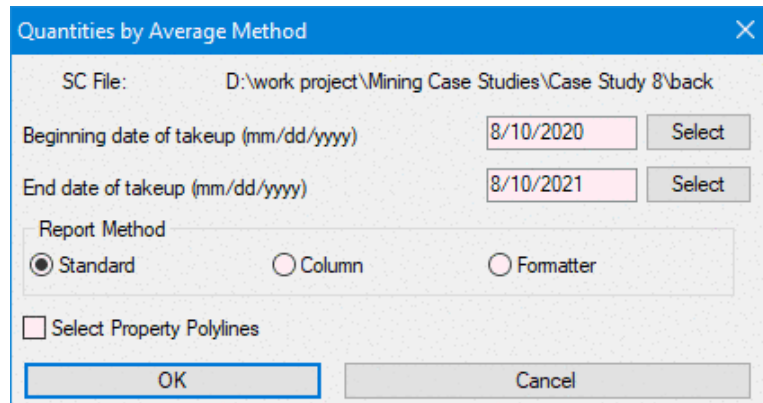

polylines in the PILLARS and PERIM layers respectively. As its name suggests, the average method uses the average values from sample section points to compute its quantities. The grid method actually models the values of the sample points over the mined area which results in more accurate tonnages. For now, let's use the average method because it is much faster and requires fewer sample points.

Select Quantities by Average Method in the Works dropdown.

Select a Mining Project Definition (MPD) File or Create a new one

Select the file that defines the section sample points

Specify the Beginning and Ending dates of take-up and Report Format in the dialog below

Quantities by Average Method

SC File: D:\work project\Mining Case Studies\Case Study 8\back

Beginning date of takeup (mm/dd/yyyy) 8/10/2020 Select

End date of takeup (mm/dd/yyyy) 8/10/2021 Select

Update coal tonnage files (<Y>/N)? Y This option updates data files for tonnage reports.

Enter a mine name: Mine

Enter a panel name: press Enter for none

Enter the estimated coal reserves for mine Mine: 300000

(4) Draw and compute volumes for pillar cuts on retreat

One of the final steps in underground mining is cutting into the pillars on the "retreat". The results of these cuts can be quickly drawn on the mine map using the Pillar Cut routine in the Works dropdown. The procedure is simply to pick a cut pattern and then place the pattern inside the pillar to be cut. That's it. Depending on the selected method, this routine will either redraw the pillar's polyline with the cuts removed, or it will create new perimeter polylines inside the pillar in the cut out spaces. The pillars must be closed polylines in the PILLARS layer. The rotation of the placed pattern will follow the current snap. If the cut pattern you need is not already in the table, you can define your own by first drawing a polyline of your pattern and then selecting the user-defined box in the Pillar Cut symbol table.

After redrawing the cut pillars with Pillar Cut, Quantities by Average Method or Quantities by Grid Method can be used to compute the quantities of the cuts. If the Cut option of Pillar Cut was used, then you will get the total

quantities from the area between the pillars plus the pillar cuts. To get the quantities of only the pillar cuts, use the Perim option of Pillar Cut. This will create perimeter polylines inside the pillars. Then use Quantities by Average Method and select all these perimeter polylines. Let's practice pillar cuts.

Locating a pillar cut pattern

Select Pillar Cut from the Works dropdown.

Choose the Cut 14 symbol or the symbol of your choice.

Perimeter layer <PERIM>: *press enter*

Enter the azimuth for the cuts <0.0>: *10.0*

Cut the pillar or create new perimeter? (<Cut>/Perim) *Perim*

Hatch the new perimeter polylines? (Y/<N>) *press Enter*

Select mine pillars Polylines in the PILLARS layer.

Select objects: *select all the pillars*

Pick a point for the symbol: *pick a point as shown in the figure above*

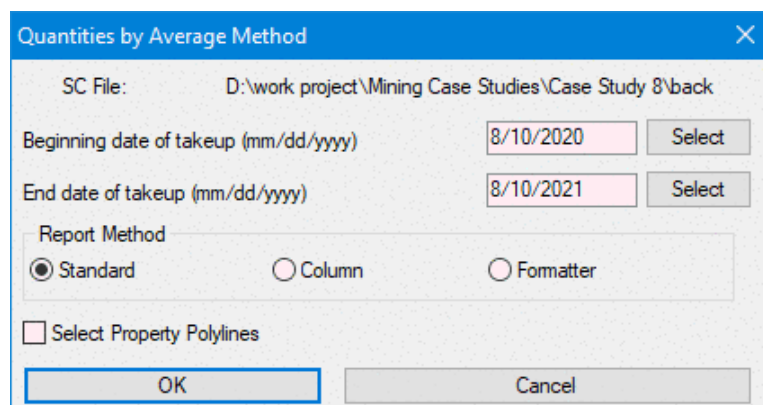

Do another cut [<Yes>/No]? *Y*

Pick a point for the symbol: *pick a point in the other pillars*

Pick a point for the symbol: *press Enter to exit*

Now let's get the quantity mined from the pillar cuts.

Select Quantities by Average Method in the Mining Works dropdown. Choose Section2 or the file that defines the section sample points.

The Cuts "Selection Type" filters out everything except perimeter polylines and sample points. This allows you to select by windowing the area of the pillar cuts. Be sure not to include the main, outside perimeter.

Command: C:QAVG

MINE=Round Moutain

Composite: COAL Density: 80.000000 lbs/ft³

Composite: ROCK Density: 150.000000 lbs/ft³

Which type of selection [<Standard>/Cuts**]? Cuts**

Select objects: *select the perimeter polylines and sample points*

Pick location to draw results or Enter for none: *pick a point above the mine*

Another Area (Y/N) **<Y>:** N

Update coal tonnage files (<Y>/N**)?** Y This option updates data files for tonnage reports.

Enter a mine name: Mine

Enter a panel name: *press Enter for none*

Enter the estimated coal reserves for mine Mine: 300000

This creates the following plot.

Pillar cut quantities

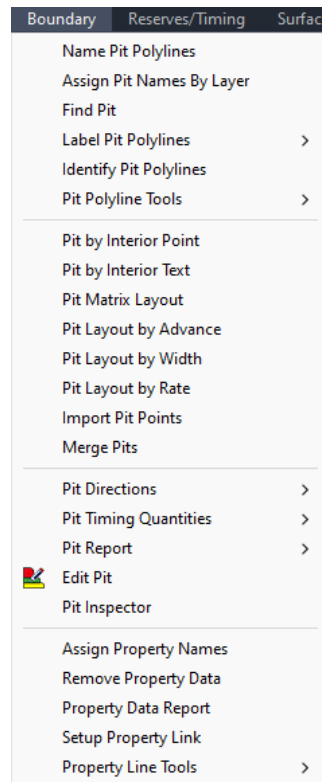

Surface Mining Module 17

The Surface Mining Module consists of various commands for planning and scheduling a surface mining operation. Major features include pit and spoil design, haulage analysis, and mine scheduling. Commands are accessible from the Boundary, Reserves/Timing, Surface, and Spoil pulldown Menus.

Boundary Menu

The Boundary menu has commands for managing pit and property polylines. The property polyline commands are described in the Underground Mining section of the manual.

Name Pit Polylines

This command attaches a pit name and site name to closed polylines that are used as inclusion or exclusion perimeter routines like Surface Mine Reserves and Surface Equipment or Production Timing.

Prompts

Label area names [**<Yes>/No**]? Choose whether or not to label.

Text height **<4.00>**: *press Enter to accept 4 drawing units (ft or m tall) or enter a new text height*

Auto place labels in center [**<Yes>/No**]? *press Enter to accept To manually pick the label position, answer No to this prompt.*

Prompt for inclusion, exclusion or both [**<Inclusion>/Exclusion/Both**]? *Bfor Both.* If you are only choosing inclusion areas, then you can answer Inclusion to this prompt to skip the exclusion polyline prompt and speed up entry. Or you can use Exclusion if you're just going to add exclusion areas to existing inclusion pit areas.

Site name **<Site 1>**: *press Enter to accept Site 1, or type a new site name*

Pit name **<Pit 1>**: *press Enter to accept Pit 1, or type a new pit name*

Select Inclusion perimeter polylines.

Select objects: *pick closed polylines for areas to include in calculations*

Select Exclusion perimeter polylines.

Select objects: *pick closed polylines for areas to exclude from calculations*

Specify another area [**<Yes>/No**]? *press Enter to accept Yes or type N for no* If you do specify another area, then the Site Name remains the same, but the Pit Name is automatically incremented by one for efficient naming.

Pulldown Menu Location: Boundary

Keyboard Command: pitname

Prerequisite: Closed polyline

Assign Pit Names By Layer

When the linework is layerized so that each polyline for pits is placed in the separate layer, this routine may be used to assign pit names by layer name. The user is prompted for site name and pit names are derived from the layer names of each polyline selected.

Prompts

Site name <Site 1>: *Enter to accept or type in a new site name*

Select polylines to set pit name by layer.

Select objects: *pick polylines*

Pulldown Menu Location: Boundary in the Advanced Mine Module

Keyboard Command: layerpit

Find Pit

This command will find a certain pit on screen. It will zoom to the pit extents and center it. The pit line is also dashed or highlighted to distinguish it from surrounding pits.

Prompts

Enter a name of the pit to find: *x-38*

Pulldown Menu Location: Boundary

Keyboard Command: findpit

Label Pit/Site Names

This command labels the pit name and site name that are attached to the selected polyline. The Horizontal and Align placement methods will draw the labels in the center of the polyline. The difference is that the horizontal option will draw the label horizontal to the current twist and the Align method will rotate the label to follow the main direction of the pit. The Pick method prompts you for a center point to pick and an alignment for the text.

Prompts

Text height <4.0>: *press Enter to accept 4.0, or type in a new text height*

Include Site Name in Label [<Yes>/No]? *press Enter for yes or type N for no*

Label placement method [<Align>/Horizontal/Pick]? *press Enter for Align, or type H for horizontal alignment, or P to pick the alignment and location*

Select pit polyline to label: *pick a polyline*

Site Name: Site 1

Pit Name: Pit 1

Pick point for label: *pick a point*

Pick alignment point: *pick a point*

Select pit polyline to label: *press Enter to end*

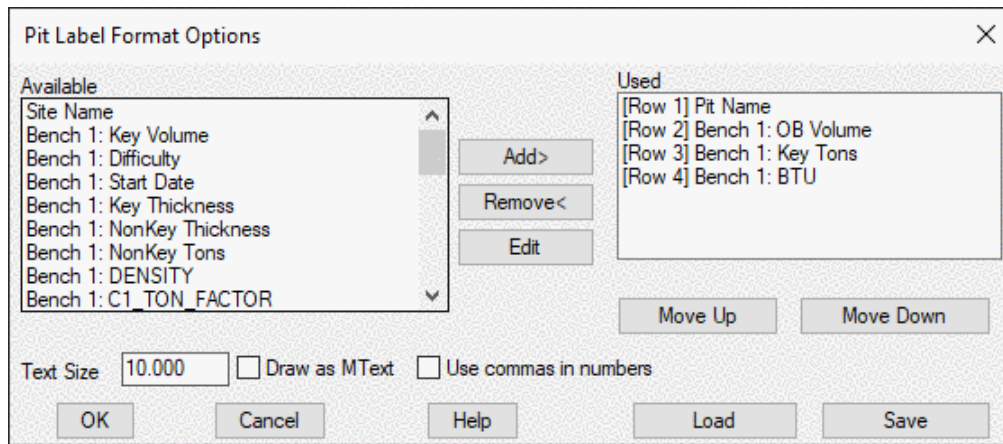

Pulldown Menu Location: Boundary in the Advanced Mine Module under Label Pit Polylines

Keyboard Command: pitlabel

Pit Label Formatter

This command places text inside each pit, labeling values such as name, quantities, and quality. Anything that is stored in the selected pits will be shown under the Available column. The formatter screen allows for placement of text in the pits by row, selecting a justification, text size, layer, and color. The text can either be drawn horizontally,

aligned to a specific angle, or aligned with the long axis of the pit. There must be values stored in the pits and the pits must have direction assigned in order to use this command.

Only items in the Used column will be labeled. Items may be moved to the Used column by double clicking the item or by selecting an item and clicking **Add**.

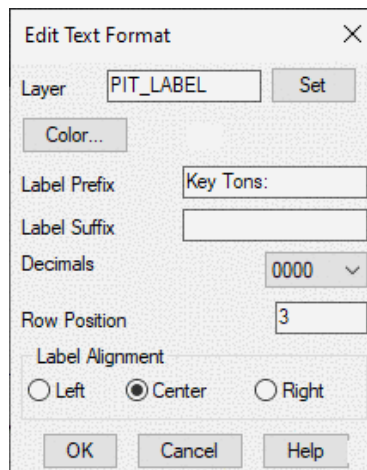

Items may be moved up or down in the Used column with the **Move Up/Down** buttons, but this does not set the row position for the label. If two items are on the same row, the item higher in the list will be labeled first.

Text Size: The size of the label.

Draw as MText: This option will use MText entities for the labels rather than standard Text entities.

Use commas in numbers: This option will insert commas into the numbers.

When an item is added, the below dialog will appear to specify the settings for that item (this is the same as clicking the **Edit** button).

Layer: The layer used for the specific label.

Color: The color of the label.

Label Prefix/Suffix: A text prefix/suffix for the label/

Decimals: The number of decimals to use in the label. Note that this will truncate the labels rather than round the value.

Row Position: The row on which the label will be placed.

Label Alignment: Sets the alignment point for the text.

An example set of labeled pits is shown below.

Prompts

Select pit polylines to label.

Select objects: Specify opposite corner: 192 found

Select objects:

Label placement method [**<Align>/Horizontal**]? *H*

Pulldown Menu Location: Boundary in the Advanced Mine Module under Label Pit Polylines

Keyboard Command: pitlabel2

Prerequisite: There must be quantities assigned to the pits either from Surface Mine Reserves or Import Timing Data. The pits must have direction assigned to be recognized.

Hatch Pits

This command hatches the selected pit areas. A reason to hatch the pits is to visually check that the whole site is covered by pit polylines. In the options dialog, there are settings for the hatch pattern, color, hatch scale and layer name for the hatches to draw.

Prompts

Select pit polylines to hatch.

Select objects: *pick pit polylines*

Hatch Settings dialog

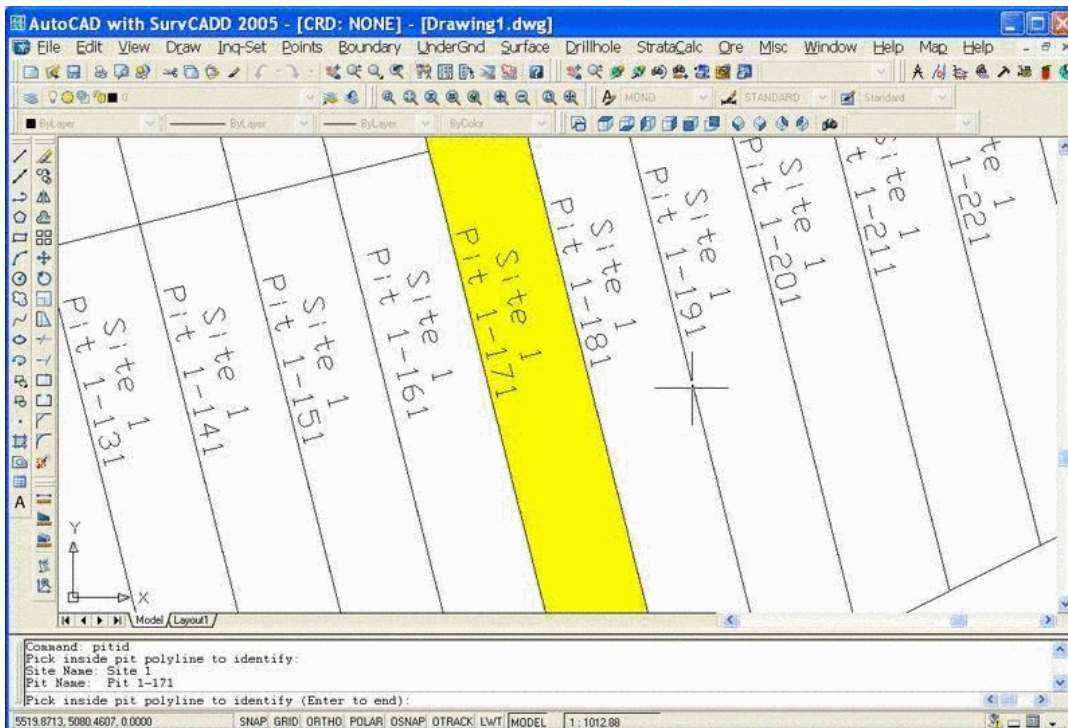

Pulldown Menu Location: Boundary

Keyboard Command: pithatch

Prerequisite: Pit polylines

Identify Pit Polylines

This command reports the pit name and site name that are attached to the selected polyline at the command line and shows the pit graphically with a yellow solid fill.

Prompts

Pick inside pit polyline to identify (Enter to end): *pick inside a polyline* If you pick on or near a common line, one pit is highlighted and you are prompted to Press N for next selection or Enter to accept current, highlighted pit line. The selected pit line is filled with a solid yellow hatch that erases when the next pit is selected, or the command is finished.

Site Name: Site 1

Pit Name: Pit 1

Select pit polyline to identify: *press Enter to end*

Pulldown Menu Location: Boundary in the Advanced Mine Module

Keyboard Command: pitid

Remove Pit Names

This command removes the extended entity data of pit/site names from the selected polylines. For example if you are done calculating for an area, you can use this command to clear the pit names from the polylines in the old area so that these polylines are not picked up as pits anymore by routines such as Surface Mine Reserves and the Timing Routines.

Prompts

Select polylines to remove pit names from.

Select objects: *pick the polylines*

Removed pit names from 11 polylines.

Pulldown Menu Location: Boundary

Keyboard Command: clearpitnm

Check Pit Polyline Overlaps

This command checks whether pit polylines overlap each other. Pits should never overlap since this would lead to extra volumes with the quantities in the overlap area getting reported twice. The program reports any overlaps at the command line.

Prompts

Select pit polylines to check.

Select objects: *pick the polylines*

Pits P-100 and P-101 overlap at 1501884.209,506497.414

Pits P-101 and P-100 overlap at 1504444.952,509533.437

Found 2 overlaps between 56 pits

Pulldown Menu Location: Boundary > Pit Polyline Tools

Keyboard Command: pitcheck

Prerequisite: pit polylines

Pit by Interior Point

This routine is used to create pit polylines from the existing linework by making closed polylines around points picked. The site and pit names are user-specified and the pit name is incremented after each new pit created. This command uses the Boundary Polyline logic, using any linework (open or closed) and searches out from the picked point for the closed perimeter. It draws a new polyline in the selected layer.

Prompts

Label area names (<Yes>/No)? Choose whether or not to label.

Text height <4.00>: *Enter to accept or type new text height*

Auto place labels in center (<Yes>/No)?

Site name <Site 1>:

Pit name <Pit 1>:

Layer name <0>: Enter to accept or type in new layer name.

Pick point inside pit perimeter: *pick inside a loop or linework representing the pit to use as a pit*

Specify another area (<Yes>/No)? If yes is selected, then the Pit Name is automatically incremented by one for efficient entry.

Pull-down Menu Location: Boundary in the Advanced Mine Module

Keyboard Command: pickpit

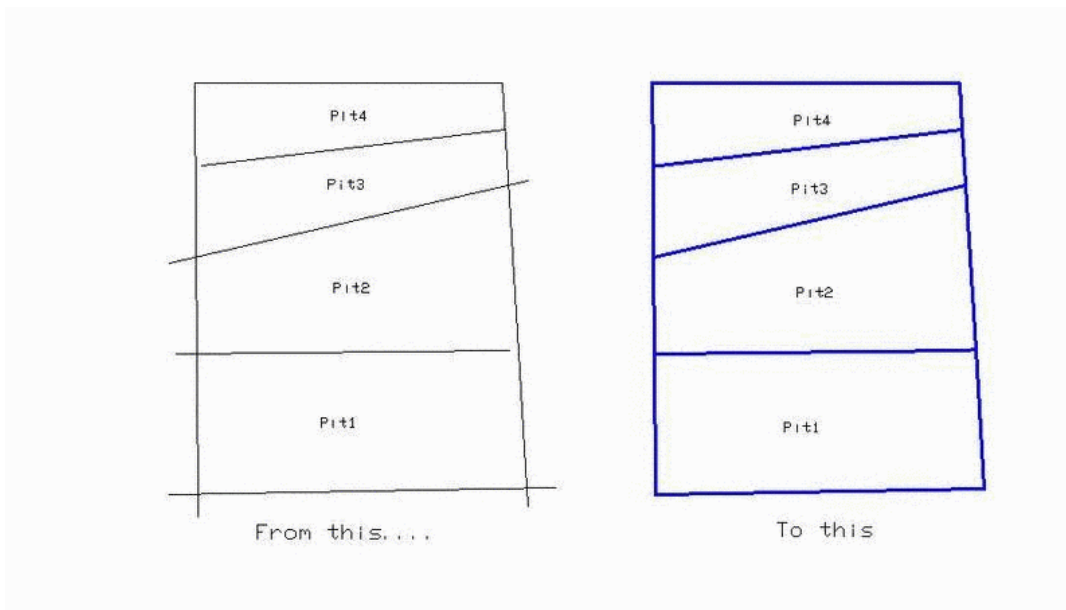

Pit By Interior Text

This command converts lines and polylines that enclose text into Carlson pits, with the text becoming the pit name. It is best used in conjunction with "Sequential Numbers", a command under the "Draw" pull-down menu that allows the user to place text in increasing order. If pits are to be numbered from U10 through U50, Sequential Numbers places this text with a single pick. The text inside the pits does not need to be in the same layer as the polylines/lines making up the pits. Since the text is selected by the user, care should be taken not to select extraneous text such as contour elevations.

The user should also avoid selecting contours and other polylines not associated with the pits. It should also be noted that this command makes entirely new polylines in a new layer from the source lines and polylines. If "Boundary Polylines" was used to make closed polylines, and Sequential Numbers is used to place text, then "Pit By Interior Text" will make a new set of polylines in a new layer (this time as "official" pit polylines), resulting in two sets of identical closed polylines. You should use "Delete Layer" or other Carlson tools such as "Freeze Layer" to delete or hide the duplicated polylines. The command will handle arcs. But note that "Pit By Interior Text" will make polylines out of any combination of polylines and lines enclosing text, even where the lines are shared by two adjacent pits and no duplicated lines exist.

"Sequential Numbers" and "Pit By Interior Text" work together to make pits. The location of the text containing the pit name can be used to assign the direction of mining. Therefore, the very location picked within "Sequential Numbers" can set the direction of mining across the pit. If "Assign Directions" is selected within the "Surface Mining" options, the sub-option "Text" will utilize the text insertion position and start the mining through the pit from the side closest to the insertion point. Note that "Sequential Numbers" will middle-justify the text used for the pit name. To emphasize the linkage with "Sequential Numbers", the prompting sequence shown below includes the prompting for "Sequential Numbers".

Using "Pit Plines from Mineplan" you don't need to use "Boundary Polylines" in advance to create the closed pit polylines. "Pit By Interior Text" makes the new polylines and associates the pits all in one step. This command is a great time saver to convert old mine plans with just linework (sometimes sloppy) and the pit name inside to Carlson pits used in reserves and timing.

Prompts

[Sequential Numbers]

Text Height <8.0>: 50

Pick point at center of label: *pick insertion point for centered text*

Pick point for label alignment: *pick text alignment point*

Number <1>: U10 (or 50 in the second example)

Auto increment labels (Yes/<No>)? Y

Pick point at center of label: *pick next point and U11 (or 51) prints*

Pick point at center of label: *pick next point and U12 (or 52) print, etc.*

[Pit Plines from Mineplan]

Site Name for Pits: Site 1

Layer Name for Pits: PITS

Select pit lines, polylines and text.

Enter snap tolerance <0.0>: This is the size of the gap that the routine can handle to "jump" across and create a closed boundary.

Select objects: *select the text and linework* New pit lines should appear in the selected layer.

Pulldown Menu Location: Boundary

Keyboard Command: minepitlines

Related Commands: Sequential Numbers, Boundary Polylines, Assign Directions

Pit Matrix Layout

The Pit Matrix Layout function will divide a polyline (preferably closed, but not necessary) into surface pits of any arrangement you specify utilizing temporary alignment polylines. The site and pit names are also defined in this routine. This allows for a great deal of imaginative pit configurations and layouts around difficult geometric and individual situations. The routine will insert the specified number of rows and columns of pits in a matrix form directly inside the baselines, and if used, crosslines. The mine boundary will then serve as an inclusion perimeter and create pits in the matrix form only inside of it.

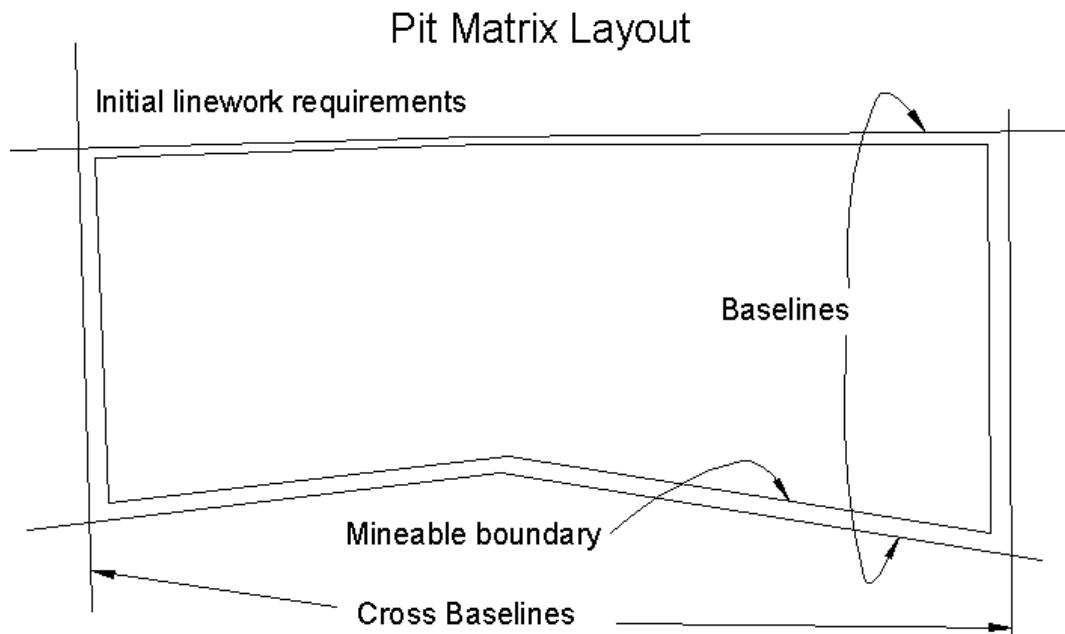

Prompts

Select mine boundaries:

Select TWO baselines: *select objects* The best pit configurations result from baselines with equal number of vertices.

Select TWO crosslines or hit Enter for none: *select objects* Similarly with the baselines, the crosslines should have the same number of vertices.

Note: Baselines are required. Crosslines are not. If just long strips of pits are desired, then just use baselines with no crosslines and enter in 1 for number of pits in the Cutting Across Baselines tab. It is also important to note that the order the base and cross lines are selected will determine where the pit naming will begin. The first baseline selected will be where Pit 1 will start, for example. The same applies to cross lines, for sub pit or block labeling. If there are no crosslines used, then the direction the baselines were drawn will affect the naming of the blocks or sub-pits.

Baselines and crosslines can and probably should be drawn directly on top of the boundary to get exact pit sizing starting at the boundary. They are shown off the boundary line here for clarification of what they should look like. The matrix will begin at the base and cross lines, wherever they are drawn.

With the initial linework completed and knowledge of the general dimensions of the layout, the user can use the

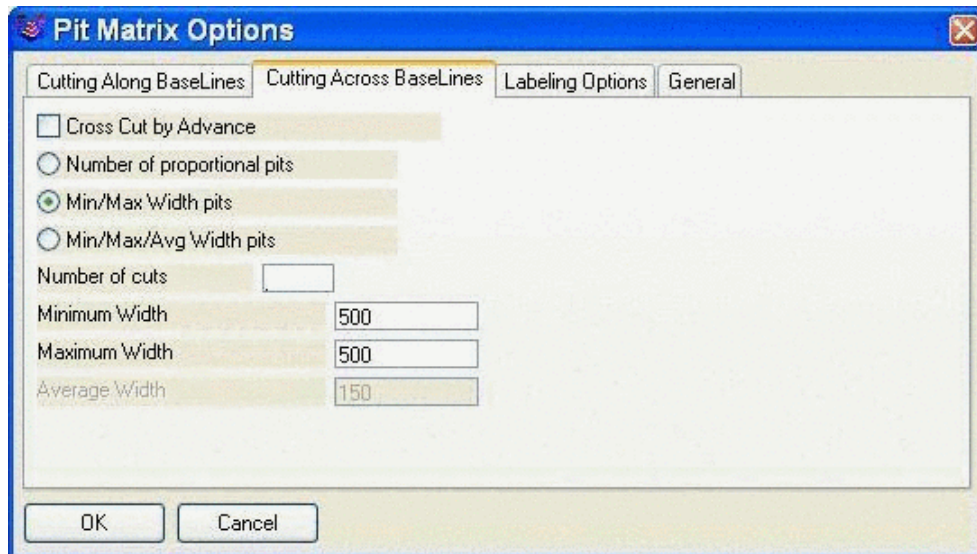

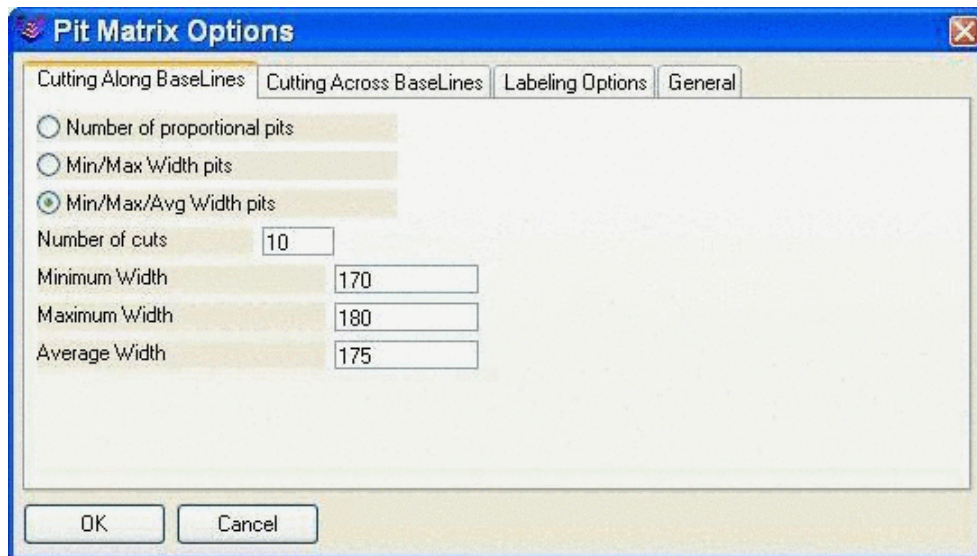

following options.

Number of proportional pits: This will measure the distance between the baselines and divide the pits proportionally, evenly distributing the size of the pits as they are cut along the baselines using the Number of cuts entry. If the Min/Max options are used, Number of cuts will still be applied. For example, if only 10 pits are desired in a certain layout direction, the routine will stop at 10 pits, then a different plan may be applied from there.

Min/Max Width pits: Enter in the minimum and maximum pit widths that will be allowed and the routine will stay within that range to fan pits around corners etc. If the min and max are the same, then all pits will be that width.

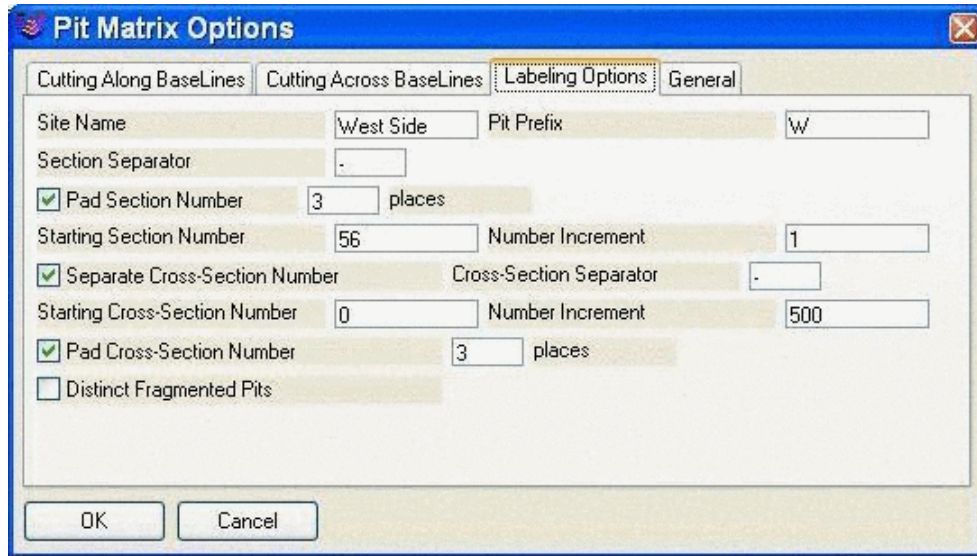

Min/Max/Avg Width Pits: This is very similar to Min/Max Width, except the average value will be the width that it will use unless it has to fan around a corner. Again, if the minimum and maximum and average are the same, say 175, then all pits will be 175 wide.

The Cross Cut by Advance option in the Cutting Across Baselines Tab should be checked if a certain pit or block size is desired, with little flexibility. Everything is grayed out if this is selected and the block sizing will begin at the cross lines.

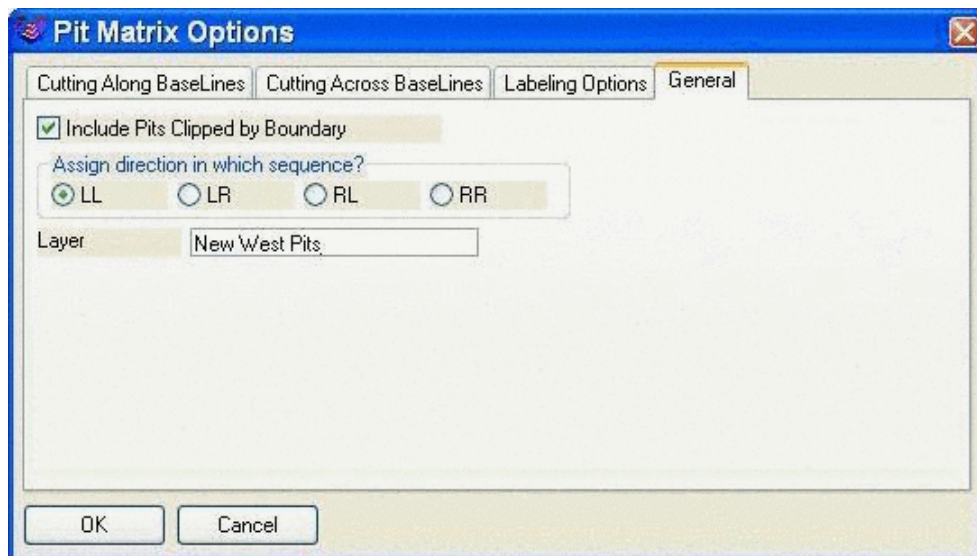

Labeling Options: Consider the pit and block scenario. A pit is defined by the base lines and broken into blocks by the cross lines. For labeling, enter a Site Name and Pit Prefix. Both base lines and cross lines can have a section separator (here a dash -). The total number of places can be set with Pad Section and Cross-Section Number so that a resulting pit number such as 056 (for 3 places) can be obtained. The starting pit (section) and block (cross-section) numbers are set in their own windows. The increment is set for both pit and block, here the pit is set to 1 and the

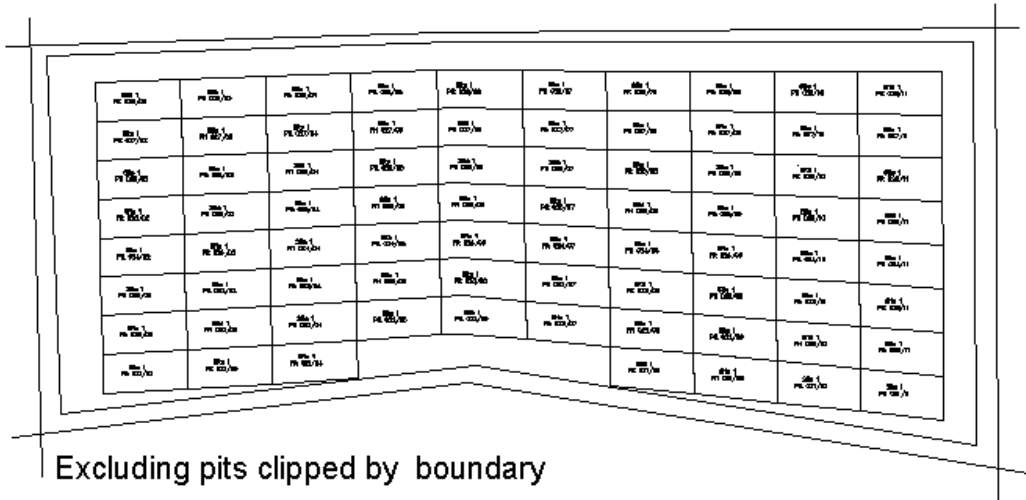

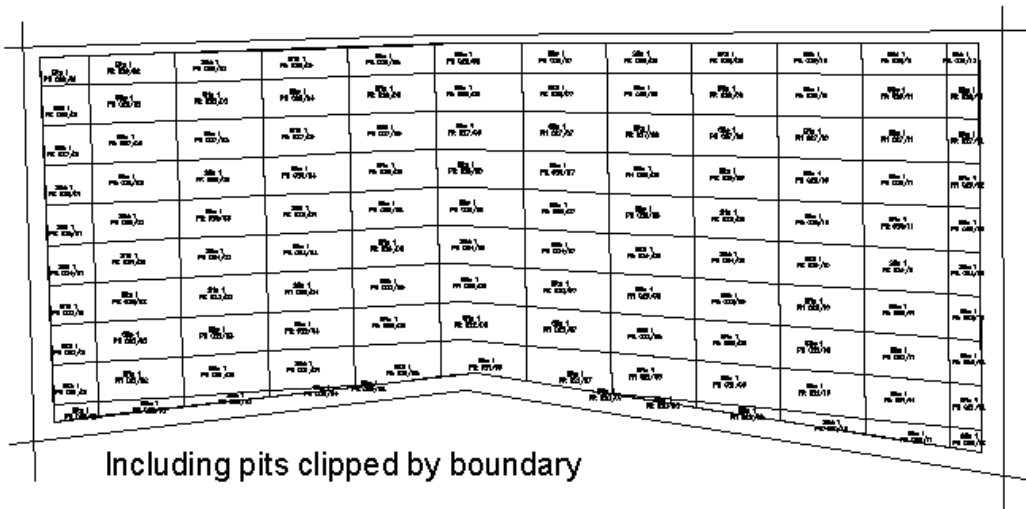

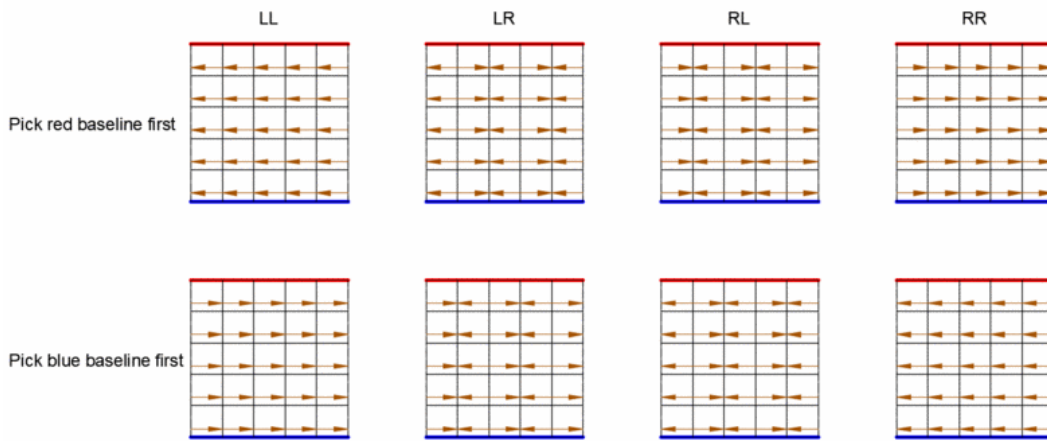

block is set to 500. The first few pits in this example will be named: W-056-000, W-056-500, W-057-000 and so on. Distinct Fragmented pits will give a unique name to a pit that is broken due to a gap in the boundary. For example, if the long dragline pit is broken by a washout of coal, and this option is checked, then the pit will have two names: Pit 56a and Pit 56b. It automatically uses a, b, c, etc. If it isn't selected, then both will be named Pit 56.

General: The option to include clipped pits (any pit that touches the boundary) is found under the General tab. An example of both options is shown below. The layer of the new pits is set in the Layer box. The pits are assigned direction for timing with the "Assign direction in which sequence?" option. If you imagine looking down the boundary, from the first selected base line to the second, LL will be mining from the left in each pit, to the right. LR will be from the left in the first pit, then back from the right in the second pit etc. RL and RR are just the opposite.

The below image shows an example of the various types of pit directions that may be assigned.

Labeling options allow special separators.

When geometric layouts for the pits become more complicated, Pit Layout by Matrix will allow the user to design the pits to most any situation presented. It is extremely useful for "fanning" of the pit where corners or varied widths are encountered. This example above shows how a matrix of [10 X 50] can be fit inside a varied boundary such as this angular mine boundary.

Prompts

Select mine boundaries: *select the boundary*

Prerequisite: The routine requires a polyline boundary for the pits to be designed inside of (better if closed), two baselines, one on each side of the boundary, and optionally, two crosslines to further define the extent of the "sides"

of the pits.

Pit Layout by Advance

This command creates pits of the desired advance width by intersecting a closed pit polyline and a direction line indicating the direction the pits will be developed. In the first 2 examples below the outcrop has been created as the outer limit of the pit. The first example shows the impact of laying out a straight direction polyline. The direction polyline must enter the pit boundary from outside and exit the boundary to be valid. The program advances along the direction polyline the distance entered for the Cut Advance and intersects for each pit 90 degrees from the direction line. There are two options on where to start the advance. The first is at the end of the direction line and the second is where the direction line intersects the pit boundary. Most of the time the second option is used. The main use for starting the advance at the beginning of the direction line is if all direction lines start at a known "station", then all pit blocks will be uniform, named by station and in line with each other.

Example 1 uses a straight directional polyline and was done in 3 sections. Each pit is drawn 90 degrees from it at the desired Cut Advance.

Example 1

Example 2 uses a bent directional polyline to follow the contour of the outcrop. Here it uses a bent polyline to conform to the contour of the outcrop. The direction polyline cannot contain any arcs, however an arc can be initially drawn for the layout and converted to polyline segments using the command *Remove Polyline Arcs* on the Edit menu. Again, each pit is created by intersecting the direction line at a 90 degree angle. Going around corners will often look better with a smooth line, hugging the inside corner.

Example 2

This third example will go through two iterations of Pit Layout by Advance to first create long strips of pits 175 wide, then break them into blocks that are 500 long, named with the appropriate stationing in the pit name. This is a unique application that is not apparent by just running the command, so a simple case study will follow. Step 1 is to create a mine boundary and draw a direction line through it. Step 2 is the first iteration of Pit Layout by Advance. This example used 175 for the pit width and created long strips of pits with a unique name, such as A-8 and A-9. Step 3 will prepare to break them up into blocks. First, create direction lines through each pit strip. The fastest way to do this is to draw the first direction line through the first strip. Then the ARRAY command will copy that multiple times, placing a direction line down the middle of each pit strip. Running the Pit Layout by Advance will first prompt to select the pit boundaries. Select all of the boundaries at once with a window, fence or by picking. Then it

prompts to select the direction lines, select them all at once. In this type of example, the option to start advance at the beginning of the direction lines is chosen. This gives blocks that are named by station along the direction lines. Notice on the south end where the pit strips are not horizontal. Not using the option to calculate from the starting of the advance line will give pit blocks that are offset and not named by station along the direction centerlines. The pit blocks are created and can be labeled with Label Pit Polylines. Notice the pit names and the stationing of the pit blocks incrementing by 500, which is the length of each block.

Pit Layout by Width

This command creates closed polylines that represent pit inclusion areas for Surface Reserves and Timing. The pit polylines are created by advancing a baseline polyline by a fixed pit width. The sides and end of the pit polylines are defined by the minable boundary polyline. This polyline should be open at the end of the baseline polyline. Be sure to create the baseline polyline longer than the minable boundary so that the program can always find the intersection of the advancing baseline with the minable boundary. There is an option to automatically assign pit and site names to the polylines. The name of the first pit is set in the dialog shown below. The next pits will be named by incrementing the pit name by one. There is an option to prompt for each pit width or use the same width for all the pits.

Prompts

Pit Sizing dialog Set the pit width, layer and names

Select baseline polyline: *pick the polyline*

Select minable boundary polyline: *pick the polyline*

Pulldown Menu Location: Boundary

Keyboard Command: pitsz2

Prerequisite: One open polyline boundary and one baseline polyline extending across the boundaries open end.

Pit Layout by Rate

This command creates closed polylines that represent pit inclusion areas for Surface Mine Reserves or the Surface Timing routines. The pit polylines are created by advancing a baseline polyline along a minable boundary. The sides and end of the pit polylines are defined by the minable boundary polyline. This polyline should be open at the end of the baseline polyline. Be sure to create the baseline polyline longer than the minable boundary so that the program can find the intersection of the advancing baseline with the minable boundary. The next pits will be named by incrementing the pit name by one. The baseline polyline is advanced a distance such that the pit volume equals the target volume.

The surface model is either represented by contours on screen or a grid file. If neither is available, there is an option to Use drillhole surface elevations in surface model. The Ignore zero elevations will ignore anything on screen with no elevation. When modeling from the drillholes, there are 5 modeling methods available, which are defined elsewhere in detail. If a roof and floor grid exist of the strata to target, then use the Grid File option and these two grids will be prompted for. If Triangulation is the selected modeling method, then the options to Use Triangulation Subdivision (defined in Triangulate and Contour) and Use Global Trend Extrapolation (explained in Make Strata Grids) are active. There is the box to create a new layer name for the new pits. If coming from drillholes, there is the option to choose which strata to include. If Selected is checked, then the following Choose Strata box appears. Holding the CTRL or Shift buttons down allow for multiple strata selection. The grid cell size and resolution are set in the Make 3D Grid window, also only if coming from drillholes.

Pit Layout Parameters

The cubic yards or meters / hour is set here with the shift hours per day and number of days worked per period. This will calculate the Target Pit Size. In this example, 480,000 CY of OB_TOP strata is the targeted pit size. Turning on the Name Pits box activates the Site and First Pit Name windows. The subsequent pit names will be incremented by one from the starting pit name.

Import Pit Points

This creates pit polylines using pit names and geometry data stored in a text file. The fields in the text file must contain pit name, site name, easting and northing. Here's a sample text file for two pit polylines:

```
PIT 1,SITE 1,243431.6415685746,1646709.1759626027
PIT 1,SITE 1,243480.4441474760,1646852.2833508430
PIT 1,SITE 1,243914.2811566577,1646640.1845039858
PIT 1,SITE 1,243723.9315959779,1646566.2781082289
PIT 2,SITE 1,243480.4441474765,1646852.2833508428
PIT 2,SITE 1,243529.2467263769,1646995.3907390833
PIT 2,SITE 1,243972.3966978462,1646778.7388722666
PIT 2,SITE 1,243948.5580873627,1646653.4930947539
PIT 2,SITE 1,243914.2811566577,1646640.1845039858
```

After selecting the file to import and the layer for the pit polylines, there is a dialog to set the order of the fields and the delimiter between fields. To import the example, fill out the Names in the top row of the spreadsheet as shown.

Prompts

Import Pit Points dialog

Input Data File Select text file to import

Imported 9 pits.

Pulldown Menu Location: Boundary

Keyboard Command: importpit2

Prerequisite: Text file with pit data

Merge Pits

This routine takes two adjacent pits or blocks and merges them to create just one. Routines such as Pit Matrix Layout can sometimes leave small irregular shaped pits along complex boundaries. Usually, the user would like to combine or add a small sliver of a pit with an adjacent one so that the volume is reported, but not as its own tiny pit. The volumes are combined if they are stored in the pits as values. This command will also remove precedence rules that would be invalid following the merge. For example, if Pit 2 has a precedence rule that does not allow it to be mined until after Pit 1 has been mined, but Bench 1 is removed by this command, the precedence rule in Pit 2 will also be removed.

There are two methods for selecting the pits to merge. The Pick method prompts to pick points inside the pits to merge. The Size method prompts for a minimum area size and then a selection of pit polylines to process. Then any pits less than the minimum area are merged with a neighboring pit. For the pick method, pick first in the pit you want to keep, then in the pit you want to remove. A new polyline is drawn around both, representing the new pit with the same name as the first pit you picked inside of. The last step is to simply erase the text of the smaller, deleted pit (if they were labeled). If a pit is selected on or near a line, then the pit is highlighted and you are prompted to hit Enter to accept the pit or press N to highlight the other nearby pit.

Prompts

Select pits by individual pick or size filter [**<Pick>/Size**]? *press Enter*

Pick inside 1st pit polyline to merge: *pick a point*

Pick inside 2nd pit polyline to merge: *pick a point*

Created a shrink-wrap polyline successfully.

If the pick is near a pit line, then the following prompts appear:

Pick inside 1st pit polyline to merge (Enter to end):

Press N for next selection or Enter to accept current:

Pick inside 2nd pit polyline to merge:

Press N for next selection or Enter to accept current:

Created a shrink-wrap polyline successfully.

Done.

Pulldown Menu Location: Boundary

Keyboard Command: mergepit

Prerequisite: Two adjacent Carlson named pits that you want to combine into one pit.

Assign Directions

In order to schedule equipment through pits, pits (which are closed polylines) must have three distinct types of Extended Entity Data (EED, extra information) associated with them. They must have (1) a pit name, (2) NonKey Volume, Key Volume and Key Tons and optionally quality information and (3) direction of mining. The Assign Directions command places the direction of mining into the pit itself, where it is permanently stored along with other aspects of the drawing. Directions can vary by bench. The command prompts to assign the same direction to the Whole pit, or by bench. If doing by bench, the routine must be run separately for each bench.

Assign Directions is found within Boundary in the Carlson Surface Mining. There are six methods employed to assign direction: Automatic, Text, Sequence, Linework, Bearing, Azimuth and Gon. The "automatic" method will

mine "longways" across the pit, following the longest axis detected, but may not choose the preferred direction along that axis. The text method finds the side closest to the insertion point of the pit name and will mine from that side perpendicular across the pit away from the text. The sequence method will mine left to right and/or right to left across a series of pits as specified by the user, the linework method will follow a "direction polyline, line or leader" across a pit or series of pits and the Bearing or Azimuth method will mine at defined bearing or azimuth angle. Below is the prompting and results obtained with each method:

Prompts

Assign direction using which method [/Text/Sequence/Linework/Bearing/AZimuth/Gon]: *A or press Enter*

Select pit polylines to have direction assigned to:

Select objects: *Pick the pits and the direction is assigned as shown below*

In this example, the left most pits were given a direction opposite from the remaining pits. For long-term studies or quick estimates using smaller pits, the direction can be considered a moot point, since you will get where you're going to be whether you mined left to right or right to left through an individual pit. But for larger pits or short-term studies, direction is critical. A pit direction can be easily reversed using the *Reverse Directions* command.

Next we will look at the Text option.

Assign direction using which method [/Text/Sequence/Linework/Bearing/AZimuth/Gon]: *T*

Select pit polylines to have direction assigned to:

Select objects: *pick the pits and the required pit text as shown below*

The highlighted pit has the direction information assigned already.

Would you like to overwrite this (<No>, Yes, None, All): *A for All.* This prompt only occurs when pits are chosen that already have pit direction. Note that the command "Clear Directions" could be used to remove directions prior to using Assign Directions.

The arrows show the resulting directions. Note that this routine looks for the pit name for the direction, not for the "site" name. (All pits have a two-tiered naming convention: site and pit, which can be re-worked as pit and block or any other two-level form, to adapt to company practices.) In Pit 5, for example, the "Site 1" text is ignored and the "Pit 5" text is used for direction. In Pit 7, the Site 1 text is completely outside the pit, but is irrelevant since only the Pit 7 text is used for direction. If pits were named Pit 1, Block U15A, then the insertion position of "Block U15A" would be used for setting directions.

Next we will look at the Sequence option.

Assign direction using which method [`<Auto>/Text/Sequence/Linework/Bearing/AZimuth/Gon`]: *S*

Select pit polylines to have direction as signed to:

Select objects: *select the pits* (Don't worry if you also select other polylines. It only finds pits.)

Select a direction polyline.

Select objects: *select a polyline that crosses all of the pits* This would be the short south to north polyline in our example.

Assign direction in which sequence (`<LL>`, `LR`, `RL`, `RR`): *LR*

In our example, we selected LR, which causes the pits to be mined left to right on the first pit (with respect to the south-to-north direction polyline—imagine yourself standing at the beginning of the polyline looking down it. LL would mine all pits coming from your left. LR would mine from the Left first, then the Right in the next one and so forth. RR and RL are just the opposite.), then right to left on the second pit, then left to right on the third, etc. An entry of LL would cause the pits to be mined from the left side to the right side. An entry of RR, for example, would mine all the pits from right to left. The entry of RL would mine first right to left, then left to right. The sequence method is ideal for assigning direction to a series of long and narrow pits that have not been broken up into small blocks.

If these same pits were each subdivided into 10 or more blocks, or there are many pits that would not be intersected by the sequence polyline, for example, then the following method, direction by polyline, is most appropriate.

Next we will look at the Polyline option.

Assign direction using which method [`<Auto>/Text/Sequence/Polyline/Bearing/AZimuth`]: *P*

Select pit polylines to have direction assigned to:

Select objects: *select the pits* (Don't worry if you also select other polylines. It only finds pits.)

Select all direction polylines.

Select objects: *In the example above, select the single direction polyline.*

The polyline-based selection is ideal for contour mines or outer pits in a mountaintop removal situation in Appalachia, or for pits that follow sinuous property lines. Most Midwest and western pit mining is linear, but the polyline technique for setting direction is still applicable. Direction polylines cannot have arcs, so if you've used an arc to draw the polyline, use the command *Remove Polyline Arcs* on the Edit menu to remove them.

Last we will look at the Bearing and Azimuth option

Bearing Option:

Assign direction to whole pit or to a specific bench [`<Whole>/Bench`]: *W* or Enter to assign direction to whole pit

Assign direction using which method [`<Auto>/Text/Sequence/Linework/Bearing/AZimuth/Gon`]: *B* for Bearing

Select pit polylines to have direction assigned to:

Select objects: *select the pits* (Don't worry if you also select other polylines. It only finds pits.)

Enter Bearing (Qdd.mmss): 145.0000

The highlighted pit has the direction information assigned already.

Would you like to overwrite this [`<No>/Yes/None/All`]: *A*

The Bearing is entered in the format (Qdd.mmss), the following figure shows the quarter numbers and the angle is calculated clockwise.

Azimuth Option:

Assign direction to whole pit or to a specific bench [\langle Whole \rangle /Bench]: W or Enter to assign direction to whole pit

Assign direction using which method [\langle Auto \rangle /Text/Sequence/Linework/Bearing/AZimuth/Gon]: B for Bearing

Select pit polylines to have direction assigned to:

Select objects: *select the pits* (Don't worry if you also select other polylines. It only finds pits.)

Enter Azimuth (ddd.mmss): 135.0000

The highlighted pit has the direction information assigned already.

Would you like to overwrite this [\langle No \rangle /Yes/None/All]: A

The Azimuth angle is calculated from the true north.

Pulldown Menu Location: Boundary

Keyboard Command: assign_dir

Related Commands: Display Directions, Reverse Directions, Clear Directions, Create Pit Plines from Mineplan

Display Directions

If directions have been assigned to pits, this command will display the directions. It therefore serves two purposes: (1) to verify that directions have, in fact, been assigned previously, and (2) to review the direction of mining. When pit directions are detected, arrows are displayed as shown below. These direction arrows will disappear with any "Zoom" command such as Pan or Window, and will also disappear if a Redraw or Regen is executed. The direction leaders can be used to draw direction arrow entities in the drawing. The sample drawing is a good demonstration of the use of Assign Direction by Text.

Prompts

Display direction to whole pit or to a specific bench [<Whole>/Bench]: W

Draw directions as leaders or temporary arrows [Leaders/<Arrows>]? L for Leaders or A for Arrows

Select pit polylines to have direction displayed:

Select objects: *Pick the pits to review*

Pull-down Menu Location: Boundary

Keyboard Command: display_dir

Related Commands: Assign Directions, Reverse Directions, Clear Directions, Create Pit Plines from Mineplan

Reverse Directions

This command reverses the direction of mining within a pit. It is particularly useful in conjunction with the command Assign Directions, <Auto>, since the automatic mode may assign direction to many of the pits opposite from the desired direction. The result is shown below, where the two pit 10s were reversed.

Prompts

Reverse direction to whole pit or to a specific bench [<Whole>/Bench]:

Select pit polylines to have direction reversed:

Select objects:

Pull-down Menu Location: Boundary

Keyboard Command: reverse_dir

Related Commands: Assign Directions, Display Directions, Clear Directions, Create Pit Plines from Mineplan

Clear Directions

This command removes the directions from pits. The Extended Entity Data (EED) designating pit direction is removed from the pit polyline entity. This command has no effect if direction has not been previously assigned to a pit. Keep in mind that it is not necessary to first remove "old" directions before assigning "new" directions. The Assign Direction command will recognize that directions exist and will prompt the user to overwrite the direction for individual pits or for all pits.

Prompts

Clear direction to whole pit or to a specific bench [<Whole>/Bench]:

Select pit polylines to have direction removed:

Select objects: *pick the pit polylines* This can be done individually or with a window.

Pulldown Menu Location: Boundary

Keyboard Command: clear_dir

Related Commands: Assign Directions, Display Directions, Create Pit Plines from Mineplan

Assign Pit Precedence

This command will automatically reassign the precedence for multi-bench pits. If the pits have been edited or cleared of precedence, this command will restore them to the default setting. Bench 2 will always require that Bench 1 gets mined first. Bench 3 will always require that Bench 2 gets mine first and so forth. This is the default setting that should be there, unless the pits have been edited. This will ensure the benches will not under-mine themselves. This command also detects pit overlap and automatically sets precedence accordingly, if the overlap area is greater than the tolerance area.

Prompts

Enter Overlap Area Tolerance (ft²) <0.0>: *Specify the allowed tolerance area*

Select pit polylines to process.

Select objects: Specify opposite corner: 3 found

Select objects:

Done.

Pulldown Menu Location: Boundary > Pit Timing Quantities

Keyboard Command: pitprec

Related Command: Edit Pit

Pit Precedence by Polylines

This command allows you to quickly assign precedence to timing blocks by drafting directional polylines to indicate the direction of precedence. Before the command is executed, a polyline must be drawn on the PRECEDENCE layer, and must be over the pits to be modified. It is important to note that a vertex must exist inside each pit boundary to be affected (a polyline with only 2 vertices will only modify 2 pits).

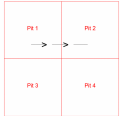

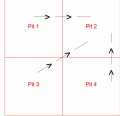

When the command is executed, you will be prompted to select the pits to be modified and the Precedence polylines. You will then be prompted to select the benches to be affected. A brief description of each method is given below.

- **Single** - This option will affect a single bench. The pit at the start of the precedence polyline will not have a precedence rule assigned to it.
The second pit along the polyline will be modified so that it cannot be mined until the first pit is mined.
The third pit will be modified so that it cannot be mined until the second pit is mined.
This process repeats down the length of the polyline
- **All** - This option will affect all benches, but each bench is analyzed separately. This produces the same result as using the Single option on each bench separately.
- **Upward Staircase** - This option will affect multiple benches in a staircase method, with higher benches being mined after lower benches.
In this case, the highest bench in the first pit will not have a precedence rule assigned to it.
The second pit will be modified so that the highest bench cannot be mined until the lower bench of the first pit is mined.
The third pit will be modified so that the highest bench of the third pit cannot be mined until the lower bench of the second pit is mined.

- Downward Staircase - This option is the inverse of the Upward Staircase method, with lower benches being mined after higher benches.
 In this case, the lowest bench in the first pit will not have a precedence rule assigned to it.
 The second pit will be modified so that the lowest bench cannot be mined until the higher bench of the first pit is mined.
 The third pit will be modified so that the lowest bench of the third pit cannot be mined until the higher bench of the second pit is mined.

A simple example using three of the four assignment methods is provided in the below table. Here the black polylines with arrows represent the Precedence polylines.

Pulldown Menu Location: Boundary

Keyboard Command: pit2plprec

Prerequisite: Pit Polylines and directional polyline(s) on the PRECEDENCE layer

Clear Pit Precedence

This command will erase the precedence for multi-bench pits. Removing the precedence is somewhat dangerous, as now Bench 2 can be mined before Bench 1. It is recommended to run Assign Pit Precedence after clearing them, to restore them to the default setting.

Prompts

Select pit polylines to process.

Select objects: Specify opposite corner: 6 found

Select objects:

Done.

Pulldown Menu Location: Boundary > Pit Timing Quantities

Keyboard Command: clear_pitprec

Clear Pit Bench Quantities

This command removes all quantity values and grid paths from the selected pits. There is the option to clear all benches at once, or if Specific is selected, then it will prompt to enter a bench number to clear.

Prompts

Clear all bench quantities or a specific bench [All/<Specific>]? A

Select pit polylines to clear.

Select objects: Specify opposite corner: 5 found, 5 total

Select objects:

Cleared 10 bench quantities.

Pulldown Menu Location: Boundary > Pit Timing Quantities

Keyboard Command: clearpit

Related Commands: Edit Pit, Assign Timing Grids, Import Timing Data

Remove Empty Benches

This routine looks at all the pits and benches and removes the bench completely from the pit if the volume and/or tons are less than the specified tolerance. This is useful to remove very small quantities that have been stored in pits by mistake, or just from calculations on the edges of the data. Running this command will remove the pit bench with volume below the tolerance, so when running timing routines, the pits won't show up. This is useful for the 3D Pick option in Surface Equipment Timing to remove upper benches that are in the pit, but have no volume assigned.

This command will also remove precedence rules that would be invalid following the merge. For example, if Bench 2 has a precedence rule that does not allow it to be mined until after Bench 1 has been mined, but Bench 1 is removed by this command, the precedence rule in Bench 2 will also be removed.

Prompts

Command: emptypit

Key volume tolerance (CY) <0.0>: 100

Non-Key volume tolerance (CY) <0.0>: 100

Key tons tolerance <0.0>: 100

Select pit polylines to remove empty benches.

Select objects: all

7 found

Removed 2 empty benches.

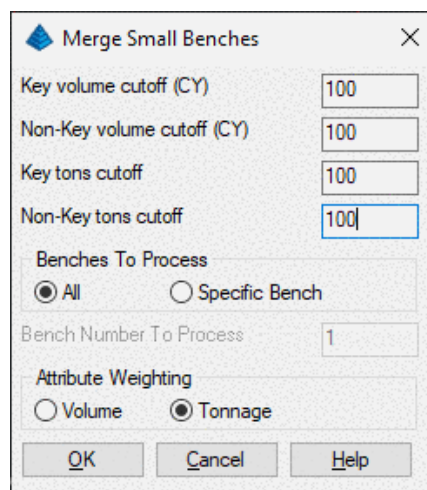

Pulldown Menu Location: Boundary, Pit Timing Quantities

Keyboard Command: emptypit

Prerequisite: Pits with bench quantities assigned

Merge Small Benches

This command combines benches in a pit polyline that have quantities less than a set tolerance. The program prompts for the cutoff tolerances for the bench quantities and then prompts for the pit polylines to process. For each pit polyline, the program checks for a bench with all quantities less than the set tolerances and then moves these quantities to the next bench in the pit polyline and removes the bench with the small quantities.

Volume/tons cutoff: In order for a bench to be merged to a lower bench, all four cutoff values must be greater than

the volumes on the bench being considered. For example, if a bench contains 150 CY of nonkey material and 50 CY of key material, and the cutoff for all values is 100 (as shown above), then the bench would not be merged to a lower bench because the nonkey volume is greater than the cutoff value.

Benches to Process: This option determines if all benches will be considered for merging, or just a specific bench. If all benches are considered, the program will start at the uppermost bench and check to see if it can be merged to a lower bench. The next bench will then be considered, all the way down the pit. Note that if multiple benches can be merged, they will. For example, if both benches 1 and 2 are very small, they could both be merged into bench 3 if their sum is less than the cutoff. If The **Specific Bench** option is selected, then any small benches overlying the specific bench will be considered for merging. For example, if benches 1 and 2 contain small volumes/tonnage, while bench 3 contains significant volumes/tonnage, processing bench 3 would merge both benches 1 and 2 into bench 3.

This command will also remove precedence rules that would be invalid following the merge. For example, if Bench 2 has a precedence rule that does not allow it to be mined until after Bench 1 has been mined, but Bench 1 is removed by this command, the precedence rule in Bench 2 will also be removed.

Attribute Weighting: This option determines if quality values will be averaged based on the volume or the tonnage of the material.

Key attributes will be weighted by either the key tonnage or the key volume.

Nonkey attributes will be weighted by either the nonkey tonnage or the nonkey volume.

Any attributes that include `_TON_FACTOR` or `_VOL_FACTOR` will be handled in such a way that the sum of all similar attributes does not exceed 1.000, as these attributes represent the percentage of each strata contributing to the total volume/tonnage of key or nonkey material in the bench. Any of these attributes ending in "_NK" refer to the nonkey portion of the bench, whereas attributes without this suffix refer to the key portion of the bench.

The below example shows two benches before merging (left) and after merging (right). Notice how different strata were merged into a single bench, but the relative percentage of `TON_FACTOR` and `VOL_FACTOR` has been recalculated so that the sum of all key tonnage/volume percentages does not exceed 1.000, and the sum of all nonkey tonnage/volume percentages does not exceed 1.000. In this example, attributes were weighted by tonnage, and the cutoff values were set to very large values to allow these benches to merge.

Prompts

Merge Small Benches dialog

Select pit polylines to merge benches.

Select objects: *pick the pit polylines to process*

Pulldown Menu Location: Boundary

Keyboard Command: pitmerge

Prerequisite: Pit polylines with quantities

Assign Pit Attributes

This command assigns the attributes to the pits that are in the current PTA file defined with the Mining Project Manager. The only reason to do this is if more than one PTA file is being used for different areas of the mine, or the attributes have completely changed, and new ones need to be assigned. These may be verified with the Edit Pit command.

Prompts

Enter Bench Number to Assign Qualities To:1

Select pit polylines to have qualities assigned:

Select objects:

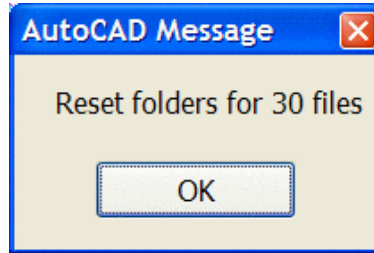

Pulldown Menu Location: Boundary > Pit Timing Quantities

Keyboard Command: setpitattr

Related Commands: Default Pit Attributes, Edit Pit

Reassign Pit Attr Grids Folder

This command will reassign the pit attribute grids folders to a new location if they are moved to a new location or computer. It will prompt for the first grid on the list, then reset all to the same location.

Prompts

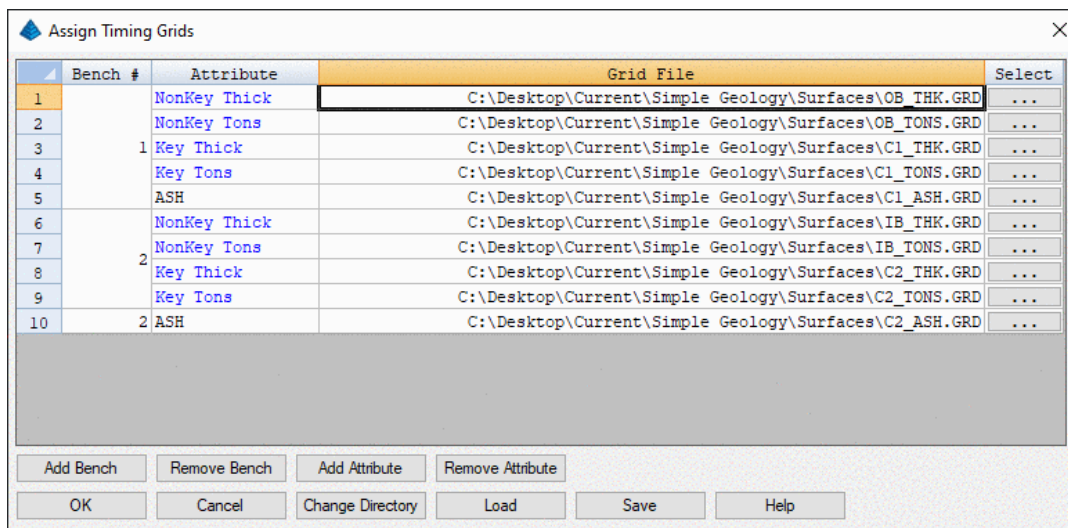

Select the first grid in the list.

Drop-Down Menu Location: Boundary

Keyboard Command: resetpitattr

Assign Timing Grids

This command will assign key thickness, non-key thickness, key tonnage grid files, and non-key tonnage a series of pits or timing blocks. This is an alternate, manual way of assigning grids instead of through the Output Thickness Grids option in the Surface Mine Reserves. These grids are associated with a bench number and stored in the pit polylines. This data is used by the Surface Equipment Timing routine, and these four values are required. Optionally, attribute grids can be assigned here for each bench. You can use the Pit Report or Edit Pit routines to verify which grids are assigned for each bench. The key tonnage grid is tons/ft² (or tonnes/m²). Tonnage grids are easily made with the thickness grid and a density grid in Grid File Utilities. For example: Thickness Grid (feet) x Density (tons/cubic foot) = tons/square ft. The following dialog box allows for interactive entry so all benches can be entered and viewed together as one step. The blue colored text represents required attributes and the black colored text represents optional, user added attributes.

Prompts

Assign Timing Grids Dialog Box.

Select pit polylines to assign grids.

Select objects: *select polylines with pit/site names*

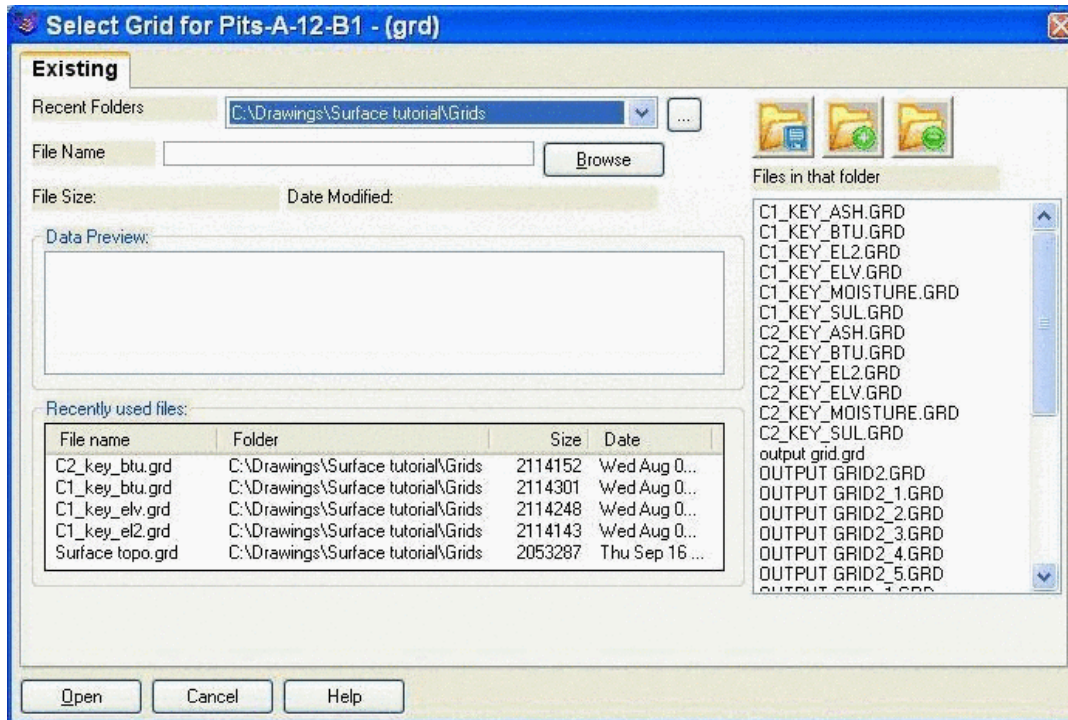

Pulldown Menu Location: Boundary

Keyboard Command: tmgrids

Prerequisite: Key thickness grid, non-key grid, key tons grid, polylines with pit/site names

Reassign Timing Grids Folder

This command reassigns the path of the pit attribute grids stored in the pit perimeters. It is useful when moving the grids folder to a new location, the entire pit attributes do not need to be reassigned, just run this command to point the pit perimeters to the new grid locations. An useful AutoCAD command is XDLIST to view the extended entity data stored within the polyline. This shows the current path of the pit attributes.

Prompts

Select the site/pit perimeter polylines.

Select objects: Specify opposite corner: 10 found

Select objects:

Reset grids for 8 pit perimeters.

Pulldown Menu Location: Boundary > Pit Timing Quantities

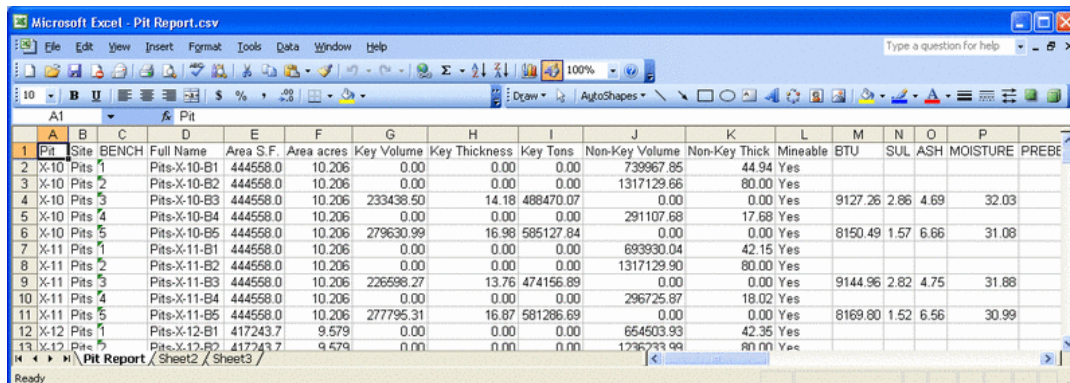

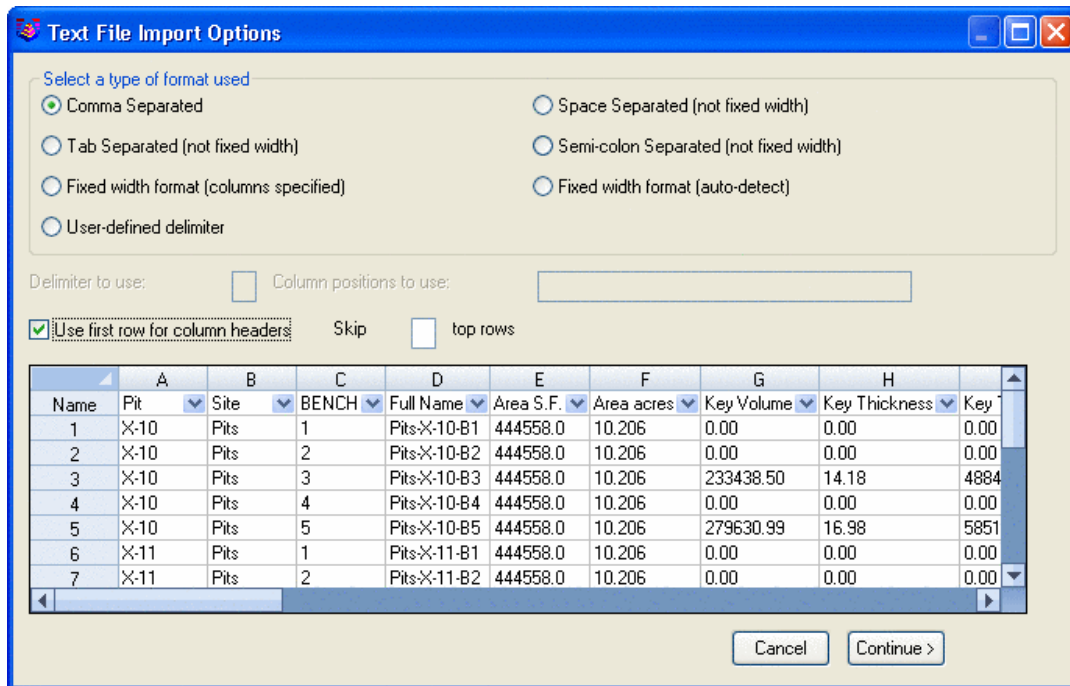

Keyboard Command: reset_tmgrids

Related Commands: Default Pit Attributes, Edit Pit

Import Pit Timing Data

This routine imports timing data values into pits from an external text file. The command can bring in the following pre-assigned parameters: Pit Name, Site Name, Key Volume, Key Tons, Non-Key Volume, Difficulty Factor, Start Date and Bench Number, Precedence and other attributes. Also, any user added quality attribute is inserted with the "Add Attribute" button.

The following example is saved as a comma-delimited file (*.csv), which the routine will bring directly in. It imports files with extensions of TXT, CSV, DAT and ASC. Be sure the Site and Pit names are spelled and identified exactly as they appear in the drawing. Shown below is a sample file in Excel. The program will automatically recognize the data that has been exported by the Pit Report command. Changes and additions can be made to the pit report file, and then reimported to attach the data to the pits.

The Formatter Window is very easy to use. Simply dropdown the arrow in the Name row to define what each column is. This will match the data up with the fields in the pits and import the data.

Use first row for column headers: When enabled, this option will use the first row of the .csv file to set the column headers

Skip _ rows: This option will skip the specified number of rows when importing. This is useful if you have header information in the .csv file

Excel style text quotation: When enabled, the program will look for quotation marks around text in the .csv file and remove them. For example, if a piece of text is found in the .csv file such as "Pit 1", it will only import Pit 1.

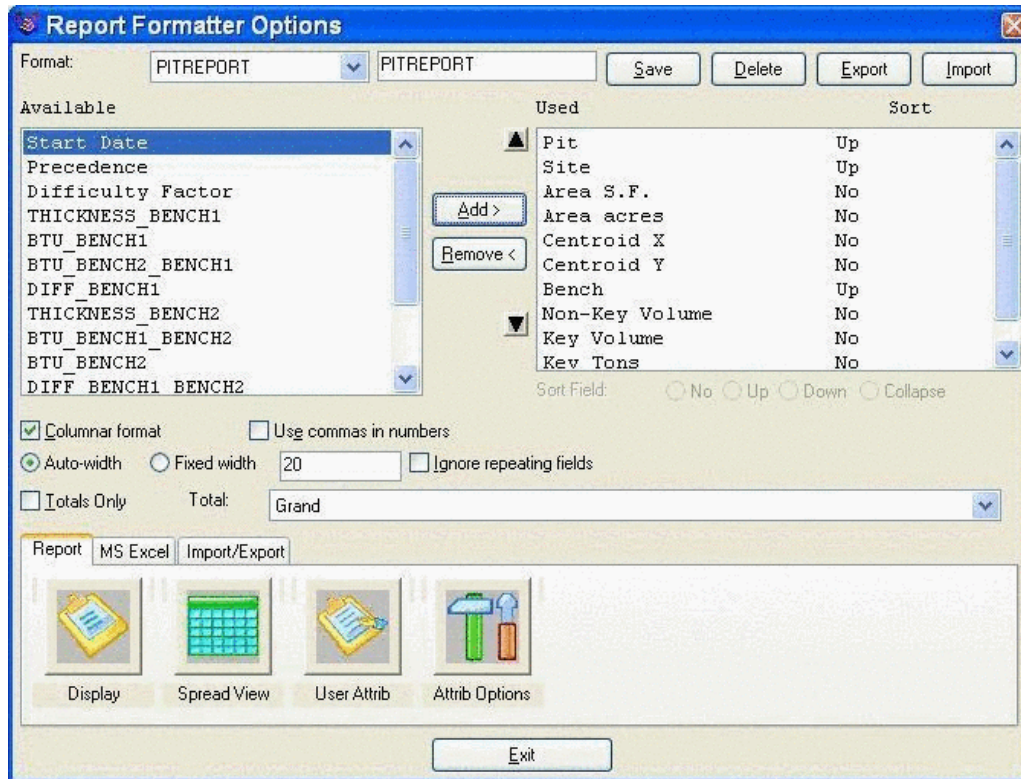

Pulldown Menu Location: Boundary, Pit Timing Quantities

Keyboard Command: tmimport

Prerequisite: A pit data file and pits on screen

Pit Quantities Report

This command will generate a customized report of all data contained in the pit polylines. It is the compliment of the Import Pit Timing Data command. This command uses the Report Formatter which allows you to customize the report fields layout, and to export the data to a spreadsheet or database. There must be data already assigned to the pit polylines before running this routine.

Edit Pit

Edit Pit allows you to review and edit the quantities and attributes stored in each pit which are used for scheduling in the Surface Equipment Timing and Pit Scheduler commands.

Storing Data in Pits

Quantities and attributes may be stored in the pits using the Surface Mine Reserves, Assign Timing Grids, or Import Pit Timing Data commands (explained below). These values are stored in the pits as Extended Entity Data (EED), along with the pit name and the mining direction. In the pits themselves, some pit data (key tonnage, key thickness, nonkey tonnage, and nonkey thickness) may be stored as discrete values or as grid files. The primary difference between these methods is in how Surface Equipment Timing will use the information for scheduling. When data is stored in the pit as a discrete value, it is assumed that the pit is homogenous in regards to that value. When data is stored as a grid file, the value can be treated as variable across the pit. For example, if the OB Volume is represented with a discrete value, it is assumed that the overburden thickness is the same across the entire pit. When mining through the pit, one side of the pit will be mined just as quickly as the other side. If the OB Volume is represented with a grid, however, the true thickness of the overburden will be taken into account during scheduling. This will show how one side of the pit may be mined more quickly/slowly than another side of the pit due to a change in overburden thickness.

1. The Surface Mine Reserves command provides an option to Use Named Pit Polylines and to Store Results in Pits. These options will store all relevant quantities and attributes in the pit on a specific bench as discrete values. Surface Mine Reserves also has an option to Output Thickness Grids. When this option is used, the thickness grids will be stored in the pits in place of the respective discrete values. If the pit needs to be divided into multiple benches, the values for each bench may be calculated simultaneously with the use of the Use Auto-Run option.
2. The Assign Timing Grids command will prompt you for three grids to assign to each bench: a nonkey thickness grid, a key thickness grid, and a key tons grid. The key tons grid should represent tons/square foot or tonnes/square meter.
3. The Import Pit Timing Data command will import pit information from a .csv file.

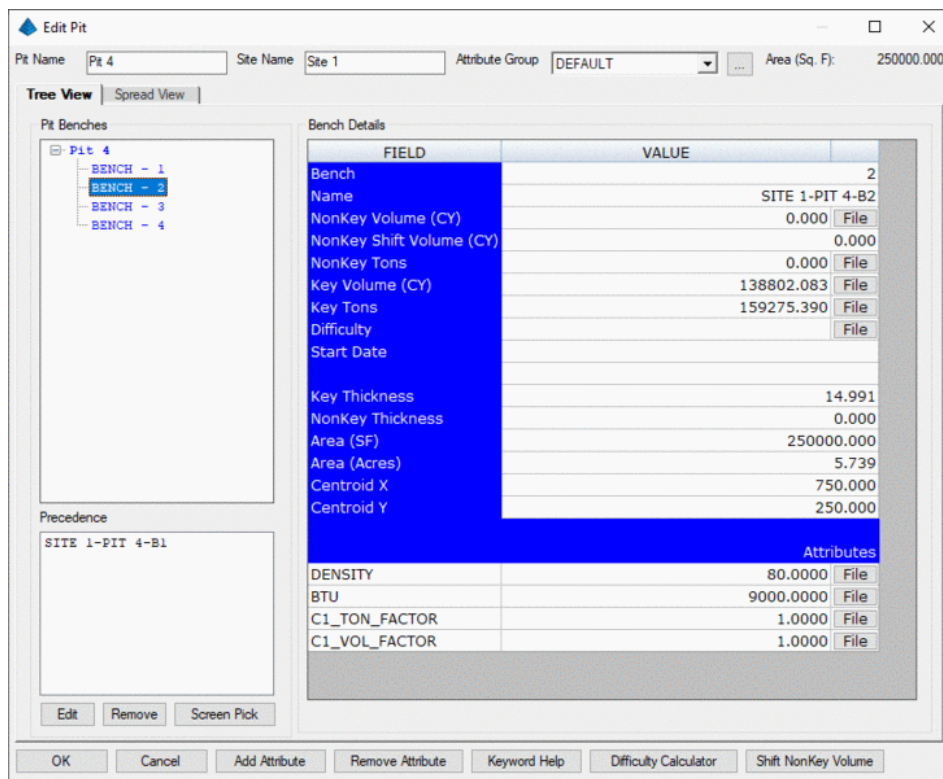

For more information regarding these three commands, see the section of the help manual corresponding to each command.

Edit Pit Dialog

When executing this command, you will be prompted to pick inside a pit polyline. The selected pit will be hatched with a yellow fill and the Edit Pit dialog will appear. If two pit polylines overlap in the location you select, one pit polyline will be highlighted and you will be prompted if the selection is correct. If the program does not detect any named, directional pits with stored quantities, the command will not execute.

Tree View:

The below dialog shows the tree view for a typical pit. In this view, all benches in the pit are listed in the Pit Benches tree view on the left side of the dialog. The information relating to the selected bench will be shown under Bench Details on the right side of the dialog. Most of the values listed under Bench Details may be edited by simply typing a value in the cell of interest or by clicking the File/Edit button to the right of the cell. Precedence rules for the selected bench are shown in the bottom left corner of the dialog.

Spread View:

The below dialog shows the spread view for a typical pit. This view is simply a different way of viewing the pit information shown in the tree view and may be accessed by clicking the Spread View tab near the top of the dialog. In this view, benches are displayed in a spreadsheet for easier side-by-side comparison.

The screenshot shows the 'Edit Pit' dialog box with the 'Spread View' tab selected. The dialog contains a spreadsheet with the following data:

Pit Name and Site Name: These fields set the name of the pit.

Attribute Group: This dropdown menu sets the attribute group for the pit. Attribute groups may be used to assign attribute values/grids to many pits at one time. New Attribute Groups may be defined in the Timing Project Manager.

Bench: This field displays the bench number.

Name: This field displays the full bench name. This is a concatenation of the Pit Name, the Bench Name, and the Bench Number separated by hyphens.

NonKey Volume: This value sets the volume of nonkey material (overburden) in the bench. This value can also be represented by a thickness grid of the nonkey material.

NonKey Shift Volume: This value displays the volume of nonkey material that has been shifted into the current bench from another bench. Nonkey material may be shifted between benches with the use of the Shift OB Volume button at the bottom of the dialog.

NonKey Tons: This value sets the tonnage of nonkey material in the bench. This value can also be represented by a grid of tons/square foot or tonnes/square meter.

Key Volume: This value sets the volume of key material in the bench. This value can also be represented by a thickness grid of the key material.

Key Tons: This value sets the tonnage of key material in the bench. This value can also be represented by a grid of tons/square foot or tonnes/square meter.

Difficulty: This value sets the difficulty factor associated with the bench. The difficulty factor temporarily modifies the equipment mining rate set in the Timing Project Manager. The adjusted mining rate is the quotient of the original mining rate and the difficulty factor. A difficulty factor of 1.0, or if the difficulty factor is not specified, will maintain the original mining rate. A difficulty factor of 2.0 will double the amount of time required to mine the bench (original mining rate is divided by 2.0). A difficulty factor of 0.5 will half the amount of time required to mine the bench (original mining rate is divided by 0.5). To quickly calculate the difficulty factor, you may want to use the Difficulty Calculator at the bottom of the dialog. The difficulty factor may also be represented by a grid file.

Here it is important to note the difficulty value set in this dialog may be overridden according to a 4-level hierarchy.

1. The manual entry of the value or grid file set here is at the bottom of the hierarchy.
2. The second level is specifying the difficulty within an Attribute Group in the Timing Project Manager. There, an attribute named DIFF_BENCH* (where * is a bench number) may also be represented by a discrete value or a grid file. When this DIFF_BENCH* attribute is added to the attribute group, it will actually create a new attribute in the pit itself called DIFF.
3. The DIFF attribute in the pit is the third level in the hierarchy. This allows you to use a generic difficulty for the entire attribute group, but still manually set the difficulty for individual benches.
4. The fourth and highest level in the hierarchy is layerized text in the drawing. The text should be the difficulty factor (no prefixes or suffixes) and should be placed on a layer named DIFF_BENCH* (where * is a bench number). For example, if the text "1.2" on the DIFF_BENCH1 layer is placed inside a pit polyline, the difficulty factor for the first bench in that pit will be set to 1.2. This difficulty factor will override all others.

Start Date: This field sets the earliest start date for the pit. This can be used to prevent mining an area due to waiting for permit approval, waiting to finalize the purchase of new land, etc. Most of the time this field will be left blank, however.

Key Thickness: This value displays the average key thickness of the bench.

NonKey Thickness: This value displays the average nonkey thickness of the bench.

Area: These values display the area of the bench.

Centroid X and Centroid Y: These values display the coordinates of the geometric center of the pit.

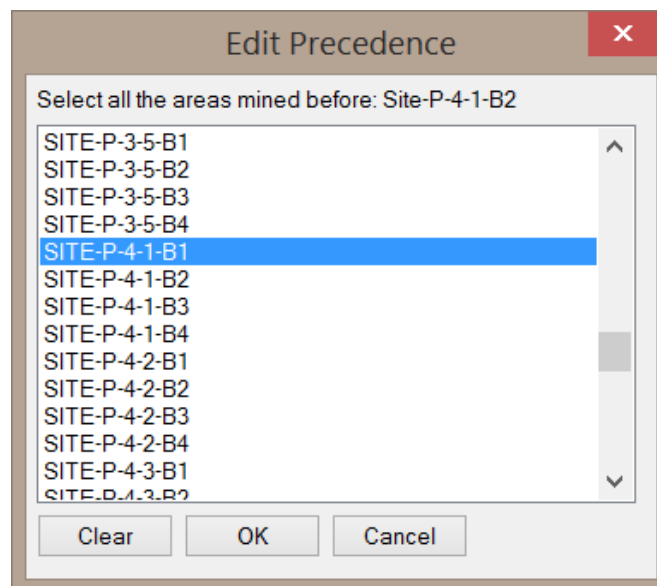

Other Attributes: The bottom of the Bench Details list leaves spaces for a variety of other attributes. Most of these attributes are used to define qualities of the bench. For example, if a bench contains an attribute for Moisture, this attribute will apply to the entire bench. If two strata are added to the same bench, this Moisture attribute will relate to both strata. If you are storing values in the pits using Surface Mine Reserves, the weight-averaging of the attribute will be applied automatically based on the volume and the density of the material. Here it is important to note that the weight averaging of attributes will not account for null values. For example, if Strata A has a Moisture attribute of 0.3, but Strata B does not have a Moisture attribute defined, then the combined Moisture content for the two stratum will be 0.3. To properly weight attributes, it is necessary to define an attribute value for each strata.

Some attributes may be shown with a _NK suffix. This suffix will be applied to differentiate between key attributes and nonkey attributes. For example, if Strata A is key and has a Sulfur value of 0.1 and Strata B is nonkey and has a Sulfur value of 0.15, these two Sulfur values will be handled separately. The Sulfur value for Strata A will be stored as "Sulfur" with a value of 0.1 whereas the Sulfur value for Strata B will be stored as "Sulfur_NK" with a value of 0.15.

Some attributes may be in the form of XXXX_VOL_FACTOR or XXXX_TON_FACTOR where XXXX is a strata name. This is used to define ratios of material when more than one key strata or more than one nonkey strata are added to the same bench. For example, if strata A and B are both key strata, an attribute for B_TON_FACTOR will be shown in the list. If this value is 0.4, then 40% of the key tonnage in the bench comes from strata B. If the attribute A_VOL_FACTOR is 0.56, then 56% of the key volume comes from strata A. For nonkey strata, a suffix of "_NK" will be applied to these attributes.

Precedence: This section of the dialog controls precedence rules for scheduling. The precedence list is simply a list of other benches that need to be mined before the current bench can be mined. Basic top-down precedence rules will be automatically entered to prevent mining a lower bench before the upper bench has been mined.

Edit: This button will open a list of all other benches found in the drawing, as shown below. Selecting benches of interest and clicking OK will add the benches to the precedence list. Multiple benches may be selected by clicking and dragging in the list or by holding the CTRL key while clicking.

Remove: This button will remove the highlighted bench from the precedence list.

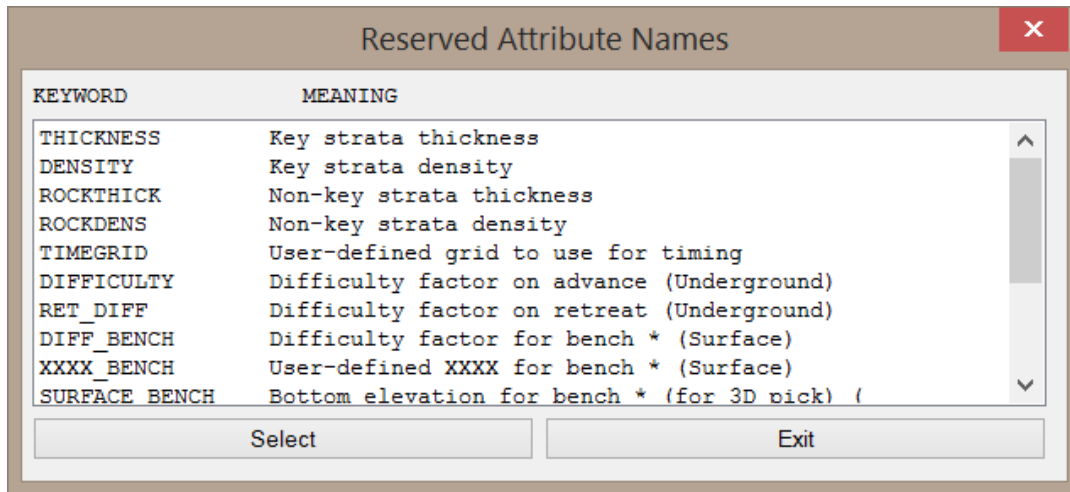

Screen Pick: This button will allow you to add benches to the precedence list by picking them in the drawing. As soon as you click inside a pit polyline, the uppermost bench for that pit will be added to the precedence list. Clicking in the pit polyline multiple times will add lower benches.

Add Attribute: This button will add a new row to the Attributes list.

Remove Attribute: This button will remove the currently selected attribute from the Attribute list.

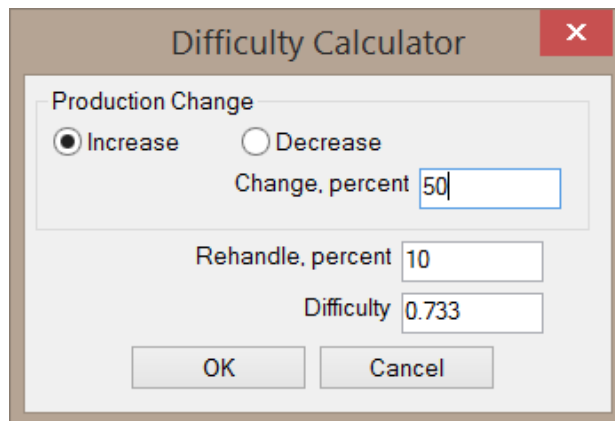

Keyword Help: This button will open the list of keyword attributes, as shown below. These keyword attributes may also be added to an Attribute Group in the Timing Project Manager. When an attribute with the _BENCH* suffix (where * is a bench number) is added to the Timing Project Manager, it will also appear in the Edit Pit dialog.

Manually editing the value in the Edit Pit dialog will override the value set in the Attribute Group. Attributes that are added to the Attribute Group that do not have the `_BENCH*` suffix, however, will not appear in the Edit Pit dialog. Note that some of these keywords are only intended for use with the Underground Mining Module. For more information on the specifics of each keyword, see the section of the help manual corresponding to the Timing Project Manager.

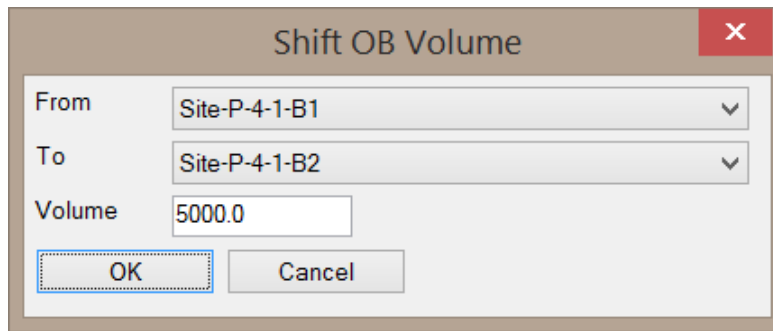

Double clicking one of the keywords in the above dialog will add it to the Attributes list on a new row.

Difficulty Calculator: This button will open the difficulty calculator as shown below. This dialog will calculate the difficulty factor based on an increase/decrease in the mining rate and a percentage of rehandle. For example, if the mining rate is expected to increase by 50% and 10% of the material will need to be rehandled, the calculated difficulty factor will be 0.733.

Shift OB Volume: This button will open the Shift OB Volume dialog as shown below. This will move nonkey volume from one bench to another. This dialog will not allow you to move more material than what exists in the source bench.

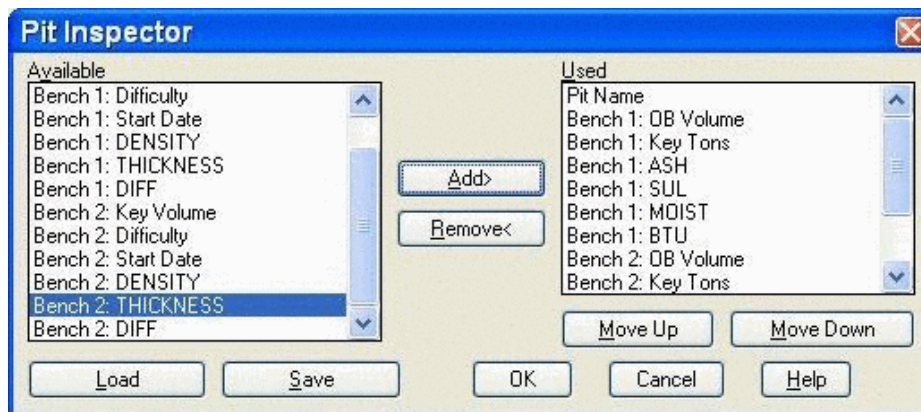

Pulldown Menu Location: Surface Mining Module > Boundary

Keyboard Command: editpit

Related Commands: Surface Mine Reserves, Timing Project Manager, Surface Equipment Timing

Pit Inspector

This command follows the "inspector" theme found throughout Carlson. Any variable or attribute will be displayed within the inspector window as the cursor is moved from pit to pit. When each pits information is being displayed, the pit perimeter is dashed to highlight the pit. If a grid is stored in the pit, then just the grid name path is displayed or labeled, not the value. Picking with the mouse inside a pit will bring up the Edit Pit dialog box where changes may be made if necessary. Options will activate the Pit Inspector window to add or edit the items. Label will allow for labeling the Used items on the screen. The text alignment and height is prompted for at the command line.

Prompts

Options/Label/<Pick To Edit>: L (for label)

Pick starting point for label:

Pick label alignment point:

Text height <50.00>:

Options/Label/<Pick To Edit>:O (brings up the settings window again)

Drop-Down Menu Location: Boundary

Keyboard Command: pitinspect

Files:

Assign Property Names

In order to evaluate the quantity and/or quality of ore mined on the particular property, Carlson employs the use of closed polylines representing the property boundary. This function is used for assignment and modification of the owner and property ID names to these polylines. The following commands support property lines:

Quantities by Average
Quantities by Grid
Surface Equipment Timing
Surface Production Timing
Underground Timing
Surface Mine Reserves
Reserve Classification

This command simply prompts to select the polyline and type in the owner and ID. Property polylines supersede the Boundary Enclosure command for the purposes of calculation, since the use of property polylines does not require actual subdivision of the mine plan into properties. Instead the subdivision is performed internally "on-the-fly" by the cutting of a given polyline (such as whole mine property or monthly production pit polyline) against an underlying set of property lines.

In its current implementation the use of property lines has the following limitations: property lines should be closed polylines and make sure that they do not overlap other property lines. If a portion of a pit or panel is outside of all property lines, then in the report, the owner will be reported as UNKNOWN.

Prompts

Select property polyline:

Property Owner Name<>: *Federal*

Property ID<>: *#J1267*

Pulldown Menu Location: Boundary

Keyboard Command: property_line

Remove Property Data

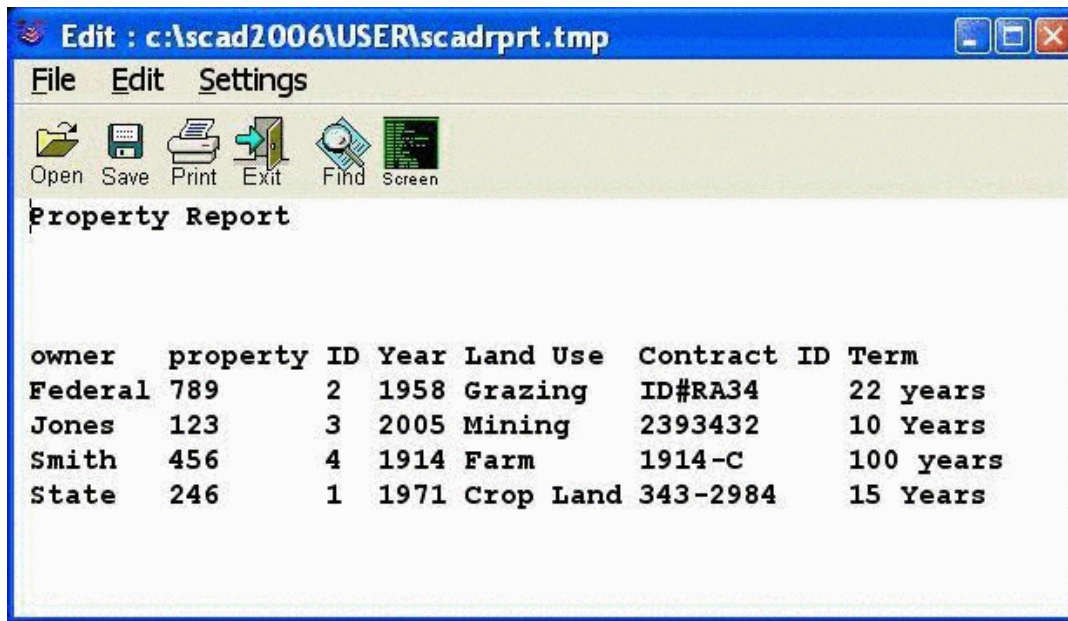

When property information attached to the polyline is no longer needed, it may be removed by using this command. Multiple polylines may be processed at once.

Pulldown Menu Location: Boundary

Keyboard Command: clearprop

Property Data Report

This command uses the report formatter to create a report showing all property data associated with the selected property lines. They must be linked to the MPD file where all of the property data is stored.

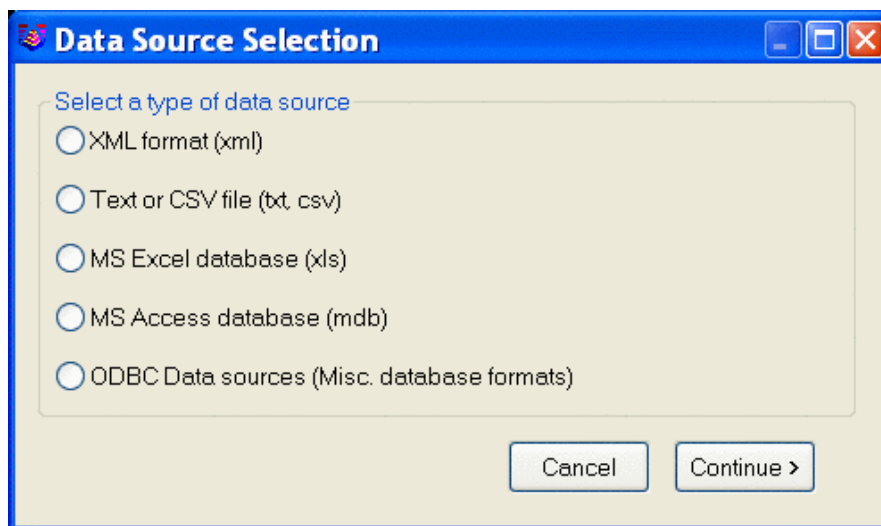

Pulldown Menu Location: Boundary, Property Line Tools

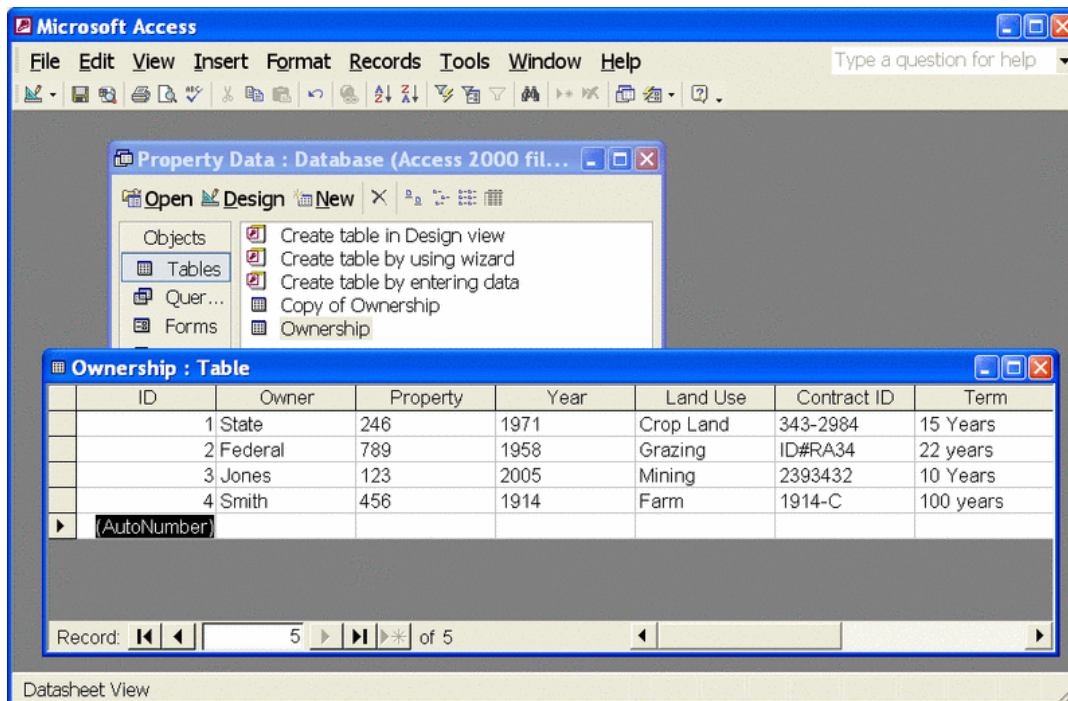

Keyboard Command: reportprops

Setup Property Link

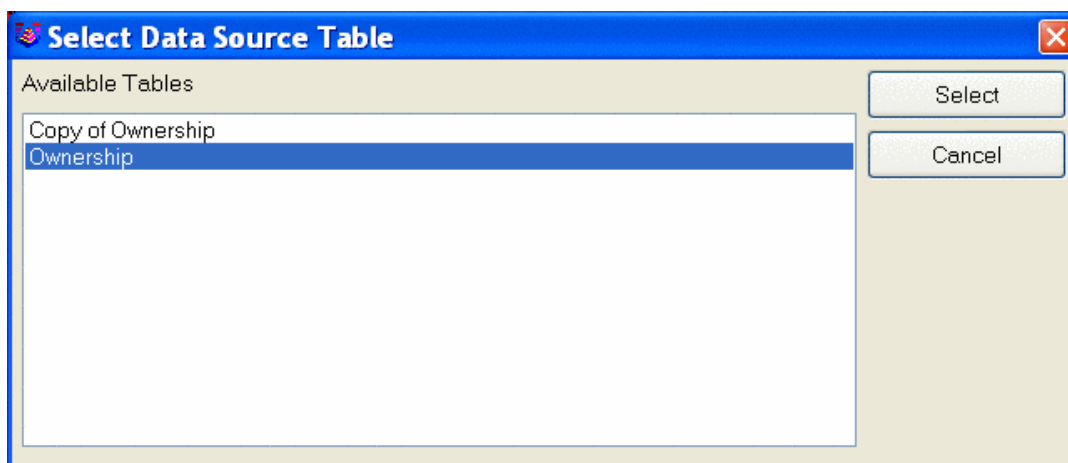

This command creates the link between the property lines in the drawing and the database. The data can come from an XML file, a TXT or CSV file, an XLS file, an Access MDB file, or miscellaneous ODBC data sources.

After choosing which format it is, select the Continue button.

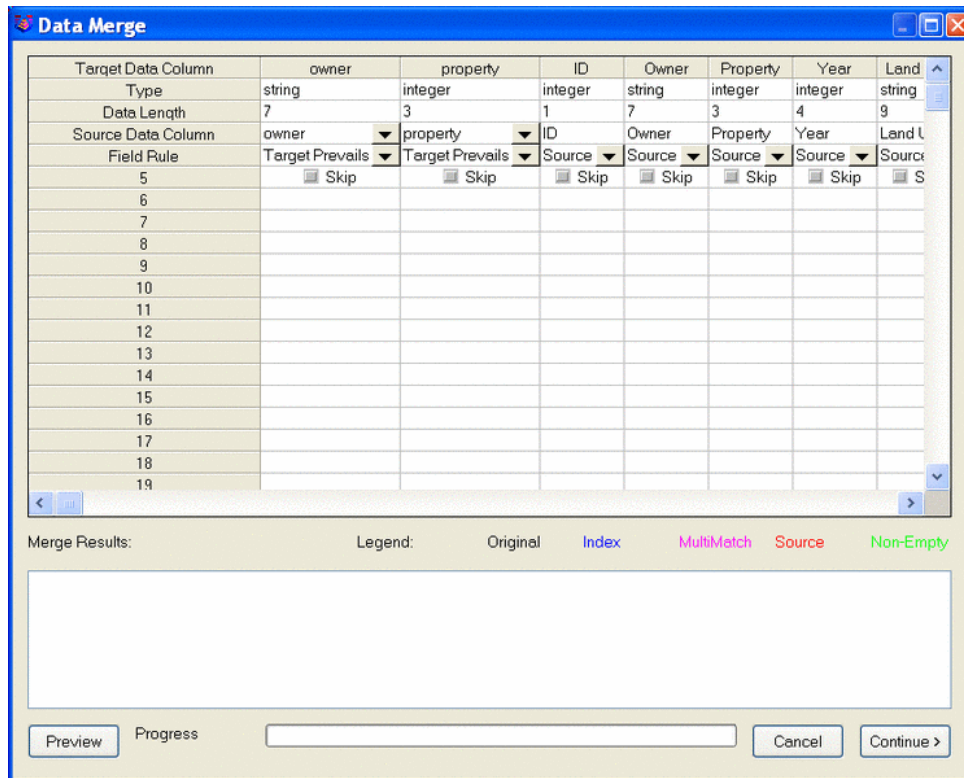

This Access database shows some data entered in for four different properties.

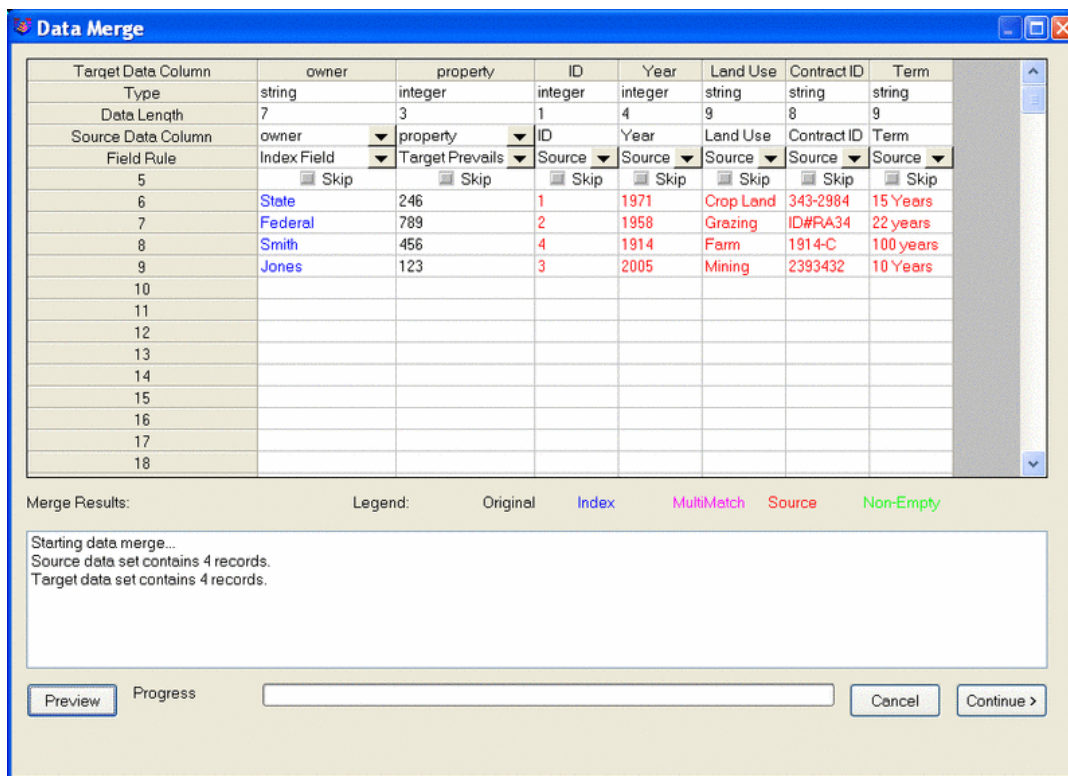

After choosing the source file, this selection window appears if it is from an Access database. Choose the table the data is stored in.

There are then four choices on how to join the data. The first is to empty the existing data set which would delete the property and ownership line data. The second is to merge the data, using both data sets. The third option is to append all to the end of the data, and finally, the last option is to append any new data, and merge the common data. The next Data Merge table displays all of the available fields. Notice in this example, there are two Owners and two Properties. In this case, the Merge option is the way to go.

Choosing Index Field on the first Owner gives the following result. The data is now merged and ready to be used for reporting and reserve runs. Any time these property lines are used in reserves, all of this data is available for reporting. Choose Continue will process the data and return to the command line.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: setuppropdblclick

Property Names By Text

This command converts a large number of closed polylines into property lines by using text label placed inside of the polyline. You are prompted to select closed polylines to become property lines and then the program tries to locate a text label inside each closed polyline that has the same layer as that closed polyline. The text is used as the owner name and the property ID is set to blank.

When you have text labels to start with but no closed polylines, use the Boundary Polyline command under Draw menu to create closed polylines from appropriate linework by using the text insertion point.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: grabprop

Identify Property Lines

This command is one of several property line tools available to identify and trouble shoot property lines. To identify a property line, simply click inside the polyline and the name of the owner and property ID will be displayed in the command text window.

Prompts

Pick on or inside of property polyline:

Owner: State

Property: 459a

Pick on or inside of property polyline:

Owner: Jones

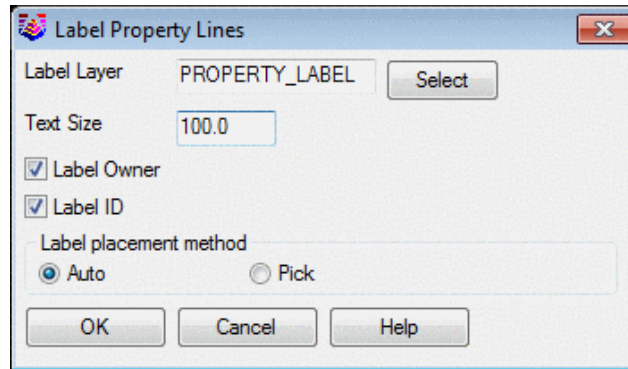

Property: 34

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: idprop

Label Property Lines

This command labels property lines in the drawing. The dialog contains option set the label layer and text size in feet or meters. There are options to label the owner, ID or both. When the Automatic mode is selected, the label is placed at the center of the property line. If the placement method is Pick, then each property line text location will need to be prompted for.

Prompts

Select all property polylines to label:

Select objects:

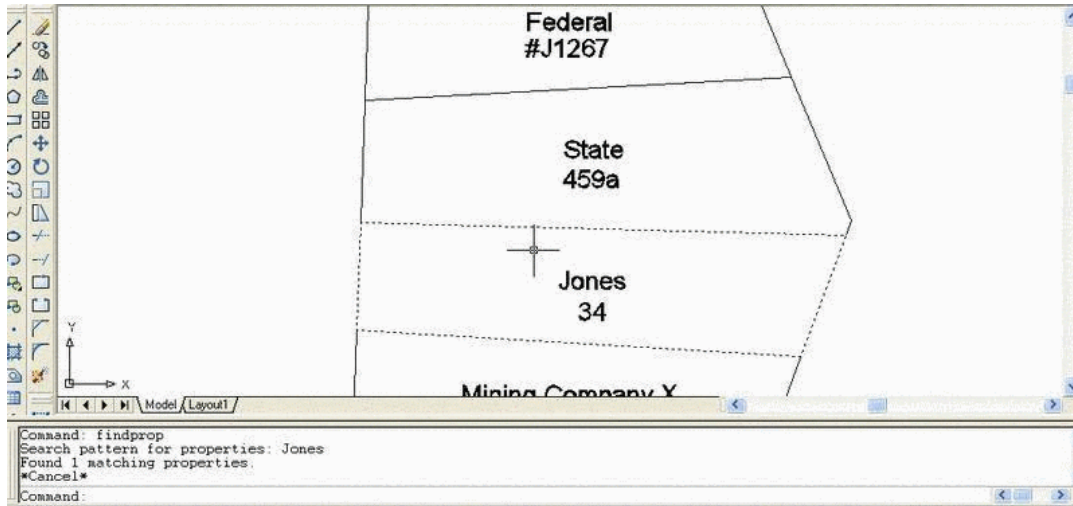

Dialog Box.

Pulldown Menu Location: Boundary in Surface Mining and Underground Mining Modules

Keyboard Command: labelprop

Find Property Lines

This command locates property lines by matching the user provided search pattern against owner name and property ID of all property lines in the drawing. All matching property lines will be highlighted. The wildcard character (*) can be used in the search pattern.

Pulldown Menu Location: Boundary, Property Line tools

Keyboard Command: findprop

Show All Property Lines

This function displays all property lines in the drawing either by highlighting them or by using solid fill. The latter option works for detection of the unassigned properties totally surrounded by the other properties. It is also convenient for location of tiny gaps between properties shown in the timing report as small areas with an UNKNOWN owner.

Prompts

Solid-fill the properties [Yes/<No>]? Y

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: showprop

Check Property Polyline Overlaps

This command checks whether property polylines overlap each other. Properties should never overlap since this would lead to extra volumes with the quantities in the overlap area getting reported twice. The program reports any overlaps at the command line.

Prompts

Select pit polylines to check.

Select objects: *pick the polylines*

Found 0 overlaps between 56 properties

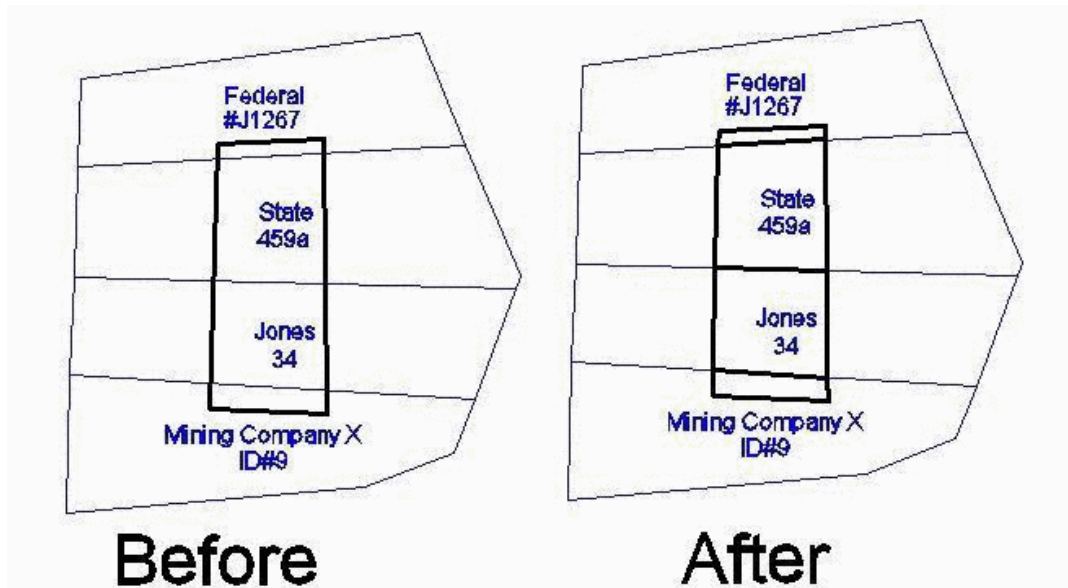

Pulldown Menu Location: Boundary > Property Line Tools

Keyboard Command: propcheck

Prerequisite: property polylines

Break Polyline by Property

This command breaks a closed polyline into separate closed perimeters where they cross property lines. This is useful when smaller, individual perimeters are desired for pits or panels.

Prompts

Select polyline to divide by owners:

Pulldown Menu Location: Boundary

Keyboard Command: ownerdivide

Extract Centroid Data

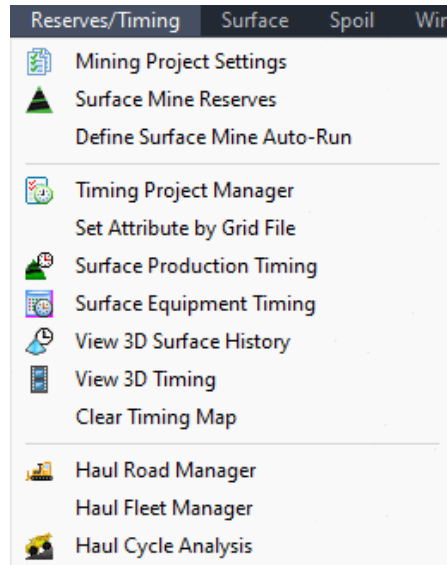

This command is used to convert property information imported from ArcInfo using shape files into property lines. It searches for polyline centroids, extracts the necessary information stored there and attaches it to the property line. This will only work in AutoCAD MAP.

Pulldown Menu Location: Boundary, Property Line Tools

Keyboard Command: import_shape

Reserves Timing Menu

The Reserves/Timing menu has commands for calculating mining quantities and surface timing. The Mining Project Manager and Surface Mine Reserves commands are described in the Geology section of the manual.

Mining Project Settings

This command sets the current file names used for several Carlson definition files. For example, this command assigns the Drillhole Configuration file (.ch file) to be used for drillhole placement in other routines such as Place Drillhole and Drillhole Data Sheet. The Mining Project Manager lets you set up different groups of definitions. For example, if you work with two mines, then you can have two sets of strata definitions (strata1.sdf and strata2.sdf), two sets of attribute definitions (attrib1.atr and attrib2.atr), etc. When switching between the projects, you can load the .mpj file to instantly update all of your relevant settings.

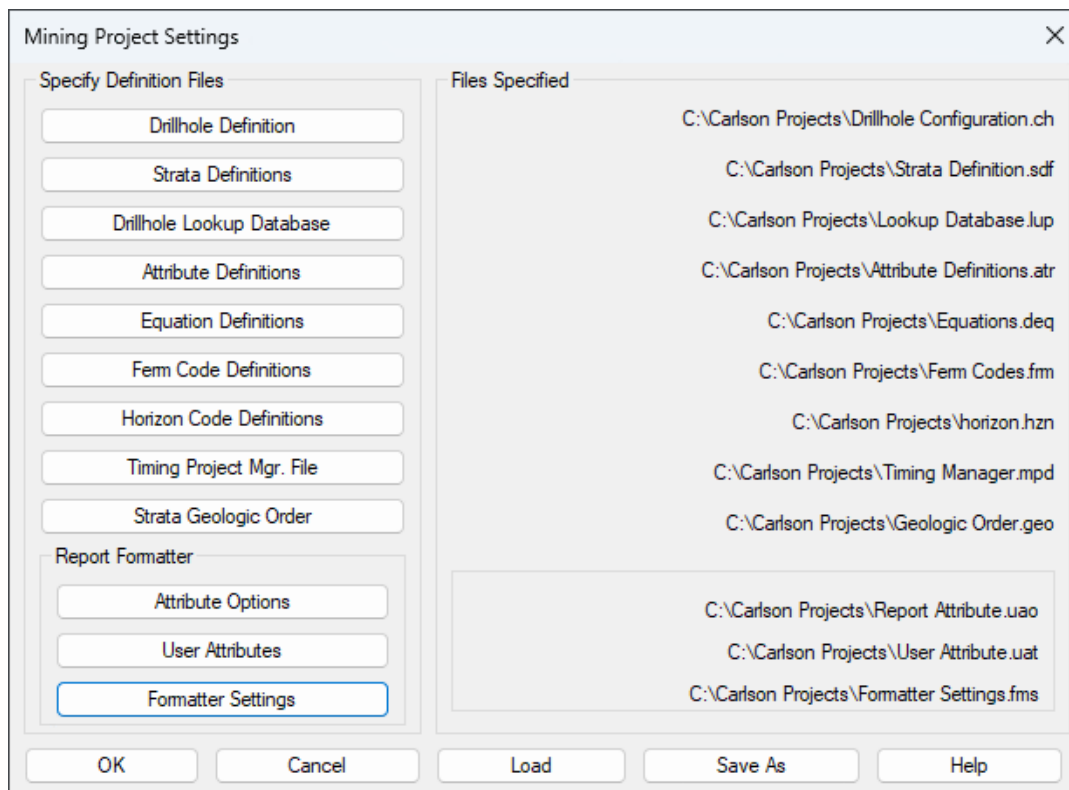

Whenever a command is executed that creates one of the below files, it will be automatically added to the Mining Project Manager. However, you can also specify the file names directly from this command.

All the file names in Mining Project Manager are saved with the drawing in the drawing .INI file. You can also save this set of file names to a mining project file (.mpj) by picking the Save button. The Load button will then recall the set of file names from the selected .MPJ file.

Following is a list of commands that will create the files shown in the Mining Project Manager. The extensions of the files are shown in the dialog window below.

1. Drillhole Definition: Define Drillhole
2. Strata Definitions: Define Strata/Bed

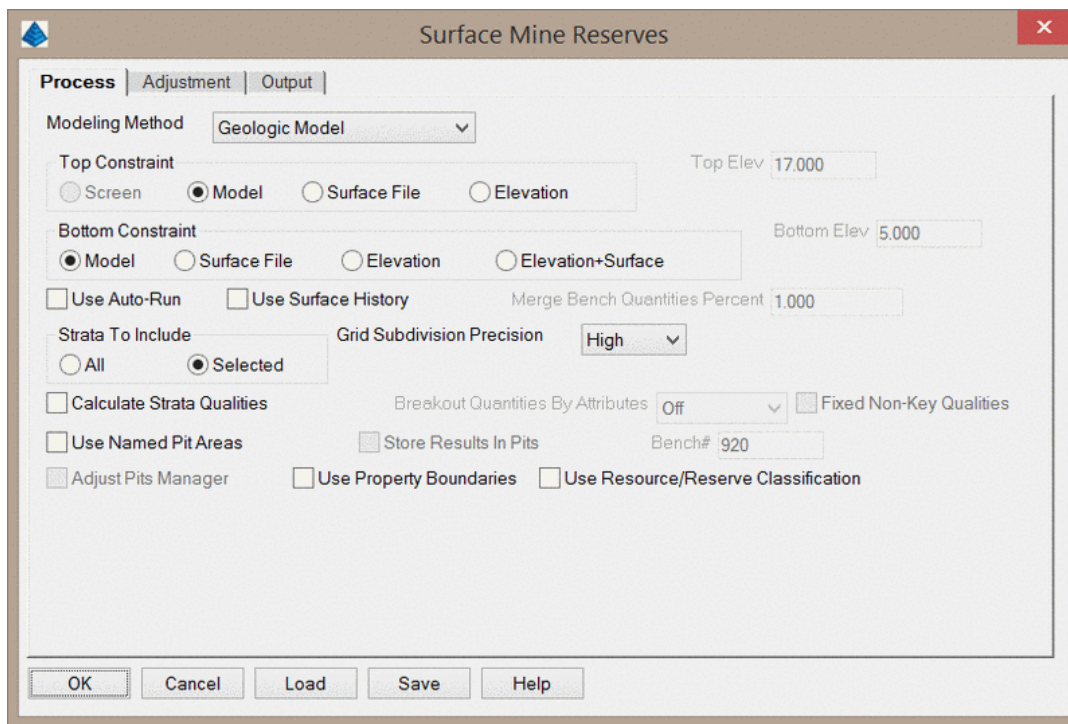

3. Drillhole Lookup Database: Define Lookup Database
4. Attribute Definitions: Define Attributes
5. Equation Definitions: Define Equations
6. Ferm Code Definitions: Define Ferm Codes
7. Horizon Code Definitions: Define Horizon Codes
8. Timing Project Mgr. File: Underground Timing, Surface Equipment Timing, Solids Timing
9. Strata Geologic Order: Define Geologic Order
10. Attribute Options: In the Report Formatter, Attribute Options
11. User Attributes: In the Report Formatter, User Attributes.
12. Formatter Settings: In the Report Formatter, Export

Pulldown Menu Location: Drillhole
Keyboard Command: mproject

Surface Mine Reserves

This command calculates quantities and qualities directly from drillholes or from predefined Geologic/Mining Models. Additional outputs include stripping ratio contours, composite thickness grids, and more. The dialog is divided into three tabs - Process, Adjustment, and Output - as shown below. It is important to note that if an option is grayed out (not editable) it will not affect the calculations. Some options cannot be used together, and so the unnecessary options will be grayed out to avoid confusion.

Modeling Method: This dropdown menu sets the modeling method to be used for calculations.

The first seven options (Triangulation, Inverse Distance, Kriging, Polynomial, Linear Least Squares, ABOS Method, and Nearest Neighbor) will calculate the reserves from drillholes, strata polylines, and pit/channel samples using the selected modeling method. This option will create grids for calculations, but the grids will not be saved. For more information, see the section of the help manual corresponding to the Make Strata Grids command.

The Block Model option will also calculate the reserves from drillholes, strata polylines, and pit/channel samples by first creating a block model. This block model will not be saved.

The Geologic Model and Mining Model options will calculate the reserves from pre-calculated grid files stored in a .pre or .mmd file. It is highly recommended that you use either a Geologic Model or Mining Model for calculating reserves, as the other options will need to generate grids on-the-fly every time the command is run. Using a Geologic/Mining Model will greatly increase calculation time and reproducibility of the results.

The only difference between a Geologic Model and a Mining Model is the file extension (however, a Mining Model must be based on elevation grids whereas a Geologic Model may be based on elevations or thickness grids). The distinction is made purely for organizational purposes in that the Geologic Model can be used to represent the true geology while the Mining Model can be used to represent the strata as they will be mined. For example, some strata layers may need to be composited in the Mining Model. For more information on creating Geologic/Mining Models, see the sections of the help manual corresponding to the Define Geologic Model, Define Mining Model, and Geologic to Mining Model commands.

Here it is important to note that this command will temporarily extrapolate grid files in the Geologic/Mining Model. This replaces all null values with the nearest known data point. These changes are not saved to the .grd file itself however. When grids are extrapolated, you will receive a notification of which grids were temporarily modified for the calculation. This can increase the amount of time required to complete the calculation, and for this reason, it is recommended that you manually extrapolate grid files using either Grid File Utilities, or the Extrapolate function in Define Geologic Model. When the program automatically extrapolates surface, it will hold the values at the edge of the grid and extrapolate horizontally. An example of a surface file with null values, and the resulting grid that

would be temporarily created for this calculation is shown below.

Top Constraint: This option sets the upper limit for the reserve calculation. All calculations will be based on a layering of strata grids. This upper limit will omit any strata information that may exist above it. Four options are available for use:

The Screen option will prompt you for 3D entities (usually elevation contours) to create a grid file. This grid file will not be saved, however.

The Model option will use the surface file specified in the Geologic/Mining Model.

The Surface File option will prompt you for an existing grid or TIN file.

The Elevation option will use a flat elevation as set in the **Top Elev** field.

Bottom Constraint: This option sets the lower limit for the reserve calculation. This lower limit will omit any strata information that may exist below it. Four options are available for use:

The Strata Model option will use the bottom-most elevation grid file specified in the Geologic/Mining Model.

The Surface File option will prompt you for an existing grid or TIN file. This is most commonly used when calculating the reserves within a pit shell.

The Elevation option will use a flat elevation as set in the **Bottom Elev** field.

The Elevation+Surface option will allow you to define both an elevation and a surface file to limit the calculation. For example, you can constraint the calculation with a pit shell surface, but also with a bench elevation.

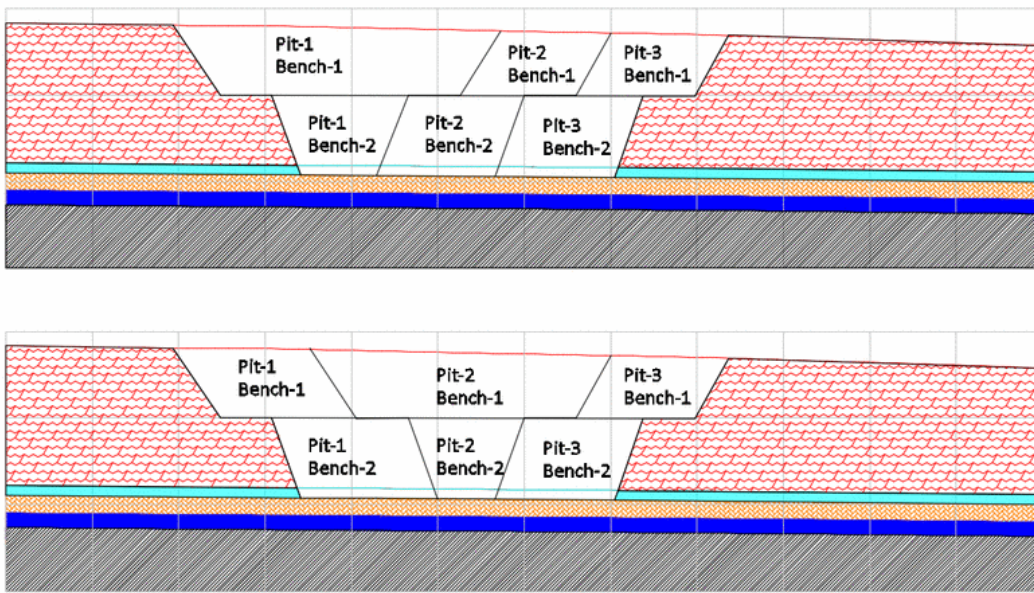

Top Elev and Bottom Elev: These fields will set the elevation limits for the reserve calculation.

Whenever selecting the upper and lower limits of the reserve calculation, it is important to visualize the options you are selecting. The below illustrations show some of the ways that the upper and lower limits can be used to constrain the calculation.

Use Auto-Run: This option will allow you to divide the reserves into benches according to a Surface Mine Reserves Autorun file (.sma file). Dividing reserves into separate benches is useful when using the Store Results in Pits option as it allows for more selective mining with the Surface Equipment Timing command. If this option is not used, results can still be stored in pits, but all data will be stored on a single bench. For more information, see the section of the help manual corresponding to the Define Surface Mine Auto-Run command.

Use Surface History: This option will calculate reserves according to a Surface History file (.gsq file). This file is essentially a list of grid or TIN files and can be created manually or with the Design Bench Pit command. When this option is used, reserves will be divided according to the volumes between the surface files (i.e. the first volume is calculated between the first and second surface file, the second volume is calculated between the second and third surface file, etc.). The below images show an example of how the reserves will be divided into three pits and two benches using a surface history file. The ordering of the surfaces in the Surface History file will have a significant impact on the calculations as it determines the cut angles to be used. For example, the first image shown below cuts out Pit 1 first, whereas the second image cuts out Pit 2 first. For more information on the Surface History file, see the section of the help manual corresponding to the View 3D Surface History command.

Merge Bench Quantities Percent: This option is only available when using a Surface History File. When active, this value is used as a tolerance for reporting volumes. For example, if this value is set to 1%, any volumes less than 1% of the total bench volume will be merged into the previous bench.

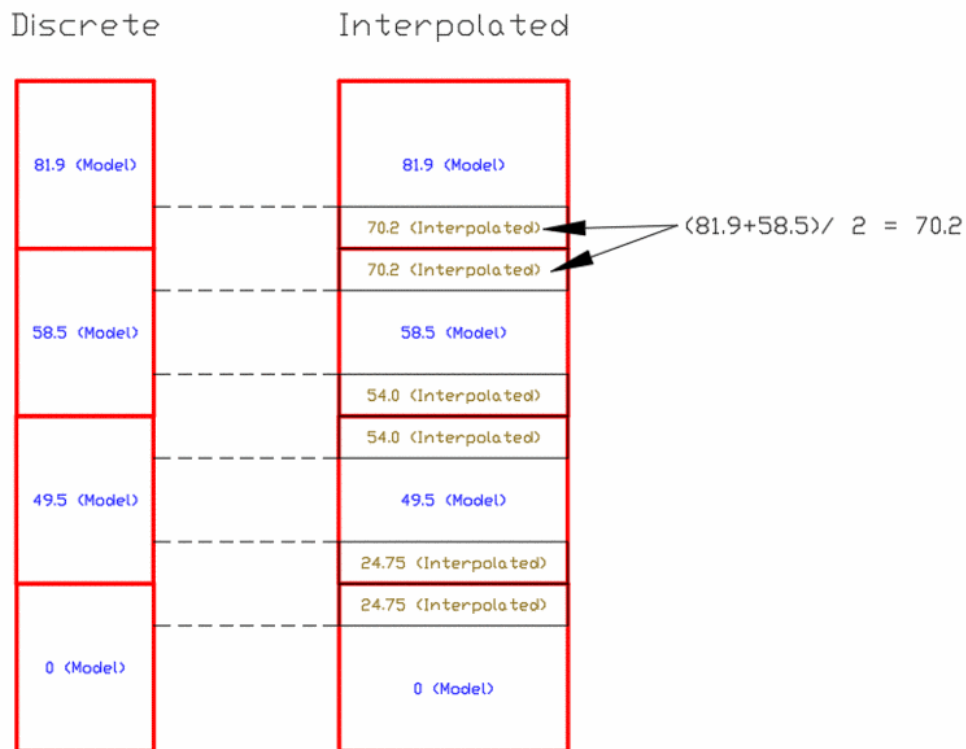

Strata to Include: This option determines which strata layers will be calculated for the Report. If the Selected option is chosen, you will be prompted with a dialog for which strata to include. If you are not using the Auto-Run option, the Selected option can be useful for storing specific strata layers onto a bench.

Grid Subdivision Precision: This option controls how grid cells will be subdivided along angled borders for more precise calculations. For the most accurate results, use the High option. Using the Low option will decrease accuracy in exchange for improved calculation time. For grid volume calculations, the program subdivides grid cells that cross a boundary. This setting controls how many times the cell is subdivided. Subdividing more increases the volume accuracy but takes longer. The default for this setting is High. It only makes sense to set it to Low when you're in a hurry and you've got a huge model and a lots of pits. Otherwise, the routine should be fast anyway that you might as well use High and get full precision.

Calculate Strata Qualities: This option controls if strata qualities will be calculated. These are the user defined attributes such as BTU, Ash, Moisture, etc. Non-user defined attributes such as thickness, area, etc. will always be calculated. When qualities are merged for reporting, by default they will be weight averaged according to the strata volume and density. Here it is important to note that the weight averaging of attributes will not account for null values. For example, if Strata A has a Moisture attribute of 0.3, but Strata B does not have a Moisture attribute defined, then the combined Moisture content for the two stratum will be 0.3. To properly weight attributes, it is necessary to define an attribute value for each strata. Besides reporting the averaged quality, the program also reports the minimum and maximum quality values. When qualities have not been defined for all strata, you may find the Fixed Non-Key Qualities option useful.

Breakout Quantities by Attributes: This option can only be used when a .blk file is used (either generated on-the-fly from drillholes or when it is stored in a Geologic/Mining Model). When enabled, you will be prompted for a Grade Parameter File (.gpf file) which defines the various grades of the material. This option will report the quantities of material according to this file. For example, if the .gpf file relating to a limestone project defines Grade A material as having 90-100% Calcium, Grade B as having 80-90% Calcium, etc., then the report will calculate the tonnage, volume, and average Calcium content for each grade individually.

The Off option will not breakout quantities by attribute. You will not be prompted for a .gpf file with this option. The Interpolated option will actually interpolate block values between data points, thus allowing for variation of grade within each block. The Discrete option will treat block values as discrete for the entire block. This prevents any variation of grade within individual blocks. A comparison of the Discrete and Interpolated options is shown below. Notice that in the Discrete method, each red block is homogeneous. There is no variation of quality within the block. For the interpolated option, however, each red block is subdivided. Half of the block retains the modeled value, while the upper and lower fourth of each block is a calculated average.

Fixed Non-Key Qualities: This option will prompt you to enter a fixed value for each strata attribute found in the drillholes or in the Geologic/Mining Model. These values will be used for all non-key strata. This option is useful for properly weighting attributes due to dilution with non-key material. For example if you have defined an attribute for Sulfur content in your key strata, but not your non-key strata, this option will allow you to quickly assign a Sulfur value to the non-key material for attribute weighting. Using this option for proper attribute weighting is faster than modifying the drillholes or Geologic/Mining Model with these attributes. Here it is important to note that if a non-key strata attribute has been defined in the Geologic/Mining Model, this option will overwrite that value.

Use Named Pit Areas: This option will restrict the calculation to use only closed polylines that have been tagged as pits. Polylines may be tagged as pits using one of the various pit tagging commands in the Surface Mining Module > Boundary Pulldown Menu. These commands include Name Pit Polylines, Assign Pit Names By Layer, Pit by Interior Point, Pit by Interior Text, Pit Matrix Layout, Pit Layout by Advance, Pit Layout by Width, and Pit Layout by Rate. When this option is used, reserves will be split into their respective pits. When this option is not used, you may still use pit polylines (or other, untagged polylines) as inclusion areas, but the reserves will not be divided by pit.

Store Results in Pits: This option is only available when the Use Named Pit Areas option is used. This option will store the total non-key volume, key volume, key tons and all quality attributes in the pit polyline as extended entity data. These quantities and attributes can then be used by the Surface Equipment Timing command. Besides the

quantity and attribute values, a Bench number is also stored with the quantities for sequencing each bench. Here it is useful to note that all the material stored on a single bench must be mined together. If two types of material are to be mined separately, they should be placed on separate benches with the Use Auto-Run option or by repeating the Surface Mine Reserves command and incrementing the Bench Number while selecting specific strata.

Rather than storing discrete values in the pits, the non-key volume, key volume, and key tonnage may be stored in the pits as grid files. If the Output Thickness Grids option on the Output tab is used, these three values will be stored in the pits as grids rather than discrete values. Note that you may also store grids in the pits with the Surface Mining Module > Boundary Pulldown Menu > Pit Timing Quantities > Assign Timing Grids command. When this command is run, the grids will overwrite the discrete values.

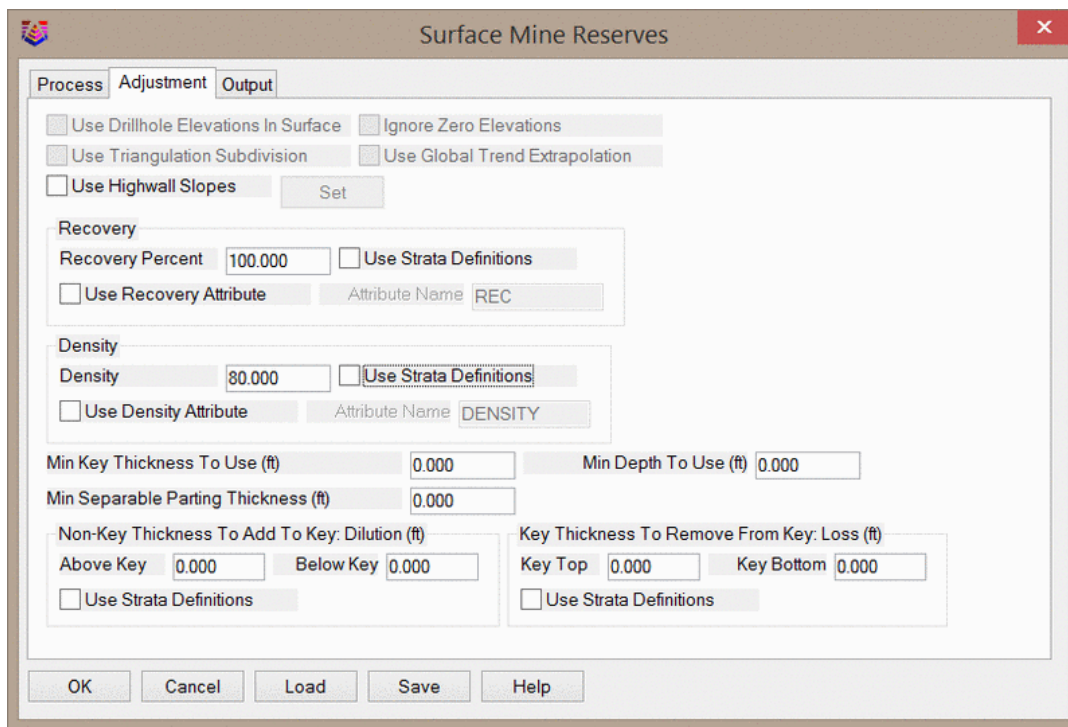

Bench #: This value will set the bench number for storing results in pit polylines. Note that any reserves calculated will be stored together on this bench number. Note that benches must be integer values - alphanumeric bench numbers are not supported.

Adjust Pits Manager: This option will allow you to adjust the pit boundaries after the calculation is complete, then reprocess to check the updated results. This can be useful when trying to target a specific volume/tonnage to store in a pit. When this option is enabled, the below Pits Manager dialog will be docked to the bottom of the screen. You can then modify the pit polylines with standard CAD commands (move, grip edit, etc.). Clicking the Process button will then rerun the calculation and display the results. Clicking the Report button will send the results to the Report Formatter. Clicking the Exit button will close the Pits Manager without generating a report.

Process	Pit	Strata	Pit Area S.F.	Total C.Y.	COAL Tons	BTU
Report	Pit 1	C1_TOP	410462.8	1242447.5		
	Pit 1	C1_KEY	410462.8	101102.0	120109.2	12007.713
	Pit 1	C2_TOP	410462.8	325767.2		
	Pit 1	C2_KEY	410462.8	91401.2	108584.6	11492.317
	Pit 2	C1_TOP	233272.6	961928.5		

Use Property Boundaries: This option will divide the reserves according to Property Boundaries, which are closed polylines that have been tagged using the Assign Property Names or Property Names by Text command (available in Surface Mining Module > Boundary Pulldown Menu and Underground Mining Module > Property Pulldown Menu). As long as an inclusion polyline is selected, these property boundaries will be automatically selected when the calculation is performed, even if the property boundaries are on a frozen layer. If an area lies outside of a tagged property boundary, the reported field for Owner will simply say "Unknown" rather than using one of the tagged owner names. It is important to note that "island" property boundaries are supported - for example, if Property A is completely inside of Property B, the program will not double-count the volume/tonnage in Property A.

Use Reserve Classification: This option will divide the reserves according to a Reserve Classification file (.rsv file) into Measured, Indicated, Inferred, and Hypothetical categories. This file can be generated with the Geology Module > Grids Pulldown Menu > Reserve Classification command. When this option is used, the Report Formatter will include a new attribute called "Reserve Class."

Use Drillhole Elevations in Surface: When calculating the reserves directly from drillholes, this option determines if the drillhole collar elevations will be used to generate the topographic surface.

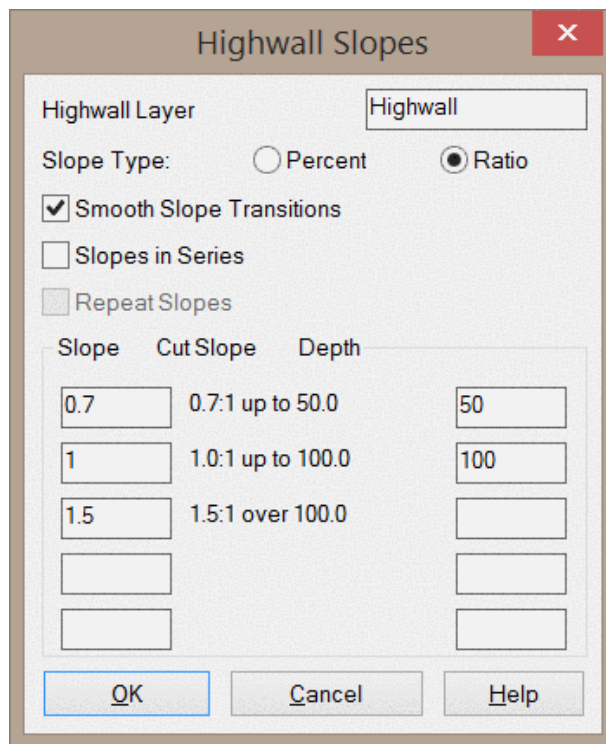

Ignore Zero Elevations: When calculating reserves directly from drillholes, this option will determine if entities at zero elevation will be used to generate the topographic surface. Generally, this option is useful in that it allows you to broadly select entities in the drawing without manually filtering out zero elevation entities.

Use Triangulation Subdivision: This option only applies when using the Triangulation or Polynomial modeling methods to calculate reserves directly from drillholes. When enabled, this option will subdivide triangles to create smoother surfaces.

Use Global Trend Extrapolation: This option only applies when using the Triangulation or Polynomial modeling methods to calculate reserves directly from drillholes. When enabled, this option finds the average slope and direction of the interpolated data and applies this slope to extrapolate to the full extents of the grid.

Use Highwall Slopes: This option will apply highwall slopes to the inclusion polylines to simulate a more realistically shaped pit. This option is limited in that the inclusion polylines selected for reserve calculation must represent the toe of the highwall. This option will project highwalls upwards until it reaches the topography. This option does not account for benches, and so more complex calculations will need to be made using a Surface History File generated from the Design Bench Pit command.

Set (Slopes): This button will open the dialog shown below, which controls the highwall slopes to use.

Highwall Layer: This field sets the layer to use for the highwall linework. This linework will be drawn as a 3D polyline where the highwall projection meets the surface.

Slope Type: This option controls if the highwall slope is expressed as a percent or as a ratio.

Smooth Slope Transitions: This option will gradually transition between slope angles as depth increases around the pit. In the above example, the pit will have an overall slope ratio of 1.0 where the cut depth is between 50 and 100', and a slope ratio of 1.5 for cut depths greater than 100'. In areas where the cut depth is exactly 100', this option will smoothly transition from a slope ratio of 1.0 to 1.5 rather than abruptly changing the slope angle.

Slope in Series: This option will use all slope angles specified in the dialog. Using the above dialog as an example, the cut angle from 0-50 feet (or meters) will always be a 0.7 ratio. After this first 50 feet (or meters) of cut, the slope will be a 1.0 ratio for the next 50 feet (or meters). Any remaining cut will use a 1.5 ratio.

Repeat Slopes: This option will repeat the slopes with specified depths until the projection meets the surface topography. In the above example, the program will repeat cut ratios of 0.7 and 1.0 until it reaches the surface. Since no cut depth has been specified for the 1.5 cut ratio, this slope angle will not be used with this option.

Recovery Percent: This value will set the overall recovery percent for key strata. This is applied after adjustments for non-key dilution and key loss. The volume of material that is not recovered will be reported as non-key material.

Use Strata Definitions: This option will use the recovery percent specified in the current Strata Definition file. This allows you to set a recovery for each strata individually.

Use Recovery Attribute: This option will set the recovery percent according to an attribute defined in the drillholes or in the Geologic/Mining Model. This allows you to use a grid file to set the recovery percent, thus allowing the recovery of each strata to vary.

Attribute Name: This field sets the recovery attribute name to search for in the drillholes or Geologic/Mining Model. This attribute name must exactly match the attribute in the drillholes/model, or else the recovery percent will not be applied.

Density: This value sets the density to use for all strata. Density is always expressed in lbs/ft³ or kg/m³.

Use Strata Definitions: This option will use the density specified in the current Strata Definition file. This allows you to set a density for each strata individually.

Use Density Attribute: This option will set the density according to an attribute in the drillholes or in the Geologic/Mining Model. This allows you to use a grid file to set the density, thus allowing for a varying density within each individual strata.

Attribute Name: This field sets the attribute name to use for density in the drillholes or Geologic/Mining Model. This attribute name must exactly match the attribute in the drillholes/model, or else the density will not be applied.

Min Key Thickness to Use: This value sets a minimum key thickness for reporting. Any areas where the key strata is less thick than this value, the strata will be reported as non-key discard material.

Min Depth to Use: This value sets a minimum depth of cover for key strata for reporting. Any areas of key strata that have less than the specified thickness of cover will be reported as non-key discard material. An example use of this option is accounting for oxidized coal that is (or is close to) outcropping.

Min Separable Parting Thickness: This value will be used as a tolerance for calculating volume of non-key material between key strata based on thickness. For example, if this value is set to 0.5, any non-key material sandwiched between key strata that is less than 0.5 feet (or meters) thick will be reported as key material. Areas where the non-key strata is greater than 0.5 thick will not be affected.

Non-Key Thickness To Add To Key (Dilution): Above Key/Below Key: These values set the amount of non-key thickness above/below each key strata that will be mined with the key strata. This diluted non-key material will not be mixed with the key strata, but will instead be reported as another key strata layer. The final report, however, can be formatted to account for the dilution of strata qualities. Note that dilution will be accounted for determining the Stripping Ratio in the final report and in grid/contour output.

Use Strata Definitions: This option will use the Dilution values set in the Strata Definition File. This allows you to set the Dilution for each strata individually.

Key Thickness To Remove From Key (Loss): Above Key/Below Key: These values specify the amount of key thickness above/below the key strata that will be subtracted from the key. This amount will be subtracted from the key quantities and reported as non-key material. Note that loss will be accounted for determining the Stripping Ratio in the final report and in grid/contour output.

Use Strata Definitions: This option will use the Loss values set in the Strata Definition File. This allows you to set the Loss for each strata individually.

Output Elevation Grids: This option will create grid files for the bottom elevation of each strata. Each grid will need to be named separately, and so it is recommended to instead use the Strata Grids Autorun to make these grids quickly.

Output Thickness Grids: This option will create composite grid files for the total key thickness, non-key thickness, and key tonnage (expressed in tons/sq ft or tonnes/sq m). Each grid file will need to be named separately. Note that when the option to Store Results in Pits is used, these grids will be referenced in the pit polylines. When this option is used, you will also be prompted to Divide Bench by Thickness. This division will create three more grid files that represent the divided thickness.

Output Volume Solids: This option will create solids of the mined bench according to the pit names. These solids will be automatically saved in a PIT_MODEL folder as .mdl files. This PIT_MODEL folder will be automatically created in the current project folder.

Report Format: This option controls the format of the report.

The One Row per Strata option will report each strata layer on a separate row. This default option is the most commonly used report format.

The All Strata on Same Row option will report all strata layers on a single row. This creates many extra columns for the report, but allows for easier comparison of pit volumes.

The Group Key/Non-Key Pairs option will place overburden strata on the same row as the key strata. This option searches for similar naming in the strata names. For example, the strata COAL_KEY and COAL_OB will be grouped together due to the similarity of the strata names.

Output Spoil File: This option allows you to create a Spoil Source File (.spo file) for use with the Spoil Placement Timing command. This file includes the volume and centroid location of waste material to be placed in spoil piles.

The Off option will not create a Spoil Source File.

The Non-Key Only will only include non-key strata in the Spoil Source File.

The All Strata option will include all strata in the Spoil Source File.

Strip Ratio Output: This option allows you to output stripping ratio as contours or a grid file. The units of stripping ratio will default to $(\text{yd}^3 \text{ waste})/(\text{ton key})$ or $(\text{m}^3 \text{ waste})/(\text{tonne key})$, but different units may be selected in Carlson Configure.

The None option will not output the stripping ratio as contours or a grid file. Note that when this option is used, the stripping ratio will still be calculated in the final report.

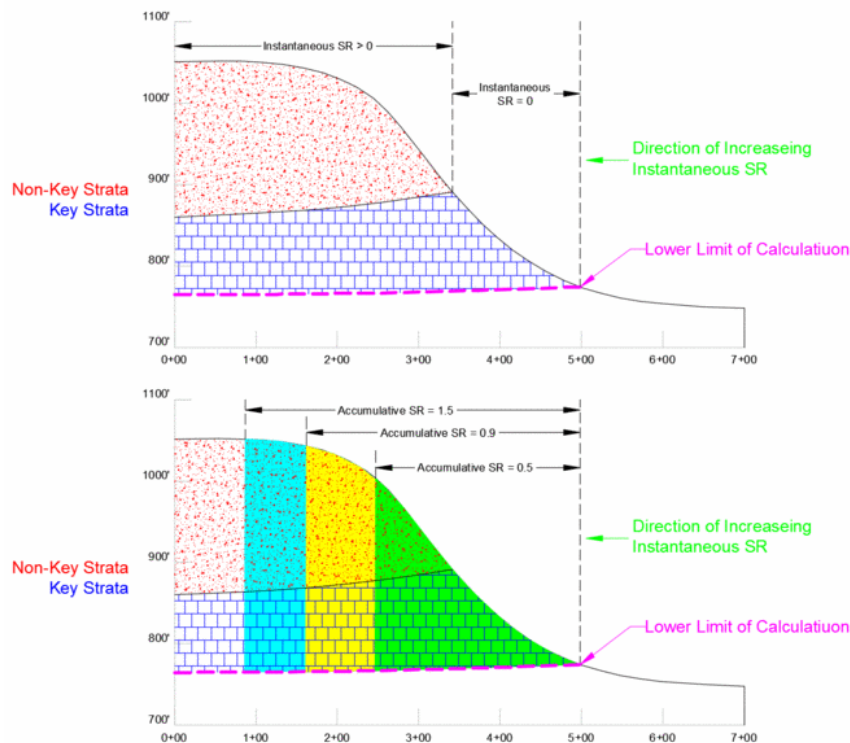

The Draw Contours option will output contour lines of the stripping ratio. This option will use settings similar to those used in the Contour from Grid File command.

The Grid File option will create a grid file that represents the stripping ratio.

Type of Strip Ratio Contours/Grid: This option controls how the stripping ratio is expressed when it is output to contours or a grid file

The Instantaneous option will calculate the stripping ratio for each individual grid node. This stripping ratio will account for all non-key and all key material within the calculation limits - any non-key material existing below the last key strata will also be used for the calculation of the stripping ratio. When the reserves are divided into benches, the stripping ratio will be reported by-bench.

The Accumulative option is intended for use in situations where the key strata outcrops and is relatively flat. The below images illustrate the way this form of stripping ratio is calculated based on direction. The program will first determine the lowest Instantaneous stripping ratio in the calculation area. The program will then determine in which direction the stripping ratio increases the least. If mining were to start in the area of lowest stripping ratio and then move one grid node in the direction of least increasing stripping ratio, the Accumulative stripping ratio would be based on all key and non-key strata between the start point and the next grid node location. In other words, imagine that mining starts at the outcrop of the key material. As mining progresses into the hillside, the accumulative stripping ratio is the overall stripping ratio of all material mined up to the current position.

There are some situations in which a stripping ratio cannot be calculated, as shown in the below illustration.

For areas in which neither waste or key material are included, the stripping ratio will be undefined - if a stripping ratio grid is created, it will be null in this area.

For areas in which only waste material is included, the stripping ratio will also be undefined- if a stripping ratio grid is created, it will be null in this area.

For areas in which no waste material is included, the stripping ratio will be zero.

For areas in which waste material is included, but only a very small portion of key material is included, the stripping ratio can approach an undefined value, which may appear as spikes in the stripping ratio grid file. This is normal for areas with a very small amount of key material. However, the stripping ratio output grid will not exceed a value of 1000. Spikes in the stripping ratio grid can be further filtered with Grid File Utilities.

The Report Formatter displays all information calculated with this command, as shown below. For general information on using the Report Formatter, see the corresponding of the help manual.

Here it is important to note that when a parent seam has been configured to split into two child seams according to the strata definition file, the program will automatically report the splits. For example, if seam A splits into B and C, the program will report tonnage for seam A where it exists as a parent as well as seams B and C where they exist as child seams.

As an additional means of dividing reserves, Cut Sets defined by the GIS Module > GIS Tools Pulldown Menu > Polygon Processor command will be considered when the reserves are calculated. If a Cut Set has been defined for wetland areas with a name of "Wetlands", an additional reporting field will be available in the report format called PP_Wetland. This will show the amount of strata inside the wetland area. Any strata outside the wetland area will be reported separately.

The report formatter will include two forms of stripping ratio: "Strip Ratio" and "Strip Ratio Accumulative". The latter term should not be confused with the Accumulative Stripping Ratio for the stripping ratio grid/contour output. Consider four strata layers: A, B, C, and D where stratum A and C are non-key while stratum B and D are key. When these four stratum are calculated on a single bench, the report will include a "Strip Ratio" and "Strip Ratio Accumulative" for stratum B and D. Both attributes reported for strata B report the stripping ratio as if only strata A and B were mined. The "Strip Ratio" for strata D will report the stripping ratio as if only strata C and D were mined. The "Strip Ratio Accumulative" reported for strata D will report the stripping ratio as if all strata above it were also mined (stratum A and B will be included). The below image is an illustration of this concept.

Miscellaneous note on block models: When the program detects a Geologic Model containing one or more Block Models (.blk files), the thickness of the strata containing the block model will be compared to the thickness of the block model itself. Recall that each strata in a Geologic Model is defined by the difference between two elevation grids (or a thickness grid). Also, a block model will be defined with upper and lower limits (also two elevation grids). If the strata thickness is greater than the block model thickness, the program will extend the block model thickness an extra half-block height on the top and bottom of the model.

Carlson block models will always have top/bottom layers of blocks with half the height of other blocks (for more information on this, see the section of the help manual corresponding to the Make Block Model command). To account for the full block size, surface mine reserves applies the above logic. The idea is that whenever the true strata thickness is thicker than the block model thickness, the extra top/bottom block height needs to be accounted for.

Two types of thickness values can be reported for each strata: Thick Geologic and Thick Mined. Thick Geologic is the full Geologic Thickness, as if no constraints were applied to the model. Thick Mined, however, reports the thickness with all constraints applied (such as a pit shell that only cuts through a portion of the strata). When reporting Pit Volumes, it is recommended to report Thick Mined, as it will reflect the thickness extracted only within the pit shell. It is worth mentioning that when average thickness is calculated, an area-based weight is applied rather than a volume-based weighting.

Two types of areas are included in the report: Area and Pit Area. The Pit Area is the area of the inclusion line used for the report. The Area, however, is not a measurement, but rather a calculation based on the volume and the full Geologic Thickness. The Area is calculated as Volume divided by Thick Geologic.

Prompts

Surface Mine Reserves dialog

Select surface entities and at least 3 drillholes. (Unless using a Geologic Model File PRE.)

Select objects: *select the drillhole symbols and surface entities.* Surface entities can include points, lines, and polylines.

Select the Inclusion perimeter polylines and ENTER for none:

Select objects: *select the polylines or named pit polylines.* The area within these polylines will be included in the calculations. They must be closed polylines.

Select the Exclusion perimeter polylines and ENTER for none:

Select objects: *select the polylines.* The area within these polylines will be excluded from the calculations. They must be closed polylines.

Keyboard Command: mtntop

Define Surface Mine Auto-Run

This command is the setup routine to create the autorun file for batch processing of multiple benches with one run of the Surface Mine Reserves command. Without this predefined autorun file, then the Surface Mine Reserves command needs to be run separately for each bench. With this Autorun file, all benches are predefined by the Geologic Model file, a top and bottom Grid or TIN, or an Elevation.

The steps necessary to create or edit the file are detailed below. Choosing Add or Edit will bring up the Edit Auto-Run window. This is where the Bench# is set. The Strata to Process can either be set to one, multiple, or all to define the benches. If coming out of the Geologic Model file, then the elevation grids defined in there will define the benches here. Alternately, the benches can be other grid or TIN surfaces, or flat elevations, and they will be intersected by the seams that appear in the Geologic Model file.

To utilize this Autorun file, turn on the option in the Surface Mine Reserves window for "Use Auto-Run" as circled below. Once this is on, the program will prompt to select the *.SMA file this command created.

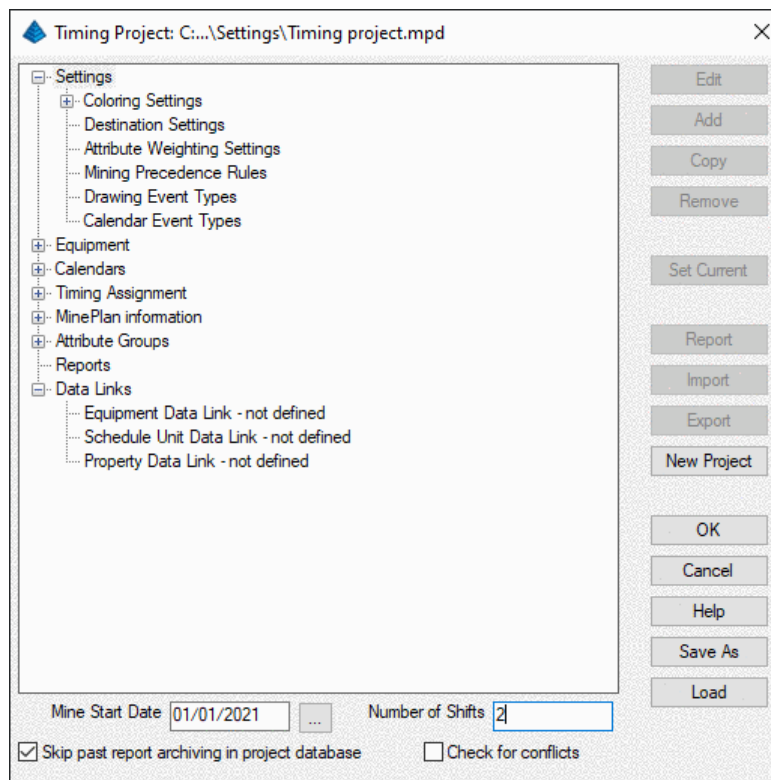

Pull down Menu Location: StrataCalc

Keyboard Command: mntop_atorun

Prerequisite: Grids and PRE Calculated Grids file, named pits

Timing Project Manager

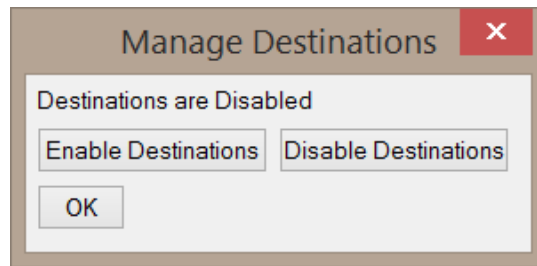

The Timing Project Manager (Surface Project Manager or Underground Project Manager) applies to both surface and underground mining for file organization and selection. All files and most settings and configurations used in the mine scheduling are found in the manager. Each topic is described below in detail. Note that some topics listed below may refer to panels for Underground Timing or Pits for Surface Equipment Timing.

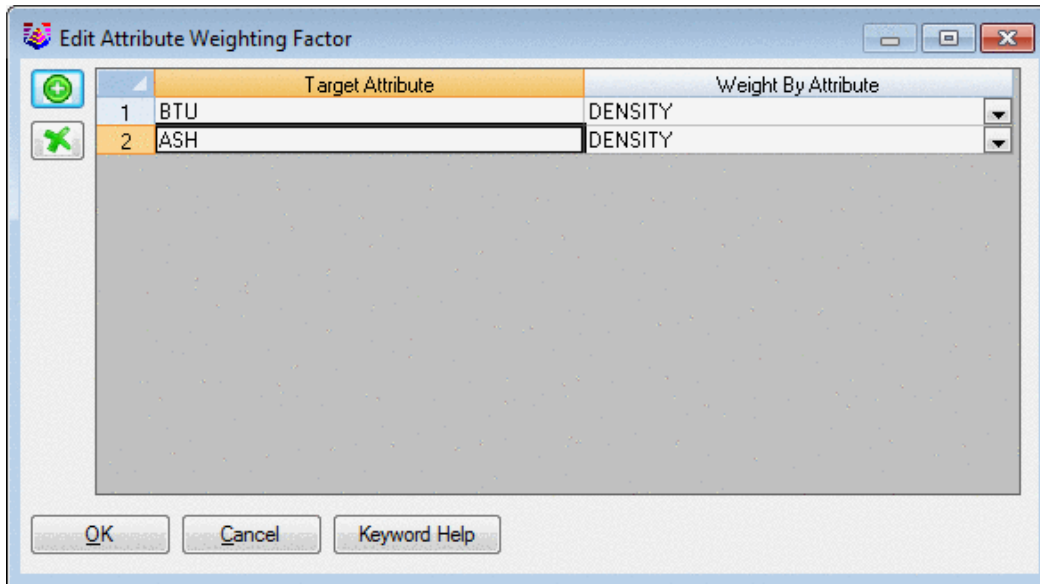

Settings

- **Coloring Settings:** These settings are from the Report Options screen from the equipment timing command. Defaults can be set here before running the actual schedule. Explanation of this dialog is found in the help documentation for Underground Timing or Surface Equipment Timing.
- **Destination Settings:** This gives the ability to assign destinations to pits, which can then be reported separately in the timing report. For example, if the material from some pits need to be sent to the waste pile while the material from other pits need to be sent to the processing plant, adding destinations attributes will provide an additional category for reporting. To assign destinations to pits, you must open the Timing Project Manager through the Surface Equipment Timing command and select pit polylines. When editing destination settings, the below dialog will appear. Clicking the **Enable Destinations** button will simply add a DESTINATION attribute to each bench in each pit polyline. This Destination can be modified manually with the Edit Pit

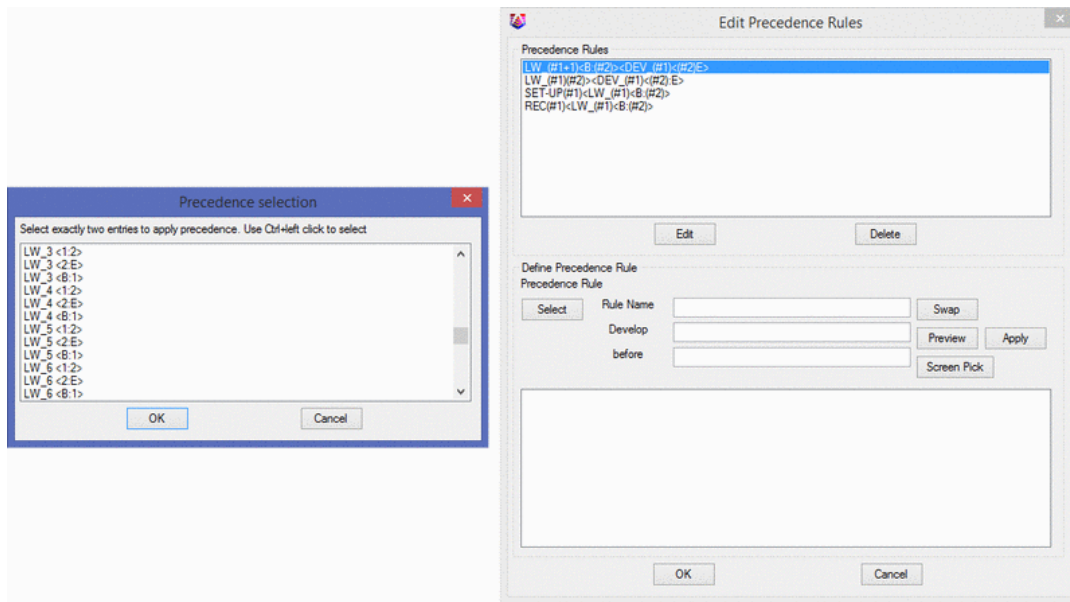

command or according to a grade parameter file via the 3D Pick Function within Surface Equipment Timing. Clicking the **Disable Destinations** button will remove this DESTINATION attribute from the pit polylines.

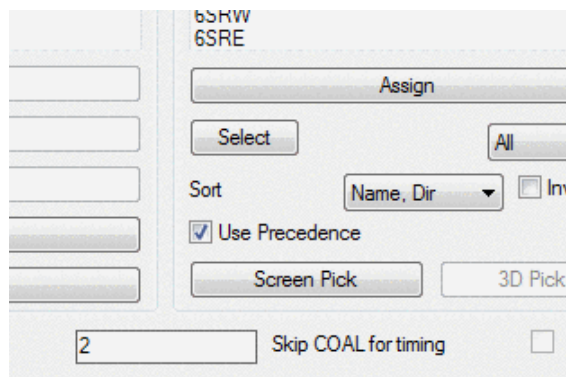

- **Attribute Weighting Settings:** This gives the ability to weight average attributes by other attributes, both calculated and internal. Add new lines with the + button. Enter in the Attribute, or pick it from the Keyword Help button. Then dropdown the Weight By Attribute. This will show up in the Report Formatter once the schedule is ran.

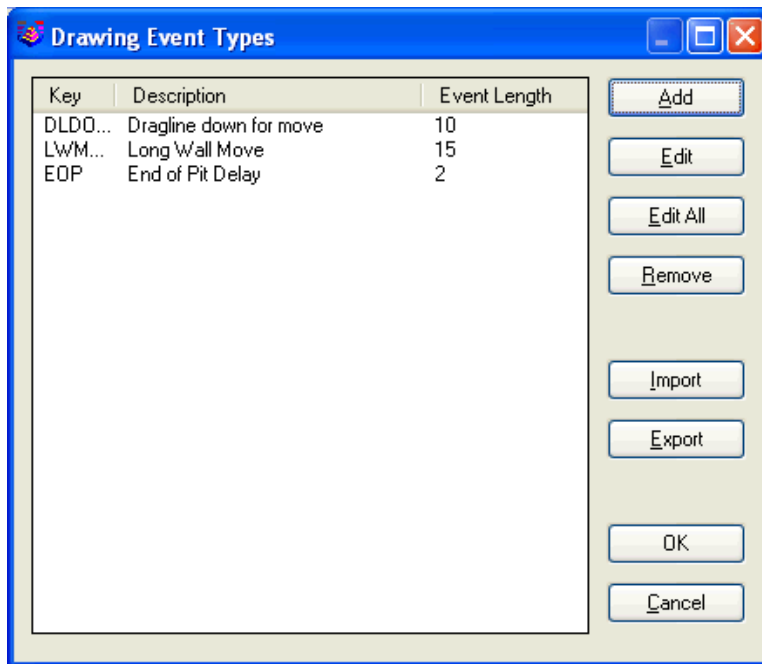

- **Mining Precedence Rules:** This allows for automatic precedence using an user-defined sequence. When using commands such as AutoPlace Panel by Text, it does not set precedence. Using this command makes sure panels do not start before they are exposed or available to be mined. Each rule is shown at the top. Start by choosing the Select button and select two entries that are compared. Then choose which one goes first, if it is wrong, use the Swap button. Give it a name (optional) and hit Apply. The Preview button will show the order in the lower window. The Screen Pick button allows for choosing precedence on a screen. When using Screen Pick start by picking on or inside of first panel polyline and then pick on or inside of second panel polyline.

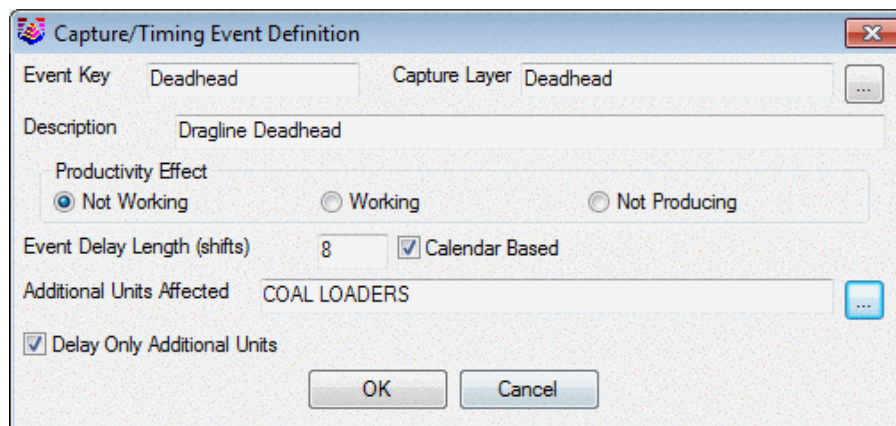

To use this precedence, turn on the Use Precedence option in the Sequence Window, as seen here and the blocks and panels will reorganize to fit the order.

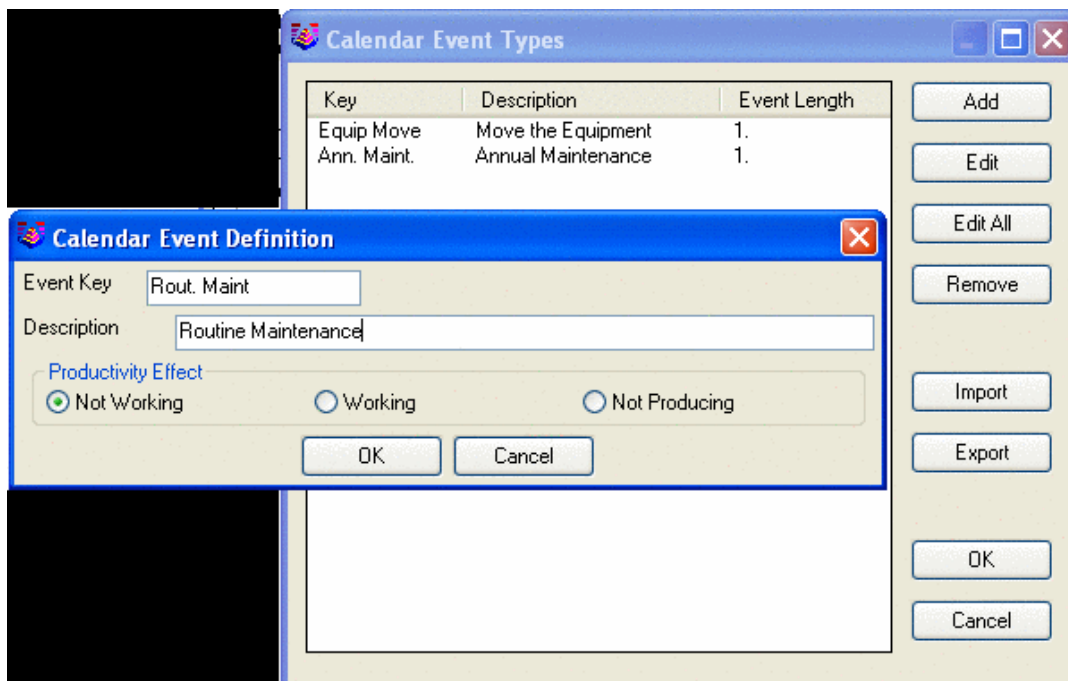

- Drawing Event Types:** Drawing events are entities in the drawing at a specific location that will be used for a marker in the schedule as an option for a delay. This event can be used to delay equipment, switch crews, move other equipment, etc. When the schedule crosses over the insertion point of the drawing event (usually text) the event will trigger the delay or effect. The text/drawing entity in the drawing should be inserted to the position where the delay will occur and in the AutoCAD layer defined in the Capture Layer window. The Event Key and description can be used in the reporting of the schedule to create additional reported items.

There are options to set the layer, give it a full description and internal event key name. The Productivity can be set to not working, working (as normal), and not producing (working, but not moving any material). The event delay length is set here by number of shifts. Calendar based will determine if the shift is off in the calendar. If the box is checked, and that shift is off in the calendar already, then it will not take off any more. If it is off, then it will apply to only the next working shift(s) for not working or producing. Additional Units can be used to also set other units off during the same period. For example, if a longwall is down due to a move, then the CM working with it can also be down for the same time. There is also an option to Delay Only Additional Units. This can be used to set one unit down, when a different unit crosses the drawing event. This allows for clever equipment delays and precedence by using different drawing events.

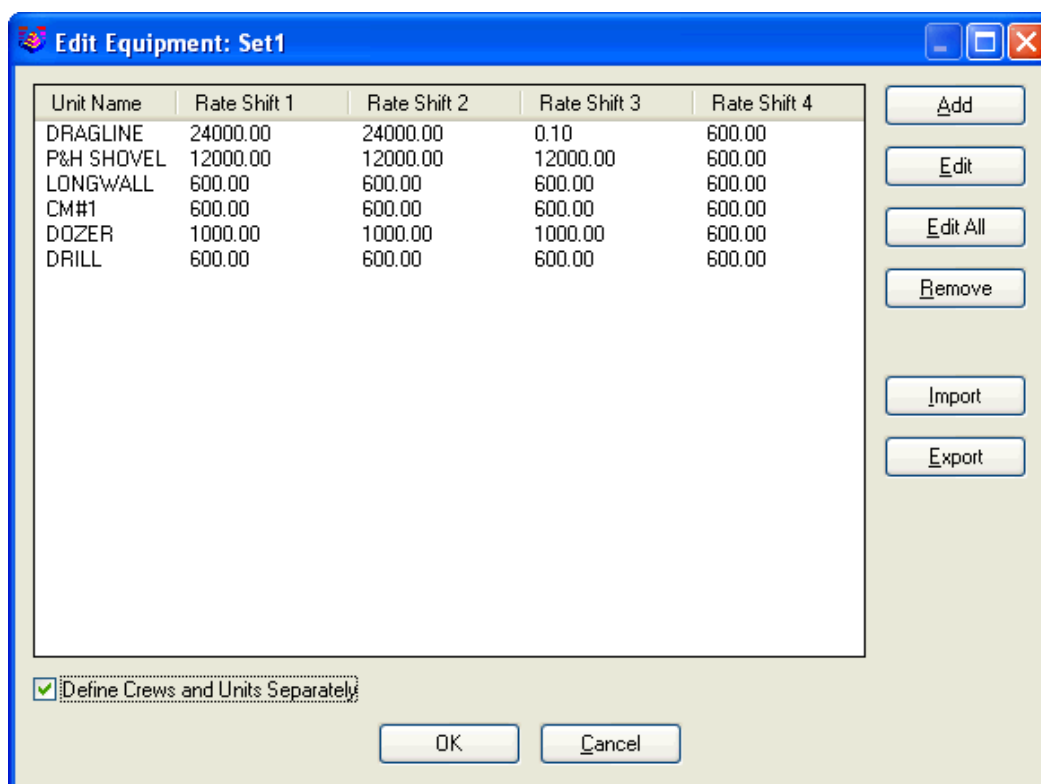

- Calendar Event Types:**Calendar events are named events that will determine equipment down time. The default event in the calendar is Manual. The other events are set under the Calendar Event Types and Calendar Event Definition. Calendar events can be any event that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working with crews, using hours, but not mining).

Equipment

- **Equipment Set:** The productivity of the unit (crew) may vary from shift to shift, up to 4 shifts a day. The number of shifts is set in the Timing window where the sequence of pits or panels is set. The average productivity rate is used for scheduling, however the production rate for the particular pit or panel may be adjusted by setting the difficulty factor or adding delays for that pit or panel. The first window is the edit equipment screen with a columnar display of equipment. Crews can be defined to work with a specific unit, or can switch from unit to unit based on the schedule.

Add and Edit will bring up the next screen for detailed entry.

The Unit of the Production value is defined by a rate unit setting. Equipment may mine either tons, tonnes, CY or CM, Distance and Linear Advance. The difference between distance and linear foot of advance settings is that latter one is a combined length of all pathways/entries mined (underground only), and distance is just distance moved, of a longwall for example.

Enter the Advance Rate/shift or the Advance Rate/hour and the other will be automatically calculated based on the Hours/shift. The Retreat Rate/shift is for Distance and Linear ft of Advance in underground equipment only. The availability value of less than 1.0 will reduce effective production rate of the equipment. 0.94 is a 94% productivity of the full shift.

Underground units may be assigned an Advance minimum and/or maximum height, so that the extra rock will have to be mined or correspondingly unmined coal will be left in the seam if the maximum miner height is less than combined coal and rock parting thicknesses. These settings affect the underground mine timing only. The maintenance settings provide the ability to schedule a delay for routine or major maintenance/repair of the equipment based on the number of shifts worked. Add in the length of the delay and the number of shifts to determine the frequency.

If operational cost per hour is specified, the total cost will appear in the production report.

The extraction (recovery) factor is used to adjust the amount of material mined from given area to account for certain technical limitations of the equipment such as inability to mine out corners, or not cleaning the top and bottom of ore. This machine will always use that recovery rate.

Under the Advanced options the variation of equipment-related Difficulty Factor with time, depth or bench number may be specified. Resulting from the advanced options, the difficulty factor is a product of coefficients calculated for given date, thickness and bench number. The final difficulty factor used in calculations is a product of location-specific and equipment-specific difficulty factor.

In the Period End Date column, the difficulty for the date is for next, later date, or last one if no later entry exists. For the thickness column the value of difficulty factor between two entries in the table is a linear approximation. The rehandle value is calculated in the same fashion and passed over to the report, not being used in calculations, but can be used in the report in equations to calculate the total amount mined. The difficulty will modify the rate, and the rehandle is reported. These are not necessarily always the same, linear factors. The Bench Specific Difficulty will be used for surface equipment mining on that bench number, and use that difficulty factor to change the rate of the equipment.

Selecting Edit All from the first screen brings up this editor where all equipment may be viewed and edited. Both the first screen and this one have the import and export buttons.

Calendars

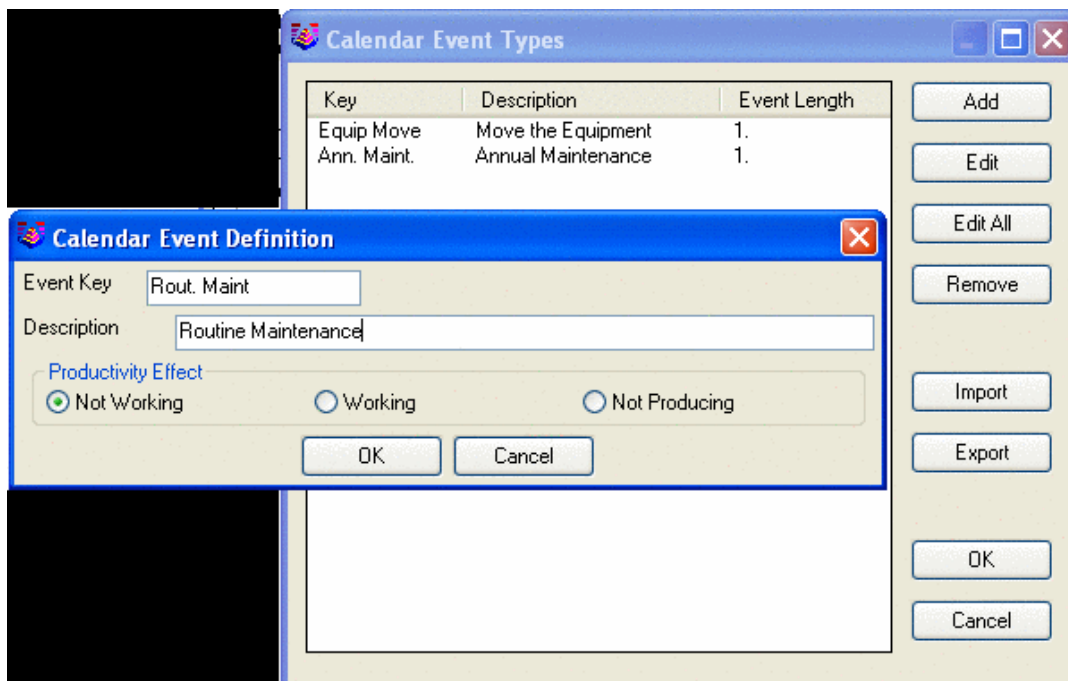

- New or Existing Calendar: Highlight the Calendar tree, and the New Calendar button is activated if no calendars are present. If some are present, the edit button will also be active for editing a calendar. If it is a new calendar, the Calendar Name box appears to enter a name.

The Equipment Calendar allows for entity production down time. By default, entities are working every day, every shift. Entities include equipment, crews, pits and panels. Days and shifts defined in this calendar as down-time are taken into account during scheduling routines. The assignment pattern is very flexible: it works for a particular crew or all crews, for a particular shift or the whole day and allows replication of the defined behavior over period of time as desired. The calendar will clean out, or purge a schedule for a crew which is no longer present.

- **Date Selection:** The calendar should initiate on the current day. Use the left/right arrows to scroll through the months and years. The current or selected day is shown in blue. The shifts appear on the right of each day. There can be up to 4 shifts. If the shift is green, then all entities are working; if it is yellow, then some are working and some are down. If the shifts are black, then all entities are down on that day and shift.
- **Event Rule Definition:** This section is where the event down times are created and edited. Apply adds the event, Reset clears it for the next assignment.
- **Event Entity Filter:** The event list contains the Equipment, Pits or Panels and Crews. The choices for filtering are All Entities, All Equipment, All Crews, All Pits/Panels, Selected (highlight the desired Entity), and Matching (highlight the Entity to find the match).
- **Shifts:** The number of shifts checked here will display next to each day.
- **Due to/Calendar Events:** The options for down time are selected here. The default event is Manual. The other events are set under the Calendar Event Types, activated by clicking the button next to the "Due to" window. Calendar events can be anything that will cause a delay, such as a routine maintenance, a long wall move, or a dragline dead head. The Productivity Effect allows the option of Not Working at all, Working as normal, or Not Producing (yet still working).

- **Repeat for/Label:** This setting is how often the down time will repeat. This can be from a day, month, year or indefinite. This event can have a name, which is entered in the Label window. The calendar will refer to this label when encountering and reporting this event.
- **Events for Date Selected/All Defined Events:** This window displays the events for the highlighted day. If the List All Rules is on, then all the Events will be displayed here, no matter which day is highlighted.
- **Rule Report:** This report displays all of the rules defined for down time within the calendar.

- **Year Report:** This reports all days for the selected calendar year.
- **Unit Report:** This reports all equipment and dates defined in the calendar. See example below.

- **SaveAs/Load:** This saves the calendar, optionally as a new name. Load will open a new one, and give the option to append to the existing, open calendar.

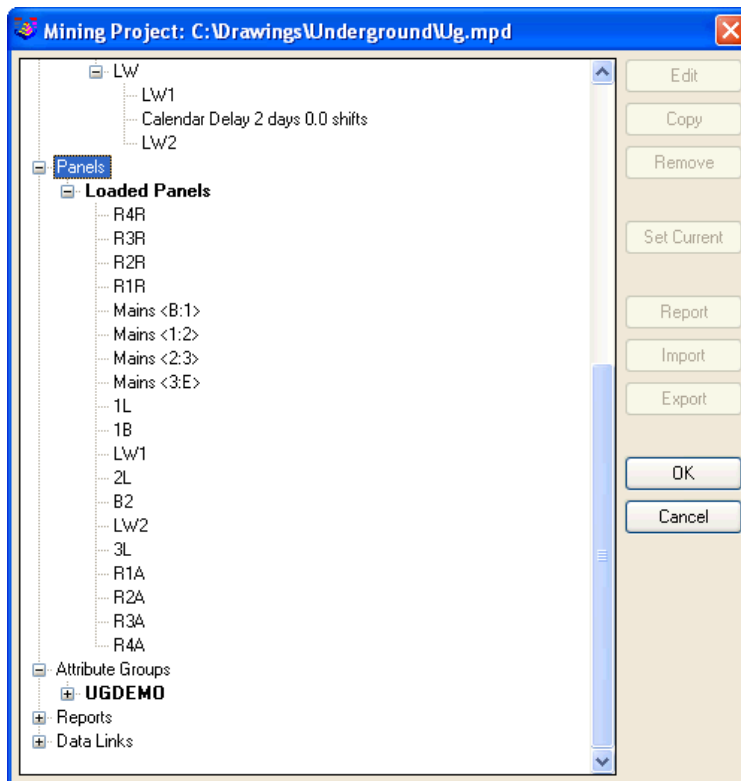

Timing Assignment

The Timing Assignment allows for setting the current sequence. The Assignment is similar to the TIM file in the timing routines. The equipment used and which panels or pits they are mining are shown. The Set Current button controls which one will be loaded and used. Shown here is both a surface mine and an underground mine example.

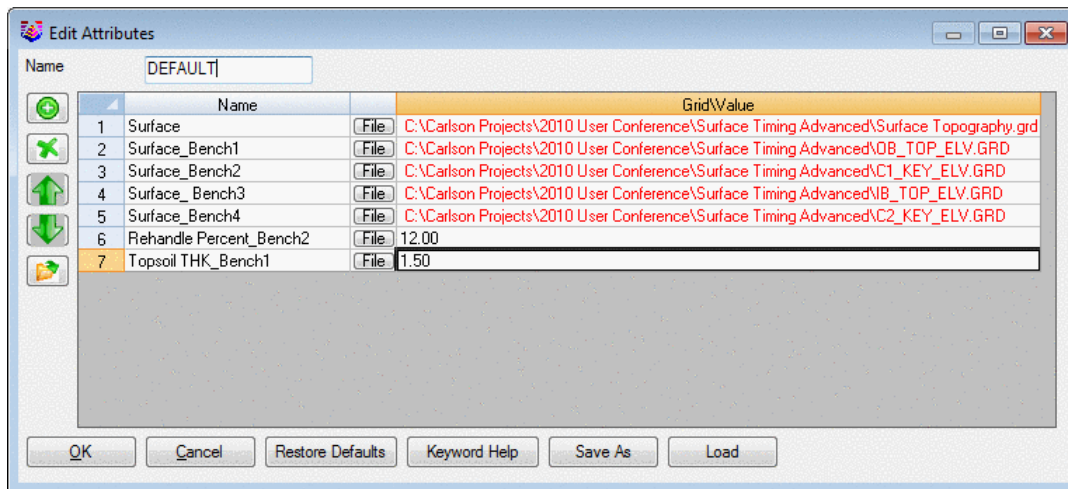

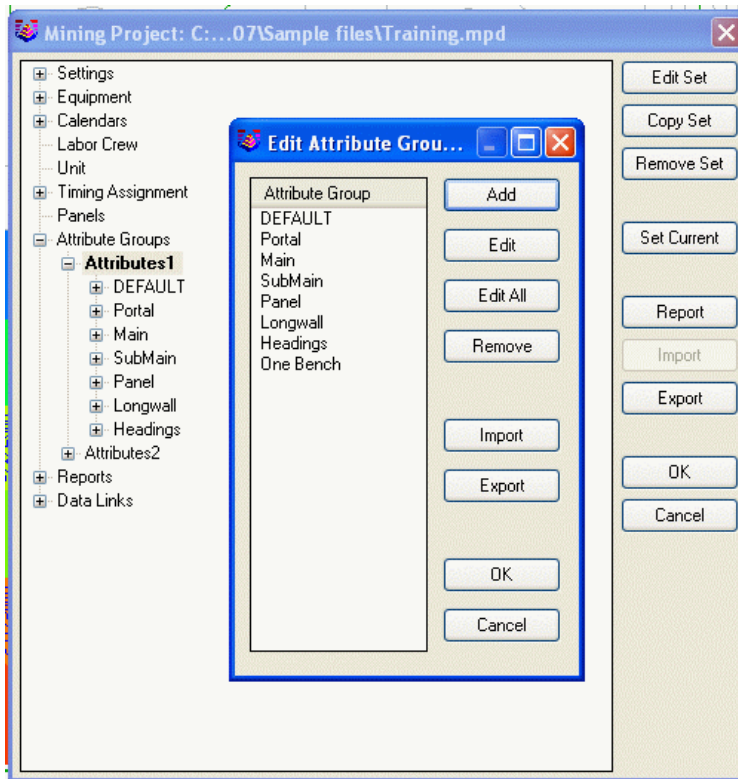

Panels

This displays the selected underground panels in the mine plan assignment. An example is shown here.

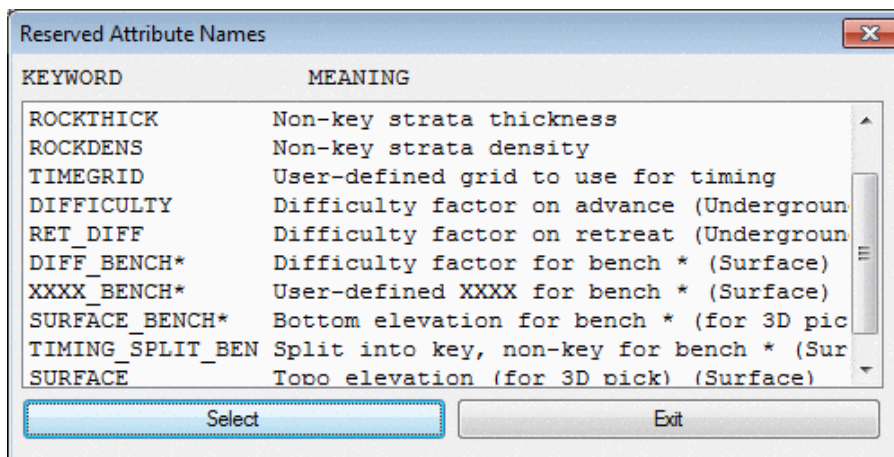

Attribute Groups

Attribute groups are Pit or Panel Attributes assigned to the pits and panels for timing. When timing the pits or panels, there are additional attributes that will be calculated and reported in addition to the Non-Key and Key quantities. If these are defaults that should be applied to all the panels or pits, then they should be entered here. Any quality values, density, or difficulty attributes can be defined here either just as a value, or as a grid file with varying values. The Reserved Attribute Names window displays the reserved words that will be recognized in the timing routines, and how they should be entered in. Selecting Keyword Help brings up the Reserved Attribute Names. If the grid name is red, as shown here, then the file cannot be found. They need to be colored black for successful use.

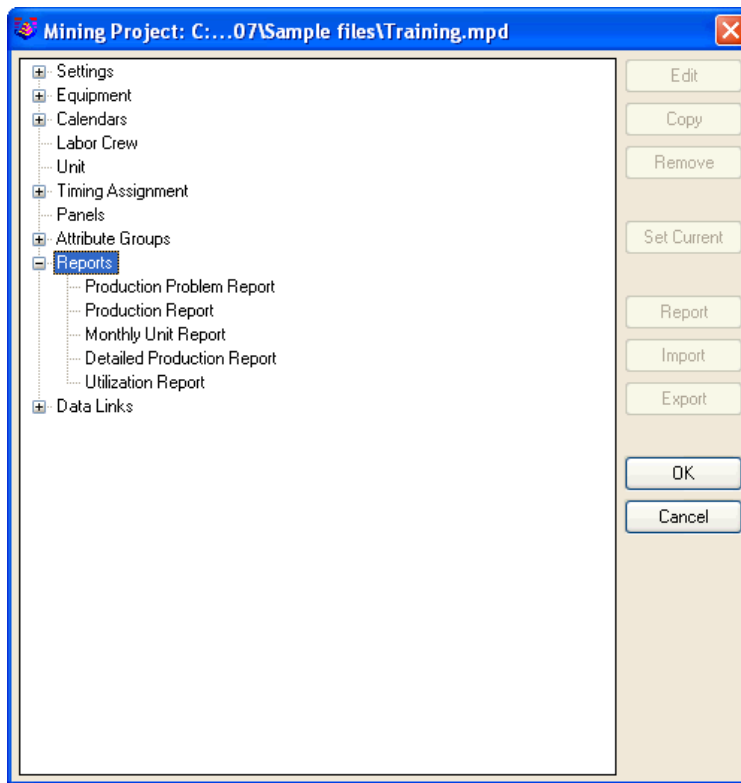

The Reserved Attribute Names are defined in a little more detail here:

- **THICKNESS:** Key strata thickness: Will report any other thickness values, this is used mostly for underground timing.
- **DENSITY:** Key strata density: Will report Key density, is used mostly in underground timing to calculate the tons. In surface timing, the tons are already in the pits.
- **ROCKTHICK:** Non-key strata thickness: Reports the Non-Key thickness mostly for underground timing.
- **ROCKDENS:** Non-key strata density: Reports the Non-Key density mostly for underground timing.
- **TIMEGRID:** User-defined grid to use for timing: This will be any additional grid the user would like to add for reporting.
- **DIFICULTY:** Difficulty factor on advance just for underground timing: This will alter the underground equipment rate on advance.
- **RET_DIFF:** Difficulty factor on retreat for underground timing: This will alter the underground equipment rate on retreat.
- **DIFF_BENCH*:** Difficulty factor for bench * for surface timing: This will speed up or slow down the equipment as it mines the specified bench. If a value is above 1, such as 1.2, then it will mine 20% slower at that point in the grid, or everywhere if it is set to value. If it is less than 1, then it will mine faster at that point. Difficulty is calculated by the equation: $DIFF=100/(100-\%reduction)$.
- **XXX_BENCH*:** This is the dominate attribute that is most widely used in this command for surface pits. All quality grids will be defined in this fashion, for each bench. The example above, BTU_BENCH1, is defined in this way. All quality parameters need to be entered as the NAME_BENCH*.
- **SURFACE:** This attribute is used for the 3D Pick window to drape the pit blocks onto the ground surface.
- **SURFACE_BENCH*:** This attribute defines the bottom elevation grid for each bench. It is used to display the blocks in the 3D Pick window properly, so the benches are represented accurately.
- **TIMING_SPLIT:** This will globally split all blocks that contain both Key and Nonkey material into two blocks that may be scheduled separately, by either the same unit, or different units. The split is into two portions - key and non-key. Entering a non-zero value will cause a split. Additionally three values are supported as pertains to precedence. Enter in one of these values in for the attribute to split it.
 1 = Both OB and KEY needs to be completed to satisfy precedence
 2 = OB portion needs to be completed to satisfy precedence
 3 = KEY portion needs to be completed to satisfy precedence
- **TIMING_SPLIT_BENCH*:** This attribute is the same as TIMING_SPLIT, but is only applied to the specified bench number.

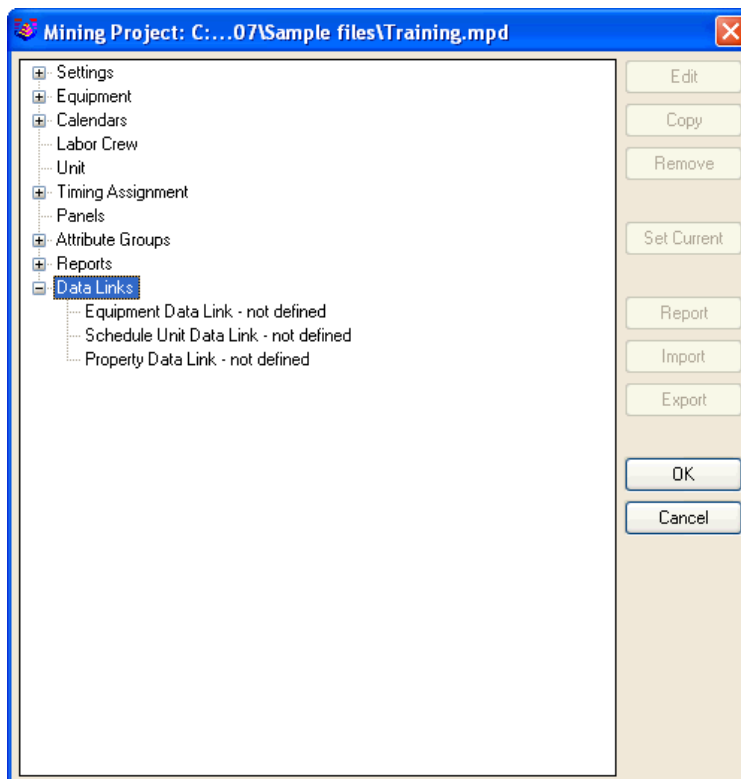

Reports

Some of the reports generated in the scheduling will appear here for other options to report. These are also accessed in the calendar or after a schedule is run.

Data Links

This shows the link of the data when it is linked to an external source for reporting.

Skip Past Report Archiving in Project Database: By default, all reports generated with timing commands will be saved in a backup of the Timing Project Manager as an .mrd file (the file name will be the same as the .mpd file,

just with a different extension). If many reports are generated, this archive can become quite large, and may even slow down processing time when running the timing command. When this option is enabled, no reports will be archived, preventing potential slow-down from large .mrd files. It is recommended to enable this option when you have no need for old timing reports.

Check for Conflicts: When enabled, this option will check for any conflicts in the pits. If a conflict is detected, you will be prompted to display a report of the conflicts when you start the Surface Equipment Timing command.

Conflict checks include:

1. Pits with duplicate names
2. Empty pits (no tonnage/volume in the pit)
3. Pits with invalid direction assignment
4. Pits with invalid precedence (can occur if a precedence rule is assigned, but the preceding pit is deleted or not selected for timing). For example, If Pit A must be mined prior to Pit B, but Pit B is later deleted/not selected for timing.
5. Pits outside the bounds of Attribute Group Grids

Keyboard Command: stime_project or utime_project

Set Attribute By Grid File

This command assigns an attribute grid value such as thickness or BTU to a panel or pit area. The program prompts for the attribute name and the grid file that represents the attribute. Then multiple panel/pit perimeter polylines can be selected and the program calculates the average grid value in each panel/pit polyline and stores this value. This command works similar for both surface pits or underground panels. This is the surface pit description.

Another method for using grids is to define the attribute as the actual grid file name instead of the average value. Then the timing routines will calculate attribute values for each timing block from the grid value. The advantage to using Set Attribute by Grid File instead of using the actual grid file is speed. Timing runs a bit slower when reading the grids.

The average value is stored in each pit and can be verified with the Edit Pit command. If the attribute exists there already, it will not overwrite it. Choose the Attributes button and the attribute should be there, as shown in the Edit Pit window. It matches the first BTU value calculated in the example.

Prompts

Surface Production Timing

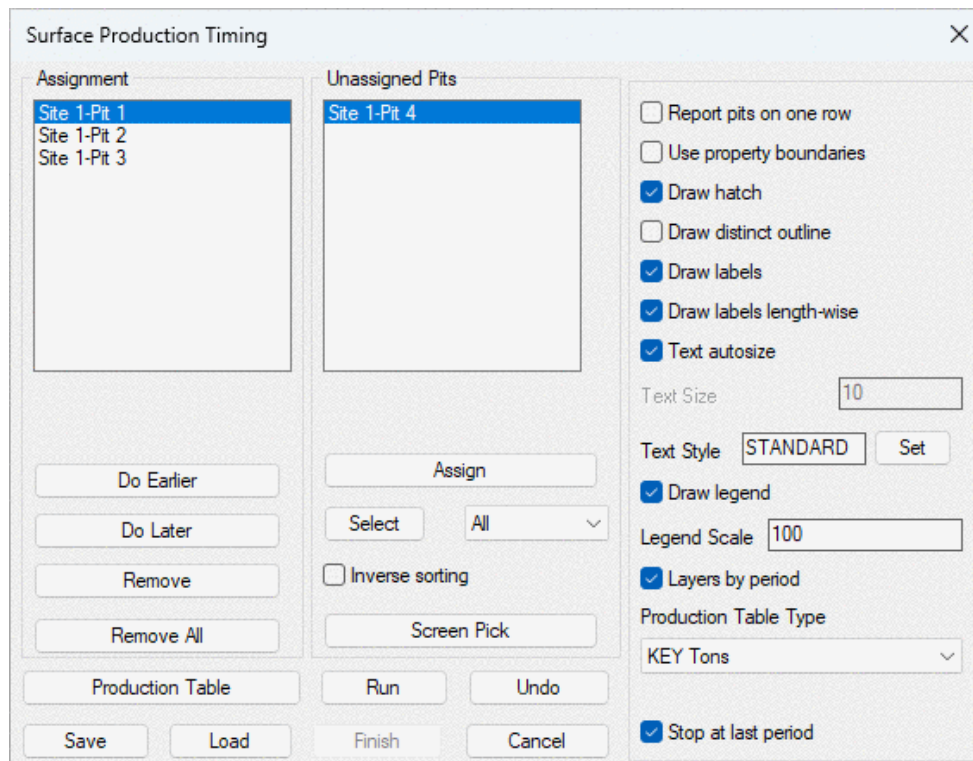

This command is used for production based timing of a mineplan to see the mine progress when defining production by time period. It is sometimes referred to a pre-scheduler, prior to running Surface Equipment Timing to get an estimate of mine progression. There are 3 steps needed to prepare for Production Timing as shown in the flow chart below. First, the mining model needs to be set up in the Geologic Model file (PRE). This could also be the geologic model. Next, there must be named, Carlson pit polylines representing the mine plan. Finally, the pits lines must have direction assigned for mining. Once these 3 items are created, the command may be run. This command does not use highwall angles or laybacks. It loads the mining model and vertically intersects it with the directioned pits to obtain timing blocks.

Make Geologic Model File —> Create Named Carlson Pits —> Assign Directions to Pits —> Surface Production Timing

The first step is to choose the Geologic Model file to process. After it is selected, the first dialog box appears with some initial settings. The Key Strata Recovery can be entered in the window with Set Value, or can be set By Strata Definitions, where it will refer to the Strata Definition File created with the Define Strata command, or the recovery can be an attribute grid surface found in the geologic model, with the attribute name of REC, which may be customized. The grid would need to contain values from 0-100 for recovery. Each strata can have it's own recovery with the second two options. The Key Strata Density is set in the same way. Either by entering it here, or as defined in the SDF file. The units are either pounds/cubic foot or kg/cubic meter, depending on US units or metric units in the drawing. Finally, the Source of Bottom Surface Model can be set here. If Strata Model is chosen, then the routine will use all seams from the surface topography down to the lowest strata surface in the Geologic Model file. If Surface File is selected, then volumes will only be calculated from the topography down to that bottom surface grid or TIN file, which could be a flat bench elevation for example, or a complex benched pit with many levels. A file-select window will appear next, to choose the grid or TIN if that option is used.

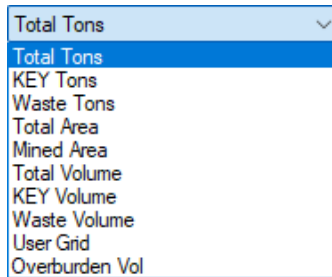

Next, after selecting the pits and the mining project file, the Surface Production Timing window appears as follows.

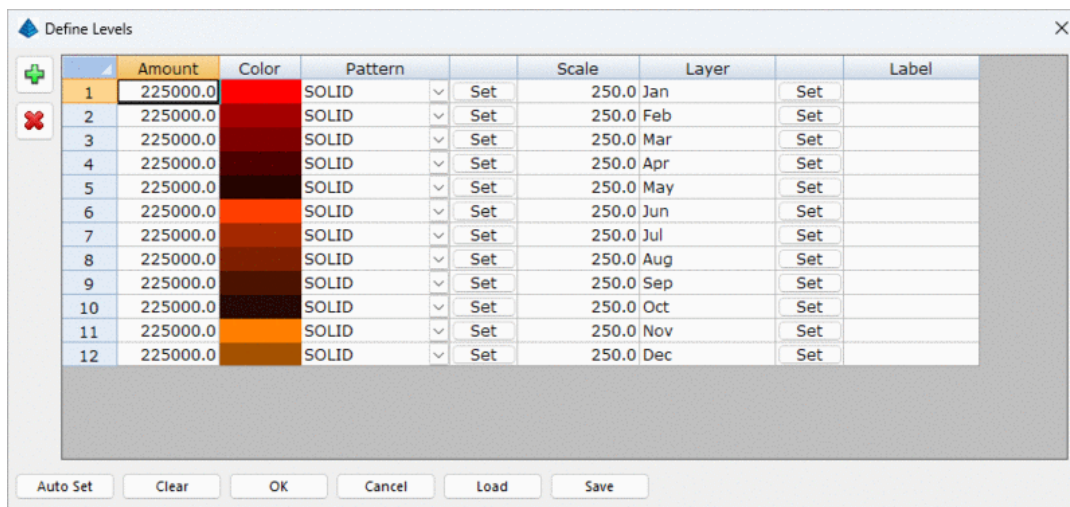

The first step is to select pits and move them over to the Assignment box on the left with the Assign button. Following is a detailed description of each item in the dialog box.

- **Do Earlier / Do Later:** These buttons move the pits up or down in the Assignment window.
- **Remove, Remove All:** These buttons will move either the selected pit, or all pits from the Assignment window to the Unassigned Pits window
- **Assign:** This button will move the highlighted pits from the Unassigned window to the Assignment window.
- **Select All:** This is a quick way to highlight all pits in the Unassigned Pits.
- **Inverse sorting:** If this is checked, then the pits will appear in reverse order in the Unassigned Pits window, otherwise they are in alphabetical and numeric order.

- **Screen Pick:** Allows for manual selection of pits in plan view with a cross-hairs. Simply place the cursor in the pits and pick in the order to mine. Hit enter when done. The selected pits should appear in the Assignment window in the order they were picked.
- **Report pits on one row:** This option is for report formatting. If this is checked, the report will have one row per time period and all strata quantities and qualities will follow on that row, each in their own column. If this is not checked, then each strata will be in its own row in the report, with its quality to follow. This option is usually not selected.
- **Use property boundaries:** There must be named property boundaries on screen for this option. Production timing will automatically detect them and break out the production by owner and property if desired.
- **Draw hatch:** One of the main items of output from this command. It draws the periods as blocks of solid fill or any hatch pattern inside the pits in plan view. They are colored by period. As they are being drawn, the direction and progress of the mineplan can be seen for review.
- **Draw distinct outline:** This is very similar to the timing blocks, except that they are just closed polylines with no fill or hatch. They are in their own color, and optionally, layer. They can be used later for further reserve calculations, or to save the mineplan without hatch or fill.
- **Draw labels:** This option places the period name in the block or outline. It is either the user defined label, or will just use "Period1", "Period2" etc.
- **Draw labels length-wise:** Selecting this option orients the text lengthwise to the long axis of the block outline. Otherwise it will be placed horizontally.
- **Text autosize:** If this is selected, the text will be automatically sized to fit the size of the block outline. Otherwise, the text might be too large for some of the smaller blocks.
- **Text Size:** Enter in the text size for labels. It will use this if Text Autosize is not selected.
- **Text Style:** Enter the AutoCAD Text Style for labels and legend.
- **Draw Legend:** Select this option to draw a legend of the timing blocks showing the color and the name of the period. It will ask to pick the legend position.
- **Legend Scale:** Enter in a legend scale size to size the legend.
- **Layers by Period:** This option will create a new layer for each time period and draw the blocks and outlines in those layers.
- **Production Table Type:** This is a very important setting that needs to be selected for the target material. There are 10 choices to use for production targeting. Most common are Key Tons and Overburden Volume, but others are available. Total Tons converts all strata to tonnages and mines them accordingly. The NonKey density is set in a window that appears as soon as Run is selected. Key Tons are tons of the combined key material, which name is set in Configure /Mining. Waste Tons will combine all NonKey strata, calculate the tons for it and target that tonnage for production. Mined Area will target a defined area in square feet or meters for production. Total Volume will combine all strata, both Key and NonKey and target the total CY or CM. Key Volume or Coal Volume will target the CY or CM of all Key strata in the selected Geologic Model file. Waste Volume combines all NonKey strata and targets the CY or CM of them. User Grid will take any grid and target total quantities for production. An example of this would be a power plant that wants to target total BTU. The grid to select would be total BTU/area. Finally, the Overburden Volume will take just the first NonKey strata in the Geologic Model and target that, but still report any additional NonKey seams below it.

- **Stop at Last Period:** If this is checked, then the routine will stop after the last period entered in the Production Table. If it is not checked, then it will continue with the last target amount all the way through the last selected pit polyline.
- **Production Table:** This is the screen to set the production amount and time period or date. The first column is the amount to target. This is what you have selected under Production Table Type. The second column is the color for that period. The next column is the hatch pattern for the block. If it is a hatch pattern other than SOLID, then it must have a scale factor, set in the next column. the AutoCAD Layer is set in the next column and finally, the Label is set in the last column. This can be anything from dates, to owners and areas. If the Labels are left blank, then it will fill in labels such as Period3, Period4, or month or year, etc. The Clear button will clear the entire screen. There are Save and Load buttons for easy retrieval of the CQT files.

- **Auto-set:** This button will open the below dialog, which can be used to automatically populate the table with

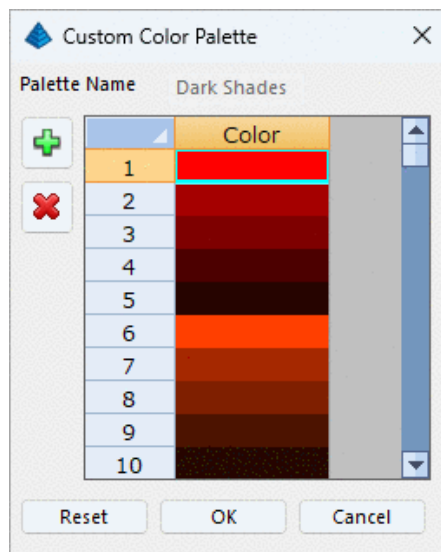

values.

The screenshot shows the 'Auto-Set Amounts/Colors' dialog box. It features the following fields and options:

- Starting Line:** 1
- Starting Amount:** 225000.000
- Amount Interval:** 0.000
- Hatch Scale:** 250.00
- Hatch Pattern:** SOLID
- Set Layer:** (checked)
- Layer (top):** Single Layer
- Number of Rows to Create:** 12
- Layer (bottom):** MINETM
- Color Options:**
 - Set Colors:** (checked)
 - Color Palette:** Dark Shades (selected), with Add, Edit, and Remove buttons.
 - Color Increment:** (unselected), with Increment: 10 and Start Color: 10.

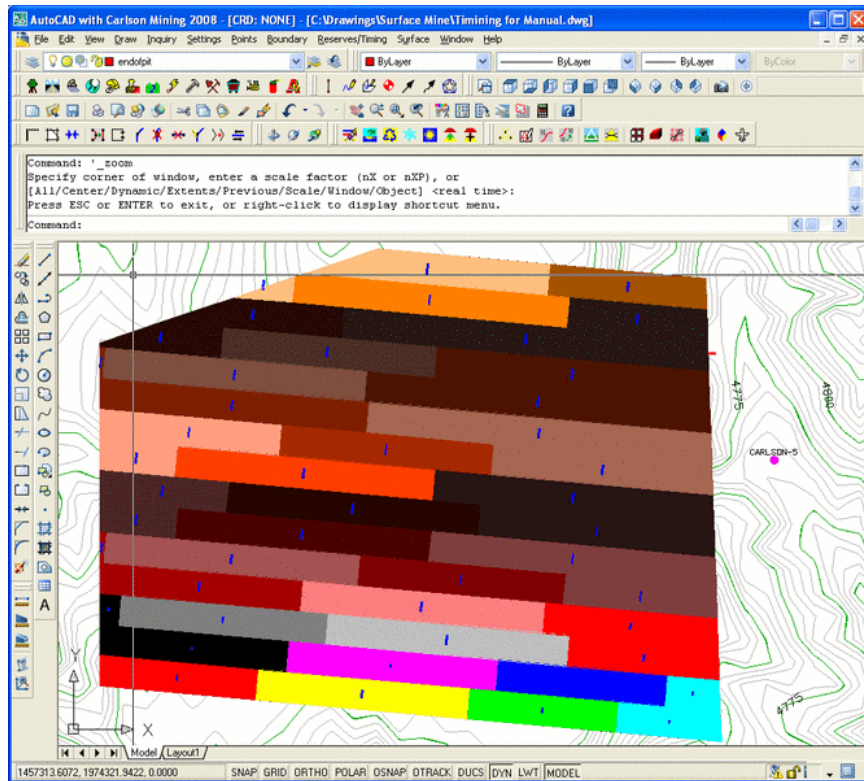

Buttons: OK, Cancel

- **Starting Line:** This value will set the row to begin the automatic population of the Custom Date table.
- **Starting Amount:** This is the initial amount used in the table.
- **Amount Interval:** This value will be added to the Starting Amount in each additional row. If the Starting Amount needs to be applied to all entries in the table, you can set this value to zero.
- **Hatch Scale:** This value will set the hatch scale for the new periods.
- **Hatch Pattern:** This field will set the hatch pattern for the new periods. The ellipsis button will open the list of available hatch patterns.
- **Set Layer:** This option will overwrite the Layer names when enabled.
- **Layer by:** This drop list determines how the layers will be populated. If the *Single Layer* option is selected, all layers will be the same, according to the **Layer** text box.
- **Set Colors:** This option will set custom colors for the new periods. There are two options for setting colors - by using a Color Palette, or by using a Color Increment.
- **Color Palette:** This option will use a predefined color palette to color the periods. When the end of the palette is reached, the colors will start over. Palettes may be added, edited or removed using the corresponding buttons. An example color palette is shown below. Colors may be added or removed from the palette by clicking the Plus or X icons, and colors may be modified by double-clicking them. Any of the predefined palettes may not have their name modified. If you modify the colors in a predefined palette, you may click the **Reset** button to return to the default colors.

- **Color Increment:** This option will color the periods by using a **Start Color** and a **Color Increment**. All colors in the CAD color palette range from 1 to 255. You may want to inspect the color palette when using this option to relate colors back to their numeric value. For example, a Start Color of 10 and a Color Increment 10 will increment through colors 10, 20, 30, etc.
- **Undo:** This will undo a previous run, removing the colored blocks and outlines.
- **Run:** This is the button to start the actual timing and sequencing of the pits. After the Production Table and all the settings are good, then choose Run.
- **Finish:** After the blocks are drawn and the Surface Production Timing window comes back, selecting the Finish button will start the calculations and generate the quantities and qualities in the Report Formatter. Here items are selected to appear in the report and exported to a file, such as Excel or Access.

A finished map with the blocks drawn on it and the corresponding report are shown here. In this example, the amount was set to 225,000, then 250,000 tons. In the report, notice the accuracy of the tons. Most are within a couple of hundred tons.

Surface Mine Reserves

Pre-Calc Definition: C:\Drawings\Surface Tutorial\MODEL.pre

Pulldown Menu Location: Surface Mine Module - Reserves/Timing

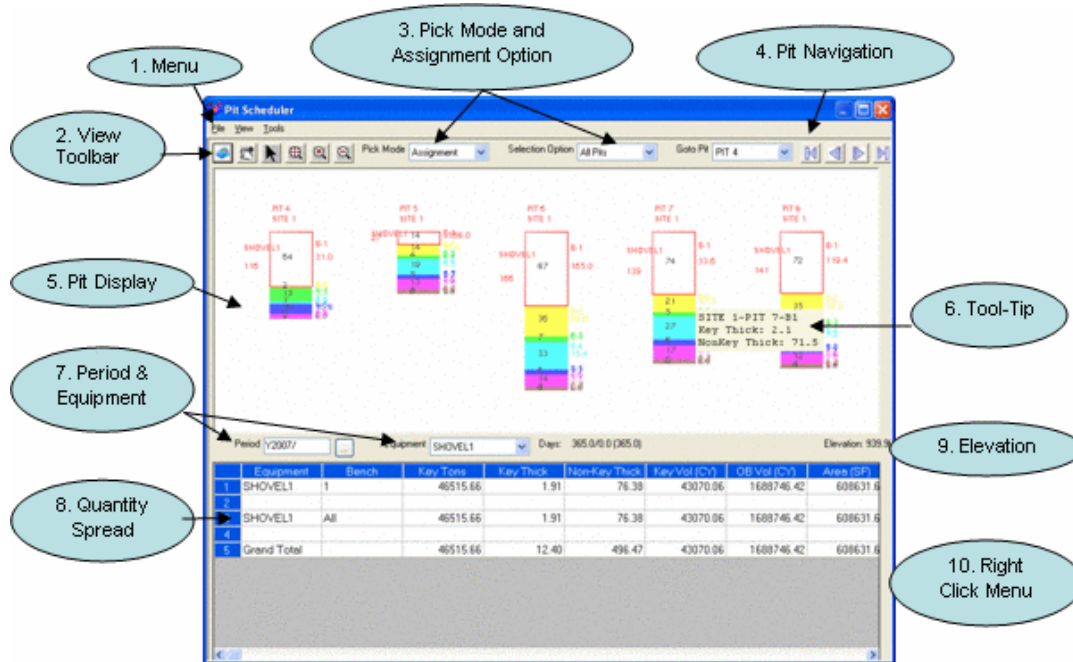

Keyboard Command: calcplan

Prerequisite: Timing pit polylines

Pit Scheduler

Pit Scheduler is a short-range surface mine scheduling command and is located under Reserves/Timing dropdown menu in Carlson Surface Mining. It displays selected pits in a cross section view with benches and allows user to assign equipments to pit benches by time period. The planner can simply pick on a bench to mine/un-mine it and the updated quantities will appear in the quantity spreadsheet. These quantities can be reported using report formatter at any time.

Interface Components

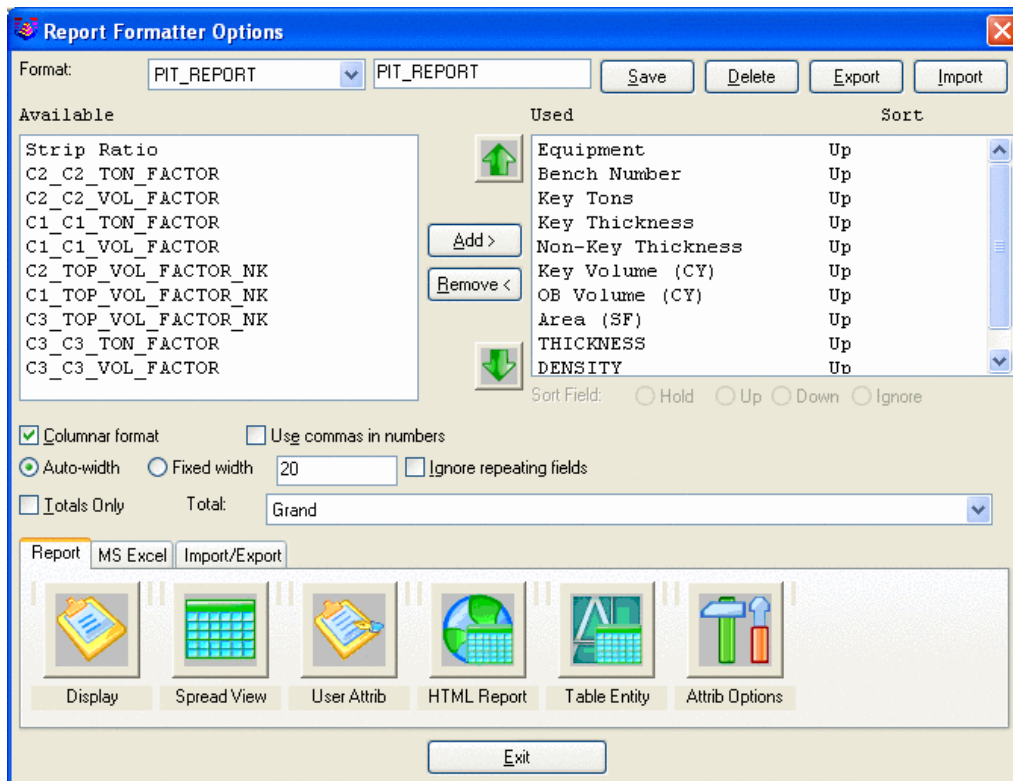

1. Menu

The Pit Scheduler has three main dropdown menus.

a. File Menu

- i. Read Pit Blocks: This command can be used to read in the new pits in the view to work on.
- ii. Report: This command can be used to report the currently assigned quantities.

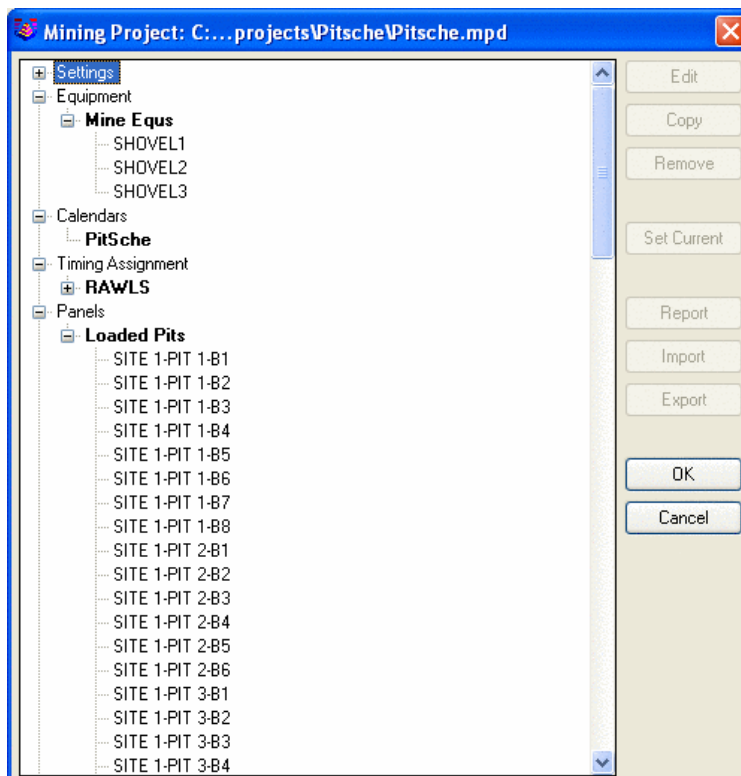

iii. Export to Bitmap: This command can be used to save the current pit display in to a bitmap file.

iv. Save and Exit: This command saves all the assignment and exits from the Pit Scheduler.

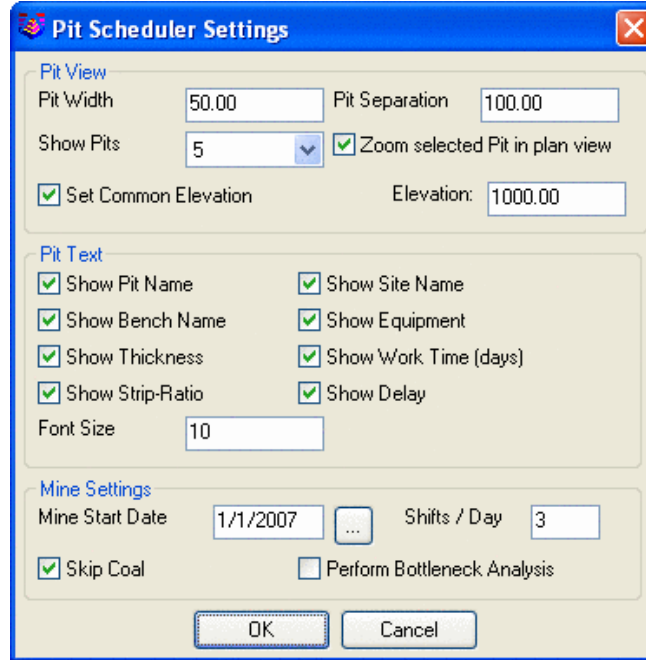

v. Exit: This will exit from the Pit Scheduler without saving any assignments.

b. View Menu

i. Project Manager: This command brings up the Surface Project Manager that can be used to define equipments, timing calendar, and other components to be used in scheduling and to view assignments and loaded pit names.

ii. Settings: This command shows the settings for Pit View, Pit Text and Mining.

- Pit View: These settings can be used to modify the pit display to view it more efficiently. The "Pit Width" and "Pit Separation" can be set for better viewing the pits based on their thickness. The pit width is the width of the pit column and pit separation is the separation between two pit columns. The "Show Pit" allows user specify the number of pits to view in current view. If "Zoom selected Pit in plan view" is on as soon as used clicks on a pit it will be highlighted in the AutoCAD drawing plan view and the view will be zoomed in to current pit. The "Set Common Elevation" option allows pits to be hanged from a common elevation specified in the "Elevation" edit box, if this option is turned off the program looks for the "SURFACE" attribute for the pit and reads the elevation from there.

- Pit Text: The Pit Text settings can be used to display different text in the pit display for a pit column.

- Mine Settings: These settings are used in timing the pits similar to used in Equipment Timing.

c. Tools Menu

i. Clear Assignments: This command clears all the assignments for the current equipment selected in "Equipment" dropdown list. This will allow user to select the assignments for equipment from the beginning.

ii. Clear All Assignments: This command will clear all the assignments for all the equipments and bring the mine to the starting point, and allows user to start the scheduling from the beginning.

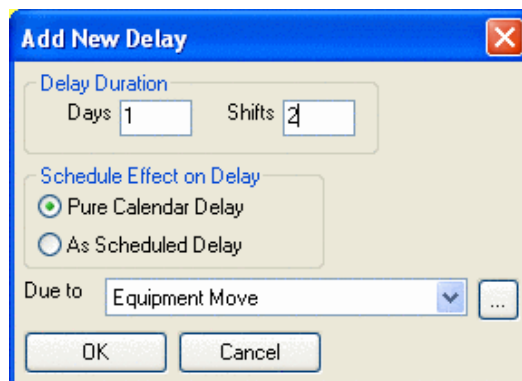

2. View Toolbar

3. Pick Mode and Selection Option

a. Pick Mode: is used to set the mode for selection of pit benches. There are three pick modes:

- i. Assignment: This mode is used to assign the current equipment selected in the "Equipment" dropdown list to the selected bench/benches based on the "Selection Option".
- ii. Waste Bench: This mode is used to specify whether a bench will be mined or treated as waste bench. The waste bench quantities will not be added to the quantities as it will not be mined.
- iii. Add Delay: This mode allows user to add delays associated with a bench. If this mode is selected than based on the selection option delay will be added to the bench/benches and mining will be delayed by delay duration. (Look in Surface Equipment Timing for more information on adding delays)

b. Selection Option: is used to apply the pick mode to the benches. There are five selection options user can choose from.

- i. Individual Pit: the pick mode will be applied to the selected bench in selected pit.
- ii. Current View: the pick mode will be applied to the selected bench for all the pits in the current view.
- iii. All Pits: the pick mode will be applied to the selected bench for all the pits loaded in the Pit Scheduler.
- iv. Pits to the Right: the pick mode will be applied to the selected bench for selected pit and to all the pits on right side.
- v. Pits to the Left: the pick mode will be applied to the selected bench for selected pit and to all the pits on left side.

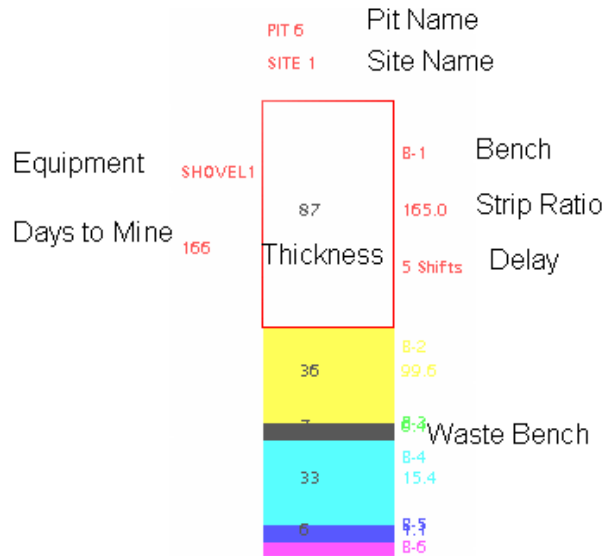

4. Pit Navigation

The Pit Navigation can be used to scroll through the loaded pits. The "Goto" pit allows user to select the starting pit for the view. The Left or Right View scrolls the view to left or right respectively by the number of pits selected in "Show Pits" in the Settings dialog under View Menu. The Move Left or Right scrolls the view by a single pit.

5. Pit Display

The Pit Display shows the pits with benches in a plan view based on the view and text settings. Following figure shows a typical Pit with all text options turned on.

6. Tool-Tip

A Tool-Tip window is shown with the full name of bench (Site-Pit-Bench) and Key and Non-Key thickness when user cursor over a bench.

```
SITE 1-PIT 6-B1
Key Thick: 0.5
NonKey Thick: 86.0
```

Period: Y2007/Q1 ... Equipment: SHOVEL2 Days: 69.0/21.0 (90.0)

7. Period & Equipment

a. Period: can be used to view the number of days used and available for the selected equipment. The Period string can be formatted using the Period Formatter dialog or can directly be typed in the edit box. The Period string must be in the specified format. As soon as the user updates the Period and hit enter the "Days:" label is updated to show "Used Days/Available Days (Period Days)".

b. Equipment: This dropdown lists all the defined equipments in the Project Manager. The current selected equipment is used for assignments.

8. Quantity Spread

The quantity spread shows the quantities and qualities for the equipment selected in "Equipment" dropdown for each bench it is assigned to. The spread shows Equipment, Bench, Key-Tons, Key-Thickness, Non-Key Thickness, Key Volume, OB Volume, Area, Acres, and Strip Ratio columns followed by the pit attribute values. It is important to note that the Strip Ratio will always be reported as units of nonkey volume to key tonnage (yd³/ton or m³/tonne).

	Equipment	Bench	Key Tons	Key Thick	Non-Key Thick	Key Vol (CY)	OB Vol (CY)	Area (SF)	Coal Acres	Strip Ratio
1	SHOVEL1	1	46515.66	1.91	76.38	43070.06	1688746.42	608631.60	13.97	39.21
2	SHOVEL1	2	35676.67	1.46	21.73	33033.95	470988.28	608631.60	13.97	14.26
3										
4	SHOVEL1	All	82192.33	1.68	49.05	76104.01	2159734.70	1217263.19	27.94	28.36
5										
6	Grand Total		82192.33	21.88	637.69	76104.01	2159734.70	1217263.19	27.94	28.36

9. Elevation

The current elevation of cursor is show on the "Elevation" label. If the "SURFACE" attribute is defined for the pit it will show the actual elevation for that pit and its benches.

10. Right Click Menu

A Right Click menu pops-up when user right click on a Pit Column. This menu lists Edit Pit followed by the full name of benches in that pit. The thickness of a bench can be very small that it becomes hard to pick that bench using left click, in that case right click menu can be used to pick that particular bench. It shows the mined benches with a check mark. The "Edit Pit" command can be used to edit the pit values and attributes. (For more information refer to "Edit Pit" command under Boundary dropdown menu of Carlson Surface Mining).

Pulldown Menu Location: Reserves/Timing in Surface Mining

Keyboard Command: pit_scheduler

Prerequisite: Pits with assigned quantities

Surface Equipment Timing

Surface Equipment Timing schedules through distinct pits on a bench-by-bench basis. Each bench is mined by a single piece of equipment according to a working calendar. This is unique compared to the Surface Production Timing command in that it requires the use of grids/quantities stored in pits, adheres to a work calendar, and allows for varying rates of production for each piece of equipment. This command requires careful preparation and organization. The following documentation explains the details of this command according the below outline:

1. Required Setup
2. Surface Equipment Timing Dialog
3. Reporting Options

Before Surface Equipment Timing may be executed, proper setup is required. This includes 1) creating pits/benches with quantities and mining direction and 2) defining the project working parameters via the Timing Project Manager.

1) Create pits/benches

In order to create pits/benches ready for timing, the following steps must be taken.

1. Create Pits

As previously mentioned, the Surface Equipment Timing command schedules through pits on a bench-by-bench basis. These benches are the base unit used for scheduling, making proper layout of pits/benches key to effective scheduling. It is helpful to first define the scope of the planning process (long-range vs. short-range and schedule flexibility required for equipment). It is important to note that only one piece of equipment may work on one bench at a time, and that partial mining of a bench is not allowed; once a piece of equipment begins mining a bench, it must finish that bench before it can start on another bench.

Short range planning can require more flexibility in the sequencing of pits/benches, which requires pits/benches to be divided into smaller distinct units. Long range planning, however, often requires less

detail, and can therefore consider larger areas to be mined as a single unit. Consider the below image, which shows how an area of land may be divided into pit outlines for different planning scenarios. The pits shown on the right do not allow for much flexibility in planning. If only one piece of equipment is working, at least one bench of each long pit must be fully mined before mining another bench. The pits on the left, however, allow for a greater amount of flexibility. In this scenario, a piece of equipment may mine Bench 1 of Cut 1-1, then mine Bench 1 of Cut 1-2, followed by Bench 2 of Cut 1-1, etc.

Pits are simply closed polylines that are tagged with a pit name and additional information. To create pits from linework, one of the below commands may be used. All of these commands are found under the Boundary Pulldown Menu of the Surface Mining Module. Detailed information about each command is listed in the corresponding section of the help manual.

- Name Pit Polyline
- Assign Pit Names By Layer
- Pit by Interior Point
- Pit by Interior Text
- Pit Matrix Layout
- Pit Layout by Advance
- Pit Layout by Width
- Pit Layout by Rate
- Import Pit Points

2. Store Quantities/Qualities to Pits by Bench

Once the pits have been created, the quantity and quality of material to be mined must be calculated within those boundaries. This information is stored within each pit in distinct benches. This is done by one of the below commands. The Surface Mine Reserves command is found under the Reserves/Timing Pulldown Menu, while the other two are found under the Boundary Pulldown Menu. Detailed information about each command is listed in the respective location of the help manual.

- Surface Mine Reserves
- Assign Timing Grids
- Import Pit Timing Data

3. Assign Mining Direction

Before pits/benches may be scheduled, a mining direction must be assigned. Some of the pit layout tools will assign mining directions automatically. Pits without a mining direction may be assigned direction via the Assign Directions command. Mining direction may vary by bench. It is important to note that the mining direction does not control the sequencing of pits. For example, a long row of pits may be sequenced to mine the west end first and progress to the east, but mining of each individual pit does not have to progress from west to east.

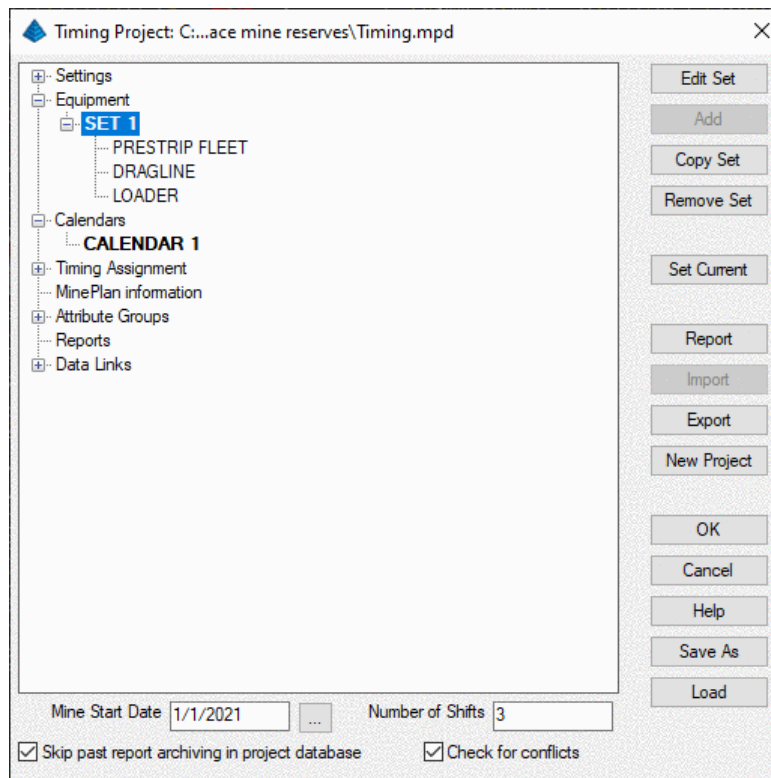

4. Optional - Verify Pits

Once pits have been named, assigned quantities/qualities by bench, and assigned a mining direction, they may be verified that they are ready for timing via one of the following commands, all of which are found under the Boundary Pulldown Menu.

- Identify Pit Polylines
- Edit Pit
- Pit Quantities Report
- Pit Points Report
- Pit Inspector

2) Timing Project Manager

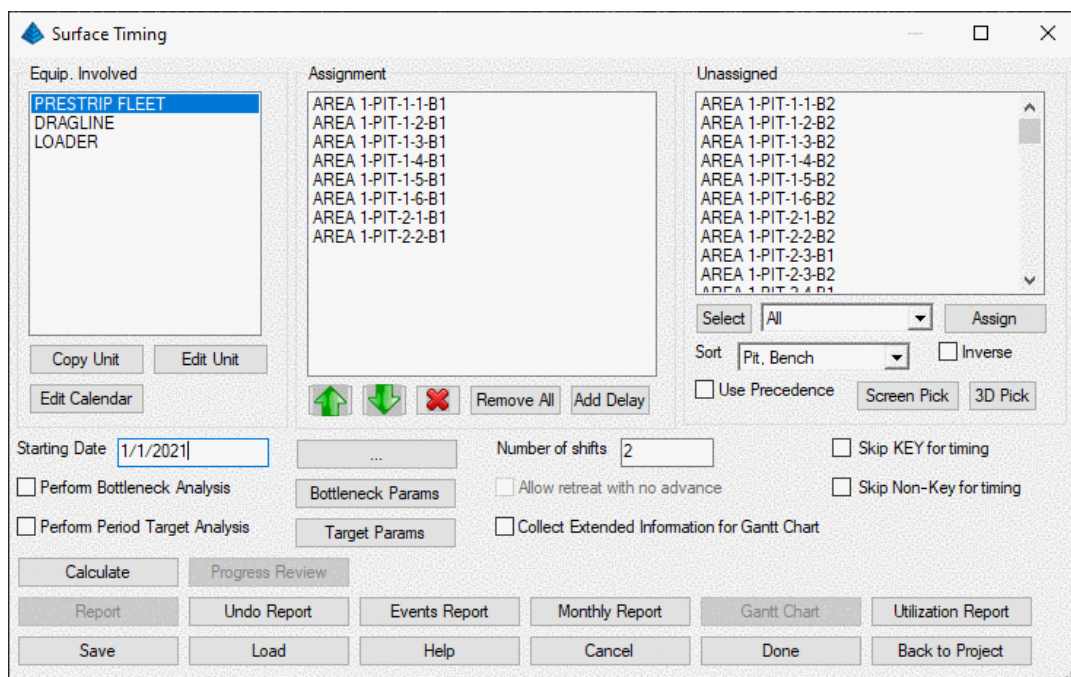

Working parameters are defined in the Timing Project Manager. This includes information such as the number of working units, equipment working rates, number of shifts, working calendars, etc. Each time the Surface Equipment Timing command is executed, the current Timing Project Manager settings will be displayed before continuing. An example of the Timing Project Manager is shown below. Detailed information about the Timing Project Manager is found elsewhere in the help manual.

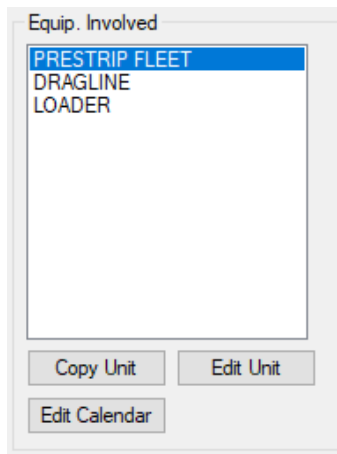

After clicking OK on the timing project, the program will check to see if any pits previously assigned to a piece of equipment were omitted from the timing. If this occurs, the below message box will appear asking if you want to remove the omitted pits from the assignment list. Any undetected pits will not be accounted for in the timing report.

Once the pits/benches and working parameters have been defined, the Surface Equipment Timing command may be used. After accepting the settings in the Timing Project Manager, the Surface Equipment Timing Dialog will appear as below. The primary purpose of this dialog to move pits from the Unassigned Column to the Assignment column in the order in which they will be extracted. Each piece of equipment has its own assignment list.

The Equip. Involved Column lists all pieces of equipment to be used for the mine scheduling. Benches must be assigned to a specific piece of equipment in order to be mined.

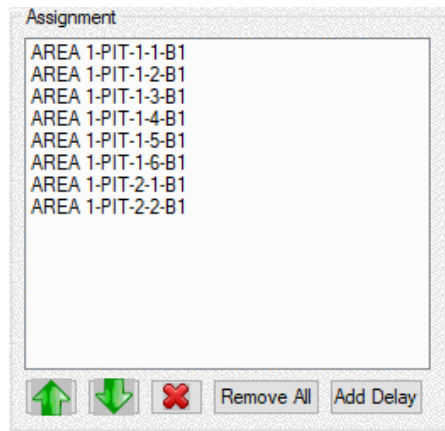

Copy Unit: This button will create a copy of the currently select unit.

Edit Unit: This button will allow you to edit the specifications of the currently selected equipment. More information on defining equipment specifications is available in the Timing Project Manager section of the help manual.

Edit Calendar: This button will allow you to edit the current work calendar. More information on defining the work calendar is available in the Timing Project Manager section of the help manual.

The Assignment Column lists the benches assigned to the currently selected equipment. Selecting a different unit will update this column with the list of benches assigned to that unit. This column lists benches in the order that they will be mined, with benches at the top of the list being mined first.

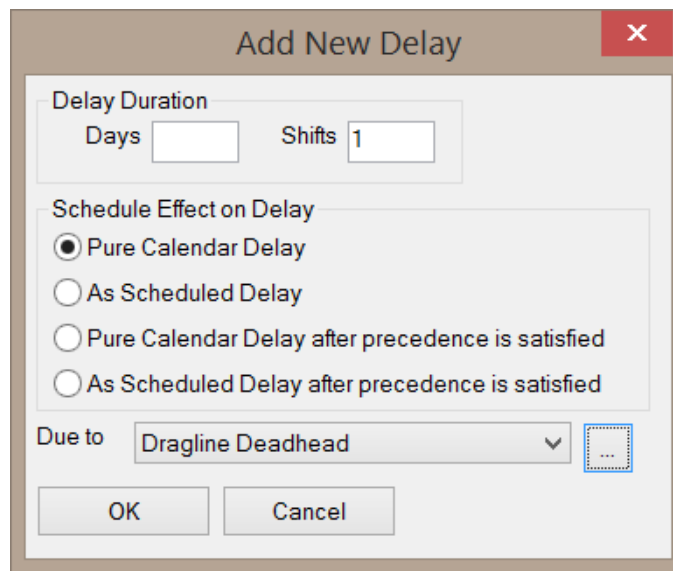

The green **Up/Down Arrow Icons** will move the currently selected bench(es) upward or down in the list, causing it to be mined earlier or later in the sequence.

The red **X icon** will remove the currently selected bench(es) from the list, allowing it to be re-assigned to another piece of equipment.

Remove All: This button will remove all assignments from the currently selected unit.

Add Delay: This button will open the dialog shown below, which controls how delays are handled. A delay will appear in the Assignment Column as if it were another bench to be mined, and may be moved up or down in the sequence.

Delay Duration: These values control how long the delay lasts. In the above example, the equipment will be delayed for a full shift. Note that partial shift delays are allowed.

Pure Calendar Delay: This option will not force a delay. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay: This option will force a delay even if the equipment already has scheduled downtime when the delay is encountered. The delay will wait until the scheduled downtime is complete, then the delay will be applied.

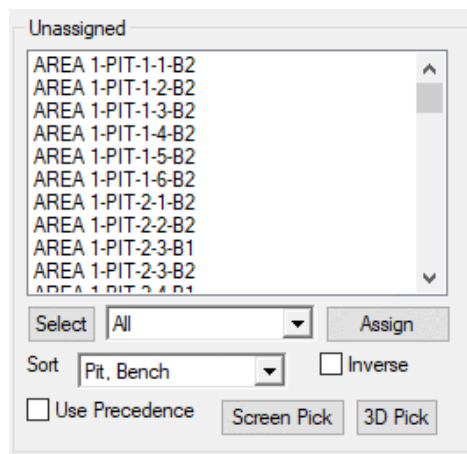

Pure Calendar Delay after precedence is satisfied: This is similar to a Pure Calendar Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the scenario shown in the below table. Equipment E1 is scheduled to mine Pit A and Pit C. Equipment E2 is scheduled to mine Pit B and Pit D. A precedence rule has been created that does not allow Pit D to be mined until Pit A is complete. A delay of this type is placed on Equipment E2 after Pit B. In this scenario, the finish date of Pit A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime when the delay is encountered, additional time will not be taken off.

As Scheduled Delay after precedence is satisfied: This option is similar to an As Scheduled Delay, but will not attempt to apply the delay until precedence rules have been satisfied. Consider the below scenario. Equipment E1 is scheduled to mine Pit A and Pit C. Equipment E2 is scheduled to mine Pit B and Pit D. A precedence rule has been created that does not allow Pit D to be mined until Pit A is complete. A delay of this type is placed on Equipment E2 after Pit B. In this scenario, the finish date of Pit A will first be calculated, then the delay will be applied. If the equipment already has scheduled downtime, the delay will be applied in addition to this downtime.

Due To: This dropdown menu lists the Drawing Event delays defined in the Timing Project Manager. The ellipsis button will allow you to define a new Drawing Event.

Equipment	E1	E2
Assignment Sequence	Pit A	Pit B
	Pit C	Delay
		Pit D (Precedence rule: Pit A)

The Unassigned Column lists all benches that have not yet been assigned to a piece of equipment.

Assign: This button will assign the selected bench(es) to the selected piece of equipment.

Select: This button will select all benches according to the drop-down menu to the right of this button. If the drop-down menu is set to NONE, all benches will be unselected. If the drop-down menu is set to ALL, all benches will be selected. If the drop-down menu is set to Bench 1, Bench 1 from all pits in the list will be selected.

Sort: This drop-down list will sort the benches according to a variety of options.

- Pit, Bench: this option will sort the list in order of increasing pits, then in order of increasing benches (for example Pit1-B1; Pit1-B2; Pit2-B1; Pit2-B2; etc.)
- Bench, Pit: this option will sort the list in order of increasing bench, then in order of increasing pit number (for example Pit1-B1; Pit2-B1; Pit1-B2; Pit2-B2; etc.)
- X-Bench Staircase: this option will sort the benches in a staircase method according to the number of benches available. A three-bench scenario will sort the benches in a staircase-fashion such as Pit1-B1; Pit2-B1; Pit1-B2; Pit3-B1; Pit2-B2; Pit1-B3; Pit4-B1; Pit3-B2; Pit2-B3 etc.

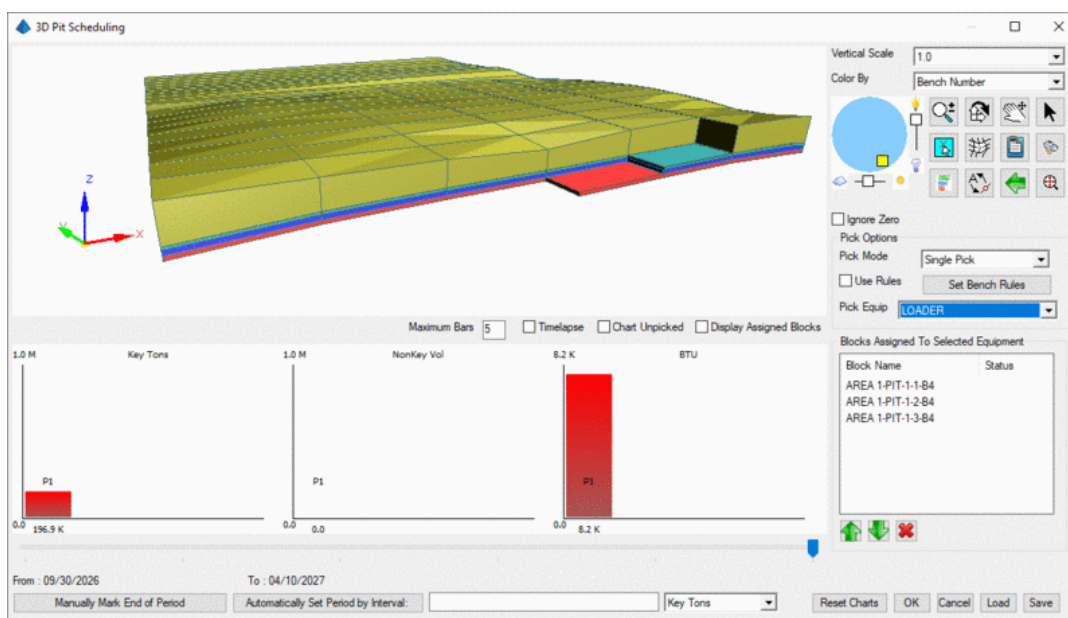

Inverse: This checkbox will invert the sorting order of the Unassigned Column.

Use Precedence: This checkbox will ensure that precedence is satisfied in the list. For example if Pit1-B1 is assigned to precede Pit1-B2, toggling this option on will reorder the list so that Pit1-B1 is listed before Pit1-B2.

Screen Pick: This button will allow you to sequence the pits by selecting them in the drawing. When activated, the Surface Equipment Timing Dialog will disappear and the drawing area will be visible. The command line will prompt you to click inside the pit to assign to the currently selected piece of equipment. Pits/benches that have already been assigned to a piece of equipment will be filled with a transparent color. Clicking inside a pit will assign the top available bench in that pit to the selected equipment. Clicking inside the pit a second time will assign the next available bench and the fill color will change to indicate that the second available bench has been assigned. Pressing ENTER after selecting the benches will return to the Surface Equipment Timing dialog. An example of the Screen Pick method of selection is shown below.

3D Pick: This button will open a new window, as shown below, to show a 3D view of the available pits and the volumes/qualities associated with them. This interactive window allows you to sequence pits in a 3D environment.

The benches shown in the 3D graphics window will be shown as flat benches by default. However, benches may be associated with elevation surfaces to show realistic dimensions via the Timing Project Manager attribute groups. More information on this feature is available in the corresponding section of the help manual.

Vertical Scale: This value controls the vertical exaggeration of the graphics window.

Color By: This drop-down list controls how benches are colored in the graphics window.

The *Bench Number* option will color each bench level with a color specified in the **Set Bench Rules** options.

The *Grade* option will color each bench according to a grade parameter file. Any attribute in the pit may be used for grade categorization.

The *Destination* option will color each bench according to its assigned destination. Note that destinations must be enabled in the Timing Project Manager in order for this option to be made available.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display.

Switches to Dynamic Zoom mode. Click and drag to zoom in and out.

Switches to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switches to Pan mode. Click and drag to pan.

Switches to Pick mode. When active, double-clicking benches in the graphics window assign benches to the equipment or destination based on the **Pick Action** option.

Prompts you to select linework such as contours or 3D faces to add to the 3D viewer window. This linework can be used to identify reference points in the drawing to assist in pit selection.

Toggle shading of Pits and 3D Faces.

Exits the 3D Pick window, calculates the amount of time required to mine the assigned benches, and generates a report. This function is discussed later in this section of the help manual.

Displays a detailed report of the current timing assignment. This is similar to the standard Report function, but provides more detailed information and does not attempt to create a timing map. An example report is shown below.

Unit	Days	Pit name	Start date	Finish date	Days pit
1	PRESTRIP FL	0 AREA 1-PIT-9/27/2016	10/1/2016		
2	DOAGLINE	6.8 AREA 1-PIT-10/2/2016	10/7/2016		
3	LOADS	10.8 AREA 1-PIT-10/7/2016	10/19/2016		
4	PRESTRIP FL	0 AREA 1-PIT-10/9/2016	10/7/2016		
5	DOAGLINE	0 AREA 1-PIT-10/7/2016	10/12/2016		-4
6	LOADS	0 AREA 1-PIT-10/19/2016	10/19/2016		-9
7	PRESTRIP FL	0 AREA 1-PIT-10/7/2016	10/9/2016		10.3
8	DOAGLINE	0 AREA 1-PIT-10/12/2016	10/17/2016		3.2
9	LOADS	0 AREA 1-PIT-10/18/2016	10/28/2016		6
10	PRESTRIP FL	0 AREA 1-PIT-10/9/2016	10/12/2016		12.4
11	DOAGLINE	0 AREA 1-PIT-10/17/2016	10/29/2016		5.2
12	LOADS	0 AREA 1-PIT-10/28/2016	10/29/2016		0
13	PRESTRIP FL	0 AREA 1-PIT-10/12/2016	10/19/2016		15.8
14	DOAGLINE	0 AREA 1-PIT-10/29/2016	10/29/2016		4.0
15	LOADS	0 AREA 1-PIT-10/29/2016	11/9/2016		1.0
16	PRESTRIP FL	0 AREA 1-PIT-10/19/2016	10/25/2016		22.0

The calculator icon at the top left of the screen will recalculate the timing results of the currently assigned benches. This allows additional pits to be added/removed from the assigned equipment and then quickly recalculate the impact on the scheduling.

The slider bar at the top of dialog represents the timeline of the mining progression. Clicking-and-dragging the slider will update the displayed information. The spreadsheet report will display benches to be mined in the currently selected time period.

Controls the information displayed on the bar charts. When clicked the below dialog will appear.

This dialog contains two columns: Available and Used. Only items in the Used column will be shown in the Quantity and Qualities chart. Items may be moved between the two columns by selecting the item and clicking one of the green arrows between the two columns. To the right of the Used column are four icons. The green arrows can be used to move the selected item up and down in the list. The red pencil can be used to edit the selected item as described below. The blue reset icon will clear out all used attributes and return them to the available column.

When an item is first moved to the Used column, the below dialog will appear to control that item's appearance on the chart, including minimum value to display, maximum value to display, and color. If destinations have been enabled in the pits, you will be able to define charts for each grade of material according to the grade parameter file used to color the pits by Grade.

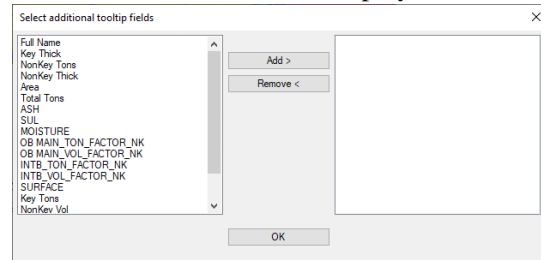

Total Method: This drop list controls how the attribute will be totaled. For volumes/tonnages, it is most sensible to simply Sum the parts to calculate the total, whereas quality attributes often need to be calculated as a Simple Average or a Weighted Average. When using the Weighted Average option, you will be able to use another attribute for weighting.

Enable Targets: This option will simply draw two horizontal lines across the bar charts, according to the Target Max and Target Min values.

Create/Edit Equation: These buttons allow you to create/edit new equations to display in the bar charts (and the tooltip). These equations are the same as those available in the Define Equations dialog.

Controls the attributes that are displayed in the tooltip when the cursor is hovering over a bench. Attributes in the left column will not be displayed.

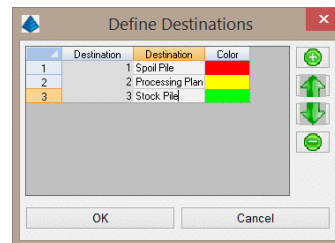

Undoes the last pit(s) selected in the 3D pick window.

Zooms to the extents of the items shown in the 3D window.

This icon will only be shown when destinations have been enabled in the Timing Project Manager. When clicked, the below dialog will appear. Here you can define various destinations and assign a color. Destinations may be added/removed with the plus/minus icons, and reordered with the up/down arrows.

This icon will only be shown when destinations have been enabled in the Timing Project Manager. Clicking this button will prompt you for a grade parameter file. Benches will then be automatically assigned to their various destinations based on the grade of the material. Please note that the color assigned to the grade category in the grade parameter file must match the color of a pit destination. If no match is found, the bench will be assigned to the first destination in the above list.

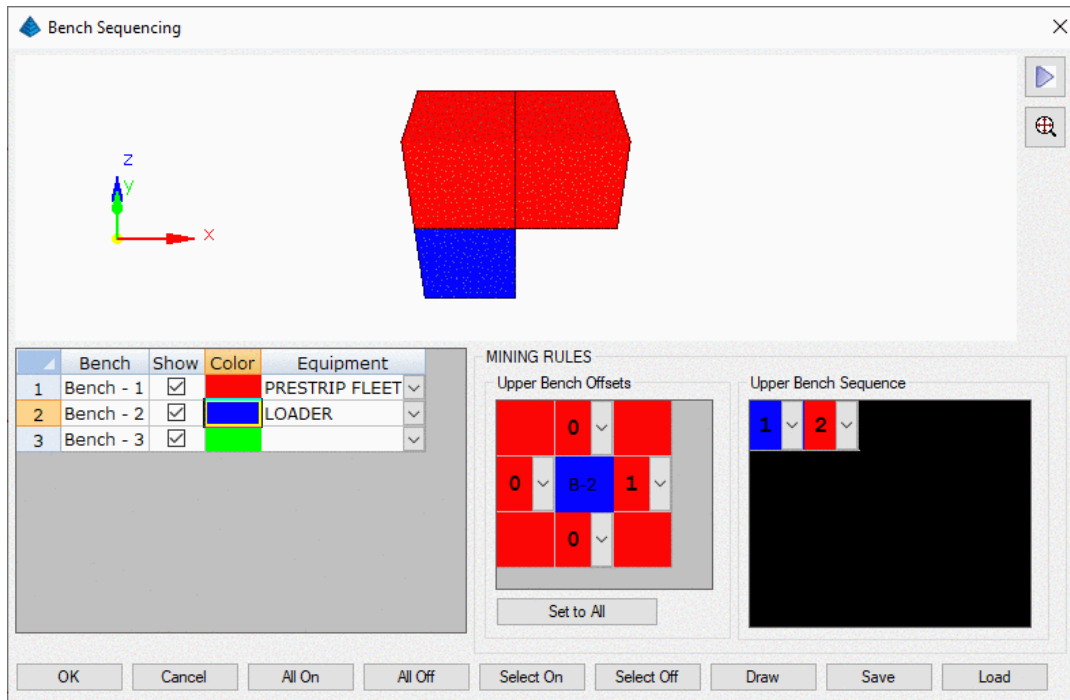

Ignore zero elev: This option will toggle the visibility of surface features at zero elevation in the graphics window.

Pick Mode: This drop-down list controls how benches are assigned to equipment. When the Single Pick option is selected, benches will be selected one at a time by double-clicking on each bench. When the Multi Pick option is selected, multiple pits may be assigned by double-clicking the first pit in a line to be mined, then double-clicking the last pit to be mined. Once two pits have been selected, they may be assigned to the equipment by right-clicking anywhere in the graphics window. Additional lines of pits may be added with additional double-clicks.

Use Rules: This option will apply the bench rules when selecting benches. These option can be defined with the Turn Benches On/Off icon.

Set Bench Rules: This button will open the Bench Sequencing dialog, shown below. This is intended to assist with sequencing when using the Single Pick option of selecting benches. When a bench is selected for mining, other benches will be automatically selected based on these bench rules. Note that in order to use the Bench Rules, pits must be oriented in the N-E-S-W directions. If the pits are not naturally oriented this way, the Twist Screen command may be used (prior to executing the Surface Equipment Timing command) to align the pits in the N-E-S-W directions.

The Graphics window at the top of this dialog will show an example of the bench rules to be applied. The List of Benches on the left side of this dialog controls various options for the benches. The Mining Rules on the right side of this dialog control the automatic sequencing of the benches.

Bench Column: This column lists the benches in order from top to bottom.

Show Column: This column controls if benches are shown in the graphics window.

Color Column: This column controls the color of each bench. Double-clicking one of the color cells will open the CAD color palette for color selection.

Equipment Column: This column controls which piece of equipment the bench will be assigned to. If no equipment is specified, the benches will be assigned to the current equipment selected on the 3D pick dialog.

Upper Bench Offsets: This graphic controls how many benches should be developed in addition to the bench that is actually selected in the 3D Pick dialog. The center square represents the bench that is selected in the 3D pick window. The numbers on each side of this square control how many upper-level benches must be sequenced in addition to the selected bench. In the above image, anytime a bench on level-2 is selected for sequencing, the bench on level-1 just to the east will also be sequenced. These benches will be assigned to the equipment specified in the Equipment Column.

Upper Bench Sequence: This graphic controls actual sequencing of the automatically sequenced benches. In the above image, the upper bench (red) will be mined first, then the level 2 bench will be mined.

Set to All: This button will apply the current bench sequencing rule to all other benches. For example, if a rule is defined for level 2 to mine one bench to the east on level 1, clicking this button will apply a similar rule to lower benches.

All On/Off: These buttons will toggle the "Show" option for all benches.

Select On/Off: These buttons will toggle the "Show" option for the currently selected benches.

Draw: This button will draw a preview of the selection in CAD. Picking a bench will fill in that bench with a yellow hatch. All other benches to be automatically sequenced along with this bench will be outlined with the same Bench Color. In the below example, Pit 1-3 Bench 2 has been picked for scheduling, and Pit 1-4 Bench 1 has been outlined to show that it will be automatically sequenced.

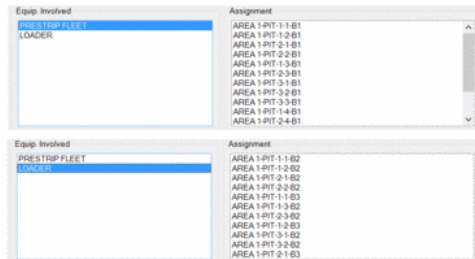

Pit-2-1	Pit-2-2	Pit-2-3	Pit-2-4	Pit-2-5
			Pit-1-4	Pit-1-5

Bench Sequence Rules Example:

The below images show the bench rules for a 3-bench example. In this example, whenever a level-2 bench is selected, up to 3 level-1 benches will also be sequenced. Whenever a level-3 bench is selected, up to 3 level-2 benches will also be sequenced. These rules compound, meaning that whenever a level 3-bench is selected, up to 8 level-1 benches may also be sequenced.

Using these bench rules, 5 benches were manually picked as shown below. The yellow number, indicating the order of selection, lies on top of the bench that was actually selected; all other benches were automatically assigned to the appropriate equipment. The final sequence applied to each piece of equipment is also shown below this progression. This allows a total of 26 benches to be sequenced by selecting only 5 benches. This can save tremendous amounts of time when working with multi-bench pits.

Pick Action: This option will only be shown when pit destinations have been enabled in the Timing Project Manager.

The *Set Equipment* option will assign benches to the current equipment.

The *Set Destination* option will assign the destination of the selected bench.

Pick Destination: This option will only be shown when pit destinations have been enabled in the Timing Project Manager and when the Pick Action is set to *Set Destination*. When shown, any benches selected will be assigned to the currently selected destination.

Pick Equipment: This drop-down list includes all equipment that have been added to the main Surface Equipment Timing dialog. Benches will be assigned to the selected equipment.

Blocks Assigned To Selected Equipment column: This list shows all benches that have been assigned to the selected equipment. The benches are listed in the order they will be mined. The green arrows to the right of this list will move the currently selected bench up and down in the list. The green X to the right of this list will remove the selected bench from the list and make it available for assignment to another piece of equipment.

Bar Charts: The charts at the bottom of the dialog show the quantities and qualities of the pits assigned to the current piece of equipment. As benches are assigned to a piece of equipment, the charts will dynamically update. The appearance of each chart is controlled with the Chart Settings icon, as discussed above. Each chart may show multiple vertical bars, with each bar representing a period of one or more pits. Periods may be defined manually or automatically. It is important to note, however, that the periods that define these charts are only temporary tools for inspection - these periods will not be used in the final timing report. It is important to note that the bar charts are intended to be a short-term inspection tool. The bar charts will not be saved when you exit the 3D Pick window.

Maximum Bars: This value controls the maximum number of periods (and thus, the number of vertical bars) that may be shown in each chart.

Timelapse: This checkbox will create a new period each time a bench is selected, thus adding another bar to the charts. Once the maximum number of periods is displayed, older periods will be removed from the charts. You will need to click the Reset Charts button before this option can be disabled.

Chart Unpicked: This option will reset the charts and only show information pertaining to benches that have not yet been assigned to a piece of equipment.

Display Assigned Blocks: This option will display timing blocks that have already been assigned to a piece of equipment. The blocks will display with a transparent gray color to indicate they have been assigned. When this option is enabled, selecting a pit in the "Blocks Assigned to Selected Equipment" list will highlight that block with a yellow color. With this option, you can quickly review the progression of blocks that have already been assigned to a piece of equipment.

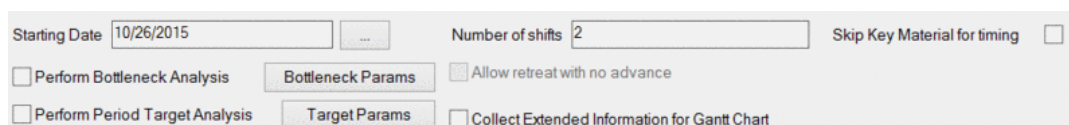

Period Slider Bar: The slider bar below the charts is only available when the Timelapse option is disabled. This slider bar allows you to control how many benches are represented in the last vertical bar of the charts. For example, if the slider bar is moved to the right end of the bar, all assigned pits will be represented in the last vertical bar chart. If the slider bar is moved closer further to the left, then fewer pits will be represented in the last vertical bar chart.

Manually Mark End of Period: This option is only available when the Timelapse option is disabled. The slider above this button controls which benches are in the current period. When this button is clicked, the current period will end and a new vertical bar will be added to the charts. You may then repeat the process to create additional periods. This allows you to compare attributes for multiple periods, thus showing, how the quality of the material mined will change over time. When manually marking the ends of the periods, none of the benches from a previous period will be considered in the new period.

Automatically Set Period by Interval: This button will define periods according to a set value. The pulldown menu to the right of this field controls which attribute is to be used for the definition of each period. For example, if this option is set to mark periods at 10,000 Key Ton intervals, the program will determine how many benches are needed to hit that target. Each time the value is exceeded, a new vertical bar will be added to the charts. It is often useful to reset the charts before using this option.

Reset Charts: This button will clear the charts.

Additional scheduling options are shown at the bottom of the Surface Equipment Timing dialog.

The screenshot shows a software interface for scheduling. It includes a 'Starting Date' field with the value '10/26/2015' and an ellipsis button to its right. Next to it is a 'Number of shifts' field with the value '2'. To the right of that is a checkbox labeled 'Skip Key Material for timing'. Below these are two rows of options. The first row has a checkbox for 'Perform Bottleneck Analysis', a 'Bottleneck Params' button, and a checkbox for 'Allow retreat with no advance'. The second row has a checkbox for 'Perform Period Target Analysis', a 'Target Params' button, and a checkbox for 'Collect Extended Information for Gantt Chart'.

Starting Date: This value sets the date to begin mining operations. The ellipsis button to the right of this field will open a small calendar to assist in date selection. By default, this value will be set the Mine Start Date set in the Timing Project Manager.

Number of Shifts: This value will set the number of working shifts in a day.

Skip Key for timing: This checkbox controls if key material is used for the timing. When this option is on, the key material (be it coal or some other resource) will not be included in the scheduling. Instead, it will be assumed that all key material will be mined quickly enough so that it never delays the removal of waste material.

Skip Non-Key for timing: This checkbox controls if Non-Key material is used for the timing. When this option is on, the Non-Key material will not be included in the scheduling. Instead, it will be assumed that all Non-Key material will be mined quickly enough so that it never delays the removal of Key material.

Perform Bottleneck Analysis: This option will perform a bottleneck analysis by limiting the total production from several pieces of equipment.

Bottleneck Params: This button will open the below dialog (left), which controls the Bottleneck Analysis.

The above dialog (left) lists all bottleneck parameters. The green plus icon to the left of the list will add a new parameter to analyze. The green ink quill icon will edit the selected parameter. The green minus icon will remove the selected parameter. When a new parameter is added, or a current parameter is edited, the dialog shown above (right) will open.

Field Name: This field sets the value to be used for bottleneck analysis, such as NONKEYVOLUME. This name must EXACTLY match an attribute used in the Detailed Report. A partial list of available names is given below. Note that user-defined attributes are not shown below. A full list of available attributes may be found in the Detailed Report > Report Formatter > Settings Tab > Attrib Options.

- KEYVOLUME
- NONKEYVOLUME
- KEYWEIGHT
- NONKEYWEIGHT
- WEIGHT
- etc.

Threshold: This value is the limit to be placed on the Field Name. In the above dialog, a maximum of 10,000 cubic yards of waste may be mined in a single shift.

Unit Name: This value sets the equipment to be limited by the Field Name. In the above example, the 10,000 cubic yard threshold is applied to all units. If only one or two units are listed, then the combined production of those units may not exceed the threshold value. The order in which units are listed will be used in the Restriction Scheme option.

Restriction Scheme: This drop-down list controls how units are scaled back due to bottlenecks.

The *Normal Rotation* option will alternate production through all units.

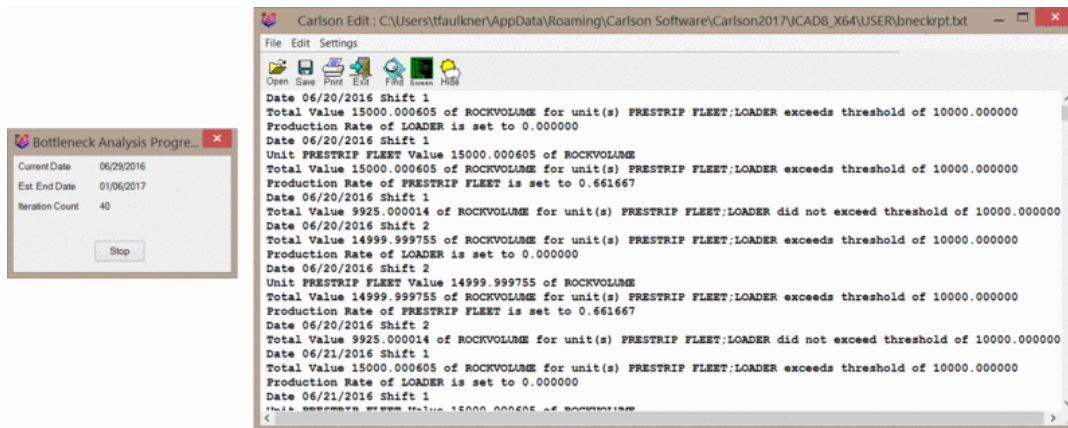

The *Hold Lead, rotate rest* option will operate the first unit listed in the Unit Name field at full production and all other units will be rotated through production.

The *Hold Tail, rotate rest* option will operate the last unit listed in the Unit Name field at full production and all other units will be rotated through production.

The *Fixed order option* maintains the order of unit preference and reduces production beginning with the tail unit until it is completely idled, then the next unit in the preference order is reduced until the objective is met.

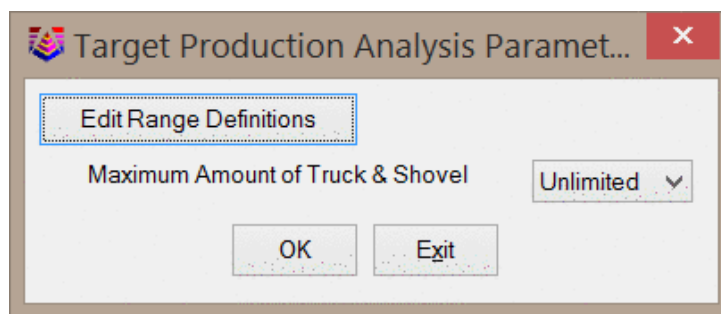

Bottleneck Example: Consider a PRESTRIP FLEET with a production capacity of 15,000 cubic yards per shift and a LOADER with a production of 12,000 cubic yards per shift. All the material excavated must be loaded and hauled away. Only 10 trucks are available to haul material, each with a hauling capacity of 1,000 cubic yards per shift. In this case, the trucks are the bottleneck in the mining process, limiting the overall production to 10,000 cubic yards per shift.

Using the Hold Last, rotate rest option for the Restriction Scheme, the PRESTRIP FLEET will be scaled back as necessary to ensure the LOADER is always operating at full capacity. When the schedule is calculated, the production capacity of each shift is checked, as indicated in the timing window shown below (left). After the schedule is checked for bottlenecks, a report of the shifts that require units to be scaled back will be generated, as shown below (right).

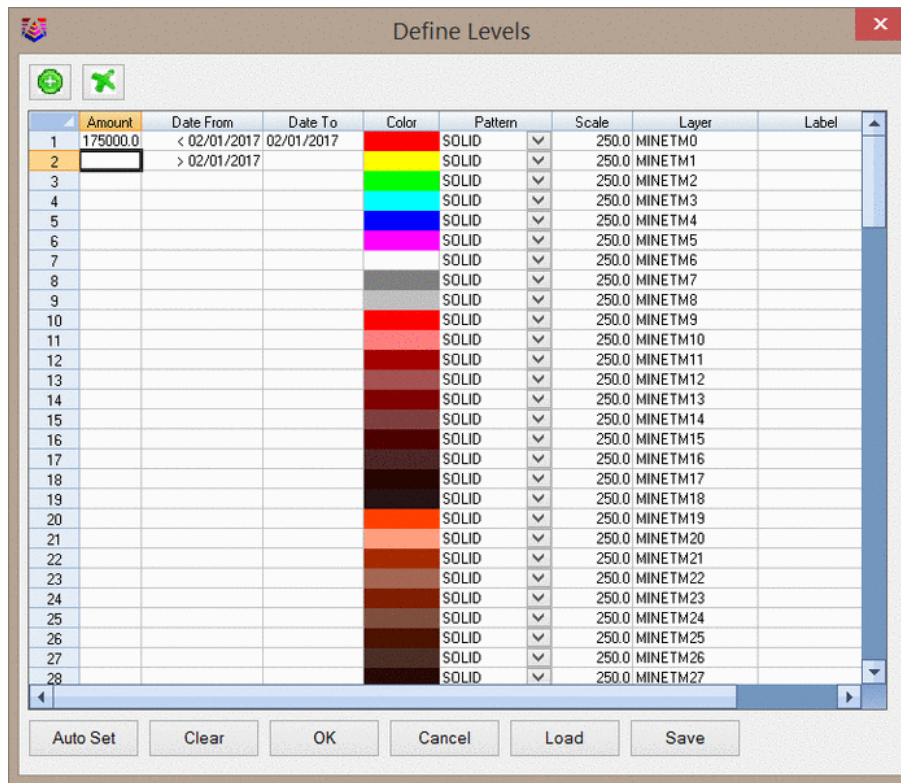

Perform Period Target Analysis: This option will perform a Period Target Analysis, which will add extra truck and shovel units for overburden removal as needed in order to ensure production targets are met. It is important to note that this option can only be used to increase overburden removal - additional units will not be added to increase the production rate of key material. To use this function, a piece of equipment named TRUCK&SHOVEL must be defined in the Timing Project Manager.

Target Params: This button will open the dialog shown below.

Maximum Amount of Truck and Shovel: This drop-down list will set the maximum number of Truck and Shovel units to be added to meet the production target.

Edit Range Definitions: This button will open the below dialog. In this dialog, the AMOUNT column represents the amount of Key material (in tons/tonnes) to be uncovered during the specified time period. This dialog is similar to the Amounts table, which is discussed in the Reporting Options section of this document. In the below example, a target production of 175,000 tons of key material must be uncovered by 02/01/2017.

Target Production Analysis example:

Consider the dialog shown above and the below reports. In the first report, only 146,000 tons of coal are uncovered. This is accomplished by mining three pits to completion and partially mining a fourth pit. If the target production shown above is applied, however, truck and shovel units are used to remove additional overburden in order to uncover the targeted 175,000 tons of coal.

Without Target Production Analysis

Period	Pit Name	Rock (c.y.)	Key Material (tons)	PRESTRIP FLEET Volume
01/01/2017 - 02/01/2017	Pit-1-1	296,296	44,212	296,296
01/01/2017 - 02/01/2017	Pit-1-2	296,296	46,654	296,296
01/01/2017 - 02/01/2017	Pit-1-3	296,296	48,792	296,296
01/01/2017 - 02/01/2017	Pit-1-4	41,111	7,227	41,111
Total		930,000	146,886	930,000

With Target Production Analysis

Period	Pit Name	Rock (c.y.)	Key Material (tons)	PRESTRIP FLEET Volume	TRUCK&SHOVEL Volume
01/01/2017 - 02/01/2017	Pit-1-1	296,296	44,212	252,818	43,478
01/01/2017 - 02/01/2017	Pit-1-2	296,296	46,654	252,818	43,478

Total		1,089,935	175,003	930,000	159,935

Allow Retreat with No Advance: This option is only used for the Underground Timing command. It will be disabled in the Surface Equipment Timing command.

Collect Extended Information for Gantt Chart: When enabled this option will allow the Gantt Chart to include extra information such as the pit volume, quality, etc.

The bottom of the Surface Equipment Timing dialog, shown below, has several buttons for generating reports.

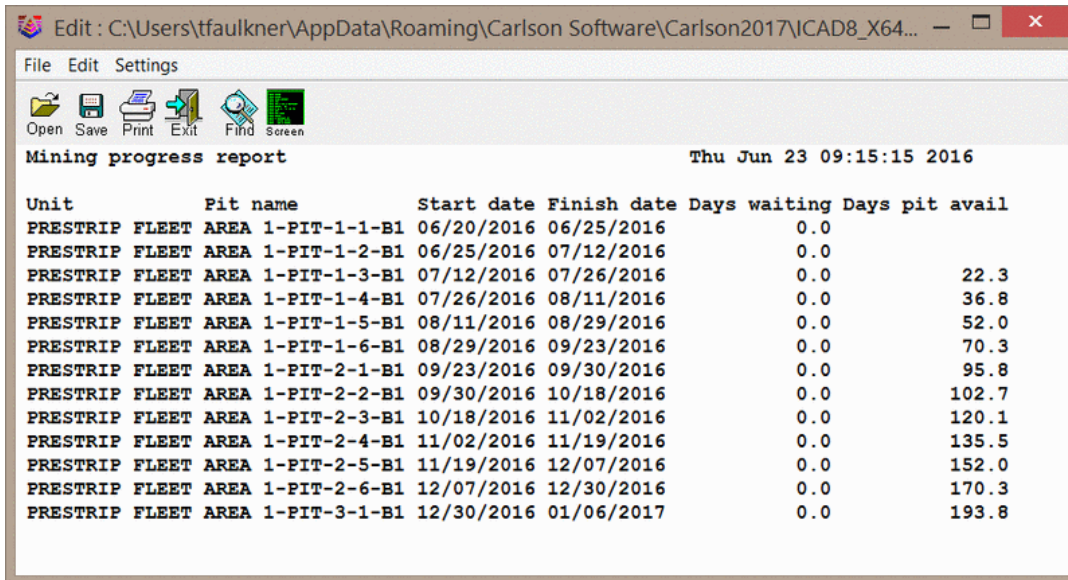

Calculate: This button will calculate the mine schedule. If any errors are encountered, the below dialog (left) will appear. The problem report generated will appear similar to below (right). In this example, a precedence rule has been violated for the PRESTRIP FLEET equipment. Pit-1-2-B1 cannot be mined until Pit-1-1-B1 has been mined. This will require an edit to the assignment order.

If no problems are encountered, the schedule will be calculated and the below dialog will appear.

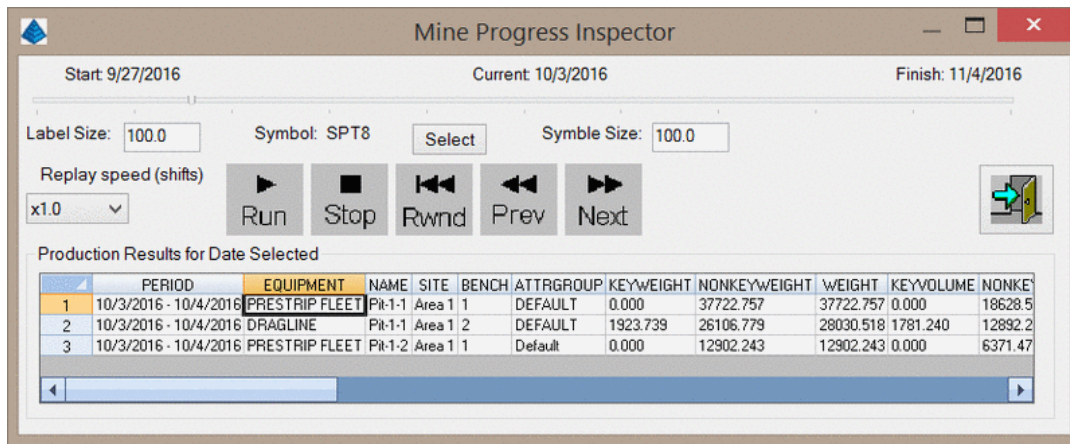

Report: This button will generate a very simple report as shown below. Note that this report does not include information about the amount of material mined. The Days Waiting in this report refer to the number of days in which a pit is waiting to be excavated due to precedence rules, or due to a scheduled delay. The Days Pit Avail refers to the number of days the pit is ready for mining (no waiting needed due to precedence)

Detailed Report: This button will generate a more detailed report, including information such as the amount of material mined, quality of material, downtime, etc. This report is discussed in more detail later in this help document.

Progress Review: This button will open the Progress Inspector shown below. The Progress Inspector will only be generated with information after the mine schedule has been calculated.

The Progress Inspector allows you to step through the day-by-day schedule of each piece of equipment. The slider bar at the top of the window may be used to cycle through the dates quickly. Various information about each piece of equipment is shown in the spreadsheet view. As you progress through each day with the below controls, a symbol and label will appear on the drawing to indicate the location of the equipment. The size of the labels/symbols may be set with the **Label Size** and **Symbol Size**. A different symbol may be selected by clicking the **Select** button.

Run: This button steps through the overall mine progression day-by-day. You may modify the playback speed by changing the **Replay speed** option.

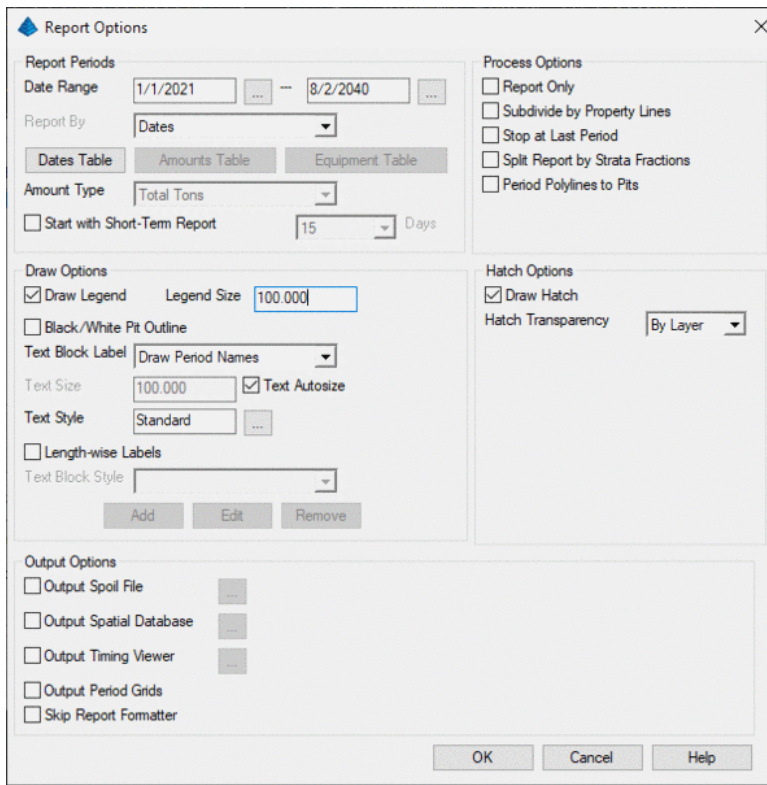

Stop: This button stops the action of the Run button.

Rwnd: This button returns the inspector to the first working day of the schedule.

Prev: This button steps to the previous day in the mine schedule.

Next: This button steps to the next day in the mine schedule.

Report: This button is only available after calculating the mine schedule. This button will open the Detailed Report dialog. This is the same dialog that will appear after selecting the Detailed Report option after clicking the Calculate button.

Date Range: This option will set this range of dates to report.

Report by: This drop list will determine how the timing map is generated.

If the *Dates* option is selected, the timing map will be colored by date ranges.

If the *Amounts* option is selected, the timing map will be colored by amount intervals.

If the *Equipment* option is selected, the timing map will be colored by equipment.

Dates Table: This button will open the Dates Table, shown below, which is used to define the various time periods used for reporting.

	End Date	Range	Color	Pattern	Scale	Layer	Label
1	2/1/2028	< 2/1/2028	Red	SOLID	Set	250.0 MINETM	Set
2	3/1/2028	2/1/2028 - 3/1/2028	Dark Red	SOLID	Set	250.0 MINETM	Set
3	4/1/2028	3/1/2028 - 4/1/2028	Red-Orange	SOLID	Set	250.0 MINETM	Set
4	5/1/2028	4/1/2028 - 5/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
5	6/1/2028	5/1/2028 - 6/1/2028	Dark Orange	SOLID	Set	250.0 MINETM	Set
6	7/1/2028	6/1/2028 - 7/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
7	8/1/2028	7/1/2028 - 8/1/2028	Dark Orange	SOLID	Set	250.0 MINETM	Set
8	9/1/2028	8/1/2028 - 9/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
9	10/1/2028	9/1/2028 - 10/1/2028	Dark Orange	SOLID	Set	250.0 MINETM	Set
10	11/1/2028	10/1/2028 - 11/1/2028	Orange	SOLID	Set	250.0 MINETM	Set
11	12/1/2028	11/1/2028 - 12/1/2028	Dark Orange	SOLID	Set	250.0 MINETM	Set
12	1/1/2029	12/1/2028 - 1/1/2029	Orange	SOLID	Set	250.0 MINETM	Set
13	2/1/2029	1/1/2029 - 2/1/2029	Dark Orange	SOLID	Set	250.0 MINETM	Set
14	3/1/2029	2/1/2029 - 3/1/2029	Orange	SOLID	Set	250.0 MINETM	Set
15	4/1/2029	3/1/2029 - 4/1/2029	Dark Orange	SOLID	Set	250.0 MINETM	Set
16	5/1/2029	4/1/2029 - 5/1/2029	Yellow	SOLID	Set	250.0 MINETM	Set

The above dialog can be used to create custom time periods to show in the timing map. The green and red icons at the top of the dialog will add and delete rows of information.

End Date: This column sets the ending date of the period.

Range: This column is automatically generated, and simply identifies the Date Range for the period. Dates may be preceded by > or < to mark indefinite time periods.

Color: This column sets the color of the time period. Double clicking one of these cells will open the CAD color palette.

Pattern: This column sets the hatch pattern for the timing blocks. The Set button to the right of this column will open a dialog of available hatch patterns.

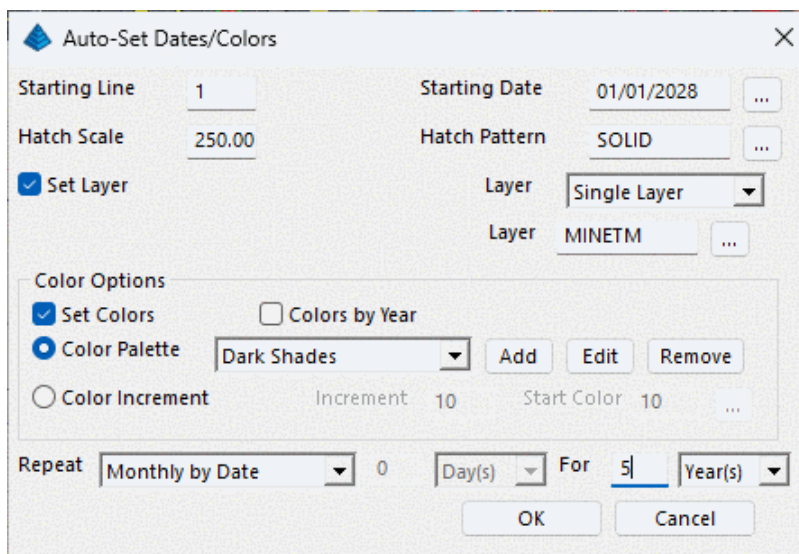

Scale: This column sets the scale of the hatch pattern.

Layer: This column sets the CAD layer on which to draw the timing block.

Label: This column sets a custom label for the timing block.

Clear: This button will clear the table of all information.

Auto Set: This button will open the below dialog, which allows for quick population of the Custom Dates table.

Starting Line: This value will set the row to begin the automatic population of the Custom Date table.

Starting Date: This is the Date From that will be used on the Starting Line. The ellipsis button will open a small calendar to assist in date selection.

Hatch Scale: This value will set the hatch scale for the new time periods.

Hatch Pattern: This field will set the hatch pattern for the new time periods. The ellipsis button will open the list of available hatch patterns.

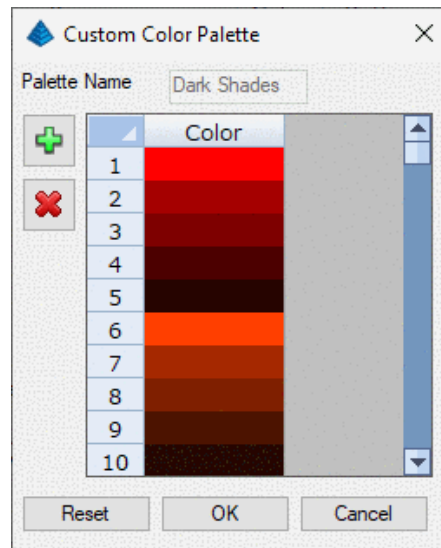

Set Layer: This option will overwrite the Layer names when enabled.

Layer by: This drop list determines how the layers will be populated. If the *Single Layer* option is selected, all layers will be the same, according to the **Layer** text box. If the *Year* option is selected, the layer will be set by the year of the time period.

Set Colors: This option will set custom colors for the new time periods. There are two options for setting colors - by using a Color Palette, or by using a Color Increment.

Colors by Year: When this option is enabled, the colors will only increment when the starting date for a row changes. This option is handy for drawing timing maps that have the same color for an entire year, but generate the report on a monthly basis.

Color Palette: This option will use a predefined color palette to color the time periods. When the end of the palette is reached, the colors will start over. Palettes may be added, edited or remove used the corresponding buttons. An example color palette is shown below. Colors may be added or removed from the palette by clicking the Plus or X icons, and colors may be modified by double-clicking them. Any of the predefined palettes may not have their name modified. If you modify the colors in a predefined palette, you may click the **Reset** button to return to the default colors.

Color Increment: This option will color the periods by using a **Start Color** and a **Color Increment**. All colors in the CAD color palette range from 1 to 255. You may want to inspect the color palette when using this option to relate colors back to their numeric value. For example, a Start Color of 10 and a Color Increment 10 will increment through colors 10, 20, 30, etc.

Repeat: This option will determine the length of the time periods. Selecting the *Every* option will allow you to set a custom length for the time periods. You can also specify the length of time to define. For example, you could set the date ranges on a weekly basis for 2 years.

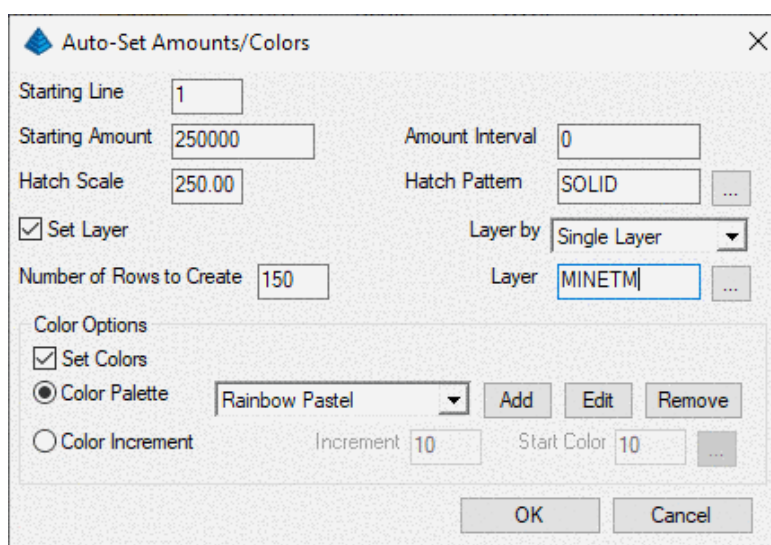

Amounts Table: This button will open the Amounts Table, shown below, which is used to define the various amount intervals used for reporting.

The above dialog is very similar to the Custom Dates table previously discussed. The primary difference is that the dates are replaced with the **Amounts** column. These values may represent one of the following values to be mined, set according to the **Amount Type**:

- Total Tons
- Key Material Tons
- Waste Tons
- Total Area
- Mined Area
- Total Volume
- Key Material Volume
- Waste Volume
- User Grid

Auto Set: This button will open the below dialog, which is very similar to the Auto Set dialog used in the Custom Dates table, as previously discussed. This dialog differs in that amounts are specified rather than dates, and the periods are set to repeat for a set number of times, rather than being based on the dates.

Equipment Table: This button will open the Equipment Table, shown below, which is used to set the colors for each piece of equipment to be reported. This is like a simplified version of the Dates Table and Amounts Table. Here there is no option to set a report period - only the color, hatch, layer, and label for each piece of equipment.

	Equipment	Color	Pattern	Scale	Layer	Label
1	PRESTRIP FLEET	Red	SOLID	100	MINETM	Prestrip
2	DRAGLINE	Yellow	SOLID	100	MINETM	Dragline
3	LOADER	Green	SOLID	100	MINETM	Loader

Start with short-term report: This option will include a shift-by-shift report for the beginning of the timing report. The drop list specifies the number of days to be reported in this manner. After this number of days, the program stops reporting shift-by-shift and reverts to reporting based on the defined periods.

Report Only: This option will not create a timing map; only the mine schedule will be reported. When selected, many other options on the dialog will be ghosted out.

Subdivide by Property Lines: This option will sub-divide the report by property owner.

Stop at last period: This option is only available when the Custom Amount Table report option is selected. This option will end the schedule at the last entered user row in the Custom Amount Table.

Split report by strata fraction: This option will utilize the tonnage and volume factors stored as pit attributes and report out the volume and tons of each named strata (rather than simply reporting Key and Non-key values).

Period Polylines to Pits: This option will generate new Pit Polylines from the period boundaries. The pit names will match the name of the period used to create them.

Draw Legend: This option will draw a color legend of the timing map. The **Legend Size** can be used to make the legend larger or smaller.

Black/White Pit Outline: This option will draw the boundaries of the timing periods with a white/black color as opposed to matching the color of the hatch.

Text Block Label: This drop list will determine how the labels are drawn in the timing map.

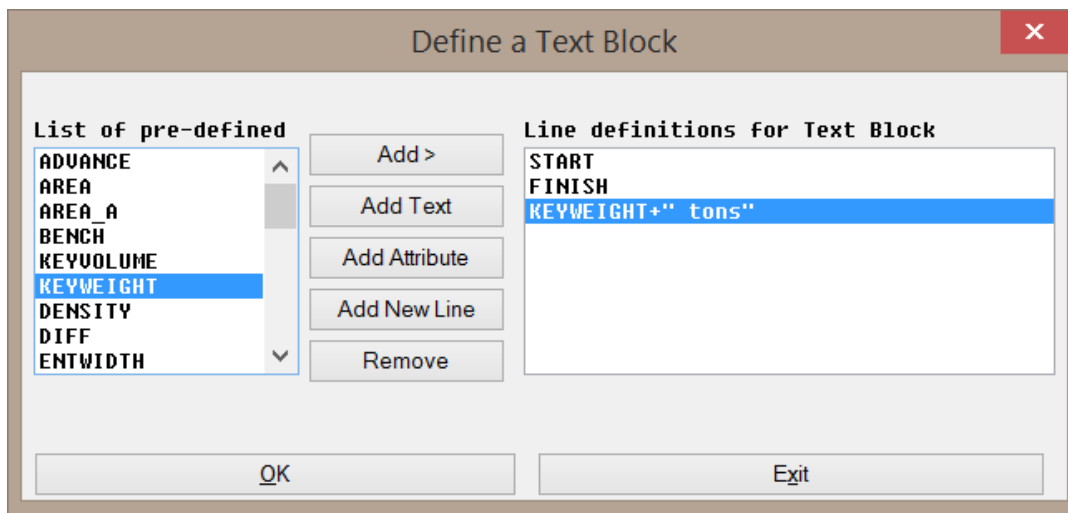

The *No Block Labels* option will not draw labels.

The *Draw Actual Dates* option will label the starting and ending date of each period.

The *Draw Period Names* option will draw labels defined in the Custom Date Table.

The *Use Custom Names* option will draw labels defined in the Custom Amount Table.

The *Use Custom Text Block* option will draw labels according to the below dialog. When selected, the **Text Block Style**, **Add**, **Edit**, and **Remove** buttons will become available. The Text Block Style dropdown list will list all available text block labels. The Add button will create a new text block. The Edit button will edit the currently selected text block. The Remove button will remove the currently selected text block.

The left side of the above dialog contains pre-defined keys that may be used in the labels. The right side of the dialog shows how the text block label will appear.

Add: This button will add the selected attribute to the current line. Multiple attributes may be added to a single line.

Add Text: This button will add custom text to the current line. In the above example, "tons" has been added as a suffix to the KEYWEIGHT attribute.

Add Attribute: This button will add any attribute that is not defined in the pre-defined list. This attribute name must match an attribute available in the final text report.

Add New Line: This button will create a new line in the text block. In the above example, three lines have been created.

Remove: This button will remove the selected line from the text block.

Text Size: This value will set the text size of the block labels.

Text Autosize: This option will automatically size the text of the block labels.

Text Style: This option will set the text style to use for the period labels. The **Select** button will allow you to select one of the existing text styles.

Length-wise labels: This option will rotate the block labels in line with the mining direction of each bench. If not selected, labels will be drawn perpendicular to the mining direction.

Draw Hatch: This option will create boundaries for the timing periods and fill them in with the specified hatch pattern/color.

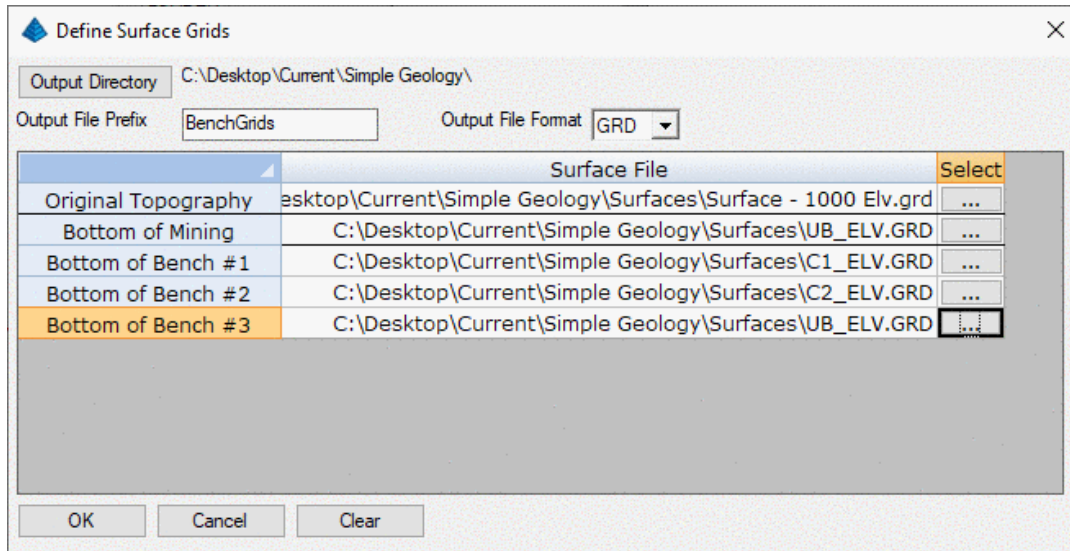

Hatch Transparency: This drop list sets the transparency of the hatches.

Output Spoil File: This option will create a .spo file to be used with the spoil timing commands found under the Spoil Pulldown Menu. The .spo file includes the amount of waste material excavated from each pit, the date the pit was excavated, etc. You may specify the .spo file by clicking the ellipsis button to the right of the checkbox.

Output Spatial Database: This option will output the report information to an SQLITE database. The database will retain the coordinate system of the drawing for linkage with GIS software packages. You may specify the file by clicking the ellipsis button to the right of the checkbox.

Output Timing Viewer: This option will output a .tv file and solids of each timing block. The .tv file may be reviewed to show a 3D playback of the timing, very similar to the Period Grids, but with the use of solids (.mdl files) rather than surfaces. You may specify the file by clicking the ellipsis button to the right of the checkbox. When using this option, you will need to specify the elevation of each bench using the dialog shown below.

Output Period Grids: This option will create a grid or TIN file of the updated surface at the end of each period. When the report is generated, the below dialog will appear.

The surfaces in the above dialog will be automatically set according to the files found in the Attribute groups of the Timing Project Manager. If these surfaces have not been assigned in the Timing Project Manager, they will need to be manually selected. It is important to note that the output surfaces will display near-vertical highwalls when the mining face advances. Each surface will be colored by the period/disturbance area that matches the color displayed on the timing map for each period.

Output Directory: This button will set the folder in which to save the output surfaces.

Output File Prefix: This button will set the prefix for each surface file to be saved.

Output File Format: This option determines if the output surfaces will be grids or TIN's.

Original Topography: This surface file defines the existing surface topography.

Bottom of Mining: This surface file defines the ultimate pit floor.

Bottom of Bench# : Each of these surfaces define the bottom of each bench.

Skip Report Formatter: This option will skip the report formatter. Rather than customizing the format of the report, the information will be automatically sent to a text file preview.

Examples of a timing map and a generated text report are shown below. Note that there are MANY ways that a

timing map and report may be formatted. The Report Formatter is used to generate the text report, but this dialog is not discussed at length here.

Key Material production report

Fri Jun 24 11:18:04 2016

Period	Pit Name	Equipment	Rock (c.y.)	Key Material (tons)	Key thickness	Strip ratio	Work shifts
06/20/2016 - 07/01/2016	Pit-1-1	PRESTRIP FLEET	174087.404	0.000	0.000	999.990	11.606

01/01/2017 - 02/01/2017	Pit-3-1	PRESTRIP FLEET	176813.269	0.000	0.000	999.990	11.788
01/01/2017 - 02/01/2017	Pit-3-2	PRESTRIP FLEET	529950.265	112312.183	28.078	4.719	35.330
01/01/2017 - 02/01/2017	Pit-3-3	PRESTRIP FLEET	223236.467	52636.365	29.248	4.241	14.882
02/01/2017 - 03/01/2017	Pit-3-3	PRESTRIP FLEET	272939.698	64355.765	29.248	4.241	18.196
02/01/2017 - 03/01/2017	Pit-3-4	PRESTRIP FLEET	537388.929	124065.383	31.016	4.331	35.826

There are many attributes available in this report. Most of these attributes are self explanatory, but some are not as clear. The below definitions are therefore provided.

- Difficulty Factor: This mining rate factor represents the difficulty of mining a specific area. A value of 1.0 means that mining progresses at a normal rate. This value is the product of the Equipment Difficulty and the

- Location Difficulty.
- **Equipment Difficulty:** This value is the product of the optional difficulty rates set in the equipment definitions. This can include
 - Date Difficulty
 - Thickness Difficulty
 - Bench Difficulty
 Note that pits have a dedicated Difficulty attribute that will be used as an additional multiplier for the Equipment Difficulty. This is not the same as specifying difficulty with the DIFF_BENCHX attribute.
 - **Location Difficulty:** This value is a difficulty factor determined by a hierarchy of the following three options. If the high priority item is detected, it will be used instead of the other two options. If the high priority option is not detected, the medium priority item will be used. If neither of these items are detected, the low priority item will be used. The low priority item defaults to a value of 1.0, so if no location difficulty is defined, the mining rate will not be affected.
 - Highest priority: text in the drawing on the DIFF_BENCHX layer (where X is a bench number)
 - Medium priority: DIFFICULTY attribute value/grid in the Timing Project Manager Attribute Groups
 - Lowest priority: Difficulty value assigned to the specific pit (set with the EDITPIT command)
 - **Calendar Days:** Actual period length between start date and end date (allows for partial days). Note that a day is not necessarily a 24 hour period, but is instead defined by the equipment definition. For example a piece of equipment working two 8-hour shifts means that one calendar day is equivalent to 16 hours.
 - **Operating days:** Scheduled shifts divided by number of shifts per day (as defined in equipment definition)
 - **Days:** Scheduled Hours divided by day length in hours (as defined in equipment definition). Note that if all shifts are the same length, this attribute will be the same as the Operating Days.
 - **Weekdays Worked:** Shifts scheduled on weekdays divided by number of shifts per day
 - **Saturdays Worked:** Shifts scheduled on Saturdays divided by number of shifts per day
 - **Sundays Worked:** Shifts scheduled on Sundays divided by number of shifts per day
 - **Days Waiting:** Number of days equipment cannot work due to a precedence rule
 - **Work Shifts:** Number of scheduled work shifts. A shift that is not scheduled to work (due to a Calendar Delay) will not contribute to this value.
 - **Hours Scheduled:** Number of hours equipment is scheduled to work (this includes Hours Utilized, Hours Delayed, and Hours Available)
 - **Hours Down:** Number of hours equipment is not scheduled to work (due to downtime scheduled on the calendar)
 - **Hours Utilized:** Number of hours equipment is actually working
 - **Hours Delayed:** Number of hours equipment is delayed due to a Drawing Event or Scheduled Delay (note, this is not the same as Hours Down caused by a Calendar Delay). Note that a Scheduled Delay will appear on the Assignment List for each piece of equipment
 - **Hours Available:** Number of hours is scheduled to work, but is neither being utilized nor is it actually delayed. If a piece of equipment encounters a delay during the middle of the shift, the partial shift time remaining will be counted as Hours Available (the delay will be applied to the next shift)

The below image helps visualize the organization of the different definitions of Hours.

Hours in a day	Hours Scheduled	Hours Utilized
		Hours Delayed
	Hours Down	Hours Available

Undo Report: This button will delete a previous timing map and clear the calculated schedule. This allows for quick what-if analysis of the scheduling.

Events Report: This button will display the Events Report, which lists all Drawing Events encountered during the mine schedule. Drawing Events are discussed in more detail in the Timing Project Manager. This report is only available after a Detailed Report has been generated. An example of the Events Report is shown below, in which four drawing events were encountered.

Event Key	Event Layer	Description	Period	Unit	Pit/Panel Name	Northing	Easting	Event Value	Station	Event Date	Year (start)	Month/Year
Deadhead	Delay1	Dragline at end of strip	08/01/2016 - 09/01/2016	DRAGLINE	Pit-1-6	1970979.55	1460575.17	Delay1	654.59	08/01/2016	2016	08/2016
Deadhead	Delay1	Dragline at end of strip	09/01/2016 - 10/01/2016	DRAGLINE	Pit-2-6	1971179.55	1460575.17	Delay1	654.59	09/16/2016	2016	09/2016
Deadhead	Delay1	Dragline at end of strip	10/01/2016 - 11/01/2016	DRAGLINE	Pit-3-6	1971379.55	1460575.17	Delay1	654.59	10/31/2016	2016	10/2016
Deadhead	Delay1	Dragline at end of strip	12/01/2016 - 01/01/2017	DRAGLINE	Pit-4-6	1971579.55	1460575.17	Delay1	654.59	12/16/2016	2016	12/2016

Monthly Report: This button will generate a monthly report, similar to the Detailed Report, but with less information available and without the ability to set custom time periods for reporting. An example of the Monthly Report is shown below.

Unit	Month	Year	Operating days	Days	Weekdays Worked	Saturdays Worked	Sundays Worked	Calendar days	Work shifts	Hours Utilized	Scheduled hours	Hours Availa
PRESTRIP FLEET	June	2016	30.00	30.00	22.00	4.00	4.00	30.00	60.00	263.99	719.99	456

Gantt Chart: This button will generate a Gantt chart of the mine schedule. This button is only available after calculating the mine schedule. For more information, see the Gantt Chart section of the help manual.

Utilization Report: This button will generate a Utilization Report of the mine schedule. This report lists each shift for each piece of equipment. Scheduled delays will be reported as such. An example of the Utilization Report is shown below.

Event Date	Shift	Equipment	Shift Hours	Util.	Ratio	Type	Calendar Rule
06/20/2016	1	PRESTRIP FLEET	12	1.00	1.00	UTILIZATION	
06/20/2016	2	PRESTRIP FLEET	12	1.00	1.00	UTILIZATION	
06/21/2016	1	PRESTRIP FLEET	12	1.00	1.00	UTILIZATION

Back to Project: This button will return to the Timing Project Manager window.

Prompts

Select all pit polylines.

Select objects: *Pick all polylines* **Pull-Down Menu Location:** Reserves/Timing

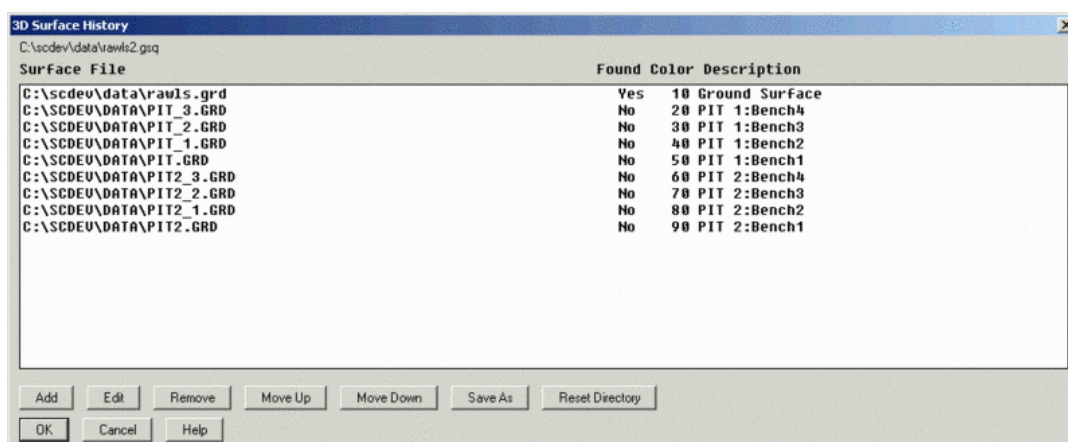

Keyboard Command: timepit

Related Commands: Surface Mine Reserves, Assign Directions, Surface Project Manager, Assign Timing Grids, Import Timing Data, Define Pit Attributes

View 3D Surface History

This command allows you to modify and playback the surface sequence history generated by several Carlson commands such as Design Bench Pit. The surfaces can be either grid or triangulation files. The command initially displays a list of surface files in the sequence. You can add more surfaces, modify surface colors or change the surface order. The Report function creates a report of the files and their parameters. The Add and Edit functions have a dialog to set the surface file name, description and color for the step. There are also settings for the optional pit and perimeter polylines. The pit polyline is the base of the pit where the cut slopes start. The perimeter polyline is the limit of the pit where the cut slope ties into the ground surface. When the Surface History has the pit and perimeter polylines assigned, then the Surface Mine Reserves command has an option to use the Surface History to report strata quantities for each step in the history.

When editing is complete, pick the OK button which brings up the playback 3D viewer window.

In the right side of the Viewer window, there are buttons allowing you to move from step to step in a surface sequence. On each step the surface displayed has elevations of the surface assigned for that step and the color of the last surface when the elevation at a particular location changed. For example the unaffected regions will have the color assigned to original ground surface. The Run Speed controls the rate of showing the surface with the Run button.

The blue circle icon with yellow dot represents the sky and sun position. You can move the yellow dot to change the shading for the sun. There are sliders to control the brightness of the ambient and sun lighting. The Display Axis toggle shows an X/Y/Z axis icon in the scene.

The zoom button activates zoom mode, where if you hold left mouse button and drag the mouse pointer up or down the picture zooms out or in correspondingly. In the rotate mode, the horizontal drag rotates the X axis (around Y), the vertical drag rotates the Y axis around X. The circular movement along the periphery of the picture rotates picture around the Z axis.

When pan button used, the picture will pan if mouse is dragged with the left button pressed.

The shade button turns the shading of the surface on or off.

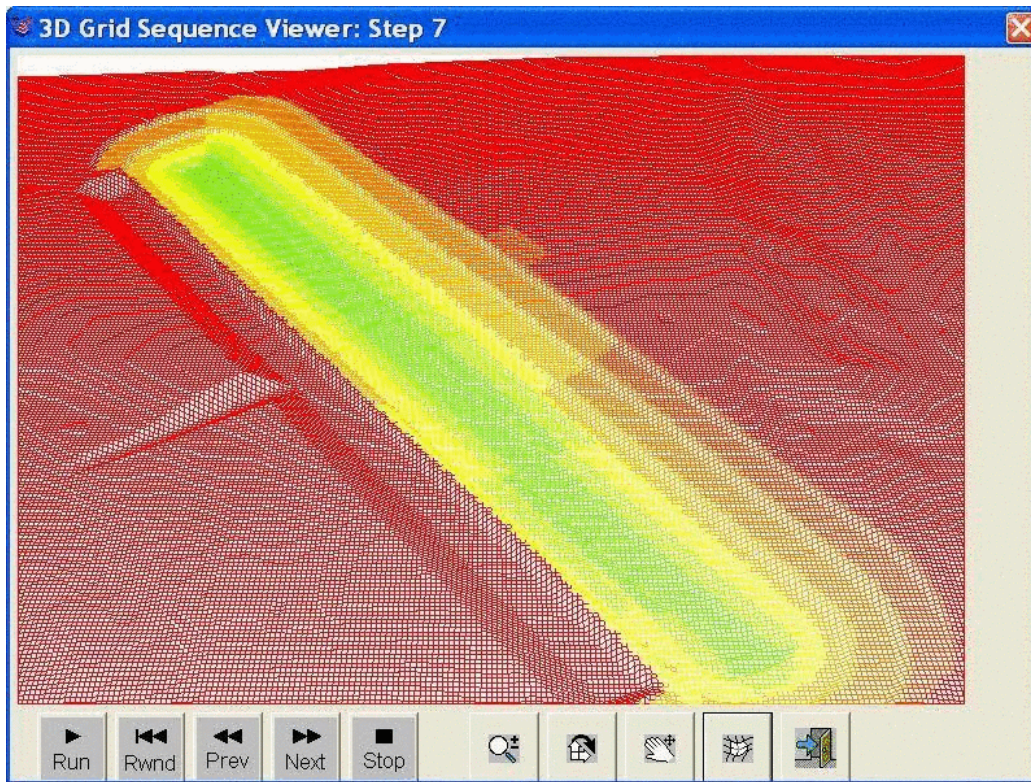

The camera button saves an image file of the current view.

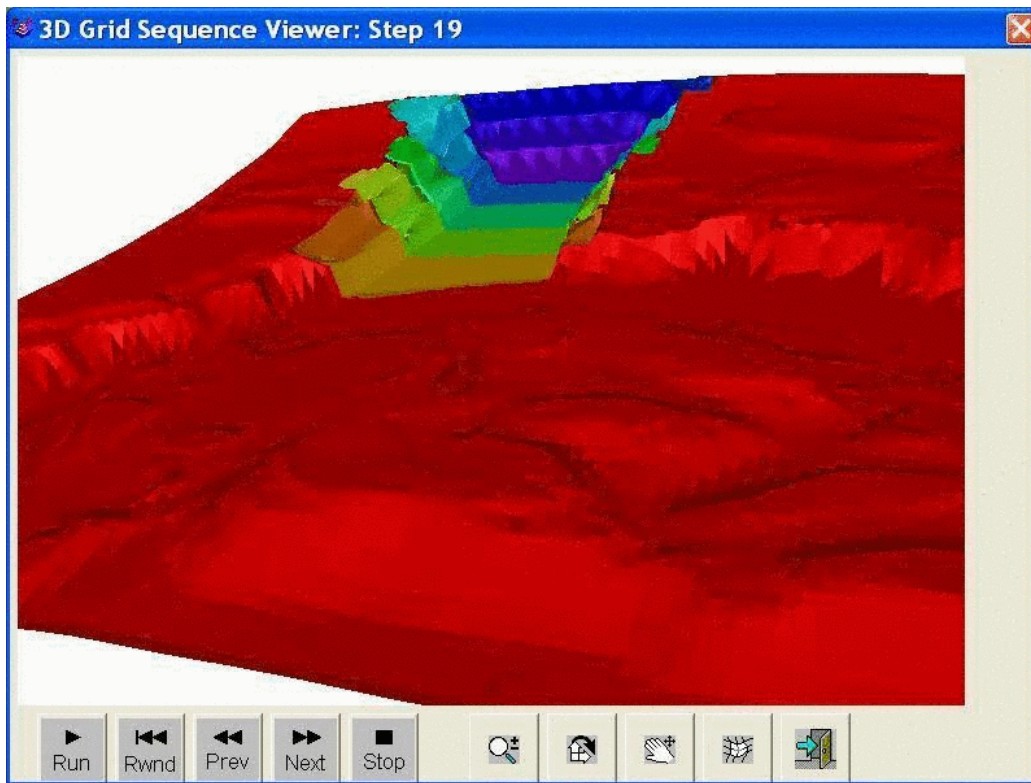

This GSQ file can be used in Surface Mine Reserves to automatically calculate the quantities by bench for the pits with highwalls.

Prompts

Surface Sequence File file selection dialog Choose the .gsq file to update.

Here are a couple of examples:

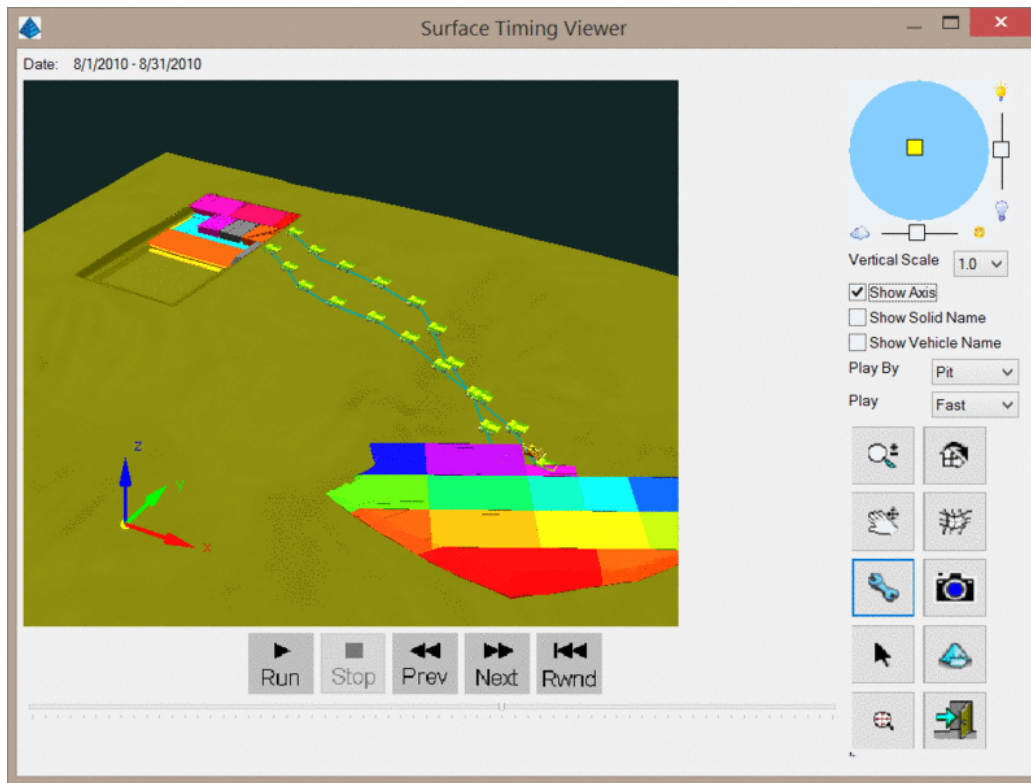

Pulldown Menu Location: Surface

Keyboard Command: gridstep

View 3D Timing

This command will open a .tv file to playback the progression of the mine. This file can be created from Surface Equipment Timing, Spoil Placement Timing, and Haul Cycle Analysis.

When the command is executed, you will be prompted to select a TIN file representing the topography at the end of the mine life. You will then be prompted to select a .tv file to view, after which the below dialog will appear. It is important to note that in order to view a .tv file, the linework for the spoil piles, haul routes, and the period polylines (output from Surface Equipment Timing as Pits) must be present in the drawing.

Vertical Scale: This value sets the vertical exaggeration for the 3D view.

Show Axis: This toggle controls the display of the X-Y-Z Axis icon in the lower left corner of the 3D view.

Show Solid Name: This toggle controls the display of labels above each solid. Names will only be displayed for solids that are being moved during the current time period.

Show Vehicle Name: This toggle controls the display of labels above each piece of equipment.

Play by: This option controls the playback of the 3D View. The *Pit* option will increment the time period based on when each pit is completely mined out. The *Spoil* option will increment the time period based on when a spoil polyline is completely filled.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display.

Switch to Dynamic Zoom mode. Click and drag to zoom in and out.

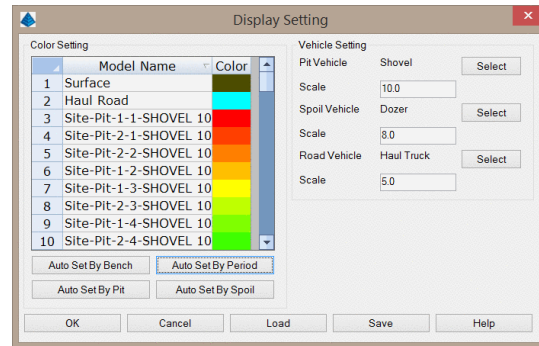

Switch to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switch to Pan mode. Click and drag to pan.

Toggle shading of 3D Faces and Surfaces.

Controls coloring and appearance of 3D symbols. When clicked, the below dialog will appear.

The spreadsheet shown in this dialog lists the name and color of each feature in the 3D window. You can automatically color the solids using one of the Auto Set By... buttons.

Auto Set By Bench: This option will color pits and spoil piles by bench number. For example, all instances of bench 1 will be red, all instances of bench 2 will be orange, etc.

Auto Set By Period: This option will color pits and spoil piles by the time period in which they are modified. For example, all material moved in the first month will be red, all material moved in the second month will be orange, etc.

Auto Set By Pit: This option will color pits and spoil piles by the pit. For example, all material from the first pit mined will be red, all material from the second pit mined will be orange, etc.

Auto Set By Spoil: This option will color pits and spoil piles by the spoil pile. For example, all material that is placed in the first spoil pile will be red, all material placed in the second spoil pile will be orange, etc. All of these buttons will display a similar dialog, shown below.

In this dialog, you can set a **Starting Color #** and a **Color Increment** according to the CAD color palette. The default option of a Starting Color # of 10 and a Color Increment of 10 will produce a rainbow gradient. A Starting Color # of 11 and a Color Increment of 10 will produce a lighter shade of a rainbow gradient.

The **Vehicle Settings** allow you to set different 3D models for the pit equipment, the haulage equipment, and the spoil equipment. The **Select** button will open the 3D Model Library, which includes several pieces of mining equipment. The **Scale** value controls the size of the model in the 3D view.

Takes a screenshot of the 3D Viewer. Several different image file formats are supported including bmp, png, jpg, xpm and gif. The image resolution and color depth may be set with this option.

Switches to Inspection mode. In this mode, hovering the cursor over a solid will display the name of the solid.

Outputs the current time period as a TIN file. With this command, you can progress through the timeline to key points in the mine life and export a surface model.

Exit the command.

Starts playback of the mine timeline.

Stops playback.

Steps back one time period.

Steps forward one time period.

Resets the playback to the beginning of the timeline.

The slider bar shows the current position in the timeline. You can manually click-and-drag the slider bar to progress through the timeline.

Pulldown Menu Location: Reserves/Timing

Keyboard Command: tvviewer

Clear Timing Map

Removing the coloring after the timing routines are completed may be a tedious task. This routine removes and erases all text labels and hatching from surface pits and underground panels for a specific bench or mining direction in one step. It is a quick and efficient procedure, even for objects on many layers. Items are permanently removed from the drawing screen. It supports both surface and underground mining.

Prompts

For Surface Timing:

Enter Bench Number to Remove coloring for (Bench Number/<All>):

Select parts of mineplan to have timing coloring removed:

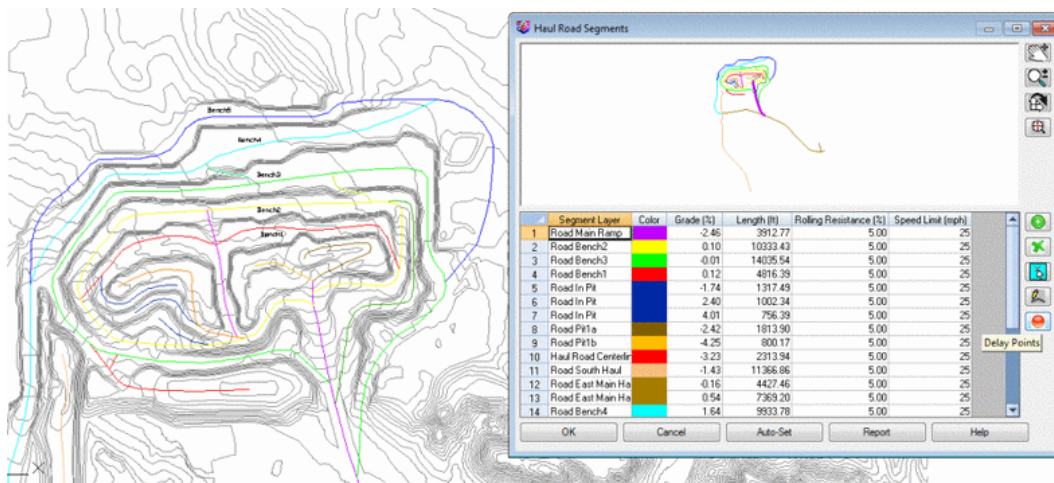

(Bench Number/<All>): *press Enter*

Pulldown Menu Location: Surface

Keyboard Command: utime_clear, stime_clear

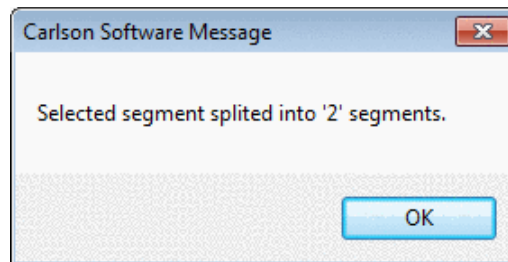

Haul Road Manager

This command builds and links the haul road network, recognizing 3D polylines and adding them to the network. All possible roads must be drawn as 3D polylines in CAD, either draped onto the surface model, or snapped to contours. Individual layers can be used for clarity to see the roads in the manager by color and layer. There aren't any tagged segments to select the first time this command is run, so the preview image will be blank. The segments must be added by picking the green "+" button to bring them into the editor.

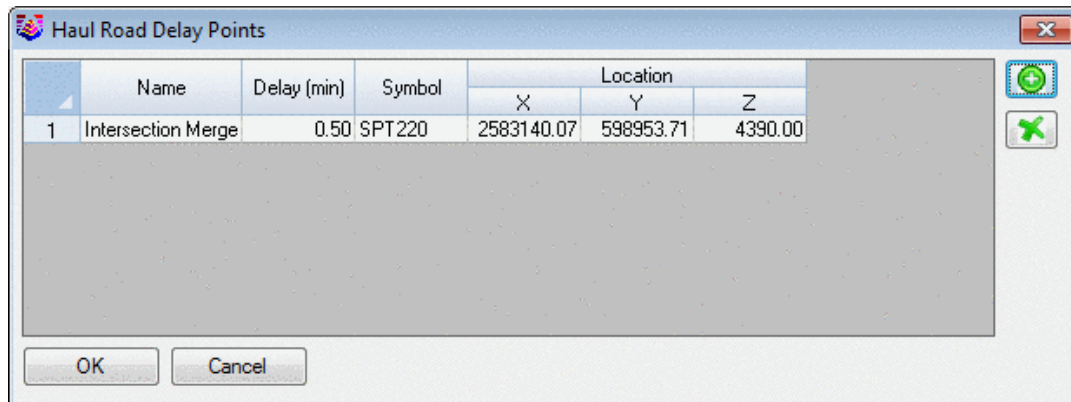

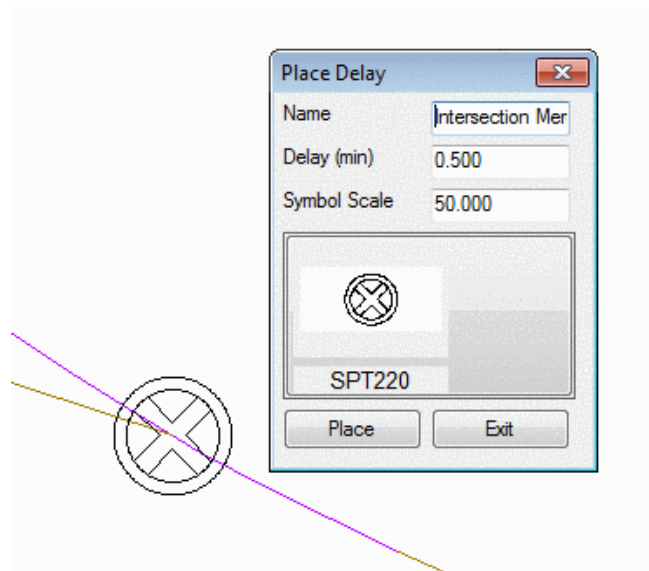

- **Preview Window Display:** The upper preview window has four buttons for Pan, Zoom Realtime, Rotate and Zoom Extents.
- **Add Segments:** Selecting the green "+" button will prompt for selecting the 3D polylines in CAD to add to the haul road network. This must be done initially if there are no segments found.
- **Remove Segment:** This green "X" button will remove the highlighted segment from the manager.

- **Pick Segments:** The Select from Screen, Pick Segments button is used to pick already named haul road segments, and add them to the manager. They must be already tagged with the Add Segments for them to be recognized.
- **Split at Grade Break:** Selecting this button will split the haul roads into smaller segments, based on the percent grade tolerance so that each segment is within that slope tolerance. This isn't a requirement, but the idea is to have segments with constant grade as the truck speed is depended on the grade of the road, and this will divide the road into smaller segments if desired. This will also break the 3D polylines into the smaller segments, so it is recommended to Save the drawing as a new name before breaking, so that there is a back up to go back to if necessary. There are two dialogs that appear from this command. It will only break the highlighted segments, so it is easy to control which roads are being divided.

- **Delay Points:** These are point symbols inserted into the drawing the will trigger a delay event for the specified number of minutes. Examples would be a stop sign at an intersection, or a one lane bridge where trucks have to stop. Any symbol from all of the libraries can be inserted to represent the location. These delays will be accounted for when the trucks pass over that spot.

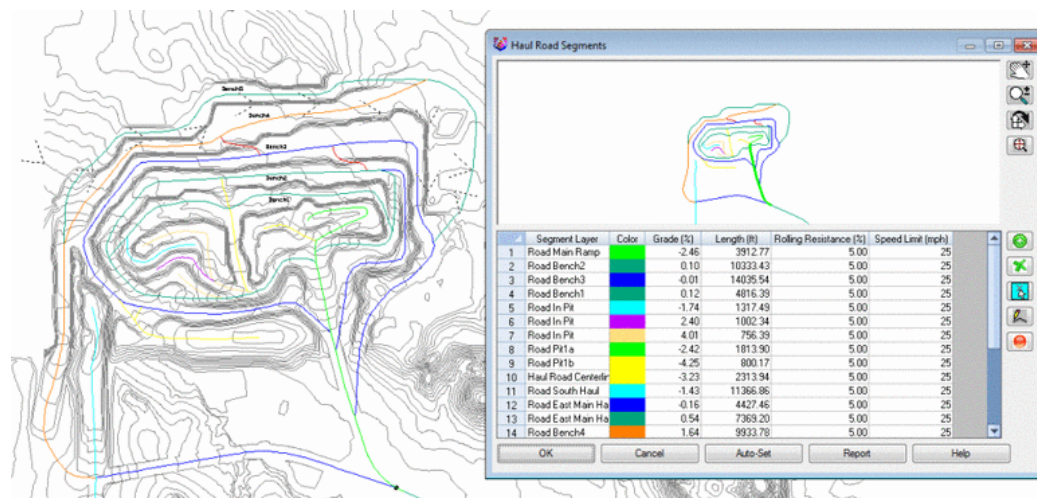

- AutoSet:** The AutoSet Segment Parameters based on Grade option colors all the haul roads based on their percent slope. This is an option to graphically see the slope of each road, simply by the color it is drawn in. This will also change the color of the 3D polylines in the plan view. They will stay on their original layers, so they can be set back to color ByLayer if desired. The slope interval was set here to a 1 or 2%, starting at -5%, as an example.

	If Grade is	Grade (%)	Color	Rolling Resistance (%)	Speed Limit (mph)
1	<	-5.00	Red	5.00	25
2	<	-3.00	Yellow	5.00	25
3	<	-2.00	Green	5.00	25
4	<	-1.00	Cyan	5.00	25
5	<	0.00	Blue	5.00	25
6	<	1.00	Black	5.00	25
7	<	2.00	Orange	5.00	25
8	<	3.00	Purple	5.00	25
9	<	5.00	Yellow-Orange	5.00	25

Notice in the image below, that the new colors are set by the percent slope of the road. These colors are now different than the initial image where they were colored by the layer.

Now that the haul roads are defined in the manager, they can be used in the haul road processing commands.

Haul Fleet Manager

This command manages the haul trucks that can be used in the Haul Cycle Analysis command. The main dialog of this command is shown below.

24 trucks are included in the program (more can be added manually), The default values are shown in yellow on this initial screen, and in the Edit Performance section, and are the same for each truck. All other values are specific to the truck type. Therefore, all truck specifications should be verified before implementing Haul Cycle Analysis.

- **Model #:** This is a customizable name that can be used to identify the truck model
- **Amount:** Haul Cycle Analysis allows you to calculate the potential production from a pre-defined fleet of trucks. Entering this value will determine the fleet to be considered when calculating production based on a given fleet
- **Loading Spot Time (sec):** This is the time in seconds, on average, the truck takes to position itself at the loading point
- **Loading Time (sec):** This is the time in seconds, on average, required to load the truck
- **Dumping Spot Time (sec):** This is the time in seconds, on average, the truck takes to position itself at the dumping point
- **Dumping Time (sec):** This is the time in seconds, on average, the truck requires to dump its load
- **Load Capacity (Payload):** This is the weight of the load the truck will haul

Trucks can be manually added or removed from the Haul Fleet Manager using the green Plus Button or the green Exit button, respectively. Both buttons are shown below.

Individual trucks can also be saved or loaded from a .hrt or .xml file using the green Save button or the Folder button. Both are shown below.

Selecting a truck and clicking 'Edit Performance' will open the dialog shown below. Yellow fields are default values, while the other fields are truck specific parameters.

An explanation of how each of these variables is implemented in the performance of the truck is discussed in more detail in the help documentation of the Haul Cycle Analysis command.

- **Traction Coefficient:** This value determines the force of friction that will act to prevent the truck tires from slipping
- **Normal Payload:** This value is dynamically linked to the Load Capacity of the truck shown on the main dialog of the Haul Fleet Manager; this value is dynamically linked to the Loaded Truck Weight and the Empty Truck Weight
- **Gross Vehicle Weight:** This value is NOT always a simple addition of the weight of the truck and the weight of the load. Instead, it is the intended operating weight of the truck as provided by the truck manufacturer. In many cases, however, the loaded truck weight will match this value
- **Max. Accel.:** This is the maximum allowable acceleration of the truck
- **Brake Reliance:** This is essentially a measure of confidence that can be placed on the defined traction coefficient to slow the truck in braking situations. For example, the default traction coefficient is 0.36 and the default brake reliance is 0.7. If the truck needs to come to an immediate halt, the maximum braking force is

determined in part by the traction coefficient. However if you are only 70% confident in the traction of the road, the maximum braking force would be calculated as if the traction coefficient were $0.36 \times 0.7 = 0.252$

- **Driver Perception Response Time (DPRT):** This is the usual time it will take for a truck driver to respond to a need to stop. Using the default value as an example, it would take a driver 2.5 seconds to actually press on the brake pedal once a threat presents itself.
- **Loaded Weight:** This is the actual operating weight of the truck when it carries a normal payload
- **Empty Weight:** This is the actual weight of the truck itself; this does not include the weight of the payload
- **Front Axle Weight Factor:** This is the portion of the truck weight that is supported by the front axle
- **Rear Axle Weight Factor:** This is the portion of the truck weight that is supported by the rear axle. This value and the Front Axle Weight Factor should sum to 1.0
- **Max. Decel.:** This is the maximum allowable deceleration of the truck
- **Brake System Response Time (BSRT):** When a truck brake is activated, the full braking force will not be immediately applied; the braking force will instead increase gradually. This value is the delay between the initial depression of the brake pedal and when the full braking force is applied

The Mine Speed Guidelines Table allows you to enter in the maximum allowable operating speed for a given Total Resistance. The default value is 50, and should be edited based on the mine guidelines. This table can be saved to and loaded from a .htr file. This dialog is shown below.

Mine Speed Guidelines Table

Truck Model: CAT_769D

Mine Speed Limits and Corresponding Equipment Usage

	Total Resistance	Loaded Oper. Speed	Empty Oper. Speed
1	-30.00	50.00	50.00
2	-25.00	50.00	50.00
3	-20.00	50.00	50.00
4	-15.00	50.00	50.00
5	-10.00	50.00	50.00
6	-5.00	50.00	50.00
7	.00	50.00	50.00
8	5.00	50.00	50.00
9	10.00	50.00	50.00

Buttons: OK, Cancel, Load, Save, Help

- **Total Resistance:** This is the force that works either for or against the truck's movement, expressed as a percentage of the truck weight. This is a combination of the grade of the road and the rolling resistance of the tires on the road. For example, a 5% rolling resistance on an uphill slope of 7% would equate to a total resistance of 12%
- **Operating Speed:** This is the maximum allowable speed of the truck. Unless another constraint requires the truck to move at a slower speed, the truck will accelerate until it reaches this speed

This table provides information on the rimpull force that will be exerted to maintain various speeds of the truck at normal operating conditions.

This information will be used when calculating the acceleration of the truck for various conditions. This table can be saved to and loaded from a .htp file.

This table allows you to set speed limits for both loaded and empty hauling conditions on downhill segments. The downgrade is the slope of the road expressed as a percentage. The dialog is shown below:

This table can be saved to and loaded from a .tdt file.

- Thank you to the late Peter Nahan of Goldcorp for his suggestions, references and help in developing this command.

Pull-Down Menu Location: Reserves/Timing in Surface Mining

Keyboard Command: haul_fleet

Haul Cycle Analysis

This command is used for detailed analysis of haul routes using various haul trucks to determine either 1) the required truck fleet required to meet a target production or 2) the attainable production based on a given haul fleet. This command requires the user to have executed the Haul Road Manager to define the haulage route. Although optional, it is recommended to define and customize truck parameters using the Haul Fleet Manager command to ensure the most accurate results. The first section of this document discusses the basic use of this routine, while the second section discusses the actual calculations that are performed to analyze the haul cycle.

First, you will be prompted to select the start and ending points of the haul road to be considered. The dialog that appears will show a spreadsheet view of all potential routes between the starting and ending point which will be sorted by distance in increasing order. The dialog will change slightly depending on the 'Calculate' option selected (either Fleet Size or Production).

	Haul	Length	#	Cycle time	Fleet Size	Fleet Capacity	Loaded Haul	Empty Haul
1	Road # 1	6.50	20	24.54	16	15.13	9.16	8.46
2	Road # 2	6.54	24	24.64	16	15.19	9.16	8.55
3	Road # 6	6.54	24	24.64	16	15.19	9.26	8.46
4	Road # 3	6.54	18	24.64	16	15.19	9.16	8.56
5	Road # 1	6.54	18	24.49	16	15.10	9.11	8.46
6	Road # 7	6.58	28	24.73	16	15.25	9.26	8.55
7	Road # 8	6.58	22	24.73	16	15.25	9.26	8.56
8	Road # 1	6.58	22	24.58	16	15.16	9.11	8.55

- **Preview Window:** highlights the currently selected haul route. This window works very similar to the 3D

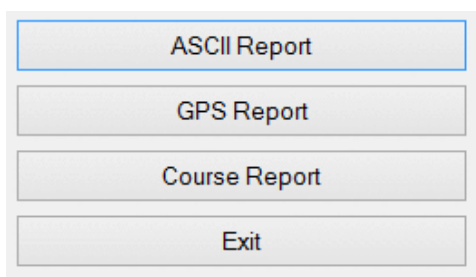

Viewer Window. Using the four icons next to this screen, you can pan, zoom, rotate, and zoom to the extents of the haul route.

- **Production Data Section:** allows you to choose the type and amount of haul trucks to be used for the cycle analysis. The 'Assign Single Truck Type' option will allow you select one of the trucks defined in the Haul Fleet Manager library. The 'Assign All Fleet Trucks' option will use the types and amounts of trucks defined in the same library. Clicking the 'Fleet' button will allow you to edit this library. Using the 'Assign All Fleet Trucks' option will only allow you calculate the attainable production rate. For more information on the Haul Fleet Manager, see the appropriate section of the help manual.
- **Truck Starts option:** allows you to specify if the selected starting point represents the loading or the dumping point of the route.
- **Use Density:** This option allows you specify the density of the material being hauled. When used, the tonnage of the material hauled will be included with the Process Spoil Timing option.
- **Calculate option:** changes the routine to calculate either the required fleet size based on a production target, or the attainable production target based on the haul fleet.
- **Production Rate:** This value can be set when calculating the required fleet size. This sets the target production the haul fleet must meet.
- **Number of trucks used:** This value can be set when calculating the attainable production when using the 'Assign Single Truck Type' option.
- **Estimated Queuing time:** This the estimated time that the truck must wait in line at either the loading or the dumping point per cycle (25 second wait at the loading point and 15 seconds at the dumping point would be a total Estimated Queuing time of 40 seconds).
- **Minutes per production hour:** This is the expected working time per hour. This is essentially a measure of work efficiency, and should therefore account for variable delays due to factors such as:
 - Excavating equipment delays
 - Personnel delays
 - Climate delays
- **Truck Filling Efficiency:** This is the fill percentage of the truck. A 90% filling efficiency applied to a truck that is intended to carry 100 tons will only carry 90 tons per cycle.
- **Truck Availability X Utilization:** This value is multiplied by the Minutes per Production Hour to determine the total working time of the truck. It is intended to account for fixed delays and mechanical availability of the truck. For a truck listed as working 50 minutes per production hour, an Availability X Utilization value of 90% will result in only 45 working minutes per hour.
- **Use Report Formatter:** This option will allow you use the Report Formatter for the Cycle Report and the Cycle Detail Report to customize the reported information.

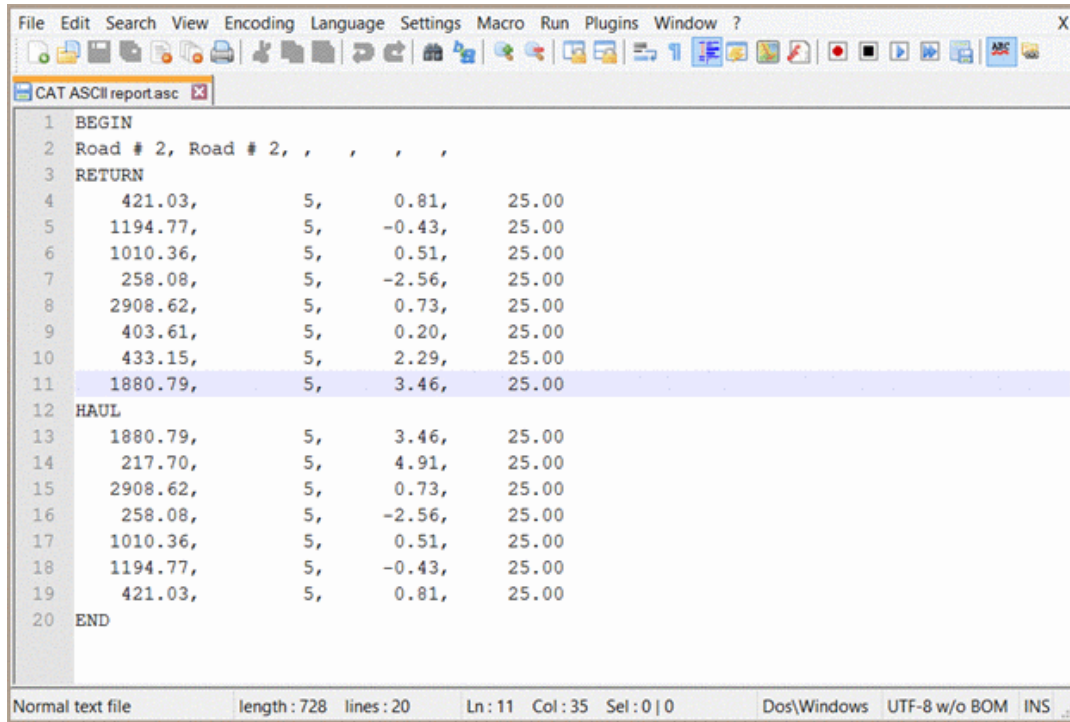

Reports

The Haul Cycle Analysis command is very quick and dynamic. Whenever a value is edited, the results in the spread sheet view will be automatically updated. These results can be reported in a variety of formats as discussed below.

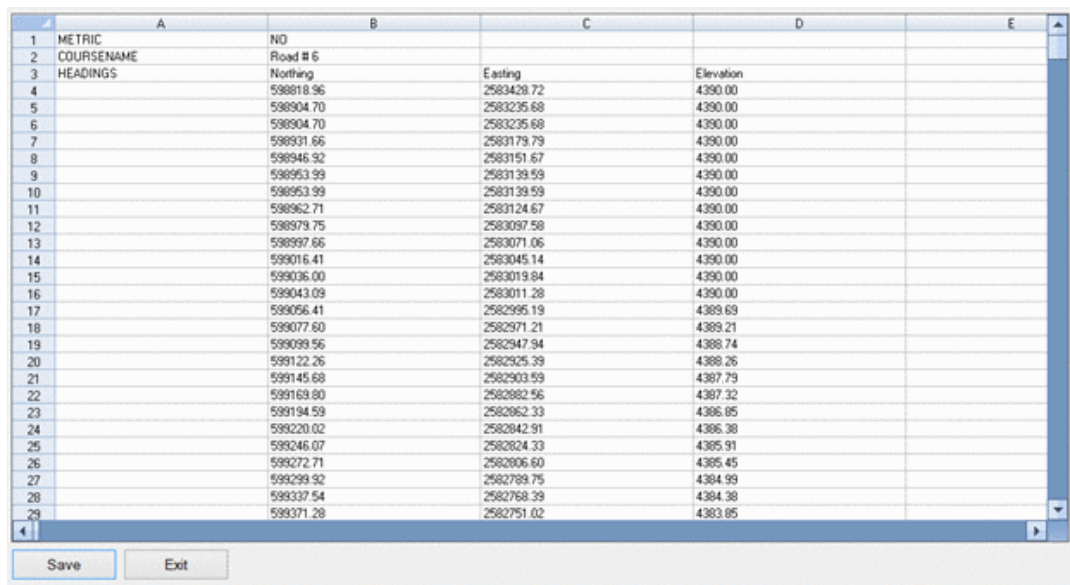

CAT FPC Reports: This option will allow you to export one of three report types: ASCII, GPS, and Course.

The ASCII report will export the segment distance, the rolling resistance, the slope, and the speed of the truck along each segment into an .asc file as shown below:

The GPS report will export the coordinates and elevation of the haul road at each vertex representing the road. This report can be saved as an Excel spreadsheet (.xls file) as shown below:

The Course Report is reported in a spreadsheet with three tabs: General Info, Haul, and Return. This file can also be saved as an Excel spreadsheet, as shown below:

	A	B	C	D	E
1	..BEGINCOURSE	Road # 1			
2	Distance (m)	Rolling Resistance %	% Grade	Speed Limit (kph)	Comments
3	100	4	0	100	Dump
4	352	4	-10	100	Ramp
5	200	4	0	100	Bridge
6	100	4	-5	40	Corner

Create Flyby Log: This option will create a .pos file which can be reviewed with the Surface 3D Flyover command in the Civil module. You will be prompted to enter a road width, then you will be allowed to specify the file name.

Process Spoil Timing: This command will perform a timing analysis on an exported .sph file from Spoil Placement Timing. This will give a more detailed analysis of the haul cycle during each time period of the spoil placement. An example report is provided below:

ID	Volume (C.M.)	Source Name	Destination Name	Starting Date	End Date	Fleet Size	Total Days	Haul Cycle Time (min)	Production Rate (tonnes/Hr)	Loaded Haul Distance (km)	Empty Haul Distance (km)	Total Distance (km)	Source Centroid X	Source Centroid Y	Source Centroid Z

It is worth mentioned the way that some of the values included in the report are calculated. These are provided below

- *HaulCycle-Lift (Source):* This value is the change in elevation from the pit centroid to the start of the road
- *HaulCycle-Lift (Road):* This value is the change in elevation from the start of the road to the end of the road
- *HaulCycle-Lift (Destination):* This value is the change in elevation from the end of the road to the centroid of the destination
- *HaulCycle-Lead (Source):* This value is the horizontal distance from the pit centroid to the start of the road, plus half the width and half the length of the pit. The half width/length of the pit is included to account for additional ramp length required to travel out of the pit.
- *HaulCycle-Lead (Road):* This value is the horizontal distance of the road.
- *HaulCycle-Lead (Source):* This is the value is the horizontal distance from the end of the road to the centroid of the spoil pile, plus half the width and half the length of the pile. The width/length of the pile is included to account for additional ramp length required to travel to the top of the pile.

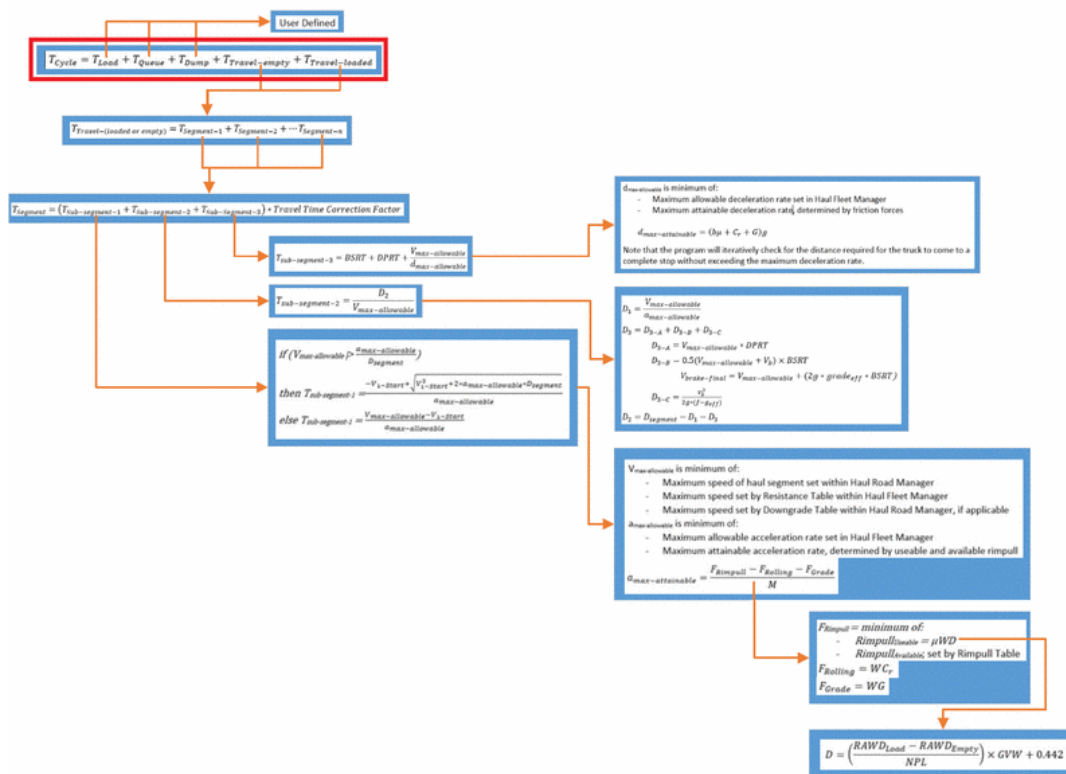

Calculation Methods

A good planner will be cautious about blindly accepting calculations. For this reason, the following section details the logic and calculations used in Haul Cycle Analysis so that the user can fully understand how the routine works.

As previously stated, this routine seeks to calculate either the attainable production based on the truck fleet or the fleet size required to meet a target production. Actually determining these values is rather simple once to the true cycle time has been calculated. However, calculation of the cycle time considers many factors. The first sub-section of this section details how the program calculates cycle time. The following sub-section details how the attainable production and required fleet size are calculated based on the calculated cycle time.

Calculation of Cycle Time

The diagram shown below is visual outline of the equations used to calculate the haul cycle time. This is provided to allow for a better understanding of how Haul Cycle Analysis uses input variables to determine various operating parameters. Note that this diagram is simplified, and does not detail all of the logic used in the actual routine.

The total haul cycle time can be calculated with the following equation:

$$T_{Cycle} = T_{Load} + T_{Travel-loaded} + T_{Queue} + T_{Dump} + T_{Travel-empty} \text{ where}$$

- T_{Cycle} is the total cycle time
- T_{Load} is the time required to load the truck
- $T_{Travel-loaded}$ is the time required for the truck to travel from the loading point to the dumping point
- T_{Queue} is the total estimated queuing time (sum of queuing time at both the loading point and the dumping point)
- T_{Dump} is the time required for the truck to dump its payload

- TTravel-empty is the time required for the truck to return to the loading point from the dumping point

Three variables, TLoad, TDump, and TQueue, are manually entered. The remaining variables, TTravel-loaded and TTravel-empty, are calculated similarly to one another, but with different values based on the road profile and truck specifications for loaded and empty scenarios. TTravel-loaded and TTravel-empty are calculated with the following formula: $T_{Travel-(loaded\ or\ empty)} = T_{Segment-1} + T_{Segment-2} + \dots + T_{Segment-n}$

where

TSegment-1 is the travel time of the first segment of the haul route

TSegment-2 is the travel time of the second segment of the haul route

Etc.

The travel time for a single haul segment will be further divided into three sub-segments according to the following chart.

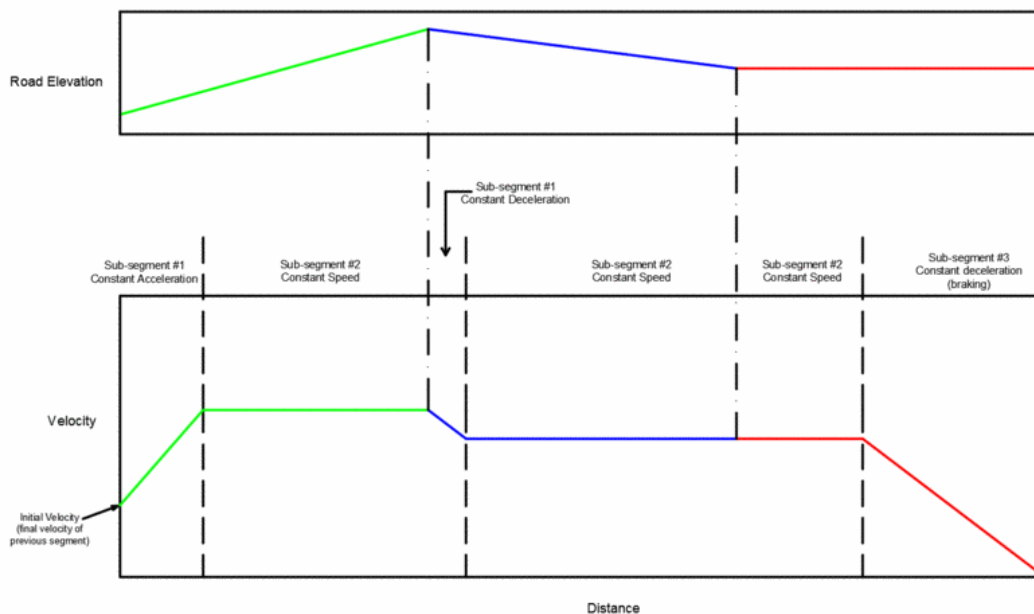

Sub-segment #1: the truck is accelerating/decelerating at a constant rate

Sub-segment #2: the truck is traveling at a constant velocity

Sub-segment #3: the truck is braking. Note that sub-segment #3 is only used when the truck comes to a complete stop.

In the below picture:

- The top portion of colored lines represent the road profile, broken into three haul segments
- The lower portion of colored lines represent the velocity of the truck along the haul road
- Haul Segment 1 (green line)
 1. Sub-segment #1 shows the truck accelerating as it travels uphill to meet the new road speed limit
 2. Sub-segment #2 shows the truck traveling at a constant velocity once it reaches the road speed limit
- Haul Segment 2 (blue line)
 1. Sub-segment #1 shows the truck decelerating as it starts to travel downhill to meet the new road speed limit
 2. Sub-segment #2 shows the truck traveling at a constant velocity once it reaches the road speed limit
- Haul Segment 3 (red line)
 1. Sub-segment #2 shows the truck traveling at a constant velocity. It is traveling at the speed limit when it approaches Haul Segment 3.
 2. Sub-segment #3 shows the truck braking as the truck comes to a complete stop.

The total travel time for a haul segment is simply a sum of the sub-segment travel times, as shown below:

$$T_{\text{Segment}} = (T_{\text{Sub-segment-1}} + T_{\text{Sub-segment-2}} + T_{\text{Sub-segment-3}})$$

The travel time of each sub-segment is calculated using the following formulae:

$$T_{\text{sub-segment-1}} = \frac{V_{\text{max-allowable}} - V_1}{a_{\text{max-allowable}}}$$

$$T_{\text{sub-segment-2}} = \frac{D_2}{V_{\text{max-allowable}}}$$

$$T_{\text{sub-segment-3}} = \text{BSRT} + \text{DPRT} + \frac{V_{\text{end}} - V_{\text{max-allowable}}}{a_{\text{max-allowable}}}$$

where

- TSub-segment-1 is the travel time of sub-segment #1
- Vmax-allowable is the maximum allowable truck velocity along the haul segment
- V1-Start is the truck velocity at the start of sub-segment #1, equal to zero at the beginning of the haul route
- amax-allowable is the maximum allowable acceleration of the truck on sub-segment #1
- TSub-segment-2 is the travel time of sub-segment #2
- D2 is the distance of sub-segment #2
- TSub-segment-3 is the travel time of sub-segment #3
- BSRT is the Brake System Response Time
- DPRT is the Driver Perception Response Time
- dmax-allowable is the maximum allowable deceleration rate of the truck

Sub-Segment #1 Supplement

Vmax-allowable is minimum of:

- Maximum speed of haul segment set within Haul Road Manager
- Maximum speed set by Resistance Table within Haul Fleet Manager
- Maximum speed set by Downgrade Table within Haul Road Manager, if applicable

amax-allowable is minimum of:

- Maximum allowable acceleration rate set in Haul Fleet Manager
- Maximum attainable acceleration rate, determined by useable and available rimpull

Note that a truck's velocity does not necessarily have to increase during sub-segment #1. If a truck enters a haul segment at a speed which exceeds the maximum allowable velocity for the haul segment, then sub-segment #1 will refer to a decelerating situation.

Sub-Segment #2 Supplement

In the final report, sub-segment distances will be reported as D1, D2, and D3, which refer to the distances of the respective sub-segments. The distance for each sub-segment is calculated as shown below. Here it is also important to note that the sub-segment #3 is further divided into three sections which represent A) the time required for the driver to realize that a stop is required, B) the time from when the driver first applies the brake to the time when the brake system applies the full braking force, and C) the time required for the truck to stop once the full braking force is applied.

$$D_1 = \frac{V_{max-allowable}}{a_{max-allowable}}$$

$$D_3 = D_{3-A} + D_{3-B} + D_{3-C}$$

$$D_{3-A} = V_{max-allowable} * DPRT$$

$$D_{3-B} = 0.5(V_{max-allowable} + V_b) \times BSRT$$

$$V_{brake-final} = V_{max-allowable} + (2g * grade_{eff} * BSRT)$$

$$D_{3-C} = \frac{V_b^2}{2g*(f-g_{eff})}$$

$$D_2 = D_{segment} - D_1 - D_3$$

Note that in many situations one or two of these sub-segments will not be used in the final calculations. For example, if a truck enters a new haul segment and does not need to accelerate/decelerate to meet the speed limit, the distance and travel time for sub-segments #1 and #3 will be zero. As another example, sub-segment #3 will only be used when the truck is braking to a complete stop.

where

- D1 is the distance of sub-segment #1
- D2 is the distance of sub-segment #2
- D3 is the distance of sub-segment #3
- D3-A is the distance of sub-segment #3, section A
- D3-B is the distance of sub-segment #3, section B
- D3-C is the distance of sub-segment #3, section C
- DSegment is the length of the current haul segment
- Vb is the truck velocity at the end of the Brake System Response Time
- g is the acceleration due to gravity
- f is the coefficient of friction available for braking (
- geff is the effective grade, which is a sum of the road grade and the rolling resistance of the road on the tires

Sub-segment #3 Supplement

dmax-allowable is minimum of:

- Maximum allowable deceleration rate set in Haul Fleet Manager
- Maximum attainable deceleration rate, determined by friction forces

$$d_{max-attainable} = (b\mu + C_r + G)g$$

Note that the program will iteratively check for the distance required for the truck to come to a complete stop without exceeding the maximum deceleration rate.

Max Truck Acceleration/Deceleration

Both sub-segments #1 and #3 must check for the maximum allowable acceleration/deceleration rate, and one of the rates to be considered is the rate limited by friction, also referred to as the useable rimpull. The below equations show how the acceleration/deceleration rates are calculated.

As previously shown, Haul Cycle Analysis analyzes truck movement by constant acceleration/deceleration along sub-segments and sections of sub-segments. For this reason, the acceleration of the truck can be defined by scalar quantities in Newton's Second Law of motion, shown below and simplified:

$$F = Ma_{max-attainable} = F_{Rimpull} - F_{Rolling} - F_{Grade}$$

$$a_{max-attainable} = \frac{F_{Rimpull} - F_{Rolling} - F_{Grade}}{M}$$

where

F is the sum of all forces acting on the truck

M is the mass of the truck

amax-attainable is the maximum possible acceleration of the truck

FRimpull is the effective rimpull force (minimum of available rimpull and useable rimpull force)

FRolling is the force of rolling resistance, which is set within the Haul Road Manager for each haul segment

FGrade is the grade resistance force, defined as positive for uphill and negative for downhill movement

FRimpull

$$F_{Rimpull} = \text{minimum of:}$$

- $Rimpull_{Useable} = \mu WD$
- $Rimpull_{Available}$; set by Rimpull Table

Available Rimpull is determined from standard Rimpull Curves provided by truck manufacturers. This data is entered into the Haul Fleet Manager in a tabular format in the Rimpull Table. From the entered values, the program will determine the available rimpull at various operating speeds.

Useable rimpull is the maximum force the truck can apply before the tires start to slip on the road. This value is calculated with the following equation

$$Rimpull_{Useable} = \mu WD$$

where

- RimpullUseable is the useable rimpull force
- μ is the traction coefficient between the road and the tires, which is set in the Haul Fleet Manager
- W is the truck weight
- D is the ratio of the truck weight on the rear axle

Furthermore, D can be calculated with the following equation

$$D = \left(\frac{RAWD_{Load} - RAWDE_{Empty}}{NPL} \right) \times GVW + 0.442$$

where

RAWDLoad - drive (rear) axle weight distribution percentage in loaded condition, expressed as a decimal

RAWDEEmpty - drive (rear) axle weight distribution percentage in empty condition, expressed as a decimal

NPL - nominal payload

GVW - gross vehicle weight; note that will not always equal the loaded truck weight

F_{Rolling}

$$F_{Rolling} = WC_r$$

Where

Cr is the haul segment rolling resistance, expressed as a decimal; this is set in the Haul Road Manager

F_{Grade}

$$F_{Grade} = WG$$

Although this calculation does not perfectly calculate the resistive/assistive force due to the grade of the road, the difference between the calculated value and the 'true' value is considered insignificant. Once the maximum possible acceleration of the truck has been calculated, this value is compared to the maximum acceleration limit set in the Haul Fleet Manager. The minimum of these two values is used for the calculation of the distance and travel time of sub-segment #1 for each haul segment.

Maximum Deceleration

When a truck slows down, it is limited to using the lesser of two possible deceleration rates. One rate is defined directly in the Haul Fleet Manager. The other rate is calculated based on Newton's Second Law using the below formulae:

$$F_{Available} = Md_{max-attainable} = F_{Retard} + F_{Rolling} + F_{Grade} = b\mu Wg + C_r Wg + GWg$$

$$d_{max-attainable} = (b\mu Wg + C_r Wg + GWg) / M = (b\mu + C_r + G)g$$

where

- F_{Available} is the total available retarding force
- d_{max-attainable} is the maximum attainable retarding deceleration rate
- M is the mass of the truck
- F_{Retard} is the retarding force
- F_{Rolling} is the rolling resistance force
- F_{Grade} is the grade resistance force
- b is the braking reliance on traction
- μ is the traction coefficient
- Cr is the rolling resistance coefficient
- G is the road grade; uphill is positive, downhill is negative
- g is the acceleration due to gravity
- W is the truck weight

Calculation of Required Fleet Size and Attainable Production

Once the total cycle time has been calculated, the calculation of the required fleet size/attainable production is very simple. The calculations for these values are shown below

$$\text{Attainable Production} = \sum N_{\text{trucks}-i} \frac{NPL_i * \text{Mins}_{\text{hr}} * \text{Fill} * \text{Avail_Util}}{T_{\text{Cycle}-i}}$$
$$\text{Required Fleet Size} = \frac{\text{Target Production Rate}}{\left(\frac{NPL * \text{Mins}_{\text{hr}} * \text{Fill} * \text{Avail_Util}}{T_{\text{Cycle}}} \right)}$$

Where

- NTrucks-i is the number of trucks of a specific model
- NPLi is the nominal payload of a specific truck model
- Minshr is the minutes working per production hour
- Fill is the truck filling efficiency
- Avail_Util is the truck availability multiplied by the truck utilization
- TCycle-i is the truck cycle time for a specific truck model

Note that the total attainable production is the sum of each attainable production rate of each truck in the haul fleet.

Keyboard Command: haul_cycle

Gantt Charts

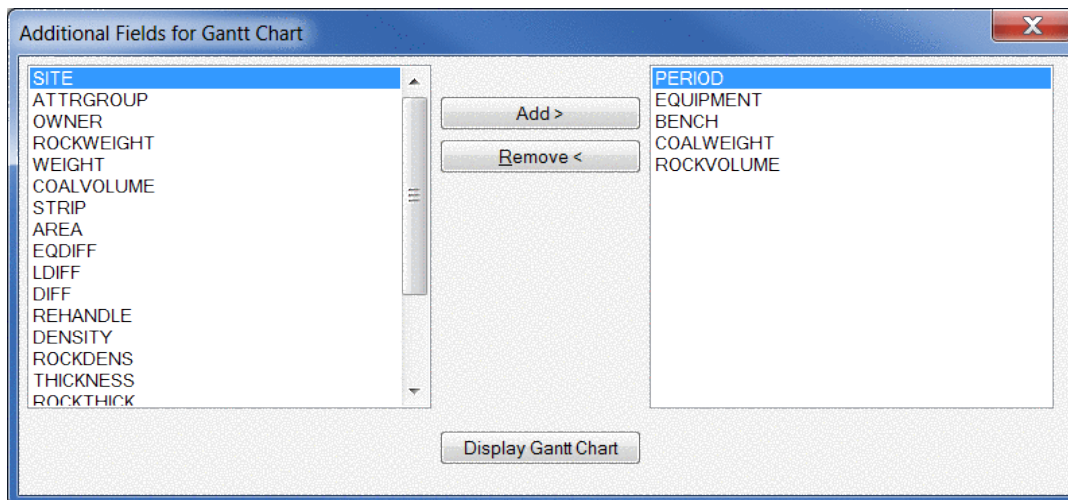

Gantt Charts are used to show the starting and ending dates for scheduled events, making it simpler to understand the progress of the project. These charts can be created for scheduling commands including Underground Timing,

Surface Equipment Timing, and Spoil Placement Timing. Underground Timing and Surface Equipment Timing are very similar commands, and thus Gantt charts are made in the same way for both commands. The below example shows Gantt charts used with these commands. Gantt charts for Spoil Placement Timing appear on a slightly different dialog, but all functionality is the same.

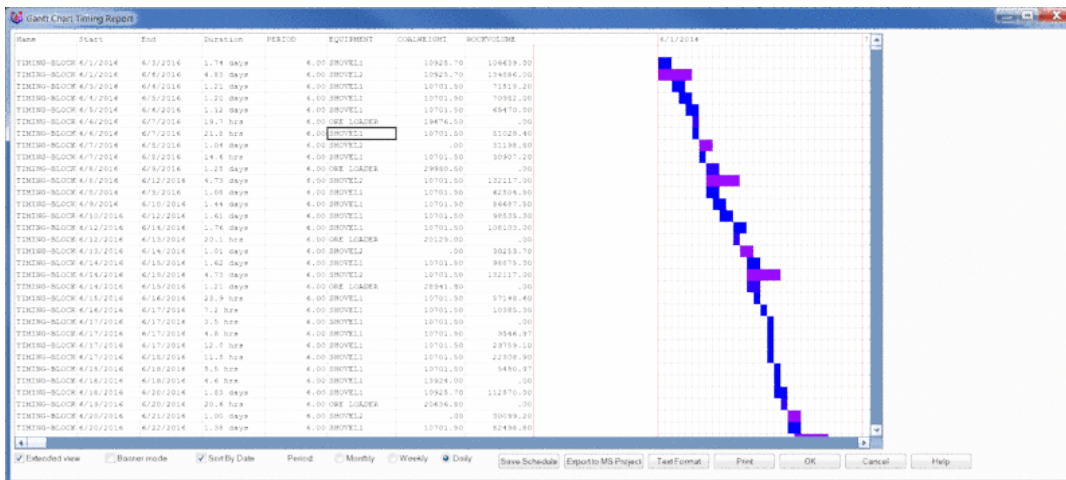

In the Underground and Surface Equipment Timing dialog shown below, panels have been assigned to equipment. Clicking **Calculate** will make the **Gantt Chart** button available, as outlined in red in the below image.

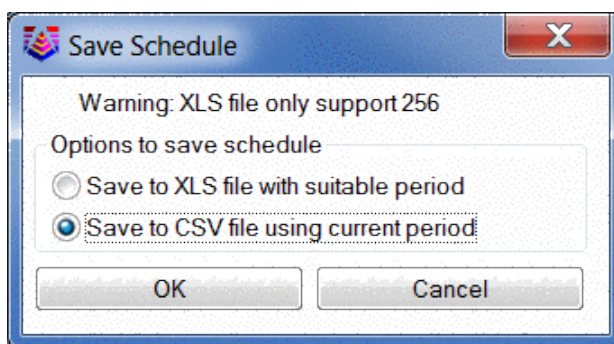

Clicking the **Gantt Chart** button will open the dialog for Additional Fields for Gantt Chart shown below. This screen allows to Add> items from left to right to include in the chart report.

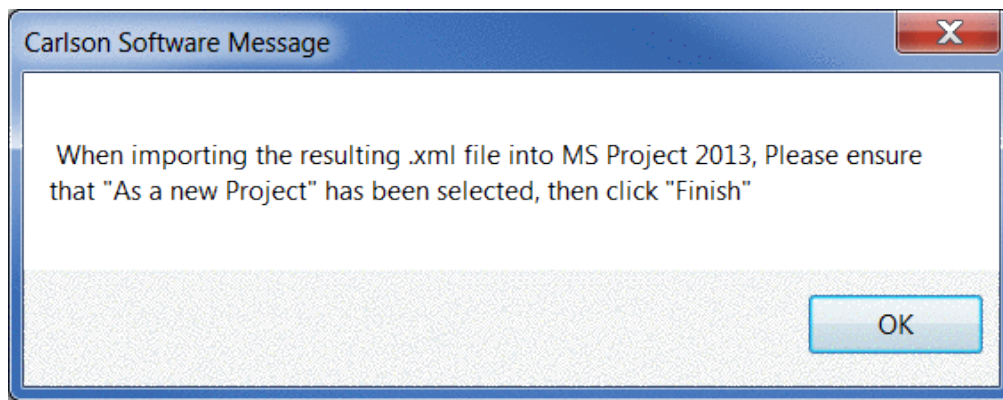

After adding the selected attributes, choosing the Display Gantt Chart brings up the report screen shown here.

- **Extended View:** This option will toggle the first four columns of the Gantt chart. If this option is turned on, the Gantt chart will be shown as above. If this option is turned off, the first four columns of the Gantt chart will not be shown.
- **Banner Mode:** This option changes how the chart is printed. When this option is turned on, the chart will be printed on multiple pages. This maximizes the chart on each page and makes it more readable, which is very helpful when printing a complex schedule. When this option is turned off, the chart will be scaled to fit on a single sheet. For complex schedules, this can result in an unreadable chart. However, you can change the size of the print paper if you would like to keep the chart on a single sheet.
- **Sort By Date:** This option sorts the rows by the dates of the schedule. This is useful to see all the equipment grouped together in the chart.
- **Period:** This option sets the time duration of each cell of the Gantt chart. In the above example, the **Daily** option is used. In this case, each cell of the Gantt chart represents one day.
- **Save Schedule:** This option will allow you to save the Gantt chart to an Excel spreadsheet that is limited to 256 fields, or to a CSV file, which is unlimited.

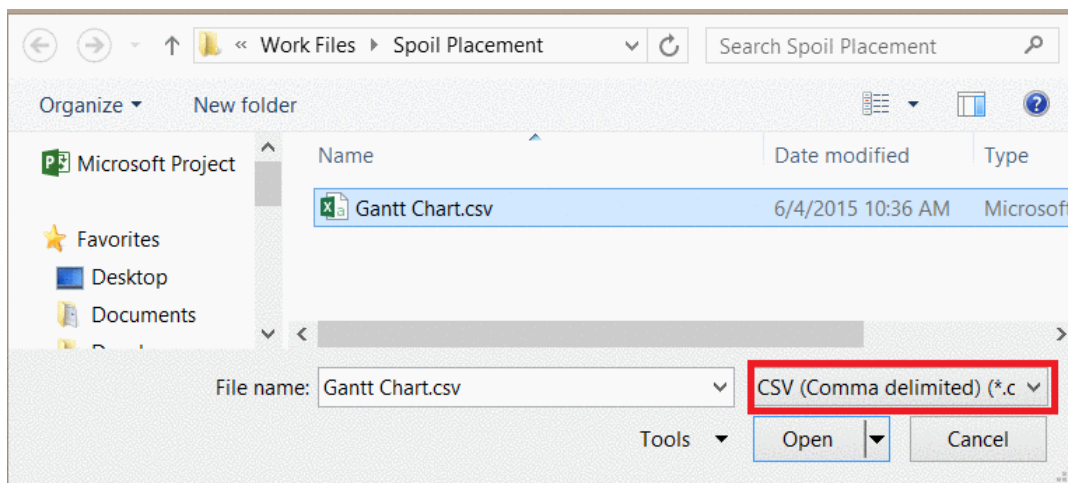

- **Export to MS Project:** This option will allow you to export the Gantt chart to an XML file, which can be imported into Microsoft Project. A detailed description of this process is provided further down in this document.

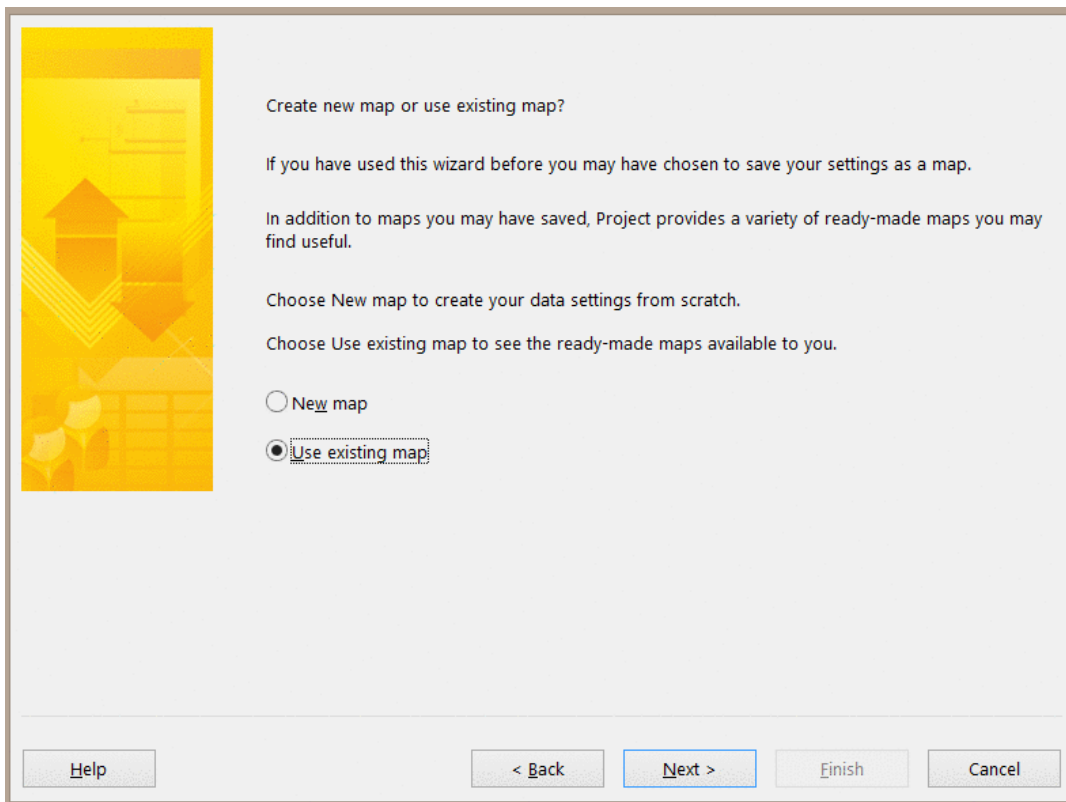

- **Text Format:** This option allows you to set the format of the text of the exported chart.
- **Print:** This option allows you to print the Gantt chart to any of the printers installed on your computer, or to save it as PDF file.

Opening CSV file with MS Project

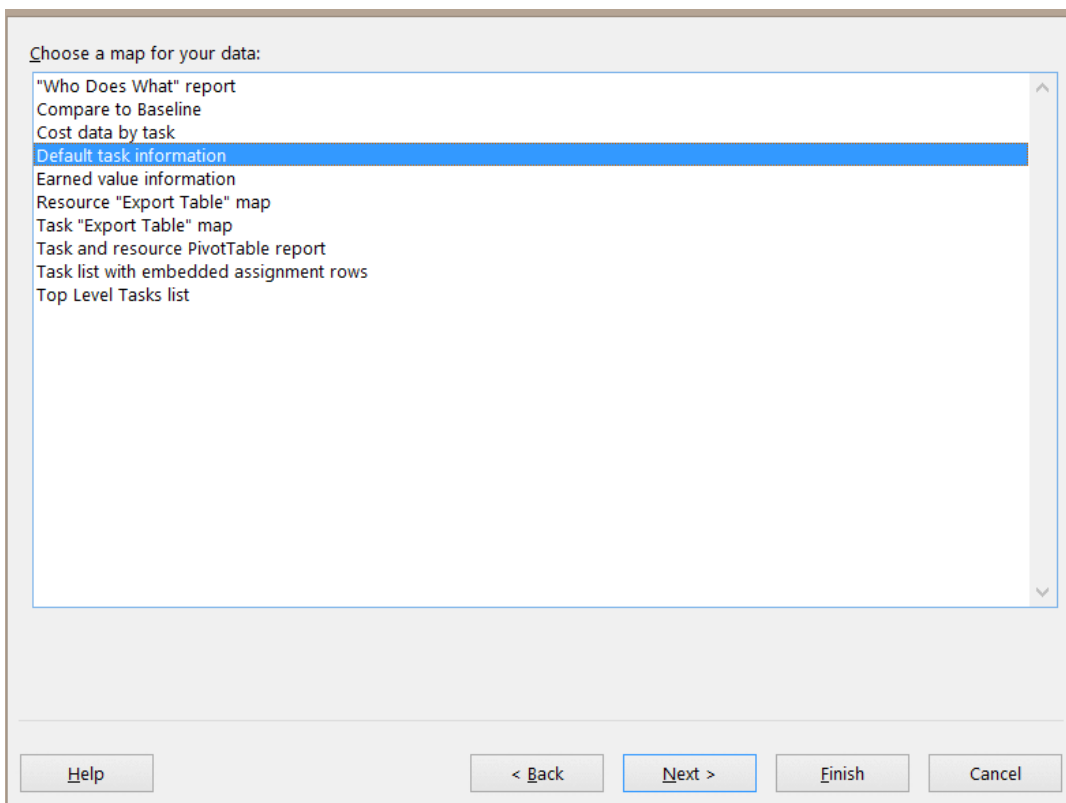

This section describes how to open a CSV file with MS Project. Before opening the .csv file, you will need to enable Legacy Formats. This can be done via File Menu > Options > Trust Center > Trust Center Settings > Legacy Formats > Allow loading files with legacy or non-default file formats. Note that this refers to Microsoft Project 2013. With this setting enabled, you may open an existing file and specify the format as a .csv as shown below:

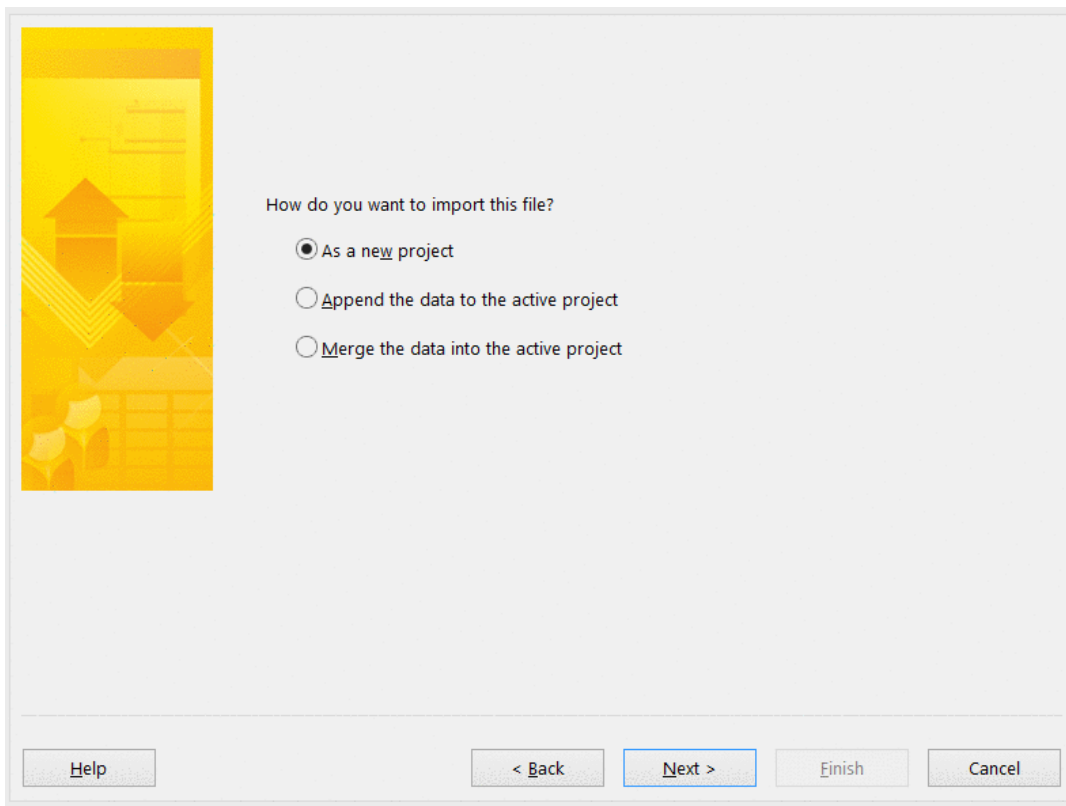

This will open the Import Wizard. On the **Map** dialog, select **Use existing map** and click **Next**.

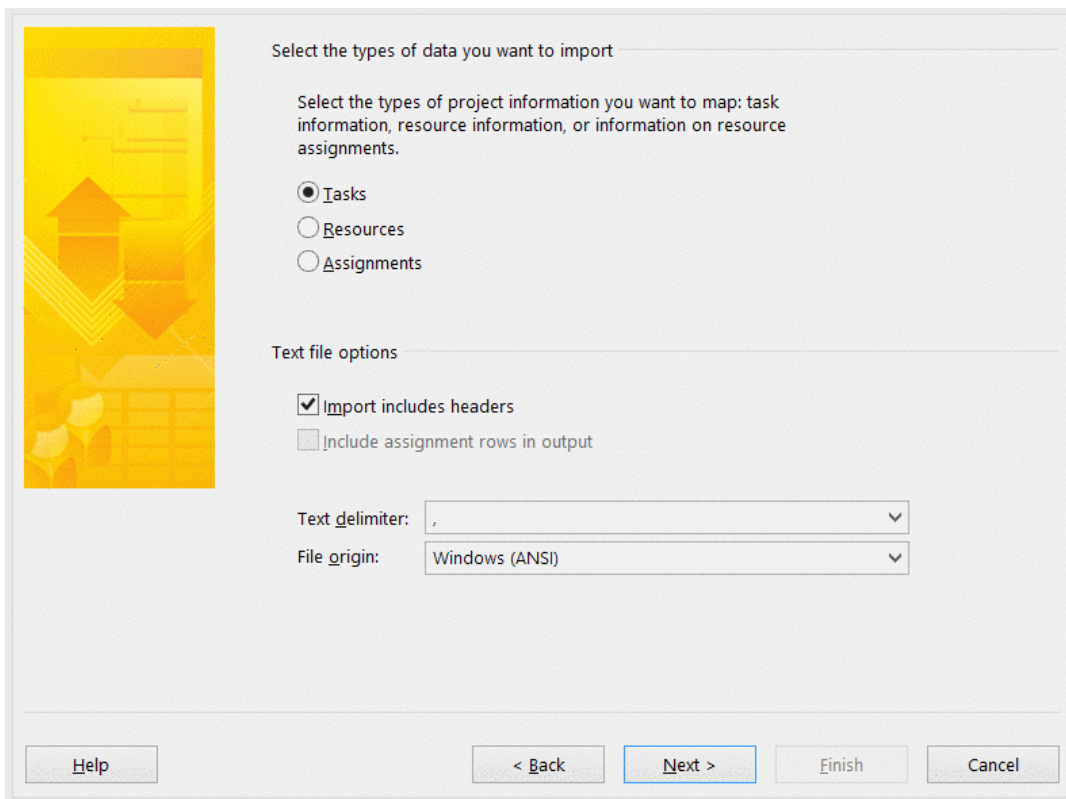

On the **Map Selection** dialog, select **Default Task Information** and click **Next**.

On the **Import Mode** dialog, select **As a new project** and click **Next**.

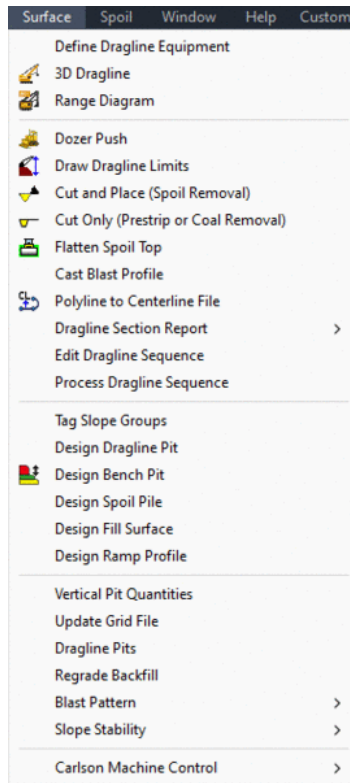

On the **Map Options** dialog, use the settings shown below and click **Finish**.

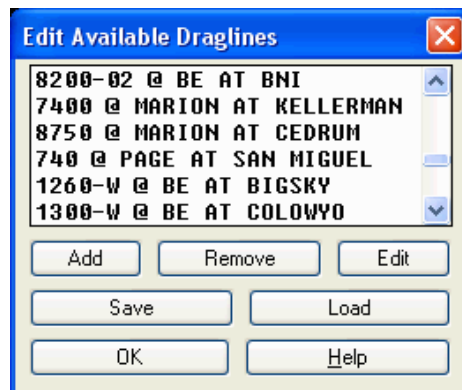

Surface Menu

The Surface menu has commands for cross section and surface modeling.

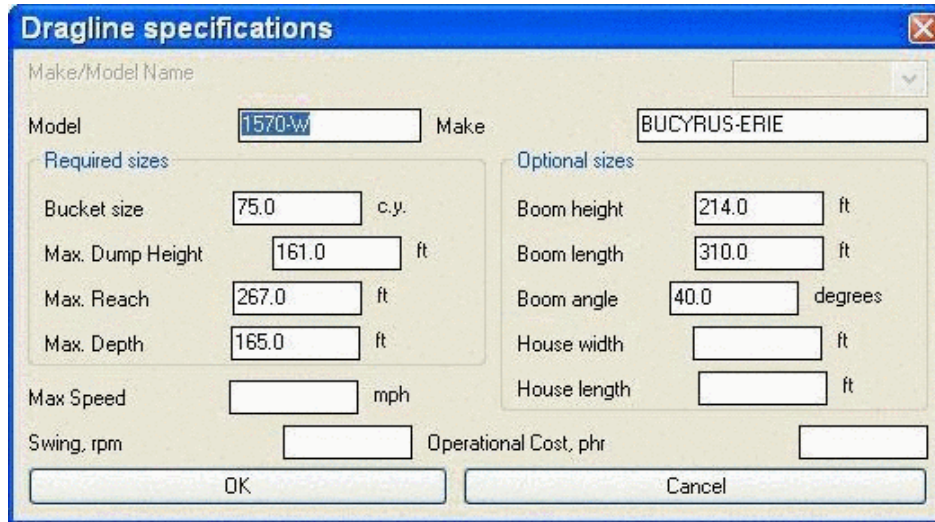

Define Dragline Equipment

The description of available draglines is created and edited using this function. While the most important parameters are those which define dragline operational range for the Cut and Place commands, there is a number of others which are used in the 3D dragline modeling. Bucket size is used to calculate a number of cycles needed to transport a given amount of material, which is used to get the time spent on material handling, together with swing speed and calculated average swing angle. Dragline house sizes are used to estimate how the dragline travels within a given area, while maximum speed gives the time required to complete these moves. Finally, if operational cost is specified, the total cost will appear in the final report. The first screen shows the draglines that are defined within the program.

Choosing Add or Edit will bring up the next screen. Notice the Required Sizes section. These must be all filled in. The remaining windows are all optional. Defaults will be used if they are not defined in the 3D Dragline command.

Depending on the Drawing Setup, either CY and FT, or CM and M are displayed as the units to enter. Carlson saves this information in the "dragline.dta" file in the USER folder of Carlson. The Save and Load buttons of the main dialog allow you to save and recall the dragline settings to a .DLN file.

The Save and Load buttons allow you to save and recall the dragline settings to a .DLN file.

Prompts

Edit Available Draglines and Dragline Specifications dialogs.

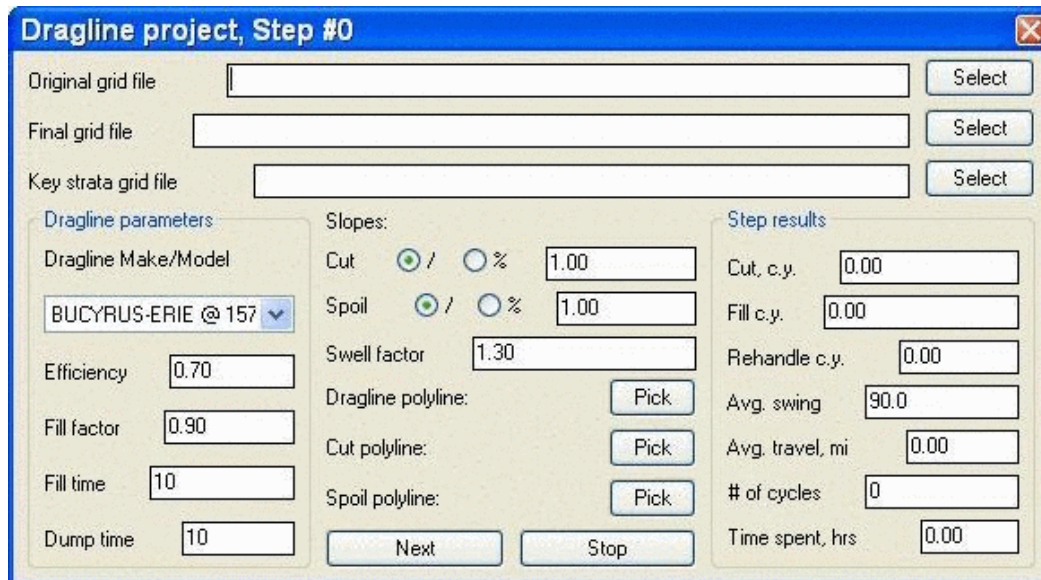

Pulldown Menu Location: Surface

Prerequisite: None

3D Dragline

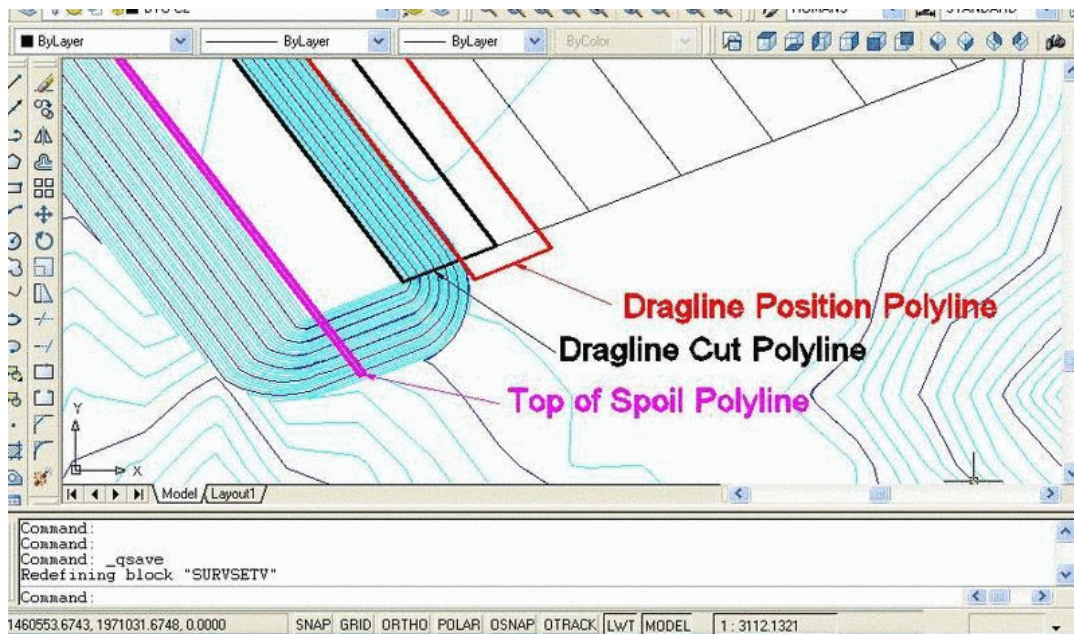

This command gives a 3D approach to the design and placement of dragline pits. Unless all the seams are perfectly uniform and horizontal, and pits are straight, the usual cross-section dragline modeling with range diagrams will not provide the appropriate level of precision and visualization. This function allows you to specify the cut and spoil areas and watch the ground surface change in 3D. Surface updates are recorded on every step and may be played back later.

The first step is to define the three grid files at the top of the Dragline project window. They are the original topogrid file, the final grid file (create a new grid if one doesn't exist) and the top of the Key strata grid file.

The Dragline parameters section is for choosing the dragline. Then set its Efficiency %, Fill Factor %, Fill time (seconds) and Dump time (seconds). The Slope and Swell factor are set next, in the center of the screen. Slope is either set as ratio or percentage. A swell factor of 1.3 gives 30% swell.

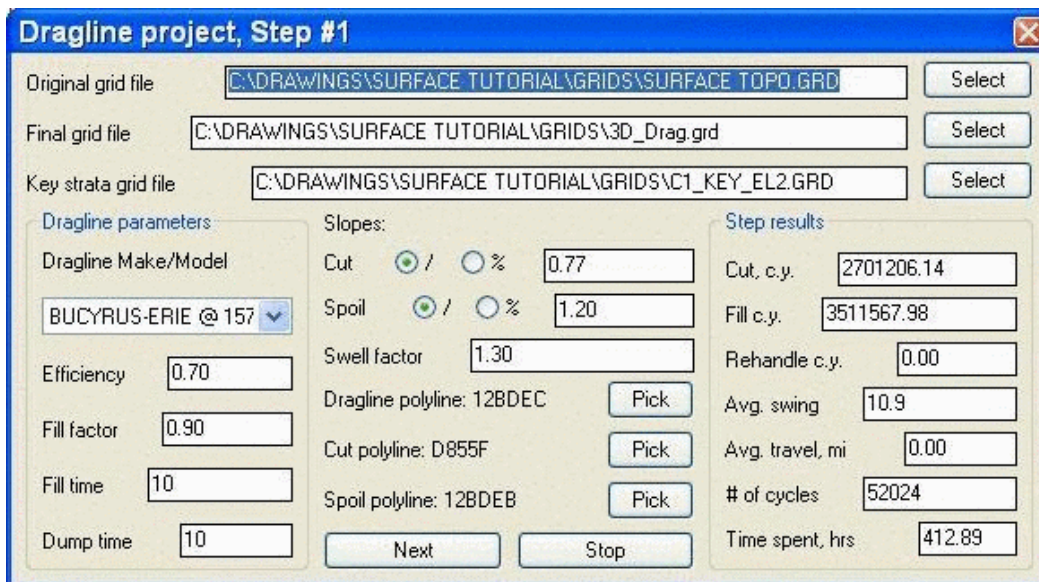

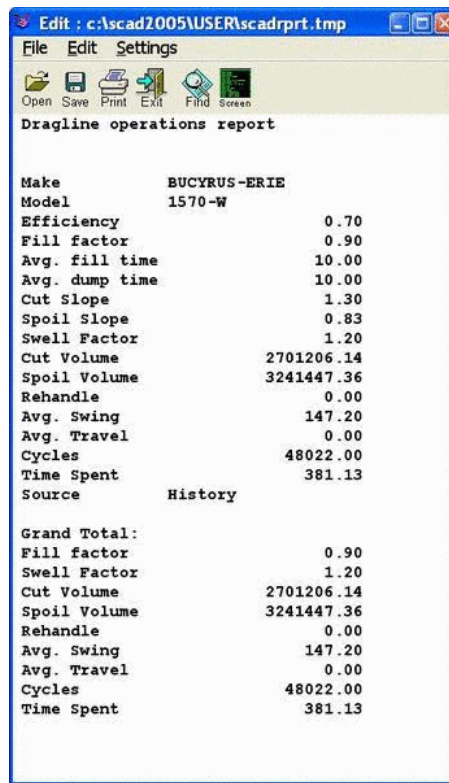

Finally, on each step of the sequence, three pre-drawn closed polylines are chosen: a polyline enclosing the area within which dragline is allowed to move, a bottom of cut area polyline (usually the next pit line), and a top of spoil area polyline (usually the previous pit line). The program then offsets the dragline polyline by the maximum reach distance and crops out the portions of cut and spoil polylines within the dragline reach. These modified polylines will be used in calculations. This allows the program to use larger cut and spoil polylines and move only the dragline on each step.

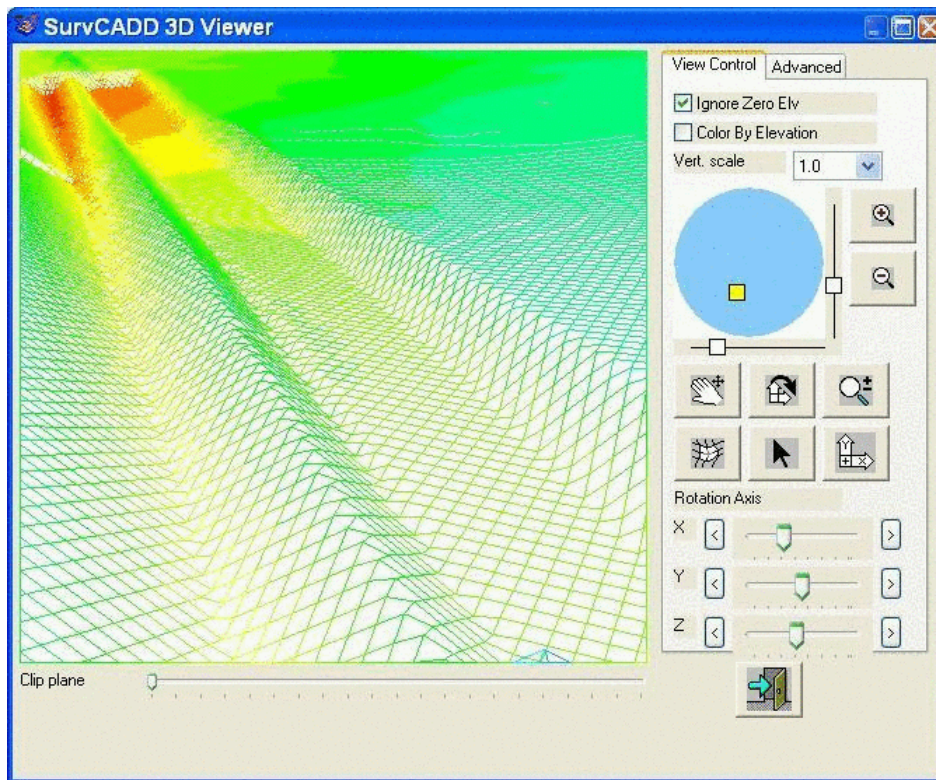

The program then calculates the overburden volume by using surface grid on top, coal top grid on bottom, and the highwall calculated using the cut polyline and given cut slope. The cut polyline is projected onto the bottom grid prior to calculations. The swell factor is then applied to the freshly cut material, while the rehandled material amount is taken as is. If the spoil polyline is a 3D polyline, its profile will be the elevations of the polyline. Otherwise the spoil ridge is considered to be at the same elevation. The spoil polyline is then moved up and down until the amount of the material between the spoil pile and the existing surface matches the given amount. If any dragline parameters are too small to physically mine here, then error messages, are displayed accordingly.

The calculated cut, spoil, rehandle and timing results are then displayed in the dialog. You may then modify the selection of cut, spoil or dragline polylines and proceed to the next step, or use the Stop button to exit. With use of the history file, the scheduling may be restarted from the point it was finished. Surfaces are updated with each step. To get to the next step, simply select then next 3 polylines, change the first two grid names (the top of coal usually remains the same) and choose next. After each step, the report formatter appears, allowing for customized reports of the steps.

3D View of the first step
The grid has been colored by elevation to show the ranges better.

Range Diagram

The Range Diagram command is an interactive tool for analyzing dragline cut scenarios. This is a quick and easy way to find parameters such as pit width, or to size a dragline to fit the geology. Methods of mining include Side Cast, Extended Bench, Dozer Bench, and Spoil Bench. Output includes both drawing the sections in CAD and printing out reports as PDF files, where each step is a separate page. The main dialog is shown below.

Show Current Dragline Only: This option will only show the current dragline, rather than showing all dragline passes at once.

Show ___ Label: These options will label the respective items in the graphics window.

Automatically Center Drawing: This option will automatically center the range diagram on the PDF report.

PDF X/Y: These settings control the position of the range diagram in the PDF when it is not automatically centered.

This section of the help document discusses the Input Parameters, shown below.

Many of these options are visually explained below.

Plan Type: This option sets the mining method. Four options are available:

The *Side Cast* method places the dragline on the waste material with a previously cut pit on one side. The dragline strips the waste material and places it into the open pit.

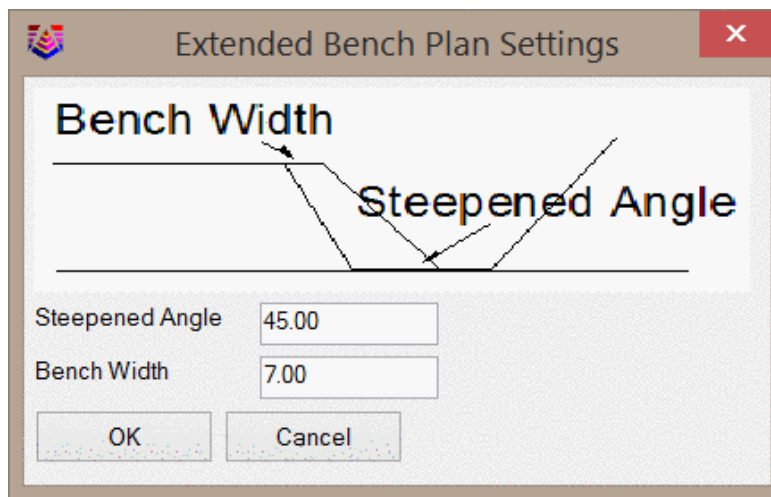

The *Extended Bench* method is similar to the Side Cast method, but the dragline will first place waste material at the edge of the existing highwall, thus extending the current bench further into the open pit. This allows the dragline to position itself on the extended bench, where it can then resume side casting material further into the open pit. This allows the dragline to spoil the material further into the open pit, but requires rehandle of the material used to create the extended bench.

The *Dozer Bench* method is similar to the Side Cast method, but is preceded by a dozer pushing a portion of the existing bench into the open pit. This allows draglines with a shallower digging reach to effectively dig out greater depths of overburden.

The *Spoil Bench* method is similar to the Side Cast method, but the dragline is positioned on the spoiled material rather than on the active bench.

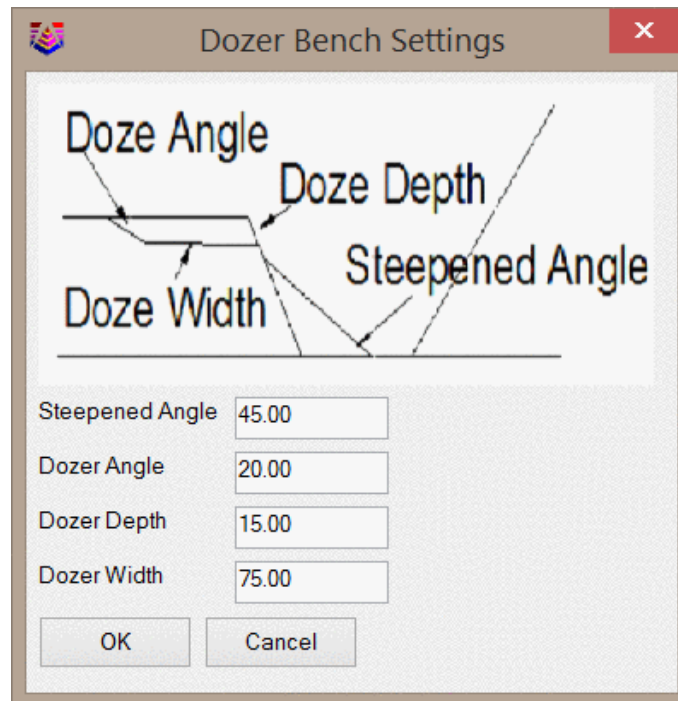

Settings: This button controls settings specific to the Extended Bench, Dozer Bench, and Spoil Bench Plan Types, depending on which Plan Type is currently selected. Each setting is visually represented in the settings dialog.

The Extended Bench Settings are shown below.

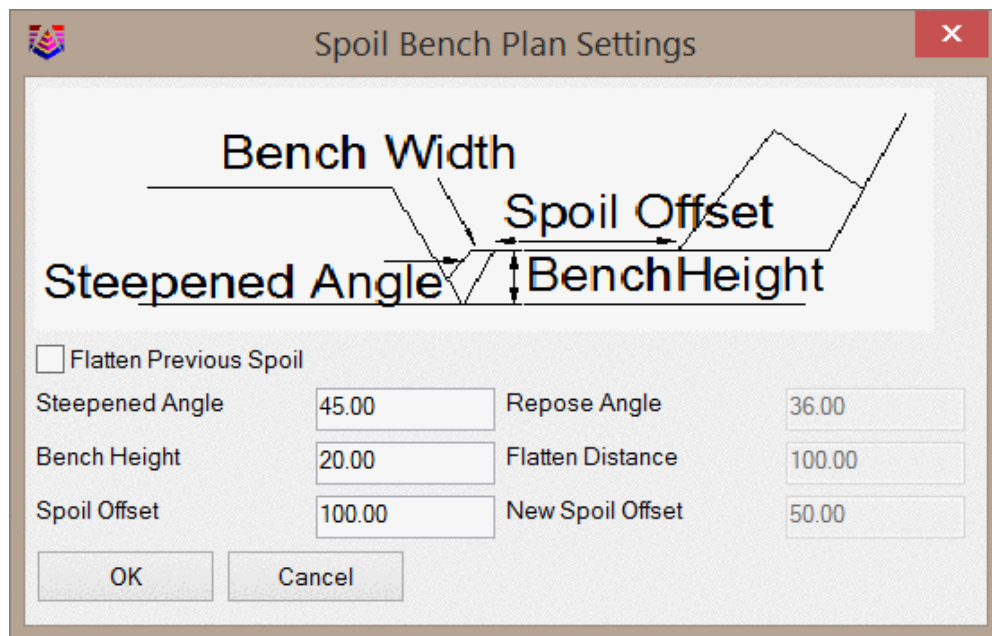

Steepened Angle: This value controls the angle, in degrees, of the new slope of the extended bench.
Bench Width: This value controls the width of the extended bench.

The Dozer Bench Settings are shown below.

Steepened Angle: This value controls the angle, in degrees, of the spoil pushed by the dozer into the pit.
Dozer Angle: This value controls the push angle of the dozer until it reaches the Dozer Depth.
Dozer Depth: This value controls the digging depth of the dozer.
Dozer Width: This value controls the width from the existing highwall to the start of the flat portion of the dozer bench. Note that the full dozer bench may be longer than this value depending on pit geometry.

The Spoil Bench Settings are shown below.

Flatten Previous Spoil: This option is only applied when two dragline passes are designed. When selected, the left three settings of this dialog will be made unavailable and the right three setting will become available. When a previous spoil pile is flattened for the dragline bench, it is always pushed further into the pit, away from the unmined ore.

Steepened Angle: This value controls the spoil angle from the pit floor up to the dragline spoil bench.

Bench Height: This value controls the height of the dragline spoil bench.

Spoil Offset: This value controls the width of the dragline spoil bench.

Repose Angle: When flattening a previous spoil pile for the new dragline bench, this value controls the repose angle, in degrees, of the pushed material.

Flatten Distance: When flattening a previous spoil pile for the new dragline bench, this value controls the width of the spoil that is flattened in preparation for the dragline.

New Spoil Offset: When flattening a previous spoil pile for the new dragline bench, this value controls the spoil offset from the previous spoil pile.

Cut Direction: This options determines whether the cut is advancing to the right or the left in the graphics window.

Pit Width: This value sets the width of the existing, open pit. This can represent a previous pass, or a box-cut.

Spoil Angle: This value sets the angle of repose, in degrees, for the spoiled material.

Coal Fender Height: This value sets the height of the remaining coal that may be covered with spoil. This wedge of coal that is covered by the spoil is known as a fender.

Spoil Toe Offset: This value places the toe of the spoil the specified distance from the bottom of the coal seam.

Cut Width: This value sets the width of the new cut. This is the field that is frequently changed in order to find an adequate pit size.

Back Face Angle: This value sets the highwall angle, in degrees, for the new cut for all strata.

Spoil by Reach: This option places the top of the pile at a distance specified in the **Spoil by Reach** column of the Dragline and Seam Data section of the dialog. When selected, the Coal Fender Height and Spoil Toe Offset fields will be unavailable.

This section of the help document discusses the Dragline and Seam Data inputs, shown below.

DRAGLINE AND SEAM DATA											
Dragline	Reach	Max Height	Max Depth	SW Dig	SW Dump	Strata	Offset				
650 @ BE AT KELLERMAN	175.0	105.0	90.0			OB	25.0				
Required	188.5	9.2	50.0	-90.0	90.0						
Strata	Key	Thickness	Front Face Angle	Density	Toe Offset	Swell %	Sh/Truck Thickness	Key Cut	Spoil By Reach	Coal Fender Height	Spoil Toe Offset
OB	NO	50.00	70.0	120.00	.00	20.0%	.00	Edit	300.00	.00	.00
C1	YES	30.00	80.0	80.00	.00						

Note that this section of the dialog uses colored text to highlight design flaws. Black text is used for simple input values, blue text is used for maximum available values, green text is used for values that are attainable with the current design, and red text is used for values that are not attainable with the current design.

Dragline: This dropdown menu sets the dragline to use for the current pass. When selected, a list of predefined draglines will be shown. Draglines may be added/edited via the Define Dragline Equipment command (Surface Mining Module > Surface Pulldown Menu).

Reach: This value displays the horizontal reach of the selected dragline.

Max Height: This value displays the vertical dumping height of the selected dragline, as measured from the bottom of the dragline.

Max Depth: This value displays the vertical digging depth of the selected dragline, as measured from the bottom of the dragline.

SW Dig: This value displays the required dragline Swing Angle, in degrees, on the digging side. If this value is shown in red, then the dragline cannot reach the entire cut, even with a -90 degree swing angle.

SW Dump: This value displays the required dragline Swing Angle, in degrees, on the dump side. If this value is shown in red, then the dragline cannot reach far enough into the pit to adequately dump the waste material, even with a 90 degree swing angle.

Strata (Top Section): This option sets the strata on which the dragline is positioned.

Offset: This value sets the distance between the highwall and the center of the dragline tub.

Strata (Bottom Section): This column lists all strata to be handled in the current dragline pass.

Key: This column marks each strata as key or non-key (waste) material. Only non-key material will be spoiled.

Thickness: This column controls the thickness of each strata.

Front Face Angle: This column controls the highwall angle, in degrees, of each strata. Note that a value of 90 represents a vertical highwall.

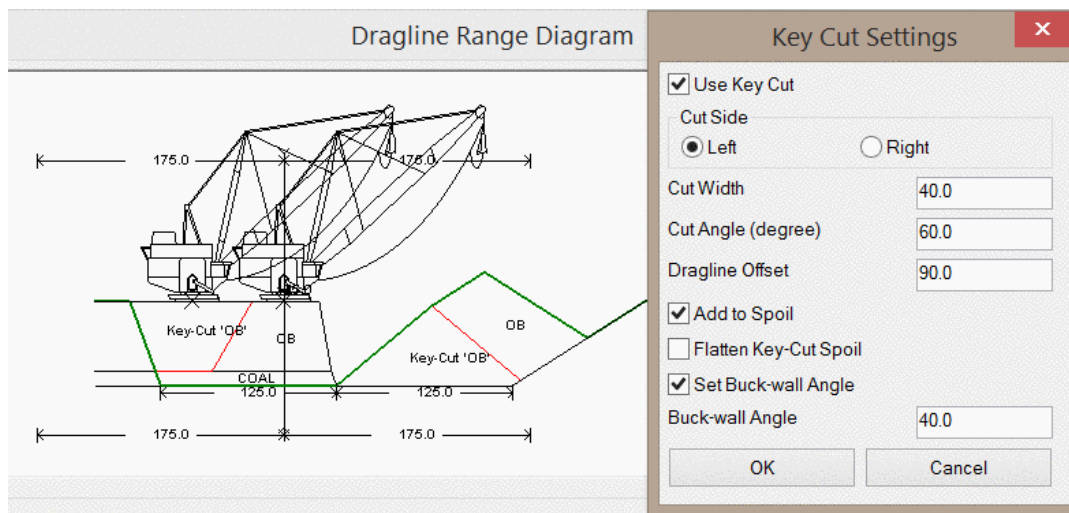

Density: This column sets the density for each strata. English units are set to lbs/ft³ and metric units are set to kg/m³.

Toe Offset: This column controls the bench width between strata.

Swell %: This column lists the swell percent of the spoiled material. A material with a swell of 10% will occupy 1.1 times it's original volume after it has been spoiled.

Sh/Truck Thickness: This column controls the thickness of each non-key strata that is to be excavated by truck and shovel (material that won't be spoiled into the open pit).

Key Cut: This column controls if each non-key material is to be excavated with a key cut. Clicking the **Edit** button will open the below dialog, which is shown next to an example of the results it will produce.

Use Key Cut: This option toggles the use of the key cut.

Cut Side: This option controls the location of the key cut - either the right or the left side of the cut area.

Cut Width: This value controls the width of the key cut.

Cut Angle (degree): This value controls the cut angle of the key cut.

Dragline Offset: This value controls the distance between the crest of the highwall and the center of the dragline, during the key cut.

Add to Spoil: This option will actually spoil the material excavated in the key cut. If not selected, the material from the key cut is assumed to be haul away to another dump location.

Flatten Key-Cut Spoil: This option is only available when the Add to Spoil option is selected. This option will flatten the top of the spoil pile created from the key cut. When selected, the Spoil Bench Settings dialog will be used to set the parameters for the flattened bench.

Set Buck-wall Angle: This option will set the angle of repose for material spoiled from the key cut. This allows for two angles of repose to be displayed in the overall spoil pile. Several of the above parameters are represented below.

Coal Fender Height: This column displays the required coal fender height for the given Spoil by Reach value. This value is calculated automatically.

Spoil Toe Offset: This column displays the required spoil toe offset for the given Spoil by Reach value. This value is calculated automatically as the distance from the toe of the spoil to the toe of the strata.

Spoil by Reach: Yes or No. This column sets the spoil distance for each strata when the Spoil by Reach toggle above is selected.

Bottom-row Icons: At the bottom of the Dragline and Seam Data section of the dialog are six icons, shown below.

Listed in order from left to right:

Add Pass: This icon will add an additional dragline pass to the cut. This can be a different dragline or an additional pass of the same dragline. Each dragline pass is listed on a separate tab. Note that any strata layers listed for one dragline pass will be completely excavated in that pass. If a strata is to be excavated with dragline pass #2, that strata should not be listed in dragline pass #1. An example of the tabs shown for three dragline passes are shown above.

Remove Pass: This icon will remove the currently selected dragline pass.

Add Strata: This icon will add a new strata to the current dragline pass.

Remove Strata: This icon will remove the currently selected strata.

Move Up: This icon will move the currently selected strata up in the list.

Move Down: This icon will move the currently selected strata down in the list.

The output window will output the results of each step of the dragline sequence. Steps will be added and removed automatically.

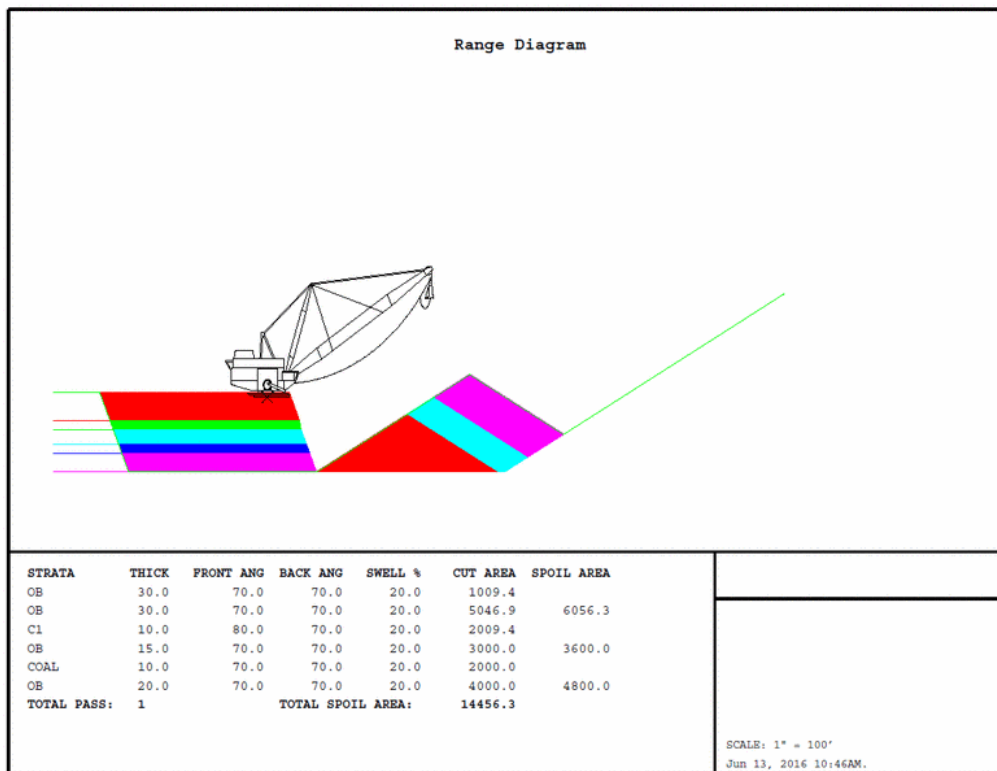

OUTPUT	
Report Title	
Generic Cut	
1. Ext Bench Rehandle	
Cut Area	5050.9
Spoil Area	5050.9
Toe Offset	50.8
Rehandle Rate%	24.9
2. Remove 'OB'	
650 @ BE AT KELLERMAN	
Cut Area	10281.5
Spoil Area	12337.8
Toe Offset	85.7
3. Remove 'C1'	
Cut Area	6084.4

650 @ BE AT KELLERMAN	
Cut Area	10000.0
Spoil Area	12000.0
Toe Offset	157.3
5. Remove 'COAL'	
Cut Area	2000.0
Total Spoil Area	29388.7

This section of the help document discusses the additional commands on the dialog, shown below.

Draw: This button will draw the dragline sequence in CAD. No dimensions will be labeled; only strata. Each step of the sequence will be drawn separately, with the first step shown at the bottom.

Report: This button will create a multi-page PDF document where each step in the section will be on a separate page. The last page of the report will show all steps, as shown below.

Profile: This button will save a profile (.pro file type) of the final step of the dragline sequence.

Sequence: This button will save the dragline sequence (.seq file type). This file can be used to extrude the dragline steps across a centerline via the Process Dragline Sequence command (Surface Mining Module > Surface Pulldown Menu).

Pulldown Menu Location: Surface

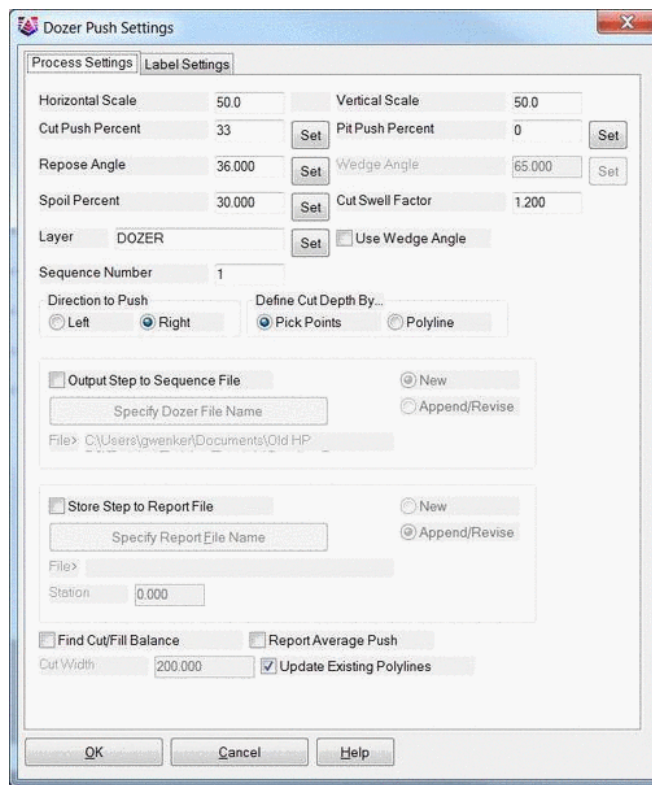

Keyboard Command: ranged

Prerequisite: dragline equipment defined

Dozer Push

This command simulates a dozer push design from a highwall into a pit on a cross section. The program draws closed polylines that represent the cut and fill areas and the path of the dozer. Dozer Push works with a cross-section view of the pit made from either the Fence Diagram command or Sections and Profiles from Civil. A prerequisite for this command is a polyline that defines the existing ground including the top surface, highwall and pit bottom. A second polyline optional polyline can represent the depth to the Cut Bench to push along, and a third polyline option could be one for the bench or pit bottom for spoil start. The Cut Bench polyline could be the top of of a seam to dig down to, for example. This command does one push at a time. To perform multiple cuts, run Dozer Push for each one.

The Dozer Push command starts with the dialog box shown here:

- **Horizontal Scale** and **Vertical Scale:** These are the scale factors for the drawing to generate text, symbols, and vertical exaggeration, among other things.
- **Cut Push Percent:** The Cut Push Percent is the percent grade the dozer cuts down from the surface to the bench polyline or to the selected cut point. There are separate angles for the left and right sides.
- **Pit Push Percent:** The Pit Push Percent is the percent grade that it will push out into the pit before spilling over to the repose angle. Enter as a percent, positive or negative, where positive will push down into the pit, and negative will push up, into a spoil fill pile.
- **Repose Angle:** Repose Angle is the angle that gravity pulls down the fill slope, as it spills over the edge. Enter as an angle.
- **Spoil Percent:** Spoil Percent is the percent grade of the spoil pile as the dozer pushes uphill. Enter as a percent (up). When there is not enough room in the pit to fit the cut at the pit push percent, the remainder will get placed by building up a spoil pile at this specified Spoil Percent. The program will prompt for a base point to start building the spoil slope with the prompt to Select bottom bench polyline for spoil start. This point is typically at the top or bottom of a seam at the pit bottom so that the spoil pile will not overlap the ore and create extra rehandle. The end point of the Bottom Bench Polyline is where the spoil slope will begin. To verify this, take an imaginary line and draw up from the endpoint of the bottom bench polyline, at the spoil slope, and it will pass through the fill, right on top of the spoil slope position.

- **Cut Swell Factor:** The Cut Swell Factor is multiplied by the cut area to determine the amount of fill. Enter as 1.2 for 20 percent swell.
- **Layer:** This layer is used to draw the new entities created by this routine such as the cut and fill polylines and labels.

- **Use Wedge Angle:** With the Wedge Angle option, the cut will begin by starting at the top of pit and moving down at the Wedge Angle for the specified Cut Width. It will continue down at the wedge angle for the specified horizontal width. The Cut Push Percent is not used if the Wedge Angle is used.
- **Sequence Number:** This is the sequence step number that is added to the SEQ sequence file for Process Dragline Sequence.
- **Direction to Push:** The dozer must be specified to push to the right or to the left.
- **Define Cut Depth By:** The Polyline Method will prompt to select the Cut Bench Polyline. The polyline method can use either a closed or open polyline. For a closed polyline, the cut area is defined by the polyline. For the open polyline, the polyline represents the surface that the dozer will cut down to. The dozer cut will be located by finding the top of the pit and then moving back along the top surface for the Cut Width entered below. The top of the pit is identified by finding the first grade that is greater than or equal to the Push Percent grade. Then the dozer will cut down at the Push Percent until it reaches the bench polyline. The Pick Points method will prompt for the lower left point and the lower right point. The line drawn between them is then set to the cut surface. This controls the cut width, so the value entered below for Cut Width will not be used.

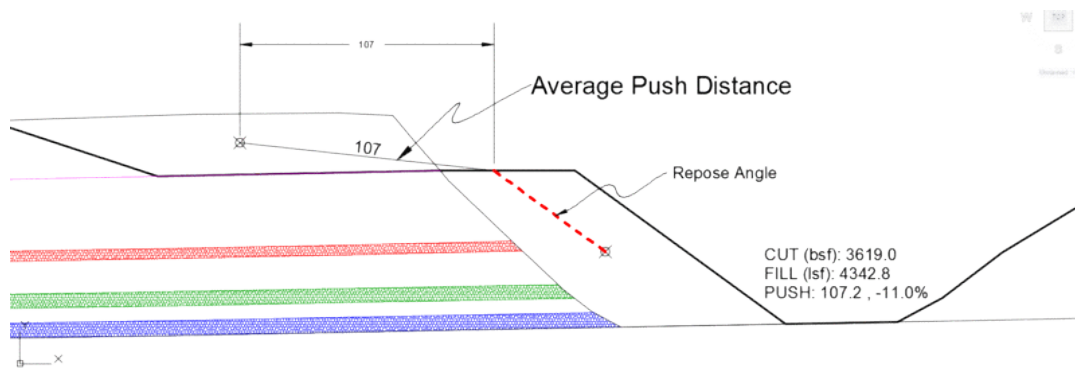

- **Output Step to Sequence File:** Turn this option on to add the step to a new or existing SEQ file. This file is processed with Process Dragline Sequence.
- **Store Step to Report File:** This option will create or append a CUT file that is processed with the command Dragline Section Report. This option requires the Dozer Push design on each cross section station the length of the pit.
- **Find Cut/Fill Balance:** The Find Cut/Fill Balance is an option that automatically calculates the cut area, where the cut and fill balance (plus swell factor) and so it does not prompt for picking the cut points and the bench polyline is not used. The command line prompt states "Select existing grade polyline at dozer push start:". The selected point along the existing ground polyline sets the Cut Push percent point. The program will cut down at this slope to define the cut, and then the fill is automatically placed for a Cut/Fill balance.

- **Report Average Push:** This option labels the average horizontal push distance from the cut centroid, to a

point that is up from the fill centroid, at the angle of repose.

- **Cut Width:** When using the Polyline method to Define the Cut Depth, this is the total width of the push, from the Cut Push distance down to the Cut Polyline, then across the Cut Polyline the remaining distance to get to the entered width. See the image above for Define Cut Depth By for the Cut Width labeled.
- **Update Existing Polylines:** This option will replace the existing ground polyline with the updated ground polyline. Otherwise the existing ground polyline will remain unchanged, and the cut and fill areas are drawn as separate polylines.
- **Label Style:** Sets the style for the text entities.
- **Text Size Scaler:** This scaler is multiplied by the Horizontal Scale to set the size of the text entities.
- **Area Decimals:** Sets the precision for the end areas.
- **Cut/Fill/Rehandle Labels:** Sets the names for these values.
- **Label Push Distances:** This option will label the distance from the centroid of the cut block to the edge of the highwall to a point above the fill centroid, where the repose angle intersects the fill surface. See the image above for Report Average Push
- **Draw Centroids:** Draws the specified symbol at the centroids for the cut and fill areas.

Prompts

This command handles many types of the dozer push. Which values to use from the dialog and the prompting depend on the design type of the dozer push.

Command: DOZER

To Define Cut Depth by Picking Points:

Select existing grade polyline: *pick the ground polyline*

Pick lower Left cut point:

Pick lower Right cut point:

Select fill areas to rehandle (Enter for None).

Select objects:

CUT (bsf): 9182.6 REHANDLE (bsf): 0.0 FILL (lsf): 9182.6

PUSH: 141.4,3.6%

Pick Point for Label (Enter for none):

Select existing grade polyline: *pick the ground polyline*

Select cut bench polyline: *pick the bench polyline*

Select fill areas to rehandle (Enter for none)

Select objects: *press Enter*

Cut: 308.7 **Fill** 308.7

Pick Point for Label (Enter for none): *pick a point*

Using the Find Cut/Fill Balance option:

Select existing grade polyline at dozer push start: *pick the ground polyline where the cut is to begin Calculating...*

Pulldown Menu Location: Surface

Keyboard Command: dozer

Prerequisite: Surface and strata polylines

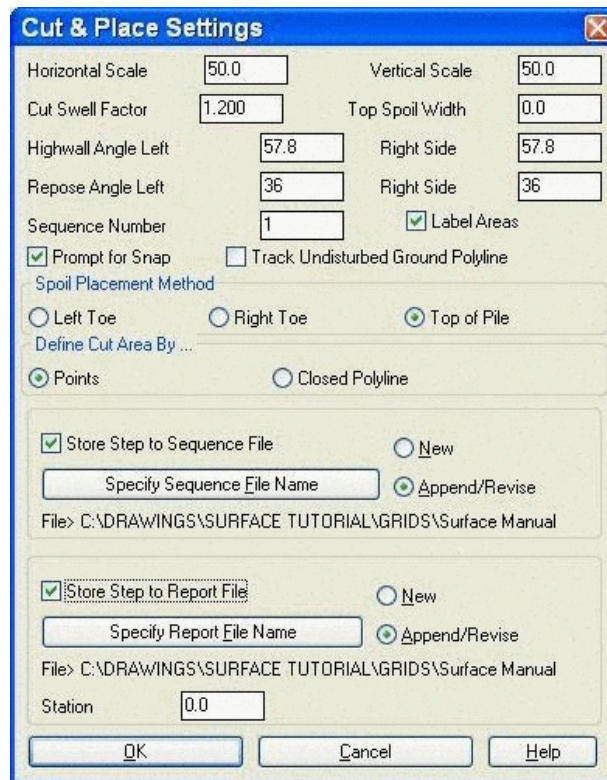

Draw Dragline Limits

This command draws an outline in profile view of the dragline reach, depth and height limits. The program draws the limits of the dragline as polylines in the current layer. These limit polylines serve as guides in other dragline commands like Cut & Place. Also these dragline commands will check the dragline limits and report if the dragline limits are exceeded when processing the sequence file. The dragline parameters are set in the Define Dragline Equipment command. Before starting this command, the dragline should be defined in Define Dragline Equipment and the surface where the dragline sits should be drawn as a polyline in profile view. This polyline can be drawn with the Draw Fence Diagram command or the profile commands in the Civil Design module.

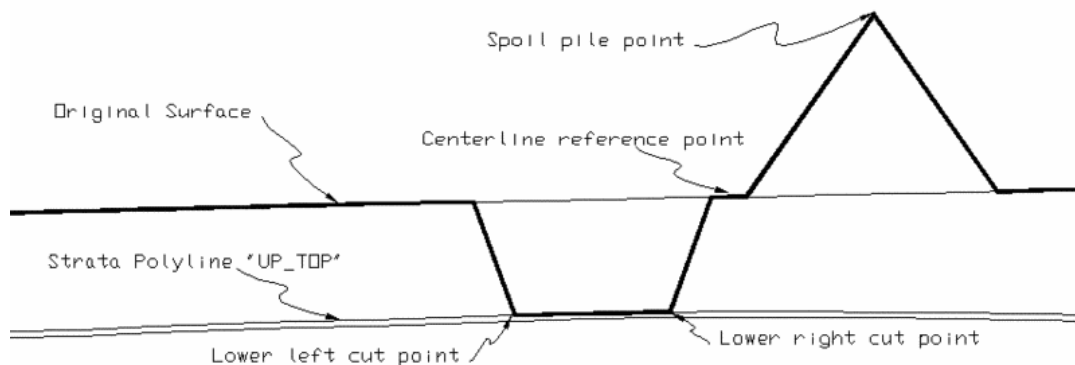

The window prompts for the horizontal and vertical scale. This is to determine the vertical exaggeration if any. There is an option to draw an icon of the dragline. Otherwise the limits are only drawn as polylines. Choose a direction for the boom to be facing, left or right. The draw swing angles option will label the angles along the top of the limit polyline. The Group Dragline Entities will keep it together as a block instead of individual polylines. If the program detects that dragline limits are already in the drawing, then there is an option to erase the existing limits. This option is useful for automatically erasing old limits before drawing the new limits, as the program tracks where the dragline is located to measure the reach. Then pick the surface polyline and where along the polyline the dragline is located. There is an option to specify the dragline location by picking a reference point such as the top of the highwall and then entering an offset distance from the reference point to the center pin of the dragline (left offset is a negative value).

Station, then set to Append/Revise for additional stations. These are processed with the Dragline Section Report commands.

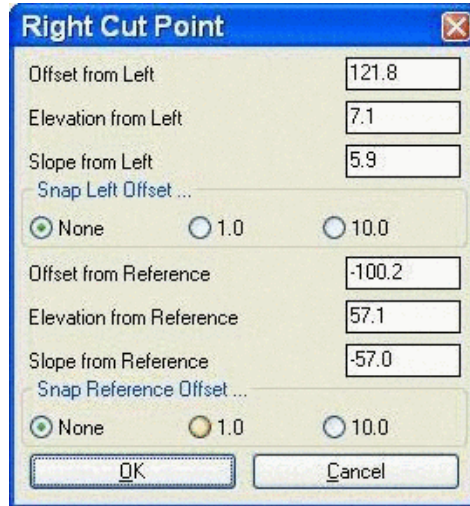

When picking points, there is an option to select a strata polyline which will be used as the bottom cutoff for the cut area. Also while picking the points, there is a real-time window that shows the point offset, slope and distance as you move the cursor. Once the point is picked a snap dialog allows you to adjust the picked point. For example, you could use the real-time window to visually pick the right cut point. The actual picked right position could be 201.32 from the left point and then you can use the snap dialog to round the position to 200. This adjust point dialog only appears if the Prompt for Snap option is on. You can also specify a reference point by typing 'R' for the Reference option at the command prompt. This option will prompt you to pick a reference point in the section. For example you could choose the toe of the existing highwall as the reference point and make the right cut point offset by 10.0.

After choosing the cut area, the spoil pile is placed by picking a point to place the spoil. This point can be either the left toe of slope, right toe of slope or top of pile. After defining the cut and spoil, there is an option to go back and adjust the cut or spoil points. Select L, R or S for left point, right point or spoil location. Adjusting the cut points will automatically resize the spoil pile-watch it dynamically change. Once everything is set, press Enter to end the routine. The surface profile polyline is redrawn with the cut area removed and the spoil added. The changed segments of the original surface are drawn a different color, usually gray.

The user input for this command can be saved to a sequence file (.SEQ) for the Process Dragline command or a section report file (.CUT) for the Dragline Section Report command. With the sequence file active, the program will prompt for a centerline reference point which is the point in the cross-section view that the centerline for Process Dragline passes through. It needs this point to locate the cross-section horizontally in the plan view relative to the centerline drawn in plan view. If you choose a strata polyline, the program will ask for the strata name of this polyline. The Process Dragline command will then prompt for a grid file that models this strata name. The data that is saved includes the depth and offset of the cut points, the spoil pile offset, and the slopes. Besides specifying the sequence file name to write to, the sequence number is also stored. This number orders the steps in Process Dragline. For the Dragline Section Report, the program will store the station, sequence number, and cut and fill areas.

The Track Undisturbed Ground Polyline option is for calculating rehandle. With this option on, the program will prompt for the existing ground polyline as usual plus an additional undisturbed ground polyline. The undisturbed polyline is the same as the existing ground polyline except that the undisturbed polyline does not have the spoil piles. One way to start this process is just copy the Surface line onto itself, then move one away from the other on one of the ends for ease of selecting for the first cut. After the first cut, it should be easy to select one or the other. Cut & Place will update the undisturbed polyline by removing the cut area and will not add the spoil pile. The program will also report any rehandle using the undisturbed polyline. The swell factor is not applied to the rehandle.

This command will also fill in for some of the Dozer Push short comings. If there is a simple extended bench needed, the set one of the spoil slopes to 0 and it will create a flat spoil for that step. Be sure to hit enter when prompted for the top of coal line. The next cut could be a pre-drawn, closed polyline or a series of cuts to remove the material. The lower right cut slope in the case could be the same as the spoil slope to create the left slope of the spoil.

Cut Only (Coal Removal)

This command is similar to Cut & Place. Cut Only removes a cut area in cross-section view from a surface polyline. The difference with Cut & Place is that this command does not place the cut area as a spoil pile. The cut area is just removed from the surface polyline for operations like remove coal. Try to stay away from a 90 degree face on the coal, AutoCAD doesn't like vertical faces (89 is entered below). The Type of Cut chooses between Coal (Key Only) and Prestrip (Non-Key Only). This setting is used in reporting and doesn't affect the rest of the routine. The same prompting and snap dialogs appear here as in the Cut and Place command.

Flatten Spoil Top

This command takes a surface polyline drawn with a spoil pile and flattens the top of the spoil pile. There are two methods to set the flatten width. The **By Distance** method sets the horizontal distance across the top to equal the user-specified distance. The **By Height** method sets the elevation of the flatten to the specified height above a reference point like the pit floor. With this method, the program will prompt to pick the reference point.

The flatten direction will either push to the left, right or both directions. This step can be stored to a sequence file (.seq) for the Process Dragline Sequence command.

Cast Blast Profile

This command applies a blast profile to a cut area in cross-section view. Before starting this command, the surface should be drawn as a polyline from left to right.

Cast Blast first brings up a dialog where you can set the scale, highwall angle and swell factor. The Horizontal Scale and Vertical Scale are used to determine the vertical exaggeration of the cross-section view. The Highwall Angle is used with the Define Blast Area By Points option as the angle from the picked points at the bottom of the blast area up to the surface. The Cut Volume Swell Factor is multiplied by the cut area to determine the fill area of the spoil pile.

The area to cut can be either a closed polyline or defined by picking the lower left and lower right points. When picking points, there is an option to select a strata polyline which will be used as the bottom cutoff for the blast area. The blast profile can be defined by either a polyline drawn from left to right on the screen or by a Carlson profile (.pro) file. Refer to the Section & Profile module for how to create a profile file.

After placing the blast profile, there is an option to adjust the blast profile points. To adjust a point, pick on the blast profile near the point to modify. This will pick up that point and you can pick a new position. When a point is moved, the program will automatically fit the updated blast profile. Once everything is set, press Enter to end the routine. The surface profile polyline is redrawn with the blast area showing the blast profile. The changed segments of the original surface are drawn in a different color.

The program reports the cut and fill end areas and the cast to final percent which is the percent of the fill area that is in the final spoil area. The cast to final area is defined by the area past the line starting at the toe of cut and going up at the Repose Angle. This starting point can be offset from the toe of cut by using the Spoil Toe Offset field. A negative offset moves to the left and a positive to the right. The Auto Fit Cast To Final option will adjust the blast profile by moving the profile horizontally such that the placed profile balances the cut and fill areas and meets the specified Target Cast to Final percent.

There is an option to save the user input for this command to a sequence file (.seq) for the Process Dragline command and to a section report file (.cut) from the Dragline Section Report command. With the sequence file active, the program will prompt for a centerline reference point which is the point in the cross-section view that the centerline for Process Dragline passes through. If you choose a strata polyline, the program will ask for the strata name of this polyline. The Process Dragline command then prompts for a grid file that models this strata name. Besides specifying the sequence file name to write to, the sequence number is also stored. This number orders the steps in Process Dragline.

Polyline to Centerline File

This command is described in the Centerlines section of the manual. Please refer to it there.

Area To Section Report

This command stores the area of closed polylines into a section report file (.cut) that is used by the Dragline Section Report command. Along with the area of cut and fill, this command associates a station and sequence number. The station is the distance along the dragline centerline and the sequence number orders the area in the steps at that

station. There can be several steps at each station. This command prompts to select a cut area polyline which should be a closed polyline in section view. There is also an option to select a fill polyline. The areas can be assigned a description that is used in the Dragline Section Report.

Prompts

Dragline Section Report

This command reports the end areas at different stations based on the accumulated stored results of various dragline routines. The report data is read from a section report file (.CUT). The commands that can add to the section report include Cut & Place, Cut Only, Dozer Push, Cast Blast Profile and Area to Section Report.

The report formatter is used to create the section report. This formatter allows you to choose the fields to report and the report layout. The report can also be output to Excel or Access.

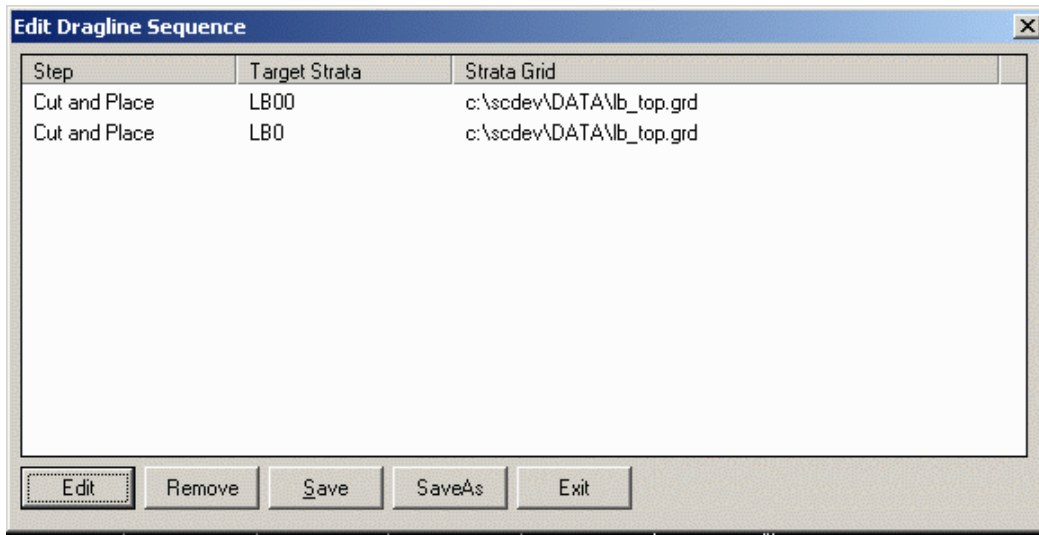

Pulldown Menu Location: Surface

Keyboard Command: cutreport

Prerequisite: A section report file (.cut)

Edit Dragline Sequence

This command edits the steps in a sequence file (.seq). The sequence file can be created with other commands such as Dozer Push, Cut and Place, and Cast Blast Profile. This command allows you to remove a step or edit a step. For editing, the target strata and surface file for the step can be changed.

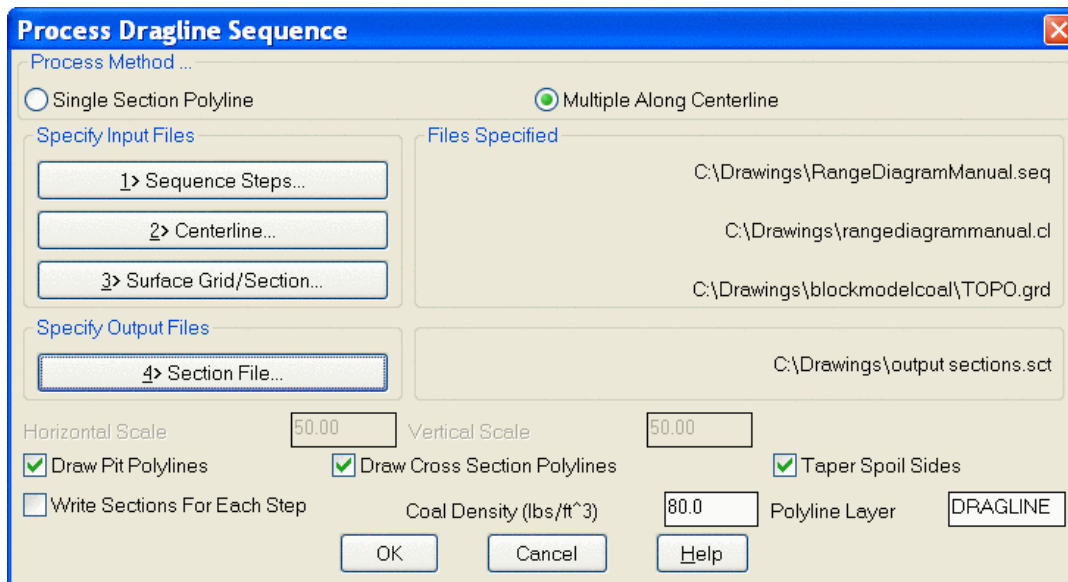

Pulldown Menu Location: Surface

Keyboard Command: edit_seq

Prerequisite: .seq file

Process Dragline Sequence

This command applies 2D cross-section dragline steps along a centerline to create a 3D model. The dragline steps are stored in a sequence file (.SEQ file) that can be created by the Cut & Place, Cut Only, Dozer Push, Flatten Spoil Top and Blast Cast commands.

There are two different methods for Process Dragline Sequence. The Multiple Along Centerline method applies the dragline sequence along a centerline for a range of stations. The centerline defines the dragline alignment and the mining surfaces are defined by grid files and/or section files. This method outputs section files, 3D polylines and a volume report. The Single Section Polyline method applies the dragline sequence to one station in cross section view. The dragline position is defined by picking the centerline position in section view and entering the elevation at this point. The mining surfaces are defined by picking polylines for the ground surface and strata in section view. The output is drawn as polylines in section view for this one station.

Each of the steps has a centerline reference point and the control points for the step are relative to this reference point. For example, the top of the spoil pile for Cut & Place could be 75 feet right of the centerline. Process

Dragline Sequence runs the steps along the centerline. A centerline file (.CL file) can be created from a polyline with the Polyline to Centerline command.

The existing ground can be modeled by either a grid file (.GRD file), triangulation file (.TIN file) or section file (.SCT file). Process Dragline Sequence works by repeating the 2D cross-section steps for each section along the centerline. When using a grid file surface, the program will prompt for a station interval and will create ground cross-sections at the specified offset left and right of the centerline at this interval before applying the dragline steps. When using a section file surface, the program will apply the dragline steps at the interval of the section file. There is an option to output the results of dragline steps to a section file. Besides outputting the final section results, sections at the end of each step can be saved to section files. The section files of each step are named automatically by adding the step sequence number to the original final section name.

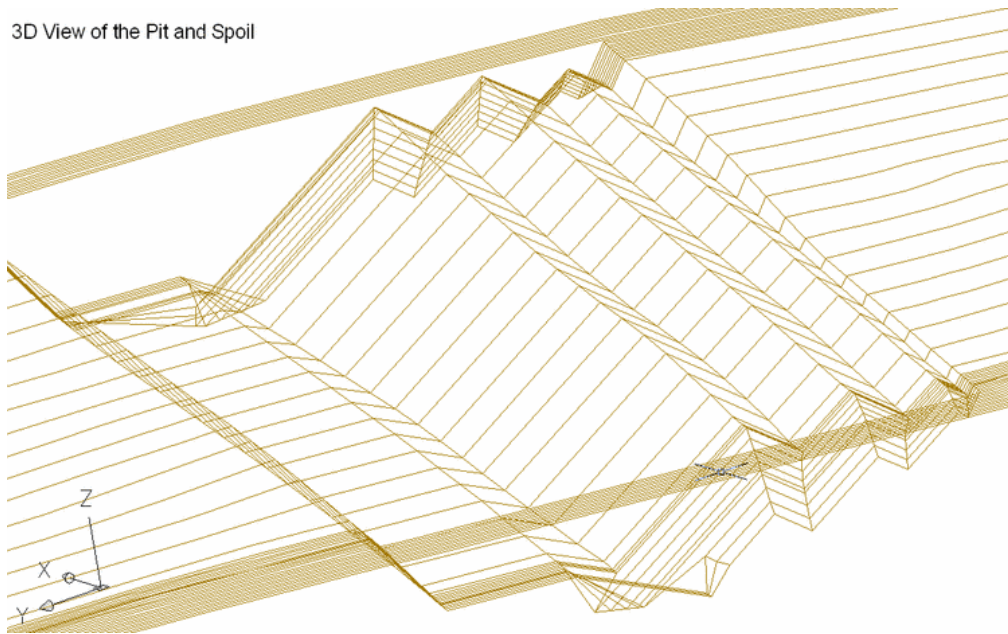

The dragline steps have an option to use a strata polyline which makes the control points relative to the strata. If strata polylines are used, then the Process Dragline will prompt for a grid file that models the strata. For example, you could use a use a top of coal polyline in the Cut & Place command to define the bottom of the cut area. With the store sequence file (.SEQ) option on, the program will prompt for a name for the polyline and you could enter "coal". This name is stored in the sequence file and when Process Dragline Sequence in run, the program will prompt for you to select the "coal" grid file.

The program creates a report of the volumes for each step in the sequence. The Coal Density field in the dialog is used for calculating the coal tons for the report. The Taper Spoil Sides option adds stations before the first cut and after the last cut to show the repose angle of the ends of the fill spoil piles. There are options to draw 3D polylines of the pits. Draw Pit Polylines creates 3D polylines parallel to the centerline along the dragline control points such as the top of the spoil pile. Draw Cross Section Polylines creates 3D polylines perpendicular to the centerline for each cross section.

Tag Slope Groups

This command places special symbols on pit polylines to indicate different slope groups to use in Design Bench Pit. The Design Bench Pit command supports up to four separate sets of cut slope definitions to be used on different sides of the pit polyline. Using the symbols from Tag Slope Groups is a way to batch process many pit polylines with separate slope groups. When Design Bench Pit finds symbols from Tag Slope Groups, the program skips the prompting to specify and slope group sides and uses the assignments from the symbols. For each edge in the pit polyline, the program looks for a slope group symbol. If a symbol is not found on a segment, then slope group #1 is used. So only symbols only need to be placed for slope groups 2-4.

The options dialog defines the symbol from the Symbol Library to use for each slope group as well as the symbol size, layer and color. There are a few methods for placing the symbols. The Pick Individually method prompts to a pick point on the pit segment and the symbols are added one pick at a time. The Crossing Line method prompts for two points and places a symbol at each pit polyline intersection along the line between the two points. The Window Area method prompts for a series of points to define the perimeter of an area and a symbol is drawn on the midpoint of all pit segments within this area.

Pulldown Menu Location: Surface

Keyboard Command: tag_slope_groups

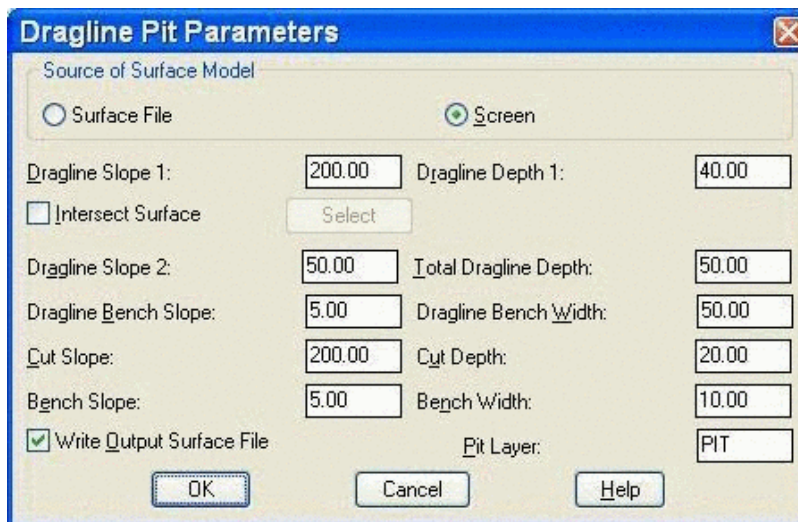

Prerequisite: Pit polylines

Design Dragline Pit

This command designs a pit into the existing ground surface using a set of dragline and bench slopes. The dragline slopes are for the portion of the pit excavated by the dragline and the bench slopes represent the truck-shovel excavation. The pit is drawn with 3D polylines and the pit volumes for the dragline and truck-shovel are calculated.

Before running this command, the base of the pit should be drawn as a closed 3D polyline. This pit polyline should also be assigned the elevations for the bottom of the pit. One way to set the elevation is to create a grid file for the bottom of the pit. For example, use Make Strata Grid Files to make a grid of the top of coal elevation. Then use the command 2D to 3D Polyline by Surface Model to convert the pit polyline into a 3D pit polyline with the grid elevations. This 2D to 3D command usually creates more vertices than necessary for Design Dragline Pit. So it is good to run Reduce Polyline Vertices.

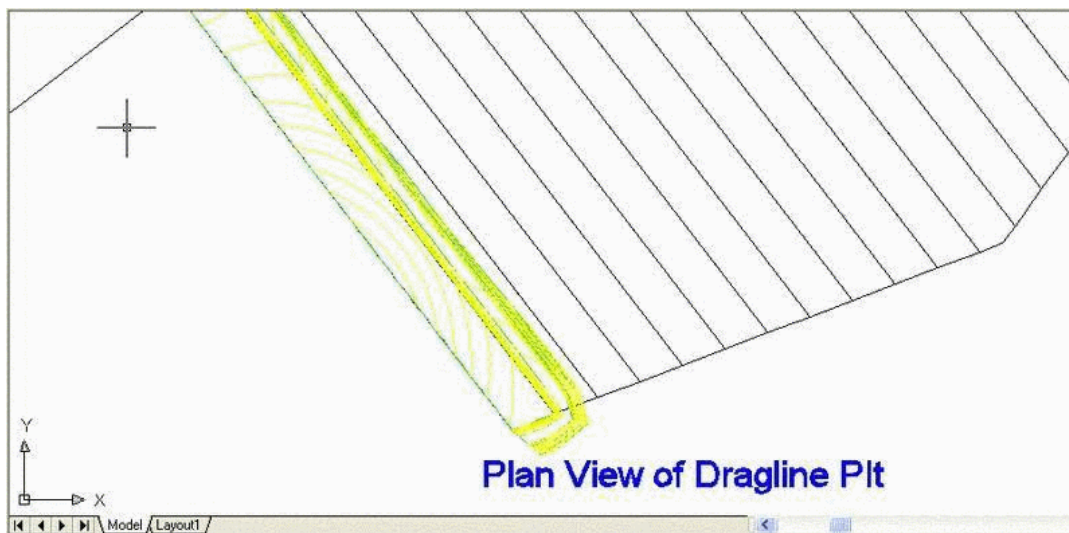

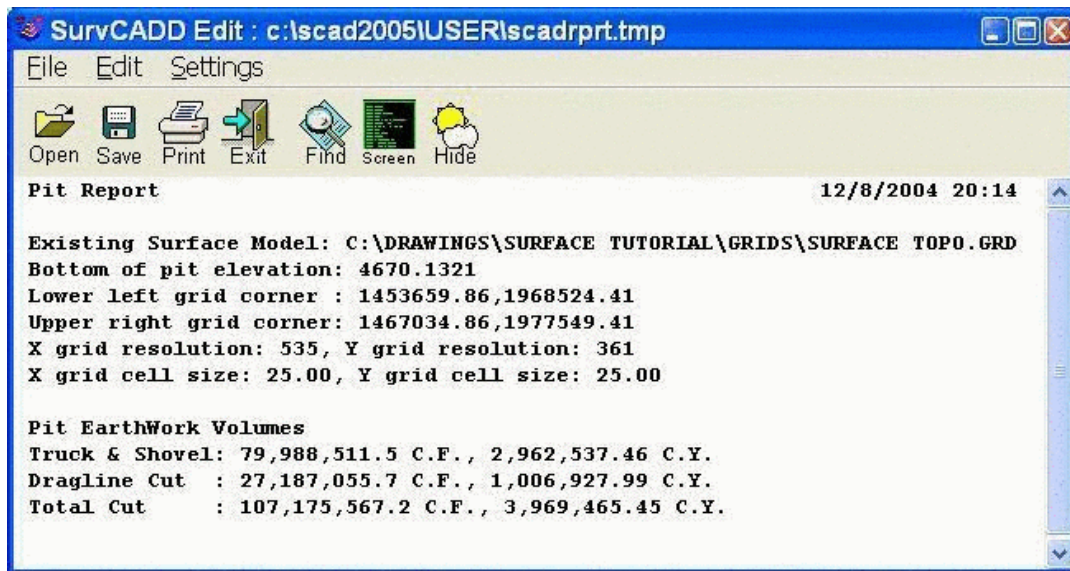

Design Dragline Pit starts with the dialog shown below. All slopes are entered as percent. There is an option for two dragline slopes to allow for different slopes in different material, though it will be reported as one volume. The break point between these slopes can be set as either depth or at a grid surface. The grid surface could be a grid file for the transition strata. Next there is a dragline bench width and slope followed by cut and bench slopes. The cut-bench slopes repeat until intersecting the surface. The resulting modified surface can be saved as a grid file (.grd) with the Write Output Grid File option.

The program works by starting from the base pit polyline and applying the slopes until the surface is reached. The surface is modeled either by a grid file or from the entities on the screen. With the screen option, all 3D entities in the pit area are used to model the existing surface.

If a pit already exists to one side of the current pit, then this existing pit should be part of the surface model. Then the program will intersect the surface right away on this side without creating all the dragline and bench slopes. The Write Output Grid File allows you to save a grid file at the end of the command that represents the surface updated with the new pit. Then you can run Design Dragline Pit for the next pit and use the grid file output from the previous time as the new surface model.

The volume report shows the dragline cut and the truck-shovel cut. The dragline cut includes the volume from the pit base up to the top of Dragline Slope 2. The truck-shovel cut is the remaining volume up to the surface.

Plan view of dragline pit polylines

Profile view of dragline pit slopes

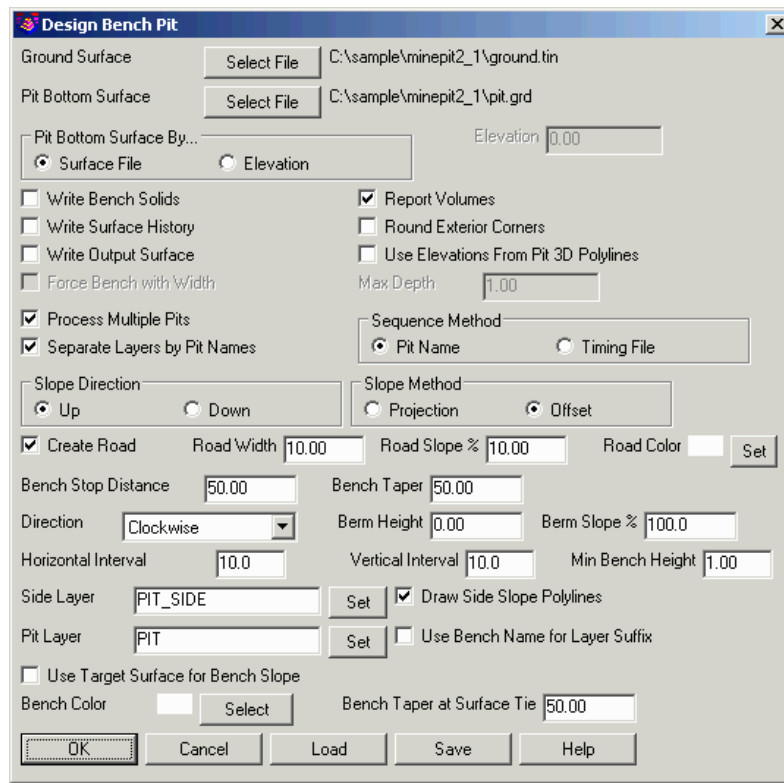

Pulldown Menu Location: Surface

Keyboard Command: minepit

Design Bench Pit

This command creates pits where the sides are a series of slopes with benches. The side slopes start from a closed polyline. This pit polyline can be either the bottom of the pit and the slopes run up and out to intersect the ground surface, or the pit polyline can represent the top of the pit and the slopes run down and in, to intersect the pit bottom grid. Different slopes can be used for different sides of the pit. The pit is drawn as 3D polylines and the pit volumes are reported.

Before starting this command, the pit perimeter should be drawn as a closed polyline, 2D at zero elevation, or at 3D elevations on a surface. The program also needs triangulation or grid files for the existing ground surface and the bottom of pit surface. Design Bench Pit starts with the dialog shown below to specify these grid file names.

- **Ground Surface:** This is the surface for the top of pit perimeter.
- **Pit Bottom Surface:** This is the surface that will represent the bottom of the pit.
- **Pit Bottom Surface By:** This option chooses between using a surface model or fixed Elevation for the target for the bottom of the pit.
- **Write Bench Solids:** This option creates solid model files (.MDL) for the volume of each bench in the design.
- **Report Volumes:** You can turn off this option to save processing time if you don't need this routine to report the pit earthworks.
- **Write Surface History File:** This output file is a GSQ file that is used for volumes in Surface Mine Reserves which leads up to surface mine timing and scheduling on these volumes, or for 3D Viewing as a movie with View Surface History File command.
- **Round Exterior Corners:** This option will create rounded corners on the outside edges of the pit for a more realistic design. When this is off, the corners are sharp and angular.
- **Write Output Grid File:** This option will create a grid file (GRD) of the design. It includes the original ground surface grid file, with the pits built onto it.
- **Merge Design With Ground:** This option combines the bench pit surface with the existing ground for the output surface.
- **Use Elevations From Pit 3D Polyline:** This will use the elevations on the polyline as the start of the design. It will start the pits at the elevations the polylines are drawn at instead of starting at the Pit Bottom Grid for going up, or the topography when going down.
- **Force Bench with Width and Max Depth:** This option applies when the Slope Method is in Projection mode. This option creates the bench up to the specified Max Depth beyond the target surface.
- **Process Multiple Polyline by Pit Names:** This option is to process multiple pit perimeter polylines all at

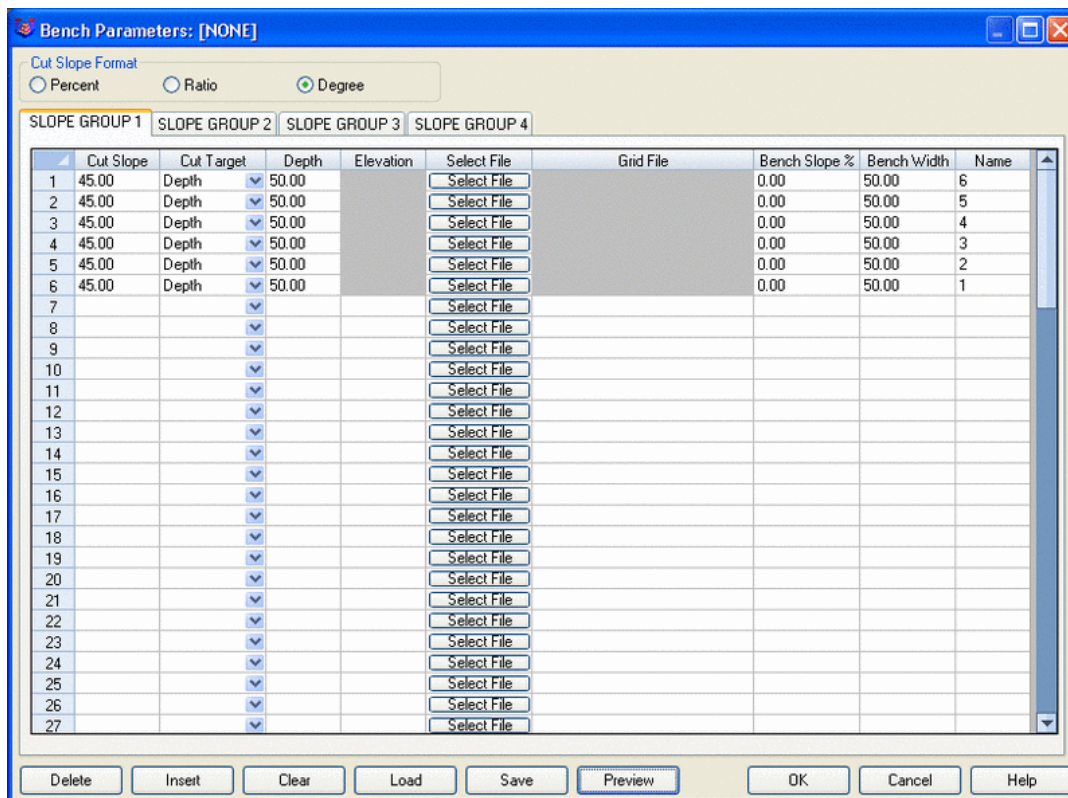

once. The pit polylines must have pit/site names assigned and the program will process them in the order of their pit names. As each pit polyline is processed, the ground surface is updated with the pit volume removed. Then the next pit will use this updated ground surface. When Process Multiple is active, the **Sequence Method** choose the way to order the pits for processing. The **Pit Name** method processes the pits in alphabetical order. The **Timing File** method uses the pit assignment order from Surface Equipment Timing from the .TIM file.

- **Separate Layers by Pit Names:** This option puts the 3D polyline break lines of each pit on their own separate layer. It takes the Pit Layer, and increments them by -2, -3 etc.
- **Create Road:** This option carves a rough road into the pit design. In the dialog, the road **Direction**, **Road Width** and **Road Slope %** are specified along with a **Road Color** for the road polylines to create. When this option is active, the program will prompt for a road starting point along the pit perimeter. The cut slopes are shifted to make room for the road. The **Bench Stop Distance** is for suspending the bench as it crosses the road to avoid combining the road and bench widths at the crossing which tends to shift the cut slopes too much. Within the Bench Stop Distance, the bench has a zero width. The Bench Stop is centered at the road crossing. The **Bench Taper** to the distance that the bench transitions from full width to zero at the Bench Stop. The **Berm Height** adds a berm and makes the road wider to fit the berm. The slope of the berm is set by the **Berm Slope**.

- **Slope Direction:** Up will start at the pit bottom and bench up and out to the surface topography. Down will start at the top surface, and bench down and in to the pit bottom.
- **Slope Method:** Projection is a method that projects the 3D polylines down the slope, across the benches. Offset is a method that offsets the horizontal "toe and crest" lines to create the pit shells this way. Both methods will have horizontal and vertical breaklines, but the method they are generated is different. Each method has its benefits and might work better than the other for each unique scenario. If there is a problem with one method, try the other to see if it handles it better.
- **Horizontal & Vertical Interval:** These settings control the distance to draw the 3D breakline polylines. The horizontal interval will run down the slope, and across the bench. The vertical interval will run parallel with the benches. It should be a factor of the bench height if possible, but not required.
- **Min Bench Height:** The bench is not created when the side slope depth is less than the specified amount.
- **Side Layer:** This is the layer of the 3D polylines drawn perpendicular to the benches, and running down slope.
- **Pit Layer:** This layer is applied to the 3D polyline break lines running parallel to the benches.

- **Use Bench Name for Layer Suffix:** This option adds the bench name to the Pit Layer so that each bench can have a unique name which can be useful for having different colors for each bench for visualization or for isolating benches by layer.
- **Draw Side Slope Polylines:** This option chooses whether to draw the 3D polylines running perpendicular to the benches, and down slope.
- **Use Target Surface for Bench Slope:** When the benches use a surface file for the target, this option makes the bench slope follow the target surface model. Otherwise, the bench slope is set in the next dialog.
- **Bench Color:** This setting puts the bench 3D polylines in the Pit Layer on a different, specified color so they stand out against the slope breaklines.
- **Bench Taper At Surface Tie:** When a bench meets the Ground Surface, this option tapers the bench width to zero over this specified distance.

The next dialog defines the cut and bench slopes. **Cut Slopes** are entered as ratios. The **Cut Target** can be either a fixed depth number, a fixed elevation, a fixed width or to a grid file. For a grid file, the program will find the intersection of the cut slope with the grid surface and will end the cut slope at this intersection. For example, you could make a grid file for a second coal seam and have the bench occur at this coal seam. For the width method, the program creates a cut slope to the target surface with a variable slope to reach the surface at a fixed cut slope width. This width method can only be used on the final bench.

Cut Slope by Width method

After the cut slope, the bench slope and width are used. The cut and bench slopes are applied in order until there is an intersection with the surface. Once you have all the cut slopes defined, you can use the Save button to save these slope settings to a .PIT file. Then these settings can be recalled later with the Load button.

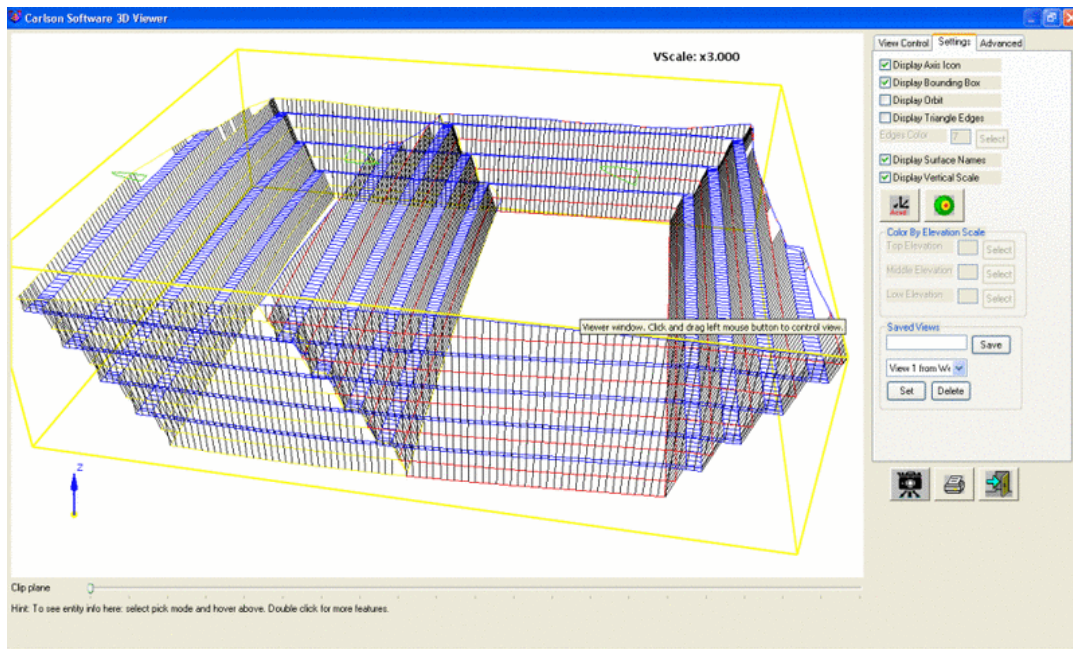

The **Pick Perimeter For Z Range** function prompts to select a perimeter polyline from the drawing. This function reports the elevation range of the Ground Surface along this perimeter which is useful as a reference for setting the bench elevations.

Four different sets of slope schemes can be defined. To define the another slope scheme, select other Slope Group tab. The set of slopes that you are currently editing is indicated by the selected tab. If you define different sets of slopes, then the program will prompt you to pick which sides to apply each set of slopes to. All sides are assumed to be slope type one. So you only have to identify types two, three and/or four. If only one slope group is defined, then you will not be prompted to select any additional sides.

If a pit already exists to one side of the current pit, then this existing pit should be part of the Ground Surface grid file. Then the program will intersect the surface right away on this side without creating all the bench-cut slopes.

Here are a couple of examples of the various settings in Design Bench Pit.

- Offset Method:

Keyboard Command: minepit2

Design Spoil Pile

This command creates a spoil pile at a target volume or elevation. There are a few design methods. The Perimeter Polyline method takes a 3D polyline outline of the top of a spoil pile and adjusts this polyline by either changing the elevation or extending a side to reach a specified volume for the pile. The resulting pile is drawn as 3D polylines showing the side slopes and where the pile ties into the existing surface. The Cone methods take a single point and slope to build a spoil cone. The cone can be sized by either target volume or by height.

For the Perimeter Polyline method, you can choose between Extend Bench and Adjust Elevation. The extend bench option will prompt for a side of the pile to offset. Holding all the other sides with their elevations, the program will offset the selected side until the target volume is reached. For the adjust elevation, the entire pile polyline is moved up or down to obtain the target volume. Before starting this command in Perimeter Polyline mode, you need to draw a closed 3D polyline that represents the top of the pile. The fill slopes will start at this polyline and will run out and down until the slopes intersect the surface model.

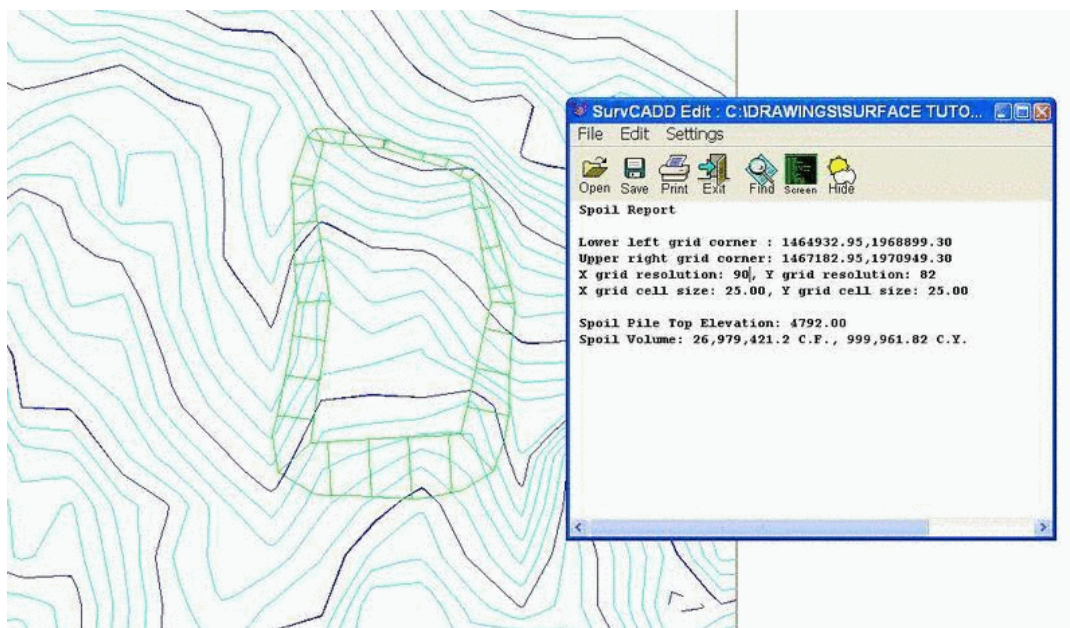

The Fill Slope can be specified in ratio, percent or degree format. The Pile Layer is for the 3D polylines that this command creates for the spoil. The Write Output Grid File option creates a .grid file of the spoil surface.

As the program runs, it will seem to draw several piles as it tries to find the target volume. The resulting volume will not match exactly the target volume but will be very close. The smaller the grid cell size, the closer it will be. This difference is just to save processing time.

Spoil Pile by Cone method

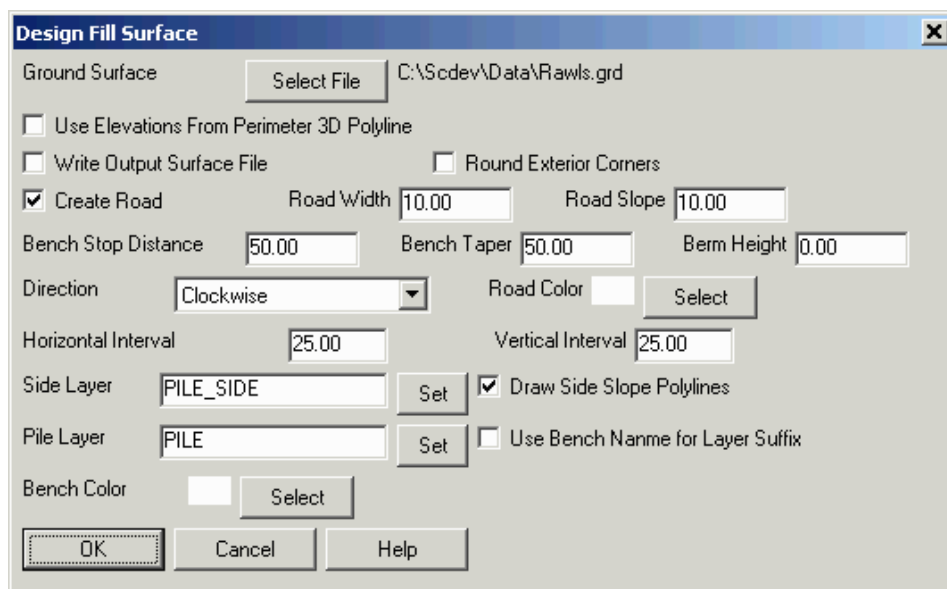

Pulldown Menu Location: Surface
Keyboard Command: spoil2

Design Fill Surface

This command creates fill pile where the sides are a series of slopes with benches. The side slopes start from a closed polyline. The perimeter polyline is the toe of the pile, and the slopes will be up and in from the footprint of the pile. Different slopes can be used for different sides of the fill. The fill is drawn as 3D polylines and the fill volumes are reported.

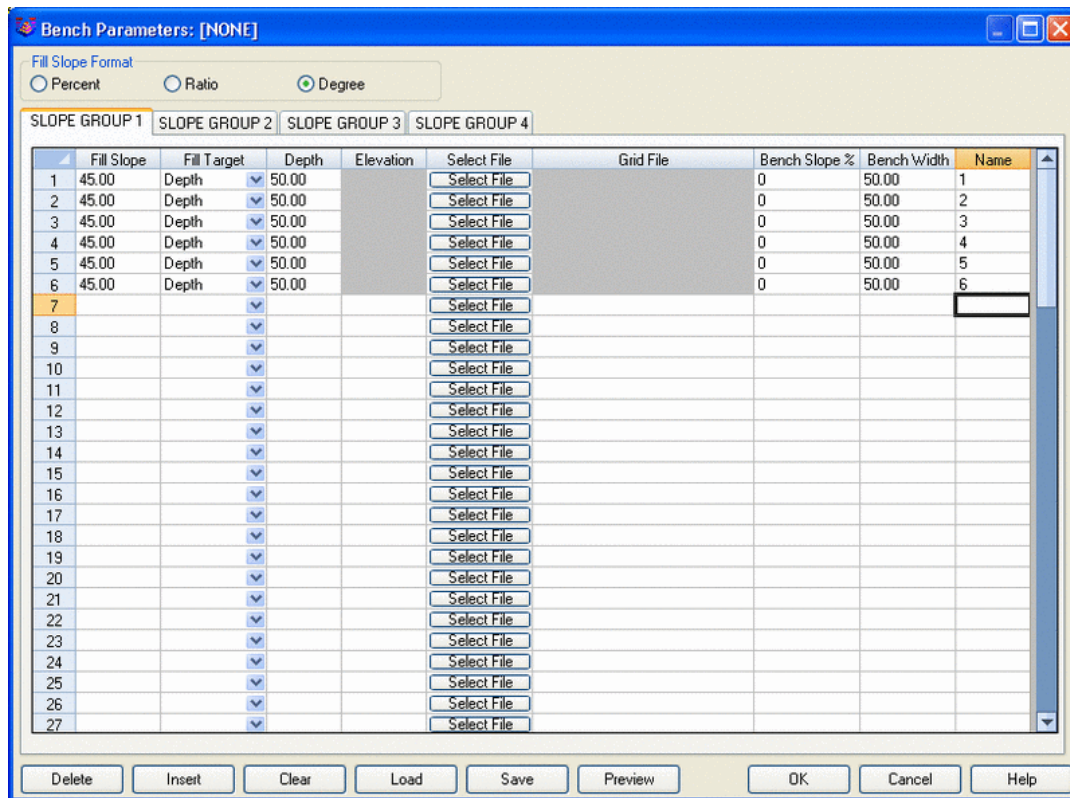

Before starting this command, the perimeter should be drawn as a closed polyline, 2D at zero elevation, or at 3D elevations draped onto a surface. You also need a grid file for the existing ground surface. Design Fill Surface starts

with the dialog shown below where you specify the grid file name.

- **Ground Surface:** This is the grid or triangulation surface to place the fill pile on.
- **Use Elevations From Perimeter 3D Polyline:** This will use the elevations on the polyline as the toe of the fill pile to start the design.
- **Write Output Grid File:** This option will create a grid file (GRD) of the fill. It includes the original ground surface grid file, with the fill pile built onto it.
- **Round Exterior Corners:** This option will create rounded corners on the outside edges of the pile for a more realistic design. When this is off, the corners are sharp and angular.
- **Create Road:** This option carves a rough road into the pile design. In the dialog, the road **Direction**, **Road Width** and **Road Slope %** are specified along with a **Road Color** for the road polylines to create. When this option is active, the program will prompt for a road starting point along the pile perimeter. The cut slopes are shifted to make room for the road. The **Bench Stop Distance** is for suspending the bench as it crosses the road to avoid combining the road and bench widths at the crossing which tends to shift the cut slopes too much. Within the Bench Stop Distance, the bench has a zero width. The Bench Stop is centered at the road crossing. The **Bench Taper** to the distance that the bench transitions from full width to zero at the Bench Stop. The **Berm Height** adds a berm and makes the road wider to fit the berm. The slope of the berm matches the cut slope.
- **Horizontal & Vertical Interval:** These settings control the distance to draw the 3D breakline polylines. The horizontal interval will run down the slope, and across the bench. The vertical interval will run parallel with the benches. It should be a factor of the bench height if possible, but not required.
- **Min Bench Height:** The bench is not created when the side slope depth is less than the specified amount.
- **Side Layer:** This is the layer of the 3D polylines drawn perpendicular to the benches, and running down slope.
- **Pile Layer:** This layer is applied to the 3D polyline break lines running parallel to the benches.
- **Draw Side Slope Polylines:** This option chooses whether to draw the 3D polylines running perpendicular to the benches, and down slope.
- **Use Bench Name for Layer Suffix:** This option adds the bench name to the Pile Layer so that each bench can have a unique name which can be useful for having different colors for each bench for visualization or for isolating benches by layer.

- **Bench Color:** This puts the bench 3D polylines in the Pile Layer on a different, specified color so they stand out against the slope breaklines.
- **Bench Taper At Surface Tie:** When a bench meets the Ground Surface, this option tapers the bench width to zero over this specified distance.

Fill Slope Format: The slope angle can be defined in percent, ratio or degrees. This is what is entered in the Fill Slope.

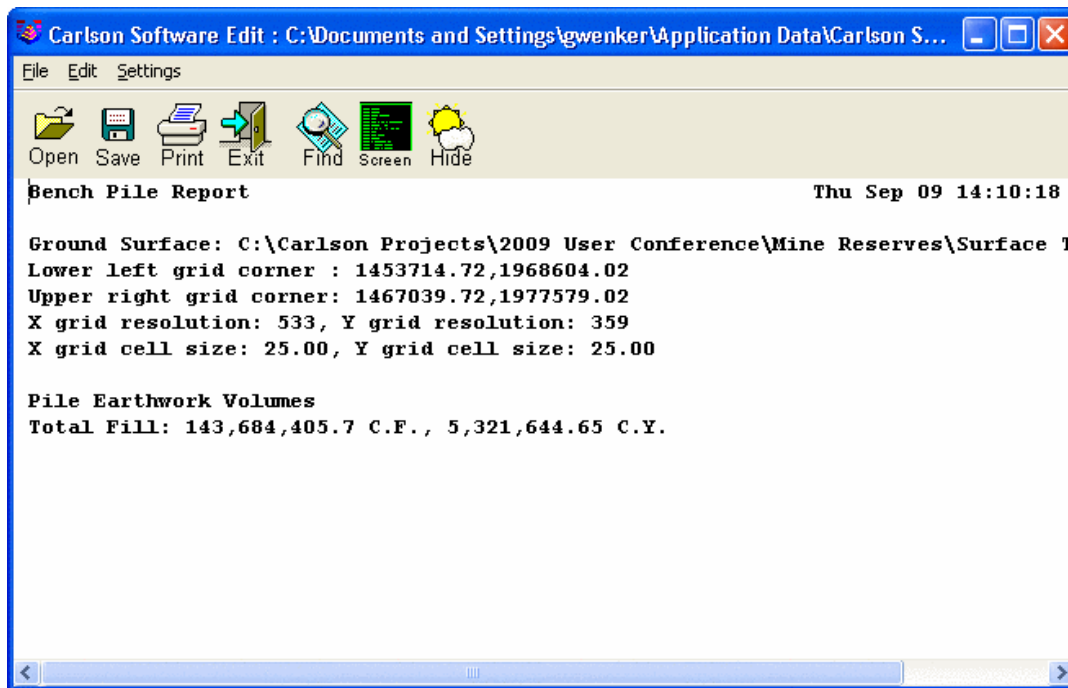

- **Slope Group:** Four different sets of slope schemes can be defined. To define the another slope scheme, select other Slope Group tab. The set of slopes are currently being edited is indicated by the selected tab. If different sets of slopes are defined, then the program will prompt to pick which sides to apply each set of slopes to. All sides are assumed to be slope type one. it is only necessary to select types two, three and/or four. If only one slope group is defined, then it will not prompt to select any additional sides.
- **Fill Slope:** The slope angle can be defined in percent, ratio or degrees. This is what is entered in the Fill Slope.
- **Fill Target:** The target to fill to for each bench can be a flat elevation, a depth above the previous surface or bench, or up to a grid file surface.
- **Depth:** The Depth must be filled in when the target is set to depth.
- **Elevation:** The Elevation must be filled in when the target is set to elevation.
- **Select File:** The file must be selected when the target is set to file.
- **Bench Slope %:** This setting will slope the benches down for drainage if desired. Normal setting for flat bench is 0.
- **Bench Width:** This is the horizontal width for the bench in feet or meters.
- **Bench Name:** This is used for pile design to name the benches for volumes. It does not have much application in the Fill version of this command.

- **Delete:** This deletes one line of data.
- **Insert:** This inserts a blank row to be filled in.
- **Clear:** This clears the entire slope group page, only the current group.
- **Load:** This loads a previously saved PIT file with the template saved.
- **Save:** This saves the template as shown in the window.
- **Preview:** This displays a preview of the current group to show how the cross section of the fill will look.

Design Ramp Profile

This command creates a profile as well as the centerline for a ramp between two benches. The program uses two triangulation or grid surfaces for the top and bottom of the profile. The program prompts for the starting point for the ramp which can be either on the top or bottom surfaces depending on the Slope Direction setting in the dialog. The dialog also has settings for the Ramp Slope and the Vertical Curve for the ramp profile to use at the top and bottom of the profile. Besides the starting point for the ramp, the program also prompts for a point to set the ramp direction. A centerline file is created from the starting point and going straight in the direction for the length needed for the profile.

Vertical Pit Quantities

This command calculates overburden and strata quantities. The strata thicknesses are defined in coal sections or drillholes. This routine requires a 3D closed polyline with elevations of the top of the seam. This polyline is also used as the perimeter of the pit. The routine calculates a surface model for the top of seam using this 3D polyline. Then a surface model for the ground surface is calculated from the selected surface entities such as points, lines or polylines with elevation (contour polylines). The overburden volume is calculated as the volume between these two surfaces within the 3D polyline. Each strata is modeled and the volume calculated for the area within the 3D polyline. It is important to note that the strip ratio reported in this command will use units of nonkey volume to key tonnage (yd^3/ton or m^3/tonne)

Update Grid File

This command recalculates the surface model in a .grd file by using additional point data along with the original point data. Only .grd files created by the Make Drillhole Grid File command, in StrataCalc, can be used by Update Grid File. Make Drillhole Grid file stores a point file of the original data used to calculate the grid in a file with the

same name as the grid file plus the extension .pnt. For example Make Drillhole Grid File will create strata.grd and strata.pnt.

The new point data for recalculation can be specified by picking points, entering point numbers that reference stored points in the current coordinate file, or selecting coal sections (from Place Coal Sections). When updating from coal sections, the program will prompt for a grid file that models the top of the coal sections. Since coal sections have thickness values but no Z values, this top of section grid is used to set the coal sections in the real Z axis. The program then updates the grid files that model each of the bottom elevation surfaces of the strata in the coal sections.

The updated grid can be saved in a new .grid file name or overwrite the original grid file by specifying the same file name. The location and resolution of the grid cannot be updated. So the original location and resolution should be made large enough to include any new area of point data to be added by Update Grid File.

Dragline Pits

This command calculates the total volume cut from a pit and the volume of a strata cut from the pit. The program requires two closed 3D polylines that represent the top and bottom of the pit. The top surface for volume calculations is modeled by the top polyline and any points in the bottom polyline that are outside the top polyline. Likewise the bottom surface is modeled by the bottom polyline and any points in the top polyline that are outside the bottom polyline. The top and bottom polylines are used as inclusion area polylines to limit volumes to within these polylines.

The program also processes two grid files that define the top and bottom of a strata. This volume is calculated between these two grids. This volume is the amount of strata cut from the pit. The inclusion area for the strata volume is the bottom pit polyline. The program assumes that the strata is entirely above the bottom of the pit and below the top of the pit.

This example shows a pit that is advancing from left to right. The left side of this pit was the edge of the previous pit.

Regrade Backfill

This command applies to narrow valleys such as in Appalachia where the goal is to regrade an existing valley fill with benches and specific slopes. Before starting this command you must create grid files (.grd) that represent the existing surface without any fill and the surface with the existing backfill. These grid files can be created with the Make 3D Grid File routine of the Civil Design module.

Regrade Backfill also requires a pre-drawn alignment polyline which defines the shape of the face of the regrade. This polyline must be drawn below the existing backfill and it must be at least long enough to reach across the widest part of the regrade.

To run the routine, specify the two grid files, the alignment polyline, the direction up the valley, the slopes, and the bench dimensions. The program then draws in the regrade as 3D polylines and calculates the cut and fill. To balance the cut and fill, choose the *Adjust parameters and redesign* option.

Prompts

Select Existing Surface Grid File

Select Backfill Grid File

Pick existing backfill perimeter polyline: *pick a closed polyline that represents the limits of the backfill disturbed area*

Pick the regrade alignment polyline: *pick a polyline*

Bench width: 15.00

Bench slope percent: 2.00 slope ratio: 50.00:1

Top slope percent: 2.00 slope ratio: 50.00:1

Total fill: 13105.1 C.Y., 353840.0 C.F.

Total cut: 13288.2 C.Y., 358782.9 C.F.

Existing backfill and existing contours

3D view of regrade backfill. Also showing existing contours.

Pulldown Menu Location: Surface

Keyboard Command: backfill

Prerequisite: Grid files of the existing surface and existing backfill and an alignment polyline.

Blast Pattern Layout

This command creates a pattern of points in rows and columns using surface and shot bottom grids and dip direction. The options for this command are set in the dialog. Grid or triangulation files for the ground surface and drill bottom are required. The Number By Row/Column option will number the holes by the hole row and column. Otherwise the holes are simply numbered sequentially. Up to four descriptions can be assigned to the holes such as pattern name, driller name, etc. The row and column distances can be specified separately. The drilling angle can be set in the Vertical Dip field which is entered as an angle where 0 degrees is straight down and 90 degrees is horizontal. The Dip Direction defines the horizontal orientation of the vertical dip. The row and column directions are entered as bearing angles. You need to figure these angles before running Blast Pattern Layout by using routines such as Inverse or Bearing & 3D Distance. The format is in dd.mmss where the degrees.minutes.seconds are separated by a decimal.

This command can generate a report using the report formatter that lets you choose the fields for the report and the fields layout. The report formatter can also output to Excel and Access. The points can be also be stored to the current coordinate file (.crd). The Preview button shows a preview of the pattern in the drawing so that if something isn't right, it can be adjusted before choosing OK. If the Create Points is turned on, then the points will be drawn in the blast perimeter. Use the Create Lines option to draw 3D lines for each blast hole on the specified layer.

Interval Along Entity

This command is described in the Survey section of the manual. Please refer to it there.

Blast Point Report

This command projects points either from the blast bottom up to the surface at a dip direction or from the surface down to the blast bottom. These points are then reported using the report formatter that lets you customize the fields to report and the layout. Before running this command, you need the ground surface grid file, the blast bottom grid file and points drawn on the screen. While the Blast Pattern Layout routine also can generate a report, this routine is more flexible because it uses all selected points from the screen and is not limited to only pattern points. For example, you could use Blast Pattern Layout to create a grid of points. Then use Interval Along Entity to create points along a polyline that represents the setback line for the first row of holes. You could also use any of the other Carlson point routines to add or remove points. Then once all the points are placed, you can run Blast Point Report.

Prerequisite: Ground and bottom grids; points in drawing

Cast Blast Report

This command uses before and after grid files to report blast volumes, swell and cast to final. Before running this command, you need four grid files and an inclusion perimeter. The inclusion perimeter is a closed polyline that follows the back of the cut area and the toe of the previous spoil pile. The first grid file is the original ground surface before the blast. The second grid file is the ground surface after the blast. The third grid file represents the bottom of the pit (design, or bottom of ore). For example, if you are blasting down to the top of ore, this grid should be the top of ore surface. The fourth grid defines the final pit surface including the final cut and spoil pile. This final grid can be created with the Make 3D Grid File command using 3D polylines for the toe of the highwall, toe of the spoil pile and top of the spoil pile.

The program calculates the volume between the original ground grid and the pit bottom grid within the inclusion

perimeter. This volume is reported as the Original Volume. The After Blast Volume is the volume between the final ground grid and the pit bottom grid. The difference between the After Blast Volume and Original Volume is reported as the Swell Factor. The After Blast volume that is below the final pit surface is the Cast to Final volume.

Cast Blast Report:

```
Original Surface: C:\scad\DATA\ex.gnd.grd
Final Surface   : C:\scadv\DATA\final.grd
Pit Bottom      : C:\scad\DATA\coal.grd
Final Spoil     : C:\scad\DATA\spoil.grd
Lower left grid corner : 509141.84,595450.20
Upper right grid corner: 511087.39,596727.09
X grid resolution: 100, Y grid resolution: 100
X grid cell size: 19.46, Y grid cell size: 12.77
```

```
Original Volume: 1602319.50 C.F., 59345.17 C.Y.
After Blast Volume: 2066992.20 C.F., 76555.27 C.Y.
Blast Swell Factor: 1.29
Cast to Final Volume: 144689.22 C.F., 5358.86 C.Y.
Cast to Final: 9.03%
```

Prerequisite: Original, final, pit and spoil grid files. Inclusion perimeter polyline.

Output To Reame

Output to Reame creates a file with a .dat extension that is readable by the REAME2004 stability analysis program for cylindrical failure. The REAME program was developed by Dr. Huang of the University of Kentucky and is widely used in coal mine permitting in the state of Kentucky. The linkage has been tested and verified with the REAME2004.

The program is typically used after a final surface profile is laid graphically over an existing ground profile. You then graphically select the profiles to create the REAME input file. The routine not only creates the input file but provides options to draw the failure study region and key coordinates on the actual profile drawing. The only significant condition to be aware of is that the profiles should rise upwards from left to right in the direction of increasing station.

To run the Reame program after Output to Reame, it is best to copy the .dat file just made into the directory containing REAME.EXE. Then run REAMEINP to revise the .dat file (to change aspect like cohesion, friction angle and unit weight) or REAME to run the stability analysis. It will ask: FILE NAME -? Enter the name with the .dat extension included. The enter 1 to input from file. The analysis is then completed and stored in a file REAME.TXT.

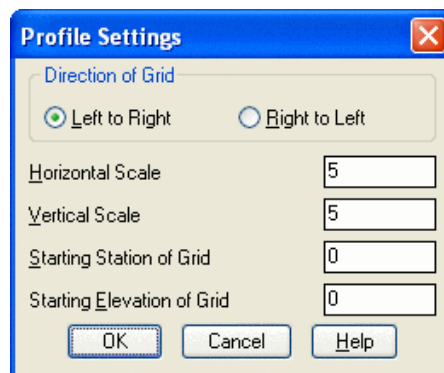

NOTE: The REAME program has been renamed to LEAME (Limit Equilibrium Analysis of Multilayered Earthworks). This software is distributed as an instructional tool by ASCE Press (<https://ascelibrary.org/doi/book/10.1061/9780784477991>). A companion slope stability analysis book is also available (<https://ascelibrary.org/doi/book/10.1061/9780784412886>).

Prompts

Title of Stability Report: *Valley Fill No. 1 (Reame expects this title line, so enter something!)*

[end on] Pick Points for Coord. Label (enter to continue):

[none] Pick Starting Point for Text:

[end on] Pick Points for Coord. Label (enter to continue):

[none] Pick Starting Point for Text:

[end on] Pick Points for Coord. Label (enter to continue):

Number of divisions along face of slope <4>:

Number of divisions perpendicular to slope <8>:

This would lead to 32 radius points from which to test cylindrical failure.

Pulldown Menu Location: Surface > Slope Stability

Keyboard Command: reame

Prerequisite: Surface profiles or polylines

Draw Reame File

The function allows the user to import their existing Reame file and draw it in the drawing. It prompts to select the RME file created in Reame.

Pulldown Menu Location: Surface > Slope Stability

Keyboard Command: reameplt

Prerequisite: Stability Reame file

Output to SB-Slope

The widely accepted and computationally powerful stability analysis package, SB-Slope has very limited functions for data and geometry modification. The procedure outputs the data files in the SB-Slope data format, thus providing powerful interface for geometry editing. The meaning of all data parameters remains the same as in conventional SB-Slope.

The user is prompted with a single dialog defining the majority of necessary parameters, followed by prompts for soil and water polylines, soil properties and finally the parameters of applied loads if any. For each soil type, the program prompts first to pick polylines which denote upper boundary of the soil (multiple polylines may be selected), and then to pick polylines which represent boundary of the soil and are phreatic lines.

Polylines from the second set may appear in the first set as well.

After all soil polylines, the free-water surface is entered if any and then user is prompted for the soil mechanical properties. At last, distributed loads are entered by picking a horizontal line, representing the load support area, and input of the load value.

Pulldown Menu Location: Surface > Slope Stability

Keyboard Command: sbslope

Draw SB-Slope File

The function allows user to import his existing SB-Slope file into the drawing. Segments of the neighbor lines corresponding to the same soil are joined to simplify creation of new SB-Slope data file from the drawing. The following color scheme is used to mark elements of the layout:

blue = free water surface

green = phreatic surface

red = places of load application

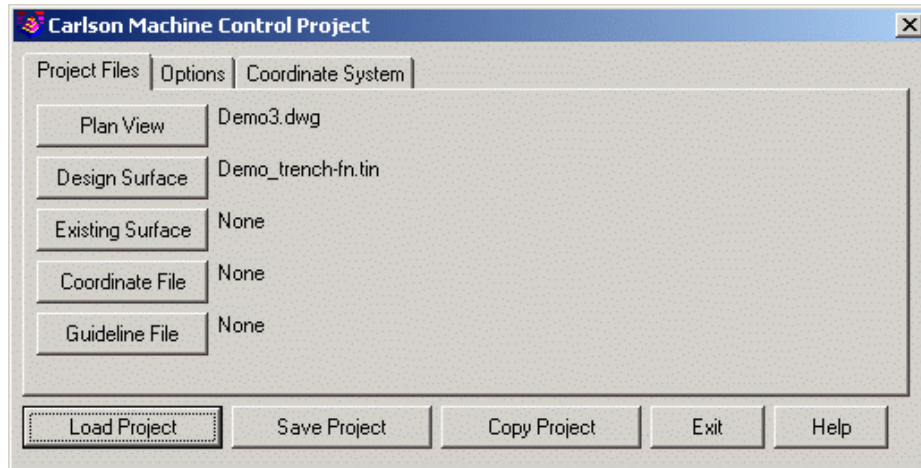

Pulldown Menu Location: Surface > Slope Stability

Keyboard Command: rsbslope

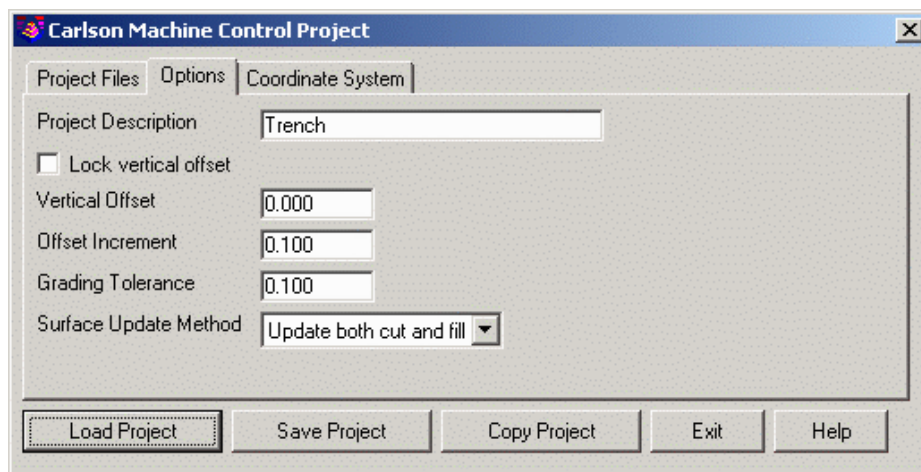

Carlson Grade Project

This command creates a project file (.PRJ) to use for Carlson Machine Control programs including Carlson Grade. The project file is a text file that contains the names of the data files for the project (ie. the Design Surface) and the project options (ie. Units). The Load Project and Save Project functions read and write the .PRJ file. The Copy Project function both saves the .PRJ file and copies the data files into the DESIGN and ACTUAL sub-folders. So after setting up the project in the dialog, the Copy Project button is a handy way to send the data to Carlson Grade by copying the .PRJ and related data files onto a USB drive to take to the field or to a folder for Fleet Manager Office to use.

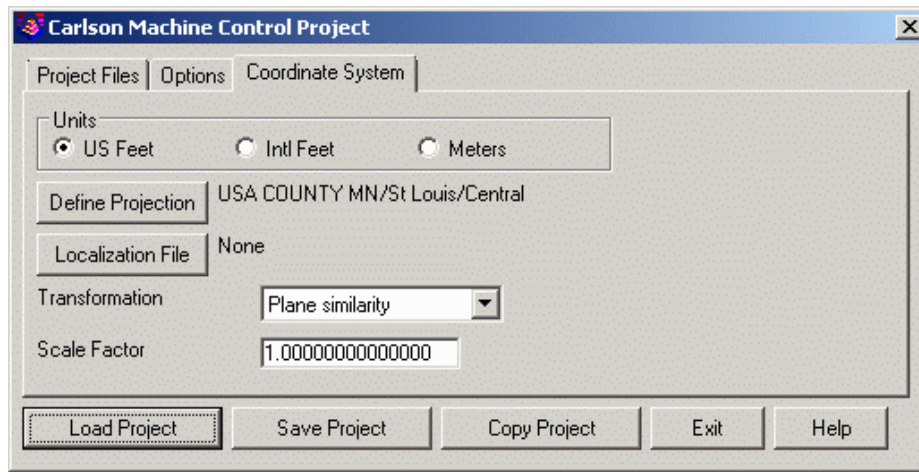

On the Project Files tab, the Plan View for the map view can be a DWG, DXF or PLN file. The PLN file is created by the File > Polyline File > Write Polyline File command. The Design Surface is the target grading surface and can be a triangulation or grid file (TIN or GRD). The other files are optional and are explained in the Carlson Grade manual.

The settings on the Options tab are specific to Carlson Grade and described in the Carlson Grade manual.

On the Coordinate System tab, define the units and projection for the project. In Define Projection, you can use a CSL file from SurvCE or the projection from the Settings > Drawing Setup command. The Localization File takes either .DAT or .LOC file formats. The Drawing Setup command can create a localization file. Or you can use a localization created by SurvCE or Carlson Grade.

Pulldown Menu Location: Surface > Carlson Machine Control in Surface Mining and Construction modules

Keyboard Command: grade_project

Prerequisite: Surface file

3D Grade Simulation

This command selects a project file (.PRJ) and loads the associated design surface into the 3D simulation. This simulation is a way to verify the surface. You can choose a Vehicle Icon, set the Speed and pick Run to drive over the surface. See the Surface 3D Flyover topic in the manual for descriptions on the controls in this viewer.

The program looks for the design surface in the DESIGN sub-folder from the PRJ file location. The Copy Project function in the Carlson Grade Project command is a way to prepare the PRJ file with the surface in the DESIGN folder.

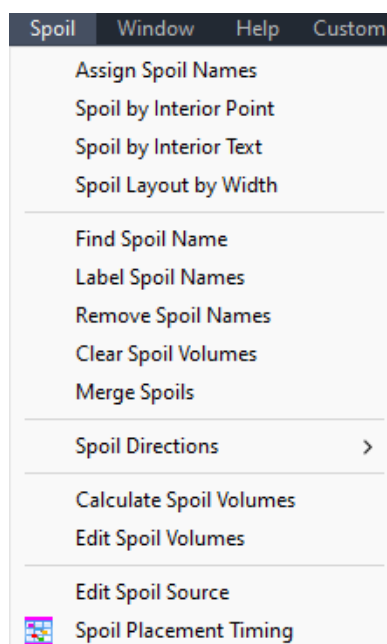

Pulldown Menu Location: Surface > Carlson Machine Control in Surface Mining and Construction modules

Keyboard Command: grade.flyby

Prerequisite: PRJ file

Spoil Menu

The Spoil menu commands are for spoil placement.

Assign Spoil Names

This command attaches a spoil name and site name to closed polylines that are used as inclusion perimeters in the spoil routines like Calculate Spoil Volume and Spoil Placement Timing. This will create them one at a time, and is recommended if there are just a few to name. Other commands will create more advanced layouts of spoil perimeters for designs that require more perimeters.

Prompts

Label area names [**<Yes>/No**]? Choose whether or not to label.

Text height **<2.78>**: *press Enter to accept 2.78 drawing units (ft or m tall) or enter a new text height*

Auto place labels in center [**<Yes>/No**]? *press Enter to accept to manually pick the label position, answer No to this prompt.*

Select Inclusion perimeter polylines.

Select objects: *pick closed polylines for areas to include in calculations*

Site name **<Site 1>**: *press Enter to accept Site 1, or type a new site name*

Pit name **<Pile 1>**: *press Enter to accept Pile 1, or type a new pit name*

Specify another area [**<Yes>/No**]? *press Enter to accept Yes or type N for no* If you do specify another area, then the Site Name remains the same, but the Pile Name is automatically incremented by one for efficient naming.

Keyboard Command: spoilname

Prerequisite: Closed polyline

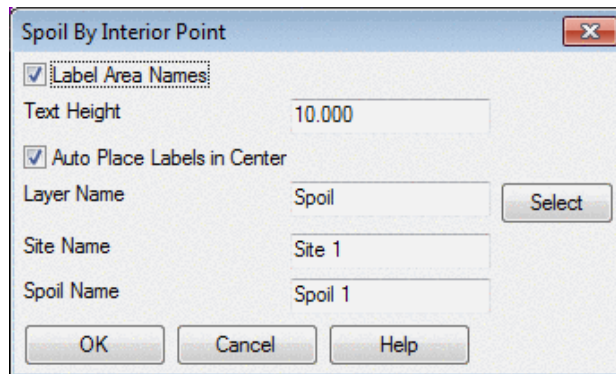

Pulldown Menu Location: Spoil in Surface Mine Module

Spoil by Interior Point

This routine is used to create spoil polylines from the existing linework by making closed polylines around points picked. The site and spoil names are user-specified and the spoil name is incremented after each new pile perimeter

is created. This command uses the Boundary Polyline logic, using any linework (open or closed) and searches out from the picked point for the closed perimeter. It draws a new polyline in the specified layer.

- **Label Area Names:** Choose whether to label the pile perimeters or not
- **Text Height:** Set the text height in feet or meters based on the drawing setup
- **AutoPlace Labels in Center:** Yes to put the text insertion point on the centroid of the perimeter
- **Layer Name:** Select or enter the layer name to draw the perimeter and text
- **Site Name:** Specify a site name to give to all the new pile perimeters
- **Spoil Name:** Specify a name to give the first pile perimeter. Subsequent piles will increment the name by one automatically.

Prompts

Pick point inside pile perimeter: *pick inside a loop or linework representing the pile for the spoil polyline*

Specify another area (<Yes>/No)? If yes is selected, then the Pile Name is automatically incremented by one for efficient entry, such as Spoil 2. **Site name <Site 1>:**

Pit name <Spoil 2>:

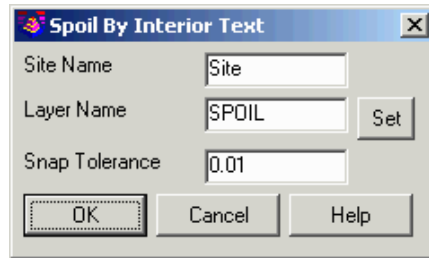

Pulldown Menu Location: Spoil in Surface Mine Module

Keyboard Command: pickspoil

Spoil By Interior Text

This command creates closed polylines assigned spoil names using selected interior text and surrounding linework. The text is used as the spoil name. For each text, the program finds the bounding linework to create the closed polyline for the spoil area.

In the options dialog, set the Site Name to assign the spoil polylines and set the Layer Name for the polylines. The Snap Tolerance is the amount of gap in the linework to close automatically.

Prompts

Spoil dialog

Select spoil lines, polylines and text.

Select objects: *pick linework and labels*

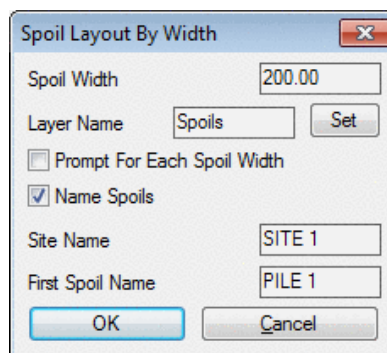

Pulldown Menu Location: Spoil

Keyboard Command: txtspoil

Prerequisite: linework and spoil labels

Spoil Layout by Width

This command creates closed polylines that represent spoil placement inclusion areas for the spoil timing routines. The spoil polylines are created by advancing a baseline polyline by a fixed pile width. The sides and end of the pit polylines are defined by the disturbance boundary polyline. This polyline should be open at the end of the baseline polyline. Be sure to create the baseline polyline longer than the overall boundary so that the program can always find the intersection of the advancing baseline with the boundary. There is an option to automatically assign pile and site names to the polylines. The name of the first pile is set in the dialog shown below. The next spoils will be named by incrementing the spoil name by one. There is an option to prompt for each spoil perimeter width or use the same width for all the piles.

Prompts

Spoil Layout By Width dialog Set the spoil width, layer and names

Select baseline polyline: *pick the polyline*

Select spoil boundary polyline: *pick the polyline*

Calculating spoils ...

Created 7 spoils.

Pulldown Menu Location: Spoil

Keyboard Command: spoilsz

Prerequisite: One open polyline boundary and one baseline polyline extending across the boundaries open end.

Find Spoil Name

This command will find a certain named spoil polyline on screen. It will zoom to the pile extents and center it. The spoil line is also dashed or highlighted to distinguish it from surrounding polylines.

Prompts

Spoil name to find: **pile 4**

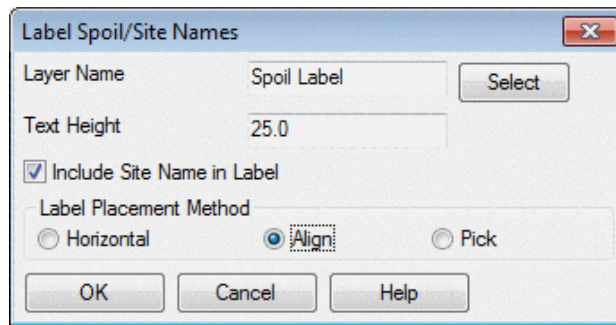

Site name to find <*>:

Pulldown Menu Location: Boundary

Keyboard Command: find_spoil

Label Spoil Names

This command labels the spoil name and site name that are attached to the selected polyline. Options for layer and text height are provided. The Horizontal and Align placement methods will draw the labels in the center of the polyline. The difference is that the horizontal option will draw the label horizontal to the current twist and the Align method will rotate the label to follow the main direction of the spoil line. The Pick method prompts you for a center point to pick and an alignment for the text.

Prompt

Label Spoil/Site Names Dialog

Pulldown Menu Location: Spoil

Keyboard Command: spoillabel

Remove Spoil Names

This command removes the extended entity data of spoil/site names from the selected polylines. For example if you are done calculating for an area, or you just want to clear and rename them, you can use this command to clear the spoil names from the polylines in the old area so that these polylines are not picked up as spoil perimeters anymore by routines for timing the spoil.

Prompts

Select polylines to remove spoil names from.

Select objects: *pick the polylines*

Removed pit names from XX polylines.

Pulldown Menu Location: Spoil
Keyboard Command: clearspoilnm

Clear Spoil Volumes

This command removes all quantity values and grid paths from the selected spoil polylines. There is the option to clear all benches at once, or if Specific is selected, then it will prompt to enter a bench number to clear.

Prompts

Clear all bench quantities or a specific bench [All/<Specific>]? A

Select spoil polylines to clear.

Select objects: Specify opposite corner: 5 found, 5 total

Cleared 10 bench quantities.

Pulldown Menu Location: Spoil

Keyboard Command: clearspoilvol

Merge Spoils

This routine takes two adjacent spoil perimeters and merges them to create just one. Routines such as Spoil Layout by Width can sometimes leave small irregular shaped pits along complex boundaries. It is common to combine or add a small sliver of a spoil perimeter with an adjacent one so that the volume is added to that one. Pick first in the larger spoil that is to be kept, then in the smaller spoil that is to be removed. A new polyline is drawn around both, representing the new spoil with the same name as the first, larger spoil picked inside of. The last step is to simply erase the text of the smaller, deleted spoil (if they were labeled). If a spoil is selected on or near a common line, then the spoil is highlighted it prompts to hit Enter to accept the spoil or press N to highlight the other nearby spoil. The volumes are combined if they are already stored in the spoils as values.

The images below show the before and after of the Merge Spoils command.

Prompts

Pick inside 1st spoil polyline to merge: pick inside perimeter to keep

Pick inside 2nd spoil polyline to merge: pick inside perimeter to remove, and merge with previous

Created a shrink-wrap polyline successfully.

Done.

If the pick is near a common spoil line, then the following prompts appear:

Pick inside 1st spoil polyline to merge (Enter to end):

Press N for next selection or Enter to accept current:

Pick inside 2nd spoil polyline to merge:

Press N for next selection or Enter to accept current:

Created a shrink-wrap polyline successfully.

Done.

Pulldown Menu Location: Spoil

Keyboard Command: mergespoil

Prerequisite: Two adjacent Carlson named spoil perimeters to be combined into one larger spoil perimeter.

Assign Directions

In order to schedule the spoil polylines (which are closed polylines), they must have directions assigned. The Assign Directions command places the direction of spoil placement into the spoil polyline itself, where it is permanently stored along with other aspects of the drawing. Directions can vary by bench. The command prompts to assign the same direction to the Whole spoil polyline, or by bench. If doing by bench, the routine must be run separately for each bench.

Assign Directions is found within the Spoil menu in the Carlson Surface Mining. There are six methods employed to assign direction: Automatic, Text, Sequence, Polyline, Bearing and Azimuth. The "automatic" method will move "longways" across the pile, following the longest axis detected, but may not choose the preferred direction along that axis. The text method finds the side closest to the insertion point of the pile name and will mine from that side perpendicular across the pile away from the text. The sequence method will mine left to right and/or right to left across a series of piles as specified by the user, the polyline method will follow a "direction polyline" across a pile or series of piles and the Bearing or Azimuth method will mine at defined bearing or azimuth angle. Below is the prompting and results obtained with each method:

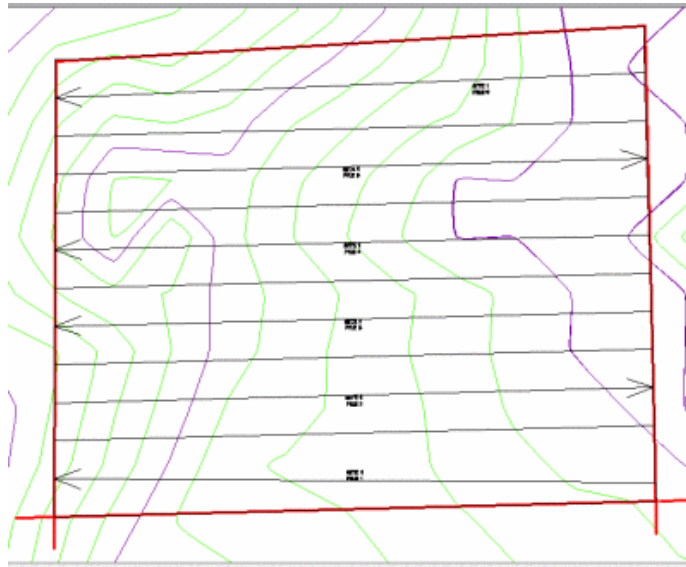

Prompts

Assign direction using which method [`<Auto>/Text/Sequence/Polyline/Bearing/AZimuth`]: *A or press Enter*

Select pile polylines to have direction assigned to:

Select objects: *Pick the piles and the direction is assigned as shown below*

In this example, it uses the long axis of the pile, and alternates back and forth for direction. It is a quick way to get directions assigned. A pile direction can be easily reversed using the *Reverse Directions* command.

Next are the prompts for the Text option.

Assign direction using which method [`<Auto>/Text/Sequence/Polyline/Bearing/AZimuth`]: *T*

Select pile polylines to have direction assigned to:

Select objects: *pick the piles and the required pile text as shown below*

The highlighted pile has the direction information assigned already.

Would you like to overwrite this (`<No>`, Yes, None, All): *A for All.* This prompt only occurs when piles are chosen that already have pile direction. Note that the command "Clear Directions" could be used to remove directions prior to using Assign Directions.

The arrows show the resulting directions. Note that this routine looks for the pile name for the direction, not for the "site" name. (All piles have a two-tiered naming convention: site and pile, which can be re-worked as pile and block or any other two-level form, to adapt to company practices.)

Next is the Sequence option.

Assign direction using which method [`<Auto>/Text/Sequence/Polyline/Bearing/AZimuth`]: *S*

Select pile polylines to have direction assigned to:

Select objects: *select the piles (Don't worry if you also select other polylines. It only finds piles.)*

Select a direction polyline.

Select objects: *select a polyline that crosses all of the piles*

Assign direction in which sequence (`<LL>`, LR, RL, RR): *LR*

In our example, we selected LR, which causes the piles to be filled left to right on the first pile (with respect to the south-to-north direction polyline—imagine yourself standing at the beginning of the polyline looking down it. LL would fill all piles coming from your left. LR would fill from the Left first, then the Right in the next one and so forth. RR and RL are just the opposite.), then right to left on the second pile, then left to right on the third, etc. An entry of LL would cause the piles to be filled from the left side to the right side. An entry of RR, for example, would fill all the piles from right to left. The entry of RL would fill first right to left, then left to right. The sequence method is ideal for assigning direction to a series of long and narrow piles that have not been broken up into small blocks.

If these same piles were each subdivided into 10 or more blocks, or there are many piles that would not be intersected by the sequence polyline, for example, then the following method, direction by polyline, is most appropriate.

Next is the Polyline option.

Assign direction using which method [\langle Auto \rangle /Text/Sequence/Polyline/Bearing/AZimuth]: P

Select pile polylines to have direction assigned to:

Select objects: *select the piles*

Select all direction polylines.

Select objects: *In the example above, select the single direction polyline.*

The polyline-based selection is ideal for piles that follow sinuous property lines. Direction polylines cannot have arcs, so if you've used an arc to draw the polyline, use the command *Remove Polyline Arcs* on the Edit menu to remove them.

Lastly, are the Bearing and Azimuth option

Bearing Option:

Assign direction to whole pile or to a specific bench [\langle Whole \rangle /Bench]: W or Enter to assign direction to whole pile

Assign direction using which method [\langle Auto \rangle /Text/Sequence/Polyline/Bearing/AZimuth]: B for Bearing

Select pile polylines to have direction assigned to:

Select objects: *select the piles*

Enter Bearing (Qdd.mmss): 145.0000

The highlighted pile has the direction information assigned already.

Would you like to overwrite this [\langle No \rangle /Yes/None/All]: A for all

The Bearing is entered in the format (Qdd.mmss), the following figure shows the quarter numbers and the angle is calculated clockwise.

Azimuth Option:

Assign direction to whole pile or to a specific bench [\langle Whole \rangle / \langle Bench \rangle]: W or Enter to assign direction to whole pile

Assign direction using which method [\langle Auto \rangle / \langle Text \rangle / \langle Sequence \rangle / \langle Polyline \rangle / \langle Bearing \rangle / \langle AZimuth \rangle]: B for Bearing

Select pile polylines to have direction assigned to:

Select objects: *select the piles*

Enter Azimuth (ddd.mmss): 135.0000

The highlighted pile has the direction information assigned already.

Would you like to overwrite this [\langle No \rangle / \langle Yes \rangle / \langle None \rangle / \langle All \rangle]: A

The Azimuth angle is calculated from the true north as 0, rotating clockwise.

Pulldown Menu Location: Spoil

Keyboard Command: spoil_assign_dir

Related Commands: Display Directions, Reverse Directions, Clear Directions, Create pile Plines from Mineplan

Display Directions

If directions have been assigned to spoil polylines, this command will display the directions. It therefore serves two purposes: (1) to verify that directions have, in fact, been assigned previously, and (2) to review the direction of filling spoils. When pile directions are detected, arrows are displayed as shown below. These direction arrows will disappear with any "Zoom" command such as Pan or Window, and will also disappear if a Redraw or Regen is executed. The direction leaders can be used to draw direction arrow entities in the drawing, with the leader arrow size a prompt option.

Prompts

Display direction to whole pile or to a specific bench [<Whole>/Bench]: *W*

Draw directions as leaders or temporary arrows [Leaders/<Arrows>]?: *L for Leaders or A for Arrows*

Select pile polylines to have direction displayed:

Select objects: *Pick the polylines to display*

Pulldown Menu Location: Spoil

Keyboard Command: `spoil_display_dir`

Related Commands: Assign Directions, Reverse Directions, Clear Directions

Reverse Directions

This command reverses the direction of advance within a spoil polyline. It is particularly useful in conjunction with the command Assign Directions, <Auto>, since the automatic mode may assign direction to many of the piles opposite from the desired direction. The result redraws the arrows in the new direction. If Leader arrows were drawn, then they are erased and redrawn in the updated direction.

Prompts

Reverse direction to whole pile or to a specific bench [<Whole>/Bench]:

Select pile polylines to have direction reversed:

Select objects:

Pulldown Menu Location: Spoil

Keyboard Command: `spoil_reverse_dir`

Related Commands: Assign Directions, Display Directions, Clear Directions

Clear Directions

This command removes the directions from piles. The Extended Entity Data (EED) designating pile direction is removed from the pile polyline entity. This command has no effect if direction has not been previously assigned to a spoil polyline. Keep in mind that it is not necessary to first remove "old" directions before assigning "new" directions. The Assign Direction command will recognize that directions exist and will prompt the user to overwrite the direction for individual piles or for all piles.

Prompts

Clear direction to whole pile or to a specific bench [<Whole>/Bench]:

Select pile polylines to have direction removed:

Select objects: *pick the pile polylines* This can be done individually or with a window.

Pulldown Menu Location: Spoil

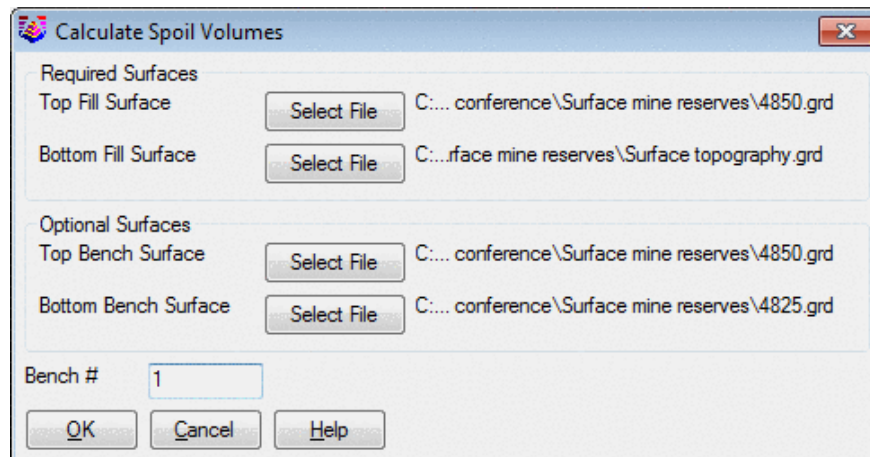

Keyboard Command: spoil_clear_dir

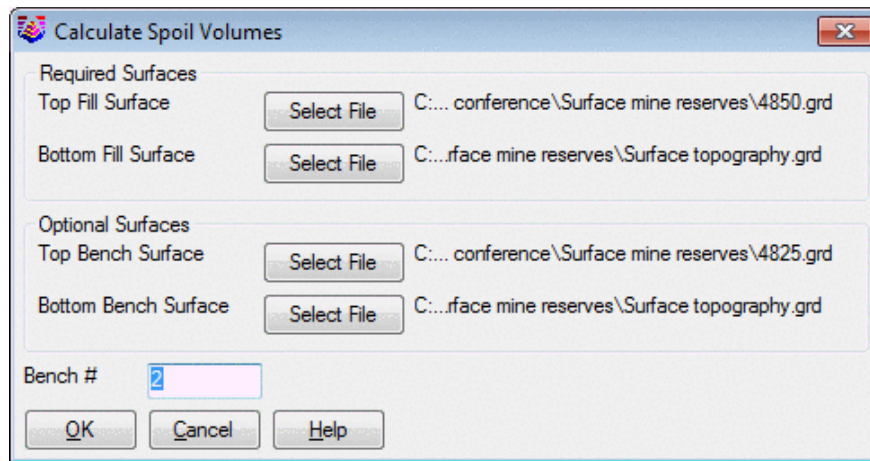

Related Commands: Assign Directions, Display Directions

Calculate Spoil Volumes

This command calculates the volume of the spoil based on the selected grid surfaces. There are options to select the Top Fill Surface, Bottom Fill Surface and two optional top and bottom of bench grids. This command needs to be run separately for each bench to calculate the volumes for each one. The volumes are automatically stored in the spoil polylines, ready for the timing process. They can be verified and edited with the command Edit Spoil Volumes.

The following example shows how to store volumes for two benches. The required surfaces are set by picking the top of the pile elevation of 4850, and the bottom of the pile, stacked onto the original Surface Topography grid. Bench 1 will be from the top of pile, also 4850, down to 4825 elevation grid. Bench 2 will then be from 4825 elevation to the bottom surface, the Surface Topography grid.

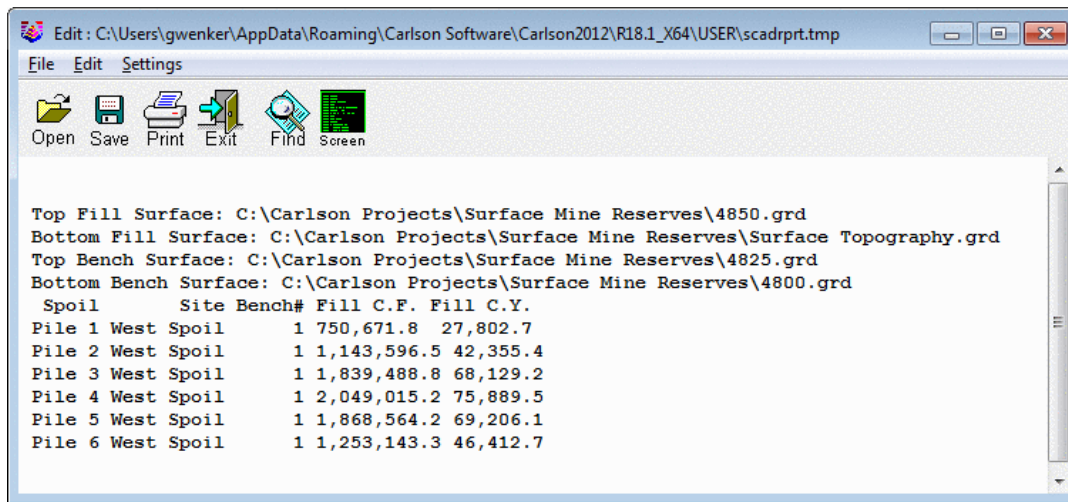

The Report Formatter window displays the available attributes to report, such as Spoil, Site Name, Bench#, Fill in CF, CY or CM if metric.

The report can be viewed with the Display button, or taken into Excel with the export to Excel option.

Edit Spoil Volumes

This command displays the spoil destination results in a spreadsheet editor. The Site Name, Pile Name, Bench, Volume and Centroid are in individual columns. This is an editor where the data can be reviewed to see what the volumes are. Any changes made here can be used for the spoil timing and reporting.

Edit Spoil Source

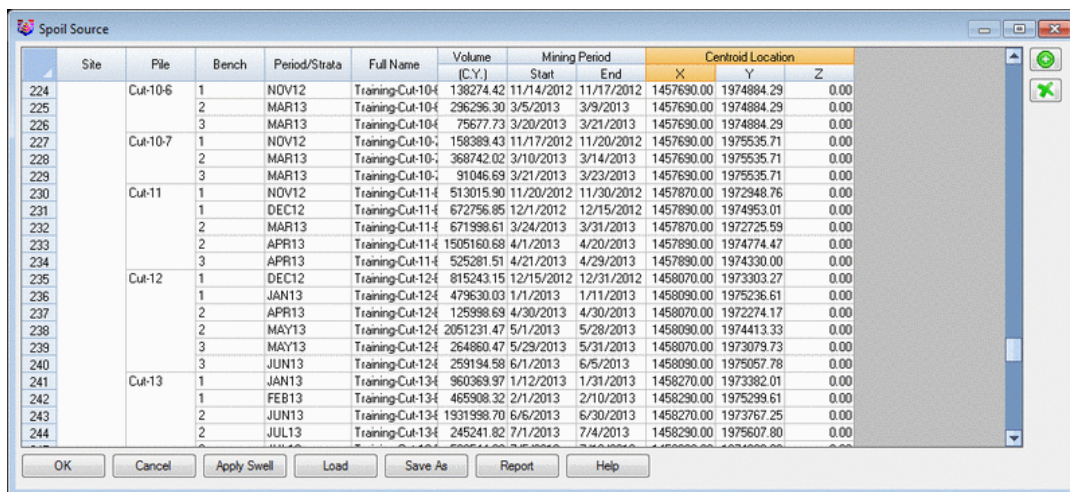

This command brings up a table of the Spoil Source that is required for the Spoil Timing commands. This displays where the material to be placed in the spoil polylines will come from. It shows the Site and Pit names to be mined. It also shows the Bench number, period or strata for each bench, full name and volume. If the SPO was created with the Surface Equipment Timing commands, then the Period will be used instead of the Strata Names, and the Mining Period Start and End dates will be correctly assigned. Otherwise, from Surface Mine Reserves, just the Strata Names and their volumes will apply.

This image shows the source of the spoil material calculated with Surface Mine Reserves.

The Apply Swell will swell the calculated volume stored in the SPO file. If it isn't swelled, then it will use the in-place, bank volume. The value is a percentage greater than 1.0. For example, 1.2 is a 20% swell of the spoiled material. Once OK is selected, the volumes should change on screen to a larger, swelled volume.

The Report button will bring up the Report Formatter where the requested fields will be reported in the text window, or exported to Excel. Shown here is an example text report.

Keyboard Command: edit_spo

Prerequisite: SPO file from Surface Mine Reserves or Surface Equipment Timing.

Pulldown Menu Location: Spoil in Surface Mine Module

Spoil Placement Timing

This command brings all the spoil commands together as a final step and performs the timing and scheduling of the spoil placement. The first screen will allow you to choose two options for timing; either 'Use Spoil Source Dates' or 'Use Fleet for Timing' (shown below). These two options will produce very different results, and should be selected depending on the needs of spoil removal and placement.

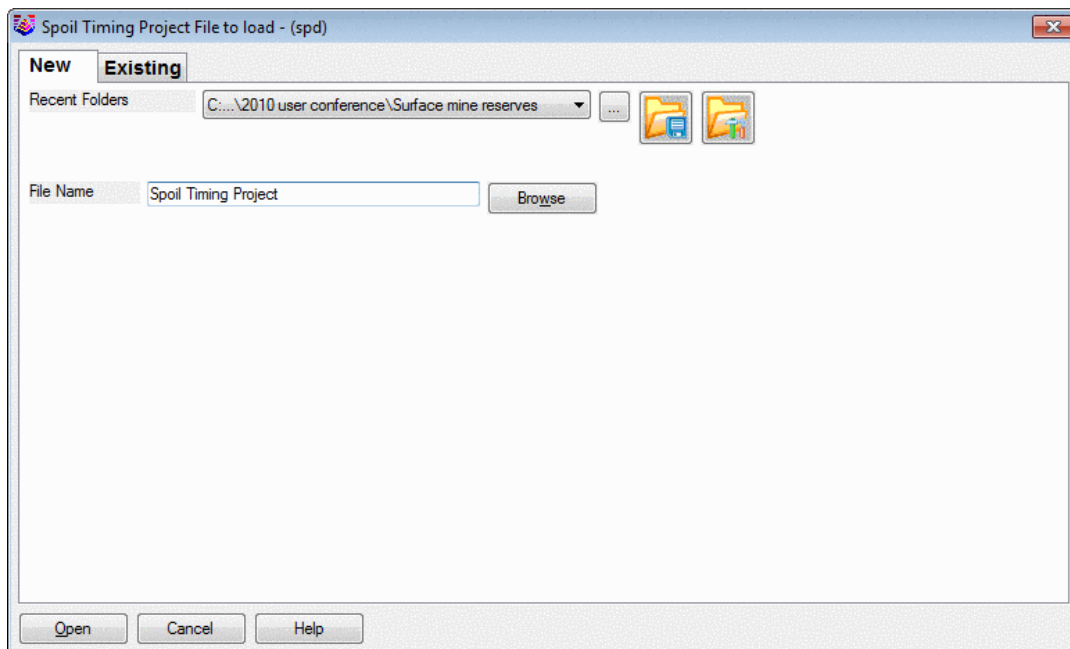

The 'Spoil Source Dates' option will move the material to the spoil area as it is excavated from the pit based on the production schedule. This option requires a spoil file (.spo) generated from Surface Equipment Timing. A .spo file

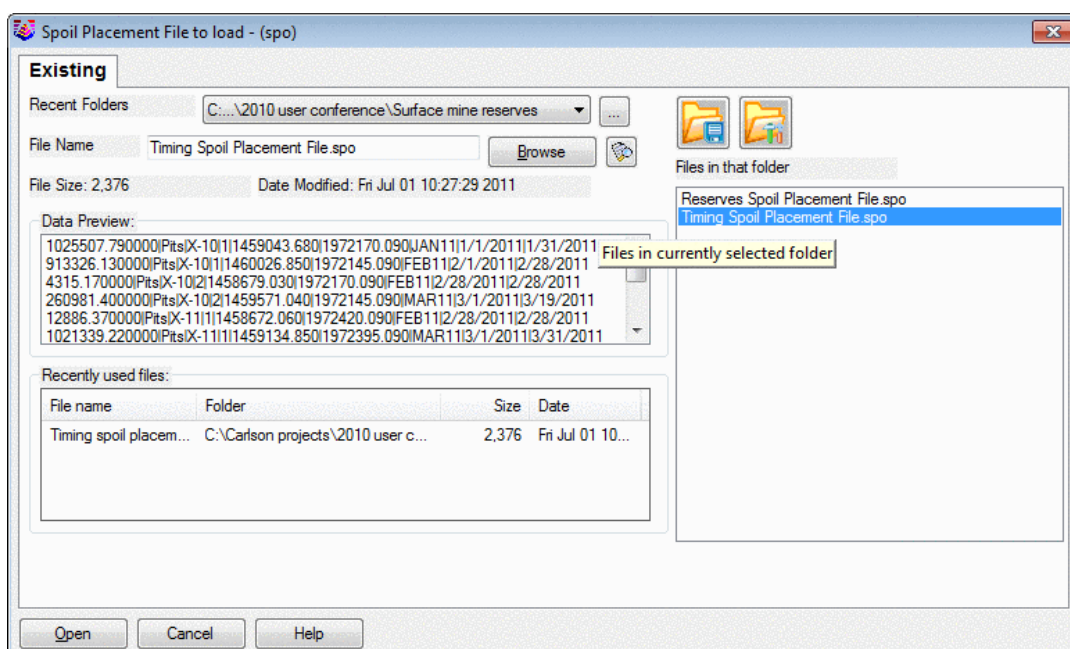

generated from Surface Mine Reserves does not include start and end dates for the pit excavation, and therefore there are no Spoil Source Dates to be used.

The 'Use Fleet for Timing' option can be used with a .spo file generated from either Surface Mine Reserves or Surface Equipment Timing. This option does not consider the production schedule of the mine, and will instead move the spoil material as quickly as the haulage fleet will allow. As this option does not consider the production schedule, in general it will be sensible to only use a .spo file generated with Surface Mine Reserves with this option.

After selecting the timing option, you will be prompted for a Spoil Timing Project file (.spd). This file stores information concerning the spoil sources, spoil volumes, start and end dates of excavation, spoil/pit centroid locations, haul fleet production capacities, spoil attributes, etc.

After specifying the .spd file, you will be prompted to select the .spo file.

Once the .spo file has been selected, you will see a preview of the file which can be edited before it is used for the spoil timing. The preview of the spoil source is shown below.

The next dialog shown will be the Spoil Timing Project Manager. This shows a tree structure of the project, which includes the haul fleet (if used), the spoil sources, the spoil destinations, and the spoil attributes. Certain aspects of this dialog can be edited using the 'Edit' button when a field is highlighted. This dialog is shown below.

The assigned and available lists shows the spoil destinations that can be used for timing. Spoil destinations can be moved between the available and assigned lists by using the left/right arrows between the two lists. The up/down arrows between the lists controls the order in which the spoil areas will be filled. The arrow-and-road icon will automatically assign spoil destinations based on the shortest haul distance between the spoil source and the spoil destination. This command requires you to have selected the haul roads using the Haul Road Manager command.

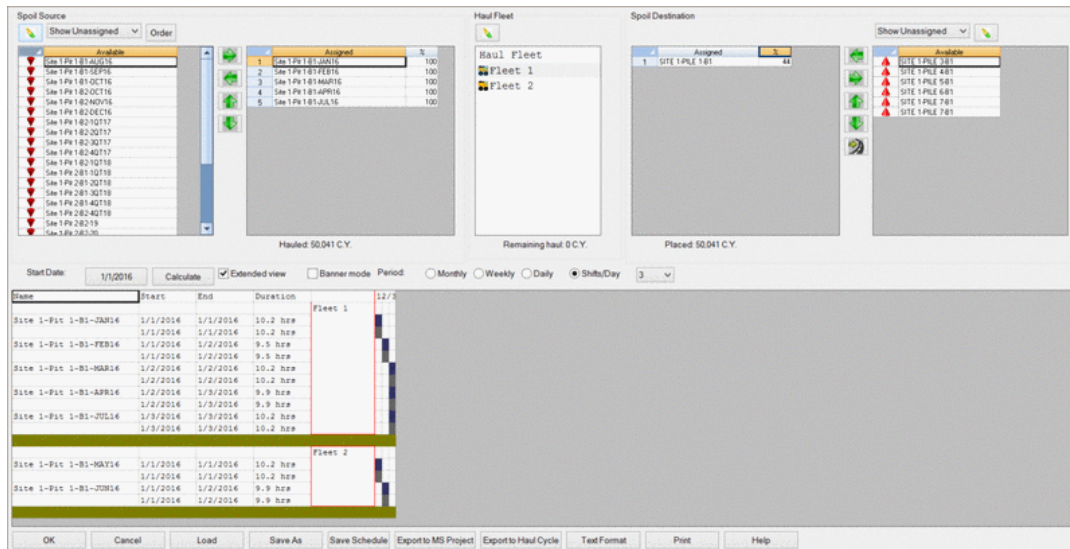

The assigned list also shows the fill percentage of each spoil pile. Note that each spoil pile will be filled to capacity before spoil is placed in the next pile. Both the spoil source and spoil destination information can be directly edited by clicking the green pen icons above each list. The total amount of spoil to be moved is listed under the spoil source list. The total amount of spoil that has been assigned to a spoil destination is listed under the assigned list.

The bottom section of the dialog shows a Gantt chart of the spoil placement timing. The use of Gantt charts are discussed in the Surface Equipment Timing section of the help manual. Clicking 'Calculate' will determine the final timing of the spoil placement. As the dialogs shown after clicking 'Calculate' are the same for both the 'Use Spoil Source Dates for Timing' and the 'Use Fleet for Timing' options, discussion of the output is discussed in the Spoil Calculation Output section of this page. One item that is specific to Gantt charts in the Spoil Timing dialog is the Export to Haul Cycle option. This option exports a .sph file which can be used with the Haul Cycle Analysis command to calculate a more detailed report of the timing associated with spoil placement.

You may also save and load the spoil timing assignments in a Spoil Assignment file (.stm)

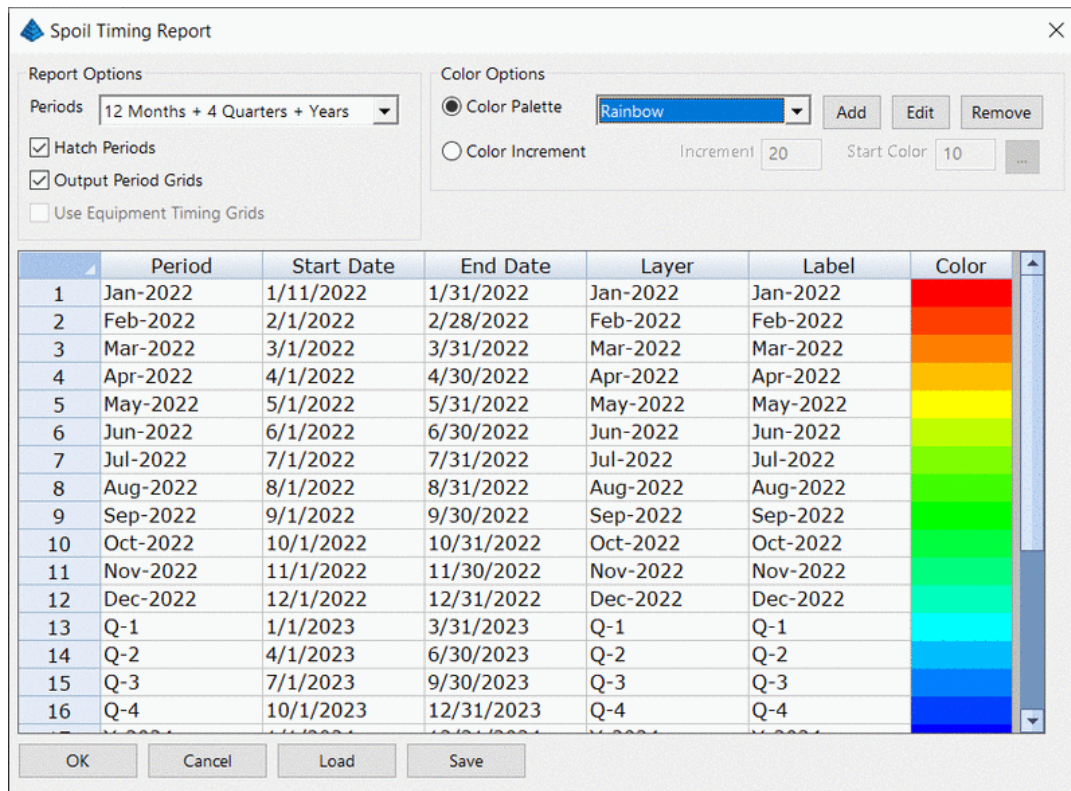

Note that this option will require a haulage fleet for timing. With this option, you may create multiple haulage fleets, which can be assigned to various spoil sources and destinations for timing.

The Spoil Placement Timing dialog for this option will appear as shown below.

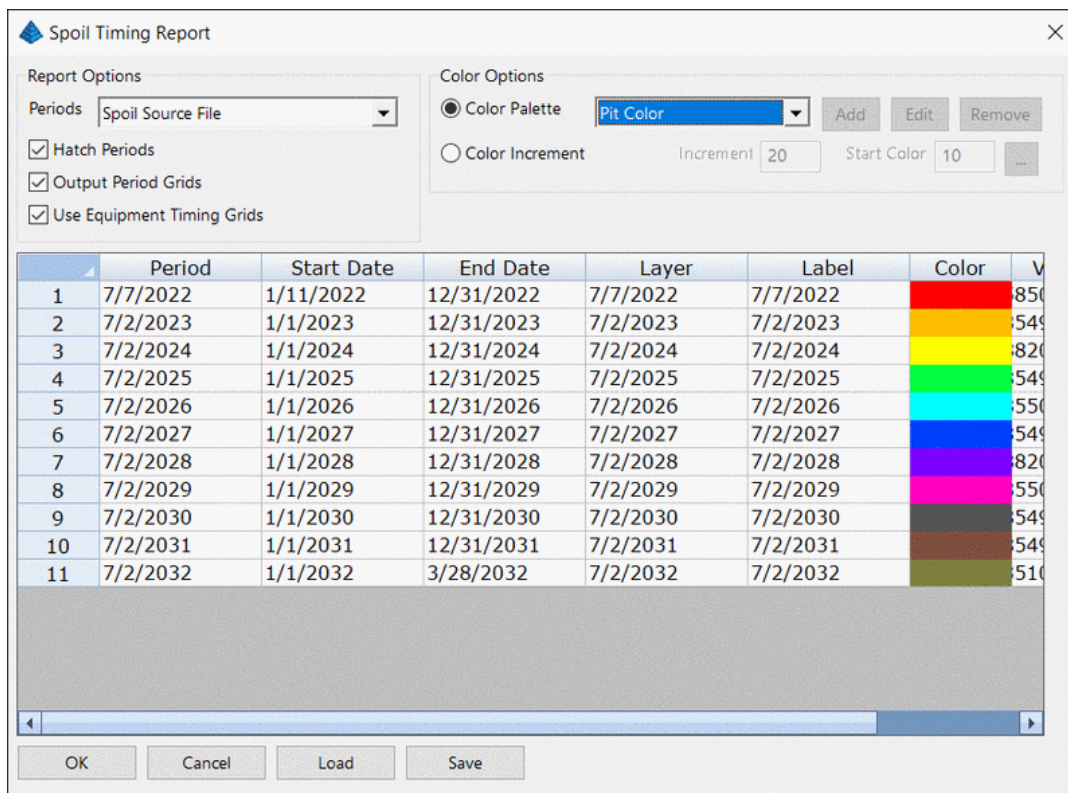

Unlike the dialog shown for the 'Use Spoil Source Dates for Timing' option, this dialog allows you to use only specified spoil sources for timing. Aside from this difference, the two dialogs are similar in functionality. Spoil sources and destinations can be moved between the assigned and available lists and reordered using the green arrows between the lists. This dialog also shows a new list of the haul fleets that can be used. Selecting a haul fleet will list the spoil sources and destinations that are assigned to that fleet. Another additional feature to this dialog is that you can specify a start date for the spoil timing.

After clicking the 'Calculate' button, you will see the dialog shown below. This allows you to set the type and appearance of the hatch, text and timing report output.

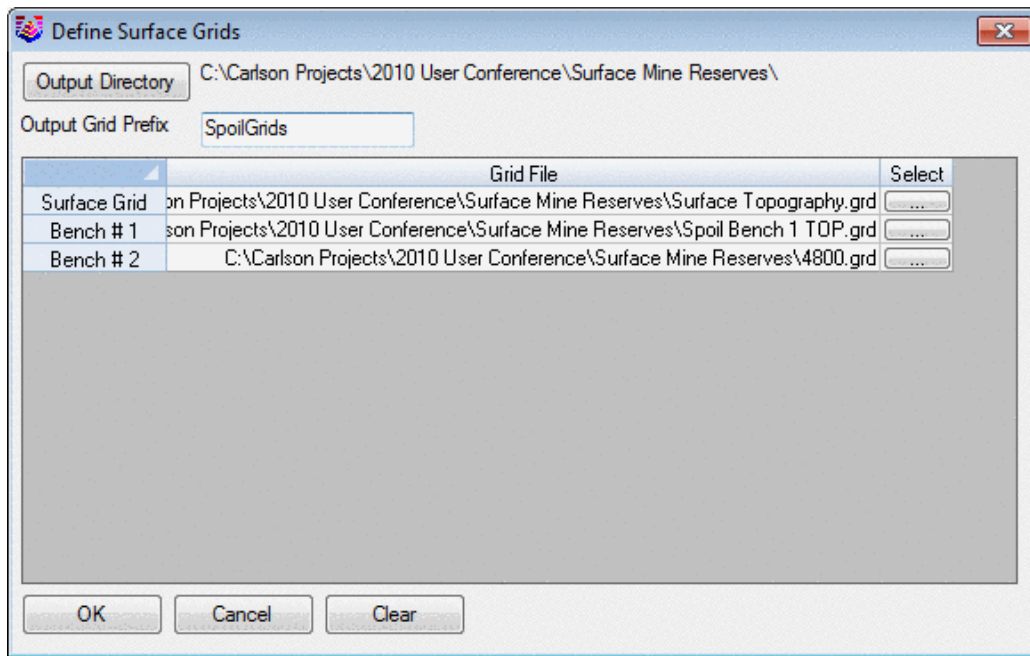

The Report Options will set the time periods for the timing report. The spreadsheet will be automatically updated based on the selected report type. The Layer, Label, and Color columns may be manually updated, but the Period, Start Date, and End Date columns are fixed. If the Spoil Source File report type is selected, the periods will be set by the .spo file created in Surface Equipment Timing. This option will also enable the Use Equipment Timing Grids option, which will merge the spoil timing output grids or TIN's with a .gsq file created from the Surface Equipment Timing command (shown below) The Pit Color option in the Color Palette will match up the period colors of the spoil timing map to the period colors of the pit advance periods.

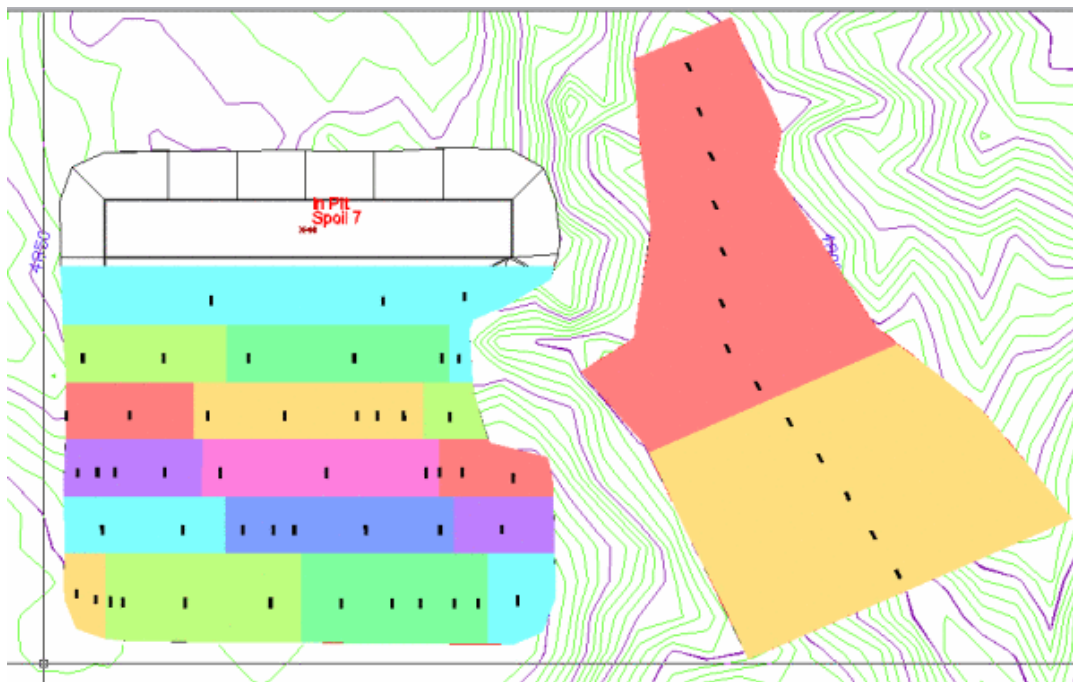

- **Hatch Periods:** This option will allow you to hatch the time periods with a solid fill color. If this option is turned off, the timing map will only show outlines and labels of the timing periods.
- **Output Period Grids:** This option will output grid or TIN files representing the surface at various time periods. These surfaces can be used to review the development of the mine area.
- **Use Equipment Timing Grids:** This option will merge the grid/TIN files created with the Output Period Grids option with a .gsq file created from Surface Equipment Timing. This can be used for detailed review of the surface development, showing the timing and locations of material movement.

If you use the Output Period Grids option, you will see the Define Surface Grids dialog after clicking OK (shown below). This dialog allows you to set the surfaces which define the existing ground and bench surfaces of the spoil piles.

If you use the Use Equipment Timing Grids option, you will be prompted to select a .gsq file to update. Note that you must have an existing .gsq file for this option. This command will merge the output surfaces with the .gsq file at the respective time periods, which can be saved as a new .gsq file. This will represent the full mining progression, showing the advance of the pits, and the following of the spoil and dumps.

The below plan view map is hatched with the color period blocks to illustrate where each spoil is placed in each period.

Viewing the new .gsq file with the View 3D Surface History command will show the mining progression with the spoil fills.

Using the Report Formatter can export the report directly into Excel. An example Excel dump is shown here.

Keyboard Command: timespoil

Prerequisite: SPO file from Surface Mine Reserves or Surface Equipment Timing, spoil polylines with direction, and haulage fleet.

Pulldown Menu Location: Spoil in Surface Mine Module

Case Studies

Case Study #7: Dragline Range Diagrams

This tutorial shows how to design steps of Cast Blast Profile, Dozer Push and Cut & Place in cross section view for dragline extended bench and spoil side methods. It then takes this design "template" and applies it to plan view in 3D, extruding along the pit using a centerline file (CL). Other routines we will use include Define Dragline Equipment, Cut Only (coal removal), Draw Dragline limits, and Flatten Spoil Top.

Creating Surface and Strata Cross-Sections

(Geology module > Surface pull-down menu> Cast Blast Command)

The first step is to generate a cross section of the ground surface and desired strata. This can be accomplished with the fence diagram routine, or drawing multiple profiles or sections that represent these surfaces on a grid. If the fence diagram method is used, be sure to turn off hatching, and turn on draw strata polylines as single polylines. Otherwise, the strata will be closed polylines and the program won't use them correctly. If the profile crosses an existing, open pit and seams are cropping, be sure to turn on Draw Surface Polyline in Fence Diagram. This will draw a continuous polyline across the entire length of the section, needed for Cut & Place. Shown below is a cross-section of an existing pit.

EXTENDED BENCH EXAMPLE

Cast Blast

(Surface Mining module > Surface pull-down menu> Cast Blast Command)

The first operation is to simulate the cast blast for creating the extended bench. The generic profile of the blast can be defined as either a Carlson profile (*.pro) or as a polyline drawn on the screen, above the fence diagram. The profile file or polyline must be created before running Cast Blast. For example, you can draw the typical blast profile on the cross-section view. The program will move the polyline up or down to balance the cut and fill areas. The program can also save your blast profile polyline into a *.pro file via the Create Profile from Polyline on Profile Grid command. First, the program will display the below dialog box for options.

In this case, the swell factor was set to 1.2, or 20% and the profile by polyline option was used. Then select the ground and top-of-strata polylines. Next pick the blast or cut area, this example used the lower left and lower right cut points. The left point in this case should be at the cut width, and the right point is snapped to the intersection of the top of coal outcropping at the existing ground surface.

After the program places the blast, it prompts the user if there is any vertex on the blast that needs to be moved or changed. Simply pick the position and the line will move to that location. The existing ground surface line has now been changed, and is ready for the next step.

Steps needed to complete a Cast Blast (required blast profile file)

1. Select cast blast profile command.
2. Adjust settings in the dialogue to the image shown above accordingly.
3. Command: C:BLAST
 - Select existing grade polyline: *pick existing surface polyline*
 - Select strata polyline (Enter for none): *none*
 - Pick lower Left cut point: *any point along the top of the coal seam (upperblue polyline)*
 - Pick lower Right cut point: *intersection of the top of coal outcropping at the existing ground surface*
 - Cast to Final: 20.15%
 - Pick profile point to modify (Enter to end):

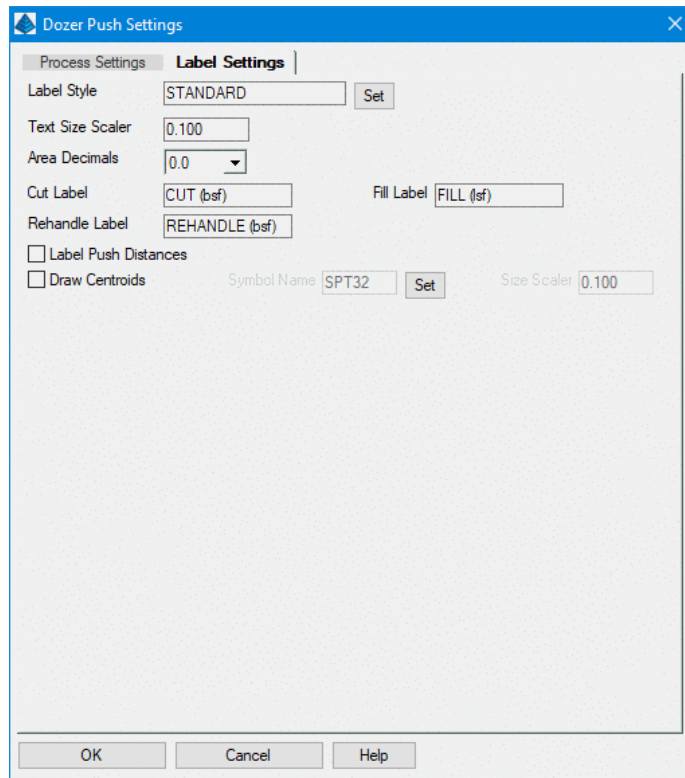

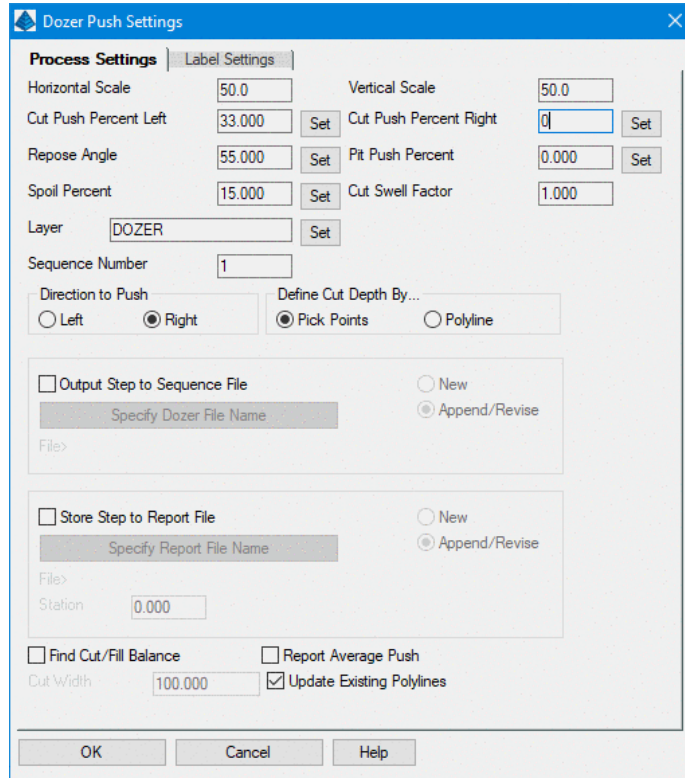

CUT: 17220.87 (sf) FILL: 20665.04 (sf)

4. Command is finished, check fence diagram for polyline updates.

Dozer Push

(Surface Mining module > Surface pull-down menu > Dozer Push Command)

Now the Dozer Push command is used to create the extended bench.

In the dialog box, set the Pit Push Percent to 0%. This will push the material horizontally out into the pit. Turn off Label Push Distances, otherwise it will label the complete surface line. Also set the swell to 1.0 since this material has already had the swell factor applied from the Cast Blast. Choose OK and pick the left and right cut points as shown below. Use the Nearest Snap to pick the right cut point so it connects directly on the existing surface line. The left and right cut points should be selected at the same elevation if the push is to be flat before the pit also. The existing surface polyline has now been updated and is ready for the next operation.

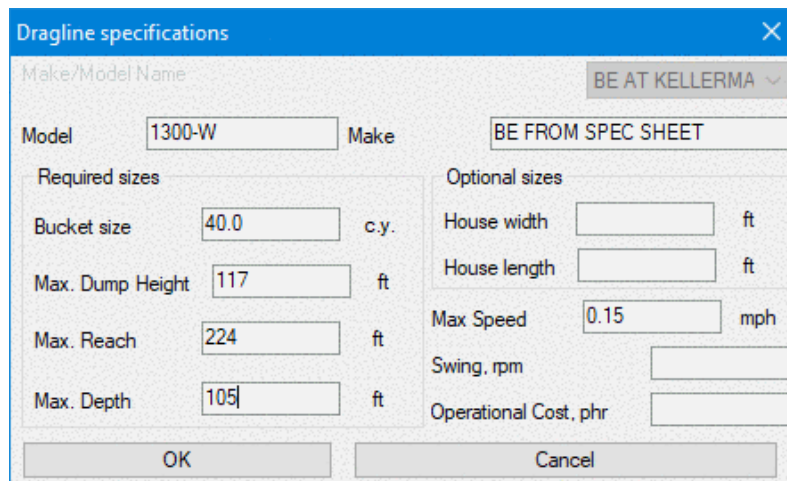

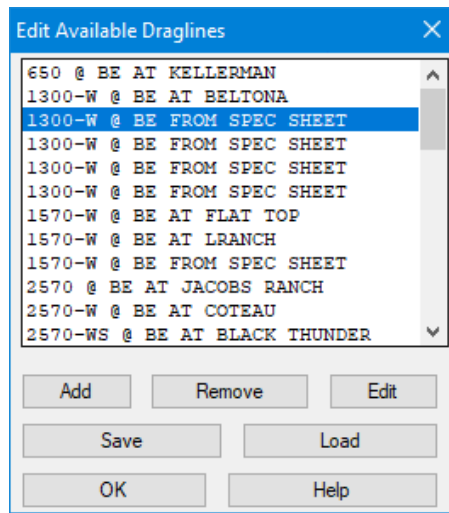

Steps needed to complete a Dozer Push

1. Select cast dozer push command.
2. Adjust settings in the dialogue to the image shown above accordingly.
3. Command: C:DOZER
 Select existing grade polyline: *pick new existing surface polyline*
 Pick lower Left cut point: *shown above*
 Pick lower Right cut point: *shown above*
 Select fill areas to rehandle (Enter for None). *none*
 CUT (bsf): 2640.5
 REHANDLE (bsf): 0.0
 FILL (lsf): 2640.5
 PUSH: 97.1, 0.0% to 2.9, 0.0%
 Total: 100
 Pick Point for Label (Enter for none): *anywhere on the fence diagram to show the summary*
4. Command is finished, check fence diagram for polyline updates.

Define Dragline Equipment

(Surface Mining module > Surface pull-down menu> Define Dragline Equipment Command)

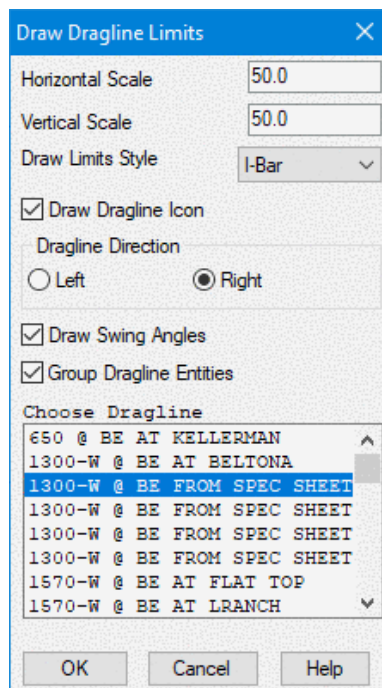

This routine simply defines the dragline parameters and dimensions for drawing its reach, depth and height on the range diagram. Fill in at least the required size parameters on the left side of the box. Example dragline dimensions are provided for your convenience.

Draw Dragline Limits

(Surface Mining module > Surface pull-down menu> Draw Dragline Limits Command)

This draws the workable limits of the dragline on the range diagram cross-section. Pick the existing ground polyline and the location that the center of the machine is sitting. A block of three lines is drawn representing the height, digging depth and horizontal reach of the dragline. There is a vertex placed at the intersection of the ground surface, this is the point to pick for moving the block to the next cut. The vertical line above the vertex is the height, and the line below the vertex is the digging depth. These are the limits to stay within when cutting and placing spoil. There is an option to draw a dragline icon, and also to label the swing angles across the top. This allows you to keep the spoil placement within a certain swing angle. There is a prompt to use a reference point. This could be the crest of the highwall. If one is picked, then it prompts for a distance from that reference point to the center pin of the dragline. Negative values will offset it to the left.

Steps needed to complete Draw Dragline Limits

1. Select draw dragline limits command.
2. Adjust settings in the dialogue to the image shown above accordingly.
3. Command: C:DLIMITS
 Select ground polyline: *pick new existing surface polyline*
 Pick reference point (Enter for None): *Press Enter*
 Dragline distance from reference <0.0>: *-35.84 (distance from center of dragline base to rightmost edge of the dragline main body/machinery house, but any distance closer to the right most edge is acceptable)*
4. Command is finished, check fence diagram for polyline updates.

Cut and Place (Spoil Removal)

(Surface Mining module > Surface pull-down menu> Cut and Place Command)

The next step is the Cut & Place command for the dragline work. In the dialog, set the right highwall angle to the repose angle of the spoil. This will ensure the cut and spoil are the same angle. Also set the spoil placement method to Left Toe.

Cut and Place Settings [X]

Horizontal Scale: 50.0 Vertical Scale: 50.0

Cut Swell Factor: 1.000 Top Spoil Width: 0

Highwall Angle Left: 70.000 Right Side: 36

Station: 0.0

OK Cancel Help

After selecting OK, pick the ground and strata (top) polylines. Next, pick the left cut, right cut and spoil location points as shown. It is very helpful to use the Osnap endpoint and intersection to get the exact points. Notice how the right highwall angle and the spoil match for an accurate representation of the slope. Again, there is no need to swell the material as it has been already swollen from previous operations.

Steps needed to complete Cut and Place (Spoil Removal)

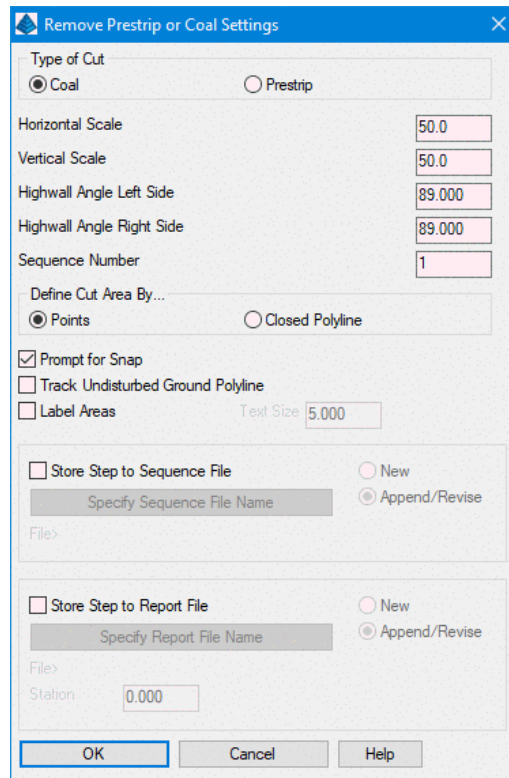

1. Select cut and place command.
2. Adjust settings in the dialogue to the image shown above accordingly.
3. Command: C:RANGE1
 Select current ground polyline:
 Select bottom strata polyline (Enter for none): *pick new existing surface polyline*
 Reference/Limits/<Pick lower Left cut point>: *shown above*
 Reference/Limits/<Pick lower Right cut point>: *shown above*
 Reference/Limits/<Pick spoil position>: *(snap spoil peak to dragline right side 60 degree)*
 Control point to adjust [Left/Right/Spoil/<None>]? *None*
 CUT: 15159.16 (sf)
 FILL: 15159.16 (sf)

4. Command is finished, check fence diagram for polyline updates.

Cut Only (Coal Removal)

(Surface Mining module > Surface pull-down menu > Cut Only (Coal Removal))

The final step in this example sequence is the removal of the coal to prepare the new existing ground surface for the next cut/spoil placement. Like Cut and Place, this routine also allows for differing left and right cut slopes. The strata polyline in this case will be the bottom of coal polyline, which will bring the existing ground polyline down to it.

Steps needed to complete Cut and Place (Coal Removal)

1. Select cut and place coal removal command.
2. Adjust settings in the dialogue to the image shown above accordingly.
3. Command: C:RMCOAL
Select existing grade polyline:
Select strata polyline (Enter for none): *pick new existing surface polyline*
Reference/<Pick lower Left cut point>: *shown above*
Reference/<Pick lower Right cut point>: *shown above*
Control point to adjust [Left/Right/<None>]? *None*

CUT: 1886.68 (sf)

4. Command is finished, check fence diagram for polyline updates.

SPOIL SIDE BENCH EXAMPLE

Cast Blast

The initial cast blast is the same as the extended bench example in the previous pages. Shown is the cross-section after the cast.

Spoil Side Bench

The Cut & Place routine will be used to create the spoil side bench in this example. In the dialog box, set the Top Spoil Width to the bench width (in this case, 100 feet). Then choose OK and select the ground polyline and cut points as shown. Again, the snap nearest is useful for selecting the right cut point. Do not select a strata polyline, as we are not going down that deep in the cut. To place the spoil, be sure to select either left or right toe for location method, as there is no spoil peak with which to place it. After placing the spoil pile, there is an option to adjust the left and right cut points. Any adjustment of the cut area is automatically reflected in the spoil bench, which allows you to adjust the spoil bench height.

Cut and Place Settings

Horizontal Scale	50.0	Vertical Scale	50.0
Cut Swell Factor	1.000	Top Spoil Width	100
Highwall Angle Left	70.000	Right Side	36
Repose Angle Left	36.000	Right Side	36.000

Station: 0.0			
<input type="button" value="OK"/> <input type="button" value="Cancel"/> <input type="button" value="Help"/>			

Draw Dragline Limits

The next step is to show the dragline limits when placed on the spoil side bench. Use the same procedure as in the extended bench example. Another option is to create a block drawing of a dragline and insert it into the drawing to represent the correct dimensions. Shown below is a block of a dragline to scale, inserted into the above range diagram.

Cut & Place

The next step is the Cut & Place routine for the dragline pass. In the dialog, set the right highwall angle to the repose angle and set the spoil placement method to Left Toe. Also set the Top Spoil Width back to zero. Then click OK and select the ground and strata polylines. Next, pick the left cut, right cut and spoil pile points as shown. Notice the right cut point is to the right of the coal block to ensure it is uncovered and minimize rehandling. You can use

the Osnap-endpoints to get the exact points. To start the spoil pile 20 feet from the spoil side bench, use the distance option and pick the edge of the spoil side bench as the reference. Type in a positive value to offset to the right and negative to offset to the left.

Cut Only (Coal Removal)

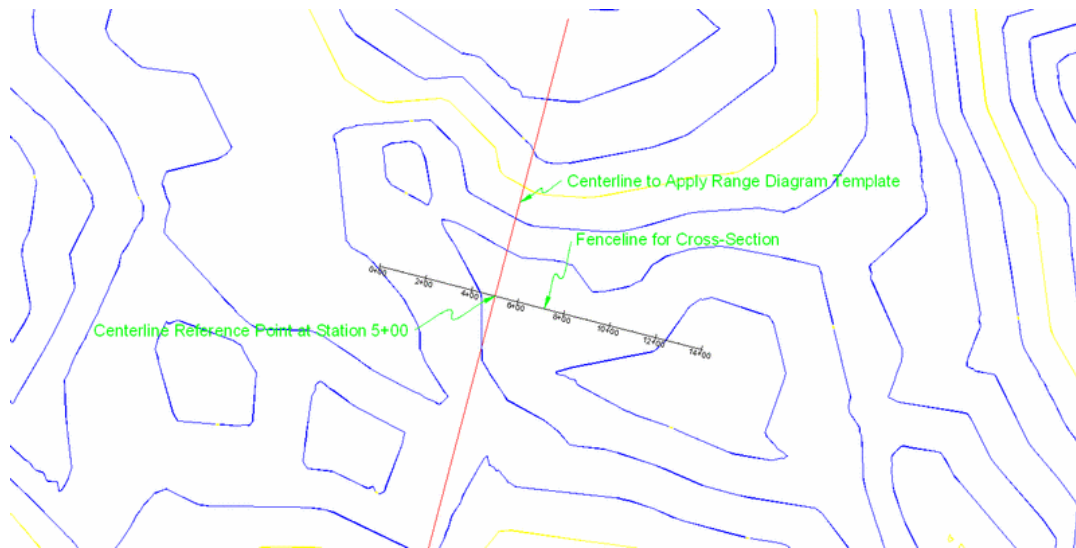

As in the previous example, the coal removal is the last step to prepare the existing ground surface for the next cut. The right side cut angle is again set to the same angle as the spoil repose to simulate the spoil down to the bottom of the removed coal block.

Process Dragline Sequence

(Surface Mining module > Surface pull-down menu > Process Dragline Sequence Command)

One thing not mentioned in the previous examples is the saving of each step to a dragline sequence file. The option to store each step in a sequence file is set at the bottom of the dialog boxes. Typically the first step is saved to a New file as sequence step #1, and each subsequent step is appended to that file as #2 and up. The next example will show a simplified two-cut Cut and Place on a fence diagram and then processed with a centerline to generate 3D polylines drawn in plan view and sections. The first step is drawing the fence line and intersecting it with the centerline for laying out the cuts/pits as shown in the diagram below. This intersection will be known in the commands as the centerline reference point. Then draw the fence diagram with the hatching turned off and draw as single polylines turned on. This will provide an existing ground surface with the strata lines below it. It is usually better if there is no exaggeration in the cross-section. Since this fence diagram is already available in the drawing file, use the first fence diagram under Processing Dragline Sequence on the left of the drawing.

New dragline dimensions

Dragline specifications			
Make/Model Name			BE AT KELLERMA
Model	1300-W	Make	BE FROM SPEC SHEET
Required sizes		Optional sizes	
Bucket size	40.0 c.y.	House width	ft
Max. Dump Height	170.0 ft	House length	ft
Max. Reach	300.0 ft	Max Speed	0.15 mph
Max. Depth	130.0 ft	Swing, rpm	
		Operational Cost, phr	
OK		Cancel	

Processing Dragline Sequence

Cut & Place

After drawing the dragline limits, the Cut & Place settings need to be set as shown to the right. A 20% swell has been set, and it will be stored to a new step file as shown with sequence number one. This will be a simple box cut for the first sequence. Step two will be the coal removal, and step three will be the next cut and spoil placement. After step three, the sequence file will be processed and turned into 3D polylines and a section file (*.sct). The first step is shown below:

Cut and Place Settings

Horizontal Scale	50.0	Vertical Scale	50.0
Cut Swell Factor	1.2	Top Spoil Width	0.0
Highwall Angle Left	70.000	Right Side	55
Repose Angle Left	36.000	Right Side	36.000

Help			

The first prompt after selecting the existing ground surface is to pick the centerline reference point. In this example, it is station 5+00 and it should be "snapped" to at the intersection of the horizontal grid line and the 5+00 tick mark. After selecting the top of strata polyline, you are prompted to enter the name of the strata. This name will be used later in prompting to select that surface grid file. Select the left and right cut points and the spoil location. Notice the two cuts were drawn in by hand to guide the user in the correct location of the cuts. This is sequence step number one.

Cut Only (Coal Removal)

Step number two will be the removal of the coal block. The cut angle will be set to 89 degrees on each side to simulate a near vertical face of coal after it is removed. Try to stay away from pure 90 degree slopes, as this can create difficulties for the program. The strata line will be the bottom of coal this time, and you will be prompted to specify a name for that surface. (BOC for bottom of coal works) You will also be asked to snap to the centerline reference point (5+00).

Cut & Place

The third and final operation in the sequence will be the second cut with spoil placement into the first cut. Everything is about the same except for the sequence number needs to be set to three, and it should change automatically. Shown below is the final result, sort of a template that will be applied now to our centerline (*.CL file) utilizing the surface grids and create a new surface for possible PMT application.

Process Dragline Sequence

If it has not already been done, use the routine Polyline to Centerline File to create the *.CL necessary for the processing of the sequences. The following window will appear, and needs to have at least the first three files set. It will also create an output section file for later manipulation. The Taper Spoil Sides will taper the ends of the spoil gradually down to the existing ground. The draw pit polylines will create new pit/cut polylines to run for scheduling. After selecting OK, you will be prompted for the grids representing the strata named in the previous routines.

Steps needed to create a Centerline file

1. Select polyline to centerline command. (Surface Mining module > Surface pull-down menu> Polyline to Centerline Command)

2. Command: C:CLPLINE

Centerline File to Write (*creating a new file, enter file name*)

Polyline should have been drawn in direction of increasing stations.

Select polyline that represents centerline:

Centerline station [Reverse/Ending/<Beginning: 0+00>]: *Reverse (centerline arrow direction is from north to south, if the direction is not correct press Reverse. otherwise press enter to skip this step)*

Centerline station [Reverse/Ending/<Beginning: 0+00>]: *(Press enter to finish this step)*

Station North(y) East(x) Description (*centerline summary*)

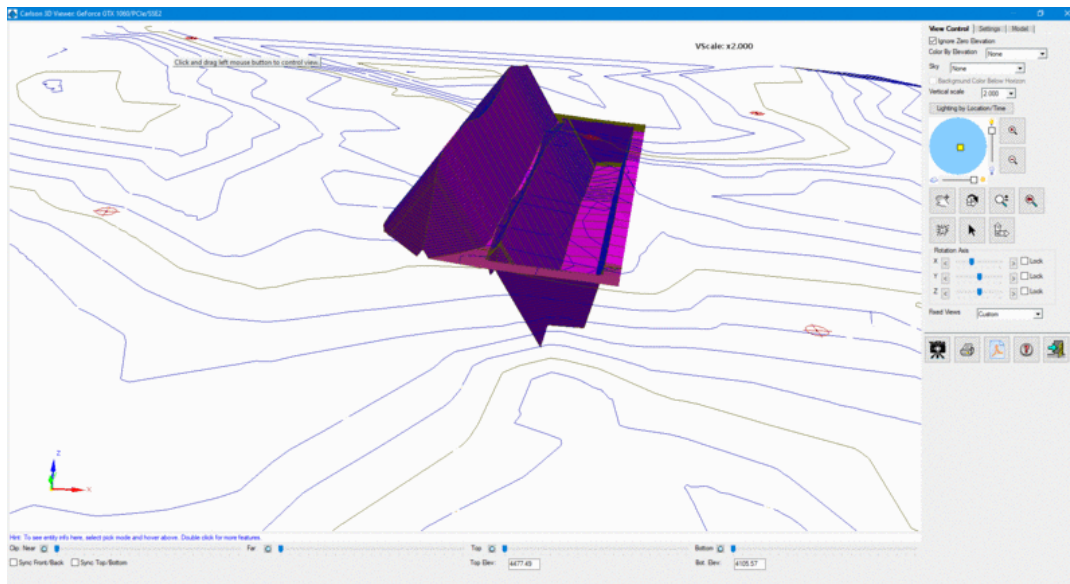

0.000 935218.592 1003501.740 LI

2364.899 932932.065 1002897.967 LI (2364.899 is the total distance of the centerline)

Press ENTER to continue.

3. Centerline file created

Shown below is 3D view of the cross section. For visual clarification, the 3D polylines were also contoured to begin building the new surface. Notice the pit is only as long as my centerline was drawn. The top image is a rendered image of Triangle Faces that were drawn.

Draw Section File

(Civil module > Section pull-down menu > Draw Section file Command)

Another step is to draw the section file created in the processing of the sequence. Shown is a partial series of sections created with the Carlson Range Diagram routines.

Case Study #9: Surface Timing With Benches

This tutorial shows how to run Surface Equipment Timing through a series of benches in pits. This example starts with a pit layout mineplan and structure grids. It is assumed that you already know those operations. Then Design Bench Pit is run on the pits, creating final pit grids and a Grid Sequence File. Next the quantities for each bench will be calculated and stored in the pit polylines. Then the sequence of mining the benches and pits is assigned with Surface Equipment Timing.

Creating Pit Polylines

(Surface Mining module > Boundary pull-down menu > Pit Layout By Advance Command)

The first step is to sub-divide the overall pit perimeter into smaller pits. In this example, the larger rectangular mine perimeter is subdivided into 5 smaller pits, named Pit-1 through Pit-5. These will be draped onto the bottom of the pit and benches will go up and out from them. The command Pit Layout By Advance was used to lay them out.

Steps needed to create pit polylines

1. Select Pit Layout by Advance command.
2. Command: C:CUTPITADV
Select all pit polylines. *select one large rectangle that will be including pit 2 to pit 5.*
Entities in set: 1
Select all direction polylines. *(In this command, direction polyline indicates direction of the pit advance in an area. So choose black vertical line as directional polyline)*
Entities in set: 1
3. Command is finished, New pit polyline has been created.

Assigning Pit Directions

(Surface Mining module > Boundary pull-down menu > Pit direction Tab > Assign Direction Command)

In order to schedule the equipment through the pits, the direction of mining needs to be assigned to each pit. In this case, the direction of mining for each pit will be from left to right. First draw a direction polyline through the pits from bottom to top. Then run the Assign Directions command and use the Sequence method with the LL option.

Steps needed to assign pit direction

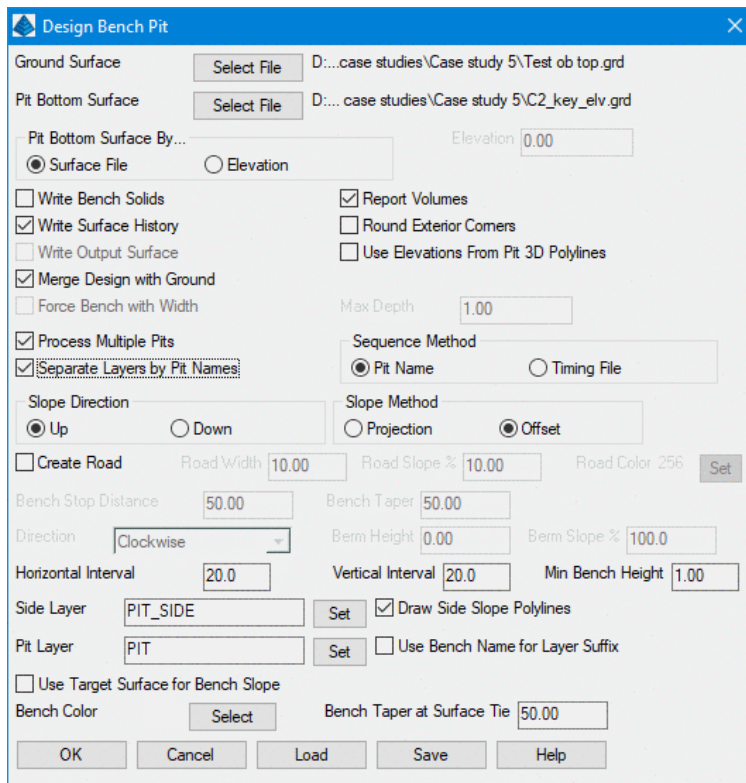

1. Select Assign Direction Command.
2. Command: C:ASSIGN_DIR
 Assign direction to whole pit or to a specific bench [*<Whole>/Bench*]? *Whole*
 Assign direction method [*<Auto>/Text/Sequence/Polyline/Bearing/AZimuth/Gon*]? *Sequence*
 Select pit polylines to have direction assigned to. *Select all the pits*
 Entities in set: 5
 Select a direction polyline:
 Assign direction in which sequence [*<LL>/LR/RL/RR*]? *LL*
3. Command is finished, directional polyline has assigned.

The pits now have direction assigned from west to east.

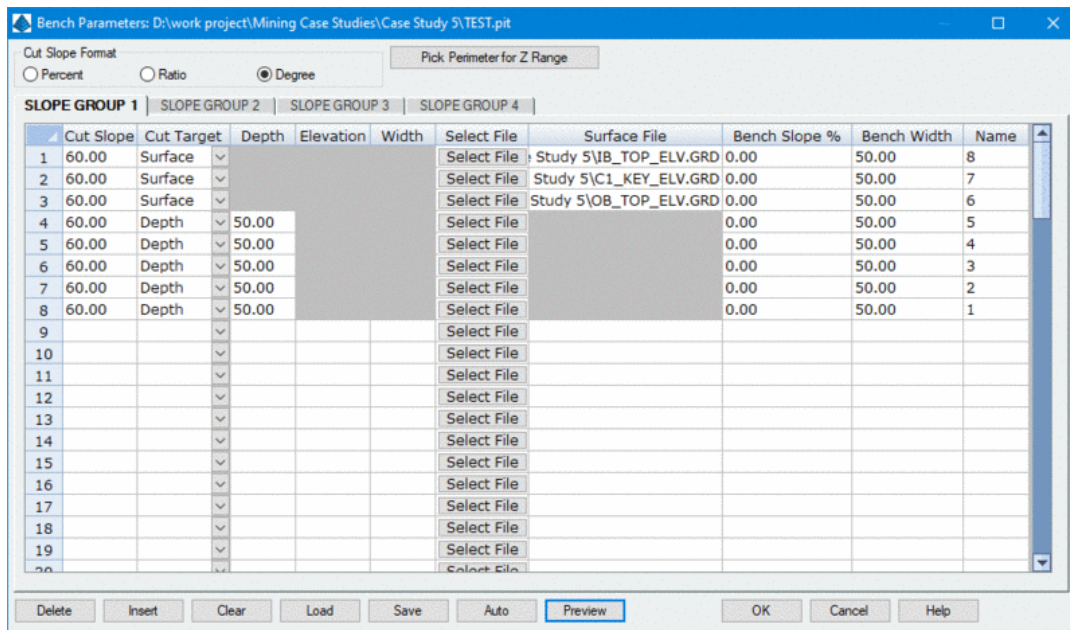

Design Bench Pit

(Surface Mining module > Surface pull-down menu > Design bench pit Command)

Using the pit perimeters as the inclusion areas, the program will draw the 3D pit shells, output grids, and calculate volumes for each pit and bench. Before running Design Bench Pit, you need the pit bottom perimeter polylines and grid files for the ground surface and benches. In the first dialog, specify the ground surface grid and the bottom elevation grid for the last bench. Also be sure to enable the options for Process Multiple Pits, Separate Layers by Pit Names, and Write Surface History. A grid file for each pit and each bench will be created and automatically organized in the Grid History File (GSQ).

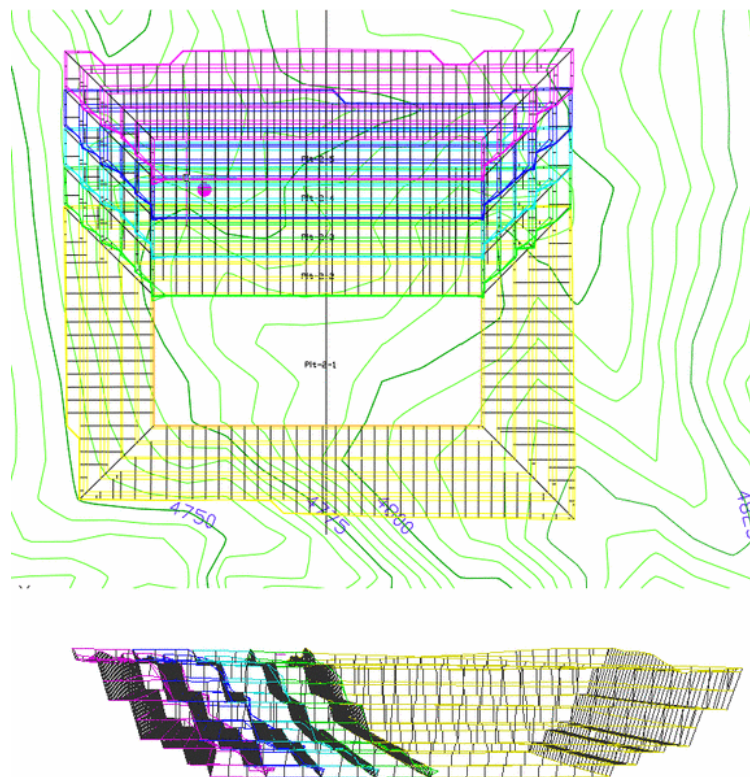

In the next dialog, you specify the side and bench slopes. The height of the side slopes can be specified by either a depth number or a grid file. In this case we will use grid files as well as by depth. Four different sets of slopes can be applied to different sides of the pit. For this example, the same slopes will be used on all sides. You can use up to 100 benches.

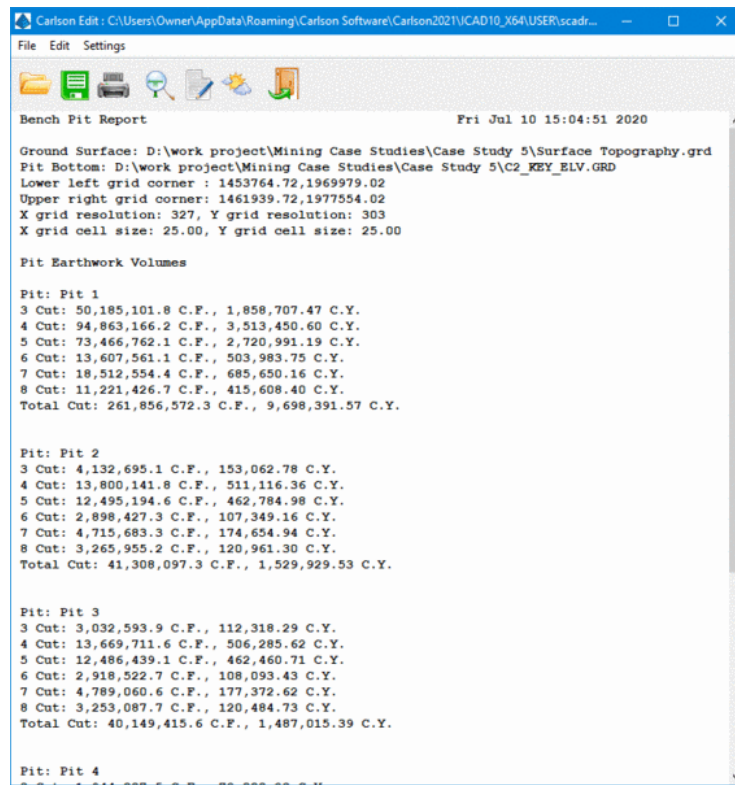

The output will look as such. Each pit/pushpack is in its own layer and colored differently. In the above view, the pits are laid down on the side, to show the slope to each grid.

Each pit and bench quantity is reported in the basic text report.

Steps needed to design bench pit

1. Select design bench pit command.
2. Follow design bench pit dialogue and bench parameters dialogue that are shown above. Click "OK" to finish each command
3. Save Surface History file
4. Command: minepit2
Select the site/pit perimeter polylines. (select all 5 pit perimeters)
Entities in set: 5
Preparing bench grids ...
Calculating bench pit ...
Processing edge 9059, intersections found 3622
Calculating grid elevations
Writing grid file: D:\work project\Mining Case Studies\Case Study 5\pit.grd
... program is writing grid files for each pit
...
...
5. Report dialogue will show up and give summary in volume for all the cuts.
6. Command is finished, New pit polyline has been created.

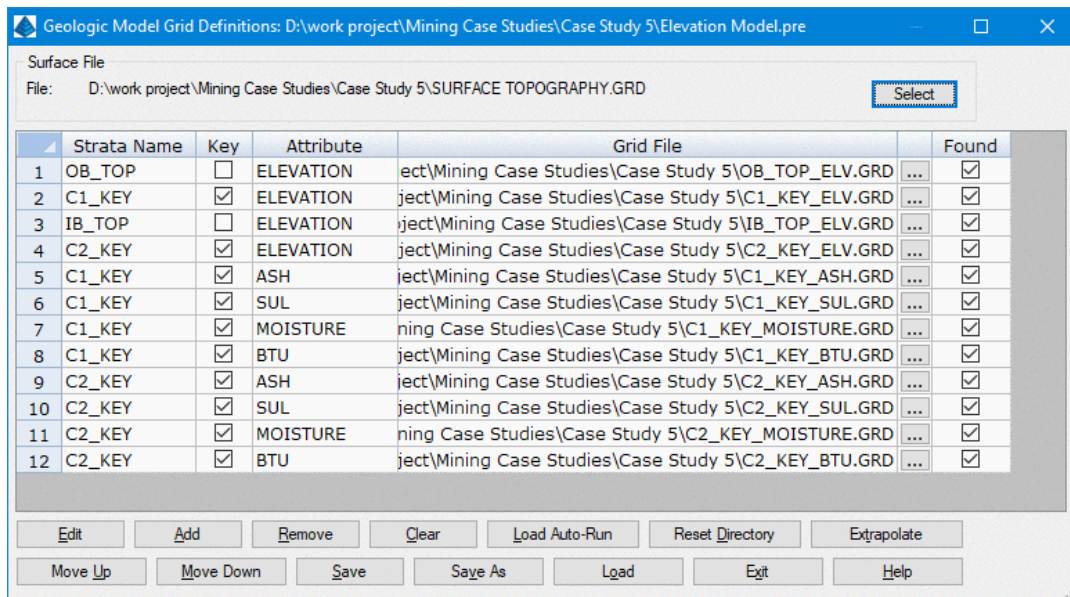

Assigning Bench Quantities

(Geology module > StrataCalc pull-down menu > Define Geologic model Command)

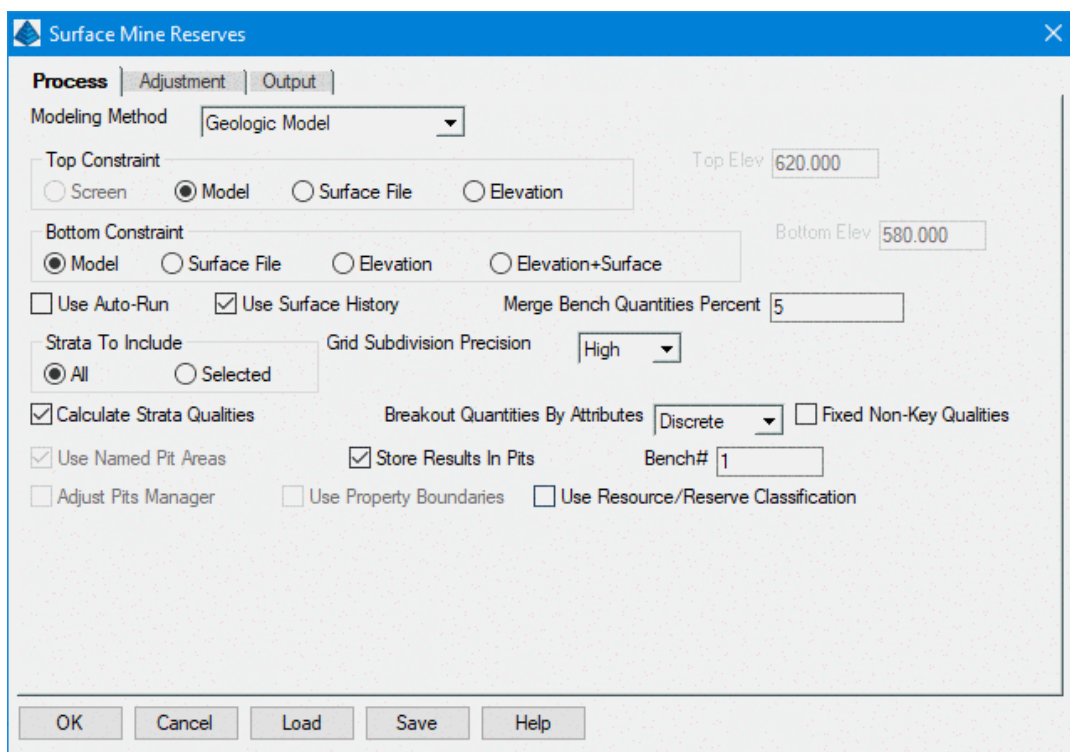

(Geology module > StrataCalc pull-down menu > Surface Mine Reserves command Command)

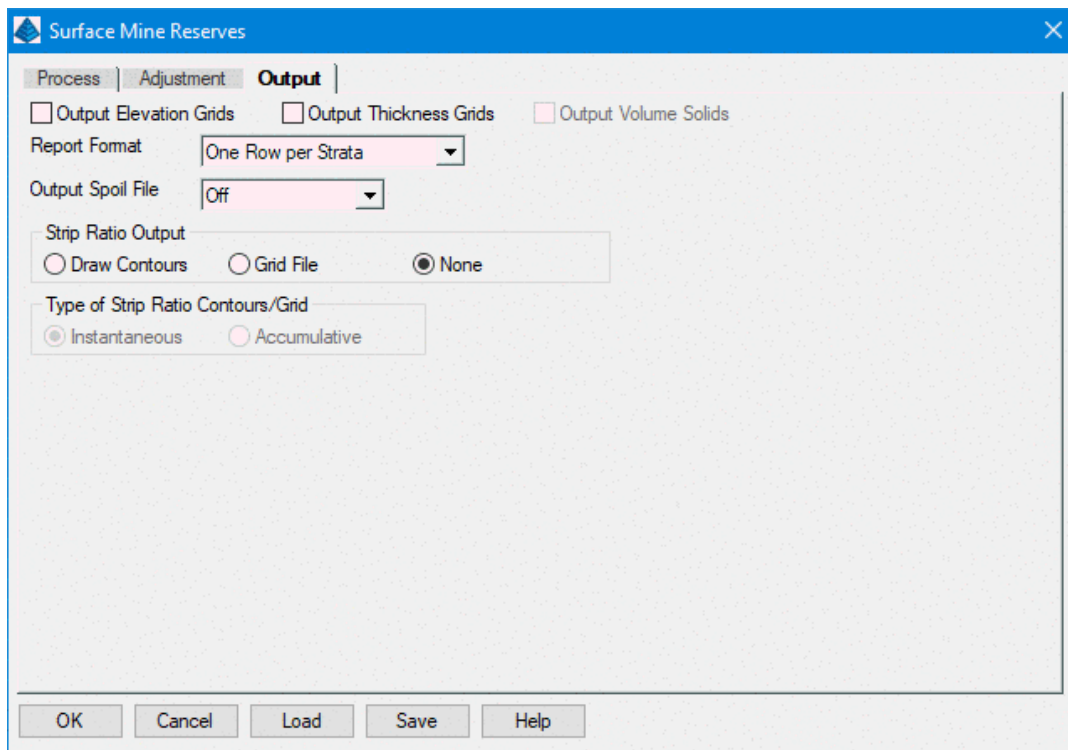

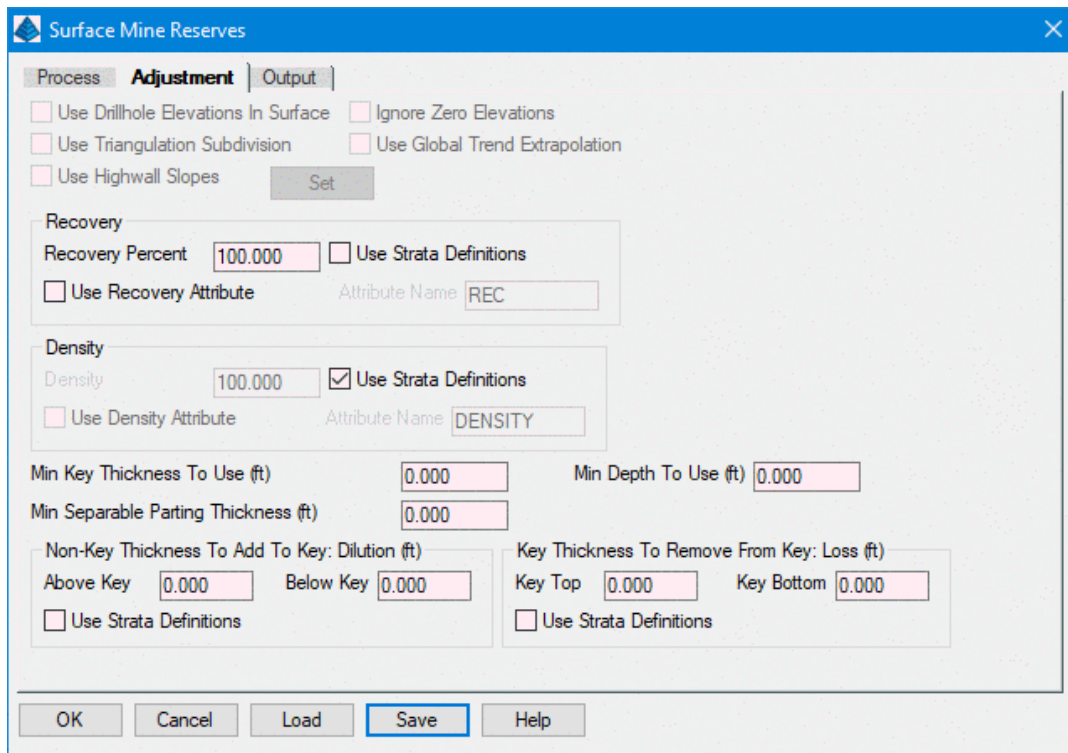

The next step is to store quantities in each pit for each bench using the Surface Mine Reserves command. Before running this command, you need to have a Pre-Calc Grid file (.PRE) in addition to the GSQ history file. This is

what determines the bench quantities and automatically assigns them to the benches.. Use the Define Geologic model command to specify the grids as shown below.

Then run Surface Mine Reserves. The dialog shown below appears. Set the Modeling Method to Geologic Model. Since we are using the Surface History File, all five benches will be assigned automatically. Turn on all the options you see here.

After clicking OK on the dialog, select the Geologic Model to use for the calculation. Next the program prompts for the Grid History File created earlier by the Design Bench Pit routine. The Merge Bench Quantities Percent applies here. If there is some grid "bleeding" where one seam bleeds into another bench due to the grid cell size, then this option will put that material back into the correct bench, as long as the amount is not less than this percentage.

Now the program will calculate the quantities of all the benches for all the pits. A report formatter allows you to optionally print or display the results. The quantities are stored in the pit polylines for scheduling. If you are not

using the GSQ file, then you will have to run this for each bench number, with all the same options except set the Bench # to 2 and choose only Bench 2 from the strata list (Selected Strata turned on). Then repeat this command a third time using bench 3, etc. That is what is nice about the GSQ file, it does them all at once, even calculating and assigning the layback slope volume accordingly. Shown next is the pit by pit and bench by bench volume report.

Surface Mine Reserves Mon Aug 3 13:33:40 2020

Pit: Pit 3

Strata Bench#	KEY Tons	Non-key C.Y.	Thick	Area acres
OB_TOP 1		111,381.6	87.04	0.793
OB_TOP 2		505,909.8	82.07	3.821

These values are now stored in the pits and can be verified with Edit Pit under Boundary. Click inside any one of the pits to see the values. All benches can be accessed by selecting the bench number in the tree view on the left of the dialog or by selecting the Spread View tab to view data for all benched at a time.

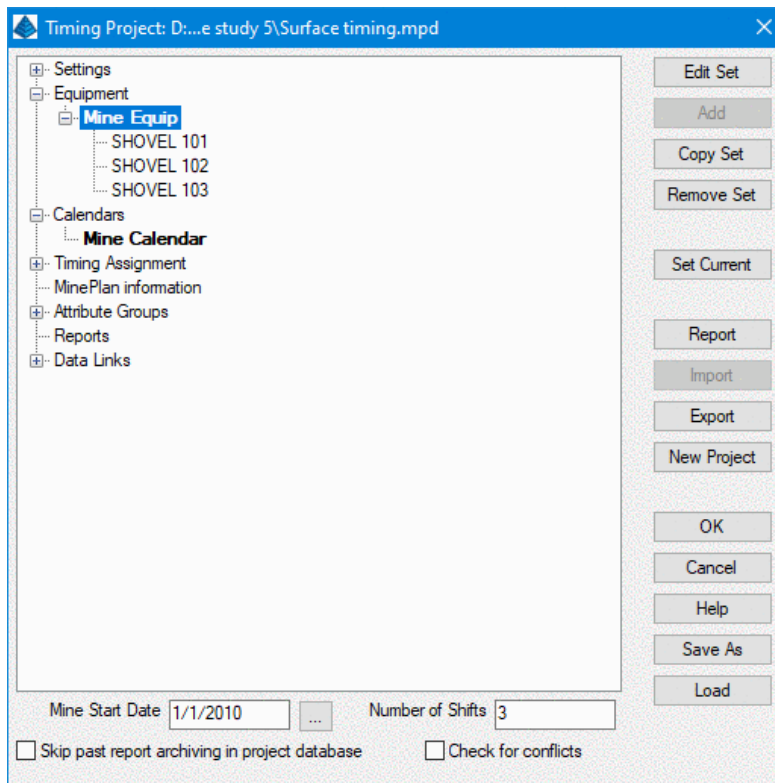

Note: Surface mine reserve command will not completely overwrite previous run. In case of recreating new bench pit, use the Clear Bench Qualities Command to clear all the information that is stored in the pit. (Surface Mining module > Boundary pull-down menu > Pit Timing Qualities Tab > Clear Bench Qualities Command)

(Surface Mining module > Boundary pull-down menu > Edit pit Command)

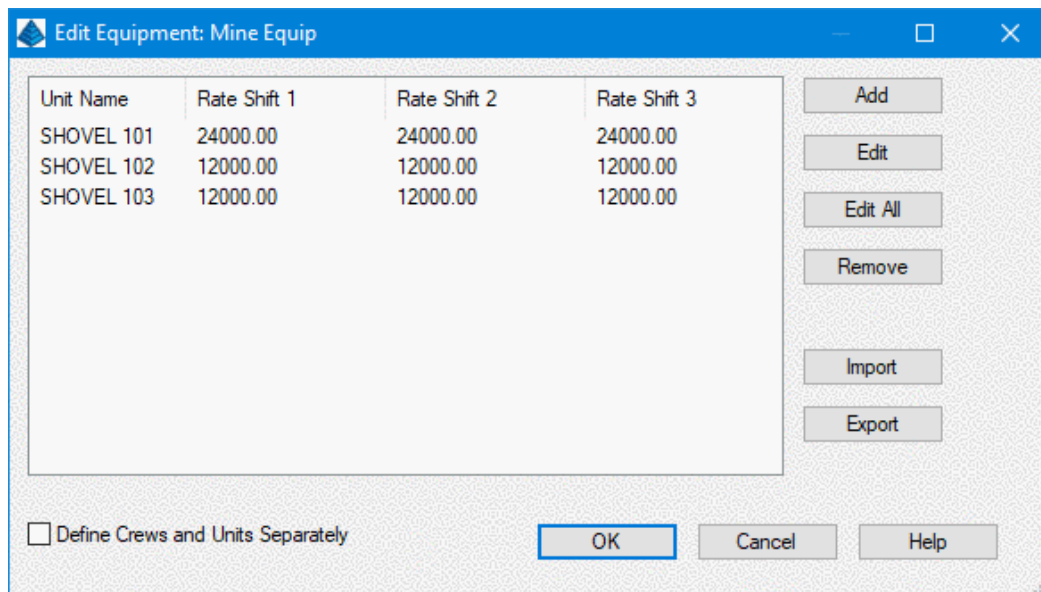

Surface Timing Project Manager (Surface Mining module > Reserve/Timing pull-down menu > Timing Project Manager Command)

The Timing Project Manager can be accessed under the Reserves/Timing pull-down menu. It allows user to define Equipment, Timing Calendar, and Pit Attributes as well as other essential parameters to be used in the timing.

Define Equipment

Select the Edit Set in Project Manager to create an equipment definition to mine the pits. This example will use three shovels. This command shows a list of existing equipment definitions. Choose the Add button and fill out the dialog as shown below for a three shift operation for all shovels. Shovel1 mines 24000 CY/shift and Shovel 2 and Shovel3 mines 12000 CY/Shift.

Equipment Production Rate

Define Calendar

The next step is to define the calendar. By default, both units are working every day, every shift. It is your job to take off holidays, weekends, and maintenance down time. Select a date and press apply to schedule downtime.

Editing Calendar: Mine Calendar

Surface Equipment Timing

(Surface Mining module > Reserve/Timing pull-down menu > Surface Equipment Timing Command)

The Surface Equipment Timing command schedules the equipment through the pits. The first dialog shows three list boxes for the equipment, the pits assigned to the equipment and the unassigned pits. The pit benches are listed

as site name - pit name - bench number. For example, "Site 1-Pit 1-2" is for bench 2 in pit 1. To set the equipment to use, choose the Add Equip button and select the equipment name defined in the last step.

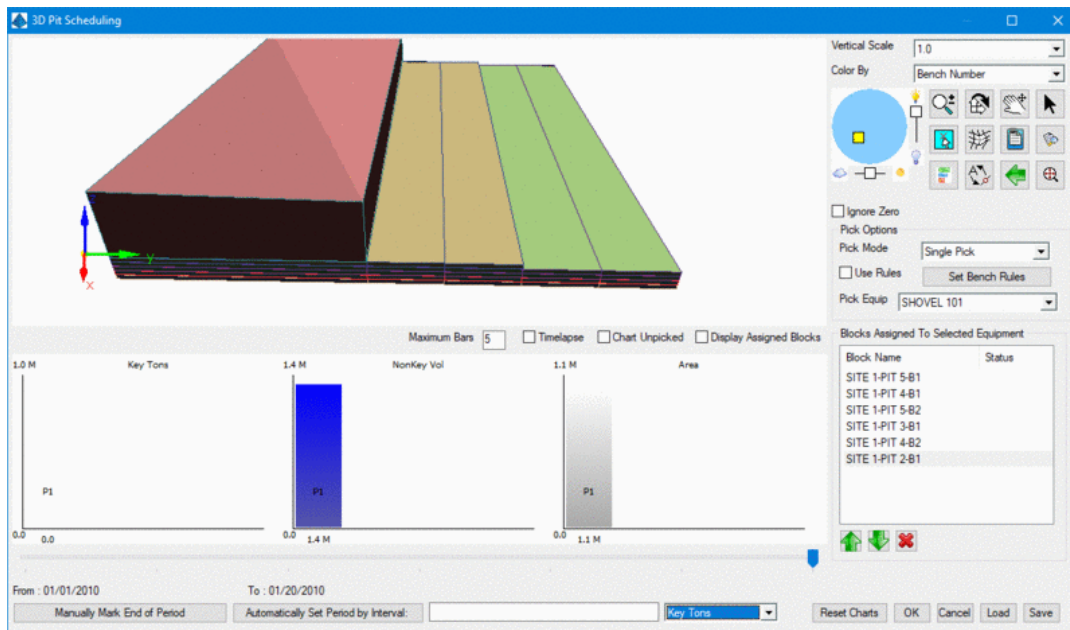

The sequence of mining the pit benches must be assigned. In this case, we want a 5-step staircase that advances through the pits. By default the pit benches are sorted in the unassigned list by pit number then bench number. To arrange the pit benches in the staircase order, choose the Sort dropdown list and select 5-Bench Staircase. Then pick the Select button followed by the Assign button. This will assign the pit benches to the equipment in staircase order. In this example, just manually select the first pit/bench, and holding the CTRL button down, select every other one. Then hit Assign, assigning them to Shovel1. Then highlight Shovel2, hit Select All, and assign the remaining pits/benches to Shovel2.

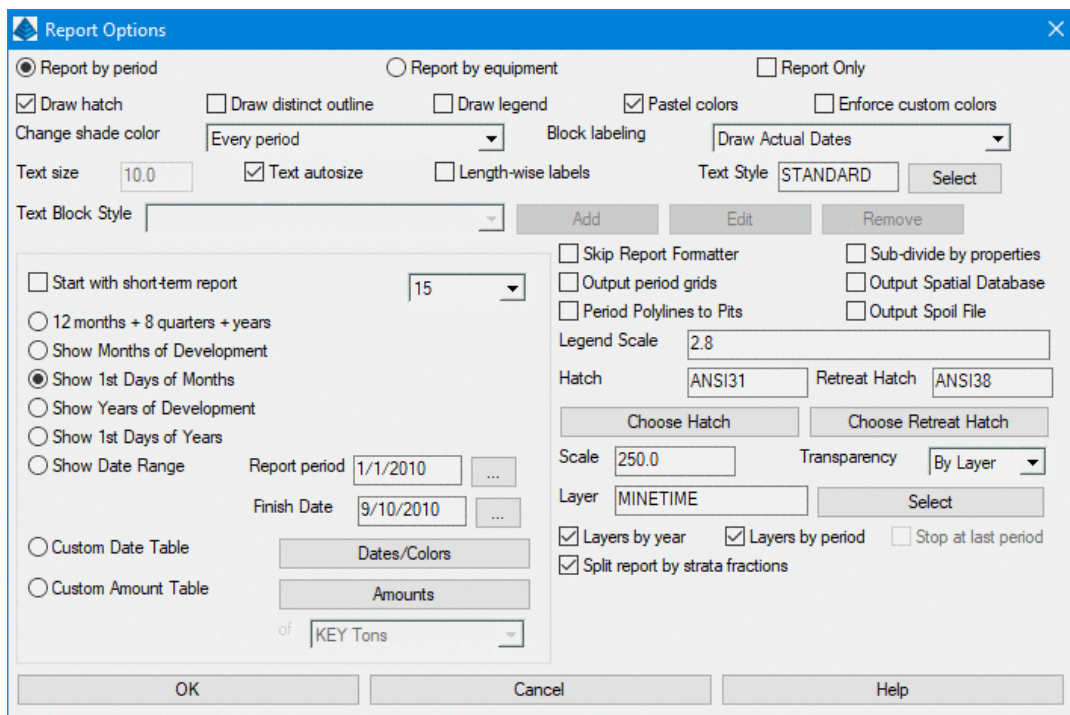

Shown above are 6 profiles of the bench pits. They have been manually connected with polylines and the pits and benches are labeled to show the "blocks". This is to illustrate the real bench width in cross section view. The lower graphic shows this profile exaggerated and numbered exactly as each block is going to be sequenced in the 5 bench staircase method. The sequencer automatically sorts them in this order.

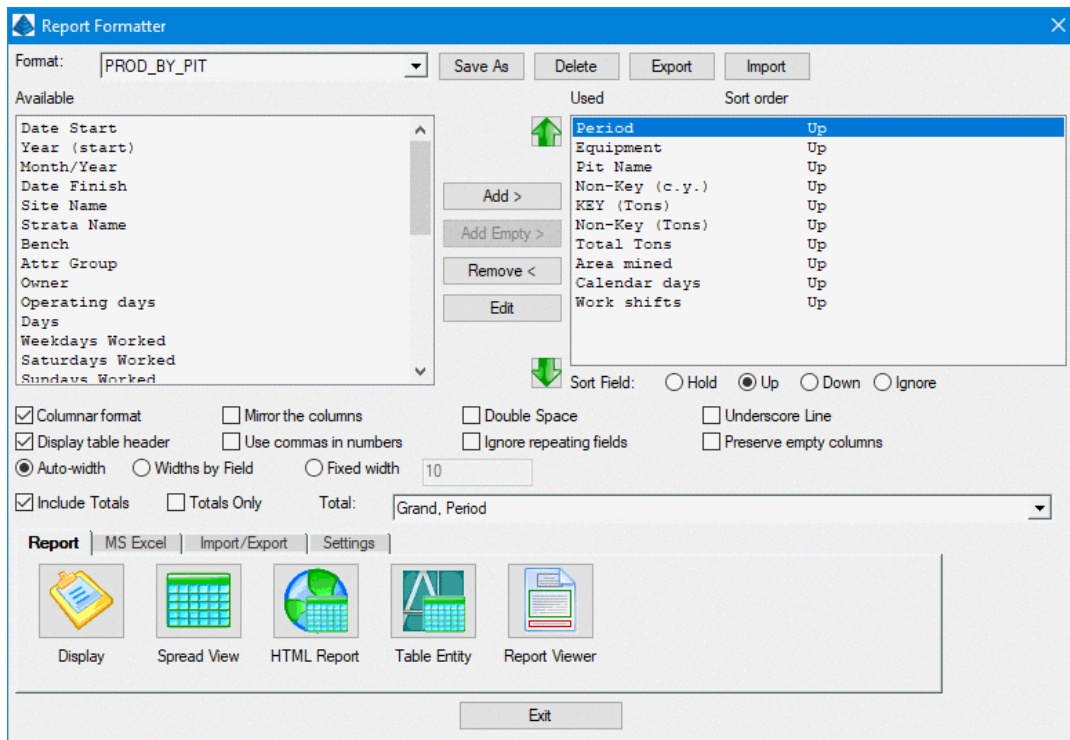

The 3D Pick option can be used to graphically select each bench and pit in the order to be mined. It is very useful for short-term scheduling. Just select 3D Pick, rotate it to an useful 3D view and then double click on each block. It will be removed and assigned to the highlighted unit.

When all the pit benches are assigned as shown in the dialog, click the Calculate button. The program will then run the equipment through the pits and report the completion date. Then click the Detailed Report button. This brings up the Report Options button.

In this case, the report period is set to Show 1st Days of Months. This will give a monthly schedule from the first of each month. Following is a report by monthly period. This can be formatted in many ways and exported to Excel.

KEY production report Mon Aug 3 14:21:34 2020

Period: 1/1/2010 - 2/1/2010

Multi-Bench Mining Example Setup:

The defining of equipment, crews and equipment calendar are (potentially) one-time operations. Similarly, the making of the Geologic Model needs be done only once in advance of numerous timing runs. Surface Equipment Timing, also distinct from Surface Production Timing, allows multi-bench mining by use of different equipment or the same equipment mining different benches, with different production rates. Since single-bench mining is a subset of multi-bench mining, this will illustrate the command with a multi-bench example. Surface Mine Reserves

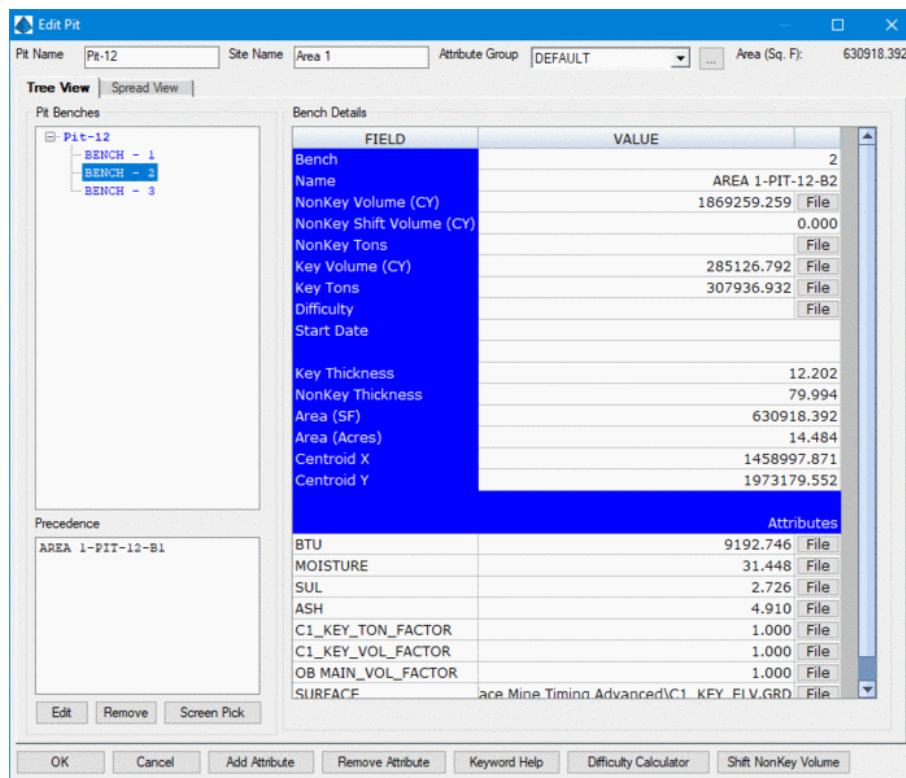

is one of three methods to place quantity and quality information into the pits, by bench. This example will use Surface Mine Reserves. If there are two benches, Surface Mine Reserves must be run twice, one time for each bench. The dialog within Surface Mine Reserves should be completed as follows for Bench 1:

The key is to choose "Selected" strata (for benching) as well as "Store Results in Pits". You should also select "Calculate Strata Qualities" to assign quality information to the pits. If single-bench mining is conducted, you may omit the "Selected" option. Other items in the dialog are set according to user preference. Note the option "Output Thickness Grids". If this is not selected, total quantity and composited quality information is placed in the pits, and mining across a single pit is proportional. However, if the "Make Thickness Grids" option is selected, mining across the pits picks up the varying of the overburden thickness, coal thickness and quality information. For small pits or "blocks" as they are sometimes called, storage of total information will still lead to reliable results. Thickness grids are recommended for large and long pits, where the thickness will vary. The choice of "Selected" strata requires that the user select which strata will be mined in Bench 1. The following Choose Strata dialog at will appear:

Holding the CTRL or SHIFT keys, select Overburden and C1 to mine down to the bottom of the first coal (C1). Bench 2 would be comprised of Parting and C2. Following two runs of Surface Mine Reserves, new information has been added to the pits. Pits contain up to three categories of information: pit name (verified by using "Identify Pit Polylines"), pit direction, and pit quantities/qualities organized by bench. Pit quantities and qualities are needed only for Surface Equipment Timing, and can be verified using the command "Edit Pit". For example, the information in Edit Pit is shown below. Select the "Attribute" option to reveal the quality attributes.

You will note that Bench 2 has Bench 1 as a "precedence" bench. In other words, you cannot mine Bench 2 unless

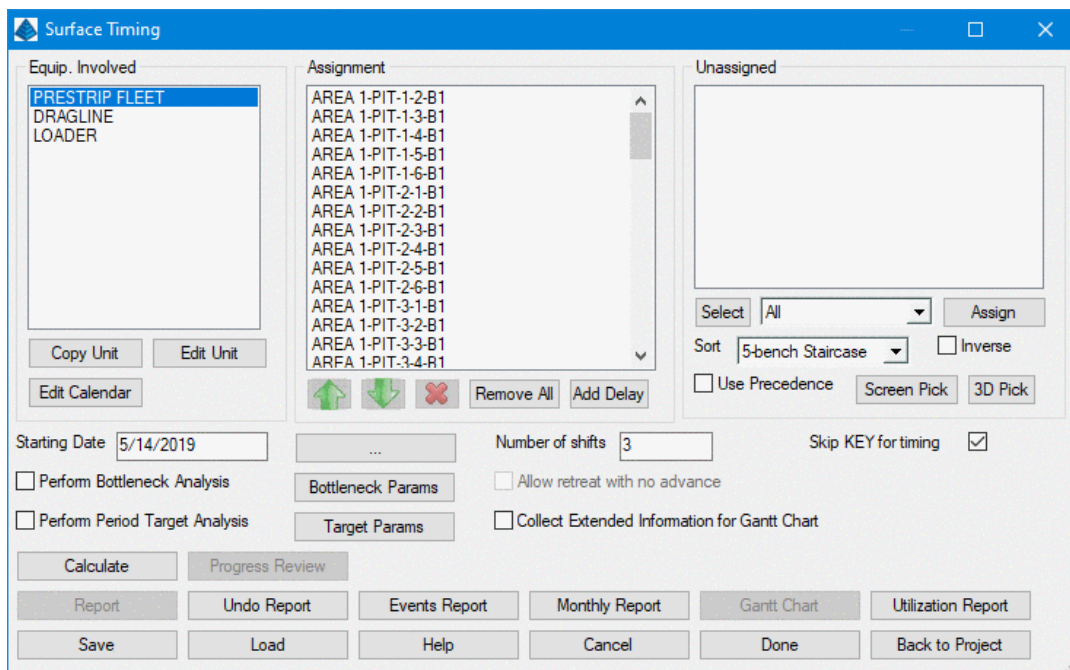

you first mine Bench 1. Lower benches are automatically set to require prior mining of upper benches (The ordering of the mining comes later!). The Pit Attributes show any attributes set by Define Pit Attributes. Some may be seen above.

Assuming that a calendar has been established (multiple calendars can be saved and recalled), and assuming that equipment has been defined, we are now ready for Surface Equipment Timing. In our three-bench mine, we will use one piece of equipment for the prestrip and different piece of equipment for the lower bench (parting).

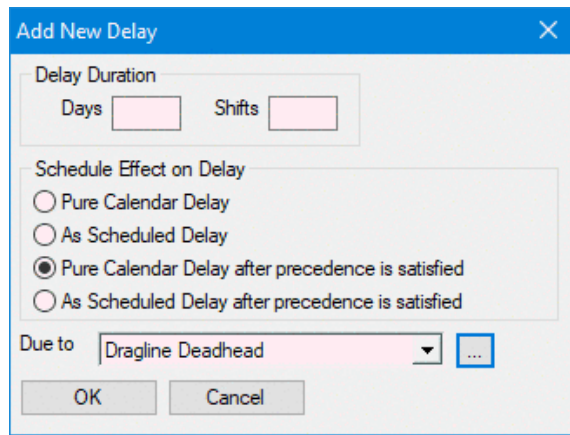

Technically, separate equipment would probably be used to remove the coal, but in this example, the coal is not included in the schedule quantities, just uncovered reporting. In fact, a 4-bench mine could be set up that considers each of the two coal seams as separate benches. In reality, however, the overburden and parting removal rate will typically govern the overall progress of the mining. When "Add Unit" is selected, the following dialog appears.

Select the equipment and add them one at a time. The draglines used here are defined based on three 8 hour shifts. The "Availability" option can be used to de-rate the mining speed in the Edit Equipment. Any of the above items can be revised from within Surface Equipment Timing. The next step is to assign "Dragline" to Bench 2. It is best to Sort by "Bench, Pit" and then Select "Bench 2", using the options at middle right in the Surface Timing Dialog.

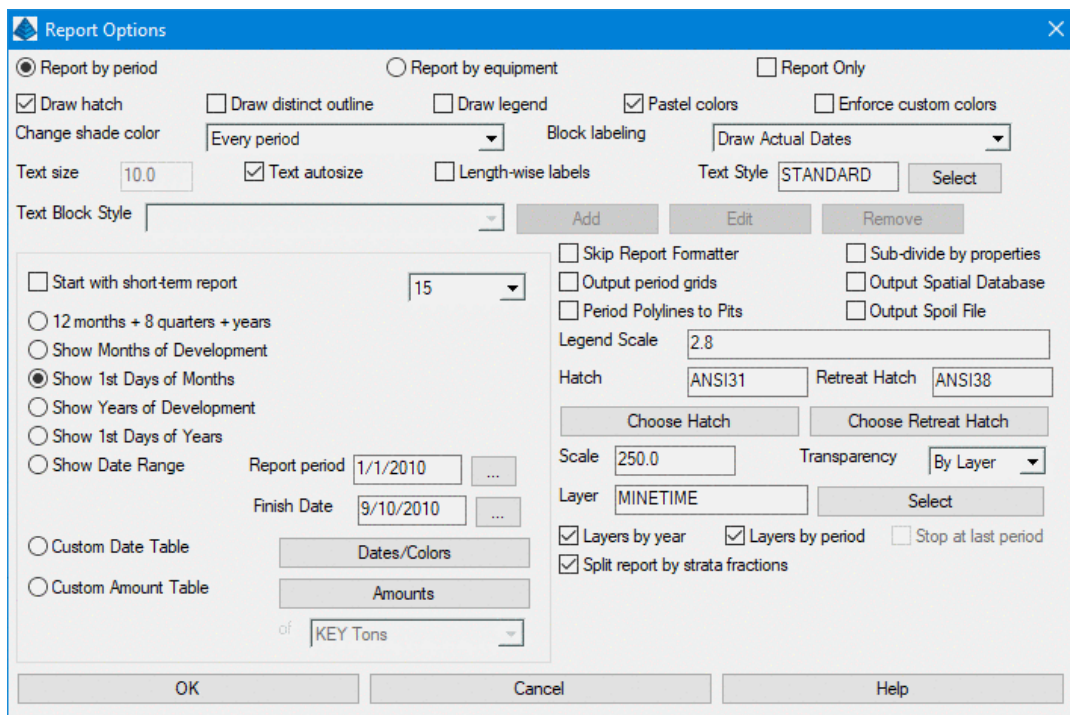

Also, assign all the Bench 3 to loader. These leads to the following appearance:

It is also important to note the option "Skip Coal for timing" at the lower right of the dialog box. Here you can base all progress on the NonKey overburden and parting only, on the assumption that the loaders or other equipment digging the coal will "keep pace" with the equipment removing the overburden and interburden. If "Skip Coal for timing" is not selected, the coal volume will be included in the total quantity mined by the equipment. We can add a second piece of equipment, then highlight it within the Surface Timing dialog and assign all the remaining pits to it (Select All or Bench 2, then Assign). Note also that we can add a delay between completing the Bench 1 pit and beginning the Bench 2 pit. Delays are automatically inserted below the highlighted pit, so if a pit is highlighted, a delay will be added below it that can be moved up or down also. There is a dialogue to add this as a calendar or schedule delay (described below). Shown below is the assignment for Bench 2.

To complete the calculation, fill in the Starting Date (if the default is not correct), then click on Calculate. This leads to a completion date and the option of a unit report or going directly to the Report Options screen. The Unit Report is very instructive because it highlights when equipment has been idled. Our Bench 2 dragline is waiting each time for the "slower" Bench 1 dragline to complete bench 1 before it can launch into bench 2. The planner could try lower rated equipment, or reverse the assignments of the equipment, or simply re-shuffle the assignments in any desired manner to maximize efficiency. The last step is to choose "Detailed Report" when returned to the Surface Timing dialog which brings up the Report Options dialog.

This example will show the first days of months. This leads to the final hatching shown below as bench 1 (the bench 2 layers were frozen for better appearance), as well as the quantity report which can be formatted many different ways and exported to Excel or Access:

Period	Equipment	Pit Name	Site Name	Bench	Operating Days	Weekdays	Saturdays	Sundays	Work shifts	KEY (Tons)	Non-Key (Tons)	Total Tons	KEY (c.y.)	Non-Key (c.y.)

Summarized below are numerous Carlson tutorials and the (*module[s]*) they cover. If you are new to CAD (*e.g.* IntelliCAD or AutoCAD) or are starting Carlson for the first time, it is suggested you explore:

- CAD Basics (*General/All*)

As you get familiar with the basics of CAD and Carlson, numerous tutorials designed to assist you in learning the Carlson Desktop CAD product line. They are:

- Lesson 1 - Entering a Deed (*Survey*)
- Lesson 2 - Making a Plat (*Survey*)
- Lesson 3 - Field to Finish - Faster Survey Work (*Survey*)
- Lesson 4 - Intersections and Subdivisions (*Survey*)
- Lesson 5 - Contouring DTM and Design (*Civil*)
- Lesson 6 - Contour Break Lines Stockpiles (*Survey*)
- Lesson 7 - Basic Road Design with Volumes (*Civil*)
- Lesson 8 - Hydrology & Watershed Analysis (*Hydrology*)
- Lesson 9 - Dozen Tools of Surface Design (*Civil*)
- Lesson 10 - Takeoff Basics (*Construction*)
- Lesson 11 - Takeoff Drillholes and Strata (*GeoTech*)
- Lesson 12 - Trenches (*Construction, Trench*)
- Lesson 13 - Digitizing (*CADnet, Construction*)

Other tutorials of interest include:

- Cut Sheets (*Survey*)
- ESRI Office Field (*GIS, SurvCE, Survey*)
- Geodetic Reports (*Survey*)
- SurvNET Least Squares Adjustment (*Survey*)
- Calculate Volumes By 5 Methods (*Civil*)
- Road Rehab (*Civil*)
- Carlson Hydrology/Hydrocad Tutorial (*Hydro*)
- Stormwater Network Design (*Hydro*)
- Pressure Pipe Network (*Hydro*)
- PDF Section Import (*CADnet, Construction*)
- GeoTech Reports (*GeoTech*)

CAD Basics

Carlson Software's office products utilize either an AutoCAD or IntelliCAD-based CAD engine. This section will review some basics of CAD software that will be useful in running Carlson Software. Running Carlson on IntelliCAD is largely the same as running on AutoCAD.

Once installed to your computer, one or more Carlson start-up icons (based on the product[s] contained within the product serial number) will typically be placed on your computer desktop. Carlson recommends launching the software through the desktop icon so proper software initialization parameters can be set. Once the Carlson software environment has been initialized, you can choose to open an existing document type (*e.g.* an existing *.DWG file) or create a new document type (*e.g.* a new *.DWG file). Based on your desired (or established) interface settings, one of three "start-up" environments may be presented:

1. **Start Page** (IntelliCAD users) - When this environment is active (*i.e.* variable STARTMODE = On), a generic "Start Page" will be displayed with common first-time commands and the software will wait for you to generally create a New Drawing or Open Files that the CAD application supports:

- Clicking **New Drawing** will launch the Startup Wizard which provides a step-by-step process for the creation of a new, supported document type.
- Clicking **Open Files** will launch a File Selector which permits navigation to a desired folder location on your computer (and/or shared network drive, if available) which provides the ability to directly open an existing, supported document type.

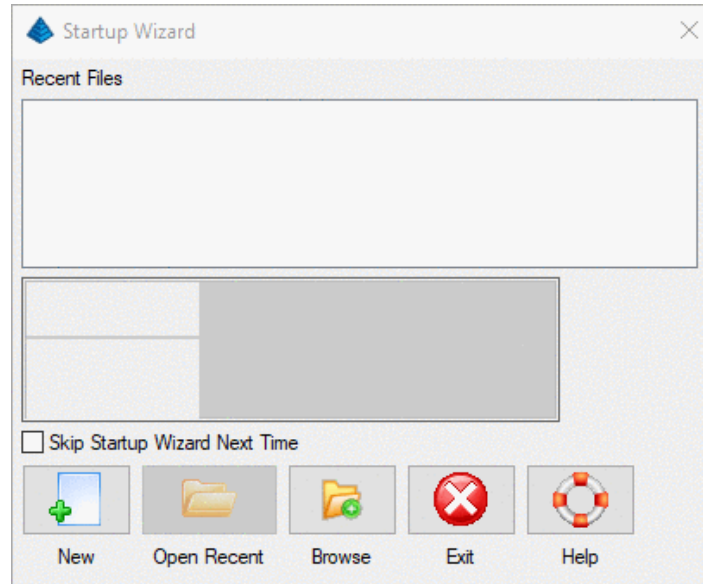

A primary benefit of the **Start Page** environment is that only the drawing(s)/documents that you choose to create or open will be in use by the application. In this fashion, when exiting from the software, you'll have the benefit of only having to save changes to documents that are open and that have changed.

NOTE: The complement of commands offered by the Carlson module(s) will not be fully loaded until at least one supported drawing document type is either created or opened.

NOTE: The "Start Page" environment can be suppressed by enabling the **Skip Start Page Next Time** toggle in the lower left corner of the "Start Page." Enabling this feature will (by default) revert to the Startup Wizard interface the next time the application is restarted. The "Start Page" environment can be re-enabled by:

- (a) Opening an existing drawing document, and,
 - (b) Keying-in **STARTMODE** into the Command: prompt, and,
 - (c) Setting the value of the variable to **On**.
2. **Startup Wizard** - When this environment is active, CAD will launch with a default drawing document (*e.g.* Drawing1.dwg) pre-loaded along with an interface with a step-by-step (*aka wizard*) approach for the creation

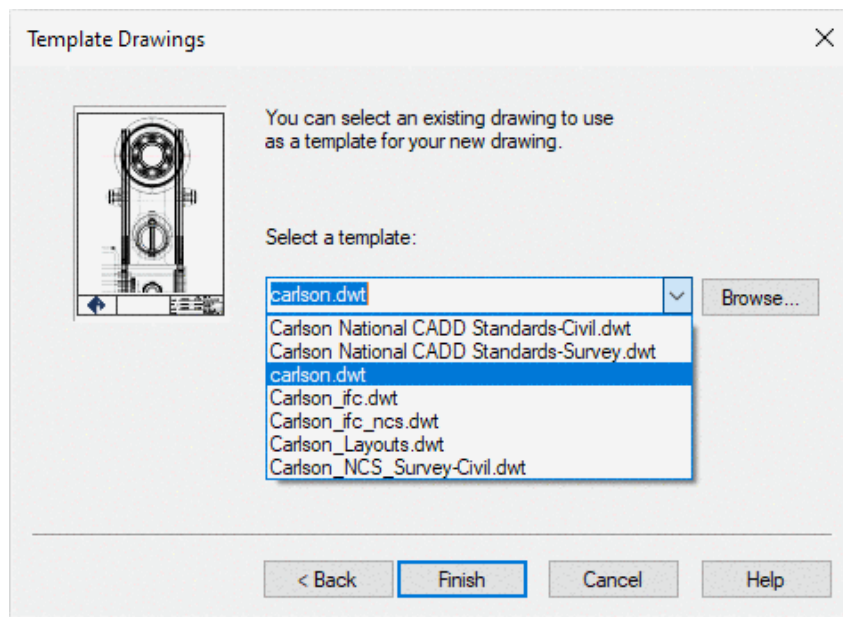

of a new drawing document type:

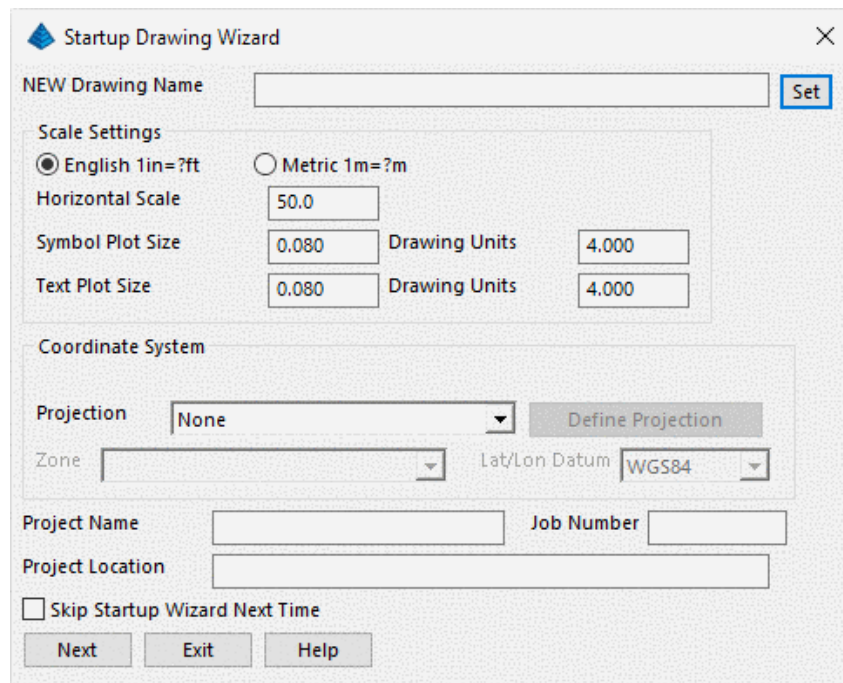

- Clicking **Browse** will launch a File Selector which permits navigation to a desired folder location on your computer (and/or shared network drive, if available) which provides the ability to directly open an existing, supported document type.
- Clicking **Open Recent** will open the currently selected/highlighted drawing document which has been previously opened by the application.
- Clicking **Exit** will dismiss the Startup Wizard dialog box and leave the default drawing document active and available for data entry.
- Clicking **New** will start the formal Startup Wizard process which generally entails the following sequence:
 - (a) Establish the desired document type (and/or source) and click **Next** >:

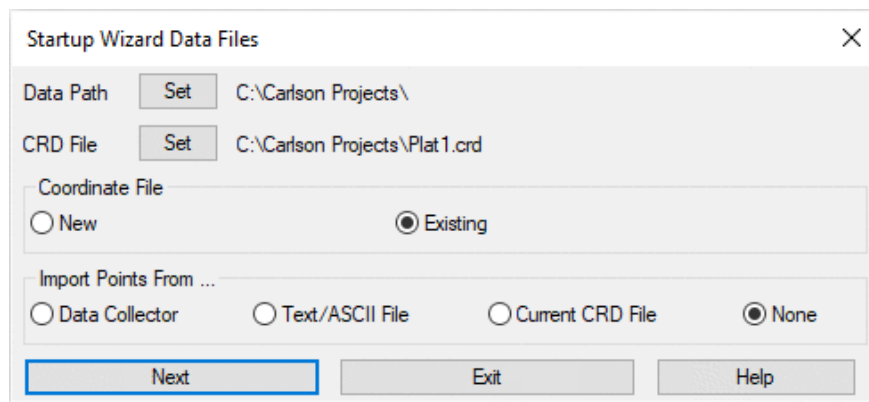

- (b) Establish the source document type (*aka* "template") and click **Finish** to launch into the drawing-specific settings:

- (c) Establish the document name (e.g. use the **Set** button to establish the desired Folder and Document name) along with expected plot scale and desired Coordinate System information as desired and click **Next** to continue with additional information:

- (d) Validate the Destination Folder and establish the related "Coordinate File" name to house designated point data and whether an existing Coordinate File (e.g. such as that created by Carlson SurvPC or SurvCE) or if a new Coordinate File should be created along with the source for any inbound Point Data and click **Next** to continue with further processing instructions (if applicable):

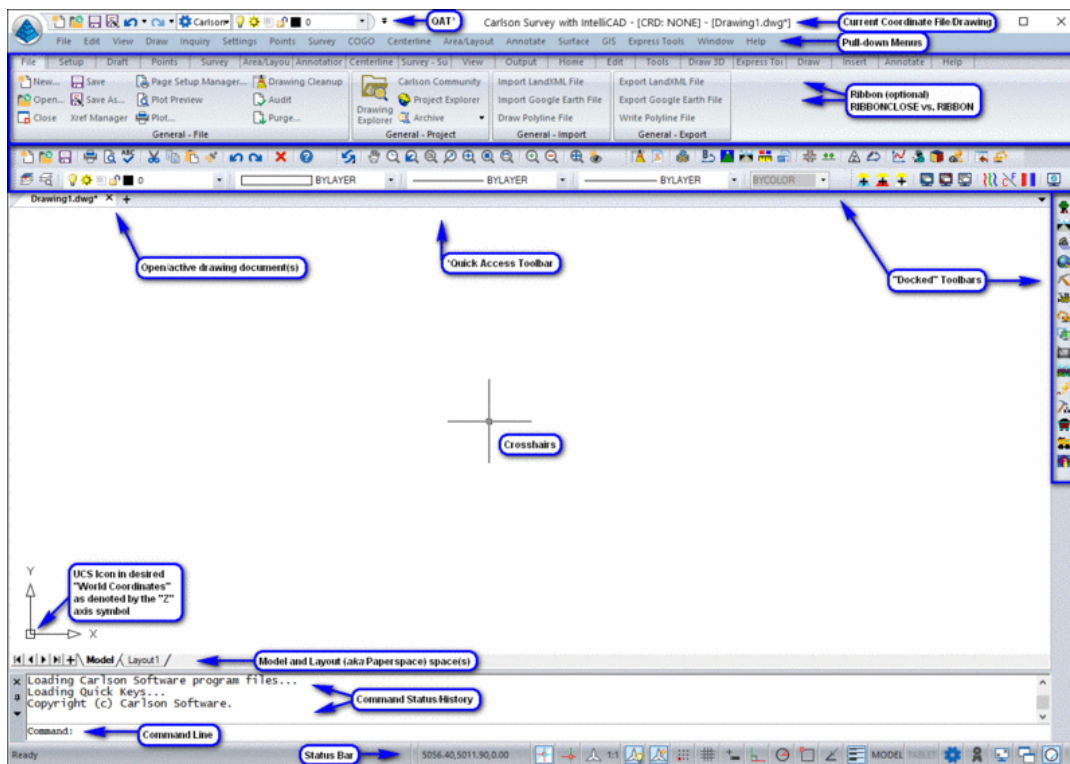

NOTE: The precise sequence of steps within the Startup Wizard will vary based on the option(s) selected within each step of the Wizard. It is recommended that the Wizard be followed to its logical conclusion and the click of a resulting **Finish** button.

NOTE: The "Startup Wizard" environment can be suppressed by enabling the **Skip Startup Wizard Next Time** toggle in the lower left corner of the opening "Startup Wizard" dialog box or the tertiary Document Setup Name dialog box. Enabling this feature will (by default) revert to the standard CAD interface the next time the application is restarted. The "Startup Wizard" environment can be re-enabled by:

- (a) Opening an existing drawing document, and,
 - (b) From the Settings menu, click Carlson Configure, and,
 - (c) Clicking the General Settings and enabling the **Use Startup Wizard** option.
3. **Standard CAD** - When this environment is active, the CAD application starts with a default document name (e.g. Drawing1.dwg) pre-loaded and ready for data entry. It is up to the user to properly save and rename the drawing document to a desired folder and file name.

When configuring the "GUI" (goeey) interface and/or effectively communicating with Carlson Technical Support, it is helpful to understand the various components, terminology and their locations within the CAD application:

Virtually all commands in CAD software have three or more ways they can be initiated. The two most common are

through the Pull-down Menus and the Toolbars, but the persons who are comfortable with the "Ribbon" interface or Command line interface (for quick keystroke entry) have various options available to them. Using the Menus and Toolbars should be second nature to Windows users, so this section will mainly focus on the Command line usage in CAD.

Command Line Prompt (Command:)

CAD softwares have a Command line prompt where commands are issued and the status of a command is reported. When you select a command from a menu or toolbar, that key-in command name is sent to the Command line and is executed. When a command is issued, the Command line acts as a status bar that will show the available options and prompt for input from you (either in the form of Command line options and/or a dialog box).

Before most commands can begin, all other commands must be terminated. The exceptions are referred to as Transparent commands. The easiest way to see if no commands are running is to look at the Command line. If it displays "Command:" no commands are currently in progress.

Enter

When you are required to press the Enter key in CAD, you can use the Enter key on the keyboard or you can press the spacebar or click the right mouse button.

Pressing the Enter key will perform different operations depending on your location within a command:

- If you are in the process of running a command which has no sub-options, the Enter key will end the command.
- If you are in the process of running a command which has sub-options and a desired sub-option other than the default option has not been specified, the Enter key will initiate the default sub-option (the option between the < > characters).
- If you are in the process of running a command which has sub-options and you wish to exercise a sub-option other than the default, left-click the desired sub-option or type the Capitalized character(s) (not case-sensitive) and press Enter.
- If you are in the process of selecting entities for a desired action, the Enter action will complete the current selection method and a second Enter will initiate the command on the selected entity(ies).

To avoid any problems with using the above methods to end a command, you can press the Escape key (**Esc**) as described below.

Repeating Commands

When you press the Enter key (or its equivalents) at the Command: prompt without a command running, you will repeat the last command.

Right Mouse Button

As mentioned above, the right mouse button can be used as Enter. However, you can set the right mouse button to perform different functions as well. When so configured, a right mouse may provide a context-sensitive list of commands and can select the desired one (*e.g.* Move the cursor the desired option and click on it with the left mouse button).

Canceling a Command (Esc)

The Escape key (**ESC**) key can be used to cancel any command. Some commands (such as Transparent commands) may require pressing the Escape key more than once.

For example, if the command line displays something other than Command: or if a command you want to run does not start because you are using another command, you will want to end the command and return to the command prompt. Using the Escape (Esc) key will accomplish this every time.

NOTE: If you accidentally left-click a location on the screen and start a selection window, the command prompt will prompt for another corner. Either select another point on the screen to finish the selection (not advised) or press the **Esc** key to return to the Command: prompt.

Undo

Undo reverses the effect of the previous command. Type **U** or use the shortcut **Ctrl+Z** to run Undo.

Redo

Redo reverses an UNDO command. You must use the UNDO command before you can use the REDO command. Type **REDO** or use the shortcut **Ctrl+Y** to run Redo.

NOTE: Panning and Zooming is made easy if your mouse has a center wheel. You can use it to zoom in and out by rolling the mouse wheel up or down. By holding the center wheel down on the mouse, you can pan in any direction.

Pan

Press and hold the middle (wheel) button of a 3-button mouse and drag the view to the desired location. Alternatively, type **P** for a transparent Pan then click and hold the left-button of the mouse on the point from which you want to move the display. Drag the mouse to the desired area, then release the mouse.

Zoom

Typing **Z** for Zoom will give you several options: To specify the scale, enter the magnification value. To zoom in, choose In. To zoom out, choose Out. To display the entire drawing, choose All. To view a window defined by a center point and the magnification value or height, choose Center. To display the drawing extents, choose Extents. To view a window by selecting the desired area in the drawing, choose Dynamic. To view a window defined by the left point and the magnification value or height, choose Left. To return to the previous display, choose Previous. To view a window defined by the right point and the magnification value or height, choose Right. To view a window defined by specifying two (opposite) corners, choose Window.

Transparent Commands

Several commands in CAD software can be run transparently. This means that they can be performed while another command is running. For example, if you are in a command and are trying to select something in the drawing but it is too small to see, you can use the zoom command transparently. Zoom to the area where the object is, then select the object without ending the initial command. The most commonly used commands are the View commands of Zoom and Pan, and the Properties commands including the Layer dialog box.

To issue a transparent command, type an ' (apostrophe) before the command name. For example, **'Z** would be Transparent Zoom. Note that many commands will automatically be assumed to be transparent if they are issued from the toolbar while another command is running.

When you are in a command that is running transparently, this will be indicated with a >> at the far left of the command line preceding any options or other text. When a transparent command is complete, you will return to the command you were previously running. If you are in a transparent command and want to end the command to get back to the command prompt, you will need to press the **Esc** key twice.

NOTE: If you select a View command while running another command, the other command will not end. You will be running the View command transparently. This is one of the exceptions to the rules for ending a command. If you do not want to run the View command transparently, you need to complete the other command or end it by pressing the **Esc** key.

Command Sub-options

The Command line changes as a command is running. When there are options available for the command you are running, they will display at the Command line with capital letters in the option name. To use one of the options, type the capital letter(s) at the prompt (but know that these "accelerators" are case-insensitive).

For example, if you issue the Zoom command, the Command prompt will typically show sub-options of *[In/Out/All/Center/Dynamic/Extents/Left/Previous/Right/Window/ENtity/Scale]<Scale (nX/nXP)>*:

To select the Dynamic option, type **D** (or **d**) at the Command line, then press the Enter key. If you do not input an option and press Enter, you will be selecting the option that appears between the < > brackets. For the example shown above, that is the Zoom – Scale option.

Most commands in CAD software require the selection of objects. When you need to select objects, the command line will prompt **Select objects:** (or **[FILter]/<Select entities ...>**: in IntelliCAD) . When you are at this prompt, your next step will be to create a selection set. While creating the selection set, the prompt **Select Objects:** repeats and you can continue to select objects until you press the Enter key, at which time the command you are using will continue and use the objects selected.

Selection Sets

There are several ways to create a selection set from the **Select objects:** prompt. With all selection methods, the number of objects selected will be displayed in the Command line along with any objects that were duplicated. Following are the most commonly used methods for creating a selection set:

Single

A single selection is made when you move the object selection target to an object on the screen and click on it. The selected object will highlight and the **Select objects:** prompt will return. The cursor changes to a small square when the Command line displays **Select objects:**.

Window

A Window will select all objects completely inside of the rectangle drawn. Create a window by selecting a point on the view screen and then moving the cursor right. The window will display as a solid rectangle. You can also create a window by typing **W** at the **Select objects:** prompt. In this case, the direction of the window creation does not matter.

Crossing

A crossing will select all objects within the rectangle as well as those touched by the rectangle. If you select a point on the view screen and move the cursor to the left, you are creating a crossing. The crossing will display as a dashed rectangle. You can force a crossing by typing **C** at the **Select objects:** prompt, allowing you to move the cursor to the right and create the crossing.

Previous

After you select several objects, they will be temporarily stored as a selection set. Should you want to re-use the same objects that were selected by the last command for a different command, you can generally type **P** at the **Select objects:** prompt.

Remove

If you select incorrect objects, you can type **R** to remove objects from the selection set. When you are in Remove mode, the prompt will be **Remove objects:**. Click on the objects that you do not want to include in your selection. To return to select (or "add" mode), type **A** at the Command line.

Snaps

When creating geometry, it is often desirable to locate aspects of the new geometry piece to the precise location of key-points of an existing piece of geometry (*i.e.* setting the endpoint of one line to the midpoint of another line). This can be accomplished through the use of *entity snaps* (object snaps in AutoCAD). Desired snaps can be turned on to be available all the time (through the status bar area of the GUI or via the **F3** function key) or issued within a command through a key-in of the first three letters of the snap (*e.g.* **end**point, **mid**point, **near**est, **int**ersection, **per**pendicular, *etc*).

Grips

Objects may also be selected before issuing the command and receiving the **Select objects:** prompt. This selection will turn on CAD grips. Grips appear as small blue squares (*aka* "cool grips") in the drawing. All objects with grips will be used when a command is issued. Grips are turned on similar to selecting objects as described in the previous section, but with the command line at the **Command:** prompt, not the **Select Objects:** prompt. You can select single objects by clicking on an object with the standard cursor or you can select multiple objects by clicking in the view where there are no objects, then creating the window (right) or crossing (left). To remove grips, press the **Esc** key twice.

Using Grips

Grips can also be used to edit or change the location of objects in the drawing. Move your cursor to a grip and click. You should notice the cursor snap to the grip. The grip will turn from blue to red (*aka* a "hot grip"). The object grip is now attached to the cursor so you can move the object to the desired location and release it by clicking again.

Layers (and pertinent layer properties) define how an object in CAD is organized and/or displayed. One of the most common properties is the Layer. Layers can be turned off or frozen so the objects on that layer are hidden from the view of the drawing. Layers that are turned off can still be selected while frozen layers are essentially removed from the working set of the drawing. After layers are turned off or on, a redraw (which is done automatically) will update the view. A redraw of a file is a rather quick process. After a frozen layer is thawed, a regeneration may be required to update the view. Regenerations on large files may take a considerable amount of time depending on your hardware.

If this toolbar (or any toolbar) is not displayed, you can open it using the Toolbars dialog box. Type **toolbar** at the Command line or right-click on an existing toolbar for toolbar options. Common usage of this toolbar includes:

Common Name	Key-in	Toolbar	Description
Set Current	SETLAYER		<p>The "MOLC" (Make Object Layer Current) button permits you to select an existing entity in the drawing which makes the layer of the selected entity current. The current layer will be the one shown in the Layer drop list box. You can change the current layer by selecting the desired current layer from the drop list. Finally, you can highlight a layer in the Layer dialog box and click on the Current button to make the highlighted layer current.</p>
Layer	LA		<p>The Layer dialog box provides control of the drawing layers. You can turn layers on, off, freeze or thaw them, change the layer color and linetype, set the current layer, add new layers, delete layers, <i>etc.</i> To perform any of these functions, click on the Layers button. In the Layer dialog box, you can highlight several individual layers to perform actions on at once by holding down the Control key and clicking on the desired layers. You can also highlight a continuous range of layers by highlighting one layer, holding down the Shift key, and clicking on another layer. All layers between the two will be selected. To select all of the layers, hold down the CTRL key and press A on the keyboard. You cannot freeze the current layer, but you can turn that layer off (not recommended).</p>
Current Layer	-na-		<p>The Current Layer is the layer that you are on and will be working with. The Current Layer is the one shown in the Layer drop list. For example, in the above toolbar illustration, the Current Layer is PNTS. When you click on the</p>

For additional assistance on general CAD software basics, please consult the Introduction section of the Carlson documentation or visit our **Knowledge Base** at www.carlsonsw.com/support/knowledge-base/.

Entering a Deed

<<<<<<<< .mine

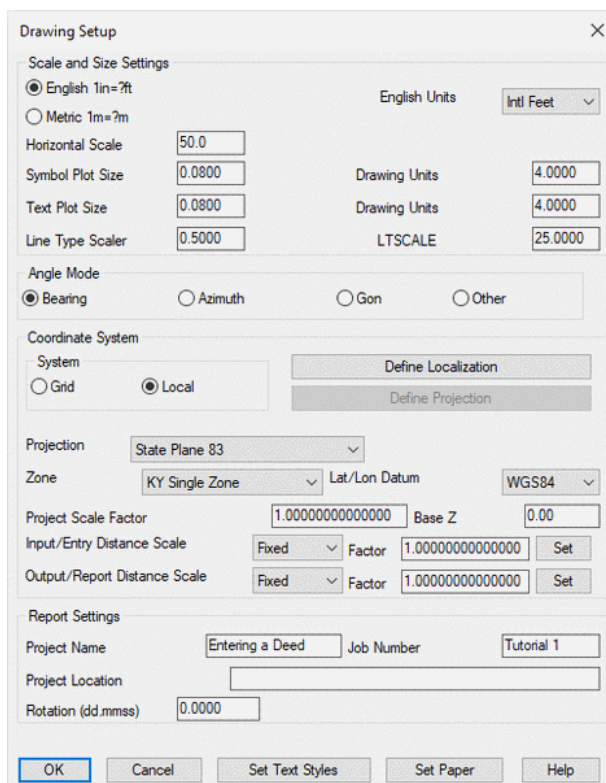

In this short lesson you will create a simple drawing. You will enter a 6-sided deed, add a title block, bar scale, and north arrow, add a title and certification text, and plot the deed area.

Note that the Esc key will cancel most commands, so if you choose the wrong command or enter something incorrectly and want to start over, just press Esc.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the **Exit** button.
 - If you are taken directly into CAD, continue as is.

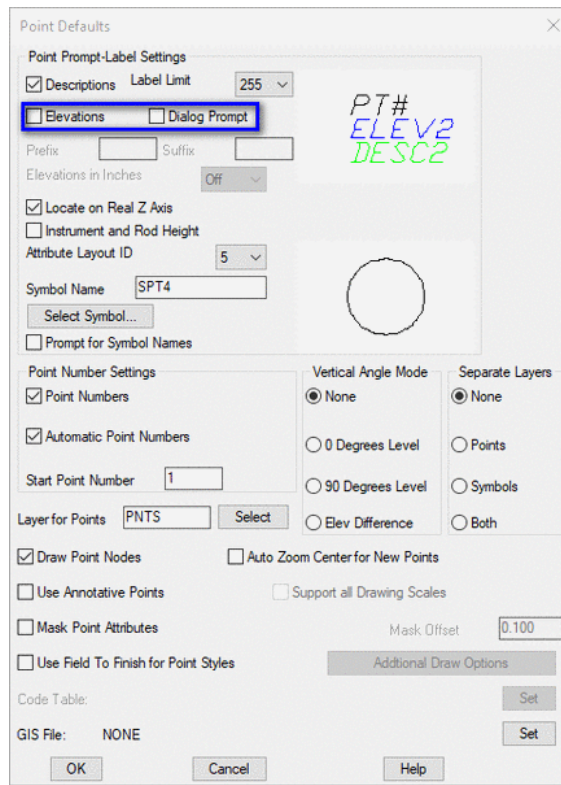

Verify the Survey module is loaded by clicking Settings – Carlson Menus – Survey Menu.

2. Issue the Settings – Drawing Setup to display a dialog box similar to that shown below:

Set the unit setting to **English** and the **Horizontal Scale** to **50**. Match other settings as desired and as shown below and click **OK**.

3. Issue the Points – Point Defaults command and perform the following:
 - Clear the Elevations toggle to eliminate the Elevation prompt, and,
 - Enable the Descriptions toggle, and,
 - Use the Select Symbol button to set the Point Symbol name to symbol 4 (SPT4), which is the open circle, and,
 - Enable the Automatic Point Numbering toggle, and,
 - Match other settings as desired and as shown below and click **OK**.

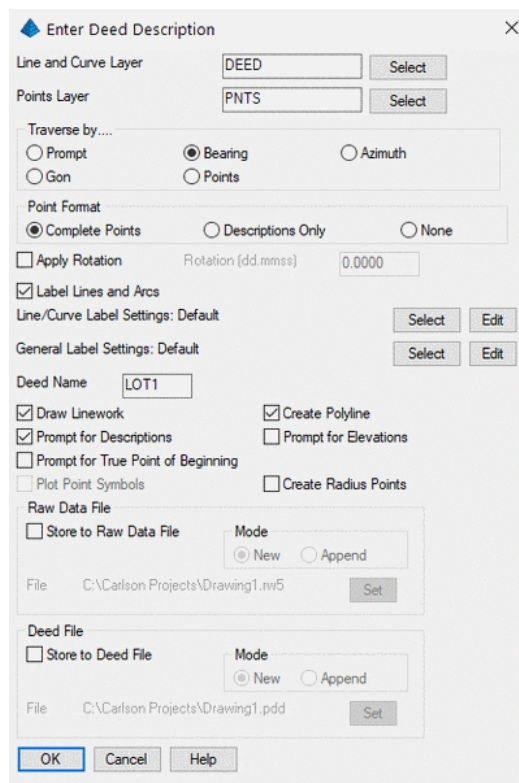

- Issue the Survey – Enter Deed Description. The following dialog box will appear so you can specify where to store the coordinates:

Select the **New** tab and set the file name as shown above which will externally house any collected or computed point locations.

- Utilize the default settings as shown below in the dialog box image:

Review and click **OK** when ready. When prompted at the Command line:

Pick point or point number: Left mouse click a point in the lower left quadrant of your screen to start the deed plotting.

Enter Point Description <>: respond with **Fence Post** and press Enter.

With our Point of Beginning established, supply the additional course information cited below:

125.3500

The quadrant (Q) is 1 for Northeast (2 is Southeast, 3 is Southwest and 4 is Northwest). The bearing is 25 degrees, 35 minutes, and 00 seconds.

If all digits for the minutes and seconds are entered as shown above, then the deed call will be fully plotted, including the seconds. If only the degrees and minutes were entered (as in 125.35), then the plot would appear as "N 25° 35' E".

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

200.51

Note that you can enter old deeds in the forms of Poles and Links, Chains and Links and even Varas (a unit of measurement formerly used in the southwestern states of the U.S.)

Enter Point Description <Fence Post>:

Iron Pin
Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<125.3500>:

189.4321

NOTE: In the data entry prompts you'll see an Undo option (*e.g.* Undo/Exit/Curve.... Pressing U for Undo would allow you to reenter the previous deed call.

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

225.00

Enter Point Description <Iron Pin>:

press Enter

Pressing Enter selects the default, which in this case is **Iron Pin**.

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<189.4321>:

press C (or c)

This initiates the Curve sub-command option.

Curvecalc/Tangent-out/<Radius>:

75

Curve direction [Left(-)/<Right(+)>]?

press Enter for right

Non-tangent/Reverse-tangent/Bearing/Chord/DeltaAng/Tangent/<Arc Len>:

118.17

If you don't know the arc length, but you know the tangent, you would choose "T" for tangent.

Enter Point Description <Iron Pin>:

press Enter

Undo/Exit/Curve/Select/Tangent/Bearing (Qdd.mmss)<c>:

200.0000

This is due South. If you were to enter just 2 (no degrees, minutes, or seconds), then the deed call would be plotted "S 000 E".

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

178.00

Enter Point Description <Iron Pin>:

Concrete Monument

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<200.0000>:

488.2300

This entry specifies Northwest 88 degrees, 23 minutes.

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

300.34

Enter Point Description <Concrete Monument>:

Fence Post

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<488.2300>:

454.1109

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

Enter Point Description <Fence Post>:

press Spacebar, then press Enter

Simply pressing Enter uses the default text (Fence Post) again. To avoid drawing the text "Fence Post" twice on the end point, press the spacebar, skip a blank character, and press Enter.

You have now completed the 6-sided figure (including one curve).

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<454.1109>:

press E

This entry specifies Exits the Deed Entry input algorithm.

Select entity for area calculation:

Graphically select the polyline representation of the deed.

Deed Description Courses

The following results are reported:

Area = 83921.758997 sq. units, Perimeter = 1128.95

SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003

ACRES: 1.9266

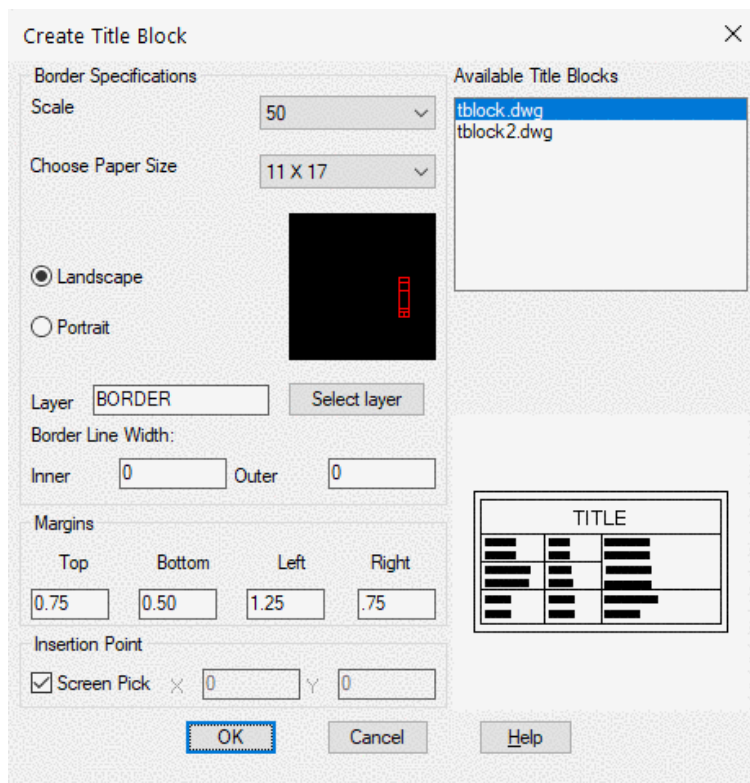

Closure error distance> 0.0171 Error Bearing> S 52°5'26" E

Closure Precision> 1 in 66076.9 Total Distance Traversed> 1128.950

The resulting deed has a closure of 1:66076.9.

Use the View – **Extents** command (key-in short-cut **ze**) to see the entire area. Then choose Zoom Out (key-in short-cut **zout**) under the View menu giving you adequate room for the next step.

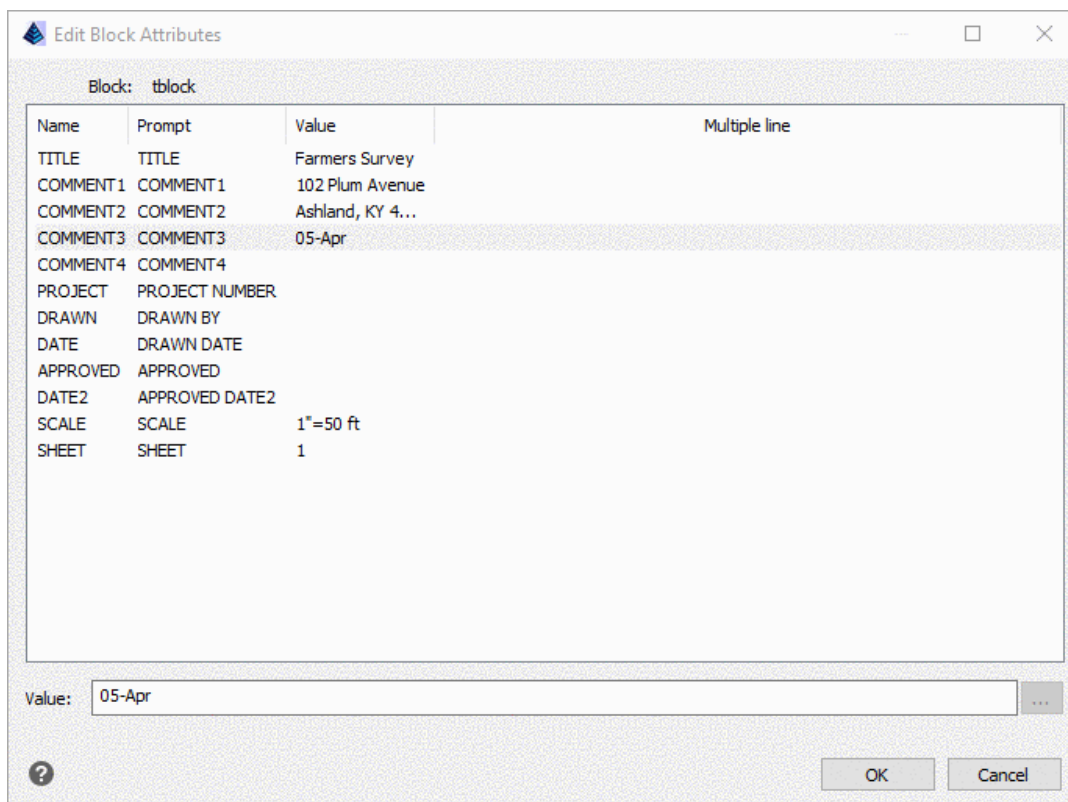

Issue the Settings – Title Block – Standard command to display a dialog box similar to that shown below:

Complete the title block entries, as shown above. Select Paper Size B2 (11 x 17), and enter the layer name of BORDER, then choose **OK** and when prompted:

Pick location: pick a point in the lower left of the survey

The following dialog appears, allowing you to enter the attributes for the *Title Block*:

Set the values as suggested above and click **OK** when ready.

NOTE: The title line is plotted in large text on the title block. Its length, therefore, should not exceed 15 characters. Your drawing should look similar to the example below at this point:

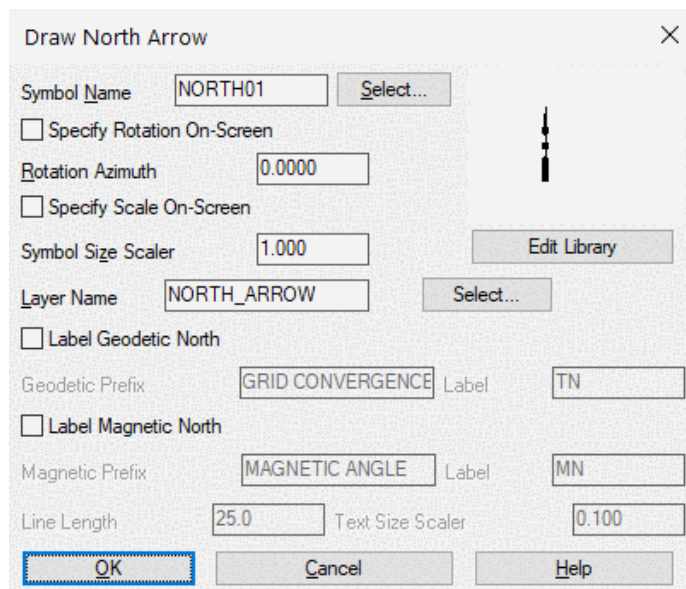

Use the View – **Extents** command to see the entire working area. If you want to move the border, use the Edit – **Move** command (keyin shortcut **M**). Pick the border lines and the title block objects (up to 3 picks total), press Enter (to end object selection), then pick two points representing the vector of the move.

If you want to see a margin around the working area after you use the Extents command, use the View – **Zoom Out** command. Then use the View – **Window** command to capture the view and margin you prefer.

If you make a mistake, enter U for Undo, or select the back arrow toolbar icon that appears at the top of the screen.

Issue the Annotate – Draw North Arrow command to display a dialog box similar to that shown below:

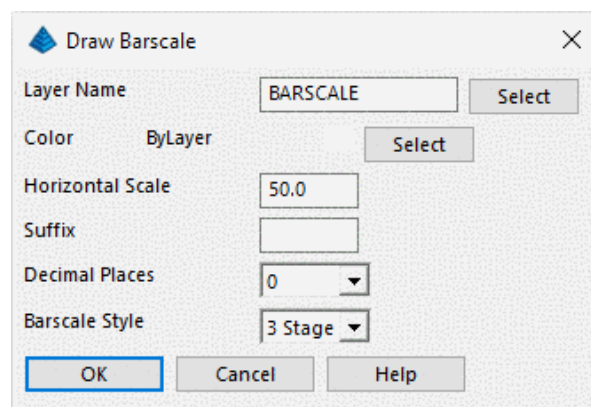

Accept the default north arrow that is shown at the right side of the dialog, click **OK**, and when prompted:

Pick insertion point: place it in the above the *Title Block* (leave enough space for the *Barscale* to follow)

If you want to reposition the North Arrow, issue the Edit – **Move** command.

Issue the Annotate – Draw Barscale to display a dialog box similar to that shown below:

Accept the defaults and click **OK** and when prompted:

Pick location for barscale: pick an insertion point below the *North Arrow* and directly above the "a" in *Farmer*, and approximately the same distance from both.

You can use the Edit – **Move** command if you want/need to re-position the barscale.

Issue the Draw – Text – **Standard** command and when prompted:

Specify start point of text or [Justify/Style]: J

Enter an option [Left/Center/Right/Align/Middle/Fit/TL/TC/TR/ML/MC/MR/BL/BC/BR]: C

Center point of text: pick a point near the top-center of the drawing

Height of text <4.00>: 10 (Entering 10 makes the title text bigger than the default).

Rotation angle of text <E>: press Enter

Text: Farmer Survey

Text: Ashland, KY

Text: press Enter

To enter a certification in the lower-right of the drawing, again select Draw – Text – **Standard** (or type "dtext" at the Command line).

NOTE: If you haven't done anything else, such as Zoom or Pan, you can simply press Enter to repeat the last command. If pressing Enter does not repeat the Text command, restart the command as suggested above and respond to the resulting prompts as shown below:

Specify start point of text or [Justify/Style]: Pick a point above and to the left of the *Title Block* for the certification. You don't have to enter L for left-justification. The DText command defaults to left-justification every time.

Height <10.00>: 4

Rotation angle <E>: press Enter

Text: Surveyor's Certification

Text: *press spacebar, then press Enter*

Text: I do hereby certify that the survey shown hereon

Text: is a true and correct representation.

Text: *press spacebar, then press Enter*

Text: -----

Text: John Doe, PLS #1234

Text: *press Enter twice to end*

Enlarge the two title lines (*i.e.* **Farmer Survey** and **Surveyor's Certification**) by a factor of 2.0 using the Edit – Text – Text Enlarge/Reduce command. When prompted:

Scaling Multiplier: type 2 and press Enter

Select Text for Scaling.

[FILter/?]/<Select entities>: pick the **Farmer Survey** text and press Enter

[FILter/?]/<Select entities>: pick the **Surveyor's Certification** text and press Enter

[FILter/?]/<Select entities>: press Enter

NOTE: When you are selecting objects, if you select something you don't want, you have the option to remove undesired entities with the (R) option.

The following is a closeup of the *North arrow*, *Bar Scale* and *Certification label* that we just entered:

Surveyor's Certification

I do hereby certify that the survey shown hereon
is a true and correct representation.

John Doe, PLS #1234

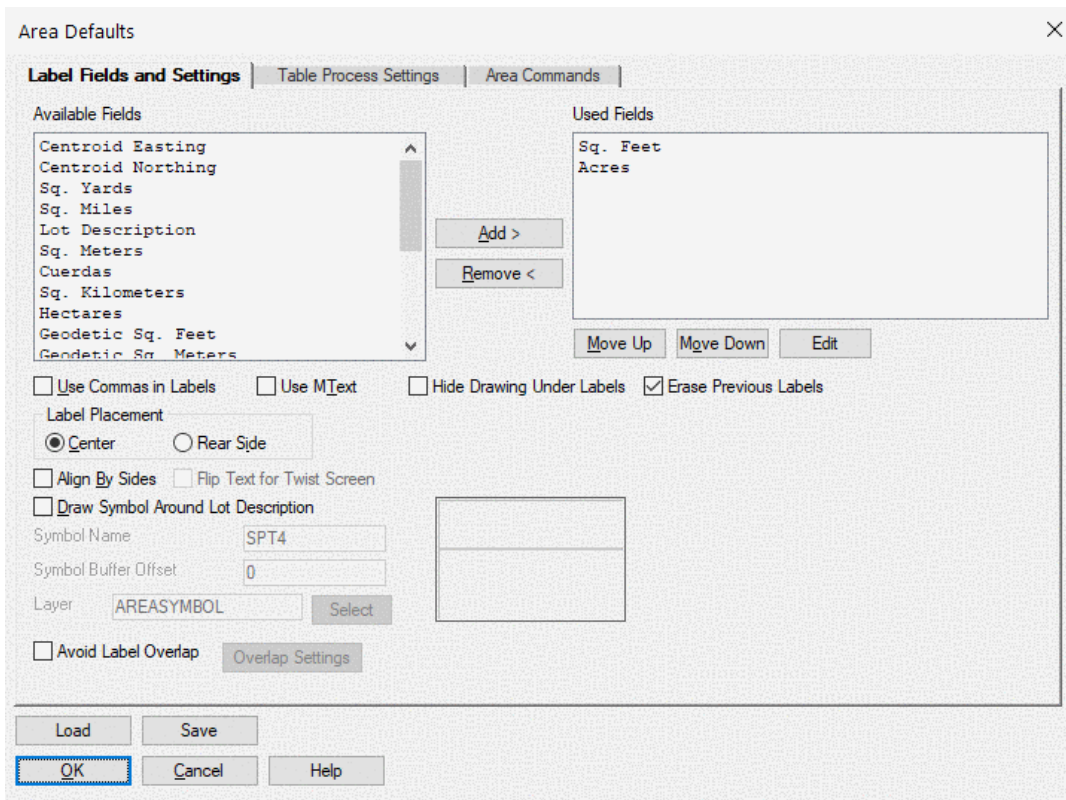

Farmers Survey		
DRAWN	DATE	102 Plum Avenue Ashland, KY 40202
APPROVED	DATE	05-Apr
SCALE 1"=50 ft	SHEET 1	PROJECT NO.

Our next task will be to refine a bearing label; click the Edit – Text – **Edit Text** command. When you are prompted:

Select Text to Edit: pick the due South bearing text of S 00°00'00" E and change it to S 00° E.

NOTE: The degree symbol in CAD *SHX* fonts is represented as `%%d`. For example, if you had typed N 15%%d25'35" E in the *DText* command, Carlson would draw that entry as N15°25'35"E. Click in the text to the immediate right of the quotation mark and press the Backspace key until the text reads "S 00%%d E and press Enter (or click **OK** if in a dialog box) to exit the command.

Prepare for area labeling by selecting the Area/Layout – Area Defaults command. The dialog box shown below appears:

Select the **Sq. Feet** item and click on the **Edit** button and make the **Area Text Size Scaler** 0.2 (doubled from the default of 0.1) as shown below. Click **OK** when complete.

Next select the **Acres** item and click on the **Edit** button. Also, make the **Area Text Size Scaler** 0.2 and click **OK** to dismiss the *Acres* dialog box and click **OK** to dismiss the *Area Defaults* dialog box.

You are going to compute the area by point number by inverting from 1 through 7 and back to 1. Select the Area/Layout – Inverse with Area and respond to the prompts as shown below:

¹
Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

2-3

Supplying a point range (separated by a dash) is very helpful when dealing with many consecutive straight-leg courses.

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

r

Point 3 is the PC of the curve so we need to find the radius point of the curve.

Radius point number or pick point:

cen

We wish to use a CENter snap.

Snap to CEN of:

pick the arc-portion of the polyline
Curve direction [Left/<Right>]?

r

Pressing Enter would have also
executed the default <Right> option.

Pick End of Arc or point number (U-Undo,Enter to end):

4

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

5-6

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

1

We are establishing the desire to
Inverse back to the starting point.

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

press Enter to end.

Inverse with Area

A Standard Report Viewer dialog box showing the *Inverse with Area* results will appear. Click the **Exit** (Doorway) button at the top of the dialog box and also note the results to the Command window:

Area = 83921.725598 sq. units, Perimeter = 1128.97
SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003
ACRES: 1.9266 PERIMETER: 1129.0
You should be prompted:

Pick area label centering point (Enter for none): Pick a point near the center of the figure, in its interior. The area units you chose in Area Defaults are labeled on the screen.

You snapped to the radius point using the manually keyed "cen" snap. Additional object snaps appear under Settings – Object Snap. Since all plotted points have a node, you could have inverted around this figure by using the "nod" snap for points 1 through 7, and the "cen" snap to capture the radius point. Snaps are typically entered at the keyboard as 3 characters (for example, "int" for intersect and "end" for endpoint).

Also, you could have chosen the Area by Lines & Arcs command. In that command, you would pick the lines and arcs that make up the figure. But since the closure was 0.017 off (the distance from point 7 to point 1), you would exceed the default Max gap tolerance. Unless you change that tolerance in the command to something larger than 0.017, you would not get a result using this method.

Freeze the point numbers to finish the drawing by choosing View – Layer Control. In the **PNTNO** row, click the Sun icon to change it to a Snowflake icon, which freezes the PNTNO layer. Click **OK**. The point numbers remain in the drawing, waiting to be "thawed", but they are not displayed.

The final drawing is shown here:

This completes the Lesson 1 tutorial: Entering a Deed.

_____ .r4440

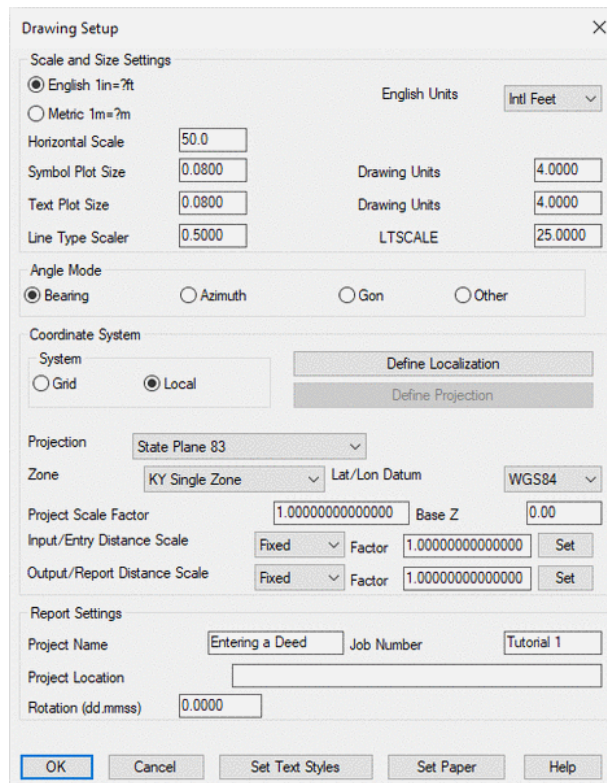

In this short lesson you will create a simple drawing. You will enter a 6-sided deed, add a title block, bar scale, and north arrow, add a title and certification text, and plot the deed area.

Note that the Esc key will cancel most commands, so if you choose the wrong command or enter something incorrectly and want to start over, just press Esc.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the **Exit** button.
 - If you are taken directly into CAD, continue as is.

Verify the Survey module is loaded by clicking Settings – Carlson Menus – Survey Menu.

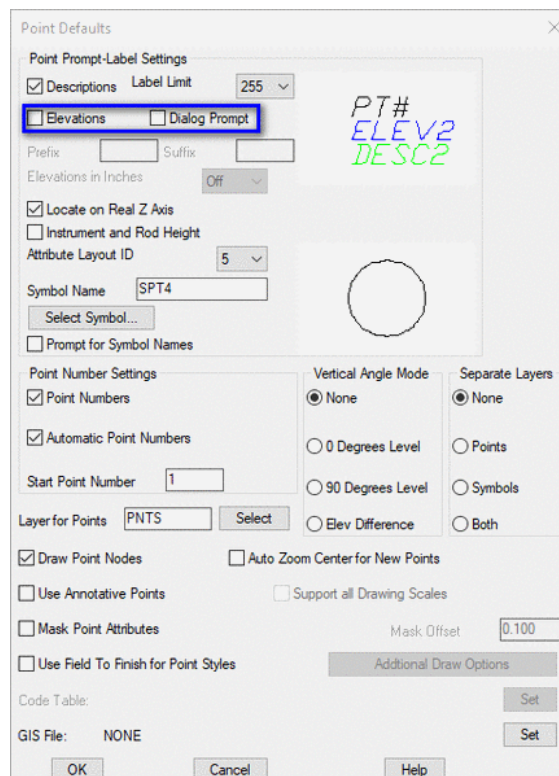

2. Issue the Settings – Drawing Setup to display a dialog box similar to that shown below:

Set the unit setting to **English** and the **Horizontal Scale** to **50**. Match other settings as desired and as shown below and click **OK**.

3. Issue the Points – Point Defaults command and perform the following:

- Clear the Elevations toggle to eliminate the Elevation prompt, and,
- Enable the Descriptions toggle, and,
- Use the Select Symbol button to set the Point Symbol name to symbol 4 (SPT4), which is the open circle, and,
- Enable the Automatic Point Numbering toggle, and,
- Match other settings as desired and as shown below and click **OK**.

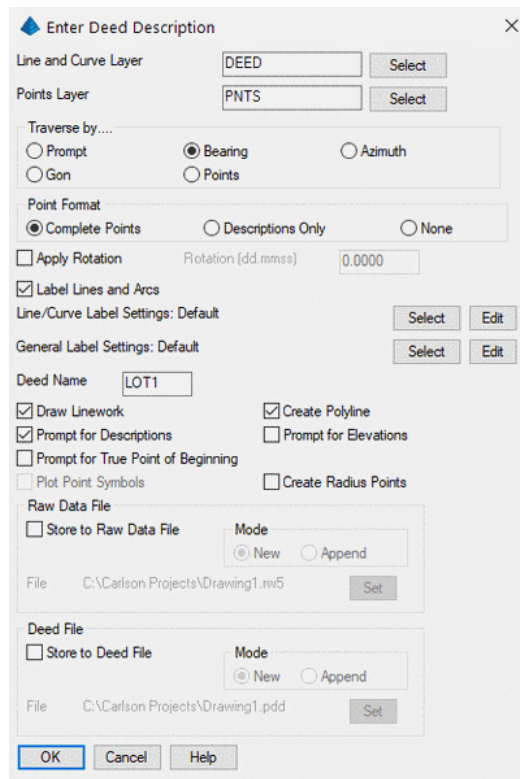

- Issue the Survey – Enter Deed Description. The following dialog box will appear so you can specify where to store the coordinates:

Select the **New** tab and set the file name as shown above which will externally house any collected or computed point locations.

- Utilize the default settings as shown below in the dialog box image:

Review and click **OK** when ready. When prompted at the Command line:

Pick point or point number: Left mouse click a point in the lower left quadrant of your screen to start the deed plotting.

Enter Point Description <>: respond with **Fence Post** and press Enter.

With our Point of Beginning established, supply the additional course information cited below:

125.3500

The quadrant (Q) is 1 for Northeast (2 is Southeast, 3 is Southwest and 4 is Northwest). The bearing is 25 degrees, 35 minutes, and 00 seconds.

If all digits for the minutes and seconds are entered as shown above, then the deed call will be fully plotted, including the seconds. If only the degrees and minutes were entered (as in 125.35), then the plot would appear as "N 25° 35' E".

Undo/Select/Varas/Meters/Rods/Chains/Distance(ft):

Note that you can enter old deeds in the forms of Poles and Links, Chains and Links and even Varas (a unit of measurement formerly used in the southwestern states of the U.S.)

Enter Point Description <Fence Post>:

Iron Pin

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<125.3500>:

189.4321

NOTE: In the data entry prompts you'll see an Undo option (*e.g.* Undo/Exit/Curve.... Pressing U for Undo would allow you to reenter the previous deed call.

Undo/Select/Varas/Meters/Rods/Chains/Distance(ft):

225.00

Enter Point Description <Iron Pin>:

press Enter

Pressing Enter selects the default, which in this case is **Iron Pin**.

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<189.4321>:

press C (or c)

This initiates the Curve sub-command option.

Curvecalc/Tangent-out/Radius>:

Curve direction [Left(-)/Right(+)]?

press Enter for right

Non-tangent/Reverse-tangent/Bearing/Chord/DeltaAng/Tangent/Arc Len>:

118.17

If you don't know the arc length, but you know the tangent, you would choose "T" for tangent.

Enter Point Description <Iron Pin>:

press Enter

Undo/Exit/Curve/Select/Tangent/Bearing (Qdd.mmss)<c>:

200.0000

This is due South. If you were to enter just 2 (no degrees, minutes, or seconds), then the deed call would be plotted "S 000 E".

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

178.00

Enter Point Description <Iron Pin>:

Concrete Monument

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<200.0000>:

488.2300

This entry specifies Northwest 88 degrees, 23 minutes.

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

300.34

Enter Point Description <Concrete Monument>:

Fence Post

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<488.2300>:

454.1109

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

106.93

Enter Point Description <Fence Post>:

press Spacebar, then press Enter

Simply pressing Enter uses the default text (Fence Post) again. To avoid drawing the text "Fence Post" twice on the end point, press the spacebar, skip a blank character, and press Enter.

You have now completed the 6-sided figure (including one curve).

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<454.1109>:

press E

This entry specifies Exits the Deed Entry input algorithm.

Select entity for area calculation:

Graphically select the polyline representation of the deed.

Deed Description Courses

The following results are reported:

Area = 83921.758997 sq. units, Perimeter = 1128.95

SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003

ACRES: 1.9266

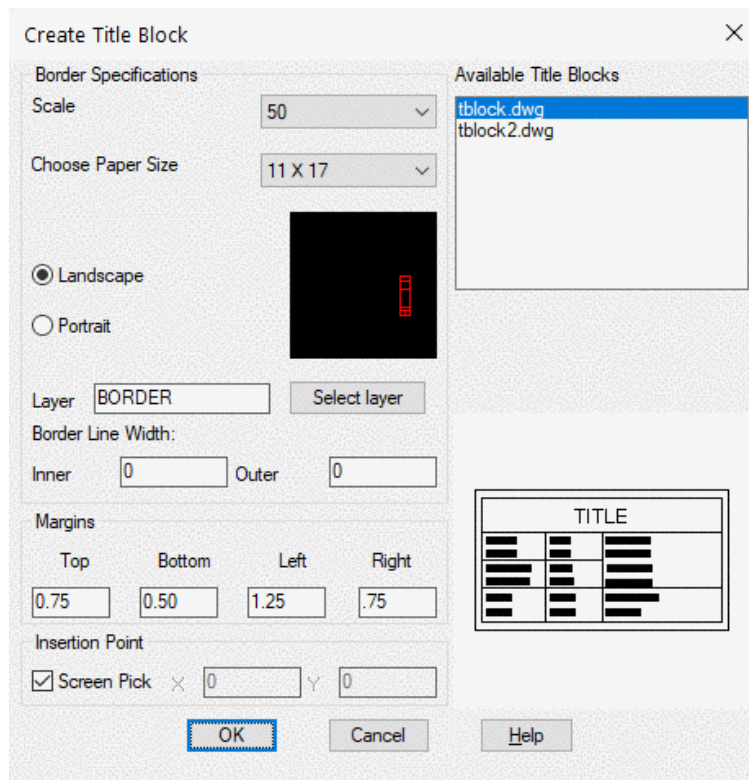

Closure error distance> 0.0171 Error Bearing> S 52Â°5'26" E

Closure Precision> 1 in 66076.9 Total Distance Traversed> 1128.950

The resulting deed has a closure of 1:66076.9.

Use the View – **Extents** command (key-in short-cut **ze**) to see the entire area. Then choose Zoom Out (key-in short-cut **zout**) under the View menu giving you adequate room for the next step.

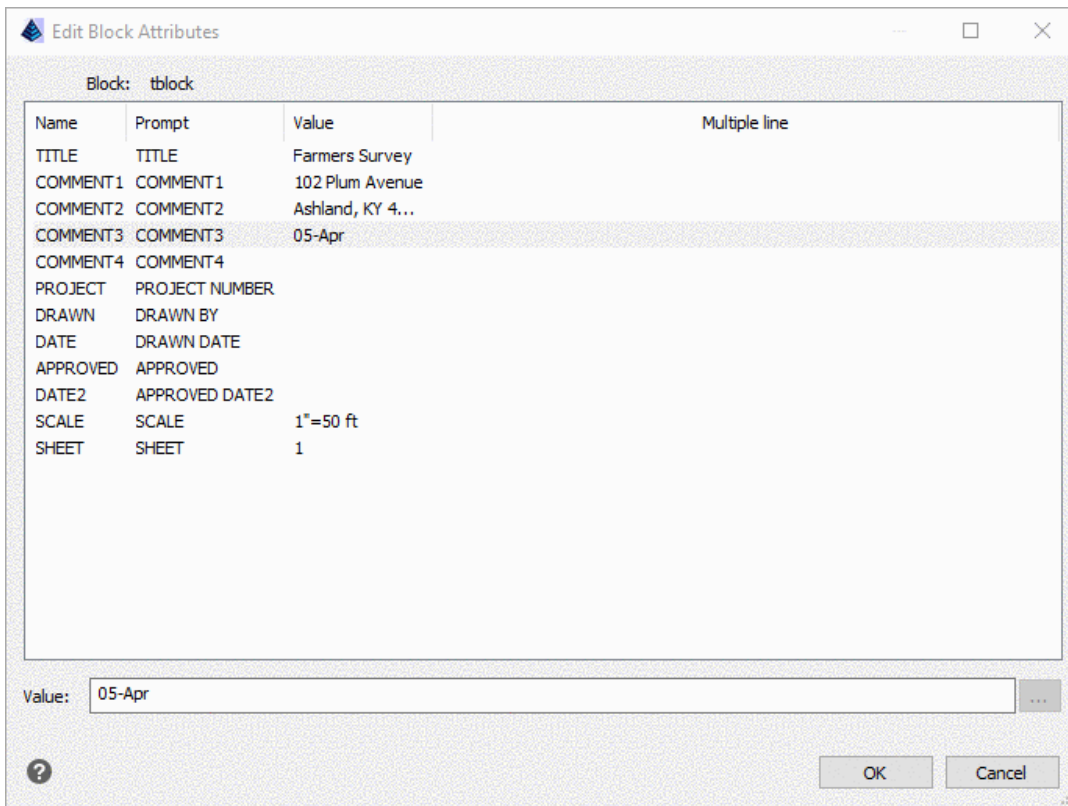

Issue the Settings – Title Block – Standard command to display a dialog box similar to that shown below:

Complete the title block entries, as shown above. Select Paper Size B2 (11 x 17), and enter the layer name of BORDER, then choose **OK** and when prompted:

Pick location: pick a point in the lower left of the survey

The following dialog appears, allowing you to enter the attributes for the *Title Block*:

Set the values as suggested above and click **OK** when ready.

NOTE: The title line is plotted in large text on the title block. Its length, therefore, should not exceed 15 characters. Your drawing should look similar to the example below at this point:

Use the View – **Extents** command to see the entire working area. If you want to move the border, use the Edit – **Move** command (keyin shortcut **M**). Pick the border lines and the title block objects (up to 3 picks total), press Enter (to end object selection), then pick two points representing the vector of the move.

If you want to see a margin around the working area after you use the Extents command, use the View – **Zoom Out** command. Then use the View – **Window** command to capture the view and margin you prefer.

If you make a mistake, enter U for Undo, or select the back arrow toolbar icon that appears at the top of the screen.

Issue the Annotate – Draw North Arrow command to display a dialog box similar to that shown below:

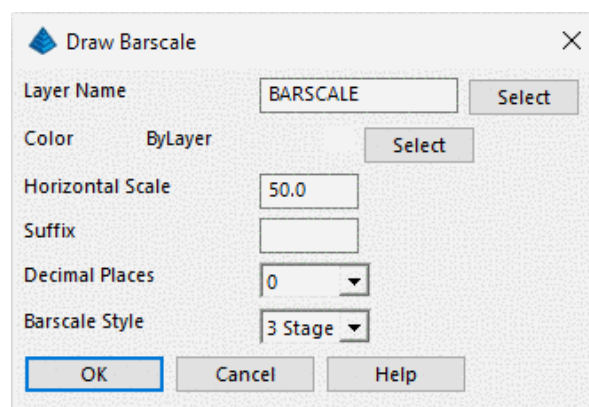

Accept the default north arrow that is shown at the right side of the dialog, click **OK**, and when prompted:

Pick insertion point: place it in the above the *Title Block* (leave enough space for the *Barscale* to follow)

If you want to reposition the North Arrow, issue the Edit – **Move** command.

Issue the Annotate – Draw Barscale to display a dialog box similar to that shown below:

Accept the defaults and click **OK** and when prompted:

Pick location for barscale: pick an insertion point below the *North Arrow* and directly above the "a" in *Farmer*, and approximately the same distance from both.

You can use the Edit – **Move** command if you want/need to re-position the barscale.

Issue the Draw – Text – **Standard** command and when prompted:

Specify start point of text or [Justify/Style]: J

Enter an option [Left/Center/Right/Align/Middle/Fit/TL/TC/TR/ML/MC/MR/BL/BC/BR]: C

Center point of text: pick a point near the top-center of the drawing

Height of text <4.00>: 10 (Entering 10 makes the title text bigger than the default).

Rotation angle of text <E>: press Enter

Text: Farmer Survey

Text: Ashland, KY

Text: press Enter

To enter a certification in the lower-right of the drawing, again select Draw – Text – **Standard** (or type "dtext" at the Command line).

NOTE: If you haven't done anything else, such as Zoom or Pan, you can simply press Enter to repeat the last command. If pressing Enter does not repeat the Text command, restart the command as suggested above and respond to the resulting prompts as shown below:

Specify start point of text or [Justify/Style]: Pick a point above and to the left of the *Title Block* for the certification. You don't have to enter L for left-justification. The DText command defaults to left-justification every time.

Height <10.00>: 4

Rotation angle <E>: press Enter

Text: Surveyor's Certification

Text: *press spacebar, then press Enter*

Text: I do hereby certify that the survey shown hereon

Text: is a true and correct representation.

Text: *press spacebar, then press Enter*

Text: -----

Text: John Doe, PLS #1234

Text: *press Enter twice to end*

Enlarge the two title lines (*i.e.* **Farmer Survey** and **Surveyor's Certification**) by a factor of 2.0 using the Edit – Text – Text Enlarge/Reduce command. When prompted:

Scaling Multiplier: type 2 and press Enter

Select Text for Scaling.

[FILter/?]/<Select entities>: pick the **Farmer Survey** text and press Enter

[FILter/?]/<Select entities>: pick the **Surveyor's Certification** text and press Enter

[FILter/?]/<Select entities>: press Enter

NOTE: When you are selecting objects, if you select something you don't want, you have the option to remove undesired entities with the (R) option.

The following is a closeup of the *North arrow*, *Bar Scale* and *Certification label* that we just entered:

Surveyor's Certification

I do hereby certify that the survey shown hereon
is a true and correct representation.

John Doe, PLS #1234

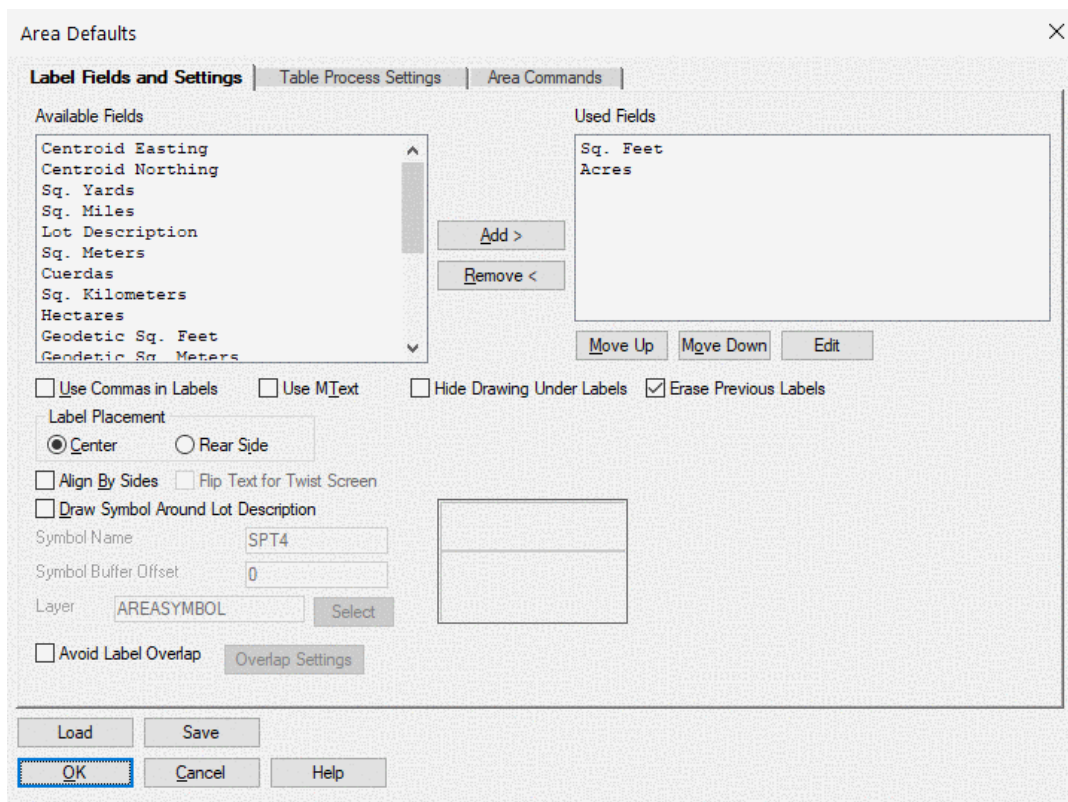

Farmers Survey		
DRAWN	DATE	102 Plum Avenue Ashland, KY 40202
APPROVED	DATE	05-Apr
SCALE 1"=50 ft	SHEET 1	PROJECT NO.

Our next task will be to refine a bearing label; click the Edit – Text – **Edit Text** command. When you are prompted:

Select Text to Edit: pick the due South bearing text of S 00°00'00" E and change it to S 00° E.

NOTE: The degree symbol in CAD *SHX* fonts is represented as `%%d`. For example, if you had typed N 15%%d25'35" E in the *DText* command, Carlson would draw that entry as N15°25'35"E. Click in the text to the immediate right of the quotation mark and press the Backspace key until the text reads "S 00%%d E and press Enter (or click **OK** if in a dialog box) to exit the command.

Prepare for area labeling by selecting the Area/Layout – Area Defaults command. The dialog box shown below appears:

Select the **Sq. Feet** item and click on the **Edit** button and make the **Area Text Size Scaler** 0.2 (doubled from the default of 0.1) as shown below. Click **OK** when complete.

Next select the **Acres** item and click on the **Edit** button. Also, make the **Area Text Size Scaler** 0.2 and click **OK** to dismiss the *Acres* dialog box and click **OK** to dismiss the *Area Defaults* dialog box.

You are going to compute the area by point number by inverting from 1 through 7 and back to 1. Select the Area/Layout – Inverse with Area and respond to the prompts as shown below:

¹
Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

2-3

Supplying a point range (separated by a dash) is very helpful when dealing with many consecutive straight-leg courses.

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

r

Point 3 is the PC of the curve so we need to find the radius point of the curve.

Radius point number or pick point:

cen

We wish to use a CENter snap.

Snap to CEN of:

pick the arc-portion of the polyline
Curve direction [Left/<Right>]?

r

Pressing Enter would have also
executed the default <Right> option.

Pick End of Arc or point number (U-Undo,Enter to end):

4

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

5-6

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

1

We are establishing the desire to
Inverse back to the starting point.

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

press Enter to end.

Inverse with Area

A Standard Report Viewer dialog box showing the *Inverse with Area* results will appear. Click the **Exit** (Doorway) button at the top of the dialog box and also note the results to the Command window:

Area = 83921.725598 sq. units, Perimeter = 1128.97
SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003
ACRES: 1.9266 PERIMETER: 1129.0
You should be prompted:

Pick area label centering point (Enter for none): Pick a point near the center of the figure, in its interior. The area units you chose in Area Defaults are labeled on the screen.

You snapped to the radius point using the manually keyed "cen" snap. Additional object snaps appear under Settings – Object Snap. Since all plotted points have a node, you could have inversed around this figure by using the "nod" snap for points 1 through 7, and the "cen" snap to capture the radius point. Snaps are typically entered at the keyboard as 3 characters (for example, "int" for intersect and "end" for endpoint).

Also, you could have chosen the Area by Lines & Arcs command. In that command, you would pick the lines and arcs that make up the figure. But since the closure was 0.017 off (the distance from point 7 to point 1), you would exceed the default Max gap tolerance. Unless you change that tolerance in the command to something larger than 0.017, you would not get a result using this method.

Freeze the point numbers to finish the drawing by choosing View – Layer Control. In the **PNTNO** row, click the Sun icon to change it to a Snowflake icon, which freezes the PNTNO layer. Click **OK**. The point numbers remain in the drawing, waiting to be "thawed", but they are not displayed.

The final drawing is shown here:

This completes the Lesson 1 tutorial: Entering a Deed.

=====

In this short lesson you will create a simple drawing. You will enter a 6-sided deed, add a title block, bar scale, and north arrow, add a title and certification text, and plot the deed area.

Note that the Esc key will cancel most commands, so if you choose the wrong command or enter something incorrectly and want to start over, just press Esc.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the **Exit** button.
 - If you are taken directly into CAD, continue as is.

Verify the Survey module is loaded by clicking Settings – Carlson Menus – Survey Menu.

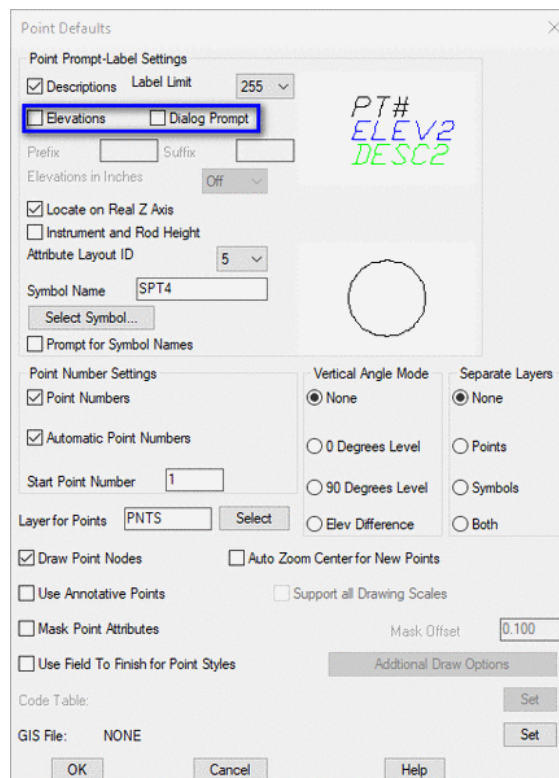

2. Issue the Settings – Drawing Setup to display a dialog box similar to that shown below:

Set the unit setting to **English** and the **Horizontal Scale** to **50**. Match other settings as desired and as shown below and click **OK**.

3. Issue the Points – Point Defaults command and perform the following:

- Clear the Elevations toggle to eliminate the Elevation prompt, and,
- Enable the Descriptions toggle, and,
- Use the Select Symbol button to set the Point Symbol name to symbol 4 (SPT4), which is the open circle, and,
- Enable the Automatic Point Numbering toggle, and,
- Match other settings as desired and as shown below and click **OK**.

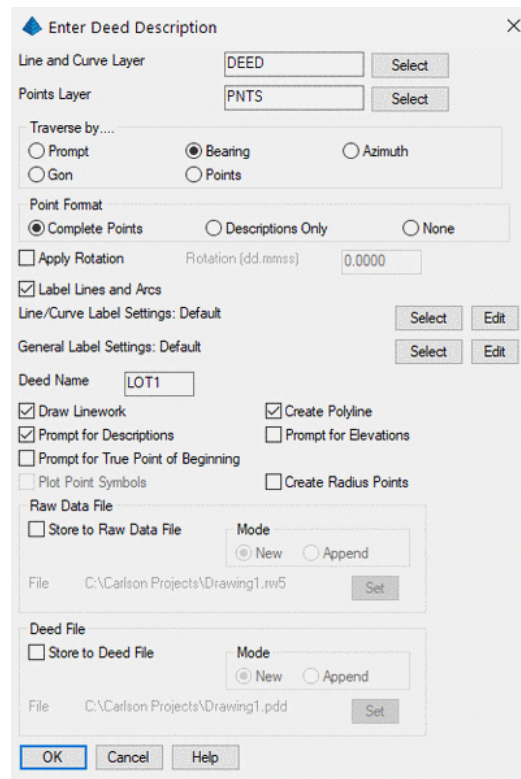

- Issue the Survey – Enter Deed Description. The following dialog box will appear so you can specify where to store the coordinates:

Select the **New** tab and set the file name as shown above which will externally house any collected or computed point locations.

- Utilize the default settings as shown below in the dialog box image:

Review and click **OK** when ready. When prompted at the Command line:

Pick point or point number: Left mouse click a point in the lower left quadrant of your screen to start the deed plotting.

Enter Point Description <>: respond with **Fence Post** and press Enter.

With our Point of Beginning established, supply the additional course information cited below:

125.3500

The quadrant (Q) is 1 for Northeast (2 is Southeast, 3 is Southwest and 4 is Northwest). The bearing is 25 degrees, 35 minutes, and 00 seconds.

If all digits for the minutes and seconds are entered as shown above, then the deed call will be fully plotted, including the seconds. If only the degrees and minutes were entered (as in 125.35), then the plot would appear as "N 25° 35' E".

Undo/Select/Varas/Meters/Rods/Chains/Distance(ft):

200.51

Note that you can enter old deeds in the forms of Poles and Links, Chains and Links and even Varas (a unit of measurement formerly used in the southwestern states of the U.S.)

Enter Point Description <Fence Post>:

Iron Pin

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<125.3500>:

189.4321

NOTE: In the data entry prompts you'll see an Undo option (*e.g.* Undo/Exit/Curve.... Pressing U for Undo would allow you to reenter the previous deed call.

Undo/Select/Varas/Meters/Rods/Chains/Distance(ft):

225.00

Enter Point Description <Iron Pin>:

press Enter

Pressing Enter selects the default, which in this case is **Iron Pin**.

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<189.4321>:

press C (or c)

This initiates the Curve sub-command option.

Curvecalc/Tangent-out/Radius>:

Curve direction [Left(-)/Right(+)]?

press Enter for right

Non-tangent/Reverse-tangent/Bearing/Chord/DeltaAng/Tangent/Arc Len>:

118.17

If you don't know the arc length, but you know the tangent, you would choose "T" for tangent.

Enter Point Description <Iron Pin>:

press Enter

Undo/Exit/Curve/Select/Tangent/Bearing (Qdd.mmss)<c>:

200.0000 This is due South. If you were to enter just 2 (no degrees, minutes, or seconds), then the deed call would be plotted "S 000 E".

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

178.00
Enter Point Description <Iron Pin>:

Concrete Monument
Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<200.0000>:

488.2300 This entry specifies Northwest 88 degrees, 23 minutes.

Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

300.34
Enter Point Description <Concrete Monument>:

Fence Post
Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<488.2300>:

454.1109
Undo/Select/Varas/Meters/Rods/Chains/<Distance(ft)>:

106.93
Enter Point Description <Fence Post>:

press Spacebar, then press Enter Simply pressing Enter uses the default text (Fence Post) again. To avoid drawing the text "Fence Post" twice on the end point, press the spacebar, skip a blank character, and press Enter.

You have now completed the 6-sided figure (including one curve).

Undo/Exit/Curve/Select/Bearing (Qdd.mmss)<454.1109>:

press E This entry specifies Exits the Deed Entry input algorithm.

Select entity for area calculation:

Graphically select the polyline representation of the deed.

Deed Description Courses

The following results are reported:

Area = 83921.758997 sq. units, Perimeter = 1128.95
SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003
ACRES: 1.9266
Closure error distance> 0.0171 Error Bearing> S 52°5'26" E
Closure Precision> 1 in 66076.9 Total Distance Traversed> 1128.950

The resulting deed has a closure of 1:66076.9.

Use the View – **Extents** command (key-in short-cut **ze**) to see the entire area. Then choose Zoom Out (key-in short-cut **zout**) under the View menu giving you adequate room for the next step.

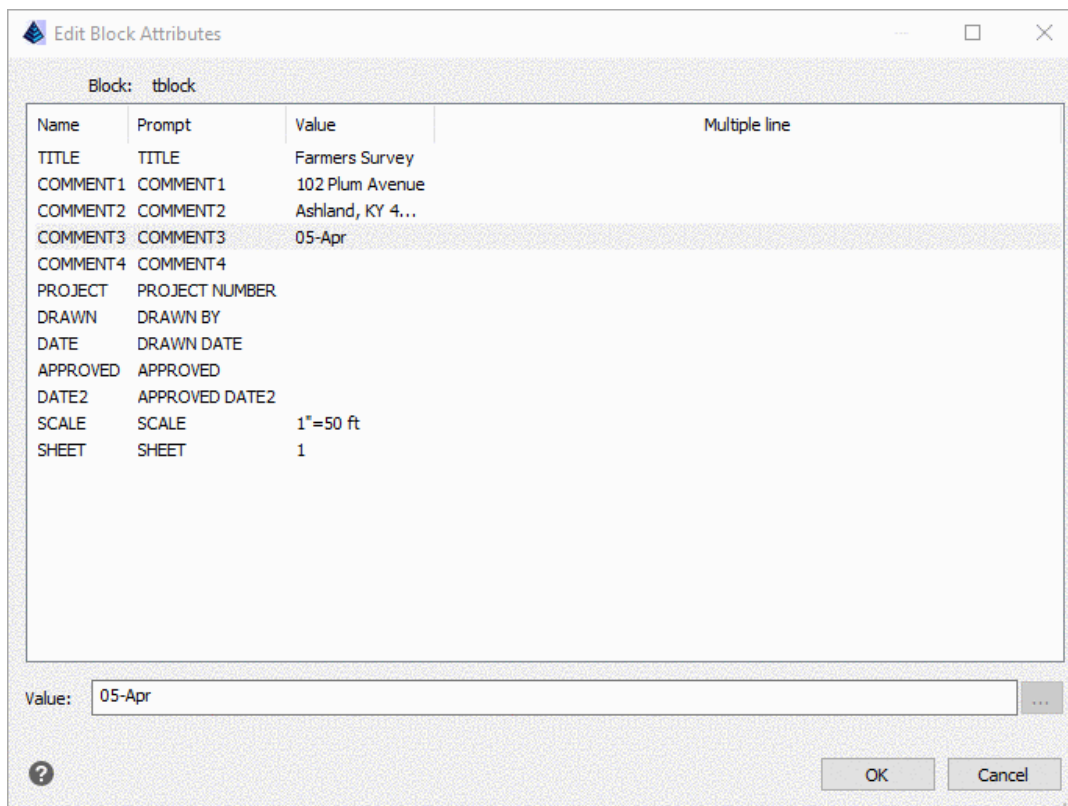

Issue the Settings – Title Block – Standard command to display a dialog box similar to that shown below:

Complete the title block entries, as shown above. Select Paper Size B2 (11 x 17), and enter the layer name of BORDER, then choose **OK** and when prompted:

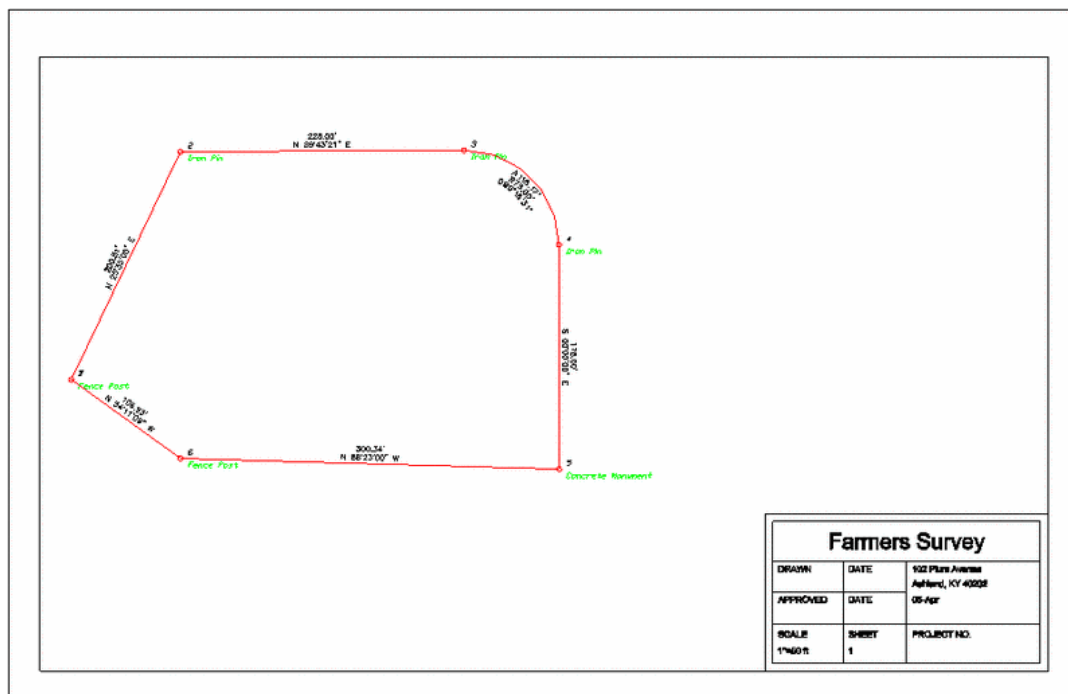

Pick location: pick a point in the lower left of the survey

The following dialog appears, allowing you to enter the attributes for the *Title Block*:

Set the values as suggested above and click **OK** when ready.

NOTE: The title line is plotted in large text on the title block. Its length, therefore, should not exceed 15 characters. Your drawing should look similar to the example below at this point:

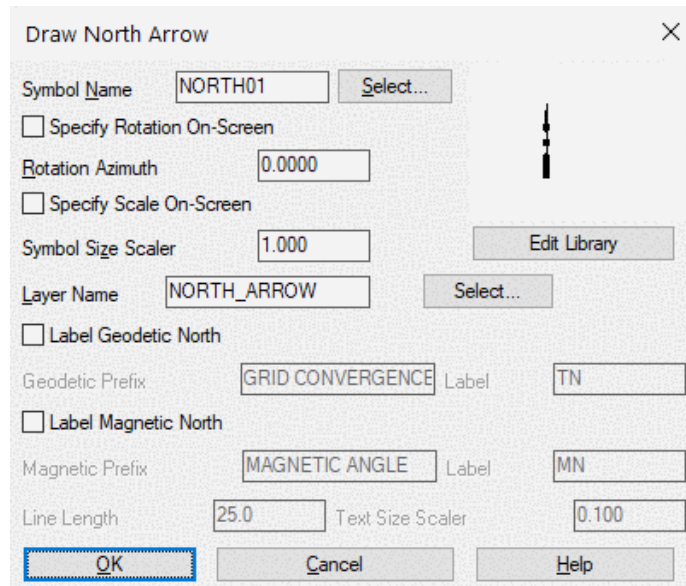

Use the View – **Extents** command to see the entire working area. If you want to move the border, use the Edit – **Move** command (keyin shortcut **M**). Pick the border lines and the title block objects (up to 3 picks total), press Enter (to end object selection), then pick two points representing the vector of the move.

If you want to see a margin around the working area after you use the Extents command, use the View – **Zoom Out** command. Then use the View – **Window** command to capture the view and margin you prefer.

If you make a mistake, enter U for Undo, or select the back arrow toolbar icon that appears at the top of the screen.

Issue the Annotate – Draw North Arrow command to display a dialog box similar to that shown below:

Accept the default north arrow that is shown at the right side of the dialog, click **OK**, and when prompted:

Pick insertion point: place it in the above the *Title Block* (leave enough space for the *Barscale* to follow)

If you want to reposition the North Arrow, issue the Edit – **Move** command.

Issue the Annotate – Draw Barscale to display a dialog box similar to that shown below:

Accept the defaults and click **OK** and when prompted:

Pick location for barscale: pick an insertion point below the *North Arrow* and directly above the "a" in *Farmer*, and approximately the same distance from both.

You can use the Edit – **Move** command if you want/need to re-position the barscale.

Issue the Draw – Text – **Standard** command and when prompted:

Specify start point of text or [Justify/Style]: J

Enter an option [Left/Center/Right/Align/Middle/Fit/TL/TC/TR/ML/MC/MR/BL/BC/BR]: C

Center point of text: pick a point near the top-center of the drawing

Height of text <4.00>: 10 (Entering 10 makes the title text bigger than the default).

Rotation angle of text <E>: press Enter

Text: Farmer Survey

Text: Ashland, KY

Text: press Enter

To enter a certification in the lower-right of the drawing, again select Draw – Text – **Standard** (or type "dtext" at the Command line).

NOTE: If you haven't done anything else, such as Zoom or Pan, you can simply press Enter to repeat the last command. If pressing Enter does not repeat the Text command, restart the command as suggested above and respond to the resulting prompts as shown below:

Specify start point of text or [Justify/Style]: Pick a point above and to the left of the *Title Block* for the certification. You don't have to enter L for left-justification. The DText command defaults to left-justification every time.

Height <10.00>: 4

Rotation angle <E>: press Enter

Text: Surveyor's Certification

Text: *press spacebar, then press Enter*

Text: I do hereby certify that the survey shown hereon

Text: is a true and correct representation.

Text: *press spacebar, then press Enter*

Text: -----

Text: John Doe, PLS #1234

Text: *press Enter twice to end*

Enlarge the two title lines (*i.e.* **Farmer Survey** and **Surveyor's Certification**) by a factor of 2.0 using the Edit – Text – Text Enlarge/Reduce command. When prompted:

Scaling Multiplier: type 2 and press Enter

Select Text for Scaling.

[FILter?]/<Select entities>: pick the **Farmer Survey** text and press Enter

[FILter?]/<Select entities>: pick the **Surveyor's Certification** text and press Enter

[FILter?]/<Select entities>: press Enter

NOTE: When you are selecting objects, if you select something you don't want, you have the option to remove undesired entities with the (R) option.

The following is a closeup of the *North arrow*, *Bar Scale* and *Certification label* that we just entered:

Surveyor's Certification

I do hereby certify that the survey shown hereon
is a true and correct representation.

John Doe, PLS #1234

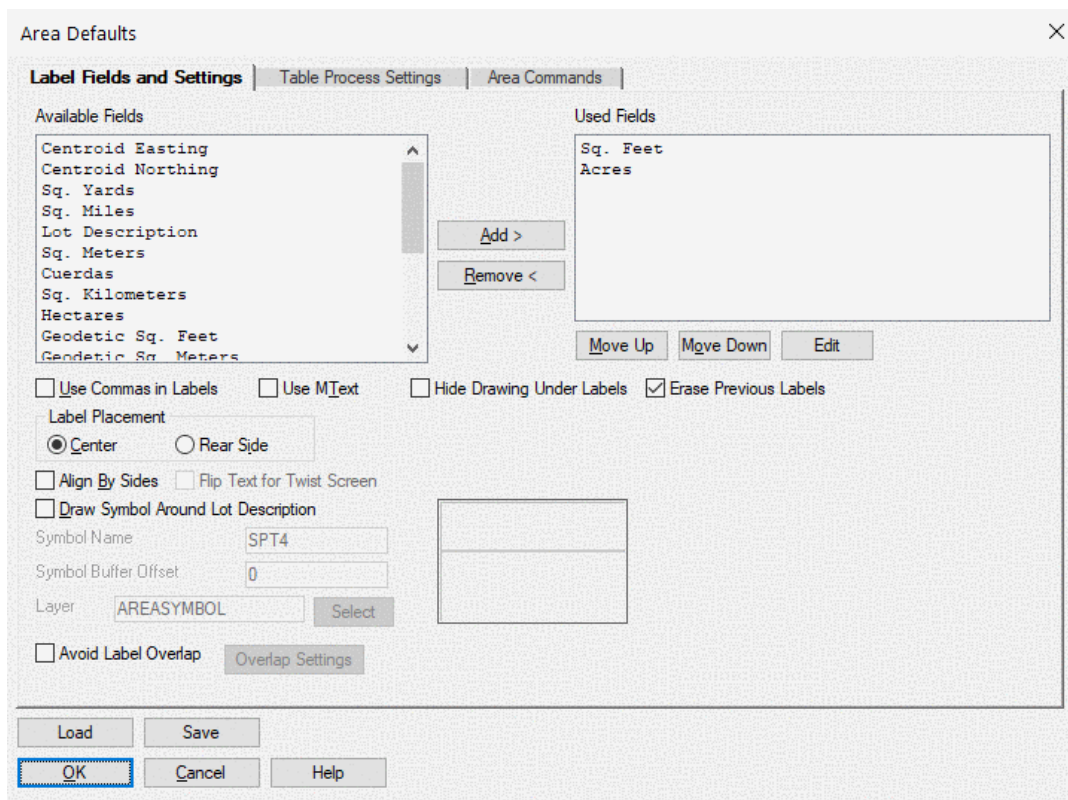

Farmers Survey		
DRAWN	DATE	102 Plum Avenue Ashland, KY 40202
APPROVED	DATE	05-Apr
SCALE 1"=50 ft	SHEET 1	PROJECT NO.

Our next task will be to refine a bearing label; click the Edit – Text – **Edit Text** command. When you are prompted:

Select Text to Edit: pick the due South bearing text of S 00°00'00" E and change it to S 00° E.

NOTE: The degree symbol in CAD *SHX* fonts is represented as `%%d`. For example, if you had typed N 15%%d25'35" E in the *DText* command, Carlson would draw that entry as N15°25'35"E. Click in the text to the immediate right of the quotation mark and press the Backspace key until the text reads "S 00%%d E and press Enter (or click **OK** if in a dialog box) to exit the command.

Prepare for area labeling by selecting the Area/Layout – Area Defaults command. The dialog box shown below appears:

Select the **Sq. Feet** item and click on the **Edit** button and make the **Area Text Size Scaler** 0.2 (doubled from the default of 0.1) as shown below. Click **OK** when complete.

Next select the **Acres** item and click on the **Edit** button. Also, make the **Area Text Size Scaler** 0.2 and click **OK** to dismiss the *Acres* dialog box and click **OK** to dismiss the *Area Defaults* dialog box.

You are going to compute the area by point number by inverting from 1 through 7 and back to 1. Select the Area/Layout – Inverse with Area and respond to the prompts as shown below:

¹
Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

2-3 Supplying a point range (separated by a dash) is very helpful when dealing with many consecutive straight-leg courses.

1

We are establishing the desire to
Inverse back to the starting point.

Pick point or point numbers (R-RadiusPt,U-Undo,Enter to end):

press Enter to end.

Inverse with Area

A Standard Report Viewer dialog box showing the *Inverse with Area* results will appear. Click the **Exit** (Doorway) button at the top of the dialog box and also note the results to the Command window:

Area = 83921.725598 sq. units, Perimeter = 1128.97
SQ. FEET: 83922 SQ. YARDS: 9324.6 SQ. MILES: 0.003
ACRES: 1.9266 PERIMETER: 1129.0
You should be prompted:

Pick area label centering point (Enter for none): Pick a point near the center of the figure, in its interior. The area units you chose in Area Defaults are labeled on the screen.

You snapped to the radius point using the manually keyed "cen" snap. Additional object snaps appear under Settings – Object Snap. Since all plotted points have a node, you could have inverted around this figure by using the "nod" snap for points 1 through 7, and the "cen" snap to capture the radius point. Snaps are typically entered at the keyboard as 3 characters (for example, "int" for intersect and "end" for endpoint).

Also, you could have chosen the Area by Lines & Arcs command. In that command, you would pick the lines and arcs that make up the figure. But since the closure was 0.017 off (the distance from point 7 to point 1), you would exceed the default Max gap tolerance. Unless you change that tolerance in the command to something larger than 0.017, you would not get a result using this method.

Freeze the point numbers to finish the drawing by choosing View – Layer Control. In the **PNTNO** row, click the Sun icon to change it to a Snowflake icon, which freezes the PNTNO layer. Click **OK**. The point numbers remain in the drawing, waiting to be "thawed", but they are not displayed.

The final drawing is shown here:

This completes the Lesson 1 tutorial: Entering a Deed.

>>>>>>> .r4753

Making a Plat

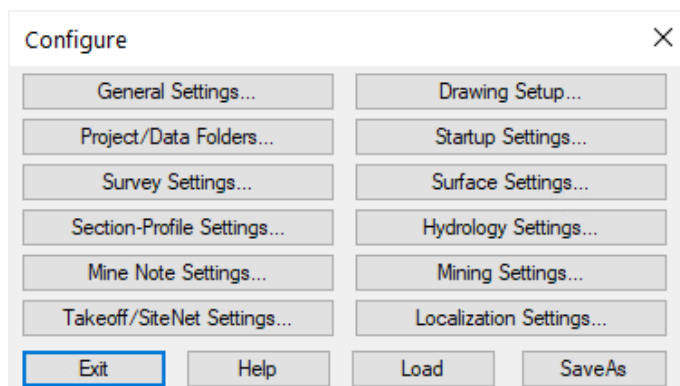

In this lesson you will draw out a plat of a single lot, using Carlson drafting techniques. You will make the plat from an ASCII file of points named **Plat.txt**.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the **Exit** button.
 - If you are taken directly into CAD, continue as is.

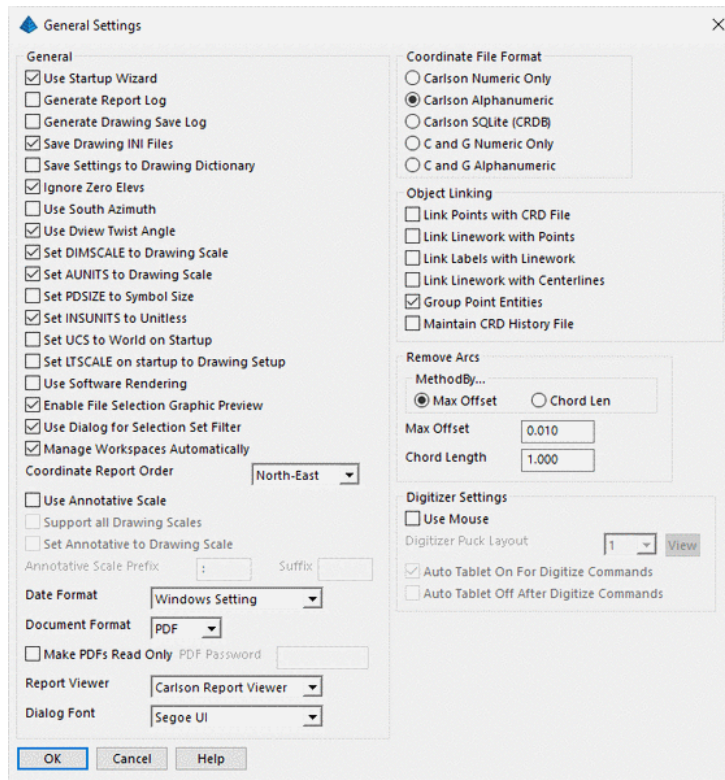

Verify the Survey module is loaded by clicking Settings – Carlson Menus – Survey Menu.

NOTE: You will use the Startup Wizard in Lesson 3 to perform a series of commands to begin a drawing.

2. We'd like to explore some basic configuration settings. Click Settings – Carlson Configure to display the following menu:

Click General Settings to display the dialog box shown here:

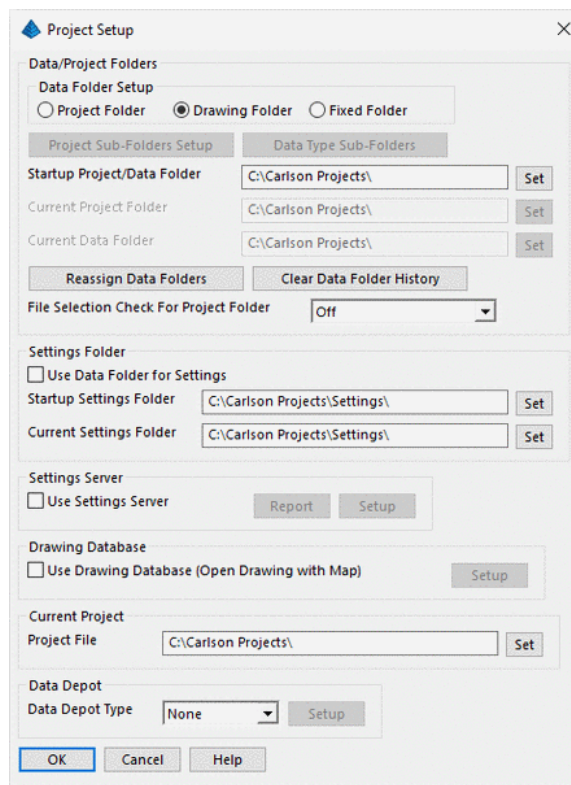

The options in this dialog box, along with the options in other Configure sub-options, determine default working conditions for Carlson. Make/set the following values:

- In anticipation of Lesson 3, make sure the **Use Startup Wizard** is enabled.
- Choose **Carlson AlphaNumeric** to provide the ability to store points in alphanumeric form (*e.g.* 1A, 1B, 1C, HUB5, CTRL, SS10, *etc.*). Generally, there is a slight speed advantage to working with purely numeric point numbers. The highest numeric-only point number allowed is 99999. However, there is no limit to the number of points in an alphanumeric coordinate file.
- Enable the **Group Point Entities** option which groups point elevations, numbers, and descriptions (all aspects of the points) into a single entity for moving, erasing and other commands.

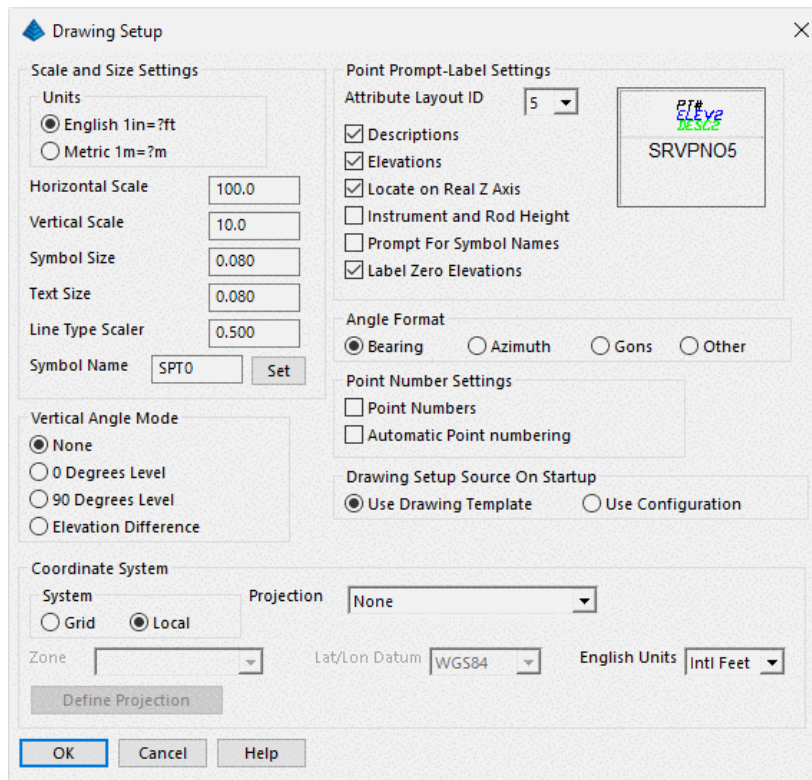

Click **OK** at the bottom of this dialog box.

3. Now we want to set the data path. Another of the Configure sub-options is Project/Data Folders. Click this option and you will see this dialog box:

For this lesson, you will keep it simple. Enable the **Drawing Folder** at the top. This option will, by default, send any data files to the same folder location where the active drawing is located. Notice the **Current Data Folder** section at the bottom. This specifies where data files, such as .crd files in this case, are to be stored. Set the folder to **C:\Carlson Projects** and click **OK** to return to the main *Configure* dialog box.

4. Select Drawing Setup from the *Configure* dialog box to display the dialog box below:

The **Horizontal Scale** acts as a multiplier on all text annotation. For example, $100 * \text{Text Size} (0.08) = 8$ (text

height of 8 CAD units). The **Text Size** setting is the effective height, in inches, that the text will appear when plotted at the specified *Horizontal Scale* (example here, 100).

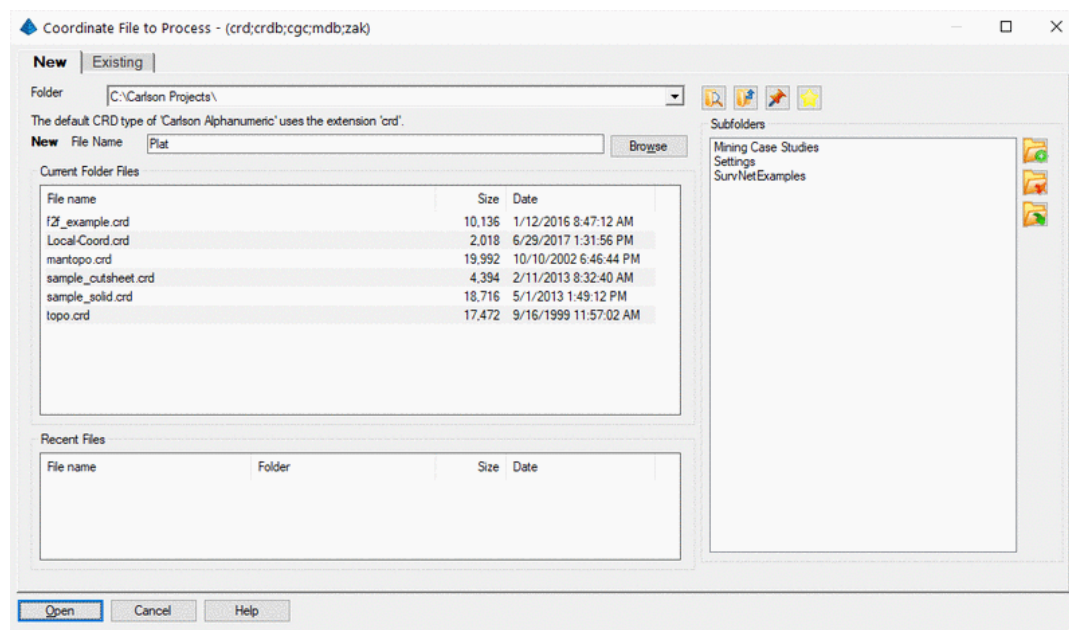

Bearing and Distance labels, Legends, Title Blocks, and Point Symbols will size up or down on the basis of the **Horizontal Scale** set within *Drawing Setup*. Set the Horizontal Scale to **100** and match other settings as desired. Then click **OK** to dismiss the dialog box then click **Exit** to close the Configure dialog box. If prompted:

Click on the **Current and Future** button.

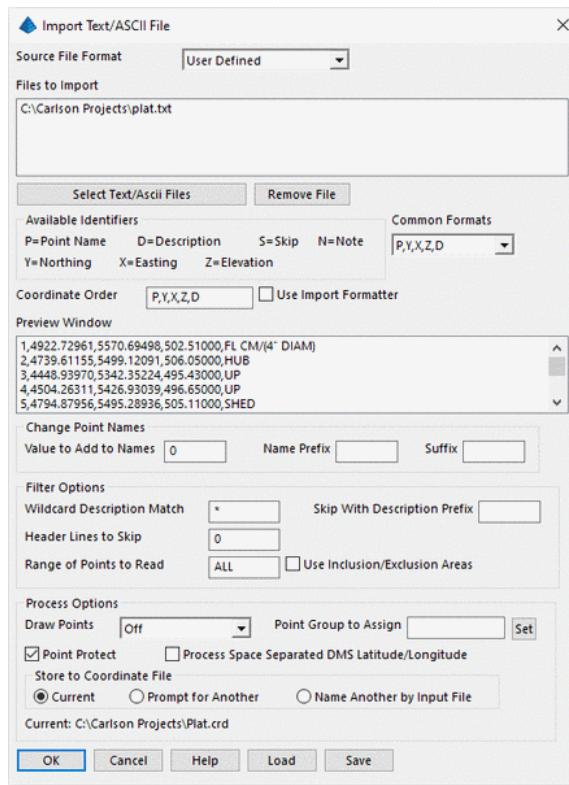

5. If you have not already saved your drawing, now is a good time to do it. Use the File – **Save** command and call the file Lesson2.dwg (store in the C:\Carlson Projects\ folder).
6. Next, you will import the ASCII file called **Plat.txt** and store the points in a Coordinate file called **Plat.crd**. However, since you are in a new drawing, you have not yet set a coordinate file to store the points in. You must have a Carlson coordinate file (.crd) open and established as the container for your points.

Click Points – Set CoORDinate File to display a dialog box similar to that shown below:

Click the **New** tab, as shown here. To the right of File name, type **Plat** and click **Open**. You have now created the required coordinate file.

7. You are now ready to import the points. Click the Points – Import Text/ASCII File command to display the dialog box:

Click the **Select Text/ASCII Files** button and then choose **Plat.txt** listed in the file list. It is found in the default data folder (C:\Carlson Projects) and click **Open** when ready.

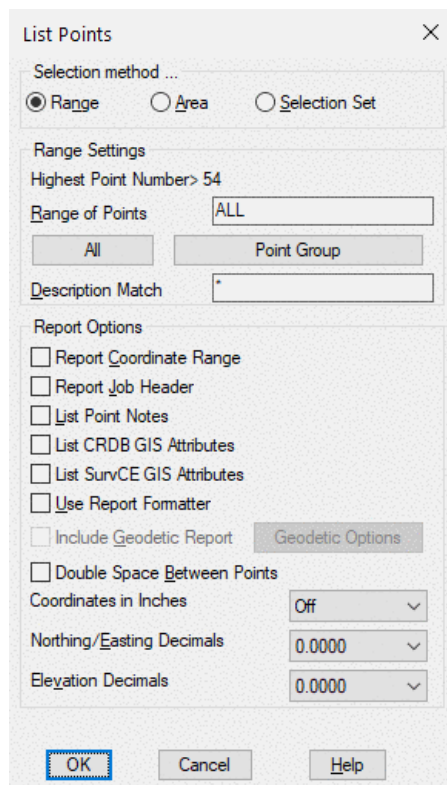

Plat.txt is an ASCII file containing 54 points in the form of *Point Number, Northing, Easting, Elevation* and *Description*. The format of the points appears in the **Preview Window**. The format is: Point (P), Northing (Y), Easting (X), Elevation (Z), Description (D), or, in short, **P,Y,X,Z,D**. You must match this format in the **Coordinate Order**. If you don't see P,Y,X,Z,D in the **Coordinate Order** box, then select that format from the **Common Formats** option. Or, you can type the list directly into the **Coordinate Order** box. Make sure that **Draw Points** is set to Off.

Click **OK** to save/store the data in **Plat.crd**. A confirming dialog appears as follows:

Click **OK** to dismiss the alert.

8. Choose the **Points – List Points** command to display the dialog box below:

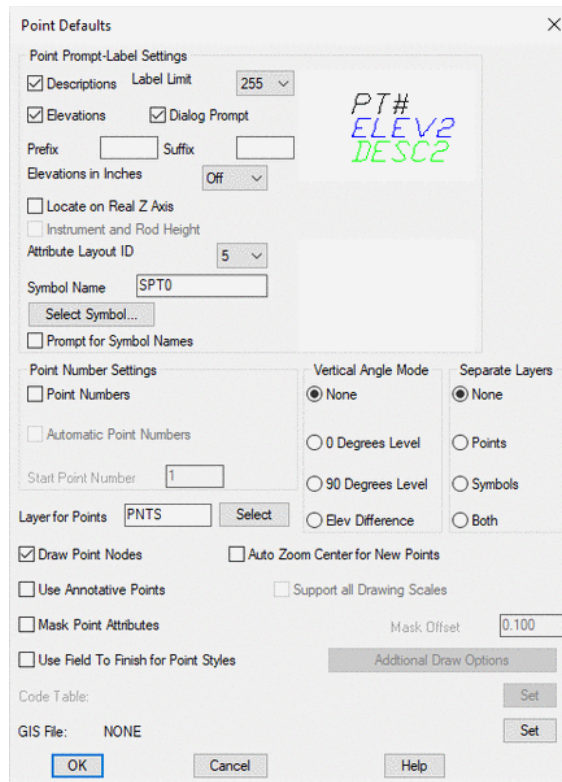

The List Points dialog box will typically default to the full range of points (ALL), which is 1 through 54 in this exercise. You can control the decimal places for the Northing/Easting and the Elevation of the points in the lower portion of the dialog box. Click **OK** and the settings shown above result in the report exhibited below in the Standard Report Viewer:

PointNo.	Northing (Y)	Easting (X)	Elev (Z)	Description
1	4922.7296	5570.6950	502.5100	FL CM/ (4" DIAM)
2	4739.6115	5499.1209	506.0500	HUB
3	4448.9397	5342.3522	495.4300	UP
4	4504.2631	5426.9304	496.6500	UP
5	4794.8796	5495.2894	505.1100	SHED
6	4771.8550	5486.6609	505.5300	SHED
7	4782.6478	5457.8611	505.8200	SHED
8	4854.7655	5357.2213	501.9700	IP FL
9	4467.7479	5476.2376	496.3700	IP
10	4571.0030	5617.4467	499.1300	IP
11	4889.9902	5551.4909	503.0100	18D/OAK
12	4811.6154	5579.1710	504.1200	24D/OAK
13	4675.9325	5564.3498	504.9700	12P
14	4714.7994	5608.3889	502.7500	8P
15	4684.3432	5652.9519	501.4700	IP
16	4573.4034	5443.7462	497.9400	PL
17	4792.0208	5435.9996	505.9000	UP
18	4651.5225	5516.5361	504.0300	BLD
19	4656.3297	5535.9497	504.7200	BLD
20	4854.6447	5565.3310	503.5700	18D/OAK
21	4528.3876	5369.1237	496.9300	HUB
22	4667.4819	5449.3567	501.2700	LP
23	4760.9888	5397.1521	502.1700	X

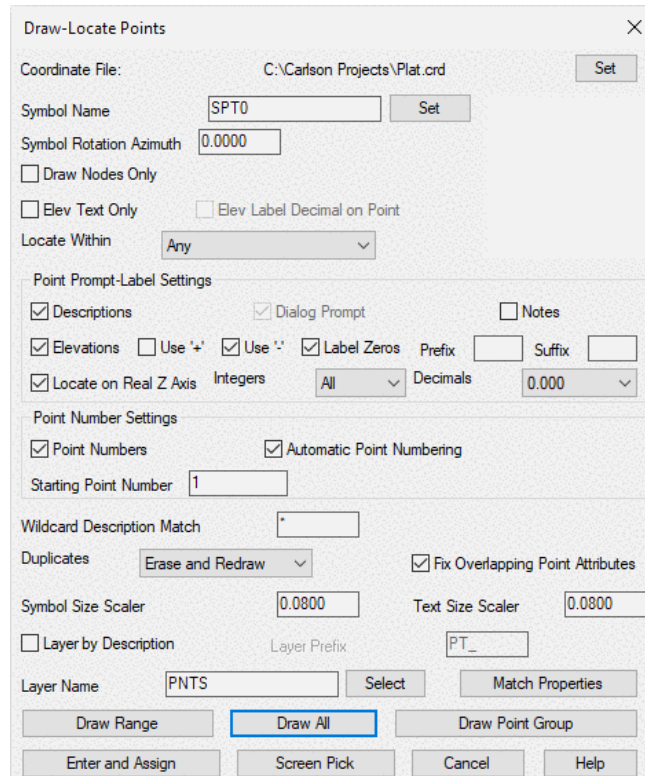

Exit the report by selecting the **Exit** (doorway) icon at the top of this report viewer box, or by clicking the X in the upper right of the window.

9. Issue the Points – Point Defaults command and perform the following:

- Enable the Elevations toggle, and,
- Enable the Descriptions toggle, and,
- Use the Select Symbol button to set the Point Symbol name to symbol 0 (SPT0), which is a standard point, and,
- Enable the Automatic Point Numbering toggle, and,
- Match other settings as desired and as shown below and click **OK**.

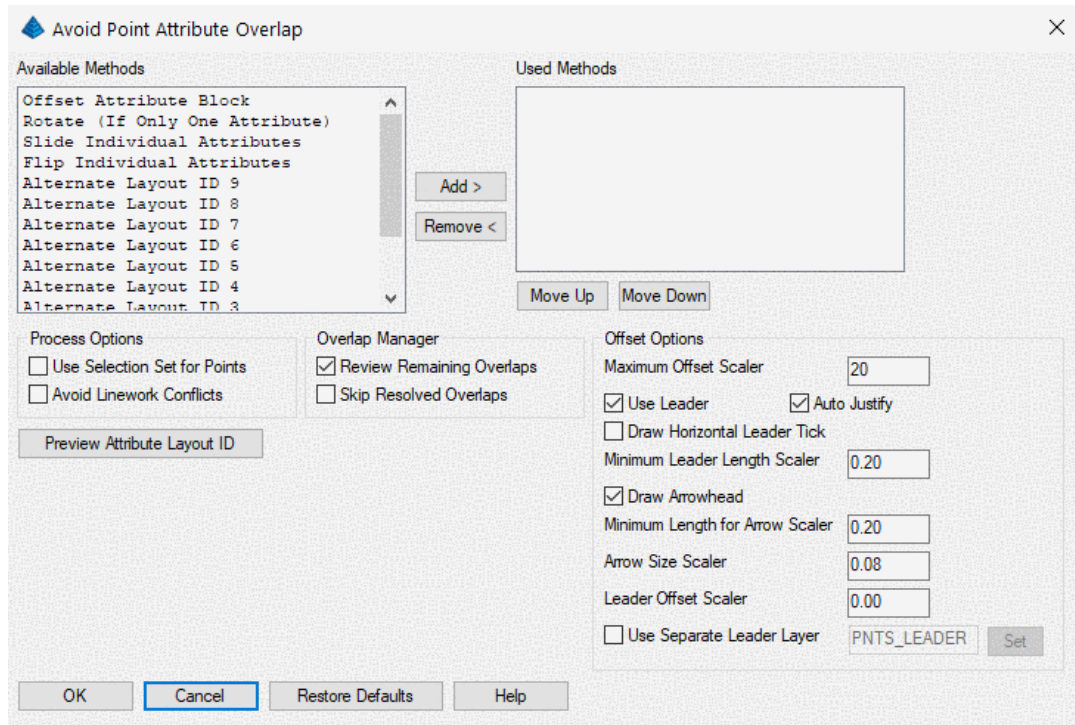

10. Select the Points – Draw-Locate Points command to draw the points on the screen:

As shown in the figure shown above, the current **Symbol Name** is showing as SPT0, which is a standard CAD node symbol (*i.e.* a point). You can select a different default symbol using the Points – Point Defaults command.

In this exercise you, let's continue to use SPT0. Later, you will add official property corner and utility symbols. Although you are working without a default symbol, there will always be a "dot" or a node at the correct insertion point of each point number.

Enable the Fix Overlapping Point Attributes toggle if it is not already checked. Click **Draw All** and the following dialog will display:

The Avoid Point Attribute Overlap dialog uses different adjustment methods, such as moving attributes and creating leader lines, to fix conflicts with the point labels. Click **Cancel** for now so we can view these conflicts:

Select Carlson Software points.

[FILter]/<Select entities>: wp

First vertex of inclusive polygon: click a starting point for the polygon

Next vertex: continue picking desired locations

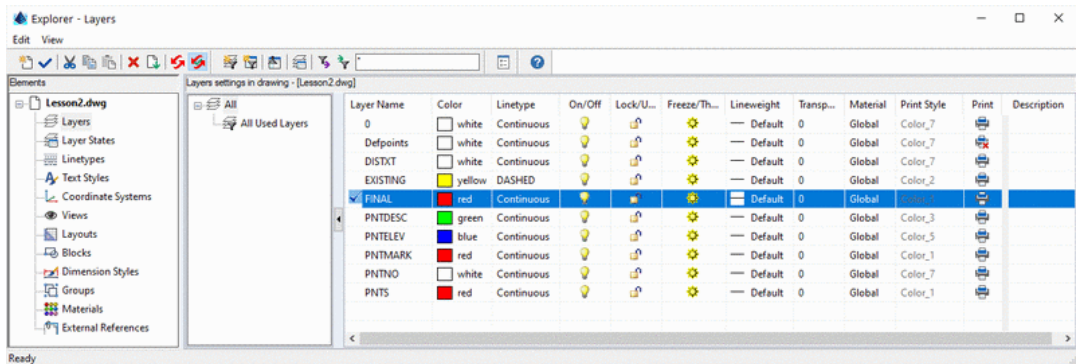

Next vertex: when satisfied, press Enter to complete the Window Polygon

[FILter]/<Select entities>: press Enter to complete the selection set

The following shows the scaled points:

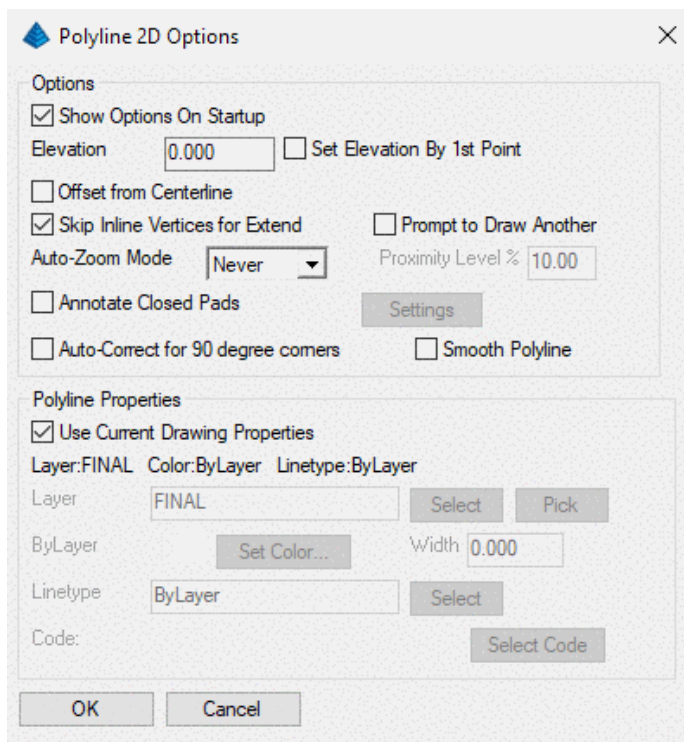

- Next, you will prepare for drawing linework by setting the current layer. You should draft linework and symbol work in designated layers. In this example, you will put linework and symbol work in a layer named **Final**. A "best-practice" would be to place property linework on a **PropLines** (or similar) and utility linework on a **Utilities** layer, *etc*, but for now, you will put all linework and symbols on the layer Final. To pick the current working layer, select the View – Layer Control command (IntelliCAD shown):

Click **Final**. Right click, select **Current** and close the Layer control.

NOTE: If the "Final" layer does not exist, create it and assign it a suggested color of red.

- Issue the Draw – 2D Polyline command which allows you to easily draw a polyline between point numbers. A dialog box might appear as illustrated below. If it does, accept the defaults and click **OK**.

First, connect portions of the property line via the steps outlined below:

1 This instructs the 2D polyline to commence at Point #1.

[Arc/Close/Distance/Follow/Undo/⟨Pick point or point numbers⟩]:

8 This instructs the 2D polyline to be drawn to Point 8

[Arc/Close/Distance/Follow/Undo/⟨Pick point or point numbers⟩]:

press Enter This creates a polyline. Keep this as a separate polyline because later you will turn this back lot line into a fence line. Press Enter to repeat the **2D Polyline** command.

[Arc/Close/Distance/Follow/Undo/⟨Pick point or point numbers⟩]:

8-10 This instructs the 2D polyline to be drawn through Points 8, 9 and 10.

⟨Pick point or point numbers⟩

a This indicates a tangential arc to be drawn starting from Point 10.

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/⟨Endpoint or point number⟩]:

15 This indicates the arc shall terminate at Point 15.

[Arc/Close/Distance/Extend/Follow/Line/Undo/⟨Pick point or point numbers⟩]:

1 This instructs the polyline to be drawn back to the starting point. The segment from 15 to 1 is not guaranteed to be tangent to the previous arc.

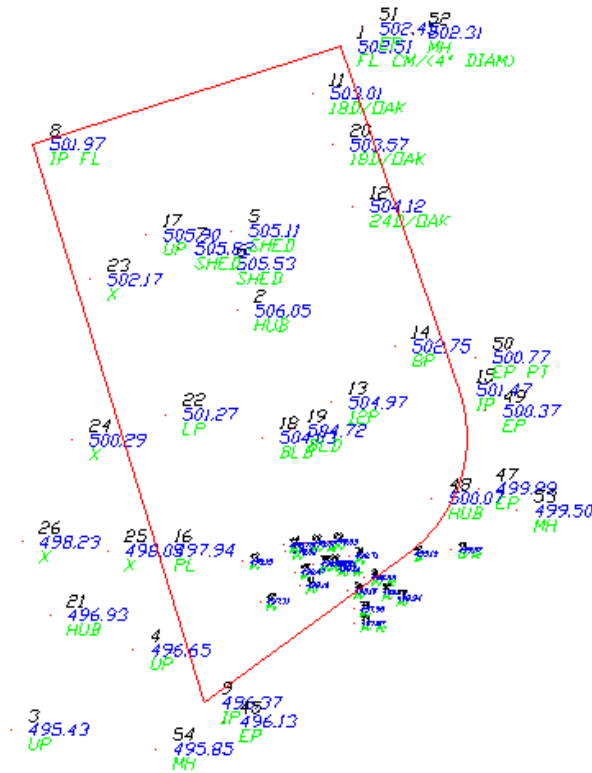

[Arc/Close/Distance/Follow/Undo/⟨Pick point or point numbers⟩]:

press Enter

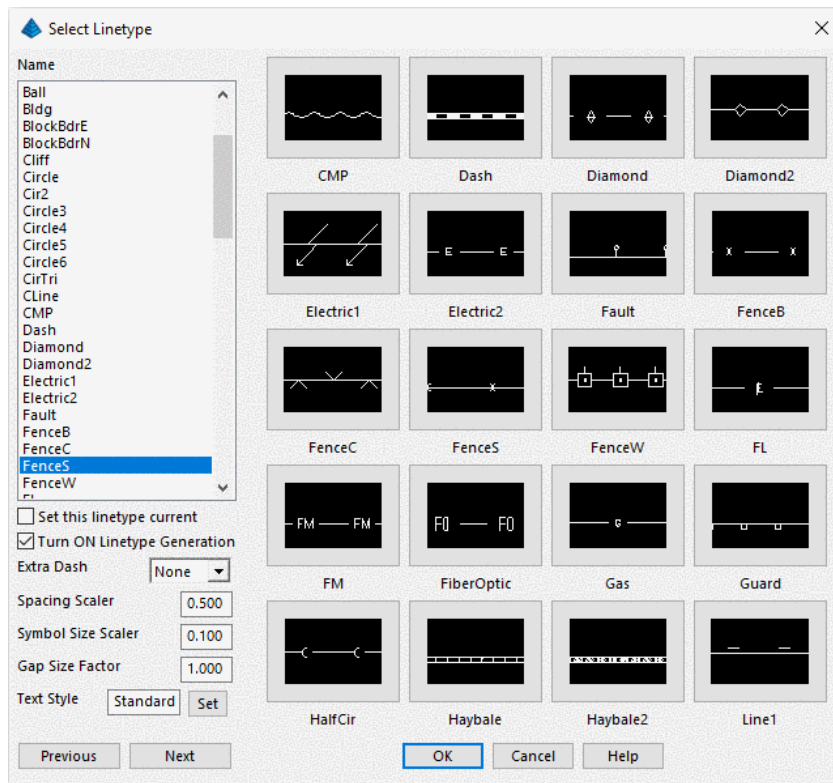

This creates the full lot.

2D Polyline Courses

You should have the following linework at this point:

You will now create a fence line on the polyline you drew from points 1 to 8. Click the Annotate – Line Types – Change Polyline Linetype command. This command creates polylines that respond as one entity when selected.

Notice in the dialog box above that the current Line Type Scaler, governing spacing, should be 0.5 (inches) and the Text (height) Scaler is 0.1. If your settings are different, you may want to set these items to match the example.

Choose the **FenceS** option (the solid fence line) and click **OK** and when prompted:

Select linework to change.

[FILter/?]/<Select entities>: pick the polyline you created from points 1 to 8

[FILter/?]/<Select entities>: press Enter

Inspect the result by clicking View – Isolate Layers command and when prompted:

Select objects on layers to isolate.

[FILter/?]/<Select entities>: pick the property line

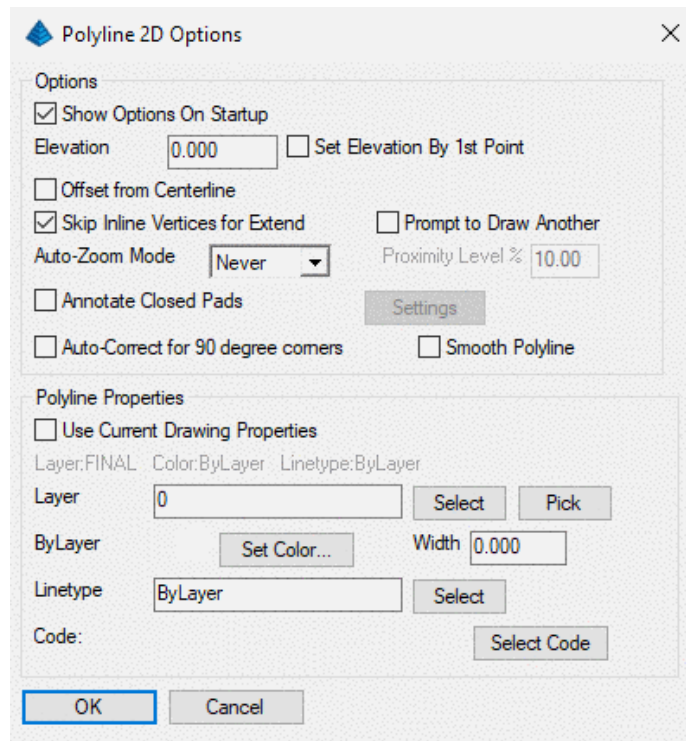

[FILter/?]/<Select entities>: press Enter

Here is the result:

Select the View – Restore Layers command to recover your points. Experiment with the "cadence" of *Isolate Layers* and *Restore Layers*. Select **Isolate Layers**, pick the layer(s) to isolate and then press Enter twice. Then select **Restore Layers**.

Next, you will connect up the edge of pavement. Select the Draw – **2D Polyline** command. Again, a dialog box might appear as shown below. If it does, make sure that the options selected are the same. In the future you can choose not to see this box:

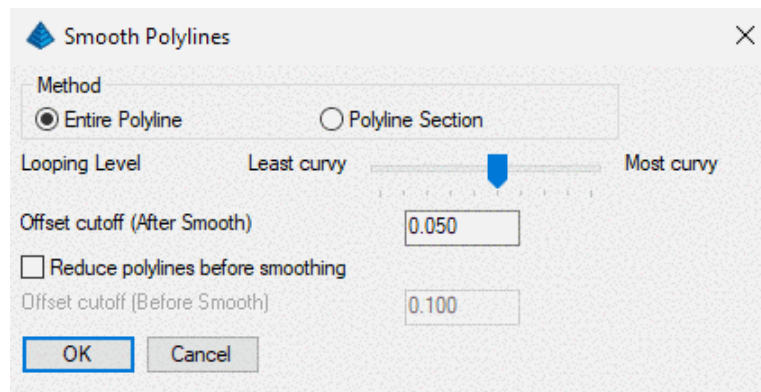

Click **OK**. Proceed as follows to connect up the edge of pavement:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 45-47,49-51

Press Enter at the next prompt to exit the command and create the road. Note how you can separate range entries using a comma.

To smooth the edge of the road, select the Edit – Polyline Utilities – Smooth Polylines command and set the values as shown below and click **OK**:

When prompted:

Select polylines to smooth.

[Filter/?]/<Select entities>: pick the edge of road polyline

[Filter/?]/<Select entities>: press Enter

To offset the smoothed edge-of-road polyline by 24 feet to make the opposite edge of the road, select the Edit – Offset – **Standard Offset** command and provide the following responses:

Offset: ENTER for Through point/<Distance>: 24

[Undo]/<Select entity>: Pick the edge-of-road polyline

[Both sides]/<Side for parallel copy>: Pick to the right of the polyline

[Undo]/<Select entity>: press Enter

Now, select the View – **Isolate Layers** command again. Pick on any of your linework and only the entities on the picked layers are displayed.

Next, you will draw the shed. Select the Draw – **2D Polyline** command. To draw a two-sided shed, connect points 5 through 7 as follows:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 5-7

Press Enter at the next prompt to exit the command and create two-sides of a shed as shown here:

Turn the 2-sided shed into a 4-sided shed by issuing the Survey – 4 Sided Building command. Complete the command as follows:

Options/Points/<Pick a line or polyline>: Pick the shed

Options/Points/<Pick a line or polyline> (Enter to end): press Enter

Now the 2-sided building looks like this:

Focus your attention on the area of tightly spaced points with point numbers ranging from 27 to 44. This is the driveway and paving area. In the case of the driveway, assume that the surveyor who collected the points shot in 3-point arcs. They came up to a PC, shot a point on the arc, and finished up at the PT.

Click on the View – **Window** and pick a lower left and upper right point that windows the driveway area. If you wish to use the View – **Previous** command to zoom out, then use View – **Window** to zoom in again.

Select the Draw – **2D Polyline** command and walk the polyline through the two arcs as follows:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 27

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 28

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: a

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: s (Use S for 3-pt arcs)

Second point or point number: 29

Endpoint or point number: 30

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: 31

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: a

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: s

Second point or point number: 32

Endpoint or point number: 33

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter

In the above exercise you started at point 27, went to the PC at point 28 and inserted a 3-point arc through points 29 and 30. You proceeded on a tangent direction to point 31, which was another PC, then completed a 3-point arc through points 32 and 33, and ended. Now, connect up the basketball court area. Run the Draw – **2D Polyline** (or press Enter to repeat the previous command).

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 27

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 44

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: 43-39 (you can enter "backwards" ranges)

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: a

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: s

Second point or point number: 38

Endpoint or point number: 37

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: 36

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: a

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: s

Second point or point number: 35

Endpoint or point number: 34

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter

Shown below is your drawing to this point.

Next you will make a building footprint. Points 18 and 19 are two shot corners of a building and assume that the surveyors taped the main house, going clockwise from point 18, as follows:

10'L, 20'R, 40'L, 20'R, 20'L, 83'L, 60'L, 23'L, 10'R.

Let's begin by using the **2D Polyline** (keyin **2dp**) command to draw the first wall:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 18
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 19
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: press Enter

You can easily create the building "jogs" through the Edit – Extend – by Distance command. Complete the prompts as follows:

Pick arc, line or polyline to extend: pick the building line closer to point 18 (This makes the arrow point toward 18 rather than 19. Now you can go clockwise:)

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L10 (lower case "l" and "r" also work)

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): R20

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L40

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): R20

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L20

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L83

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L60

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L23

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): C

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): press Enter

Next, you will complete the linework for the sewer line and the electric utility line. Use the View – **Extents** (keyin ze) command so you can see all your points.

The sewer line runs from points 52 to 53 to 54. Use the **2D Polyline** command and create the sewer line as follows:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 52-54

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: press Enter

To annotate the sewer line with an S, initiate the Annotate – Line Types – **Change Polyline Linetype** command as used earlier. Within the dialog box, set the **Spacing Scaler** to **1.5**. This will label "S" on the sewer line every 1.5" when plotted at the current scale (1"=100'). Then select the **Sewer** linetype from the list, and then select the sewer polyline that runs next to the road. The polyline will be annotated.

Next, create the electric utility line with the **2D Polyline** which runs from point 3 to point 4 to point 17:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 3

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 4

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: 17

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: press Enter

No points were taken beyond point 17, due to obstructions from the various setups in the field. So you must extend the polyline from point 17 to beyond the property. Click the Edit – Extend – **By Distance** command as used earlier. Pick on the electric utility polyline near point 17. Then pick beyond the property line and press Enter to end.

Before you annotate the electric utility line, you must offset it 25' on both sides, for a 50' total right-of-way. You will do this using Edit – Offset – **Standard Offset** command. Enter the offset distance of 25. Pick the electric utility polyline and then pick to one side for the first offset. Repeat for the other side, by first picking the electric utility polyline, then picking the other side for the offset. Press Enter to end.

The next task will be to annotate the central electric line using the Annotate – Line Types – Polyline to Special Line command. Choose the **Electric** linetype, which appears on the third page of linetypes and then click **OK**. Then select the electric utility polyline to annotate it, and press Enter.

Next, make the Property lines bold. Use the Edit – Polyline Utilities – Change Polyline Width command and provide the responses as indicated:

New width <0.00>: 1.5

Select polylines to change width of.

[FILter]/<Select entities>: Pick once for the fence line portion

[FILter]/<Select entities>: Pick once for the remaining property lines

[FILter]/<Select entities>: press Enter

To add color and improve layer management, make a layer for your road and driveway. Select the View – Layer Control command.

- Click the New Layer button, and enter the name **Road** for the new layer.
- Choose the color **Cyan** by clicking the color square to the right of the layer name.
- Close the dialog.

Initiate the View – Change Layer command. When prompted:

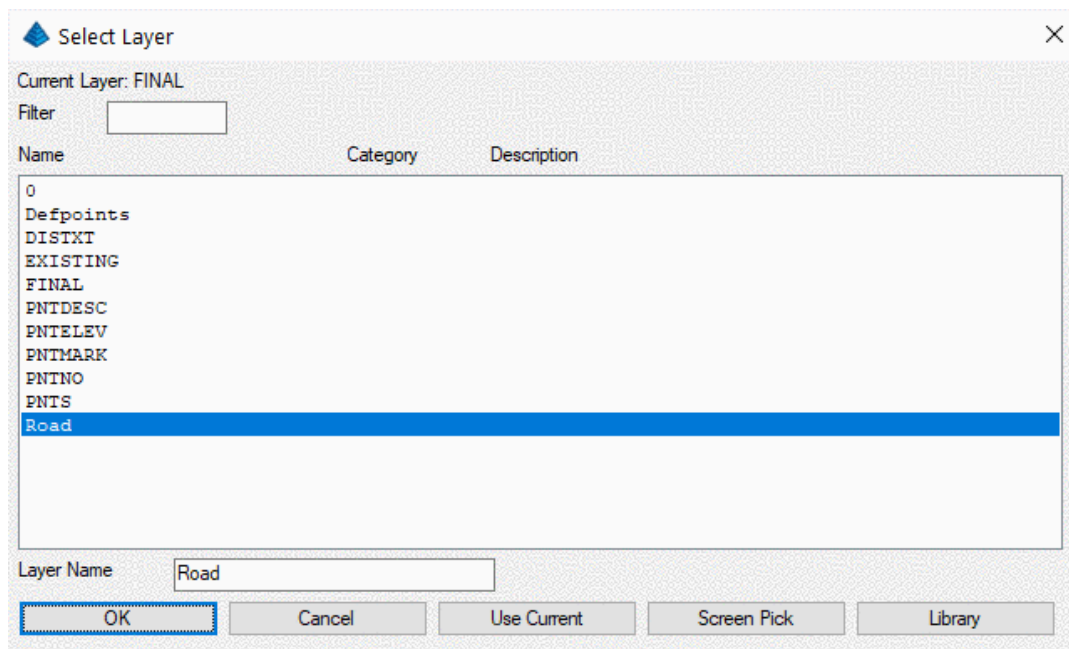

Select entities to be changed.

[FILter]/<Select entities>: Pick all driveway and road entities

[FILter]/<Select entities>: press Enter

Specify new layer [Name/Current/<pick entity>]: n

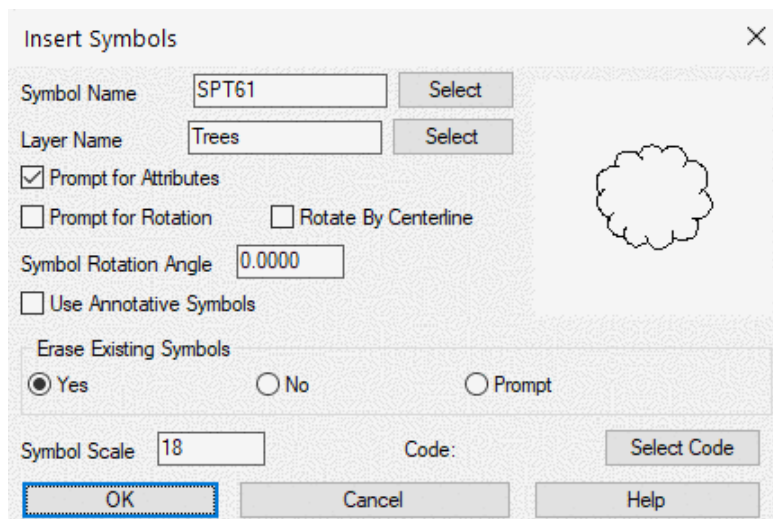

This brings up the dialog box shown below. Select **Road** and click **OK**.

Your linework is now complete and is shown below:

You will add symbols for trees, property corners, manholes and a light pole. Start with the trees. Points 11, 12, and 20 are oak trees of different sizes, and point 14 is a pine tree. Use symbol 61 for the deciduous oak trees and symbol 53 for the pine tree. We'll use the Draw – Symbols – Insert Symbols command. The following dialog box appears:

The various items to place are summarized below:

Small Deciduous Tree: Symbol: **SPT61**, Layer: **Trees**, Size: **18**
Options/Select entities/Enter coords/<Pick point or point numbers>: 11
Options/Select entities/Enter coords/<Pick point or point numbers>: 20
Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

Press Enter to re-run the command for:

Large Deciduous Tree: Symbol: **SPT61**, Layer: **Trees**, Size: **24**
Options/Select entities/Enter coords/<Pick point or point numbers>: 12

Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

Press Enter to re-run the command for:

Small Coniferous Tree: Symbol: **SPT53**, Layer: **Trees**, Size: **8**

Options/Select entities/Enter coords/<Pick point or point numbers>: 14

Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

Press Enter to re-run the command for:

Found Iron Pins: Symbol: **SPT5**, Layer: **FINAL**, Size: **8**

Options/Select entities/Enter coords/<Pick point or point numbers>: 8-10,15

Wildcard match of point description <*>: press Enter

Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

Press Enter to re-run the command for:

Concrete Monument: Symbol: **SPT13**, Layer: **FINAL**, Size: **8**

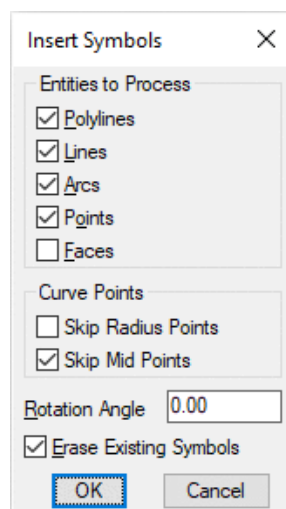

Options/Select entities/Enter coords/<Pick point or point numbers>: 13

Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

Press Enter to re-run the command for:

Sewer Manholes: Symbol: **SPT34**, Layer: **FINAL**, Size: **8**

Options/Select entities/Enter coords/<Pick point or point numbers>: s (the following dialog box appears, click **OK**:)

Select arcs, circles, faces, points, text, lines and polylines.

[FILter]/<Select entities>: pick the Sewer polyline

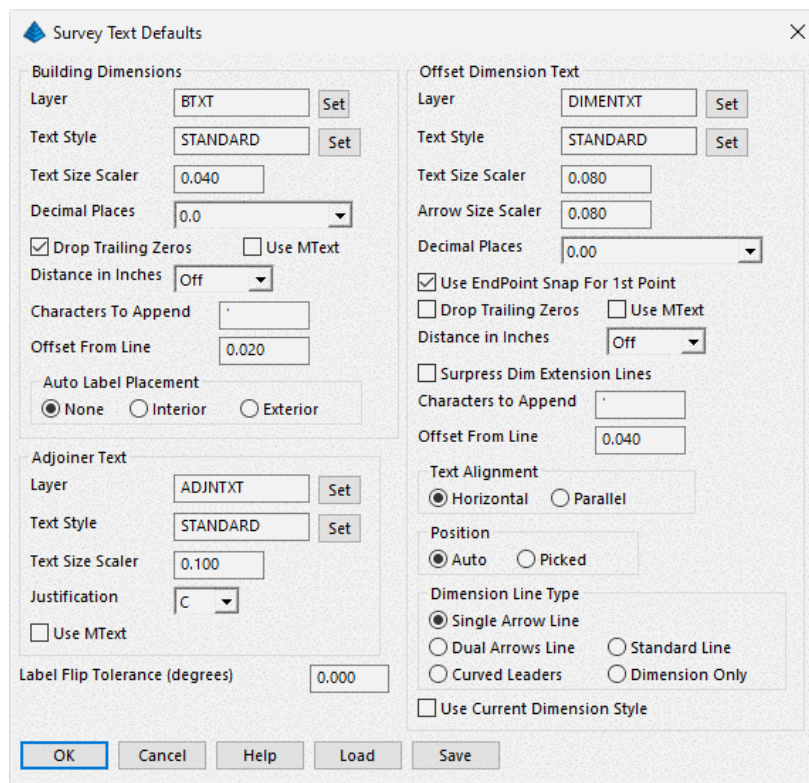

[FILter]/<Select entities>: press Enter to terminate the selection option

Options/Select entities/Enter coords/<Pick point or point numbers>: press Enter

The symbols are inserted at the three polyline endpoints.

Reduce clutter by selecting the View – Freeze Layer by Selection command and picking a point number. The points freeze, leaving only linework and symbols. To bring the points back, use the View – Thaw Layer command. The Freeze Layer/Thaw Layer commands go together, just like the **Isolate Layers/Restore Layers** commands.

Next, you will create (in reduced size) your building dimensions. You can set the building dimension text size for the current work session using the Annotate – Survey Text – Survey Text Defaults command. The following dialog box appears:

The changes you will make are in the upper-left section "Building Dimensions." Change the following:

- set the **Layer** to BTXT, so that building dimensions can be frozen to reduce the clutter even more. It is generally a good strategy to use layers for selective freezing and thawing.
- set the **Text Size Scaler** to 0.04
- enable the **Drop Trailing Zeros** (this option will label 17.0' as 17').
- set the **Offset From Line** to 0.02.

Click **OK** on the above dialog box. Run the Annotate – Survey Text – Building Dimensions command. Click on the middle of the bottom segment of the building and then drag the alignment to the right, along the same bottom segment being dimensioned. The resulting label is shown below.

If you had dragged the cursor to the left rather than to the right, with the same near-parallel angle to the line, the 83' would be drawn below the building rather than above.

Another example is shown below. Select Annotate – Survey Text – **Building Dimensions** and click on the left-most segment of the building. Then click roughly perpendicular to the left. This creates a perpendicular, rather than parallel, label as shown below.

Label the rest of the building. Notice that the sides of the building that you are dimensioning are measured in even feet. Because you had selected the **Drop Trailing Zeros** option when you set the **Survey Text Defaults** (and even with the **Decimal Places** defaulting to 0.00), the ".00" is not reflected in the labels:

NOTE: If you choose the wrong direction while you are labeling, a suggestion would be to re-pick the segment and place it in the correct direction and complete the command. Then **Erase** the undesired label(s) at the conclusion of the command.

Next, you will label the offset dimension from property lines to two building corners, the SE corner as offset from the south property line, and the SW corner as offset from the west property line. Because of the options you set in the **Survey Text Defaults** dialog box above, **Offset Dimensions** will be created on layer DIMENTXT, and they will be horizontal, with arrowheads.

Re-issue the Annotate – Survey Text – **Survey Text Defaults** command. The dialog previously shown will reappear. Change the following in the **Offset Dimension Text** grouping:

- set the **Text Size Scaler** to 0.04
- set the **Arrow Size Scaler** to 0.04
- enable the **Dual Arrows Line** option

Click **OK** on the above dialog box. Run the Annotate – Survey Text – Offset Dimensions command and complete the prompts:

[end on] Pick Bldg/Object Corner: pick on the SE building corner

[perp] Pick Line To Offset From: pick on the South property line (before the arc, near the end of the driveway)

The setback is labeled 43.49'. Note the distance suffix is/was labeled as an apostrophe "" rather than "ft." If you desire an alternate label, re-examine the *Characters to Append* control of the **Survey Text Defaults** command.

Re-issue the Annotate – Survey Text – **Survey Text Defaults** command. The dialog previously shown will reappear. Change the following:

- set the **Text Alignment** to Parallel

Click **OK** on the above dialog box. Run the Annotate – Survey Text – **Offset Dimensions** command again and complete the prompts:

[end on] Pick Bldg/Object Corner: pick on the SW building corner

[perp] Pick Line To Offset From: pick on the West property line (avoid the electric right-of-way lin

The result is shown below:

Notice within the above prompts, the use of the [end on] and [perp] snaps. When Carlson sets a snap for temporary use, it displays the snap within the brackets as shown. A building corner is always an endpoint, so the **end** snap always applies to the first pick. The offset is the perpendicular distance to the property lines, so the **[perp]** snap always applies to the second pick. The **per** (perpendicular) snap applies to offsets from arcs as well. In the case of arcs, the **per** snap finds the shortest, radial distance to the arc.

You could use the **Offset Dimension** command to label the Electric utility right-of-way distance of 50' total by entering **nea** (for nearest snap) for the first pick, then entering the default **per** snap for the second pick on the other side of the right-of-way.

Next, you will add adjoiner ownership text to the property lines. Annotate – Survey Text – **Survey Text Defaults** command. The dialog previously shown will reappear. Change the following:

- set the **Adjoiner Text Justification** to C for centered
- set the **Text Size Scaler** to 0.06

Click **OK** on the above dialog box. Run the Annotate – Survey Text – Adjoiner Text command and complete the prompts:

Pick Line Or Polyline: pick the west property line

Starting point: pick a centering point west of the property for the adjoiner text

Enter text at the cursor, press Enter to finish the command... supply the text as follows:

Brian W. and Mary T. Jones (press Enter)

D.B. 101, P. 37 (press Enter twice) This produces parallel, center-justified text on the west side of the property.

Press Enter to repeat the command and complete the following prompts:

Pick Line Or Polyline: pick the north property line

Starting point: pick a centering point north of the north property line

Enter text at the cursor, press Enter to finish the command... supply the text as follows:

Stan W. Bosworth (press Enter)

D.B. 94, P. 272 (press Enter twice) The results are shown here:

Next, you will add bearing annotation. Select the Annotate – Angle/Distance – **BearingDistance** option to place Bearing and Distance above the line and follow the prompts below:

Select line or polyline [Size/Points]: pick the northern property line to the east, or right side. The bearing direction will be labeled towards the picked end, which is Northeast.

Select line or polyline [Size/Points] (Enter to end): pick the eastern property line closest to the southern endpoint of the line

Select line or polyline [Size/Points] (Enter to end): press Enter

To label the western property line on the lower (western) side of the line, select the the Annotate – Angle/Distance – **BearingDistance** option to place Bearing and Distance below the line and follow the prompts below:

Select line or polyline [Size/Points]: pick the western property line closest to the northern endpoint of the line

Select line or polyline [Size/Points] (Enter to end): press Enter

To label the southern line segment with a leader, run the Annotate – Annotate with Leader – Brg-Dist with Leader command and follow the prompts below:

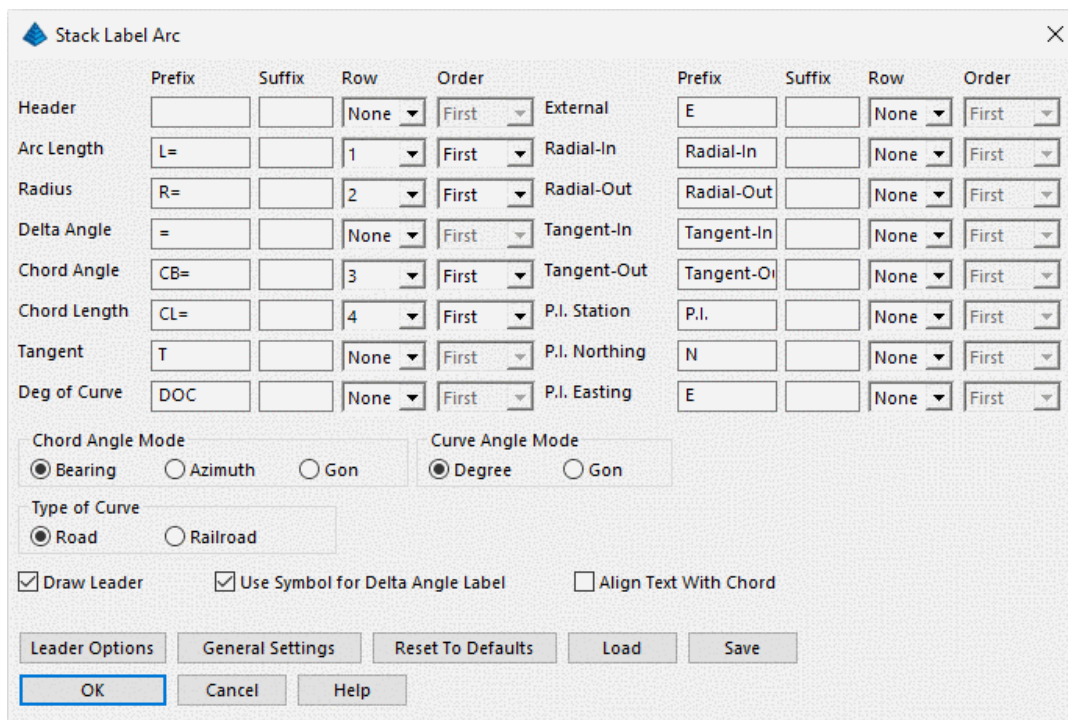

Select line or polyline [Options/Size/Points]: pick the southern property line segment on the southwest side

Pick end point for leader: pick a point for the label position

Select line or polyline [Options/Size/Points] (Enter to end): press Enter

Next, you will want to annotate the arc in the drawing. The label will consist of four entries: arc length, radius, chord bearing (direction) and chord distance. Run the Annotate – Annotate Arc – Stack Label Arc Pick Side command and follow the prompts below:

Options/Points/<Select arc>: type O for Options and the Stack Label Arc dialog box appears

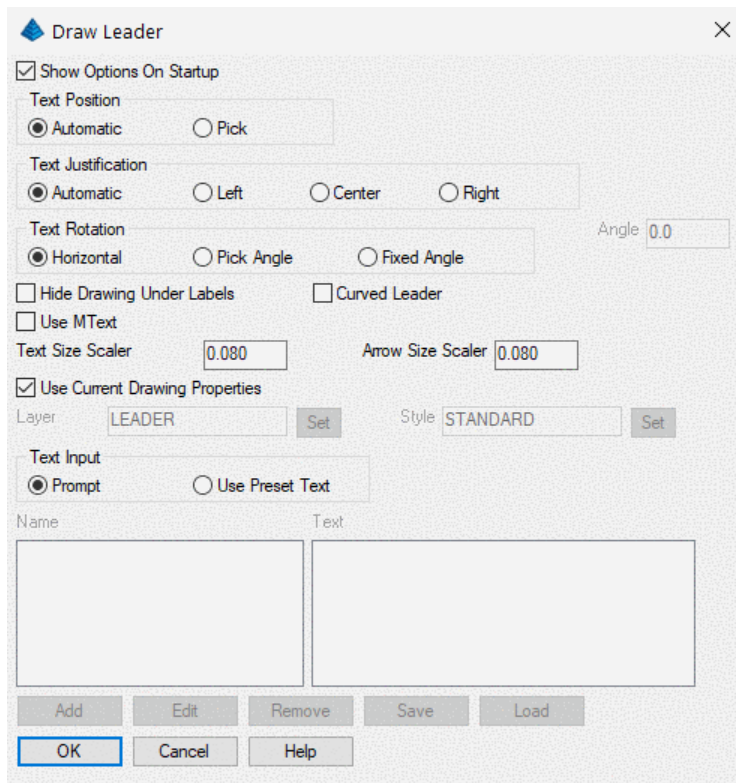

Set the sequence column to 1, 2, 3 and 4 as shown. When you are done with the dialog box, click **OK** to resume the command prompts:

Options/Points/⟨Select arc⟩ (Enter to end): pick the arc

Pick end point for leader: pick a point to the right to place the label. As the cursor moves, the text "ghosts" which allows you to make the best possible placement decision

Options/Points/⟨Select arc⟩ (Enter to end): press Enter

Next, you will label the trees, the shed, and the building using a special leader, for a hand-drafted appearance. Use the Draw – Leader – Special Leader command which displays the following dialog box:

Click **OK** and complete the prompts as follows:

Options/Size/Pick Arrow Location: pick near the southernmost corner of the shed

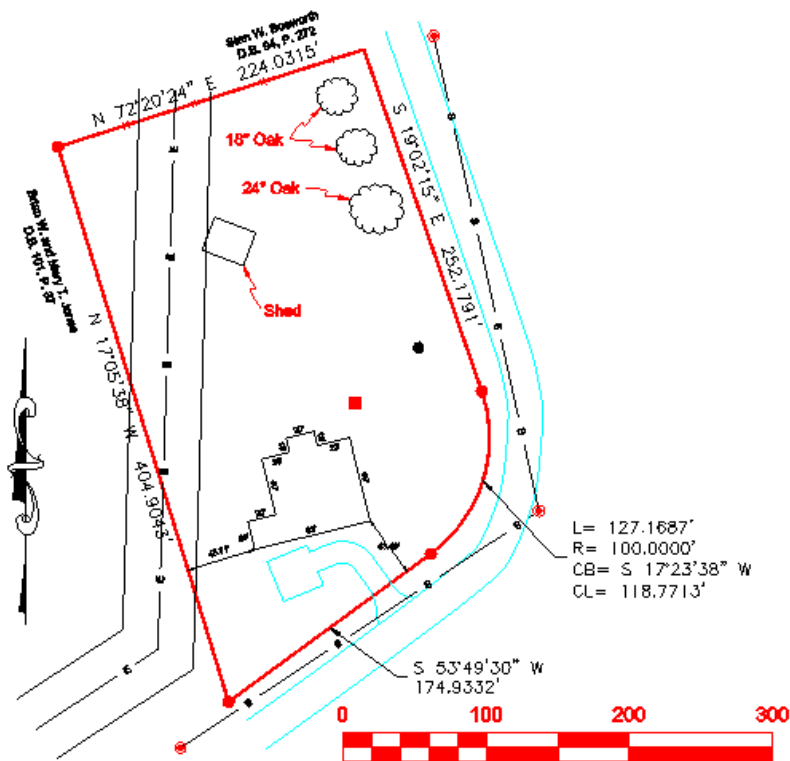

Text location: pick slightly down and to the right

Text: Shed

Text: press Enter

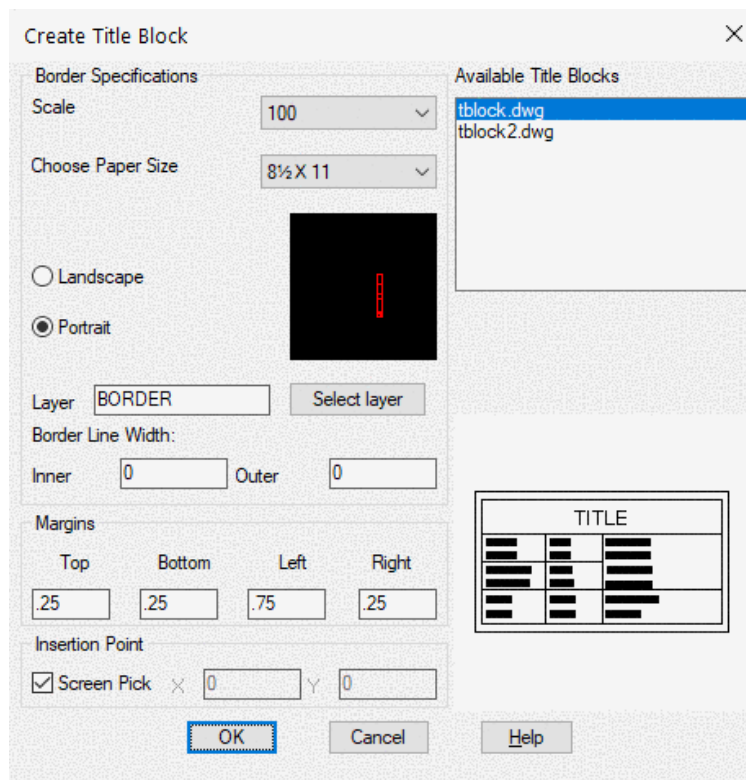

Repeat the process for all the special leader text items shown in the drawing below. In the case of the 18" Oak trees, create just one leader with text and on the second oak tree, create only the leader and then press Enter when asked for Text.

Your drawing should be similar to this one:

You can add a North Arrow and Bar Scale by selecting these options under the **Annotate** menu. When you place the North Arrow, pick your North Arrow symbol, maybe change the scale, and click **OK**. Then pick an insertion point. You place the Bar Scale by answering the prompts and picking a location. Both the North Arrow and the Bar Scale can be moved to desired locations with the Edit – **Move** command.

Next, you will insert a title block with a border. Select the Settings – Title Block – Standard command to display the dialog box below:

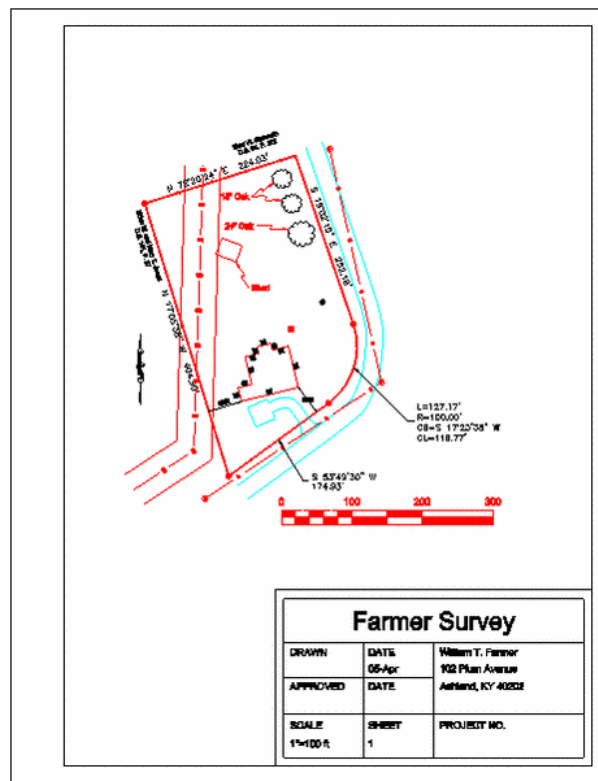

Choose paper size A1 (portrait view, 846mm by 1194mm) and click **OK**. Pick a point below and to the left of the survey in order to locate the lower-left corner of the border outer line. Remember that the title block will be at the bottom, so leave extra room at the bottom.

The following dialog appears, prompting you for the attributes of the title block. Be sure to also click Next in order to enter in more attributes.

Name	Prompt	Value	Multiple line
TITLE	TITLE	Farmer Survey	
COMMENT1	COMMENT1	William T. Farmer	
COMMENT2	COMMENT2	102 Plum Avenue	
COMMENT3	COMMENT3	Ashland, KY 40202	
COMMENT4	COMMENT4		
PROJECT	PROJECT NUMBER		
DRAWN	DRAWN BY		
DATE	DRAWN DATE	05-Apr	
APPROVED	APPROVED		
DATE2	APPROVED DATE2		
SCALE	SCALE	1"=100 ft	
SHEET	SHEET	1	

Your drawing should resemble the one shown below:

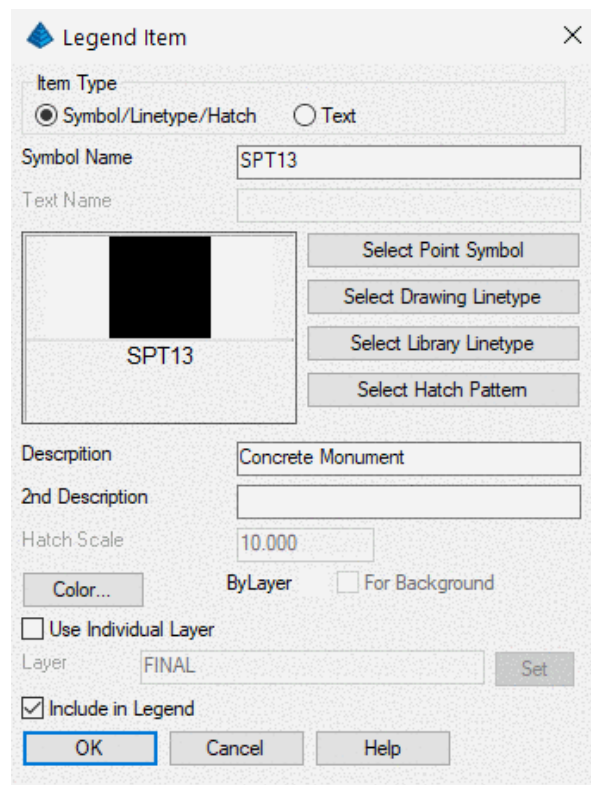

Our next task will add a legend. Pick the Annotate – Draw Legend command. Choose the **New** tab and then open a default legend name (*i.e.* Plat1). When the dialog box appears, select **Add from Drawing**. Window select each symbol/linetype you want to appear in the legend and press Enter. You will then see the symbols that you picked listed.

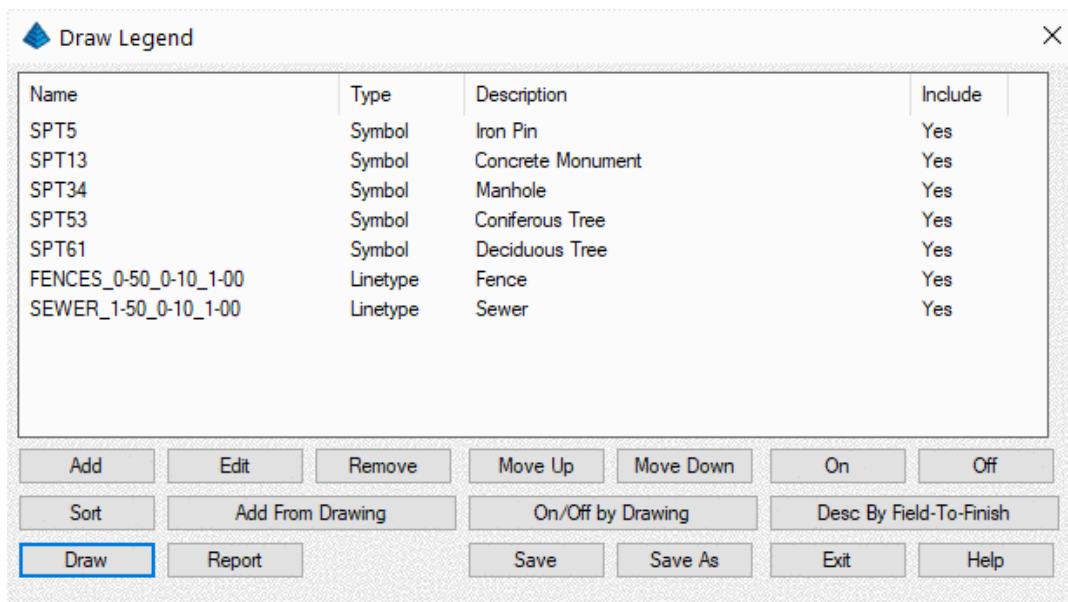

If you want to change the order of the items in the list, use the **Move Up** and **Move Down** buttons, after first selecting and highlighting the item to be moved. After the list is ordered correctly, highlight one item on the list and click the **Edit** button to edit the symbol definition. Edit each symbol definition individually and type the following descriptions in the description box:

- SPT5 = **Iron Pin**
- SPT13 = **Concrete Monument**
- SPT34 = **Manhole**
- SPT53 = **Pine Tree**
- SPT61 = **Oak Tree**

Below is the symbol definition, with Description, for SPT13:

Save the completed legend which is shown below:

Select the **Draw** option from the Legend Definitions dialog box. Set the defaults as shown below:

Draw Legend [X]

Text Size Scaler: 0.100

Symbol Size Scaler: 0.100

Hatch Size Scaler: 2.000

Line Size Scaler: 1.000

Gap Factor: 1.000

Layer Name: LEGEND [Select]

Style Name: STANDARD [Select]

Draw 2nd Description

Draw Legend Title Underline Title

Name: LEGEND Size Scaler: 0.200

Title Line 1: These standard symbols

Title Line 2: be found in the drawing.

Draw Header Symbol: Symbol

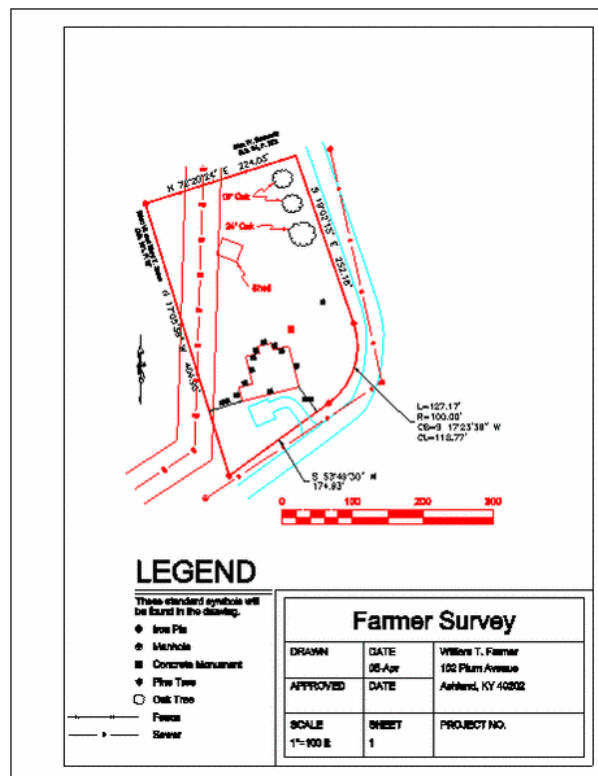

Desc: Description 2nd Desc: Code

Draw Grid Lines

Layout: Left Justified Right Justified Right Symbol

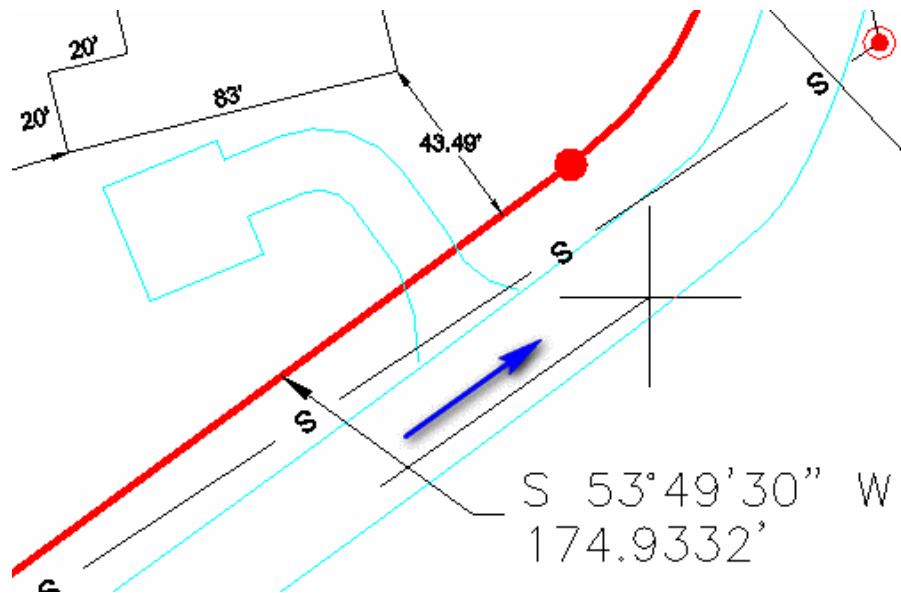

[OK] [Cancel] [Help]

Click **OK**. Pick a point for the legend at a coordinate location approximately at 5311.5,4275 (CAD coordinates) then click Exit. You may need to adjust the position and/or portions of the legend to fit in the tight space. You also may need to move the previously drawn bar scale. Use the Move command to do this. The following shows the drawing to this point:

NOTE: If you wish to reset the spacing of the sewer and electric utility annotation, set a desired value for the LTSCALE box in the Settings – Drawing Setup dialog box (the setting is 50 in this example).

Next, you will use DText (Dynamic Text) to label the road and MText (Multiline Text) to create a certification block. Zoom in on the area shown below:

At the command line, type **dtext** and complete the following prompts:

Specify start point of text or [Justify/Style]: j

Enter an option [Left/Center/Right/Align/Middle/Fit/TL/TC/TR/ML/MC/MR/BL/BC/BR]: r

Right point of text: pick a point as shown below, just to the left of the leader annotation

Height of text <8.00>: 10

Rotation angle of text <E>: pick a point as shown below by the location of the crosshair

Text: Meadow Lane

Text: press Enter

This right-justifies the label **Meadow Lane**, ending it before it contacts the leader line.

Now you will enter a certification using MText. The MText command stretches an entire block of text. This command breaks up the lines in the block of text depending on how you edit and adjust the MText window. First, use the View – **Extents** command to view the entire drawing. Then type **mtext** at the command line and follow the prompts:

Multiline Text: First corner for block of text: 5660,4980 (or pick an approximate location)

[Justification/Rotation/Style/Height/Width]/<Opposite corner for block of text>: pick a point below and to the right of the first, but inside the inside border line

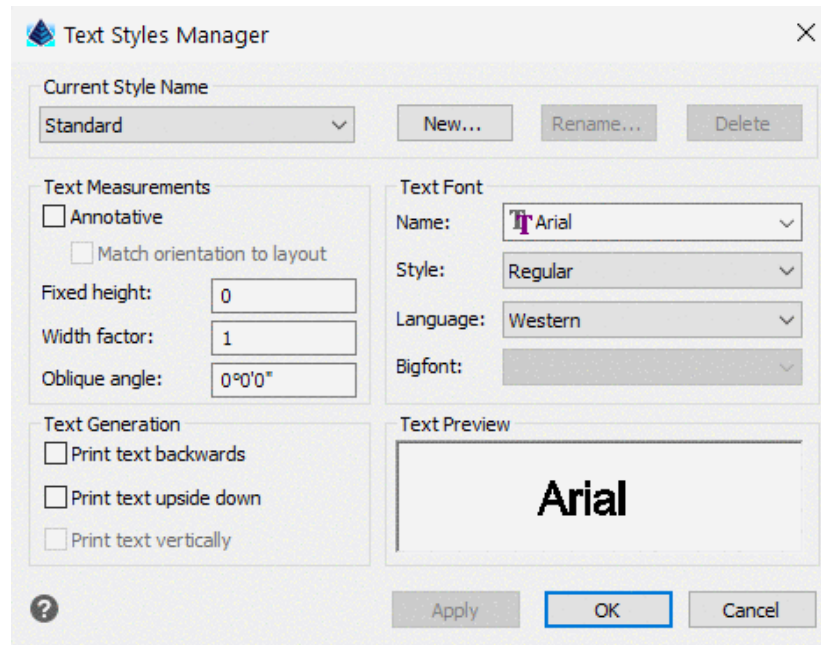

You now see the MText interface that displays word-processing style editing options. Indicate text height of 8 (press Enter to commit) then type the following into the dialog box: Surveyor's Certification

I do hereby certify that the survey shown heron was performed under my direction by method of random traverse and that the error of closure was 1:52544.

John Doe, PLS #1234 The command "wraps" the text when it runs out of space in the MText window. Click **OK** at the upper right to place this text into the drawing.

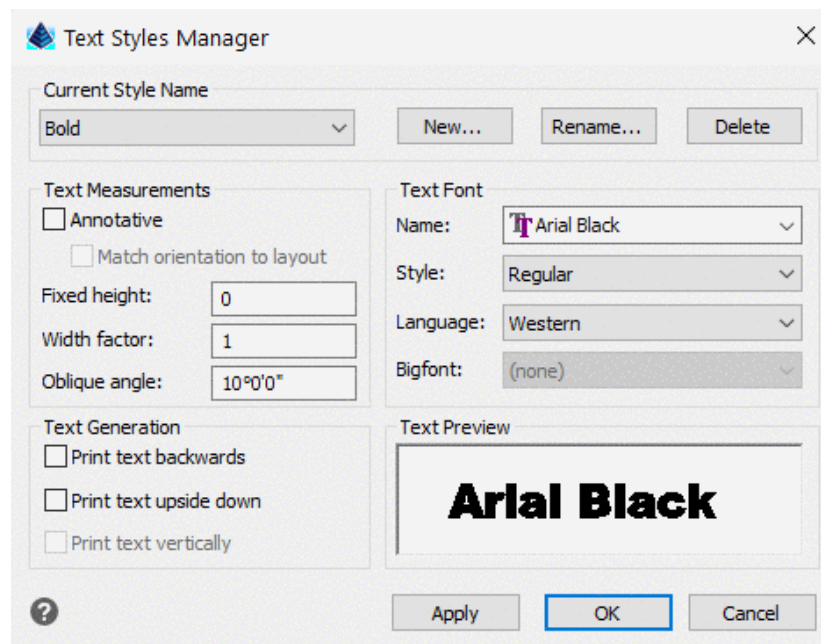

After the MText is placed, you can click on the text to activate the grips. All four corners highlight as grips. When you pick on a grip, you can expand or change the shape of the MText rectangle. When you do this the text adjusts automatically, wrapping into more or fewer lines of text based on the size of the MText window. You can also move the entire text block to a new location.

Next, you will define a text style and then add text using that style. Use the Draw – Text – **Set Style** command to display the dialog box below:

Click **New**, enter **Bold** in the New Text Style dialog, and click **OK**.

Define the **Bold** style consisting of the **Arial Black** font and an Oblique Angle of 10° by entering the settings as show below:

Then click **OK**. Now, run the DText command by typing **dtext** at the command line, and place the text at the top of the drawing as follows:

Specify start point of text or [Justify/Style]: pick a point near the northwest corner of the drawing

Height of text <8.00>: 20

Rotation angle of text <N53d56'51"E>: E (for due East)

Text: William T. Farmer

Text: press Enter

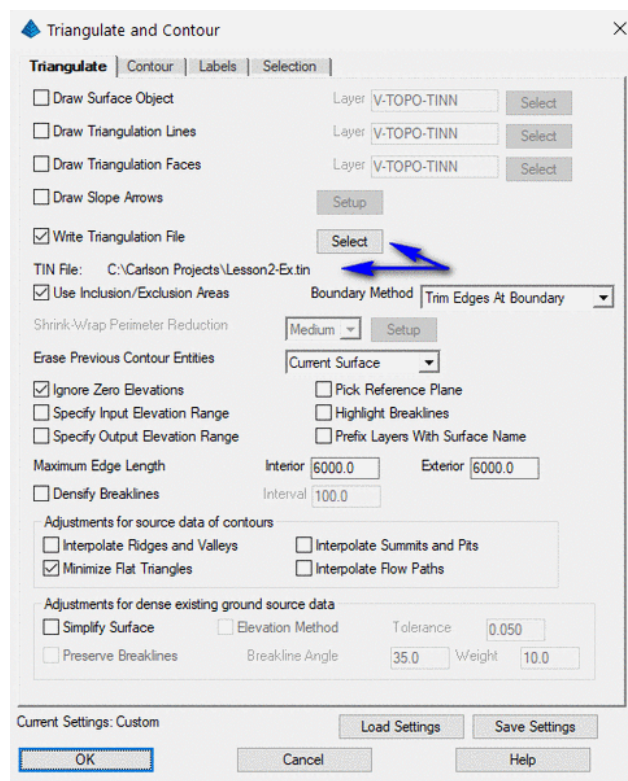

Next, you will create an area label for the drawing. Select the Area/Layout – Area Defaults command. Select the Acres entry and click **Edit** to change the Precision for the Acres labels to 2 decimal places. Click **OK** to dismiss the *Acres* settings dialog box and click **OK** to dismiss the *Area Defaults* dialog box.

Select the Area/Layout – Area by Lines & Arcs command. When prompted to **Select objects**, pick the two polylines that taken together, completely enclose the property.

Pick an area labeling centering point for the area label under the **William T. Farmer** title at the top of the drawing.

Next, bring the points back and draw a contour map. To re-see the points, use the View – Thaw/On All Layer command.

Initiate the Surface – Triangulate & Contour command. On the Triangulate tab, set the following values:

Also make sure to enable the **Use Inclusion/Exclusion Areas** option. Navigate to the **Contour tab** and set the **Contour Interval** to 1.0. Click **OK** and then answer as follows:

Select Inclusion perimeter polylines or ENTER for none.

[FILTER]/<Select entities>: press Enter for none.

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: select the building and the shed, and then press Enter. Since the building and shed are closed polygons acting as exclusion perimeters, the contours will not pass through them when they are created.

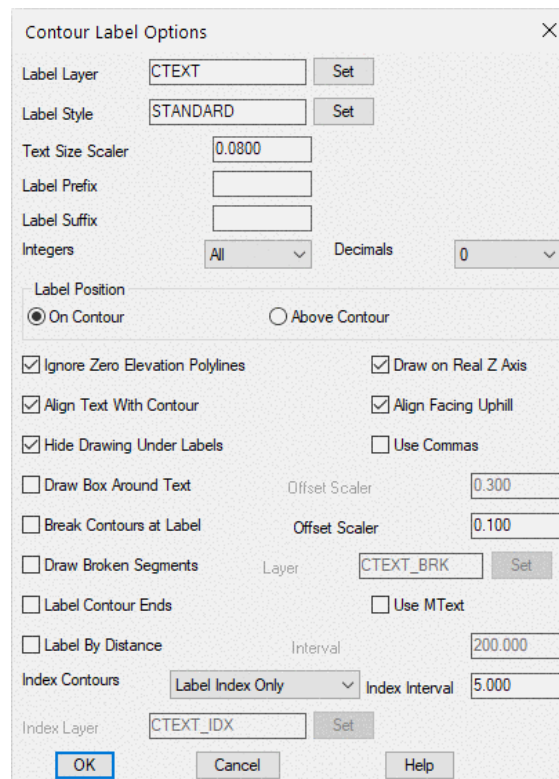

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: all

[FILter]/<Select entities>: press Enter

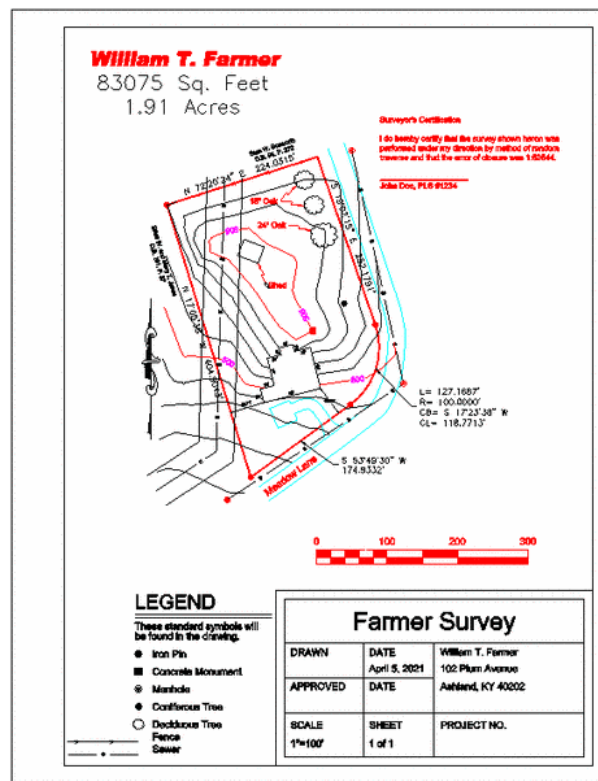

The contour map is created. Freeze the points again by using View – **Freeze Layer by Select** and picking one of the points.

Next, label the contours (this could have also been accomplished via the **Triangulate & Contour** interface but this approach gives us more control). Run the Surface – Contour Utilities – Contour Elevation Label command. Select **OK** after matching the settings in the dialog box shown here:

Specify the surface model (*.tin) created earlier and click the **Open** button on the Carlson File Selector dialog box. Now pick two points that cross through one or more Index contours. The contours are automatically labeled using the specified text style.

The Completed Plat is shown here:

If you have not saved your drawing for awhile, now is a good time to do it. Use the File – **Save** command.

This completes the Lesson 2 tutorial: **Making a Plat**.

Field to Finish for Faster Drafting

In this lesson, you will make a plat using "Field to Finish" techniques, with the help of the **Startup Wizard**.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click **New**.
 - If you are taken directly into CAD, click the File – **New** command.

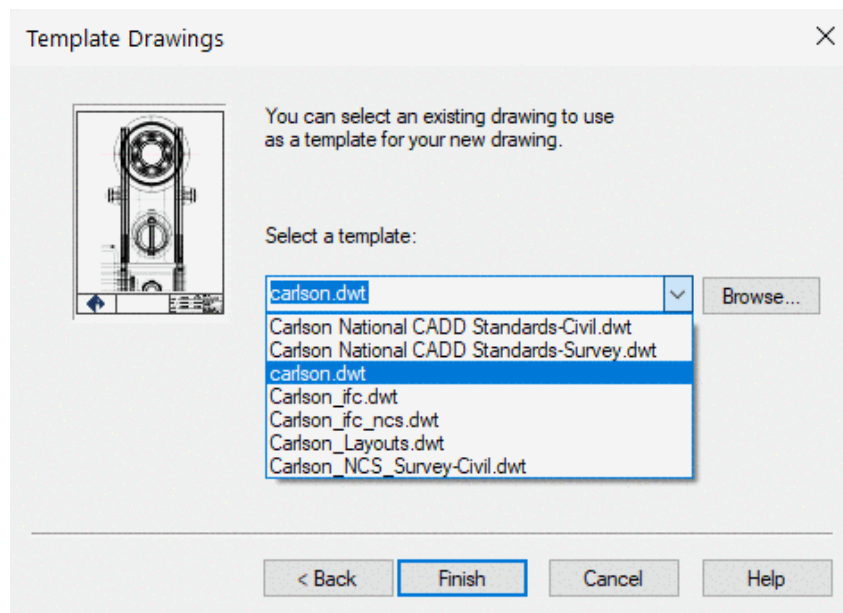

NOTE: If you want to consistently use the **Startup Wizard**, issue the Settings – Carlson Configure – General Settings and enable the **Use Startup Wizard** option. Click **OK** to dismiss the dialog boxes. The **Startup Wizard** will be used the next time the software is started.

The first of several Startup Wizard dialog boxes appears:

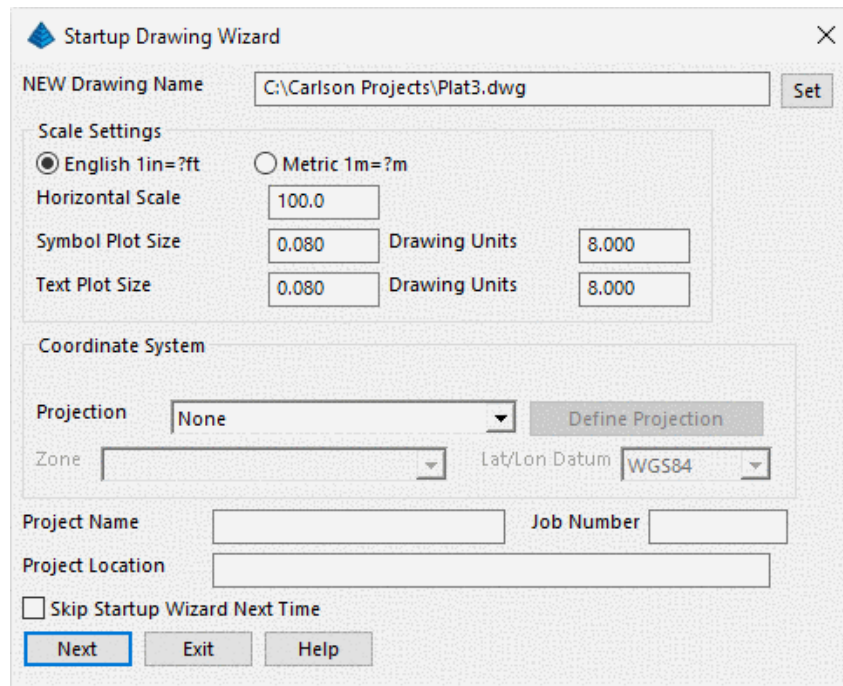

- (a) Choose the DWG document type and the desire to base the document on a **Drawing Template** as illustrated below and then click **Next >**:

(b) Choose the **carlson.dwt** as illustrated below (or *surv.dwt* if *carlson.dwt* is not available) and click **Finish**:

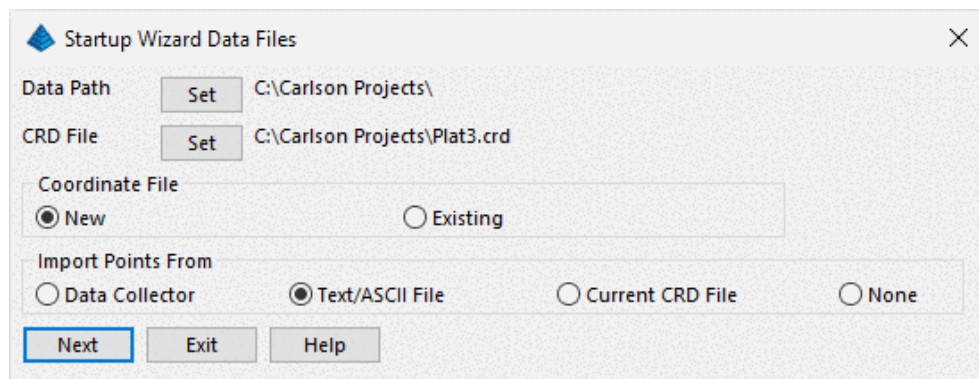

(c) We can now begin the more pertinent settings for the project to come based on some preliminary settings that should be similar to the default scenario shown below:

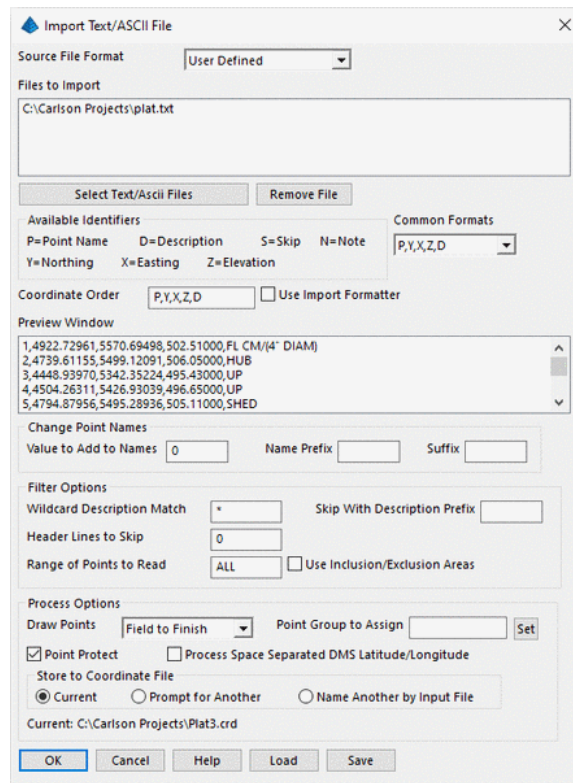

Click **Set** at the top of the dialog box, and enter in a NEW Drawing Name called **Plat3**. Verify that the other settings match the settings shown below, and click **Next**.

- (d) You will see the Startup Wizard Data Files dialog to set/confirm where to store data and indicate an information source for points/coordinates. Set/match the values as shown below and click **Next**:

- (e) The Import Text/ASCII File dialog box appears. Our source is the same file as in Lesson 2 (e.g. the ASCII-based **Plat.txt** file). Click the **Select Text/ASCII Files** button and navigate to and choose the **C:\Carlson Projects\Plat.txt** file and click Open when ready. Set the other values as shown in the dialog box below paying particular attention to the **Draw Points** toward the bottom of the dialog box and click **OK** when ready:

(f) When you complete the import, the following dialog box appears (click **OK** to dismiss):

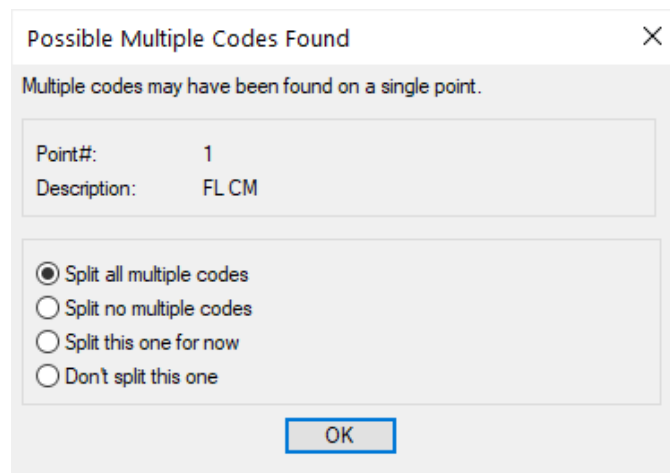

(g) A **Draw Points** confirmation dialog box displays. Set/confirm the Field to Finish option, and click Next:

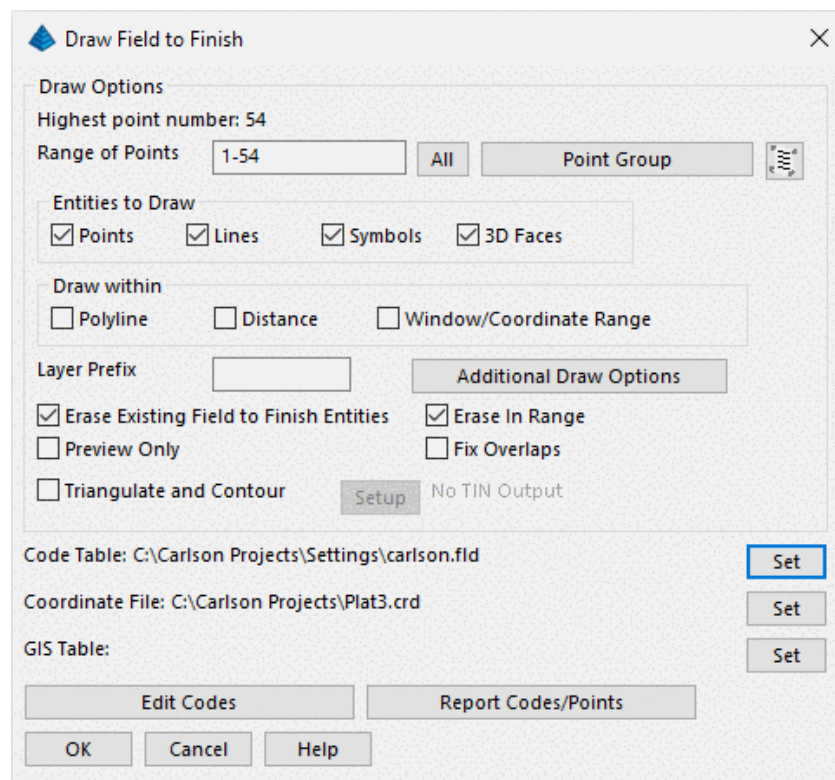

(h) If this is your first time running Field-To-Finish, then the program will prompt to select a **Field Code Definition** file. In this case, select the **C:\Carlson Projects\Settings\carlson.fld** file and click Open when ready.

(i) A dialog box now appears with a warning that some codes have two descriptions:

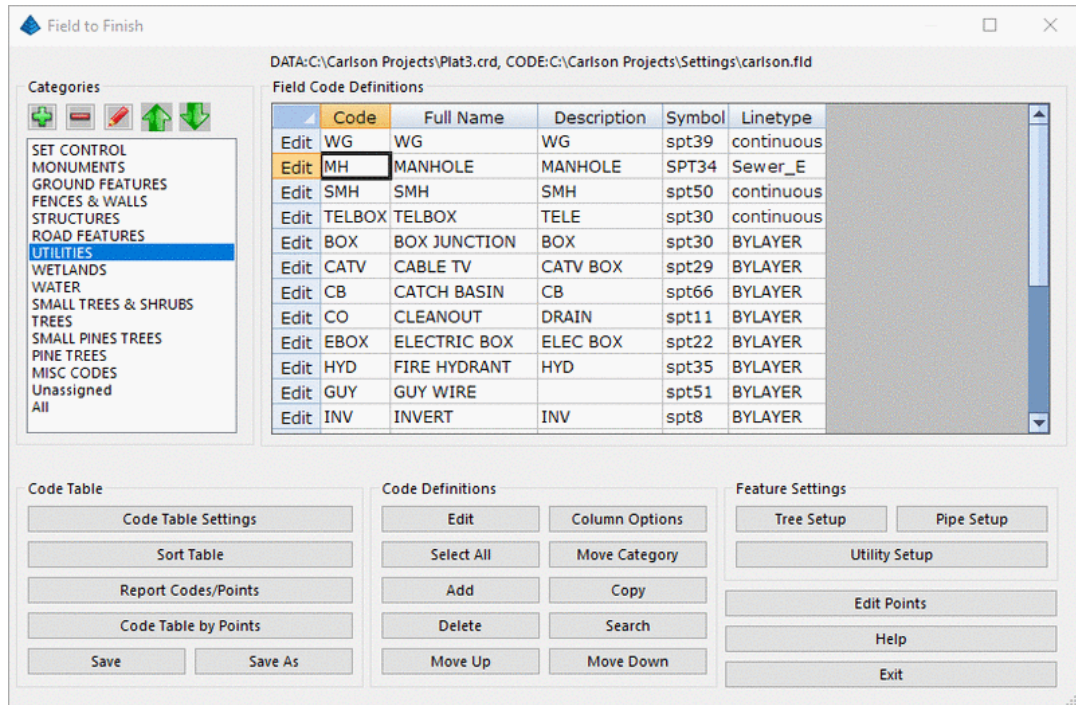

The command is asking whether these codes are to be treated as two separate descriptions, or as one description that has a space in it. Choose the **Split all multiple codes** to tell the command that codes with spaces are really two separate descriptions and click **OK**.

- (j) We are about ready to place the Field to Finish data into the drawing. Take a moment to review (and optionally set) the values shown below:

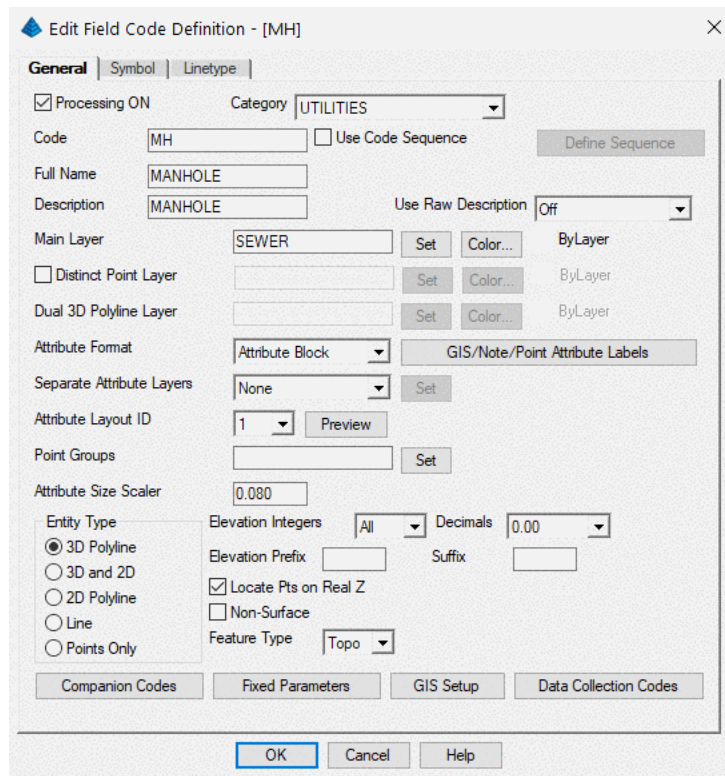

- (k) Let's review/set some additional options. Click **Additional Draw Options** to display the dialog box below:

prompted about **Possible Multiple Codes Found**, accept the default to **Split all multiple codes** option and click **OK**. On the Draw Field to Finish dialog box, select the **Edit Codes** button. This takes you to the **Field to Finish** dialog box as shown below:

The display window shows a list of point codes, such as IP for iron pin and FL for fence line, that are converted to special symbols and linetypes by **Draw Field to Finish**. For an example of how the codes are used, look at the sewer line running from point 52 to 53 to 54 (the southernmost point), which is based on a field code of MH. Select the **Utilities** category and select the **MH** (for Manhole) code as shown above, and then click **Edit**. The following dialog box is displayed:

The MH code has several attributes that are used by **Draw Field to Finish**. For this code, **Draw Field to Finish**:

- places the manhole on layer SEWER
- labels a text description of MANHOLE underneath the symbol (Descriptions can be upper or lower case)
- Click on the **Symbol** tab and notice that it draws a manhole using the symbol SPT34
- Click on the **Linetype** and notice that it draws a sewer line with the letter S (for Sewer)

When you are done looking at the MH field code definition dialog, click **OK**.

Other codes have different attributes:

- LP is set only to draw a symbol and text (Light Pole), but not to draw linework
- FL (for fence line) is set to draw linework but not corner symbols or points descriptions

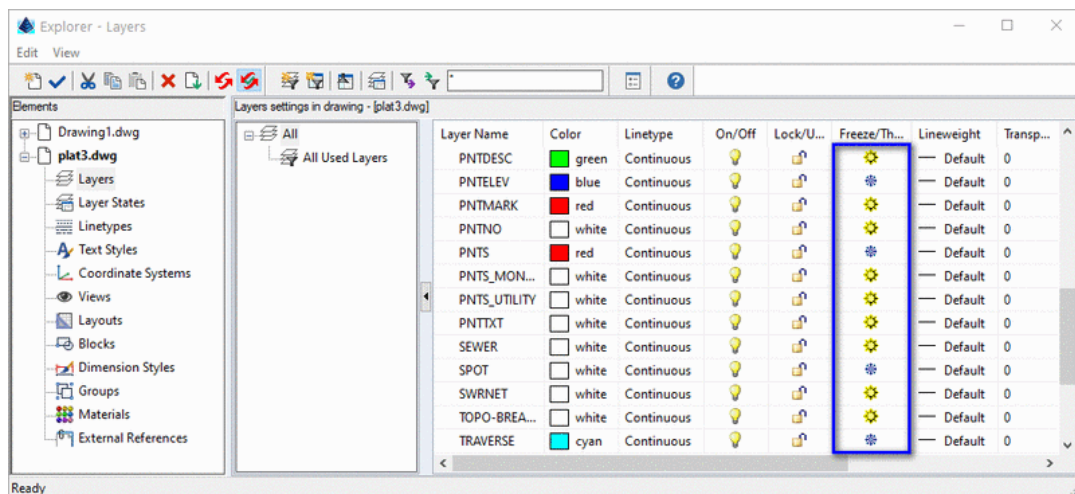

The CAD symbology attributes for a code depends on the entries in the Layer, Description, Entity Type, Set Symbol and Set Linetype options (among others).

The "Carlson.fld" Field to Finish code table is provided with Carlson Software. This table shows one possible system, but with likely far too many codes for a field crew to remember. You can make your own code table by:

- choosing the **Code Table Settings** option from the Field to Finish dialog box
- choosing the **Set** button at the top right, and,
- selecting the **New** or the **Existing** tab from the top of the **Specify the Code Definition File** dialog box.

Click **Exit** to dismiss the Field to Finish dialog box and then click **OK** to re-draw the data again.

- Use the **Inquiry – Layer ID** command to verify the layers of the various entities that have been placed into the drawing. Pick on the fence line, the road and the utility line, and notice the different layers (FENCE, EOP, UTILITY). You can also use the **Inquiry – Drawing Inspector** command to hover over entities to see their layer. You should study the layers in a drawing before deciding what to freeze and thaw. To reduce clutter on the screen, select the **View – Layer Control** command (the appearance of this dialog box might vary from that shown below). Freeze the following layers by turning the sun into a snowflake:
 - PNTS
 - PNTELEV
 - SPOT

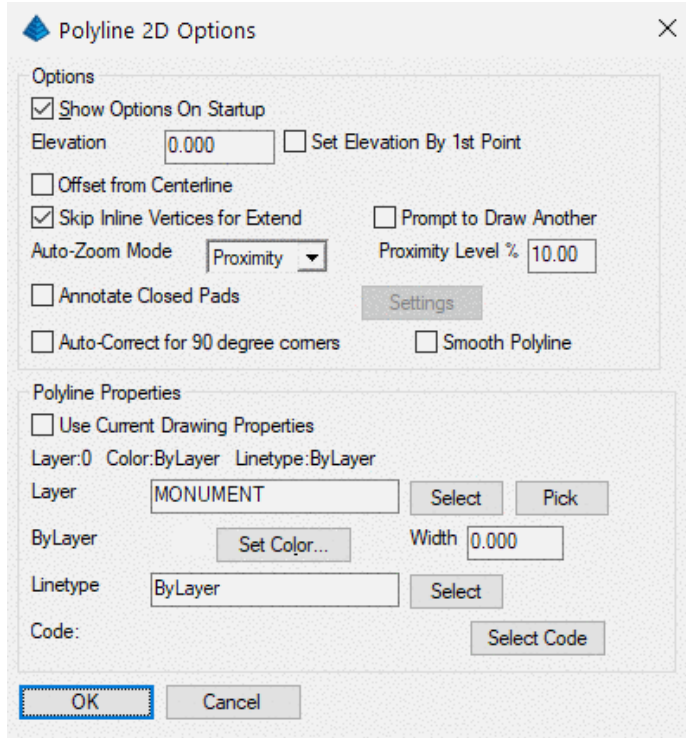

Exit the *Layer Manager* when done.

- Now you will do some drawing cleanup. Note that a single property line is drawn from point 8 to 9 to 10 and to 15. The chord from point 10 to 15 should be an arc. You will erase the segment from 9 to 10 and from 10 to 15, so that you can re-draw it, establish the tangent, then draw the arc and finish back at point 1. Click **Edit – Polyline Utilities – Remove Polyline – Remove Polyline Segment** command and follow the prompts below:

Mode: break polyline at removal

- Select polyline segment to remove [Options]:** Pick the segment from 9 to 10
- Select polyline segment to remove (Enter to end):** Pick the segment from 10 to 15
- Select polyline segment to remove (Enter to end):** press Enter

To draw the correct polyline, use the Draw – 2D Polyline command (keyin **2dp**). Presuming the **Polyline 2D Options** dialog box appears, use the **Pick** button to and select the western property line to get its layer as shown below (this keeps the new linework and the existing linework on the same layer) and click **OK** and follow the prompts below (these steps are also covered in Lesson 2):

9-10

This instructs the 2D polyline to be drawn through Points 9 and 10.

<Pick point or point numbers>

a

This indicates a tangential arc to be drawn starting from Point 10.

[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]:

15

This indicates the arc shall terminate at Point 15.

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]:

1

This instructs the polyline to be drawn back to the starting point. The segment from 15 to 1 is not guaranteed to be tangent to the previous arc.

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]:

press Enter

This completes the needed polyline segments.

Turn the 2-sided shed into a 4-sided shed by issuing the Survey – 4 Sided Building command. Complete the command as follows:

Options/Points/<Pick a line or polyline>: Pick the shed

Options/Points/<Pick a line or polyline> (Enter to end): press Enter

Next, we will create a building which will be less complex than the building you created in Lesson 2 but with an added twist. Thankfully, **Field to Finish** already started one building wall segment for us. Click the Edit – Extend – by Distance command. Complete the prompts as follows:

Pick arc, line or polyline to extend: pick the western side of the small line segment west of the 12" pine and north of the driveway (This makes the arrow point toward 18 rather than 19. Now you can go clockwise:)

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): T50 ("T" or "t" means "total" distance or "to" the distance - so extend "to" 50 feet total)

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L62.5

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L35

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): L30

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): R15

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): C

Enter or pick distance to Draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,V,Z,?,Help): press Enter

In Extend by Distance, the "T" option (for total distance) solves the dilemma of making an existing line of unknown length extend to an exact known length. The end result is shown below:

NOTE: Not every drawing can (or should) be plotted "due North." Sometimes the plat needs to be oriented so that property lines and important features run nearly left-to-right or top-to-bottom on the plotted page. In this drawing, you want the western line from point 8 to point 9 to run left-to-right on a sheet that will be plotted in landscape

style (longer left-to-right than top-to-bottom). Use the View – Twist Screen – Line, Polyline or Text command to accomplish this and follow the prompts below:

Pick a line, polyline or text: pick the western line from point 8 to point 9, closer to point 9
Twist azimuth for selected POLYLINE (Use 90 for Due East) <90.0>: press Enter

Now the drawing appears as shown below:

NOTE: Within CAD, the desired **World Coordinate System** (as indicated by the USCICON, if shown at the lower left) is still maintained and coordinate locations for all points and directions of lines have not changed. In other words, only the orientation of the data on the screen has changed!

Much of the text in the above drawing, such as tree sizes and types, the manhole text, and the light pole text can be used in the final drawing. But some of the text, such as the text placed for iron pins and poles, can be fully described in a **Legend** without the redundancy of plotting to the screen. However, if you use the Edit – **Erase** command to remove the iron pin and pole text, the entire point will be erased because the attributes are grouped with the point. Instead, use the Points – Erase Point Attributes command and follow the prompts below:

Select attribute(s) to erase (Enter to end): pick the 3 poles and the 4 iron pins and then press Enter when complete

Let's correct the orientation of the attributes. Use the Points – Twist Point Attributes command and follow the prompts below:

Twist by [<Twist screen>/Azimuth/Entity segment/Follow polyline]? press Enter for Twist Screen
Attributes to twist [<All>/Symbol/Name/Elevation/Description]? press Enter for All
Enter angle relative to current twist screen<45.0>:? 0 (press Enter)
Select points from screen, group, or by point number [<Screen>/Group/Number]? press Enter for Screen
Select Carlson Software points.

[FILter]/<Select entities>: all (press Enter)

[FILter]/<Select entities>: press Enter

The points then twist back orthogonal to the screen, reading once again from left-to-right.

The remaining descriptions associated with the points can be used in the final drawing, but they should be moved slightly for a better appearance. For example, the tree descriptions would look better if they were not inside the tree canopies. Use the Points – Move Point Attributes. The steps of the command are:

Select attribute(s) to move: pick an attribute to move

Displacement: pick the new location for the attribute

Rotation: press Enter to keep the existing orientation or pick the new orientation for the attribute

Then the command repeats. Notice how the text "ghosts" as it moves, which helps you place it in the best position. Try to duplicate this result:

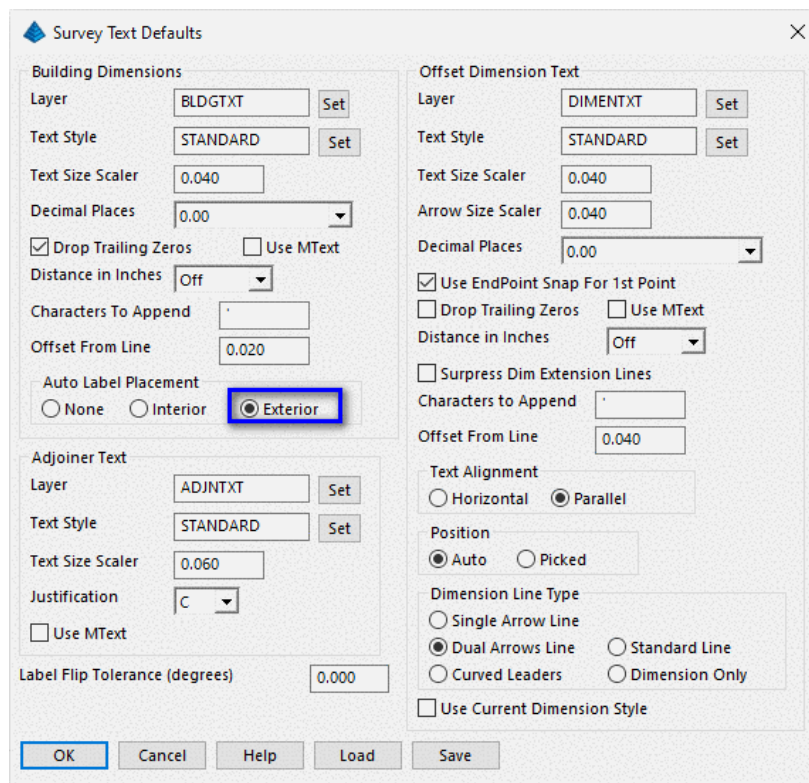

Because of the earlier **Twist Screen** command, the E's in the electric utility polyline are upside down. Use the Edit – Text – Flip Selected Text command to correct this through the prompt below:

Select the text to flip.

[FILter]/<Select entities>: pick the upside down E's individually and then press Enter (see above image)

We wish to apply building dimension labels to the exterior of the building created earlier. Click the Annotate – Survey Text – Survey Text Defaults command and set the **Exterior** option and set other values as shown below:

Click **OK** when complete. Then click the Annotate – Survey Text – Building Dimensions command and pick on the house.

In preparation for the vector annotation to follow, let's check (set) some desired annotation values. Click the Annotate – Annotate Defaults command. On the various tabs, check/set the following:

- **General** tab - **Previous Labels**: Erase
- **Angle** tab - **Bearing Annotation Precision**: Deg, Min, Sec
- **Distance** tab - **Decimals**: 0.00

Click **OK** when ready.

We now wish to annotate linear bearings and distance, as well as arcs. Pick Annotate – Auto Annotate command. When the dialog box appears, under the **Lines** tab, select the options you would like to use so that the bearings and distance labels appear as you would like and click **OK**. Then pick the three polylines that fully define the perimeter:

- the fence line
- the polyline containing the arc
- the lower polyline, which is still the western polyline although you have twisted the screen so that it runs along the lower portion of the drawing

Use the Move command to move the bearing and distance labels to avoid overwriting other features.

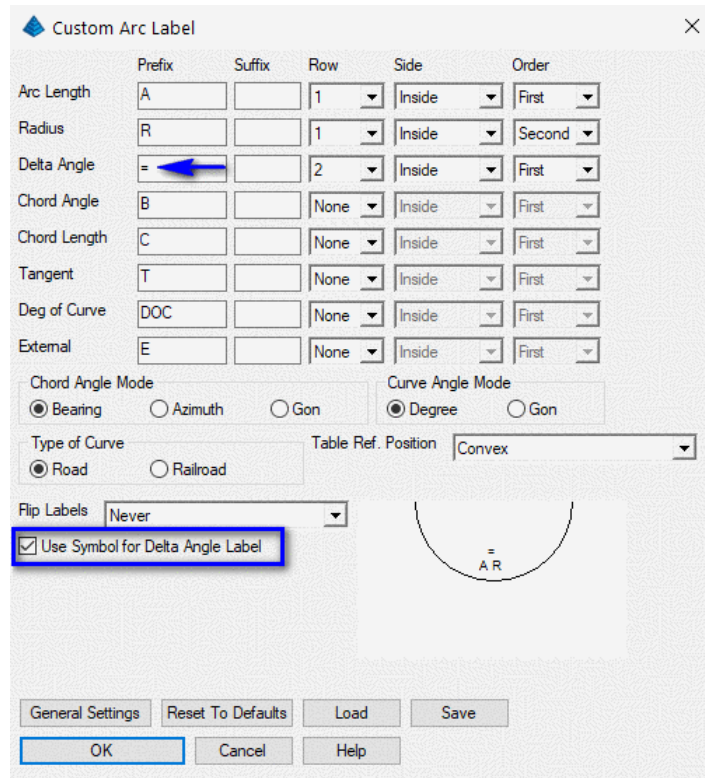

NOTE: When you move the lower bearing or distance label (the 404.90' or S 17°05'38" E bearing) to the left, you want to move perfectly level to the screen, since this was the line you used to twist the screen, and it runs perfectly left-to-right. To do this, press the F8 function key to activate Orthogonal (ortho) mode. Then pick the desired piece(s) of text and move it/them to the left, picking the final position. After you move the item(s), press F8 again to turn off Ortho. Sometimes you will load a drawing from another client or source, and the Ortho setting has been left on. This may initially confuse you during the Move commands. Press F8 to deactivate Ortho. Notice that F8 works even with **Twist Screen** active.

Auto Annotate may center the arc annotation above and/or below the arc, which may cause the arc data to overwrite the surveyed edge-of-pavement (EOP) polyline. Let's experiment with some more precise annotation.

If needed, erase selected portions of the arc annotation via Edit – Erase – **Select** (keyin e). When prompted to **Select objects**:, simply click the pieces of arc annotation and press Enter when complete:

As needed, use the Annotate – Annotate Arc – Label Arc command to better control the placement of the arc annotation. When prompted, select the arc from the screen. The Label Arc Settings dialog box appears:

Experiment with:

- locate the Arc Length and Radius inside and closest to the arc and in the order cied, and,
- locating the Delta Angle inside the arc and a bit further from the arc, and,
- replacing the "D" letter with the triangular Greek "Delta" letter as is often commonly practiced.

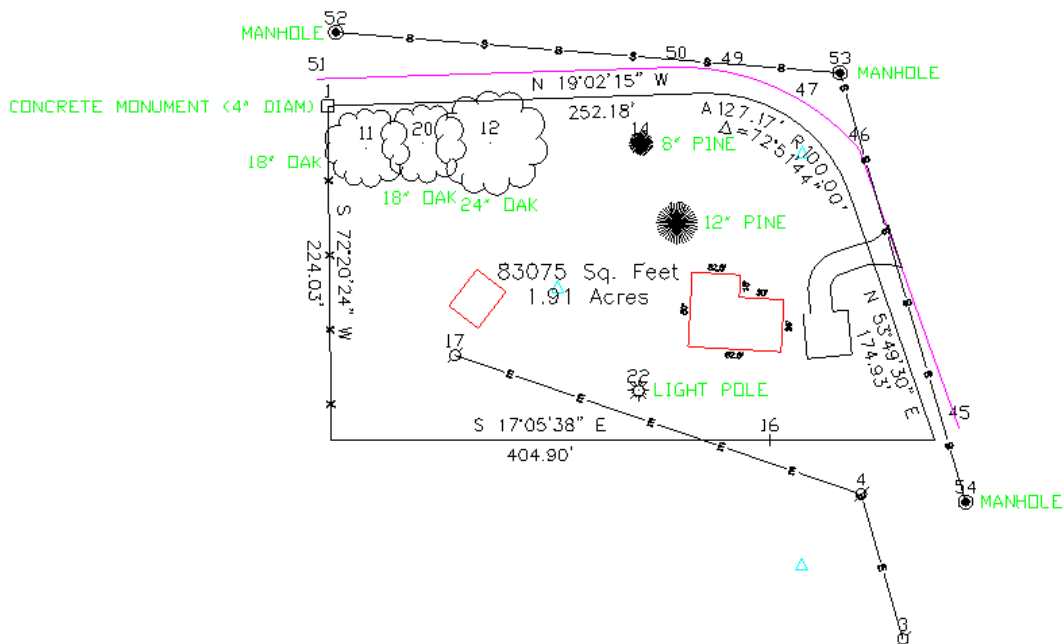

Click **OK** when ready. The new arc text might overwrite the **8" Pine** and if it does, use the previously discussed Points – **Move Point Attributes** command to relocate the **8" Pine** description. With the annotations placed in new positions, your drawing should be similar to the one shown below. Move your annotations to match this drawing:

Next, you will create an area label for the drawing. Select the Area/Layout – Area Defaults command. Select the **Sq. Feet** entry and click **Edit** to change to the nearest whole unit (no decimals) with a Text Size of 0.100 and Acres to 2 decimal places with a Text Size of 0.100. Click **OK** to dismiss the Acres settings dialog box and click **OK** to dismiss the Area Defaults dialog box.

Select the Area/Layout – Area by Lines & Arcs command. When prompted to **Select objects**, pick the three polylines that taken together, completely enclose the property.

Pick an area labeling centering point for the area label approximately centered within the parcel as shown below:

Before completing the final formatting of your drawing, you need to do some minor cleanup. Items we don't want

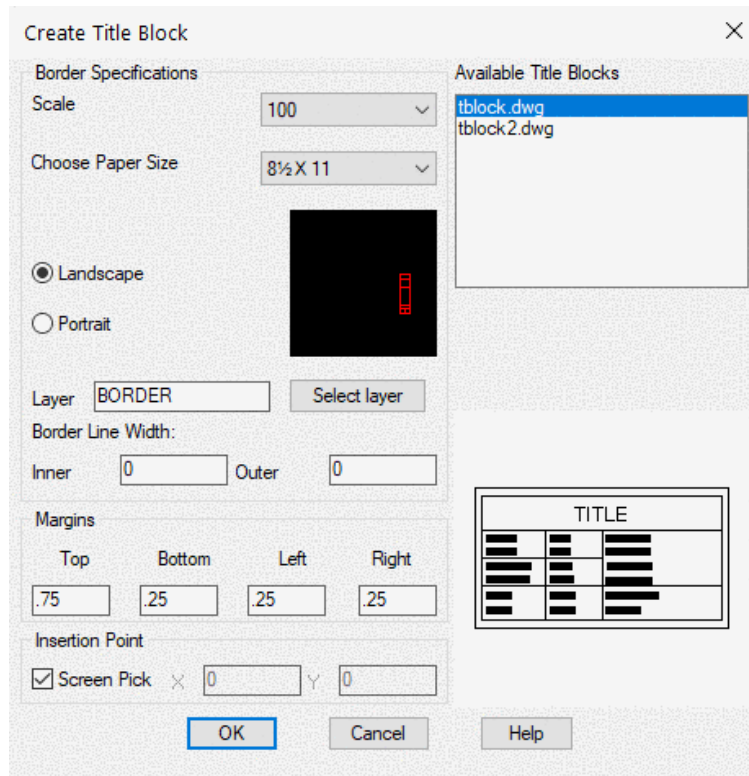

to see prior to plotting are:

- the symbol of Point 16 (the PL point)
- the "hub" symbols (triangles)

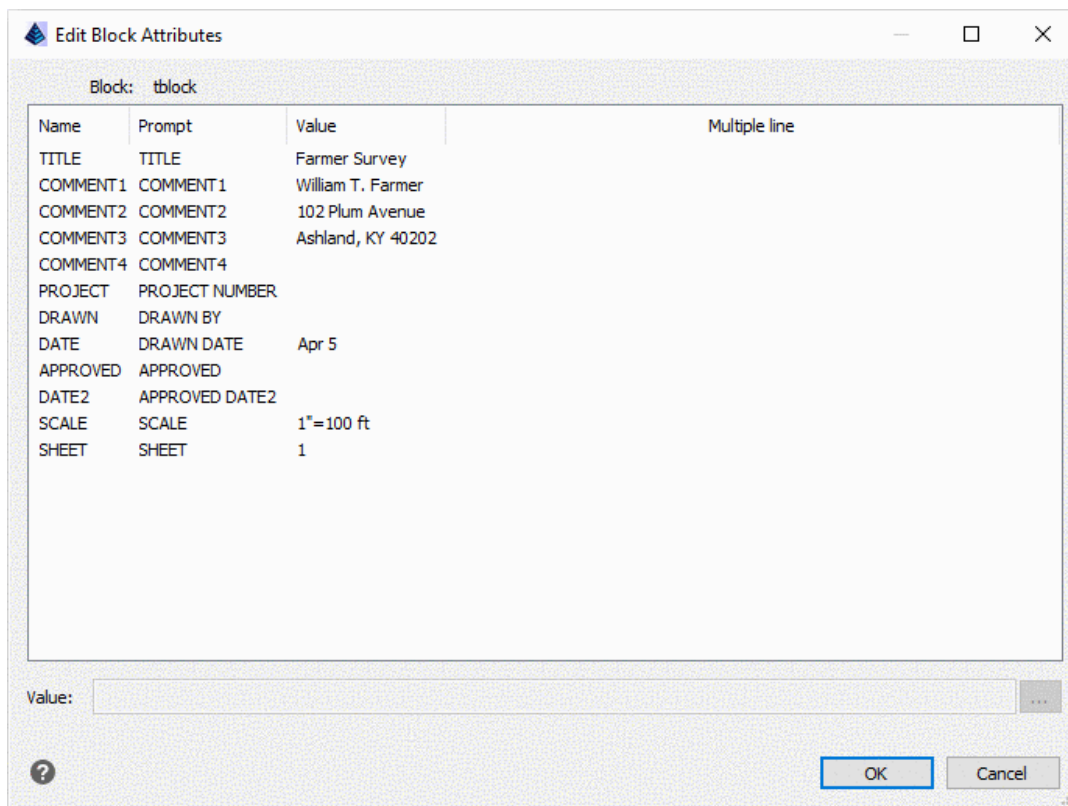

We'll freeze these items via the View – Freeze Layer by Pick command. Pick each of the items specified above and press Enter when done.

We'll complete the remainder of the cleanup process by manually freezing the PNTNO layer via the View – **Layer Control** command. Locate the PNTNO layer and turn the sun icon into a snowflake and close the Layer Control dialog box when complete.

To insert an A1 (8 1/2 x 11) border and title block with a landscape orientation (not portrait), select the Settings – Title Block – Standard command to display this dialog box.

Be sure the items above match your own. Click **OK**. For the insertion point, select a point at the very lower-left of the screen, so that your drawing plan entities fit inside the border and somewhat nearer to the top. Pick your screen location. You will then be prompted for the attributes of the title block. Fill them in and click **OK**.

If you prefer, you can use the Edit – **Move** (keyin **m**) command (pick the title block and two border perimeters) to a desired location. Refrain from moving the drawing because you will change the coordinates if you do.

Click the Annotate – Draw Legend command. Select the Existing tab and choose the **.lgd** file that you saved in Lesson 2 and click Open. Then select Draw and **OK** to close out the dialog boxes that follow, and then click Exit.

Pick an upper-left location point in the available space to the lower-left of the plat. If you did not save a legend in Lesson 2 (or you skipped Lesson 2), follow the steps in that lesson. As desired, you may use the Points – Resize Point Attributes command and scale up the oak tree symbol in the Legend by a factor of 1.5.

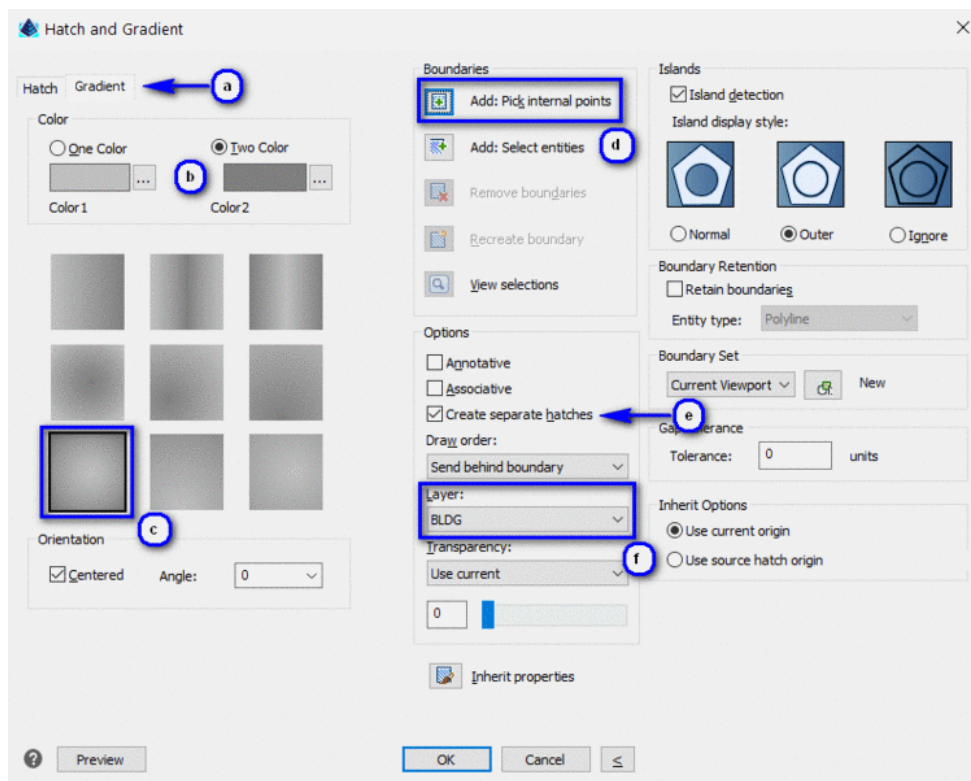

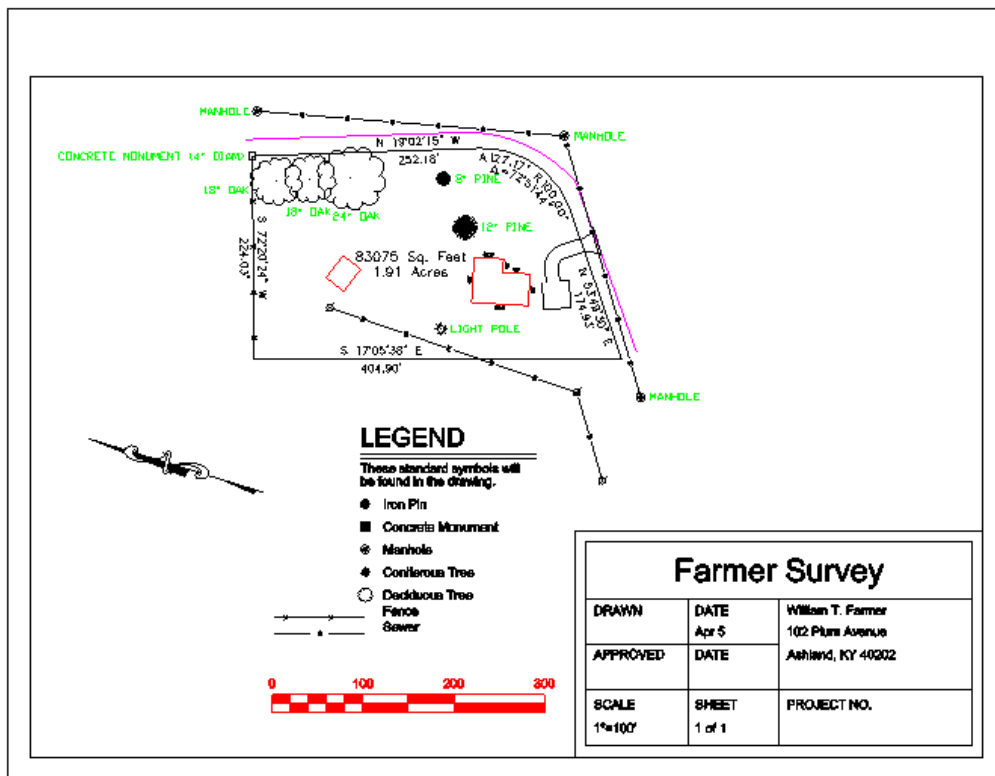

Use the Annotate – Survey Text – **Survey Text Defaults** command. Change the **Offset Dimension Text - Text Alignment** to Horizontal and click **OK**. Then, click the Annotate – Survey Text – Offset Dimensions command and pick the lower right corner of the building, and then the lowermost property line (in the current twist screen position). This labels the offset dimension horizontal to the current twist screen.

Click the Annotate – Draw North Arrow command and find and select the North Arrow symbol that is shown in the figure below. Change the Symbol Size Scaler, if necessary. Click **OK**. Then pick an appropriate location and press Enter. Note how the arrow draws due North, respecting the twist screen.

Click the Annotate – Bar Scale command and pick a location near the lower-left portion of the drawing.

Your drawing should now look similar to this:

Pick the Draw – Hatch – **Standard Hatch** command to display a dialog similar or as shown below:

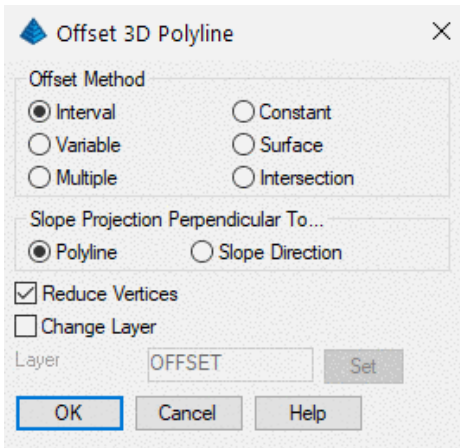

1. Select the Gradient tab
2. Use the "... " color-picker and choose Index color 9 for Color 1 and Index color 8 for Color 2
3. Click the "Radially centered" tile

4. Click the **Add: Pick internal points** and when prompted, pick an internal point in the house and the shed, and press Enter
5. Enable the **Create separate hatches** toggle
6. Set the Layer to be **BLDG** (the same as the house and shed)

Click **OK** when ready.

To offset the EOP polyline:

1. First try using the Edit – Offset – **Standard Offset** command and try offsetting the edge-of-pavement polyline that runs roughly parallel to the sewer line. You will see an error message because that object is a 3D Polyline, created by the **Draw Field to Finish** command.
2. To offset a 3D Polyline, you must use a command specifically designed to offset 3D Polylines. Use the Edit – 3D Polyline Utilities – Offset 3D Polyline command. Enter the offset method as Interval, press **OK**.

When prompted:

Vertical/<Horizontal offset amount>: 30

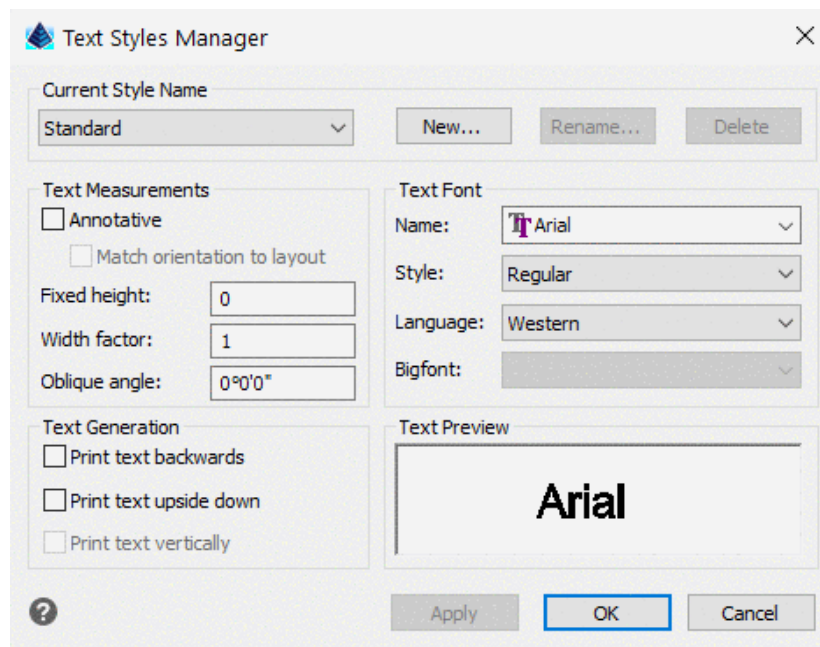

Percent/Degree/Ratio/Vertical offset amount <0>: press Enter

Select a polyline to offset: pick the EOP polyline

Select side to offset [Both]: pick out and away from parcel for the other side of the road

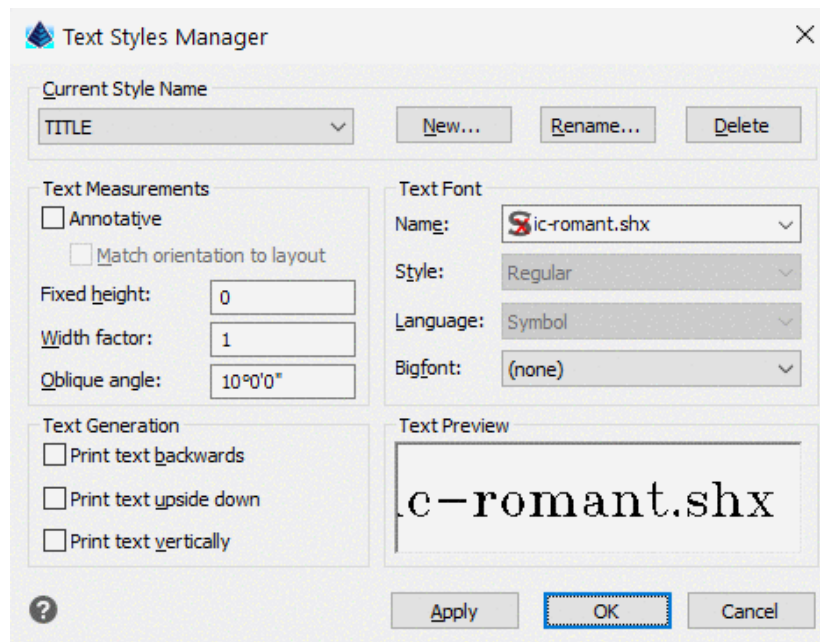

Select a polyline to offset (Enter to end): press Enter

Before you add a title to the drawing, create a text style for the title. Use the Draw – Text – **Set Style** command to display the dialog box below:

Click **New**, enter **TITLE** in the New Text Style dialog, and click **OK**.

Define the **TITLE** style consisting of the **ic-romant.shx** font (or **romant.shx** if using an AutoCAD-based platform) and an Oblique Angle of **10°194'** by entering the settings as show below:

Then click **OK**. Now, run the DText command by typing **dtext** at the command line, and place the text at the top of the drawing as follows:

Specify start point of text or [Justify/Style]: J

Enter an option [Left/Center/Right/Align/Middle/Fit/TL/TC/TR/ML/MC/MR/BL/BC/BR]: c

Specify start point of text or [Justify/Style]: pick a point near the top-right of the drawing

Height of text <8.00>: 20

Rotation angle of text <E>: pick a point to right of first point with <Ortho on> (F8), dynamically stretch right

Text: Farmer Survey (press Enter)

Text: April 5, 2021 (press Enter) **Text:** press Enter

Use the Edit – Text – Text Enlarge/Reduce command. When prompted for Scaling Multiplier, enter 0.8 and pick the date you just entered.

Verify your Horizontal plot scale through the Settings – Drawing Setup command. Your drawing should have a Horizontal Scale of 100 with a Text Plot Size of 0.08. Change the Text Plot Size to 0.06 to shrink the building labels we are about to place and click **OK**.

Click Draw – Leader – Leader with Text command and follow the prompts below:

Options/Size/Pick Arrow Location: nea (we want to use a NEArrest snap)

Snap to NEA of: pick near or on the left side of the house

To point: pick off to the left

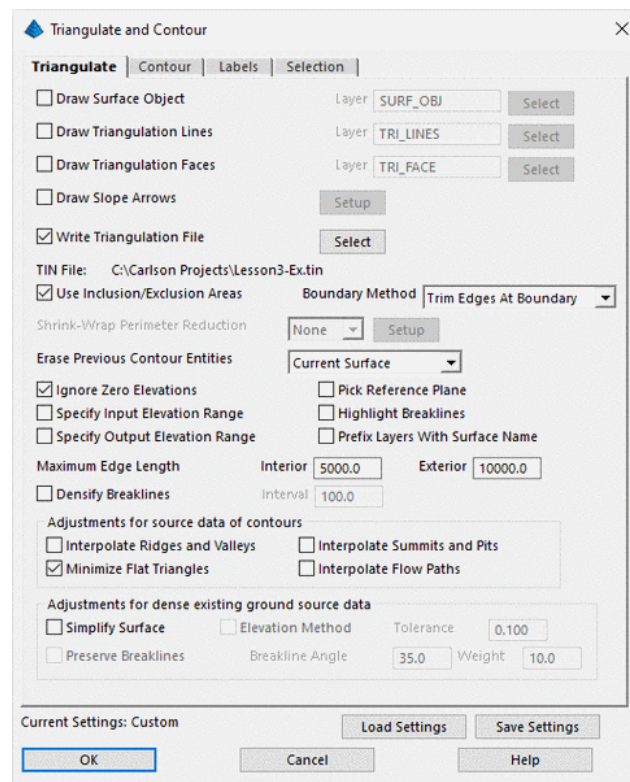

Next point (Enter to end): press Enter

Text: 2-Story

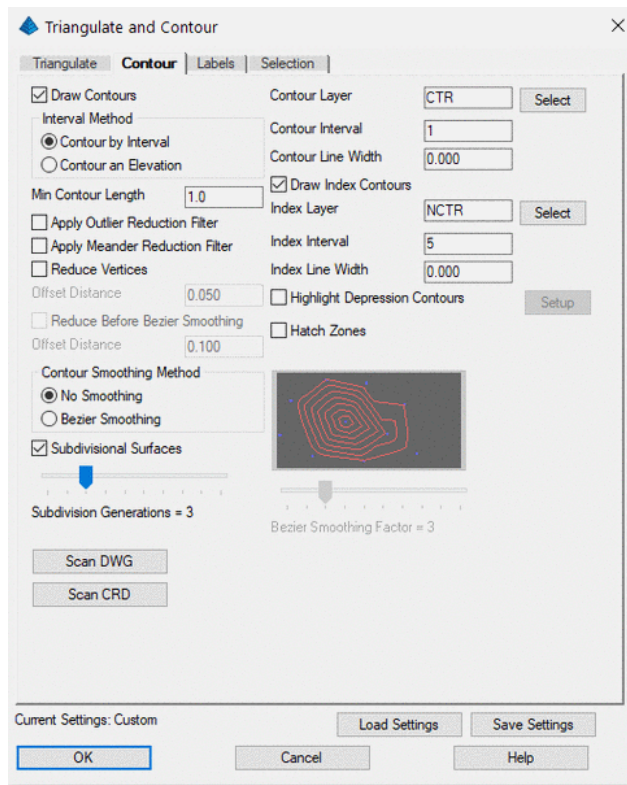

Text: Farm House

Text: press Enter

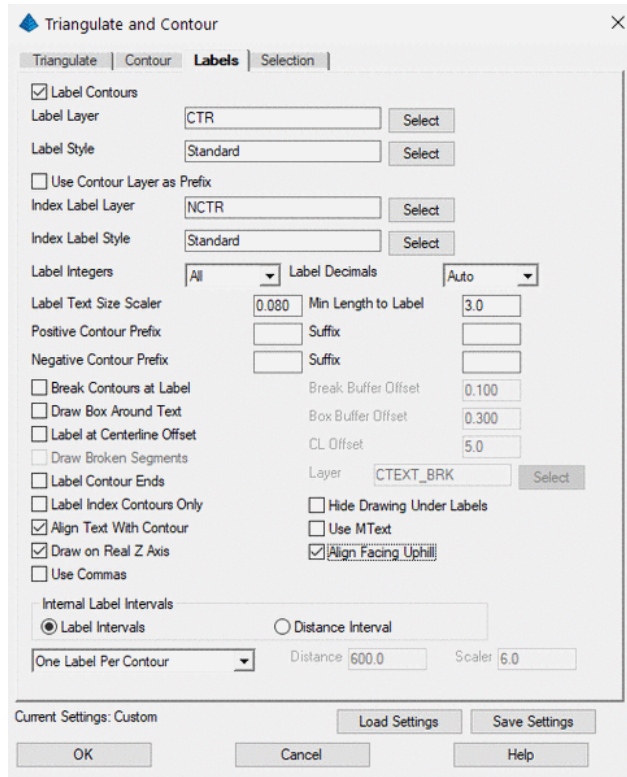

Initiate the Surface – Triangulate & Contour command. On the Triangulate tab, set the following values:

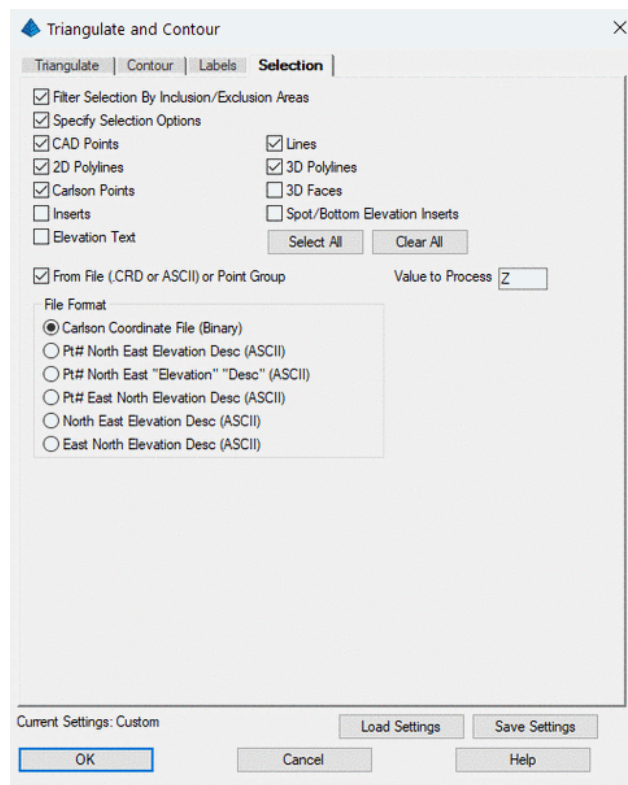

Also make sure to enable the **Use Inclusion/Exclusion Areas** option. Navigate to the **Contour** tab and set the values as shown below:

Click on the Labels tab and match the following dialog:

Click on the Selection tab and fill out to match the following:

Press **OK** and then answer as follows:

Select Inclusion perimeter polylines or ENTER for none.

[FILTER]/<Select entities>: press Enter for none.

Select Exclusion perimeter polylines or ENTER for none.

[FILTER]/<Select entities>: select the outlines of the building and the shed, and then press Enter

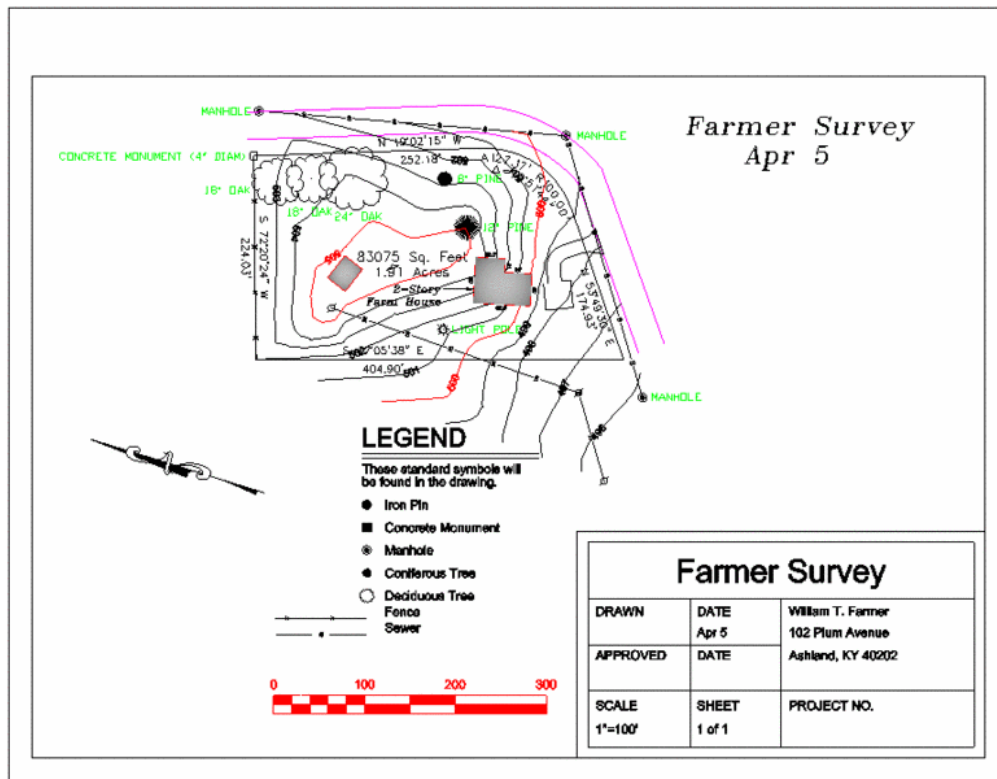

Select points and breaklines to Triangulate.

[FILTER]/<Select entities>: press Enter (we're going to fetch the coordinates out of a specified coordinate file)

Select Coordinate File to Read (dialog): plat3.crd (and click Open)

Points to Triangulate (dialog): click **OK**

The contour map is created. The final drawing will look similar to this:

This completes the Lesson 3 tutorial: Field to Finish for Faster Drafting.

Intersections and Subdivisions

In this lesson you will create a basic subdivision including a street intersection. You will make the subdivision from a drawing file named **Plat4.dwg**.

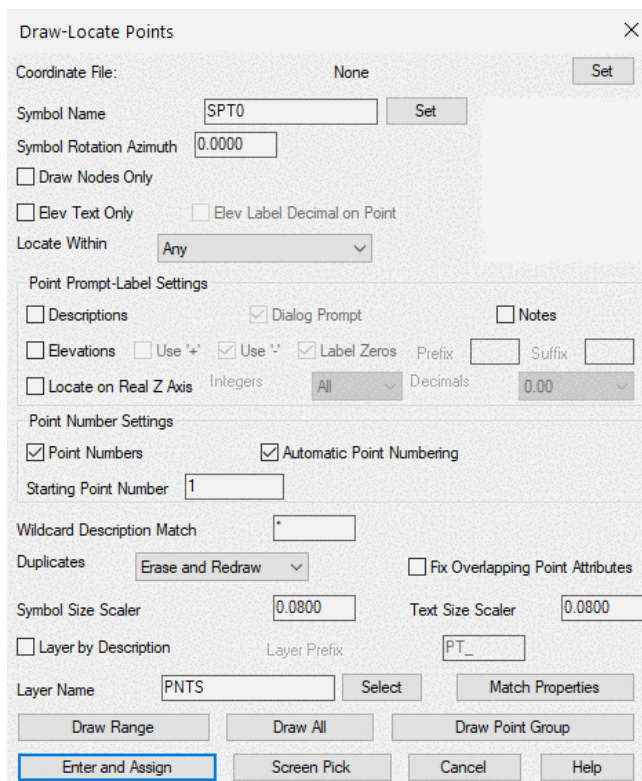

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Plat4.dwg** file.

Verify the Survey module is loaded by clicking Settings – Carlson Menus – Survey Menu.

2. We'd like to establish a starting coordinate for a street centerline to follow. Select the Points – Draw-Locate Points command and obtain the dialog shown below:

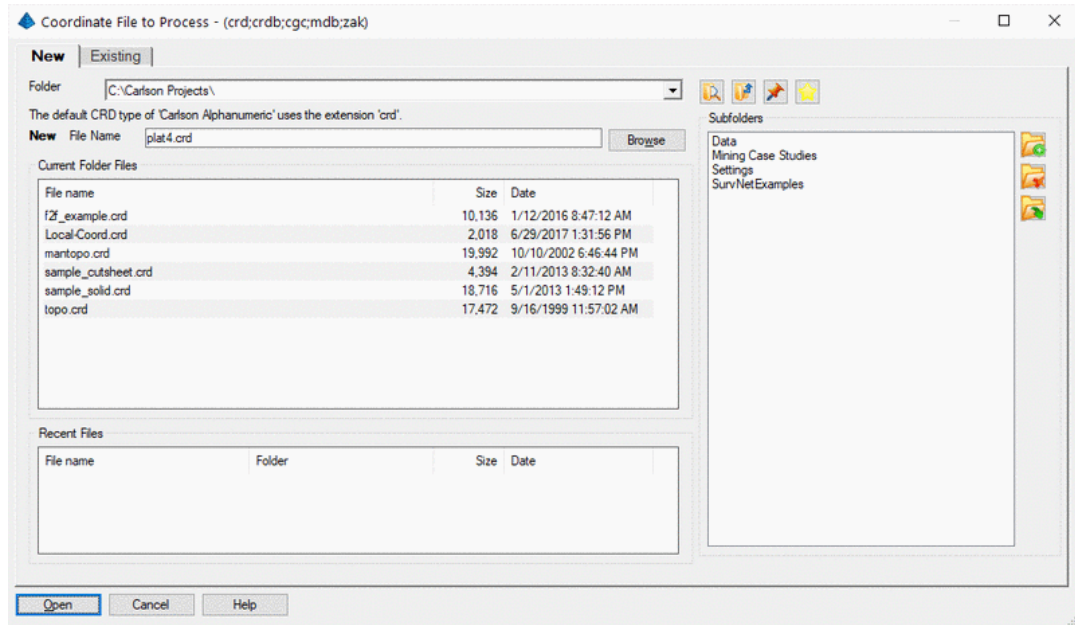

At the top, change the symbol to SPT0 by picking Select at the very top of the dialog, and choosing symbol SPT0 from the dialog of symbol choices (not shown here). Disable the prompting and labeling for **Descriptions, Elevations and Locate on Real Z Axis** (make them blank as shown). Match the other entries

as shown (which are mostly the default conditions) and click **Enter and Assign** at the lower left and respond to the prompts as follows:

Enter North(y): 4809.17

East(x): 4391.28

The program will recognize that you have not yet started a coordinate file, so click the **New** tab and enter the File Name as **Plat4.crd** (which should be the default). If you enter Plat4, you do not need to enter the extension .crd. The program will add extensions automatically. You will see this:

Click Open. You will be prompted again:

Enter North(y): press Enter

3. We'd like to start the creation of a roadway centerline. Select the COGO – Traverse command (or alternately just enter **T** at the command line. **T** is one of several "hotkeys." Other hotkeys are **I** for Inverse and **SS** for Sideshot). We're going to traverse from PI to PI (to the two endpoints of our centerline) so reply to the prompts as follows:

Traverse, Line OFF, RAW FILE OFF

Occupied Point ?

Pick point or point number: 1

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <7>: 1

Enter Bearing Angle (dd.mmss) <90.0000>: 58.1848

Points/<Distance>: 736.73

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <1>: e (to exit)

You could keep on traversing, but we will stop here to review. You have created point 2, traversing NE from point 1. To review, code:

- 1 is for NE
- 2 for SE
- 3 for SW
- 4 for NW

- 5 for Azimuth
- 6 for Angle Left
- 7 for Angle Right
- 8 for Deflection Left
- 9 for Deflection Right

This is the standard way that traverses and sideshots are entered in Carlson with a code entry (followed by Enter), then the angle or bearing entry (followed by Enter). Lesson 1: Entering a Deed, presented another method, where the angle and bearing are together in the form of *158.1848*. That is a rare form, designed to save keystrokes, and used primarily only in Enter Deed Description. Now you have been exposed to both!

- Let's explore the including linework with the traverse information. Click COGO – Line On/Off to turn on simultaneous linework with traversing. This command toggles on and off each time you click it, with the **On** status indicated by a check mark. Now repeat the **Traverse** command (try *T* at the command line and follow the prompts below:

Traverse, Line ON, RAW FILE OFF

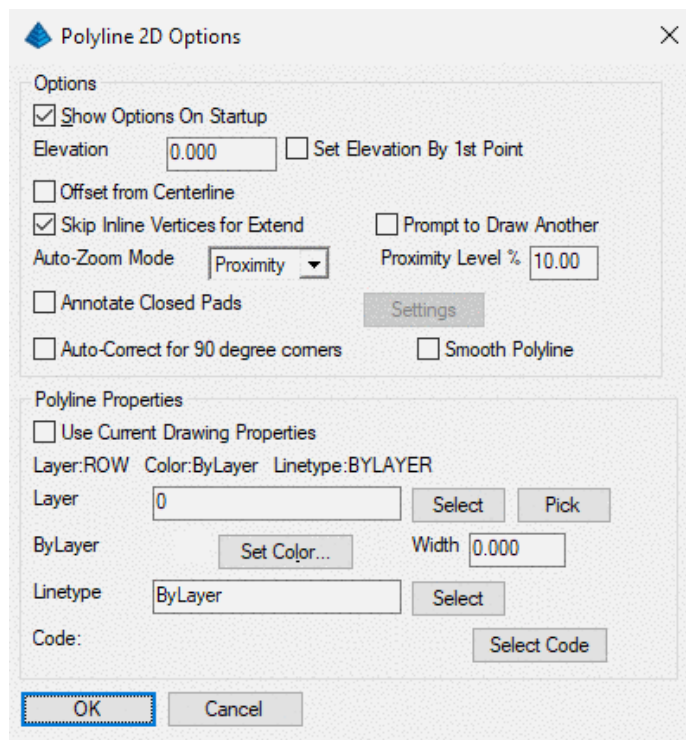

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <1>: 2

Enter Bearing Angle (dd.mmss) <90.0000>: 75.0627

Points/<Distance>: 553.69

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <2>: e (to exit)

- We'd like to draw a polyline from Point 1 to Point 2 and then connect the segments together (we could have turned linework with traverse on before we got started, but now we will do it after-the-fact for illustrative purposes). Pick the Draw – 2D Polyline command (or simply type-in **2DP** at the command line) which starts the Carlson enhanced Polyline command. If the Polyline 2D Options dialog box appears, set the values shown below and click the **OK** button:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 1-2

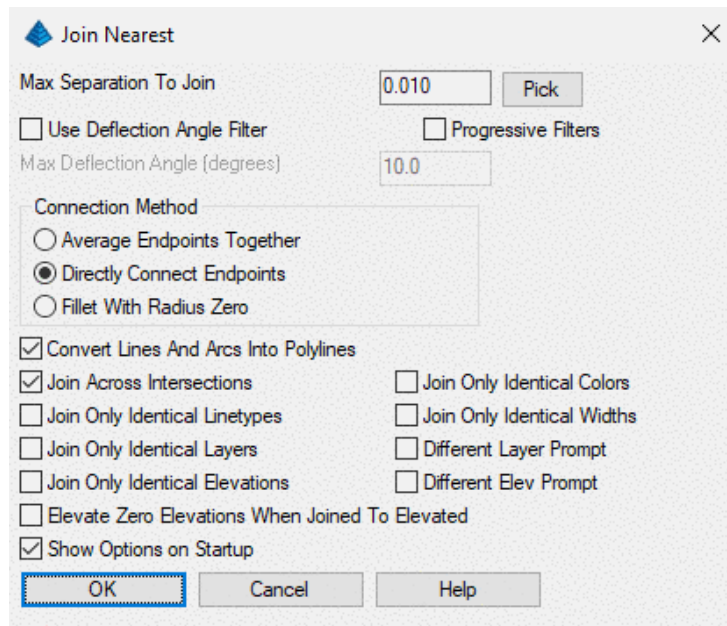

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter to end

Now we have two vector entities. The first, from point 2 to point 3 is a **Line**. The second, from point

1 to point 2, is a **Polyline** (even though it is only one segment long). It will (by default) be a lightweight polyline (LWPOLYLINE). This can be verified by picking it using the Inquiry – **List**. Polylines are linked combinations of one or more line/arc segments that behave as one unit. Carlson encourages the use of polylines versus lines because they offset as a unit, will take on a thickness or width, are easier to select and have superior editing capabilities.

NOTE: Many entities (*e.g.* lines, arcs, *etc*) can be turned into a polyline by issuing the Edit – Polyline Utilities – Entities to Polyline command but our next command will also offer this functionality.

To join the polyline and line entities into a single polyline, pick the Edit – Join Nearest and set the prompts to those shown below and click **OK** when ready:

Select lines, arcs and unclosed polylines to join [Settings].

Select entities: pick the polyline from 1 to 2 and the line from 2 to 3, and then press Enter for no more

Now, see the grips on the new polyline by picking it with the cursor. See how the whole thing highlights? That is proof that it is joined up as a polyline.

- Let's design an arc with a 500' Radius by using the Draw – Arc – 2 Tangents,Radius command and following the prompts below:

Radius of Arc <0.000>: 500

[nea] Pick Point on 1st Tangent Line: pick on the 1st polyline segment closer to point 2

[nea] Pick Point on 2nd Tangent Line: pick on the 2nd polyline segment close to point 2

The arc draws in, and the centerline remains a polyline, now with 3 segments.

- The **Inverse** command is a handy way to reset a new "occupied point" to get on a point to begin another traverse so let's practice inversing. Key-in **I** at the Command prompt and inverse from point 1, then to point 2, then to point 3 then back to 1. Notice the results being echoed to the Command prompt window (pressing the **F2** function button on most keyboards toggles the visibility of the text window results).

You can also inverse (go to) a snapped position on a line or polyline, such as the midpoint of an arc. Let's do that, because we want to traverse south from the *midpoint* of the arc. Key-in **I** and follow the prompts below:

Calculate Bearing & Distance from starting point?

Traverse/SideShot/Options/Arc/Pick point or point number: mid (for midpoint snap of)

Snap to MID of: select the arc

Traverse/SideShot/Options/Arc/Multiple/Pick point or point number: T

Traverse, Line ON, RAW FILE OFF

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <2>: press Enter

Enter Bearing Angle (dd.mmss) <75.0627>: 10.11

Points/<Distance>: 400

Exit/Help/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <2>: press E to exit

Notice that you can transition from Inverse, to Traverse, to Sideshot, *etc.*, with these COGO options. We were in inverse, but we did T for traverse, and could have done I for inverse to return to inverse. This cuts down on keystrokes, and adds to the sense of fluidity of the software.

Turn the resulting Line into a Polyline with the aforementioned Edit – Polyline Utilities – **Entities to Polyline** command as the following command requires Polyline entities.

8. We'd now like to create edge of pavement lines and form the intersection. Pick the Area/Layout – Layout Utilities – Offsets & Intersections command and follow the prompts below:

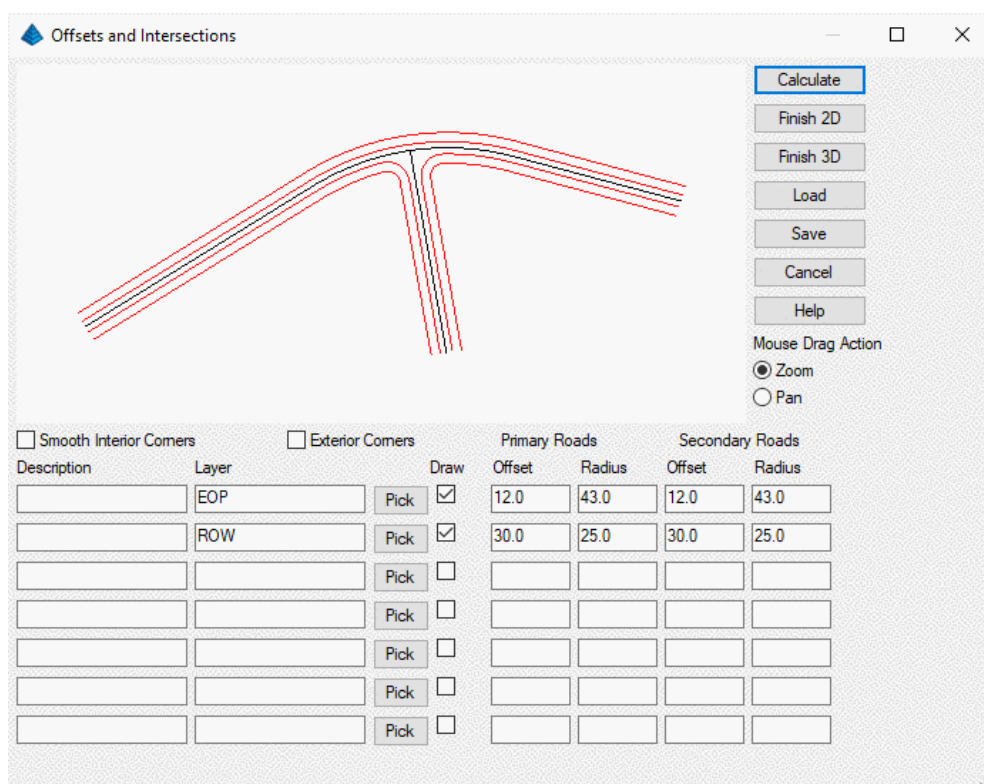

Select all PRIMARY road polylines.

[FILter]/<Select entities>: press Enter (we will consider both these subdivision streets secondary)

Select all SECONDARY road polylines.

[FILter]/<Select entities>: pick the main centerline and pick the side road

[FILter]/<Select entities>: press Enter

The street intersections are presented in a dynamic dialog as shown above. Try experimenting with different radii under the **Secondary Roads** column, then clicking Calculate. The streets will re-draw in the upper graphical area. But after experimenting, change the four values under Secondary Roads to those shown (ignore Primary Roads – those don't apply here), and click **Calculate**. Then click **Finish 2D**. Note the drawn-out street intersection.

Now select the Inquiry – Drawing Inspector command. Right click and make sure **Layer** is checked. Hover over the outside polyline (it is layer ROW). Hover over the next polyline inwards from the outer polyline (it is layer EOP). For example, if you had clicked off EOP under the **Draw** column in the above dialog, the edge-of-pavement polyline would not have drawn.

9. We'd now like to add some cul-de-sacs to the project. Click the Area/Layout – Layout Utilities – Cul-de-Sacs command. You may want to zoom into the area of the bottom center, near point 4. When finished with the procedure below, zoom back out:

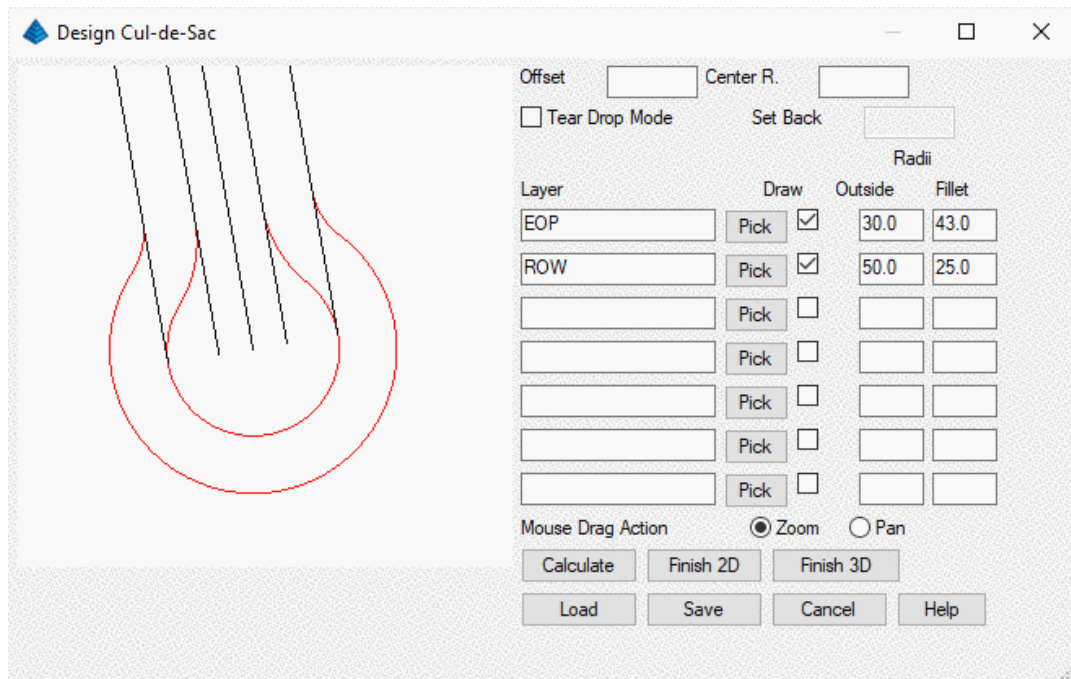

Select all offset polylines to end with cul-de-sac.

[FILter]/<Select entities>: form a crossing selection from right to left across the lower side road, selecting all 5 polylines (ROW-L, EOP-L, CL, EOP-R, ROW-R)

[FILter]/<Select entities>: press Enter

Pick cul-de-sac center projection onto centerline: pick near the endpoint of the centerline of the lower side road near point 4. Make sure the pick is on the centerline polyline, or the routine will say the centerline was not found.

This brings up the following dialog:

Again, you can change the **Fillet Radius** and the **Outside Radius** on the EOP or ROW, click **Calculate**, and check out its effect (don't make the Outside radii too small or it will fail to Calculate if there is no workable solution). Set values as shown above and then click on **Finish 2D**.

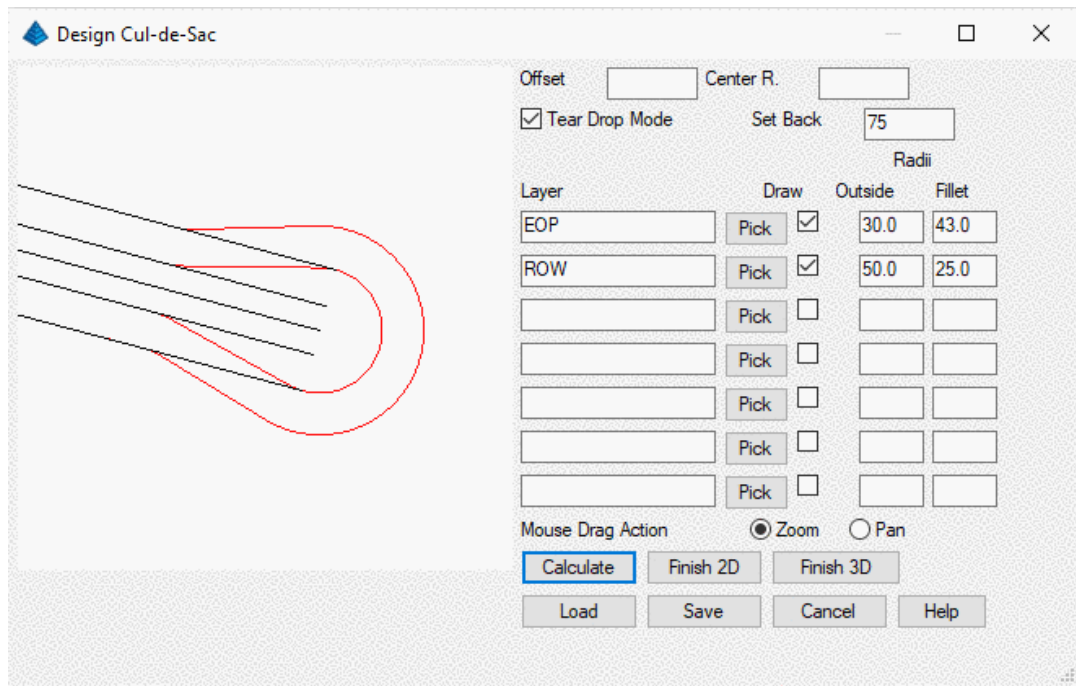

10. Repeat the Area/Layout – Layout Utilities – **Cul-de-Sacs** command to place a tear-dropped shape Cul-de-Sac:

Select all offset polylines to end with cul-de-sac.

[FILter]/<Select entities>: form a crossing selection pick from right to left across the right main road, selecting all 5 polylines (ROW-L, EOP-L, CL, EOP-R, ROW-R)

[FILter]/<Select entities>: press Enter

Pick cul-de-sac center projection onto centerline: pick the endpoint of the centerline of the lower side road near point 3

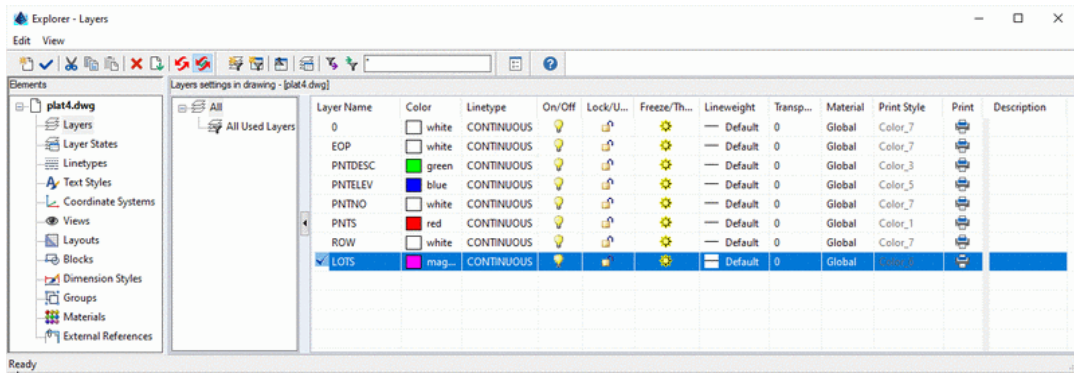

For a teardrop cul-de-sac, fill out the dialog as shown above then click on **Calculate** and **Finish 2D**.

NOTE: Teardrop cul-de-sacs allow moving vans and other large vehicles more turning room, and have been popular in many residential subdivision areas. Our drawing now appears as shown below, with the exception of the filled reference dots:

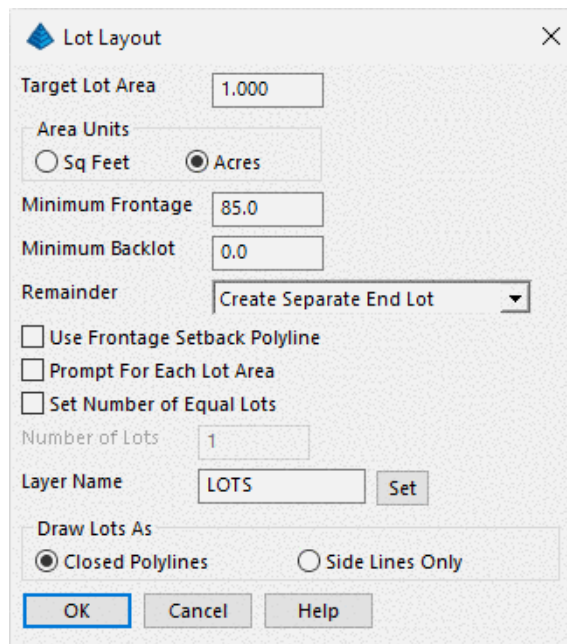

11. It's a good idea to create a layer and set it current before beginning the design process. Let's make a layer called LOTS using the View – **Layer Control** command and set the values as shown below:

- (a) Click on for New layer
- (b) When *Layer1* highlights, type over it with LOTS
- (c) Click under the Color column and change the color to Magenta
- (d) Click the (Set) Current button up top to make this layer current and then dismiss the dialog box

Our goal is to make 1-acre lots. The automated parcel creation tool prefers frontage lines that do not contain lots of zigs, zags, and jogs in the polylines as this may cause the perpendicular offset logic to fail to find a solution (Lot sidelines will radiate perpendicular from the frontage polyline). Not only should the front and back lines tend to run parallel with each other, but they should end at some point before the calculation runs into difficulty with impossible math.

12. Pick the Area/Layout – Layout Utilities – Lot Layout command. A dialog appears:

Fill out as shown. In particular, change the **Remainder** to *Create Separate End Lot* so that we force 1.000 acre lots and don't just get equal lots of some size such as 1.0017 (because the remainder lot that would not fit was added onto all lots). Using the **Closed Polylines** option means that our side lines will be doubled up, each lot sharing a side line. Click **OK**.

Select front polyline: pick north ROW

[Offset/<Select back polyline>]: Pick northernmost polyline (the back property line)

The 1.00 acres lots are laid out as far as possible. However, due to the geometry, it is likely that more Lots are able to be generated. As it turns out, the direction of the **front polyline** can have an impact on what is able to be created.

13. Let's reverse the direction of the **front polyline** to see what we get. Click the Edit – Polyline Utilities – Reverse Polyline command and when prompted:

Select polyline or line to reverse: pick the ROW polyline and shows phantom direction lines of the new current direction (which are automatically removed when the command ends)

Re-run the Area/Layout – Layout Utilities – **Lot Layout** command. Use same dialog entries and when prompted:

Select front polyline: pick the ROW polyline in a convenient location

[Offset/<Select back polyline>]: pick the outer polyline at a convenient location

The result should look similar to that below, with the exception of the open reference dots:

Let's clean this up for new work to follow:

- Click the Edit – Erase – **Standard Erase** command and erase the Lot as shown above.
- Let's remove polyline **vertex** locations which permits to keep parts of the Lots intact. Click Edit – Polyline Utilities – Remove Polyline – Remove Polyline Vertex and when prompted:

Select polyline to remove from: pick one of the LOTS polyline (cue markers will display where vertex locations can be found)

Pick point to remove: pick one of the circled vertex locations shown above (the polyline changes shape)

Pick point to remove (Enter to end): pick the other indicated vertex location

Pick point to remove (Enter to end): press Enter

- Re-run the **Remove Polyline Vertex** command by pressing Enter and repeat the process for the other Lot indicated

The Lots are now more regularly shaped but less than the 1 acre target area we desire.

14. Let's adjust the two smaller lots to the exact 1 acre target size we desire through the use of the Area/Layout – Adjust Areas – Sliding Side Area command as illustrated below:

When prompted:

Define area by points or closed polyline [Points/<Linework>]? press Enter to accept the Linework option
Select polyline segment to adjust: pick the easterly-line of the Western lot as indicated by the dashed line
Keep existing polyline [Yes/<No>]? indicate the No response so the end result is a single lot polyline
Define new line by selected line, another line, angle or points [<Selected>/Line/Angle/Points]? press Enter to indicate the new lotline should be simply slid
(the current area is echoed for reference purposes)
Remainder/Yards/SF/<Enter target area (acres)>: type 1 to indicate the desired acreage size
Calculating ...
Done.

The new lot at the target size is drawn. Press the **Enter** key to repeat the command to adjust the westerly-line of the Eastern lot.

- The lower back property line is still continuous. We can work with it in small pieces rather than as one big polyline. Say we want to break it at the inside corner identified by the points **B1** and **B2** as cited in a previous image (reproduced below):

To do this, use the Edit – Break – At Intersection command and when prompted:

Select Line, Arc, or Polyline to Break: pick the lower back property line

[app on] Pick Intersection to break at: pick the **B1** intersection point

Press the Enter button to repeat the command to break the lower back property line at **B2**.

16. Our next task will be to draw a Polyline from the lower back property line to the Right-of-Way polyline. Use the Draw – **2D Polyline** command. If the Polyline 2D Options dialog box appears, click the **OK** button:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: use a NEArest snap to start the polyline just south of **B1**

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: use a PERpendicular snap to end the polyline at the ROW polyline

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter to end

Press Enter to re-run the command and repeat the process starting just south of **B2**.

17. We have just created two new lots, but the lots are not defined by one, single, closed polyline and are likely not the target 1 acre lot size. To verify the areas, select the Area/Layout – Area by Interior Point command. When prompted:

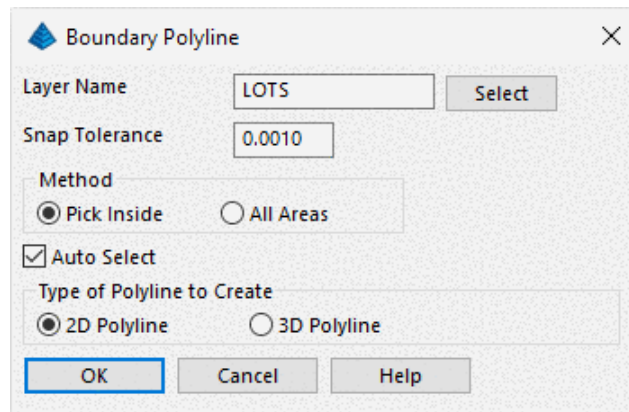

Pick point inside area perimeter: pick inside either (or both) of the new lots (the results are echoed to the Command line area)

Pick area label centering point (Enter for none): press Enter to end

Pick point inside area perimeter: press Enter to end

The lot(s) is/are probably not the 1 acre target. We wish to obtain the target size but would prefer to work with a closed polyline perimeter for the new lots.

18. We'll use the Draw – Boundary Polyline command that will trace out the bounded perimeter (if available) for a point we pick. Set the values as shown below and click **OK** when ready:

When prompted:

Pick an internal point: pick inside the new lot(s) (the new boundary polyline(s) are created).

19. We'll continue to create the lots at the target size. Re-issue the Area/Layout – Adjust Areas – **Sliding Side Area** command and adjust the southern property line of the newly created lots. When completed, our layout should resemble that shown below:

20. Let's create the remaining lots. Re-issue the Edit – Break – **At Intersection** and when prompted:

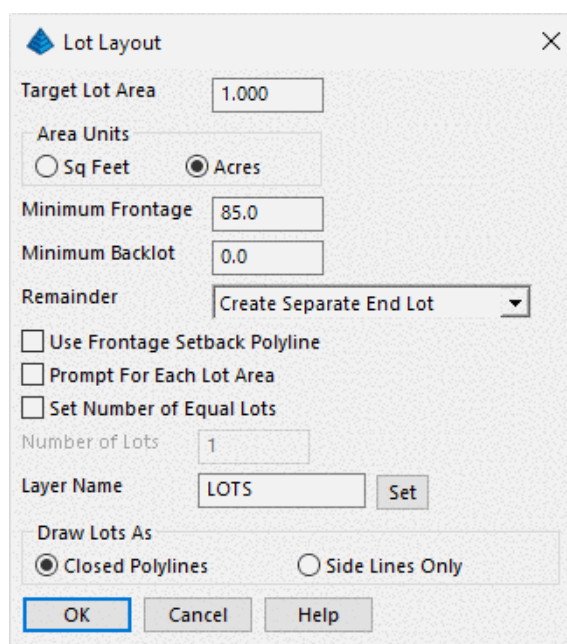

Select Line, Arc, or Polyline to Break: pick the lower back property line

[app on] Pick Intersection to break at: pick a lower back property line break location cited in the image above

Press the Enter button to repeat the command to break the lower back property line at its other designated break point.

Press the Enter button in succession to repeat the command to break the right-of-way property line at its designated break points.

21. Re-issue the Area/Layout – Layout Utilities – **Lot Layout** command. A dialog appears:

Fill out as shown, *except* change the **Remainder** to *Apply Equally to All Lots* so that we force a minimum of 1.000 acre lots and spread the remainder equally between the lots. Click **OK** and when prompted:

Select front polyline: pick the remaining ROW polyline

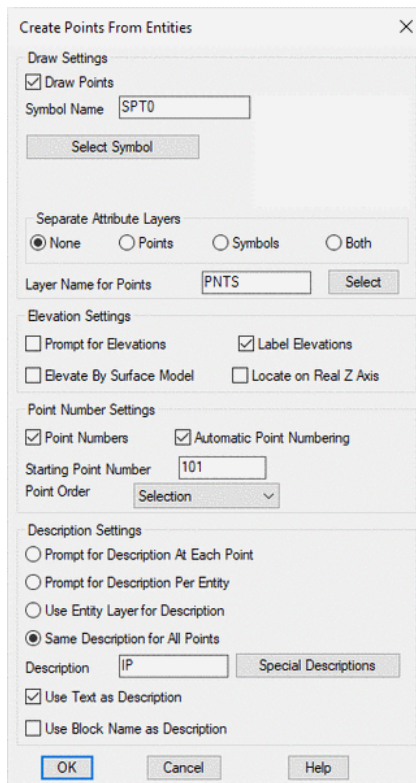

[Offset/<Select back polyline>]: pick the remaining lower back property line

The lots are laid out as evenly as possible and our completed site should resemble the following:

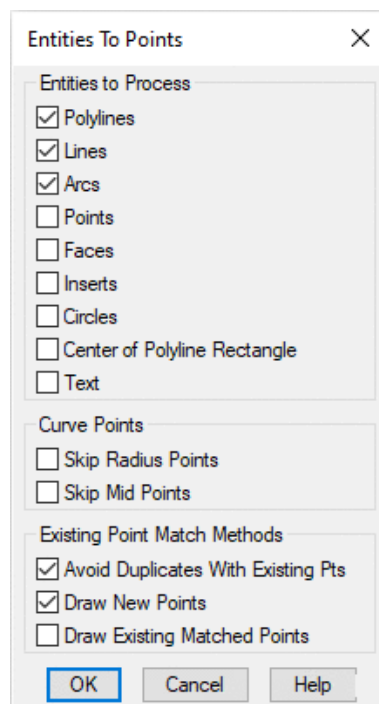

It may not be the most aesthetic subdivision, but we learned a lot of tools making it. But we're not done. There's some real automation ahead.

22. We have designed a subdivision, in effect, without point numbers. This is the beauty of CAD. But it is often desirable to make point numbers in order to stake-out the subdivision. To do this, run the COGO – Create Points from Entities which displays the following dialog box:

Set the **Starting Point Number** to 101 (helpful as our previously entered points [1-4] can be thought of as "control" points) and verify the dialog as shown and click **OK**. A second dialog, covering what entities to capture, appears next:

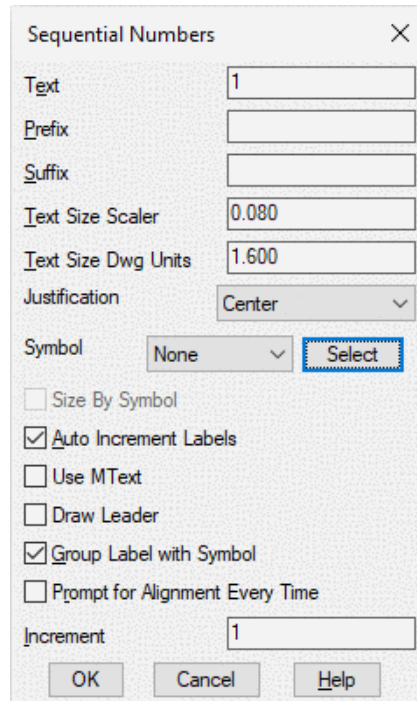

Accept the default settings and click **OK**. When prompted:

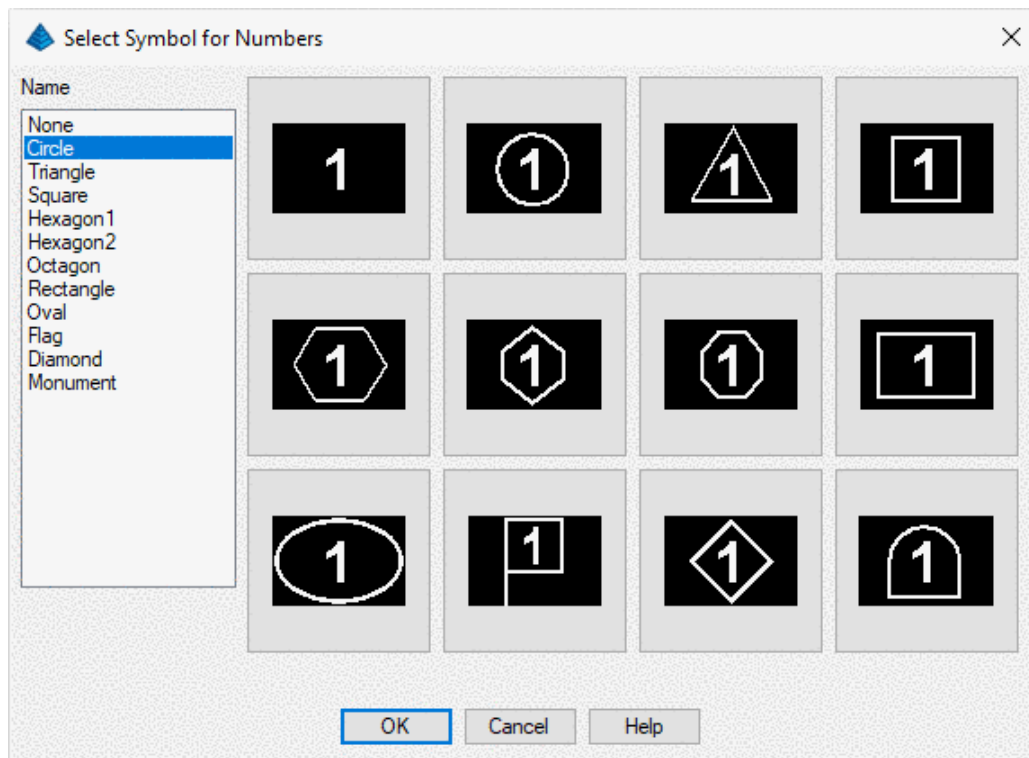

Select arcs, circles, faces, points, text, lines and polylines.
[FILter]/<Select entities>: type ALL and press Enter twice

All the point numbers for stakeout are created and stored into the active Coordinate File.

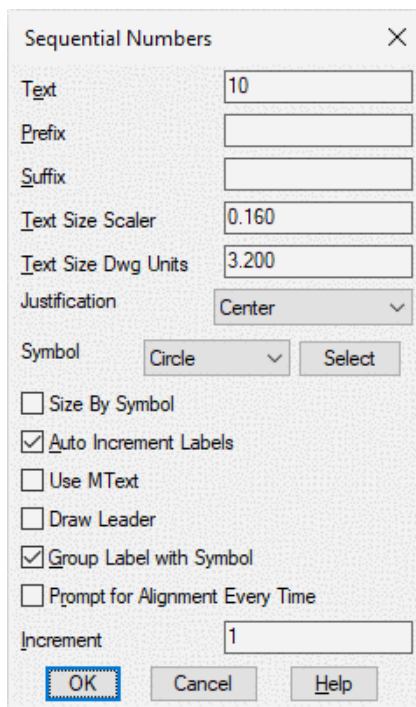

23. Our next goal is to number the lots, clockwise from the upper left. Use the Draw – Sequential Numbers command which displays the following dialog box:

Click on the **Select** button to select a desired symbol to circumscribe our sequential numbers as illustrated below:

Choose the circled text and click **OK** to return to the Sequential Numbers dialog box:

Set the Text value to **10** and the Text Size Scaler to **0.16** as shown and then click **OK**. When prompted:

Pick point for label position: pick near the center of the first upper left lot

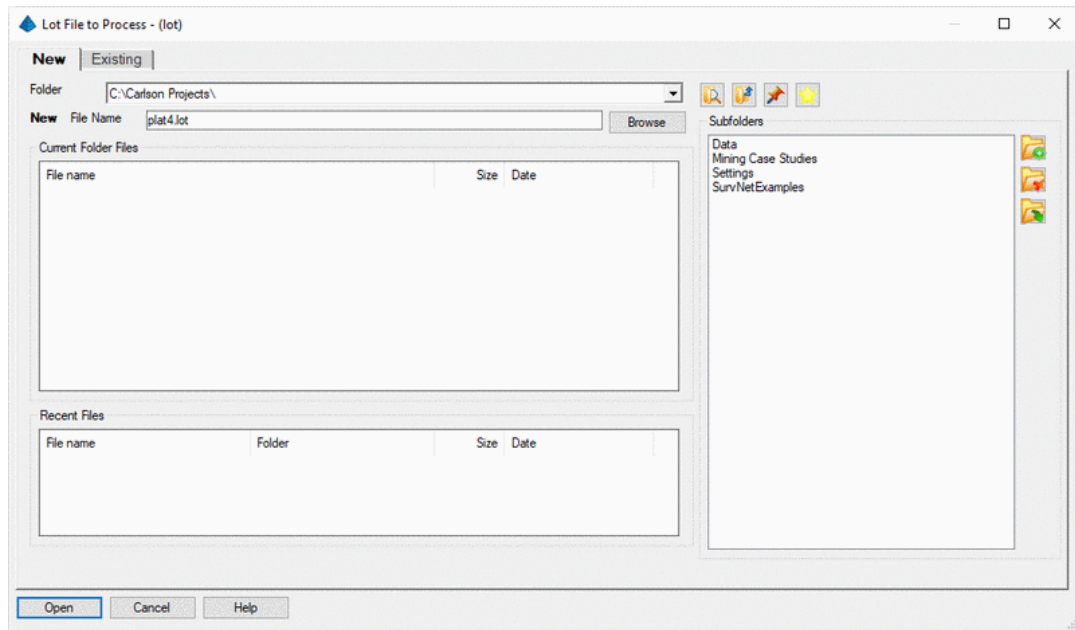

Pick point for label alignment: press F8 for <Ortho on>, pick to the right

Now pick near the center of all of the lots, going clockwise and press Enter at the conclusion of the last lot. When complete, press F8 again to set Ortho off. The resulting drawing, with point numbers, is shown below (enhanced for clarity):

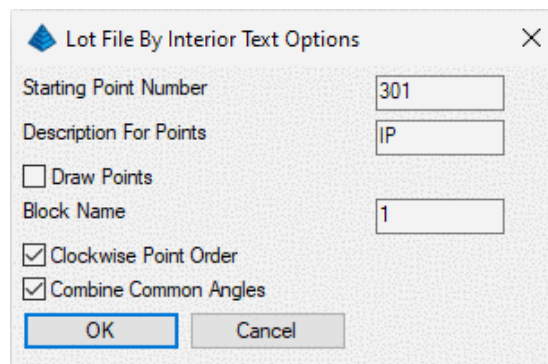

24. Official **Lot Files** can be created whenever a lot number or name exists within a lot as the sole text (other text may be present but could/would/should be frozen). We will play it safe and first freeze the points (PNTS) layer. Use the View – Freeze Layer by Selection command and pick on one of the points.

Next, issue the Area/Layout – Create Lots – Lot File by Interior Text. Supply the Lot File to Process value as shown below and click the Open button:

A dialog box will appear:

Set the values as shown above and click **OK**. When prompted:

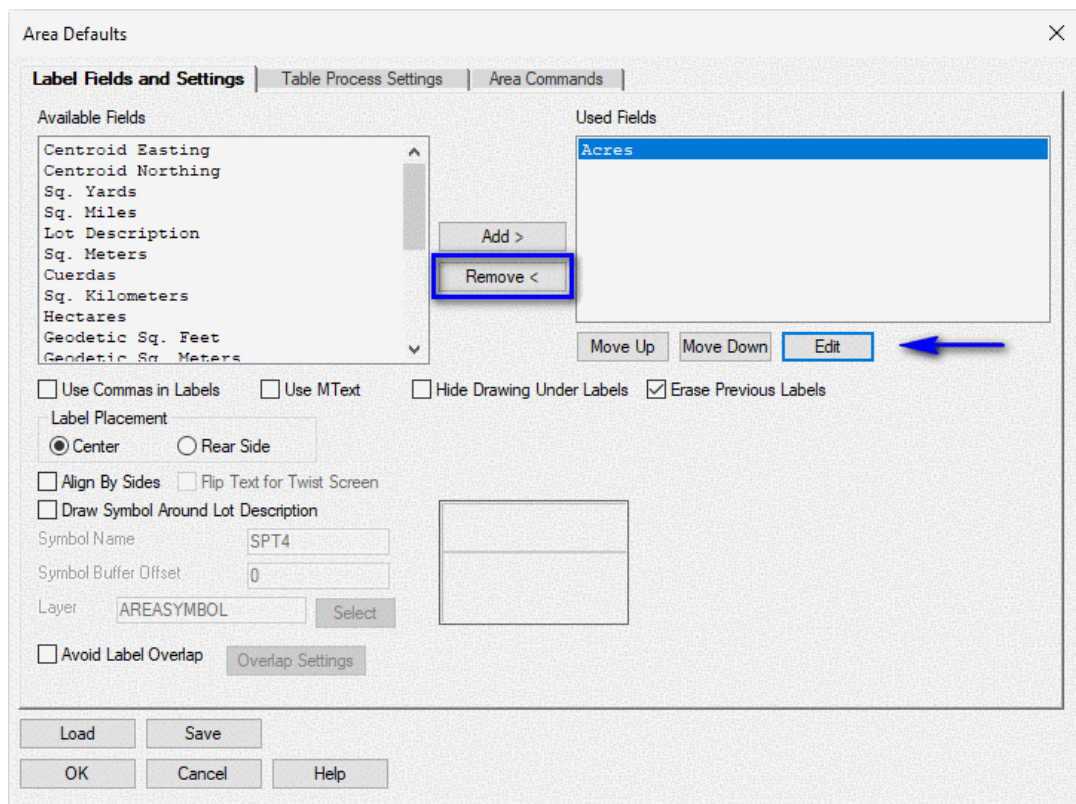

Select lot lines, polylines and text.

[FILter]/<Select entities>: type ALL and press the Enter button twice

The Lot File will be created.

NOTE: If we had not made points at all lot corners using **Create Points from Entities** command, the **Lot File by Interior Text** would create points at the Lot corners. This is the reason for the **Starting Point Number** prompt. If points are found, no new ones are created. Lot files must have points at all the corners.

25. Before we look at the Lot File, let's finish up and perform area annotation on the upper Lots. Select the Area/Layout – Area Defaults command:

Use the **Remove <** button to remove the **Sq. Feet** entry leaving only the **Acres** item in the *Items Used* portion of the dialog box. Use the **Edit** button to verify it is set to plot to 3 decimal places (*i.e.* 0.000) and click **OK** to complete the command.

Now choose the Area/Layout – Area by Interior Point command and when prompted:

Pick point inside area perimeter: pick inside Lot 10

Pick area label centering point (Enter for none): Pick near the center of Lot 10

Pick point inside area perimeter (Enter to end): repeat as prompted for Lots 11 through at least Lot 16 (continue with all Lots if you're so inclined) and press Enter when complete

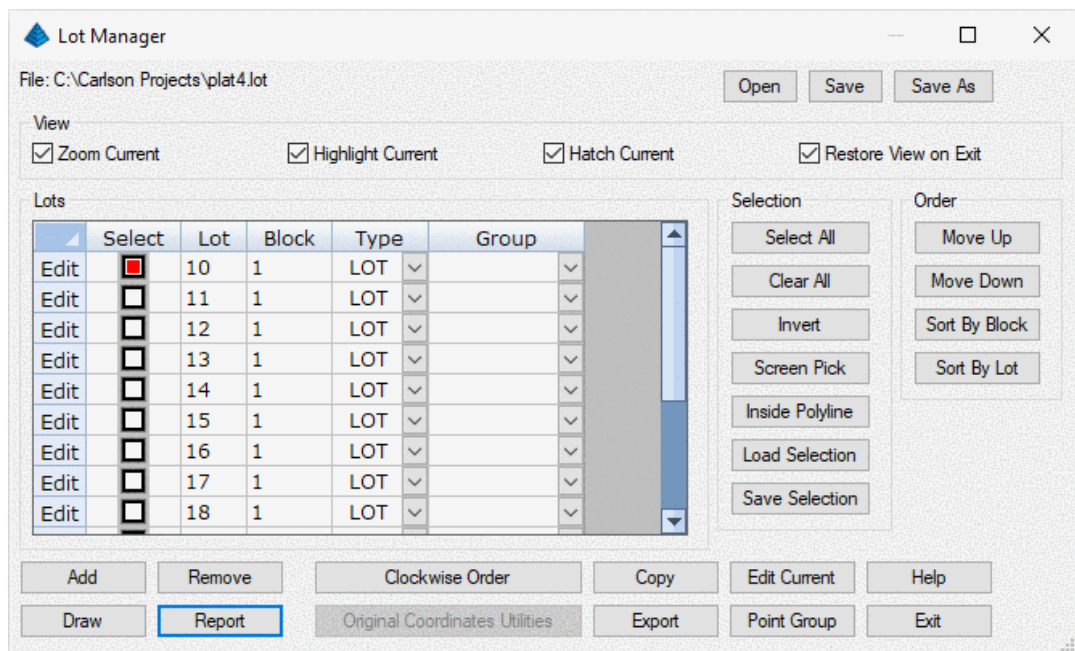

A detailed illustration is shown below:

21

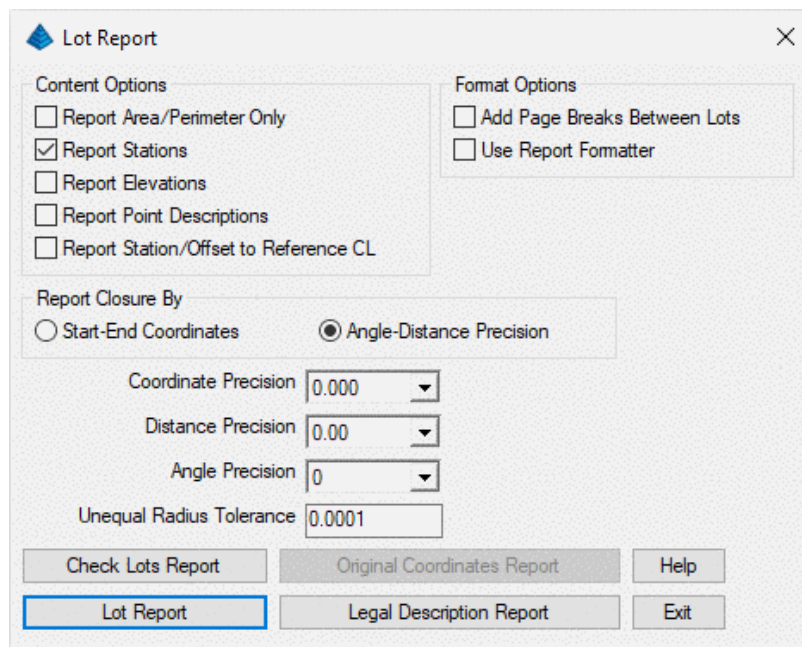

1.285 Acres

NOTE: For precise centroid placement, consider the use of the transparent Centroid snap ('centroid').

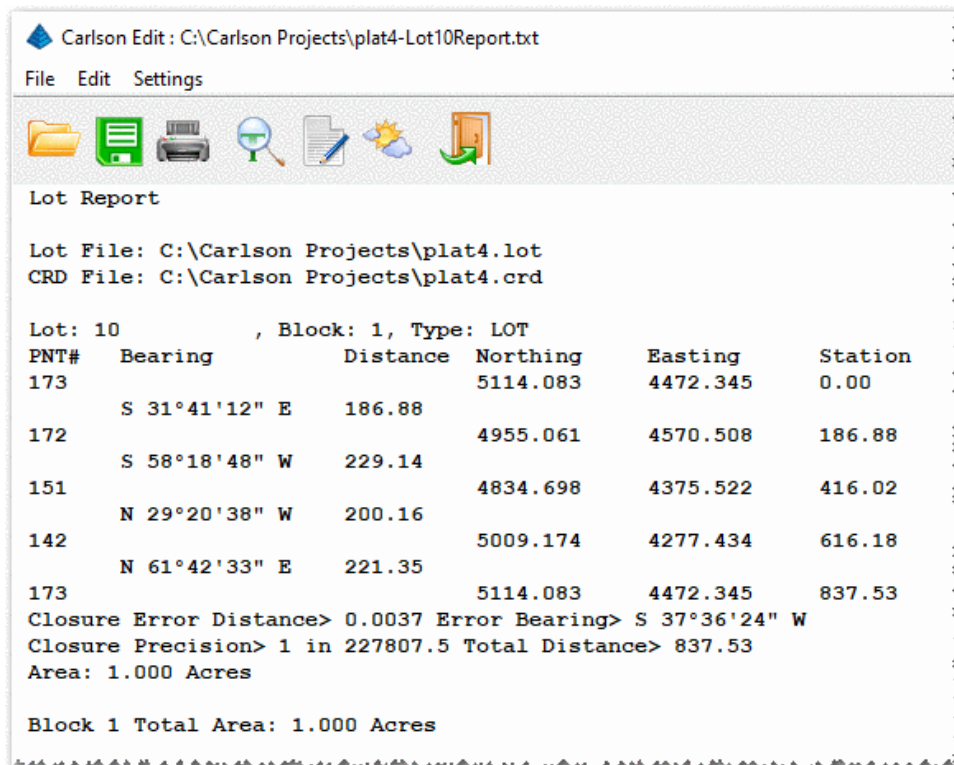

26. Let's explore the Lots created earlier. Run the Area/Layout – Lot File Manager command which displays the following dialog box:

Pick on Lot 10 and click **Report**. This will lead to the Lot Report dialog box:

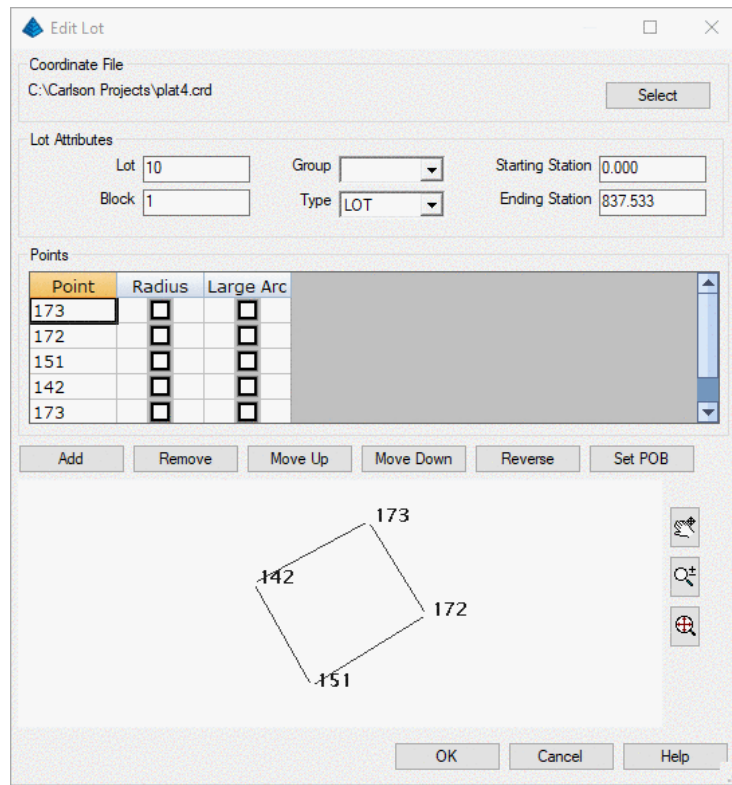

Be sure that your settings are as shown above and then click **Lot Report**:

This dialog is typical of the many Carlson Standard Report Viewer dialogs. You can click on one or more lines, highlight them and hit the delete key on the keyboard, and these lines will delete. You can edit lines directly in the dialog. You can also save the report to disk with the Save icon shown above. To exit, click the **Exit** (Doorway) button. The **Lot Manager** dialog box returns.

- The **Edit Current** option within the Lot Manager dialog box can be used to describe a lot by different point numbers, or to assign a lot to a different block. This is explained here and shown below for reference purposes only:

With Lot 10 selected, click **Edit Current** to display the dialog box above. Note the graphic display in the lower half, which maps the Points associated with the Lot. Also note the **Northwest corner** point number for Lot 10 as we'll use this information in the next step. Click Cancel and then Exit on the Lot Manager dialog box.

28. Presume you actually changed the point numbers that define Lot 10. That would cause the Lot to draw differently. Also, you could simply alter the coordinate values of a point in the current Lot File. That would also cause the Lot to draw differently. Let's take the latter approach.

Remember the **Northwest corner** point number for Lot 10? Let's change its coordinate value. Issue the Points – Edit Points command. A spreadsheet appears. Scroll down to your point number (142 in the image cited above):

Coordinate Data Sheet: C:\Carlson Projects\plat4.crd

File Edit Search Group Help

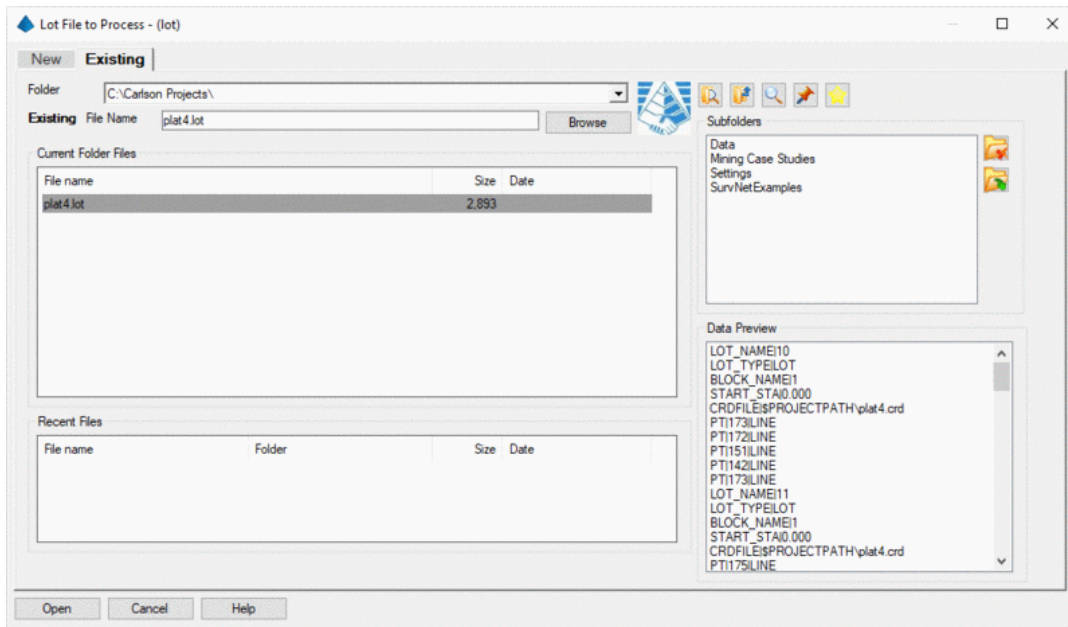

Point#	Northing	Easting	Elevation	Description
41	140	5072.8910	4841.3482	0.0000 IP
42	141	4798.9588	4397.5833	0.0000 IP
43	142	5009.1743	4277.4342	0.0000 IP

Point 142 Notes	
1	Original Northing = 5009.1743 Optional
2	
3	
4	

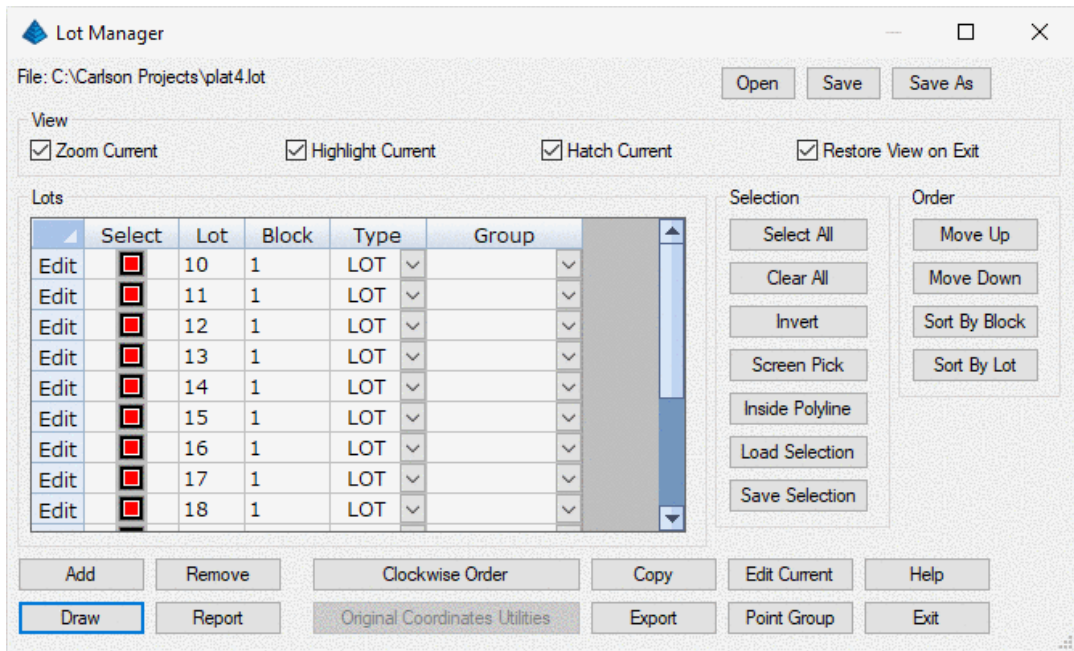

Click on the **Northing** and edit it to 5050. This is for illustration purposes. In reality, you might be fine-tuning your subdivision design points. As long as the same points define the lots, you are, in effect, able to make a ready-made new drawing. Once complete, issue (from the **Coordinate Data Sheet** dialog box) the File – **Save and Exit** option.

- Let's see what the change(s) look like in a brand new drawing. Before we draw the Lot File, save your drawing through the File – **Save** command.

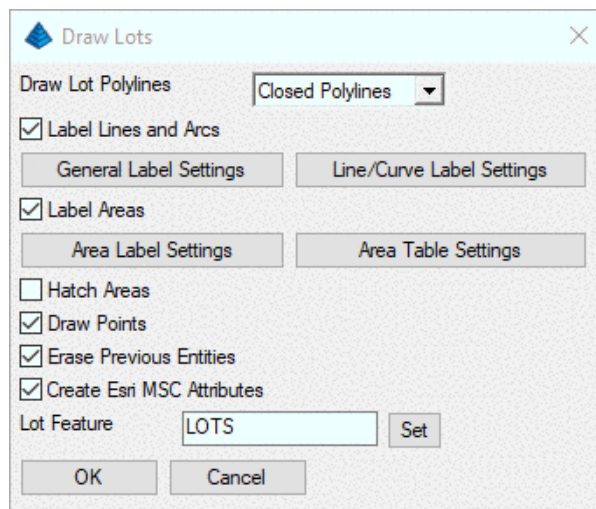

Then choose File – **New** and exit the Startup Wizard (if it appears), and go straight to the Area/Layout – **Lot File Manager** command as it also provides the tools for drawing Lot Files into the drawing:

From the **Existing**, select the *.lot file specified above and click Open. Follow this and select the existing **Plat4.crd** file from the earlier project. When the **Lot Manager** dialog appears, choose all Lots by clicking **Select All** and then click **Draw**.

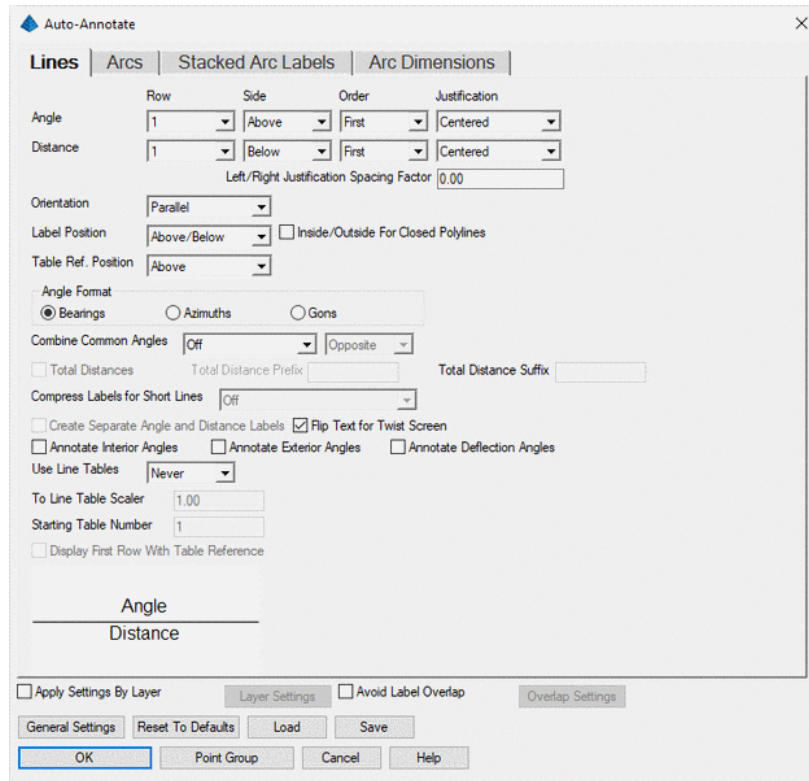

We have the ability to further define how the Lots are drawn and/or labeled:

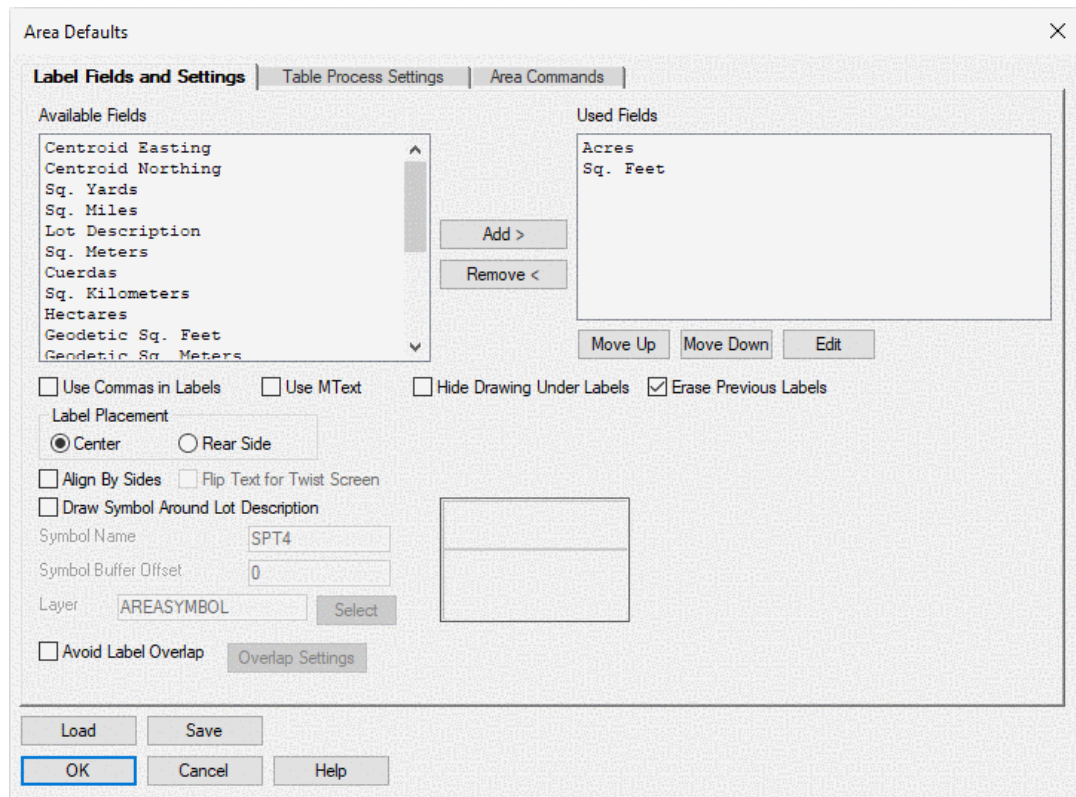

Apply settings required or as shown in the image above and:

- Click the **Line/Curve Label Settings** button to display the Auto-Annotate dialog box (also found under the **Annotate** menu) and set the values as shown below:

Click its **OK** button when complete.

- Click the **Area Label Settings** button to re-confirm the display the **Area Defaults** options discussed earlier (also found under the **Area/Layout** menu). Let's reuse the **Sq. Feet** item to the **Used Items** as shown below:

Click its **OK** button when complete.

Click **OK** to draw the Lots and eventually return to the **Lot Manager** dialog box (click its **Exit** when complete).

This leads to the plot shown below (drawn at 1" = 60' for clarity), created entirely from stored Lot Files, and showing our revision of Lot 10:

This completes the Lesson 4 tutorial: Intersections and Subdivisions.

SurvNET

This tutorial is divided into two lessons:

1. Processing an Assumed Coordinate System 2D Total Station Network
2. Processing a 3D Network With Both Total Station Data and GPS Vectors

Least Squares is very flexible in terms of how the survey data needs to be collected. Generally speaking, any combination of angles and distances, combined with a minimal amount of control points and azimuths, are needed. This data can be collected in any order. But there needs to be at least some redundancy in the measurements.

Redundant measurements are measurements that are in excess of the minimum number needed to determine the unknown coordinates. Redundancy can be created by including multiple GPS, and other control points, within a network or traverse. Measuring angles and distances to points in the network that have already been located create redundancy. Running additional cut-off traverses, or additional traverses to existing control points, creates redundancy. Following are some general rules and tips in collecting data for least squares reduction:

- Backsights should be to point numbers. Some data collectors allow the user to backsight an azimuth not associated with a point number. SurvNET requires that all backsights be associated with a point number.
- There has to be at least a minimum amount of control. There has to be at least one control point. Additionally, there needs to be either one additional control point or a reference azimuth. Control points can be entered in either the raw data file, or there can be a supplemental control point file containing the control point. Reference azimuths are entered in the raw data file. The control points and azimuths do not need to be for the first points in the raw file. The control points and azimuths can be associated with any point in the network or traverse. The control does not need to be adjacent to each other. It is permissible to have one control point on one side of the project, and a reference azimuth on the other side of the project.
- At least one of the control points needs to be occupied. There may be situations where no control point is ever occupied in the network, but only backsighted. In these situations, a preliminary value for one of the occupied points needs to be computed and entered as a floating point control point.

- Some data collectors do not allow the surveyor to shoot the same point twice using the same point number. SurvNET requires that all measurements to the same point use a single point number. The raw data may need to be edited after it has been downloaded to the office computer to ensure that points are numbered correctly.
- The majority of all problems in processing raw data are related to point number problems. Using the same point number twice to different points, not using the same point number when shooting the same point, misnumbering backsights or foresights, and misnumbering control points are all common problems.
- It is always best to explicitly define the control for the project. A good method is to put all the control for a project into a separate raw file. A big source of problems with new users is a misunderstanding in defining their control for a project.
- Some data collectors may have preliminary unadjusted coordinates included with the raw data. These coordinate records should be removed from the raw file. The only coordinate values that should be in the raw file are the control points.
- When a large project is not processing correctly, it is often useful to divide the project into several raw data files and debug and process each file separately, as it is easier to debug small projects. Once the smaller projects are processing separately, they can be combined for a final combined adjustment.

It is suggested that **Lesson 1** be completed before starting into **Lesson 2**. Throughout the lessons, we will cover the process of reducing and adjusting raw survey data into final adjusted coordinates, using the SurvNET program. The tutorial will describe the reviewing and editing of the raw data prior to the processing of the raw data. Next, the least squares project settings will be described, and then the final report generated from the least squares processing will be reviewed. Let's begin.

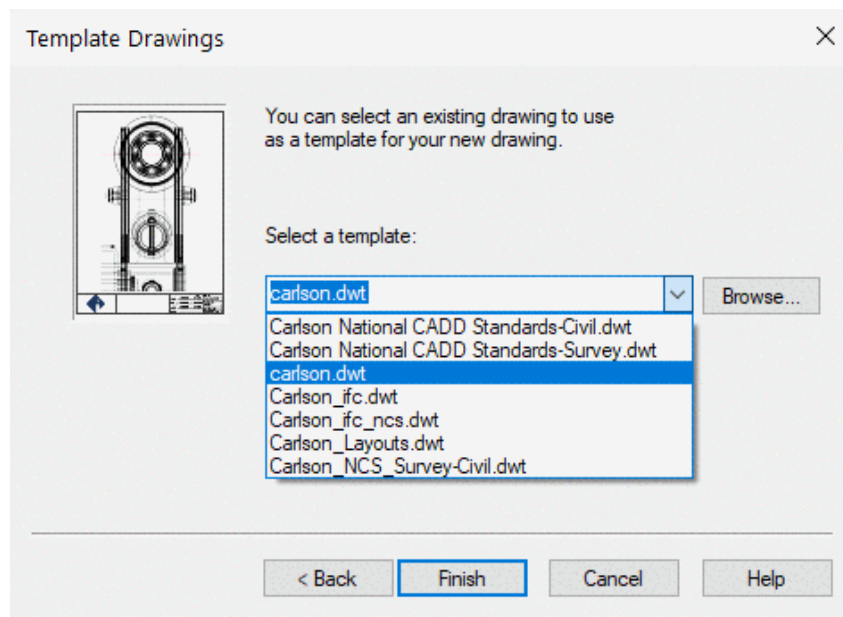

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click **New**.
 - If you are taken directly into CAD, click the File – **New** command.

The first of several Startup Wizard dialog boxes appears:

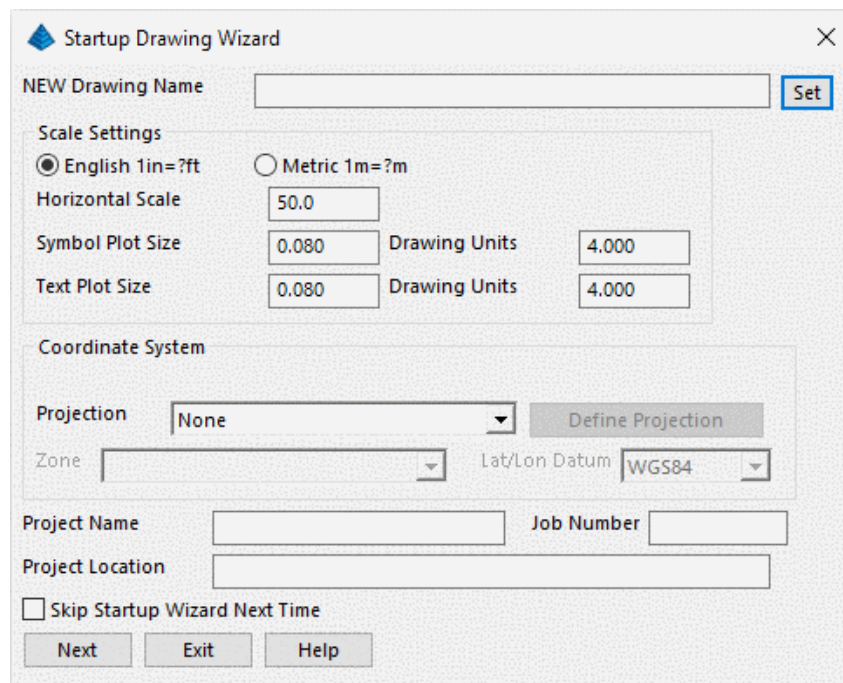

- (a) Choose the DWG document type and the desire to base the document on a **Drawing Template** as illustrated below and then click **Next >**:

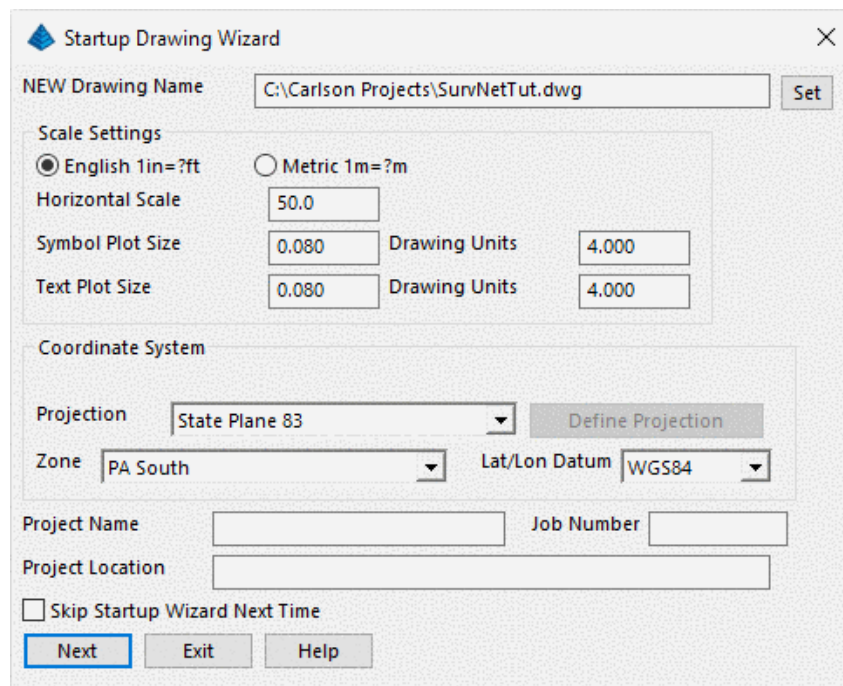

- (b) Choose the **carlson.dwt** as illustrated below (or *surv.dwt* if carlson.dwt is not available) and click **Finish**:

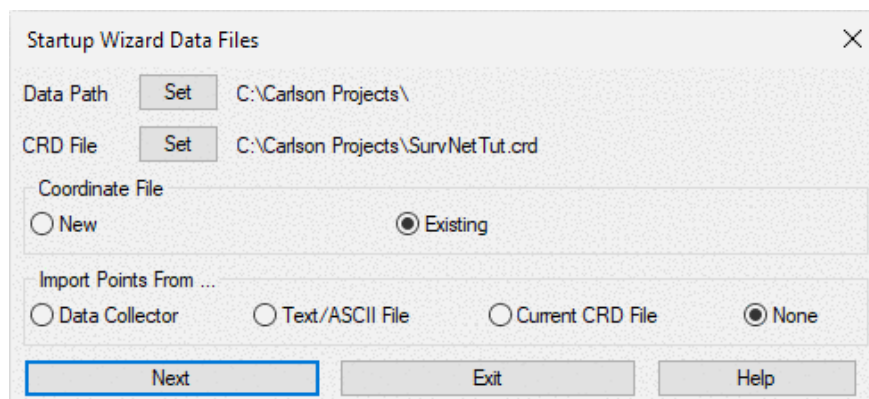

- (c) We can now begin the more pertinent settings for the project to come based on some preliminary settings that should be similar to the default scenario shown below:

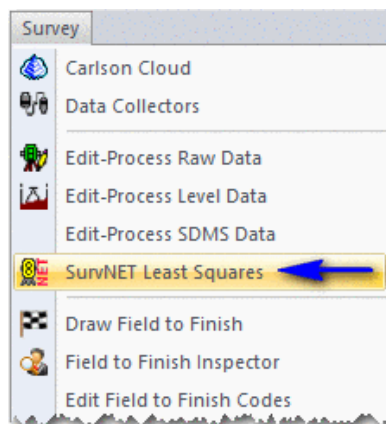

- (d) Click **Set** at the top of the dialog box, and enter in a NEW Drawing Name called **SurvNetTut**. Verify that the other settings match the settings shown below, and click **Next**:

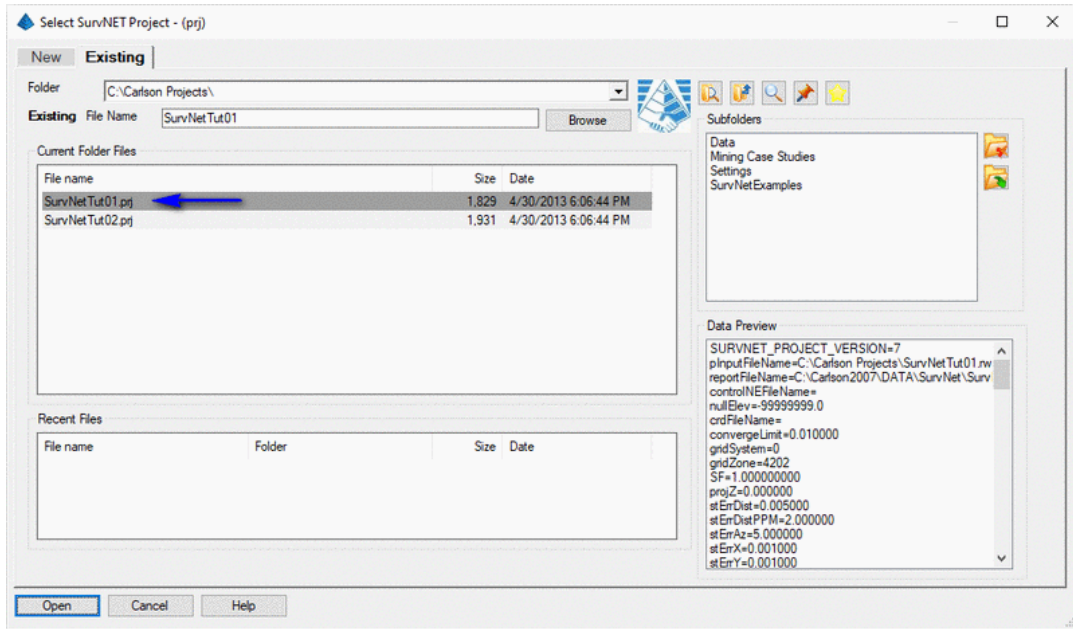

- (e) You will see the Startup Wizard Data Files dialog to set/confirm where to store data and indicate an information source for points/coordinates. Set/match the values as shown below and click **Exit**:

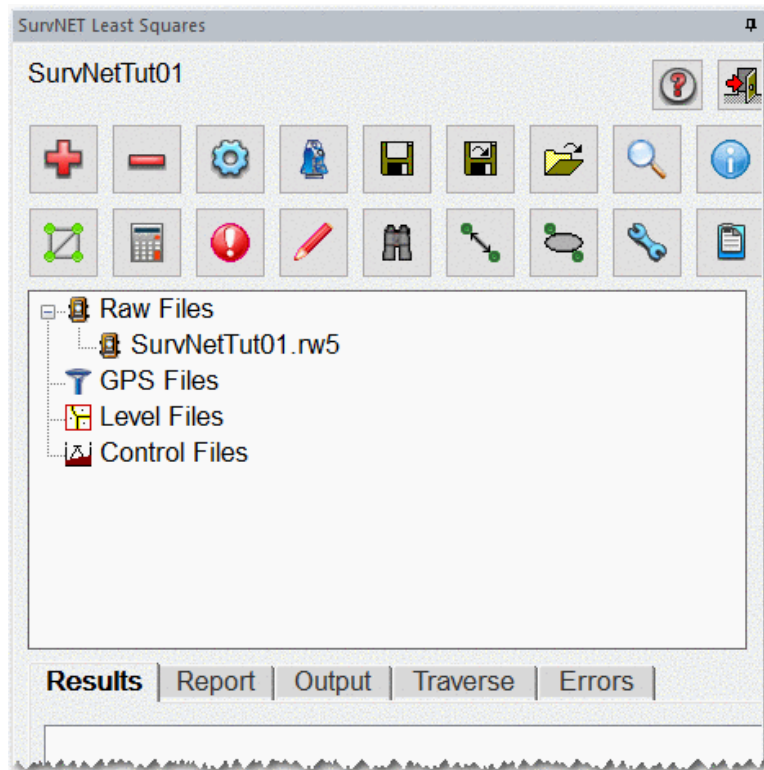

2. **Lesson 1 - Processing an Assumed Coordinate System 2D Total Station Network.** The raw data files associated with this tutorial are located in the *Carlson Projects* folder, under the installation folder on your computer (example: C:\Carlson Projects). Activate the Survey menu via Settings – Carlson Menu – **Survey Menu**.
3. The easiest way to start the program is to issue the Survey – SurvNET command as illustrated below:

This, in turn opens the following dialog box:

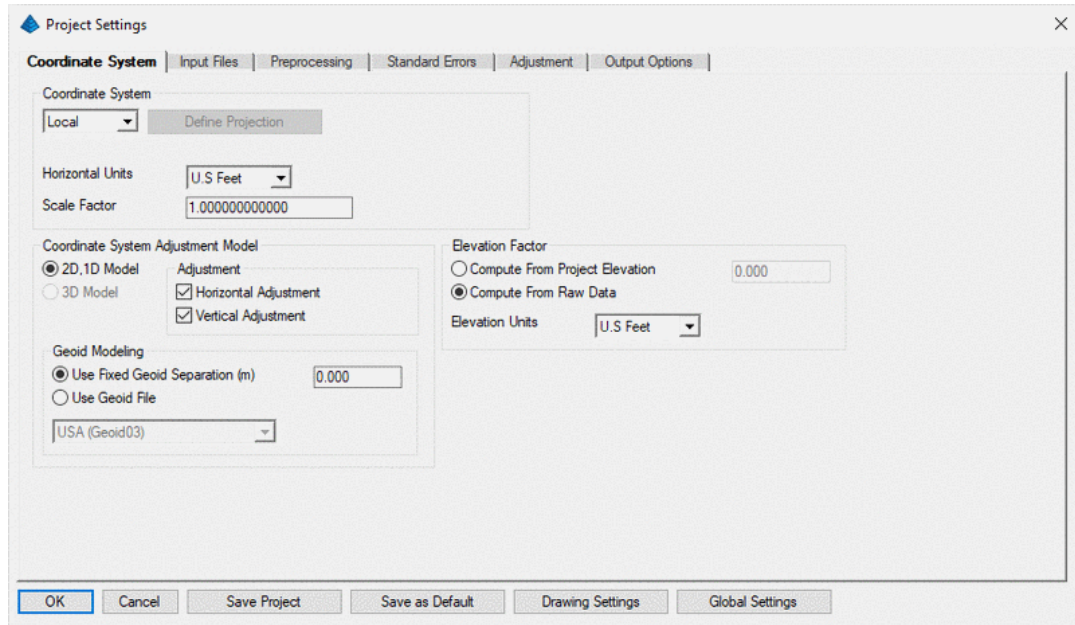

Select the **SurvNetTut01.prj** project and click **Open**. This will open the default SurvNET *project-tree* docked dialog box interface as shown below where we will process the contents of the **SurvNetTut01.rw5** "raw" file:

- Learning the meaning and implications of the different project settings is the most critical initial step in learning how to use SurvNET. Let's review the different project screens. Click the Settings (Gear) button as shown below:

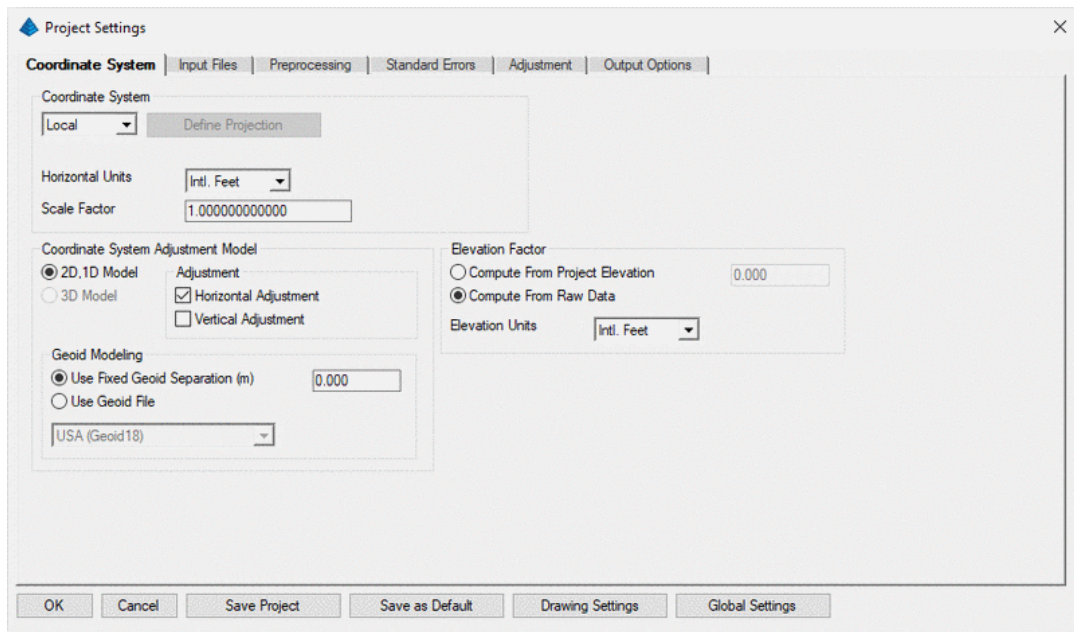

to display the dialog box below:

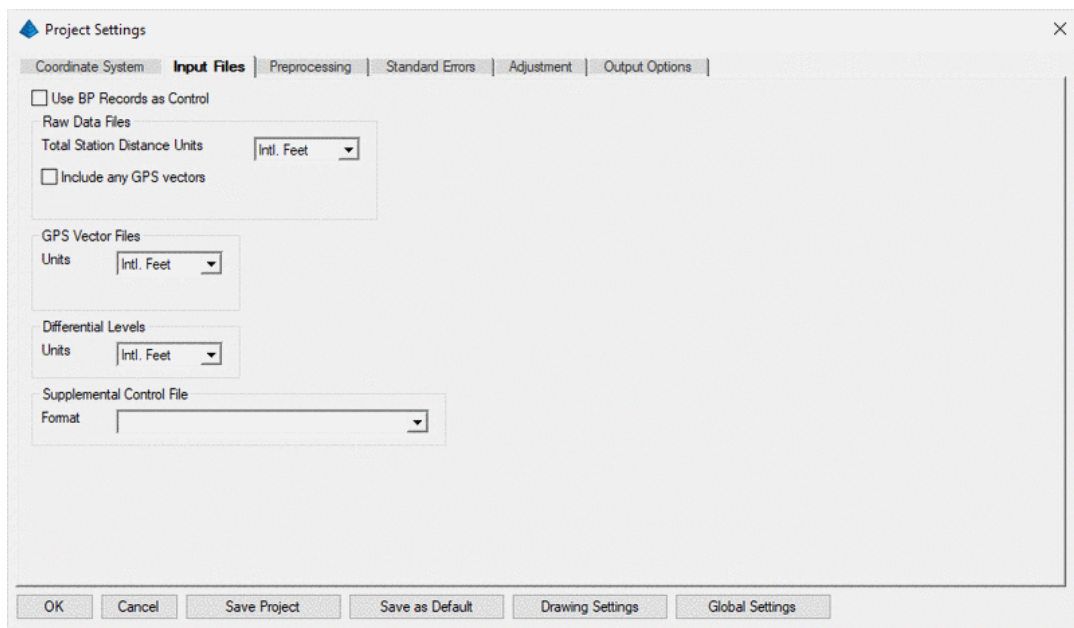

NOTE: In this dialog, the different settings required for the Least Squares reduction are available in the different tabs of the dialog box. When all of the settings are set as desired, click **OK** to save the changes.

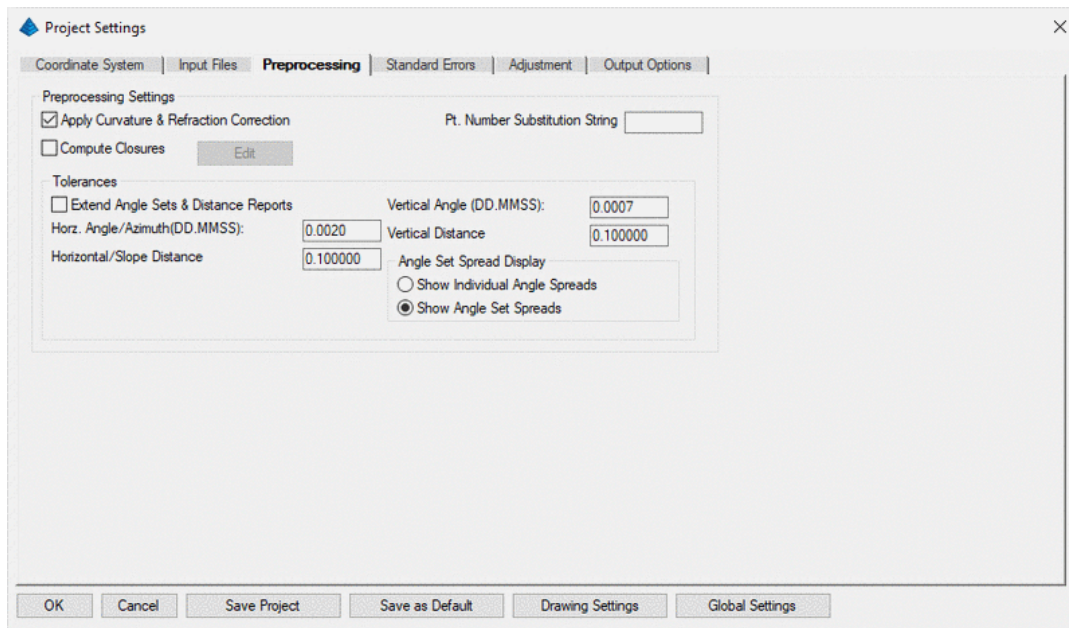

- Settings - Coordinate System: For the purpose of this tutorial, the **Coordinate System** settings tab should look as follows before proceeding to the next step. To use an assumed coordinate system, the **Local Coordinate System** needs to be selected, and the 2D,1D Adjustment Model must be chosen. When using a local coordinate system, the distance units are not important other than for display purposes in the report. Computing elevation factors and performing *Geoid* modeling is not applicable to assumed datums. Notice that in this example we are not performing a vertical adjustment (make this and other changes as applicable):

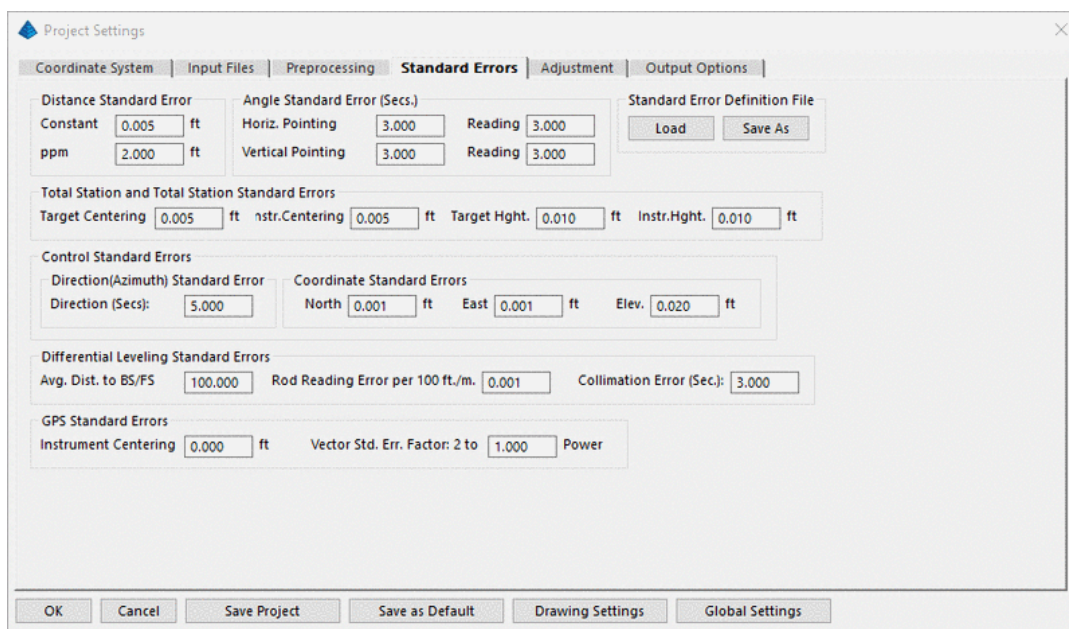

- Activate the Input Files tab. The Input Files settings is where you establish pertinent values for how the files are treated. SurvNET allows you to have multiple raw files in a single project. The ability for multiple raw files allows flexibility in collecting the data and processing large projects. It is typically easier in a large project to analyze and edit subsets of the total project, before combining all the data for a final adjustment. Notice that since we are working in a *Local* coordinate system and using the *2D, 1D Adjustment Model*, GPS vectors cannot be incorporated into this project. Make any necessary changes to match the values shown below:

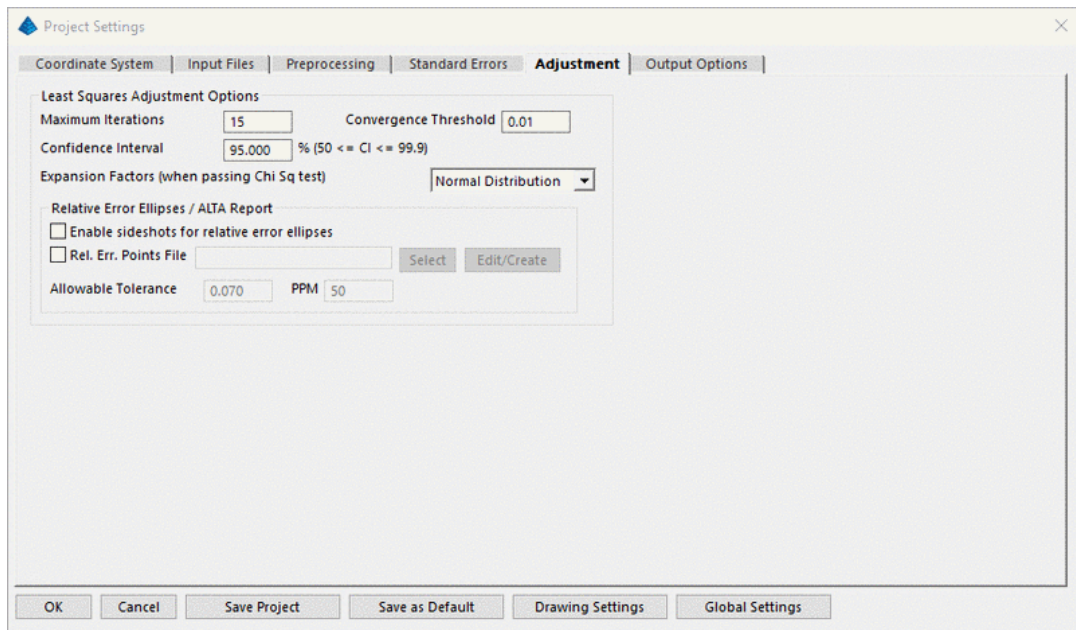

- Activate the Preprocessing tab to review the Preprocessing settings. Preprocessing consists of reducing and averaging all the multiple measurements, applying curvature and refraction correction, reducing the measurements to grid if appropriate, and computing unadjusted traverse closures if appropriate. Much of the data validation is performed during the preprocessing step. For the purpose of this tutorial, the **Preprocessing** settings should look as follows before proceeding to the next step:

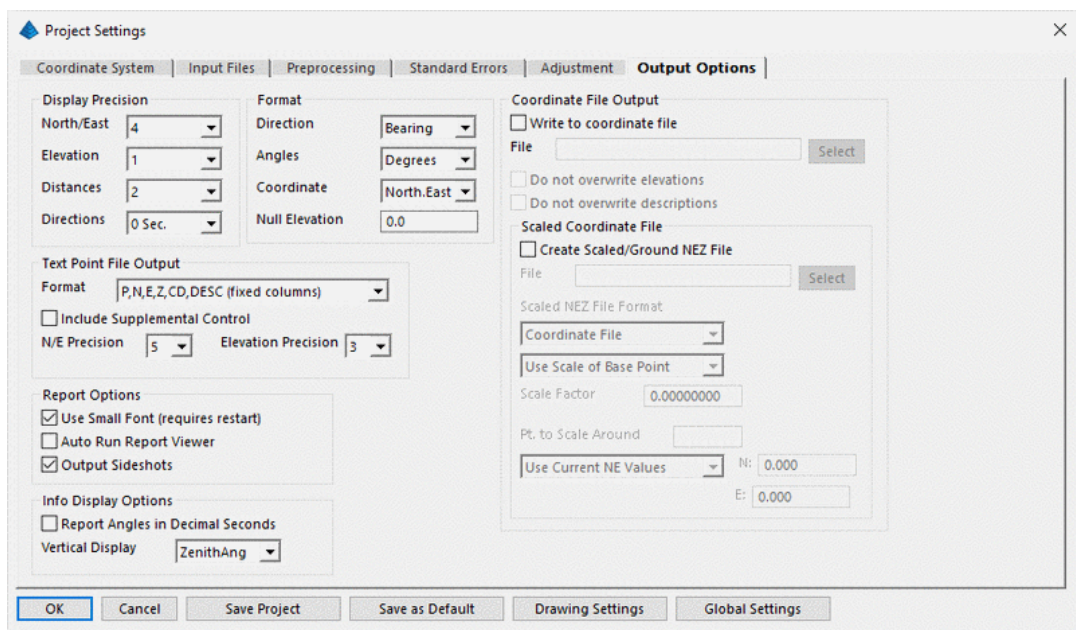

- Activate the Standard Errors tab to review the Standard Errors settings. Standard Errors are an estimate of the different errors you would expect to obtain based on the type equipment and field procedures you used to collect the raw data. For example, if you are using a 5 second theodolite, you could expect the angles to be measured within +/- 5 seconds (Reading error). The **Standard Errors** settings should look as follows before proceeding to the next step:

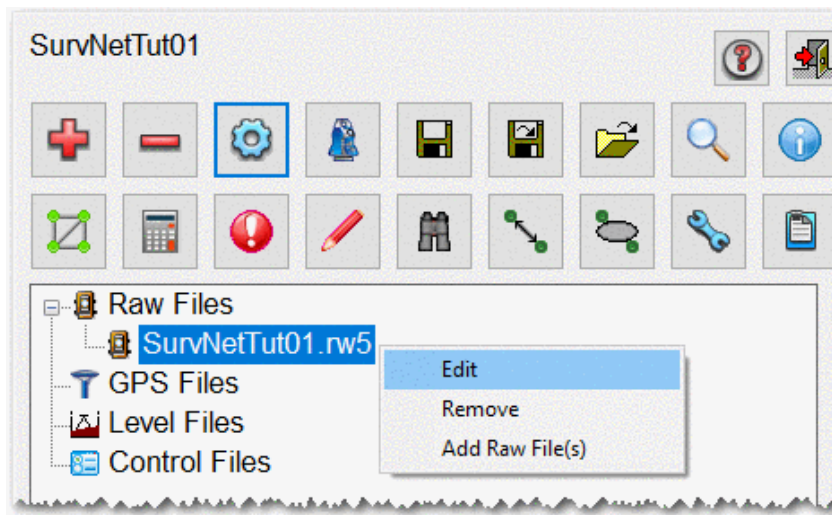

- Activate the Adjustment tab to review the Adjustment settings. The Adjustment settings affect how the actual Least Squares portion of the processing is performed. Additionally, from the screen the user can set whether ALTA reporting is performed. The Adjustment settings should look as follows before proceeding to the next step:

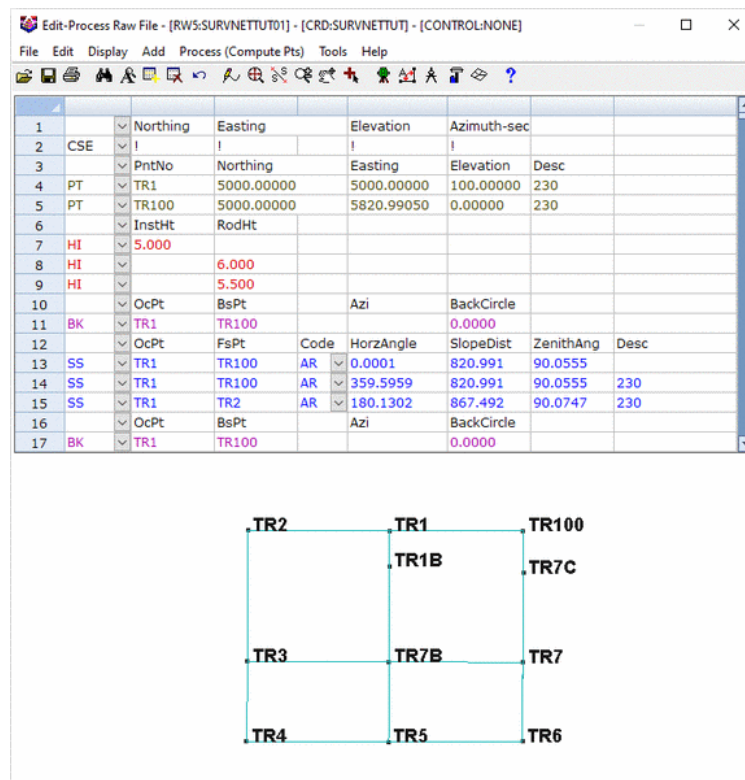

- Activate the Output Options tab to review the Output Options settings. These settings apply only to the output of data to the report files. These settings do not affect computational precision. For the purpose of this tutorial, the **Output Options** settings should look as follows before proceeding to the next step. Press **OK** to return to the main SurvNET screen.

5. Let's examine the underlying *raw* data associated with this project. Right-click on the file shown below and choose the **Edit** option:

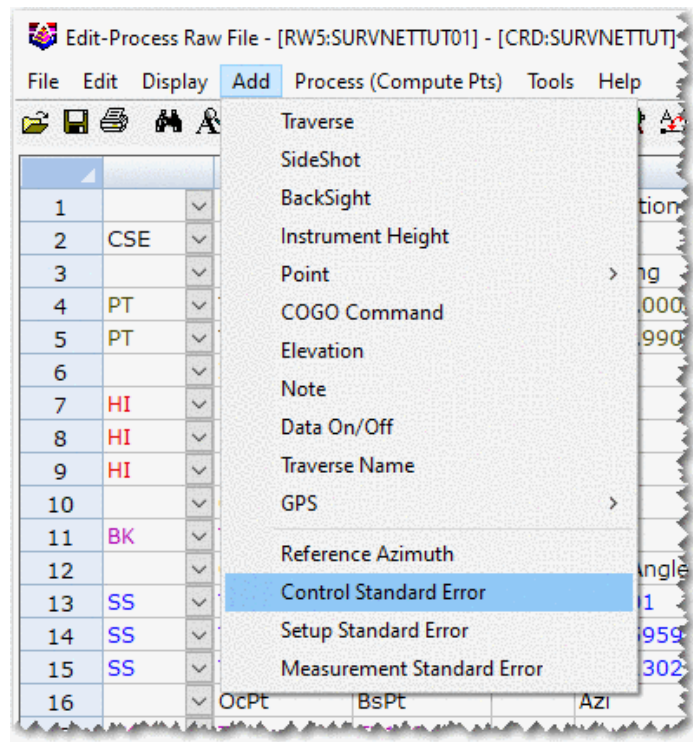

- The Carlson Edit-Process Raw File dialog box appears. If there are problems with the raw data (*i.e.* point numbering problems or incorrect rod heights), the raw data can be edited from this dialog:

Review the following Standard Errors and Control Points discussion before exiting the Raw File editor:

- The default **Standard Errors** for points are defined in the Standard Errors tab of the **Settings** command as discussed earlier. There are times when the default values may need to be overridden. For example, the control may be from GPS and the user has differing Standard Errors for various GPS points. Or maybe some of the control points were collected with RTK methods, and other GPS points collected with more accurate static GPS methods. Standard Error for individual points can be inserted into the raw data file that will supersede the otherwise default values. The following is the menu option used to insert *Control Standard Errors* into the raw file:

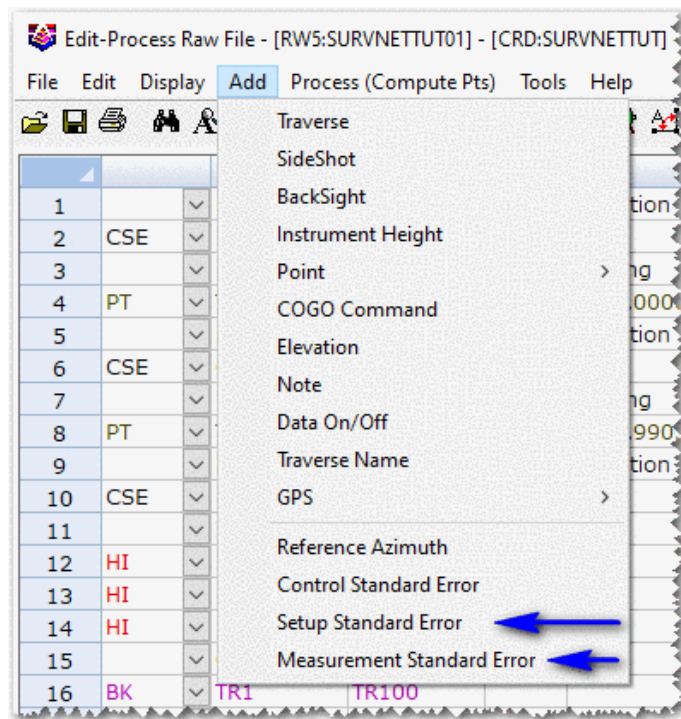

Notice in the above raw data file that points **TR1** and **TR100** are the *Control Points* for this project. Also, notice there is a Standard Error record (**CSE**) preceding the control points.

- The CSE record has the Exclamation (!) character in the N,E,& Z field. The '!' character designates that all following control points will be "fixed." Points that are fixed will not be adjusted during the adjustment. Placing a very small Standard Error on a control point is almost equivalent to fixing the point. Points can also be designated to be floating points by using the Number sign (#) character. The only practical use of creating a floating point is if SurvNET cannot compute preliminary coordinates because no control point is occupied. The surveyor can compute a preliminary value for one of the occupied points, and insert that point as a floating point. The floating point will be adjusted, and no weight will be given to the floating coordinate values.
- Standard Error records affect all the records that follow the Standard Error record. To revert the Standard Errors back to the default values, a CSE record can be inserted containing the Asterix (*) character. In the following example (shown for illustrative purposes), point **TR1** has been designated as a fixed point. **TR100** has a Northing Standard Error of **0.02** and an Easting Standard Error of **0.01**. Additionally, the Elevation for point **TR100** would not change. Following the **TR100** point record is a CSE record containing the '*' character in all fields. So, if there were any control points further down in the raw data file, they would use the default Standard Errors as set in the **Settings** dialog box.

		Northing	Easting	Elevation	Azimuth-sec			
1								
2	CSE	!	!	!	!			
3		PntNo	Northing	Easting	Elevation	Desc		
4	PT	TR1	5000.00000	5000.00000	100.00000	230		
5		Northing	Easting	Elevation	Azimuth-sec			
6	CSE	0.02	0.01	!	*			
7		PntNo	Northing	Easting	Elevation	Desc		
8	PT	TR100	5000.00000	5820.99050	0.00000	230		
9		Northing	Easting	Elevation	Azimuth-sec			
10	CSE	*	*	*	*			
11		InstHt	RodHt					
12	HI	5.000						
13	HI		6.000					
14	HI		5.500					
15		OcPt	BsPt	Azi	BackCircle			
16	BK	TR1	TR100		0.0000			
17		OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng	Desc

- There may be times when non-Control Standard Errors need to be overridden for certain measurements. For example, if fixed tripods were used for backsights and foresights for part of the traverse, and hand-held rods were used for another portion of the traverse, it would be appropriate to have differing **Rod Ctr** Standard Errors for the different sections of the raw data.
- Standard Errors for angles and distances can also be inserted into the raw data file using **Setup Standard Error** and **Measurement Standard Error** commands as indicated below:

The Standard Errors set by these inserted records override the default Standard Errors. In the following example, a Setup Standard Error (SSE) record has been inserted in record 11. The SSE record affects all setup data that follow until another SSE record is inserted. In the following example, the Foresight Rod Centering error is set to 0.005, the Total Station Centering error is set to 0.005, the Total Station Measure-up error is set to 0.005 and the Foresight Measure-up error is set to 0.005:

1		▼ Northing	Easting	Elevation	Azimuth-sec		
2	CSE	▼ !	!	!	!		
3		▼ PntNo	Northing	Easting	Elevation	Desc	
4	PT	▼ TR1	5000.00000	5000.00000	100.00000	230	
5	PT	▼ TR100	5000.00000	5820.99050	0.00000	230	
6		▼ InstHt	RodHt				
7	HI	▼ 5.000					
8	HI	▼	6.000				
9	HI	▼	5.500				
10		▼ Rod Ctr	Inst Ctr	Inst Hgt	Rod Hgt		
11	SSE	▼ 0.005	0.005	0.005	0.005		
12		▼ OcPt	BsPt	Azi	BackCircle		
13	BK	▼ TR1	TR100		0.0000		
14		▼ OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng
15	SS	▼ TR1	TR100	AR	0.0001	820.991	90.0555
16	SS	▼ TR1	TR100	AR	359.5959	820.991	90.0555
17	SS	▼ TR1	TR2	AR	180.1302	867.492	90.0747

- The following is another example where it would be appropriate to insert a Measurement Standard Error (MSE) record into the raw data. If two different total stations with different accuracy specifications were used to collect the data, it would be appropriate to have different standard errors for the different sections of the raw file, depending on which total station was used to collect the data. In the following example, a MSE record has been inserted for record 27. The Horizontal Pointing and Reading error has been changed to 5 seconds, and the Vertical Pointing and Reading error has been changed to 10 seconds. The inserted MSE record will affect all following raw data until another MSE is inserted:

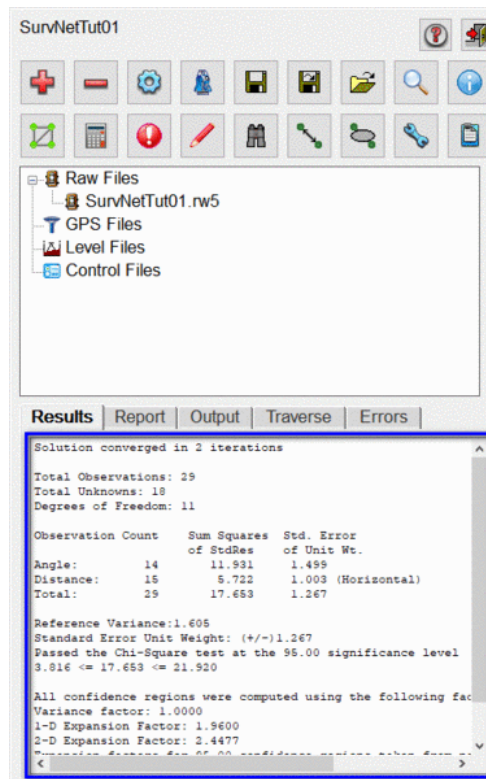

21		▼ OcPt	BsPt		Azi	BackCircle		
22	BK	▼ TR1	TR100			0.0000		
23		▼ OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng	Desc

33		▼ OcPt	BsPt		Azi	BackCircle		
34	BK	▼ TR1	TR100			0.0000		
35		▼ OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng	Desc
36	SS	▼ TR1	TR100	AR	359.5959	820.991	90.0555	230
37	SS	▼ TR1	TR2	AR	180.1316	867.492	90.0745	230

Issue the File – **Exit** to dismiss the Raw File editor (discard any/all changes).

7. After exiting the raw data editor, we are ready to perform the Least Squares adjustment. Click the **Network Adjustment** (Double Triangle) button as shown below:

The least squares adjustment is performed, and the results from the adjustment are displayed. If the solution converged correctly, the report should look similar to the following window:

If there were errors or the solution did not converge, an error message dialog will be generated. If there are errors, you will need to return to the **Raw File Editor** to review and edit the raw data. Since the tutorial example should have converged, we will next review the various forms of output, including *graphical* representations of the adjusted network which can be:

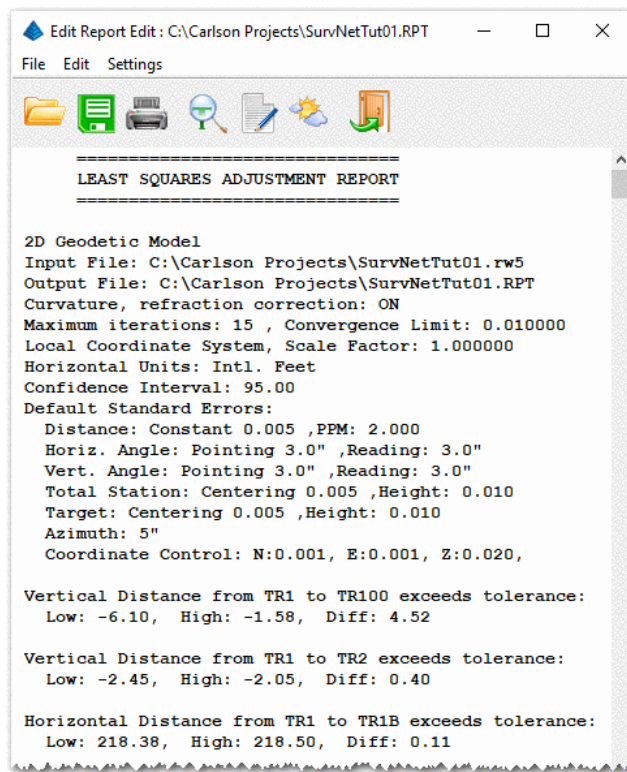

- Drawn into CAD through the **Draw** (Pencil) button, and/or
- Temporarily previewed through the **Quick View** (Binoculars) button.

Additionally, there are four reports created by the Least Squares program during processing. These include:

- The .rpt file (Main Report), which is the primary Least Squares report file summarizing the data and the results from the adjustment,
- The .out file (Output Report), which contains a listing of the final coordinates,
- The .err file (Error Report), which contains any errors or warnings that were generated during processing,
- The .res file (Results Report), which contains statistical data that was generated during processing.

To obtain these reports, click on the **Report** (Clipboard) button to specify the desired report which will display in the Standard Report Viewer which will be discussed below.

8. In this section, the different sections of the Least Squares reports are explained. As mentioned above, for the items to follow click on the **Report** (Clipboard) button and click on the:
 - **Main Report** button to display a report similar to that shown below:

The excerpt from the report above shows the header information and the preprocessing results. The header information consists of (among other things), the input and output file names, the coordinate system, the curvature/refraction setting, maximum iterations, and distance units. During the preprocessing process, multiple angles are reduced to a single angle and multiple slope distances, vertical angles, HI's, and rod heights are reduced to a single horizontal distance and vertical difference. During this process the horizontal angle, horizontal distance and vertical difference spreads are computed. If the spreads exceed the tolerance settings from the Settings dialog box, then a warning message is displayed showing the high and low measurement and the difference between the high and low measurement. Continue to explore this report...

- In the **Unadjusted Observations** section will be data similar to that shown below:

Edit Report Edit : C:\Carlson Projects\SurvNetTut01.RPT

File Edit Settings

TR100	TR1	103	279°19'36"	20
			.	
			.	

The excerpt from the *Unadjusted Observations* report above consists of some combination of control X, and Y, horizontal distances, horizontal angles, and azimuth measurements. These measurements consist of a single averaged measurement. For example, if multiple distances were collected between two points during data collection, only the single averaged measurement is used in the Least Squares adjustment. Also, Standard Errors for the measurements are displayed in this section of the report. The Standard Errors are computed from the Standard Error settings in the **Settings** dialog box using error propagation formulas. The Standard Error of an angle that was measured several times would typically be lower than an angle that was measured only once.

NOTE: If the data had been adjusted into NAD 83 coordinates both the ground distances and the grid distances would be displayed. The grid, elevation, and combined factor would also be displayed in this section of the report. Continuing into the report:

- In the **Adjusted Observations** section will be data similar to that shown below:

Edit Report Edit : C:\Carlson Projects\SurvNetTut01.RPT

The excerpt from the *Adjusted Observations* report above shows the final adjusted measurements. This section is one of the most important sections to review when analyzing the results of the adjustment. In addition to the adjusted measurement, the Residual is displayed. The Residual is the amount of adjustment applied to the measurement and is computed by subtracting the unadjusted measurement from the adjusted measurement.

The Standard Deviation of the measurement is also displayed. Ideally, the computed Standard Deviation and Residual and the Standard Error displayed in the unadjusted measurement would all be of similar magnitude. The Standard Residual is a measure of the similarity of the Residual to the *a-priori* Standard Error. The Standard Residual is the measurements Residual divided by the Standard Error displayed in the unadjusted measurement section. A Standard Residual greater than 2 is marked with an "*". A high Standard Residual may be an indication of a blunder. If there are consistently a lot of high Standard Residuals it may indicate that the original Standard Errors set in the **Settings** dialog box were not realistic.

- If the **Enable sideshots for relative error ellipses** option is not set in the Adjustment section of the **Settings**, sideshots are computed separately after the adjustment is completed.

Edit Report Edit : C:\Carlson Projects\SurvNetTut01.RPT

File Edit Settings

Sideshots

From Sta	To Sta	Bearing	Distance	Northing	Easting	StDev N	StDev E
TR1	100	S 72°22'23"E	20.66	4993.7449	5019.6865	0.0064	0.0085
TR1	101	S 74°30'42"E	23.26	4993.7893	5022.4128	0.0063	0.0085
TR1	102	N 04°55'59"E	124.11	5123.6541	5010.6728	0.0088	0.0072

TR1	105	N 65°59'21"W	152.17	5061.9176	4861.0016	0.0081	0.0087
TR1	106	N 68°32'48"W	169.16	5061.8696	4842.5590	0.0083	0.0088

If the project had valid elevation benchmarks and measured HI's and rod heights the project could have been defined to adjust elevations. When using the **2D/1D Least Squares model**, the horizontal and the vertical adjustments are separate Least Squares adjustment processes. As long as there are redundant vertical measurements, the vertical component of the network can also be reduced and adjusted using Least Squares. In the vertical adjustment, benchmarks are held fixed. Click the **Exit** (Doorway) button to dismiss this report.

- **Output Report** button to display a report similar to that shown below:

This section of the report shows the final adjusted coordinates. Click the **Exit** (Doorway) button to dismiss this report.

- **Error Report** button to display a report similar to that shown below:

This section of the report is one of the simplest and effective tools in finding blunders. Time spent learning how this function works will be well spent. If the project is not converging due to an unknown blunder in the raw data, this tool is one of the most effective tools in finding the blunder. Many blunders are due to point numbering errors during data collections, and the **K-matrix** analysis and **Point Proximity** search are great tools for finding these types of blunders. Click the **Exit** (Doorway) button to dismiss this report.

- **Results Report** button to display a report similar to that shown below:

This report displays some statistical measures of the adjustment including the number of iterations needed for the solution to converge, the degrees of freedom of the network, the reference variance, the standard error of unit weight, and the results of a Chi-square test.

The degree of freedom is an indication of how many redundant measurements are in the survey. Degree of freedom is defined as the number of measurements in excess of the number of measurements necessary to solve the network.

The standard error of unit weight relates to the overall adjustment and not to an individual measurement. A value of one indicates that the results of the adjustment are consistent with the prior standard errors. The reference variance is the standard error of unit weight squared.

The Chi-square test is a test of the "goodness" of fit of the adjustment. It is not an absolute test of the accuracy of the survey. The *a-priori* standard errors which are defined in the project settings dialog box or with the SE record in the raw data file are used to determine the weights of the measurements. These standard errors can also be looked at as an estimate of how accurately the measurements were made. The Chi-square test merely tests whether the results of the adjusted measurements are consistent with the *a-priori* standard errors. Notice that if you change the project Standard Errors and then reprocess the survey, the results of the Chi-square test change, even though the measurements themselves did not change.

In our example, the Chi-square test passed at the 95% significance level. Had our example failed the Chi-square test on the low end (e.g. a value < 3.816), indications would be that our data is actually better than expected compared to our *a-priori* standard errors. If we were to increase the Pointing and Reading Standard Error in the Settings menu by 10-20 seconds, we would probably fail the Chi-square. Also notice that if you change the Standard Errors by only 5-10 seconds and reprocess the data the final coordinates will not change significantly.

This is the final step in the adjustment. The final adjusted coordinates are now stored in the current project point database and can now be used for mapping and design.

9. Relative Error Ellipses are a statistical measure of the expected error between two points. *Regular* Error Ellipses are a measure of the absolute error of a single point. Some survey accuracy standards such as the ALTA standards state the maximum allowable error between any two points in a survey. Relative Error Ellipses can give you this information. Press the **Relative Error Ellipse** (Ellipse between Two Points) button to display a dialog box similar to that shown below:

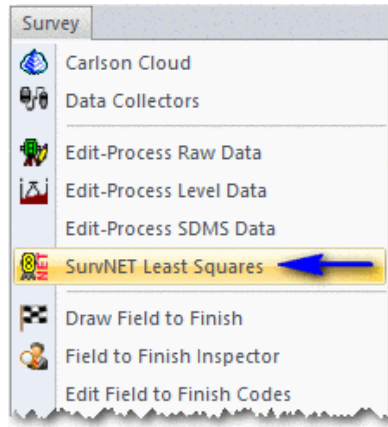

Enter **TR3** and **TR7** in the **From Pt.** and **To Pt.** fields, respectively, and click the **Calculate** button. At the 95% confidence level there should only be around 0.03 feet of error between points TR3 and TR7. If you need to compute Relative Error Ellipses for sideshots, make sure the **Enable Sideshots for Error Ellipse** toggle is set in the Adjustment tab of the Settings dialog box. Click the **Exit** button to dismiss the *Relative Error Ellipse* dialog box. Click the **Exit** (Doorway) button to dismiss the *SurvNET* docked dialog box.

Lesson Two - Processing a 3D Network With Both Total Station Data and GPS Vectors

In this lesson we will process a project that contains both total station measurements and GPS vectors.

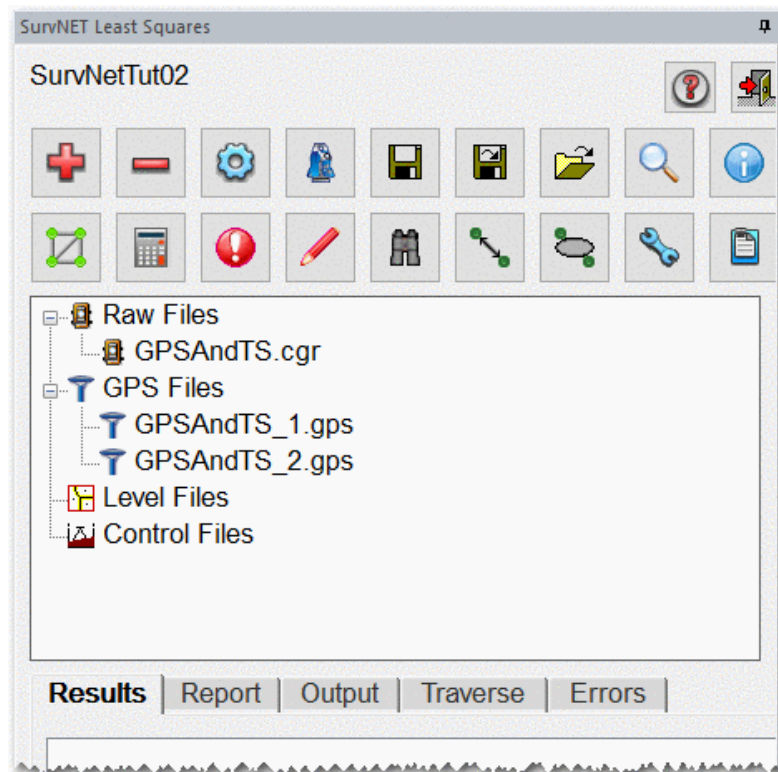

1. Issue the Survey – SurvNET command as illustrated below:

If the previous SurvNET project re-appears, click the **Load/New** (Open Folder) button. This, in turn opens the following dialog box:

Select the **SurvNetTut02.prj** project and click **Open**. This will open the default SurvNET *project-tree* docked dialog box interface as shown below where we will process the contents of the **GPSAndTS.cgr** "raw" file and a pair of GPS vector files (**GPSAndTS_1.gps** and **GPSAndTS_2.gps**):

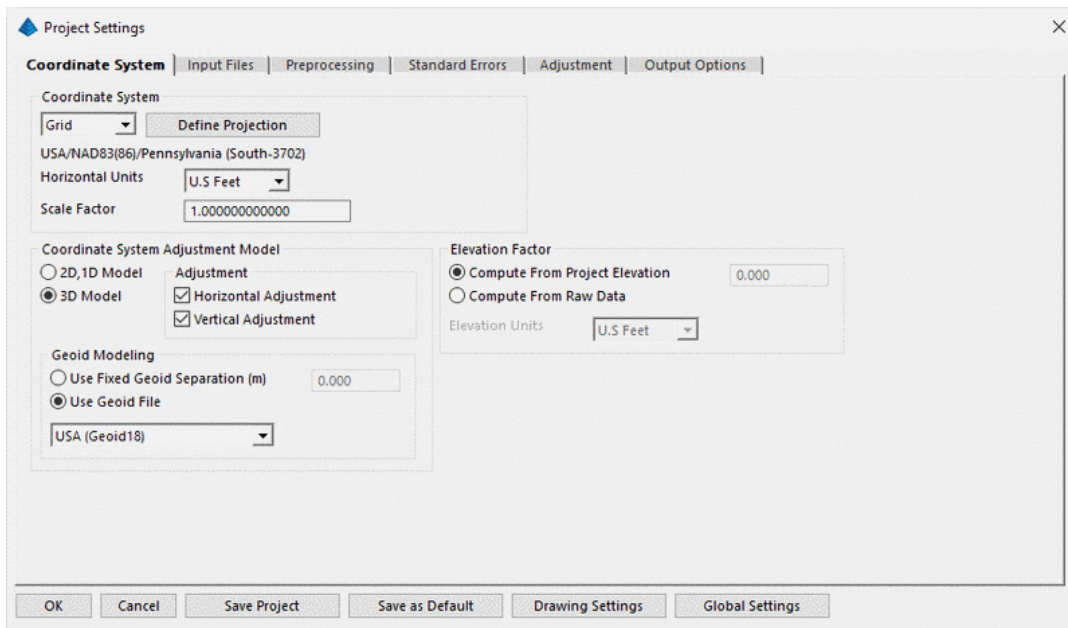

NOTE: The sample tutorial project has the input raw file in the default folder of **C:\Carlson Projects**. If you have a different data directory, then set the correct data file by highlighting the default file, pick Delete and then pick Add and select **GPSAndTS.cgr** (C&G format raw file) from your data folder. Do the same for the GPS Vector files of **GPSAndTS_1.gps** and **GPSAndTS_2.gps**.

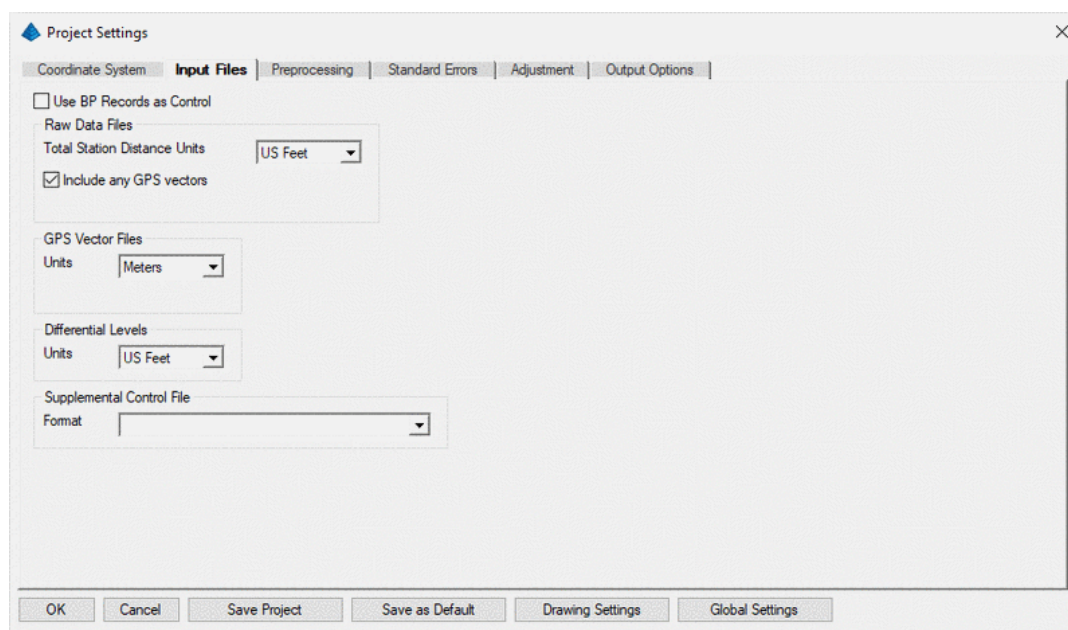

2. Let's review the project settings. Click the Settings (Gear) button as shown below:

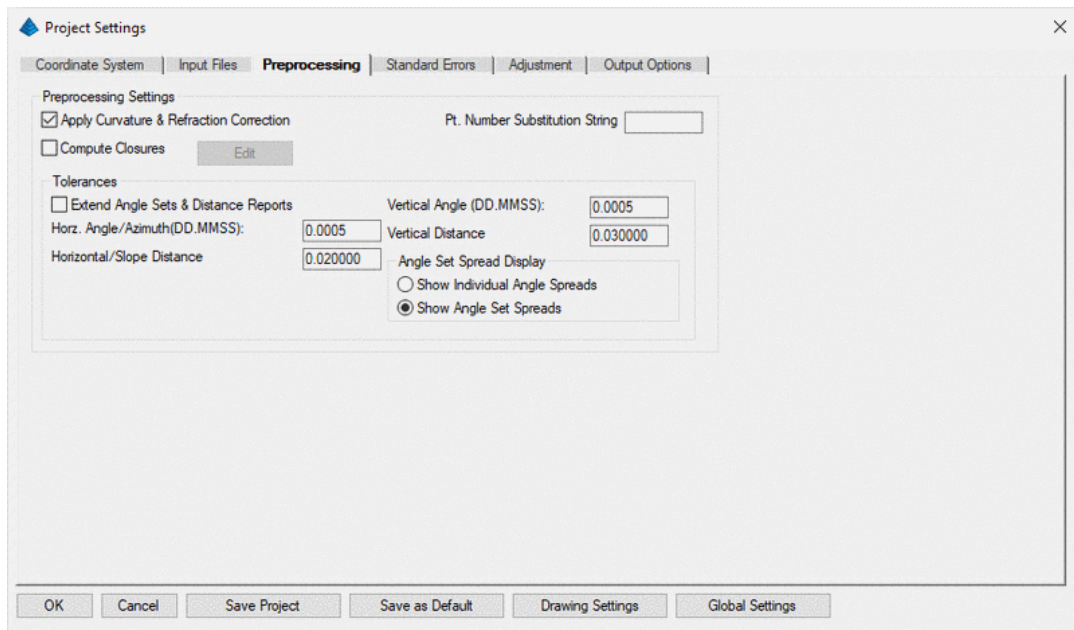

to display the dialog box similar to that shown below:

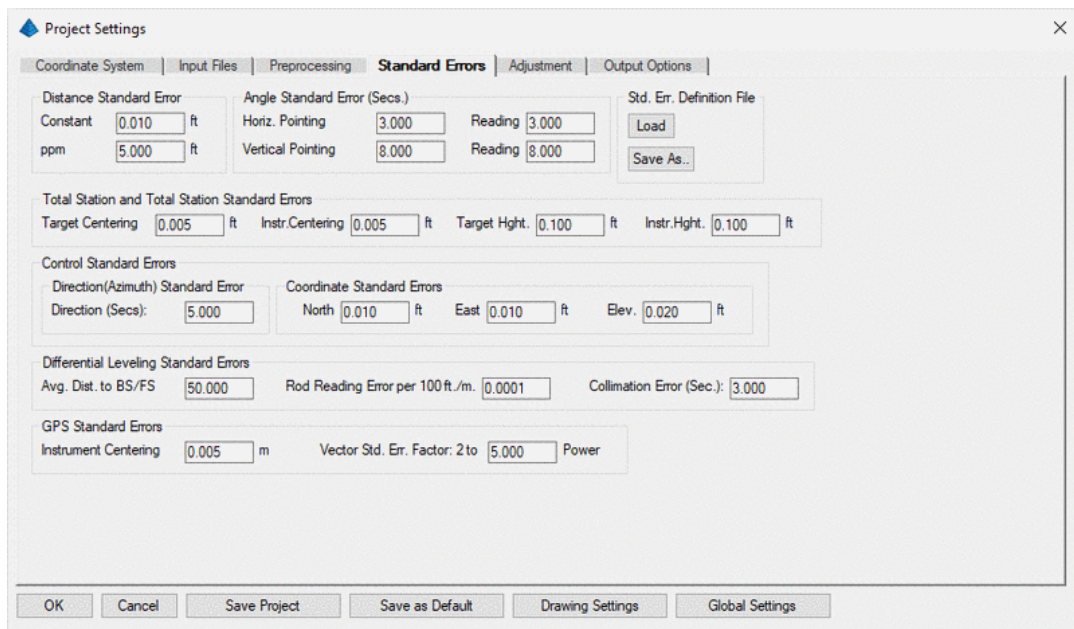

- Settings - Coordinate System: In order process GPS vectors, a coordinate system must be set (*e.g.* **SPC 1983**) with the appropriate State Plane zone. Further, the **Coordinate System Adjustment Model** must be set to the **3D Model**. With the 3D model, horizontal units and vertical units must be the same in regards to output and total station raw data. Geoid modeling may or may not be important depending on the extent of the project and the accuracies required. The most accurate results are typically obtained by using a **Geoid File**. Set the values as shown above.
- Activate the Input Files tab. Notice that the units need to be specified for both the GPS vector data and the total station raw data. Typically, but not always, GPS vectors are in meters while the total station and the final output may need to be in feet. Also make sure that the correct GPS vector format is correct. Some GPS formats are binary and cannot be edited easily. Sometimes it is needed to edit the GPS vectors, usually in terms of point numbers.

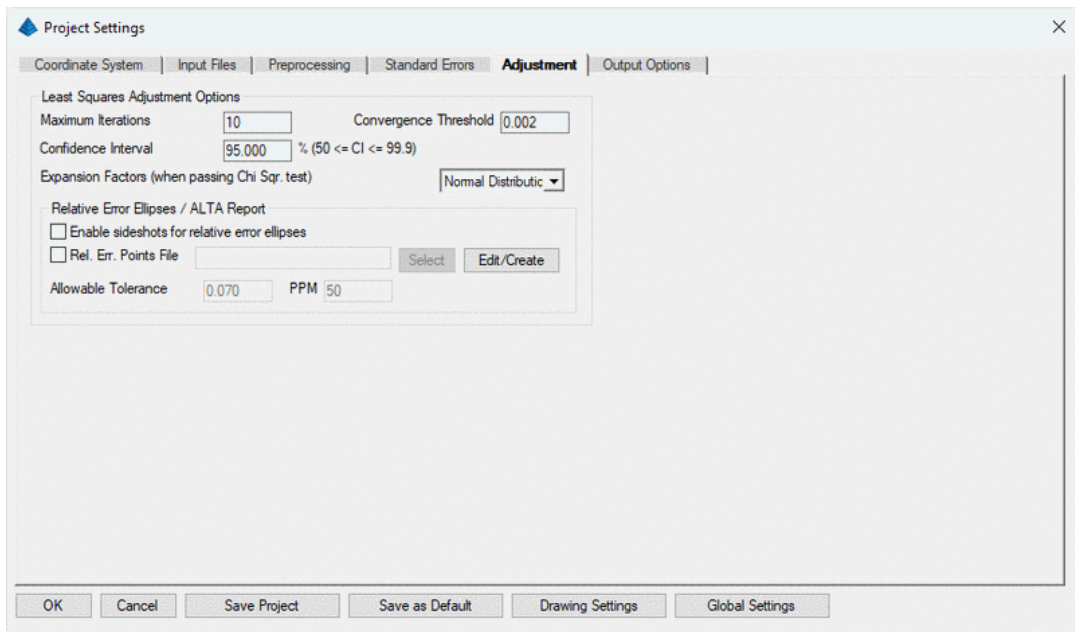

- Activate the Preprocessing tab. Though this tutorial does not cover the topic, it is from this screen that you would define the traverse file needed to compute either GPS Loop closures or total station traverse closures.

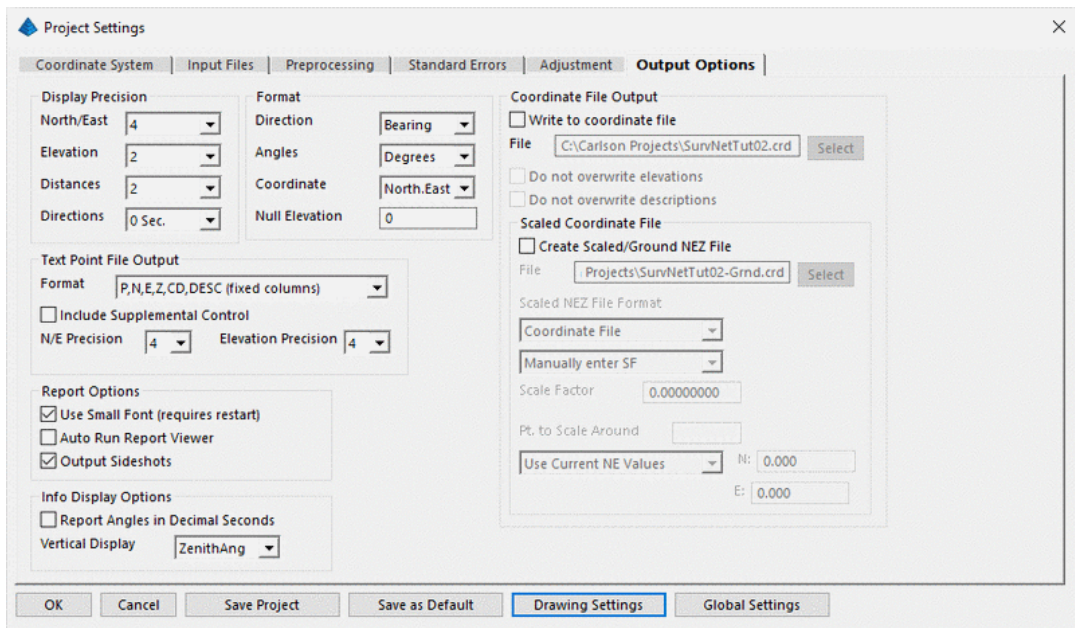

- Activate the Standard Errors tab. Notice the standard error settings related to GPS. The GPS instrument centering error can be defined. The vector standard error is a factor that can be used to increase the standard errors as defined in the GPS vector files.

- Activate the Adjustment tab. None of the settings in this screen are specific to processing GPS vectors:

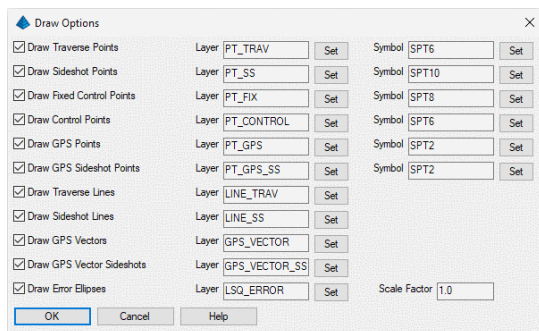

- Activate the Output Options tab. None of the settings in this screen are specific to processing GPS vectors.

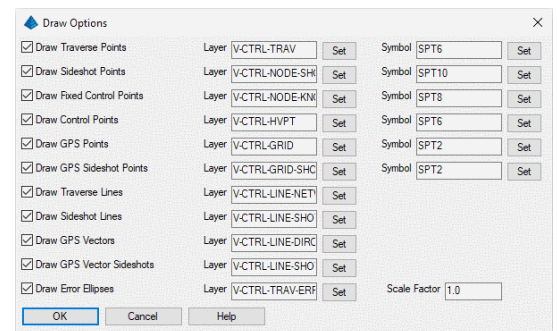

- Click the Drawing Settings button to display a dialog box similar to those shown below:

Carlson SurvNET Defaults

Suggested National CAD Standards Defaults

Suggested Drawing Settings

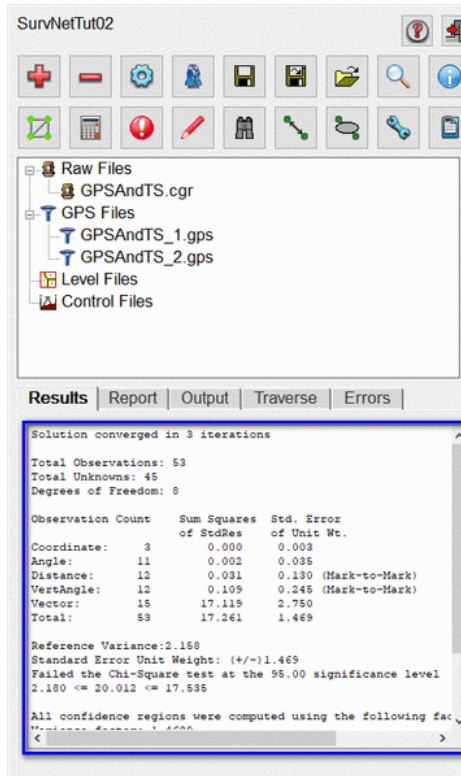

Set the desired value(s) as illustrated above and click **OK** when ready. We'll use this information later in

the Draw Results discussion.

3. Click the **Network Adjustment** (Double Triangle) button as shown below:

The Least Squares adjustment is performed. The project should process and converge and the following windows should be displayed:

Let's review sections of the report that are unique to the processing of GPS vectors and the 3D model.

4. Click the **Reports** (Clipboard) button and select the **Main Report**. Scroll through the report to the section similar to that shown below:

◆ Edit Report Edit : C:\Carlson Projects\SurvNetTut02.RPT

3-DIMENSIONAL ADJUSTMENT REPORT

Unadjusted Observations

Control Coordinates:	1 Observed Points,	0 Fixed Points,	0 Approx. Points			
Sta.	Latitude	Longitude	Z (Ellip.)	StErr N:	StErr E:	StErr Z:NE
200	40°18'38.58302"N	76°12'53.64149"W	744.12	0.0100	0.0100	0.0200

Grid XYZ	N:	E:	Z (Geoid):	StErr N:	StErr E:	StErr Z:
200	359769.1900	2396585.1700	858.21	0.0100	0.0100	0.0200

Geocentric XYZ	X:	Y:	Z:	StErr X(m):	StErr Y(m):	StErr Z(m):
200	1160578.5446	-4730339.6491	4104501.5919	0.0032	0.0050	0.0046

Notice that now that we are working with a specific datum (as opposed to an assumed coordinate system) the latitude/longitude, state plane coordinates and geocentric coordinates are all displayed. Continuing into the **Main Report** is the following:

◆ Edit Report Edit : C:\Carlson Projects\SurvNetTut02.RPT
File Edit Settings

Mark to Mark Slope Distances: 192 Observations

From Sta.	To Sta.	Dist.	StErr
200	201	352.78	0.02
200	202	344.09	0.02
200	203	170.89	0.01
200	204	149.60	0.01
.	.	.	.

Mark to Mark Vertical Angles: 192 Observations

From Sta.	To Sta.	Vertical Ang.	StErr (Sec.)
200	201	097°58'35"	11
200	202	077°56'37"	11
200	203	066°54'34"	11
200	204	079°12'50"	11
.	.	.	.

Horizontal Angles: 191 Observations

BS Sta.	Occ. Sta.	FS Sta.	Angle	StErr (Sec.)
201	200	202	131°40'05"	08
201	200	203	243°43'37"	11
201	200	204	176°40'38"	12
.

GPS Vectors: 17 Observations (Meters)
Multiplication factor applied to Variance and Covariance values: 32 (2 to 5 power)

From Sta.	Delta X	Variance Delta X	Covariance XY	Bearing
To Sta.	Delta Y	Variance Delta Y	Covariance XZ	H.Distance
	Delta Z	Variance Delta Z	Covariance YZ	V.Distance
BAS1	-219.104	1.038	0.007998	N 42°21'42"W
PIN9	109.035	1.047	-0.1474	277.25
	134.526	1.048	-0.0737	-33.53
FN11	86.739	0.0001678	-1.463E-06	N 25°22'14"E
BAS1	273.779	0.001389	6.92E-06	348.84
	205.297	0.001205	-0.0008282	-54.21

In the above *Unadjusted Observations* section of the report, notice that distances have been converted to mark to mark distances. Note that vertical angles are now treated as measurements in the 3D model. And lastly, notice that the GPS vectors are also displayed. The GPS vectors are displayed as Delta X,Y,Z in the geocentric coordinate system. Continuing further into the report is:

202	BAS2	63.2396	-0.2167	0.3	0.7548

In the above *Adjusted Measurements* section, the adjusted measurements are shown along with their residuals, standard residuals, and standard deviation. Click the **Exit** (Doorway) button to dismiss this report.

- Let's look at the visual representation of the processed project. Click on the **Draw** (Pencil) button. You may encounter the following prompt:

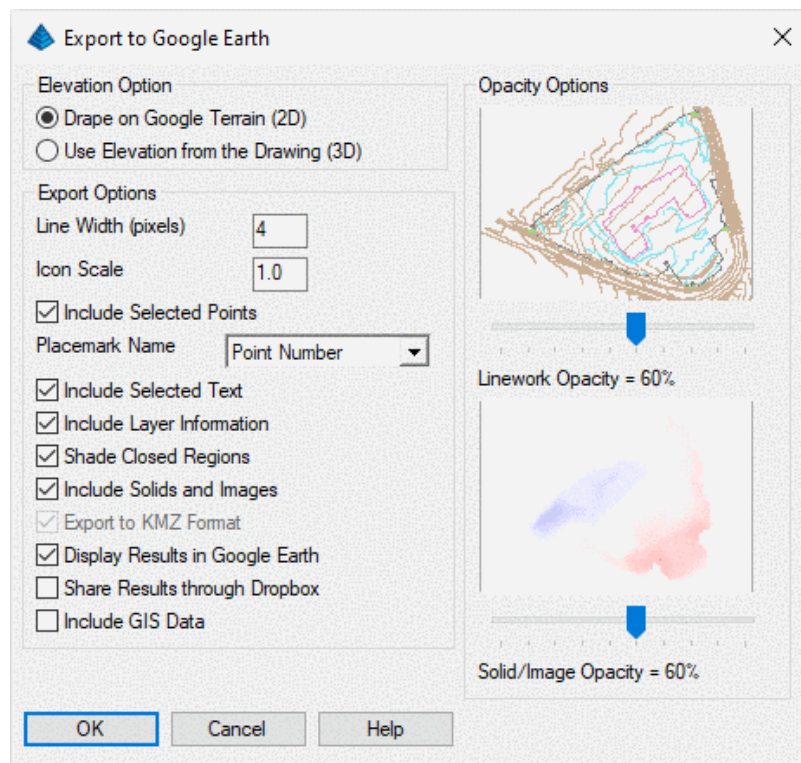

Click **Yes** to obtain graphical results similar to that shown below (National CAD Standards layer configuration shown):

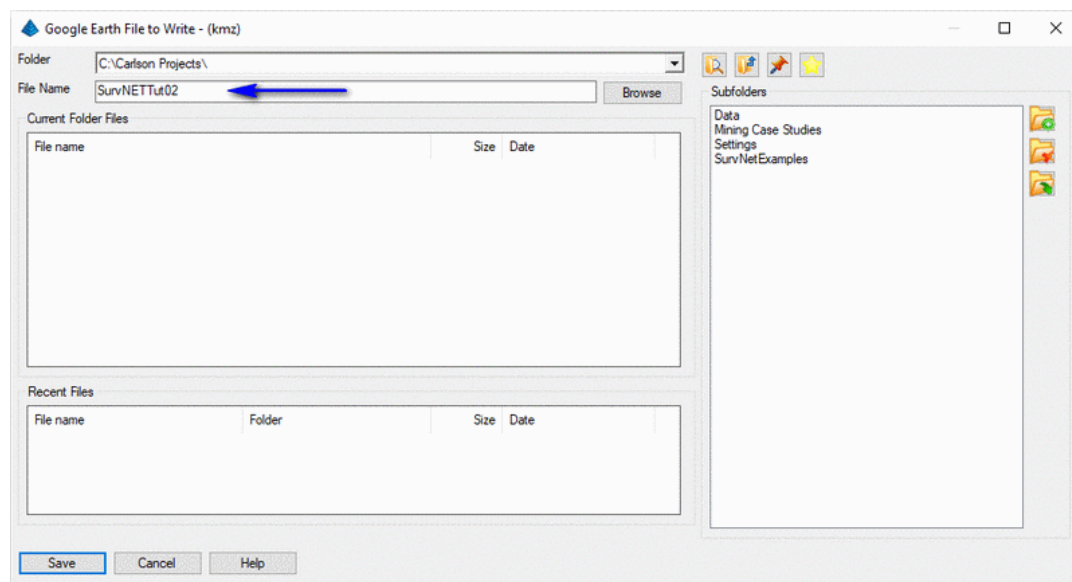

Click the **Exit** (Doorway) button to dismiss the SurvNET dialog box.

6. *Optional:* Lastly, for computers that have Google Earth™ Pro on desktop installed, let's see how the site looks when overlaid on this application (or any other application which can display Keyhole Markup Language (KML) files). As you may recall, we set a desired Coordinate System during the initial drawing setup and this system also matches the Coordinate System as specified in the **Settings** for this SurvNET project. Issue the File – Export – Google Earth File command to display the dialog box below:

Review and set the values as suggested above and click **OK** when ready to display a dialog box similar to that shown below:

Provide the file name specified above and click the **Save** button when ready. When prompted:

Select points, polylines, text, solids, images, lines and arcs to write.

[FILter]/<Select entities>: type **all** and press Enter twice

The results are overlaid on Google Earth as illustrated below:

This completes the tutorial: SurvNET.

Contouring, DTM and Design

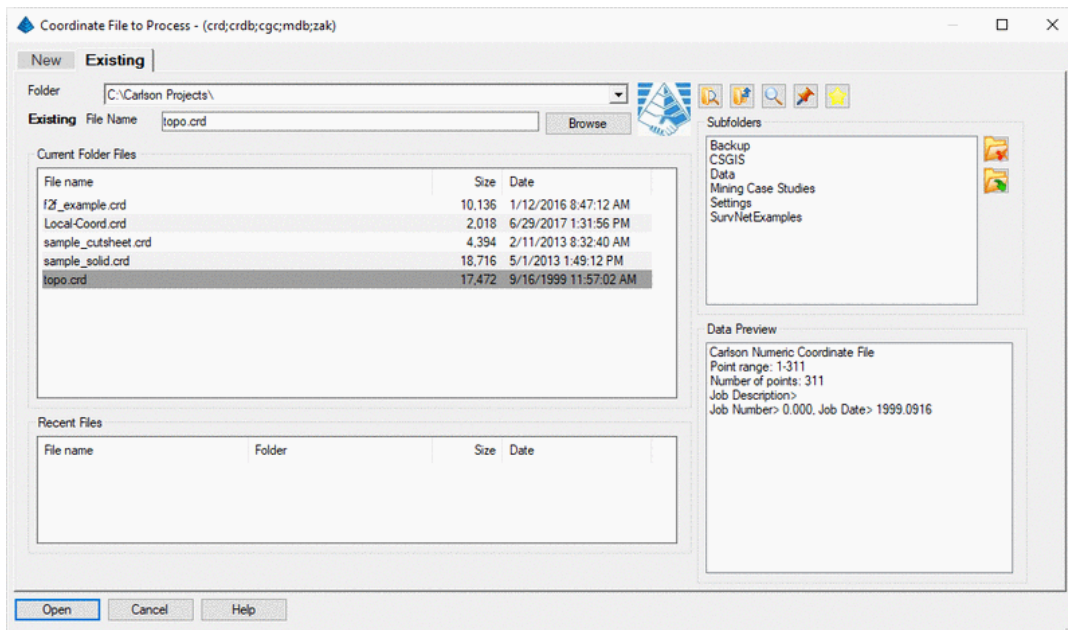

This is the easiest of the tutorials, and could be completed in as little as five minutes. If that is all the time you have, and you have purchased the Civil Design program, do this one first!

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the Exit button.
 - If you are taken directly into CAD, continue as is.

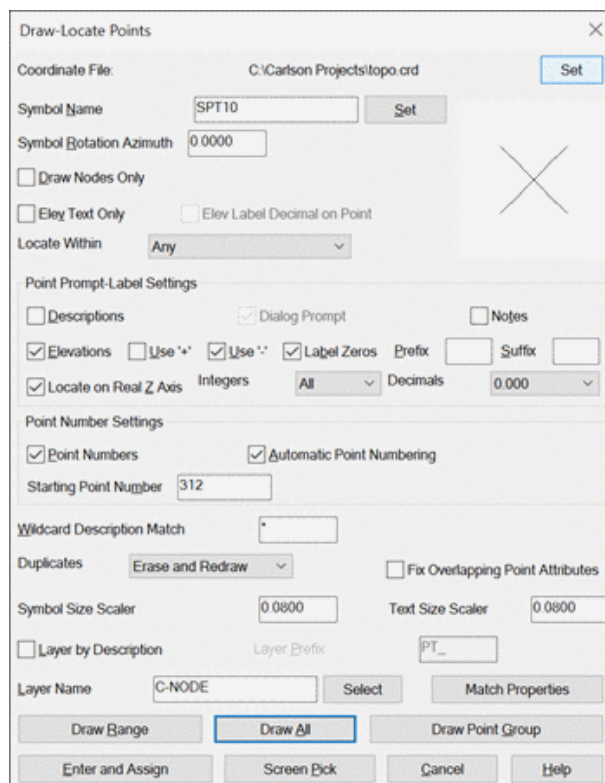

Ensure you are in the Civil Design program by issuing the Settings – Carlson Menu – **Civil Menu** command.

NOTE: Many of the routines below can also be accomplished with the Carlson Survey and/or Construction modules but our focus herein will presume use of the Civil module.

2. Once in Carlson, establish a coordinate (*.crd) file to work with via the Points – Set CoORDinate File command. You will then be asked to choose the coordinate file that you want to use. Select **Topo.crd** as shown below and click Open:

Next, issue the Points – Draw-Locate Points command which displays the dialog box similar to that shown below:

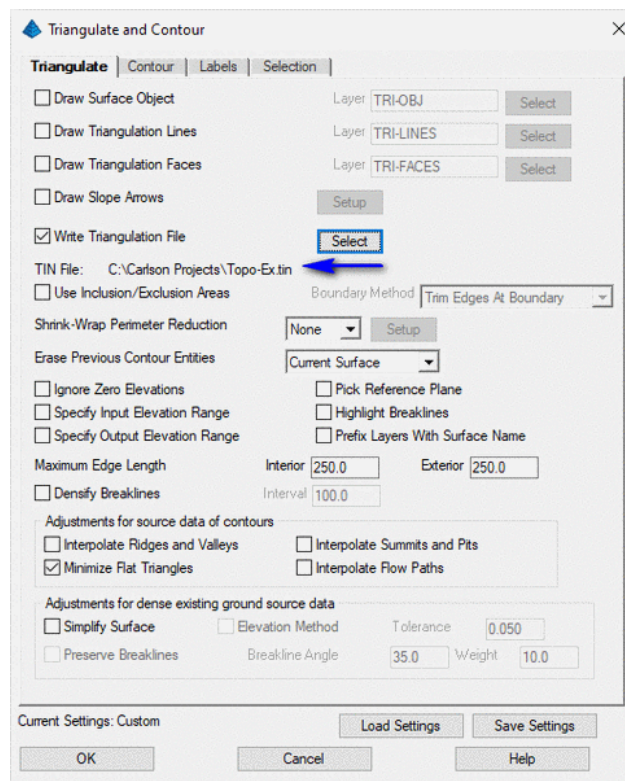

Choose Symbol "SPT0" by clicking **Set** to the right of Symbol Name then picking Symbol SPT0 from the options that appear. Establish the other settings as shown above and then click the **Draw All** button.

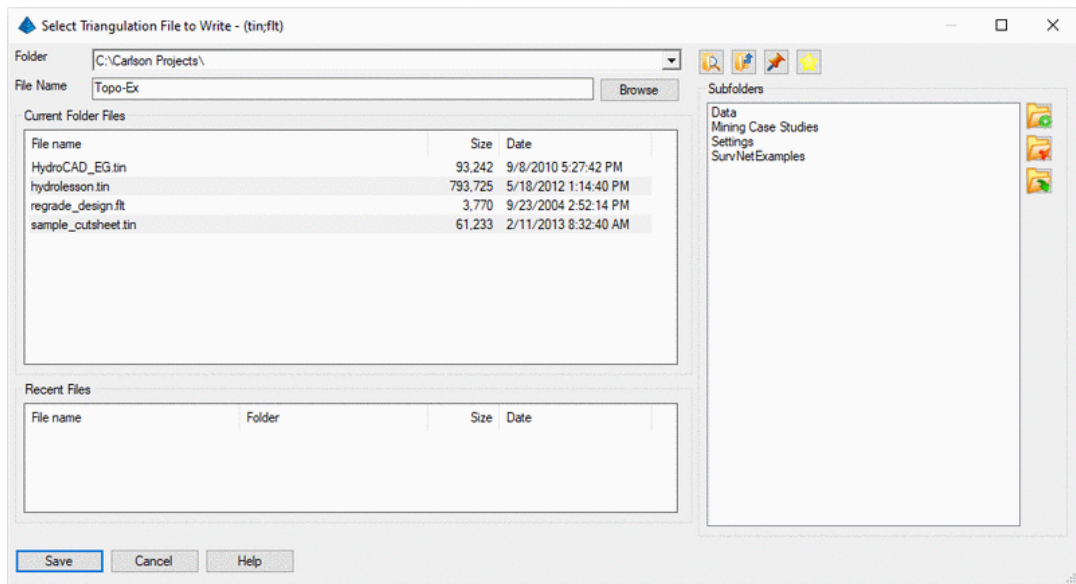

The points immediately plot on the screen, and the program should zoom to the extents of the points. If you don't see the points, issue the View – **Extents** command. Your drawing should resemble that shown below (drawn with a horizontal plot scale factor of **50** as established in Settings – Drawing Setup):

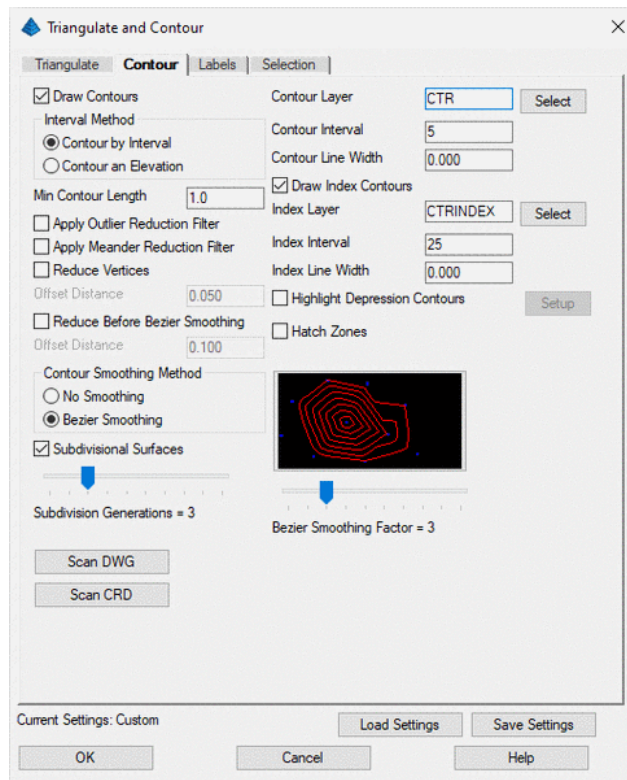

3. Issue the Surface – Triangulate & Contour command. The following dialog box (with several "tabs") will appear which you should fill out as discussed below:

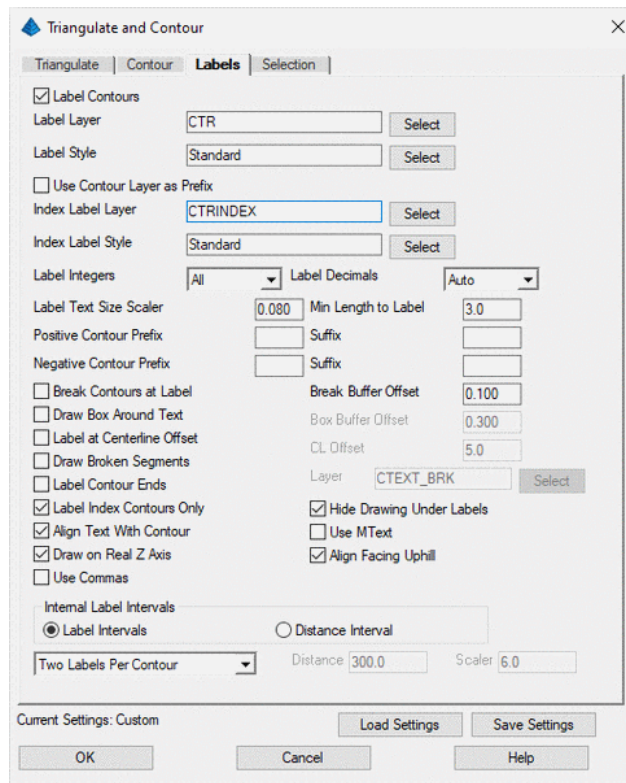

- In the Triangulate tab (as shown above), enable the **Write Triangulation File** toggle and click its **Select** button to set the name of a triangulation (*.tin) file as illustrated below. Click the **Save** button on this dialog box so that the results of the triangulation can be re-used for future purposes. Set the **Maximum Edge Length** values to 250 in all cases. If the goal of the field crew was never to shoot points further apart than 100 feet, then certainly triangulation lengths over 250 feet (or less) can be ignored. Set the **Shrink-Wrap Perimeter Reduction** to None (again, as illustrated above):

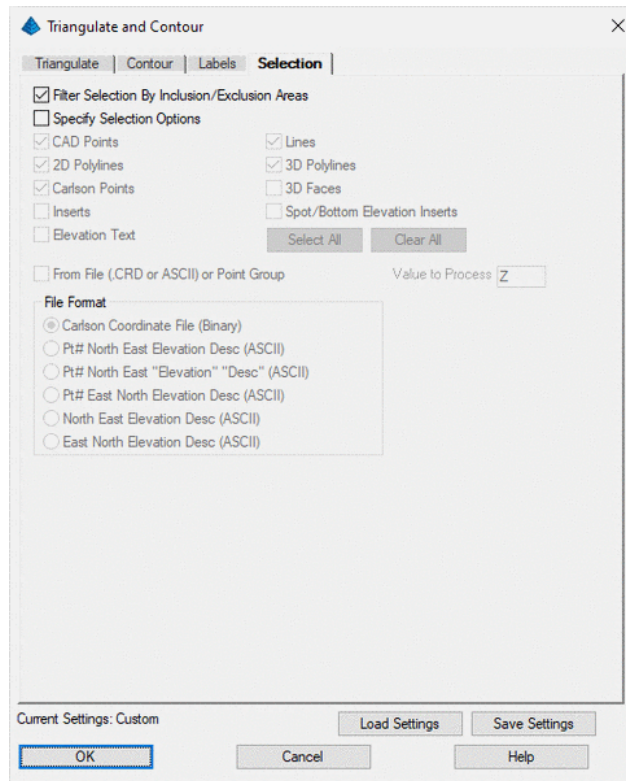

- In the Contour tab, as shown below, set the **Contour Interval** to 5, turn on **Draw Index Contours** and set its interval to 25 (index intervals are most often 5 times the standard contour interval):

- In the Labels tab, as shown below, enable the **Label Index Contours Only** toggle. Also set the Layers for the Intermediate and Index contour labels to be the same as that for the contours themselves:

- In the Selection tab, as shown below, clear the **Specify Selection Options** toggle:

Click the **OK** button from any tab. When prompted:

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter twice

A "TIN" file is written and the contours are drawn. Here is the plot so far:

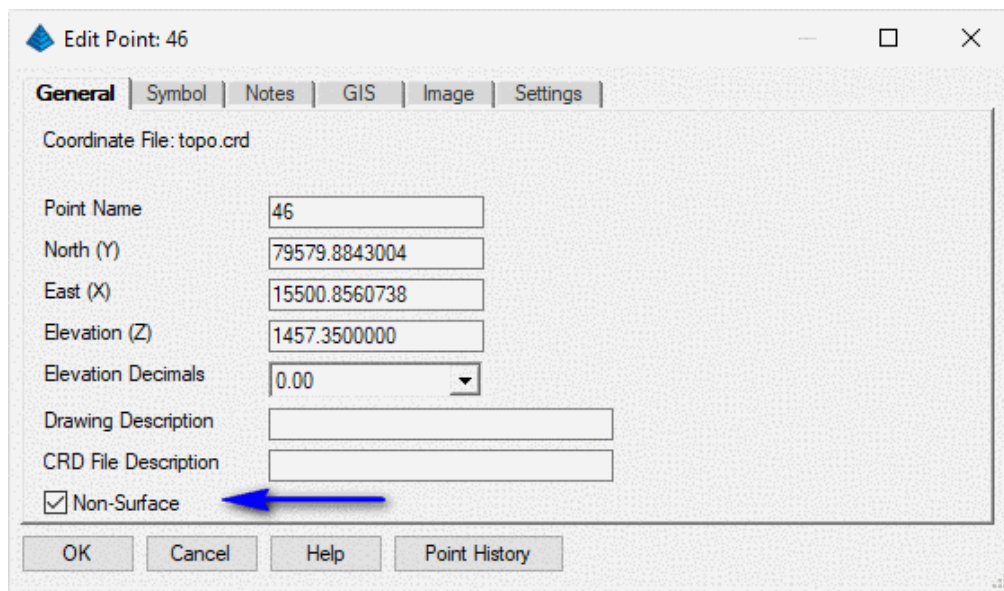

- The arrows above point to an area that needs editing. This area is enlarged below. You may want to zoom into this area for the next edit operation, and zoom back out when you are finished:

While some may prefer to directly change the contours (e.g. through the Surface – Modify Contours – Edit Contours command), we'll simply instruct Carlson to ignore the point for the purposes of contributing to a TIN.

"Double-click" (two left-mouse clicks in rapid succession) on Point 46 which will display the **Edit Point Attributes** dialog box (which can also be found under Points – Edit Point Attributes) as shown below:

Simply enable the **Non-Surface** option as shown above and click **OK**. This is essentially the same as using the 3D Data – Non-Surface Points/Entities – Tag Non-Surface Points command.

Also double-click on Point 48 to set its Non-Surface setting. When done, re-issue the Surface – **Triangulate & Contour** using the exact same settings and sequence as cited above. Issue the View – Freeze Layer by Selection and pick on one of the points (its number or its elevation), and press Enter. The points freeze. The results are below:

Tip: Whenever you make Carlson files, such as coordinate files (crd), TIN files (tin), and even pond capacity files (cap), they store to disk. When you do an Undo command (U for undo), you undo the graphics, but the files are safely stored and are not undone. Carlson does not like to overdo making files. Make them if you want, but we will not make any that are not needed.

5. Draw a 2D Polyline across the valley to represent the centerline of a dam through the use of the Draw – 2D Polyline command. Click the **OK** button on the **Polyline 2D Options** dialog box if it appears. The Carlson

"2dp" command is an enhanced version of the standard polyline command which draws the same polyline entity that you get when you type **PL** at the command prompt. Try to split the valley with the polyline as illustrated below:

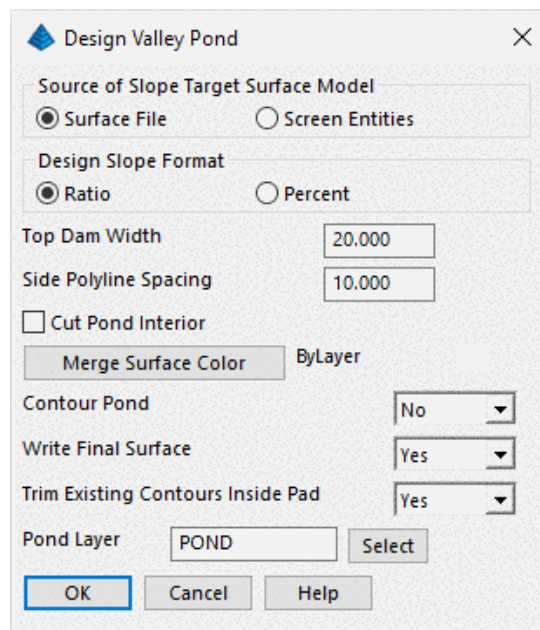

When prompted:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: pick the southerly starting location

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: pick the northerly ending location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter to terminate the command

6. Let's create an earthen dam from the polyline we just drew through the use of the Surface – Design Pond – Design Valley Pond command. Set the values as shown below and click **OK** when complete:

When prompted:

Pick top of pond polyline: pick the polyline as drawn earlier

Select the TIN file Topo-Ex.tin created earlier and then click Open.

Pick point within pond: pick upstream (northwesterly) of the polyline

Outslope ratio <2.00>: type 3 and press Enter

Interior slope ratio <3.00>: type 4 and press Enter

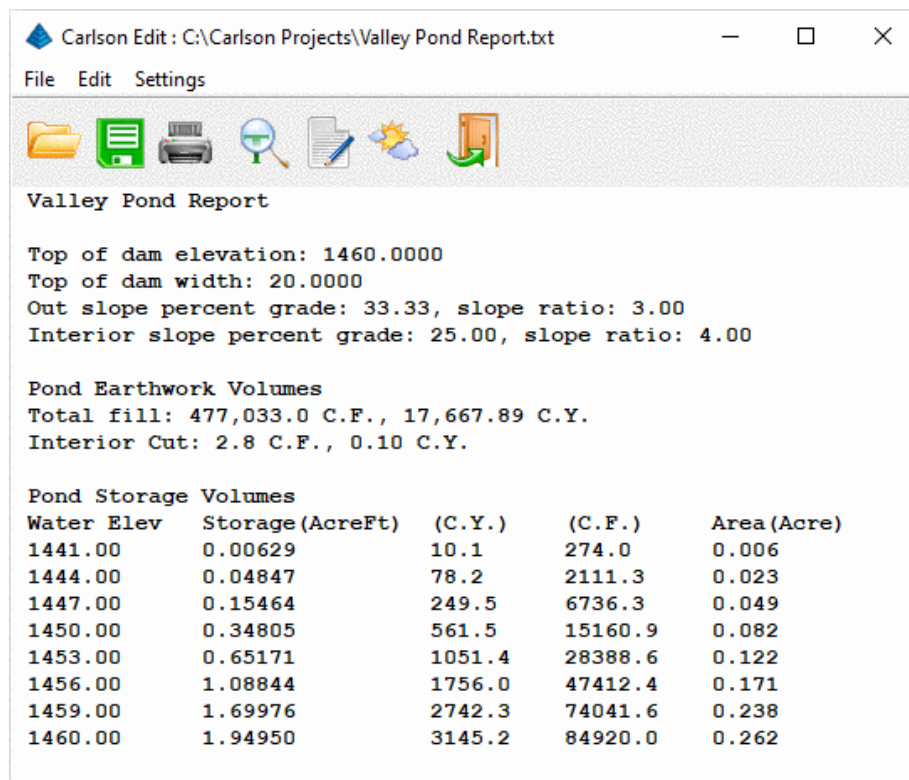

Range of existing elevations along dam top: 1420.63 to 1572.11

Top of dam elevation: type 1460 and press Enter

Calculate stage-storage values [<Yes>/No]? type Y and press Enter

Method to specify storage elevations [<Automatic>/Interval/Manual]? press Enter

The following report includes earthwork volumes and water storage volumes (your report will be slightly different):

Click the **Exit** (Doorway) button to continue forward in the process:

Output dam merged with existing or dam only [Merge/<Dam>]? press Enter and save the surface of just the dam in the file Topo-D.tin (for Topo with Dam)

Write stage-storage file [Yes/<No>]? type Y and press Enter to create a Topo-D.cap file

Adjust parameters and redesign pond [Yes/<No>]? type N and press Enter

Retain trimmed polyline segments [Yes/<No>]? type N and press Enter

Contour the pond [<Yes>/No]? type N and press Enter

The process is complete. At the Command line, enter **E** (for Erase) and when prompted:

[FILter]/<Select entities to delete>: pick on the centerline of the dam (there might be two of them)

[FILter]/<Select entities>: press Enter

Tip: The stage-storage curve that you save will plot in the **Carlson Hydrology** program. It makes a nice, handy plot for report purposes. See Tutorial - Hydrology and Watershed Analysis. Let's save the drawing through the File – **Save** and name the drawing **Topo-D.dwg**.

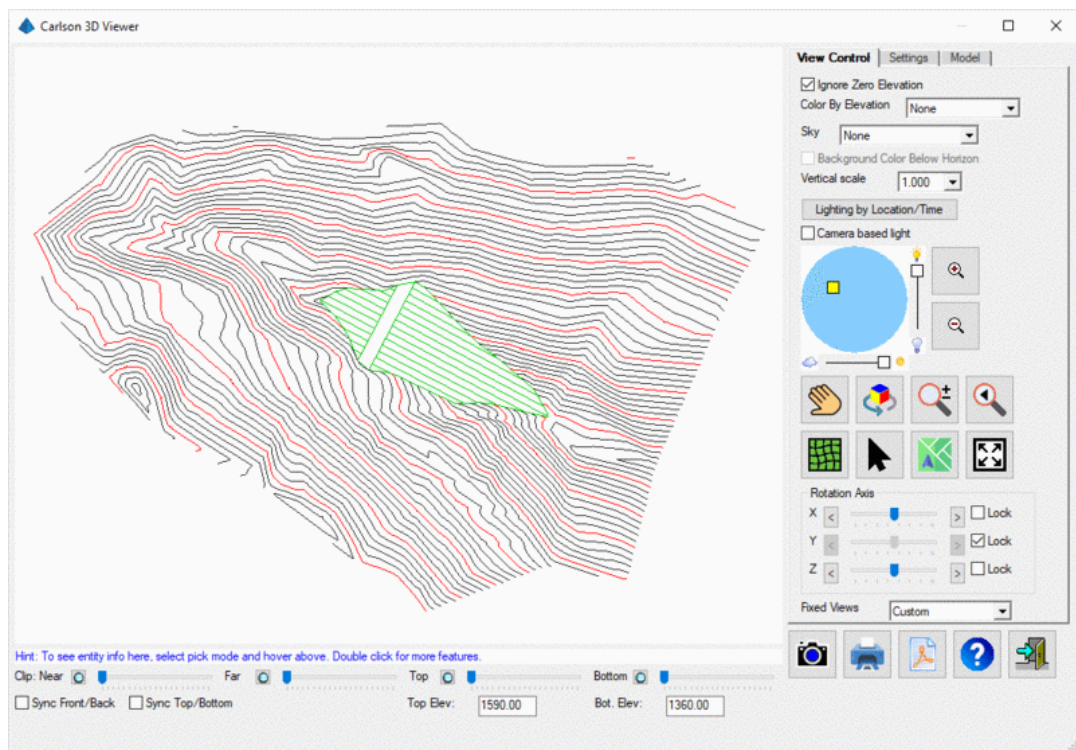

- Let's check out the data in 3D through the use of the View – 3D View – Drawing Viewer command. When prompted:

Select entities for the scene.

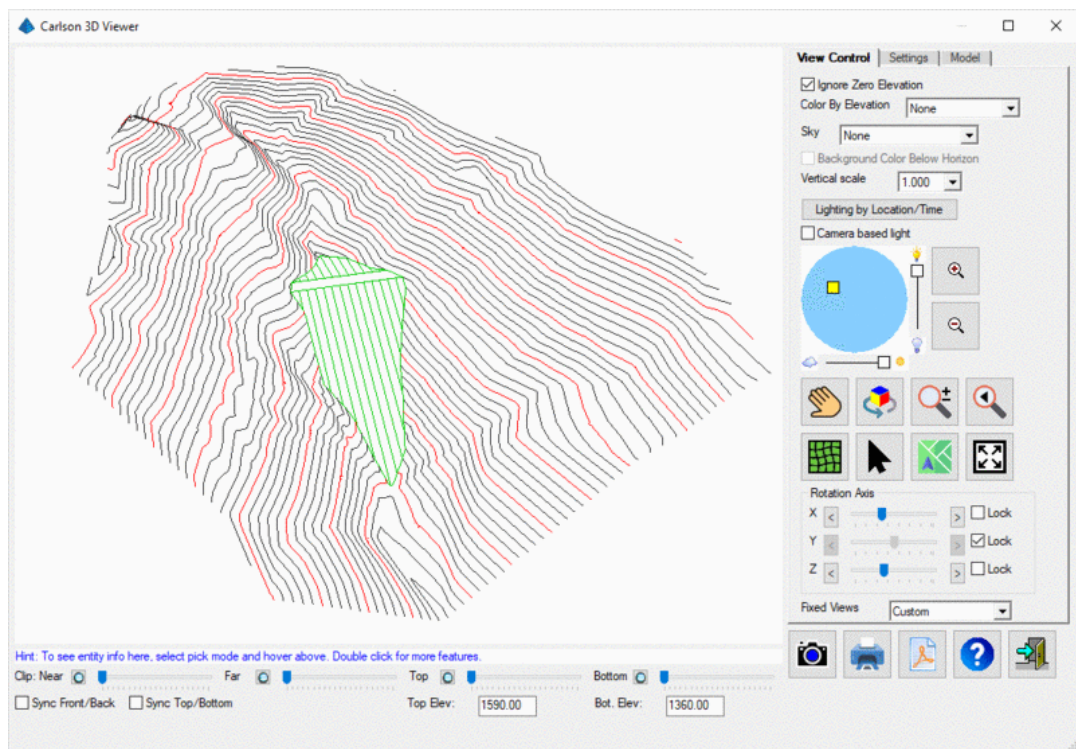

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

This leads to the starter view (a plan view) shown below:

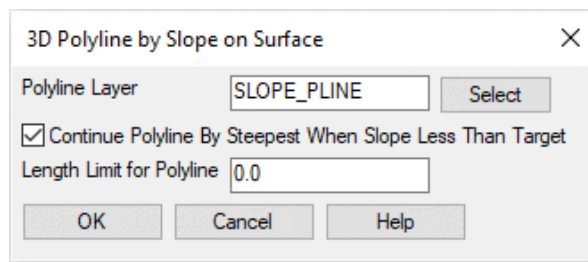

The main trick is to move the X-Axis bar to the left. Avoid the Y-Axis dial for now, and then grip on the Z-Axis dial and move it back and forth relatively fast, or just click on the Z-Axis arrows and watch things move slower. It's like you are in a helicopter over the site. Here's an example:

Click the **Exit** (Doorway) button to dismiss the 3D Viewer dialog box.

- Let's create a simple access road to service the dam via the 3D Data – 3D Polyline Utilities – 3D Polyline by Slope on Surface command. The following dialog box appears:

Complete the values as shown above and click **OK**. When prompted: **Choose a Grid or Triangulation File** specify the Topo-Ex.tin file created earlier

Pick origin point of 3D polyline: pick a point on the south side of the top of the dam, just before it contacts the ground as shown above

Direction of 3D polyline [<Up>/Down**]?** D

Direction of 3D polyline facing down slope [<Left>/Right**]?** R

Slope format [<Percent>/Ratio/Degree**]?** press Enter

Enter design slope percent: 10 (the values below should be similar to your results)

Horizontal distance: 415.34, **Slope distance:** 417.41

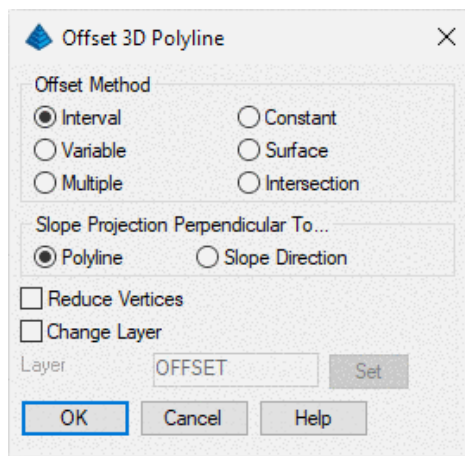

Vertical drop: 41.53, **Avg slope:** 10.00%, **Max slope:** 10.00%

Adjust slope [Yes/<No>**]?** N

Pick origin point of 3D polyline (Enter to end): press Enter

This created a smooth, 10% downhill grade 3D polyline which we can use to construct a maintenance road to service the dam.

9. Let's create the other side of the maintenance road through the use of the 3D Data – 3D Polyline Utilities – Offset 3D Polyline command (also found under Edit – 3D Polyline Utilities – Offset 3D Polyline):

This is a Carlson specialty; a high-powered Civil Design feature. In short, you can work in 3D because you can offset and manipulate 3D polylines using Carlson. Set the values shown in the dialog box above and click **OK**. When prompted:

Vertical/ <Horizontal offset amount>: 30 (for a 30' wide road)

Percent/Degree/Ratio/Vertical offset amount <0>: press Enter for a zero vertical offset from the original

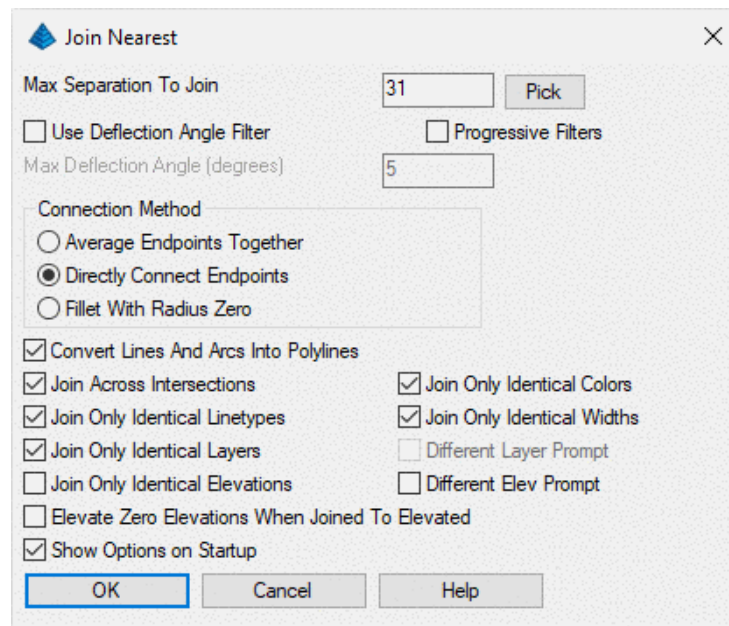

Select a polyline to offset: pick our new 3D polyline

Select side to offset [Both]: pick into the hill (to the left or southwesterly)

Select a polyline to offset (Enter to end): press Enter

This creates the other side of the road parallel, but not joined yet.

- Let's connect the two 3D polylines together through the use of the Edit – Join Nearest command. A dialog appears which you need to fill out as follows:

Because the two polylines are 30' apart, specify the **Max. Separation to Join** value to be 31. That way, they will join! The most important aspect is to specify the **Directly Connect Endpoints** option. Click **OK**. When prompted:

Select lines, arcs and unclosed polylines to join [Settings].

Select entities: pick both sides of the road one at a time, carefully avoiding picking a contour and press Enter

when complete

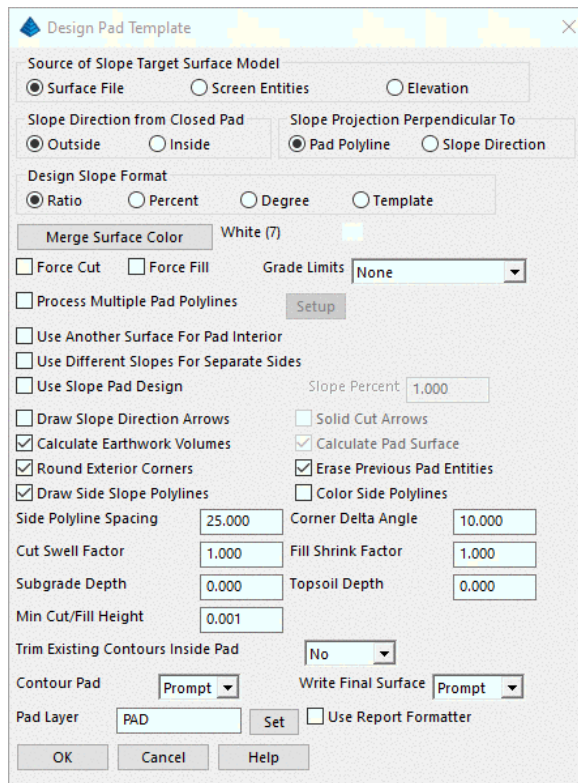

NOTE: If a contour is picked, press the Esc key to exit the command and start over or use Selection options (*e.g.* press R for remove, pick it to remove it from the selection set, then A to Add, and pick again on the road) to build the proper selection set.

Tip: This may be obvious, but when it is difficult to pick what you want (*e.g.* because several objects are nearby or are over top of what you want), it pays to do View – **Window** and zoom in closer, followed by View – **Previous** after you are done.

We have a road, or at least a sloping pad, seen below:

11. Let's project catch-slopes from the access road to the ground surface through the use of the Surface – Design Pad Template command to display the dialog box below:

Design Pad Template is one of the more diverse and powerful commands in Carlson. We will use it here to make a simple cut and fill slope from our road pad. We will go 0.5:1 in cut, but 1:1 in fill. You might think a 2:1 in fill is better, but remember, our hillside edge of the road (the original edge) follows very closely to the hill itself, as designed. If it cantilevers out a few inches, and the natural slope of the ground is 1.5:1 (which it is!), 2:1 will never catch, and we will create big fill areas. So we will go with 1:1 in fill, and get very tiny, quick tie-ins in those few cases where there is any fill at all.

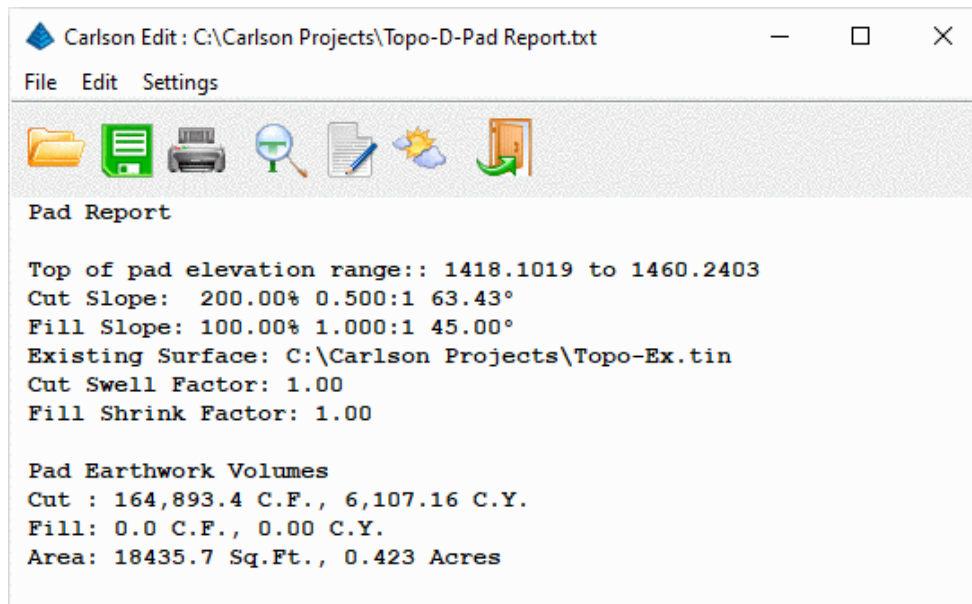

Set the entries as shown above and click **OK**. When prompted:

Pick pad polyline: pick the road pad

Select Slope Target Surface (dialog): specify the Topo-Ex.tin file created earlier

Fill outslope ratio <2.000>: 1

Cut outslope ratio <1.000>: 0.5 (a summary of the earthwork volumes will appear, your report will be slightly different):

Click the **Exit** (Doorway) icon to continue forward in the process:

Adjust parameters and redesign pad [Yes/<No>]? N

TIN Output: click Create New Surface

Merge Pad with Target Surface: click No

Output Triangulation to Write: use Topo-R.tin (R for Road)

Contour the pad [<Yes>/No]? N

Re-run the View – 3D View – **Drawing Viewer** command to view the drawing now with a road and click the **Exit** (Doorway) button when you're done reviewing the data.

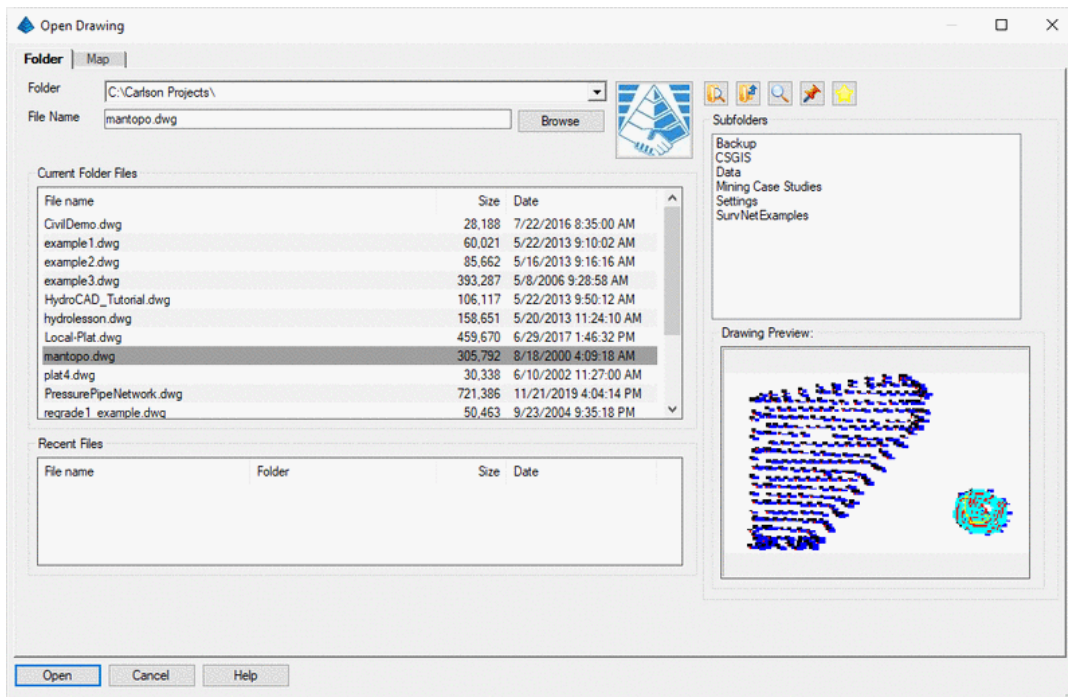

This completes the Lesson 5 tutorial: Contouring, DTM and Design.

Contouring, Break Lines and Stockpiles

In this lesson, you will explore routines centered around creating contours, working with breaklines and volumes from stockpiles.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

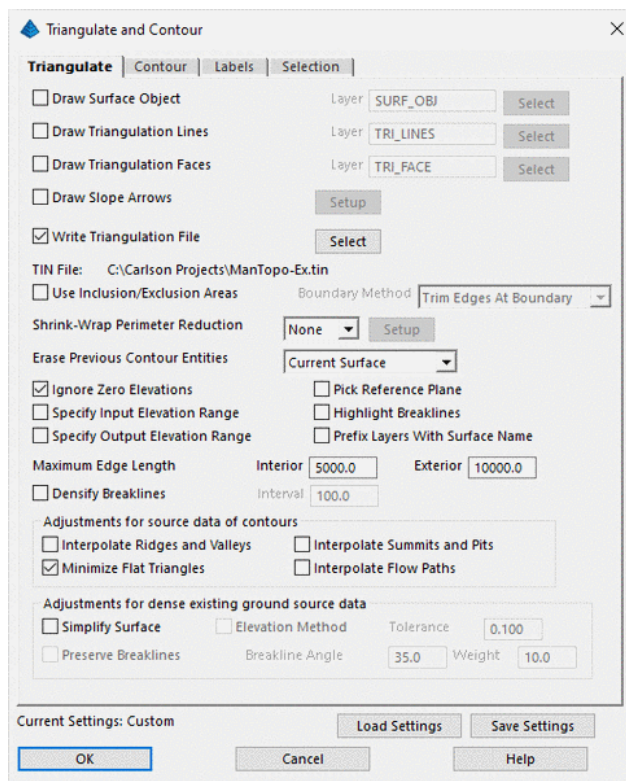

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Mantopo.dwg** file:

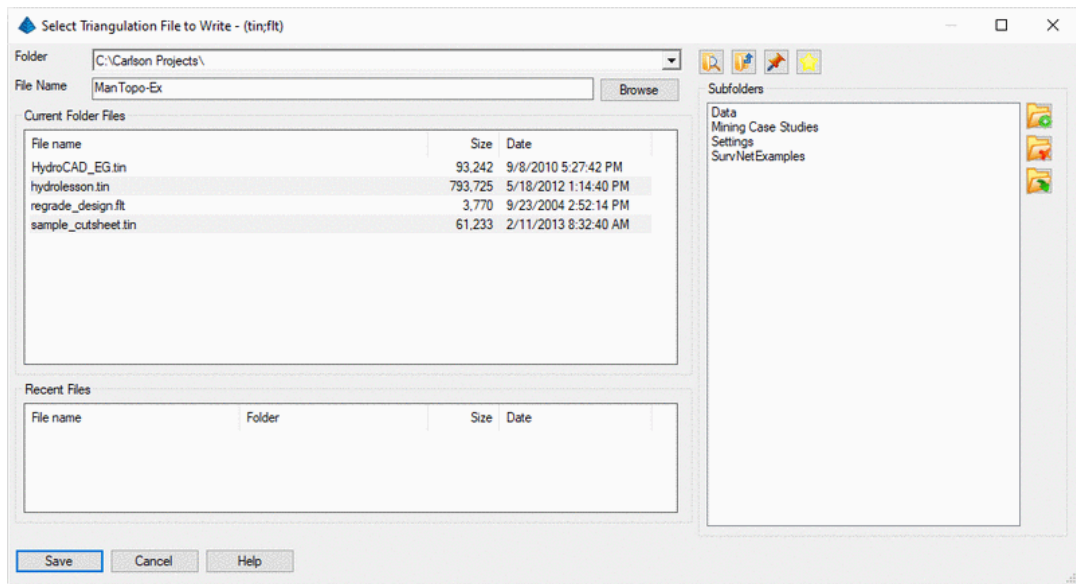

2. Ensure you are in the Survey program by issuing the Settings – Carlson Menus – **Survey Menu** command.

NOTE: Many of the routines below can also be accomplished with the Carlson Civil and/or Construction modules but our focus herein will presume use of the Survey module.

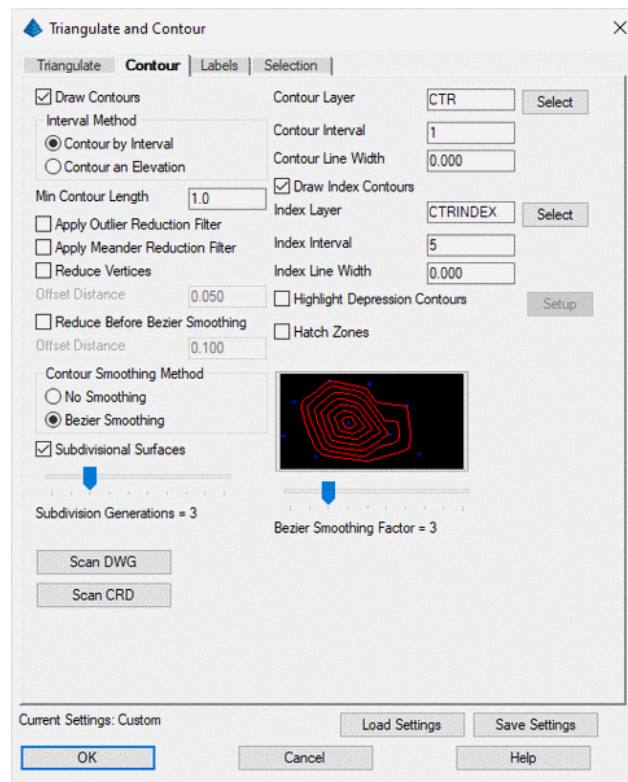

Issue the Surface – Triangulate & Contour command. The following dialog box (with several "tabs") will appear which you should fill out as discussed below:

- In the Triangulate tab (as shown above), enable the **Write Triangulation File** toggle and click its **Select** button to set the name of a triangulation (*.tin) file as illustrated below:

- Click the **Save** button on this dialog box so that the results of the triangulation can be re-used for future purposes. Back in the *Triangulate & Contour* dialog box, turn off the **Use Inclusion/Exclusion Areas** toggle and also turn off the various **Draw** options. Set any remaining options as illustrated above.
- In the Contour tab, as shown below, set the **Contour Interval** to 1, turn on **Draw Index Contours** and set its interval to 5:

Click the **OK** button from any tab. When prompted:

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter twice

If a secondary dialog box appears prompting for a coordinate file (*.crd), select **Mantopo.crd** as your coordinate file and then specify the following default options:

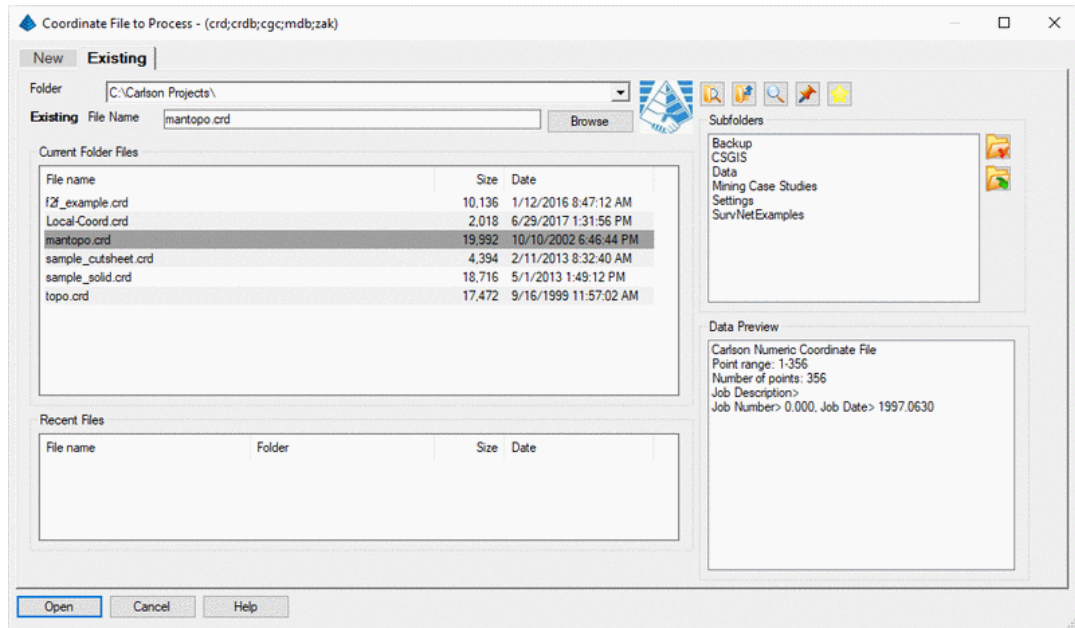

Range of Points: All

Description Match: *

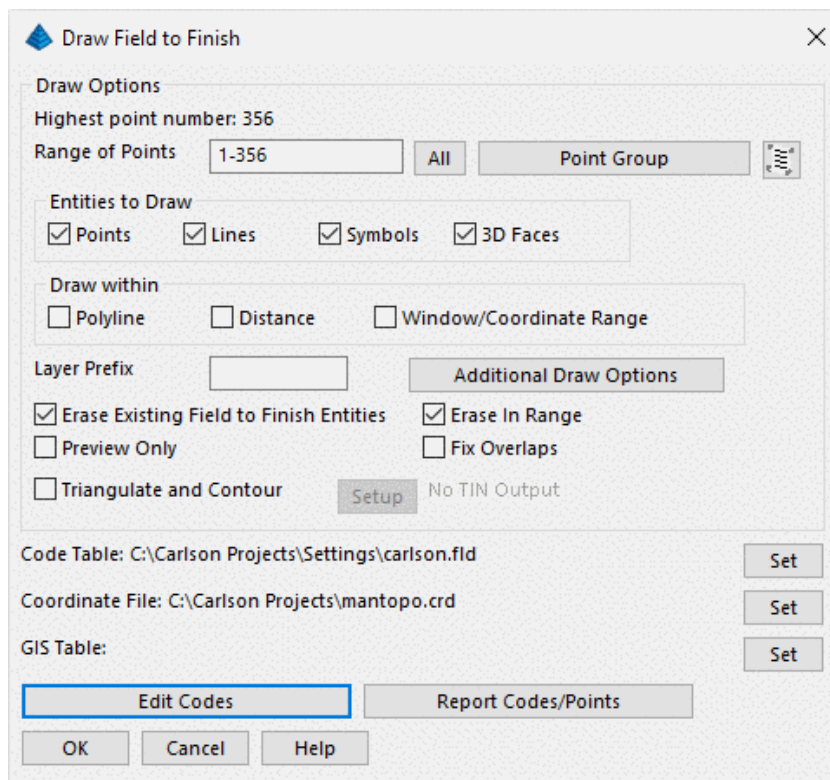

A "TIN" file is written and the contours are drawn. However, notice the unacceptable wavy look around the perimeter, an area which is meant to be a ditch. Let's clean this up through the use of *breaklines*.

3. We'd like to use some automated routines that will automatically generate the breaklines from description data encoded with points collected in the field. Issue the Survey – Draw Field-to-Finish command.

The program will recognize that you have not yet established a coordinate file, so click the **Existing** tab and pick the File as **mantopo.crd** as shown below:

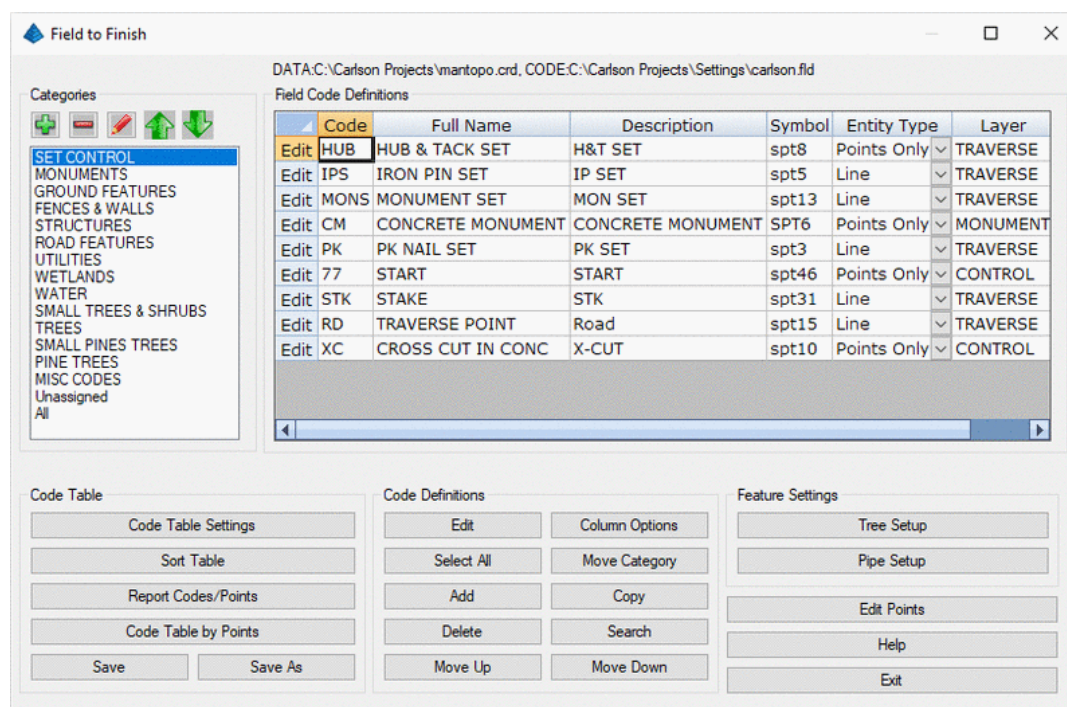

Click **Open**. The **Draw Field to Finish** dialog appears which may (should) resemble the following:

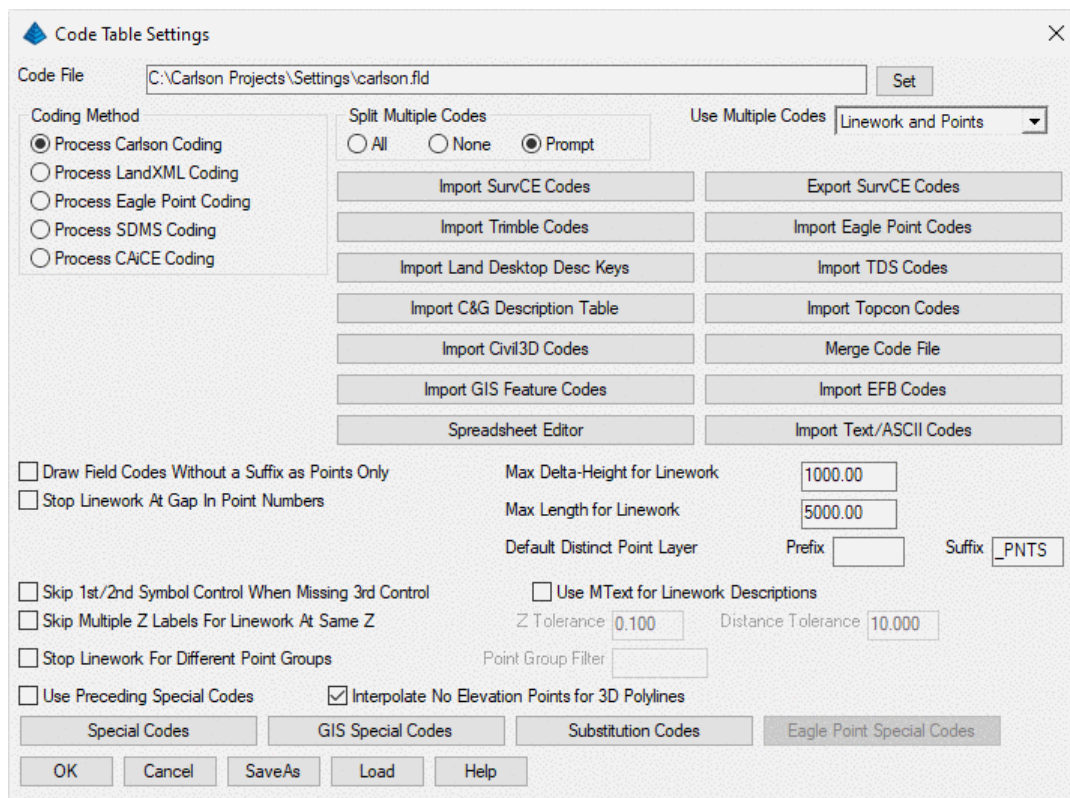

NOTE: You may need to click the **Set** button to the right of **Code Table:** to specify/use the "C:\Carlson Projects\Settings\Carlson.fld" file.

At the lower left of the Draw Field to Finish dialog, click **Edit Codes**. The Field to Finish dialog appears:

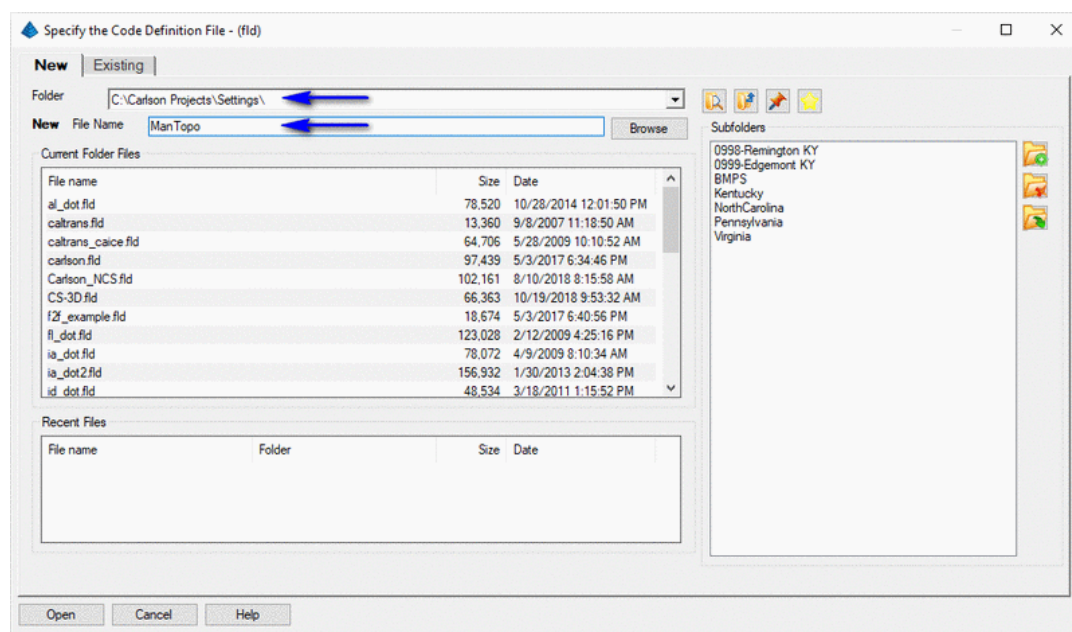

On the left side of the Field to Finish dialog, under the heading Code Table, there is an option called **Code Table Settings**. Click on it to display this dialog:

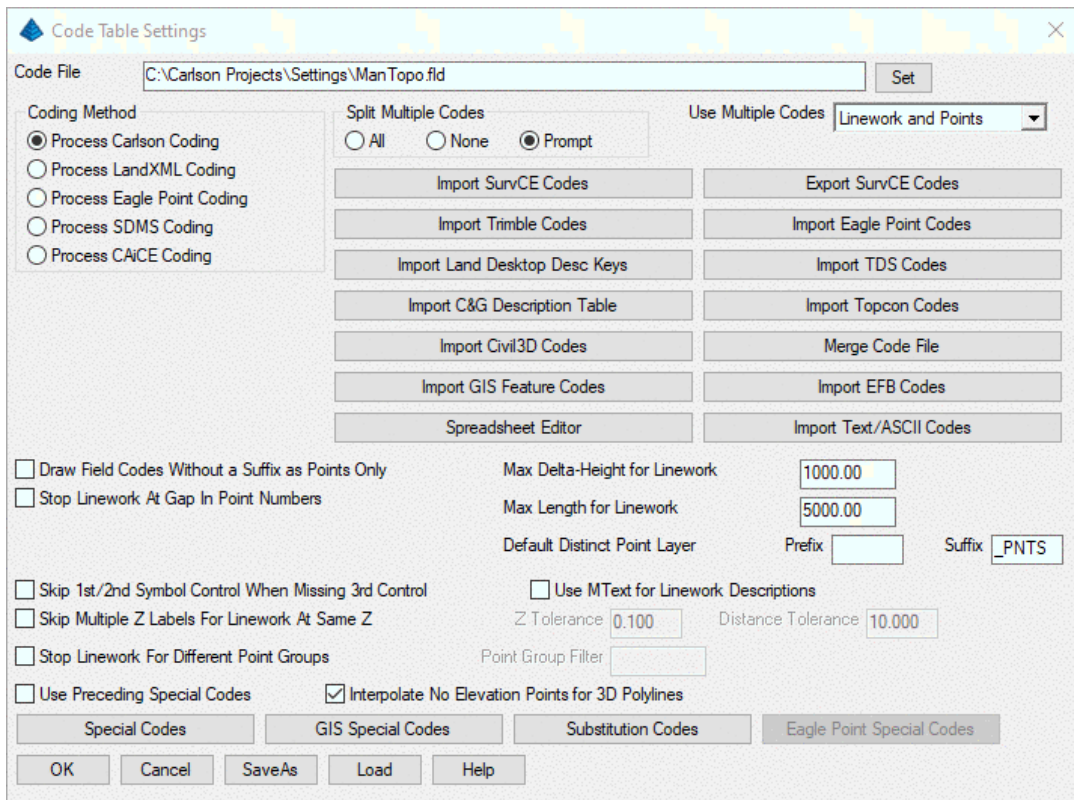

As you can see at the top of the Code Table Settings dialog, the current Field to Finish code definition (.FLD) file is **Carlson.fld**. We want to make a new code table because the coordinate file for the field survey includes special coding (e.g. 17 and 18) for ditch lines and top of banks.

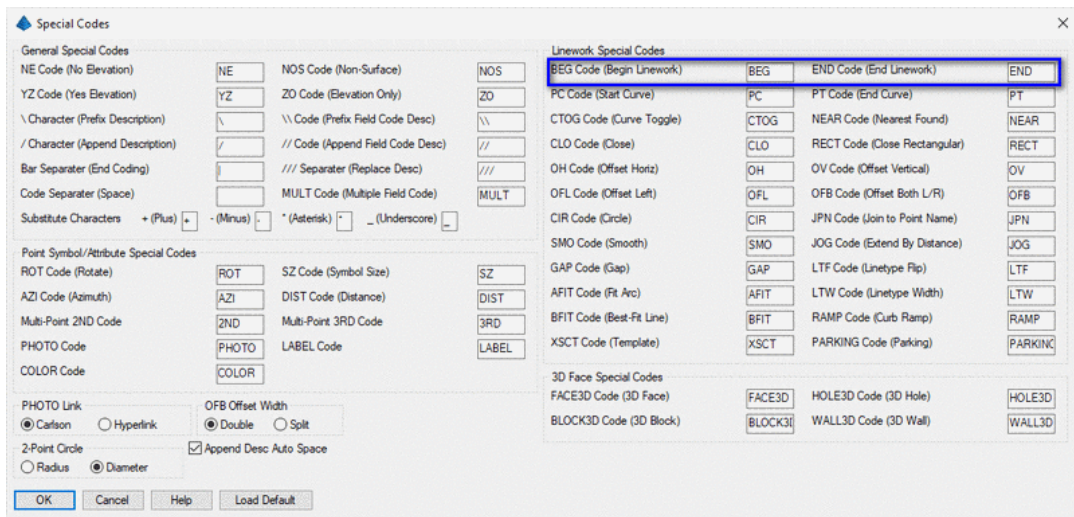

To do this, click **Set** at the upper-right of the Code Table Settings dialog, then choose the New tab (for new file) and name it **ManTopo**, as shown below (noting the "\\Carlson Projects\Settings" folder):

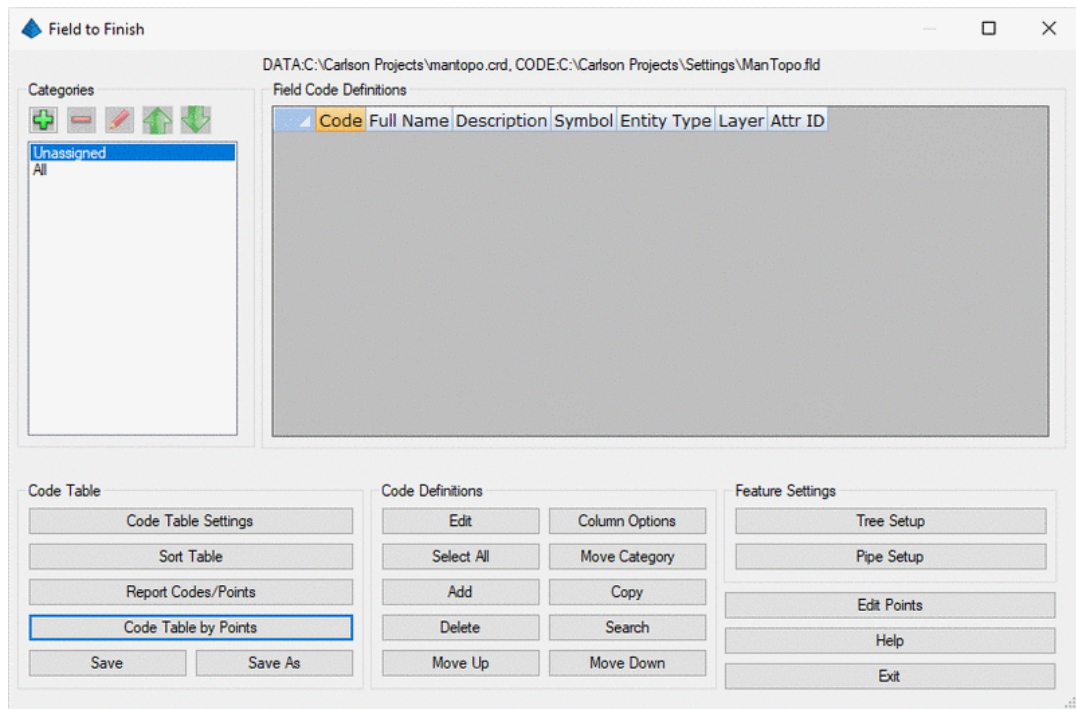

Click Open. You will be taken to the previous dialog.

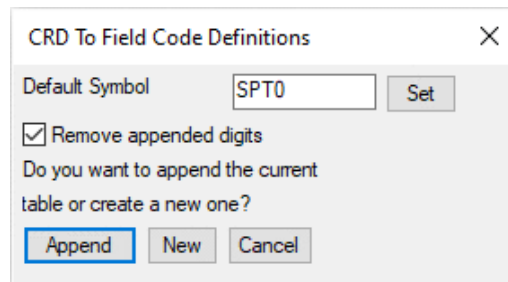

Notice how "C:\Carlson Projects\Settings\ManTopo.fld" is now listed at the top which is our new field code library. Let's also explore some additional capabilities. Click the **Special Codes** button to display the dialog box below:

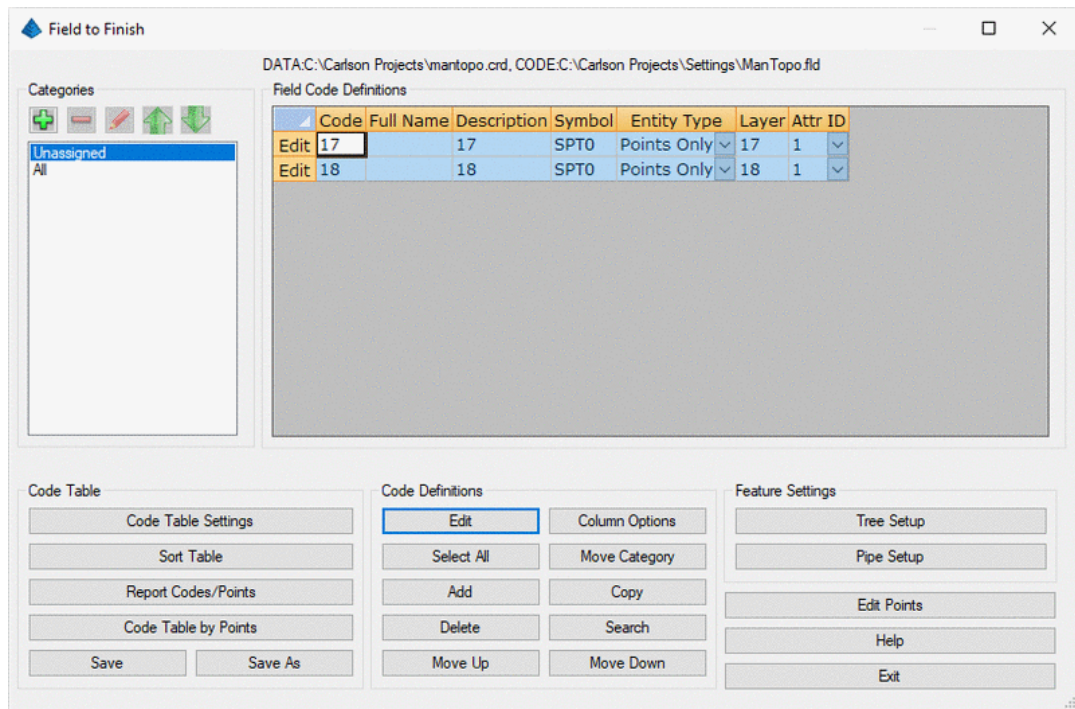

Make note of the **BEG Code (Begin Linework)** and the **END Code (End Linework)** special codes. These can be used to indicate special instances in the data set where linework is to begin and/or end, respectively. We'll use the END code later. Click **OK** to return to the previous dialog box. From it, click **OK**. You will return to the main Field to Finish table, completely empty, as shown below:

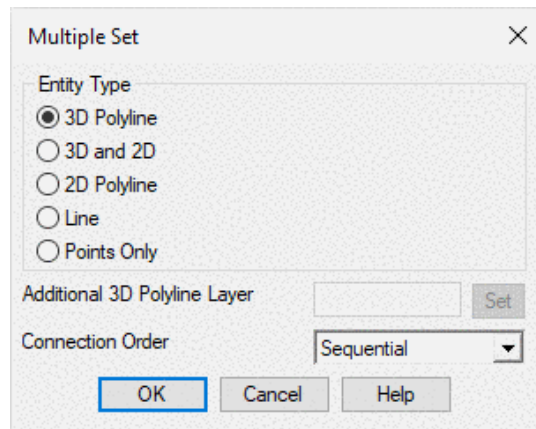

Now, get a jump start on the table by choosing the option **Code Table by Points** (located in the lower left of the dialog). Choose Append on the subsequent dialog box (shown below).

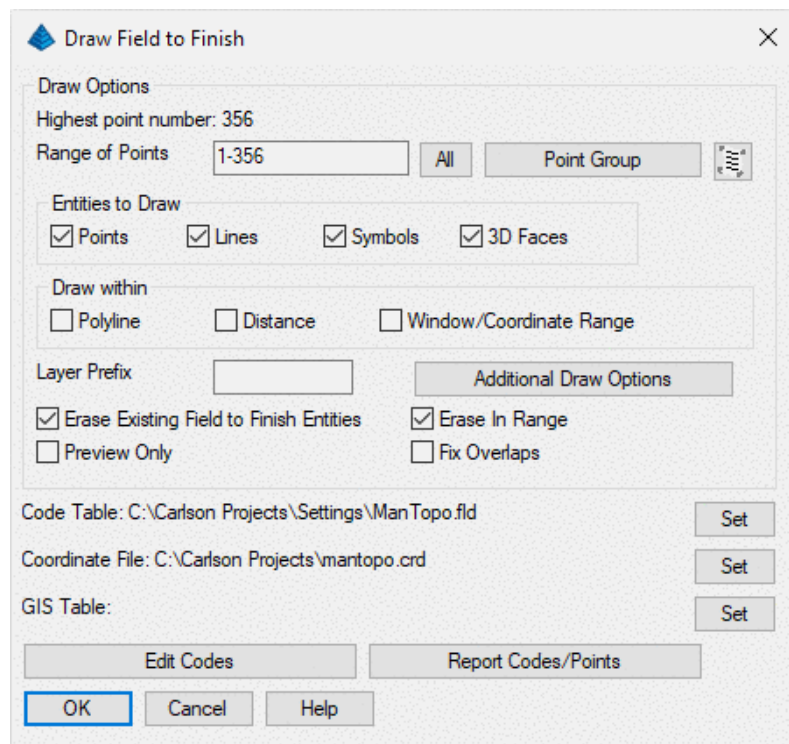

In this lesson, we only care about codes 17 and 18. Select all other codes (the *GROUND* code in this case) and click the **Delete** button to remove that Code from the list. Now select Codes 17 and 18 (by holding the CTRL or SHIFT key down while picking or using the **Select All** button) as shown below:

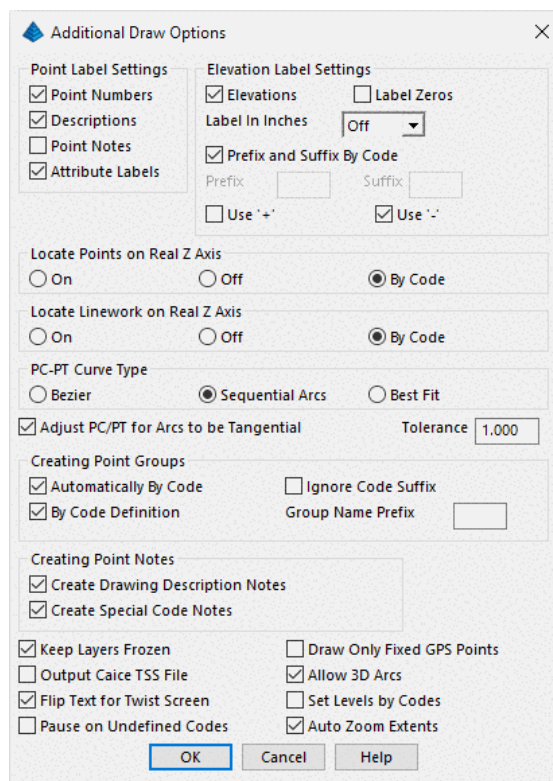

Pick the **Edit** button under Code Definitions. The *Multiple Set* dialog appears. Click the **Entity** button to establish the type of entity that should be drawn for codes 17 and 18 as shown below. Make all settings as shown in this box. We will instruct them to both generate 3D Polylines (which will act as breaklines or barrier lines for contouring). Accept the 3D Polyline choice by clicking **OK**:

Click the **Layout ID** button to establish positions and style for the attributes (*i.e.* Point Number, Elevation and Description) for codes 17 and 18. Specify Attribute Layout ID **5** and click **OK**. Then click **Exit**, which will take you back to the Field to Finish dialog. The last steps are to first to save the **ManTopo.fld** Field-to-Finish by clicking the **Save** button. Then click **Exit** (lower right). You will return to the following dialog which allows you to control the details of what to draw:

Click the **Additional Draw Options** button and make sure that the **Point Label Settings** are set so that you can see the points properly as shown below:

Click **OK** to both dialog boxes. The following drawing is created. All the ditch lines and top of bank lines, because they were coded 17 and 18, are drawn in one quick procedure (previous contours removed and coloring added for clarity):

- Because the field crew did not use start and stop logic (e.g. appending **END** or some agreed upon code to a description could end a polyline and start another), some polylines connect that should not. In particular, the line near the NW corner is clearly crossing the ditch line. It must be removed. One approach would be to use the Edit – Polyline Utilities – Remove Polyline – Remove Polyline Segment command. When prompted:

Mode: break polyline at removal

Select polyline segment to remove [Options]: select the polyline segment to the right of point 127 indicated by the arrow below (you will recognize this as a long segment running from point 127 to point 52)

Select polyline segment to remove (Enter to end): press Enter

The problem with this approach is that if the **Draw Field to Finish** routine is ever re-run (e.g. perhaps due to

- additional data coming in from the field), the polyline segment would return. We'll address this shortly.
5. Re-run the Surface – **Triangulate & Contour** command and use the same settings as before and click **OK**. When prompted:

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter twice

NOTE: With breaklines added to the site, you may be alerted of a crossing breakline scenario located at the northeast corner of the site. Use the **Zoom To** and **Zoom In/Out** buttons to explore the data geometry at this area of the site. Let's permanently take care of this by modifying the descriptions of two key points... #10 and #52 (and optionally a third point, #94).

Use the Points – Edit Points command and make the following changes to the **Description** value:

Point Number	Old Description	New Description
10	17	GROUND
52	17	17 END
94	18	18 END

Edit Point Descriptions

Re-run the Survey – **Draw Field to Finish** command and use the same settings as before and click **OK**.

Re-run the Surface – **Triangulate & Contour** command and use the same settings as before and click **OK**. When prompted:

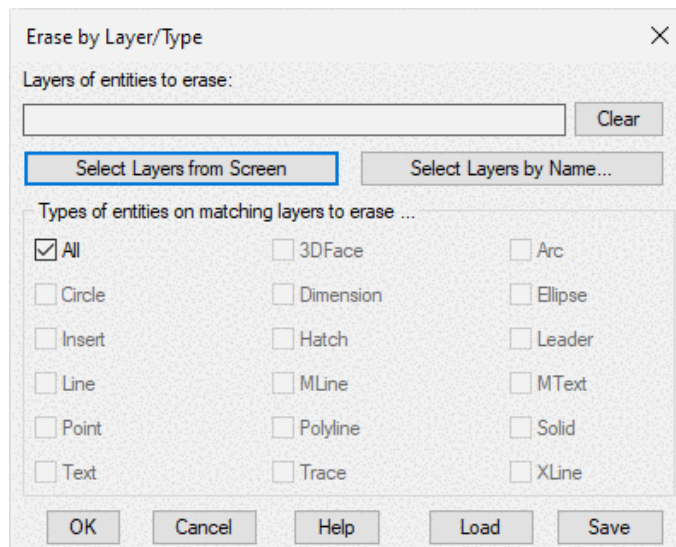

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter twice

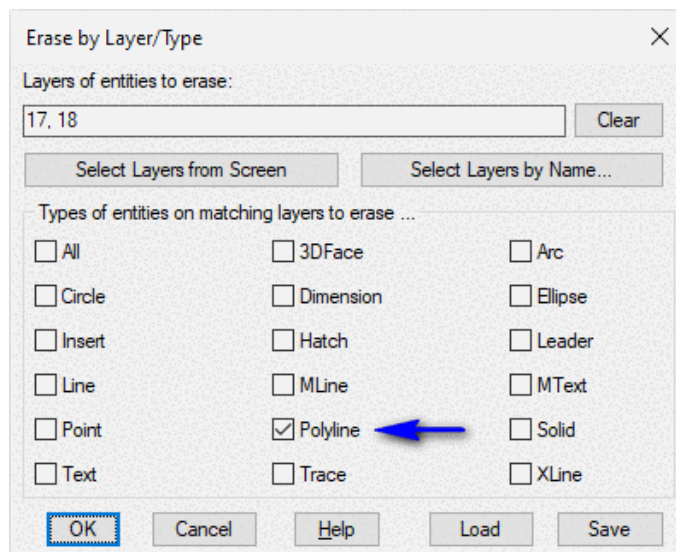

Now we get excellent contours, with a sharply defined ditch. Also note we did not get any processing errors when making the TIN. Use the View – Freeze Layer by Selection and pick on one of the points (its number or its elevation), and press Enter. The points freeze. Here is the improved drawing, helped out by 3D polylines that were produced by Draw Field-to-Finish:

6. Let's say that now you don't want the breaklines in the drawing (since they can be easily recreated with **Draw Field to Finish**). You don't want to even freeze them; you want to fully delete them. There is a command for that through the use of the Edit – Erase – Erase by Layer command. This dialog appears:

If you know the layer names, you can just type them in. If you know where they are but not their names, then click on **Select Layers from Screen**. If you'd recognize the layer name if you saw it in a list, click **Select Layers by Name**. Click on **Select Layers by Name** and pick 17 and 18, then **OK**. Set the Entities to Erase as shown below:

Notice the change in the drawing.

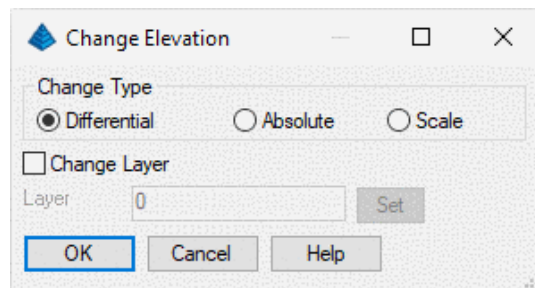

- To the east of the data set we've been working on is a "block" (one single "insert" entity composed of one or more source entities) which represents a stockpile. Because the stockpile data is currently packaged into this single block insert, erasing one component of the block would erase all other components within the block. We'd like to return it to its component parts. Issue the View – **Window** command and window in on the stockpile at the lower right of the drawing. Issue the Edit – Explode – **Standard Explode**. When prompted:

[FILter]/<Select entities to explode>: pick the stockpile block

[FILter]/<Select entities to explode>: press Enter

The exploded block reverts into individual components that can be worked on separately. It's also worth noting that while the block has been exploded, its "block definition" still exists in the drawing. This means that now that it's exploded, it is essentially taking up twice the amount of storage space in the drawing. As such, a common practice would be to "purge" (as obtained through the File – Drawing Utilities – **Purge** command).

- Let's assume our stockpile drawing is too high and should be lowered in elevations by 540 units (feet in this example). To best see the effect of this command, bring back the points by selecting View – Thaw/On All Layers command. Now run the Edit – Change – Elevations to display the dialog box below:

Set the value(s) as shown above and click **OK**. When prompted:

Positive number increases, negative number decreases elevation.

Elevation Difference <0.00>: -540

Ignore zero elevations [Yes/<No>]? Y

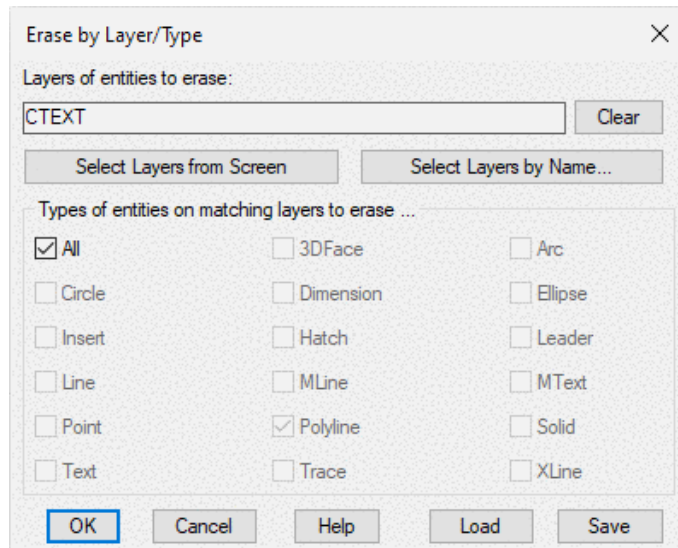

Select Entities for Elevation Change. do a lower right pick to upper left pick selection around the stockpile (automatic crossing)

[FILter]/<Select entities>: press Enter

Notice in the drawing below how the points, breaklines and contour polylines have changed in elevation with the exception of the contour text labels:

Issue the Inquiry – **List Elevation** command and pick on an index contour. Notice how the elevation has indeed changed. Reissue the Edit – Erase – **Erase by Layer** command and set the values as shown below to erase the 5 index contour labels which are no longer accurate.

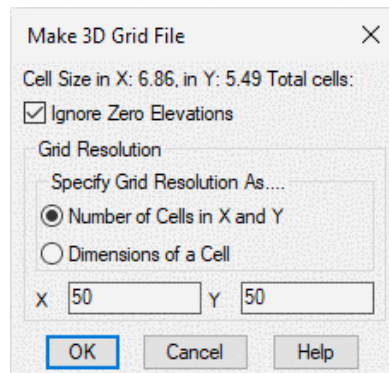

- One of the powerful commands of Carlson (Volumes by Layer) will produce accurate volumes without making any files. The only prerequisite is that the data for the existing and final surfaces exist in the drawing on separate layers. It is also very important to have an inclusion perimeter (boundary polyline) to define the limits where the volumes should be calculated. In our example, the original ground will be the 3D polyline connecting points 1 through 15, and everything else above will be the final ground (including the 3D perimeter itself). Issue the Surface – Volumes by Layers command. When prompted:

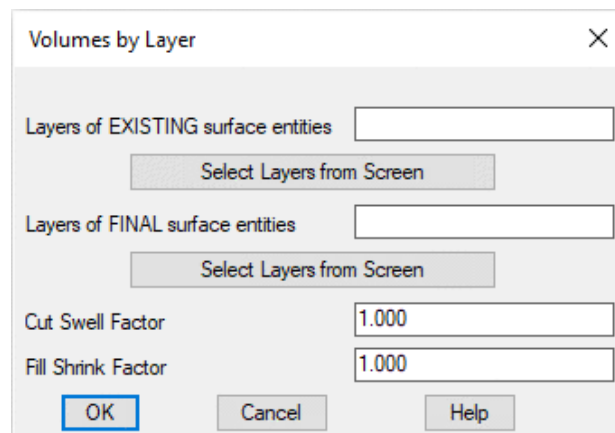

Pick Lower Left limit of surface area: pick below and to the left of the stockpile, but as close as possible to the stockpile without clipping it in the window (you want to totally include it, but with little wasted margin)

Pick Upper Right limit of surface area: pick above and to the right of the stockpile

A dialog appears:

We will stick with the defaults, as shown. Notice that we are using 50 grid cells within our window and since our window was not a perfect square, the cell sizes are not whole numbers. In this example it is 6.86 x 5.49. You may have slightly different sizes. Seeing this, if we wanted a 5 x 5 cell size, we could click the **Dimensions of a Cell** option and set the size to 5 x 5. Hundreds or thousands of cells in both directions will increase calculation time. You can experiment with larger cells or, if you prefer, smaller cells (which makes more cells). However, you will begin to see diminishing returns in terms of accuracy changes as your cell size continues to shrink. After a while (depending largely on the spacing of the source data), tighter, smaller cell sizes don't add any value to the precision of the calculation. Click **OK** to display a dialog box similar to that shown below:

Use the **Select Layers from Screen** buttons to select entities as outlined as follows:

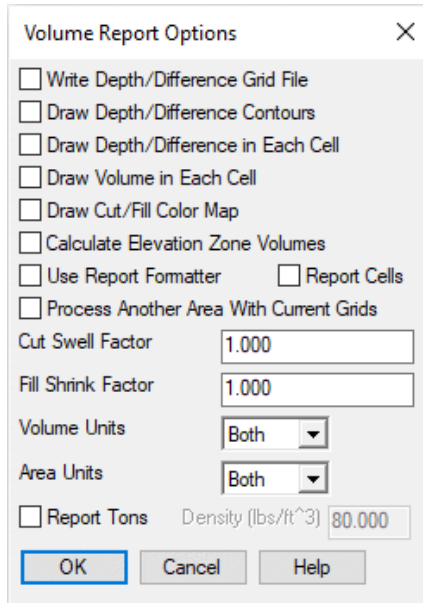

- **Layers of EXISTING surface entities:** PERIMETER
- **Layers of FINAL surface entities:** PERIMETER, BARRIER, CTRINDEX, CTR, PNTS

Notice how the Perimeter layer is common to both. If you want to be a master of volumes, remember this as a mantra: The perimeter should be a 3D polyline in a distinct layer, common to both surfaces. A stockpile is just a special case in that sometimes the 3D perimeter is all you know about the base surface. Click **OK** and when prompted:

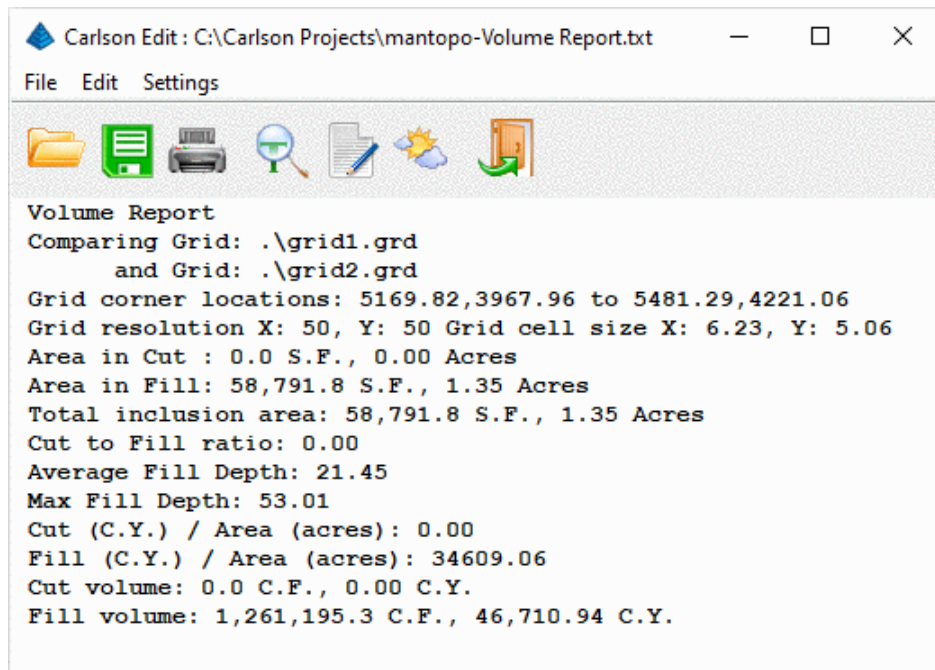

Select surface entities on corresponding layers.

[FILter]/<Select entities>: do a right-to-left (crossing) selection of the entire stockpile area
[FILter]/<Select entities>: press Enter
Select the Inclusion perimeter polylines or ENTER for none:
[FILter]/<Select entities>: pick the perimeter polyline
[FILter]/<Select entities>: press Enter
Select the Exclusion perimeter polylines or ENTER for none.
[FILter]/<Select entities>: press Enter

This leads to a flexible reporting and output dialog:

Elevation Zone Volumes, for example, would produce volumes in any desired increment from the base of the stockpile going up. If the stockpile consists of coal (80 lbs/c.f.), then **Report Tons** can be clicked on and a Density value entered. Click **OK** and the basic report is produced, as seen below:

Click the **Exit** (Doorway) button to return to the command prompt.

10. (Optional): The Stockpile is naturally well-suited for applying the simplest volume command of all **Stockpile Volumes**. It requires that the 3D perimeter polyline for the stockpile be placed in a layer called **Perimeter**, which ours is. So let's try it. Ensure you are in the Civil program by issuing the Settings – Carlson Menus – **Civil Menu** command. Issue the Surface – Stockpile/Ponds/Pit Volumes – Calculate Stockpile Volume. When prompted:

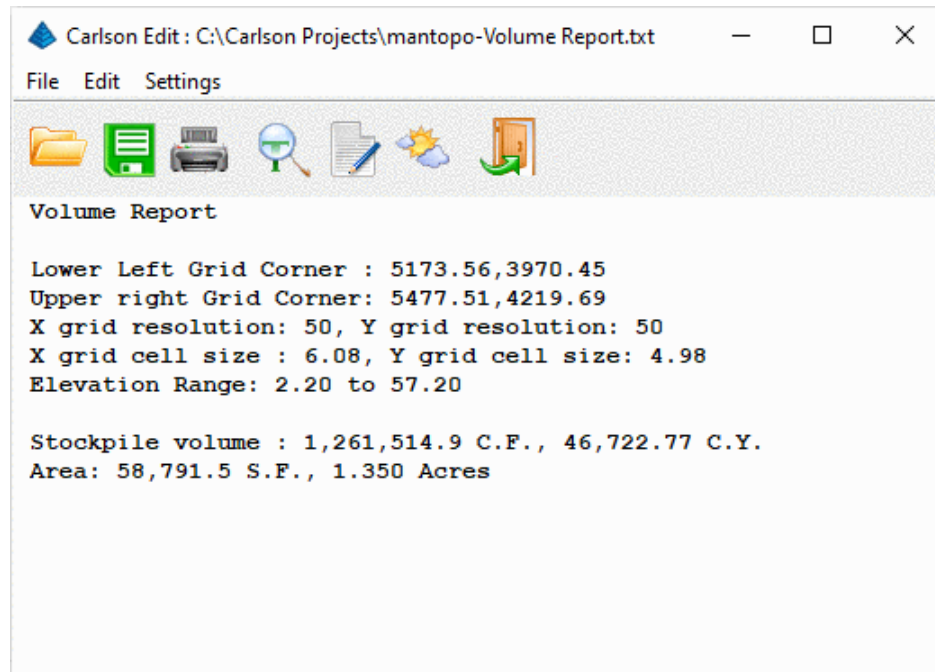

Select stockpile entities and perimeter.

[FILter]/<Select entities>: crossing select (right-to-left picks) the entire stockpile area

[FILter]/<Select entities>: press Enter

Stockpile Volume Report (dialog): accept the default values and click **OK**

The grid resolution dialog (note that it is still at 50x50 but the cell dimensions are likely different from before) appears again. Click **OK**. A report is generated:

This completes the tutorial: Contouring, Break Lines and Stockpiles.

A Dozen Tools for Surface Design

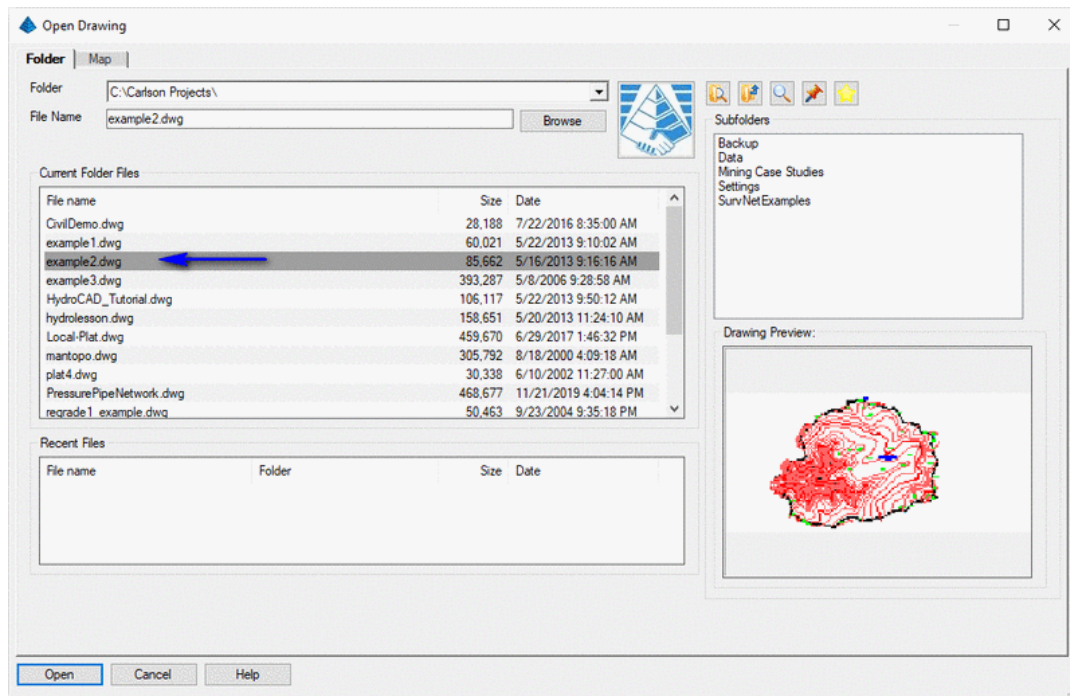

Throughout this tutorial, we'll focus on a variety of commonly used tools for site grading and surface design, including:

1. Draw 2D Polyline
2. Design Pad Template
3. Bench Pond
4. Draw 3D Polyline
5. Join Nearest
6. Offset 3D Polyline
7. Valley Pond
8. 3D Polyline by Slope on Surface
9. 2D to 3D Polyline by Surface Model
10. Profile Editor
11. Profile to 3D Polyline
12. Design Template

Let's begin.

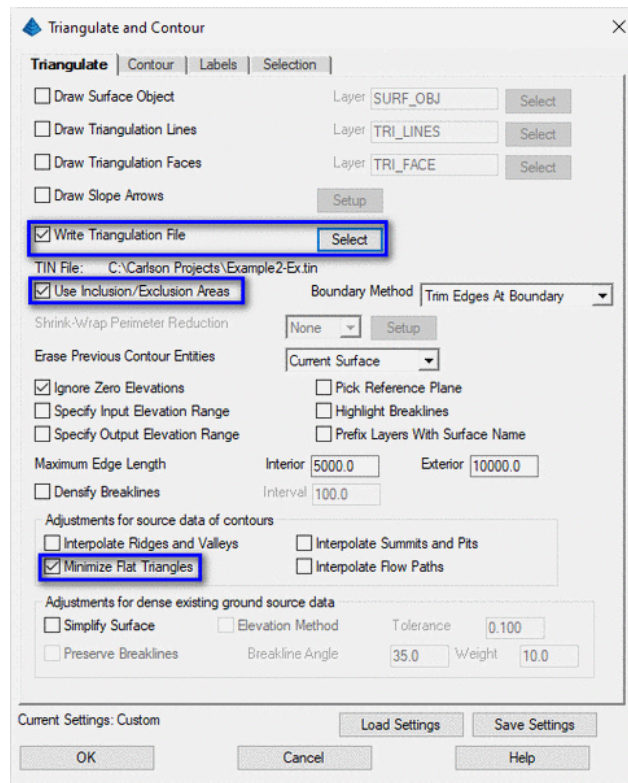

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **example2.dwg** file.

Use the File – **Save As** to save a copy named **example2-s.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties.

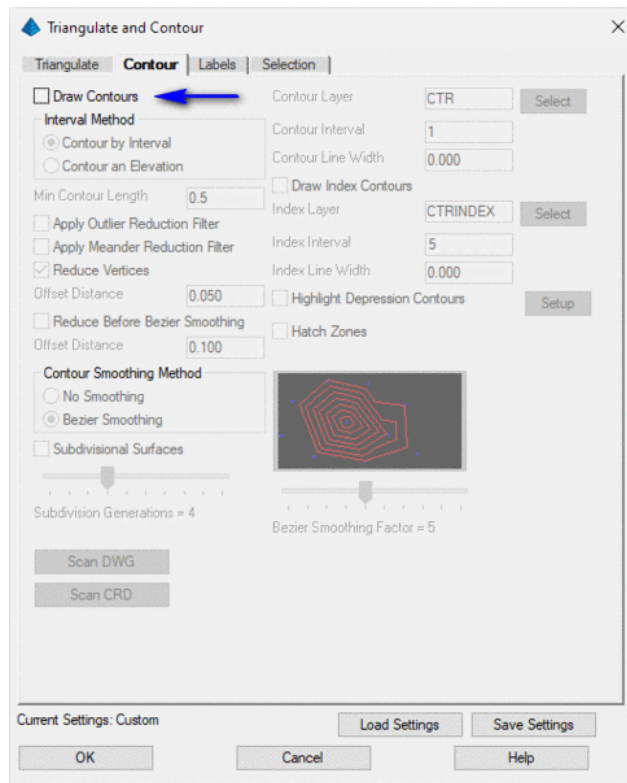

2. Ensure you are in the Civil program by issuing the Settings – Carlson Menus – **Civil Menu** command. Since the bulk of the following commands are designed to integrate into an existing surface, let's make one now. Issue the Surface – Triangulate & Contour command. The following dialog box (with several "tabs") similar to the one shown below will appear which you should fill out as discussed below:

- In the Triangulate tab (as shown above), enable the **Write Triangulation File** toggle and click its **Select** button to set the name of a triangulation (*.tin) file as illustrated below. Click the **Save** button on this dialog box so that the results of the triangulation can be re-used for future purposes. Enable the **Use Inclusion/Exclusion Areas** toggle and also turn on the **Minimize Flat Triangles** option. This will help form a more accurate model. Set any remaining options as illustrated above:

- In the Contour tab, as shown below, toggle off the **Draw Contours** option as there are already contours in the drawing:

Click the **OK** button from any tab. When prompted:

Select Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the BORDER polyline and press Enter

[FILter]/<Select entities>: press Enter

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter twice

A "TIN" file is written that we'll use again and again. Let's zoom in closer to our desired area of interest. Issue the View – **Window** command. When prompted:

Zoom: [In/Out/All/Center/Dynamic/Extents/Left/Previous/Right/Window/Entity/Scale]<Scale (nX/nXP)>: _w

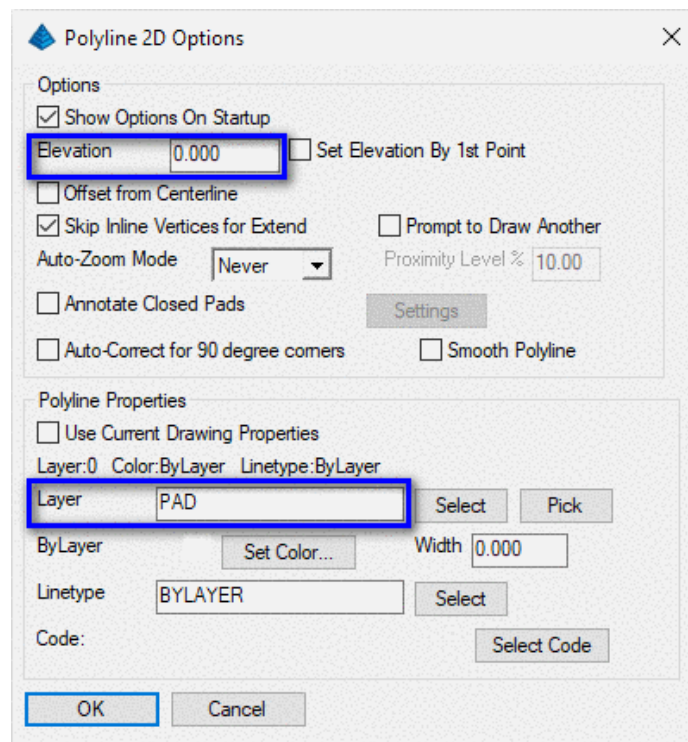

First corner: pick the lower left location of the area of interest shown below

Opposite corner: pick the upper right location of the area of interest shown below

NOTE: Many of the routines below can also be accomplished with the Carlson Survey and/or Construction modules but our focus herein will presume use of the Civil module.

- Tool 1:** The most basic use of a 2D polyline is for the creation of flat-bottomed pits and flat "building pads" at any desired elevation. Let's start with a "free-form" building pad at a specified elevation. Issue the Draw – 2D Polyline command to display a dialog box shown below:

Set the values as shown above making particular note of the highlighted items. Click **OK** when ready. When prompted:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: pick a first pad location as shown below

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: pick the second pad location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick the third pad location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick the fourth pad location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick the fifth pad location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick the sixth pad location

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press **C** to mathematically close the pad

Let's sketch out a simple rectangular pond bottom. Issue the Draw – **Rectangle** (key-in is *rectang*) and when prompted:

[Chamfer/Elevation/Fillet/Rotated/Square/Thickness/Width]/<Select first corner of rectangle>: type **end** (for an endpoint snap) and press Enter

Snap to END of: pick the endpoint on the contour as shown below

Specify other corner point or [Area/Dimensions/Rotation]: type **D** and press Enter

Enter rectangle length <10.0000>: type **300** and press Enter

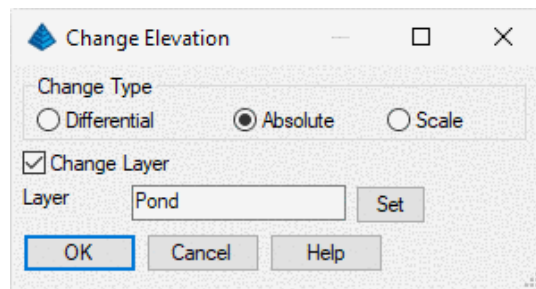

Enter rectangle width <10.0000>: type **170** and press Enter

Specify other corner point or [Area/Dimensions/Rotation]: pick a location northwest of the initial point

NOTE: Unlike the **2D Polyline** command discussed above which has added functionality permitting you to establish the elevation for the 2D polyline, the **Rectangle** command will inherit the elevation of the first pick point (a contour in this case).

Let's set the pond bottom polyline to a better target elevation. Issue the Edit – Change – Elevations command to display the dialog box as shown below:

Set the values as shown above and click **OK** when ready. When prompted:

Select/⟨Enter Elevation <0.0000>⟩: if the default value is other than 0, type 0 and press Enter

Select Entities for Elevation Change.

[FILter]/⟨Select entities⟩: pick the pond bottom polyline just drawn

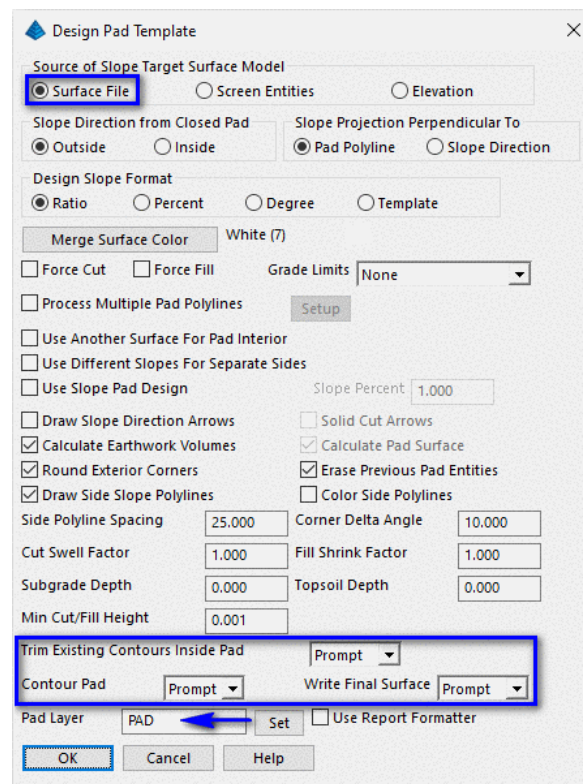

[FILter]/⟨Select entities⟩: press Enter

Select/⟨Input another Elevation (Enter to end)⟩: press Enter

Our resulting polylines should resemble that shown below:

4. **Tool 2:** With the **pad** and **pond** polylines drawn, we'd next like to project slopes to tie back to the *existing ground surface* to produce volumes. Issue the Surface – Design Pad Template routine. A dialog box similar to that shown below appears:

Set the values as shown above and click **OK** when ready. When prompted:

Pick pad polyline: pick the non-rectangular pad polyline (the first that was drawn)

A dialog box similar to that shown below appears. Select the surface model file created earlier and click **Open** when ready. Prompting will resume:

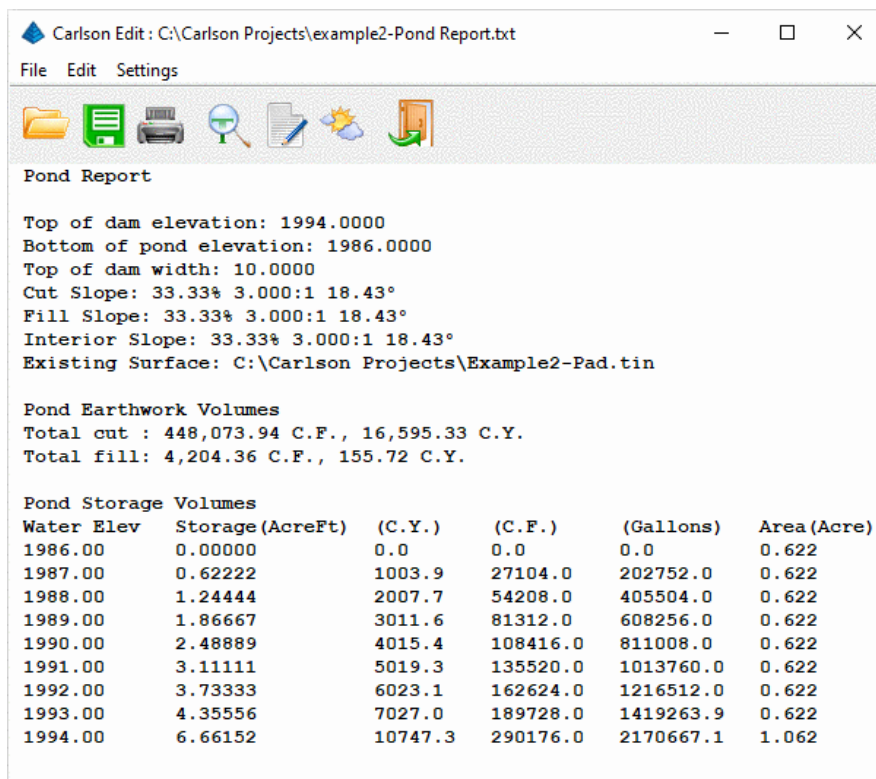

Fill outslope ratio <3.000>: press Enter

Cut outslope ratio <3.000>: press Enter

Range of existing elevations along pad: 1992.33 to 1995.37 (your values may vary)

Pad elevation <1992.33>: type 1993.5 and press Enter (we'll try to target a balanced Cut vs. Fill)

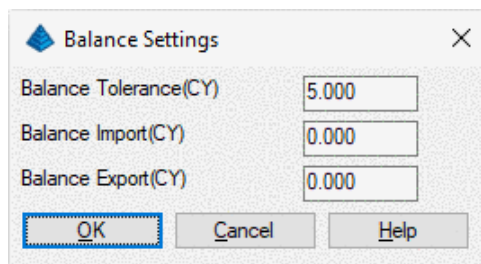

Slope projections from the source polyline are projected to the surface model file and preliminary results are displayed in the Standard Report Viewer similar to that shown below:

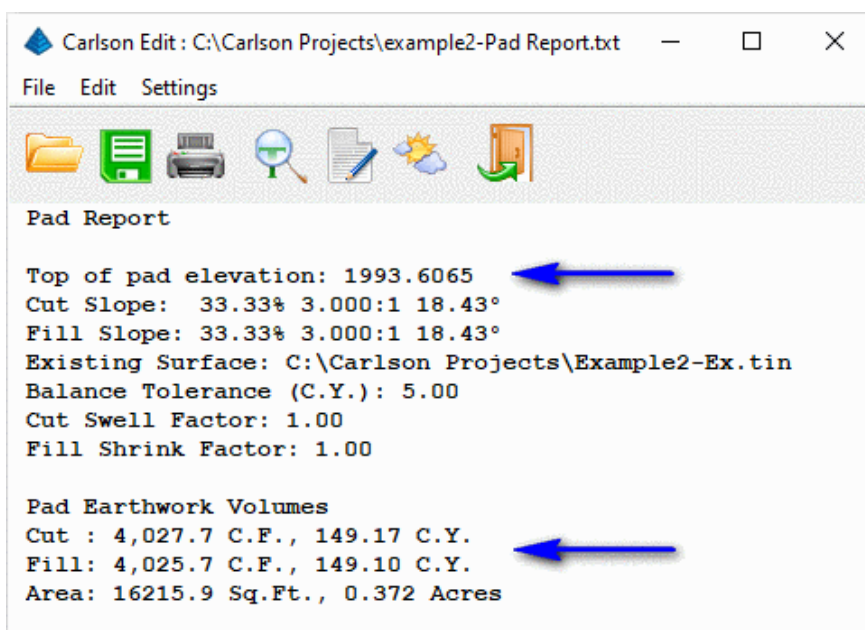

Review the report and notice the *Cut Volume* will be different from that of the *Fill Volume*. Click the **Exit** (Doorway) button to dismiss the report. Prompting resumes:

Adjust parameters and redesign pad [Yes/<No>]? type Y and press Enter
Balance cut/fill [Yes/<No>]? type Y and press Enter

A dialog box similar to that appears. Set the values as shown below and click **OK** when ready:

The solution is iterated until the balance tolerance is achieved and an updated report similar to that shown below appears:

Let's accept the solution. Click the **Exit** (Doorway) button to dismiss the report. Prompting resumes:

Adjust parameters and redesign pad [Yes/<No>]? type N and press Enter

A dialog box as shown below appears, prompting us with an option to commit the **Final** surface to an external *triangulation* file which could ultimately be used again in the future. Click the **Create New Surface** button as shown below:

A secondary dialog box as shown below appears prompting if we'd like to merge the **Final** surface into the **Existing** surface file produced earlier.

NOTE:

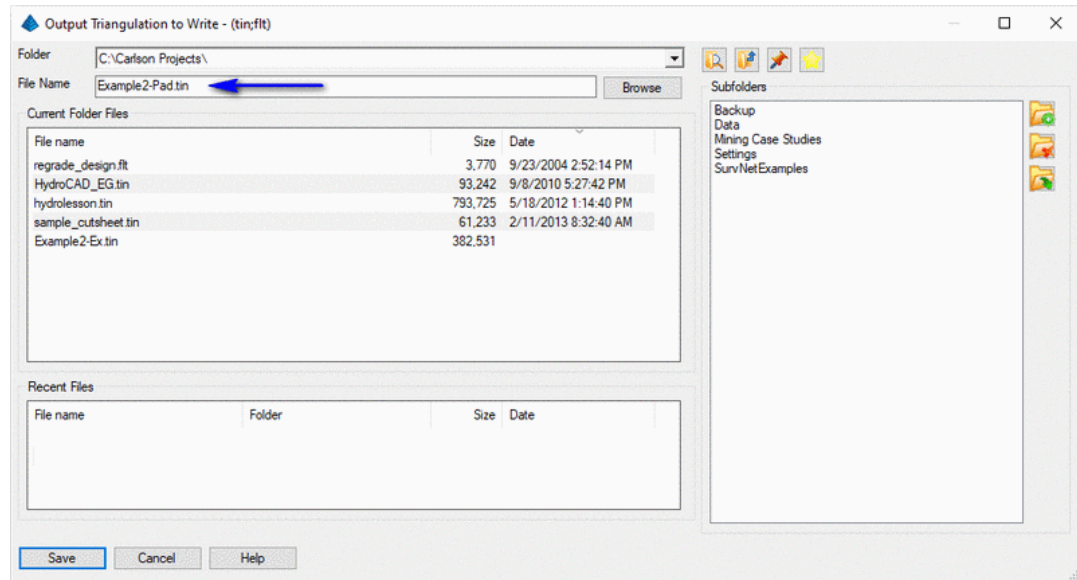

- Clicking **Yes** takes the *existing* surface model and "stitches in" the pad polylines to form a composite surface model which is typically given a new name (thereby preserving the original *existing* surface).

- Clicking **No** takes the pad polylines to form an individual model of the design features which is typically given a new name (thereby preserving the original *existing* surface).

Click the **Yes** button as this will help us later:

You are then prompted for the name of a *triangulation* (*.tin) to write. Specify the value as shown below and click the **Save** button when ready:

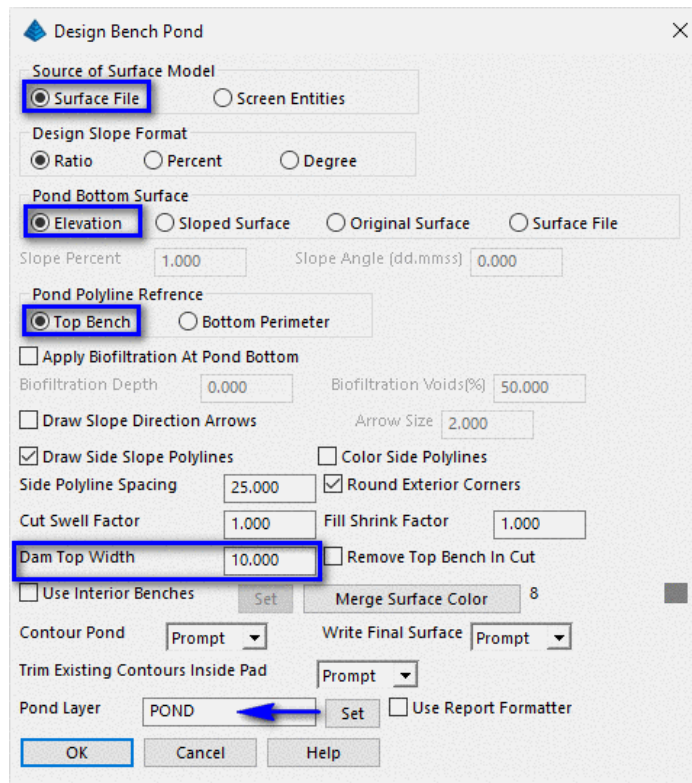

Prompting resumes:

Trim existing contours inside pad perimeter [Yes/<No>]? type N and press Enter

Contour the pad [<Yes>/No]? type N and press Enter

With the pad polyline completed, let's work on the pond.

5. **Tool 3:** In certain situations, we might desire a "bench" (or "bermed") pond. Issue the Surface – Design Pond – Design Bench Pond command to display a dialog box similar to that shown below:

Set the values as shown above paying particular attention to the highlighted items and click **OK** when ready. When prompted:

Pick top of pond polyline: pick the rectangular pond polyline

A dialog box appears prompting for the **Existing** surface. Specify the surface model we just made as illustrated below and click **Open** when ready:

Prompting resumes:

Fill outslope ratio <3.000>: press Enter

Cut outslope ratio <3.000>: press Enter

Interior slope ratio <3.000>: press Enter

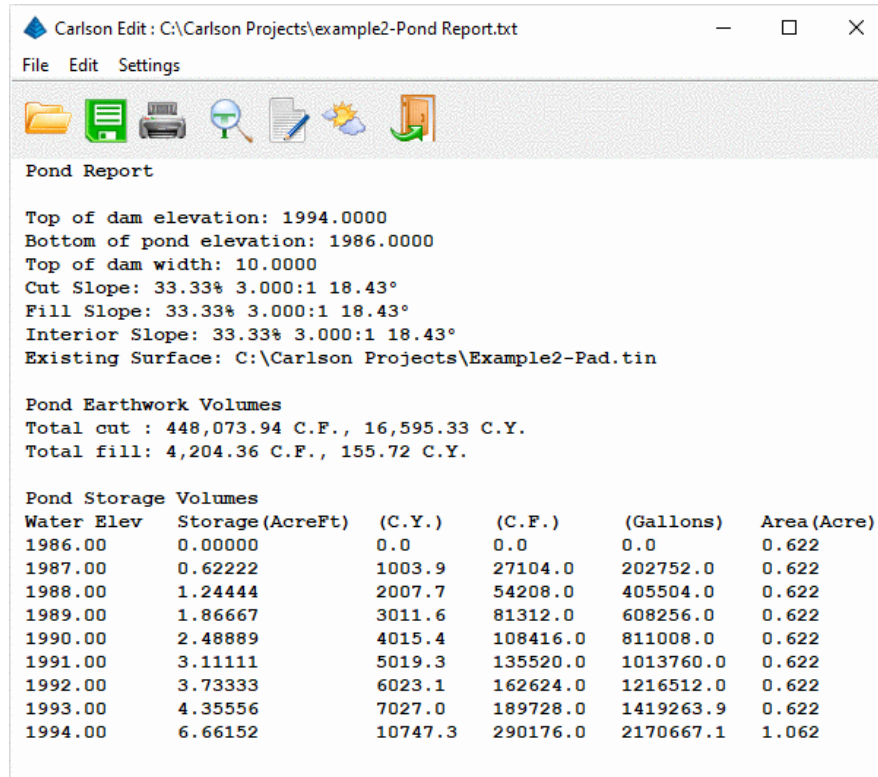

Range of existing elevations along dam top: 1991.51 to 2000.56 (your results may vary)

Top of bank elevation <1991.51>: type 1994 and press Enter

Pond bottom elevation: type 1986 and press Enter

Method to specify storage elevations [<Automatic>/Interval/Manual**]?** type A and press Enter

Slope projections from the source polyline are projected to the surface model file and preliminary results are displayed in the **Standard Report Viewer** similar to that shown below:

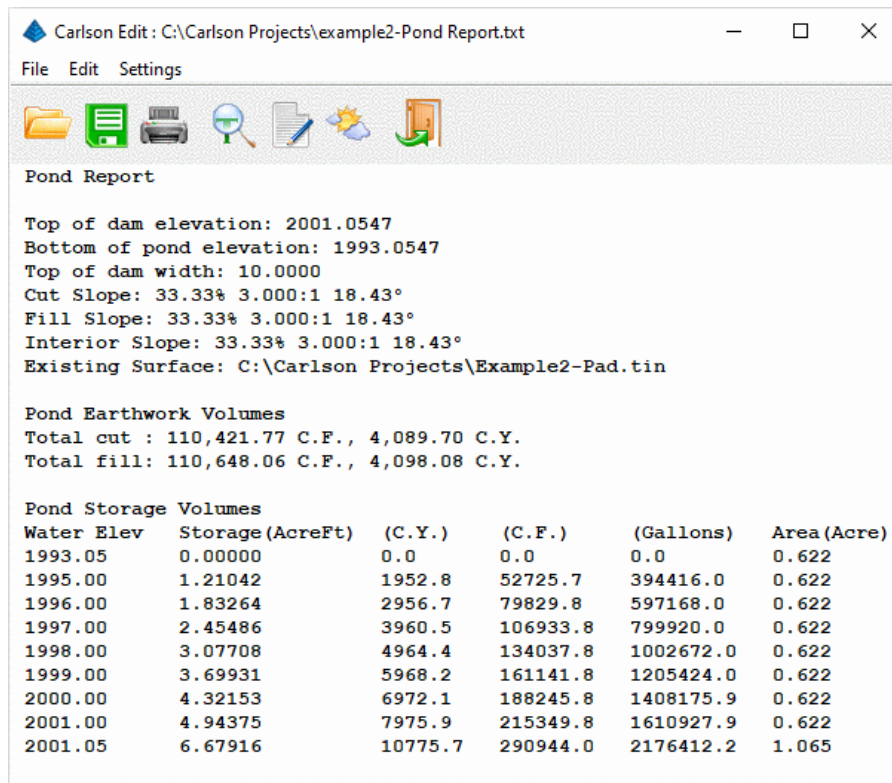

Review the report and notice the *Cut Volume* will be different from that of the *Fill Volume*. Click the **Exit** (Doorway) button to dismiss the report. Prompting resumes:

Adjust parameters and redesign pond [Yes/<No>]? type Y and press Enter

Balance cut/fill [Yes/<No>]? type Y and press Enter

Method to specify storage elevations [<Automatic>/Interval/Manual**]?** type A and press Enter

The solution is iterated until the balance tolerance is achieved and an updated report similar to that shown belows appears:

Let's accept the solution. Click the **Exit (Doorway)** button to dismiss the report. Prompting resumes:

Adjust parameters and redesign pond [Yes/<No>]? type N and press Enter

Write stage-storage file [Yes/<No>]? type N and press Enter

Write final surface to triangulation file [Yes/<No>]? type Y and press Enter

Merge pond with target surface [<Yes>/No]? type Y and press Enter

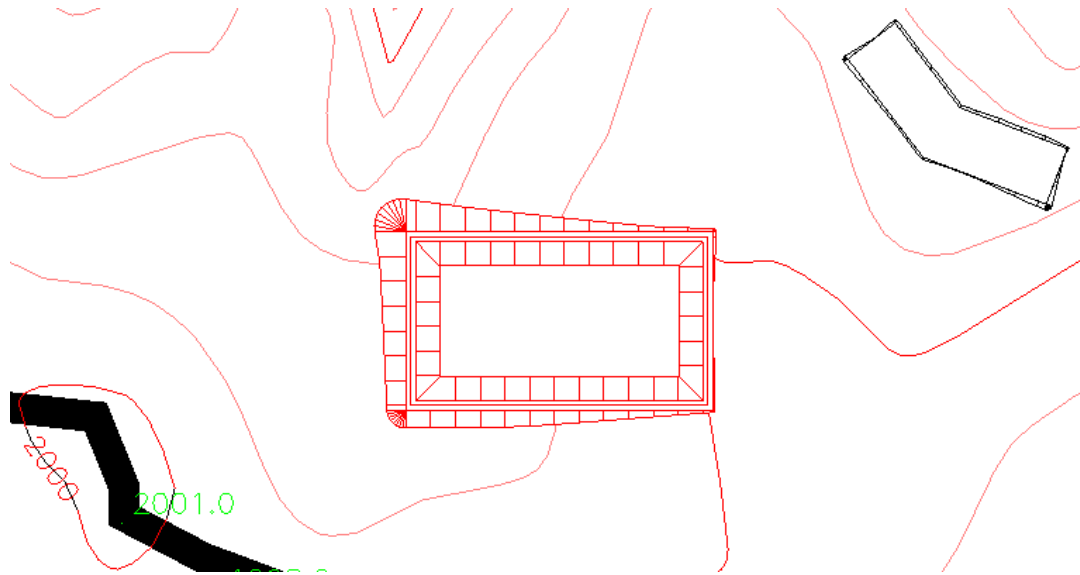

You are prompted for an output file. Specify the value as shown below and click the **Save** button when ready:

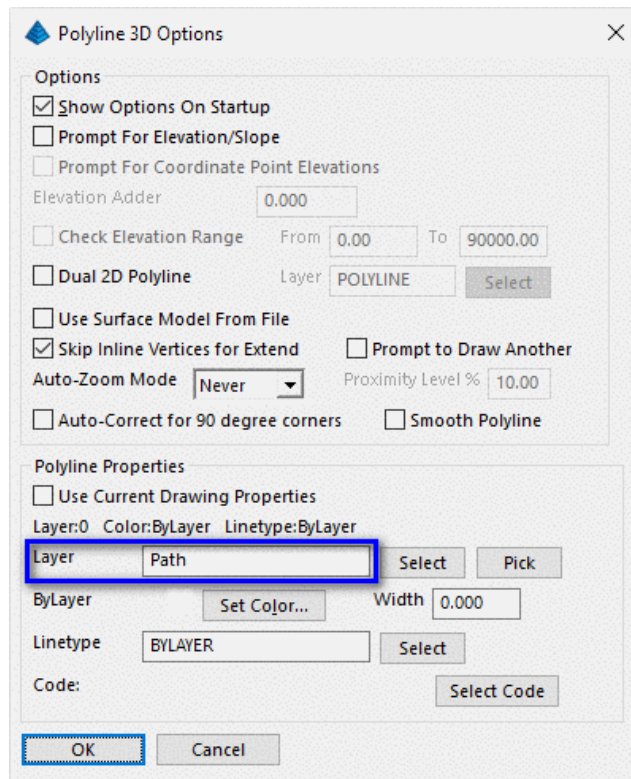

Prompting resumes:

Trim existing contours inside pad perimeter [Yes/<No>]? type Y and press Enter
Retain trimmed polyline segments [Yes/<No>]? type N and press Enter
Contour the pond [<Yes>/No]? type N and press Enter

The result is a partial Fill, partial Cut Bench Pond as shown below:

- Tool 4:** With the two primary structures designed, let's try a graded path between the two with an interior angle point that allows each end to be perpendicular to its intended structure. Issue the Draw – 3D Polyline command to display a dialog box similar to that shown below:

Set the values as shown above paying particular attention to the highlighted information and click **OK** when ready. When prompted (using the illustration below as a guide):

[Continue/Extend/Follow/Options/<Pick point or point numbers>]:type END and press Enter

Snap to END of: pick northeast rectangular corner of pond structure

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: press **F8** function key to enable "ortho" mode ('_ORTHOgonal)

ORTHOMODE is currently off: [ON/OFF/Toggle]<Off>: **_T**

(ORTHOMODE is currently On):

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: pick the hinge location then press **F8** function key to disable "ortho" mode

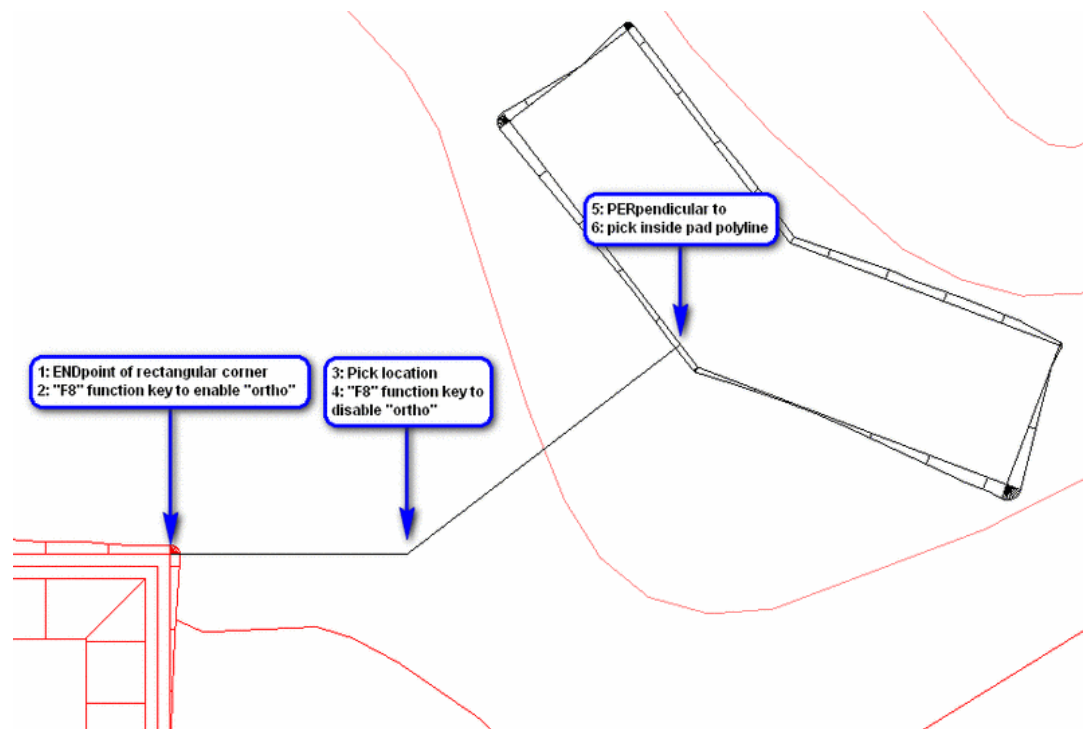

ORTHOMODE is currently on: [ON/OFF/Toggle]<On>: **_T**

(ORTHOMODE is currently Off): type **PER** and press Enter

Snap to PER of: pick inside pad polyline

Warning: last 3D polyline point at 0 elevation

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter

This is an obvious tool for creating design considerations. Our 3D polyline has one problem... the hinge vertex may not have the elevation we desire. Let's fix this.

NOTE: *Bonus Tool!* Issue the 3D Data – Polyline Elevation Editor command. When prompted:

Select a polyline to edit: pick the polyline you just drew

Before Edit

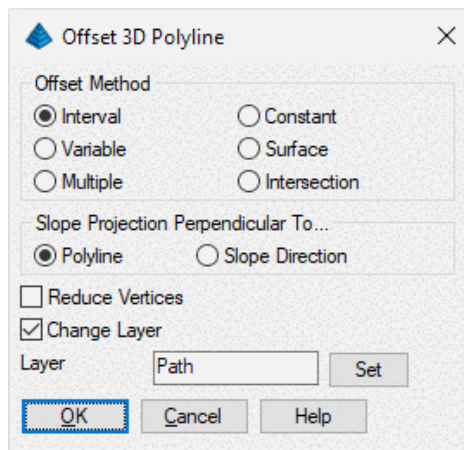

A "docked" dialog box similar to that shown below appears:

Polyline Elevation Editor

You'll note that each of the three vertex locations are toggled as **Control** locations. Presuming your snap locations were correct, vertex 2 may very well be at elevation 0. Clear its **Control** toggle so its elevation is interpolated from the two surrounding **Control** locations. Experiment with this "Swiss Army Knife" tool with the end goal of a uniform grade between the two structures. Click **OK** when ready.

- Tool 5:** We'd like to offset this graded polyline by the same width as the **Bench Pond Width** as created earlier. Issue the Edit – 3D Polyline Utilities – Offset 3D Polyline to display a dialog box similar to that shown below:

Set the values as shown above and click **OK** when ready. When prompted:

Percent/Ratio/<Horizontal offset amount>: type 10 and press Enter

Select/<Enter the common elevation <0.0000>: press Enter

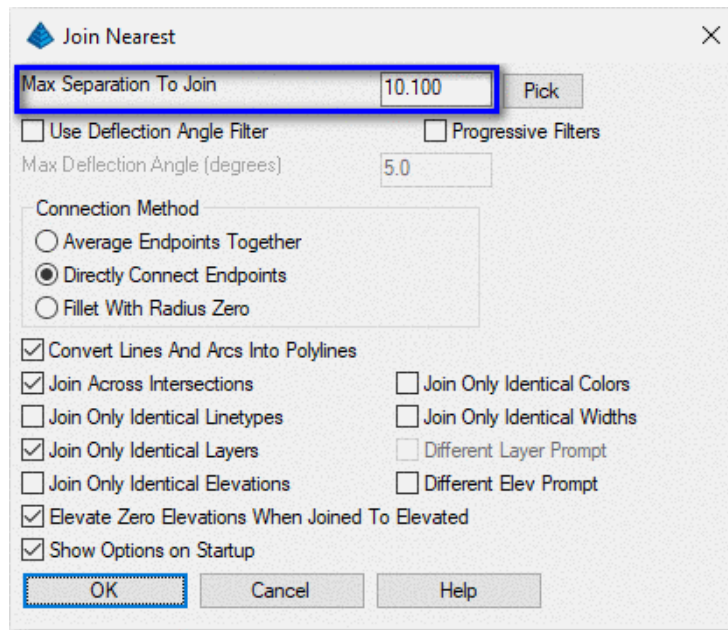

Select a polyline to offset: pick the polyline you just edited

Select side to offset [Both]: pick to the South of the polyline

Select a polyline to offset (Enter to end): press Enter

We now have a 3D-parallel offset of the initial polyline.

- Tool 6:** We'd like to connect these two polylines together to form one closed region. Issue the Edit – Join Nearest command to display a dialog box similar to that shown below:

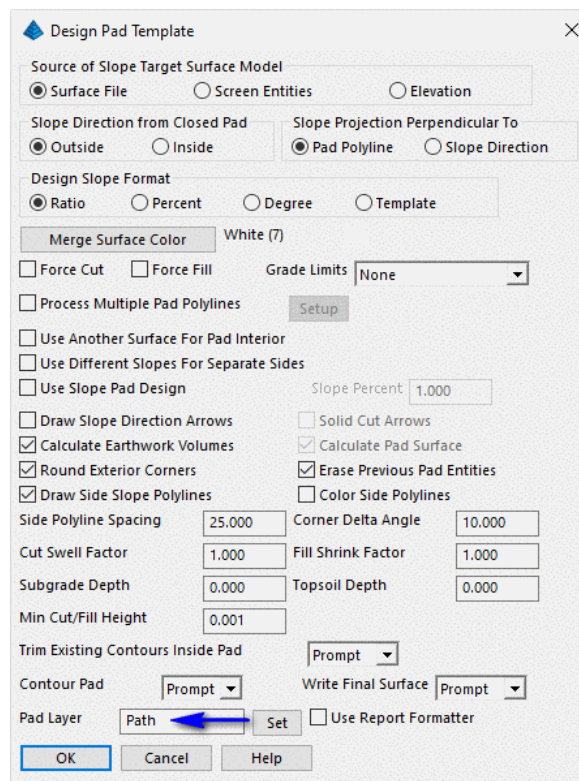

Note the **Max Separation to Join** value. Common practice is to pick the distance to span and then increase slightly to ensure the desired items will join. Set the values as shown above and click **OK** when ready. When prompted:

Select lines, arcs and unclosed polylines to join [Settings].

Select entities: pick the two polylines

Select entities: press Enter

Now we have a 3D polyline closed perimeter, which can act as a pad. Re-issue the Surface – **Design Pad Template** command to display a dialog box similar to that shown below:

Set the values as shown above and click **OK** when ready. When prompted:

Pick pad polyline: pick the closed path polyline

Select Slope Target Surface (dialog): select the surface model recently created in the Bench Pond discussion and click **Open**

Fill outslope ratio <3.000>: press Enter

Cut outslope ratio <3.000>: type 5 and press Enter

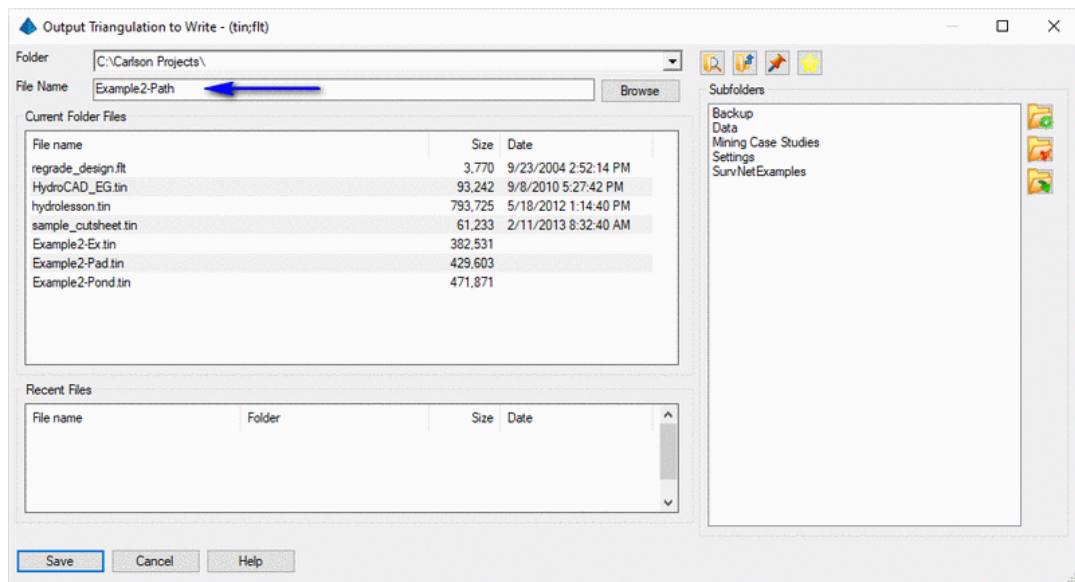

Slope projections from the source polyline are projected to the surface model file and preliminary results are displayed. Review the report and click the **Exit** (Doorway) button to dismiss the report. Prompting resumes:

Adjust parameters and redesign pad [Yes/<No>]?: type N and press Enter

Write Final Surface (dialog): click **Create New Surface**

Merge Final Surface (dialog): click **Yes**

Write Triangulation Surface (dialog): set the value as shown below and click **OK**

Prompting resumes:

Trim existing contours inside pad perimeter [Yes/<No>]?: type Y and press Enter

Retain trimmed polyline segments [Yes/<No>]?: type N and press Enter

Contour the pad [<Yes>/No]?: type N and press Enter

With the path completed, let's work on a new pond structure.

9. **Tool 7:** We'd like to create a berm utilizing the walls of an existing valley to form a *Valley Pond*. We have a small amount of "prep" work:
 - (a) To help distinguish from the **Bench Pond** we created earlier, create a new layer called **POND2** and give it a color of **Magenta** and set it as the *current* layer. Dismiss the layer properties dialog box.
 - (b) Issue the Draw – Arc – 3 Point command and when prompted:

Pick PC point or point numbers: pick a south end of the arc as shown below

Point on arc.

Pick point or point number: pick an interior arc point

PT point.

Pick point or point number: pick a north end of the arc as shown below

(c) Issue the Edit – Polyline Utilities – Entities to Polylines command. When prompted:

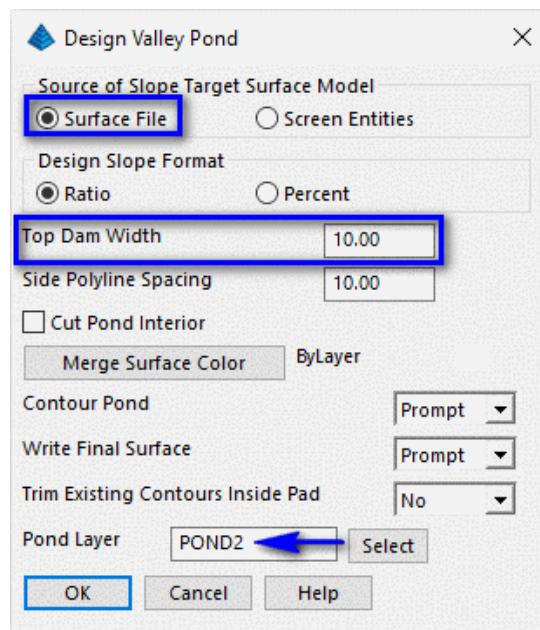

Select lines, arcs, circles, 3DFaces, ellipses, splines, multilines, regions and solids to convert.

[FILter]/<Select entities>: pick the arc you just drew and press Enter twice

Unlike Design Bench Pond, the Design Valley Pond routine requires only a polyline axis line for the center of the dam. The polyline can be a 2-point polyline, or it can have several vertices along its length to create a concave or convex dam structure. The main thing is to "overdraw" the axis polyline, make it ride up on the left and right hillside, well beyond the desired top of dam elevation. This allows the routine to look inward and find the extents of the dam on each hillside, without doing an artificial extension of the polyline. Just "overdo" the length of the axis line and you are in business.

Our curved polyline runs from approximately 1976 on the south side of the valley to approximately 1976 on the north side. It crosses the valley at 1947. Let's decide to put the top of the dam at 1974 even. We will make the dam top 10' wide, with 4:1 downstream and 3:1 upstream slopes.

Issue the Surface – Design Pond – Design Valley Pond command. For this pond, use the starting values as shown below and click **OK** when ready:

When prompted:

Pick top of pond polyline: pick the polyline we just created

Select Existing Surface: specify the TIN file shown below and click the **Open** button when ready:

Pick point within pond: pick within the storage area (east of the arc polyline)

Outslope ratio <2.00>: type 4 and press Enter

Interior slope ratio <2.00>: type 3 and press Enter

Top of dam elevation: 1974

Calculate stage-storage values [<Yes>/No**]?** press Enter

Method to specify storage elevations [<Automatic>/Interval/Manual**]?** specify the Interval (i) method

Starting elevation <1947.68>: 1946 (your values may vary, we'll start just below the lowest elevation)

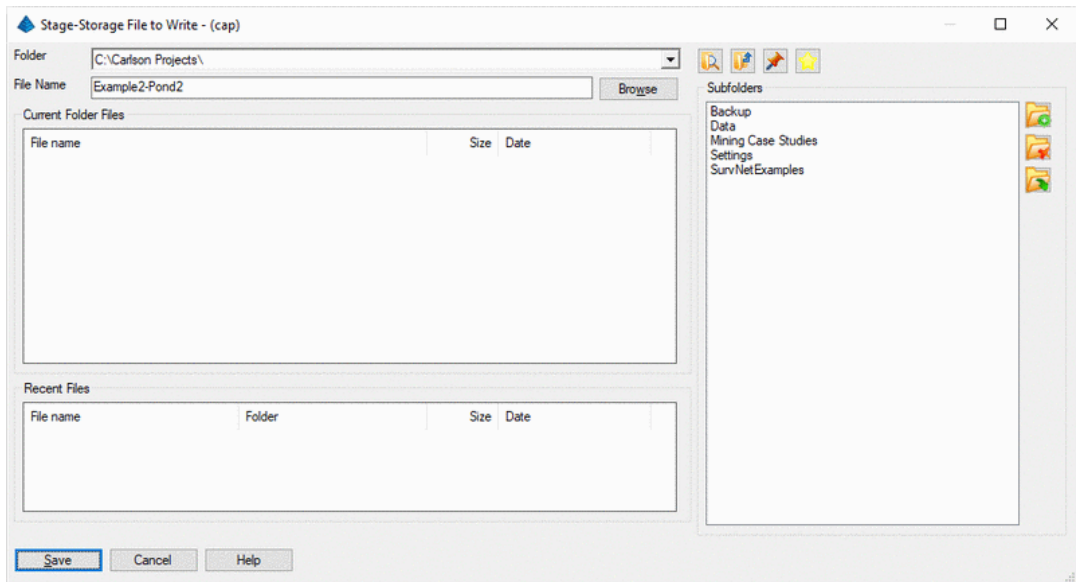

Elevation interval <2.00>: press Enter (review the report, click the **Exit** (doorway) button when ready)

Output triangulation file of final pond surface [Yes/<No>**]?** indicate Yes

Output dam merged with existing or dam only [Merge/<Dam>**]?** indicate M and press Enter (indicate the file name below and click **Save** when ready)

Write stage-storage file [Yes/<No>]? indicate Yes (indicate the file name below and click **Save** when ready)

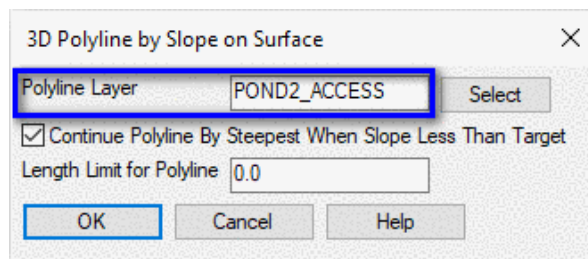

Adjust parameters and redesign pond [Yes/<No>]? press Enter
Contour the pond [<Yes>/No]? indicate No

You should now have a pond that looks like the one in the following image:

10. **Tool 8:** How would you start at the top of the dam (elevation 1974) and build a road running uphill (or downhill) at a 6% grade? Or, in general, how would you obtain 3D polylines for roads and diversion ditches that follow the terrain at prescribed grades starting at desired points? The answer is to issue the 3D Data – 3D Polyline Utilities – 3D Polyline by Slope on Surface command to display the following dialog box:

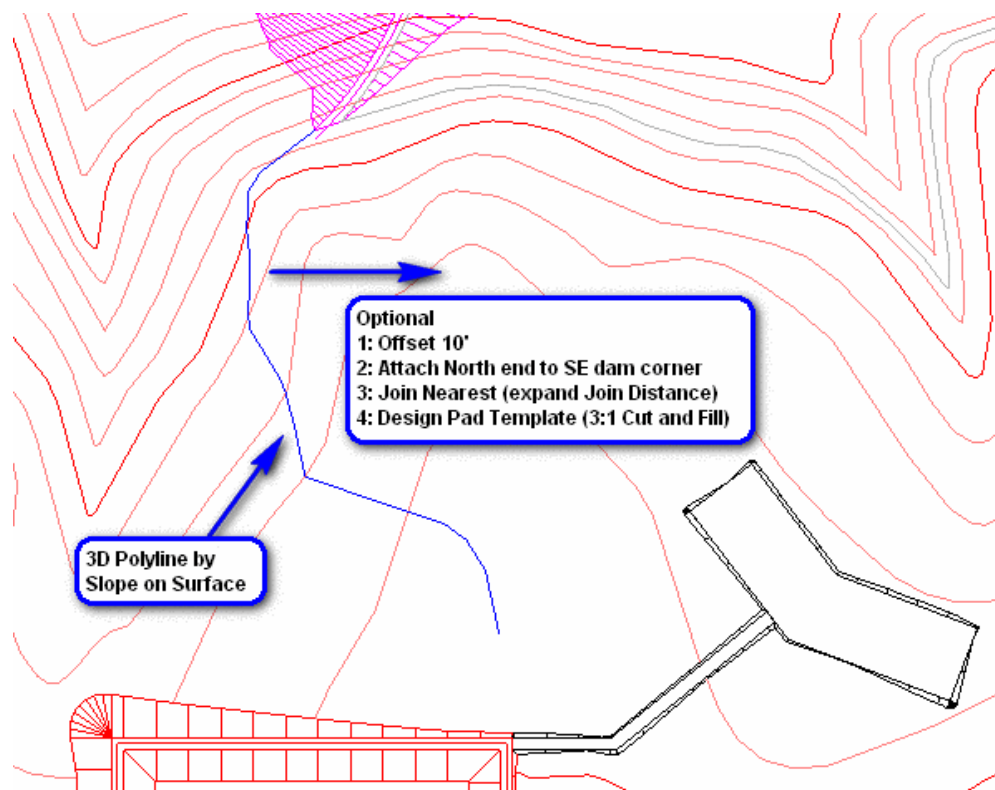

Set the values as shown above and click **OK** when ready. When prompted:

Choose Grid or Triangulation File (dialog): open the surface created in the previous step

Pick origin point of 3D polyline: pick the starting location as shown below

Direction of 3D polyline [\langle Up \rangle / \langle Down \rangle]? type U and press Enter
Direction of 3D polyline facing up slope [\langle Left \rangle / \langle Right \rangle]? type R and press Enter
Slope format [\langle Percent \rangle / \langle Ratio \rangle / \langle Degree \rangle]? press Enter
Enter design slope percent: type 6 and press Enter (a 3D polyline at the cited slope is drawn as illustrated below, your results will vary)
Adjust slope [Yes/ \langle No \rangle]? type N and press Enter
Pick origin point of 3D polyline (Enter to end): press Enter

As optional exercises, construct the **Haul** surface through steps we've already discussed:
 (a) Offset 3D Polyline (offset 10' to the East)

- (b) Perform some minor clean-up (at the north end through the use of grips)
 - (c) Join Nearest (connect the two lines, an expanded Join Distance is warranted if the clean-up work above is performed)
 - (d) Design Pad Template (3:1 Cut and 3:1 Fill slopes, create a surface called *Example2-Haul*)
11. **Tool 9:** In our next example, we wish to create a borrow-pit whose outer perimeter we know and we desire to excavate down to a given elevation with stable side slopes. For the "prep" work, use the image as a guide below to create a **2D polyline** at elevation 0:

NOTE: For this type of shape, it is recommended you use the standard CAD "polyline" (key-in **pline**) with alternating combinations of:

- line
- arc
- line
- follow
- arc
- line
- follow
- (*etc* repeating)
- close

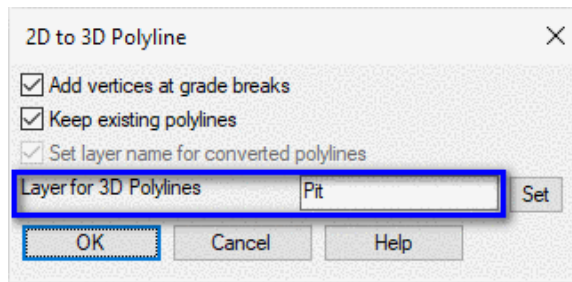

Once complete, issue the 3D Data – 2D to 3D Polyline – By Surface Model command (sometimes called the "drape" command) and when prompted:

Choose Grid or Tmesh File to Process (dialog): open the surface created in the previous step

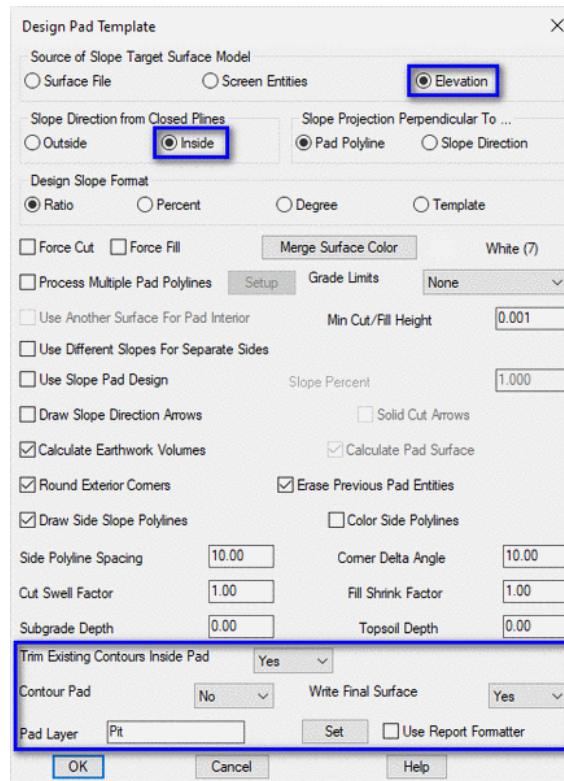

Select polylines and lines to convert.

[FILter]/<Select entities>: pick the 2D polyline

[FILter]/<Select entities>: press Enter

Set the values as shown above and click **OK** when ready. Re-run the Surface – **Design Pad Template** command to display a dialog box similar to that shown below:

Set the values as shown above paying particular attention to the highlighted items and click **OK** when ready. When prompted:

Pick pad polyline: pick the 3D polyline just created

Fill outslope ratio <3.000>: press Enter

Cut outslope ratio <3.000>: press Enter

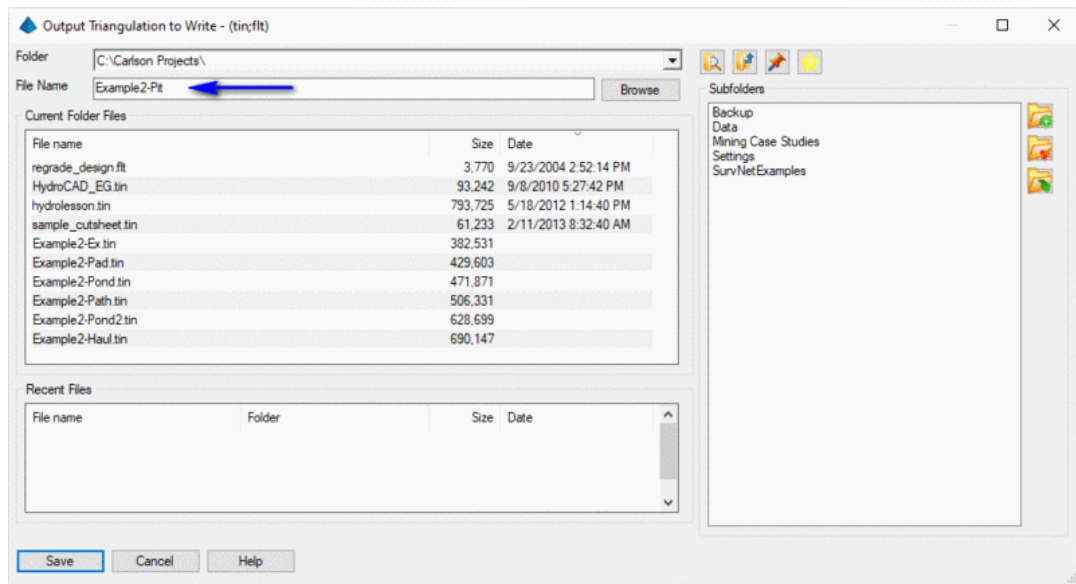

Target surface elevation: type 1976 and press Enter

Select Existing Surface for Volumes (Cancel for None) (dialog): open the surface created in the previous step

Review the **Pad Report** and click the **Exit** (Doorway) button when ready. Prompting resumes:

Adjust parameters and redesign pad [Yes/<No>]? press Enter

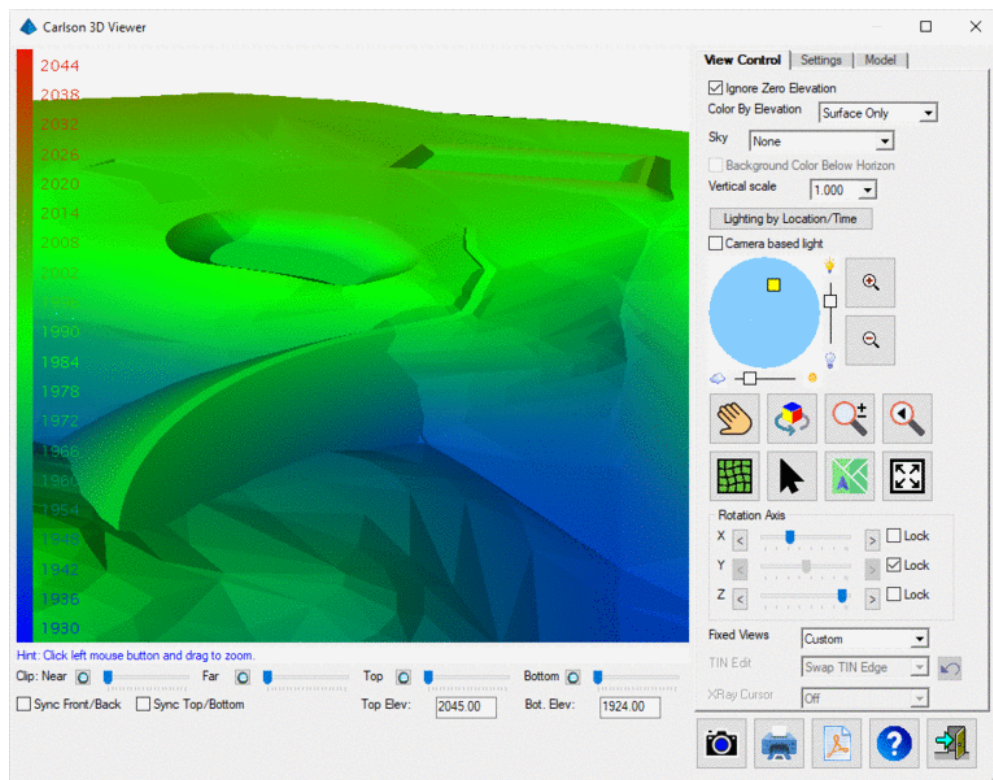

Output Triangulation to Write (dialog): set the value as shown below and click **Save**

Prompting resumes:

Retain trimmed polyline segments [Yes/<No>]? type N and press Enter

Issue the View – 3D View – Surface File Viewer command to examine the results of the most recently created surface model thus far as illustrated below:

Click the **Exit** (Doorway) button when ready.

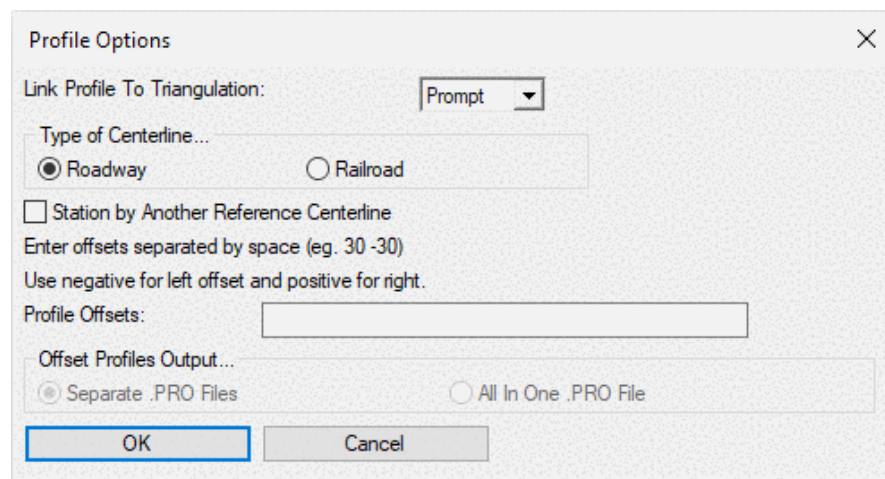

12. **Tool 10:** Our next goal is to build a diversion ditch around the dam. Re-issue the **Draw 2D Polyline** command that starts on the water-side of the valley dam near the 1972 contour (as you may recall, the valley dam has a top elevation of 1974) and curves around into the hill and into the drainage below the dam as shown below:

Let's create an *existing ground* ground profile from the TIN so that we can use this profile as a reference for the *design* profile to follow. Issue the Profiles – Create Profile From – Profile from Grid or Triangulation Surface command. When prompted:

Choose Grid or Triangulation File to Process (dialog): open the surface created in the previous step

Profile Options (dialog): set the options as shown below and click **OK**

Choose Profile File to Write (dialog): set the options as shown below and click **Save**

Polyline should have been drawn in direction of increasing stations.

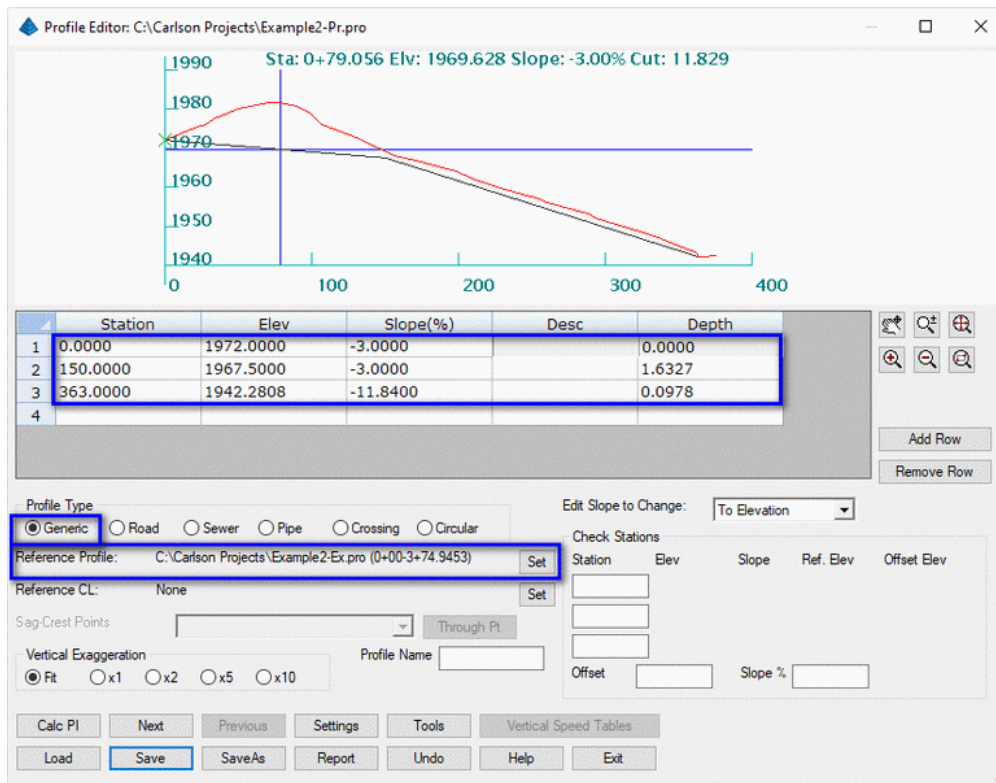

CL File/⟨Select centerline polyline⟩: pick the polyline you just drew

Starting station <0.0>: press Enter

Issue the Profiles – Profile Editor and when prompted, create the new file as illustrated below and click the **Open** button ready:

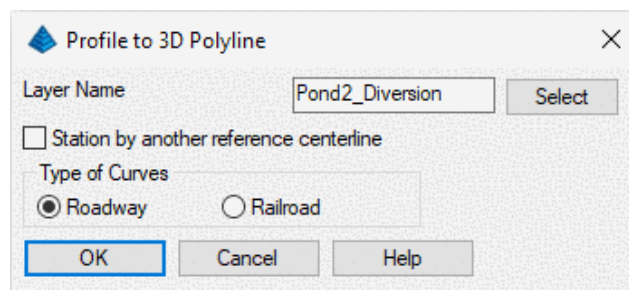

This displays a dialog box similar to that shown below:

Within this dialog box, perform the following actions:

- Use the **Set** to set the **Reference Profile** of the *existing ground* profile you just created
 - Specify a starting **Station** of **0** and give it a depth of **0**
 - Specify an ending **Station** of approximately that shown in the *Reference Profile* and give it a depth of **0**
 - Use the **Add Row** button to specify an internal vertical hinge point at a station of your choosing and a depth ≥ 0.75 . With the elevation/grade calculated, adjust the grade for the first record to be the next even percent as illustrated above
 - In all cases, make sure the new profile is always completely below *existing ground* so that the diversion ditch is always in cut
 - Alternatively, end the profile at a station where desired so that any pond overflow is clear of the dam and simply flows over hill
 - Save and exit from the **Profile Editor** when complete
13. **Tool 11:** Our next topic of discussion will focus on converting/combining the 2D polyline we drew along with that of the design profile to create a properly sloped 3D polyline representing one edge of the diversion ditch. Issue the Profiles – Profile to 3D Polyline command to display a dialog box similar to that shown below:

Set the values as shown above and click the **OK** button when ready. When prompted:

Polyline should have been drawn in direction of increasing stations.

CL File/<Select centerline polyline>: pick the 2D polyline we created earlier

Starting station <0.0>: press Enter

Select Profile to Read (dialog): select the design profile we created earlier and click **Open**

Erase centerline [Yes/<No>]? type Y and press Enter

The result is a 3D polyline along the length of the 2D polyline but at elevations defined by the design profile.

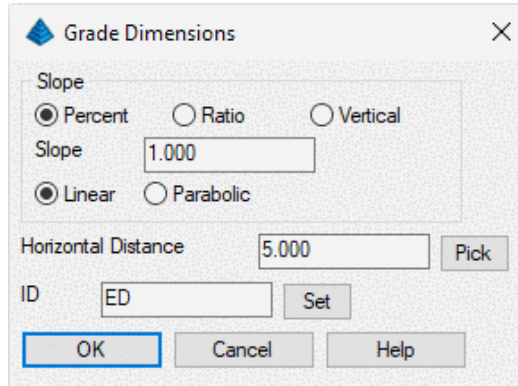

- 14. Tool 12:** Our next task will be to line the diversion ditch with concrete, include a traditional roadway curb element (to help control erosion) and create tie-slopes from the back of the curb feature. Issue the Roads – Design Template command to display a dialog box similar to that shown below:

We'll focus on this horizontal strip of icon options:

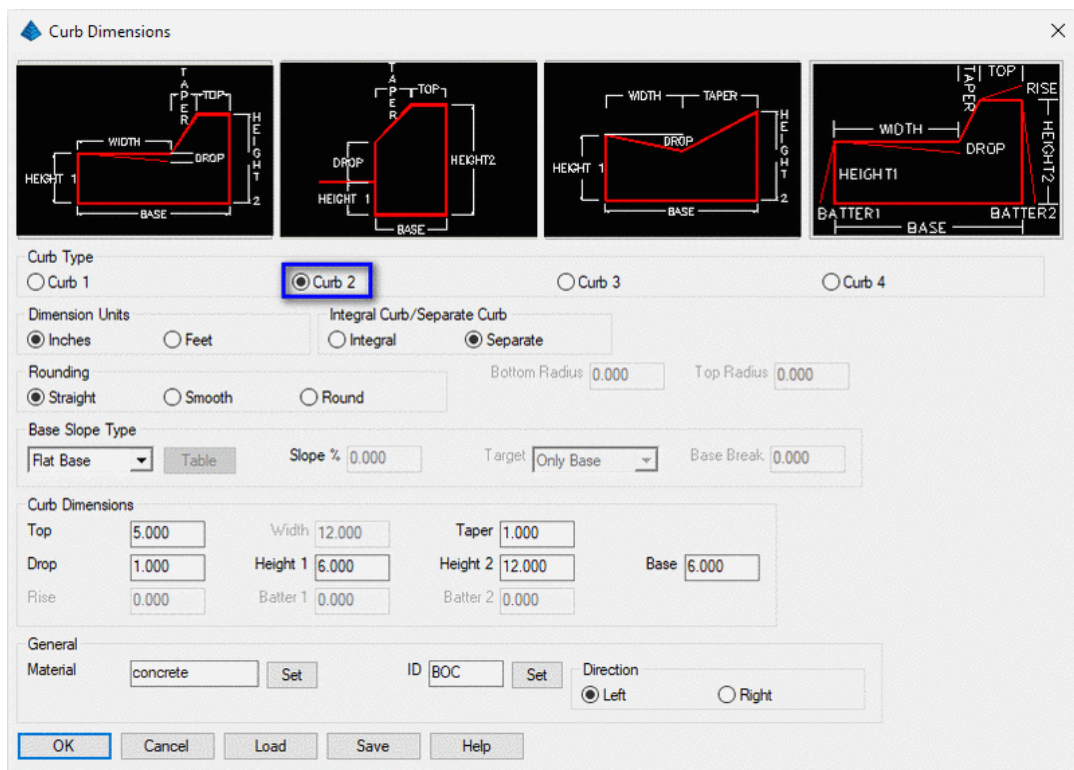

- To begin, click on the **Grade** button to display a dialog box similar to that shown shown below:

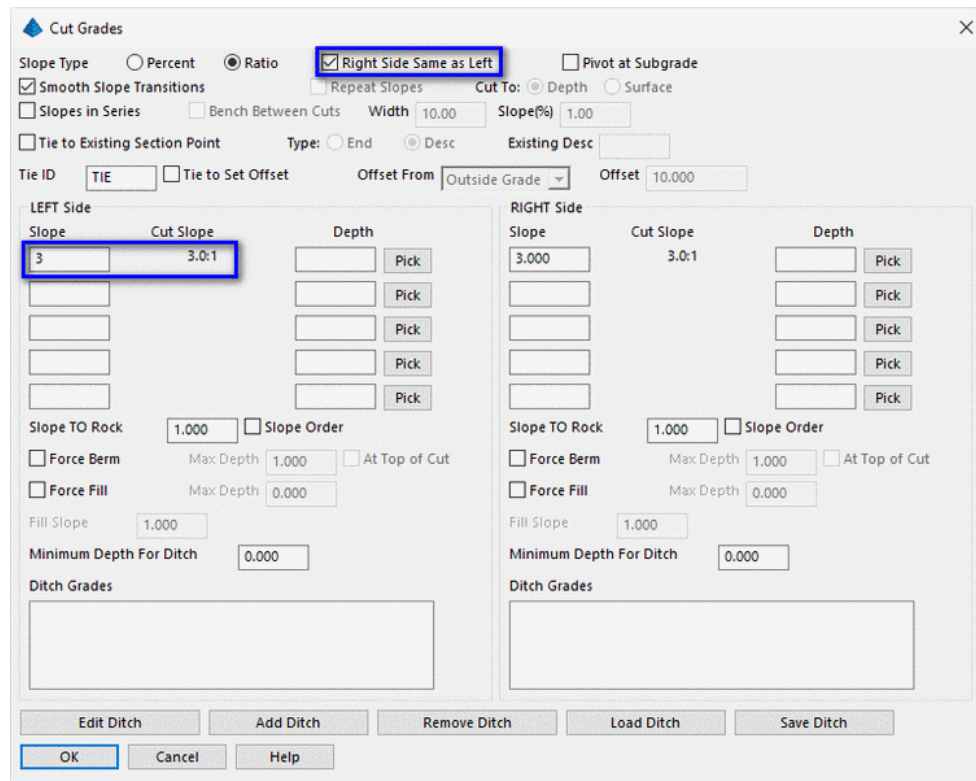

Set the values as shown above to ultimately create a 10' wide surface that drains to the center at a 1% slope and terminates with an **ID** of **ED** (edge drainage). Click **OK** when ready.

- Click on the **Curb** button to display a dialog box similar to that shown shown below:

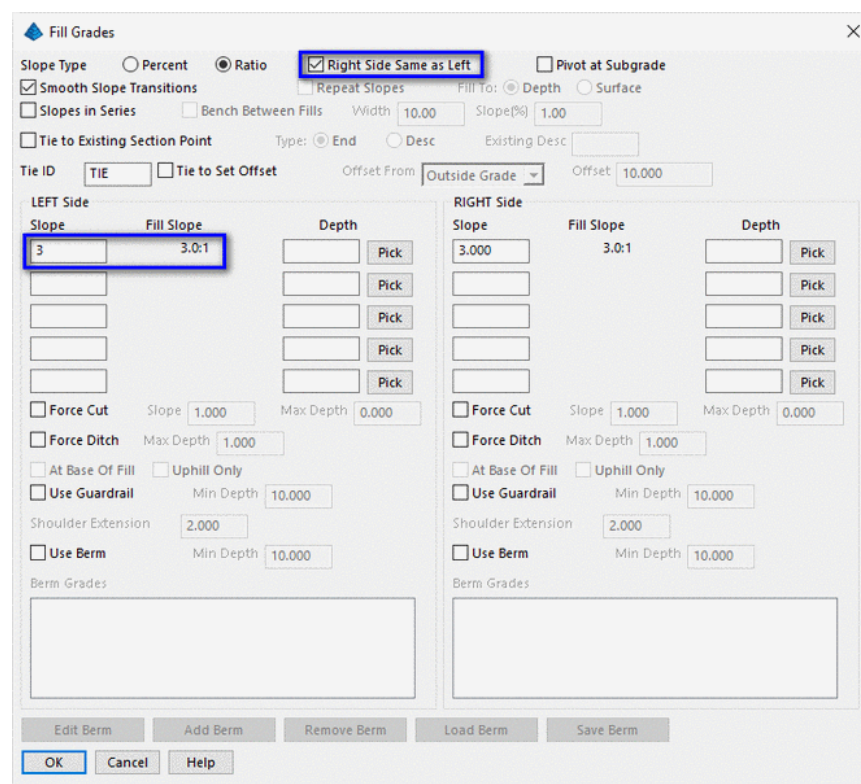

Set the values as shown above to ultimately create a simple concrete curb with an **ID** of **BOC** (back of curb). Click **OK** when ready.

- Click on the **Cut** button to display a dialog box similar to that shown shown below:

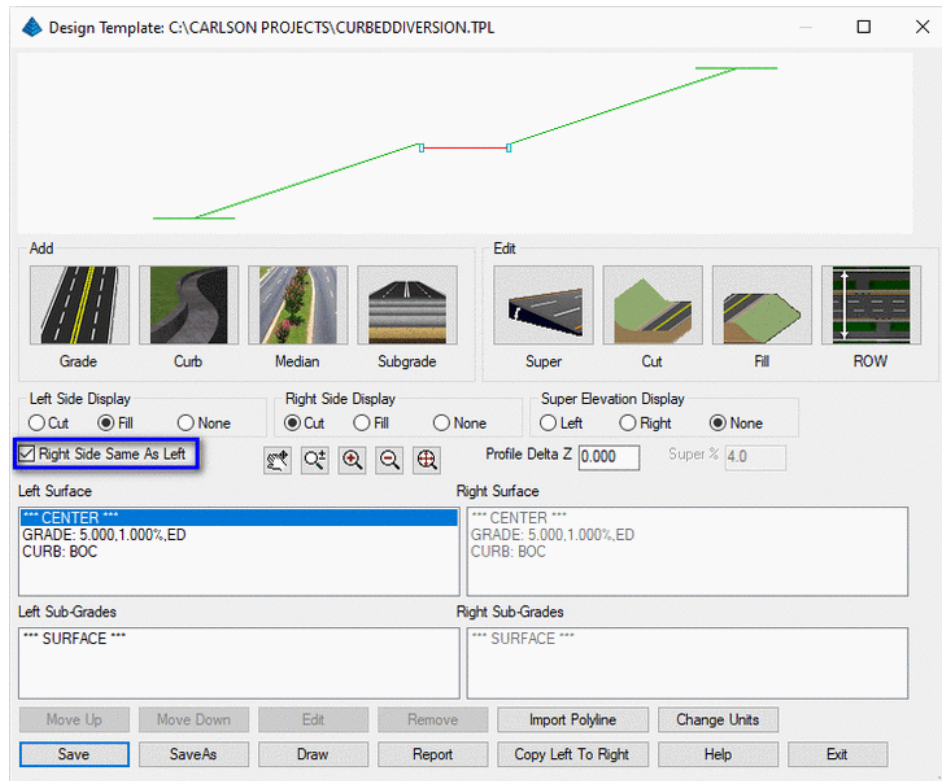

Set the values as shown above to ultimately create a single catch-slope used on both sides of the template for Cut scenarios with an **ID** of **TIE** (tie point). Click **OK** when ready.

- Click on the **Fill** button to display a dialog box similar to that shown shown below:

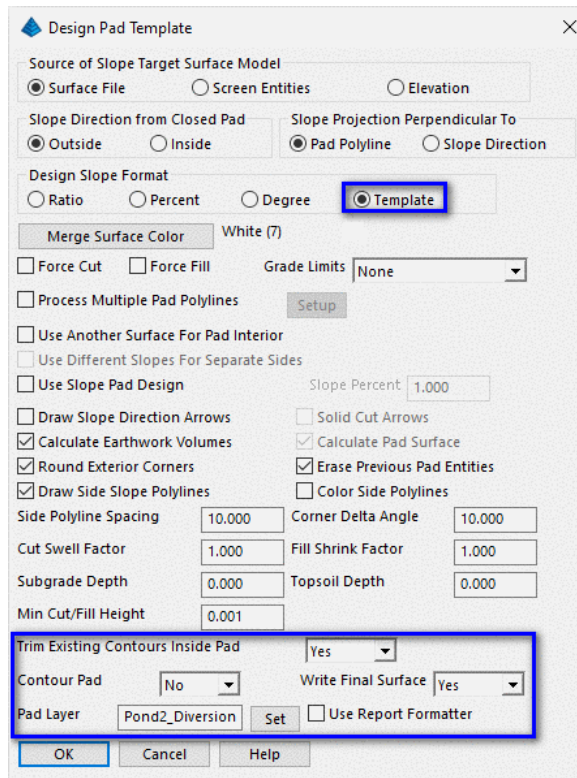

Set the values as shown above to ultimately create a single catch-slope used on both sides of the template for Fill scenarios with an **ID** of **TIE** (tie point). Click **OK** when ready.

Verify the completed template resembles that shown below (paying attention to the highlighted item) and click **Save** and **Exit** when ready:

Now let's use the Surface – **Design Pad Template** routine one more time as illustrated below:

For the first time, we have selected the **Template** option as illustrated above. Set the values as shown above

paying particular attention to the highlighted items and click **OK** when ready. When prompted:

Pick pad polyline: pick the 3D polyline created earlier

Select Slope Target Surface (dialog): open the most recent surface for the project

Select Template (dialog): pick the template file created earlier

Review the **Pad Report** and click the **Exit (Doorway)** button when ready. Prompting resumes:

Merge Final Surface (dialog): click **Yes**

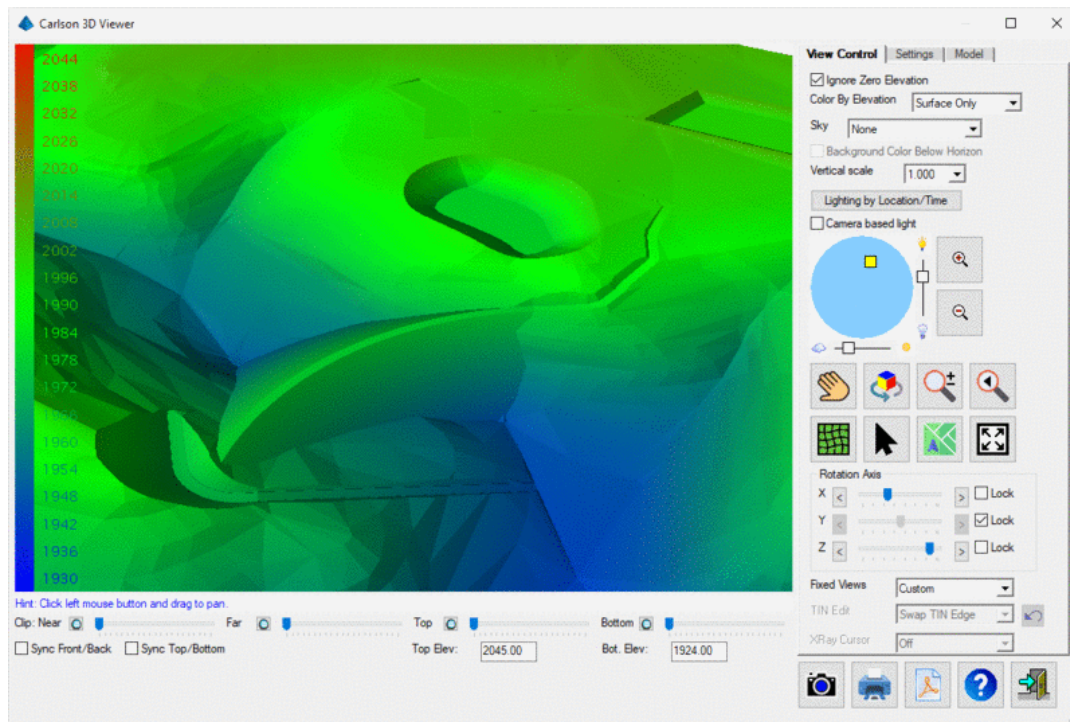

Output Triangulation to Write (dialog): set the value as shown below and click **Save**

Prompting resumes:

Retain trimmed polyline segments [Yes/<No>]? type N and press Enter

Issue the View – 3D View – **Surface File Viewer** command to examine the results as illustrated below:

Click the **Exit (Doorway)** button when ready.

Finally, let's see how much earthwork has been moved since we started. Issue the **Surface – Volumes by Triangulation – Two Triangulation Surface Volumes** command. When prompted:

Select EXISTING Surface Triangulation File (dialog): open the first surface model created in this project

Select FINAL Surface Triangulation File (dialog): open the last surface for the project

Volume Report Options (dialog): accept the default values

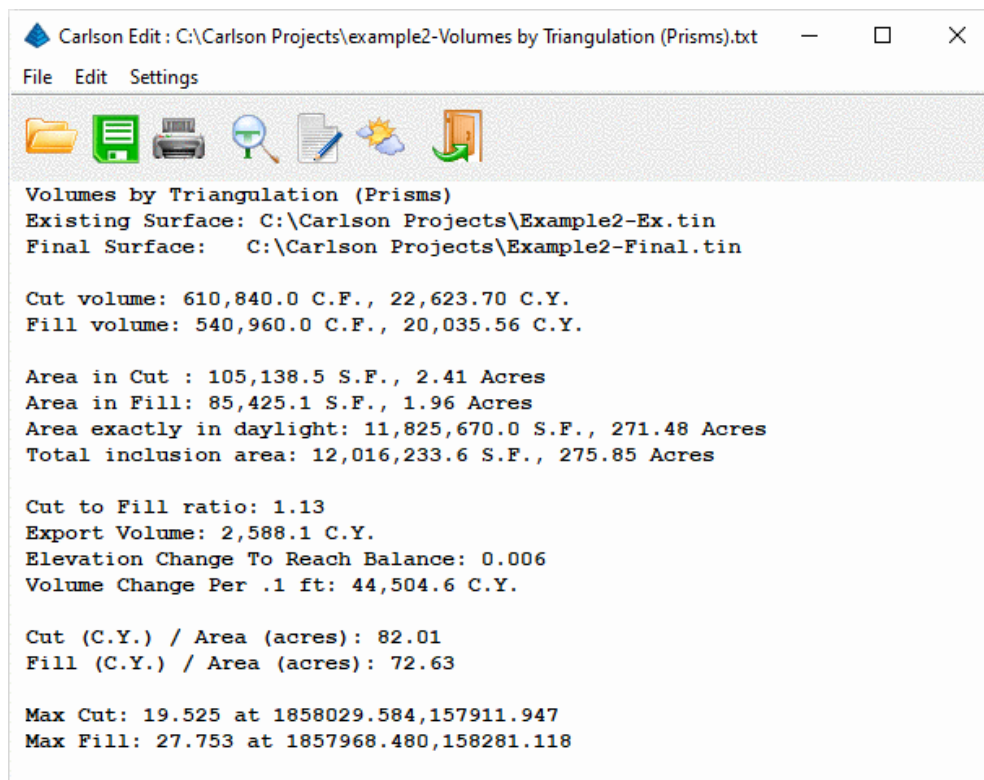

Select Inclusion polylines or press Enter for none.

[FILter]/<Select entities<: press Enter

Select Exclusion polylines or press Enter for none.

[FILter]/<Select entities<: press Enter

Review the results as illustrated below (your results will be different):

Click the **Exit** (Doorway) button when ready.

This completes the tutorial: A Dozen Tools for Surface Design.

Calculate Volumes by Five Methods

For this tutorial, we'll be using a sample stockpile drawing and calculating its volume using five distinct techniques:

1. **Stockpile Volumes:** Creates grid surfaces from perimeter polyline and surface entities and calculates volumes in one command
2. **Volumes By Layers:** Creates grid surfaces from existing and design layers and calculates volumes in one command
3. **Two Grid Surface Volumes:** Calculates volumes between two grid files
4. **Volumes By Triangulation:** Calculates volumes between two triangulation files
5. **Calculate Sections Volumes:** Calculates volumes between two section files using volumes by average end areas

Each of these routines has its own advantages. You can choose the routine that best suits your data or run multiple methods as a check of the volumes. The volume reports for each of these routines will vary slightly due to using different types of surface models that have different resolutions. These volume differences should be less than 2%.

A Results Summary of the various volume methodologies is also provided.

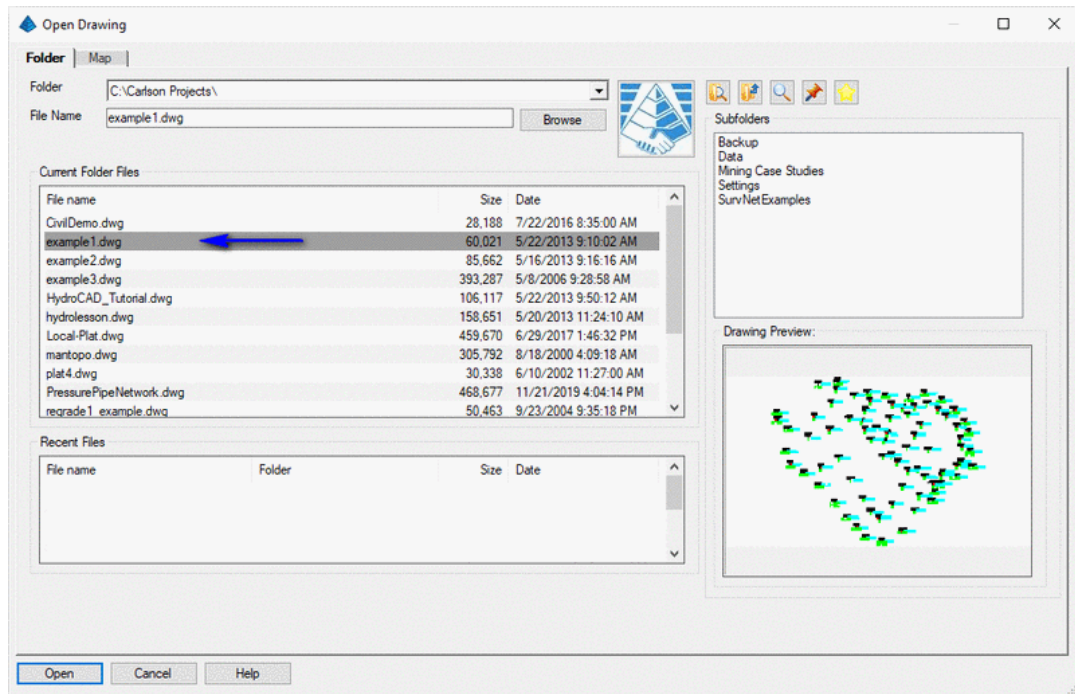

If there is a greater difference, try increasing the resolution of the surface models. For grids, make the grid cell size smaller and for sections, make the station interval smaller. If there is still a significant difference, then the cause should be investigated by checking the source data.

Common Steps

The following are common preparation steps for all five volume methods:

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.

- If you are taken directly into CAD, click File – **Open**.
Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **example1.dwg** file.

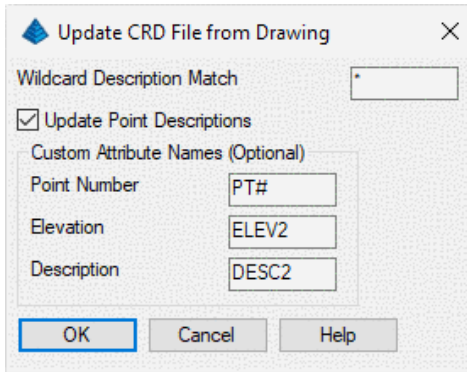

Use the File – **Save As** to save a copy named **example1-v.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties.

2. Ensure you are in the Civil program by issuing the Settings – Carlson Menus – **Civil Menu** command. Since our drawing contains point data, let's house it in a related *coordinate file* for future use. Issue the Points – Set Coordinate File command to display a dialog box similar to that shown below:

Set the value as shown above and click **Open** when ready. Next, issue the Points – Point Utilities – Update CRD File from Drawing command (also found under Points – Coordinate File Utilities) to display a dialog

box similar to that shown below:

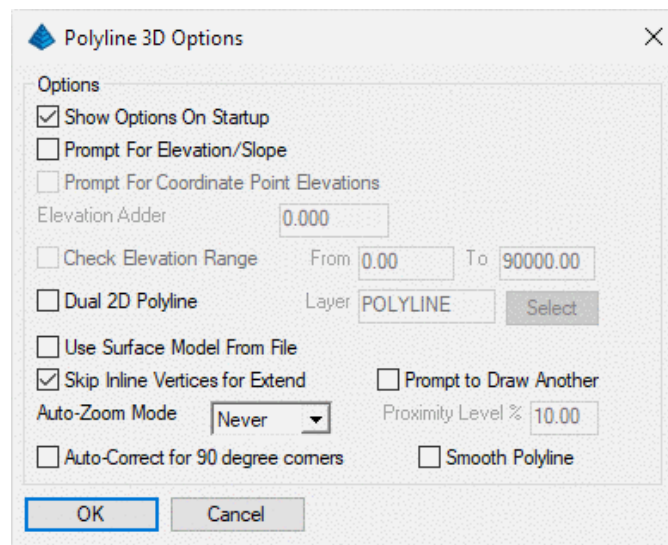

Accept the default values and click **OK** when ready. When prompted:

Select Carlson, LDD, Softdesk, InRoads, EaglePt, Geodimeter, Leica or MicroSurvey Points.

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

3. Due to the shape of the data (and in an effort to get consistent results), we'd like to develop a boundary (or *inclusion*) polyline around the data set. There are several ways to accomplish this:
 - Through the use of the **Survey** module and its Survey – Draw Field to Finish command, or,
 - Through the use of the Draw – 3D Polyline command, or,
 - Through the use of the Draw – Shrink-Wrap Entities command, or,
 - Through the use of the Surface – Stockpile/Pond/Pit Volumes – Draw 3DPoly Perimeter command (run it now) to display a dialog box similar to that shown below:

Set the values as shown above (click **OK** when ready) and when prompted:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: type the range of 2000-2028 and press Enter

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: type C and press Enter

The drawing should resemble that shown below:

Let's begin the volume calculation processes.

Volume Method 1 - Calculate Stockpile Volume

The **Calculate Stockpile Volume** routine is based on a *grid* surface methodology like the Two Surface Volumes discussion below. The difference with this routine is that it builds the grid surfaces within the routine to save time otherwise needed to build the grid files. The fewer steps make this routine faster and easier but it doesn't have options for checking surfaces. Instead the input data entities should be checked before running this routine. Also, **Calculate Stockpile Volume** only applies to volumes calculations when the volume is all Fill.

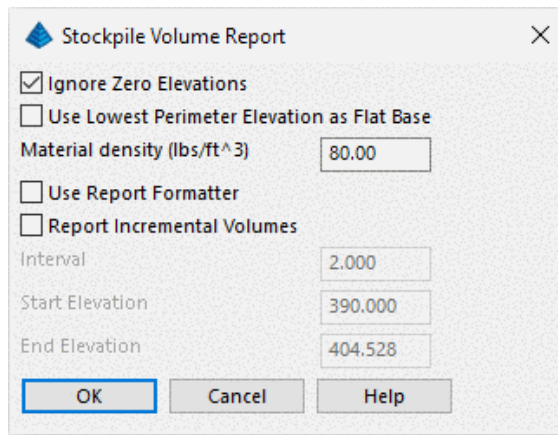

1. Issue the Surface – Stockpile/Pond/Pit Volumes – Calculate Stockpile Volume command. When prompted:

Select stockpile entities and perimeter.

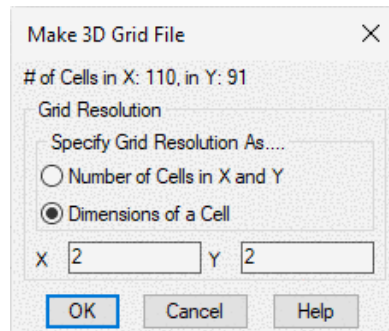

[FILTER]/<Select entities>: type ALL and press Enter (The program looks for a closed 3D polyline on the PERIMETER layer to use as the inclusion perimeter and the base surface model. If this polyline is not found, then the program will prompt to select the perimeter polyline. All the selected entities including the perimeter are used to model the second surface of the stockpile top).

[FILTER]/<Select entities>: press Enter

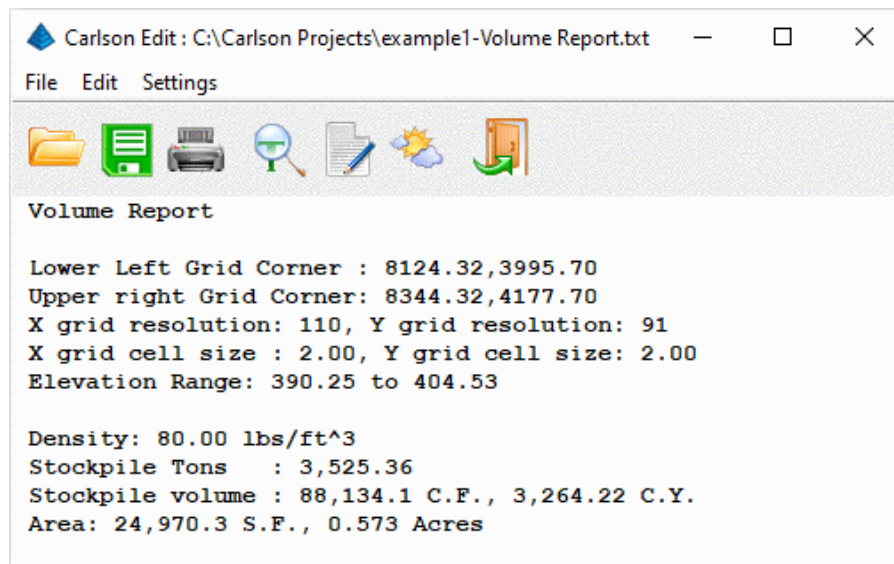

The routine offers various reporting capabilities. Let's assume a typical density for a pile of road salt as illustrated below and click **OK** when ready:

Specify the grid resolution as shown in the dialog below and click **OK** when ready:

The result is summarized in a volume report in the Standard Report Viewer similar to that shown below:

Click the **Exit** (Doorway) button to dismiss the report.

NOTE: The limits of the grid are determined automatically and shown in the report. For the sake of accuracy, the next two methods will use the grid parameters shown above.

NOTE: For situations involving a Cut-only scenario (such as a pond or pit), use the Surface – Stockpile/Pond/Pit Volumes – Calculate Pond/Pit Volume command.

Volume Method 2 - Volumes By Layers

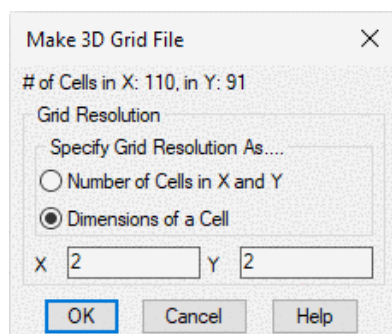

Let's explore a simple routine that handles both Cut and Fill scenarios.

1. Issue the Surface – Volumes By Grid Surface – Volumes By Layers command. When prompted:

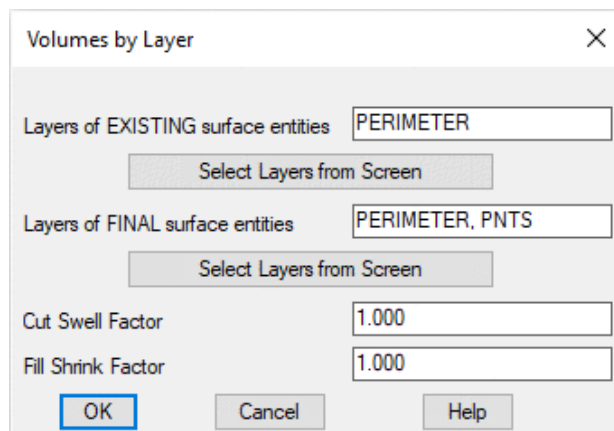

Pick Lower Left limit of surface area <8124.32,3995.70>: indicate the values shown to the left and press Enter (or pick a lower left limit)

Pick Upper Right limit of surface area <8344.32,4177.70>: indicate the values shown to the left and press Enter (or pick an upper right limit)

Specify the grid resolution as shown in the dialog below and click **OK** when ready:

A dialog box similar to that shown below appears:

Click the **Select Layers from Screen** buttons and when prompted:

- **Select entities on layers of Existing surface.**
[FILter]/<Select entities>: pick the PERIMETER polyline and press Enter
- **Select entities on layers of Final surface.**
[FILter]/<Select entities>: type ALL and press Enter twice

Once the values are as shown above, click **OK** when ready. Prompting resumes:

Select surface entities on corresponding layers.

[FILter]/<Select entities>: type ALL and press Enter twice

Select the Inclusion perimeter polylines or ENTER for none:

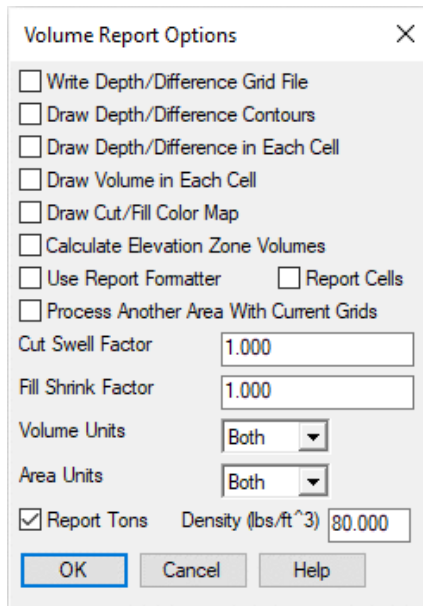

[FILter]/<Select entities>: pick the PERIMETER polyline and press Enter

[FILter]/<Select entities>: press Enter

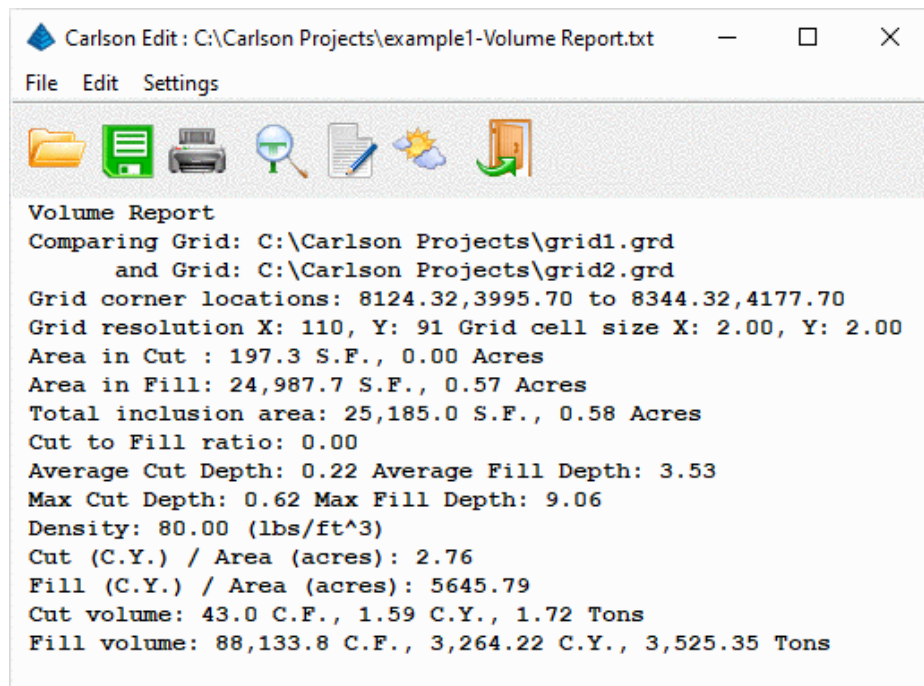

Select the Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Volume Report Options (dialog): set the values as shown below and click **OK** when ready:

The volume report similar to that shown below appears:

Click the **Exit** (Doorway) button to dismiss the report.

NOTE: Similar to Calculate Stockpile Volume, this routine builds the grid surfaces within the routine to save the steps of creating grid files. The difference between this routine and the *Calculate Stockpile Volume* routine is that **Volumes By Layers** uses entities on specified layers for **Existing** and **Final** scenarios to build the surfaces and it will calculate both Cut and Fill volumes.

Volume Method 3 - Two Grid Surface Volumes

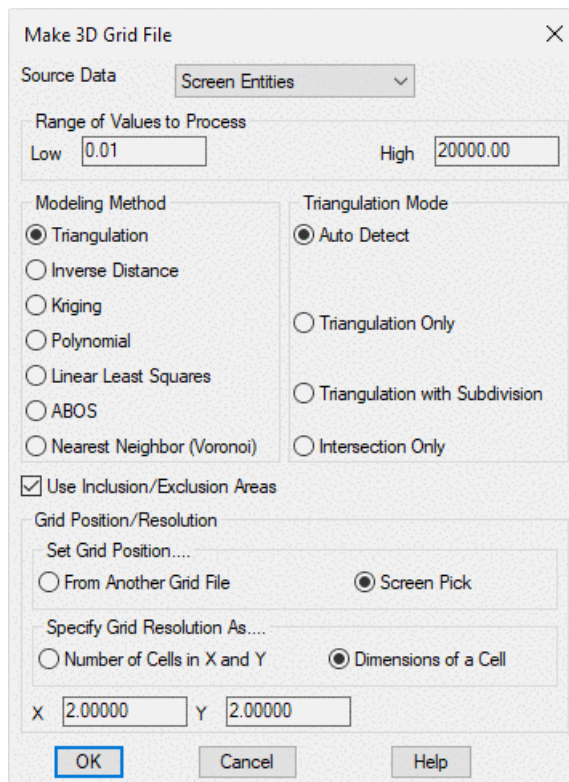

For the next example, we must create the two grid files; one representing an assumed base-ground (*Existing*) surface, the other representing the surface of the pile (*Final*).

1. Issue the Surface – Make 3D Grid File command. When prompted:

Grid File to Create (dialog): supply the file name indicated below and click **Save** when ready:

A dialog box similar to that shown below appears. Set the values as shown and click **OK** when ready:

Prompting resumes:

Pick first grid corner <8124.32,3995.70>: press Enter (notice the grid limit from the previous example is defaulted)

Pick opposite grid corner <8344.32,4177.70>: press Enter

Select the Inclusion perimeter polylines or ENTER for none.

[Filter]/<Select entities>: pick the PERIMETER polyline

[FILter]/<Select entities>: press Enter

Select the Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Select points, lines, polylines and faces to grid from.

[FILter]/<Select entities>: pick the PERIMETER polyline again and press Enter

[FILter]/<Select entities>: press Enter

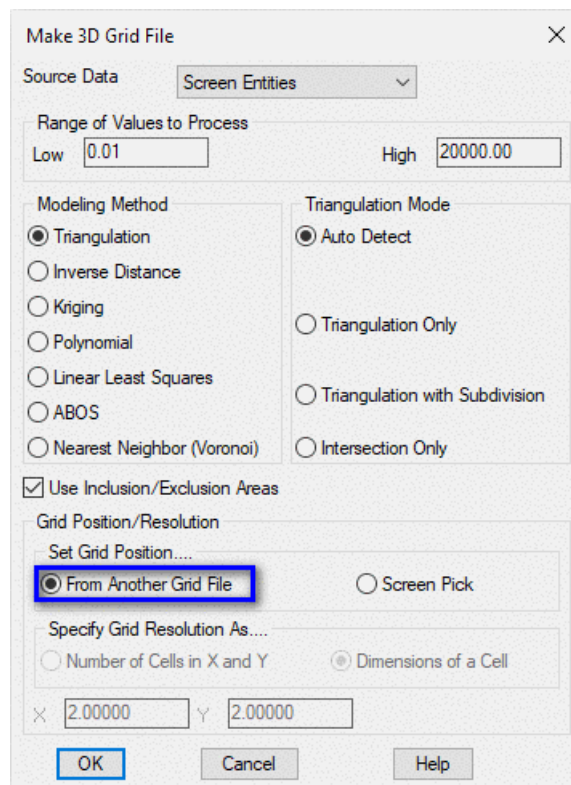

A grid file representing an assumed base-ground (*Existing*) surface is written.

2. Re-run the Surface – **Make 3D Grid File** command. When prompted:

Grid File to Create (dialog): supply the file name indicated below and click **Save** when ready:

A dialog box similar to that shown below appears. Set the values as shown and click **OK** when ready:

NOTE: For the volume routine to follow, the two grids to compare should have matching grid positions and resolution. Prompting resumes:

Grid File to Get Position From (dialog): select the grid file created earlier and click **Open** when ready
Select the Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the PERIMETER polyline

[FILter]/<Select entities>: press Enter

Select the Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Select points, lines, polylines and faces to grid from.

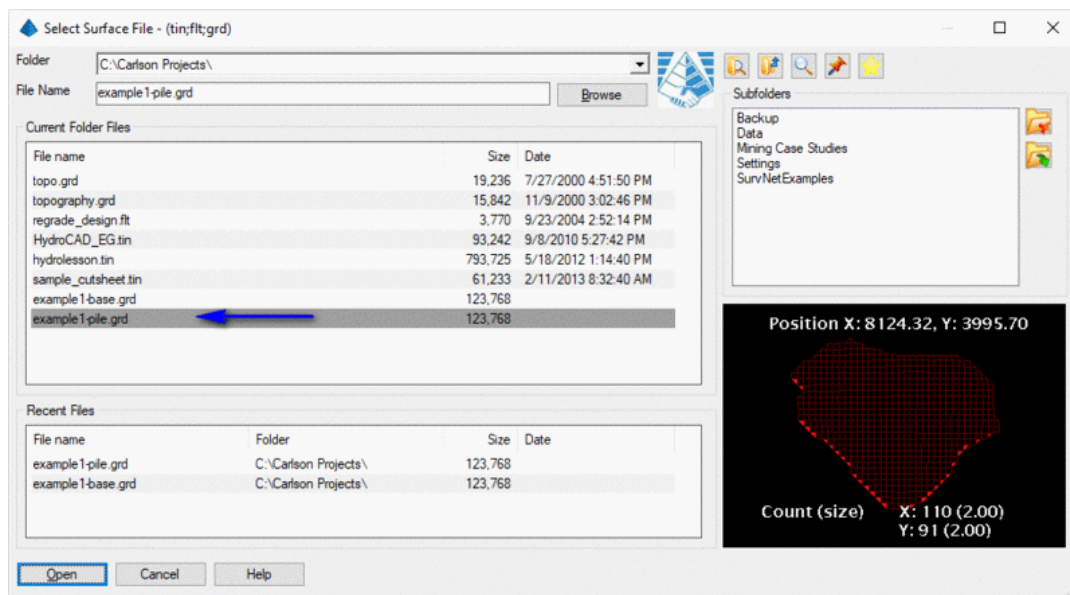

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

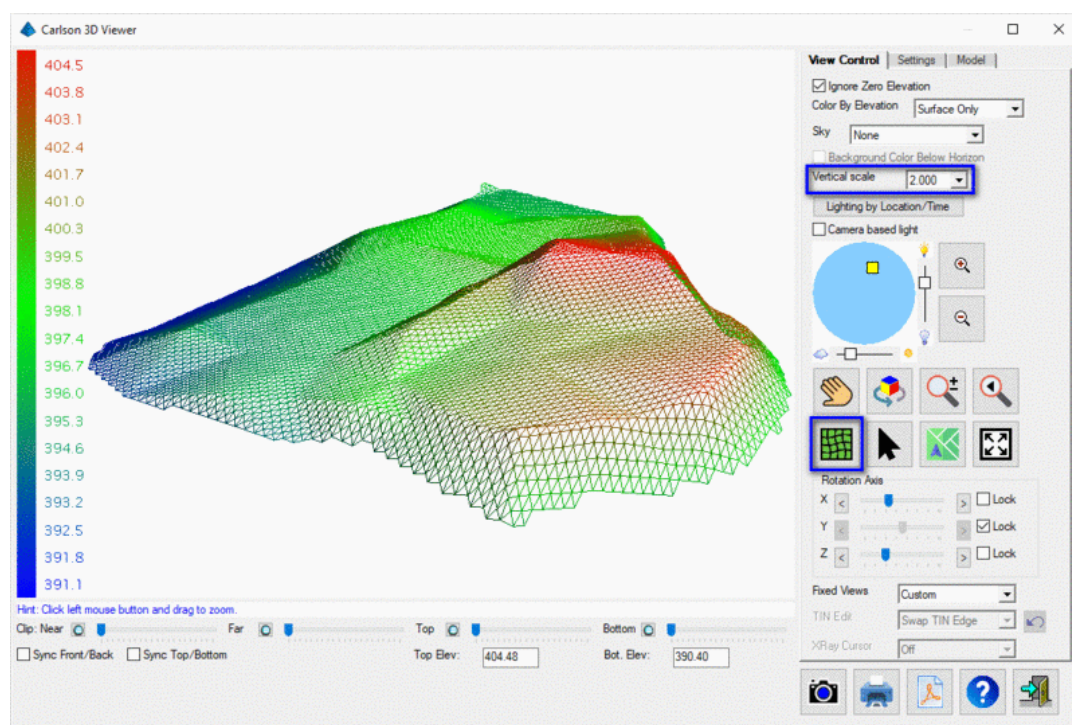

A grid file representing the surface of the pile (*Final*) is written.

3. *Optional:* Presume we might want to check the surface(s) just created. This step is optional to verify that the surfaces are good by checking for bad elevation data points and that the surfaces follow the data points. Issue the View – 3D View – Surface File Viewer and when prompted:

Select Surface File (dialog): select the grid file that was just created and click **Open** when ready:

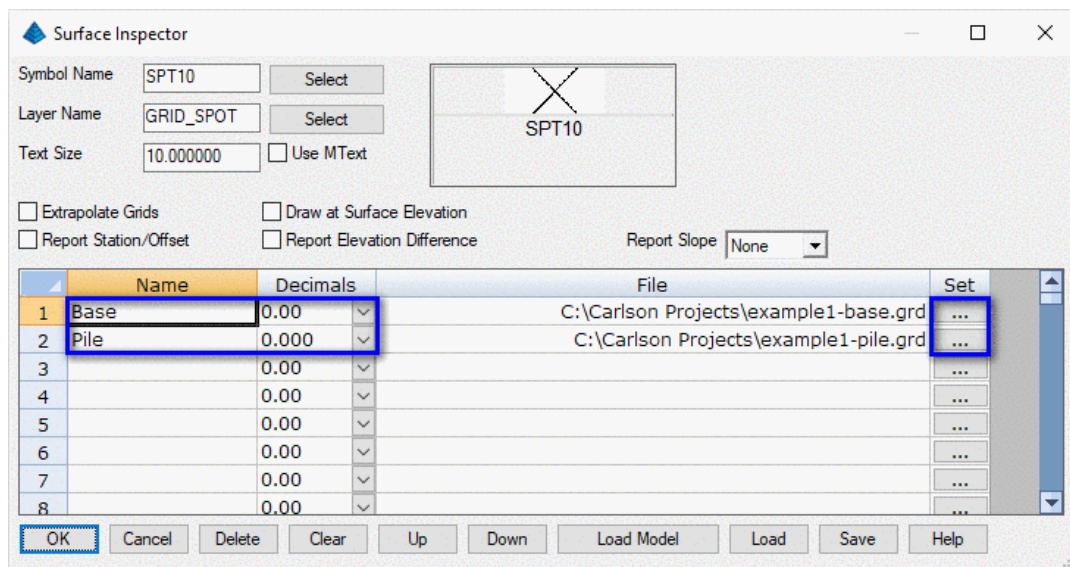

A 3D Viewer window similar to that shown below appears:

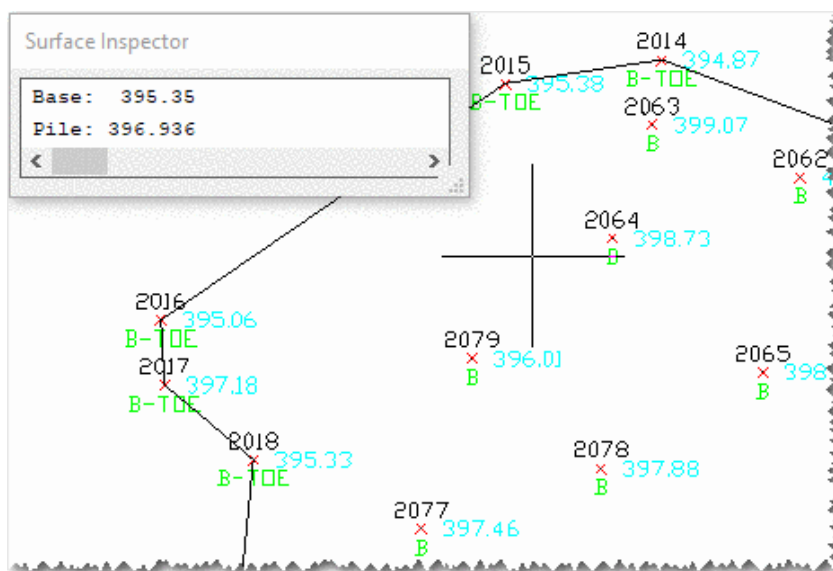

In the 3D Viewer dialog, move the pointer near the outer edge of the graphic and the cursor will change to an Z symbol which orients the view about the vertical axis. Moving the cursor to the interior of the graphic and the cursor will change to an X/Y symbol. Click and drag from the bottom upward to change the isometric viewing angle. You can also set the **Vertical Scale** to 2.0 and enable the **Color By Elevation** toggle for better viewing of the elevation difference. Experiment with any desired remaining options. When ready, click the **Exit** (Doorway) button.

- Now, let's check some spot elevations. Issue the Surface – Surface Inspector command to display a dialog box similar to that shown below:

Use the highlighted controls to set the values as shown above. When ready, click the **OK** button. As you position the cursor into the data set, notice a real-time reporting of the two surface elevations as illustrated below:

Check that the grid elevations match the point elevations reasonably well. Remember that the base elevations are using only the B-TOE points. The elevations won't match exactly with grid surfaces because the grid model is at the resolution of the grid cells. When finished checking, press **Enter**.

- Now that you have the *Base* and *Pile* grid files, issue the Surface – Volumes By Grid Surface – Two Grid Surface Volumes command. When prompted:

Select the Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the PERIMETER polyline

[FILter]/<Select entities>: press Enter

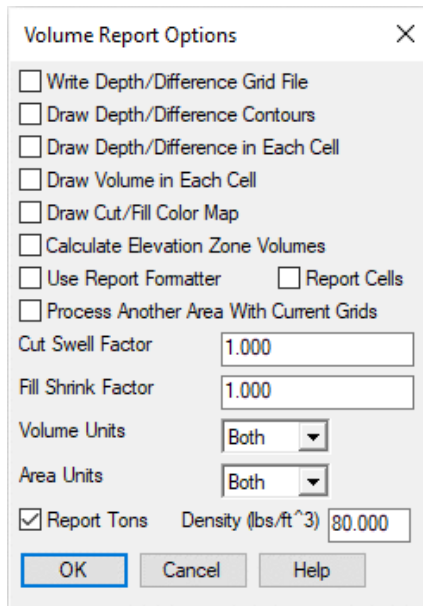

Select the Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

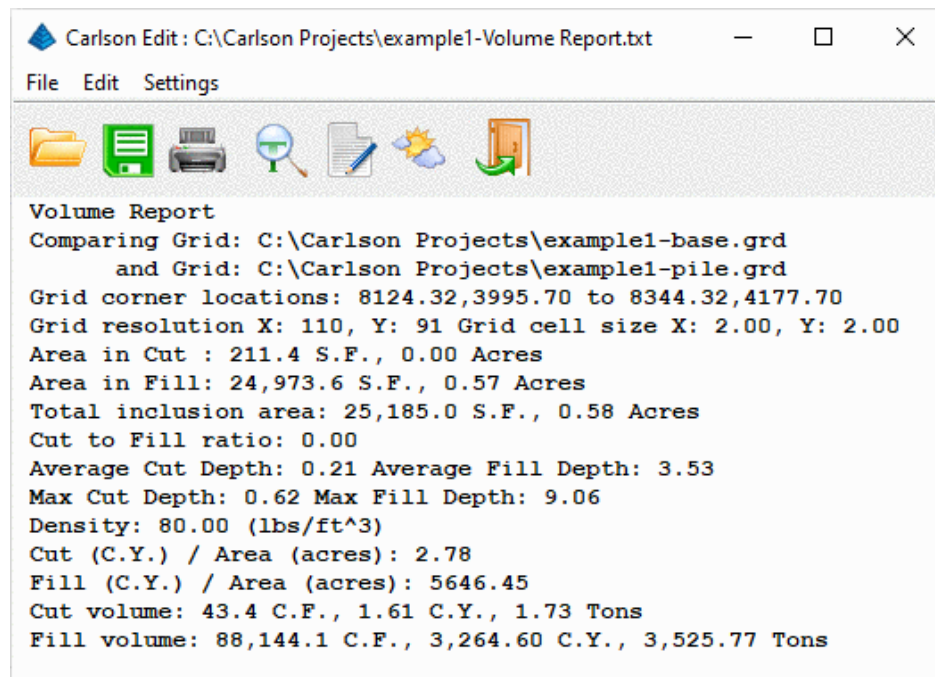

Select Base Grid File (dialog): select the *Base* grid file and click **Open** when ready

Select Final Grid File (dialog): select the *Pile* grid file and click **Open** when ready

Volume Report Options (dialog): set the values as shown below and click **OK** when ready:

The volume report similar to that shown below appears:

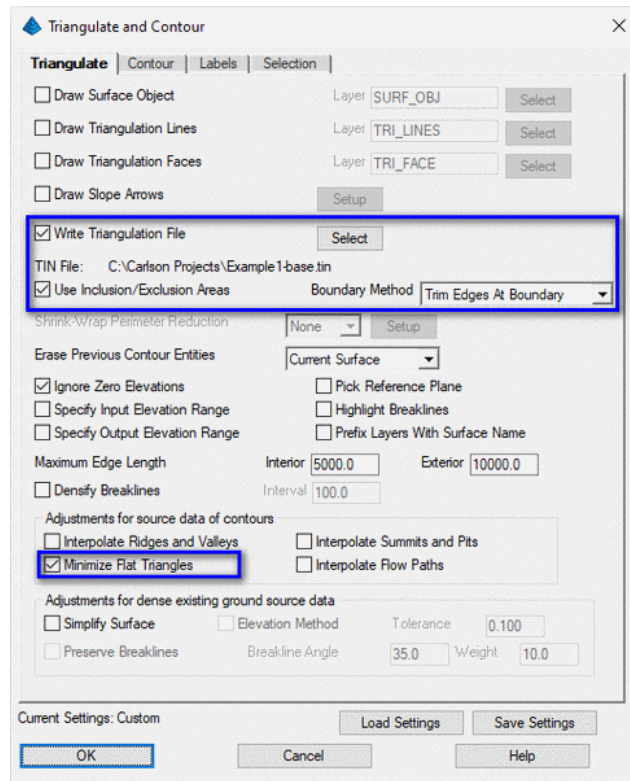

Click the **Exit** (Doorway) button to dismiss the report.

NOTE: Although *grid* files produce relatively accurate volumes (based on the *grid resolution*), their primary value lies in the ability to hand-calculate the results for validation purposes. With a grid resolution (*e.g.* 2' x 2') and the average elevation of each grid cell (resulting in a grid depth), a grid cell volume can be computed through traditional means.

Volume Method 4 - Volumes By Triangulation

For precise surface-to-surface volumes, creating *triangulated irregular network* (TIN) files is the preferred methodology.

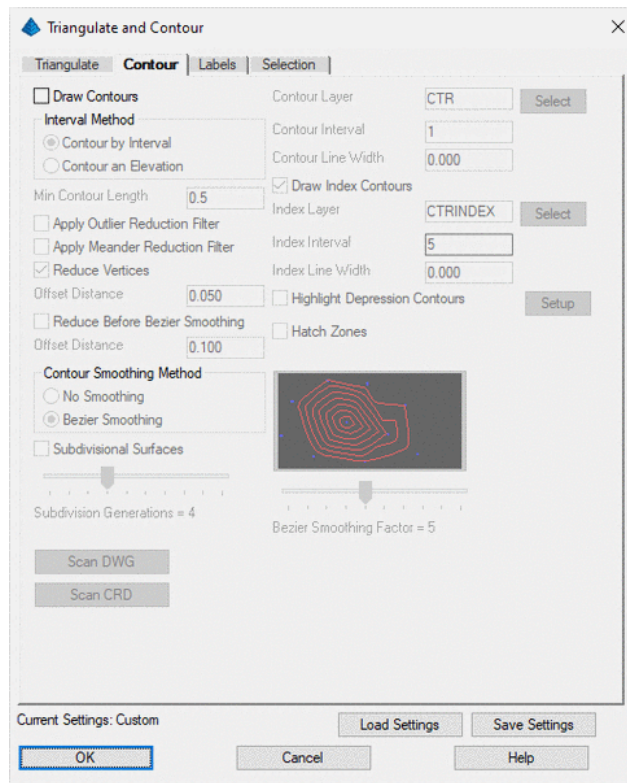

- Issue the Surface – Triangulate & Contour command. The following dialog box (with several "tabs") will appear which you should fill out as discussed below:

- In the Triangulate tab (as shown above), enable the **Write Triangulation File** toggle and click its **Select** button to set the name of a triangulation (*.tin) file as illustrated below. Click the **Save** button on this dialog box so that the results of the triangulation can be re-used for future purposes. Turn on the **Use Inclusion/Exclusion Areas** toggle and set any remaining options as illustrated above:

- In the Contour tab, as shown below, toggle off the **Draw Contours** option:

Click the OK button from any tab. When prompted:

Select Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the PERIMETER polyline

[FILter]/<Select entities>: press Enter

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

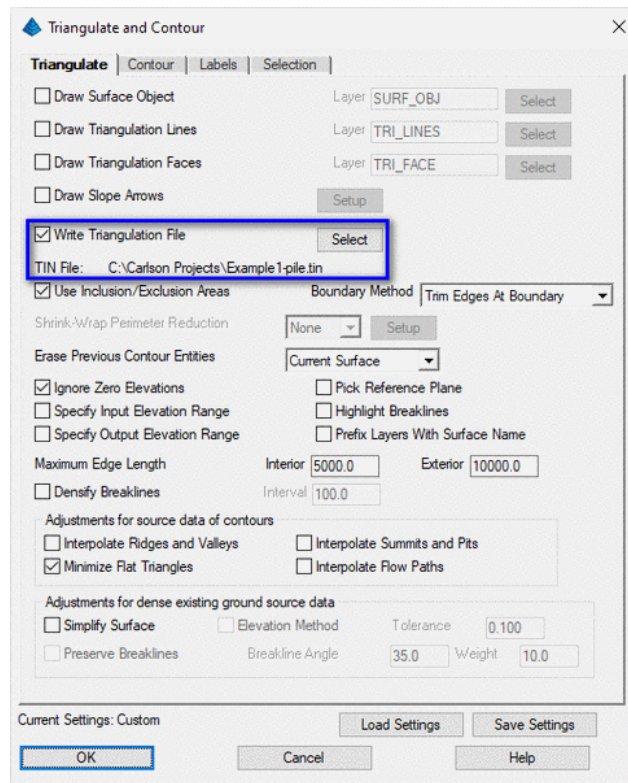

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: pick the PERIMETER polyline again and press Enter

[FILter]/<Select entities>: press Enter

If a secondary dialog box appears prompting for a coordinate file (*.crd), click **Cancel**. A "TIN" file representing an assumed base-ground (*Existing*) surface is written.

- For the *pile* TIN, we'll follow the same general procedure as above but with a few small tweaks. Re-issue the Surface – **Triangulate & Contour** command and set the values as shown below (click **OK** when ready):

When prompted:

- Select Inclusion perimeter polylines or ENTER for none.**
- [FILter]/<Select entities>:** pick the PERIMETER polyline
- [FILter]/<Select entities>:** press Enter
- Select Exclusion perimeter polylines or ENTER for none.**
- [FILter]/<Select entities>:** press Enter
- Select points and breaklines to Triangulate.**
- [FILter]/<Select entities>:** type ALL and press Enter
- [FILter]/<Select entities>:** press Enter

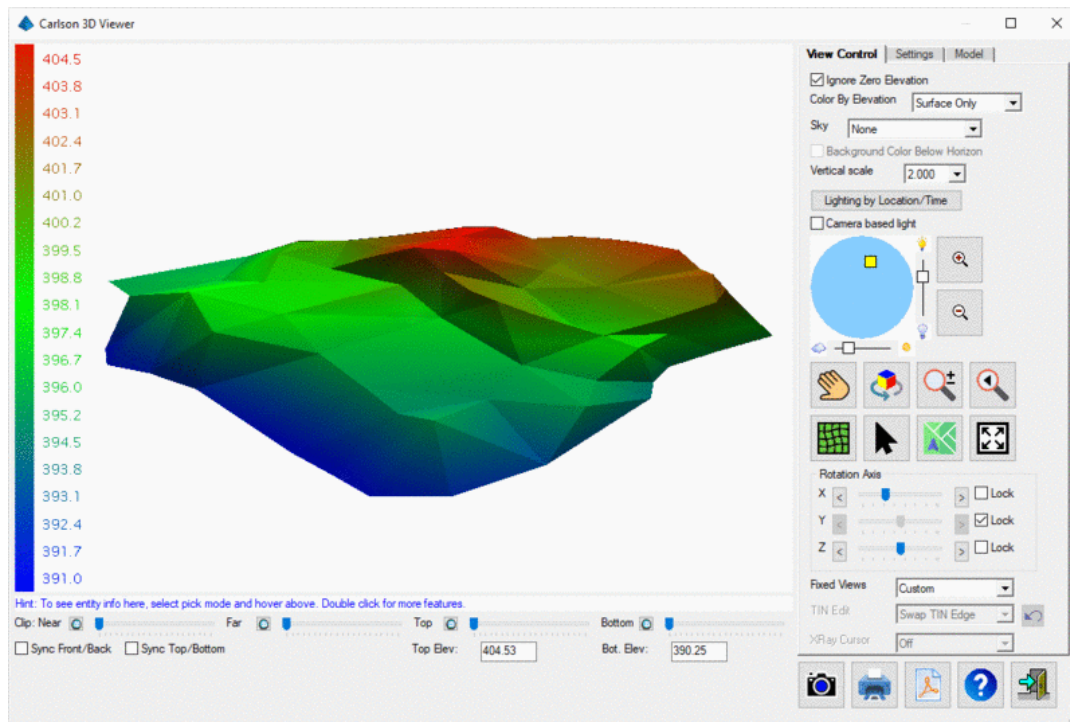

If a secondary dialog box appears prompting for a coordinate file (*.crd), click **Cancel** or select the coordinate file created earlier in this lesson if you so choose and accept the default parameters that follow.

A "TIN" file representing the pile (*Final*) surface is written.

3. *Optional:* Similar to the Check Surfaces step under Two Grid Surface Volumes, this is an optional step to check that the surface(s) are correct. Re-issue the View – 3D View – **Surface File Viewer** command and when prompted:

Select Surface File (dialog): select the TIN file that was just created and click **Open** when ready.

A 3D Viewer window similar to that shown below appears:

When ready, click the **Exit** (Doorway) button.

4. Now that we have our two triangulation files, we can generate a TIN to TIN prismatic volume calculation. Of all the volume methods, this one is the most accurate since all the source data points are used in the volume model. Issue the Surface – Volumes By Triangulation – Two Triangulation Surface Volumes command. When prompted:

Select EXISTING Surface Triangulation File (dialog): select the *Base* TIN file and click **Open** when ready

Select FINAL Surface Triangulation File (dialog): select the *Pile* grid file and click **Open** when ready

Select Inclusion perimeter polylines or ENTER for none.

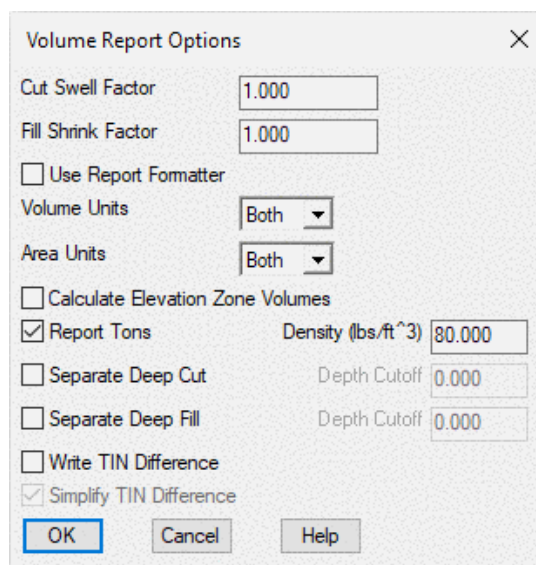

[FILter]/<Select entities>: pick the PERIMETER polyline

[FILter]/<Select entities>: press Enter

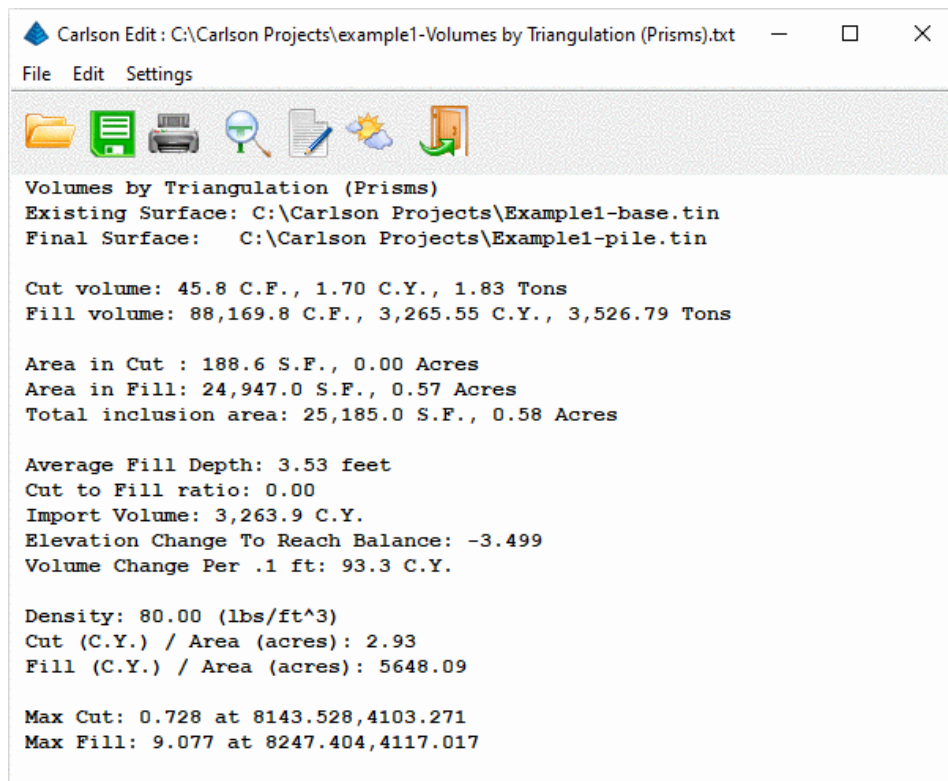

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Volume Report Options (dialog): set the values as shown below and click **OK** when ready:

The volume report similar to that shown below appears:

Click the **Exit** (Doorway) button to dismiss the report.

Volume Method 5 - Calculate Section Volumes

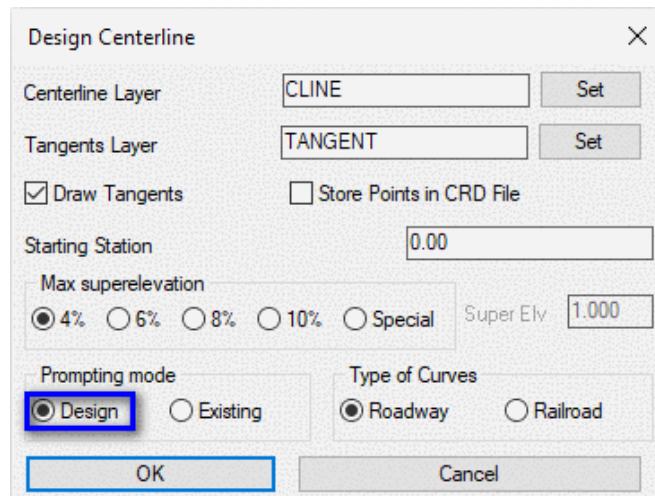

In roadway/corridor types of projects, volumes by *Average End Area* are commonly used. Let's see the results of this process.

1. Our first task will be to draw a centerline (baseline) upon which the corridor will be based. Issue the Centerline – Design Centerline command and when prompted:

Centerline File to Design (dialog): set the file name as shown below and click **Open** when ready

Design Centerline (dialog): set the values as shown below and click **OK** when ready

Pick Point or Point number: type 2016 and press Enter

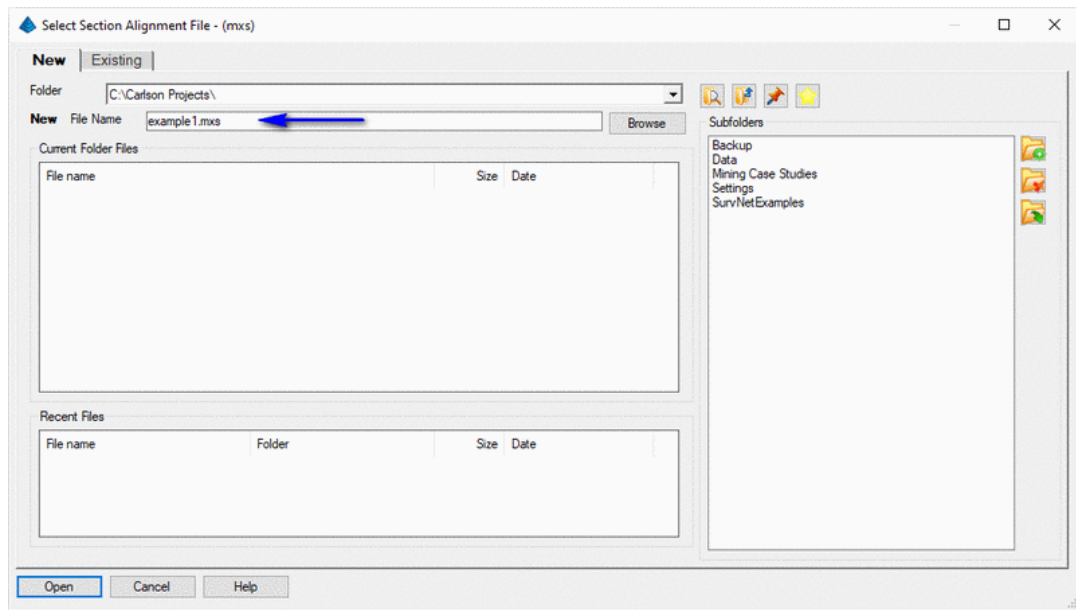

Bearing/PI/Exit/Undo/<Pick Point or Point number>: type 2004 and press Enter

Bearing/PC/PI/Exit/Undo/<Pick Point or Point number>: press Enter

A centerline is generated between the two points.

NOTE: Double-clicking on the polyline on the screen will open the Centerline Editor command.

- Our next task will be to establish the cross-section limits along this corridor centerline. Issue the Sections – Section Alignment Editor to display a dialog box similar to that shown below:

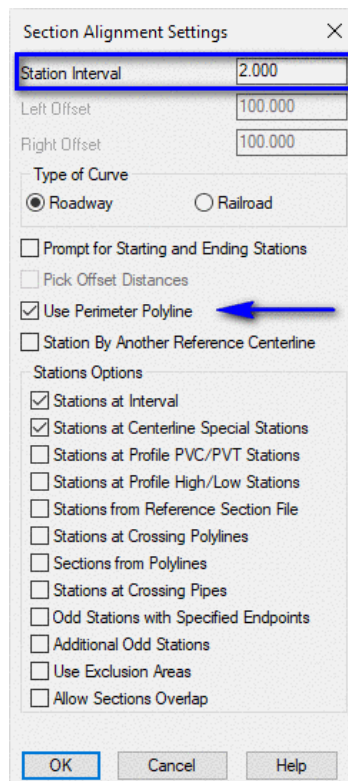

Set the file name as indicated above and click **Open** when ready. When prompted:

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: pick the centerline polyline

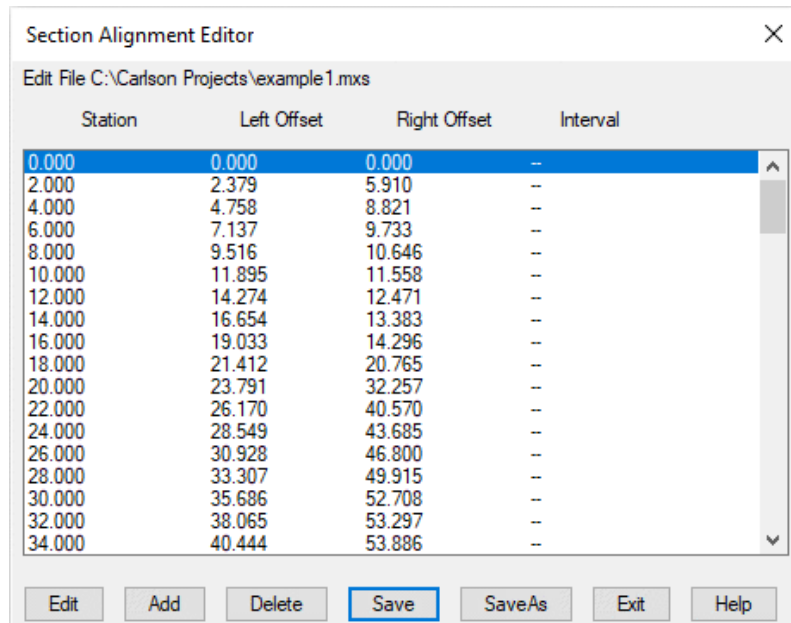

Enter Beginning Station of Alignment <0.00>: press Enter

Section Alignment Settings (dialog): set the values as shown below and click **OK** when ready

Select boundary polyline: pick the PERIMETER polyline

The program draws temporary lines in the drawing to show the positions of the sections and displays a summary of the section alignment as illustrated below:

Click the **Save** button followed by the **Exit** button.

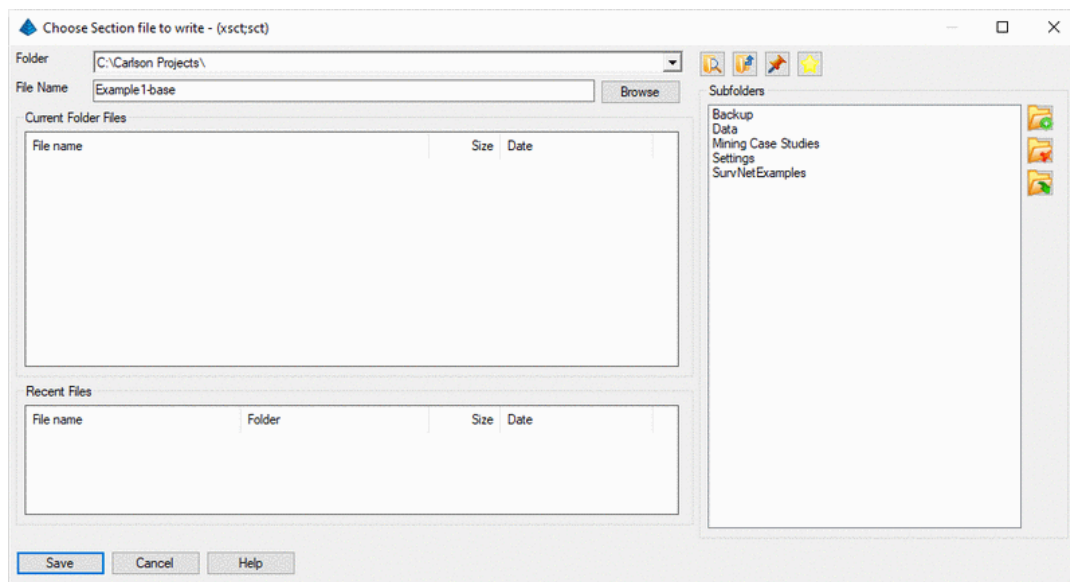

- To create the section file for the *Existing* (base) surface, issue the Sections – Create Sections from... – Sections from Grid or Triangulation Surface command. When prompted:

Choose Grid or Triangulation file to Process (dialog): specify the base.tin created earlier and click **Open** when ready

Section Options (dialog): set the option to **Prompt** and click **OK** when ready (with *Prompt* specified, you'll be prompted if the Section should change if there is an underlying change to the source TIN file)

Section Alignment File to Process (dialog): specify the section alignment (*.MXS) created earlier and click **Open** when ready

Choose Section File to Write (dialog): specify a file name as illustrated below and click **Save** when ready

The first of two section files is written.

- Let's follow the same general process for the *Final* (pile) surface with a few minor adjustments. Re-issue

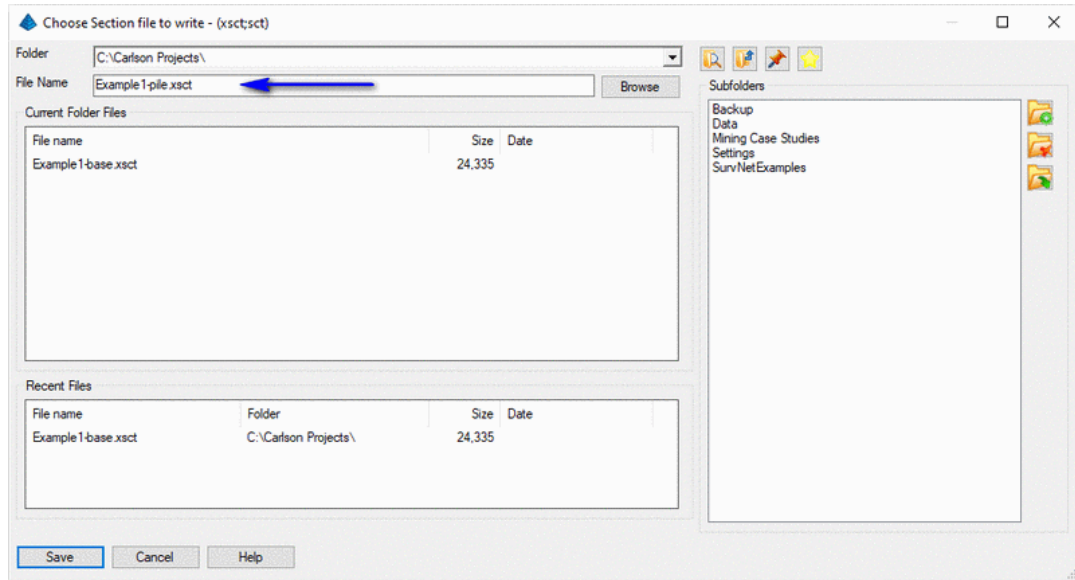

the Sections – Create Sections from... – **Sections from Grid or Triangulation Surface** command. When prompted:

Choose Grid or Triangulation file to Process (dialog): specify the pile.tin created earlier and click **Open** when ready

Section Options (dialog): set the option to **Prompt** and click **OK** when ready

Section Alignment File to Process (dialog): specify the section alignment (*.MXS) created earlier and click **Open** when ready

Choose Section File to Write (dialog): specify a file name as illustrated below and click **Save** when ready

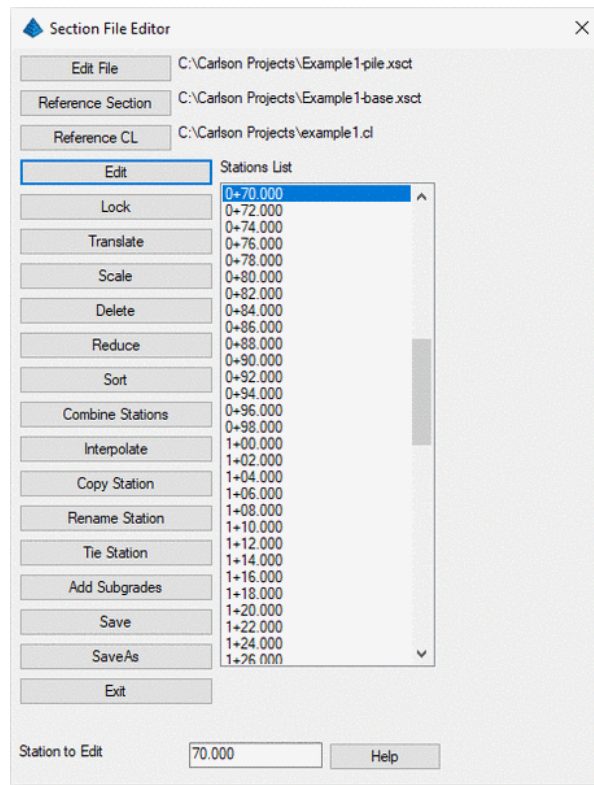

The second of two section files is written.

5. *Optional:* Similar to the Check Surfaces (grid) and the Check Surfaces (TIN) steps discussed earlier, this is an optional step to check that the section(s) are correct. Issue the Sections – Section **File** Editor command and when prompted:

Section File to Process (dialog): select the **pile** section file that was just created and click **Open** when ready.

A Section File Editor dialog box similar to that shown below appears:

Set the remaining values as shown above. To examine a specific section, scroll through the list and select a desired station (e.g. 0+70.00) and click the **Edit** button to display a dialog box similar to that shown below:

Review the controls in this dialog box and click **OK** when ready and then click **Exit** on its parent dialog box.

- Now that we have two section files, we can derive the volume between them. Issue the Sections – Calculate Section Volumes command. When prompted:

Section File (Existing Ground) to Read (dialog): select the *Base* section file and click **Open** when ready

Section File (Final Ground) to Read (dialog): select the *Pile* section file and click **Open** when ready

Calculate Section Volumes (dialog): set the values as shown below and click **OK** when ready

The volumes are calculated and reported, along with the cut and fill end-areas at each station as illustrated below:

Station	Cut(sf)	Fill(sf)	Interval	Cut(cy)	Fill(cy)
0+00.00	0.00	0.00			
0+02.00	0.00	0.04	2.00	0.00	0.00
0+04.00	0.00	0.17	2.00	0.00	0.01
0+06.00	0.00	0.39	2.00	0.00	0.02
0+08.00	0.00	0.69	2.00	0.00	0.04
0+10.00	0.00	1.07	2.00	0.00	0.07
0+12.00	0.00	1.55	2.00	0.00	0.10
0+14.00	0.00	2.10	2.00	0.00	0.14
0+16.00	0.00	2.75	2.00	0.01	0.18
0+18.00	0.16	3.64	2.00	0.06	0.24
0+20.00	1.37	5.63			

Review the results and click the **Exit** (Doorway) button to dismiss the report.

Results Summary

As mentioned earlier, each volume methodology has a particular use and knowing the application(s) for each method will serve you well. Here is a summary of our results:

Method	Fill (c.y.)	Cut (c.y.)	When to use
Stockpile Volumes	3,264.22	- na -	Quick and approximate Fill-only volumes are sufficient
Volumes By Layers	3,264.22	1.59	Quick and for large data sets when approximate Cut and Fill volumes are sufficient
Two Grid Surface Volumes	3,264.60	1.61	Large data sets when approximate Cut and Fill volumes are sufficient
Volumes By Triangulation	3,265.55	1.70	Large or small data sets when precise surface-to-surface Cut and Fill volumes are needed
Calculate Sections Volumes	3,265.59	1.70	Corridor studies where end-area averages are sufficient

Volume Summary/Comparison

This completes the tutorial: Calculate Volumes By Five Methods.

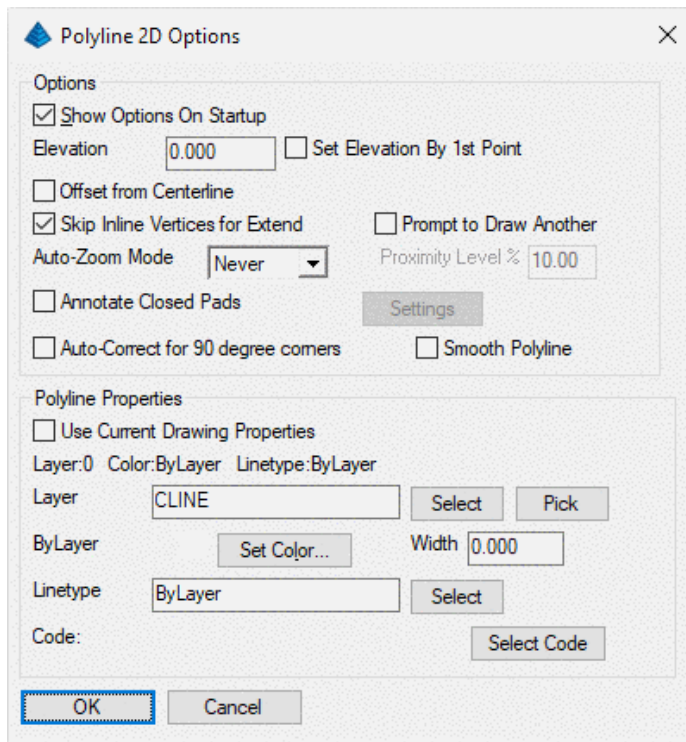

Basic Road Design with Volumes

This tutorial requires the Civil Design program.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Example2.dwg** file. It will look like the illustration below (without the curved road).

2. Activate the Civil module via Settings – Carlson Menus – **Civil Menu**. Since *Example2.dwg* will also be used multiple times throughout this tutorial, you might want to make a copy so that you don't overwrite the initial drawing. Issue the File – **Save As** command and specify a different name, such as **Example2r.dwg**.
3. We'd like to generate a sample roadway centerline. Pick the Draw – 2D Polyline command (or simply type-in **2DP** at the command line) which starts the Carlson enhanced Polyline command. If the Polyline 2D Options dialog box appears, set the values shown below and click the **OK** button:

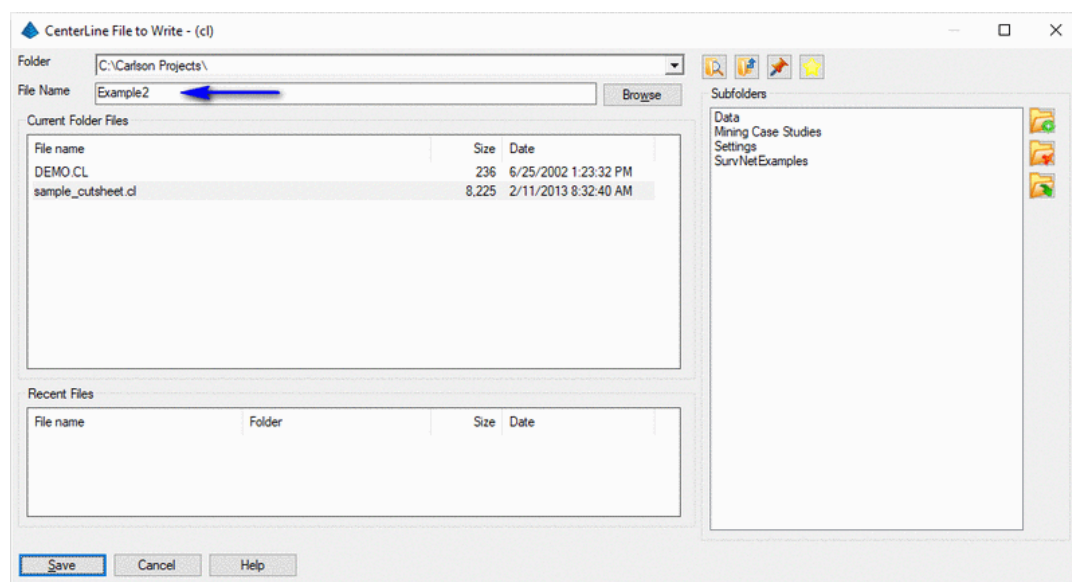

When prompted:

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: 1857700,159400
[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: D
Enter Distance [Meters/<Feet>/Chains/Links/Rods/Pick/Quit]: F
Enter Distance [Meters/<Feet>/Chains/Links/Rods/Pick/Quit]: 310
Define direction method [Cursor/Line/Pick/<Angle>]? press Enter
Code: 1-NE 2-SE 3-SW 4-NW 5-AZ 6-AL 7-AR 8-DL 9-DR
Enter angle code (1-9) <4>: 1 (for a northeast bearing)
Enter bearing (dd.mmss): 68.5525
Enter Distance [Meters/<Feet>/Chains/Links/Rods/Pick/Quit]: Q
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: A
[Radius pt/radius Length/Arc length/Chord/Second pt/Undo/<Endpoint or point number>]: L
Specify radius length: 500
Curve direction [Left/<Right>]? press Enter
[Arc length/Chord length/Delta angle/Tangent-out/<End point or point number>]: D
Specify delta angle (ddd.mmss): 76.2405
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: L
<Enter or pick distance>: 1663.2721
Segment length: 1663.27, Total length: 2640.00
[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: press Enter

The result should resemble the image below:

- Our next task will be to create a centerline file necessary for the final road design routine. Issue the Centerline – Polyline to Centerline File command (other methods are available for Centerline creation as described in the Centerline Menu of the documentation). Provide a centerline (*.cl) file name as shown below and click **Save** when ready:

When prompted:

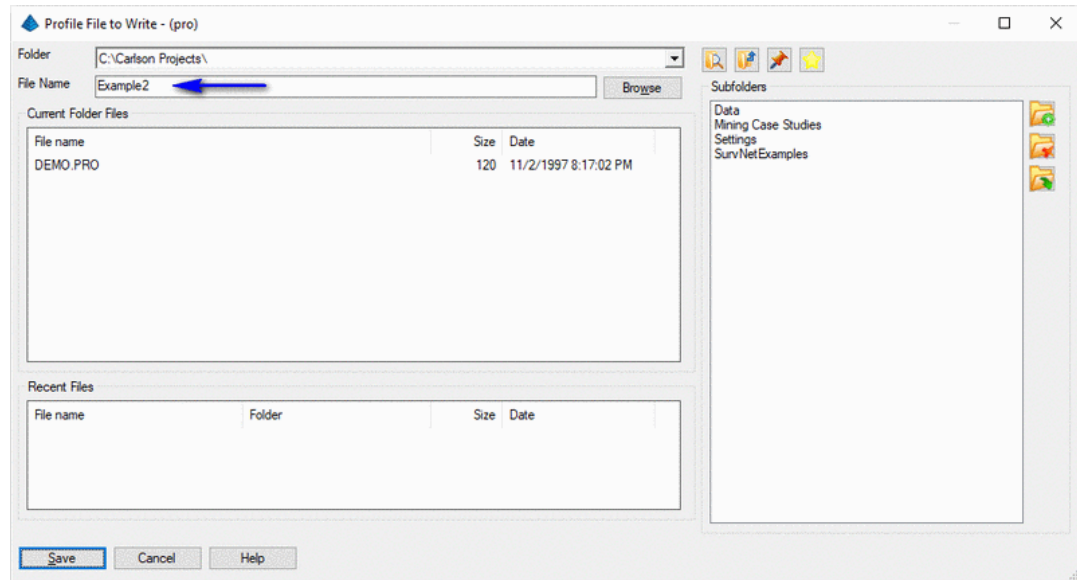

Polyline should have been drawn in direction of increasing stations.

Select polyline that represents centerline: pick polyline representing the centerline

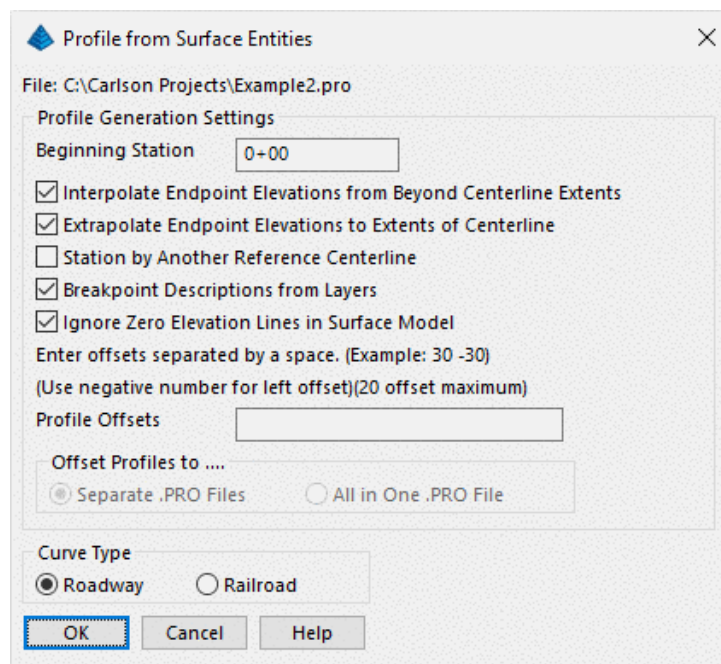

Centerline station [Reverse/Ending/<Beginning: 0+00>]: press Enter

Press ENTER to continue. press Enter

- Now we will make a profile file (*.pro) based on the centerline geometry we just created. Issue the Profiles – Create Profile From – Profile from Surface Entities. Supply the new profile name as shown below and click **Save** when ready:

A settings dialog as shown below appears. Set the values as shown and click **OK**:

When prompted:

Polyline should be drawn in direction of increasing stations.

CL File/<select centerline polyline>: C (and select the *.cl file created above)

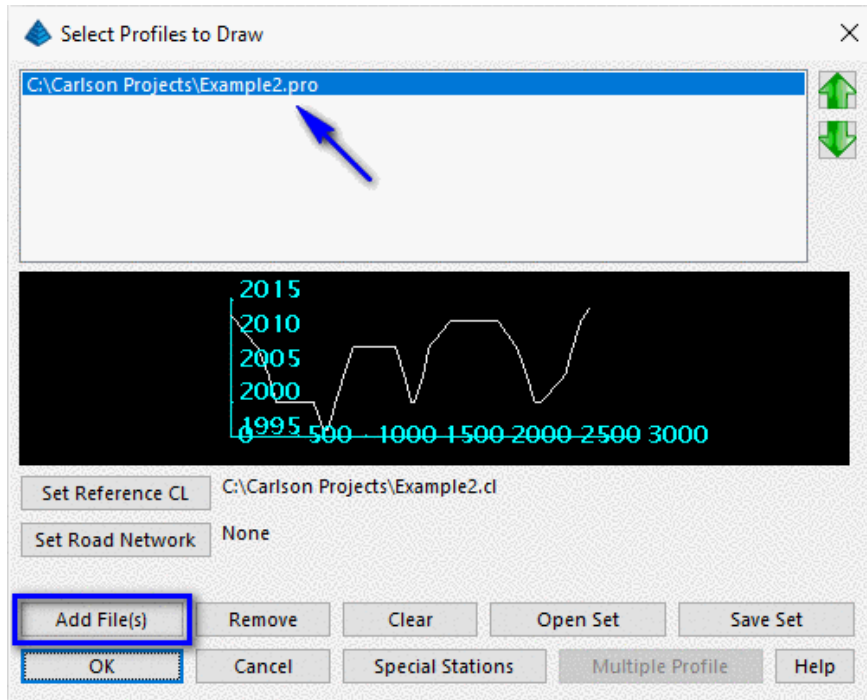

Select Lines, PLines, and/or 3DFACEs that define the surface for profiling.

[FILter]/<Select entities>: type ALL and press Enter twice

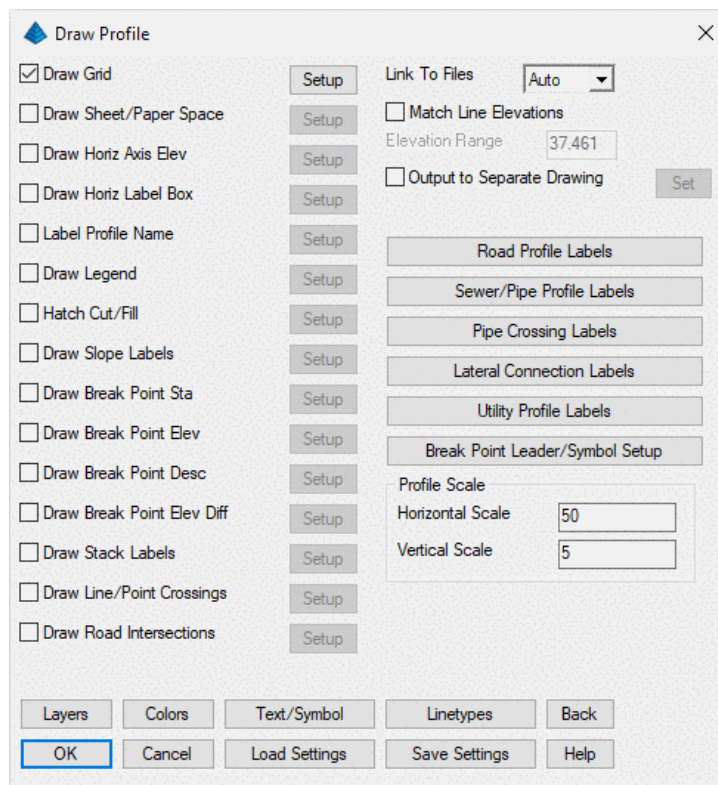

The profile data is written to file.

NOTE: Common practice is to build a surface model from any and all data that carries an elevation. However, there are several Carlson **Create Profile from...** routines and we opted to work with a routine that gets its information "direct from the source" (*i.e.* the contours themselves).

6. With the profile created, let's place the data into the drawing for visualization purposes. Use the Profiles – Draw Profile command and use the **Set Reference CL** and **Add** buttons to set the values as shown below. Click **OK** when ready:

The window below will appear. Set the values as shown making note to set the **Horizontal Scale** to **50** and the **Vertical Scale** value to **5**. This will establish a 10X vertical exaggeration of the profile. Click **OK** when ready:

When prompted:

Profile Grid Range (Dialog):

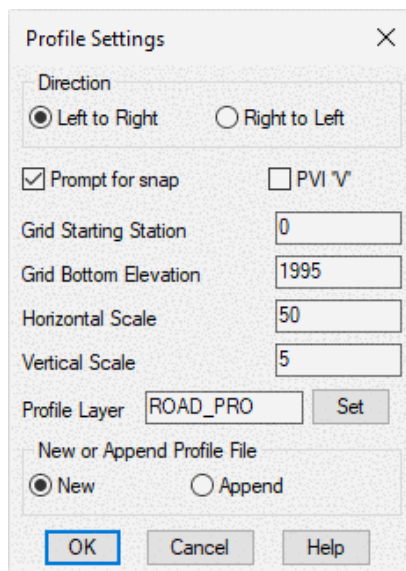

Pick Starting Point for Grid <0.00,0.00>: pick an arbitrary and desirable location on screen

Use the View – **Window** command to study the result as desired. Your profile should look similar to this.

NOTE: The "flat spots" shown in this profile are the result of extracting the profile data directly from the contours. Extracting a profile from a surface model is a more common approach in today's computer age.

- Now we will design a proposed road centerline profile in relation to the existing ground profile. Use the Profiles – Design Road Profile – Design Road On Profile Grid. The following dialog box will appear. Since we followed up the **Draw Profile** command with this one, it was able to determine proper startup values for the dialog:

Choose **OK** on this dialog. A new file creation dialog box will appear, asking for an output file name. Enter a name such as **Example2-Pr**, and click **Save**. When prompted:

Pick Lower Left Grid Corner <0.00,0.00>[endp on]: if you have not moved your profile grid, press Enter (Carlson has *endpoint* osnap active to make the pick accurate)

At this point another dialog will appear in the upper left corner. Initially, it will display only station and elevation. Once a beginning point has been designated, it will also display the relative difference from the last point to the cursor position (illustrated below). This can be an aid in determining acceptable slopes for your design.

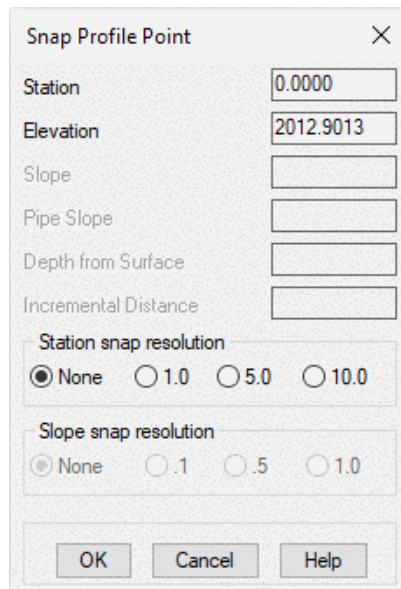

When prompted:

Enter station or pick a point (Enter to End): end

Snap to END of: pick the left-most endpoint of the existing ground profile as a tie in point

The following dialog appears. Choose **OK** to accept the defaults:

prompting resumes:

Station of second PVI or pick a point (U,E,D,Help): 1111.01

Percent grade entry/<Elevation of PVI>: 1999.37

Station of next PVI or pick a point (U,E,D,Help): 1911.64

Percent grade entry/<Elevation of PVI>: 2002.66

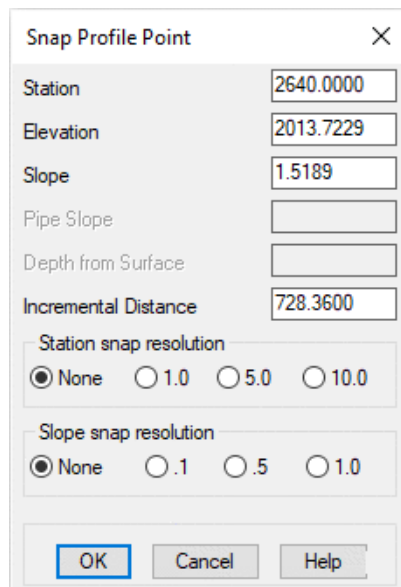

View table/Unequal/Through pt/Sight dist/K-value/<Vert Curve Length>: 500

Use these values [<Yes>/No]? Y

Station of next PVI or pick a point (U,E,D,Help): end

Snap to END of: pick the far-right endpoint of the existing ground profile as a tie in point

The following dialog appears. Choose **OK** to accept the defaults:

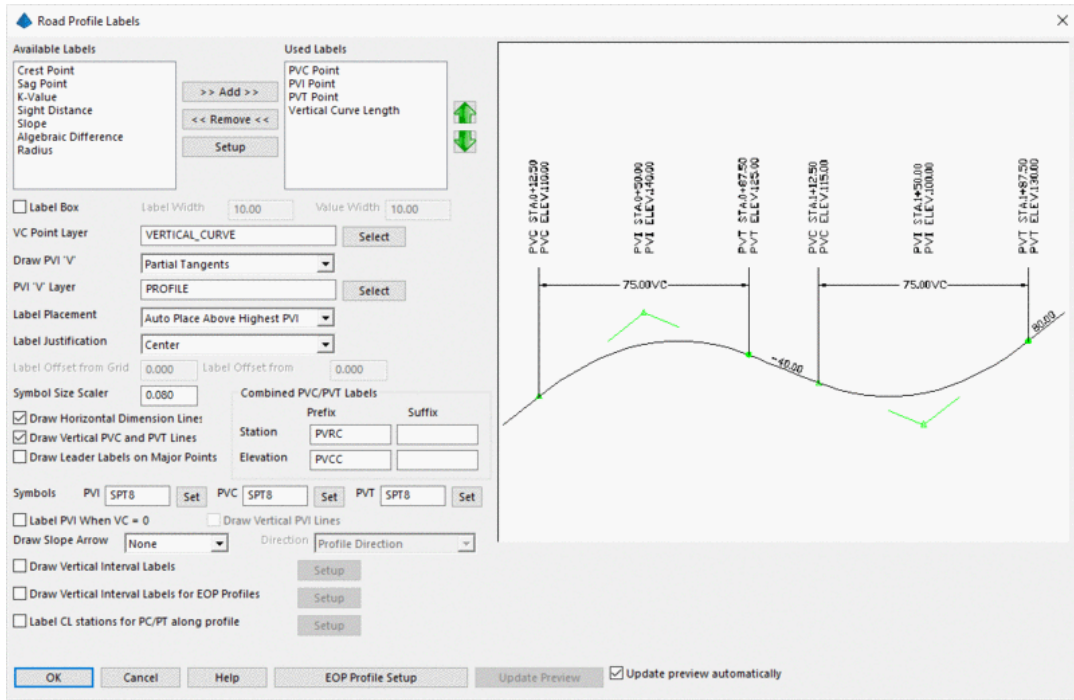

prompting resumes:

View table/Unequal/Through pt/Sight dist/K-value/<Vert Curve Length>: 500

Use these values [<Yes>/No]? Y

Station of next PVI or pick a point (U,E,D,Help): press Enter

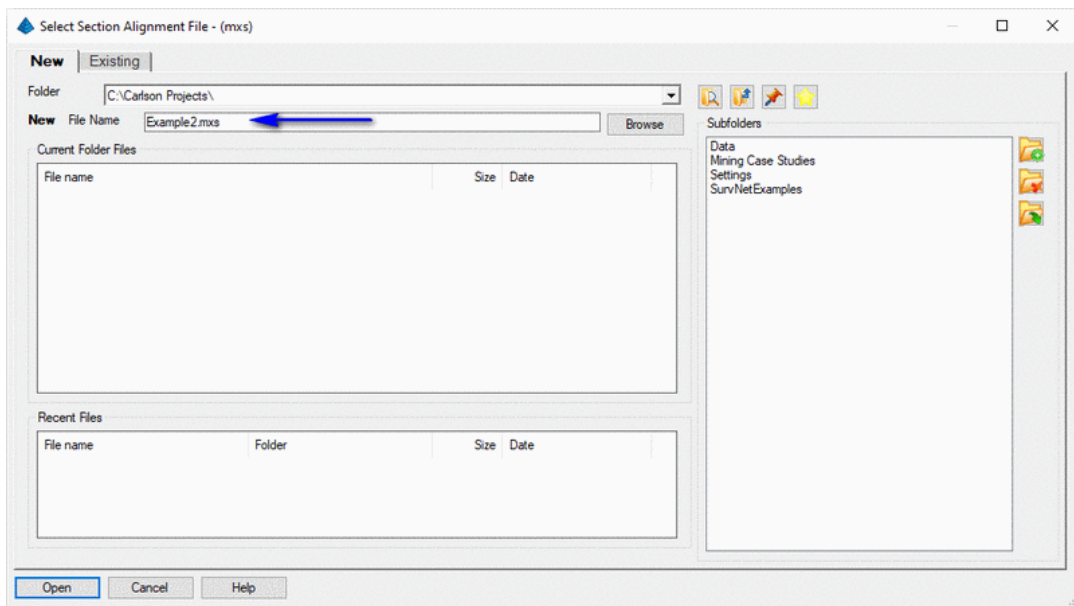

At this point the following dialog appears. Change settings to match, and choose **OK**:

Carlson will now finish the road design, and your drawing should like the following:

- Now we will create the alignment for our cross-section file. This step gives the section interval and the offset left and right from our centerline. Use the Sections – Section Alignment Editor command and choose the **New** tab. Type the name indicated below and click **Open**:

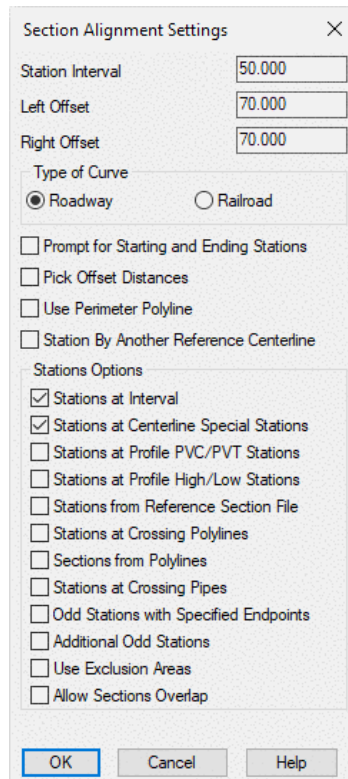

Notice how all files can have the same name in this road design portion, as they all have a unique file extension. So for the organization of various jobs, it is sometimes helpful to have all of the files with the same name. When prompted:

Polyline should have been drawn in direction of increasing stations.

CL File/<Select centerline polyline>: C (and select the Centerline file created earlier)

The dialog will appear as shown, enter in the stations and offsets exactly as they appear here. This will give the needed detail for the road design routine:

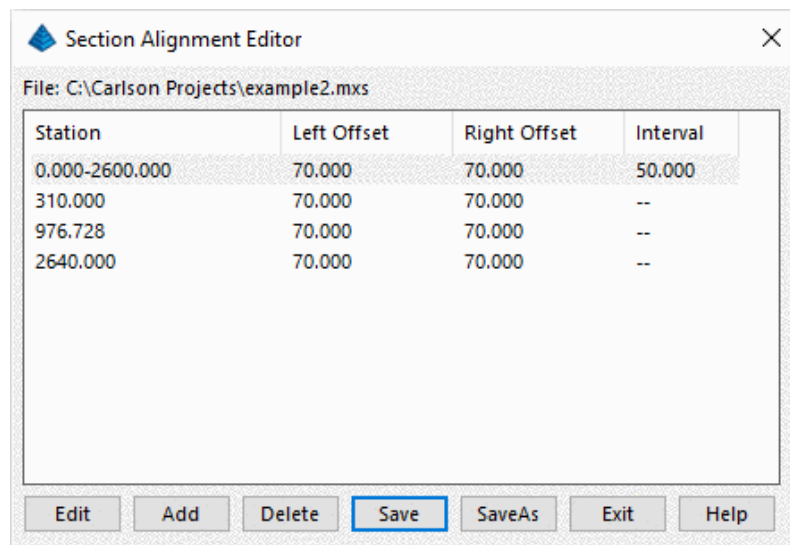

The dialog box 'Section Alignment Settings' contains the following fields and options:

- Station Interval: 50.000
- Left Offset: 70.000
- Right Offset: 70.000
- Type of Curve: Roadway, Railroad
- Prompt for Starting and Ending Stations
- Pick Offset Distances
- Use Perimeter Polyline
- Station By Another Reference Centerline
- Stations Options:
 - Stations at Interval
 - Stations at Centerline Special Stations
 - Stations at Profile PVC/PVT Stations
 - Stations at Profile High/Low Stations
 - Stations from Reference Section File
 - Stations at Crossing Polylines
 - Sections from Polylines
 - Stations at Crossing Pipes
 - Odd Stations with Specified Endpoints
 - Additional Odd Stations
 - Use Exclusion Areas
 - Allow Sections Overlap

Buttons: OK, Cancel, Help

Choose **OK**, and another window appears that allows for any station editing or changes. It all looks good here, so click **Save** and then **Exit**:

The dialog box 'Section Alignment Editor' shows the following table:

Station	Left Offset	Right Offset	Interval
0.000-2600.000	70.000	70.000	50.000
310.000	70.000	70.000	--
976.728	70.000	70.000	--
2640.000	70.000	70.000	--

Buttons: Edit, Add, Delete, Save, SaveAs, Exit, Help

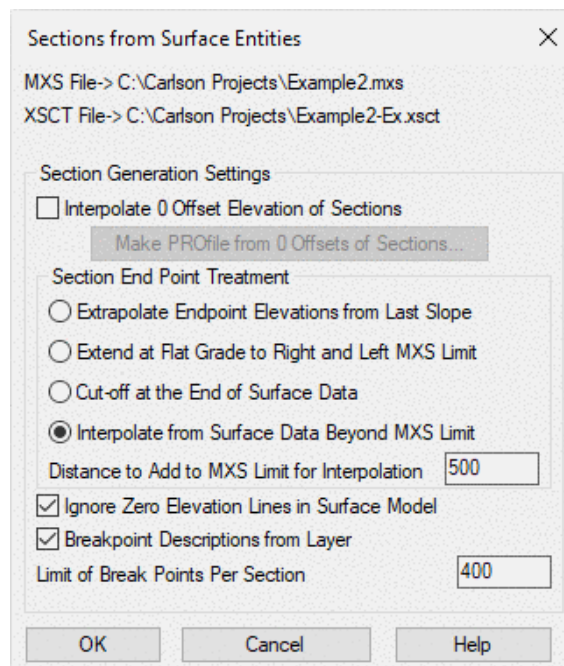

The Section Alignment file (*.xms) is now written. There is now a preview of the section alignment lines shown on the centerline. These are just images, if the drawing is regenerated, they will disappear (they can be drawn permanently if desired).

9. Next, we will create the actual section file (*.SCT) from the contours, in combination with the Section Alignment file (*.MXS). Run the Sections – Create Sections from – Sections from Surface Entities command. We will use the contours and breaklines for surface elevations, as we did with generating the profile. When prompted:

MXS File to Process (Dialog): Specify the MXS file that we just created to read for the alignment

Section File to Write: Provide a file name such as Example2-Ex (e.g. the "-Ex" portion of the name signifying *Existing* section conditions)

A dialog box with additional settings appears:

We'll enter a distance of 500 feet to add to our MXS limit of 70. This will search farther for contour elevations, then choose **OK**. When prompted:

Select Lines, Polylines, and/or 3DFaces that define the surface.

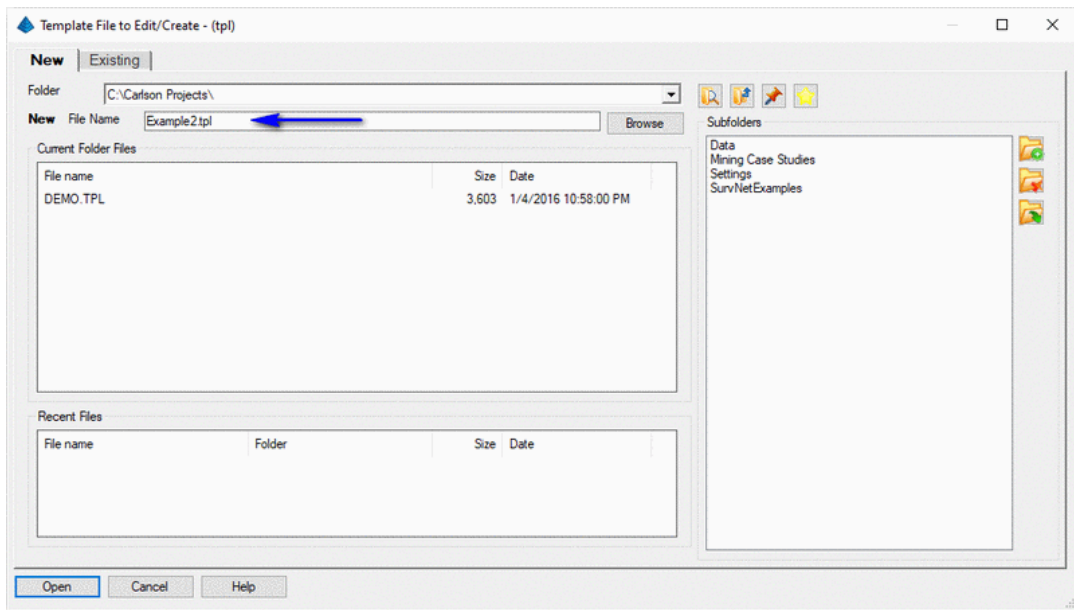

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

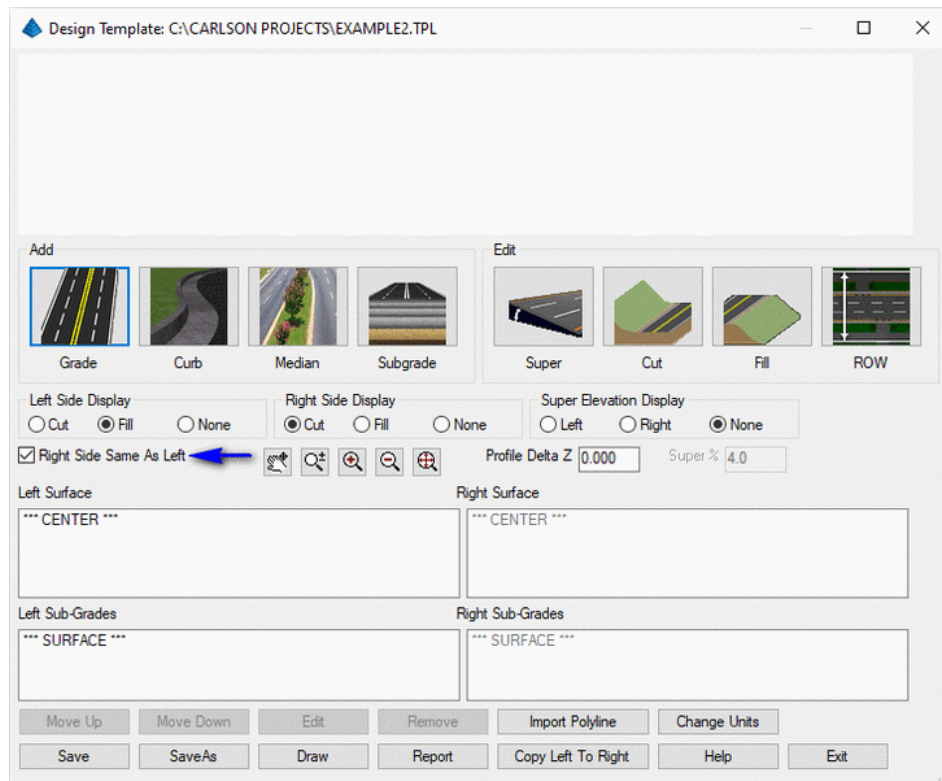

The section file is generated.

10. To continue the road design, let's design a wide boulevard, 27' of drivable pavement, with curb and gutter on the outside. Whenever a cut is within rock, the cut slope will employ a 0.5:1 slope rather than the typical 3:1 slope. At the top of rock, the cut will revert to 3:1. In fill, the condition will be 3:1 for fill under 6' and 2.5:1 for fill over 6' in depth. Pavement depths will be 6" of asphalt (consisting of a 2" wearing coat and a 4" asphalt base) and 8" of crushed aggregate.

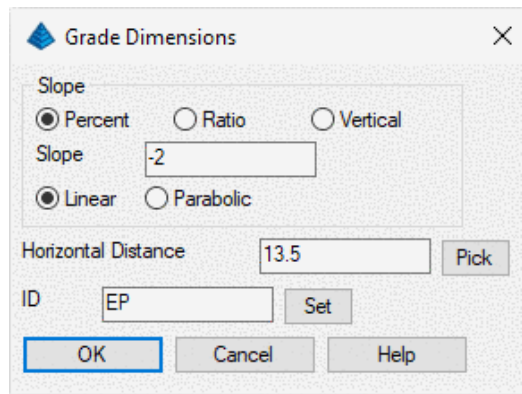

Issue the Roads – Design Template command and click on the **New** tab to create the file name as shown below. Click on **Open** when ready:

A large dialog box appears as shown below. In it, you enter segments of the template, which typically work outwards from the middle as you add more lanes, curbs and shoulders. We will enter a symmetrical template, with 13.5' pavement sections either side of centerline, connecting to a curb and gutter. Then we'll add an 8' shoulder.

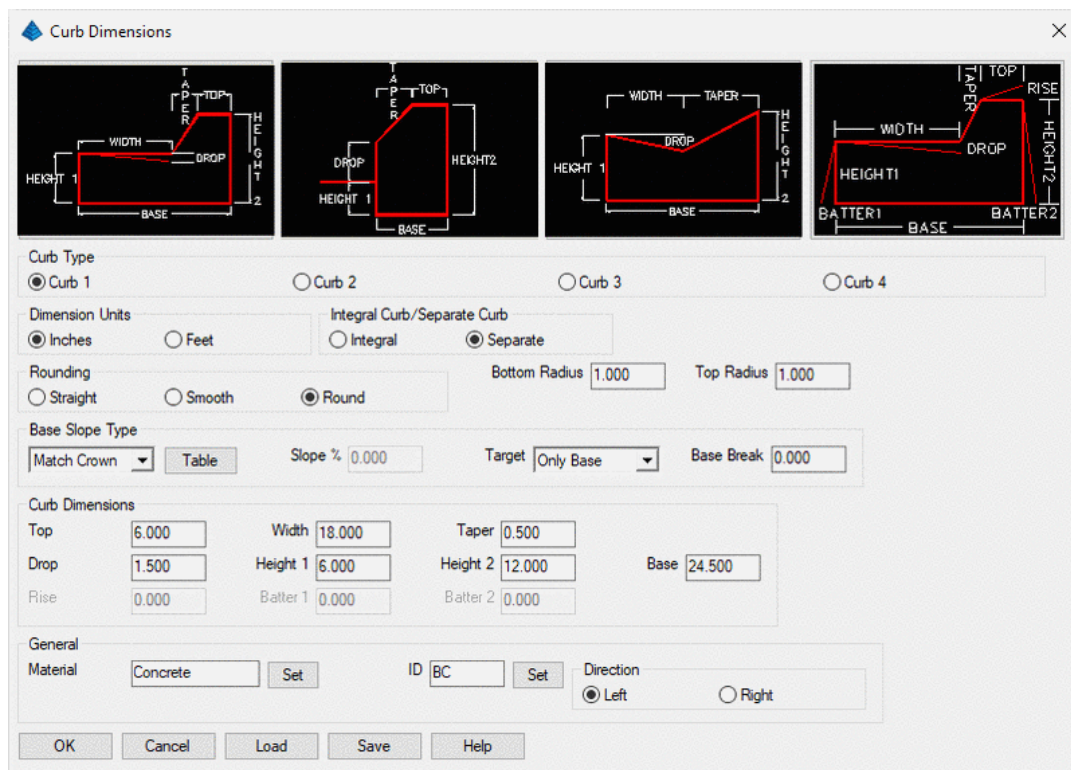

For the lanes, click the **Grades** icon. This leads to a child dialog as shown next:

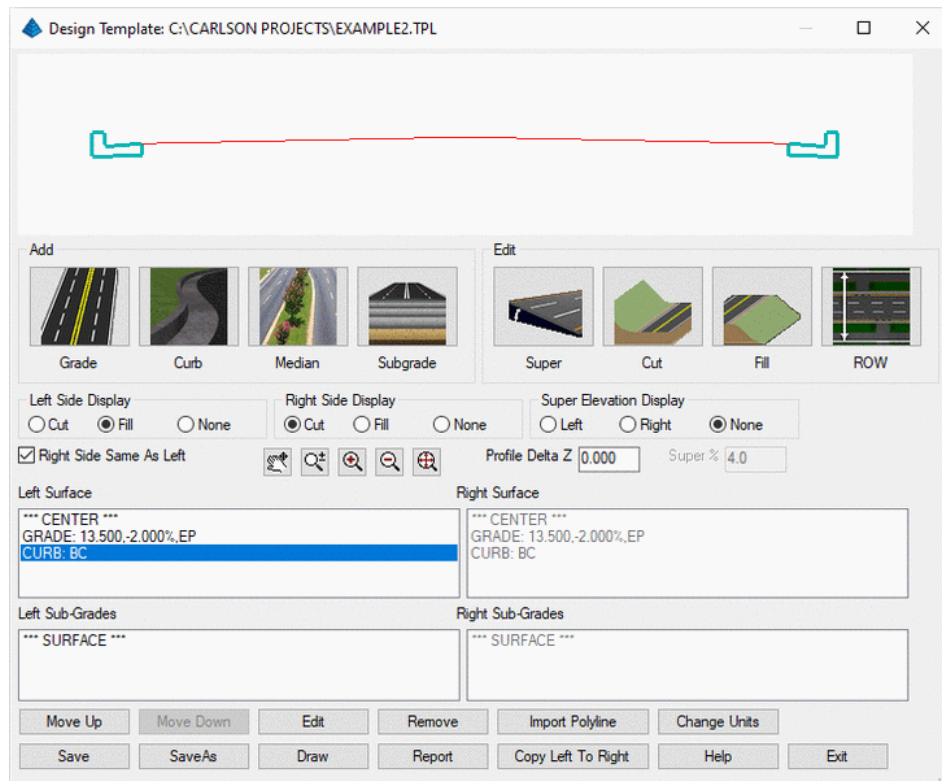

Fill out as shown. It's important to note that a downhill pavement from a crown in the middle is entered as a negative slope. That is, it is -2% heading from centerline outward, regardless of which side of centerline we are speaking of. Slope is independent of the profile grade point. It is also important to enter an ID whenever requested as these can be referenced later for advanced placement control.

A breakpoint in a shoulder in superelevation could be defined as occurring at $EP+3$, as opposed to the exact offset distance from centerline. The advantage of the parametric $EP+3$ equation is that if the road lane width expands (e.g. for a passing lane), but the shoulder always breaks 3 feet beyond the edge of pavement, then $EP+3$ is the most effective way to reference the breakpoint. Click **OK** and note that the lanes show up in the preview window at the top.

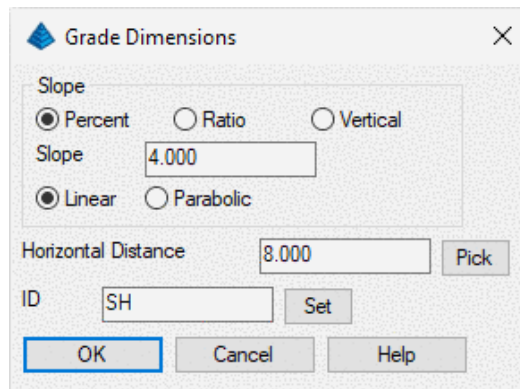

Next, we will add a curb. Click the **Curb** icon and fill out as shown:

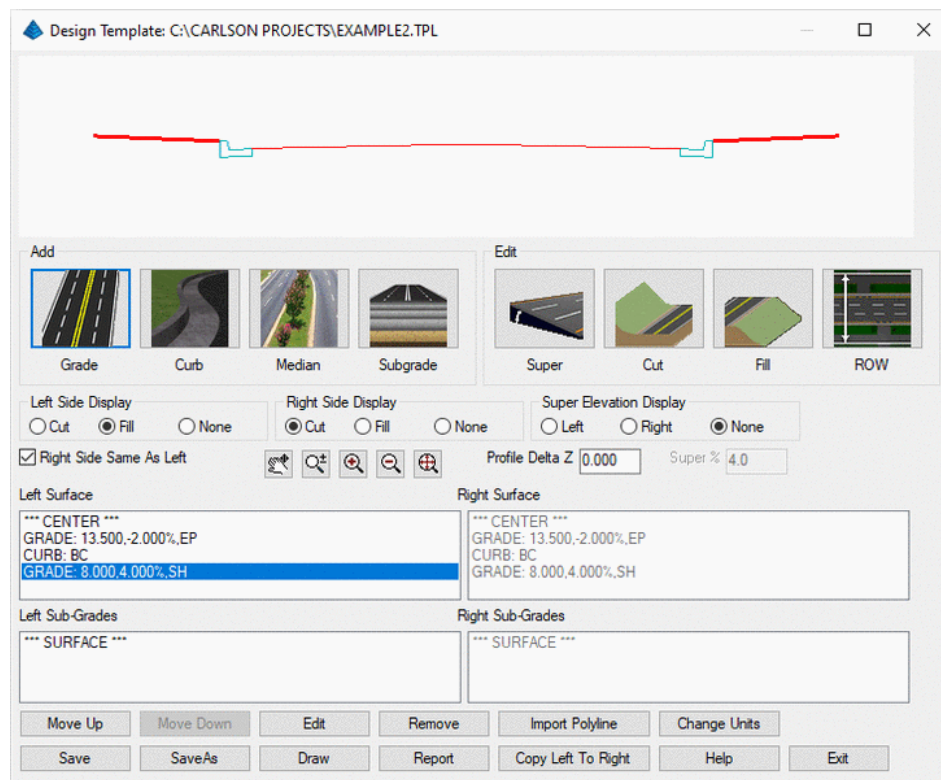

It is often a good idea to "match crown"... to make the curb match the slope of the last pavement lane (e.g. the 2% pavement slope above). But if your curb tilts downward more (like -3%), then use a *Special Base Slope Type*. If it is flat, by all means click on *Flat Base*. Click **OK**. Here's what our screen looks like so far:

Next, we will add a shoulder, going uphill at 4% for 8'. Notice what is happening. You are "current" on the *Curb* entry, so if you add another *Grade*, it will append after the curb, and add to the back of the curb. If you were to click on the *GRADE: 13.500, -2.000%, EP* segment, you would add a second "lane" before the curb, which is NOT what you want. Click on the **Grades** icon with the *CURB: BC* item highlighted. Fill out the dialog as shown:

That's it for the surface! Here's what our screen looks like now:

NOTE: As you select the different items within the component list, the viewer window will highlight the current selection.

Now we have subgrade material(s) and catch-slopes to consider. Let's turn our attention to subgrade materials and consider: if our road materials are a total of 14" deep (2" wearing, 4" asphalt, 8" stone) and our concrete gutter is 6" deep, do we want an aggregate stone "bed" to extend past the curb & gutter which is then covered by dirt? The most complex concept is the "wrap-around" subgrade, so let's go for it.

Select the **Subgrade** icon. We'll do three subgrade surfaces: first asphalt-wearing, which will run straight out and hit the curb, then asphalt-base which will extend to the gutter face and then tie vertically upward and then aggregate, which will run out past the back-of-curb and wrap back.

For any subgrade, we still do the vertical offset as a negative distance (negative meaning down). But follow this concept: we start it from the offset 0 and keep going at "Continue Slope" until it hits something (the curb). This approach isn't recommended if there is nothing to intersect. But it will run into the curb in this case. This *Continue Slope* concept works perfectly for shallow asphalt and concrete materials that will bump into a curb, when extended.

Subgrade Dimensions

Subgrade Type: Roadway Cut Slopes Fill Slopes

Distance Direction: Out In

Slope Type: Match Surface Special

Slope (%) 0.000 Tie Undershoot Vertically at Hinge

Intersect Surface: Continue Slope

Wrap Height (in) 0.000 Tie Slope (%) 0.000

Horizontal Offset: 0

Vertical Offset (in): -2.000 Units: Feet Inches Match Existing Surface

Distance: EP

Material: Asph-Wearing Coatings/Notes:

Super Elevation Settings

Low Side	High Side
Pivot Offset: <input type="text"/>	Pivot Offset: <input type="text"/>
Max Slope After Pivot (%): <input type="text"/>	Max Slope After Pivot (%): <input type="text"/>
Slope Type After Pivot: <input checked="" type="radio"/> Normal <input type="radio"/> Special	Slope Type After Pivot: <input checked="" type="radio"/> Normal <input type="radio"/> Special
Standard Slope Percent: 0.000	Standard Slope Percent: 0.000
Minimum Slope Percent: 0.000	Minimum Slope Percent: 0.000

Complete as shown above, and click **OK**. Repeat the **Subgrade** option to place the base asphalt material as shown below and click **OK** when complete:

Subgrade Dimensions

Subgrade Type: Roadway Cut Slopes Fill Slopes

Distance Direction: Out In

Slope Type: Match Surface Special

Slope (%) 0.000 Tie Undershoot Vertically at Hinge

Intersect Surface: Straight Up

Wrap Height (in) 0.000 Tie Slope (%) 0.000

Horizontal Offset: 0

Vertical Offset (in): -6.000 Units: Feet Inches Match Existing Surface

Distance: EP

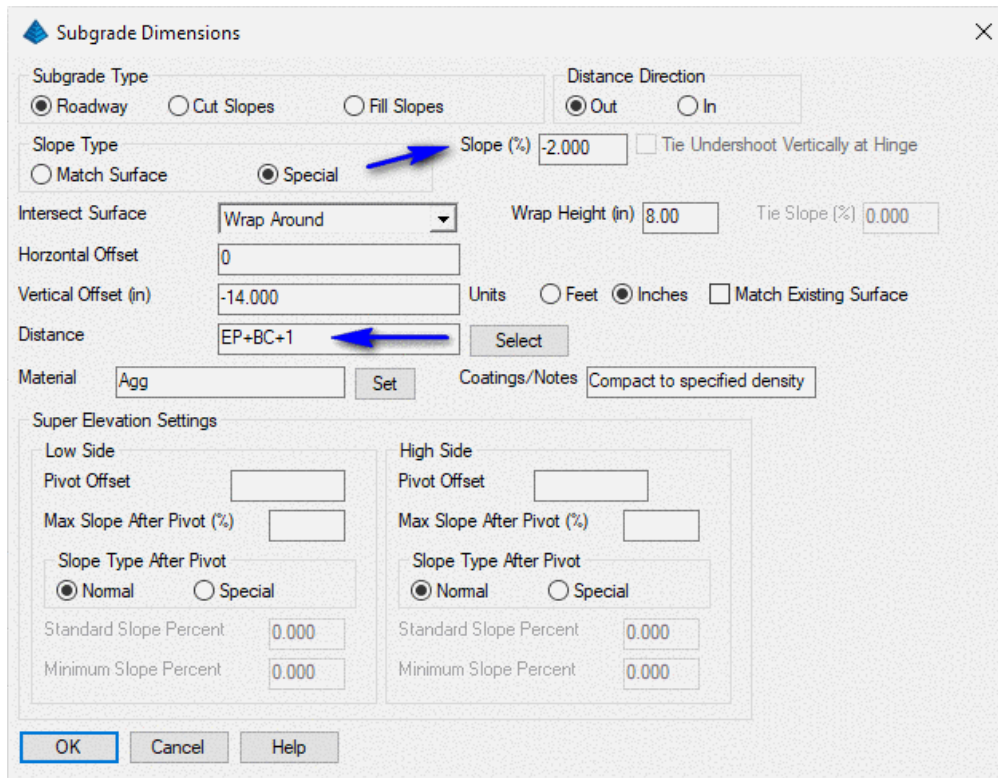

Material: Asph-Base Coatings/Notes: Apply tack coat

Super Elevation Settings

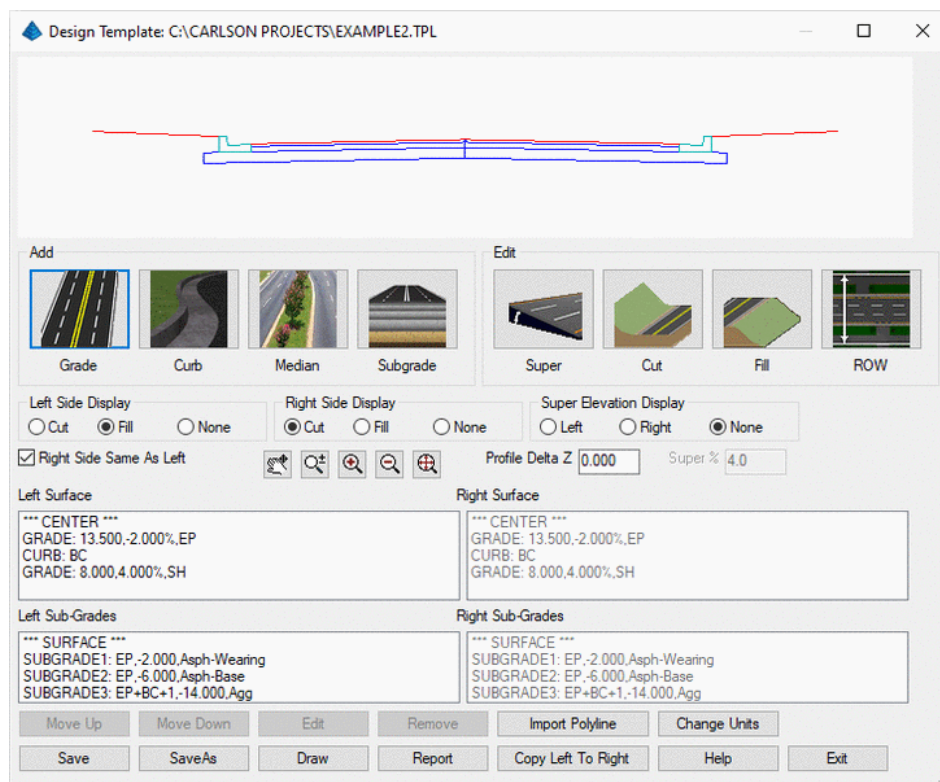

Low Side	High Side
Pivot Offset: <input type="text"/>	Pivot Offset: <input type="text"/>
Max Slope After Pivot (%): <input type="text"/>	Max Slope After Pivot (%): <input type="text"/>
Slope Type After Pivot: <input checked="" type="radio"/> Normal <input type="radio"/> Special	Slope Type After Pivot: <input checked="" type="radio"/> Normal <input type="radio"/> Special
Standard Slope Percent: 0.000	Standard Slope Percent: 0.000
Minimum Slope Percent: 0.000	Minimum Slope Percent: 0.000

Now for the final subgrade... the aggregate bed beneath the asphalt. Follow this: if the stone can't "Match Surface" (note this option under *Slope Type*), it will start uphill with the shoulder as it passes beyond the curb. So it must have a *Special Slope Type*, a consistent 2% cross-slope all the way. The "Wrap Height" is the vertical rise at the end of the aggregate base before it wraps back and returns back to the curb. Select the

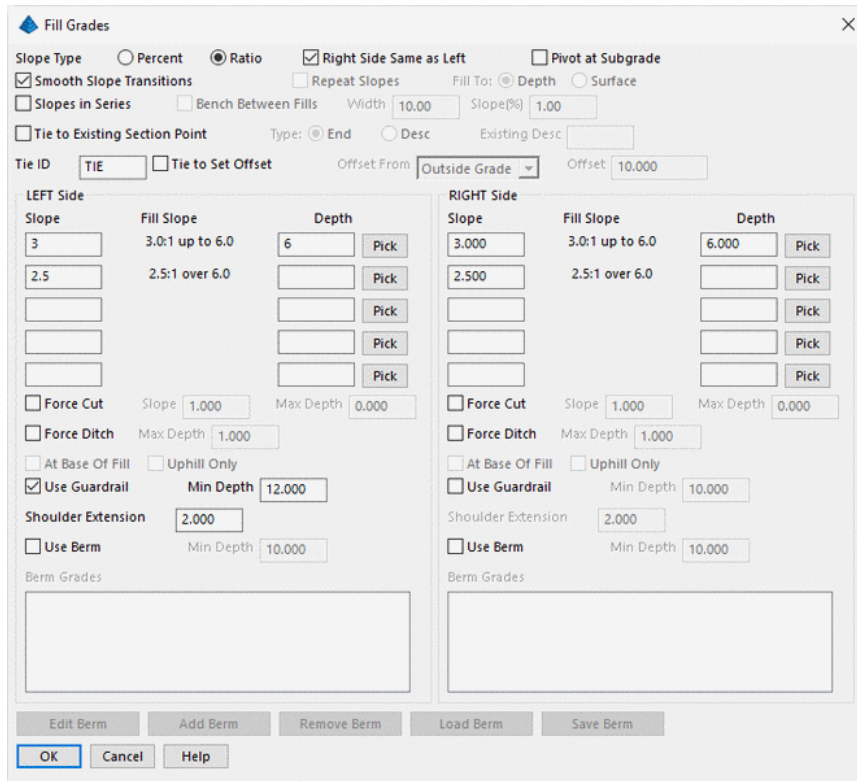

Subgrade icon again, complete the values as shown and click **OK** when ready:

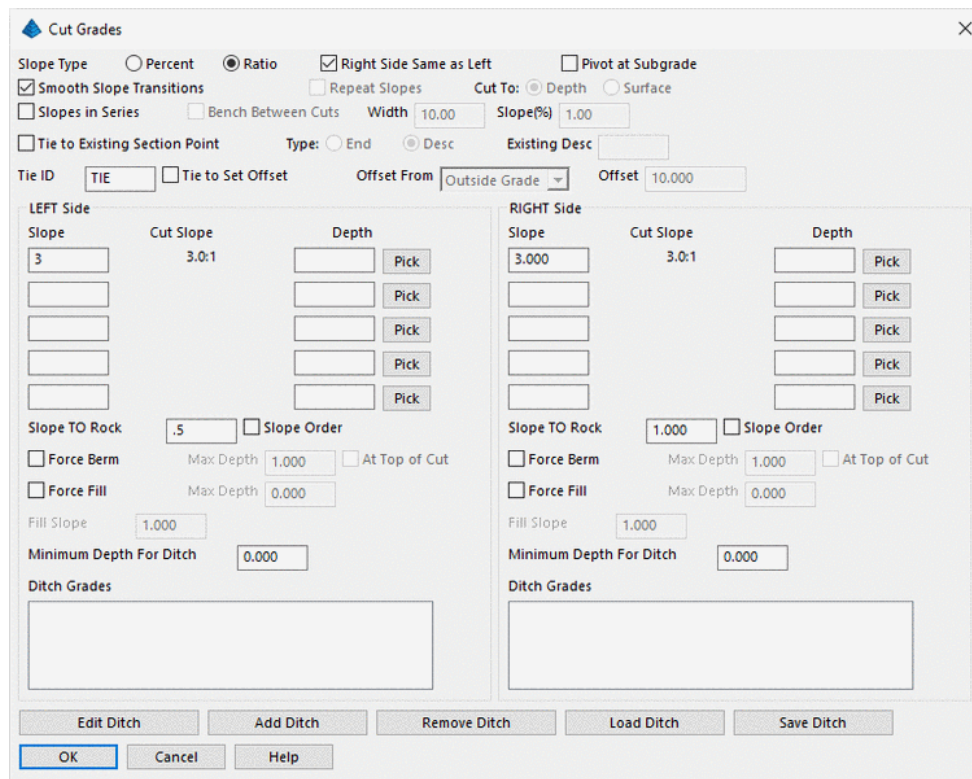

Note the preview screen:

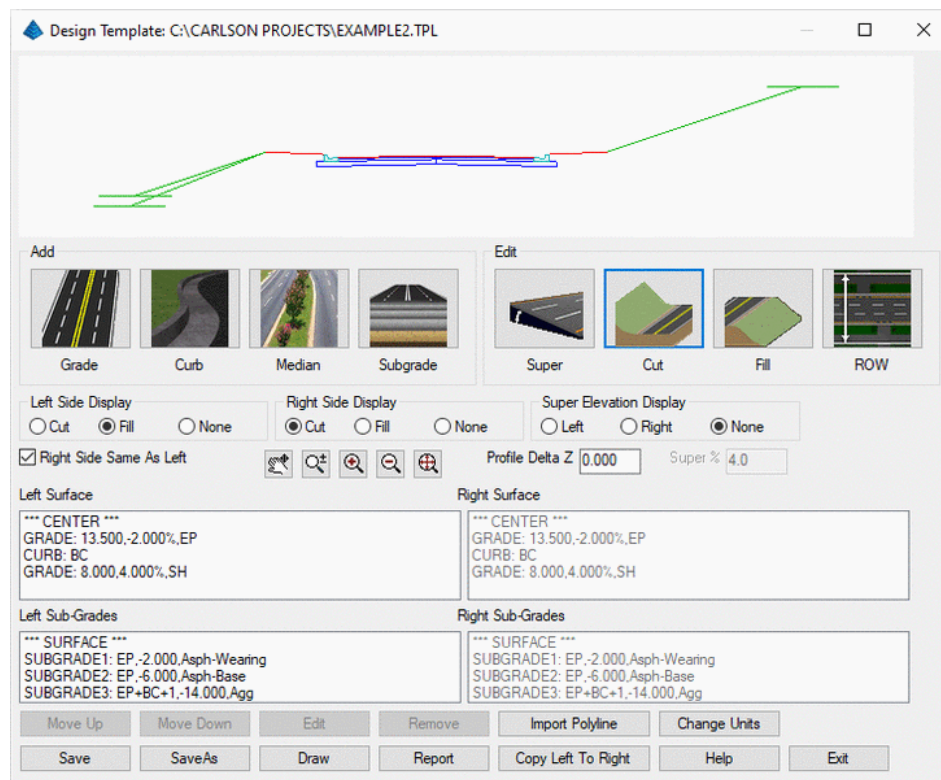

We still need to enter the tie-slope conditions. Let's continue and click the **Fill** as it is easy in our example:

Just four entries total: 3 (for 3:1), 6 (up to 6'), 2.5 (for 2½:1 over 6'), then enable the **Use Guardrail** toggle as shown. Click **OK**. Next, click the **Cut** button:

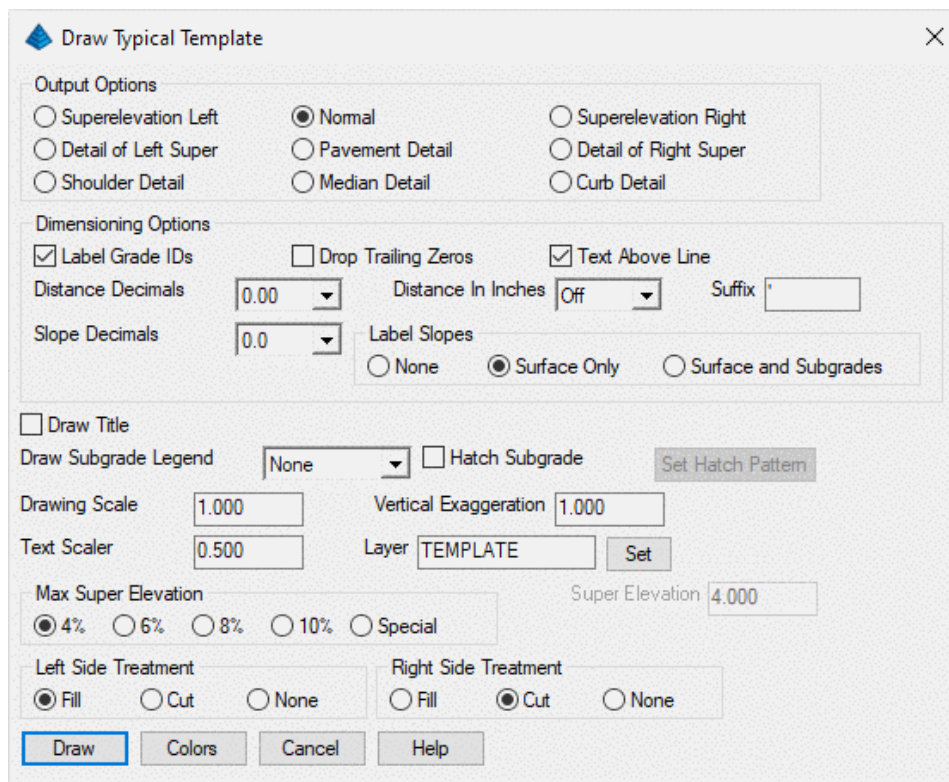

This too, is easy (in terms of total entries). Just two entries do it: 3 (for 3:1 normal cut) and in the **Slope TO Rock** area, specify 0.5 (for 0.5:1 cut when in rock). Click **OK**.

The template is complete. Click **Save** and then click **Exit** to close the dialogue box.

- Now let's prove we have a good template by issuing the Roads – Draw Typical Template command (this is the same as the *Draw* button as found in the previously discussed **Design Template** command). The file extension for templates will be *.tpl. Select the template file as named above and click **Open** to display the following dialog box:

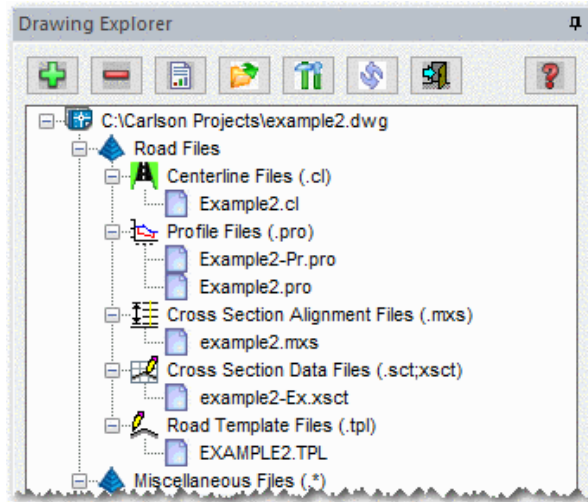

We have doubled the text scaler to **0.5** for better appearance in this tutorial. Click on **Draw** and pick a starting

position point. Here is the look of the plotted template:

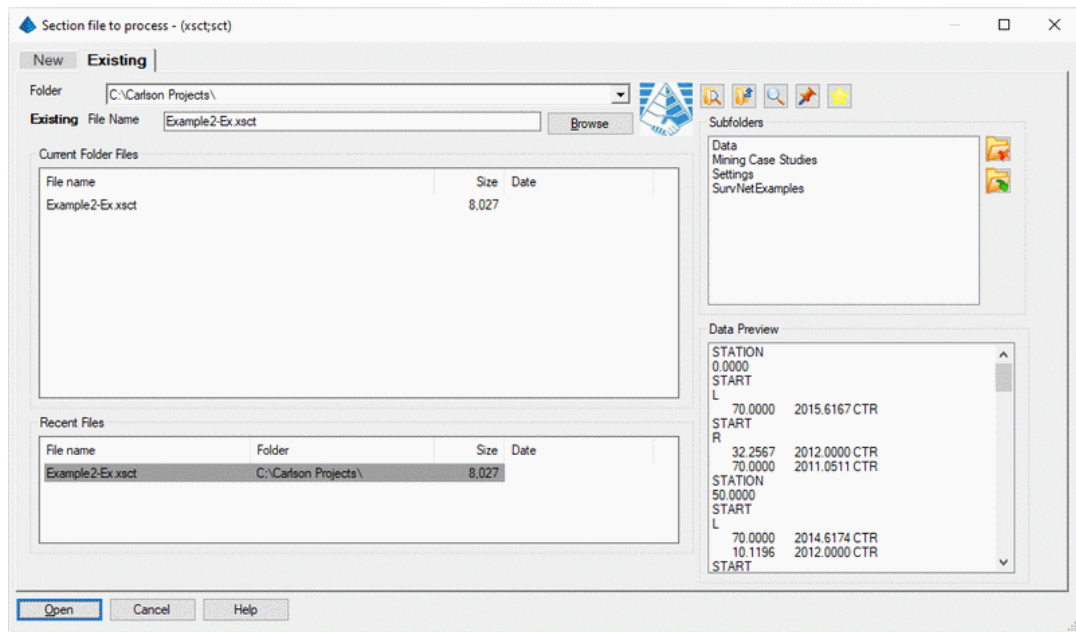

- As more files are created, edited, loaded and reviewed within a work session, the *.ini file associated with the active drawing takes note. You can review your active files as you work, or days later, because they save to the *.ini file that shares the same name as the drawing file. To see the files associated with this tutorial drawing file, issue the File – Drawing Explorer command to display a docked dialog box similar to that shown below:

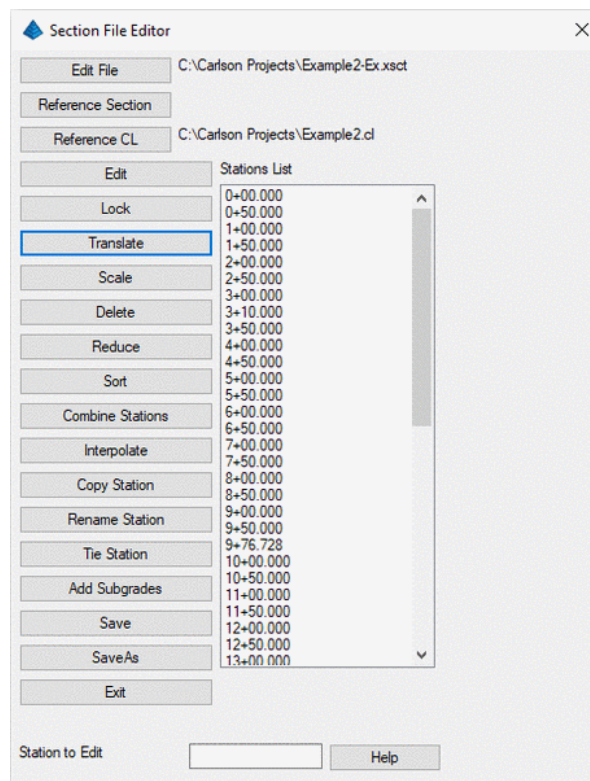

To edit any given file, simply double-click it or right-click it to show a series of sub-options. Click the **Exit** (Doorway) button when complete.

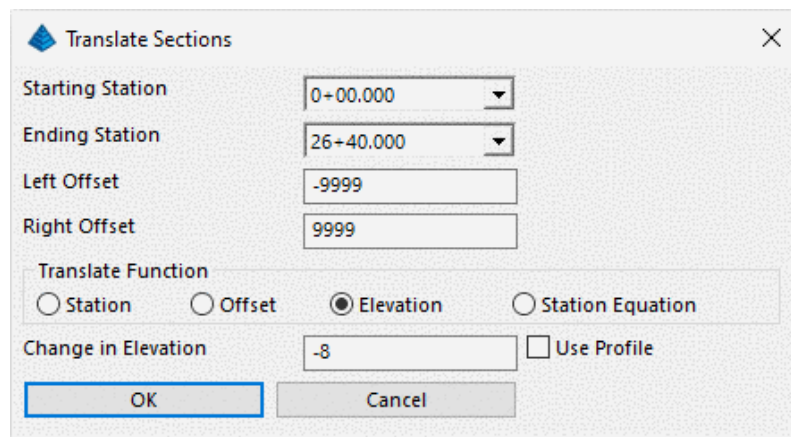

- Although Carlson has dedicated technology for using soil-boring logs to determine subsurface strata (*e.g.* topsoil thickness, depth to rock, *etc.*), we'll develop an approximate rock surface to demonstrate rock-section cuts. Issue the Sections – Section File Editor command, select the section file you created earlier and click **Open** as illustrated below:

Section File Editor has many uses. One of them is to translate or lower the elevations of a file and re-save. If we lower the elevations of our ground sections 8 feet, we can call that the rock line. Rock lines react with templates and profiles to create rock cuts and rock quantities when we process the road corridor template through the project. The next dialog that appears is shown below:

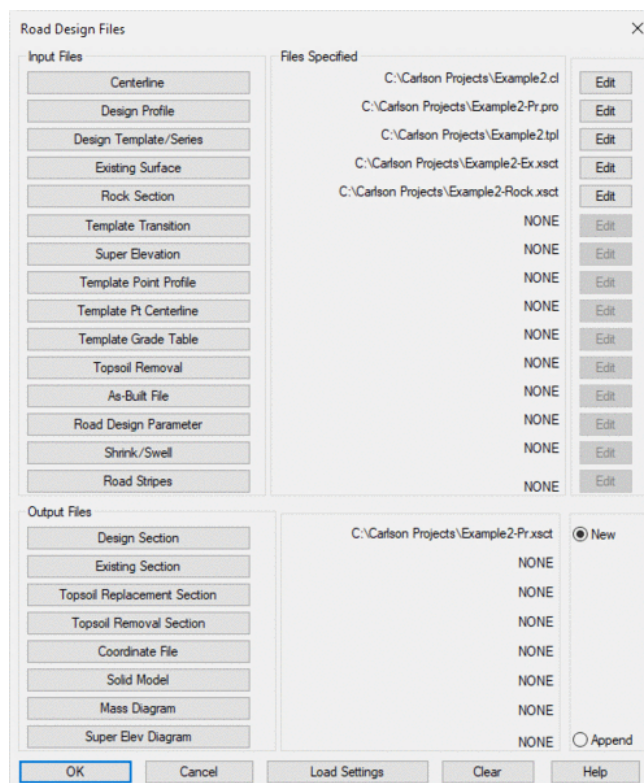

Click the **Translate** button to display the dialog box shown below. Make sure the dialog looks that same as shown below, and click **OK**:

Control returns to the *Section File Editor* dialog box. Click **SaveAs**, and enter a different name, such as *Example2-Rock*, and save the file. Then click **Exit**. *Section File Editor* can do much more through its **Edit** option (although we will not be making any other edits to either section file). However, when using *Edit*, you would first highlight one station, then click *Edit* to review and/or revise it.

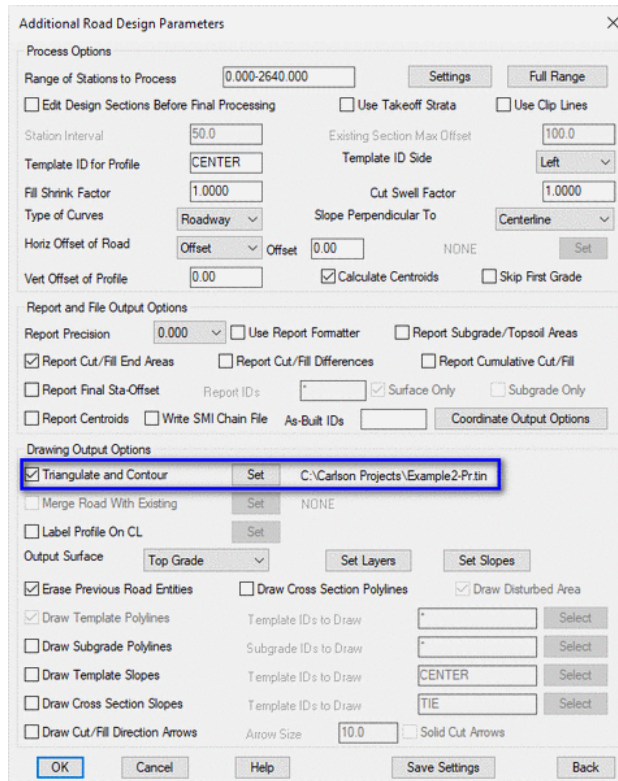

14. It's time to pull everything together. Issue the Roads – Process Road Design to display the dialog box shown below:

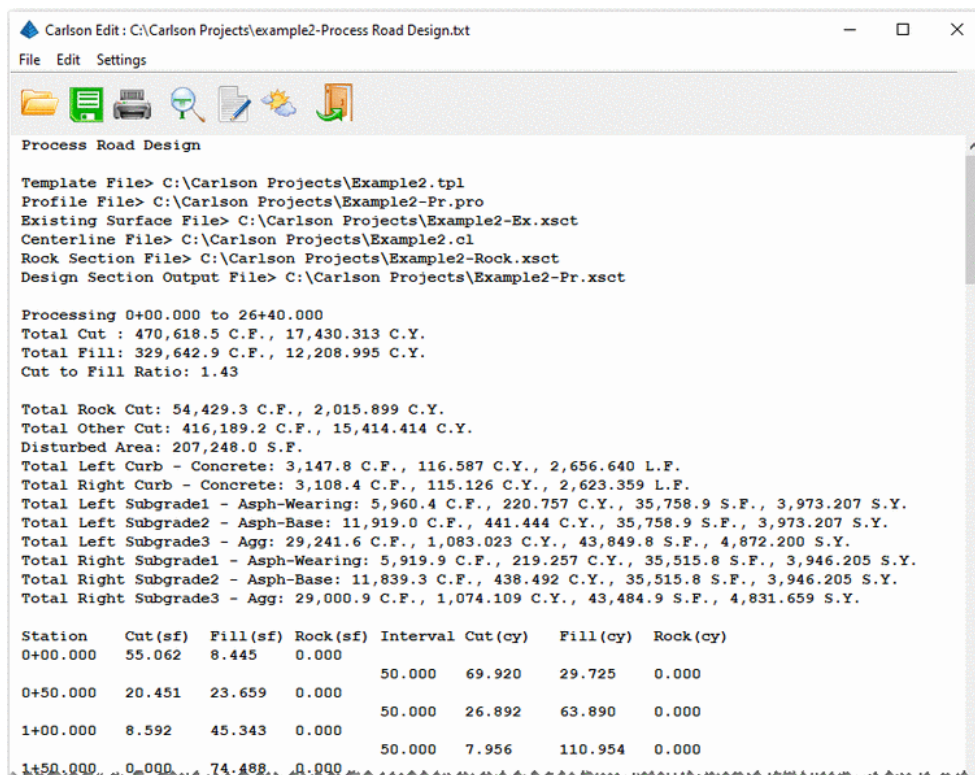

Fill out the dialog as shown above, making sure to:

- (a) correctly specify your **Design Profile**, and,
- (b) specify a *New* **Design Section** file as found in the Output Files section of the dialog box.

Click **OK** to initiate the design process. On the next dialog, be sure to enable the **Triangulate & Contour** and specify an output TIN file and contours of the completed road as illustrated below:

Now click **OK**. Here is a partial view of the final report, with itemized quantities:

Click the **Exit** (Doorway) button when finished reviewing the report. Depending on your *Triangulate & Contour* settings, you may be prompted:

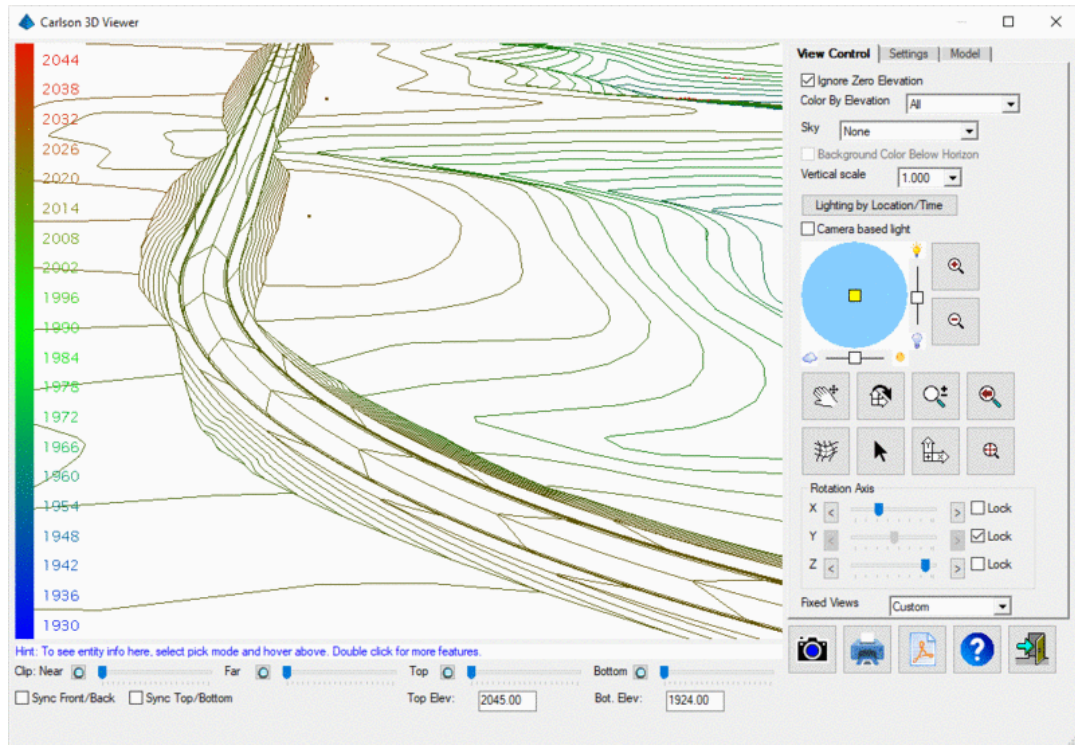

Retain trimmed polyline segments [Yes/<No>]? press Enter

15. Let's inspect the result visually through the use of the View – 3D View – Drawing Viewer command. When prompted:

Select entities for the scene.

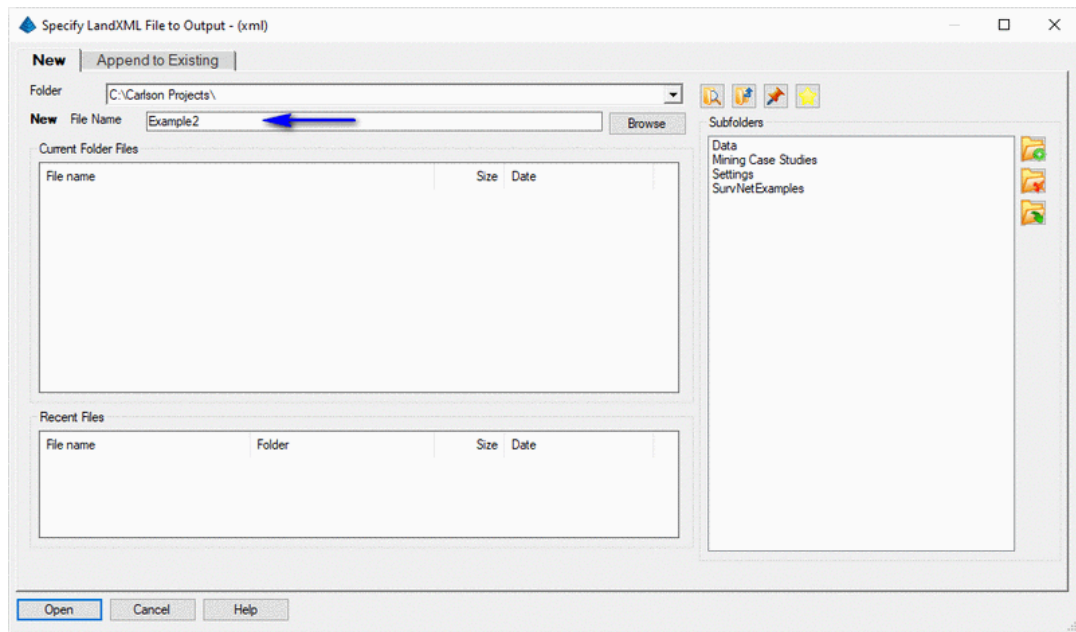

[FILter]/<Select entities>: type ALL and press Enter twice

Here is a resulting graphic:

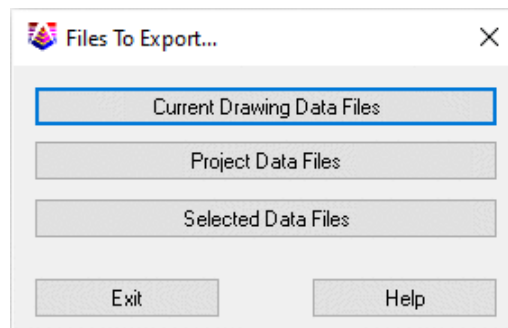

Click the **Exit** (Doorway) button when finished.

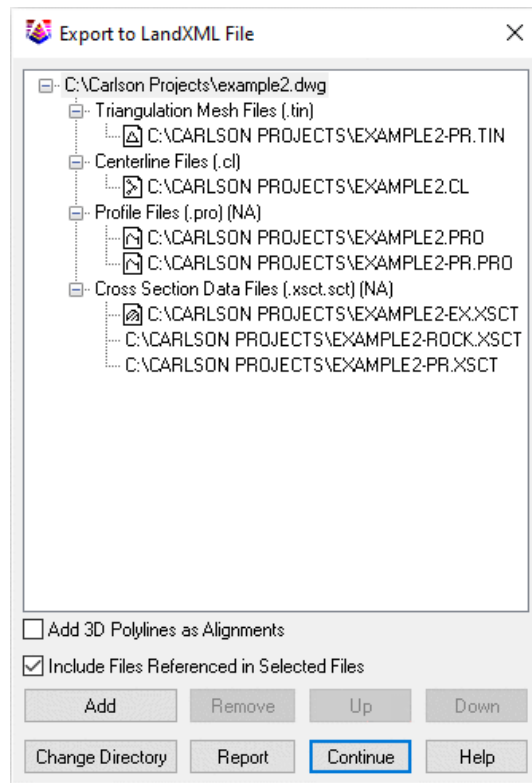

16. Our last task will be to package up the various files used in this example to a CAD-neutral, vendor-neutral *LandXML* format that is often used when needing to convey (or archive) the intent of the design to another party (*i.e.* stake-out crews, machine-control paving crews, *etc.*). Issue the File – Export – LandXML File command to create a LandXML file as shown below and click **Open** when ready:

We'll automate the process of the data files that should be packaged into the LandXML file through the use of the **Current Drawing Data Files** option as highlighted below:

A summary of the files associated with the drawing should look similar to that shown below:

Click on **Continue** once you are satisfied with the list to display the dialog box below:

Set the values as shown above and click **Export**. In the event you are notified about a potential *Units* conflict (for this example), initiate the desired response (as offered below):

The LandXML file is written and can be validated through the LandXML Validator.

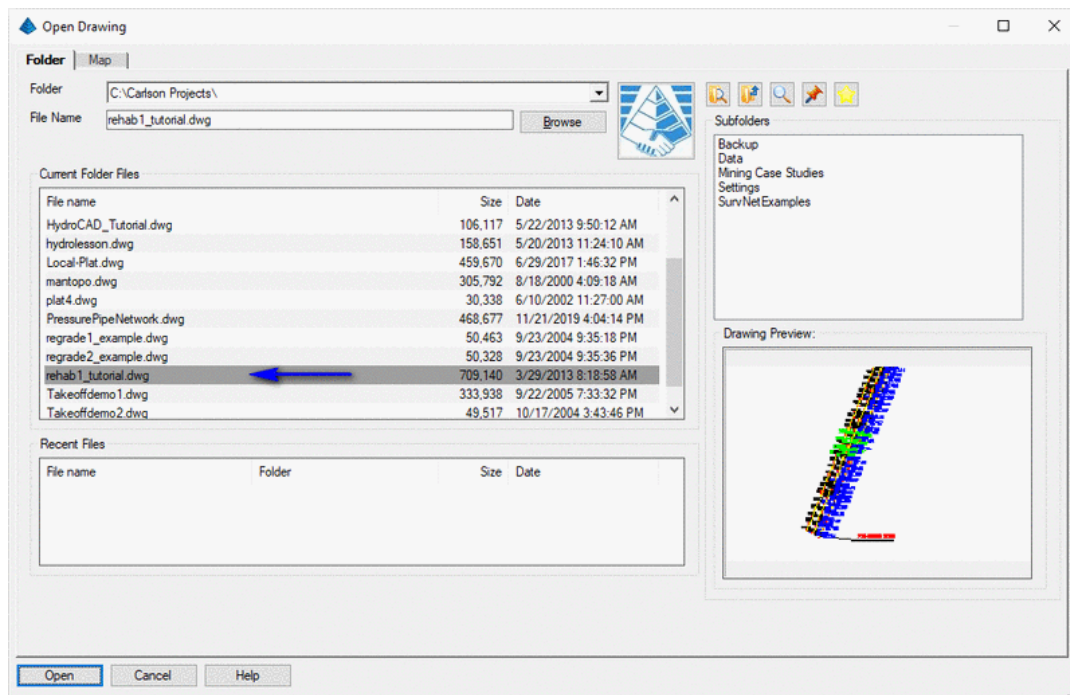

This completes the tutorial: Basic Road Design with Volumes.

Road Rehabilitation

This lesson designs a road rehabilitation project for two lanes of an Interstate highway. The top surface of the existing road has already been milled and the top of the milled surface has been surveyed. The two lanes are crowned in the center with a typical cross slope of approximately 1%. The design is to add 8" of concrete with a minimum cross slope of 1.56%. Let's get started.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

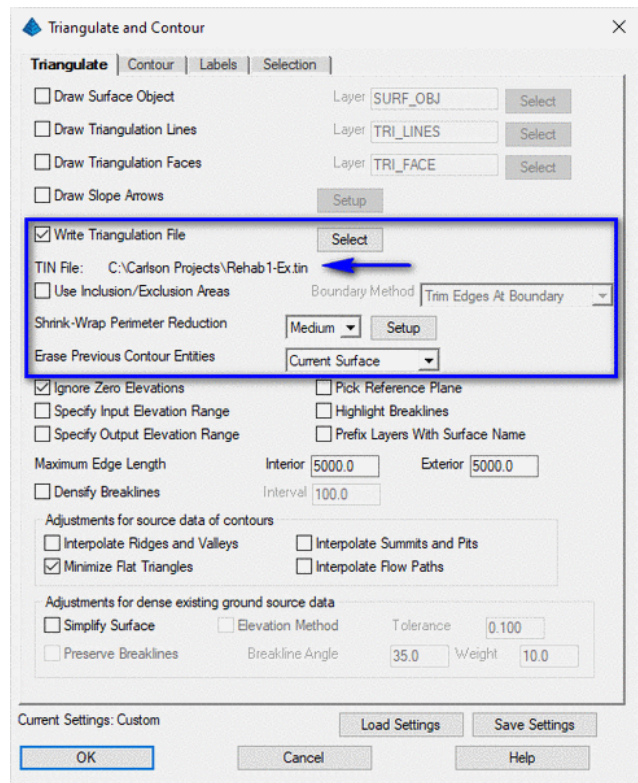

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **rehab1_tutorial.dwg** file.

Use the File – **Save As** to save a copy named **rehab2_tutorial.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties. The drawing should resemble that shown below:

- Ensure you are in the Civil program by issuing the Settings – Carlson Menu – **Civil Menu** command.
- Our immediate goal will be to create an existing ground surface model (TIN). Issue the Surface – Triangulate & Contour and set the values shown in the dialog box below and click **OK** when ready:

When prompted:

Select the points and breaklines to Triangulate.
[FILTER]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

A surface model (TIN) file representing existing conditions is created.

3. Our next task will be to create a horizontal centerline from polyline data found in the drawing. Before we complete this task, we'll want to freeze the *BREAKLINE* layer to expose the polylines on the **PROPOSED PAVEMENT** layer. Issue the View – Freeze Layer by Pick and when prompted:

Pick entities on layers to be frozen: pick one of the pavement edge polylines

Pick entity on layer to be frozen (U-Undo,Enter to end): press Enter

Issue the Centerline – Polyline To Centerline File to display the dialog box shown below:

Set the desired file name as shown above and click **Save** when ready. When prompted:

Polyline should have been drawn in the direction of increasing stations.

Select polyline that represents centerline: pick the centerline polyline

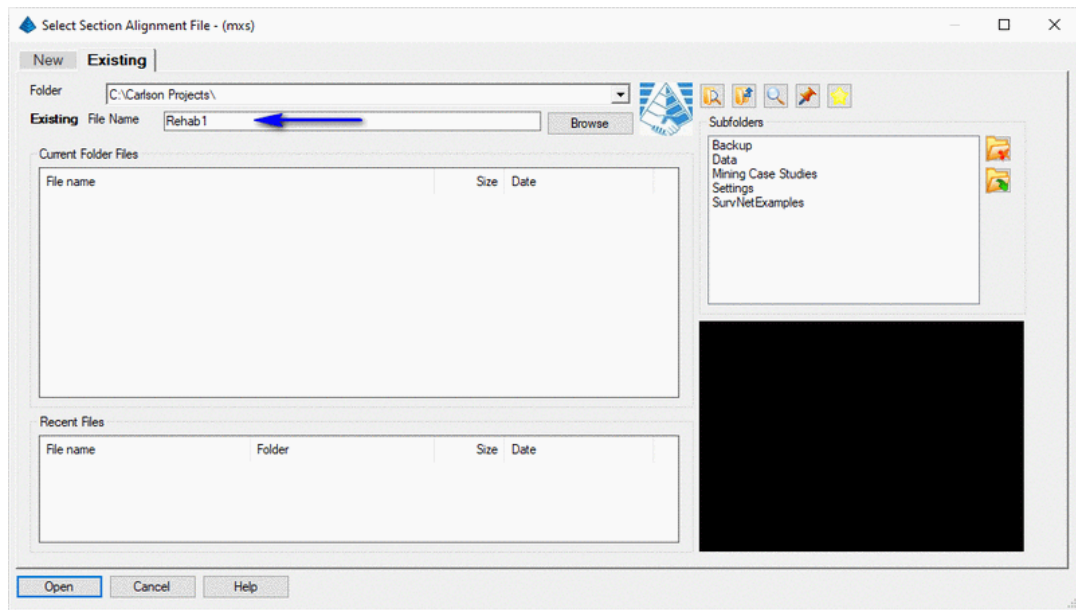

Centerline station [Reverse/Ending/<Beginning: 0+00>]: type 73258.51 and press Enter

Press ENTER to continue. press Enter

A centerline alignment is created.

NOTE: Double-clicking on the polyline on the screen will open the Centerline Editor command.

4. Now that the horizontal path of the road has been established, the next step will be to generate cross-section information of existing conditions. Issue the Sections – Section Alignment Editor to display a dialog box similar to that shown below:

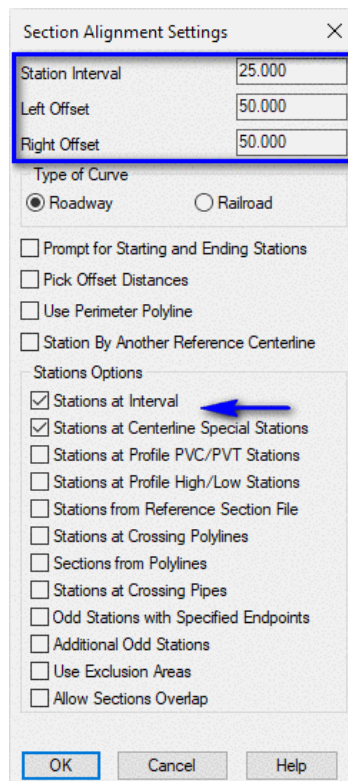

Set the file name as indicated above and click **Open** when ready. When prompted:

Polyline should have been drawn in the direction of increasing stations.

CL File/ <Select polyline that represents centerline>: indicate the Centerline option

Specify a CL File (dialog): select the Centerline created in the previous step and click **Open**

Section Alignment Settings (dialog): set the values as shown below and click **OK** when ready

- The program draws temporary lines in the drawing to show the positions of the sections and displays a summary of the section alignment cross-section stations. Click the **Save** button followed by the **Exit** button.
- To create the section file for the *Existing* (base) surface, issue the Sections – Create Sections from... –

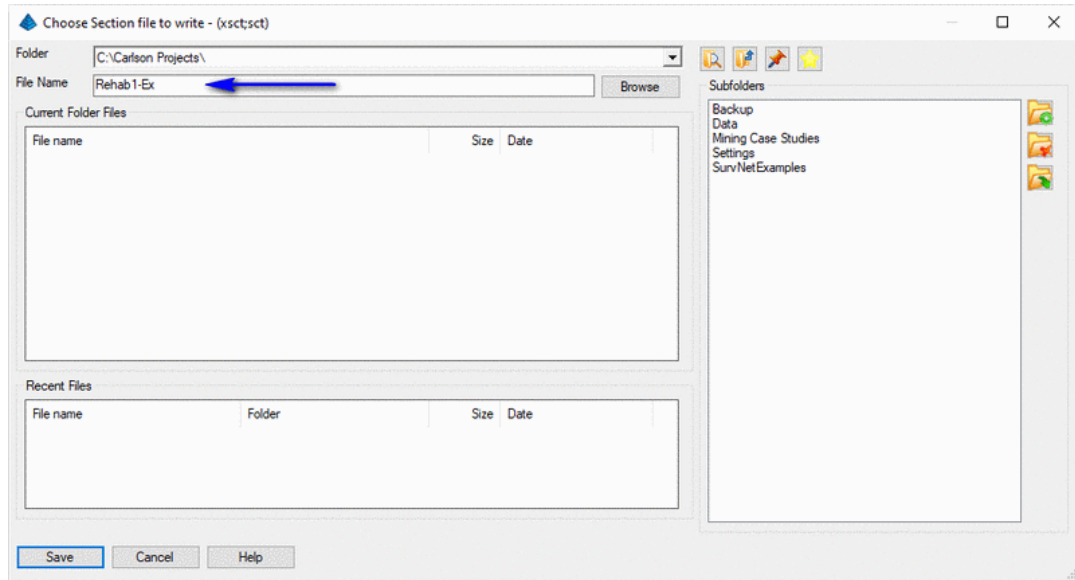

Sections from Grid or Triangulation Surface command. When prompted:

Choose Grid or Triangulation file to Process (dialog): specify the TIN file created earlier and click **Open** when ready

Section Options (dialog): set the option to **Prompt** and click **OK** when ready (with *Prompt* specified, you'll be prompted if the Section should change if there is an underlying change to the source TIN file)

Section Alignment File to Process (dialog): specify the section alignment (*.MXS) created earlier and click **Open** when ready

Choose Section File to Write (dialog): specify a file name as illustrated below and click **Save** when ready

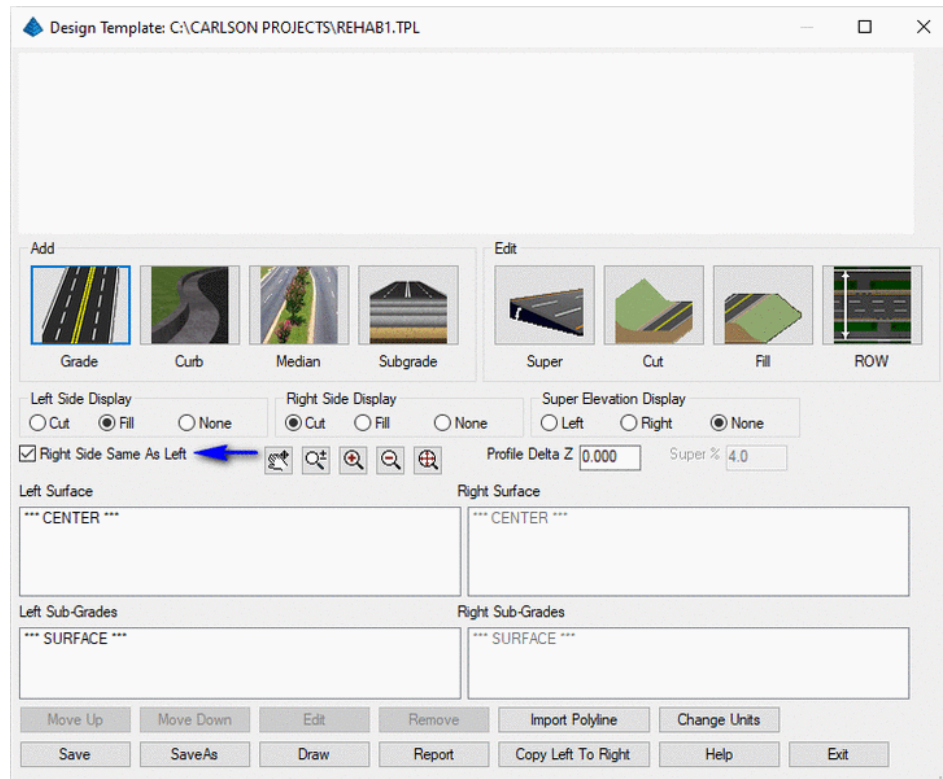

The section file is written.

6. Now that we've generated existing cross-section data, our next task will be to create a design template "overlay" for the road surface we wish to construct. Issue the Roads – Design Template and click on the **New** tab to create the file name as shown below. Click on **Open** when ready:

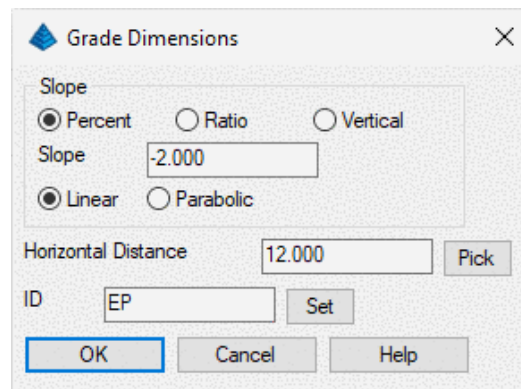

A large dialog box appears as shown below. In it, you enter segments of the template, which typically work

outwards from the middle as you add more lanes, curbs and shoulders. We will enter a symmetrical template, with 12' pavement sections either side of centerline with an 8" subgrade.

For the lanes, click the **Grades** icon. This leads to a child dialog as shown next:

Fill out as shown. It's important to note that a downhill pavement from a crown in the middle is entered as a negative slope. That is, it is -2% heading from centerline outward, regardless of which side of centerline we are speaking of. Slope is independent of the profile grade point. It is also important to enter an ID whenever requested as these can be referenced later for advanced placement control. Click **OK** and note that the lanes show up in the preview window at the top.

Click the **Subgrade** button and indicate the following desired values for the subgrade surface:

The image shows a software dialog box titled "Subgrade Dimensions". It contains several sections for configuring subgrade parameters:

- Subgrade Type:** Radio buttons for "Roadway" (selected), "Cut Slopes", and "Fill Slopes".
- Distance Direction:** Radio buttons for "Out" (selected) and "In".
- Slope Type:** Radio buttons for "Match Surface" (selected) and "Special".
- Slope (%):** Text input field with "0.000".
- Tie Undershoot Vertically at Hinge:** Check box (unchecked).
- Intersect Surface:** Dropdown menu with "Straight Up" selected.
- Wrap Height (in):** Text input field with "0.000".
- Tie Slope (%):** Text input field with "0.000".
- Horizontal Offset:** Text input field with "0".
- Vertical Offset (in):** Text input field with "-8.000".
- Units:** Radio buttons for "Feet" and "Inches" (selected).
- Match Existing Surface:** Check box (unchecked).
- Distance:** Text input field with "EP" and a "Select" button.
- Material:** Text input field with "Concrete" and a "Set" button.
- Coatings/Notes:** Text input field.
- Super Elevation Settings:** A sub-dialog box with settings for "Low Side" and "High Side", including "Pivot Offset", "Max Slope After Pivot (%)", "Slope Type After Pivot" (Normal/Selected, Special), "Standard Slope Percent" (0.000), and "Minimum Slope Percent" (0.000).

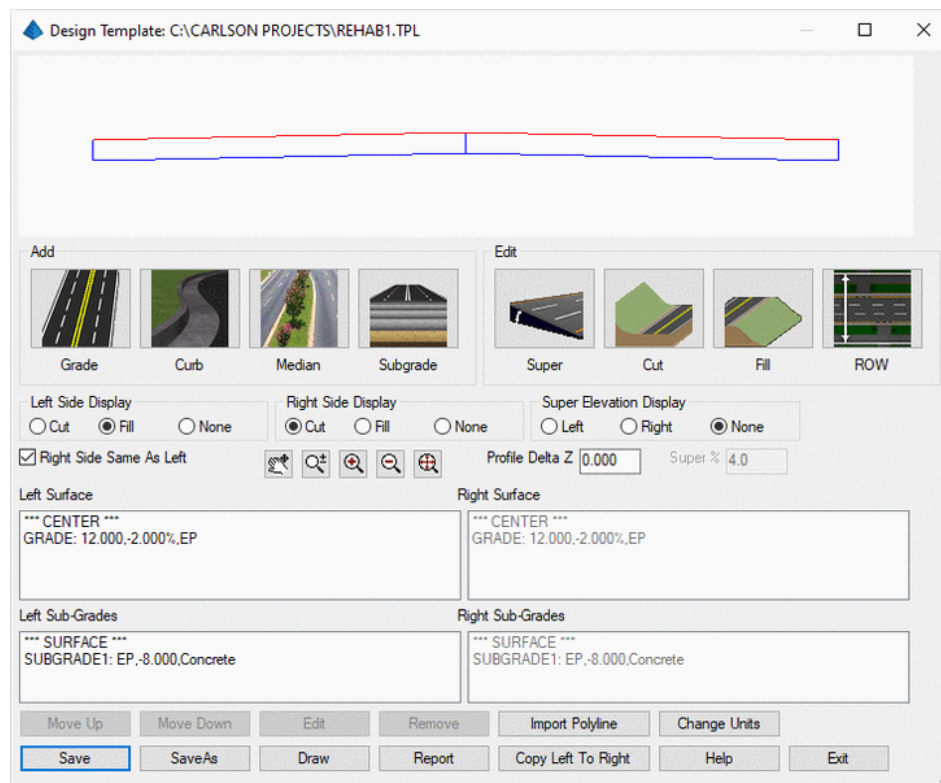

At the bottom are "OK", "Cancel", and "Help" buttons.

NOTE:

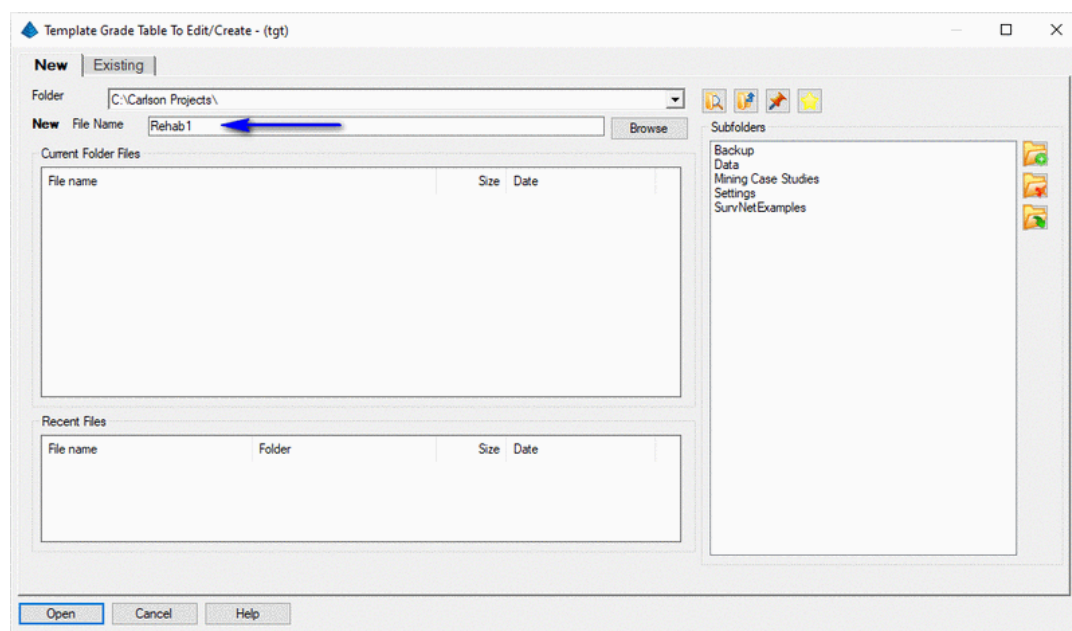

- **Straight Up** for the Intersect Surface option instructs the subgrade surface to intersect vertically to the grade surface above.
- **0** for the horizontal offset distance instructs the subgrade surface to start directly under the centerline of the road.
- **8 inches** for the Vertical Offset instructs the subgrade to be 8 inches below the grade surface above and will generate the minimum 8" pavement thickness specified earlier in this lesson.
- **EP** for the Distance instructs the subgrade width to be the same width as the EP (edge-of-pavement) width specified in the *Grade Dimensions*.

NOTE: By using the parametric/variable ID points (*e.g.* the "EP" code *vs* the 12' Horizontal Distance, the subgrade width will vary as needed to accommodate the pavement grade width!

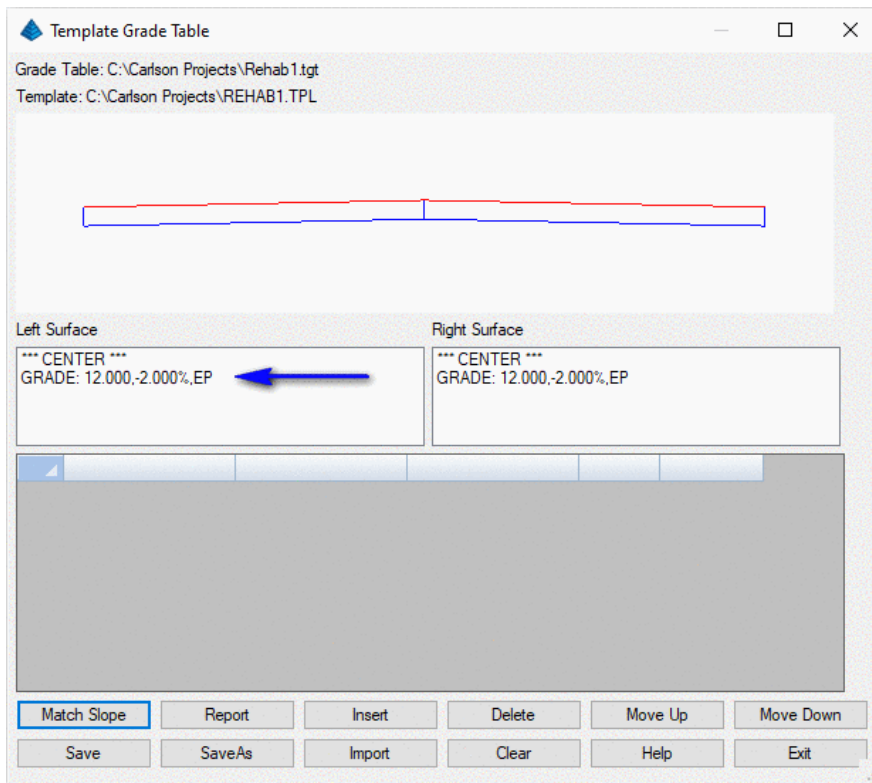

Click OK when ready to dismiss the Grade Dimensions dialog box. The proposed road template should resemble the following:

- That's all that needs to be defined in the template. Click the **Save** button and then click **Exit**.
7. The next step is to design the proposed cross-slopes to follow the existing section grades as much as possible. Issue the Roads menu – Template Grade Table to display a dialog box similar to that shown below:

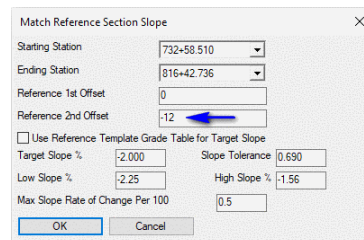

Set the file name as shown above and click when ready. A dialog box similar to that shown below appears:

- Highlight the **GRADE** surface from the Left Surface list, then
- click the **Match Slope** button, then
- select the **section** file created earlier as the *Section File to Process* and click **Open** when ready. A dialog box similar to that shown below appears:

Left Side Settings

Right Side Settings

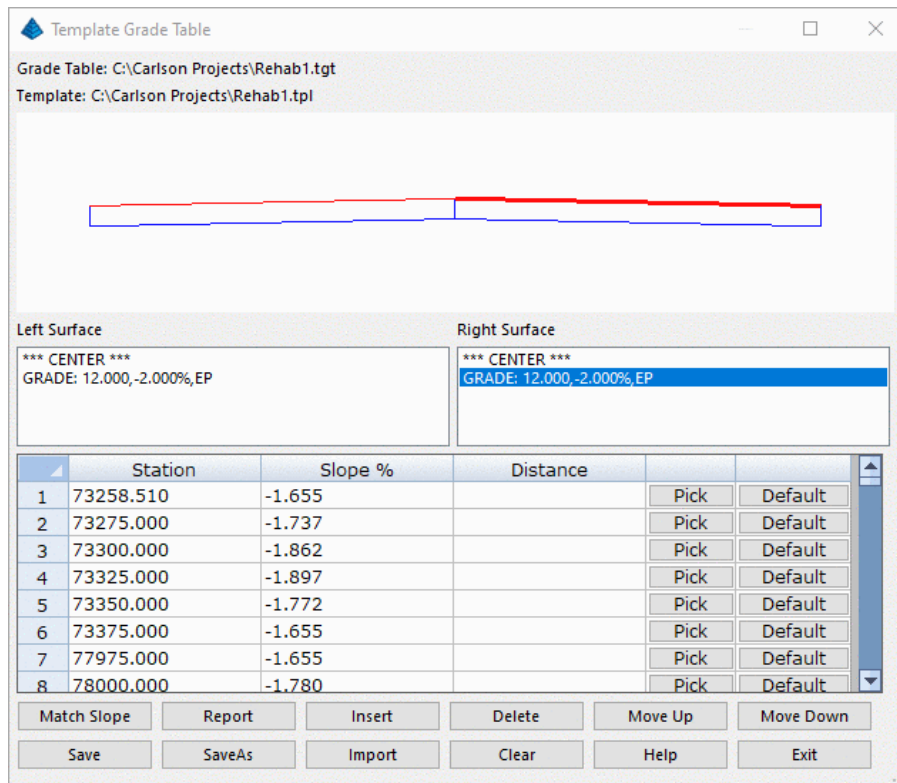

Match Reference Section Slope

Set the appropriate values for the Left/Right side as shown above and click **OK** when ready.

NOTE:

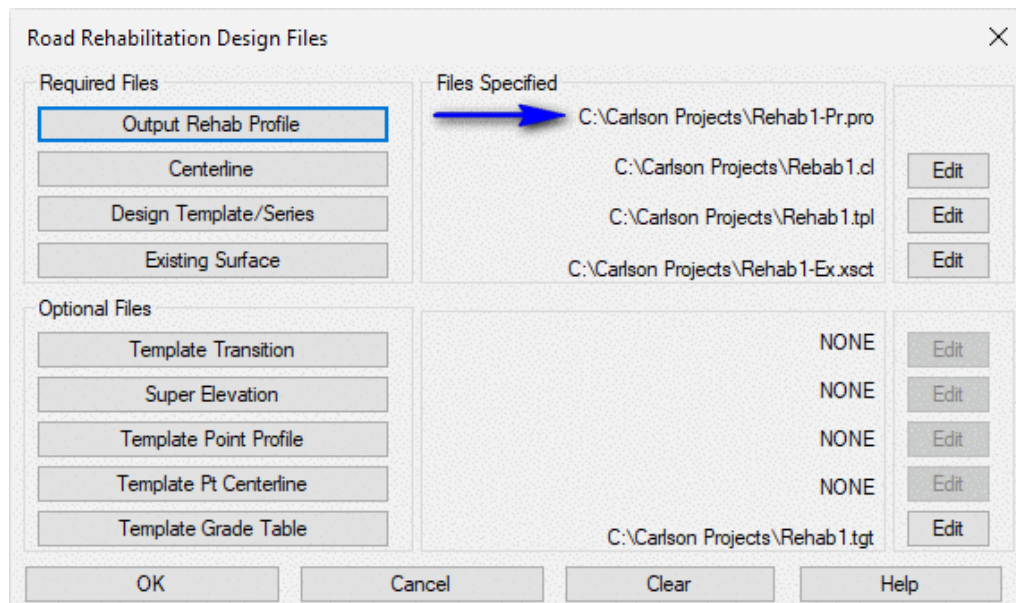

- The **Reference 1st/2nd Offset** values are used to sample the existing sections at the specified offsets to get the existing cross slope.
- The **Lowest/Highest Slope %** values restrict the design cross-slopes to be within the range specified.
- The **Max Slope Rate of Change Per 100** restricts how much the design cross-slope can change between stations. For example, with the maximum set to 0.5 and a cross-slope of -2.0% at station 1+00, the cross-slope at station 2+00 must be between -2.5% and -1.5%.

After picking **OK** on the dialog box above, highlight the **GRADE** surface from the Right Surface list and repeat the steps above. The resulting *Template Grade Table* should resemble that shown below:

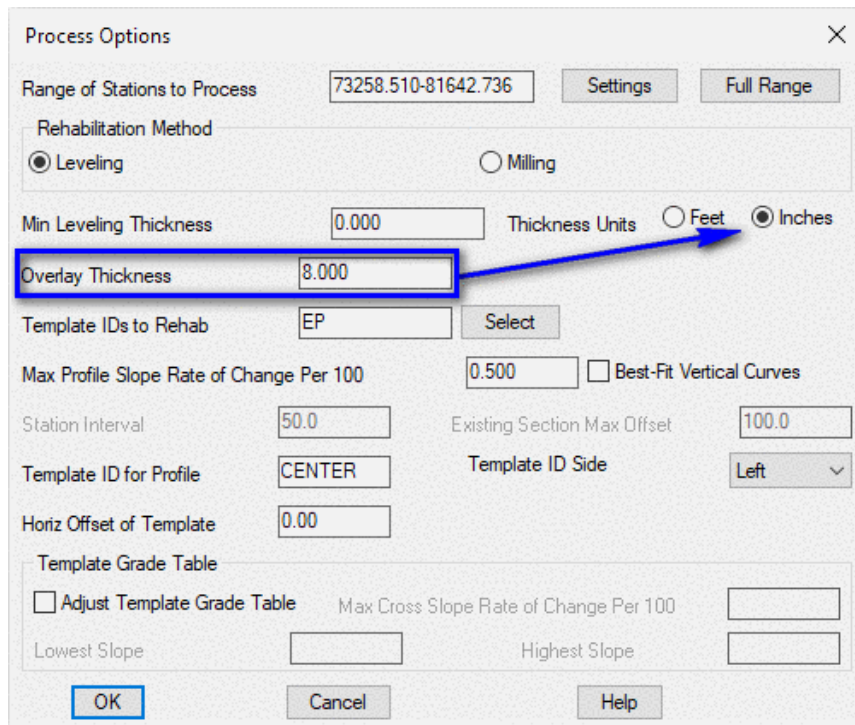

Click **Save** and then click **Exit**.

- The next step is to define the design profile that minimizes quantities while satisfying the design parameters. Issue the Roads – Road Rehabilitation Profile command to display a dialog box similar to that shown below:

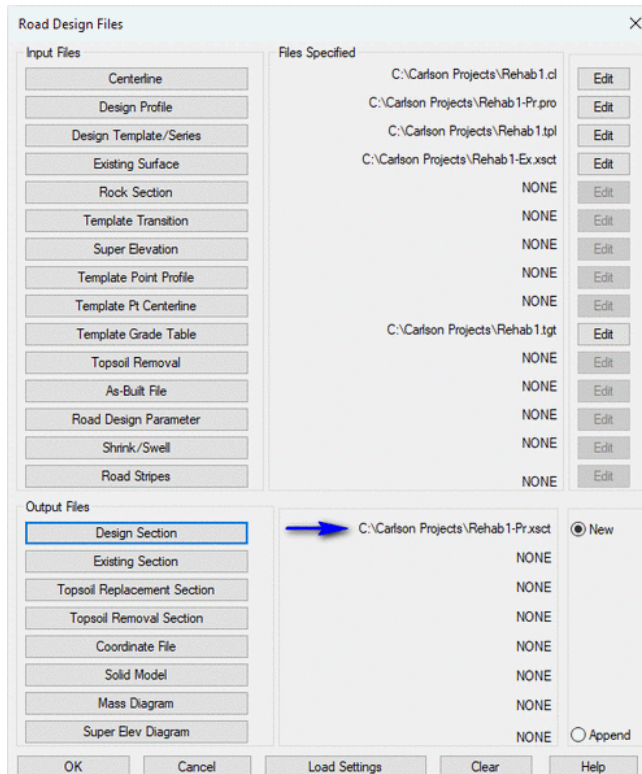

Set the values as shown above and click **OK** when ready to display a dialog box similar to that shown below and click **OK** when ready:

NOTE: The **Max Profile Slope Rate of Change Per 100** option is essentially identical to the *Max Slope Rate of Change Per 100* value found in *Template Grade Table* except this one applies to the profile slope instead of the cross-slope.

A profile for the data is generated and any adjustments to the profile can be made through the Profiles – Design Road Profile – Road Profile Editor command.

9. The road design is now ready to be computed. Issue the Roads menu – Process Road Design command to display a dialog box similar to that shown below. Make sure the **Centerline**, **Profile**, **Design Template**, **Existing Surface** and **Template Grade Table** options are each utilizing the files created earlier. Click on the **Design Section** button to create a new file as illustrated below:

Click **OK** when ready to continue. On the **Additional Road Design Parameters** dialog box, accept the default values as illustrated below and click **OK** to initiate the processing of the design:

The program reports the quantities per station and totals in a report similar to that shown below:

```

734+00.000 0.000      5.313

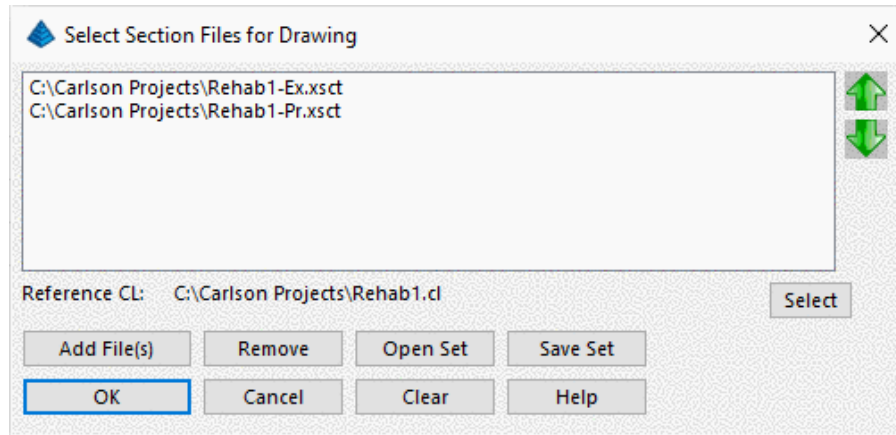

```

Review the report and click the **Exit** (Doorway) button when ready.

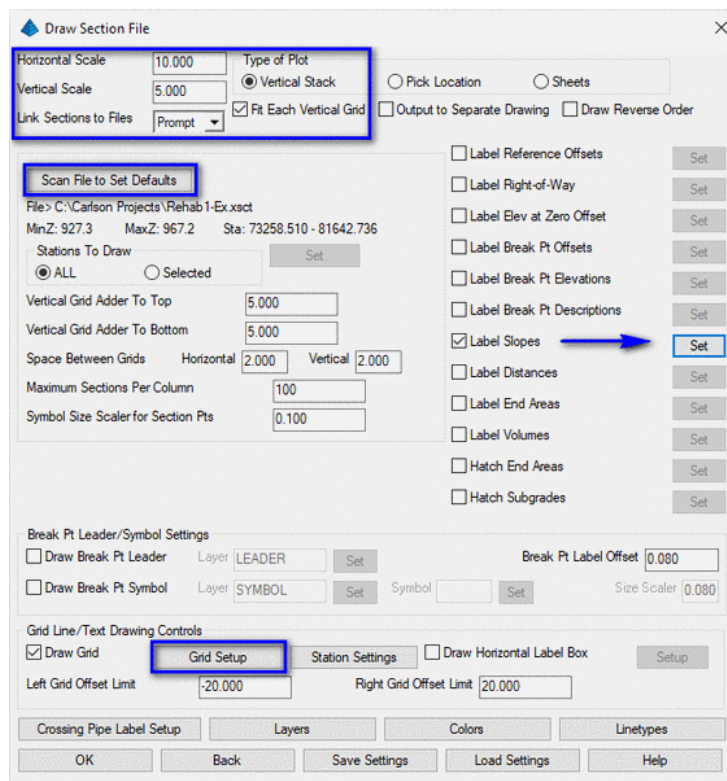

NOTE: Be aware of the following important values:

- The *Total Fill* is the amount of extra leveling.
- The *Subgrade Volumes* are the amount of overlay.

10. Our next task will be to visually verify the design by generating cross-section plots. Issue the Sections – Draw Section File command to display a dialog box similar to that shown below:

Click the **Add File(s)** button to add the two section files we've created earlier and use the *Up/Down* arrow buttons to set them in the order shown. Click **OK** when ready to display a dialog box similar to that shown below:

Set the values as shown above paying particular note to:

- Set **10** for the Horizontal Scale value.
- Set **5** for the Vertical Scale value.
- Click the **Scan Files to Set Defaults** button to "read" the section files specified earlier and retrieve data from them.

- **Vertical Stack** for the Type of Plot.
- Enable the **Label Slopes** option and then click the **Set** button to ensure:
 - (a) **Label Section 1** is enabled (use its **Set** button to enable the *Label Below* option).
 - (b) **Label Section 2** is enabled (use its **Set** button to enable the *Label Below* option).

NOTE: You can click the **Grid Setup** to set the **Horizontal/Vertical Grid Spacing** values to be the same as that of the *Horizontal/Vertical Scale* values as cited above.

Click the **OK** button and when prompted:

Select Starting Point for Row of Sections <0.00,0.00>: pick a location to the left of the roadway shots

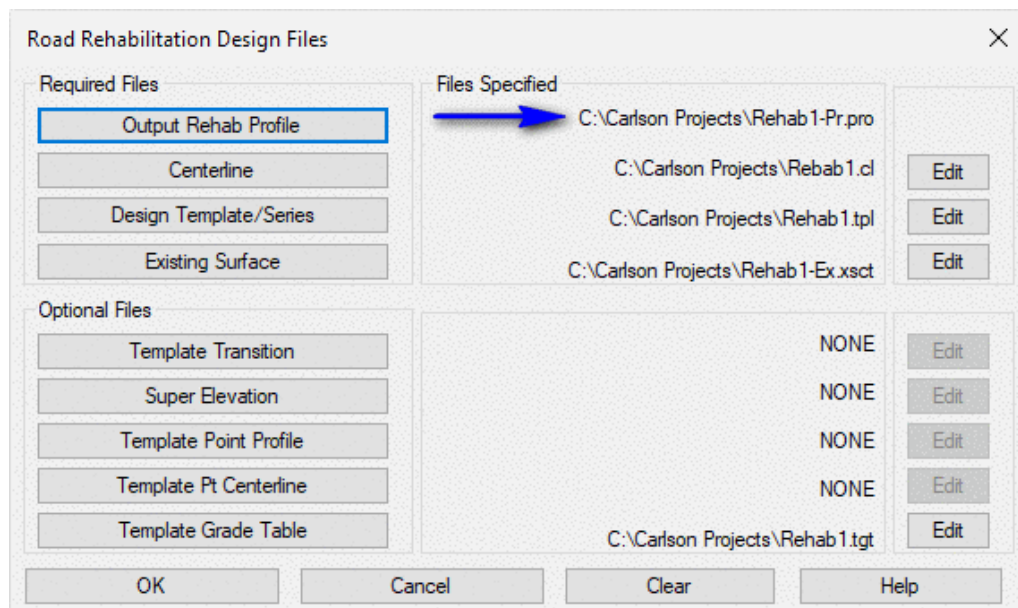

The collection of cross-section stations will be placed into the drawing similar to that shown below:

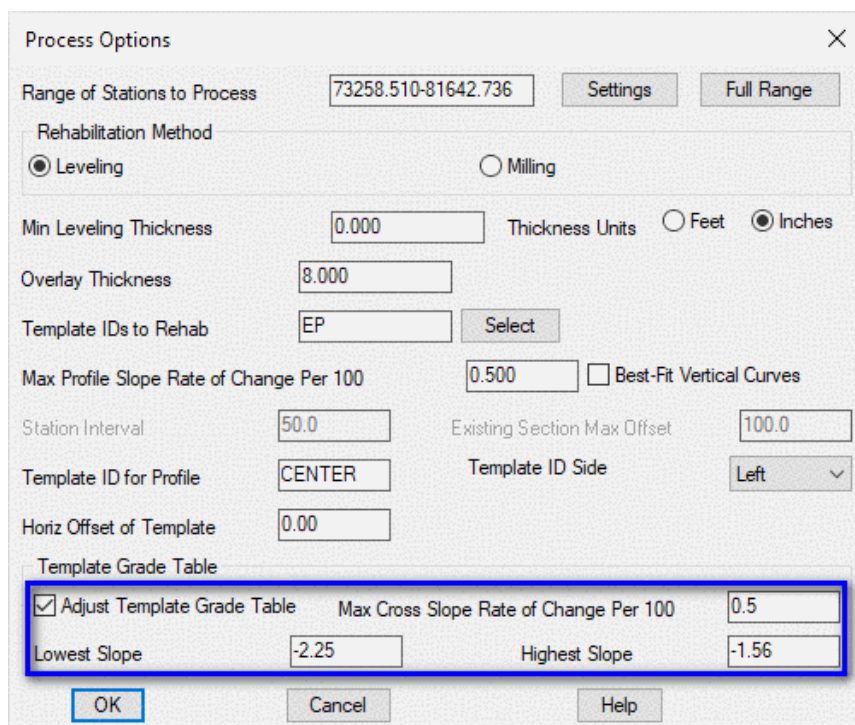

This station shows the existing surface with slopes ranging from 1.41% left to 0.57% right and the design with slopes 1.56% left and right. Since 1.56% was the minimum design cross slope, the design is steeper than existing and there is some leveling needed between the design overlay and the existing.

The profile elevation for this station was set by the right edge since this was the highest point. There is some extra leveling fill needed on the left side. This left side slope can be steeper because our design cross-slope range is 1.56% to 2.25%.

11. Let's continue with additional steps to refine the design! Re-issue the Roads – **Road Rehabilitation Profile** command again. Use all the same files as we did earlier:

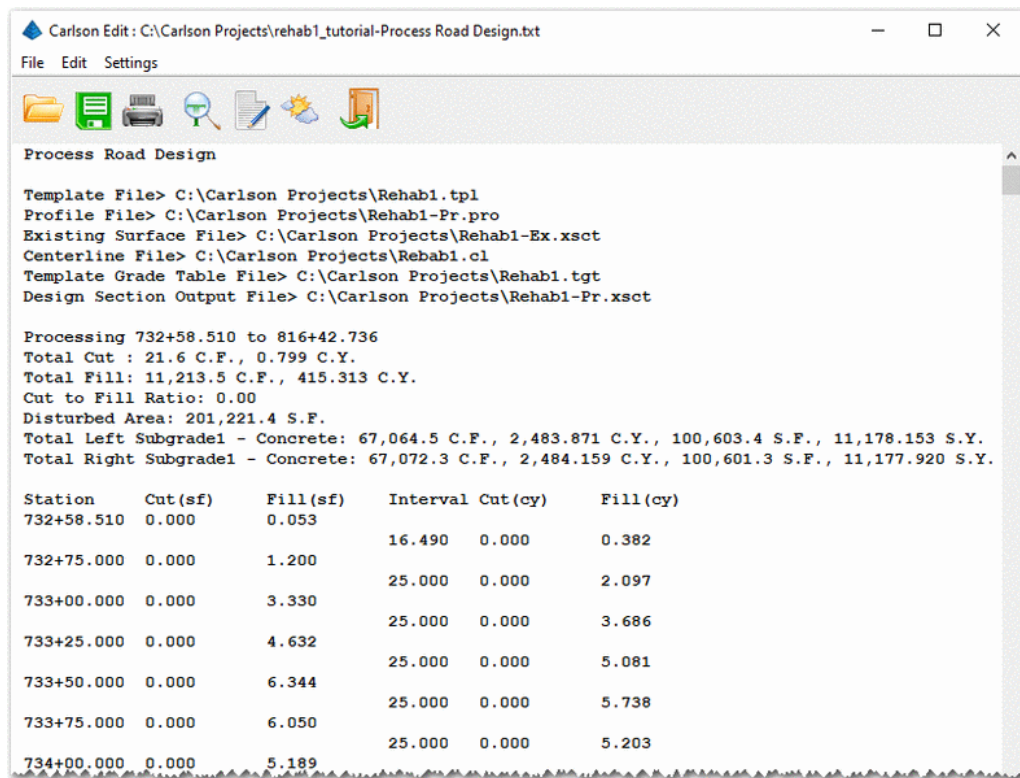

Set the values as shown above and click **OK** when ready to display a dialog box similar to that shown below. Enable the **Adjust Template Grade Table** toggle and set the **Lowest/Highest Slopes** and the **Max Cross Slope Rate** to the same design parameters used during *Template Grade Table* as shown below and click **OK** when ready:

NOTE: The **Adjust Template Grade Table** option checks the left and right grades while creating the rehabilitation profile and adjusts the slope on the side that is not controlling the profile grade.

12. Re-issue the Roads – **Process Road Design** command again with all the same settings from the previous run to display a report similar to that shown below:

Review the report and click the **Exit (Doorway)** button when ready.

NOTE: Because we had the **Link Sections to Files** option set to **Prompt**, let's update the already placed sections! Click **Yes** on the dialog box shown below:

For this run, the **Template Grade Table** has been adjusted. In the report, the overlay quantities are the same and the fill quantity for the extra leveling has been reduced as expected. In this case, the *Template Grade Adjustment* reduced the Total Fill (extra leveling) amount from 463.142 C.Y. to 415.313 C.Y. (about a 10% reduction in needed leveling material) with an updated cross-section representation similar to that shown below:

The only difference in the final section is that the left side is steeper to better match the existing surface.

This concludes this tutorial lesson: Roadway Rehabilitation.

Hydrology and Watershed Analysis

This tutorial requires the Hydrology module.

This lesson will step through some of the more common *Hydrology* module routines, and design structures based on the analysis of a watershed.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

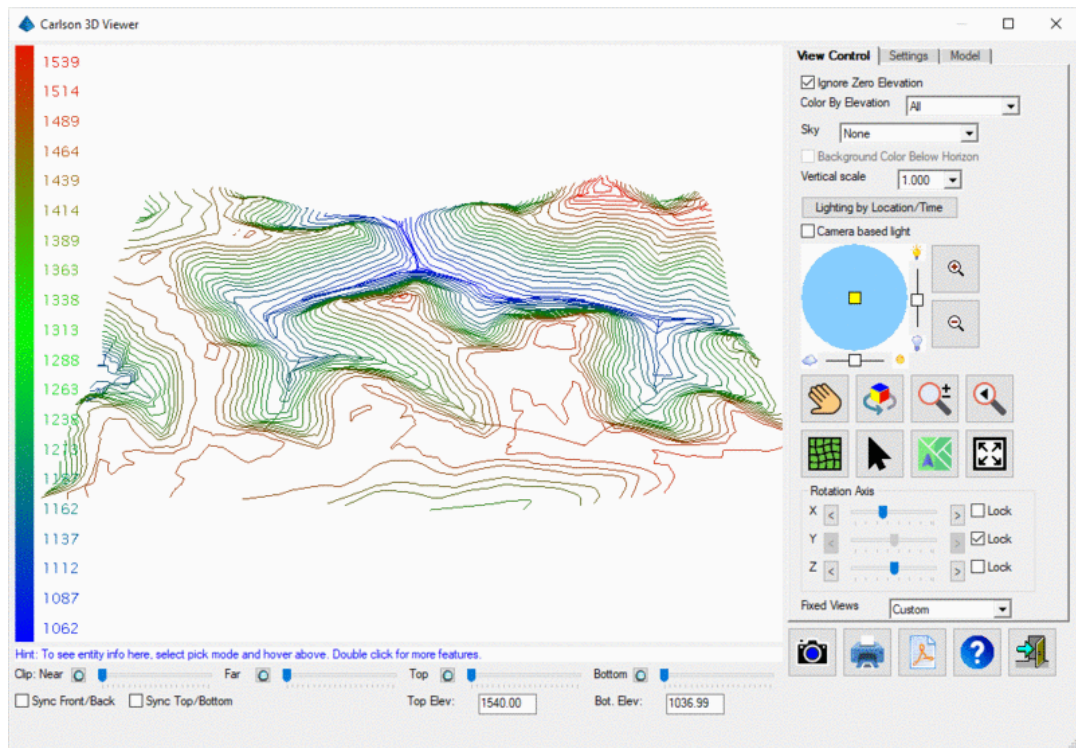

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **HydroLesson.dwg** file. Activate the Hydrology module via Settings – Carlson Menus – **Hydrology Menu**.

2. The drawing file **HydroLesson.dwg** is a nice example to show the features of the Hydrology module. A surface file (**hydrolesson.tin**) is needed for these routines and is also supplied. Use the View – **Layer Control** command to become familiar with the various layers, and then go to the View – 3D View – Drawing Viewer command to see the change of elevations in the surface. When prompted:

Select entities for the scene.

[FILter]/<Select entities>: type ALL and press Enter twice

Here is a resulting graphic:

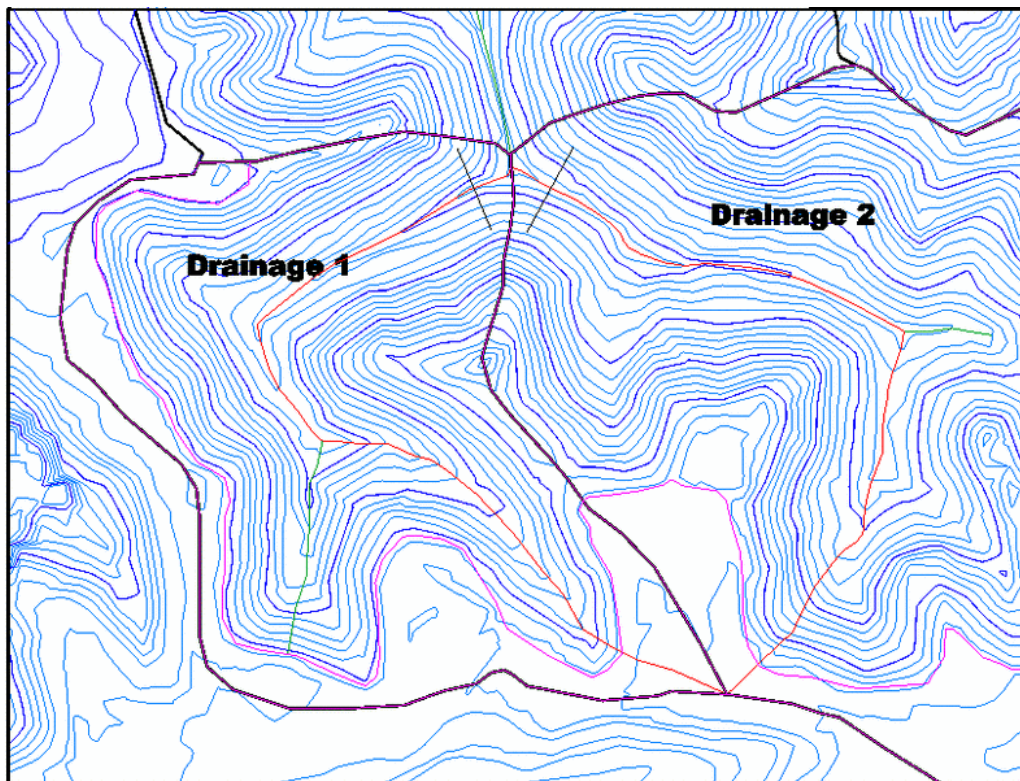

Click **Exit** (the doorway button) when finished.

There are two main drainage areas that we will be looking at:

- Drainage 1
- Drainage 2

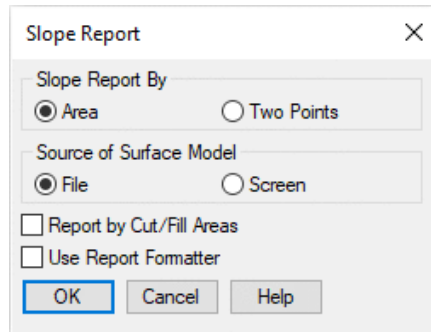

They are labeled in the below graphic. The other drainage areas in this region will be ignored, as they do not drain to the same area we are looking at, the north central low spot:

There are routines for finding these watersheds based on *grid* (*.grd) or *TIN* files, but this drawing has the closed polylines already generated. We will walk through some of the steps to gather the slope and area information.

- Issue the View – Freeze Layer by Pick command to freeze all contours, which are on two separate layers. Also pick the Magenta-colored **PILLARS** layer.

We would next like to evaluate the terrain data within each of the two watersheds available to us. Issue the Surface – Slope Report command which displays the dialog box below:

Set the values as shown above and click the **OK** button. On the subsequent dialog box, select the surface shown below and click the **Open** button when ready:

When prompted:

Select entities for the scene.

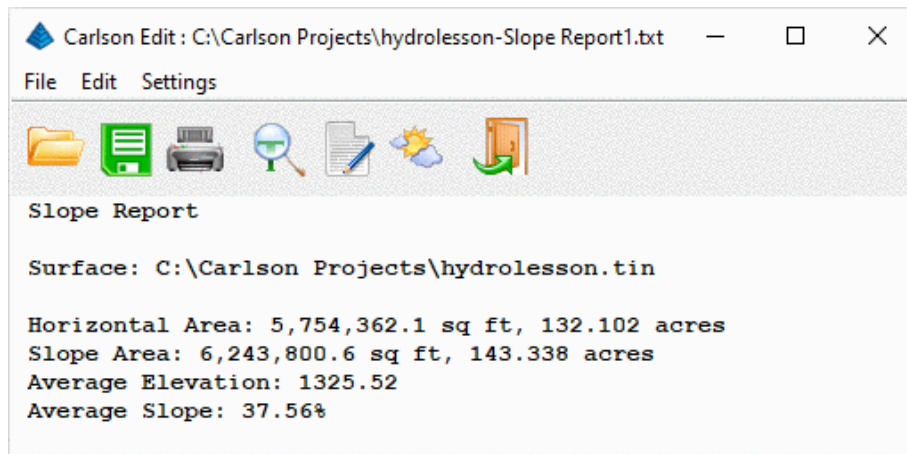

Select the Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: select the closed perimeter line that runs around Drainage 1 (press Enter when complete)

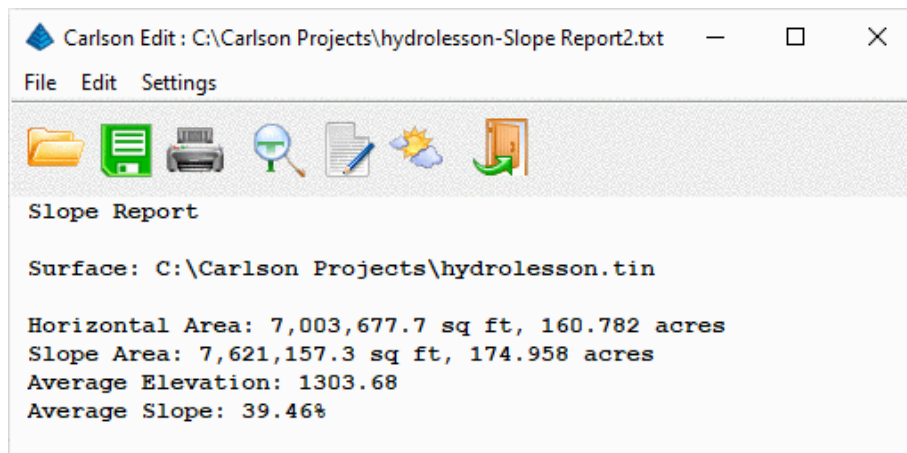

Select the Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

The surface information from the selected TIN that is enclosed by the watershed perimeter polyline is echoed to the Standard Report Viewer as shown below:

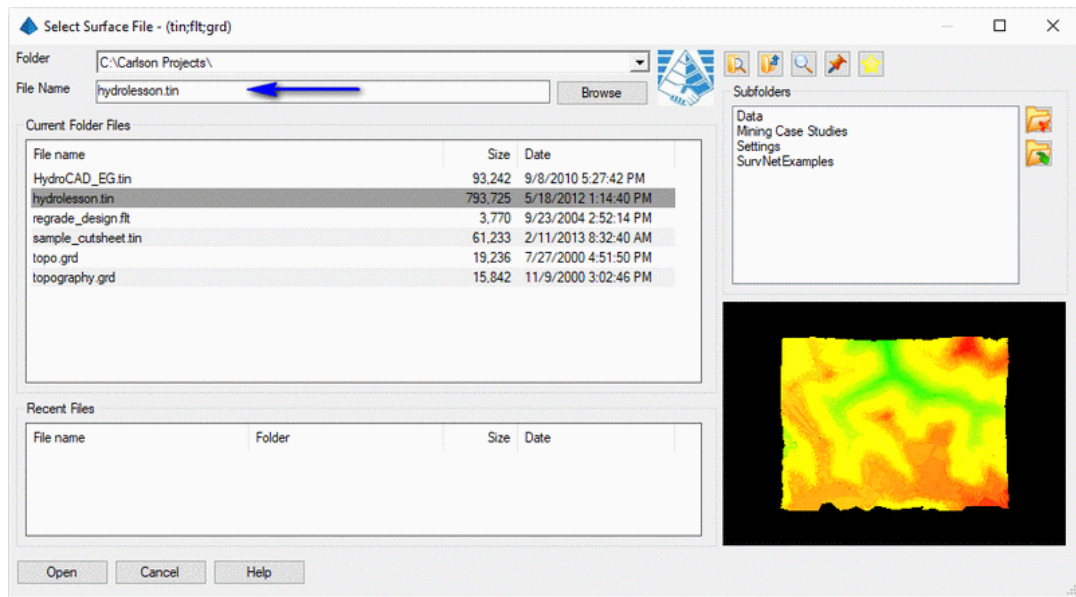

Click the **Exit** (Doorway) button when finished. Immediately press **Enter** to re-run the command and this time, select the closed perimeter line that runs around **Drainage 2**. Contrast its results to that shown above:

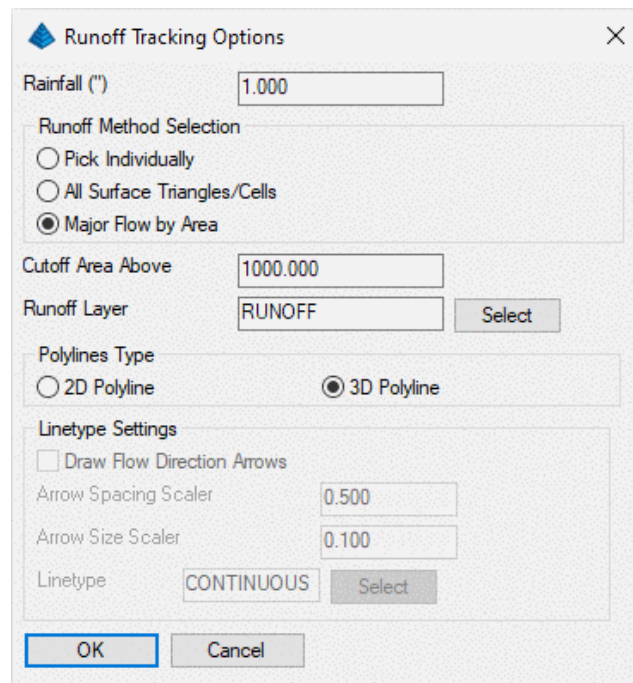

Notice that the watersheds are similar in size, and have approximately the same average slope. Click the **Exit** (Doorway) button when finished. Use the View – Thaw/On All Layers command to thaw the layers that you froze earlier.

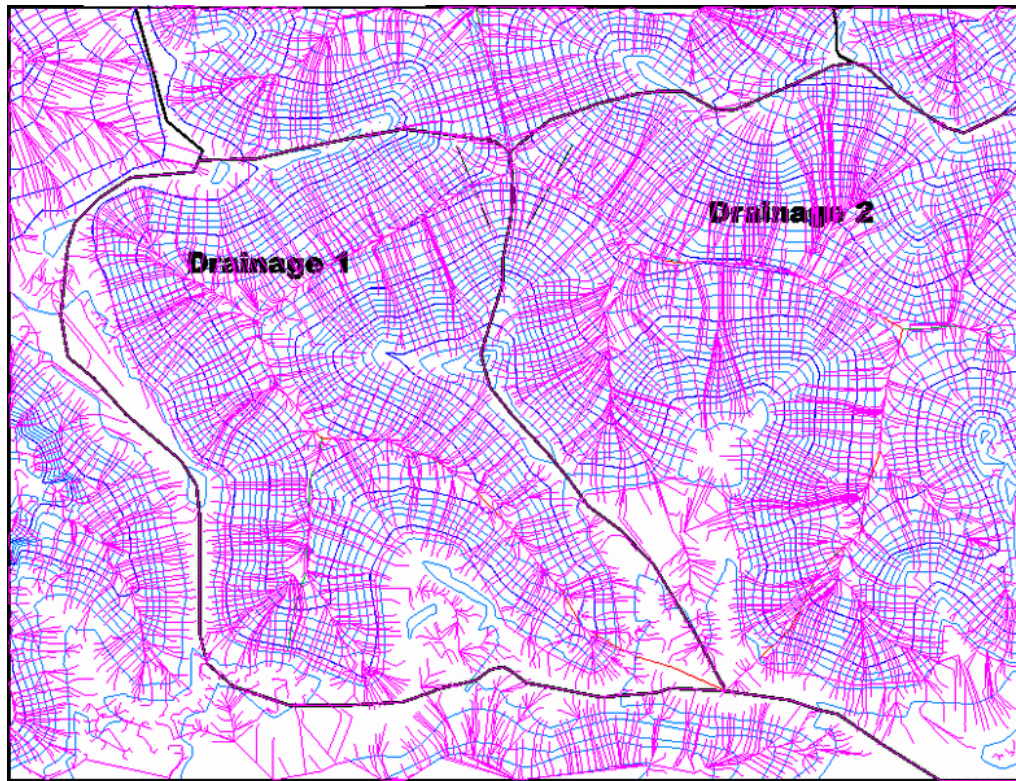

4. Our next task will be to evaluate the drainage characteristics of the site. Issue the Watershed – Runoff Tracking command. On the subsequent dialog box, select the surface shown below and click the **Open** button when ready:

On the following dialog box, accept the parameters as shown below and click **OK** when ready:

The result will be a collection of 3D polylines showing the path(s) water will take from a given rainfall intensity amount. Among other things, the command is useful to fine-tune a watershed boundary. For example, the *Pick Individually* option can be used to spot-pick locations near a boundary line. You can see which direction the water will flow and adjust the watershed perimeter accordingly. Shown is an example of the drawing with the runoff tracking lines falling within their respective watersheds:

Issue the View – **Freeze Layer by Pick** command and pick one of the previously generated flowlines and the two types of contour lines to remove them from the display.

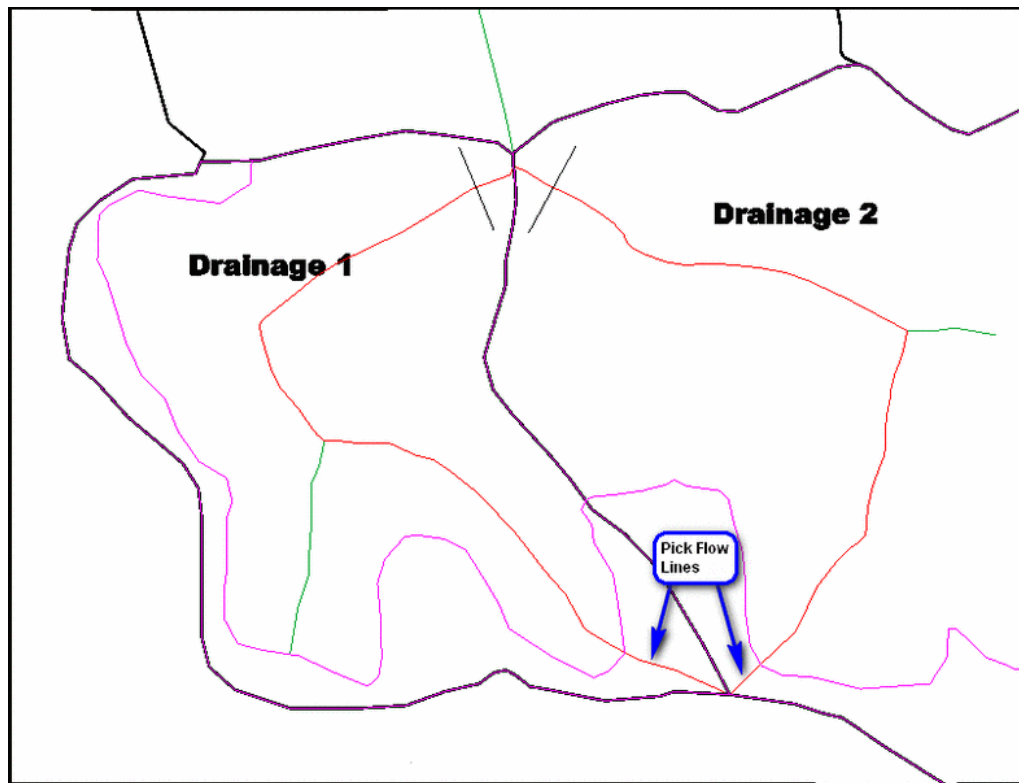

5. The next step is to see information for the longest flow line data within the watersheds. Issue the Watershed – Report Flow Values command. When prompted:

Type of flow line [<3DPolyline>/Profile]? press Enter for the 3D Polyline option

Select 3D polyline flow line: pick the Flowline for Drainage 1 as shown below

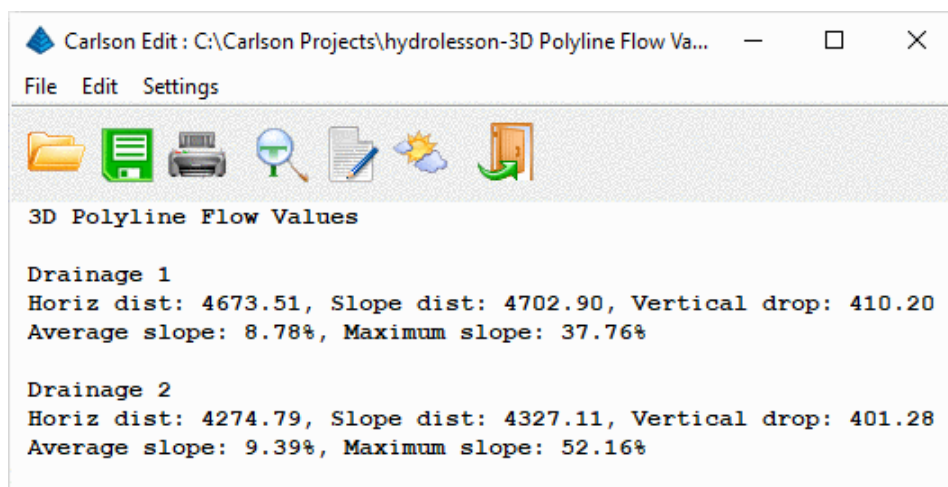

Select 3D polyline flow line: pick the Flowline for Drainage 2 as shown below

Select 3D polyline flow line: press Enter

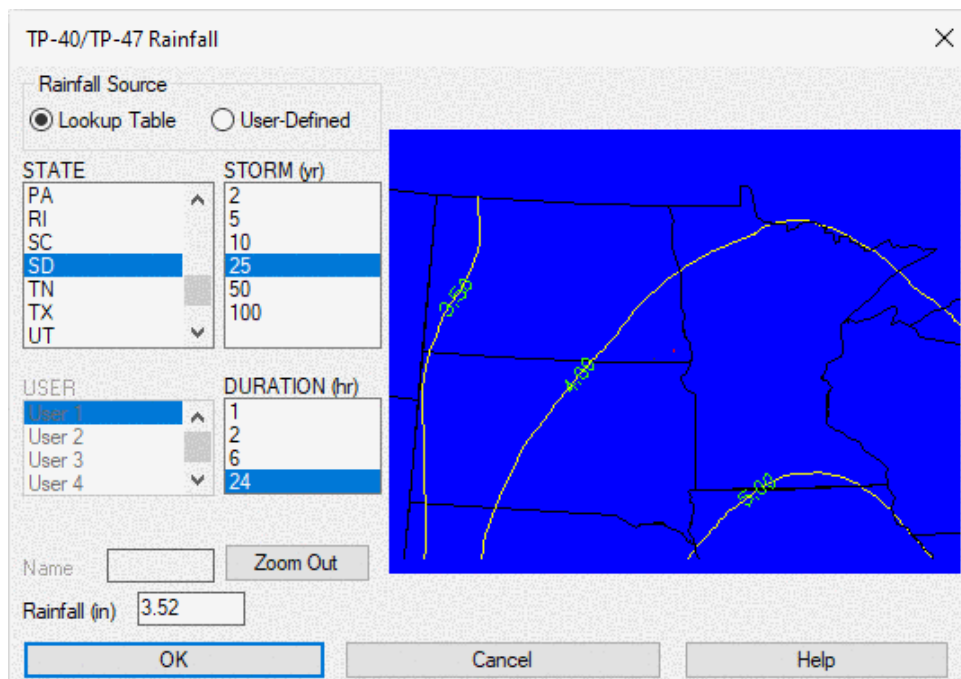

NOTE: The 3D polylines in the drawing were created (with runoff tracking and some editing) to represent the longest flow line.

The results are summarized in a nice report as illustrated below (with additional annotation added for clarity) showing the slopes and vertical drop. The report can be saved for future reference but "screen picks" of these polylines can be used in other aspects of the software:

Click the **Exit** (Doorway) button when finished.

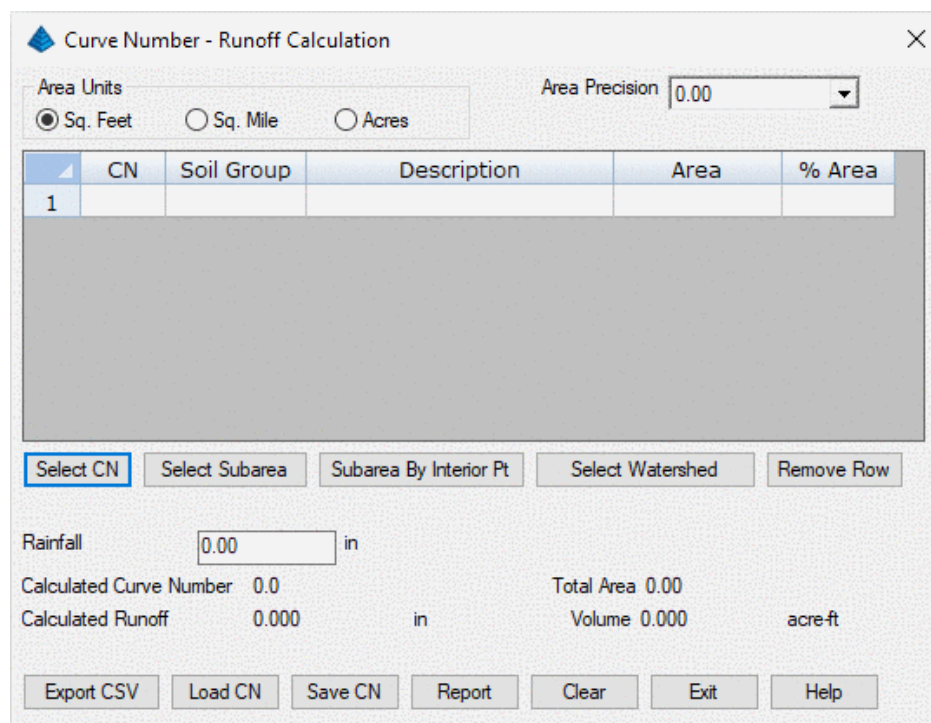

- Our next task will be to determine (or establish) the rainfall intensity/depth based on a given location, storm event and durations. Issue the Watershed – Rainfall Frequency & Amount – TP-40/TP-47 command to display the dialog box similar to that below:

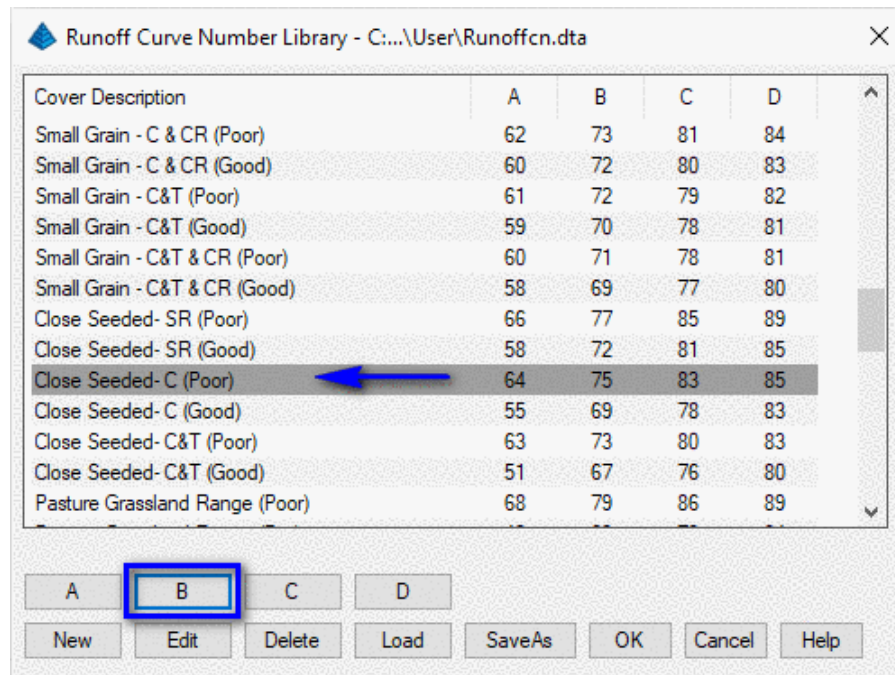

Set the values as shown above and note that as you click on the map, the rainfall intensity of the selected location will be reflected into the dialog box. For the sake of consistency, we will use the value of **3.52** inches (key this value in if you can't select it from the screen). For customizing this table to suit your needs, there is the **User Defined** toggle that permits individual entry in the lower left portion of the dialog box allowing for future retrieval if desired. Click **OK** when finished.

- Next, we'd like to obtain the runoff and volume of the storm based on the curve number and acreage of each sub-watershed. Use the View – Isolate Layers and click on the **Magenta "PILLARS"** layer and the **Black (or White) "Watershed.Perim"** layer.

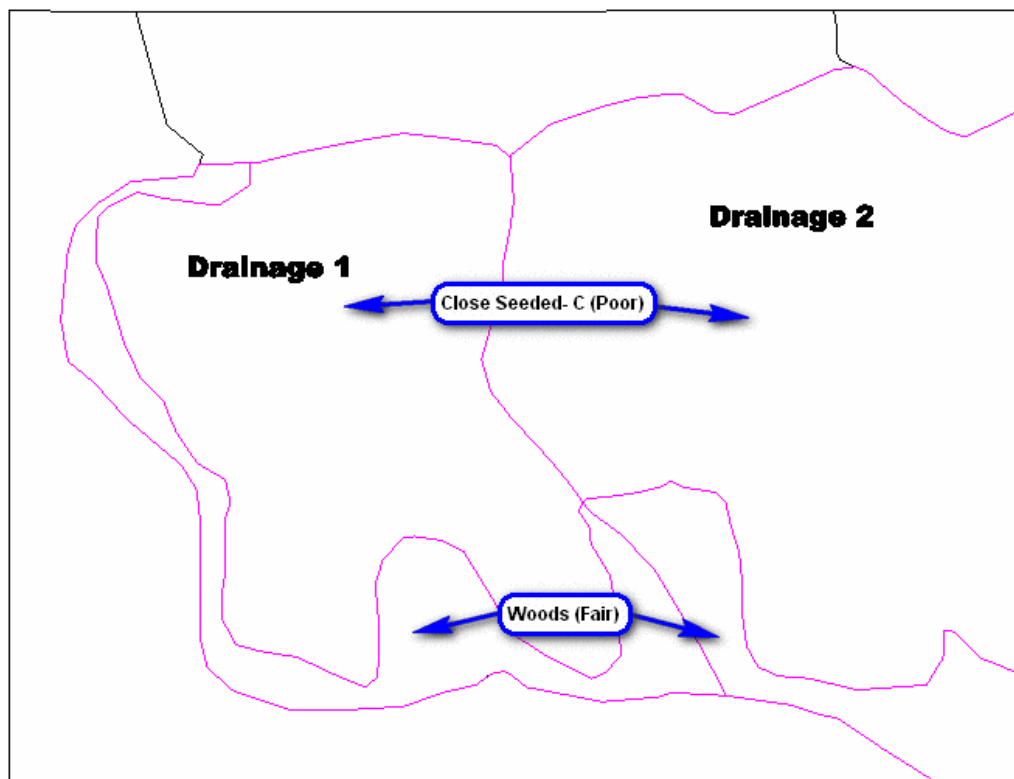

We will calculate a weighted curve number representing two land use types and will run this twice, once for each watershed. Issue the Watershed – Curve Numbers (CN) & Runoff command. The following dialog box appears:

Let's specify the first of our two Curve Numbers. Click the **Select CN** button to display a dialog box similar to that below:

Scroll through the list to locate and highlight the Land Use cited above and then click soil type button **B**. The entry is loaded into the *Curve Number - Runoff Calculation* dialog box. Use the land use guide below for the exercise to follow:

With this entry active in the list, click the **Subarea By Interior Point** button and when prompted:

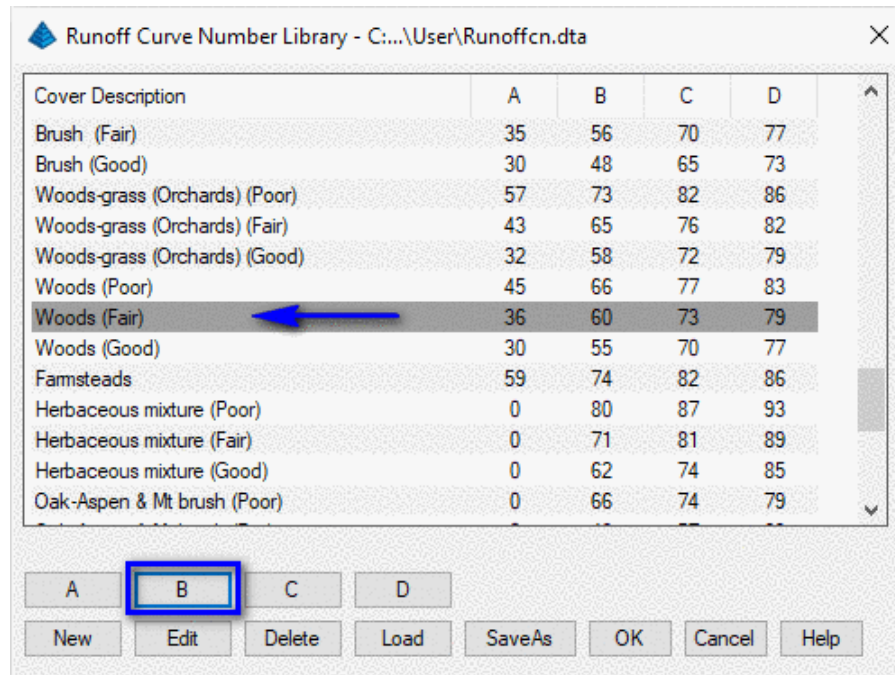

Pick point inside area perimeter: click within the *Drainage 1* area for the land use identified as **Close Seeded- C (Poor)** as shown above

(the selected area will shade)

Use the Selected Area? click Yes when you have the correct watershed sub-area

Pick point inside area perimeter (Enter to end): press Enter

Let's specify the second of our two Curve Numbers. **Highlight/select** the empty Row 2, and click the **Select CN** button to display a dialog box similar to that below:

Scroll through the list to locate and highlight the Land Use cited above and then click soil type button **B**. The entry is loaded into the *Curve Number - Runoff Calculation* dialog box. Again, with the *Row 2* entry active in the list, click the **Subarea By Interior Point** button and when prompted:

Pick point inside area perimeter: click within the *Drainage 1* area for the land use identified as **Woods (Fair)** as shown above

(the selected area will shade)

Use the Selected Area? click Yes when you have the correct watershed sub-area

Pick point inside area perimeter (Enter to end): press Enter

Set the remaining values as shown below:

Curve Number - Runoff Calculation

Area Units: Sq. Feet Sq. Mile Acres

Area Precision: 0.00

	CN	Soil Group	Description	Area	% Area
1	75	B	Close Seeded- C (Poor)	98.93	74.89
2	60	B	Woods (Fair)	33.17	25.11
3					

Select CN Select Subarea Subarea By Interior Pt Select Watershed Remove Row

Rainfall: 3.52 in

Calculated Curve Number: 71.2 Total Area: 132.10

Calculated Runoff: 1.090 in Volume: 11.997 acre-ft

Export CSV Load CN **Save CN** Report Clear Exit Help

Click on the **Save CN** button to save this weighted Curve Number data to a file as shown below:

Save Cancel Help

Control returns to the *Curve Number - Runoff Calculation* dialog box and click the **Exit** button to complete the command.

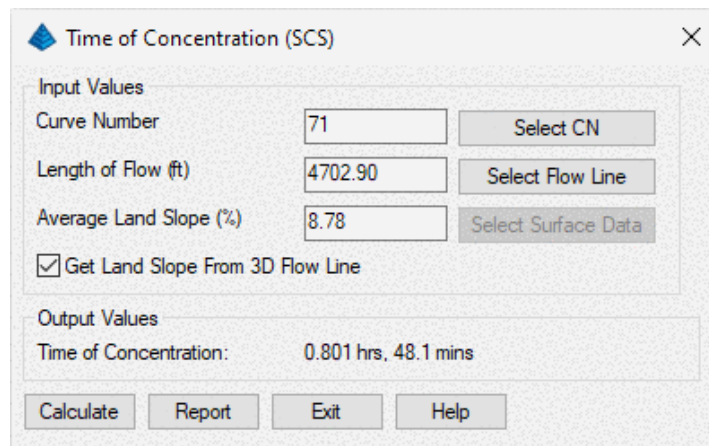

- The next thing we'd like to do is establish the Time of Concentration (T_c) for the two watersheds. This is a quick step necessary for ultimately getting the *Peak Flow*. Issue the View – Restore Layers command to bring back the visibility of the **Drainages** (flowlines) layer previously frozen as a result of the *Isolate Layers* command.

NOTE: The *CN number* from the previous exercise (for *Drainage 2*) will be considered "active" and we'll need to exercise care to make sure the proper flowline is selected. Let's follow the Drainage 1/Drainage 2 process to make sure!

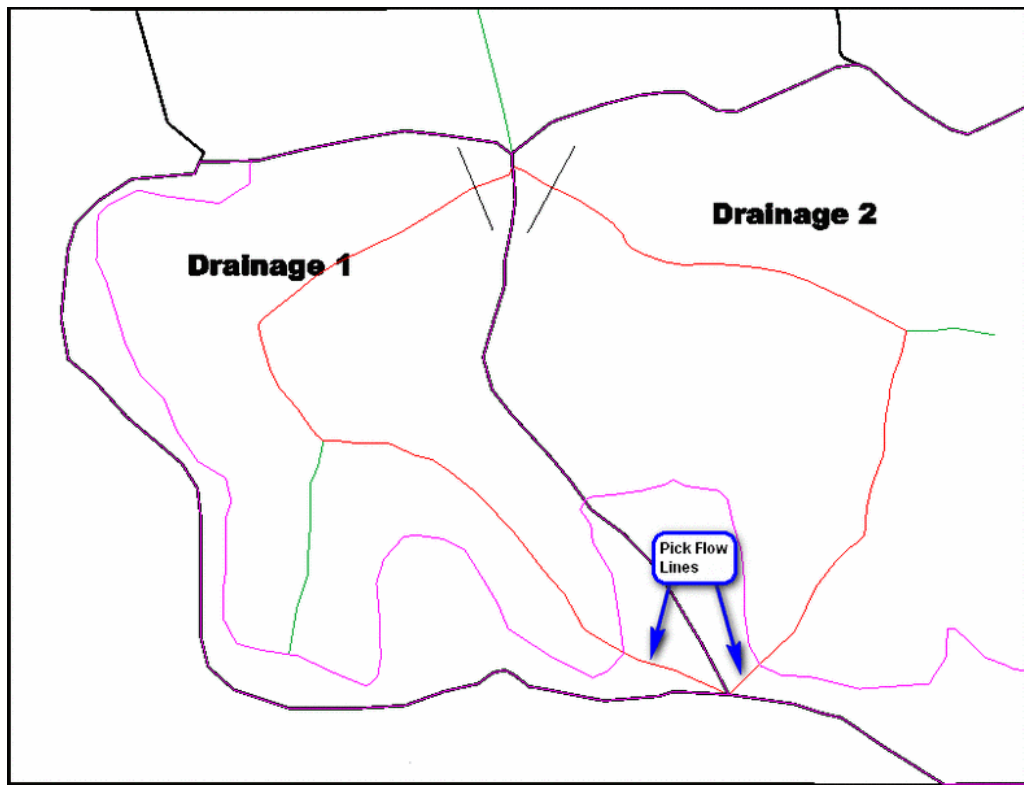

- (a) Recall the Curve Number information for *Drainage 1* by re-issuing the Hydrology – **Curve Numbers (CN) & Runoff** command.
- (b) Click the **Load CN** to load the *.cn file as illustrated below (use the **Open** button rather than the button shown here):

- (c) Click the **Exit** button.
- (d) Issue the Watershed – Time of Concentration (Tc) – SCS Method command. This will launch the *Time of Concentration (SCS)* dialog box similar to that shown below:

- (e) Click the **Select Flow Line** button and graphically select the *Red* flowline that contributes to **Drainage 1**:

(f) With the settings shown, click the **Calculate** to obtain the T_c for *Drainage 1*:

Time of Concentration (SCS) ✕

Input Values

Curve Number	71	Select CN
Length of Flow (ft)	4702.90	Select Flow Line
Average Land Slope (%)	8.78	Select Surface Data

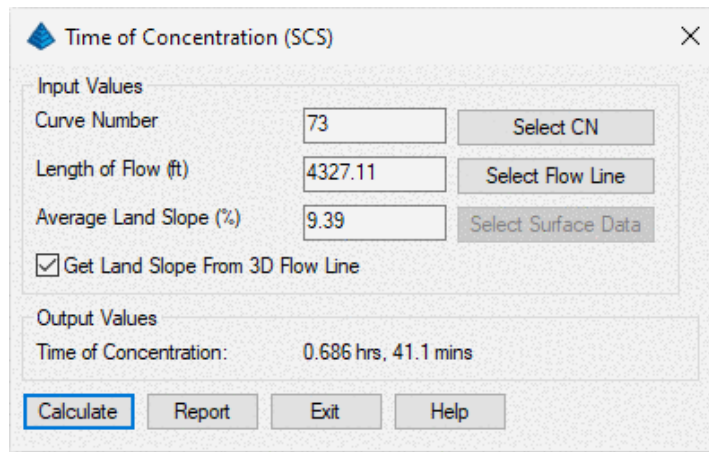

Get Land Slope From 3D Flow Line

Output Values

Time of Concentration: 0.801 hrs, 48.1 mins

Calculate
Report
Exit
Help

Repeat the steps above (loading the Curve Number information for *Drainage 2* and graphically selecting the *Red* flowline that contributes to **Drainage 2**), obtaining the results shown below:

Note the two results and click **Exit** when ready.

9. Now, let's see what the peak flow will be in each drainage. Issue the Watershed – Run Peak Flow – Graphical Method command. The drainage area of the last watershed calculated should appear in the **Drainage Area** window. If not, then use either:

- the View – **Freeze Layer by Pick** command to leave the *Watershed_Perim* layer visible and follow with the **Select Area from Screen** button, or
- keying-in the value as reported in the Curve Number Runoff Calculation 1 exercise from above

Set the *Rainfall Depth*, *24 hr. Rainfall Frequency*, *Runoff Curve Number* and *Time of Concentration* values as shown in the table below (summarized for convenience):

	132.10198	162.94296	
Rainfall Depth (Inches)			
	3.52	3.52	
24 hr. Rainfall Frequency (Year)			
	25	25	
Runoff Curve Number			
	71	73	
Time of Concentration (Minutes)			
	48.1	41.1	
Percent of Pond and Swamp Areas			
	0.00	0.00	
Pon and Swamp Adjustment Factor			
	1.00	1.00	
Storm Type			
	II	II	
Peak Discharge		80.726	123.399

Peak Flow Data Values

With the appropriate values entered, click **Calculate** to obtain the peak discharge values as shown below:

Drainage 1

Drainage 2

Peak Discharge Values

Notice that all of these routines have a **Report** button to keep a running log of all the calculated data.

Now we need to see how large the ponds need to be to detain this size of a storm event. Initiate the Structure – Detention Pond Sizing – TR-55 Method command to achieve this.

The *Drainage Area* and *Peak Inflow Discharge* values from the last area calculated will appear. In this example, we will allow for a combined maximum 10 ft³/sec (cfs) to be discharged from the ponds combined (in other words, 5 cfs from each will be our **Desired Peak Outflow**). Use the summary of values below and click **Calculate**. The *Runoff Volume* and the *Storage Volume* will appear at the bottom of the window:

	132.10198	162.94296
Peak Inflow Discharge (cfs)		
	80.726	123.399
Desired Peak Outflow (cfs)		
	5.00	5.00
Runoff Q - Post-Dev (inches)		
	1.090	1.198
Storm Type		
	II	II

Detention Pond Sizing Data Values

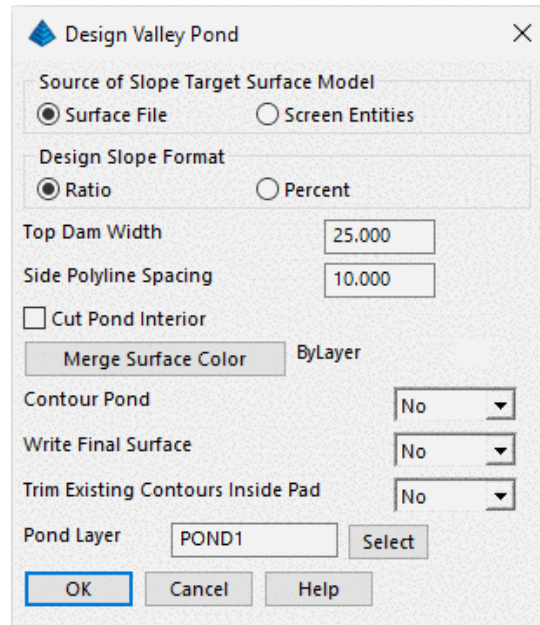

Drainage 1

Drainage 2

Detention Pond Size

With the storage areas determined, we now have a starting point and we can now create the ponds with these sizes.

We know approximately where we want the two ponds, and have the dam centerline polylines drawn in the drawing already. They are in the *Top-of-Dam* layer. If it is frozen, use the View – **Layer Control** command to thaw it now. Issue the Structure – Design Valley Pond command. For Pond 1 (corresponding to Drainage 1), use the starting values as shown below and click **OK** when ready:

When prompted:

Pick top of pond polyline: pick the polyline for the Drainage 1 region

Select Existing Surface: specify the TIN file shown below and click the **Open** button when ready:

Pick point within pond: pick within the storage area (southwest of the dam centerline for Drainage 1)

Outslope ratio <2.00>: press Enter

Interior slope ratio <2.00>: press Enter

Top of dam elevation: 1109

Calculate stage-storage values [<Yes>/No**]?** press Enter

Method to specify storage elevations [<Automatic>/Interval/Manual**]?** specify the Interval (i) method

Starting elevation **<1078.65>:** 1078 (we'll start just below the lowest elevation)

Elevation interval **<2.00>:** press Enter (notice the **Storage** capacity of the pond is greater than the desired *Storage Volume*, click the **Exit** (Doorway) button when ready)

Write stage-storage file [Yes/<No>**]?** indicate Yes (indicate the file name below and click **Save** when ready)

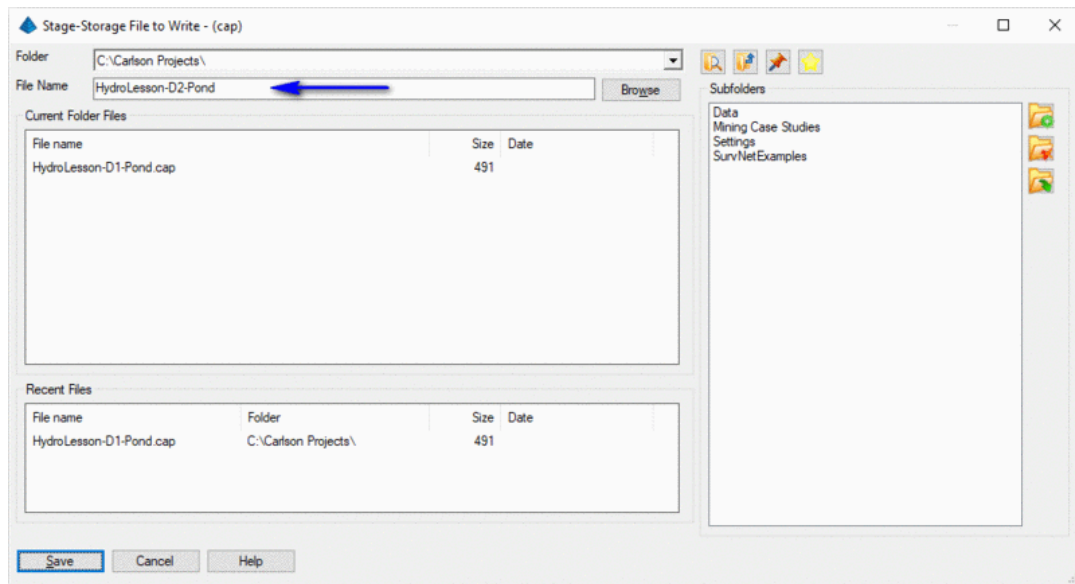

Adjust parameters and redesign pond [Yes/<No>**]?** press Enter

You should now have a pond that looks like the one on the left in the following image (emphasis added for clarity):

Repeat the routine for Pond 2 using the same parameters except:

- **Top of dam elevation:** 1087
- **Starting elevation **<1063.01>**:** 1062
- **Write stage-storage file [**Yes/<No>**]?** indicate Yes (indicate the file name below and click **Save** when ready)

Now let's see what the spillway will need to be for the storage calculated. Run the Structure – Rectangular Weir Design command to display the dialog similar to that below:

Drainage 1/Pond 1

Drainage 2/Pond 2

Rectangular Weir Design Values

Supply the following values (pressing the **Tab** key between entries):

- **C-Factor:** 0.30
- **Peak Outflow Discharge (cfs):** 5.00
- **Weir Width (ft):** 5.00 (the Weir Depth will be found, however, we'll use a Drop Pipe in Pond 1, and a channel in Pond 2)
- **Required Storage Volume (acft):** provide the respective values shown above

Click the **Apply to Actual Pond** button and choose the Pond 1 stage-storage capacity file created earlier. This should yield two elevations shown in the dialog: the **Peak Pool Elevation** and the **Weir Crest Elevation** (bottom of spillway). This will be our principal spillway. Our emergency spillway will be assumed to be 1.5 feet higher.

Now that we have the spillway elevations and a capacity file (*.CAP) for each pond, let's draw the *Stage Storage/Area Curve Graphs* to get a graphic of the curves. Issue the Structure – Stage-Storage – Draw Stage-Storage Curve which displays a dialog box similar to that below. Use the settings below for Pond 1 and click **OK** when ready:

Draw Stage-Storage Curve

Click **Exit** to dismiss the dialog box.

Now we will look at creating a schematic illustration of the project with annotation placed on them. We will first produce a hydrograph of the two drainages without the ponds, then add the ponds to the flow polylines and regenerate the hydrographs. We hope to reduce the discharge to a much smaller amount, but over a longer period of time.

Issue the Watershed – TR-20 Routing – Draw Flow Polylines to approximate the direction of flow: As seen in the diagram, pick from SW to NE to simulate the general direction of flow for *Drainage 1*:

When prompted:

Text size <4.00>: press Enter

Draw from highest to lowest elevation (direction of flow).

Exit/Pick point: pick a starting location

Undo/Exit/Join/Pick point: pick an ending location to the northeast

Undo/Exit/Join/Pick point: press Enter and complete the values as shown and click **OK** when ready:

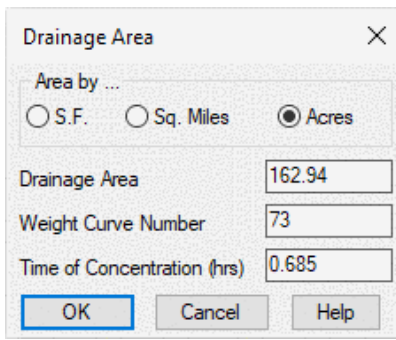

Drainage Area		
Area by ...		
<input type="radio"/> S.F.	<input type="radio"/> Sq. Miles	<input checked="" type="radio"/> Acres
Drainage Area	132.10	
Weight Curve Number	71	
Time of Concentration (hrs)	0.80	
OK Cancel Help		

Draw another flow polyline [<Yes>/No]? press Enter

Exit/Pick point: pick a starting location

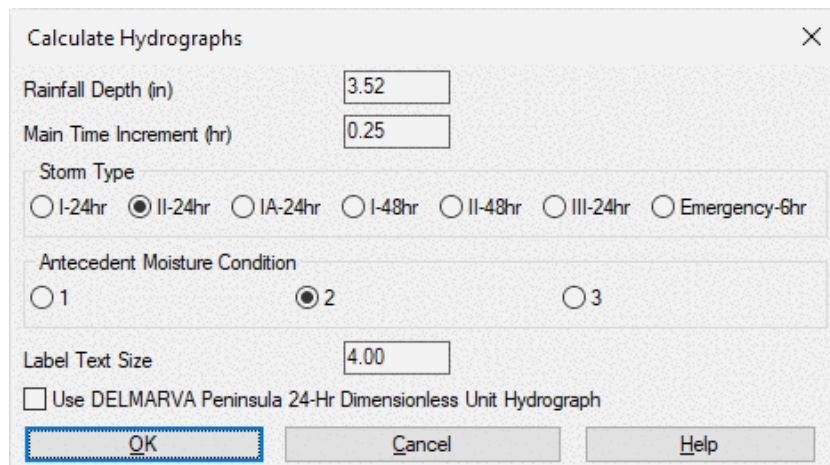

Undo/Exit/Join/Pick point: pick an ending location to the northwest

Undo/Exit/Join/Pick point: press Enter and complete the values as shown and click **OK** when ready:

Draw another flow polyline [<Yes>/No**]? indicate No**

Our next task will be to run the TR-20 program and generate a hydrograph file that we can draw on screen. Run the Watershed – TR-20 Routing – Hydrograph Development command supply the values as shown below and click **OK** when ready:

When prompted:

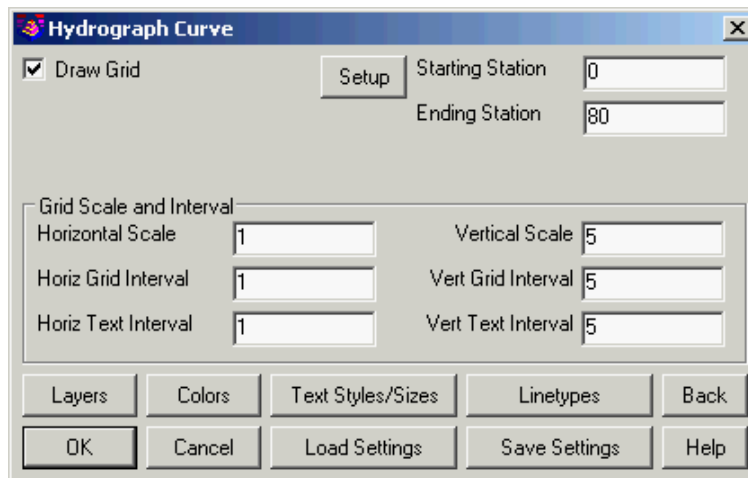

Select flow polylines, structure and reach symbols.

[FILter]/<Select entities>: *crossing Window* the flow line entities and annotation

[FILter]/<Select entities>: press Enter

The routine will run TR-20 and give a **Standard Report Viewer** report. There are now some hydrograph files that we can draw in the next step.

We'd now like to draw our hydrographs. Issue the Watershed – Draw Hydrograph and select the J1ADD.h1. This is the file of both drainages combined.

The scales to be used should be about 1,1,1,5,5,5 and we will draw the grid on the first one, and turn off the grid for additional hydrographs. Choose starting time of 0, and an ending time of 80 (the next one will go that long):

Our next task will be to create a schematic representation of the ponds and spillways. Issue the Watershed – TR-20 Routing – Locate Structures command which will create a small triangle at the end of each flow line where they were picked. You will run this on each flow line individually:

	Elevation (Ft)	Discharge (CFS)	Storage (Acre-Ft)
1	1105.0000	0.0100	0.0000
2	1106.0000	4.1560	0.0000
3	1107.0000	5.8774	0.0000
4	1108.0000	7.1984	0.0000
5	1109.0000	8.3120	0.0000
6	1110.0000	9.2931	0.0000
7			
8			
9			

Water Elev at T = 0: 0.00 ft

Click the **Load** button twice:

1. once to pick the *.cap file, and,
2. once again to pick the *.stg file

Click **OK** and re-issue the **Hydrograph Development** command again to generate the new hydrographs.

This completes the tutorial: Hydrology and Watershed Analysis.

Stormwater Network Design

In this tutorial, we'll lay out the structure and pipes for the stormwater drainage and analyze the flow for a portion of a site. We'll use the tools to automatically calculate the drainage and runoff coefficients. These automated methods require setup of a surface and runoff regions. Alternatively, these tools can be skipped in which case the drainage areas and runoff coefficients for the inlets can be entered manually into the sewer network.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of C:\Carlson Projects and open the **Example3.dwg** file.

2. Activate the Hydrology menu via Settings – Carlson Menus – **Hydrology Menu**. Your drawing should resemble that shown below:

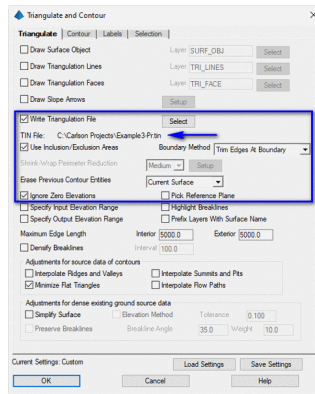

3. We'd like to create a surface model of proposed site conditions. The drawing entities for the design surface that we will use to model drainage have already been prepared. These entities consist of:
 - design contours
 - elevated pad perimeter polylines
 - spot elevations
 - 3D polylines for the road centerlines and face of curbs

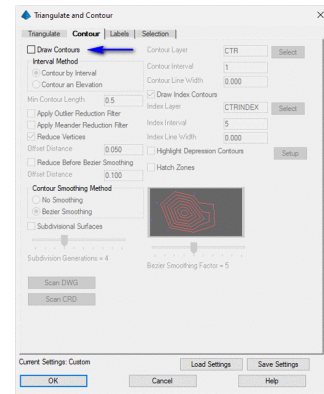

To model the drainage watershed surface, it is suggested that a **triangulated irregular network (TIN)** file be used (as opposed to a *grid* surface) so that the flow can properly follow the edges of the road. Issue the

Surface – Triangulate & Contour command to display a dialog box similar to that shown below:

Triangulate Tab

Contour Tab

Triangulate & Contour

NOTE: Use the **Select** button on the *Triangulate* to create an output TIN file as illustrated above. Once set, click the **OK** button and when prompted:

Select Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the perimeter polyline

[FILter]/<Select entities>: press Enter

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

Select points and breaklines to Triangulate.

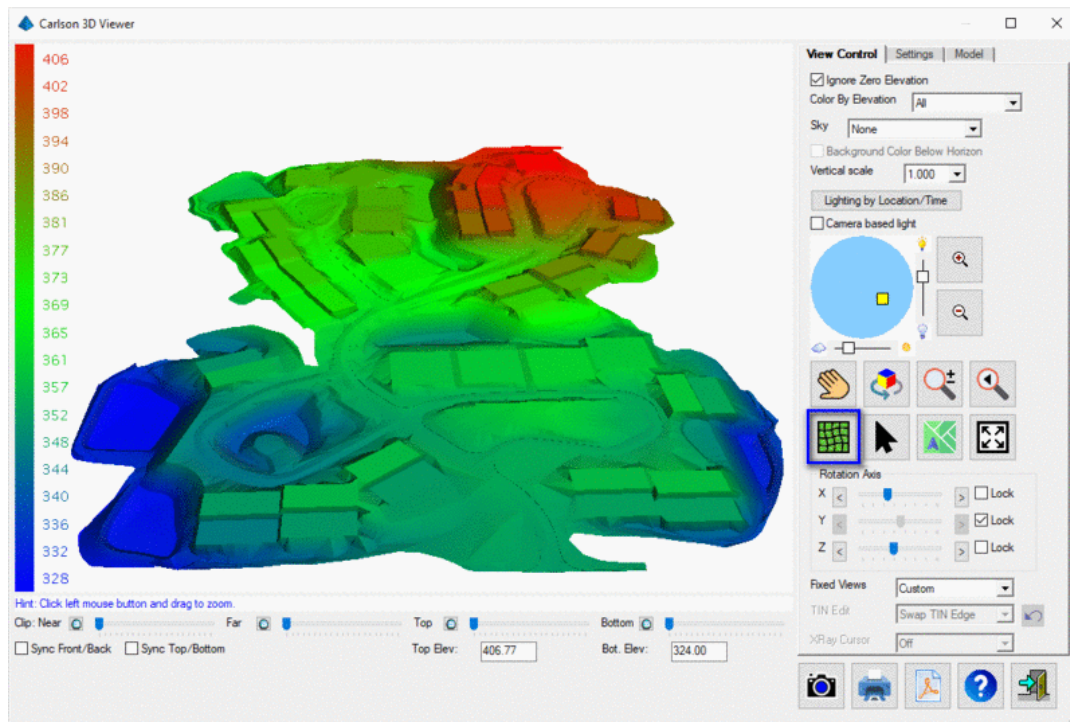

[FILter]/<Select entities>: type ALL and press Enter twice

The surface model *.TIN file is created.

4. *Optional:* Let's verify that the surface is good by checking for bad elevation data points and that the surface follows the data points. Issue the View – 3D View – Surface 3D Viewer command. When prompted:

Select Surface File (dialog): pick the TIN file created in the previous step and click **Open**

A display similar to that shown below appears:

NOTE: In the 3D Viewer dialog, move the pointer near the outer edge of the graphic and the cursor will change to an Z symbol which orients the view about the vertical axis. Moving the cursor to the interior of the graphic and the cursor will change to an X/Y symbol. Click and drag from the bottom upward to change the isometric viewing angle. You can also set the **Vertical Scale** to 2.0 and enable the **Color By Elevation** toggle for better viewing of the elevation difference and the *Surface Shading* toggle (highlighted above) can be used to shade/unshade the surface. Experiment with any desired remaining options.

The surface looks correct in the 3D Viewer. The site has a slope from the top road circle down towards the detention ponds at the bottom. When ready, click the **Exit** (Doorway) button.

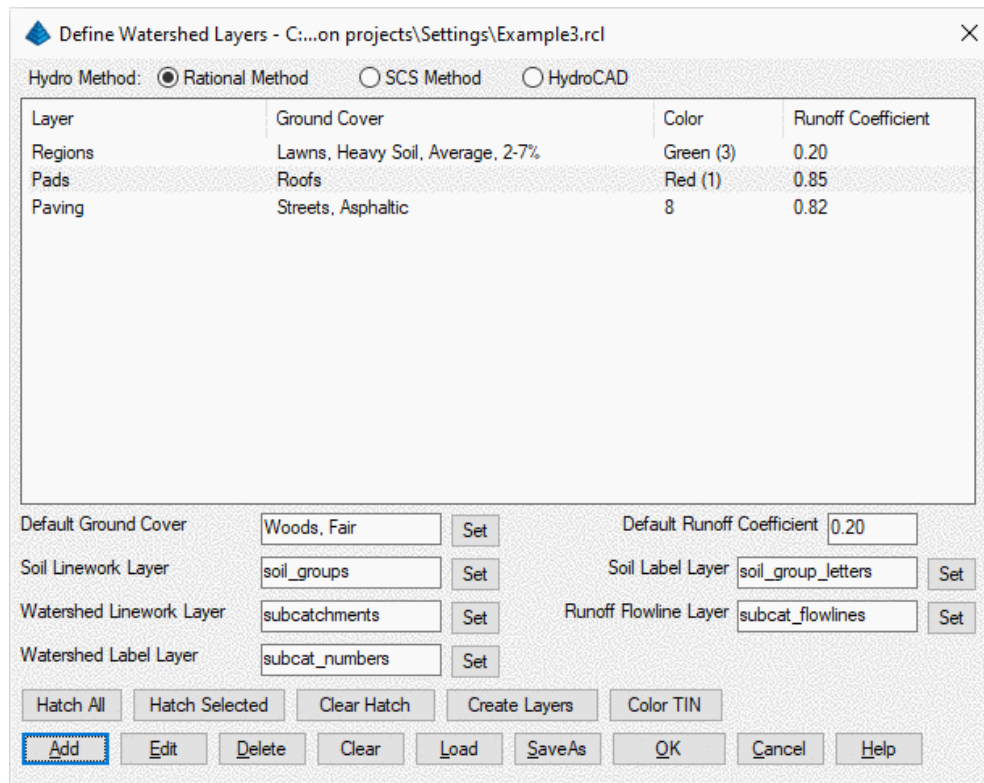

5. Step 4 - Runoff Coefficients. This step sets up layers that are assigned Rational Method runoff coefficients and applied to closed polylines on the specified layers. The runoff coefficients are the C-Factors in the Rational Method formula $q = CiA$, where:

- Q is flow
- C is a runoff coefficient
- i is rainfall intensity
- A is area

The runoff polyline areas use *region logic* where a polyline inside another on the same layer is used as an exclusion. A limitation is that polylines on the same layer must not intersect each other. For polylines on different layers, there can be polylines within other polylines and for any given point; the smallest enclosing polyline is used to determine the runoff coefficient. In this example, the:

- site perimeter polyline is on the *Regions* layer
- building pads are on the *Pads* layer
- edge of pavement polylines are on the *Paving* layer

All these polylines are already closed polylines so we're ready to assign the runoff coefficients to the layers. Issue the Watershed – Define Watershed Layers command to display a dialog box similar to that shown below:

Begin with an empty dialog by clicking the **Clear** button to delete any existing layers from the table. Click the **Add** button and use the *Runoff Summary* information below for each of the specified layers:

Regions Layer

Pads Layer

Paving Layer

Runoff Layers

For each entry:

- Click the **Select** button associated with *Layer* to set each layer
- Click the **Library** button associated with *Ground Cover* to set the associated ground cover
- Click the **Select** button associated with *Hatch Color* to set the color for each layer ground cover
- Click **OK** to save each item

Repeat the above sequence for each ground cover. Let's visually check the results. Click the **Hatch All** button that should generate an image similar to that shown below:

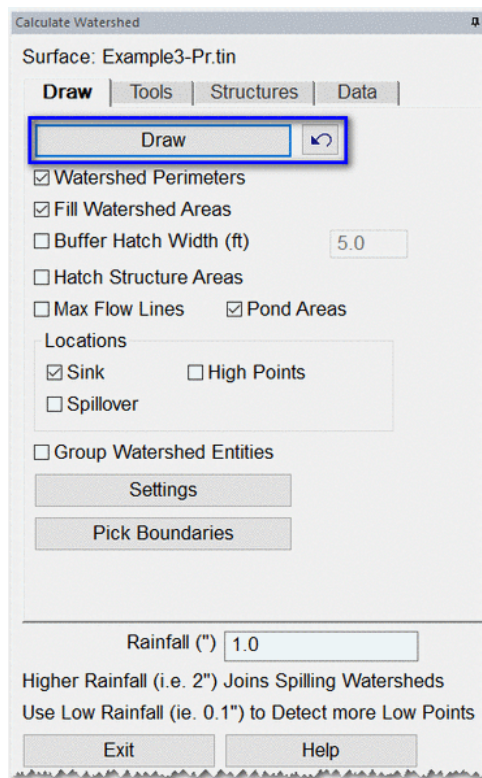

NOTE: The areas within the buildings are inside both the Regions and Pads polylines and the Pads govern because they are the smaller area. Likewise the road areas are governed by the Paving layer and road interior islands are not counted for Paving because the interior Paving polylines act as an exclusion perimeters. The rest of the area is set to the Regions layer.

We don't need to keep the runoff hatches. Remove them by clicking the **Clear Hatch** button and click **OK** when ready to dismiss the main dialog box (save the configuration using the file name shown in the top of the image cited earlier).

6. The next thing we'd like to do is analyze the watershed characteristics of the site. Issue the Watershed – Watershed Analysis command and when prompted:

Select Surface File (dialog): pick the TIN file created in the previous step and click **Open**

A "docked" dialog box similar to that appears:

On the **Draw** tab, enable the toggles for:

- Watershed Perimeters
- Fill Watershed Areas
- Sink Locations (low points)
- Pond Areas

Before processing the watersheds, set the **Rainfall** to 1 inch.

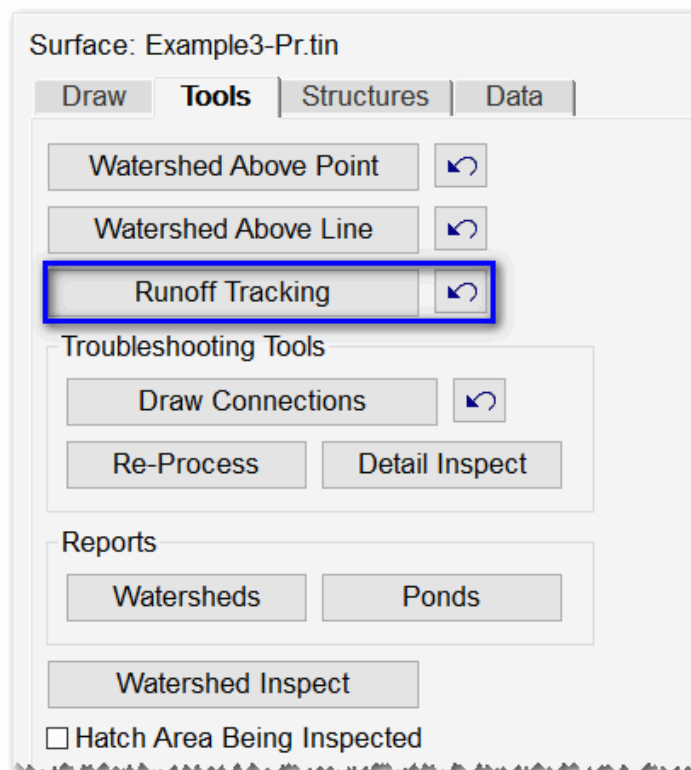

NOTE: The program uses the runoff volume calculated from the rainfall depth and drainage areas to figure when the runoff is enough for the flow to go through a low point. If the Rainfall Depth is set to zero, then the flow lines will stop at every low point or dimple in the surface. At this point, we have not defined our storm event to know the actual rainfall depth. If we did get the storm rainfall depth, we could enter it. For now we're just using *Watershed Analysis* to give a general idea of the watershed areas and runoff flow lines.

Click the **Draw** button. Each watershed area is drawn with a closed polyline and solid filled with different colors. Also, for each watershed the sink (lowest point) is drawn with a solid circle symbol. The areas covered by ponding are drawn as solid blue hatches. The depth and size of the pond areas is determined by the runoff volume. In many places, the pond areas are inside the detention pond structures. In a few places, the ponds are at low points in the road which indicate areas that we need to add storm sewer inlets:

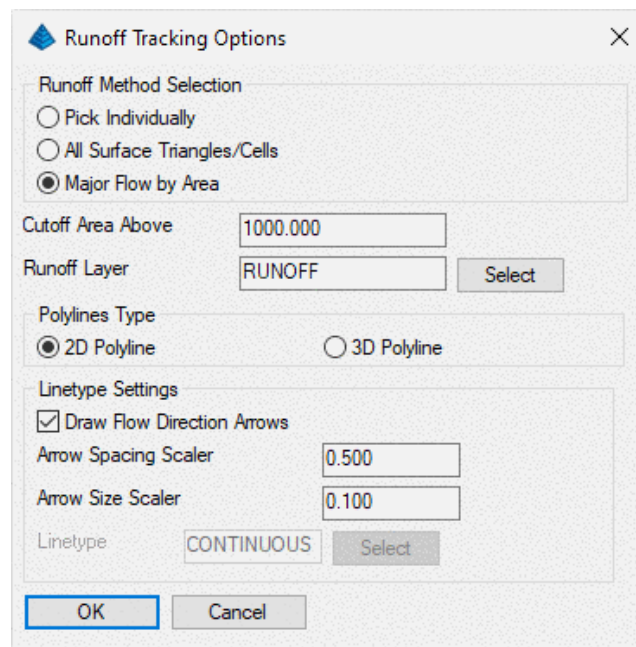

When you are done inspecting the watersheds, click the **Undo** arrow next to the *Draw* button (as illustrated earlier) to erase all the watershed entities.

Next, activate the *Tools* tab as illustrated below:

Click the **Runoff Tracking** button to display a dialog box similar to that shown below:

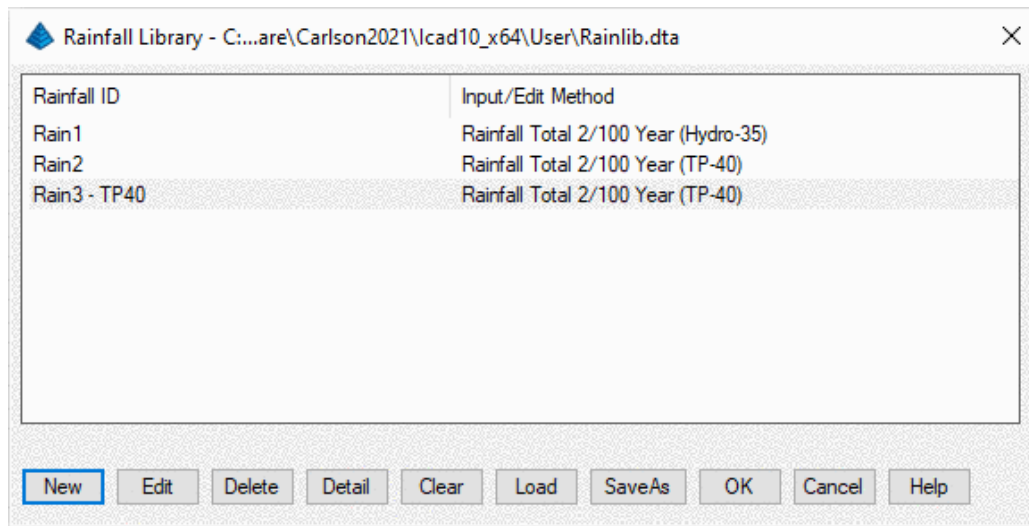

Set the values as shown above to draw flow lines only when the drainage area for the flow line is greater than the specified area and click **OK** when ready. The graphic below shows the flow lines coming off the road circle at the top of the site and following the curbs. We're going to leave the runoff flow lines on the drawing to help guide the placement of inlets.

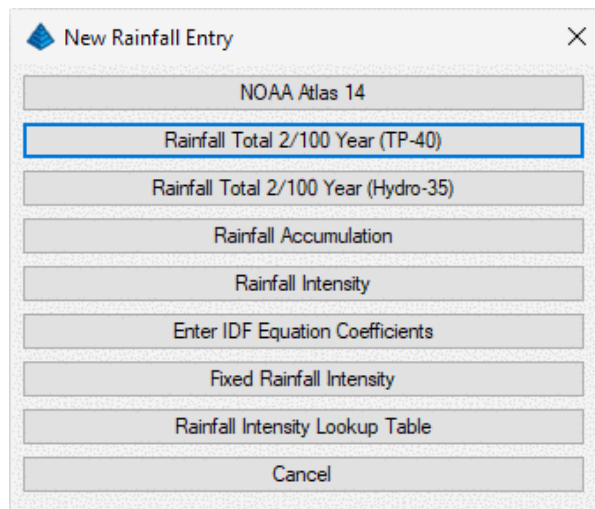

Click **Exit** to end Watershed Analysis.

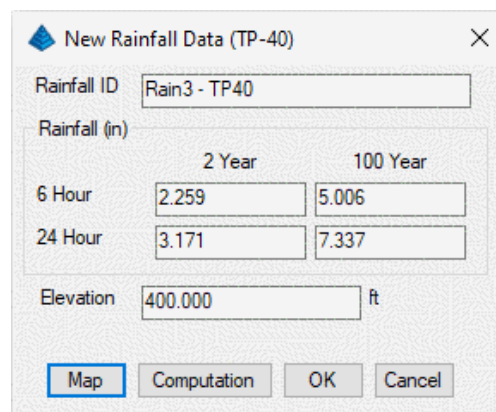

7. To setup the storm event to apply to this site, issue the Network – Sewer Network Libraries – Rational Rainfall Library command to display a dialog box similar to that shown below:

This command keeps a list of different storm events that you can use for different locations and requirements. Let's add a storm by clicking the **New** button. There are numerous types of rainfall definitions:

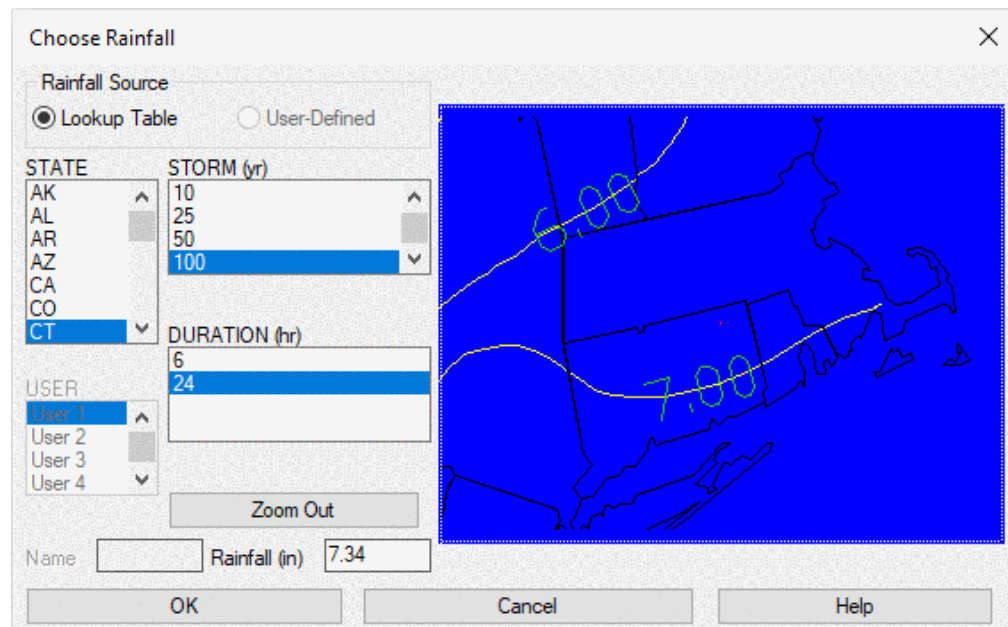

For this example, select the **Rainfall Total 2/100 Year (TP-40)** method to display a dialog box similar to that shown below:

Within the dialog box, supply the rainfall name as shown above and either:

- Use the **Map** button to show the TP-40 rainfall maps for the different storms. And if you pick on the

map display, the program will interpolate the rainfall from the maps. In this case, south central CT was picked:

- Supply the rainfall amounts for the 2 and 100 year storms for 6 and 24 hours, and the Average Elevation for the site.

Click **OK** on the *New Rainfall* dialog and click **OK** on the *Rainfall Library* dialog to save the changes.

8. *Optional*: In preparation to align the inlet symbols with the road centerlines, we prefer to create centerline files (.cl) for the roads. Activate the Civil menu via Settings – Carlson Menus – **Civil Menu**. Issue the Centerline – Polyline To Centerline File command and when prompted:

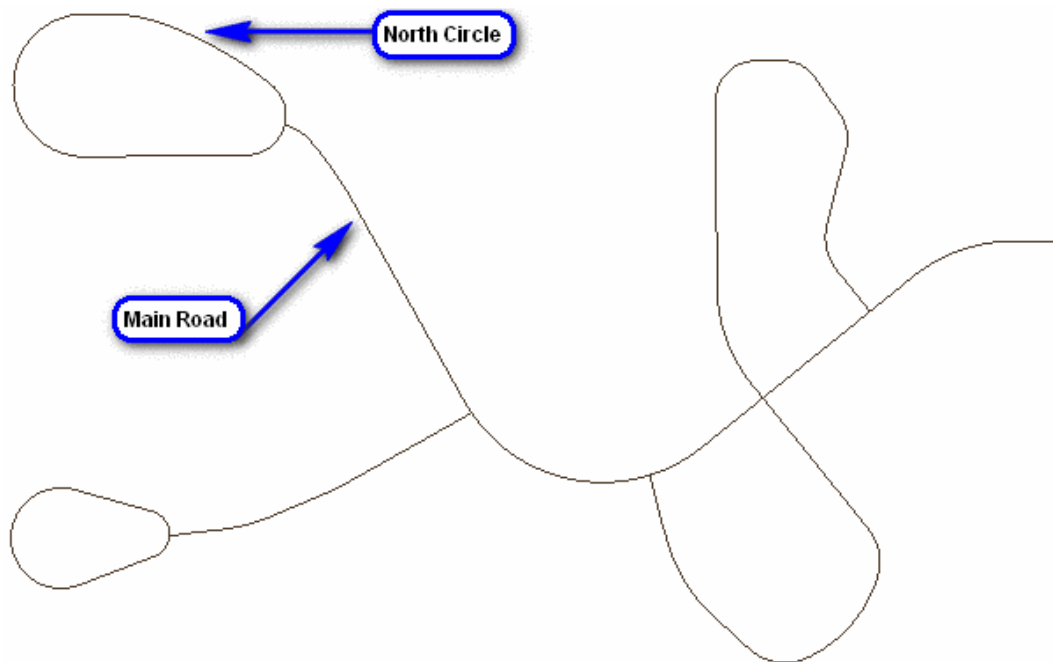

Centerline File to Write (dialog): supply a name of **North.cl** and click **Save**

Polyline should have been drawn in the direction of increasing stations.

Select polyline that represents centerline: pick the road centerline for the loop road at the top of the site as illustrated below

Centerline station [Reverse/Ending/<Beginning: 0+00>]: press Enter

Press ENTER to continue. press Enter

A centerline file is created. Immediately press Enter to re-run the **Polyline To Centerline File** command and when prompted:

Centerline File to Write (dialog): supply a name of **Main.cl** and click **Save**

Polyline should have been drawn in the direction of increasing stations.

Select polyline that represents centerline: pick the road centerline for the main road as illustrated above

Centerline station [Reverse/Ending/<Beginning: 0+00>]: press Enter

Press ENTER to continue. press Enter

Activate the Hydrology menu via Settings – Carlson Menus – **Hydrology Menu**.

- Storm sewer network structures and pipes are stored in a sewer (.SEW) file. Once a .SEW file is set as current, the program will continue to automatically use that file. To start a new sewer network, issue the Network – Sewer Network Setup – Set Sewer File command to display a dialog similar to that shown below:

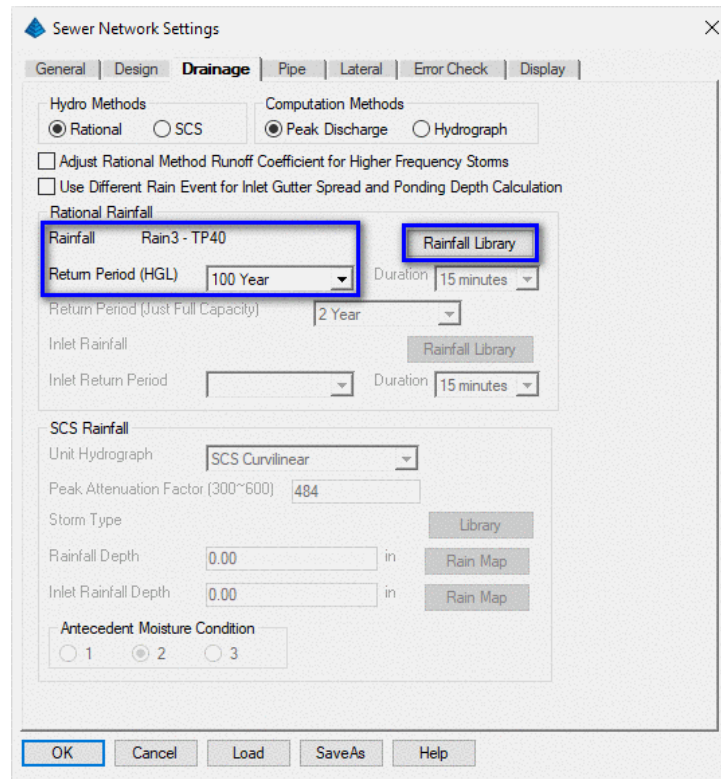

Set the filename as shown above and click **Open** when ready. The sewer network also works with a current

surface model that is used for the default rim elevations, reporting pipe cover and calculating inlet drainage areas. To set the current surface, issue the Network – Sewer Network Setup – Set Surface File and when prompted:

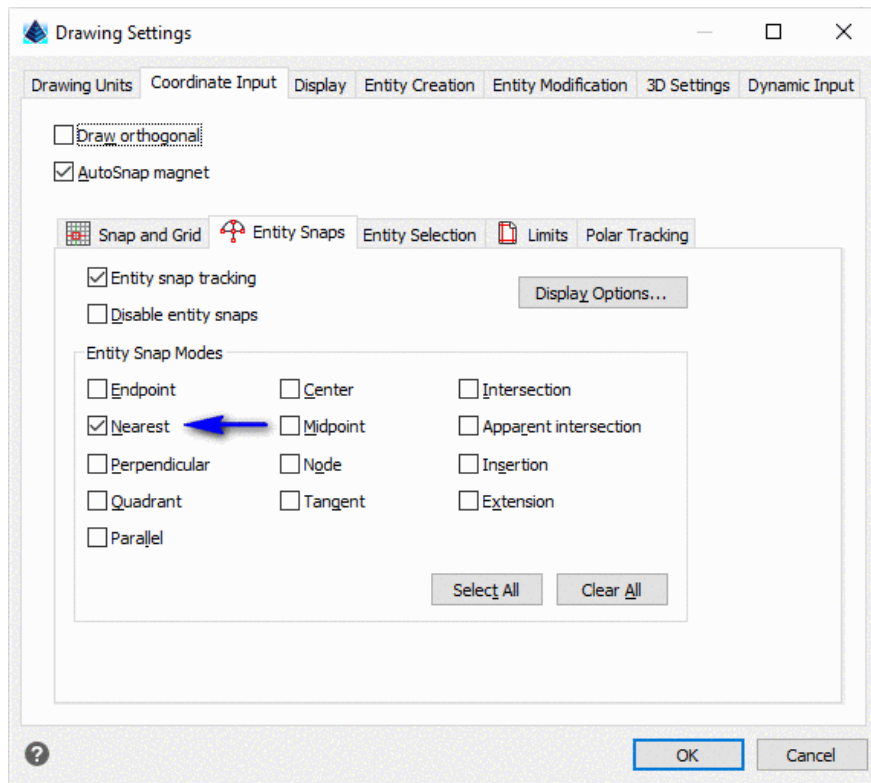

Surface Model to Reference (dialog): pick the TIN file created earlier and click **Open**

Additionally, issue the Network – Sewer Network Settings command to display a dialog box similar to that shown below. Click the *Drainage* and the click the **Library** to set the Rainfall to the data created earlier and specify a **Return Period** of 100 years as illustrated below:

Review the content of the other tabs and click the **OK** button when ready.

10. As we start into the creation of the storm sewer network, let's set a running entity/object snap (esnap/osnap) to nearest (nea) to use for locating the inlets along the curb polylines. Issue the Settings – **Object Snap** and turn on only the *Nearest* snap mode as illustrated below (click **OK** when ready):

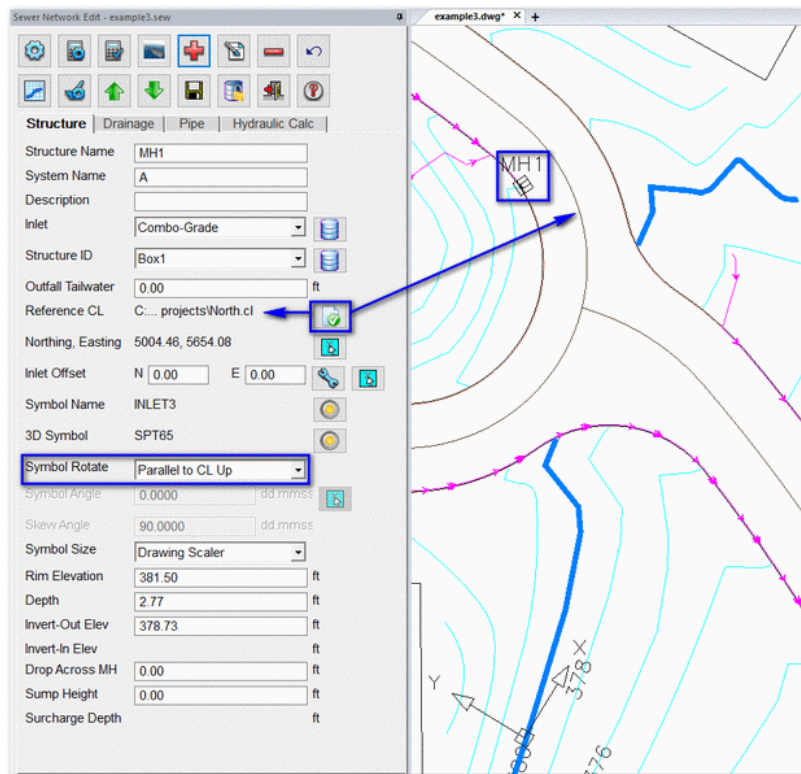

Now we're ready to lay out the inlets and pipes. Let's work on the drainage for the roads of the North loop and the Main road and run this flow to an outlet in the central pond. Issue the Network – Create Sewer Structure command and when prompted:

Locate by pick point, point number or station-offset [<Pick>/Number/CL/Curb**]?** press Enter

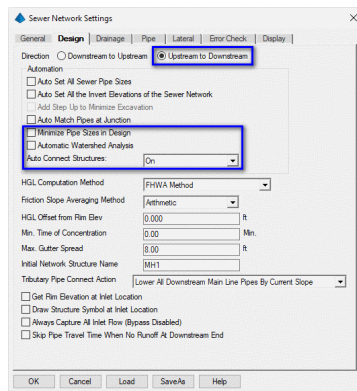

Pick structure location: zoom in very close so that you can see the curb line and pick a location on the inner curb line

NOTE: Be sure to pick the end of the flow line at the inside curb polyline and not the top of curb. Otherwise, the routine to find the drainage area from the surface model will not capture flow along the curb:

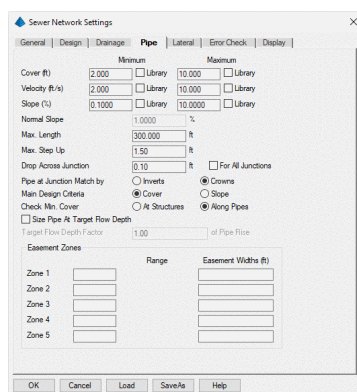

After this first inlet location is picked, the *Sewer Network* "docked" dialog is placed on the left side of the drawing as illustrated above. Click the **Select** (Paper) button next to the **Reference CL** label, select **By Centerline File** and select **North.cl** for the centerline. This centerline can/will be used to align the inlet symbol. In the **Symbol Rotate** field, select **Parallel To CL Up**. Let's establish some desired settings. Click the **Settings** (Gear) button and on the various tabs shown below, set the highlighted values:

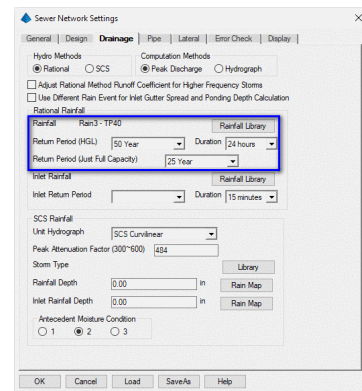

Design Tab

Pipe Tab

Drainage Tab

Display Tab

Storm Sewer Settings

Click the **OK** button when ready.

11. Now let's work on the *Structure* settings. Keeping the docked dialog box open, click the **Library** (Cylinder) button to the far right of the *Structure ID* field to display the list of structures as otherwise defined through the Network – Sewer Network Libraries – Sewer Structure Library command. For this example, use **MH3**. To check the dimensions for this structure, pick the **Edit** button to display the dialog box below:

Circular Structure

Structure ID:

Structure Desc:

Taper Format:
 Symmetric Taper Upstream Taper Downstream

Top Diameter: ft
Fixed Taper Height: ft
Taper Offset: ft
Bottom Diameter: ft

Custom Properties

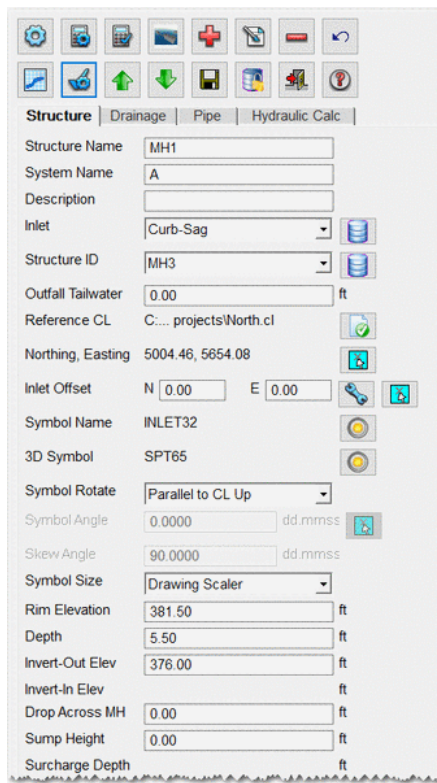

ID	Name	Value
----	------	-------

Buttons: Draw, **OK**, Cancel, Help

These dimensions are used for hydraulic calculations as well as drawing the structure in the profile and 3D views. Click **OK** from the *Edit* dialog, select/highlight **MH3** from the library list and pick **OK**.

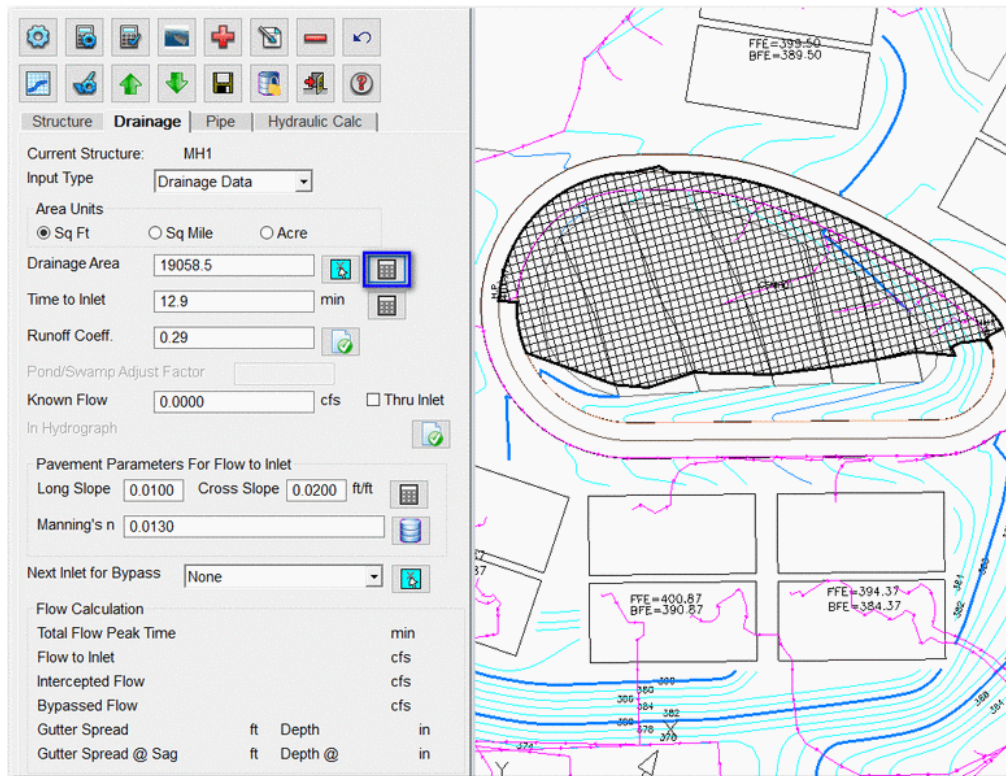

Next, pick the **Library** button next to the *Inlet* field. This function shows the inlets as otherwise defined through the Network – Sewer Network Libraries – Inlet Library. Like the **Structure Library**, you can add to and edit the Inlet Library. For this inlet, choose the **Curb-Sag** from the list and click **OK**.

The last change for the *Structure* tab is to set the **Depth** to 5.50. After making these changes, your dialog should match the settings as shown below:

Pick the **Apply Pipe Rules** (Checkmark with Gear) button to save the changes and you should see the plan view symbol for the inlet change to a grate symbol.

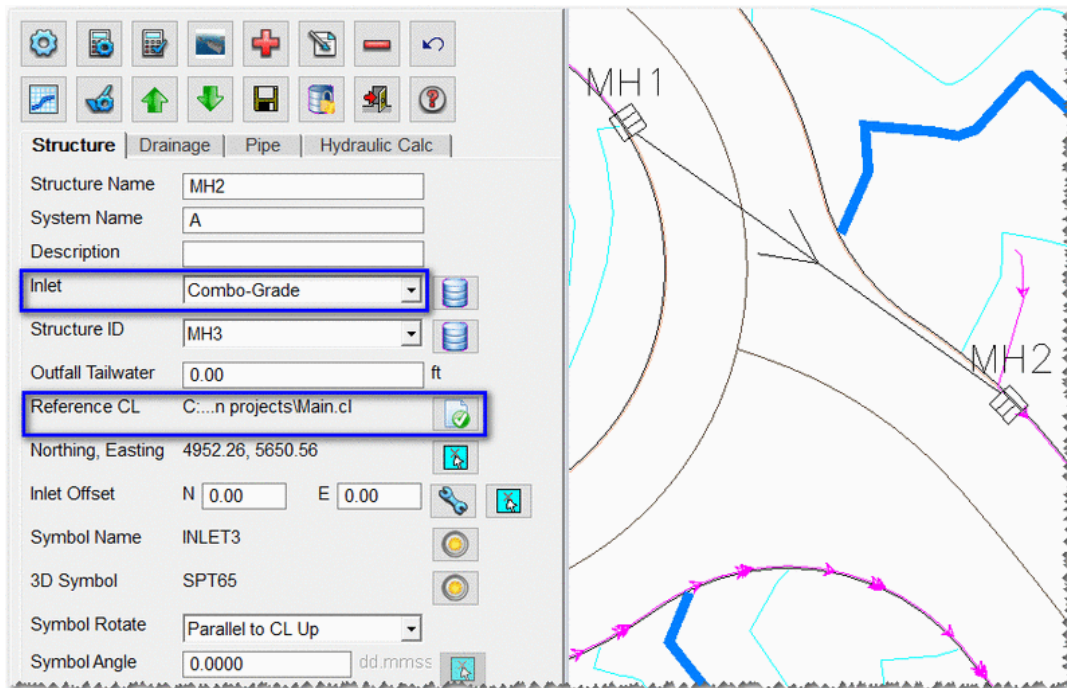

12. Now move onto the *Drainage* tab. Here the drainage area, time of concentration, runoff coefficient and pavement parameters are set (among other things) for the inlet. You can manually enter them in or have the program calculate these values. With the *Pick* button, you can select a drainage polyline perimeter and the program will calculate the area and the weighted average runoff coefficient from the runoff layers (if defined). In this example, use the **Calc** (Calculator) button to calculate all the parameters from the surface model. The first time that **Calc** is called, the program takes time to calculate the triangulation flows. Then the values are filled in and the drainage area is hatched in plan view as illustrated below:

- The Time To Inlet comes from the Max Flow Line within the drainage area and accounts for the surface slopes along the path.
- The Runoff Coefficient is calculated as the weighted average of the runoff sub-areas within the drainage using the runoff layers that we defined in the **Define Runoff Layers** command.
- In the Pavement Parameters section, the Calc button will calculate the Pavement slopes from the surface aligned by the Reference CL at the inlet location.

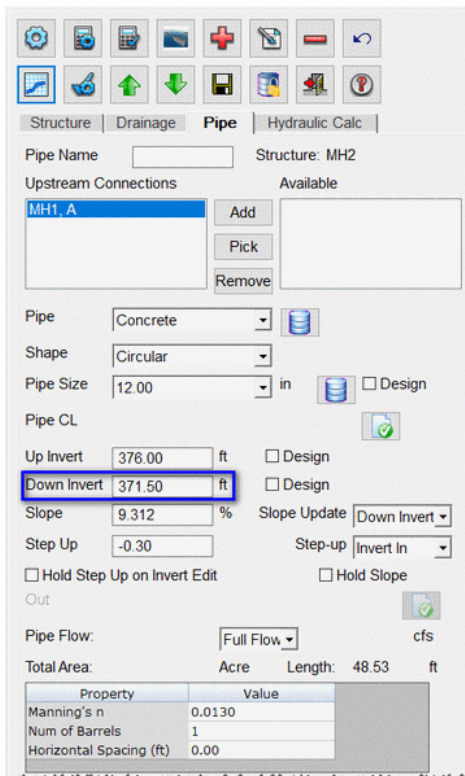

Notice how the drainage area for MH1 starts from the road high point and follows the crown of the road to the inlet. We're done for now with this first inlet.

13. To add the next inlet, pick the **Add** (Plus) button from the *Structure Actions* row. Pick a position along the right side curb polyline of the **Main** road near the intersection as shown below (MH2). Again, you may need to zoom in to be sure to snap onto the curb polyline:

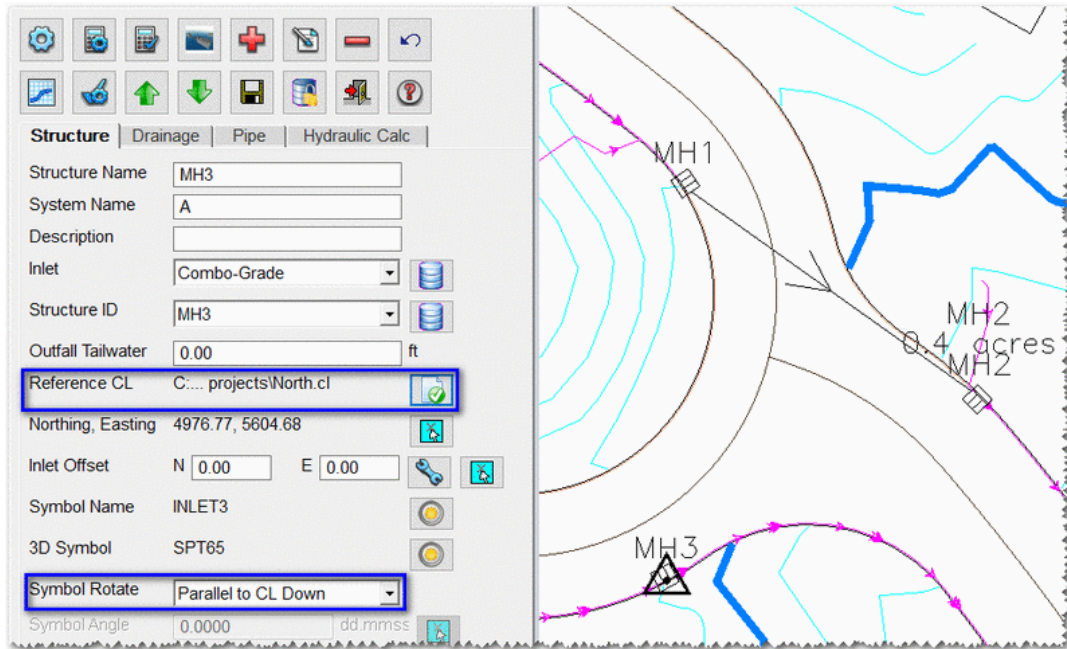

Go to the *Structure* tab for MH2 and change the **Inlet** type to **Combo-Grade** and the **Reference CL** to **Main.cl**. Then go to the *Drainage* tab and click the **Calc** to fill out all the drainage values.

Next, select the *Pipe* tab. The program lists all the used and available structures for a pipe connection to the current structure. By default, a connection is made to the nearest structure as long as it's within the *Maximum Pipe Length* as defined under **Settings**. Set the **Down Invert** to 371.5 (as illustrated below) and switch back to the *Structure* tab and set the **Invert-Out** as 371.5:

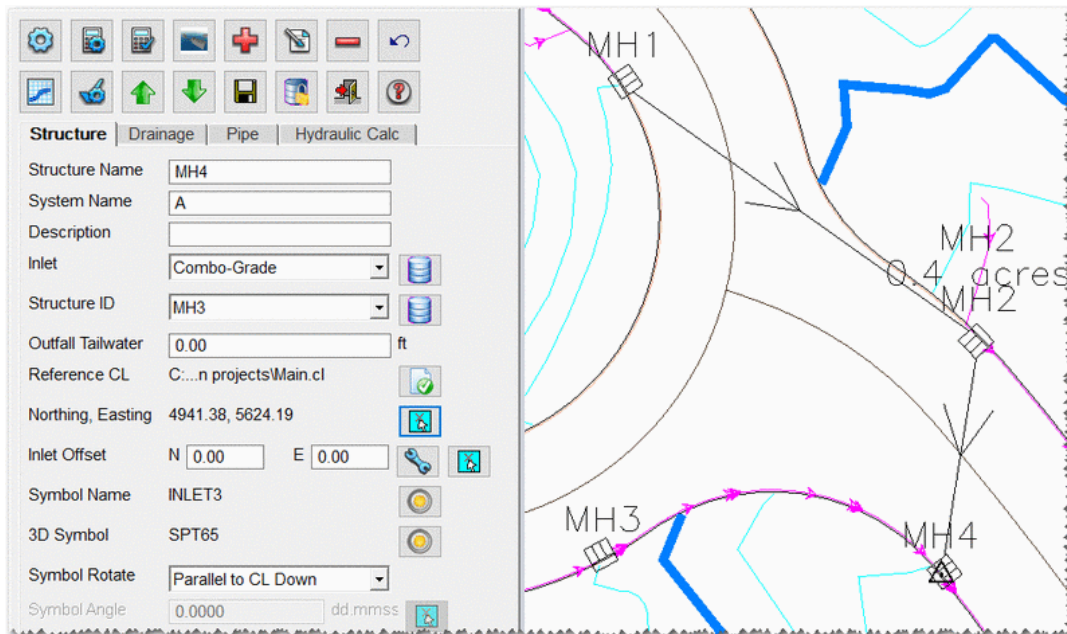

To add the next inlet, click the **Add** button again. Then pick a position along the inside North loop curb

polyline to the left of the intersection as shown here (MH3):

A pipe is automatically connected to the nearest structure (MH1). But for this network, we don't want MH3 to connect to MH1. Instead, we're going to start a new branch with MH3. So go to the *Pipe* tab, highlight the **Upstream Connection** of MH1 and click the **Remove** button. On the *Structure* tab for MH3, set the **Depth** to 7.0 and on the *Drainage* tab, click **Calc**.

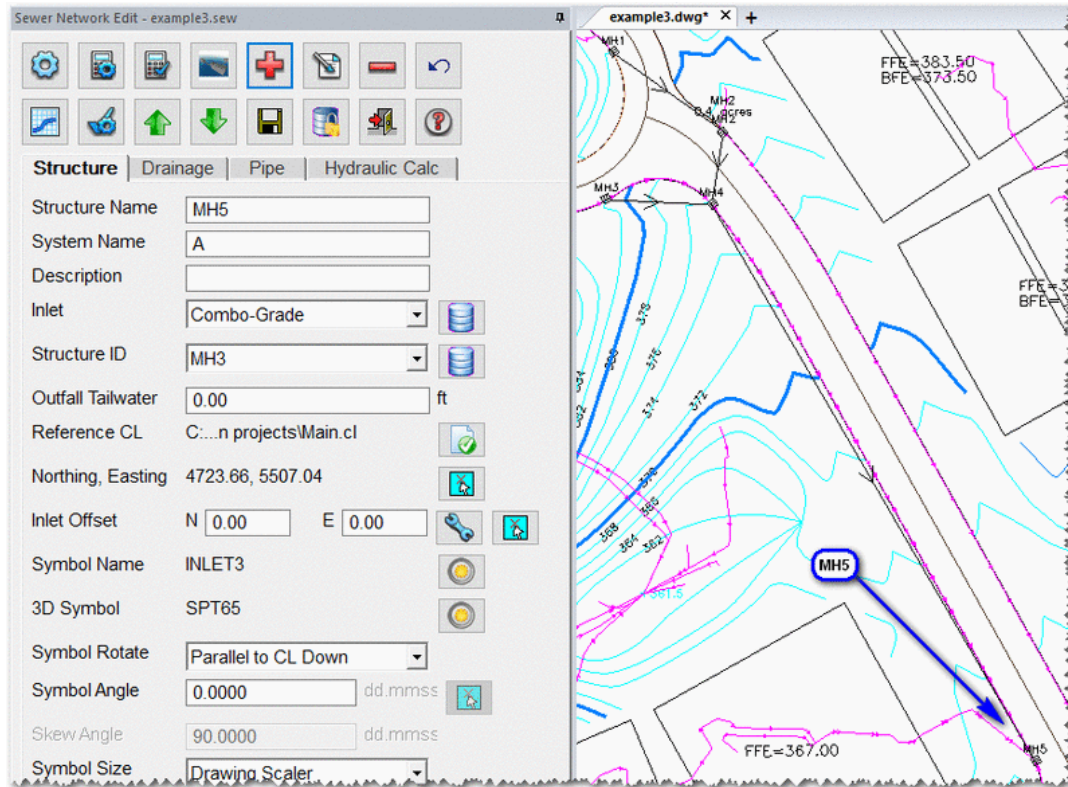

14. Now we're ready for the next inlet. Click the **Add** button from the *Structure Actions* row and screen pick the position along the main road across from MH2 as shown here (MH4):

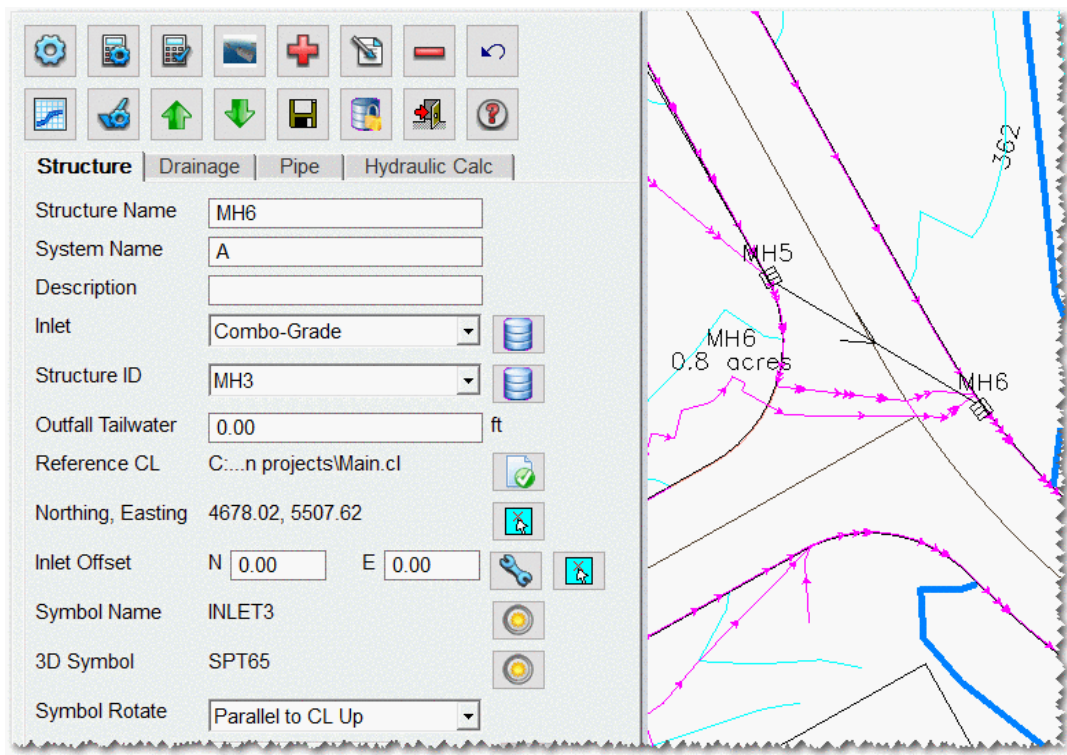

This inlet is on the other side of the road and the symbol is rotated the wrong way. To fix this, go to the *Structure* tab and change the **Symbol Rotate** to **Parallel To CL Down**. Also, change the **Invert-Out** to 371.0 and pick **Apply** to update the drawing. Next go to the *Drainage* tab and pick the **Calc** button. Again the pipe connection defaulted to the nearest structure of MH2. We want the connections from MH3 and MH2 to

go to MH4. Under the *Pipe* tab, highlight the **Available** connection for MH3 and click **Add**. For the pipe parameters, change the Down Invert to 371.1. Then go back to the Structure tab and set the Invert-Out to 371.0.

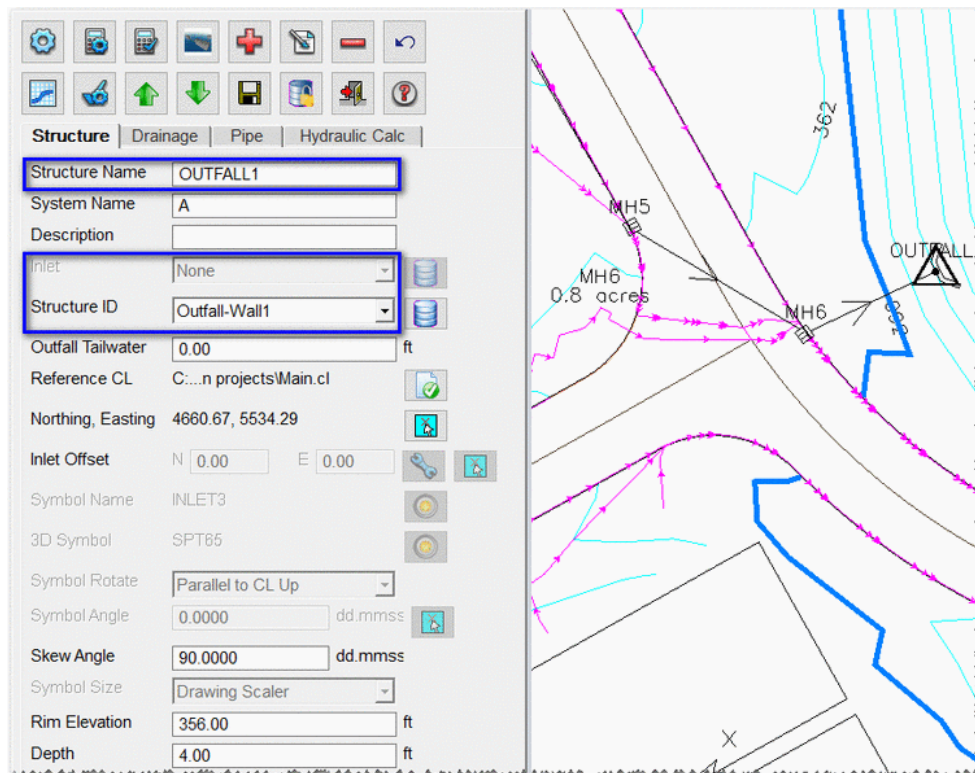

15. Now let's add the next inlet. Click the **Add** (Plus) button from the *Structure Actions* row and pick a position further down the Main road from MH4 as shown here (MH5):

Under the *Drainage* tab, pick **Calc**. We have one more inlet to add. Click the **Add** button from the *Structure Actions* row and screen pick along the curb on the other side of the Main road from MH5. See MH6 in the graphic below:

Under the *Structure* tab, set the **Symbol Rotate** to **Parallel To CL Up** to flip the symbol around. Under the *Drainage* tab, pick **Calc**. For the last structure, click the **Add** button from the *Structure Actions* row and pick on the 356 contour in the pond to the right of MH6:

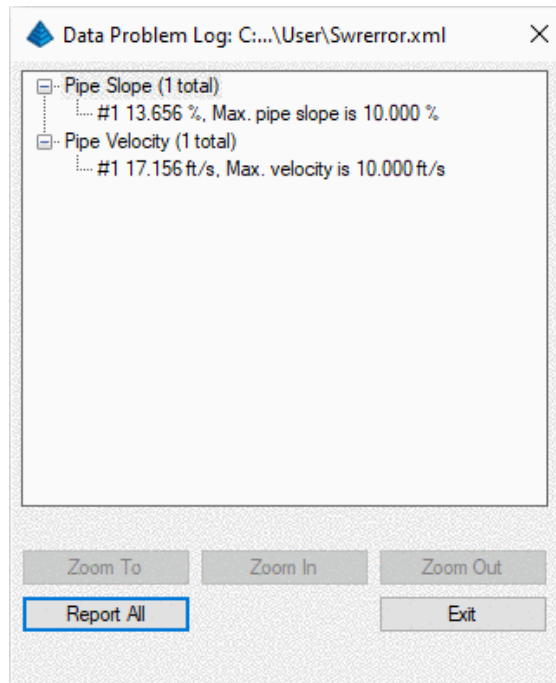

In the *Structure* tab, make the highlighted changes and click **Apply**.

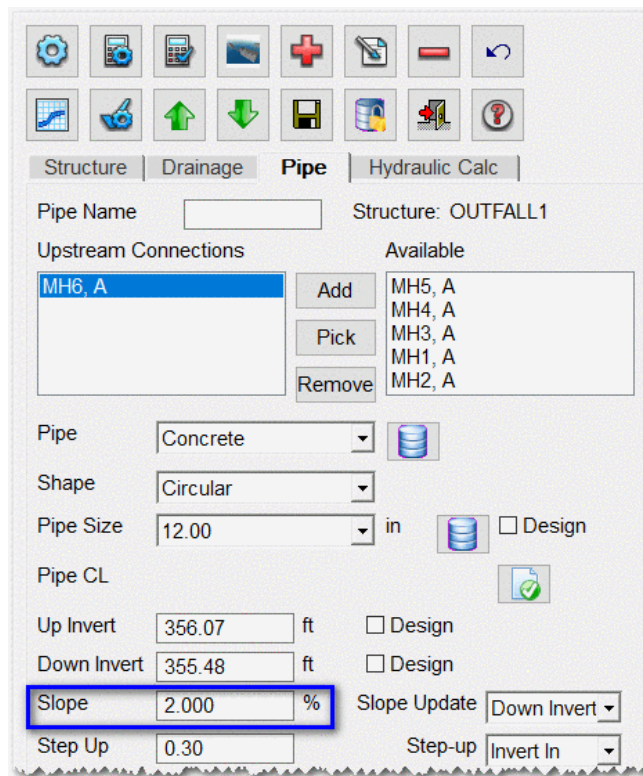

NOTE: You may get a *Pipe Rules* alert indicating potential problems with the network. If this is the case, click the **Update All** button.

The initial sewer network layout is done. Click the Save (Floppy Disc) button.

- The network flow can be analyzed. Click the **Analyze** (Calculator with Checkmark) button which runs the selected storm event through the system. If any of our design parameters are exceeded as specified under Settings, the program displays a report. Here's the report for our first analysis (your results may vary):

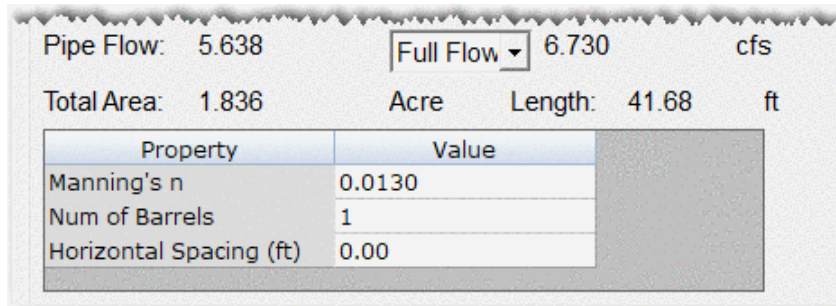

Let's take care of Warning #1 for the pipe slope. Use the **Up/Down Arrows** to navigate or click the **Edit** (Paper with Pencil) button on the *Structure Actions* row and pick the Outfall label or symbol to edit the **Outfall** structure. Set a target slope for the MH6 to Outfall as suggested below:

Click the **Analyze** button again. The warning report should only have the flow velocity warning(s), if any. Exit the report if it comes up. The flow velocity warnings can be resolved by resizing pipes and setting inverts which we will do later. Now let's review the flow results from the dialog. From the Outfall structure, click the **Up** button to move up to MH6. From the *Drainage* tab, the flow results are displayed in the **Flow Calculation** section. The **Flow To Inlet** is calculated by the Rational Method using the *Drainage Area*, *Time Of Concentration* and *Runoff Coefficient* for this inlet. The *Intercepted Flow*, *Bypassed Flow*, *Gutter Spread* and *Gutter Depth* are calculated from the inlet dimensions using formulas from HEC-22. These values can be used to determine whether you have the right inlet structure to capture the flow.

Switch to the *Pipe* tab. The *Flow*, *Area* and *Length* are displayed for the pipe connection currently highlighted from the **Upstream Connections** list. The **Total Flow** is the accumulated flow for the current pipe and the **Total Area** reports the accumulated drainage areas for all the inlets coming into this pipe:

Switch to the *Hydraulic Calc* tab which shows a graphic of the pipe structure, ground surface, hydraulic grade line (HGL) and energy grade line (EGL), along with the **HGL** and **EGL** elevations, **Flow Depth** and **Flow Velocity** at the pipe upstream and downstream connections. The **Min Cover** (calculated using the surface model to the top of the pipe) is also displayed:

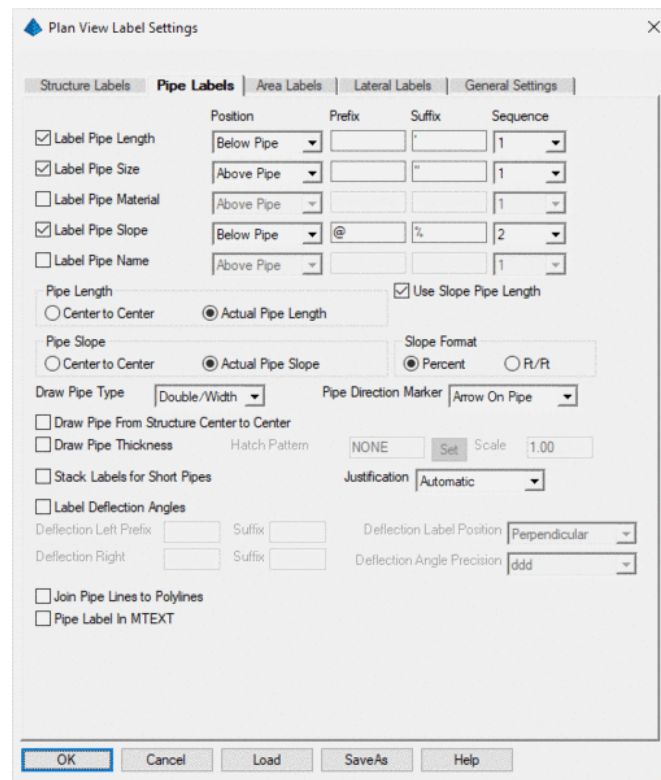

You can go to other structures to check the flow values for them or use the Network – Report Sewer Network

command to review the values in a report view. For our storm event, many of the pipes can be resized. To resize the pipes, you can go to the *Pipe* tab and change the **Pipe Size**. The program can also automatically size the pipes based on the flow:

- (a) To size specific pipes, go to the *Pipe* tab and pick on the **Design** toggle next to the **Pipe Size** field. Then click the **Design** (Calculator with Gear) button in the *Structure Actions* row and the program will run a flow analysis and set the pipe size for these pipes marked for *Design*.
- (b) To have the program size all the pipes, click the **Settings** button and select the *Design* tab and enable the **Auto Set All Pipe Sizes** option (click **OK**) and then click the **Design** button.

For this example, let's have the program assign all the pipe sizes. Issue the sequence described above. The pipes are resized to match the flow. Pick on the *Pipe* and *Hydraulic Calcs* tabs to see the changes. Pipes that can change would change and the different pipe sizes that the program uses are defined in the Network – Sewer Network Libraries – Pipe Size Library command. After the pipe sizing, there are likely a few lingering flow velocity warnings. Experiment with the flow velocity by adjusting invert elevations of the affected pipe(s) in your network. Click the **Edit** button in the *Structure Action* row and pick the structure whose invert elevations need to be modified. Now run **Analyze** function which should now complete without any warnings. Click the **Apply** button to save the results and then click the **Exit** (Doorway) button.

17. At this point, the sewer network labels are only showing the inlet name and pipe direction arrow. To change the label format, issue the Network – Sewer Network Setup – Plan View Label Settings command and click on the **Pipe Labels** tab to display a dialog box similar to that shown below:

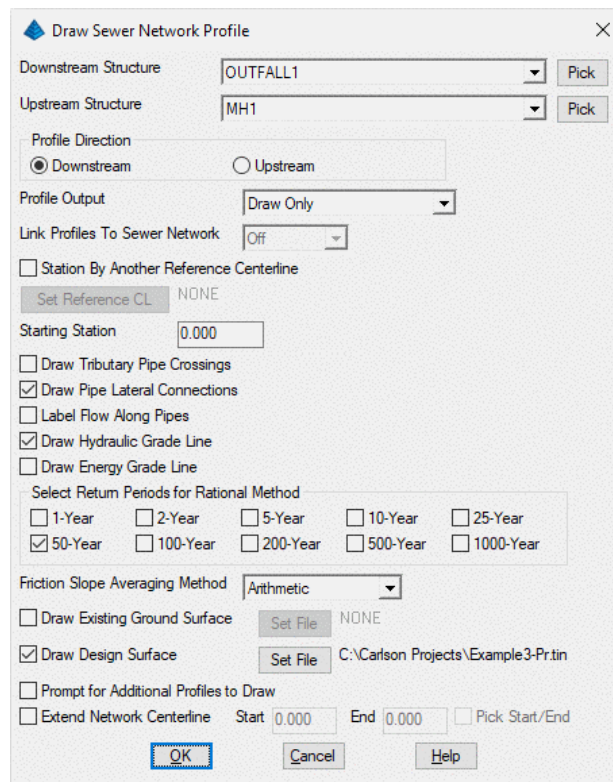

Set the values as illustrated above and click the **OK** button. The labels should update in the drawing.

NOTE: The sewer labels are linked to the sewer network definition so that any change to the sewer network updates the labels. If you want to explicitly update the sewer labels, issue the Network – Draw Sewer Network – Plan View command.

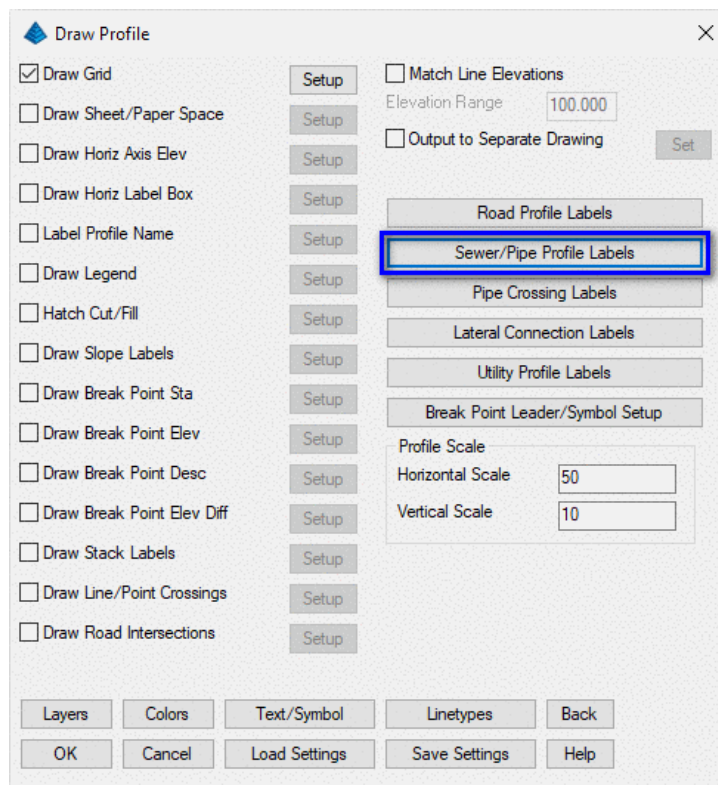

When sewer labels overlap other drawing entities, you can use the Network – Sewer Labels – Move Plan View Label command. Let's run this command and move the **MH4** label to the left of the inlet as illustrated in the example below:

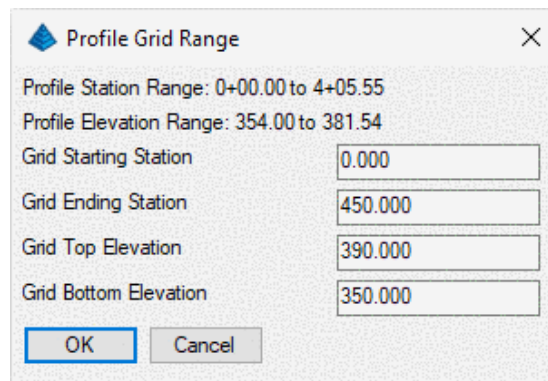

- To create a profile for the sewer network, issue the Network – Draw Sewer Network – Profile command to display a dialog box similar to that shown below:

Set the values as shown above and click **OK** when ready. A dialog box similar to that shown below appears:

NOTE: Explore the **Sewer/Pipe Profile Labels** button to further detail the content to be shown. Set the values as shown above and click **OK** when ready. A dialog box similar to that shown below appears:

The elevations default to fit the profile, so click **OK**. When prompted:

Pick Starting Point for Grid <0.00,0.00>: pick the lower left profile grid point

Your profile may appear similar to that shown below:

19. Next, let's draw the sewer network in 3D. Issue the Network – Draw Sewer Network – 3D Faces command and when prompted:

Draw Sewer Network 3D Faces (Dialog): click OK

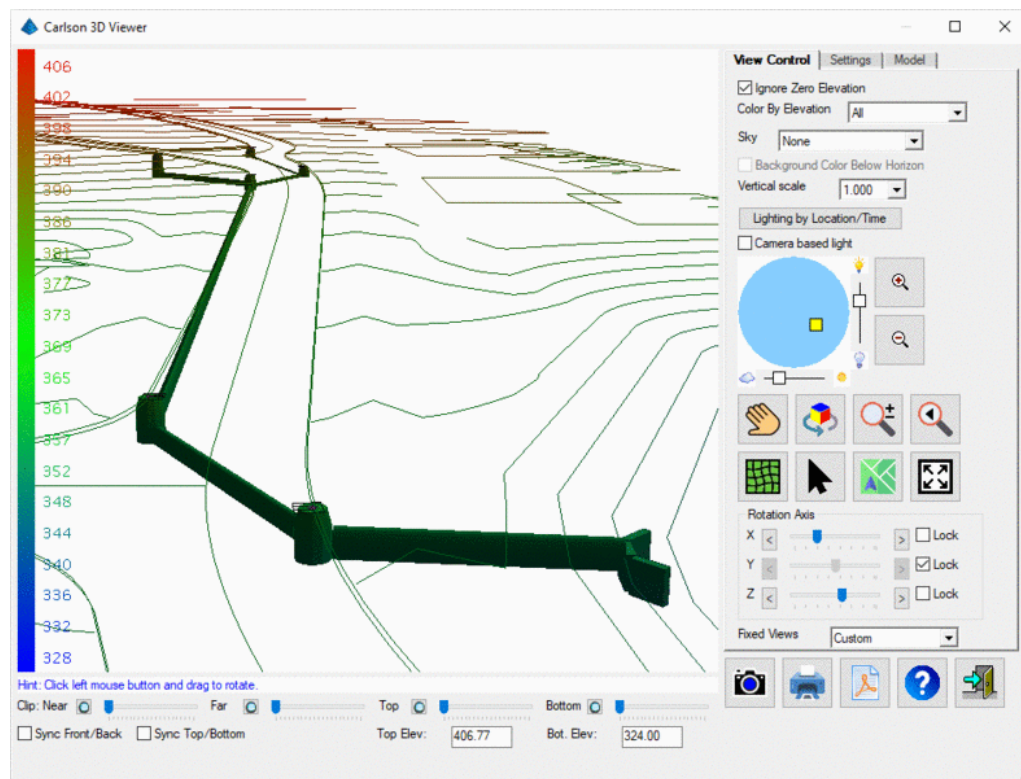

To view the 3D Faces, issue the View – 3D Viewer Window command and when prompted:

Select entities for the scene.

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

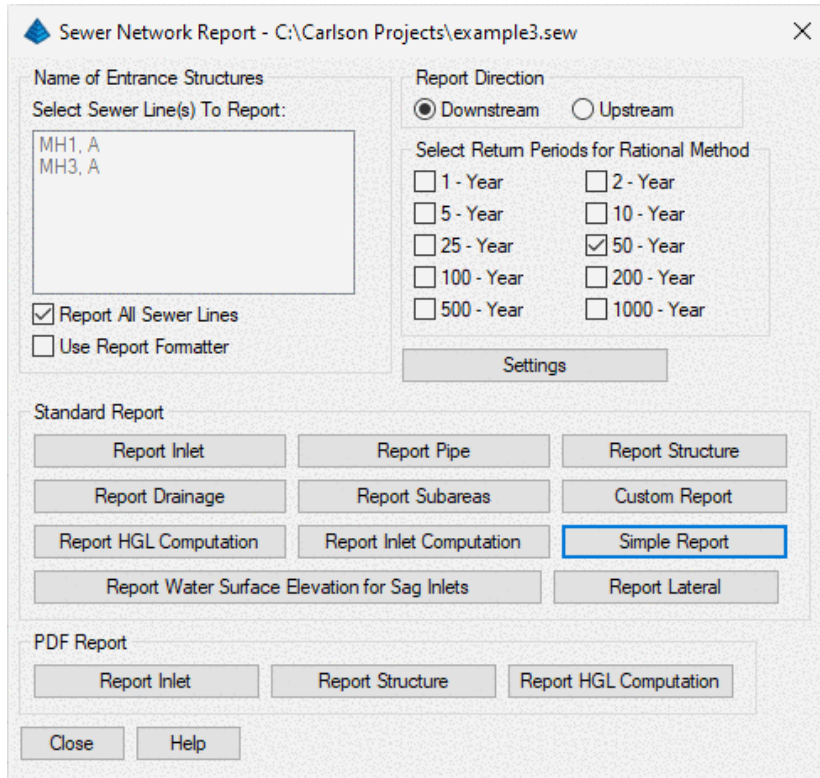

Click and drag the mouse to rotate the view to a good viewing angle as shown below:

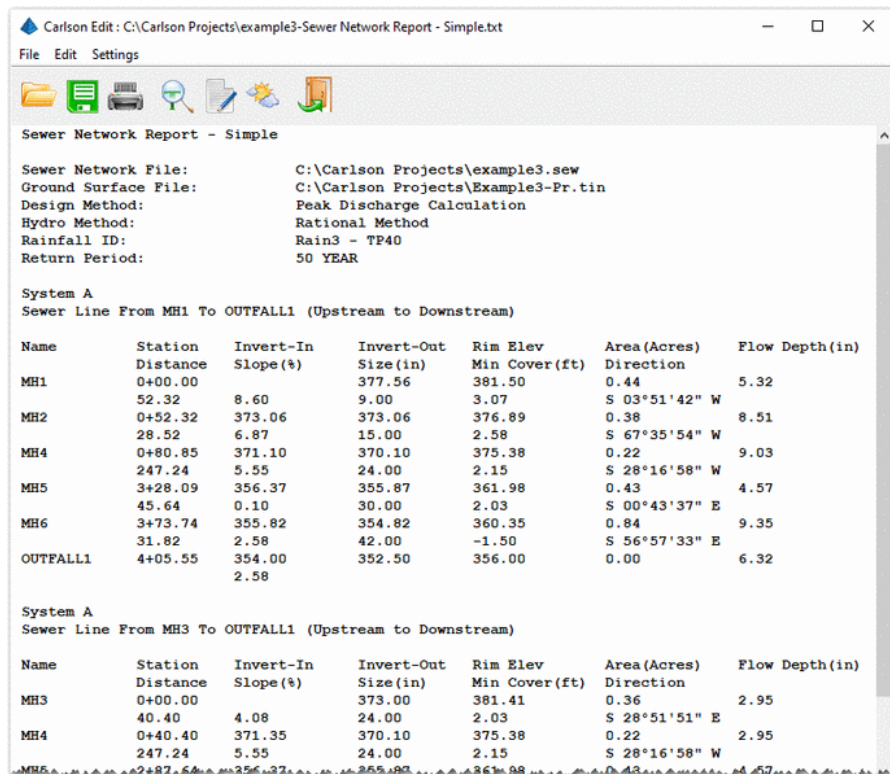

When done inspecting, dismiss the viewer by picking the **Exit (Doorway)** button.

20. Finally, let's check out the reports available and issue the Network – Report Sewer Network command to

display a dialog box similar to that shown below:

Let's run the **Simple Report** to get the summary of the system that displays in the Standard Report Viewer similar to that shown below:

Review the report and then click the **Exit** (Doorway) button and then click the **Close** button to dismiss the

Sewer Network Report dialog box.

This completes the tutorial: Stormwater Network Design.

Data Extraction for HydroCAD

This lesson covers extracting watershed data for HydroCAD stormwater modeling using Carlson Hydrology. The goal of this functionality within Carlson Hydrology is to automatically extract the sub-areas needed by HydroCAD to do its stormwater modeling. There are 3 main considerations to prepare a dataset for extraction:

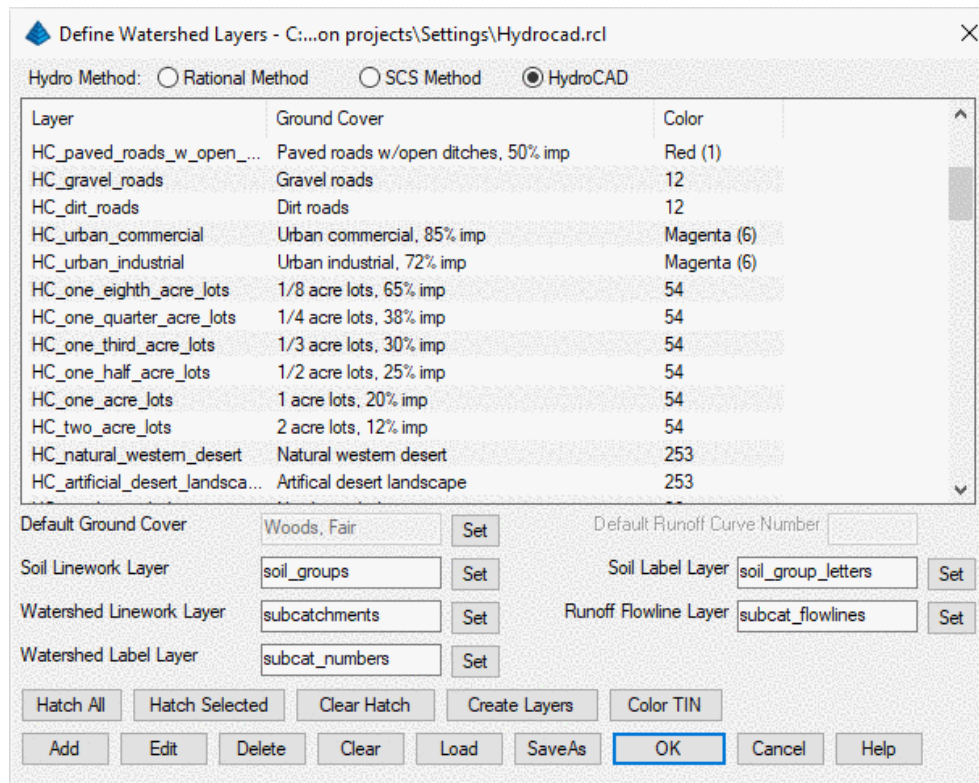

1. Watershed (subcatchment) delineation, with either:
 - (a) Longest flow path and average slope information for Curve Number/Lag method, or
 - (b) T_c with sheet, shallow, and channel flow information defined for TR55 method
2. Delineation of Hydrologic Soil Group (HSG) with:
 - (a) HSG boundaries defined on one layer, and
 - (b) HSG labels on another layer
3. Ground cover delineation, with:
 - (a) Each type of different ground cover area defined as closed polylines on specific layers, corresponding with entries in the hydrocad.rcl library

Let's get started.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

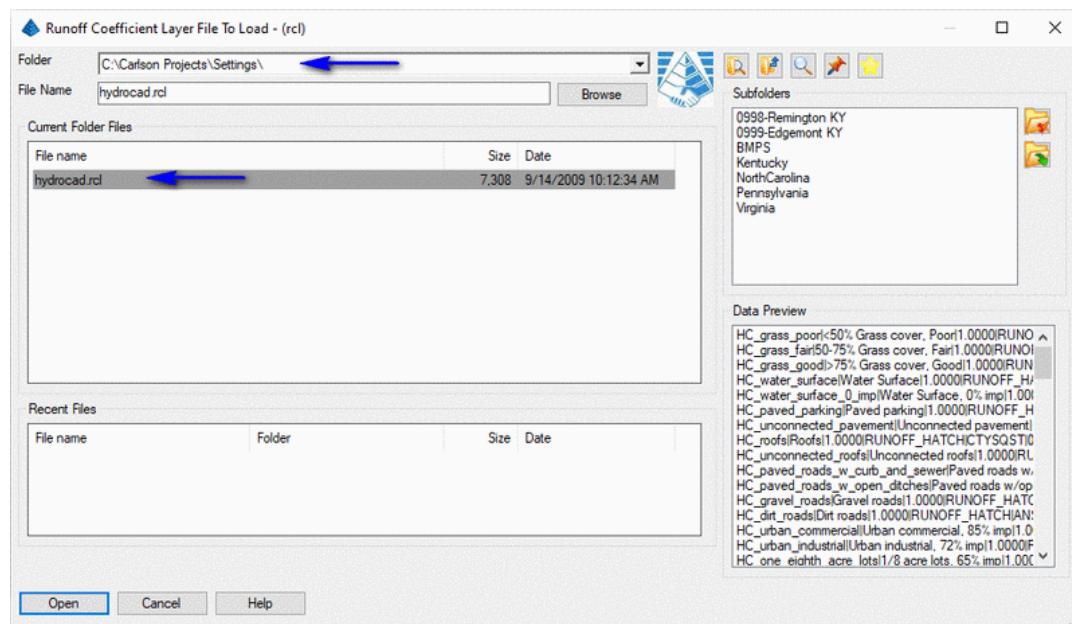

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **HydroCAD.Tutorial.dwg** file. Use the File – **Save As** to save a copy named **HydroCAD_Tutorial-A.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties.

2. Activate the Hydrology menu via Settings – Carlson Menus – **Hydrology Menu**. The entire process described herein is essentially a *layer-based* process, meaning that it is the drawing layers that everything is placed upon that makes the process work. So before going any further, take a look at the dialog box in which those layers are defined. Issue the HydroNet – Define Watershed Layers command to display a dialog box similar to that shown below:

NOTE: If you have a predetermined grouping of watershed layers you wish to preserve, click the **Save** button to save your previous layers to a named *.RCL file. The step to follow will replace the existing layers with established *HydroCAD* default layers.

Click the **Load** button and load the **hydrocad.rcl** file as shown below and click **Open** when ready:

Once loaded, enable the **HydroCAD** radio button at the top of the dialog box. Any layer names in this dialog box can be changed to whatever you like, but the linework created must use the layers you decide on. A helpful trick is to highlight the layers in the list that you think you will need for the project at hand (using standard Windows *Shift+click* and/or *Ctrl+click* functionality) and then click the **Create Layers** button which would display a dialog box as shown below:

The layers will be created for you thereby eliminating the need to type them all in by hand, and also avoiding typos that will cause the data extraction to fail. Dismiss the *Create Watershed Layers* dialog box and click the **OK** button to dismiss the *Define Watershed Layers* dialog box. Now that the layers are established, you can focus on creating the geometry in the drawing.

3. In this example drawing, sample subcatchments (watersheds) for HydroCAD have been delineated for us with polyline geometry on the following layers:
 - subcatchments
 - subcat_numbers
 - subcat_flowlines
 - longest_flow_paths

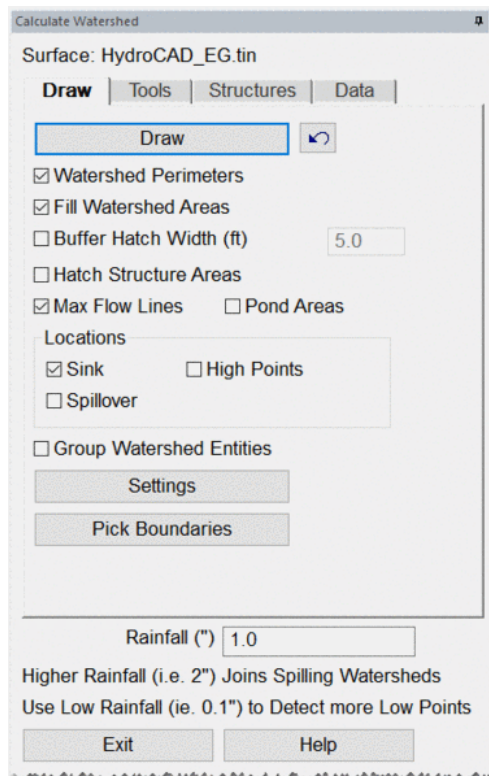

These subcatchment delineations can be done using any process desired... looking at the contours, looking at aerial photos, whatever method is most useful and comfortable is fine. It is the end result of linework that delineates the areas that are needed... the method to get them is inconsequential. The example data for this project is shown below (colors modified for clarity):

If there is a surface (TIN) for the project site (as there is for this example), **Carlson Hydrology** can greatly aid in the process of delineating watersheds (subcatchments) and determining the longest flow path for each subcatchment. These tasks are accomplished by issuing the HydroNet – (or Watershed –) Watershed Analysis command. When prompted:

Specify the surface model file as indicated above and click **Open** when ready. A "docked" dialog box similar to that shown below appears:

Set the various toggle options as cited above and click the **Draw** button when ready. The following should be displayed (layers frozen for clarity):

Once the watersheds and max flow lines are drawn, you can make decisions on them:

- Are there too many?
- Are there too few? *etc?*

Adjusting the **Rainfall** value and/or clicking the **Settings** button can assist with the desired delineation.

Tip: To combine several watershed perimeters into one, use the Draw – Shrink Wrap Entities command with the **Bound** method. You would pick the combination of watersheds, and a new boundary would be drawn around them.

For the purposes of this tutorial, let's use the polyline geometry already established for us. Click the **Undo** button (next to the *Draw* button) to remove the **Watershed Analysis** results from the drawing. Ultimately, you should be left with a closed polyline for each watershed, labeled with a designator and containing a single 3D polyline within each watershed representing the longest flow path as shown below (certain layers frozen for clarity):

Click on the **Exit** button to dismiss the **Watershed Analysis** dialog box.

4. Soil conditions (Hydrologic Soil Groups or *HSG* for short) must also be properly delineated. What you'll need, ultimately, from whatever source(s) you have is a drawing with:
 - the soil groups drawn as polylines, all on one layer, and
 - the HSG types (A, B, C, or D) labeled within the areas on another single, specific layer.

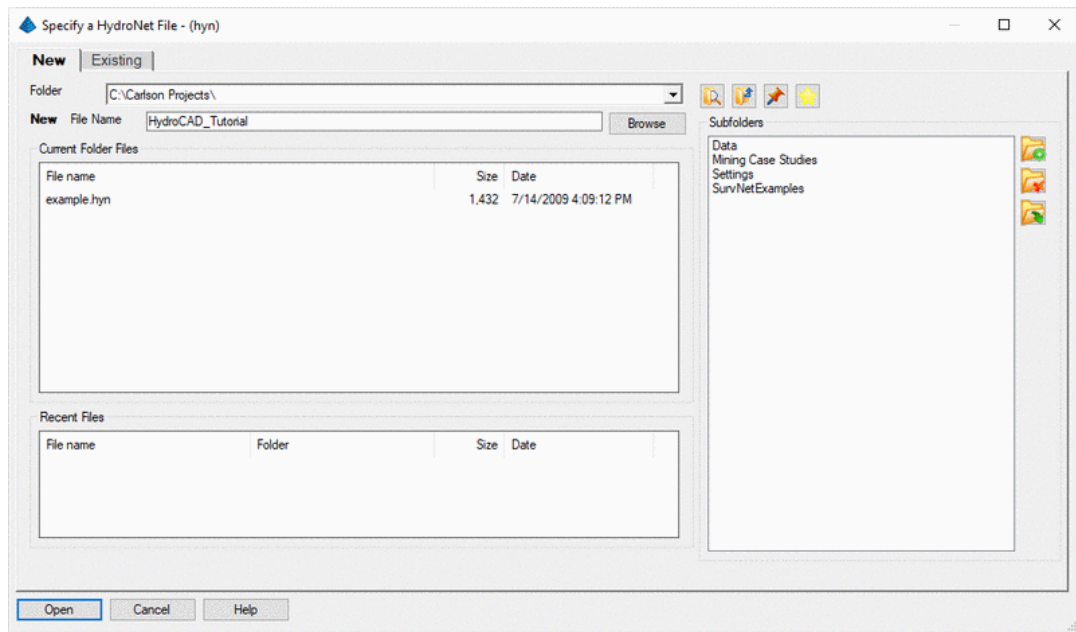

NOTE: The soil areas must be closed, but do not have to be individual specific closed polylines. The software will run a "boundary polyline" (*bpoly*) on each area to "close" it. The soils information can come from a shape (*SHP*) file such as that from USDA - NRCS or , from a ground soils survey, from digitized plans... it doesn't matter. The only thing necessary is the linework and labels such as those shown below (certain layers frozen for clarity):

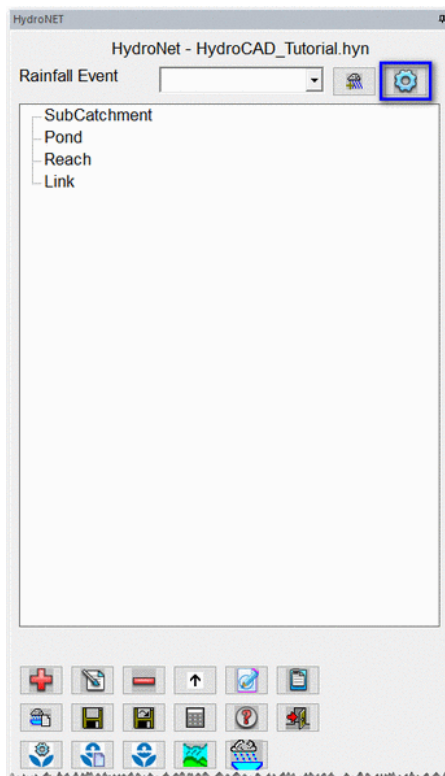

5. Finally, ground cover. In standard use, this term applies only to the ground cover which is independent of the underlying soil group(s). Neither layer equates to a specific Curve Number (CN) value which can only be determined after we analyze the intersection of these layers. The actual CN value(s) will be assigned by HydroCAD after this analysis is complete. Once again, with whatever method you like, create closed polylines on the various ground cover layers as illustrated below:

6. Now that you've drawn all the watershed and site data, we can start to extract the information we need for hydrologic analysis. Issue the HydroNet – HydroNet Explorer. When prompted, create the HydroNet file as cited below and click **Open** when ready:

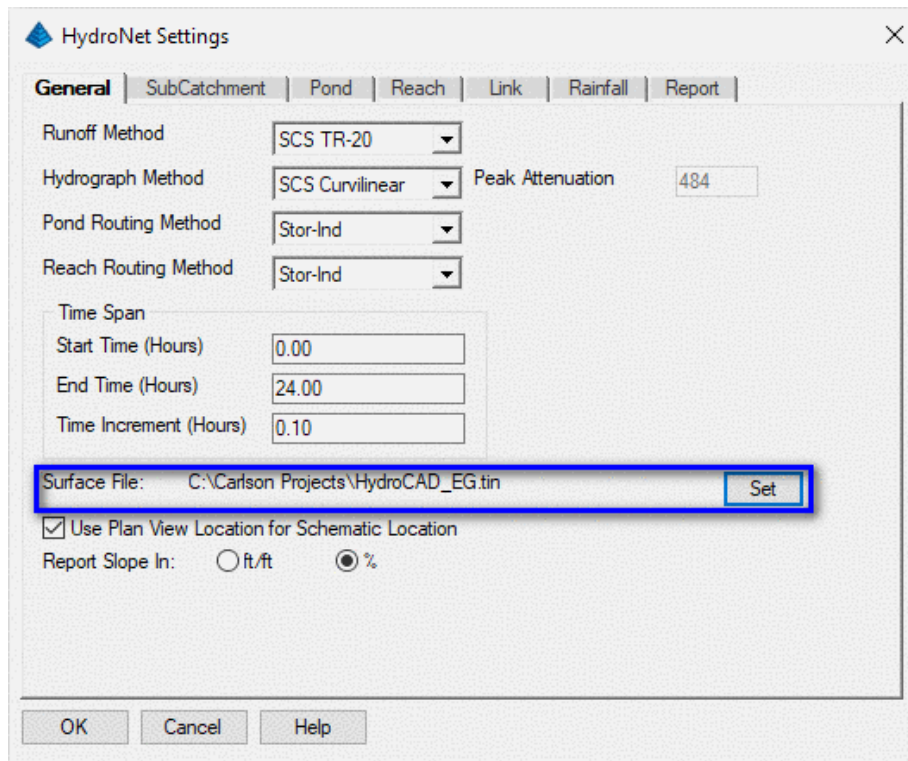

In the resulting "docked" dialog box, pick the **Settings** (Gear) button as highlighted below:

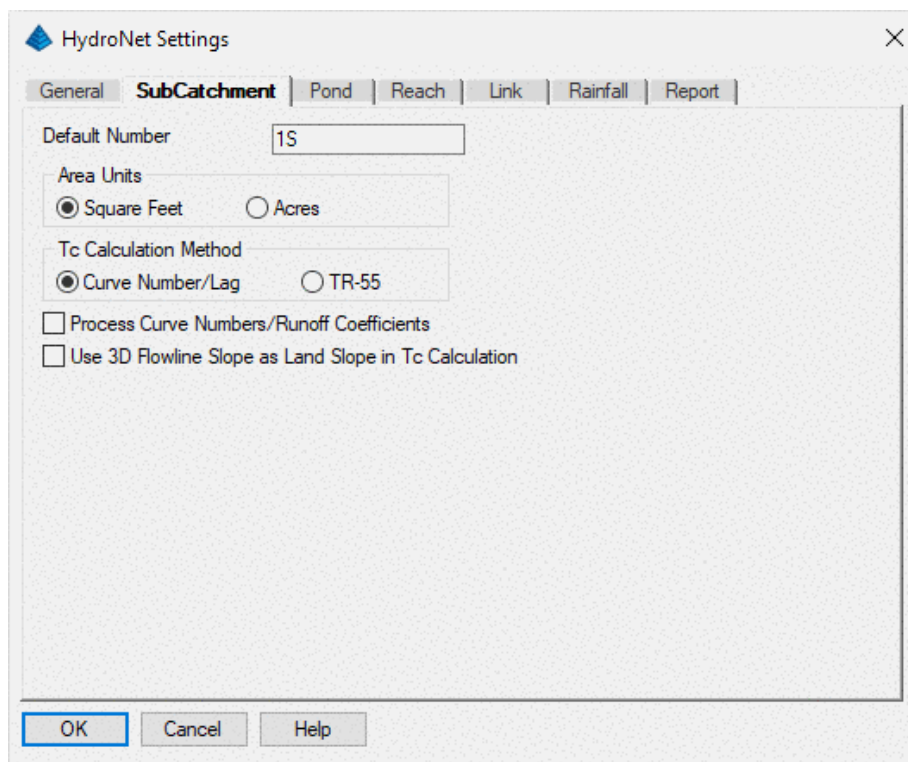

In the Settings dialog box:

- on the *General* tab, set the click the **Set** to set the **Surface File** we used earlier as shown below:

Set the other values as shown.

- on the *SubCatchment* tab, set the **T_c Calculation Method** to **Curve Number/Lag** as illustrated below:

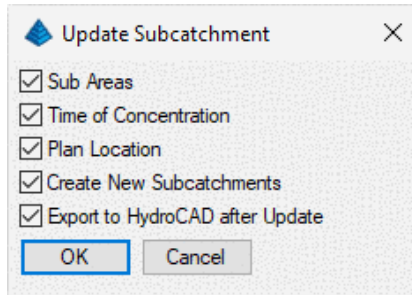

Also, clear the box to **Process Curve Numbers/Runoff Coefficients** as they will be determined in HydroCAD.

- Review the other tabs of settings as found in this dialog box and click **OK** when ready.
7. You are ready for the data extraction to be performed and the results exported to HydroCAD but we must make sure all pertinent layers are *On/Thawed*. Issue the View – Thaw/On All Layers command so the data

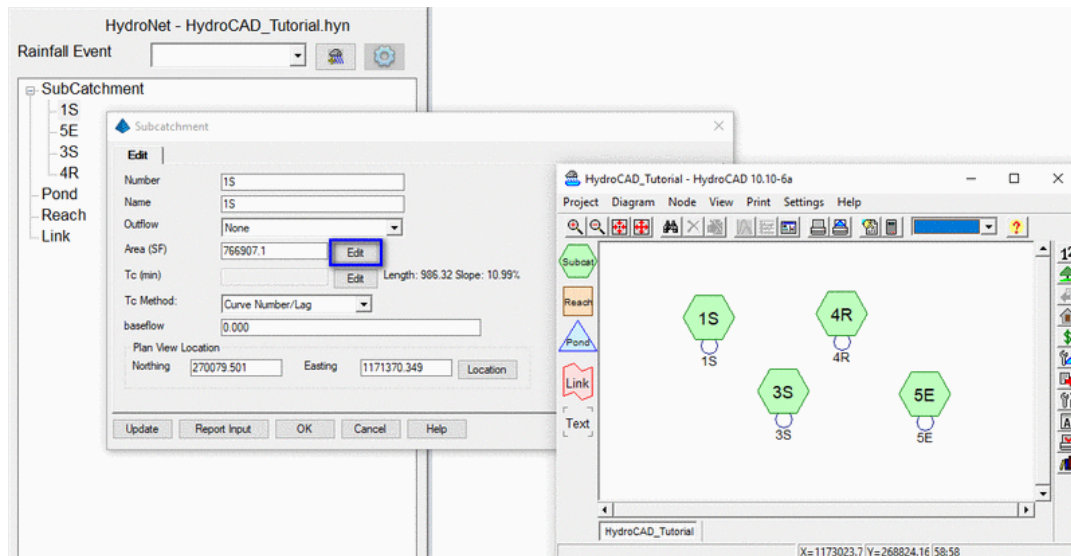

can be processed. From the main HydroNet docked dialog, click the **Update** (Up Arrow) button as illustrated below:

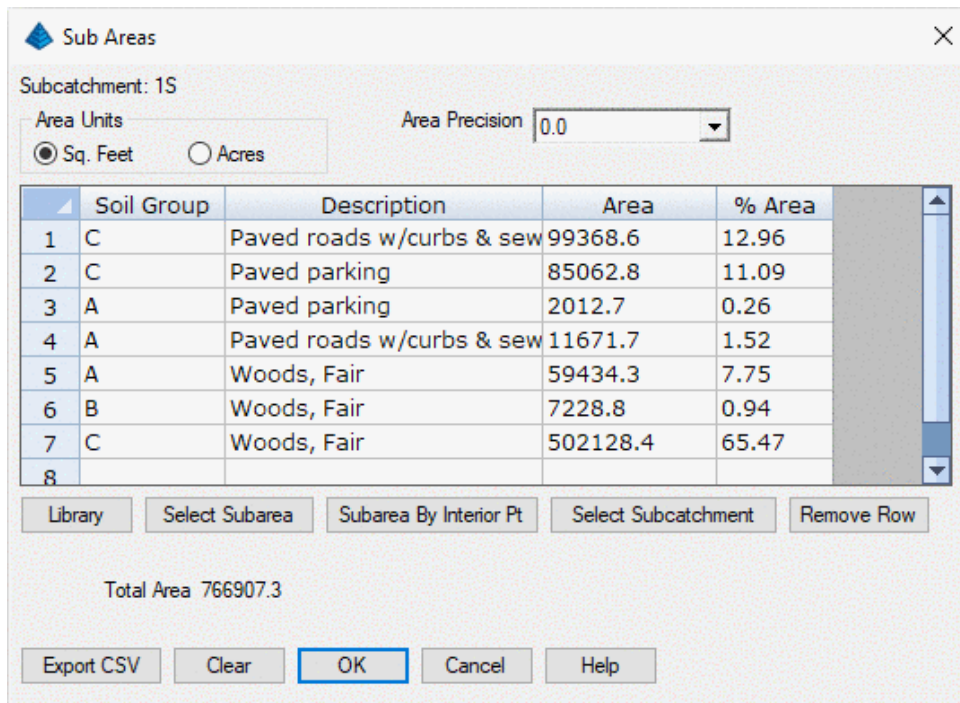

A secondary dialog box appears with the options for the update. Select the options as shown below and click **OK** when ready:

The subcatchments are listed in the **HydroNet Explorer** and *HydroCAD* (if installed), is launched. Double-clicking on any subcatchment name brings up a dialog with its data as shown below:

NOTE: The same subcatchments now exist in *HydroCAD*, ready for any further analysis and/or reporting. Click the **Edit** button next to the *Area* value shows all of the sub-area statistics as illustrated below:

Click **OK** to dismiss the **Sub Areas** dialog box and then click **OK** to dismiss the **Subcatchment** dialog box to return to the *HydroNet Explorer* docked dialog box. Click the **Exit** (Doorway) button to dismiss the **HydroNet Explorer** docked dialog box.

8. Double-clicking a subcatchment in *HydroCAD* opens the **Hydrograph** and **Summary** report windows as summarized below:

Subcat 1S: 1S - HydroCAD_Tutorial

Any changes made in the drawing can instantly update the data in *HydroCAD* simply by picking the **Update** button.

This completes the tutorial: Data Extraction for HydroCAD.

ESRI to Office to Field and Back

This lesson takes an ESRI geodatabase from ArcView into Carlson GIS and then to Carlson SurvCE for data collection. Next the data is taken from SurvCE into Carlson Survey and processed by Carlson GIS back into ArcView.

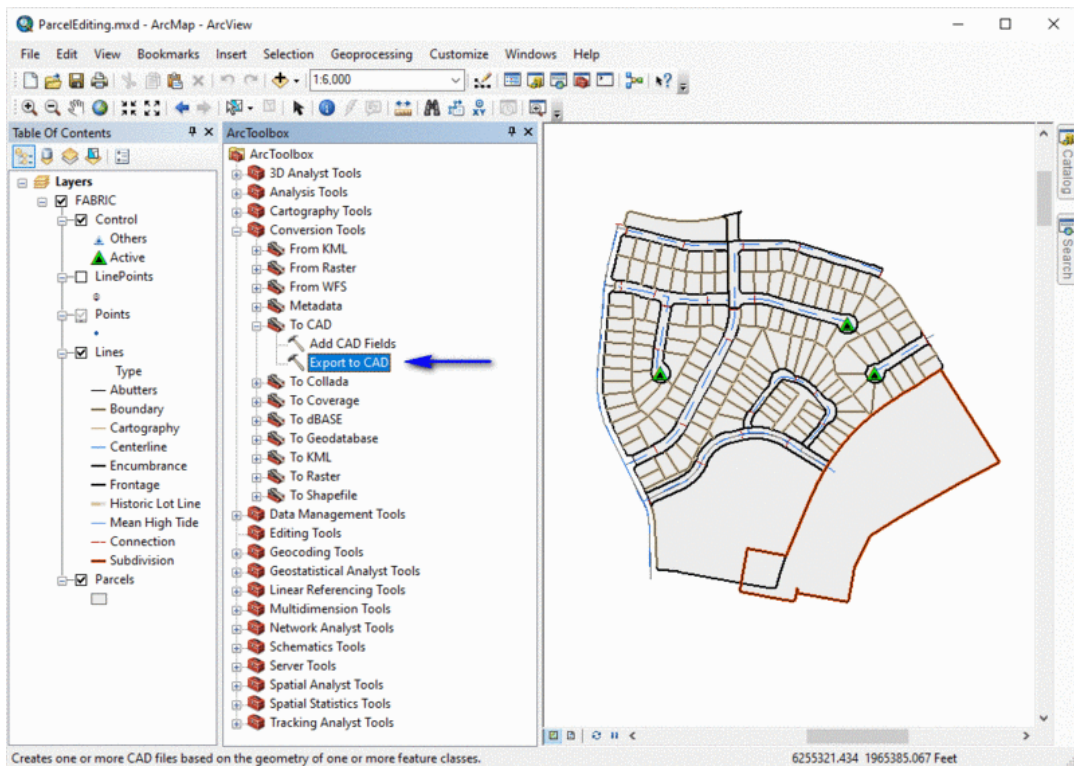

1. ArcGIS Desktop has a routine to output a geodatabase to a DWG file. The DWG file contains all the information in a single file. It has the graphic geometry, feature definitions and feature attribute data. The feature information is stored in a format defined by ESRI called Mapping Specification for DWG (MSD) using standard DWG entities and dictionary entries. In this tutorial, we're going to use ArcView 10.x to create the DWG with MSD. Launch ArcView (sold separately) and open a desired project. In this case, we are illustrating an Esri-supplied tutorial geodatabase:

Opens the ArcToolbox window so you can access geoprocessing tools and toolboxes

6254170.392 1966666.317 Feet

If not already open, launch the **ArcToolbox** as illustrated above. Issue the ArcToolbox – Conversion Tools – To CAD – Export To CAD as illustrated below:

Creates one or more CAD files based on the geometry of one or more feature classes.

6255321.434 1965385.067 Feet

The next task will be to select the features to export in the **Export To CAD** dialog box. To select a feature, click the **Input Features** drop-down list (as illustrated below) and pick a desired feature from the list:

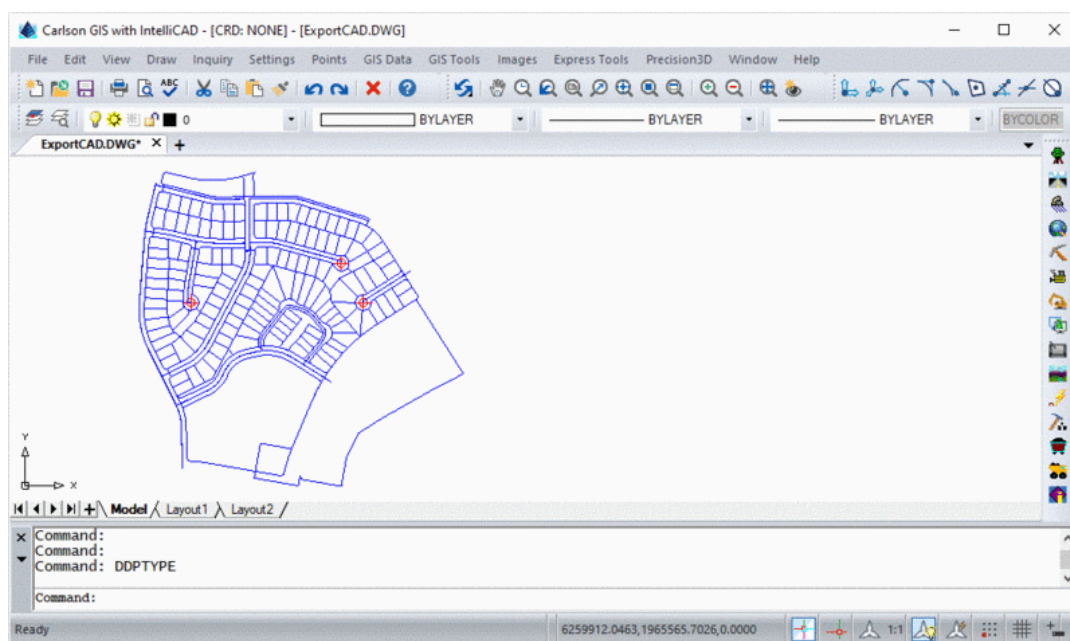

Set the remaining fields as desired including a desired DWG version (Carlson currently suggests the AutoCAD 2010 format for SurvCE users) and a path/filename for the DWG. Click **OK** when ready.

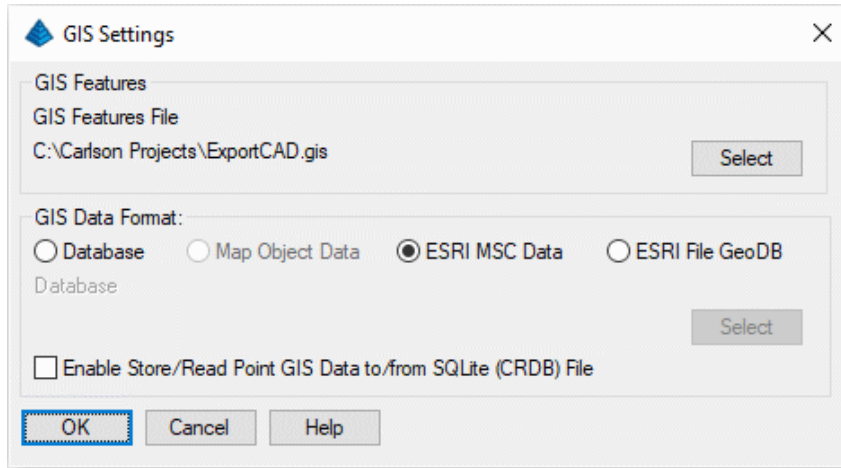

2. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **DWG** file you just exported from ArcView

3. Activate the GIS menu via Settings – Carlson Menus – **GIS Menu**. Your drawing should resemble that shown below (CAD formatting applied for clarity):

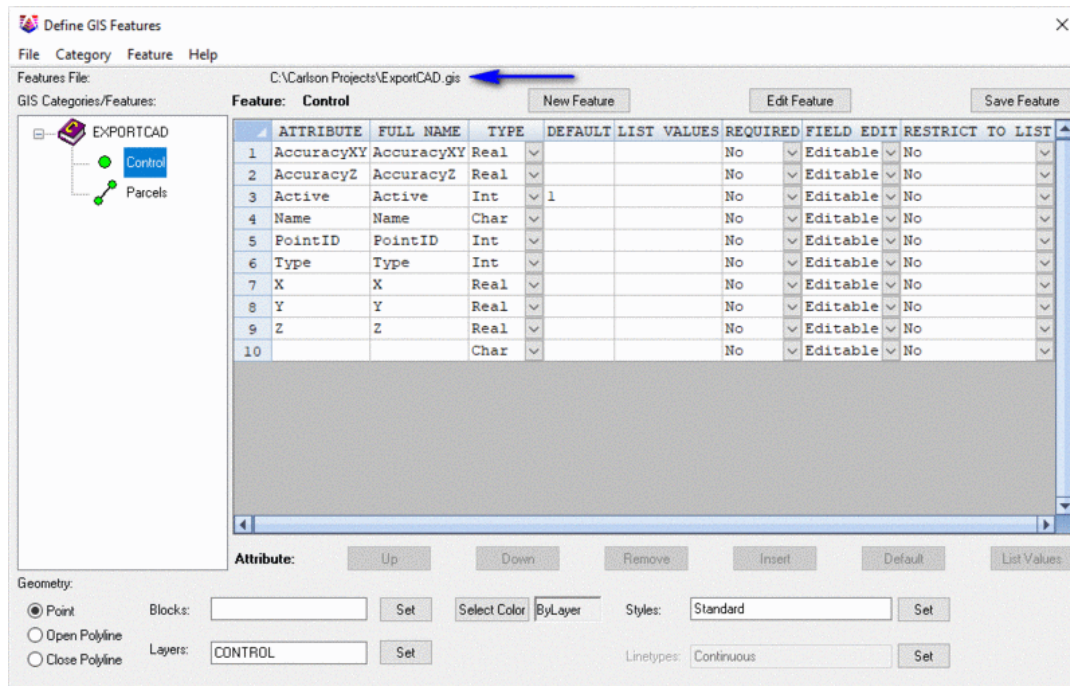

Next, run GIS Data – GIS Database Settings to display a dialog box similar to that shown below:

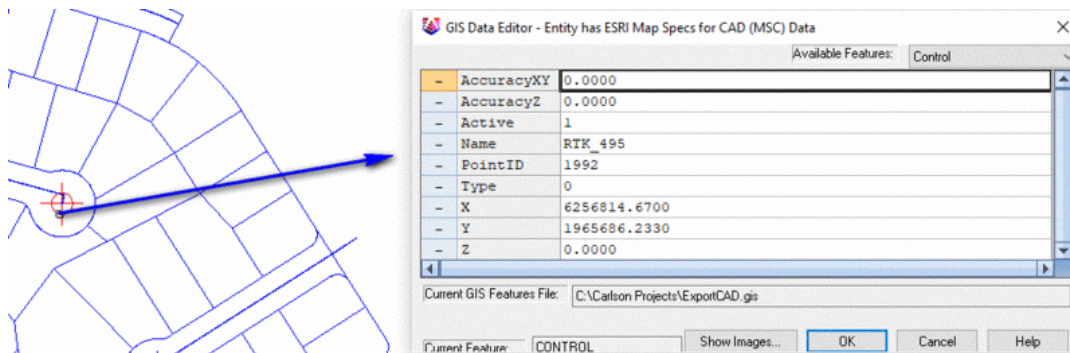

Set the values as shown above and click **OK** when ready.

- Now that we have a GIS "container" for the various GIS features, let's populate the container. Issue the GIS Data – Define GIS Features command to display a dialog box similar to that shown below:

Issue its File – Import From – **ESRI Map Specs for CAD (MSC)** command which should populate the dialog box with the various fields of data as defined by the geodatabase. Dismiss the dialog box via its File – **Save** command followed by its File – **Exit** command.

- To verify that the GIS attribute data is in the drawing, issue the GIS – GIS Data Editor and pick on an entity in the drawing (in this case, a *Control* point). The attribute data is shown in a spreadsheet editor (click **OK** when ready):

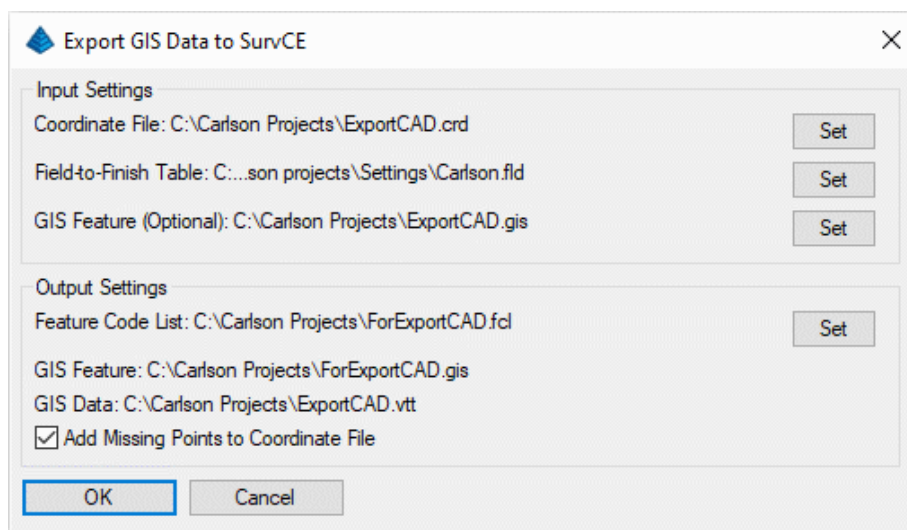

NOTE: Some graphical features may not have associated GIS data!

- Now that we have data available, let's package it up for Carlson SurvCE. Issue the GIS Data – Export GIS Data – Export GIS Data to SurvCE. You may be prompted:

Set the filename as shown above and click **Open** when ready to display a dialog box similar to that shown below:

This command takes selected data from the drawing and creates the GIS files that SurvCE uses. Set the values as shown above and click **OK** when ready. When prompted:

Select entities to export.

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

For a brief summary on the files and content cited above:

For input files:

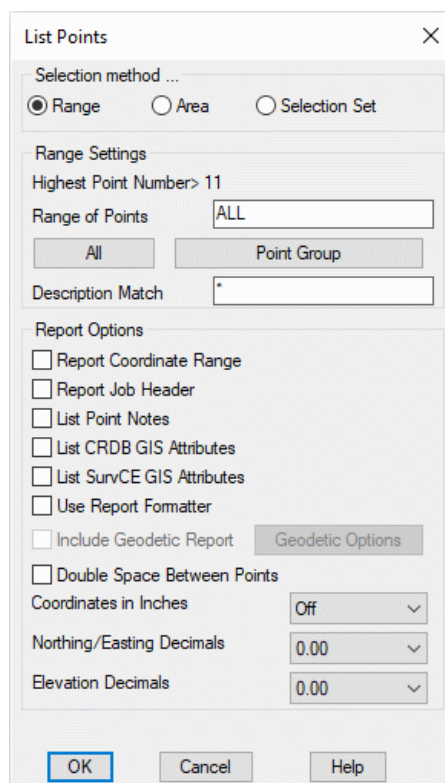

- **Coordinate File:** Contains the point database with Point#, Northing, Easting, Elevation and Description.
- **Field-to-Finish Table:** Defines the coding used by Carlson Survey for the description field that will be converted into a *Feature Code List* (FCL) for SurvCE.
- **GIS Feature:** Defines the feature and attribute names. Using this file is optional and applies in case the feature definitions contain more features or attributes than the data entities.

For Output files:

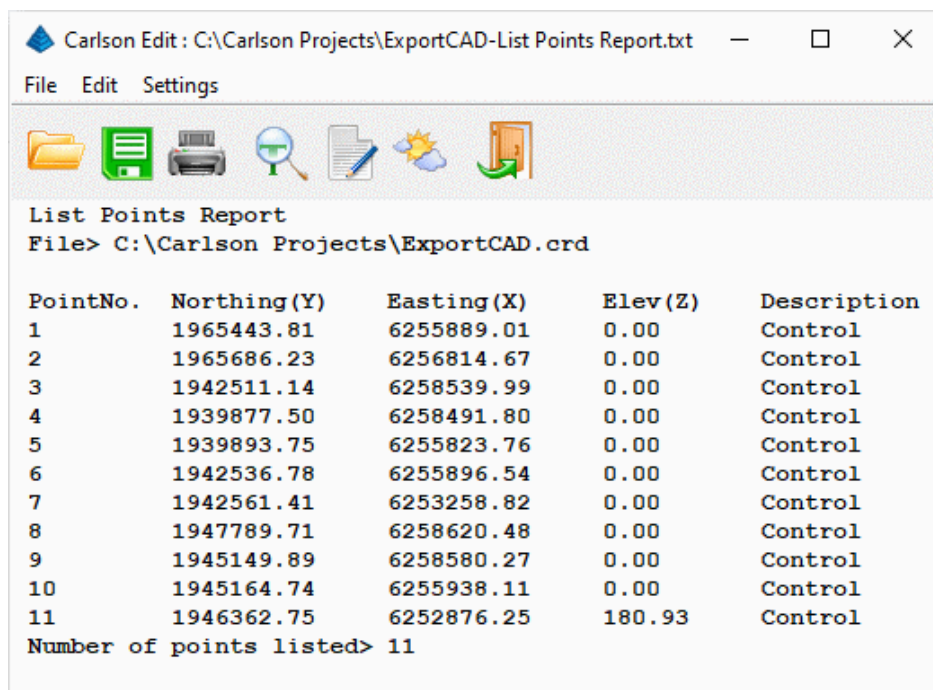

- **Feature Code File:** This is the SurvCE *Feature Code List* file for the description field coding definitions.
- **GIS Feature:** This defines the feature and attribute names. This file is automatically named after the *Feature Code File*.
- **GIS Data:** This file contains the attribute data. This file is automatically named after the *Coordinate File*.
- **Add Missing Points to Coordinate File:** This option creates points in the *Coordinate File* for any selected point entities that aren't already in the *Coordinate File*.

The program will read the GIS data from the selected entities to create the SurvCE GIS data file (.vtt) for SurvCE.

7. Let's confirm we have point coordinates for SurvCE. Issue the Points – List Points command to display a dialog box similar to that shown below:

Set the values as shown above and click **OK** when ready to display the results in the Standard Report Viewer as is illustrated below:

Review the list and click the **Exit** (Doorway) button to dismiss the report.

8. Now that the project data is converted to SurvCE format, upload/copy the following files on to the SurvCE collector:
 - Coordinate File (*.crd) as specified in the *Input Files* section.
 - Feature Code File (*.fcl) as specified in the *Output Files* section.
 - GIS Feature (*.gis) as specified in the *Output Files* section.
 - GIS Data (*.vtt) as specified in the *Output Files* section.

NOTE:If you have SurvCE 2.5 or later, then you can also use the DWG file format for the drawing. For earlier versions, use the DXF format.

9. With the data on the SurvCE collector, let's see what the process should look like. Launch SurvCE and open the *Coordinate File* generated earlier. You may get prompted for a coordinate system projection. It is often advisable to keep the projection systems consistent between the applications as illustrated below:

Application

Where to Find

Example

ArcView

View – Data Frame
Properties – Coordinate
System

Carlson GIS/Survey

Settings – Drawing Setup

Carlson SurvCE/SurvPC

File – Job Settings – System
tab

Coordinate System Summary

Let's also explore the SurvCE **Feature Code List** (button #5 on the Main Menu – File tab) to display a dialog box similar to that shown below:

Code List: ForExportCAD

Category: ALL Set

Code	Linework	Line Type	Layer Name	Full Text	Co
2D	No	2D	TREE-SML	SMALL 2" TREE	2
2P	No	2D	PINE-SML	SMALL 2" PINE	2
4D	No	2D	TREE-SML	SMALL 4" TREE	4
4P	No	2D	PINE-SML	SMALL 4" PINE	4
6D	No	2D	TREE-SML	SMALL 6" TREE	6
6P	No	2D	PINE-SML	SMALL 6" PINE	6

Add Edit Remove
Load Save As Special Codes

NOTE: If not previously available in the source **Field-to-Finish Table** (*.FLD) file as specified in the Export GIS Data to SurvCE command above, it would be advisable to **Add** the code(s) to the SurvCE *Feature Code Library* as illustrated below:

When defined, the associated *attributes* will be available and presented to the user when the collect a shot using the cited code:

Attribute	Type	Req.	Editable	Select-Only
ACCURACYXY	Real	No	Allow	No
ACCURACYZ	Real	No	Allow	No
ACTIVE	Int	No	Allow	No
NAME	Char	No	Allow	No
POINTID	Int	No	Allow	No
TYPE	Int	No	Allow	No

Collect/measure data in the field with SurvCE using conventional data gathering procedures. It is suggested that new features be coded at a point number range in excess of the existing point numbers to prevent confusion.

10. With data collected in the field, let's prepare it for its return trip. Migrate the following files from the data

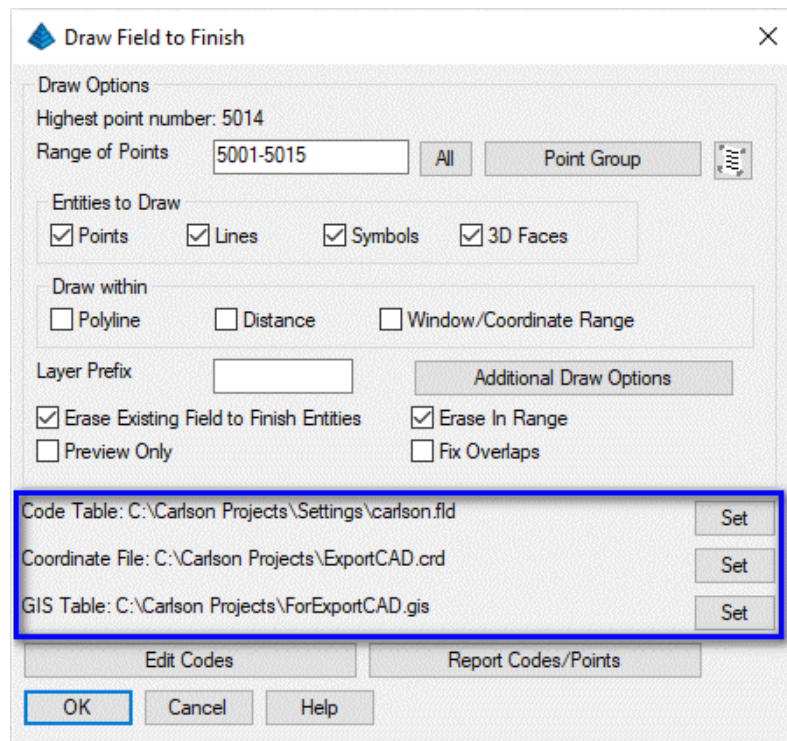

collector/controller of SurvCE back to the desktop computer:

- Updated Coordinate File (*.crd) as amended by *SurvCE*.
- GIS Data (*.vtt) as augmented by *SurvCE*.
- GIS Feature (*.gis) as used in the *SurvCE*.
- (Optional): DWG/DXF file as produced by *SurvCE*.

Re-launch the Carlson Survey desktop CAD application and then issue the Points – Set Coordinate File to set the coordinate file from SurvCE as current as illustrated below:

Activate the Survey menu via Settings – Carlson Menus – **Survey Menu**. Issue the Survey – Draw Field-to-Finish command and make note of the highlighted values illustrated below (as brought over from SurvCE):

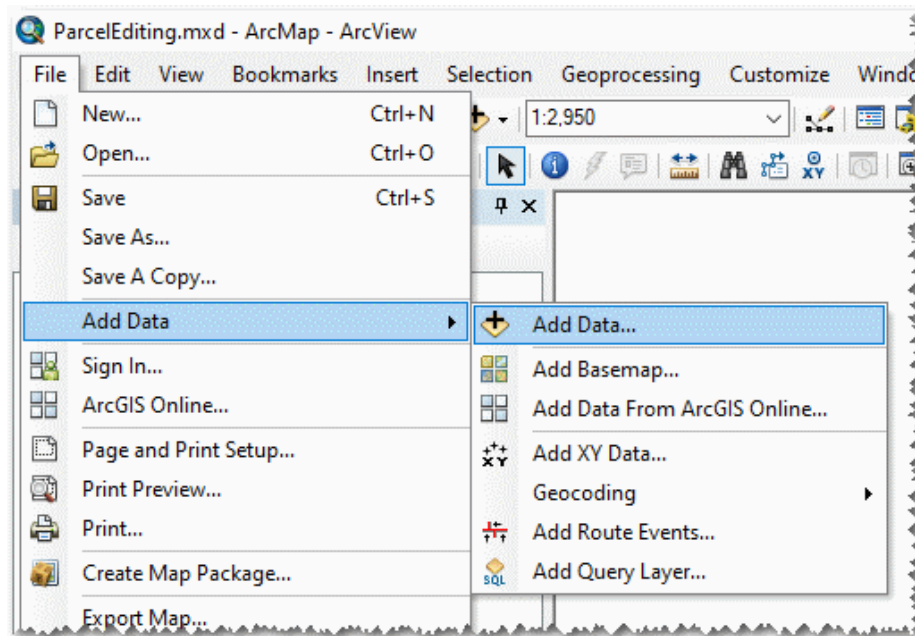

Click **OK** when ready to place the updated information into the drawing.

11. Activate the GIS menu via Settings – Carlson Menus – **GIS Menu**. Issue the the GIS Data – Import GIS Data from SurvCE command and when prompted:

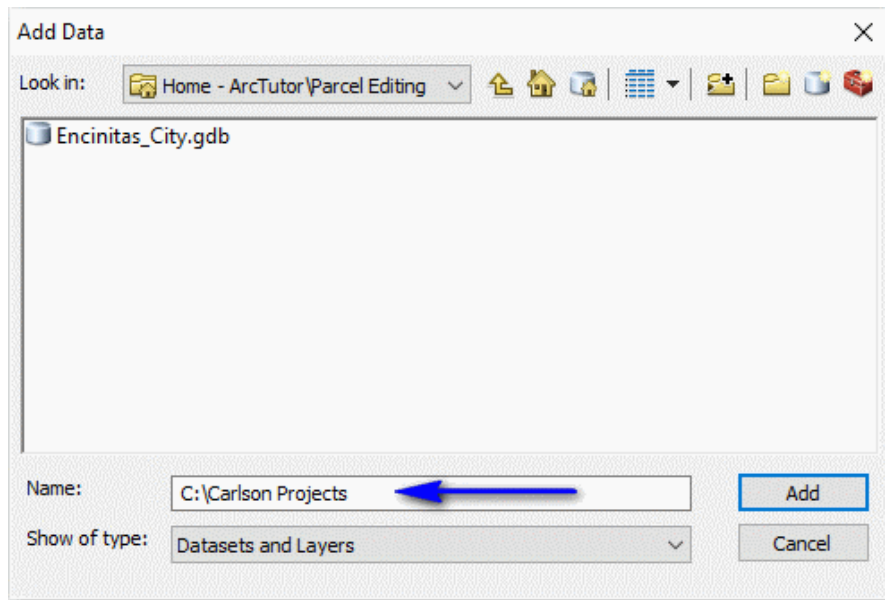

Select the *.GIS file that had been placed onto the collector (and possibly modified in the field) and click **Open** when ready. The DWG entities are packaged into an Esri MSC format. Save and exit from the DWG file.

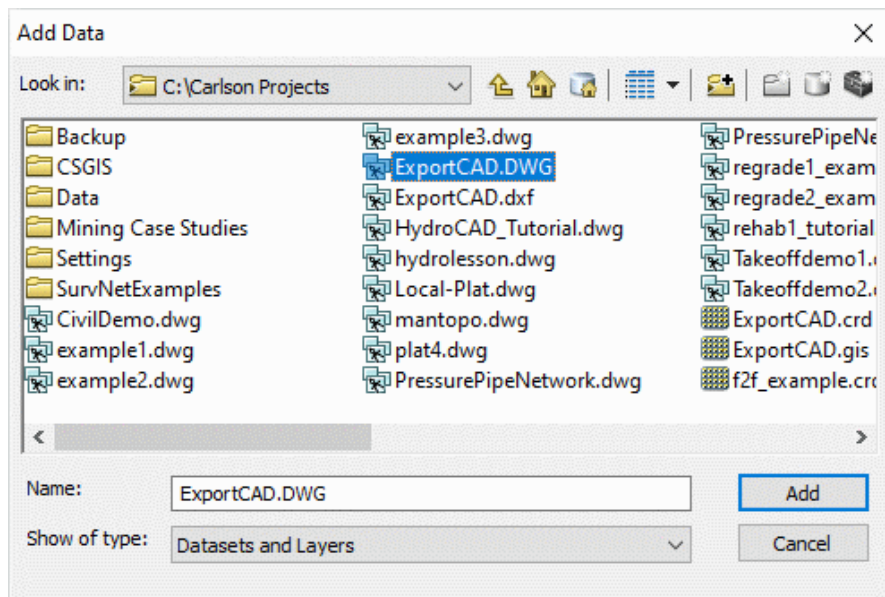

12. With the DWG saved, re-run ArcView and load the original project. Issue the File – Add Data – **Add Data** command as illustrated below:

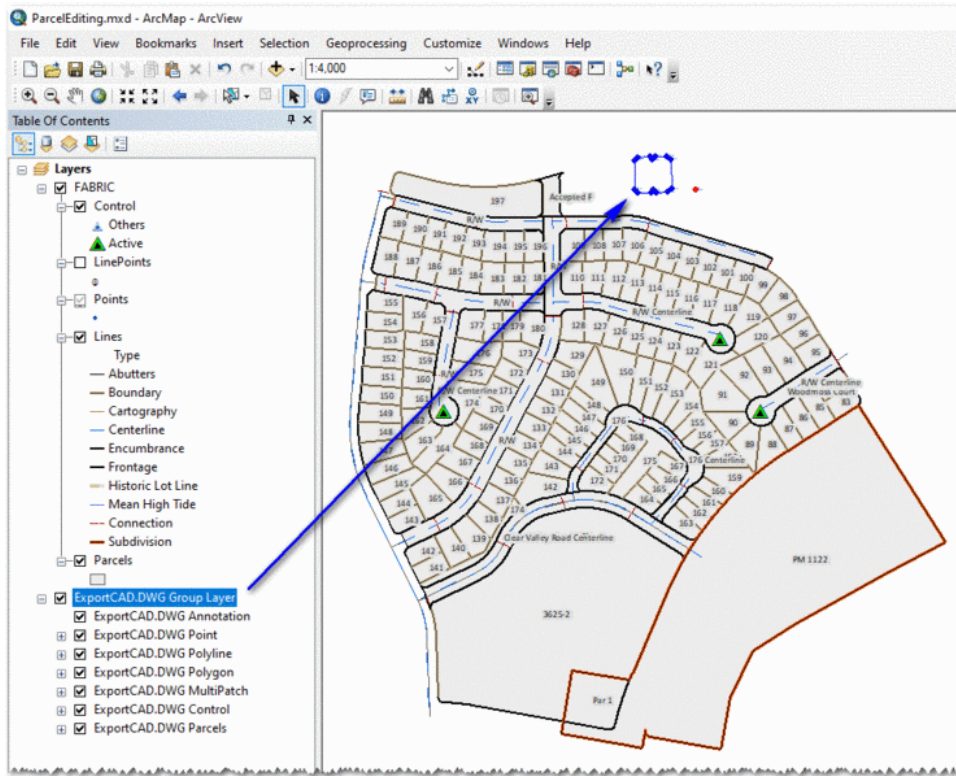

It might be generally easier to indicate the folder path where the DWG file is stored as illustrated below (click **Add** when ready):

Select the DWG file that was saved earlier and click on the **Add** button when ready:

The data is added to the ArcView project as illustrated below:

This completes the tutorial: ESRI to Office to Field and Back.

Takeoff/SiteNET CAD File From Start To Finish

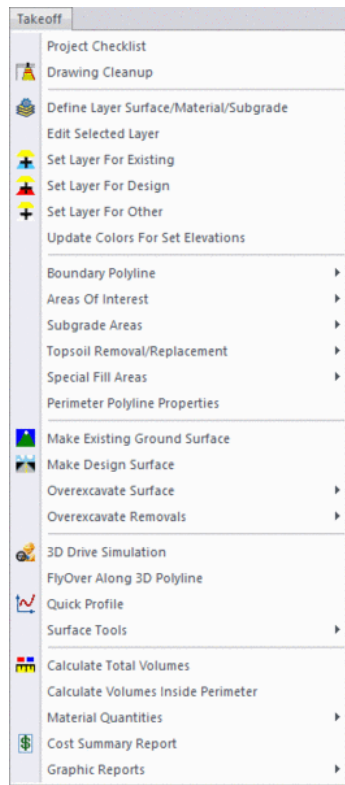

This lesson takes a drawing file from drawing cleanup to volume calculations and surface viewing.

NOTE: This tutorial is written for the Construction module. However, many of these steps can be completed using the SiteNET pull-down menu in the **Civil** module.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Takeoffdemo1.dwg** file. Use the File – **Save As** to save a copy named **Takeoffdemo1-A.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties.

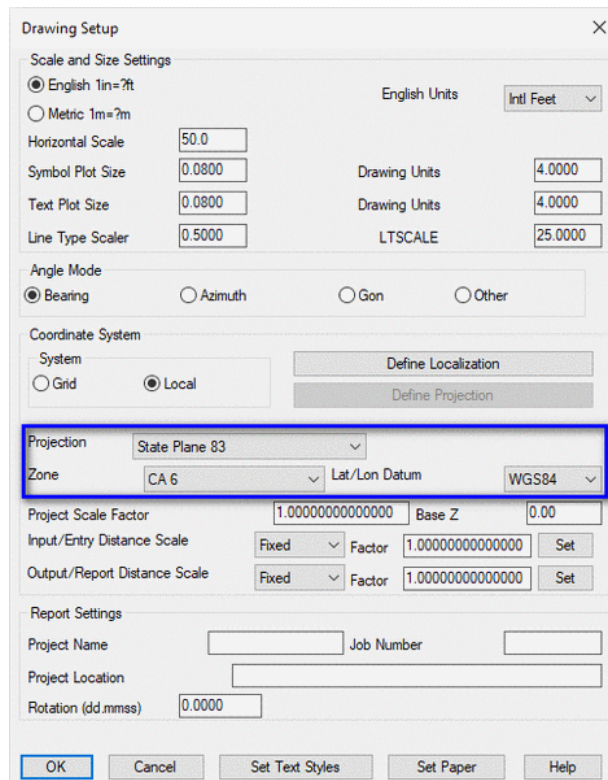

2. Activate the Construction menu via Settings – Carlson Menus – **Construction Menu**. Now we can begin to process this drawing. The main Takeoff commands are listed in processing sequence in the Takeoff (or SiteNET in the Civil module) pull-down menu:

Many of these commands are also grouped as icons in the **Takeoff General** toolbar shown here:

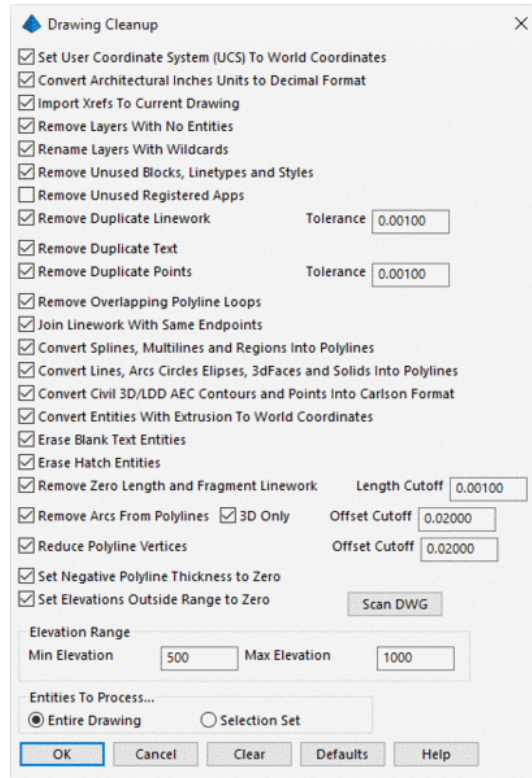

- As is often the case with construction-oriented projects, it is desirable to establish the drawing in its correct geo-location so the site can be constructed through the use of GPS-assisted machine control applications. Issue the Settings – Drawing Setup command to set the values shown below and click **OK** when ready:

- Typically, drawings have lots of drafting fixes that must be done before the surfaces can be modeled with any

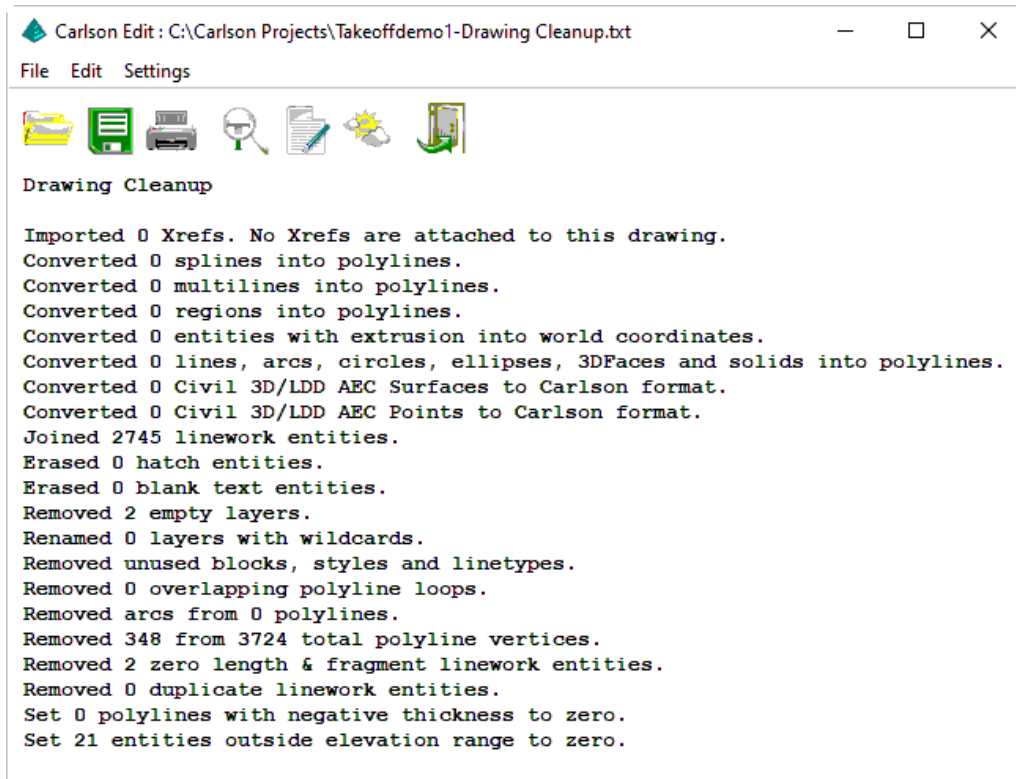

accuracy. Issue the Takeoff – Drawing Cleanup to display the dialog box shown below:

This command will apply the selected cleanup function(s) on the drawing to help automate the cleanup. Here's a brief description of the most important of these functions:

- **Remove Layers With No Entities:** Drawings often have lots of layers. This routine removes layers that have no entities in the drawing so that we don't have to deal with them.
- **Join Linework With Same Endpoints:** This routine will take linework that is broken into multiple segments and join them into a single linework entity. For example, it will join together broken segments of a contour polyline into a single polyline.
- **Reduce Polyline Vertices:** This routine removes extra vertices from polylines as long as the removing does not shift the polyline more than the specified *Offset Cutoff* distance. This will reduce the size and complexity of the drawing.
- **Set Elevation Outside Range To Zero:** In case the drawing contains entities that are outside the range of valid elevations for the site, this routine will set them to zero elevation. The program treats zero elevations as "no elevation" and modeling will filter out these zero elevation entities.

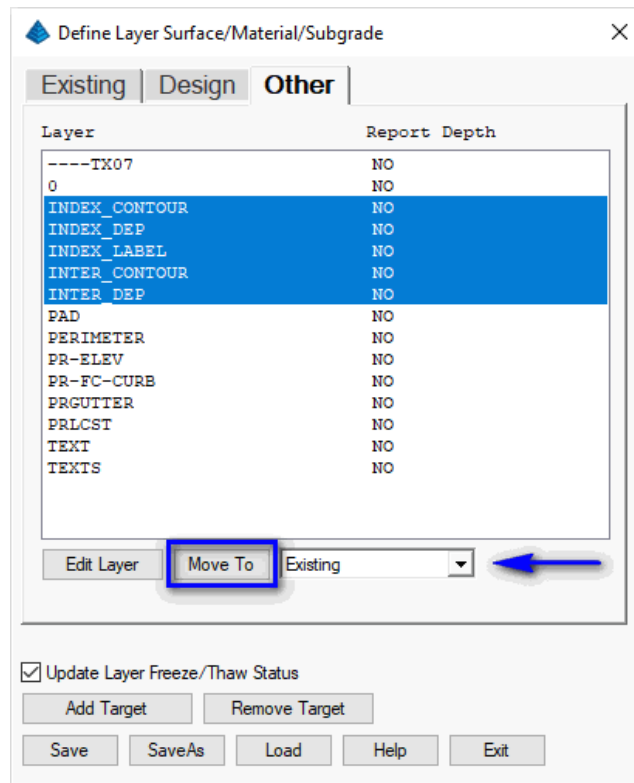

For this site, the elevations are around 800. So let's set the **Min Elevation** and **Max Elevation** fields to the values shown above. The cleanup will set any entities outside this elevation range to 0 (zero). With other Takeoff functions, we can later assign proper elevations to any of these zero elevation entities that need to be used in modeling. Set the remaining values as shown above and click **OK** when ready. When the cleanup is done, the program will show a report of the cleanup results. Click the **Exit** (doorway) button to exit the Standard Report Viewer:

5. Our next task will be to specify the layer(s) in the drawing which contain *existing* site conditions. Takeoff uses the layer name(s) to categorize data into one of three general categories for the purpose of building surface models:

- **Existing** - Used to model initial/pre-construction site conditions.
- **Design** - Used to model proposed/post-construction site conditions.
- **Other** - Used as a collection of unknown/irrelevant site conditions (text notes, hatches, *etc*).

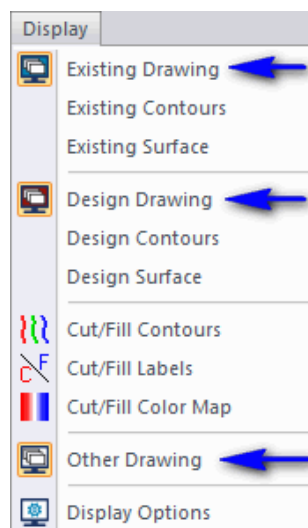

These surfaces are referred to as the "Target" surfaces. By default, everything starts in the *Other* classification. Use the Takeoff – Define Layer Surface/Material/Subgrade command to display a dialog box similar to that shown below:

To switch between lists, pick the tabs at the top of the dialog. In this drawing, all the contours are for the existing ground surface. In the layer list, all the layers that start with **INDEX** and **INTER** are for these existing ground contours. Select/highlight these layers and then click the **Move To** button with the **Existing** target as shown above (to highlight multiple layers at a time use standard Windows Ctrl+click and/or Shift+click functionality).

Next move the layer names that start with **PR** (for *proposed*) to the **Design** target by highlighting these layers and clicking **Move To** with the **Design** target selected. Also move the layer **PAD** to Design. Finish by clicking the **Save** button to save the changes and then pick **Exit**.

6. In the Display menu, you can turn on/off whether to display layer targets by using the Existing Drawing, Design Drawing and Other Drawing commands:

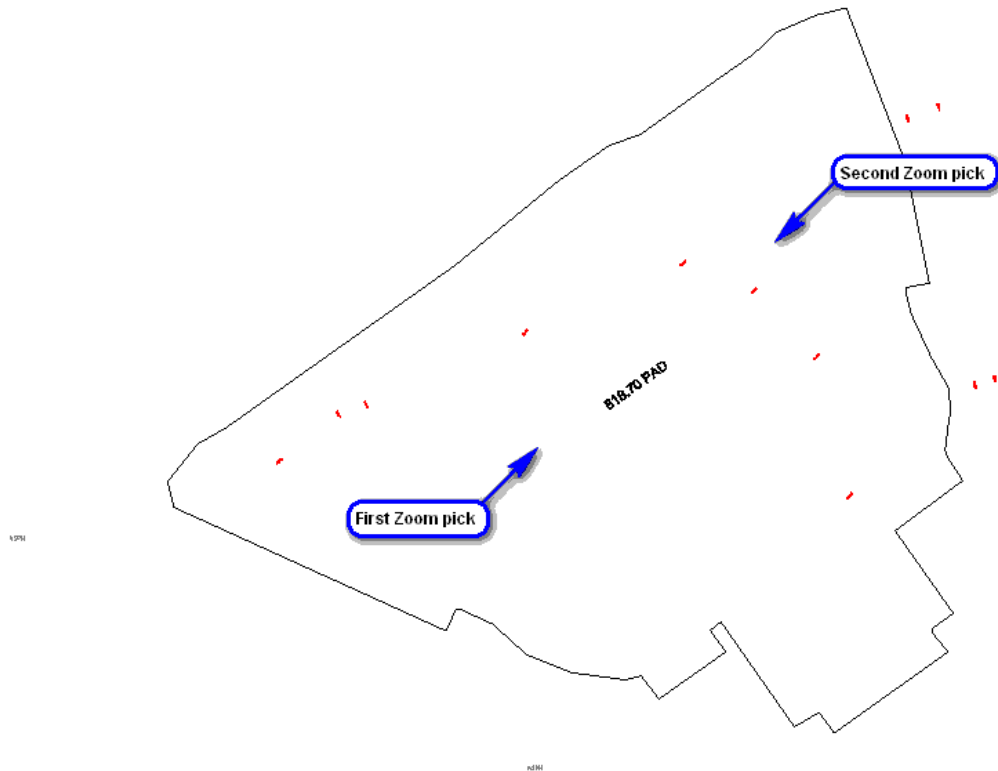

Practice turning on/off the **Existing Drawing**, **Design Drawing** and **Other Drawing**. When only *Existing Drawing* is on, you should see just the contours. When only *Design Drawing* is on, you should see just

the design polylines and leader labels. When only *Other Drawing* is on, you should see the entities that are assigned to neither Existing nor Design. Set this condition as active:

- Existing is **Off**
- Design is **Off**
- Other is **On**

to resemble the drawing as shown below:

Some of these layers we *do* want to assign to the Existing and Design targets. To better see the entities, use the View – **Window** command and pick two points that make a window around the entities as shown above. Once zoomed in, you can see a text label of **818.70 PAD** which is for the **Design** target. Other labels **817.00**, **818.00**, *etc.*, are contour labels for the Existing contours. There are a few commands in the Inquiry menu to find out the layer names for these entities and two quick ones are:

- **List**
- **Layer ID**

Let's run the Inquiry – Layer ID command and when prompted:

Pick entity to read layer: pick the **818.70 PAD** label (the entity is reported as being on the **—TX07** layer)

Pick entity to read layer: pick the **818.00** label (the entity is reported as being on the **TEXTS** layer)

Pick entity to read layer: press Enter

With this information known, we could return to the **Define Layer Surface/Material/Subgrade** but let's explore the use of organizing the data through a visual screen-pick. Issue the Takeoff – Set Layer for Design command and when prompted:

Select entities for design surface.

[FILter]/<Select entities>: pick the **818.70 PAD** label

[FILter]/<Select entities>: press Enter

The layer of the selected entity is migrated to the Design classification and its visibility set consistent

with that target. Issue the Takeoff – Set Layer for Existing command and when prompted:

Select entities for existing surface.

[FILTER]/<Select entities>: pick the **818.00** label

[FILTER]/<Select entities>: press Enter

The layer of the selected entity is migrated to the Existing classification and its visibility set consistent with that target.

NOTE: To short-cut these commands, explore the use of the **Takeoff/SiteNET Display** toolbar as shown below:

With this work complete, we can return the drawing view back by running View – **Ex-tents** command. Let's validate our layer classifications. Re-issue the Takeoff – **Define Layer Surface/Material/Subgrade** command and visit each tab to the values suggested below:

Existing Layer Targets

Design Layer Targets

Other Layer Targets

Takeoff1 Layer Targets

Check that your Layer Surfaces match the three lists shown above and then click **Save** and **Exit**.

7. Besides assigning target surfaces by layer, layers are also used to define material names and/or subgrades depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the designated surface (subgrade depths in the Existing target would represent potential material to be demolished). The polylines used for subgrade depths must be closed polylines. Takeoff supports nested subgrade polylines for exclusion areas such as parking lot islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the area is not part of the subgrade. Use the Takeoff – Display menu commands to set this condition as active:

- Existing is **Off**
- Design is **On**
- Other is **Off**

First, we need to know the layer names for our subgrades. Re-run Inquiry – **Layer ID** command and when prompted:

Pick entity to read layer: pick the large pad polyline (it reports the **PAD** layer)

Pick entity to read layer: pick the curb polyline (it reports the **PR-FC-CURB** layer)

Pick entity to read layer: press Enter

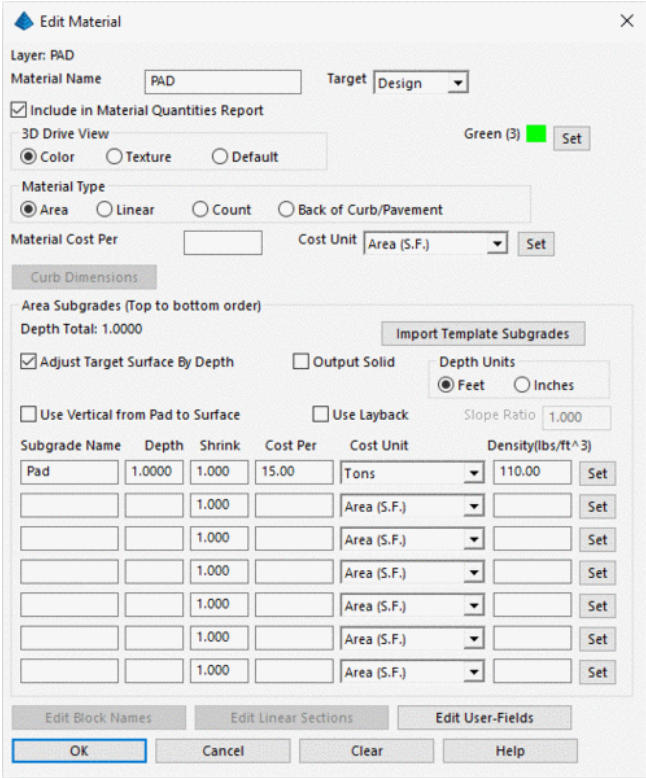

Next we need to make sure that these polylines are closed. In this example, the outside curb polyline is open at the top. To close the polylines, run Edit – Polyline Utilities – Edit Polyline – Close Polylines and when prompted:

Select Polylines to set closed.

[FILTER]/<Select entities>: pick each of the pad and curb polylines (six in all) and press Enter when done selecting

Re-issue the Takeoff – **Define Layer Target/Material/Subgrade** command and activate the **Design**

tab. Select/activate the **PAD** layer and click the **Edit Layer** button. A dialog appears for defining the *Pad* material properties. Set the values as shown below and click **OK** when ready:

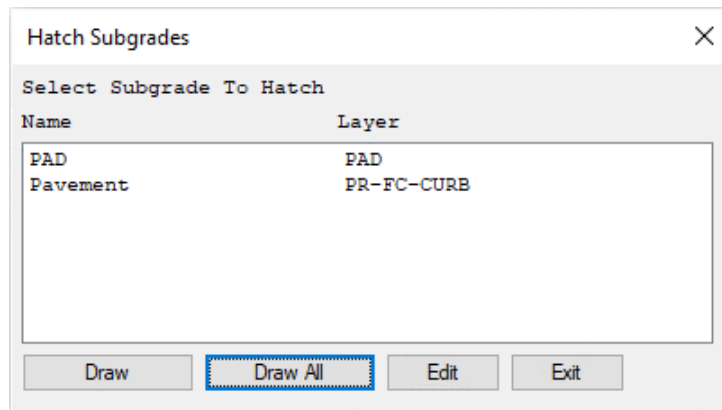

NOTE: Calculating cost is an optional feature. For this example, we cited a Cost of "\$15" per "Ton" with a density of "110."

Next pick layer **PR-FC-CURB** and choose **Edit Layer**. Set the values as shown below and click **OK** when ready:

Review the summary depths of the pay materials we just modified. Click the **Exit** button and indicate **Yes** to save changes.

- Now let's visually verify the subgrade areas. Issue the Takeoff – Subgrade Areas – Hatch Subgrade Areas to display the dialog box below:

Click the **Draw All** button. The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. Also note that the smaller pad area is not hatched because this polyline layer is different from the bigger pad polyline.

Optional: Re-run the **Hatch Subgrade Areas** command, select a desired subgrade layer and click the **Edit** and attempt to match the look of the image below through the following settings:

Subgrade	Hatch Pattern	Color
PAD	Conc	Green
Pavement	Asphalt	Red

Subgrade Hatch Settings

When finished viewing the subgrade areas, issue the Takeoff – Subgrade Areas – Erase Subgrade Hatches command.

9. Takeoff will model the existing ground and design surfaces based on points, lines and polylines with elevation. It is essential for these drawing entities to have correct elevations in order to get correct surface models. Often the provided drawings will have the drawing entities at elevation of zero with text labels indicating the true elevation. Takeoff has many tools for assigning elevations to these entities. To help visualize which entities need to be assigned elevation, Takeoff will color entities at zero elevation in grey (as established under Settings – Carlson Configure – Takeoff/SiteNET Settings). As entities get assigned elevation, they return to their original color. This elevation coloring is applied to layers that have been assigned to the Existing or Design surfaces.

Let's start by working on the Existing surface. To isolate the existing entities, use the Takeoff – Display menu commands to set this condition as active:

- Existing is **On**
- Design is **Off**
- Other is **Off**

Let's explore real-time elevations through the use of the Inquiry – Drawing Inspector command. Once activated, right+click and make sure **Display Elevation** is checked (you might also find it valuable to have the *Display Layer* and *Display Entity* options checked). Next, hover over a contour polyline and *Drawing Inspector* will report the elevation. Other info may be displayed as well depending on what is selected from the right+click options:

INTER_CONTOUR
816.000
LWPOLYLINE

In this example, the existing ground surface is defined by just contour polylines and these polylines already have elevation. So there are no changes needed for preparing the existing surface entities. If the contour polylines were at zero elevation, then you could use the Elevate – Assign Contour Elevation menu commands (such as Multiple in Series).

10. Next let's prepare the design surface. To isolate the existing entities, use the Takeoff – Display menu commands to set this condition as active:
 - Existing is **Off**

- Design is **On**
- Other is **Off**

Notice that all the design linework has a grey color because it is at zero elevation. Run the Inquiry – **List Elevation** command and when prompted:

List Elevation [Options/<Select Entity>]: pick the main pad polyline (its elevation of 0 is confirmed)

Select Entity (Enter to end): press Enter

To set the pad polyline elevation, run the Elevate – Set Polyline To Elevation command and when prompted:

Enter/<Select text or linework of elevation>: pick the **818.70 PAD** text (the non-numerical information is stripped and the numeric value is reported)

Enter elevation to add to text values <0.0>: press Enter

Select entities for elevation change.

[FILter]/<Select entities>: pick the larger pad polyline

[FILter]/<Select entities>: press Enter

Next, let's set the elevation of the smaller pad under the main pad. Use the View – **Window** command to zoom in around the smaller pad so that we can read the text label. The label of **17.56** is short for *817.56*. In this example, the *800* was dropped from many of the elevation labels to save on label clutter. Run the **Set Polyline To Elevation** again. This time when prompted:

Enter/<Select text or linework of elevation>: pick the **17.56** text (any non-numerical information is stripped and the numeric value is reported)

Enter elevation to add to text values <0.0>: type **800** and press Enter

Select entities for elevation change.

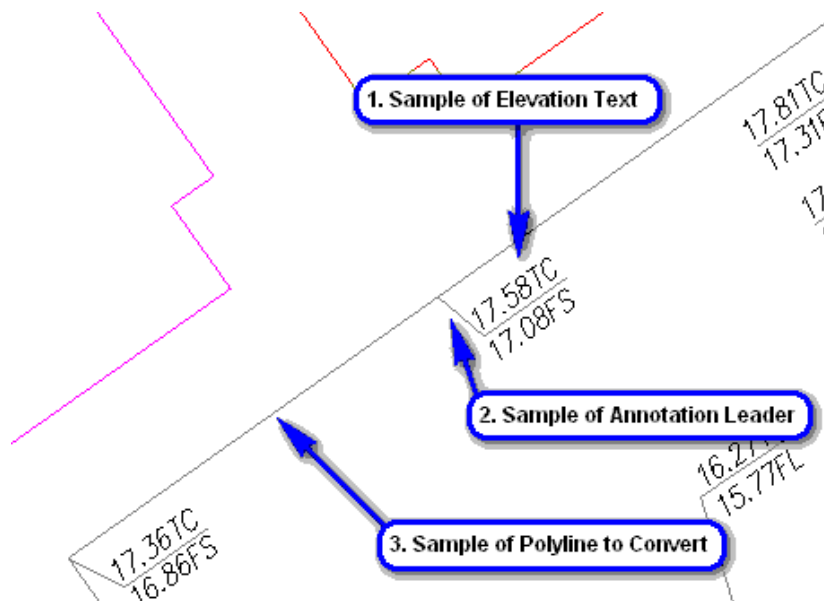

[FILter]/<Select entities>: pick the smaller pad polyline

[FILter]/<Select entities>: press Enter

Then run View – Zoom – **Previous** (keyin short-cut **ZP** to get back to the full view of the site (color changed for clarity):

Finally, we need to set the elevations for the curb polylines. First, use the View – **Window** to zoom in around some of the curb labels below the smaller pad as illustrated below:

Next, issue the Elevate – 2D to 3D Polyline – Text With Leader command. This command will assign the elevations from the labels to the polylines by following the label leader to find the position on the polyline. For polyline vertices without elevation labels, the elevations will be interpolated from the other labels. When prompted:

Options/Select sample of elevation text: pick one of the labels with a "TC" suffix as cited in **item 1** above and press Enter

Select sample of an annotation leader: pick the associated leader line as cited in **item 2** above and press Enter

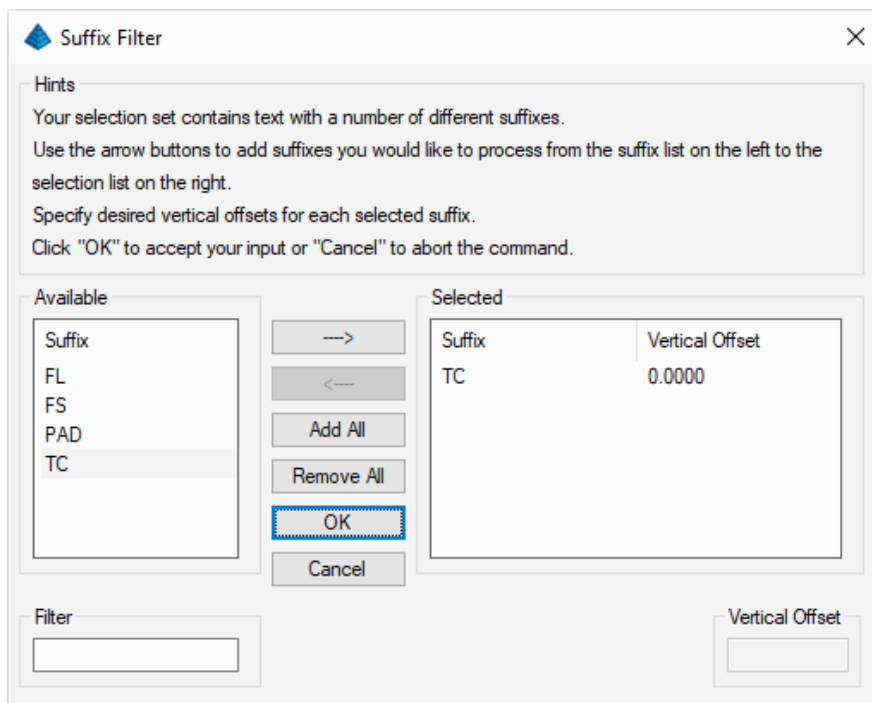

Select sample of a polyline to convert: select a sample of a polyline for conversion as cited in **item 3** above and press Enter

Select polylines to convert, leaders and elevation labels to process.

[FILter]/<Select entities>: type **all** and press Enter twice

Enter elevation to add to label values <0.00>: type **800** above and press Enter

Next, a dialog appears for selecting which label names to use:

When Takeoff detects different text labels within the elevation labels, you need to choose which ones to process. In this case, we only want the labels with **TC** (Top of Curb), so highlight **TC** and click the **—>** (Add) button and then click **OK** when ready. All the curb polylines now have elevations and should also have colors because the elevations are assigned. Finally, issue the View – **Extents** to return to the full site view.

11. The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. In this example, there is a closed polyline on the **PERIMETER** which is currently part of the *Other* target. Use the Takeoff – Display menu commands to set this condition as active:
 - Existing is **Off**
 - Design is **On**
 - Other is **On**

Issue the run Takeoff – Boundary Polyline – Set Boundary Polyline command and when prompted:

Select boundary polylines.

[FILter]/<Select entities>: pick the perimeter polyline as shown below:

This selected polyline is now set as the boundary polyline for the rest of the Takeoff routines.

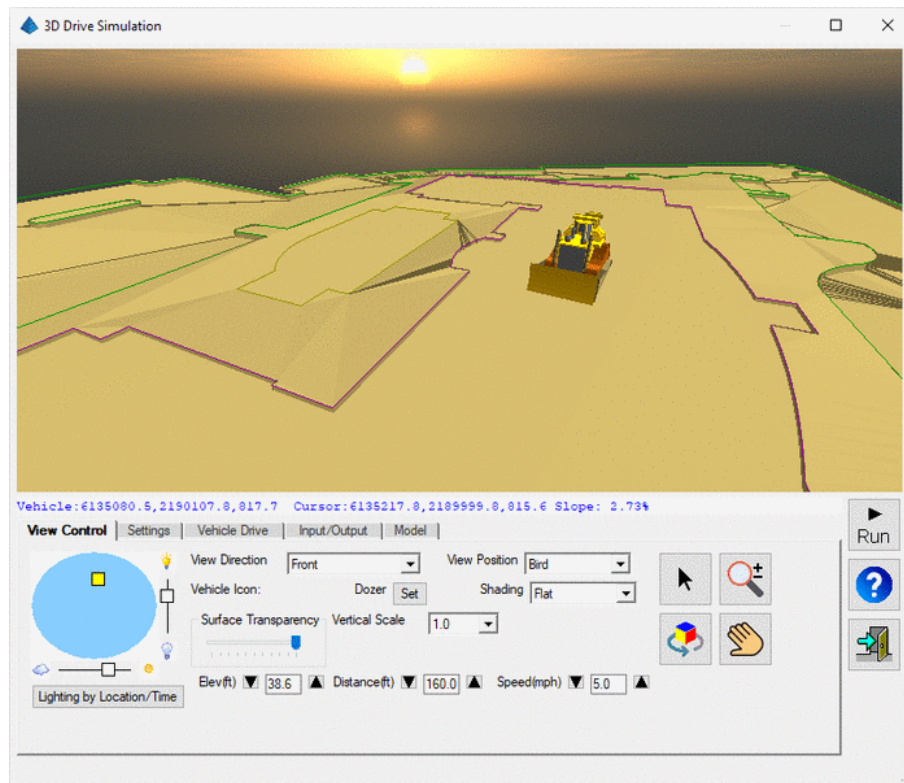

12. To calculate volumes, the program needs two surfaces:

- existing ground, and,
- design considerations

These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to make the models. The drawing entities have been cleaned up, assigned elevations and assigned target surfaces by layer. Making each model is now a one step process:

- To make the Existing Ground surface, issue the Takeoff – Make Existing Ground Surface. The program will process the entities (regardless of their screen visibility) and make the triangulation surface.
- To make the Design Ground surface, issue the Takeoff – Make Design Surface.

13. As a visual check that the Design Surface was formed correctly, let's explore the site in a 3D isometric view. Run the Takeoff – 3D Drive Simulation command to display a dialog box similar to that below:

This routine shows a 3D view of the site and allows you to "drive" around through the use of the arrow keys on most standard keyboards. This is a good way to check that the surface triangulated correctly. We want to make sure that there are no elevation spikes and that the subgrade depths are modeled. To drive the site:

- choose a *View Direction*, and,
- choose a *View Position*, and,
- choose a *Vehicle*, and,
- choose a *Speed*

Then click the **Run** button and use the arrow keys to turn. Click the **Stop** button to pause the moving. Experiment with the various **Shading** options and "tabs" of other settings to achieve an appealing visualization style. Click the **Exit** (doorway) button when complete.

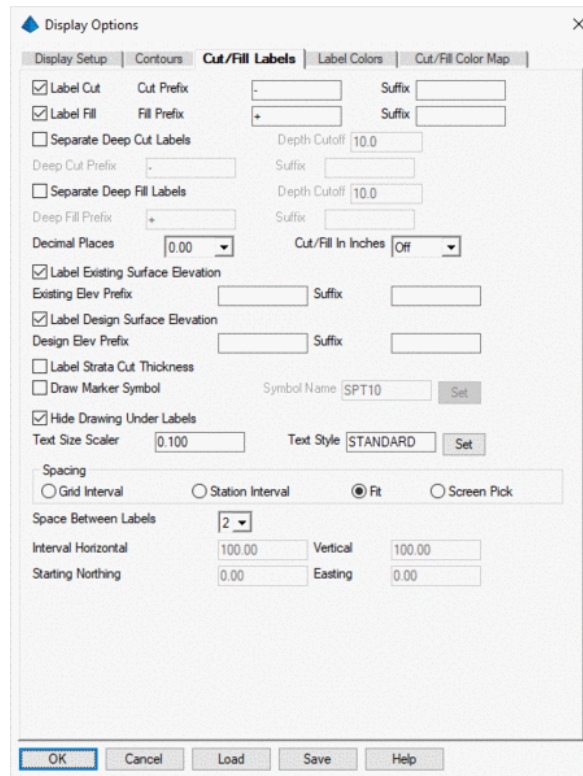

14. Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as another check that the models are correct. Issue the Display – Cut/Fill Color Map command to display an image similar to that shown below (also shown with *Cut/Fill Labels*):

Under default conditions:

- *Cut* areas are drawn in different shades of red (deeper colors represent deeper cut), and,
- *Fill* areas are drawn in blue, and,
- regions in Cut/Fill neutral areas tend to shade white

Continuing, issue the Display – Cut/Fill Labels to more closely resemble the image above. To change the size, color, spacing and other label options, run the Display – Display Options and go to **Cut/Fill Labels** tab shown below:

The resolution of the color blocks in the map can be changed through the **Spacing** group of controls. Turn off the *Cut/Fill Labels* by re-issuing the Display – **Cut/Fill Labels** command to uncheck it.

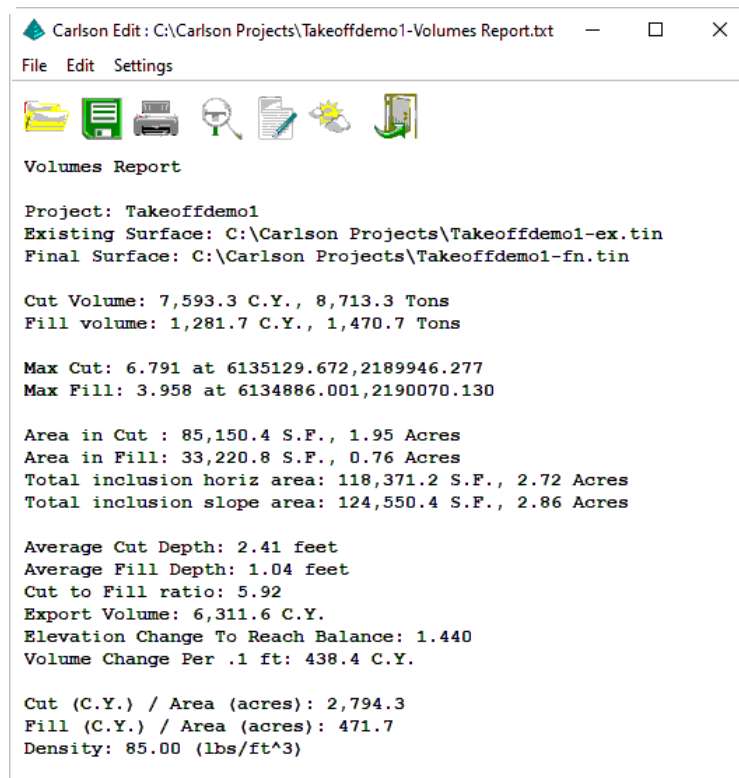

15. To calculate volumes, run the Takeoff – Calculate Total Volumes command to display a dialog box similar to that below:

The screenshot shows a dialog box titled "Volume Options" with a close button (X) in the top right corner. The dialog contains the following fields and controls:

- Cut Swell Factor: 1.000
- Fill Shrink Factor: 1.000
- Report Output: Standard Report Viewer (dropdown)
- Report Units: English (dropdown)
- Report Order: Total on top (dropdown)
- Report Tons: Density(lbs/ft^3) 85.000
- Report Cut Depth Zones: Interval 10.000
- Report Fill Depth Zones: Interval 10.000
- Report Cut/Fill in Color: Page Settings (button)
- Balance Cut/Fill
- Balance Tolerance (CY): 10.00
- Import Volume (CY): 0.00
- Export Volume (CY): 0.00
- Report Title: Volumes Report
- Project: Takeoffdemo1
- Comments: (empty text box)

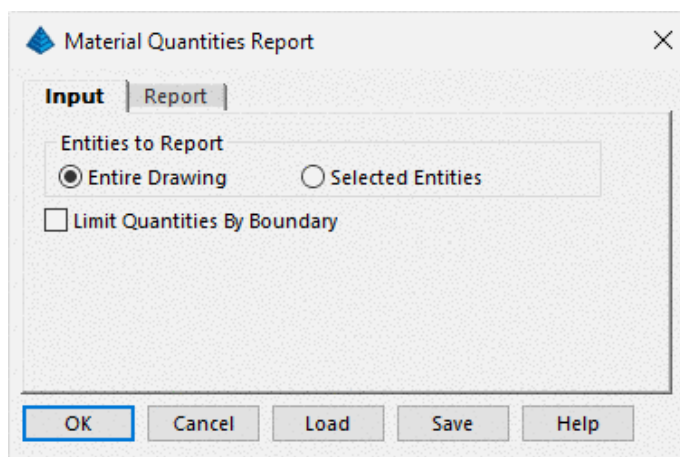

At the bottom of the dialog are three buttons: OK, Cancel, and Help.

The settings the *Cut Swell* and *Fill Shrink* factors get multiplied into the cut/fill volumes. Set these factors as desired and click **OK** when ready. The results are displayed similar to that shown below:

Click the **Exit** (doorway) icon when ready. Run the command again and change the **Report Output** mode to see the volumes in different formats like PDF or Excel.

16. To report the material (paving) quantities, issue the Takeoff – Material Quantities – Standard Report routine to display the dialog box below:

Specify the options as shown above (feel free to explore the options in the *Report* tab) and click **OK** when ready. The report includes (among other this) the:

- *Count*, and,
- *Length*, and,
- *Area*, and,
- *Volume*

for each type of material that was assigned for reporting in the previously discussed Takeoff – **Define Layer Target/Material/Subgrade** command and generates a report similar to that below:

Carlson Edit : C:\Carlson Projects\Takeoffdemo1-Material Quantities.txt

File Edit Settings

Material Quantities

Breakout Quantities

Material	Count	Length (Ft)	Area (S.F.)	Volume (C.Y.)	Shrink	Depth	Cost
PAD	1	927.6	22,331.6			1.00ft	
Pad				827.1	1.000	1.00ft	\$18,423.60
Pavement	4	3,284.1	63,106.3			1.50ft	
Pavement			63,106.3	3,505.9	1.000	1.50ft	\$674,448.96
				45.6		0.375sf	
Total							\$692,872.56

Sub-Total Quantities

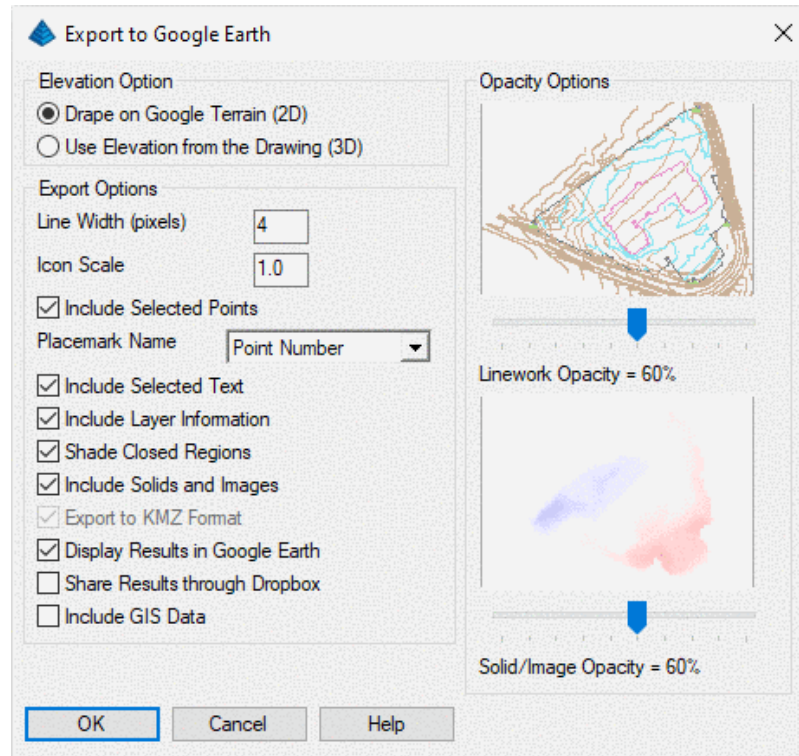

Material	Count	Length (Ft)	Area (S.F.)	Volume (C.Y.)	Tons	Cost
Pad	1	927.6	22,331.6	827.1	1,228.2	\$18,423.60
Pavement	4	3,284.1	63,106.3	3,505.9	4,496.3	\$674,448.96
Total	9	7,495.8	85,438.0	4,378.6	10,220.9	\$692,872.56

Material Parameters

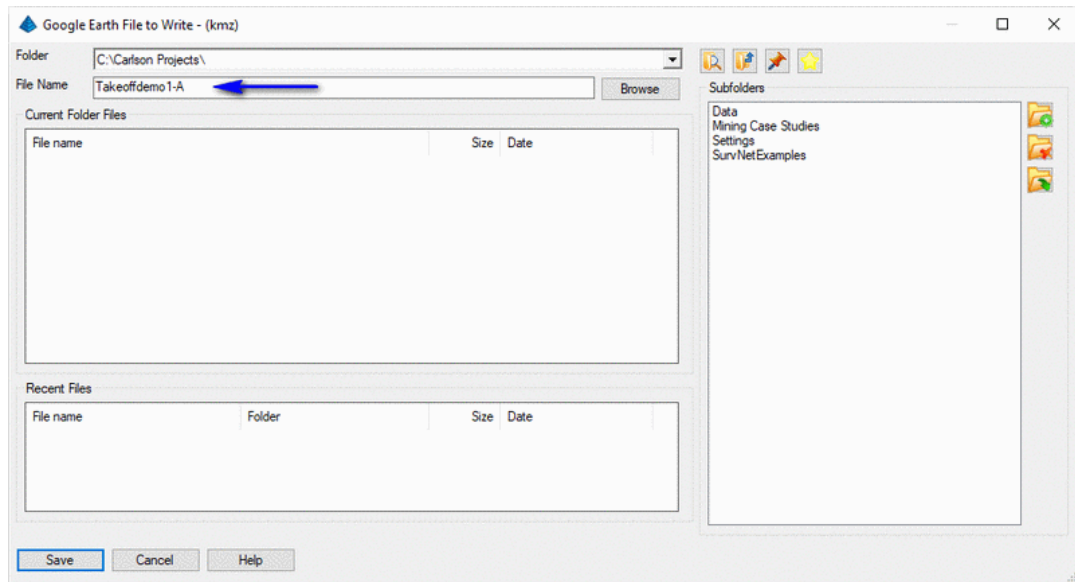

Material	Unit Cost	Shrink	Density (lbs/ft^3)
		1.000	0.00
Pad	\$15.00/Ton	1.000	110.00
Pavement	\$150.00/Ton	1.000	95.00

Click the **Exit** (doorway) icon when ready. The Takeoff – Material Quantities – **Custom Report** command can be used to report these values with control of the report format and the option to export to Excel.

17. *Optional:* For computers that have Google Earth™ Pro on desktop installed, let's see how the site looks when overlaid on this application (or any other application which can display Keyhole Markup Language (KML) files). Issue the File – Export – Google Earth File command to display the dialog box below:

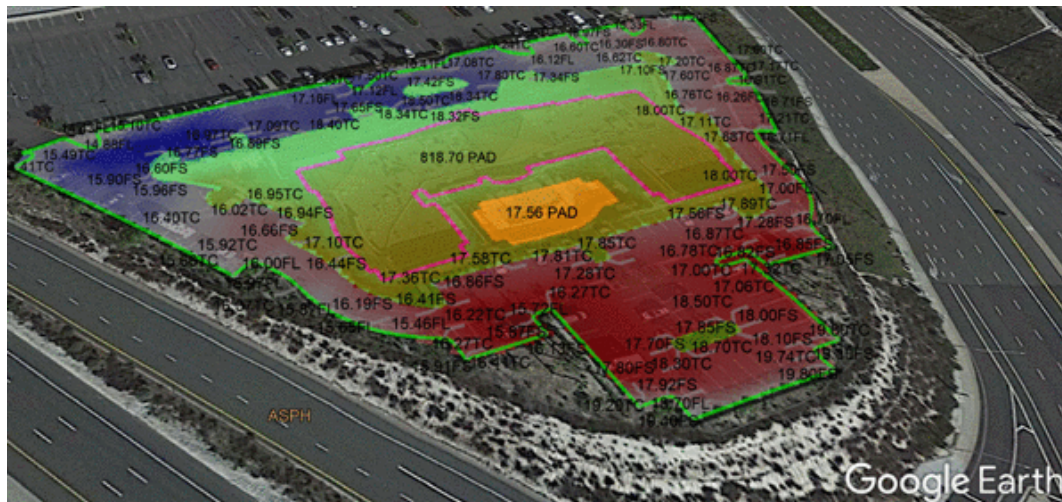

Review and set the values as suggested above and click **OK** when ready to display a dialog box similar to that shown below:

Provide the file name specified above and click the **Save** button when ready. When prompted:

Select points, polylines, text, solids, images, lines and arcs to write.
[FILter]/<Select entities>: type **all** and press Enter twice

The results are overlaid on Google Earth as illustrated below:

18. Lastly, let's remove the shaded hatch of the Cut/Fill color map through the use of the Display – **Cut/Fill Color Map** command.

This completes the tutorial: Takeoff/SiteNET CAD File From Start To Finish.

GeoTech Drillholes and Strata

This lesson creates and processes drillhole data in the GeoTech module.

1. This drillhole lesson builds on the results of the Takeoff/SiteNET Basics tutorial. Before continuing with this tutorial, complete that tutorial up through the Make Existing Ground Surface/Make Design Surface section of that tutorial. When the **Takeoff/SiteNET Basics** tutorial is completed, we're now ready to add drillholes for the drawing as shown below:

2. Activate the GeoTech menu via Settings – Carlson Menus – **GeoTech Menu**. Our initial task will be to establish a desired drillhole symbol and the default strata names. Issue the Drillhole – Define Drillhole and Strata Settings (*aka Define Drillhole*) command to display the dialog box similar to that shown below:

Drillhole and Strata Settings

Drillhole Settings

Select Symbol

Symbol Name: SPT12

Symbol Size: 10.0

Strata Definitions

Strata name	Model	Method	Density	Swell
DIRT	Elevation	InvDist-2	80.000	1.100
ROCK	Elevation	InvDist-2	165.000	1.150

Buttons: Add, Edit, Remove, Move Up, Move Down

Place Drillhole Prompts

Depth Thickness Dialog

Default Last Thickness Thickness: 1.00

Use Drillhole Surface Elevation for Existing Surface

Buttons: OK, Cancel, Load, SaveAs, Help

For this tutorial, we are interested in rock quantities and we need to define two strata:
 (a) **DIRT** (material above the rock), and,

(b) **ROCK**

Click the **Add** button to create a material strata as described below and click **OK** when ready:

Next, pick the **Add** button again. This time, fill out the dialog with a strata name of "ROCK" and use the information below to add the second strata material into the project and click **OK** when complete:

Values	Strata 1	Strata 2
Name	DIRT	ROCK
Density	80	165
Swell Factor	1.10	1.15
Model Values	By Elevation	By Elevation
Modeling Method	Inverse Distance - Power 2	Inverse Distance - Power 2

Strata Definitions

NOTE: There are three options of modeling methods:

- **Inverse Distance** will not carry trends and the calculated strata model will never be higher or lower than the original drillhole data and uses a weighted average of the drillhole data. In general, closer drillholes are weighted more than drillhole farther away:
 - **Inverse Distance - Power 2** will weigh drillholes more that are further away.
 - **Inverse Distance - Power 3** will weigh drillholes less that are further away.
- **Linear Least Squares** extrapolates trends and allows for a strata model to create new highs and lows that don't appear in the original drillhole data.

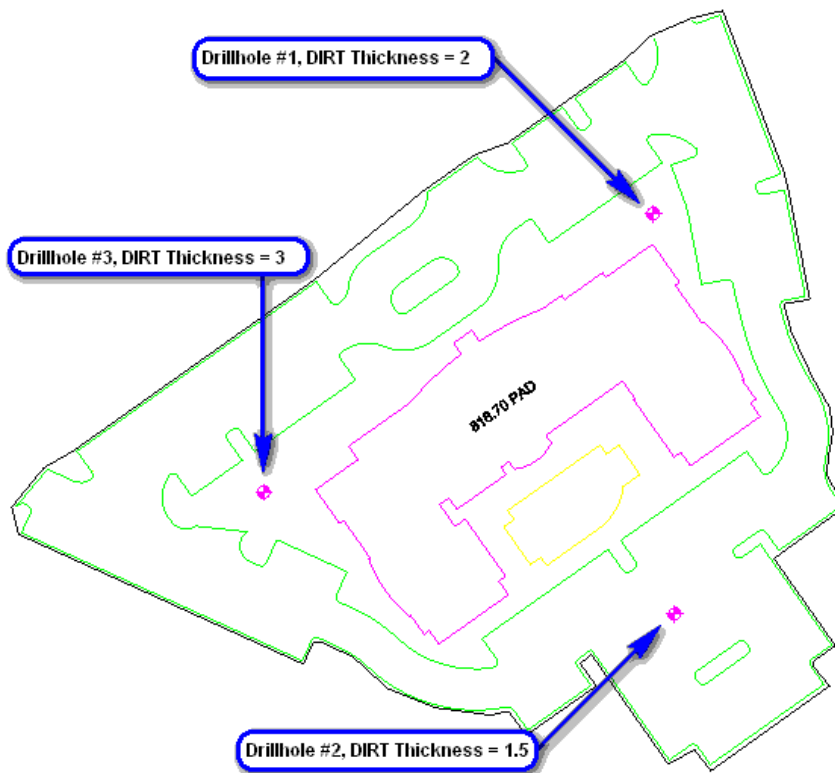

The *Strata Materials* in the main dialog need to be in top to bottom order. To change the order, highlight a strata name and use the **Move Up** or **Move Down** buttons. In this case, we want *DIRT* then *ROCK*. Click **OK** from the main dialog.

3. There are two different methods for entering drillhole data:

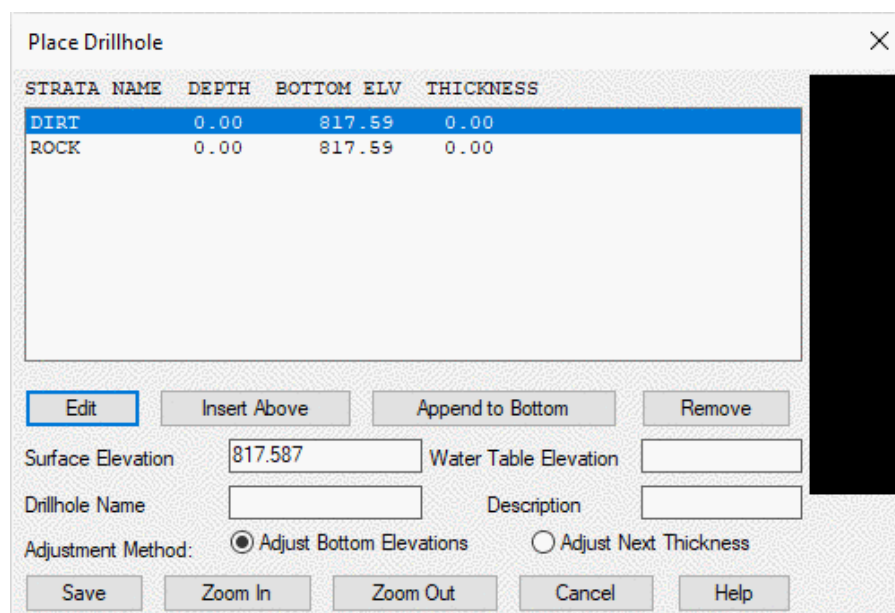

- **Drillhole Import** which reads the drillhole data from a text file. This command supports customizing the sequence of drillhole data fields to match the format of the text file. This process is discussed in the GeoTech Reports tutorial.
- **Place Drillhole** creates the drillholes at picked positions in the drawing and enters the data in a dialog.

For this tutorial, issue the Drillhole – Place Drillhole command. When prompted:

Station/<Pick Drillhole Location>: pick a location northeast of the building pad as shown below:

A dialog box similar to that shown below appears. The *Surface Elevation* is automatically filled in using the Existing Ground Surface. The *Drillhole Name*, *Water Table Elevation* and *Description* are optional. The list of strata defaults to the strata defined in **Drillhole/Strata Settings**. Each strata defaults to a thickness of zero.

Select/Highlight the **DIRT** entry and click the **Edit** button to display a secondary dialog box similar to that shown below:

Edit Strata ×
 Strata # 1
 Name:
 Thickness:
 Bottom Elev:
 Depth:
 Return Prev Strata Next Strata

For this location, indicate the DIRT strata has a *Thickness* of **2** (press the *Tab* key to see the updated values) and then click **Next Strata**.

For this example, we only know the depth to the top of rock depth and not the total rock thickness. We will treat all cut below the top of rock as ROCK strata. So we'll set the rock thickness deep enough to be lower than the Maximum Cut on site. In this case, indicate the ROCK strata has a *Thickness* of **15** (press the *Tab* key to see the updated values and then click **Return** to display a dialog box similar to that shown below:

Place Drillhole ×

STRATA NAME	DEPTH	BOTTOM ELV	THICKNESS
DIRT	2.00	815.59	2.00
ROCK	17.00	800.59	15.00

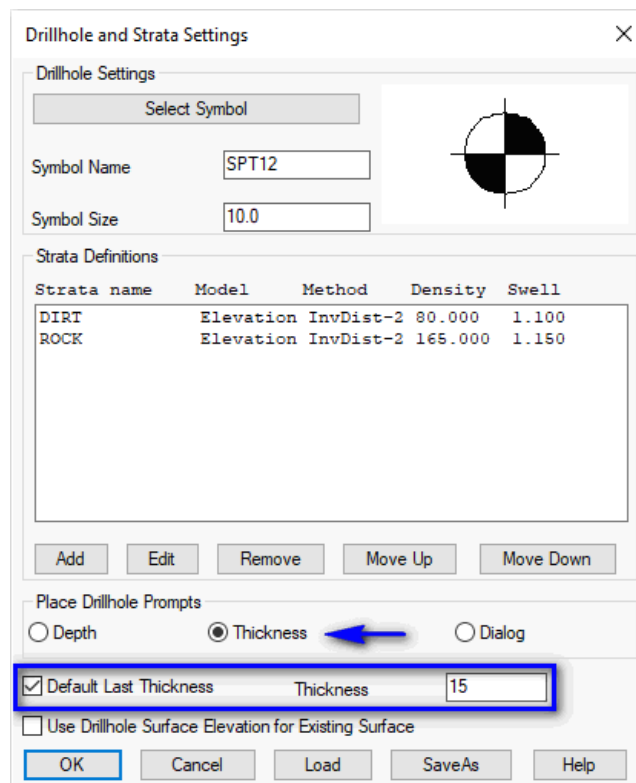

Edit Insert Above Append to Bottom Remove
 Surface Elevation: Water Table Elevation:
 Drillhole Name: Description:
 Adjustment Method: Adjust Bottom Elevations Adjust Next Thickness
 Save Zoom In Zoom Out Cancel Help

Complete the remaining values as desired and click **Save**. When prompted:

Pick Drillhole Location (Enter to end): press Enter

NOTE: If you had known the coordinates for the drillhole, you can type in the *Easting,Northing* format instead of picking on the screen.

Now let's locate two more drillholes using a different method. Return to the **Define Drillhole and Strata Settings** command and set the changes as illustrated below and click **OK** when ready:

Re-issue the **Place Drillhole** again and when prompted:

Station/<Pick Drillhole Location>: pick a position in the lower parking lot

Strata DIRT Thickness: type **1.5** and press Enter (complete any remaining items for DH2 and click **Save**)

Pick Drillhole Location (Enter to end): pick a position left of the main building

Strata DIRT Thickness: type **3** and press Enter (complete any remaining items for DH3 and click **Save**)

Pick Drillhole Location (Enter to end): press Enter

Now that the drillholes are in the drawing, we can explore the creation of sub-surface strata models.

4. To make the strata triangulation surfaces, run the StrataCalc – Make Strata Surfaces command. There are no prompts for this routine. The strata surfaces are modeled from the drillholes and saved with the project. The file names for the strata surfaces use the drawing name plus **-ch#** where the # is the strata sequence number. For this example, the file names will be **Takeoffdemo1-ch1** for bottom of DIRT and **Takeoffdemo1-ch2** for bottom of ROCK. Now that the strata surfaces are created, there are several Takeoff/Construction routines that will use these surfaces including (but not necessarily limited to):

- Calculate Total Volumes
- Calculate Volumes Inside Perimeter
- Define Topsoil Depths
- Cut/Fill Labels
- Surface Inspector
- Quick Profile
- Trench Network Quantities

5. Let's see where our ROCK cut locations are. Issue the StrataCalc – Draw Strata Cut Color Map command. When prompted:

Select Strata to Process: indicate the **ROCK** surface as illustrated below:

Select point for color legend (Enter for None): pick a location of your choosing (top center of the legend)

Legend size <10.0>: press Enter

Label all zones or summary [All/<Summary>]? press Enter

This command compares the design surface with the strata surface to make a cut color map of the cut depths for the strata. This command is one way to verify that the strata surfaces are modeled correctly. The result should be similar to that shown below:

Optional: Remove the Strata Cut Color Map through the StrataCalc – Erase Strata Cut Color Map command.

6. Let's explore the impact of the ROCK cut in terms of its contribution to the project volumes. Activate the Construction menu via Settings – Carlson Menus – **Construction Menu**. Next, issue the Takeoff – Calculate Total Volumes command to display a dialog box similar to that below:

Volume Options

Cut Swell Factor: 1.000

Fill Shrink Factor: 1.000

Report Output: Standard Report Viewer

Report Units: English

Report Order: Total on top

Report Tons Density(lbs/ft^3): 85.000

Report Cut Depth Zones Interval: 10.000

Report Fill Depth Zones Interval: 10.000

Report Cut/Fill in Color Page Settings

Report Strata Depth Zone Volumes: By Zone Area

Strata: ROCK

Depth Interval: 2.000

Balance Cut/Fill

Balance Tolerance [CY]: 10.00

Import Volume [CY]: 0.00

Export Volume [CY]: 0.00

Report Title: Volumes Report

Project: Takeoffdemo1

Comments:

OK Cancel Help

When strata surfaces are defined, the volume routine will separate the cut volume into the different strata. **Depth Zones** (2 ft zones in this case) can also be defined in this command. Set the values as shown above and click **OK** when ready. The resulting dirt and rock quantities are summarized in a report similar to that shown below:

```

```

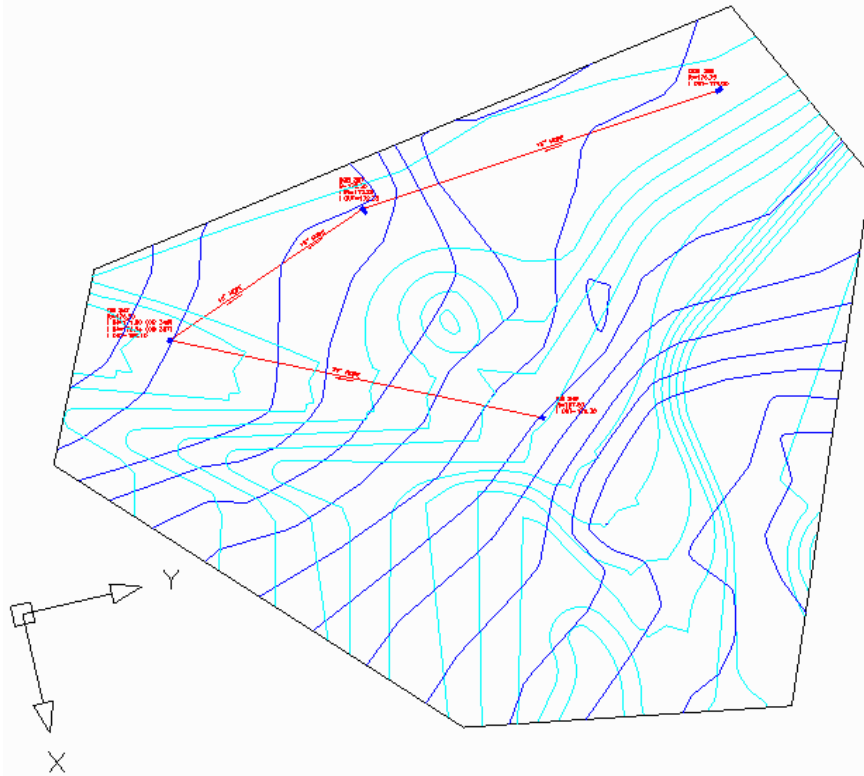

Review and click the **Exit** (Doorway) button when complete.

Takeoff Trench Network Quantities

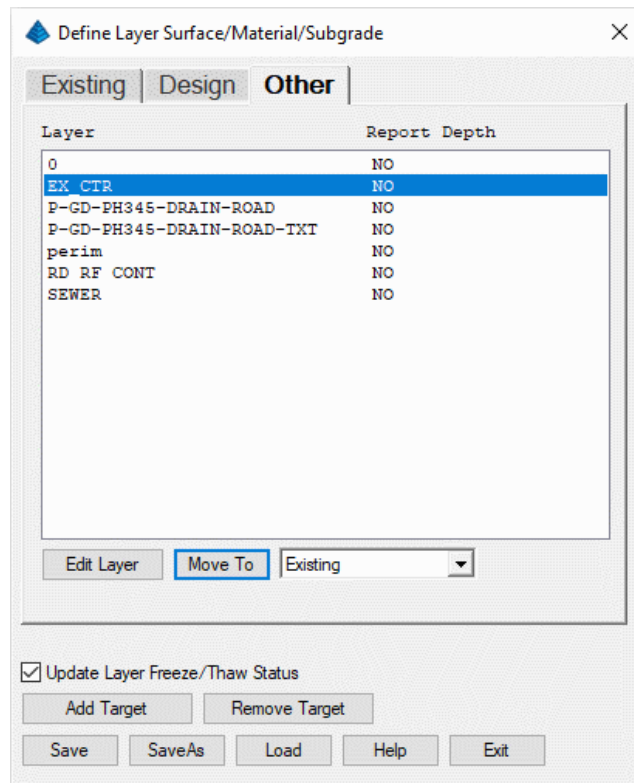

This lesson takes a drawing file through the steps of trench network quantities in the Trench module after some initial preparation through the use of the Construction module.

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Takeoffdemo2.dwg** file. Use the File – **Save As** to save a copy named **Takeoffdemo2-A.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties. The following drawing is displayed:

2. Activate the Construction menu via Settings – Carlson Menus – **Construction Menu** (or the Civil module). In order to calculate trench quantities and profiles in this drawing, we need surfaces for the Existing Ground and Design Surface. We'll follow the general process as introduced in the Takeoff/SiteNET CAD File From Start To Finish tutorial. Issue the Takeoff – Define Layer Surface/Material/Subgrade command to display a dialog box similar to that shown below:

Use the table below along with the **Move To** button to assign the layers cited below to their desired target:

Existing	Design	Other
EX_CTR	RD RF CONT	0
		P-GD-PH345-DRAIN-ROAD
		perim
		SEWER

Takeoff2.dwg Layer Targets

Click the **Save** and then the **Exit** buttons when ready. This assigned layer **EX_CTR** to the Existing Ground Surface and **RD RF CONT** to the Design Surface.

- Issue the run Takeoff – Boundary Polyline – Set Boundary Polyline command and when prompted:

Select boundary polylines.

[FILter]/<Select entities>: pick the perimeter polyline

This selected polyline is now set as the boundary polyline for the rest of this tutorial.

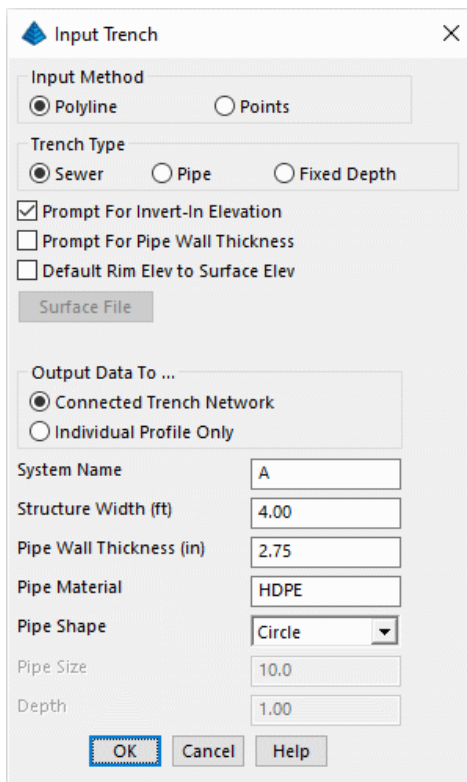

- Our next tasks will be to create the two surfaces:
 - To make the Existing Ground surface, issue the Takeoff – Make Existing Ground Surface.
 - To make the Design Ground surface, issue the Takeoff – Make Design Surface.
- Now that we have Existing and Design surfaces, we are ready to activate the Trench module via Settings – Carlson Menu – **Trench Menu**. The trench network data consists of linked structures where each structure has a:
 - name*
 - location (x,y)*
 - rim elevation*
 - invert-in*
 - invert-out*

Each "link" (pipe) between structures has a *pipe size*. There are two ways of entering the trench data (and we'll explore both methods):

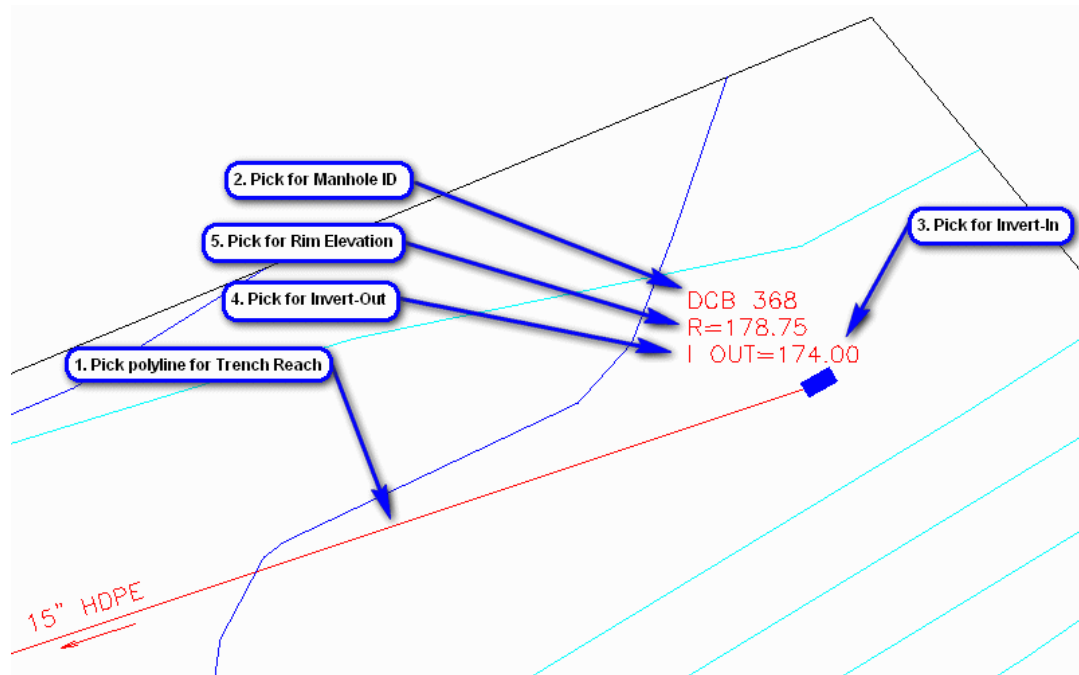

- (a) **Input Trench From Polyline** is used when the drawing contains polylines for the trench lines and labels with the trench data.
 - (b) **Create Trench Network Structure** lets you pick the structure locations and enter the data in a dialog.
6. In our first example, there is trench data already drawn in the drawing. Use the View – **Window** command to establish the view as shown below:

Issue the Trench – Input Trench Line command to display the dialog box below:

With the data available to us, set the values as shown in the dialog box and click **OK** when ready. For each point in the trench polyline, the program zooms the drawing to that point. The trench data can be picked from labels in the drawing:

When prompted:

Pick a polyline that represents a trench reach: pick the pipe polyline
Starting Station of trench reach <0.0>: press Enter
Select/<Enter Manhole ID>: type s and press Enter
Enter/<Select text of Manhole ID>: pick the **DCB 368** label
Undo/Select/Interpolate/<Enter Invert-in Elevation <0.0000> >: type s and press Enter
Undo/Enter/Interpolate/<Select text of Invert-in elevation>: pick the **I Out=174.00** label (since this is the upstream starting manhole, there really isn't a separate invert-in so we are using the invert-out)
Undo/Select/<Enter Invert-out Elevation <0.0000> >: type s and press Enter
Undo/Enter/<Select text of Invert-out elevation>: pick the **I Out=174.00** label
Undo/None/Select/<Enter manhole rim elevation <0.0000> >: type s and press Enter
Undo/None/Enter/<Select text of manhole rim elevation>: pick the **R=178.75** label
Enter/<Select text of Manhole ID> [DCB 369]: pick the **DCB 367** label
Undo/Enter/Interpolate/<Select text of Invert-in elevation>: pick the **I In=172.85** label
Undo/Enter/<Select text of Invert-out elevation>: pick the **I Out=172.35** label
Undo/None/Enter/<Select text of manhole rim elevation>: pick the **R=178.50** label
Undo/Select/Group/<Enter Pipe Size in <0.0000> >: type s and press Enter
Undo/Enter/Group/<Select text of pipe size>: pick the **15" HDPE** label
Enter/<Select text of Manhole ID> [DCB 368]: pick the **CB 347** label
Undo/Enter/Interpolate/<Select text of Invert-in elevation>: pick the **I In=170.54 (CB 367)** label
Undo/Enter/<Select text of Invert-out elevation>: pick the **I Out=166.10** label
Undo/None/Enter/<Select text of manhole rim elevation>: pick the **R=176.50** label
Undo/Enter/Group/<Select text of pipe size>: pick the **15" HDPE** label
Another Trench Line [<Yes>/No]? type n and press Enter

That completes this trench run and Takeoff/Trench draws its own trench polyline and labels.

NOTE: If the drawing doesn't have labels for the data, then you can enter the values.

7. The drawing contains another trench polyline and we could use **Input Trench Line** again. However, for

practice, let's use another method for data entry. Issue the View – **Extents** command followed by View – **Window** command to zoom to the drawing location (CB 349) as illustrated below:

Next, run the Trench – Create Trench Network Structure command. When prompted:

Locate by pick point, point number or station-offset [<Pick>/Number/CL**]?** press Enter for the **Pick** option

Pick structure location: pick the pipe polyline near the **CB 349** end-point

A dialog box similar to that shown below appears:

Trench Structure Data ✕

Structure Data

N: 207062.8 E: 409437.6 Z: 187.8

Structure Name: Symbol Name:

System Name:

No Structure (Junction Only) Structure Type:

Structure Template:

Rim Elevation (ft): Structure Width (ft):

Invert Elev OUT (ft): Depth (ft):

CB 347	A

Invert Elev IN (ft): Slope Percent: Pipe Material:

Use Pipe Group

Pipe Interior Size (in): Pipe Width (in): Pipe Shape:

Pipe Wall Thickness (in): Trench Type:

Set the values as shown and click **OK** when ready. Prompting resumes:

Pick structure location (Enter to end): press Enter

Since the downstream location for this reach has already been created from the **Input Trench Line**

exercise, we don't need to create it again. Use **Zoom** and/or **Pan** functionality to center the display in the *CB 347* area. Initiate the Trench – Edit Trench Network Structure command. When prompted:

Select sewer structure to edit: pick either the symbol for **CB 347** or its recently created label

A dialog box similar to that shown below appears:

Trench Structure Data

Structure Data

N: 206876.4 E: 409351.8 Z: 176.5 Set Location

Structure Name: CB 347 Symbol Name: SPT5

System Name: A Set Symbol

OK Cancel Next Previous Set Min Cover Help

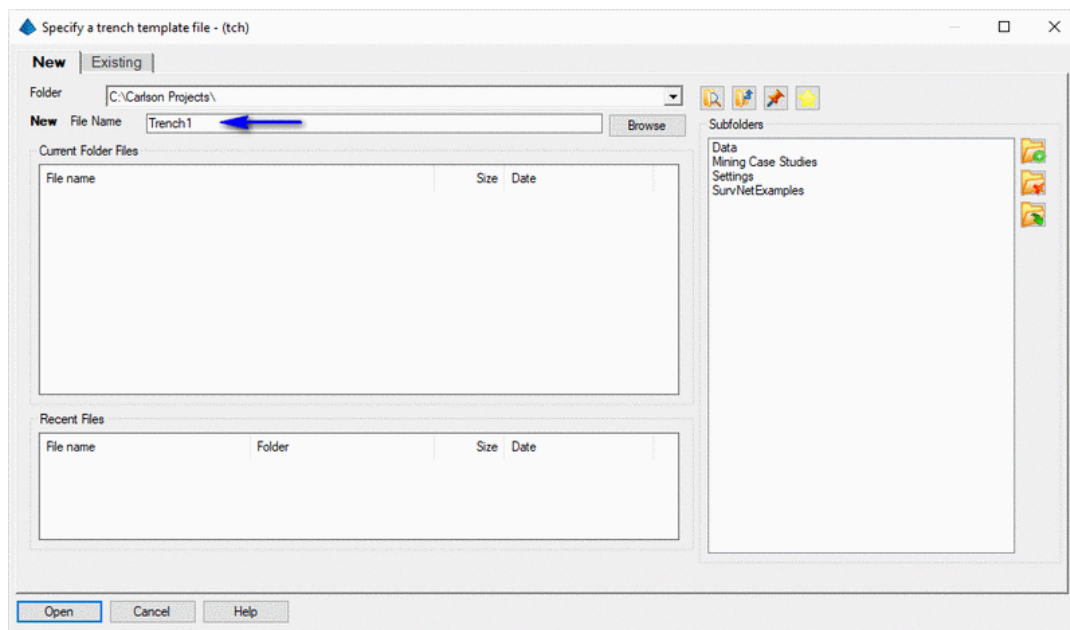

Since this is the downstream terminus for the network, highlight/select the **CB 349** structure and click the **Add** button. Fill the values as shown above. When complete and as needed, highlight/select the **DCB 367** structure and click the **Add** button. Fill the values as shown below:

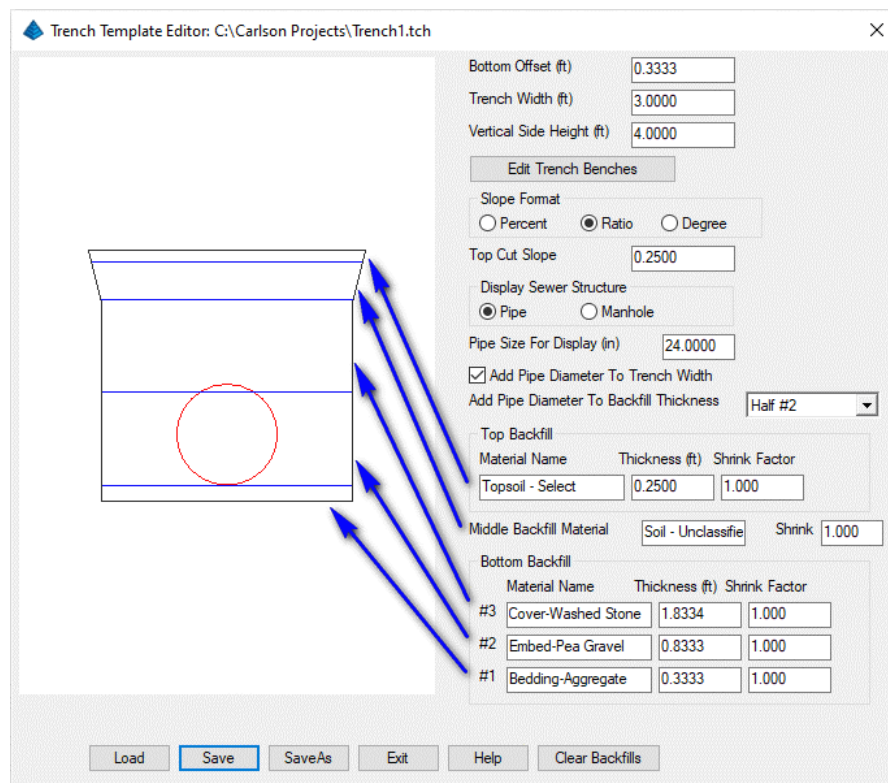

When complete, click the **OK** button. This creates a link from **CB 347** to its upstream location(s).

NOTE: It is also possible to directly edit the structure data by using double-click functionality on the *Trench*-placed structure or its label.

8. With the network structures defined, let's create the trench geometry that will ultimately yield the trench quantities. Run the Trench – Trench Template Editor command. Provide the name as shown below and click **Open** when ready:

The primary dialog box appears, similar to that shown below:

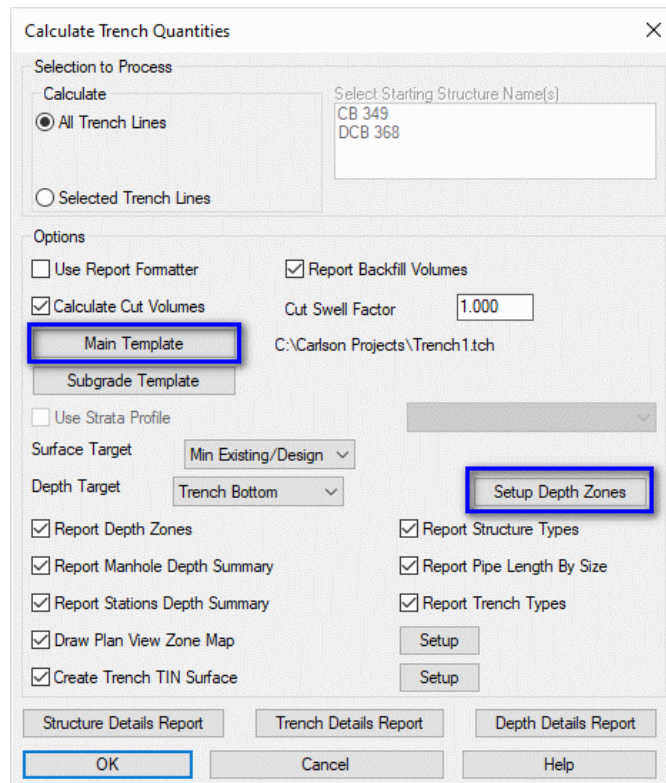

Supply the values as illustrated below (or design your own!). In the above example, we are:

- (a) assuming the in-situ material is of suitable composition (e.g. not "fatty clays", peat moss, *etc*),
- (b) using 4" of crushed aggregate, granite, *etc*,
- (c) placing the pipe directly on top of the bedding material,
- (d) using 10" of pea gravel, for the embedment material (this thickness will vary by $\approx \frac{1}{2}$ of the pipe diameter),
- (e) using 22" of washed stone, for the cover material,
- (f) using a variable thickness of unclassified, excavated material to fill in the remainder of the trench (except the final 3"), and,
- (g) using 3" of select topsoil to complete the backfill.

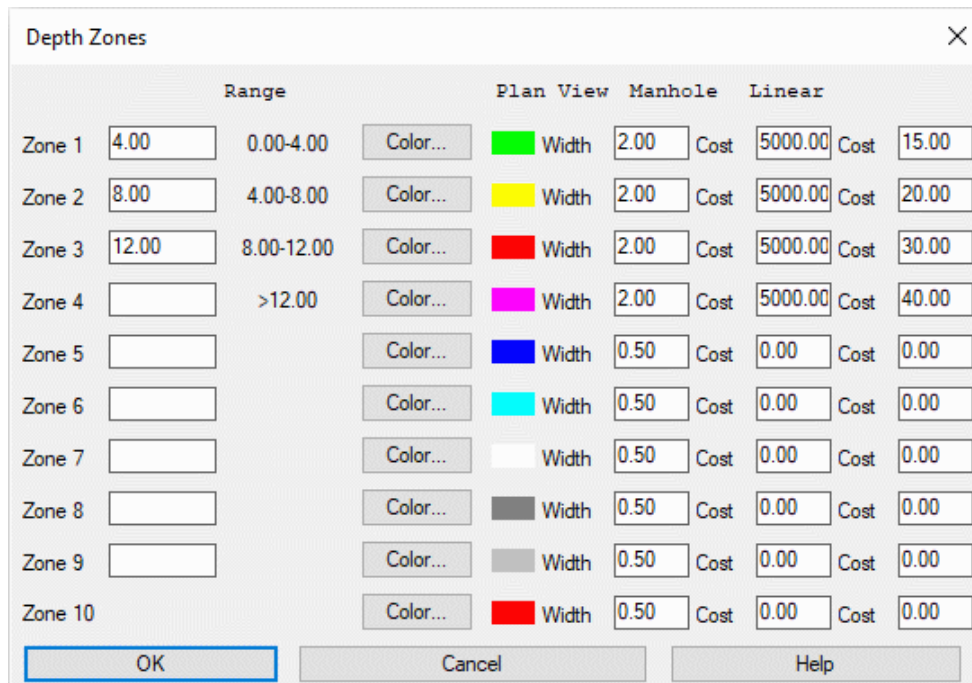

Click **Save** and **Exit**.

9. To calculate and report the trench quantities, run the Trench – Trench Network Quantities command. A dialog similar to that shown below appears:

Set the values shown above making particular note of:

- Specifying the **Main Template** trench configuration we just created, and,
- Setting the **Surface Target** to **Min Existing/Design** (permitting quick excavation of the site to the lower of *Existing* vs. *Design* elevation before trenching commences), and,
- Setting the **Setup Depth Zones** to the values as shown in the dialog box below (click **OK** when complete)

Finally, click **OK** in the main dialog and the report similar to that shown below is displayed:

Carlson Edit: C:\Carlson Projects\Takeoffdemo2-Trench Quantities Report.txt

Trench Quantities Report

Starting Structure	Length	Avg Depth
DCB 368	327.1	7.1
CB 349	205.2	7.5
Total	532.4	7.2

Trench Dimensions
 Bottom Offset: 0.33 ft

Blank	201.4	37.8
TRENCH	330.8	62.2

Structure Type	Count
Blank	4

Manhole	Depth
DCB 367	6.48
DCB 368	5.08
CB 347	10.73
CB 349	9.83
Total	32.13

Review the report and click the **Exit** (doorway) button when ready. When prompted:

Draw zone map color legend on the screen [Yes/<No>]? type y and press Enter

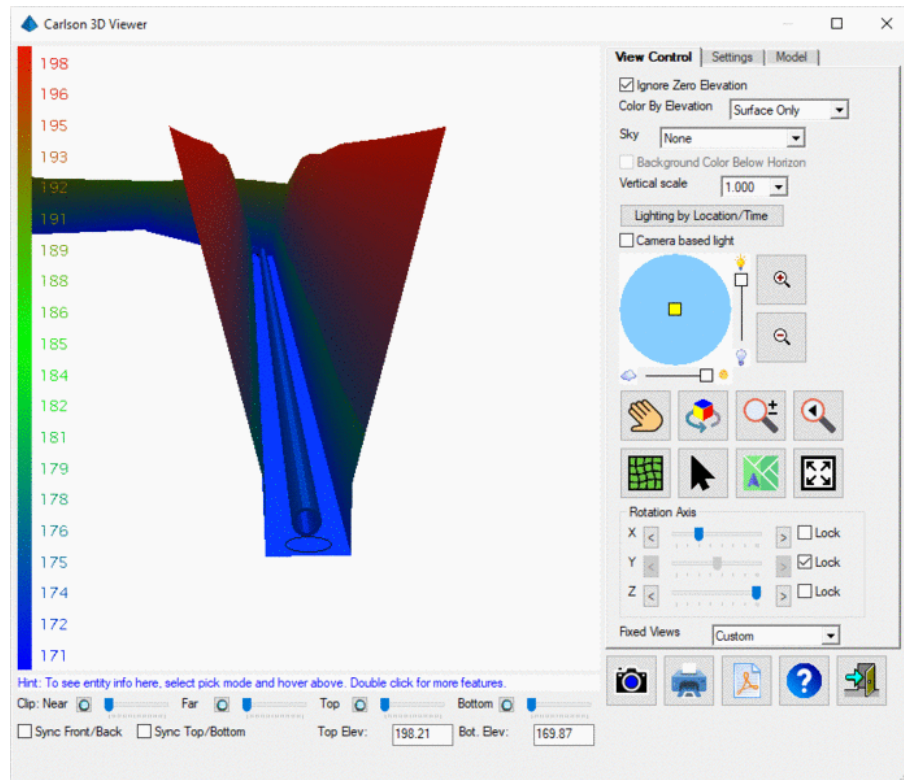

Pick a point for color legend: pick a location toward the upper left of the project site

Legend size <4.00>: press Enter

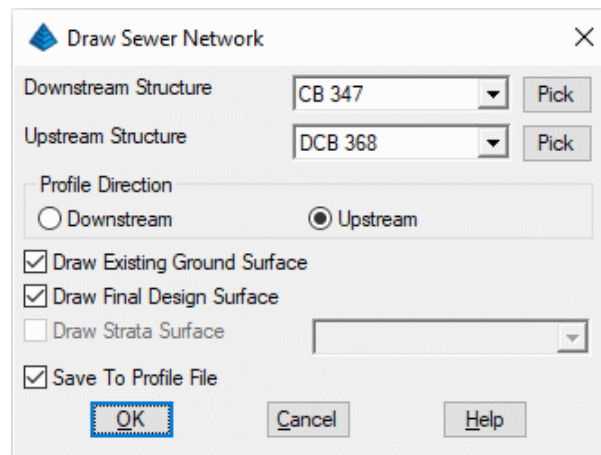

The depth zones in the plan view with Zone Map Color Legend are shown similar to that below (certain layers have been frozen for clarity):

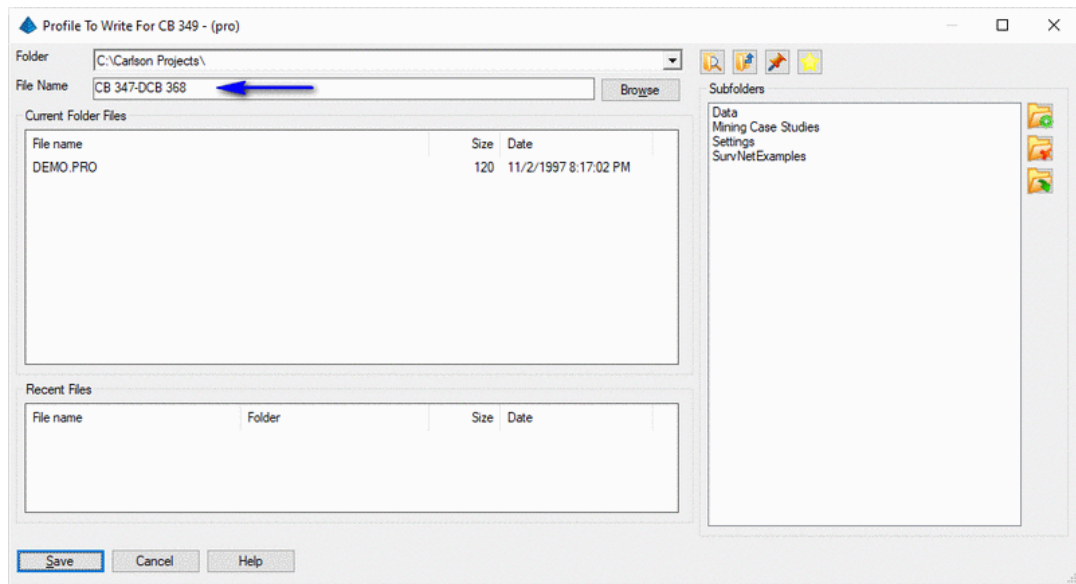

Finally, use the Display – 3D Viewer Window and window around the 3D faces to view the trench in 3D as illustrated below:

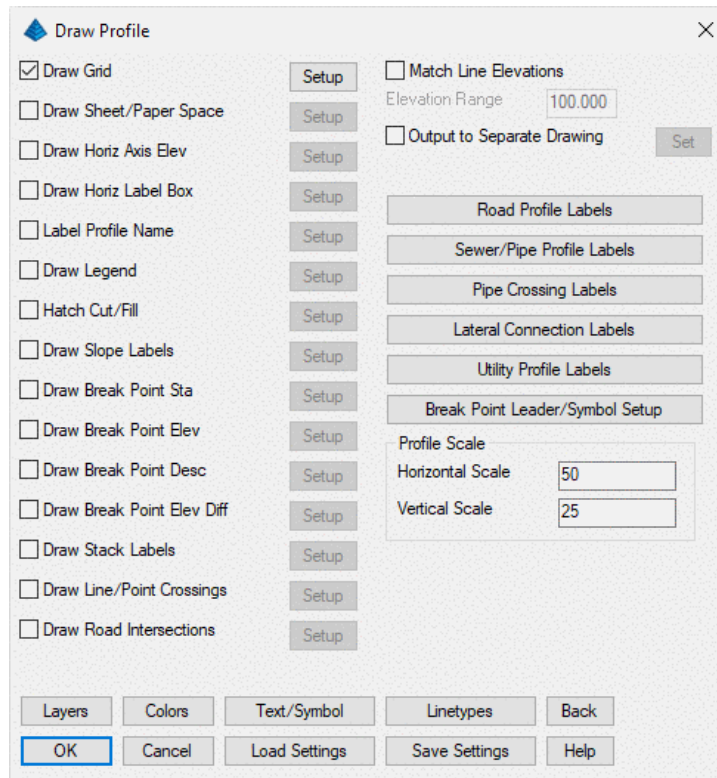

10. To draw a profile of the trench line, run the Trench – Draw Trench Network (Profile) command. Set the values as shown below and click **OK** when ready:

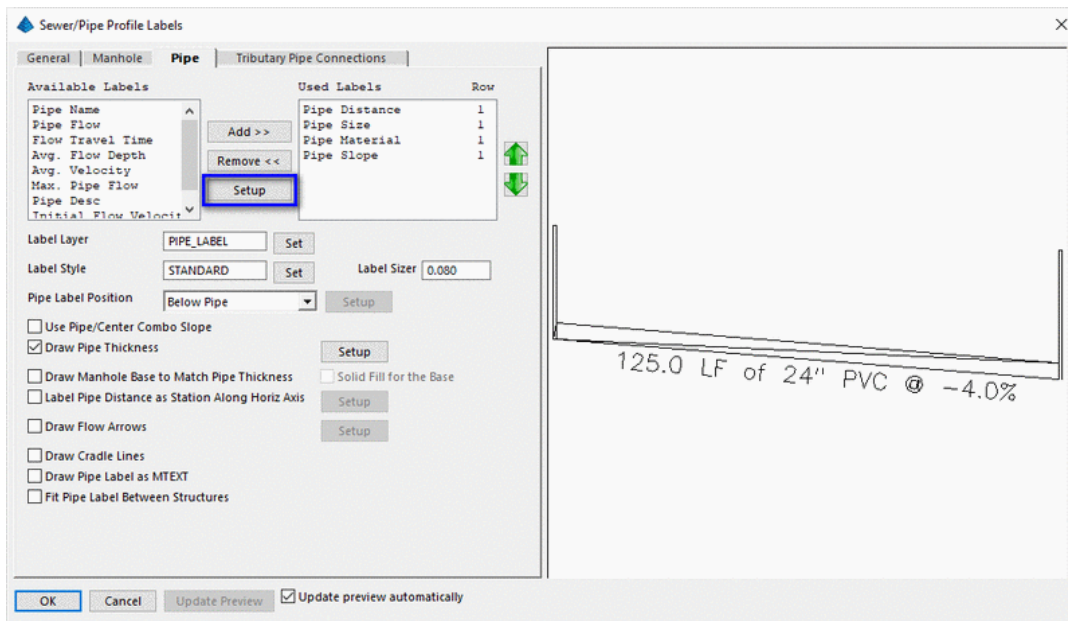

When prompted:

Supply the profile name as cited above and click **Save** when ready. Next, the Draw Profile dialog appears as illustrated below:

We'd like to fine-tune the content of the forthcoming annotation. Click the Sewer/Pipe Profile Labels button and navigate to the **Pipe** tab as illustrated below:

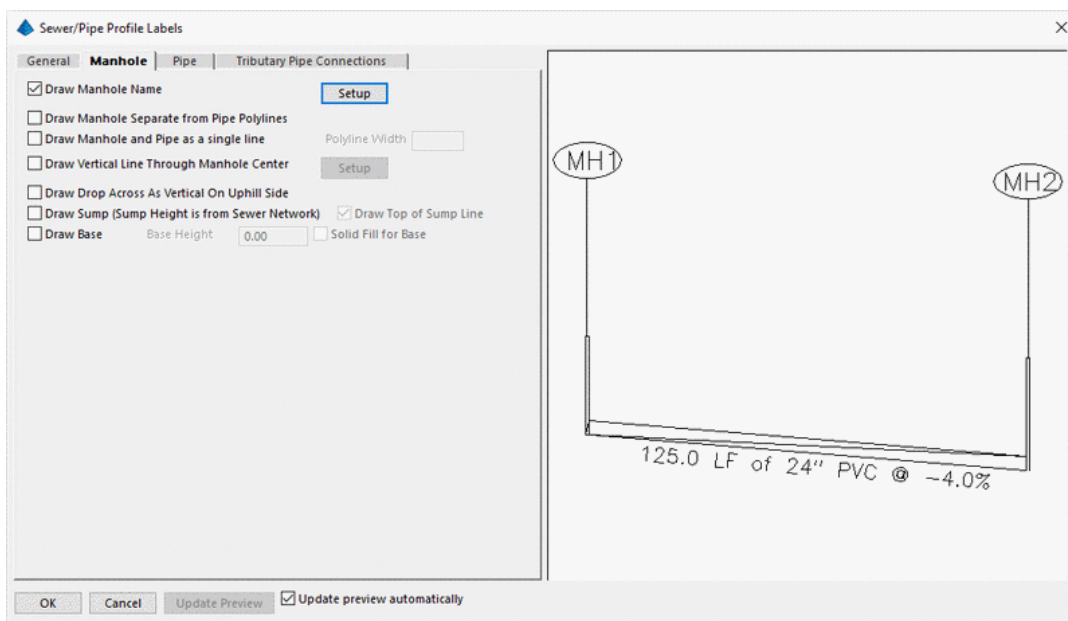

Use the **Add >>** button to add the following annotation items with the specified settings (use the **Setup** button to adjust for particular preferences):

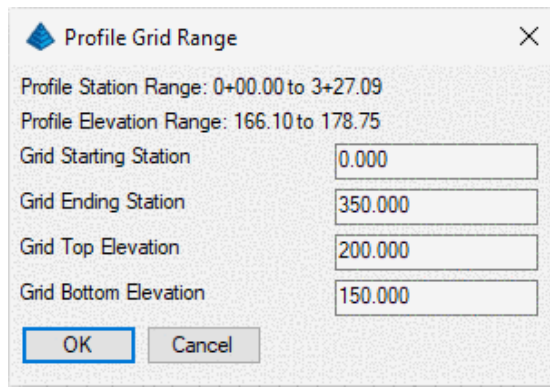

Item	Prefix	Suffix	Other
Pipe Distance		LF	
Pipe Size	of	"	Decimals: 0
Pipe Material			
Pipe Slope	@	%	Slope Format: %

Sewer/Pipe Profile Label Settings

Navigate to the **Manhole** tab and modify as desired to obtain the illustration below:

Click **OK** to dismiss the **Sewer/Pipe Profile Labels** dialog box. Set the **Horizontal Scale** and **Vertical Scale** as shown earlier and click **OK** when ready. When prompted:

Accept the default values and click **OK** when ready. When prompted:

Pick Starting Point for Grid <0.00,0.00>: pick a desired location for the profile as illustrated below

NOTE: Some layers frozen for clarity.

This completes the tutorial: Trench Network Quantities.

Digitizing

This lesson transfers a paper plan-set into a DWG drawing using Carlson CADnet and then uses Carlson Construction to calculate volumes from the digitized linework.

1. **Setup:** To digitize from a paper plan in CADnet, you need to install the Wintab digitizer driver. See Digitizer Setup in the manual if you have not installed or have problems with the Wintab driver. If Wintab is installed, then make sure your drawing board is on and take the paper plan provided with the manual and place it on your drawing board.
2. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.

- If you get the Startup Wizard dialog box, click **New**.
- If you are taken directly into CAD, click the File – **New** command.

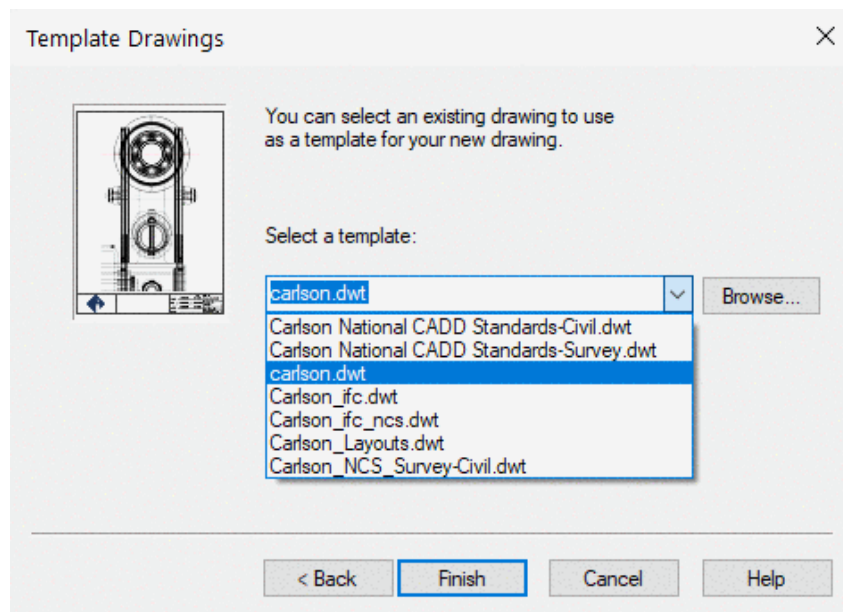

NOTE: If you want to consistently use the **Startup Wizard**, issue the Settings – Carlson Configure – General Settings and enable the **Use Startup Wizard** option. Click OK to dismiss the dialog boxes. The **Startup Wizard** will be used the next time the software is started.

The first of several Startup Wizard dialog boxes appears:

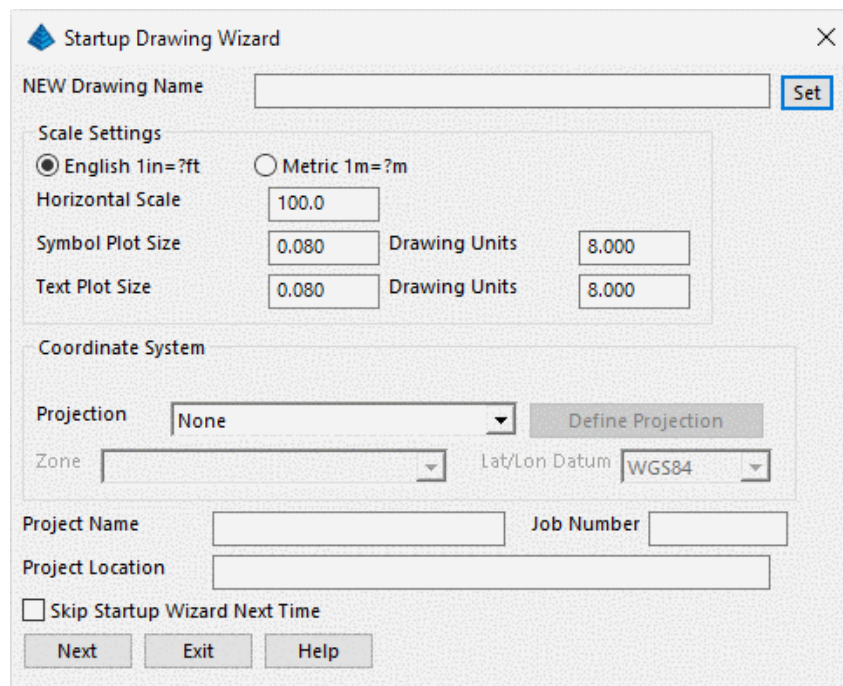

- Choose the DWG document type and the desire to base the document on a **Drawing Template** as illustrated below and then click **Next >**:

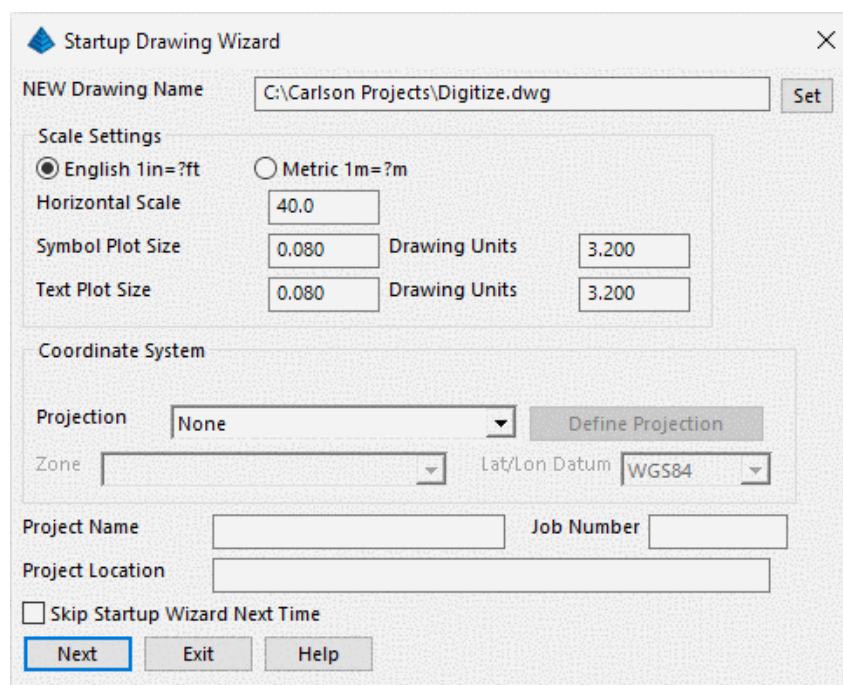

- Choose the **carlson.dwt** as illustrated below (or *site.dwt* if *carlson.dwt* is not available) and click **Finish**:

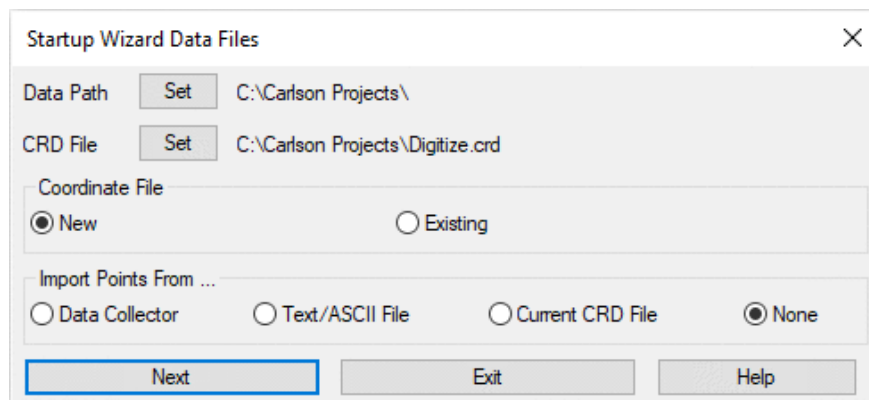

- We can now begin the more pertinent settings for the project to come based on some preliminary settings that should be similar to the default scenario shown below:

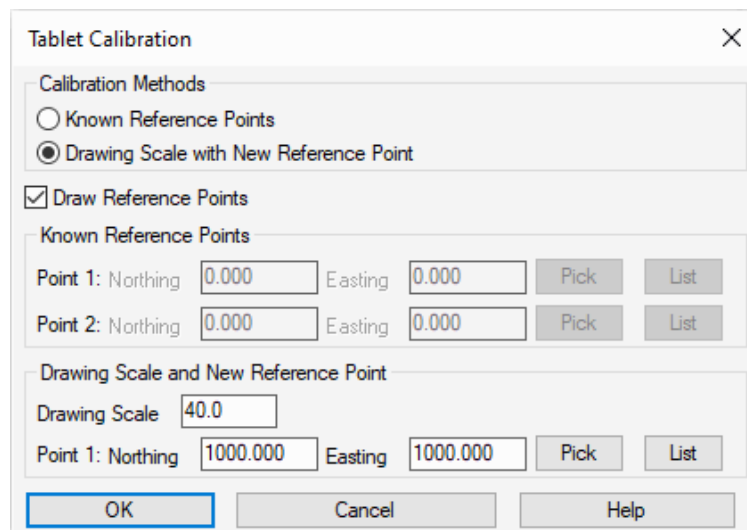

- (d) Click **Set** at the top of the dialog box, and enter in a NEW Drawing Name called **Digitize**. Verify that the other settings match the settings shown below, and click **Next**:

- (e) You will see the Startup Wizard Data Files dialog to set/confirm where to store data and indicate an information source for points/coordinates. Set/match the values as shown below and click **Next**:

3. Activate the CADnet menu via Settings – Carlson Menus – **CADnet Menu**. To start things off, you need to set the coordinate system for the paper plan by running the Digitize – Tablet – Calibrate command. Calibration is required to let the program know the orientation and scale of the paper plan.

There are two different Calibration methods:

- (a) **Known Reference Points:** allows you to enter in the coordinates of two marked points on the paper plan. This method applies when you know the coordinates of at least two points on the paper plans.
- (b) **Drawing Scale with New Reference Points:** allows you to set up a coordinate system for the plans by entering the plan scale and picking any two points from the paper plan with the digitizer puck.

In this case, we will use **Drawing Scale with New Reference Points**. For this drawing, the scale is 1:40, so enter in **40**. Use the default coordinates for Point 1 and click **OK**. Our target icon is shown as follows:

When prompted:

Digitize the First Reference Point: digitize on the target icon in the lower left

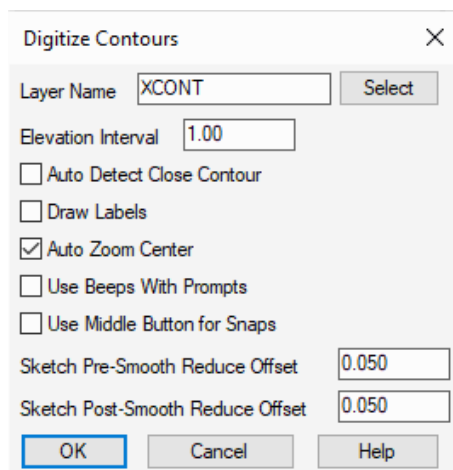

Digitize the Second Reference Point: digitize on the target icon in the upper right

The first point is assigned the coordinate specified earlier in the **Calibrate** dialog box and the second point is assigned coordinates to match with the plan scale. From now on, all of your points will be in relation to these two points.

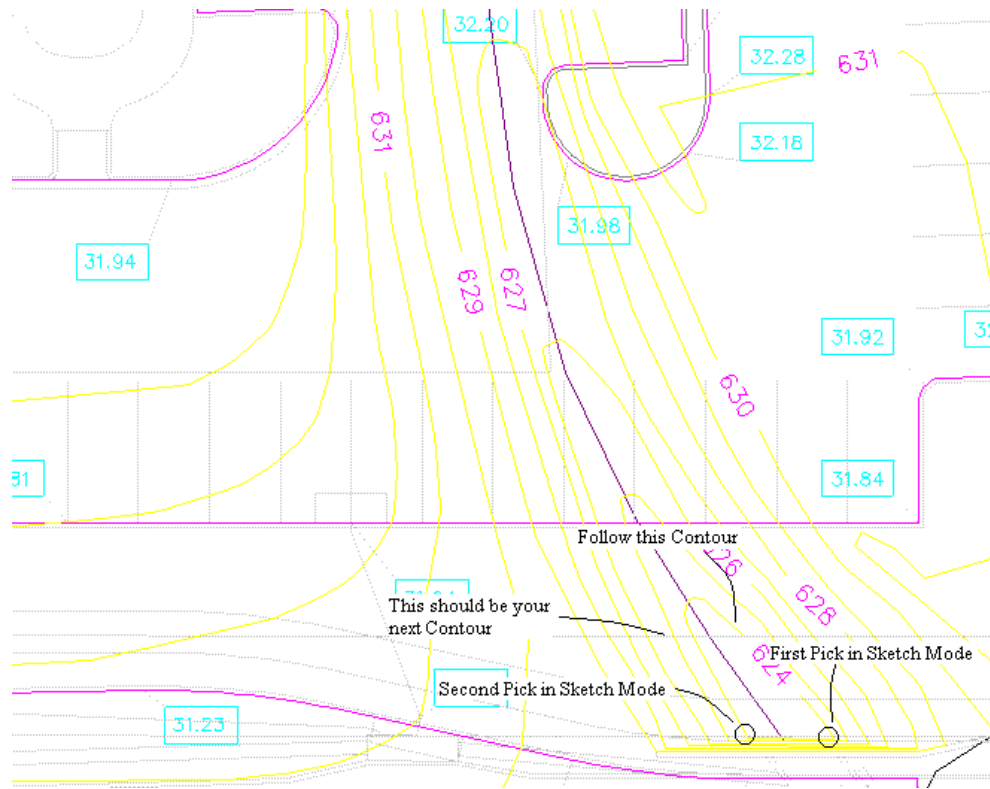

NOTE: Generally, you want to pick points on the drawing that you can find and use again in case you need to recalibrate. Also, the further away the points are from each other, the more accurate the coordinate system will be.

- We will now digitize the existing contours. The digitize routines in CADnet can be used to populate the *Existing*, *Design*, and *Other* targets used in Carlson Construction and the SiteNET portion of Carlson Civil. Issue the Digitize – Existing Surface command. Next, issue the Digitize – Contour Polyline command which will display the dialog box below:

Set the values as shown above (making note of your applicable contour interval) and click **OK** when ready. The rest of the prompting occurs at the command line and starts with the contour elevation. Find the lowest elevation for the Existing contours labeled in the bottom right corner of the paper plan zoomed in on below. In this example, the lowest elevation is 624 feet. You want to enter in the lowest contour so that as Carlson CADnet adds the Elevation Interval, it is from lowest to highest. The elevation can be entered either with the digitizer puck keys or with the computer keyboard. The layout of the digitizer keys is set in Digitize – Digitizer Settings – **Puck Layout**.

When prompted:

Increment(1.00)[A]/Direction(+)[B]/Elevation <0.00>: indicate 624 and press Enter

Sketch[0]/Exit[A]/Pick the first point: type in [0] and press Enter to get into Sketch Mode. In Sketch Mode, you will be prompted to "Pick and drag." The first point you pick is the starting point of a contour. Drag is asking you to follow that contour with the digitizer puck on the paper plan. Click a second time when you have traced the entire contour and have reached the end of the contour. You will then be prompted as follows:

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): indicate [A] to close the contour. Indicate [B] for Undo if you made a mistake and need to sketch part of the contour again. [0] will switch you into Pick Mode.

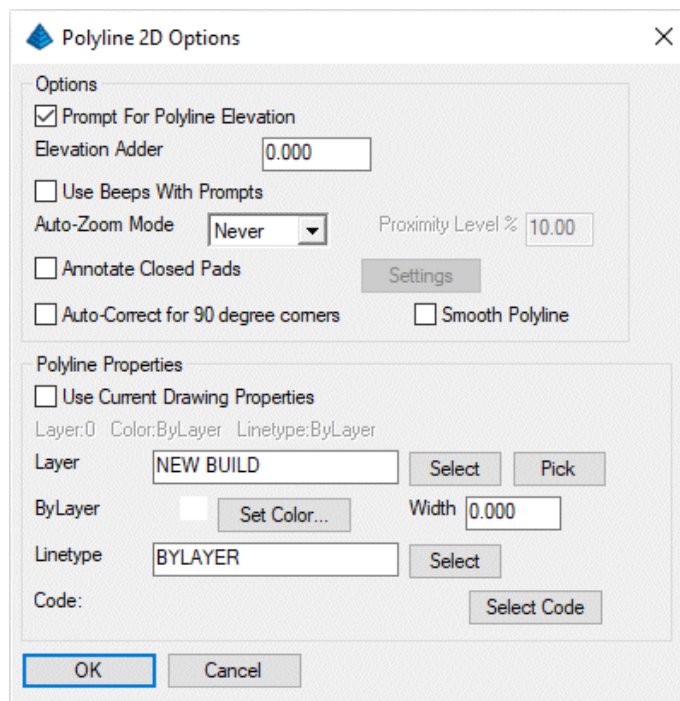

Increment(1.00)[A]/Direction(+)[B]/Elevation <625.00>: press Enter to accept the next elevation in the series and continue to digitize the next contour elevation. However, pick [0] to get into *Pick Mode*. In *Pick Mode*, you do not have to trace the contour. Rather, pick with the digitizer puck to create points that will make up the contour. When all contours are digitized, press **E** to exit the routine.

NOTE: When in *Pick Mode*, less picks are needed on fairly straight segments. Conversely, more picks will give you a more accurate contour. When completed, the Existing contour map should resemble the following:

5. Now we will digitize the building and curb line work of the *Design Surface*. In this example, there are no design contours, only the design building and curb line work and spot elevations. We will also assign layer names to the line work that we will use later to identify the types of linework. Issue the Digitize – Design Surface command.

Let's begin by digitizing the main building. Issue the Digitize – 2D Polyline command (**2D Polyline** is used to digitize line work entities with one elevation) to display the dialog box below:

Set the values as shown above and click **OK** when ready. When prompted:

Enter polyline elevation <0.00>: 634.41 and press Enter (this is the value annotated in the middle of the building)

First point: pick a building point

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick the next building point

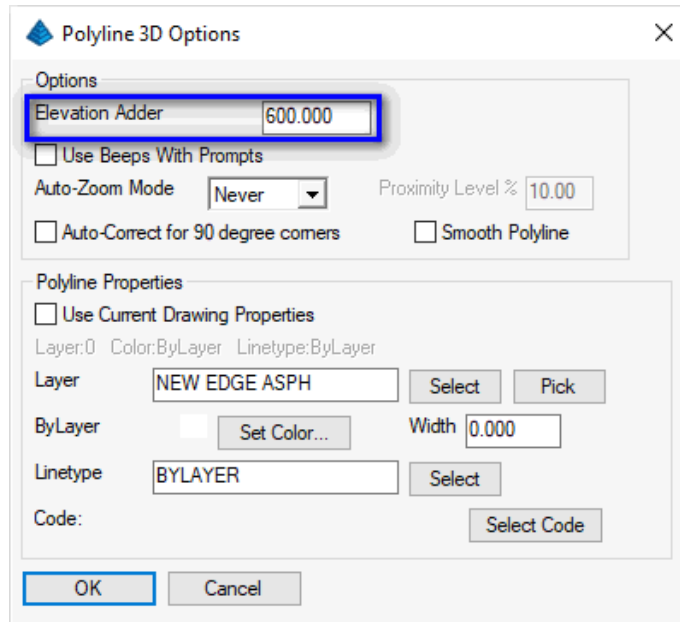

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): repeat...

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick the last building point

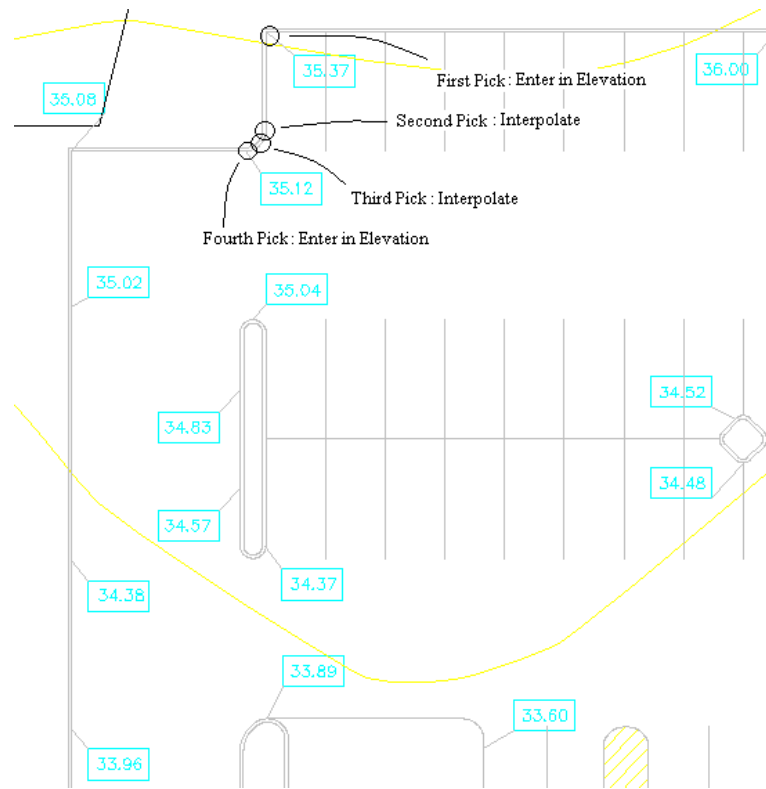

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): A to close

Digitize Another NEW BUILD Polyline [Yes(A)/<No(B)>]? B for No

Notice that the parking lot line work consists of different elevation levels. For this scenario, we'll use the Digitize – 3D Polyline command which displays a dialog box similar to that shown below:

NOTE: Because the parking lot elevation labels have been shortened on the paper plan (*e.g.* they read 35.37 and 35.12), be sure to set the desired **Elevation Adder**. Set the remaining values as shown and click **OK** when ready. Let's start by digitizing the parking lot starting from the zoomed in section below:

The edge of asphalt is the inside line. When prompted:

First point: Click on the point with the digitizer puck where the 35.37 elevation label points to in the upper left corner of the parking lot

Elevation[B]/Object/Osnap[.]/Next point or elevation<Interpolate>: 35.37 and press Enter

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick below the first point where the line work starts to curve. We do not have an elevation for this point, but we can interpolate the elevation from the two points around it using the Interpolate option.

Percent/Ratio/Interpolate[A]/Degree/Object/<Elevation[B]> <635.37>: A

This point elevation will be interpolated upon completion.

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): A

Percent/Ratio/Elevation[B]/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: pick the middle point of the curve

This point elevation will be interpolated upon completion.

Percent/Ratio/Elevation[B]/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: pick the end of the curve at the 35.12

Percent/Ratio/Interpolate[A]/Degree/Object/<Elevation[B]> <635.37>: 35.12 and press Enter

Continue digitizing for the rest of the edge of asphalt linework. Digitize each point where there is an elevation label and each point where the curb line changes direction and press Enter when complete.

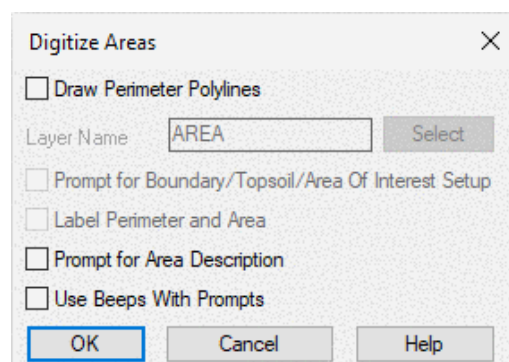

Digitize Another NEW EDGE ASPH Polyline [<Yes(A)>/No(B)]? indicate No

To check the elevations of the interpolated points, issue the Inquiry – Drawing Inspector command and hover over the polyline you just created. A window will appear showing you information about the polyline. If no elevations appear, right+click and enable the **Display Elevations** option.

Use the 3D Polyline command to digitize the rest of the parking lot as seen below.

6. Now that we have digitized the **Design Surface**, let's check the area of certain portions of the site. Run the Digitize – Areas command and match the below dialog and click **OK** when ready:

To approximate the area of the main building, pick the points of the building outline.

Pick starting point: Pick points as close to the building design line work as you can

Undo[B]/Pick next point (Enter to end): repeat... (press Enter when done)

Digitize Another Area [<Yes(A)>/No(B)]? B

An Area Report similar to the one shown below appears:

Carlson Edit : C:\Carlson Projects\Digitize-Area Report.txt

File Edit Settings

Area Report

Digitized Areas

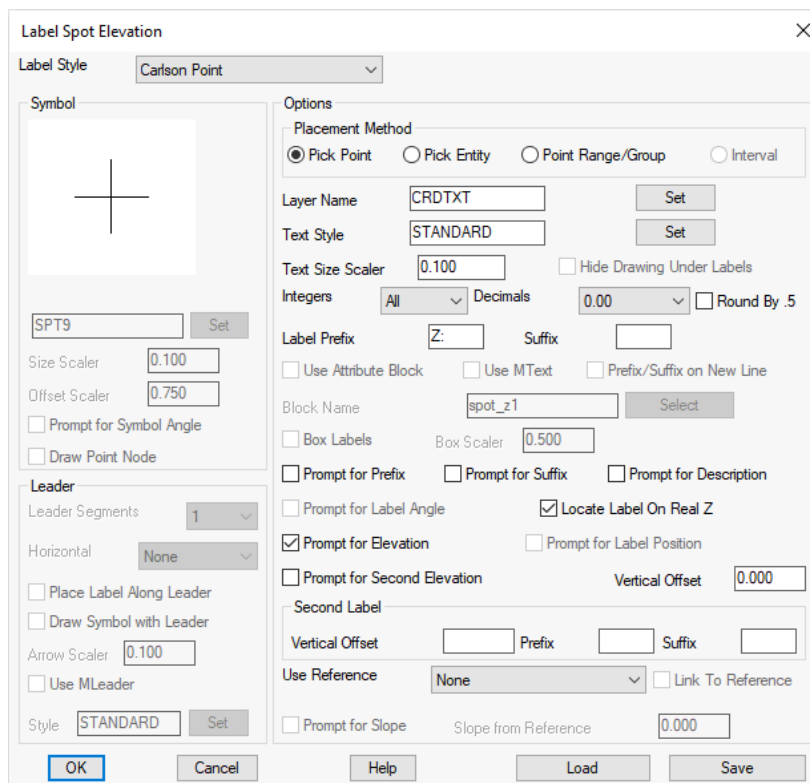

Area Index	Perimeter	Square Feet	Acres
1	405.14	9459.93	0.22
Total:	405.14	9459.93	0.22

Click the **Exit** (doorway) icon.

- In our paper drawing, we have two spot elevations labeled 32.57 and 32.41 shown in the bottom left below.

To digitize these elevations, we can use the Digitize – Spot Elevation command. Fill out the dialog as shown and pick **OK** when ready:

When prompted:

Point to Label?

Pick point or point number: find and click on the spot elevation labeled 632.57

Elevation <0.00>: 632.57

Point to Label (ENTER to End)?

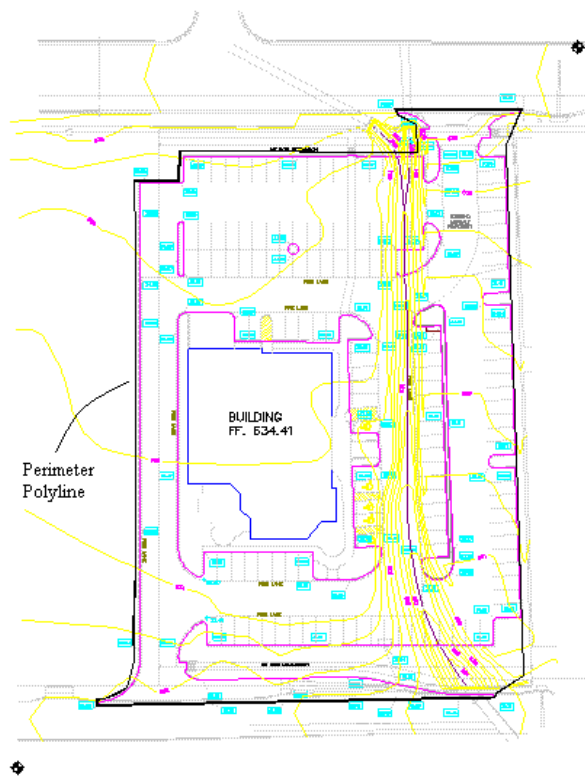

Pick point or point number: find and click on the spot elevation labeled 632.41

Elevation <0.00>: 632.41

Point to Label (ENTER to End)?

Pick point or point number: press Enter

8. The limits of the site are defined by a closed polyline. This polyline is used as the boundary for the models and the volumes. Set a new target via the Digitize – Other Drawing command. Follow this with the Digitize – Perimeter command. The goal will be to digitize around the bold, outside line shown below:

When prompted:

Layer name <PERIM>: PERIMETER and press Enter

First point: pick the first point on the boundary

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): pick the next point on the boundary

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): repeat...

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): C

Digitize Another PERIMETER Polyline [<Yes(A)>/No(B)]? indicate No

9. Now that we have digitized line work with CADnet, we can continue to calculate Cut/Fill volumes and material quantities. Activate the Construction (or Civil) menu via Settings – Carlson Menus – **Construction Menu** (or **Civil Menu**, respectively). Issue the Takeoff (SiteNET in Civil) – Boundary Polyline – Set Boundary Polyline command and when prompted:

Select boundary polylines.

[FILter]/<Select entities>: pick the perimeter polyline created in the previous step

10. Our next task will be to specify the layer(s) in the drawing which contain *existing* site conditions. Every entity (line, polyline, point, *etc*) in the drawing was assigned a layer name and pre-categorized for us based on our digitize target specification. Takeoff uses the layer name(s) to categorize data into one of three general categories for the purpose of building surface models:

- **Existing** - Used to model initial/pre-construction site conditions.
- **Design** - Used to model proposed/post-construction site conditions.
- **Other** - Used as a collection of unknown/irrelevant site conditions (text notes, hatches, *etc*).

Use the Takeoff – Define Layer Surface/Material/Subgrade command and review/set the dialog boxes similar

to that shown below:

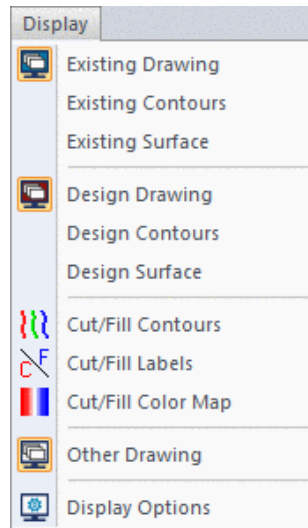

Example Digitizing Layer Targets

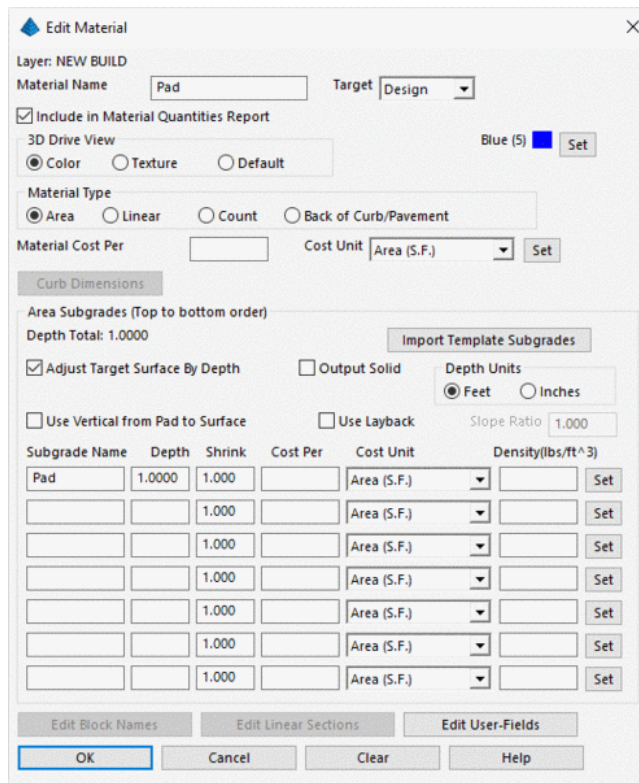

To switch between lists, pick the tabs at the top of the dialog. Check that your Layer Targets resemble the three lists shown here. If a layer is out of place, highlight it, and click the **Move To** button after selecting the correct target to send it to.

Now that the layer targets are defined, there are several commands that can be applied. In the Display menu (SiteNET in Civil), you can turn on/off whether to display layer targets by using the Existing Drawing, Design Drawing and Other Drawing commands:

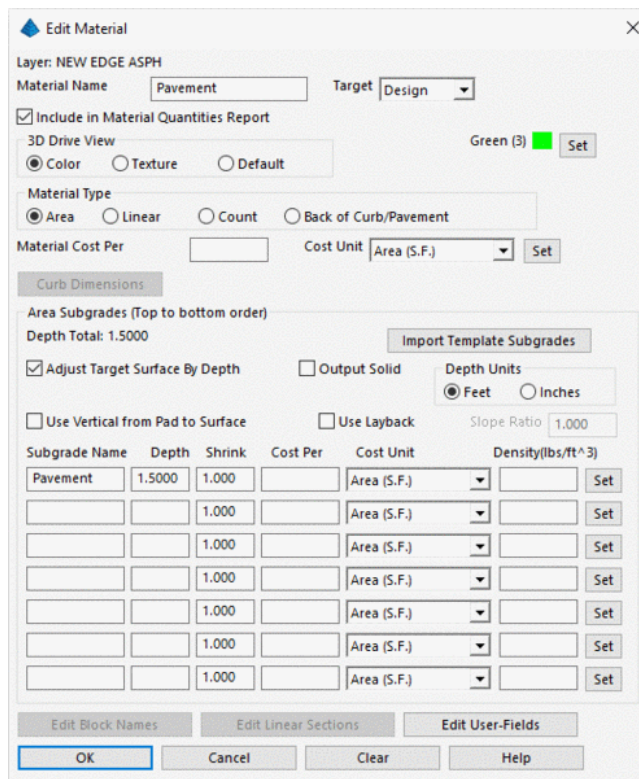

Practice turning on/off the **Existing Drawing**, **Design Drawing** and **Other Drawing** through the Display menu:

11. Besides assigning target surfaces by layer, layers are also used to define material names and subgrade depths. By assigning material names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface. The polylines used for subgrade depth must be closed polylines. Takeoff supports nested subgrade polylines for exclusion areas such as islands by counting how many subgrade polylines surround an area. If the number is odd, then the area is inside the subgrade. Otherwise the area is not part of the subgrade. Activate the **Design** tab. Select/activate the **NEW BUILD** layer and click the **Edit Layer** button. A dialog appears for defining what will be the *Pad* material properties. Set the values as shown below and click **OK** when ready:

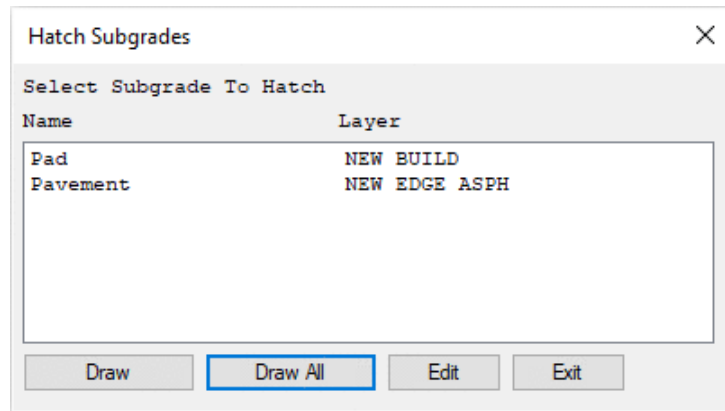

Next pick layer **NEW EDGE ASPH** and click the **Edit Layer** button. A dialog appears for defining what will be the *Pavement* material properties. Set the values as shown below and click **OK** when ready:

After the modifications have been made, pick **Save** and **Exit**.

Now let's visually verify the subgrade areas. Issue the Takeoff (or SiteNET) – Subgrade Areas – Hatch Subgrade Areas to display the dialog box below:

Select a desired subgrade layer and click the **Edit** and establish the following settings:

Subgrade	Hatch Pattern	Color
Pad	Hex	Blue
Pavement	Asphalt	Green

Subgrade Hatch Settings

Click **Draw All** on the dialog box above:

The resulting hatch areas show where the subgrade is applied. Notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. Takeoff – Subgrade Areas – Erase Subgrade Hatches command.

12. To calculate volumes, the program needs two surfaces:

- existing ground, and,
- design considerations

These surfaces are modeled by triangulation. With the preparation of the previous steps, we're now ready to

make the models. The drawing entities have been cleaned up, assigned elevations and assigned target surfaces by layer. Making each model is now a one step process:

- To make the Existing Ground surface, issue the Takeoff – Make Existing Ground Surface. The program will process the entities (regardless of their screen visibility) and make the triangulation surface.
 - To make the Design Ground surface, issue the Takeoff – Make Design Surface.
13. Cut/Fill color maps can be used for a visual output of the site cut/fill areas and also serves as another check that the models are correct. Issue the Display – Cut/Fill Color Map command to display an image similar to that shown below:

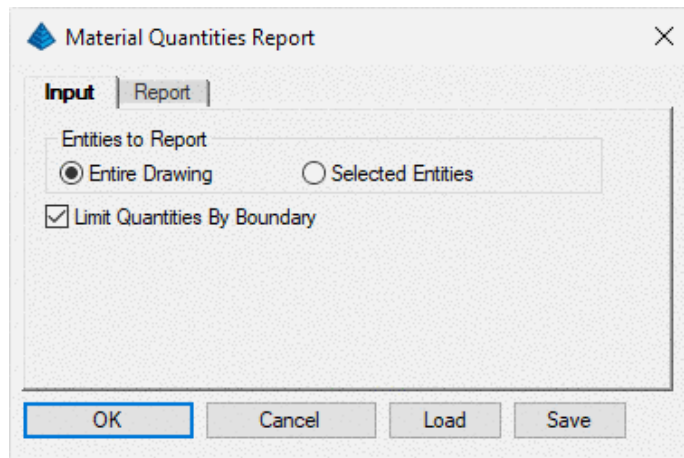

Let's remove the shaded hatch of the Cut/Fill color map through the use of the Display – **Cut/Fill Color Map** command.

14. To determine volumes, issue the Takeoff – Calculate Total Volumes command to display a dialog box similar to that below:

Set the as shown above and click **OK** when ready to display a volume report similar to that shown below:

Click the **Exit** (doorway) button to exit the report viewer.

- To report the material (paving) quantities, issue the Takeoff – Material Quantities – Standard Report routine to display the dialog box below:

Specify the options as shown above (feel free to explore the options in the *Report* tab) and click **OK** when ready. The report includes (among other this) the:

- *Count*, and,
- *Length*, and,
- *Area*, and,
- *Volume*

for each type of material that was assigned for reporting in the previously discussed Takeoff – **Define Layer Target/Material/Subgrade** command and generates a report similar to that below:

Material Quantities

Breakout Quantities

Material	Count	Length(Ft)	Area(S.F.)	Volume(C.Y.)	Shrink	Depth	Cost
Pad	1	409.8	9315.3			1.00ft	
Pad				345.0	1.000	1.00ft	
Pavement	10	3100.8	56318.8			1.50ft	
Pavement				3128.8	1.000	1.50ft	

Sub-Total Quantities

Material	Count	Length(Ft)	Area(S.F.)	Volume(C.Y.)	Tons	Cost
Pad	1	409.8	9315.3	345.0		
Pavement	10	3100.8	56318.8	3128.8		
Total	11	3510.6	65634.1	3473.8	0.0	

Material Parameters

Material	Unit Cost	Shrink Density (lbs/ft^3)
Pad		1.000
Pavement		1.000

Click the **Exit** (doorway) icon when ready. The Takeoff – Material Quantities – **Custom Report** command can be used to report these values with control of the report format and the option to export to Excel.

This completes the tutorial: CADnet Paper Plan Digitizing to Volumes.

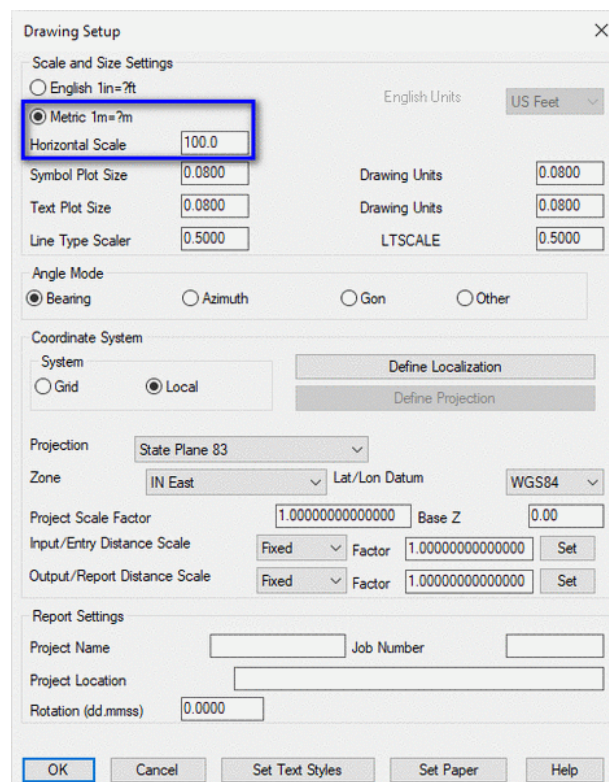

PDF Section Import

This lesson imports cross sections from a PDF into Carlson cross-section format. PDF files can contain different types of data. Some PDF's contain:

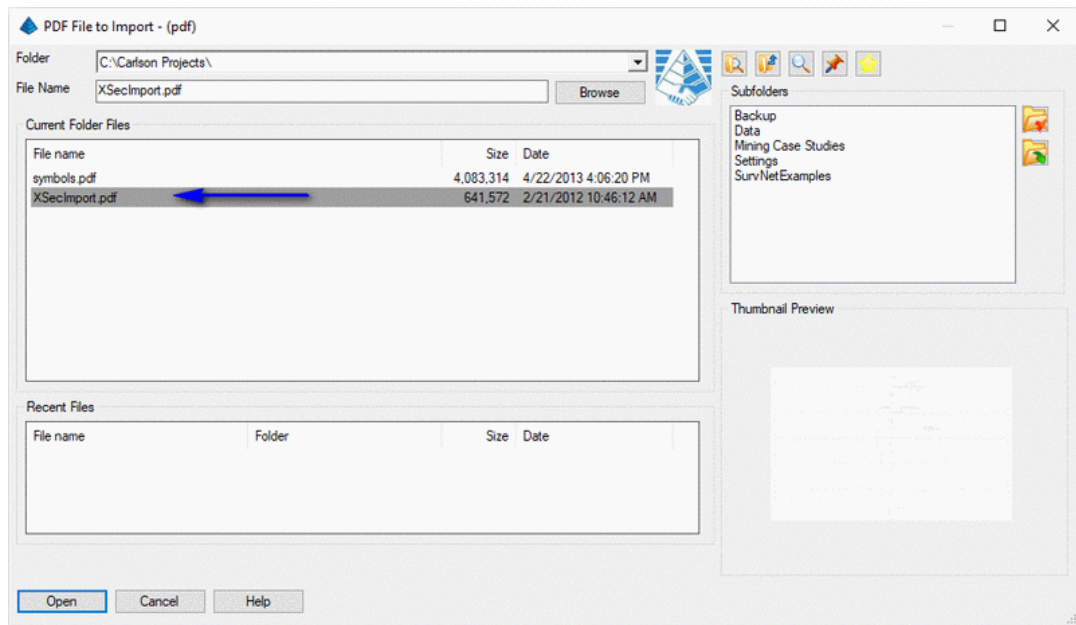

- linework vectors... this is the preferred format as the program can restore the CAD data (*i.e.* polylines) with minimal loss of accuracy and fidelity, and/or
- raster images... depending on the scan resolution used to represent the data, it may be possible to perform a raster-to-vector conversion process to create linework in the drawing. Many times, the scan resolution is not sufficient and the operator might be relegated to either raster-trace the data or perform on-screen digitizing.

In this example, the PDF file contains vector information.

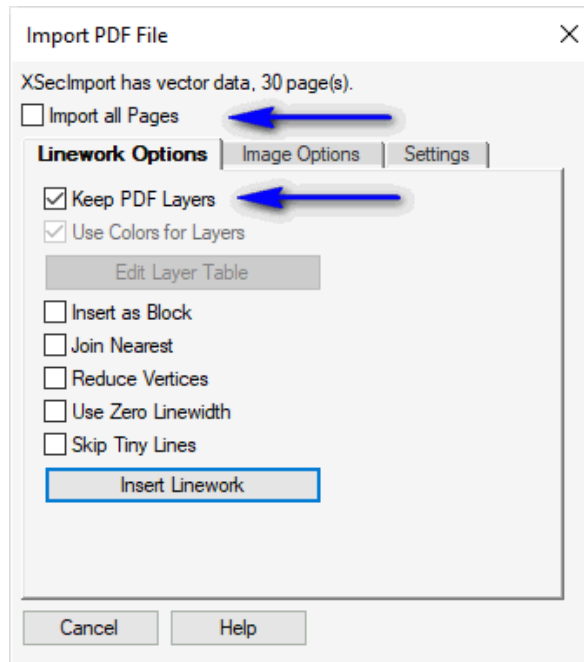

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **New Drawing**.
 - If you get the Startup Wizard dialog box, click the **Exit** button.
 - If you are taken directly into CAD, continue as is.
2. Activate the CADnet menu via Settings – Carlson Menus – **CADnet Menu**. Additionally, issue the Settings – Drawing Setup command to set the desired values as shown below for this project and click **OK** when ready:

3. With an empty drawing, issue the PDF – Import PDF File to display the dialog box shown below:

Select the file as shown above and click **Open** when ready to display the following dialog box:

NOTE: For the purposes of this tutorial, we do not need to process all pages within the PDF. Set the values as shown above and click the **Insert Linework** button when ready. A secondary dialog box displays as shown below:

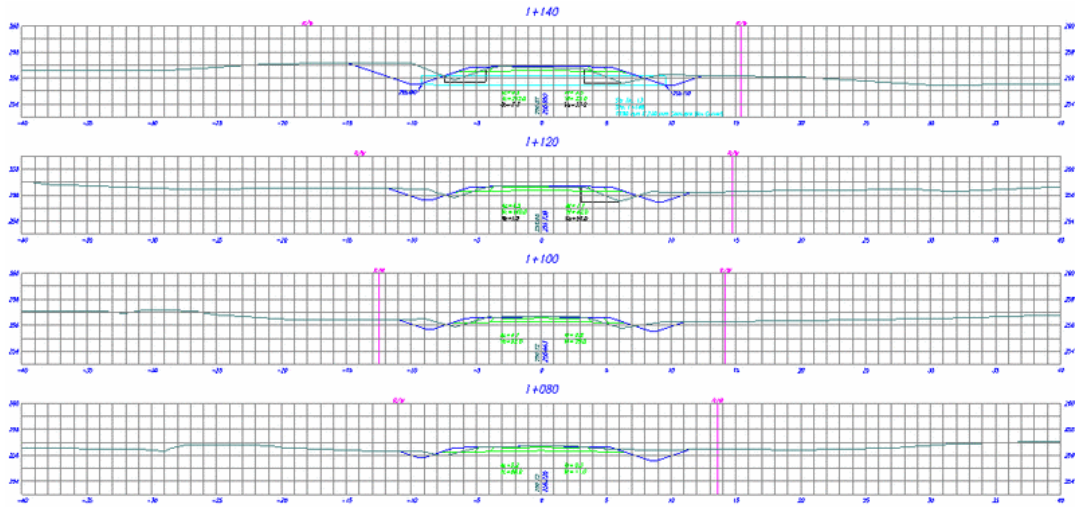

Set the values as shown above and click **OK** when ready. When prompted:

Pick point to insert PDF: pick a point

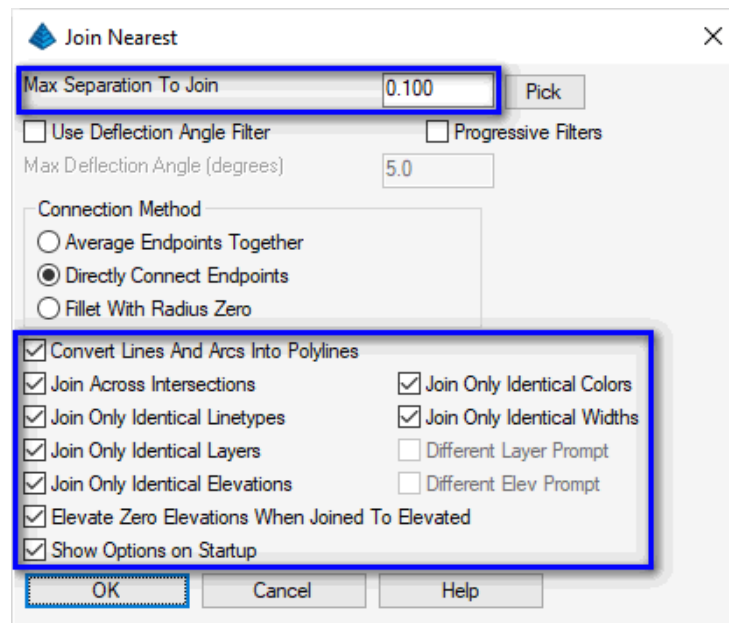

Specify rotation angle <0.0>: 0

Specify scale <1.0>: press Enter

Issue the View – **Extents** to display the imported data as shown in the example below:

As is often the case with PDF documents, there may be linework that needs to be joined for efficient processing of the PDF document. Issue the Edit – **Join Nearest** command to display the dialog box below:

Set the values as shown above and click **OK** when ready. When prompted:

Select lines, arcs and unclosed polylines to join [Settings].

Select entities: type ALL and press Enter

Select entities: press Enter

4. The next thing we'll want to do is validate the horizontal and/or vertical scale based on grid-spacing. Issue

the Inquiry – **Standard Distance** command and when prompted:

Starting point for distance: pick the ENDpoint of the grid line illustrated below

End point: pick the ENDpoint of the grid line illustrated below

With correct picks (and a proper PDF insertion scale from earlier), the corresponding "X" and "Y" distance units should display on the Command line similar to that shown below:

Delta X = 5.00, Delta Y = 3.00, Delta Z = 0.00

Because the distances picked in CAD match with the distances annotated on the grid sheet, no further action is needed.

NOTE: In the event that further scaling action is needed, two commands that can help overcome this would generally be either:

- Edit – Scale – Scale Wizard command, or the,
 - Edit – Align – 2D Align command.
5. With proper polyline vector data and a correct scale, we can now make use of this data to create physical cross-section data sets. For the purposes of this tutorial, we'd like to process 400-meters of cross-section data from 1+100 - 1+500. Depending on your application, activate one of the two section-processing modules through the:
- Settings – Carlson Menu – **Construction Menu** (commands found in the *Roads* menu)
 - Settings – Carlson Menu – **Civil Menu** (commands found in the *Sections* menu)

For the purposes of the discussion below, we will make the assumption that *Carlson Construction/Takeoff* is being used.

6. Issue the Roads – Create Sections – Sections from Polylines on Section Grids – Individual Selection command to display a dialog box similar to that shown below:

Set the values as shown above paying particular attention to the highlighted items and click **OK** when ready. A series of prompts will be presented for each cross-section station as illustrated below:

When prompted for the first section:

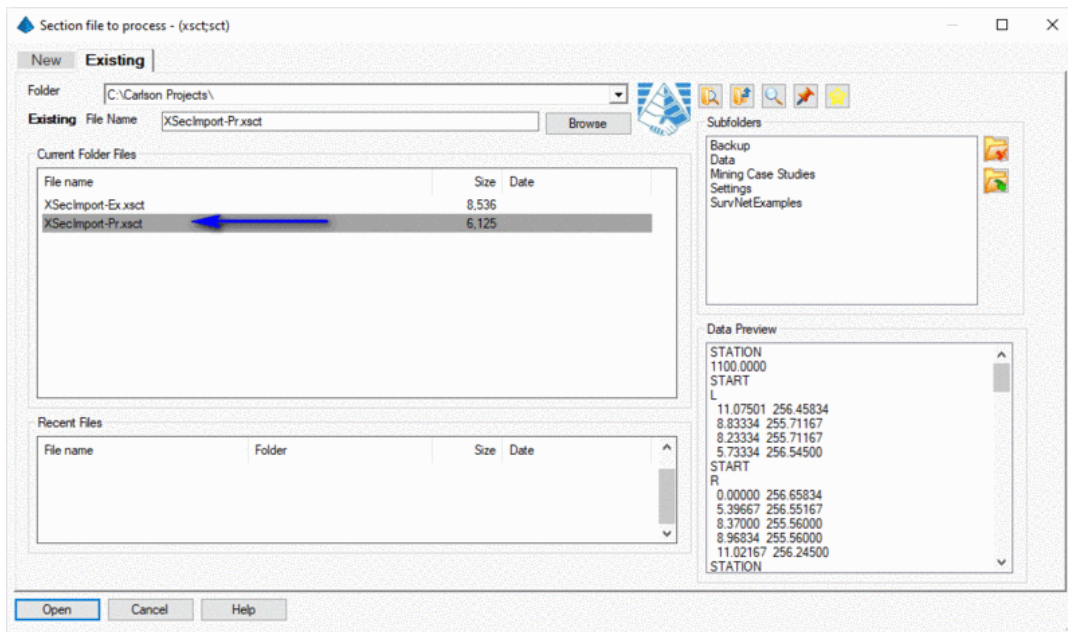

- Exit/Pick text/Station <0.00>>**: type 1100 and press Enter
- Exit/Pick text/Starting elevation of grid <100.00>>**: type 253 and press Enter
- [int on] Pick point at starting elevation and zero offset of section ([Enter] for none)**: pick the starting grid elevation at the 0 offset
- Select station 1100.00 [section file 1] section polyline**: pick the appropriate polyline
- Select station 1100.00 [section file 2] section polyline**: pick the appropriate polyline

The sequence will restart for the next expected cross-section station. Accept the default value or override with a desired value.

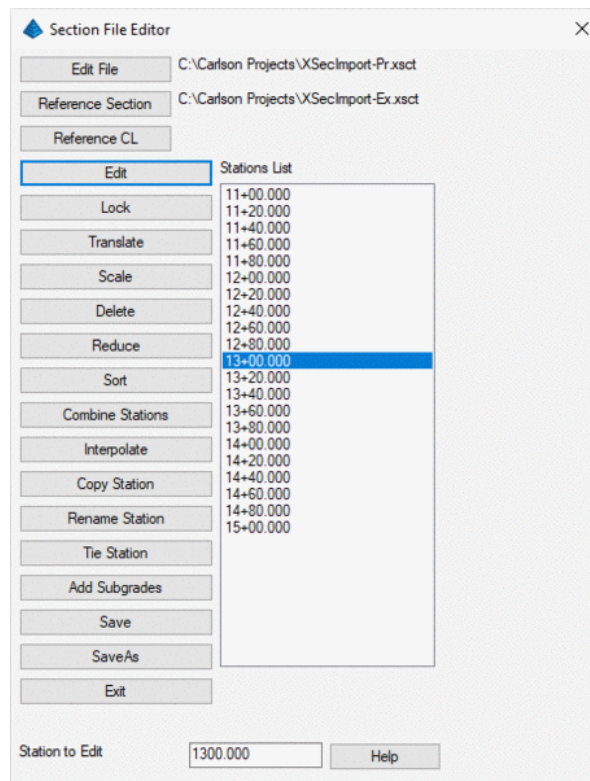

NOTE: There will be a starting grid elevation changes starting at **1+300!** Make the appropriate adjustment during the prompting!

Pan the drawing to see the next available cross-section station and note its starting grid elevation. Repeat the sequence until you reach station **1+500** and then issue the **Exit** to complete the conversion process.

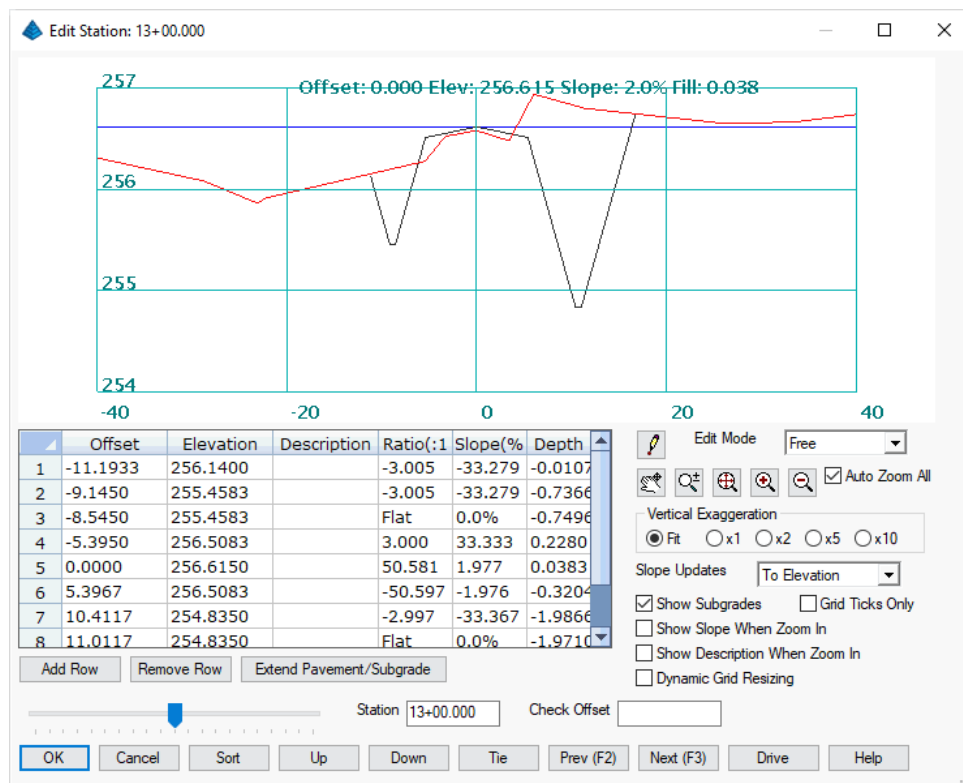

- When complete, let's review/check the section data. Issue the Roads – Section File Editor command to display a dialog box similar to that shown below:

Select the file as illustrated above and click **Open** when ready to display a dialog box similar to that shown below:

Set the **Reference Section** file as shown above, highlight a desired to inspect and click the **Edit** button to display a dialog box similar to that shown below:

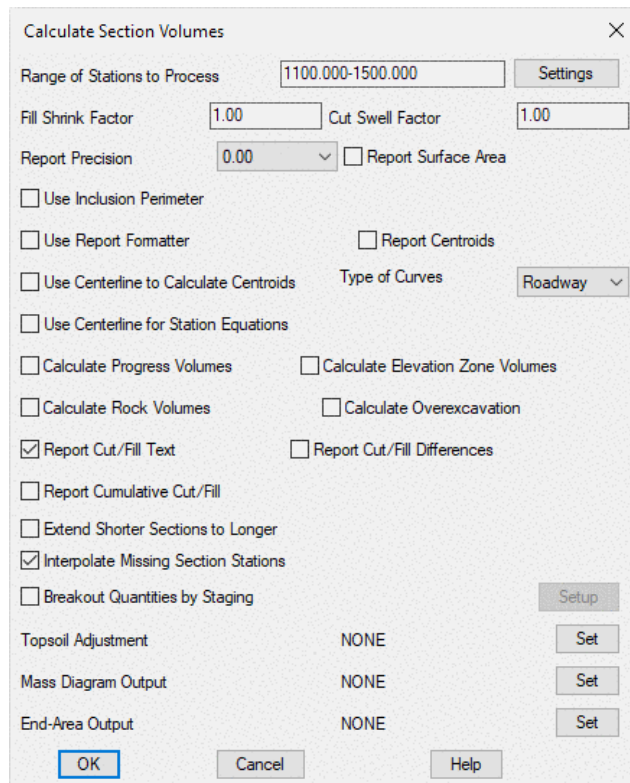

The command shows a graphic preview of the sections along with a spreadsheet of the *Edit File* values. Explore the remaining controls on this dialog box and click the **Cancel** button to dismiss it when ready. Click the **Exit** button to dismiss its parent dialog box.

- Now that we have two section files, we can derive the volume between them. Issue the Sections – Calculate Section Volumes command. When prompted:

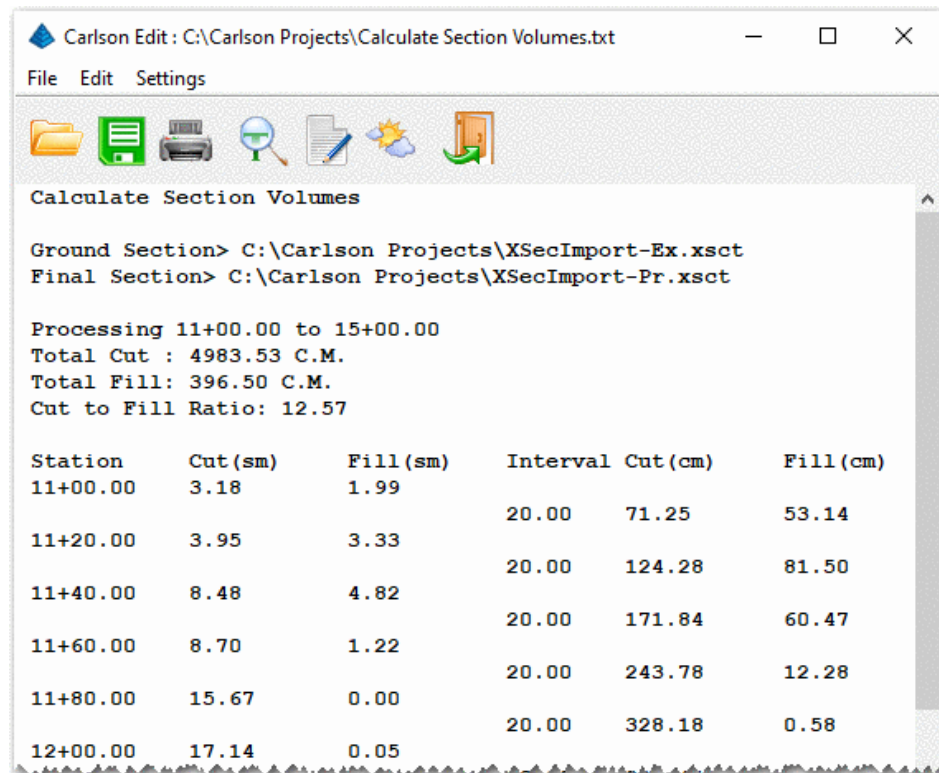

Section File (Existing Ground) to Read (dialog): select the *-Ex* section file and click **Open** when ready

Section File (Final Ground) to Read (dialog): select the *-PR* section file and click **Open** when ready

Calculate Section Volumes (dialog): set the values as shown below and click **OK** when ready

The volumes are calculated and reported, along with the cut and fill end-areas at each station as illustrated below:

Review the results and click the **Exit** (Doorway) button to dismiss the report.

This completes the tutorial: CADnet PDF Section Import.

GeoTech Reports

This lesson creates and reports drillhole data.

1. This drillhole lesson builds on the results of the Takeoff/SiteNET Basics tutorial. Before continuing with this tutorial, complete that tutorial up through the Make Existing Ground Surface/Make Design Surface section of that tutorial. When the **Takeoff/SiteNET Basics** tutorial is completed, we're now ready to add drillholes for the project.
2. Activate the GeoTech menu via Settings – Carlson Menus – **GeoTech Menu**. For mapping the drillholes, we don't need to see all the drawing layers. Run the View – Freeze Layer By Pick command and pick on a contour polyline and a curb elevation label. In this case, the contours are on a few different layers. As a result, re-run the **Freeze Layer By Pick** command and keep picking contour polylines and labels until all contours are gone and the drawing resembles that shown below:

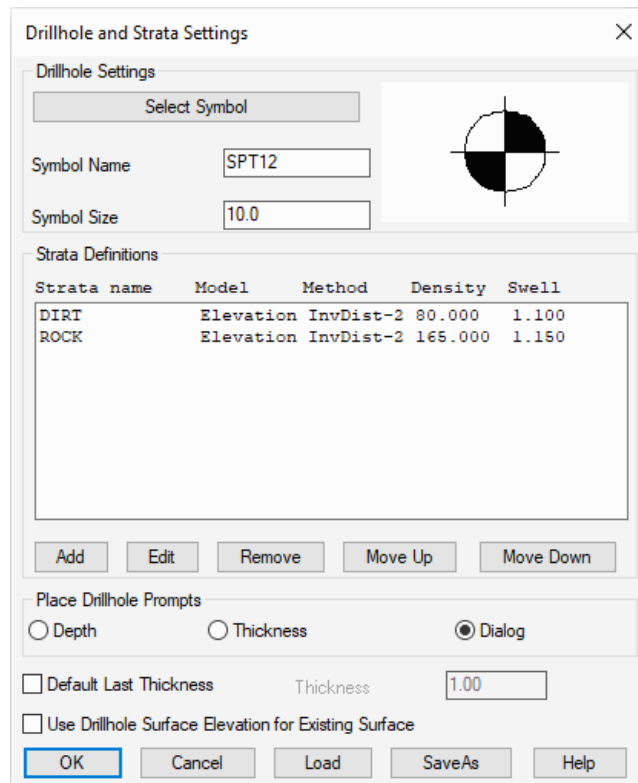

Next, let's orient the drawing so that the building better aligns with the screen. Issue the View – Twist Screen – Line, Polyline or Text command. When prompted:

Pick a line, polyline or text: pick on the northeast end of one of the building as shown above
Twist azimuth for selected LWPOLYLINE (Use 90 for Due East) <90.0>: press Enter

The drawing view is changed (and the coordinates remain as-is).

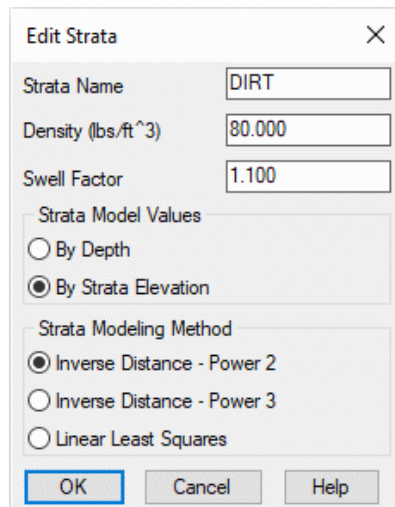

3. Issue the Drillhole – Define Drillhole and Strata Settings (*aka* **Define Drillhole**) command to display the dialog box similar to that shown below:

For this tutorial, we need to define two strata:

- (a) **DIRT** (material above the rock), and,
- (b) **ROCK**

Click the **Add** button to create a material strata as described below and click **OK** when ready:

Next, pick the **Add** button again. This time, fill out the dialog with a strata name of "ROCK" and use the information below to add the second strata material into the project and click **OK** when complete:

Values	Strata 1	Strata 2
Name	CLAY	LIMESTONE
Density	80	165
Swell Factor	1.10	1.15
Model Values	By Elevation	By Elevation

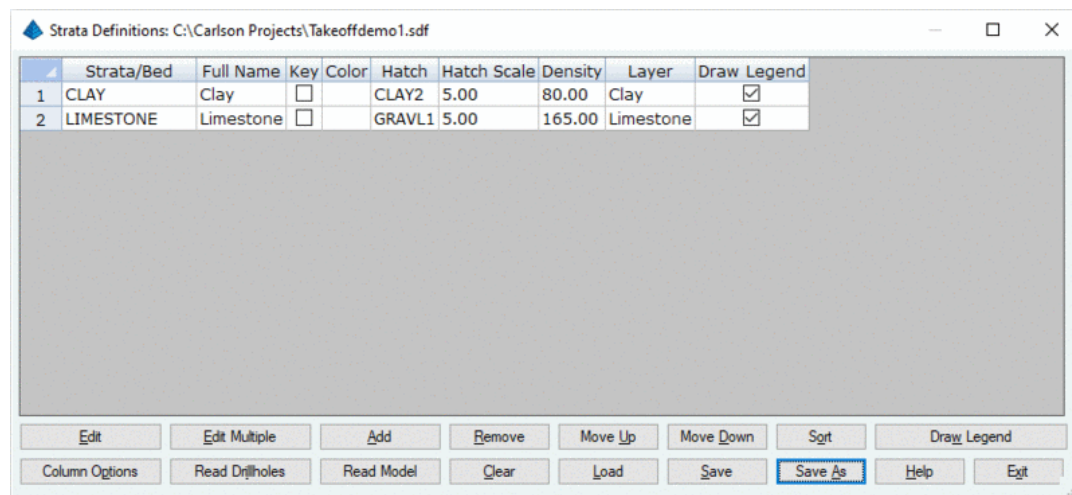

Strata Definitions

NOTE: There are three options of modeling methods:

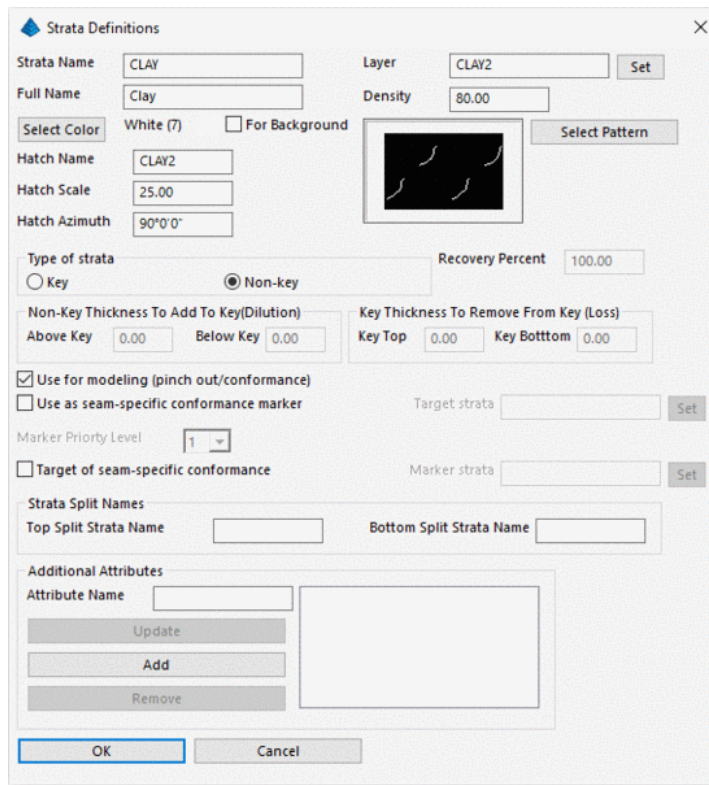

- **Inverse Distance** will not carry trends and the calculated strata model will never be higher or lower than the original drillhole data and uses a weighted average of the drillhole data. In general, closer drillholes are weighted more than drillhole farther away:
 - **Inverse Distance - Power 2** will weigh drillholes more that are further away.
 - **Inverse Distance - Power 3** will weigh drillholes less that are further away.
- **Linear Least Squares** extrapolates trends and allows for a strata model to create new highs and lows that don't appear in the original drillhole data.

The *Strata Materials* in the main dialog need to be in top to bottom order. To change the order, highlight a strata name and use the **Move Up** or **Move Down** buttons. In this case, we want *DIRT* then *ROCK*. Click **OK** from the main dialog.

4. Next, we'd like to define the label name, hatch pattern and color for the strata. Run the Drillhole – Define Strata/Bed command to display a dialog box similar to that shown below:

Click **Add** and fill out the data as shown below and click **OK** when ready:

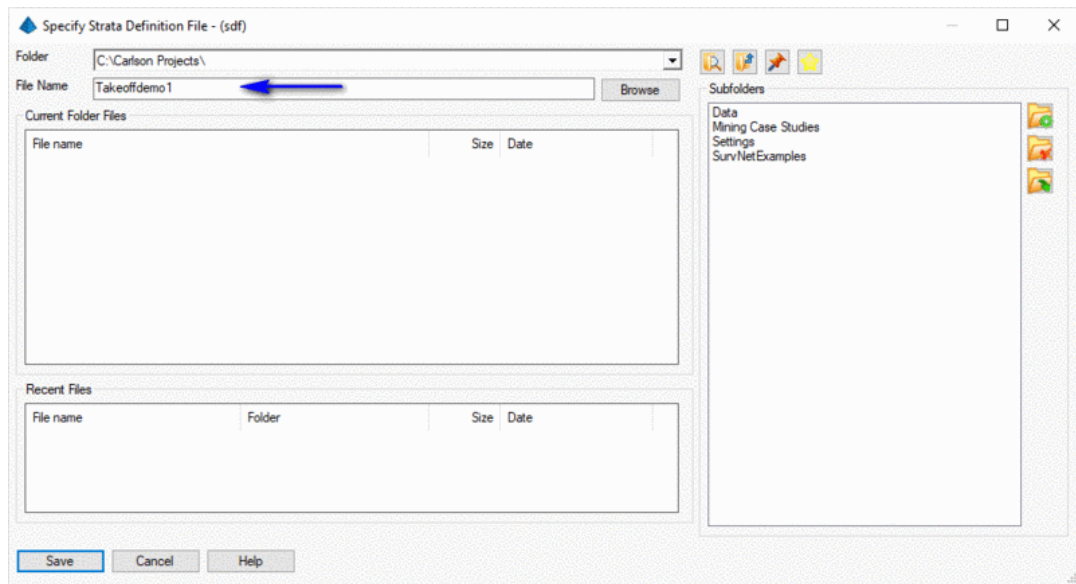

Use the table below for the specific values:

Values	Strata 1	Strata 2
Strata Name	CLAY	LIMESTONE
Full Name	Clay	Limestone
Layer	Clay	Limestone
Density	80	165
Hatch Name	CLAY2	GRAVL1
Hatch Scale	5.00	5.00
Hatch Azimuth	90°0'00"	90°0'00"

Strata Definitions

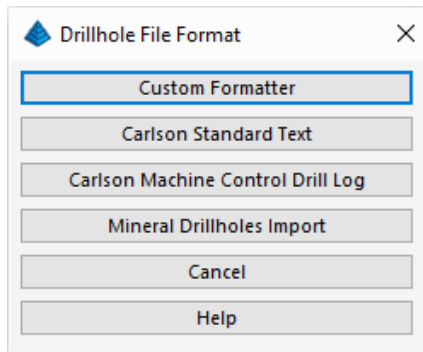

Once created, pick **SaveAs** and when prompted:

Supply the name as shown above and click **Save** when ready. Finally, click the **Exit** button to dismiss the **Define Strata/Bed** dialog box.

5. There are two different methods for entering drillhole data:
 - **Drillhole Import** which reads the drillhole data from a text file. This command supports customizing the sequence of drillhole data fields to match the format of the text file.
 - **Place Drillhole** creates the drillholes at picked positions in the drawing and enters the data in a dialog. This process is discussed in the Takeoff Drillholes and Strata tutorial.

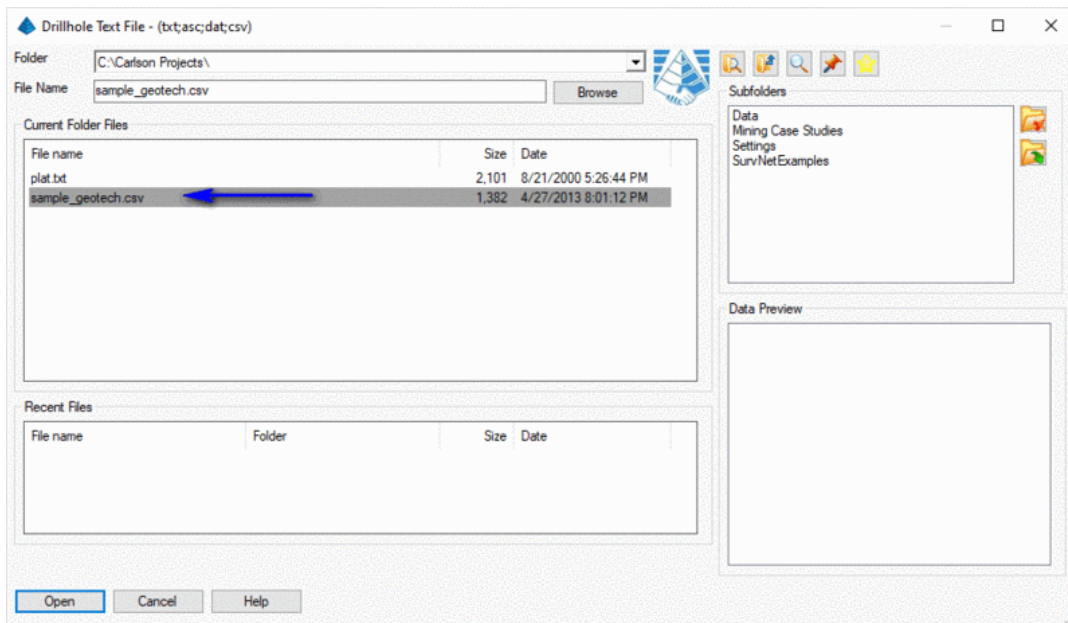

For this tutorial, issue the Drillhole – Import/Export Drillholes – Drillhole Import command. When prompted:

Choose the **Custom Formatter** option. When prompted:

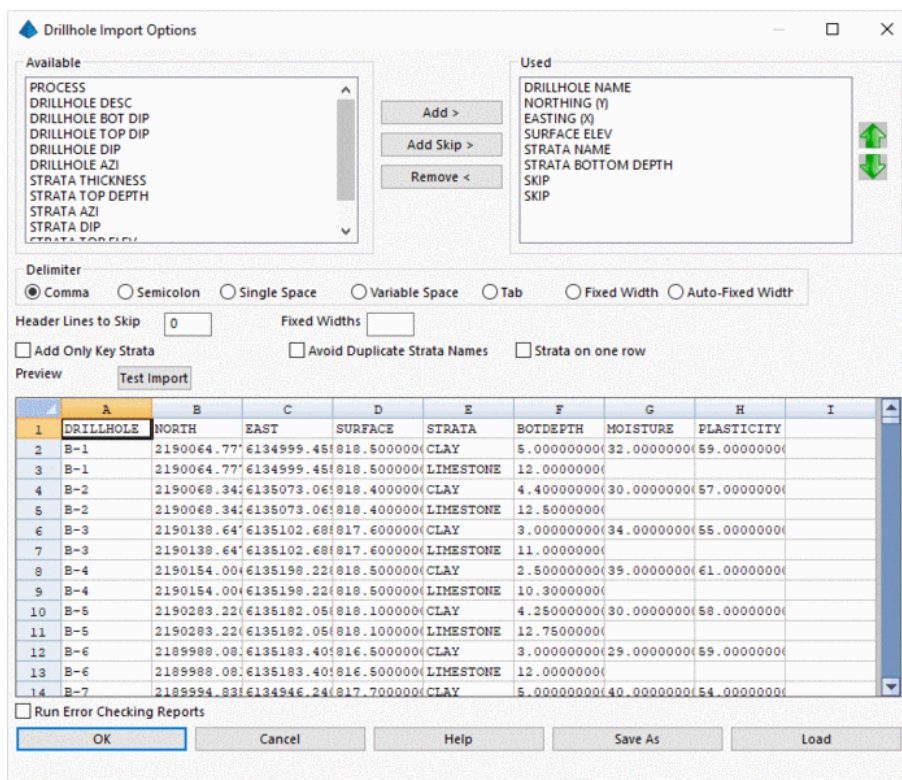

Indicate **No** as both the drillhole and strata data are stored in the same file. For the **Drillhole Text File**, specify the file shown below and click **Open** when ready:

NOTE: The file contains fields of data in the following order:

- (a) DRILLHOLE
- (b) NORTH
- (c) EAST
- (d) SURFACE
- (e) STRATA
- (f) BOTDEPTH
- (g) MOISTURE
- (h) PLASTICITY

Use the **Add >**, **Add Skip >** and/or **Remove <** buttons to fill out the *Used* list at shown and click **OK** when ready:

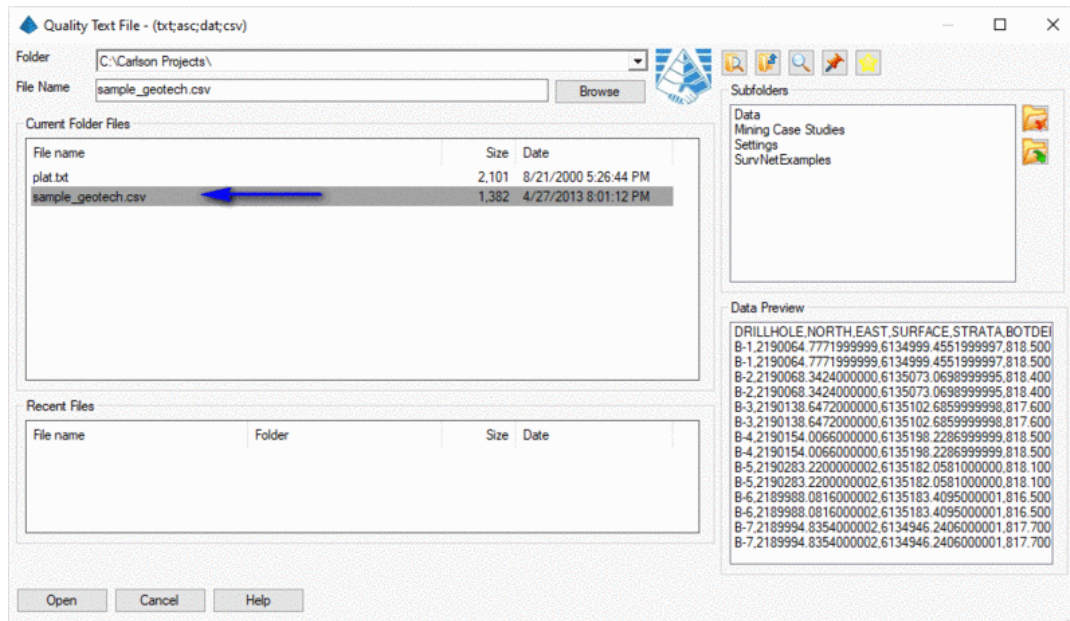

The drillhole data is imported into the project.

- The **Drillhole Import** has brought in the structure for the drillhole and strata but not the attributes (*i.e.* the strata attributes for Moisture and Plasticity). Issue the Drillhole – Import/Export Drillholes – Import Qualities command and when prompted:

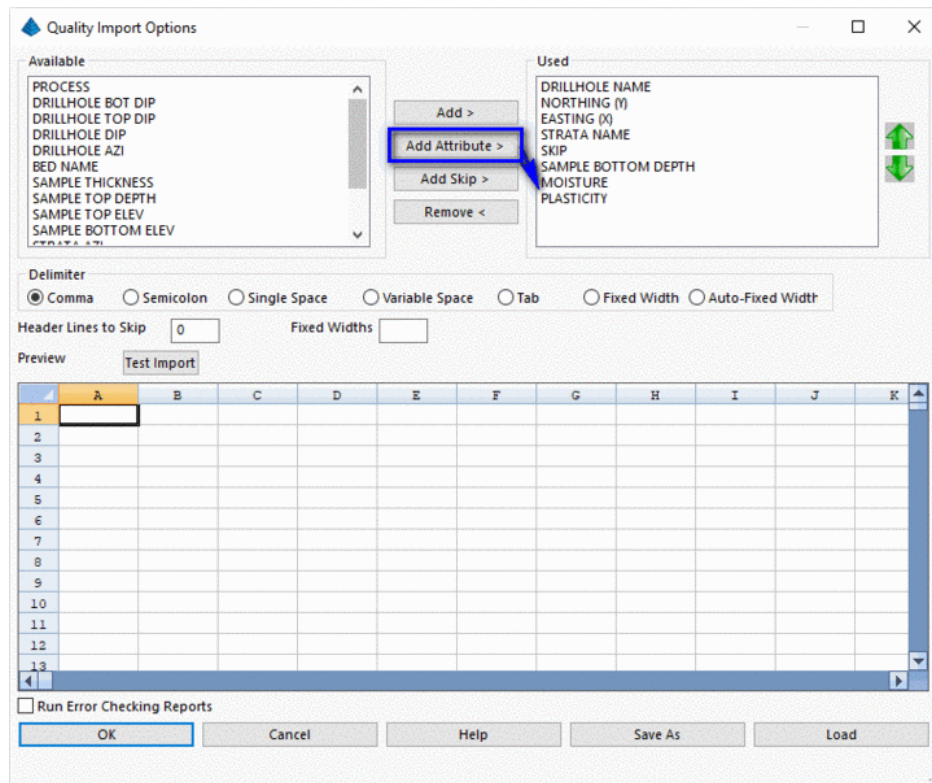

Select Drillholes to update.

[FILter]/<Select entities>: type ALL and press Enter twice

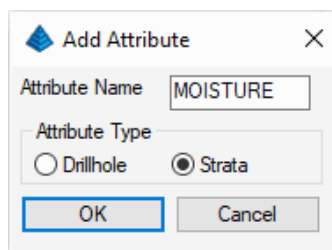

Re-select the drillhole file as illustrated earlier and click **Open** when ready:

A **Quality Import Options** dialog box similar to that shown below appears:

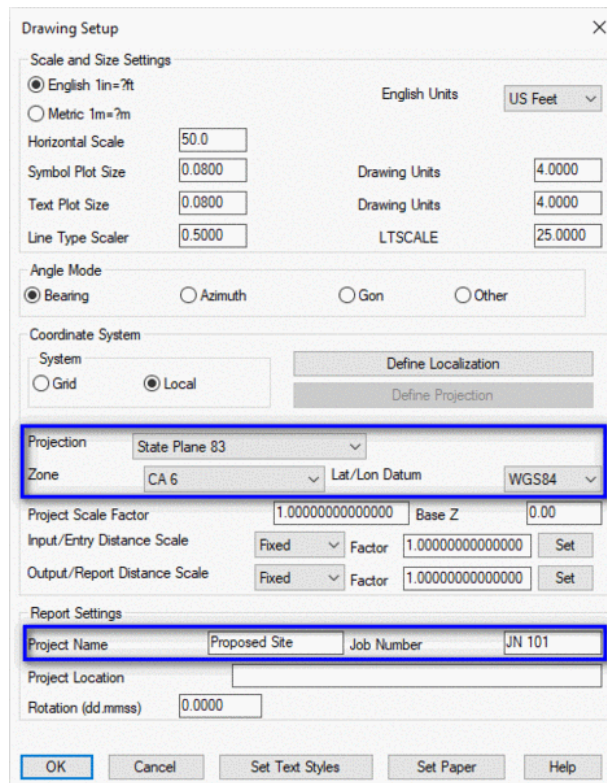

Use the **Add >**, **Add Skip >** and/or **Remove <** buttons to fill out the *Used* list at shown. Use the **Add Attribute >** button to create fields for the *Moisture* and *Plasticity* fields. When creating these fields, indicate they are **Strata** properties as illustrated below (click **OK** when ready):

Lastly, click the **OK** button on the *Quality Import Options* dialog box when ready to import the drillhole qualities.

7. To setup the project name for the reports, issue the Settings – Drawing Setup command to set the values shown below and click **OK** when ready:

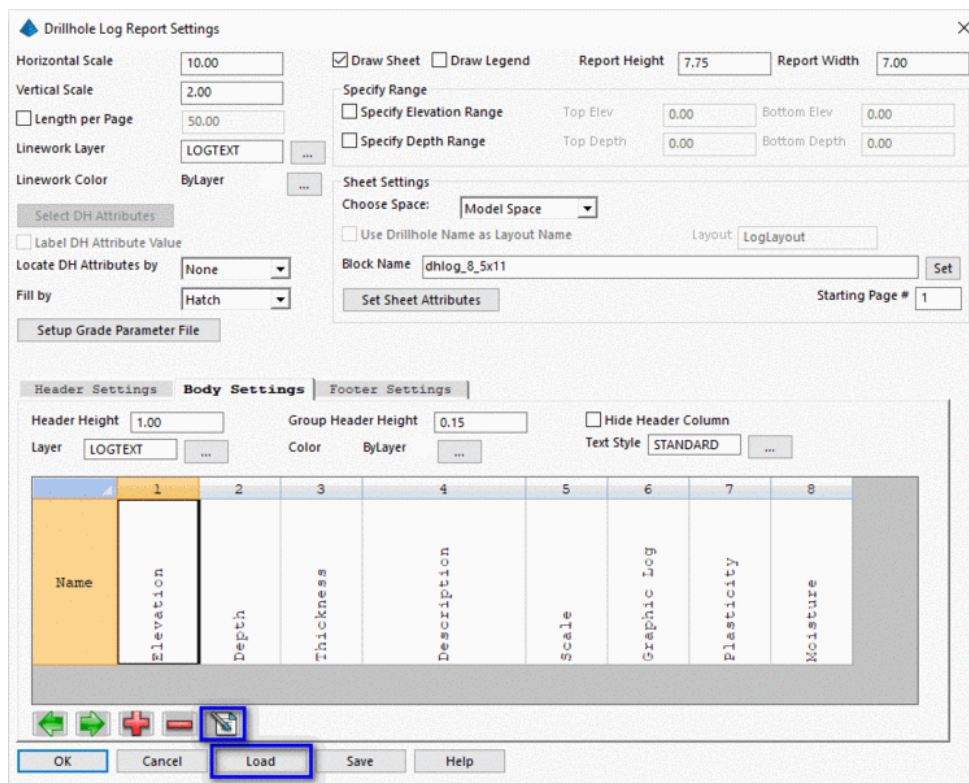

8. To make log reports, issue the Drillhole – Graphic Drillhole Report command. When prompted:

Select Drillhole [**<Select>/Name/Dialog**]: press Enter

Select drillholes

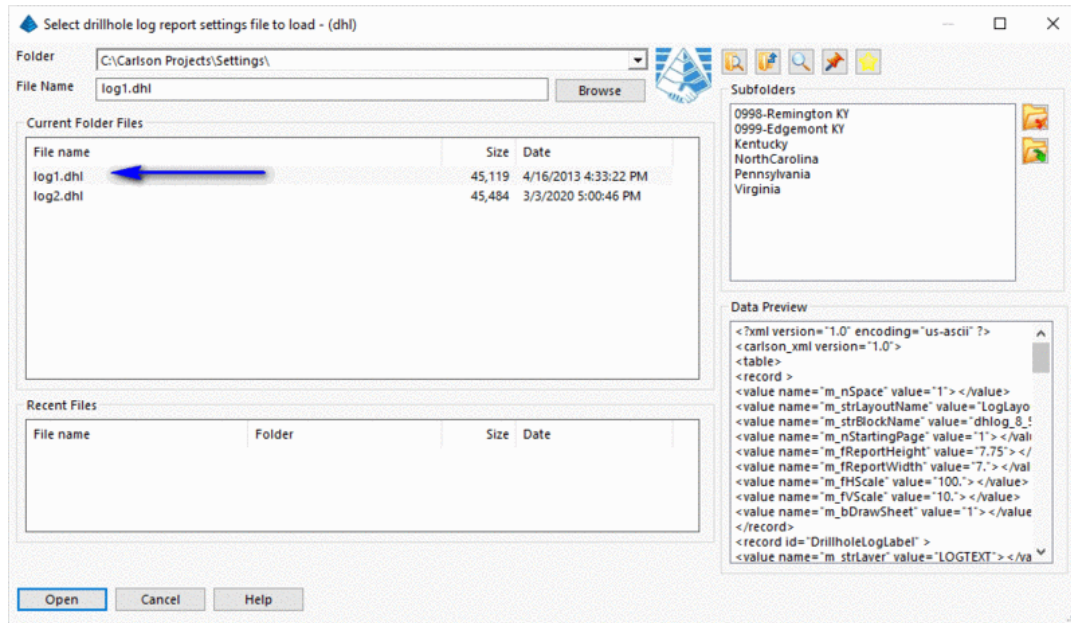

[FILter]/<Select entities>: type ALL and press Enter twice

A dialog box similar to that shown below appears:

NOTE: The contents of the various Drillhole Log columns can be customized through the **Edit Column** button highlighted above.

Use the **Load** button to load a predefined Drillhole Log as shown below (click **Open** when ready):

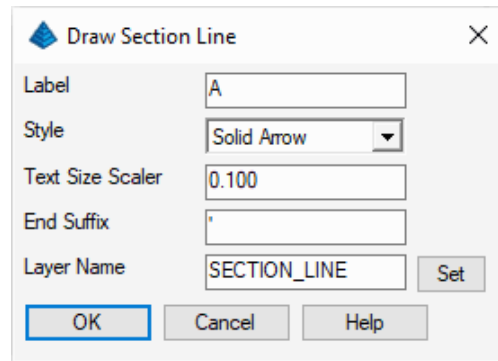

Click **OK** on the *Drillhole Log Report Settings* dialog box. When prompted:

Pick a point to insert log report: pick an empty location within the drawing

An example of the report is shown below:

9. Now, let's create a cross section view of the drillholes across the building pad. Issue the Draw – Section Line command to display a dialog box similar to that shown below:

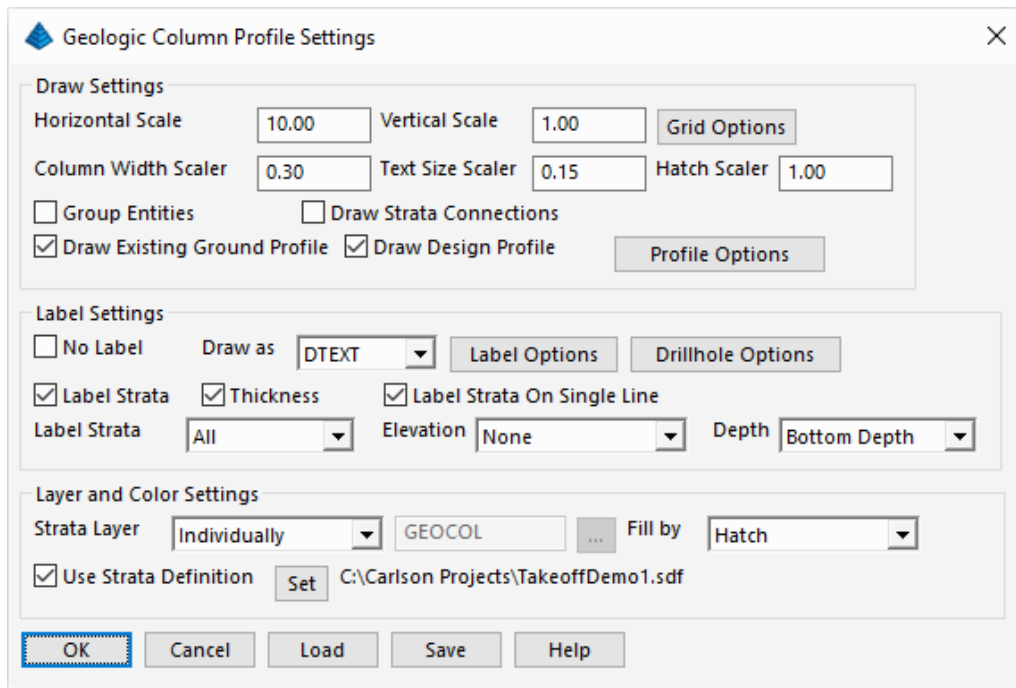

Fill out the dialog as shown above and click **OK** when ready. When prompted:

Pick 1st point: pick a location left of the building

Pick 2nd point: pick a location right of the building as illustrated below

Next, run the StrataCalc – Geologic Column Profile command which displays a dialog box similar to that shown below:

Set the values as shown above. Click the **Set** button to load the file saved in the Define Strata/Bed discussion section above. Use the table of sub-options outlined below within this command to further control the eventual report:

Grid Options

Profile Options

Label Options

Drillhole Options

Select Attributes (Prompt)

Geologic Column Profile Sub-options

Click **OK** when ready. When prompted:

Select Drillholes for geologic column.

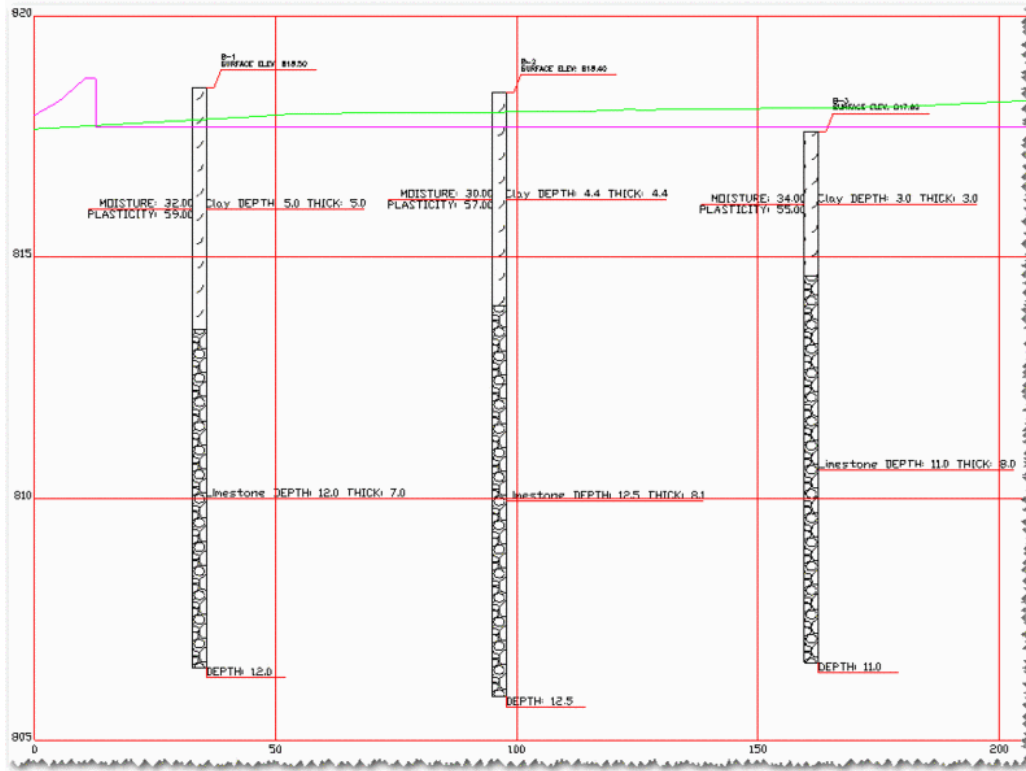

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

Select Fence alignment polyline: pick the section "A" line created earlier

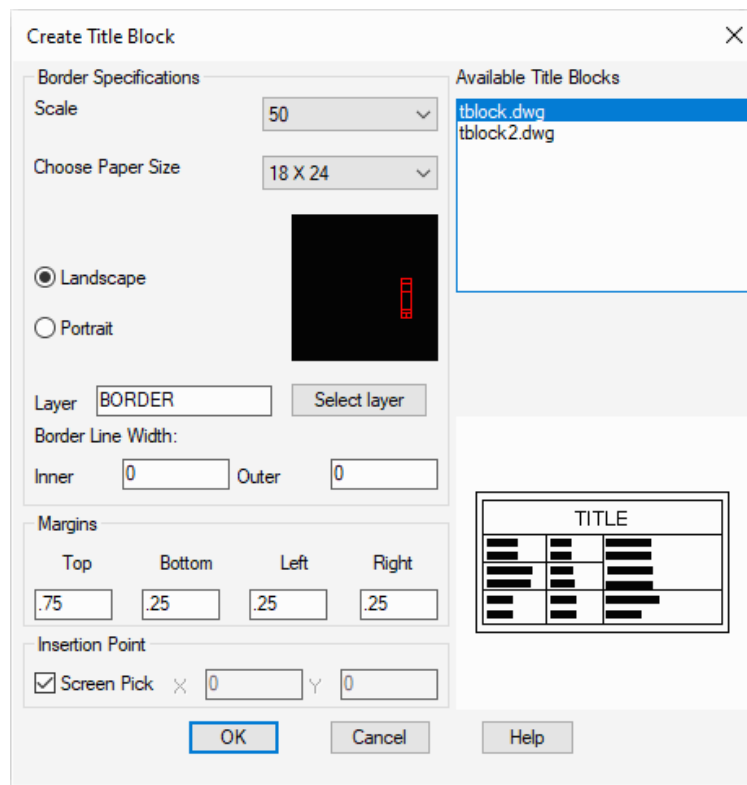

Maximum drillhole distance from alignment polyline <1000.0>: type 100 press Enter
Select Attributes (dialog): select the Attributes cited in the table above and click **OK**
Pick location for geologic column(s): pick a lower left location for the report

The report similar to that shown below is placed into the drawing:

NOTE: As a reminder, complete the **Takeoff/SiteNET Basics** tutorial to see the *Existing Ground* and/or *Design* profiles.

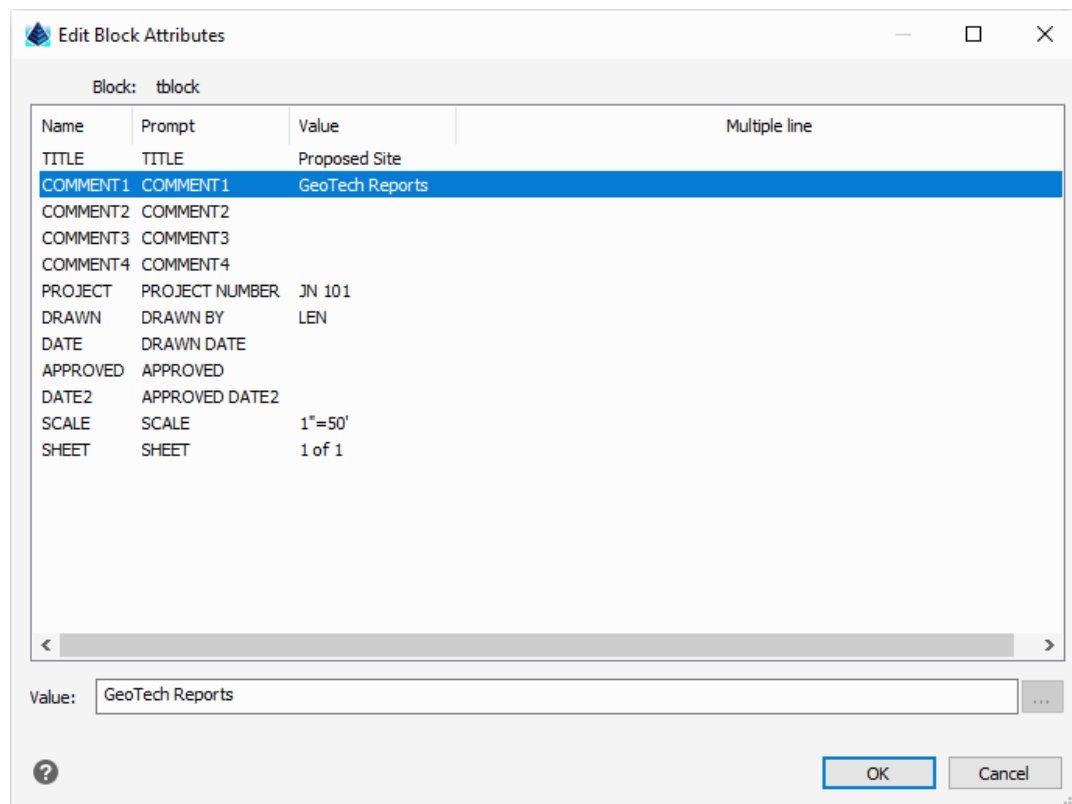

- To prepare for plotting, run the Map – Title Block command (the same as that found under Settings – Title Block) to display a dialog box similar to that shown below:

Set the values as shown above and click **OK** when ready. When prompted:

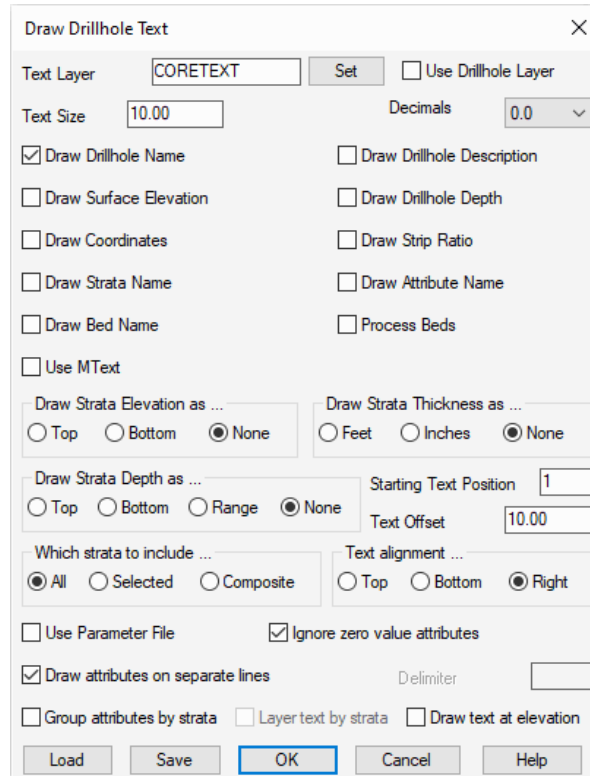

Pick location: pick a desired location for the Title Block

Enter attribute values: supply values as suggested below and click **OK** when ready

11. Let's add some annotation to the drawing for the plan view. Run the Drillhole – Label Drillholes – Standard

Drillhole Text command to display a dialog box similar to that shown below:

Set the values as shown above (a very minimal drillhole label) and click **OK** when ready. When prompted:

Select the Drillholes to label.

[FILter]/<Select entities>: type ALL and press Enter

[FILter]/<Select entities>: press Enter

Select Attributes (dialog): select the Attributes cited in the table above and click **OK**

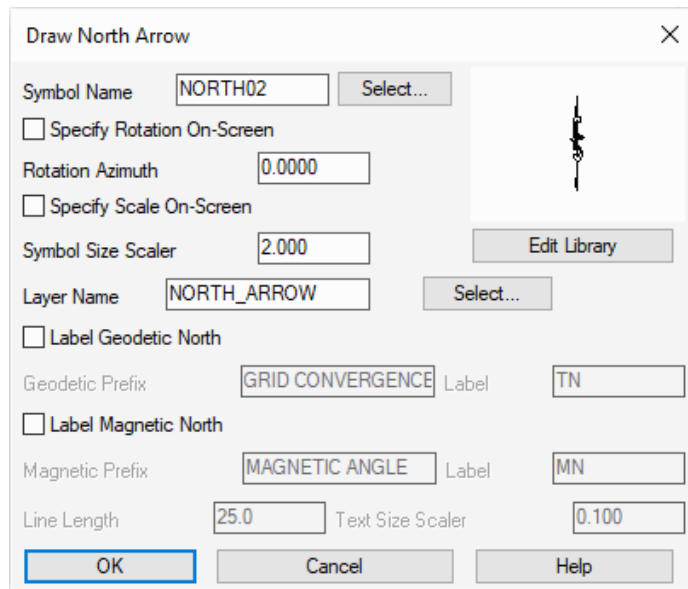

Next, run the Map – Bar Scale command to display the dialog box shown below:

Click **OK** when ready. When prompted:

Pick location for barscale: pick a desired location for the barscale

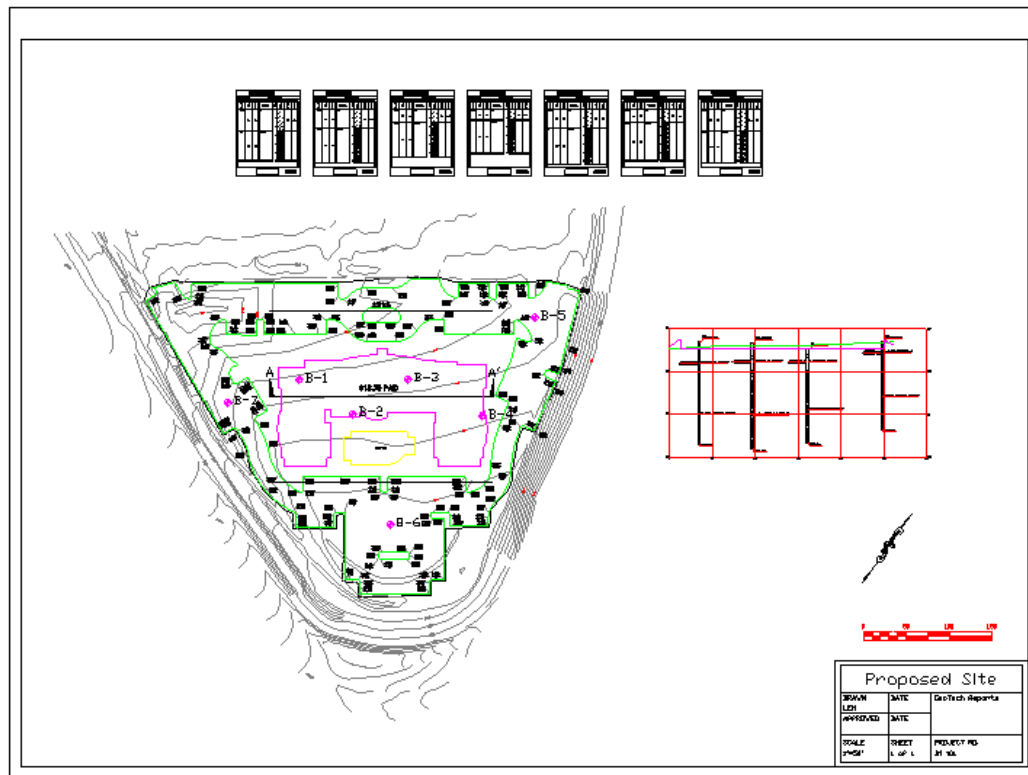

Next, run the Map – North Arrow command to display the dialog box shown below:

Click **OK** when ready. When prompted:

Pick insertion point: pick a desired location for the North arrow

When complete, your drawing could resemble that shown below:

This completes the tutorial: GeoTech Reports.

Cut Sheet

In this lesson you will create a Cut Sheet report for staking grade for a proposed parking lot. This tutorial utilizes the data limits of the Contouring, Break Lines and Stockpiles tutorial. Once opened, you will:

1. import a *LandXML* comprised of digital data content
2. draw a *centerline file* for spatial reference
3. draw a *polyline file* for additional spatial reference
4. offset the centerline "alignment" to establish a Back of Curb (BOC)
5. create stake-out points along the BOC but at existing ground elevations
6. create a cutsheet to compare the points against a design surface model

Let's get started.

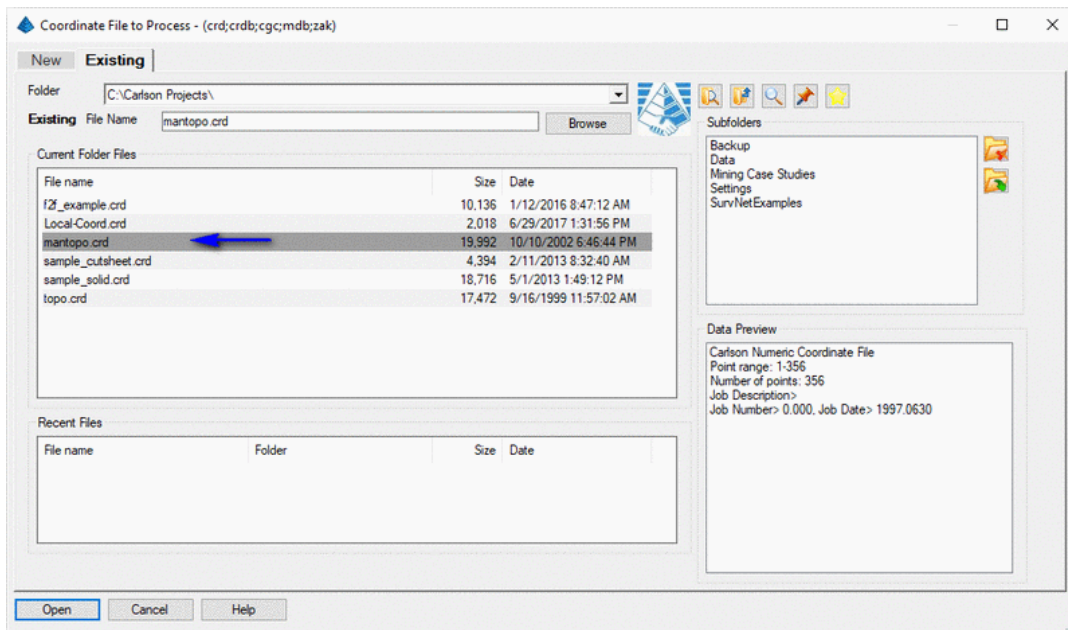

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Mantopo.dwg** file. Use the File – **Save As** to save a copy named **Mantopo-C.dwg**. Completing this tutorial will alter the drawing file and by renaming the file from the start, you'll keep the original file intact (allowing you to run through the tutorial a second time if desired). This is also a good practice to keep when working on drawings from 3rd parties.

2. Activate the Survey menu via Settings – Carlson Menus – **Survey Menu**. Your drawing may (should) resemble that shown below:

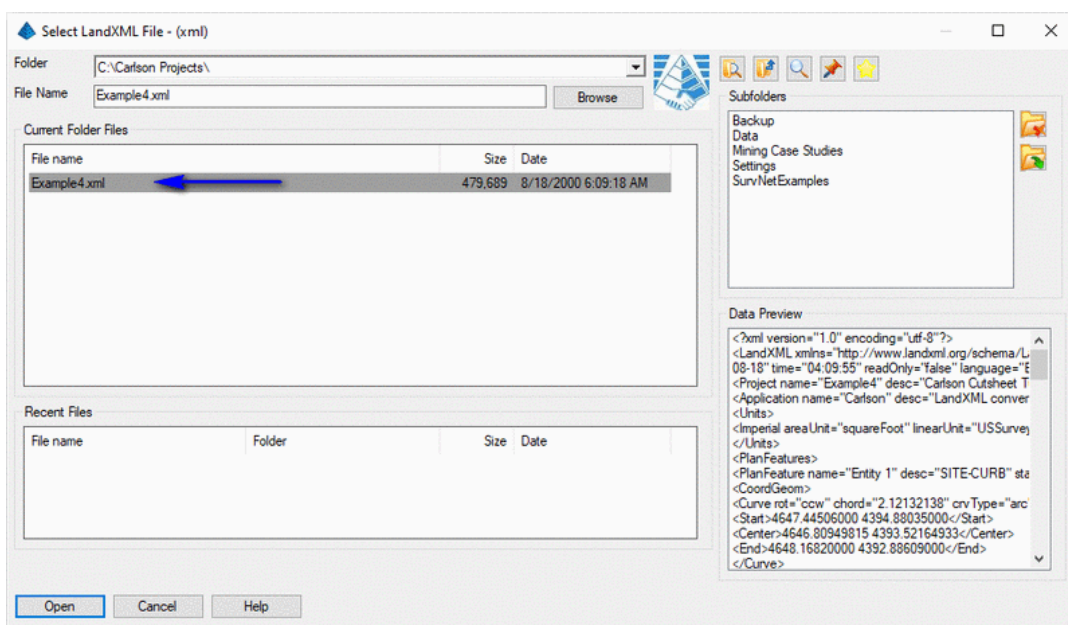

Issue the Points – Set Coordinate File command to display the following dialog box:

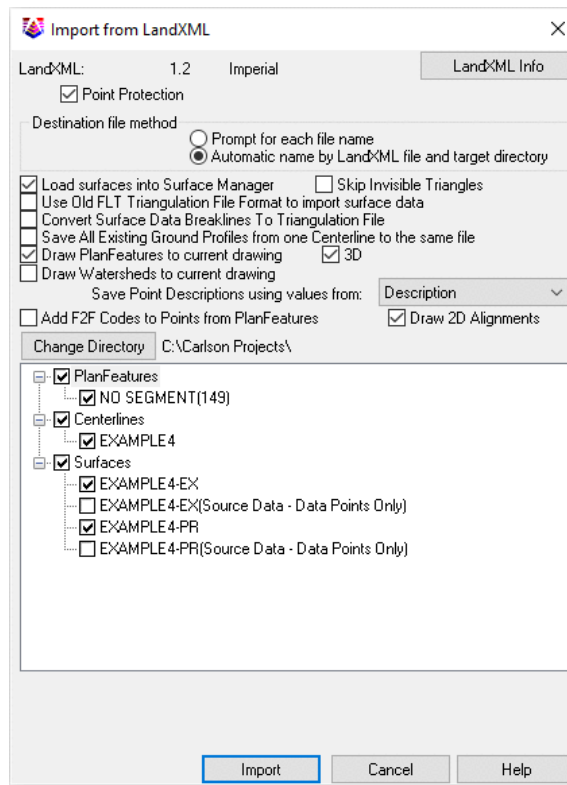

Select the file as shown above and click **Open** when ready.

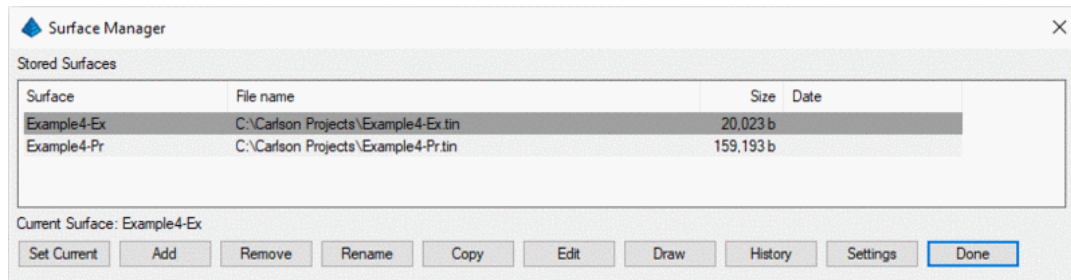

- For the content to follow, a LandXML file containing various pieces of design data will be used to complete this tutorial. Issue the File – Import – LandXML File to display the following dialog box:

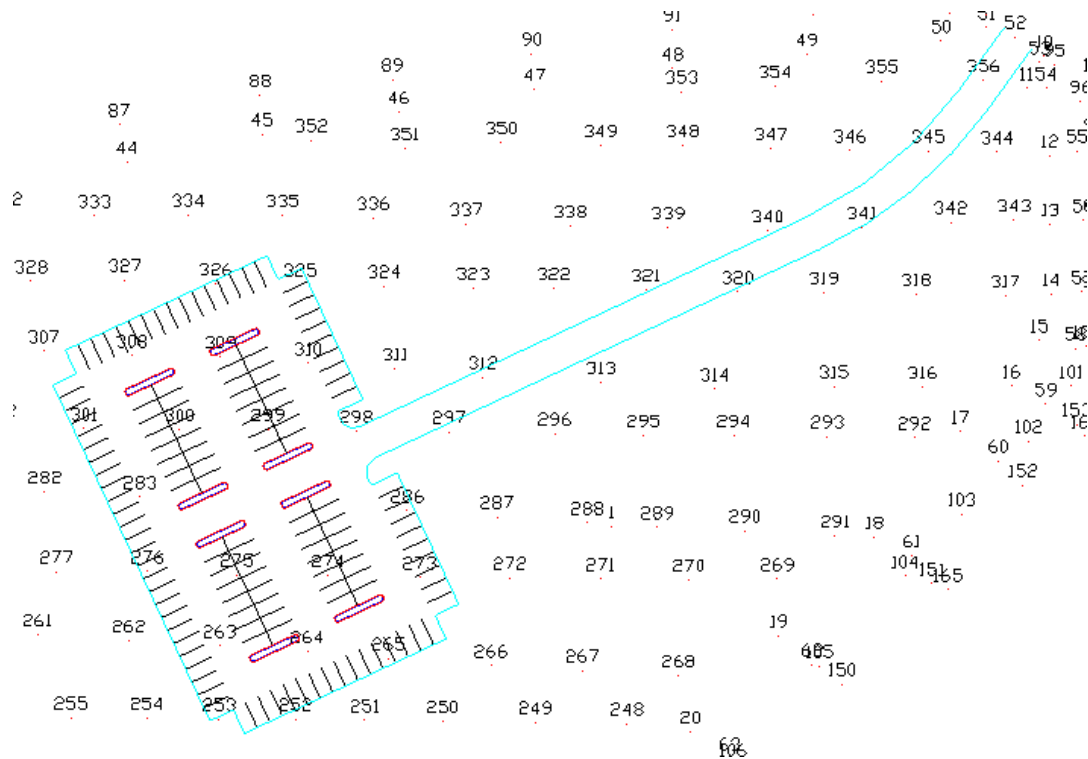

Select the file as shown above and click **Open** when ready. A secondary box similar to that shown below will appear:

Set the various options as shown above and click **Import** when ready. A summary of the surface model *TIN* files will appear in the Surface Manager similar to that shown below:

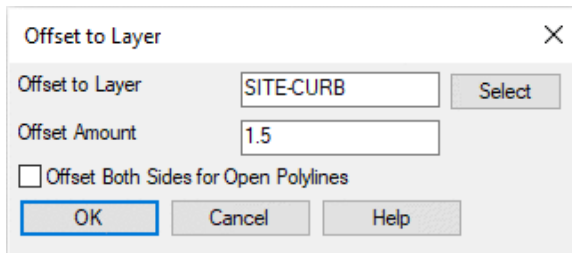

Click the **Done** button when ready. The drawing should resemble that shown below (layer colors and visibility altered for clarity):

The drawing contains a proposed parking lot with striping and curb islands. A closer examination will reveal that the entire length of the roadway and parking lot perimeter has been defined as a *centerline* (aka alignment, **Existing4.cl**) file as created by the Polyline to Centerline File command (e.g. double-clicking the perimeter should display the Centerline Editor command).

- Our next task will be to offset this alignment by 1.5' to simulate *back-of-curb* geometry. Issue the Edit – Offset – Offset to Layer command to display the dialog box below:

Set the values as shown above and click **OK** when ready. When prompted:

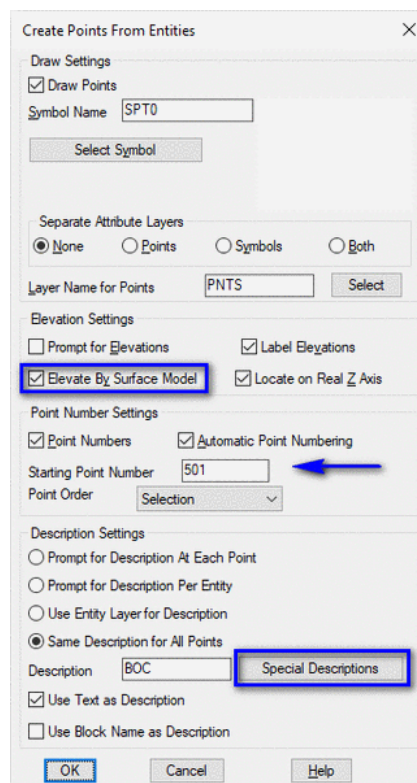

Select a polyline to offset: pick the perimeter polyline as shown below

Select side to offset: pick to the outside as shown below

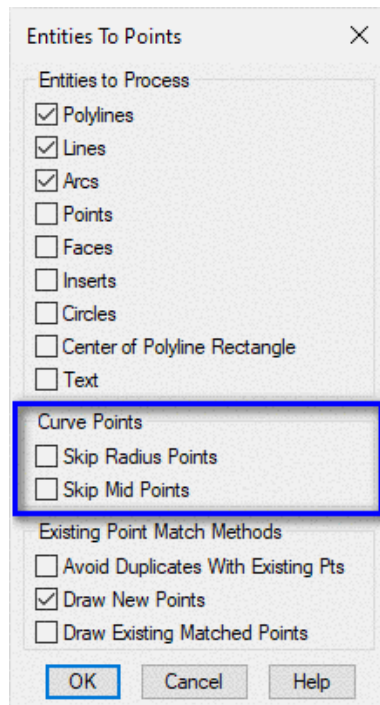

Select a polyline to offset (Enter to end): press Enter

- The next thing we'd like to do is locate stake-out points along the *Back-of-Curb* at important inflection points. Issue the COGO – Create Points from Entities command to display the dialog box below:

Set the values as shown above (making particular note of the highlighted items above) and click **OK** when ready. A secondary dialog box as shown below appears:

Set the values as shown above (making particular note of the highlighted items above) and click **OK** when ready. A dialog box prompting for the surface model use for the point elevation appears (similar to that shown below):

Select the surface model as indicated above and click **Open** when ready. When prompted:

Select arcs, circles, faces, points, text, lines and polylines.

[FILter]/<Select entities>: pick the **back-of-curb** polyline created in the previous step

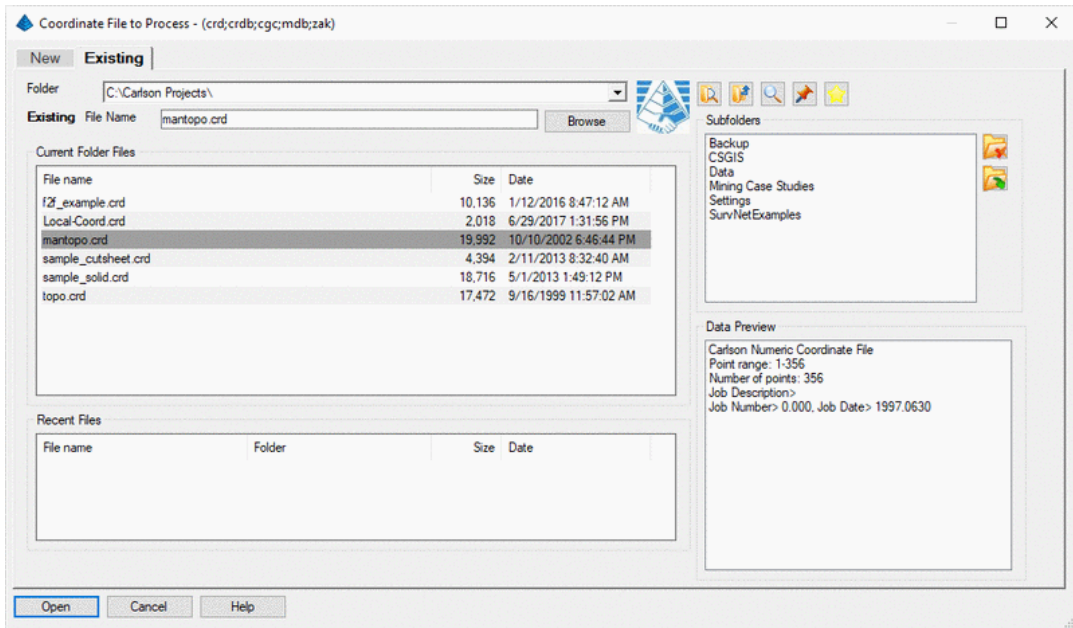

[FILter]/<Select entities>: press Enter

A collection of points is inserted into the drawing and at an elevation governed by the previously cited surface model.

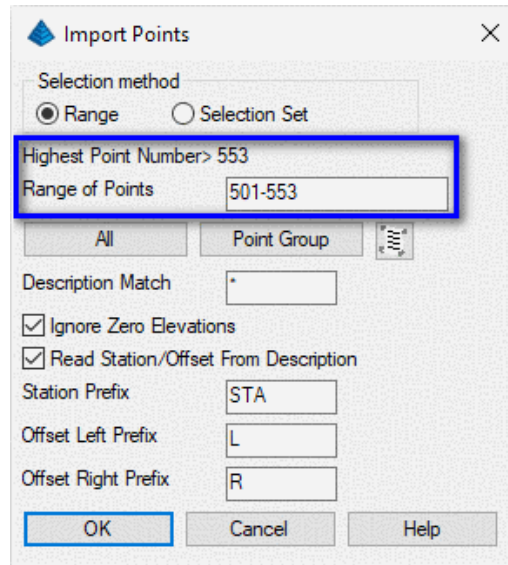

6. Issue the Survey – Cut Sheet command to display the dialog below:

- Click the Import – **Coordinate File** as illustrated above and when prompted for a coordinate file, select the file shown below and click **Open** when ready:

- A secondary dialog box appears similar to that shown below:

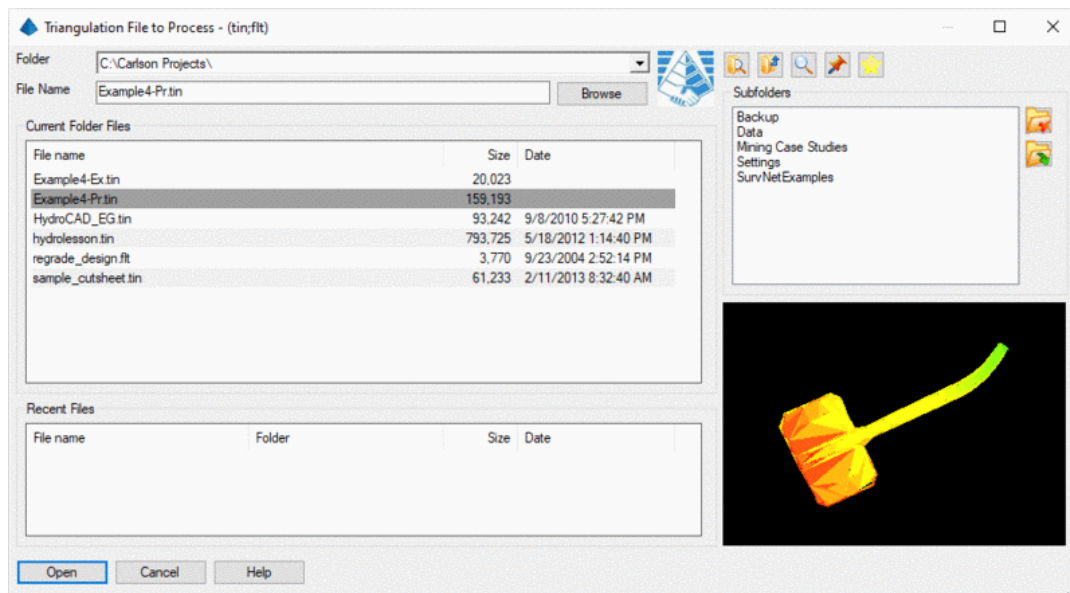

The coordinate file may have more data than we need (*i.e.* original ground points from an earlier lesson). Set the values as shown above, paying particular attention to the **Range** of points in the range of **501-553**. Click **OK** when ready. The **Cut Sheet Data** dialog box is populated with data similar to that shown below:

Point#	Description	Survey Z	Design Z	Cut/Fill	Station	Offset	Comment	Hz Error	Survey Northing	Survey Easting	Design Northing	Design Easting	Design Pt#	Design Desc
1	501 BOC	7.6089							4841.1399	4931.4045				
2	502 BOC PC	10.5818							4797.8752	4899.9818				
3	504 BOC MID	12.2363							4742.5712	4848.0103				
4	505 BOC PT	13.8053							4701.9972	4783.8752				
5	506 BOC	14.4081							4683.0379	4743.3803				
6	507 BOC PC	16.4646							4557.8698	4476.0839				
7	508 BOC RADPT 8.50	16.5773							4550.1732	4479.6911				
8	509 BOC MID	16.5298							4553.0650	4471.6982				
9	510 BOC PT	16.6231							4546.5664	4471.9943				

9. The next thing we'd like to do is bring in the target elevations for each of these points. Issue the Grade – **Triangulation File** command (but note the additional methods of determining the proposed grades) as illustrated below:

When prompted, select the triangulation (TIN) file cited below and click **Open** when ready:

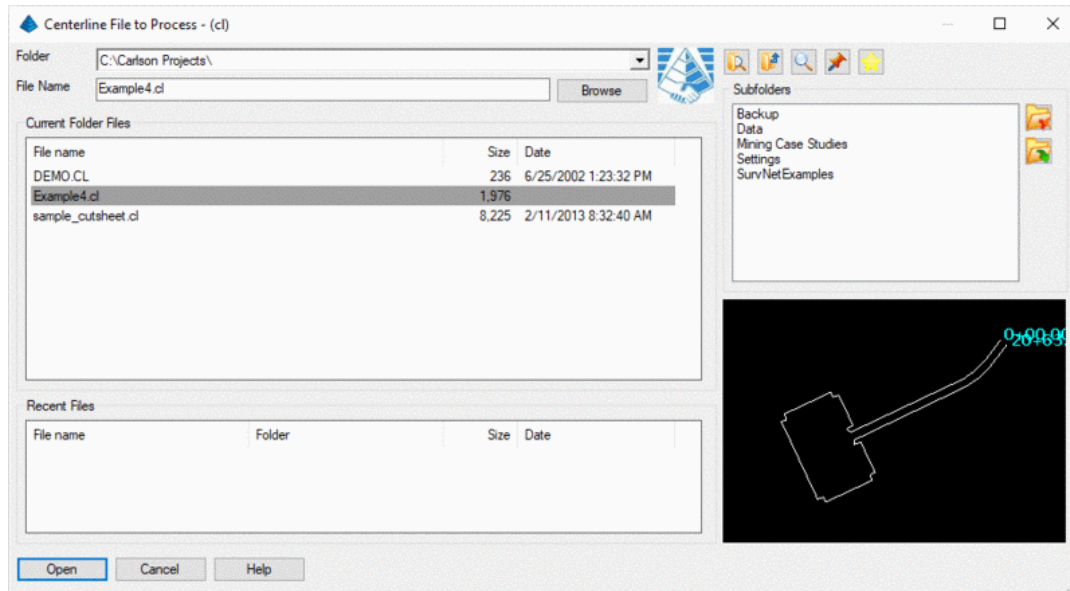

This process will select a design surface model for the proposed grades. The **Design Z** elevation field is populated from the proposed TIN and the **Cut/Fill** amount per point is calculated as illustrated below:

Point#	Description	Survey Z	Design Z	Cut/Fill	Station	Offset	Comment	Hz Error	Survey Northing	Survey Easting	Design Northing	Design Easting	Design Pt#	Design Desc
1	501 BOC	7.6089							4841.1399	4931.4045				
2	502 BOC PC	10.5818	8.9270	C1.655*					4797.8752	4899.9818				
3	504 BOC MID	12.2363	9.7978	C2.438*					4742.5712	4848.0103				
4	505 BOC PT	13.8053	10.6408	C3.165*					4701.9972	4783.8752				
5	506 BOC	14.4081	11.1468	C3.261*					4683.0379	4743.3803				
6	507 BOC PC	16.4646	14.4870	C1.978*					4557.8698	4476.0839				
7	508 BOC RADPT 8.50	16.5773	16.3361	C0.241*					4550.1732	4479.6911				
8	509 BOC MID	16.5298	14.5756	C1.954*					4553.0650	4471.6982				
9	510 BOC PT	16.6231	14.6647	C1.958*					4546.5664	4471.9943				

10. The next piece of information we would like to obtain is an alignment from which Station/Offset information can be derived. Issue the Centerline – **Centerline File** command as illustrated below:

Point#	Descrip	Polyline	Cut/Fill	Station	Offset	Comment	Hx Error	Survey Northing	Survey Easting	Design Northing	Design Easting	Design Pt#	Design Desc
1	501	BOC						4841.1399	4931.4045				
2	502	BOC PC	10.5818 8.9270	C1.655*				4797.8752	4899.9818				
3	504	BOC MID	12.2363 9.7978	C2.438*				4742.5712	4848.0103				
4	505	BOC PT	13.8053 10.6408	C3.165*				4701.9972	4783.8752				
5	506	BOC	14.4081 11.1468	C3.261*				4683.0379	4743.3803				
6	507	BOC PC	16.4646 14.4870	C1.978*				4557.8698	4476.0839				
7	508	BOC RADPT 8.50	16.5773 16.3361	C0.241*				4550.1732	4479.6911				
8	509	BOC MID	16.5298 14.5756	C1.954*				4553.0650	4471.6982				
9	510	BOC PT	16.6231 14.6647	C1.958*				4546.5664	4471.9943				

When prompted, select the centerline (*.cl) file shown below and click **Open** when ready:

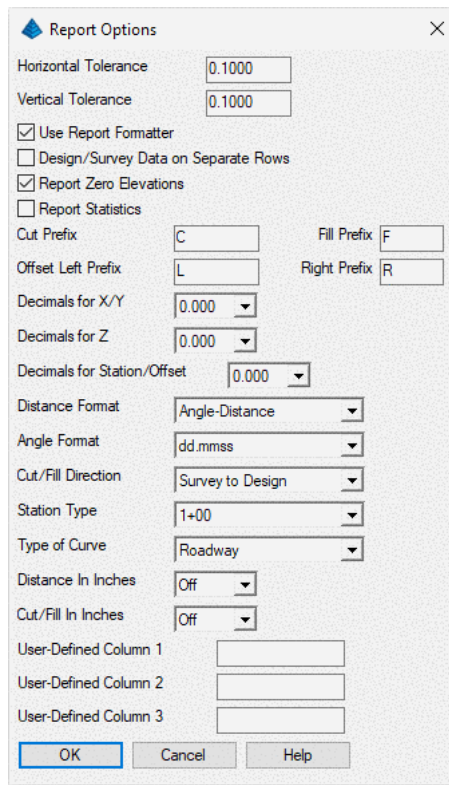

The Cut Sheet now contains the station and offset information for the curb line as illustrated below:

Point#	Description	Survey Z	Design Z	Cut/Fill	Station	Offset	Comment	Hx Error	Survey Northing	Survey Easting	Design Northing	Design Easting	Design Pt#	Design Desc
1	501	BOC	7.6089		2063.831	1.5000			4841.1399	4931.4045				
2	502	BOC PC	10.5818 8.9270	C1.655*	2010.36	1.5000			4797.8752	4899.9818				
3	504	BOC MID	12.2363 9.7978	C2.438*	1934.64	1.5000			4742.5712	4848.0103				
4	505	BOC PT	13.8053 10.6408	C3.165*	1858.93	1.5000			4701.9972	4783.8752				
5	506	BOC	14.4081 11.1468	C3.261*	1814.22	1.5000			4683.0379	4743.3803				
6	507	BOC PC	16.4646 14.4870	C1.978*	1519.06	1.5000			4557.8698	4476.0839				
7	508	BOC RADPT 8.50	16.5773 16.3361	C0.241*	1488.21	6.0000			4550.1732	4479.6911				
8	509	BOC MID	16.5298 14.5756	C1.954*	1511.21	1.5000			4553.0650	4471.6982				
9	510	BOC PT	16.6231 14.6647	C1.958*	1503.36	1.5000			4546.5664	4471.9943				

- Our next task will be to configure the content of the *Cut Sheet Report* we'd like to generate. Issue the Report – **Report Settings** command as illustrated below:

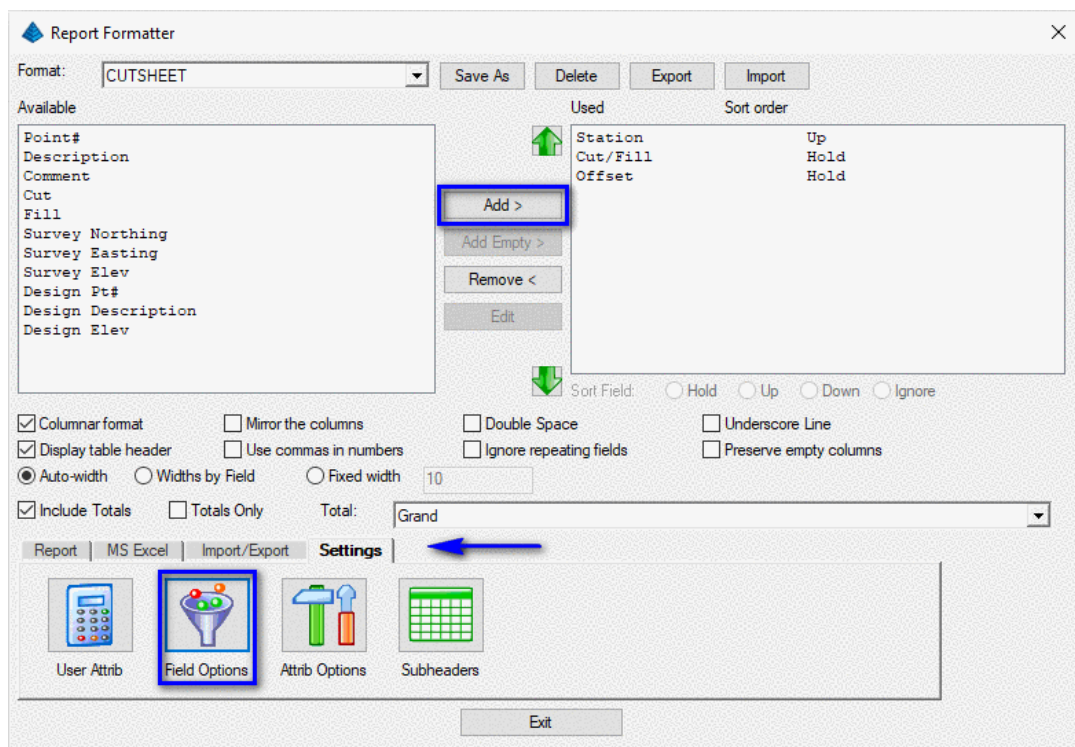

The **Report Options** dialog box appears permitting the eventual report to be customized:

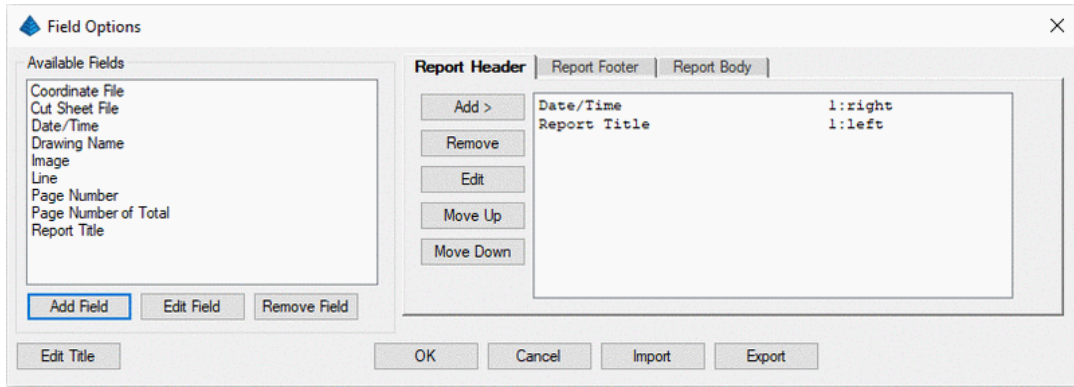

Ensure the **Report Options** are set as shown above and click **OK** when ready.

- Let's create the report. Issue the Report – **Create Report** command to display the Report Formatter dialog box similar to that shown below:

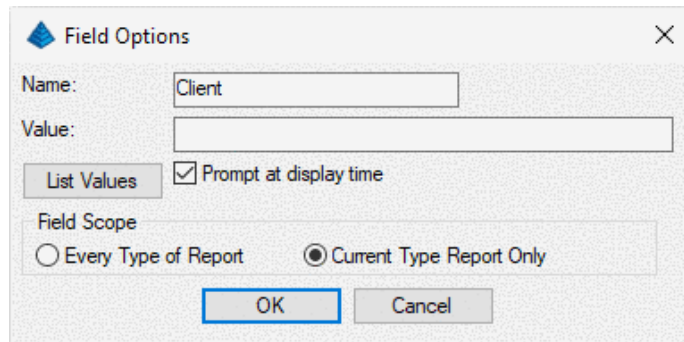

Select the desired **Available** fields on the left and click **Add >** to move them to the **Used** fields on the right. For this lesson, just select **Station** (sorted *Up*), **Offset** and **Cut/Fill** to create a simple cut/fill report.

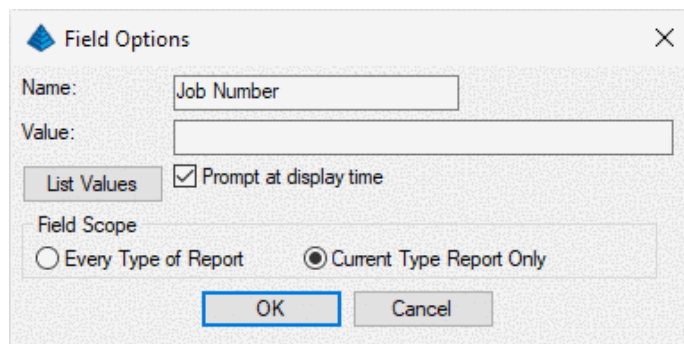

- Click the **Settings** tab as seen above and click **Field Options** button to display the **Field Options** dialog box as shown below:

14. To create *user-defined* additional fields to include in the report, click the **Add Field** button and set the values as shown below. Click **OK** when ready:

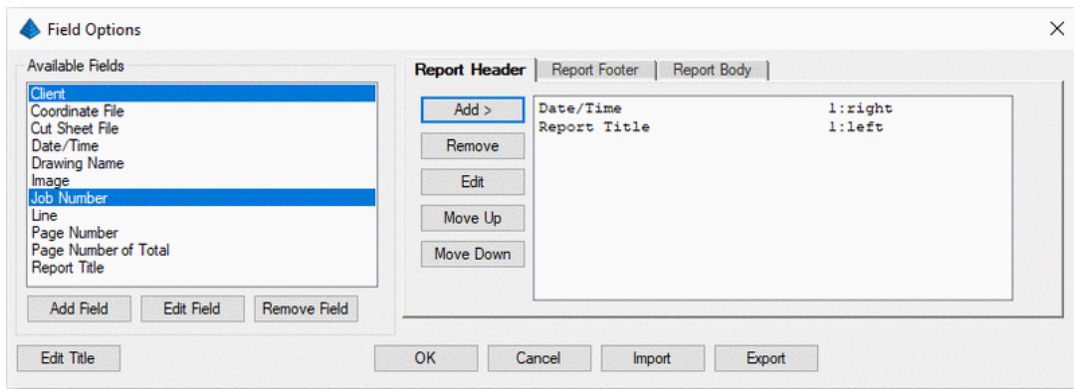

This new *user-defined* field is added to the list of **Available Fields**. Click the **Add Field** button again to set the values as shown below and click **OK** when ready:

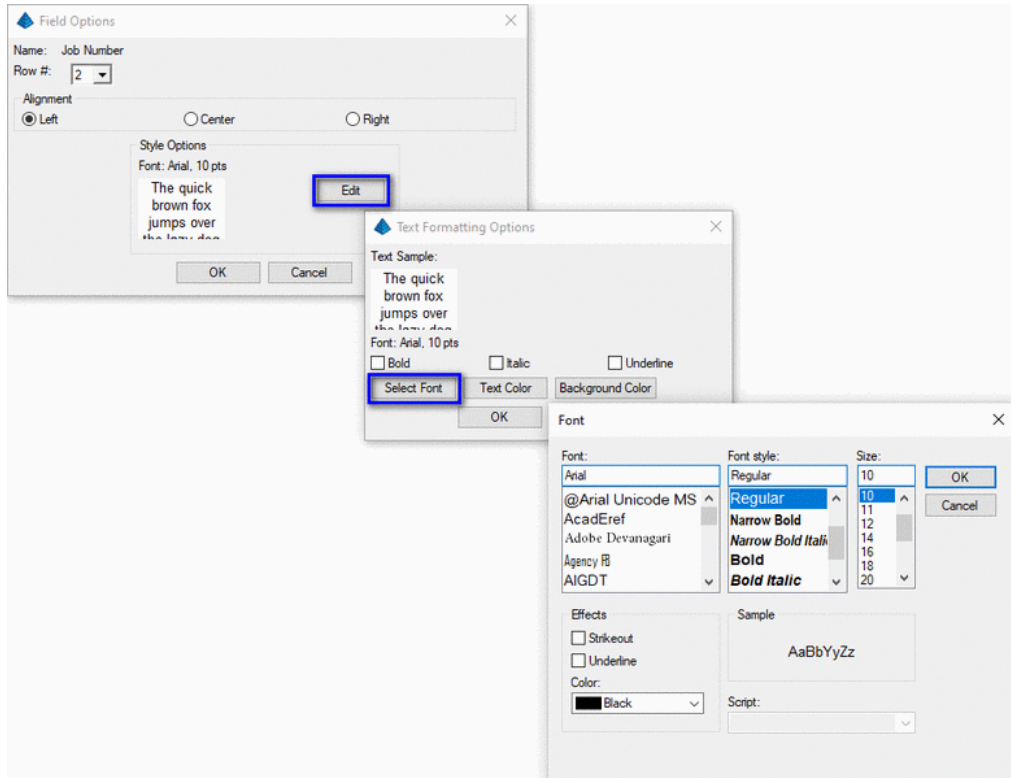

NOTE: Make sure to enable the **Prompt at display time** toggle. This will cause the program to pause for user input at the time of creating the report.

15. Select the two new fields and click the **Add >** button to add them to the **Report Header** tab as illustrated below:

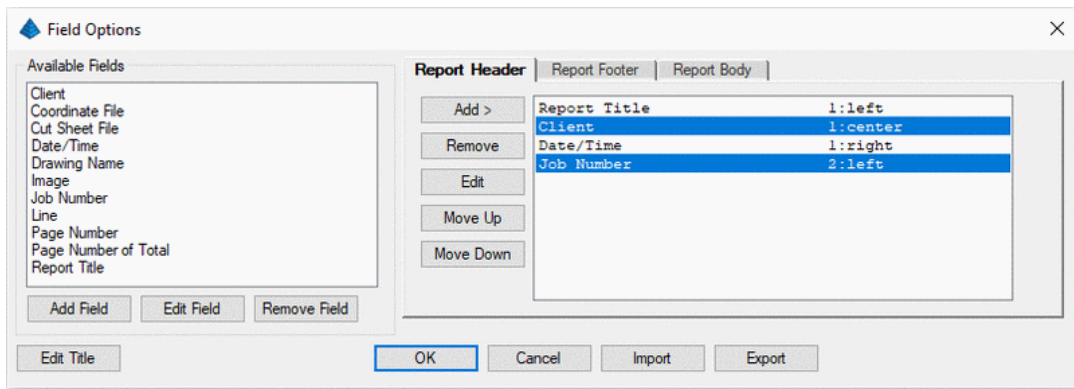

When the fields are moved, you will be prompted to select various format options as illustrated below:

16. Set the following fields:

- **Client** to:
 - Row #1
 - Center justified
 - Bold Font
 - 14 pt text size
- **Job Number** to:
 - Row #2
 - Left justified
 - Regular Font
 - 10 pt text size

The result should look similar to that shown below:

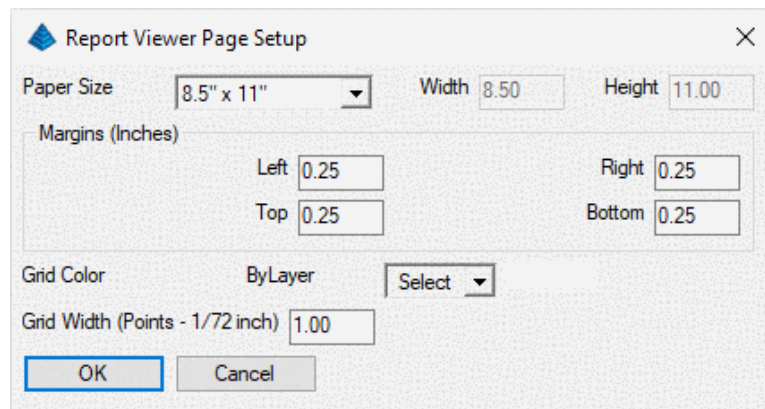

Click **OK** when ready.

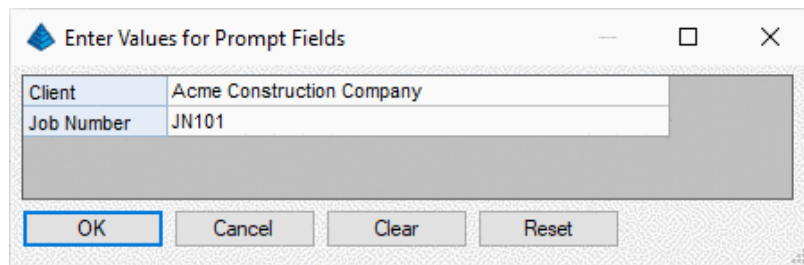

17. Select the **Report** tab and click on the **Report Viewer** button as shown below:

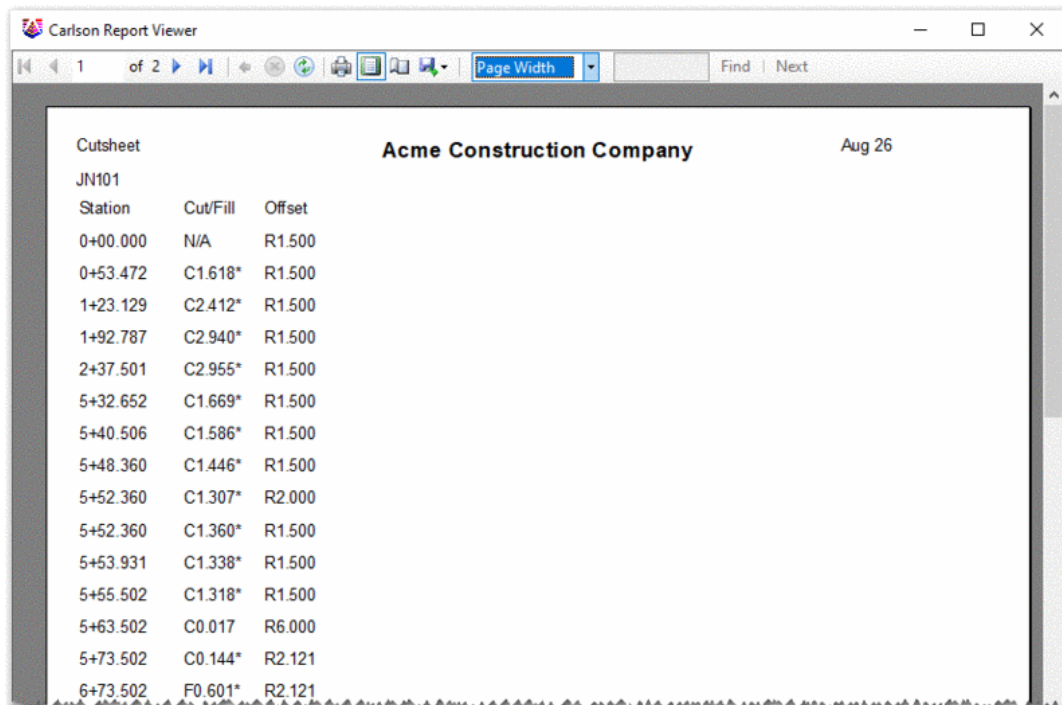

Select an **8.5" x 11"** paper size with **0.25"** margins all around as shown below and click **OK** when ready:

18. When prompted for the values of the *user-defined* fields, set the values as shown below and click **OK** when ready:

The resulting report is displayed similar to that shown below which can be printed or exported to various formats:

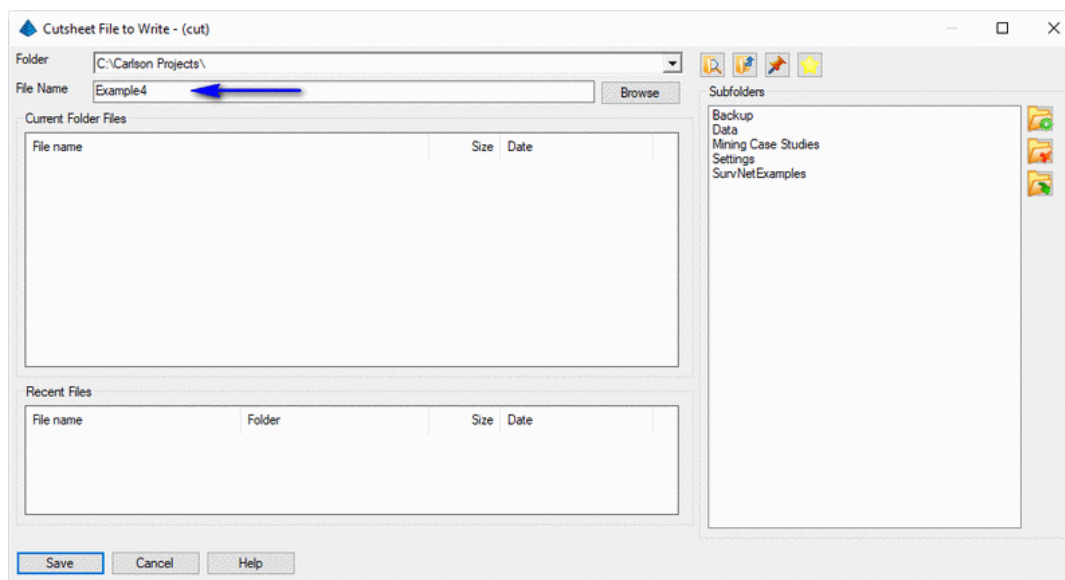

19. Close the report to return to the **Report Formatter** dialog box as shown below:

NOTE: The above process can be repeated for any number of fields and exported as a *.FMS file for future use or to develop company or client report standards. Click the **Exit** button to dismiss the *Report Formatter* dialog box.

20. Back in the main *Cut Sheet Data* spreadsheet editor, click File – **Save** and save the file as shown below and click the **Save** button when ready:

Click File – **Exit** to close the command.

This completes the tutorial: Cut Sheet.

Geodetic Reports

In this lesson you will create a geodetic report containing both local and Grid coordinates from a survey based on an assumed local datum. The plan geometry will be annotated with both ground and grid distances. This is useful when a survey has been performed with assumed coordinates and elevations but must be reported in Grid coordinates or in instances where both ground and grid coordinates need to be reported.

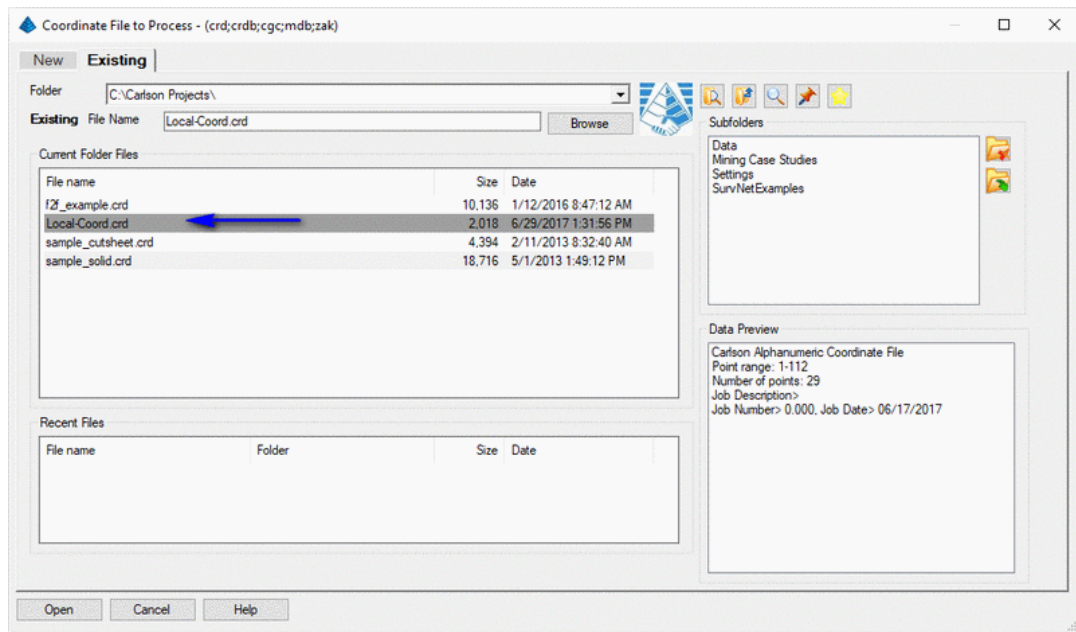

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **Local-Plat.DWG** file.

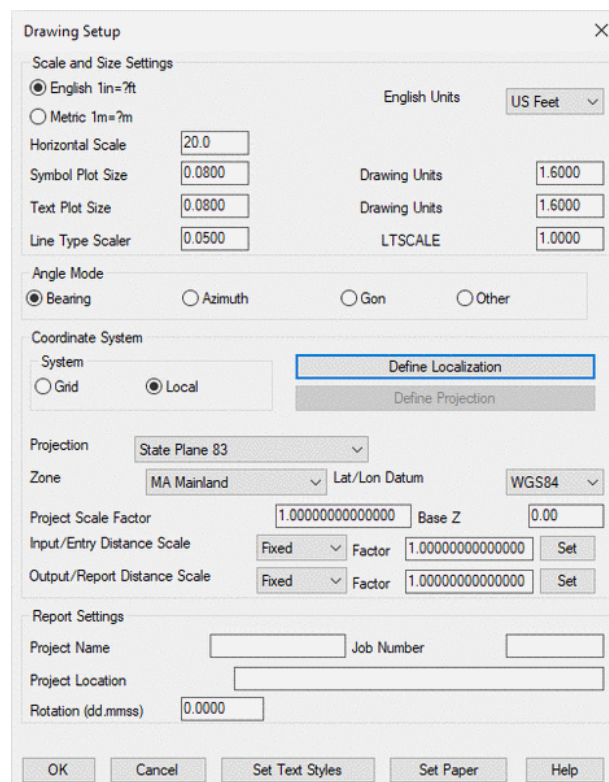

2. Activate the Survey menu via Settings – Carlson Menus – **Survey Menu**. Your drawing should resemble that shown below:

3. Issue the Points – Set Coordinate File command and select the supplied file **Local-Coord.CRD** as shown below:

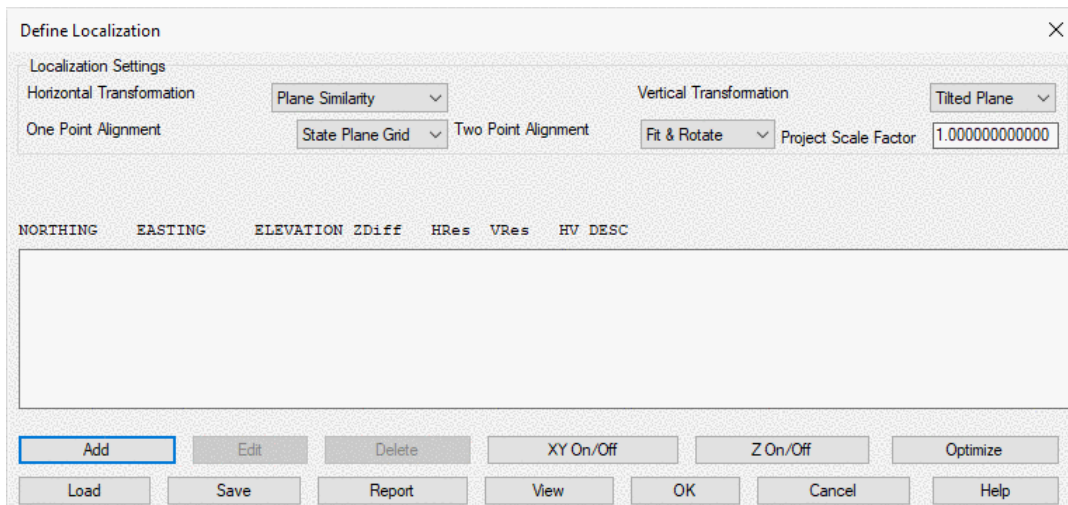

4. Issue the Settings – Drawing Setup command to display a dialog box similar to that shown below:

Set the:

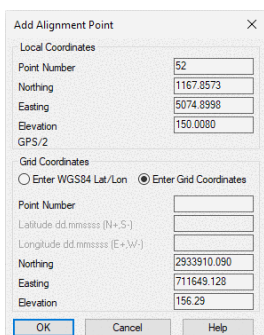

- (a) **Projection** to **State Plane 83**, and
- (b) **Zone** to **MA Mainland**.

5. Click the **Define Localization** button to display a dialog box similar to that shown below:

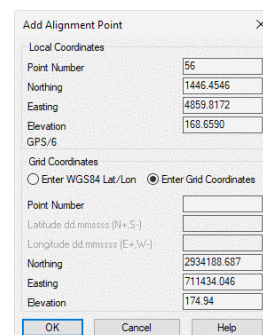

6. We'd like to localize the drawing based on two RTK GPS points that were located to establish grid coordinates. We'll be using points **52** and **56**. Click the **Add** button to display a dialog box similar to those shown below:

Point 52

Point 56

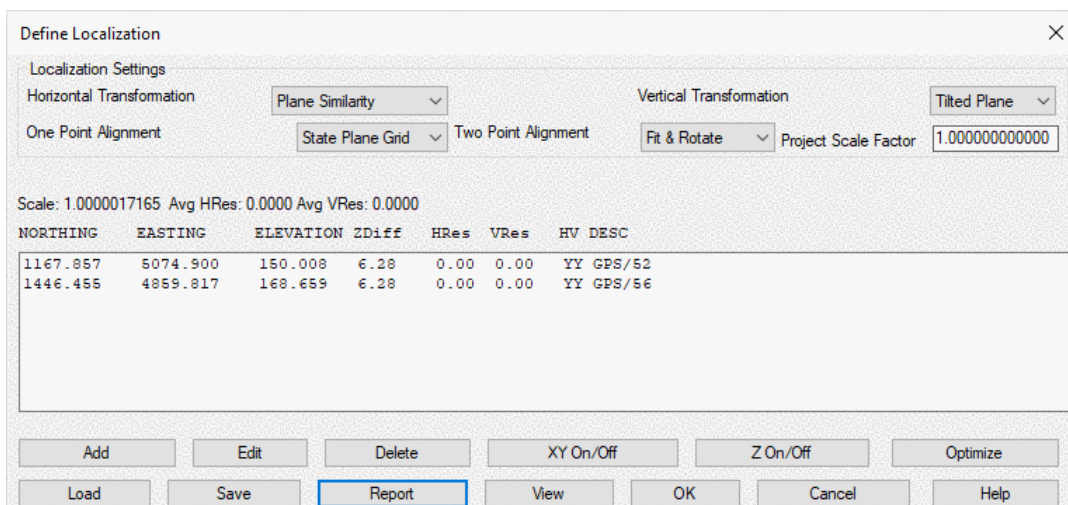

Localized Points

Add the point and coordinate information for each point by entering the **Local Point Number** (press the *Tab* key to complete the Local data) and their respective **Grid Coordinates** as outlined in the table below (click **OK** when ready and subsequently click **OK** to accept the default point descriptions):

Point Number	Local Northing	Local Easting	Local Elevation	Grid Northing	Grid Easting	Grid Elevation
52	1167.8573	5074.8998	150.0080	2933910.090	711649.128	156.29
56	1446.4546	4859.8172	168.6590	2934188.687	711434.046	174.94

Localized Point Data

7. The results should resemble that shown below:

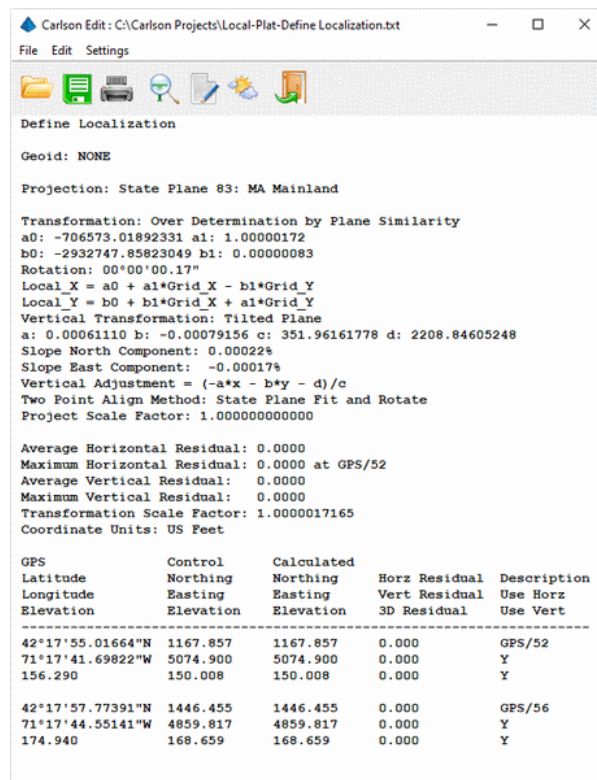

NOTE: For each point, make sure the **HV** (Horizontal/Vertical) fields are set to **YY** (indicating *Yes*, both the Horizontal and Vertical components should be used in the solution). Use the **XY On/Off** button and/or the **Z On/Off** button as necessary.

- Click the **Report** button to display the dialog box below:

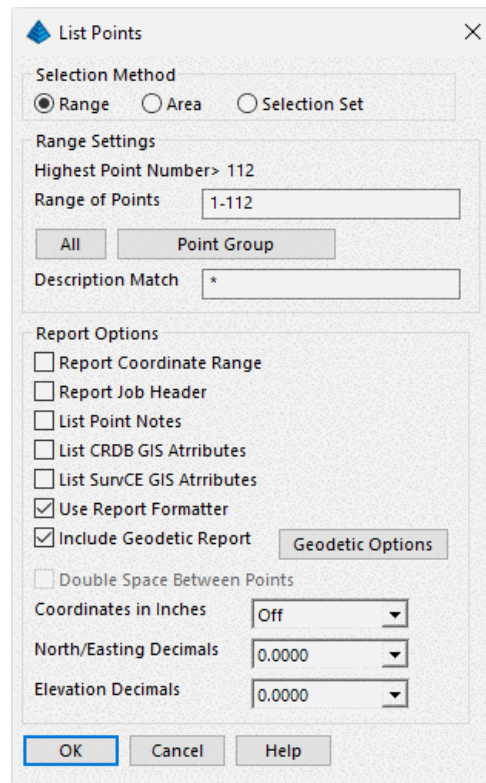

Ensure all of the report options are enabled and click **OK**. The localization report similar to that shown below is displayed in the Standard Report Viewer:

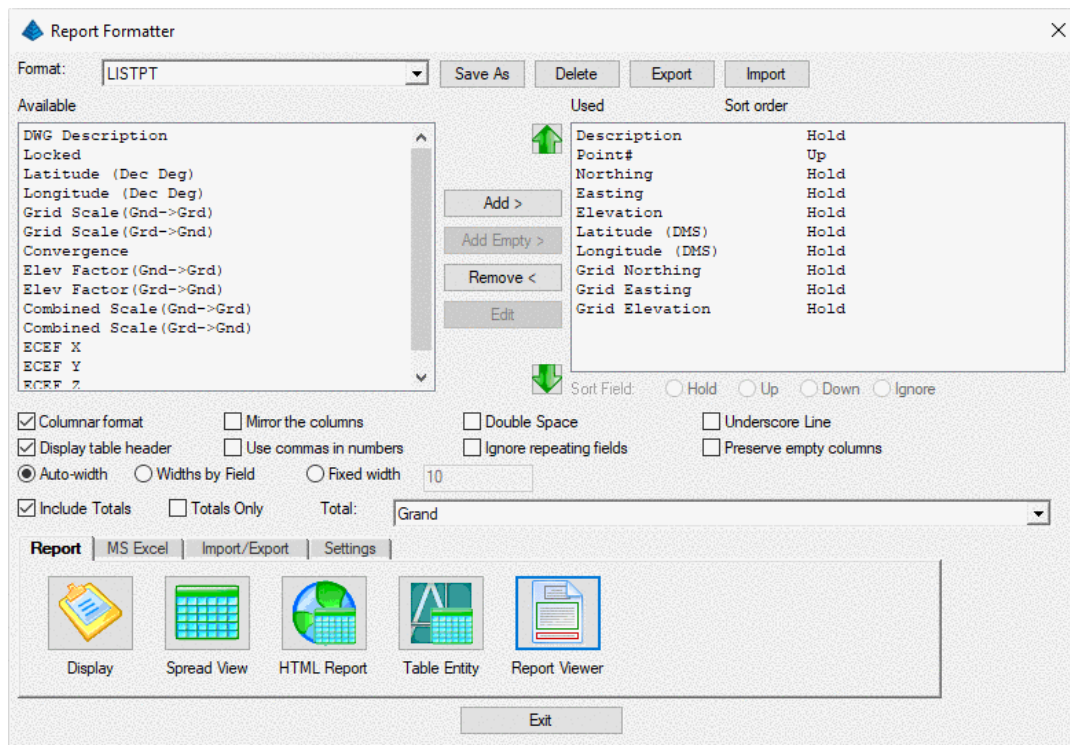

Click the **Exit** (Doorway) button to dismiss the report. Further, click the **OK** button on the *Define Localization* and *Drawing Setup* dialog boxes, respectively.

- Issue the Points – List Points command to display the dialog box similar to that shown below:

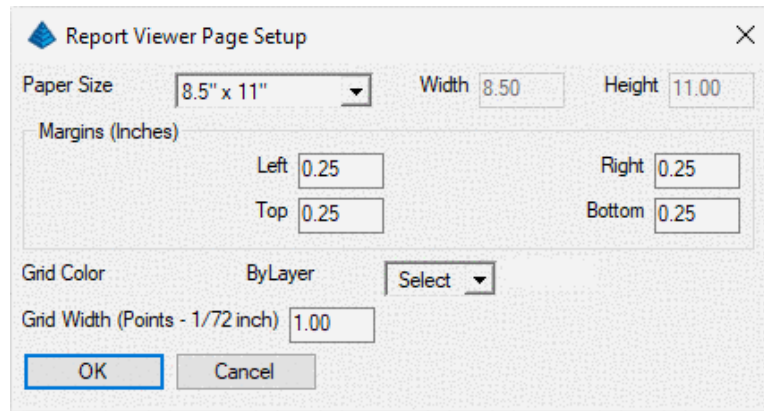

Enable the **Use Report Formatter** and **Include Geodetic Report** options and click **OK** when ready.
 10. The Report Formatter dialog box appears similar to that shown below:

Select the desired **Available** fields on the left and click **Add >** to move them to the **Used** fields on the right. Set the fields to that shown above.

11. From the **Report** tab, click on the **Report Viewer** button. Select an **8.5" x 11"** paper size with **0.25"** margins all around as shown below and click **OK** when ready:

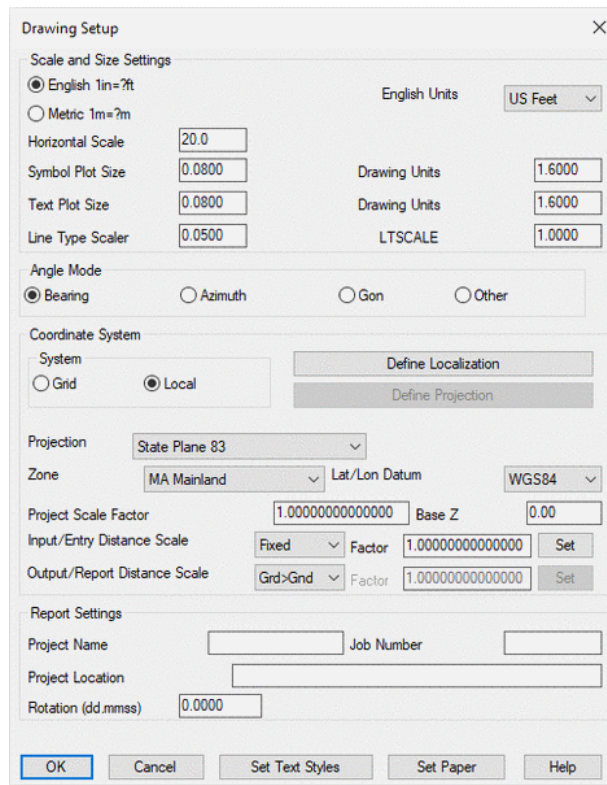

The resulting report is displayed similar to that shown below which can be printed or exported to various formats:

Description	Point#	Northing	Easting	Elevation	Latitude (DMS)	Longitude (DMS)	Grid Northing	Grid Easting	Grid Elevation
MNS	1	1000.0000	5000.0000	154.2940	N42°17'53.36"	W71°17'42.70"	2933742.2331	711574.2282	160.5762
MNS	2	1167.8269	5074.8863	150.0289	N42°17'55.02"	W71°17'41.70"	2933910.0596	711649.1145	156.3109
MNS	3	1333.8035	4915.3038	164.0529	N42°17'55.66"	W71°17'43.82"	2934076.0360	711489.5324	170.3343
SPKS	4	1207.9257	4765.4906	183.2189	N42°17'55.42"	W71°17'45.81"	2933950.1586	711339.7194	189.5003
MNS	5	1161.3941	4926.7535	162.2223	N42°17'54.96"	W71°17'43.67"	2933903.6269	711500.9820	168.5041
MNS	6	1446.5046	4859.8772	168.5987	N42°17'57.77"	W71°17'44.55"	2934188.7370	711434.1060	174.8797
CHK1	11	1000.0037	4999.9885	154.2903	N42°17'53.36"	W71°17'42.70"	2933742.2367	711574.2167	160.5725
CHK5	15	1161.3935	4926.7549	162.2113	N42°17'54.96"	W71°17'43.67"	2933903.6263	711500.9833	168.4931

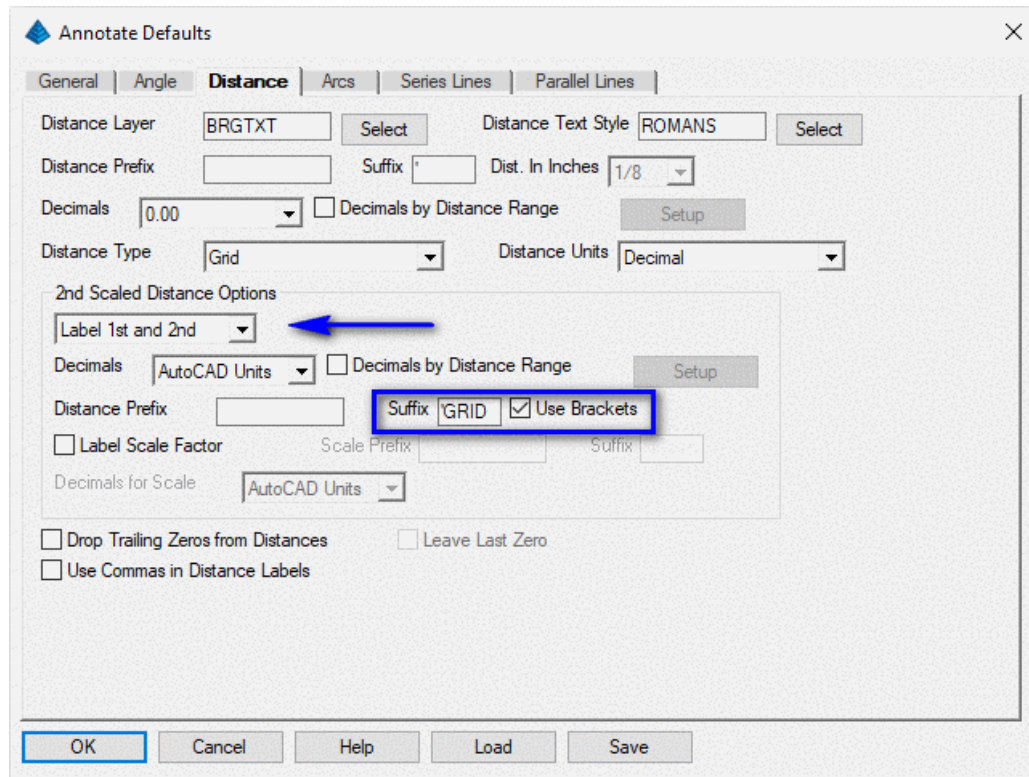

Both local and grid coordinates are displayed.

NOTE: To further control the report by adding user-defined fields, customized Headers and Subheaders, Fonts *etc.*, refer to the Cut Sheet tutorial.

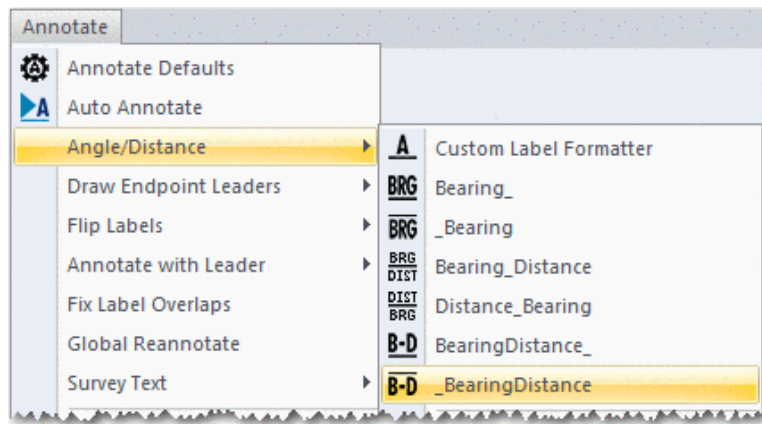

12. Close the report to return to the **Report Formatter** dialog box. Click the **Exit** button to dismiss the *Report Formatter* dialog box.
13. Re-run the Settings – Drawing Setup as discussed earlier:

- Set the **Report Distance Scale** option to **Gnd>Grd** for ground to grid distances and click **OK** when ready.
- Issue the Annotate – Annotate Defaults command to display the dialog box similar to that shown below:

- In the *Distance* tab, set the **2nd Scaled Distance Options** to **Label 1st and 2nd**. Also, set the **Suffix** to **'GRID** and enable the **Use Brackets** option. Click **OK** when ready.
- Issue the Annotate – Annotate Defaults – **_BearingDistance** command:

When prompted:

Select line or polyline [Size/Points]: select the most northerly property line of the parcel

Select line or polyline [Size/Points] (Enter to end): press Enter

Both the ground distance and the projected scaled distance are labeled as shown below (layer visibility altered for clarity):

This completes the tutorial: Geodetic Reports.

Pressure Pipe Network Design

In this tutorial, we'll design the features and pipes for a pressure pipe network and analyze the flow for the site and ultimately prepare an input file for EPANet (Application for Modeling Drinking Water Distribution Systems).

1. Click the Windows desktop icon for Carlson to start the program.
 - If you get the Start Page, pick **Open Files**.
 - If you get the Startup Wizard dialog box, click the **Browse** button.
 - If you are taken directly into CAD, click File – **Open**.

Browse/navigate to the default folder location of **C:\Carlson Projects** and open the **PressurePipeExample.dwg** file.

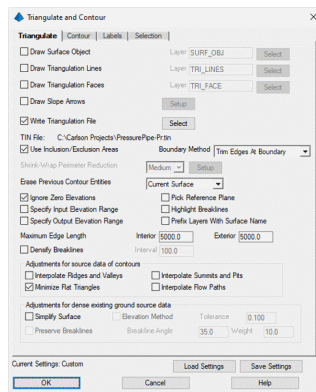

2. Activate the Hydrology menu via Settings – Carlson Menus – **Hydrology Menu**. Your drawing should resemble that shown below:

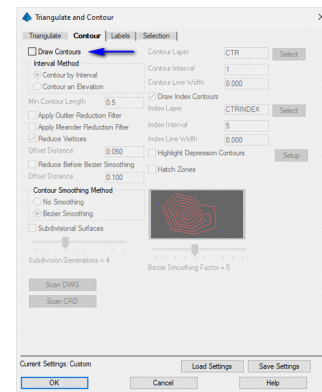

This project contains a series of polylines that represents the pressure pipe network we are designing.

3. The drawing entities for the design surface that we will use to model drainage have already been prepared. These entities consist of design contours. Issue the Surface – Triangulate & Contour command to display a dialog box similar to that shown below:

Triangulate Tab

Contour Tab

Triangulate & Contour

NOTE: Use the **Select** button on the *Triangulate* to create an output TIN file as illustrated above. Once set, click the **OK** button and when prompted:

Select Inclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: pick the boundary polyline

[FILter]/<Select entities>: press Enter

Select Exclusion perimeter polylines or ENTER for none.

[FILter]/<Select entities>: press Enter

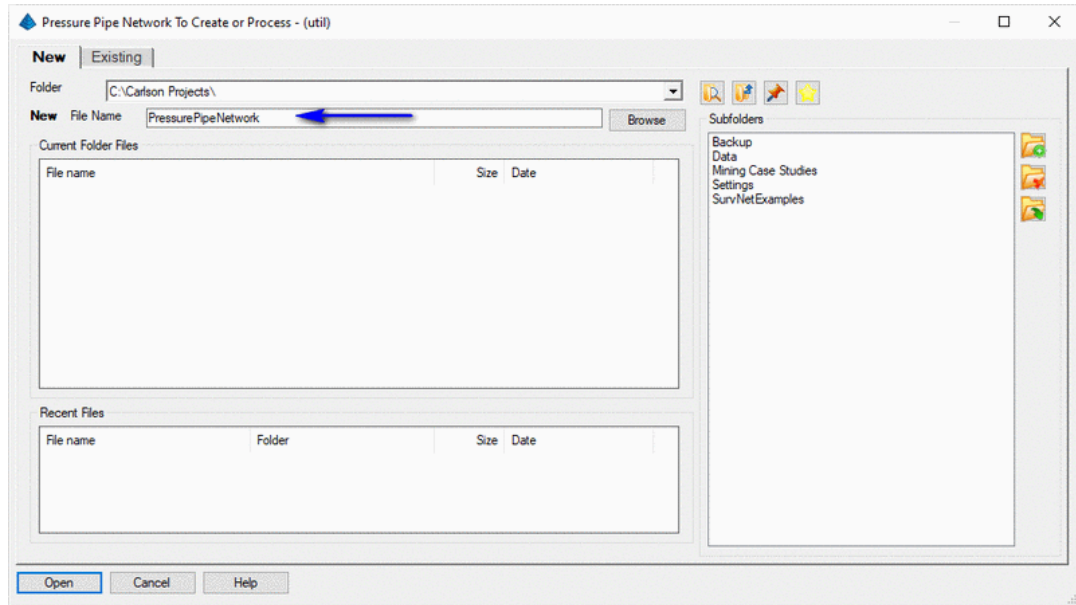

Select points and breaklines to Triangulate.

[FILter]/<Select entities>: type ALL and press Enter

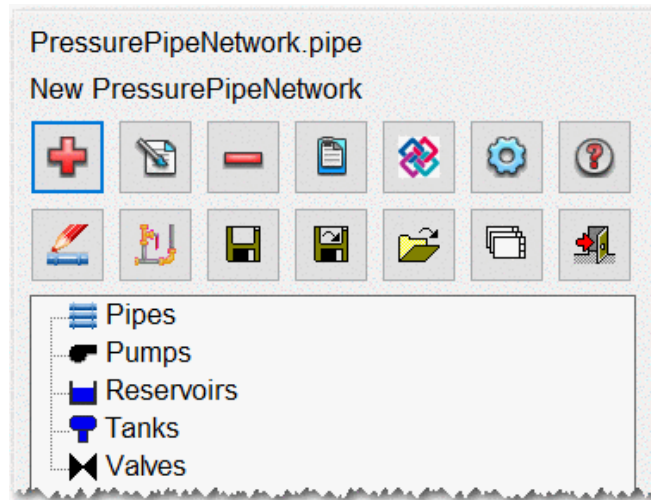

[FILter]/<Select entities>: press Enter

The surface representing proposed conditions is written.

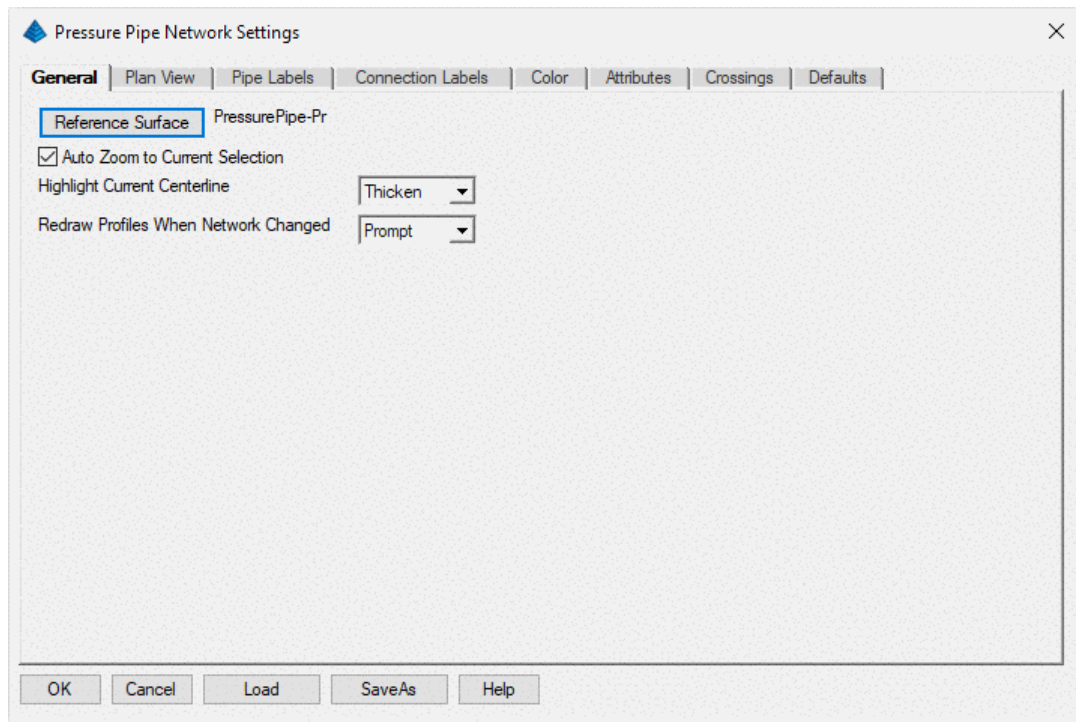

- Let's create a pressure pipe network file from the geometry presented. Issue the Network – Pressure Pipe Network command to display a dialog box similar to that shown below:

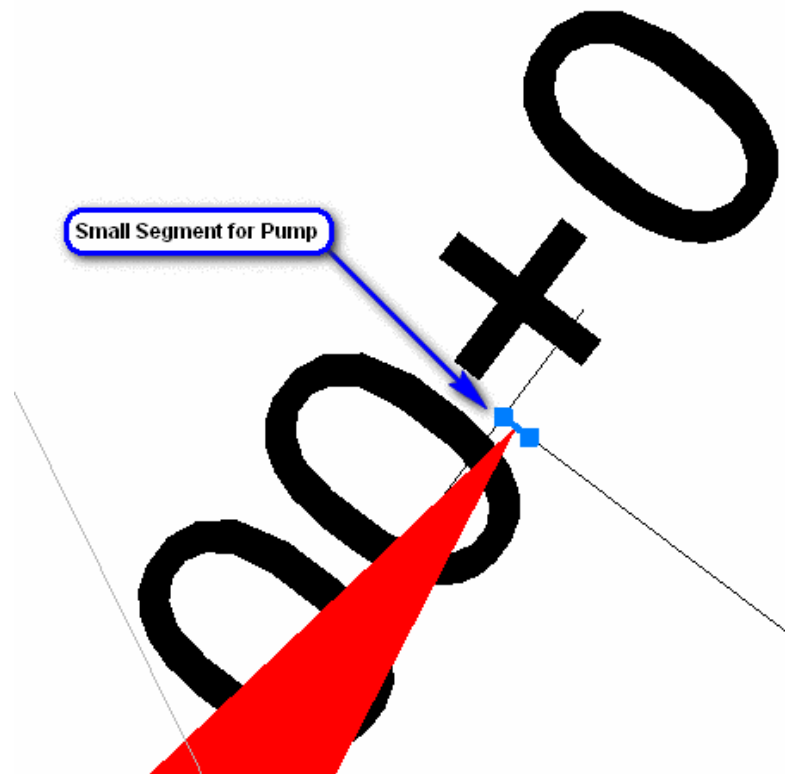

Set the file name as illustrated above and click the **Open** button to display a "docked" dialog box as shown below:

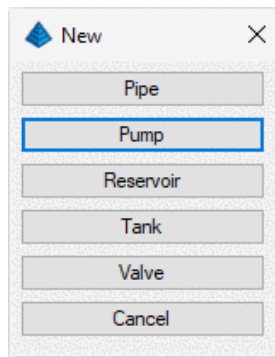

- We'd like to establish some initial, default settings for the project. Click the **Settings** (Gear) button to display a dialog box similar to that shown below:

- Click the **Reference Surface** button to select the TIN file created earlier and then click the **OK** button.
6. For this example, zoom in to the upper left start of the pipe run so that we can select a small segment for our pump. The display should look like the following:

Click the **Add** (Plus) button from the *Network Actions* row to display a dialog box similar to that shown below:

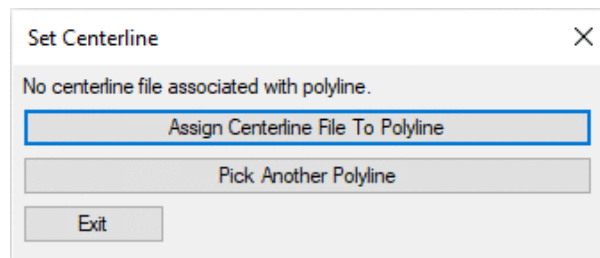

To create a new pump, click the **Pump** button and the following dialog will appear:

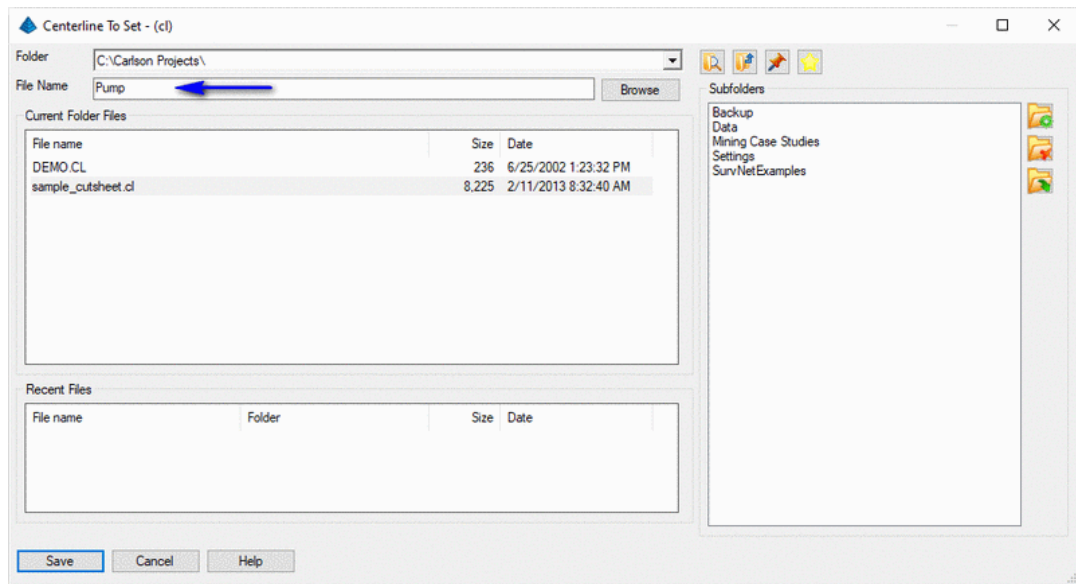

For this example, click the **Screen Pick Polyline** button and when prompted:

Select centerline polyline: pick the small polyline segment

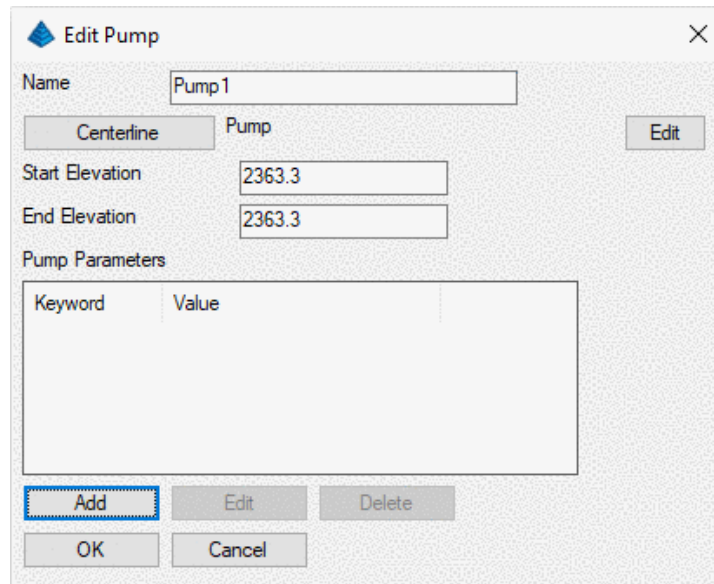

NOTE: Make sure the small segment is selected and not the longer pipe polyline.
After selecting the small segment, the following dialog will appear:

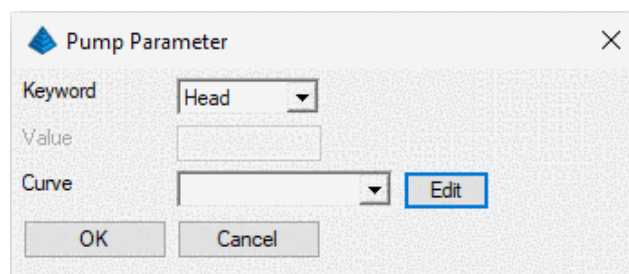

Click the **Assign Centerline File to Polyline** to display a dialog box similar to that shown below:

Set the file name as shown above and click **Save** when ready. Upon creation of the centerline file, a dialog box similar to that shown below appears:

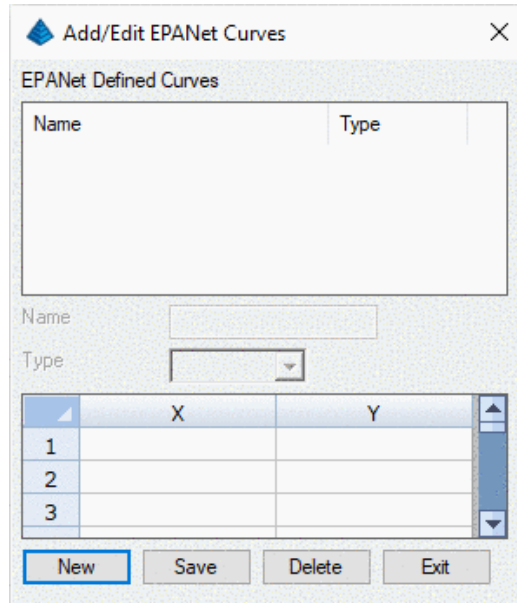

Set a name for the pump as suggested above and also set the **Start Elevation** and **End Elevation** to **2363.3** (the surface model elevation at the pump location). The next step is to add the required pump parameters. Click the **Add** button and the following dialog box will appear:

Select the **Head** keyword and the **Value** field will be disabled and the **Curve** field will be enabled. To create

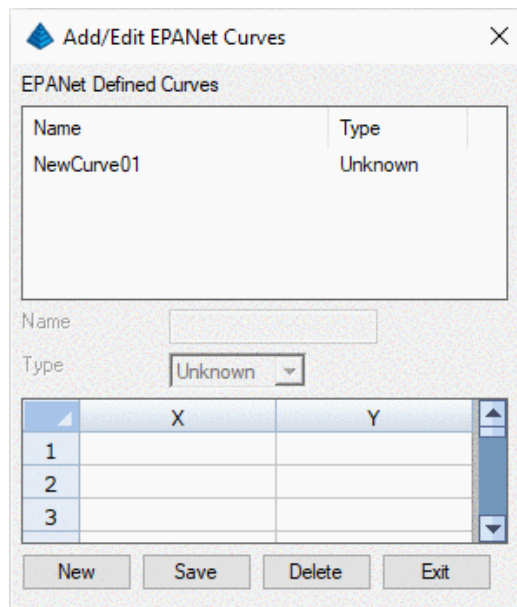

a new pump curve, click the **Edit** button and the following dialog will appear:

This dialog allows for the entry of any one of the four EPANet Curves:

- (a) Pump
- (b) Efficiency
- (c) Volume
- (d) Headloss

Click **New** and a new table will be created with a default name of *NewCurve01*:

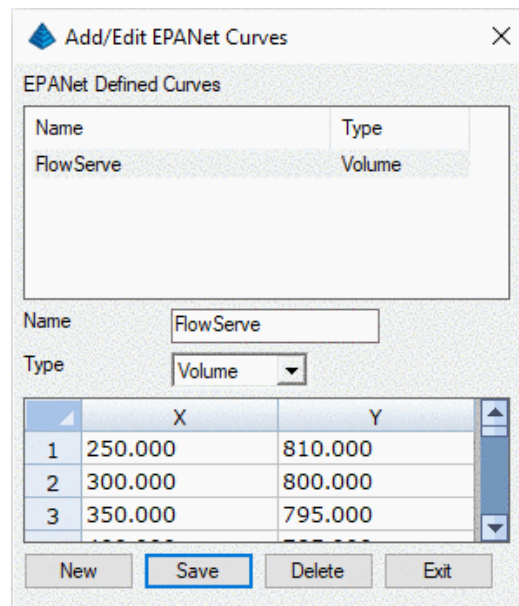

Select the *NewCurve01* entry and enter a new name of **FlowServe** and enter the following X, Y values:

Entry #	X (Head) Value	Y (Flow) Value
1	250	810
2	300	800
3	350	795
4	400	785

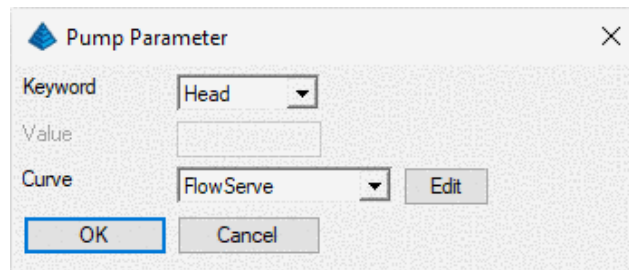

5	500	750
6	600	700
7	700	640
8	800	575

FlowServe Pump Curve Parameters

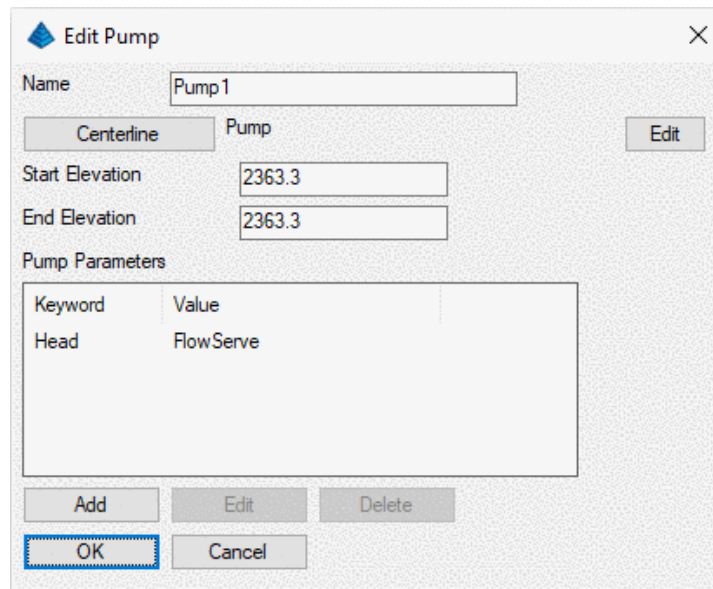

The result should look similar to that shown below:

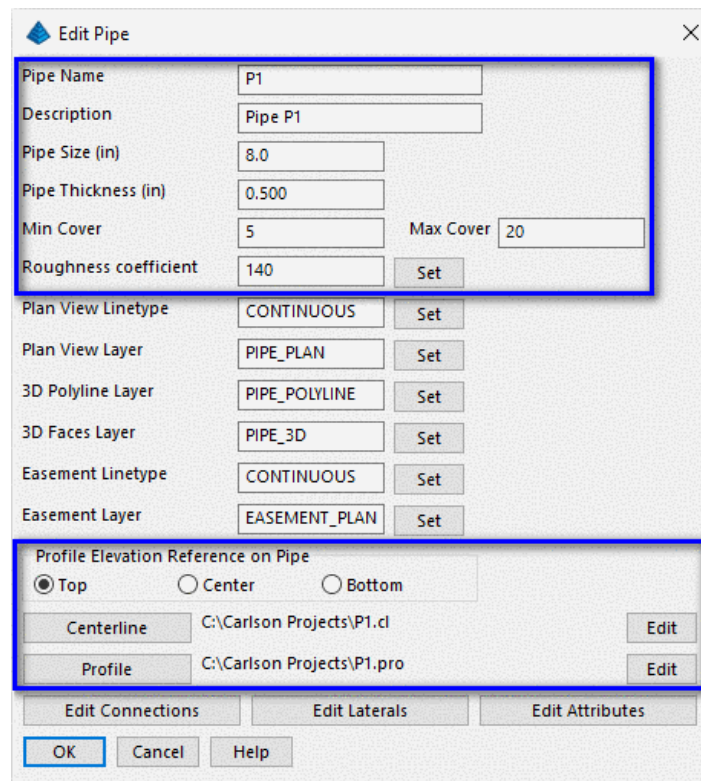

Click the **Save** button and then click **Exit** to return to the **Pump Parameter** dialog box. Select the pump curve you created in the **Curve** field as illustrated below and click **OK** when ready:

The **Edit Pump** dialog box should look as follows:

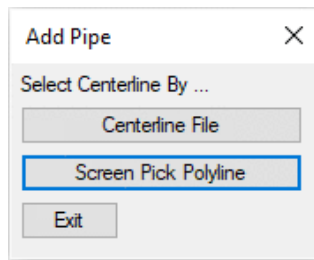

Click **OK** to return to the docked dialog box which should look as follows:

7. To add a new pipe, either:

- Click the **Add** (Plus) button on the *Network Actions* row and choose the **Pipe** option, or
- Right-click on the **Pipes** category in the tree-view list and choose the **Add Pipe** option

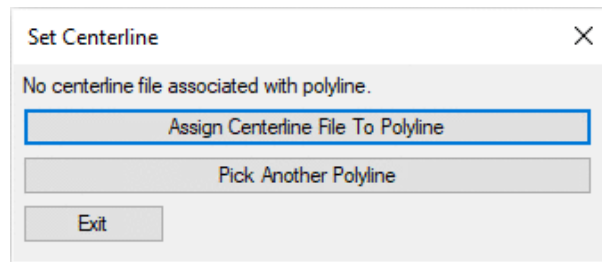

Do either option now to display the dialog box similar to that shown below:

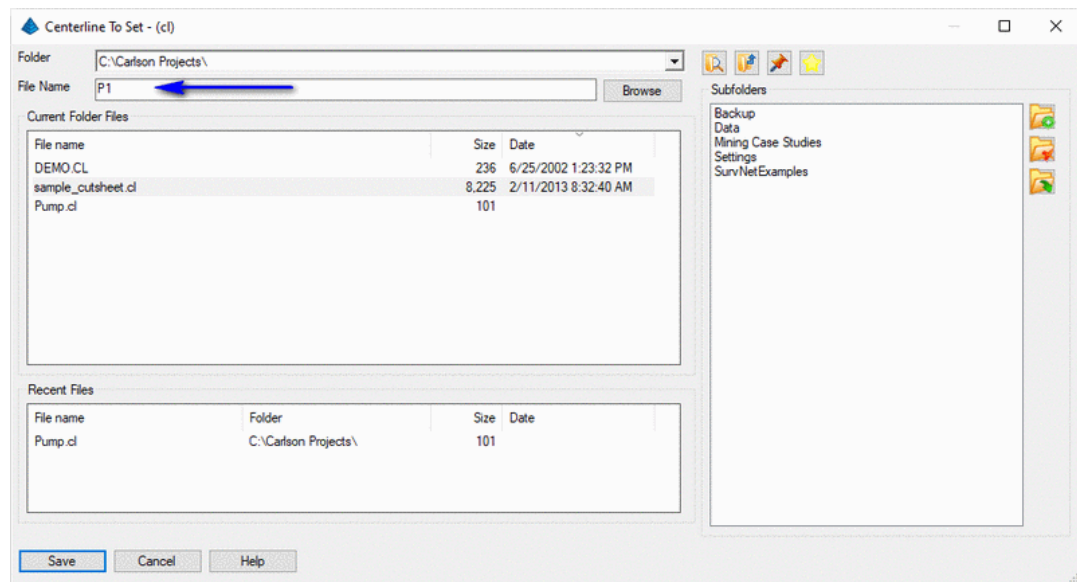

For this example, click the **Screen Pick Polyline** button and when prompted:

Select centerline polyline: pick the **Pipe 1** polyline segment

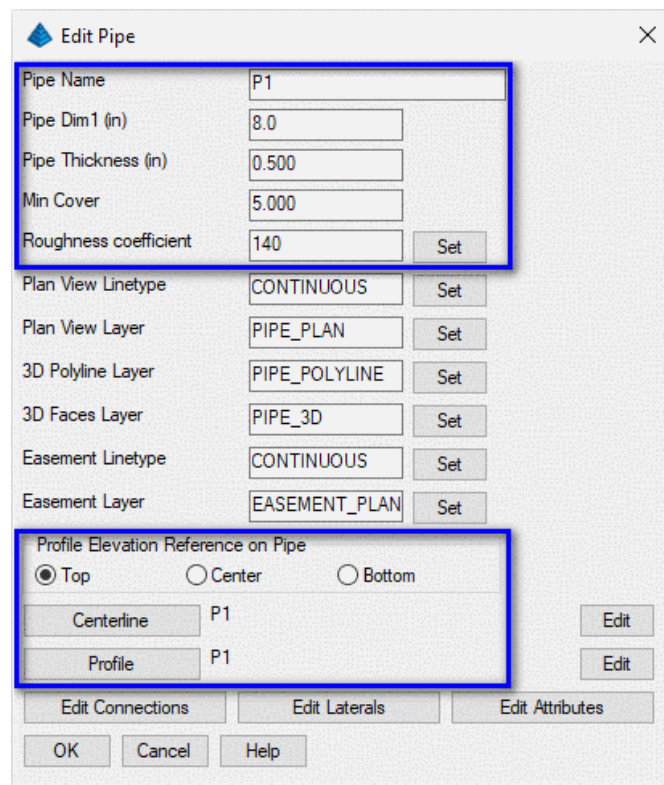

A dialog box similar to that shown below appears:

Press the **Assign Centerline File to Polyline** to display a dialog box similar to that shown below:

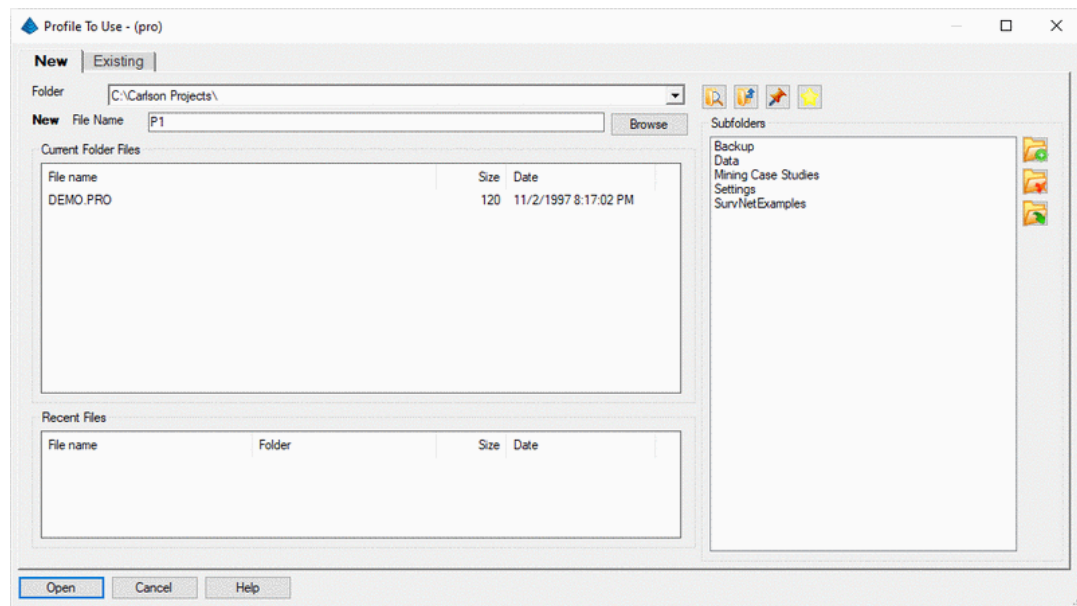

Set the filename as shown above and click **Save** when ready to display a dialog box similar to that shown below:

Update the following values:

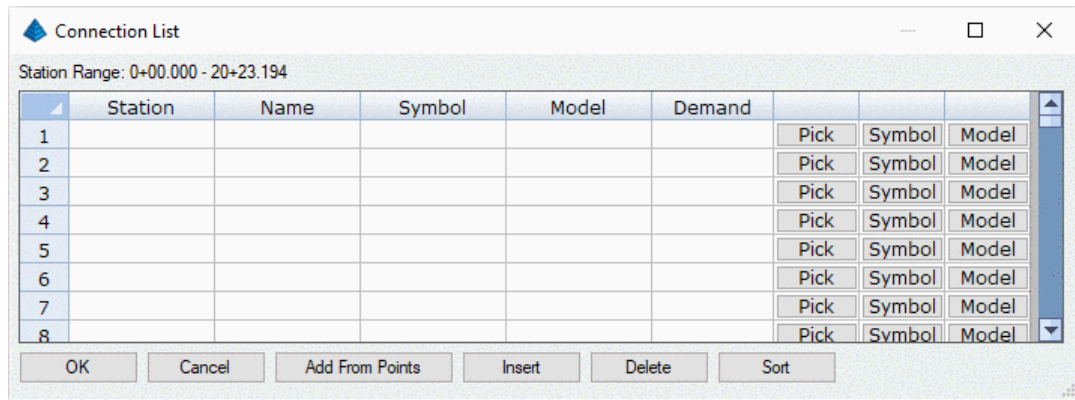

- **Pipe Dim 1** to 8.0
- **Pipe Thickness** to 0.500
- **Min Cover** to 5.0
- **Roughness Coefficient** to 140
- **Profile Elevation Reference on Pipe** to Top

Additionally, click the **Profile** button to open a dialog box similar to that shown below:

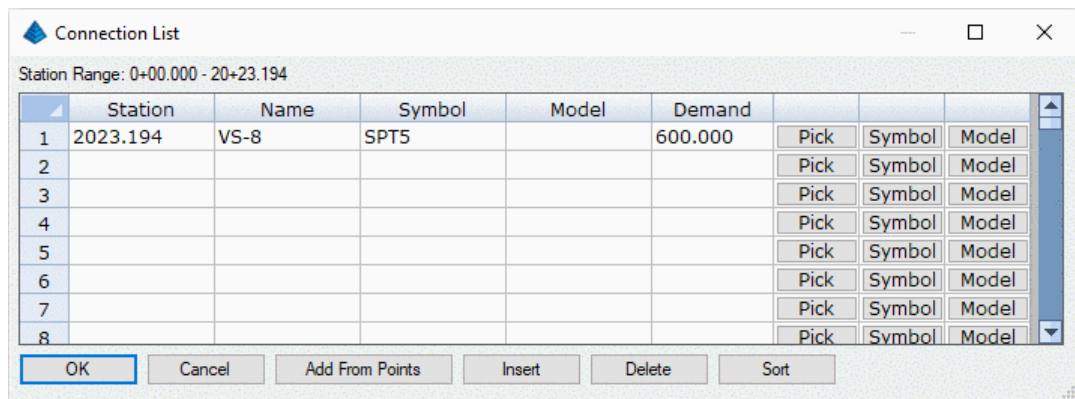

Set the profile file name to be the same as the centerline name cited earlier and click **Open** when ready. Click **OK** to dismiss the *Edit Pipe* dialog box and add the pipe to the tree-view collection.

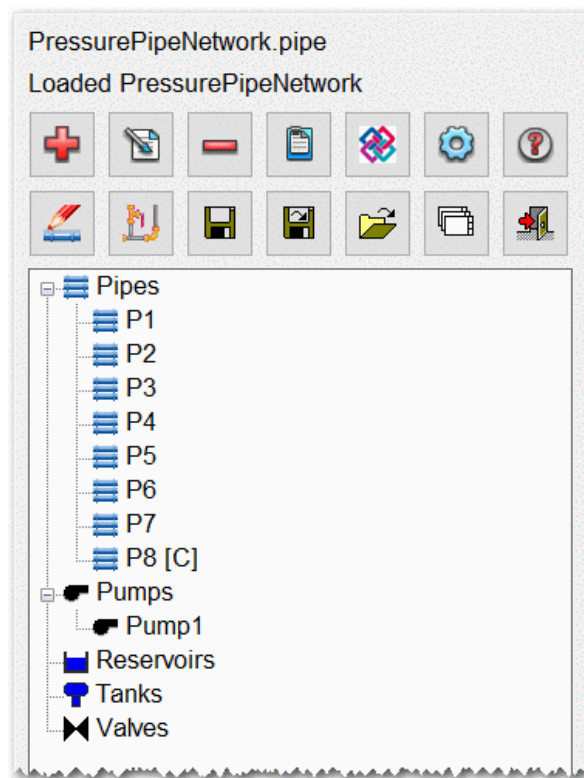

- Repeat the process of adding pipes for all eight pipes and use the same parameters for each pipe.
- Pipe **P8** has an required outflow of **600 cfs**. To enter the demand, right-click on pipe **P8** and click its **Edit Pipe** option. On the **Edit Pipe** dialog box, click the **Edit Connections** button at the bottom of the dialog to display a dialog box similar to that shown below:

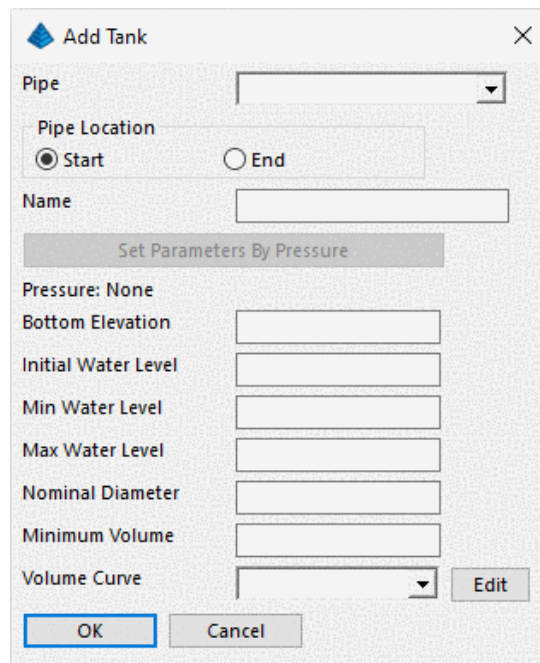

Enter the **End Station** value 2023.194 which is displayed at the top of the dialog. The remaining values should be as shown in the following:

Click **OK** to dismiss the *Connection List* dialog box and click **OK** to dismiss the *Edit Pipe* dialog box. The docked dialog should now look like the following:

9. In this example, we have two tanks. The **Upper Tank** and the **Lower Tank** as indicated on the drawing. To add a new tank, right-click the **Tanks** category in the tree-view and click the **Add Tank** button to display a dialog box similar to that shown below:

The **Pipefield** contains a list of *pipes*, *pumps*, and *valves* that are currently defined in the project. For the **Upper Tank**, select the **pump** created earlier and indicate the tank is at the **Start** of the pump. Enter the remaining tank parameters as follows and click **OK** when ready:

The 'Add Tank' dialog box is shown with the following settings:

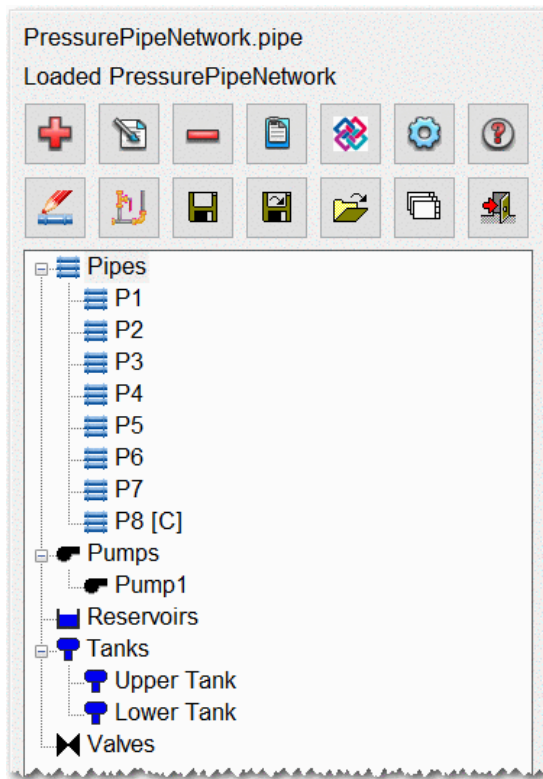

- Pipe:** Pump1
- Pipe Location:** Start (selected)
- Name:** Upper Tank
- Set Parameters By Pressure:** (button)
- Pressure:** None
- Bottom Elevation:** 2363.5
- Initial Water Level:** 35
- Min Water Level:** 10
- Max Water Level:** 38
- Nominal Diameter:** 30
- Minimum Volume:** 0
- Volume Curve:** (dropdown menu)
- Buttons:** OK, Cancel, Edit

Repeat the process and add the second **Lower Tank** with the following parameters and click **OK** when ready:

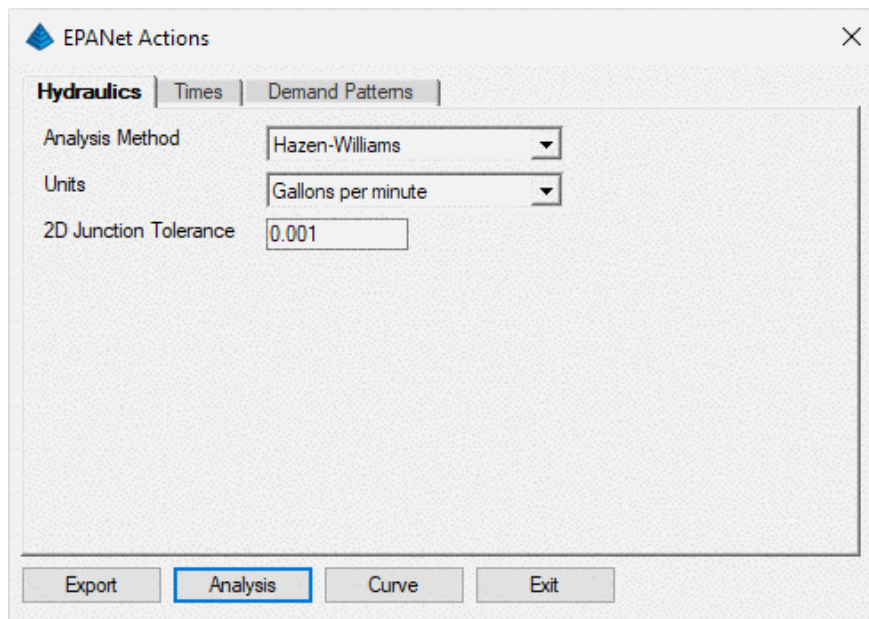

The 'Add Tank' dialog box is shown with the following settings:

- Pipe:** P7
- Pipe Location:** End (selected)
- Name:** Lower Tank
- Set Parameters By Pressure:** (button)
- Pressure:** None
- Bottom Elevation:** 2322.500
- Initial Water Level:** 35
- Min Water Level:** 15
- Max Water Level:** 38
- Nominal Diameter:** 30
- Minimum Volume:** 0
- Volume Curve:** (dropdown menu)
- Buttons:** OK, Cancel, Edit

NOTE: The *Lower Tank* is located to be at the **End** of P7.
The docked dialog should now look like the following:

10. Now that the model has been developed, an analysis can be performed. Click the **EPANet (Pipes with Valve)** button on the *Network Actions* row and the following dialog box will be displayed:

Set the values as shown above and click the **Analysis** button to run the analysis which displays the results in the Standard Report Viewer similar to that shown below:

LDT Migration Guide

19

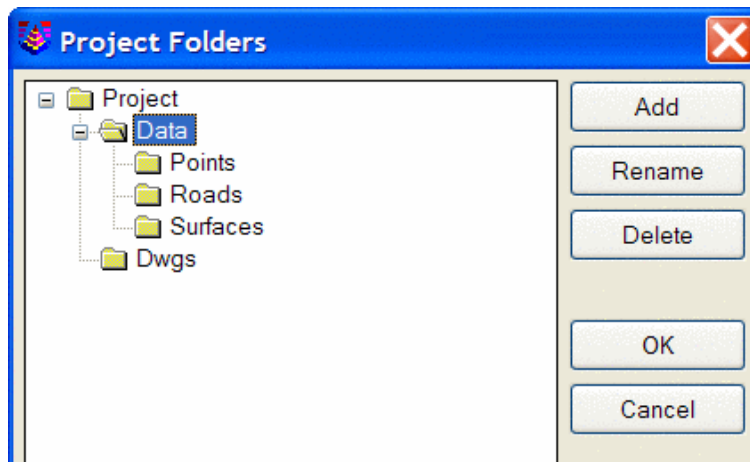

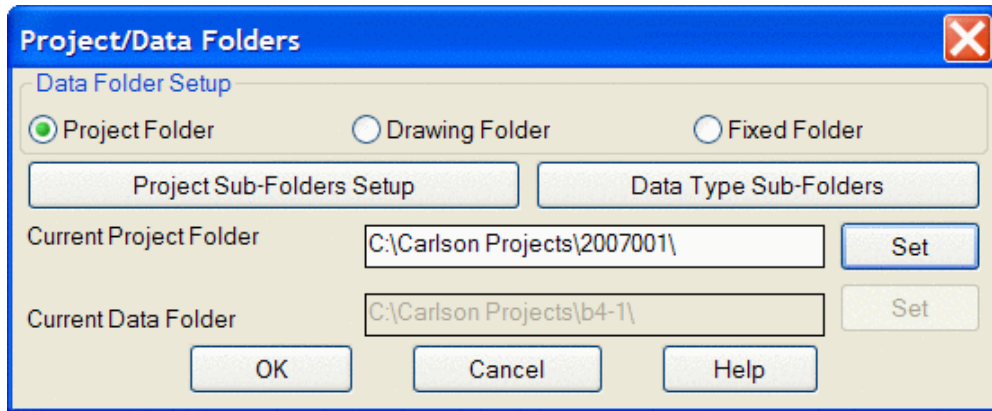

Carlson Civil Suite encompasses all of the functionality of Survey, Site Grading, Road Design, Hydrology and GIS, along with a comprehensive set of drafting and annotation tools. Carlson Civil Suite runs atop any installed AutoCAD executable, running as plain AutoCAD, or found within Map, Land Desktop or Civil 3D as well as IntelliCAD.

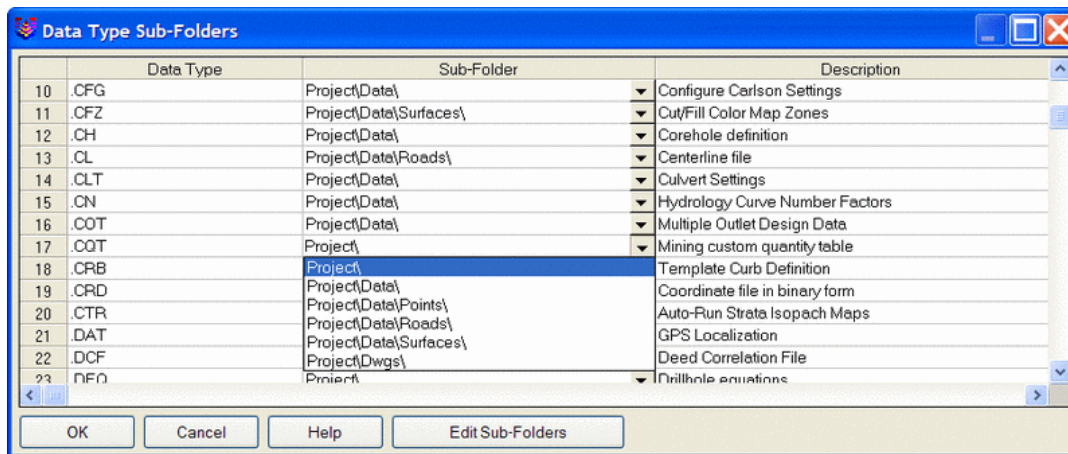

Evolved from the Carlson SurvCADD product line, first introduced in 1989, Carlson Civil Suite introduces several brand new state of the art tools, including a dynamic road design program called Road Network, and a dynamic storm drain design program called HydroNet. While these functions automatically respond to design changes, adjusting sections, profiles, and grading, Carlson Civil Suite accomplishes this automation without introducing custom objects, so sharing drawings with others is not an issue.

Carlson Civil Suite continues the Carlson Software tradition of unlimited free tech support, so when needed, help is always a free phone call away, and also introduces the newest support technology in the form of an online, web-based reference manual, complete with demonstration and training movies.

Data File Types and Storage

Carlson Civil has a similarity to Land Desktop in the use of external files to store design data, but differs significantly in that in Carlson Civil the naming and placement of these files is determined by the user, not the software. Carlson Civil offers three distinct methods of file storage, the choice is up to the end user. Carlson Civil data files can either be placed in a single location, known as a data folder, placed with the drawing they are associated with, or placed in a user-defined folder structure. The placement of files within that structure is also totally user-defined, based on the assignment of file types (extensions) to folders.

File types used by Carlson Civil include:

.crd - Point data, coordinate file

.rw5 - raw survey data, contains all observations

.cl - centerline, describes a 2D alignment

.tin - Surface, newer format, more efficient than .flt in most cases, especially for machine control

.flt - Surface, original format

.grd - Surface grid file, used for volumes

.cfg - Stores configuration settings

.fld - Field to Finish file, stores rules for inserting symbols for points (LDT Description Key functionality) and automated linework functionality (Autodesk Survey Figures equivalent)

.lot - Lot file, stores parcel geometry

.adf - Annotation Default file

.pro - Profile file

.mxs - Section Alignment file

.grp - Point Group definitions

.rdn - Roadway Networks

.sct - Road Sections

.tpl - Road Templates

.rdf - Road Design Files

Settings

Carlson Civil uses several techniques to store settings. There are three main categories of settings; Drawing Setup settings, such as drawing scale and units, Command-specific settings, such as the layer to draw contours on, and Generic control settings, such as whether to link drawing points to the external coordinate file (.CRD).

Drawing Setup settings are stored directly within the drawing files (.DWG). Carlson Civil also creates a file for each drawing using the drawing name with a (.INI) file extension. This file stores a list of all of the design files that are used or created from within the drawing, such as centerline files (.CL), profile files, (.PRO), etc.

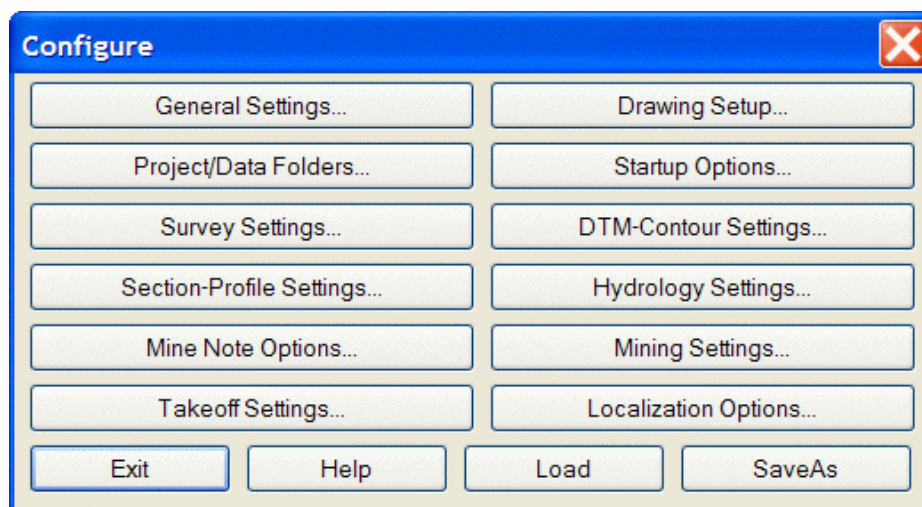

Command-specific settings are stored within a set of files with (.INI) file extensions, with the command name as a filename, such as roadnet.ini, or mapcheck.ini. These are typically stored in the \USER folder, and are created as the commands are first accessed.

Generic control settings are stored within a special (.INI) file named Carlson.ini. When new drawings are created, this file is read to set these type of generic controls.

Drawing Setup settings can be accessed directly from the Settings menu, or through the Configure command. If the Drawing Setup dialog is accessed through the Configure command, when exiting the main Configure dialog, the user is prompted whether to save changes to Current and Future drawings, or Future drawings only. Current and Future saves the Drawing Setup settings to the current drawing internally, and updates the Carlson.ini file, while the choice of Future Only does not affect the current drawing, only the Carlson.ini file, and therefore any new drawings created. To change Drawing Setup settings for only the current drawing, do not go through Configure, but use the Drawing Setup command directly off of the Settings menu.

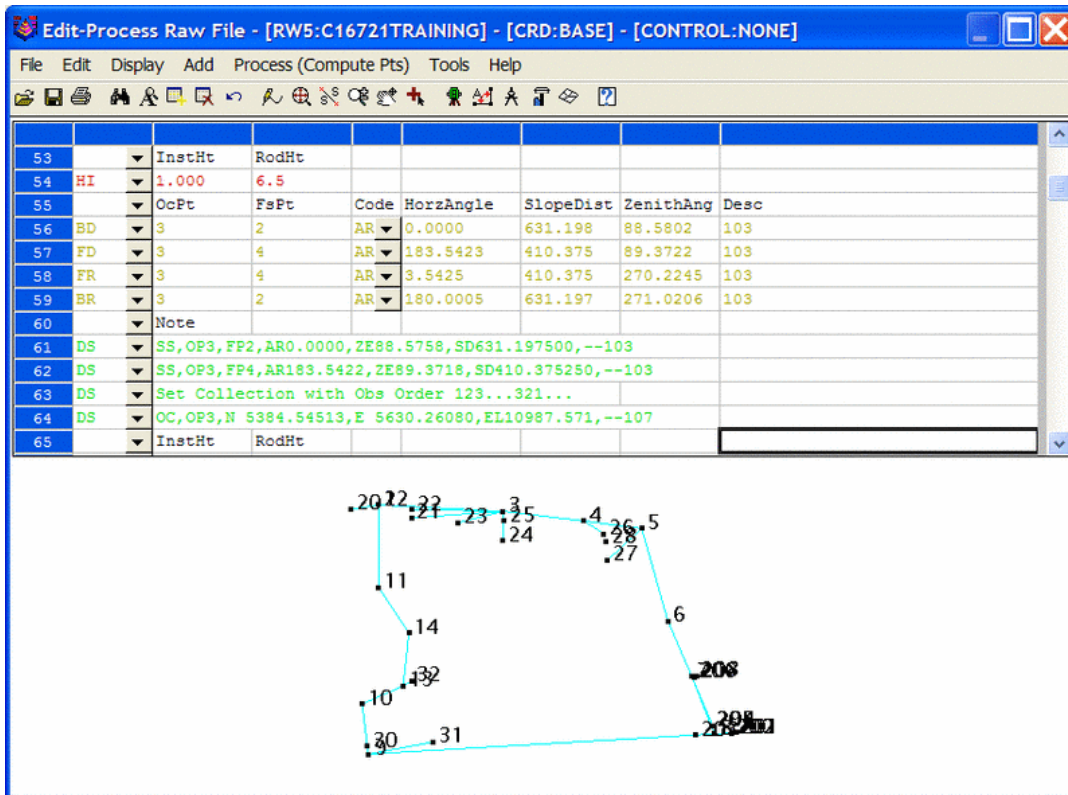

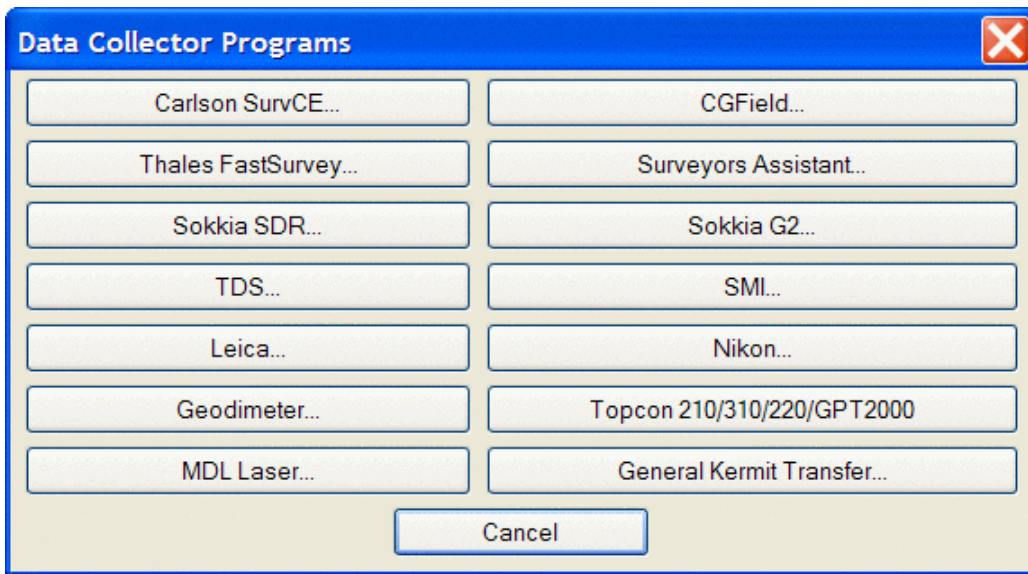

Command-specific settings are accessed when the commands are actually run. The settings displayed are being read from the command's own specific (.INI) file, and any changes made are written to the same files. This way the commands automatically recall the settings that were used for the previous run. Alternatively, the Configure command can be used to access command-specific settings.

The Configure command provides access to a dialog box with 12 buttons, each leading to settings for specific aspects of the software. Changes made within any of these are also automatically saved to the corresponding command (.INI) file, or to the Carlson.ini file in the case of generic settings. The Configure command also provides a Save and Load functionality, utilizing configuration files (.CFG). Saving a configuration file (.CFG) saves all settings currently stored in all of the command-specific (.INI) files, and the Carlson.ini file. Loading a configuration file (.CFG) sets all settings within all these files.

Survey

The complete range of Survey functionality is contained within the Carlson Civil, and is also available in the Carlson Survey program. This includes communication with data collectors, editing and processing of raw survey data, including traverse adjustment, and Field to Finish, which controls the generation of point symbols and linework.

Land Desktop uses Description Keys for point-based symbol insertion, and Autodesk Survey uses Figure notation for the generation of linework. Autodesk requires field coding to produce linework, and the processing of that information takes place when the raw file (.fbk) is Imported. Carlson inserts symbols and linework with one function known as Field to Finish (F2F), and performs this task using the point descriptions from the coordinate file, not the raw observations file. So linework can actually be generated from any set of points, even if no field coding has taken place. However, the addition of field coding can certainly make the generation of linework more precise. Carlson Civil can use LDT Description Key file to start a Field to Finish Code File.

Code Table

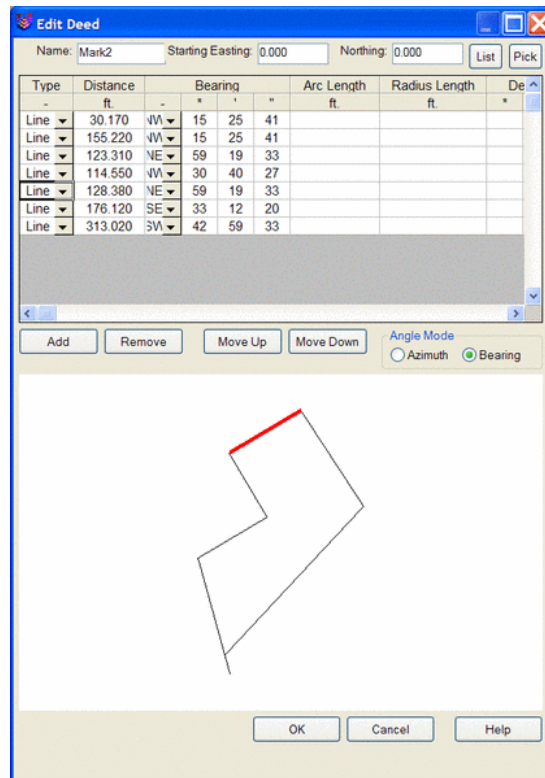

Code Definitions

Coordinate File

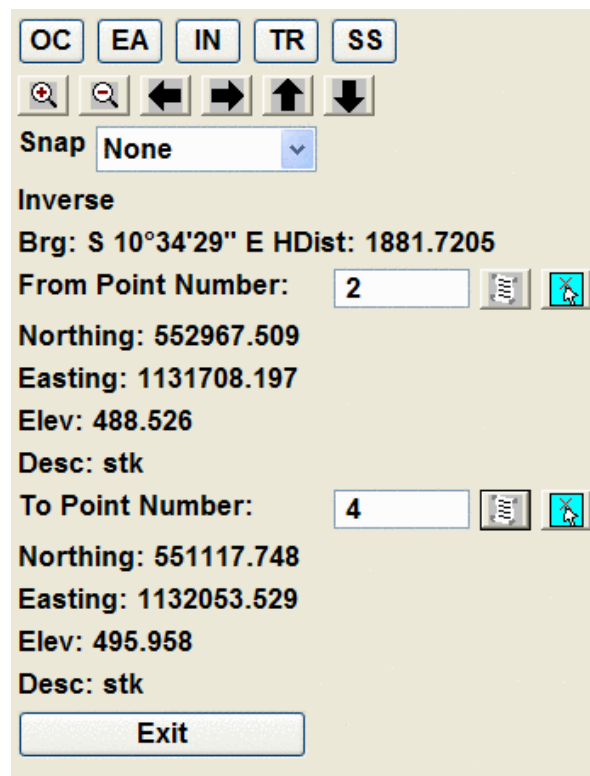

Carlson Civil also has powerful functions to Enter Deeds to draw linework, and a Deed Reader which reads a text file of a deed and extracts the data needed to define and draw the deed in the drawing.

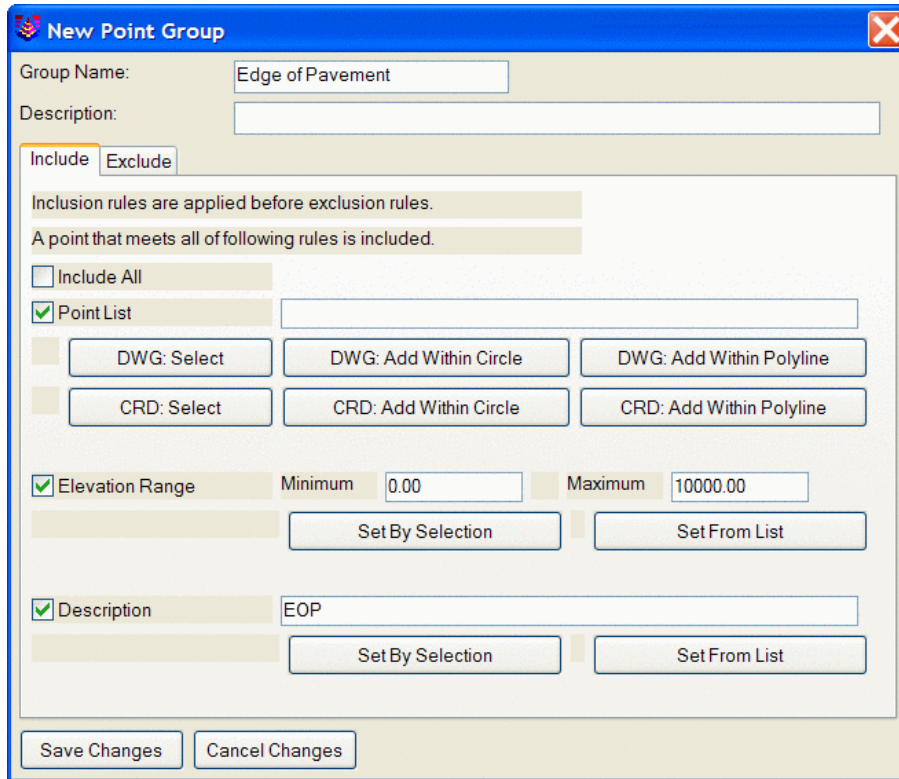

Carlson Civil also has a sidebar COGO function called Visual COGO to enter Traverse, Sideshot and other survey data.

Points and Point Groups

This use of point data in Carlson Civil revolves around the use of .crd files, also known as coordinate files.

Carlson Civil supports the creation of Point Groups similar to LDT and applies them in many applications, such as using them to create surfaces, editing and listing. Carlson Civil stores Point Group definitions are associated individually to each .crd file.

Surfaces and Contours

In Carlson Civil, Surfaces can be written out as external files, but a lot of design and computations involving surfaces can also be accomplished directly within the drawing without writing out external files. Triangulation surfaces can be written out as .tin or .flt and grid surfaces as .grd files. When an external file is generated, a named Surface is also stored in the drawing. This named Surface is accessed through the Surface Manager, where it can be edited.

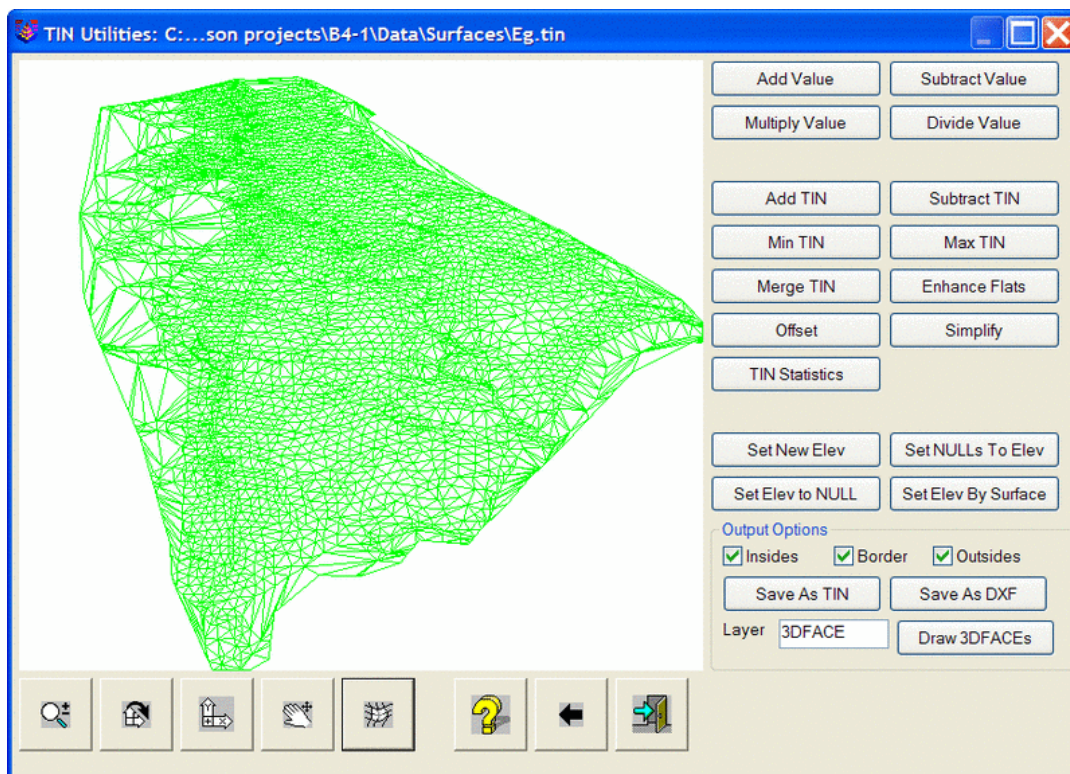

The main Carlson Civil command for working with Surfaces is called Triangulate and Contour. It is a single dialog box with four tabs, and covers the entire process of specifying the general settings to generate the Surface, creating Contours, generating Labels, and specifying the data source(s) for the Surface.

In Carlson Civil, Contours are generated as regular AutoCAD Polylines. Contours can be generated and automatically labeled simultaneously, or labeled after they are generated. Labels can be generated with wipeouts to hide the contour beneath them, and can also be slid along the contour to easily change their location.

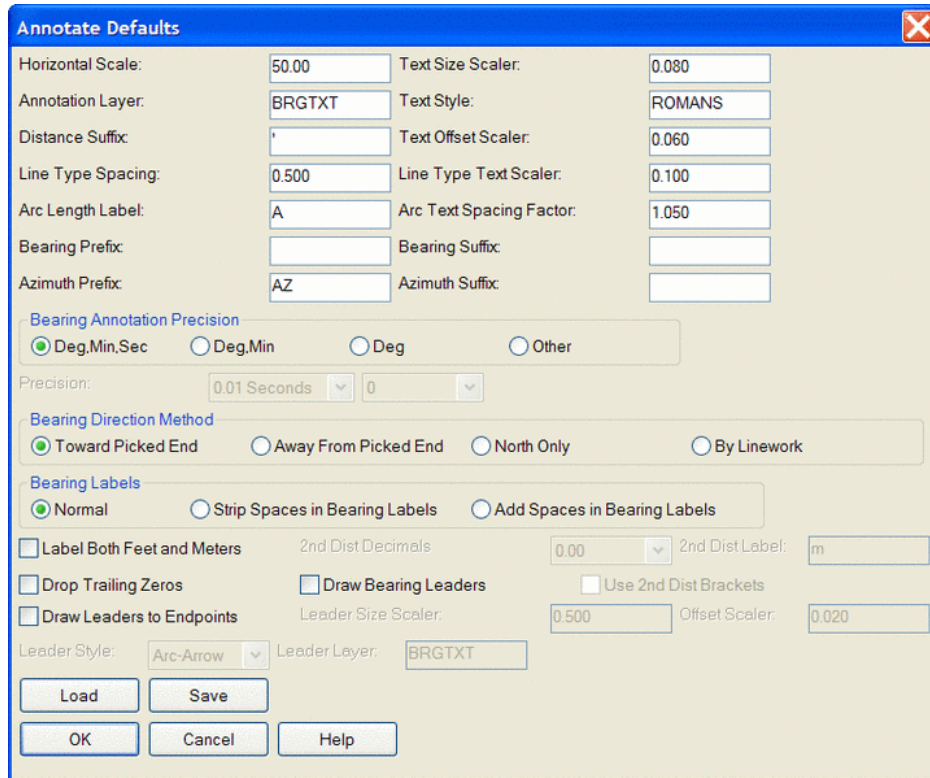

The Triangulation Surface Manager has tools to edit, add and remove data points and breaklines and update the triangulation dynamically. It also allows you to change the display properties for the triangulation, contours and labels.

The TIN Utilities function provides a powerful set of editing tools.

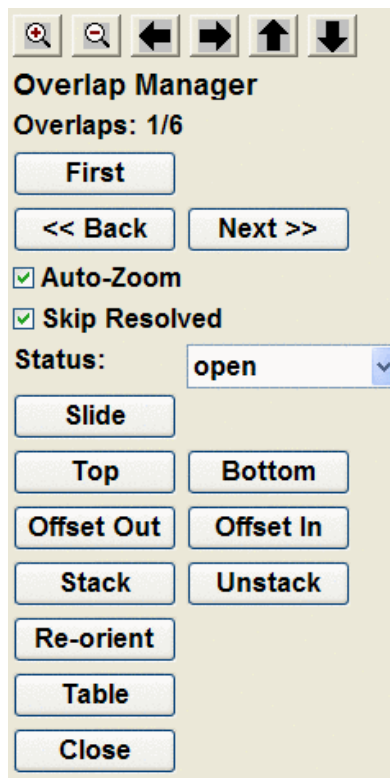

Line and Curve Labeling

Carlson Civil refers to the process of labeling lines and curves as Annotation. Lines and curves can be labeled in a dynamic or static mode, depending on the label settings.

There is also a powerful set of tools to check for and correct overlapping labels.

Volumes

There are several ways to generate volumetric calculations within Carlson Civil. Volumes By Layers, Volumes by Triangulation, Calculate Section Volumes and Two Surface Volumes (Grid volumes).

Volumes by Layers is potentially the quickest method. It needs no existing data files and creates no files in the process. You simply specify which layers to use for each of the 2 surfaces.

Volumes by Triangulation uses two triangulated surface files as the source of the data. These files are created through the Triangulate and Contour command. You can choose to create contours in the drawing when you create the TIN files, or just create the files without generating contours.

Calculate Section Volumes calculates volumes by end areas from two cross section files.

The Two Surface Volumes method uses two predefined Surface files as the data source for the calculations.

Once calculated, you can generate Cut and Fill Color Maps, Cut and Fill Centroids, and Cut and Fill Labels to illustrate the volumes.

Alignments

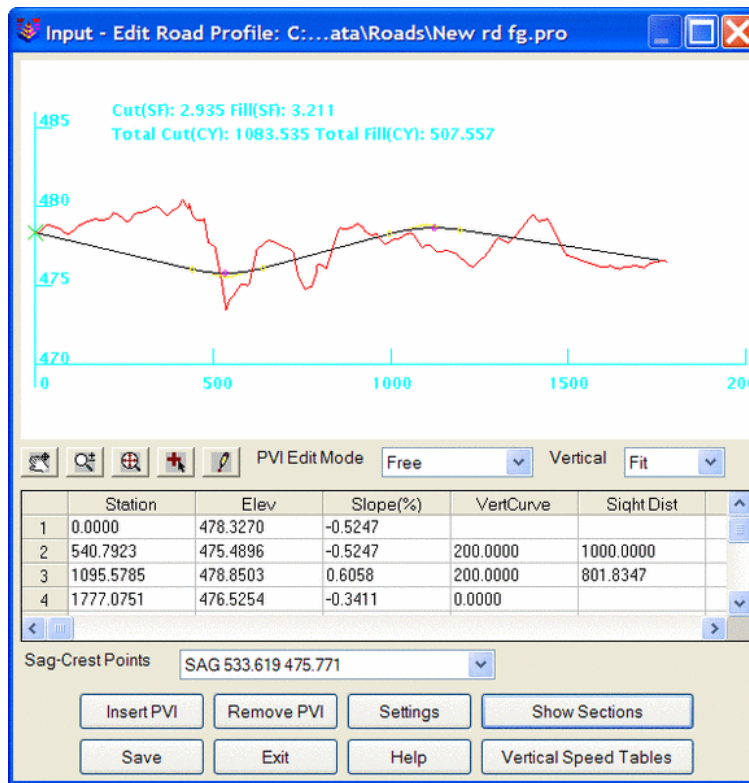

Horizontal Alignments in Carlson Civil are known as Centerlines. They are stored in .cl files. They can be created and edited through the Centerline Editor command. Polyline can be drawn first and then used to define Centerlines. Once defined as a centerline, double-clicking on the polyline invokes the editor dialog box.

Profiles

Profiles are stored within .pro files, with user-defined names. Existing Ground/Surface Profiles and Proposed Finished Grade/Design Profiles both use this filetype. Multiple .pro files can be drawn on the same Profile Grid.

There are several different routines for creating profiles including Profiles From Triangulation Files, Profile From Surface Entities and Profile From Points On Centerline. Before using these profile creation routines, the horizontal alignment needs to be created as a centerline file or polyline. The Quick Profile routine can be used to create profiles in one step.

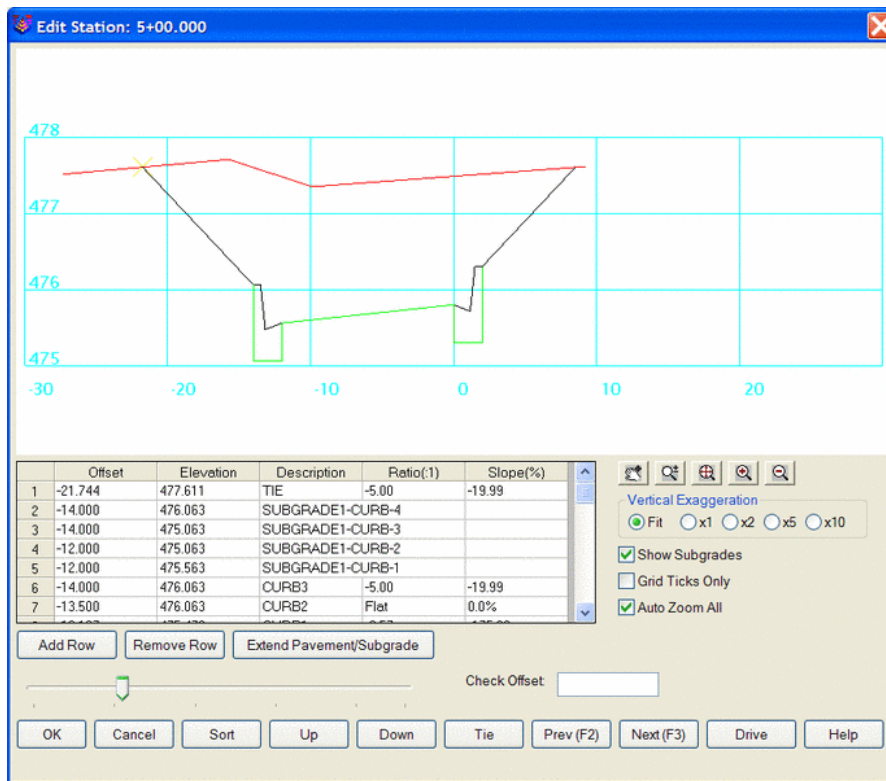

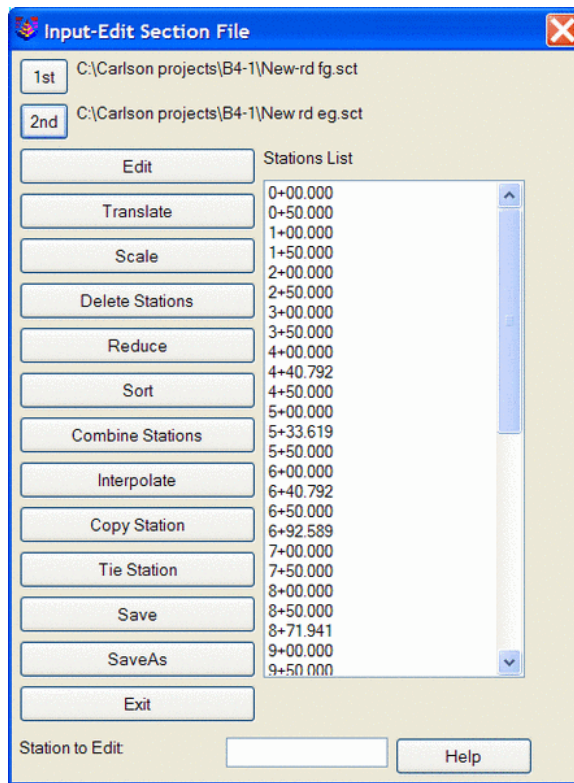

When using Process Road Design or RoadNet, the existing ground Profile can be generated automatically as part of the process, simply by specifying the Surface to use, and so is not a separate prerequisite. The Proposed Finish Grade Profile can then be added in the editor, and the Roadway processed, all without ever drawing anything in the drawing itself. The more traditional LDT approach of generating an existing ground Profile in the drawing and then adding a proposed finish grade Profile by drawing on it in the drawing is also an option.

Roadway Cross Sections

Roadway Cross Sections are based on Cross Section Alignments (.mxs files) that are defined by the Section Alignment Editor command to set the station interval and max offsets left and right. Similar to profile creation, there are several routines to create sections including Sections From Triangulation, Sections From Surface Entities and Sections From Points. The Process Road Design and RoadNet commands can create final sections.

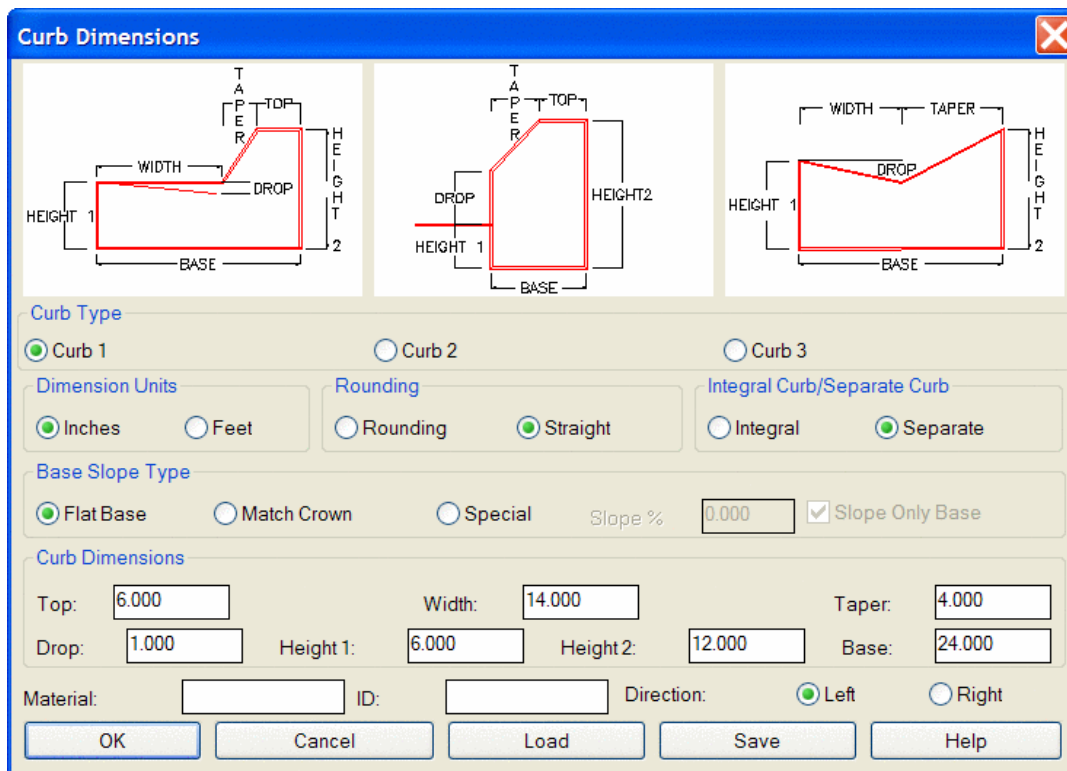

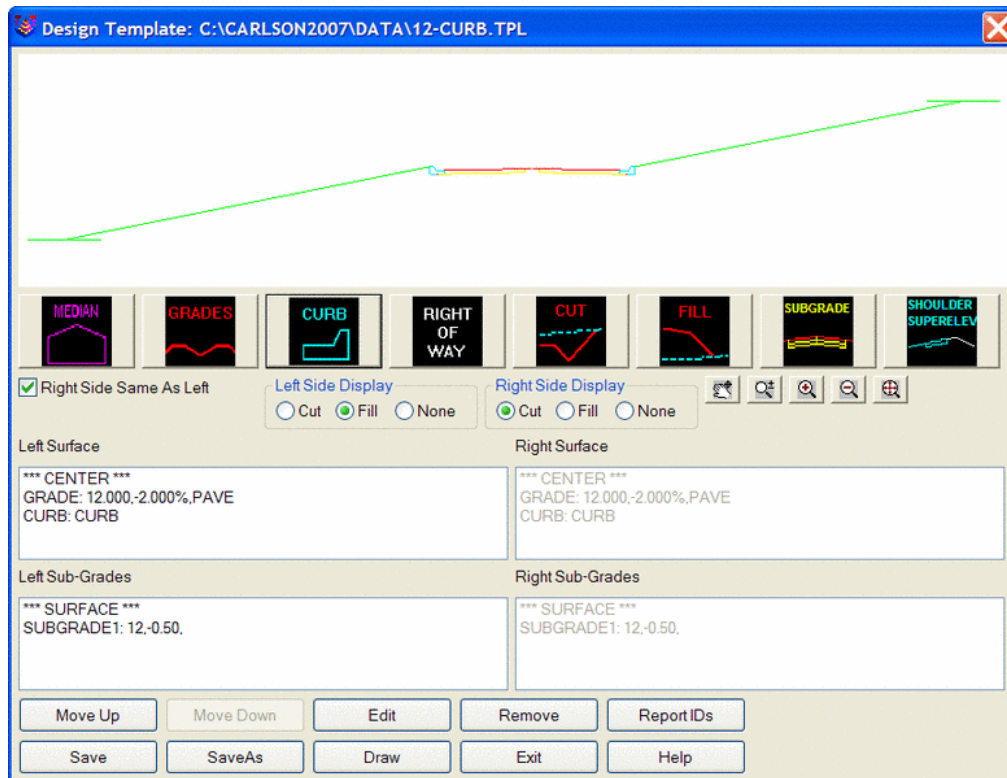

Once section files (.sct) are created, the Section File Editor command allows you to review and edit the section data. Also the Draw Section File and Section Report commands can be used.

Roadway Templates

Roadway Templates are created within the Design Template dialog box. They are stored as .tpl files, and can be applied to any road design. Templates are used in Process Road Design, Road Network and within the Road Profile Editor dialog.

The Design Template defines the road grades, subgrades, curb, superelevation break points and cut/fill slope treatments.

Design Control

The idea of Design Control in LDT exists in Carlson Civil in a number of places.

- Template Control - Templates are assigned to centerlines either in the Process Road Design dialog box, or in the Road Profile Editor dialog.
- Slope Control - In Carlson Civil, side slopes are actually part of the Template definition.
- Ditches - Ditches are defined within the Design Template as part of the cut/fill treatment.

Transitions - There are four methods to work with Transitions in Carlson Civil.

The first is called a Template Series, in which multiple Templates are assigned to a single Centerline at different stations. Next is a Template transition, in which a single Template is assigned to the entire Centerline and the user edits it at different stations. Next is a Template Point Centerline, in which a secondary Centerline is defined and attached to a point on the Template for specific horizontal control, such as a lane widening. Last is a Template Point Profile, in which an additional Profile is defined and attached to a point on the Template for specific vertical control, like the flow line of a ditch.

Superelevations - The template breakpoints for superelevation pivots are defined within Design Template. The stations for the superelevation transitions are set in the Superelevation Editor command.

Roadway Intersections

One of the very exciting features of Carlson Civil is the use of Roadway Networks. These are sets of centerlines that are aware of each other and clean up at intersections, horizontally and vertically.

Grading

Carlson Civil includes a variety of tools to accomplish the task of grading, including point commands, 3D polylines commands, contour commands and a grading mechanism known as a Pad Template, which is essentially the equivalent of an LDT Grading Object. Pad Templates provide some significant improvements, however, such as the ability to have a separate surface for the area inside the "pad", which moves horizontally and vertically with edits to the pad, and the ability to use a template for the side slopes, so they can project complex grading designs.

The screenshot shows a software interface for grading. At the top, there is a checkbox labeled "Use Slope Groups" with a "Set" button to its right. Below this are several input fields: "Fill Slope:" with a value of "2.00", "Cut Slope:" with a value of "2.00", and "Pad Elevation:" with a value of "480.8799". Underneath these are labels for "Pad Volume:", "Fill: 0.0 C.Y.", and "Cut: 61169.9 C.Y.". The "Surface:" is set to "EG" with a "Set" button. At the bottom, there is a grid of buttons: "Move Pad", "Move Vertex", "Offset", "Rotate Pad", "Balance", "Delete", "Report", "Exit", "Help", and "Process".

LandXML Data Transfer

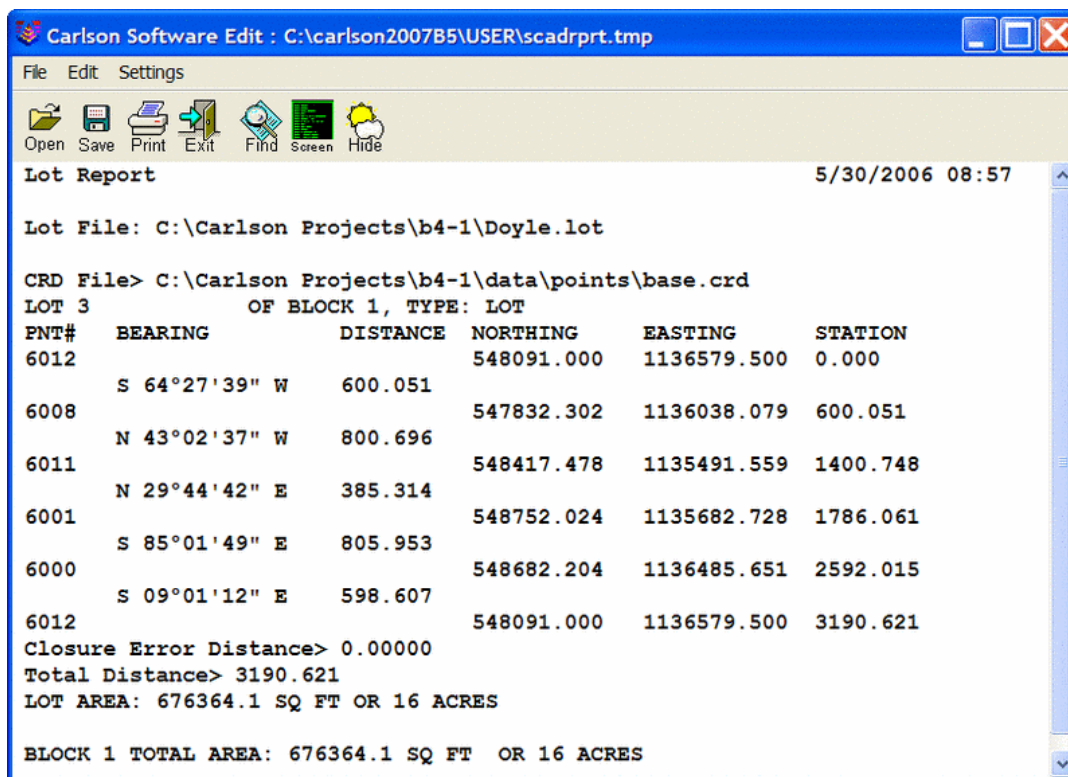

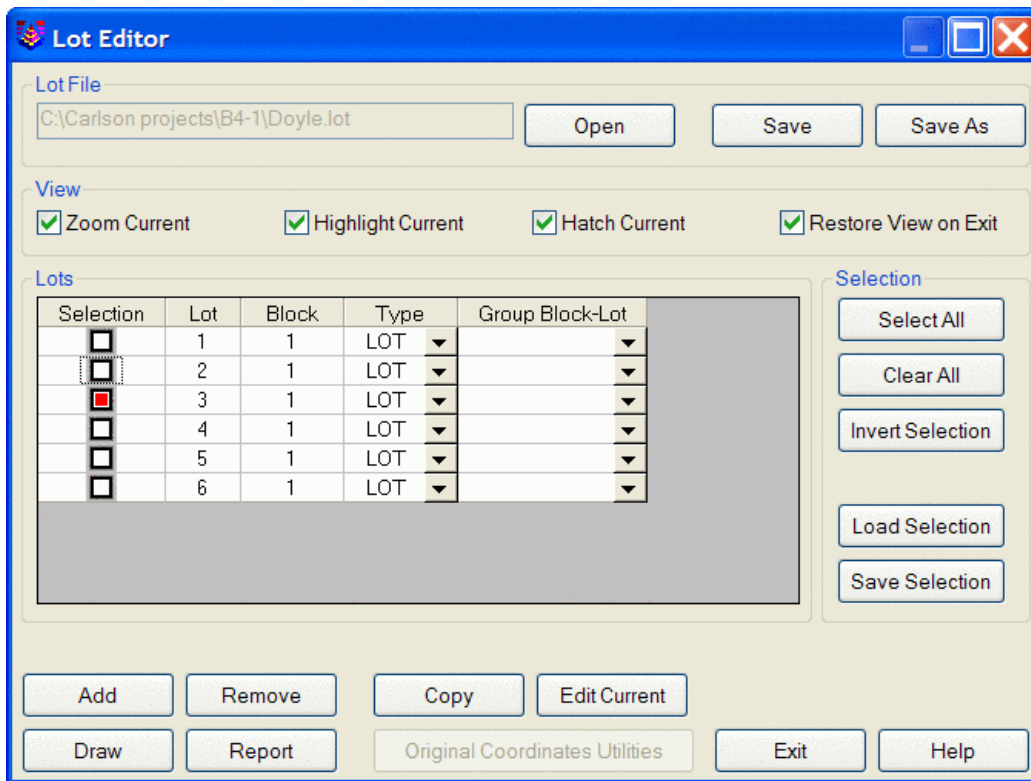

Transfer of data between LDT and Carlson Civil can be accomplished in several ways, depending on the type of data in question, but the best overall method is the use of LandXML files.

Pipes

Pipe Profiles can be designed and edited in the Profile Editor dialog, and then drafted in the drawing. In Hydrology, Pipe Networks can be created, which are dynamic and "intelligent", and so automatically respond to design changes.

Lots

Carlson Civil includes a set of tools for lot layout and lot design. Defined lots can be stored in a lot file (.lot). Another way to define a set of Lots automatically is with the Lot by Enclosed Text command, which searches for closed areas with enclosed text, and creates lots out of them, using the enclosed text for the lot name/number. Defined Lots can be accessed and edited through the Lot Editor.

Text Height

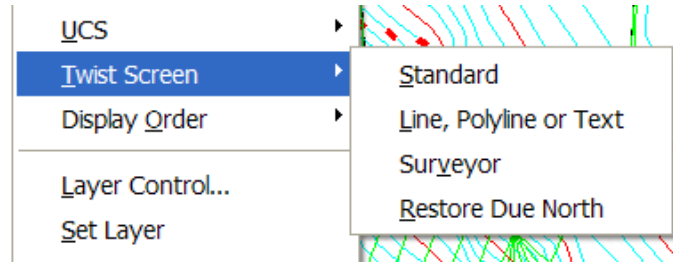

In LDT, as part of drawing setup, a set of text styles is created based on information contained in a file with a .STP file extension, most commonly used is the LEROY.STP. These text styles all have fixed heights assigned to them,

based on the current horizontal scale set in the drawing. If the horizontal scale is changed, the heights of the text styles are all changed.

In Carlson Civil, each of the various commands that involve annotation set the text style to be used and the desired height for the text, using a "scaler", which is multiplied by the current drawing scale. The AutoCAD text style should be set with a height of zero.

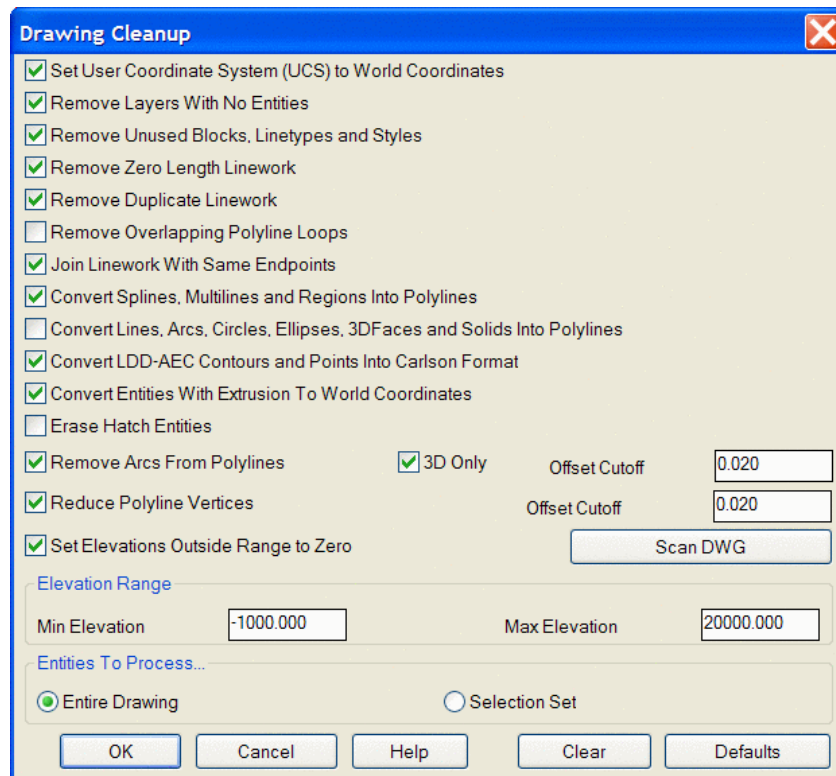

North Rotation

Carlson Civil does not support the concept of a secondary UCS to define and store North, as is done with LDT North Rotation. Instead, Carlson Civil relies on the use of DVIEW Twist to reorient North, and contains a thorough set of tools to work with that command. Any LDT drawings that are going to be brought into Carlson Civil should first have their LDT Base Point and North Rotation checked. If they are not all zeros, they should all be set to 0, have all points inserted to the drawing, and all linework moved and rotated to the location of the points.

Drawing Cleanup

If you're not running Carlson Civil on top of Map, or even if you are, Carlson Civil includes an awesome Drawing Cleanup function to find and resolve a wide range of common drawing problems.

Programming Interfaces 20

LSP Functions

Overview

Many of the Carlson functions and program environment settings are defined in LSP. These functions and variables are available for you to use in your own LSP routines.

The following is a list of useful functions:

scad_getfiled - file selection dialog

The following is a list of useful variables:

lspdir\$ - Carlson LSP folder where program files are located (string)

tmpdir\$ - current project data folder (string)

usrdir\$ - folder for program settings and temporary files (string)

psname - Carlson Support folder (string)

sv:sm - horizontal scale (real)

sv:vs - vertical scale (real)

sv:ts - text size scaler (real)

sv:ps - symbol size scaler (real)

is_metric - english/metric mode (0=english, 1=metric)

crdfile - current coordinate file (string)

scad_getfiled

Runs a file selection dialog. The function returns a string of the selected file name.

Usage: **(scad_getfiled title folder extension mode)**

title - A string for the dialog title

folder - A string for the initial default folder

extension - A string for the file type extension

mode - An integer for the selection mode (0 = existing file, 1 = new file)

Example: **(setq file_name (scad_getfiled 'Pick Surface To Process' tmpdir\$ 'tin' 0))**

centroid

Calculates the centroid point of a polyline. The function returns a point for the centroid. This function is within the poly3d program which must be loaded using scload.

Usage: **(cf:poly3d usrdir\$ 112 ename)**

ename - entity name of closed polyline

Example: **(scload (strcat lspdir\$ 'poly3d'))**
(setq pnt (cf:poly3d usrdir\$ 112 ename))

Coordinate API

Overview

We have created a Lisp file, CrdAPI.FAS, that contains some simple and easy-to-use functions for accessing, modifying, drawing and selecting any type of coordinate file that Carlson Software supports. The CrdAPI.FAS file is located in the Carlson LSP folder. This collection of functions can help you write your own tools. We call this toolkit the Coordinate File Application Programming Interface, or CRD API.

This document describes the Lisp interface of the CRD API.

Supported Types of Coordinate Files

The following enumerated variables are available for specifying the different types of coordinate files that are supported by the CRD API.

```
;;; Coordinate File format number
```

```
(setq
enCrdTypeUnrecognized -2 ;file exists but is not a recognized type.
enCrdInvalid -1 ;not a valid type - used in creating new files.
enCrdSurvCADDNumeric 0 ;Carlson original; point name is numeric. Extension
'crd'.
enCrdSurvCADDAlpha 1 ;Carlson sequel; point names can be alphanumeric.
Extension 'crd'.
enCrdMemory 2 ;NOT YET IMPLEMENTED.
enCrdCgAlpha 3 ;C&G alphanumeric. Extension 'cgc'.
enCrdCgNumeric 4 ;C&G numeric. Extension 'crd'.
enCrdSimplicity 5 ;Simplicity 'Sight Survey'. Extension is 'zak'.
enCrdLDD 6 ;Land Desktop Development. Filename is 'points.mdb'.
enCrdCivil3D 7 ;Civil 3D; point name is numeric.
enCrdSQLite 8 ;Carlson SQLite. Extension 'crdb'.
)
```

Working with Points in Coordinate Files

The following functions are for working with Crd Point structures.

Internally, the Crd Point looks like the following list.

```
(name desc x y z)
```

To allow for expansions and changes of the Crd Point in the future, please use only the following Crd Point functions for setting and accessing Crd Points.

CrdPointInit

A Crd Point structure will be returned that can be passed into CrdAddPoint, etc. *name* and *desc* must both be strings.

```
(defun CrdPointInit( x y z name desc)
(list name desc x y z)
)
```

CrdPointSetName

Sets the name of the Crd Point structure. The Crd Point is returned.

```
(defun CrdPointSetName( point name)
  (cons name (cdr point))
)
```

CrdPointGetName

Gets the name of the Crd Point structure.

```
(defun CrdPointGetName( point)
  (car point)
)
```

CrdPointSetDesc

Sets the description of the Crd Point structure. The Crd Point is returned.

```
(defun CrdPointSetDesc( point desc)
  (cons (car point) (cons desc (caddr point))))
)
```

CrdPointGetDesc

Gets the description of the Crd Point structure.

```
(defun CrdPointGetDesc( point)
  (cadr point)
)
```

CrdPointSetXYZ

Sets the x, y, z values of the Crd Point structure given a list of (x y z). The Crd Point is returned.

```
(defun CrdPointSetXYZ( point xyz)
  (append (list (car point) (cadr point)) xyz)
)
```

CrdPointGetXYZ

Gets the x, y, z values of the Crd Point structure as a list of (x y z).

```
(defun CrdPointGetXYZ( point)
  (caddr point)
)
```

Working with the Coordinate File

The following functions are for working with coordinate files.

CrdOpen

Opens a coordinate file with the given filename. Only one coordinate file can be open at a time through the Lisp interface. If CrdOpen is called twice, the first crd file is closed automatically.

filename – The file name of the coordinate file with required extension (.crd, .cgc, .mdb).

bOverwrite – If 1 (integer), then any existing file of the same name will be destroyed. Use nil to select default value which is 0.

crdType – See enCrdType above. This specifies the type of CRD file to create if the given name does not already exist. Use nil to select the default value which is enCrdSurvCADDAlpha.

Returns 1 (integer) if successful and 0 if there was some kind of failure. Call CrdGetLastError() to get the text message of the error.

```
(defun CrdOpen( filename bOverwrite crdType)
```

```
(cf:crdapi 'CrdOpen' filename bOverwrite crdType)
)
```

CrdClose

Closes the current Crd file, if it is open.

```
(defun CrdClose()
(cf:crdapi 'CrdClose')
)
```

CrdAddPoint

Adds the given CrdPoint to the current open Crd File, overwriting any point with the same name that may already exist. The CrdPoint is a (list name desc x y z).

Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to get text message of error.

```
(defun CrdAddPoint(CrdPoint)
(cf:crdapi 'CrdAddPoint' point)
)
```

CrdBegin

Starts a traversal of all the points of the Crd File by resetting internal state so that CrdNext will start from beginning of file.

range – if not nil, then it must be a Carlson-style string of point names suggested by the following examples: "1-5,6,12-19" or "all". If nil, that is the same as all. The points will be returned on successive calls to CrdNext() in the order listed in the range.

```
(defun CrdBegin( range)
(cf:crdapi 'CrdBegin' range)
)
```

CrdNext

Gets the next point in the Crd File. Returns a Crd Point if successful and nil if there are no more points or some other failure.

```
(defun CrdNext()
(cf:crdapi 'CrdNext')
)
```

CrdGetPoint

Gets the named point from the current open Crd File. A Crd Point is returned if successful and nil is returned if the point could not be found. Call CrdGetLastError() to get text message of error.

```
(defun CrdGetPoint( name)
(cf:crdapi 'CrdGetPoint' name)
)
```

CrdRemovePoint

Removes the named point from the current open Crd File. Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to get text message of error.

```
(defun CrdRemovePoint( name)
(cf:crdapi 'CrdRemovePoint' name)
)
```

CrdRemovePoints

Removes the given range of points (a string) from the current open Crd File. For example, the range could be "1-5,7,10-12".

```
(defun CrdRemovePoints( range)
(cf:crdapi 'CrdRemovePoints' range)
)
```

CrdTestPointName

Returns nil if the point name is valid for the current Crd type. Otherwise, returns an error string describing the error.

```
(defun CrdTestPointName( name)
(cf:crdapi 'CrdTestPointName' name)
)
```

CrdTestPoint

Returns nil if the Crd Point is valid for the current Crd type. Otherwise, returns an error string describing the error.

```
(defun CrdTestPoint( point)
(cf:crdapi 'CrdTestPoint' point)
)
```

CrdGetLastError

Returns the error string of the result of the last operation.

```
(defun CrdGetLastError()
(cf:crdapi 'CrdGetLastError')
)
```

CrdDeleteFile

Deletes the data file(s) underlying the Crd File and closes the Crd File. May not work if the original filename was not a full path including drive letter. Returns 1 (integer) if successful and 0 otherwise. Call CrdGetLastError() to get text message of error.

```
(defun CrdDeleteFile()
(cf:crdapi 'CrdDeleteFile')
)
```

GetCrdType

Returns the crd type of the current open Crd File.

```
(defun GetCrdType()
(cf:crdapi 'GetCrdType')
)
```

GetCrdTypeName

Returns the official name of the given crd type.

```
(defun GetCrdTypeName( enCRDType)
(cf:crdapi 'GetCrdTypeName' enCRDType)
)
```

CrdDraw

Accepts an argument list to indicate a set of points to be drawn, which at a minimum takes the form ' ('Points' '<points designator>')'.

```
(defun CrdDraw(arglist)
(eval (append '(cf:crdapi 'CrdDraw') arglist)))
)
```

The syntax for additional optional parameters which may be included in arglist (indicated by "[]") is as follows:

```
(CrdDraw ('Points' '<points designator>'
['SymbolName' '<symbol block name>']
['SymbolXScale' <X scale>]
['SymbolYScale' <Y scale>]
['SymbolRotation' '<symbol rotation in AUNITS>']
['SymbolLayer' '<symbol layer name>']
```

```

['BlockName' ' '<attribute block name>']
['BlockXScale' <X scale>]
['BlockYScale' <Y scale>]
['BlockRotation' ' '<attribute block rotation in AUNITS>']
['BlockNameLayer' ' '<layer for point name>']
['BlockElevationLayer' ' '<layer for point elevation>']
['BlockDescriptionLayer' ' '<layer for point description>']
['PointLayer' ' '<layer for POINT>'])
)
)

```

CrdSelect

Accepts an argument list to indicate a set of points to be selected, which at a minimum takes the form `nil` to select all points.

```

(defun CrdSelect (arglist)
  (eval (append '(cf:crdapi 'CrdSelect') arglist))
)

```

The syntax for additional optional parameters which may be included in `arglist` (indicated by "[]") is as follows:

```

(CrdSelect '( ; Select all points in drawing
['Points' ' '<points designator>'] ; Select all points in <point
designator>
['Prompt' ' '<prompt for points>'] ; Interactive (spatial) select points
in drawing
['P0' point 'P1' point] ; Select all points in window having corners
P0,P1
)
)

```

Note that all optional parameters within "[]" are mutually exclusive. The function returns the selected points as a list of points, each of which is itself a sublist indicating the point identifier and its associated drawing entity name.

Example Code

```

;;; Examples on how to use.
(CrdOpen 'junk2.crd' nil nil)
(princ (strcat 'Created a file of type: ' (GetCrdTypeName (GetCrdType))
'\n'))

; create a couple of points in memory.
; This first point is at coordinate 100,101,10.5 and has the point name
; of 1012 and the description of IP.
(setq point1 (CrdPointInit 100 101 10.5 '1012' 'IP'))
(setq point2 point1)
(setq point2 (CrdPointSetXYZ point2 '(105 101 10.5)))
(setq point2 (CrdPointSetName point2 '3'))
(setq point3 (CrdPointSetName point2 '7'))

; adding a point and checking for errors.
(setq bSuccess (CrdAddPoint point1))
(if (= bSuccess 0)
  (princ (strcat 'Error on point ' (CrdPointGetName point1) ': '

```

```

(CrdGetLastError))) '.\n')

; adding points without checking for errors.
(CrdAddPoint point2)
(CrdAddPoint point3)

; now print out the points 1 through 5
(princ 'Listing the point names.\n')
(CrdBegin '1-5') ; nil or 'all' would select all the points.
(while (setq point (CrdNext))
(princ (strcat (CrdPointGetName point) ' ' (CrdPointGetDesc point) '\n'))
)
;
; Drawing points.
; Draw all points in the drawing using defaults. Argument list ('Points'
'<points designator>') is required as a minimum.
(CrdDraw ('Points' 'ALL'))
;
; Syntax for additional optional parameters indicated by '[' is as
follows:
; (CrdDraw ('Points' '<points designator>'
; ['SymbolName' '<symbol block name>']
; ['SymbolXScale' <X scale>]
; ['SymbolYScale' <Y scale>]
; ['SymbolRotation' '<symbol rotation in AUNITS>']
; ['SymbolLayer' '<symbol layer name>']
; ['BlockName' '<attribute block name>']
; ['BlockXScale' <X scale>]
; ['BlockYScale' <Y scale>]
; ['BlockRotation' '<attribute block rotation in AUNITS>']
; ['BlockNameLayer' '<layer for point name>']
; ['BlockElevationLayer' '<layer for point elevation>']
; ['BlockDescriptionLayer' '<layer for point description>']
; ['PointLayer' '<layer for POINT>']))
;
; Selecting points.
; Select all points in the drawing
(CrdSelect nil)
;
; Select all points in window
(CrdSelect ('P0' (setq p0 (getpoint 'First Corner: ')) 'P1'
(getcorner p0 'Opposite corner: ')))
;
; Syntax for additional optional parameters indicated by '[' is as
follows.
; (CrdSelect (['Points' '<points designator>'] ; Select all points in
<point designator>
['Prompt' '<prompt for points>'] ; Interactive (spatial) select points
in drawing
['P0' point 'P1' point] ; Select all points in window
; All parameters within [] are optional and are mutually exclusive.
;
;

```

```
(CrdDeleteFile) ;the only proper way to delete the file(s). C&G uses two files, for example.
```

```
(CrdClose) ;not necessary because of CrdDeleteFile, but doesn't hurt.
```

```
(princ '--the end--\n')
```

DTM API

Overview

A lot of functionality of Carlson triangulation and TIN file manipulation is now available from LISP for the advanced users to use in their routines. This part of the Carlson interface is called DTM API.

API supports the older FLT file format, which stores only edge information, and the new TIN format, which is a binary format containing all the structure of triangulation and therefore is faster to load and takes less space. The file extension controls which file type is being created.

The functionality of DTM API is implemented in TRI4.ARX. It would be the responsibility of the caller to make sure that this file gets loaded by adding this line at the beginning:

```
(scload (strcat lspdir$ 'tri4'))
```

The ARX should never be unloaded by the caller.

The following is a list of currently supported functions (it can be obtained at any time by calling **(cf:dtm.api)**):

create_tin - create a TIN from selection set

draw_tin - draws a TIN as 3d faces;

tri_volume - produce volume report from 1 or 2 TINs

tri_change - modify tin using inc/exc and operators

tri_contour - contour tin using inc/exc and ini file with settings

tri_profile - creates a profile of the TIN along a centerline

tri_diff - produce a difference TIN from two TINs

tin_combine - produce a combined TIN performing a specified operation to elevation

tri_store_regions - create and store TIN difference

tri_apply_region - apply a specific region revision

tri_forget_region - forget all region revisions

surface_util - routines for tin surface manager

load_tin - loads TIN into memory for tin.z function

unload_tin - unloads the current TIN from memory

tin_z - returns the z at the specified x,y for the current TIN set by load_tin

create_tin

Creates TIN from a given selection set, optionally using inside/outside logic.

Usage: **(cf:dtm.api 'create_tin' entities_ss inclusion_ss exclusion_ss regions_ss file_name options)**

entities_ss - Selection set of all entities to be used for triangulation. Currently supported are point, line, arc, polyline, insert, circle, 3dface, solids, text, and mtext.

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being

used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

file_name - Full path of file to be created. Extension controls a type of TIN file created.

options - Optional. String containing one or more of the following keywords, space separated:

ignore_zero - Ignore zero elevation data points.

view_error_log - In case of warnings during triangulation, bring up the report at the end.

densify - Perform ridge/valley detection and improve triangulation as needed.

draw_tin

Draws TIN file at a given layer as 3DFACES.

Usage: `(cf:dtm_api 'draw_tin' file_name layer_name is_road)`

file_name - Full path of file to be loaded.

layer_name - Layer name to use. If does not yet exist, new layer will be created. Color of entities is set to BYLAYER.

is_road - Optional. If set to 1 and route follows completion of Process Road Design feature it will turn on road coloring.

tri_volume

Calculates volume of the TIN within a given polyline, optionally with report generated.

Usage: `(cf:dtm_api 'tri_volume' inclusion_ss exclusion_ss regions_ss filename filename2|elevation is_report is_silent)`

Return values: If successful, the function returns a list with 4 real values: cut, fill, cut area, and fill area. The volume is in cubic ft or meters and area is in square ft or meters, depending on the configuration.

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename - Full path of main TIN file to be used.

filename2 - Full path of secondary TIN file to be used. If used, two surface volumes will be calculated between the first and second TINs.

elevation - Reference elevation passed as real value. If this option is used, one surface volume will be calculated between the first TIN and this reference elevation.

is_report - 0/1. Specifies whether to bring up the report with calculation results.

is_silent - 0/1. If 0 value is supplied the routine will provide no output at the command line and no progress indicators.

tri_change

Change TIN file using specified optional inclusion polylines and using one of the possible math operations. For all

operations but "embed" the inclusion/exclusion polylines are offset a 0.1 so that a reasonably sharp wall could be produced by modifications.

Usage: **(cf:dtm_api 'tri_change' inclusion_ss exclusion_ss regions_ss filename operation value)**

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename - Full path of main TIN file to be modified.

operation - keywords describing what operation is to be performed on the TIN:

add - Add a value to elevation of inside nodes.

scale - Scale elevation of inside nodes by the value.

set - Set elevation of inside nodes to the value specified.

perp - Sets elevation of nodes as if TIN is offset by value along normal at the point. The node is not moved horizontally, just elevation is adjusted.

nil - Removes inside nodes. No value is needed.

embed - No change of elevations, but the inclusion polyline is still added to TIN.

tri_contour

Contours TIN file as defined by INI file and inclusion polylines

Usage: **(cf:dtm_api 'tri_contour' inclusion_ss exclusion_ss regions_ss tin_filename ini_filename)**

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

tin_filename - Full path of main TIN file to be used.

ini_filename - Full path of INI file defining how contouring is performed. For list of values, check tri4.ini in USER folder which stores values used in Triangulate and Contour function.

tri_profile

Creates a profile of the TIN along a centerline

Usage: **(cf:dtm_api 'tri_profile' tin_filename cl_filename pro_filename)**

Return values: If successful, the function returns 1, otherwise nil.

tin_filename - Full path of main TIN file to be used.

cl_filename - Full path of centerline (.cl) file to be used.

pro_filename - Full path of the profile file to be created.

tri_diff

Calculates difference between two TIN files and creates combined TIN with elevation being the difference of elevations. TINs do not have to match perfectly - face intersections will be performed. Inclusion logic will be applied if needed.

Usage: `(cf:dtm_api 'tri_diff' inclusion_ss exclusion_ss regions_ss filename1 filename2 diff_filename)`

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename1, filename2 - Full path to TIN files to be used. Second TIN is subtracted from first one.

diff_filename - Full path of differential TIN file to be created.

tin_combine

Combines two TINs into one while applying one of the specified operations. First two TINs are combined into one intersecting all faces which need to be intersected and then elevations are assigned as specified.

Usage: `(cf:dtm_api 'tin_combine' inclusion_ss exclusion_ss regions_ss filename1 filename2 merged_filename operation)`

inclusion_ss - Selection set containing inclusion polylines if needed. Pass nil if inclusion polylines are not being used.

exclusion_ss - Selection set containing exclusion polylines if needed. Pass nil if exclusion polylines are not being used.

regions_ss - Selection set containing region polylines if needed. Pass nil if regions are not being used. Regions logic is on/off - crossing region line reverses the inside/outside state. Note: Only one of inside/outside methods can be used for one call (either inclusion/exclusion or regions).

filename1, filename2 - Full path to TIN files to be used.

merged_filename - Full path to the file where results are stored.

operation - Keywords describing the operation to perform. The following operations are supported:

keep - The elevations of first TIN are used.

copy - Elevations of second TIN are used.

min - Lesser of two elevations is used.

max - Greater of two elevations is used.

join - Points inside are given elevations of first TIN, outside - second one.

tri_store_regions

Evaluates "before" and "after" TIN and stores "affected" area as a region with two revisions "0" and "1". The regions then can be applied as needed using other commands. This functionality only works with binary .TIN files.

Usage: `(cf:dtm_api 'tri_store_regions' filename1 filename2 mark_name filename3)`

filename1, filename2 - Full path to TIN files to be used.

mark_name - String label for region to be used.

filename3 - Full path to TIN files to be Save As. If omitted, the file specified by filename1 will be replaced with resulting file.

tri_apply_region

Applies a specific pre-stored region revision, so that when TIN file is used it has that revision of the region in use.

Usage: **(cf:dtm_api 'tri_apply_region' filename mark_name revision)**

filename1 - Full path to TIN file to be modified.

mark_name - String label for region to be used.

revision - Integer. Optional ID of revision to apply. If omitted, the latest revision of the region is used.

tri_forget_region

Removes any knowledge of a specific pre-stored region revision from TIN file. Optionally remove triangles found in the region from the TIN.

Usage: **(cf:dtm_api 'tri_forget_region' filename mark_name remove_first)**

filename - Full path to TIN file to be modified.

mark_name - String label for region to be used.

remove_first - 0/1. Optional flag indicating whether region triangles should be removed, leaving a hole in the TIN.

surface_util

Utilities for dealing with surfaces stored in the drawing.

Usage: **(cf:dtm_api 'surface_util' filename operation)**

filename - Full path to TIN file to be modified.

operation - Keywords describing the operation to perform. The following operations are supported:

check - Check if TIN is used in one of the surfaces. Returns 0 or 1 depending on outcome.

process - Apply current surface parameters to TIN file. This function should be used to update surface in the drawing after TIN has been modified.

load_tin

Loads a TIN into memory for use with the tin_z function.

Usage: **(cf:dtm_api 'load_tin' file_name)**

file_name - Full path of file to be loaded.

unload_tin

Unloads the current TIN from memory.

Usage: `(cf:dtm_api 'unload_tin')`

tin_z

Calculates the elevation of the TIN at the specified x,y location. The TIN to process must be already loaded by the `load_tin` command. The calculated elevation is returned to LSP on success. A nil is returned to LSP if the command arguments are invalid, a TIN is not loaded or the point is off the surface.

Usage: `(setq elev (cf:dtm_api 'tin_z' point))`

point - List of doubles in x,y format

Examples:

Calculate TIN Elevation at Point

```
(scload (strcat lspdir$ "tri4"))
(setq file_name (scad_getfiled "Select TIN to Process" "" "tin" 0))
(cf:dtm_api "load_tin" file_name)
(setq pnt (getpoint "\nPick point:"))
(setq elev (cf:dtm_api "tin_z" pnt))
(cf:dtm_api "unload_tin")
```

Road API

Overview

The Road API is a collection of functions for centerline location and road design calculations. These functions are available from LISP for advanced users to use in their own routines.

The functionality of Road API is implemented in the Carlson EWORKS.ARX program file. This ARX program file must be loaded before calling the Road API functions. Use the following LSP code to load the ARX:

```
(scload (strcat lspdir$ 'eworks'))
```

The following is a list of currently supported functions (it can be obtained at any time by calling `(cf:road_api)`):

cl_location_at_pt - calculates the station-offset and centerline position from a specified centerline and point

cl_location_at_sta - calculates the point and vectors for a specified station on a centerline

cl_sta_range - returns the start and end stations for the specified centerline

profile_z - calculates the profile elevation for the specified station on the profile

profile_sta_range - returns the start and end station for the specified profile

road_z - calculates the road design elevation for the specified point and design files

cl_location_at_pt

Given a centerline file name and a point, this function calculates the station-offset and the projected location of the

point along the centerline. On success, the function returns a list of the station, offset and projected centerline point. On failure, the function returns nil.

Usage: `(cf:road_api 'cl_location_at_pt' file_name point is_rr)`

file_name - Full path of the centerline file to process (string).

point - Coordinates (x,y) of the point to process (list of reals).

is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

cl_location_at_sta

Given a centerline file name and a station, this function calculates the point on the centerline at the specified station along with the vectors for the tangent and normal of the centerline at that station. On success, the function returns a list of the point on centerline, the tangent vector and the normal vector. On failure, the function returns nil.

Usage: `(cf:road_api 'cl_location_at_sta' file_name station is_rr)`

file_name - Full path of the centerline file to process (string).

station - Target station to process (real).

is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

cl_sta_range

This function simply return the starting and ending stations for the specified centerline. On success, the function returns a list of the starting station and the ending station as reals. On failure, the function returns nil.

Usage: `(cf:road_api 'cl_sta_range' file_name is_rr)`

file_name - Full path of the centerline file to process (string).

is_rr - Optional integer parameter for station type (0 = roadway stations (default), 1 = railroad stations)

profile_z

Given a profile file name and a station, this function calculates the elevation on the profile at the specified station. On success, the function returns the elevation. On failure, the function returns nil.

Usage: `(cf:road_api 'profile_z' file_name station)`

file_name - Full path of the profile file to process (string).

station - Target station on profile (real).

profile_sta_range

This function simply returns the starting and ending stations for the specified profile. On success, the function returns a list of the starting and ending stations as reals. On failure, the function returns nil.

Usage: `(cf:road_api 'profile_sta_range' file_name)`

file_name - Full path of the profile file to process (string).

road_z

This function calculates elevation of a road design at the specified point. The road design is defined by the design files names. The centerline, profile and template files are required. The other design files are optional. On success, the function returns the elevation. On failure, the function returns nil.

Usage: **(cf:road_api 'road_z' point cl_file pro_file tpl_file sup_file tpt_file tpc_file tpp_file tgt_file)**

point - Coordinates (x,y) of the point to process (list of reals).

cl_file - Full path of the centerline file (.cl) (string).

pro_file - Full path of the profile file (.pro) (string).

tpl_file - Full path of the template file or template series file (.tpl or .tsf) (string).

sup_file - Full path of the superelevation file (.sup) (string).

tpt_file - Full path of the template transition file (.tpt) (string).

tpc_file - Full path of the template point centerline file (.tpc) (string).

tpp_file - Full path of the template point profile file (.tpp) (string).

tgt_file - Full path of the template grade table file (.tgt) (string).

3D Viewer API

Overview

It is now possible to call 3d viewer from LISP for the advanced users to use in their routines.

The functionality of 3D Viewer API is implemented in CUBE.ARX. It would be the responsibility of the caller to make sure that this file gets loaded by adding this line at the beginning:

```
(scload (strcat lspdir$ 'cube'))
```

Displaying a selection set of entities

Prompts the user for a selection set and displays it in a 3d viewer window

Usage: **(cf:sc3dview)**

Loading a surface file into 3D viewer

Loads the surface given as grid (.GRD) or triangulation (.FLT or .TIN) file.

Usage: **(cf:sc3dview file_name)**

Lat/Lon and Grid Projections API

Overview

To use these functions, the Coordinate System must be set under Settings >Drawing Setup.

Drawing X/Y to Lat/Lon

Converts a drawing coordinate to latitude and longitude.

Usage: (setq result (cf:lablat 8 x_val y_val is_dms))

x_val - Easting

y_val - Northing

is_dms - Optional parameter to control format of result (0-decimal degrees (default), 1=dd.mmss)

result - Function output containing list of latitude and longitude

Lat/Lon to Drawing X/Y

Converts latitude and longitude to a drawing coordinate.

Usage: (setq result (cf:lablat 9 lon_val latitude_val is_dms))

lon_val - Longitude

lat_val - Latitude

is_dms - Optional parameter to define format of input (0-decimal degrees (default), 1=dd.mmss)

result - Function output containing list of easting and northing
