Additional CL Distance (Front Main, Back Main, Left Side, Right Side): These options allow you to extend the station range of the intersection. By default the intersection station range is between the PC points where the intersection arcs begin.

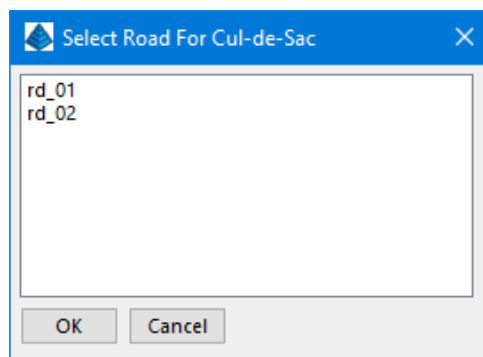

Cul-de-Sacs may be added to any Road in the Network and are managed in the **Cul-de-Sac** area of the **Road Network: Task Pane**.

Add: Pick the Add button or right-click on Cul-de-sacs in the project tree and choose Add to display a list of Roads in the Network and prompt the user to "**Select Road for Cul-de-Sac**".... After selecting the Road, the **Edit Cul-de-Sac** dialog box is displayed allowing the user to specify the **Input Data** and **Output Files** for the Cul-de-Sac.

Edit: Use this button to display the **Edit Cul-de-Sac** dialog box and make changes to the **Input Data** and **Output Files** for the selected Cul-de-Sac.

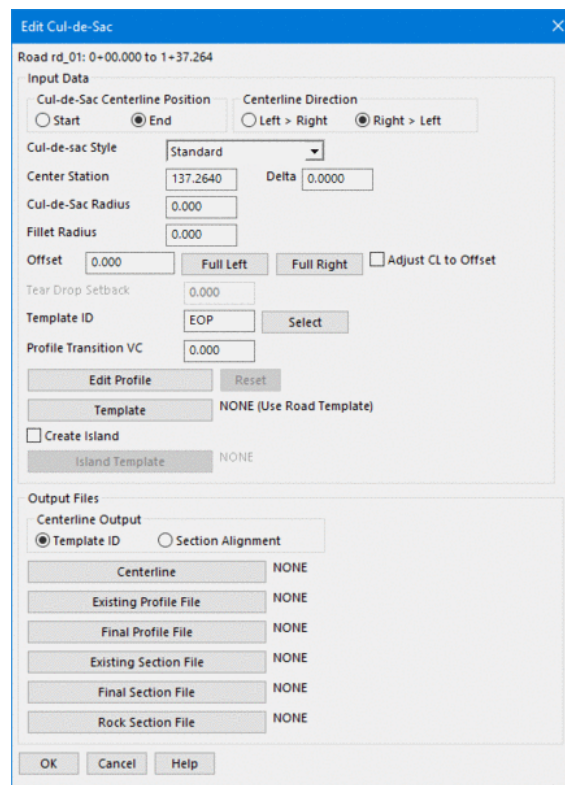

Remove: Use this button to **Remove** the selected Cul-de-Sac from the Road.

Add: Picking this button displays a dialog box listing the Roads in the Network and prompting the user to **Select Road for Cul-de-Sac**.

Select Road for Cul-de-Sac

After choosing the Road and picking the **OK** button, the **Edit Cul-de-Sac** dialog box is displayed.

Edit Cul-de-Sac Dialog Box

Cul de Sac Input Data

Cul-de-Sac Centerline Position: Use this radio button to specify whether the Cul-de-Sac is drawn at the starting or the ending station of the Centerline.

Centerline Direction: This setting applies only if the horizontal alignment of the Cul-de-Sac is to be saved externally as an **Output Centerline (.CL) file**. If so, this setting determines which end of the Cul-de-Sac is the starting and which is the ending station of the new Centerline (.CL) file.

Cul-de-Sac Style: Standard: This style has a rounded bulb and fillet curves to connect with the road. **Tear Drop Mode:** Enabling this option creates a longer transition between the Road and the Cul-de-Sac. When enabled, a value larger than the Cul-de-Sac Radius must be entered as the Setback. An example of a "Tear Drop" Cul-de-Sac having a 45' radius and 75' setback is shown below. **Straight:** This style simply connects the left and right sides of the road which is a way to create curb at the end of the road. This style can be combined with a short end road to make a T-intersection into a hammerhead type cul-de-sac.

Center Station: Use this setting to precisely locate the center of the Cul-de-Sac along the Road Centerline. By default, the **Center Station** is the starting or ending station of the Centerline depending on whether the user has chosen **Start** or **End** as the desired **Cul-de-Sac Centerline Position**. The station for the center of the Cul-de-Sac may also be entered in the text box or may be specified using a **Delta** value. When using the **Delta** option, the Cul-de-Sac will be shifted the specified distance along the Centerline.

Cul-de-Sac Radius: Use this value to specify the radius of the Cul-de-Sac bulb. The **Cul-de-Sac Template ID** determines the point on the cross-section being affected by this setting.

Fillet Radius: Use this value to specify the radius of the curve that transitions between the Road and the Cul-de-Sac. The **Cul-de-Sac Template ID** determines the point on the cross-section being affected by this setting.

Offset: When set to "0", this setting places the center of the Cul-de-Sac on the Centerline of the Road. Setting this value to a negative(-), greater than "0" value will shift the center of the Cul-de-Sac left of the Centerline by that distance. A positive, greater than "0" value will shift it to the right by that distance.

Adjust CL to Offset: This option adjusts the end of the road centerline to end at the cul-de-sac offset point.

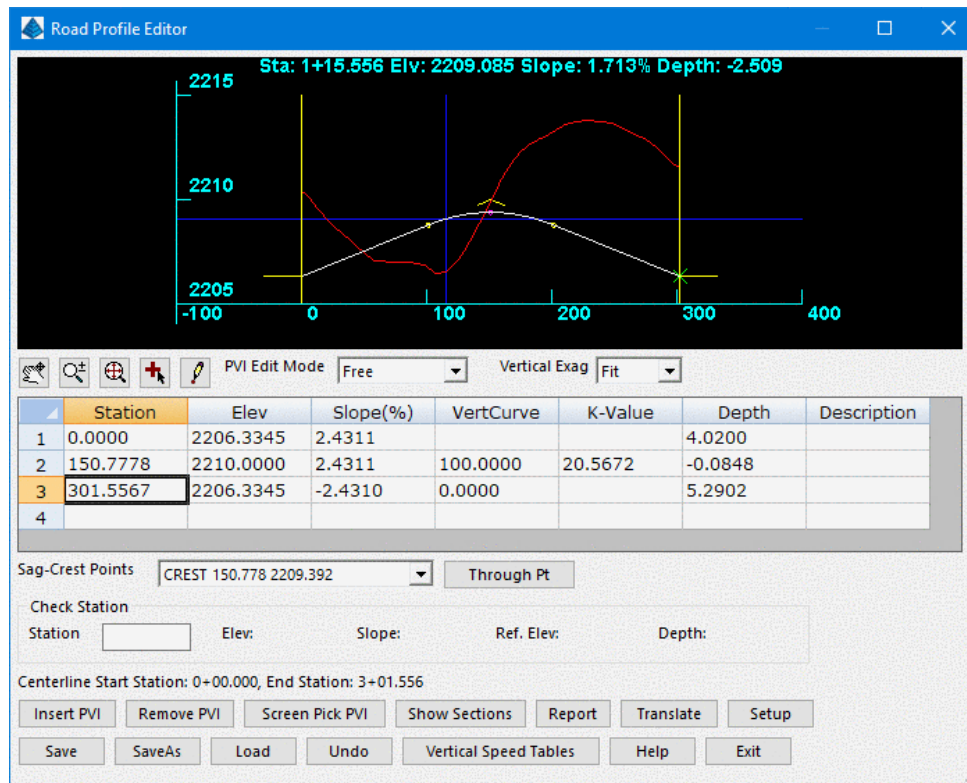

Example of Tear Drop Cul-de-Sac

Template ID: This is the point on the cross-section used to define the horizontal (Centerline) and vertical (Profile) alignments around the bulb of the Cul-de-Sac. The Template ID may be specified as any point on the cross-section - such as edge of pavement (EP) or the back of curb (BC) - as long as it has been defined as a **Template ID** in the Template (.TPL) file used for the Road. Type the **Template ID** in the text box or use the **Select** button to choose from a list.

Profile Transition VC: When adding a Cul-de-Sac to the Road Network, the Profile around the Cul-de-Sac is automatically generated having 3 PVI's - one on each end connecting to the Road and one at the mid-point of the alignment. The **Profile Transition VC** setting is the default length of vertical curve inserted at the middle PVI of the Profile. As shown below, adding a vertical curve at this PVI can have a significant, positive impact on the resulting surface model and contours of the Road Network.

Effect of Adding a Vertical Curve to Cul-de-Sac Profile

Edit Profile: Pick this button to open the **Road Profile Editor** and make changes to the Profile of the Cul-de-Sac. The **Cul-de-Sac Template ID** determines the point on the cross-section being represented in the Profile Editor. See **Road Network: Road Profile Editor** for more **Help** with this feature.

Edit Profile for a Cul-de-Sac

Reset: Use this button to overwrite all edits to the Profile of the Cul-de-Sac and reset to the original Profile.

Template: Use this button to browse to and select an existing Cul-de-Sac Template (.TPL or .TSF) file. Specifying a different Template than the main Road allows the user to define different features for the Cul-de-Sac area such as sidewalk and curb.

Create Island: This option creates a circular island in the middle of the cul-de-sac. The template (.TPL) file uses the grade in the template for the island radius and the template grade slope for the island slope. The island template file does not use the cut/fill slopes.

Cul de Sac Output Files

Centerline: Pick this button to output a Centerline (.CL) file representing the horizontal alignment around the Cul-de-Sac. The **Cul-de-Sac Template ID** determines the point on the cross-section exported to the Centerline (.CL) file.

Existing Profile: Creates a profile of existing ground along the cul-de-sac centerline.

Final Profile: Pick this button to output a Profile (.PRO) file representing the vertical alignment around the Cul-de-Sac. The **Cul-de-Sac Template ID** determines the point on the cross-section exported to the Profile (.PRO) file.

Existing Section File: : Pick this button to output an Existing Section (.SCT) file for the Cul-de-Sac.

Final Section File: Pick this button to output a Final Section (.SCT) file for the Cul-de-Sac.

Rock Section File: Creates a cross section (.SCT) file for the rock surface.

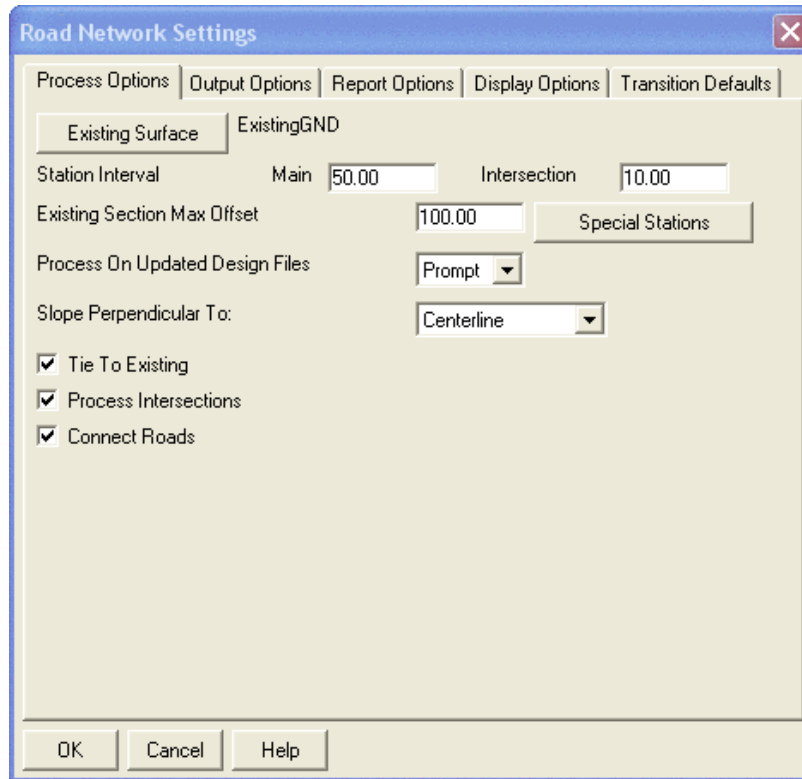

Note: Driveways around a cul-de-sac can be easily added simply by drawing polylines for their centerlines and snapping them to the EOP of the cul-de-sac.

Step 1: Start Road Network and Configure Settings

Open a Drawing (.DWG) file containing the 2D zero-elevation polylines representing Road Centerlines for the project. Start the **Road Network** command and create a **New Road Network** (.RDN) file. After creating the Road

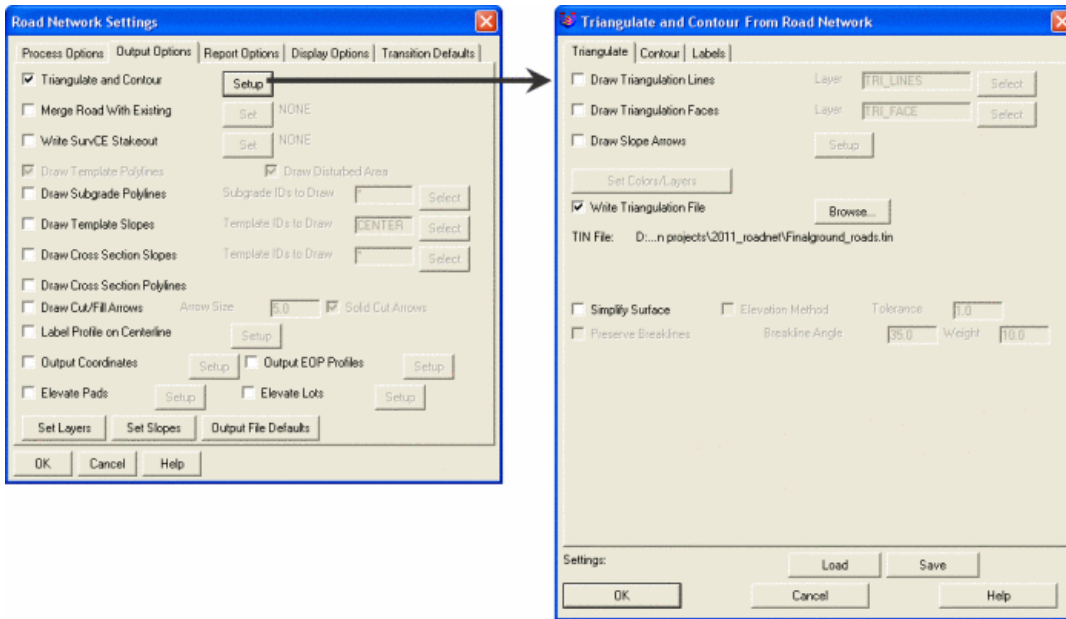

Network file, the **Road Network Task Pane** loads as a docked dialog-box on the left side of the drawing screen.

Configure the Road Network by *picking the **Settings** button* and displaying the **Road Network Settings** dialog box. In the **Process Options** tab, *pick the **Existing Surface** button* and browse to and select the Existing Ground Surface (.TIN or .FLT) file to be used for the project.

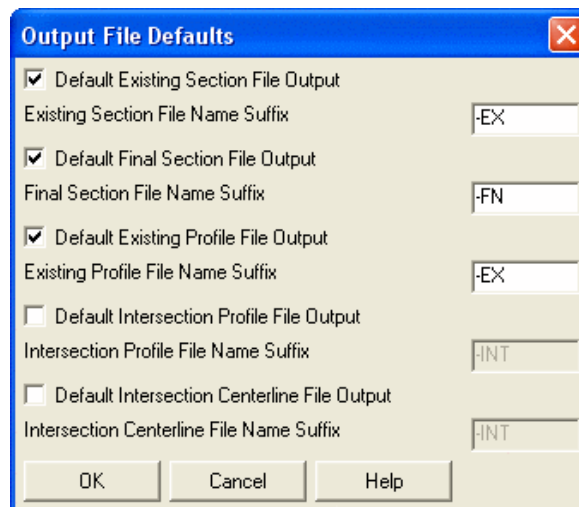

Process Options Tab

Next, *switch to the **Output Options** tab* and *pick the **Setup** button* next to **Triangulate and Contour**. *Select the **Write Triangulation File** option* and then *pick the **Browse** button* to set the path and filename for the design Surface (.TIN) file for the Roads.

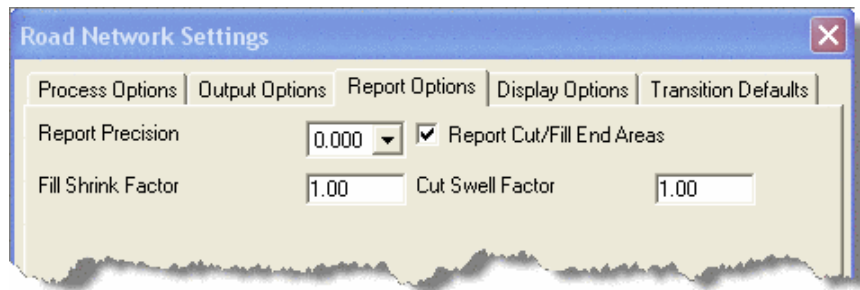

Output Options Tab

Also in the **Output Options** tab, pick the **Output File Defaults** button to display the **Output File Defaults** dialog box. Pick the **Output File Defaults** button to specify additional Centerline (.CL), Profile (.PRO) and Section (.SCT) files to be saved when Processing the Road Network.

Output File Defaults Dialog Box

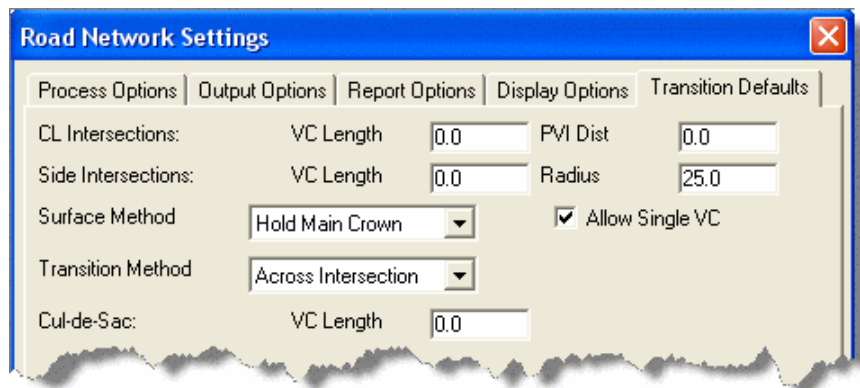

Next, review the **Report Options**, **Display Options** and **Transition Defaults** tabs of the **Road Network Settings** dialog box and make any necessary changes.

Report Options Tab

Display Options Tab

Transition Defaults Tab

Pick the **OK** button to close the **Road Network Settings** dialog box and then pick the **Save** button on the **Task Pane** to save the settings to the Road Network (.RDN) file.

Step 2: Add Roads to the Network

RD.01 and RD.02

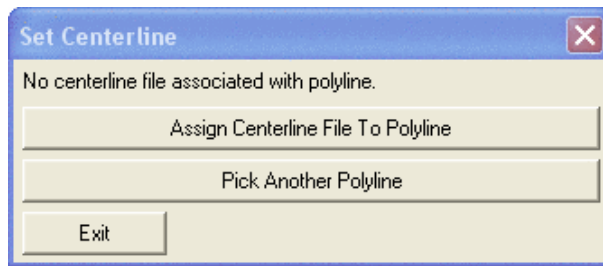

In the project tree, highlight Roads and right-click and choose Add Road.

After picking the **Add** button, the **Add Road** dialog box provides two methods for adding a Road to the Network. *Pick the **Screen Pick Polyline** button.*

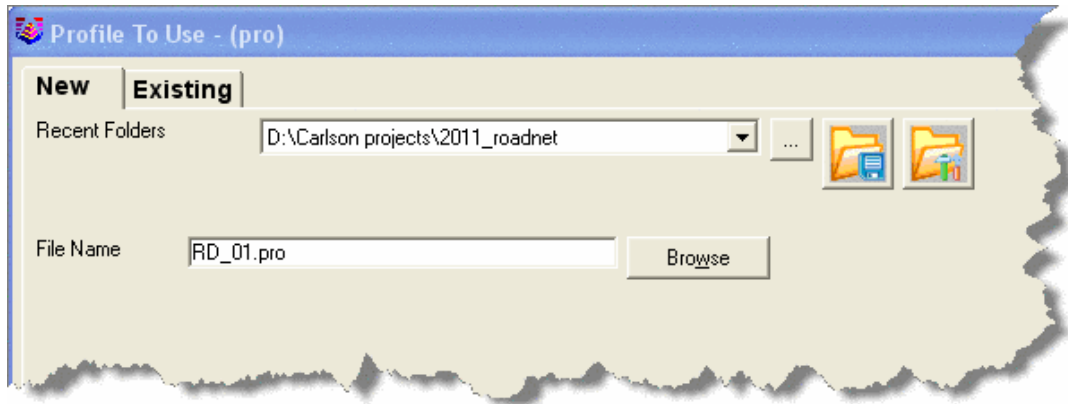

Specify Method to Use to Add Road

The prompts then switch to the Command: line where you are prompted to *Select Centerline Polyline* in the drawing. At the next prompt, *pick the **Assign Centerline File to Polyline** button* and set the path and filename for the new Centerline (.CL) file.

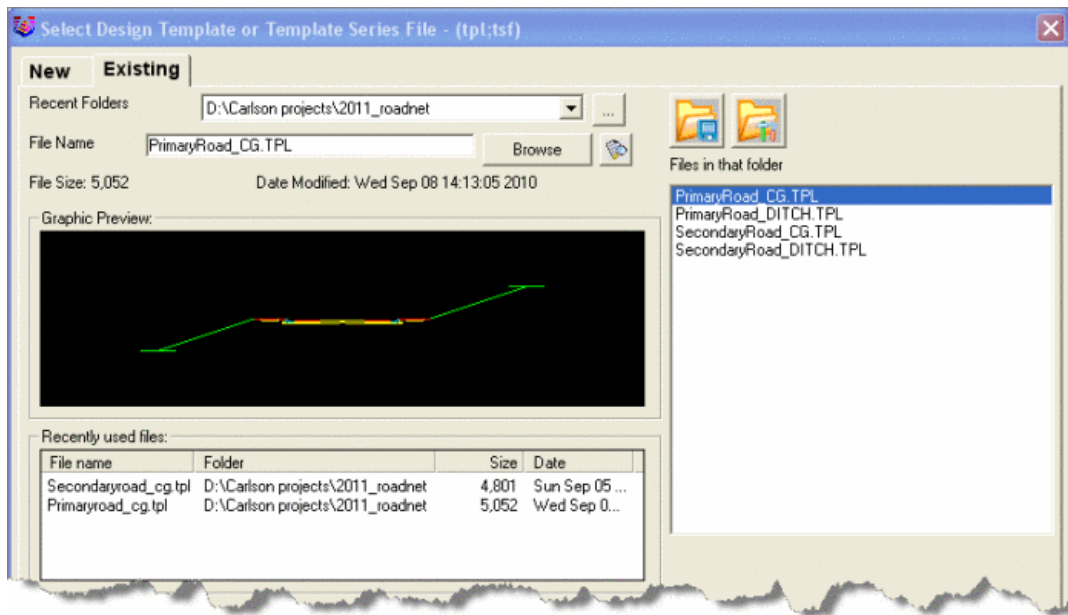

Set Centerline Dialog Box

Immediately after creating the new Centerline file, the **Profile to Use** file dialog box is displayed. In this box, you must set the path and filename for the proposed Profile (.PRO) file for the Road. By default, the new Profile (.PRO) file is named the same as the Centerline (.CL) file.

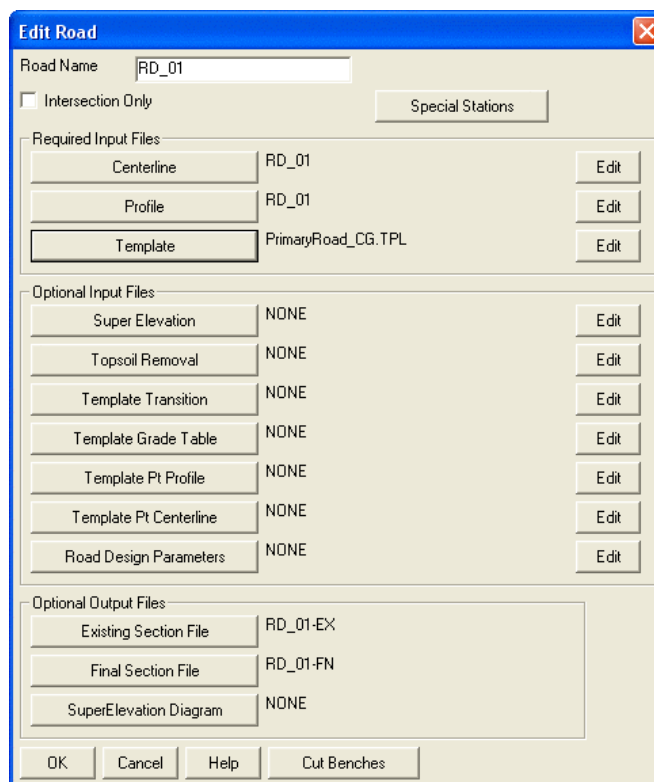

Profile to Use File Dialog Box

After specifying the Centerline (.CL) and Profile (.PRO) files for the Road, the **Edit Road** dialog box is displayed. The only other **Required Input File** is a Template (.TPL) file. *Pick the **Template** button* to browse to and select the desired Template file.

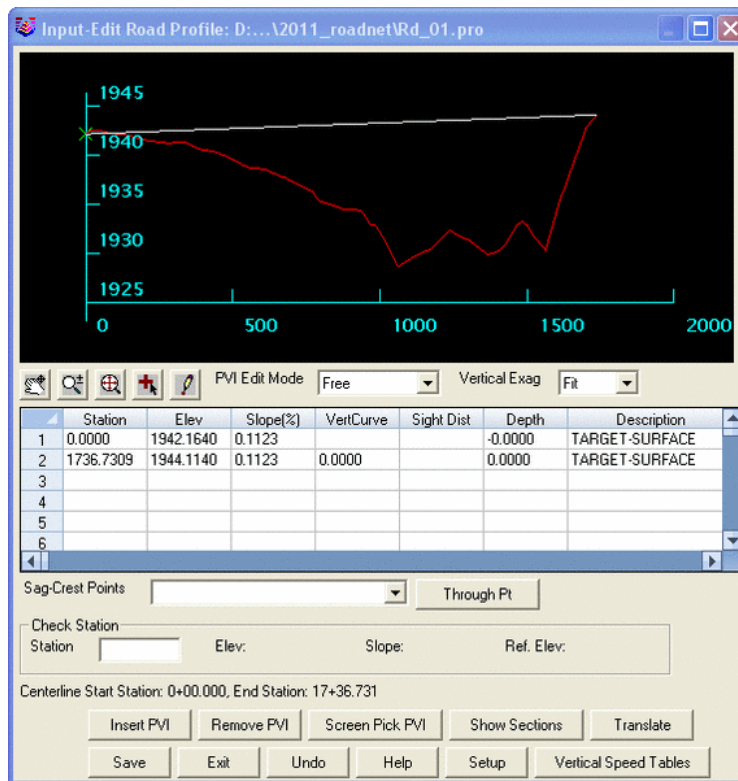

Select Template (.TPL) file Dialog Box

The **Edit Road** dialog box serves as the "manager" for all files relating to the specific Road. The **Edit** button in the **Road Name** area of the **Road Network: Task Pane** also displays the **Edit Road** dialog box.

Edit Road Dialog Box

Pick the **Edit** button to the right of the **Profile** button to open the **Road Profile Editor**.

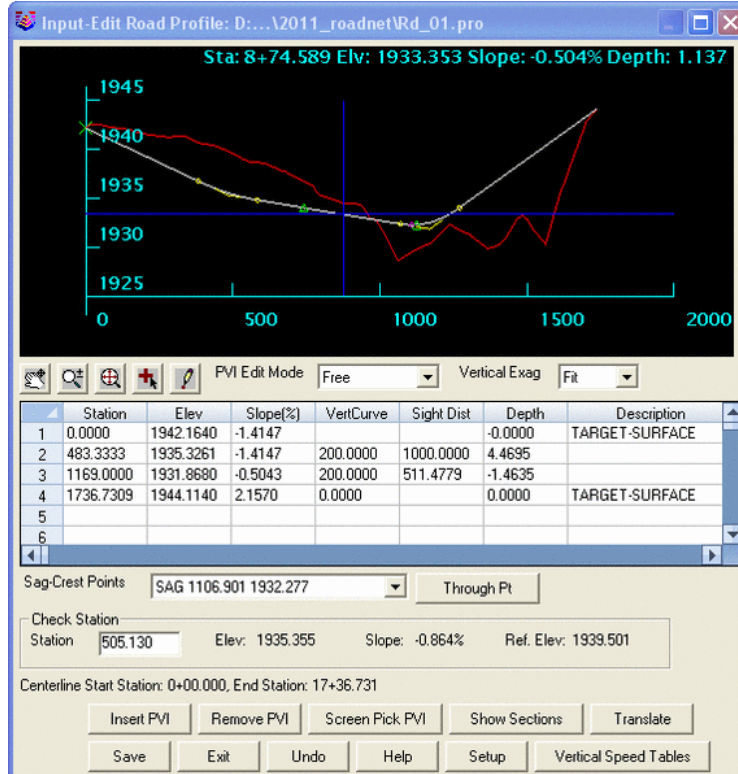

Road Profile Editor

In Carlson's **Road Network** feature, the initial design Profile is automatically generated and has only a starting and ending PVI - with the elevation at both ends tying into existing ground. The movement of the crosshairs is locked to the design Profile. The initial PVIs can be seen in the profile-grid-view where the existing ground Profile is shown in red and the design Profile in white. The initial PVIs are shown in the table-view with the "PVI Description" indicating the PVI elevation is tied to the "TARGET-SURFACE" (existing ground).

Pick the  **Add PVI** button to create a new PVI by screen-picking a point in the profile-grid-view at the top. After picking the **Add PVI** button, the **New PVI** dialog box is displayed.

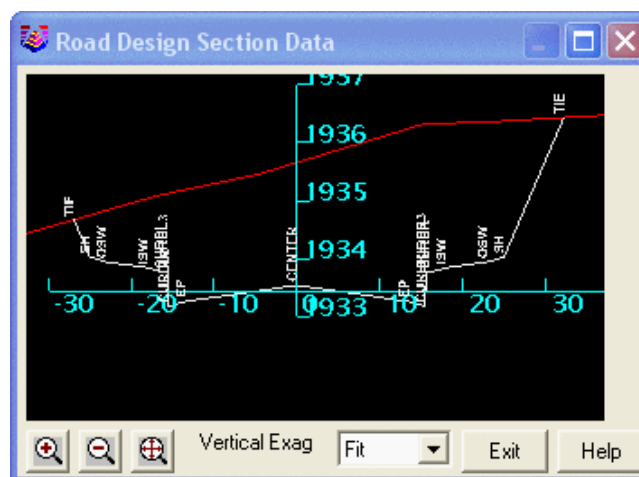

New PVI Dialog Box

Enter a length for a vertical curve or change other settings as desired and then pick the **OK** button. Repeat as needed for additional PVIs and vertical curves.

Road Profile Editor

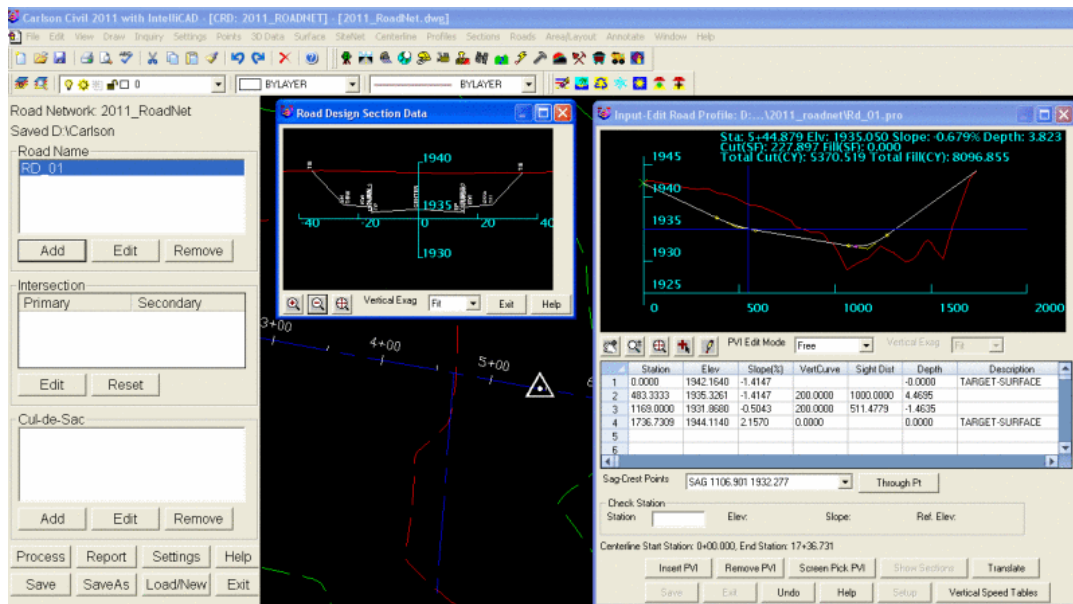

Pick the **Show Sections** button at the bottom of the **Road Profile Editor** to display a **Section View** of the Road. Moving your crosshairs along the design Profile dynamically updates the **Section View**.

Section Viewer

When the **Section View** window is open and active, the **Road Profile Editor** also remains open and active. If you

position the **Road Profile Editor** and the **Section View** window so that the drawing view of the Road is unobscured, you can move your crosshairs along the design Profile and have a dynamic design environment allowing you to see the plan-, profile- and section-views at one time. Additionally, when the **Section View** window is open, the notes at the top of the profile-grid-view include the "Cut" and "Fill" end-area at the current station along with the "Cut" and "Fill" volume for the entire Road. These calculations are dynamic and will update if changes are made to the design Profile.

Road Profile View and Section Viewer with Station Indicator in Drawing

Pick the **Exit** button to close the **Section Viewer** and then pick the **Save** button in the **Road Profile Editor** to save changes to the Profile (.PRO) file. Pick the **Exit** button to close the **Road Profile Editor**.

Repeat the steps above to define additional Roads in the Network.

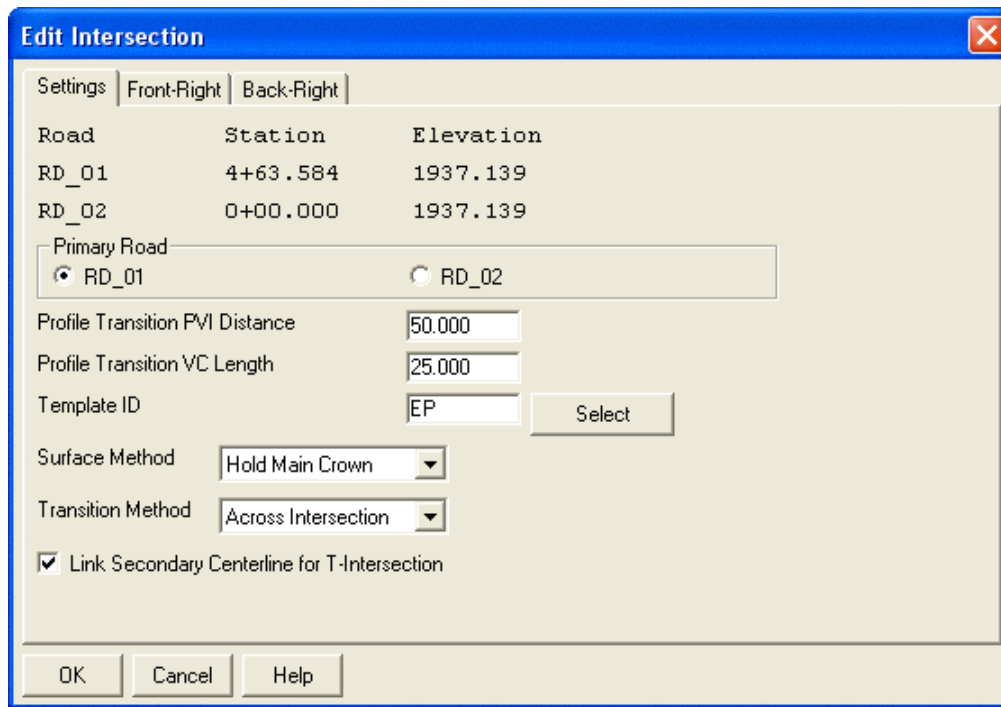

See **Road Network: Adding and Editing Roads** if you need additional assistance.

Step 3: Adding and Editing Intersections

After Adding the next Road, the **Road Network** command recognizes the creation of an Intersection and the Primary and Secondary Roads are displayed in the **Intersection** area of the project tree.

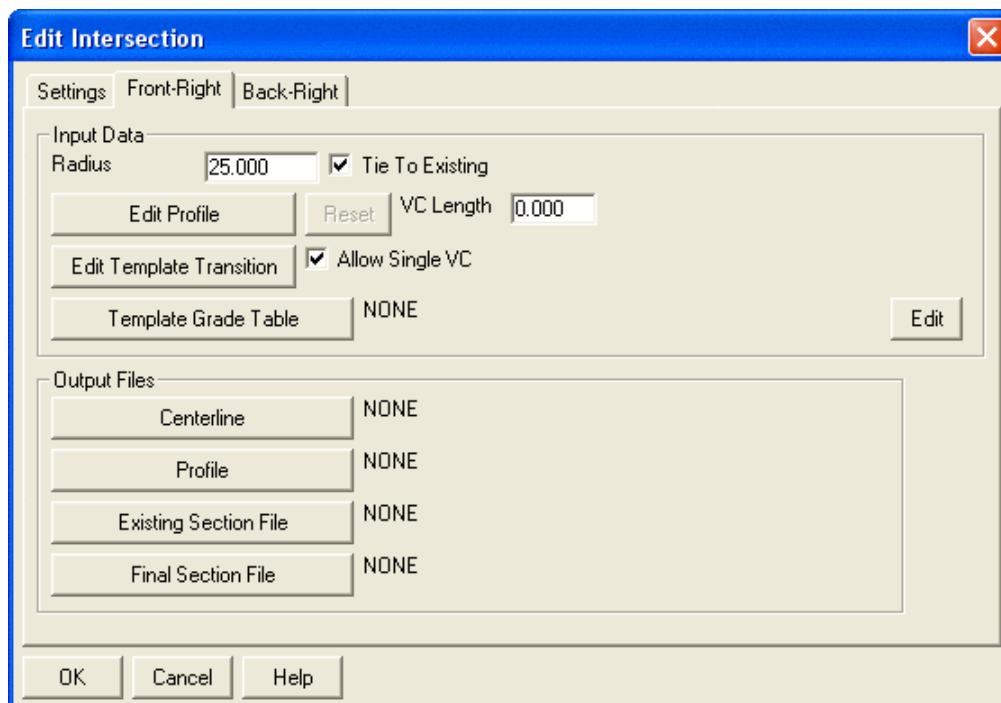

Select the Intersection, right-click and pick the **Edit Intersection** function to display the **Settings** tab of the **Edit Intersection** dialog box. Make changes as needed.

Note: Changes made here apply to all Corners of the Intersection.

The Settings Tab of the Edit Intersection Dialog Box

Or, you can switch to one of the **Corner** tabs - *Front-Right*, *Back-Right*, *Front-Left*, *Back-Left* to make changes to only one Corner of the Intersection.

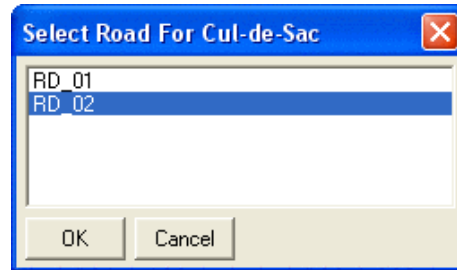

One of the "Corner" Tabs of the Edit Intersection Dialog Box

Pick the **OK** button to close the **Edit Intersection** box and save changes.

See **Road Network: Adding and Editing Intersections** if you need additional assistance.

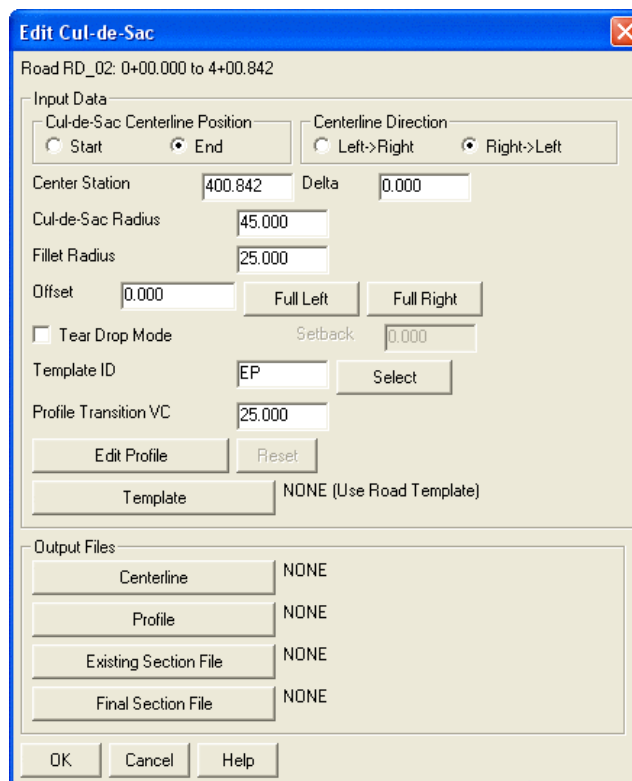

Step 4: Adding and Editing Cul-de-Sacs

Pick the **Add** button in the **Cul-de-Sac** area of the **Road Network Task Pane** to display a dialog box listing the Roads in the Network and prompting you to **Select Road for Cul-de-Sac**.

Select Road for Cul-de-Sac

After choosing the Road and picking the **OK** button, the **Edit Cul-de-Sac** dialog box is displayed. At a minimum, you must enter a **Cul-de-Sac Radius** and **Fillet Radius** to define the Cul-de-Sac.

Edit Cul-de-Sac Dialog Box

Pick the **OK** button to close the **Edit Cul-de-Sac** box and save changes.

See **Road Network: Adding and Editing Cul-de-Sacs** if you need additional assistance.

Step 5: Save, Process and View the Road Network

Pick the *Save* button on the **Road Network Task Pane** to **Save** the Road Network (.RDN) file.

Then, pick the *Process* button on the **Road Network Task Pane** to calculate the road design and perform the functions specified in **Road Network Output Options**. The resulting contours and breaklines are shown below.

Contours and Breaklines After Processing Road Network

The elevated breaklines and contours can now be viewed using the **3D Viewer Window** command as shown below.

Breaklines and Contours as Seen in the 3D Viewer Window

Or, use the **Surface 3D Viewer** command to view the Surface (.TIN) file as shown below.

Surface (.TIN) File as Seen in the Surface 3D Viewer

Or, use the **Surface 3D Flyover** command to drive the Surface (.TIN) file as shown below.

Surface (.TIN) File in the Surface 3D Flyover Command

Step 6: Reports

Pick the **Report** button on the **Road Network Task Pane**. Then, pick the **Output Processing** button to display the report. This report displays the cut/fill and material quantities for each Road, Intersection and Cul-de-Sac of the Road Network.

Road Network Output Processing Report

Repeat this step but, this time, pick the **Input Data Files** button to display the report. This report displays all of the user-specified design files associated with the Road Network. For this report, you are given the option of reporting only the filename or both the path and filename.

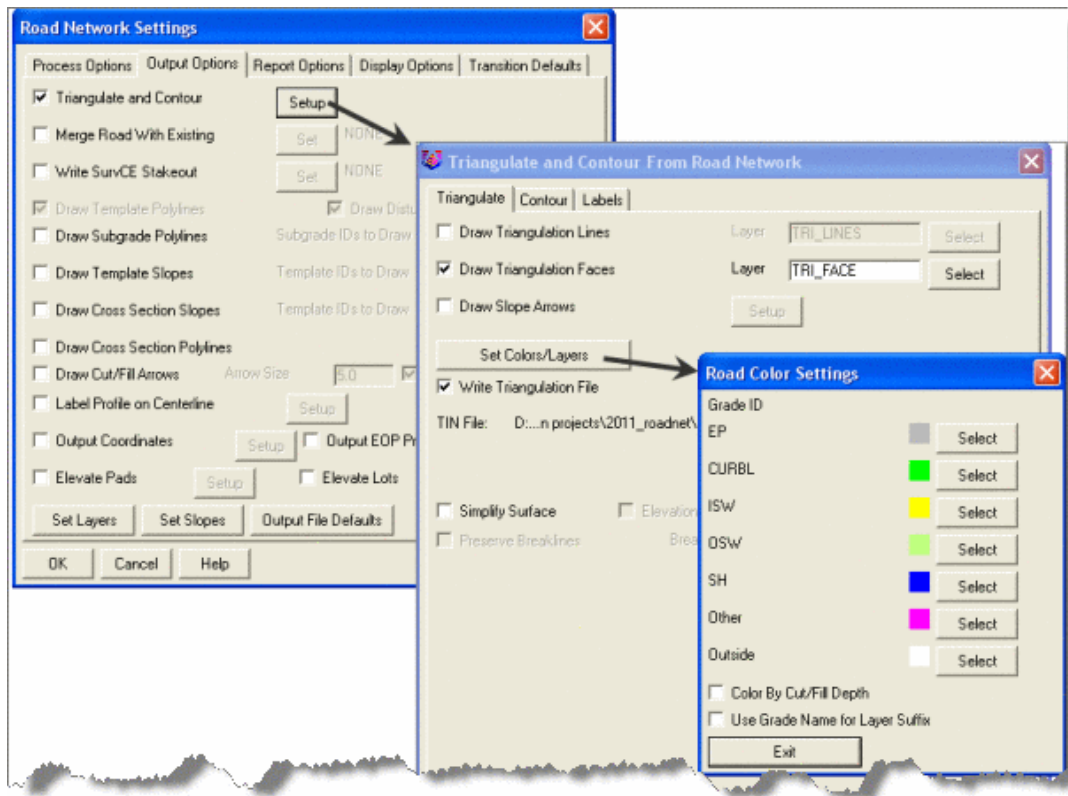

Road Network *Input Data Files* Report

Step 7: Additional Settings and Tools in the Road Network

Draw Triangulation Faces with Color and View in 3D Viewer Window

Pick the **Settings** button on the **Road Network Task Pane** and then pick the **Output Options** tab. Now, pick the **Setup** button next to **Triangulate and Contour** to open the **Triangulate and Contour from Road Network** dialog box.

Select the **Draw Triangulation Faces** option and then pick the **Set Colors/Layers** buttons to display the **Road Color Settings** dialog box (shown below). The color of the faces can be set either by using the **Template IDs** defined in the Template (.TPL) file or using a color range based on the "Cut & Fill Depths".

Set Road Colors In the "Triangulate and Contour From Road Network" Dialog Box

*Pick the **Exit** button to close the **Road Color Settings** box and then *pick the **OK** button twice to exit both the **Triangulate and Contour** and **Road Network Settings** dialog boxes.**

*Pick the **Save** button on the **Road Network Task Pane** to **Save** the Road Network (.RDN) file.*

Then, *pick the **Process** button on the **Road Network Task Pane** to calculate the road design and perform the functions specified in **Road Network Output Options** The image below shows only the Triangulation Faces after Processing.*

Triangulation Faces with Color After Processing Road Network

The elevated Triangulated Faces can now be viewed using the **3D Viewer Window** command as shown below.

Contours and Triangulation Faces with Color in the 3D Viewer Window

Merge Road with Existing

Pick the **Settings** button on the **Road Network Task Pane** and then pick the **Output Options** tab. Select the **Merge Road with Existing** option and then pick the **Set** button to set the path and filename of a 3rd Surface (.TIN) file to be created by combining the design Surface file and the Existing Ground Surface file.

Pick the **OK** button to close **Road Network Settings**.

Pick the **Save** button on the **Road Network Task Pane** to **Save** the Road Network (.RDN) file.

Then, pick the **Process** button on the **Road Network Task Pane** to calculate the road design and perform the functions specified in **Road Network Output Options**

The combined Surface (.TIN) file can now be viewed using the **Surface 3D Viewer** command as shown below.

Merged Existing Ground and Road Surfaces in 3D Surface Viewer Window

Add Knuckle Intersection

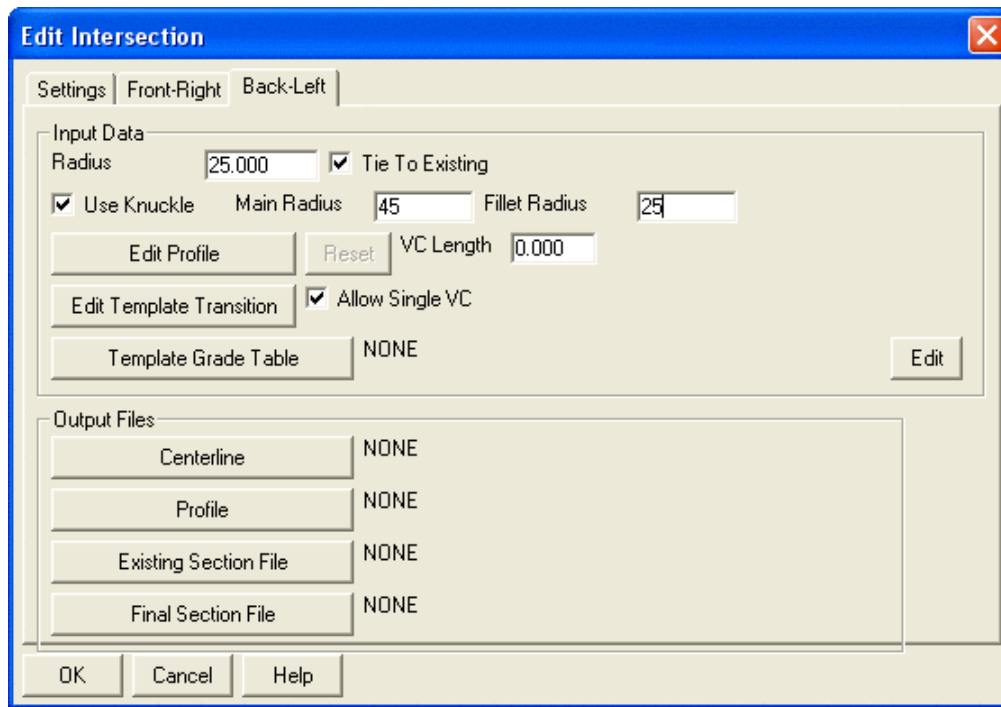

Using the steps outlined in **2 Add Roads to the Network** above, Add two more Roads to the Network.

RD_03 and RD_04

Upon adding the Roads, the new Intersections are automatically added to the **Intersection** area of the **Road Network Task Pane**.

To create a "Knuckle" style Intersection between RD_03 and RD_04, *select the **RD_03 (Primary)/ End:RD_04 (Secondary)** Intersection* in the project tree and then right-click and *pick the **Edit Intersection** function* to display the **Settings** tab of the **Edit Intersection** dialog box. *Pick one of the "Corner" tabs* of the **Edit Intersection** dialog box. *Select the **Use Knuckle** option* and *enter a **Main Radius** and **Fillet Radius** value* for the Knuckle Intersection.

A "Corner" Tab of the Edit Intersection Dialog Box

Pick the **OK** button to close **Edit Intersection**.

Pick the **Save** button on the **Road Network Task Pane** to **Save** the Road Network (.RDN) file.

Then, pick the **Process** button on the **Road Network Task Pane** to calculate the road design and perform the functions specified in **Road Network Output Options**. The resulting contours and breaklines are shown below.

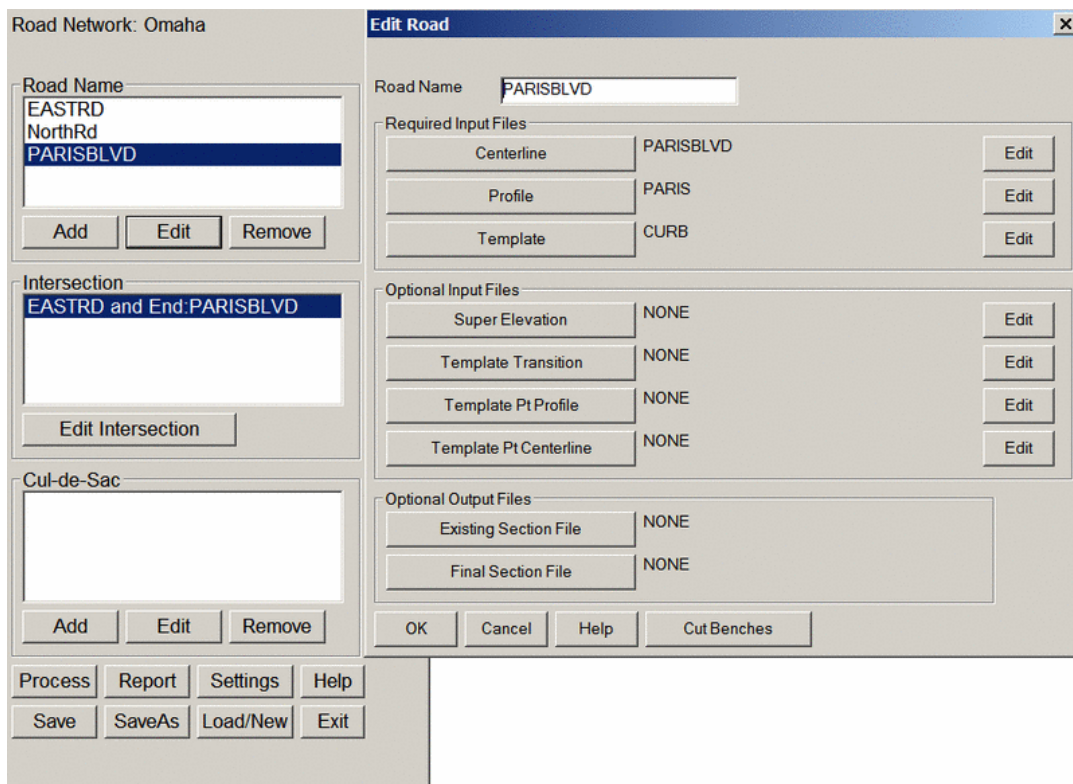

Step 1: Start New Road Network

Start the Road network command. If you have previously run Road Network with the current drawing, the Road Network docked dialog will open with the last Road Network (.RDN) file you worked with. If this happens, but you prefer to create a new Road Network (.RDN) file, click the Load/New button at the bottom of the Road Network docked dialog.

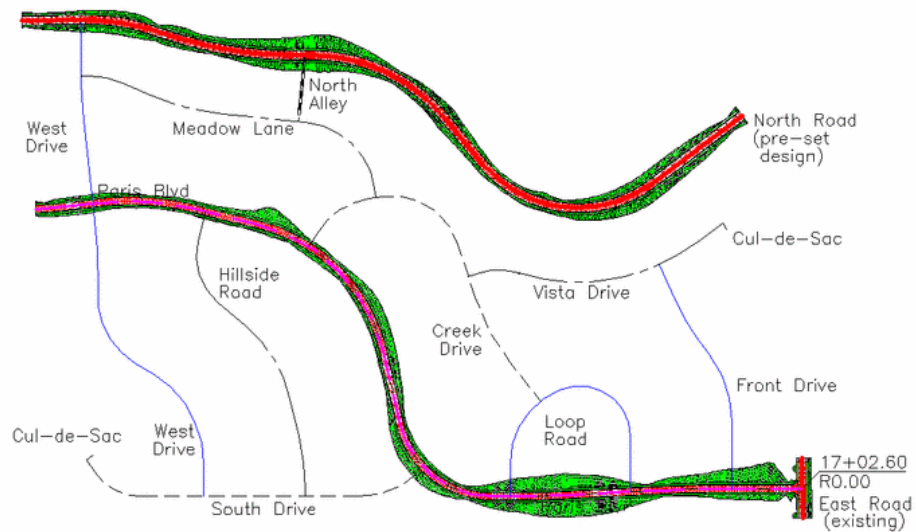

Step 2: Add Roads

Back in the main dialog, click "Add" in the upper left "Road Name" portion, and identify all of the main road and secondary (intersecting) road centerlines. For this example, we will start by identifying North Road and East Road as the main roads and Paris Boulevard as the first secondary road. Note that centerlines may be picked as polylines or loaded as centerline files. All centerlines (horizontal alignments) must have, at minimum, an associated profile (vertical alignment) and an associated template. In the Road name dialog portion, select a road and click Edit to review the files. Note that by selecting Paris Boulevard and East Road, the program automatically detects the first intersect. As you follow the design below, you will see that we follow the hierarchy of the road precedence as outlined in the graphics. At every intersection, there needs to be a primary controlling road (template cross slopes are held) and secondary adjusting road (centerline profile adjusts to template of primary road at some transition distance).

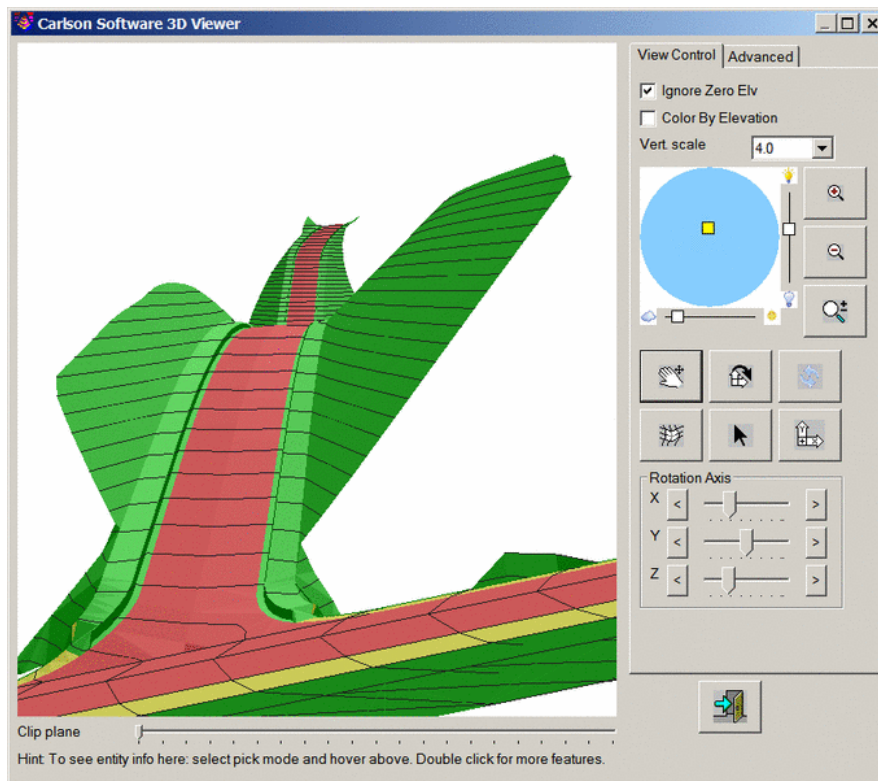

Step 3: Process, Review and Add more

Click Process to compute the design. With the Triangulation option enabled under the "Settings" dialog, the program will Triangulate and Contour and create the drawing shown below. If you edit any road feature or dialog entry and click Process again, the program automatically clears the last Triangulate and Contour drawing and creates a new final design drawing. In this way, you can trial-and-error your design for all roads, or build the design in stages.

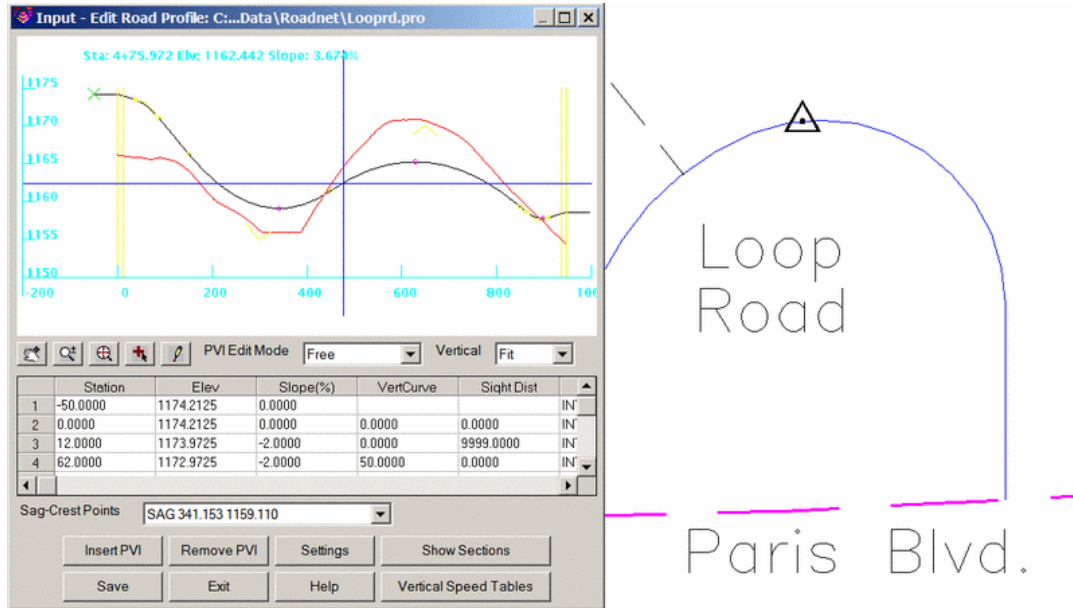

Viewing the file in the 3D Viewer Window command with a 4.0 vertical exaggeration, you can even see how the curb-and-gutter Paris Boulevard ends abruptly as it transitions to the roadside ditch template of East Road.

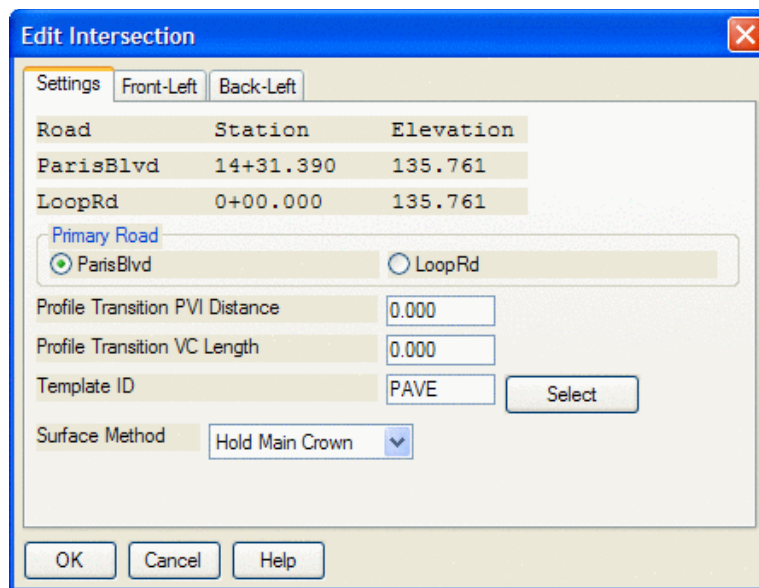

Next we can review the effect of adding Front Drive, Loop Road and West Drive into the equation. If you click Edit after adding Loop Road as above, you have the option to change any aspect of the centerline, profile or template file, and you can add optional files such as road width change files and superelevation files. For example, if you choose to edit the profile, the program derives the existing grade from the existing surface triangulation file specified

in Settings, and you are able to design graphically and interactively as shown:

You can also more closely analyze the intersections of any road. If you select the intersection at ParisBlvd and Start:LoopRd, you obtain the multi-tab dialog:

Since we do not have a crossing intersection, we only obtain a "Front-Left" tab and a "Back-Left" tab, left being the left side of the primary road (Paris) and front being the first "curve return" treatment on the outside of the loop and back being the second "curve return" treatment on the inside of the loop. If this was a crossing intersection, you would have 2 more tabs in the dialog: "Front-Right" and "Back-Right". Completing West Drive, Front Drive and South Drive leads to the following plan view and 3D view. Clicking Add within the Cul-de-Sac portion of the docked dialog enables you to specify at cul-de-sac at the end of South Drive.

Clicking Process now produces the following:

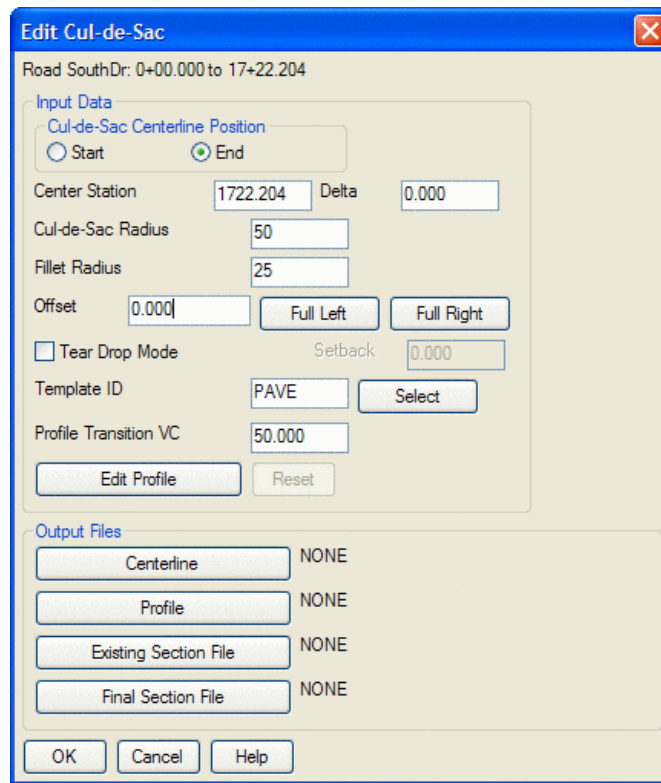

A close-up view of the cul-de-sac, in 3D, reveals the detail of the design, showing a raised "fold" due to no vertical curve transition at the projected high point at the back of the cul-de-sac:

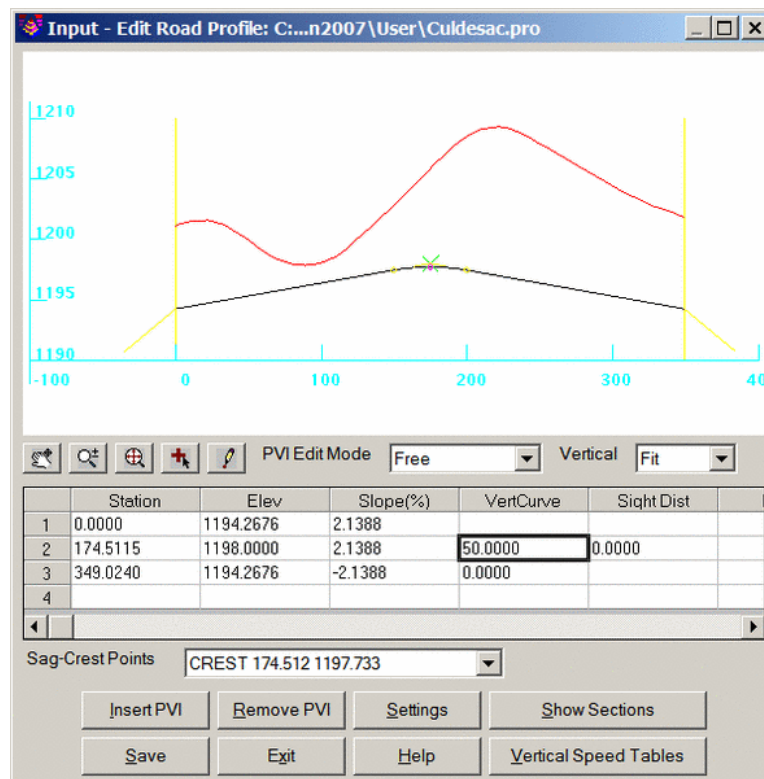

This dimple effect can easily be eliminated by lowering the elevation of the "PVI" at the projected intersect point in the back of the cul-de-sac, and by adding a vertical curve transition of, say 50'. This is done by highlighting the South Drive Cul-de-Sac and clicking Edit.

Clicking Edit on the selected SouthDr at End cul-de-sac leads to this dialog:

The first thing we do is change the Profile Transition VC from 0.0 to 50.0, as shown. Then we need to click Edit Profile to lower the profile at the back of the cul-de-sac. This profile refers to the edge-of-pavement grade.

Now, after clicking Process, the cul-de-sac has a better design:

Pulldown Menu Location: Roads → Road Network

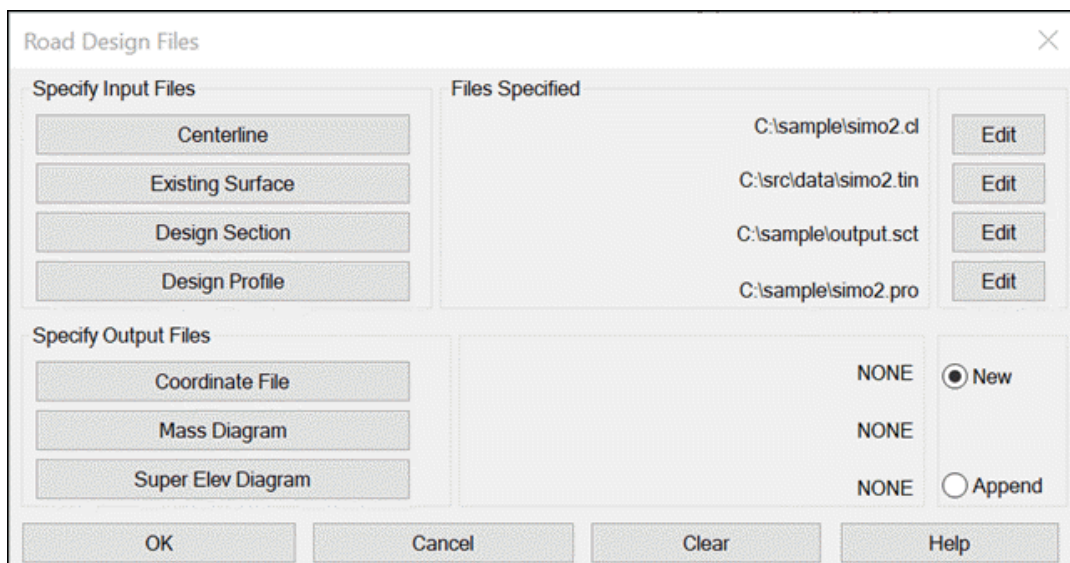

Keyboard Command: roadnet

Prerequisite: Existing Ground Surface (.TIN) file, Template (.TPL) file

Process Design Sections

This command will process design sections to calculate volumes and output surfaces. The main purpose is to process design sections that have been manually adjusted. One workflow is to use Process Road Design to generate design sections from a centerline, profile and template design. Next these design sections can be adjusted with Section File Editor for special stations as needed. Then use Process Design Sections to run these modified sections.

The first dialog specifies the required input files of the centerline, existing surface, design sections and design profile. The optional output files for coordinates, mass diagram and superelevation diagram are set here.

The second dialog has the processing and output settings which are a subset of the settings from Process Road Design. The only setting specific to Process Design Sections is the Interpolate Stations which allows for processing a smaller station interval than the input Design Sections. These interpolated stations interpolate from the Design Sections and use the Design Profile to account for any non-linear variations in the profile between stations.

Please see the Process Road Design section of this manual for a description of rest of these settings.

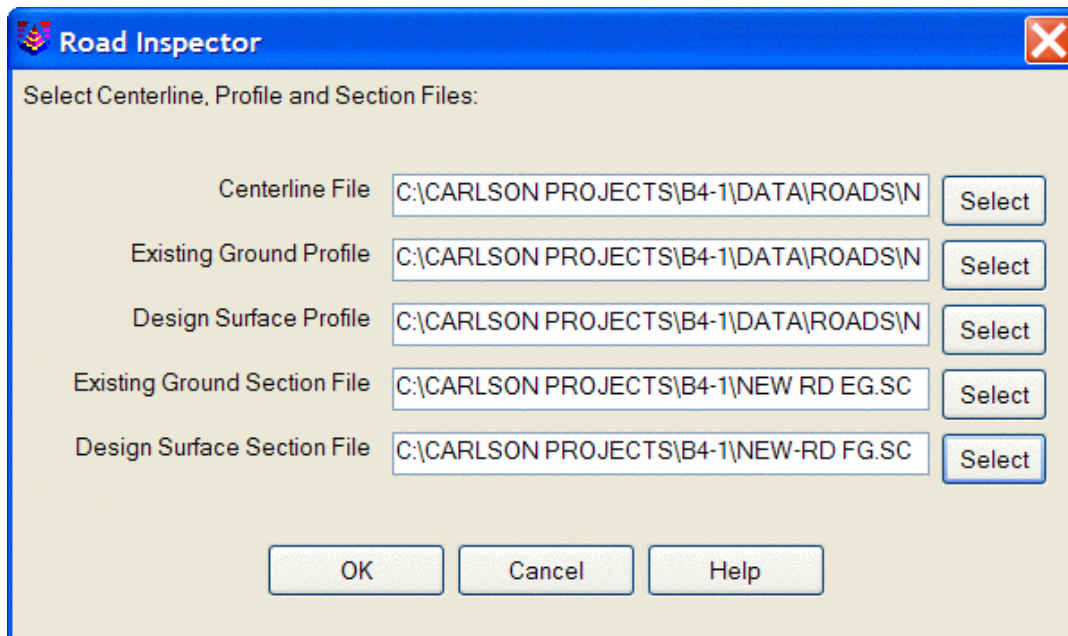

Pulldown Menu Location: Roads

Keyboard Command: reworks

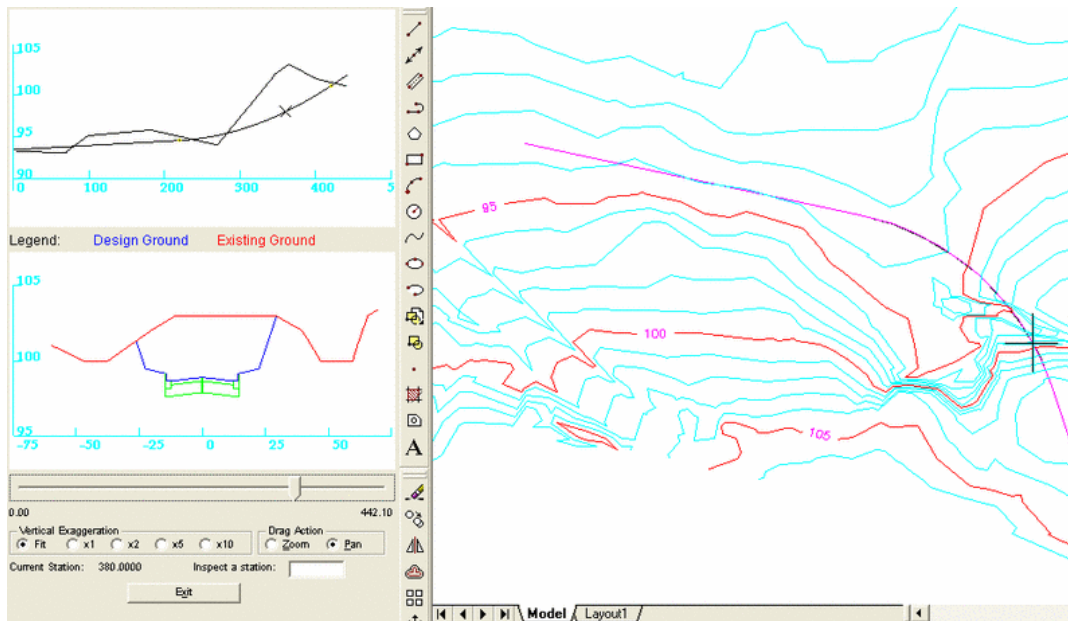

Prerequisite: Centerline, Profile, Existing and Final Cross Sections

Road Design Inspector

This routine takes a full suite of road files (existing and final profiles, existing and final cross sections and the centerline) and presents three graphical windows showing the road in plan view, profile view and section view, with a slide bar that let's you "drive" the road or project from start to end. In addition to applying to roads, the command applies to any set of existing and final sections that follow a horizontal alignment (centerline), such as for channels and embankments. As you move the slide bar left and right, your position is shown in profile view, in plan view and in cross section view. The cross section graphics can be scaled to fit the allotted screen space, or can be set to a scale such as 1H:1V or set to exaggerated scales (2H:1V up to 10H:1V).

The current station is displayed as you move the slide bar. You can zoom and pan the cross section view, and you can also enter a specific station to study. Stations that do not exist in the cross section files will be interpolated.

Pulldown Menu Location: Roads

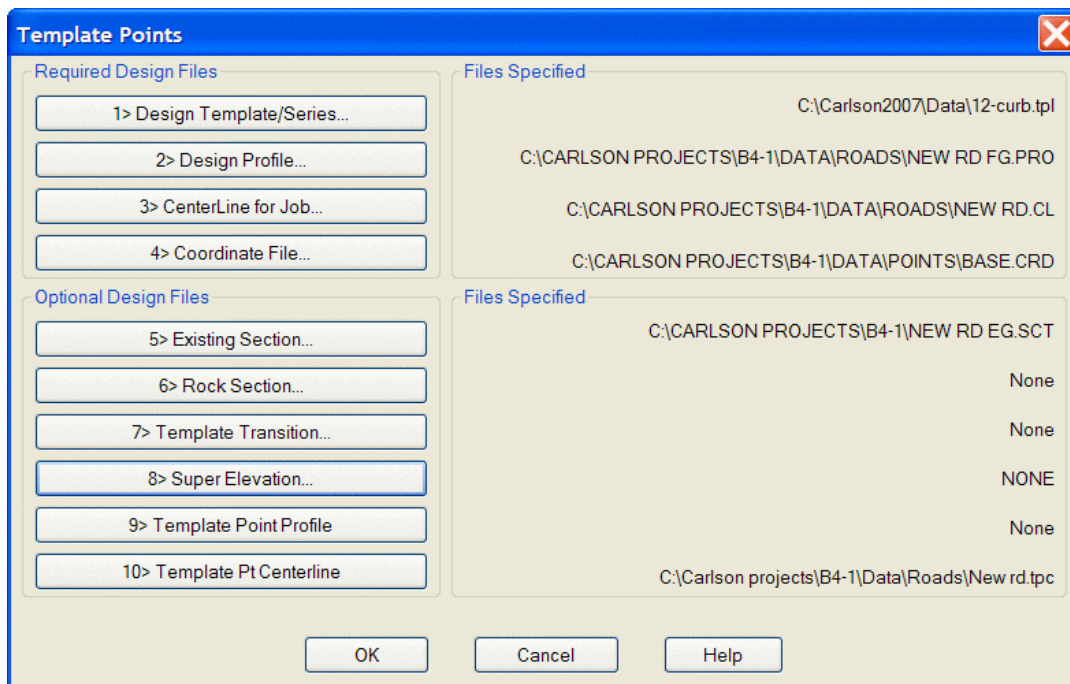

Keyboard Command: rdcheck

Prerequisite: Existing and final Profiles (vertical alignment), Centerline (horizontal alignment), Existing and Final Cross Sections

Locate Template Points

This command creates Carlson points along a centerline either at picked points, point numbers, entered individual station and offset or at station interval with offset, in all cases using the elevations calculated from the template design files. The first offset prompt is for the location of the point. The second offset prompt is for what elevation to use. For staking template points (e.g. edge of pavement) you usually enter the same offset for the position and for the elevation. But if you are staking back of curb, which might be at offset 14.5, you might enter 16.5 for the

position (to stake 2' back of curb) and 14.5 for the vertical elevation (to use the elevation of back of curb itself). The points are stored in a coordinate (.CRD) file. The station and offset of the point is stored in the point descriptions. If the points method is used and existing Carlson points are selected by number, range or "point group", then new points at the same position are created with interpolated elevations and new descriptions. The command starts with the dialog shown below. The required design files include the template file, the profile which defines the vertical alignment, the centerline file which contains the horizontal alignment and the coordinate file for storing the resulting points. All these design files must be created before running this command. To specify a design file, pick on the type of file button. The optional files include an existing section file for calculating the cut and fill slopes, a rock section file for special cut slopes in rock, a template transition file and a super elevation file. For example, if an existing section is specified, template points can be calculated further from the centerline, all the way from the shoulder out to the "catch" or tie point in cut and fill.

If you choose the Station/Offset method, you can specify whether to create points at a station interval. Otherwise the program prompts for each station at which to create points. If the Station/Offset method is used, you will be prompted whether to calculate points on the left, right or both sides of the centerline and whether to offset the calculated elevation by a delta Z amount. If you choose the Points method, you can pick points on the screen (using snaps on entities if desired) or you can specify point numbers individually, by selection set, by range or by point group. You can also select whether to calculate elevations from the template surface or from a subgrade and you can add a description prefix to all descriptions.

A classic application of this routine would be for road staking such as setting back of curb points. Many survey companies prefer to stakeout roads by pre-calculated point numbers rather than calculating from road design files in the field to stakeout road offsets. So if the goal was, for example, to stake 2 feet behind the back of curb, but use the elevation of the top of curb, and the shoulder rose at 4% behind the curb, then the vertical difference to the top of curb would be $-2 \times 0.04 = -0.08$. The program will calculate this automatically by the method of asking for the distinct offset to use for the elevation. Obviously, if you want to stake to the exact surface elevation at the offset specified, then enter the same offset for both position and elevation. The prompting for this back of curb example is shown below.

Offset for X,Y position: 16.5 In this case, this is the pavement width (12.5) plus curb width (2) plus back-of-curb offset (2). The northing and easting for the points will be calculated with this offset.

Offset for elevation <16.5>: 14.5 The elevations for the points will be calculated at this offset (back of curb in this example).

Apply offset to left, right or both sides (Left/Right/<Both>)? press Enter Note that if you want to have the points number sequentially on the left side and sequentially on the right, then do L for left first and R for right

second. If you answer "Both" then the numbering will go sequentially left to right on each station (see below).

Offset to process (Enter to End): *press Enter* Or, enter an offset to calculate another X,Y position, or the same X,Y position but on a different side of the road if doing L and R distinctly.

Pulldown Menu Location: Roads

Keyboard Command: tplpts

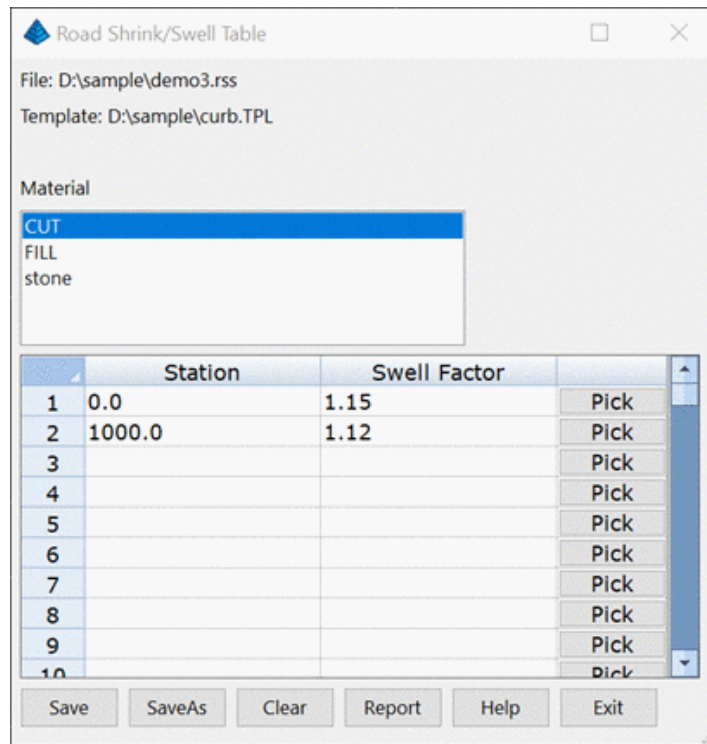

Prerequisite: A template file, profile file and centerline file

Shrink/Swell Table

This command defines different shrink/swell factors by station range for cut/fill quantities and subgrade materials. These factors are stored in a .RSS file which can be used in the Process Road Design command as an optional input file. Without the shrink/swell table, Process Road Design uses a single factor for shrink and a single factor for swell for the whole road. These single factors are set in the second dialog of Process Road Design.

This command prompts for a Design Template file (.tpl) and reads the material names from the subgrades in the template.

The stations and shrink/swell factors are entered in the spreadsheet in the dialog shown here. In the dialog, first highlight the material in the list and then the table of stations and factors for that material are shown in the spreadsheet. The cut material uses a swell factor, and the fill and subgrade materials use a shrink factor. Use the Pick button to screen pick a station along the centerline in the drawing.

Pulldown Menu Location: Roads
Keyboard Command: shrinktable

Hydrology Module

6

Surface Menu

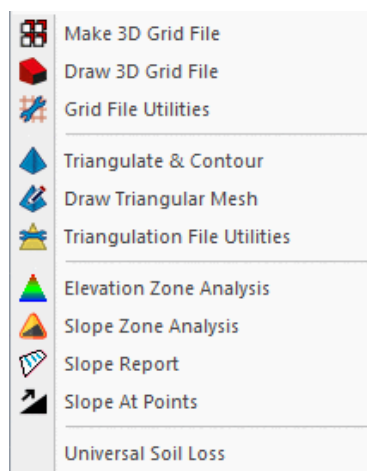

Surface Commands

The Hydrology Module contains many routines that perform Hydraulic and Hydrological calculations for Civil Engineering Design. Each command is designed to work with other commands to complete a design task. For example, the automated pond grading software creates a Stage-Storage Table that can be dynamically linked into Detention Basin Routing Calculations.

Carlson Hydrology was developed using industry standard calculation methods and models. The following represents the standards followed. Stormwater Collection Calculations follows HEC-22 methods and guidelines for surface drainage collection and the Energy Equation for Pipe Networks. Calculations from HEC-22 include Inlet Spread/Capture calculations and Pipe Network Capacity using the Energy Equation per HEC-22. The Rational and SCS TR-55 methods are used to calculate peak design discharge along with development of runoff Hydrographs. In addition to calculations, Carlson also provides a wide range of tools that can be used to obtain public information needed to model a Site. NOAA Precipitation totals and NRCS Soil Data can be queried based on the site location using webservices. In addition to stormwater permitting and design calculations for Site Development, Carlson also provides tools to prepare input files for HEC-RAS which use Carlson DTM and channel alignments to create the input file to HEC-RAS. Pressure Pipe Networks can setup a Utility Network such as a Public Water System where pressure/flow analysis are performed. Many other tools are provided which are commonly used in stormwater design such as a Culvert and Lined Swale designs.

Surface Commands

The pull-down menu for the Surface commands of the Hydrology module is shown here. These commands are identical to the same commands used in the Civil and Survey Modules and are provided here so that Carlson Hydrology can be a stand along product. Much more detailed instruction can be found in the Help Menu for Surfaces in the Civil and Survey Help Topics. The following describe the use of these tools for Hydraulic and Hydrological Design.

Make 3D Grid File

Almost all Civil Engineering Stormwater Design require a surface model. Surface models are used to determine drainage areas and provide a reference elevation model for Stormwater Systems. In many cases, surface models created by Triangulation Methods need to be simplified in order for operations such as automated watershed delineation. Grid files are much simpler and provide enough detail to delineate watersheds and are recommended when delineating watersheds.

Draw 3D Grid File

The main purpose of drawing a 3D grid file is to check the dataset used to create the grid file. They can also be used in processes that evaluate and map each grid for a particular property such as slope. These include the creation of Slope Maps and calculation of Sediment Runoff using the Universal Soil Loss Equation.

Grid File Utilities

Grid File Utilities is included when changes need to be made to a grid surface.

Triangulate & Contour

In addition to grid surface files, Triangulate Surfaces can also be created with the Hydrology Module. Whereas grid files can be used to determine watershed boundaries, tin surfaces are used when precision is needed. Tin surfaces produce much more detailed surface models that should be used for determining Inlet and pipe invert elevation. They provide a more exact surface model and do not average any of the input data.

Draw Triangular Mesh

Triangular meshes should always be drawn to determine if any errors exist in the model.

Elevation Zone Analysis

Elevation Zone Analysis produces maps where elevation ranges are delineated and group together. They are very helpful in Pressure Pipe Design to determine service areas for water systems such as locating storage tanks and the design of booster pumps.

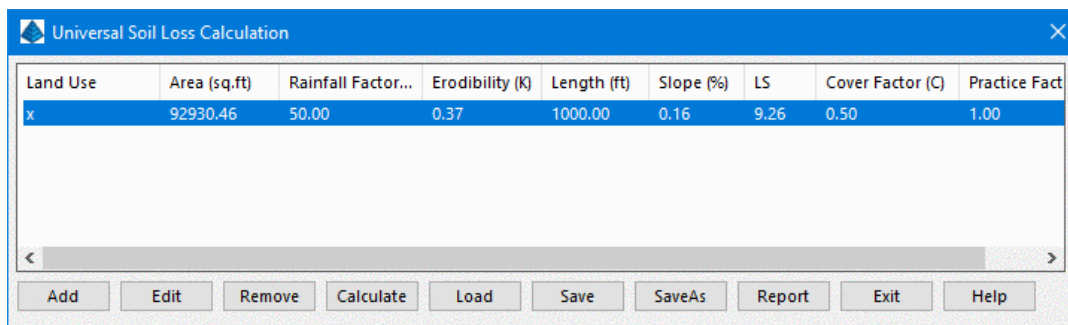

Slope Zone Analysis

Slope Analyses creates a map where areas with similar slopes are grouped together. The main purpose for stormwater and erosion control design is to delineate steep areas that must be avoided with collection systems and area that will require additional erosion control provisions. A common use of slope analysis for erosion control design is to quickly delineate slope banks that will require matting and additional erosion control provisions. **Slope Report** Slope reports provide the same information as slope maps in a non graphical format. **Slope at Points** Slope at Points provide graphed numerical values for the slope which can be used in a wide range of Hydraulic Design such as Swale Design. It is recommended that Slope Points be provided along with Slope Zone Analysis.

Universal Soil Loss

This command calculates the volume of sediment that can be expected from a watershed by soil erosion due to precipitation. It allows the user to specify multiple watershed areas, each with its own set of geometric and hydrological parameters. The Universal Soil Loss Equation (USLE) is used in calculating the soil loss. For each area, the area, slope and length can be manually entered by the user or it can be calculated by the program directly. For direct calculation of the geometric properties of the area, the user must have a grid file that models the surface. This can be created using the *Make 3D Grid File* command. In addition, the area must be defined by closed polylines for inclusion perimeter. Exclusion perimeters are optional for excluding areas from calculations.

The program starts with the dialog below, where the user can add as many areas as needed to include in the USL calculation. Each area added is shown in the list box with all its parameters listed. To add a new area, click the "Add" button. To edit the parameters of an existing area, highlight that item and click the "Edit" button. To remove an existing area, highlight it and click "Remove".

The "Edit" or "Add" button brings up the dialog box shown here, where the various parameters of the area can be specified or edited. The "Landuse" is just an identifier for the area and has no further significance. Soil Erodibility, K (tons/acre) is a property of the soil, which determines the amount of sediment resulting from a precipitation event in an area. The rainfall factor, R, is a dimensionless factor that accounts for the relationship between erosive forces of falling rain and runoff. The Cover factor, C, is a dimensionless factor that relates the effectiveness of vegetal cover in reducing erosion. The Topographical factor, Ls, is a dimensionless length slope factor that accounts for variations in length and slope in the area. The (Conservation) Practice factor, P, is a dimensionless factor to determine how landuse effects its erodibility.

If the area of the watershed is known and is entered manually, then the length and slope of the area have to be entered manually as well and the Ls factor will be calculated from these geometric properties. The area can also be calculated directly if the boundary is defined as a closed polyline and the grid file that models the surface is also made. The user clicks the button "Select area" and the program asks the user to select the grid file as well as the closed polyline representing the area. Then, the Ls factor and the slope are calculated by the program and displayed (the "length" is not needed in this case). After filling in all values, click on "Calculate USL" to calculate the soil loss rate per unit area for the area selected. The user can change the parameters corresponding to this area and recalculate, if needed. Click "OK" to return to the main dialog box. The area should now appear in this dialog box if the parameters as specified.

After all required areas are input, the sediment volume can be calculated by clicking the "Calculate" button on the main dialog. This brings up the USLE Calculation dialog box as shown here. Specify the Delivery ratio, which determines what portion of the gross erosion is actually left for deposition at the final destination, accounting for losses during sediment transport. Also, specify the Time period for which deposition has occurred. Specify the Density of the sediment, so as to be able to determine the volume of the deposit from its mass in tons. Also, specify the amount of Rainfall (inches or cm) for which runoff volume has to be calculated. The program then calculates the Runoff volume based on the total area and the amount of rainfall. It also calculates the sediment volume, using the Universal Soil Loss Equation (USLE) and adds it to the sediment volume and reports it as the total pond volume. A report of the form shown below is generated. This report also gives a detailed account of the calculations performed. For further information about the estimation of the various parameters used in this program or about the USLE, please refer to "Applied Hydrology and Sedimentology for Disturbed Areas" (1981), Barfield, B.J., Warner, R.C. and Haan, C.T., Oklahoma Technical Press.

Pond Volume Calculation based on Universal Soil Loss Equation Sun Jan 29 15:36:33 2023

Input Data

Landuse	Area (ft^2)	Rainfall Factor	Erod-ability	Length (ft)	Slope (%%)	Ls	Cf	Pf
Development	92913.5	50.0	0.37	1000.0	16.2	9.26	0.50	1.00

Runoff = 1.000 inch.
Sediment Density = 62.400
Time = 1.0 years
Drainage Ratio = 0.37

Total Area = 2.133 acres
Gross Erosion = 182.748 Tons/yr.
Total Yield = 67.617 Tons/yr.
Runoff Volume = 0.178 acre-ft
Sediment Volume = 0.050 acre-ft
Total Volume = 0.228 acre-ft

Universal Soil Loss Equation : Application in this Program

Required User Input :

Note : The following values are to be entered by the user for each area in the watershed. The method for obtaining these parameters is left to the user.

Rainfall Factor (R) : Default = 50;
Erodability Factor (K) : Default = 0.37
C Factor (C) : Default = 0.5
P Factor (P) : Default = 1.0

Geometric Information :

Area (sq units) : Can be entered by the user or the program calculates the area of a user-selected closed polyline. The user also has the option to enter the area in different units.

Slope, S (%) : Can be entered by the user or the program calculates the slope when the user selects an area from the screen.

Length (L) : Can be entered by the user. If the user selects an area from the screen, the length is not calculated since the Gross Erosion is directly calculated.

Keyboard Command: soilloss

Prerequisite: Use *Make 3D Grid File* to create a grid file that models the surface

Watershed Menu

The Watershed menu is shown below. The first section of commands are for watershed analysis and are primarily based on TR-55. These commands are arranged in the order that they would be applied. The first commands calculate the watershed boundary. Using the watershed area and land use types, the curve number can be calculated, which leads to time of concentration and hydrographs. Then the peak flow can be calculated. The second section of commands are for hydrograph routing using TR-20. The bottom section has commands for linking to SEDCAD, HEC-RAS and HEC-2.

Define Watershed Layers

This dialog box is the interface to assign specific Ground Covers to closed polylines in a drawing, based on their drawing layers. There are 3 modes of operation; Rational Method, SCS Method, and HydroCAD.

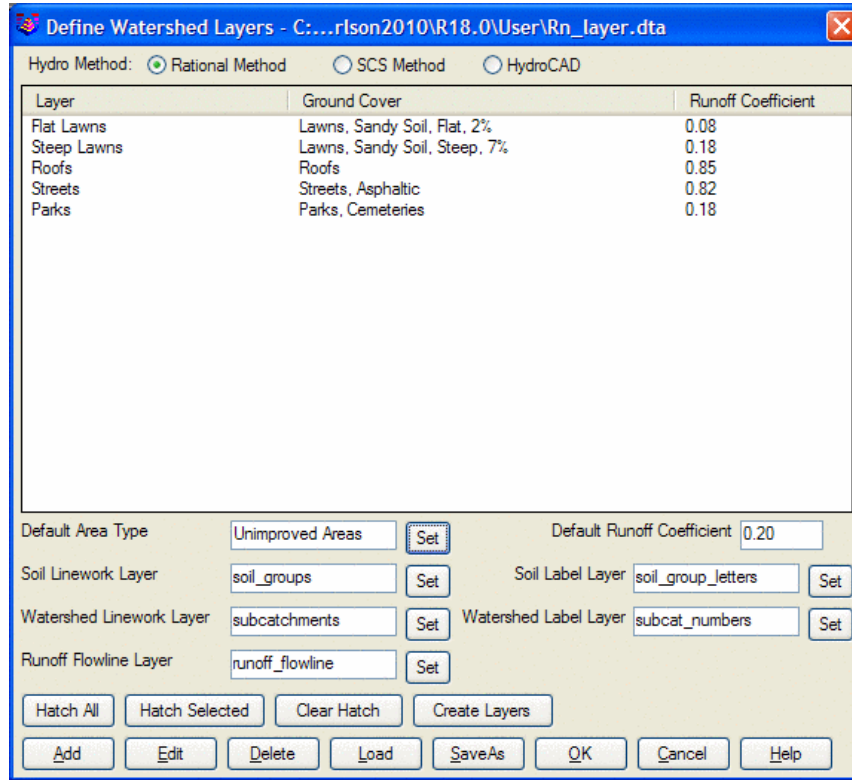

With the dialog set to Rational Method, the runoff coefficients are the C-Factors in the Rational Equation $Q = C \cdot I \cdot A$. Q is flow, I is rainfall intensity and A is area. The Rational Method is often used for urban and residential flow analysis. For example, building layers can be assigned a high runoff coefficient (C factor) such as 0.85 and wooded areas would be assigned a low runoff coefficient such as 0.20.

With the dialog set to SCS Method, the coefficients are set to values from 0-100, so Roofs might be 85 and Woods 20. A Soil Type must also be specified for each Ground Cover.

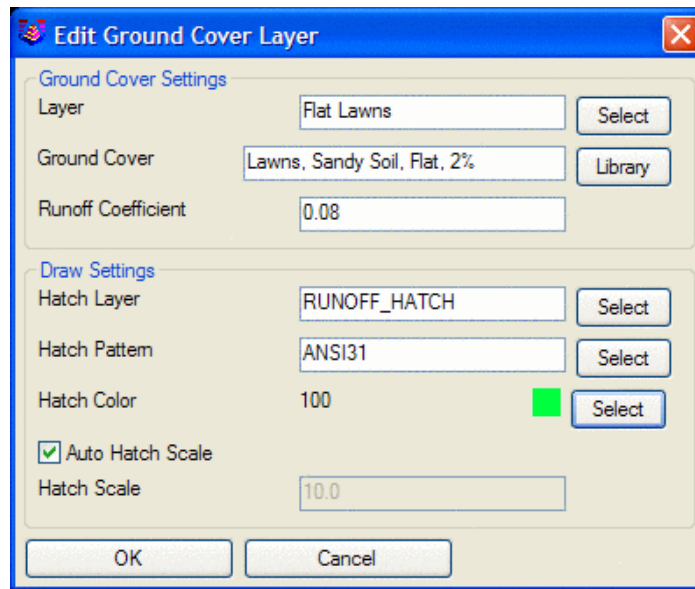

With the dialog set to HydroCAD, the runoff coefficients are not set at all, but are added when the data is exported to HydroCAD.

With the Rational or SCS Methods, the runoff coefficient area polylines are used to determine the weighted runoff coefficients for drainage areas in conjunction with other Carlson Hydrology commands such as Watershed Analysis and Edit Sewer Structure. The runoff coefficient polylines are automatically clipped by the drainage perimeter polyline to find the coefficient sub-areas within the drainage perimeter. Therefore, it is important to close all polylines, use distinct layers for features that have distinct runoff values, and to assign a runoff coefficient to the unassigned, "remainder" areas. It is also important to enclose areas beyond the site with closed polylines and assign runoff coefficients to those layers to account for the off-site water entering the site.

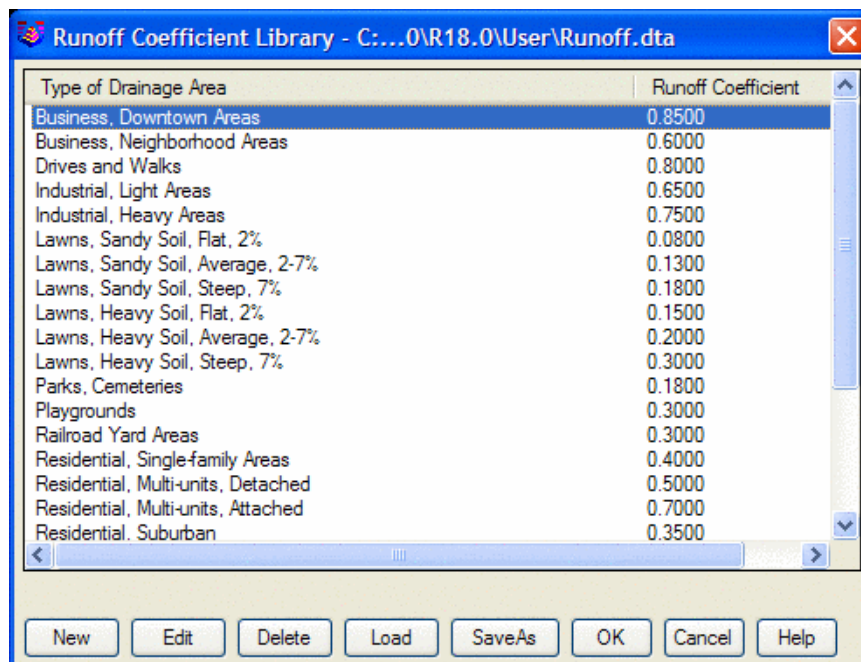

Looking at Rational Method first, the initial dialog box would look something like this:

Adding or editing a layer brings up the next dialog:

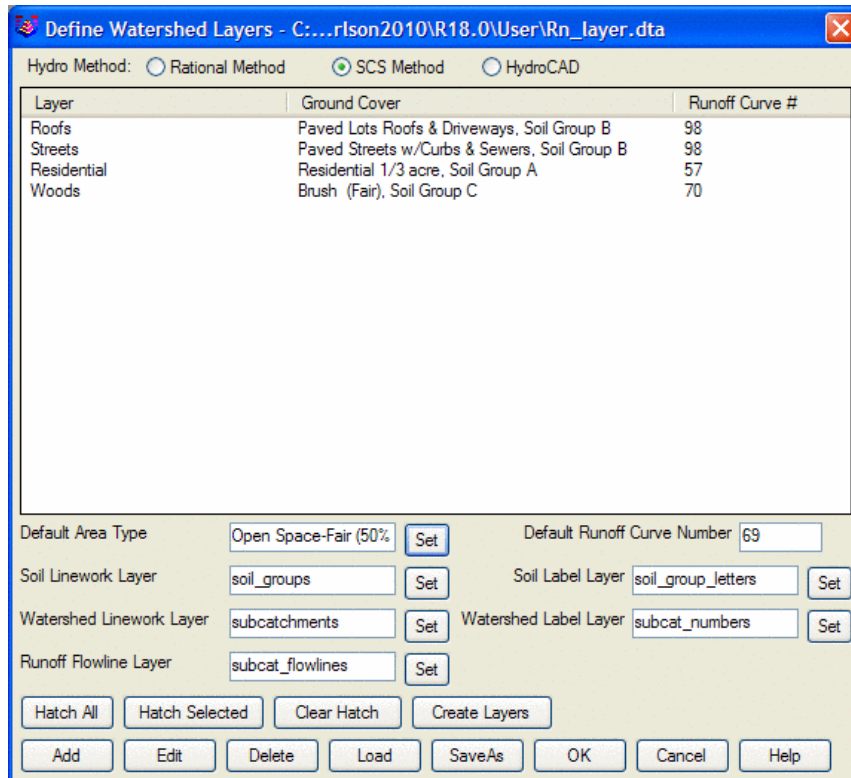

The Library button brings up the next dialog, where new Ground Covers can be added from the Rational Method library.

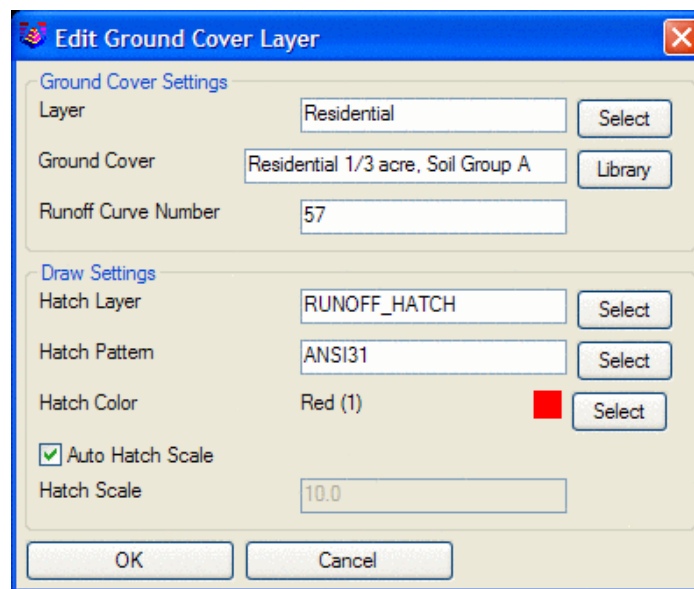

For each layer, an area name and runoff coefficient are assigned and can be selected from the library. This library itself is defined under the Network pulldown menu, option Drainage Runoff Library within the Sewer Network Libraries "flyout". Each layer also has hatch settings for drawing the runoff areas. The hatch settings include the layer, color, pattern and scale. The Auto Hatch Scale option will size the hatch scale to fit the runoff area. The Hatch All button will hatch all the runoff areas in the drawing as closed polylines and defined in the list. The Hatch Selected will hatch the area of the currently selected layer from the list. The purpose of the hatch functions are for visual checks that the layers and closed polylines are set right.

With the SCS Method in use, the primary dialog would look something like this:

Adding or editing a layer brings up the next dialog:

The Library button brings up the next dialog, where new Ground Covers can be added from the SCS Method library. Select a Cover Description line, and then pick a Soil Group button, A, B, C or D.

Runoff Curve Number Library - C:\...R18.0\User\Runoffcn.dta

Cover Description	A	B	C	D

Default Area Type: Woods, Good [Set] Default Runoff Curve Number: 0

Soil Linework Layer: soil_groups [Set] Soil Label Layer: soil_group_letters [Set]

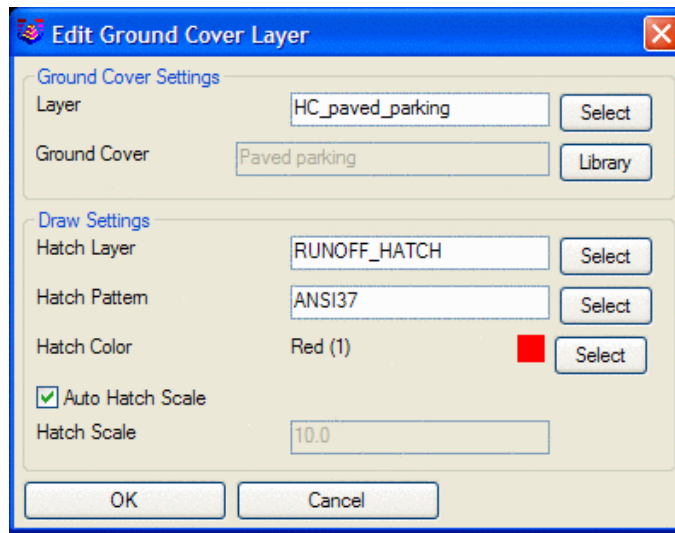

Watershed Linework Layer: subcatchments [Set] Watershed Label Layer: subcat_numbers [Set]

Runoff Flowline Layer: subcat_flowlines [Set]

Buttons: Hatch All, Hatch Selected, Clear Hatch, Create Layers, Add, Edit, Delete, Load, SaveAs, OK, Cancel, Help

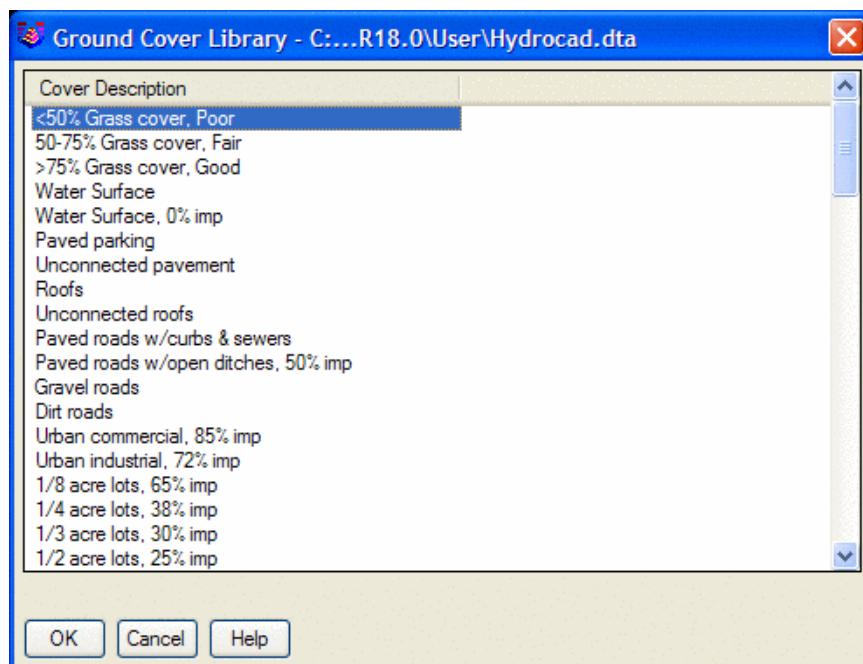

Note there are no Curve Numbers listed, and the Default Runoff Curve Number field is grayed out.

Editing a layer brings a dialog like this:

Note that you can change the Layer name, but not the description of the Ground Cover. This is because the specific descriptions provided for HydroCAD Ground Covers must exactly match the description specified within HydroCAD itself.

Picking the Library button accesses the HydroCAD Ground Cover library.

Back in the primary Define Watershed Layers dialog box, the list of layers and other settings can be saved as .RCL files. It is useful to save and recall the configurations in .RCL files using the SaveAs and Load options. The currently loaded assignment is applied within the command Watershed Analysis.

The Create Layers button creates the layers from the list in the current drawing. All layers can be created, or certain layers can be selected before picking the Create Layers button and you can specify to create only the selected layers.

The Color TIN button applies the colors defined for the ground cover areas to colorize a triangulation file which is helpful for visualizing the surface in 3D viewers.

There are settings for the default area name and default coefficient that are used for any part of the drainage area that is not covered by one of the runoff layer polylines.

The Soil layers are optional for finding the soil sub-areas within each runoff sub-area. These Soil layers are used in commands that calculate the runoff sub-areas within a watershed boundary such as the Select Watershed function within the Curve Numbers & Runoff command. When the Soil layers are assigned, the program will get all the linework on the Soil Linework layer to build a topology of the soil areas. The linework does not need to be made of closed polylines but the linework collected together should enclose the soil areas. Then the program takes the text entities in the drawing that are on the Soil Label layer. The text is used to identify the soil group. The first character in the text should be A, B, C or D for the four soil groups. The program looks for the text to be within the soil area to assign the soil group to that area.

The Watershed Linework layer is used in commands for selecting the watershed area by picking a point within the area. For instance, the Select Watershed routine in Curve Numbers & Runoff will prompt whether to select by perimeter (closed polyline) or interior point (watershed layer method), when the Watershed layer is defined. Similar to the Soil Linework layer, the program will get all the linework in the drawing that is on the Watershed layer and build a topology of the watershed areas. The linework does not need to be made of closed polylines but should make closed watershed areas when taken together. When you pick the interior point, the program finds the watershed linework that encloses the point to get the watershed perimeter.

The Watershed Label layer is used by the Hydro Network commands to match the drawing watershed area with the subcatchment node in the network. The match is between the value of a text entity on the watershed layer with the name of the subcatchment node.

The runoff polyline areas use region logic where a polyline inside another on the same layer is used as an exclusion. A limitation is that polylines on the same layer must not intersect each other. For polylines on different layers, there can be polylines within other polylines and for any given point, the smallest enclosing polyline is used to determine the runoff coefficient.

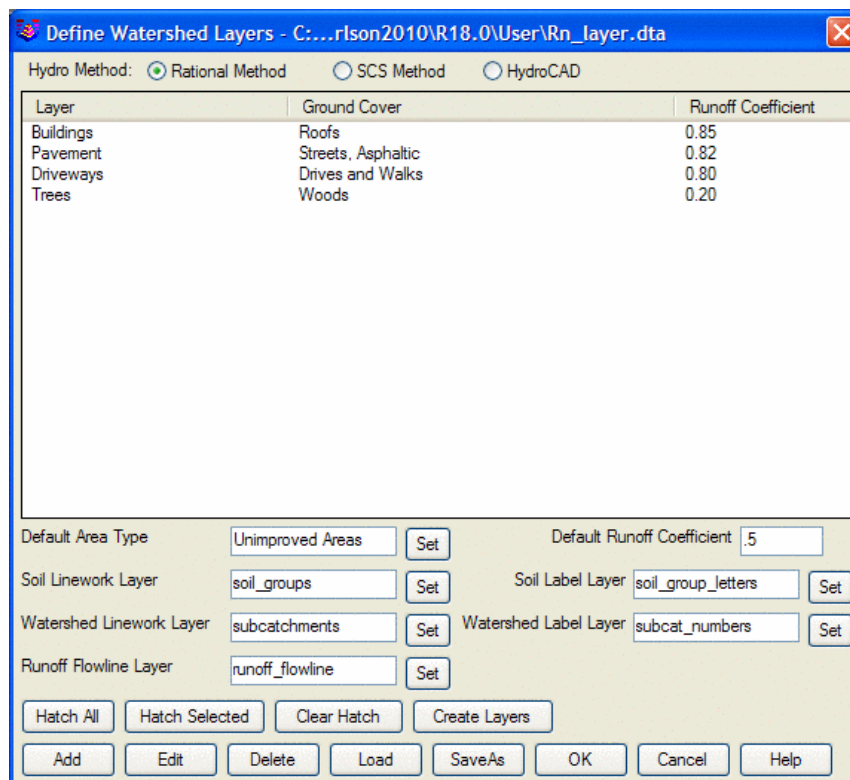

Example 1: In the example below, the site perimeter polyline is on the Regions layer, the building pads are on the Pads layer and the edge of pavement polylines are on the Roads layer. All these polylines are closed polylines. The areas within the buildings are inside both the Region and Pads polylines and the Pads govern because they are the smaller area. Likewise the road areas are governed by the Roads layer and road interior islands are not counted for Roads because the interior Roads polyline acts as an exclusion perimeter. The rest of the area is set to the Regions layer.

Example 2: Consider the subdivision shown below.

Buildings, roads, driveways, lot lines and wooded areas are in distinct layers. As soon as the command is selected the dialog below appears. The applicable layers can then be organized as follows within the command. Note that the lot lines do not have any hydrology impact and are not included in the layer-runoff coefficient assignment.

Example 1 used the built-in logic to remove closed polylines from outer enclosing closed polylines. So in the example 2 case, the overall property boundary had a runoff coefficient of 0.2 that was assigned its runoff coefficient by layer, and all other assigned closed polylines found within it (roads, buildings, driveways) will be calculated distinctly. For example 2, the entire "remainder" area that is not assigned and is given a default runoff coefficient, such as 0.5 shown above. Therefore, within any site perimeter, both the "unassigned" method for remainder areas or the assigned, outer boundary layer method for the remainder areas can be used. When the "Hatch All" button is clicked, the drawing will hatch in the defined colors and layers, as shown below:

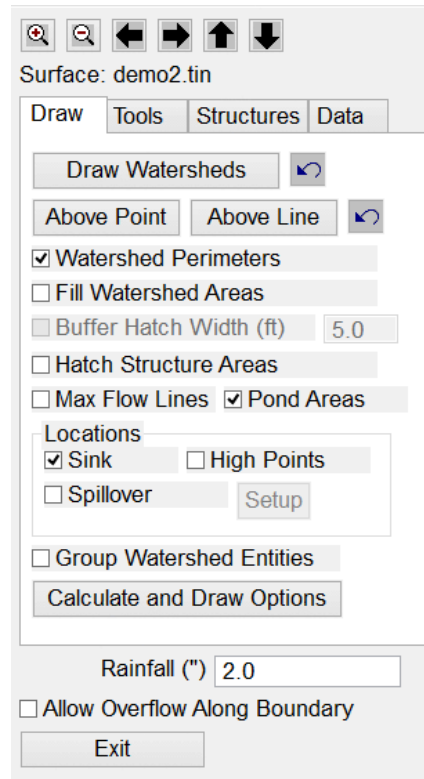

Pulldown Menu Location: Watershed

Keyboard Command: define_runoff_layers

Prerequisite: Closed polylines on different layers for the different areas

Watershed Analysis

This command has a collection of tools to analyze the runoff of a surface defined by a triangulation or grid surface file. After selecting the surface file of the surface, the program docks a dialog on the left side of the drawing window. While the Watershed Analysis dialog is running, other AutoCAD and Carlson commands are not available. To zoom or pan the drawing view, use the buttons at the top of the dialog, or use the middle button of a wheel-mouse.

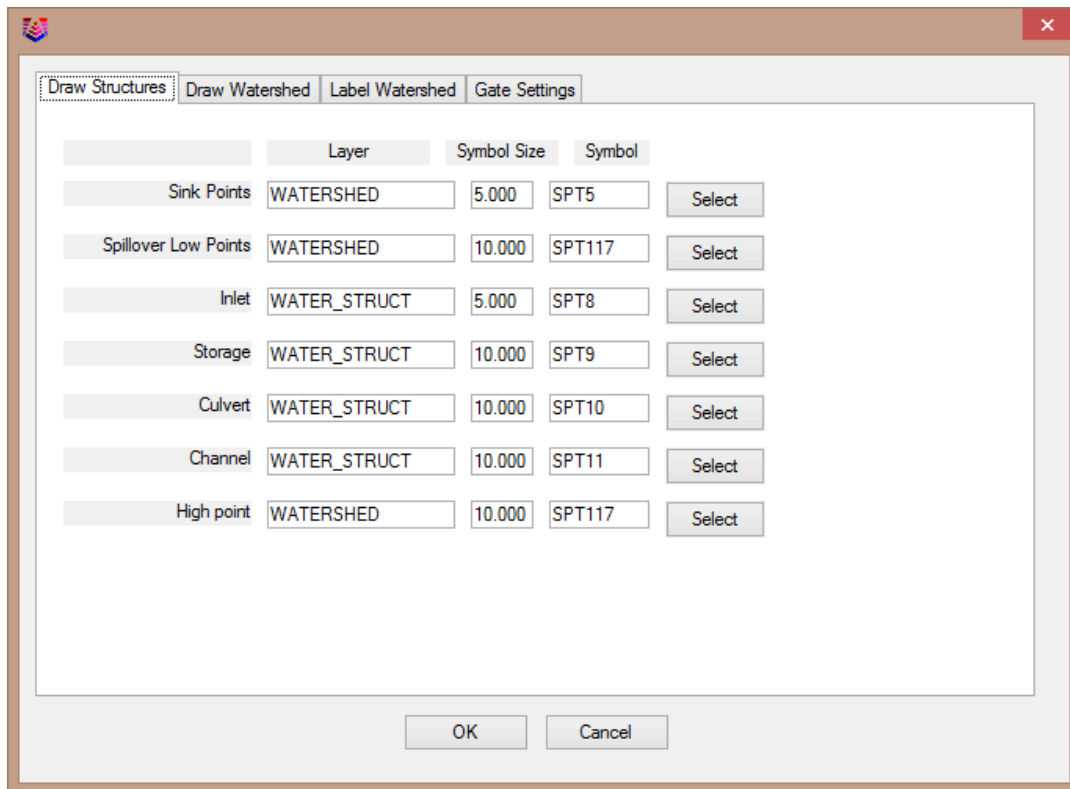

Watershed Analysis calculates the flow connections between the triangles and along the edges of the triangulation. The **Rainfall** amount is used in the processing for figuring the runoff volume to determine when the volume is enough to spillover a local depression in the surface. Besides the Rainfall amount, the runoff coefficients as defined in Define Runoff Layers are also used to calculate the runoff volumes. When the local depression is small enough the runoff will continue through. Otherwise this spot is called a sink for where the runoff stops. The **Allow Overflow Along Boundary** option applies to watersheds that have runoff that hits the surface border. This option will check whether this border runoff can spillover and merge with the neighboring watersheds along the border.

The **Draw Watersheds** function draws the watershed areas using the settings under the Draw tab. The back arrow next to the Draw Watersheds button will erase any previous Draw Watershed entities. The **Watershed Perimeters** option will draw closed polyline perimeters for each watershed area. The **Fill Watershed Areas** option will solid fill hatch each area using different colors. The **Buffer Hatch** option will hatch the perimeters of the watershed areas with the specified width instead of hatching in the entire watershed area. The **Hatch Structure Areas** option will hatch the drainage areas covered by structure inlets defined in the Structures tab. The **Sink Locations** setting draws a symbol at the low point for each drainage area. The **High Point Locations** option draws a triangle symbol at the highest point within each watershed. Typically, this high point will be along the watershed boundary polylines that follow the high points along the ridges between the watersheds. The **Pond Areas** option draws a solid fill hatch in blue for the area covered by the runoff volume of low points. In the example shown, the Fill Watershed Areas and Sink Locations options are active. The **Max Flow Lines** option draws polylines for the longest flow line within each watershed. These longest flow polylines can be used to calculate the time of concentration. The **Group Watershed Entities** option will make AutoCAD groups for the set of entities drawn for each watershed.

The **Spillover Location** option draws symbols at low points within the watershed area that fill up with runoff and spillover on the way to the lowest (sink) location of the watershed. The Setup button allows you to specify criteria for identifying spillover points. These settings include the minimum drainage area, storage volume, drainage volume.

These settings allow you to filter out small spillover points (ie a pothole) and only draw the significant ones. The **Calculate and Draw Options** buttons allow you to control what is going to be drawn how, it contains settings for the symbol, size and layers to use for the entities created by Watershed Analysis and a number of labeling options.

Gate Control

The watershed calculation can be controlled through use of "gates". Gate is placed at the points of likely overflow from one watershed to another. The gate in its natural state is simply an indication that potentially the connection can occur at the point, joining two watershed areas into one if there is too much runoff volume in at least one of the watershed areas to be contained within. The gate can also be forced closed, which indicates that two areas will not be joined regardless the runoff amount. The example of such case is when there are two large ponded areas you want to treat separately in calculations or further design. On flip side, there are instances when you may want two areas to be joined regardless the overflow actually occurring, for example one area is very small. This is accomplished with a gate forced open. There two ways to control gate state: automatically and manually. Here are the settings for automatic control.

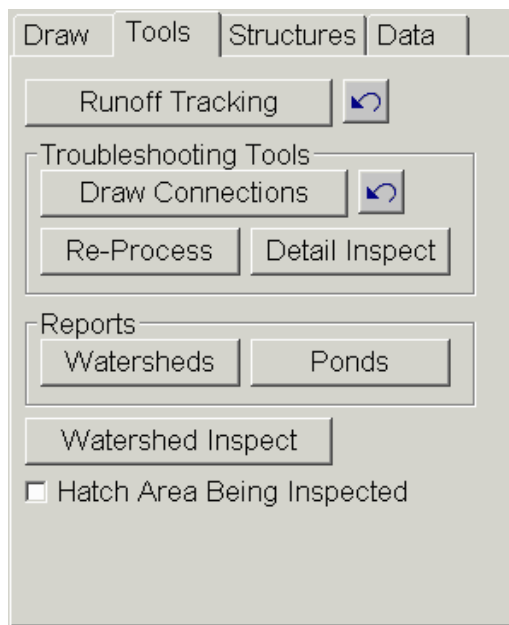

If amount of ponded runoff in an area exceeds the maximum pond volume to merge, the downstream gate will be closed automatically. If area is too small or too shallow, its downstream gate will be forced open, joining it with watershed downstream.

To control gates manually, please first draw gate labels, exit Watershed Analysis, then double-click on gate labels in the drawing to control their state. Once done editing the gate state, just re-run the calculation to draw and report the new adjusted watersheds.

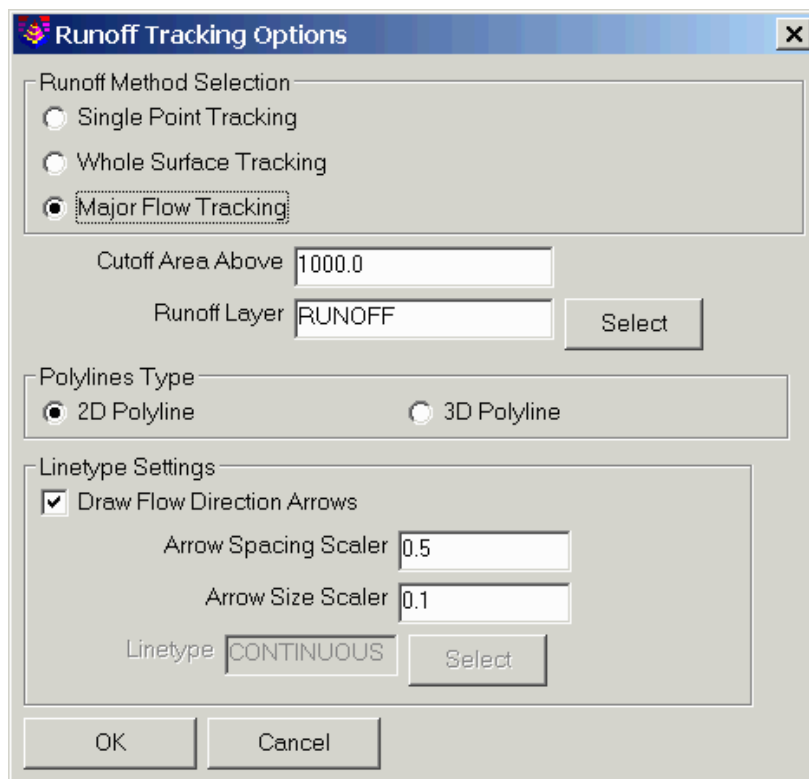

Runoff Tracking

The **Above Point** function reports the watershed data of the current pointer position in real-time as the pointer is moved around. The watershed data is shown in a tooltip next to the pointer position. This data has values for the overall watershed that the position is in including the sink elevation, sink name, drainage area and average slope percent. This data also has values for the watershed above the current point including the drainage area and runoff volume. Plus this data shows the elevation and runoff coefficient at the current point. If the position is picked with the mouse, then the program draws a polyline perimeter for the drainage area above the current point.

The **Above Line** function is similar to Above Point except that you pick two points and the program draws the watershed for all flow that crosses the line between these two points. For example, you can pick points at the left and right banks of a stream to get the drainage area for that stream above these points.

Under the Tools tab there are several analysis routines. The **Runoff Tracking** function draws flow lines that follow the surface. The **Single Point Tracking** method draws the flow lines starting from the picked high points. The **Whole Surface Tracking** method draws a flow line starting from the middle of each triangle in the triangulation. The **Major Flow Tracking** method draws starting in triangles where the drainage area coming into triangle exceeds the specified **Cutoff Area Above** value. The flow lines can be drawn as either 2D or 3D polylines. For 2D polylines, the linetype can be specified or the special linetype with flow direction arrows can be used. This special flow linetype has controls for the size and frequency of the flow arrows.

The **Draw Connections** function draws lines with arrows between the triangles for how the program has determined their flow connections.

When a triangulation file is processed by Watershed Analysis, some of the flow connection data is stored into the triangulation file to speed up reprocessing. The **Re-Process** function resets this flow connection data to start the flow calculations from scratch.

The **Detail Inspect** function reports flow connection data at the pointer position in real-time as the pointer is moved. This data includes the current position triangle number, connecting flow triangle number, sink node number, watershed name, border elevation, ridge elevation, low elevation, downstream sink number, number of source triangles, number of source nodes, current elevation and spillover elevation.

The **Watershed Inspect** function reports runoff flow data at the pointer position in real-time as the pointer is moved. The runoff data is shown in a tooltip next to the pointer and in the **Data** tab. This data has values for the overall watershed that the position is in including the sink elevation, sink name, drainage area and average slope percent. This data also has values for the watershed above the current point including the drainage area and runoff volume. Plus this data shows the elevation and runoff coefficient at the current point. When the Hatch Area Being Inspected option is active, the watershed area for the current position is hatched during inspection.

The **Watersheds Report** function runs the report formatter to choose which of the watershed parameters to report. The **Ponds Report** function reports the position and depth of each ponding area.

Here are some of the values contained in watershed report:

Rain volume - total volume of the runoff for the area

Holding volume - the maximum volume the watershed can contain near the sink

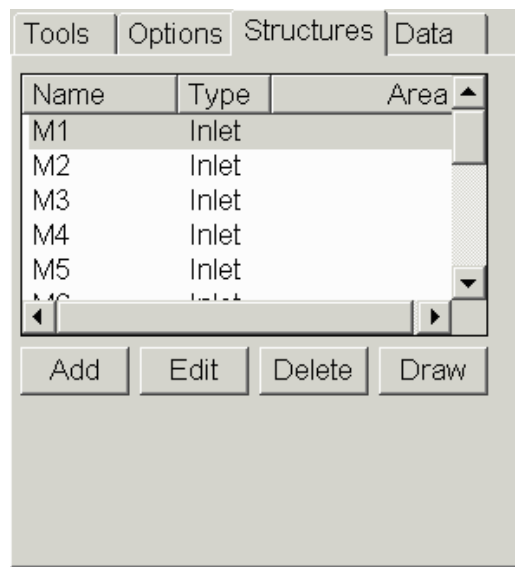

Ponding volume - the volume of all the ponds within the watershed

Uncontained volume - the difference between amount of runoff and the volume of runoff trapped on the slope or at the sink

Additionally, the properties of the pond at the sink are reported: surface elevation, max depth, volume and area.

Structures

Besides calculating the runoff of the triangulation surface, Watershed Analysis can also process the runoff effects from structures for inlets, storage ponds, culverts and channels. The structures in Watershed Analysis are simply for placement and watershed delineation. These structures do not have design considerations for parameters like pipe size. In the **Structure** tab, there is a list of the structures to apply with the current surface. The list shows the name, type and drainage area for each structure. The Draw function will draw symbols for each structure. The Inlet structures act as sinks in the watershed and capture all the flow that comes to the inlet point. Each inlet is defined by a single point and a name. The Storage Tank structures also act as sinks and are defined by a single point and name. The Culvert structures route the flow from the culvert inlet to the outlet. The culverts are defined by two points for the inlet and outlet and by a name. The Channel structure is the same as the Culvert except that it can have more than two points to define the flow path. The structure data can be stored to a Watershed Structure File (wst) using the **Save** button. The **Load** button can read the structure data from either a wst file or from a sewer network file (.sew).

Pulldown Menu Location: Watershed

Keyboard Command: watershed

Prerequisite: Triangulation File

Merge Watersheds

This command combines the polyline perimeters of two neighboring watersheds into a single polyline. The original two polylines are erased. The original polylines must have a common side and must be closed polylines on the layer of Watershed Linework Layer defined in the Define Watershed Layers command. To select the watershed polylines to merge, the program prompts to pick a point inside the watershed area.

Prompts

Pick inside 1st watershed: *pick a point*

Pick inside 2nd watershed: *pick a point*

Pulldown Menu Location: Watershed

Keyboard Command: wshed_merge

Prerequisite: closed polylines on watershed layer

Run Off Tracking

This command draws 3D polylines starting at user picked points downhill until they reach a local minimum or the end of the grid or TIN. In effect it simulates the path of a rain drop. The surface is modeled by a grid file as created by Make 3D Grid File or a triangulation file created by Triangulate & Contour. The program also reports the horizontal and slope distances, average slope, maximum slope, and vertical drop. These values can be used for time of concentration calculations. Runoff tracking is a convenient way to identify distinct watershed areas and is an alternative to the automated Watershed Analysis command.

Prompts

Enter the run off path layer <RUNOFF>: *press Enter*

Select Surface Model dialog box

Choose the grid file or triangulation file that models the surface. If a grid is selected, it will prompt:

Extrapolate grid to full grid size (Yes/<No>)? *Yes* If the limits of the surface data doesn't cover the entire grid area, then the values for the grid cells beyond the data limit must be extrapolated in order to compute slopes in that area. This prompt only appears if there are grid cells without values.

Local pond spillover depth <4.80>: *press Enter* This allows the runoff line to continue past flat or low points in the grid or TIN, by allowing these area to fill up with water, in essence, up to the specified depth, thus letting the runoff polyline continue on.

Draw tracking for all grid cells or pick individuals [All/<Pick>]: *press Enter* Pressing Enter leads to individual picking of runoff tracking lines, while A for All would fill draw runoff polylines starting from each grid cell or each triangulation triangle.

Pick origin of rain drop: *pick a point at the top of the run off polyline*

Pick origin of rain drop (Enter to end): *press Enter*

Pulldown Menu Location: Watershed

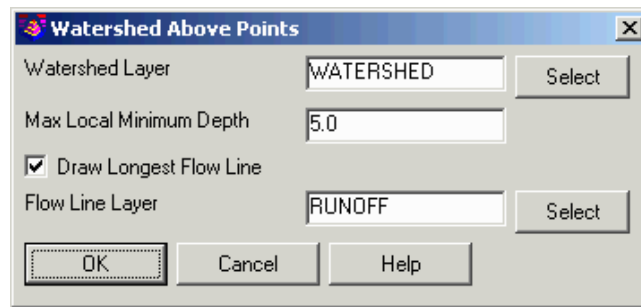

Keyboard Command: runoff

Prerequisite: A .grd file created by Make 3D Grid File or a .flt (TIN) file created by Triangulate & Contour.

Watershed Above Points

This command creates a closed 3D watershed polyline of the area that flows through a line connecting two points. The command also creates a watershed report of the area, slopes and longest flow line. There is also an option to draw a 3D polyline for the longest flow line. In the options dialog, the Max Local Minimum Depth is the most the program will allow the flow to jump over.

This command uses a surface model defined by a grid file. The Watershed Analysis method is another command to generate watersheds that uses triangulation surfaces. A triangulation surface model has the advantage of finding sharp breaks that a grid might skip over such as for narrow ditches or curbs. For regular surfaces such as a surface defined by existing contour polylines, the grid surface model has the advantage of efficiently modeling the surface which makes it faster. Also when using a grid surface model, it is sometimes better to decrease the grid resolution (have fewer grid cells) because this helps avoid local minimums.

Watershed Report

Surface: C:\sample\Quads3b.grd
Lower left grid corner : 940321.80,365189.63
Upper right grid corner: 967093.86,381003.90

Pick bottom LEFT bank of watershed: *pick a point*

Pick bottom RIGHT bank of watershed: *pick a point*

Pulldown Menu Location: Watershed > Watershed By Grid Surface

Keyboard Command: waterabove

Prerequisite: surface .GRD file

Watershed Area Grid

This command creates a grid model of the drainage area above each node. A grid of the surface is used for input. For each grid node, the program calculates the drainage area above this node. The Max Local Minimum Depth is used to merge drainage areas that have a depth less than this specified value. The units of the area grid are square units of the horizontal dimension of the surface grid. When the surface grid is in feet, the area grid values are in square feet. Likewise a surface grid in meters will make an area grid in square meters. The values of the area grid can get very large and difficult to view in 3D. To handle these large values, you can use Grid File Utilities math functions to scale down the values.

3D view of contours from original surface grid

3D view of watershed area grid

Pulldown Menu Location: Watershed > Watershed By Grid Surface

Keyboard Command: watergrd

Prerequisite: surface GRD file

Run Off Tracking - Grid Surface

This command draws a 3D polyline starting at a picked point and going downhill until reaching a local minimum or end of the surface. In effect this flow line simulates the path of a rain drop. The program also reports the distance and slope of the flow line. These values can be used in time of concentration calculations. This command uses a grid model for the surface which works well for existing ground surfaces. The Run Off Tracking command that is in the main Watershed menu works with triangulation surfaces which works well for design surfaces.

In the options dialog, the Max Local Minimum Depth is the most the program will allow the flow to jump over.

Prompts

Select Surface Model *Choose .grd file*

Watershed options dialog

Pick origin point of rain drop: *pick a point*

Horizontal distance: 10315.58, Slope distance: 10392.95

Vertical drop: 982.08, Avg slope: 9.52%, Max slope: 52.34%

Pick origin point of rain drop (Enter to end): *press Enter*

Pulldown Menu Location: Watershed > Watershed By Grid Surface

Keyboard Command: runoff_grd

Prerequisite: surface .GRD file

3D Polyline Flow Values

This command simply reports the horizontal and slope distances, vertical drop, maximum slope, and average slope of a 3D polylines or Carlson Profile File(.pro). 3D polylines may be created by the Watershed Analysis or Run Off Tracking commands. The profile can be any vertical alignment saved as a .pro file. When using the profile file option, The profile file can represent the vertical alignment of a swale or channel. The reported values could be applied to the Time of Concentration routine.

Prompts

Pulldown Menu Location: Watershed

Keyboard Command: flowvals

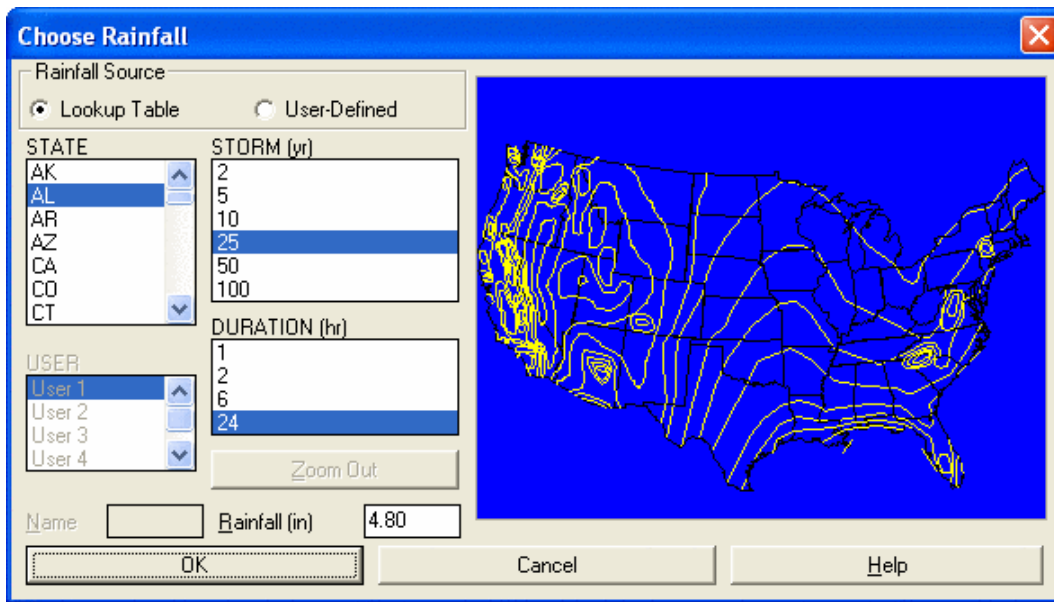

Prerequisite: 3D polyline or Vertical Profile file(.pro)

Rainfall Frequency and Amount

This command allows you to view rainfall maps while entering the rainfall amount to be used by other hydrology commands. First choose a storm and duration from the list. Then choose your location from the State list or pick your location on the map. You can enter the rainfall amount in the box in the lower left or pick your location on the map.

Reference maps based on TP-40 and TP-47 are provided for all fifty states for the different storm intervals. You can also setup user-defined lookup tables for up to five areas. For each area, you can specify a name and rainfall amounts for each storm interval. The first time the you select a user-defined storm interval, the rainfall amount will be blank. Enter in the rainfall amount and the next time that interval is selected, your entered value will be there. All rainfall amounts are in inches. The user-defined values are stored in a file called rainmap.ini in the Carlson USER directory.

TP-40 and TP-47 are older rain tables. The NOAA Atlas 14 is a more recent rain table.

Pulldown Menu Location: Watershed

Keyboard Command: rainmap

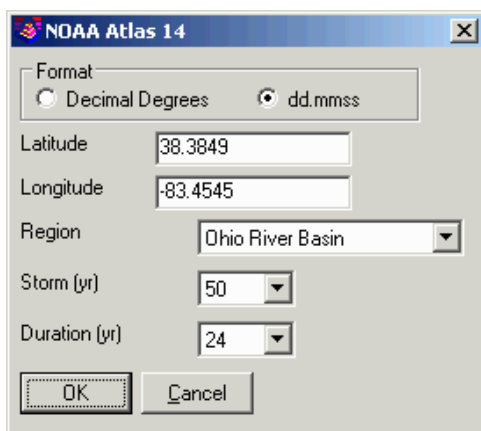

Prerequisite: None

Rainfall Frequency and Amount - NOAA Atlas 14

This command looks up the rainfall depth from NOAA Atlas 14 for the specified rain event and location. In the dialog, enter the lat/lon and NOAA region of the location and choose the storm event. The first time that you look up a storm event for a region, then program will download the rainfall model from NOAA. The rainfall depth is reported at the command line.

Currently, data is available for all US States except the northwest: WA, OR, ID, MT and WY.

For information on NOAA Atlas 14, go to the NOAA website at: <http://hdsc.nws.noaa.gov/hdsc/pfds/>

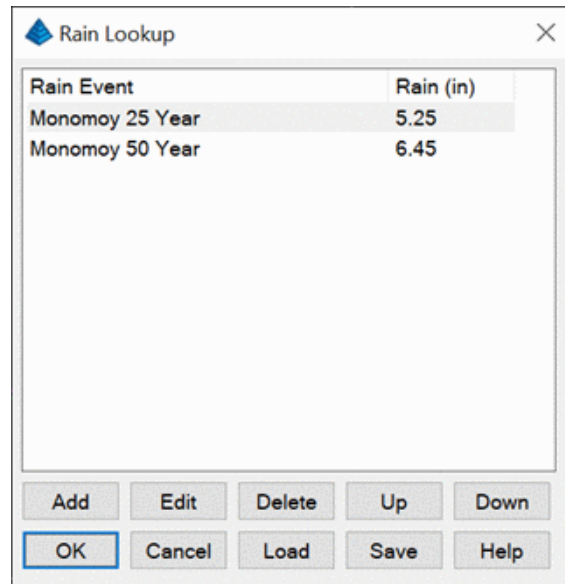

Pulldown Menu Location: Watershed

Keyboard Command: noaa14

Prerequisite: None

Rainfall Frequency and Amount - Lookup Table

This command stores a list of rain event names and their rainfall depths. To set the current rainfall depth for the Watershed routines, double-click on a rain event from the list or highlight the rain event on the list and pick OK. Use the Add, Edit, Delete, Up and Down buttons to setup the rain events. The Load and Save buttons store and recall the rain events to a .rain file.

Pulldown Menu Location: Watershed

Keyboard Command: rain_lookup

Prerequisite: None

USDA Soil Area Download

This command stores a list of rain event names and their rainfall depths. To set the current rainfall depth for the Watershed routines, double-click on a rain event from the list or highlight the rain event on the list and pick OK. Use the Add, Edit, Delete, Up and Down buttons to setup the rain events. The Load and Save buttons store and recall the rain events to a .rain file.

Pulldown Menu Location: Watershed

Keyboard Command: rain_lookup

Prerequisite: None

Sub-Watersheds By Land Use

This command divides land-use polylines into closed polylines within a watershed polyline. The closed land-use polylines inside the watershed can then be used to determine the area of each land-use for the watershed. The Curve Numbers & Runoff command has an option to select closed polylines for determining the weighted average curve number from the polyline areas.

Prompts

Select closed polyline of watershed: *pick the polyline*

Select land-use closed polylines.

Select objects: *pick the polylines*

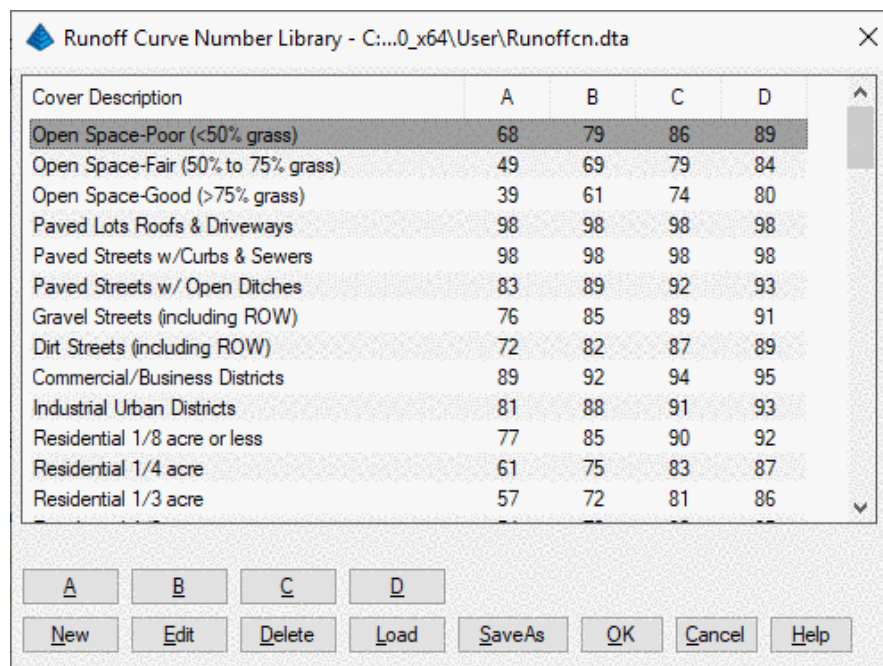

Pulldown Menu Location: Watershed

Keyboard Command: landarea

Prerequisite: Closed polylines for the watershed and land-use areas.

Curve Numbers & Runoff

This command calculates the weighted curve number (CN) as used by the SCS Method of runoff calculation. It will also calculate total, potential runoff from an area. The curve number is used by routines based on the TR-55 program. The weighted curve number is a weighted average of the curve numbers for each subarea of the watershed. The weights are based on the areas. The Description and Soil Type fields are used in the report. Shown here is the Curve Number Library from which to select curve numbers. The initial Curve Number Library is taken from the SCS TR-55, Urban Hydrology for Small Watersheds. You can modify the library using the New and Edit buttons and you can use the Load and SaveAs buttons to store the library to separate .rcn files.

Cover Description	A	B	C	D
Open Space-Poor (<50% grass)	68	79	86	89
Open Space-Fair (50% to 75% grass)	49	69	79	84
Open Space-Good (>75% grass)	39	61	74	80
Paved Lots Roofs & Driveways	98	98	98	98
Paved Streets w/Curbs & Sewers	98	98	98	98
Paved Streets w/ Open Ditches	83	89	92	93
Gravel Streets (including ROW)	76	85	89	91
Dirt Streets (including ROW)	72	82	87	89
Commercial/Business Districts	89	92	94	95
Industrial Urban Districts	81	88	91	93
Residential 1/8 acre or less	77	85	90	92
Residential 1/4 acre	61	75	83	87
Residential 1/3 acre	57	72	81	86

First highlight a row on the spreadsheet, and then select the curve number from the library using the Select CN button and click on the Select Subarea button to select all the subarea closed polylines. These polylines can be generated by the Sub-Watershed by Land Use command. The program will sum the polylines that are selected for a total area. The Subarea By Interior Point button allows you to select subarea closed polylines by picking inside the polylines. If you have the runoff layers defined for the watershed beforehand, you can simplify the process by selecting the closed polyline of the whole watershed, the subareas and their curve numbers, soil types, cover descriptions as well as area values will be filled into the spreadsheet automatically. More information regarding the soil types is given below.

When all the land-use curve numbers and areas are entered, enter the rainfall for the storm in question and then click on the Calc button to calculate the weighted curve number and the runoff given the weighted curve number. This

curve number can then be used in the Time of Concentration and Peak Flow commands. The Runoff Volume equals the Runoff Q times the total area. You can also save the table entries to a curve number (.cn) file and reload these values later.

The following information regarding soil types comes from Part 630 of the National Engineering Handbook. This can be found at the following link: <https://directives.sc.egov.usda.gov/OpenNonWebContent.aspx?content=17757.wba>

The four hydrologic soil groups (HSGs) are described as:

Group A-Soils in this group have low runoff potential when thoroughly wet. Water is transmitted freely through the soil. Group A soils typically have less than 10 percent clay and more than 90 percent sand or gravel and have gravel or sand textures. Some soils having loamy sand, sandy loam, loam or silt loam textures may be placed in this group if they are well aggregated, of low bulk density, or contain greater than 35 percent rock fragments. The limits on the diagnostic physical characteristics of group A are as follows. The saturated hydraulic conductivity of all soil layers exceeds 40.0 micrometers per second (5.67 inches per hour). The depth to any water impermeable layer is greater than 50 centimeters [20 inches]. The depth to the water table is greater than 60 centimeters [24 inches]. Soils that are deeper than 100 centimeters [40 inches] to a water impermeable layer are in group A if the saturated hydraulic conductivity of all soil layers within 100 centimeters [40 inches] of the surface exceeds 10 micrometers per second (1.42 inches per hour).

Group B-Soils in this group have moderately low runoff potential when thoroughly wet. Water transmission through the soil is unimpeded. Group B soils typically have between 10 percent and 20 percent clay and 50 percent to 90 percent sand and have loamy sand or sandy loam textures. Some soils having loam, silt loam, silt, or sandy clay loam textures may be placed in this group if they are well aggregated, of low bulk density, or contain greater than 35 percent rock fragments. The limits on the diagnostic physical characteristics of group B are as follows. The saturated hydraulic conductivity in the least transmissive layer between the surface and 50 centimeters [20 inches] ranges from 10.0 micrometers per second (1.42 inches per hour) to 40.0 micrometers per second (5.67 inches per hour). The depth to any water impermeable layer is greater than 50 centimeters [20 inches]. The depth to the water table is greater than 60 centimeters [24 inches]. Soils that are deeper than 100 centimeters [40 inches] to a water impermeable layer or water table are in group B if the saturated hydraulic conductivity of all soil layers within 100 centimeters [40 inches] of the surface exceeds 4.0 micrometers per second (0.57 inches per hour) but is less than 10.0 micrometers per second (1.42 inches per hour).

Group C-Soils in this group have moderately high runoff potential when thoroughly wet. Water transmission through the soil is somewhat restricted. Group C soils typically have between 20 percent and 40 percent clay and less than 50 percent sand and have loam, silt loam, sandy clay loam, clay loam, and silty clay loam textures. Some soils having clay, silty clay, or sandy clay textures may be placed in this group if they are well aggregated, of low bulk density, or contain greater than 35 percent rock fragments. The limits on the diagnostic physical characteristics of group C are as follows. The saturated hydraulic conductivity in the least transmissive layer between the surface and 50 centimeters [20 inches] is between 1.0 micrometers per second (0.14 inches per hour) and 10.0 micrometers per second (1.42 inches per hour). The depth to any water impermeable layer is greater than 50 centimeters [20 inches]. The depth to the water table is greater than 60 centimeters [24 inches]. Soils that are deeper than 100 centimeters [40 inches] to a restriction or water table are in group C if the saturated hydraulic conductivity of all soil layers within 100 centimeters [40 inches] of the surface exceeds 0.40 micrometers per second (0.06 inches per hour) but is less than 4.0 micrometers per second (0.57 inches per hour).

Group D-Soils in this group have high runoff potential when thoroughly wet. Water movement through the soil is restricted or very restricted. Group D soils typically have greater than 40 percent clay, less than 50 percent sand, and have clayey textures. In some areas, they also have high shrink-swell potential. All soils with a depth to a water impermeable layer less than 50 centimeters [20 inches] and all soils with a water table (210-VI-NEH, May 2007) 7-3 Part 630 National Engineering Handbook Chapter 7 Hydrologic Soil Groups within 60 centimeters [24 inches] of the surface are in this group, although some may have a dual classification, as described in the next section, if they can be adequately drained. The limits on the physical diagnostic characteristics of group D are as follows. For soils with a water impermeable layer at a depth between 50 centimeters and 100 centimeters [20 and 40 inches], the saturated hydraulic conductivity in the least transmissive soil layer is less than or equal to 1.0 micrometers per second (0.14 inches per hour). For soils that are deeper than 100 centimeters [40 inches] to a restriction or water table, the saturated hydraulic conductivity of all soil layers within 100 centimeters [40 inches] of the surface is less than or equal to 0.40 micrometers per second (0.06 inches per hour).

Dual hydrologic soil groups-Certain wet soils are placed in group D based solely on the presence of a water table within 60 centimeters [24 inches] of the surface even though the saturated hydraulic conductivity may be

favorable for water transmission. If these soils can be adequately drained, then they are assigned to dual hydrologic soil groups (A/D, B/D, and C/D) based on their saturated hydraulic conductivity and the water table depth when drained. The first letter applies to the drained condition and the second to the undrained condition. For the purpose of hydrologic soil group, adequately drained means that the seasonal high water table is kept at least 60 centimeters [24 inches] below the surface in a soil where it would be higher in a natural state.

Matrix of hydrologic soil group assignment criteria-The decision matrix in tables 7-1 and 7-2 can be used to determine a soil's hydrologic soil group. Check both tables before making a final decision. If saturated hydraulic conductivity data are available and deemed to be reliable, then these data, along with water table depth information, should be used to place the soil into the appropriate hydrologic soil group. If these data are not available, the hydrologic soil group is determined by observing the properties of the soil in the field. Factors such as texture, compaction (bulk density), strength of soil structure, clay mineralogy, and organic matter are considered in estimating the hydraulic conductivity of each layer in the soil profile. The depth and hydraulic conductivity of any water impermeable layer and the depth to any high water table are used to determine correct hydrologic soil group for the soil. The property that is most limiting to water movement generally determines the soil's hydrologic group. In anomalous situations, when adjustments to hydrologic soil group become necessary, they shall be made by the NRCS state soil scientist in consultation with the state conservation engineer.

Calculate C-Factor

One of the most commonly used equations for the calculation of peak stormwater discharge from small watersheds is the Rational Formula. The C-Factor in this equation is a dimensionless runoff coefficient that represents the fraction of rainfall that becomes stormwater runoff. Although there are many factors that affect this ratio, the type of surface coverage is the one most often implemented. For watersheds with mixed surface coverage, a weighted C-Factor can be calculated using a weighted average method.

Average C-factor is calculated by dividing the product of Coverage Area and C-factor which is divided by the total watershed area.

C-Factor Calculation

Area Units: Sq. Feet Sq. Mile Acre

Area Precision: 0.00

	C-Factor	Description	Area	% Area
1	0.250	WOODS	144348.33	39.18
2	0.950	DRIVEWAY	11526.10	3.13
3	0.950	PAVEMENT	18400.07	4.99
4	0.950	HOUSE	20400.00	5.54
5	0.300	GRASS	173752.99	47.16

C-Factor Calculation dialog

This tool can be used like a spreadsheet by manually selecting a C-Factor along with the type and total surface coverage. However, the C-Factor can also be calculated using closed polylines within your design drawing. To do so, draw the outside boundary of the total watershed and create closed polylines for each Sub Area. Please note that there will always be one area that is calculated as the total drainage area minus the sum of all the sub-areas. This is typically a pervious layer such as lawns. Be sure and have the overall watershed boundary and each sub-area boundary created. The following procedure describes this pMethod.

Within the C-factor Calculation window, set your units as you want them to be reported along with area precision. Please note that you do not have to use a pre-defined C-factor definition.

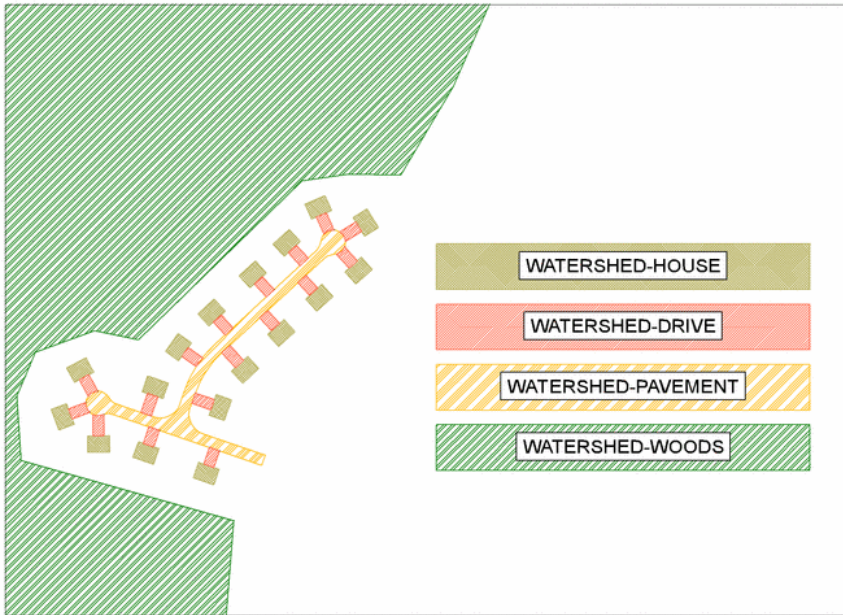

Select the first row, first cell of the dialogue and click the Select C-Factor command button.

Use the Select Subarea command to select a sub-area represented by a closed polyline within the overall watershed boundary.

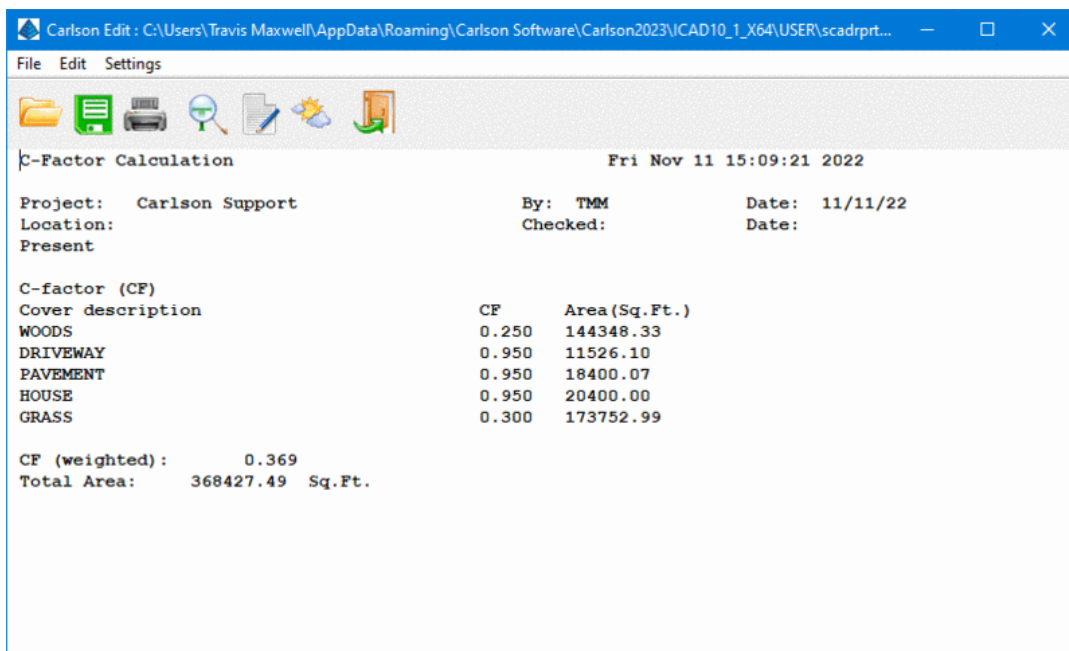

After all subareas have been selected for each C-Factor, use the Subarea By Interior Pt command to calculate the remaining area to complete the C-Factor calculation.

Select the Report Button to report the calculation.

If a Watershed Layer Definition file has been setup and the design drawing has sub-areas delineated by layer accordingly, C-Factor will be calculated automatically when the overall watershed is selected. To make sure each sub-areas are assigned correctly, use the Watershed Layer Definition tool to hatch them as shown below.

Time of Concentration - SCS Method

This command calculates the time of concentration (T_c) by the SCS method from *A Method of Estimating Volume and Rate of Runoff in Small Watersheds*. The T_c is the time required for water to flow from the most distant point in the watershed to the measurement point.

The SCS method calculation based on the curve number, length of flow, and average slope. The curve number defaults to the weighted curve number from the Curve Numbers & Runoff routine. When the three inputs are entered, click on Calculate to compute the Tc. Select CN from Table button opens the CN dialog and allows you to select the CN based on the drainage area type and the soil type. Click on Select Flow Line from Screen button to use a 3D polyline in the drawing. This sets the length of flow and average land slope. A 3D polyline that models the flow can be created with the Watershed Above Point or Run Off Tracking commands. While reading in the 3D polyline, the Tc is calculated by adding the Tc's for each segment of the polyline. This yields a different and more accurate Tc than using the average slope with the Calculate button.

Time of Concentration - TR-55 Method

This command calculates the time of concentration (Tc) by the TR-55 method. Time of concentration is the time required for water to flow from the most distant point in the watershed to the reference point.

The TR-55 method for calculating Time of Concentration(Tc) is a velocity method for determining Tc. Stormwater runoff is assumed to begin as Sheet Flow. Once the depth of Sheet Flow increases, stormwater runoff concentrates into shallow concentrated flow. Channel Flow occurs when multiple channel flows join together and travel along a channel. In the case of un-urbanized existing conditions, Sheet Flow is assumed to be at least 100'. For developed conditions, there is no limitation on the length of sheet flow. Total Time of Concentration is equal to the sum of each flow segment. If grade or surface changes occur along a flow segment, that flow segment can be sub-divided where slope changes. Use the Add button to add flows. Sheet, Shallow and Channel flows can be added individually or all together.

When adding a flow, the Select Flow Line From Screen function allow you to pick a 3D polyline and split it into segments of sheet, shallow and channel flow precisely. The Manning's n for the sheet and channel flow can be chosen from a table by clicking the Select button. Clear button will clear all fields in the dialog for entering new data.

Time of Concentration - Rational Method

This command calculates the time of concentration (Tc) by the Rational method. The Tc is the time required for water to flow from the most distant point in the watershed to the measurement point.

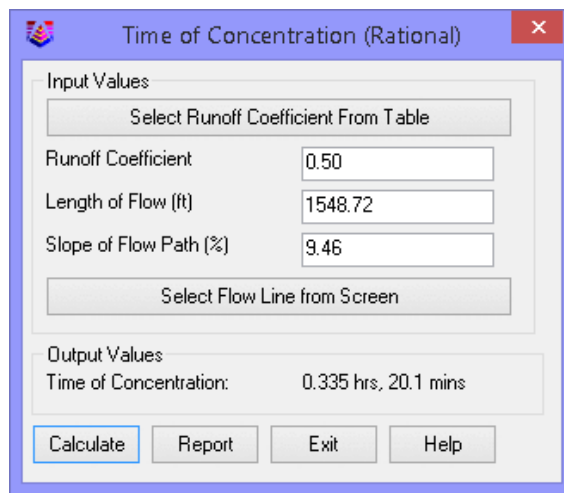

The Rational method calculation based on the runoff coefficient, length of flow and average slope. These values are set in the dialog shown. The formula is:

$$Tc = (1.8(1.1 - c)L^{1/2}) / S^{0.33}$$

Where: c = Runoff coefficient

L = flow length (ft or m)

S = average land slope (%)

Time of Concentration - Kinematic Wave Method

Kinematic Wave Equation is often used to calculate the time of concentration for overland flow. This equation has the rainfall intensity as a dependent variable, which is a function of the time of concentration. Therefore it's an iterative process to determine the time of concentration.

Where,

tc = time of concentration (minutes)

i = rainfall intensity (in/hr)

L = overland flow length (ft)

n = manning's roughness coefficient

S = slope of the surface (ft/ft or m/m)

Time of Concentration - Regression Equation, LA County

The regression method uses an iterative process to calculate the time of concentration. The study of regression equation relied on Tc computations from a large number of subareas. The subareas were taken from diverse hydrology studies that used the kinematic wave theory equations to calculate Tc. The following equations are from Hydrology Manual of Los Angeles County Department of Public Works.

$$T_c = \frac{0.31 * L^{0.483}}{(C_d * I_t)^{0.519} * S^{0.135}}$$

$$I_t = I_{1440} * \left(\frac{1440}{t}\right)^{0.47}$$

$$C_d = (0.9 * IMP) + (1.0 - IMP) * C_u$$

where: T_c = Time of concentration, in minutes

L = Longest flow path length from watershed boundary to outlet, in feet

C_d = Developed runoff coefficient, ratio of runoff rate to rainfall intensity, in in/in

I_t = Intensity at time t , in in/hr

S = Slope of longest flow path, in ft/ft

IMP = Percent Impervious, percent expressed as 0.0 to 1.0

C_u = Undeveloped runoff coefficient, ratio of runoff rate to rainfall intensity, in in/in

Select Regression Equation Method from Watershed > Time of Concentration menu. In the dialog, specify the Soil Type, Proportion Impervious Data, Flow length and Slope, and the Rational rainfall data. The flow path data can be obtained from picking a 3D polyline and the program calculates the length and slope of the flow automatically. Click on Calculate button to see the result.

Time of Concentration - Maricopa County, AZ

This command calculates the time of concentration (Tc) by the following equation developed by Papadakis and Kazan in Maricopa County, AZ. This is due to the extent of imperviousness associated with urban watersheds and to the fact that the time of concentration is usually very short.

$$T_c = 11.4L^{0.5}K_b^{0.52}S^{-0.31}i^{-0.38}$$

where: Tc = time of concentration, in hours

L = length of the longest flow path, in miles

S = watercourse slope, in feet/mile

Kb = watershed resistance coefficient, see table taken from design manual

i = rainfall intensity, in inches/hour

Table 3.1
EQUATION FOR ESTIMATING K_B IN THE T_C EQUATION

$K_B = m \log_{10} A + b$				
Where A is drainage area, in acres				
Type	Description	Typical Applications	Equation Parameters	
			m	b
A	Minimal roughness: Land surfaces that are relatively smooth and/or well graded. Surface runoff is sheet flow.	Commercial/industrial areas Residential areas Parks and golf courses	-0.00625	0.04
B	Moderately low roughness: Land surfaces have irregularly spaced roughness elements that protrude from the surface but are still relatively uniform. Surface runoff is predominately sheet flow around the roughness elements.	Agricultural fields Pastures Desert rangelands Undeveloped urban lands	-0.01375	0.08
C	Moderately high roughness: Land surfaces that have significant large to medium-sized roughness elements and/or poorly graded land surfaces that cause the flow to be diverted around the roughness elements. Surface runoff is sheet flow for short distances draining into meandering drainage paths.	Hillslopes Brushy alluvial fans Hilly rangelands Disturbed lands, mining, etc. Forests with underbrush	-0.025	0.15
D	Maximum roughness: Rough land surfaces with torturous flow paths. Surface runoff is concentrated in numerous short flow paths that are often oblique to the main flow direction.	Mountains Some wetlands	-0.030	0.20

Note: A is the area of the entire subbasin, not the area of the surface type A, B, C or D within the subbasin.

Select Maricopa County Method from Watershed > Time of Concentration menu. In the dialog, specify the unit of area, flow length and slope, and the basin surface type. The flow path data can be obtained from picking a 3D polyline and the program calculates the length and slope of the flow automatically. Click on Calculate button to see the result.

Time of Concentration - Kirpich Method

This command calculates the time of concentration (T_c) by the Kirpich method, which is developed for small drainage basins in Tennessee and Pennsylvania, with basin areas from 1 to 112 acres. The formula is:

$$T_c = KL^{0.77} / S^n$$

where: L = basin length (ft)

S = basin slope (ft/ft)

K = 0.0078 for Tennessee, 0.0013 for Pennsylvania

n = 0.385 for Tennessee, 0.5 for Pennsylvania

The estimated T_c is multiplied by 0.4 if the overland flow path is concrete or asphalt, or by 0.2 if the channel is concrete-lined.

Select Kirpich Method from Watershed > Time of Concentration menu. In the dialog, choose a location of either Pennsylvania or Tennessee, and specify the basin conditions. The flow path data can be obtained from picking a 3D polyline and the program calculates the length and slope of the flow automatically. Click on Calculate button to see the result.

Time of Concentration - Kerby-Kirpich Method

The Kerby-Kirpich method offers an alternative means of calculating the time of concentration for a watershed. With this method, the overall time of concentration is divided into two components: overland flow and channel flow. The Kerby equation is used to calculate overland flow, and the Kirpich equation is used to calculate channel flow.

Kerby equation (overland flow)

$T_{ov} = K (LN)^{0.467} / S^{-0.235}$ where: T_{ov} = Overland Flow Time of Concentration (min)

K = Unit Conversion Coefficient, in which K = 0.828 for traditional units and K = 1.44 for SI units

L = Overland Flow Length (in feet or meters as dictated by K) (ft/ft)

N = Retardance Coefficient - The Select button will show Common Kerby Coefficient

S = Slope of Terrain conveying the overland flow (ft/ft)

Kirpich equation (channel flow)

$T_{ch} = KL^{0.0770} S^{-0.385}$ where: T_{ch} = Channel Flow Time of Concentration (min)

K = Unit Conversion Coefficient, in which K = 0.0078 for traditional units and K = 0.0195 for SI units

L = Channel Flow Length (in feet or meters as dictated by K) (ft/ft)

S = Slope of Terrain conveying the main channel flow (ft/ft)

Select Kerby-Kirpich Method from Watershed > Time of Concentration menu.

In the dialog for the Overland Flow, input the Kerby - Overland Flow Length (can be user entered), or Select Flow Line. The flow data can be obtained from picking a 3D polyline and the program calculates the length and slope of the flow automatically. User can also Select Surface Data and choose a surface model to get the flow slope. Enter or Select Retardance Coefficient. For the Channel Flow, input the Kirpich - Channel Flow Length (can be user entered), or Select Flow Line. User can also Select Surface Data and choose a surface model to get the flow slope. Calculate button to see the result.

Keyboard Command: peakflw3
Prerequisite: None

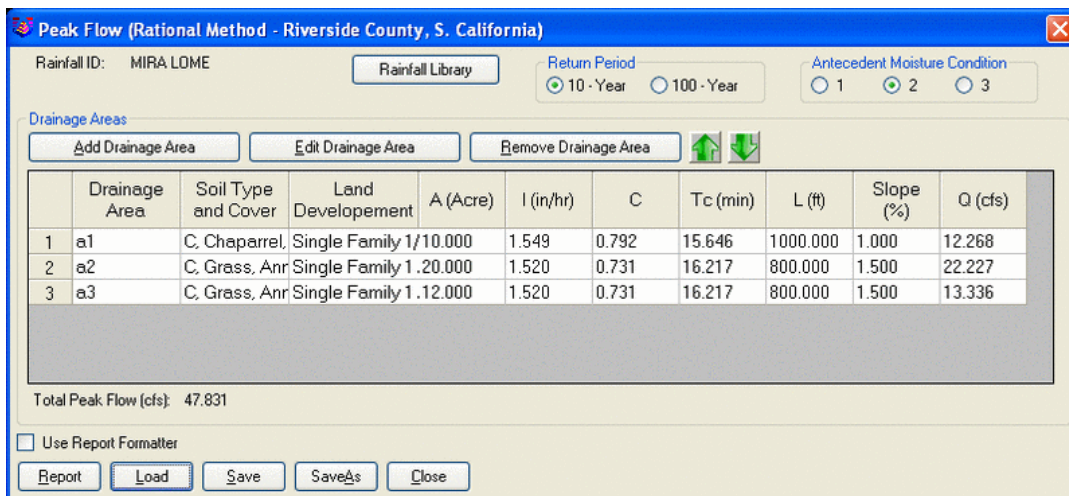

Peak Flow - Rational Method(Riverside S. California)

This command is design to compute peak flow in the Riverside County, southern California. In Riverside county as well as Southern California, peak flow is calculated based on the Rational method, $Q = CIA$, but it also has its own computing criteria because of its extremely varied topography, soil types and land uses, and its storm events that are different than other regions.

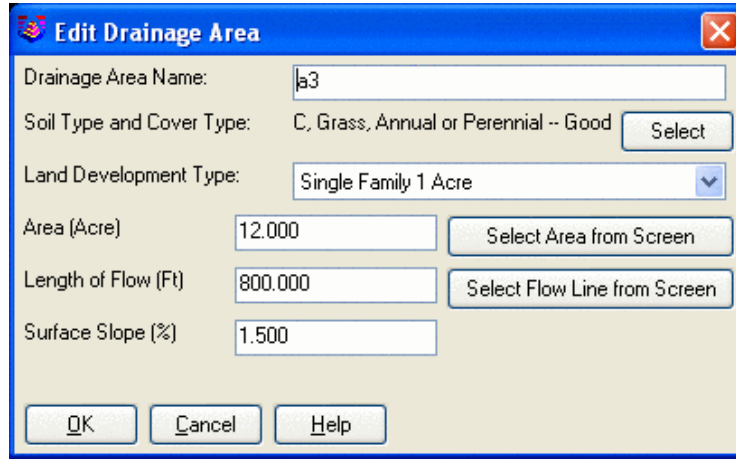

First, Riverside County usually requires a peak flow calculation on 10-year and 100 year storm events. So rainfall data of riverside county should be defined in the rainfall library. We provide two methods, Rainfall Accumulation and Rainfall Intensity, which allows any combination of return periods of 2-year, 5-year, 10-year, 25-year, 50-year and 100-year rainfall definition. IDF curves would be calculated. Second, Riverside County defines a list of land development types, which affect the subarea runoff index and percentage of the impervious cover, and therefore lead to the calculation of the time of concentration, rainfall intensity, runoff coefficient and then peak flow. The types of land development are: Commercial, Apartment, Mobil home park, Condominium, Single family(1/4 Acre lot, 1/2 Acre lot, 1 Acre lot), Undeveloped with poor, fair or good cover. Please refer to the Riverside County Hydrology Manual for details.

Select Rational Method (Riverside County) from Watershed > Peak Flow menu. In the peak flow dialog, choose a rainfall from the rainfall library, and specify the return period and the antecedent moisture condition. The spreadsheet displays the list of drainage area data in design. Add Drainage Area button allows you to add a new drainage entry, Edit Drainage Area button allows you to edit the highlighted entry and Remove Drainage Area button removes the highlighted entry. When you add or edit a drainage area, the Add/Edit Drainage Area dialog opens. Enter the drainage area name, specify the soil type and cover type from a look up table, and choose the land development type. The area can be entered either manually or automatically by selecting a closed polyline from screen. The flow line data can also be obtained from picking a 3D polyline and the program calculates the length and slope of the flow automatically. Click on OK button to commit the drainage area entry.

The design data can be saved to a .riv file, and loaded back to the dialog. Report button reports the design data and hydrology calculation results. The Use Report Formatter option allows you to report data to a spreadsheet instead.

Prerequisite:

Peak Flow - Rational Method (KYDOT)

This command calculates peak flow using the rational method, $Q=CIA$, with rainfall intensity coefficients specific to regions of Kentucky. The program is run through the dialog shown below. The weighted Runoff Coefficient or C-factor can be calculated by the Curve Number & Runoff routine. The peak flow value can then be used for Detention Pond Sizing or Channel Design.

Pulldown Menu Location: Watershed

Keyboard Command: peakflw2

Prerequisite: None

Peak Flow - Tabular Hydrograph Method

This command calculates peak flow using the tabular hydrograph method from the TR-55 program. The program is run through the dialog shown below. The Curve Numbers & Runoff and Time of Concentration routines can be used to calculate the subarea input values. When all the inputs are entered, click on the Calculate button. The input values can be saved to a file by clicking the Save button. Then the Load button can be used later to recall these entered values. The peak flow report lists the flow for each subarea at different time. The peak flow value is listed at the end of the report. This value can then be used for Detention Pond Sizing or Channel Design.

See the TR-55 manual for more details on this routine. One difference between Carlson and the TR-55 example is that Carlson interpolates the flow for the subarea Ia/P between the two nearest table Ia/P values whereas TR-55 uses the one closest Ia/P table entry. Consider a subarea with an Ia/P value of 0.14 and table entries of 100 cfs at 0.1 Ia/P and 75 cfs at 0.3 Ia/P. TR-55 would use 100 cfs from the nearest 0.1 Ia/P entry. Carlson would interpolate between 100 and 75 cfs resulting in 95 cfs.

Peak Flow - Modified Rational Method (LA County)

The Peak Flow - Modified Rational Method is an extension of the rational method used to create runoff hydrographs from a watershed of any size over a specific time period. The Rational method is limited to considering storms with a duration equal to the time of concentration and provides only a peak flow. The Modified Rational Method can consider single event storms with changing intensities and longer durations. It was developed as a means to produce hydrographs for storage design based on the rational method. Please refer to Chapter 12, Hydrology Manual of Los Angeles County Department of Public Works for hydrograph calculation.

Select Modified Rational Method (LA County) from Watershed > Peak Flow menu. In the dialog, specify the Drainage Area, Soil Type, Proportion Impervious Data, Time of Concentration, Storm duration and the Rational rainfall data. The drainage area can be obtained from picking a closed polyline and the program calculates the area automatically. Click on Calculate button to see the result.

The Soil Type library has all the tables from the Appendix C in the Hydrology Manual. New Soil Type and Runoff Coefficient Data can be added to the library.

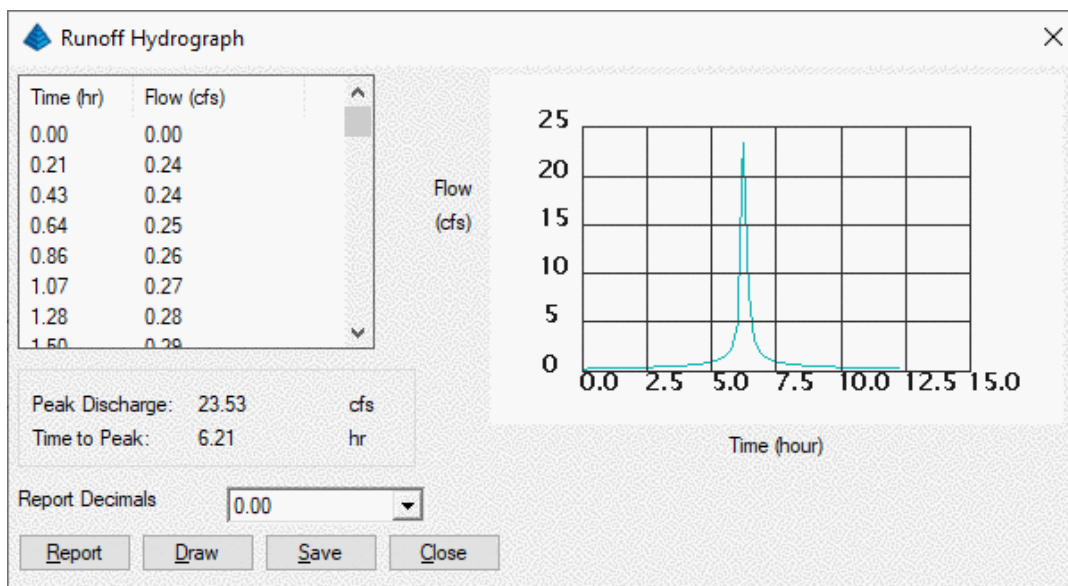

The Proportion Impervious Data library is from the Appendix D in the Hydrology Manual. New data is allowed to add to the library.

Peak Flow Hydrograph:

Peak Flow Report:

Pulldown Menu Location: Watershed > Peak Flow

Keyboard Command: peakflw_modrat

Prerequisite: None

Watershed Settings (Save and Load)

These commands save and load watershed parameters to a data file with a .HYD file name extension. The watershed values include settings from the commands in the top portion on the Watershed menu such as rainfall, storm type, weighted curve number. These commands allow you to recall these values after reloading the drawing at a later time.

Pulldown Menu Location: Watershed

Keyboard Command: saveshed, loadshed

Prerequisite: none

Pipe Routing Hydrograph

Pipe routing transforms a sub-basin runoff hydrograph from the point of discharge in the pipe to a downstream location. As the hydrograph flows to the downstream area it undergoes changes in shape and distribution due to translation and reach storage effects. This program implements the Storage-Indication methodology, which accounts for storage effects and is derived from the continuity equation:

$$\Delta S / \Delta t = I - O$$

Where: ΔS = Change in storage (cubic ft or cubic meter)

Δt = Routing time step (hours)

I = Inflow discharge (cfs or cms)

O = Outflow discharge (cfs or cms)

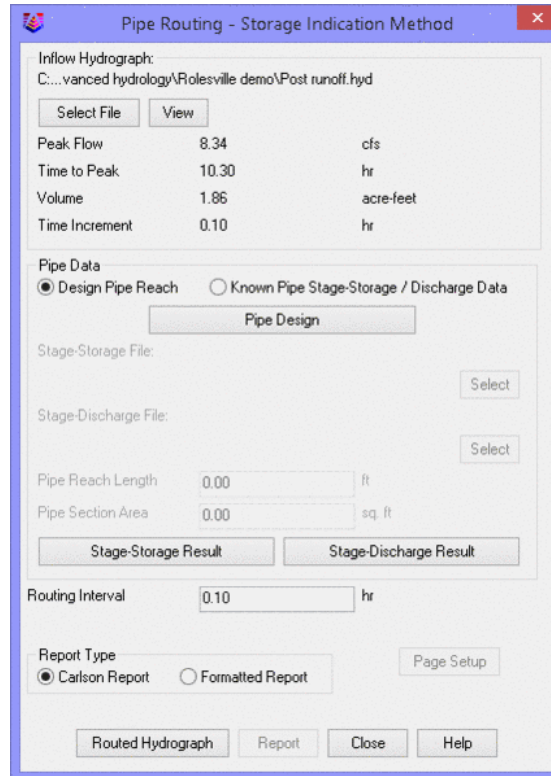

Please refer to the National Engineering Handbook Section 4 for the detail of the Storage-Indication method.

Select Pipe Routing from Watershed > Hydrograph Routing menu. This command opens a dialog for hydrograph routing. First, select the inflow hydrograph file. Second, either design a pipe or enter the stage-storage and

stage-discharge data of a known pipe. When design a pipe, enter pipe parameters in the pipe design dialog, the headwater and tailwater elevations are also need to be specified for stage-discharge calculation. If the pipe is known, select its stage-storage and stage-discharge files, and then specify the pipe length and its section area for calculating flow travel time.

The numerical accuracy and stability of pipe routing is sensitive to the routing interval Δt . The average reach travel time is computed by dividing the flow velocity corresponding to the average discharge for the inflow hydrograph into the pipe. If the travel time is less than the time interval, then negative outflow could occur and the calculation is not accurate and the program generates a warning message asking for a smaller routing interval.

After entering all information, click Routed Hydrograph button to generate the routing hydrograph. A dialog is opened with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

Routing Hydrograph - Pipe Routing

Design Detention Pond

This command calculates peak flow using the regional method, as stated in the DR-401 manual. Regression Equation Methodology has been adopted by the Cabinet to calculate peak flows. The method is described in USGS Water Resources Investigations Report 03-4180 (2003) titled "Estimating the Magnitude of Peak Flows for Streams in Kentucky for Selected Recurrence Intervals". The method divides the state into seven regions. Regression

equations have been developed for each region based on stream gage station data and other parameters that are applicable to the watersheds that were analyzed.

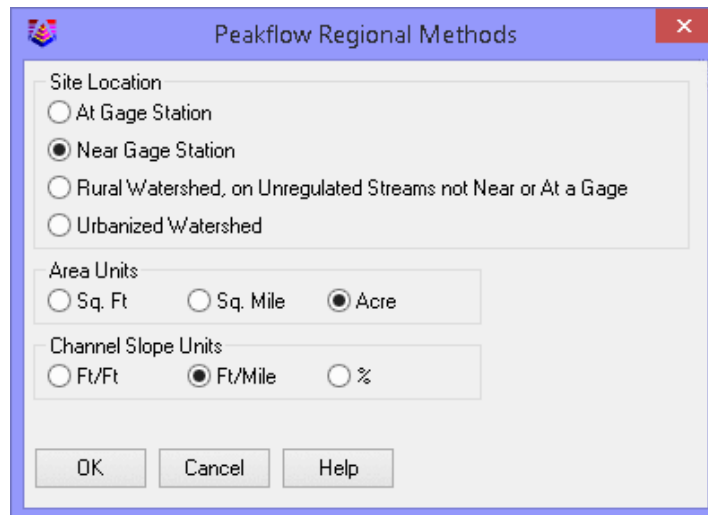

When you first run the command, the Select Peak Flow File - (peak) dialog box opens. You can start a completely new pond project or open an existing pond project.

Select or Create *.peak File

Peak Flow Regional Methods:

When you start a new Peak Flow Regional project, the Peak Flow Regional Methods settings dialog will open first to let you select the Site Location, Area Units, and Channel Slope Units. Select OK

Peak Flow Regional Methods

Rural Regional Methods:

Set Project Name, Select Region, Return Period, Input manually or select a closed polyline to calculate Drainage

Area. Input manually or select a Flow Line from drawing file to define Channel Slope. Press Calculate to see the Peak Flow (cfs).

Keyboard Command: regional_peakflow

Prerequisite: none

Hydrograph Editor

This command can edit an existing Hydrograph file (.hyd) or be used to create a custom Hydrograph file by manually entering time and flow rate in a spreadsheet style table.

If a design requires a special hydrograph that is either developed by a method outside of Carlson or is used to simulate a special runoff series created by a non standard outlet structure such as a storm system with a pump, a Hydrograph file can be created with this command by manually entering the time series.

This hydrograph file can then be used as the input runoff time series when routing a storm water detention model.

In the Graph function, the dialog shows a graph of the data and has functions to make a report and to draw the graph.

Pulldown Menu Location: Watershed > Hydrograph Routing

Keyboard Command: spreadhyd

Prerequisite: None

Runoff Hydrograph - SCS Method

This function applies the SCS hydrograph procedure and the same methodology as used in TR-20 to generate runoff hydrograph by specifying either a triangular hydrograph shape or a curvilinear one. There are five unit hydrograph options: Delmarva, SCS Curvilinear, SCS Triangular, Clark and Snyder unit hydrograph method. The SCS method is best suited for large watersheds.

Runoff Hydrograph - SCS Method

Time Increment: 0.10 hr

Peak Attenuation Factor: 484

Calculation

Peak Discharge: 126.919 cfs

Time to Peak: 12.70 hr

Volume: 20.70 acre-ft

SCS Curvilinear Unit Hydrograph uses the dimensionless unit hydrograph developed by Victor Mockus. This dimensionless hydrograph has its ordinate values expressed in a dimensionless ratio Q/Q_p (discharge at time t to total discharge) or Q_a/Q (accumulated volume at time t to total volume) and its abscissa values as T/T_p (time t to peak time). When calculating the unit hydrograph for certain watershed, Delta, the internal calculation increment, is $0.1333T_c$ for each given subarea. Slightly adjust Delta so that T_p on the unit hydrograph will fall exactly on one of the ordinates spaced at Delta. This method creates the unit hydrograph for one inch of direct runoff using the 51 evenly spaced Q/Q_p ratios used internally by TR-20.

SCS Triangular Unit Hydrograph uses an equivalent triangular hydrograph having the same units of time and discharge to represent the dimensionless curvilinear unit hydrograph. Please refer to National Engineering Handbook Section 4 for the equations used in generating both SCS Curvilinear and SCS Triangular unit hydrograph.

Delmarva Unit Hydrograph is an alternative to the 484 dimensionless unit hydrograph developed for the Delmarva region (Delaware, Maryland, Virginia peninsula) based on data from four gaged watersheds. Peak rate factor of 284 is used in this method.

Clark Unit Hydrograph is a synthetic unit hydrograph method. There's no need to develop a unit hydrograph through the analysis of past observed hydrograph. Instead, a time vs. area curve built into the program is used

to develop the translation hydrograph resulting from a burst of precipitation. The resulting translation hydrograph is routed through a linear reservoir to account for storage attenuation effects across the subbasin. The time of concentration defines the maximum travel time in the subbasin; the storage coefficient is used in the linear reservoir that accounts for the storage effects.

Snyder Unit Hydrograph is based on a study of watersheds in the Appalachian Highlands. In basins ranging from 10 to 10,000 square miles.

Snyder relations are: $t_p = C_t(LL_c)^{0.3}$

Where:

t_p = basin lag (hr)

L = length of the main stream from the outlet to the divide (mi)

L_c = length along the main stream to a point nearest the watershed centroid (mi)

C_t = Coefficient usually ranging from 1.8 to 2.2

$Q_p = 640C_pA/t_p$

Where:

Q_p = peak discharge of the unit hydrograph (cfs)

A = drainage area (mi²)

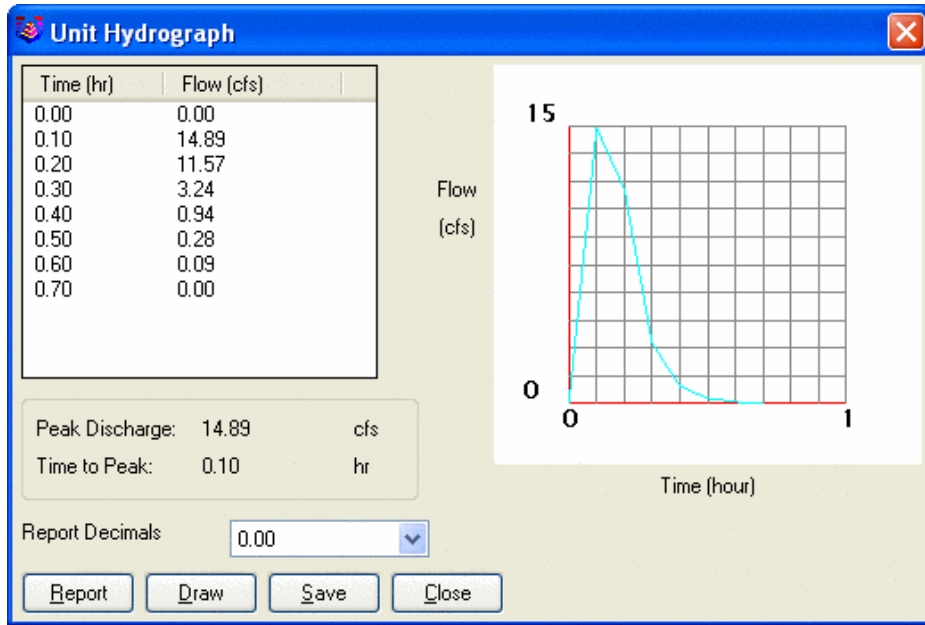

C_p = storage coefficient ranging from 0.4 to 0.8, where larger values of C_p are associated with smaller values of C_t

Select SCS Method from Watershed > Hydrograph Routing > Watershed Hydrograph menu. This command opens a dialog for hydrograph calculation. First choose which method to use, SCS Curvilinear or SCS Triangular. Then enter the sub-basin and rainfall data. When creating an SCS Triangular unit hydrograph, you need to enter the unit hydrograph peak attenuation factor, which controls the area under the unit hydrograph before the time to peak. Usually a factor of 484 is used. This factor varies from about 600 in steep terrain to 300 in very flat swampy areas. When creating an SCS Curvilinear unit hydrograph, the peak attenuation factor is default to 484.

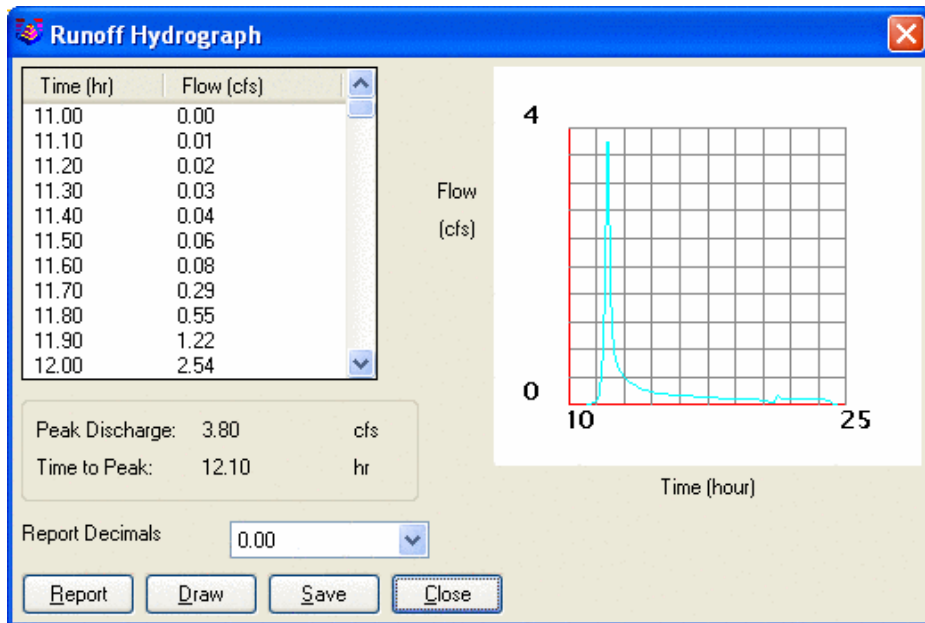

The program can get Rainfall Depth automatically based on user specified Rational rainfall ID, return period and time of concentration.

After entering all information, click Calculation button to generate the unit and runoff hydrograph. Unit Hydrograph button and Runoff Hydrograph button open a dialog with the tabular and graphic data of the unit and runoff hydrograph correspondingly, from there you can draw the hydrograph on screen, generate the hydrograph data in the report format and save the hydrograph to a file.

The calculation result can be reported in PDF format with design data and hydrograph curve.

Unit Hydrograph Dialog

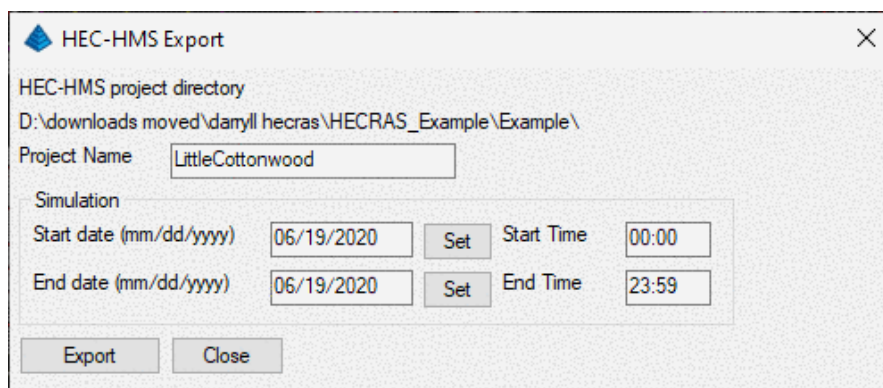

Runoff Hydrograph Dialog

Data can also be exported to HEC-HMS. Clicking the HEC-HMS button reveals the HEC-HMS Support dialog. Use the Set button to assign a job directory. Input an existing HEC-HMS project name for import or create a project name for export. Then click the desired function - Import, Export or Close at the bottom to interface with HEC-HMS. You may learn more about HEC-HMS, which stands for Hydrologic Engineering Center - Hydrologic Modeling System, a very robust system for modeling both large and small areas with tributary flows, as well as download the software here:

<https://www.hec.usace.army.mil/software/hec-hms/>

Input the Project Name, choose Start Date, End Date, Start Time, End Time then click Export.

Runoff Hydrograph - TR-55 Tabular Method

The TR-55 Tabular Method approximates TR-20, which is a more detailed hydrograph procedure. This method can develop partial composite runoff hydrographs at any point in a watershed by dividing the watershed into homogeneous subareas. The tabular discharge values for the various rainfall distribution, presented in *TR-55, Urban Hydrology for Small Watersheds* (U.S. Soil Conservation Service), are used in this method. Tabular discharges expressed in csm/in are given for a range of subarea Tc's from 0.1 to 2 hours and reach Tt's from 0 to 3 hours.

Select TR-55 Tabular Method from Watershed > Hydrograph Routing > Watershed Hydrograph menu. This command opens a dialog for hydrograph calculation. Choose the area unit and select the appropriate storm type for the project location. See the storms maps in the TR-55 manual to determine the storm type. Enter the rainfall depth for the watershed. Select the Ia/P Interpolation option to interpolate the Ia/P ratio, otherwise the calculated Ia/P value would be rounded to the constants 0.10, 0.30 or 0.50. Next, enter the watershed data in the spreadsheet. In the Subarea Name column, enter a short name for each subarea, using numbers or letters. In the Area column, type the area value. You can also click the Select Area button on the bottom of the spreadsheet to calculate the drainage area by selecting a closed polyline.

In the Tc (time of concentration) and Tt (Travel Time) columns, enter the corresponding values. Tt specifically refers to the total time for water to flow from a subarea's outfall to composite outfall point. When the Tc value for a particular subarea doesn't exist in the tabular hydrograph for the given distribution, it will be rounded off in order to determine which hydrograph table to read from. Please refer to Tr-55 for the method used for rounding off Tc and Tt values.

In the Downstream Subarea Name column, type the list of the names of the downstream subareas. Separate each name with a comma. In the CN (Runoff Curve Number) column, enter the CN value of the subarea. Insert Row and Delete Row buttons allow you to do the spreadsheet editing. You can also load a runoff tabular file that you previously saved by clicking on Load button, and save current calculation by Save and SaveAs buttons. The data is stored in a .tab file.

After entering all information, click on Calculation button to generate the runoff hydrograph. Runoff Hydrograph button opens a dialog with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

Area Units: Sq. Ft Sq. Mile Acres

Prerequisite: None

Runoff Hydrograph - Rational Method

The Rational Method is best known for estimating peak stormwater discharge which is used to evaluate collection system capacity. However, the Rational Method cannot be used on its own to determine capacity of Stormwater Systems that involve storage and are non-steady state. It can be combined with one of the following methods to produce a hydrograph capable of modeling non-steady state stormwater systems such as a detention basin.

Modified Rational

Dekalb Rational

Universal Rational

User Defined Rational.

Each method requires a predefined IDF curve and the time of concentration to determine the peak flow using the Rational formula. This value is the peak discharge value in each Hydrograph.

The **Modified Rational Method** calculates the peak discharge rate using the standard $Q=CIA$ formula where

Q=Peak Stormwater Discharge

C=The Rational Runoff Coefficient

I=Stormwater Runoff Intensity (in/hr)

A=Watershed Drainage Area in Acres

Note that the Intensity value "I" is the **Runoff Intensity** which is equal to the rainfall intensity at the Time of Concentration for a given design storm event. However, this value does not give us any indication of the total volume of stormwater runoff which is needed for modeling Stormwater Detention Systems. If the Storm Event duration is exactly equal to the time of concentration, the Runoff Hydrograph is represented by the following.

This represents a rare storm event. Most storm events last much longer than the time of concentration and will produce greater runoff Volume than what is represented in the previous Hydrograph. To determine storage volume requirements, the length of the storm event must be included in the Hydrograph as shown below:

The stormwater duration is either provided in Regulatory Requirements or can be estimated related to a storm frequency by total Volume of Runoff. For collection system design, only the peak rate is needed to size a collection system to a specific storm event. However, systems with detention volume must be able to handle both peak discharge and total Runoff Volume in order to handle all the variations of the 10-year storm. A 10-year storm event with a high intensity will have a short duration compared to a 10-year event with a low intensity. As shown on the table below, each rainfall event represented a 10-year storm.

By using the 24-hour storm event, we can assume that the detention basin will have enough storage for the storm events shown in the following table.

Using the 24-hour volume is not written in stone. It is common to design detention basins using the 6-hour storm event. . The **Rising Limb Factor** is used to multiply the time of concentration to get the peak time when it's not at the time of concentration; the **Receding Limb Factor** changes the slope of the receding limb. Both factors are default to 1. Peak flow Q_p is calculated by CIA, where the rainfall intensity I is at rainfall duration T_d . The **Flow Multiplier** is used to multiply the Q_p for the hydrograph peak flow. The **Time Steps Before Peak** determines the hydrograph time increment.

Modified Rational Hydrograph

The Delta Rational method uses the Modified Rational method as its foundation. Peak discharge is computed using the Rational formula, then the time to peak and the time of base are adjusted to five and ten times the time of concentration. Ten discharge values at increments of time of concentration are computed by scaling the peak discharge appropriately according to the following template.

T/T_c	Q/Q_p if $T_c < 20.0$ min	Q/Q_p if $T_c \geq 20.0$ min
0	0	0
1	0.16	0.04
2	0.19	0.08
3	0.27	0.16
4	0.34	0.32
5	1.00	1.00
6	0.45	0.30
7	0.27	0.11

8	0.19	0.05
9	0.12	0.03
10	0.0	0.0

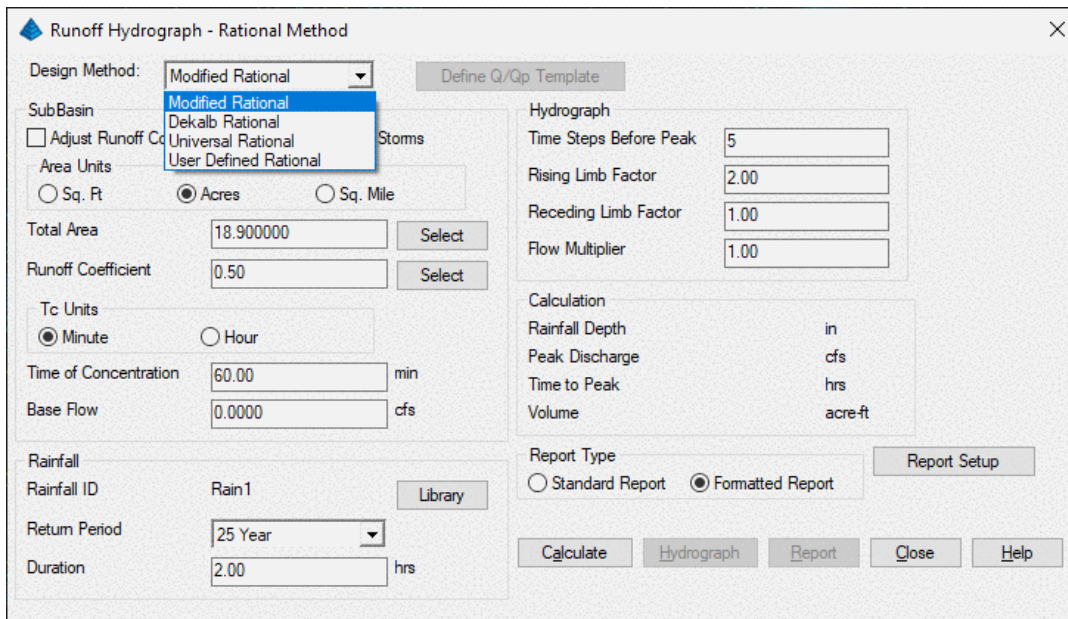

The Universal Rational method uses multiples of predefined coefficients (see the following table) and the peak discharge to compute ordinates at different times. Peak discharge is assumed to be reached at a time equal to three times the time of concentration. The time of base of the hydrograph is computed as eleven times the time of concentration.

Time (min)	Q
0	0.0
Tc	0.21Qp
2Tc	0.30Qp
3Tc	Qp
4Tc	0.54Qp
5Tc	0.39Qp
6Tc	0.25Qp
7Tc	0.18Qp
8Tc	0.15Qp
9Tc	0.14Qp
10Tc	0.13Qp
11Tc	0.0

The User Defined Rational method is similar to the Dekalb Rational method and the Universal Ration method, but with different templates provide by users. This method computes a hydrograph by using a dimensionless hydrograph template that has values for T/Tc versus Q/Qp.

Select Rational Method from Watershed > Hydrograph Routing > Watershed Hydrograph menu. This command opens a dialog for hydrograph calculation. First choose what method to use, then enter the sub-basin and rainfall data. The IDF curves will be computed after you choose a rainfall from the rainfall library. When use the User Defined Ration method, you will need to define the Q/Qp template.

After entering all information, click Calculation button to generate the runoff hydrograph. Runoff Hydrograph button opens a dialog with the tabular and graphic data, from there you can draw the hydrograph on screen and save the hydrograph data to a file.

Runoff Hydrograph - Rational Method

Pulldown Menu Location: Watershed > Hydrograph Routing > Watershed Hydrograph > Rational Method

Keyboard Command: runoffhyd3

Prerequisite: None

Pipe Routing Hydrograph

Pipe routing transforms a sub-basin runoff hydrograph from the point of discharge in the pipe to a downstream location. As the hydrograph flows to the downstream area it undergoes changes in shape and distribution due to translation and reach storage effects. This program implements the Storage-Indication methodology, which accounts for storage effects and is derived from the continuity equation:

$$\Delta S / \Delta t = I - O$$

Where: ΔS = Change in storage (cubic ft or cubic meter)

Δt = Routing time step (hours)

I = Inflow discharge (cfs or cms)

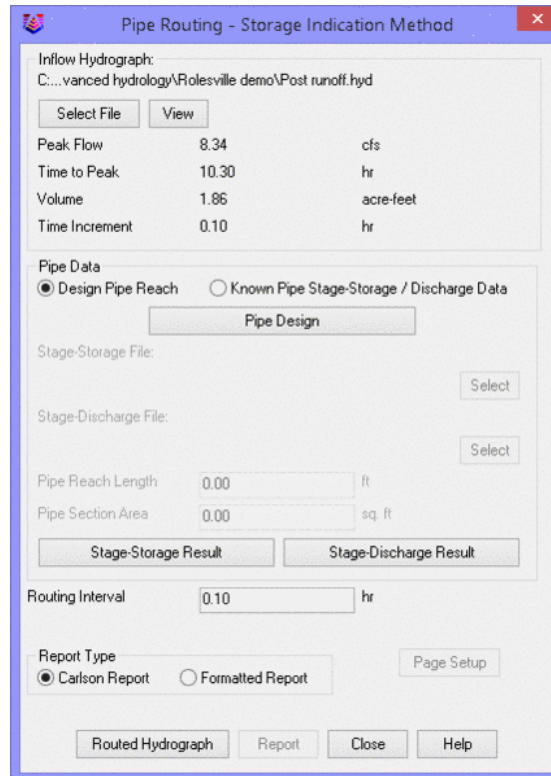

O = Outflow discharge (cfs or cms)

Please refer to the National Engineering Handbook Section 4 for the detail of the Storage-Indication method.

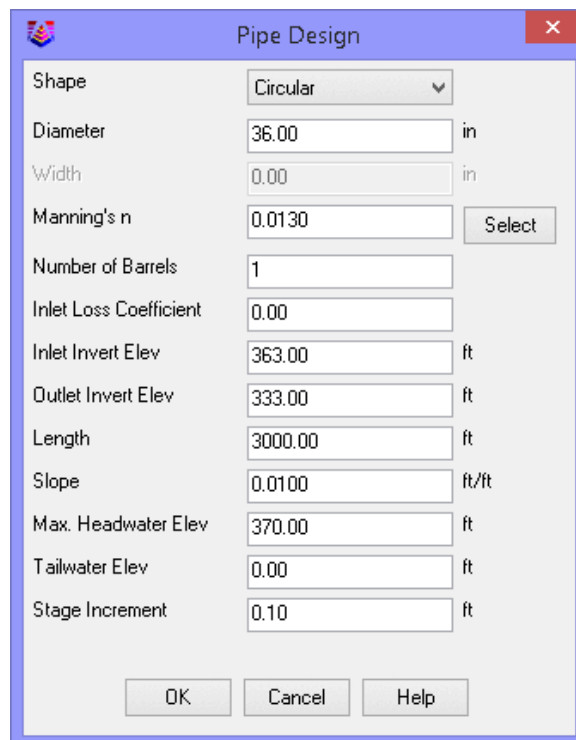

Select Pipe Routing from Watershed > Hydrograph Routing menu. This command opens a dialog for hydrograph routing. First, select the inflow hydrograph file. Second, either design a pipe or enter the stage-storage and stage-discharge data of a known pipe. When design a pipe, enter pipe parameters in the pipe design dialog, the headwater and tailwater elevations are also need to be specified for stage-discharge calculation. If the pipe is known, select its stage-storage and stage-discharge files, and then specify the pipe length and its section area for calculating flow travel time.

The numerical accuracy and stability of pipe routing is sensitive to the routing interval Δt . The average reach travel time is computed by dividing the flow velocity corresponding to the average discharge for the inflow hydrograph into the pipe. If the travel time is less than the time interval, then negative outflow could occur and the calculation is not accurate and the program generates a warning message asking for a smaller routing interval.

After entering all information, click Routed Hydrograph button to generate the routing hydrograph. A dialog is opened with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

Routing Hydrograph - Pipe Routing

Pipe Routing - Pipe Design Dialog

Routed Hydrograph Dialog

Pulldown Menu Location: Watershed > Hydrograph Routing > Pipe Routing

Keyboard Command: piperout

Prerequisite: None

Reservoir Routing Hydrograph

Reservoir routing is used to determine the peak flow attenuation that a hydrograph undergoes as it enters a reservoir. A reservoir is defined by a stage-storage curve and a stage-discharge curve, which can be entered or computed using commands in the Structure pull-down menu. A runoff hydrograph travels through the reservoir to an outlet. The outflow hydrograph is calculated by Storage Indication method, which is developed from the continuity equation:

$$\Delta S / \Delta t = I - O$$

Where: ΔS = Change in storage (cubic ft or cubic meter)

Δt = Routing time step (hours)

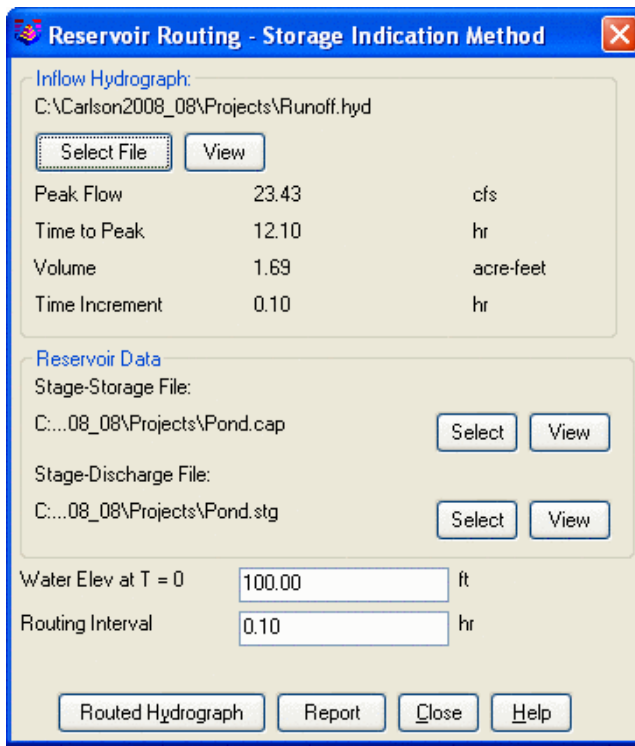

I = Inflow discharge (cfs or cms)

O = Outflow discharge (cfs or cms)

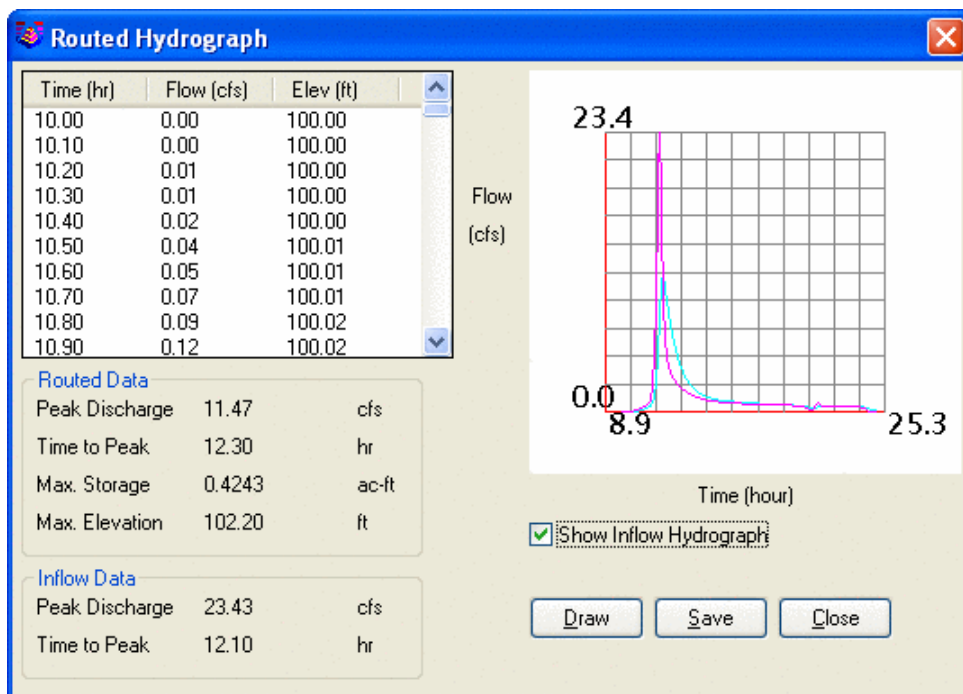

Please refer to the National Engineering Handbook Section 4 for the detail of the Storage-Indication method.

Select Reservoir Routing from Watershed > Hydrograph Routing menu. This command opens a dialog for hydrograph routing. First, select the runoff hydrograph file that you want to do the reservoir routing. Second, select the stage-storage and stage-discharge curve files of a known reservoir. Then specify the initial water elevation at the time when the routing starts and the routing interval. When the routing interval is too large, negative outflows can occur and the program would prompt a error message asking for a smaller interval.

After entering all information, click Routed Hydrograph button to generate the routing hydrograph. A dialog is opened with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

Routing Hydrograph - Reservoir Routing

Routed Hydrograph Dialog

Pulldown Menu Location: Watershed > Hydrograph Routing > Reservoir Routing

Keyboard Command: pondrout

Prerequisite: None

Channel Routing Hydrograph - Convex Method

Channel routing is used to model the attenuation of a hydrograph's peak flow rate as it travels along a channel. Attenuation occurs due to the inherent storage capacity of a channel when the capacity of the channel is greater than the flow capacity.

The Convex method is derived from inflow-outflow hydrograph relationships. The following equation is used:

$$O_{i+1} = CI_i + (1 - C)O_i$$

where: O_{i+1} = Outflow discharge at (i+1)th time step (cfs or cms)

C = Routing Coefficient

I_i = Inflow discharge at (i)th time step (cfs or cms)

O_i = Outflow at (i)th time step (cfs or cms)

The routing coefficient C can be computed using an empirical equation by SCS.

$C = V / (V + 1.7)$ for English units

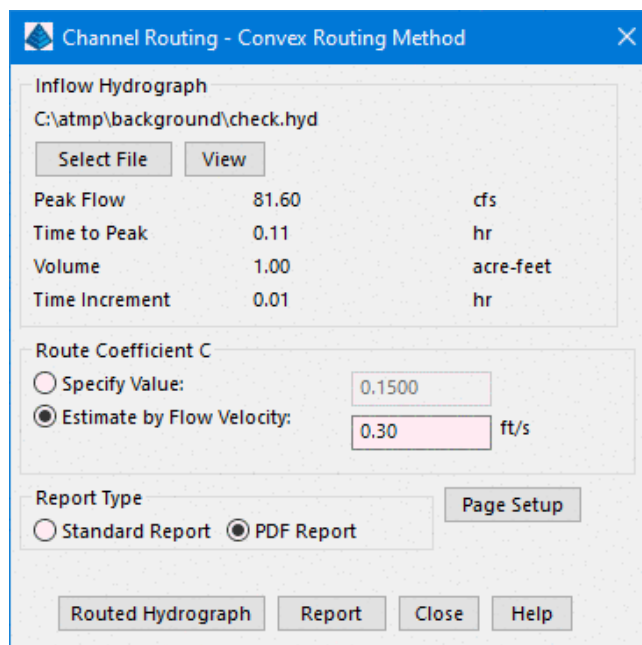

$C = V / (V + 0.518)$ for Metric units

where: V = Flow velocity (ft/s or m/s)

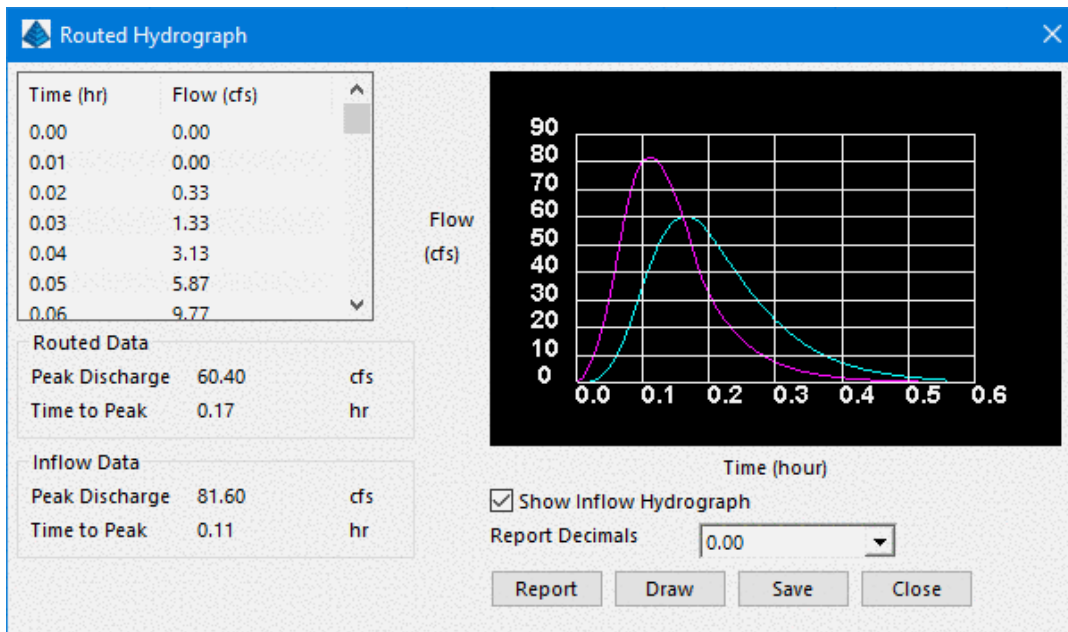

Please refer to the National Engineering Handbook Section 4 for the detail of the Convex method.

Select Convex Method from Watershed > Hydrograph Routing > Channel Routing menu. Specify the inflow hydrograph and enter the routing coefficient C or channel flow velocity to let the program to calculate the coefficient. The routing interval is the same as the time increment of the inflow hydrograph.

After entering all information, click on Routed Hydrograph button to generate the routing hydrograph. A dialog is opened with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

Channel Routing Hydrograph - Convex Method

Routed Hydrograph Dialog

Pulldown Menu Location: Watershed > Hydrograph Routing> Channel Routing > Convex Method

Keyboard Command: chanrout

Prerequisite: None

Channel Routing Hydrograph - Modified Att-Kin Method

Channel routing is used to model the attenuation of a hydrograph's peak flow rate as it travels along a channel. Attenuation occurs due to the inherit storage capacity of a channel when the capacity of the channel is greater than the flow capacity. .

The Modified Att-Kin (attenuation-kinematic) method is used in the TR-20 and TR55 methodologies. It is a combination of the storage indication method and the kinematic wave method to reflect the reservoir and translation effects on natural flood waves. The hydrograph is first routed through a reservoir assuming that the outflow is proportional to the storage. The resulting outflow hydrograph is then translated using kinematic wave principles. The storage routing portion allows for attenuation and translation. Kinematic routing translates the outflow hydrograph but doesn't attenuate the peak.

The continuity equation is

$$I_i - (O_{i+1} - O_i) / 2 = (S_{i+1} - S_i) / \Delta t$$

where: I_i = Inflow hydrograph discharge at (i)th time step

O_i = Outflow hydrograph discharge at (i)th time step

O_{i+1} = Outflow hydrograph discharge at (i+1)th time step

S_i = Storage at (i)th time step

S_{i+1} = Storage at (i+1)th time step

Δt = Routing time step

Substitution of $S = KO$ leads to

$$O_{i+1} = C_m I_i + (1 - C_m) O_i$$

where: $C_m = 2\Delta t / (2K + \Delta t)$

$K = L / (60mV)$

$V = Q / A$

$A = (Q / x)^{1/m}$

where: L = Channel length (ft or meter)

V = Average velocity in the channel (ft/s or m/s)

Q = Average channel flow, default value is the peak discharge of the inflow hydrograph (cfs or cms)

A = Wet cross section area of the channel (sq. ft or sq. meter)

x = Flow equation multiplier, > 0.0

m = Flow equation exponent, default value is 5/3, usually is $1.0 \leq m \leq 2.8$

The coefficient x can be estimated using Manning's Formula:

$$x = S^{1/2} / nP^{2/3}$$

where: S = Average slope of the channel

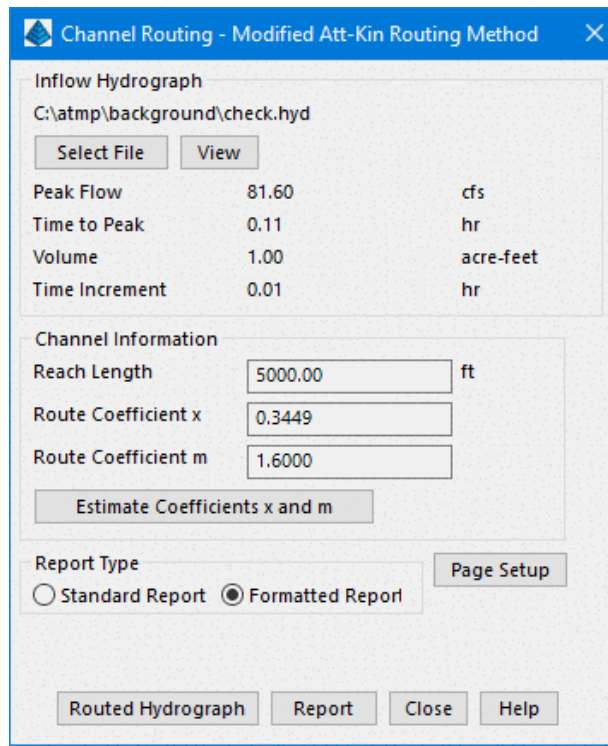

n = Manning's n value

P = Wetted perimeter of the flow (ft or m)

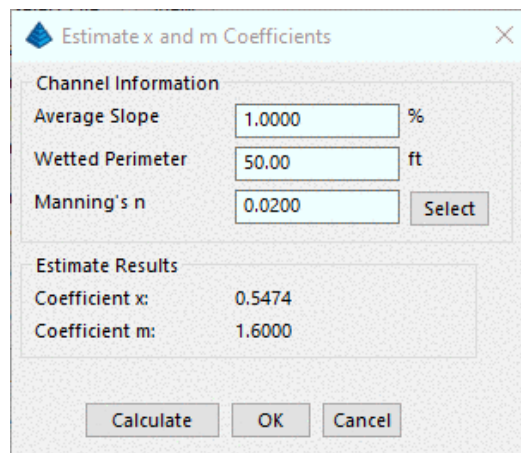

Please refer to the TR-66 for the detail of the Modified Att-Kin method.

Select Modified Att-Kin Method from Watershed > Hydrograph Routing > Channel Routing menu. Specify the inflow hydrograph and enter the channel length, the routing coefficient x and the time coefficient m. The routing interval is as same as the time increment of the inflow hydrograph. Button Estimate Coefficients x and m allows you to enter the parameters of the Channel to determine the x and m coefficients. Once the parameters are entered, click on the Calculate button to compute the coefficients. OK button accepts the values and proceeds to the previous dialog.

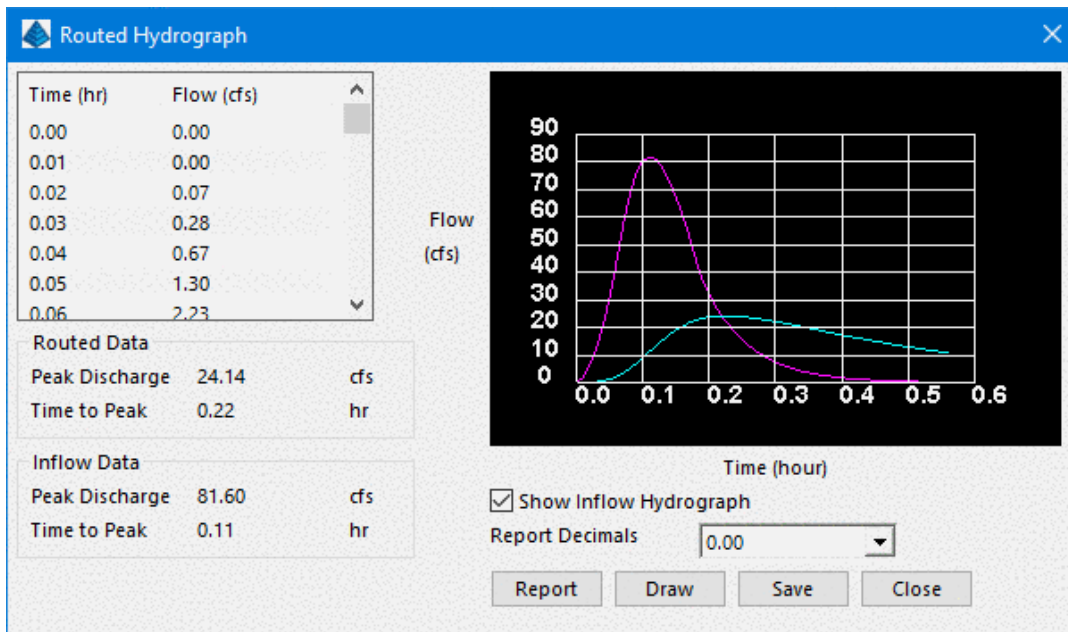

After entering all information, click Routed Hydrograph button to generate the routing hydrograph. A dialog is opened with the tabular and graphic hydrograph data, from there you can draw the hydrograph on screen and save it to a file.

This command is no longer being supported. Running the command will produce the message "Program is removed as obsolete. Please use NRCS WinTR20."

Single Runoff Hydrograph

Program is removed as obsolete. Please use NRCS WinTR20

Add Hydrographs

This function takes two hydrograph files, .hyd and or .h1 format, and produces a new hydrograph file that is a combination of the two. Please note if the peak rates in the hydrographs do not occur at the same time step, the

resulting peak will be less than if the two peak rates were added together.

This is useful when a combined hydrograph is needed when two existing hydrographs already exist. They can either be Carlson format time,flow rate or TR-20 format which has a file extension of .h1. The program adds the two sets of data as they would combine when routed together in a storm water system.

Please note that the time interval used in the output hydrograph is the smaller of the two hydrographs time steps if they are not equal. However, the units for time and discharge rate of each input hydrograph must match. The command is completed by selecting a name and location for the combined hydrograph using the provided file dialogue.

Pulldown Menu Location: Watershed > Hydrograph Utilities

Report Hydrograph

This command reports a hydrograph from a hydrograph file with the extension of:

- .h1 - *.h1 files are created by SEDCAD, Hydrograph Development, or the Single Runoff Hydrograph commands.
- .hyd - *.hyd files are created by all commands under Watershed > Hydrograph Routing menu and sewer network hydrograph routing programs.

After specifying the desired hydrograph file, the following dialog box is presented:

Hydrograph Values and Graphical Representation: The Time vs. Flow values for the hydrograph are displayed in a list and a graphical representation of the hydrograph are provided.

Peak Flow and Time: The Time to Peak (T_p) and Peak Discharge (Q_p) are provided.

Report Decimals: Indicate the desired level of Precision to be displayed in the *Text Report*.

Use Report Formatter: When enabled, this control displays the *Report Formatter Options* dialog box that gives you greater control over the content and type of report you would like to produce.

Report: Displays a hydrograph report showing Time vs. Flow values.

Draw: When clicked, a graphical representation of the hydrograph will be placed into the drawing through the functionality found in the Draw Hydrograph command.

Pulldown Menu Location: Watershed

Keyboard Command: viewhyd

Prerequisite: A hydrograph file

Draw Hydrograph

SEDCAD

Civil Software Design is the author of SEDCAD, which is sold separately from Carlson. SEDCAD is a comprehensive hydrology and sedimentology package, useful for all varieties of runoff and sediment control design calculations. SEDCAD can be run directly from the Carlson Hydrology menu. The directory where SEDCAD is installed must be defined in the Carlson Configure command.

Pulldown Menu Location: Watershed > SEDCAD Structure Layout

Keyboard Command: sedcad

Prerequisite: Installed and licensed version of SEDCAD

SEDCAD Draw Flow Polylines

This command draws polylines in the SEDCAD layer that represent flow lines. When drawing a network of flow lines, first draw the main branch. Then begin drawing the other flow lines from the top of flow and use the Join option to connect onto the main branch. Draw Flow Polylines is the first command in a series that produce the Junction, Branch, and Structure labels for SEDCAD.

Prompts

End/Pick point: *pick a point*

Undo/End/Join/Pick point: *pick a point*

Undo/End/Join/Pick point: *pick a point*

Undo/End/Join/Pick point: *press Enter*

Draw another flow polyline (<Yes>/No)? *press Enter*

End/Pick point: *pick a point*

Undo/End/Join/Pick point: *pick a point*

Undo/End/Join/Pick point: *Join*

Select flow polyline at place to join: *pick the main branch at the junction*

Draw another flow polyline (<Yes>/No)? *No*

Pulldown Menu Location: Watershed > SEDCAD Structure Layout

Keyboard Command: sedcad1

Prerequisite: None

SEDCAD Locate Structures

This command is the second step for creating the SEDCAD layout. Locate Structures places triangle symbols on flow polylines that represents structures for SEDCAD.

Prompts

Symbol size <4.0>: *press Enter*

Pick location on flow polyline for structure: *pick a point on a polyline*

Pick location on flow polyline for structure: *pick a point on a polyline*

Pulldown Menu Location: Watershed > SEDCAD Structure Layout

Keyboard Command: sedcad2

Prerequisite: flow polylines

SEDCAD Label Structure Layout

This command is the third and final step for creating the SEDCAD layout. Label Structure Layout draws text labels for the junctions, branches, and structures in the network. A junction, branch, and structure report is also generated. Flow polylines and structure symbols must be drawn before running this routine. This command uses the labeling rules as described in the SEDCAD manual.

Prompts

Symbol size <4.0>: *press Enter*

Junction offset tolerance <10.0>: *press Enter* Flow lines that meet the main branch within this distance of each other are considered the same junction.

Select flow polylines and structure symbols.

Select objects: *pick the polylines and symbols*

Prerequisite: flow polylines and structure symbols

HEC-RAS Manager

Hydrologic Engineering Center's (CEIWR-HEC) River Analysis System, also known as HEC-RAS is a computer program developed by the US Army Corps of Engineers to perform one-dimensional steady flow, one and two-dimensional unsteady flow calculations, sediment transport/mobile bed computations, and water temperature/water quality modeling for major rivers and streams. Although the software has many features for modeling natural and man made channels, it does not have a CAD platform that enables automated channel geometry input. HEC-RAS Manager works with HEC-RAS to provide that additional functionality.

HEC-RAS Manager interfaces directly with HEC-RAS to provide needed surface, reach and cross-section alignments needed by HEC-RAS to perform hydraulic calculations. The advantage of this method is final results are calculated entirely by HEC-RAS so that there are no compatibility issues when submitting flood studies as part of FEMA's Flood Insurance Program. Although HEC-RAS is capable of performing unsteady state, 2 dimensional analysis, the Manager was designed for Steady State, one dimensional studies which is the most common application of the software. The latest version of HEC-RAS software can be obtained from Hydrologic Engineering Center <http://www.hec.usace.army.mil/software/hec-ras/>.

However, the Manager cannot support the most current version of HEC-RAS. It is recommended that version 6.0 be obtained from the Corps Github page.

<https://github.com/HydrologicEngineeringCenter/hec-downloads/releases>

HEC-RAS projects require a surface (tin), a Reach Alignment file (mxs) and a Reach Section file (xsct) in order to produce cross section geometry used by HEC-RAS. Additionally, left and right bank location at each cross section can be determined from one of the following options.

1. Left and Right Bank are calculated by specifying the percentage of flow that occurs in the center of the channel.
2. Left and Right Bank are specified within the section file as point descriptions.
3. Left and Right Bank are determined by polylines that represent left and right bank.

to create or edit the .mxs Reach Alignment file.

To create cross sections for HEC-RAS, the following items are needed.

1. A tin file representing terrain within the study area.
2. A polyline representing the center of channel/stream, drawn from downstream to upstream.
3. If applicable, two polylines representing right and left bank of the channel/stream.

Using these items, create a Reach alignment file(.mxs) with the stream centerline and create a Reach Section file to establish cross section width, spacing and station spacing. The stream centerline file is used to create the section alignment using the command **editmxs** and cross sections are created using the command **setgrid**. For additional information on creating these files, see the chapter on creating Road Sections in the Help files for the CIVIL module.

Select the "Create/Update Project" and specify the .MXS and .XSCT created in the previous step. Specify Steady State Flow Rates, set left, channel and right bank Mannings values and name the River and Reach Name.

Next specify the Upstream and Downstream Boundary Condition type. These values are used to estimate flow condition both upstream and downstream of the Study Area. The following are typical boundary condition methods and their use.

1. **None.** Note that None is only a place holder and will not result in a functioning model.
2. **Known Water Surface.** This is the most common Upstream/Downstream method when performing analysis on an existing Studied area. A good strategy in this situation is to start and end your study area using an Existing FEMA Cross Section and known water surface elevation.
3. **Normal Depth.** Normal Depth should only be used as a downstream boundary condition for an open ended Reach. Depending on conditions, either provide the slope of the channel or friction slope just downstream of the study area.
4. **Critical Depth.** Critical Depth should be used when there is instability in the model and can be used as an upstream or downstream condition.
5. **Rating Curve.** Rating Curves represent stage/discharge table values and are not often used for Steady State studies. Use this method when upstream or downstream stage/discharge is non linear.

In all cases, locate the starting and ending cross section far enough away from the area of study to reduce error in the model.

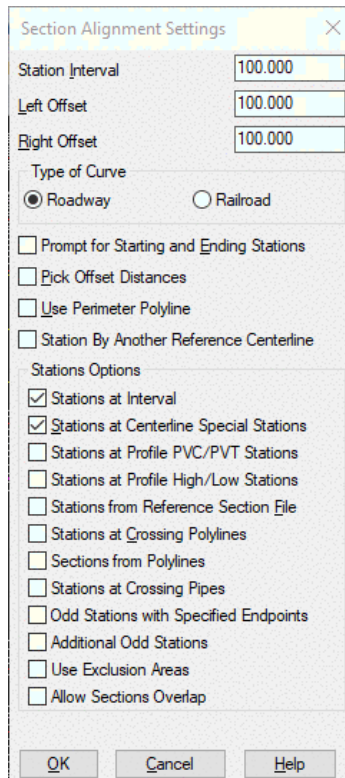

Example HEC-RAS Flood Study

The following must be obtained prior to performing HEC-RAS model calculations.

1. Tin File Digital Terrain Model representing elevation data within the area of study.
2. Centerline polyline representing the centerline of the stream/channel.
3. Reach Alignment file, .mxr, representing stream centerline and station locations. Use the command "EDITMXS" to specify the center line alignment and Cross Section spacing.
4. Reach Section File created using the command "SCTGRID". Use the alignment file created in step 3.
5. Determine left, center and right Mannings Runoff Coefficient for channel. If an existing flood study is available, use the n values used in that study if conditions match.
6. Polylines representing Left and Right Bank, drawn in the same direction as the Reach.
7. Upstream/Downstream Boundary Condition Method and Values.
8. Channel Discharge Rate(s) by Station. For FEMA Limited and Detailed Studies, flow rate will be located within the County's FIS Report. For Existing Non-FEMA Flood Models, use discharge rates within the model under Steady State Conditions. For Unstudied Areas with large drainage areas, USGS Regression Equations can be used once drainage area is determined. For Small Drainage Areas, calculate design flow using the Rational or Curve Number Methods.

Channel Geometry Modeling

With the Section Alignment File, issue the command **sectgrid** and specify the correct .tin and .mxs files to create the .xsct Reach Section file. Also specify Station Interval, Left and Right Offset Distance and select OK. Use the command **scto3dp** to draw the Reach Section file. Remove any cross sections that do not represent the entire channel cross section.

Input-Edit Section Alignment

HEC-RAS Model Creation

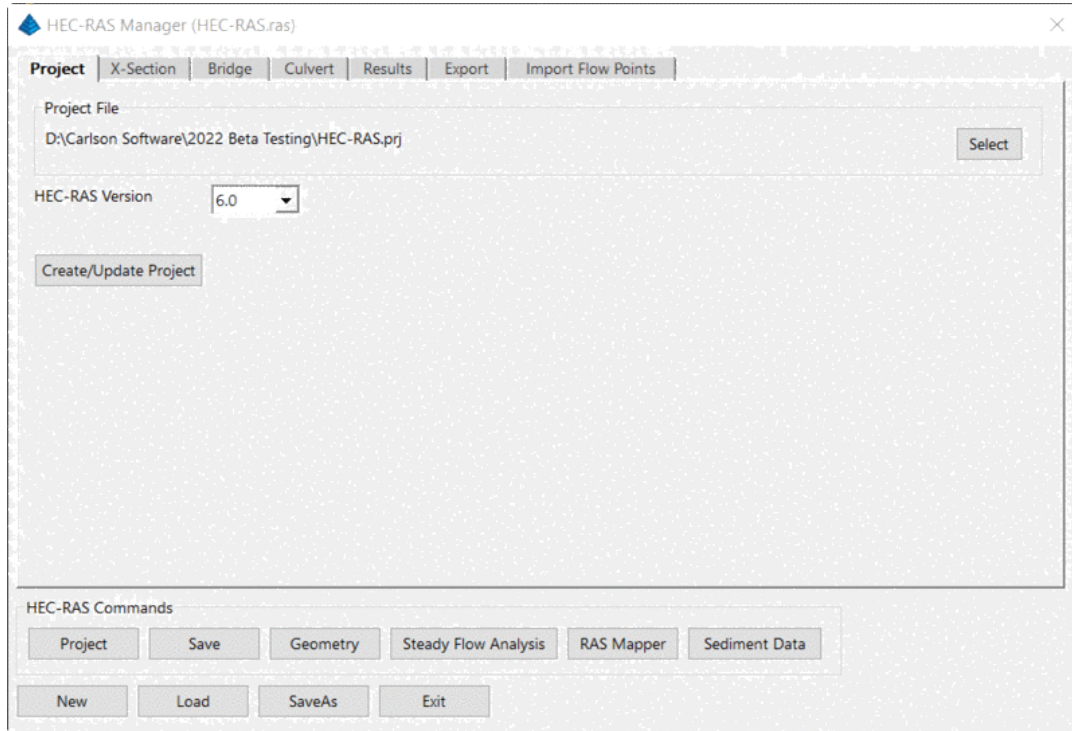

To start the HEC-RAS Manager, run the command **hecrcas** which may be typed in the Command Ribbon or found

in the Hydrology module, Watershed dropdown, HEC-RAS Surface Model, HEC-RAS Manager.

Specify a Project File Name. Please note that HEC-RAS project files use the same file extension as projection files for shape files.(.prj)

Specify the version of HEC-RAS installed on your system. Please note that you may be required to uninstall the latest version of HEC-RAS if it is a later version than 6.0. Currently, version 6.0 is the newest version of HEC-RAS that will work with this tool. This version is available at <https://github.com/HydrologicEngineeringCenter/hecdownloads/releases>

Select the **Create/Update Project** button to update an existing project or to create a new one. When clicked the Create HEC-RAS Project dialog appears. Use the Set buttons to assign the Reach Alignment file, the Reach Section file and the HEC-RAS project name. Fill in the River Name and the Reach Name. Use the Set buttons to assign the Manning's friction coefficient (n) to the banks and bottom of the channel. Choose the Bank Position Method, which determines where the bank is located. Choices are Percentage of Width, Section Description or Bank Polylines. If one or more Steady State Flows need to be included, click the Add button below the box and add Station and Flow. Once added, you may edit or delete these by highlighting the flow and clicking the appropriate button below.

Assign Boundary Conditions

Select the Upstream and Downstream Boundary Condition method and assign values. The following are the available Boundary Conditions and their typical application.

None represents a place holder for one of the following Boundary Conditions. Using "None" as a boundary condition will cause an error. .

Known Depth is the best boundary condition to use when trying to duplicate an existing FEMA Flood Study or when depth of flow is known by other means.

Critical Depth occurs when flow in a channel has a minimum specific energy and a Froude number of 1. It represents the inflection point between super and sub-critical flow. Critical Depth is a good boundary condition for the following.

1. The supercritical flow regime has been specified.
2. The calculation of critical depth has been requested by the user.
3. This is an external boundary cross section and critical depth must be determined to ensure the user entered boundary condition is in the correct flow regime.
4. The Froude number check for a subcritical profile indicates that critical depth needs to be determined to verify the flow regime associated with the balanced elevation.
5. The program could not balance the energy equation within the specified tolerance before reaching the maximum number of iterations.

For additional information on using Critical Depth for Boundary Conditions, see HEC-RAS documentation.

Normal Depth is the depth of flow in a channel when the slope of the water surface and channel bottom is the same and the water depth remains constant along the Reach. Normal depth occurs when gravitational force of the water is equal to the friction drag along the channel and there is no acceleration of flow. Normal depth is only used as a downstream boundary condition for an open ended reach. To use the Normal Depth Option, the slope of the

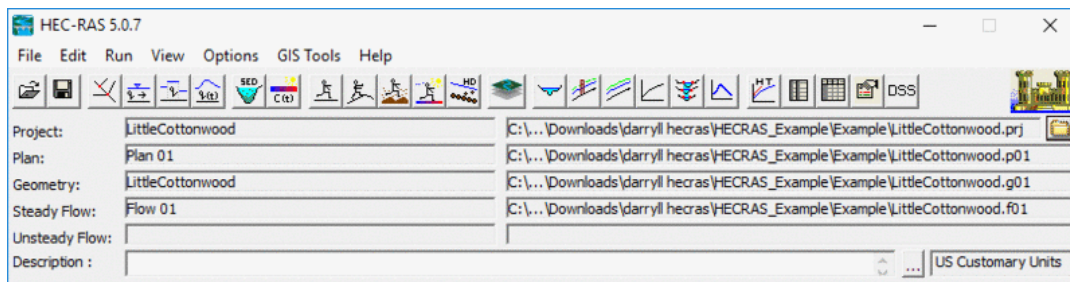

energy grade line must be entered and can be assumed to be the slope of the water surface near the end of the Reach. Another good value to use is the slope of the channel near the downstream boundary. It is recommended that if this option is used the most downstream section of the reach should be beyond the area of study. A good rule of thumb is to have at least two cross sections below the study area to minimize any error in the estimated slope.

Rating Curve option assigns a stage-discharge relationship either at the beginning or end of the study area. An example of when a downstream Rating Curve can be used is when the outfall of the system is a detention pond or other structure where stage-discharge cannot be determined by channel geometry. For upstream conditions, a common rating curve represents calculated depths of upstream flow for each storm event such as the 50 and 100 year event storm events. By using a rating curve, upstream boundary flow condition will adjust according to discharge rate.

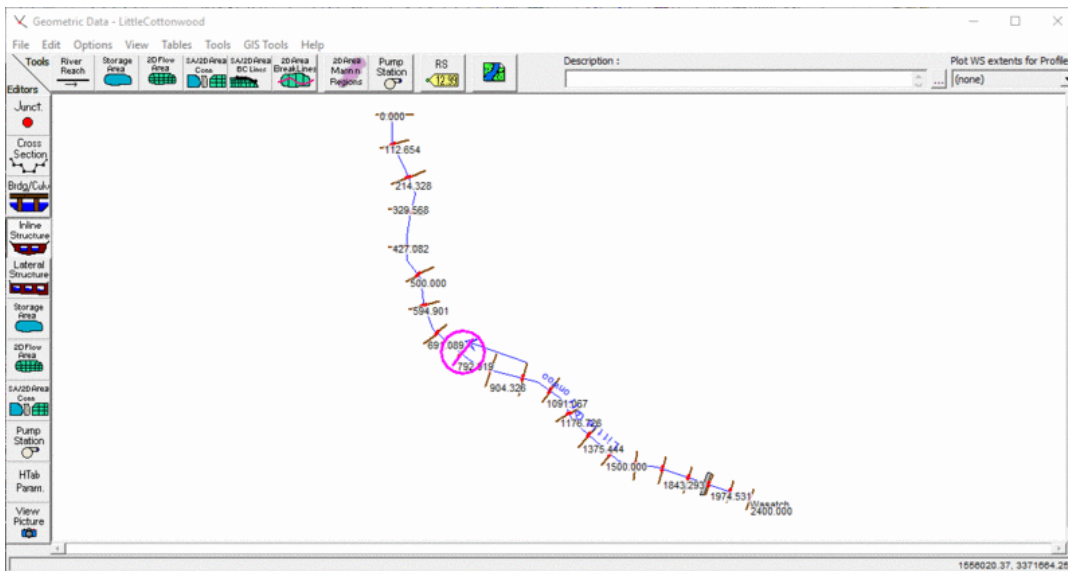

Export HEC-RAS Model

Select the Export Button which will create the minimum inputs needed to create a HEC-RAS project. The HEC-RAS project file .prj, plan file .p01, geometry file .g01 and a steady flow .f01 files are created. These are the minimum files needed for a HEC-RAS project. The user is returned to the HEC-RAS Project Manager dialog after the Export.

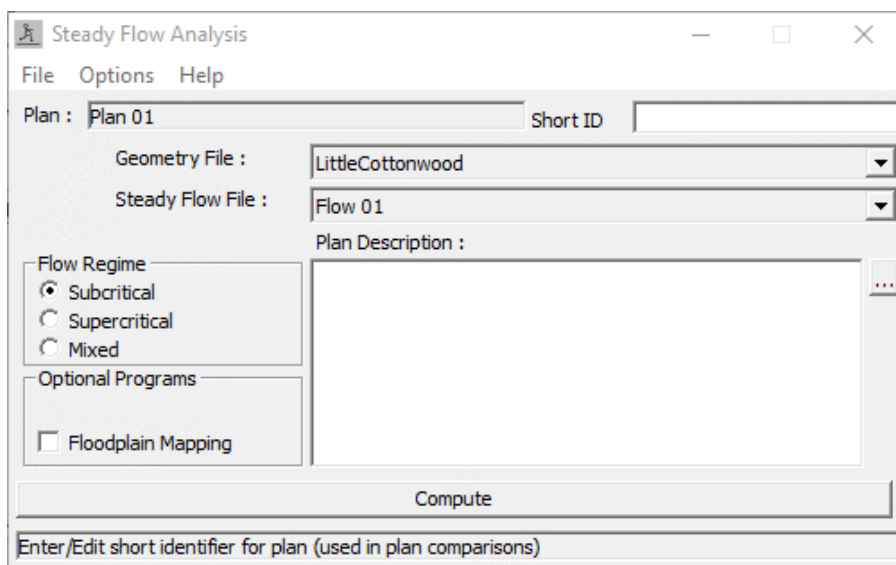

Selecting the **Project** button calls the main HEC-RAS project screen, allowing for viewing, editing and calculation of the Model.

Selecting the **Geometry** button calls the HEC-RAS Geometric Data dialog, with tools and editors to add complexity to the reach.

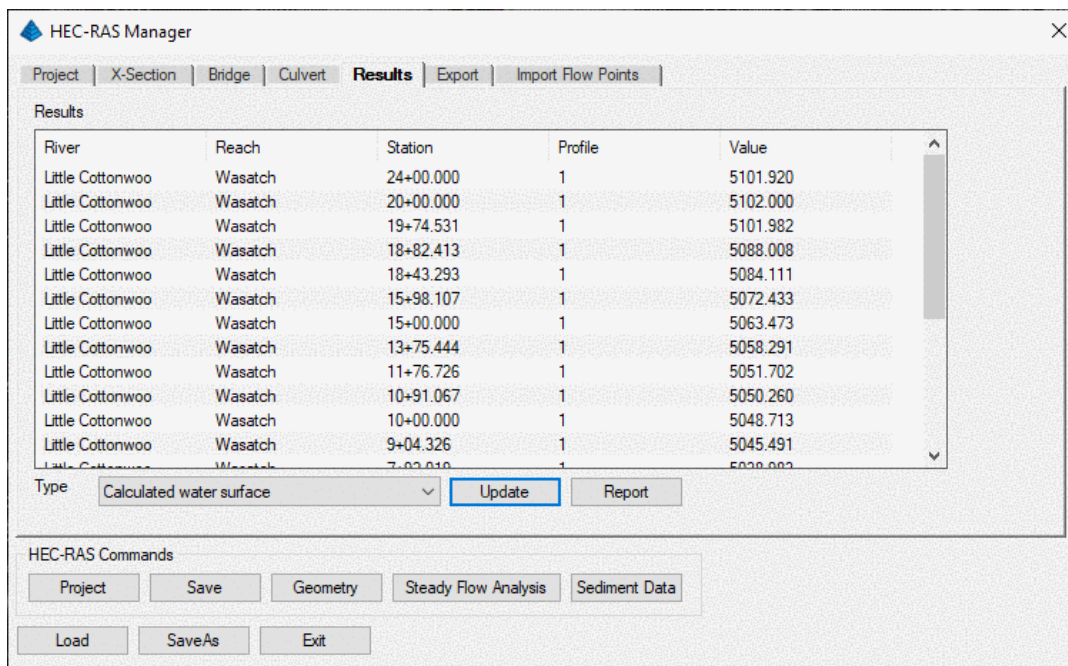

Selecting the **Steady Flow Analysis** button calls the HEC-RAS Steady Flow Analysis dialog. Select the type of Flow Regime to model and check the Floodplain Mapping option if needed. Click the **Compute** button to analyze the model.

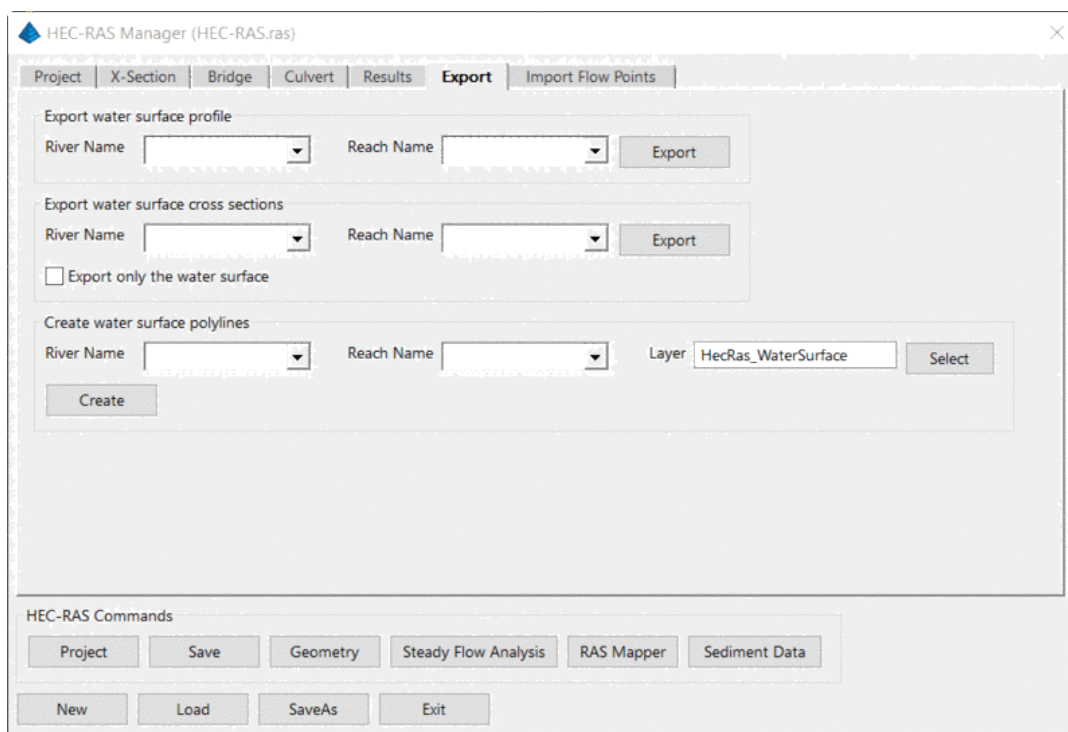

Once the computations are completed, the HEC-RAS Finished Computations dialog is displayed or errors are listed.

Viewing Results In addition to the reports available from HEC-RAS, the HEC-RAS Manager can produce tables representing the following results.

To view Results such as the Calculated water surface for each cross section, select this option for the type of results and select the Update button to show water surface elevations for each cross section. To create a report, select the Report Button. Make sure that the current model has been calculated before creating Reports.

Export Options

Export water surface profile.

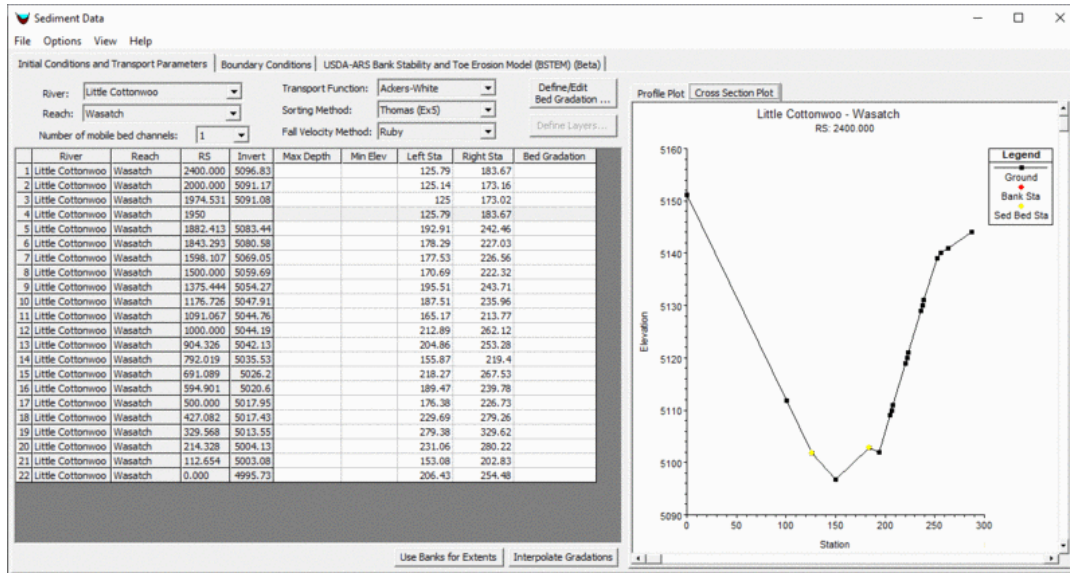

This option will export the water surface profile for the selected River/Reach. A profile file(.pro) will be created

which can be used to plot Station/WSELV using Carlson's Draw Profile Copmmand. **Export water surface cross sections.**

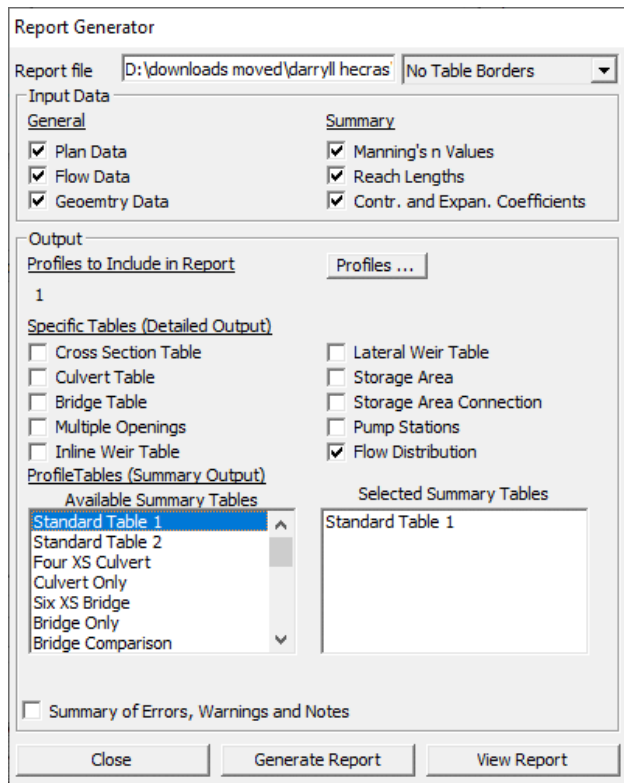

This option will export the water surface in cross section view for the selected River/Reach. A cross section file (.xsct) will be created which can be drawn using the command **drawxsct**. **Create water surface polylines.**

This option will create polylines representing the left and right edge of flood inudation. These polylines will be drawn in the current cad file.

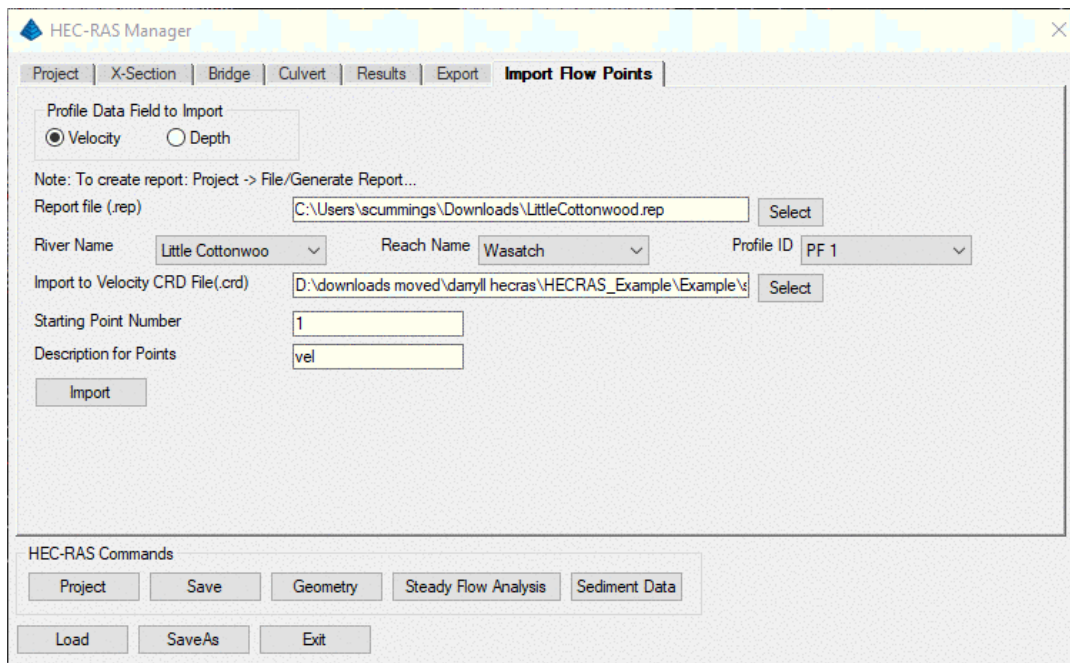

Advanced Options In addition to Hydraulic Modeling, HEC-RAS is capable of performing sediment transport operations as shown below. Please see HEC-RAS documentation for additional details.

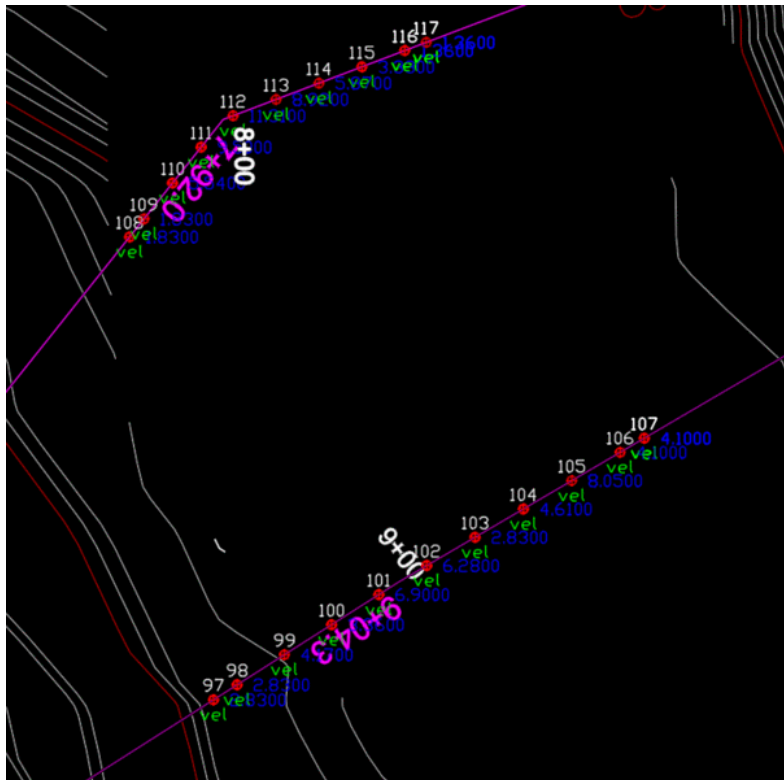

The HEC-RAS **Export Flow Points** Command is used to Export flow or velocity points from the HEC-RAS geometric model to a Carlson CRD file for use in the drawing. To prepare, select the Project tab, then select "Generate Report" found under the HEC_RAS project File dropdown. Set the report up as shown below, naming the file, choosing Profiles and clicking the "Generate Report" button.

Importing Flow Points to HEC-RAS Manager Select the **Import Flow Points** Tab and specify import Velocity or Depth. Select the previously generated Report file just generated. The River Name, Reach Name and Profile ID should appear in the dropdowns. Pick the River, Reach and Profile you want to extract. Select the filename and location of the CRD file that will contain the flow points. Starting Point Number and a Description for Points. Click the "Import" button to write the points into the drawing's CRD file. **Draw-Locate Points.**

Pulldown Menu Location: Watershed
Keyboard Command: HECRAS
Prerequisite: HEC-RAS v. 6.0.0 or newer

Prepare HEC-RAS Input File

HEC-RAS is designed to perform one-dimensional hydraulic calculations for a full network of natural and constructed channels. It could be considered to be an advanced Windows-based version of the HEC-2 program. This program makes it easier for CADD and GIS systems to import their data directly for river network analysis. It is also very convenient because the output from the program can be exported directly to CADD programs where this data can be used to create water surface models for inundation mapping. The software is free and can be downloaded from <http://www.hec.usace.army.mil/software/hec-ras/>.

In the program of Prepare HEC-RAS Input File, every channel is defined by a cross-section file (with or without multiple skews) and a MXS file (please see the material on Sections in Chapter 6 of this manual). This program reads cross-section files and the corresponding MXS files, and then creates a HEC-RAS geometry data file.

Data Format

HEC-RAS input files consist of three data sections:

- * A header, containing data relevant to all sections of the data in the file.
- * A description of the stream network, containing reach locations and connectivity.
- * A description of the model cross-sections, containing cross-section location and geometric data as well as additional HEC-RAS modeling information.

The header information is mainly for the purpose of identifying the project and is mostly not used by the program. The only important information needed by the program is the "Units" section and the value must be "ENGLISH" or "METRIC".

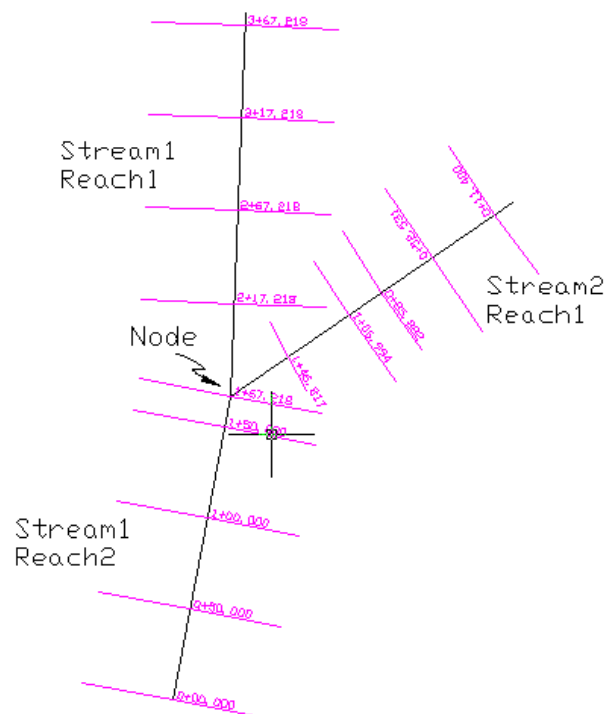

The network is modeled as a set of interconnected streams. Each stream is a set of interconnected reaches. Each reach, hence, **MUST** have a unique Stream ID and Reach ID.

The Stream Network section contains a series of Point Numbers and the corresponding coordinates. In addition, this section has information pertaining to each Reach. For each Reach, the following information is provided:

- * Stream ID and Reach ID. These are 16 character alphanumeric strings. Together these two items uniquely identify a Reach.
- * Starting (FROM or upstream) point and ending (TO or downstream) point of the Reach. The FROM point and TO point here are given by their Point Numbers, as identified above.
- * The coordinates on the Centerline of the Reach, starting with the FROM point coordinates and ending with the TO point coordinates.

The Cross-Sections portion of the input file contains data describing the geometric properties at each cross section in the network. The following information is provided at each Cross-Section:

- * Stream and Reach ID, to identify which Reach the Cross-Section is on.
- * Station, position of the Cross-Section, relative to the Stream. The Station is taken as the distance from the current station to the end of the stream. For this purpose, the stream **MUST** be drawn Downstream to Upstream. **THIS IS THE MOST FUNDAMENTAL REQUIREMENT OF THE PROGRAM.** If the Stream is drawn in the other direction, then, it must be reversed using the command *Reverse Polyline* under *Edit>Polyline Utilities*
- * Cut Line: Series of point coordinates, identifying the surface line of the Cross-Section. HEC-RAS identifies the cross-sections as going from left to right as seen from upstream to downstream. The user only needs to make sure that the stream network is drawn in the right direction (downstream to upstream); all other conventions are taken care of by the program.

Modeling Guidelines

Some additional guidelines in drawing the river network in the CAD so as to model correctly for HEC-RAS:

* All the Reaches in the Stream Network must be connected at common End Points; disjointed Stream Networks are not allowed; Reaches must also NOT cross each other.

* Streams cannot contain parallel flow lines. If three reaches connect at a node or End Point, at the most TWO of them can have a common Stream ID. (Please note that a Reach is uniquely identified by a Reach ID and a Stream ID.)

* Cross-Section lines can cross a Reach line only once and cannot cross other cross section lines.

Program Execution

Before starting the "Prepare HEC-RAS Input File" command, all the SCTfiles and their corresponding MXS files should have been created for every Reach. Points where two streams meet would form a node in the stream network. Sections of a stream between such nodes should be modeled as a Reach. and drawn as a separate polyline. Now, change to the Civil Design Menu. The MXS file for each Reach is created using the command *Input Edit Section Alignment* under the *Sections* pulldown menu. Based on any of the methods for creating section files (described in chapter 6 of this manual), the Section file for the Reach is created. The user must manage the .MXS file and the .SCT file corresponding to each Reach. At this point, a Stream ID and Reach ID may be assigned to every Reach, based on a convenient naming convention, which is entirely up to the user. These IDs would be needed when creating the HEC-RAS input file.

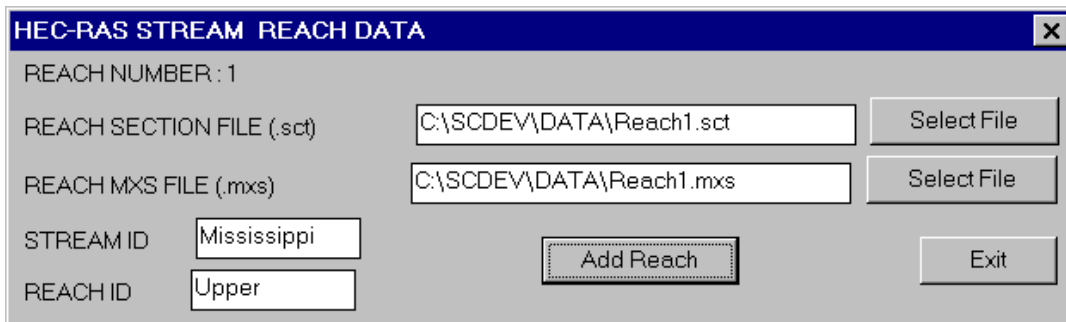

The program starts by asking the user for the Header information. The user can input as much information in this dialog box as possible. The "Units" can be "Metric" or "English".

The screenshot shows the "HEC-RAS Header Information" dialog box. It features a title bar with a close button (X). The main area contains several configuration options:

- Units:** Two radio buttons are present. "English" is selected, and "Metric" is unselected.
- DTM Type (TIN, Raster etc.):** A dropdown menu is set to "Raster".
- Stream Layer:** A dropdown menu is set to "Stream".
- Cross-Section Layer:** A dropdown menu is set to "Xsect".
- Map Projection:** A dropdown menu is set to "StatePlan".
- Datum:** A dropdown menu is set to "NAD27".
- DTM Name:** A text input field contains the text "Mississip".
- Number of Reaches:** A text input field contains the number "3".
- Number of Cross-Sections:** A text input field contains the number "20".
- Projection Zone:** A text input field contains the number "5101".
- Vertical Datum:** A dropdown menu is set to "NAD27".

At the bottom of the dialog, there are two buttons: "OK" and "Cancel".

Next, the user will be prompted to enter the .MXS and .SCT file names, the Stream ID and Reach ID for each Reach that you wish to add to your model. The user can enter data (IDs and file names) for as many Reaches as wished. That is, the user can create input files for each Reach individually and import them individually into HEC-RAS or create a combined input file for all the Reaches in the Stream Network. This makes it very convenient to add more Reaches to the HEC-RAS model at a later stage or do the analysis for various sections separately. After entering as many Reaches as needed, the user presses "Exit" to stop entering any further Reaches and to continue with the program execution.

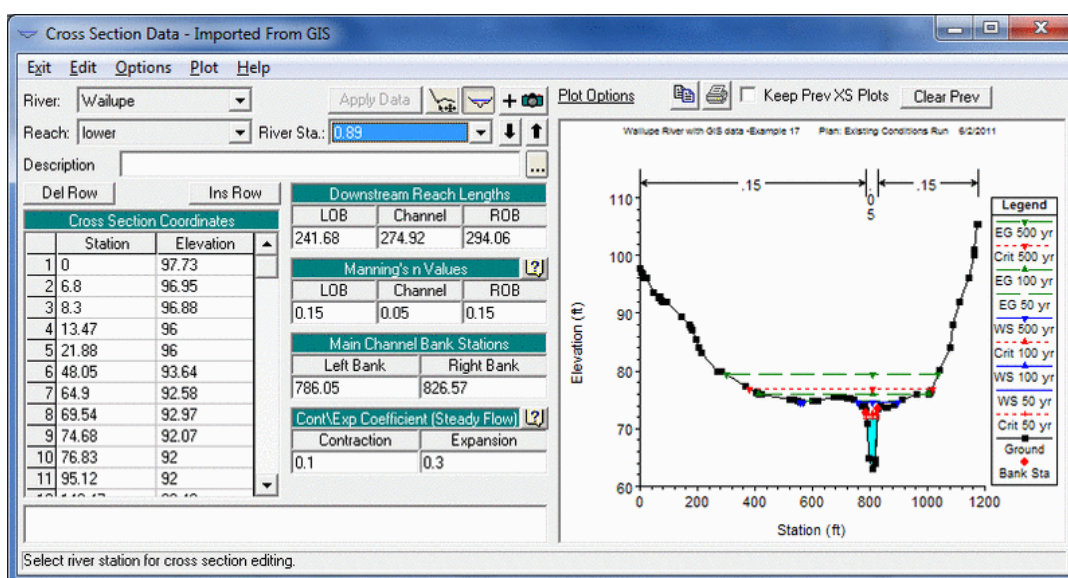

On pressing "Exit", the user is prompted for the Input HEC-RAS file to be created. HEC-RAS input files have a .GEO extension. When the file is chosen at the prompt, the program creates the input file for HEC-RAS. This file can be used to import geometric data into HEC-RAS, as described below. You must have HEC-RAS version 2.0 or higher installed on your computer.

HEC-RAS

After starting HEC-RAS, select "Geometric Data" from under the "Edit" pulldown menu to open the Geometric data editor, which has a CAD screen and various options. From the "File" pulldown menu on the Geometric data editor, run "Import Geometric Data -> GIS Format" command and select the .GEO file just created. This loads the geometric data into HEC-RAS and displays it in the form of a Stream network, with EndPoint, Stream ID and Reach IDs, Cross Sections stationing information, along with directions of in each Reach.

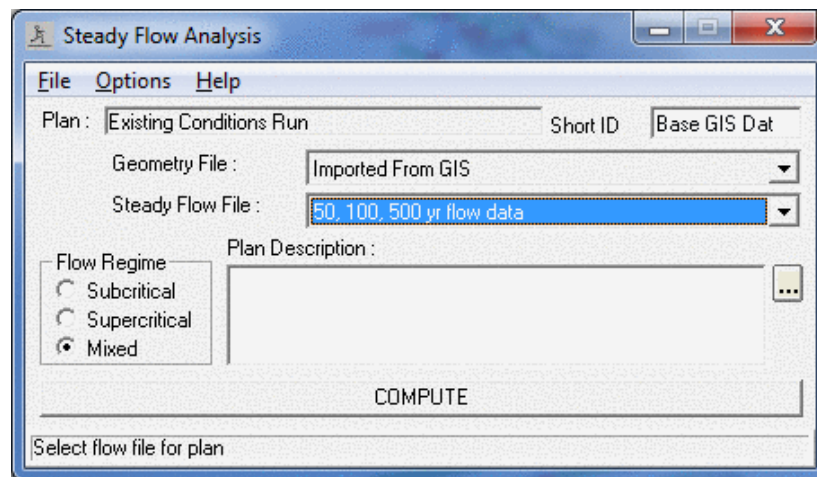

Since Carlson only provides default values, the cross section data should be checked next. For example the manning's n, left over bank and right over bank position, and the lengths of the left and right over banks. By default, the left bank is given to be at 0.45 times the cross-section length and the right bank is given to be at 0.55 times the cross-section length. In order to correctly model the channel geometry, the location of the banks must be accurately defined for each cross-section. The left and right over bank lengths are defaulted to the centerline length (which may not be equal in the case of a sharp bend in the stream).

Geometric data can be stored by running "Save Geometric Data" from the "Geometric Data Editor". The file extension assigned for Geometric data files is *.g*, which means that successive geometric data files will be given file extensions in a numeric sequence, beginning with *.g01.

Flow data can be entered in the "Steady Flow Data Editor", which can be brought up by selecting "Steady Flow Data" from the Edit pulldown menu of the main HEC-RAS window. The data that can be selected here are the number of profiles that need to be run, flow in each reach for each profile simulation and the Hydraulic boundary conditions at each Reach for each Profile simulation. This information is stored in a file with the extension *.f01 and so on for successive files.

Once all the geometric data and flow data is entered, run command "Run->Steady Flow Analysis". After selecting the type of flow condition (sub-critical, super-critical or mixed), the user selects the "Compute" button to complete the analysis. If there are errors or serious warnings, the program reports them in a text editor. Otherwise, the program shells out to a DOS screen and completes all the necessary calculations. Several options are available for viewing and editing output from the HEC-RAS program, which are best explained in its manual.

Pulldown Menu Location: Watershed->HEC-Ras Water Surface Model

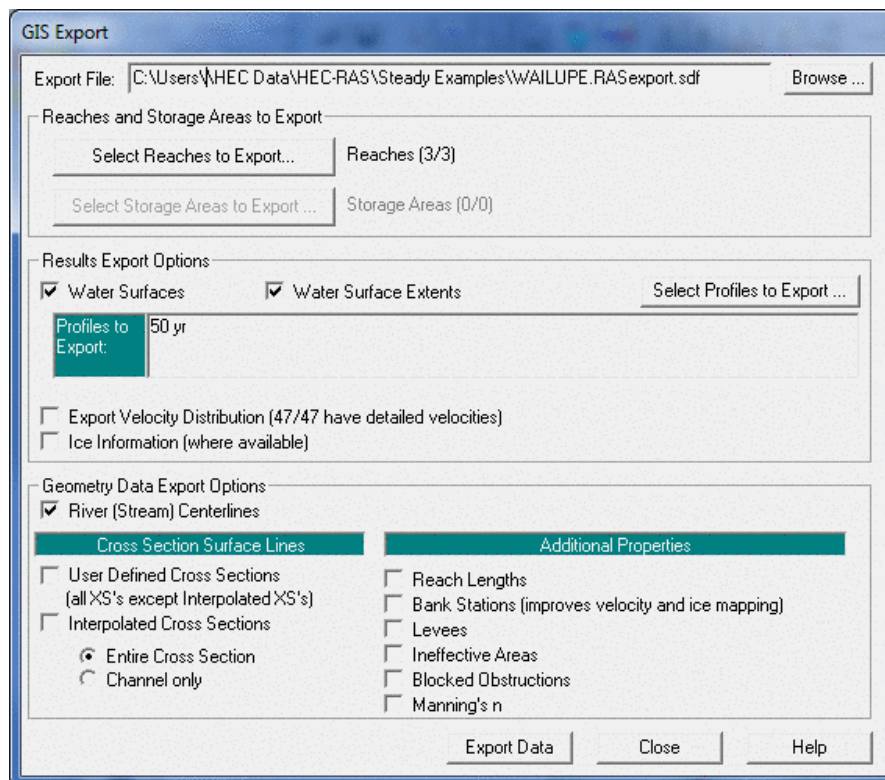

Keyboard Command: sct2ras

Prerequisite: Section data (.sct)

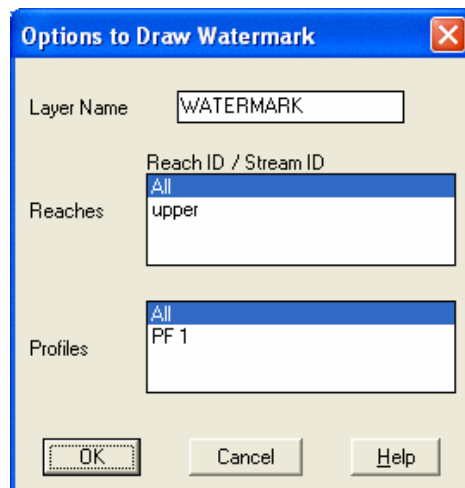

Draw Hec-Ras Watermark

HEC-RAS Watermark represents the boundary around a stream or channel model that is the extents of flooding for a given Storm Frequency Event. This boundary is more commonly referred to as the Flood Hazard Area in FEMA documentation. This command uses an existing HEC-RAS "SDF" file to transfer data from the flood model to a format that can be imported into CAD.

Please note that the flood hazard area can also be created using Carlson's HEC-RAS Manager, but if the Flood Study is completed or has been provided by an outside source, this command will map the Flood Hazard Area from an existing Flood Study without having to perform additional calculations. To export the information needed to map a model's watermark, an SDF file is needed which may come with the model package or can be created by opening the model in HEC-RAS and exporting an SDF file. If an SDF file has not been created by HEC-RAS for a completed study, it can be created using HEC-RAS. To create a SDF file in HEC-RAS, run command File->Export GIS Data to save the data needed to map the Flood Hazard Area. Below is the GIS Export dialog. Make sure to select the option "Water Surface Extents", otherwise the watermark data is not saved.

After loading the .SDF file, a dialog window prompts for the reaches and profiles that you would like to draw the watermark.

Shown next is an example HEC-RAS watermark plot based on a run of HEC-RAS using the file Hydrolesson.dwg, and using an input flow rate of 20,000 cfs, a Manning's n of 0.013 for the left and right bank conditions, and with the boundary condition set to critical depth:

Please note that this method only uses geometry at each cross section to determine watermark location. In between Stations, the location of the watermark boundary is interpolated. If additional precision is needed, additional cross sections must be added to the model.

Existing HEC-RAS models that do not have a SDF file included in their distribution must be reprocessed by HEC-RAS to create this file. This is common when obtaining existing flood studies that were performed prior to HEC-RAS having the ability to export an SDF file. When available, please compare the resulting Watermark delineation to existing published maps such as those provided by FEMA.

Pulldown Menu Location: Watershed->HEC-RAS Water Surface Model

Keyboard Command: drawras

Prerequisite: Prepare HEC-RAS Input File, and the program, HEC-RAS or programs that duplicate the output of HEC-RAS

Import Flow Velocity Points

This function extracts the flow velocity distribution from the HEC-RAS output report file (.REP). The velocity points are extracted at every cross section along the river channel. All points are imported to a Carlson coordinate file (.CRD) and can be plotted in a TIN.

Running HEC-RAS

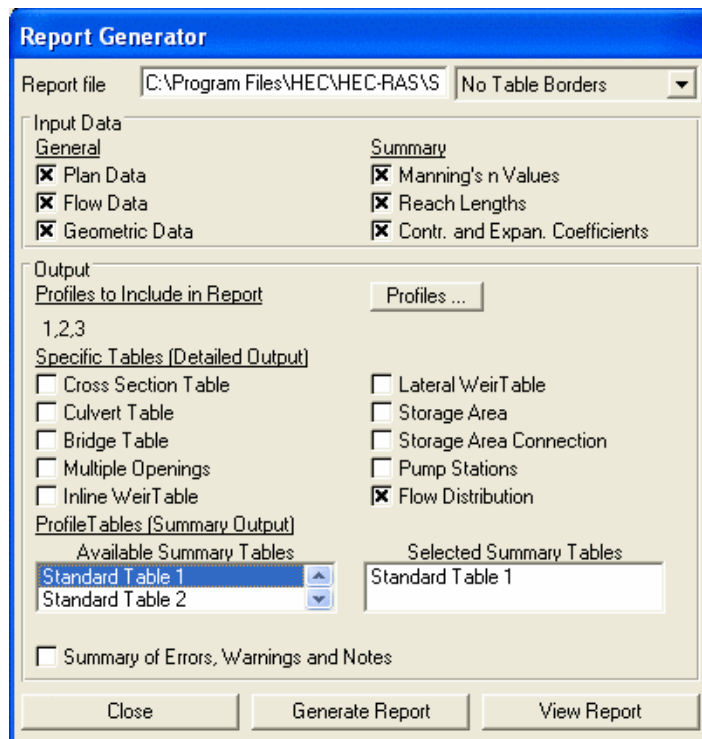

In order to get the flow velocity at all cross sections, some guide lines in running HEC-RAS are provided as below.

1. From the Watershed > HEC-RAS Water Surface Model menu in the Hydrology Module, choose Prepare HEC-RAS Input File command to make a HEC-RAS geometry file (.GEO), which contains the cross section data of one or more reaches. Then in HEC-RAS, in Geometric Data dialog, select Import Geometry Data of GIS format from File menu and load the .GEO file.
2. When running Steady/Unsteady Flow Analysis, in the Steady/Unsteady Analysis dialog, choose Flow Distribution Locations command from the Options menu. This command allows you to subdivide the left bank, channel and right bank. Specify as many subsections as needed. You can define up to 45 subsections.

HEC-RAS: Flow Distribution Dialog

3. After finishing the flow analysis, select Generate Report command from File menu to display the Report Generator dialog. In the Output field, make sure to check the Flow Distribution check box and set the Summary Tables to Standard Table 1.

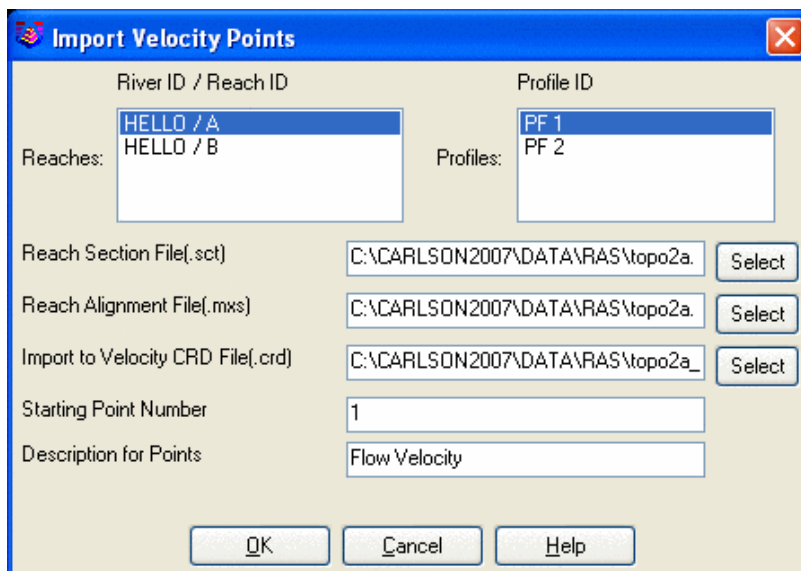

HEC-RAS: Report Generator Dialog

Importing Velocity Points

Select Import Flow Velocity Points from Watershed > HEC-RAS Water Surface Model menu. This command takes the HEC-RAS output file (.REP) and displays the Reaches list and Profiles list in the Import Hydraulic Depth Points dialog. In the Reach Section and Alignment File boxes, type or select a section file(.SCT) and the corresponding section alignment file (.MXS) that have been used to generate HEC-RAS input file (.GEO). In the Import to Flow Velocity CRD File box, type or select a CRD file. In the Starting Point Number box, enter the starting point number, the default number is 1. In the Reach and Profile lists, choose the reach and profile that you want to output, and then

click OK button to extract the flow velocity distributions and write data to the .CRD file.

Import Hydraulic Velocity Points Dialog

Prompts

Import Flow Velocity Points dialog: Fill in values.

Pulldown Menu Location: Watershed > HEC - RAS Water Surface Model > Import Flow Velocity Points

Keyboard Command: crdrasvt

Prerequisite: HEC-RAS output report file (.REP) and the corresponding section file (.SCT) and section alignment file (.MXS)

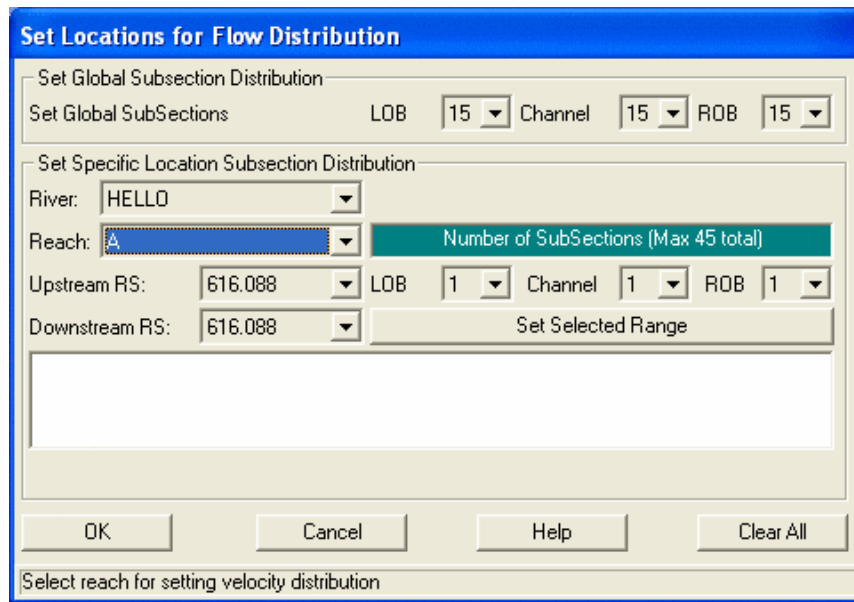

Import Flow Depth Points

This function extracts the flow depth distribution from the HEC-RAS output report file (.REP). The depth points are extracted at every cross section along the river channel. All points are imported to a Carlson coordinate file (.CRD) and can be plotted in a TIN.

Running HEC-RAS

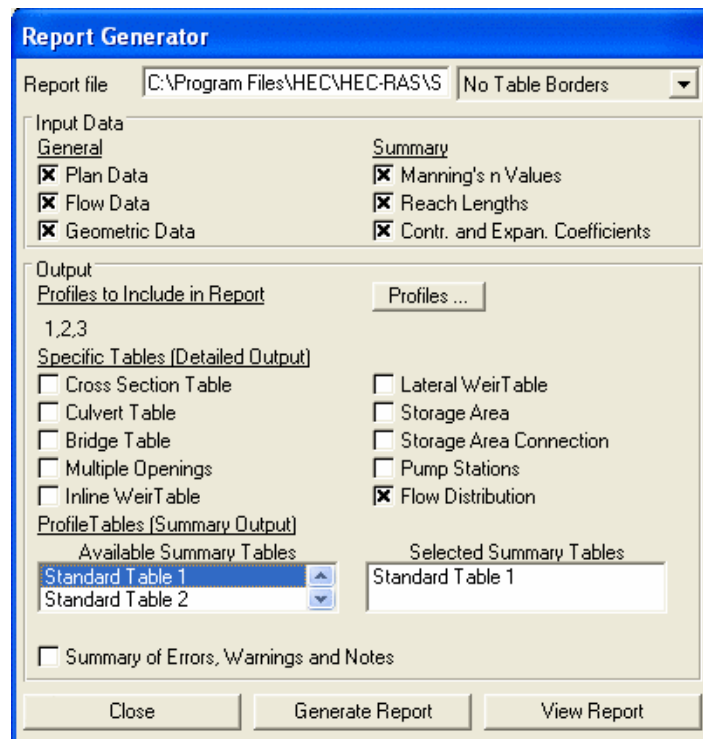

In order to get the flow depth at all cross sections, some guide lines in running HEC-RAS are provided as below.

1. From the Watershed > HEC-RAS Water Surface Model menu in the Hydrology Module, choose Prepare HEC-RAS Input File command to make a HEC-RAS geometry file (.GEO), which contains the cross section data of one or more reaches. Then in HEC-RAS, in Geometric Data dialog, select Import Geometry Data of GIS format from File menu and load the .GEO file.
2. When running Steady/Unsteady Flow Analysis, in the Steady/Unsteady Analysis dialog, choose Flow Distribution Locations command from the Options menu. This command allows you to subdivide the left bank, channel and right bank. Specify as many subsections as needed. You can define up to 45 subsections.

HEC-RAS: Flow Distribution Dialog

3. After finishing the flow analysis, select Generate Report command from File menu to display the Report Generator dialog. In the Output field, make sure to check the Flow Distribution check box and set the Summary Tables to Standard Table 1.

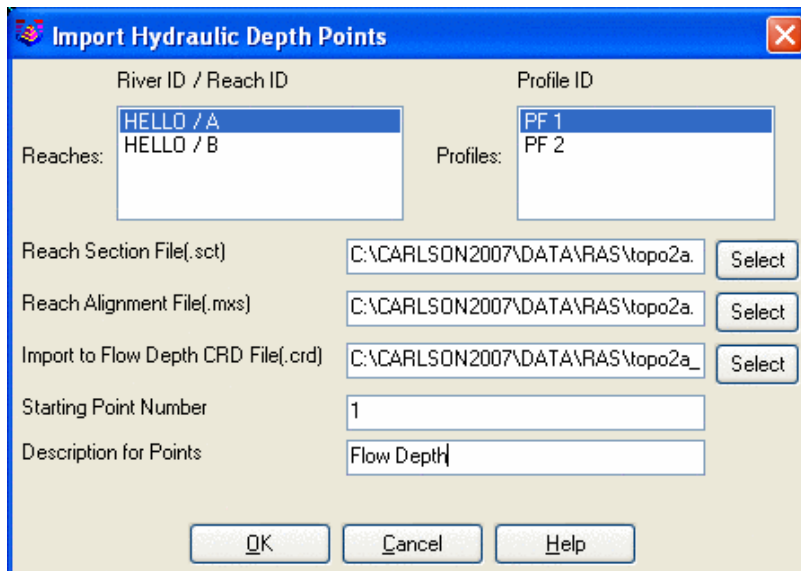

HEC-RAS: Report Generator Dialog

Importing Depth Points

Select Import Flow Depth Points from Watershed > HEC-RAS Water Surface Model menu. This command takes the HEC-RAS output file (.REP) and display the Reaches list and Profiles list in the Import Hydraulic Depth Points dialog. In the Reach Section and Alignment File boxes, type or select a section file(.SCT) and the corresponding section alignment file (.MXS) that have been used to generate HEC-RAS input file (.GEO). In the Import to Flow Depth CRD File box, type or select a CRD file. In the Starting Point Number box, enter the starting point number, the default number is 1. In the Reach and Profile lists, choose the reach and profile that you want to output, and then

click OK button to extract the flow depth distributions and write data to the .CRD file.

Import Hydraulic Depth Points Dialog

Prompts

Import Flow Depth Points dialog: Fill in values.

Pulldown Menu Location: Watershed > HEC - RAS Water Surface Model > Import Flow Depth Points

Keyboard Command: crdrasdt

Prerequisite: HEC-RAS output report file (.REP) and the corresponding section file (.SCT) and section alignment file (.MXS)

Channel Routing Hydrograph - Modified Att-Kin Method

This function extracts the flow depth distribution from the HEC-RAS output report file (.REP). The depth points are extracted at every cross section along the river channel. All points are imported to a Carlson coordinate file (.CRD) and can be plotted in a TIN.

Running HEC-RAS

In order to get the flow depth at all cross sections, some guide lines in running HEC-RAS are provided as below.

1. From the Watershed > HEC-RAS Water Surface Model menu in the Hydrology Module, choose Prepare HEC-RAS Input File command to make a HEC-RAS geometry file (.GEO), which contains the cross section data of one or more reaches. Then in HEC-RAS, in Geometric Data dialog, select Import Geometry Data of GIS format from File menu and load the .GEO file.
2. When running Steady/Unsteady Flow Analysis, in the Steady/Unsteady Analysis dialog, choose Flow Distribution Locations command from the Options menu. This command allows you to subdivide the left bank, channel and right bank. Specify as many subsections as needed. You can define up to 45 subsections.

HEC-RAS: Flow Distribution Dialog

3. After finishing the flow analysis, select Generate Report command from File menu to display the Report Generator dialog. In the Output field, make sure to check the Flow Distribution check box and set the Summary Tables to Standard Table 1.

Importing Depth Points

Select Import Flow Depth Points from Watershed > HEC-RAS Water Surface Model menu. This command takes the HEC-RAS output file (.REP) and display the Reaches list and Profiles list in the Import Hydraulic Depth Points dialog. In the Reach Section and Alignment File boxes, type or select a section file(.SCT) and the corresponding section alignment file (.MXS) that have been used to generate HEC-RAS input file (.GEO). In the Import to Flow Depth CRD File box, type or select a CRD file. In the Starting Point Number box, enter the starting point number, the default number is 1. In the Reach and Profile lists, choose the reach and profile that you want to output, and then click OK button to extract the flow depth distributions and write data to the .CRD file.

Import Hydraulic Depth Points Dialog

Prompts

Import Flow Depth Points dialog: Fill in values.

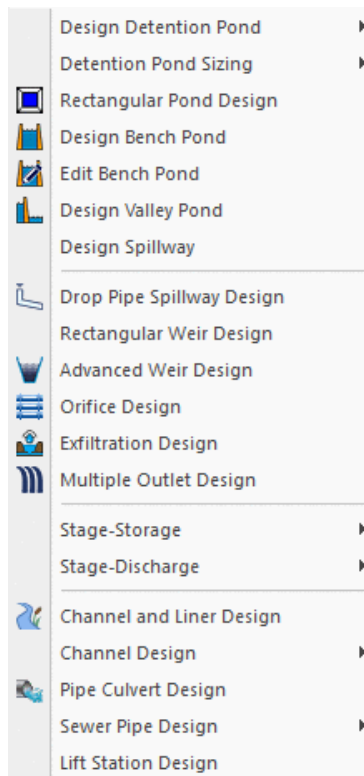

Pulldown Menu Location: Watershed > HEC - RAS Water Surface Model > Import Flow Depth Points

Structure Menu

Shown here is the Structure pulldown menu that contains commands for hydraulic structures including ponds, channels, pipes and outlets. The Design Bench Pond and Design Valley Pond commands are described in the Civil Design manual.

Design Detention Pond

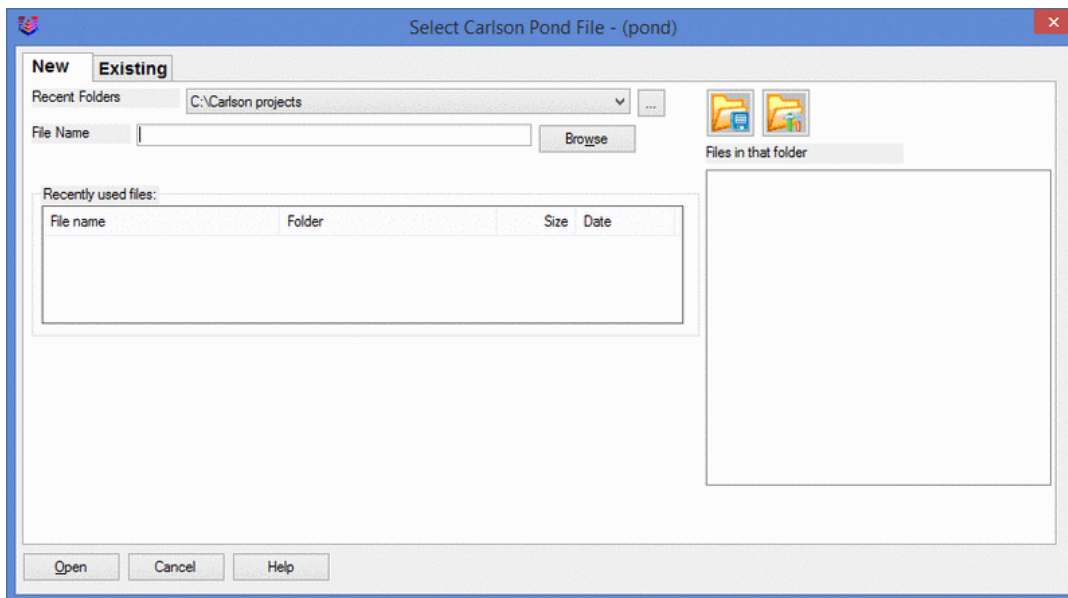

Design Detention Pond is a powerful stormwater model program that helps engineers analyze and design simple and complex watershed. This program lets you:

- Analyze pre- and post-developed watershed conditions and pond sizes;
- Analyze one watershed condition and pond sizes;

- Use any rainfall duration or distribution to compute hydrographs;
- Compute hydrographs for multiple events;

- Automate almost every aspect of drainage design computations;
- Build customized reports;

When you first run the command, the Select Carlson Pond File dialog box opens. You can start a completely new pond project or open an existing pond project.

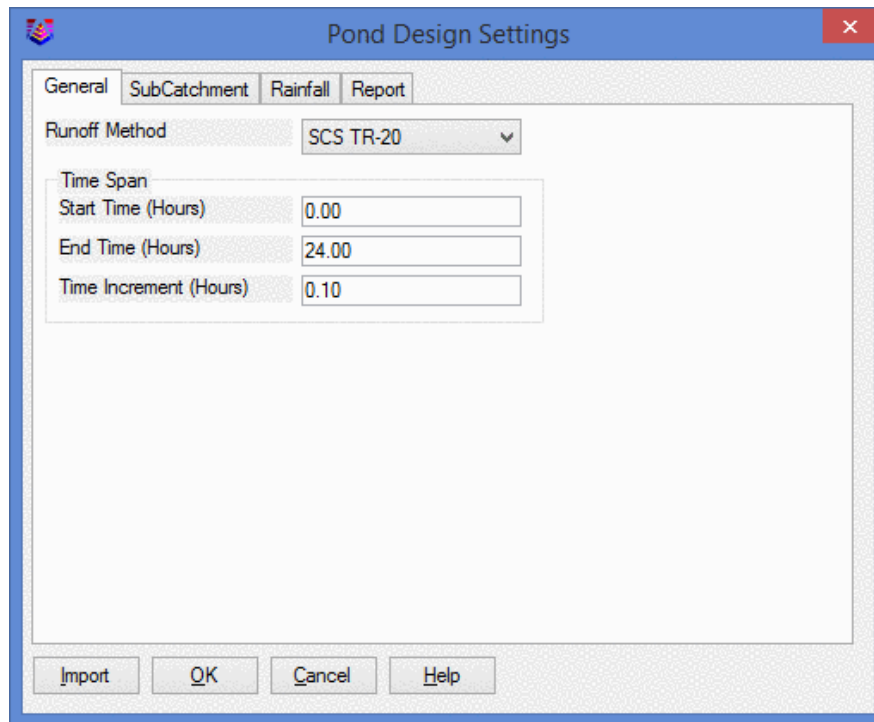

Select Carlson Pond File

Pond Design Settings

When you start a new pond project, the pond design settings dialog will open first to let you set up the project watershed information, rainfall data, calculation method and report format. The **Import** button allows you to import the project settings from an existing pond project. The pre- and postdevelopment watershed surface files and layers files are imported too.

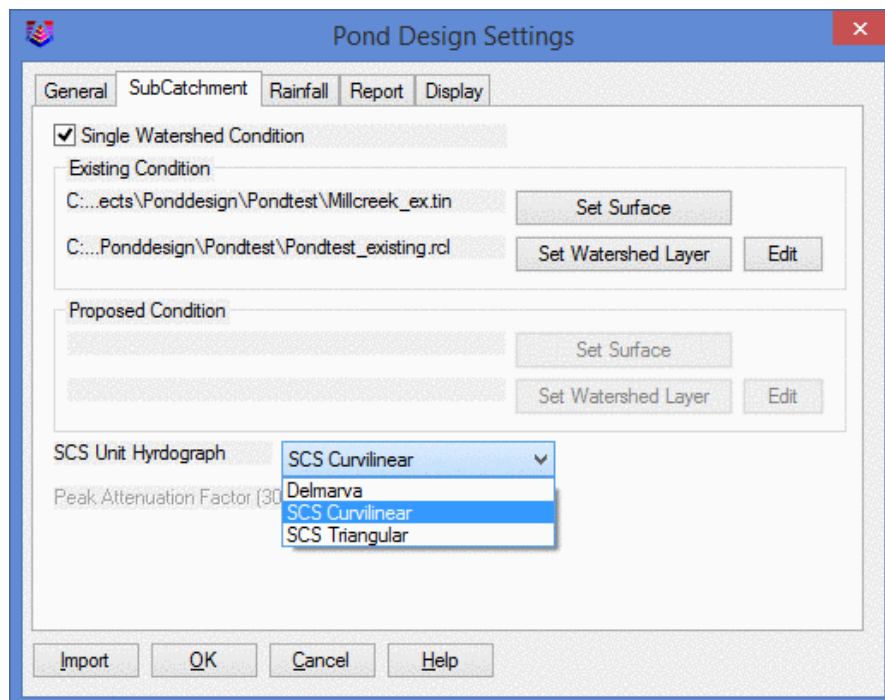

The general tab allows selection of the runoff hydrograph method, and setup of the hydrograph time span. There are SCS TR-20 method and Rational method for producing a runoff hydrograph for a given subcatchment.

Pond Design Settings

Subcatchment:

Subcatchment tab allow you to set up the watershed conditions for existing and proposed conditions. Check **Single Watershed Condition** box when designing a pond when there's only one condition, either existing or proposed condition. The watershed layer file is defined in the program of Define Watershed Layers. The Edit button can lead you to the program to make any changes. Please refer the Define Watershed Layers documentation to set up the watershed layers. Select SCS Unit Hydrograph, supported options Delmarva, SCS Curvilinear, and SCS Triangular. If SCS Triangular is selected the Peak Attenuation Factor may be set.

Rainfall:

The rainfall tab defines rainfall data for the SCS and Rational runoff methods. The storm type determines what the rainfall distribution is selected. The rain library button allows you to choose a storm type from the available rainfall distributions, and you can also create new rainfall data.

The AMC (Accident Moisture Condition) specifies the moisture level in the ground immediately prior to the storm. Use a value of 2 for normal conditions.

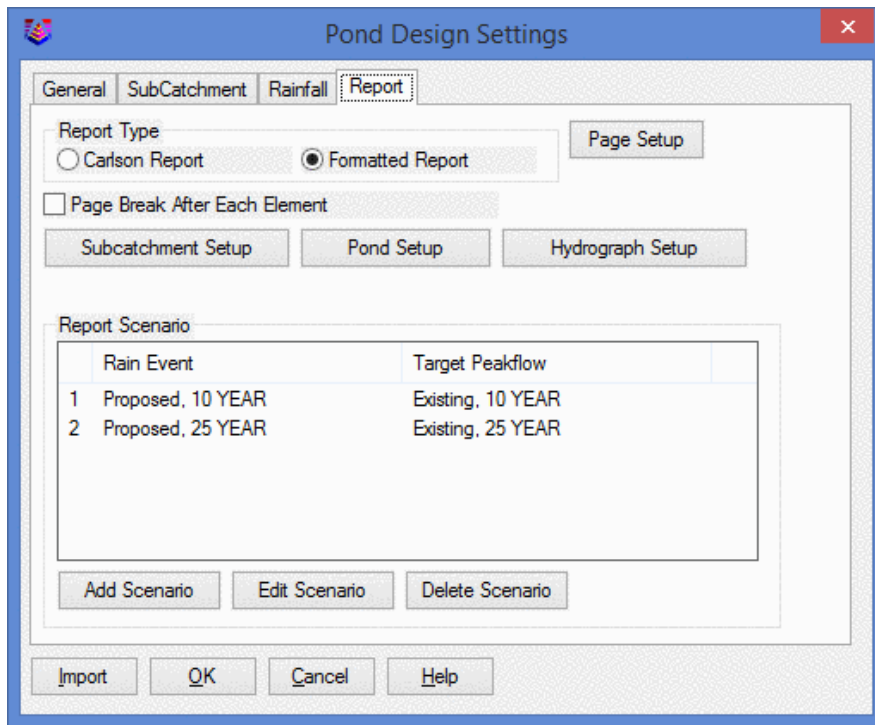

In the rainfall event spreadsheet, you can specify various storm events and their total precipitation.

The screenshot shows the 'Pond Design Settings' dialog box with the 'Rainfall' tab selected. The 'Storm Type' is set to 'TYPE II 24-HOUR' and 'Storm Duration (hr)' is 24.00. The 'AMC' section has radio buttons for 1, 2, and 3, with 2 selected. The 'Events' table lists storm events with their names and rain depths. To the right of the table are buttons for 'Rain Map', 'Add Row', 'Remove Row', 'Up', and 'Down'. At the bottom are 'Import', 'OK', 'Cancel', and 'Help' buttons.

	Event Name	Rain Depth (in)
1	1 YEAR	1.000
2	2 YEAR	2.000
3	10 YEAR	3.000
4	25 YEAR	5.000
5	50 YEAR	6.000
6	100 YEAR	8.000
7		

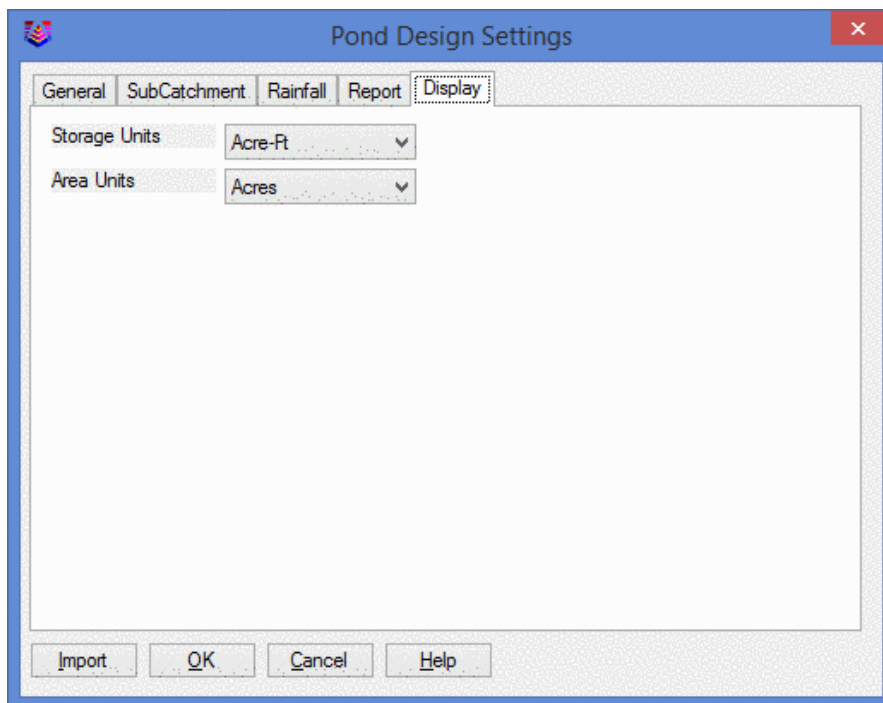

Report:

In report tab, you can select the report type: Carlson report or formatted report. The formatted report is display the report in a .pdf file format. The report scenario list allows you to report watershed runoff and pond sizes for multiple events.

Display:

In display tab, you can set up the pond storage units and subcatchment area units.

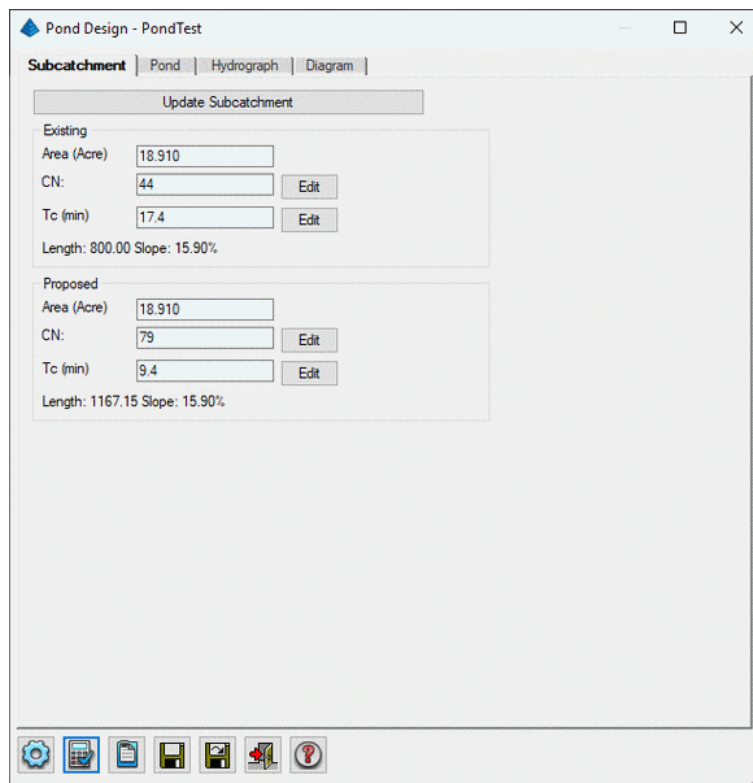

Pond Design

The pond design dialog opens when you start an existing pond project, or finish setting up the project settings for a new pond project. This dialog allows you to enter subcatchment parameters, and analyze the watershed runoff and pond sizes.

Subcatchment:

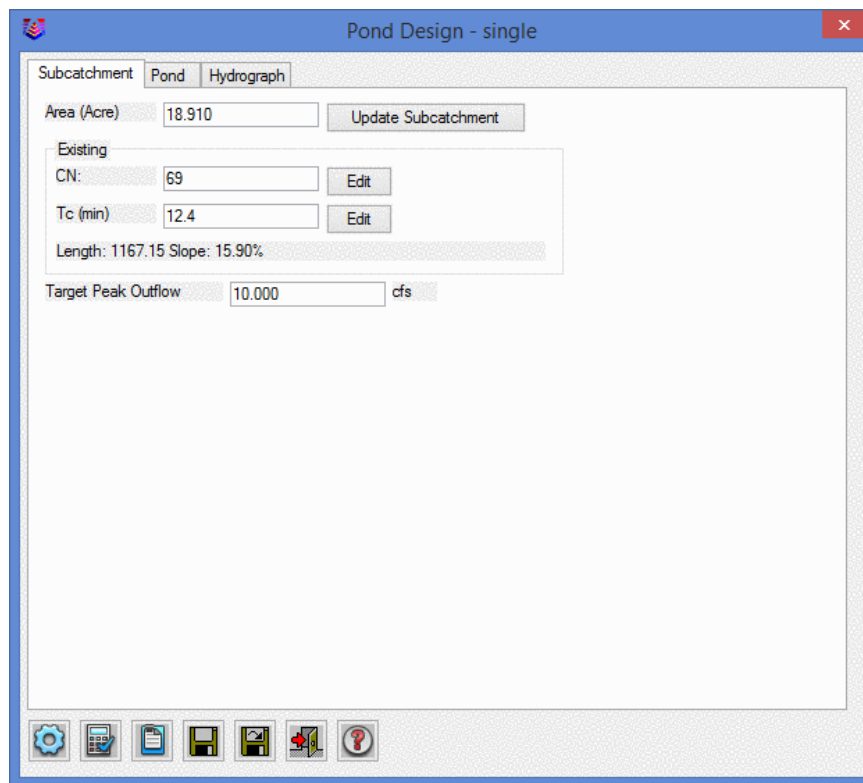

Subcatchment tab is where you enter the subcatchment data. The **Update Subcatchment** button allow the program to pull out the information from the existing and proposed watershed surface files and watershed layers files and fill all the values automatically. You can also enter values manually. The Edit buttons next to all the fields allow you to run the Curve Number program and Time of Concentration program to calculate the CN and Tc values. Please refer to the user manual on Curve Number command, and the Time of Concentration commands, both SCS method and Rational method.

When there's only one watershed condition in design, the target peakflow for outflow condition should be specified for pond sizing.

The screenshot shows the 'Pond Design - PondTest' dialog box with the 'Subcatchment' tab selected. The dialog has a title bar with standard window controls and a menu bar with 'Subcatchment', 'Pond', 'Hydrograph', and 'Diagram'. A prominent 'Update Subcatchment' button is at the top. Below it, the 'Existing' section contains input fields for 'Area (Acre)' (18.910), 'CN' (44), and 'Tc (min)' (17.4), each with an 'Edit' button. The 'Proposed' section contains input fields for 'Area (Acre)' (18.910), 'CN' (79), and 'Tc (min)' (9.4), also with 'Edit' buttons. Both sections show 'Length: 800.00 Slope: 15.90%' for existing and 'Length: 1167.15 Slope: 15.90%' for proposed. A toolbar with icons for settings, print, save, and help is at the bottom.

Parameter	Existing Value	Proposed Value
Area (Acre)	18.910	18.910
CN	44	79
Tc (min)	17.4	9.4
Length	800.00	1167.15
Slope	15.90%	15.90%

Pond:

Pond tab is where you specify the pond parameter and outlets information. The Stage-Storage Edit button opens the Stage-Storage Editor dialog to create and edit the pond data. The Stage-Discharge Edit button opens the Multiple Outlet Design dialog to create and edit the outlet data. There are two methods to estimate the pond size: TR-55 method and Linear Storage method. Please refer to the user manual on the topics of Stage-Storage Editor, Multiple Outlet Design, Detention Pond Sizing - TR-55 method and Linear Storage method.

Hydrograph:

When click on the **Compute** button, the results of all the rainfall events are shown on the Hydrograph tab. The peak flow results are shown in the spreadsheet, and the hydrograph of highlighted rainfall event are displayed on the top. The Pond Inflow hydrograph is the runoff hydrograph of proposed watershed, Pond Outflow hydrograph is the routing hydrograph, and the Target Outflow hydrograph is the runoff hydrograph of the existing watershed. When the routing hydrograph is less than the target outflow hydrograph, the project result passes.

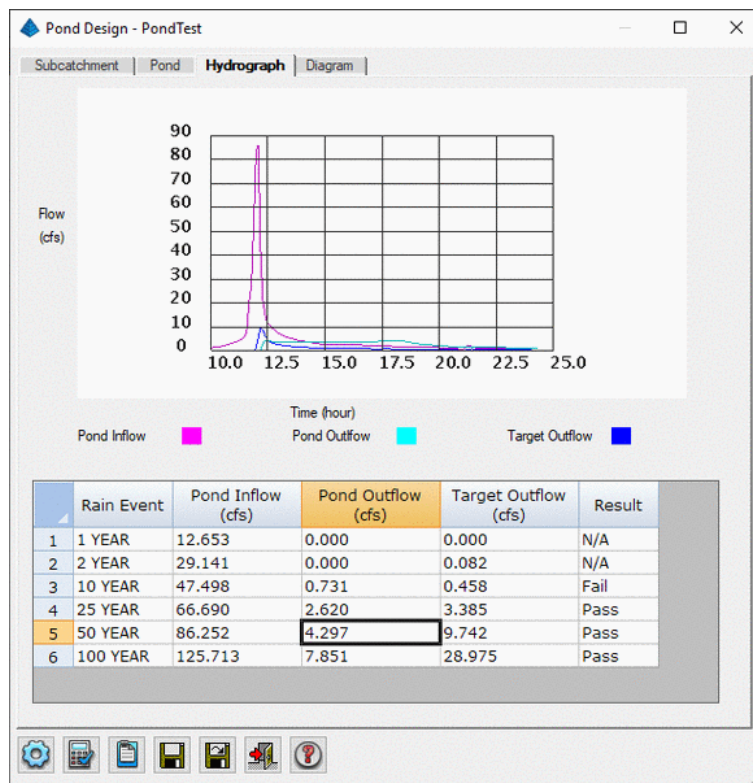

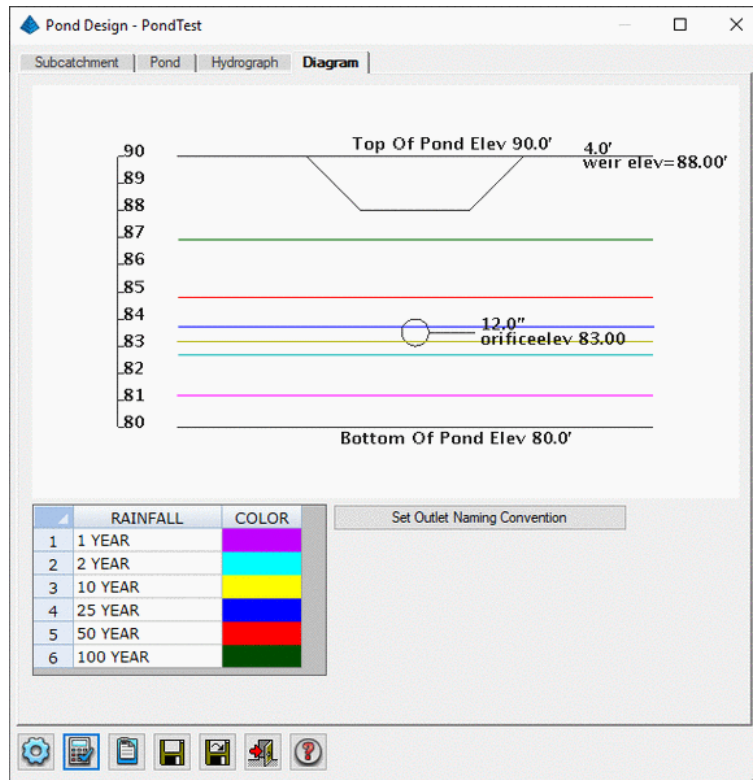

Diagram:

On this tab the outlets schematic view and the pond water levels of all the rainfall events are shown. Double-click

on the color cell to set new color for each rainfall event. The "Set Outlet Labels" button opens the label setup dialog.

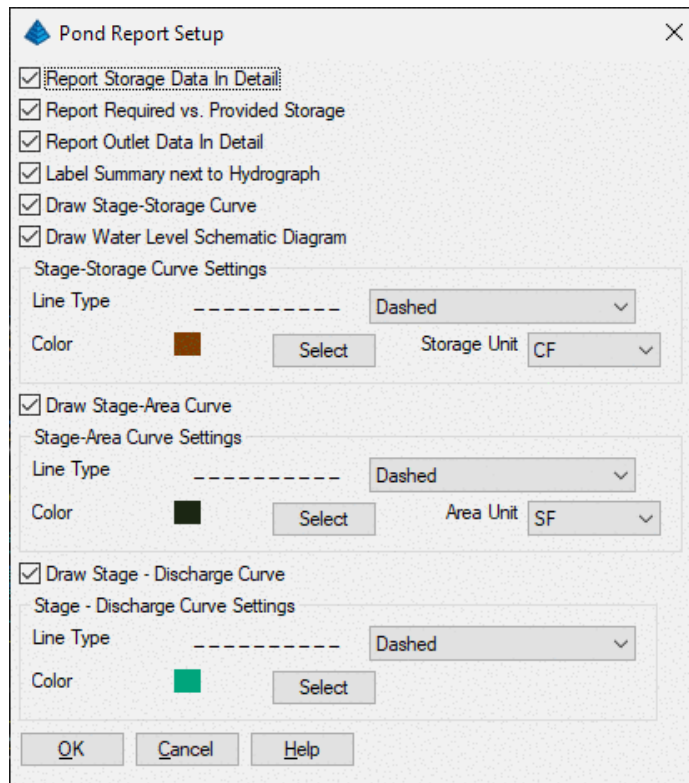

Report

The **Report** button generates report of the watershed information, pond size and outlet parameters in detail. You can setup report settings on the dialog of Pond Design Settings.

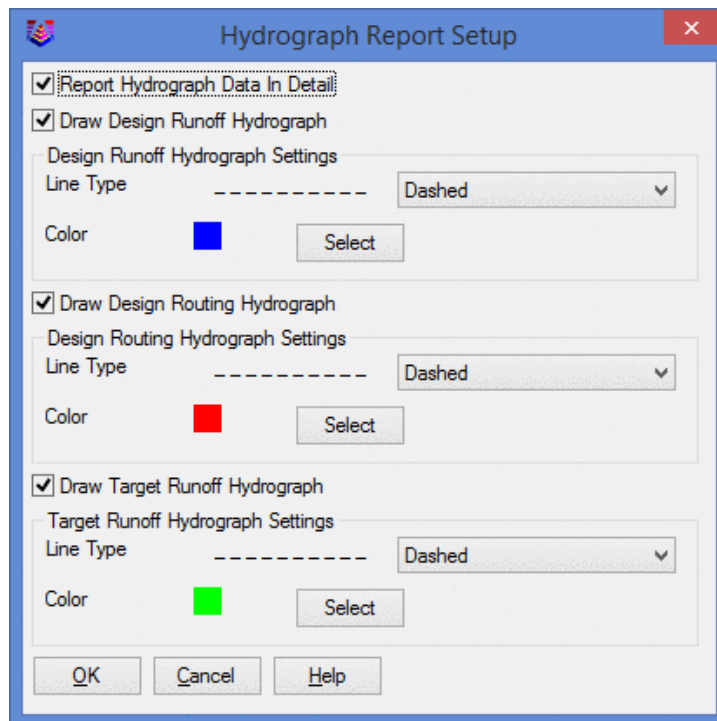

When select the option to Report Input Data In Detail on the **Subcatchment Report Setup** dialog, the area, ground cover, and runoff coefficient for every subarea will be listed in the report; otherwise only the weighted runoff coefficient and the total area will be shown.

The **Pond Report Setup** dialog has the options to report pond data and outlet data in detail, report required (estimated) storage vs. provided (designed) storage values, draw the stage-storage curves, the stage-area curves, and the stage-discharge curves, and draw water level schematic diagram.

The **Hydrograph Report Setup** dialog provides the options to report hydrograph data at every time interval; and the options to draw runoff hydrograph and routing hydrograph.

Libraries

There are four hydrology libraries used in the program: Rational Rainfall Library, SCS Rainfall Library, Curve Number (CN) Library, and Drainage Runoff (CF) Library. Please refer to the user manual on those topics.

Prompts

Design Detention Pond dialog: Fill in values.

Pulldown Menu Location: Structure > Design Detention Pond

Keyboard Command: pond_design

Prerequisite: a pond file (.pond)

Detention Pond Sizing

This command calculates the runoff and storage volumes for a detention pond. The program uses the method from the TR-55 program as described in the Urban Hydrology for Small Watersheds manual.

The command is run through the dialog box shown here. When the input values are filled in, click on the Calculate button to obtain the output values. The drainage area can be either entered directly or selected from AutoCAD by clicking on the Select Area button and then selecting the closed polyline from the screen. The peak inflow will use the value calculated in the Peak Flow-Graphical Method command. Likewise the runoff Q will use the value from the Curve Numbers & Runoff routine.

The output of this command, the storage volume value, can be applied to the Design Bench, Valley or Rectangular Pond routines. There is also an option to generate a TR-55 6A report.

Detention Pond Parameters dialog: Fill in values

Pull-down Menu Location: Structure > Detention Pond Sizing > TR-55 Method

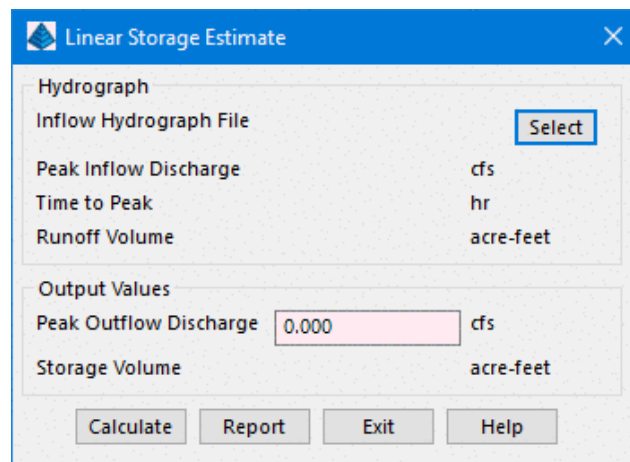

Keyboard Command: dpond

Prerequisite: None

Detention Pond Sizing - Linear Storage Estimate Method

This command calculates storage volumes for a detention pond by Linear Storage method. This method uses an inflow hydrograph and asks you to specify the peak outflow discharge from the reservoir. The program draws a straight line from the zero flow point on the hydrograph to the intersection of the specified outflow and the inflow hydrograph curve. The volume between this line and the hydrograph curve is then computed to be the storage required for the pond.

The output of this command can be applied to the Design Bench, Valley or Rectangular Pond routines. There is also an option to generate a report.

Prompts

Linear Storage Estimate dialog: Fill in values

Pulldown Menu Location: Structure > Detention Pond Sizing > Linear Storage Method

Keyboard Command: pondstorage

Prerequisite: None

Rectangular Pond Design

This program will draw rectangular ponds and calculate storage at any level in the pond corresponding to top of pond, emergency spillway, principal spillway and sediment (cleanout) level. Elevations can be "reverse-calculated" based on requested storage amounts. All calculations derive from input length-width and slope ratio values. Only one common ratio is used for the interior pond slopes (e.g. 1:1 or 2:1, etc.).

The **Draw Details** button will output scaled and fully annotated plan view, section A-A and section B-B drawings, complete with principal and emergency spillways. For simplicity, the principal spillway is considered to be a pipe spillway, and the emergency spillway is considered to be a flat-bottom weir spillway. If the pond in question has only one spillway, then the appropriate spillway elevation is entered in the dialog box, and the other spillway option is left blank.

The **Stage-Storage File** button will produce a table of storage values as .CAP file which can be plotted using the file option within the Draw Stage-Storage routine and used in hydrograph routing routines. The **Report** function creates a report that is shown in the standard report viewer and includes pond dimensions, storage volumes and "Required Freeboard". The **Draw Surface** function will draw the pond into the drawing using the Design Bench Pond command. The program will prompt for the target surface model for the pond out slopes to tie into, the location and rotation for the rectangular pond, the top of dam width and the out slope ratios. The net effect of the Rectangular Pond Design routine is that you can calculate necessary pond storages, plot the pond detail drawings, write out and import the report summary and plot the pond stage-storage curve.

There are ways to use the routine in "shortcut" form to draw ponds. Simply by completing 3 dialog entries (base width, base length and total depth) the user can draw the plan view, section A-A and section B-B. This is why the Pond Elevation items are considered "optional". The programs can also be used as a pond storage calculator. Any of the Pond Elevation options (excepting peak stage), when completed will lead to recalculated storage values. Storage values can likewise be altered and will lead to recalculated elevations. The act of pressing enter inside a dialog box activates the calculation process. If there is no need to plot the pond detail drawings, the cancel "button" in the dialog can be selected following calculations.

Prompts

The program begins by presenting the dialog. One effective way to fill out the dialog boxes is to pick the upper left box and work down and through the options by pressing the tab key after each entry. If all items are filled out as shown, the following prompts will appear:

Enter Scale Factor for Pond Drawing(s) <1>: *press Enter*

Draw Plan View: (<y>/n): *press Enter* **Pick Lower Left Corner: Plot Cleanout and Spillway Lines (<y>/n):** *press Enter*

Pick Location of Principal Spillway:

Draw Section A-A Horizontal (y<n>): *y*

Pick Left Location of Section A-A:

Pick Right Location of Section A-A:

Draw Section B-B Vertical (y/<n>): *y*

Pick One Side of Section B-B:

Pick one Side of Section B-B:

Pick Upper Left Corner for Section A-A:

Plot Cleanout and Spillway Lines (<y>/n): *press Enter*

Pick Upper Left Corner for Section B-B:

Plot Cleanout and Spillway Lines (<y>/n): *press Enter*

If no Section A-A or Section B-B identifier lines are drawn, no section A-A or Section B-B details will be drawn. Thus if you want Section A-A only, say "y" to Draw Section A-A Horizontal but "n" or Enter to Draw Section B-B Vertical. If you entered only length, width and depth in the original dialog, the resultant prompting would be:

Enter Scale Factor for Pond Drawing(s) <1>: *press Enter*

Draw Plan View? (<y>/n): *press Enter*

Pick Lower Left Corner:

Draw Section A-A Horizontal (y/<n>): y

Pick Left Location of Section A-A:

Pick Right Location of Section A-A:

Draw Section B-B Vertical (y/<n>): y

Pick One Side of Section B-B:

Pick Other End of Section B-B:

Pick Upper Left Corner of Section A-A:

Pick Upper Left Corner of Section B-B:

Plots produced by the entries in the preceding dialog

Keep in mind that the scale factor, if other than 1, will enlarge or reduce the size of the detail drawings to suit the users needs, yet will annotate dimensions correctly in all cases.

The imported text based on the output ASCII file POND.TXT (located in \SCADXML\WORK by default) would appear as follows:

Top of Pond Elevation: 1070.00 feet Peak Stage (25th year-24 hour Storm Event): 1069.45 feet Includes 1.00 feet of Freeboard Emergency Spillway Elevation: 1067.00 Emergency Spillway Bottom Width: 10.00 Principal Spillway Invert Elevation: 1065.50 feet

Principal Spillway Diameter: 42.00 in.

Principal Spillway Slope: 2.00 % Sediment Pool (Cleanout) Elevation: 1064.00 feet

Bottom of Pond Elevation: 1060.00 feet

Storage Volume at Emergency Spillway: 0.2990 ac.ft.

Storage Volume at Principal Spillway: 0.2150 ac.ft.

Storage Volume at Sediment Pool: 0.1430 ac.ft.

The routines are fully metric and will substitute meters and cubic meters appropriately for feet and acre-feet. Pipe sizes, however, will default to diameters in inches.

Pull-down Menu Location: Structure in Hydrology

Keyboard Command: rpond

Prerequisite: None

Design Spillway

This command creates a spillway with 3D polylines in the drawing. The program uses a surface model of the area for the spillway, a spillway centerline and spillway dimensions (width, elevation, etc.). The surface model of the area can be defined by contour polylines, points and 3D polylines or can be created by the Design Bench or Valley Pond commands. The spillway dimensions can be calculated by the Design Channel commands to meet the desired discharge. The amount of cut required to make the spillway is calculated and reported.

Prompts

Source of surface model (File/<Screen>)? *press Enter* Use the File option to select a .grd file.

Pick Lower Left limit of surface area: *pick lower left*

Pick Upper Right limit of surface area: *pick upper right* Be sure to pick these limits well beyond the area of the spillway centerline in order to make room for the outslopes.

Make GRiD File Dialog

After selecting the limits of the disturbed area the program will generate a 3D grid that represents the surface. Specify the grid resolution desired and select OK.

Pick the spillway centerline: *select polyline that crosses the dam*

Pick a point within the pond: *pick a point* The program needs to know which end of the spillway centerline is within the pond.

Enter slopes as percent grade or slope ratio (Percent/<Ratio>)? *press Enter*

Enter the side slope ratio <1.0>: *press Enter*

Enter the flow slope ratio <100.0>: *press Enter*

Range of existing elevations along spillway centerline.

Enter spillway elevation <1476.5>: *1475.0* This is the entrance elevation of the spillway

Enter the spillway width <10.0>: *press Enter*

Spillway Report:

Spillway inlet elevation: 1445.0000

Spillway outlet elevation: 1445.0000

Spillway width: 10.0000

Side slope percent grade: 100.00, slope ratio: 1.00

Flow slope percent grade: 1.00, slope ratio: 100.00

Spillway EarthWork Volumes

Total cut: 55.593 C.Y., 1501.00150 C.F.

Spillway added to valley pond

Pulldown Menu Location: Structure in Hydrology

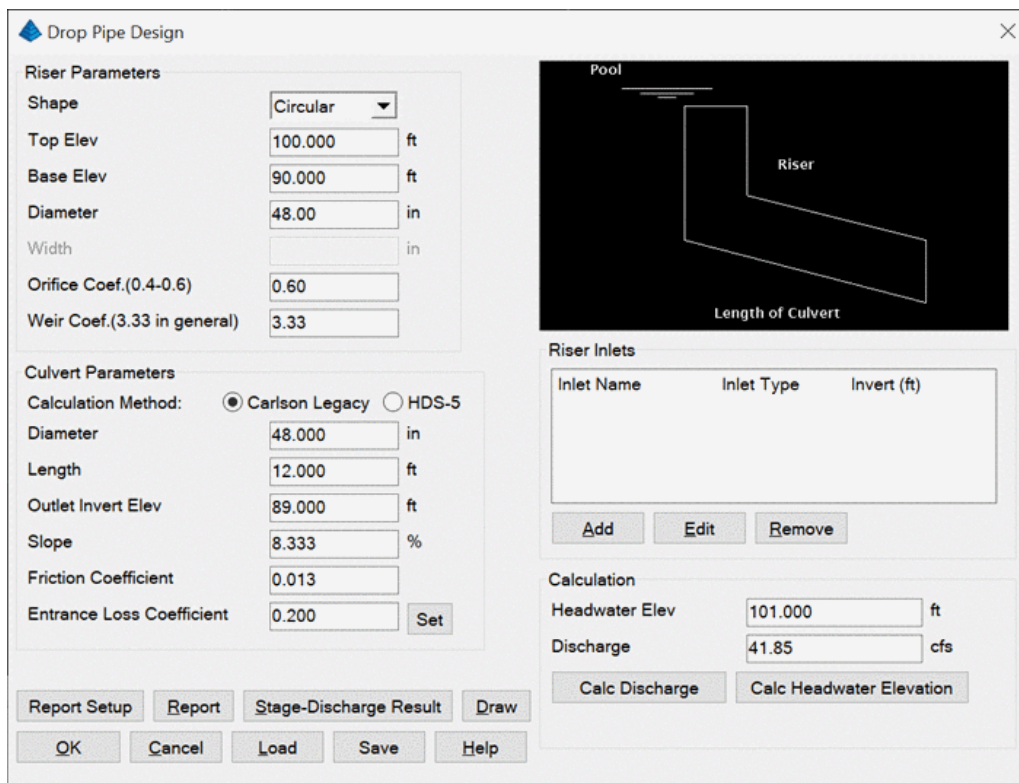

Keyboard Command: spill

Prerequisite: Surface entities that model the pond

Drop Pipe Spillway Design

This program calculates the spillway discharge at different water elevations. When the water is lower than the top of the riser, the Riser Inlets would take water when the water rise above the inlet's invert elevation. As the water elevation initially rises above the riser, the flow is controlled by weir flow. The program uses the perimeter of the riser for the weir length for the weir flow calculation. The riser can be either circular or box. At higher water elevations the flow is under orifice control. When the barrel flows full, the flow is controlled by full pipe flow. Given the water elevation and spillway dimensions, the program calculates the type of flow and discharge.

The Riser Inlets are orifice/weir openings on the riser and discharge into the riser box, and then to the culvert. There are two methods to calculate culvert discharge - Carlson Legacy and HDS-5.

The Calculate button will read the values in the dialog, calculate the flow and report this flow value at the bottom of the dialog. The Report button will generate a report of the input values and calculated flows. The File routine will create a stage-discharge (.STG) file. The Draw function will draw and label the drop pipe spillway in the drawing at the specified scale. The Graph button creates a stage-discharge graph.

Riser Parameters: Indicate the dimension of the vertical riser pipe, and the orifice and weir coefficients which are used in orifice and weir flow calculations.

Culvert Parameters: Indicate the culvert dimension and profile. The Friction Coefficient is the manning's n for calculating the pipe friction loss. The Entrance Loss Coefficient is used to calculate the energy loss at the culvert inlet end.

Headwater Elev: Indicate the water (pool) elevation.

Discharge: Discharge value at the end of the culvert.

Calc Discharge: Causes the routine to read the values in the dialog and calculate the Discharge flow at the current headwater elevation.

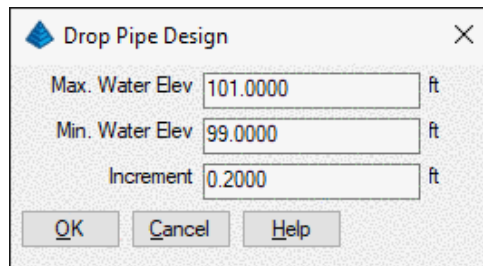

Calc Headwater Elevation: Causes the routine to read the values in the dialog and calculate the headwater elevation that's required to handle the known discharge flow.

Report Setup: Chooses between a Standard Report and a PDF Report. The Standard Report is a simple text report of the parameters and calculations. The PDF Report adds some text formatting and has the option to draw a schematic of the pipe detail and draw the stage-discharge graph.

Report: Creates a report for the current spillway.

Load/Save: Store and recall the parameters to a .drop file.

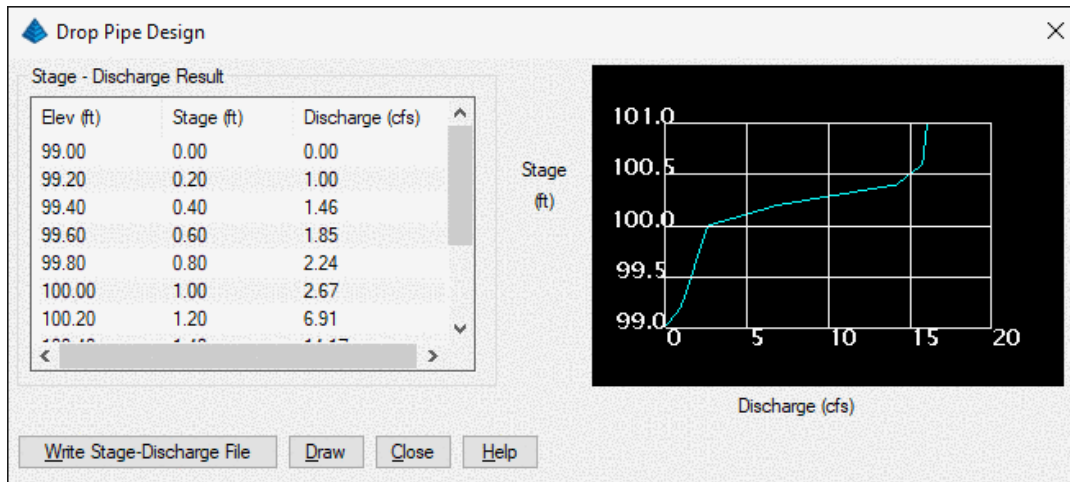

Stage-Discharge Result: Displays the following dialog box that allows you to indicate the water elevation range and increment to report:

The 'Drop Pipe Design' dialog box contains three input fields for elevation values and three buttons at the bottom.

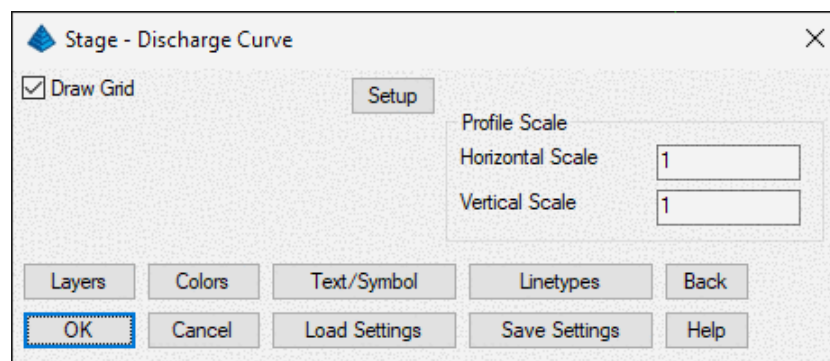

Max. Water Elev	101.0000	ft
Min. Water Elev	99.0000	ft
Increment	0.2000	ft

Buttons: OK, Cancel, Help

Write Stage-Discharge File: Creates a Stage-Discharge (.STG) file that can be used in other Carlson Hydrology commands.

Draw: Allows a graphic representation of the Stage-Discharge data to be placed into the drawing.

The 'Stage - Discharge Curve' dialog box includes a 'Draw Grid' checkbox, a 'Setup' button, and a 'Profile Scale' section with 'Horizontal Scale' and 'Vertical Scale' input fields. At the bottom are buttons for 'Layers', 'Colors', 'Text/Symbol', 'Linetypes', 'Back', 'OK', 'Cancel', 'Load Settings', 'Save Settings', and 'Help'.

Profile Scale:
Horizontal Scale: 1
Vertical Scale: 1

Buttons: Layers, Colors, Text/Symbol, Linetypes, Back, OK, Cancel, Load Settings, Save Settings, Help

Draw Grid: When enabled, this option creates a grid that accompanies the Stage-Discharge curve. Click the **Setup** button to access the grid settings which are discussed in detail in the Draw Grid section of the Draw Profile command.

Output to Separate Drawing: When enabled, this option draws the hydrograph to a separate drawing. Click the **Set** button to specify the name/location of the external drawing.

Horizontal Scale: Specify the discharge scale (in CFS).

Vertical Scale: Specify the stage scale (in Ft).

The **Layers, Colors, Text Styles/Sizes** and **Linetypes** buttons provide access to settings for each of these features of the Stage-Discharge curve.

Load Settings: Loads a saved collection of Draw Stage-Discharge settings, saved in a (.PFS) file.

Save Settings: Saves all Draw Stage-Discharge settings in a (.PFS) file.

Pulldown Menu Location: Structure

Keyboard Command: spillway

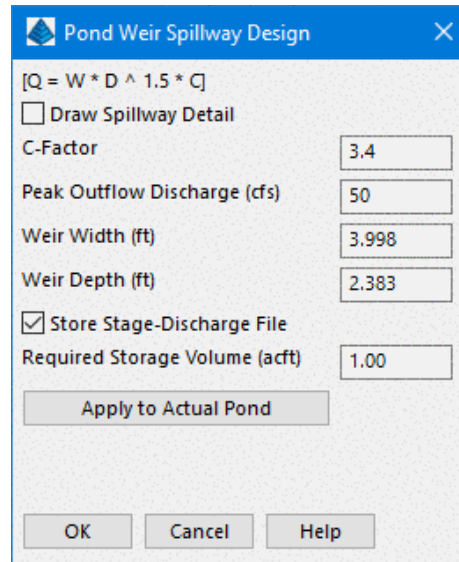

Prerequisite: None

Rectangular Weir Design

This program calculates the dimensions of a rectangular weir given the outflow discharge. The default discharge uses the value from the Detention Pond command. The weir width and depth are two free variables. Enter a value for one and press Enter. Then the value for the other is calculated.

The weir design may optionally be applied to a pond design. First enter a Required Storage Volume which can come from the Detention Pond command. Then click Apply to Actual Pond and choose a Storage Capacity File (.CAP). This .cap file can be created by Bench or Valley Pond Design and by the Stage-Storage command. The program then computes the elevation at the required storage volume and the corresponding elevation for the bottom of the weir given the weir depth.

When the Draw Spillway Detail option is checked, a drawing of the weir is created as shown below.

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: weir

Prerequisite: None

Advanced Weir Design

The Advanced Weir Design uses the methodology described in HEC-22 Manual. The weir flow is determined as:

$Q = C_w L H^{1.5}$ for the Rectangular Weir without Contracted End

$Q = C_w (L - 0.2 H)^{1.5}$ for the Rectangular Weir with Contracted End

where: Q = discharge, ft^3/s (m^3/s)

C_w = weir coefficient, 3.33 in English units (1.84 in Metric units)

L = weir length, ft (m)

H = head above weir crest, ft (m)

$Q = C_w [\tan(\emptyset/2) H^{2.5} + 5/4 L H^{1.5}]$ for Trapezoidal Weir

where: Q = discharge, ft^3/s (m^3/s)

C_w = weir coefficient, 3.33 in English units (1.84 in Metric units)

L = weir length, ft (m)

\emptyset = internal angle of the two sides, degrees

H = head above weir crest, ft (m)

$Q = C_w \tan(\emptyset/2) H^{2.5}$ for V-Notched Weir

where: Q = discharge, ft^3/s (m^3/s)

C_w = weir coefficient, 2.5 in English units (1.38 in Metric units)

θ = angle of v-notch, degrees

H = head above weir crest, ft (m)

Rectangular Weir with Contracted End

Rectangular Weir without Contracted End

Trapezoidal Weir

V-Notched Weir

This command designs a weir structure and calculates its stage-discharge curve. Select Weir Design from the Structure menu in the Hydrology Module to display the design dialog. Select the Type of the weir, Rectangular, Trapezoidal or V-notched. Enter the dimension for the weir. In the Invert Elev box, type the absolute elevation at which the weir will be attached to a reservoir. The attachment point is at the bottom of the weir. In the Coefficient box, type a weir coefficient value. In the Number of Openings box, enter the number of weirs you want to combine.

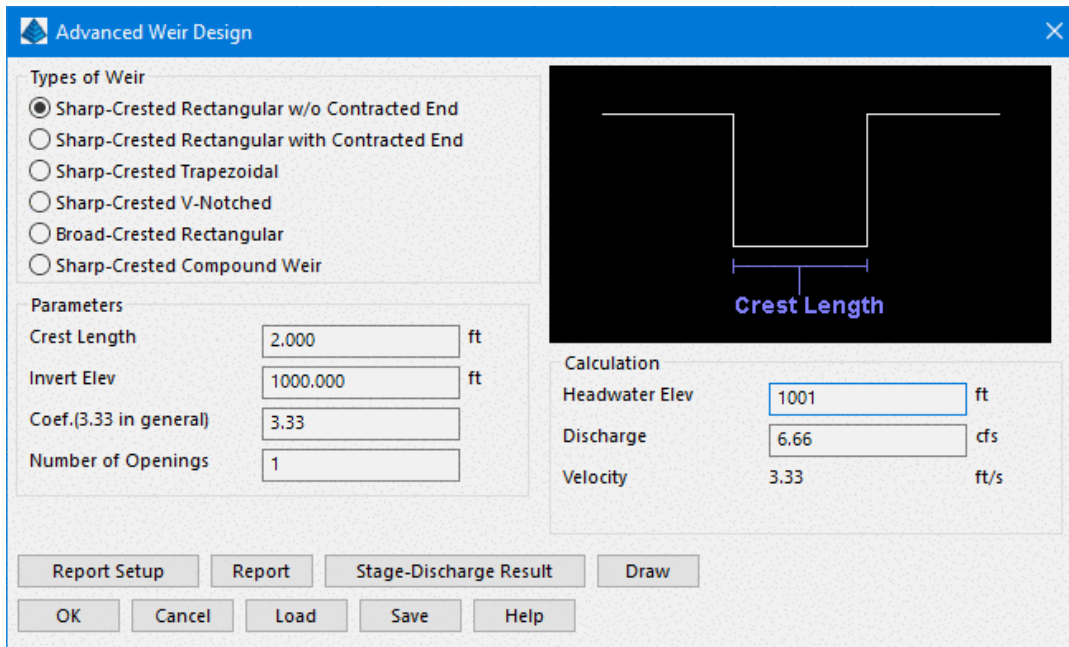

The program performs two-way calculation: calculate Discharge from Headwater, and calculate Headwater from Discharge. In the Headwater and Tailwater boxes, type the absolute headwater surface elevation and tailwater surface elevation respectively, and the maximum discharge and flow velocity through the orifice would be computed automatically. When Discharge value is entered, the Headwater elevation would be calculated automatically.

Click on the Stage-Discharge Result button to display the stage-discharge curve in the Stage-Discharge Result Dialog. This dialog allows you to write the stage-discharge data to a stage-discharge file(.STG), and draw the stage-discharge curve on the screen. From the Stage-Discharge Curve Draw Settings dialog, you can draw the curve into the drawing or write a .stg stage-discharge file.

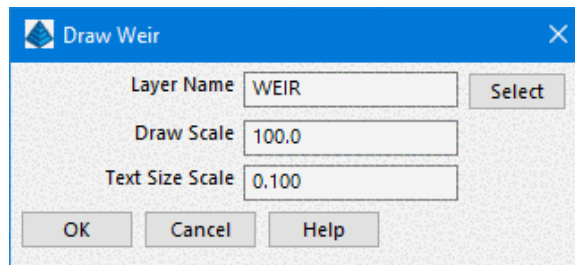

The Report Setup chooses between the Standard Report and the PDF Report. The Standard Report is a simple text report of the parameters and results. The PDF Report adds some text formatting and options to draw a schematic of the weir and draw a stage-discharge graph. The Report button generates the weir design report.

The Draw button creates a schematic of the weir with dimensions in the drawing.

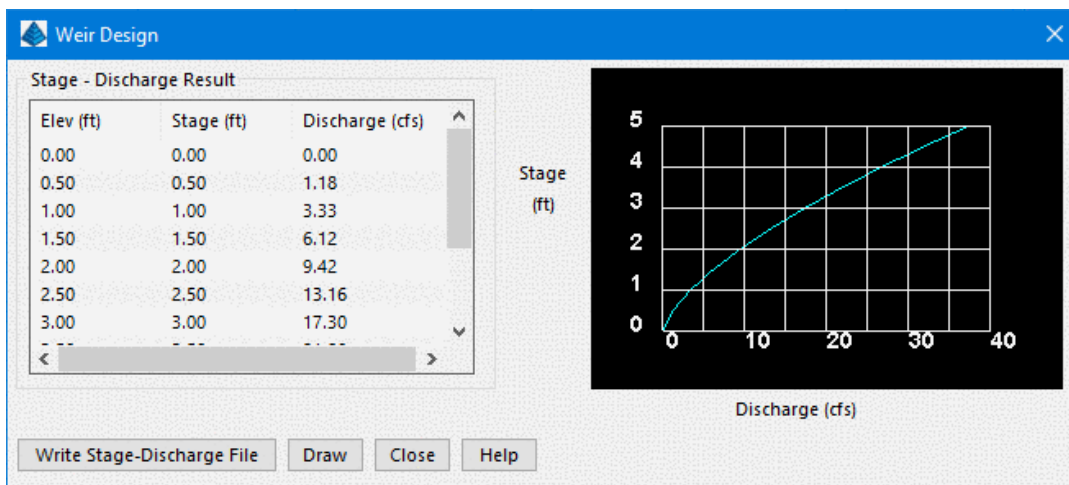

The Load and Save buttons store and recall the parameters to a .weir file.

Prerequisite: None

Orifice Design

The Orifice Design uses the methodology described in HEC-22 Manual. The orifice flow is determined as:

$$Q = C_o A_o (2 g H_o)^{0.5}$$

where: Q = discharge, ft³/s (m³/s)

C_o = orifice coefficient, unitless (0.40 - 0.60)

A_o = area of orifice, ft² (m²)

H_o = effective head on the orifice measured from the centroid of the opening, ft (m)

g = gravitational acceleration, 32.2 ft/s² (9.81 m/s²)

This command designs an orifice structure and calculates its stage-discharge curve. Select Orifice Design from the Structure menu in the Hydrology Module to display the design dialog. Select the Section Type of the orifice, Circular or Rectangular. Enter the dimension for the orifice. In the Invert Elev box, type the absolute elevation at which the orifice will be attached to a reservoir. The attachment point is at the bottom of the orifice. In the Coefficient box, type a roughness coefficient for the orifice. The coefficient ranges from 0.4 to 0.6 (HEC-22). In the Number of Openings box, enter the number of orifices you want to combine.

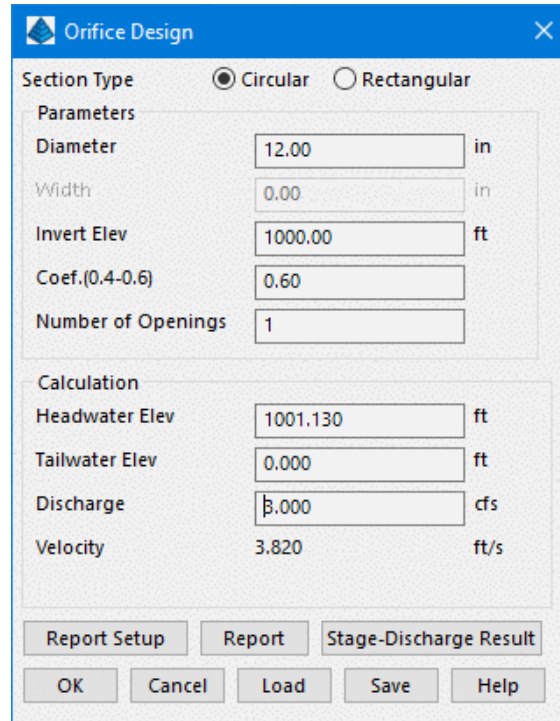

The program performs two-way calculation: calculate Discharge from Headwater, and calculate Headwater from Discharge. In the Headwater and Tailwater boxes, type the absolute headwater surface elevation and tailwater surface elevation respectively, and the maximum discharge and flow velocity through the orifice would be computed automatically. When Discharge value is entered, the Headwater elevation would be calculated automatically.

Click on the Stage-Discharge Result button to display the stage-discharge curve in the Stage-Discharge Result Dialog. This dialog allows you to write the stage-discharge data to a stage-discharge file(.STG), and draw the

stage-discharge curve on the screen. From the Stage-Discharge Curve Draw Settings dialog , you can specify how to draw the curve.

The Report Setup chooses between the Standard Report and the PDF Report. The Standard Report is a simple text report of the parameters and results. The PDF Report adds some text formatting and has the option to draw a stage-discharge graph. The Report button generates the orifice design report.

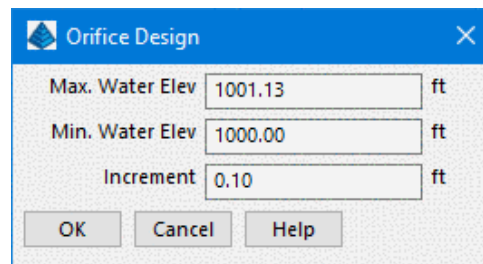

The Load and Save buttons store and recall the parameters to a .outlet file.

The Orifice Design dialog box is titled "Orifice Design" and has a close button (X) in the top right corner. It is divided into several sections:

- Section Type:** Two radio buttons are present: "Circular" (selected) and "Rectangular".
- Parameters:** A group box containing five input fields:
 - Diameter: 12.00 in
 - Width: 0.00 in
 - Invert Elev: 1000.00 ft
 - Coef.(0.4-0.6): 0.60
 - Number of Openings: 1
- Calculation:** A group box containing four input fields:
 - Headwater Elev: 1001.130 ft
 - Tailwater Elev: 0.000 ft
 - Discharge: 3.000 cfs
 - Velocity: 3.820 ft/s
- Buttons:** A row of five buttons: "Report Setup", "Report", "Stage-Discharge Result", "OK", "Cancel", "Load", "Save", and "Help".

Orifice Design Dialog

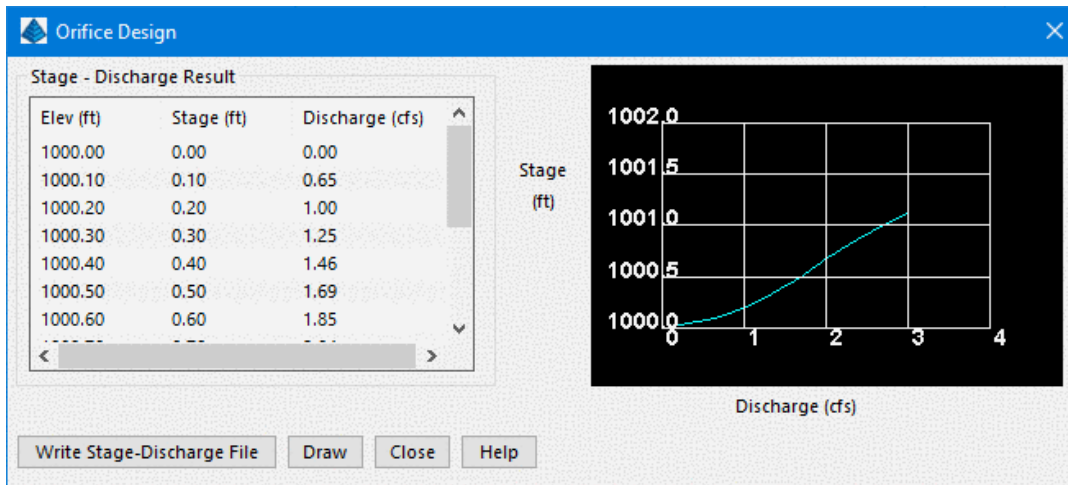

The Stage-Discharge Limits dialog box is titled "Orifice Design" and has a close button (X) in the top right corner. It contains three input fields:

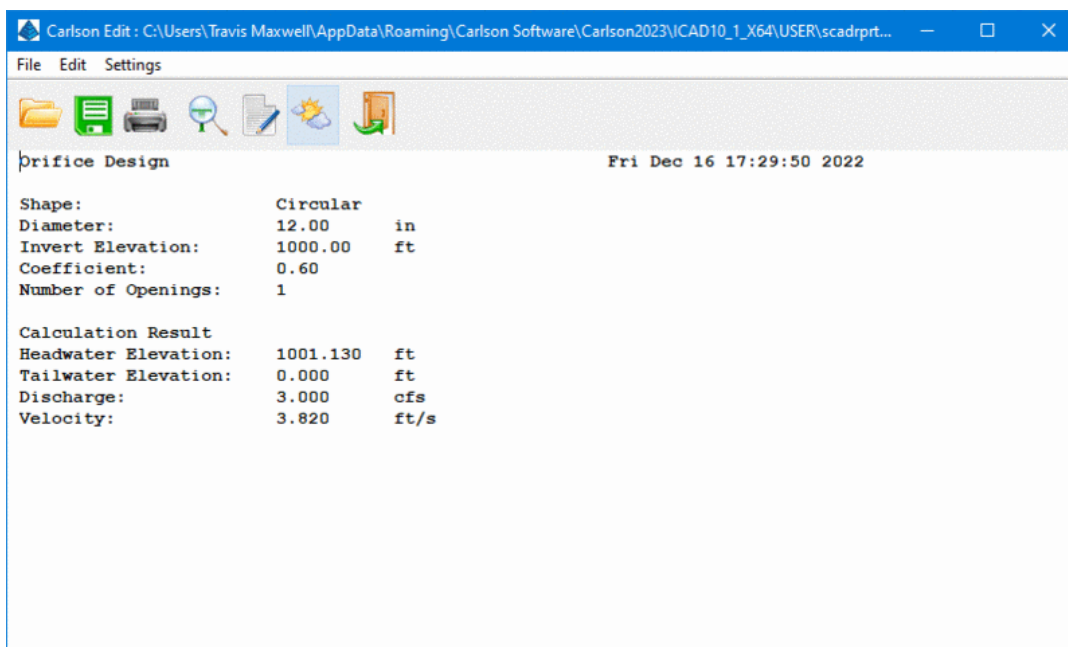

- Max. Water Elev: 1001.13 ft
- Min. Water Elev: 1000.00 ft
- Increment: 0.10 ft

At the bottom, there are three buttons: "OK", "Cancel", and "Help".

Pond Exfiltration Design

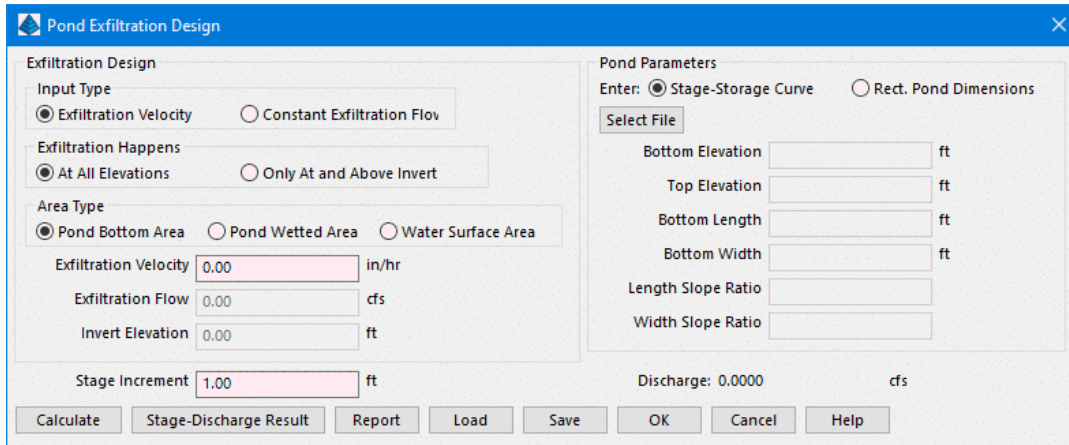

Exfiltration is classified as an outlet device and is incorporated into a pond's stage-discharge curve. But exfiltration is usually directed to the discarded outflow to prevent further routing. There are two design methods to determine exfiltration, shown below:

1. Constant exfiltration Flow: The flow value (cfs or cms) is applied whenever there is water in the pond, or only when the water level is at or above the specified invert elevation.
2. Exfiltration Velocity: The velocity (in/hr or mm/hr) is multiplied by the exfiltration area at a given elevation to determine the final exfiltration flow.

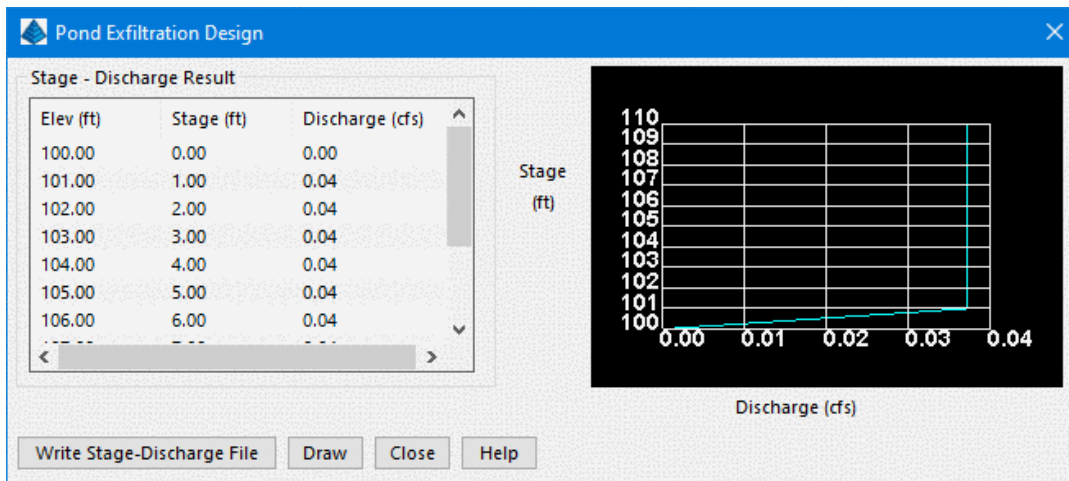

The exfiltration area may be defined in three ways: 1) Pond Bottom Area, which allows the exfiltration only through the bottom of pond; 2) Water Surface Area, which assumes the exfiltration is downward; 3) Pond Wetted Area, which allows the exfiltration occur through all exposed surfaces regardless of slope. You may also choose to exclude the area of the pond that lies at or below the specified invert elevation, which is useful in preventing exfiltration through impervious (lower) regions of the pond.

There are two ways to enter the pond parameters. If you elect to input the stage-storage curve, the program will determine the bottom and side areas automatically.

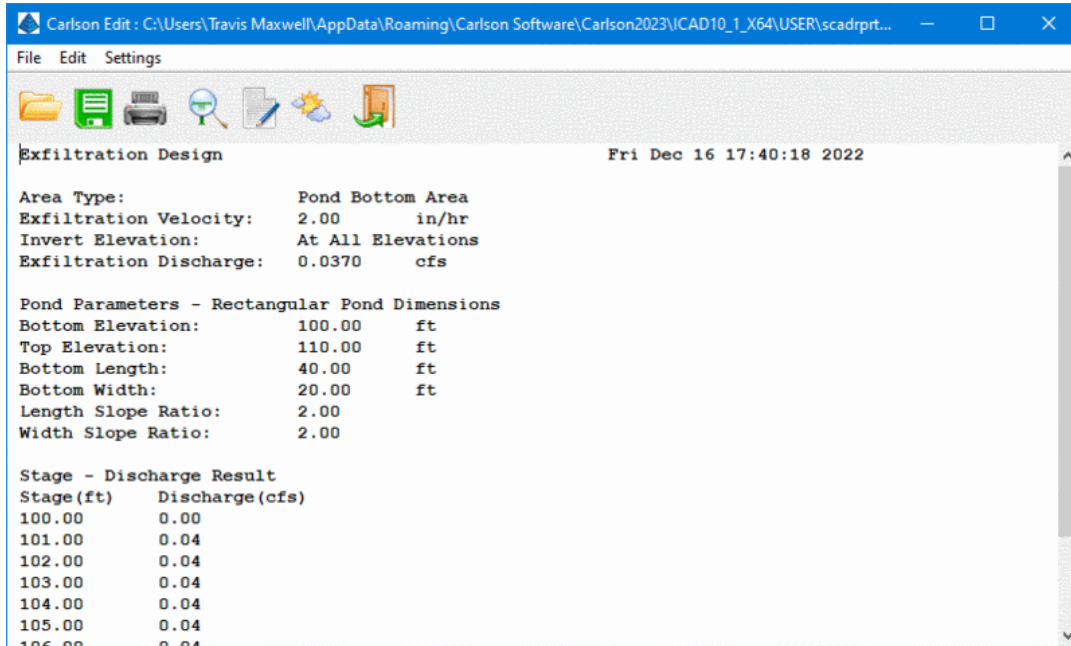

The Load and Save buttons store and recall the parameters to a .pxd file.

Prerequisite: None

Multiple Outlet Design

Multiple Outlet Design attaches multiple outlet structures to a detention pond and computes the stage-discharge data. All design parameters are stored in a combo outlet file (.COT). This command allows you to add, edit and remove outlet structures attached to a pond, and you can see how different combinations of structures affect the stage-discharge calculation. There are six types of outlet structures: culvert, drop pipe, orifice, weir, exfiltration and user defined stage-discharge curve. Please refer to the documentation of Culvert Design, Drop Pipe Spillway Design, Orifice Design, Weir Design and Stage-Discharge Editor for the details.

From the Structure menu in the Hydrology Module, choose Multiple Outlet Design command to open the design dialog. You need to specify an existing or a new combo outlet file (.COT) to load it into the design dialog. The dialog has a spreadsheet with a list of all the outlets. You can edit the Outlet Name, Invert Elevation and Outlet Type right in the spreadsheet. Or use the Edit button to bring up a dialog editor for the current highlighted outlet. The Used In Design toggle allows you to turn on and off whether to include the outlet in the discharge calculations.

Click on Add button to display the New Outlet Structure dialog. Enter the structure name and select a structure type, then click the OK button to display the outlet design dialog for that structure. Configure the structure in the design dialog and then click OK to exit the dialog and come back to the main dialog, which highlights the new structure and indicates its parameters and the stage-discharge result.

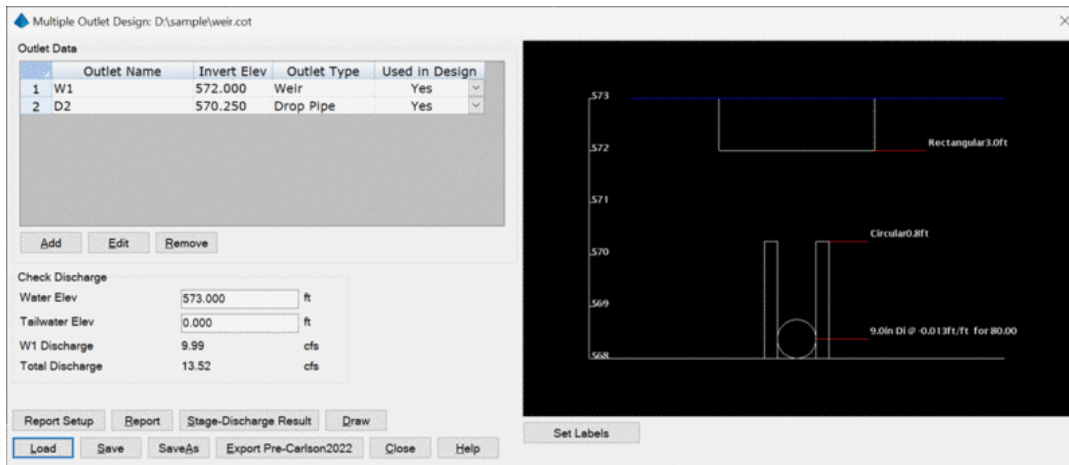

The Edit and Remove buttons allow you to edit and remove the highlighted outlet. The Stage-Discharge Result button computes the discharges at each stage from the minimum water elevation to the maximum, and displays the result in the Stage-Discharge Result Dialog.

The Report Setup chooses between the Standard Report and PDF Report. The Standard Report is a simple text report of the design parameters and the discharge results that is shown in the standard Carlson report display window, from where the information can be edited, saved, and printed to a printer or to the screen. The PDF Report adds some text formatting and options to draw a diagram of the outlets and draw a stage-discharge graph.

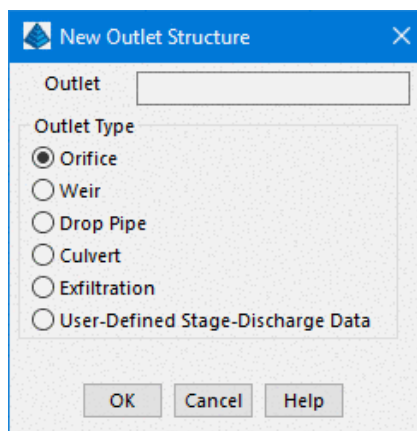

The Load button allows you to load other combo outlet files (.COT) for editing. The Save and SaveAs buttons save the current design parameters to an outlet file.

The Check Discharge section allows you to enter a Water Elevation and Tailwater Elevation and the program reports the total discharge from all the outlets along with the discharge for the currently highlighted outlet.

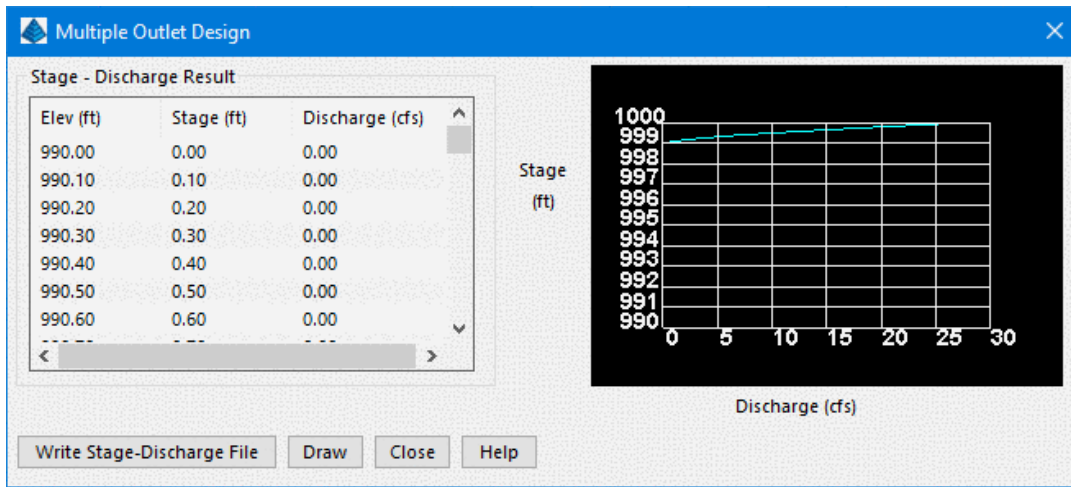

The schematic view of the pond and its outlets as well as the water elevation are shown on the right side. The Set Labels button opens the label settings dialog to set up the labels in the view.

Stage-Storage Editor

This command defines a reservoir by entering stage/storage data in five ways: stage/storage (storage-area), stage/storage(by volum,e), stage/contour area data, rectangular/trapezoidal pond definition and underground pipe definition.

From the Structure > Stage-Storage menu in the Hydrology Module, run Input-Edit Stage-Storage command to open the design dialog. Enter the pond name in the Structure Name box. There are five Storage Methods: **User Defined Storage-Volume** allows you to manually enter stage-storage or stage-volume data, **Stage-storage or stage-Area**, **Irregular Shape** allows you to select the contours of a surface model from a drawing, **Rectangular Shape** defines a rectangular or trapezoidal pond, and **Underground Pipe** defines circular or box pipe shape reservoirs.

The **Biofiltration** is at the bottom of the pond that isn't 100% water capacity. The depth is from the bottom of the pond, and the void is smaller than 100%, in the example below it is 50%. The Biofiltration is calculated in the storage and shown in the stage-storage report.

Stage-Storage Data section displays the stage-storage curve data. Click on the **Edit Detention Structure** button to create/edit the stage-storage input. The **Check Storage** fields are a tool for entering the elevation or stage and reporting the storage and area at that level. Load, Save and SaveAs buttons allow you to load and save the stage-storage data. The Report button generates the stage-storage report in either **Standard Report** or **PDF Report** format, shown below. For a customized report, check the Use Report Formatter option and then pick Report.

Stage-Storage Editor

Stage-Storage Editor

Stage-Storage PDF Report

User Defined Storage-By Area

In the spreadsheet, you can enter elevations and corresponding pond surface area to define stage storage. You can also import an exiting spreadsheet .csv file via **Import CSV** button. Click on **OK** button to save the stage-storage data.

User Defined Storage-By Volume

In the spreadsheet, you can enter elevations and corresponding storage volumes to define stage storage. You can also import an exiting spreadsheet .csv file via **Import CSV** button. Click on **OK** button to save the stage-storage data.

	Elevation (Ft)	Area (SF)
1	100	0
2	101	1000
3	102	1500
4	103	1800
5	104	2200
6		

Buttons: Insert Row, Delete Row, OK, Cancel, Help, Import CSV

User Defined Storage

Irregular Shape

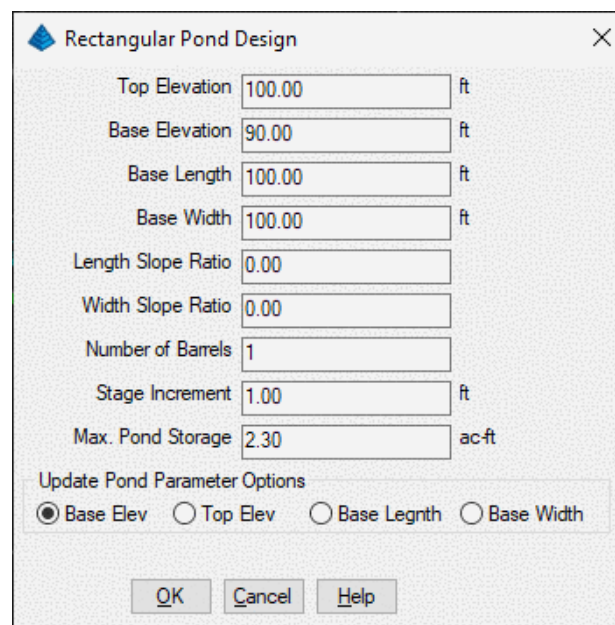

This method allows you to define an irregular shape pond from the contour polylines of a surface model, and generate the stage-storage data automatically. In order to use this method, you must have the surface drawing open, which contains the contours that you want to use to define the reservoir. Click on the **Select Pond Contours** and select as many contours as you need, the stage/storage and stage/area relationship will be then determined and displayed in the Stage-Storage Data table, starting from the lowest elevation to the maximum. Click on OK button to save the data.

Irregular Pond Design

Rectangular Shape

This method allows you to define a rectangular box or trapezoidal shape reservoir. Enter values in the Top Elevation, Base Elevation, Base Length and Base Width boxes. If you want to define a trapezoidal shape reservoir, enter the Length Slope Ratio and Width Slope Ratio. Multiple barrels are allowed in this type of pond. You also need to specify the Stage Increment. The **Max. Pond Storage** is the design capacity. When change the Max. Pond Storage value, the parameter selected in the Update Pond Parameter Options is updated automatically. Click on **OK** button to save pond parameters.

Rectangular Pond Design

Underground Pipe

This method allows you to specify a reservoir as a pipe. Pipes come in circular and rectangular shapes. Enter the pipe dimensions and the Invert Elev at which the pipe is located. Specify the Number of Barrels and the Stage

Increment. The **Stone Encasement** is around the pipe for additional storage. Click on OK button to save the pipe parameters.

Stage-Storage Curve

When you click on the Graph button, the Stage-Storage Curve dialog displays. An image is shown for you to view the stage vs. storage, stage vs area plot for the reservoir. The graph can be plotted into the CAD graphic by clicking on Draw button. When you click on the Draw button, the Stage-Storage Curve Settings dialog displays from where you can define how to plot the text and graph on screen.

Stage-Storage Curve

Stage-Storage Curve Draw Settings

Pulldown Menu Location: Structure > Stage-Storage

Keyboard Command: edit_stage_store

Prerequisite: a stage-storage file (.CAP)

Calculate Stage-Storage

This command calculates stage-storage values for a pond that is already drawn in the drawing. Before running this routine, the surface model for the pond must be created as a triangulation file with Triangulate & Contour or as a grid file with Make 3D Grid File. A closed polyline for the perimeter of the pond is also required. It has the option to save a stage-storage capacity file, in one of 2 forms (Carlson for readability, or Sedcad form, for importing into Sedcad). The type of file stored is set in Configure, Hydrology Module.

Prompts

Select Pond Surface

Select the .tin, .flt or .grd file that models the pond surface.

Pick the top of dam polyline: *pick the closed polyline perimeter*

Choose method to specify storage elevations (<Automatic>/Interval/Manual)? *Manual*

Range of pond elevations: *1202 to 1220*

Sediment Elevation (Enter for none): *1206*

Enter stage elevation (Enter for none): *1206*

Enter stage elevation (Enter for none): *1210*

Enter stage elevation (Enter for none): *1215*

Enter stage elevation (Enter for none): *1220*

Enter stage elevation (Enter for none): *press Enter*

Pond Storage Volumes Report

Pond Storage Volumes		11/23/2004 21:52		
Sediment Elevation: 1206.000				
Sediment Volume: 873.529 C.Y.				
Water Elev	Storage(AcreFt)	(C.Y.)	(C.F.)	Area(Acre)
1206.00	0.00000	0.0	0.0	0.141
1210.00	0.67919	1095.8	29585.4	0.208
1215.00	1.96486	3170.0	85589.4	0.322
1220.00	3.92578	6333.6	171007.1	0.476

Write stage-storage to file [Yes/<No>]? *press Enter* When saving a stage-storage capacity file, to be drawn in the Draw Stage-Storage Curve command, it is a good idea to limit the number of stages to a reasonable number, such as 6 to 12 stages. More than 12 will plot off the page in a long list, unless you use the option "Skip Every 2nd Table Entry". If the stages are at odd intervals, the Draw Stage-Storage Curve command will interpolate additional stages, so reducing the number of stages used works best for plotting.

Typical Pond for Calculate Stage Storage

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: postpond

Prerequisite: Surface entities that model the pond

Draw Stage-Storage Curve

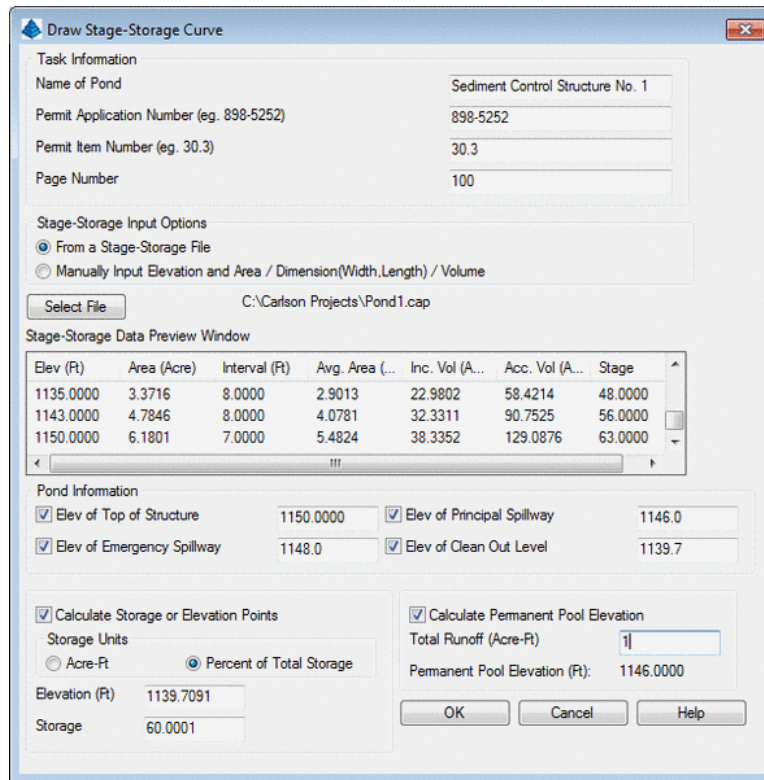

This routine draws a pond stage storage curve with pond elevation on the vertical axis and acre-feet of storage on the horizontal axis. It will plot and label the emergency spillway, principal spillway and cleanout levels and will produce a table of storage data. There is an option to plot the Stage-Area curve on the same graph. The program will read a *.CAP capacity file of pond storage, based on the surface area at each stage or elevation. CAP files (short for "capacity") are made by Design Bench Pond, Design Valley Pond, Rectangular Pond Design, Calculate Stage Storage and Calculate Pond/Pit Volumes.

In addition to CAP file-based inputs, you can enter pond dimensions directly by length-width, area at each stage, or volume at each stage. If stage-storage curves are loaded from file, which contains only volumes at different

stages, then the width and length columns are filled in as "N/A" (not applicable). Since volume-based entry does not include area information, no CAP files are stored with this option. However, the curves plot in all cases. Plots are sized to fit on standard letter sized 8.5" x 11" sheets at the selected scale for plotting. They are particularly suited for permit applications, so the program will prompt for permit number and page.

Prompts

The program is dialog-driven. The first dialog controls file loading and some pre-calculation options, and is shown below:

Task Information

This section allows for entry of the Name of the Pond, Permit numbers and the page number. These fields will be labeled on the final plot, ready to be inserted into a report.

Stage Storage Input Options

- **From a Stage-Storage File:** Using this option, load the CAP file with the Select File button. This will populate the preview window and fill in the top of structure elevation. If the goal is to set the emergency spillway at an elevation with storage at a certain acre-feet, enter the storage in the lower left, hit the Enter key, and calculate the appropriate elevation. A total runoff of the entered acre feet, subtracted from the acre-feet at the principal spillway, will set the recommended elevation of the "clean out level". If the pond silts up above that level, then the silt needs to be removed. For example, the minimum vertical separation between principal spillway and clean out level is 1.5 feet in some regions. To compute permanent pool elevations, enter the runoff quantities and hit the Enter key.

- **Elev of Top Structure:** This value is entered automatically, read in from the CAP file.
- **Elev of Emergency Spillway:** Enter this value either from the design, or from the Calculate Storage or

Elevation Points calculation.

- **Elev of Principal Spillway:** Enter this value either from the design, or from the Calculate Storage or Elevation Points calculation.
 - **Elev of Clean Out Level:** This is a value calculated usually by the Percent of Total Storage, or storage below the principal spillway, such as 60% of storage capacity.
 - **Calculate Storage or Elevation Points:** Select the units to be entered, enter either the elevation or storage, hit the Enter key to see the result.
 - **Calculate Permanent Pool Elevation:** Enter the total runoff and hit the Enter key to calculate the permanent pool elevation.
- **Manually input elevation and Area / Dimension (Width, Length) / Volume :** This option is used to manually enter the pond area, dimensions or volume at increasing stages (elevations), and all the options in the lower portion of the dialog turn off and are not available, since the pond characteristics are not yet known. Then prompting appears as shown below:

Input (A)rea, Length/Width (D)imensions or <V>olume: D

Stage No. 1

Elevation: 940

Width: 20

Length: 60

<Enter> for more, (R) to Revise, (E) to exit entry: If you made a mistake, you could enter R and then enter a revised Elevation, Width and Length. Otherwise, press Enter to continue.

Stage No. 2

Elevation: 945

Width: 30

Length: 70

<Enter> for more, (R) to Revise, (E) to exit entry: *press Enter*

Stage No. 3

Elevation <950.00>: The program defaults to the last interval.

Width: 40

Length: 80

<Enter> for more, (R) to Revise, (E) to exit entry: *E to exit*

A table appears, similar to the following:

Elev Width Length Area Interval Avg. Area Inc. Vol Acc. Vol Stage
(Ft) (Ft) (Ft) (Acre) (Ft) (Acre) (Acre Ft) (Acre Ft)

940	20.0	60.0	0.028	0.00	0.028	0.000	0.000	0.00
945	30.0	70.0	0.048	5.00	0.038	0.189	0.189	5.00
950	40.0	80.0	0.073	5.00	0.061	0.304	0.494	10.00

Areas are in acres. If the area method of entry were chosen instead, the user would have been prompted for area at each elevation (stage), and the summary table would be blank under the width and length columns. Similarly, if entry was by volume (in cubic feet), all width, length and area columns would be blank.

Calculate Storage or Elevation Points (y/<n>): y

Known (E)levation or known <S>torage:

Storage (e.g. 0.2 or %60 for 60% of total): %60

Storage: 0.30 Elevation: 946.759

Calculate Storage or Elevation Points (y/<n>): *press Enter.* This allows you to move on. The advantage of this option is the ability to find exact spillway and cleanout levels by experimenting with needed storages or desired elevations. For example, sediment cleanout levels are often set at 60% of total storage, which would be in this case 946.76.

Elevation of Top of Structure: 950

Elevation of Emergency Spillway: 948.5

Elevation of Principal Spillway (Enter if same): *press Enter*

Elevation of Cleanout Level: 946.76

Is Above Data OK (<y>/n): *press Enter.* 'n' leads to re-entry of above 4 items

Regardless of whether the stage-storage information was hand-entered or loaded from a CAP capacity file, both methods lead to the next dialog, which defines the drawing and labeling of the stage-storage/stage-area curve graph and text.

Draw Stage-Discharge Graph

This program draws a stage-discharge graph with the stage (water elevation) on the Y-axis and the discharge on the X-axis. The data to graph is read from a stage-discharge (.stg) file which can be created by several routines including Design Channel, Drop Spillway, etc.

First you are prompted to select a STG file to draw. Then the program asks for the ending discharge for the graph which defaults to the highest discharge in the file. Next this dialog is displayed to enter the graph scale and intervals. The height of the annotation equals the horizontal scale times the Axis Text Scaler.

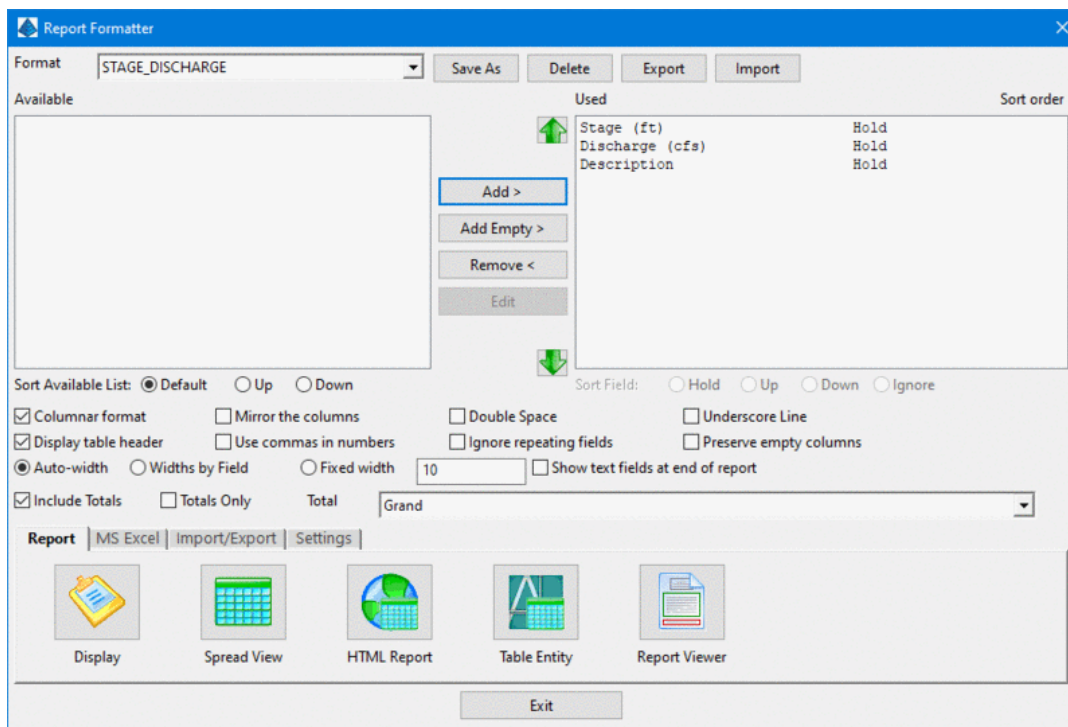

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: stage2

Prerequisite: Stage-Discharge file (.stg)

Report Stage-Discharge

This command simply loads and presents a stage-discharge file, for review and printing. The Report Formatter is used for selecting which fields to report and field properties. Also, the Report Formatter has output to different formats such as Excel. The procedure is to load the file from the normal file loading dialog, then review, edit or print it as shown below:

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: stg_report

Prerequisite: Creation of Stage-Discharge File in Pipe, Channel and Spillway Design routines

Merge Stage-Discharge Files

This command combines two or more stage-discharge files into a single, merged file. Ponds with two or more spillways (for example, a principal and emergency spillway) will outflow increasing volumes of water at higher elevations (stages) in the pond. In many ponds, a principal spillway allows baseline, non-storm flow to exit the pond, and an emergency spillway, placed at a higher elevation, permits storm flows to exit the pond as the water in the pond rises. Because flows increase for virtually all spillway types with increasing water elevation above the spillway, stage-discharge files (.STG files) will show increasing flow at increasing elevation. For ponds with more than one spillway, it is necessary to combine or merge the flows from the multiple spillways as they are encountered at higher elevation. The most typical application is to merge the flow from the principal and emergency spillways that are used on most pond designs. (See graphic in Draw Stage-Storage Curve.) These merged stage-discharge files are then used in the command Locate Structures, found under the Watershed pulldown menu. This command will also merge multiple selections of single stage-discharge files, or will accept a "pre-merged" stage-discharge file. In combination with the pond stage-storage files, the structures in a watershed layout will be used to compute hydrographs and determine the impact of pond placement and spillway design on reducing storm flows.

Prompts

The command is dialog-driven, in this order:

First Stage-Discharge File to Merge. (It is recommended to load the lowest elevation spillway file, typically the principal spillway stage-discharge file.)

Next Stage-Discharge File to Merge. (Here you would typically load the emergency spillway stage-discharge file.)

Merge Another Stage-Discharge File? Yes/No. Click Yes if there is another stage-discharge file, otherwise click No.

Choose the Output Stage-Discharge File. Name the output stage-discharge file.

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: merge_stg

Prerequisite: Spillway design routines that create Stage-Discharge Files, such as Drop Pipe Spillway Design, Pond Weir Spillway Design, Open Channel (Manning's Eq) and Pipe Culvert Design.

Channel Lining Analysis

This routine is used to design small open channels that are constructed as part of a highway drainage system. The roadside channels capture sheet flow from the highway pavement and backslope and convey the runoff to larger channels or culverts with the drainage system. There two classes of channel lining materials: rigid or flexible channel linings. Flexible linings are able to adjust to some change in channel shape and are used in this routine.

Four types of channels are available in the routine. They are **Rectangular**, **Triangular**, **Trapezoidal**, **Irregular** and **Circular Pipe** type. Enter design flow to calculate channel depth, or enter channel Depth to calculate channel flow. When lining is used, the lining shear stress is calculated too. There are six types of channel linings in the lining analysis and please refer to HEC15 for details.

The screenshot shows the 'Design Channel' software window. It is divided into several sections:

- Channel Parameters:** Includes fields for Name (Pond), Channel Type (Circular), Bottom Width (ft), Left Side Ratio, Right Side Ratio, Diameter (ft) (2.000), Channel Depth (ft), Profile Slope (%) (1.0000), and Manning's n (0.0120). There is a 'Use Lining' checkbox and a 'Select' button.
- Calculation:** Includes Design Flow (cfs) (22.348) and Flow Depth (ft) (1.5000). Buttons for 'Calculate Discharge' and 'Calculate Depth' are present.
- Results Table:** A table with columns for Parameter, Value, and Unit.
- Report Type:** Radio buttons for 'Standard Report' and 'Formatted Report' (selected). Buttons for 'Report' and 'Report Setup' are present.
- Buttons:** 'OK', 'Cancel', 'Load', 'Save', and 'Help' are at the bottom.

Parameter	Value	Unit
Flow	22.348	cfs
Depth	1.500	ft
Area of Flow	2.527	sq ft
Wetted Perimeter	4.189	ft
Hydraulic Radius	0.603	ft
Velocity	8.842	ft/s
Critical Depth	1.686	ft
Top Width	1.732	ft
EGL	2.715	ft

The screenshot shows the 'Design Channel' software window. The 'Channel Parameters' tab is active, with the 'Liner Parameters' sub-tab selected. The 'Name' field contains 'carlson' and the 'Channel Type' is set to 'Circular'. The 'Diameter (ft)' is 2. The 'Design Flow (cfs)' is 22.3480 and the 'Flow Depth (ft)' is 1.500. A table of calculated parameters is displayed below the input fields.

Parameter	Value	Unit
Flow	22.348	cfs
Depth	1.500	ft
Area of Flow	2.527	sq ft
Wetted Perimeter	4.189	ft
Hydraulic Radius	0.603	ft
Velocity	8.842	ft/s
Critical Depth	1.686	ft
Top Width	1.732	ft
EGL	2.715	ft

Grass Lining: Grass lining analysis is based on HEC15, chapter 4 - Vegetative lining and bare soil design.

The screenshot shows the 'Channel Parameters' software window with the 'Liner Parameters' sub-tab selected. The 'Lining Type' is set to 'Grass'. A table of grass lining parameters is displayed below the dropdown menu.

	Value	Unit
Grass Cover Density	Good	
Grass Growth Form	Sod	
Grass Stem Height	0.500	ft
Soil Type	Noncohesive	
Soil D75	0.050	in

Grass Turf Lining: this is a turf reinforcement with gravel/soil mixture. The gravel provides a matrix of sufficient thickness and void space to permit establishment of grass roots within the matrix. Turf analysis is based on HEC15, chapter 4 - Vegetative lining and bare soil design.

Channel Parameters **Liner Parameters**

Lining Type:

	Value	Unit
Grass Cover Density	Good	
Grass Growth Form	Sod	
Grass Stem Height	0.500	ft
Gravel D75	1.000	in

Riprap, Cobble, or Gravel Lining: These linings are considered permanent flexible linings. They may be described as a noncohesive layer of stone or rock with a characteristic size, which is D50. Its analysis is based on HEC15, chapter 6 - Riprap, cobble, and gravel lining design.

Channel Parameters **Liner Parameters**

Lining Type:

	Value	Unit
D50	0.450	ft
Stone Weight	165.000	lb/ft ³

Gabion Lining: Gabions (rock filled wire containers) represent an approach for using smaller rock size than would be required by riprap. The smaller rock is enclosed in larger wire units in the form of mattresses or baskets, and the thickness of the gabion mattress may be less than the thickness of an equivalently stable riprap lining. The analysis is based on HEC15, chapter 7 - Gabion lining design.

Channel Parameters **Liner Parameters**

Lining Type:

	Value	Unit
D50	0.450	ft
Stone Weight	165.000	lb/ft ³
Mattress Thickness	0.750	ft

RECP, Rolled Erosion Control Product: RECPs are developed for erosion protection of channels. These products consist of materials that are stitched or bound into fabric. RECP analysis is based on HEC15, chapter 5 - Manufactured (RECP) lining design.

Channel Parameters **Liner Parameters**

Lining Type:

	Value	Unit
Shear Stress On RECP	1.000	lb/ft ²
Shear Stress Mid	1.500	lb/ft ²
Manning's n Lower	0.038	
Manning's n Mid	0.034	
Manning's n Upper	0.031	
Soil Type	Cohesive	<input type="text"/>
Soil Class	GM: Silty gravels, gravel-sand	<input type="text"/>
Soil Plasticity Index	5	
Void Ratio	0.500	
Soil D75	0.050	in

Turf Reinforcement with RECPs: This is a non-degradable RECP composed of UV stabilized synthetic fibers, filaments, netting and/or wire mesh processed into a 3D matrix. Its analysis is based on HEC15, chapter 5 - Manufactured (RECP) lining design.

Channel Parameters **Liner Parameters**

Lining Type:

	Value	Unit
Grass Cover Density	Good	
Grass Growth Form	Sod	
Grass Stem Height	0.500	ft
Gravel D75	1.000	in

Report: Standard Carlson report and PDF report are available. Use **Report Setup** dialog to add/remove report contents.

Pulldown Menu Location: Structure > Channel Design > Channel Lining Analysis

Keyboard Command: channel_lining

Prerequisite: none

Channel Design - NonErodible Mannings Equation

This will compute channel depth, flow and velocity based on channel parameters such as side slopes, base dimensions and Manning's n value. It handles triangular, trapezoidal, rectangular and irregular channels. Entry of a depth leads to calculation of flow and velocity. Entry of one of the other items (flow or velocity) will lead to calculation of the remaining items. In addition to functioning as a channel calculator, the program will output a typical section or detail of the channel as well as a report of the channel output. The routine also works in metric units. It applies to

non-erodible channels, primarily. The user can select the Report button to output a report of the channel input and output values as well as a standard detail shown below for the above example.

Prompts

When the routine is selected, the dialog box shown below appears. Select, for example, a trapezoidal channel, equal sides, with side slopes of 3 (for 3:1) and a base dimension of 16. Enter the Manning's n value and channel slope as shown. Note that 0.1, in English units, means 0.1 foot drop per 100 foot of length. Then at the lower right, plug a value of 4.5 for the depth. This will calculate a flow of 862 CFS and a velocity of 6.5 fps, as shown below. If the channel is divided into two types of materials (paved lower portions and vegetated upper portion), you can specify a second Manning's n for the upper banks, as shown in the dialog.

To use the routine as a calculator, enter the known value in the lower right area of the dialog (flow, depth, or velocity), then press enter while still in the entered item. The other two items are then calculated. Note that the routine will default to the last values used during the current Carlson work session, and will capture the flow values calculated in Water Runoff under the Watershed Pull-down. When entering the Manning's n value, a table of n values can be brought up and an appropriate Manning's selected. Among the output options is "Draw Channel Detail", which will draw and annotate as shown below. Since Open Channels are often used as emergency spillways, the Write Stage/Discharge File will output an .STG file for use in the command Locate Structure under Watershed, for pond design and storm routing and hydrograph calculations.

Use Drawing Setup to activate Metric or English outputs. If English is configured, the formula $v = (1.486/n)(R^{2/3})(s^{1/2})$ is used, where n is the Manning's value, R is the water cross section divided by the wetted perimeter and s is the slope ratio. If Metric is configured, the formula becomes $v = (1.0/n)(R^{2/3})(s^{1/2})$ and outputs are in meters. To test metric, set to metric in Drawing Setup. Then for a rectangular, concrete open channel of 12.0 meters width, slope of 0.28%, Manning's n of 0.013 and depth of 2.5 meters, you should compute a velocity of 5.94 m/s and Q (flow) of 178 cubic meters/second.

Prompts

Channel Design (Manning's Eq) dialog: Fill in values.

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: channel1

Prerequisite: None

Channel Design - Erodible Mannings Equation

This command uses the same Manning's equations as non-erodible channel design. In this case, the discharge and velocity are known. The velocity must be less than a maximum to prevent erosion. The program calculates the channel dimensions that meet the requirements.

First choose the channel and water type. Then either enter the Manning's n, velocity, and tractive force or select them from a table of channel types by clicking Select from Table. Also fill in the slope and discharge. Finally, choose either Calc Base or Calc Ratios to compute the channel dimensions. You may also fill in the channel dimensions and choose to Calc Discharge or Calc Depth. The Standard Parameters are used in drawing the channel detail. When OK is selected, the routine ends and the channel is drawn if Draw Channel Detail is checked.

When choosing Calc Discharge, Calc Base, Calc Ratios or Calc Depth, there will be a message **Error: unable to solve these parameters** on the top line if the design parameters never reach erosion conditions for any channel dimension. Consider an extreme error case with a discharge of 1 cfs, a slope of 0.1%, and a velocity of 5.0 fps.

There are no dimensions that meet these requirements. So, for this case, the channel dimensions can be set anyway to avoid erosion.

Prompts

Channel Design (Erodible) dialog: Fill in values.

Pulldown Menu Location: Structure in Hydrology

Keyboard Command: channel2

Prerequisite: None

Grass Channel Design

This feature allows you to design grass lined channels having one of three different cross sections:

1. Triangular
2. Parabolic
3. Trapezoidal

The design methodology that is used is that recommended in Chapter 7, Grass Waterways, Part 650 of the Engineering Handbook published by the United States Department of Agriculture Natural Resources Conservation Service. It uses the equations found in Appendix B of Chapter 7. The solution of the equations is an iterative process and results in several possible cross sections having varied dimensions. The designer must then use engineering judgment to choose the final channel cross section dimensions based on the site layout, machine crossing restraints, excavation equipment to be used, etc.

Basic Design Parameters

Use the entries on the Basic Design tab (see below) to specify the design methodology to use and the basic shape and limiting dimensions of the cross section.

The screenshot shows the 'Grass Channel Design Parameters' dialog box with the 'Basic Design' tab selected. The dialog is divided into several sections:

- Design Methodology:** Two radio buttons are present: 'Retardance Curves' (selected) and 'Calculate using grass parameters'.
- Cross Section to Use:** Three radio buttons are present: 'Triangular', 'Parabolic', and 'Trapezoidal' (selected).
- Design Requirements:** Four input fields with units:
 - Design peak flow: 0.00 cfs
 - Channel Centerline Slope: 0.000 percent
 - Maximum Channel Top Width: 1000.00 ft.
 - Freeboard: 0.00 ft.
- Construction Considerations:** Three input fields with units:
 - Side Slope Ratio: 1.75 :1
 - Min. Channel Bottom Width (optional): 0.00 ft.
 - Channel Depth Search Increment: 0.1 ft. (with a dropdown arrow)

At the bottom of the dialog, there are four buttons: 'Draw', 'Report', 'Calculate', and 'Exit'.

Design Methodology

You may use one of two available design methodologies:

1. **Retardance Curves** - retardance curves can be used when specific data on the condition, density, height and other information for the grasses being used to line the channel are not available. This method will generally result in a safe but relatively conservative design. In this method the designer must specify one of several available design curves (A through E) for the best and worst grass conditions. (see the Retardance Curve Design tab below)
2. **Calculate using grass parameters** - this method requires the designer to have a more detailed knowledge of the specific grass being used. This allows the designer to produce a safe design that may not be quite as conservative as the retardance curve method.

Cross Section to Use

Choose the type of cross section you prefer

1. **Triangular**
2. **Parabolic**
3. **Trapezoidal**

Design Requirements

Design Peak Flow - Enter the Design Peak Flow (cubic feet or cubic meters per second) as obtained from your watershed model or other source.

Channel Centerline Slope - Enter the percent slope of the reach of the channel you are designing.

Maximum Channel Top Width - You may specify a starting maximum channel top width. This value will limit the maximum top width that will be considered in the design calculations. This should be set to match the largest channel that your site could accommodate or the maximum that is desirable.

Freeboard - Specify how much freeboard you wish to add to the channel depth above the design water flow depth. This is a matter of engineering judgment and should, among other things, consider the consequences of overtopping and the probability that that may happen. You could estimate this value by doing a preliminary design using a more severe flow than the actual design peak flow.

Construction Considerations

Side Slope Ratio - specify the minimum slope ratio for the side slopes of the channel. For a parabolic channel this will be the side slope ratio calculated at the water surface. This should be set keeping in mind construction limitations and what types of vehicles or machinery must cross the channel, along with possible erosion due to runoff, etc.

Min. Channel Bottom Width (optional) - This field is only available in the case of a Trapezoidal cross section. If this value is not specified a minimum value of 1 foot (or 30 cm) will be assumed. This value should be set to accommodate construction equipment and can also effect ease of crossing by other vehicles or machinery.

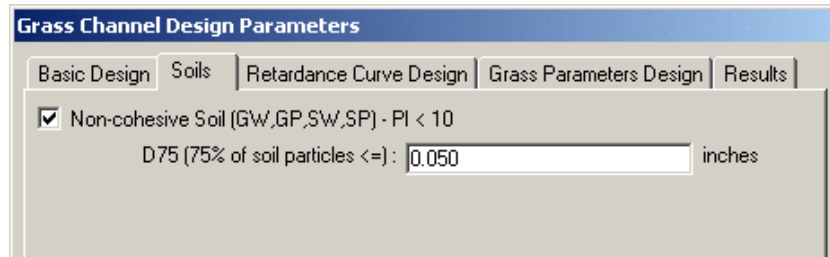

Channel Depth Search Increment - This value is used to increment the depth of the channel for the iterative solution and thus sets the significant figures used during the design calculations and the resulting design dimensions reported. This value should generally reflect the elevation accuracy expected for the construction of the channel cross section.

Soils

The **Soils** tab of the **Grass Channel Design Parameters** dialog allows you to specify the type of soil encountered along the reach of the channel being designed.

Non-cohesive Soils:

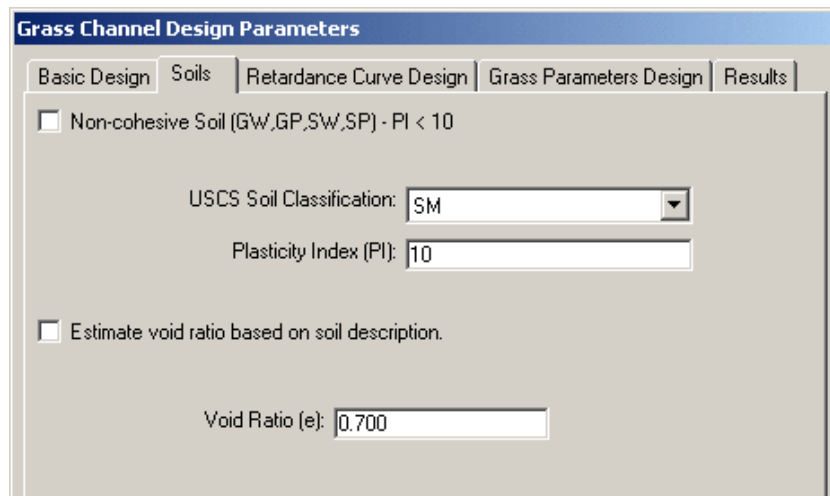

If the soil is non-cohesive then check the **Non-cohesive Soil** check box (see below). This means that the soil must have a Uniform Soil Classification System (USCS) classification of GW, GP, SW or SP (well or poorly graded gravel or sand) with a Plasticity Index (PI) that is less than 10.

When the **Non-cohesive Soil** check box is checked the **D75 (75% of soil particles <=)** edit box appears. Specify the opening size (in inches or millimeters) of the sieve that 75% of the soil particles will pass through.

Cohesive Soils

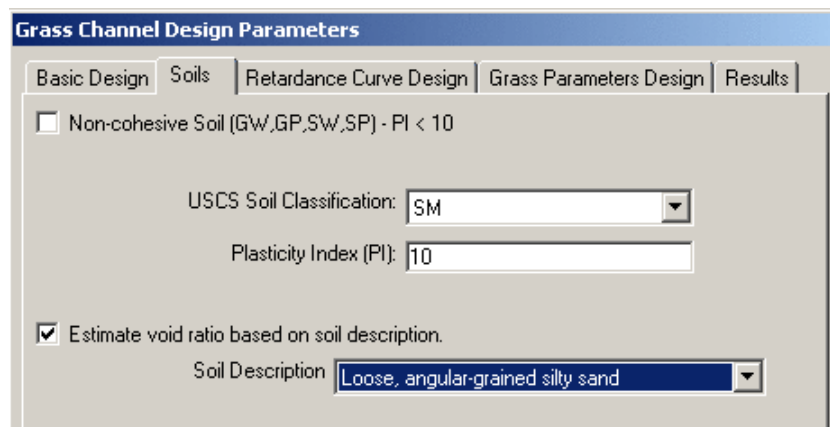

If the soils have a significant clayey or silty portion and have a $PI \geq 10$ then the **Non-cohesive Soil** check box should be unchecked (as shown below).

USCS Soil Classification - choose the correct USCS classification of the soil in this reach of the channel from the drop down list

Plasticity Index (PI) - type in the PI.

Estimate void ratio based on soil description - if this checkbox is checked the void ratio will be estimated from the soil description (see below). If it is unchecked the user must specify the void ratio.

Void Ratio (e) - enter the void ratio for the soil along this reach of the channel. (shows only if **Estimate void**

ratio based on soil description checkbox is *unchecked*) **Soil Description** - choose the description that best fits the soils encountered along this reach of the channel. (shows only if **Estimate void ratio based on soil description** checkbox is *checked*)

Retardance Curve Design

If you chose the **Retardance Curves Design Methodology** on the **Basic Design** tab, then you use this tab to specify the best and worst grass conditions for the design.

Note: If you have chosen the **Grass Parameters Design Methodology** and you click this tab, you will only see the message:

***** Using Grass Parameters Design Method *****

in the middle of the window.

Retardance Curve for Best Grass Condition

From the drop down list, choose A, B, or C retardance curves to be used for the best grass condition. This condition will control the minimum design depth of the water since grass in its best condition will offer more resistance to flow and cause the water to flow deeper. If you are unsure of which retardance curve to use, choose any one of the curves and read the grass descriptions in the window below the drop down list, then choose the one that fits the expected best site conditions.

Retardance Curve for Worst Grass Condition

Use the drop down list to choose the retardance curve (C, D, or E) to be used for the worst grass condition. This condition will control the maximum design depth of the water since grass in its worst condition will offer less resistance to flow and it or the soil may be damaged by flows above this maximum level. If you are unsure of which retardance curve to use, choose any one of the curves and read the grass descriptions in the window below the drop down list then choose the one that fits the expected worst case site conditions.

Grass Parameters Design

If you chose the **Calculate using grass parameters Design Methodology** on the **Basic Design** tab, then you use this tab to specify the grass parameters for the best and worst grass conditions for the design.

Note: If you have chosen the **Retardance Curve Design Methodology** and you click this tab, you will only see the message:

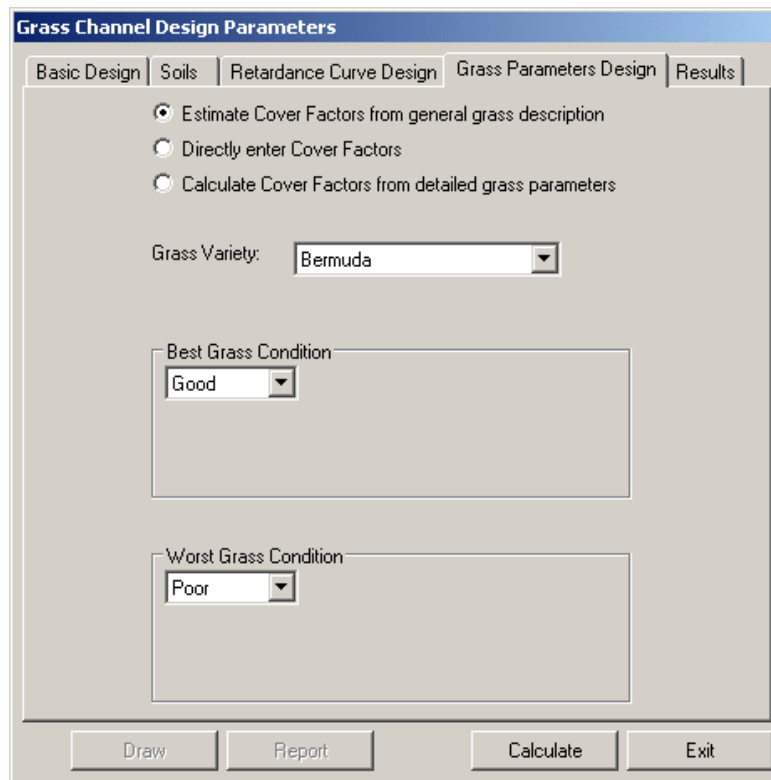

***** Using Retardance Method for Design *****

in the middle of this window

When using the Grass Parameters design method you may choose to use one of three methods to specify the cover factors (CF) for the best and worst grass conditions. Cover Factors describe the ability of the vegetal cover to reduce the maximum hydraulic stress on the soil and is related to the type and quality of the vegetal cover. The three available options are described below.

Estimate Cover Factors from general grass description

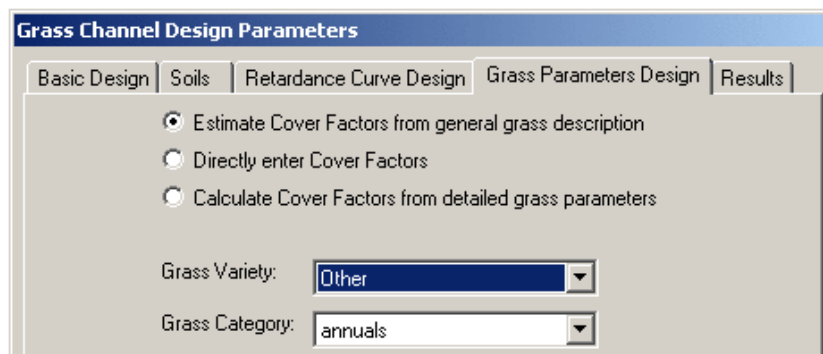

When you click the **Estimate Cover Factors from general grass description** radio button, the items that are visible in the dialog are as shown below:

The screenshot shows the 'Grass Channel Design Parameters' dialog box with the following settings:

- Radio buttons: Estimate Cover Factors from general grass description, Directly enter Cover Factors, Calculate Cover Factors from detailed grass parameters
- Grass Variety: Bermuda
- Best Grass Condition: Good
- Worst Grass Condition: Poor
- Buttons: Draw, Report, Calculate, Exit

Grass Variety - choose the grass variety that will be used to line the channel. If you cannot find the variety you wish to use in the list then choose **Other** (at the bottom of the list).

The screenshot shows the 'Grass Channel Design Parameters' dialog box with the following settings:

- Radio buttons: Estimate Cover Factors from general grass description, Directly enter Cover Factors, Calculate Cover Factors from detailed grass parameters
- Grass Variety: Other
- Grass Category: annuals

Grass Category - choose the general category of the grass to be used to line the channel. (this item only shows if you chose **Other** as the Grass Variety)

Best Grass Condition

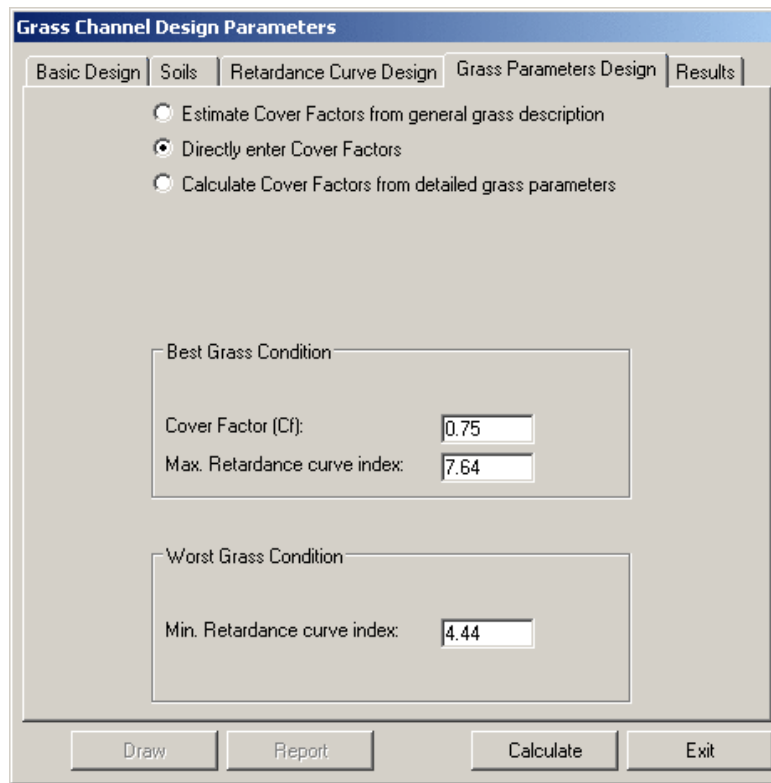

Choose the condition category that describes the expected best grass condition.

Worst Grass Condition

Choose the condition category that describes the expected worst grass condition.

Directly enter Cover Factors

When you click the **Directly enter Cover Factors** radio button the items visible in the dialog are as shown below:

Best Grass Condition

Cover Factor (Cf) - Enter the cover factor for the expected best grass condition.

Max. Retardance curve index - enter the maximum retardance curve index for the expected best grass condition.

Worst Grass Condition

Min. Retardance curve index - enter the minimum retardance curve index for the expected worst grass condition.

Note: The retardance curve index values for the various SCS retardance classes have been published in the publication quoted in the first paragraph of this help item and can be used to estimate the retardance curve index to use:

retardance Class retardance curve index (Ci)

A 10.0

B 7.64

C 5.60

D 4.44

E 2.88

Calculate Cover Factors from detailed grass parameters

If you click the **Calculate Cover Factors from detailed grass parameters** radio button, the items appearing in the dialog are as shown below:

Grass Variety - use the drop list to specify the grass variety to be used to line the channel. If none of the varieties listed are suitable you can choose **Other**.

Grass Category - choose the general category of the grass to be used to line the channel. (only appears if Grass Variety chosen is **Other**)

Best Grass Condition

Maximum Stem Density - enter the estimated stem density for the best grass condition

Maximum Stem Height - enter the estimated stem height for the best grass condition

Worst Grass Condition

Use the drop down list to choose the condition category that best fits the expected worst grass condition.

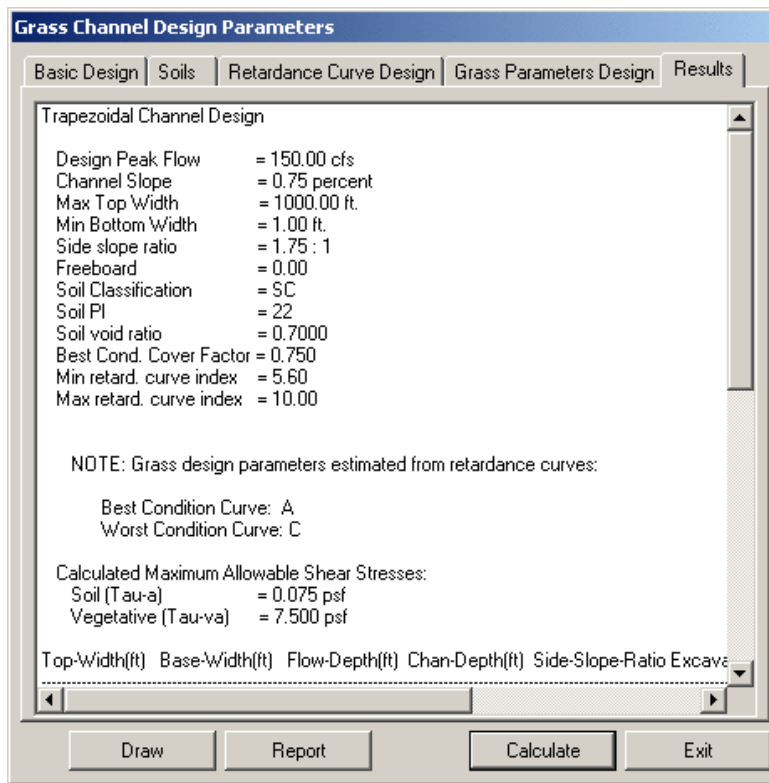

Minimum Stem Density - enter the estimated stem density for the worst grass condition

Minimum Stem Height - enter the estimated stem height for the worst grass condition

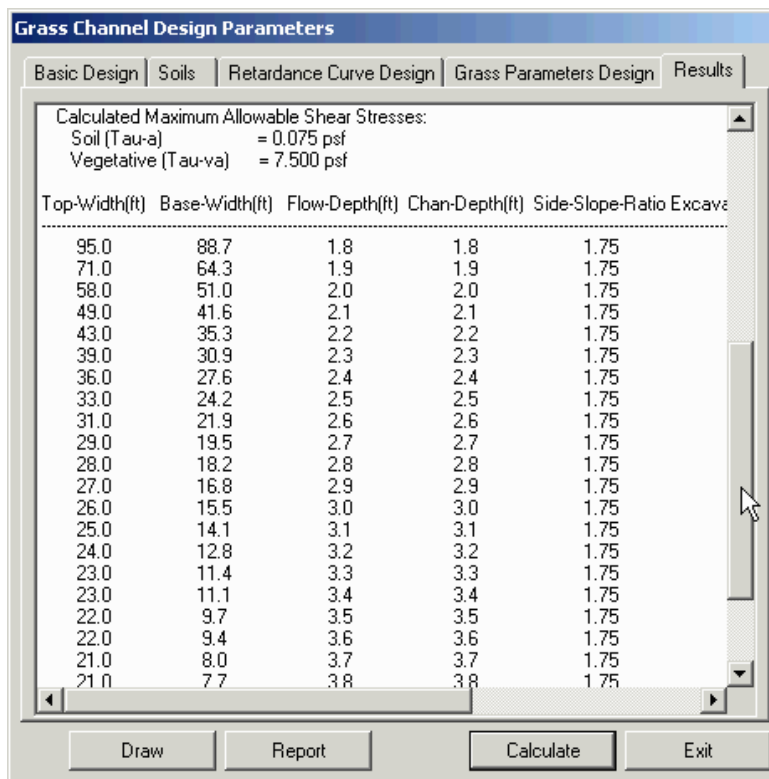

Once you have specified the basic design, soil, and grass parameters you can click the **Calculate** button. If no data entry errors are detected, the input data and the resulting channel design(s) will be listed on the **Results** tab.

Results

After the design calculations have been made, the input data and the resulting channel design information will be listed on the **Results** tab.

To view the channel design cross section information in this window, you merely left click on the scroll bar, hold the mouse button down and drag the scroll bar downward.

The Results listing starts with a recap of the design parameters and the resulting calculated maximum allowable stresses for the soil and the vegetation. Below that begins a list of channel configurations that satisfy the specified design parameters and thus will safely carry the design peak flow (with some freeboard - if specified). The channel geometry is described in six columns for a trapezoidal channel and in five columns for both triangular and parabolic (neither triangular nor parabolic have a bottom width column). The columns are labeled: Top-Width, Base-Width

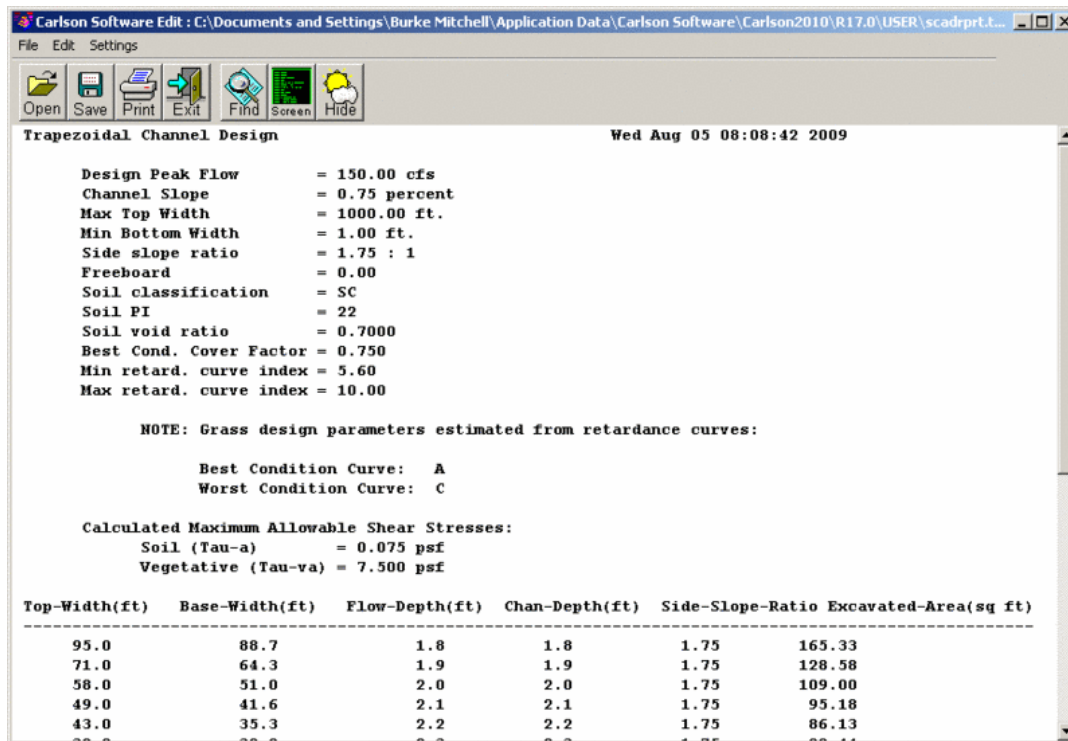

(only for trapezoidal), Flow-Depth, Chan-Depth, Side-Slope-Ratio, and Excavated-Area. The units will be specified according to the unit settings specified in Carlson Configure or CG Options. The Flow-Depth and the Chan-Depth will only differ if freeboard is not zero.

Note: If no safe design is possible for the specified input parameters the following message will appear below the column titles:

**** No valid channel cross section can be determined given specified parameters ****

Viewing, printing and/or saving the design report

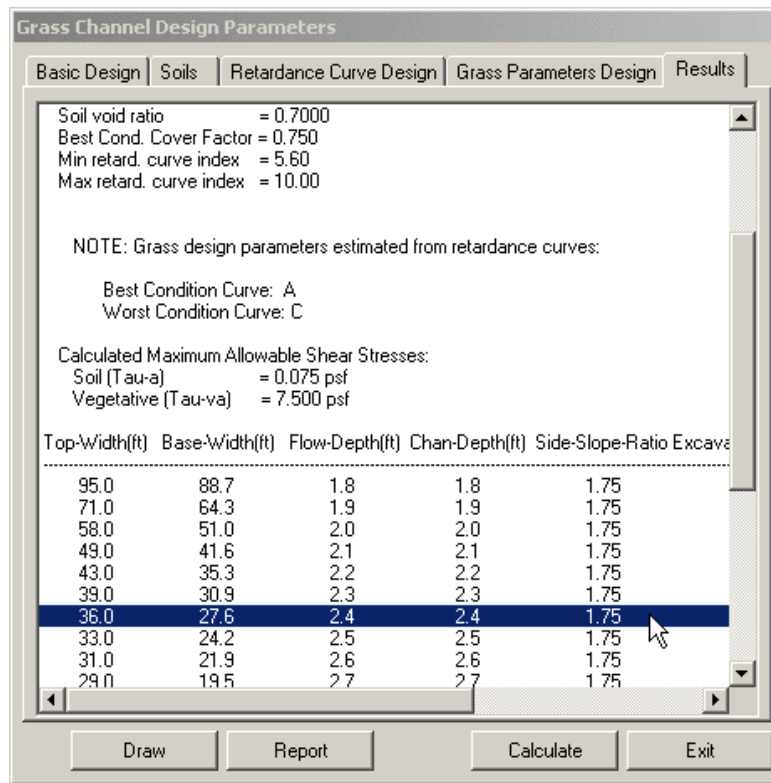

To view the design report click the **Report** button. The report will come up in the Carlson Editor, an example of which is shown below.

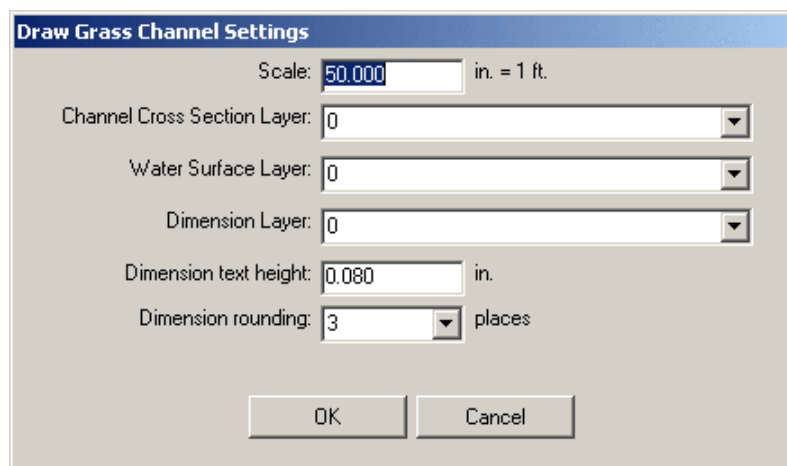

You can now view the input data and the results as well as save them to a text file and/or print them.

Draw the design channel cross section

Once the design calculations have been completed and the Results tab is showing, review the available channel geometries and choose the design you wish to use. To choose a design to be drawn to the current drawing, highlight the desired geometry on the Results tab as shown below:

After highlighting a specific design geometry by clicking on that line, click the Draw button to draw the channel cross section in the current drawing. This will bring up the **Draw Grass Channel Settings** dialog (see below).

Draw Grass Channel Settings

Scale - enter the scale at which the channel cross section is to be drawn. This may default to the current scale of your drawing but may be changed to a larger or smaller scale.

Channel Cross Section Layer - specify the layer on which the channel cross section lines are to be drawn. You may choose an existing layer by using the drop down list or you may specify a new layer by typing it in. If you specify a layer that does not currently exist, the layer will be created.

Water Surface Layer - specify the layer on which the water surface line is to be drawn. You may choose an existing layer by using the drop down list or you may specify a new layer by typing it in. If you specify a layer that does not currently exist, the layer will be created.

Dimension Layer - specify the layer on which the channel dimensions are to be drawn. You may choose an existing layer by using the drop down list or you may specify a new layer by typing it in. If you specify a layer that does not currently exist, the layer will be created.

Dimension text height - specify the height in plotted inches.

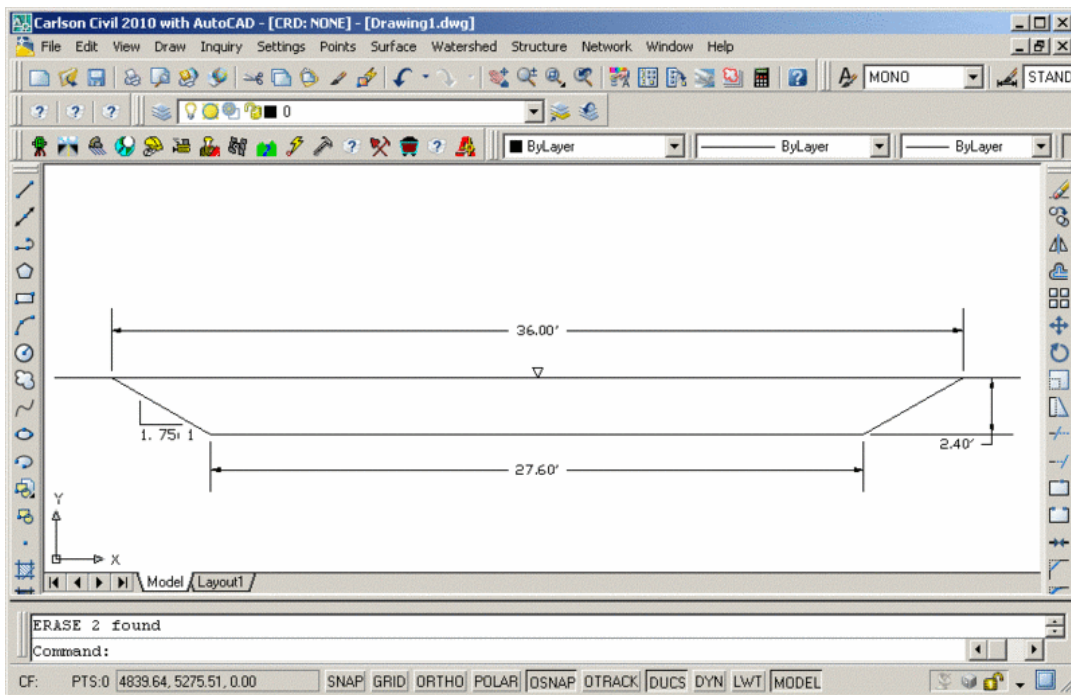

Dimension rounding - use the drop down list to specify the number of decimal places to be used for the dimensions.

Once the settings have been specified, click the **OK** button to proceed with the drawing or **Cancel** to return to the **Grass Channel Design Parameters** dialog

If you clicked the **OK** button you will be returned to the drawing with the following command line prompt:

Pick location for channel cross section drawing: pick a point on the screen for the upper left hand edge of the cross section.

The channel cross section will then be drawn (see an example below) and you will be returned to the **Grass Channel Design Parameters** dialog where you can choose to draw another cross section from the current design list or enter the design parameters for a redesign of the current reach or the design of another reach of this or another channel alignment.

When all designs are completed and you wish to close the dialog, click the **Exit** button.

Prompts

Use the dialog as described above.

When drawing the cross section, this prompt will appear:

Pick location for channel cross section drawing: pick a point on the screen for the upper left hand edge of the cross section.

Pulldown Menu Location: Hydrology Menu - Structure > Channel Design > Grass

Keyboard Command: cg_grass_chan

Prerequisite: None

Pipe Culvert Design

A culvert is a hydraulically short conduit, which can be used to convey stream flow underground through a roadway embankment or other flow obstructions, or used as an outlet structure attached to a detention pond. Culverts come

in circular and rectangular cross sections, and concrete, corrugated steel, aluminum and plastic materials.

The hydraulics of a culvert are complex since several flow control types may exist. The methods that Pipe Culvert Design uses are from FHWA Hydraulic Design Series No. 5 (HDS-5), Hydraulic Design of Highway Culverts. There are two flow controls: inlet control and outlet control. Under **Inlet Control**, the culvert's entrance characteristics determine its capacity, and the culvert is capable of conveying a greater discharge than the inlet will accept. With **Outlet Control**, the inlet can accept more flow than the culvert can carry because of the head loss due to the friction along the barrel or the high tailwater elevation. Furthermore, because culverts are generally not long enough to achieve uniform flow, the flow profile inside is often gradually or rapidly varied flow. In Pipe Culvert Design Settings tab, you may specify the flow control type to design the culvert. If you choose the Optimum option, both inlet control and outlet control calculations are performed, along with the gradually varied flow analysis. The worst-performing control condition is then used to evaluate the proposed design, i.e. the greater of the inlet control headwater and the outlet control headwater is the controlling headwater. Please refer to HDS-5 for details.

Gradually Varied Flow occurs for free surface flow conditions. This method computes water surface depth curve along the length of the barrel and are developed in an upstream direction by standard step method. In standard step analysis, the reach is divided into a number of sub0reaches. Computations are performed in steps from one section to the next, where the depth is incremented or decremented to yield a correct energy balance in the basic equation.

HY-8 Method version 7.5 was introduced in Carlson 2018. HY-8 automates the design methods described in HDS-5 and in HEC-14. Version 7.5 is the latest version and is available on FHWA website.

One significant difference in HY-8 is inlet control analysis. Carlson computes inlet control headwater strictly by the inlet control questions presented in HDS-5. HY-8 uses polynomial curve fits for inlet control headwater computation. The culvert inlets must have HY-8 Inlet Polynomial Coefficients in order to run HY-8 calculation.

The outlet control utilizes HDS-5 equations, and also conducts more complex water surface analysis based on seven flow profile types.

Please refer to HY-8 User Manuals for more details.

Outlet	part	7		M2, H2, A2		c	Critical

From the Structure menu in the Hydrology Module, choose Pipe Culvert Design to display the design dialog. Click on Load button to load an existing culvert file to view or modify it, or a new file to start a fresh design. From the Solve For list, select the value that you want to calculate. The available values are: Discharge, Headwater and Size. You may choose Size/Discharge or Size/Headwater to compute the exact discharge or headwater values after the size has been solved.

Settings

Under the Settings tab, Control Type is used to calculate culvert flow as described above. Users can also set Slope display format in either ft/ft or percentage.

Culvert Cross Section Tab

From the Shape list, select the type of culvert that you want to define. The available shapes are Circular and Box. From the Material list, select the material for the culvert such as Concrete or CMP/Aluminum. You can use the Library function next to Material to select the material and Manning's n from the pipe material library and to edit or add to this library. If you don't solve for the culvert size, enter the values in the Diameter box or Height and Width boxes depending on the culvert shape. In the Manning's n box, the Manning's n value is usually automatically set after the material type is chosen, but you can also type a different value manually. In the Number of Barrels box, enter the Number of Barrels for the culvert.

The Culvert Inlet list contains the inlet types available for the current culvert shape. It updates with different culvert shapes and materials. All the inlet types are specified in HDS-5. K_e is the entrance loss coefficient, which is depending on the culvert shapes and inlet types. It'll update with different chosen culvert shape and inlet type, you can also type the value in the box. The Library button next to the K_e field opens the Culvert Inlet Library dialog and allows users to create new Culvert Inlet Types.

Culvert Cross Section

Culvert Profile Tab

Inlet Invert is the elevation of the bottom of the culvert at the upstream end, while Outlet Invert is the elevation of the bottom of the culvert at the downstream end. In the Length box, enter the true culvert pipe length. The culvert slope will be calculated after entering the above three values and displayed in the Slope box. You may also change the outlet invert by entering a slope for the culvert. The most efficient way to get the culvert parameters filled is to select the 3D polyline that represents the culvert. Pick button allows you to pick a 3D point that represents the Inlet/Outlet invert.

Culvert Profile

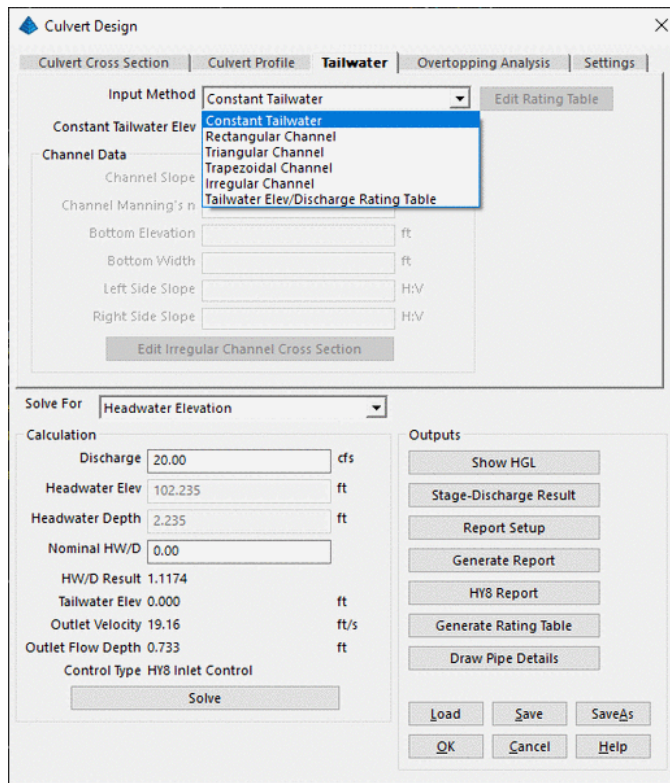

Tailwater Tab

There are six ways to calculate culvert tailwater: Constant Tailwater, Rectangular Channel, Triangular Channel, Trapezoidal Channel, Irregular Channel, and Tailwater Elev./Discharge Rating.

The Constant Tailwater method allows you to specify a single elevation for the culvert design regardless of the culvert discharge. This option is useful when the culvert is discharging into a large reservoir since the change in water surface elevation due to the culvert discharge is negligible.

The Rectangular/Triangular/Trapezoidal/Irregular Channel tailwater methods allow you to specify the channel downstream of the culvert. The culvert tailwater elevation will vary with discharge, and will be equal to the channel invert elevation plus the normal depth of flow in the channel for the current discharge. Channel Data will become available for input if chosen.

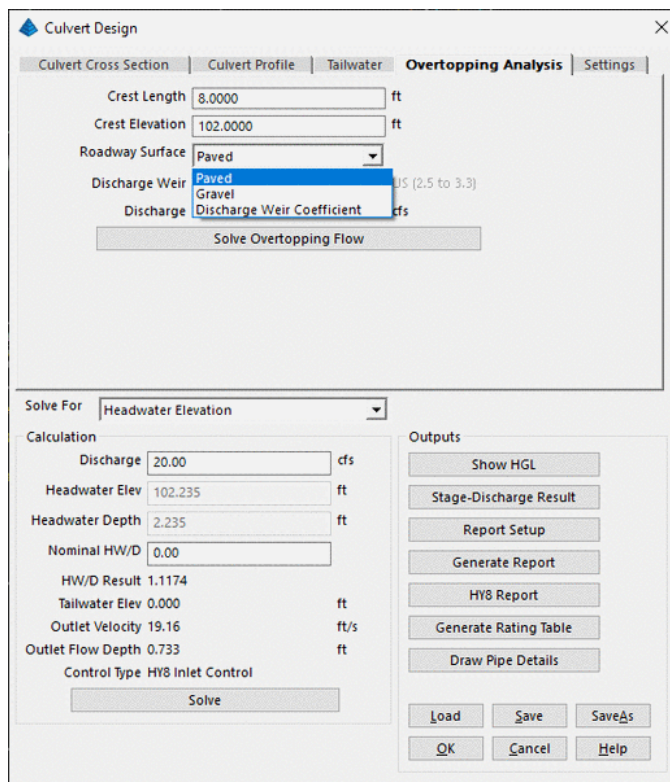

The Tailwater Rating method allows you to input a discharge/tailwater elevation table. Linear interpolation and extrapolation are used to calculate the tailwater for discharges not specified in the table.

Tailwater

Overtopping Analysis Tab

When the culvert headwater begins to rise above the elevation of the roadway, overtopping will occur. Overtopping flow is modeled as a special type of weir flow expressed by the general broadcrested weir equation. Enter values for Crest Length, Crest Elevation, Weir Coefficient in the dialog and overtopping flow can be calculated for the current culvert headwater elevation.

Overtopping Analysis

Calculation

In the Discharge box, enter the flow rate in the culvert. In the Headwater Elev box, enter the water surface elevation at the upstream end of the culvert. You can also enter the Headwater Depth then the program will add the depth value to the inlet invert to get the headwater elevation. If you are solving for either discharge or headwater, the corresponding box will be disabled. Section Size Library allows you to specify as many as available pipe sizes for solving for culvert size. After the hydraulic calculation, the smallest, large enough, available pipe size will be chosen. Please refer to the Pipe Size Library command for defining pipe sizes.

When the Nominal HW/D Ratio is greater than 0, the headwater is always set by the ratio and pipe size. The HW/D result is the ratio of the actual headwater depth and the selected pipe size.

Click on Solve button, depending on Solve For selection, the discharge, headwater elevation, culvert size and the tailwater elevation are calculated and displayed in the dialog correspondingly. The Outlet Velocity and Flow Depth are calculated and shown, and the Control Type is also illustrated.

Outputs

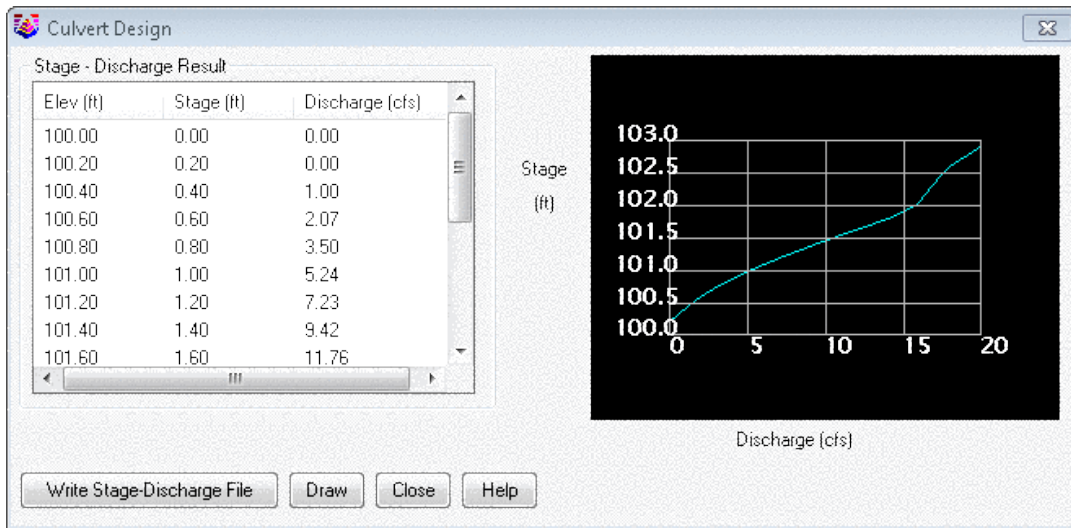

After culvert calculation, click on the **Show HGL** button to show the culvert water surface profile, normal flow level, critical flow level, as well as headwater elevation and tailwater elevation.

HGL Dialog

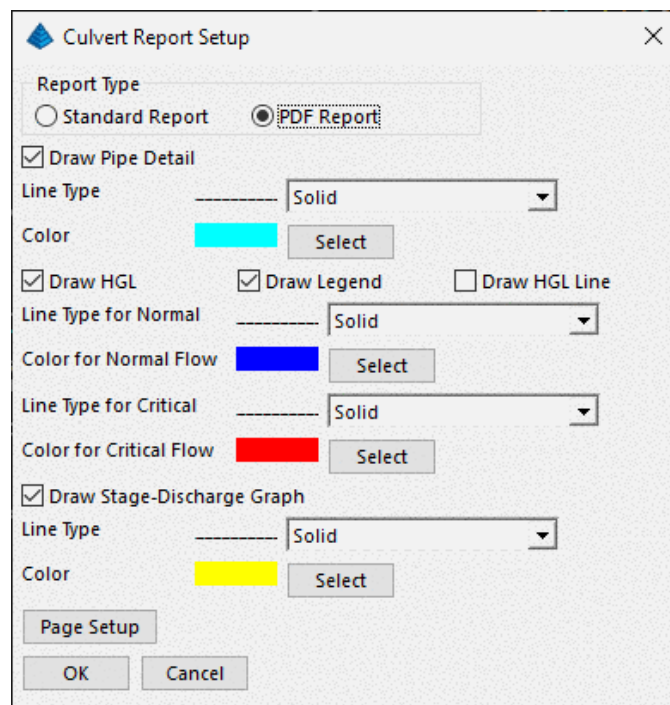

Click on the **Stage-Discharge Result** button to display the stage-discharge curve in the Stage-Discharge Result Dialog. From this dialog, you can view the stage-discharge curve, write the result to a stage-discharge file(.STG), and draw the graph into the CAD graphic. When you click on the Draw button, the Stage-Discharge Curve Settings dialog displays from where you can define how to plot the text and graph on screen.

Stage-Discharge Limits

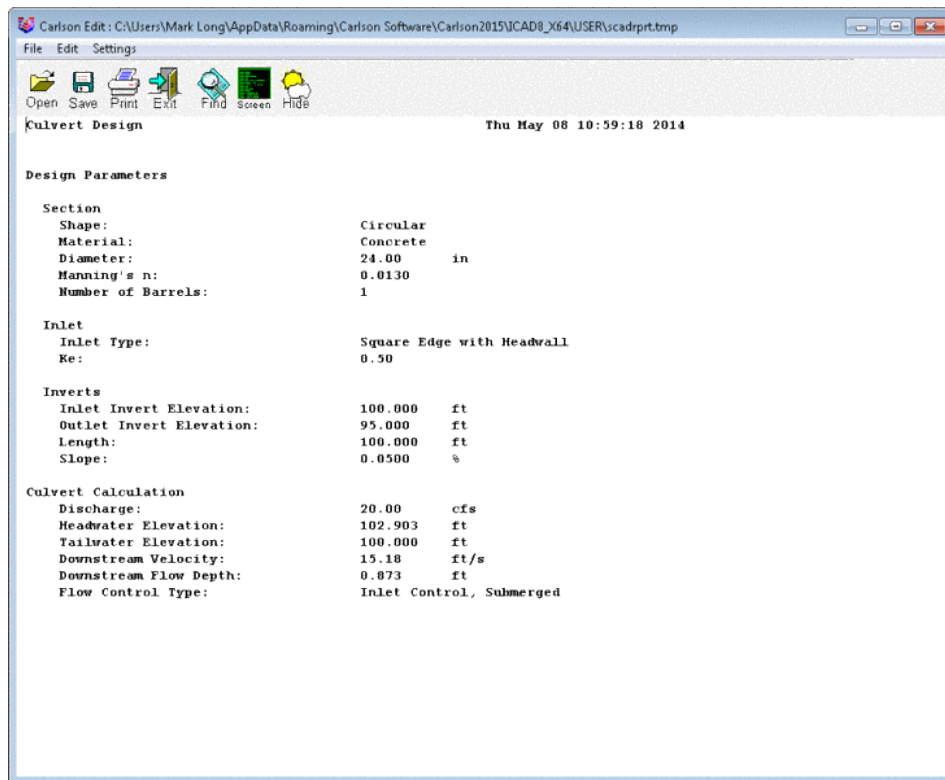

Stage-Discharge Dialog

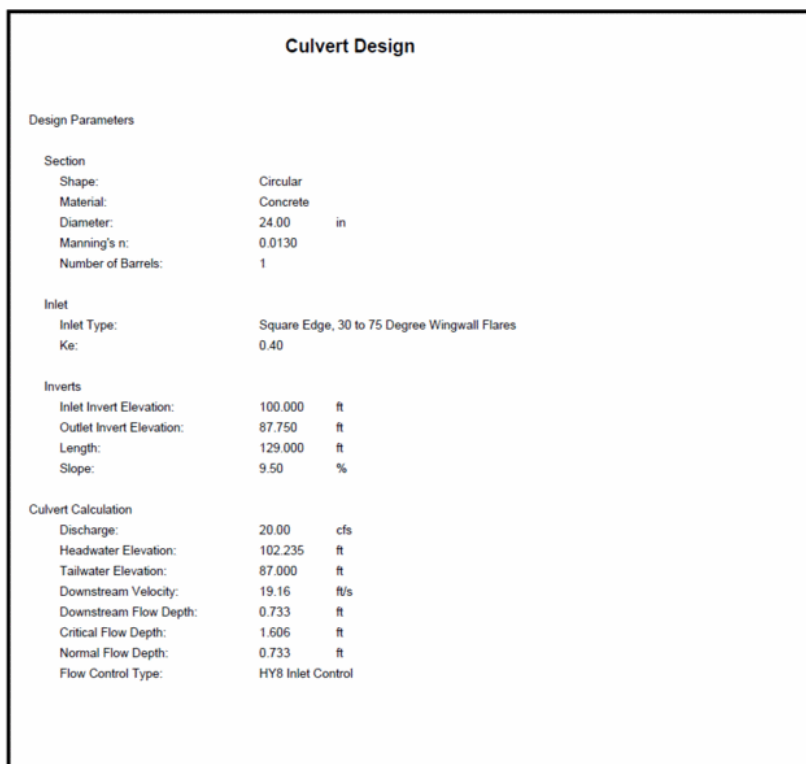

Report Setup button opens the Culvert Report Setup dialog where users can select the Report Type, what data and result to be in the report, as well as the graph color and line types.

Click on **Generate Report** button, the program will present a report screen that contains detailed information regarding the design parameters and the calculations. The report window provides the options of printing, drawing the report in AutoCAD or storing the report to a file. Shown below is an example.

Culvert Report

Culvert PDF Report

When HY8 method is used, click on **HY8 Report** button to generate the HY8 PDF report that based on the HY8 PDF report template. Shown below is an example.

A **rating table** presents the discharge-headwater relationship in the tabular form. It can be displayed in a Microsoft spreadsheet or a standard report. Click on Generate Rating Table button to open Rating Limits dialog. In the Variant list, select the independent variable. The available variables are Discharge and Headwater. Enter data in the Minimum, Maximum and Increment boxes. Enter the Tailwater Elev and select the decimal setting from the Decimals list. When you finish entering data, click on OK button to calculate the rating table. A rating table example is shown below in the standard report format. The first column Discharge is an independent variable, and the other columns are computed variables.

Draw Pipe Detail Settings

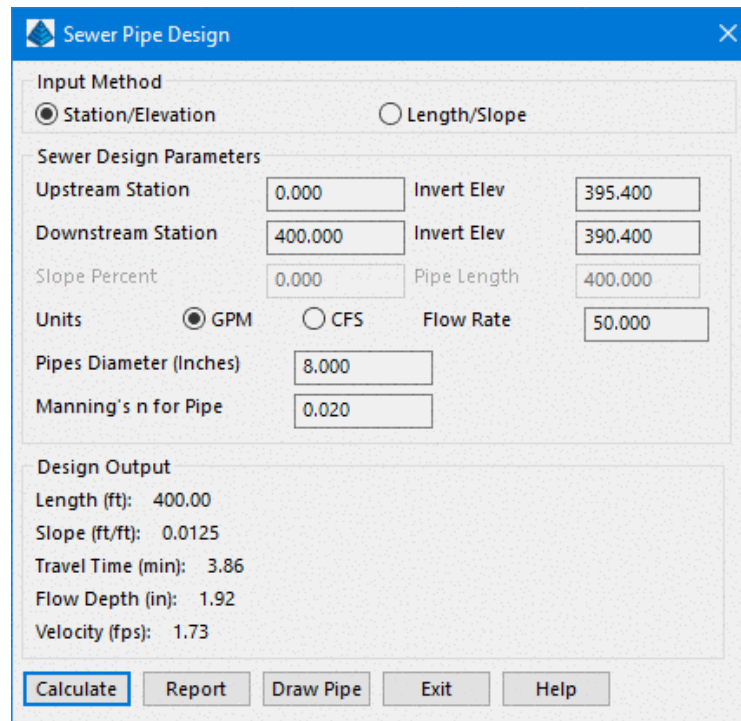

Pulldown Menu Location: Structure

Keyboard Command: culvert

Prerequisite: a culvert file

Sewer Pipe Design: Individual

This command calculates the travel time, flow depth, and velocity for a section of pipe. It calculates for one pipe section using the dialog shown here. Pipe sections can be entered as upstream/downstream stations and elevations, or as length and slope. Clicking Calculate will give you Design Output data based upon your input. Follow up Calculate by clicking Report, which will give you the Standard Report Viewer. Even after reviewing the information in the viewer and clicking on the viewers' Exit button, or its other output buttons, you still have the opportunity to change your original dialog box entries. This is because the command cycles from the viewer back into the dialog box for modifications. The Draw Pipe button draws the pipe details on the screen. The Exit within the dialog ends the command.

Sewer Pipe Design: Individual

Prompts

Sewer Pipe Design dialog Fill in variables. Click Calculate, then click Report.

Report results from the Standard Report Viewer:

Sewer Design

Upstream Station: 0.000 Invert Elev: 395.400

Flow Rate (GPM): 50.00

Pipe Diameter (in): 8.00

Manning's n: 0.020

Length (ft): 400.00

Slope (ft/ft): 0.0125

Travel Time (min): 3.86

Flow Depth (in): 1.92

Velocity (fps): 1.73

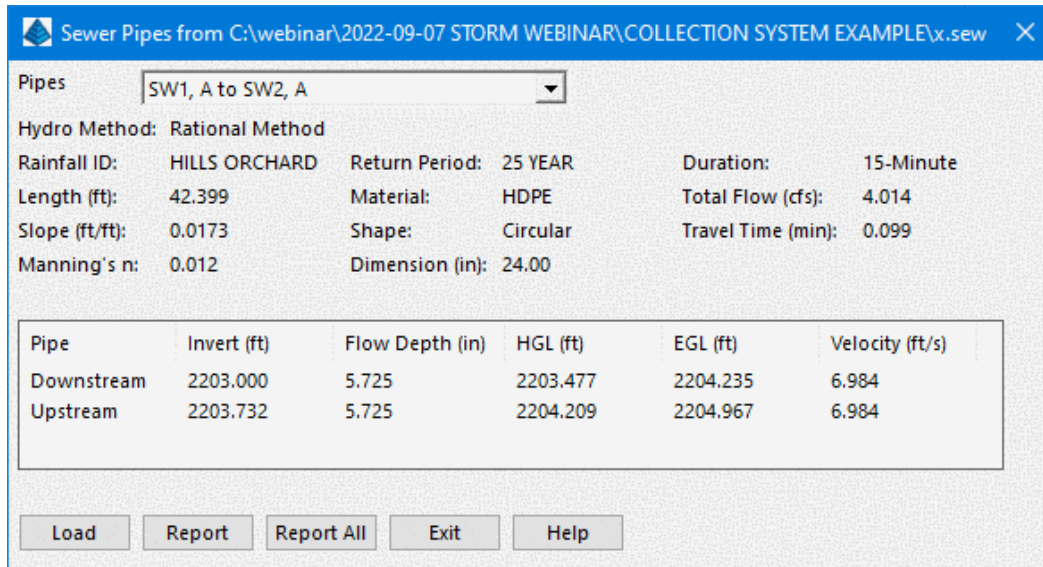

Pulldown Menu Location: Structure > Sewer Pipe Design > Individual

Keyboard Command: swrpipe

Prerequisite: None

Sewer Pipe Design: Sewer Network Segment

This command reads a sewer network and displays every pipe segment in the Sewer Pipe Design dialog. From the Structure > Sewer Pipe Design menu in the Hydrology Module, select Sewer Network Segment. The function reads a sewer network file, conducts the hydraulic calculations and displays pipe parameters and results in the dialog. Pipes list contains all pipe segments, you can select any one of them to display its data. The pipe parameters are shown in the middle part of the dialog, and the results are shown in the bottom table. Load button loads another sewer network file, Report button reports current pipe information to the standard Carlson report, and Report All button reports all pipe data to the standard report.

Sewer Pipe Design: Sewer Network Segment

Prompts

Sewer Network Segment dialog: Fill in values.

Pulldown Menu Location: Structure > Sewer Pipe Design > Sewer Network Segment

Keyboard Command: swrpipe3

Prerequisite: a sewer file (.SEW)

Sewer Pipe Design: Read Profile

This command calculates the travel time, flow depth, and velocity for a section of pipe. It reads the stations and elevations of a sewer or pipe profile (.PRO) created by the Design Sewer/Pipe Profile command in the Civil Design module. Pipe sections can be entered as upstream/downstream stations and elevations or as length and slope.

Prompts

Flow rate units [<GPM>/CFS]? *press Enter*

Flow rate <0.0>: *50*

Manning's n for pipe <0.020>: *.02*

Specify a Profile File dialog *select existing sewer or pipe .PRO file*

Number of decimal places <2>: *press Enter*

Report results from the Standard Report Viewer:

Lift Station Design

This command aids in the design of duplex sanitary or storm sewage lift stations. The program assumes a duplex station, with the second pump used solely for backup. That is, there are no provisions for multiple pump operation. The system head curve and pump curve are calculated using the least squares method of curve fitting through three points. To calculate the three points input the length of the force main (length of pressurized pipe), an assumed low-level wastewater surface elevation in the wet well, the elevation of the static lift in the force main, the sum of minor loss coefficients in the force main, and three flow rates that adequately cover the desired range of pump operation. The total dynamic head is calculated for each of the three flow rates by adding the static head, friction losses, velocity head, and minor losses that are calculated by the program from the input data. The next step is the calculation of the pump curve. The user should select one or more pumps from a manufacturer's catalog that will produce the desired operating conditions. The input data consists of the pump shutoff head (flow rate equal to zero), a head and flow rate near the desired operating point, and a head and flow rate beyond said operating point of the pump curve.

150.00	1.70	59.76	15.63	0.04	0.15	75.58
300.00	3.40	59.76	56.41	0.18	0.59	116.94
450.00	5.11	59.76	119.52	0.40	1.34	181.02

Design Characteristics

Length of Force Main= 4350.00 (ft)
Wet Well Wastewater Surface Elevation= 0.24
Elevation of Static Lift= 60.00
Pipe Diameter= 6.0 (in)

The system head curve and the pump curve are then intersected to produce preliminary operating point results. If the user is not happy with the results, click the Edit Input Values button and change any of the parameters. When the user attains the desired results then proceed with the wet well design by clicking OK.

Input for the wet well design includes type of wet well, wet well dimensions, invert elevation of the lowest line entering the wet well, and minimum wastewater depth in the wet well (usually specified by the pump maker). The lead pump's wet well volume is calculated using a formula from Metcalf & Eddy's Wastewater Engineering: Collection and Pumping of Wastewater: $V = CT/4$, where V equals required volume in gallons, C equals pump capacity (GPM), and T equals minimum time in minutes of one pumping cycle. After wet well design the program assigns a new low level wastewater surface elevation in the wet well, and then recalculates the system head curve and final operating point. At this point the user may change any or all of the input parameters. If no changes are needed then click OK to show the Final Results report.

Network Menu

The Network pull-down menu has commands for layout and analysis of storm sewer networks.

Sewer Network Model

Carlson sewer network model is a powerful program for the design and analysis of networks. A storm sewer network is generally made up of pipes, structures and inlets. A sanitary/utility network, unlike a storm sewer, doesn't have inlets. There may be more than one pipe entering a structure, but only one can exit. The network type is specified via the Sewer Network Settings command.

Sewer structure types and inlet types are defined in their libraries. The default library files are stored in the user directory. Some users would like to share library data and put the library files on a central server and can specify the libraries via Sewer Network Settings command. The sewer network file saves sewer structure and sewer inlet parameters in the .sew file so the sewer network data can be run on any computers that haven't the library files. Once load the sewer structure and inlet data, the program would check the default or user-specify library files and add the new data to the library if it's not in the library.

Sewer Network Settings

This command sets up the working environment for the design and analysis of sewer, sanitary and utility networks and should be done before starting the construction of networks.

Network Type: Indicate if the sewer network conveys storm runoff flow (Storm Sewer) or man-made flow (Sanitary/Utility). If the Sanitary/Utility network type is specified, the controls found in the Drainage tab are disabled.

Active Files: Select a new or existing sewer (.SEW) file to become the active sewer file and a "surface file" for ground cover calculations:

- *Surface by Rim Elevations* - When this option is enabled, the ground surface elevation is derived as an interpolated grade from structure rim elevation to structure rim elevation and the Surface Model option is disabled, or,
- *Surface Model* - When the *Surface by Rim Elevations* option is disabled, select a valid surface model (.TIN, .FLT, .GRD) that blankets the sewer network. The ground surface elevation is obtained from the surface model along the pipe reach.

Link Sewer Network to Reference Surface and Centerlines: Indicate the method of how the sewer network should react if there are changes to either the specified Surface Model or any related Centerlines that are specified in either the Create Sewer Structure command or the Edit Sewer Structure command. The following types of corrections can be made:

1. If the reference Surface Model changes, the structure rim elevation can be updated and there are two options for updating the invert elevation, discussed in the *Elevation Update Method* section below.
2. Each structure has the option to assign a reference centerline and the structure will record the station and offset from this centerline. When the reference centerline of a structure changes, the structure can be moved to the position of the recorded station and offset along the newly modified centerline.

Depending on the desired level of end-user control vs. automation, one of the following corrective options can be specified:

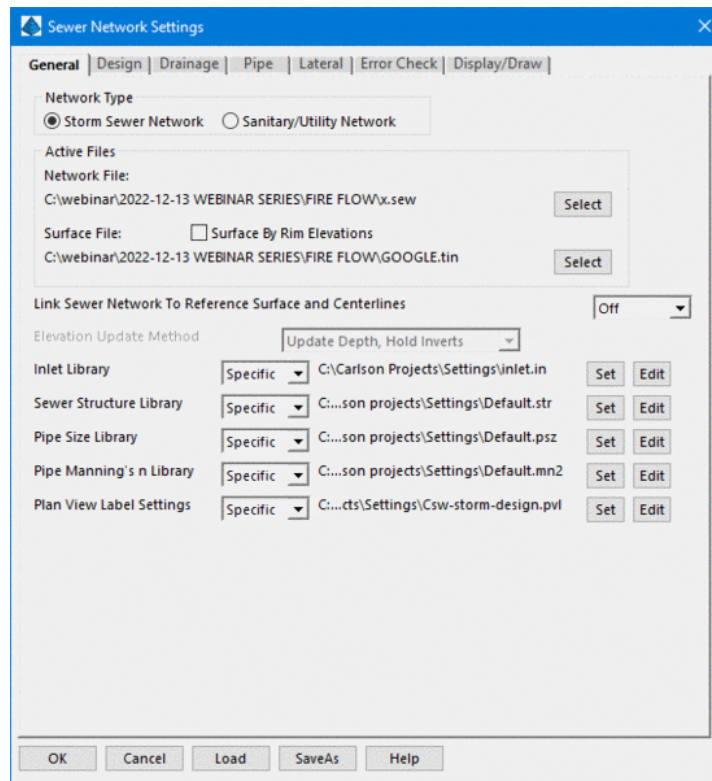

- *Off* - When a Surface Model or a Centerline changes, corrective action to the sewer network is not performed. Any corrections to the sewer network will need to be performed manually or through the use of the Check Reference Centerlines and Surface command which will compare the sewer network with the referenced file(s),
- *Prompt* - When a Surface Model or a Centerline changes, you will be offered a choice for a follow-up action of whether to update the structures or not.
- *Auto* - When a Surface Model or a Centerline changes, corrective action is automatically performed on the sewer network and any elevation updates will be calculated based on the *Elevation Update Method*.

Elevation Update Method: Indicate how the invert elevation(s) should change as a result of a change to a Surface Model (when the "linking" method is set to *Auto*):

- *Update Depth, Hold Inverts* - When this option is selected, the former invert elevations are retained and new depth of cover amounts are re-calculated, or,
- *Update Inverts, Hold Depth* - When this option is selected, the former depth of cover amounts are retained and new invert elevations are calculated

The Inlet Library, Sewer Structure Library, Pipe Size Library, Pipe Manning's N Library, and Plan View Label Settings can be set to the current project file CURRENT or SPECIFIC. If specific is specified the user can SET the location of the library files to be used.

The SaveAs button saves all the settings to a .SNS file and Load button loads all the settings from a previously saved .SNS file.

Direction: The network can be designed from Downstream to Upstream or vice versa. If the design direction is from Downstream to Upstream, the first structure created is generally the outfall and the current structure and its downstream pipe are highlighted in the plan view. Otherwise, the network is created from one of its entrances toward the eventual outfall and the current structure and one of its upstream pipes are highlighted.

Auto Set All Sewer Pipe Sizes: When enabled, this option disables the *Pipe Size* control found on the Pipe tab of the **Create/Edit Sewer Structure** command and sizes the pipe(s) automatically to the closest available pipe size as specified in the Pipe Size Library.

Auto Set All the Invert Elevations of the Sewer Network: When enabled, this option:

1. calculates initial *Invert* elevations found on the Structure tab and the Pipe tab of the **Create/Edit Sewer Structure** command, and,
2. enables the *Add Step Up to Minimize Excavation* control, and,
3. disables the *Auto Match Pipes at Junction* control.

Add Step Up to Minimize Excavation: When enabled, this option allows pipe inverts to be placed above the current invert elevation up to the **Max. Step Up** value to minimize excavation and create a potential "drop manhole."

Auto Match Pipes at Junction: When enabled, this option sets the pipe inverts automatically when creating a new pipe in order to match it to other pipes at the same junction.

Auto Set Invert In When Change Invert Out So Invert Out Not Higher: When enabled, this option will adjust the invert in to the pipe to be higher than the invert out.

Use The Connection Wizard When Add Pipes: This will open the pipe connection wizard when the user selects the ADD or PICK an available pipe connection on the docked dialog box under the Pipe Tab.

Minimize Pipe Sizes in Design: When enabled and if the sewer network is being designed, this option will ensure the pipes are not oversized as extra calculation iterations are performed.

Automatic Watershed Analysis: When enabled, this option performs an automatic watershed analysis of the referenced *Surface File* found on the General tab to determine the drainage area serviced by the new structure. This

action is the same as clicking the *Drainage Area - Calc* button found on the Drainage tab of the **Create/Edit Sewer Structure** command.

Auto Connect Structures: This option determines how to connect a newly created structure to the network:

- *On* - Automatically connects a pipe between the new structure and the closest structure, or,
- *Off* - Does not connect a pipe to the newly created structure (the structure would need to be manually connected to the network via the *Connection* control found on the Pipe tab of the **Create/Edit Sewer Structure** command or,
- *Prompt* - Provides an option as to whether or not a pipe should connect to the new structure.

HGL Computation Method: There are three methods to calculate HGL and EGL: FHWA Method, Virginia DOT Method and Just Full Capacity - Ohio Method. The differences are shown below.

1. FHWA Method

The complete description can be found in "Drainage of Highway Pavement (HEC12) form the FHWA Hydraulic Engineering Circular 12. In this method, when the HGL at the downstream is above the critical depth, use the HGL elevation as the initial elevation and conduct non-uniform flow calculation; when the HGL is below the critical depth and normal depth is above critical depth (subcritical flow), set the HGL at critical depth and conduct non-uniform flow calculation; when the HGL is below the critical depth and normal depth is below critical depth (supercritical flow), set the HGL at normal depth and conduct uniform flow calculation.

2. Virginia DOT Method

VDOT method is a simplified FHWA method. The first difference is the determination of the HGL at the downstream side of the pipe. In determining the HGL, begin with the actual tailwater elevation or an elevation equal to 0.8 times the diameter of the outlet pipe, whichever is higher. The second difference is that because the HGL is always greater than critical depth, non-uniform flow is conduct through all the pipes. Another difference is the velocity is normal flow velocity.

3. Just Full Capacity - Ohio Method

One difference between FHWA method and this method is the optimal pipe size. The optimal pipe size is based on the smallest diameter pipe in which the design discharge for the selected storm frequency will not exceed the just full capacity of the pipe. This storm frequency is called Just Full Capacity Frequency. Just full capacity with a free water surface is considered to occur at 93.8% of the pipe diameter for circular conduits. Another difference is the determination of the HGL at the downstream side of the pipe, this method uses the tailwater elevation or critical depth plus half of the diameter of the pipe, whichever is greater, to determine the starting HGL.

Friction Slope Averaging Method: Available methods are:

- *Arithmetic* - $S_{fav} = (S_{fu} + S_{fd})/2$, or,
- *Conveyance* - $S_{fav} = ((Q_u + Q_d)/(K_u + K_d))^2$, where
 - Q = Flow
 - K = Conveyance = $(1.486/n) * a * r^{2/3}$ (based on English units)
 - n = Manning's n-value
 - a = Flow area
 - r = Hydraulic radius
- *Geometric* - $S_{fav} = (S_{fu} * S_{fd})^{1/2}$

HGL Offset from Rim Elev: This value is used to check the hydraulic grade line result. If some of the hydraulic grade lines are within this value from the rim elevation, alerts are presented to indicate the potential problem(s).

Min. Time of Concentration: This value will replace any calculated Tc that is shorter than this value.

Max. Gutter Spread: Indicate the largest allowable gutter spread for determining inlet effectiveness.

Initial Network Structure Name: In creating a new network, this name is used as the first structure name, and then increment from it for every new structure.

Tributary Pipe Connect Action: When the tributary pipe line is from upstream to downstream and the downstream invert of the last pipe is lower than the manhole base elevation, there are five actions defined in the Sewer Network Settings to adjust the network pipe inverts.

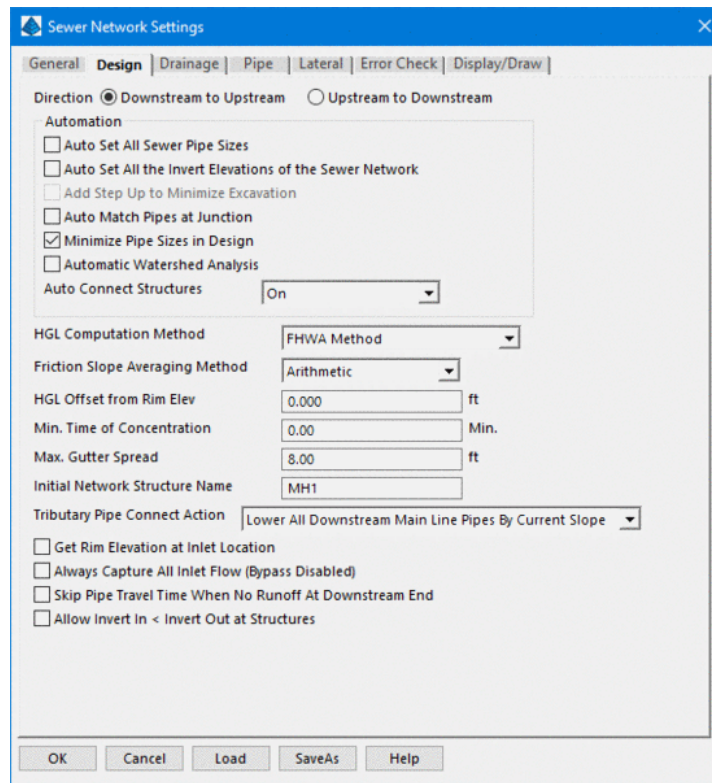

1. Lower All Downstream Main Line Pipes By Current Slope - Lower all downstream mainline pipes by the current slope to match the tributary pipe elevation, and create a step up for upstream mainline pipe.
2. Lower All Downstream Main Line Pipes By Current/Minimum Slope - Lower the downstream mainline pipes by the current/minimum slopes match the tributary pipe elevation, and create a step up for the upstream mainline pipe. Use a slope between the current and minimum slope to minimize the change of the manhole inverts.
3. Raise All Tributary Pipes By Current Slope - Raise the tributary pipes by the current slope to match the connection invert/crown.
4. Raise All Tributary Pipes By Current/Minimum Slope - Raise tributary pipes by the current/minimum slope to match the connection invert/crown. Use a slope between the current and minimum slope to minimize the change of the manhole inverts.
5. Raise Tributary Pipe At Downstream Side - Only raise the downstream invert of the last tributary pipe.

Get Rim Elevation at Inlet Location: When inlet is not placed at the structure location, use the surface elevation at inlet for structure rim elevation.

Draw Structure Symbol at Inlet Location: When inlet is not placed at the structure location, draw structure symbol at the inlet location in plan view.

Always Capture All Inlet Flow (Bypass Disabled): You may elect to let the inlets to capture all drainage runoff.

Skip Pipe Travel Time When No Runoff At Downstream End: When there's no runoff at the downstream catch basin, you can choose to skip its pipe travel time in composite peakflow calculation; otherwise the peakflow at downstream catch basin will be smaller than its upstream catch basin.

The drainage settings are used to set up the hydrology calculation method and rainfall information for the design of Storm Sewer networks.

Hydro Methods: Select either the Rational method (the SCS Rainfall group becomes disabled) or SCS method (the Rational Rainfall group becomes disabled) for Peak Discharge calculations.

Computation Methods: Indicate the computation method for the Storm Sewer network:

- *Peak Discharge* - The Rainfall Durations are disabled and the peak flow of each drainage area is calculated by the selected **Hydro Method** and the Storm Sewer network is designed to pass the peak flow, or,
- *Hydrograph* - The Rainfall Durations are enabled and a runoff hydrograph of each area is generated and routed through the network.

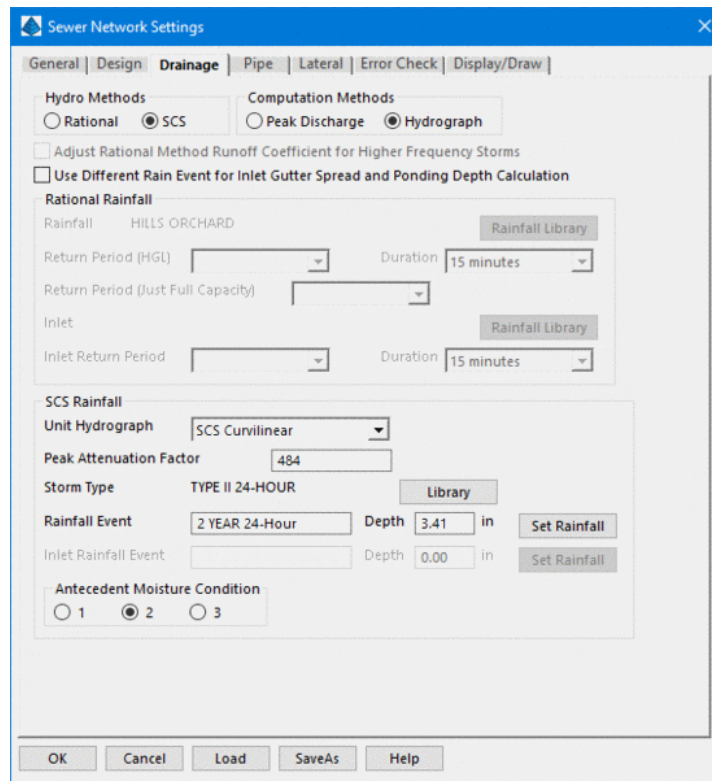

Adjust Rational Method Runoff Coefficient for Higher Frequency Storms this option would time the runoff coefficient with a constant to adjust the runoff coefficient. The constant for 25 year is 1.1, 50 year is 1.2 and 100 year is 1.25. The adjusted runoff coefficient is checked to make sure it's not greater than 1.0

Use Different Rain Event for Inlet Gutter Spread and Ponding Depth Calculation: When enabled, this option enables an alternate rainfall event for either Rational or SCS calculation methods to determine inlet efficiency.

Rational Rainfall: Specify the Rainfall, Return Period and Duration (if using the Hydrograph method) if using the Rational equation.

SCS Rainfall: Specify the Antecedent Moisture Condition, Storm Type and rainfall map if using the SCS methodology.

Unit Hydrograph: For SCS Rainfall, choose between SCS Curvilinear, SCS Triangular and Delmarva unit hydrographs. For SCS Triangular, the Peak Attenuation Factor controls the height of the hydrograph and needs to be a value between 300 and 600. The default of 484 matches the height used by the SCS Curvilinear method.

Cover: Enter the minimum and maximum depth of cover which is the distance from the surface elevation to the crown elevation along the pipes. Alternatively, enable either (or both) *Library* toggle(s) to use the value(s) specified in the Pipe Size Library.

Velocity: Enter the minimum and maximum flow velocity for the pipes. The minimum velocity is about 2 to 3 ft/s (0.6 to 0.9 m/s) when the pipe is flowing full for self-cleansing. The maximum velocity should be less than approximately 15 ft/s (4.5 m/s) to prevent erosion of the pipe interior by suspended sediment and debris. Alternatively, enable either (or both) *Library* toggle(s) to use the value(s) specified in the Pipe Size Library.

Slope: Enter the minimum and maximum slope range for the pipes in the network. The minimum slope should be sufficient to maintain the minimum velocity and the maximum slope is related to the maximum velocity. Alternatively, enable either (or both) *Library* toggle(s) to use the value(s) specified in the Pipe Size Library.

Normal Slope: The normal slope is the initial slope used to place a pipe in the network.

Max. Length: This is the maximum length between structures in a network before an alert is presented indicating a potential problem.

Drop Across Junction: This is the drop across the inside of a junction. Depending on the *Direction* specified on the Design tab, the Invert Up is either raised by this amount or the Invert Down is lowered by this amount.

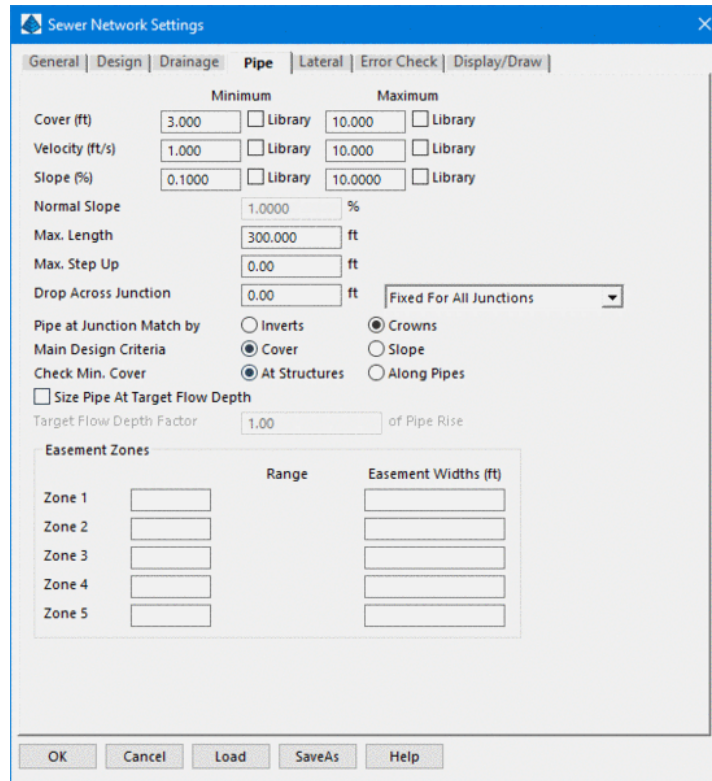

Pipe at Junction Match by: Indicate if pipes should be aligned by their inverts or crowns.

Main Design Criteria: Indicate which criteria should be maintained if both the *Minimum Cover* and *Minimum Slope* cannot be satisfied. If *Cover* is selected, the Slope will yield and vice versa.

Check Min. Cover: Define whether to check the minimum cover at the structures only or along the entire length of each pipe.

Size Pipe At Target Flow Depth: When this option is enabled in design mode, the sewer pipes will be set to the sizes that are sufficient to maintain the target flow depth.

Easement Zones: When this option is enabled, Utility Easements are drawn according to depth of Utility and corresponding Easement Width. Up to 5 widths can be defined which typically increase as depth increases.

Lateral Slope: Allows the user to set a minimum and maximum lateral slope.

Lateral Normal Slope: The normal slope is the initial slope used to place a lateral in the network.

Hold All Lateral Pipe Slopes: This option sets how the lateral should change if mainline edits are made, and will hold the lateral slopes should the mainline be adjusted. Therefore both the connection and the cleanout elevation would change to hold the slopes. For more than one cleanout, all lateral slopes are preserved after modifying the main line pipe.

Hold Slope of the Lateral Pipe Connected to Mainline: This option will adjust the first cleanout and lateral elevation if the mainline is adjusted.

Hold Lateral Inverts At Cleanouts: This option will adjust the lateral connection to the mainline pipe and the cleanout invert would remain at the original elevation.

Use Default Lateral Cleanout Symbol: Allows the user to select a symbol to be used as designation of the cleanout.

Use Default Lateral Connection Symbol: Allows the user to select a symbol to be used as designation of the connection

Initial Lateral Cleanout Name: The user can specify the initial cleanout name. A sequential numbers will start from this setting. For example CO1, CO2, CO3, etc.

Initial Lateral Connection Name: The user can specify the initial connection name. A sequential numbers will

start from this setting. For example CONN1, CONN2, CONN3, etc.

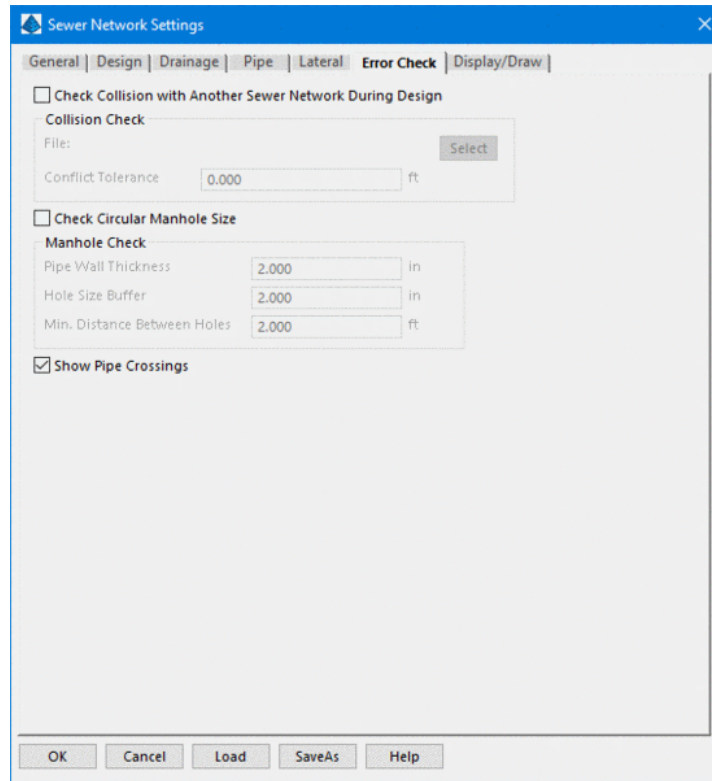

Default Lateral Connection Height: The user can specify the default connection height value for all lateral pipes.

The image shows a screenshot of the 'Sewer Network Settings' dialog box, specifically the 'Lateral' tab. The dialog has a blue title bar and a close button in the top right corner. The main area contains several input fields and checkboxes. At the top, there are tabs for 'General', 'Design', 'Drainage', 'Pipe', 'Lateral', 'Error Check', and 'Display/Draw'. Below the tabs, there are two columns for 'Minimum' and 'Maximum' values for 'Lateral Slope (%)', with values 0.1000 and 10.0000 respectively. Below that is a 'Lateral Normal Slope' field with the value 2.0000 and a '%' symbol. A section titled 'Lateral Edit Options For Mainline Edits' contains three radio buttons: 'Hold All Lateral Pipe Slopes' (selected), 'Hold Slope of the Lateral Pipe Connected to Mainline', and 'Hold Lateral Inverts At Cleanouts'. Below this are two checkboxes: 'Use Default Lateral Cleanout Symbol' and 'Use Default Lateral Connection Symbol', both with 'SPT 65' as a label and a 'Symbol' button. At the bottom, there are four text input fields: 'Initial Lateral Cleanout Name' (CO1), 'Initial Lateral Connection Name' (CONN1), and 'Default Lateral Connection Height' (0.00). The dialog box has a standard Windows-style button bar at the bottom with 'OK', 'Cancel', 'Load', 'SaveAs', and 'Help' buttons.

Check Collision with Another Sewer Network During Design: When enabled, this option allows for potential conflict detection with another sewer network. Should the placement of a structure or pipe encroach on the *Conflict Tolerance*, an alert will be displayed to caution against the potential collision.

Check Circular Manhole Size: When enabled, this option will check if the manhole is big enough to hold the incoming and outgoing pipes and will display an alert if any of the settings are violated.

Show Pipe Crossings: When enabled, this option allows you to display the pipe crossings of current network opposed to any sewer networks or pipes that are drawn in the drawing.

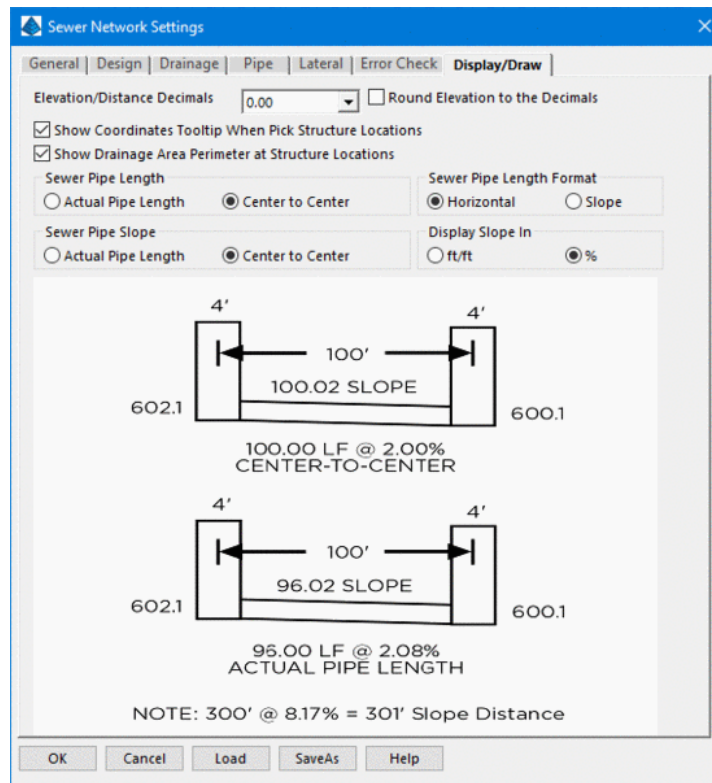

Pipe Length: Specify how the pipe length should be displayed.

Pipe Slope Annotation: Specify how the pipe slope should be displayed.

Display Slope In: Specify to display slope in the unit of either distance/distance or %.

Elevation Decimals: Indicate the desired amount of precision to display for elevation values.

Show Coordinates Tooltip When Pick Structure Locations: Show cursor's coordinates in a tooltip when pick new structure locations.

Pulldown Menu Location: Network > Sewer Network Setup

Keyboard Command: swrconfig

Prerequisite: None

Set Sewer File

This command sets a sewer network file as the current file. The other sewer network commands will reference this file. Either a new file can be created or an existing sewer file can be modified. The sewer network file stores all the sewer structure data (elevation, flow) and all the network connection data (slopes, pipe sizes). This file has a .sew file extension.

Pulldown Menu Location: Network

Keyboard Command: setswr

Prerequisite: none

Set Surface File

Use this command to set the grid or triangulation file to be used to compute sewer manhole surface elevations and minimum cover along pipe lengths, within the Sewer Network commands, and in particular the command Create Sewer Structure. A dialog will appear requesting the name of the surface file to be used.

Pulldown Menu Location: Network

Keyboard Command: setgrd

Prerequisite: None

Plan View Label Settings

This command sets the drawing format for sewer pipeline and inlet/manhole annotations drawn for the sewer network. The settings are entered in a dialog with tabs for Structure Labels, Pipe Labels and General Settings.

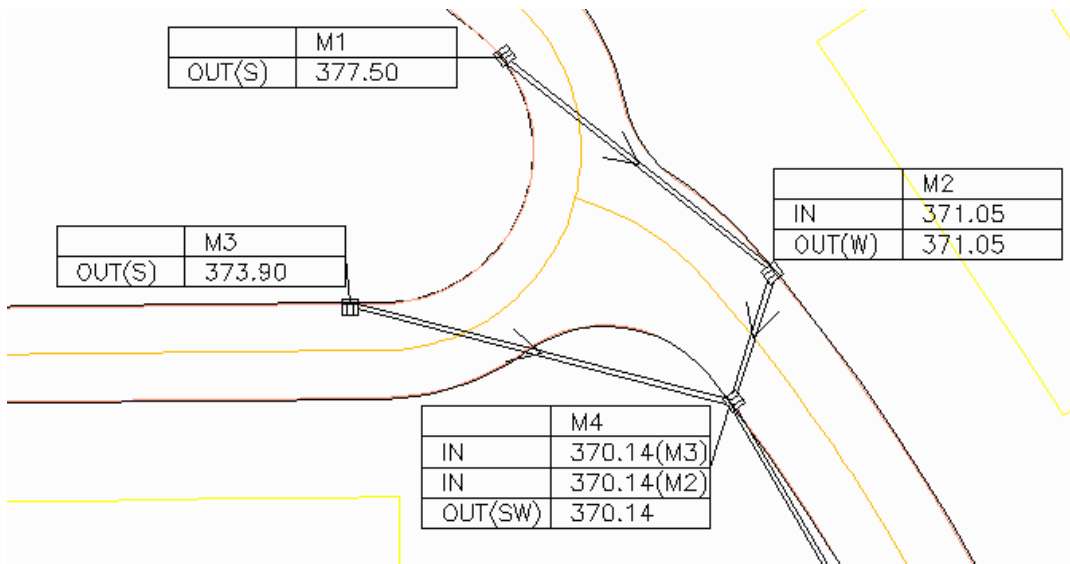

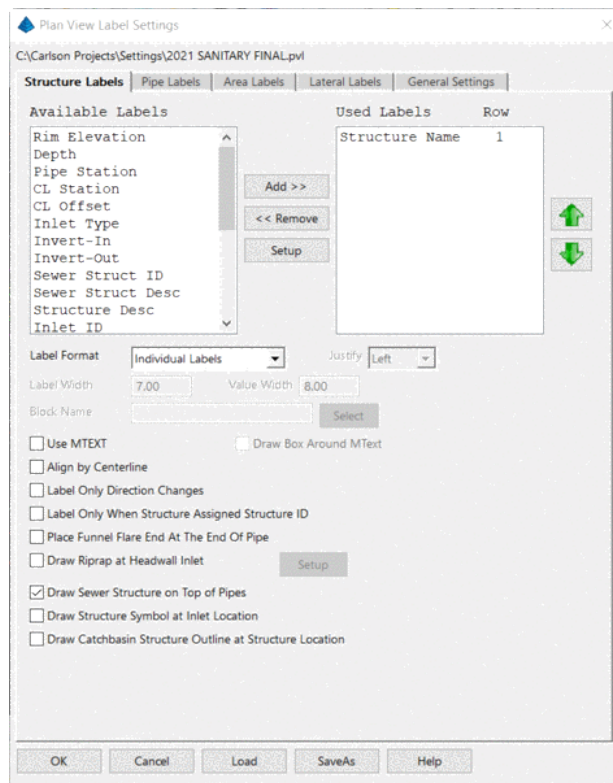

Shown below is the manhole or inlet name, along with rim elevation, invert elevation and the labeling of the sewer pipe itself. When the network entities are selected by the 3D Viewer Window command, they are automatically converted into 3D entities.

Under **Structure Labels**, you can choose whether to label the structure name, structure description, northing, easting, rim elevation, depth, pipe station, CL station, CL offset, inlet type, invert-in elevation, invert-out elevation, structure ID, Inlet ID or custom offsets. The custom offsets label elevations relative to either the structure rim elevation or invert elevation with a specified offset. The list of available fields is on the left and the list of fields to label is on the right. The order of the fields in the right side list is the order of the labels in the drawing. Use the Add, Remove and Up/Down arrow buttons to move fields between the lists and change their order. To edit the parameters for a field, highlight the field name on the right list and pick Setup. You can set the label prefix and suffix and whether to start a new row. If new row is off, then the field will be put on the same row as the previous field in the list. The pipe station is the accumulative length of the pipes from the outfall up to the structure. The CL station and offset values are calculated from the reference CL that is assigned to the structures in the sewer network. The invert elevations can be positioned either above the structure or along the associated pipe direction. For Inverts, the Add Quadrant option adds the bearing quadrant of the associated pipe direction to the invert label prefix.

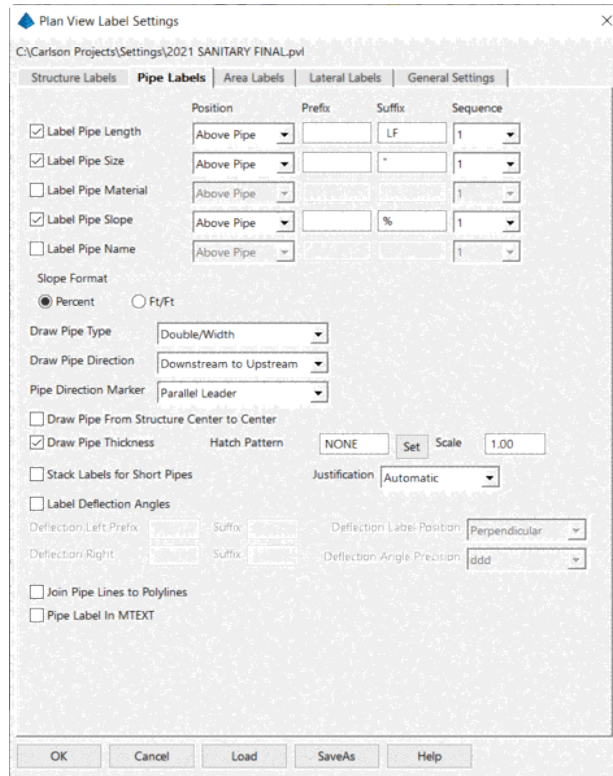

The options for **Label Format** are Individual Labels, Data Table and Attribute Block. For Individual Labels, the program draws regular text entities. The **Use MText** option will draw the labels as MTEXT entities. Otherwise they are drawn as TEXT entities. When draw in MText, the option **Draw Box Around MText** will draw a box around the MText Structure Labels. The **Data Table** method will put the labels in a block as shown below. There are settings for the size of the block columns and the block label justification. The **Attribute Block** method inserts a block and puts the labels into the block attributes. The **Align By Centerline** option will rotate the labels to be parallel with the pipe. Otherwise the labels are drawn horizontal to the current twist screen. The **Locate Only Direction Changes** will only label when the pipes to the structure have a deflection angle. This setting applies to utility networks that have a lot of nodes in straight lines and you only want to label the end nodes. The **Label Only When Structure Assigned Structure ID** option will only draw the structure labels when the structure has an ID other than None. This option is meant for clearing up unnecessary labels for cases like utility networks that have a lot of structures without ID's. The Place Funnel Flare End At The End Of The Pipe relocates the funnel to be part of the pipe length. The **Draw Riprap At Headwall Inlet** draws a hatch pattern using the pattern and size set under

Setup. In default, the pipe entities are drawn on top of sewer structure entities. The **Draw Sewer Structure on Top of Pipes** allows you to draw structures on top of pipes. **Draw Structure at Inlet Symbols at Inlet Locations** if the user has an inlet offset specified this will place symbol at the inlet location. **Draw Catch Basins Structure Outline at Structure Location** will draw the outline with the structure dimension at the structure location.

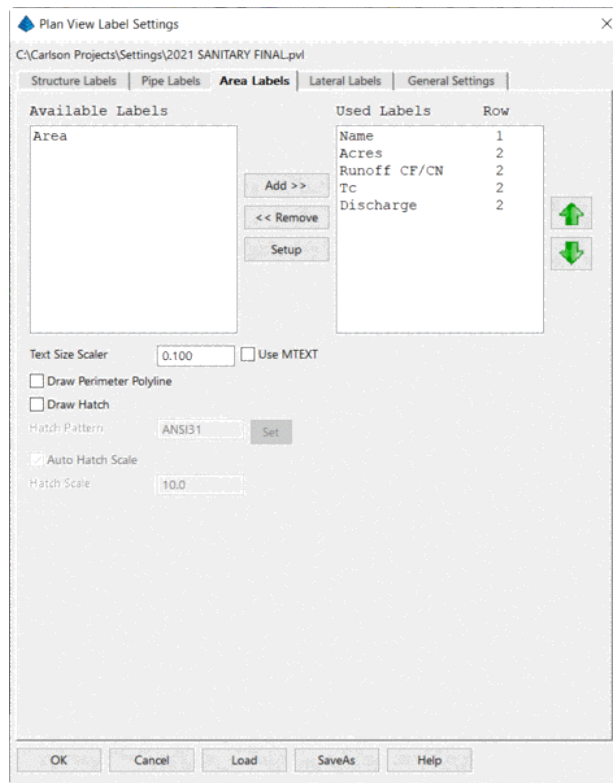

Under **Pipe Labels**, you can choose whether to label the pipe size, material, length, name or slope. For each label, there are settings for the prefix and suffix, for whether to put the label above or below the pipeline, and controls for label sequence of the fields. **Draw Pipe Direction** allows user to select Downstream to Upstream or Upstream to Downstream. The **Pipe Direction Marker** has two styles for flow direction arrows. The **Draw Pipe Line Type** sets the method for drawing the pipelines as 2D polylines, 3D polylines or parallel 2D polylines set apart with the width of the pipe. The pipe is drawn at outside border of the symbols, however the **Draw Pipe From Structure Center to Center** will draw pipes from structure center to center. The **Draw Pipe Thickness** will show the thickness of the pipe

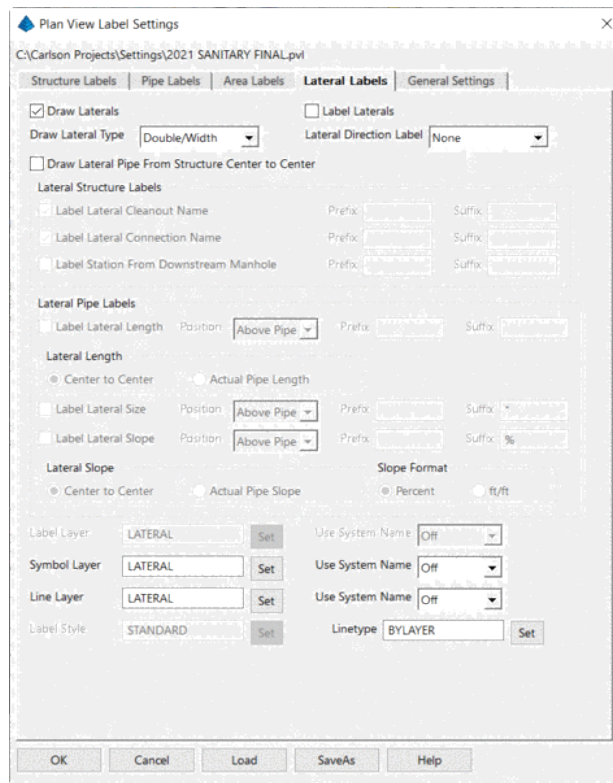

with the option to hatch. The **Stack Labels For Short Pipes** option will automatically make a stacked row of labels when the pipe segment is too short to fit on a single row. The **Deflection Angle** options have separate prefix/suffix settings for left and right, and the label rotation can be horizontal to the current screen view or perpendicular or parallel to the pipe. **Pipe Label in MTEXT** allows the user to label pipe runs using MTEXT.

For **Area Labels**, the program can label the drainage parameters for each inlet including area, runoff coefficient, T_c and discharge. There is also the ability to draw a perimeter polyline for the drainage area and to hatch the area.

For **Lateral Labels**, you can choose whether to Draw Laterals and Label Laterals. The Draw Lateral Type allows the user to select 2D Polyline, 3D Polyline, Double/Width, or Dashed/Width. Lateral Direction Label has three styles None, Parallel Leader, or Arrow On Pipe to show the direction of flow along the lateral. For the Lateral Structure Labels the user can specify a Prefix or Suffix for the Label Cleanout Name, Label Lateral Connection Name, and Label Station From Downstream Manhole by placing a check box with these two options if you choose to label. The check box toggle for Label Lateral Length the user can control the position of either Above Pipe or Below Pipe and also add a Prefix or Suffix. For Lateral Length the labels can be based on structure center-to-center or actual pipe dimension that removes the width of the structure and goes from the structure edges, and also specify what is to be labeled with a position, Prefix, or Suffix. The Lateral Slope the labels can be based on structure center-to-center or actual pipe slope, and toggle between the Slope Format of Percent or ft/ft. Layers can be assigned for the Labels, Symbols, and Linework and also the System Name as either Off, Prefix, or Suffix. Use the Label Style to assign text standard and set the Linetype.

Under **General Settings**, there are controls for the layers, styles, decimal places, sizes and linetypes.

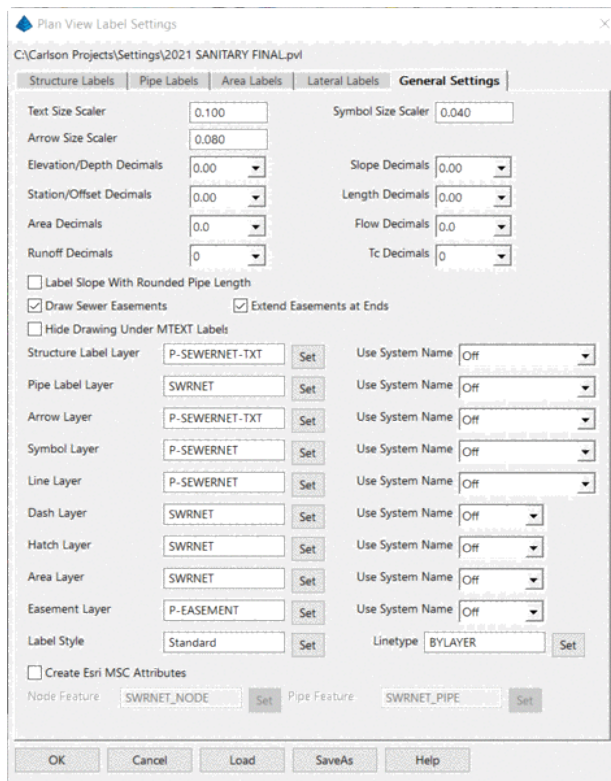

Label Slope With Rounded Pipe Length: would calculate and label pipe slope based on the rounded pipe length by the Length Decimals.

Draw Sewer Easements: would draw easement polylines, which width is based on the easement data defined in sewer network settings dialog.

Extend Easements at Ends: Will extend easement polylines past both ends of a network based on 1/2 of the easement total width.

Hide Drawing Under MText Labels: uses wipeout w or w/o a frame, which uses the Draw Box feature, to hide drawing under the MText labels.

The Use System Name has settings for adding to the layer names using any combo of the system name, line name, pipe size and pipe material. The linetype is on used when the pipe is draw as a 2D polyline. The Create ESRI MSC Attributes option will tag the network entities with ESRI format feature attributes which ESRI version 9.3 and higher will recognize as the specified feature names instead of plain CAD entities.

You are free to move the text anywhere desired for better appearance after it plots. The labeling will change automatically on the drawing if any of the sewer network information is edited or if the label settings are changed. This automatic redraw will put the labels back in their original positions if you moved the labels with standard drafting edit tools. If the Move Sewer Label command is used, the labels will stay at their modified position even after the automatic redraw. The labeling and manhole itself will be removed from the screen by the command Remove Sewer Structure, along with connecting pipe sizes and invert elevations of the immediate upstream and downstream manholes. The command Draw Sewer Network–Plan View will also redraw and label the sewer network that is "set" and current, according to the annotation parameters of this command.

Pulldown Menu Location: Network

Keyboard Command: swrsetup

Prerequisite: None

Save Sewer Network File

This routine re-saves the current sewer network file in another name, which can act as a backup file or "snapshot" of the sewer network design at a certain point in time. The file can be re-loaded later and re-used.

Pulldown Menu Location: Network

Keyboard Command: save_sewer

Prerequisite: Sewer network (.SEW) file

Import Haestad Network

This routine converts Haestad files into Carlson sewer files. Haestad sewer network files have fourteen pieces of information in an ASCII text file. Unfortunately, they do not contain two-dimensional coordinates of the manholes locations. Therefore, the routine must assume locations along some arbitrary datum. Examine the example output below. The program searches for the longest path along the sewer network, and places it on the X axis. The next

longest set(s) of network traces branch from the longest path. The process is repeated until the last upstream manhole on the network tree branches is encountered. While true coordinate locations of the manholes is unknown, additional hydraulic analysis of the system can be made on this Carlson pseudo-layout.

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: ha2csnet

Prerequisite: Haestad file

Rational Rainfall Library

Rainfall is the source of the ground runoff. Along with the watershed conditions, the rainfall that neither infiltrates nor gets trapped in low areas and depressions contributes to the direct surface runoff, upon which the storm drainage system design is based.

The Rational Rainfall Library use IDF curves to provide average rainfall intensity data for particular storm events. With a known rainfall duration and frequency, an intensity is calculated via the IDF curve and applied to the Rational Method to obtain the peak flow for designing the sewer network. There are six methods to input rainfall data: TP-40 rainfall map, Hydro-35 rainfall map, rainfall accumulation, rainfall intensity, IDF equation coefficients and fixed rainfall intensity. Rainfall maps provided by government organizations are practical rainfall data resources for engineering design. TP-40 maps show precipitation depths in the US for storm durations from 1 hour to 24 hours and for recurrence intervals from 1 to 100 year. Hydro-35 maps are for the central and eastern US, and provide rainfall data for durations as short as 5 minutes. Please refer to HEC-12 for details on methodology for computing IDF curves from rainmaps. In addition to TP-40 and Hydro-35 method, you can input rainfall accumulations or intensities at various storm durations to define IDF curves. If you already have the IDF equation coefficients calculated, you can enter the coefficients directly to define the IDF curves. The IDF curves are interpolated linearly between the data points. If you choose to use fixed rainfall intensity, no IDF curve is calculated and this value is used directly. You may also input rainfall intensity data with lookup table method, where IDF curve is not used, rainfall intensity will be interpolated linearly from the lookup table.

The IDF equation for a given return period is defined as follows. The coefficients A, B and M are calculated by log-log regression of the rainfall intensity and (t + B).

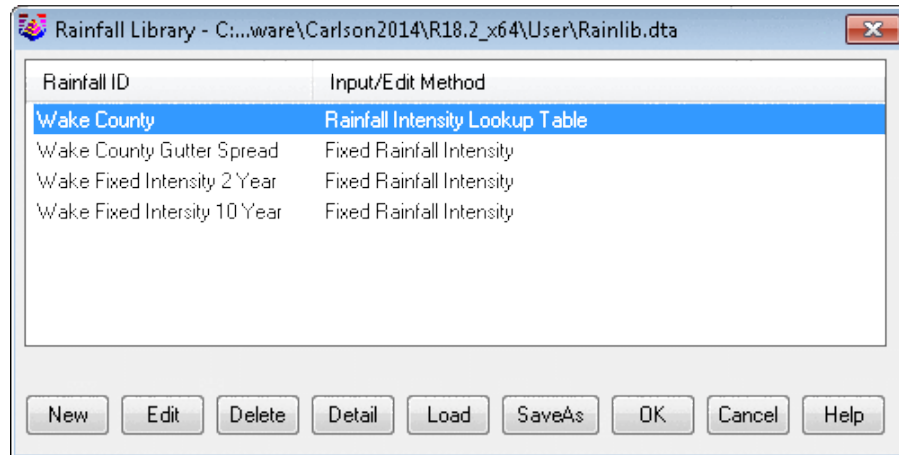

$$I = A / (t + B)^M$$

where: I = rainfall intensity (in/hr, or mm/hr in metric)

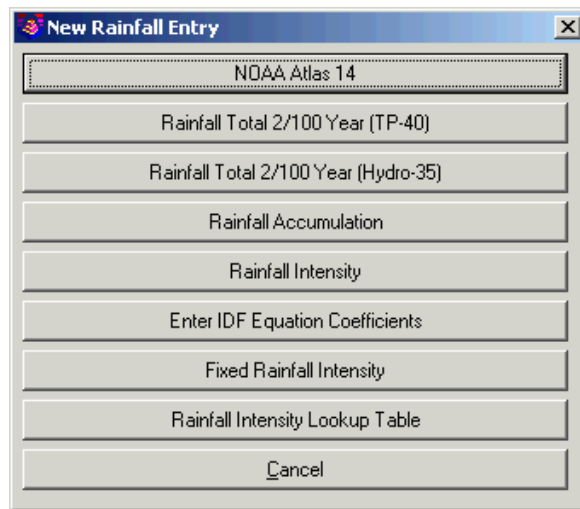

A, B, M = equation coefficients for a given return period

t = rainfall duration (min.)

The Rainfall Library stores rainfall data in a library file under the ...\\USER folder and is available for all projects. From the Network > Sewer Network Libraries menu in the Hydrology Module, select the Rainfall Library to open the library dialog to edit rainfall data. The dialog lists all rainfall entries by their ID and their input/edit method. New button creates a new rainfall through one of the seven methods: TP-40, Hydro-35, Rainfall Accumulation, Rainfall Intensity, Enter IDF Equation Coefficients, Fixed Rainfall Intensities, and Rainfall Intensity Lookup Table. Edit button allows you to modify an existing rainfall, and the Delete button removes the highlighted rainfall from the library. Load and SaveAs buttons allow you to load and save the rainfall data.

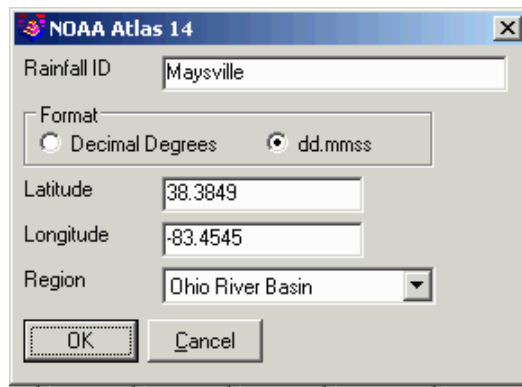

Rainfall Library Dialog

New Rainfall Dialog

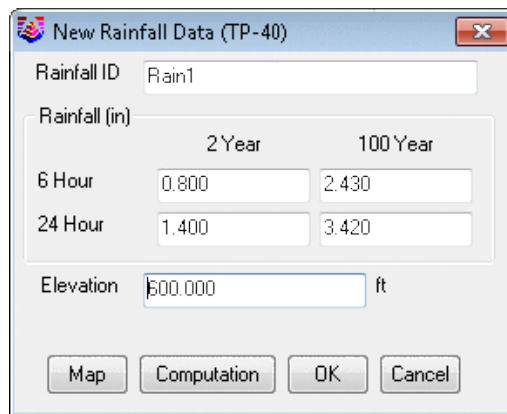

NOAA Atlas 14

This method fills out the rainfall intensity values using the NOAA Atlas 14 rainfall models. In the dialog, enter a name and lat/lon for your location and choose the NOAA Atlas 14 region. The first time that you run a region, the program downloads the rainfall models to your computer.

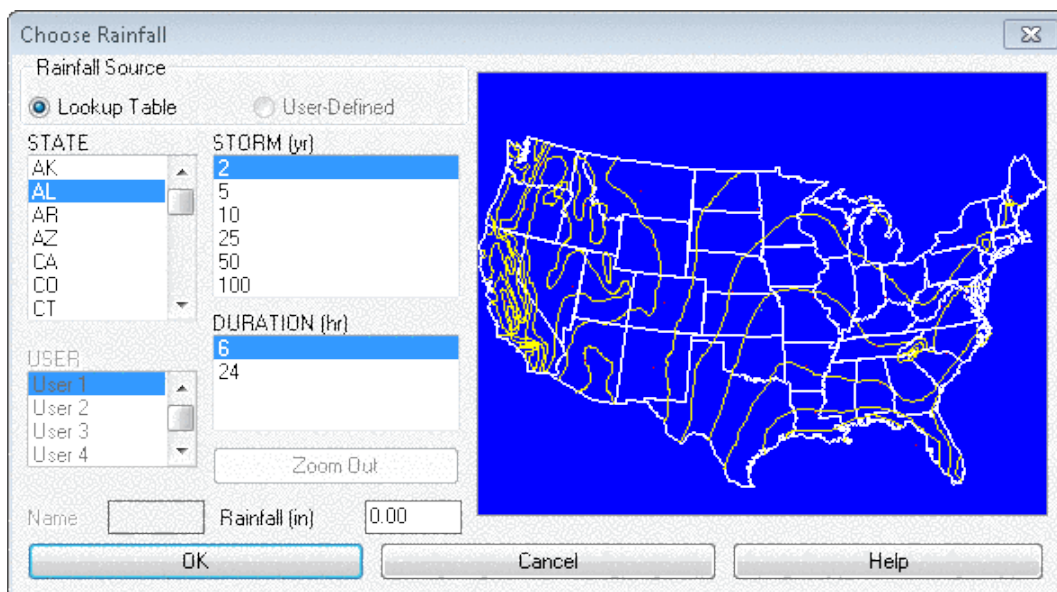

Rainfall Total 2/100 Year (TP-40)

The TP-40 method is used to define IDF curves for the Western states in the US. It requires rainfall accumulations of 6-hour and 24-hour storm durations for the 2-year and 100-year storms, and the elevation of the location. In the TP-40 dialog, type the rainfall name in the Rainfall ID box. The rainfall depth can be entered either manually or from the TP-40 maps. Click on Map button to open the rainfall map, pick a state on the map to zoom in to the state map, and then pick a location to get the rainfall depth of 6-hour and 24-hour duration for 2-year, 5-year, 10-year, 25-year, 50-year and 100-year storm events. In the Elevation box, enter the surface elevation at the design location. Computation button computes the rainfall intensities and the IDF coefficients, and displays the result in the Rainfall Intensity dialog. Click on OK button to commit the rainfall entry.

Rainfall Intensity Results

Rainfall Total 2/100 Year (Hydro-35)

The Hydro-35 method is used to define IDF curves for the Central and Eastern states in the US. It requires rainfall accumulations of 5-min, 15-min and 60-min storm durations for the 2-year and 100-year storms. In the Hydro-35 dialog, type the rainfall name in the Rainfall ID box. The rainfall depth can be entered either manually or from the Hydro-35 maps. Click on Map button to open the rainfall map, pick a state on the map to zoom in to the state map, and then pick a location to get the rainfall depth. Computation button computes the rainfall intensities and the IDF coefficients at 2-year, 5-year, 10-year, 25-year, 50-year and 100-year return periods, and displays the result in the Rainfall Intensity dialog. Click on OK button to commit the rainfall entry.

Hydro-35 Rainfall Data

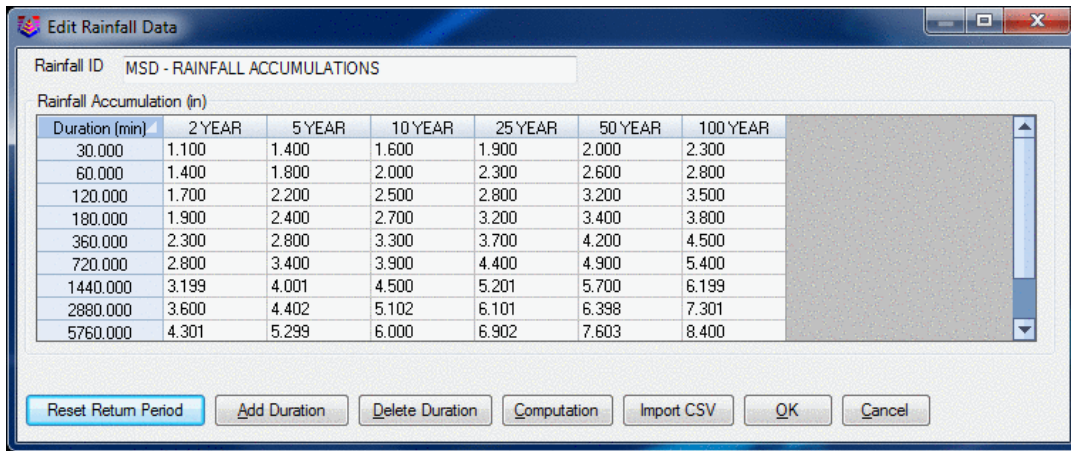

Hydro-35 Rainfall Map

Rainfall Accumulation

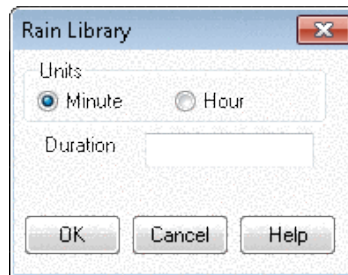

This method allows you to enter the rainfall accumulations of various durations for any of 1-year, 2-year, 5-year, 10-year, 25-year, 50-year, 100-year, and a User-Defined return periods for computing the IDF curves. The **Reset Return Period** button allow the user to add or remove Return Periods as needed. **Add a Duration** button adds new duration entry to the spreadsheet. For accuracy, three or more durations are required. **Delete a Duration** button deletes the highlighted duration entry. **Computation** button computes the rainfall intensities and the IDF coefficients, and displays the result in the Rainfall Intensity dialog. The **Import CSV** button allows you to import the rainfall depth values in a comma separated values text file. In the CSV file, the first column is the duration value in minutes, the rest columns are rainfall depths associated to the chosen return periods. Click on OK button to commit the rainfall entry.

Return Periods Dialog

Customed Rainfall Accumulations

New Duration Entry

Rainfall Intensity

This method allows you to enter the rainfall intensities of various durations for any of 1-year, 2-year, 5-year, 10-year, 25-year, 50-year 100-year, and User Defined return periods for computing the IDF curves. The **Reset Return Period** button allow the user to add or remove Return Periods as needed. **Add a Duration** button adds new duration entry to the spreadsheet. For accuracy, three or more durations are required. **Delete a Duration** button deletes the highlighted duration entry. **Computation** button computes the rainfall intensities and the IDF coefficients, and displays the result in the Rainfall Intensity dialog. The **Import CSV** button allows you to import the rainfall intensity values in a comma separated values text file. In the CSV file, the first column is the duration value in minutes, the rest columns are rainfall intensities associated to the chosen return periods. Click on OK button to commit the rainfall entry.

Customed Rainfall Intensities

Enter IDF Equation Coefficients

When you have the coefficients calculated, you can use this method to enter the coefficients to obtain the actual IDF curve equation. In the following spreadsheet dialog, enter the known coefficients A, B and M to create the IDF equation. **Computation** button computes the rainfall intensities and displays the result in the Rainfall Intensity dialog. Click on OK button to commit the rainfall entry.

	A	B	M
2-Year	22.170	5.090	0.670
5-Year	29.910	5.090	0.670
10-Year	35.760	5.090	0.670
25-Year	43.500	5.090	0.670
50-Year	49.350	5.090	0.670
100-Year	55.210	5.090	0.670

IDF Equation Coefficients

Fixed Rainfall Intensity

The method creates a rainfall entry with the fixed rainfall intensity. When you choose to use this storm event, this fixed intensity will be used in your hydrology calculation directly.

Return Period	A	B	M
2-Year	22.170	5.090	0.670
5-Year	29.910	5.090	0.670
10-Year	35.760	5.090	0.670
25-Year	43.500	5.090	0.670
50-Year	49.350	5.090	0.670
100-Year	55.210	5.090	0.670

Fixed Rainfall Intensity

Rainfall Intensity Lookup Table

The method allows you to enter the rainfall intensities of various durations for any of 1-year, 2-year, 5-year, 10-year, 25-year, 50-year, 100-year, and User Defined return periods and creates a rainfall intensity lookup table. The rainfall intensity will be interpolated linearly from the table.

Rainfall ID: Rain7

Rainfall Intensity (in/hr)

Duration (min)	2-Year	10-Year	25-Year	100-Year
5.000	5.580	7.080	7.780	8.640
10.000	4.460	5.660	6.190	6.860
15.000	3.740	4.780	5.240	5.780
30.000	2.580	3.460	3.880	4.430
60.000	1.620	2.250	2.580	3.050
120.000	0.940	1.330	1.540	1.850
360.000	0.400	0.580	0.680	0.840
1440.000	0.140	0.210	0.240	0.300

Rainfall Intensity Lookup Table

Users in Kentucky and some states

Users in Kentucky and some states have started using rainfall data from NOAA Atlas 14 and require project specific rainfall information. The rainfall data can be obtained here: http://hdsc.nws.noaa.gov/hdsc/pfds/orb/ky_pfds.html. After selecting the data type and the location, the precipitation frequency estimate table from NOAA Atlas 14 would be shown as follows. You can then enter the data by either the Rainfall Accumulation method or Rainfall Intensity method into Carlson. You are not require to enter all the data, three durations of rainfall data is enough for creating the IDF curves for each return period.

Point Precipitation Frequency Estimates From NOAA Atlas 14

Default Libraries

A default library is included in the install and placed in the Carlson Projects\Settings folder. This library is for Ohio and includes 4 IDF curves for different regions. Use the Load function to select this library. There are also many default libraries for North Carolina under Carlson Projects\Settings\NorthCarolina.

Pulldown Menu Location: Network > Sewer Network Libraries > Rational Rainfall Library

Keyboard Command: rainlib

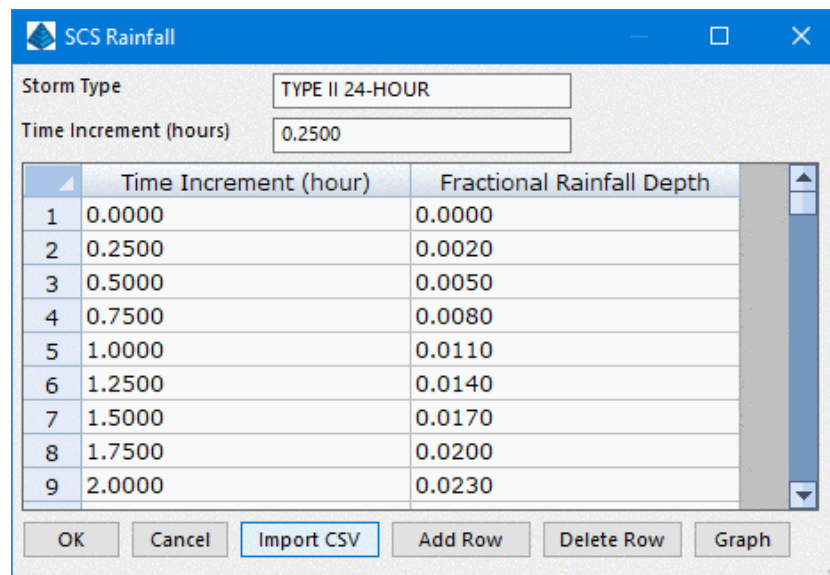

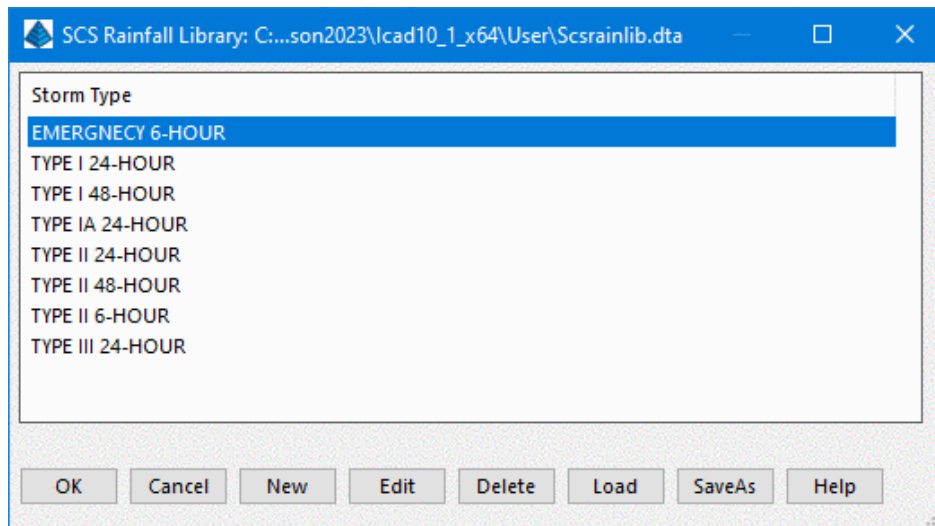

Prerequisite: None

SCS Rainfall Library

The SCS Rainfall Library command allows you to store commonly used storm types for SCS method. The SCS has developed several standard distributions that cover the entire US, commonly known as the Type I, IA, II, and III storms. For situations where a standard rainfall distribution is not available or appropriate, you can create a

localized rainfall distribution table in the SCS Rainfall Library. The default library file is in the Carlson Install Directory\USER folder and is available for all projects in sewer network design.

From the Network > Sewer Network Libraries menu in the Hydrology Module, select SCS Rainfall Library to open the library dialog. New button creates a new storm type entry, Edit button allows you to modify the highlighted entry, and Delete button removes the highlighted entry from the library. Load and SaveAs buttons allow you to load and save the library data. The Import CSV or (comma-separated values) allows the user to import rainfall depth data in csv or txt file formats. In the CSV file, only the fractional rainfall depth at every time increment is required. The fractional rainfall depth data should be between 0 and 1, and delimited by comma. The time increment value is entered on the dialog.

We have collected most of the rainfall distributions that are published on the NOAA website. The rainfall distribution data are all in 24-hour duration, and 90% frequency, the fractional rainfall depth value is between 0 and 1. You can

load the SCS rainfall library file (.srn) of the desired region to the library to use it. Available regions are as follows:

California:

Data Files: Region 1 - NOAA California Region 1.srn

Region 2 - NOAA California Region 2.srn

Region 3 - NOAA California Region 3.srn

Region 4 - NOAA California Region 4.srn

Inlet Library

In storm sewer systems, inlets are the surface components that gather the ground runoff and convey the flow to a subsurface storm sewer network. The inlet capacities should be sufficient to intercept the flows that the sewer system can handle. Inlets can be located "on-grade" or in sag locations. Inlets located "on-grade" may be designed to intercept either all or part of the runoff in the gutter whereas inlets that are installed in sag points should be sized to capture the entire runoff approaching them. The longitudinal and cross-slope of the roadway along with the *Manning's "n"* value of the gutter influence the performance of the inlet. These parameters can be obtained automatically in the watershed modeling of the sewer network design. The details of the inlet design procedures can be found in the HEC-22 Manual.

The Inlet Library command allows you to make, edit and store inlets. The working Inlet library data file is stored (by default) in the `%AppData%\Carlson Software\...\User\Inlet.dta` file and is available across all Carlson Software projects.

The Custom Properties function defines additional fields for each inlet. Values for these fields can be entered into the Inlet Library. Then these fields are available in the Report Sewer Network command.

When you create or edit an inlet, the New/Edit Inlet dialog box displays (shown below).

Inlet ID: Indicate the name of the inlet.

Inlet Type: Indicate the type of inlet:

- Grate
- Curb
- Slotted
- Combo (Grate/Curb)
- Ditch

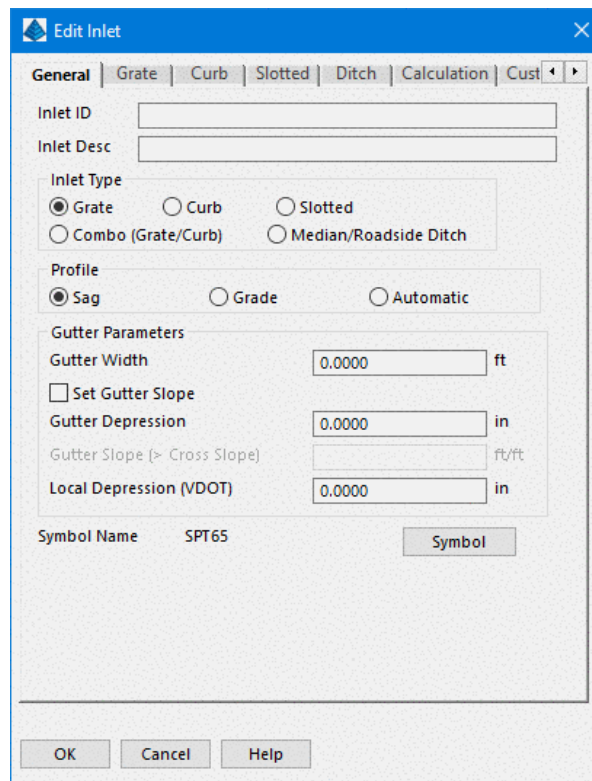

Profile: Indicate whether the inlet is located in a sag portion of a vertical curve or "on grade."

Gutter Parameters: A gutter is a section of pavement adjacent to the roadway, which conveys flow during a storm runoff event. Gutters can have uniform and composite sections. A uniform gutter has the same cross-slope value as the cross-slope of the roadway adjacent to the gutter. A composite gutter section is depressed in relation to the

adjacent pavement cross-slope. Therefore, the Gutter Depression should be entered when using a Composite gutter. The Local Depression is the depression for curb inlets that are off the gutter section.

Design Inlet Length: When enabled, the inlet length is calculated based on Design Constraints of the maximum allowable ponding width (spread) on the roadway and the interception efficiency. When disabled, the spread and efficiency are computed. When the inlet is at a sag location, the interception efficiency is always 100%.

Symbol Name: Click on Symbol button to select a symbol for displaying the inlet in the plan view on the screen.

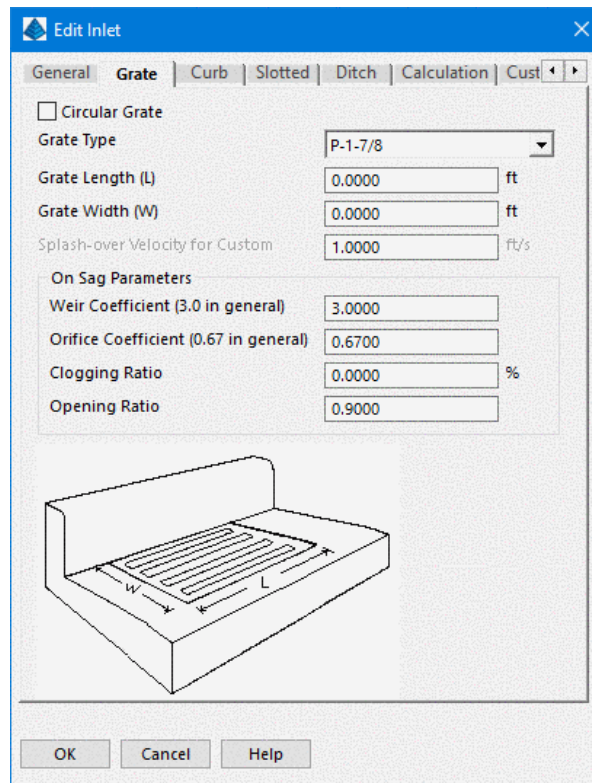

When either the Grate or Combo inlet type is specified, the controls on the Grate Inlet tab are enabled allowing you to create or edit the Grate details. Grate inlets perform well on grades where clogging with debris is not a problem. Their capacity decreases as the pavement longitudinal slope increases. Grate inlets are not generally recommended for use in sag locations because of their tendency to clog. There are seven types of standardized grates:

P-1-7/8 (P-50), P-1-1/8 (P-30), 45d Tilt Bar, Reticuline, P-1-7/8-4 (P-50x100), Curved Vane, 30d Tilt Bar

Please refer to HEC-22 for additional details. You can also define your own type of grate by selecting **Other** in the Grate Type list. If you use a non-standard grate on grade, you must specify a splash-over velocity. Enter the grate dimensions in the Grate Length and Grate Width boxes. When a grate inlet is used, its width can't exceed the Gutter Width.

If the grate inlet is in a sag location, sag-related parameters need to be specified. A grate inlet in a sag operates as a weir at small ponding depths and like an orifice at large depths and these are dependent on the size of the grate. The Clogging Ratio is the percent area of the inlet covered by debris whereas the Opening Ratio is the ratio of the open area to the total area, which can be obtained from HEC-22. You need to specify the Opening Ratio if you use a non-standard grate.

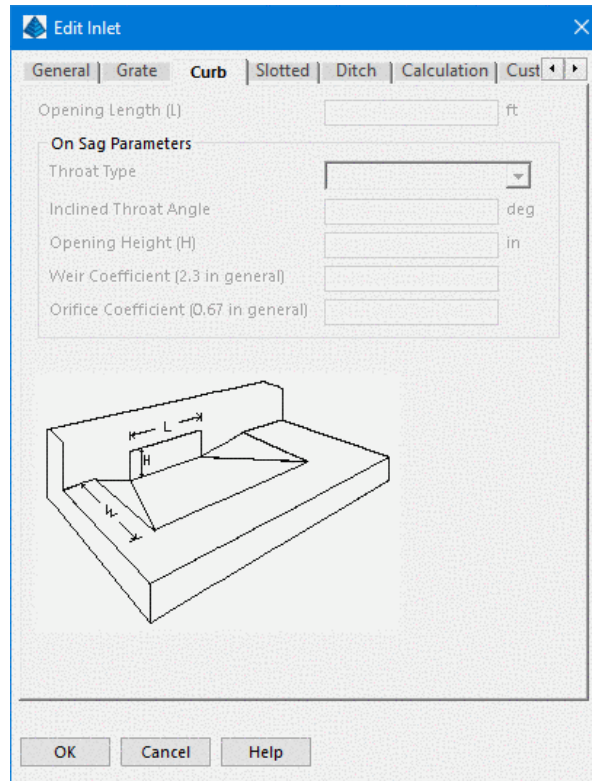

When either the Curb or Combo inlet type is specified, the controls on the Curb Inlet tab are enabled allowing you to create or edit the curb inlet. Curb inlets are less inclined to clog than are grate inlets and have little interference on traffic operation. When placed "on grade," their interception capacity decreases more significantly than that of Grate Inlets as the pavement longitudinal slope increases. As such, Curb Inlets are suitable for use in sag locations or on relatively flat roadways.

When the Curb Inlet is located in a sag, you need to specify the Throat Type:

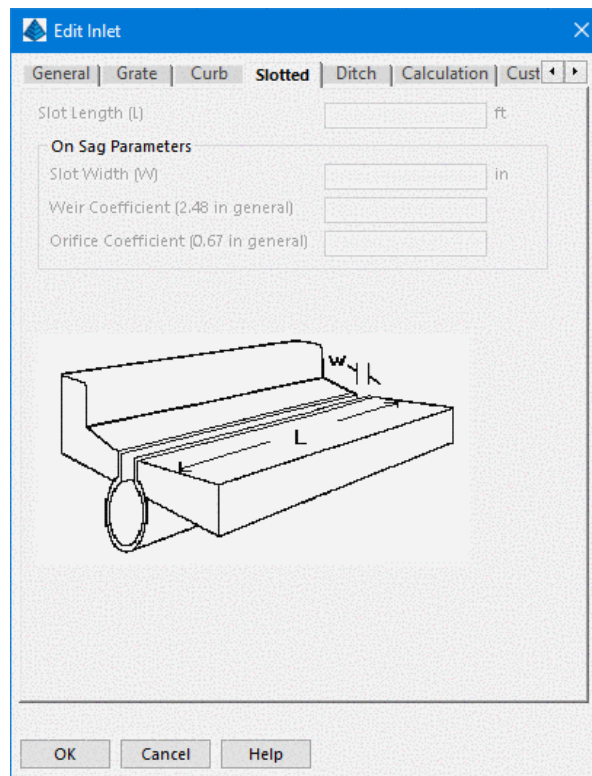

- Horizontal
- Inclined
- Vertical

Please refer to HEC-22 for details on throat types. Additional parameters including the Opening Height, Weir and Orifice Coefficients must also be specified. A curb inlet in a sag behaves as a weir when the depth of water ponding at the curb is less than or equal to the height of the curb opening and like an orifice when ponding depth is greater than 1.4 times the height.

When a Slotted inlet type is specified, the controls on the Slotted Inlet tab are enabled allowing you create or edit a Slotted inlet. Slotted inlets are very effective in intercepting sheet flows due to their long lengths and are suitable to place on roadways. They are very sensitive to clogging and therefore not recommended for use in sags and other locations where debris loadings are considerable. When the slot width is at least 1.75 inches (45 mm) and placed on the pavement along the length of the gutter, the slotted inlet operates similarly to a Curb Inlet.

When installed in a sag, Slotted Inlets perform as weirs to depths up to 0.2 ft (0.06m) and like orifices when the depth is greater than 0.4 ft (0.12m). Refer to HEC-22 for more information.

When the Combo inlet type is specified, the controls on the Grate Inlet tab and Curb Inlet tab are enabled and offer the advantages of both inlet types. The grate is usually the same length as the curb opening and placed alongside it; also called an Equal Length inlet. When the curb opening is longer than the grate, it effectively intercepts trash and debris which may clog the grate and is otherwise known as a Sweeper Inlet.

When a Ditch inlet type is specified, the controls on the Ditch Inlet tab are enabled allowing you create or edit a Ditch inlet. Ditch inlets are typically placed only in sag locations making their capture efficiency 100%. Care should be taken when utilizing Ditch inlets such that the opening does not create a dangerous traffic hazard. In addition to specifying the Bottom Width of the Ditch Inlet, also specify the Left and Right Side ratios as an H:1 ratio.

The Calculation tab allows you to determine how the active inlet will perform against the following parameters:

Flow to Inlet: Specify an assumed amount of flow that will be traveling to the inlet.

Longitudinal Slope: Specify the slope that leads into the inlet.

Pavement Cross Slope: Specify the slope of the pavement that abuts the inlet.

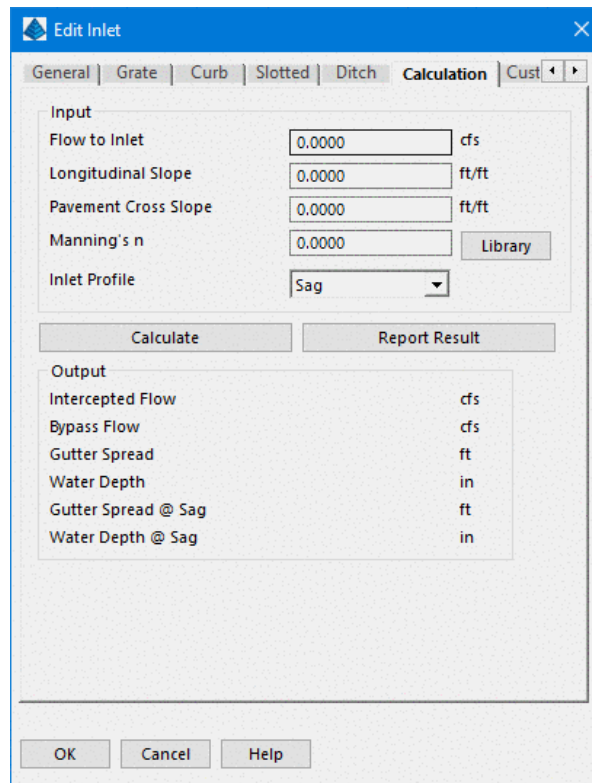

Manning's n: Indicate the *Manning's n* value for the pavement that abuts the inlet or click the **Library** to retrieve the *Manning's n* value from the Pavement Manning's n Library.

Intercepted Flow: The amount of flow that is intercepted by the inlet is reported.

Bypass Flow: The amount of flow (if any) that by-passes the inlet is reported.

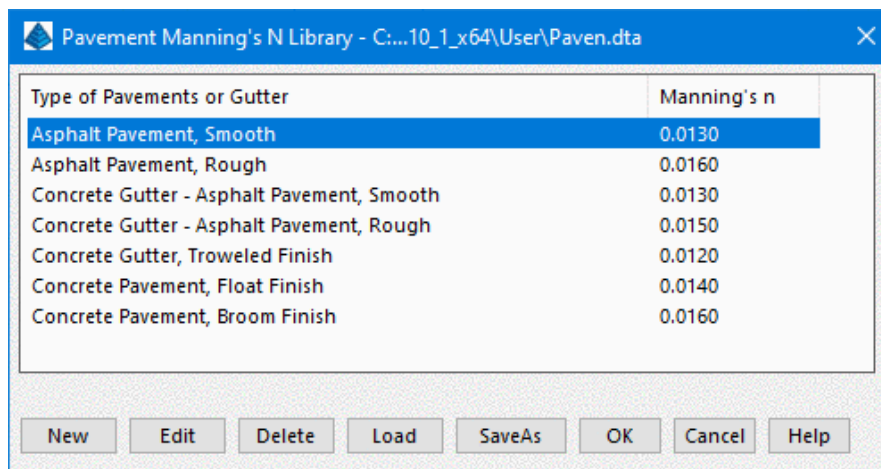

Gutter Spread: The gutter spread (distance from the curb to the outermost edge of the flow of water) is reported.

Water Depth: The water depth in the gutter is reported.

Pavement Manning's n Library

The working Pavement Manning's n library data file is stored (by default) in the `%AppData%\Carlson Software\...\User\Paven.dta` file and is available across all Carlson Software projects. Selecting a desired pavement value and clicking the **OK** button returns the selected *Manning's n* value back to the Calculation tab.

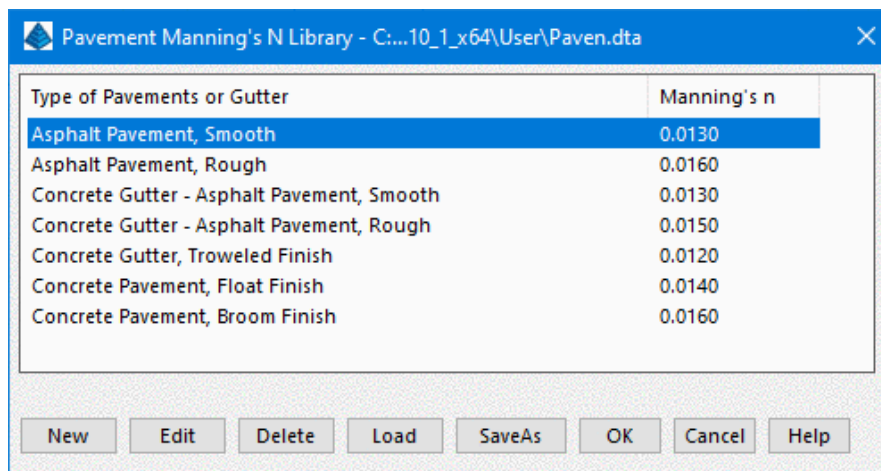

Clicking the **New** or **Edit** button allows a new pavement type and its corresponding *Manning's n* value to be specified.

Pavement Manning's n New Entry

Type of Pavement: Indicate the desired type of pavement.

Manning's n Value: Indicate the *Manning's n* value associated with the pavement type.

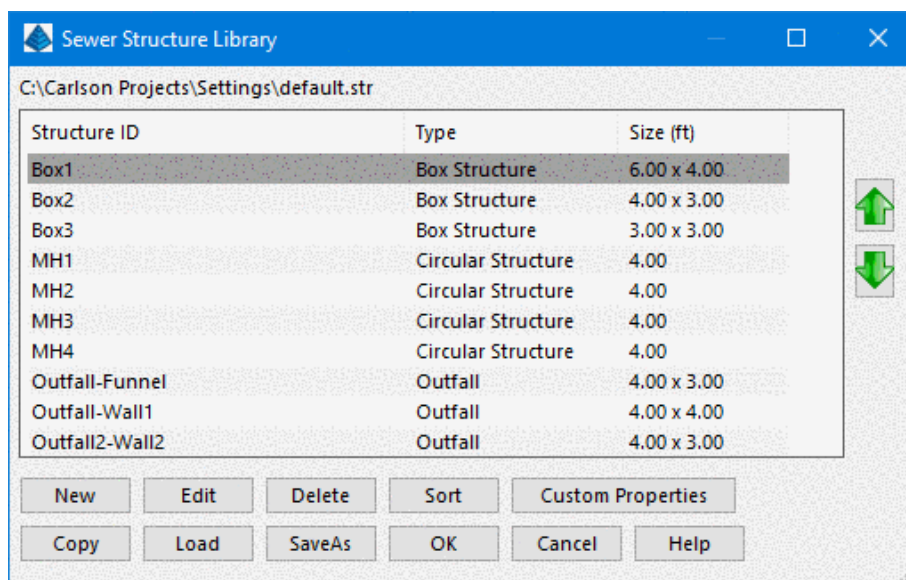

Pulldown Menu Location: Network > Sewer Network Libraries

Keyboard Command: inletlib

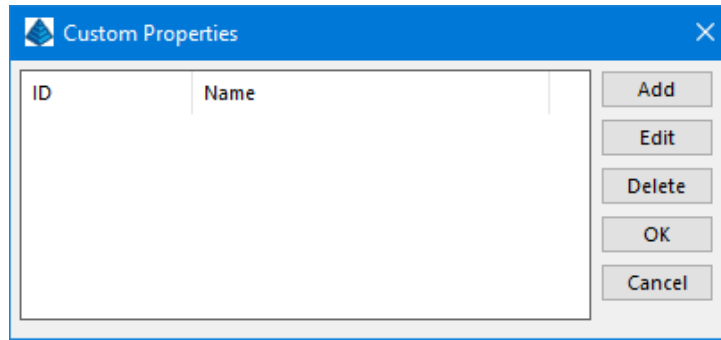

Prerequisite: None

Sewer Structure Library

In a sewer network, there are a few types of structures used at the junctions. The Sewer Structure Library command allows you to create, edit and store sewer structures. The details of the design and construction of sewer structures can be found in the HEC-22 manual.

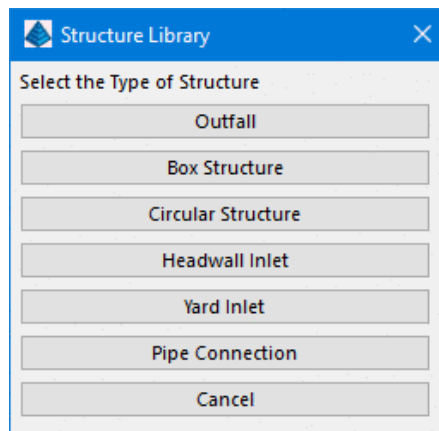

The working structure data file is stored (by default) in the **Carlson Software Install\User** directory and is available across all Carlson Software projects. Existing structures can be edited, sorted or removed from the Structure Library and the Library itself can be saved or re-loaded as desired. The Copy function makes a new structure with the dimensions copied from an existing structure.

The Custom Properties function defines additional fields for each structure. Values for these fields can be entered into the Structure Library. Then these fields are available in the Report Sewer Network command.

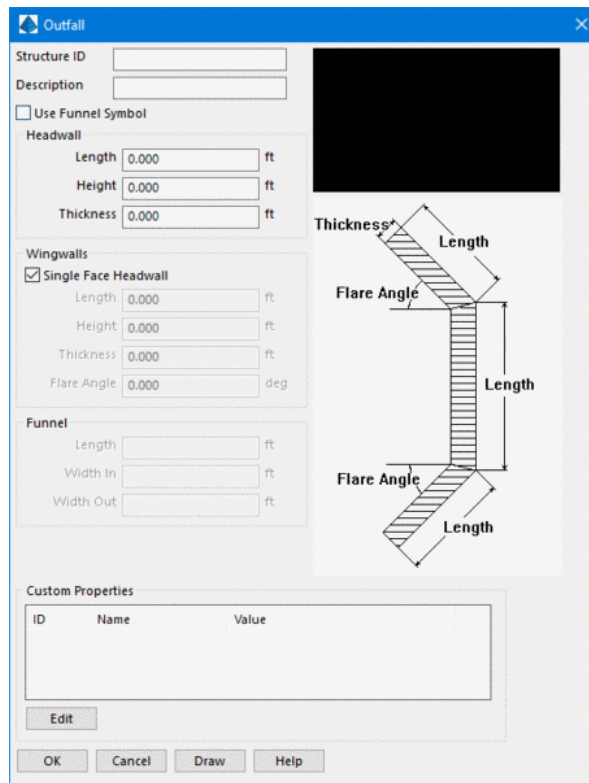

Clicking New gives you the ability to create one of the five types of sewer structures allowed in the Carlson Hydrology module:

- Outfalls are outlet structures at the sewer outlet location. A regular outfall may consist of a headwall and two wingwalls while a funnel outfall consists of a funnel shape structure.
- Box Structures are usually used to support inlet openings and connect them to the underground piping system.
- Circular Structures are manholes that provide access to the sewer network for inspection and maintenance. Manholes are usually installed where pipes change direction (horizontally, vertically or slope), where two or more pipes join or where the pipe sizes change.
- Headwall Inlets are an open-end section similar to a culvert entrance and is used to capture flows at low points.
- Pipe Connections used for lateral connection to main network.

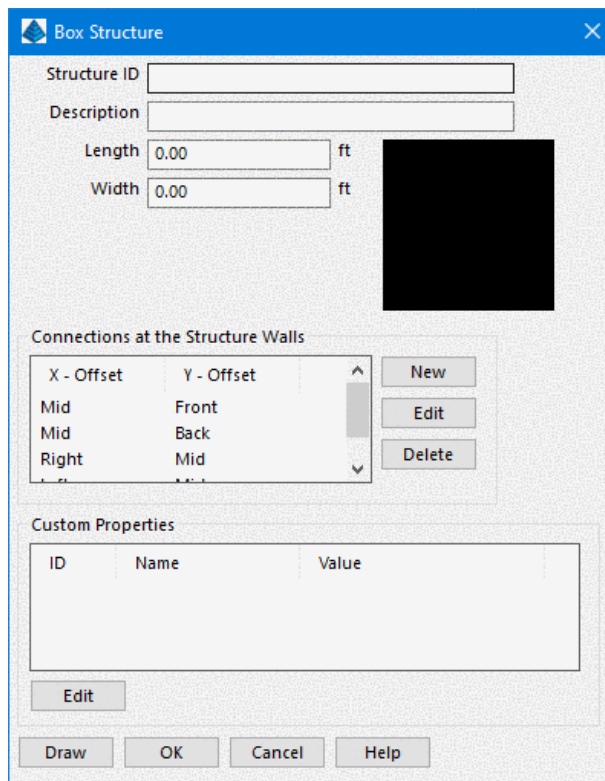

For each structure type, a Draw option allows you to place a "profile aspect" detailed image of the structure (complete with annotation) into your drawing.

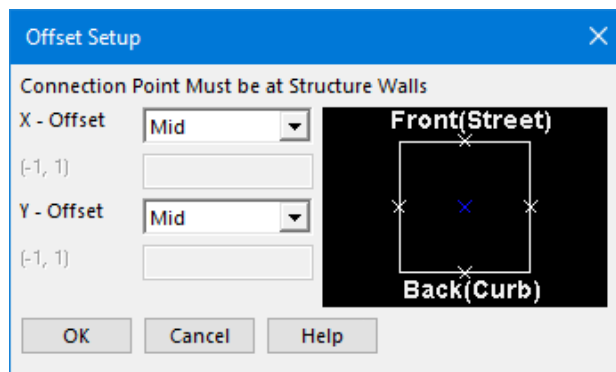

In the Structure ID box, type the structure name. For the regular outfalls, enter the dimensions of the headwall and wingwalls. For the funnel type outfalls, enable the *Use Funnel Symbol* toggle and enter the length and widths of the funnel.

In the Box Structure dialog, type the name of the structure in the Structure ID box, enter the length and width of the structure.

In addition to specifying the physical dimensions of the box structure, you also have the ability to indicate one or more "offset locations" that may better position the box structure around the pipes in situations where the roadway direction is skewed relative to the orientation of the pipes:

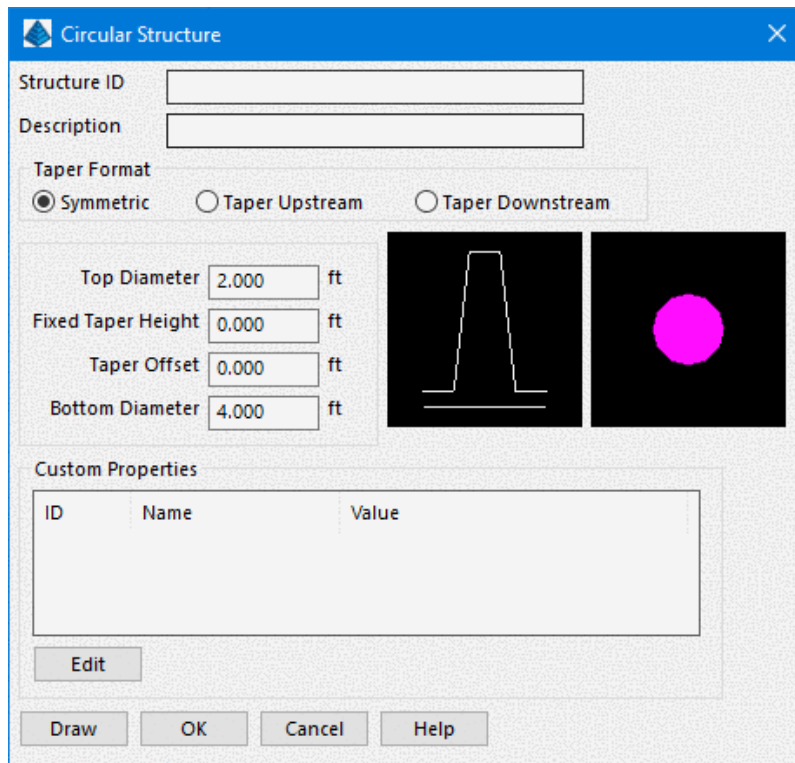

Consider the following example showing a Box Structure with custom offset:

"X" offsets can vary between -1 (Left) through 1 (Right) as a decimal factor relative to the structure length.

"Y" offsets can vary between -1 (Back) through 1 (Front) as a decimal factor relative to the structure width.

In the Structure ID box, type the structure name. Select a Taper Format and enter the Bottom Diameter, Top Diameter, Taper Offset and Taper Height of the structure. A graphic box on the right side of the dialog displays the graphic of the currently defined manhole.

Circular Structure

Pulldown Menu Location: Network > Sewer Network Libraries > Sewer Structure Library

Keyboard Command: strlib

Prerequisite: None

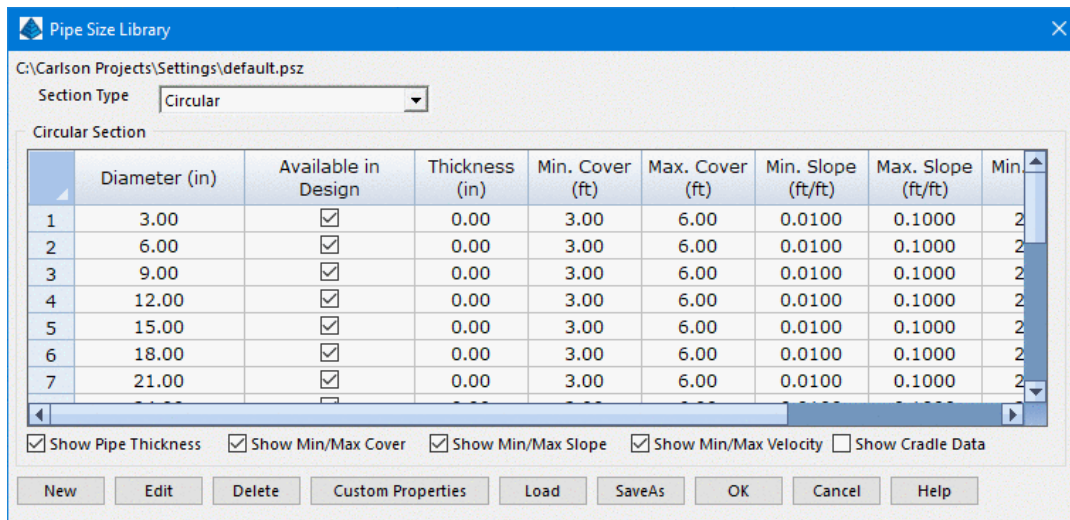

Pipe Size Library

The Pipe Size Library command allows you to store the dimensions of the widely used pipes. There are four pipe sections: box, circular, horizontal ellipse and vertical ellipse. The working structure data file is stored (by default) in the `%AppData%\Carlson Software\...\User\PipeSize.dta` file and is available across all Carlson Software projects.

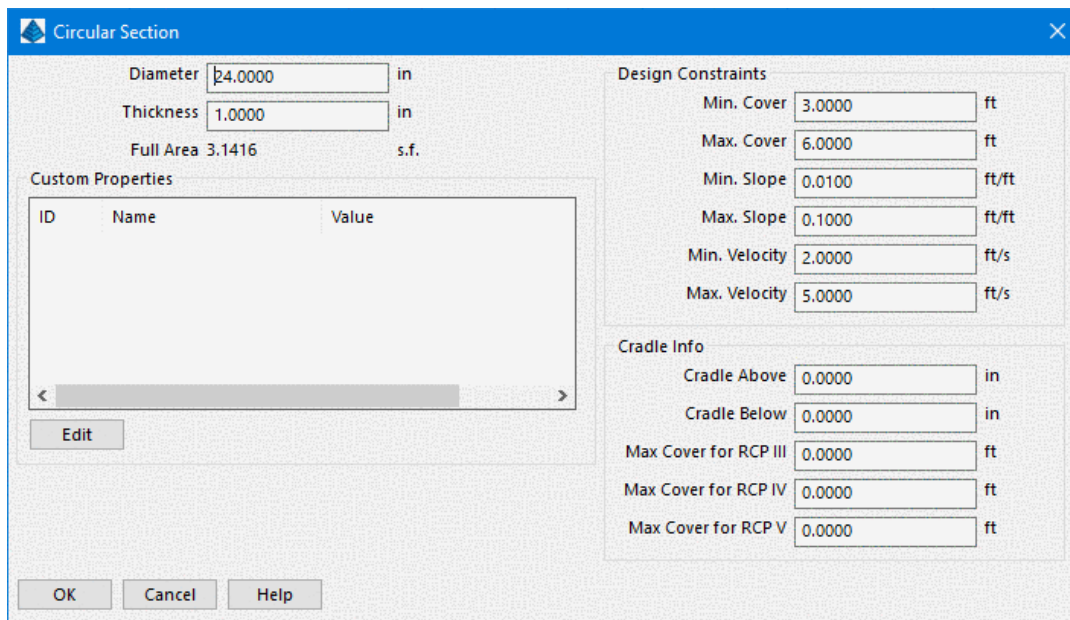

From the Network > Sewer Network Libraries menu in the Hydrology Module, select Pipe Size Library to open the library dialog. The Section Type list contains four section types. You can select one pipe shape to display all the pipe sizes of that shape in the spreadsheet. In the right column of the spreadsheet, the Available in Design check boxes are listed next to the pipe sizes indicating that whether the pipe sizes are available in the pipe size design or not. You may choose to display the Min/Max Cover, Min/Max Slope, Min/Max Velocity and Cradle Data on the spreadsheet. These parameters are used in sewer network design and analysis.

The Custom Properties function defines additional fields for each pipe. Values for these fields can be entered into the Pipe Size Library. Then these fields are available in the Report Sewer Network command.

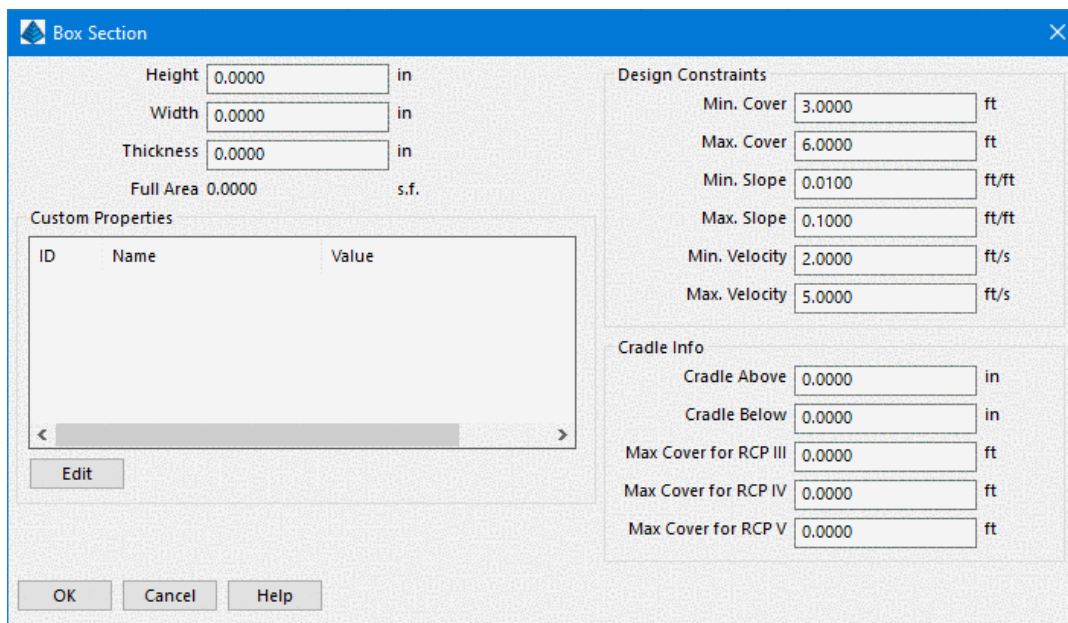

New button adds a new pipe size, Edit button allows you to modify an existing pipe size, and Delete button removes the highlighted pipe size from the library. Load and SaveAs buttons allow you to load and save the pipe size data.

In the Circular Section dialog, type the value in the Diameter box, and then the full cross-section area is calculated and displayed. You may fill in the Design Constraints and Cradle Info for sewer network analysis and sewer profiles. Click on OK button to commit the pipe size entry.

In the Box Section dialog, type the values in the Height and Width boxes, and then the full cross-section area is calculated and displayed. You may fill in the Design Constraints and Cradle Info for sewer network analysis and sewer profiles. Click on OK button to commit the pipe size entry.

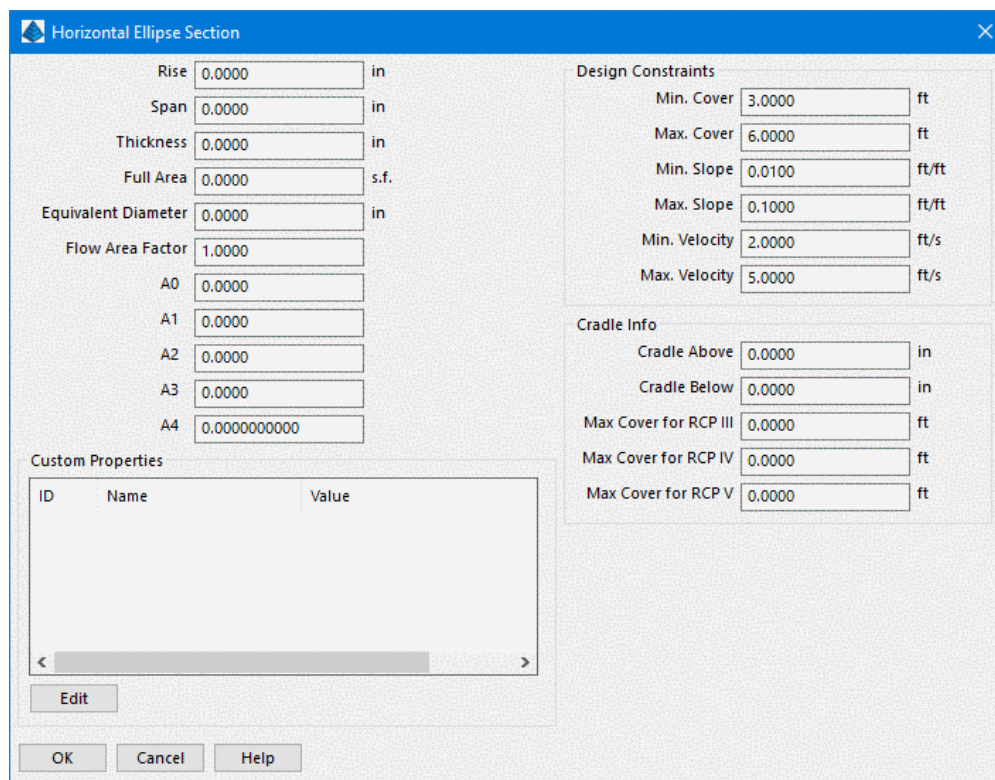

In the Horizontal and Vertical Ellipse Section dialog, type the values in the Rise, Span and Full Area boxes. The Equivalent Diameter is the diameter of a circular section that is equivalent to the ellipse. The Flow Area Factor is the ratio of the calculated full area to the specified full area. A0, A1, A2, A3 and A4 are the five coefficients to the 4th order polynomial equation, which describes the relationship between the wetted perimeter (in) of the ellipse and the depth/rise ratio, as below.

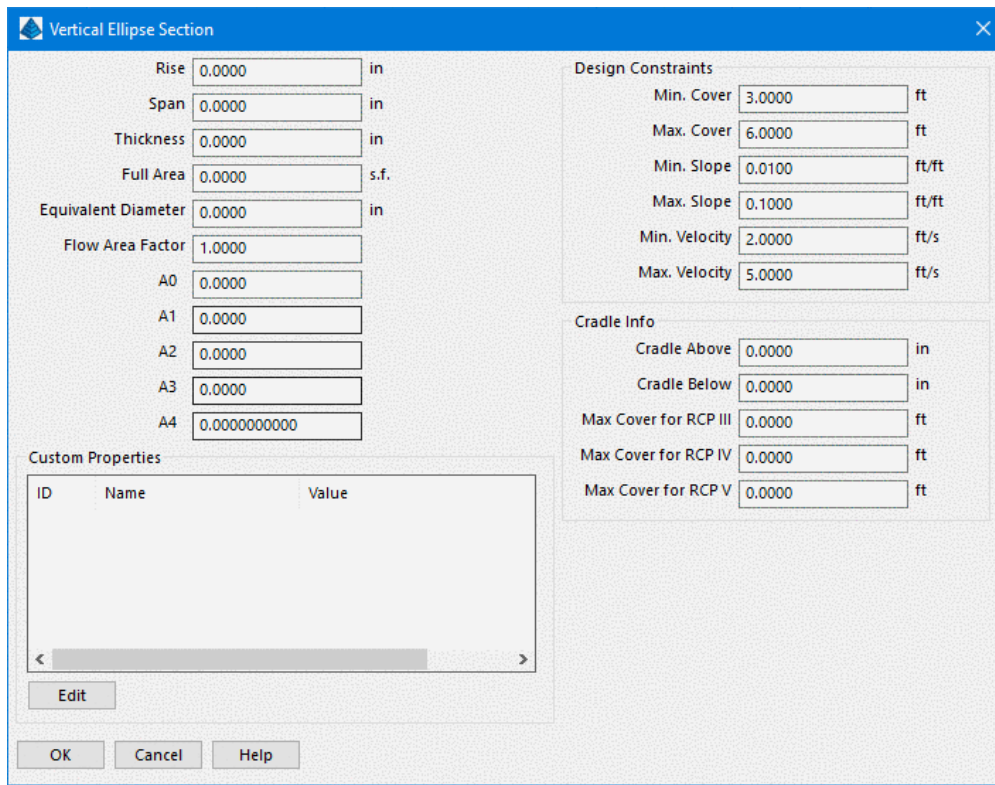

$$p = A_0 + A_1 (d/r) + A_2 (d/r)^2 + A_3 (d/r)^3 + A_4 (d/r)^4, \text{ where:}$$

p = wetted perimeter (in or mm)

d = water depth in the pipe (ft or m)

r = pipe rise (ft or m)

Default Libraries

There are several default libraries for North Carolina under Carlson Projects\Settings\NorthCarolina. Use the Load function to select a library.

Pulldown Menu Location: Network > Sewer Network Libraries > Pipe Size Library

Keyboard Command: pszlib

Pavement Mannings N Library

The Pavement Manning's N Library command allows you to store commonly used pavement types and their manning's n values. The library file is in the ... \USER folder and is available for all projects.

From the Network > Sewer Network Libraries menu in the Hydrology Module, select Pavement Manning's N Library to open the library dialog. The Type of Pavements of Gutter list displays all the stored pavement types and the Manning's N list displays the corresponding manning's n values. New button creates a new pavement manning's n entry, Edit button allows you to modify the highlighted entry, and Delete button removes the highlighted entry from the library. Load and SaveAs buttons allow you to load and save the library data.

Pavement Manning's N Library

Pavement Manning's N New Entry

Prompts

Pavement Manning's N Library dialog: Fill in values.

Keyboard Command: pavenlib

Prerequisite: None

Pipe Manning's n Library

The Pipe *Manning's n* Library command allows you to store commonly used pipe types and their Manning's n values. The working pipe Manning's n data file is stored (by default) in the **%AppData%\Carlson Software\...\User\Pipen.dta** file and is available across all Carlson Software projects for both culvert design and sewer network design.

The Custom Properties function defines additional fields for each pipe material. Values for these fields can be entered into the Pipe Material Library. Then these fields are available in the Report Sewer Network command.

The New button creates a new pipe Manning's n entry while the Edit button allows you to modify the highlighted entry while the Delete button removes the highlighted pipe entry from the library. The Load and SaveAs buttons allow you to load and save the library data.

Pipe Material	Manning's n	Material Type
Cast Iron Pipe	0.0150	Steel
Clay	0.0150	Concrete
Concrete	0.0130	Concrete
Corrugated Metal	0.0250	Steel
Ductile Iron	0.0150	Steel
HDPE	0.0120	Plastic
PVC	0.0200	Plastic
RCP III	0.0130	Concrete
RCP IV	0.0130	Concrete
RCP V	0.0130	Concrete

Pipe Material Name: Indicate the desired pipe material name.

Material Type: Select the closest available pipe material.

Manning's n Value: Indicate the appropriate Manning's n value for the pipe.

Pipe Material New Entry	
Pipe Material Name	Cast Iron Pipe
Material Type	Steel
Manning's N Value	0.015

Pulldown Menu Location: Network > Sewer Network Libraries

Keyboard Command: pipenlib

Prerequisite: None

Input Sewer Line

This command creates a sewer network by placing structures on polyline vertices. Before running this command, draw a polyline connecting where you want to create structures. An advantage of this command over Create Sewer Structure is that the polyline defines the connections between the structures. Also before running this routine, go to Sewer Network Settings to assign the Network File, Surface File and settings.

In the options dialog, set the default values for the structures and pipes. See the Create Sewer Structure topic for information on these settings.

After the dialog, the program prompts to select the polyline. Then temporary arrows are drawn to show the flow direction that the program will use. There is a prompt to reverse this direction if needed. Then the program creates structures at each vertice in the polyline. The design settings such as Min Cover and Min Slope from Sewer Network Settings are used to set the pipe slopes and invert elevations. After creating the structures, the Edit Sewer Structure dialog shows the new structures. You can review and edit the structure properties.

Prompts

Edit Sewer Structure dialog

Pulldown Menu Location: Network

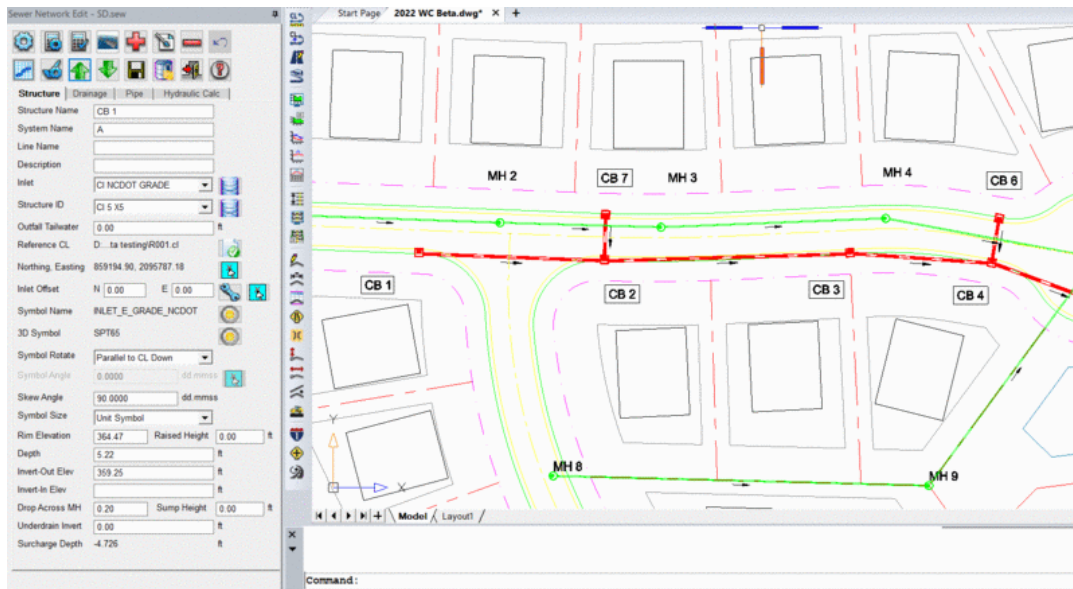

Keyboard Command: plswr

Prerequisite: polyline and Sewer Network Settings

Edit Sewer Structure

The Create Sewer Structure or Edit Sewer Structure command is a very powerful program for the design and analysis of networks. A storm sewer network is generally made up of pipes, structures and inlets. A sanitary/utility network, unlike a storm sewer, doesn't have inlets. There may be more than one pipe entering a structure, but only one can exit. The network type is specified via the Sewer Network Settings command. Depending on the type of sewer network being created or edited, you'll either have the full-featured editing control (described below) for Storm Sewer networks or a more stream-lined Create/Edit Sanitary/Utility Structure command.

This command allows you to construct a graphical representation of a pipe network in the active drawing with associated data including (but not limited to) pipe, structure, inlet, watershed and rainfall details. The Edit/Create Sewer Structure command takes the form of a "docked dialog box" as illustrated below. This flexible interface allows direct access to the *Command*, graphic window, pull-down menus and toolbar... all while the docked dialog box is open.

The storm sewer network is solved using the standard step gradually varied flow methods. This is an iterative procedure used to determine the energy and hydraulic terms at the end of each pipe. The direction of computation is from the most downstream pipe of the network to the most upstream pipe. The following steady state energy equation is used between the upstream and downstream ends of every pipe. Please refer to HEC-22 manual for details. You can design the sewer system with one rainfall return period, and analyze it with another return period.

$$Z_u + V_u^2 / 2g = Z_d + V_d^2 / 2g + H_f$$

where: Z_u = upstream water surface elevation

$V_u^2 / 2g$ = upstream velocity head

Z_d = downstream water surface elevation

$V_d^2 / 2g$ = downstream velocity head

H_f = friction loss

The Manning's equation is applied to determine the friction slope.

$$Q = (M/n) A R^{2/3} S_f^{1/2}$$

where: Q = discharge

M = 1.49 for English unit, 1.0 for Metric units

n = Manning's roughness coefficient

A = cross-sectional area

R = hydraulic radius

S_f = friction slope

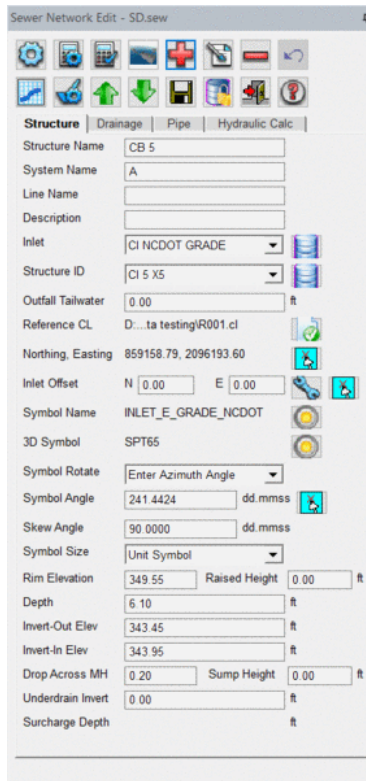

Then the friction loss along the pipe is computed by the following equation:

$$H_f = S_f L$$

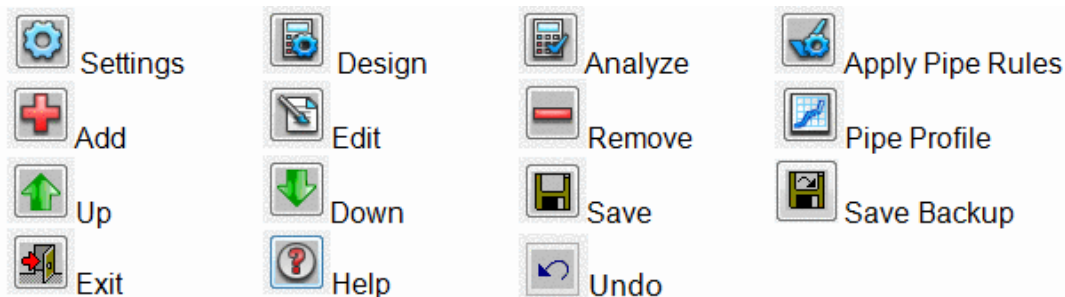

where: L = pipe length

With the friction loss calculated, the elevation of the upstream water surface can be determined.

First set up the working environment by running command Sewer Network Settings under Network > Sewer Network Setup menu. Then select Edit/Create Sewer Structure. If you are creating a sewer structure, pick a location in the plan view where you want to locate the structure, otherwise click on an existing structure symbol. After a structure has been located, the dock dialog displays, and the current structure symbol is highlighted in the drawing. Following is an example of the dock dialog.

The top of the docked dialog box has thirteen buttons, the buttons are as followed. Hover mouse over each icon to see its name.

Common icon controls include the following:

Settings: This function performs as same as the Sewer Network Settings command except for the settings found on the General tab.

Design: When you select any Automation settings in the Sewer Network Settings, i.e. Auto Set All Sewer Pipe Sizes, Auto Set All the Invert Elevation of the Sewer Network and etc., this function would design the profile of sewer lines, such as pipe inverts and sizes, depending on the design settings, and then performs the hydraulic calculation. If you don't choose any Automation settings, this button would work just as the **Analyze** button.

When designing pipe sizes, the program first estimates the design flow for each pipe in the system and makes an initial selection of the size, from the pipe size library, required for each pipe.

Typically, pipe slope is set to the actual invert slope. If the pipe invert elevations are to be designed, pipe slope is assumed as the same as the normal slope. The Manning's equation is then used to solve the required pipe size given the pipe Manning's n coefficient, design discharge and slope. The calculated size is then rounded up to an available

size in the pipe size library. When designing pipe invert elevations, the criterion of minimizing ground cover at all locations along pipe lines is used.

After initial design, the program analyzes gradually varied flow with the standard step method for a few iterations. It uses the actual velocity from the previous calculation to determine the total time of concentration, and therefore the actual flow and hydraulic grade line, modifies the pipe sizes and invert elevations based on the design constraints, and then performs next iteration of computation, until the result is stable and meets the design constraints. Any violations of the design settings will be shown in a warning message dialog window.

Analyze: This function conducts the hydraulic calculation on the existing sewer network.

The program analyzes gradually varied flow with the standard step method and reports the results such as hydraulic grade line, energy grade line, flow velocity, drainage flow rate and inlet interception, *etc.* Any violations of the design settings will be shown in a warning message dialog window.

Add Tributary Pipe Line: This function adds a tributary pipe connecting to an existing structure of the main network.

When adding a tributary pipe line from upstream to downstream, you would choose **Pick New Structure Location to Start**, and then keep picking to create new structures, and in the end pick an existing structure to connect to the main network and finish the tributary line. When choose **Pick Existing Structure to Start**, you would start the tributary pipe line from downstream to upstream, and in the end you hit **Enter** to finish the tributary line.

When the tributary pipe line is from upstream to downstream and the downstream invert of the last pipe is lower than the manhole base elevation, there are five actions defined in the Sewer Network Settings to adjust the network pipe inverts.

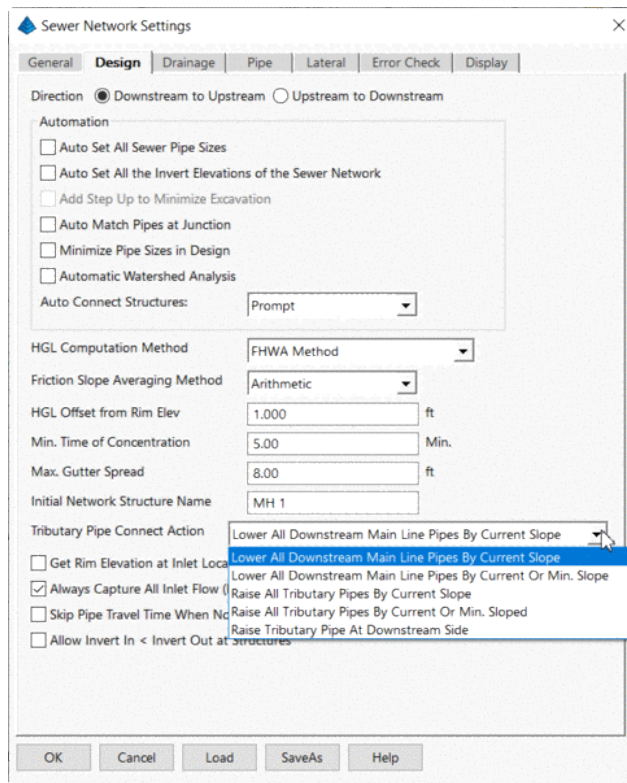

Lower All Downstream Main Line Pipes By Current Slope: This will lower all downstream mainline pipes by the current slope to match the tributary pipe elevation, and create a step up for upstream mainline pipe.

Lower All Downstream Main Line Pipes By Current/Minimum Slope: This will lower the downstream mainline pipes by the current/minimum slopes match the tributary pipe elevation, and create a step up for the upstream mainline pipe. Use a slope between the current and minimum slope to minimize the change of the manhole inverts.

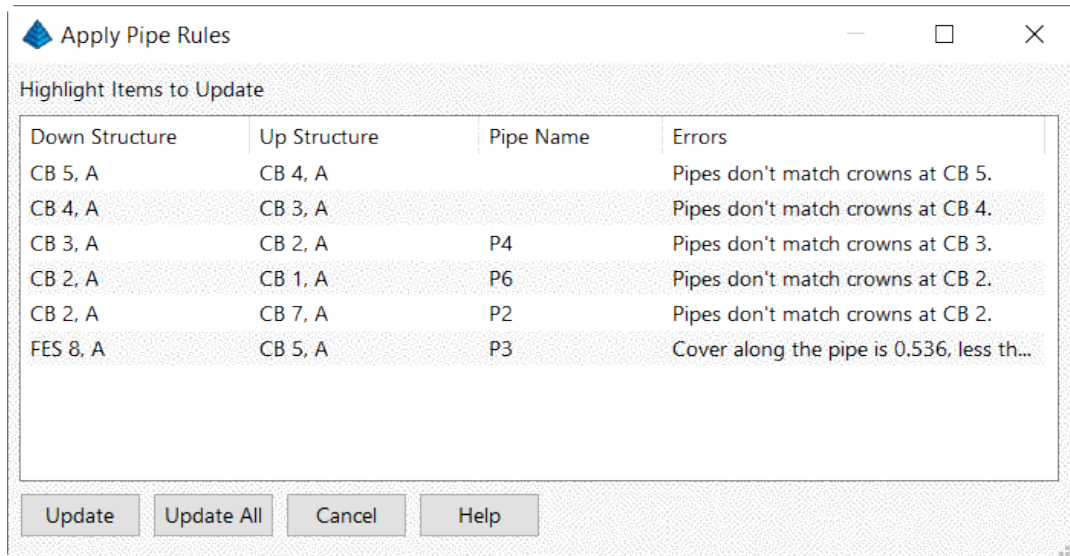

Raise All Tributary Pipes By Current Slope: This option will raise the tributary pipes by the current slope to match the connection invert/crown.

Raise All Tributary Pipes By Current/Min Slope: This option will raise tributary pipes by the current/minimum slope to match the connection invert/crown. Use a slope between the current and minimum slope to minimize the change of the manhole inverts.

Raise Tributary Pipe At Downstream Side: This option will only raise the downstream invert of the last tributary pipe.

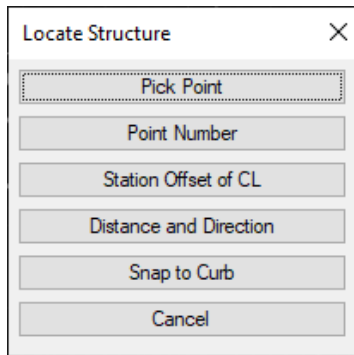

Apply Pipe Rules: Click this button to correct detected pipe problems against those specified in the Pipe Size Library. Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select multiple pipes at the same time.

Pipe Profile: This function will open the Spreadsheet Sewer Editor and allow edits to be made while reviewing multiple pipe runs.

Add: This function allows you to create a new structure. The new structure will connect to the nearest structure found in the network if you select the **Auto Connect Structures** option. There are five ways to pick a location: **Pick Point** in the drawing, enter **Point Number**, enter **Station and Offset** of the centerline, enter **Distance and Direction** from current structure, and **Snap to Curb** and then pick a curb polyline to place the new structure right at the curb line.

Edit: This function allows you to pick an existing structure symbol in the plan view to make the structure active for editing.

Remove: This function removes the structure that you pick and also removes the corresponding pipes and then reconstructs the network.

Up: Moves to the upstream structure and makes it active.

Down: Moves to the downstream structure and makes it active.

Save: Prompts to save any pending network changes.

Save Backup: Prompts to save the network data in a backup file.

Undo: Can undo the changes made to the sewer network. One click reverts one change.

Exit: Dismisses the docked dialog box.

Just below the icons are four tabs. The tabs and each function are described below tabs:

1. Structure - Controls information related to sewer structures (manholes, inlets, rim elevation, *etc*).
2. Drainage - Controls drainage information including watershed information.
3. Pipe - Controls information related to sewer pipes (connection points, size, material, *etc*).
4. Hydraulic Calc - Controls and reports information related to junction losses and the hydraulic calculations.

Structure Name: Provide a unique value to identify the structure in the network.

System Name: A name for current network. All the structures within a sewer line must have the same System Name (there can be more than one sewer line in a sewer (.SEW) file).

Line Name: Provide a unique value to identify the lines names in the network.

Description: Provide an optional note that further describes the structure.

Inlet: Select a pre-defined inlet to be associated with the structure or click the *Library* button to select an Inlet or make changes to the Inlet Library. In addition to associating an Inlet with the Structure, the *Library* button also populates the **Symbol Name** control with the default value stored in the Inlet Library. For a box/circular structure without an inlet, the structure is not a catch basin, but a junction box.

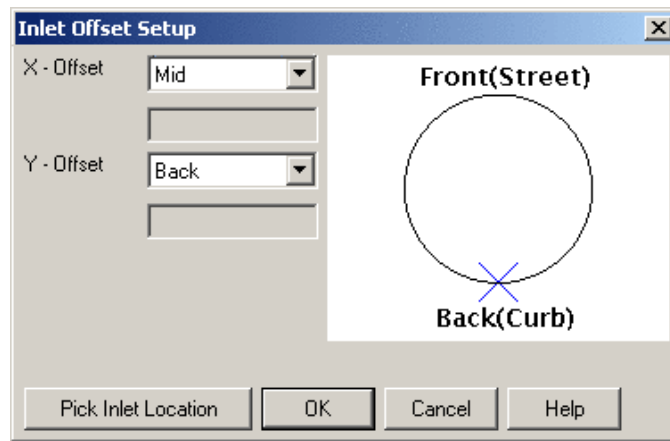

Structure ID: Select a pre-defined structure or click the *Library* button to select a Structure or make changes to the Structure Library. For a box/circular structure without an inlet, the structure is not a catch basin, but a junction box.

Outfall Tailwater: Assign a tailwater elevation for the current outfall. There can be multiple outfalls in a sewer file and each outlet has a tailwater value. This feature becomes active if current structure is an outfall.

Reference CL: Use the *Select* button to determine the station and offset location of the structure relative to a Centerline File or polyline in the drawing.

Northing, Easting: Use the *Location* button to identify the coordinate location where the Structure should be located.

Inlet Offset: Specify the placement of the inlet relative to that of the structure or click the *Setup* button for common offset configurations:

X-Offset: Specify the Easting/Departure of the inlet relative to that of the structure.

Y-Offset: Specify the Northing/Latitude of the inlet relative to that of the structure.

Pick Inlet Location: Graphically identify the placement of the inlet relative to that of the structure.

Symbol Name: This is the plan view symbol for inlets. Use the *Symbol* button to select a symbol for the Structure or to over-ride the value associated with the current **Inlet**.

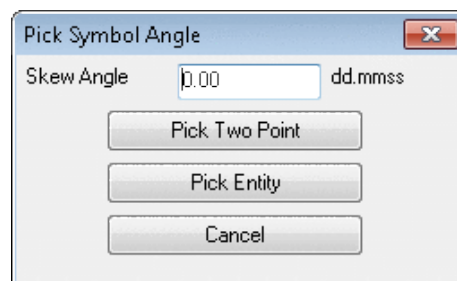

3D Symbol: This is the 3D symbol for inlets when drawing sewer network in 3D. Use the *Symbol* button to select a symbol for the Structure or to over-ride the value associated with the current **Inlet**.

Symbol Rotate: Indicate the method to orient the **Symbol Name** in the drawing. If a **Reference CL** has been specified and depending on how the symbol was originally drawn, consider using one of the *Parallel to CL...* or *Perp to CL...* options to orient the symbol relative to the direction of the centerline.

Symbol Angle: When the **Symbol Rotate** value is set to *Enter Azimuth Angle*, use this field to specify the rotation angle for the symbol, or pick using the screen pick icon

If selecting the icon for symbol rotation the follow options are available for use.

Symbol Size: Indicate how the size of the symbol should be determined:

- *Inlet Library Width* - The symbol is sized according to the *Gutter Width* specified in the Inlet Library.
- *Drawing Scaler* - The symbol block is scaled based on the **Drawing Scaler** derived in Drawing Setup.
- *Unit Symbol* - The symbol is sized based on the size of the symbol block itself.

Rim Elevation: Indicate the rim elevation for the structure this can user input or based off a surface model. Use raised height option to add additional height to a rim elevation.

Depth: Indicate the distance between the Rim Elevation and the base (bottom) elevation of the structure.

Invert-Out Elev: Indicate the invert elevation of the pipe that exits the structure.

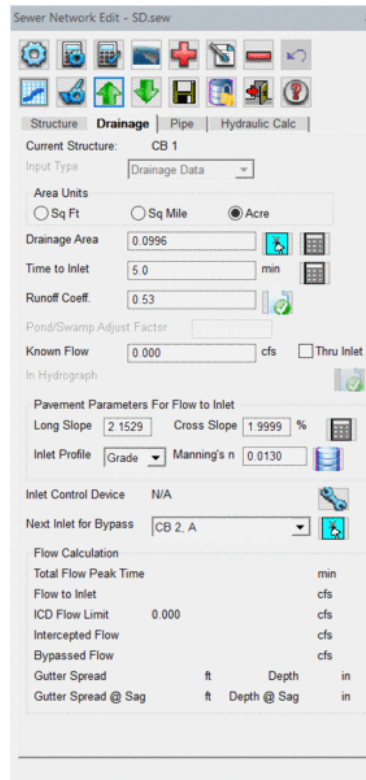

Invert-In Elev: Indicate the invert elevation of the pipe that enters the structure.

Drop Across MH: Indicate the amount of vertical drop across the manhole/structure.

Underdrain Invert: Indicate the invert elevation of an Underdrain Invert system.

Sump Height: Indicate the sump distance below the manhole bottom. Use Sump Height to add additional depth for a structure

Surcharge Depth: The distance between the hydraulic grade line and the Rim Elevation. If the value is negative, the hydraulic grade line is below the rim elevation; otherwise, the water has blown out the structure.

Current Structure: The **Structure Name** from the Structure tab that is current. Use the *Up*, *Down* or *Edit* buttons to navigate through the network to set an alternate structure current.

Input Type: If the **Computation Method** option located in the Drainage tab of the **Sewer Network Settings** is set to *Peak Discharge*, then this option is disabled. If the **Computation Method** is set to *Hydrograph*, two input types are available:

- *Drainage Data* - will let the program generate runoff hydrograph, or,
- *Hydrograph* - specify a known runoff hydrograph directly.

Area Units: Choose a unit to display the area values.

Draw: When this button is clicked, a watershed analysis is performed on the surface model and the drainage area that contributes to this inlet is hatched in the drawing.

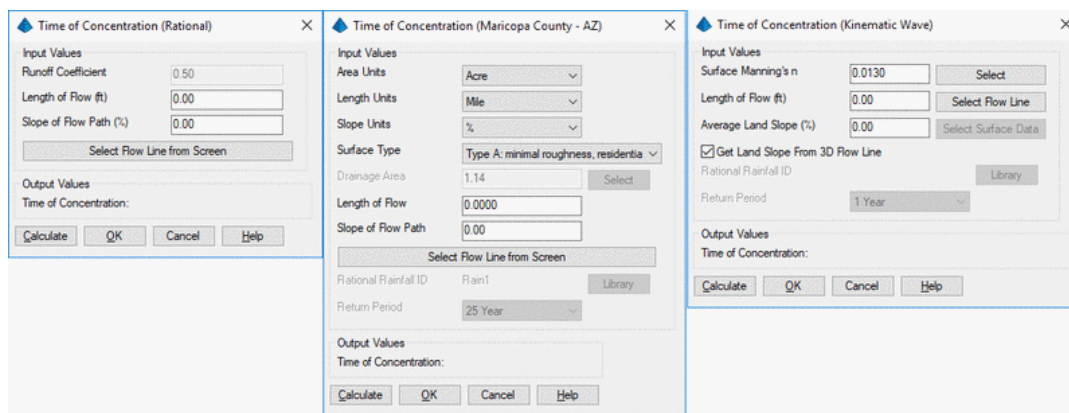

Drainage Area: The drainage area that contributes to this inlet only.

Pick: Use this button to select a closed polyline that represents the boundary of the drainage area. The area will be calculated and displayed.

Calc: This function triggers the watershed analysis routine to calculate the drainage area and weighted runoff coefficient (curve number for SCS method) and displays the values.

Time to Inlet: Enter the time to inlet value or click on the **Set** button to calculate the Time of Concentration. There are three methods to calculate Time to Inlet. Choose one of the method and open its dialog to enter the flow path

data to calculate Time of Concentration.

Runoff Coeff: Indicate the runoff coefficient or click the **Select** button to derive a weighted runoff coefficient from land uses and their respective areas. Please refer to the documentation on Define Runoff Layers for details.

Pond/Swamp Adjust: When the **Hydro Methods** option located in the Drainage tab of the **Sewer Network Settings** is set to *SCS*, indicate the Pond and swamp adjustment factor used in *SCS* peak flow calculations.

Known Flow: You may elect to let any known flow enter into the downstream pipe directly or go through the inlet by enabling the **Thru Inlet** toggle. This provides flexibility to input the calculated drainage runoff directly to the program and to also enter known sanitary flow, infiltration/exfiltration flow, *etc.*, into the sewer network.

Thru Inlet: When enabled, the known flow will enter the sewer network through the inlet rather than simply being considered system flow, and inlet calculation is conducted. Depending on the inlet capacity, some known flow may be bypassed and flow to the downstream inlet. Otherwise, all the known flow is added to the network flow directly.

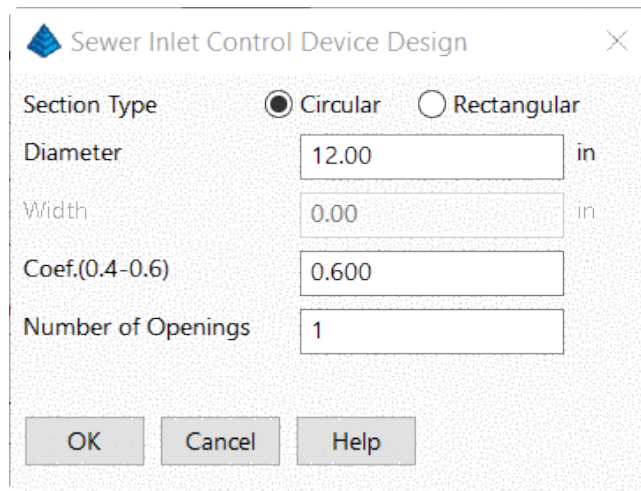

In Hydrograph: When the **Input Type** is set to *Hydrograph*, use the **Select** button to specify the Runoff Hydrograph file name (.HYD) that enters into the structure.

Long Slope: Enter the longitudinal slope of the pavement. This edit field is only available if the inlet is "on-grade."

Cross Slope: Enter the pavement cross slope.

Inlet Profile: Choose between **Grade** or **Sag** type inlet.

Inlet Control Devices: Add inlet control devices, options include **Circular** and **Rectangular**.

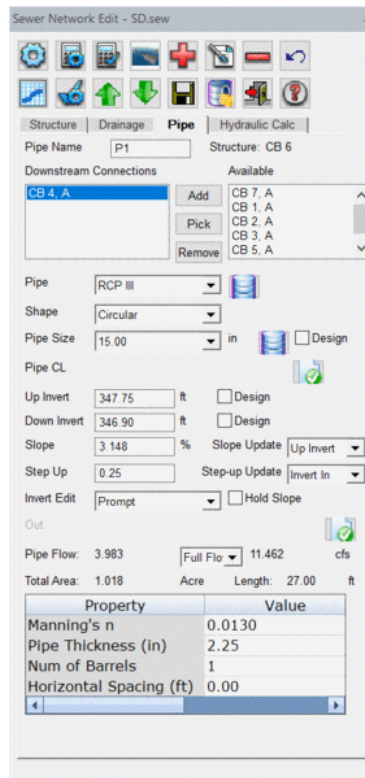

Calc: This function triggers the watershed analysis routine to analyze the surface model and extract the longitudinal slope and cross slope.

Manning's n: Indicate the *Manning's n-value* for the pavement or click on the **Library** button to retrieve this value from the Pavement Manning's n Library.

Next Inlet for Bypass: Indicate the inlet that shall receive any by-pass flow from current catch basin.

Flow Calculation: After you issue either the **Design** or the **Analyze** command on the network, the inlet calculation results are displayed. The inlet results help you to determine if the inlet is sufficient for conveying the ground flow into the network.

Pipe Name: Provide a unique value to identify the pipe in the network.

Downstream (Upstream) Connections: A list showing the connection that exits the structure or the connection(s) that enters the structure, depending on the *Direction* setting found on the Design tab of the **Sewer Network Settings**.

Available: A list that contains all of the structures that are not connected to the current structure, *i.e.* the potential structures that can be connected to the current structure.

Add: Select an available structure to connect to the current structure and click on the *Add* button to form the connection.

Pick: Select a structure symbol in the plan view graphic to form a connection between it and the current structure. If the connection cannot be completed, a warning message appears.

Remove: Highlight a connection in the *Downstream (Upstream) Connections* list and click on the *Remove* button to remove the connecting pipe between the structures.

Pipe Material: Select the pipe material or click on the **Library** button to select a pipe and its corresponding *Manning's n* value from the Pipe Manning's n Library.

Pipe Shape: The pipes can have four different cross-sectional shapes:

- Circular
- Box
- Horizontal Ellipse
- Vertical Ellipse

Refer to the Pipe Size Library for additional details.

Pipe Size: If the *Auto Set All Sewer Pipe Sizes* option found on the Design tab of the **Sewer Network Settings** dialog box is disabled, select the desired pipe size from the list of available pipe sizes or click on the **Library** button to access the Pipe Size Library.

Design: When enabled, the program calculates an appropriate pipe size based on the flow and design settings and selects the closest available pipe size from the *Pipe Size Library*.

Pipe CL: This option allows you to design a curvilinear (non-straight) pipe. The pipe centerline should start from one structure and end at the other structure exactly. Use the **Select** button to identify a Centerline File or polyline in the drawing that represents the pipe path. When one of the structures is relocated, the pipe centerline association will be removed. The pipe bending loss is computed for pipe friction loss when the pipe is curvilinear.

Down Invert/Up Invert: If the *Auto Set All the Invert Elevations of the Sewer Network* option found on the Design tab of the **Sewer Network Settings** dialog box is disabled, indicate the upstream and/or downstream invert elevation of the current pipe or enable either **Design** toggle to have the program calculate the design invert elevation(s).

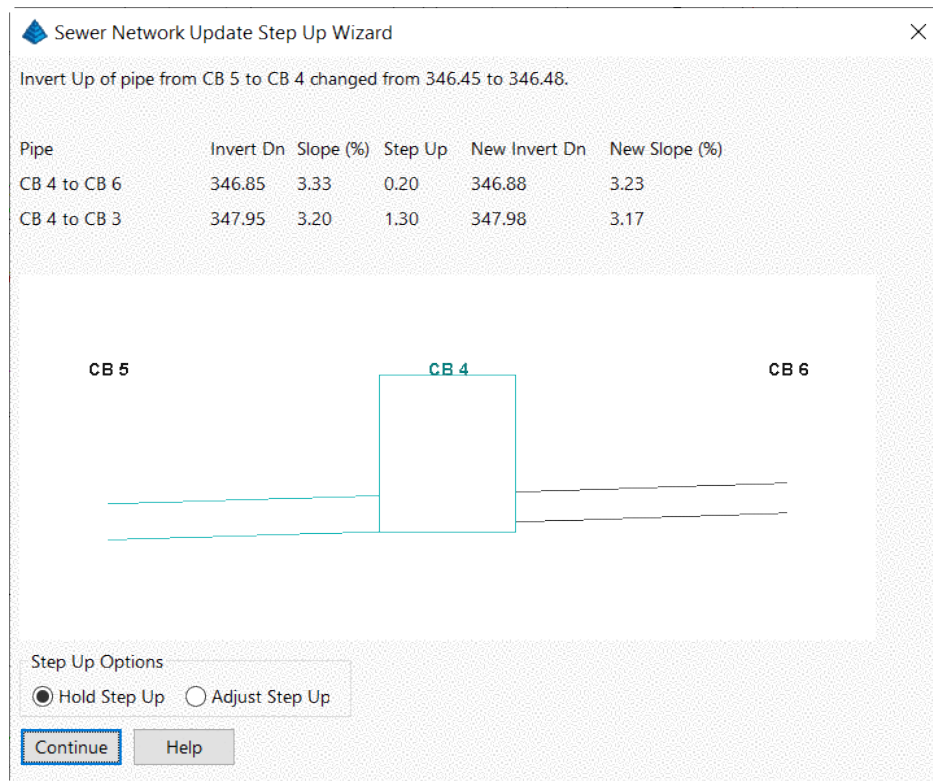

Slope: If neither the *Up Invert Design* toggle nor the *Down Invert Design* toggle is enabled, indicate the pipe slope. Changing the Slope value will alter the *Up Invert* value unless the **Hold Upstream** toggle is enabled.

Slope Update: Allows the user to specify which invert will be adjusted if user changes slope manually.

Step Up: Indicate the "step up" amount of the *Downstream Invert* elevation with respect to the "invert out" elevation of the structure to which it connects. In general the invert out elevation is lower than the invert in elevation of the structure as water flows from upstream to downstream. In Carlson 2018, we introduced **negative step up** in network design, when the invert out is lower than the invert in at the junction.

Slope Update: Allows the user to specify which invert will be adjusted if user changes step-up.

Invert Edit: When a structure has multiple invert in's the step-up wizard will show. Step-up Options are to Hold the original Step-Up or to Adjust Step-Up to a new value.

Hold Slope: This option will hold the pipe slope when editing inverts and step up values..

Out: When the computation method is hydrograph, you are able to generate the outflow hydrograph at the outlet of each pipe. Use the **Select** button to specify the file name.

After you issue either the **Design** or the **Analyze** command on the network, the pipe calculation results are shown.

Pipe Flow: Flow that is being carried by the pipe:

- **Full Flow:** Flow that is being carried by the pipe when flowing full.
- **Max Flow:** The maximum flow that can be carried by the pipe.

Total Area: Total of all the drainage areas that contribute to the flow inside the pipe.

Length: The length of the pipe based on the *Pipe Length* setting found on the Display tab of the **Sewer Network Settings**.

Properties and values may also be entered in the following

Manning's n: Indicate the Manning's n coefficient is used to calculate the friction loss of the pipe.

of Barrels: Indicate the number of pipe barrels that can be found between the *Upstream* and *Downstream* structures.

Hori. Spacing: Indicate the amount of horizontal spacing between each of the *Barrels*.

The energy losses through a pipe junction are specified in the Hydraulic Calc tab. There are six methods to calculate the junction losses: Approximate Method, Dynamic Method, Fixed Head Loss and Energy-Loss Method.

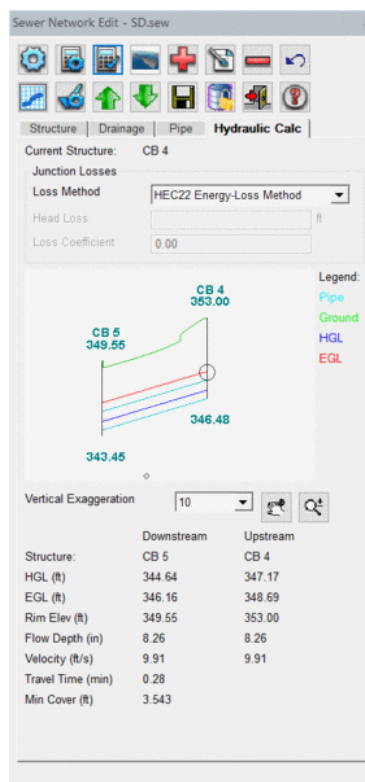

Junction Losses: Indicate one of the following methods for junction loss consideration:

- *Approximate Method* - uses the difference between the downstream velocity head and the upstream velocity head multiplied by the junction **Loss Coefficient**.
- *Dynamic Method* - uses the downstream velocity head multiplied by the junction **Loss Coefficient**.
- *Fixed Head Loss* - uses the actual **Head Loss** you specify.
- *HEC22 Energy-Loss Method* - similar to the Dynamic Method, uses the downstream velocity head multiplied by the adjusted junction loss coefficient. The adjusted junction loss coefficient is defined as the initial head loss coefficient based on relative size of structure multiplied by the correction factors for pipe diameter, flow depth, plunging flow and benching. Calculations use the HEC-22 2009 3rd edition method. Please refer to the HEC-22 manual for details.
- *Total Loss Method* - uses uniform pipe velocities to compute the contraction loss, expansion loss and the greatest bend loss and sums them to get the total head loss. If surface inflow into the structure is greater than 20% of the total flow, then the total head loss should be increased by 30%.
- *Total Loss Smoothed Method (Inlet Shaping)* - is similar to **Total Loss Method**. The difference is that the total head loss should be decreased by 50% if the manhole or junction incorporates partial diameter inlet shaping or channel smoothing.

After you run either the **Design** or the **Analyze** command on the network, the hydraulic calculation results are displayed. The hydraulic grade line, energy grade line, flow depth, flow velocity at both downstream and upstream ends are reported, Travel Time, which is how long the flow takes to travel through the pipe, and **Min. Cover, which is** the minimum distance from the surface elevation to the crown elevation along the length of the pipe.

A graphic box also shows the hydraulic and energy grade lines, pipe outlines and the ground surface, which help you to observe the design result easily.

VDOT Velocity is the velocity based on VDOT calculation method that assumes an 80% full tailwater condition for the pipe run. It's not available for other methods. The **Travel Time** is also calculated from VDOT velocity when VDOT method is used. **Velocity** is the actual velocity based on the true tailwater condition.

Prompts

Select sewer structure to edit: Pick a manhole symbol.

Pulldown Menu Location: Network

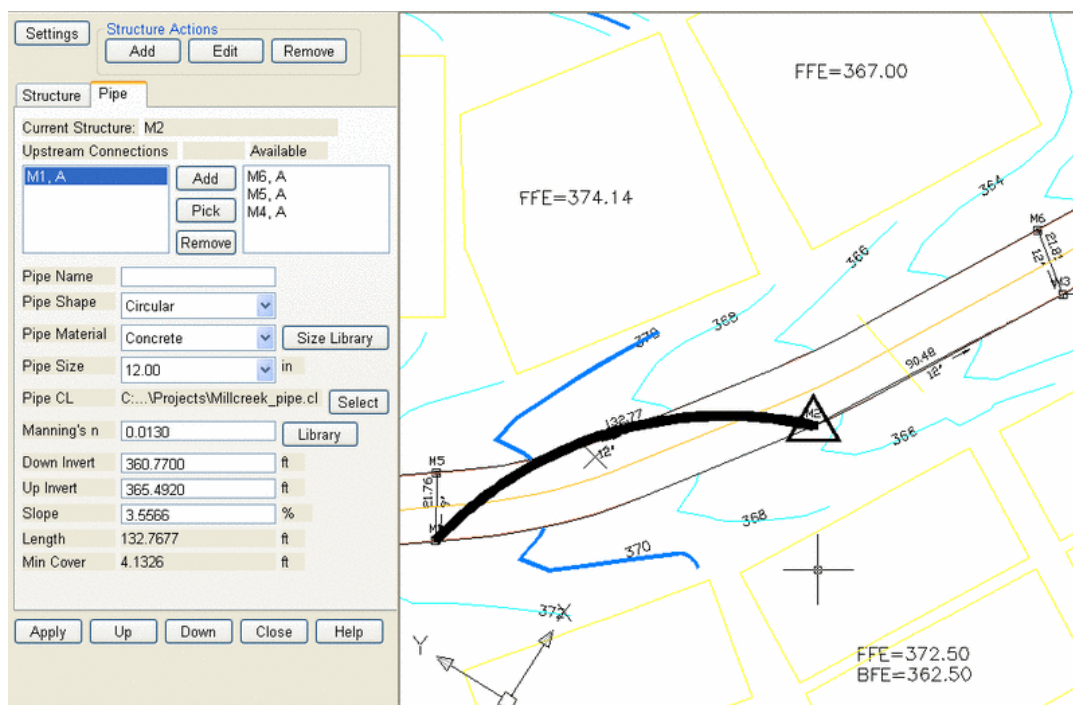

Keyboard Command: editswr

Prerequisite: A sewer (.SEW) file

Edit/Create Sanitary/Utility Structure

This is an alternative version of Edit/Create Sewer Structure for the design of sanitary and utility networks. A sanitary or utility network is generally made up of pipes and structures. There may be more than one pipe entering a structure, but only one can exit. The network type is set in the Sewer Network Settings dialog, and the default type is storm sewer. When you run Edit/Create Sewer Structure, the program performs differently based on the network type. If you work on a storm sewer network, please refer to the documentation on the Edit/Create Sewer Structure.

This command constructs a graphical representation of a pipe network in active drawing, which contains all your design data, such as pipe and structure data. The following is an network example. The Edit/Create Sanitary/Utility Structure dock dialog is on the left, while the network plan view in the active drawing is on the right with current structure and pipe highlighted. When you modify the edit fields on the dock dialog and click on Apply button, the network plan view will be updated automatically. Furthermore, you are allowed to work on the active drawing while the dock dialog is open. This command doesn't perform hydrology calculation, so no flow data is needed.

Edit/Create Sanitary/Utility Structure Dialog and Dynamic Editing in the Active Design Drawing

1. Dock-Dialog Components

First set up the working environment by running command Sewer Network Settings under Network > Sewer Network Setup menu. Then select Edit/Create Sewer Structure. If you are creating a sewer structure, pick a location in the plan view where you want to locate the structure, otherwise click on an existing structure symbol. After a structure has been located, the dock dialog displays, and the current structure symbol is highlighted in the drawing. Following is an example of the dock dialog.

Edit/Create Sewer Structure

This dialog window has two tabs, Structure and Pipe, which are used to enter structure and pipe parameters. The following is the description of the functionalities of the buttons for designing sanitary/utility network.

Settings: This function performs as same as the Sewer Network Settings command except for the generate settings of setting up the network file and surface file etc. Please refer to the documentation on Sewer Network Settings.

Add: Adds a new structure to the network at the location you pick in the plan view. The just created structure will become the active structure for editing.

Edit: This function allows you to pick an existing structure symbol in the plan view to make the structure active for editing.

Remove: This function removes the structure that you pick, and also removes the corresponding pipes and then reconstruct the network.

Apply: Save the changes of the network.

Up: Moves to the upstream structure and makes it active.

Down: Moves to the downstream structure and makes it active.

Close: Quit the sewer network dock dialog.

2. Structure

The structure data is entered through the Structure tab.

Structure		Pipe	
Structure Name	<input type="text" value="M2"/>		
System Name	<input type="text" value="A"/>		
Structure ID	<input type="text" value="Box1"/>	<input type="button" value="Library"/>	
Reference CL		<input type="button" value="Select"/>	
Northing, Easting	<input type="text" value="1012.468, 1072.840"/>	<input type="button" value="Location"/>	
Symbol Name	<input type="text" value="INLET4"/>	<input type="button" value="Symbol"/>	
Symbol Rotate	<input type="text" value="Parallel to CL Up"/>		
Symbol Angle	<input type="text" value="0.0000"/>	<small>dd.mmss</small>	
Symbol Size	<input type="text" value="Drawing Scaler"/>		
Rim Elevation	<input type="text" value="365.9025"/>	<input type="text" value="ft"/>	
Depth	<input type="text" value="5.1325"/>	<input type="text" value="ft"/>	
Invert-Out Elev	<input type="text" value="360.7700"/>	<input type="text" value="ft"/>	
Sump Height	<input type="text" value="0.0000"/>	<input type="text" value="ft"/>	

Sanitary/Utility Network Edit Structure

Structure Name: An identical name of the structure in the network.

System Name: A name for current network. All the structures in the same network have the same system name.

Structure ID: This is the ID of a predefined structure in the structure library. The **Library** button next to it allows you to select or define a sewer structure in the structure library. Once you select the structure, the dimension of the structure are retrieved from the library. Please refer to the documentation of the Sewer Structure Library for details.

Reference CL: The reference centerline is used to locate the structure by station/offset of the centerline points, and align the structure symbol in the graphic. The **Select** button allows you to select a centerline from either a centerline file or a polyline.

Location: This button allows to relocate the structure by pick a position in the drawing.

Symbol Name: This is the name of the symbol that represents the structure in the network plan view. The **Symbol** button allows you to select a symbol from a list of symbols.

Symbol Rotate: There are 10 options to rotate the structure symbol for displaying in the drawing.

Symbol Angle: When the Symbol Rotate value is set to Enter Azimuth Angle, this edit field is enabled for entering an angle.

Symbol Size: Three options to determine the size of the structure symbol.

Rim Elevation: The rim elevation for the structure, it's usually the surface elevation.

Depth: The distance between the rim elevation and the base elevation of the structure.

Invert-Out Elev: The invert elevation of the pipe that exits the structure.

Sump Height: The distance between the base elevation and the invert-out elevation.

3. Pipe

The pipe data is entered through the pipe tab. The **Downstream/Upstream** list contains the connection that exits the structure or the connections that enter the structure, depending on the design direction. The **Available** list contains all the structures that are not connected to the current structure, i.e. the potential structures that can be connected to

the current structure. There is two ways to add a connection. The first one is clicking on the **Add** button to connect the highlighted structure in the Available list to the current structure. The other one is clicking on the **Pick** button and then select a structure symbol in the plan view to connect it. If the connection is unable to be performed, a warning message pops up. By selecting the available structure to **Add** or **Pick** the **Pipe Connection Wizard** dialog will open to allow the user to visualize the connection to be made. See the following section for more information on the **Connection Pipe Wizard**. The **Remove** button allows you to remove the highlighted connection from the Downstream/Upstream list.

Sewer Network Edit Pipe

Pipe Name: An identical name of the pipe in the network.

Pipe Shape: The pipes can have four different cross-sectional shapes: circular, box, horizontal ellipse and vertical ellipse.

Pipe Material: There are nine material options.

Pipe Size: The value can be chosen from a list of pipe sizes stored in the size library.

Pipe Size Library: This button allows you to store commonly used pipe sizes. Please refer to the documentation on the Pipe Size Library for details.

Pipe CL: This option allows you to design a non-straight pipe. The pipe centerline should start from one structure and end at the other exactly. If you change the location of one of the structures, the centerline would be deserted and the pipe would become straight.

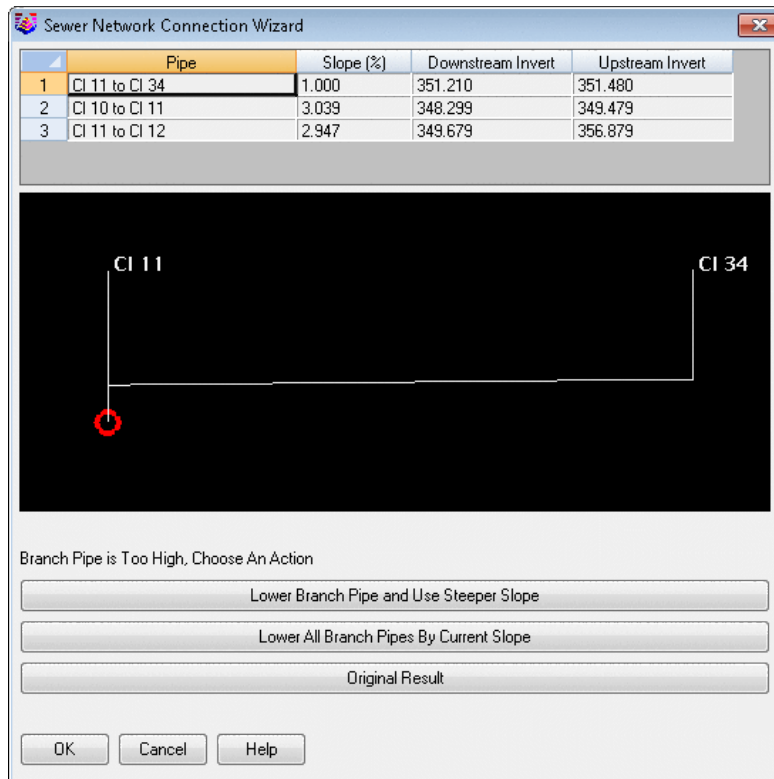

Manning's n: The Manning's n coefficient is used to calculate the friction loss of the pipe. The **Library** button allows you to select a Manning's' n value. Please refer to the documentation on the Manning's N Library for details.

Down Invert/Up Invert: They are the downstream invert and upstream invert elevations of the pipe.

Slope: Pipe slope.

Min. Cover: The minimum distance from the surface elevation to the crown elevation all along the pipe, is calculated automatically.

Selecting the available structure to **Add** or **Pick** the **Pipe Connection Wizard** dialog will open to allow the user to visualize the connection to be made. If the normal slope based from the **Sewer Network Settings** file CAN be created the following dialog box will appear.

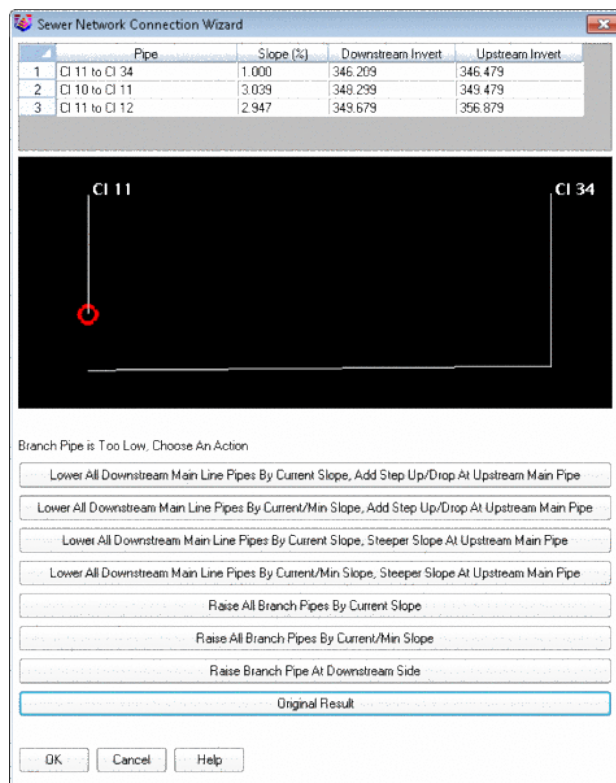

Lower Branch Pipe and Use Steeper Slope: This will change the slope of the branch pipe to match the invert of other upstream connection.

Lower All Branch Pipes By Current Slope: This will lower both inverts and maintain the current slope.

Original Results: This will reset changes made to the original results.

If the normal slope based from the **Sewer Network Settings** file CANNOT be created the following dialog box will appear and offer other design changes for the connection.

Lower All Downstream Main Line Pipes By Current Slope, Add Step Up/Drop At Upstream Main Pipe: This will lower all downstream pipes by the current slope to the branch pipe elevation, therefore creating a step up/drop structure for upstream pipes.

Lower All Downstream Main Line Pipes By Current/Minimum Slope, Add Step Up/Drop At Upstream Main Pipe: This will use the Sewer Network Settings to lower all downstream pipes by the current/minimum slopes to the branch pipe elevation, therefore creating a step up/drop structure for upstream pipes.

Lower All Downstream Main Line Pipes By Current Slope, Steeper Slope At Upstream Main Pipe: This will use the Sewer Network Settings to lower all downstream pipes by the current slope to the branch pipe elevation increasing the upstream pipe connection.

Lower All Downstream Main Line Pipes By Current/Minimum Slope, Steeper Slope At Upstream Main Pipe: This will use the Sewer Network Settings to lower all downstream pipes by the current/minimum slopes to the branch pipe elevation increasing the upstream pipe connection.

Raise All Branch Pipes By Current Slope: This option will raise branch pipes by the current slope

Raise All Branch Pipes By Current/Min Slope: This option will raise branch pipes by the current/minimum slope.

Raise Branch Pipe At Downstream Side: This option will raise the downstream invert of the branch pipe.

Original Results: This will reset changes made to the original results.

Prompts

Select sewer structure to edit: *pick a manhole symbol*

Sewer Structure Data dialog: Fill in values

Pull-down Menu Location: network > Edit/Create Sewer Structure

Keyboard Command: editswr/putswr

Prerequisite: a sewer file (.SEW), a surface file (.TIN, .GRD, .FLT)

Edit/Create Sewer Structure - Plan View

The Edit Plan View command allows the user to select a plan view structure and make fast, easy edits to a sanitary\storm network (*.SEW). These edits will automatically update the network file (*.SEW), update the profile drawn, and update other design features such as Energy Grade Line (EGL) and Hydraulic Grade Line (HGL) data as long as the user applies the feature to Save to Profile File when drawing the profile itself.

Command Prompt: *Select sewer structure to move [Options]: Press O for Options*

Sewer Plan View Grip Update Option allows the user to define what happens to the relocated structure. Hold Structure Invert would maintain the original invert elevation to the new location. Hold Structure Depth would hold the original depth to the new location. Hold Downstream or Upstream Pipe Slope maintains the original pipe slopes to the new location.

Prompts

Select sewer structure to move [Options]:

Pull-down Menu Location: Network

Keyboard Command: sewer_plan_grip

Prerequisite: A sewer (.SEW) file

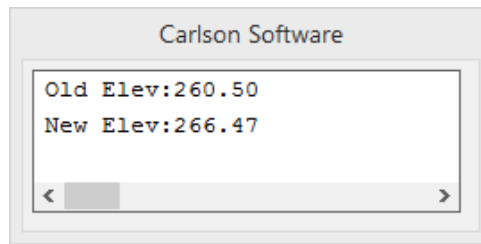

Edit/Create Sewer Structure - Profile View

This command allows you to select a structure or a pipe on a profile and make fast, easy edits to a sanitary\storm network (*.SEW). These edits will automatically update the network file (SEW), update the profile drawn, and update other design features such as Energy Grade Line (EGL) and Hydraulic Grade Line (HGL) data as long as the feature to Save to Profile File when drawing the profile is active.

When making profile edits you can select either a structure or a pipe to edit. When a structure is selected, you can make elevation edits to the selected structure. When a pipe is selected, there are options to modify the pipe invert in or invert out by selecting on the appropriate end of the pipe, or by selecting the middle of the pipe to hold the pipe slope and move the entire pipe for vertical revisions.

First select the structure to edit. The following dialog box will open showing the Old Elev: and the New Elev: for the structure invert elevation. You can then enter new elevation or pick a point for elevation on screen. You can also edit the structure rim elevation by typing R for Rim at the command line. Structures can only be edited in the

profile vertically.

Structure Edits can be made by selecting the structure to edit and screen picking or entering new elevations.

Select the pipe to edit. The following dialog box will open showing the invert elevations and pipe slope. You can then enter new elevation or pick a point for elevation on screen. At the command line, you can also enter keywords for Size, Slope or Step up to change the pipe size, pipe slope or step-up.

The pipe edit mode depends on where you select the pipe. Selecting near the mid point holds the pipe slope and you can edit the elevations together. Selecting near an invert edits only that end of the pipe and you can change the slope.

Prompts

Select sewer entity to move (Enter to End): *pick a structure*

Enter new elevation or pick a point for elevation [Rim Elevation](Enter to End): *pick elevation*

Select sewer entity to move (Enter to End) [Undo/Exit]: *pick a pipe*

Enter new elevation or pick a point for elevation [Size/STepup] (Enter to End): *pick elevation*

Select sewer entity to move (Enter to End) [Undo/Exit]: *press Enter*

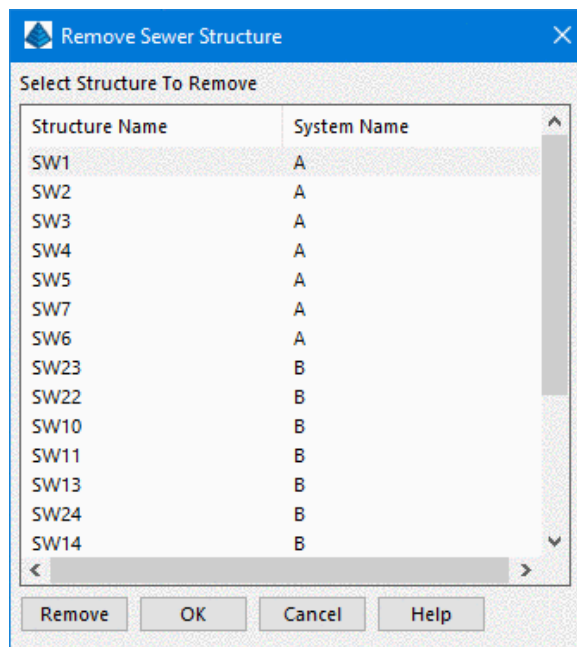

Pulldown Menu Location: Network > Edit Sewer Structure

Keyboard Command: sewer_prof_grip

Prerequisite: A sewer (SEW) file and saved (PRO) profile pipes.

Remove Sewer Structure

This command removes a structure from the sewer network. The structure to remove can be selected from a list of structure names or screen picked. To screen select a manhole, pick on the manhole symbol. The manhole symbol and labels are erased from the screen and the manhole is removed from the sewer network file.

Prompts

Select structures to erase by screen pick or name list [**<Pick>/List**]? *press Enter for Pick*

Select sewer structure to remove: *pick a manhole symbol*

Select sewer structure to remove: *press Enter to end*

Pulldown Menu Location: Network

Keyboard Command: rmswr

Prerequisite: Sewer network manholes

Lateral Design Overview

Lateral design is available in both the storm sewer and sanitary sewer design programs. A lateral pipe is very much like a regular pipe in sewer network. A lateral is the underground pipe that connects a residence or business to the main line pipe. The lateral connection has a property of offset elevation relevant to the mainline sewer invert at the point of connection. Both the cleanout and connection can be either a box or circular structure. The lateral data is stored in the main network / current network file, although designed using a different command. A prerequisite for Lateral Design the user must have completed either a Storm Network or Sanitary Sewer Network as the main line, and set the file as the Active File to be used in the Sewer Network Settings dialog box.

There are five options to locate a Lateral Connection Point. If connecting to a structure, select "Pick A Structure". If the lateral is to connect at the main, there are 4 options.

Pick a Pipe.

Using this option, a connection is made where a pipe is selected.

Pick a Pipe and Exact Location on Main.

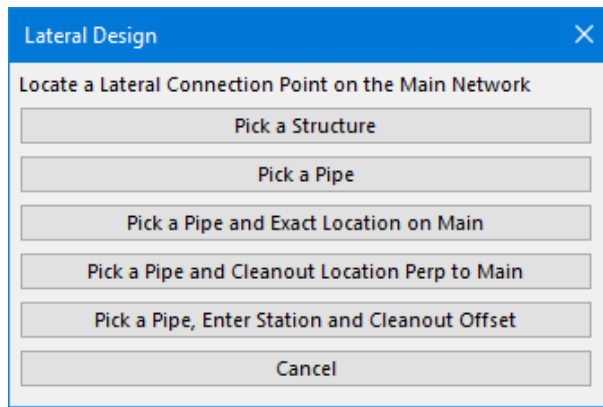

Using this option, a pipe is selected, then the connection location is selected.

Pick a Pipe and Cleanout Location Perpendicular to Main

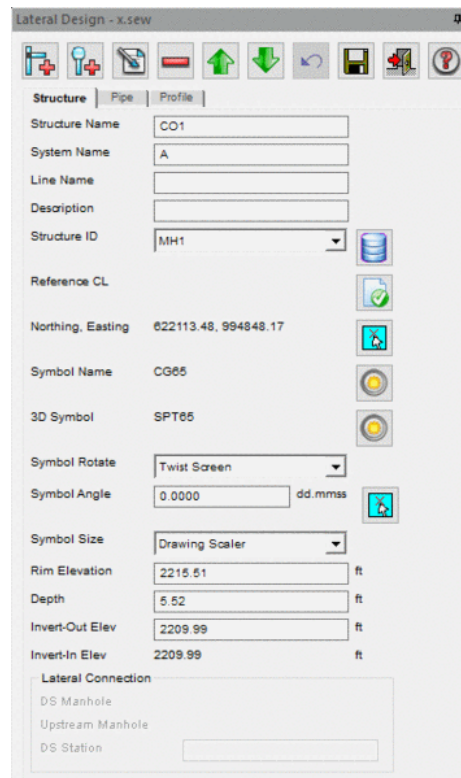

Using this option, a target pipe is selected, then the cleanout is located perpendicular to the selected pipe.

Pick a Pipe, Enter Station and Cleanout Offset.

Using this option, a target pipe is selected and the connection is made at a specified Station and offset.

The Pick a Structure allows the user to select a structure within the Main Network File and opens the following Docked Dialog. This dialog box works similar to the regular pipe in sewer network. By hovering the mouse over the icons at the top of the dialog box the user can see the command associated with each. Starting from left to right the commands are as followed Add Connection, Add Cleanout, Edit, Remove, Up, Down, Save, Exit, and Help. The Structure Tab gives the user information of the selected structure. The dialog box specifies the downstream and upstream manhole connections as well as the station along the main network pipe measured from the downstream structure. The Connection Height allows the user to specify the entrance height of the connection on the main network structure. Depending on the type of the connection point some of the dialog box will only supply data while others may be edited. In the following example we selected to connect to a structure, therefore data present related to the actual manhole with only the connection height available for editing.

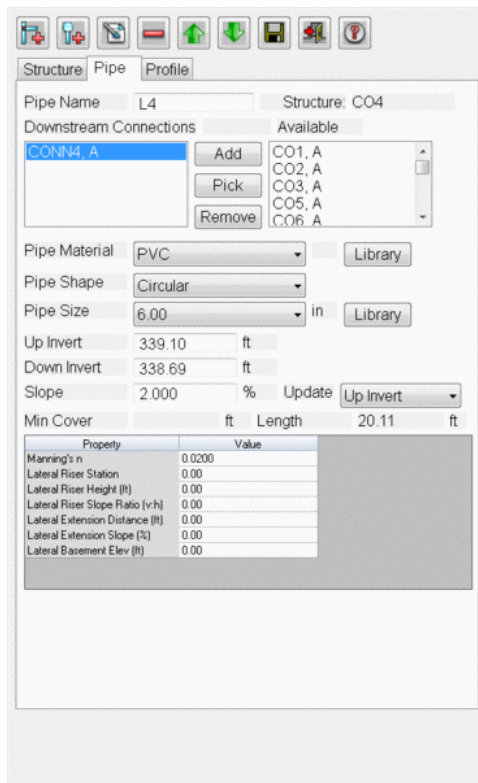

When one of the 4 Pick a Pipe options is selected other fields in the docked dialog box are available for selection allowing the user to specify a Structure Name, System Name, Description, Symbol Rotate, Symbol Angle, and Symbol Size. Rim Elevations and Depth are calculated and the downstream and upstream manholes shown. The user is given the downstream station for the connection that can be adjusted if desired, as well as a connection height.

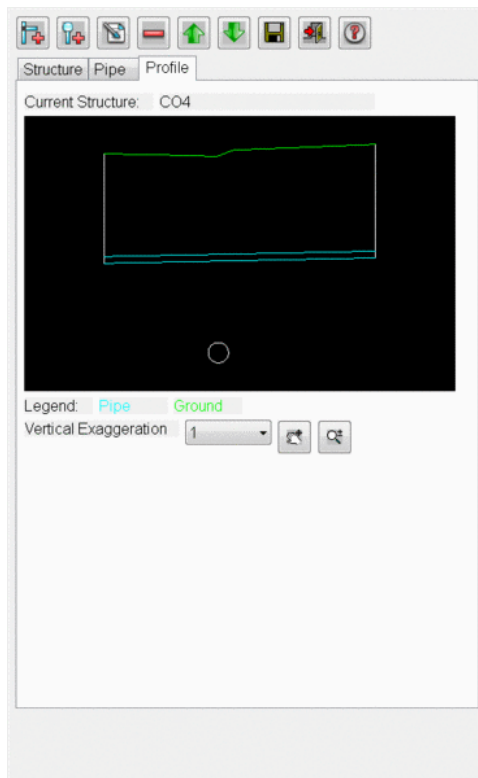

The screenshot shows a software dialog box titled "Pick a Pipe" with three tabs: "Structure", "Pipe", and "Profile". The "Pipe" tab is active. The dialog contains the following fields and controls:

- Structure Name: CONN147
- System Name: A
- Description: (empty)
- Structure ID: None (dropdown menu) with a "Library" button
- Reference CL: (empty) with a "Select" button
- Northing, Easting: 801043.24, 2032895.27 with a "Location" button
- Symbol Name: Spt6 with a "Symbol" button
- 3D Symbol: (empty) with a "Symbol" button
- Symbol Rotate: Twist Screen (dropdown menu)
- Symbol Angle: 0.0000 dd mmss
- Skew Angle: 90.0000 dd mmss
- Symbol Size: Unit Symbol (dropdown menu)
- Rim Elevation: 347.46 ft
- Depth: 9.22 ft
- Invert-Out Elev: 338.24 ft
- Invert-In Elev: (empty) ft
- Lateral Connection section:
 - DS Manhole: MH20, A
 - Upstream Manhole: MH21, A
 - DS Station: 107.97
 - Connection Height: 0.00 ft

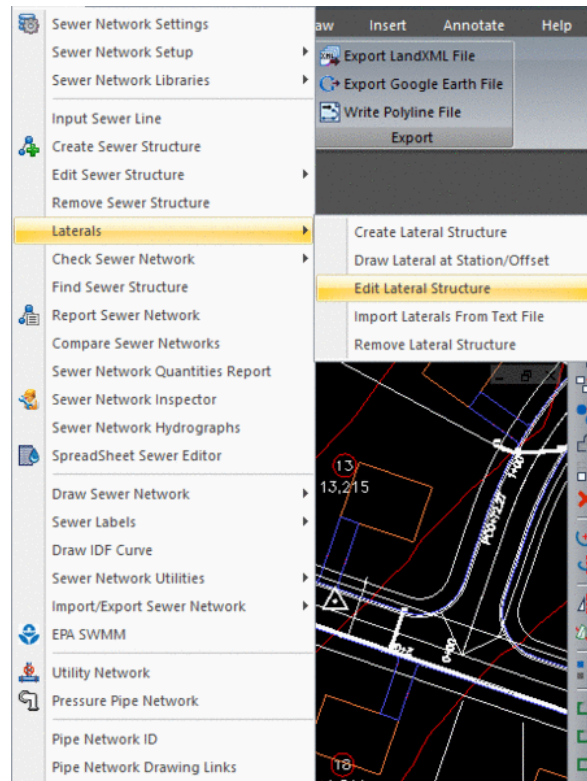

The Pipe Tab of the docked dialog will display the pipe lateral data once a cleanout location is located. This is the same for both types of connections. This dialog box allows the user to design pipe data associated with the lateral pipe, and is used to assign Pipe Name, to assign Downstream Connections, Pipe Material, Pipe Shape, Pipe Size, set the Inverts Upstream and Downstream, or to adjust the Pipe Slope and which invert to Update. The properties box at the bottom displays other properties and values assigned.

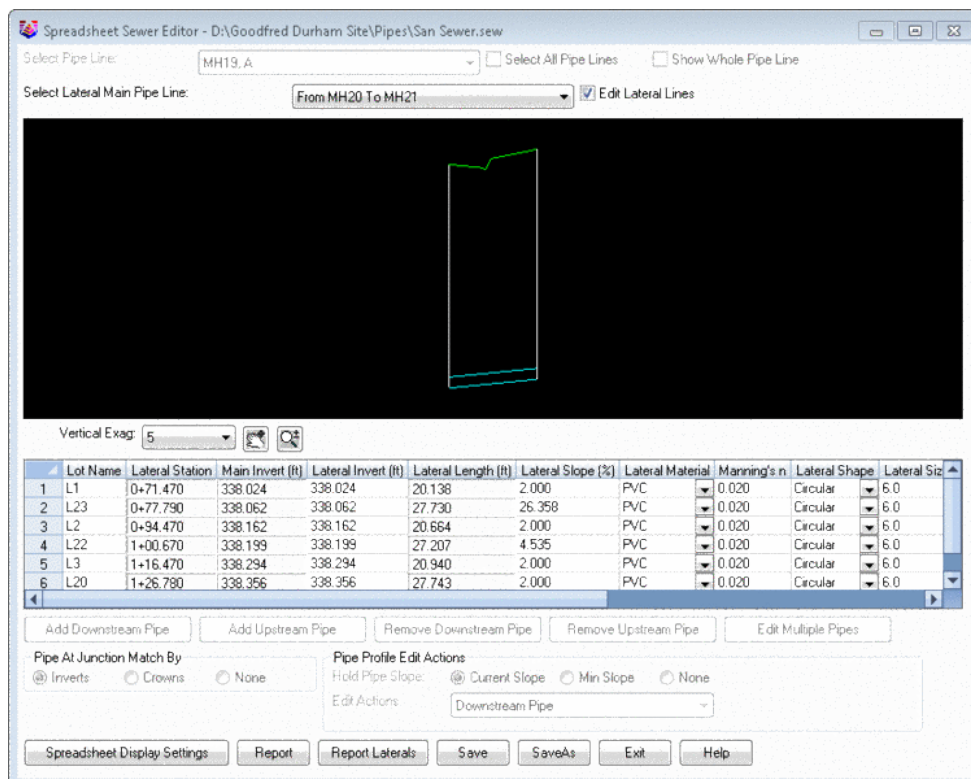

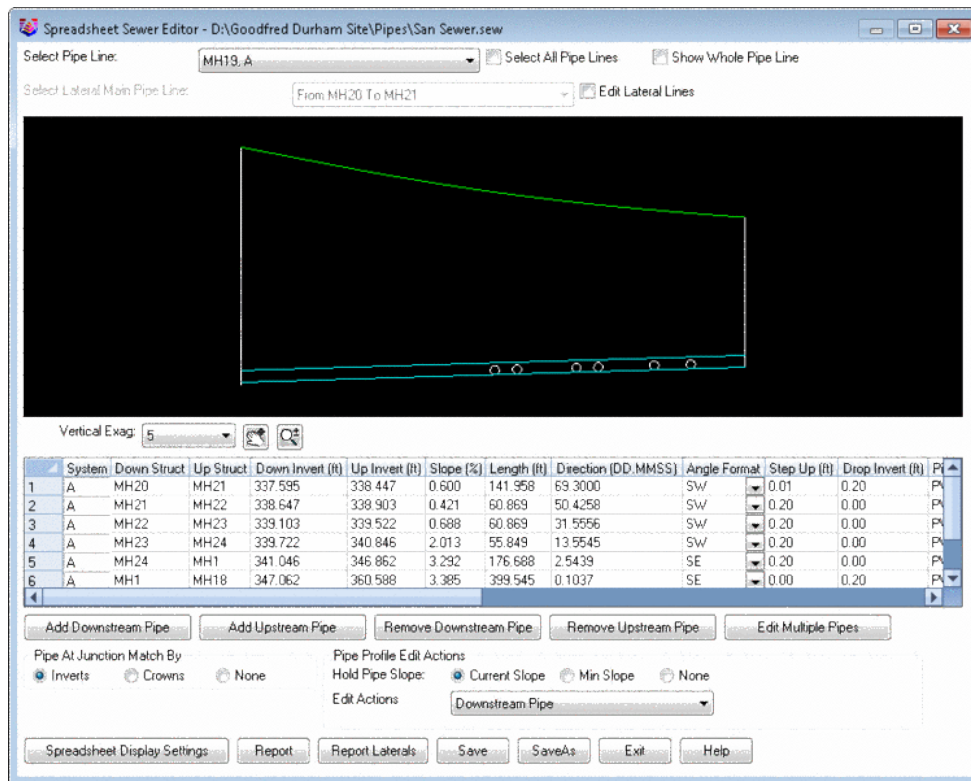

The Profile Tab provides a visual aid showing the lateral pipe and other associated pipe crossings for consideration during design. A Vertical Exaggeration can also be applied for an increased aid.

Editing a lateral is similar to a regular pipe. The invert elevation of both ends of the lateral can be modified the same as a regular pipe. To edit a lateral structure the user can select from the following image in the network menu or double click the lateral structure to edit. After selecting the docked dialog box opens and edits can be made on the Structure or Pipe Tab.

The Spreadsheet Sewer Editor can also be used to review and edit lateral connections. Toggle the Edit Lateral Line to revise or adjust laterals.

With the toggle on the user Selects Lateral Main Pipe Line, and the laterals associated with that main line pipe can be edited.

Editing a lateral is similar to a regular pipe. The invert elevation

Pulldown Menu Location: Network

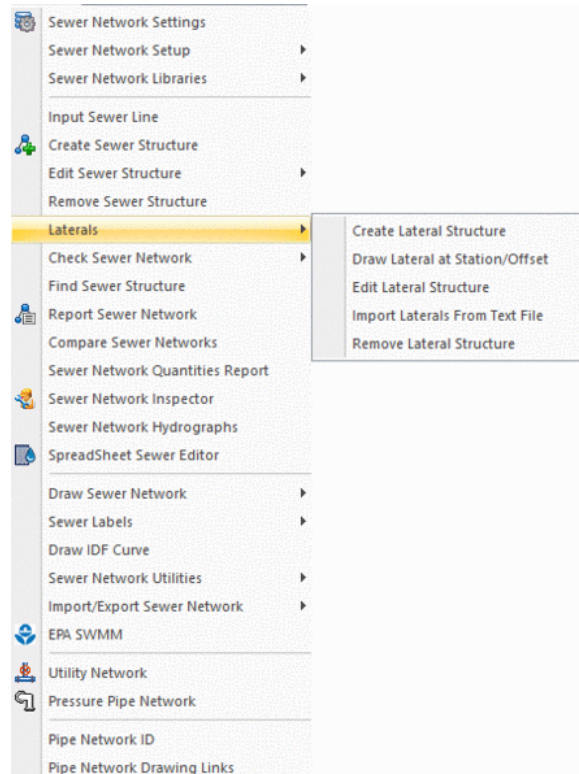

Keyboard Command: editlat

Prerequisite: A sewer (.SEW) file

Create/Edit Lateral Structure

Lateral design is available in both the storm sewer and sanitary sewer design programs. A lateral pipe is very much like a regular pipe in sewer network. A lateral is the underground pipe that connects a residence or business to the main line pipe. The lateral connection has a property of offset elevation relevant to the mainline sewer invert at the point of connection. Both the cleanout and connection can be either a box or circular structure. The lateral data is stored in the main network / current network file, although designed using a different command. A prerequisite for Lateral Design the user must have completed either a Storm Network or Sanitary Sewer Network as the main line, and set the file as the Active File to be used in the Sewer Network Settings dialog box.

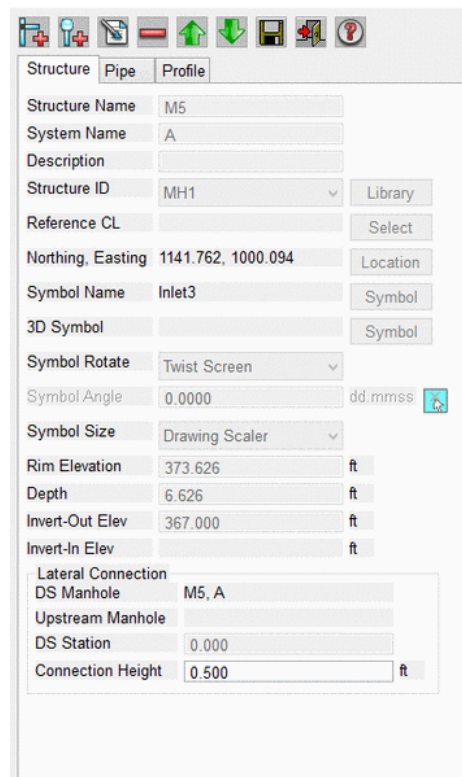

There are two commands to open the Lateral Network dialog: Create Lateral Structure and Edit Lateral Structure. To Create a Lateral Structure, you are required to locate a lateral connection on the existing network; To edit a lateral structure the user can run the command from the the network menu or double click the lateral structure to edit.

There are five options to locate a Lateral Connection Point. **Pick a Structure**, this can be any structure created in the main line file such as a manhole or a box structure. Multiple lateral connections are allowed at a manhole or a box structures. **Pick a Pipe** is to create a pipe connection along an existing pipe, where the only one lateral is allowed. **Pick a Pipe and Exact Location on Main** is to create a pipe connection at an exact location on the main pipe. **Pick a Pipe and Cleanout Location Perp to Main** allows users to pick the main pipe first, and then pick where the cleanout is, the program would create a lateral pipe perpendicular to the main pipe.

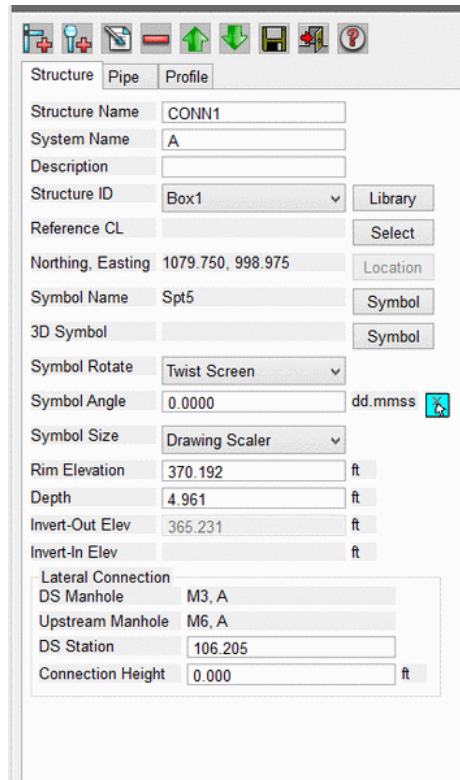

The **Pick a Structure** options allows the user to select an existing structure within the Main Network File and opens the following Docked Dialog. By hovering the mouse over the icons at the top of the dialog box the user can see the command associated with each. Starting from left to right the commands are as followed **Add Connection, Add Cleanout, Edit, Remove, Up, Down, Save, Exit,** and **Help**. The Structure Tab gives the user information of the selected structure. The dialog box specifies the downstream and upstream manhole connections as well as the station along the main network pipe measured from the downstream structure. The Connection Height allows the user to specify the entrance height of the connection on the main network structure. Depending on the type of the connection point some of the dialog box will only display data while others may be edited. In the following example we selected to connect to a structure, therefore data present related to the actual manhole with only the connection height available for editing. The **Connection Height** is the value how much the lateral invert elevation is higher than the main pipe invert elevation at the lateral connection.

When the **Pick a Pipe** option is selected other fields in the docked dialog box are available allowing users

to specify a Structure Name, System Name, Description, Symbol Rotate, Symbol Angle, and Symbol Size. Rim Elevations and Depth are calculated and the downstream and upstream manholes shown. The user is given the downstream station for the connection that can be adjusted if desired, as well as a connection height.

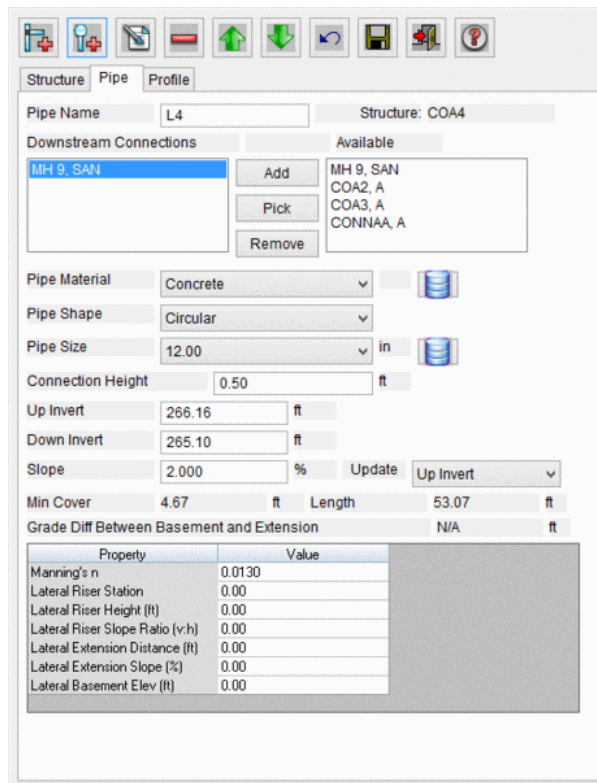

The image shows a software dialog box with three tabs: Structure, Pipe, and Profile. The 'Pipe' tab is selected. The dialog contains the following fields and controls:

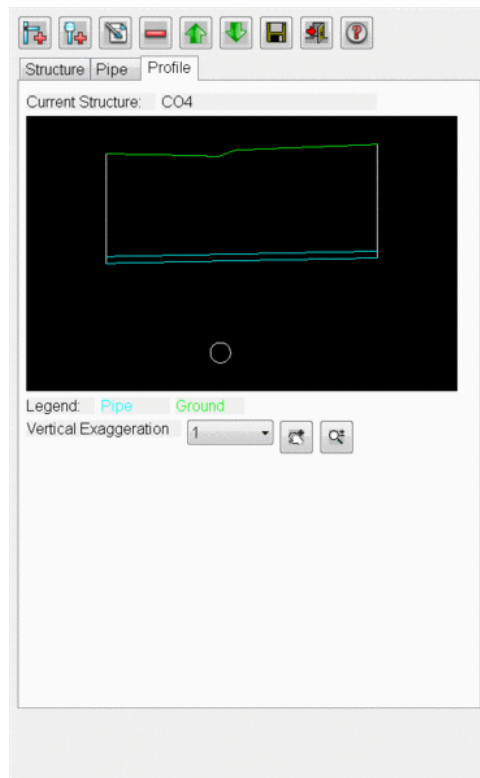

- Structure Name: CONN1
- System Name: A
- Description: (empty)
- Structure ID: Box1 (dropdown menu) with a Library button
- Reference CL: (empty) with a Select button
- Northing, Easting: 1079.750, 998.975 with a Location button
- Symbol Name: Spt5 with a Symbol button
- 3D Symbol: (empty) with a Symbol button
- Symbol Rotate: Twist Screen (dropdown menu)
- Symbol Angle: 0.0000 with a unit dropdown set to dd.mmss and a help icon
- Symbol Size: Drawing Scaler (dropdown menu)
- Rim Elevation: 370.192 ft
- Depth: 4.961 ft
- Invert-Out Elev: 365.231 ft
- Invert-In Elev: (empty) ft
- Lateral Connection section:
 - DS Manhole: M3, A
 - Upstream Manhole: M6, A
 - DS Station: 106.205
 - Connection Height: 0.000 ft

The Pipe Tab of the docked dialog displays the lateral pipe data once a cleanout location is located. This is the same for both types of connections. This dialog box allows the user to design pipe data associated with the lateral pipe, and is used to assign Pipe Name, to assign Downstream Connections, Pipe Material, Pipe Shape, Pipe Size, set the Inverts Upstream and Downstream, or to adjust the Pipe Slope and which invert to Update.

The properties box at the bottom displays other properties and values assigned.

The Profile Tab provides a visual aid showing the lateral pipe and other associated pipe crossings for consideration during design. A Vertical Exaggeration can also be applied for an increased aid.

Laterals can be created using the Draw Lateral by Station Offset command. For this command, "Station Number of reference" is the distance from the nearest downstream storm structure to the lateral connection.

Command: drswrlat

Select the downstream sewer structure (Esc to exit):

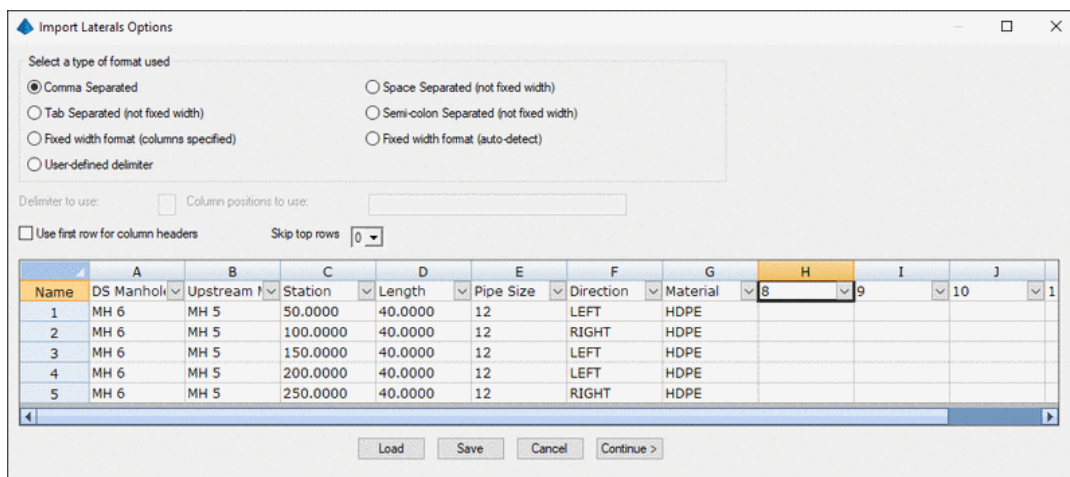

Enter Lateral Station (> 0): 100

Enter Lateral Offset: 15

The command will draw a lateral at the lineal distance of 100 feet upstream of the selected downstream sewer structure. The service connection will be located 15' from the pipe main, perpendicular to the proposed Utility.

This command imports the lateral pipe data from text file to the current sewer network file. The text file has the lateral data with one lateral pipe per row in the text file with the fields separated by a comma or other delimiter. The text file requires main pipe downstream manhole, main pipe upstream manhole name, station from downstream manhole name, lateral pipe length, pipe size, direction that lateral pipe on the left or right side of the main pipe by looking at upstream direction, and pipe material.

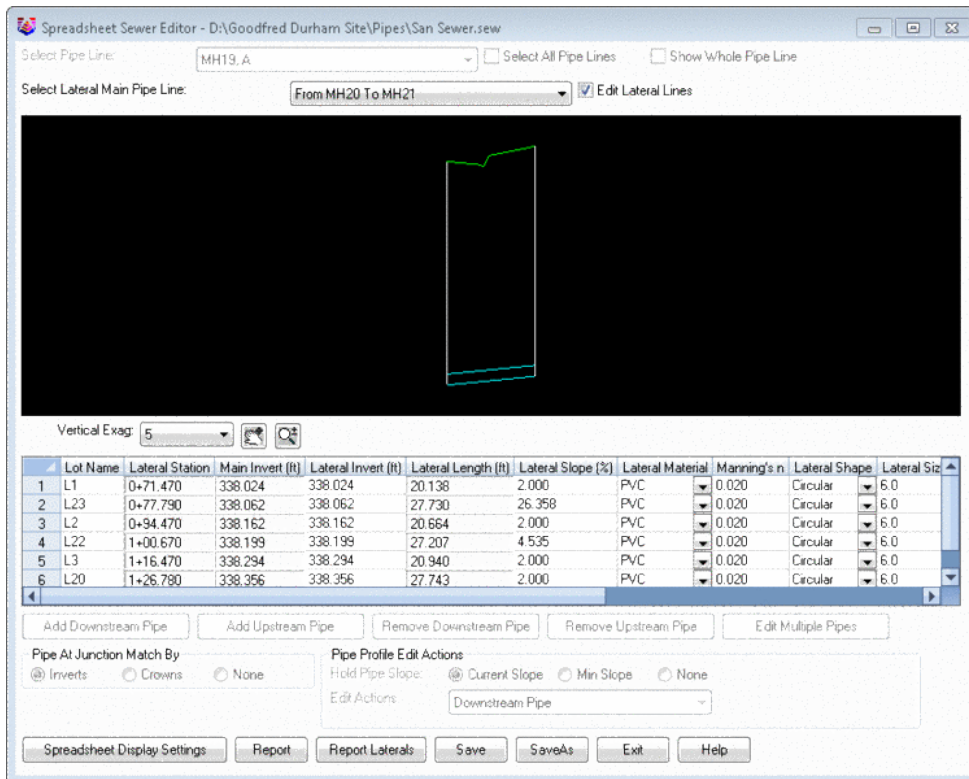

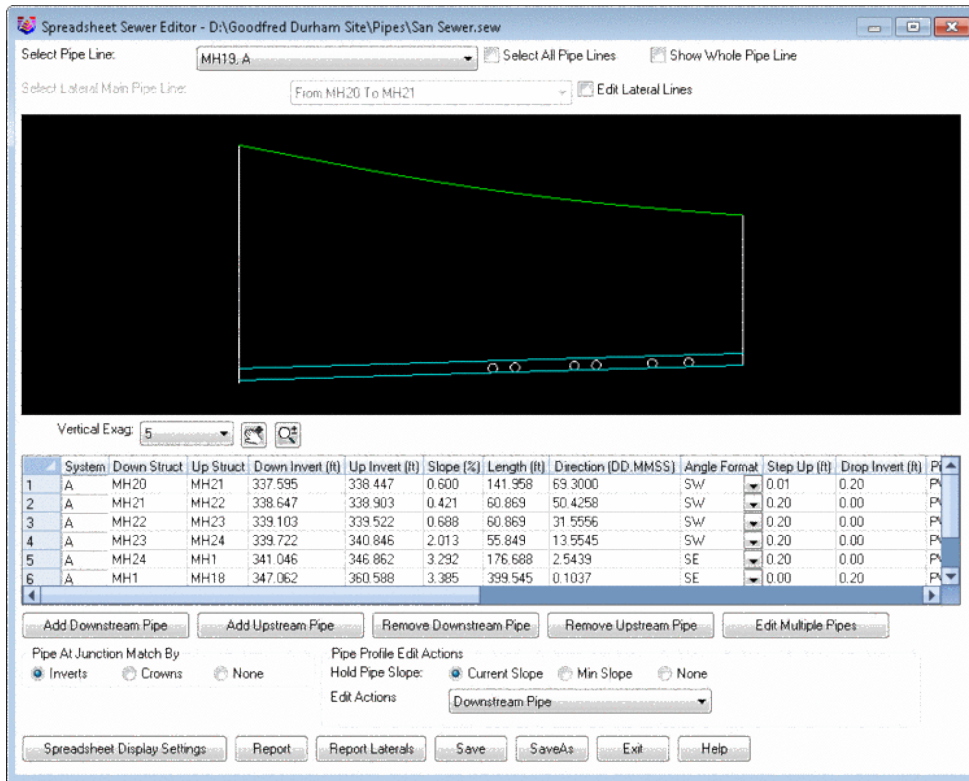

The program prompts for the lateral file to import. Then there is a dialog to specify the format of the input text files. For each column of data in the input files, choose which field to assign.

Example lateral data file:

DS Manhole, Upstream MH, Station from DS Manhole, Lateral Length, Pipe Size, Direction, Pipe Material
MH 6,MH 5,50.0000,40.0000,12,LEFT,HDPE
MH 6,MH 5,100.0000,40.0000,12,RIGHT,HDPE
MH 6,MH 5,150.0000,40.0000,12,LEFT,HDPE
MH 6,MH 5,200.0000,40.0000,12,LEFT,HDPE
MH 6,MH 5,250.0000,40.0000,12,RIGHT,HDPE

The Spreadsheet Sewer Editor can also be used to review and edit lateral connections. Toggle the Edit Lateral Line to revise or adjust laterals. With the toggle on the user Selects Lateral Main Pipe Line, and the laterals associated with that main line pipe can be edited.

Pulldown Menu Location: Network

Keyboard Command: putlat

Prerequisite: A sewer (.SEW) file

Import Laterals From Text File

This command imports the lateral pipe data from text file to the current sewer network file. The text file has the lateral data with one lateral pipe per row in the text file with the fields separated by a comma or other delimiter. The text file requires main pipe downstream manhole, main pipe upstream manhole name, station from downstream manhole name, lateral pipe length, pipe size, direction that lateral pipe on the left or right side of the main pipe by looking at upstream direction, and pipe material.

The program prompts for the lateral file to import. Then there is a dialog to specify the format of the input text files. For each column of data in the input files, choose which field to assign.

Name	DS Manhole	Upstream MH	Station	Length	Pipe Size	Direction	Material	8	9	10	1
1	MH 6	MH 5	50.0000	40.0000	12	LEFT	HDPE				
2	MH 6	MH 5	100.0000	40.0000	12	RIGHT	HDPE				
3	MH 6	MH 5	150.0000	40.0000	12	LEFT	HDPE				
4	MH 6	MH 5	200.0000	40.0000	12	LEFT	HDPE				
5	MH 6	MH 5	250.0000	40.0000	12	RIGHT	HDPE				

Example lateral data file:

DS Manhole, Upstream MH, Station from DS Manhole, Lateral Length, Pipe Size, Direction, Pipe Material

MH 6,MH 5,50.0000,40.0000,12,LEFT,HDPE

MH 6,MH 5,100.0000,40.0000,12,RIGHT,HDPE

MH 6,MH 5,150.0000,40.0000,12,LEFT,HDPE

MH 6,MH 5,200.0000,40.0000,12,LEFT,HDPE

MH 6,MH 5,250.0000,40.0000,12,RIGHT,HDPE

Pulldown Menu Location: Network > Laterals

Keyboard Command: csv2lat

Prerequisite: structure and pipe text files.

Remove Lateral Structure

Look at the command prompt:

Select structures to erase by screen pick or name list [<Pick>/List]?

Pulldown Menu Location: Network

Keyboard Command: rmlat

Prerequisite: A sewer (.SEW) file

Check Sewer Network Parameters

This command reads a sewer network file and audits the sewer network for any invalid data fields or values that don't follow the specified design constraints. If any problems are found with the sewer data, a report is displayed indicating all invalid values.

Pulldown Menu Location: Network > Check Sewer Network

Keyboard Command: chkswr

Prerequisite: A sewer file (.SEW) and corresponding Inlet Data and Pipe Size Data.

Check Reference Centerlines and Surface

This command is a manual alternative to the *Auto* linking method found on the General tab of the **Sewer Network Settings**. This routine compares the sewer network structure locations to that of the reference surface and centerline(s). The current sewer surface file is used as the elevation reference for the structure rim elevations.

Each structure has the option to assign a reference centerline and the structure will record the station and offset from this centerline. If this routine finds a difference between the structure location and the referenced centerline, an option will be provided to either update the sewer structures to their new and relative station/offset or simply leave the structures where they are located.

For reference surface changes, the structure rim elevation can be updated and there are two options for updating the invert elevation. One method is to hold the structure depth and change the invert elevation. The other method is to hold the invert elevation and change the depth.

Pulldown Menu Location: Network > Check Sewer Network

Keyboard Command: chkswrref

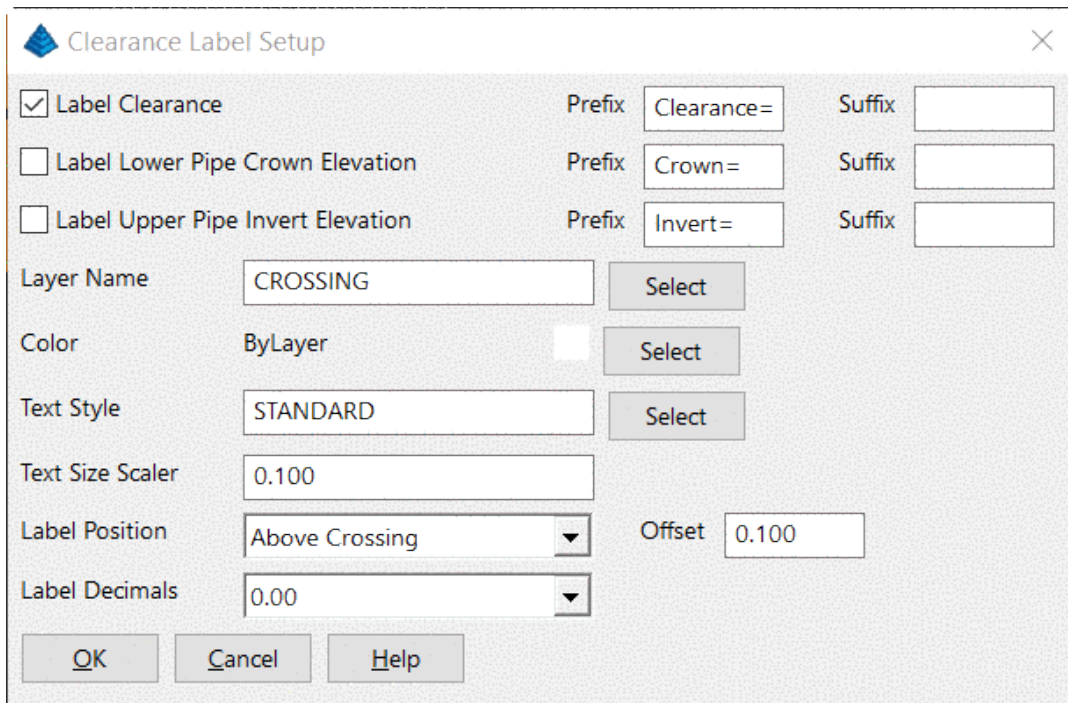

Prerequisite: Sewer (.SEW) file

Check/Label Clearance

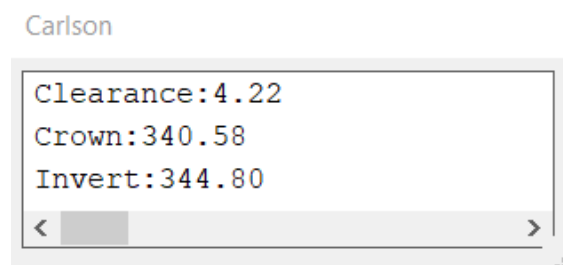

This command check clearance of a crossing between any sewer network pipes, utility network pipe, and 3D pipe polylines. It displays clearance value, as well as the invert and crown elevations on the command line. Users can also label the results next to the crossing on screen.

From the Network > Check Sewer Network menu in the Hydrology Module, select Label Clearance at Crossings. In the drawing, first have all the networks drawn in plan view. Hovering over a pipe crossing in plan-view will give real time information on screen dialog box.

The Clearance Label Setup Dialog is used to draw the clearance labels on screen. The settings are saved and no need to bring it up next time to check and label clearance. Clear the Draw Labels box and the program won't label the results on screen.

Pulldown Menu Location: Network > Check Sewer Network

Keyboard Command: label_clearance

Prerequisite: sewer network/utility network/3D pipe polyline crossings in plan view

Collision Conflicts Check

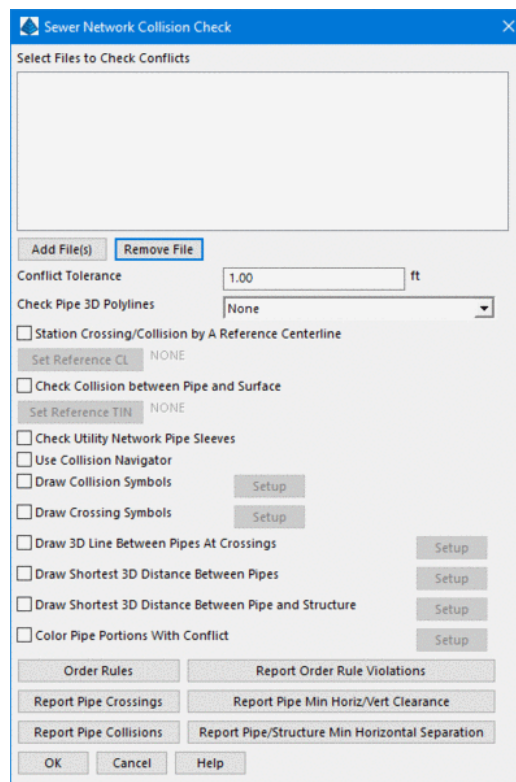

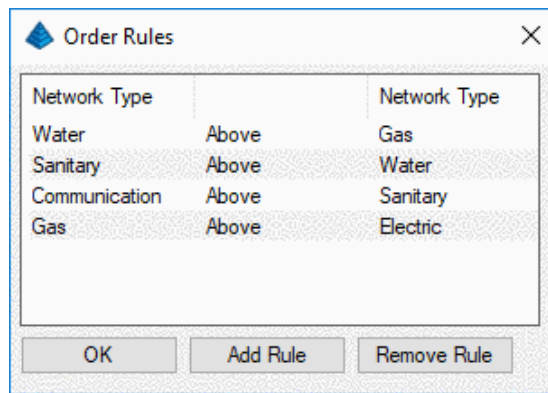

When there are two or more sewer networks in one area, it's very important to know if there are any collisions among pipe lines. The Collision Conflicts Check command performs a three dimensional check on unlimited sewer .SEW, utility .UTIL networks and 3D pipe polylines. If any portions of the these systems are too close to each other, i.e their distance is closer than the safety buffer, the conflicting pipes and their collision locations would be reported. The program also checks for any collisions within the same sewer network. Besides checking unlimited sewer networks, the Check Pipe 3D Polyline option will check for collisions with 3D polylines that have been tagged as pipes with the Assign Pipe Data To Polyline command.

From the Network > Check Sewer Network menu in the Hydrology Module, select Collision Conflicts Check. In the dialog, select two or more network files that you want to check the collisions and/or select the Check Pipe 3D Polyline option. The program can also check collisions for 3D Pipes only and allow you to pick 3D pipe polylines on screen.

In the Conflict Tolerance box, specify the value of the distance buffer that any two of the sewer systems shouldn't violate. Optionally, use the Station Crossing/Collision by Reference Centerline switch and set the Reference CL to report any crossings and collisions by Station and Offset from the reference centerline. The Use Collision Navigator toggle provides an Data Problem Log dialog to navigate you to the location of every collision, otherwise the collisions would reported in Carlson standard report format.

Draw Collision Symbols and Draw Crossing Symbols option will draw a symbol at each collision or crossing. Besides drawing symbols, there are options to label the clearance and pipe elevations.

The **Order Rules** button displays the Order Rules dialog, allowing the user to specify and report violations of the "depth order" of a set of various utilities. For example, if Gas is supposed to be below Water, as indicated in the dialog below, but is actually above, the program will note this as a violation and report this in the Report Order Rule Violations formatted report.

Sewer Network Collision Conflict Check

The **Report Crossings** and **Report Collisions** buttons would show all the pipe crossings and collisions in a formatted report.

Report Pipe Crossings Report Pipe Crossings

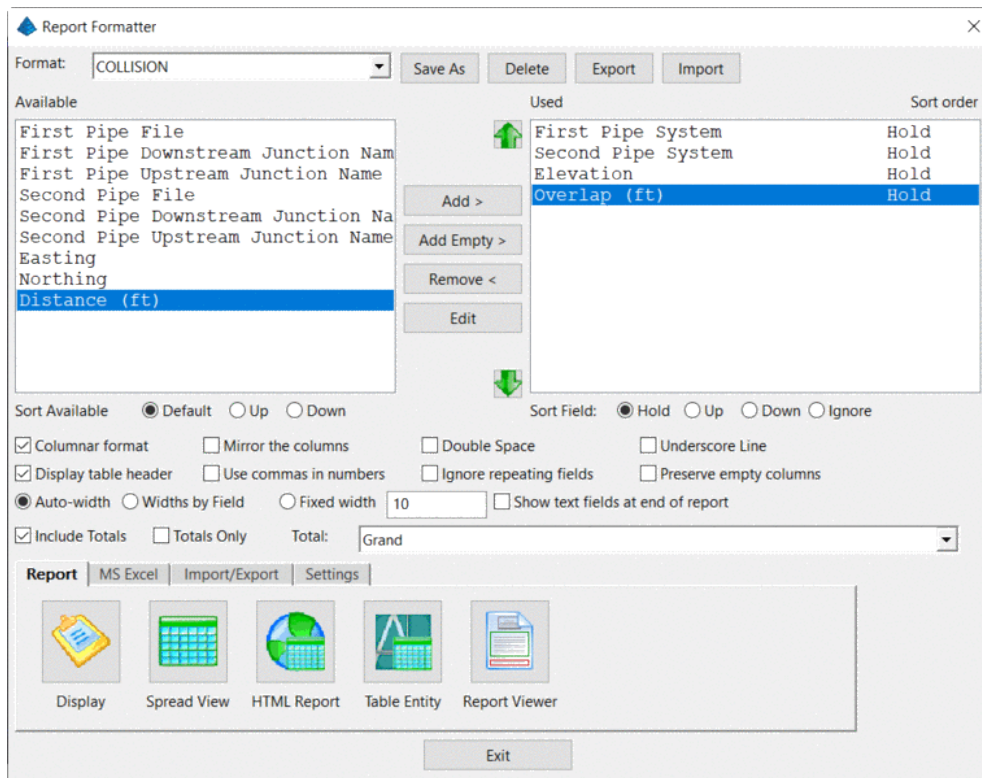

Opens the Report Formatter Options Dialog Box. The user can select from the Available List and Add the to the Used list to customize the report, and select output options. For more information on using the Report Formatter see Report Viewer in this manual.

Report Collisions

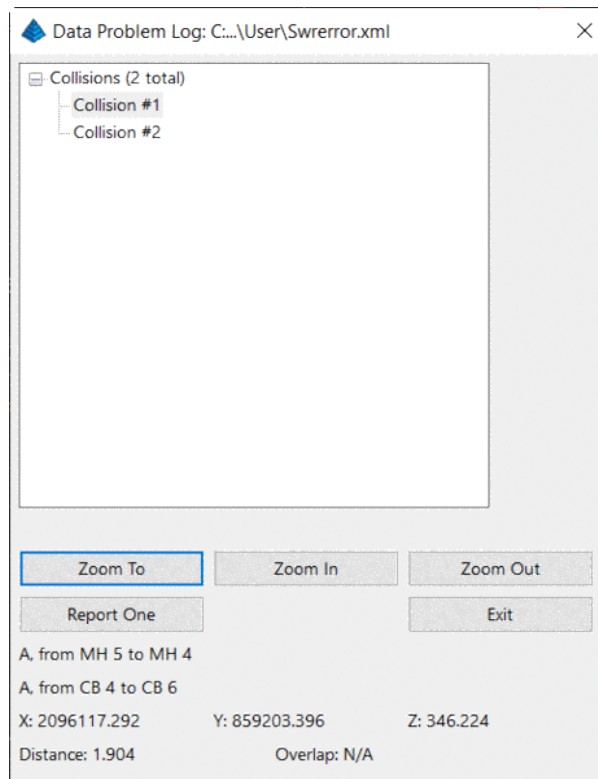

Report Pipe Collisions

Opens the Report Formatter Options Dialog Box. The user can select from the Available List and Add the to the Used list to customize the report, and select output options. For more information on using the Report Formatter see Report Viewer in this manual.

Data Problem Log dialog

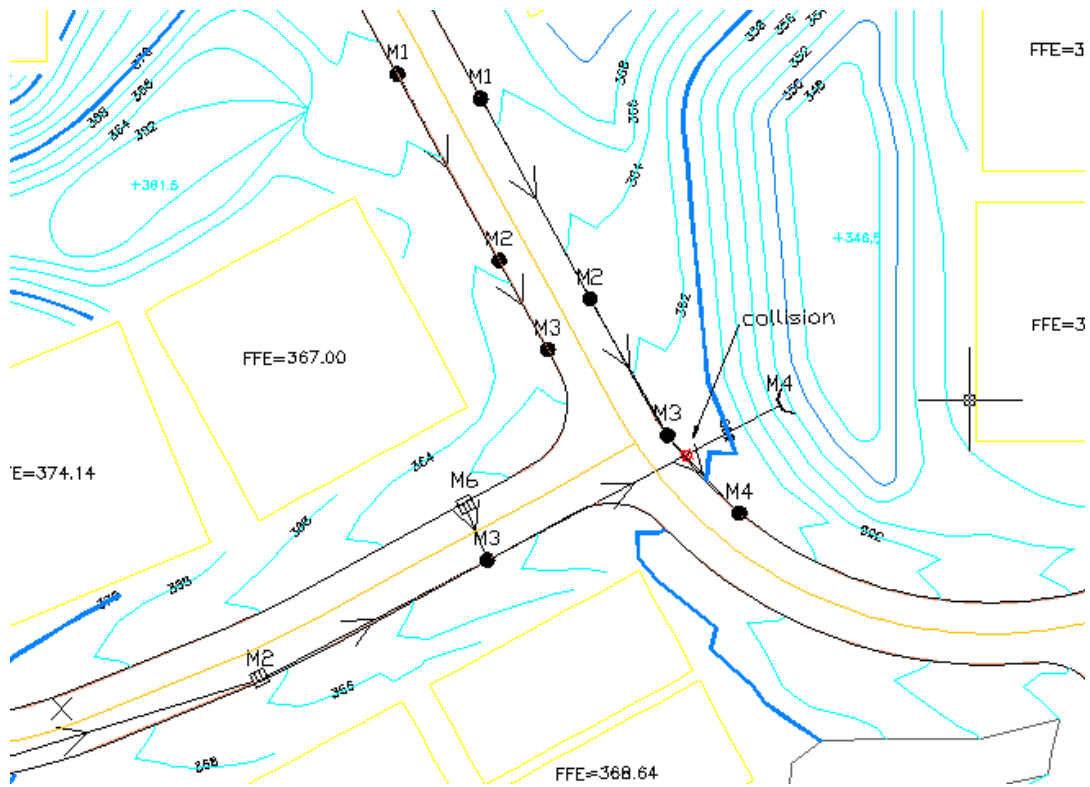

When the **Use Collision Navigator** toggle is on, an Data Problem Log is generated if there are any collisions. Clicking to the "+" sign beside the Collisions Total will display the individual collisions. When a collision item is selected, click on **Zoom To** button and the drawing is centered to the exact location of the highlighted collision. **Zoom In** button zooms in on the highlighted collision for a closer inspection. **Zoom Out** zooms out away from the collision. **Report All/One** button between One and All depending on whether a single collision or all collisions are selected from the Log. An error Report is generated listing the positions of the entities in conflict.

Collision Navigator

Report Pipe Min Horiz/Vert Clearance  button would report the Horizontal Separation and the Vertical Clearance of pipes in a formatted report.

Report Pipe/Structure Min Horizontal Clearance  button would report the pipe and structures horizontal separation in a formatted report.

Collision Example

Sewer Network Collision Report

System Name: A, File: C:\Carlson2008_08\Projects\millcreek\MillCreek.sew
 System Name: B, File: C:\Carlson2008_08\Projects\millcreek\MillCreek2.sew
 System Name: C, File: C:\Carlson2008_08\Projects\millcreek\MillCreek3.sew
 Conflict Tolerance: 1.00 ft

Collision 1:
 System A, Pipe from M4 to M3 and System B, Pipe from M4 to M3 collide at (1219.903, 927.383, 355.137).

Pipe Crossings:

#	Lower Pipe	Upper Pipe	Easting	Northing	Crown	Invert	Distance

Pulldown Menu Location: Network > Check Sewer Network

Keyboard Command: chkmswr

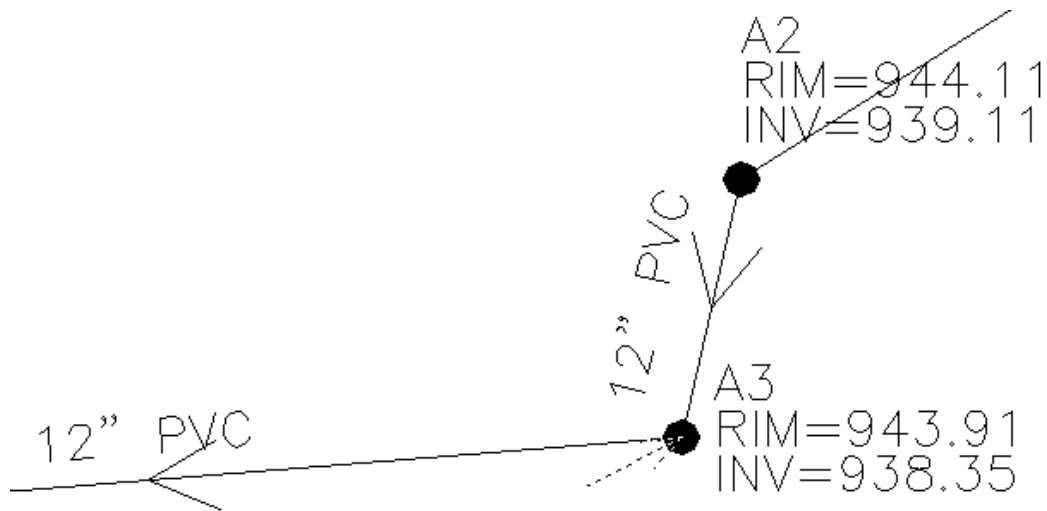

Prerequisite: two to four sewer files (.SEW)

Find Sewer Structure

This command will find a sewer structure by name.

Prompts

Structure Name to Find: A3

The program will then display a temporary arrow locating the structure, and zoom to it at the current zoom resolution.

Pulldown Menu Location: Network

Keyboard Command: findswr

Prerequisite: Sewer network (.SEW) file

Report Sewer Network

This command reads a sewer network file and reports its design parameters and hydraulic results. Select Report Sewer Network from the Network menu in the Hydrology Module, the report dialog displays. The **Select Sewer Line(s) To Report** list displays all upstream entrance structure names, which represents pipe lines from every entrance to the outfall. Select one entrance to report one pipe line. If you want to report the whole sewer network, turn on the Report All Sewer Lines toggle. Select one or multiple return periods for reporting. The **Settings** dialog allows the user to set decimal variables to Station, Elevation / Depth, Pipe Length, Pipe Slope, and Other for precision.

The sewer network report has four categories: **Inlet**, **Pipe**, **Structure** and **Drainage**, in order to report all information thoroughly.

Report Subareas lists subarea type, area, runoff Coefficient and increment Runoff Coefficient for every catchbasin.

Custom Report allows you to choose which portion of data you would like to report from the combination of drainage and pipe categories.

Report HGL Computation lists the result of the friction losses of every pipe and the junction losses of every structure.

Report Inlet Computation reports the drainage runoff and pavement parameters, and the result of the gutter and inlet calculation for every surface inlet.

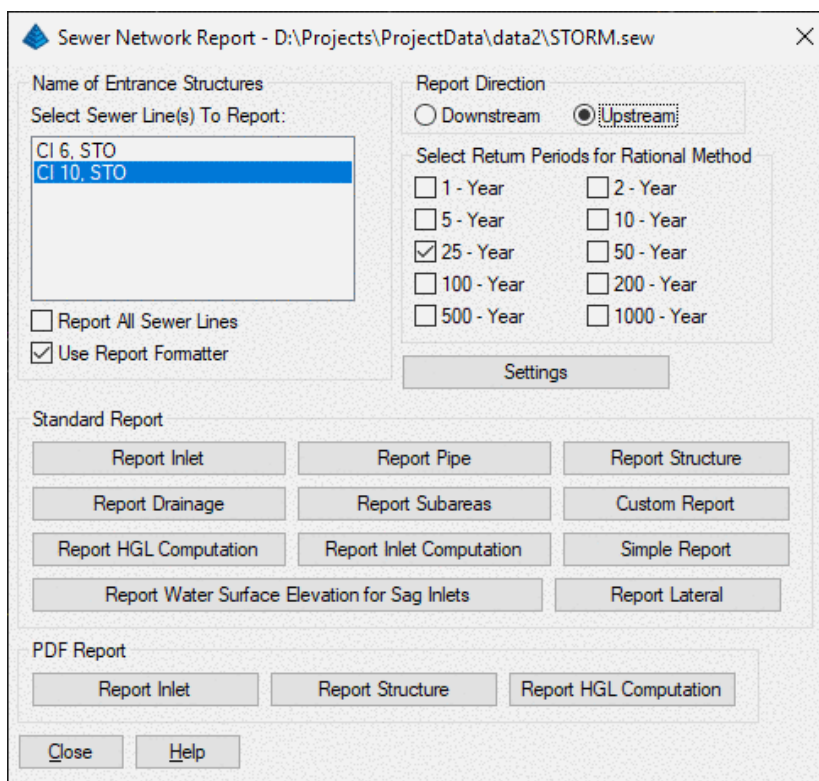

Simple Report lists some portion of information from all four categories.

Report Water Surface Elevation for Sag Inlets lists the orifice and weir calculation of the sag inlets.

Report Lateral lists the data for lateral connections.

Check the **Use Report Formatter** toggle to report the sewer network data in a Microsoft Excel spreadsheet or as a Table Entity in the plan; otherwise in the standard Carlson report window from where the information can be edited, printed to a printer or to the screen, and saved.

The **PDF report** allows you to report sewer data and results by various PDF report templates. Currently we support **Inlet**, **Structure** and **HGL Computation** PDF report based on PDF report templates come with the install.

Notes:

Prompts

Report Sewer Network dialog: Fill in values.

Pulldown Menu Location: Network > Report Sewer Network

Keyboard Command: reportswr

Prerequisite: a sewer file (.SEW), a surface file (.TIN, .GRD)...\\USER\\RainLib.dta, ...\\USER\\inlet.dta, ...\\USER\\pipesize.dta (mpipesize.dta in Metric unit), ...\\USER\\swrStruct.dta

Sewer Network Quantities Report

This command reports pipe and structure quantities by depth range for the current sewer network file. In the options dialog, you can choose to report all the pipes or selected pipes.

Use **Report Formatter** is used to customize reports and output to various formats like Excel.

Under **Setup Depth Zones**, you can define the different depth ranges to report and assign costs for the structures and the pipe length per depth range.

Report Depth Zones reports the structures and pipe length for each depth range.

Report Stations Depth Summary reports the pipeline stations for the different depth ranges.

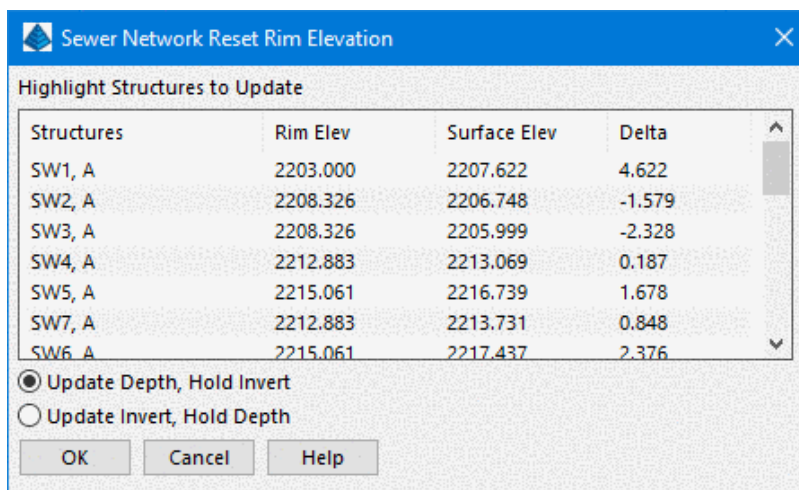

Report Manhole Depth Summary reports the depth of each structure and the sum of these depths.

Report Pipe Length By Size reports the total pipe length per pipe size.

The **Draw Plan View Zone Map** option draws the pipe lines in different colors by depth and has the option to label the zones along the pipes. The colors and line widths for the map are set in the Setup Depth Zones dialog.

Pipe Details report includes the length, depth, size, material and other parameters for every pipe.

Depth Details report includes the pipe parameters broken out by depth zone.

Pipe Network Quantities Report

Depth	Manholes	Linear(ft)	% of Total
0-5.0	4	338.9	60.2
5.0-10.0	1	223.8	39.8
>10.0	0	0.0	0.0
Total	5	562.7	

Stations	Depth	Starting Structure
0+00.0 to 3+25.3	0-5.0	M1
3+25.3 to 5+49.1	5.0-10.0	M1
5+49.1 to 5+62.7	0-5.0	M1

Pipe Size(in)	Linear(ft)	% of Total
9	288.2	51.2
12	274.5	48.8

Manhole	Depth
M5	3.99
M4	8.31
M3	4.73
M2	4.01
M1	4.00
Total:	25.04

Pulldown Menu Location: Network

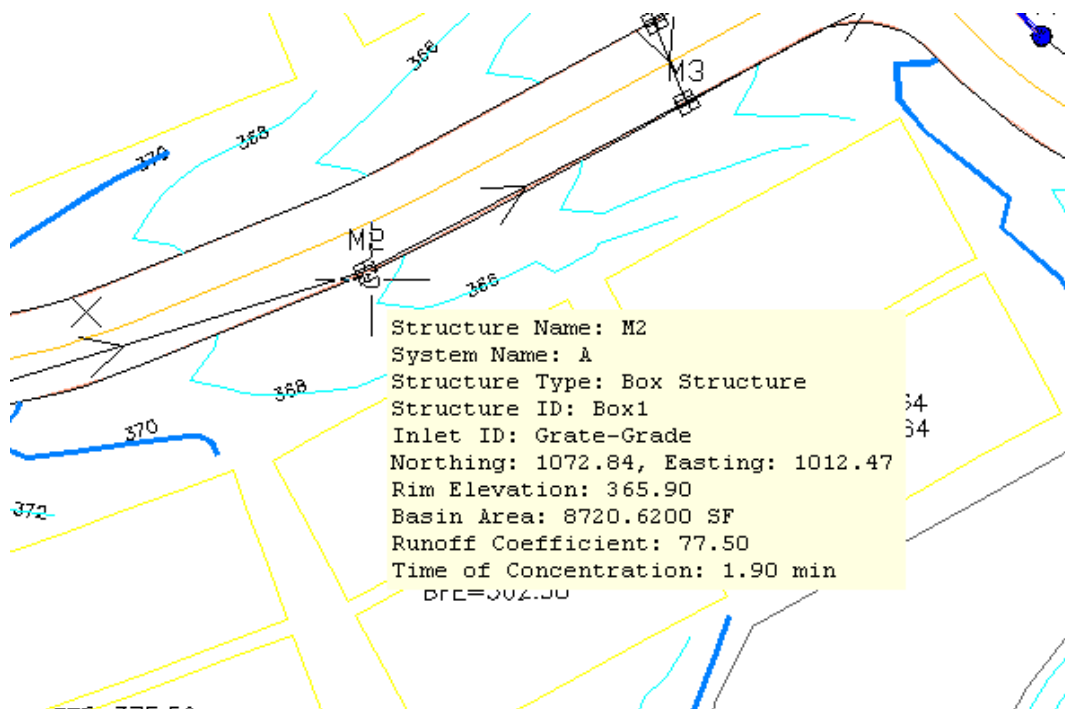

Keyboard Command: swrdepth

Prerequisite: .sew file

Sewer Network Inspector

The command allows you to inspect the active sewer network on screen.

Select Sewer Network Inspector from Network menu. Move your cursor to the sewer network in plan view. When the cursor hovers over a structure or a pipe, its parameters will be shown on screen. After finishing inspection, press Enter key to exit.

Sewer Network Inspector Example of Structure

Sewer Network Inspector Example of Pipe

Prompts

Pulldown Menu Location: Network > Sewer Network Inspector

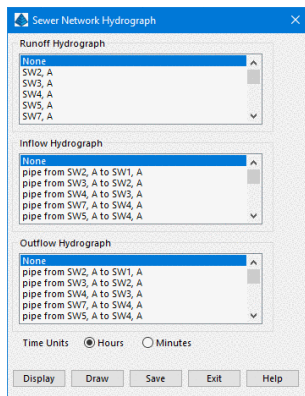

Keyboard Command: swrinspect

Prerequisite: active sewer network in plan view

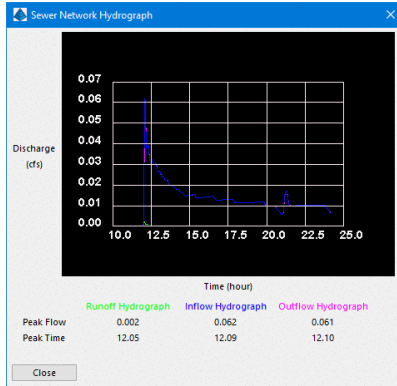

Sewer Network Hydrographs

This command generates the runoff hydrograph for every catch basin, inflow hydrograph for every pipe at upstream and outflow hydrograph for every pipe at downstream. If the sewer network uses Rational method to calculate the peak flow, the runoff hydrograph is calculated by Universal Rational method; otherwise, the runoff hydrograph is calculated by SCS method. The storage-indication method is used to route the inflow hydrograph through the whole network.

Select Sewer Network Hydrographs from the Network menu in the Hydrology Module. The command reads the current active sewer network file and conducts the hydraulic computation. If the computation is successful, a dialog opens with the lists of inflow and outflow hydrographs identified by the structures and pipes. Select a runoff, inflow and outflow hydrograph and click on Display button to show the hydrographs in the Hydrograph dialog.

Sewer Network Hydrograph by Carlson

Hydrograph Example by Carlson

Prompts

Sewer Network Hydrographs dialog: Fill in values.

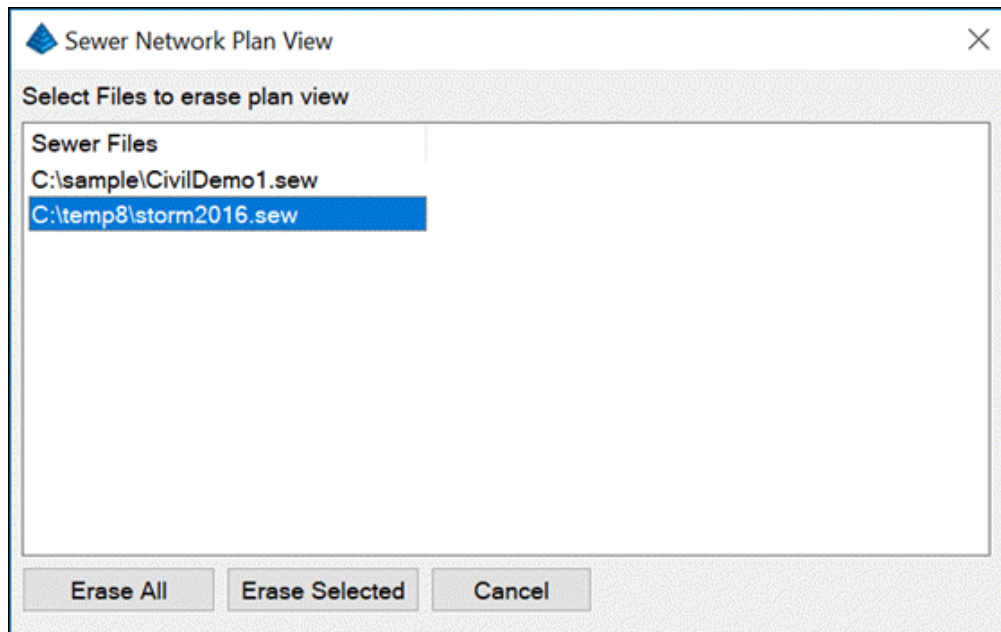

Pulldown Menu Location: Network > Sewer Network Hydrographs

Keyboard Command: swrhyd

Prerequisite: a sewer file (.SEW), a surface file (.TIN, .GRD)... \USER\RainLib.dta, ... \USER\inlet.dta, ... \USER\pipesize.dta (mpipesize.dta in Metric unit), ... \USER\swrStruct.dta, ... \USER\paven.dta, ... \USER\pipen.dta, ... \USER\runoff.dta

Erase Plan View

This command erases entities created by Draw Sewer Network > Plan View. This command looks in the current drawing for sewer network plan view entities and shows a list of all the sewer network models that are found. Select a sewer network model from the list and pick Erase Selected to erase its plan view entities. Or pick Erase All to erase all sewer network plan view entities. The sewer network model data is not erased.

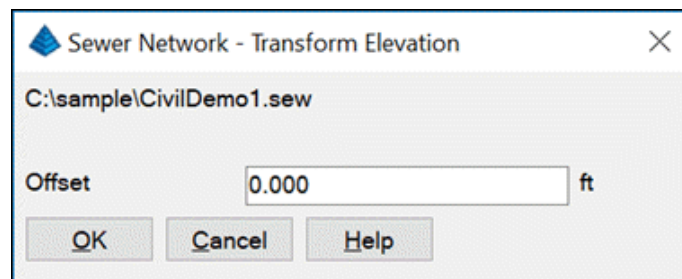

Pulldown Menu Location: Network > Draw Sewer Network

Keyboard Command: swrdel

Prerequisite: sewer network plan view entities

Transform Elevations

This command changes all the elevation in the current sewer network by the same amount. Both the rim elevations and invert elevations are changed. This command applies when a site design has been adjusted vertically by the same amount and you want to update the sewer network to match.

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: set_swr_elev

Prerequisite: sewer network structures

Identify Sewer Network Entity

This command prompts to select an entity in the drawing and reports the sewer network model that the entity belongs to.

Prompts

Select sewer network entity: *pick an entity*

Network: C:\sample\CivilDemo1.sew

Select sewer network entity ([Enter] to End): *press Enter*

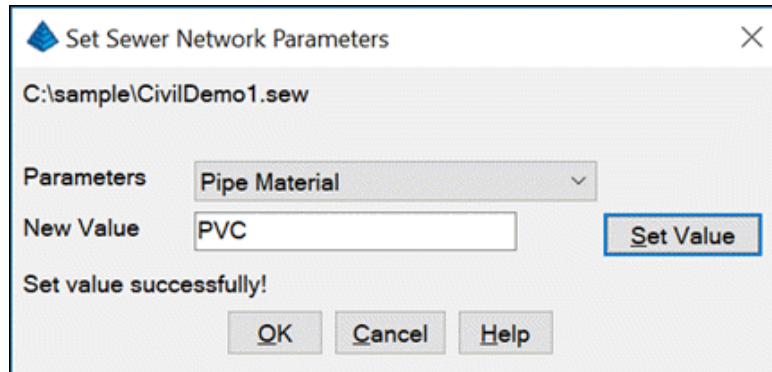

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: id_swrnet

Prerequisite: sewer network entities

Set Parameter For Entire Network

This command sets a parameter to the same value for all elements in the current sewer network. In the dialog, choose the parameter from the list and fill in the value in the edit box. Pick the Set Value button to apply this value to the sewer network.

Pulldown Menu Location: Network->Sewer Network Utilities

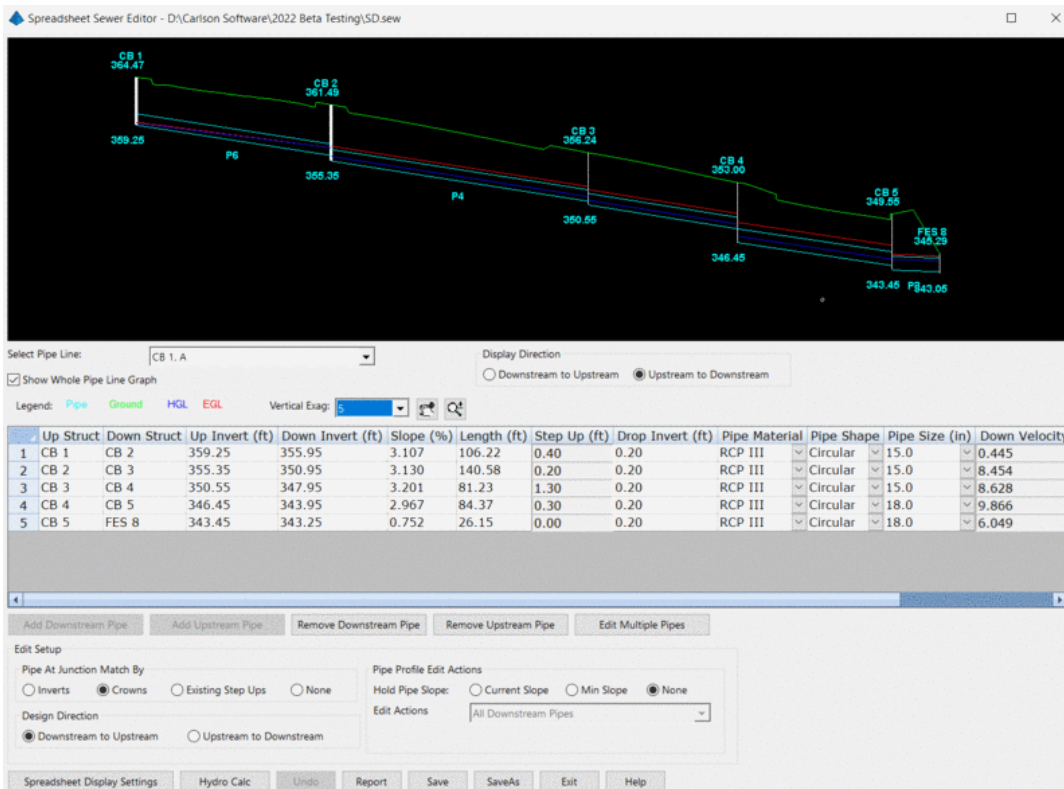

Keyboard Command: set_swr_value

Prerequisite: sewer network structures

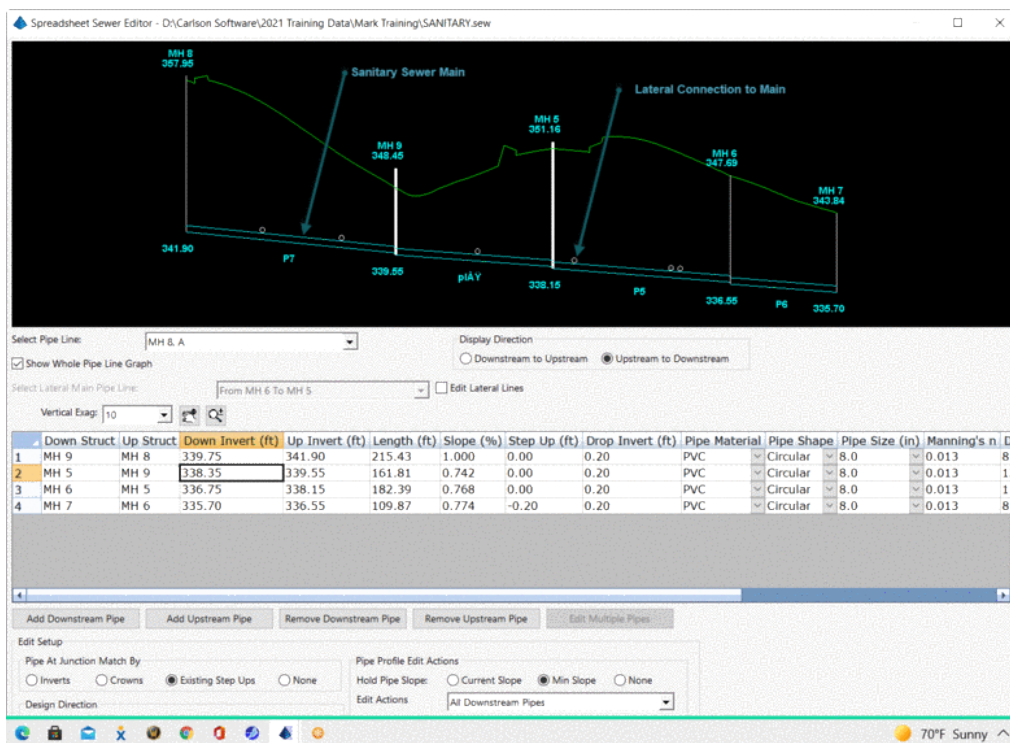

Spreadsheet Sewer Editor

This command is an alternative method to the Edit Sewer Structure command for editing existing sewer networks in a tabular format. Data changes can be applied more quickly in the spreadsheet editor and the content and position of displayed data is customizable.

Storm Drainage Sewer Editor

Sanitary Sewer Editor with Laterals

Show Lateral Lines: Select Lateral Main Pipe Line

Select Pipe Line: Select the sewer reach that will be displayed in the dialog box or enable the **Select All Pipe Lines** toggle to display the entire sewer network.

Show Whole Pipe Line: When enabled, the entire sewer network reach of the selected pipe is displayed.

Display Direction: To Display the network in either downstream to upstream or upstream to downstream direction, in order to match the **Design Direction**.

Design Direction: When downstream to upstream is selected, change a pipe's downstream invert elevation, its upstream invert will be updated automatically by pipe slope; otherwise change a pipe's upstream invert to update its downstream invert by pipe slope.

Vertical Exag: Indicate the desired amount of vertical exaggeration to be applied to the selected pipe display.

Edit Multiple Pipes: To globally change the value within a given column to a specific value, "click and drag" or use standard Windows **shift+click** functionality to select a range of cells within a given column and then click *Edit Multiple Pipes*.

Pipe at Junction Match By: Indicate the method by which pipes are vertically aligned at each junction:

- **Inverts:** Sets the pipe inverts at the same elevation at a given junction.
- **Crowns:** Sets the pipe crowns at the same elevation at a given junction.
- **Existing Setup:** The program will hold step-up values when edits are made.

- **None:** No vertical adjustment is performed.

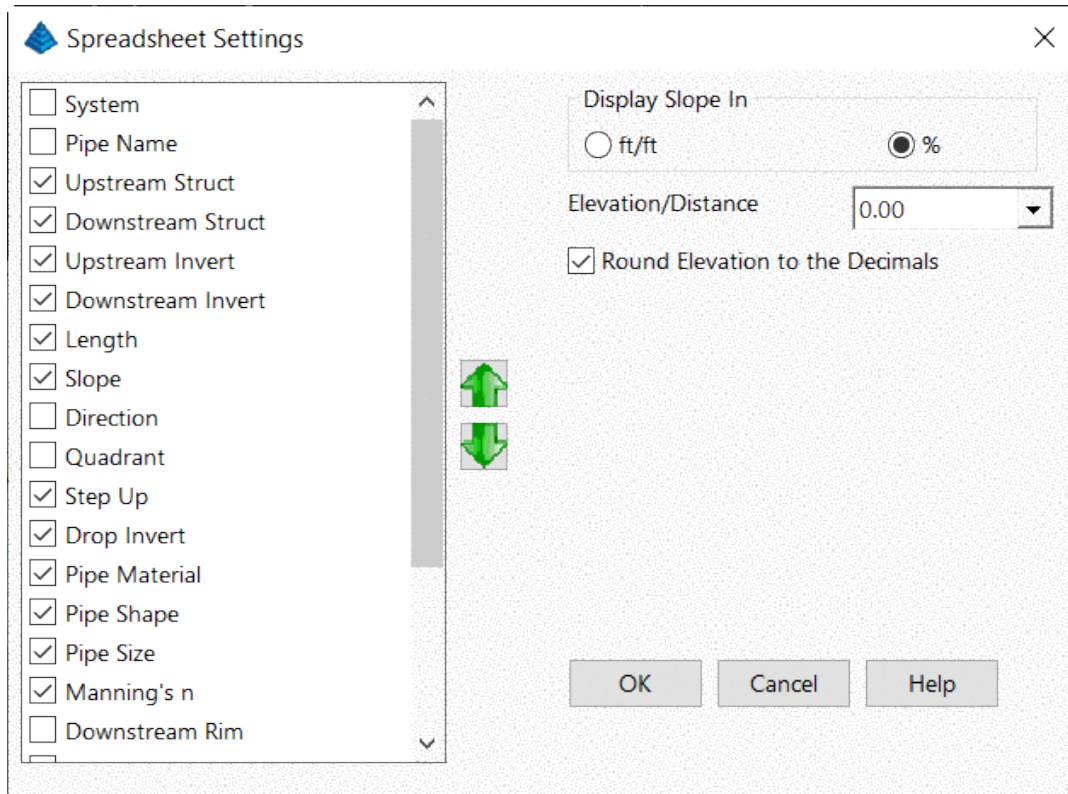

Pipe Profile Edit Actions: Indicate what should happen when *Hydro Calc* is clicked:

Hold Pipe Slope: Indicate how to manipulate the slope of the identified pipe(s):

- **Current Slope:** The slope of the current pipe is held.
- **Min Slope:** The minimum pipe slope is held.
- **None:** No vertical adjustment is performed.

Edit Actions: Set the desired method of how the sewer network should be adjusted when the *Hydro Calc* button is clicked.

Spreadsheet Display Settings: Enable the options for the value(s) you would like displayed in the Sewer Spreadsheet Editor and position each them using the Move Up and Move Down buttons.

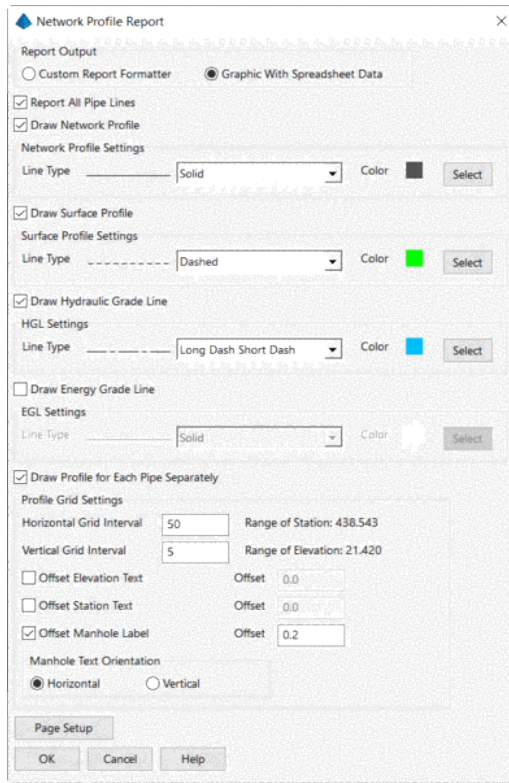

Display Slope In: Indicate the unit of measure to be used for the display of the pipe slope.

Elevation/Distance: Decimal Place Value for rounding, use drop down arrow for settings Round Elevation to the Decimal place.

Hydro Calc: The hydraulic calculations are performed on the network and the results are displayed.

Report: This option allows data or graphical reports of the network to be generated.

Report Output: Indicate the desired type of report output:

- **Custom Report Formatter:** Produces a user-customized report format using the standard Carlson Report Formatter functionality.
- **Graphic with Spreadsheet Data:** Produces a PDF-based report of the sewer network (see an example below) along with data results in a tabular format.
- **Report All Pipe Line:** If checked will include all pipe runs in the network report. If unchecked on the main dialog box what is displayed will be reported by using the Select Pipe Line.
- **Draw Network Profiles:** Will include the following image in the report.

Draw Profile for Each Pipe Separately: Draws each pipe run on its own page in the report.

Draw Network Profile, Draw Surface Profile, Draw Hydraulic Grade Line, Draw Energy Grade Line: When enabled, the appropriate item is included in the graphical portion of the report and allows the **Linetype** and **Color** to be specified for each, respectively.

Draw Profile for Each Pipe Separately: When enabled, each pipe is detailed into the report as illustrated above. When disabled, each reach of the sewer network is drawn into the report.

Profile Grid Settings: Set the desired Grid Setting to be used in report.

Manhole Text Orientation: Can be toggled between Horizontal or Vertical for display in the report

Page Setup: Allows the look and size of the eventual PDF report to be customized using the standard Carlson PDF Report Generator.

Pulldown Menu Location: Network

Keyboard Command: sizeswr

Prerequisite: A sewer (.SEW) file, a surface (.TIN, .GRD, .FLT) file

Draw Sewer Network Plan View

This command draws and labels the manhole symbols and pipe connections for the current sewer network (.SEW) file. An arrow can be drawn on the connections to indicate the direction of flow. The format for the labels is defined in the Plan View Label Settings command.

Example drawn sewer network

Pulldown Menu Location: Network

Keyboard Command: drawswr

Prerequisite: Sewer network (.SEW) file

Draw Sewer Network Data Table

This command draws the sewer network structure and pipe data tables on screen.

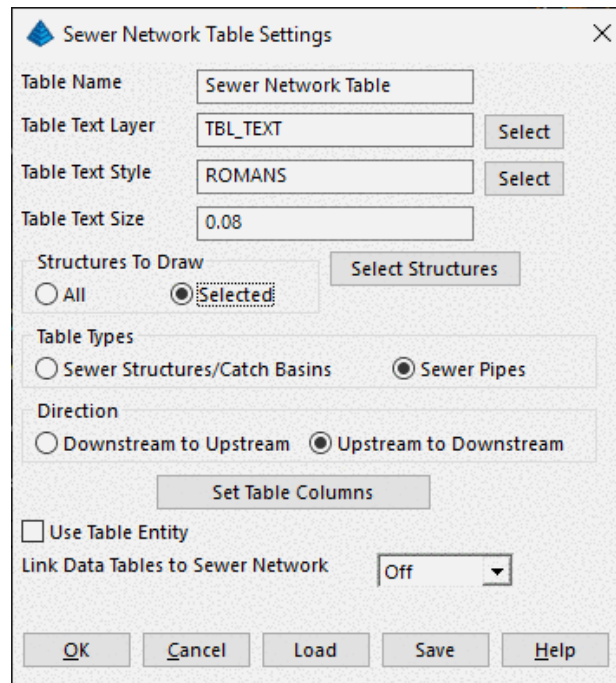

Select Data Table from Network > Draw Sewer Network menu. In the Table Settings dialog, specify the table name that will be shown as the table title, the layer name, the text style and the text size. Choose the table

type, either the sewer structures or sewer pipes, and also the direction how you want to display the sewer network: downstream to upstream or upstream to downstream. Click on Set Table Columns button to open a spreadsheet dialog, from where you can specify how you want to display the data table: which fields to display and in what order, the label, width, alignment and precision of each field. Choose Use Table Entity option to draw the data tables as the table entities, otherwise the tables are drawn as the traditional table block. After entering all parameters, click on OK button to draw the data table.

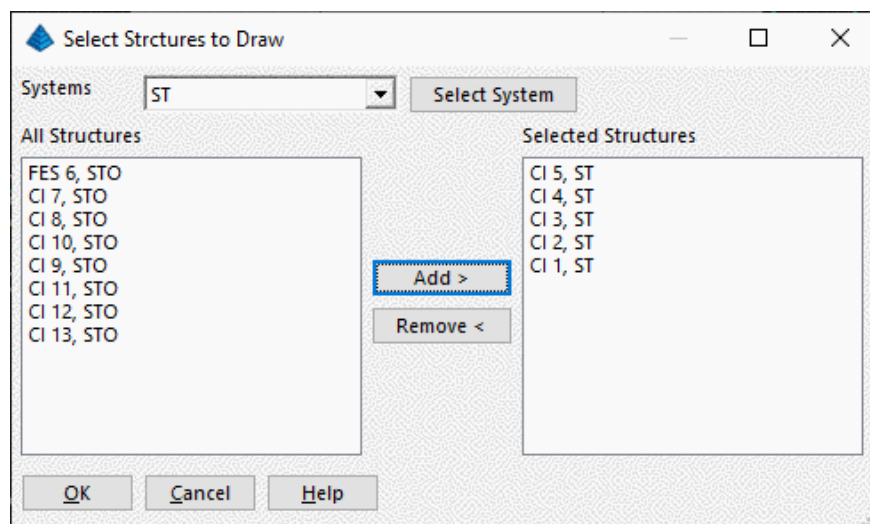

Structure to Draw if toggled to All, then all pipes will be in the data table. **Selection** toggle allows the user to select specific data to be included in the data table.

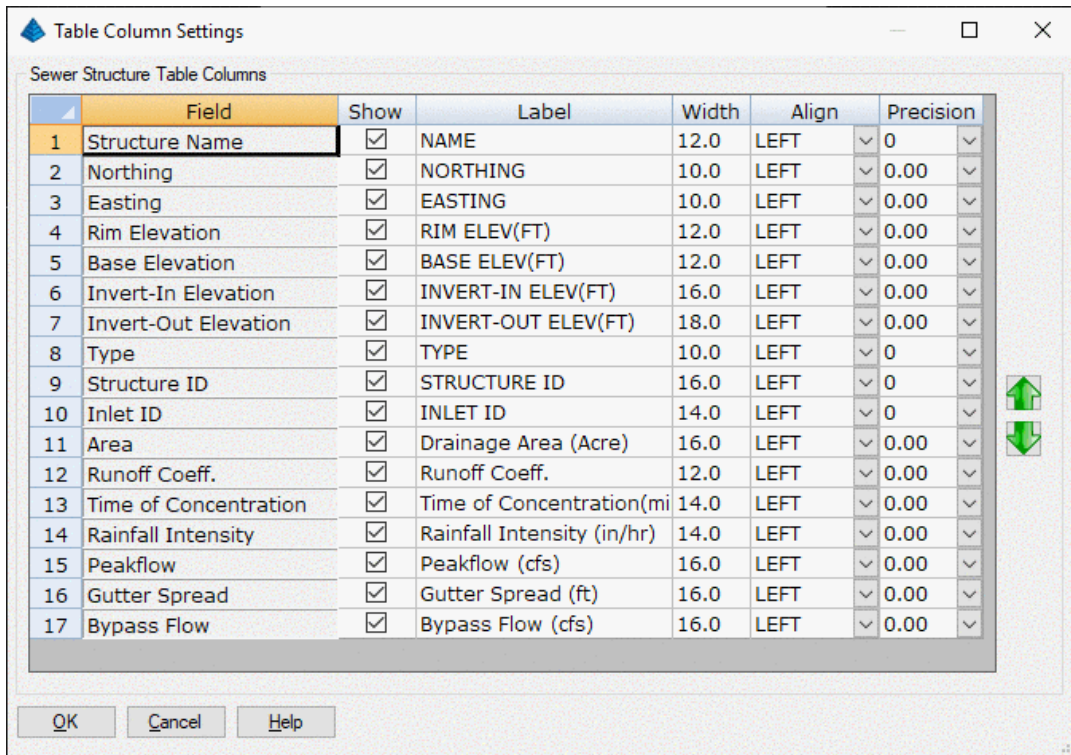

In the **Sewer Structure/Catch Basins** table, multiple invert-in elevations are reported.

When select the option **Link Data Tables to Sewer Network**, the data tables are redrawn automatically when the sewer network is revised.

Sewer Pipe Data Table Example

Prompts

Sewer Network Table Settings dialog: Fill in values

Pulldown Menu Location: Network > Draw Sewer Network > Data Table

Keyboard Command: swrtbl

Prerequisite: a sewer network file

Draw Sewer Network Centerlines

This command creates a centerline that connects each pipeline between the selected structures. The centerline can be drawn as a polyline or saved to a centerline (.cl) file. The direction of the centerline can go either upstream or downstream.

Account for Structures Connections Point for Box Structures: When this checkbox is unchecked, The centerline is from structure center to center; when the box checked on, centerline is from pipe point at the wall to structure center, and then to next pipe point at the wall.

Pulldown Menu Location: Network

Keyboard Command: drwswrcl

Prerequisite: Sewer network (.SEW) file

Draw Sewer Network Profile

This command will read the active sewer network (.SEW) file, which contains invert elevations, rim elevations, pipe sizes and structure dimensions, and draw the network as a profile, using the standard prompting in Draw Profile. In the options dialog, you can select the structure names for the start and end of the profile and set the profile direction as either upstream or downstream. The **Save To Profile File** option will save the sewer profile to a .pro file in addition to drawing the profile. When the Save option is active, there is an option available to **Link Profiles To**

Sewer Network. This Link option will update the sewer profile drawing whenever the sewer network is modified. Also, this link option will update the sewer network if the profile is changed. For example, if Profile Editor is used to change an invert elevation and the link option is active, then the invert elevation will also be updated in the sewer network. If you have a road and want to use it to reference the sewer network, you can choose the **Station by Another Reference Centerline** to do that. When not using a reference centerline, the **Starting Station** value is used for the beginning station of the sewer profile.

Draw Tributary Pipe Connections draws ellipses at the profile structures for any branch pipes that connect to the structure.

Draw Pipe Lateral Connections draws ellipses at the profile structures or pipes for lateral pipe connections.

Label Flow Along Pipes option pulls out the total flow that runs through each pipe and labels it on the profile.

Draw Hydraulic and **Energy Grade Line** options record the hydraulic flow calculation result and draw hydraulic and energy grade lines with network profile. You may choose to draw HGL/EGL for multiple storm events.

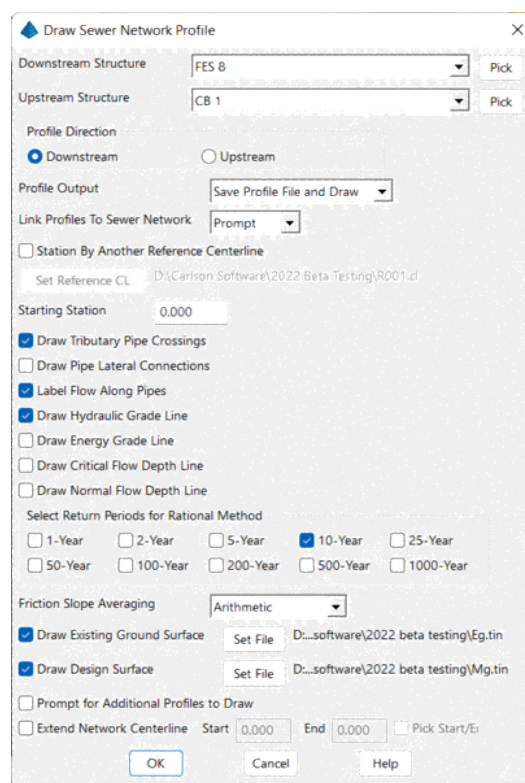

Draw Critical Flow Depth Line: Critical depth is defined as the depth of flow where energy is at a minimum for a particular discharge.

Draw Normal Flow Depth Line: Normal depth is the depth of flow that would occur if the flow was uniform and steady, and is usually predicted using the Manning's Equation.

Draw Existing Ground Surface and **Draw Design Surface** options would extract a profile from the surface to draw with the network profile. The **Set** button sets the surface files and the program stores the file names in the settings for redraw. If the files are not set on the dialog, the program would prompt for a surface file.

Prompt for Additional Profiles to Draw allows you to draw other profiles, such as a road profile, along with the network as a reference.

Extend Network Centerline lengthens the sewer network centerline by the specified amounts for extracting the surface profile for the existing and design surfaces. The **Pick Start/End** option allows users to pick start/end points that are not on the extension of sewer pipe lines.

Draw Sewer Network Profile Dialog

Consider the Storm Drainage Line shown in the plan view below:

When this network main storm drainage line is entered using Locate Sewer Structure, starting at the upstream rim elevation of 364.47 and running downhill to 1328.54, a new .SEW file is created. Prompting asks you to select a starting structure. If you created 8 structures named CB 1 through CB 5, you could choose CB 1 to plot all 5. This file will then plot, in profile view, as shown below (this example was drawn with ground surface and hydraulic grade lines). If you pick Draw Existing Ground Surface, you will be prompted for the grid or triangulation file for the ground surface, and similarly if you turn on Draw Design Surface.

Profile view of Sewer Network

Prompts

Draw Sewer Network Profile dialog: Fill in values

Pulldown Menu Location: Network->Draw Sewer Network

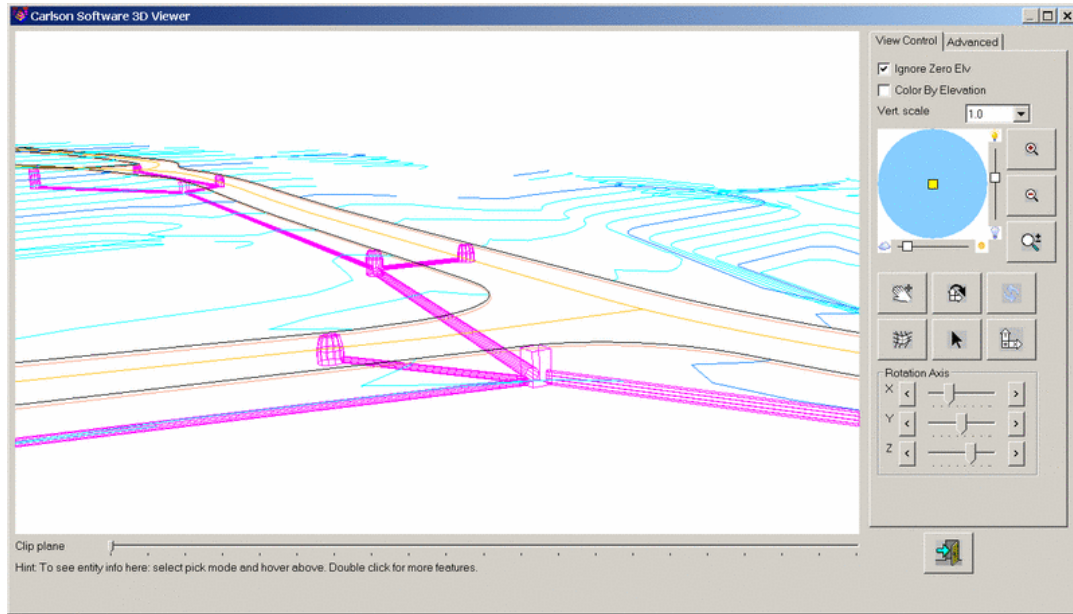

Keyboard Command: drswrpro

Prerequisite: Sewer network (.SEW) file

Draw Sewer Network-3DFaces

The command will read the active sewer file as set through the Set Sewer File command and draws the sewer pipelines as 3D faces for viewing in 3D. A primary use for this routine is to perform visual checks to help verify if

there are sufficient clearances with other 3D objects.

The 3D faces are drawn directly on the plan view in a layer of your choosing. The structures are drawn using the dimensions as defined in the Sewer Structure Library.

3D Face Layer: Key-in or use the **Select** button to identify the target layer for the 3D Face entities.

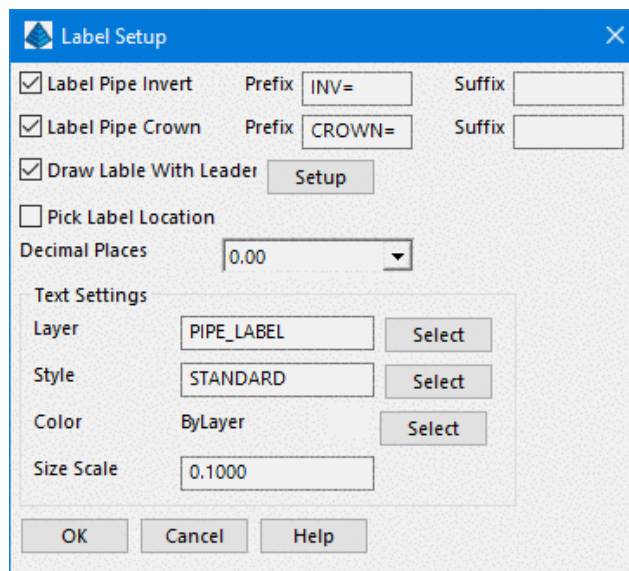

Pulldown Menu Location: Network > Draw Sewer Network

Keyboard Command: swr3d

Prerequisite: Sewer network (.SEW) file

Move Sewer Label

This command moves the selected plan view sewer network labels with the option to draw a leader from the labels to the sewer network reference location. Both structure and pipe labels can be moved. The purpose is to clean up label overlaps. To move a label, pick any one of the text labels and the program will pick up all the other associated labels. Then pick the new location and while the pointer is moved, the program shows an outline of the label area. The program remembers the moved locations for each label so that when the plan view labels are redrawn, the moved locations are retained.

At the command prompt, there are keyboard options to show command Options, change the Angle and to Restore. The Options function brings up a dialog for command options for when to draw the label leader and whether to include an arrow head. The Minimum Leader Length Scaler value is multiplied by the current Horizontal Scale defined in Drawing Setup to set the minimum distance from the label to the structure for a leader to be drawn. There are separate leader scalers for structure and pipe labels. The Place Label Above or Below the Structure option allows for creating a leader that is vertical from the structure and using the Text Justify mode. Otherwise, the leader always puts the label to the left or right of the structure.

The Angle command line function allows you to rotate the label. The Restore function puts the labels back to their default position.

For pipe labels, there is an extra option at the command line when picking the new location to make the label horizontal. Otherwise the pipe label is aligned with the pipe segment.

These graphics show the sewer labels before and after Move Sewer Label was used to clean up the label overlaps.

Prompts

Select sewer label to move [Options/Angle/Restore]: *Pick a sewer label text entity*

Pick label position: *pick a point*

Select sewer label to move or Enter to end [Options/Angle/Restore]: *press Enter to end*

Pulldown Menu Location: Network

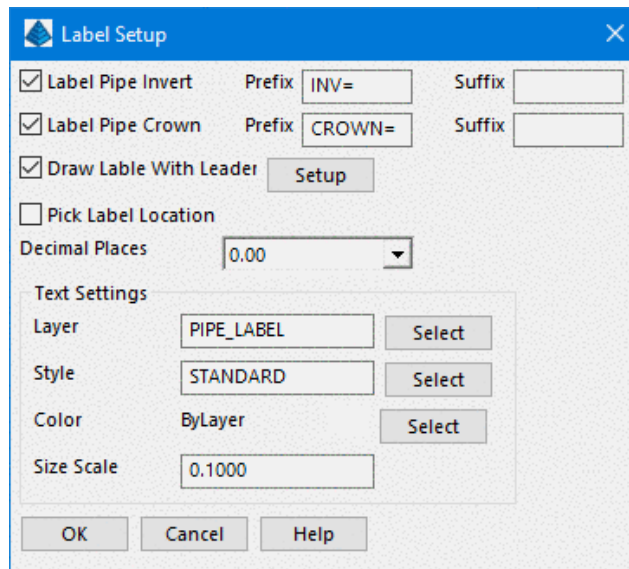

Keyboard Command: move_swr_label

Prerequisite: Plan view sewer network labels

Pipe Elevation Label

The command labels pipe elevations in plan view at specified points. In the options dialog, there are options whether to label the pipe invert elevation and pipe crown elevation. Also, there are options for the label prefix, suffix, layer, size, style, color, decimal places and whether to draw a leader from the label to the pipe. The Pick Label Location option allows for manually picking the location for the label. Otherwise, the label is automatically placed next to the pipe position. After clicking OK from the options dialog, the program prompts for points to label. For each point, the program finds the closest perpendicular point along a pipe in the current sewer network and labels that pipe position.

The elevation labels are for the inside pipe elevations without using the pipe wall thickness. A reason for labeling the pipe elevations is for checking for collisions.

Prompts

Pick pipe location (Enter to end): *pick a point*

Pick pipe location (Enter to end): *press Enter*

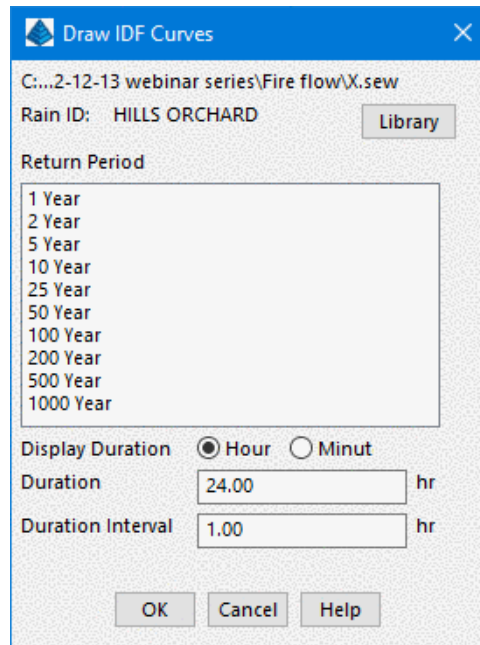

Pulldown Menu Location: Network > Sewer Labels

Keyboard Command: swrlabpipe

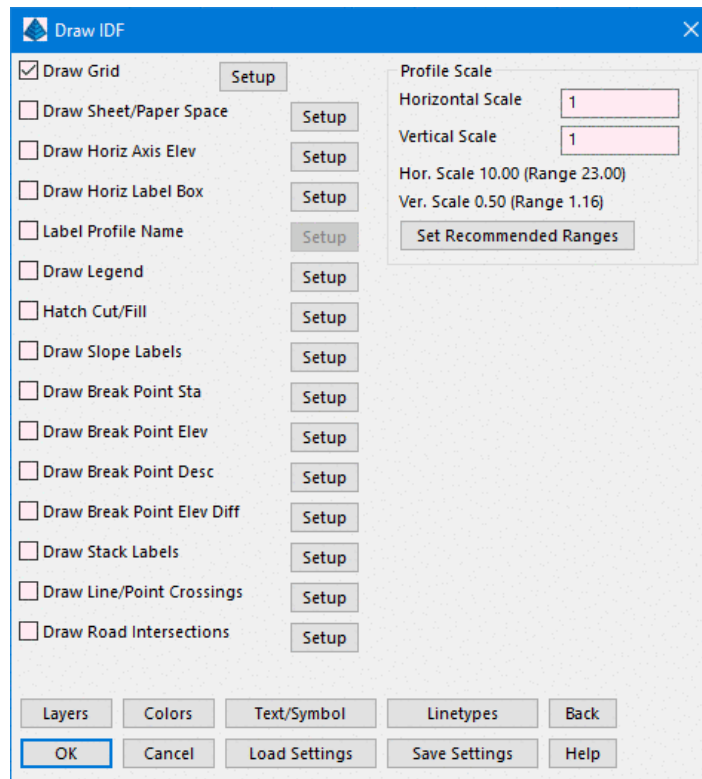

Prerequisite: sewer network in plan view

Draw IDF Curve

This command plots the Intensity-Duration-Frequency curves for the rainfall associated with the current sewer network. From the Network menu in the Hydrology Module, choose Draw IDF Curve. On the top of the dialog, the sewer network file name and the rainfall ID are shown. The Library button allows you to specify other rainfall data from the rainfall library. In the Return Period list, select one or more return periods. Select the Display Duration in either Hour or Minute, and enter the values in the Duration and Duration Interval boxes. Click on OK button to plot. The Draw IDF Settings dialog allows you to specify how to plot IDF curves on screen.

Draw IDF Curves

Draw IDF Settings

IDF Curve Example

Prompts

Draw IDF Curve dialog: Fill in values.

Pull-down Menu Location: Network > Draw IDF Curve

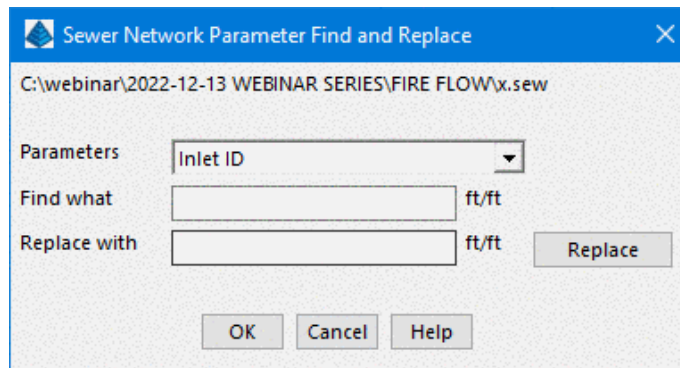

Keyboard Command: drwidf

Prerequisite: a sewer file (.SEW), ... \USER \RainLib.dta

Find And Replace Data Values

The Edit Sewer Structure command allows you to modify the parameters of a sewer network. However, it can be tedious when the network is large and when you need to change just one parameter of most of the sewer structures or pipe lines. For example, you'll have to go through all pipe lines if you want to change pipe manning's n to 0.014 for all pipes whose manning's n is currently 0.013. Here, the Find and Replace Data Values command would help you to find and replace the pipe manning's n values for all pipes at once.

From the Network > Sewer Network Utilities menu in the Hydrology Module, select Find and Replace Data Values to open the dialog. The sewer file name is displayed on the top of the dialog. In the Parameters list, choose what parameter you want to replace. In the Find what Box, type the value that you want to change, and in the Replace with box type the new value. Click on Replace button to find all pipes with manning's n values of 0.013 and replace their manning's n with 0.014. A message will be displayed on the dialog showing how many values have been replaced. Click on OK button to commit the changes or Cancel button to abandon the changes.

Find and Replace Sewer Network Parameters

Prompts

Find and Replace Data Values dialog: Fill in values.

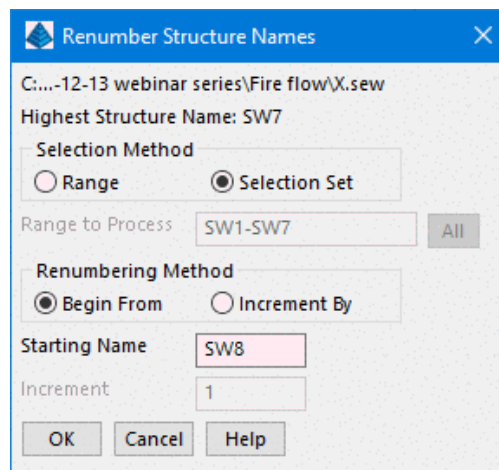

Pulldown Menu Location: Network > Sewer Network Utilities > Find and Replace Data Values

Keyboard Command:swr_find_replace

Prerequisite: a sewer file (.SEW)

Renumber Structure Names

The Renumber Structure Names routine provides an easy method to quickly rename/renumber all or part of a sewer network. Once a sewer file has been specified or set as Active via the Set Sewer File command, the following dialog box is presented.

Sewer Network File: The active sewer file that will be acted upon.

Highest Structure Name: The ID of the structure with the largest numerical value.

Selection Method: Indicate the method of which structures should be renumbered. *Range* allows the structures to be identified via the dialog box; *Selection Set* allows the structures to be identified via a graphical selection method.

Range to Process: When the **Selection Method** is set to *Range*, manually identify the structure(s) that should be part of the renumber process or click on the **All** button to select all structures in the network.

Renumbering Method: Indicate how structures should be renumbered. *Begin From* assigns the **Starting Name** value to the lowest structure name and increments by one until the network has been renumbered; *Increment By* adds the **Increment** value to each structure.

Note:

- Caution should be exercised when specifying a negative value for the **Increment** setting as duplicate structure numbers may result if the Increment value forces the renumbered structures to values less than 0.
- For network structures that do not contain a numerical value (*e.g.* MHA, MHB, MHC, MHD, *etc.*), a trailing numerical value of 1 is assumed (*e.g.* MHA1, MHB1, MHC1, MHD1, *etc.*) before the Increment process commences.

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: renumswr

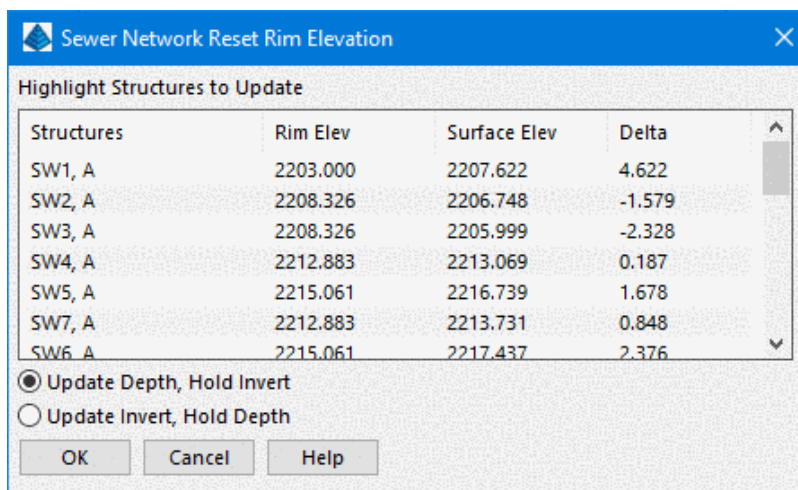

Prerequisite: A sewer (.SEW) file

Set Rim Elevation to Match Surface

This command compares the rim elevations for the current sewer network with the current surface model. If any differences are found, the program shows a dialog box with the rim elevations, surface elevations, structure names and elevation differences. You can highlight structures from this list to update their rim elevations to match the surface model. There are two update methods:

Update Depth, Hold Invert: Keeps the invert elevations while updating the rim elevations so that the depths are adjusted.

Update Invert, Hold Depth: Adjusts the invert elevations by the same amount as the rim elevations so that the depths are maintained.

Pulldown Menu Location: Network->Sewer Network Utilities

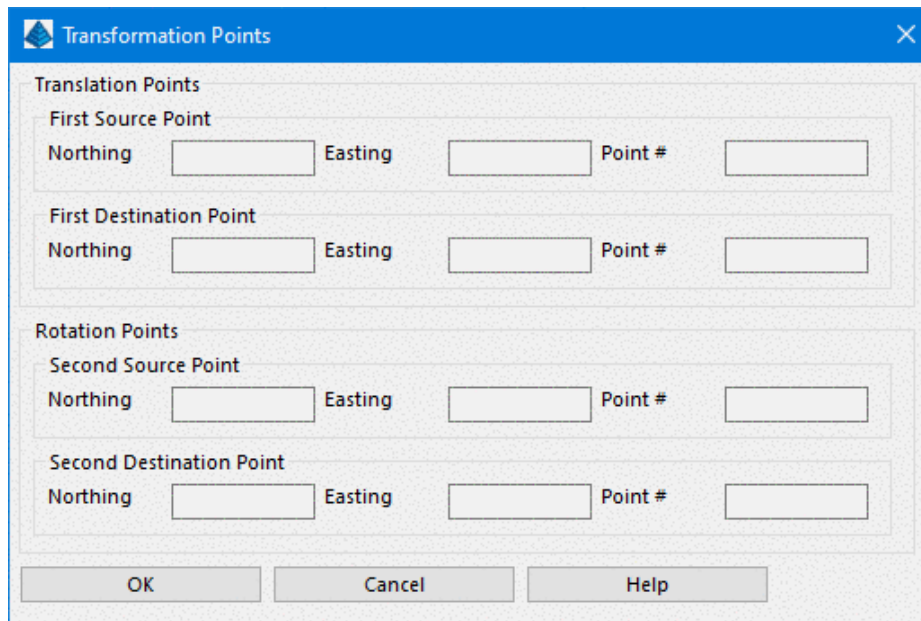

Keyboard Command: swrsurf

Prerequisite: sewer network structures

Transform Coordinates

This command translates and rotates the x,y coordinates of the structures in the sewer network model which can be used in case the coordinate system of the job is changed after creating the sewer network. The transform is defined by two pairs of source and destination points. The first pair of points defines the translation. The second pair defines the rotation by the angular difference between the angle of the two source points and the angle of the two destination points. The rotation pivot point is the first destination point. The points can be entered by point number from the current coordinate file or by typing in the coordinates. This transformation works similar to the Align Points command in the Points menu.

The program reports the amount of translation and rotation at the command line. The program creates a backup of the original sewer network model by copying the original .sew file to a .bak file of the same name.

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: swrtransform

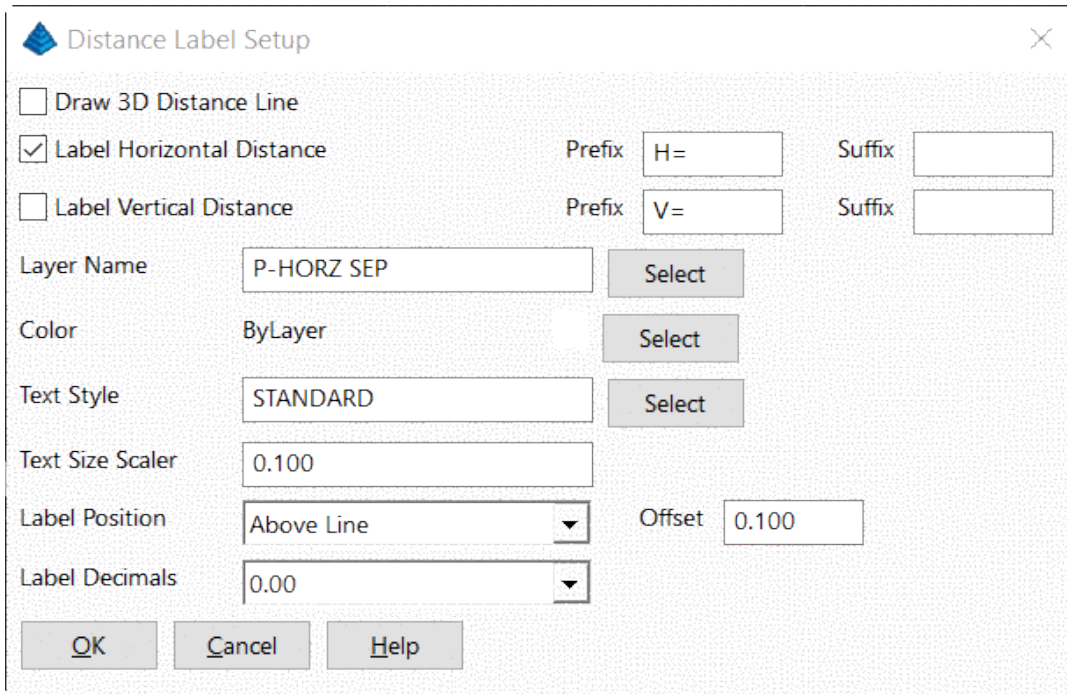

Prerequisite: Sewer Network File

Check/Label Clearance

This command checks for horizontal separation between any sewer network pipes, utility network pipes, and 3D pipe polylines. It displays horizontal separation value, as well as the Vertical Distance on command line and real time dialog box. Users can also label the results in plan-view.

From the Network > Check Sewer Network menu in the Hydrology Module, select Label Separation for Parallel Pipes. In the drawing, first have all the networks and pipes drawn in plan view. Hovering between two sets of pipes in plan-view will give real time information on screen dialog box and picking in the plan view will place a label at the location picked.

The Label Separation for Parallel Pipes is used to draw the horizontal separation labels on screen. The settings are saved and no need to bring it up next time to check and label clearance. Clear the Draw Labels box and the program won't label the results on screen.

Distance Label Setup

Carlson

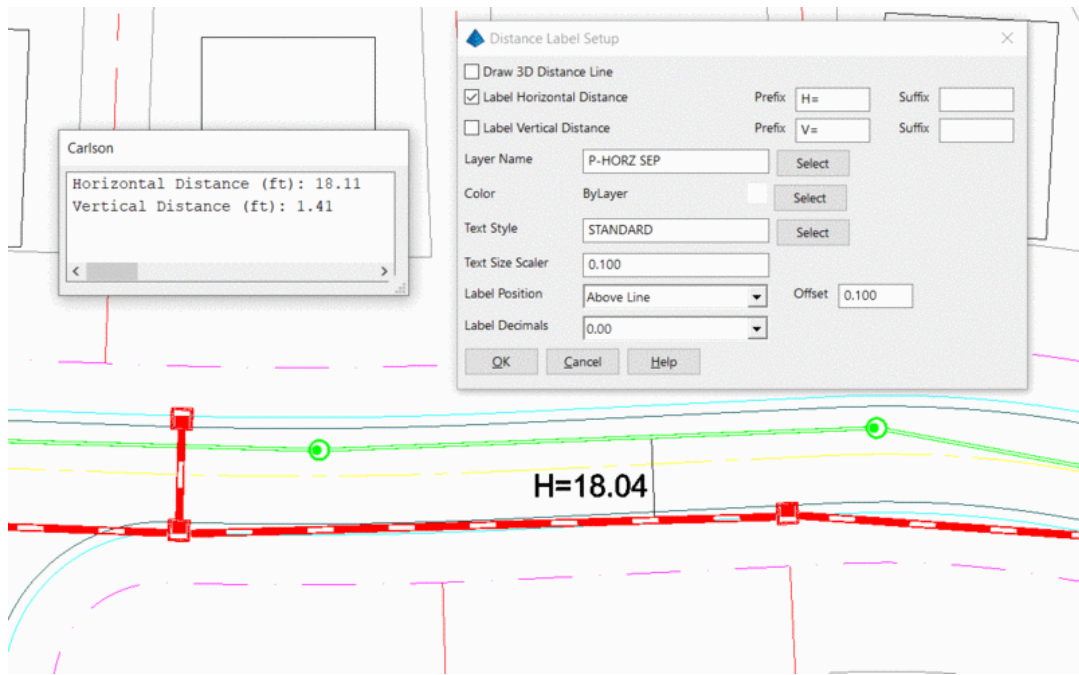

Real Time Clearance Result Dialog Box on Screen

```

Command: label_parallel
Inspect Distance Between Pipes

Structure Changes

1 FES 8
  Name has changed from CI 8 to FES 8.
  Structure has changed from CI 5X5 to FES 24".
  Location has changed from (2096119.386, 859215.762) to (2096210.919, 859139.198).
  Base Elevation has changed from 347.500 to 343.250.
  Rim Elevation has changed from 353.664 to 345.290.

2 CB 5
  Name has changed from CI 5 to CB 5.
  Structure has changed from CI 5X5 to CI 5 X5.
  Location has changed from (2096191.138, 859157.567) to (2096193.600, 859158.794).
  Base Elevation has changed from 342.000 to 343.450.
  Rim Elevation has changed from 348.953 to 349.550.
  Drop Across Manhole has changed from 0.200 to 0.000.
  Inlet has changed from COMBO-GRADE to CI NCDOT SAG.
  Drainage Area has changed from 15929.253 to 15469.700.
  Runoff Coefficient has changed from 0.470 to 0.480.

3 CB 4
  Name has changed from CI 4 to CB 4.
  Structure has changed from CI 5X5 to CI 5 X5.
  Base Elevation has changed from 347.000 to 346.450.
  Rim Elevation has changed from 353.664 to 353.000.
  Inlet has changed from COMBO-GRADE to CI NCDOT GRADE.
  Drainage Area has changed from 1960.074 to 2027.583.

4 CB 6
  Name has changed from CI 6 to CB 6.
  Structure has changed from FES 24" to CI 5 X5.
  Location has changed from (2096204.173, 859128.891) to (2096119.386, 859215.762).
  Base Elevation has changed from 341.800 to 347.750.
  Rim Elevation has changed from 344.776 to 353.000.
  Inlet has changed from to CI NCDOT GRADE.
  Bypass Catchbasin has changed from to CSMH3.
  Drainage Area has changed from 0.000 to 44364.527.
  Tc has changed from 0.000 to 9.000.
  Runoff Coefficient has changed from 0.000 to 0.650.
  Curve Number has changed from 0.000 to 50.000.

```

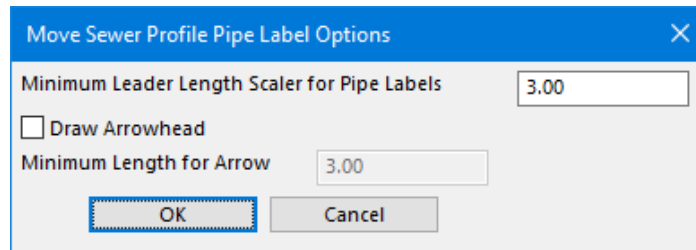

Pulldown Menu Location: Network
Keyboard Command: diffswr
Prerequisite: 2 Sewer network (.SEW) files

Move Sewer Profile Pipe Labels

This command will allow the user to move profile pipe labels. See Command Prompt.

Command Prompt `Select profile Pipe label to move [Options/Restore]:`

Press O for Options

Select Pipe text within a Profile and move to new location (Press H to make label Horizontal)

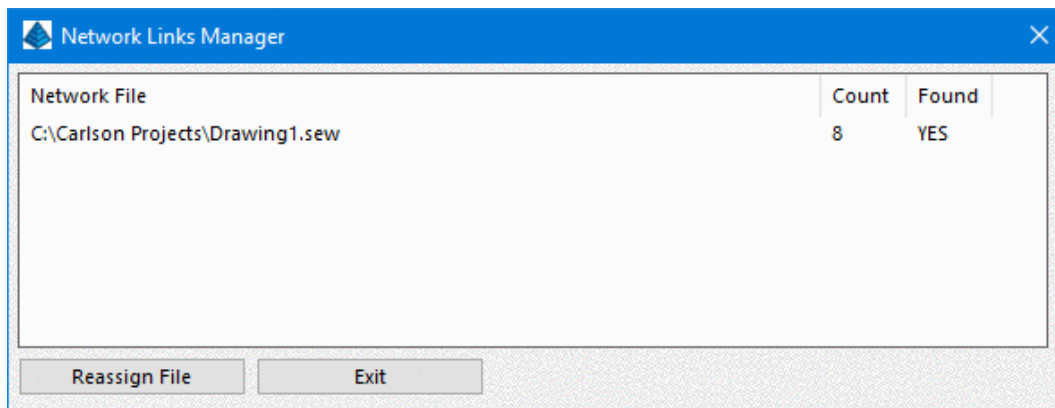

Pulldown Menu Location: Network > Sewer Labels > Move Profile Pipe Labels

Keyboard Command: move_swrprof_pipelabel

Prerequisite: Sewer network (.SEW) file

Pipe Network Drawing Links

This command finds all the Sewer, Utility or Pressure Pipe network entities in the drawing and reports the network file names that created the entities, how many entities were found for each network file, and whether that network file is found on the computer. The Reassign File button applies when the network file has been moved to another folder. This function prompts to select the new folder for the file and then updates the entities in the drawing to use the new folder location.

Pulldown Menu Location: Network

Keyboard Command: netlink_mgr

Prerequisite: Network entities

Pipe Network ID

This command prompts to pick an entity from the drawing and then reports which Sewer, Utility or Pressure Pipe network file created the entity.

Prompts

Select pipe entity to identify: *pick an entity*

Utility Network: D: \projects\utilnet\utilnet1\FREEDOM_2.util

Select pipe entity to identify (Enter to end): *press Enter*

Pulldown Menu Location: Network

Keyboard Command: pipe_id

Prerequisite: Network entity

Edit/Create Structure With Inverts

The Create Structure With Inverts command creates structures with rim and invert elevations but without pipe connections. So these structures are standalone without connections and can't be used for hydraulic calculations. The main purpose for these structures is for plan view labeling. The labels are controlled by the Plan View Label Settings command.

After picking the location for the structure, the data for the structure is entered in the dialog shown here. You can have any number of inverts that can be entered by either elevation or depth in the spreadsheet. See the Create Sewer Structure command in the manual for details on the other fields in this dialog.

The Edit Structure With Inverts command allows you to modify the data in existing structures. To run this command, first pick on a structure symbol or label and then the dialog shown here is used to edit the data.

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: putswrstr, editswrstr

Prerequisite: None

Review Sewer Network Links

This command shows a list of all the sewer network links that the program knows about in the current drawing. These links are between the sewer network files and the drawing entities. You can use the Remove button to remove links for any obsolete sewer networks or if you don't want to link a certain sewer network.

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: swrnetdict

Prerequisite: Sewer network (.SEW) file

Review Sewer Profile Links

This command shows a list of all the sewer network profile links that the program knows about in the current drawing. These links are between the sewer network files and the sewer profiles in the drawing. You can use the Remove button to remove links for any obsolete sewer profiles or if you don't want to link a certain sewer profile.

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: swrproduct

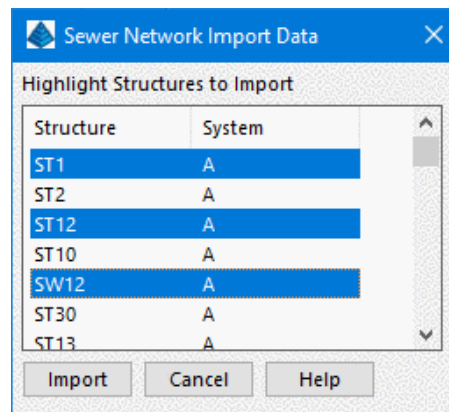

Prerequisite: none

Import Carlson Sewer Network

In certain scenarios, it may be desirable to combine the contents of one Carlson sewer project file into another sewer file and form a more comprehensive Carlson sewer project file. The Import Carlson Sewer Network routine will import selected contents of a Carlson sewer file (.sew) into the active sewer file as defined via the Set Sewer File command or the Sewer Network Settings command. If an active sewer file has not been set, you will first be prompted to select an active sewer network file and will then continue with the command as described below.

Browse to the folder location where the Carlson sewer file resides that you wish to import into the current sewer file.

Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select the structure(s) that should be imported.

Note:

- Any structure names found in the incoming sewer file that are also found in the active sewer file will not be imported.
- After being imported, the network can be drawn into the drawing via the Draw Sewer Plan command.

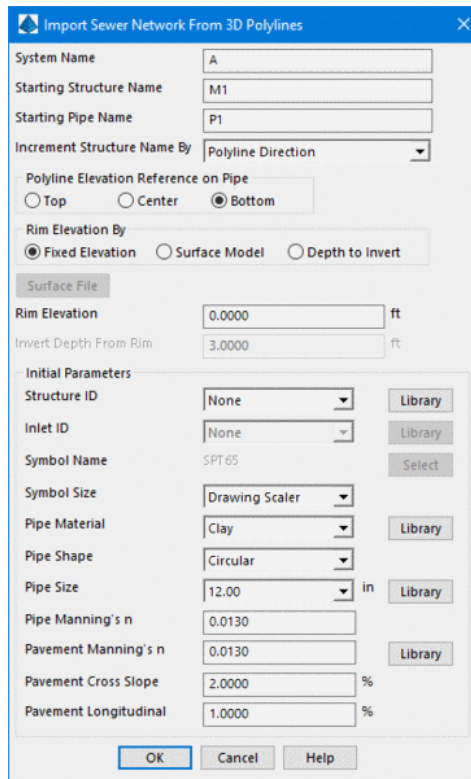

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: impswr

Prerequisite: Existing Carlson Software sewer file (*.sew)

Import Network From 3D Polylines

This function assigns pre-determined sewer parameters for pipes and structures from selected 3D polylines that have been previously drawn to the screen and converts them to a Sewer (*.SEW) file. This command is very similar to the Import Sewer Network from 2D Polylines command and the Import Network from Centerline/Profile command. Sewer structures are inserted at the polyline vertices with the base elevation of the structure taken from the polyline vertex elevation. Pipes are created to replace the polyline segments and the invert elevations of the pipes also come from the polyline vertex elevations.

System Name: Indicate the system designation for the incoming sewer entities. A *.SEW file can have multiple systems (e.g. A, B, STRM1, STRM2, etc) within it.

Starting Structure Name: Indicate the designation that is to be assigned to the first structure (i.e. a junction) to be created by the routine.

Starting Pipe Name: Indicate the designation that is to be assigned to the first pipe that will be created by the routine.

Rim Elevation By: Set toggle to desired option. Fixed Elevation, Surface Model when enabled, this option allows you to click the **Surface File** button indicate a valid Carlson surface file (generally created through the Triangulate & Contour command) as the source for the new rim elevations, and Depth to Invert

Rim Elevation: Indicate a single desired rim elevation to be applied to all new structure locations.

Invert Depth from Rim: Indicate the desired depth from the rim elevation.

Structure ID: Indicate the type of structure to be used for the new sewer data or click on the **Library** button to access the Sewer Structure Library command to create a new structure definition or edit an existing structure definition. If this is an utility network (i.e. waterline, gas line and etc.) where there's no structure, you can choose None as the Structure ID. Therefore all the junctions would become an elbow pipe connections.

Inlet ID: Indicate the type of inlet to be used for the new sewer data or click on the **Library** button to access the Inlet Library command to create a new inlet definition or edit an existing inlet definition.

Symbol Name: Select the symbol to be used. Click on the **Select** button to access the Symbol Library. If this is an utility network (i.e. waterline, gas line and etc.) where there's no structure, you can choose SPT0 for no symbols.

Symbol Size: For the size of the symbol three options are available, Inlet Library Width, Drawing Scaler, and Unit Symbol

Pipe Material: Indicate the type of material to be used for the new pipes or click on the **Library** button to access the Pipe Material and Manning's *n*-Library command to create a new pipe material or edit an existing pipe material definition.

Pipe Shape: Indicate the general pipe shape that is to be applied to the new pipes.

Pipe Size: Indicate the desired pipe size for the new pipes or click on the **Library** button to access the Pipe Size Library command to create a new pipe size or edit an existing pipe size definition.

Pipe Manning's n: Indicate the desired Manning's *n*-value to be applied to the new pipes.

Pavement Manning's n: Indicate the desired Manning's *n*-value to be applied for storm sewer network runoff considerations or click on the **Library** button to access the Pavement Manning's *n*-Library command to create a new Pavement Manning's *n*-value or edit an existing Pavement Manning's *n*-value definition.

Pavement Cross-slope: Indicate the desired pavement cross-slope for ponding width calculation purposes.

Pavement Longitudinal Slope: Indicate the desired pavement longitudinal slope for ponding width calculation purposes.

Prompts

Select 3D polylines.

Select objects: *Select the desired 3D polylines that are to be converted and press Enter when complete. If several polylines are met at one vertex, only one structure is created, and the first polyline is the main flow line, others are the upstream branches.*

The sewer network will be drawn on the screen as the routine completes and can be manually drawn later through the Draw Sewer Network > Plan View command.

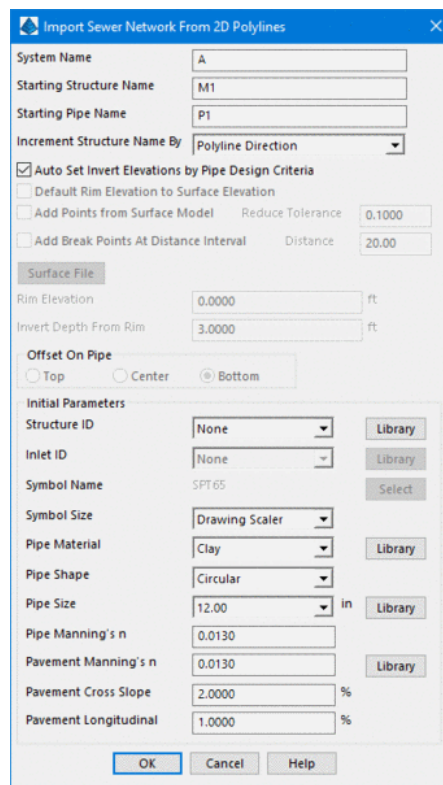

Pull-down Menu Location(s): Network > Sewer Network Utilities

Keyboard Command: swr3dp

Prerequisite: 3D polylines drawn on screen

Import Sewer Network From 2D Polyines

This function assigns pre-determined sewer parameters for pipes and structures from selected 2D polylines that have been previously drawn to the screen, places the pipes at a pre-determined offset from the structure rim elevation and converts them to a Sewer (*.SEW) file. This command is very similar to the Import Sewer Network from 3D Polyines command and the Import Network from Centerline/Profile command. Sewer structures are inserted at the polyline vertices with the base elevation of the structure taken from the polyline vertex elevation. Pipes are created to replace the polyline segments and the invert elevations of the pipes also come from the polyline vertex elevations.

System Name: Indicate the system designation for the incoming sewer entities. A *.SEW file can have multiple systems (*e.g.* A, B, STRM1, STRM2, *etc*) within it.

Starting Structure Name: Indicate the designation that is to be assigned to the first structure (*i.e.* a junction) to be created by the routine.

Starting Pipe Name: Indicate the designation that is to be assigned to the first pipe that will be created by the routine.

Default Rim Elevation to Surface Elevation: When enabled, this option allows you to click the **Select File** button indicate a valid Carlson surface file (generally created through the Triangulate & Contour command) as the source for the new rim elevations.

Add Points from Surface Model: When enabled, this option inserts additional junction points along the 2D polyline where it crosses the triangulation legs of the surface model.

Reduce Tolerance: Identify the smallest tolerance to which new points should be added to the 2D polyline.

Rim Elevation: Indicate a single desired rim elevation to be applied to all new structure locations.

Offset Invert from the Rim: Indicate a vertical offset distance rim elevation for the placement of the pipe.

Offset on Pipe: Indicate a the location on the pipe to be used for the pipe offset:

- **Top** - The top of the pipe is placed at the vertical offset from the rim elevation.
- **Center** - The center of the pipe is placed at the vertical offset from the rim elevation.
- **Bottom** - The bottom of the pipe is placed at the vertical offset from the rim elevation.

Structure ID: Indicate the type of structure to be used for the new sewer data or click on the **Library** button to access the Sewer Structure Library command to create a new structure definition or edit an existing structure definition.

Inlet ID: Indicate the type of inlet to be used for the new sewer data or click on the **Library** button to access the Inlet Library command to create a new inlet definition or edit an existing inlet definition.

Symbol Name: Use the **Select** button to access the symbol selector of the Symbol Library command to access a desired symbol for the structure.

Pipe Material: Indicate the type of material to be used for the new pipes or click on the **Library** button to access the Pipe Material and Manning's *n*-Library command to create a new pipe material or edit an existing pipe material definition.

Pipe Shape: Indicate the general pipe shape that is to be applied to the new pipes.

Pipe Size: Indicate the desired pipe size for the new pipes or click on the **Library** button to access the Pipe Size Library command to create a new pipe size or edit an existing pipe size definition.

Pipe Manning's n: Indicate the desired Manning's *n*-value to be applied to the new pipes.

Pavement Manning's n: Indicate the desired Manning's *n*-value to be applied for runoff considerations or click on the **Library** button to access the Pavement Manning's *n*-Library command to create a new Pavement Manning's *n*-value or edit an existing Pavement Manning's *n*-value definition.

Pavement Cross-slope: Indicate the desired pavement cross-slope for ponding width calculation purposes.

Pavement Longitudinal Slope: Indicate the desired pavement longitudinal slope for ponding width calculation purposes.

Prompts

Select 2D polylines.

Select objects: *Select the desired 2D polylines that are to be converted and press Enter when complete. If several polylines are met at one vertex, only one structure is created, and the first polyline is the main flow line, others are the upstream branches.*

The sewer network will be drawn on the screen as the routine completes and can be manually drawn later through the Draw Sewer Network > Plan View command.

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: swr2dp

Prerequisite: 2D polylines drawn on screen

Import Network from Centerline/Profile

The Import Network from Centerline/Profile command allows a sewer file (*.SEW) file to be created by combining the horizontal components of a centerline (*.CL) file with the vertical component of a sewer profile (*.PRO) file. The process to create the sewer file is as follows:

1. The stationing contained within the centerline file is processed into memory.
2. The stations within the sewer profile file are located along the path of the centerline to form the structure/junction locations.
3. The pipe information stored within the sewer profile file are placed linearly between the structure locations.

The resultant sewer file can be further edited with the Edit Sewer Structure command or the Spreadsheet Sewer Editor command.

Note:

- Any stations within the *.PRO file that occur after the last station in the *.CL file are not written into the *.SEW file.
- Once the *.SEW file has been created, you can activate it for editing via the Set Sewer File command and/or draw it graphically via the Draw Sewer Network > Plan View command.

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: swrc1pro

Prerequisite: Centerline (*.CL) file, Sewer Profile (*.PRO) file

Import Network From Text File

This command creates a sewer network file (.sew) from data in Bentley .sdb database file.

The program prompts for .sdb file to import and then the sewer network file to output. The data in Inlets, InletDesign, Manholes, ManholeDesign, Pipes, PipeDesign and Areas tables are imported and saved in the new sewer network file. The program would draw the sewer network plan view after it finishes importation.

Pulldown Menu Location: Network > Import/Export Sewer Network

Keyboard Command: sdb2swr

Prerequisite: Bentley database file .sdb.

Import ADAC

This routine converts ADAC storm sewer network files into Carlson sewer (.sew) files. The ADAC data is stored in XML files.

Pulldown Menu Location: Network->Sewer Network Utilities

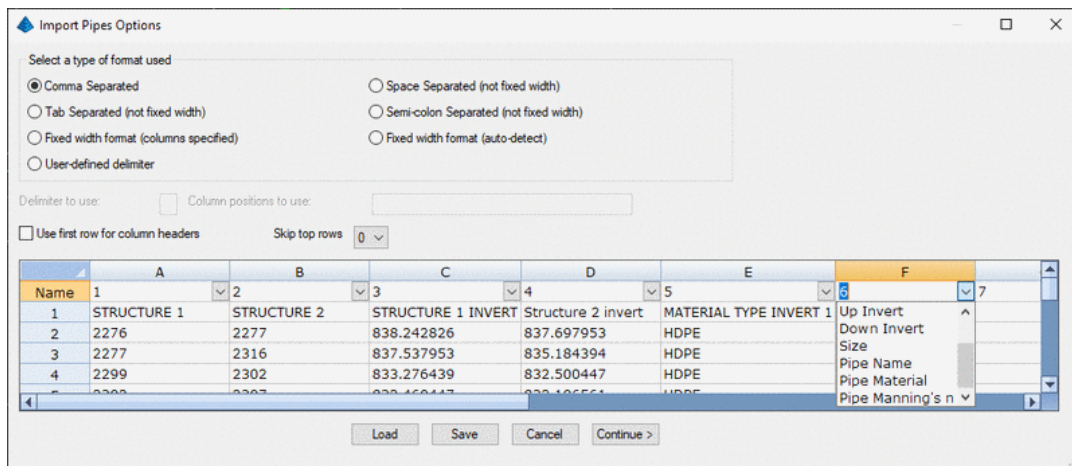

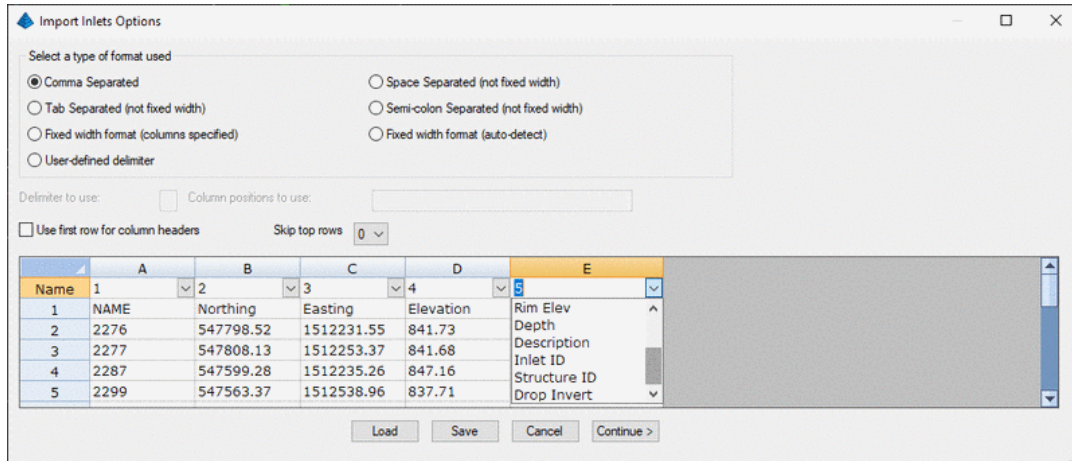

Keyboard Command: import_adac

Prerequisite: ADAC format XML file

Import Network From Bentley

This command creates a sewer network file (.sew) from data in two text files. One text file has the structure data with one structure per row in the text file with the fields separated by a comma or other delimiter. The structure file requires name, northing, easting and rim elevation. Other available fields are description, rim elevation, depth, description, inlet ID, structure ID and drop invert. The second file has the pipe data with one pipe per row. The pipe fields require the names of the connecting structures. The other fields include the upstream/downstream structure name, up/down inverts, pipe size, pipe name, pipe material and pipe manning's n.

The program prompts for the structure file and pipe file to import and then the sewer network file to output. Then there are dialogs to specify the format of the input text files. For each column of data in the input files, choose which field to assign.

Example structure data file:

Name,Northing,Easting,Rim

CB349,207062.75480,409437.63270,187.80000

DCB368,207194.02290,409287.13550,178.75000

DCB367,206993.48600,409306.21250,178.50000

CB347,206876.38490,409351.77020,176.50000

Example pipe data file:

Upstream_Node,Downstream_Node,Upstream_Invert,Downstream_Invert,Diameter

CB349,CB347,178.3000,166.1000,24.0000

DCB368,DCB367,174.0000,172.3500,15.0000

DCB367,CB347,172.3500,166.1000,15.0000

Pulldown Menu Location: Network > Import/Export Sewer Network

Keyboard Command: csv2swr

Prerequisite: structure and pipe text files.

Import StormCAD Network

This routine converts StormCAD storm sewer network files into Carlson sewer (.sew) files. The StormCAD data is stored in MDB database files. The routine prompts for the Pipes Database to read and then the Storm Database to read. The pipes data is required for the structure data. The storm data is optional for the drainage data.

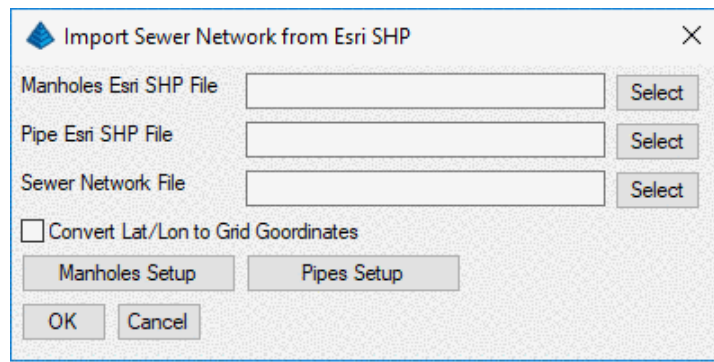

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: swrimport

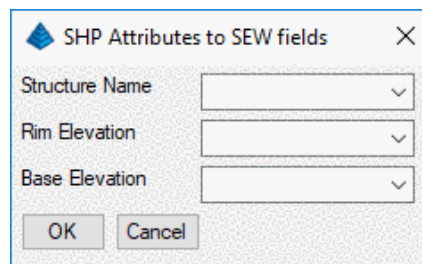

Prerequisite: StormCAD file

Import Sewer Network From Esri Shapefiles

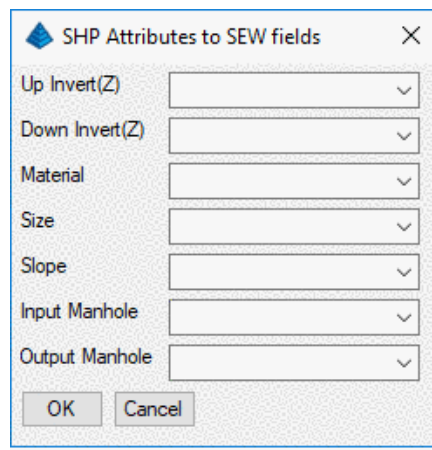

This command converts Esri sewer network shapefiles into Carlson sewer network file (.sew) . In order to create a Carlson sewer network file(.sew), a manholes SHP and a pipes SHP are required. The Manholes SHP contains manhole data, and the SHP type has to be point/pointZ/pointM. The Pipes SHP contains pipe data, and the SHP type has to be polyline/polylineZ/polylineM. There is also a setting to convert the ESRI SHP lat/lon coordinates to grid coordinates which requires the grid projection to be already defined in the Drawing Setup command.

There are **Manholes Setup** and **Pipe Setup** dialogs that match the SHP attributes to the .sew fields. This command uses Structure name as a key identifier and this field is required.

This command uses input manhole and output manhole as key identifiers to identify a pipe, and it uses these manholes to create relationship between manholes and pipe. The rest of fields matching are optional.

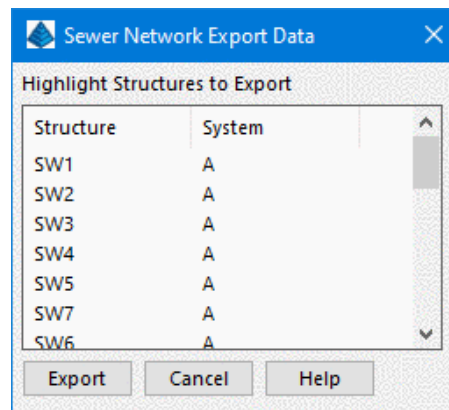

Pulldown Menu Location: >Network>Import/Export Sewer Network

Keyboard Command: shptoswr

Prerequisite: Esri Shapefiles

Export Carlson Sewer Network

In certain scenarios, it may be desirable to save all or parts of the active sewer file to an alternate sewer file name or location. The Export Carlson Sewer Network routine will export selected contents of the active Carlson sewer file (.sew) as defined via the Set Sewer File command or the Sewer Network Settings command and create a new sewer output file. If an active sewer file has not been set, you will first be prompted to select an active sewer network file and will then continue with the command as described below.

Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select the structure(s) that should be imported.

Browse to the folder location where you would like to write the new Carlson sewer file and specify the new sewer file name.

Pulldown Menu Location: Network > Sewer Network Utilities

Keyboard Command: expswr

Prerequisite: Existing Carlson Software sewer file (*.sew)

Export ADAC Network

This routine converts Carlson sewer (.sew) files into ADAC storm sewer network files. The ADAC data is stored in XML files.

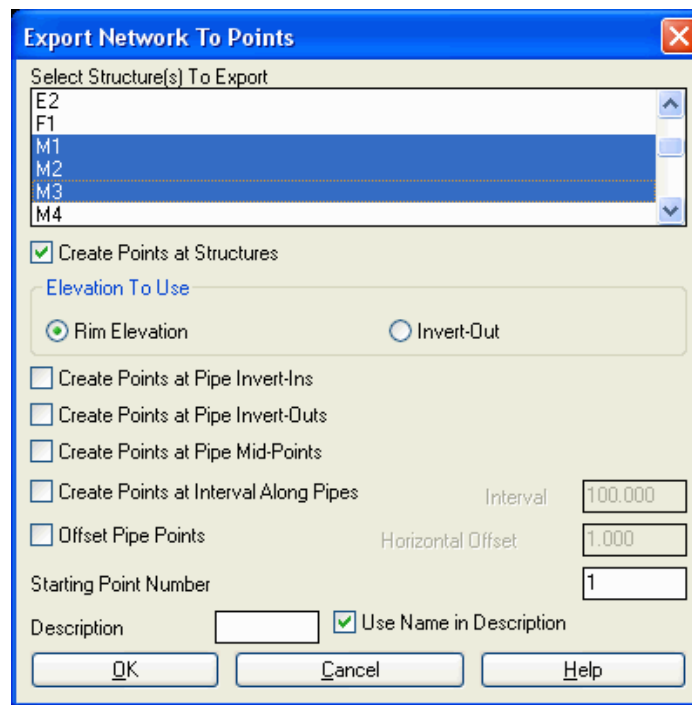

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: export_adac

Prerequisite: Carlson .sew file

Export To Points

This command creates points in the current coordinate file for the selected structures of the current sewer network. In the options dialog, you can select multiple structures from the list of structure names. You can create points at the structure locations and the pipe locations. For pipes, you can create points at the invert-in and invert-out connection points, at the pipe mid-points and at an interval along the pipe. The Offset Pipe Points option offsets horizontally perpendicular to the pipe. The elevation for the structure points can be either the rim elevation or the invert-out of the structures. The point numbers will be incremented from the specified Starting Point Number. The Use Name in Description option puts the structure name into the point description.

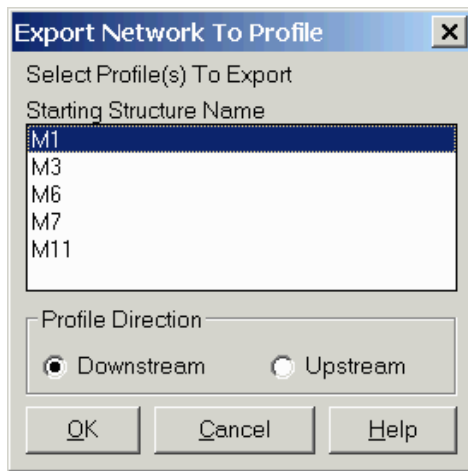

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: swr2pts

Prerequisite: Sewer network (.SEW) file

Export To Profiles

This command creates a profile (.pro) from the current sewer network. The profile is created from the specified upstream structure through all the downstream connections to the end of the pipeline. The profile direction can be either upstream or downstream for the stations.

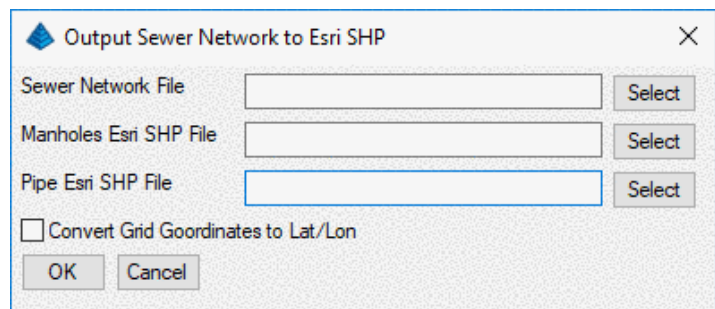

Pulldown Menu Location: Network->Sewer Network Utilities

Keyboard Command: swr2pro

Prerequisite: Sewer network (.SEW) file

Export To Esri shapefiles

This command output Carlson sewer network (.sew) to Esri Shapefiles. The command uses a .sew file as an input, then it output manholes and pipes data to two different SHP files. It is optional to convert the northings/eastings from the drawing to lat/lon by converting the drawing coordinates to lat/lon.

Pulldown Menu Location: Import/Export Sewer Network

Keyboard Command: swrtoshp

Export Pre-Carlson 2020 Sewer Network

This routine saves the current sewer network file in the older file format that was used before Carlson 2020, so the project can be used in Carlson 2019 or older releases.

Pulldown Menu Location: Network > Import/Export Sewer Network

Keyboard Command: swrsave_old

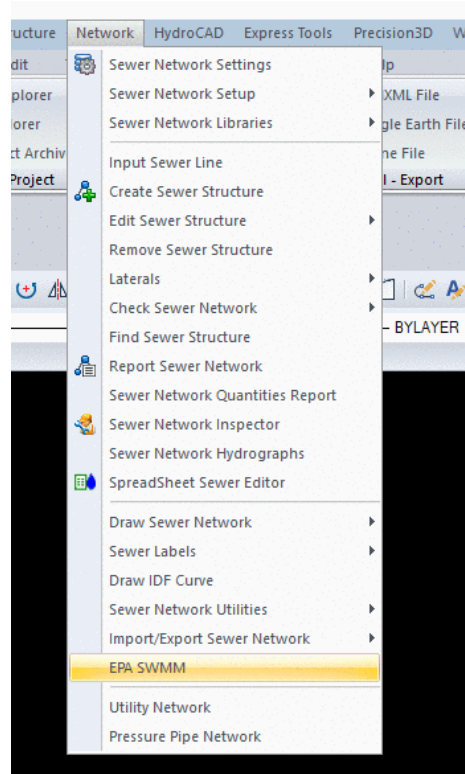

Prerequisite: Sewer network data

EPA_SWMM

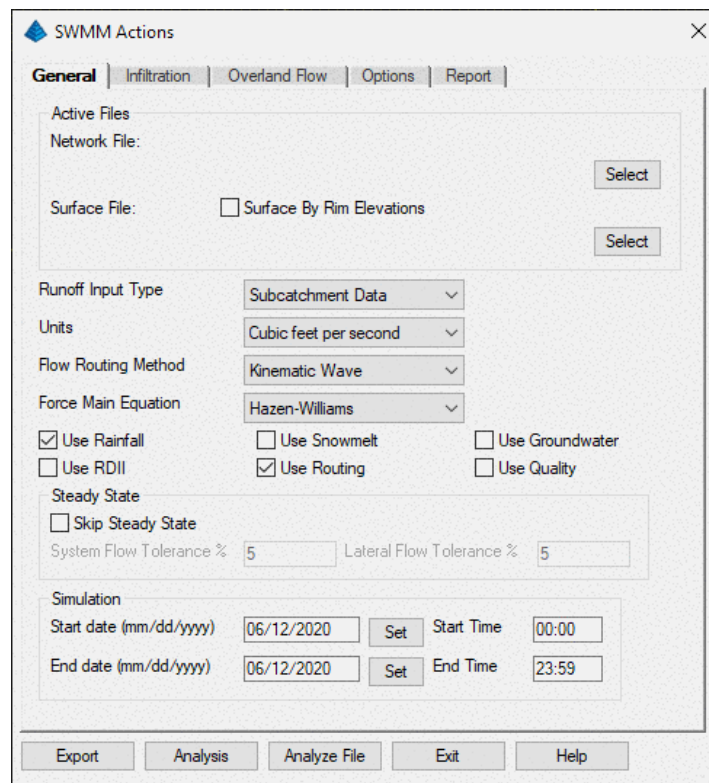

EPA SWMM (Environmental Protection Agency Storm Water Management Model) is a software package developed and provided by the EPA for modeling and reporting of storm water management systems. Many Carlson users are required to use SWMM analysis and reporting in lieu of Carlson's analysis system. This command allows the user to model the storm water system within Carlson then export a set of files that can be used to perform an analysis within the EPA SWMM program. Users may find EPA SWMM software and documentation here:

<https://www.epa.gov/water-research/storm-water-management-model-swmm>

The command, **swmm**, may be typed in the Command Ribbon or by selecting EPA SWMM from the Hydrology Network dropdown.

When executed, the **SWMM Actions** dialog appears. The General tab is presented first.

Active Files: Select an existing sewer (.SEW) file to become the active sewer file and a "surface file" for ground cover calculations:

- *Surface by Rim Elevations* - When this option is enabled, the ground surface elevation is derived as an interpolated grade from structure rim elevation to structure rim elevation and the Surface Model option is disabled, or,
- *Surface Model* - When the *Surface by Rim Elevations* option is disabled, select a valid surface model (.TIN, .FLT, .GRD) that blankets the sewer network. The ground surface elevation is obtained from the surface model along the pipe reach.

Use the **Select** buttons to browse to the correct surface and network files.

To create a .sew file, input the storm water management system using the **Create Sewer Structure** command found in the Network dropdown of the Hydrology module. It's important to note that Carlson only transfers rain event data generated by the SCS Method. If the SCS Method is inappropriate for the system, the user may input other types of rain events and watershed analysis using other methods directly into SWMM.

The **Runoff Input Type** allows for 2 options: **Subcatchment Data** and **Inlet Flow Hydrograph**. The **Subcatchment Data** specifies that the node inflow will be generated from the watershed computed flow and the **Computation Methods** must be set to **Peak Discharge** in the **Sewer Network Settings**:

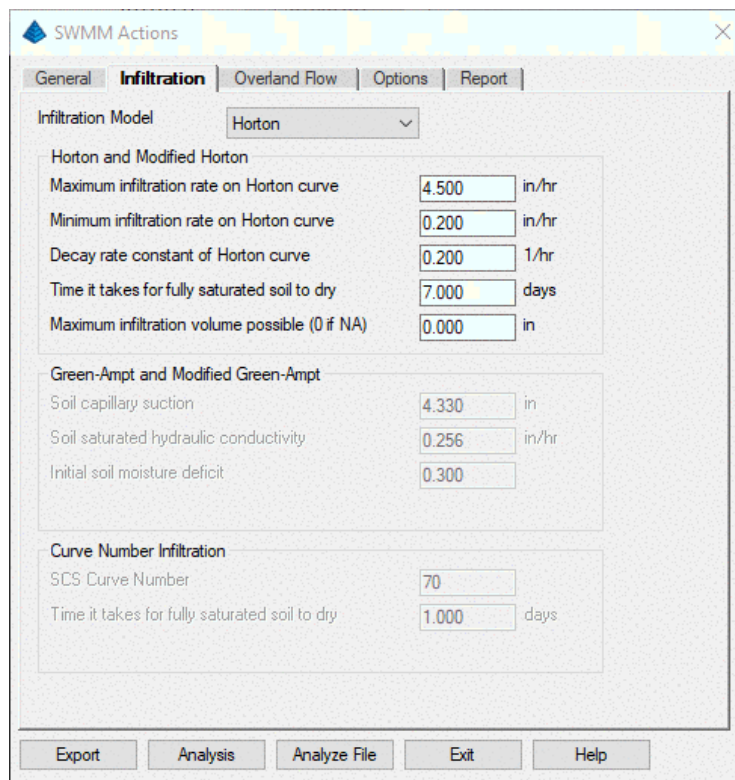

The **Inlet Flow Hydrograph** option specifies that the node input flow is from the Hydrograph:

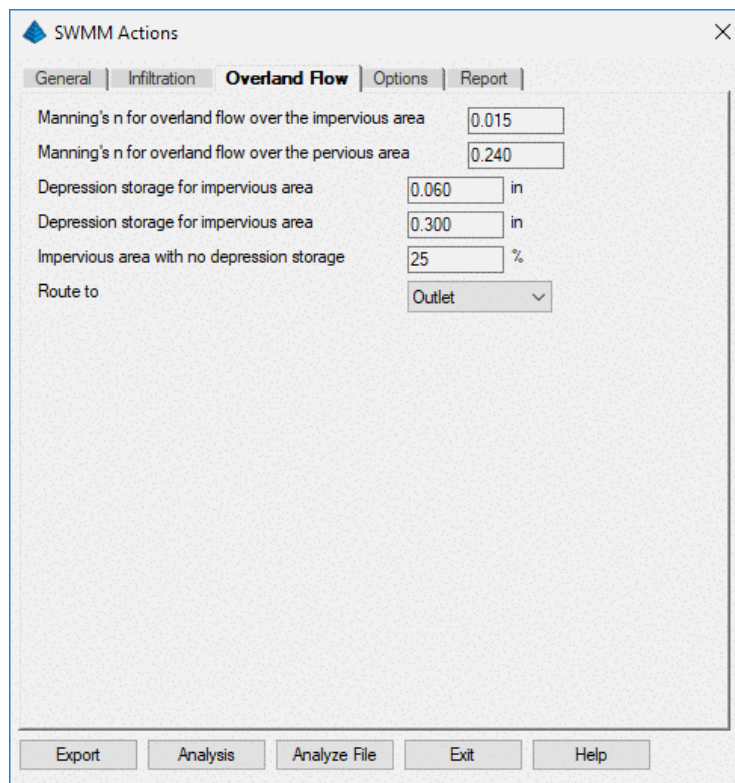

Set the desired **Units, Flow Routing Method and Force Main Equation**. Choose the physical processes to include in the analysis. Choose whether to skip **Steady State** analysis or not. If skipped, set the **System Flow Tolerance** and the **Lateral Flow Tolerance** percentages. Finally, set the **Simulation Start and End** dates and times.

Selecting the **Infiltration** tab allows the user to choose one of five Infiltration Models and exposes input parameters specifically needed for the Model selected. Parameters for Models not selected are grayed out.

Selecting the **Overland Flow** tab allows the user to set Manning's friction coefficients (n) for impervious and pervious areas, depression storage depths, the percentage of Impervious areas with no depression storage, and where Overland Flow is routed, Pervious, Impervious or Outlet.

Selecting the **Options** tab allows the user to enter additional parameters needed by SWMM for analysis.

Sweep start and Sweep end are used reduce the accumulated buildup of specific pollutants with street sweeping.

Dry Days is the number of days with no rainfall prior to the start of the simulation.

Report Step is the interval for reporting of computed results.

Wet Step is the interval for computing runoff during rainfall and continuing until standing ponds and LID devices (Low Impact Development) are dry.

Dry Step is the time step length used for runoff computations when there is no rainfall or ponding and storage devices are dry - essentially to compute pollutant buildup. Dry Step must be greater than or equal to the Wet Step.

Routing Step is the time step length used for routing flows and quality constituents through the conveyance system.

Lengthening Step is used with Dynamic Wave Routing to artificially lengthen a conduit so that the travel time of a wave is greater than this time step (Courant stability criterion).

Variable Step is a safety factor applied to variable time steps computed using Dynamic Wave Routing.

Minimum Step is the shortest time step allowed when variable time steps are used with Dynamic Wave Routing.

Inertial Damping is used to control inertial terms in the Saint Venant momentum equation used in Dynamic Flow Routing. Choosing **None** uses these terms at all times, **Partial** reduces the terms as flow approaches critical and removes them when flow becomes supercritical, **Full** removes these terms from the equation.

Normal Flow Limited specifies which condition is checked to determine if conduit flow is supercritical and should be limited to normal flow using Dynamic Wave Routing. Use Slope to determine if water surface slope is greater than conduit slope. Use Froude to check if the Froude Number is greater than 1 or Both to check both conditions.

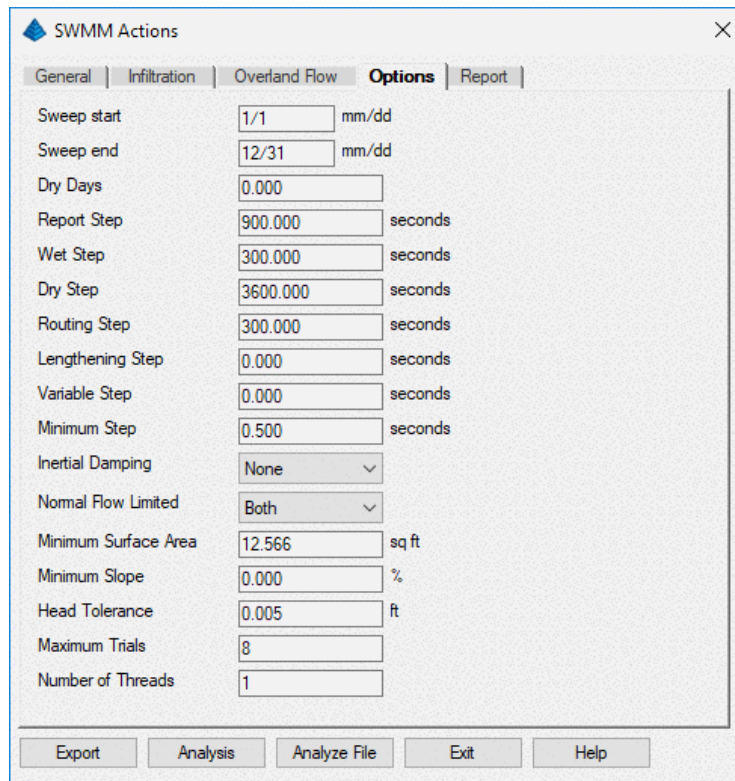

Minimum Surface Area is the minimum surface area used when computing water depth changes under Dynamic Wave Routing.

Minimum Slope is the minimum slope allowed for a conduit. Zero sets no minimum. SWMM uses a minimum of .001 ft drop during computations.

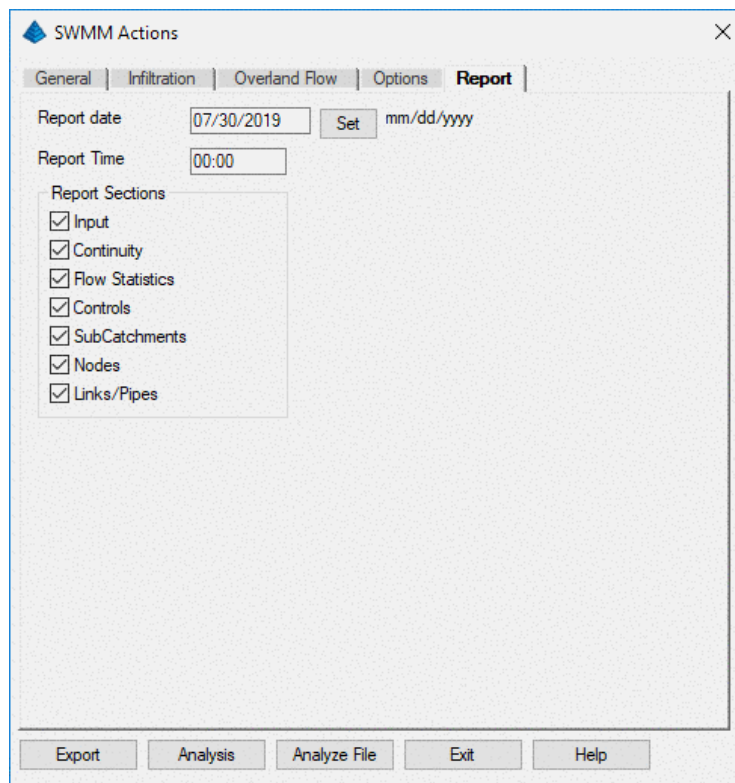

Head Tolerance is the difference at each node between successive trials. If the difference in head for a time step is less than this value, the flow solution has converged.

Maximum Trials is the maximum number of trials allowed during a time step to reach convergence when updating hydraulic heads at the system's nodes.

Number of Threads allows the user to increase the number of parallel processing threads used during Dynamic Wave Flow Routing if the computer being used has multi-core processors installed.

Selecting the **Report** tab allows the user to specify the report date and time as well as to select the Report Sections to be included.

The **Export** button exports an .inp file to be opened in EPA SWMM software.

The **Analysis** button creates a report within Carlson software for review and error checking.

The **Analyze File** button allows the user to open an existing .inp file and displays the Carlson analysis report.

Exit closes the SWMM Actions dialog.

Pulldown Menu Location: Network

Keyboard Command: swmm

Prerequisite: SWMM version 5.1

Utility Network

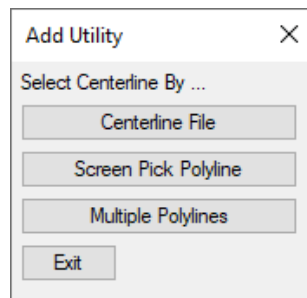

Utility Network is a command that synthesizes underground utility design for Projects which include all types of underground utilities. Interactive design for all utility centerlines, profiles and utility sizes and types is accomplished using a system similar to Carlson Road Network.

The command consists of a docked dialog on the left of the screen identifying all parameters of a Utility Network. The tool is very similar to Carlson Road Design Tool by design where utility horizontal alignments are defined by polylines or existing centerline files within the drawing. These alignments, along with a design surface specified in Settings, are used to determine proposed grade within each pipe alignment. Proposed grade, along with depth of utility, are used to set elevation for utilities that are installed a set distance below ground. For Utilities such as Gravity Sanitary and Stormwater Collection which typically have varying cover depths, the Storm/Sewer Network tool is recommended.

Once the Utility Network is setup, plan and profiles can be created for any Utility in the Network including symbols and notation. Additional output includes export of networks as 3d polylines and 3dfaces. When creating any profile such as a road profile, utility crossings will be included in the profile for any Utility in Utility Network. When all underground utilities are setup as a Utility Network, a comprehensive below ground utility collision check can be performed. If pressure calculations are needed, utility network files can be opened in Pressure Networks and setup with a pressure model.

To open the Utility Network Main dialog, enter "utilnet" at the command line or select Utility Network from the main menu "Utility" within the Hydrology module. Utility Network will dock a dialog to the side of the drawing which allows full use of the command line and menu items for other tasks.

The main console contains all utility alignments assigned to a project. An alignment is added by selecting the add(+) button which opens the Add Utility dialog.

If a tin file representing final surface elevation has not already been specified in Settings, a prompt will appear requesting the tin file name. If centerline files have not already been created, select a polyline representing horizontal alignment. Name and save the selected centerline file. Lastly, if the project contains multiple underground utilities to add to the model, Multiple Polylines can be selected and setup at one time using global settings.

The next dialog will request the method used to establish Utility depth.

Minimum Depth, Minimum Length and options for reference surface break points can be specified. Options for surface break points include the following: **None**, **At Minimum Depth**, **Min Depth Streamlined**, **Min/Max Streamlined and Maximum Deflection Angle**. The **Min Depth Streamlined** method uses fewer profile grade breaks to keep the profile below the Min Depth and will not follow the surface up for short bumps. The **Min/Max Streamlined** is similar with the addition of keeping the profile above the specified Max Depth. The **Min Length** controls the shortest distance between profile grade breaks. The **Transition Depth Between Stations** method linearly transitions the depth between two depths set at two stations. The **Maximum Deflection Angle** option is used when designing rigid pipe such as Ductile Iron which has a standard length and maximum deflection angle between pipe segments.

Once the Utility has been added, the Edit Utility dialog is displayed. Finish the addition by defining additional parameters. If adding multiple polylines, these will be named (Utility Name)1, (Utility Name)2, etc. Once Utilities are created by any manner, all will appear in the Utility Network discreetly and may then be further edited individually if desired.

Utility Name is a user defined label for the utility. Each name must be unique in the utility network.

Description is an optional setting that is used in reports and can be labeled in the Draw Profile and Draw Sections commands.

Type setting chooses the type of utility as gas, water, sanitary, storm, communication or other. The setting is used in reporting and used to set the default color for the linework.

Pipe Size is the initial Outside Diameter for the utility line. If the utility alignment contains only one size, enter the

value here. If the utility changes size along the alignment, select the edit button and specify size/station.

Pipe Thickness (in) is the difference in the Outside Diameter minus the Inside Diameter divided by 2. By providing pipe thickness, the profile of the utility can show both Interior and Exterior diameters when specified in Utility Profile Labels in the Draw Profile dialog.

Min and **Max Cover** is the minimum and maximum depths for the utility profile. These values are used to control depth of Utility and are used by Report for checking the min/max cover.

Layer and **Linetype** used to draw the horizontal alignment are specified for the Plan View options.

3d Polyline layer is the layer used if a 3d polyline is created for the Utility and 3D Faces Layer is used to draw 3 Dimensional faces.

Profile Elevation Reference On Pipe sets the reference point of a Utility used to set depth.

Pipe Shape specifies the shape of the Utility. **Circular** is typically used for most utilities, but other options may be needed. A **Rectangular** shape can be used to specify a dry utility corridor.

The **Centerline** button is used to specify the centerline file name for the utility. The **Edit** button on the same row opens the horizontal alignment editor.

The **Profile** button is used to specify the profile file name for the utility. The **Edit** button on the same row opens the vertical profile editor. This profile editor is similar to the **Road Profile Editor** which is documented in the Roads chapter. However, the Utility Network Vertical Profile editor has additional functions needed for Utility design.

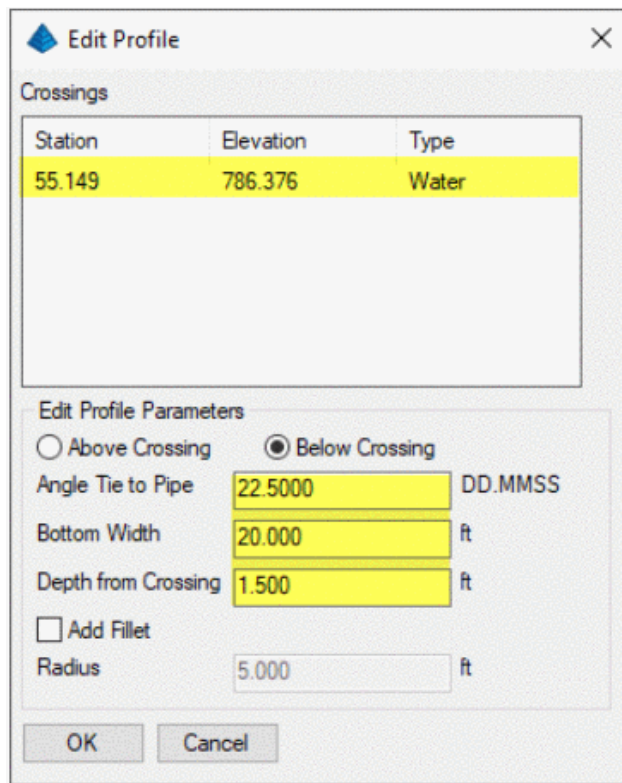

Set Depth can be used to make the utility profile a fixed depth from the reference surface. This function has an option to add stations in the utility profile at each grade break in the surface so that the utility profile can exactly follow the surface. The Min Depth Streamlined method uses fewer profile grade breaks to keep the profile below the Min Depth without setting depth of utility at every grade change which can result in a "jagged" alignment. The Min/Max Streamlined is similar with the addition of keeping the profile above the specified Max Depth. The Min Length controls the shortest distance between profile grade breaks. The Maximum Deflection Angle option, when used with a minimum nominal pipe segment length is used when each pipe segment must be shown in profile view at its nominal length. For example, a common nominal length for 6 inch Ductile Iron Pipe is 20 feet which has a gasketed fitting that must connect to the next pipe segment at an angle less than 5 degrees from center bore.

Please note that changes to depth does not have to be applied to the entire alignment. If changes are only needed for stations past a starting station, select the starting station, select set depth and check the option for Update from current location. The starting station will be displayed once Update from current location.

Reduce removes profile data points without changing the profile elevations more than the specified cutoff tolerance. **Translate** is used to raise or lower the vertical alignment by a set offset distance. The entire utility can be adjusted with this command or a specific station range can be specified.

Setup calls the **Utility Profile Settings** dialog box. These are profile settings when profiles are drawn within the Utility Network Editor.

Edit Profile at Crossing allows for editing the profile when it must pass over or under another utility. The tool automatically provides the stations where it recognizes a crossing. This tool will also recognize pipe crossings from Networks created in the Storm/Sewer Network Editor.

Choose if the profile is to pass over or under the crossing. Input the **Angle Tie to Pipe** to drop or rise. Input the **Bottom Width** of the crossing excavation (flat after drop or rise). Input the **Depth From Crossing** (clearance).

Edit Connections is an optional list of stations along the utility line where something related to the network is located. name and symbol or model is specified. The symbols specified are drawn in both plan and profile views. The **Model** is a 3D Solid such as a water system valve to draw with the Draw 3D Faces function.

Add From Points allows the user to add connections by importing coordinate file points by range or group.

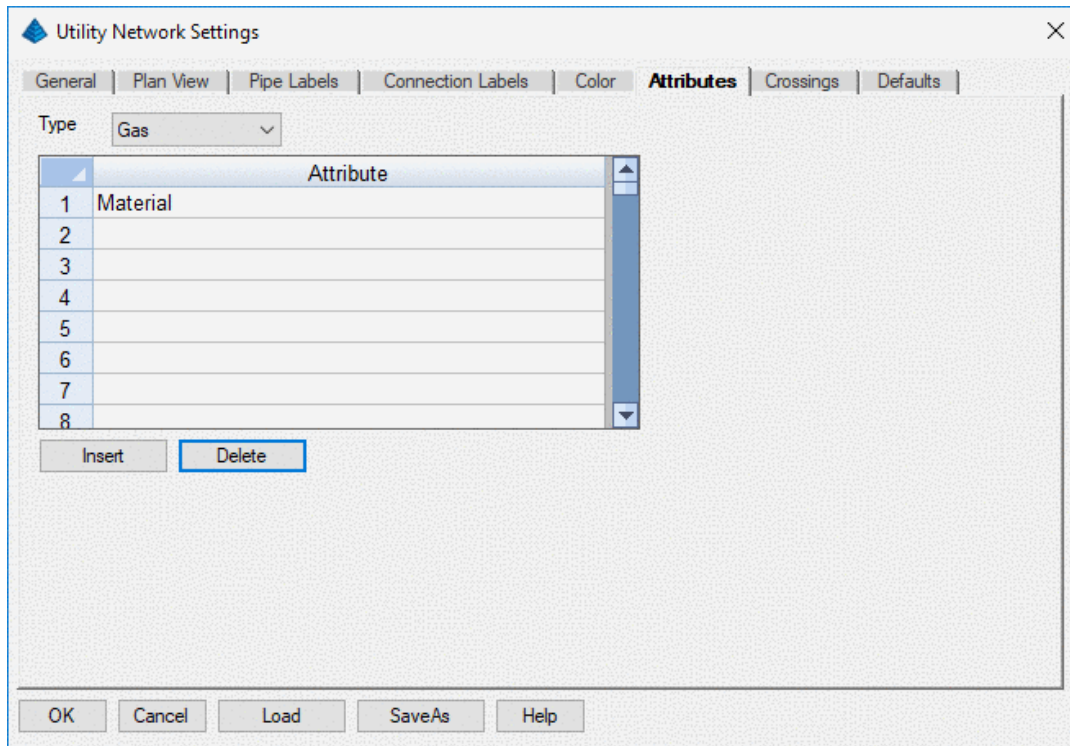

For the **Insert** function, the program first prompts for the centerline. You can either select an existing .CL file, or pick a polyline from the drawing. When you select a 3D polyline, the polyline is used both for the centerline and profile.

Delete button removes the currently highlighted utility line from the network.

The **Report** function has three type of reports. **Data Files** report includes the parameters for each utility line. The **Connection** report includes the input parameters for all the connections. The **Laterals** report includes the input parameters from the laterals. The **Min/Max Cover** report checks each utility profile and reports Min Cover Setting, Average Cover, Min Cover Station and Depth, Max Cover Station and Depth. The **Quantities** report includes the utility name, type, length, shape, pipe size and user-defined attributes.

Edit Laterals is an optional list of laterals connected to the utility line. Each lateral is defined by a station at the connection along the utility line, the pipe size for the lateral and the "cleanout" coordinates. Please Note that the "cleanout" can be any type of service connection such as a cleanout or water meter. Use the **Pick** button to screen pick the connection and cleanout points, or to pick an existing line for the lateral. The Connection and Cleanout Symbols are used with drawing the utility network in plan view.

Edit Attributes is an optional list of attribute names and values such as pipe material or construction phase to assign to the utility. The list of available attributes are defined in the Settings function. These attributes are used in reports and are entered in a spreadsheet.

The **Draw** button has four functions:

The **Draw 3D Polylines** function creates a 3D polyline for each utility line. These polylines are tagged with their pipe size in the same format as the Assign Pipe Data To Polyline command.

The **Draw 3D Faces** function draws each utility line as a 3D pipe using 3D faces. These 3D faces can then be used in the 3D Viewer commands.

The **Draw Plan View** function draws a 2D polyline for each utility line and labels the utility name and connection points.

The **Draw Profile** function draws the profile for the currently highlighted utility. Any symbols defined on the Connection List for the utility will be drawn on the profile. Besides picking the Draw button, you can also run Draw Profile by picking the utility in the list, right-click and pick Draw Profile.

The **Save**, **SaveAs** and **Load/New** functions are used to store and recall the utility network to .util files.

General Settings

For the Settings function, the **Reference Surface** is a triangulation file that is used for surface elevation reference when setting utilities to a specified depth. The **Auto Zoom To Current Selection** and **Highlight Current Centerline** apply to highlighting centerline alignments to indicate the current selected Network alignment. When Auto Zoom is on, modespace will zoom to the extents of the current alignment. **Redraw Profiles When Network Changed** dropdown allows the user to automatically redraw changed profiles, prompt for redraw, or not redraw automatically when exiting the command. Use **Load** to load an existing Utility Network Settings file (.UNS). Use

Save As to save the current Utility Network Settings to a .UNS file for later use.

Plan View Settings

The **Text** and **Symbol Size Scalers** and **Text Style** are used for the Draw Plan View function. When **Draw Easements** is selected, an easement will be drawn as part of the pipe network where the width is determined by utility depth. Entering a value for the first **Zone** sets the maximum depth for the first Zone and the Easement Width, then continue to set maximum depths for the Next Zone and the Easement Width. Easements widths increase as depth increases due to maintenance requirements for deeper utilities.

On the **Pipe Labels** tab, changes to pipe labeling functionality can be set for each type of utility by selecting Utility Type. **Type** is selected using the dropdown arrow. Available labels appear on the left. Click **Add** to select label information wanted in the drawing, **Remove** to not display this information, **Setup** to add a Prefix and/or Suffix to the label. Use the green arrows to reorder the Used Labels list. **Label Location** lets you place the label at Ends of the pipe, at an Interval, Both the Ends and at an Interval, or None. Fill in the desired interval in the **Label Interval** box. Choose **End Label Style** as Parallel, Horizontal or using MLeader arrow and text box. Choose a **Labels Above Symbol** number from 0 - 9. The labels equal to and less than the number selected are placed above the symbol with the remaining labels being located below when using Horizontal or Parallel Styles.

On the **Connection Labels** tab you can control how Connection Labels are placed. Available labels appear on the left. Click **Add** to select label information wanted in the drawing, **Remove** to not display this information, **Setup** to add a Prefix and/or Suffix to the label. Use the green arrows to reorder the Used Labels list. Type in a layer name or choose an existing drawing layer with the Set button. Choose **Label Style** as Parallel, Horizontal or using MLeader arrow and text box. Choose a **Labels Above Symbol** number from 0 - 9. The labels equal to and less than the number selected are placed above the symbol, the remaining labels below when using Parallel or Horizontal Styles. Use **Load** to load an existing Utility Network Settings file (.UNS). Use **Save As** to save the current Utility Network Settings to a .UNS file for later use.

On the **Color** tab, set the default colors to use when creating line work for each type of utility within the utility network.

On the **Attributes** tab, set the optional attribute names to assign to each utility type to be used in the Report > Quantities function. The attributes are specified by Utility Type. Select the Utility **Type** using the dropdown arrow, then enter Attributes, one per line. Use Insert to insert another Attribute between existing entries, use Delete to remove an entry. Attribute Types include Gas, Water, Sanitary, Storm, Electric, Communication, Irrigation, Fire, Utility Duct, Other and Connection.

Using the **Crossings** tab, you may specify if vertical pipe clearance is checked within the Utility. To check clearances, **Check Crossings** box must be selected. Additionally, you can check other Utility Networks for collision with the current network by clicking the **Add File** button, then browsing to the desired network file. Remove additional networks with the **Remove File** button. Disable **Check Crossings** by unchecking the box. **Do not specify the current network in the additional networks to check.**

The **Profile** tab provides the ability to add an existing and proposed surface that will be used when vertical profiles are drawn. Please note these are only used to produce existing and proposed profiles and are not used as part of the design.

The **Defaults** tab has default a symbol and model to use when adding connections.

Although all types of Utilities can be setup together in a Utility Network, they can also be setup separate from each other when additional layer control is needed.

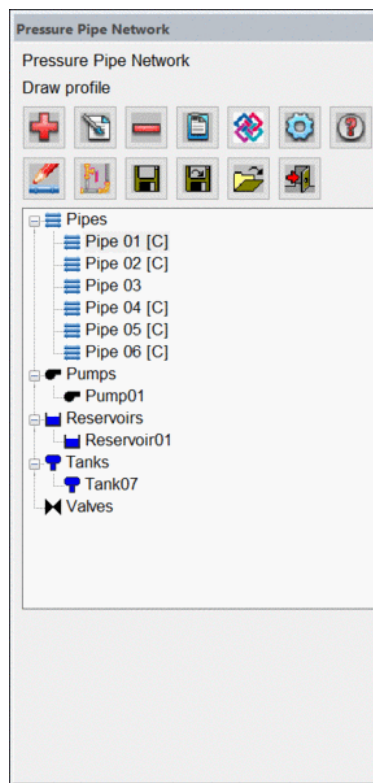

Pulldown Menu Location: Network

Keyboard Command: utilnet

Prerequisite: None

Pressure Pipe Network

Executing the command docks a dialog to the side of the drawing.

The top of the docked dialog box has thirteen buttons. Hover over each icon to see its name. Each button is described as follows:

1.  Add Pressure Pipe Element
 - (a) Pipe
 - (b) Pump
 - (c) Reservoir
 - (d) Tank
 - (e) Valve

2.  Edit Pressure Pipe Element
 - (a) Pipe
 - i. Edit Connection
 - ii. Edit Laterals
 - iii. Edit Attributes
 - (b) Pump
 - (c) Reservoir
 - (d) Tank
 - (e) Valve

3.  Remove Pressure Pipe Element

4.  Report

5.  Output IFC File
6.  Settings
 - (a) General
 - (b) Plan View
 - (c) Pipe Labels
 - (d) Connection Labels
 - (e) Color
 - (f) Attributes
 - (g) Crossings
 - (h) Defaults

7.  Help

8.  Draw
 - (a) 3D Polylines
 - (b) 3D Faces
 - (c) Plan View
 - (d) Profile

9.  EPANet

10.  Save

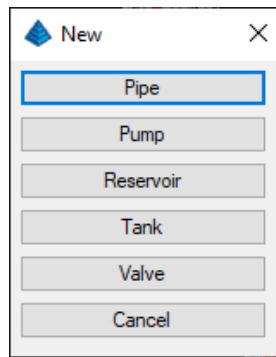

11.  SaveAs

12.  Load/New

13.  Exit

Add Pressure Pipe Element

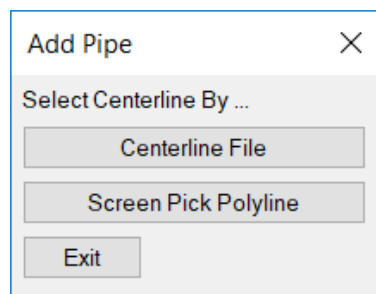

Clicking the **Add** button displays the **New** dialog box prompting the user to select an element to create.

Add Pipe
Add Pump
Add Reservoir
Add Tank
Add Valve

Add Pipe

Add Pipe dialog box prompts the user to select a Centerline file or to screen pick a polyline for a pipe. To add other entities, click the component heading, right-click to add. **Add Pipe** may also be accessed by right-clicking "Pipes" in the Pressure Pipe Network tree or by right-clicking on any existing pipe in the network.

Edit Pipe

Once the choice has been selected, the **Edit Pipe** dialog box appears. This box can also be accessed by clicking the **Edit** button or by right-clicking on an existing pipe in the network and choosing "Edit Pipe".

The **Pipe Name** is the name of the pressure pipe line. Each name must be unique in the pressure pipe network.

The **Pipe Dim1** is the exterior diameter of the pipe. Carlson currently supports only round pipe in a pressure pipe network.

The **Pipe Thickness** is the thickness of the pipe's wall.

The **Min Cover** is the minimum depth for the pressure pipe profile. This value is used to create the profile and keep it below the reference surface. Also, the Report function has a report for checking the min cover.

The **Roughness Coefficient** is used to calculate friction loss in the pressure pipe network and is specific to the pipe material and the **Analysis Method** described below. Click the Set button to display a list of pipe materials with associated roughness coefficients.

The **Plan View Linetype** is used for drawing the pressure pipe line in the Draw Plan View function.

The **Layer** settings are used for drawing the pressure pipe line in the drawing.

The **Profile Elevation Reference on Pipe** controls the pipe position in the pressure pipe profile with respect to the reference surface and the Min Cover value.

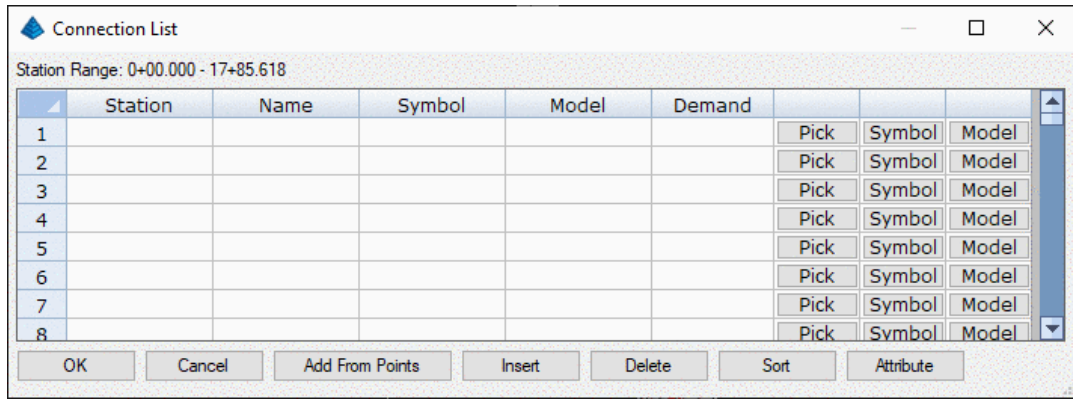

The **Centerline** defines the horizontal alignment of the pressure pipe line.

The **Profile** defines the vertical alignment for the pressure pipe line.

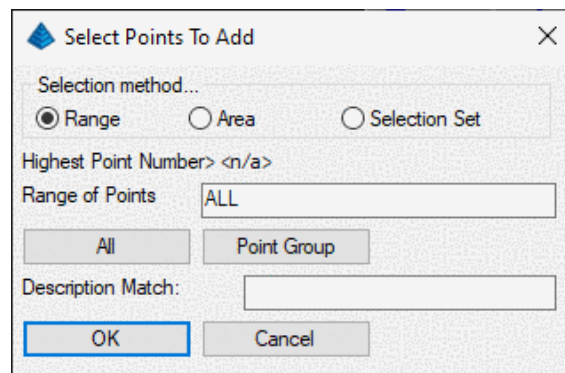

Edit Connections

The **Edit Connections** is an optional list of stations along the pressure pipe line where you can set a name,

a 2-D drawing Symbol, a 3-D drawing Model, and a Demand for pressurized water at this Station.

The **Add From Points** button displays the following dialog and allows for the creation of pipe connections from a list of points.

The **Add Multiple** button allows creating many connections at a time. A dialog prompts for the number of connections, starting station, station interval, name, symbol and demand. All the new connections will be created with the same name, symbol and demand which you can edit in the spreadsheet.

The **Insert** button allows the user to enter a new Station, a name for the new Station, 2-D Symbol, 3-D Model, and water Demand at the new Station in volume per time.

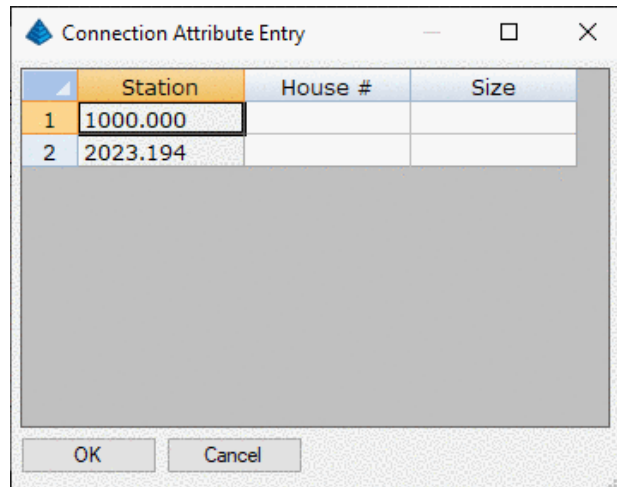

The **Delete** button removes the currently highlighted connection from the Connection List.

The **Sort** button displays the following dialog:

To sort the connection list by ascending station values click Ascending. To sort the stations in descending order, click Descending.

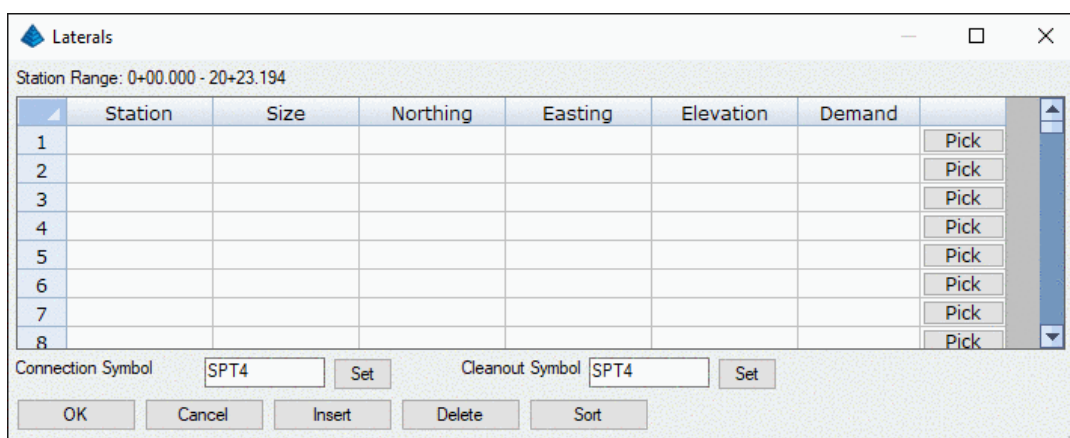

The **Attribute** button is only visible if connection attributes have been defined in the **Attributes** tab in the **Settings** dialog. When the **Attribute** button is clicked a dialog similar to the following is displayed:

A separate row for each defined station will be displayed. The number of columns displayed is based upon the number of connection attributes that have been defined in the **Attributes** tab in the **Settings** dialog. Enter the desired attribute value in each of the fields.

Edit Laterals

The **Edit Laterals** is an optional list of stations along the pressure pipe line where Laterals are connected. A Lateral is defined by a Station, pipe size, Northing and Easting location of the Cleanout, Elevation of the Cleanout, and water Demand of the Lateral. Use the **Pick** button to screen pick the connection and cleanout points, or to pick an existing line for the lateral. The Connection and Cleanout Symbols are used for drawing the lateral in plan view.

The **Insert** button allows the user to enter a new lateral on the pipe being edited.

The **Delete** button removes a lateral from the pipe being edited.

The **Sort** button displays the following dialog:

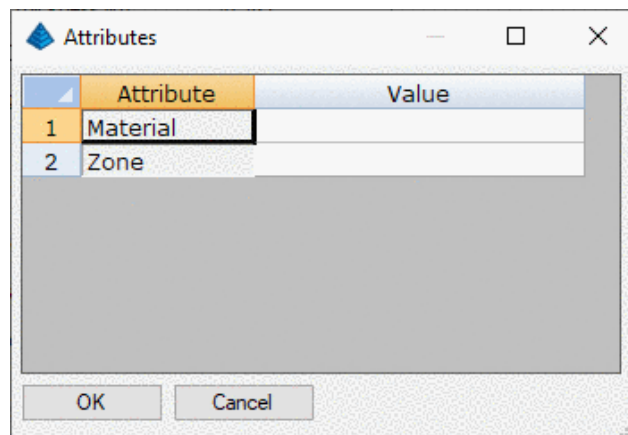

To sort the laterals station list by ascending station values click **Ascending**. To sort the stations in descending order, click **Descending**.

The **Add Multiple** button allows creating many laterals at a time. A dialog prompts for the number of laterals, starting station, station interval, size, offset and demand. All the new laterals will be created with the same size, offset and demand which you can edit in the spreadsheet.

Edit Attributes

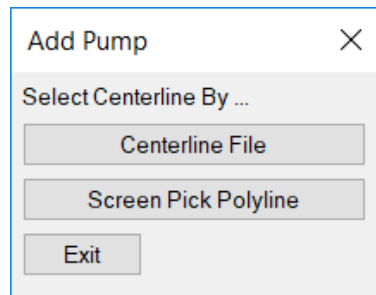

The **Edit Attributes** button allows the assignation of attributes, previously defined on the **Attributes** tab in the **Settings** function, to the pipe. These **Attributes** are used in reporting and drawing of labels. The **Water** attributes will be displayed in the **Attributes** dialog for adding or updating. If no **Water** attributes have been defined in **Settings**, then a message will be displayed.

Add Pump

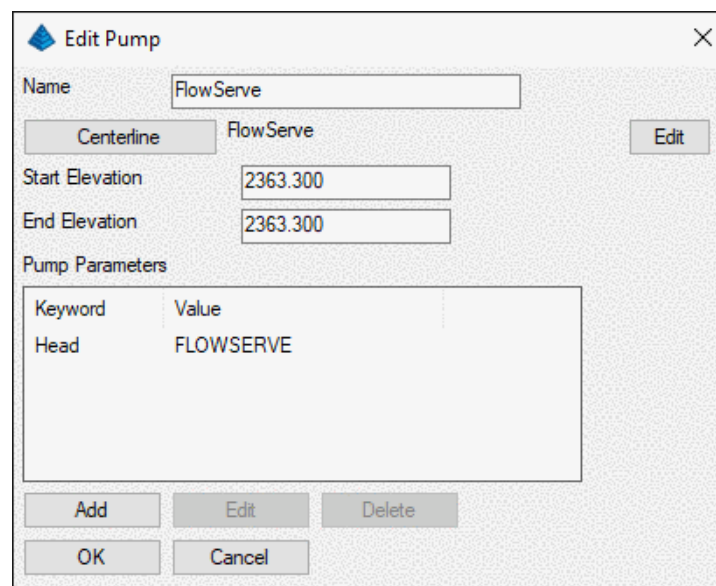

To add a Pump, highlight the heading **Pumps** in the Pressure Network tree, right-click and select **Add Pump**. Highlighting an existing pump and right-clicking allows the choices **Add Pump**, **Edit Pump**, and **Delete Pump**.

When **Add Pump** is selected, the **Add Pump** Dialog Box is displayed, allowing the user to select a Centerline file or the selection an existing polyline on-screen.

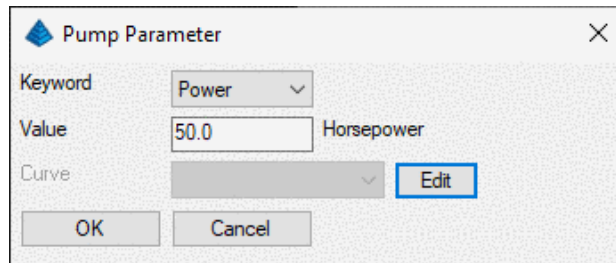

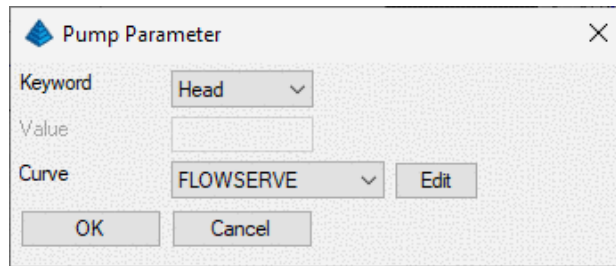

Edit Pump

Once this choice is made, the **Edit Pump** dialog box appears.

Name is the user defined name of the pump. Change the centerline file by clicking the **Centerline** button. Clicking the **Edit** Button next to the centerline file name allows the editing of the chosen centerline file. The **Start Elevation** and **End Elevation** fields are used to set the pump's elevation in the system. These values are typically equal, but not necessarily. The **Pump Parameters** define the pump's operation. The **Add**, **Edit** and **Delete** buttons below the **Pump Parameters** list allow adding and editing of pump parameters. The **Edit** and **Delete** buttons are only enabled when a pump parameter is selected in the **Pump Parameters** list. To add a new pump parameter press the **Add** button which will display the following dialog:

A pump must be defined using either a **Power** or a **Head** parameter but never both. When the **Power** keyword is selected the **Value** field is enabled where a constant energy in Horsepower or Kilo-Watts is entered, producing the same energy requirement for any combination of water volume and pressure. When the **Head** keyword is selected the **Curve** field is enabled and the **Value** field is disabled. A pump **Curve** plots the relationship between flow volume and head. Curves can be created or edited using the **Edit** button. For more details about curves, see the **Add/Edit EPANet Curves** section. **Speed** modifies the pump speed, which is 1.0 for normal speed. Double speed would be 2.0 and half speed would be 0.5. To shut the pump off, set the speed to be 0.0. **Pattern** allows the selection of a pattern curve which allows variable pump speeds through time. Once a **Keyword** and **Value** or **Curve** are selected, click **OK** to save the parameter.

Highlight a pump parameter in the **Pump Parameters** list and click **Edit** and the pump parameter dialog will be displayed for editing. Double-clicking on a pump parameter will also bring up the pump parameter dialog for editing.

Highlight a pump parameter in the **Pump Parameters** list and click **Delete** to remove the parameter.

Add Reservoir

To add a **Reservoir**, highlight the **Reservoirs** heading in the Pressure Pipe Network tree, right-click and select **Add Reservoir**. Highlighting an existing Reservoir and right-clicking allows the choices of **Add Reservoir**, **Edit Reservoir**, or **Remove Reservoir**.

When Add **Reservoir** is selected, the Add **Reservoir** Dialog Box is displayed.

Select the **Reservoir** location by clicking the arrow in the dropdown box next to "Pipe". **Reservoirs** may also be connected to pumps. A pump may be connected to only one reservoir and will disappear from the pipe and pump list if already assigned to a reservoir. Select whether the reservoir is at the **Start** or **End** of the pipe or pump. **Name** the reservoir. Set the elevation of the **Hydraulic Head**.

Edit Reservoir

To edit a reservoir, select an existing reservoir name, right click and choose **Edit Reservoir**, causing the **Edit Reservoir** dialog box to appear.

Change values as needed, click OK to save changes.

Add Tank

To add a **Tank**, highlight the **Tanks** heading in the Pressure Pipe Network tree, right-click and select **Add Tank**. Highlighting an existing Reservoir and right-clicking allows the choices of **Add Tank**, **Edit Tank**, or **Remove Tank**.

When Add Tank is selected, the Add **Tank** Dialog Box is displayed.

Clicking the arrow in the drop down box beside Pipe allows the selection of the component the tank attaches to. **Start** and **End** buttons are used to set the tank's location with respect to the component. **Name** the tank. The **Set Parameters By Pressure** button computes the tank parameters using a specified pressure. The **Bottom Elevation** is the tank's minimum gravity head, the bottom of an empty tank. **Initial Water Level** is the starting water level elevation of the analysis. The **Minimum Water Level** is the least amount of water desired in the tank entered as an elevation. **Maximum Water Level** is the maximum amount of water desired in the tank entered as an elevation. **Nominal Diameter** is the average cross-sectional area of the tank used to convert a change in water volume to the change in water level elevation in the tank. The **Minimum Volume** is the least amount of water allowed in the tank which should be equivalent to the **Minimum Water Level**. There is an option to assign a **Volume Curve** to the tank to model tanks of different shapes with cross-sections that vary by elevation.

Edit Tank

To edit a tank, select an existing tank name, right click and choose **Edit Tank**, causing the **Edit Tank** dialog box to appear.

Change values as needed, click OK to save changes.

Add Valve

To add a **Valve**, highlight the **Valves** heading in the Pressure Pipe Network tree, right-click and select **Add Valve**. Highlighting an existing Reservoir and right-clicking allows the choices of **Add Valve**, **Edit Valve**, or **Remove Valve**.

When **Add Valve** is selected, the **Add Valve** Dialog Box is displayed, allowing the selection of a Centerline file or the selection of an existing polyline on-screen.

Edit Valve

After selection, the **Edit Valve** dialog box appears.

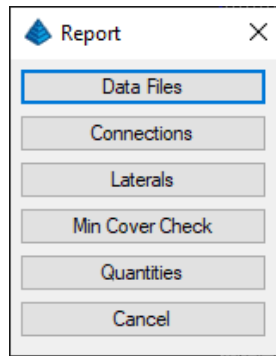

Name the Valve. Clicking the **Centerline** button allows a choice of a new **Centerline** file. Clicking the **Edit** button here allows the editing of the **Centerline**. Enter the **Start Elevation** and **End Elevation**. Assign a valve **Type**. A **Pressure Reducing Valve**, **Pressure Sustaining Valve**, or **Pressure Breaker Valve** require a **Setting** pressure. A **Flow Control Valve** requires a **Setting** of limiting volume. A **Throttle Control Valve** requires a **Setting** of a loss coefficient supplied by the manufacturer of the valve. A **General Purpose Valve** requires the application of a **Headloss Curve**. To edit or create a new curve click **Edit** and for more details about curves, see the **Add/Edit EPANet Curves** section. A **Diameter** in inches or mm of the valve is required for all valves. A **Loss Coefficient** may be applied to any valve or may be zero.

The **Edit** button edits the highlighted element from the pressure pipe network.

- Pipe
- Pump
- Reservoir
- Tank
- Valve

The **Remove** button deletes the highlighted element from the pressure pipe network. If a valid element is selected, then you will be prompted to verify the element removal with the following dialog:

The **Report** button displays the Report dialog box.

The **Data Files** Report displays the files and parameters for each component of the pressure pipe network.

The **Min Cover Check** Report displays the Reference Surface and .util files used, and, for each pipe, the minimum cover as well as the average cover elevation.

The **Quantities** displays the Carlson **Report Formatter**, allowing the user to create custom reports using pressure pipe network information, import additional information, present the information in a variety of different formats, and export the report for other use.

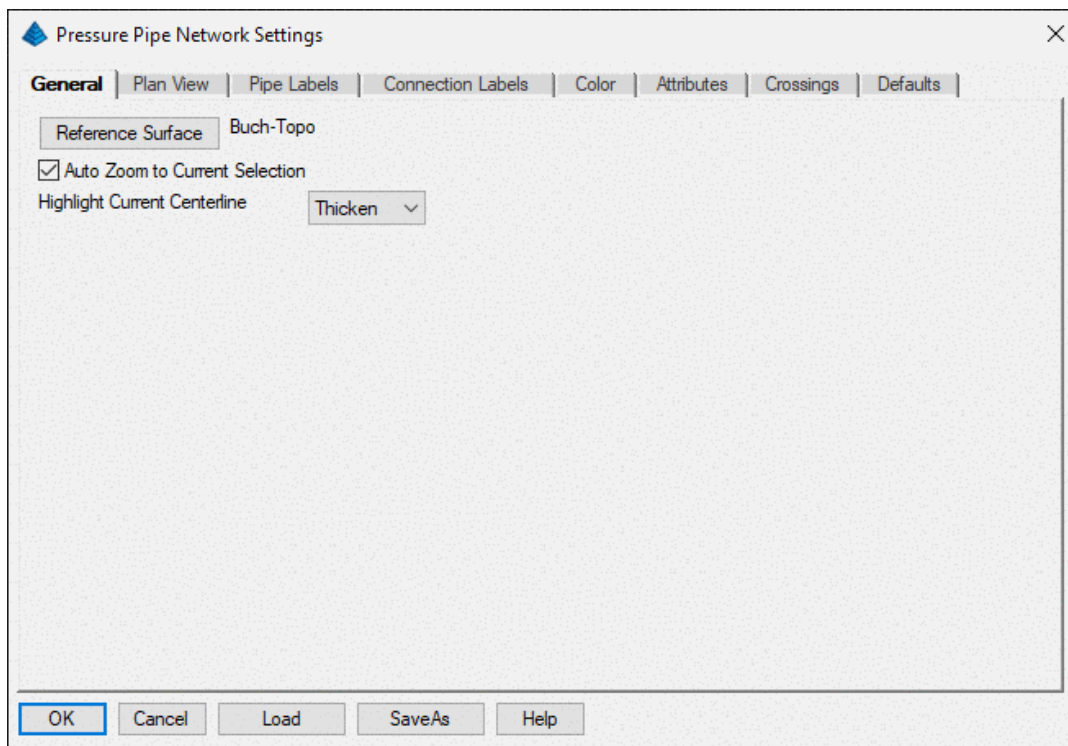

Output IFC File

The **Output IFC File** button creates a file that can be used by other software to import the 3-D model of the pressure pipe network.

Settings

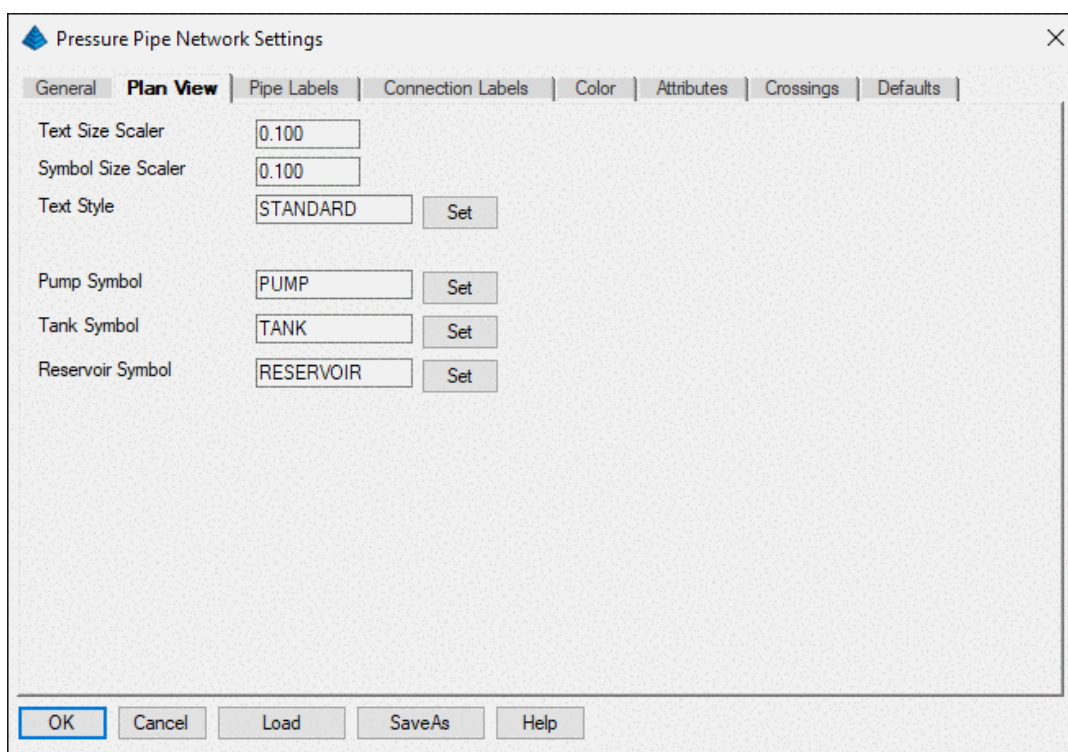

The **Pressure Pipe Network Settings** button displays a multi-tabbed dialog box, defaulting to the "General" tab. All pressure pipe network settings from all tabs can be saved to a file using the **SaveAs** button. The saved settings are stored in a .uns file. Any previously stored settings can be loaded using the **Load** button. The new settings will not be stored into the .util file until you press the **Save** button on the main docked dialog.

Setting General Tab

The **Reference Surface** is a triangulation file that is used for the min cover calculations and as a reference when editing pressure pipe profiles. The **Auto Zoom to Current Selection** check box finds and zooms to the component highlighted in the pressure pipe network tree. **Highlight Current Centerline** provides visual choices for in-drawing indication of the pressure pipe network component which has been selected.

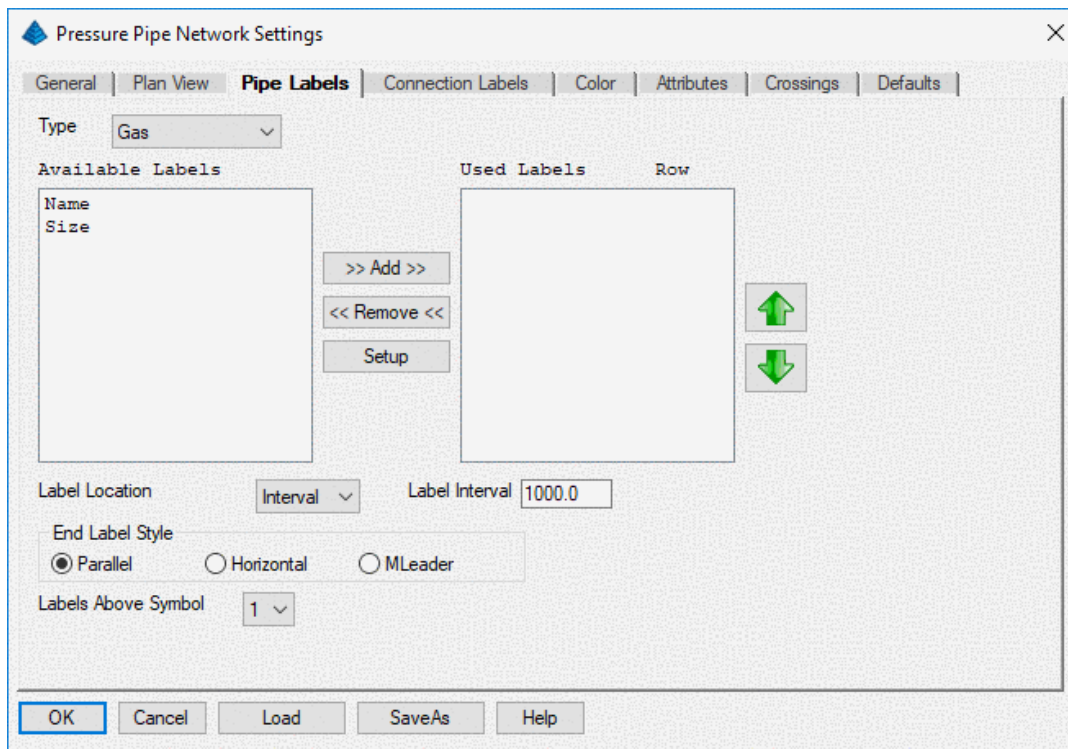

Setting Plan View Tab

On the "Plan View" tab, the **Text** and **Symbol Size Scalers** are used to set the size of pressure pipe network text

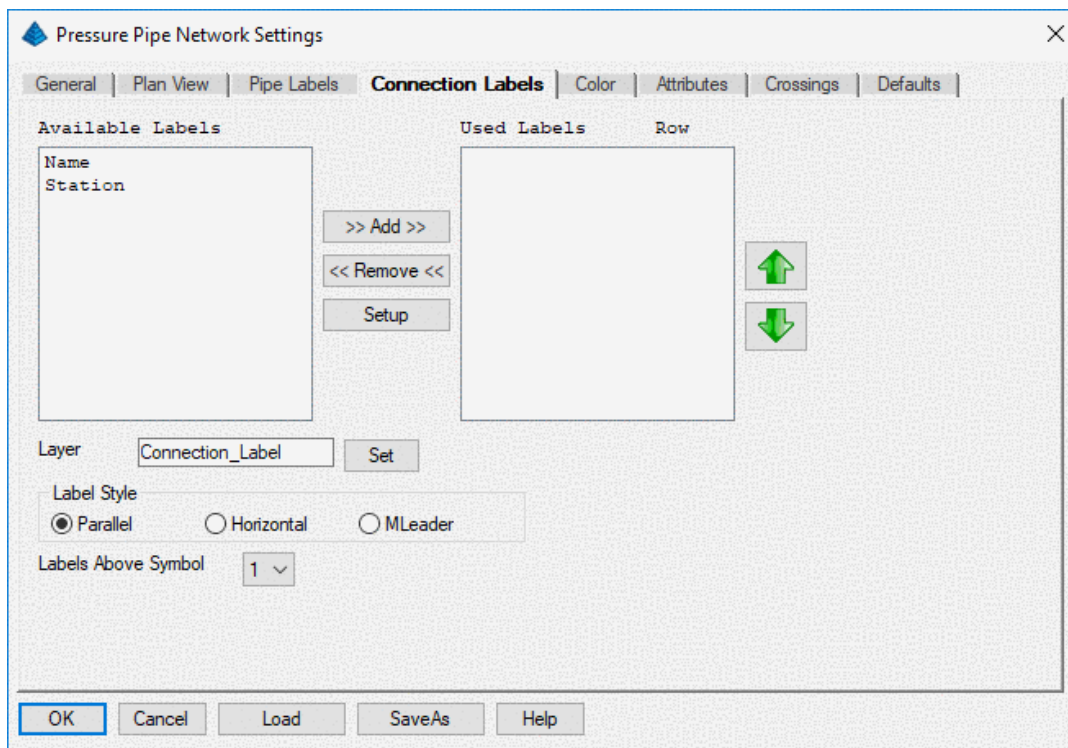

and symbols for the Draw Plan View function. Clicking the "Set" button next to the **Text Style** field controls the font used for the pressure pipe network. **The Label Name** dropdown box allows the user to place the pressure pipe network component label at either end, at intervals defined in the **Label Interval** field, or choose "None" for no labels on components. Clicking the "Set" button beside **The Pump, Tank, and Reservoir Symbols**, selects the 2-D plan view symbols used for these components.

Settings Pipe Labels Tab

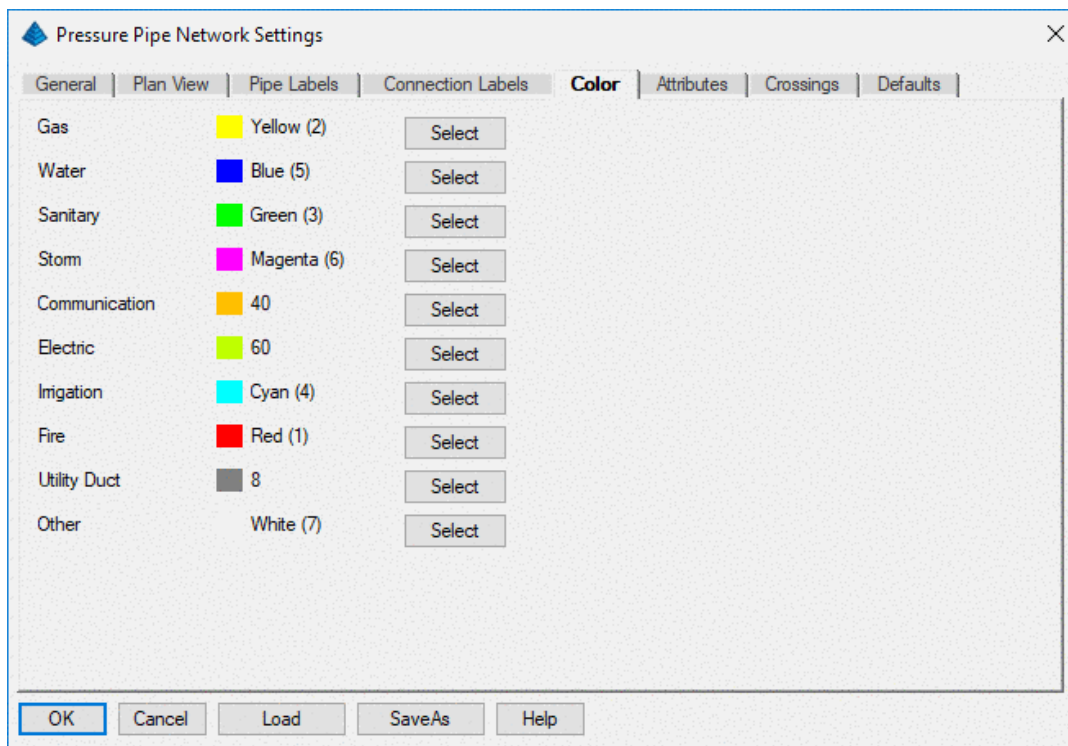

On the "Pipe Labels" tab, choose the Pressure Pipe **Type** from the dropdown, then select the **Available Labels**, moving them to be included using **Add**, then use the green arrows to reorder selections. **Label Location** may be None, Ends, Interval or Both. If Interval or Both is selected, set the **Label Interval**, then the **End Label Style**. **Labels Above Symbol** places the first X number of labels in the **Used Labels** box above the line, the rest below.

Settings Connection Labels Tab

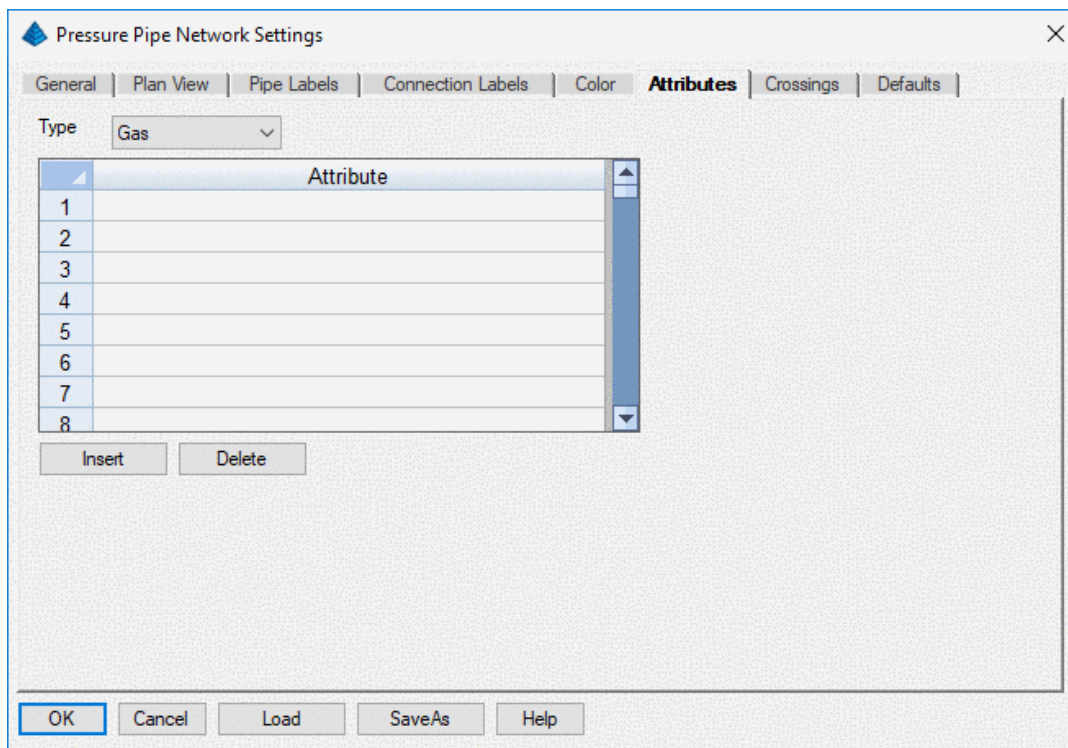

On the "Connection Labels" tab, select the **Available Labels**, moving them to be included using **Add**, then use the green arrows to reorder selections. Choose the layer for the connection labels. Choose the **End Label Style**. Labels Above Symbol places the first X number of labels in the **Used Labels** box above the line, the rest below.

Setting Color Tab

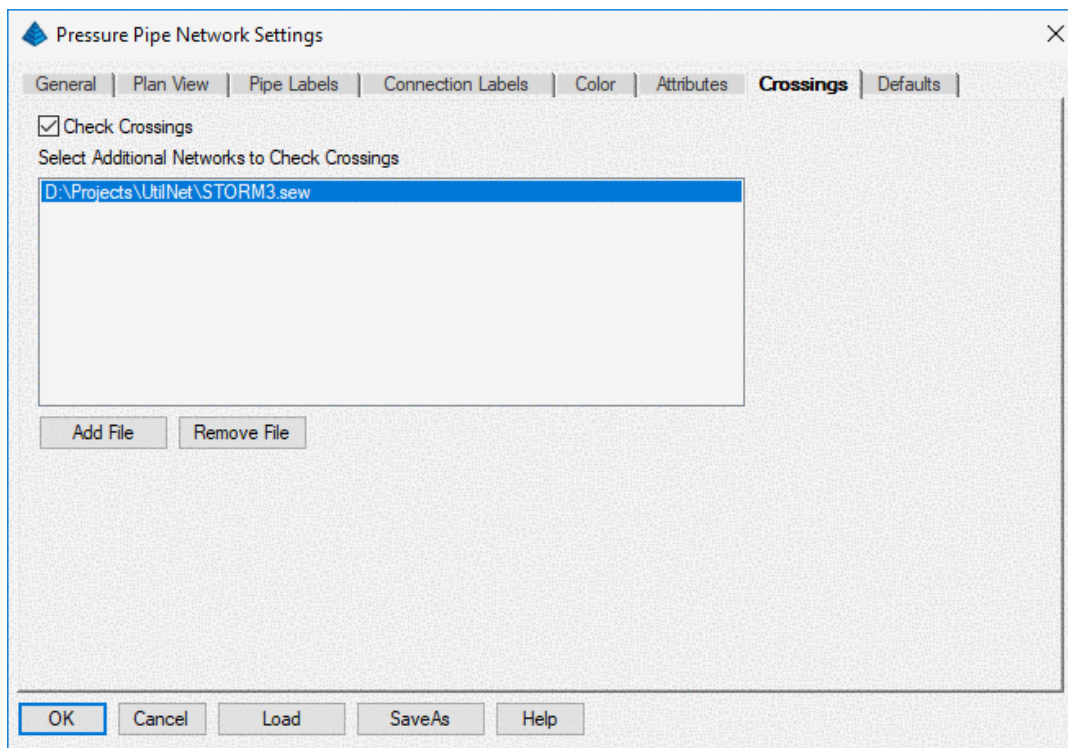

The "Color" tab sets the default colors to use when creating the layers used for drawing this and other Utility Networks.

Settings Attributes Tab

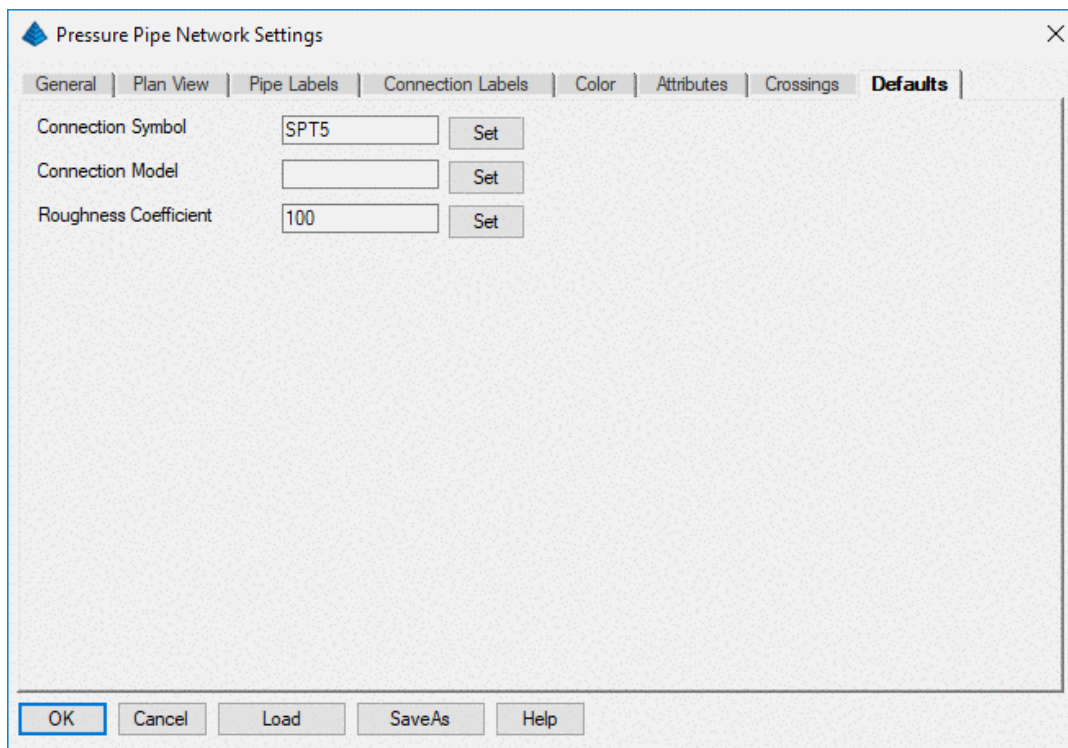

On the "Attributes" tab, choose the **Type** then add any number of **Attribute** values or descriptions to associate with any components in the pressure pipe network. These can be displayed on the **Quantities Report**.

Settings Crossings Tab

On the "Crossings" tab, select the **Check Crossings** box to activate the ability to check for crossings and collisions. Add files to be checked, .SEW or .UTIL files.

Settings Defaults Tab

On the "Defaults" tab, the initial 2-D **Connection Symbol** and 3-D **Connection Model** are defined using the "Set" buttons. These may be changed when adding or editing a Connection. Set a Manning n Roughness Coefficient for the connection.

The **Help** button displays this document..

Clicking the **Draw** button displays the **Draw** dialog box.

Draw 3D Polylines

The **3D Polylines** function creates a 3D polyline for each pressure pipe line. These polylines are tagged with their pipe size in the same format as the Assign Pipe Data to Polyline command.

Draw 3D Faces

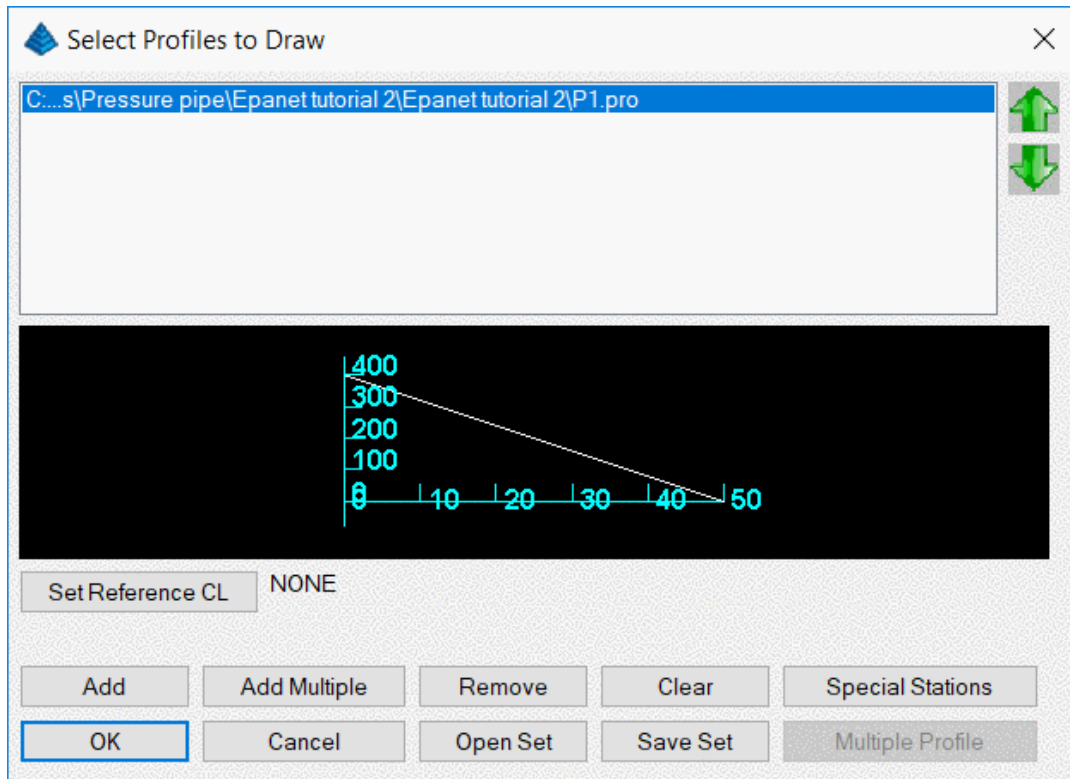

The **3D Faces** function draws each pressure pipe line as a 3D pipe using 3D faces. These 3D faces can then be used in the 3D Viewer commands.

Draw Plan View

The **Plan View** function draws a 2D polyline for each pressure pipe line and labels the line with its' name and connection points.

Draw Profile

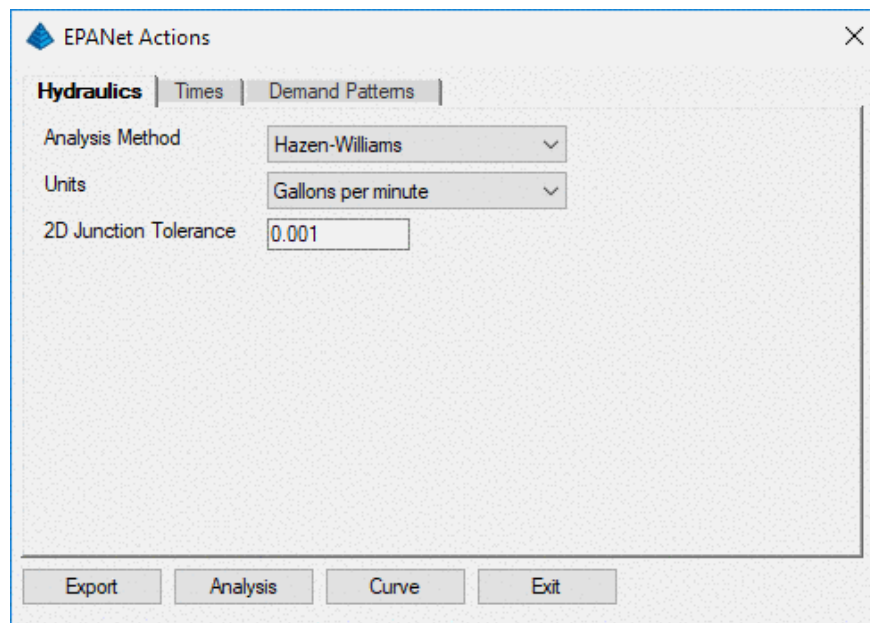

The **Profile** function displays the **Select Profiles to Draw** dialog box.

Set Reference Centerline allows the selection of a Centerline file to choose a Profile file. **Add** allows the selection of a Profile file. **Add Multiple** allows the selection of more than one Profile file choice at a time. **Remove** deletes a Profile from the list. **Clear** removes all Profiles from the list. **Special Stations** allows Station marks and elevation information to be displayed at other positions on the profile than at the beginning, end, and connection points by adding a new Station. **Save Set** saves the list of profiles to a user defined file name for recall. **Open Set** opens a previously saved Set. **Multiple Profile** allows the manipulation of Profile files containing more than one Profile.

Selecting the **EPANet** button displays EPANet Actions dialog box and defaults to the "Hydraulics" tab.

EPANet Hydraulics Tab

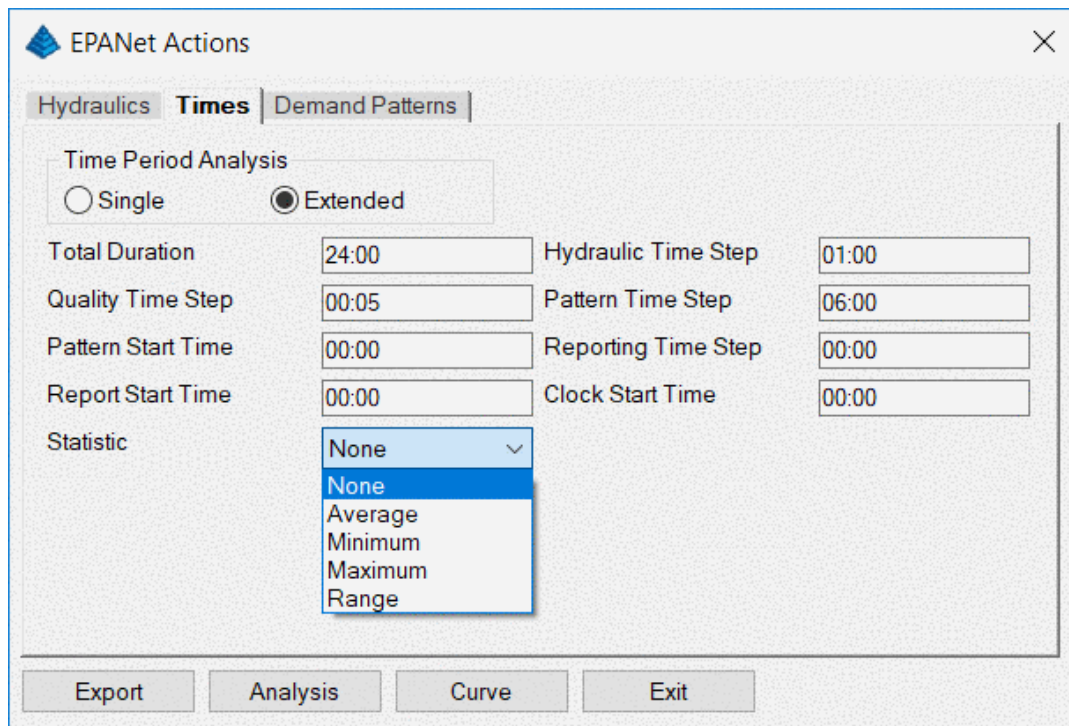

The **Analysis Method** dropdown box allows the selection of one of three methods supported by EPANet.

The **Units** dropdown box allows the selection of the desired volume per time unit.

The 2D Junction Tolerance allows the user to insert a 2D distance. Like pressure pipe network entities within the 2D tolerance will be joined even if the 3D elevation does not exactly match.

EPANet Times Tab

The "Times" tab allows setting parameters for either a single time period or an extended analysis.

If **Time Period Analysis - Single** is selected, all other fields on the tab are deactivated, setting up a "snapshot" analysis of the pressure pipe network.

If **Time Period Analysis - Extended** is selected, all fields on the tab are available for edit. **Total Duration** is the total length of time to be analyzed. Water quality is not currently being analyzed in Carlson 2024. **Quality Time Step** is not currently used. **Pattern Start Time** is the time the **Demand Patterns** created and listed on the "Demand Patterns" tab starts. **Report Start Time** is the first time shown on the analysis. **Hydraulic Time Step** is the time unit incremented as the analysis proceeds through the **Total Duration**. **Pattern Time Step** is the time unit used to step from one **Demand Pattern** to the next. **Reporting Step Time** defaults to the **Hydraulic Time Step** unless and different increment is assigned in this field. **Clock Start Time** is when the analysis begins. The **Statistic** controls how information is presented in the **Analysis** report. **None** reports data at each **Reporting Time Step** increment or, if zero, the **Hydraulic Time Step**. **Average** reports the average values found for the **Total Duration**. **Minimum** reports the minimum value, **Maximum** reports the maximum value and **Range** reports minimum and maximum values across the **Total Duration**.

EPANet Demand Patterns Tab

The "Demand Patterns" tab allows the weighting of water demand assigned to connections and laterals when creating the pressure pipe network based on time of day.

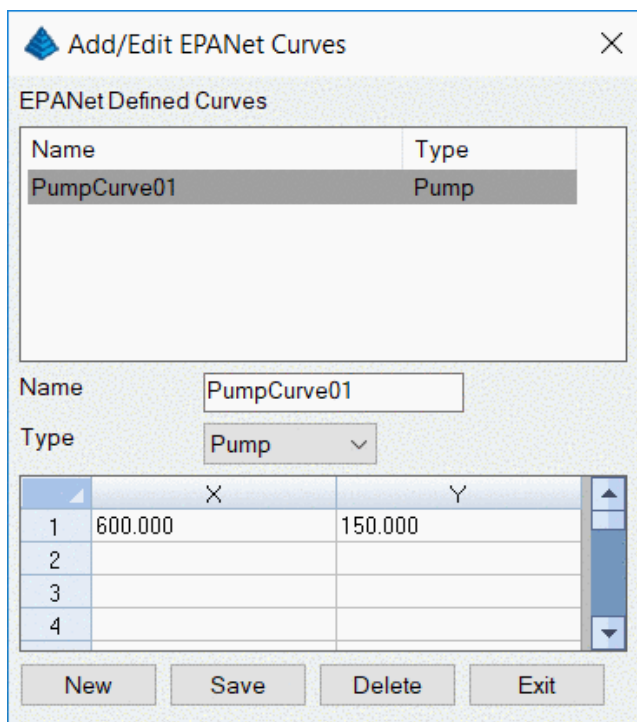

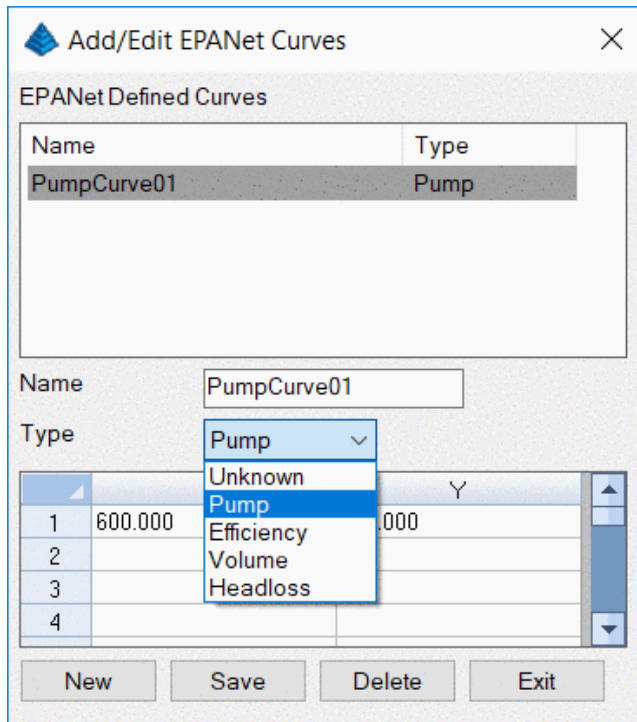

Period	Multiplier
1	0.500
2	1.300
3	1.000
4	1.200
5	
6	

Select an existing pattern to be used to weight the demand during different times of the day. To add a new Pattern, pick the Add button. Another dialog is shown to enter the parameters. Type a new **Pattern ID**, a new **Description**, desired **Multipliers** and click OK.

In the example above, the Clock and the Pattern start at midnight and the demand is reduced by the **Multiplier** 0.50 until the **Pattern Time Step** increment comes due at 6am, increasing the demand by 1.3. At noon, demand drops to its' default values, then at 6pm demand is increased by a factor of 1.20. Note that the **Pattern Time Step** and the number of **Multipliers** are synchronized.

Add/Edit EPANet Curves

Next, develop a pump curve by clicking the **Curve** button. By specifying the **Type**, the values in the X and Y columns are defined.

The Curve Type **Pump** develops a single-point or multi-point **Pump Curve** plotting volume per unit time (flow rate) in the X column, head in the Y column. An **Efficiency Curve** plots a pump's flow rate in the X column vs. energy use efficiency as a percentage in the Y column. A **Volume Curve** plots flow rate in the X column vs. the change in elevation (head) in a tank and is used to model tanks with non-uniform cross sections. A **Headloss Curve** plots the flow rate in the X column vs. the headloss in feet or meters in the Y column as water flows through a General Purpose Valve.

The **Analysis** button produces a report that can be viewed, saved, printed and search showing demands, flow rates, head, energy consumption, pressures, velocities and headlosses in the Network, either as a snapshot or with a **Demand Pattern** applied.

The **Export** button creates a file which can be imported into EPANet.

Save

The **Save** button saves any changes made to the current .util file.

SaveAs

The **SaveAs** button prompts for a new .util file and saves the current pressure pipe network and settings .

Load/New

The **Load/New** button prompts for an existing .util file or the file name for a new .util file and loads the existing file or initializes a new file.

Exit

The **Exit** button exits the Pressure Pipe Network command. If changes have been made, a prompt will be displayed asking if you want to save or discard the changes.

Pulldown Menu Location: Network

Keyboard Command: epanet

Prerequisites: Centerline files, Profile files and/or polylines representing pipes, pumps, and valves.

HydroCAD

The HydroCAD Menu is provided as a starting point for 3 stormwater design tools. The first tool is the Watershed Layer tool. This is the same tool used in Stormwater Networks that provides a method to calculate runoff coefficients. Please note changes to the runoff layer settings changes the settings for all Carlson Tools. For example, when designing a collection system with the Rational Method after designing a detention pond with HydroNet, the watershed definition must be changed from the Curve Number Method to the Rational Method. Stormwater Collection System design may use the Rational Method whereas stormwater detention calculations use the Curve Number Method. The modeling method type must be changed when It is recommended that settings files be saved so that when switching methods, the only requirement is to load your settings files. For additional information on Watershed Layer Setup, see the Layer Setup process covered in Storm Networks.

The second tool is the watershed analysis tool. This tool generates watershed delineations and travel paths given surface geometry. For additional information, see detailed instruction in the Storm Network Dialoge

The third tool opens Hydrocad which is an external program. Carlson provides this button for access to the Hydrocad application. For additional information on Hydrocad, visit their website at <https://www.hydrocad.net/>. Note that Hydrocad is very similar to Carlson's HydroNet program, uses a drag and drop dialogue and provides direct modeling support for most Stormwater detention systems.

Documentation on the Define Watershed Layers and Watershed Analysis commands is under the Watershed Menu topics.

HydroNet Explorer

HydroNet Explorer is a powerful stormwater modeling program that designs and analyze simple and complex watershed networks. In the program, you define a hydrologic network by building a collection of hydrologic nodes. There are four types of nodes: subcatchment, pond, reach and link.

The general idea for the use of the HydroNet Explorer is that you have already prepared a drawing for analysis.

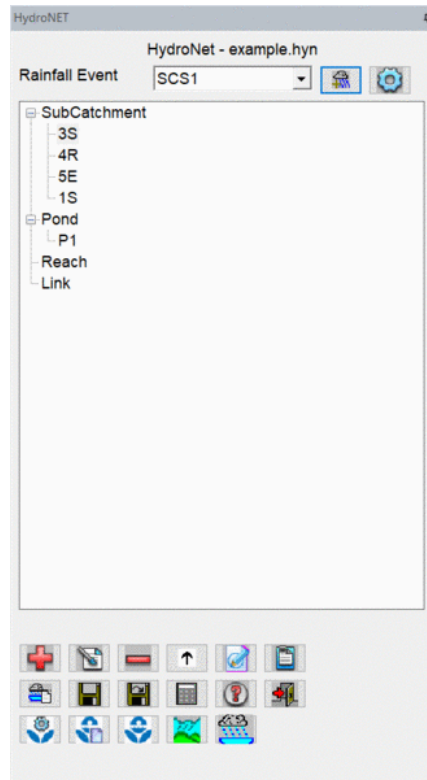

This preparation would include:

Soils: The boundaries of the Hydrologic Soils Groups should be drawn on the drawing layer specified in the Watershed Layers dialog, with the A, B, C, or D labels on the layer specified for that. These areas do not have to be closed polylines, as long as the linework encloses each area that is part of the study.

Ground Covers: The various Ground Covers in the study area should be drawn as closed polylines on the layers specified in the Watershed Layers dialog. These do not need to be labeled.

Watersheds: The Watersheds (subcatchments) for the site should be drawn and labeled. It is best to do this with closed polylines, but it is not essential, as you can use an alternative method of picking within the area and having the software define it from drawing linework.

When you run the HydroNet Explorer command, you are prompted to create a new .HYN file or open an existing one. This is the file that stores all of the data about the components in the project.

Once the HydroNet Explorer is open, the first thing you should do is check the settings for the current project. Pick the icon with the GEAR on it. In the HydroNet Settings dialog, review the various tabs containing the settings for the different aspects of the project.

On the **General** tab, choose Runoff Method either Rational or SCS TR-20, if choosing SCS-TR20 select SCS Unit Hydrograph (options include Delmarva, SCS Curvelinear, SCS Triangular (Set Peak Attenuation Factor), Clark, Snyder) and then select Pond Routing Method (Stor-Ind), and Reach Routing Method (options include Stor-Ind, Stor-Ind w. Trans, Muskingum - Cunge, Modified Puls, and Channel Lag). Set time span. There are two methods to calculate watershed runoff: SCS TR-20 and Rational method. Set the surface to be used to provide the average slope for each subcatchment when using the Curve Number/Lag method.

On the **Subcatchment** tab, set the default starting number for subareas, the default method for Tc calculation, and also set whether Curve Numbers should be calculated in Carlson Hydrology (check the box) or in HydroCAD (uncheck the box).

On the **Pond**, **Reach** and **Link** tabs, set the default starting number for each of these components.

Rainfall Tab

If you want rainfall to be added to the calculations in Carlson Hydrology, set up the rainfall parameters here. Otherwise the rainfall data can be added in HydroCAD. In this dialog, you can enter multiple rain events for reporting. Detailed information about setting up Rainfall events in Carlson is under the Watershed section of the Carlson documentation. There is also an icon at the top of the HydroNet Explorer that you can use to import a Rainfall event from another HydroNet/HydroCAD project file.

There are three Rational Hydrograph Types in HydroNet: Modified Rational, Dekalb Rational and Universal Rational methods. Storm Duration is required for Modified Rational method.

Rational Rainfall

SCS Rainfall

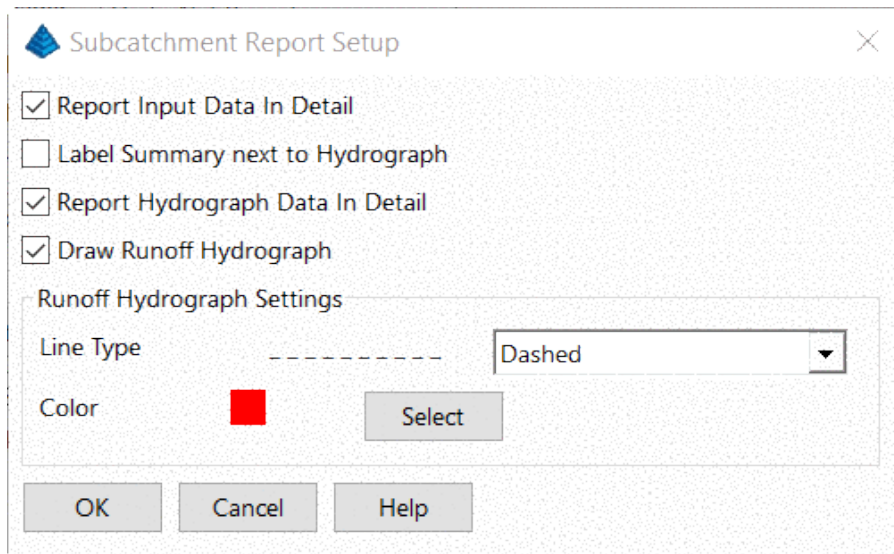

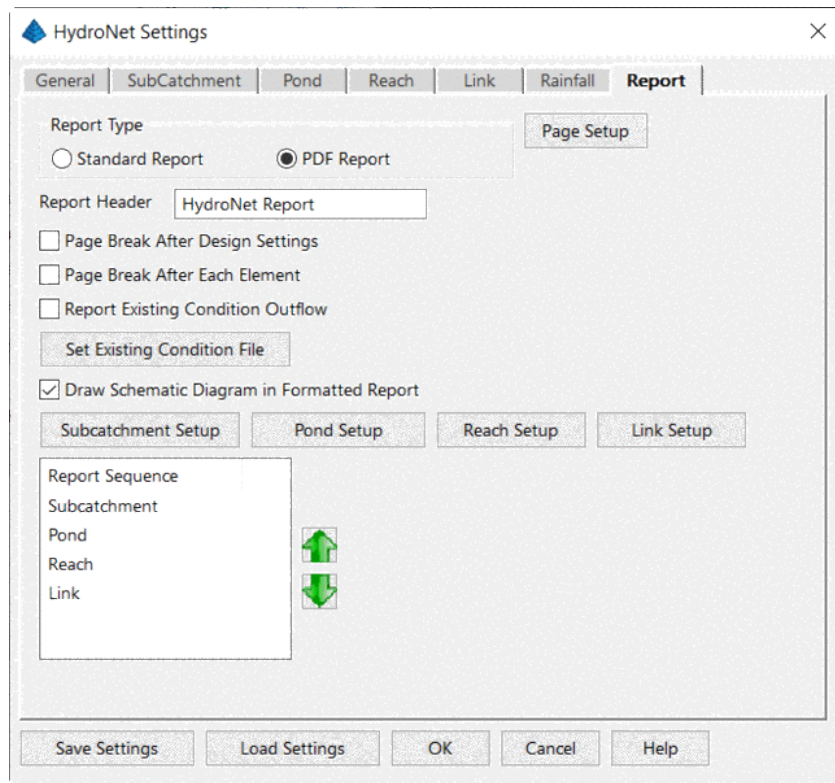

Report Tab

On the Report tab, establish the type of report and the details of the report that you want for each of the 4 component types. Each setup button allows for reporting options in detail, drawing option such as colors, and linetypes.

Report Existing Condition Outflow is to reference pre-developed runoff values when reporting proposed analysis results. **Set Existing Condition File** to to select a HydroNet file that has pre-developed watershed condition.

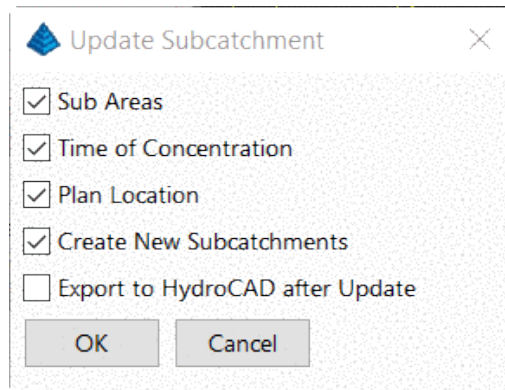

Subcatchment Setup, Pond Setup, Reach Setup, and Link Setup are used to define detailed reporting options with adjustable **Report Sequence** output. Use green arrows to adjust order.

Report Sequence: This is the order that the hydraulic components show in the report. The green Up and Down button allow users to change the report sequence.

Subcatchment contains the watershed conditions. Once the watershed layer file is defined by the command Define Watershed Layers, the program can automatically pull out the watershed data and fill all the values. There can be unlimited numbers of subcatchment in the network, which are divided by the watershed boundary polylines.

You can now use the HydroNet Explorer to automatically analyze the drawing and add all subcatchments defined in the drawing. Pick the Update button, and check all of the options. With the dialog set up as shown, when you pick OK, all subcatchments found on the specified layer are added to the Explorer and exported to HydroCAD. The detailed data for each subcatchment can now be viewed and/or edited. Double click on any subcatchment to edit.

To add Subcatchments manually, pick on the Subcatchment item in the Explorer, and either right click and pick add from the submenu or pick the Add icon.

In the Subcatchment dialog, enter the Number for the Subcatchment. If you have the Subcatchment labeled in the drawing, make the Number match the label. Pick the Edit button next to the Area. In the Sub Areas dialog, pick the Select Subcatchment button. Carlson Hydrology searches for a subcatchment on the layer specified in the Watershed Layers dialog that has a label that matches on the specified layer that matches the Number. If it finds one, it highlights it and asks you to confirm that this is the Subcatchment you are meaning to use. If you pick Yes, the SubAreas are calculated from all of the additional data in the drawing. Pick OK. Back in the Subcatchment dialog, if you specified the CN/Lag method for Tc, the Average Slope of the Subcatchment has been calculated and displayed, and the longest polyline within the subcatchment on the specified layer as been selected and it's length displayed. Define Baseflow (cfs) if needed. Pick OK. The new Subcatchment is listed in the Explorer.

Pond acts as a storage and routing element in the network, and Reach is a routing element. The upstream node of pond and reach generates a hydrograph. The procedure to add Ponds and Reaches is similar to Subcatchments, either right click and pick Add, or select the category heading and pick the Add button below. The detailed documentation on inputting data for these component types is found in the Watershed section of the Carlson Hydrology documentation.

A reach is any length of a stream, river, channel, or culvert. The term is often used by hydrologists when referring to a small section of a stream or river rather than its entire length. User can select Pick Inlet/Outlet Locations where you will be prompted to pick Reach Inlet Location or Select Reach 3D Polyline where you will be prompted to select a 3D polyline. Reach properties include Invert In, Invert Out, Length, and Slope. Reach Type can be set to Channel or Culvert with editing options for both.

Design Culvert

Link is used to model a hydrograph or a sewer network. This program assumes that the hydrologic network is a

linear system, and allows two hydrographs to be superposed by adding the two given flows at a specific time step. In the network two or more hydrographs are combined at a node by allowing multiple links to discharge to one downstream node. The procedure to add is similar to Subcatchments, either right click and pick Add, or select the category heading and pick the Add button below.

If you are using HydroCAD in conjunction with Carlson Hydrology, once the elements of the study are added to the HydroNet Explorer, pick the Export to HydroCAD button to transfer the data to HydroCAD.

Any changes made in the drawing that affect any of the components of the study can be instantly updated and sent to HydroCAD with the Update button in the HydroNet Explorer. Also, each individual component can be updated alone with the update button within it's specific dialog box.

The components listed in the HydroNet Explorer can also be drawn into the drawing file with the Draw Layout in CAD button (paintbrush). Set the desired parameters in the HydroNet Draw dialog box.

Users have the ability to access EPASWMM from within the HydroNet Manager as well as the EPASWMM command found under the Network dropdown. You must have EPASWMM on your computer to use EPASWMM.

The first icon, EPASWMM settings, calls Carlson's EPASWMM configuration dialogs. The second icon, Export to EPASWMM, creates a .inp file to be imported at a later time into EPASWMM. The third icon, Analyze with EPASWMM, directly runs EPASWMM in the background, creating and displaying the desired report.

Users may export data from Hydronet Explorer to HEC-HMS, Hydrologic Engineering Center - Hydrologic Modeling System. This software is created by the US Army Corps of Engineers and is used to simulate the effects of precipitation and runoff of areas with tributaries. Using three main components - Basin Model, Meteorologic Model and Control Specifications - each with many parameters, the user can simulate a wide range of hydrologic problems, from a large river's tributary system and resulting river flow to small, urban systems, like a storm sewer network.

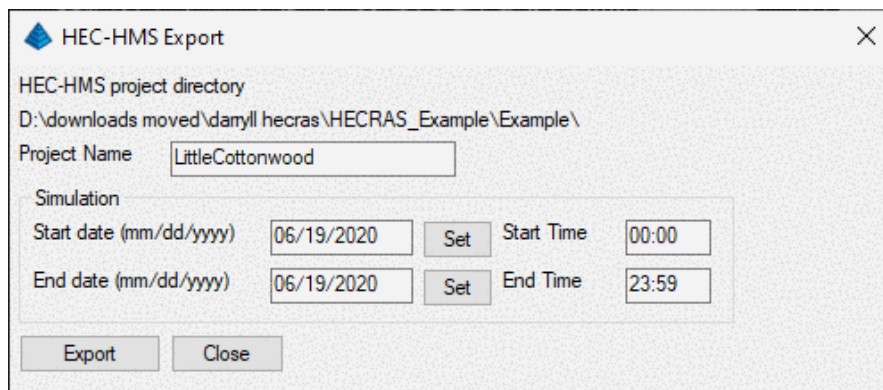

Much more information about the abilities, how to use HEC-HMS and how to download the software is available here:

<https://www.hec.usace.army.mil/software/hec-hms/>

To export, click the HEC-HMS export icon

Choose the Project Name, Start Date, Start Time, End Date and End Time. Click Export.

HEC-HMS can also be accessed using simplified inputs not requiring modeling under the Watershed => Hydrograph Routing => Watershed Hydrograph => SCS Method or by typing "RUNOFFHYD" in the Command Ribbon. Modify parameters as needed, calculate and click the "HEC-HMS" button to export data for HEC-HMS input.

Pulldown Menu Location: HydroCAD

Keyboard Command: hydronet2

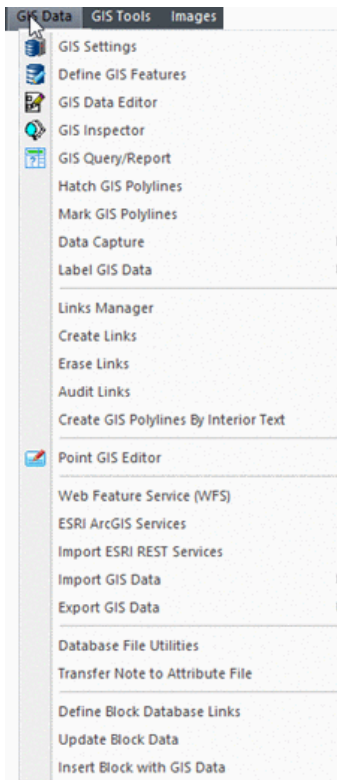

Prerequisite: Soils, soil labels, watersheds, watershed labels, a TIN, and Ground Covers, all on different layers for the different areas.

GIS Module

7

GIS Data Menu

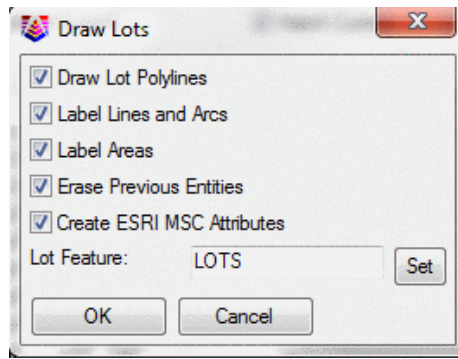

The GIS Data menu shown below has commands for managing and reporting data attached to drawing entities.

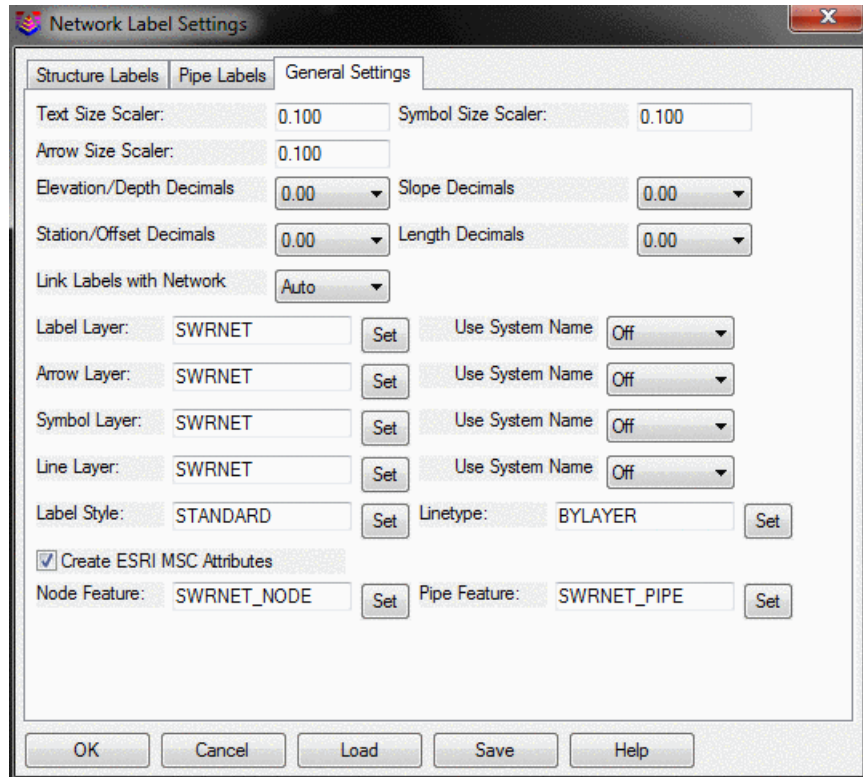

Carlson GIS and Esri

In addition to exchanging data with Esri using SHP files, Carlson GIS supports Feature Data within a drawing that is compatible with Esri ArcGIS software. This data is stored in a format created by Esri known as Mapping Specifications for CAD, or MSC. Starting with ArcGIS 9.3.1, Esri creates a DWG with MSC data using the Export To CAD function in the ArcGIS Toolbox. You can select which features to export to the DWG. The DWG with MSC contains the geometry of the features, the feature attribute definitions and the attribute values. Essentially, the DWG with MSC is a complete geodatabase. In Carlson GIS, set the data format to Esri under GIS Settings and the GIS commands such as GIS Data Editor will work with the Esri data. You can both add and edit GIS data in Esri format in the DWG. Then to bring the data into ArcGIS, choose the Add Data function in ArcGIS and pick the DWG file. With the MSC data format within the DWG, ArcGIS will recognize the features in the DWG instead of everything defaulting to generic CAD.

Several Carlson programs can create this data, such as LotNet, SewerNet, Mining Timing and Surface Mine Reserves. When lots, pipe networks or mining areas are drawn, there are new options to create Esri MSC in the process. When selected, the drawing can then be saved and loaded into ArcGIS as data, and the Features and Attributes created are available to ArcGIS. Here is where MSC is created from the Draw Lots command in Lot Manager.

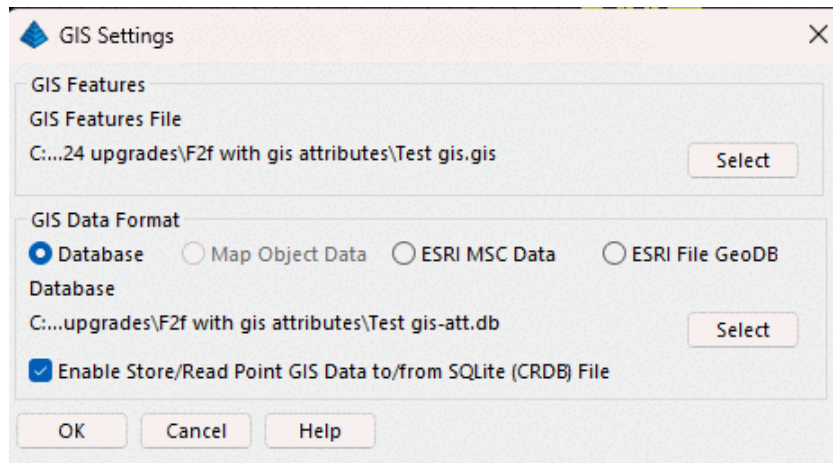

Here is where it is specified to create MSC when plan view of a Sewer Network is drawn.

GIS Database Settings

This command is the initial step to setup Carlson GIS routines. The user need to provide the GIS Features File name and Data Format type for the current drawing.

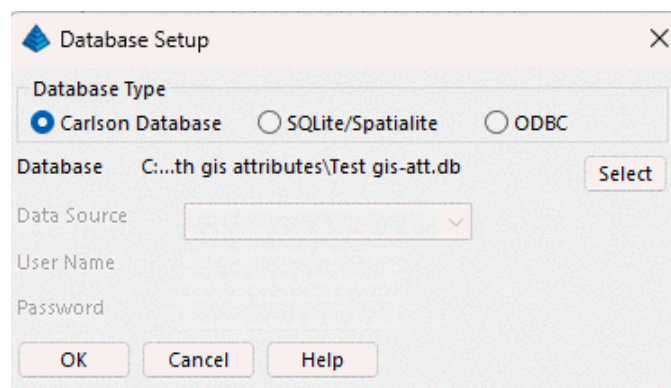

The GIS Features file (.GIS) includes the structure of the GIS features and their attribute, and it is defined in the Define GIS Features command.

The Data Format defines the type of data format and its stored location.

Currently, the GIS Data Formats include Database, Map Object Data, ESRI MSC and ESRI GeoDatabase.

The Database includes 3 types, Carlson Database(.DB), SQLite/Spatialite(.sqlite) , and ODBC Database. Carlson Database stores data in an external database in a SQLite format and the data schema is Carlson defined. The SQLite/Spatialite stores data in SQLite format(.sqlite) with spatial capabilities, and the data schema is user defined. The SQLite/Spatialite DB can be added into QGIS layer and it is also supported by ArcGIS 10.2 and above. This database can be read/write between Carlson GIS and ArcGIS/QGIS. The ODBC connection use Data source name to connect to third party database. The data schema is user defined, and it can be used by both Carlson GIS and other third party. Currently, only PostgreSQL has been tested. It is recommended to use Carlson DB if no external usage is needed.

For Carlson Database and SQLite/Spatialite need to specify the database name. For the ODBC connection, Data Source needs to be setup ahead of time. Please see How to Setup ODBC Data Source. Only import_odbc function allows to save GIS Data in ODBC database.

Map object data is attached to an individual object and stored in the object data tables in the drawing. Map Object Data is limited to Autocad Map 3D only. The Esri MSC Data stores the GIS data within the drawing file in a format that both Carlson and Esri use. Esri added support for MSC from ArcGIS V9.3. The ESRI MSC structure makes

the DWG file a type of geodatabase with all the feature definitions, GIS data and geometry stored in the file.

The Enable Store/Read Point GIS Data to/from SQLite (CRDB) File option provides an easier transferal method to and from data used in SurvCE/PC and Carlson Office products. The CRDB file format is based on SQLite structures. The CRDB format contains the same data as a CRD format but with extra information like GIS data and photos links. If Enable Store/Read Point GIS Data to/from SQLite (CRDB) File is OFF, the GIS data will be stored in a VTT format file.

If Spatialite DB/ODBC DB/ESRI FileGeoDB are selected, then there are special setup for the projection in the Settings/Drawing Setup dialog. Please see how to setup Projection for these GIS Data Format in Drawing Setup.

Pulldown Menu Location: GIS Data

Keyboard Command: gis_config

Prerequisite: None

Define Template Database

This command creates the Feature/Attribute data structure, template database or schema, for GIS functionality. The structure is stored in a Carlson Features File with a GIS file extension.

A feature, such as a manhole, can have multiple attributes, such as Number of rungs, Type of material, Number of inlets, etc. Features can be organized into Categories: Utilities, Roads, Properties. The Category designation is an arbitrary way of organizing the features. Features and attributes can be imported from:

- Carlson Coordinate File (.CRDB)
- Carlson Database (.DB)

- Carlson GIS Features file (.GIS)

- Carlson Field to Finish file (.FCL)
- Carlson SurvCE Features file (.VTT)
- Esri MSC data contained within the drawing (.DWG)
- Esri File GeoDatabase (.GDB)
- ESRI Shapefile(.SHP)

- Google Earth file (.KML)
- Map Object Data
- StarNet (.CSV)
- TDS Features file (.FEA)
- Text File (.CSV)
- Topcon GIS
- Trimble Features file (.FXL or .FCL)

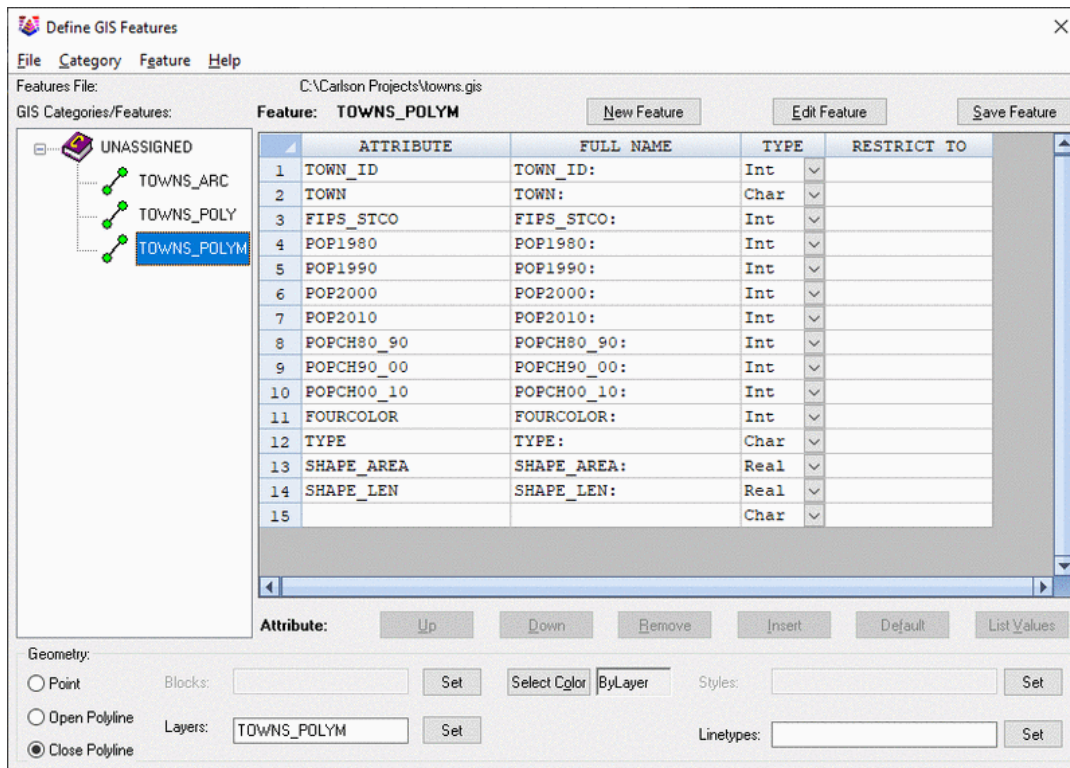

Note: Some data source such as ESRI Shape file, ESRI File GeoDatabase, ODBC Database and SQL/Spatialite Database will automatically add the new feature and its attributes when import GIS Data.

Features and attributes can of course also be defined "from scratch" in the Define GIS Features dialog box. The workflow is outlined below.

1. Set the GIS file name which will contain the features and attributes structure. Use the File menu to create a new (.GIS) file or open an existing one for editing. Please note that the system will only process correctly if a FCL and a GIS file both have the exact same file name
2. Set up one or more Category Names, using the Category menu. GIS feature codes can be categorized (e.g. STRUCTURES, UTILITIES, ROAD FEATURES, etc.). At least one category must be created.
3. Define Features, using the Feature menu. To edit a feature, double-click on the feature name.g. A category such as UTILITIES might have features such as manholes, light poles, fire hydrants, water valves, etc.
4. Define the attributes for the Feature. Each attribute has:

- a) a Name
- b) a Full Name, or Prompt
- c) a Type - Integer, Character or Real
- d) a system Default Value. Press the Default button to add a system variable from a list. For example, press Default > Elevation. The system will add \$EQN=\$LAT, a system variable that will insert the current latitude from the point measurement
- e) optionally, a List of values to pick from. Use the List Values button or type in each value followed by Enter within the field required, to build a list. The list will as a pick list when the attribute screen is shown.
- f) whether the attribute is required
- g) whether the attribute Value can be field Edited, appears as Read Only, or is Hidden
- h) whether the value used is restricted to the list

The order of attributes appearing on the data-entry screen is controlled by the Up and Down buttons.

Geometry Settings

At the bottom of the dialog box the user can specify the geometry settings for each feature. Each feature can be defined as a open/close polyline or point. Each feature can also have a layer, block text style and line type defined. Please note that GIS features can only be defined on polylines and not lines.

Note: If the GIS Data Format is ESRI MSC, then it is required to setup Layers. If the Layer name is miss-

ing, then the system will use the feature name as the Layer name

Note: If the GIS Data Format is ESRI File GeoDatabase and the feature definition is to create a GeoDatabase schema from scratch, then it is important to have an attribute as primary key. The attribute has to have type as Int and it is required. Plus, the Field Edit has to be Hidden because ESRI File GeoDatabase will automatically generate the primary key's value. Therefore, this attribute will not be available in GIS Data Editor.

Pulldown Menu Location: GIS Data

Keyboard Command: def_template

Prerequisite: None

GIS Data Editor

This routine creates, reviews and appends GIS data linked to entities stored in the drawing.

The GIS Smart Prompting dialog has a spreadsheet format for editing the data fields. The GIS table to process is selected in the pull-down list in the upper right of the dialog. The GIS tables that are available depend on the tables that are defined in the current data source. Use the *GIS Settings* and *Define GIS Features* commands to setup the tables. Once you select a table to process, the fields for that table are displayed in a spreadsheet format. If a field is related to a field in another table in the database, a "+" character is shown next to the field name. Picking the "+" will open another dialog box with the related data in the other table. The data in this related table is not editable, only the data in the initial linked table.

The bottom portion of the dialog has features for attaching images to the entity. (Note: The bottom portion is only limited to single file type database and ESRI MSC Data.) Existing image files (BMP, JPG or GIF) can be linked by choosing the New option. The Update option will replace the current image with a newly selected image. The Delete option will remove the current, attached image. The Capture button will take a shot in the field using a configured camera and then attach the image to the entity. Different digital cameras can be used by picking Pick or Set Camera.

The *GIS Data Editor* command is an excellent way to simply review the data associated with an entity. If the entity has GIS data, the banner line at the top of the dialog will display "Entity has GIS Data". If not, the banner line will display "Entity has no GIS Data". Even when the entity has no data, the default values for the prompts will appear. Pressing OK will assign this data to the entity. To avoid assigning data to the entity (if it has none), press Cancel. Alternately, you can use the commands *GIS Inspector Settings*, followed by *GIS Data Inspector*, to review the data with no possibility of editing or inputting data in the process.

There are three methods for selecting the drawing entities to process: S for Select, P for Pick and N for Number:

Select Object method: With this method, you pick the drawing entity to process the data attached to that entity. When selecting a Carlson point, the point number is used to link to the database.

Pick method: For this method, you pick inside a closed polyline to process the data attached to that polyline.

Number method: Here you simply input the point number from the current CRD file to process.

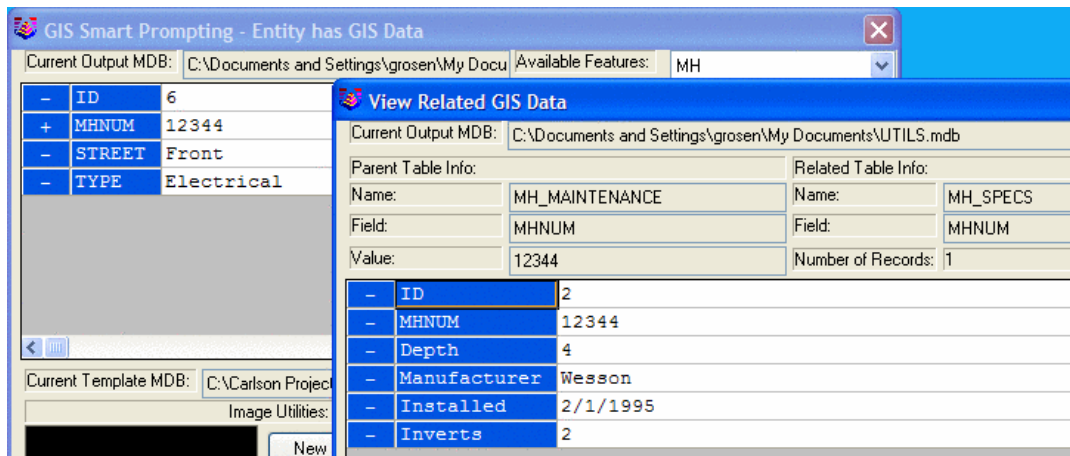

Map Object Data has different dialog that only allow user to select GIS Feature table and add/edit/delete data.

Prompts

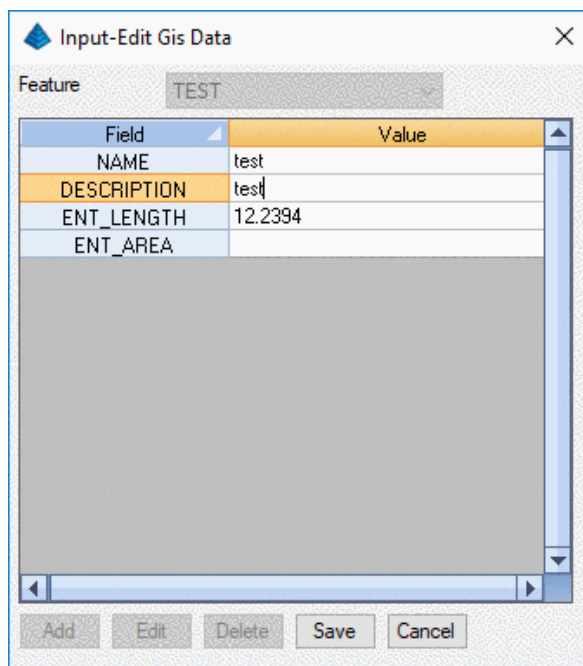

Select object (Number/Pick/<Select>): P

Pick a point inside polygon (Select/Number/<Pick>): pick a point

GIS Smart Prompting dialog make selections

Map object data/ODBC Database editor dialog

Pulldown Menu Location: GIS Data

Keyboard Command: gisdata

Prerequisite: GIS Feature file name and GIS Data Format must be defined in GIS Settings dialog

GIS Inspector

This command displays all or portions of the data attached to drawing entities in real-time. Initially, the command sets up the fields to be displayed when using the GIS Inspector.

When you move the cursor over an entity with GIS data, selected fields are displayed in a tooltip box next to the cursor. For data attached to closed polylines, you can move the cursor anywhere inside the polyline to show the data. Polylines that are closed will highlight with a solid fill as you inspect each one. Open polylines, such as road centerlines, will highlight with a solid fill generated along the length of the polyline. The solid fill color for all highlighting is set in GIS Inspector Settings.

The routine starts by prompting you to select entities. The entities that you select will be used by GIS Inspector. In the case of a large drawing, this selection allows you to limit the entities for inspector to a local area instead of

having to process the whole drawing. Then after reading the entities, you can move the cursor around the drawing to inspect the GIS data. You can also use the arrow, page up and page down keys to pan and zoom the display. Pressing enter ends the routine.

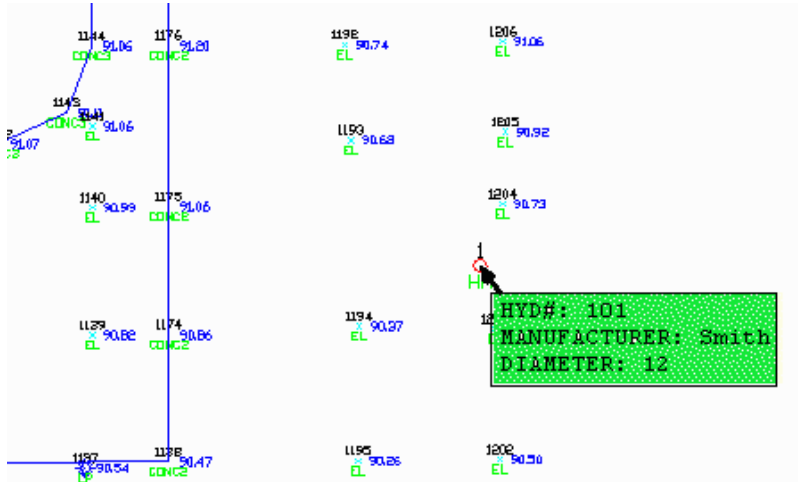

Prompts

Select objects: *select entities with attached data*

Arrow keys=Pan; PageUp/Down=ZoomOut/In;

Zoom=Pick left-lower and right-upper corner;

Move pointer over entity with Gis Data (Enter to End): *move cursor over entities with data; press Enter to end*

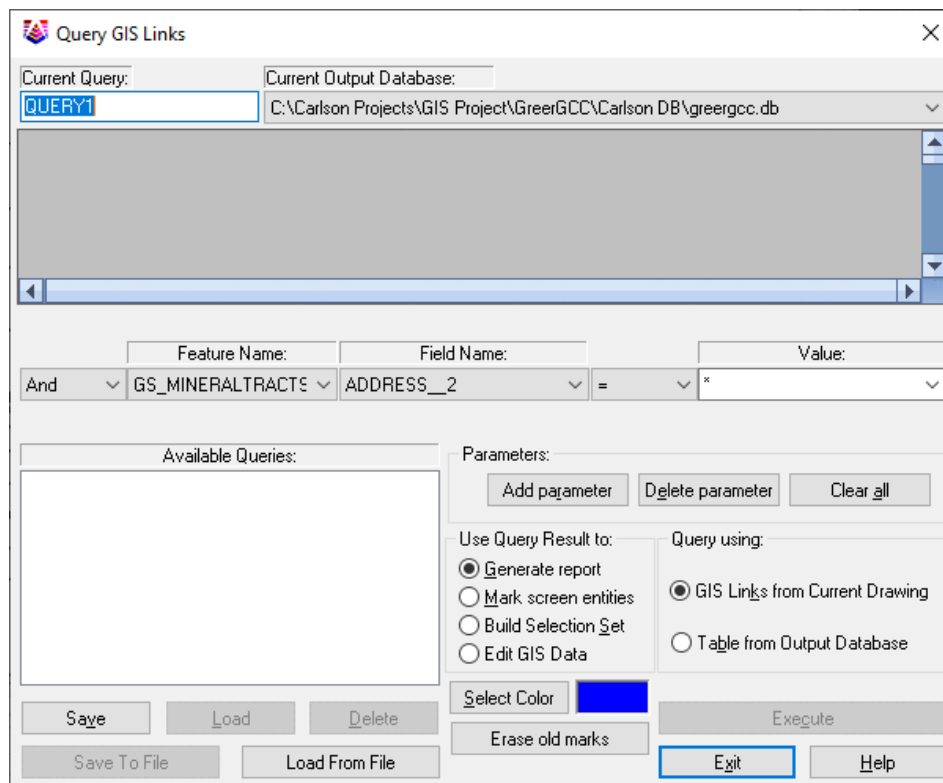

Pulldown Menu Location: GIS Data

Keyboard Command: gis.inspector

Prerequisite: MDB GIS Prompting must be created in *Define Template Database* and entities must have linked GIS information.

GIS Query/Report

This command applies a user-defined query on a data table or related tables with the database. Records in the table that pass the query can be reported or the associated entities can be highlighted in the drawing. The *Query Using* option in the main dialog box sets the source of the data table to process as either GIS data attached to selected drawing entities or from the current Output GIS Data Format source.

The query is defined in the dialog shown here. To add a query, enter a new query name in the in the space underneath Current Query. If there is already a name there, just highlight and type over it with a new name, then hit Clear All to clear out existing query lines and get full access to all Feature Names.

The top portion of the dialog contains a list of the query parameters. To add a parameter, select a Feature Name from the pop-up list. The available features will either be all the features found in the GIS links of the drawing or all the features from the GIS Data Format source depending on the *Query Using* option. Once the feature is specified, the Field Name pop-up list contains all the available fields in the feature. Choose a field from this list. Next choose the operator (=, >, etc.) from the operator list. The Value pop-up list contains all the different values for that field that are found in the current data set. You can either select one of these values or type in another value into this field. If a Field Name relates to another Feature, when you select that Field, an additional button will appear allowing you to add a query parameter from the related feature.

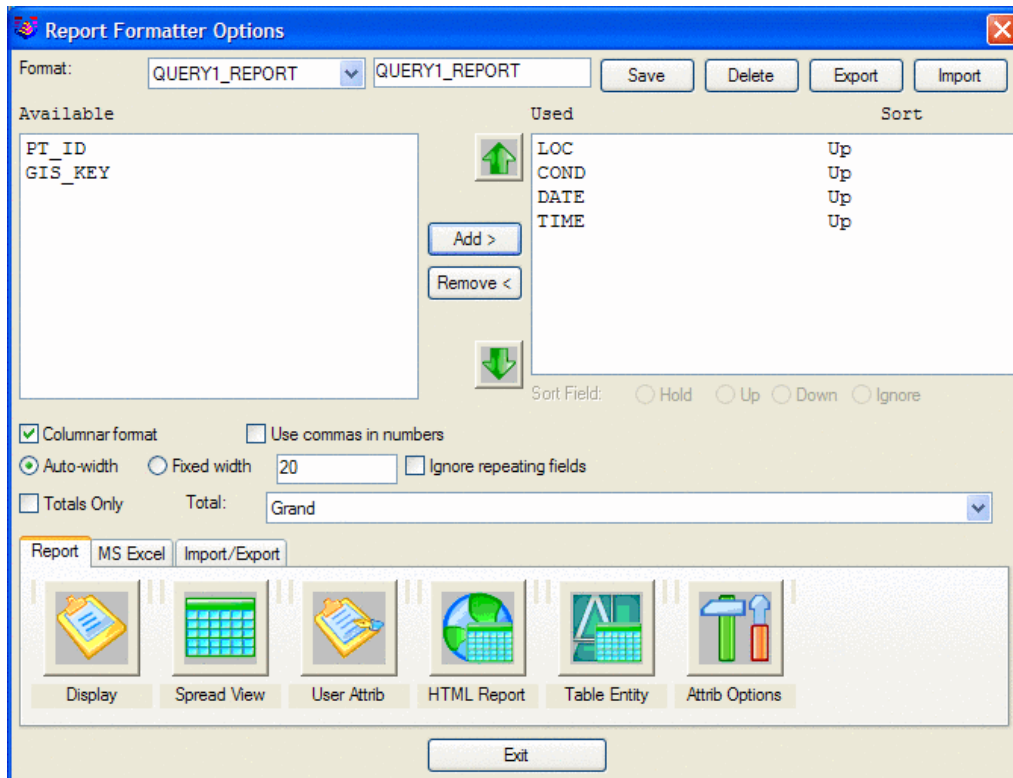

When all the parameter values are set, pick the Add Parameter button. Once a feature is selected and add a parameter is added, the Feature Names list becomes unavailable because any additional query parameters must come from that feature, or relate through that primary feature.

When all the parameters are defined for the query, you can save these settings by filling out a name Current Query field and then picking the Save button. This query can be recalled later by highlighting the query name and clicking the Load button. The Delete button removes the highlighted query. The Save, Load and Delete functions operate on the current set of queries active in the program. The Save To File and Load From File functions read and write the collection of queries to a .QRY file for managing different sets of queries and sharing with others.

Pick the Execute button to process the query. The Mark Screen Entities option will set the color of entities with GIS data that match the query to the specified color. The Build Selection Set option creates a selection set of the entities that pass the query. To use this selection set in other commands, enter "P" for previous at the "Select objects:"

prompt. With the Generate Report option, the program will bring up the Report Formatter which allows you to choose the fields to include in the report and the report format. If the Highlight Screen Entities option is on, then the program will highlight the entities with GIS data that pass the query. Point entities are highlighted by drawing a box around the point and polylines are highlighted by solid fill. Shown here is the report for all manholes with a Condition of Good.

Pulldown Menu Location: GIS Data

Keyboard Command: gis_query

Prerequisite: MDB file with data or entities with linked GIS information

Hatch GIS Polylines

This command hatches closed polylines with attached GIS data based on the value of a specified database field. The program starts by selecting closed polylines in the drawing with GIS data. Then a dialog appears for specifying the database field to process. This dialog displays a list of all the GIS table names found in the selected polylines. First choose a table to process and then choose a field to process by clicking on the down arrow underneath Current field. Next you can specify the color, hatch pattern and layer for each zone. The Auto button can be used to quickly fill out the hatch zones. The Show All The Distinct Values option chooses between processing as series of ranges or individually for each data value. Applications include hatching all commercial property red and residential yellow, coloring buildings by type of construction material, coloring properties by type of ownership, etc.

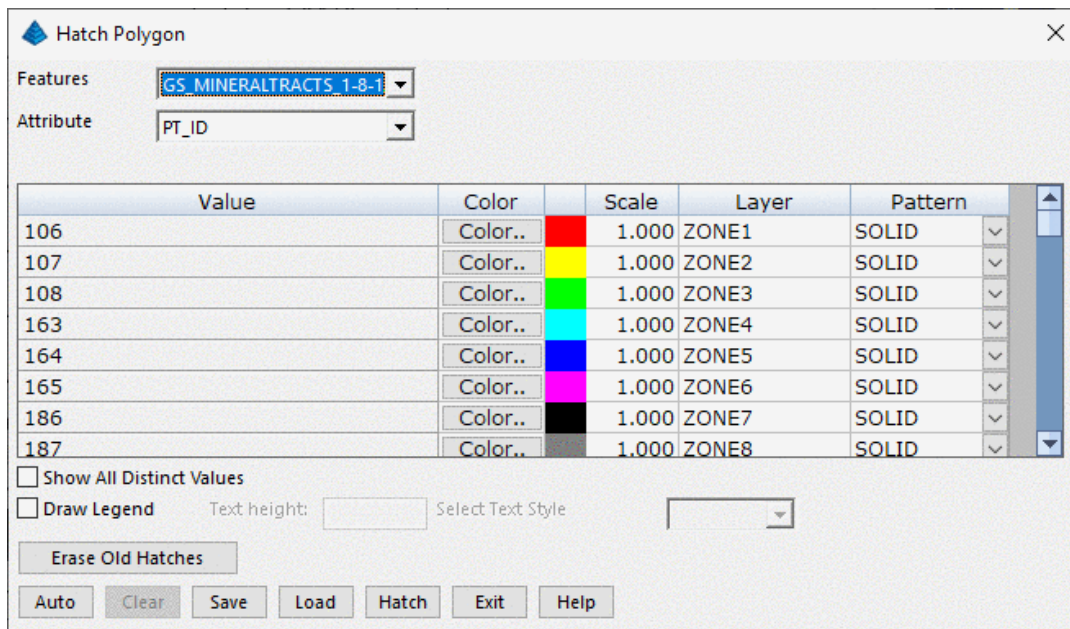

The Draw Legend option will create a legend of the hatch zones. The Erase Old Hatches button will erase any existing hatches inside the selected polylines. The settings can be saved to and recalled from a GIS settings file (.GSF) using the Save and Load buttons. Once all the settings are ready, pick the Hatch button to hatch the polylines. When using solids for the hatch pattern, the Solid Fill Float command in the View menu can be used to make the polylines appear on top of the solids.

Prompts

Select objects: *select closed polylines with GIS data*

Example country polylines hatched by population range field

Pulldown Menu Location: GIS Data

Keyboard Command: hatch_polygon

Prerequisite: Closed polylines with linked GIS data

Mark GIS Polylines

This command draws new polylines as markers along selected existing polylines. The new polyline markers are drawn with width and color based on a query of the attached GIS data. The program starts by selecting open or closed polylines in the drawing with GIS data. Then a dialog appears for specifying the database field to process. This dialog displays a list of all the GIS table names found in the selected polylines. First choose a table to process and then choose a field to process. Next you can specify the color and width for each data value. The Auto button can be used to quickly fill out the color and widths. The Show All The Distinct Values option chooses between processing as series of ranges or individually for each data value.

The Draw Legend option will create a legend of the marks. The Erase Old Marks button will erase any existing polyline markers from the selected polyline. The settings can be saved to and recalled from a GIS settings file (.GSF) using the Save and Load buttons. Once all the settings are ready, pick the Draw button to draw the marker polylines.

Prerequisite: Closed polylines with linked GIS data

Data Capture From CAD Properties

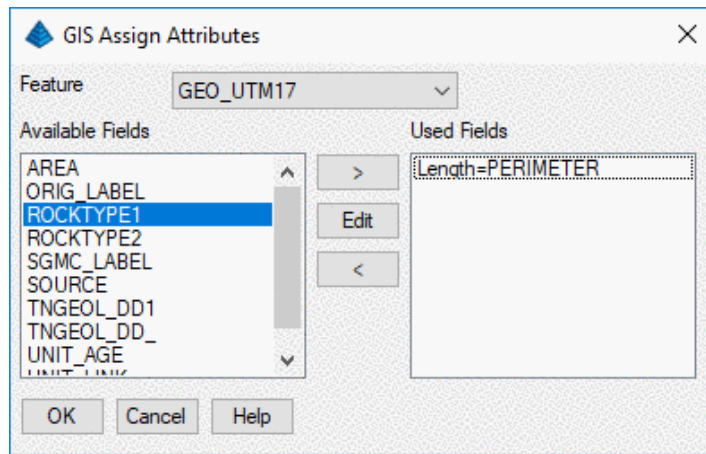

This command capture CAD properties data from selected entities and assigned them to entities's GIS values. The user needs to select GIS Feature from the drop down button and add the desired fields from the right combo box to the left combo box. Then the user need to match the GIS field with CAD Properties.

The available CAD properties are area, length, layer and elevation. Only closed polyline can assign Area to the GIS data.

After the selection, the entry in the Used Fields will have the format of *<CAD property>=<GIS attribute>*. The following picture shows "Length=Perimeter"

Prompts

Select linework entities: select linework

Pulldown Menu Location: GIS Data > Data Capture

Keyboard Command: giscaddata

Prerequisite: Linework and defined GIS feature

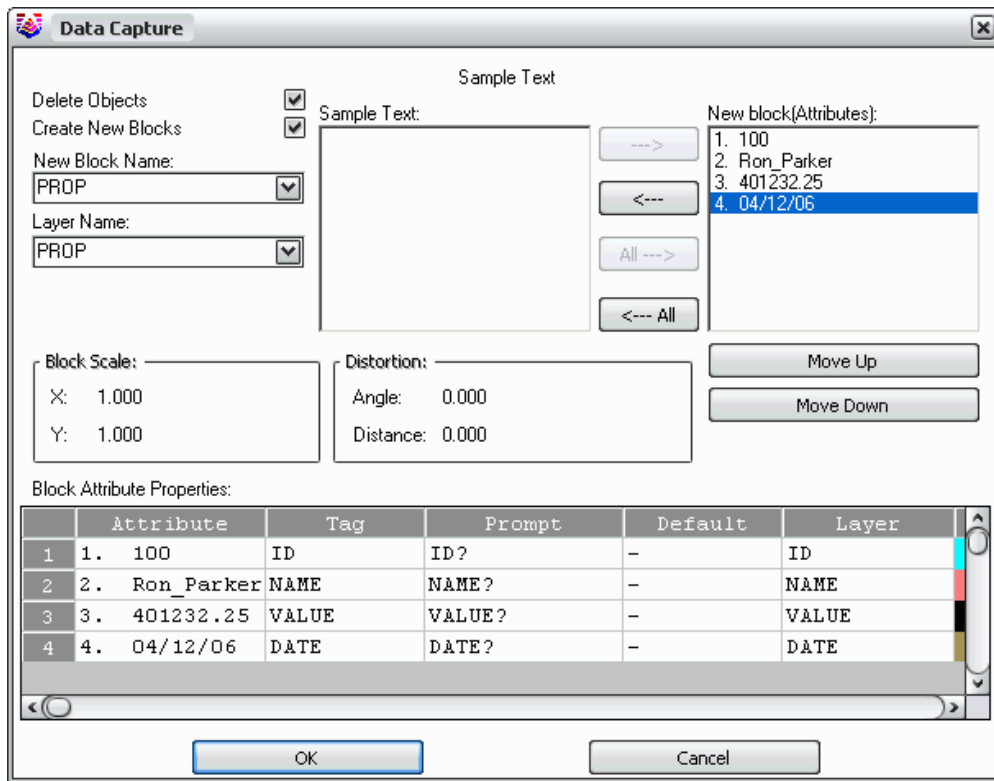

Data Capture Text By Sample

This command automates data transfer from text entities to a database table. Many drawings are warehouses of information. The Data Capture Text By Sample command applies to drawings that contain text annotations which show the information about the objects in the drawing.

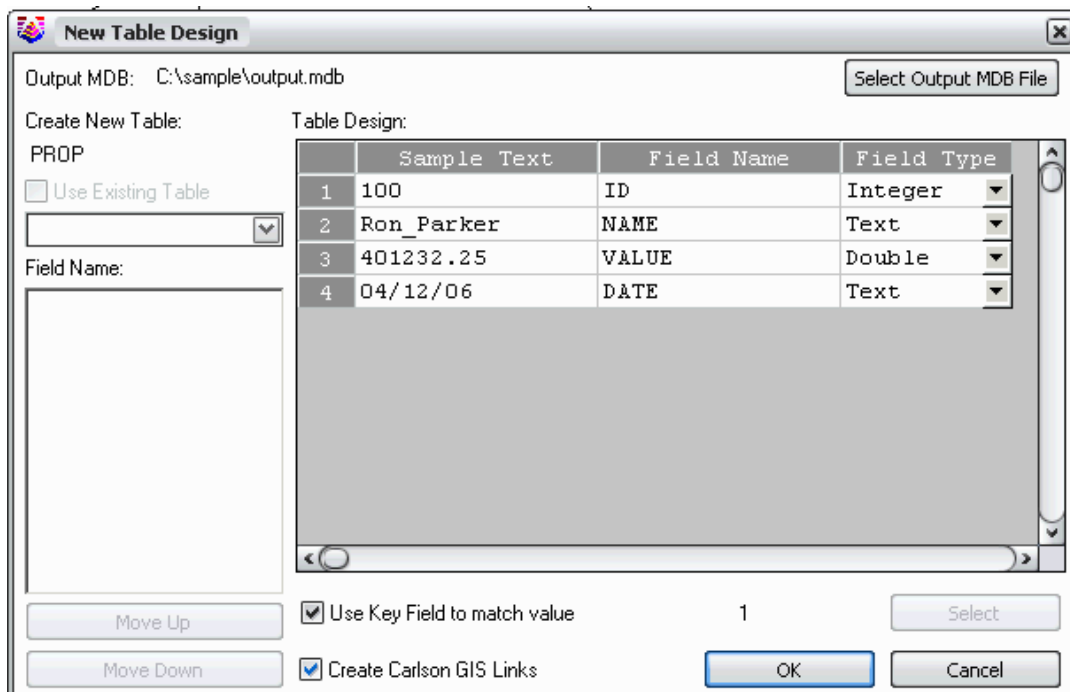

The command starts by prompting you to select one sample of the text to capture. This sample selection should consist of one instance each of the data fields to process. In the example below, the sample selection includes the property id, owner's name, property value and date.

Next, there is a dialog for specifying the text fields to capture and their order. Optionally you can convert the text entities into blocks by turning on the Create New Blocks option. Each sample text field is available to make into a block attribute by moving these fields to the block attribute list. In the New Block Name and Layer Names fields, you can specify the name and layer for the blocks. The Delete Objects option will erase the text entities. In the Block Attribute Properties spreadsheet, you can set the block tags, prompt, default and layer for each attribute.

The second dialog setups up the database table to create from the text data. The destination database is set with the Select Output MDB File button. You can either create a new table in the database or select an existing table. Under Table Design, you can set the Field Name and Field Type for each attribute when a new table is being created. When adding to an existing table, the Field Name and Field Type are read from the existing table. For with an existing table, the Field Name list in the lower left will show the field names from the existing table, and the order of these fields should be set to match the order of corresponding the text fields. The Use Key Field To Match Value option will use the selected record as the key field for the database table. The key field must have unique values for each record in the table. To set the key field, highlight the record row # in the spreadsheet and then pick the Select button. The Create Carlson GIS Links option will link the database table with the drawing entity for each record.

After the dialogs, there is a command line prompt to select the text entities to import. The program uses the sample text layout to find matches sets of text data in the text to process selection set.

Prompts

Select sample text to capture.

Select objects: *pick one instance of each type of text field*

Data Capture dialogs

Select entities to process [Select/<All>]: *all*

Created 3 GIS Links.

Done

Pulldown Menu Location: GIS Data > Data Capture

Keyboard Command: `cgis_gettxtbysmp`

Prerequisite: Text entities

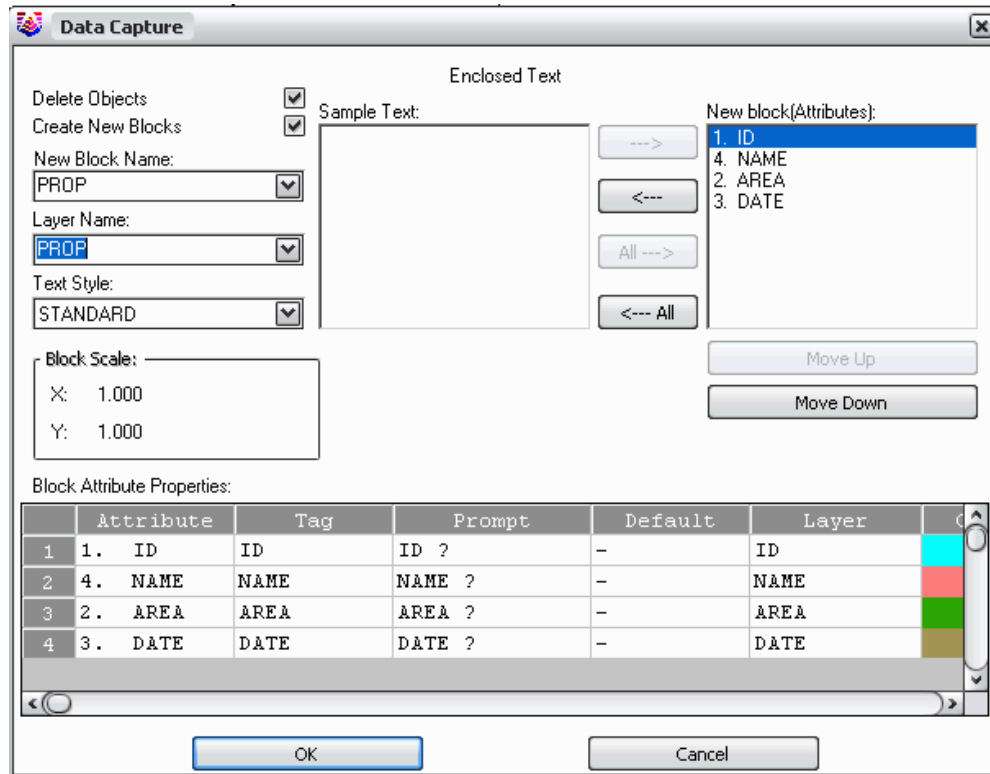

Data Capture Enclosed Text

This command automates data transfer from text entities to a database table. Many drawings are warehouses of information. The Data Capture Enclosed Text command applies to drawings that contain text annotations which are within linework perimeters.

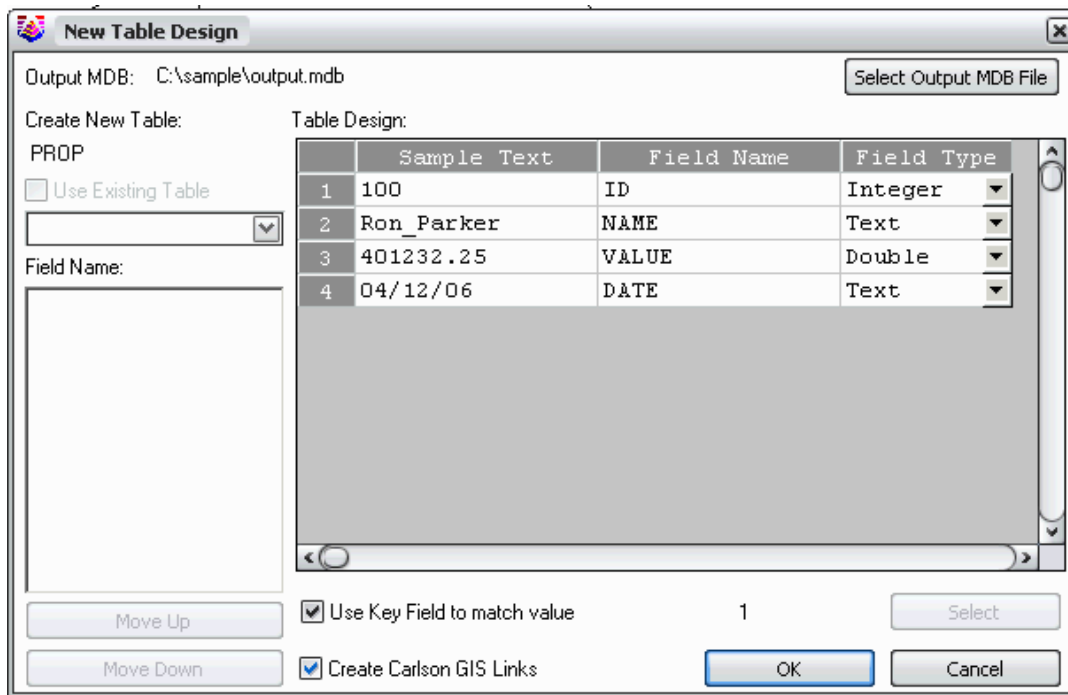

The command starts by prompting whether to identify the text to process by Group or by Layer. For the Group method, you select one sample of the text to capture. This sample selection should consist of one instance each of the data fields to process. In the example below, the sample selection includes the property id, owner's name, property value and date. For the Layer method, the program will find all the different layers for the text entities and you can select which layers to use. For the Layer method, each type of text field should be on separate layers.

Next, there is a dialog for specifying the text fields to capture and their order. With the Group method, the text fields will show the values of the selected text. With the Layer option, the text fields will show the layer names. There is an option to convert the text entities into blocks by turning on the Create New Blocks option. Each sample text field is available to make into a block attribute by moving these fields to the block attribute list. In the New Block Name and Layer Names fields, you can specify the name and layer for the blocks. The Delete Objects option will erase the text entities. In the Block Attribute Properties spreadsheet, you can set the block tags, prompt, default and layer for each attribute.

The second dialog setups up the database table to create from the text data. The destination database is set with the Select Output MDB File button. You can either create a new table in the database or select an existing table. Under Table Design, you can set the Field Name and Field Type for each attribute when a new table is being created. When adding to an existing table, the Field Name and Field Type are read from the existing table. For with an existing table, the Field Name list in the lower left will show the field names from the existing table, and the order of these fields should be set to match the order of corresponding the text fields. The Use Key Field To Match Value option will use the selected record as the key field for the database table. The key field must have unique values for each record in the table. To set the key field, highlight the record row # in the spreadsheet and then pick the Select button. The Create Carlson GIS Links option will link the database table with the drawing entity for each record.

After the dialogs, there is a command line prompt to select the text entities to import. For each text entity, the program finds the boundary perimeter from the drawing linework that encloses the text. These boundaries are used to separate the text labels into the groups that make up the table records.

Prompts

Select text to capture [Group/<Layer>]: *L for layer*

Keyboard Command: *cgis_getencltxt*

Prerequisite: text entities within linework perimeters

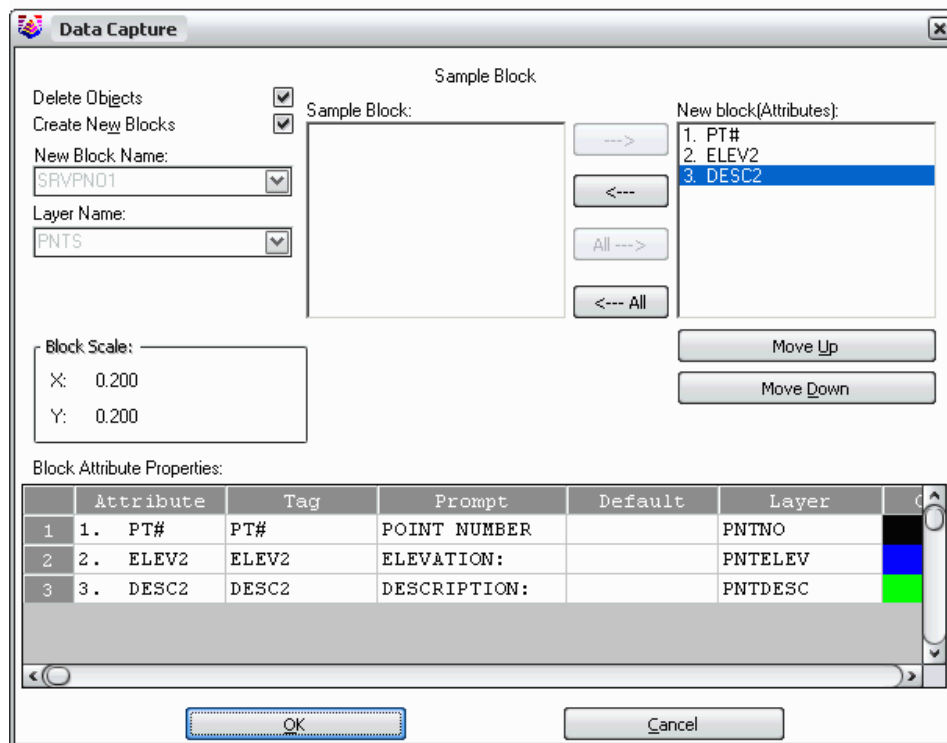

Data Capture Block Attributes

This command automates data transfer from block attributes to a database table. Many drawings are warehouses of information. The Data Capture Block Attributes command applies to drawings that contain blocks with attribute values.

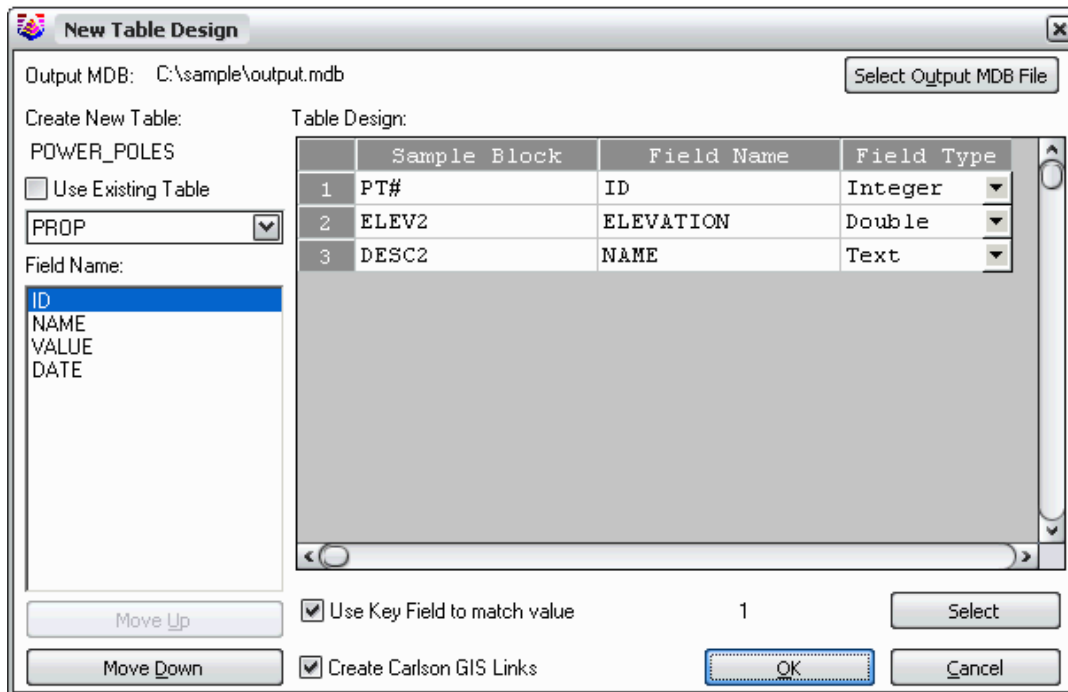

The command starts by prompting to select one sample of the block to capture. The program reads the attribute names from this sample block. This example uses Carlson point blocks that have attributes for point number, elevation and description.

Next, there is a dialog for specifying the attributes to capture and their order. Each sample attribute is available to capture by moving these fields to the block attribute list. There is an option to create a new block out of the selected attribute by turning on the Create New Blocks option. In the New Block Name and Layer Names fields, you can specify the name and layer for the blocks. The Delete Objects option will erase the source block entities. In the Block Attribute Properties spreadsheet, you can set the block tags, prompt, default and layer for each attribute.

The second dialog setups up the database table to create from the block data. The destination database is set with the Select Output MDB File button. You can either create a new table in the database or select an existing table. Under Table Design, you can set the Field Name and Field Type for each attribute when a new table is being created. When adding to an existing table, the Field Name and Field Type are read from the existing table. For with an existing table, the Field Name list in the lower left will show the field names from the existing table, and the order of these fields should be set to match the order of corresponding the text fields. The Use Key Field To Match Value option will use the selected record as the key field for the database table. The key field must have unique values for each record in the table. To set the key field, highlight the record row # in the spreadsheet and then pick the Select button. The Create Carlson GIS Links option will link the database table with the drawing entity for each record.

After the dialogs, there is a command line prompt to select the blocks to import. Only blocks that match the sample block names will be processed.

Prompts

Select sample block to capture: *select a block*

Processing entities...Please wait...

Select entities to process [Select/<All>]: *All*

Created 2 GIS Links.

Done

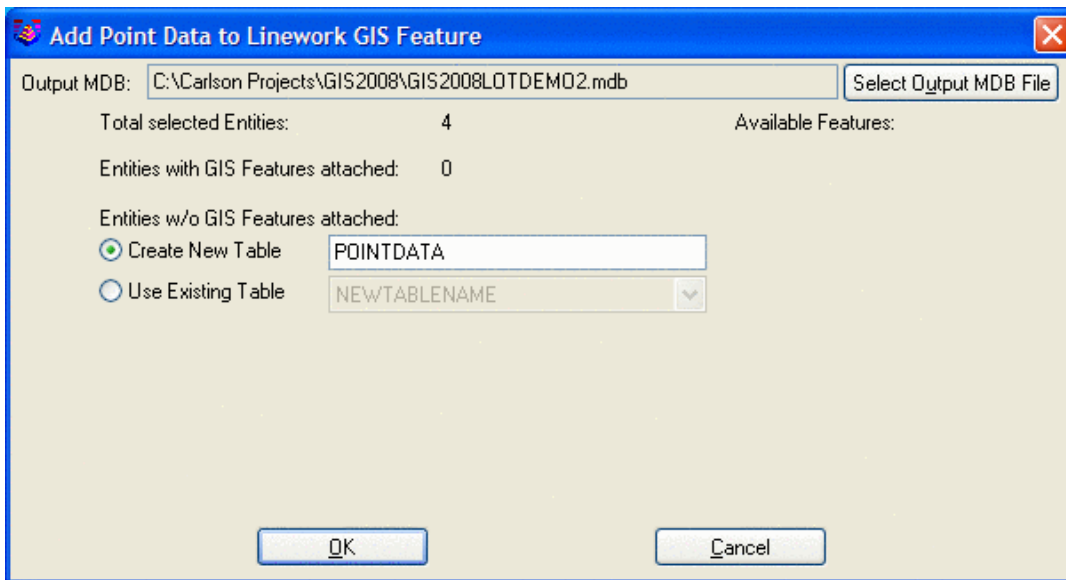

Pulldown Menu Location: GIS Data > Data Capture

Keyboard Command: `cgis_getblockattr`

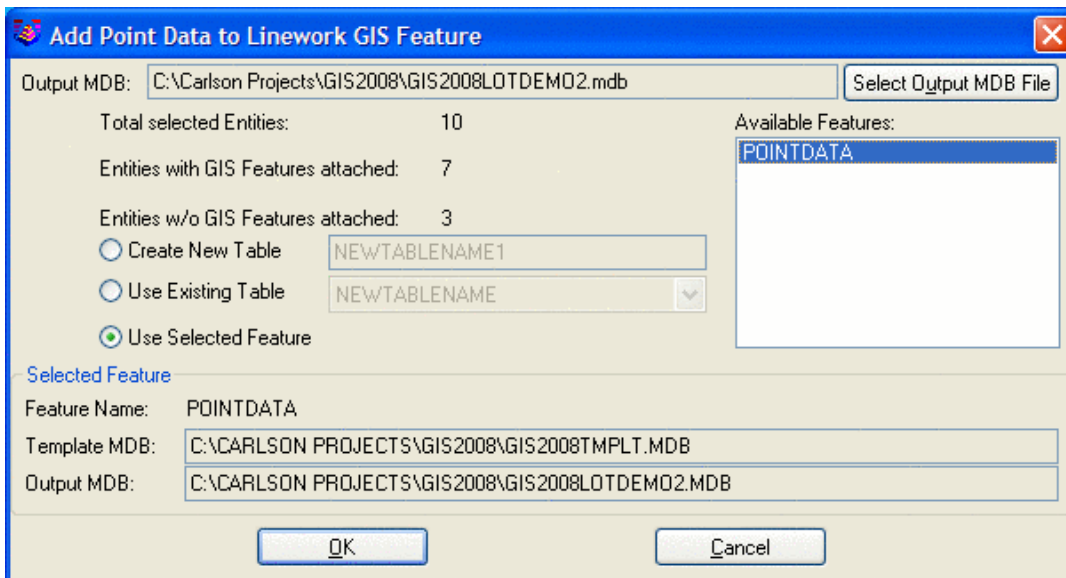

Prerequisite: Blocks with attributes

Data Capture Add Point Data to Linework

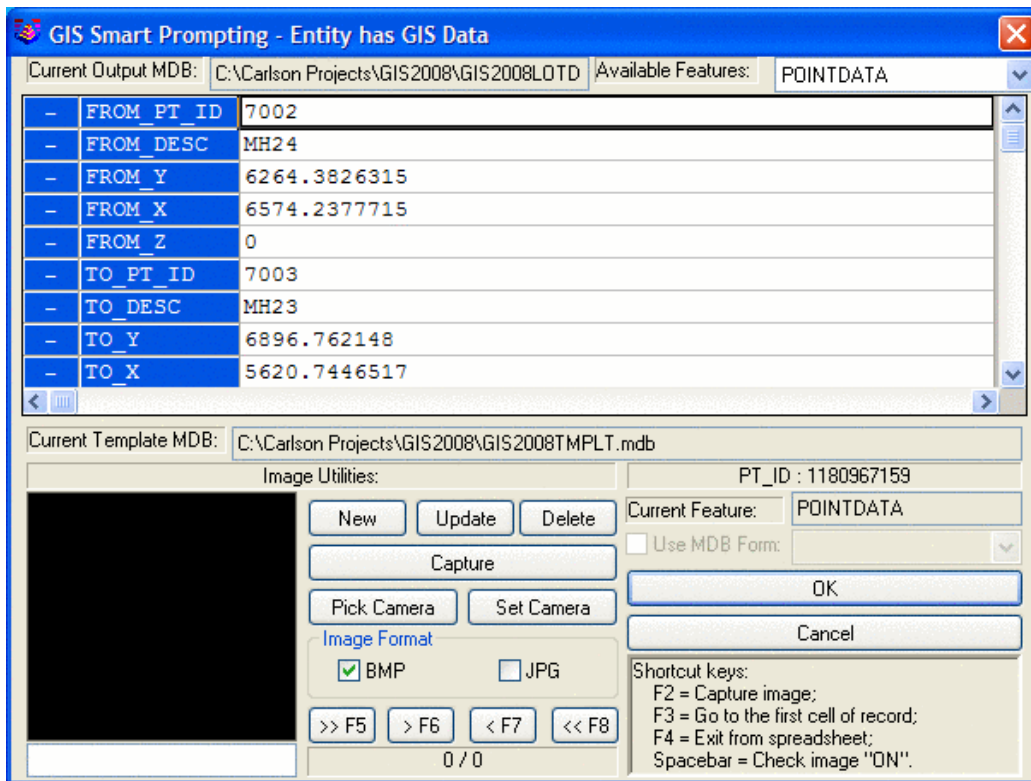

This command captures point data (Number, Northing, Easting, Elevation, Description) from Carlson Points at the ends of existing linework and writes that data to a table in the Output database. If the selected linework has no GIS data already attached, the following dialog is displayed:

If any of the selected linework has GIS data already attached, the following dialog is displayed:

In either case, you are asked to specify what table is to be used to store the point data. Once accomplished, using Input/Edit GIS data displays the point data now associated with the linework.

Prompts

Select linework entities: *select linework*

Pulldown Menu Location: GIS Data > Data Capture

Keyboard Command: gisptdata2linework

Prerequisite: Linework and Carlson Points

Label GIS Point Data

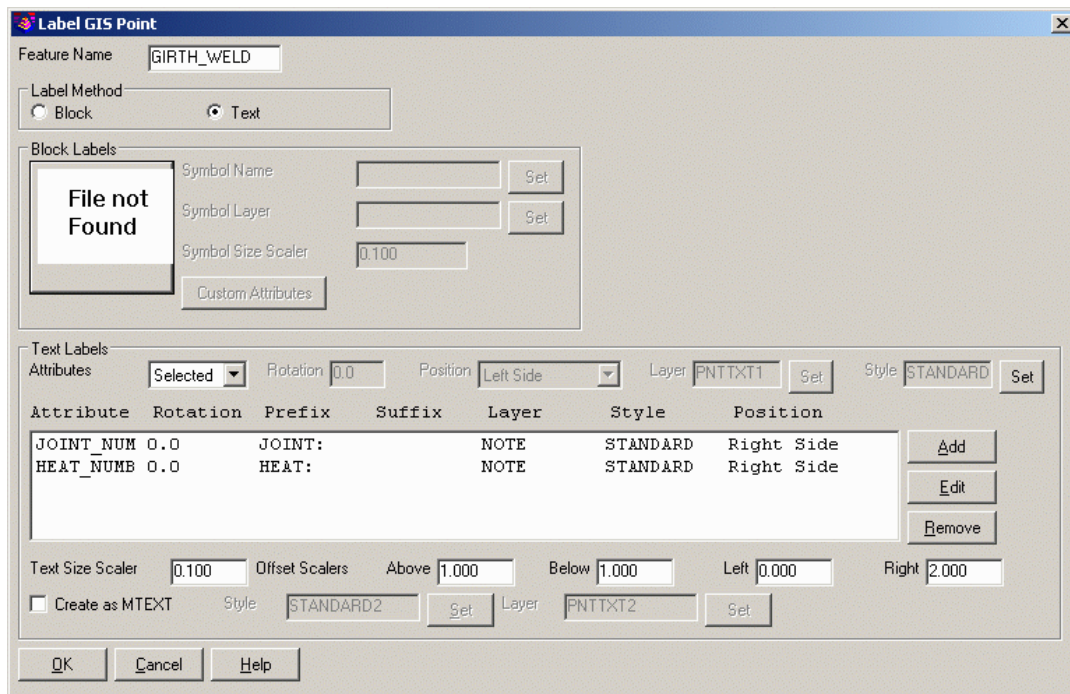

This command labels attributes for point features. The labels can be drawn as text entities or as blocks with attributes. Before running this command, use the Define GIS Features command to define the GIS point features and the attributes.

This command starts with a dialog to set the Label Settings file (.gpt) and the GIS Features file (.gis). The Label Settings file is used only for this command. Pick the Edit button to access the editor for the label settings.

The Label Settings dialog shows a list of the features with defined labels. Use the Edit, Add and Remove functions to manage the list.

The Edit and Add functions bring up the label editor dialog.

Feature Name: This name needs to match the feature name for the points as set by Define GIS Features.

Label Method: This settings chooses between creating text labels or blocks with attributes.

Block Labels

Symbol Name: This is the block drawing name. This drawing must have block attributes defined for filling out with the GIS attribute values.

Symbol Layer: The blocks will be drawn on this layer.

Symbol Size Scaler: Controls the size of the blocks. This size is multiplied by the current drawing horizontal scale to set the block size.

Custom Attributes: This function has another dialog for mapping the GIS attributes to the block attributes.

Text Labels

Attributes: Chooses whether to label all the attributes or specific attributes. When using All, there is one set

of settings for the Rotation, Position, Layer and Style for all the labels. For using Selected, there is a list of the attributes to label and the Add, Edit and Remove buttons are used to manage the list.

Text Size Scaler: Controls the size of the text entities.

Offset Scalers: Control how far to offset the labels from the point.

Create as MText: This groups all the labels into a single MText entity instead of individual Text entities for each attribute.

Prompts

Label GIS Points dialog

Select points to label.

Select objects: *pick Carlson points*

Pulldown Menu Location: GIS Data > Label GIS Data

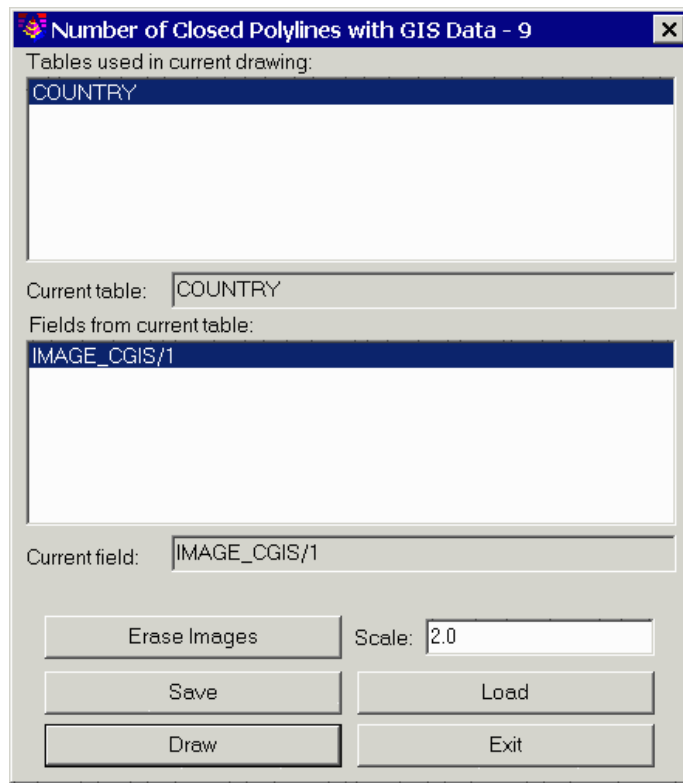

Keyboard Command: labgispt

Prerequisite: Carlson points with GIS attributes, Define GIS Features (.gis) file

Label GIS Polyline: Closed Polyline Image

This command draws images inside the selected closed polylines with attached GIS image files. Images can be assigned to polylines by the GIS Data Editor command.

The program starts by selecting closed polylines in the drawing with GIS data. Then a dialog appears for specifying the image to draw. This dialog displays a list of all the GIS table names found in the selected polylines. First choose a table to process. Then the image fields defined for this table are displayed in the lower list. Only one image can be drawn inside the polyline. The Erase Images button will erase any existing images inside the selected polylines. The settings can be saved to and recalled from a GIS settings file (.gsf) using the Save and Load buttons. Once all the settings are ready, pick the Draw button to draw the images. The images are drawn in the centroid of the polylines.

Example of images drawn inside closed polylines

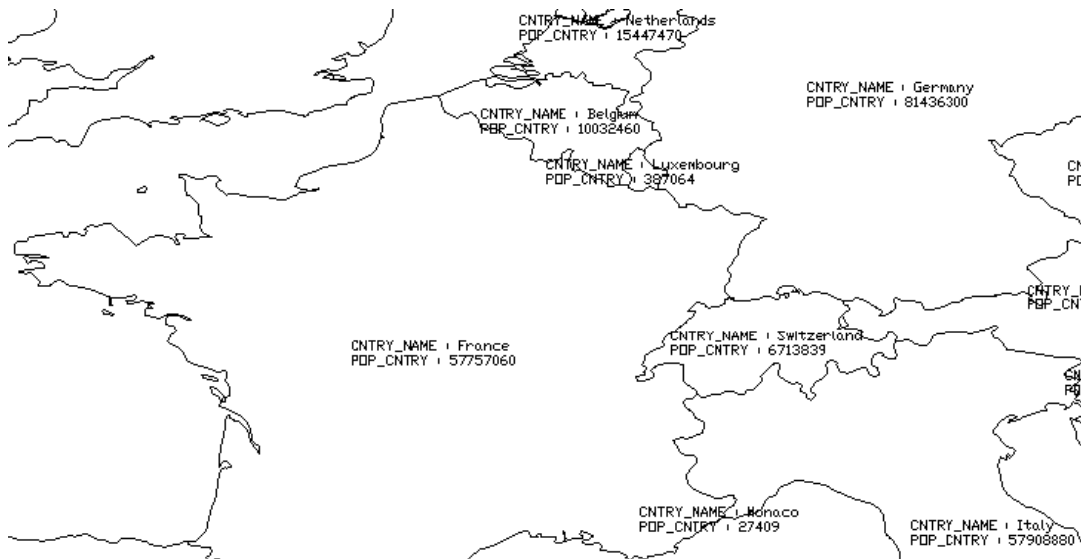

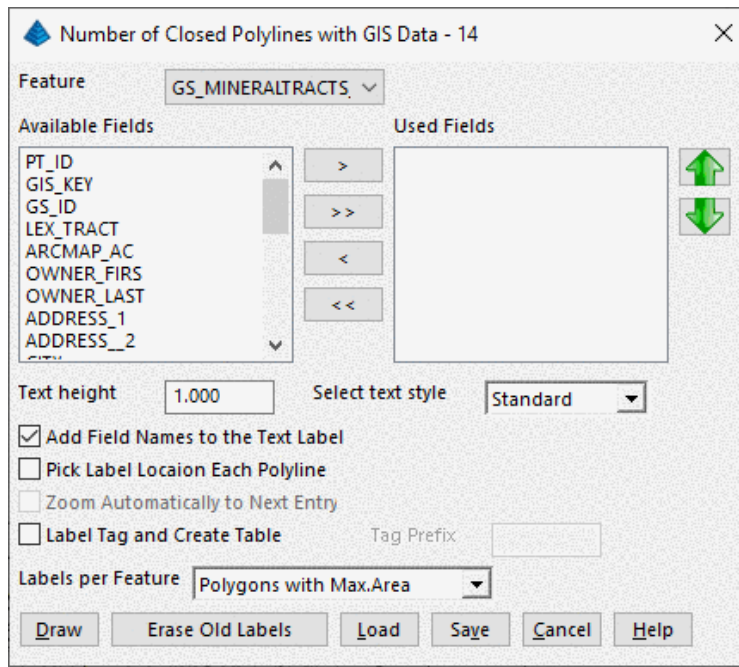

Pulldown Menu Location: GIS Data >Label GIS Data

Keyboard Command: display_polygon_image

Prerequisite: Closed polylines with linked GIS images

Label GIS Polyline: Closed Polyline Data

This command draws text labels for the specified fields inside the selected closed polylines with attached GIS data. The program starts by selecting closed polylines in the drawing with GIS data. Then a dialog appears for specifying the fields to label. This dialog displays a list of all the table names found in the selected polylines. First choose a table to process. Then the fields defined for this table are displayed in the lower left list. To add a field to the label, highlight the field name and pick the > button. The fields names in the lower right list are the fields to be labeled in order. Use the Up and Down buttons to change the field order. The settings can be saved to and recalled from a GIS settings file (.GSF) using the Save and Load buttons. Once all the settings are ready, pick the Draw button to create the labels. The labels are drawn center justified in the centroid of the polylines.

Label Closed Polyline Data result of country name and population fields

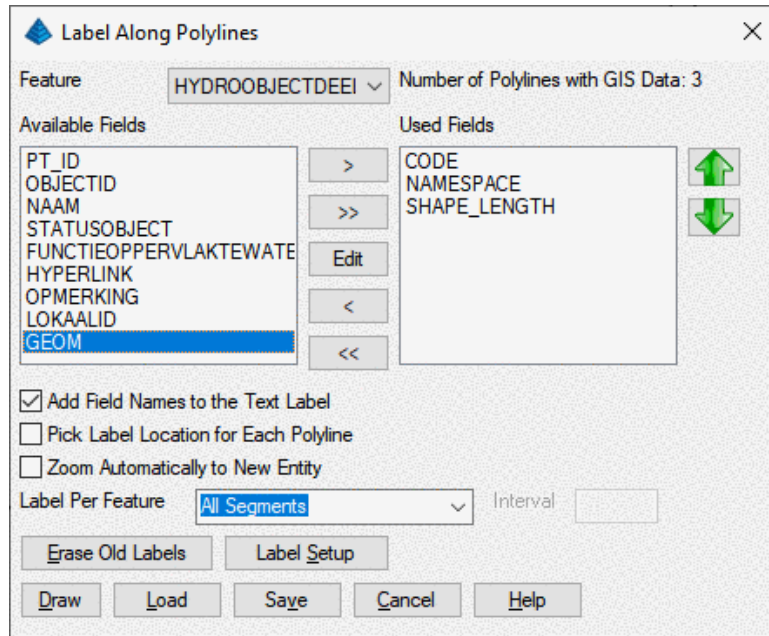

Pulldown Menu Location: GIS Data > Label GIS Data

Keyboard Command: label_polygon_text

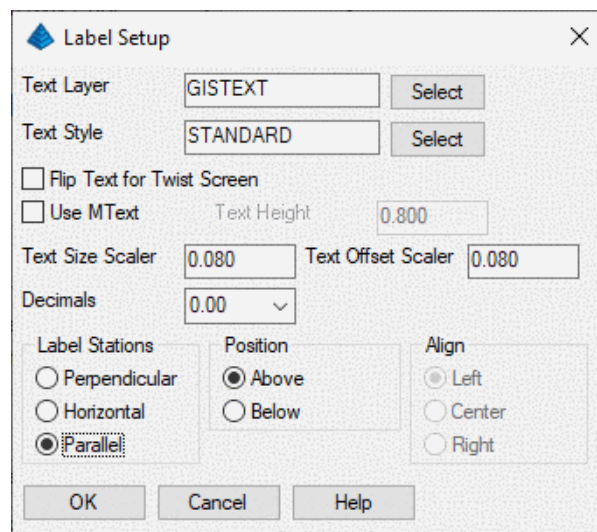

Prerequisite: Closed polylines with linked GIS information

Label GIS Polyline: Label Along Polylines

This command draws text labels for the specified fields along the selected polylines with attached GIS data. The program starts by selecting polylines in the drawing with GIS data. Then a dialog appears for specifying the fields to label. This dialog displays a list of all the table names found in the selected polylines. To label a field, highlight the field from the Available Fields list and pick the > button. Then use the Up/Down buttons to order the fields in the Used Fields list. The Erase Labels option will erase any existing field labels for the selected polylines. The settings can be saved to and recalled from a GIS settings file (.GSF) using the Save and Load buttons. Once all the settings are ready, pick the Draw button to create the labels. The labels are drawn along the polylines, and it is optional to label on all segments, maximum length segment or at interval. Also, it is optional to let the user pick label location for each polylines.

Use the Label Setup button to set parameters for the label in the used box.

Pulldown Menu Location: GIS Data > Label GIS Data

Keyboard Command: label_arc_text

Prerequisite: Polylines with linked GIS information

Links Manager

This command displays the GIS links for the selected entities and includes functionality of the GIS Data Editor, Create Links and Erase Links commands. The command starts by prompting you to select the entities to process. Then the program displays a dialog with a list of all the selected entity types (POINT, LINE, etc.).

To review and edit GIS data, highlight an entity type and the program will then list all the entities for that type. If a table is attached to the entity, the table name is displayed. Otherwise the entity reports "NO TABLE". The current table is shown in a spreadsheet editor at the bottom of the dialog. When you highlight an entity from the list, the linked record in the table is shown in the first column of the spreadsheet. Also the drawing is zoomed to the entity and a highlight box is drawn around the entity. You can use the arrow and magnify glass buttons to pan and zoom the display. The arrow, page up and page down keys also pan and zoom the display.

To add GIS data, highlight an entity from the list to process that has NO TABLE. Then select a table from the table pulldown list. The available tables for this list come from the Template MDB database shown in the top of the dialog. The spreadsheet then shows a record in the first column. Fill in the values and then pick the Create GIS Link button.

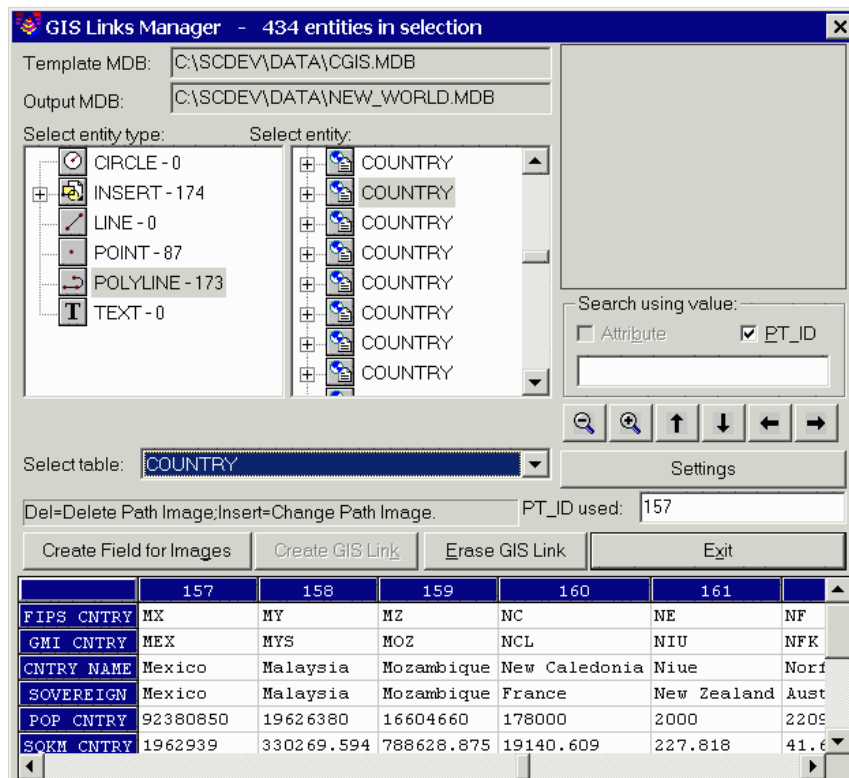

To erase a GIS link, highlight an entity from the list and pick the Erase GIS Link button.

The Create Field for Images button will add a field to the current table for image files. To add an image file, highlight the image field in the spreadsheet and press the Insert (Ins) key.

Under the Settings button you can set filters for the GIS links to process based on layer names, colors, polyline type and link status. You can also set the zoom factors for the screen display.

Prompts

Select objects: Select the entities, with linked GIS information, to process.

Pulldown Menu Location: GIS Data

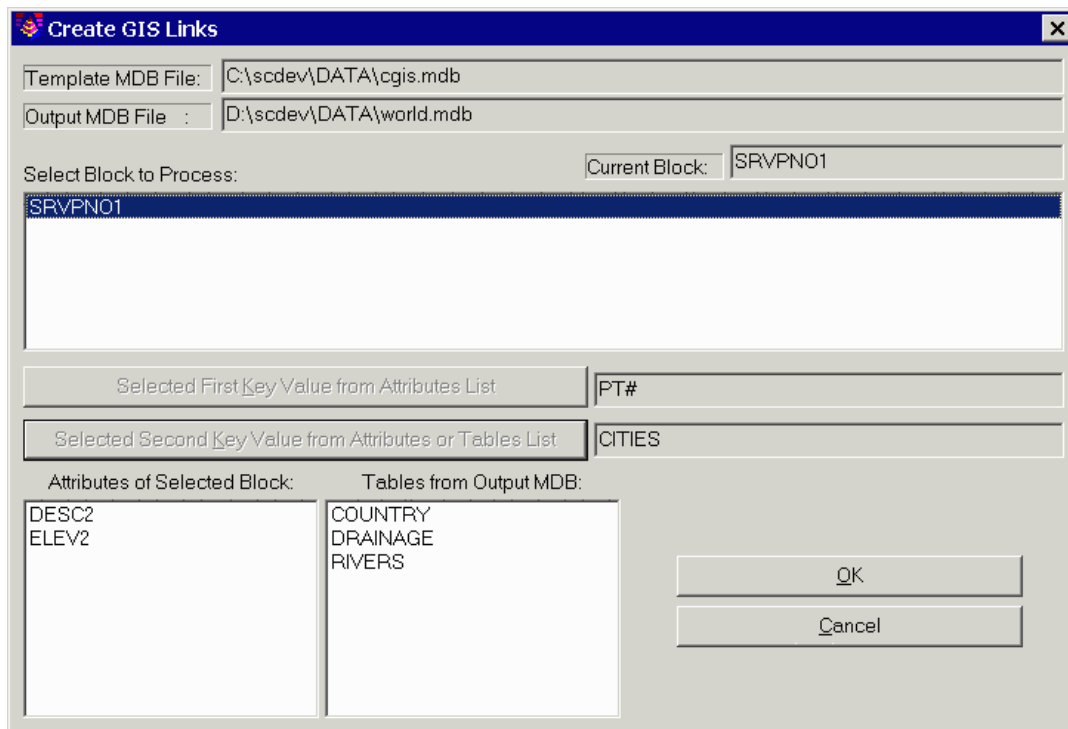

Keyboard Command: link_manager

Prerequisite: Entities with linked GIS information

Create Links

This command makes GIS links between blocks in the drawing and a database table using a key field that is in both the block attributes and the database table. Both the block entities and database records must exist before running this routine.

The routine starts by prompting you to select the block entities to process. Then a dialog appears for choosing the block attribute and table to link. The current template and output database file names are shown at the top of the dialog. Use the GIS Database Settings command to set these file names before running Create GIS Links. The dialog lists all the block names that were found in the entity selection. Choose a block name to process. Then in the lower left of the dialog, there is a list of the attributes for the selected block. Highlight the attribute name that contains the point ID key field for the blocks and then pick the Select First Key Value button. For each block entity, the program will use the value of this attribute to link to the record in database table. This value is matched to the database record using the PT_ID database table field. For example, a block with an attribute value of 402 for the specified attribute name will be linked to the database record with a value of 402 in the PT_ID field.

Next, the database table needs to be specified to either one fixed table name or to table names defined by a block attribute. A list of the available tables in the current output database is displayed. To link all the blocks to one table, highlight the table name from the list and pick the Select Second Key button. Or to link the blocks to various table names based on a block attribute, highlight the attribute name and pick the Select Second Key button. This attribute value for the blocks will then need to contain the database table name. For example, consider a block for electric utility data with two attributes: ID and TABLE. The ID is a number to use as the first key and the TABLE is the table name (i.e. POLE, BOX). Once the key fields are set, pick the OK button to create the links.

Pulldown Menu Location: GIS Data

Keyboard Command: create_links

Prerequisite: Block entities with attribute IDs and a database table with matching IDs.

Erase Links

This command removes all the GIS links from the selected entities (polylines, blocks, etc.).

Pulldown Menu Location: GIS Data

Keyboard Command: erase_links

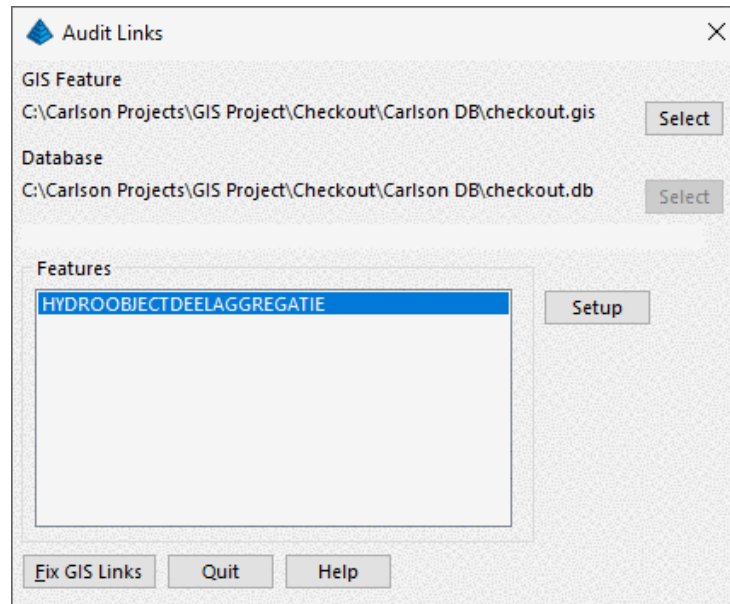

Prerequisite: Entities with GIS links

Audit Links

This command checks the GIS links for the selected entities in the drawing to make sure that the template database, output database and table exist. Any invalid links can be erased from the entities or be fixed by selecting another database or table. For example if a database file (.db) has moved to another directory, then you can use this command to specify the new location.

The routine starts by prompting you to select the entities to check. If no errors are found, then the routine is done. When there are errors, a dialog box appears. Each GIS link is defined by a template database, output database and table. For each combination of these three settings that have an error, this dialog displays the template database, output database and table name from the entities. The number of GIS link combinations with errors is shown in Table Used for Links field (i.e. 1 of 2). The template database is shown at the top. If the template database link is broken, then use the Select New Template DB button to assign another template database file. The output database

also has a Select New Output DB to set the output database file. In the lower left of the dialog is a list of the table names from the output database. You can choose the table to use for the link from this list. The Fix Links for Current Table button will assign the template database, output database and table name from the dialog to all the selected entities. The Erase Links from Table button will remove these broken links from the entities. The Go to Other Table button will process the next GIS link combination with errors.

Pulldown Menu Location: GIS Data

Keyboard Command: audit_links

Prerequisite: Entities with GIS links

Create GIS Polylines by Interior Text

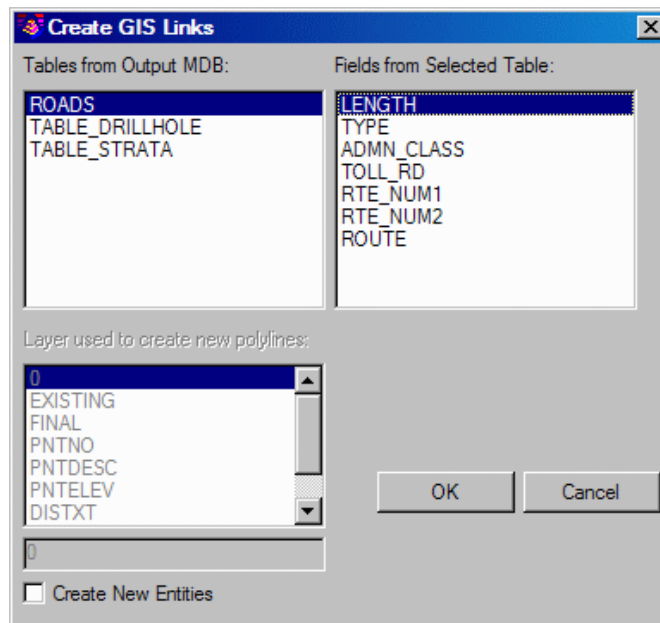

This command works with either Interior Text or Entity Handles. The initial choice of which to work with determines which dialog is displayed. In either case, the dialog box displays Tables from the Output MDB on the left, and the available Fields from that Table on the right. The use of Text gives the option of creating new GIS polylines on a specified layer by taking each text entity and creating a closed polyline around the text from the selected linework, using the text value as a field in the GIS data. If this option is not selected, the GIS data is added to existing polylines. Using Handles does not allow for the option to create new polylines.

Prompts

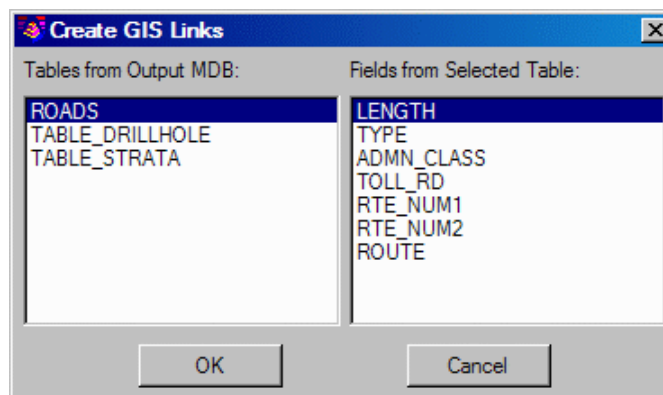

Use as key to match the records from the table Interior Text or Entity Handle[<Text>/Handle]? *press Enter*
Select lines, polylines and text. *select objects*

For the Handle option:

Use as key to match the records from the table Interior Text or Entity Handle[<Text>/Handle]? *press H*
Select lines and polylines *select objects*

Interior Text option dialog

Entity Handle option dialog

Pulldown Menu Location: GIS Data

Keyboard Command: cgis.txt2pl

Prerequisite: Text

Point GIS Editor

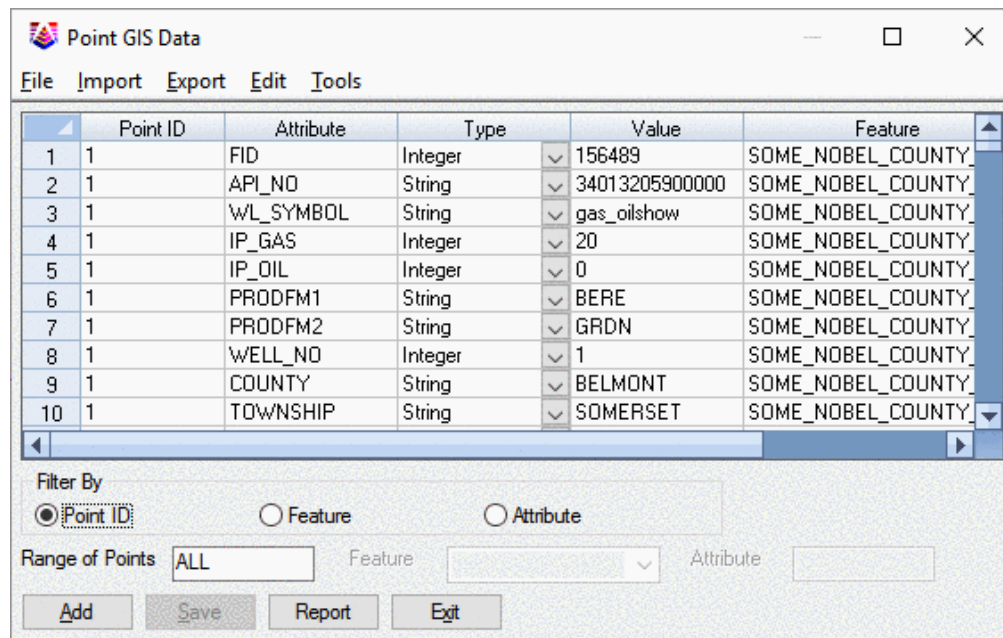

This command can be used to import, export, edit and report GIS data for points. The GIS data is stored in the current coordinate file which must be set to the CRDB format. To set this format, go to Points > Set Coordinate File and enter a file name with the .CRDB extension. To change a current coordinate file into CRDB format, go to Points > Coordinate File Utilities.

The program uses a spreadsheet for the GIS data sorted by point number. Each GIS record contains a point name, attribute name, data type, value and feature. The Point ID references a point name with x, y, z and description from the coordinate file. The Attribute is the name of the GIS data. The Type is the data type of String, Integer for whole numbers and Double for numbers that can have decimals. The Value is the actual GIS data value. The Feature is the name for a set of attributes. For example, Manhole could be a Feature name and the Manhole feature could have Attributes like material, size, condition, etc. The Feature name is optional.

The Filter By settings control the data shown in the spreadsheet. The Point ID method allows displaying data for a specified set of points. The Feature method displays data for the specified feature. The Attribute method displays data for the specified attribute. The Inclusion Perimeter method prompts to select closed polylines and only shows the point data that are inside the selected inclusion polylines.

You can edit directly in the spreadsheet. Use the Add and Delete functions to add or delete records from the spreadsheet. The Save function saves the GIS data to the CRDB. The Report function uses the Report Formatter to make a custom report of the GIS data.

The Import/Export menu has import/export functions to transfer various data with CRDB. These methods are described below. The Edit menu has Find, Replace, Delete Row, Delete Range functions. The Tools menu has a special function to add or subtract a GIS attribute value to the coordinate file elevations such as converting the rim elevations in the coordinate file to inverts by subtracting the depth attribute.

Import from SurvCE GIS Attributes(VTT)

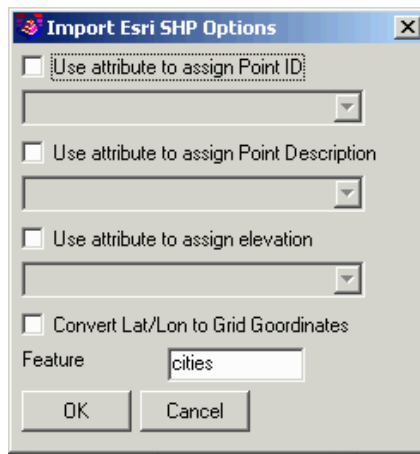

SurvCE stores GIS attribute data in a .VTT file. This file contains point numbers, attribute name, value and feature name which imports directly to the CRDB.

Import from Carlson Link

This method imports GIS data assigned to entities with the GIS Settings > Single File Database.

Import from ESRI SHP File

The SHP method imports from the ESRI SHP file. The import options include selecting which GIS attribute to use for the coordinate file point name, description and elevation. There is also a setting to convert the ESRI SHP lat/lon coordinates to grid coordinates which requires the grid projection to be already defined in the Drawing Setup command.

The MSC method reads the ESRI MSC data that is assigned to drawing entities.

Import from Google Earth File

This function reads GIS data contained in Google Earth KML or KMZ files. The program converts the lat/lon coordinates from the Google file into grid coordinates which requires the grid projection to be already defined in the Drawing Setup command.

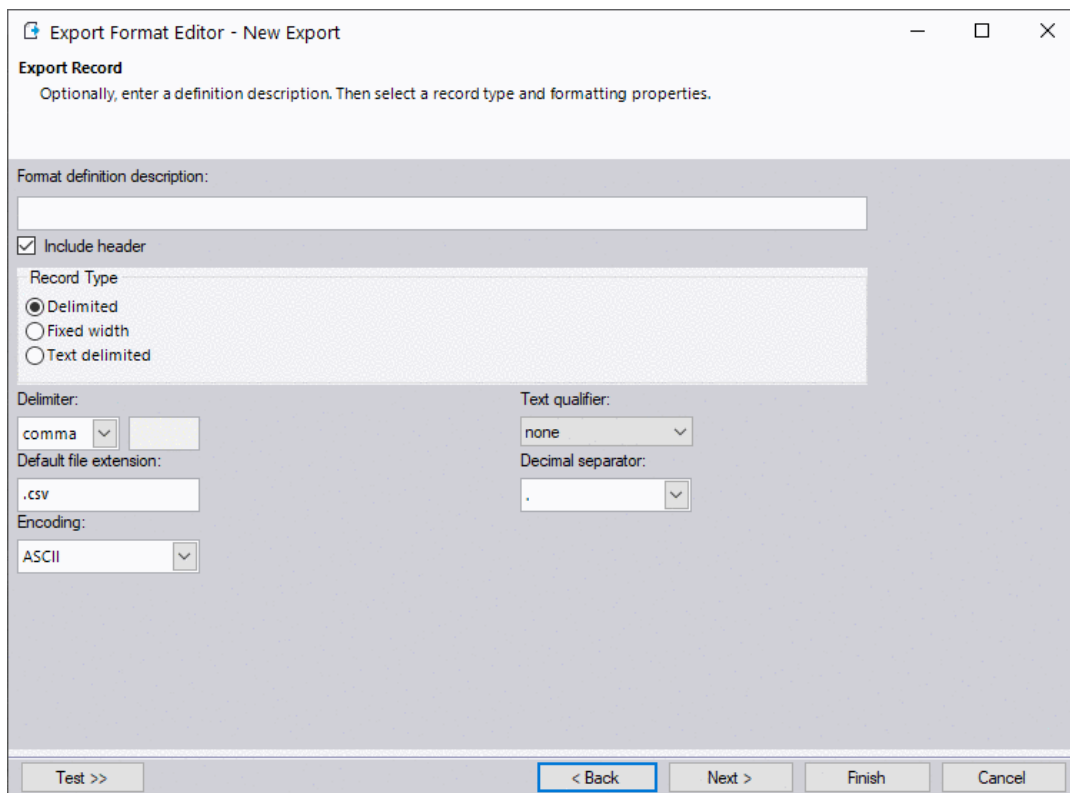

Import from StarNet PST File

This function import a PST file in from StarNet. It is required to define GIS Features first .

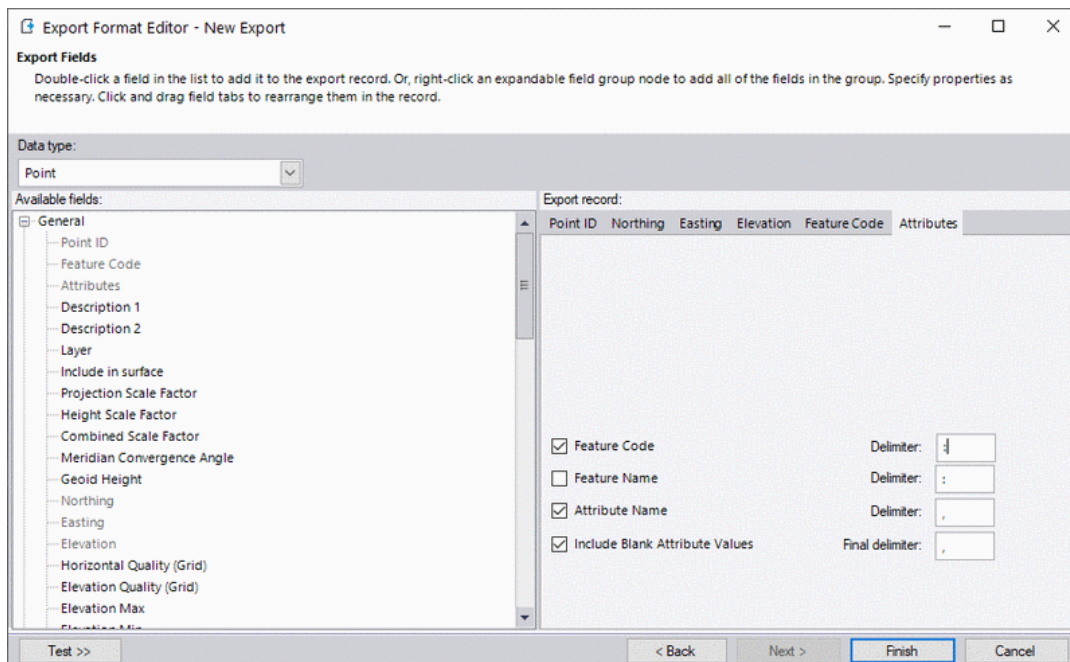

Import from Trimble CSV with Attribute File

This function imports a CSV file in from Trimble Business Center with point name and coordinates followed by attributes. Trimble allows users to modify the format of the CSV file, so it is important to match the format when exporting/importing. The below screenshots show the suggested options when using the Export Format Editor in Trimble Business Center, as well as the suggested import options in Carlson.

It is especially important to note that the encoding of the file should be set to ASCII, and the extension should be set to CSV.

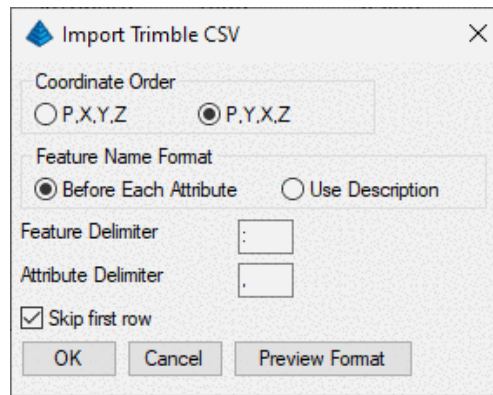

The Point ID, Northing, Easting, Elevation, Feature Code, and Attributes need to be included in the export. The main thing to modify will be the Attributes field, as shown below.

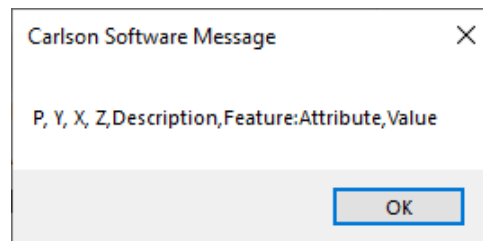

The below image shows the settings needed to import the CSV file exactly as it is configured with the above Export

Settings.

To ensure your import format matches your CSV file, you can click the Preview Format button to see exactly what the program will expect on import. An example is shown below.

Import from Trimble JXL

This import processes a Trimble JXL file which is an XML based text file.

Import from Text

This function reads the point attributes from a CSV/TXT text file. Before using this command, GIS features should be defined via the Define GIS Features command.

There are two import options on the below dialog - **Process Coordinate Info** and **Feature**. If the points are already defined in the coordinate file (Northing, Easting, Elevation, Description), then the **Process Coordinate Info** option can be disabled to only import the GIS data. If the points are not defined, you can enable this option to import the X,Y,Z,Desc for the points. The **Feature** dropdown list allows you to specify the GIS feature to associate with the newly imported data. Note that only one Feature may be selected, so if your data to import is associated with multiple features, they should be imported separately.

After selecting the appropriate options on the first dialog, the below formatter will appear. You will first need to select the delimiter used in your text file (most commonly a comma if using a CSV file). Each column must be defined used the dropdown list.

If you chose to Process Coordinate Info on the previous dialog, you will see 5 predefined fields: PointID, Northing, Easting, Elevation, and Description. When this option is enabled, you must specify a Northing and Easting for each point. If a PointID is not specified, the program will create one on import.

If you disabled the Process Coordinate Info option, the PointID will be the only predefined option. When this option is disabled, you will only need to specify a PointID for each point.

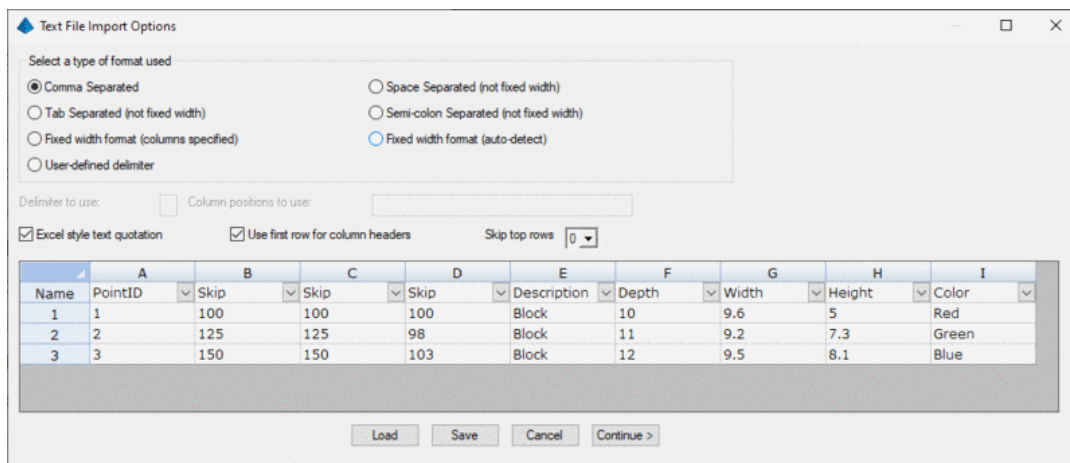

If a column does not need to be imported, you may use the Skip option for the column header to skip that row.

Each column aside from the predefined option is expected to be a GIS attribute. In the below image, four GIS attributes have been defined for Depth, Width, Height, and Color.

Use first row for column headers: When enabled, this option will use the first row of the .csv file to set the column headers. It is important to note when using this option, you should ensure that the column headers for PointID, Northing, Easting, Elevation, and Description are spelled properly, as any misspellings or abbreviations for these columns will prevent proper import.

Skip top rows: This option will skip the specified number of rows when importing. This is useful if you have header information in the .csv file. If you are using the first row for column headers, the row of headers will not be imported even if this value is set to zero.

Excel style text quotation: When enabled, the program will look for quotation marks around text in the .csv file and remove them. For example, if a piece of text is found in the .csv file such as "Red", it will only import Red.

Import from Database

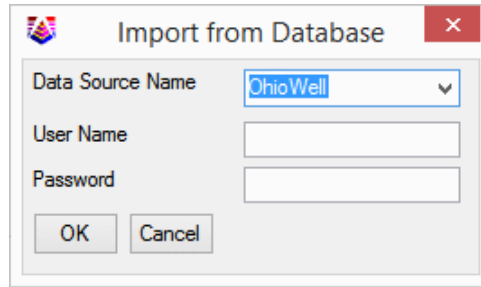

Step 1: Setup DB connection

Data Source Name = Specifies the name of the ODBC data source (DSN). The drop box contains all available DSN in the local host. Please see how to setup DSN at the end of this document.

User Name = Specifies the user name required to login to the RDBMS. (Optional)

Password = Specifies the password required to login to the RDBMS. (Optional)

Usually, DSN is sufficient to connect to the db, but there is some special case that user name and password are also needed. So User name and password are optional.

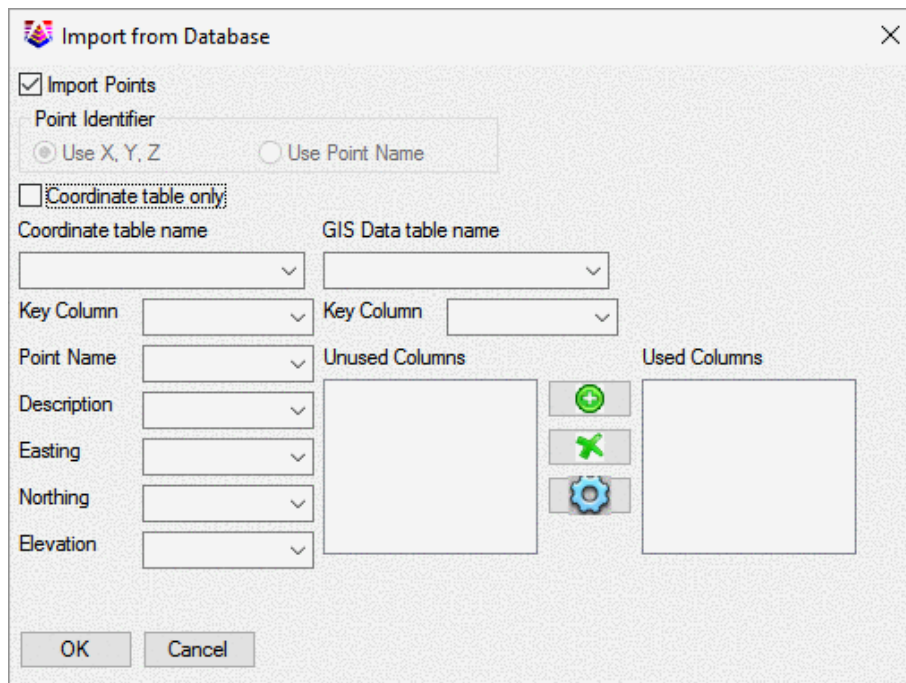

Note: need to hide the password.

Notes: 64 bits application will use 64 bits ODBC drivers. It is possible to connect 64 bits application to 32 bit ODBC driver, but it requires additional setup using ODBC-ODBC Bridge.

Click OK button to continue setup or Cancel button to exit

Step 2: Setup Data matching

Import Points - import points or skip them.

Point Identifier - use for identify points between the user data and CRDB coordinates. If the Import Points toggle box is not selected, then the dialog will prompt user to select the point identifier, either 'Use X, Y, Z' or 'Use Point

Name'.

Use X, Y, Z = use coordinate x, y, z value to identify point.

Use point Name - use point name to identify point.

Coordinate table only - coordinate table contains both coordinate info and GIS Data

Coordinate table name = the table name of the coordinates stored in the user db.

Key Column = a column which will uniquely identify a point.

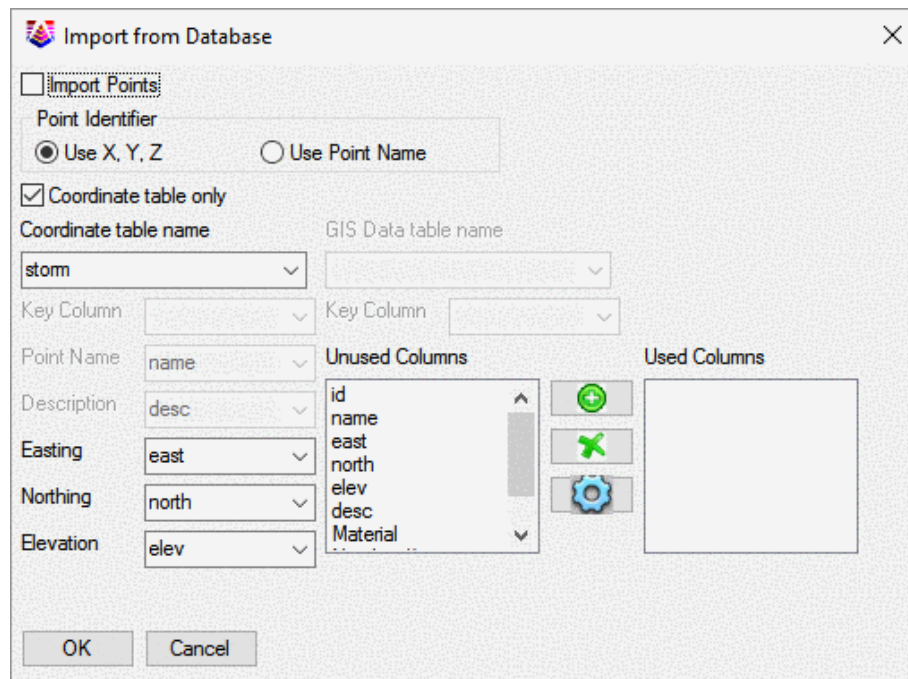

GIS Data table name = the table name of the GIS data stored in the customer's database. This table name will also be used as feature name in the CRDB.

Key Column = a column which will uniquely link to the coordinate table.

Currently, there are 6 fields in CRDB coordinates table, P, N, E, Z, D. P stands for Point Name. N stands for Y-coordinate. E stands for X-coordinate. Z stands for elevation. D stands for description. The Dialog uses Point Name, Description, Easting, Northing, and Elevation to represent the CRDB five columns.

If the 'Import Points' toggle box is selected, then all five fields will be enabled and list the name of the column in the coordinate table. The user needs to select corresponding column name. Column name could be used only once in these five field.

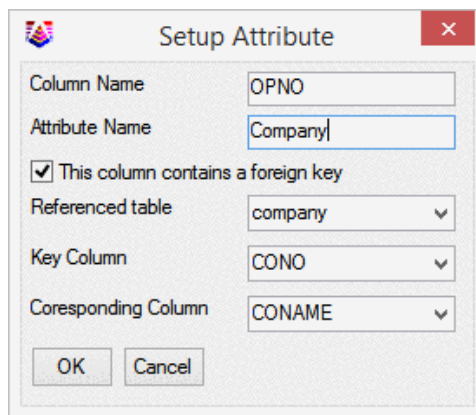

If the toggle box is not selected and if 'Use X, Y, Z' is selected, then 'Easting', 'Northing', and 'Elevation' will be enabled. Otherwise, only 'Point Name' will be enabled.

The 'Unused Columns' and 'Used Columns' are used for selection of the columns in the GIS Data table. The default content of 'Unused Columns' contains a list of columns in the GIS Data table. The user can Add/Delete/Setup each by selected it.

The Setup Button will allow user to setup the association between CRDB GIS Data attributes and the user database.

Step 3: Setup attributes

Column name = name of the column in the GIS Data table

Attribute Name = name of the CRDB GIS Data attribute.

This column contains a foreign key = If the value of the column doesn't contain actual data, but only a reference, then it contains a foreign key. For instance, a DB has a table name 'company' and a table name 'well'. A well belongs to a company, and a company has many wells. 'company' contains an ID and a name. A well will use the company ID to identify a company. In order to import the company name to the CRDB, the user needs to provide the name of the referenced table, the name of the foreign key and the name of the storage column.

Referenced table name = name of the referenced table

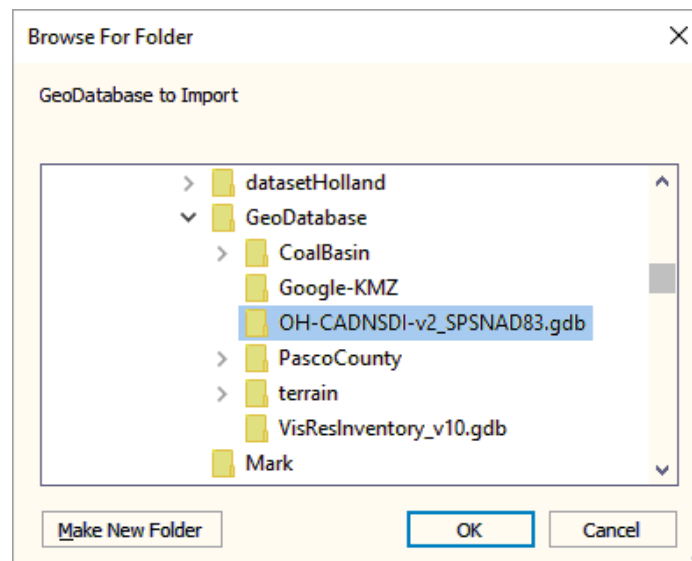

Key Column = name of the referencing key. This combo box contains all columns in the referenced table.

Corresponding Column = name of the column that data actually store. This combo box contains all columns in the referenced table.

If this toggle box is not selected, then actual data is stored in the GIS Data table.

Note: If user selected the same column for the Key Column and Corresponding Column, then just ignore the referenced.

Import ESRI File GeoDatabase to CRDB

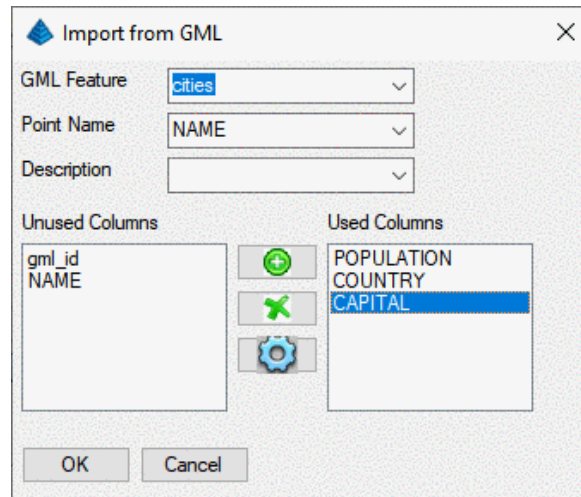

Step 2: Setup Data matching

It has the same interface as import from Database. Please see Import from Database section for detail.

Import OpenGIS GML File to CRDB

Select a feature from the list and select Point Name and Description fields. Also select unused columns and move to the used columns.

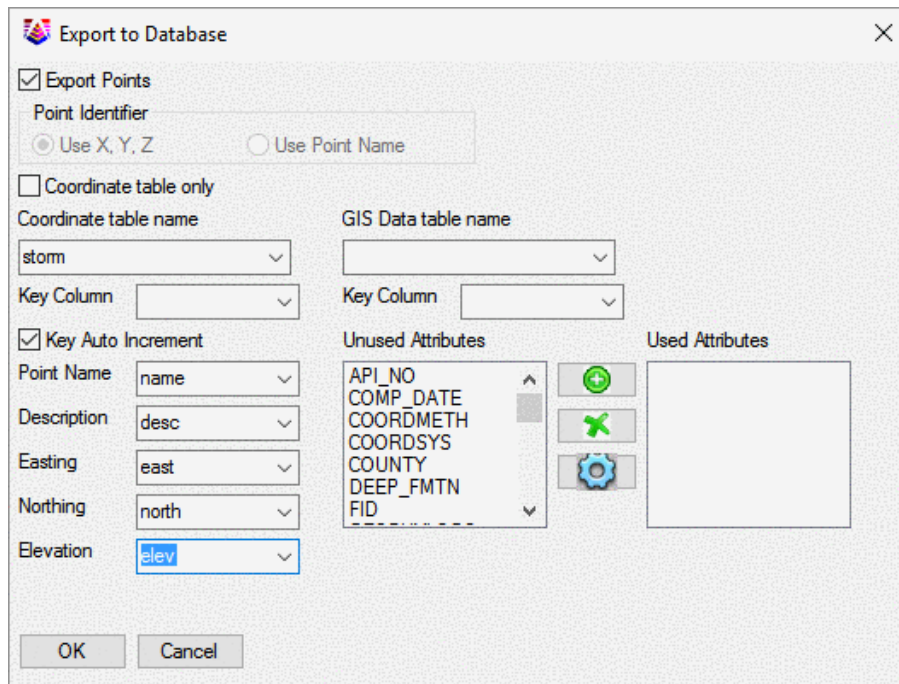

Export CRDB to a database

Step 1: Setup a db connection - this step is the same as import data from a database

Step 2: Setup data matching

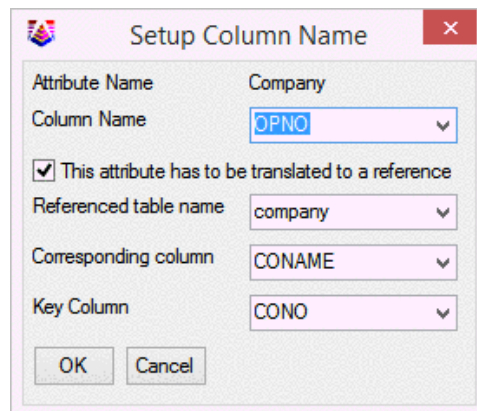

It is similar to import data from a database. Except the following,

Key Auto Increment -the user database will automatically increment the point identifier when a new point is inserted. If this toggle box is not selected, then the CRDB's point name will be used as the primary key. Then the Key Column and Point Name have to be the same column.

Instead of setup column, export function has to setup column. The Attributes list box contains a list of available attribute in CRDB GIS Data table. In order to setup the column, first, the user has selected an attribute name, and then clicks on setup button

Step 3: Setup the column name

Attribute Name = the name of attribute name in the CRDB GIS Data table.

Column Name = the name of column name in the user's GIS Data table.

This attribute has to be translated to a reference = data has to be translated and use the foreign key's value to store in the user's GIS Data table.

Corresponding column = the name of column that will match the value of the attribute

Key column = the name of column that will be the referenced key and stored in the user's GIS Data record.

Click OK button when complete setup. Cancel button to cancel and exit.

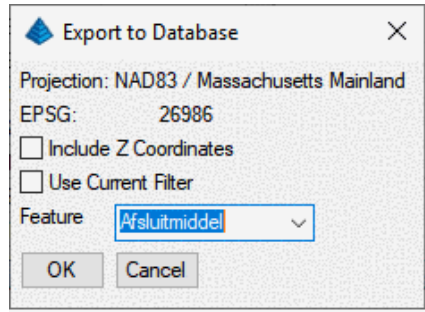

Export CRDB to ESRI File

GeoDatabase Note: make sure the GeoDatabase dataset/table is editable.

It has similar interface as export to a database.

Export CRDB to SQLite/Spatialite DB

After selecting an output file, the Export to Database dialog will display. The program will use the project which is setup in the Drawing Setup dialog. It is optional to include Z coordinates. The user can select any available point feature or select the current feature.

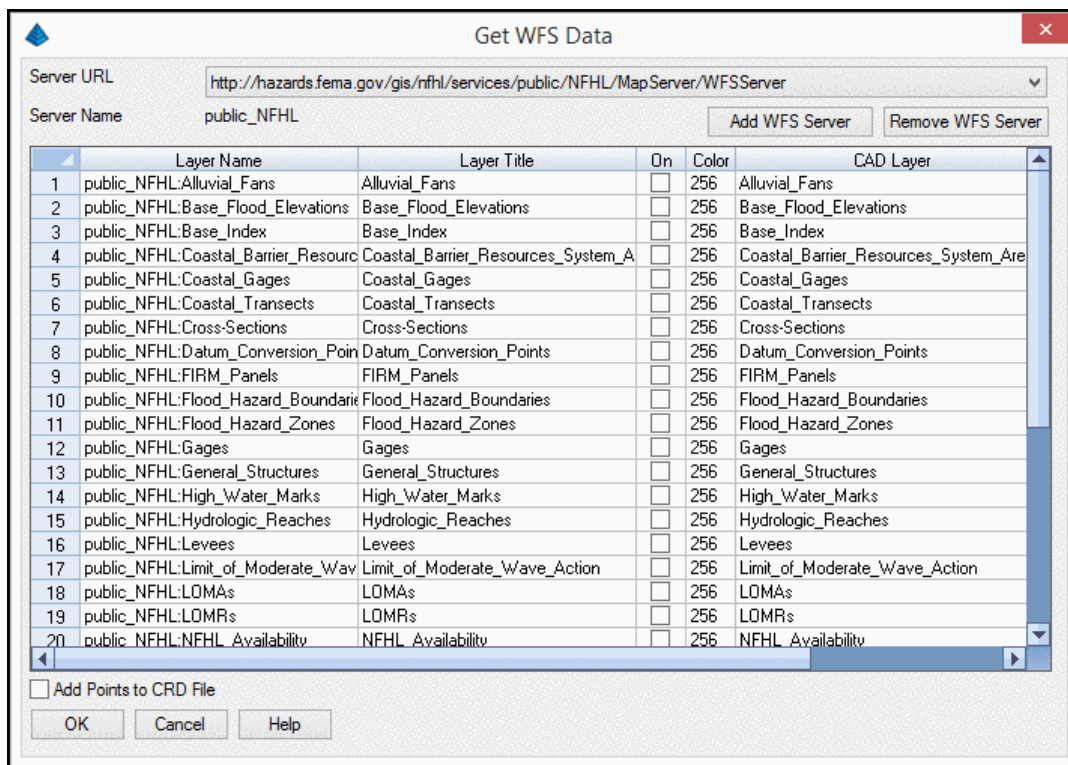

Pulldown Menu Location: GIS Data

Keyboard Command: gis_pt_editor

Prerequisite: Current coordinate file set to CRDB format

Web Feature Service (WFS)

The Web Feature Service (WFS) command provides an ability to fetch GIS data from on-line sources as a means to quickly and easily construct vector map data in and around an area of interest.

Server URL: Select the desired Uniform Resource Locator (URL) from where the geographical data will be obtained. The default URLs include:

- USGS National Map
- USDA NRCS Soil Data
- FEMA

Server Name: A read-only label identifying the name of the WFS server.

Add WFS Server: When clicked, the URL of a WFS server may be input that is subsequently added to the Server URL drop-list.

Remove WFS Server: Deletes the currently selected WFS Server from the Server URL drop-list. Prior to the removal of the WFS Server, a confirmation alert box will be displayed asking for confirmation. Any data previously placed into a drawing from the WFS Server will remain in the drawing.

Add Points to CRD File: When enabled and if point data exists for the selected layer, those points will be added to the current coordinate file.

Retrieved Feature(s): As a WFS Server is selected, its list of Features is returned for further manipulation:

- **Layer Name:** The geographical "layer" of data in a read-only format.
- **Layer Title:** The title of the geographical "layer" of data in a read-only format.
- **On:** When enabled, the content of the Feature is eligible to be imported into the drawing based on the bounding box prompts.
- **Color:** Double-click on the desired Feature Color to expose a standard "color-picker" dialog box.
- **CAD Layer:** Key-in the desired Layer name in CAD to house the Feature data and/or double-click on the desired Feature CAD Layer to expose a "layer selector" dialog box.

After layers have been selected, click **OK** and the data for each will be imported.

Note:

- Several freely available WFS addresses can be found at the USGS National Map Viewer.
- Your local governing agency could/should be consulted to see if they publish any data via their own WFS.
- Before starting this command, you might find it useful to position yourself in the desired coordinate location by utilizing the Place Google Earth Image command.
- Data limits fetched by bounding box is based on the following logic:
 1. Point features - only points within the bounding box are returned.
 2. Linear features - only polylines inside or crossing the bounding box are returned.
 3. Polygon features - polygons inside or crossing the bounding box are returned. Additionally, polygons that completely enclose the bounding box are returned (think of the polygon as a solid object upon which the bounding box is etched).

Prompts

Pick first corner of bounding box: *Indicate one corner of a rectangular box that identifies your area of interest.*

Pick second corner of bounding box: *Indicate the other corner of a rectangular box that identifies your area of interest.*

- To import Esri ArcGIS On-line Services data into your drawing, use the Esri ArcGIS Services - Retrieve Map command.
- To import Web Map Service images into your drawing, use the Place Web Map Service (WMS) Image command.

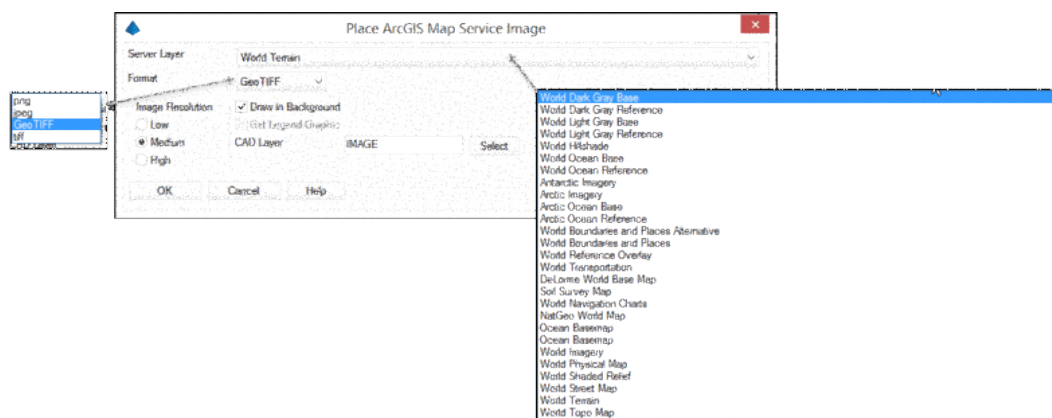

Pulldown Menu Location(s): GIS Data

Keyboard Command: getwfsdata

Prerequisite: Internet connection, Coordinate System Projection set through Drawing Setup

ESRI ArcGIS Services

The ESRI_ArcGIS_Services command provides access to existing ESRI image files.

Server Layer: Contains a list of available image files from the ESRI library

Format Type: Select the image format type from:

- PNG
- JPEG
- GeoTIFF
- tiff

Image Resolution: Sets the resolution for the image as low, medium or high. The resolution may depend on the image selected, display settings and hardware.

Draw in Background: When enabled, sets the draw order to place the image in the background.

Get Legend Graphic: When available, draws a legend graphic.

CAD Layer: Sets the layer for the image file to placed in the drawing.

After selecting the server layer, click **OK** and the data will be imported.

Prompts

Pick first corner of bounding box: *Indicate one corner of a rectangular box that identifies your area of interest.*

Pick second corner of bounding box: *Indicate the other corner of a rectangular box that identifies your area of interest.*

Image File to Save: *Create a name for the image file that will be imported.*

- To import other Web Based Layers into your drawing, use the Web Feature Service (WFS) command.
- To import Web Map Service images into your drawing, use the Place Web Map Service (WMS) Image command.

Pulldown Menu Location(s): GIS Data

Keyboard Command: eagmsExport

Prerequisite: Internet connection, Coordinate System Projection set through Drawing Setup

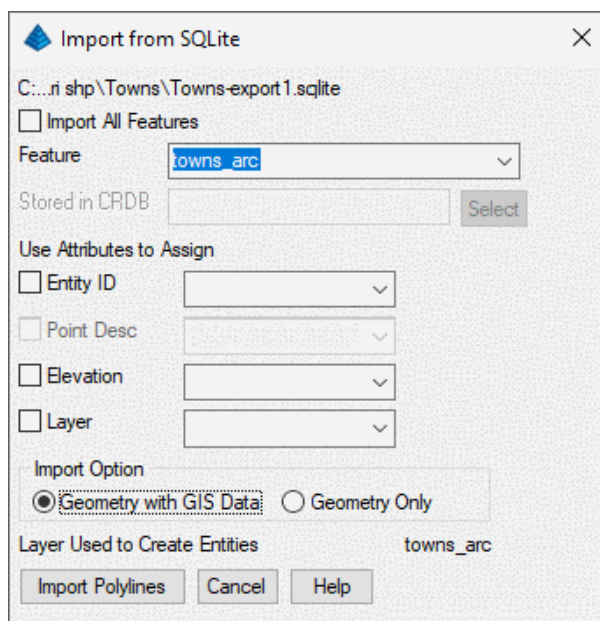

Import SQLite

The import SQLite file commands convert SQLite/Spatialite DB files into Carlson drawing entities. It is optionally write the available attribute data to GIS Data Format which specified in GIS Settings dialog, and the command create GIS links between the drawing entities and the records in the database. If SQLite/Spatial DB is selected as

the GIS Data Format in the Drawing Setup dialog, then the program will only create GIS links between the drawing entities and the records in the database.

There are primarily three types of DB files: Points/ MultiPoint, LineStrings/MultiLineString and Polygons/MultiPolygon. Each will provide different options on Import. Once the GML file is selected, Carlson detects the data contents of the file and sets the dialog options for importing either polygons, linestring or points. LineStrings are brought into Carlson as open polylines and Polygons are as closed polylines in the drawing.

Import from SQLite dialog will list all available tables in the DB File. The user can select import all tables or one of the tables in the list. Then select corresponding fields for the Point ID/Entity ID, Description, Elevation and Layer, etc. The selected fields would be used to fill Carlson internal fields. If no field is selected for Point ID/Entity ID, then the program will create a unique ID for each entity. If no field is selected for Point Desc, then the description will leave blank. If no field is selected for Layer, then the table name will be used as layer name. If the feature type is Point/MultiPoint, then it will allow user to select a name for the CRDB. The program then will also output points geometry and GIS Data to CRDB.

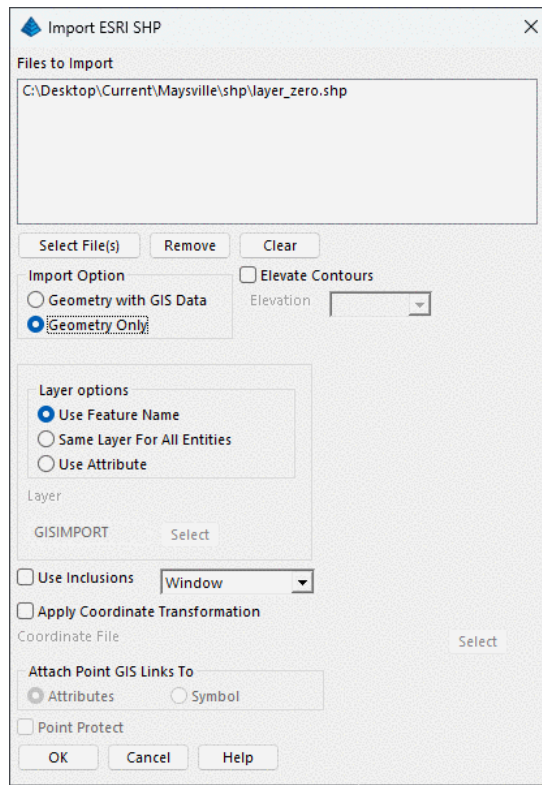

Pulldown Menu Location: GIS Data ->Import GIS Data -> Import from SQLite

Keyboard Command: import_sqlite

Prerequisite:need to specify GIS Feature File, GIS Data Format

Import ESRI SHP File

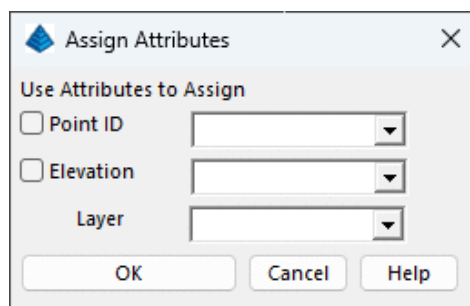

The import function allow one or more SHP to import at once. The Select File(s) can selected more than one file. This command converts ESRI SHP files into Carlson drawing entities and can also optionally write the available attribute data to an external data source which was defined in GIS Database settings. There are two Import Options, Geometry with GIS Data or Geometry only. If the Geometry with GIS Data is selected, then the GIS Data will be imported. Otherwise, if Geometry only is selected, then only the entities will be drawn .

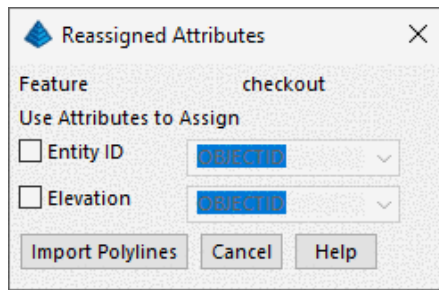

It is required to specify layer name which the entities will be created. There are three options for the layer name, Use Feature Name, Same Layer For All Entities, and Use Attribute Name. If the Same Layer For All Entities is selected, then it is required to enter the Layer Name. If the Use Attribute Name is selected, then it is required to pick a attribute name from the feature's attribute list. This option is only available if there is only one Shapefile selected.

There are primarily three types of ESRI SHP files: Points, Arcs and Polygons. Each will provide different options on Import.

If there is a points SHP in the file list, then the user has the option to setup Attach Point GIS Links to either Attributes or Symbol. Also the user can select Point Protect. Point SHP files are imported in a three step process. The first step uses the Import SHP File command to create a coordinate file (.crd/.crdb) for the points in the SHP file and a corresponding table in the the points database. The second is to use Draw Locate Points to draw the points from the CRD/CRDB file into the drawing. The third step uses Create Links to select the points in the drawing and link the database to these plotted points. Currently, we only allow you to configure attributes for the coordinate file if the Shapefiles have the same schema.

If the SHP file is Arcs or Polygons, then it is possible to reassigned attributes for entity ID or Elevation.

Note: If the SHP file you are Importing is in a different Projection or Units than that specified in the Drawing Setup, then a transformation will occur during Import, as long as the (.PRJ) Projection file is present with the SHP set of files. If there is no (.PRJ) file with the SHP, then no transformations will occur.

Pulldown Menu Location: GIS Data

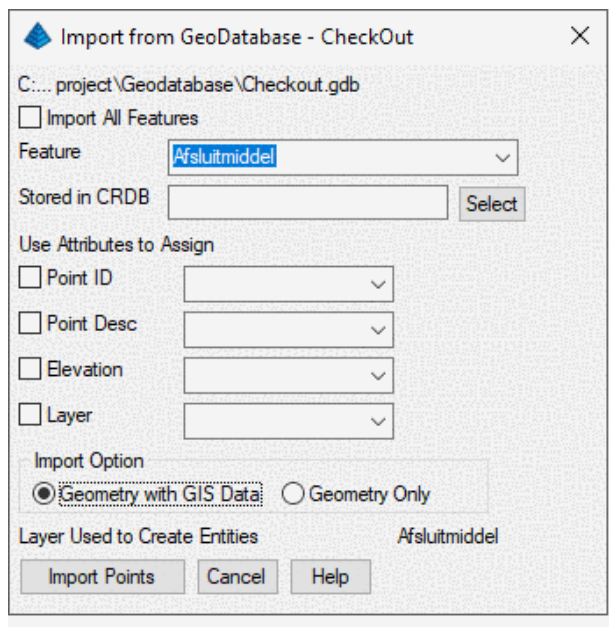

Keyboard Command: import_shp

Import ESRI GeoDatabase

The import File GeoDatabase commands convert File GeoDatabase into Carlson drawing entities. It is optionally write the available attribute data to GIS Data Format which defined in GIS Settings dialog. The command creates GIS links between the drawing entities and the records in the database.

There are primarily three types of GeoDatabase files: Points/MultiPoint, Polylines/MultiLineString and Polygons/MultiPolygon. Each will provide different options on Import. Once the GeoDatabase file is selected, Carlson detects the data contents of the file and sets the dialog options for importing either polygons, polylines or points. Polylines are brought into Carlson as open polylines and Polygons are as closed polylines in the drawing.

Import from GeoDatabase dialog will list all available features in the GeoDB File. The user can select import all features or one of the features in the list. If the user selected one of the feature from the list, then the user can select corresponding fields for the Point ID/Entity ID, Description, Elevation and Layer, etc. The selected fields would be used to fill Carlson internal fields. If no field is selected for Point ID/Entity ID, then the program will create a unique ID for each entity. If no field is selected for Point Desc, then the description will leave blank. If no field is selected for Layer, then the feature name will be used as layer name. If the feature type is Point/MultiPoint and also "Enable Store/Read Point GIS Data to/from SQLite(CRDB) File" is selected in GIS Settings dialog, then the user can select a name for the CRDB. The program will also output points geometry and GIS Data to CRDB.

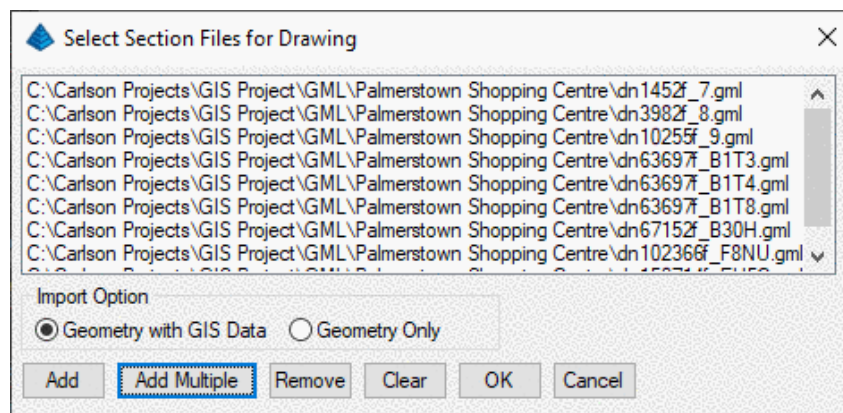

Pulldown Menu Location: GIS Data -> Import GIS Data -> Import from ESRI GeoDatabase

Keyboard Command: import_geodb

Prerequisite: need to specify GIS Feature File, GIS Data Format

Import OpenGIS GML

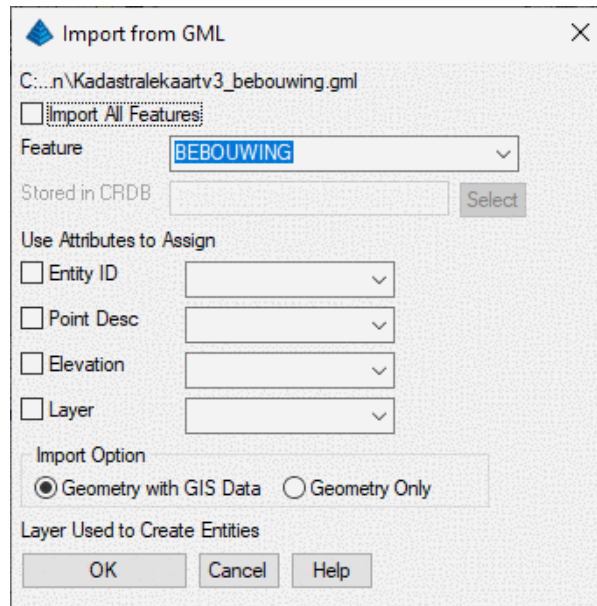

This command converts Open GIS GML files into Carlson drawing entities and can also optionally write the available attribute data to GIS Data Format which defined in GIS Settings. The command creates GIS links between the drawing entities and the records in the data source.

There are primarily three types of GML files: Points/Multipoint, LineStrings/MultiLineString and Polygons/MultiPolygon. Each will provide different options on Import. Once the GML file is selected, Carlson detects the data contents of the file and sets the dialog options for importing either polygons, linestring or points. LineStrings are brought into Carlson as open polylines and Polygons are as closed polylines in the drawing.

If single file has been selected, then it would display Import from GML dialog. This dialog will list all available features in the GML File. The user can select import all features or one of the features in the list. Then select corresponding fields for the Point ID/Entity ID, Description, Elevation and Layer, etc. The program uses the

GML feature name as the table name in the data source. The selected fields would be used to fill Carlson internal fields. If no field is selected for Point ID/Entity ID, then the program will create a unique ID for each entity. If no field is selected for Description, then the description will leave blank. If no field is selected for Layer, then the table name will be used as layer name. If the feature type is Point/MultiPoint, then it will allow user to select a name for the CRDB. The program then will also output points geometry and GIS Data to CRDB.

If multiple files have been selected, then it will not prompt for importing setting. It will automatically create a unique ID for each entity and use the feature name as the default layer name.

Pulldown Menu Location: GIS Data -> Import GIS Data -> OpenGIS GML

Keyboard Command: import_gml

Prerequisite: need to specify GIS Feature File, GIS Data Format.

Import GIS Data from SurvCE

This command reads GIS attribute data collected and imports it into the drawing and embeds it within the point blocks in the drawing as Esri MSC that can be read directly by ArcGIS. There are two import methods for SurvCE and TDS. With SurvCE, the setup is to have a coordinate file (.CRD) set current, the points drawn in the drawing, an applicable attribute definition file (.GIS), and a file that is storing the attribute values (.VTT), that was created by SurvCE. You are prompted to pick the GIS file, and then the data from the VTT is imported and embedded within the matching point blocks in the drawing. With TDS, the process is the same except that the attribute data comes from a TDS .RW5 or .RAW file instead of a .VTT.

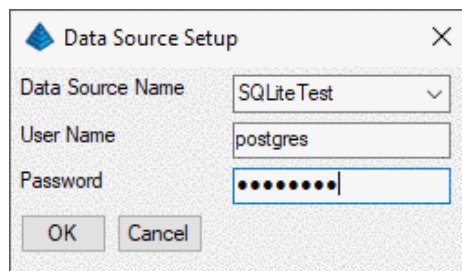

Pulldown Menu Location: GIS Data

Keyboard Command: survce2msd, tds_gis

Prerequisite: GIS file, CRD file, VTT file, or TDS .RW5/.RAW, and points in drawing

Import ODBC data source

This command use ODBC Connection to connect third party database and import database's GIS Data into Carlson drawing entities. It also optionally write the available attribute data to different format which defined in GIS Settings dialog.

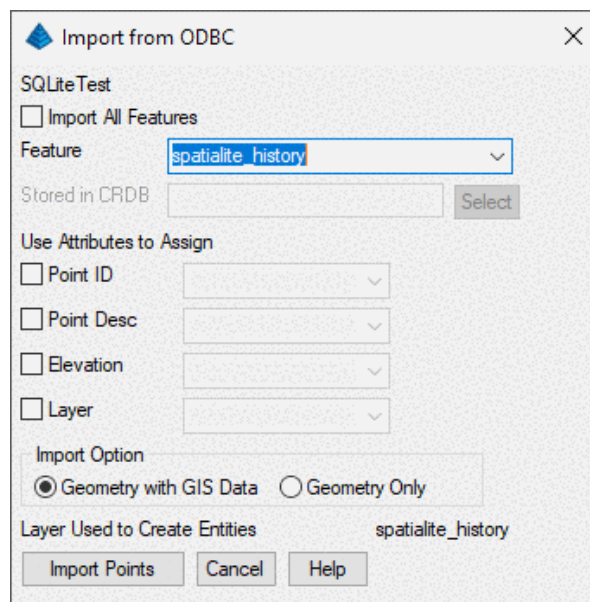

Data Source Name - a data source is a source of data combined with connection information that is required to access that data. Please see How to Setup ODBC Data Source

User Name - RDBMS login name

Password - RDBMS password

After clicked on OK, the program will connect to the data source and display the following setup dialog. This dialog will list all available features in the data source. The user can select import all features or one of the features in the list. Then select corresponding fields for the Point ID/Entity ID, Description, Elevation and Layer, etc when only one of the tables is selected. The selected fields would be used to fill Carlson internal fields. If no Point ID/Entity ID is selected, then it will use the table's primary key as the Point ID/Entity ID. If no field is selected for Description, then the description will leave blank. If no field is selected for Layer, then the table name will be used as layer name. If the table's geometry type is Point/MultiPoint and also "Enable Store/Read Point GIS Data to/from SQLite(CRDB) File" is selected in GIS Settings dialog, then it will allow user to select a name for the CRDB. The program then will also output points geometry and/or GIS Data to CRDB.

Currently, the program only supports the following geometry types, Points, LineStrings, Polygons, MultiPoint, MultiLineString and MultiPolygon. Once the table is selected, Carlson detects the geometry types of the table and sets the dialog options for importing either points, linestrings, or polygons. LineStrings/MultiLineString are brought into Carlson as open polylines and Polygons/ MultiPolygon are as closed polylines in the drawing.

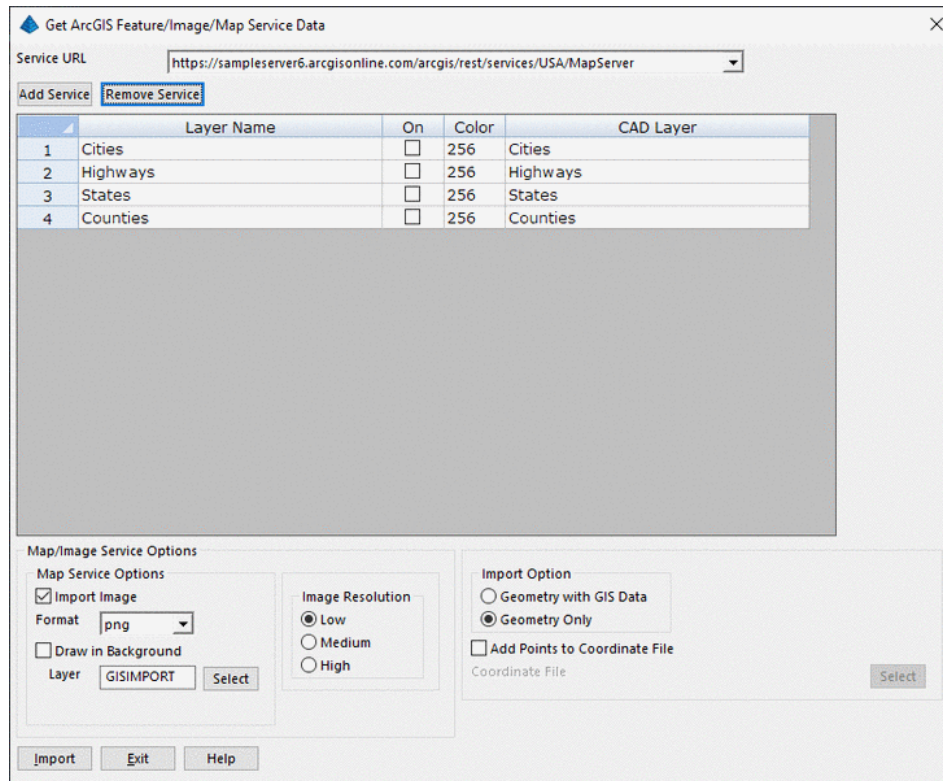

Pulldown Menu Location: GIS Data->Import GIS Data-> Import ODBC

Keyboard Command:import_odbc

Prerequisite: need to specify GIS Feature File, GIS Data Format and ODBC data source.

ArcGIS Feature/Image/Map/Services

This command provides access to ESRI Services which includes Feature Services, Image Services and Map Services. It also provide an ability to fetch GIS Data from on-line Feature/Map Services as a means to quickly and easily construct vector map data in and around an area of interest. Currently, the program only allows to import Image from the Image Services.

Service URL: Contains a list of available services.

Add Service: when clicked, the URL of a Service may be input that is subsequently added to the Server URL drop-list.

Remove Service: Delete the currently selected service from the Service URL drop-list. Prior to the removal of the Service, a confirmation alert box will be displayed asking for confirmation. Any data previously placed into a drawing from the Service will remain in the drawing.

As a Service is selected, its list of Layers is returned for further manipulation:

- Layer Name: The geographical "layer" of data in a read-only format.
- Layer Title: The title of the geographical "layer" of data in a read-only format.
- On: When enabled, the content of the Feature is eligible to be imported into the drawing based on the bounding box prompts.
- Color: Double-click on the desired Feature Color to expose a standard "color-picker"
- CAD Layer: Key-in the desired Layer name in CAD to house the Feature data and/or double-click on the desired Feature CAD Layer to expose a "layer selector" dialog box.

If **Geometry with GIS Data** is selected in Import Option, then Entity ID, Description, Elevation and Layer will be added to the spreadsheet. These options contains a list of fields in the service layer, and the field is going to be used to assign to Entity ID, Elevation and Layer. If the layer's geometry type is a point, then Description will also be included.

After layers have been selected, click **OK** and the data for each will be imported.

If Service type is Map/Image Service, then the following option will be available

Format Type:Select the image format type from:

- PNG
- JPEG
- GeoTIFF
- tiff

Image Resolution: Sets the resolution for the image as low, medium or high. The resolution may depend on the image selected, display settings and hardware.

Draw in Background: When enabled, sets the draw order to place the image in the background.

CAD Layer: Sets the layer for the image file to placed in the drawing.

Add Points to CRD File: When enabled and if point data exists for the selected layer, those points will be added to the current coordinate file.

Prompts

Pick first corner of bounding box: Indicate one corner of a rectangular box that identifies your area of interest.

Pick second corner of bounding box: Indicate the other corner of a rectangular box that identifies your area of interest.

Image File to Save: Create a name for the image file that will be imported.

Pulldown Menu Location(s): GIS Data

Keyboard Command: getesrirest

Prerequisite: Internet connection, Coordinate System Projection set through Drawing Setup

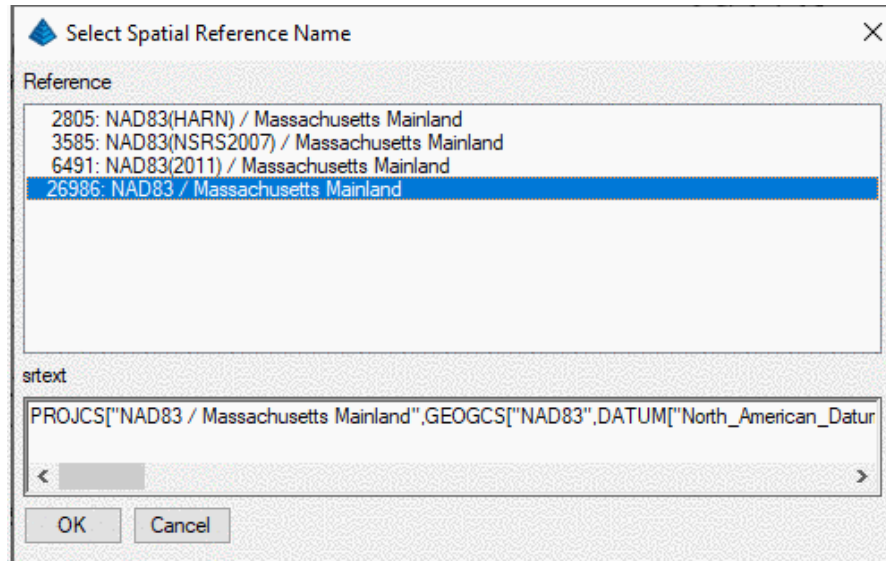

Export SQLite File

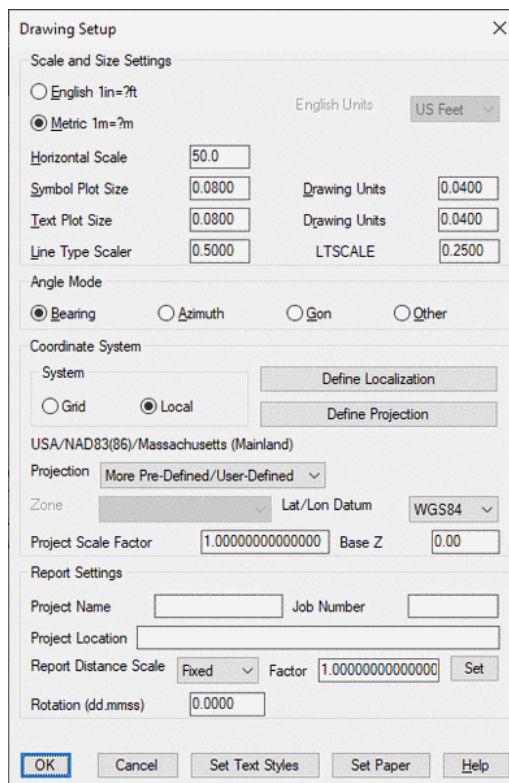

This command create a SQLite file from the entities in the drawing. A dialog shows the drawing's projection and EPSG code and an option to include Z coordinates. The function will export all entities that has linked database information. Any entity that has no linked database information would not be exported.

The command use the Projection and Units that specified in the Drawing Setup to search corresponding EPSG codes in the SQLite/Spatialite reference system. The system can resolved the EPSG code from the Pre-Defined projection and the build-in projection for State Plane 83, State Plane 27 and UTM. If the system can't resolve an unique EPSG code, then it will prompt a dialog and let the user selected the code.

For example, if a predefined project USA/NAD83(86)/Massachusetts (Mainland) is selected in the Drawing Setup, then the following dialog will be display. The dialog list all projection that is related to the predefined projection. To see more detail information about a projection, just move the cursor to the project. The srtext box will display detail information.

These SQLite files can be imported into QGIS layer.

Prompts

Specify Name for SQLite File dialog select .sqlite name

Select EPSG code: select entry

Export Carlson Entities to SQLite File dialog choose settings, click OK

Pulldown Menu Location: GIS Data -> Export GIS Data -> Export SQLite

Keyboard Command: export_sqlite

Prerequisite: None

Export SHP File

This command creates a SHP file from the selected entities in the drawing. After selecting entities to be converted, a dialog shows the number of Points, Polylines (Arcs) and Closed Polylines (Polygons) found in the drawing selection set. Those Points, Arcs and Polygons with database information linked are displayed with their database

table names. Any Points, Arcs and Polygons without linked database information display as unknown. The Coordinate System setting chooses between creating a SHP file using the northings/eastings from the drawing or using lat/lon by converting the drawing coordinates to lat/lon with the projection parameters from Drawing Setup.

Highlight the Point, Arc and Polygon tables to output or selects Export All to select all entities including the UNKNOWN entities to export into SHP files. The Export SHP File commands outputs all entities selected into SHP files with the same name as their table name into a subdirectory selected. Also Points can be stored in the ESRI Arcview database as 3D X, Y and Z coordinates when Include Z Coordinates is toggled on. SHP files do not have arc entities. So the export routine will convert arcs and polyline arcs into a series of small chords segments. The Offset Cutoff field sets the maximum horizontal shift allowed between the original arc and the chord segments.

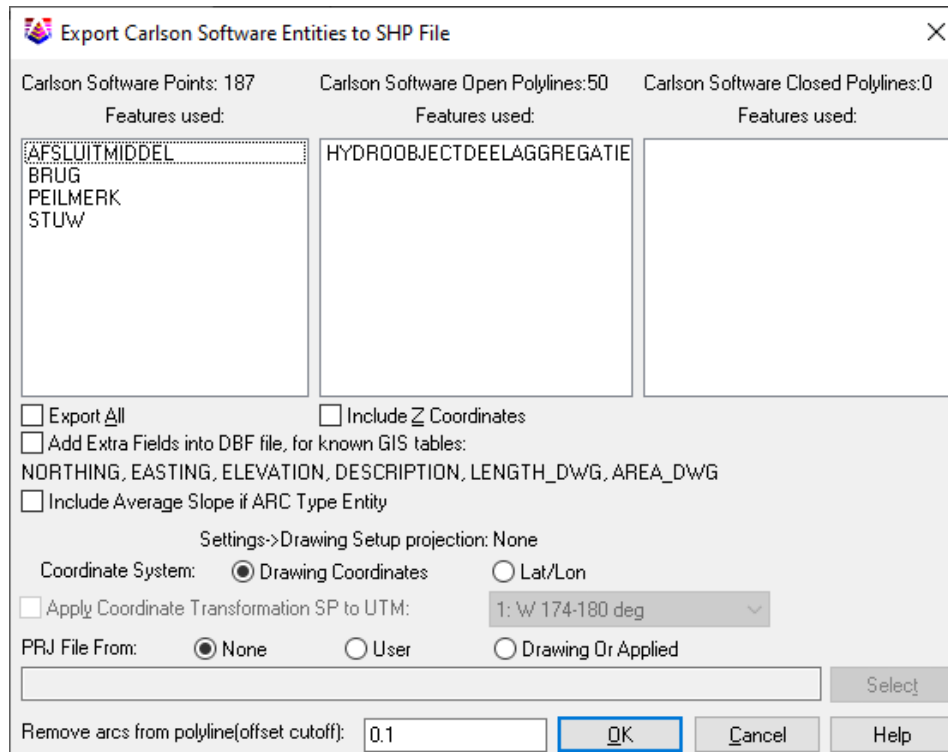

These SHP files can be imported into ESRI's Arcview product. Database GIS links in Carlson are converted to SHP files by storing the GIS database information into DBF files for ESRI's Arcview product to read and link to.

Prompts

Specify Name for SHP File dialog *select .SHP file name*

Select objects *select entities*

Export Carlson Entities to SHP File dialog *choose settings, click OK*

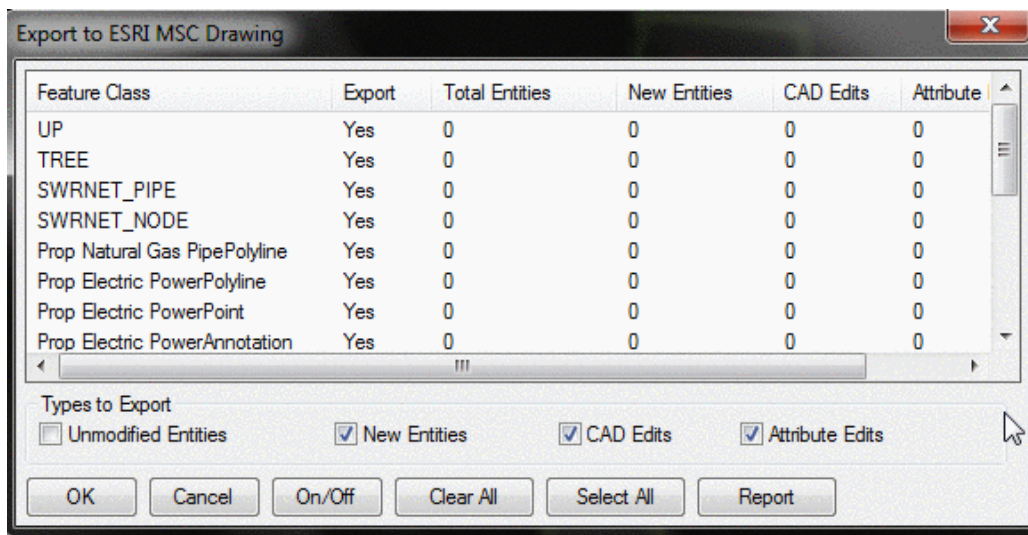

Pulldown Menu Location: GIS Data

Keyboard Command: export_shp

Prerequisite: None

Export DWG File with Esri MSC

This command is used to create a new drawing file that contains Esri MSC Feature data.

The drawing is scanned for MSC data and further, which are new entities with MSC, which are entities with edited geometry, and which are entities with edited attributes. The user specifies which are to be included in the new drawing file. On OK, a new drawing file name is specified.

The drawing is scanned for MSC data and the list is populated with represented Feature Classes. You can select which ones to include in the Export (Export Yes/No column). The check boxes at the bottom allow you to choose whether to Export the unmodified entities for the selected Features, new entities, entities with CAD edits, such as Trim, Extend, Move, etc, and entities with edited attributes. On OK, a new drawing file name is specified. There is also a Report function to review the changes and to make a record of these transactions.

One possible application of this command is to create a DWG from ArcGIS with its Export to CAD tool, open the drawing in Carlson and edit it, and then use this command to send the edits back to ArcGIS as a new DWG with MSC.

Pulldown Menu Location: GIS Data

Keyboard Command: export_msd

Prerequisite: drawing with MSC

Export ESRI Projection File

This command creates an ESRI format Projection File (ESRI PRJ) from the projection definition in Drawing Setup which must be setup before running this routine. The program prompts for the .PRJ file to create.

Pulldown Menu Location: GIS Data

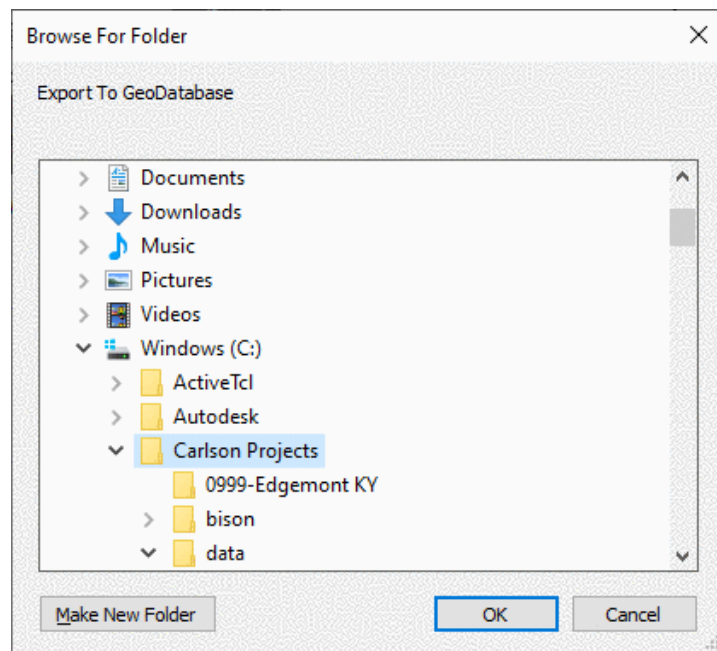

Keyboard Command: write_esri_prj

Prerequisite: projection defined in Drawing Setup

Export ESRI File GeoDatabase

This command creates an ESRI GeoDatabase File from the entities in the drawing, and it exports all that have linked database information. Entities that have no linked data will not be exported

The following dialog will display: and a directory with extension name .gdb has to be selected. If it doesn't exist, then click on "Make New Folder"

Select an existing folder or create a new one with the **Make New Folder** option. The folder must have the extension .GDB.

The ESRI GeoDatabase files will be created from the entities contained in the drawing provided they are linked to a database.

The command will not execute if the original drawing's GIS data format is ESRI File GeoDatabase.

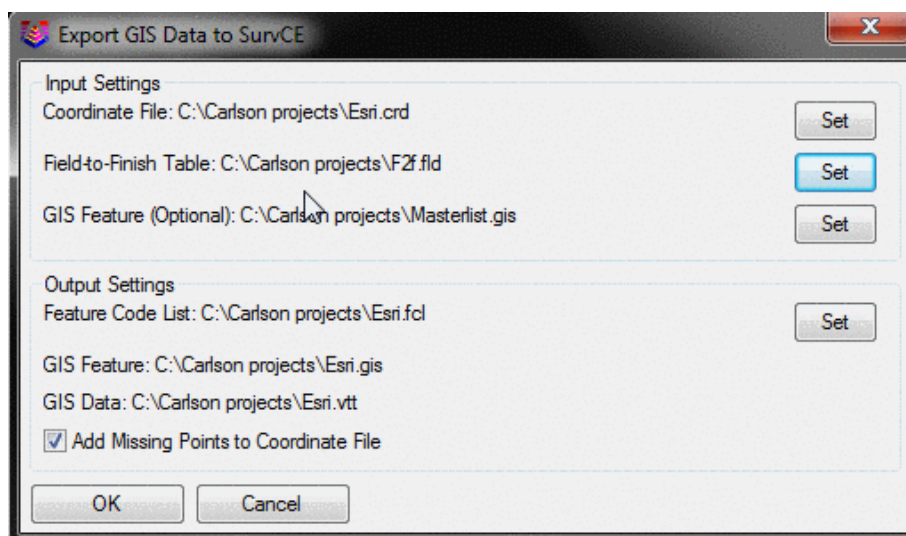

Pulldown Menu Location: GIS Data -> Export GIS Data -> Export ESRI File GeoDatabase

Keyboard Command: geodb_export

Prerequisite: Drawing Projection Set in Drawing Setup

Export GIS Data to SurvCE

This command is used to set up a SurvCE Feature Code Library (.FCL) with attributes from points in a drawing with Esri MSC data.

In this dialog box, the coordinate file is specified, as well as the Field to Finish file being used. The name of the

SurvCE FCL file is then specified. Picking OK prompts the user to select the points in the drawing with Esri MSC data.

Pulldown Menu Location: GIS Data

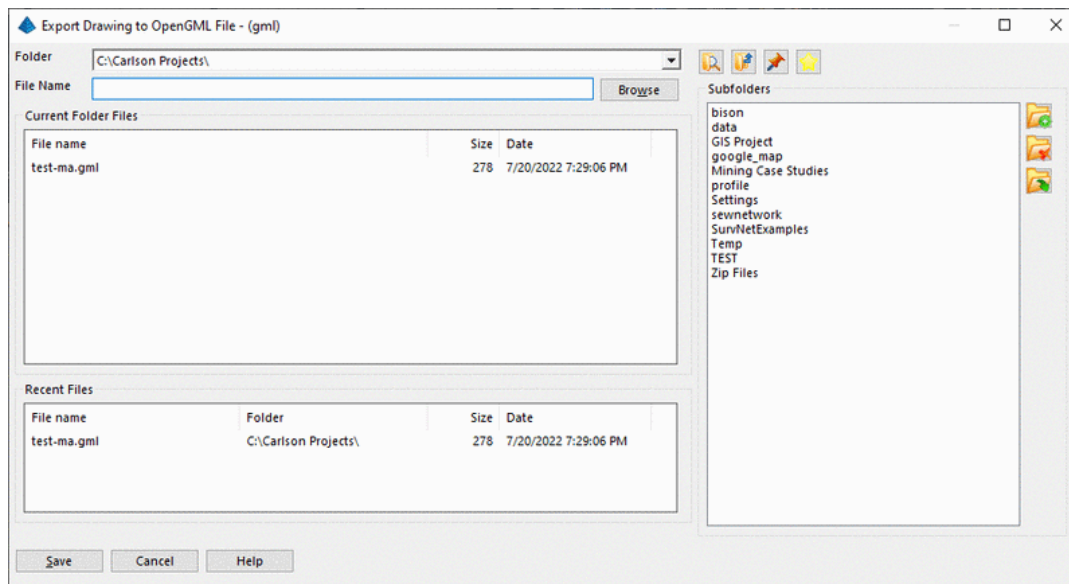

Keyboard Command: msd2survce

Prerequisite: CRD file, FLD file, points in drawing with MSC

Export OpenGIS GML

This command create OpenGIS GML file from the entities in the drawing, and it export all entities that has linked database information. Any entity that has no linked database information would not be exported

The following dialog will display and enter a file name for the GML file

Click on Save button to save, then select the entities to in the drawing to export.

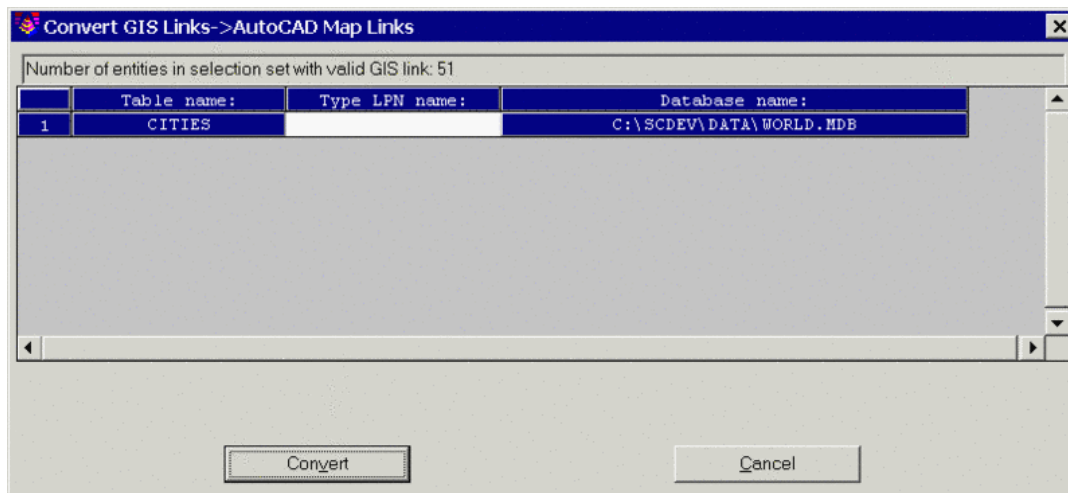

Pulldown Menu Location:GIS Data -> Export GIS Data -> Export OpenGIS GML

Keyboard Command: gml.export

Prerequisite: None

Convert GIS Links to AcadMap

This command converts Carlson GIS links to AutoCAD Map LPN links. The command starts by prompting you to select entities to process. Then the program will read all the Carlson GIS links attached to the selected entities. A dialog is shown with a list of all the pairs of database file and table names from the GIS links. Fill in the LPN name to use for the Carlson GIS link. If the LPN does not exist, it will be created. The LPN will be registered in MapPlus, if MapPlus is available. When the LPN names are filled out, pick the Convert button and the Carlson GIS links will then be removed and replaced by AutoCAD Map LPNs. This routine will run in either plain AutoCAD or AutoCAD Map.

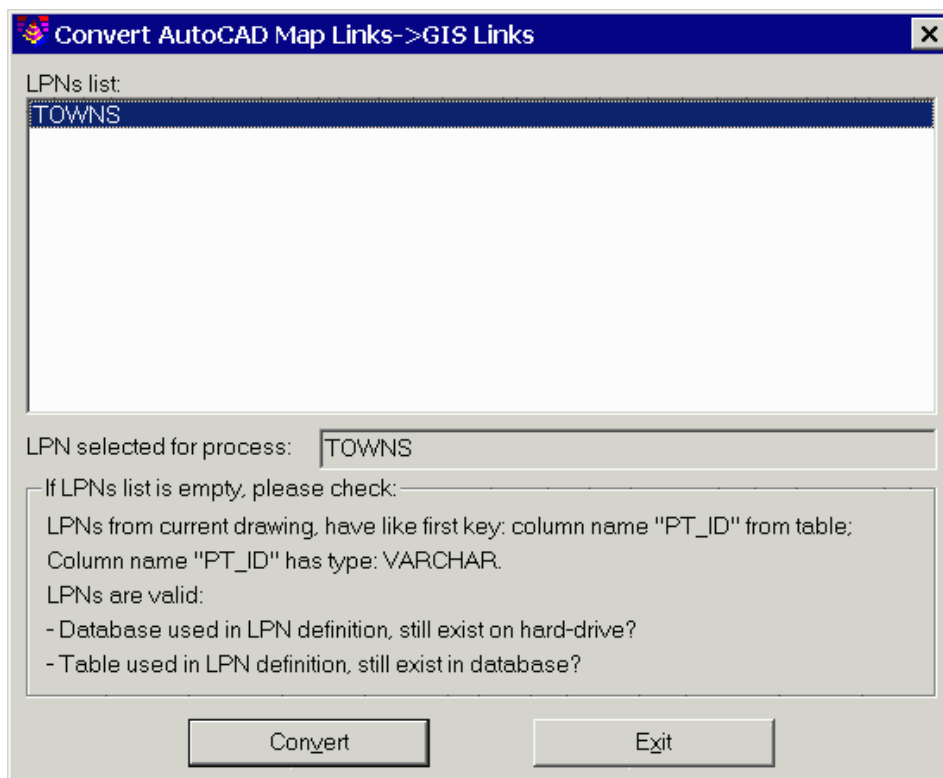

Pulldown Menu Location: GIS Data

Keyboard Command: gis2map

Prerequisite: Entities with linked GIS information

Convert AcadMap to GIS Links

This command converts AutoCAD Map LPN links to Carlson GIS links. The command starts by prompting you to select entities to process. Then the program will read all the Map LPNs attached to the selected entities. A dialog is shown with a list of the LPN names. In order to be able to convert an LPN, the LPN must have a key field called PT_ID. Also, the database file and table referenced by the LPN must exist. In the dialog, highlight the LPN to convert and then pick the Convert button. The Map links are then removed and replaced by Carlson GIS links. This routine will run in either plain AutoCAD or AutoCAD Map.

Pulldown Menu Location: GIS

Keyboard Command: map2gis

Database File Utilities

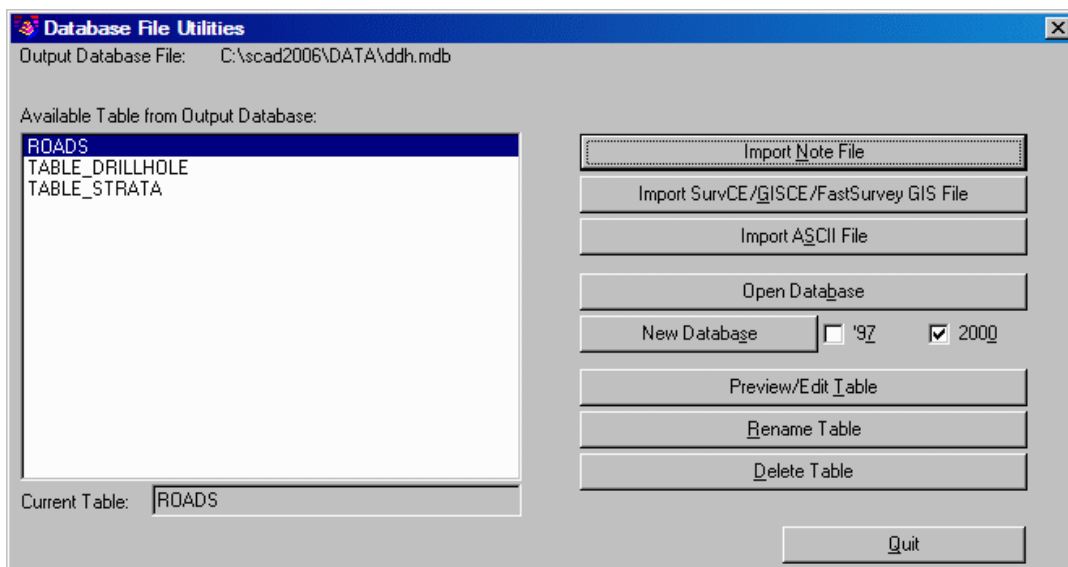

This command is designed to import GIS data from SurvCE, GISCE and FAST Survey files, as well as from user-defined text/ASCII file fields. It also exports data from Carlson Note files (.NOT or .VTT) to Microsoft® Access (.MDB) database tables. The .NOT extension is used when data transfers from desktop. The .VTT extension files are data transfers from data collector.

Note files are associated with Coordinate files (.CRD) and contain additional data for point numbers. For example, the Coordinate file for a manhole point could contain the point number, northing, easting, elevation and 32 character description, while the corresponding note file for that point contains additional data on the manhole such as diameter, depth, condition, etc.. A Carlson Note file for a Coordinate file will have the same name as the Coordinate file, except with a .NOT or .VTT extension instead of the .CRD extension (e.g. PARK.NOT goes with PARK.CRD). The Carlson Note file is a text file which consists of a point number (PT_ID) followed by field names with values. This group of point number and fields can also have a GIS_FILE name, which is used to identify this group of fields. This GIS_FILE name comes from the Note file prompting definition file (.GIS), which defines the field names for the group and is created in the Define Note File Prompts command.

You can select the Note file to process by using the Import Note File button. The program will then list all the GIS_FILE names that were found in the Note file. If a set of data for point number does not have a GIS_FILE name, then this group will appear in the list as UNKNOWN.

The name of the Microsoft® Access database to add the data to is the output database file, listed at the top-left of the Database File Utilities dialog. You can change the output database by using the Open Database button and selecting an existing database, or by clicking New Database to create a new database. The database tables will automatically have the same name as the GIS_FILE. This dialog also allows you to preview and edit a spreadsheet editor, which in turn allows you to modify values in the table. Each set of note file data for a point is displayed on one row with the corresponding record from the database shown on the next row. You can export the Note file data and create a new Access database .MDB file, in Access '97 format or in Access 2000 format, by doing a SAVEAS into .MDB format. You can rename and delete a table as well.

Database File Utilities can be combined with the Create Links command to make GIS links between the point entities in the drawing and the Microsoft® Access database records. The point entities can be drawn with the Draw/Locate Points or Field to Finish commands.

Initial dialog at start of command with primary functions

Available Table from Output Database: Selection list. Pick a table from the Output Database.

Import Note File: Imports a Carlson Note File (.NOT).

Import SurvCE/GISCE/FastSurvey GIS File: Imports a SurvCE/GISCE/FastSurvey Note File.

Import ASCII File: Imports ASCII file.

Open Database: Opens Access database .MDB file.

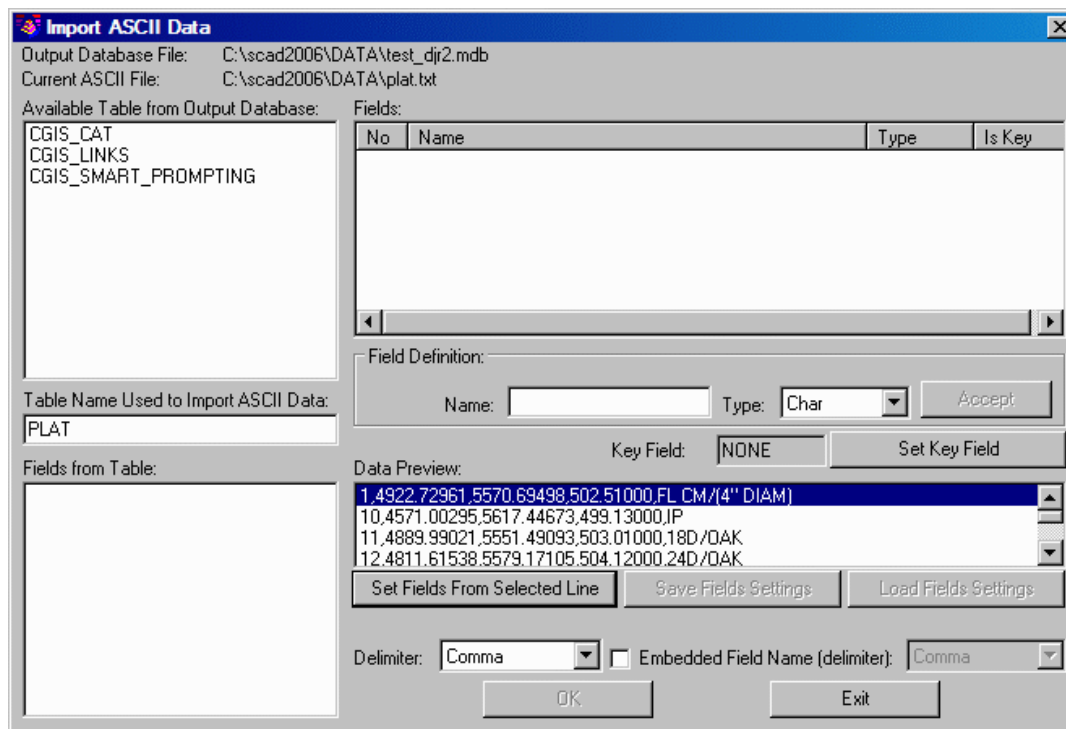

New Database: Creates a new Access database .MDB file in Access '97 format or in Access 2000 format.

Preview/Edit Table: Displays a spreadsheet editor, allowing you to preview/edit values from table.

Rename Table: For renaming a table as needed.

Delete Table: For deleting a table as needed.

Current Table: Displays the selected table from above list.

Dialog seen after choosing Import ASCII File and selecting file name

Pull-down Menu Location: GIS Data

Keyboard Command: noteutil

Prerequisite: A note file (.NOT from desktop or .VTT from data collector)

Define Block Database Links

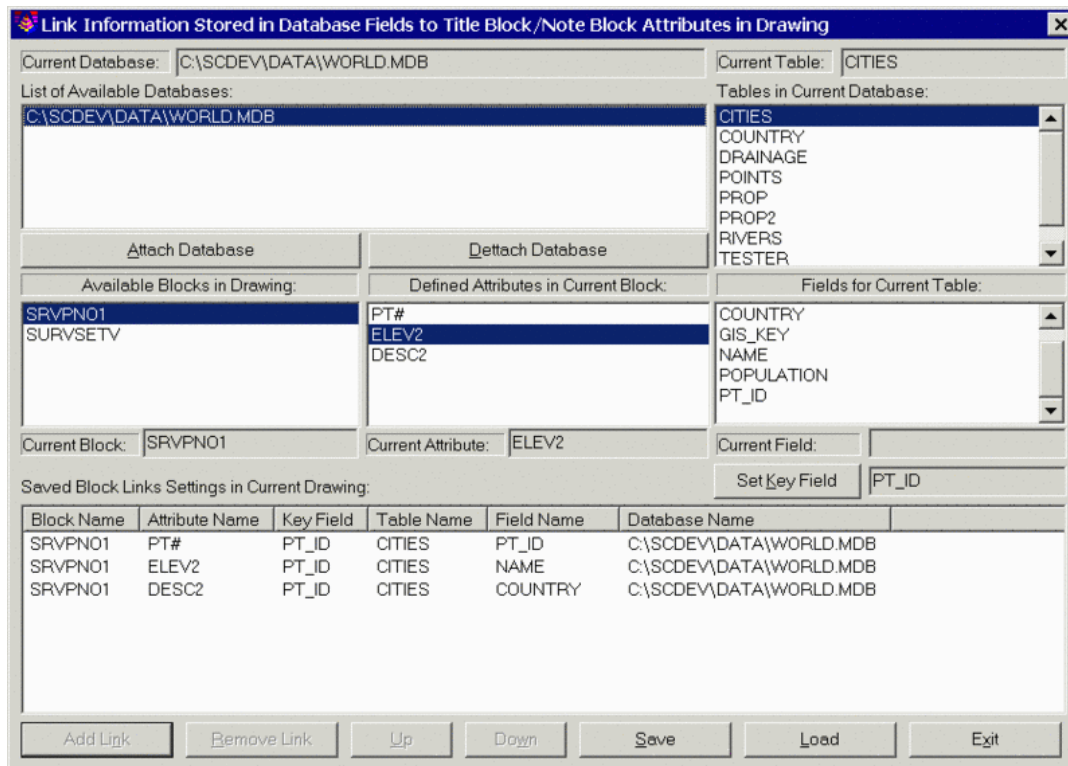

This command creates links between attributes in drawing blocks and fields in database tables for Microsoft® Access, Microsoft® Excel and DBase. The command works through the dialog shown. At the top of the dialog, you specify the database and table to process. Highlight the database and table to process from the lists. To add a database to the available list, use the Attach Database button. This routine brings up a file selection dialog to choose the database file name. Under the "Files of type" field, you can choose between selecting Microsoft® Access, Microsoft® Excel or DBase database files.

After selecting the database table to use, the key field from the table must be specified. Highlight a field name from the Fields list and then pick the Set Key Field button. One of the block attribute links to the database fields must use this field name so that the program can link the block entity with the database record and fill out the other values. For example, consider a block with three attributes: lot_id, owner_name and area. The database table has the following fields: ID, name and area. The database field of ID could be set as the key field and linked to the block attribute called lot_id. Also the database field of name could be linked to attribute owner_name and area linked with area. Programs such as Update Block Data will use the value in the attribute of lot_id to lookup the database record with

the matching value in the ID field. Then the values in the owner_name and area block attributes can be filled out from this database record.

The program lists all the block definitions found in the drawing. Highlight a block name to link to from this list. Then the program will list all the attributes for this block. To create a link, choose an attribute and a field from the database table. Then you can pick the Add Link button to link this block attribute with this database field. The links for a block can be saved and recalled by block name using the Save and Load buttons.

One application of this command is for linking drawing title blocks to a customer database. For example, the drawing title block and the database could contain a customer ID, name, address, etc. The customer ID could be used as the key field. Then you could just fill out the customer ID in the title block and then use the Update Block Data command to fill out the rest of the customer data in the title block.

Pulldown Menu Location: GIS Data

Keyboard Command: define_blk

Prerequisite: Block in drawing and database file

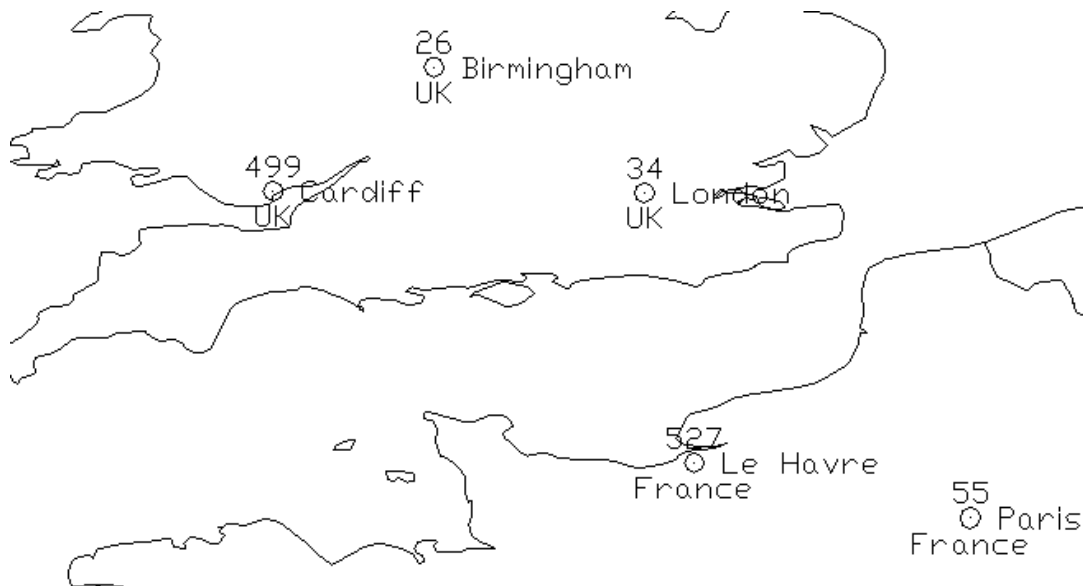

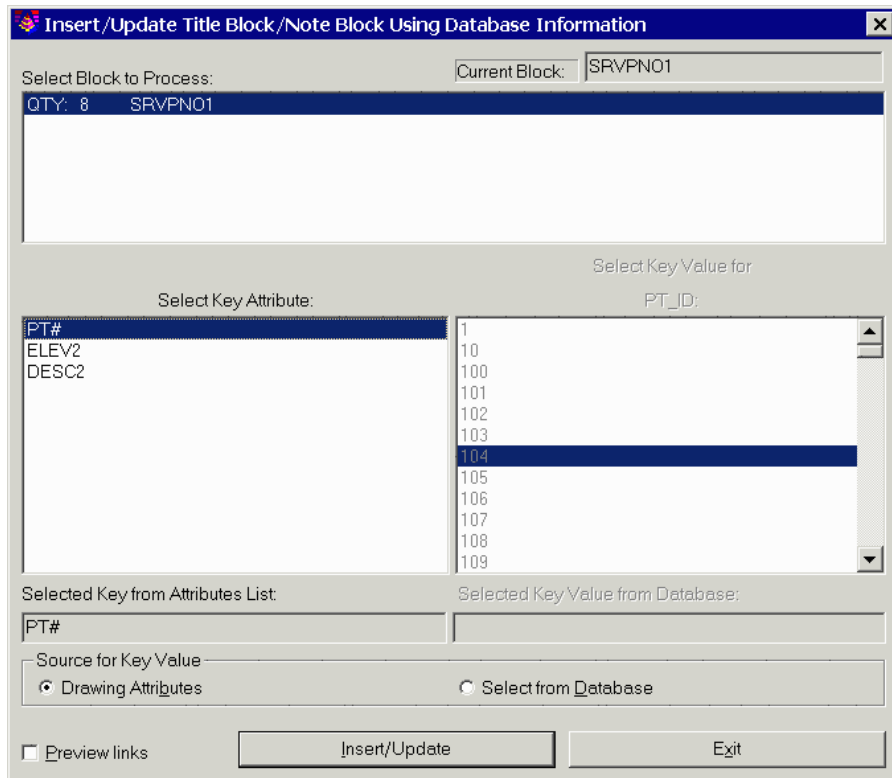

Update Block Data

This command fills out attribute values in drawing blocks using data from database tables. The links between the block attributes and the database fields are defined in the Define Block Database Links command.

The program starts by prompting you to select the block entities to process. Then a dialog is displayed with a list of the block names from the selected entities that also have database links defined. Highlight the block name to process from the list. Then the program lists the attributes for the block. Highlight the attribute that corresponds to the key field from the database table. Then choose the Insert/Update button to update the drawing block attributes.

Under Source for Key Values, the Drawing Attributes option will update each block by reading the value of the key attribute and then looking up the database record with the matching value. The other block attributes and then filled out using the values from this database record. The Select from Database option allows you to choose a database record by highlighting the value from the key field. All the block entities will be filled out using the values from this selected database record.

The Preview Links option will bring up a dialog with a spreadsheet view of the data values from the database for each block. You can edit the values, update the block or skip updating the current block.

Example point blocks updated from CITIES database table

Pulldown Menu Location: GIS Data

Keyboard Command: update_blk

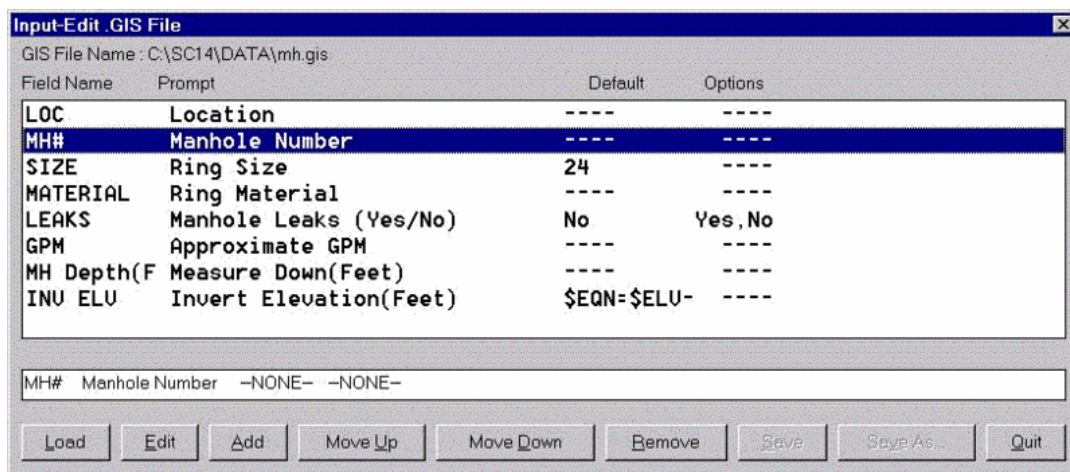

Prerequisite: Blocks, database table and link definition

Define Note File Prompts

This command allows the user to create a .GIS file for use in several other routines in Carlson GIS and other Carlson Software products, such as SurvCE or SurvStar.

The program starts with the main Define Note File Prompts dialog, as shown below. The Load button allows the user to load an existing GIS file for editing or review. The list box shows the various data capture items in the GIS file, showing the field name, the prompt, the default value and the various options for that field. The Edit button allows the user to edit the highlighted field. The Add button allows the user to add new fields after the highlighted field. The Move Up and Move Down allow the user to change the order in which fields appear in the GIS file, while the Remove button completely removes the highlighted field. The Save button saves the GIS file that is currently being edited, while SaveAs allows the user to save the current GIS file under a different name. The Quit button checks to see if the current GIS file is saved and quits the routine.

When the Edit or Add button is clicked, the dialog box shown here appears, allowing the user to enter and edit data with respect to a particular field in the GIS file. The Field Name is a unique identifier of the field in the GIS file and hence a GIS file cannot have repeated field names. The Prompt is what appears at the command prompt while waits for user input. The Default Value is the value that would be used among various options, if the user presses Enter at the command prompt without typing anything in response to the prompt. The list box, Options for value, contains a list of options that can be selected for the particular field. A new option can be added to the list or removed from the list by clicking the appropriate button. The Add Option button brings up a small dialog and accepts the option to be included in the list. Press OK to accept the values set here. At the minimum, the Field Name and Prompt must be specified.

Define Note File Prompts dialog Load a file, or change variables as required.

Pulldown Menu Location: GIS Data

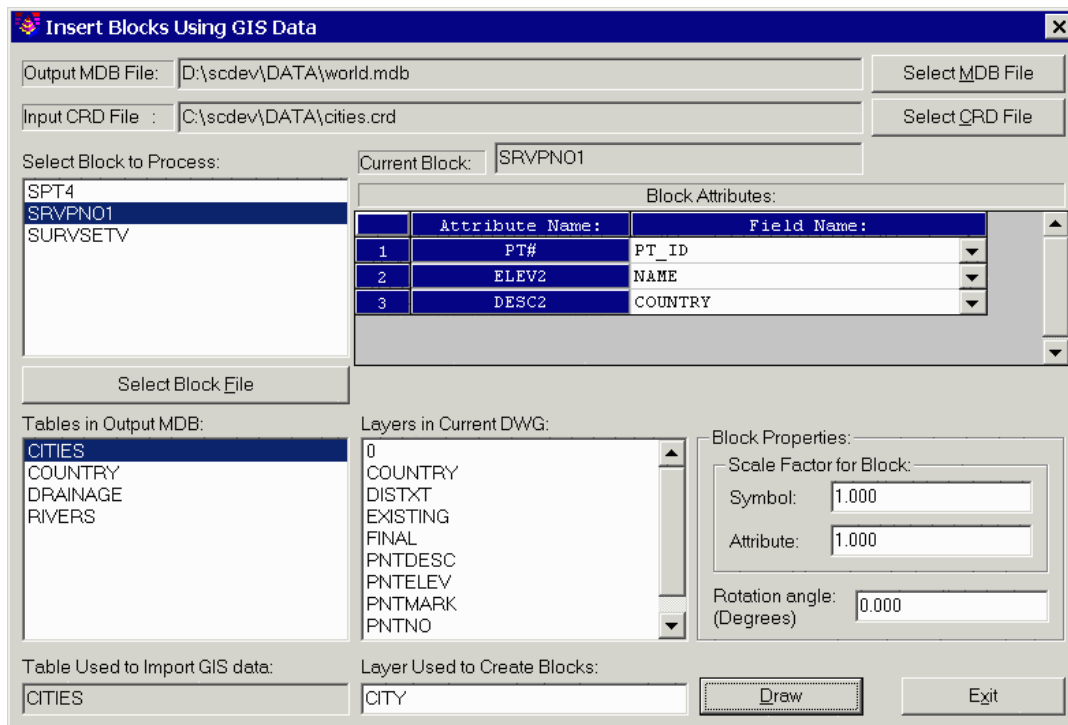

Keyboard Command: defnote

Prerequisite: None

Insert Block with GIS Data

This command draws block entities in the drawing with the attributes filled out using data from a database. The command works through the dialog shown. The MDB File is the database that to be used as the source for the attribute data. The CRD File is the coordinate file that contains point number, northing, easting, elevation, and description. A list of the block definitions found in the drawing is shown on the left. To add a block to this list, pick the Select Block File. Highlight a block name from this list. Then the program will display a list of the block attributes. The tables defined in the current MDB database are listed in the lower left of the dialog. Highlight a table name to use for the data source. Then in the attribute list, for each block attribute you can set the database field to use for the attribute value by selecting the Field Name pulldown arrow. In the lower right of the dialog, you can specify the layer name, scale factors and rotation for the blocks.

Pick the Draw button to create the blocks. For each point number in the coordinate file, the program will insert the specified block in the drawing using the point coordinates from the CRD file. The database record to use is found by matching the point number from the coordinate file with the PT_ID field in the database table.

Pulldown Menu Location: GIS Data

Keyboard Command: insert_blk

Prerequisite: CRD file and MDB database table file

Update Drawing Coordinates

This command update entities' geometry info, and it is used only when the drawing stores GIS Data in SQLite/Spatialite DB, ODBC DB and ESRI GeoDB.

Keyboard Command: update_dwg_coord

How to Setup ODBC Data Sources

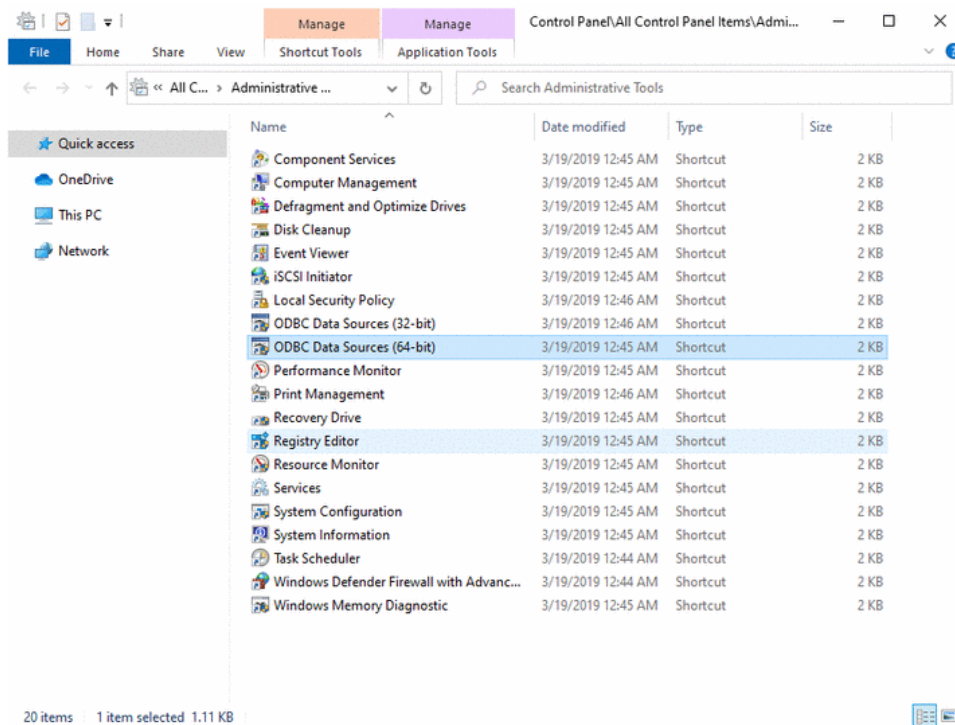

How to setup ODBC Data Source

To add and configure a new ODBC data source in a Windows environment, use the ODBC Data Source Administrator.

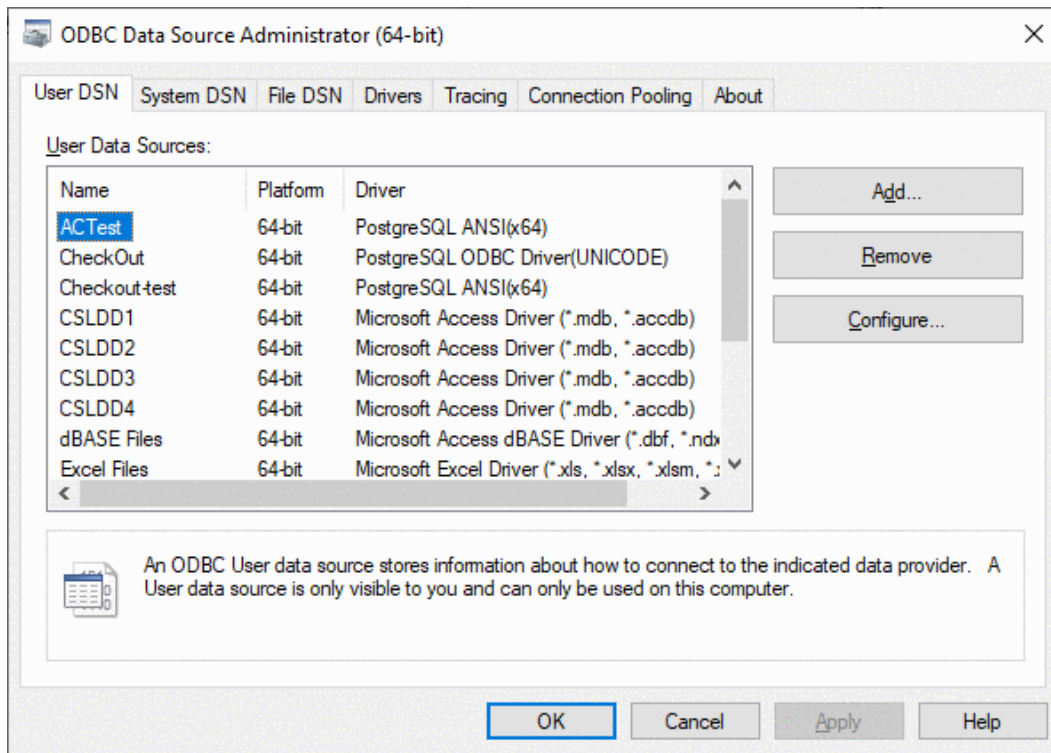

To open the ODBC Administrator from the Control Panel:

Step 1: Right click Start > Control Panel.

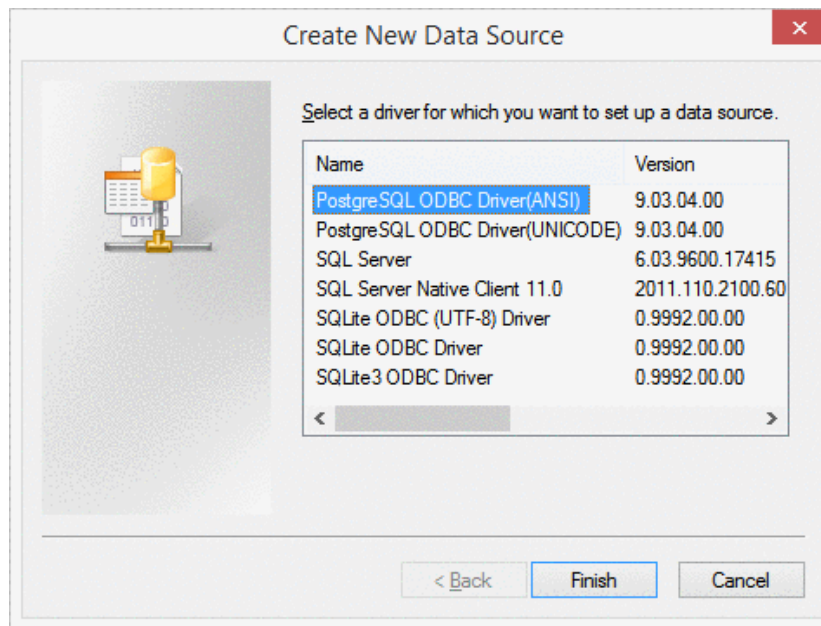

Step 2: Select Administrative Tools, then select ODBC Data Sources (64 bits).

Step 3: In the ODBC Data Source Administrator dialog box, click Add. The Create New Data Source dialog box appears.

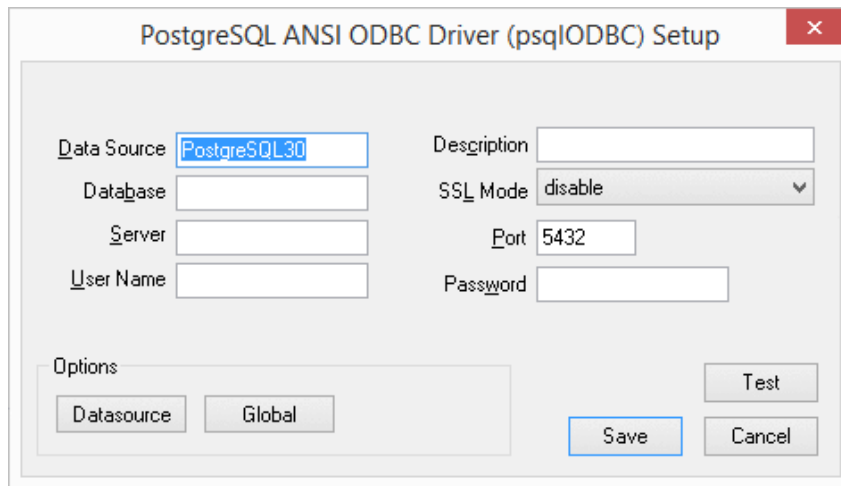

Step 4: Select a driver (e.g., PostgreSQL ODBC Driver) and then click Finish.

The driver configuration dialog box appears.

Step 5: Complete the following field entries:

Data Source Name: enter the name of the data source you want to access. It can be any valid name that you choose.

Description: enter the description needed for the data source.

Host or Server Name (or IP): enter the name of the PostgreSQL server host that you want to access. By default, it is localhost.

Database Name: enter the name of the PostgreSQL database that you want to use as the default database.

User name: enter your PostgreSQL username (your database user ID).

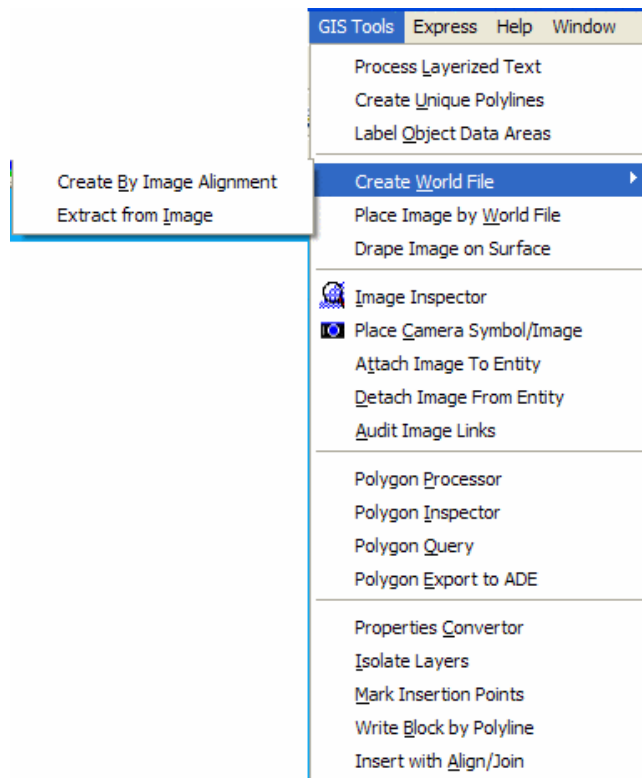

Password: enter your password.

Port: enter the port number if it is not the default value (5432).

Step 6: Click OK to add this data source.

GIS Tools Menu

The GIS Tools menu shown below has commands for processing polyline perimeters, images and other utilities.

Process Layerized Text

This routine is a simplified version of the Polygon Processor command. It uses closed polylines that enclose text. Each text label is used as the data value for the enclosing polyline. The text and polyline must have the same layer name and together they define one layer or topology. This command processes multiple layers by overlaying the layers and finding all the sub-areas. For example, one layer could be used for property boundaries with the property name inside the closed polylines. Another layer could be for soil types. This command could then be used to find all of the different areas broken out by property and soil type (Property 1-Soil 1, Property 1-Soil 2, etc.).

There is an option to draw closed polylines for the resulting sub-areas. You can also label each sub-area with the layer data values for the area (i.e. Property 1/Soil 1). The program also generates a report of the sub-areas, including the data values for each layer, the area and the perimeter. The Report Formatter is used to choose the fields to include in the report and the report layout. There is no explicit link to a database, but the Report Formatter will print and/or save a file of the displayed information, or export the data to Microsoft® Excel and Microsoft® Access.

The function prompts you for a selection set containing the closed polylines and text to be processed. The layer list is formed from the selection set, and you have to specify the sequence in which layers will be processed.

Prompts

Select objects: *choose selection set*

Draw resulting polylines [No/<Yes>]? *press Enter*

Layer name for resulting polylines : *Property*

Select a Layer processing sequence dialog *specify the sequence*

Report Formatter Options dialog *customize as needed*

Two-Layer Example:

Two properties (Johnson and Hayes) straddle Soil A, Soil B and Soil C. Note that some of the Hayes property extends beyond the soil polygons. If the properties are "cut" against the Soils, portions of the properties that extend where there are no soil zones will get a blank designation for the soils layer. This command offers a quick method of distinguishing every category of property. In our 2-layer example, the text "Soil A", "Soil B" and "Soil C" are in the same layer as the soil perimeters, and the text "Hayes" and "Johnson" are in the same layer as the property perimeters. Note also that "Soil C" is located inside both the soil and property perimeters. This is OK since it is associated only with the soil polygon because the text and polygon share the same "soil" layer.

```

PROPERTY SOILS Area Perimeter
Hayes 2,713.8 265.12
Hayes SOIL A 80,925.3 1,161.56
Hayes SOIL B 6.9 12.69
Hayes SOIL C 3,960.4 330.70
Johnson SOIL A 2,229.6 229.38
Johnson SOIL B 9,072.0 521.80
Johnson SOIL C 89,665.2 1,276.69
-- Grand Total -----
188,573.1 3,797.95

```

Pulldown Menu Location: GIS Tools

Keyboard Command: layertopo

Prerequisite: None

Create Unique Polylines

This command takes in a selection set of polylines and lines, and creates a new layer of unique lines, without duplication. They can then be successfully used for topology creation. In the example below, polylines for properties and a floodplain, with several duplicated sides, are used to create a new layer consisting of unique, non-duplicated lines. The text shown is for information only and is not critical to the process.

Prompts

Enter layer name for polylines <CLAYER>: *press Enter*

Select polylines:

Select objects: *select polylines or lines*

Source Drawing

Output drawing isolating to new layer
Certain line segments are highlighted

Pulldown Menu Location: GIS Tools

Keyboard Command: createunipl

Prerequisite: Polylines or lines

Label Object Data Areas

This command labels selected Object Data fields within MPolygon areas with smart rules for different methods to handle any labels that overlap the area perimeter. This command requires AutoCAD Map 2006. The program starts by prompting for the object data table name at the command line. To check the object data table name of an MPolygon entity, double-click on the MPolygon to bring up the Properties dialog. In the dialog, object data is shown in sections labeled OD:Object Table Name.

After selecting the object table name, there is an options dialog. The dialog lists all the field from the object table and you can select which fields to label by adding them to the list on the right. The Annotation Rules are used to position the labels. The rules are applied in order until the labels fit inside the MPolygon. You can choose which rules to use and their precedence:

Inside Area At Centroid: Places the labels at the centroid of the MPolygon

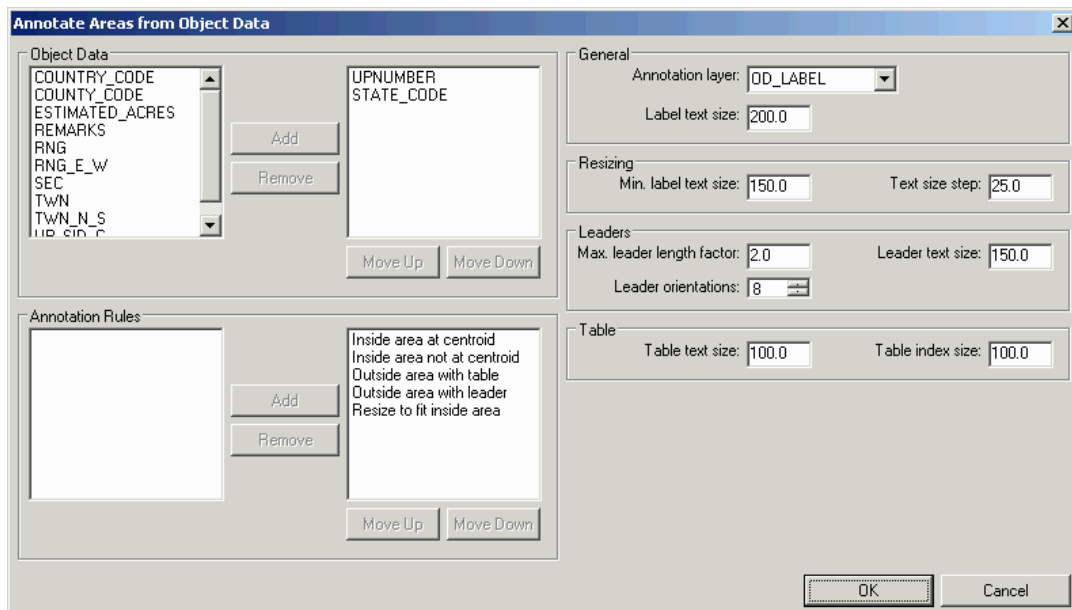

Inside Area Not At Centroid: Searches for any space inside the MPolygon that fits the labels.

Resize To Fit Inside Area: Places the labels at the centroid of the MPolygon at smaller text sizes. The options for this rule control the minimum size to use and the size increments to try starting from the initial size.

Outside Area With Leader: Places the labels outside the MPolygon and draws a leader from the label to the MPolygon center. The options for this rule control the max length of the leader as a factor of the text size, the size of the leader arrowhead, and the number of directions to try as leader positions.

Outside Area With Table: Places the labels in a separate data table and a data id label inside the MPolygon. The

settings for this rule control the size of the table and the id label.

Prompts

Specify map property table: *UP*

Object Data options dialog

Select regions to annotate

Select objects: *select the MPolygons*

Processed 9 of 9 regions.

Pulldown Menu Location: GIS Tools

Keyboard Command: label_area_obj

Prerequisite: MPolygons with object data

Polygon Processor

This routine takes sets of shapes representing land features and generates a set of non-overlapping shapes, where each shape has data attached from all shapes in the original sets it intersects. The input shapes in one layer designate one property like: lease, owner, county and etc.

Properly prepared data should follow these rules:

1. Each property layer should consist of polylines/lines and text.
2. Lines and polylines should form complete loops, with no ends not snapped to the end of the same or other line/polyline.
3. Each formed loop should contain one and only one unique text entity representing the property value for that loop. Multiple entities with the same text are permitted within the loop.
4. Corresponding text and lines should be on the same layer.

Once all the necessary entities are selected, the routine will separate entities by layer and then analyze each layer for compliance to the rules above. If problems are found, the XXXX.ERR layer is created (where XXXX is original layer name) with marks to help locate the problem. The loose ends are marked by placing a circle with center on the endpoint of the line/polyline. The loops with no text value inside are drawn in red color and ones with too much text are drawn in green.

Layers with no problems are processed and the resulting loops are created on the XXXX.RES layer. If all the layers were analyzed successfully with no problems found, these result layers are combined and one final layer called POLYPROC is created with each loop-piece bearing the data from all loops on other layers it belongs to. That data are stored as extended entity data in name-value pairs, where name is a name of the original layer.

Prompts

Select objects: *select shapes and/or polylines*

Pull-down Menu Location: GIS Tools

Keyboard Command: polyproc

Prerequisite: Shapes and/or polylines

Polygon Inspector

This routine allows you to review quickly the results generated by the Polygon Processor. As the cursor moves over a polyline with attached results, the information from that polyline is displayed and the polyline is highlighted.

For more extensive analysis of the data resulting from Polygon Processor, please refer to the Polygon Query command.

Pull-down Menu Location: GIS Tools

Keyboard Command: polyproc_inspect

Prerequisite: None

Polygon Query

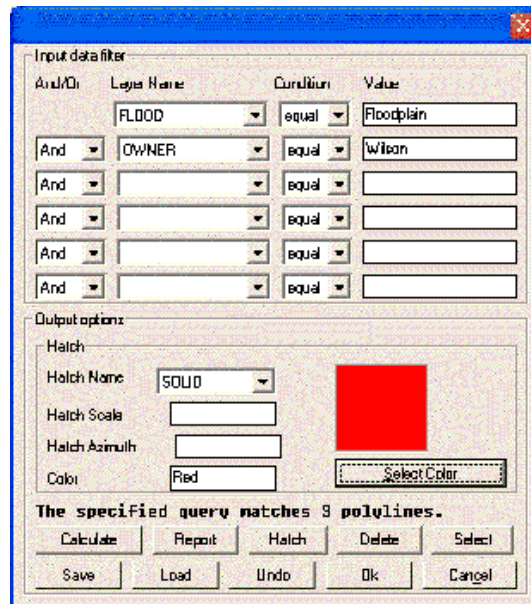

This routine provides the ability to analyze, search and represent data generated by Polygon Processor.

A query is defined based on the parameter name (original layer name) and a condition. Several expressions may be combined using ANDs or ORs to produce a complex query. To verify the query, click on the Calculate button and the number of matching polygons will be reported.

The values stored in the polygon areas are text strings from the original text labels used in Polygon Processor. The expressions are evaluated on these text strings, but the program will compare numbers embedded into strings as numbers:

A12B < A50B
A12B > A5B
A12B < ABC
123 < A123
5-ABC < 13-ABC

A complete report on all polygons matching the specified query may be obtained by clicking on the Report button. All the parameters, along with the areas and polyline handles, are shown in the standard report formatter dialog. The Hatch button applies various hatches to the polygons matching separate queries to create a visual representation of the data. To remove unwanted polygons, i.e. ones which do not contain a combination of required parameters, you may click on the Delete button. This removes processed closed polylines from the POLYPROC layer. To pre-select queried polygons to be used in some other command by means of "previous selection set", use the Select button.

Pulldown Menu Location: GIS Tools
Keyboard Command: polyproc_hatch
Prerequisite: Data generated by Polygon Processor

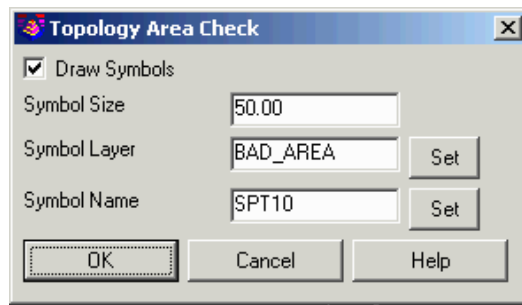

Polygon Export to Map

Polygon data stored in EED form are exported to ADE format (object data), supported by AutoCAD Map. You may then use AutoCAD Map querying functionality to research the data. Since Map's ability to query text is limited, and data coming from Polygon Processor is always stored in text format, for each XXXX parameter in original data two parameters will be present in ADE form: XXXX with text field as is and XXXX_REAL with a number converted from text (if conversion at all is valid).

Pulldown Menu Location: Tools in GIS
Keyboard Command: polyproc_export
Prerequisite: Carlson polygons

Topology Area Check

This command checks an area coverage made of closed polylines to find any gaps or overlaps. For example, the closed polylines could be for property boundaries. The coordinates at the gaps and overlaps are reported. There is also an option to draw symbols at the gaps and overlaps to highlight these problem areas in the drawing.

Topology Area Check

Gap area at 1800590.727,338038.170
Overlap area at 1800562.557,338071.789
Overlap area at 1800712.729,338371.050

Prompts

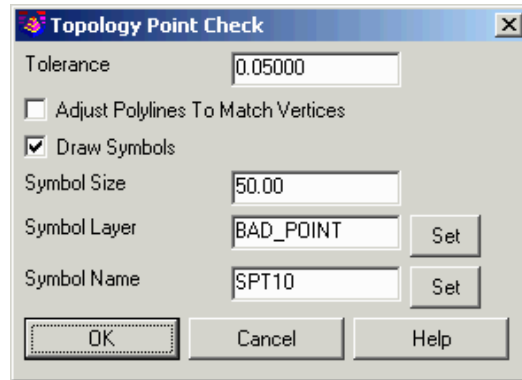

Topology Area Check dialog
Select closed polylines to process.
Select objects: *pick the polylines*

Pulldown Menu Location: GIS Tools
Keyboard Command: area_check
Prerequisite: closed polylines

Topology Point Check

This command checks closed polylines to find vertices that are within the specified tolerance distance of each other and are not identical. The closed polylines could represent an area topology such as for property boundaries. In this case, the program can be used to check that there is a single point for the corner of adjoining properties. The program reports the points that are within the tolerance.

In the dialog, the **Tolerance** is the distance to check. The **Adjust Polylines To Match Vertices** option will move the polyline vertices within the tolerance to the other near point. This option is a way to automatically repair the polylines to share the same coordinates. The **Draw Symbols** option inserts symbols at the points within the tolerance.

Topology Point Check

Tolerance: 0.05000

Point: 1799653.330,338826.420

Point: 1799653.190,338827.230

Checked 97 points

Prompts

Topology Point Check dialog

Select closed polylines to process.

Select objects: *pick the polylines*

Pulldown Menu Location: GIS Tools

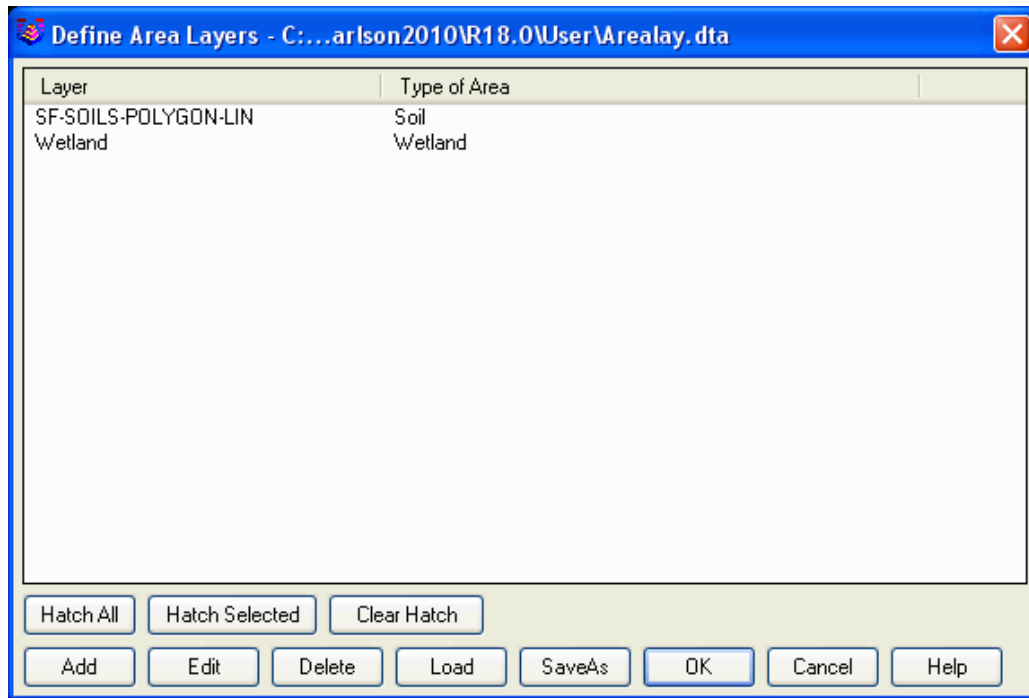

Keyboard Command: pt_check

Prerequisite: closed polylines

Define Area Layers

This command sets up a list of layer names for use with the Report Areas By Layer command. For each layer in the list, an Area Type is assigned which is used for reporting in the Report Areas By Layer command. You can also specify hatch parameters for each layer. These hatch settings are used by the Hatch All and Hatch Selected functions. The Hatch All function hatches all the closed polylines in the drawing on the defined layers. The Hatch

Selected function hatches only the currently highlighted layer. The purpose of these hatch function is to visualize and verify the areas. The Add, Edit and Delete buttons are used to manage the list of layers. The Load and SaveAs functions allow you to save and recall the defined layers to a .ALF file.

Pulldown Menu Location: GIS Tools

Keyboard Command: define_area_layers

Prerequisite: None

Report Areas By Layers

This command reports the area within a closed polyline broken out by sub-areas for areas on defined layers. For example, the main perimeter polyline could be the property boundary and the defined layer polylines could be for wetland areas. Then this routine would report the overall property boundary along with the wetland area.

The layers to process are setup in the Define Area Layers command. The defined layer polylines need to be closed polylines. The program finds all the defined layer areas within the main perimeter polyline and layer polylines that cross the perimeter are automatically trimmed to get the area within the perimeter. The program uses the report formatter to display or export the results.

Pulldown Menu Location: GIS Tools

Keyboard Command: report_area_layers

Prerequisite: Define Area Layers

Properties Converter

This routine facilitates the user in performing massive conversions of entities in the drawing. For example, it can move all blue polylines into a designated layer or change the size of all yellow text.

The user can define a number of different conversion rule sets to work with drawings coming from various sources. Within one set, multiple rules may be selected to be executed at the same time on the set of entities.

In the left upper corner dialog sets of conversion rules may be added by clicking on the Add button. When the set name and file to store a set are specified, the set is added to a list of available ones. To pick a set for editing or to run

it, highlight a particular set in the list and the list of the defined rules will appear in right upper corner of the dialog where users may either add/modify any conversion rules within the set or select rule(s) to be executed on selected entities.

When sets of rules are already defined, the dialog appears as shown below enabling the user to select multiple rules and apply them to the drawing. When a new rule is added, or when the user clicks on the Full Edit button, the dialog expands to show the actual rule definition for the currently highlighted rule. To execute rule(s), select one or more rules (hold Ctrl or Shift keys to highlight multiple items) and click on Execute button. When multiple rules are selected, these rules are applied in a top to bottom order on the entities that the user selects.

The top portion of the rule description defines additional filtering among the selected entities, allowing the user to narrow the user-provided set of entities to a small one containing only entities passing the filter. Filtering can be done by entity types, layer, linetype or color, or by any combinations of these. Filters may be defined easily by clicking on the Select button in either entity type, layer or color boxes and then selecting any entities which bear a desirable feature.

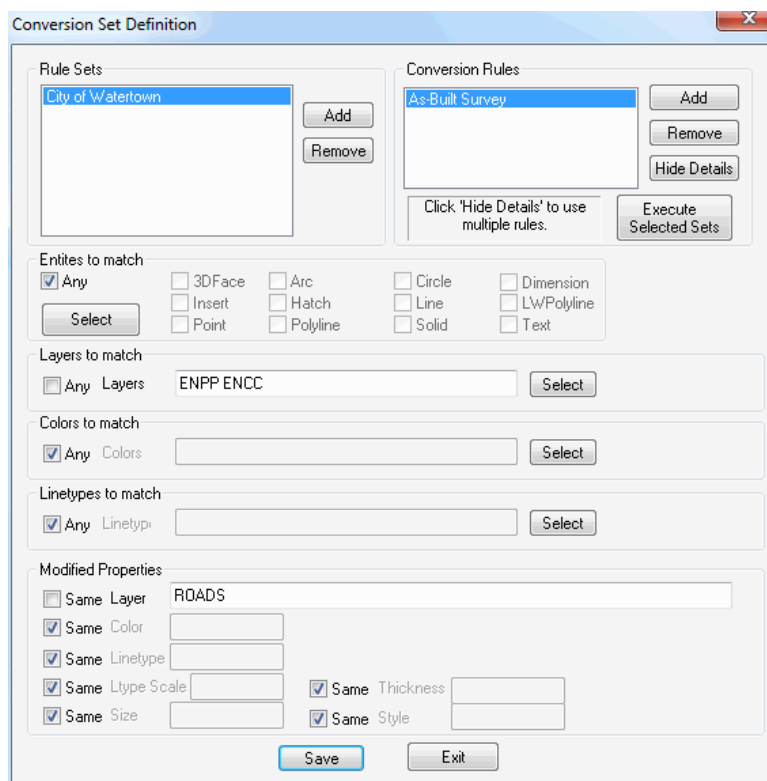

The bottom half of the dialog, Modified Properties, defines what changes will be applied to the entities which are selected and pass through the filter, if any. The following properties may be modified:

Layer: The current layer may be changed to any one on the fixed list of permitted layers. If this option is used, the user has no control over color or linetype, since they come predefined for every layer on the list.

Color: Specify color number 1..255 or BYLAYER

Linetype: Specify a valid linetype name or BYLAYER

More properties that may be modified are **Linetype Scale, Size, Thickness and Text Size.**

Pulldown Menu Location: Tools in GIS

Keyboard Command: convert_set

Prerequisite: None

Isolate Layers

This is a modified Isolate Layers command providing ability to retain entities converted by Property Converter.

This function allows the user to temporarily freeze layers which are not currently being used, to clean up the work area. By default, the function will freeze all layers which do not contain any entities modified by the Property Converter command. You may disable this behavior and specify additional entities, whose layers have to remain visible.

Prompts

Retain layers with converted entities [<Y>/N]? *N*

Select objects on layers to isolate.

Select objects: *select entities to isolate*

Pulldown Menu Location: GIS Tools

Keyboard Command: insertmark

Prerequisite: None

Mark Insertion Points

This routine defines future alignment points within the block to be inserted. It creates a point in the drawing, and that point stores the position and description of the point. When the block containing the point is inserted into the master drawing the description is used to prompt the user for the location of the matching point in the master drawing.

If one such a point is found in the block, it defines the shift. When there are two, they define the shift, rotation and scale of the block being inserted. To define an insertion point, specify the point location and a prompt you want the user to see when the block-to-be is inserted.

Prompts

Select an insertion point for the marker: *pick a point*

Type an insertion prompt <Pick Alignment Point 1>: *press Enter*

Pulldown Menu Location: GIS Tools

Keyboard Command: insertmark

Prerequisite: None

Write Block by Polyline

This command creates a smart block for future insertion into a master drawing. The block contains pre-defined insertion point(s) which define block alignment in the master drawing. This function requires a closed clipping polyline and one or two insertion points. Any linework entities which cross the specified closed polyline are broken at the intersection and only internal portions are inserted.

Prompts

Select a clipping closed polyline:

Select object: *pick a closed polyline*

Select smart insertion markers to include in a block:

Select objects: *select markers*

Pulldown Menu Location: GIS Tools

Keyboard Command: wblockpoly

Prerequisite: Closed clipping polyline

Insert with Join/Align

This command places the previously created smart block into the master drawing. After selecting a block to be inserted, the program finds insertion points and prompts the user to pick the corresponding points in the master drawing.

The next step is cleaning up an area of the master drawing which is now overlaid with the inserted block. The program detects the layers being affected and prompts user with a dialog which lists layers affected, asking the user to specify the layers containing entities of the master drawing to be removed. This list contains only layers which are present in both master drawing and a block default to be removed.

After modification of the layer list is complete, the user is given a chance to review entities to be remove from the master. At first, the entities within the insertion area on the selected layers are highlighted, but the user may unselect or select entities before removal.

Pulldown Menu Location: GIS Tools

Keyboard Command: smartinsert

Prerequisite: Smart block

Snap Linework To Points

This command changes the vertices of linework (lines and polylines) to match coordinates from the current coordinate file. The purpose is to improve linework for the case of having coordinate data that is more accurate than the linework. The program prompts to select the linework entities to process and then uses all the coordinates from the current coordinate file to snap the linework vertices. Use the Set Coordinate File command to set the current coordinate file.

In the dialog, the Snap Tolerance is the max distance that a linework vertex will move onto a point. The Match Tolerance is the distance between linework vertex and point that the program will consider equal and won't move the linework vertex.

Prompts

Snap Linework To Points Dialog

Select linework to process.

Select objects: *pick lines and polylines*

Pulldown Menu Location: GIS Tools

Keyboard Command: snap_lwork

Prerequisite: Linework in the drawing and points in the current coordinate file

Set Text Layer By Text String

This command sets the layer for each selected text entity to the string of the text entity.

Prompts

Select text to set layer.

Select objects: *pick text*

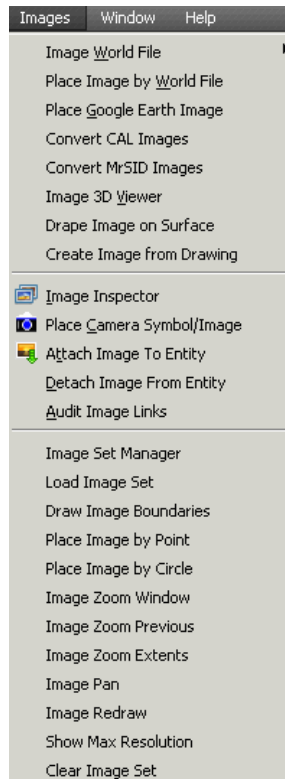

Pulldown Menu Location: GIS Tools

Keyboard Command: layertxt

Prerequisite: text entities

GIS Image Menu

The Images menu has commands for placing aerial images, attaching images to entities and managing an image database.

Create World File from Image Alignment

This command creates an image world file (TFW) from a TIF or JPG image. First the image file to be used is selected, and then two points in the drawing are specified along with two corresponding points on the image. The image is scaled and rotated to match the input data, and a World File is written with the specified data.

Prompts

Image File To Process: *choose .TIF or .JPG file*

Select First Reference Point in the Drawing: *pick a point in the drawing*

Select location of First Reference Point on the Image: *pick a point on the image*

Select Second Reference Point in the Drawing: *pick a second point in the drawing*

Select location of Second Reference Point on the Image: *pick a second point on the image*

Pulldown Menu Location: Images > Image World File

Keyboard Command: make_world_file

Prerequisite: TIF image file

Create World File by Image in Drawing

Once an image has been inserted, scaled and rotated into a drawing, it may be desirable to create a "world file" (see the frequently changing Wikipedia topic at http://en.wikipedia.org/wiki/World_file for additional information) from the image so that the image can be re-inserted into a drawing at the proper placement, scale and rotation angle by using the Place Image by World File command.

A common method for inserting raster images into a drawing that don't have an accompanying "world file" would be through the use of the Place Google Earth Image command.

Prompts

Select images to process.

Select entities: *Select the raster entities whose world file should be created*

Pulldown Menu Location: Images

Keyboard Command: make_geotiff

Prerequisite: Raster image in the DWG

Create Image World File

This command creates an image world file including TFW from a TIF image and JPW from JPEG 2000 image. The image file needs to have georeference data embedded inside the file that contains the image position and pixel size. The world file such as TFW is an externalized georeference file for this data that the Place Image By World File and Image commands use.

Prompts

Image File To Process: *choose image file*

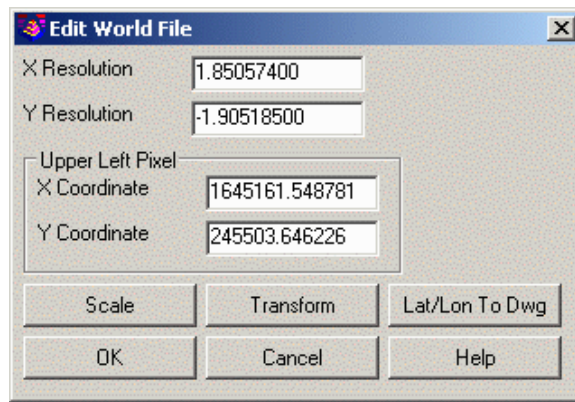

Pulldown Menu Location: Images > Image World File

Keyboard Command: maketfw

Prerequisite: TIF, JP2, J2K, JPF, JPX or JPM image file

Edit World File

This command edits the information in an image world file. After selecting the world file to edit, the parameters are shown in a dialog where you can edit the resolution or coordinates. The resolution defines the size of a pixel in drawing units. The Scale function multiplies the resolution and coordinates by a factor and can be used to convert a world file between English and metric units. The Transform function converts the world file between coordinate systems such as from UTM to State Plane. The Lat/Lon To Dwg function converts a world file in lat/lon units into units for the current drawing using the projection definition from Drawing Setup.

Pulldown Menu Location: Images

Keyboard Command: edit_world_file

Prerequisite: Image world file

Place Image by World File

This routine is intended for users of Carlson products that do not have the AutoCAD Map platform. If you have the Map extension available, it is recommended that you use the tool provided.

This function allows you to insert Geo-Referenced TIF files into the drawings. This process requires the presence of an accompanying TFW file. The TFW file contains information about the location and scaling of the actual raster image TIF file. This eliminates the guesswork in inserting, moving, and rotating raster images to the project area. You begin by selecting the TFW or JGW file to process. If the related TIF file is present in the same directory, the image will be inserted into the proper coordinates.

Prompts

Select World File: *choose existing .TFW or .JGW file*

Pulldown Menu Location: GIS Tools

Keyboard Command: geotiff

Prerequisite: None

Place Image by World File

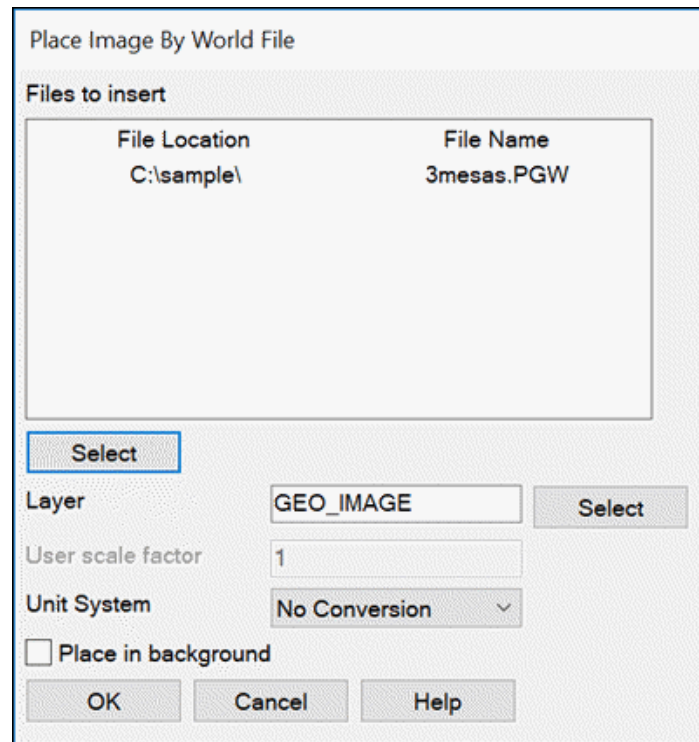

This function inserts a geo-referenced image files into the drawing. The geo-reference data supplies the position for the image so that the image can be placed without prompting for the position, rotation or scale. This eliminates the guesswork in inserting, moving, and rotating raster images to the project area. This process requires the presence of an accompanying World file. The supported World File formats include: .TFW, .JGW, .J2W, .PGW, .SDW, .JP2, .J2K, .JPF, .JPX, .JPM and .ECW.

The World Files are a separate file from the image file. For example, a .JGW is the World File for a .JPG image file. The world file and the image file need to be in the same folder. The program also supports geo-tagged images where the world file data is stored within the image file instead of having a separate file.

In addition to working with World File, this command also supports geo-referenced .TIF file that have the world data embedded in the image file.

You begin by selecting the World file to process by picking the Select button. You can import multiple images. The Layer sets the layer name for the image entity in the drawing. The Unit System allows for scaling the image such as

having an image in metric units and a drawing in feet units. Besides meters-to-feet conversions, you can also apply a custom scale factor. The Place In Background sets the display order of the image to the back.

Pulldown Menu Location: GIS Tools

Keyboard Command: geotiff

Prerequisite: A georeferenced image file

Place Google Earth Image

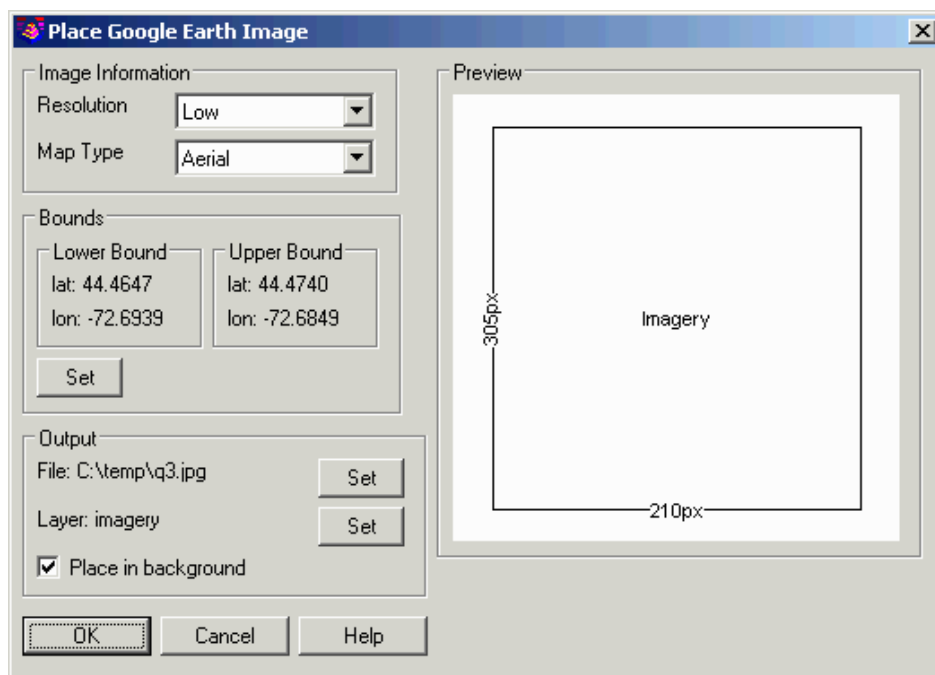

This command inserts a geo-referenced image into the drawing using the Google Earth imagery server. This command requires an internet connection. In order to automatically place the geo-referenced image in the drawing, the drawing must also be geo-referenced by defining the grid projection in the Settings > Drawing Setup command. If the drawing isn't geo-referenced, you still can place the image by manually picking the location.

The command starts by prompting for the image file to create. The Google Earth image will be saved to this file name and then inserted into the drawing.

Next the program prompts to pick the area in the drawing for the image. You can either screen pick two points to window the area for the image, or use the Map option to graphically set the image area. In the Map dialog, use the mouse wheel to zoom in/out and click-n-drag the mouse to pan. You can also enter a place name or address in the Search field to set the view.

Then there is an options dialog.

Resolution: controls the size of the image file. The Preview window shows the number of pixels for the currently selected Resolution.

Map Type: selects the type of image to create.

Bounds: shows the currently selected area in decimal lat/lon. Pick the Set button to pick a new area in the drawing.

File: the image file to create.

Layer: sets the layer for the image in the drawing.

Place in background: sets the display order for the image to back.

Note:

- Once an image has been inserted into the CAD drawing, it may be helpful to create an associated "world" file for the image in case it needs to be re-inserted into the active drawing (or an alternate drawing). Creating a "world" file assists with this task. To generate a world file, please reference the Create by Image in Drawing command.
- Once the image has been inserted into the CAD drawing, it may be helpful to control its "display order" by using the View > Display Order > Order by Layer command or View > Display Order > Send to Back command.
- The Place Google Earth Image routine fetches aerial imagery in real-time from the Google servers and requires an Internet connection to proceed.

Prompts

Select Output File *Choose image file name to create*

Pick from Screen or use Map [**<Screen>/Map**]? *press Enter*

Pick first corner of bounding box: *Identify one corner of a drawing window that should be used to set the Google Earth display*

Pick second corner of bounding box: *Identify the opposite corner of a drawing window that should be used to set the Google Earth display*

Place Google Earth Image dialog

- To import KML or KMZ content into your drawing, use the Import Google Earth File command.
- To export content from your drawing to a KML or KMZ file, use the Export Google Earth File command.

Pulldown Menu Location: Images

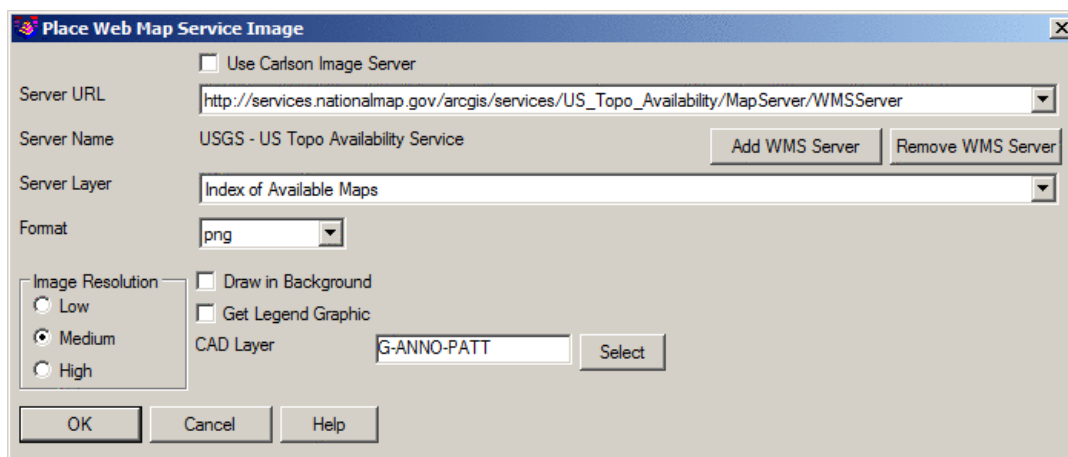

Keyboard Command: google_image

Prerequisite: Coordinate projection system, Internet connection

Place Web Map Service (WMS) Image

The Place Web Map Service (WMS) Image command provides an ability to fetch map data from on-line sources as a means to quickly and easily construct raster map data in and around an area of interest. In addition to producing a raster image, an accompanying "World" file for the image is also generated that permits the image to be properly repositioned for geo-referencing purposes.

For WMS servers that require an API Key such as NearMap, put the API Key into the Server URL at the end of the web address. The API Key needs to be between "?apikey=" and "&". For example, https://wmsus.nearmap.com/wms?apikey=your_api_key&

Use Carlson Image Server: When enabled, images are fetched from a WMS server hosted by Carlson Software.

The Carlson Image Server includes links for:

- USGS EROS Ortho Imagery (an alternative source to Google Earth for aerial images)
- USGS Vegetation
- USGS Topo

- USDA Soil Map
- US Fish and Wildlife Wetlands

- ESRI World Street and Topo
- OpenStreetMap

Server URL: Select the desired Uniform Resource Locator (URL) from where the image data should be obtained.

Server Name: A read-only label identifying the name of the WMS server.

Add WMS Server: When clicked, the URL of a WMS server may be input that is subsequently added to the Server URL drop-list.

Remove WMS Server: Deletes the currently selected WMS Server from the Server URL drop-list. Prior to the removal of the WMS Server, a confirmation alert box will be displayed asking for confirmation. Any images previously placed into a drawing from the WMS Server will remain in the drawing.

Server Layer: Choose the type of image data to retrieve from the selected Server URL.

Format: Indicate the type of image format.

Image Resolution: Controls how many "picture elements" (pixels) will be used to render the image:

- **Low:** The image is divided into a small number of pixels such that each pixel in the overall image covers a relatively large geographical region.
- **Medium:** The image is divided into a larger number of pixels (4-times as many as that produced through the *Low* resolution such that each pixel in the overall image covers a relatively smaller geographical region.
- **High:** The image is divided into the largest number of pixels (4-times as many as that produced through the *Medium* resolution such that each pixel in the overall image covers (relatively) the smallest geographical region.

Draw in Background: When enabled, the resulting image is drawn "underneath" existing entities in the drawing (essentially the same as View – Draw Order – Send to Back). An optional method to help control the visibility of placed images would be through the Order by Layer command.

Get Legend Graphic: When enabled (and for WMS "Layers" that support the generation of an image legend), a secondary image file that helps describe the content of the primary image.

CAD Layer: Key-in the desired Layer name in CAD that is to contain the image being created or use the **Select** button to select the CAD layer from the Select Layer dialog box.

Note:

- Several freely available WMS addresses can be found at the USGS National Map Viewer.
- Your local governing agency could/should be consulted to see if they publish any data via their own WMS.

Prompts

Pick first corner of bounding box: *Indicate one corner of a rectangular box that identifies your area of interest.*

Pick second corner of bounding box: *Indicate the other corner of a rectangular box that identifies your area of interest.*

- To import Esri ArcGIS On-line Services data into your drawing, use the Esri ArcGIS Services - Retrieve Map command.

- To import Web Feature Service information into your drawing, use the Web Feature Service (WFS) command.

Pulldown Menu Location: Images

Keyboard Command: getwmsimage

Prerequisite: Internet connection, Coordinate System Projection set through Drawing Setup

Convert CAL Images

This command converts .CAL format image files into .TIF format.

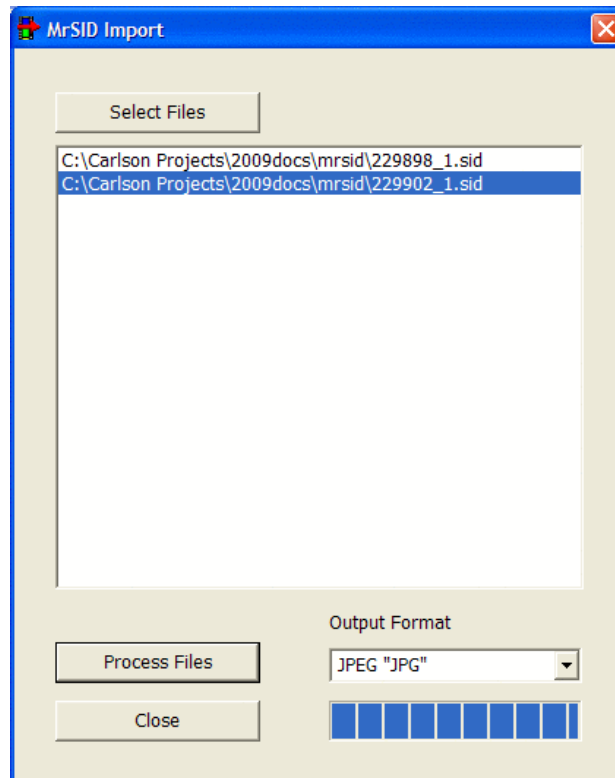

Pulldown Menu Location: Images

Keyboard Command: import_cal

Prerequisite: .CAL image

Import MrSID Images

This command allows you to select one or more image files in the MrSID format (.SID) and have them converted to either a (.TIF) or (.JPG) file format. Corresponding World files are also created. The new image files use the same file name and folder of the original MrSID image files except with the new file extension of .jpg or .tif. This conversion supports up to MG4 (Generation 4) MrSID files.

Pulldown Menu Location: Images

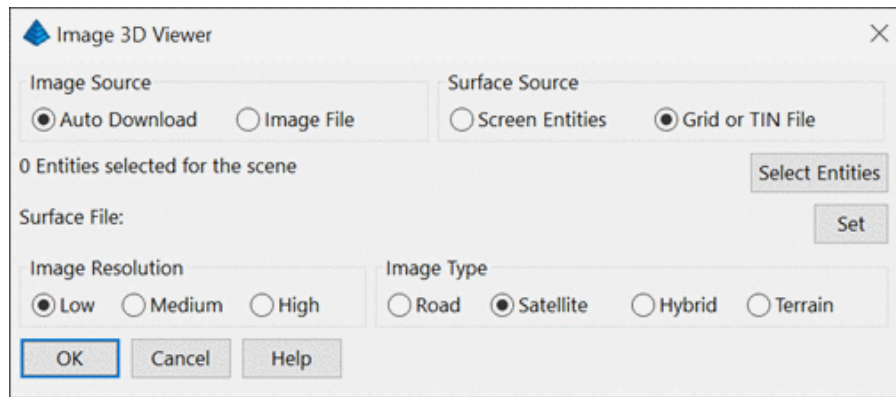

Keyboard Command: import_mrsid

Prerequisite: .SID file

Image 3D Viewer

This command provides a 3D Viewer that can be used to show a georeferenced image draped over a corresponding surface. The image can be either a georeferenced image file or automatically downloaded from Google Earth. For

the download, the dialog has choices for the image resolution and image type. The surface model can be either a surface file or 3D Face entities in a drawing.

Pulldown Menu Location: Images

Keyboard Command: view_geotiff

Prerequisite: 3D Faces or TIN or GRD file for surface and corresponding georeferenced image file

Drape Image on Surface

This command drapes (or "overlays") an image onto a surface in the drawing. You are first asked to select a TIF, JPG or SID geo-referenced image file, and then to select the 3D Faces of the surface to drape the image on.

After the image is draped on the 3D faces, you can view the image in the drawing by setting the CAD render mode. For example, use the SHADEMODE command and set it to Realistic.

Note:

- The 3D Faces of a surface can be placed by commands such as the Draw 3D Grid File, Triangulate Tab of Triangulate & Contour or Draw Triangular Mesh.
- Functionality similar to the *Drape Image on Surface* command can be found in the Image 3D Viewer command.

Prompts

Image File To Process: Choose a geo-referenced .TIF or .SID file

Select surface faces.

Select entities: *pick the 3D faces*

Pulldown Menu Location(s): Images

Keyboard Command: `drape_geotiff`

Prerequisite: geo-referenced TIF or SID image file and 3D Faces of a corresponding surface.

Color TIN By Image

This command assigns colors to the TIN faces using colors from a georeferenced image. This command applies to having an aerial image and a ground surface model that you can to colorize. The program prompts for the image file, input TIN file and output TIN file. The georeferenced image can be a TIF, JPF, JP2 or ECW format. The colorized TIN can be viewed in the 3D Viewer image.

Here's an example of the TIN before and after Color TIN By Image.

Pulldown Menu Location: Images

Keyboard Command: image_tin

Prerequisite: .TIN file and geo-referenced image

Create Image from Drawing

The *Create Image from Drawing* command allows you to create a raster image of selected entities in your drawing to produce an photographic style image with a corresponding "world" meta-data file. This combination of files (*.TIF, *.TFW) allows the image to be correctly located with routines such as the Place Image by World File and Surface 3D Fly-over commands.

Resolution: Indicate the width of the image about to be created in pixels. Higher values permit the image to carry crisper details but increases the resulting file size at a geometric rate.

Background Color: Indicate the desired color of the background portion of the image.

Note:

- For normal (best) results, a "plan" view angle is suggested and can be accomplished through the *View > Viewpoint 3D* command.
- The "X-direction" limits ("X" is normal to the current angle) of the entities selected for the image will be contained by the image width (or *resolution*) specified above to produce a "Pixel:CAD Units" ratio. This ratio is multiplied by the vertical, "Y-direction" limits ("Y" is normal to the current view angle) of the entities selected to produce the image height.
- The TIF image produced by the command will carry an X and Y "resolution" of 72 dpi (dots per inch). For an image 1000 pixels wide, the "measureable" width of the image would be 13.889 inches and is the quotient of image width divided by the resolution (*e.g.* 1000/72).

Prompts

Image File to Create: *Specify the name of the image that is to be created.*

Select entities for image.

FILter/<Select entities>: *Select the entities that are to display in the image and press Enter when complete.*

Pulldown Menu Location: Images

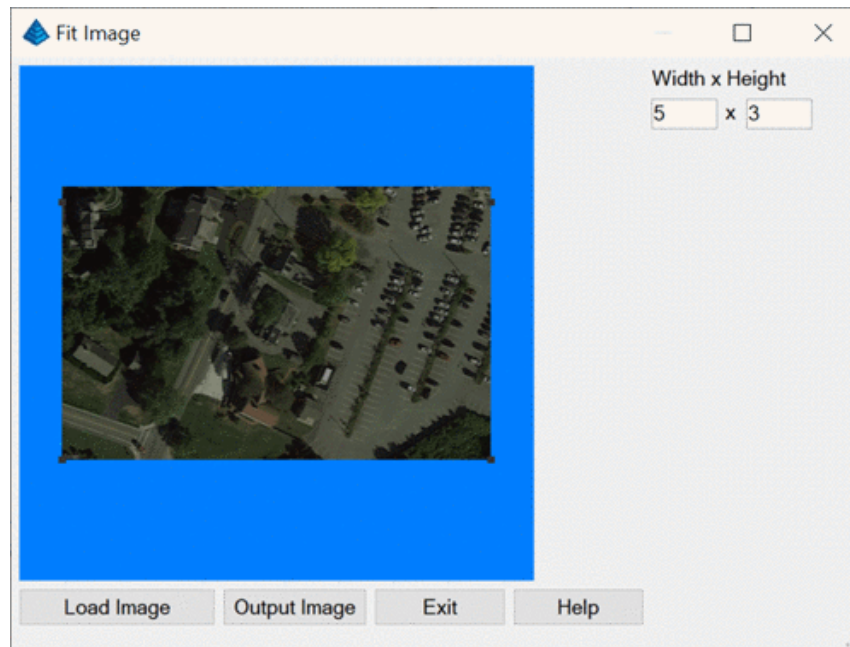

Keyboard Command: dwg2geotiff

Prerequisite: Entities in the drawing

Fit Image To Aspect Ratio

This command crops an image to fit the specified aspect ratio. After selecting an image file, the dialog shows the image with grip squares at the corners for the crop. The aspect ratio is set in the edit boxes as the ratio between width and height. Click and drag a grip square to resize the area. Pick and drag in the middle of the image to change the crop area.

The Load Image button is to select another image to process. Pick the Output Image button to save the cropped image to an image file.

Pulldown Menu Location: Images

Keyboard Command: fit_image

Prerequisite: Image file

Image Inspector

This command views images and documents attached to entities. At the start, there's a prompt for inspecting on the screen or in a dialog. For Screen, the program highlights all entities that have attached images or documents. When you move the cursor over these entities, the attached image or document name is displayed in a window. If you click within the image window, the program will start the image application editor that is setup for your system. For documents, click on the document name to start the document application. This application, such as Microsoft Internet Explorer, depends on your Windows system setup. Also while moving the cursor over drawing entities, you can use the up/down arrows to resize the image. When multiple images or documents are attached to the same entity, use the left/right arrows to cycle through the images.

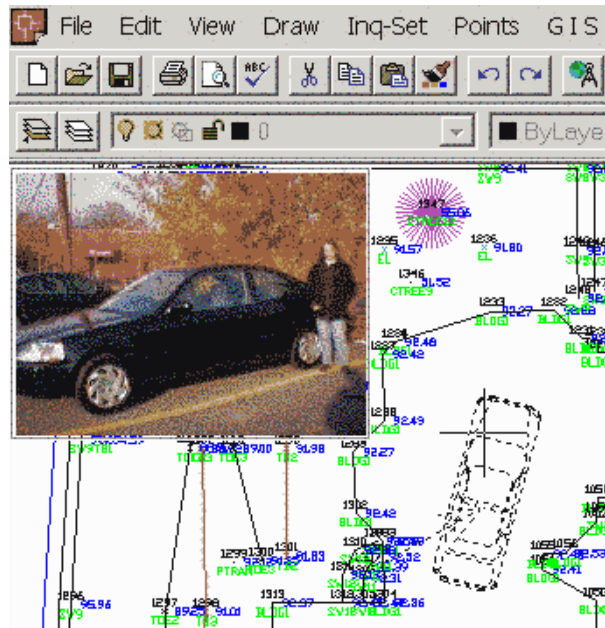

For the Dialog method, the dialog shows a list of all the images/documents found in the drawing. When the image is highlighted in the list, the dialog shows a graphic preview. You can use the Zoom buttons to zoom the drawing to the highlighted image. The Report function makes a report of all the images in the drawing.

Prompts

Inspector view [<Screen>/Dialog]? *press Enter for Screen*

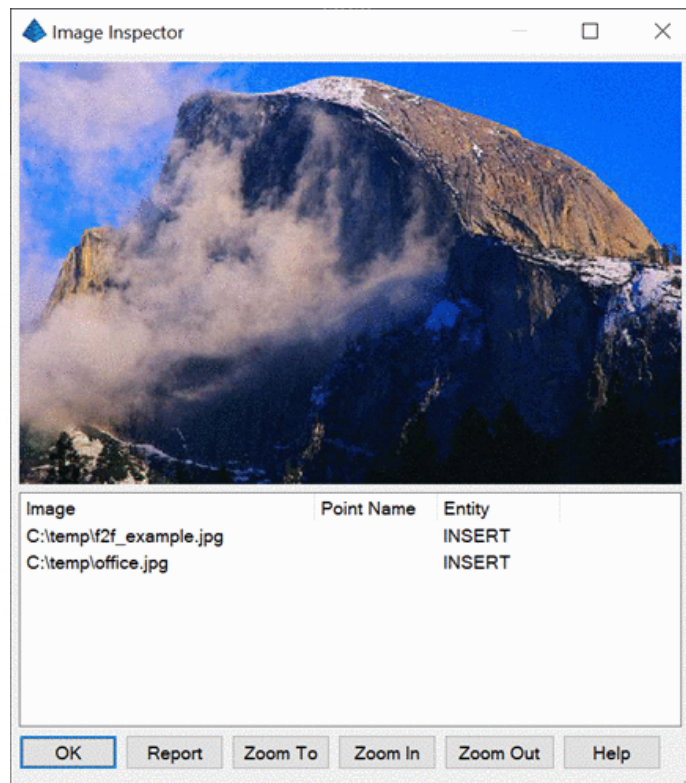

Arrow keys Up/Down=Image Size; Left/Right=Cycle Images; Pick Image=Open Image

Move pointer over entity with image (Enter to End): *press Enter*

Car image displays in upper-left of drawing when cursor is over car symbol

Inspector view [`<Screen>/Dialog`]? *D for Dialog*

Pulldown Menu Location: Images

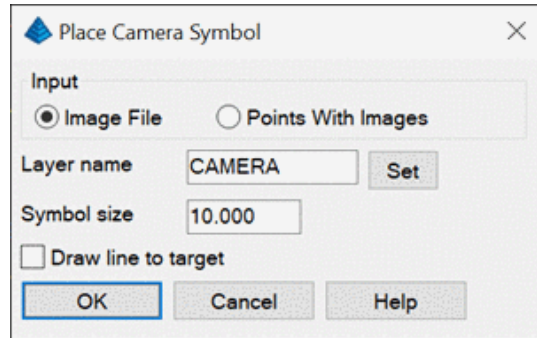

Keyboard Command: view_image

Prerequisite: drawing entity with attached image or document

Place Camera Symbol/Image

This command allows you to place the location of a camera symbol into the drawing, and then attach an image to the camera. The Draw Line To Target option draws a line from the camera symbol to the target position. There are two input methods. For the Image File, the program prompts to select an image file (.bmp, .tif, .jpg). For the Points With Images, the program prompts to select Carlson point entities in the drawing. The program will then use any images assigned to the points.

After you complete this command, use the Image Inspector command to view the attached image.

Prompts

Image File To Process *select image file*

Place Camera dialog

Pick camera position: *pick a point*

Pick target position: *pick a point to rotate camera*

Attach Image to Object dialog box

Pulldown Menu Location: Images

Keyboard Command: place_camera

Prerequisite: Image file (bmp, jpg, tif)

Attach Image to Entity

This command attaches image and document files to a drawing entity. The possible file formats are .pdf, .doc, .bmp, .jpg and .gif. Any type of drawing entity can be used such as polyline, points or symbols. To run the command, first pick an entity on the screen. Then a dialog appears for selecting the image or document. First set the image directory and then highlight the file name. A graphic of the image should appear in the preview window. Then click Attach Selected Image/Doc.

The Capture New Image button can be used to trigger an attached digital camera to take an image. The Pick Camera and Set Camera buttons can be used to configure the camera to use.

Multiple images or documents can be attached to the entity by picking Attach Selected Image/Doc or Capture New Image multiple times. To cycle the images in the preview, use the Next and Prev buttons. Use the Remove Attached Image to remove the image shown in the preview. Use Remove All Attached Images to clear all images from the entity.

The View Attached Image/Doc button will display in the preview window any image already attached to the entity instead of the selected image file. Also any image already attached to the selected entity is displayed in the Current Image field at the top of the dialog when nothing is selected in the file list.

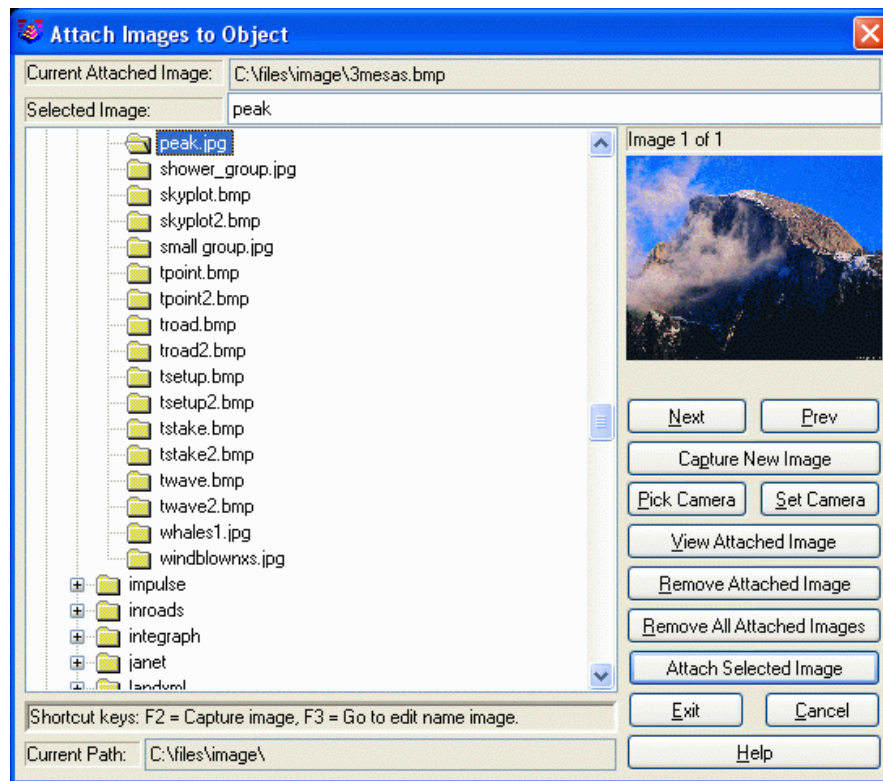

Prompts

Select object to attach symbol to: *pick an entity*

Attach Image to Object Dialog

Done.

Select object to attach symbol to: *press Enter*

Pulldown Menu Location: Images

Keyboard Command: set_image

Prerequisite: A drawing entity and an image or document file

Detach Image From Entities

This command removes image and document file links from the selected entities.

Prompts

Select entities to remove image links from.

Select objects: *select image file links*

Pulldown Menu Location: Images

Keyboard Command: detach_image

Prerequisite: image file links

Audit Image Links

This command checks links between drawing entities and attached images and documents.

Prompts

Select object to attach symbol to: *pick an entity*

Attach Image Dialog

Done.

Select object to attach symbol to (Enter to End): *press Enter*

Pulldown Menu Location: Images

Keyboard Command: `audit_image_links`

Prerequisite: a drawing entity and an image file

Draw Entity Images

This command draws images that have been attached to entities by commands such as Attach Image/Doc To Entity. The options dialog sets the layer for the images and a scale factor for sizing the images. After the dialog, the program prompts for the entities to process. The images are located at the coordinates of the entities.

Pulldown Menu Location: Images

Keyboard Command: `draw_image_links`

Prerequisite: Entity with attached image

Image Set Manager

Image Set Manager is a program within Carlson GIS that is used to create image sets for CAD and SurvCE. An image set is a collection of images that cover a geographic area. Image sets can contain thousands of images which are indexed and geo-referenced in the image set database (.IDB). Once an Image Set is created, the rest of the tools in this area of the Images menu become available to view the images, Zoom on the images, Pan through them, etc...

Supported Image Types

Image Set Manager supports GeoTIF, TIF, JPEG, SID and BMP images.

Geo-referenced, (GeoTIF), images are directly supported by reading the embedded tags in the image. TIFF, JPEG and BMP are supported with world files and the World File Editor.

File Menu

Open Image Set

Creates a new Image Set or opens an existing Image Set. The image database and set of images are stored to a project folder.

Import Image Set

Adds an existing Image Set to the current Image Set.

Open Image Files

This command will open and display individual images for processing. Geo-referencing is automatic for images with World Files or supported Geo-TIF. For GeoTIF the image coordinate positions will be displayed at the bottom of the image frame.

When the image is open the following tools become available.

Image Brightness: Generalized adjustment to the tonal range. This tool is useful to lighten the image for background display

World File Editor: Allows the user to import, view, create and edit image geo-reference information.

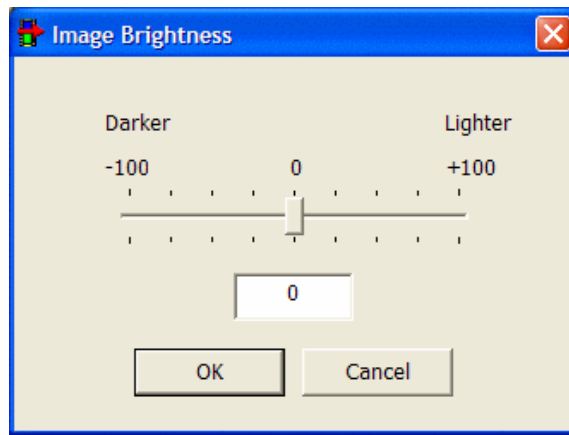

Image Properties: Displays Information about images in the Image Set.

Tools Menu

Image Brightness

The Image Brightness tool is an easy way to make generalized adjustments to the tonal range of the image.

1. Open an Image and choose Image Brightness from the Tools menu. The Image Brightness dialog box appears.
2. Drag the slider to adjust the brightness of the image. Drag the slider to the left to decrease the brightness and to the right to increase it. Values range from -100 to +100.
3. When you have finished making adjustments, click OK.

Convert to Greyscale

This command converts a color image to greyscale.

World File Editor

The World File Editor allows the user to import, view, create and edit image geo-reference information. A World File is an ASCII text file used to geo-reference image files. World files have the following format.

World File Format

```
1.0 <X Resolution>
0.000 <Amount of Translation>*
0.000 <Amount of Rotation>
1.0 <Y Resolution>
424178 <X Coordinate of 1,1 (upper-left pixel)>
4313415 <Y Coordinate of 1,1 (upper-left pixel)>
```

Image Export supports the following World File Formats.

Image Format

TIFF, TIF
JPEG, JPG
Bitmap, BMP

World File

TFW
JGW
BPW

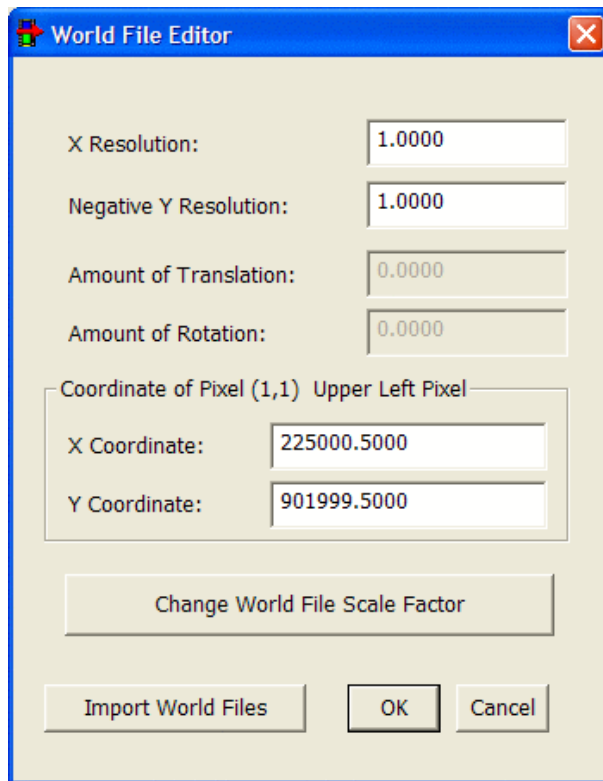

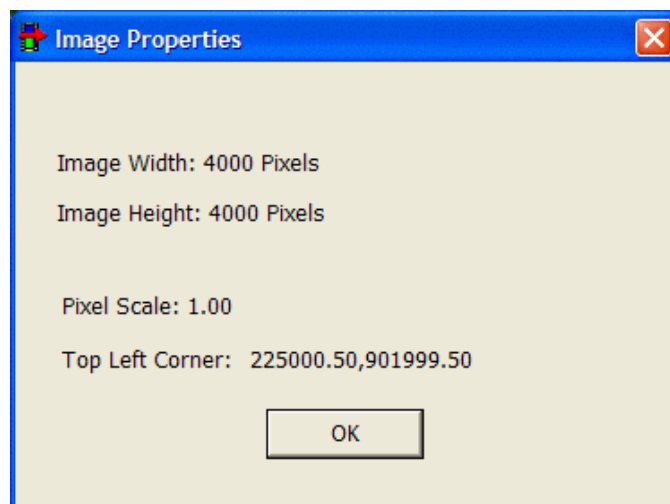

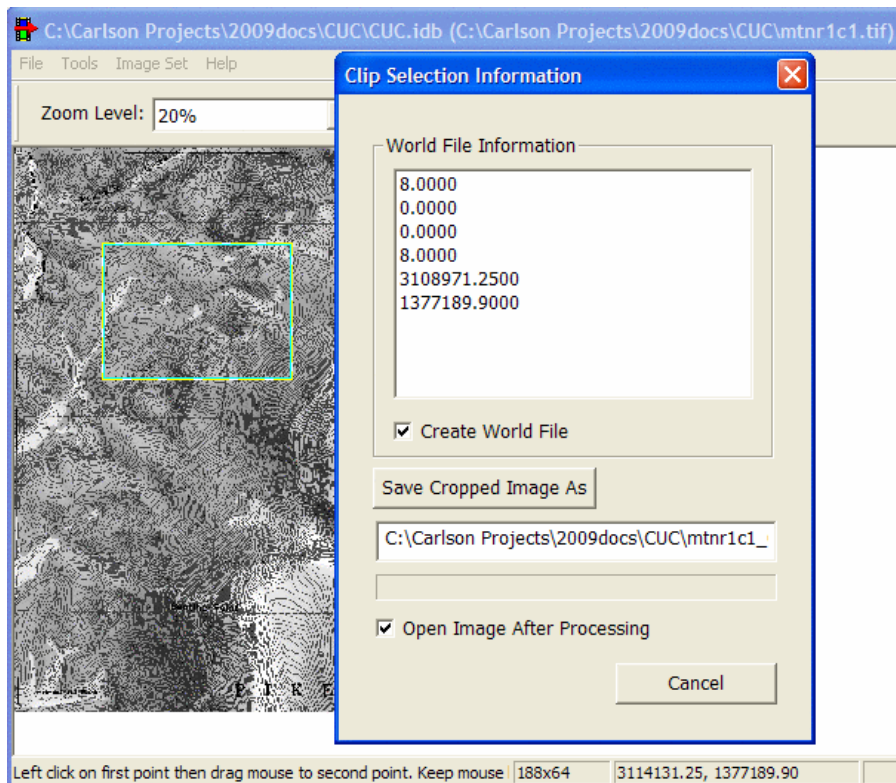

Image Properties

This option is used to display information on the current image.

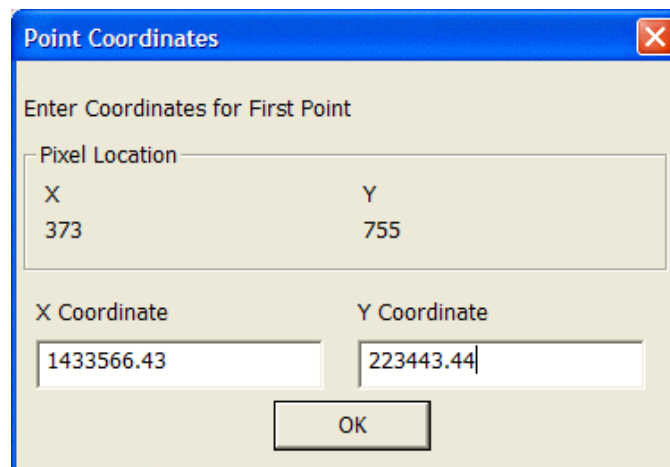

Crop Selection

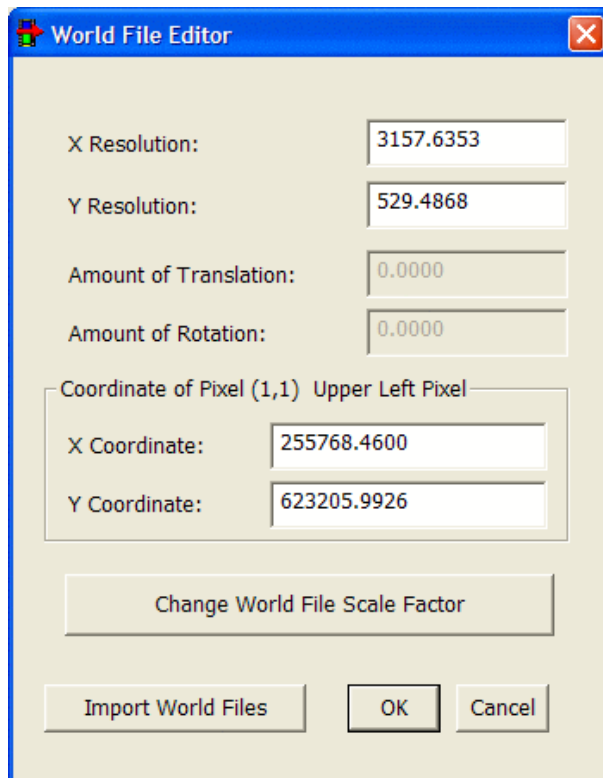

This command allows the user to crop a specific area within an image and save it as a new image.

Geo-reference by User Points

This command allows the user to pick 2 points on the image and assign coordinates to them to geo-reference the image. The user is prompted for coordinates for each point after it is picked, and then the World File Editor is displayed with the resulting data.

Change Resolution

This command allows the user to change the resolution of the image, thereby saving it as a smaller image file size.

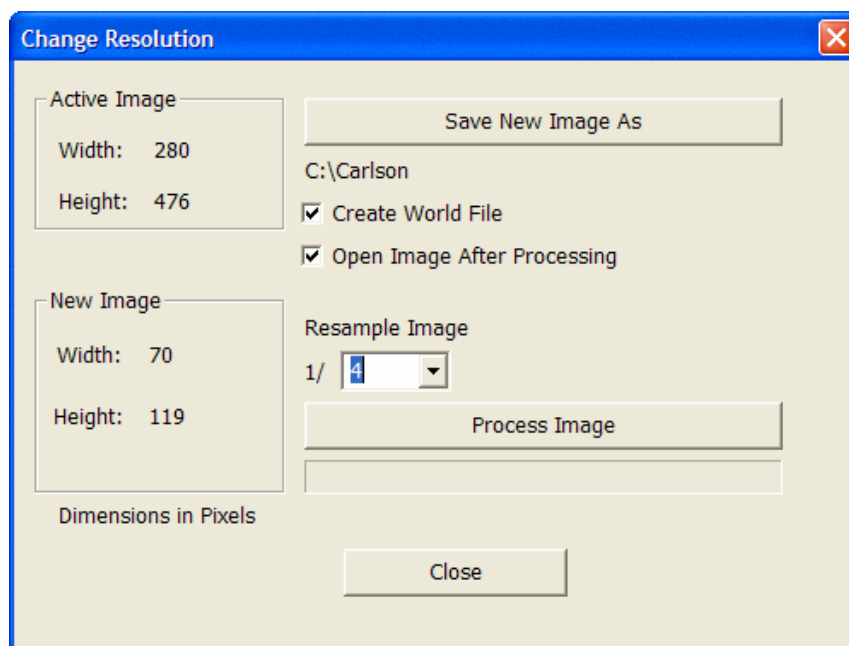

Image Viewer

Image Set Manager has an image viewer to display the current image. Zoom level is controlled by the drop down list at the top left. The X and Y pixel position and geographic coordinates are displayed in the bottom right panel.

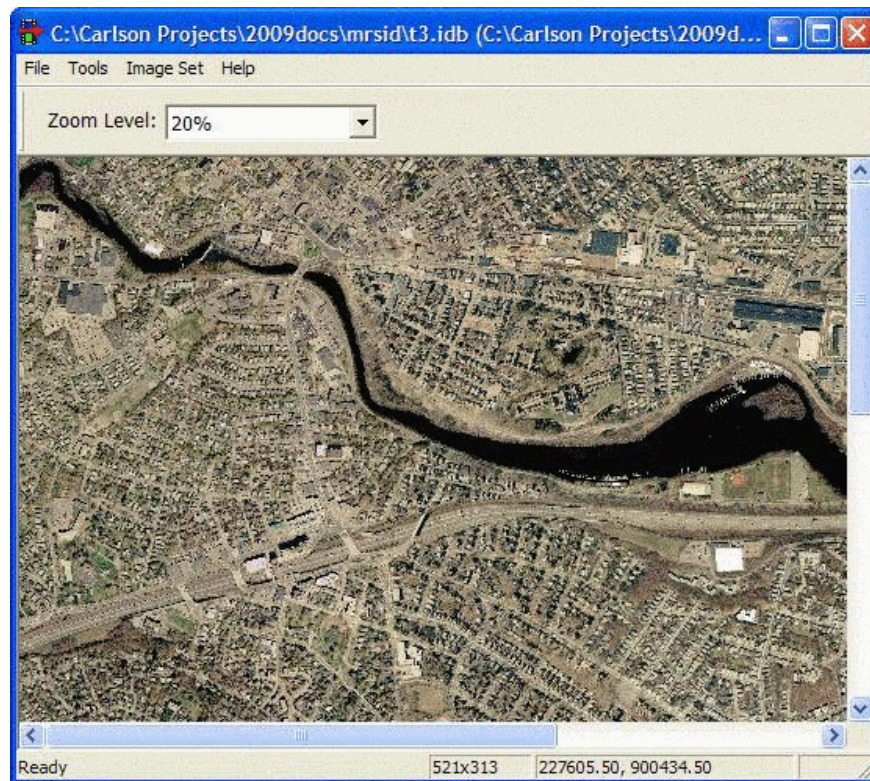

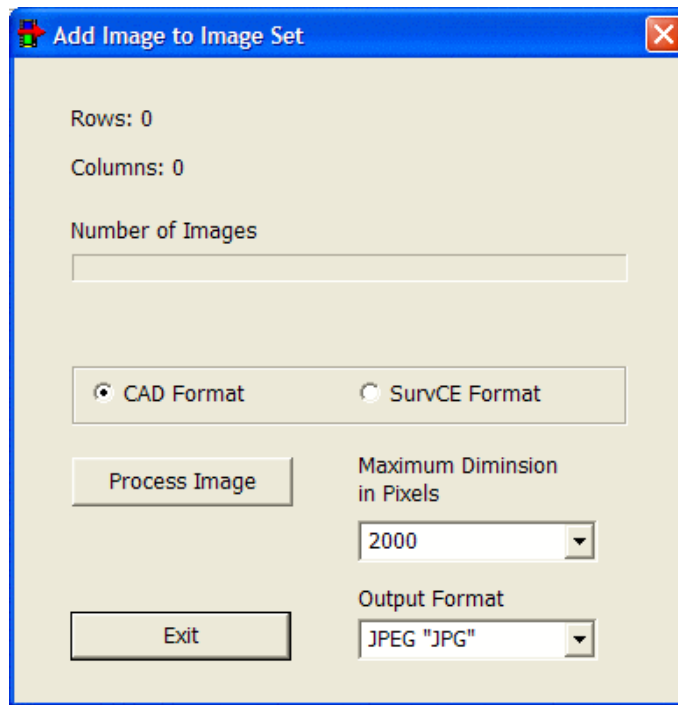

Image Set Menu

Add Image to Set

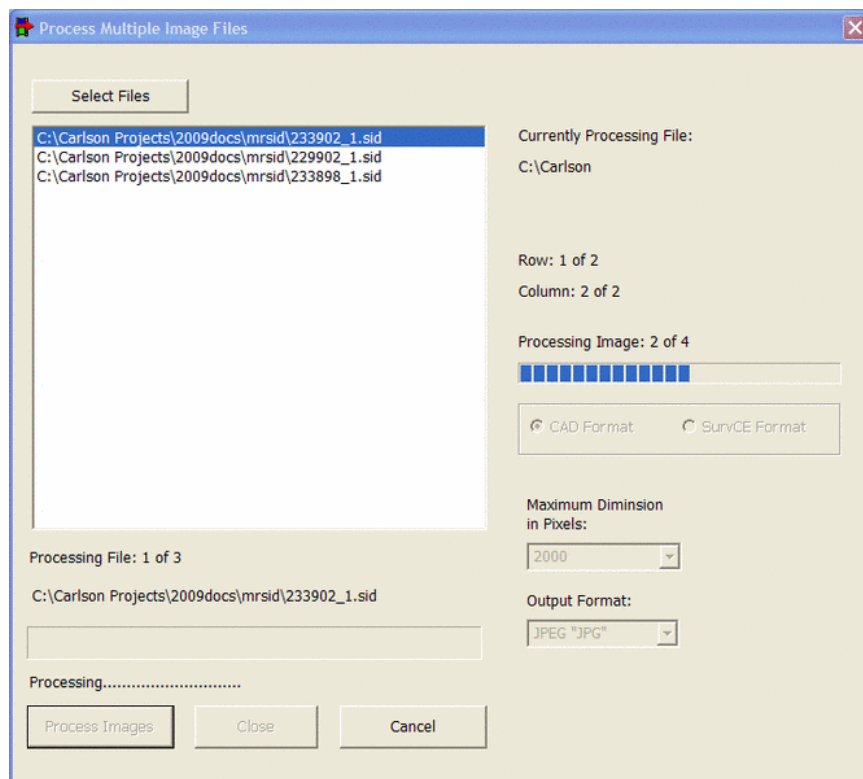

In order to display images they need to be added to the image database.

1. Open an Image using Open Image File in the File Menu.
2. Geo-reference the image. If the image is not a GeoTIF image use the World File Editor to geo-reference the image.
3. Click Process to process and add this image to the image database. This process may take several minutes. The progress bar and dialog text will keep you informed of the progress. Large images are being clipped into smaller pieces for viewing in SurvCE. When complete click OK.
4. Repeat the above steps to add multiple images to the database. Multiple images in the same database should be contiguous. Images from different locations should be placed in separate databases.

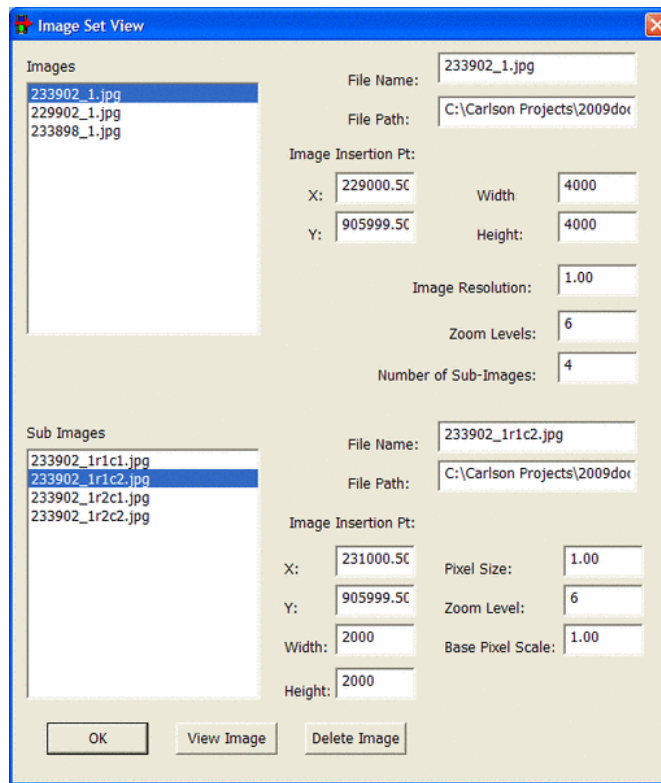

Add Multiple Images to Set

This command allows the user to add multiple images to a single Image Set. It supports the same files as the Open Image command. Images processed with this command must be geo-referenced.

View Image Set

The View Image Set command displays information for the images in the currently selected image database. The images processed are displayed in the top panel, and the sub images of the selected image are displayed in the bottom panel.

Pulldown Menu Location: Images

Keyboard Command: imagemgr

Prerequisite: None

Load Image Set

This command loads an existing Image Set into memory. Once loaded, the rest of the commands in this section of the Images menu can be utilized to view images, etc.

Pulldown Menu Location: Images

Keyboard Command: ireaddb

Prerequisite: A saved Image Set

Draw Image Boundaries

This command draws polylines in the drawing to represent the boundaries of the images in the loaded Image Set.

Pulldown Menu Location: Images

Keyboard Command: ibound

Prerequisite: A loaded Image Set

Place Image By Point

This command allows you to display images within a loaded Image Set by picking on the screen.

Pulldown Menu Location: Images

Keyboard Command: ipoint

Prerequisite: A loaded Image Set

Place Image By Circle

This command allows you display images within an Image Set that fall within the area of a specified circle.

Pulldown Menu Location: Images

Keyboard Command: icircle

Prerequisite: A loaded Image Set

Image Zoom Window

This command Zooms to an area in the loaded Image Set specified with a 2-pick Window. The image with the appropriate resolution is loaded as the Zoom level is changed.

Pulldown Menu Location: Images

Keyboard Command: izw

Prerequisite: A loaded Image Set

Image Zoom Previous

This command Zooms to the previous view of the loaded Image Set.

Pulldown Menu Location: Images

Keyboard Command: izp

Prerequisite: A loaded Image Set

Image Zoom Extents

This command Zooms to the Extents of the images in the Image Set.

Pulldown Menu Location: Images

Keyboard Command: ize

Prerequisite: A loaded Image Set

Image Pan

This command is used to Pan across images in the loaded Image Set. As you Pan, images are loaded as needed.

Pulldown Menu Location: Images

Keyboard Command: ipan

Prerequisite: A loaded Image Set

Image Redraw

This command refreshes the images in the loaded Image Set.

Pulldown Menu Location: Images
Keyboard Command: iredraw
Prerequisite: A loaded Image Set

Clear Image Set

This routine clears the loaded Image Set.

Pulldown Menu Location: Images
Keyboard Command: iclear
Prerequisite: A loaded Image Set.

Construction Module

8

The Construction module has Takeoff commands along with portions of the Survey and Civil modules. The Construction tools cover surface modeling, earthworks, takeoff, roads, machine control data prep, survey as-built mapping and stakeout. The Takeoff commands are covered in this chapter. See the Survey and Civil chapters for descriptions of those commands.

Surface

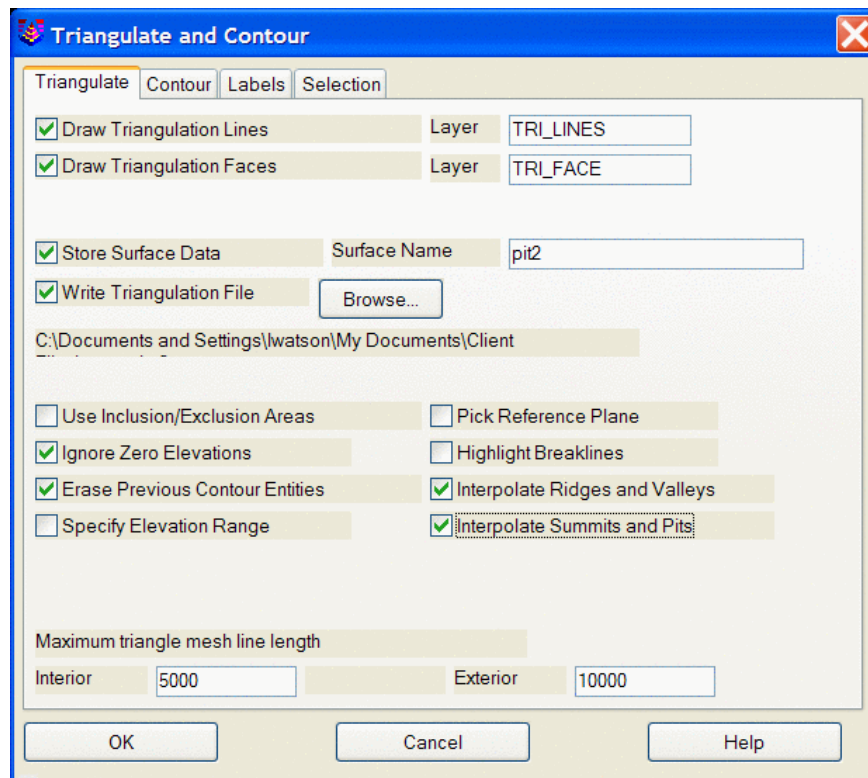

Triangulate & Contour

This command provides all of the functionality related to contouring and creating tin surface models in one routine. Given data entities that represent the surface, this command creates a final contour map with labeled, smoothed, and highlighted contours and/or a surface model that can be saved to a file (to be used in other areas of the program) or drawn on the screen as triangles or faces. Eligible data entities include points, inserts, lines, 2d polylines, 3d polylines, elevation text, 3d faces, and points from ASCII or coordinate (.CRD) files.

Triangulate & Contour has many options which are defined in the exhibits shown in the following pages. With this command, you can do any combination of drawing the triangulation network lines, drawing the contours, drawing triangulation network 3D Faces or lines, writing a triangulation file and storing a surface file.

In order to force *Triangulate & Contour* to correctly interpolate elevations between two points that define a grade break in the surface (such as points on a ridge, wall, or road), a breakline must exist between the points. A breakline line can be specified as a 3D polyline or line. In fact, all 3d polylines and lines with elevation are be treated as breaklines.

Triangulate Tab

Draw Triangulation Lines

When this option is turned on, the program will draw the triangulation as 3D lines. Specify the layer for these lines in the box to the right.

Draw Triangulation Faces

When this option is turned on, the program will draw each triangle in the triangulation network as a 3D Face. These 3D Faces can then be used in AutoCAD's modeling routines such as *HIDE* and *SHADE* or in routines such as *3D Viewer Window*, *3D Surface FlyOver* and *Slope Zone Analysis*. Specify the layer for these 3DFaces in the box to the

right.

Store Surface Data

This option names and creates a surface or surfaces that are associated with the drawing. The creation of a surface is necessary in order for the Surface Tools to function. A Triangulation file must also be specified before using the Store Surface option.

Write Triangulation File

This option stores the triangulation surface model as an .flt or a .tin file. The .flt file format is a text file depicting the edges in the triangulation network. The .tin file is a new binary file format depicting the triangulation network. The .tin file is much faster and more efficient than the previous .flt file format. The triangulation file/s can be used by several commands such as *Volumes By Triangulation*, *Spot Elevations*, and *Profile from FLT File*. Either type in the file name to create or press the Browse button to select a file name.

Use Inclusion/Exclusion Areas

When this box is activated, the program will later prompt you for inclusion and exclusion polylines which are used to trim the contours. The inclusion and exclusion polylines must be closed polylines and must be drawn before starting *Triangulate & Contour*. Only the parts of the contour lines that are within the inclusion polylines will be drawn. For example, an inclusion could be the perimeter of the site. The parts of contour lines that are inside the exclusion polylines are not drawn. Exclusion polylines can be used for areas where you don't want contours such as within buildings.

Ignore Zero Elevations

When activated, this setting will filter out all data points at an elevation of zero from the data set.

Erase Previous Contour Entities

When activated, this setting will erase previously drawn contour entities.

Specify Elevation Range

The program will automatically contour from the lowest elevation in the data set up to the highest at the increment specified in Contour Interval. If you would like to manually set the range over which to contour, select this option.

Pick Reference Plane

The triangulation network is based on the x,y position of the points. This option allows you to contour an overhang or cliff by changing the reference plane to a side view. The reference plane can be specified by first using the *Viewpoint 3D* command and then using the View option, or you can specify three data points on the cliff (two along the bottom and one at the top).

Highlight Breaklines

This option highlights breaklines in the triangulation network by drawing the triangulation lines along breaklines in yellow.

Interpolate Ridges and Valleys

This option creates additional triangulation in a ridge or valley situation to more accurately define the feature during surface modeling operations. This option would commonly be used when creating a surface model from existing contours, since it replaces the need to manually draw 3d polylines along ridges and valleys.

Interpolate Summits and Pits

This option creates additional triangulation in a summit or pit situation to more accurately define the feature during surface modeling operations. This option would commonly be used when creating a surface model from existing contours.

Before: Surface made from an existing contour map. Note the flat spots in the bottom of the valley when Interpolate Ridges and Valleys is disabled.

After: The same surface with Interpolate Ridges and Valleys enabled.

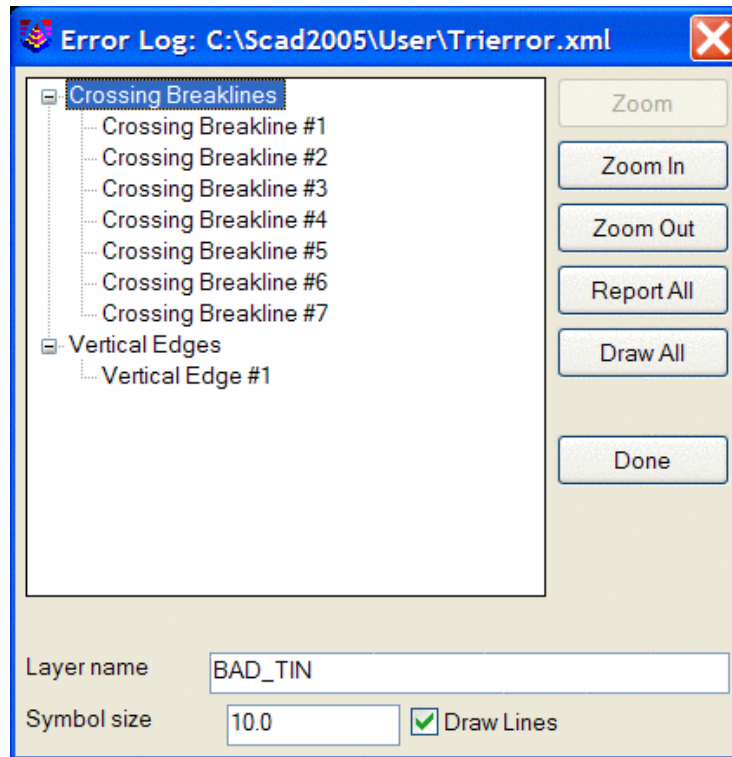

Max Triangle Mesh Line Length

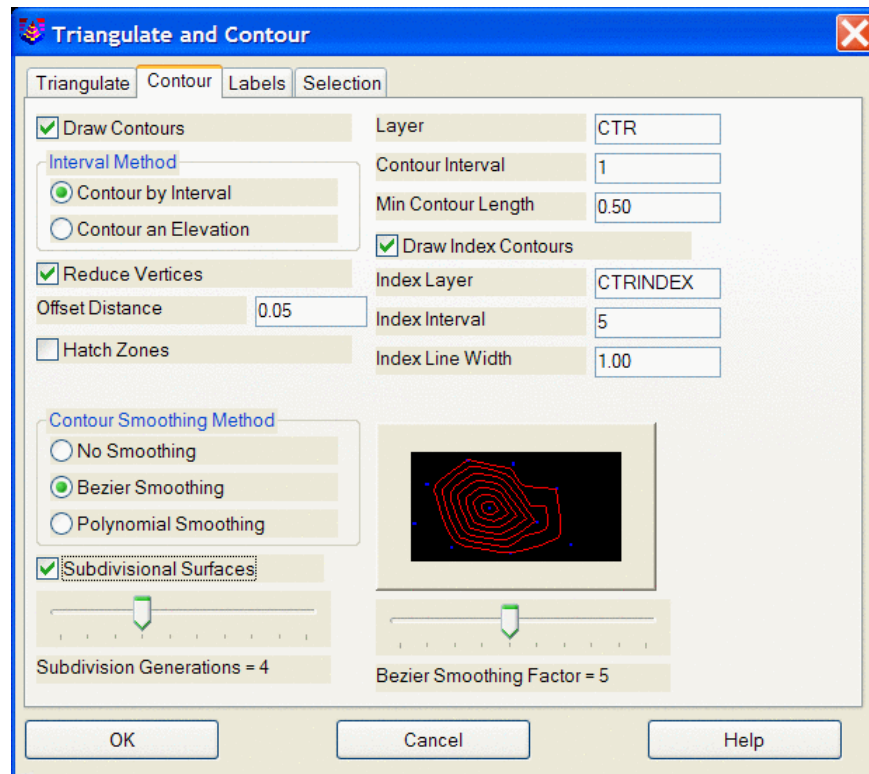

This value limits the length of the triangulation network lines. Any triangulation line that exceeds this limit will not be drawn or included in contouring. This allows you to avoid abnormally long triangulation lines where you have relatively too few data points and on the outskirts of your data points. The **Exterior** value applies to triangulation lines around the perimeter of the triangulation area and the **Interior** value applies all the other triangulation lines. Generally you would have the exterior value larger than the interior.

Error Log

The following dialog box appears when the Triangulate & Contour routine finds a conflict between breaklines or other surface entities. The type of conflict is identified, and when an item is chosen, a highlighted arrow is temporarily placed in the drawing to indicate the exact location of the specific conflict. Crossing Breaklines indicates that the intersection of two entities has two differing elevations. Vertical Edges indicates that two entities or vertexes of differing elevations have the same xy location, thus forming a vertical plane.

Contour Tab

Draw Contours

When this box is checked, the program will draw contour lines after triangulating. Otherwise, only the designated triangulation operations are performed. Specify the layer for contours in the edit box to the right.

Contour by Interval or Contour an Elevation

Select whether to contour by interval (ie: every 10 feet) or to contour a certain elevation. The elevation option allows you to contour specific values. For example, if you want just the 100ft contour, then select elevation and enter 100. The default mode is by interval.

Contour Interval

Specify the interval to contour. Note: If the above option is set to Contour an Elevation, then this field is used to specify the elevation to contour.

Minimum Contour Length

Contour lines whose total length is less than this value will not be drawn.

Reduce Vertices

This option attempts to remove extra vertices from the contour polylines which has the advantages of a faster drawing and smaller drawing size. Default is ON

Offset Distance

When the Reduce Vertices option is enabled, This value is the maximum tolerance for shifting the original contour line in order to reduce vertices. The reduced contour polyline will shift no more than this value, at any point, away from the original contour line. A lower value will decrease the number of vertices removed and keep the contour line closer to the original. A higher value will remove more vertices and allows the contour line to shift more from the original.

Hatch Zones

When activated, this option will allow you to hatch the area between the contours sequentially. A secondary dialog will load allowing the user to specify the hatch type and color.

Draw Index Contours

This option creates highlighted contours at a specified interval. When enabled, the fields for Index Layer, Index Interval and Index Line Width are activated.

Contour Smoothing Method

Select the type of contour smoothing to be performed. Bezier smoothing holds all the contour points calculated from the triangulation and only smooths between the calculated points. Polynomial smoothing applies a fifth degree polynomial for smooth transition between the triangulation faces. The smoothing factor described below affects the smoothing bulge.

Bezier Smoothing Factor

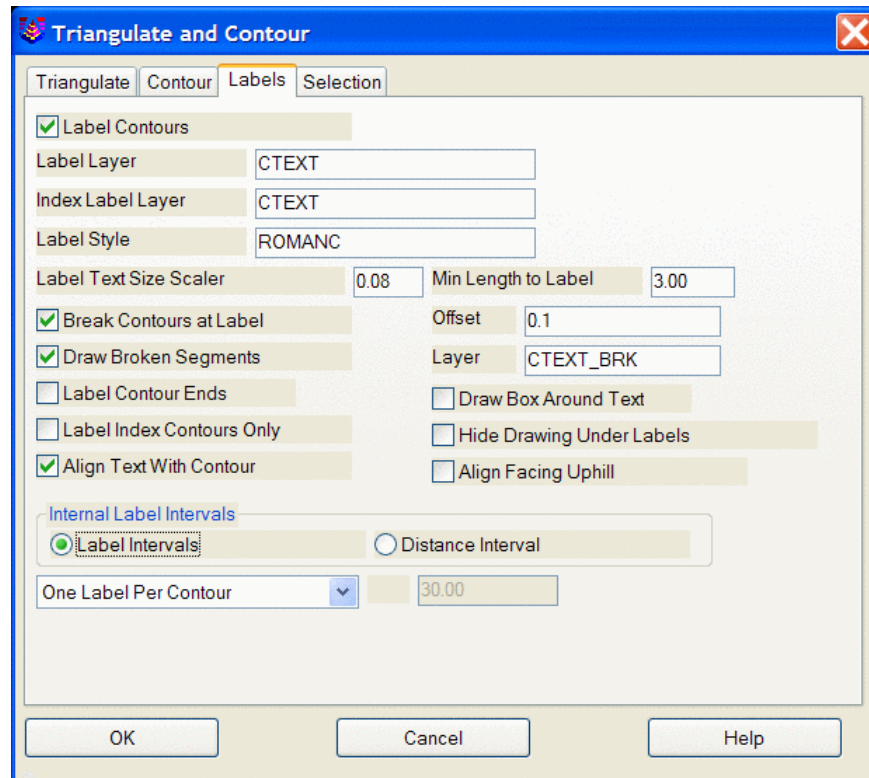

The contour preview window shows you an example of how much smoothing can be expected at each setting. Sliding the bar to the left results in a lower setting which have less looping or less freedom to curve between contour line points. Likewise, moving the slider to the right results in a setting that increases the looping effect.

Subdivisional Surfaces / Subdivisions Generation

This option causes each triangle in the triangulation surface model to be subdivided into an average of three smaller triangles per subdivision generation, with the new temporary vertices raised or lowered to provide smoother contours. More generations increases the smoothness of the algorithm at a cost of increased processing time. If Straight Lines are chosen as the contouring drawing method, then the contours are guaranteed never to cross. The original points of the surface model are always preserved. These modifications to the surface model are only for contouring

purposes and are not written to the triangulation (.FLT) file or inserted into the drawing. If some contour movement is too small for appearance's sake, consider enabling Reduce Vertices.

Labels Tab

Label Contours

When activated, contours will be labeled based on the settings below.

Label Layer

Specifies layer name for intermediate contour labels.

Index Label Layer

Specifies layer name for index contour labels.

Label Style

Specifies the text style that will be used for the contour label text.

Label Text Size Scaler

Specifies the size of the contour labels based on a multiplier of the horizontal scale.

Min Length to Label

Contours whose length is less than this value will not be labeled.

Break Contours at Label

When checked, contour lines will be broken and trimmed at the label location for label visibility. When enabled, the Offset box to the right activates. The Offset determines the gap between the end of the trimmed contour line and the beginning or ending of the text.

Draw Broken Segments

When checked, segments of contours that are broken out for label visibility will be redrawn as independent segments. Specify the layer for these broken segments in the box to the right of this toggle.

Label Contour Ends

When checked, contour ends will be labeled.

Draw Box Around Text

When checked, a rectangle will be drawn around contour elevation labels.

Label Index Contours Only

When checked, only the index contours will be labeled. This option is active only when "Draw Index Contours" has been selected in the Contour tab of the main dialog.

Hide Drawing Under Labels

This option activates a text wipeout feature that will create the appearance of trimmed segments at the contour label, even though the contour is fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels, and the contour lines themselves remain contiguous. This feature will also hide other entities that area in the immediate vicinity of the contour label.

Align Text with Contour

When checked, contour elevation labels will be rotated to align with their respective contour lines. This option also activates the Align Facing Uphill feature explained below.

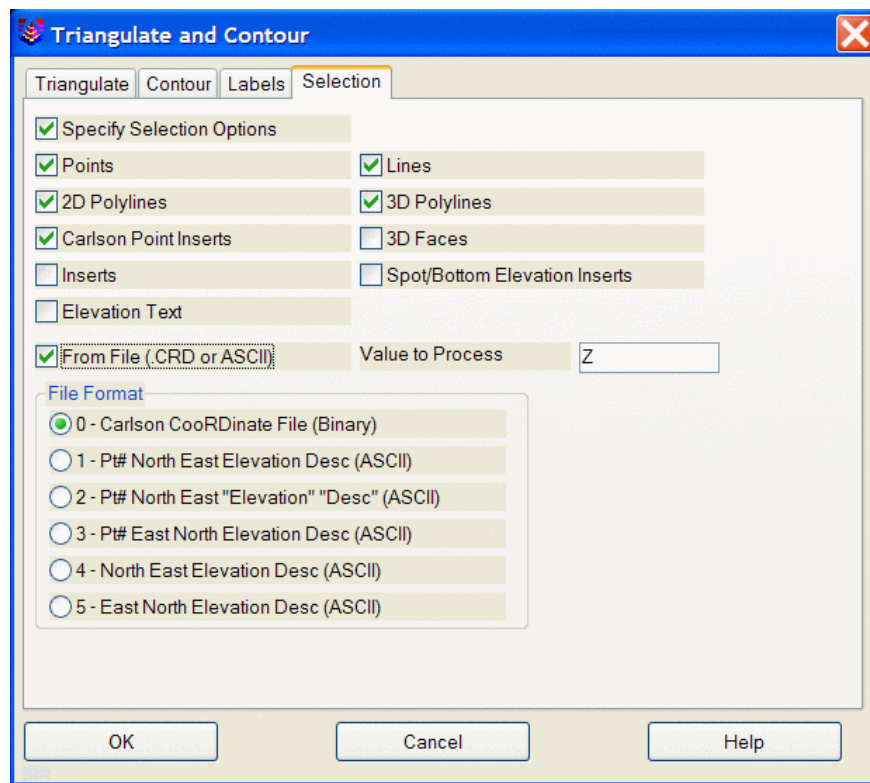

Align Facing Uphill

When checked, contour elevation labels will still be rotated to align with their respective contour lines, but the labels will be flipped in such a manner that the bottom of the text label will always be toward the downhill side of the contours. So as the labels are read right side up, you are always facing uphill.

Internal Label Intervals

Choose between label intervals or distance interval. Label intervals will label each contour with a set number of labels. Distance interval lets you specify a distance between labels.

Selection Tab

Specify Selection Options

When checked, this allows you to control what type of entities *Triangulate & Contour* uses.

Points, 3D Polylines, 2D Polylines, Lines, Inserts are standard AutoCAD entities types.

Spot/Bottom Elevation Inserts include text entities that start with 'X'.

From File allows you to triangulate from the points in a coordinate (.CRD) or ASCII file.

Label Contour Ends

Align Text With Contour ON

Align Text With Contour OFF

Draw Box Around Text

Triangulation network without contouring
Original data points with one 3D polyline

Contours without triangulation network. The contours are smoothed, reduced, drawn at an interval of 2, and highlighted at an interval of 10 with labeling on the index contours.

Pull-Down Menu Location: Tools-> Surface Tools

Prerequisite: Data points of the surface

Keyboard Command: tri

Triangulation File Utilities

This command allows you to modify TIN surfaces in a variety of different ways, then allows for 3d viewing and shading of the modified surface and finally for saving the file with a choice of output formats. The focus of the routine is to elevate or lower the TIN or selected areas within the TIN, merge TINs with other surfaces, or use data from other TIN files to apply to the current TIN. Operations can be performed on the entire TIN or just on user selected Inclusion and/or Exclusion areas. The routine will automatically rework the TIN network for conformation to a selected boundary, say a building outline. In the case of said building, a value of 10 could be subtracted from the building outline. This will drop all of the triangulation within the outline by 10', thus creating a model of the excavated area for the building. The modified TIN can then be saved to a new file, which could be used to compute an excavation volume with Volumes by Triangulation. This routine does not allow for manual reconfiguration of the TIN network. This is performed under Surface Tools, also in the Contour pulldown menu. This routine also includes conversions to and from TIN files, DXF files and 3D Face entities.

Begin with the dialog shown here. First select a TIN model. You may choose between an .flt or .tin file, a DXF file (that includes 3DFACE entities), or 3DFACE entities in the current drawing. Specify the subject area by choosing inclusion or exclusion perimeters, then press the next button.

Load TIN File: Allows you to specify a triangulation (.flt or .tin) file to load.

Load DXF File: Allows you to specify a DXF file to load. Only loads 3DFACE entities from the selected DXF file.

Select 3D Faces: Allows you to select 3DFACE entities from the current drawing. This also includes rectangular 3d faces from a plotted grid.

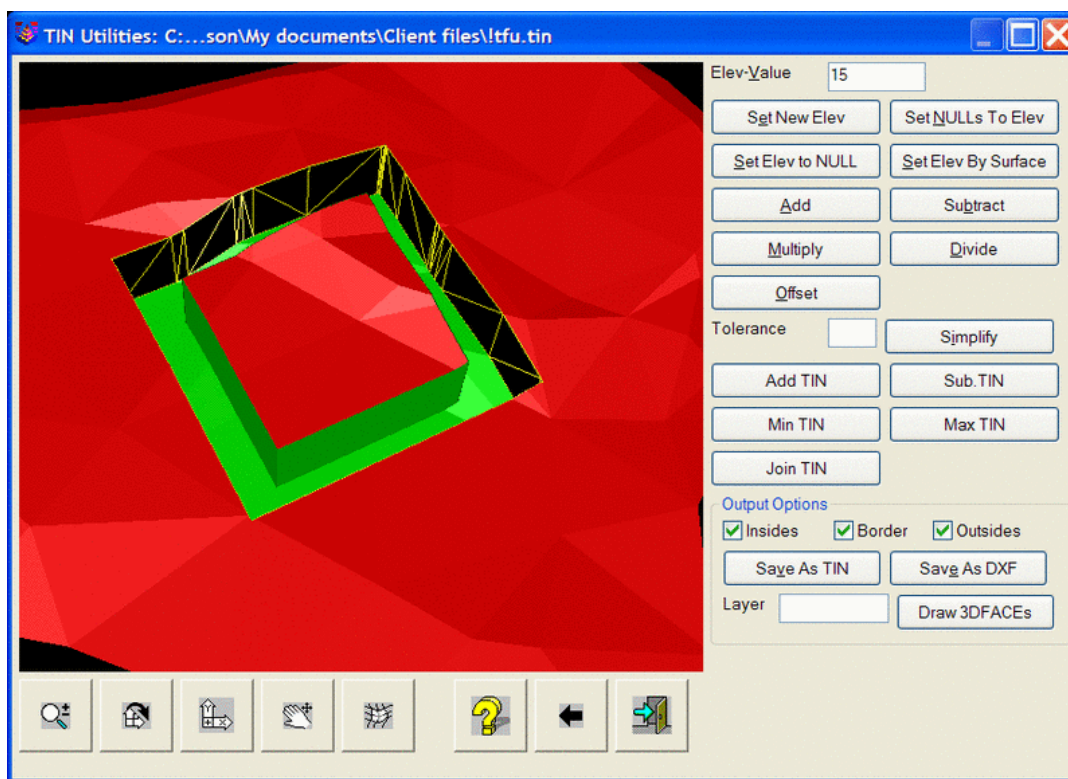

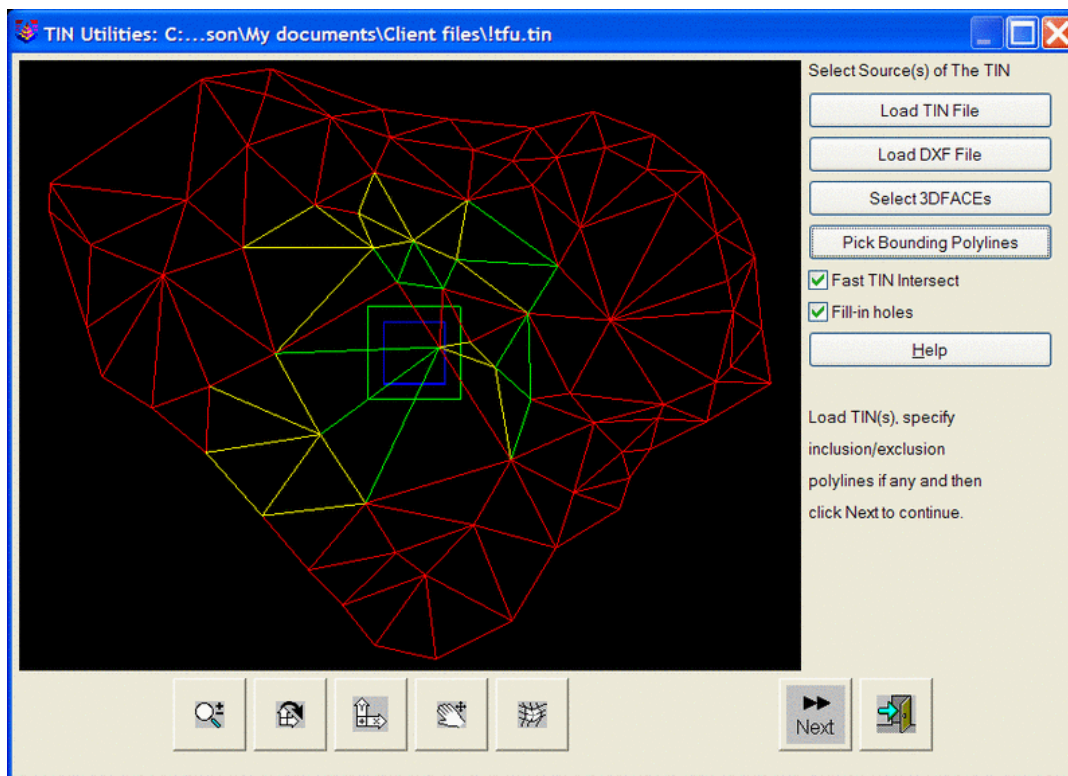

Pick Bounding Polylines: Allows you to select any inclusion/exclusion perimeter(s). When this button is selected, the user is taken back to the drawing and prompted to select the perimeters. Press Enter when the selections are finished to return back to the dialog.

Fast TIN Intersect: When checked, this command will not try and intersect 3DFACE entities.

Fill-in-holes: When checked, any missing triangulation or gap in the surface will be automatically filled in with additional triangles. This option has to set before loading the TIN file to take effect.

Next: Press this button to proceed to the next dialog after all selections have been made .

The next dialog allows you to perform mathematical operation(s) on the loaded TIN. Each operation is described below. Keep in mind that generally these operations are to be performed on an area inside your inclusion perimeter (but excluding anything inside your exclusion perimeters). If you

do not specify any perimeters, the desired operation/s will be performed on the entire TIN.

Elev-Value: Specify either an elevation or value depending on the operation. The value specified will be used for subsequent operations.

Set New Elevation: Sets all TIN faces in the subject area to the elevation specified in the Elev-Value field.

Set NULL's to Elevation: Sets all NULL values in the subject area to the elevation specified in the Elev-Value field.

Set Elevation's to NULL: Sets all of the elevation values in the subject area to NULL.

Set Elevation by Surface: Sets all TIN faces within the subject area to the elevations from a second surface file within the same area. You will be prompted to select a second TIN file or grid file. Only areas common to both surfaces will be applied to the subject TIN.

Add: Adds the value specified in the Elev-Value field to the subject area of the TIN.

Subtract: Subtracts the value specified in the Elev-Value field to the subject area of the TIN.

Multiply: Multiplies by the value specified in the Elev-Value field to the subject area of the TIN.

Divide: Divides by the value specified in the Elev-Value field to the subject area of the TIN.

Offset: Performs a perpendicular offset of the TIN surface by the specified amount.

Tolerance: This setting is used by the Simplify command described below. Specify the maximum average distance that any point can be moved outside of the plane of any triangle that connects to that point. Values might range from .01 to .1 for most purposes.

Simplify: Causes edges within the Tin mesh to be collapsed to reduce the number of triangles, edges, and points within the mesh while having a minimal impact on the overall shape of the mesh.

Add TIN: Raises the subject area of the current TIN by the elevation value from a second user selected TIN file. This function is most applicable to applying a strata thickness TIN.

Subtract TIN: Lowers the subject area of the current TIN by the elevation value from a second user selected TIN file.

Min TIN: This does a comparison between the current TIN and a second user selected TIN file, and applies the lower value of the two TINs to the subject area.

Max TIN: This does a comparison between the current TIN and a second user selected TIN file, and applies the higher value of the two TINs to the subject area.

Join TIN: Merges the existing subject TIN into a second user selected TIN file. The subject TIN file should be the smaller of the two surfaces since the subject file will be joined or merged into the second file.

Insides: If this is the only option checked, only changes made within the inclusion perimeter will be saved. TIN entities outside of the perimeter will not be saved.

Border:

Outsides: If this is the only option checked, TIN entities inside of the inclusion perimeter will not be saved. Everything outside of the perimeter will be saved.

SaveAs TIN: Saves the current TIN as an .flt or .tin file.

SaveAs DXF: Saves the current TIN as a DXF file. This format can be used by many other CAD programs.

Draw As 3DFaces: Draws the current TIN as 3D Faces in the current viewport. The Layer window is used to specify the layer that the faces will be created in.

This icon converts the right mouse button to a zoom function. Hold the button down and move the mouse up or down to zoom in and out.  This icon converts the right mouse button to a rotate function. Hold the button down to rotate the view in any X, Y or Z direction. When the XY appears in the window, the rotation will occur relative to the XY axis. When the mouse is moved toward the outer perimeter of the window, the XY will change to a Z. Holding the button down while the Z is visible will rotate the drawing on the Z axis.  This icon converts the right mouse button to a pan function. Hold down on the button while moving the mouse to pan. Holding down the mouse wheel will also serve as a pan function in any of the above modes.  This icon toggles shading on and off.  This icon restores the graphics to plan view.  This icon reverses the effects of all operations performed on the TIN and reverts it back to its original status.  This icon exits the routine. If the TIN has been modified, you will be prompted to save.

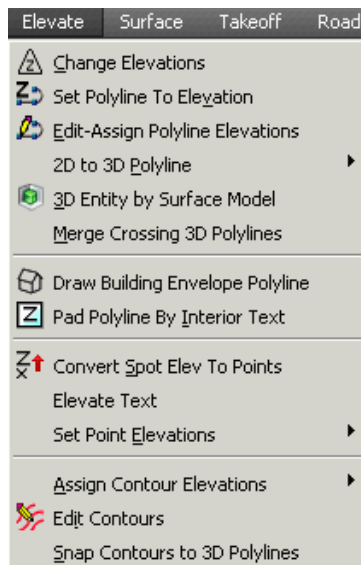

Pull-Down Menu Location: Tools-> Surface Tools

Prerequisite: 3D Faces, a TIN file or a DXF file.

Keyboard Command: TINUTIL

Elevate Menu

The Elevate menu commands convert 2D entities to 3D.

Change Elevations

This command will change the elevation of selected Entities. It can move the entity to a specified elevation from its current elevation (absolute) or do a differential change by adding or subtracting a value from its current elevation. If Carlson Takeoff points are selected, their attribute text and z axis coordinate are changed.

Prompts

Ignore zero elevations (<Yes>/No)? *Press Enter.* If you answer *No*, then entities with elevation 0 will be changed.

[A]bsolute or [D]ifferential Change <A>: A

Select/<Enter Elevation <0.0000>>: 125

Change Layer for changed entities [Yes/<No>]: No

Elevation to change to:

By using the Absolute option all entities selected are changed to the elevation 125.

Select Entities for elevation change.

Select objects: C

First corner: *(pick point)*

Other corner: *(pick point)*

Select objects: *[Enter]*

Keyboard Command: chgelev

Prerequisite: Something to change

Set Polyline to Elevation

This command allows you to assign elevations to one or more polylines. The elevation can be assigned by entering in the value or by picking a text entity that has the elevation.

Prompts

Select/<Enter Elevation <0.0000>>: Select a text entity or type in an elevation. Press enter for the default elevation in brackets.

Select Polyline for elevation change. Pick on the screen a polyline you wish to change such as:

LWPOLYLINE

Done.

Set another polyline [<Yes>/No]? Press Y to pick another polyline to assign an elevation to. Type in N to finish the command.

Keyboard Command: set_pline_z

Prerequisite: A polyline and an elevation to assign it.

Polyline Elevation Editor

This command allows very precise control of 3D Polylines, specifically in the ability to edit vertex elevations, as well as add, delete, or move vertices. If these polylines are used in the creation of surfaces as breaklines, any editing you do may update the surface automatically. You can also control the location of Polyline vertices as defined by the station and offset of the vertices relative to a Centerline. Polyline vertices are designated as either control or free vertices. The elevation of control vertices are set and held, the elevations of free vertices are interpolated. In the drawing, control vertices are shown by default with red boxes, free vertices with blue boxes, but you may configure these using the Grip Color in the Settings.

Polyline Elevation Editor Dock Dialog:

When you run the Edit Assign Polyline Elevations routine, you are first prompted to select a Polyline to edit. After selecting a Polyline to edit, the following dock dialog appears on the left side of your screen. This dialog is "modeless" meaning that CAD commands and controls are still active while this dialog is active.

Tabs:

The four tabs in the panel provide access to control of Polyline vertex **Elevation, Position, Offset** and **Distance**.

- **Elevation:** This tab displays the vertices of the Polyline, each with a check box to set whether it is a control vertex or a free vertex (Control), its assigned number (#), its elevation (Elevation), and the slope from the previous vertex to that vertex (Slope). Selecting a vertex highlights its grip in the drawing. Once selected, you can enter an "elevation" or "slope" edits for that vertex. If multiple vertices are selected with varying elevation or slopes then "[multiple]" will be displayed in the "Elevation" and or "Slope" edits. When multiple vertices are selected, entering values in the "Elevation" or "Slope" edits will set all selected vertices based on the entered elevation or slope values.
- **Position:** The Position tab displays the Easting and Northing coordinates of each vertex. When one vertex is selected Northing and Easting can be entered in the "Northing" and "Easting" edits. When Multiple vertices are selected average Northing and average Easting are displayed in the "Average Northing" and "Average Easting" edits. When multiple vertices are selected entering values in the "Average Northing" and or the "Average Easting" edits will set all selected vertices Northing and or Easting values to based on the entered values.
- **Offset:** The Offset tab requires the selection of a Centerline to reference. Once a Centerline is designated, the Station and Offset of each vertex relative to the Centerline is displayed and can be edited.
- **Distance:** The Distance tab shows the horizontal distance for each Polyline segment. You can change a distance by highlighting the segment on the list and editing the value in the "Horz Dist" edit. If multiple vertices are selected "[multiple]" will be displayed in the "Horz Dist" edit. The user cannot set multiple segment's horizontal distances at once.

Toolbar Commands:

The toolbar provides access to several commands, some of which are tab specific.

Revert All: Reverts currently selected Polyline vertex positions and control information to vertex positions and control information when Polyline was initially selected. (Note: Selecting a new Polyline resets initial reversion location)

Undo: Undoes the most recent command line action. (Equivalent to ctrl+z)

Redo: Redoes the most recent command line action. (Equivalent to ctrl+y)

Select Polyline: Select Polyline to edit. (Note: if no Polyline is selected a Polyline can be selected using CAD selection)

Control Selected: Set selected vertices controlled, elevation will not be interpolated for control points. (This toolbar command is only available when elevation tab is active)

Free Selected: Set selected vertices free, elevation will be interpolated for free points. (This toolbar command is only available when elevation tab is active)

Output Report: Brings up Report Formatter dialog. Output reports can contain Easting, Northing, and or Elevation information for each vertex as well as whether or not each vertex is controlled or free.

 **Create Vertex:** Creates a vertex at the station nearest the mouse click position. Control/free state depends on the "Create Vertex Mode" setting (see Settings dialog).

 **Create Vertex At Crossing:** Prompts user to select crossing Polyline(s). If Polyline(s) selection is(are) applicable, crossing vertex point(s) are added at the elevation of the selected Polyline(s) at crossing. All created vertices are added as control points.

 **Delete Vertices:** Deletes currently selected vertices.

 **Reduce Vertices:** Prompts user to select an offset cutoff. Removes those vertices from the active Polyline that will not change the position of the Polyline at that vertex by more than offset cutoff. Will not removed controlled vertices.

 **Move Selected:** Move currently selected vertices based on drag offset. (Equivalent of click and drag)

 **Reverse Polyline:** Reverses indices of vertices. This will be reflected by reversing the vertices in the currently active list view.

 **Pick Elevation/Position From Screen:** Elevation- prompts user to pick an entity from screen. Will set elevation based on entity's elevation information. Vertex set controlled. Position-prompts user to pick position from screen sets Northing and Easting based on selected position. (This toolbar command is only available when elevation tab or position tab is active).

 **Pick Elevation From Surface:** Prompts user to select a surface model (tin;ft). Then prompts user to pick a direction point to run the slope from highlighted vertex. Elevation of highlighted point is determined from surface and slope is then applied along the line to the next control point. (This toolbar command is only available when elevation tab is active and one or more vertices is selected).

 **Pick Elevation With Slope:** Prompts user to pick a point or elevation text. Then prompts user to pick slope. An elevation is then calculated based on the run to the point selected at the slope the user input. Elevated vertices will be set controlled. (This toolbarcommand is only available when elevation tab is active).

 **Offset Selected Elevation:** Prompts user to input an offset amount. Adds(subtracts) offset amount from currently selected vertices. Offset vertices will be set controlled. (This toolbar command is only available when elevation tab is active)

 **Select Centerline:** Prompts user to select a Centerline or Polyline to apply Centerline information from screen. (This toolbar command is only available when Offset tab is active)

OK:

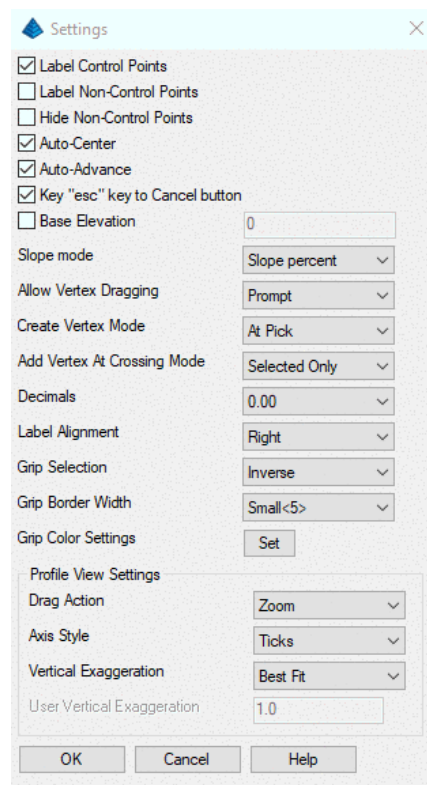

The "OK" button closes the Polyline Elevation Editor dialog, and saves the vertex position and control information of the currently selected Polyline.

Cancel:

The "Cancel" button closes the Polyline Elevation Editor dialog, and reverts the currently selected Polyline's vertex position and control information to the vertex position and control information when the Polyline was first selected.

Settings:

The "Settings" button provides control over various options pertaining to the use of the Polyline Elevation Editor routine.

- **Label Control Points:** Toggle on to display control vertices' numbers and elevations.
- **Label Non-Control Points:** Toggle on to display free vertices' numbers and elevations.
- **Hide Non-Control Points:** Toggle on to remove all free vertices' grips.
- **Auto-Center:** Toggle on to automatically center view such that all currently selected grips when they are selected.
- **Auto-Advance:** Toggle on to automatically advance the currently selected grip to the next available vertex (by vertex number).
- **Key "esc" key to Cancel button:** Toggle on to key "esc" to the Polyline Elevation Editors' dialog "Cancel" button. That is pressing the "esc" key will cancel and exit the Polyline Elevation Editor routine.
- **Base Elevation:** When toggled on the leading significant digits of the Base Elevation value will be added as a prefix to any elevation value entered. Base Elevation values must be whole numbers greater than or equal to zero. Typical use: (Base: 6000)+(User: 100)=(Elevation: 6100 displayed as 100).
 - *Conflicts:* Some user entered elevation values are ambiguous in terms of how to combine the Base Elevation, and the user entered elevation. These conflicts are dealt with as follows:
 - * *Significant Digit Conflicts:* In the case where a user entered value, and the Base Elevation value both contain significant digits in the same column(s), then the user entered value supersedes the Base Elevation value in that(those) column. Ex: (Base: 6500)+(User: 100)=(Elevation: 6100 displayed as 100).
 - * *Negative Value Conflicts:* Negative values are processed as values below the Base Elevation. However, adding a negative value can result in elevations that result in "Significant Digit Conflicts" with the Base Elevation. In this case the logic of the "Significant Digit Conflicts" applies. Ex: (Base: 6000)+(User: -100)=(Elevation: 5900 displayed as 5900).
- **Slope Mode:** Determines how slope at a vertex is displayed and interpreted.

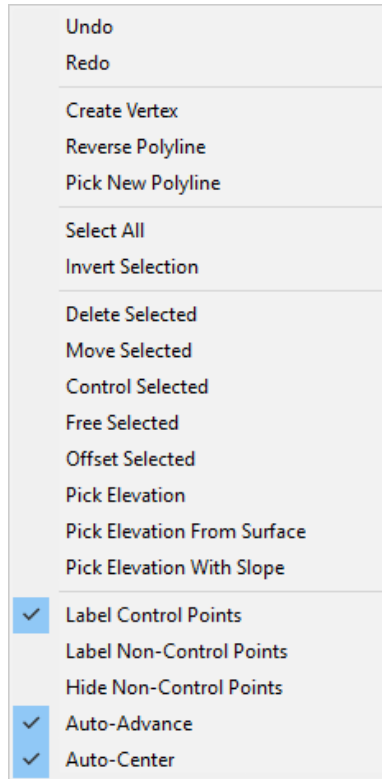

- *Slope Ratio*: Slope as a ratio of line length to line elevation [*run/rise*]
- *Slope Percent*: Slope as a percent [*rise/run*100*]
- *Slope Degree*: Slope as degree offset from 0° from -90° to 90° [*atan(rise/run)*180/PI*]
- **Allow Vertex Dragging**: Determines how dragging selected vertices functions.
 - *Never*: Never allow dragging.
 - *Prompt*: On completion of vertex dragging user is prompted on whether or not to accept the results of the dragging operation.
 - *Always*: Always allow dragging.
- **Create Vertex Mode**: Determines how elevation is calculated for vertices inserted using the Create Vertex toolbar command, double click on line, or right-click Create Vertex command.
 - *On Line*: Creates a vertex at the station nearest the pick point. Elevation is interpolated based on the equation [$elv=(InsertDistance2D/TotalDisatance2D)*(TotalElevationChange)$]. If no control points exist, then the elevation is set to the elevation of all other free vertices on the Polyline. Inserted vertex is a free point.
 - *At Pick*: Creates a vertex at pick point. Vertex is inserted in the Polyline after the vertex preceding the nearest station to the pick point. If the pick point is the result of a snap, the elevation of the new vertex is taken from the elevation of the snapped entity, and the created vertex is added as a control point. Otherwise, the created vertex is added as a free point.
- **Add Vertex Crossing Mode**: When running the function to add vertices at crossings with other linework, this option chooses whether to add intersection vertices on the crossing linework in addition to the current polyline.
- **Decimals**: Determines how many decimal places are displayed in Polyline Elevation Editor dialog. User can choose between 0 and 6 decimal places for display.
- **Label Alignment**: Determines where vertex index, and vertex elevation for all labeled vertices is drawn.
 - Right: Draw label to the "right" of vertex grip. Takes into account screen rotation.
 - Top: Draw label "above" vertex grip. Takes into account screen rotation.
- **Grip Selection**:
 - *Standard*: left-click to drag vertex, shift+left-click to select single grip vertex.
 - *Inverse*: shift+left-click to drag vertex, left-click to select single grip vertex. (legacy control)
- **Grip Border Width**: Allows user to set the relative size of the gripbox for all vertices based on the internal ACAD/ICAD GRIPSIZE variable. (Note: the values associated with each Grip Border Width choice represent the value that the internal ACAD/ICAD variable GRIPSIZE is set to for each Grip Border Width selection. If the current GRIPSIZE ACAD/ICAD variable is not one associated with any of the Grip Border Width choices ["Small," "Medium," "Large," "XLarge"] the Grip Border Width will be set to current ACAD/ICAD GRIPSIZE.)
- **Grip Color Settings**: Set the grip colors for easier editing of the vertices:
 - Hover Vertex
 - Control Vertex
 - Free Vertex
- **Profile View Settings**:
 - Drag Action: Choose between doing Zoom or Pan for click-n-drag in the profile view.
 - Axis Style: Set the profile grid display.
 - Vertical Exaggeration: Control the display for the profile vertical scale.

Help:

Display Carlson documentation for Polyline Elevation Editor.

Right-click Dialog:

There is a right-click menu available when the Polyline Elevation Editor routine is running which gives access to a variety of functions and settings. "Select All" and "Invert Selection" are the only commands unique to the right-click dialog. "Select All" selects all currently visible vertices. "Invert Selection" inverts all currently visible vertices. "Undo," "Redo," "Create Vertex," "Reverse Polyline," "Pick New Polyline," "Delete Selected," "Move Selected," "Control Selected," "Free Selected," "Offset Selected," "Pick Elevation," "Pick Elevation From Surface," "Pick Elevation With Slope," and "Pick Position" are equivalent to the Toolbar Command with the same name. "Label Control Points," "Label Non-Control Points," "Hide Non-Control Points," "Auto-Advance," and "Auto-Center" are equivalent to their settings dialog toggles with the same name.

Pulldown Menu Location: 3D Data

Keyboard Command: EDIT_PLINE.Z

Prerequisite: 3D Polylines with vertices

2D to 3D By Surface Model

This command converts a 2D polyline into a 3D polyline by calculating 3D polyline vertices at all the intersects of the 2D polyline with surface entities (contour polylines, triangulation lines) and by interpolating elevations from these intersections at the original vertices locations. An application for this command is to create breaklines. For example, a ridge breakline could be generated from contour lines by drawing a 2D polyline along the ridge and across the contours. Then this command could grab the contour line elevations along the polyline to make a ridge breakline.

In addition to using entities in the drawing, the 2D polyline can be converted to 3D using a surface model stored in triangulation (.flt or .tin) file. If you use a file, then you can also use the polyline's current elevation as a vertical offset from surface.

Prompts

By Screen Entities:

Source of surface model [File/<Screen>]? Type S for Screen

Select polylines to convert.

Select objects: *select the polyline(s) to convert*

Select surface 3DFaces, lines and polylines.

Select objects: *select the surface entities (contour polylines, breaklines, triangulation lines, etc)*

Reading points ... 692

Keep existing polylines [Yes/<No>]? Press Enter

This command creates a new 3D polyline, and this prompt allows you to keep the old polyline.

Set layer name for converted polylines [Yes/<No>]? Press Enter

This allows you to assign the new polyline to a layer.

Converting polylines ...

Converted 1 polylines.

By a .flt or .tin File:

Source of surface model [<File>/Screen]? Type F for File

Select polylines to convert.

Select objects: *select the surface entities (contour polylines, breaklines, triangulation lines, etc)*

Use current polyline elevations as vertical offset from surface [Yes/<No>]? Press Enter

This will offset the new polyline by its current elevation. That is, if a polyline has an elevation of -4 and the surface you are converting it to has an elevation of 800, then saying Yes will drape the polyline at an elevation of 796.

Keep existing polylines [Yes/<No>]? Press Enter

This command creates a new 3D polyline, and this prompt allows you to keep the old polyline.

Set layer name for converted polylines [Yes/<No>]? Press Enter

This allows you to assign the new polyline to a layer.

Keyboard Command: 2dto3dp

Prerequisite: A polyline and surface lines or grid file or triangulation file.

2D to 3D Polyline by Points

This command adds 3d data to polylines by using the elevations of points. At each vertex of the polylines, the program looks for a point with elevation at the same x,y location. The points can be Carlson point blocks or AutoCAD POINT entities. This routine can be useful if the linework is created in 2D at zero elevation, and points with elevation are located along the linework. It can also be used in conjunction with other 2D to 3D commands to elevate polylines by more than one method. The linework can be converted into 3D polylines with this command. For example, a centerline polyline with arcs may need to be created in 2D for stationing because AutoCAD does not allow arcs on 3D polylines. To use this polyline as a breakline in surface modeling, this command can convert the polyline into a 3D polyline.

Prompts

Select points and polylines.

Select objects: select polylines to convert and the points with elevation

Keyboard Command: 2dto3dpt

Prerequisite: A polyline and points

2D to 3D Polyline-By Text

This command adds 3d data to polylines by elevation labels. This command will prompt you for samples of the elevation labels and the polylines to convert. The program uses these samples to know the layer names for the labels and linework to process. Then select all the polylines with their labels you want to convert.

You will then be prompted to enter in an elevation to add to label values. Often times elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 539.97, 540.02, 540.11 sometimes, like in the example on the side, they are listed as 39.97, 40.02, 40.11. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing. This command will assign elevations from the labels to nearby vertices. If vertices do not have a close elevation label than they will be interpolated from vertices that are nearby elevation labels. The vertices elevated in this command will appear as control vertices in the command Polyline Elevation Editor. It can also be used in conjunction with other 2D to 3D commands to elevate polylines by more than one method.

Prompts

Select sample of elevation text: Pick a text label

Select sample of a polyline to convert: Pick a polyline

Select polylines to convert and elevation labels.

Select objects: Select all the entities to process
19 found, 19 total

Enter elevation to add to label values <0.00>: 500

Pre-processing entity #19 of 19

Filtering text entities

Processing elevation text #18

Remaking polyline #1

Keyboard Command: elevfb

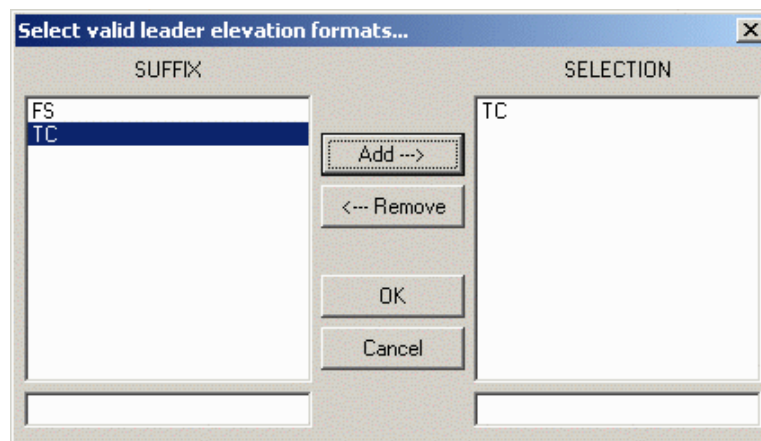

Prerequisite: 2D polyline and elevation labels

2D to 3D By Text With Leader

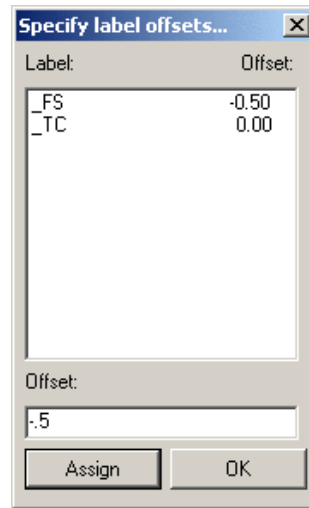

This command will assign elevations from the labels to the polylines by following the label leaders to their corresponding vertices on the polyline.

This command will prompt you for samples of the elevation labels, the leaders, and the polylines to convert. The program uses these samples to know the layer names for the labels and linework to process. Then select all the labels and leaders for the polylines you want to convert. You will then be prompted to enter in an elevation to add to label values. Often times elevations are abbreviated to save time and space. If every elevation in a drawing is in the 800s instead of labeling every elevation 817.85, 817.40, 817.30 sometimes, like in the above example, they are listed 17.85, 17.40, 17.30. This command allows you to add a given amount, such as 800, to every label elevation to produce the correct elevation in the drawing.

Carlson Takeoff searches for all leaders and gathers their associated text. If the program finds different labels in the elevation text, then this dialog box allows you to select the text you want to create 3D polylines. In this example you might want to use elevations followed by TC. This dialog box allows you to select that text and exclude the other text which is not to be used in the elevations of the polyline, such as FS.

If you are creating 3D polylines from multiple elevation labels than this dialog box will allow to offset certain labels by a given amount. In the above example you can offset an elevation labeled FS by .50 so that it matches vertices set by TC labeled elevations. The vertices elevated in this command will appear as control vertices in the command Polyline Elevation Editor. It can also be used in conjunction with other 2D to 3D commands to elevate polylines by more than one method.

Prompts

Select sample of elevation text: Pick a text label

Select sample of an annotation leader: Pick an annotation leader

Select sample of a polyline to convert: Pick a polyline

Select polylines to convert, leaders and elevation labels to process.

Select objects: Select the desired entities

Processing leader #6
Remaking polyline #1

Keyboard Command: elevfl

Prerequisite: 2D polyline, elevation labels, and leaders

2D to 3D Polyline by Start-End Elevations

This command allows you to convert a 2D polyline to a 3D polyline by specifying the starting and ending elevations of the polyline. All intermediate polyline vertex elevations are linearly interpolated from these end point elevations.

Prompts

Select polyline to assign elevations:

Enter starting elevation: 109.85

Percent/Ratio/<Enter ending elevation>: 112.16

Select polyline to assign elevations (Enter to End): *press enter to end*

Keyboard Command: 2dto3dpl

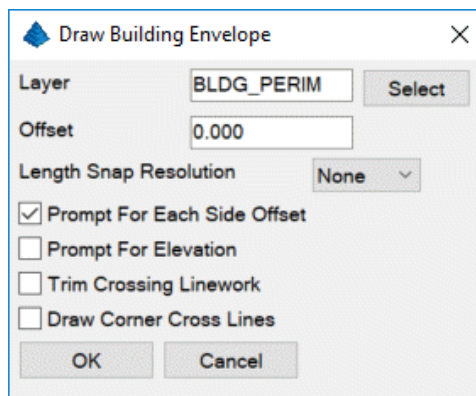

Prerequisite: A polyline

Draw Building Envelope Polyline

This command creates a rectangular polyline around selected linework. This can be used to give a building all one elevation.

Select the entities that make up the building. Next you will be prompted to name the layer and In the dialog, you can set the layer name for the rectangle and other settings.

Offset: This is the amount the building envelope will be offset out from the source linework.

Prompt For Each Side Offset: This option allows you have different offsets for each side of the rectangle.

Length Snap Resolution: Will round the dimensions of the created Building Envelope by a certain tolerance. For example, if you select None you may get a Building Envelope of 37.4 x 25.2. However, if you set the Length Snap Resolution to 0.5, you will get a Building Envelope of 37.5 x 25.0.

Prompt For Elevation: This option allows you to set the elevation for the rectangle. Otherwise the rectangle is drawn at zero.

Trim Crossing Linework: This option trims any linework that crosses the building envelope which applies to linework like contours to ensure that you have a flat pad when building the surface model.

Draw Corner Cross Lines: This option draws two lines between the corners of the rectangle.

Prompts

Select building lines.

Select objects: *pick the linework that makes up the perimeter of the building*

Enter the segment horizontal offset <0.000>: 10

Enter the segment horizontal offset <10.000>: Enter

Enter the segment horizontal offset <10.000>: 5

Enter the segment horizontal offset <5.000>: Enter

Select/<Enter Elevation <0.0000>: 400

Draw another building envelope [<Yes>/No]? No

Pulldown Menu Location: Civil > 3D Data, Survey > COGO, Takeoff > Elevate

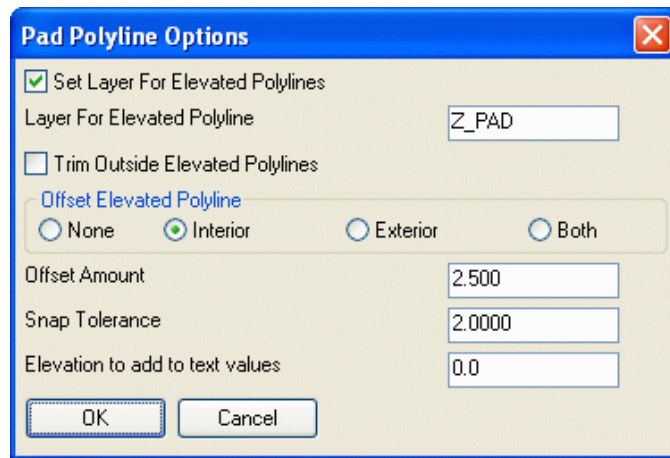

Keyboard Command: bldg_perim

Prerequisite: Building linework

Pad Polyline By Interior Text

This command allows you to set one or more pad elevations using interior text labels.

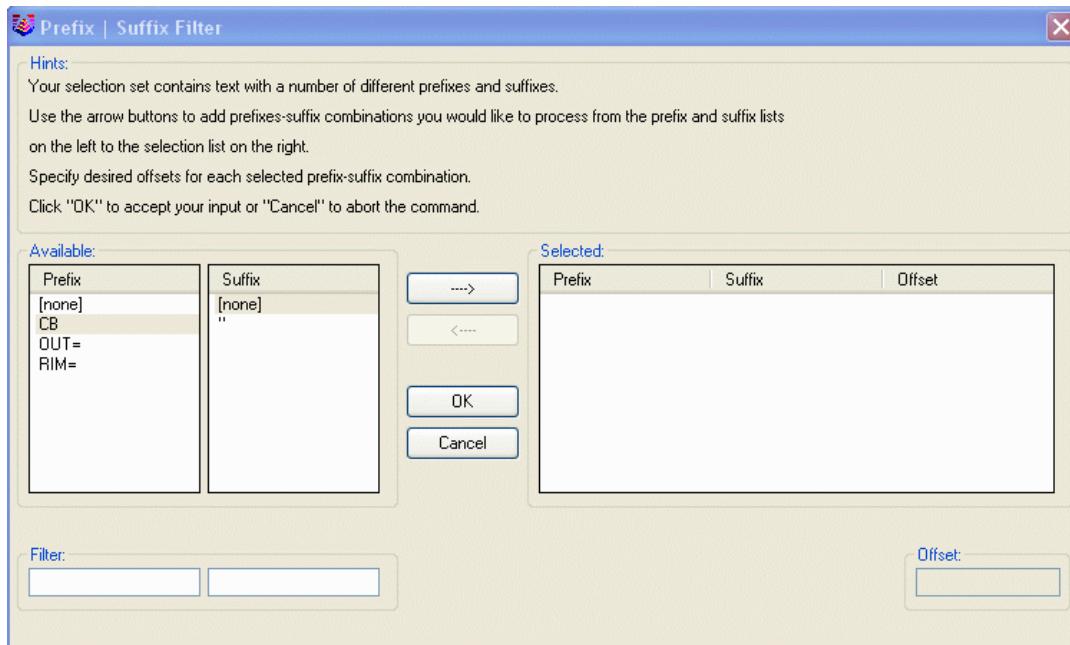

After running the command you will be prompted to select the layers you want to use for the pad elevation and for the boundary of the pad. Sometimes pads are drawn with linework from two different layers and Carlson Takeoff allows you to pick all the correct linework.

This dialog box allows you to create a new layer with the correct x,y coordinates and elevations. If the pad shares the same coordinates with other linework with different elevations than this dialog box allows you to offset the new polyline to avoid the problem of shared occupied points with different elevations. You can choose to have an interior offset or an exterior offset and also decide how much to offset the new polyline. Selecting Both will give both the interior pad elevation and the exterior contour elevations. This helps the transition from you pad elevation to the design contouring. The Snap Tolerance field joins linework which falls within the range you set to create a pad. Trim Outside Elevated Polylines will trim out contour elevations that go through your pad that you are not using elevations from within the pad.

Elevation to add to text values adds to the values from the elevation labels. Often times elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 523.5, 543.3, 537.2 sometimes they are listed as simply 23.5, 43.3, 37.2. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing.

After running the command you will be prompted to select the layers you want to use for the pad elevation and for the boundary of the pad. Sometimes pads are drawn with linework from two different layers and Carlson Takeoff allows you to pick all the correct linework. In addition, if your text has multiple Prefixes and Suffixes you will be prompted to select the ones you want to use the elevation from.

After clicking <OK> select all the pads and their elevation labels that you wish to change, press <Enter>, and the new layer with elevations will be created and placed in the Design target.

Prompts

Select layer sample of elevation text: Pick a label text

Selected text layer —TX07

Select layer sample of boundary linework:

Selected linework layer PAD

Select another layer sample of boundary linework (Enter to continue):

Select text and linework to process.

Select objects: 1 found

Select objects: 1 found, 2 total

Keyboard Command: pad_by_text

Prerequisite: Pad polylines and elevations

Convert Spot Elev To Points

This command takes spot elevation entities with zero elevations and assigns them elevations according to corresponding elevation labels. This dialog box allows you to choose the format of the spot elevations entities that you want to convert.

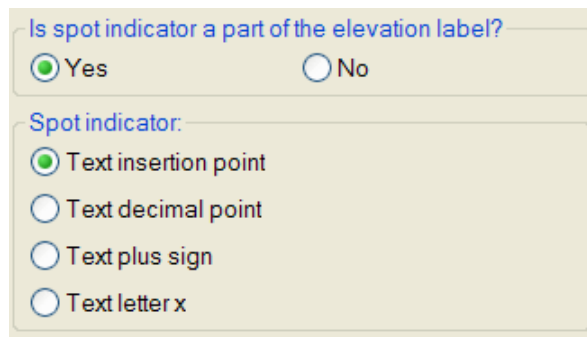

Output:

Carlson points: creates Carlson points at elevation of spot and stores them in coordinate file

AutoCAD points: creates AutoCAD point objects at elevation of spot

Is spot indicator a part of the elevation label?

If set to "Yes", four choices for **Spot indicator** are available to select from:

Text insertion point: uses the insertion point of the text for the location of the new point

Text decimal point: uses the decimal point in the text for the location of the new point

Text plus sign: uses the plus sign in the text for the location of the new point

Text letter x: uses the letter x in the text for the location of the new point

If set to "No", five choices for **Spot indicator** are available to select from:

Is spot indicator a part of the elevation label?

Yes No

Spot indicator:

Linework leader

Linework cross

Text plus sign

Text letter x

AutoCAD point

Linework leader: creates a data point at the end of a leader

Linework cross: creates a data point at the intersection of a linework cross

Text plus sign: creates a data point at the insertion point of a text plus sign

Text letter x: creates a data point at the middle of a text letter x

AutoCAD point: creates a data point at the node of an AutoCAD point

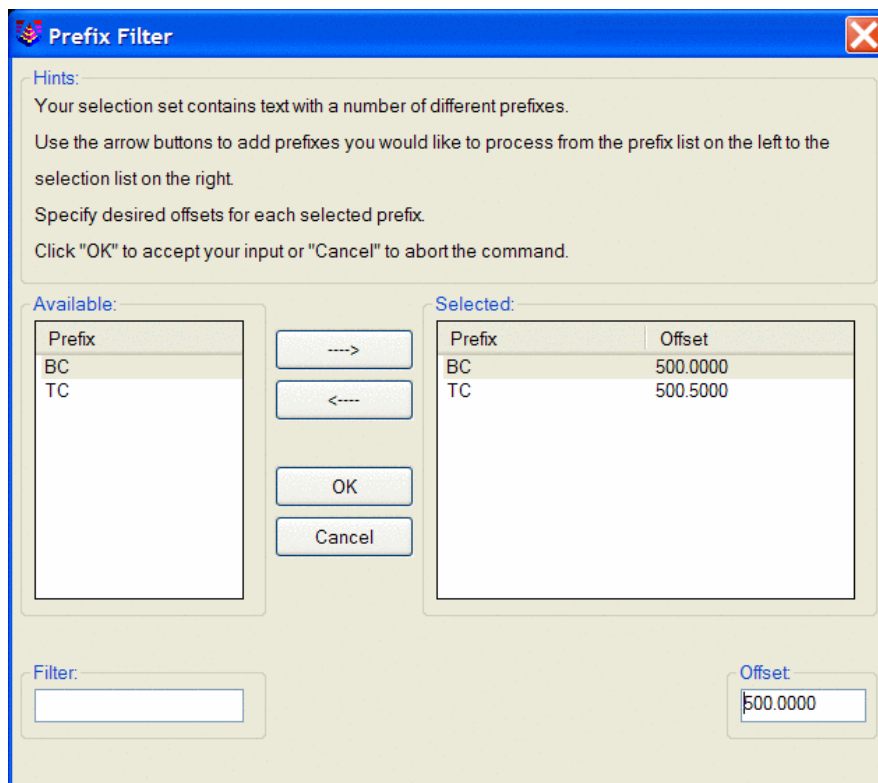

Block References:

Process Block References: If check box is cleared, Carlson Civil searches only text entities for elevations, but if checked, Carlson Civil will search block references for elevations that are stored as attributes of a block. Use this option if the elevation is an attribute and the symbol designating the location of the spot elevation are both part of the block definition.

Expand Block References: Use this option to search block references when the elevation is stored as an attribute of a block, but the symbol designating the location of the spot elevation is a different block or even other geometry that is not defined within a block.

Base elevation: The value entered here is added to the existing spot elevations for all newly created points. Often times elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 523.5, 543.3, 537.2 sometimes they are listed as simply 23.5, 43.3, 37.2. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing. Note: The base elevation will not be added to any elevations that are closer to the base elevation value than they are to 0; e.g. if a base elevation of 500 is specified, 500 will be added to elevations like 23.4, 45.5, etc, but will not be added to elevations like 456.4 or 468.9.

Prefix Filter: Carlson Civil examines all selected spot elevations for prefixes or suffixes. If they are all the same, the command proceeds, but if there are different prefixes and/or suffixes found, the Prefix Filter dialog box is invoked. This dialog box allows you to select which prefixes and/or suffixes to use to create spot elevations, and also allows you to use different offset values for each. .

Prompts

Assign Contour Elevation - Multiple in Series

This command can be used to quickly and accurately assign the elevation of series of AutoCAD polylines that have been converted from raster or digitized without correct elevations. The routine will automatically assign elevations to the polylines crossing the fence line selected by two points. At the same time the elevations are changed, the program can assign it a new layer, color, linetype, and polyline width. This process usually works best if contours are in a temporary (white) layer to start. When they are processed, they will take on the color of the new layers making it easy to distinguish which polylines have been processed.

Prompts

Settings/First Point: *(Press S to change settings or pick first point.)*

Assign Contour Elevation - From Contour Labels

This command allows you to set elevations to contours from elevation labels.

Select a sample of the elevation text to be used on the contouring. Next, select a sample of the contouring that you want to add the elevations to. In case you have contours on different layers like for major and minor contours, there is a prompt to pick a second contour line example. The program uses the Layers of the selected entities to know which entities to process as the contour labels and lines. Now select all the contours and their corresponding elevation labels. The program will then add elevations to all the contours. You may be prompted to distinguish what contour goes with what elevation label. You can either press <Enter> to accept the contour that the program has selected or you can Press <N> to choose another contour.

Prompts

Select sample of elevation text: *pick a contour label*

Select sample of a contour line: *pick a contour line*

Select second sample of a contour line (Enter for none): *press Enter*

Select objects: *pick the polylines*

Select polylines to set to elevation 510.0.

Select objects: *Press Enter*

Keyboard Command: setcelev

Prerequisite: polylines

Drape 3D Polyline On Surface

This command converts a 2D polyline into a 3D polyline by calculating 3D polyline vertices at all the intersects of the 2D polyline with surface entities (contour polylines, triangulation lines) and by interpolating elevations from these intersections at the original vertices locations. An application for this command is to create breaklines. For example, a ridge breakline could be generated from contour lines by drawing a 2D polyline along the ridge and across the contours. Then this command could grab the contour line elevations along the polyline to make a ridge breakline.

In addition to using entities in the drawing, the 2D polyline can be converted to 3D using a surface model stored in triangulation (.flt or .tin) file. If you use a file, then you can also use the polyline's current elevation as a vertical

offset from surface.

Prompts

By Screen Entities:

Source of surface model [File/<Screen>]? Type S for Screen

Select polylines to convert.

Select objects: *select the polyline(s) to convert*

Select surface 3DFaces, lines and polylines.

Select objects: *select the surface entities (contour polylines, breaklines, triangulation lines, etc)*

Reading points ... 692

Keep existing polylines [Yes/<No>]? Press Enter

This command creates a new 3D polyline, and this prompt allows you to keep the old polyline.

Set layer name for converted polylines [Yes/<No>]? Press Enter

This allows you to assign the new polyline to a layer.

Converting polylines ...

Converted 1 polylines.

By a .flt or .tin File:

Source of surface model [<File>/Screen]? Type F for File

Select polylines to convert.

Select objects: *select the surface entities (contour polylines, breaklines, triangulation lines, etc)*

Use current polyline elevations as vertical offset from surface [Yes/<No>]? Press Enter

This will offset the new polyline by its current elevation. That is, if a polyline has an elevation of -4 and the surface you are converting it to has an elevation of 800, then saying Yes will drape the polyline at an elevation of 796.

Keep existing polylines [Yes/<No>]? Press Enter

This command creates a new 3D polyline, and this prompt allows you to keep the old polyline.

Set layer name for converted polylines [Yes/<No>]? Press Enter

This allows you to assign the new polyline to a layer.

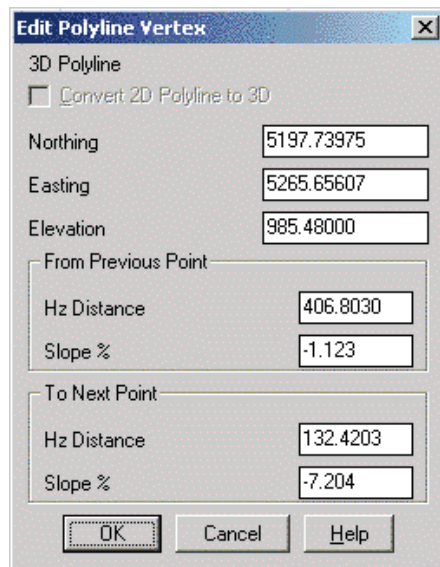

Keyboard Command: 2dto3dp

Prerequisite: A polyline and surface lines or grid file or triangulation file.

Edit Polyline Vertex

This tool allows you to make changes in the coordinates of vertices on all polyline types. Upon execution you will be asked to select a polyline to edit. Upon selection a temporary marker will be placed at all of the vertices of the polyline, making them easy to distinguish. Then pick near the vertex you wish to edit, and the following dialog appears.

At the top of the dialog it identifies the type of polyline, being 2D or 3D. In the case of 2D polylines it allows you convert the polyline. You have the ability to type in new northing, easting or elevation values. You can also determine the 3D coordinate position by using distances and slope to/from adjacent points. As you change the values in the dialog, new values for derivatives are being calculated. For example if you change the horizontal distances, the coordinates will change.

Prompts

Select polyline vertex to edit: *pick a polyline at the point to be modified*

Pick or enter position <5264.23,5048.21>: *pick a point*

Enter elevation <0.00>: *Press Enter*

Select polyline vertex to edit: *Press Enter to end*

Keyboard Command: editpl

Prerequisite: A polyline.

Edit Contours

This command revises a segment of a contour polyline. Begin by picking a point on the contour where you want to start editing. Then pick new points for the polyline. When finished picking new points, press Enter and then pick a point on the contour to connect with the new points. The polyline segment between the start and end points is then replaced with the new points.

Prompts

Select contour to edit: *pick the contour polyline at the place to start editing*

Pick intermediate point (Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *Press Enter*

Pick reconnection point on contour: *pick the contour polyline at the place to join*

Edit this contour by picking new points
Contour with segment replaced with new points

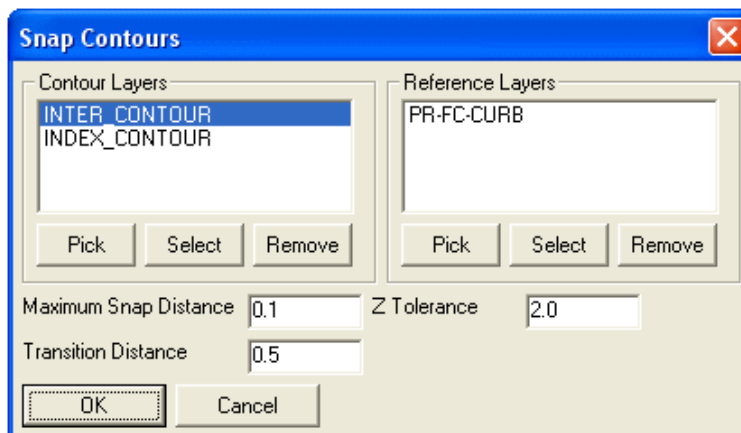

Keyboard Command: editctr

Prerequisite: polylines with elevation (contour polylines)

Snap Contours to 3D Polylines

Snap Contours to 3D Polylines can be used to align contour polylines to match elevation with intersecting of a 3D polylines. Doing so will fix spikes in a surface model. The program will ask for the Contours to be adjusted. Pick will allow you to grab the contours from the plain view, Select allows you to identify the layer(s) from a list. The layers under Contour Layers will be adjusted to match the Reference Layers at the point of intersection. A Reference layer can be identified by Pick or Select as well.

The Maximum Snap Distance is the furthest distance along the Reference line the Contour polyline will move in order to match elevations. Z Tolerance sets the minimum elevation difference between the Reference line and the Contour polyline for the program to process. Anything less than this number will not be modified. Transition Distance is the length over which the positioning change will be applied to the Contour polylines.

After selecting OK, you will be prompted for the entities to process. Pick or Window Select the linework you want to process. You can also type in "all" to select everything. Here is a standard report that is displayed on the command line:

Entities in set: 282

Select entities:

Contour polylines: 125 Processed, 12 Adjusted

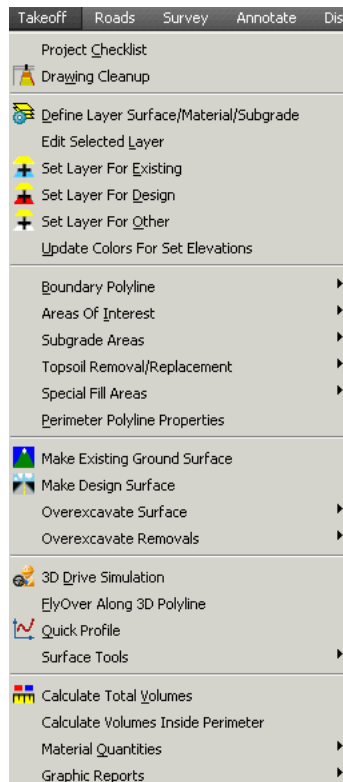

Pulldown Menu Location: Elevate (in Takeoff), 3D Data (in Civil)

Prerequisite: 3D linework

Keyboard Command: snap_cntrs

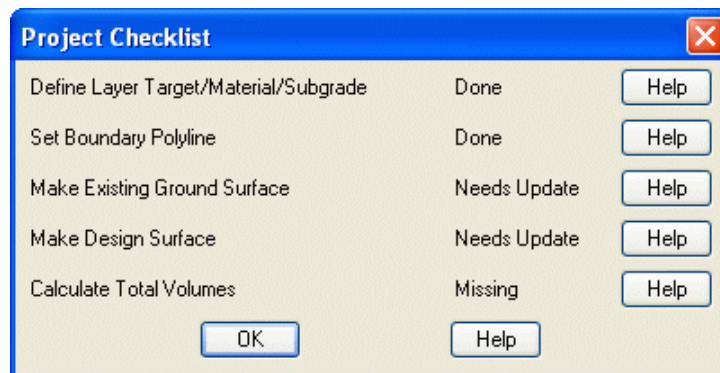

Takeoff Menu

The Takeoff menu commands are for earthwork and material quantity takeoff.

Project Checklist

This command checks the status of steps needed to calculate total volumes.

Prerequisite: None

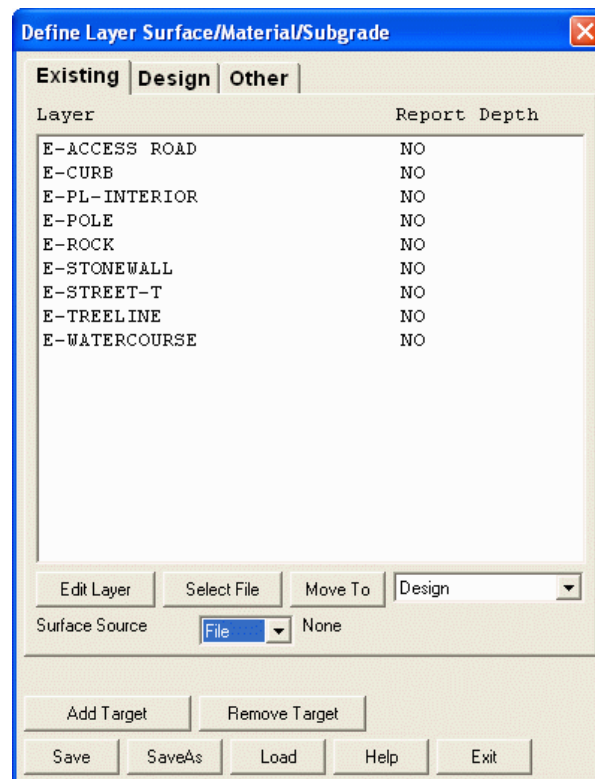

Keyboard Command: tk_checklist

Define Layer Target/Material/Subgrade

The Define Layer Surfaces dialog box (shown here) offers many functions that will ultimately make up the surface models used in volume and material calculations. Every entity (line, polyline, point, etc) in a drawing is assigned a layer name. Carlson Takeoff uses the entity layer names to define which entities represent the existing ground surface, the design surface or no surface. These surfaces are referred to as the "Target" surfaces. Any

previously created triangulation file (.tin) can be set to the design or existing Target with the Surface Source drop-down set to File. In this mode, the Select File button will allow you to pick the .tin file you want to use for the Target.

When the Surface Source drop-down is set to Layers, drawing entities are assigned to target surface by their layer name. For example, if polylines representing design contours are on the layer "Final", then "Final" will be set as a layer for the design surface. For layers of entities that are for neither existing nor design surfaces (such as text labels for street names), the layer target is set to Other. The Define Layer Surfaces dialog has three lists for layer targets: Existing, Design and Other. To switch between lists, pick the tabs at the top of the dialog. To move a layer to a target destination, highlight the desired layer, choose the target from the Move To list and pick the "Move To" button. All layers populate the "Other" target before being assigned to "Existing" or "Design".

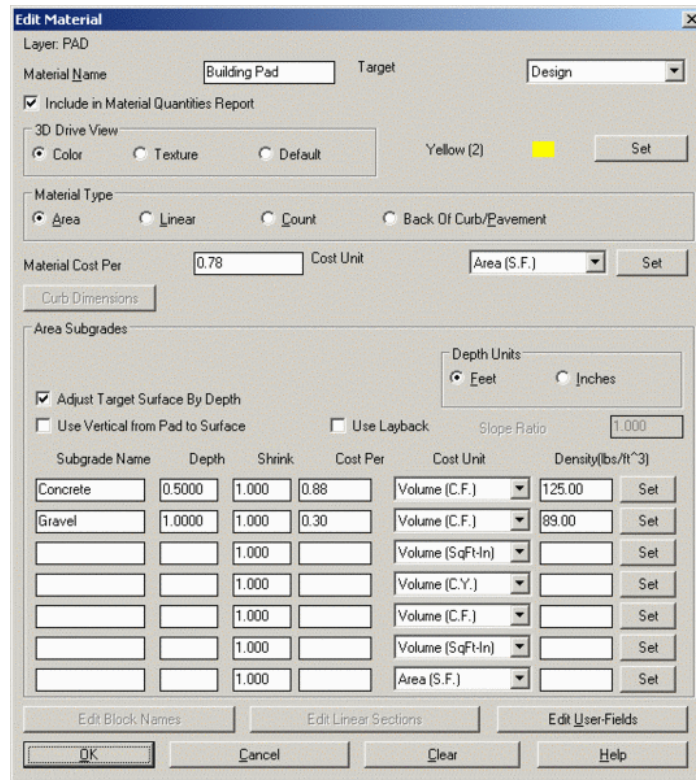

Besides the basic three layer targets (Existing, Design and Other), you can add more target surfaces with the Add Target button. When another target is defined, there will be another tab along the top of the Define Layer Surfaces dialog. Then layers can be assigned to this additional target surface. The only pre-defined additional surface is Overexcavate. The layers that are assigned to the Overexcavate target can be modeled into the Overexcavate surface using the Make Overexcavate Surface command. Besides Overexcavate, the other additional targets are user-defined. The layer targets can be modeled using the Make User-Defined Surface command. Then these surfaces can be used in Takeoff commands by assigning them to a Takeoff existing or design surface using the Set Active Surfaces command.

Edit Materials

The "Edit" button activates the Edit Material dialog box (shown here) and allows you to define the Material name and Subgrade depths and names. Besides assigning target surfaces by layer, layers are also used to define material names and subgrades depths. By assigning a material name, Subgrade names and depths to layers, the volume, area, length and count for entities on these layers can be reported. Also the depth is used to vertically adjust the design surface, or tie into the design surface by a Slope Ratio if "Use Layback" is checked on. For Area and Back Of Curb/Pavement material types, the polylines on the layer used for a Material must be closed polylines. Carlson

Takeoff supports nested Subgrade polylines for exclusion areas such as islands by counting how many Subgrade polylines surround an area. If the number is odd, then the area is included in the Subgrade. The even count regions in the area are not part of the Subgrade. To activate the Edit Material, select a layer from the list and then choose "Edit".

Include in Material Quantities Report

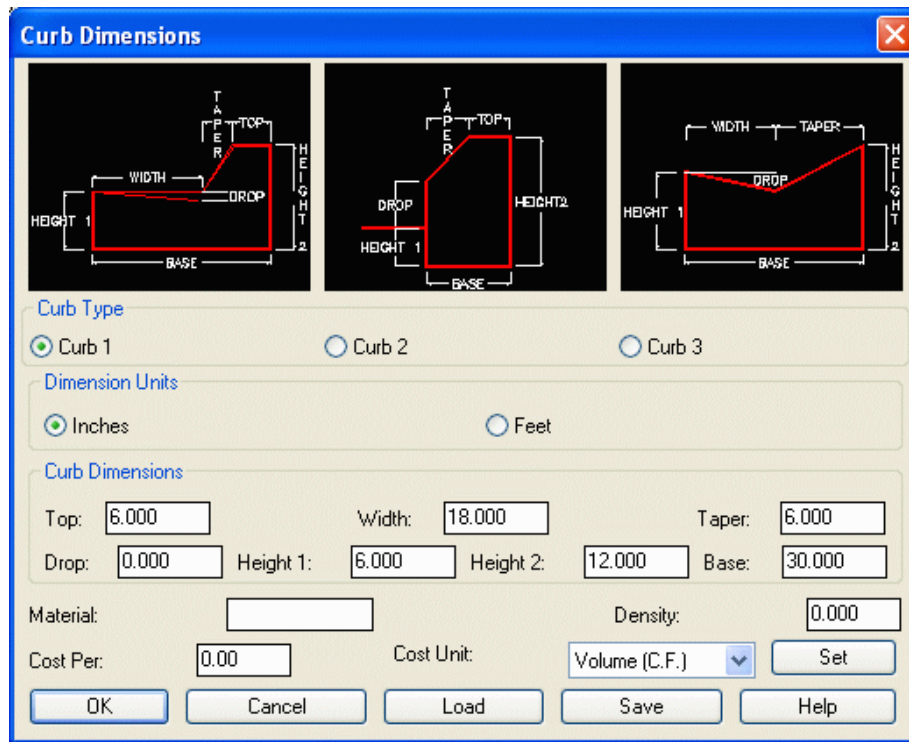

With this option checked on, the material that is named will appear in the Material Quantities Report. The report will include either the area of the material, the linear length of the material, or the number of items counted on the layer defining the material. This is accomplished by choosing "Area", "Linear", or "Count" for the Material Type.

3D Drive View

This option allows you to assign a color or texture for this particular material for display purposes during the 3D view/drive simulator. The color is assigned to the design surface TIN file.

Material Type

This will report the subgrade by area, linear length, count, or as curb/pavement area. If you choose Back of Curb/Pavement then you can pick on the Curb Dimensions button and bring you to the below dialog:

With the Back of Curb/Pavement, the 3D polylines represent the back of curb elevations. When using this method, the curb polylines alone define the pavement areas and no other design entities (ie. design contours or spot elevations) should be in the pavement area. The program will adjust the design surface for the height of the curb above ground to get the elevations to the top of pavement. Also with Curb/Pavement, the program will calculate your curb volume as well as act as the limit of the pavement. For the pavement areas bounded by the curb polylines, the program will apply the subgrade depths defined separately from the Curb Dimensions. These pavement subgrade depths are defined in the Area Subgrades section of the Edit Material dialog. The pavement limit will be from the Back of Curb polyline offset by the length of the Curb base. In the above case the base is 30 inches wide. Therefore, the pavement area will stop 30 inches before the Back of Curb polyline.

Material Cost Per Cost Unit

Use this field to add the value of the multiplier for the unit cost of your material. If the material type is an area that has multiple subgrades, use the available fields below to add each individual subgrade name, depth and cost value per unit type. If a linear or count type material type option is selected, use the "length in feet", or the "count" unit options.

Adjust Design Surface by Depth

This determines whether the subgrade depths are incorporated in the design surface or not.

Use Vertical from Pad to Surface

This will interpolate the surface model out to your layer and then vertically adjust the model to tie into the layer. With this checked off, the program will directly interpolate a surface model between your layer and the elevated entities around it.

Output Solid

This creates a solid model for area type materials using the depth for the thickness of the solid. The solid

model is saved in an .MDL file that is named automatically using the drawing name.

Area Subgrades

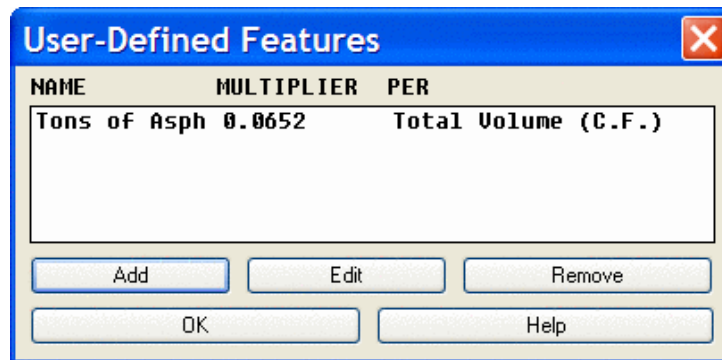

Depth Units

Select the "feet" or "inches" as the unit value desired for depth of subgrades.

Subgrade Name Depth Shrink Cost Per Cost Unit Density

Use these options for areas that are represented with a single/multiple closed polygon/polygons in the drawing, but have multiple material types defining the surface. Simply name each "lift" in the area, issue a depth value and add a cost unit if desired, or click on select and choose a material from the Materials Library (see Define Materials Library for more). Carlson Takeoff will report each subgrade material value in the material quantities report. The Shrink factor is multiplied by the subgrade volume in the material quantities report and represents the fill shrinkage. A Density factor can be entered in when using Cost Per Tons.

If user entered values are needed in the report use the "Edit User-Fields" button to activate the "User Defined Features" dialog box shown here. Choose the "Add" button to define needed fields such as TONS of material or BAGS OF GRASS SEED for reporting options.

Once all of the material subgrades, depths and cost units or user defined units have been defined, select save to preserve the settings in a .trg file, the "save as" function allows the user to name the file to load later.

Prerequisite: None

Keyboard Command: define_tk_layers

Edit Selected Layer

Use this command to click on any layer and advance to the Edit Materials dialog from the Define Layer Target/Material/Subgrade command.

Prerequisite: none

Keyboard Command: edit_tk_layer

Set Layer For Existing

Set Layer For Existing allows the user to pick the layers from objects on the screen and assign them to the Existing Layer.

Prerequisite: none

Keyboard Command: set_existing_layer

Set Layer For Design

Set Layer For Design allows the user to pick the layers from objects on the screen and assign them to the Design Layer.

Prerequisite: none

Keyboard Command: set_design_layer

Set Layer For Other

Set Layer For Other allows the user to pick the layers from objects on the screen and assign them to the Other Layer.

Prerequisite: none

Keyboard Command: set_other_layer

Update Colors For Set Elevations

This command refreshes the color of entities depending on their elevation and layer target. For entities assigned to the Existing or Design layer targets, if the entities are at zero elevation then their color is set to grey. Otherwise the entities have their true, original color. If the Automatic Update Colors command under Settings->Configure->Takeoff Module is toggled off, then this command is the way to update the entity colors after editing elevations.

Prerequisites: none

Keyboard Command: update_tk_colors

Boundary Polyline

The Boundary Polyline options allow the user to Set the Boundary Polyline, Set the Exclusion Polylines, Clear Exclusion Polylines, Hatch the Boundary Area, Erase the Boundary Hatched area.

Set Boundary Polyline

Use this command to select the "CLOSED" polyline that defines the outer most limit of the disturbed area. This boundary should dissect the site at the point where the design contours meet the existing contours, or where the limit of work will occur. If your site contains separated areas (such as different phases or isolated sections of work), then multiple Boundary Polylines can be used. Volume calculation will take place inside this boundary.

Prerequisite: a closed polyline

Keyboard Command: tag_inclu

Set Exclusion Polylines

Use this command to select the "CLOSED" polylines that define the areas inside the Boundary Polyline that will not be disturbed. These boundaries should also be at the intersection of the proposed and existing surface. A pond or wetland that will not be removed during construction is a good example of an Exclusion Area.

Prerequisite: a closed polyline

Keyboard Command: tag_exclu

Clear Exclusion Polylines

Use this command to select polylines that were previously defined as exclusion polylines but are no longer needed as exclusion areas.

Prerequisite: exclusion polylines

Keyboard Command: untag_exclu

Highlight Boundary Polylines

This command highlights the polyline you set as the Boundary Polyline.

Prerequisite: a boundary polyline

Keyboard Command: highlight_boundary

Hatch Boundary Area

Use this command to confirm the boundary polylines that have been selected are correct. This hatched area can also be utilized in exhibits of the drawing.

Prerequisite: a boundary polyline

Keyboard Command: hatch_boundary

Erase Boundary Hatch

This command erases the hatch drawn in the plan view.

Prerequisite: a boundary hatch

Keyboard Command: erase_boundary

Areas Of Interest

Areas of Interest can be used to calculate volumes and material quantities within a specified area. The Area Of Interest perimeters are defined by user-selected closed polylines and each area is assigned a name. The Area Of Interest polylines can be assigned either as inclusion or exclusion perimeters for the area. You can have any number of exclusion perimeters within an inclusion but inclusion perimeters cannot be inside exclusions. The same area name can be used with multiple inclusion polylines to combine the quantities from those polylines in the report.

The Areas Of Interest (AOI) commands allow you to Tag/Untag Areas of Interest, Identify/Report Areas of Interest and Hatch/Label Areas of Interest.

Tag Area Of Interest

This command allows the user to select polylines and exclusion perimeters that define phases of a project. Carlson Takeoff will separate each area of interest in the volume and material reports.

Prerequisite: a closed polyline

Keyboard Command: tag_aoi

Area Of Interest by Interior Text

This command allows the user to select text from the screen to name AOIs and linework to determine the area.

Prerequisite: area linework and text

Keyboard Command: txt2aoi

Untag Area Of Interest

This command allows the user to remove previously tagged areas.

Prerequisite: an area of interest

Keyboard Command: untag_aoi

Identify Area Of Interest

This command allows users to identify AOI by either picking on a polyline(s) or by searching the entire drawing. The command will then report the AOI name, layer, type, starting point, and highlight the polyline in the plan view.

Prerequisite: an area of interest

Keyboard Command: id_aoi

Report Area Of Interest Areas

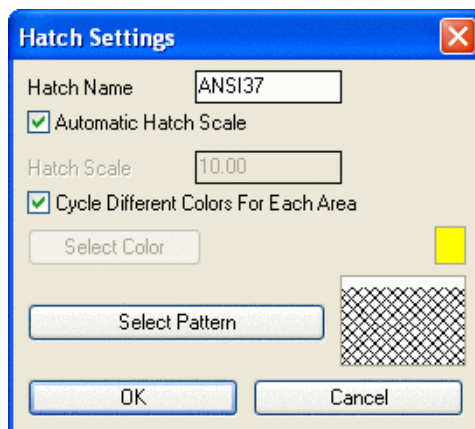

Use this command to report the Inclusion or Exclusion area (SF), the name, the layer, and the starting point.

Prerequisite: an area of interest

Keyboard Command: report_aoi

Hatch Area Of Interest Areas

This command allows the user to visually see AOIs in the plain view.

This command draws a hatch with a specified color and pattern for the Areas of Interest. The purpose is to allow you to visually review AOIs to make sure that the area coverage is correct.

The command displays a dialog for the hatch pattern, color and scale. The scale determines how spread out the pattern is within the hatch. The Automatic Hatch Scale option checks the size of the subgrade areas and sets the scale to make the pattern fit. Cycle Different Colors For Each Area will give each AOI it's own color so that you can distinguish between different AOIs.

The resulting hatch areas show where the AOI is applied. Exclusion Areas of AOIs will not be hatched.

Prerequisite: an area of interest

Keyboard Command: hatch_aoi

Erase Area Of Interest Hatch

This command erases AOI hatching.

Prerequisite: hatched area of interest

Keyboard Command: erase_aoi_hatch

Label Area Of Interest Areas

This command labels the AOI name and area in the plain view.

Prerequisite: an area of interest

Keyboard Command: label_aoi

Erase Area Of Interest Labels

This command erases AOI labeling.

Keyboard Command: erase_aoi_labels

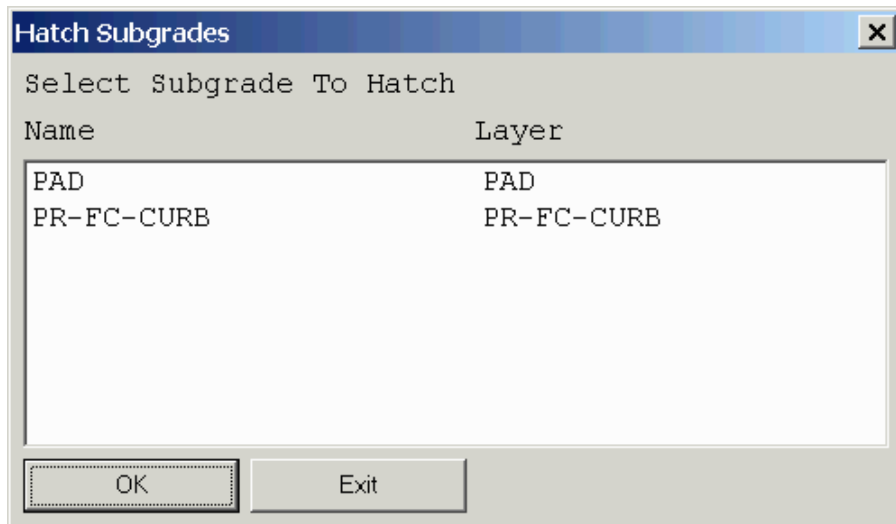

Prerequisite: hatched area of interest

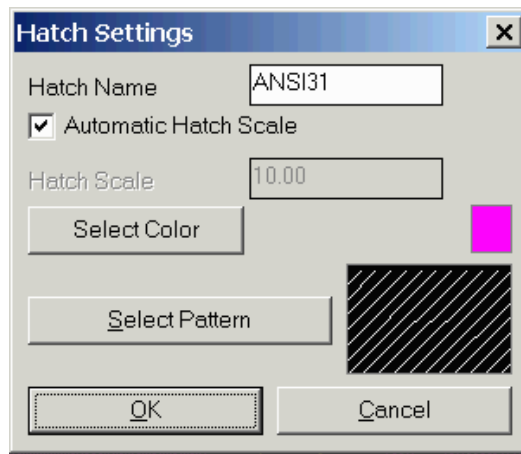

Hatch Subgrade Areas

This command draws a hatch with a specified color and pattern for the area that the selected subgrade area applies to. The purpose is to allow you to visually review a subgrade area to make sure that the area coverage is correct.

The command displays a dialog to select which subgrade to hatch. The list of available subgrades comes from the layers with subgrade depths as set in the Define Layer Target/Material/Subgrade command. Then there is a dialog for the hatch pattern, color and scale. The scale determines how spread out the pattern is within the hatch. The Automatic Hatch Scale option checks the size of the subgrade areas and sets the scale to make the pattern fit. The hatch settings are stored separately for each subgrade along with the Define Layer Target/Material/Subgrade command settings in the drawing TRG file.

The resulting hatch areas show where the subgrade is applied. In the example below, notice how the islands are not hatched because they are curb polylines that are already inside another curb polyline. Also note that the smaller pad area is not hatched because this polyline layer is different than the bigger pad polyline.

Pulldown Menu Location: Takeoff > Subgrade Areas

Keyboard Command: hatch_subgrade

Prerequisite: subgrades

Erase Subgrade Hatches

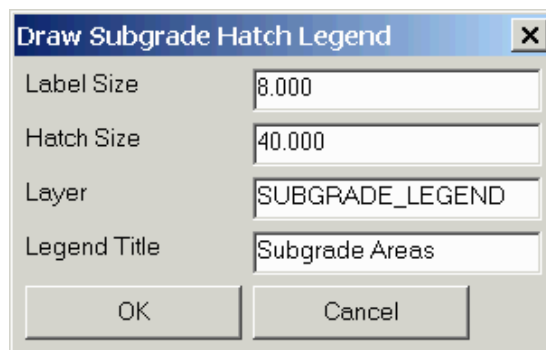

This command removes from the screen the subgrade hatches created by the command Hatch Subgrade Area.

Keyboard Command: erase_subgrade

Prerequisite: hatch subgrade areas

Draw Subgrade Hatch Legend

This command draws a legend for the subgrade areas currently in the drawing. The legend includes the subgrade names and squares of the hatch patterns. The size of the labels, size of the hatch squares, layer for the legend entities and the legend title are set in the dialog shown below. The subgrade hatches to include in the legend are automatically selected from all the subgrade hatches currently in the drawing that were created by the Hatch Subgrade Areas command.

Pulldown Menu Location: Takeoff > Subgrade Areas

Keyboard Command: draw_subgrade_legend

Prerequisite: hatched subgrade areas

Report Subgrade Areas

This command reports all the subgrade areas in the drawing. For each subgrade polyline, the report includes the layer name, subgrade depth, area and polyline starting point.

Sample Report:

Layer Depth Area Starting Point

PAD 1.500 21979.7 6135018.84,2190093.71

CURB 1.000 50420.2 6134994.81,2190125.80

CURB 1.000 114507.3 6135191.33,2190335.27

Pull-Down Menu Location: Takeoff > Subgrade Areas

Keyboard Command: report_subgrade

Prerequisite: Subgrade Areas

Label Subgrade Areas

This command lets you label the subgrade depth and area (in sq. ft. or meters). The label is placed at the center of the subgrade area, but can be moved with the Move command under Edit.

Pull-Down Menu Location: Takeoff > Subgrade Areas

Keyboard Command: label_subgrade

Prerequisite: Subgrade Areas

Erase Subgrade Labels

This command erases subgrade labels.

Pull-Down Menu Location: Inquiry-> Subgrade Areas

Keyboard Command: erase_subgrade_labels

Prerequisite: subgrade labels

Topsoil Removal and Replacement

The Topsoil Removal and Replacement options (shown here) allow the user to Define Topsoil removal and replacement depths, Set topsoil removal and replacement areas by selecting closed polylines, Clear the selected boundary polylines if needed, Hatch the topsoil removal and replacement areas and Erase the hatched areas.

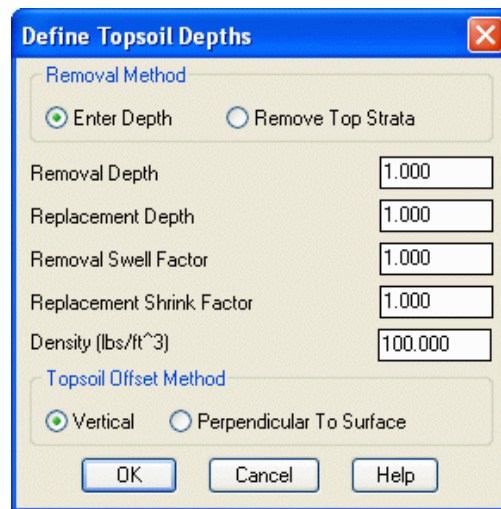

Define Topsoil Depths

This command requires user input to define the depth, or strata, of topsoil removal and replacement. Fill in the options available in the Define Topsoil Depths dialog (shown here). Carlson Takeoff will perform four functions with these values. First, the value set for the Removal Depth, or the Top Strata if selected, will be the "defined" removal amount from the Existing Ground Surface. Second, the calculated volume of topsoil removed will be included in the reporting options. Third, the value set for the Replacement Depth will be added "BELOW" the Finished Ground Surface model. Fourth, the amount of topsoil replaced will be included in the reporting options.

When topsoil depths are defined, the volume report routines will include the topsoil quantities. These topsoil quantities are in addition to the cut/fill for the existing to design surfaces for the site.

The Removal Swell Factor and Replacement Shrink Factor are multiplied by the topsoil removal and replacement quantities respectively in the volume report routines. The Density is used to report topsoil tons when the volume report option for tons is active.

The Topsoil Offset Method choose between offsetting the topsoil depth vertically or perpendicular to the surface. The perpendicular method will result in more topsoil quantities since it represents applying the topsoil depth to the slope area of the surface whereas the vertical method represents applying the topsoil depth to the horizontal area.

Prerequisite: topsoil depths

Keyboard Command: define_topsoil

Identify Topsoil Polylines

This command allows users to identify topsoil polylines by either picking on a polyline(s) or by searching the entire drawing. The command will then report the layer name and starting point for both removal and replacement polylines. These polylines are also highlighted in the plain view.

Prerequisite: topsoil polylines

Keyboard Command: id_topsoil

Report Topsoil Areas

Use this command to report the Inclusion or Exclusion area (SF), the type, the depth, the layer, and the starting point.

Prerequisite: topsoil areas

Keyboard Command: report_topsoil

Label Topsoil Areas

This command labels the topsoil type and area in the plain view.

Prerequisite: topsoil area

Keyboard Command: label_topsoil

Erase Topsoil Labels

This command erases topsoil labeling.

Prerequisite: hatched topsoil

Keyboard Command: erase_topsoil_labels

Set Topsoil Removal Polygons

Use this command to select the "CLOSED" polyline boundary defining the extents of topsoil removal and any "CLOSED" interior polylines that define the topsoil removal area. The layer names for these boundaries is irrelevant. You will be prompted to use the Removal Depth defined in the Define Topsoil Depths command or to customize your depth.

Prerequisite: polylines for removal

Keyboard Command: tag_topsoil_remove

Clear Topsoil Removal Polygons

This command allows the user to remove and previously selected Topsoil Removal Polygon boundaries.

Prerequisite: topsoil polygons

Keyboard Command: untag_topsoil_remove

Hatch Topsoil Removal Area

Use this command to display a hatch pattern over the entire area designated for topsoil removal.

Prerequisite: topsoil areas

Keyboard Command: hatch_topsoil_remove

Erase Topsoil Removal Hatch

Use this command to remove the hatch pattern that defined the topsoil removal area.

Prerequisite: hatched topsoil

Keyboard Command: erase_topsoil_remove

Set Topsoil Replacement Polylines

Use this command to select the "CLOSED" polyline boundary defining the extents of topsoil replacement, and any "CLOSED" interior polylines that define the topsoil replacement. The layer names for these boundaries is irrelevant. You will be prompted to use the Topsoil Replacement amount defined in the Define Topsoil Depths command or to customize your amount.

Prerequisite: polylines for replacement

Keyboard Command: tag_topsoil_replace

Clear Topsoil Replacement Polylines

This command allows the user to remove and previously selected Topsoil Replacement Polyline boundaries.

Prerequisite: topsoil polylines

Keyboard Command: untag_topsoil_replace

Hatch Topsoil Replacement Area

Use this command to display a hatch pattern over the entire area designated for topsoil replacement.

Prerequisite: topsoil areas

Keyboard Command: hatch_topsoil_replace

Erase Topsoil Replacement Hatch

Use this command to remove the hatch pattern that defined the topsoil replacement area.

Prerequisite: hatched topsoil

Keyboard Command: erase_topsoil_replace

Special Fill Areas

Special Fill Areas can be used to identify areas to report fill separately. This can be used for areas where a different type of fill is needed. Such as under a building pad. The Special Fill Areas perimeters are defined by user-selected closed polylines. Carlson Takeoff will separate the special fill volume within the Calculate Total Volume Report.

Tag Special Fill Area

This command allows the user to select perimeter polylines that define special fill areas. Note: The inclusion and exclusion polylines are selected at the same time. The polyline to the inside will be used as an exclusion polyline.

Untag Special Fill Area

This command allows the user to remove previously tagged Special Fill areas.

Identify Special Fill Area

This command allows the user to identify Special Fill Areas by either picking on a polyline(s) or by searching the entire drawing. The command line report the layer, starting point, and highlight the polyline(s) in the plan view.

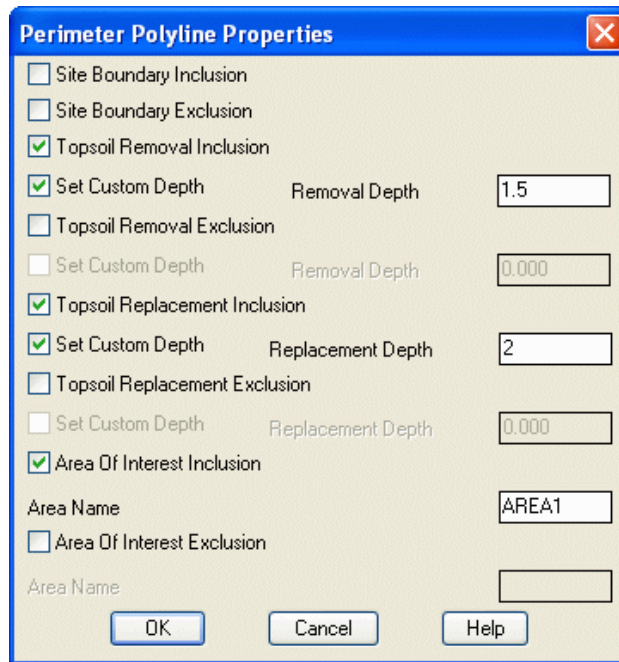

Pulldown Menu Location: Takeoff

Prerequisite: Closed polylines that represent Special Fill Areas

Keyboard Command: tag_special_area, untag_special_area, id_special_area

Perimeter Polylines Properties

This command allows you to control the properties of any perimeter polyline (Note: Perimeter polylines also have to be closed polylines). Select a polyline and the following dialog appears. Here you can define the functionality of the polyline in regards to, the Site Boundary, Areas of Interest, and Topsoil Removal/Replacement. These properties can also be set separately using the Boundary Polyline, Areas of Interest, and Topsoil Removal/Replacement commands found under the Tools menu of Carlson Takeoff.

Prerequisite: a polyline

Keyboard Command: perim_prop

Make Existing Ground Surface

This command makes the triangulation models for the existing ground surface. There are three surfaces that are created: initial original ground (og), original ground after applying subgrade zones (ze), and original ground after subgrade zones and topsoil removal (ex). These surface files are automatically named as "filename-og.tin", "filename-ze.tin" and "filename-ex.tin" respectively. The "filename" is set to the name of the current drawing (dwg) file. Also, the file extension will be .tin for the binary format triangulation and .flt for the ASCII format triangulation. This file format is set in Configure->Takeoff.

Original Ground (OG Surface)

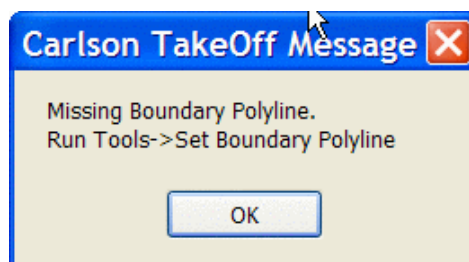

Existing Ground after subgrade zone removal (ZE Surface)

Existing Ground after subgrade and topsoil removal (EX Surface)

The surface is built using 3D entities in the drawing on the layers define in Define Layer Target/Material/Subgrade command. Also, the surface elevation for any drillholes are used for the model. The subgrade zones are defined in the Define Layer Target/Material/Subgrade command. If there aren't any subgrade zones for the Existing surface, then the original ground after subgrades surface with be the same as the initial original ground surface. The topsoil removal depths and areas are set with the commands in the Topsoil Removal/Replacement sub-menu. The topsoil removal areas will lower the ground surface by the topsoil depth. If there aren't any topsoil removal areas, then the original ground after subgrade and topsoil surface will be the same as the original ground after subgrade surface.

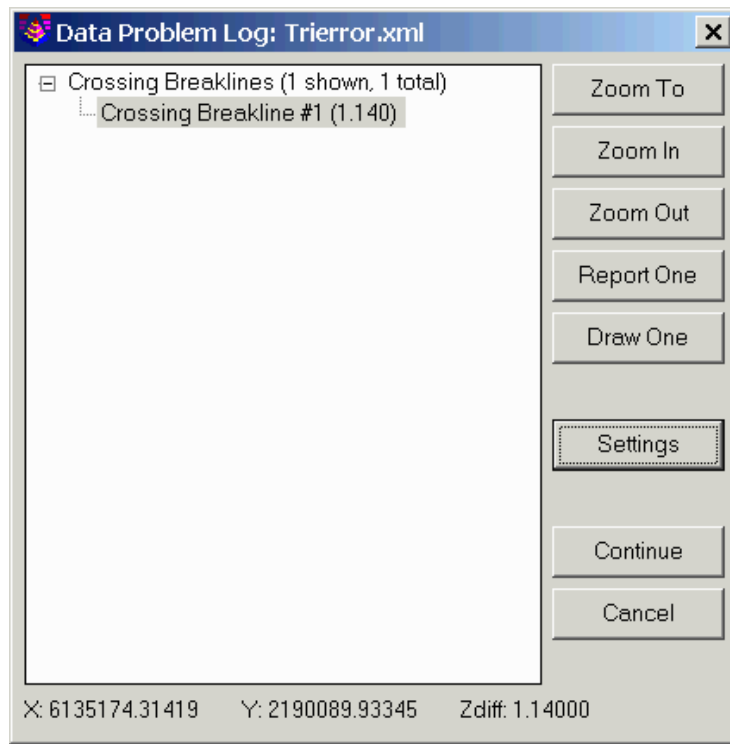

Before running this command, the layer names for the entities on the Existing layer target must be set in the Define Layer Target/Material/Subgrade command. Also these entities must be at their proper elevations. The entity elevations can be reviewed using commands from the Inquiry menu and the elevations can be assigned if needed using command from the Elevate menu. Another prerequisite is that the Boundary Polyline must be set for the site. If the boundary has not been set, the following error message will appear.

If this error message appears, run the "Set Boundary Polyline" command and pick the CLOSED polyline representing the boundary of the site.

When the program finds errors in the existing entities, a Data Error Log dialog reports these errors. Three types of conflicts are reported: Crossing Breaklines, Vertical Edges, and Breakline T-Intersections. Crossing Breaklines indicates that the intersection of two entities does not have a common elevation. Vertical Edges indicates that two entities or vertices of differing elevations have the same x-y location, thus forming a vertical plane. Breakline T-Intersections indicates that a 3d entity is abutting another entity, but the second entity doesn't have a vertex at the point of intersection. Each type of conflict is listed in its own category.

The Data Error Log shows the amount of elevation difference at each error. You can use the Data Error Log to review, report and draw markers at these error locations. Then you can exit the Data Error Log and fix the data errors with the commands in the Elevate menu or other drafting tools. After these errors are fixed, you can run Make Existing Ground Surface again.

Clicking to the "plus" sign beside a category will display the individual conflicts within that category. When a line item error is selected, a highlighted arrow is temporarily placed in the drawing to indicate the exact location of the specific conflict. Zoom functionality allows the user to more closely inspect the specific problem area, and if needed a marker can be drawn or a report generated for an individual conflict or conflicts.

Zoom To pans the drawing to move the selected conflict to the center of the screen. The zoom functions are only active when a single line item is selected.

Zoom In zooms in on the highlighted area for closer inspection. Multiple picks on the zoom button will increase the magnification.

Zoom Out zooms out away from the highlighted area.

Report All/One toggles between One and All depending whether a single line item conflict or a category is selected from the error log. An error report is generated listing the x-y position and the elevation difference of the entities in conflict.

Draw All/One toggles between One and All depending whether a single conflict or a category is selected from the list. This option draws an "X" symbol at each selected conflict. The layer and size of the symbol is controlled in the fields below.

Continue closes the Error Log and proceeds with the contouring operation.

Settings has controls for the tolerances for error reporting and for the Layer Name and Symbol Size to use with the Draw function.

Keyboard Command: mk_exist_tin

Prerequisite: a boundary polyline and elevated entities on the Existing layer target

Make Design Surface

This command makes the triangulation models for the design surface. There are three surfaces that are created: initial unadjusted design/finished grade (fg), design after applying subgrade zones (zn), and design after subgrade zones and topsoil replacement (sg). These surface files are automatically named as "filename-fg.tin", "filename-zn.tin" and "filename-sg.tin" respectively. The "filename" is set to the name of the current drawing (dwg) file. Also,

the file extension will be .tin for the binary format triangulation and .flt for the ASCII format triangulation. This file format is set in Configure->Takeoff. The subgrade zones are defined in the Define Layer Target/Material/Subgrade command. If there aren't any subgrade zones for the Design surface, then the design after subgrades surface will be the same as the initial design surface. The topsoil replacement depths and areas are set with the commands in the Topsoil Removal/Replacement sub-menu. The topsoil replacement areas will lower the design surface by the topsoil depth to leave room for the topsoil replacement. If there aren't any topsoil replacement areas, then the design after subgrade and topsoil surface will be the same as the design after subgrade surface.

Before running this command, the layer names for the entities on the Design layer target must be set in the Define Layer Target/Material/Subgrade command. Also these entities must be at their proper elevations. The entity elevations can be reviewed using commands from the Inquiry menu and the elevations can be assigned if needed using command from the Elevate menu. Another prerequisite is that the Boundary Polyline must be set for the site.

When the program finds errors in the existing entities, a Data Error Log dialog reports these errors. Refer to the Make Existing Surface command for more information on the Data Error Log dialog.

Unadjusted Design/Finished Grade (FG surface)

Design after subgrades (ZN surface)

Final Design after subgrades and topsoil (SG surface)

Keyboard Command: mk_final.tin

Prerequisite: a boundary polyline and elevated entities on the Existing layer target

View Overexcavate Surface

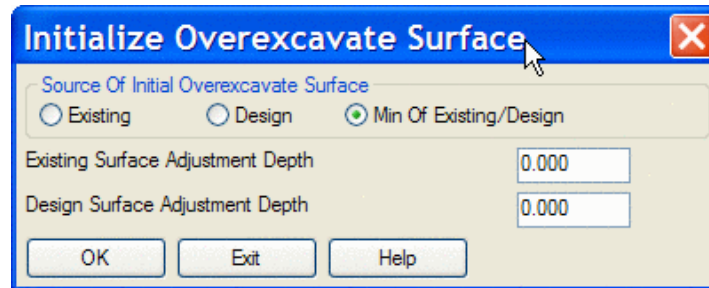

Use this command to view the current overexcavate surface. The Takeoff 3D Viewer will display the 3D faces of the adjusted surface. Shade the 3D model and adjust its perspective to view a rendered display. The surface that is displayed will depend on the latest surface created using the make and adjust routines.

Prerequisite: an overexcavate surface

Keyboard Command: cube_overx

Make Overexcavate Surface From Existing/Design Surfaces

The Initialize Overexcavation Surface dialog box shown here allows the user to select which surface model to overexcavate and to enter in the depth value for the desired adjustment. Use the Min Existing/Design option to set the overexcavate as the minimum of the existing and design surfaces. If a single surface is selected the value entered will be applied to that surface only. The resulting surface of Make Overexcavate Surface is stored in a triangulation file that is named with "-ox" appended to the current drawing name.

Prerequisite: Existing and/or Design surfaces

Keyboard Command: set_overx

Make Overexcavate Surface From Surface File

This command sets the overexcavate surface to a selected TIN surface file by copying the TIN file to the overexcavate surface. The overexcavate surface is stored in a triangulation file that is named with "-ox" appended to the current drawing name.

Pulldown Menu Location: Takeoff > Overexcavate Surface

Keyboard Command: overx_by_file

Prerequisite: .tin file

Make Overexcavate Surface From Strata

This command sets the Overexcavate surface to a selected strata surface. Before running this command, the strata surface must be created with the Make Strata Surfaces command in the Drillhole menu. The resulting overexcavate surface is stored in a triangulation file that is named with "-ox" appended to the current drawing name.

Prerequisite: Strata surfaces

Keyboard Command: overx_by_strata

Make Overexcavate Surface From Screen Entities

This command makes the overexcavate surface from entities on the layers defined as Overexcavate in the Define Layer Target/Material/Subgrade command. The resulting surface of Make Overexcavate Surface is stored in a triangulation file that is named with "-ox" appended to the current drawing name.

Prerequisite: overexcavate entities
Keyboard Command: mk_overx_tin

Adjust Overexcavate Surface

This command adjusts the overexcavate surface vertically within the selected perimeter polylines. This command allows the site to be overexcavated at a variety of depths in specified areas represented with CLOSED polyline boundaries. Select the desired areas to be adjusted when prompted at the command line.

Keyboard Command: adjust_overx
Prerequisite: an overexcavate surface

Draw Overexcavate Surface 3D Faces

Use this command to draw the 3D faces of the overexcavated surface model on the screen. The 3D faces will be drawn in the TK_OVERX_SURFACE layer and will depend on the latest surface created using the make and adjust routines.

Prerequisite: An overexcavate surface
Keyboard Command: draw_overx

Erase Overexcavate Surface 3D Faces

Use this command to remove the previously drawn 3D Faces from the screen.

Prerequisite: 3D Faces
Keyboard Command: erase_overx

Draw Overexcavate Cut Color Map

Use this command to display a cut color map on the screen that shows the areas of overexcavate cut. The colors will graduate from white to red based on zero cut depth to maximum cut depth. This command also offers the user to place a legend of the cut depths on the screen. Pick the desired location and type the desired scale of the legend when prompted at the command line.

Prerequisite: An overexcavate surface
Keyboard Command: overx_cfmap

Erase Overexcavate Cut Color Map

Use this command to remove the previously drawn Cut Color Map and Legend from the screen.

Prerequisite: An overexcavate cut color map
Keyboard Command: overx_cfmap2

Clear Overexcavate Surface

Use this command to remove the overexcavate surface. When the overexcavate surface is removed, the rest of the Takeoff commands will not calculate overexcavate volumes. You will be prompted to confirm before the remove is done.

Pulldown Menu Location: Takeoff > Overexcavate Surface

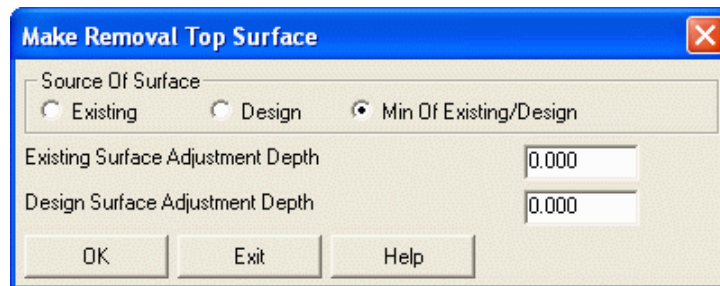

Prerequisite: An overexcavate surface

Keyboard Command: clear_overx

Make Top Surface

From Existing/Design Surfaces

This command sets the top Overexcavate surface (dwgname-rm.tin) that will be compared to a bottom Overexcavate surface for removal volumes. In the below dialog, Existing and Design surfaces created in Takeoff can be used as the top Overexcavate surface. Min Of Existing/Design is the minimum, or lowest grade, between the Existing and Design surfaces. Adjustment Depth allows you to drop either the Existing or Design surface by a specified amount.

Prerequisite: an existing or design surface

Keyboard Command: set_rm_top

From Triangulation Surface File

This routine allows a previously created surface .tin or .flt file to be loaded as the top Overexcavate surface.

Prerequisite: a previously created surface .tin or .flt file

Keyboard Command: rm_top_file

From Screen Entities

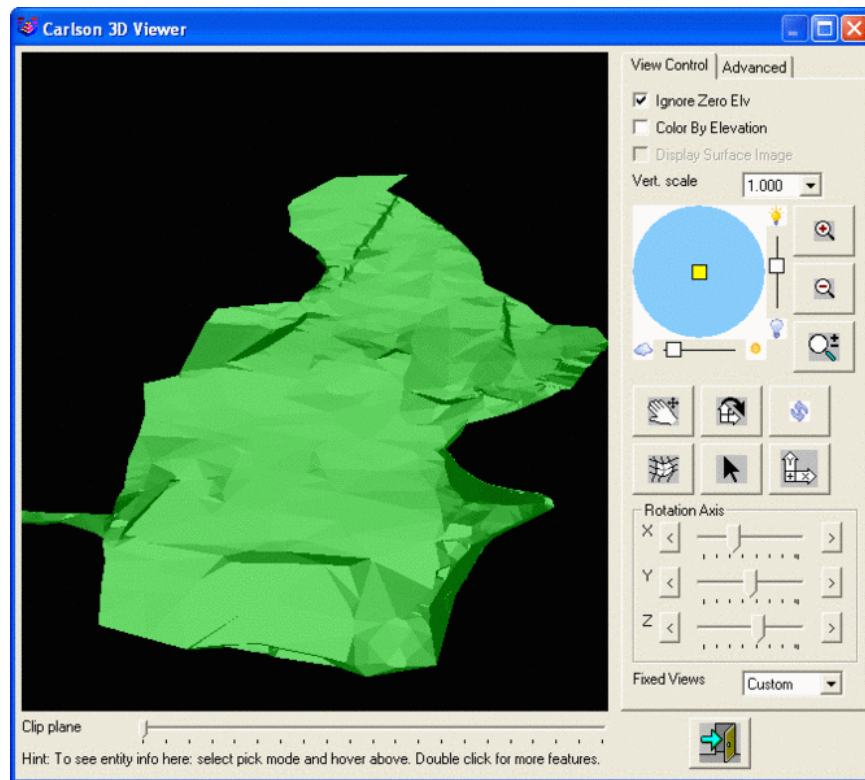

This command will create the top Overexcavate surface from entities in the plan view. Entities will need to have elevation such as contours, 3D faces, or elevated polylines.

Prerequisite: screen entities with elevation

Keyboard Command: mk_rm_top

View Top Surface

This command allows you to view the top Overexcavate surface in 3D mode.

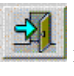

In the top right of the control bar you can check to Ignore Zero Elev and Color By Elevation and change the Vertical Scale. If you increase the Vertical Scale than elevation differences can be seen easier. Ignore Zero Elev does not display elevations of zero in the 3D viewer. Color By Elevation shows elevation change with the change of colors. Note: Color By Elevation is used in the above example. To adjust the color use the color circle on the right.

The magnify glass icons can be used to zoom in and out. Click on the plus magnify glass to zoom in and

the minus magnify glass to zoom out. With the  icon click and drag up to zoom in and drag down to zoom out. The hand icon below the color circle allows you to pan around the viewer. Click and drag the direction you

want to move. The  icon can be used to rotate the vantage point of the viewer by the x, y, or z axis. When you move the cursor to the screen it will change into a x, y symbol or a z symbol. Move the cursor around to move it from one to the other. If you have the x, y cursor move right or left to change the x axis view, or to change the y move the cursor up or down. If you have the z cursor than move it in a circular fashion to rotate the view point

according to the z axis. The  icon toggles on and off the shading of the surface (the shading is shown in the above drawing). The arrow icon reports the elevations at the bottom of the screen as you move around the surface.

The  icon restores the surface viewpoint to flat. The  icon exits 3D Driver Simulation.

Rotation Axis: These three control bars rotate the surface around the x, y, and z axis. Clip plane trims the size of the surface shown in the viewer.

Prerequisite: a top Overexcavate surface

Keyboard Command: cube_rm_top

Draw Top Surface 3D Faces

This command will display the top Overexcavate surface as 3D faces in the plan view.

Keyboard Command: draw_rm_top

Prerequisite: Make Top Surface

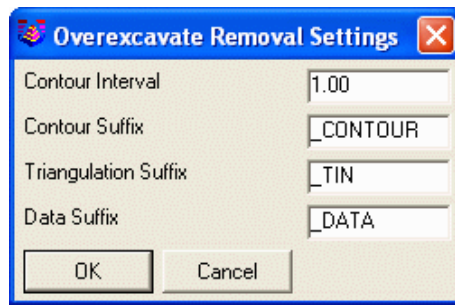

This command will erase the plan view entities created in Draw Top Surface 3D Faces.

Keyboard Command: erase_rm_top

Prerequisite: Draw Top Surface 3D Faces

Removal Settings

This command sets the layers suffixes for the entities created in the commands Draw Removal Surface and Draw Removal Contours. These Surfaces are added to the Removal Area names. For example, if Topo2 is set to Current in the Removal Manager, Draw Removal Surface will create 3D faces on the layer Topo2.TIN. Likewise, Draw Removal Contour will create contours on the layer Topo2.CONTOUR. The interval that the contours are drawn are also set here.

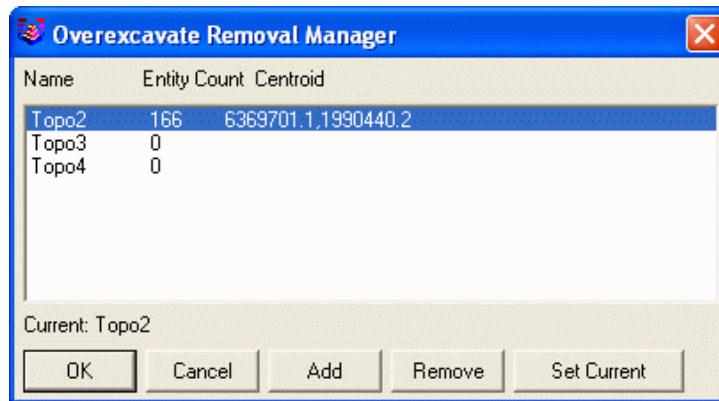

Prerequisite: none

Keyboard Command: rm_overx_setup

Removal Manager

In Removal Manager command every Removal Area in a project and the entities that define them is displayed as well as the Centroid (center coordinate) for that Area. Add allows you to name and create a new Removal Area. Remove will delete the Removal Area. When a Removal Area is set to Current, it will be used by other Removal commands when processing.

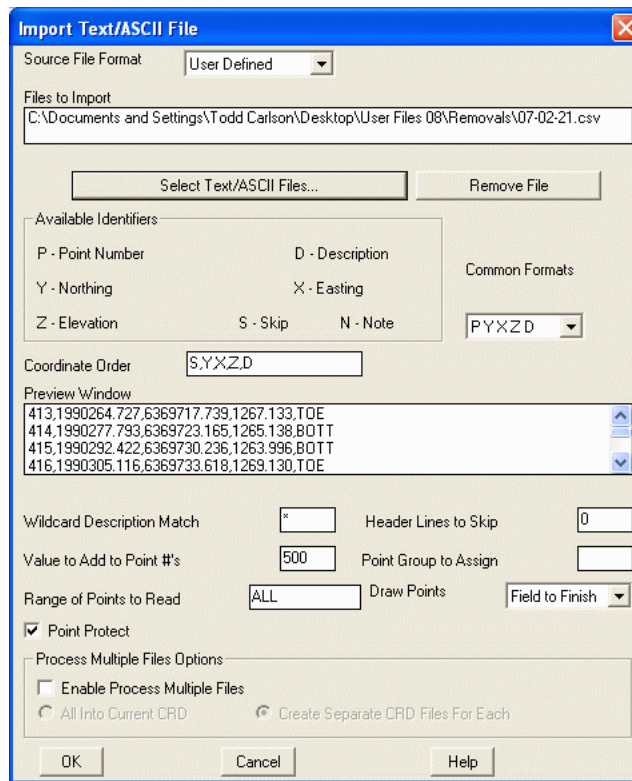

Prerequisite: none

Keyboard Command: rm_overx_mgr

Import Removal Text ASCII File

This command converts point data from an ASCII text file into the current Carlson coordinate (.CRD) file. The points brought in with this command will be assigned to the Current Removal Area if Draw Points is set to Points or Field-to-Finish. Each line of the text file can contain any combination of point number, northing, easting, elevation and description. All point information should be on one line with the values separated by a comma, space or other delimiter. Under the Source File Format setting you can choose from some specific formats or User-Defined. For User-Defined, the format of the text file is specified in the Coordinate Order field where the value identifiers are listed with the appropriate delimiters.

Common formats can be selected from the Common Format List. All the lines in the text file should contain only point data and any header lines should be removed. To read the text file, pick the Select Text/ASCII File button and choose the file to read. Then the selected file is displayed in the Preview Window to help with filling out the Coordinate Order. When the Coordinate Order is set, click OK to read the text file. The Wild Card Descriptions Match allows for only point with matching descriptions to be imported. With Point Protect active, the program will check if a point number already exists in the CRD before importing the point. If a point conflict is found, you can either assign a new point number or overwrite the old point. The Value to Add to Point Numbers allows you to renumber the points as they are imported. The Header Lines to Skip value is the number of lines not to be processed at the start of the text file. The Point Group To Assign option will create a point group with the specified name for the coordinate file containing the point numbers imported with Import Text/ASCII File. Special formats can be directly imported by choosing that File Format at the top of the dialog.

Prerequisite: Text/ASCII File and a Removal Area created and set to Current

Keyboard Command: rm_overx_mgr

Draw Removal Field to Finish

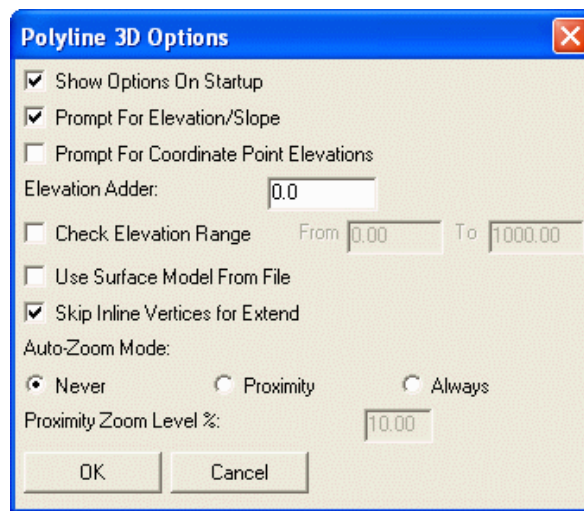

This command turns data collector field notes into Removal Area points and linework by matching the descriptions of the field points with user-defined codes. Two files are used in Field-to-Finish - a coordinate file and a field code definition file. For more on these files and their settings see Draw Field-to-Finish under Survey.

Keyboard Command: rm_overx_f2f

Prerequisite: A data file of points with descriptions and a Removal Area created and set to Current

Draw Removal Breakline

This command allows you to draw 3D linework for the Current Removal Area.

The Show Options on Startup dialog will appear every time the command is run, unless this is turned off. If it is off, then the last settings will apply. To get the box back, choose O for Options.

Prompt for Elevation/Slope controls whether the elevation of each picked point will be entered in, or hit S for slope to draw a slope line.

Use Surface Model from File will use a grid or triangulation file as a surface model. Wherever the points are picked on the surface, the elevation of the surface will be assigned to the polyline.

There are 3 options under Auto-Zoom Mode. Never will not zoom to the last point picked. Proximity will zoom to the percent proximity set below. Always will always zoom center on every point.

If the Proximity Auto-Zoom mode is checked, the percent of the proximity is set in the Proximity Zoom Level% box.

Keyboard Command: rm_overx_3dp

Prerequisite: a Removal Area set to Current

Removal Entities

Tag Removal Entities

This command allows the user to select polylines and points that define the Current Removal Area. Carlson Takeoff will separate each Removal Area in the Calculate Removals Volumes Report.

Prerequisite: linework and/or points intended for the Current Removal Area

Keyboard Command: tag_rm_overx

ID Removal Entities

This command allows users to identify Removal Entities by either picking on a polyline(s) or by searching the entire drawing. The command will then highlight the polyline in the plan view.

Prerequisite: Tag Removal Entities

Keyboard Command: id_rm_overx

Untag Removal

This command allows the user to remove previously tagged Removal Entities.

Prerequisite: Tag Removal Entities

Keyboard Command: untag_rm_overx

Set Removal Boundary

Use this command to select the "CLOSED" polyline that defines the outer most limit of the Current Removal Area. This boundary should dissect the site at the point where the Current Removal Entities end. Volume calculation will take place inside this boundary.

Prerequisite: a closed polyline

Keyboard Command: rm_overx_perim

Make Removal Surface

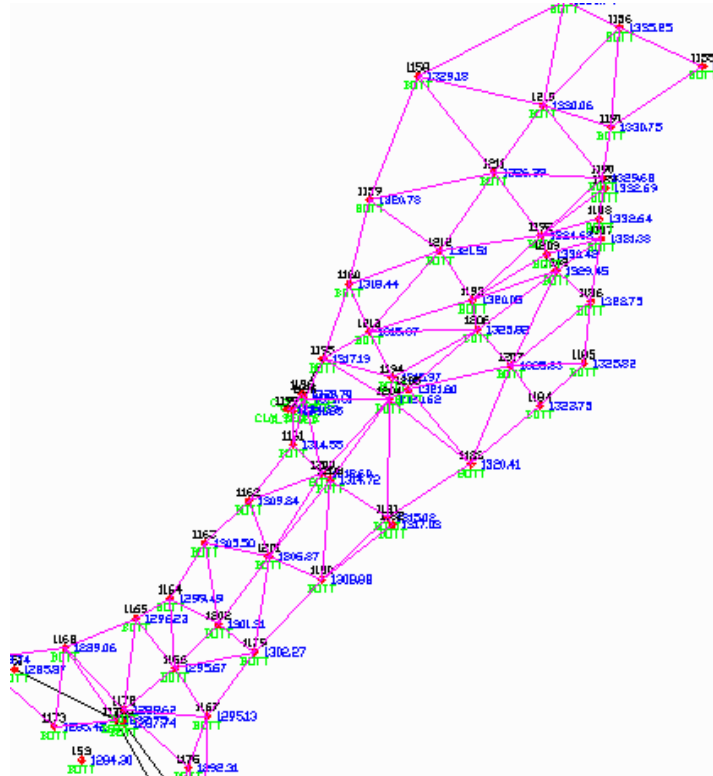

This command makes the triangulation models for the Removal Surfaces. The surface is automatically named as "filename-removalname.tin". The "filename" is set to the name of the current drawing (dwg) file. The "removalname" is determined by the Removal Area current in the Removal Manager. Before running this command, you must have a current Removal Area with elevated entities. Another prerequisite is that the Removal Boundary must be set for the site.

Keyboard Command: mk_rm_overx

Prerequisite: Removal Entities and a Removal Boundary

Draw Removal Surface

This command draws the current Removal Surface as 3D faces in the plan view.

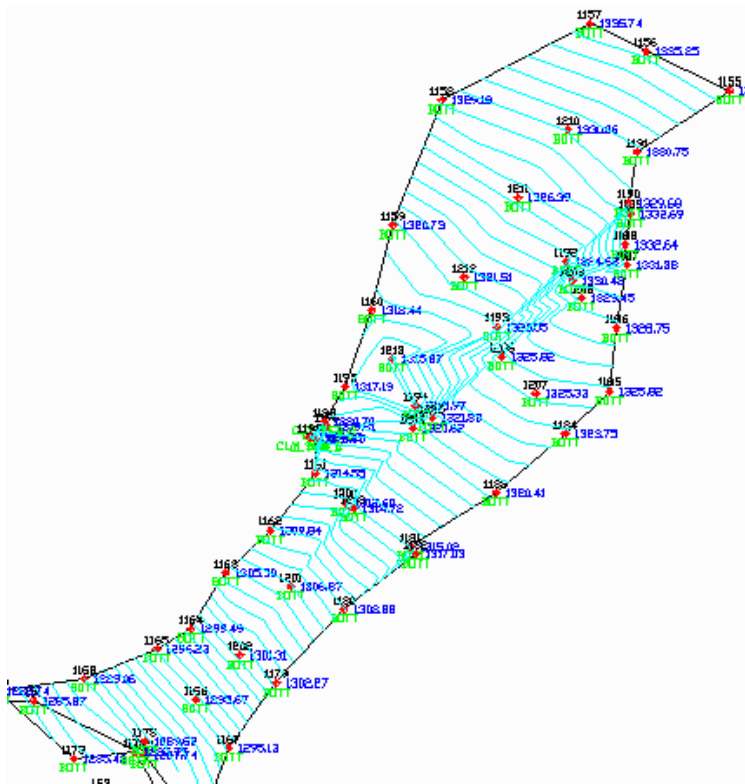

Keyboard Command: draw_rm_overx_tin

Prerequisite: Make Removal Surface

Draw Removal Contours

This command displays all the contours that represent current Removal Surface. They are created off of the Removal Area .tin model. For contour interval, see Removal Settings.

Keyboard Command: draw_rm_overx_ctr

Prerequisite: Make Removal Surface

Make Combined Removal Surface

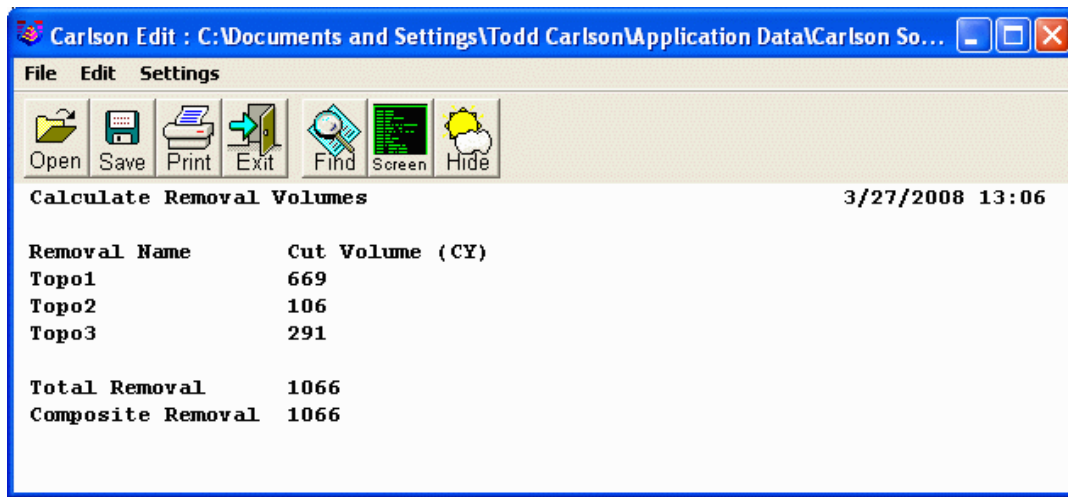

This command makes a TIN surface from all the removal surfaces from the Removal Manager. The command reports all the removal surfaces from the current drawing and then prompts for the TIN file to create.

Keyboard Command: overx_combine

Prerequisite: Overexcavate Removal Surfaces

Calculate Removals Volumes

This command reports the volumes in cubic yards for each Removal Area against the Top Removal Surface. The volumes are given for each area as well as a total for all the areas. Calculate Removal Volumes then creates and reports a Composite Surface against the Top Removal Surface taking the lowest grade in overlapping Removal Areas.

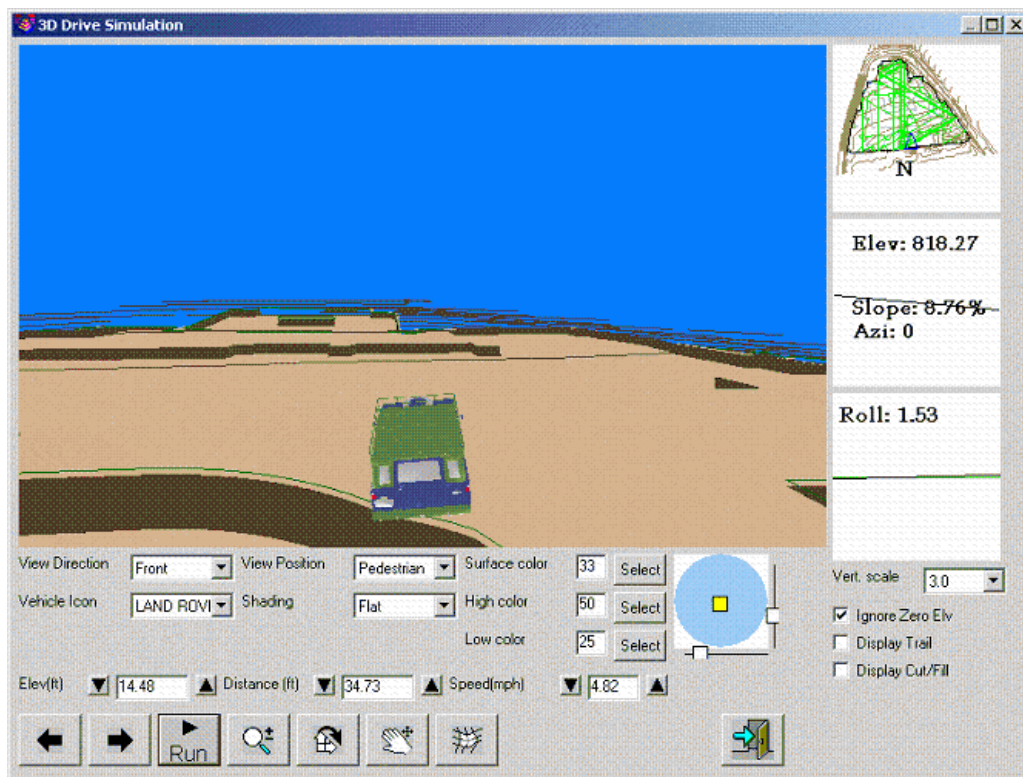

From the Standard Report Viewer, you can Save, Print, or place on the Screen the volume numbers. You can also type your own text into the report.

Keyboard Command: calc_rm_overx

Prerequisite: Make Top Surface and Make Removal Surface

3D Drive Simulation

This command allows you to view and move around the design surface in 3D mode.

Use the arrows on your keypad to move around the drawing.

At the very bottom of the window you will find the basic commands: Run will start to drive your vehicle around the surface, once your vehicle is moving the Run button turns into the Stop button. The arrows moves your vehicle left and right. The magnify glass zooms in and out. Click and drag up to zoom in and click and drag down

to zoom out. When your vehicle is stopped the  icon can be used to rotate the vantage point of the viewer by the x, y, or z axis. When you move the cursor to the screen it will change into a x, y symbol or a z symbol. Move the cursor around to move it from one to the other. If you have the x, y cursor move right or left to change the x axis view, or to change the y move the cursor up or down. If you have the z cursor than move it in a circular fashion to rotate the view point according to the z axis.

The hand icon allows you to pan around the viewer. Click and drag the direction you want to move. The 

icon toggles the shading of the surfaces. The  icon exits 3D Driver Simulation.

Above the basic command buttons you can change the Elevation and Distance away from your vehicle. Also, you can set the speed at which your vehicle travels. For a smaller drawing you may want to move around slower, for a larger drawing faster. Note: Unrealistic speeds such as 500 mph in a dozer may cause 3D Drive Simulation to freeze.

View Direction: Sets the direction of the view from the Front, Back, Left, or Right.

Vehicle Icon: You can select which Vehicle you want to use whether: Dozer, Hummer, School Bus or none at all.

View Position: Sets the elevation and distance to either that of the driver, a pedestrian, or bird.

Shading: Here you can set the shading of the surface to either Flat, Smooth, Elevation, Cut/Fill, or none. Flat just shades the contours as they are. Smooth smooths contours to look for realistic. Elevation colors different elevations in different colors so differences can visual be seen. Cut/Fill colors areas of cut differently than areas of fill so they can be visually seen. None merely shows the triangulation and does not shade in a surface.

You can select the Surface, High, and Low color by enter in an AutoCAD defined color number or you can choose Select to pick a color. The circle on the right determines the shade of the color.

In the top right of the 3D viewer is an aerial map of your surface. Below that the Elevation, Slope percentage, Azimuth, and Roll are updated as your vehicle moves around the surface. Slope and Roll are shown visually here as well.

On the bottom right you can set the Vertical Scale and check to Ignore Zero Elev, Display Trail, and Display Cut/Fill. If you increase the Vertical Scale than elevation differences can be seen easier. Ignore Zero Elev does not display elevations of zero in the 3D viewer. Display Trail draws a line where your vehicle has driven. Display Cut/Fill displays the cut and the fill.

Prerequisite: a design surface

Keyboard Command: tk_flyby

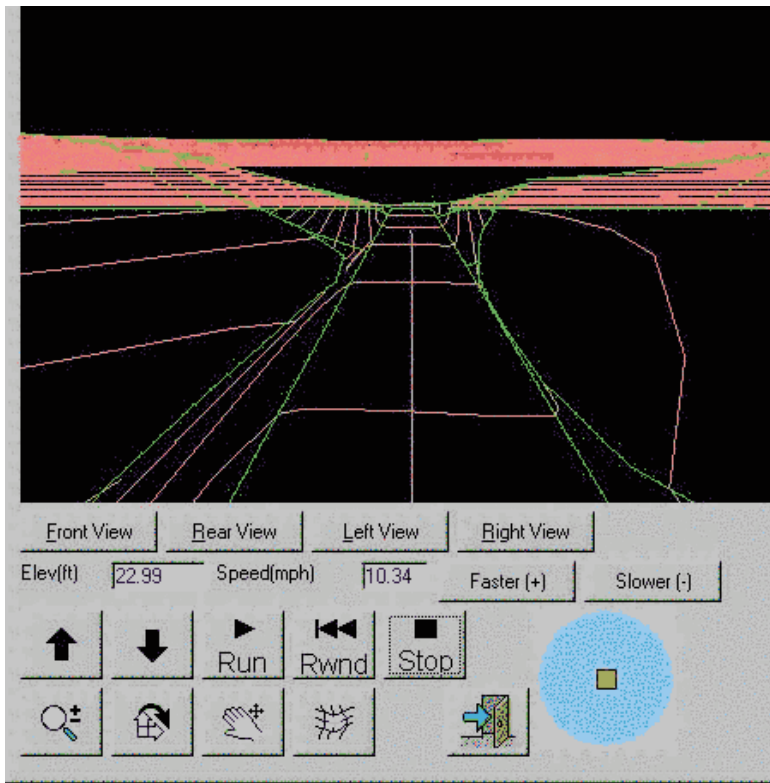

FlyOver Along 3D Polyline

This command allows you to view a self guided animation of following a path through a 3D surface model. There are two variations to this command. When the command is started, you must specify whether you want to use a surface model from file or screen entities.

Surface model from file: Using this method, you can select either a triangulation (.TIN) file or a grid (.GRD) file, then you have the option of following a polyline or following a "free" path. If you choose the polyline method, then the animation is limited to following the polyline. If you choose the "free" path method, you first specify two points to obtain a starting direction, the while inside the viewer you can point the animation in any direction.

Screen entities: Using this method, you must select a 3D polyline to follow. The animation is limited to following the polyline.

After making the above selections, the 3D graphics window is opened. The main window is for the animation, the smaller upper right window shows you the overall plan view, and the smaller window located at middle right shows you the current elevation, slope and azimuth. While following a "free" path, you will have a 3rd small window located at lower right which shows you the amount of roll at your current position.

 This button raises the elevation of your viewing position.
  This button lowers the elevation of your viewing position.
  This button turns your viewing position to the left.
  This button turns your viewing position to the right.
  This button allows you to zoom in and out.
  This button allows you to rotate the main animation window in any X, Y or Z direction.
  This button allows you to pan.
  This button toggles shading on and off.
  This button starts the animation in the main window.
  This button stops the animation.
  This button exits the 3D Surface FlyOver command.
  Control for position of the light source, viewed from above.

Prerequisite: Surface Model and optionally a 3D Polyline
Keyboard Command: flyby

Surface Manager

This command allows the user to name and manage multiple surface models. The Surface Manager dialog shown here has options to name and save the current "existing and design" surface models. The "current" surface is dictated by the layers that populate a target and the Make Surface command. If layers are removed from a target, and others assigned, multiple surfaces can be created and stored. When the Lock Status is check, the Current Surface will remain current even if you run Takeoff > Make Existing Ground Surface or Make Design Surface. If the Lock Status is uncheck, then Making the Existing or Design Surface will become the current surface, overriding the current surface selected in the Surface Manager. Highlight a named surface and select the Set Current From List option to make that model active. Use the Remove From List option to remove a named surface model from the list.

Selecting the Save Current To List options brings up the Surface Name dialog box shown here. Type the desired name that describes a particular surface model and select OK.

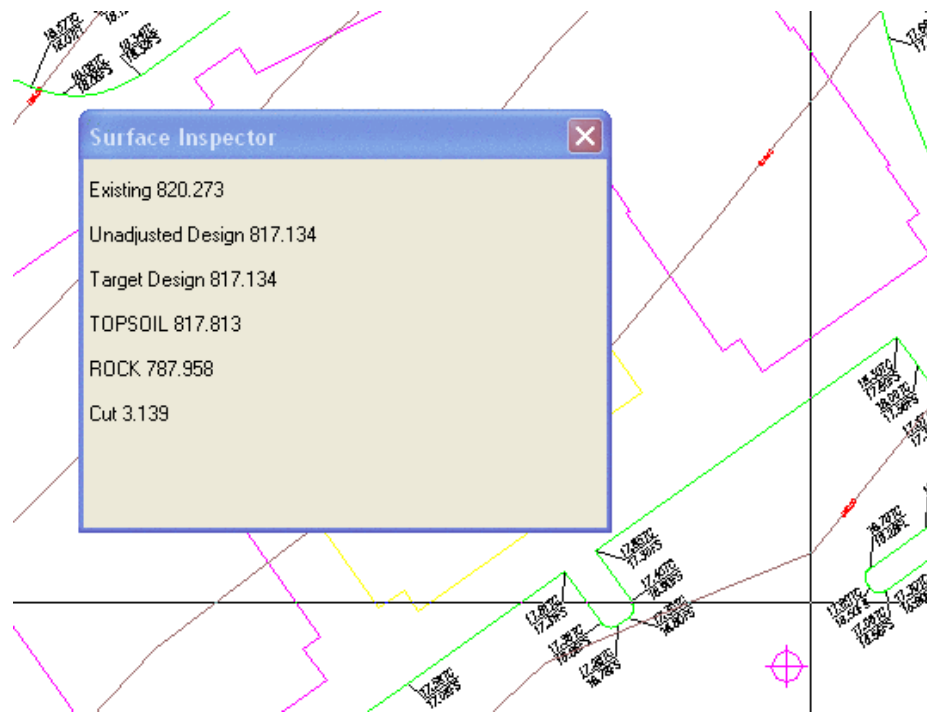

Pulldown Menu Location: Takeoff > Surface Tools

Prerequisite: none

Keyboard Command: surf_mgr

Surface Inspector

This command allows you to report and optionally label elevations from your drawing. You can analyze all of your different surface files at one time. After running the command, Surface Inspector will begin showing you real-time elevations for each surface as you move the cursor on the screen. If you pick a point or enter coordinates, the elevation will be labeled along with the surface name.

Surface inspector shows you real-time elevations as you move the cursor over your surface.

Prerequisite: Surface Model (s)

Keyboard Command: surfvals

Surface Report

This command reports a variety of information on each of your different surfaces. This is useful for checking for bad data and the file names of your surfaces. An example is below.

Surface Report

Max Cut: 18.327 at 409269.984,207196.674

Max Fill: 1.943 at 409389.586,207248.866

Prerequisites: A Surface

Keyboard Command: SURF_STATS

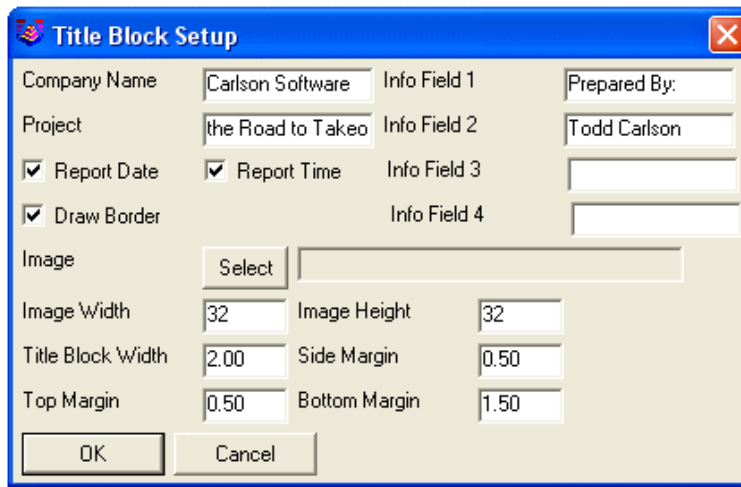

Graphic Reports

The Graphic Report commands can be used to create .PDF files for different Profiles, Cross Sections, 3D Surfaces, and of the Plan View. Adobe Reader or Pro is required for these routines to function.

The Plan Graphic Report command creates a plan view report of the site. Isolate the layers you want to show up in the report before you run this command. The routine will zoom extents to the limits of the layers you select and fit them to the Paper Size you select.

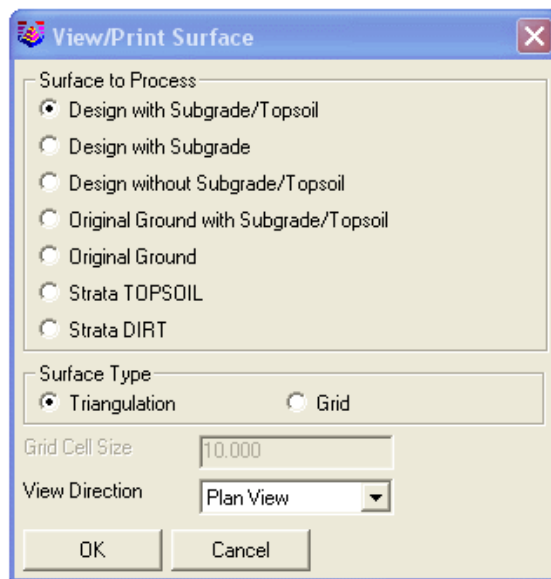

The Title Block Setup dialog draws a border and title block for the selected sheet size. Here you can enter in text you want to displayed in the report.

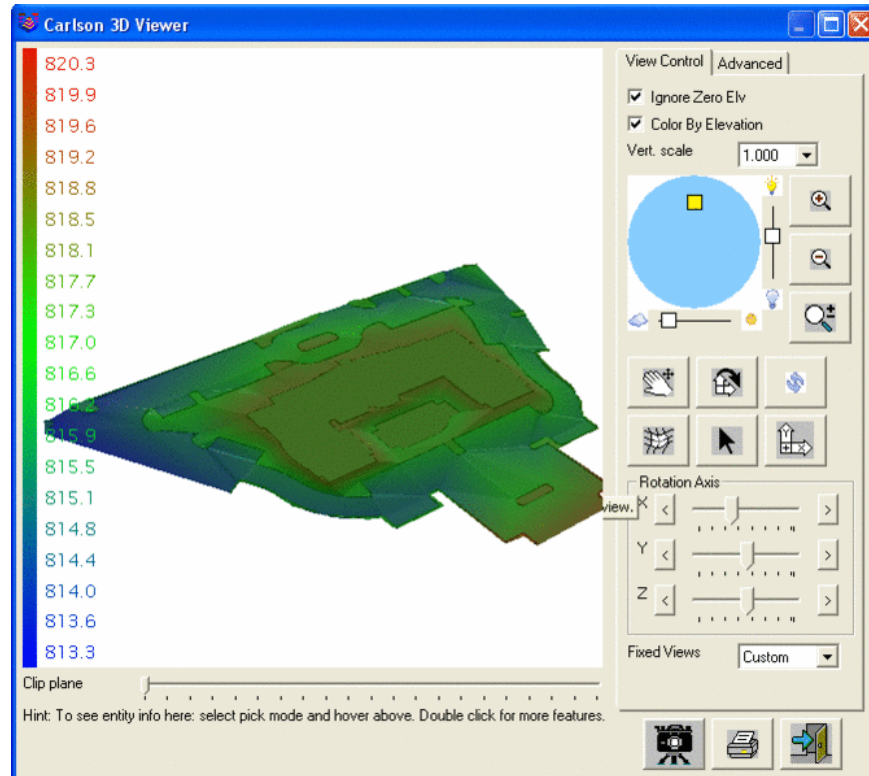

Here is an example of the Plan Graphic Report.

The Surface Graphic Report command creates a 3D view PDF report of any surface (.tin or .flt files) created in the drawing, including existing, design, and strata surfaces. In the first dialog, select the surface you wish to see in the report. This dialog also gives you the option to view the surface as a triangulation mesh or grid. View Direction determines the orientation of the surface in the next dialog.

The Carlson 3D Viewer gives you the ability to zoom in and out, pan, rotate around the X,Y,Z axis and shade the lighting. When you have orientated the model to your liking, click on the Printer icon in the lower right corner of the dialog.

Here is an example of the Surface Graphic Report.

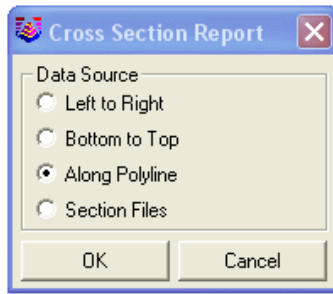

The Profile Graphic Report creates a 3D view profile of the site existing or design surface. You will first be prompted for how to create the Profile:

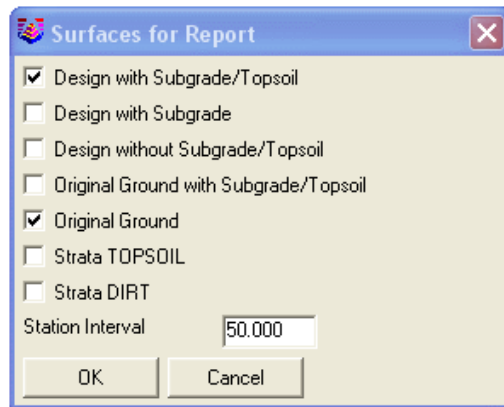

"Pick starting point (CL-Centerline,P-Polyline)". CL prompts you to load a previously created Centerline (.cl) file, P allows you to pick any polyline in the plan view, or you can pick two points on the screen that you want the program to create a profile through. Next, you will be prompted for Title Block settings similar in other Graphic Reports. Here is an example of the Profile Graphic Report.

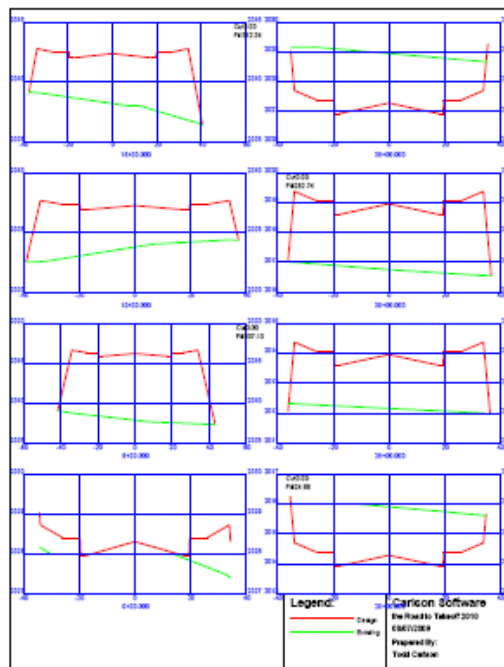

The Section Graphic Report creates cross section in a single step with option to include the plan view showing the section alignment. Cross Sections can be created within the routine from Left to Right, Bottom to Top, or along any polyline in the drawing. For more control over the orientation of the cross sections, Select Files allows you to select a previously created section file (.sct).

Like many other Graphic Reports, several of the surface models (.tin or .flt) created in the job can be used in the report. Simply select the surfaces you want to see in the report (there is no limit) and at what Station Interval (in feet) you want to see them. Note: this is not an opinion when using a .sct file.

Here is an example of the Section Graphic Report.

Pulldown Menu Location: Tools > Graphic Reports

Prerequisite: Existing and design surfaces

Keyboard Command: plotplan, plotsurf, tk_quickpro, plotsct

Quick Profile

This command allows you to create, view, edit, and report profiles from the Takeoff surfaces.

Pick starting point (CL-Centerline,P-Polyline): To make a profile you need to define the alignment by: 1) picking points on the screen; 2) typing in CL in the command prompt, and selecting a centerline file; or 3) typing in P and choosing a polyline from the screen. After doing so, the above profile viewer is created.

The far right dialog box allows you to toggle on and off different Surfaces to view in the profile viewer including: Original Ground, Topsoil Removal, Design Surface, Final Subgrade, Overex Surface, Strata Surfaces. If a surface is not defined in the current Takeoff project, like Topsoil Removal in this example, than you will not have the option to display it. In this example, the three Surfaces that can be displayed, Original Ground, Design Surface, and Final Subgrade, are displayed in the profile viewer.

When you move the cursor around the profile viewer a crosshair follows along the surface and reports the Station, Slope %, and Elevation at each point. It is displayed towards the bottom-right side of the screen next to Adjust Alignment. In this example the station is 2+16.650, the Slope is -5.6%, and the Elevation is 818.133. A crosshair can be seen in the profile drawing and along the alignment in the main drawing as well.

Vertical Exaggeration: x1 is the actual appearance of the surface(s). Depending on the flatness of the surface(s), you can select x2, x5, x10 vertical exaggerations to better see the elevation differentiation and different surfaces. The option Fit automatically exaggerates the vertical to best fit the profile viewer.

Drag Action: This dialog allows you to zoom in and out, and pan around the profile. To zoom in click and drag up, to zoom out click and drag down. To Pan, click and drag the direction you want to move.

The Adjust Alignment icon allows to pick the polyline or centerline that you used and move it to your liking. If you selected an endpoint vertex, you can pivot that vertex around 360 degrees and the profiles will update in real time. This is helpful when checking for spikes. If you select the middle vertex then you can shift the entire centerline around.

If you created a profile alignment by picking points and you want to save that polyline you created then toggle on Draw Plan View Polyline. If you do not choose Draw Plan View Polyline than the polyline will be lost when you exit out of the Quick Profile command. Grid Ticks Only marks elevations and distances but does not draw them into grids.

The Save icon allows you to save the profile as a (.pro) file by whatever name you give it. The Draw icon allows you to draw the profile right on your drawing. Set the layer name, vertical and horizontal scale as desired, pick a starting point to draw, and the profile is created. Note: the below example has a vertical scale of 5 feet per grid and a horizontal scale of 50 feet per grid.

Prompts

Pick starting point (CL-Centerline,P-Polyline): p

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>:

Loading edges...

Loaded 5057 points and 14923 edges

Created 9866 triangles

Prerequisite: a surface

Keyboard Command: TK_QUICKPRO, QUICKPRO

Cut/Fill Centroids

This command calculates all the areas of cut and fill between two triangulation surfaces. The center of mass or centroid for each area is calculated. The Minimum Region Volume is an optional filter that will skip reporting areas with volumes less than the specified amount. The Generate Labels option draws a symbol at the centroid and text for the region name and volume. The Generate Boundaries option draws closed polylines for the perimeters for each area. The Hatch Regions option is used to visually shows cut/fill areas in your drawing. Separate hatch patterns can be used for cut and fill areas.

The Use Inclusion/Exclusion Areas option will make the program prompt for polyline perimeters for the inclusion and exclusion areas on the site. For example, use an inclusion perimeter to calculate within an area of interest. When this option is off, the program uses the full extent of the surfaces.

A report is generated with the volumes and centroids for all the cut and fill areas. When the Report Optimized Earth Movement option is active, the report includes a list of the earthwork movements between cut and fill areas that minimizes the overall earthwork movement (volume * distance) where the distance is distance between the centroids.

Cut & Fill Centroids

Cut & Fill Centroid Report

Original Ground: G:\oem4\src2\work\demo1-ex.flt
Design Surface: G:\oem4\src2\work\demo1-fn.flt

Region	Volume(C.Y.)		Northing	Easting
1	3822.9	Cut	2190032.48	6135170.29
2	3053.7	Fill	2190117.40	6134982.48
3	1.8	Fill	2190334.67	6135199.41

Earth Movement Report:

From Region	To Region	Volume(C.Y.)	Distance
1	2	3053.7	206.12
1	3	1.8	303.59
1	External	767.4	
Total Internal Volume * Distance:			629972.20
Total External Volume:			767.44

Here is the Cut and Fill Centroid Report for the above example. It shows the volumes, the coordinates of the centroids, and the Earth Movement Report. The Earth Movement Report shows the minimal distances for moving Cut to Fill areas.

Prerequisite: Existing and Design surfaces

Keyboard Command: tk_cutfillc

Cut/Fill Map Legend

This command will draw a Cut/Fill Map Legend on your drawing. It will display the cut/fill amount, color, and range, as seen below.

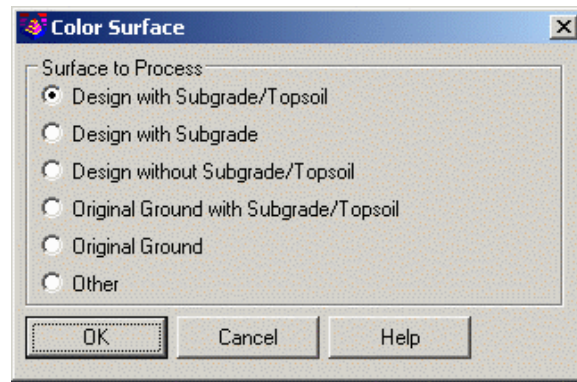

Prerequisite: Cut/Fill amounts

Keyboard Command: CF_MAP_LEGEND

Color Surface By Layer

This command sets the color of the triangles in a triangulation file for the areas within closed polylines using the layers and color assignments from Define Layer Surface/Material/Subgrade. The colored areas of the triangulation surface can then be viewed in commands like Surface 3D Viewer. For example, this command can set separate colors on the triangulation for pavement areas, building pads, ponds, etc.

The color assignments should be set before running this command by using Define Layer Surface/Material Subgrade. This command only prompts for which triangulation file to colorize. Then use a viewer command like Surface 3D Viewer to see the colored surface.

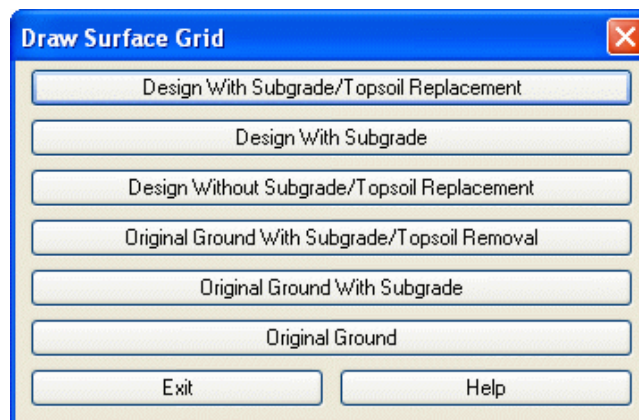

Pulldown Menu Location: Takeoff > Surface Tools

Prerequisite: A surface and colors set in Define Layer Surface/Material/Subgrade

Keyboard Command: color_tin

Draw Surface As Grid

This command writes a grid file (.grd) from an existing triangulation file (.flt or .tin) in the current drawing.

After selecting the triangulation file to convert, you are prompted for the X, Y grid interval and the Layer name.

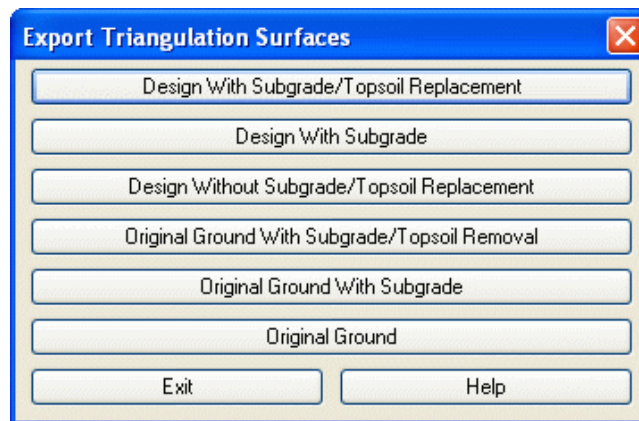

Prerequisite: an existing or design surface

Keyboard Command: draw_surface_grd

Import/Export Carlson Triangulation Files

Import Carlson Triangulation Files allows you to import an external surface file into Takeoff to use as a named surface. Export Carlson Triangulation Files allows you to take a Surface Triangulation file and save it independent of the drawing.

Prerequisite: .TIN or .FLT files

Keyboard Command: import_tin, export_tin

Make User Defined Surface

This command makes a surface from the entities on the layers defined as user-defined targets in the Define Layer Target/Material/Subgrade command. The purpose of user-defined surfaces is for modeling surfaces besides existing ground and design. The drawing needs to contain entities that represent the elevations of the user-defined surface. For example, the user-defined surface could be for alluvial soil and the drawing has contour polylines for this surface.

There is a dialog to select which surface to make. The surface is stored in a triangulation file that is named after the current drawing name with the user-defined surface name appended.

This user-defined surface can be applied to Takeoff routines by running the Set Active Surfaces command.

Pulldown Menu Location: Takeoff > Surface Tools
Prerequisite: Define Layer Target/Material/Subgrade command
Keyboard Command: mk_user_tin

Volumes By Triangulation

Volumes By Triangulation is an alternative volume method that compares two triangulation networks. This method is different from the grid based volume routines (*Stockpile Volumes, etc.*) and the cross section volume routine (*Calculate Section Volume*). Volumes by Triangulation calculates faster in most cases than the other methods, and it is the most accurate because it uses true TIN to TIN prismatic volumes. This added accuracy in general is very small. The grid resolution is usually sufficient to model the surface for the grid based volumes. The Volume By Triangulation accuracy applies well when there is a feature like a 5 foot wide ditch. Then the grid resolution would need to be less than 5 foot to model the ditch which might be difficult on a large site.

The disadvantage to this routine is that it lacks the output options that help the analysis of the volume such as Difference Contours. Also Volumes by Triangulation does no extrapolation and stops calculating volume at the perimeter of the smaller of the two triangulation networks. Volumes By Triangulation is better when used with point data instead of contour data because contour data requires triangulating all the contour polylines as breaklines which creates a large triangulation network and is slower.

The triangulation networks to compare are defined in .flt files that are created by *Triangulate & Contour* with the Write Triangulation File option. Before using this command, run *Triangulate & Contour* twice to create an triangulation (.TIN) file for each surface. The volume calculation is limited by either the extent of the triangulation networks or by an inclusion/exclusion perimeter(s). These perimeters must be closed polylines.

Output data includes area, tons by density, average thickness, shrink and swell, ratio, and total volume.

Prompts

Select EXISTING surface Tmesh File Choose a .tin file
Select FINAL surface Tmesh File Choose another .tin file
Pick inclusion perimeter polyline (ENTER for none): *pick a closed polyline perimeter*
Calculating ...
Write report to file (Yes/<No>)? *Press Enter*
Write report to printer (Yes/<No>)? *Press Enter*
Comparing Triangulation files: C:\SCADXML\DATA\TRI1.FLT
and C:\SCADXML\DATA\TRI2.FLT
Cut volume: 66891.35 C.F., 2477.46 C.Y.
Fill volume: 43458.01 C.F., 1609.56 C.Y.

Pull-Down Menu Location: Tools-> Surface Tools
Prerequisite: Two .tin files.
Keyboard Command: trivol

Calculate Stockpile Volume

This command is a customized and simplified method for calculating volumes in a situation in which the entire volume to be calculated is above the perimeter elevation, such as in the case of a stockpile of material. The complimentary command, *Calculate Pond/Pit Volume*, is for the opposite situation, in which the entire volume to be calculated is below the elevation of the perimeter.

The program internally computes base and final grid surfaces from drawing geometry. The base surface is calculated from a 3D polyline representing the perimeter of the area being analyzed. If that 3D polyline is drawn on the PERIMETER layer, the command will automatically detect and use it. If no 3D polyline is found on that layer, you have an opportunity to manually select another 3D polyline to use. The 3D polyline perimeter can be drawn with

the Draw 3D Polyline Perimeter command before using this routine.

The 3D polyline perimeter is also used as the inclusion perimeter for the volume calculation.

Additional 3D polylines can also be specified to more precisely define the base surface. These must be on the BASE_BREAKLINE layer to be used for this purpose. These can be generated by the *Draw 3DPoly Base Breakline* routine.

The final surface is calculated from all of the other selected drawing entities such as points, line, inserts, and polylines, along with the perimeter polyline, but not including the BASE_BREAKLINE polylines.

You have the option of setting the resolution of the grids.

Prompts

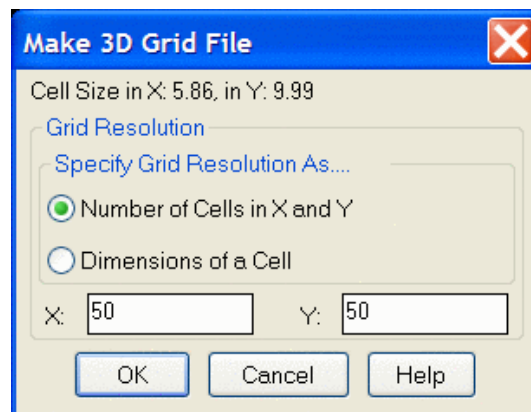

Material density lbs/ft³ (Enter for none): *enter a material density in lbs per cubic foot, or press Enter for none*

Ignore Zero Elevations [<Yes>/No**]:**

Select stockpile entities and perimeter.

Select objects: *pick the objects that define the stockpile and the 3D polyline perimeter*

Select stockpile perimeter polyline:

Make Grid File dialog Set the resolution and then click OK.

Sample volume report

Volume report

Lower left grid corner: 15965.45,12657.05

Upper right grid corner: 16269.40,12906.29

X grid resolution: 50, Y grid resolution: 50

X grid cell size: 6.08, Y grid cell size: 4.98

Stockpile volume: 1191674.87825 cubic ft, 44136.107 cubic yards

Stockpile defined by points and a 3D polyline perimeter
Window these objects to obtain the volume report

Keyboard Command: stockvol

Prerequisite: Data representing the stockpile surface and a 3D polyline representing the perimeter of the stockpile.

Calculate Pond/Pit Volume

This command is a customized and simplified method for calculating volumes in a situation in which the entire volume to be calculated is below the perimeter elevation, such as in the case of a pond or pit. The complimentary command, *Calculate Stockpile Volume*, is for the opposite situation, in which the entire volume to be calculated is above the elevation of the perimeter.

The program internally computes base and final grid surfaces from drawing geometry. The base surface is calculated from a 3D polyline representing the perimeter of the area being analyzed. If that 3D polyline is drawn on the PERIMETER layer, the command will automatically detect and use it. If no 3D polyline is found on that layer, you have an opportunity to manually select another 3D polyline to use. The 3D polyline perimeter can be drawn with the Draw 3D Polyline Perimeter command before using this routine.

The 3D polyline perimeter is also used as the inclusion perimeter for the volume calculation.

Additional 3D polylines can also be specified to more precisely define the base surface. These must be on the BASE_BREAKLINE layer to be used for this purpose. These can be generated by the *Draw 3DPoly Base Breakline* routine.

The final surface is calculated from all of the other selected drawing entities such as points, line, inserts, and polylines, along with the perimeter polyline, but not including the BASE_BREAKLINE polylines.

You have the option of setting the resolution of the grids.

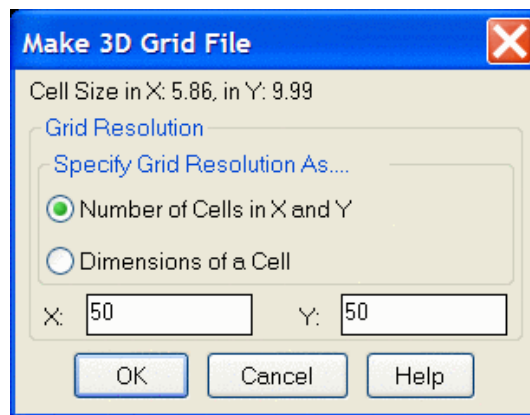

Prompts

Ignore Zero Elevations [<Yes>/No]?

Select Pond/Pit entities and perimeter.

Select objects: *pick the objects that define the surface and the 3D polyline perimeter*

Select Pond/Pit perimeter polyline:

Make Grid File dialog Set the resolution and then click OK.

Keyboard Command: pitvol

Prerequisite: Data representing the pond/pit surface and a 3D polyline representing the perimeter of the pond/pit.

Set Active Surfaces

This command assigns which surfaces to use for initial and final. These surfaces are used by all the Takeoff routine that compare surfaces including:

- Calculate Total Volumes
- Calculate Volumes Inside Perimeter
- 3D Drive Simulation
- Cut/Fill Contours/Labels/Color Map
- Surface Inspector
- Quick Profile
- etc.

The surface created by the Make Existing Ground Surface command is called "Existing" and is the default for the Initial Surface. The surface created by the Make Design Surface command is called "Design" and is the default for the Final Surface.

The purpose of this routine is for selecting user-defined surfaces to use in place of the existing ground or the design surface. For example, there could be a user-defined surface for alluvial soil that is set as the initial surface while design is set to the final surface. Then the calculate volume routines will report the quantities between alluvial soil and design. Also the Display->Cut/Fill Color Map routine will make the map for the difference between the alluvial soil and design surfaces.

These user-defined surfaces can be created using the Add Target function in the Define Layer Target/Material/Subgrade command combined with the Make User-Defined Surface command.

Prerequisite: a surface model

Keyboard Command: set_active_tins

Design Surface Vertical Offset

This command can be used to lower or raise the design surface within a defined perimeter or by the entire surface.

Prerequisite: a design surface

Keyboard Command: adjust_final

Existing Surface Vertical Offset

This command can be used to lower or raise the existing surface within a defined perimeter or by the entire surface.

Prerequisite: an existing surface

Keyboard Command: adjust_exist

Merge Existing With Design

This command allows you to merge the existing surface with design surface within perimeter polylines. The resulting merged surface can be saved to update either the Existing or Design surfaces. The program prompts for inclusion and exclusion perimeter polylines. These polylines must be closed. The merge will be applied inside the inclusion perimeters and not inside the exclusion perimeters. The exclusion perimeters are optional.

For example, if a portion of the site is completed, you can update the existing surface to match the design for the completed area. First, draw a closed polyline around the completed area. Then run Merge Existing With Design and choose the merge results target as Existing. Then select the perimeter polyline.

Pulldown Menu Location: Takeoff > Surface Tools

Prerequisite: existing and design surfaces and an inclusion perimeter polyline

Keyboard Command: merge_final

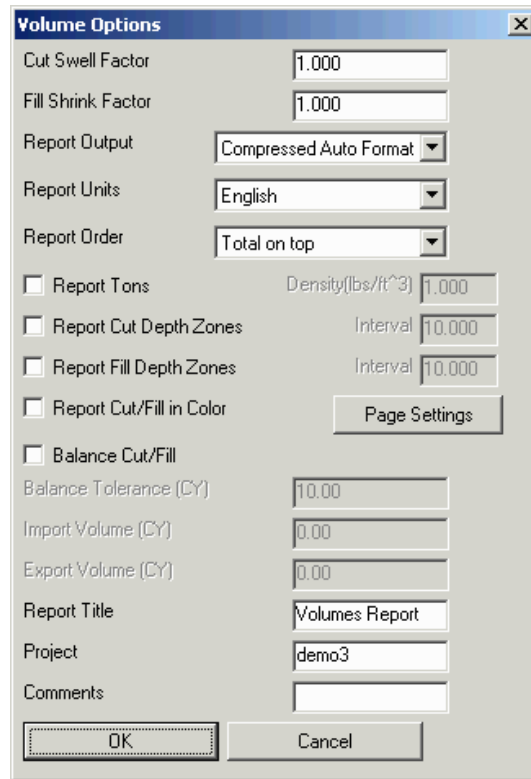

Calculate Total Volumes

Use this command to report total volume calculations within the site boundary polyline. The report includes the cut and fill quantities, slope and horizontal area, average and max strata cut depth and max cut/fill depths and locations. Also in the report, strata and topsoil quantities if the site has strata and topsoil defined. Besides reporting the total quantities for the site boundary, Area Of Interest polylines can be used to report quantities within named perimeters.

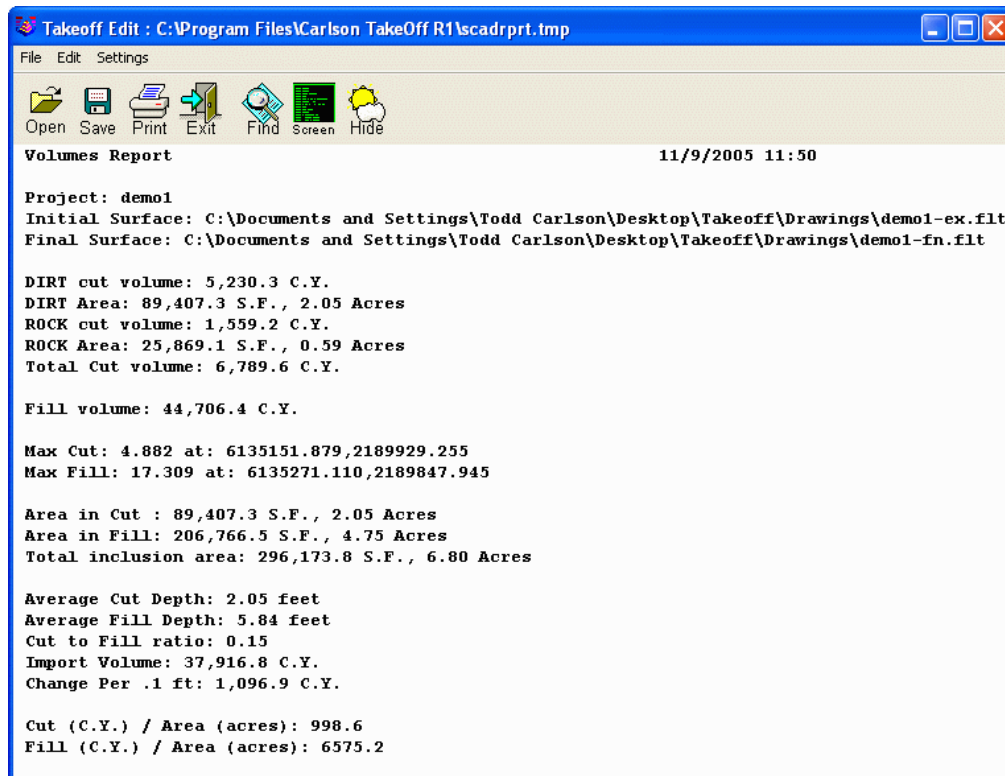

Before running this command, the existing and design surfaces must be created and the boundary polyline must be assigned. Also, the strata surfaces, topsoil and Area Of Interest polylines need to be set before this command if those features are to be reported.

The Volume Options dialog box shown here offers options for the final report. Here you can select four different types of reports: Standard Report Viewer, Custom Report Formatter, Expanded Auto Format, and Compressed Auto Format. The Cut Swell Factor is multiplied by the cut volume and the Fill Shrink Factor is multiplied by the fill volume. Report Cut/Fill Depth Zones breaks the Cut/Fill volumes up by user-defined depth intervals. The Report Units setting chooses between English and Metric quantities for the report. In Drawing Setup in Takeoff, you set the drawing units as either English or Metric. The Report Units will default to match the drawing units but you can change the Report Units to the other mode and the program will apply the conversion between English and Metric for the report. So you can have a drawing in English units and create a report with Metric quantities.

Note: As the quantities are calculated within each area, the area is hatched with a solid fill as a visual verification that the right area is being processed.

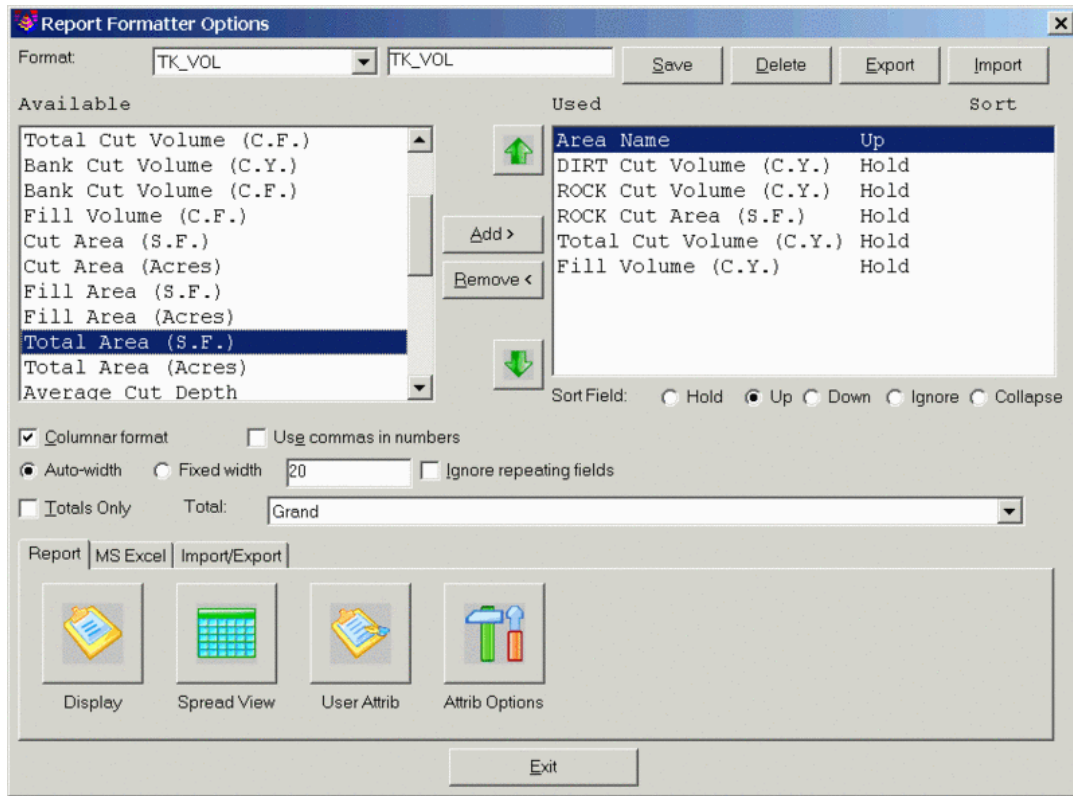

Shown here is an example of a Standard Report Viewer.

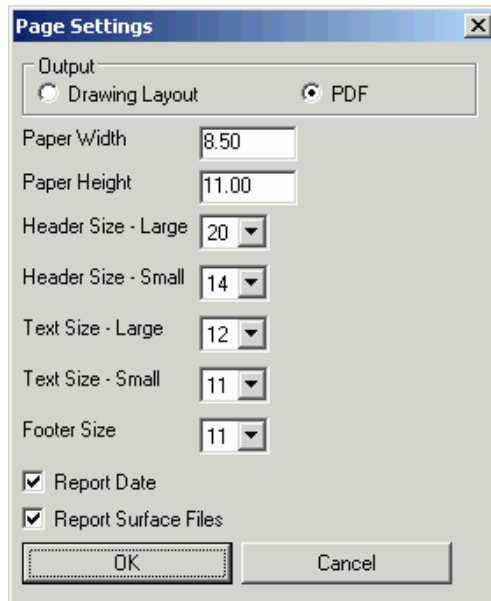

Use Customs Report Formatter to customize or "user define" the reporting options. The Report Formatter Options

dialog box shown here offers a variety of output options including Excel. You can choose the fields to report from the Available list and set their report order under the Used list.

For the Compress and the Expanded Auto Formats, the Report Cut/Fill in Color option will color the cut values in red and the fill values in blue in the report. Also, the Page Settings button has more controls for these auto formats including whether to output the report to PDF or to a drawing layout.

The Expanded Auto Format is shown below.

Volumes Report

Project: Takeoffdemo2

Date: 03/24/2008 09:59

Initial Surface: C:\Carlson Projects\Takeoffdemo2-ex.tin

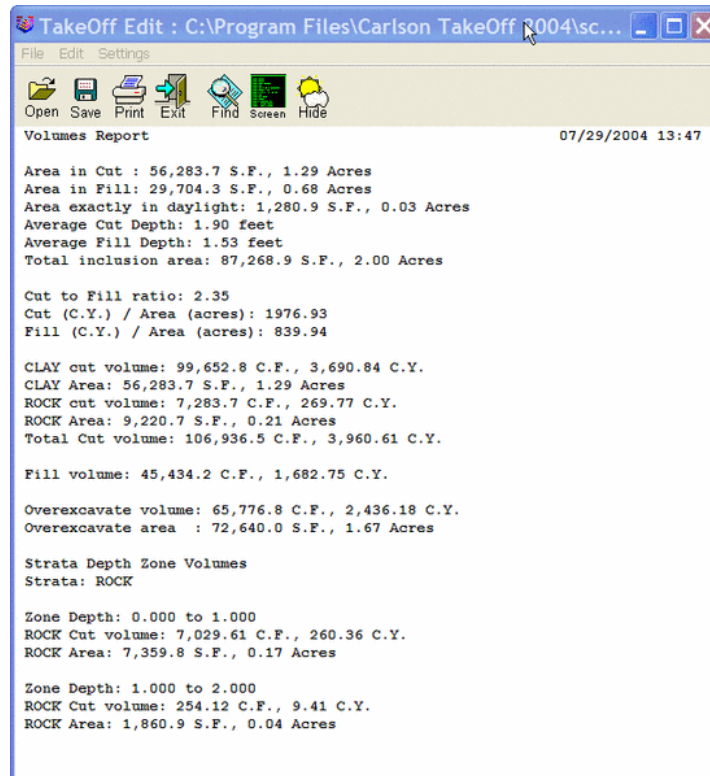

Final Surface: C:\Carlson Projects\Takeoffdemo2-fn.tin

	Bank Volume (CY)	Swell/ Shrink	Adjusted Volume (CY)	Area (SqFt)	Average Depth	Change Per .1 FT	Import Volume (CY)
Cut	5451.7	1.000	5451.7	51661.6	2.85	403.6	
Fill	5839.4	1.000	5839.4	57304.2	2.75	403.6	387.7

If drillholes have been located on the drawing and strata types and depths have been defined, a calculate Strata Depth Zones Volume option becomes available. Here strata volumes are broken down by user-specified depth intervals. The depths are either determined horizontally (By Level) or by the area of the deepest cut (By Zone Area).

Shown here is an example of the report if strata depth intervals have been defined.

The Balance Cut/Fill option vertically raises or lowers the design surface to balance the cut and fill. The report states how much the design surface was adjusted for the balance. When the drawing has grade entities, these entities can be adjusted for the balance. For example, pad polylines created by the Elevate Pads By Grade Rules can be raised or lowered for the balance. After the volumes report, the program asks whether to save the changes for the balance. This will update the grade entities and the design surface files for Design Surface After Zones/Topsoil (-sg) and Design Surface After Subgrade Zones (-zn).

With the balance routine, you can set import or export volumes. Use these options if extra material is available or needed elsewhere.

Pulldown Menu Location: Takeoff

Prerequisite: Existing and design surfaces and a boundary polyline

Keyboard Command: tin_volume

Calculate Volumes Inside Perimeter

Use this command to create volume reports inside the selected closed perimeter polyline. The same reporting options are available for this command as are for the Calculate Total Volumes command.

Keyboard Command: tin_volume2

Prerequisite: Existing and Design surfaces and a closed perimeter polyline

Draw 3DPoly Perimeter

This command draws a 3D polyline in the PERIMETER layer. This polyline is required by the *Calculate Stockpile Volume* and *Calculate Pond/Pit Volume* routines. In these routines, this polyline is used as the inclusion perimeter

for volumes. You may want to set your AutoCAD Object Snap prior to running this routine so that you obtain the elevations of existing points while creating the 3D polyline.

Prompts

Select the 3Dpolyline options you want and press enter.

Command: 3dperim

Pull-Down Menu Location: Tools->Surface Tools

Prerequisite: None

Keyboard Command: 3dbase

Design Surface 3D Viewer

This command allows you to view the design surface in 3D mode.

In the top right of the control bar you can check to Ignore Zero Elev and Color By Elevation and change the Vertical Scale. If you increase the Vertical Scale than elevation differences can be seen easier. Ignore Zero Elev does not display elevations of zero in the 3D viewer. Color By Elevation shows elevation change with the change of colors. Note: Color By Elevation is used in the above example. To adjust the color use the color circle on the right.

The magnify glass icons can be used to zoom in and out. Click on the plus magnify glass to zoom in and

the minus magnify glass to zoom out. With the  icon click and drag up to zoom in and drag down to zoom out. The hand icon below the color circle allows you to pan around the viewer. Click and drag the direction you

want to move. The  icon can be used to rotate the vantage point of the viewer by the x, y, or z axis. When you move the cursor to the screen it will change into a x, y symbol or a z symbol. Move the cursor around to move it from one to the other. If you have the x, y cursor move right or left to change the x axis view, or to change the y move the cursor up or down. If you have the z cursor than move it in a circular fashion to rotate the view point

according to the z axis. The  icon toggles on and off the shading of the surface (the shading is shown in the above drawing). The arrow icon reports the elevations at the bottom of the screen as you move around the surface.

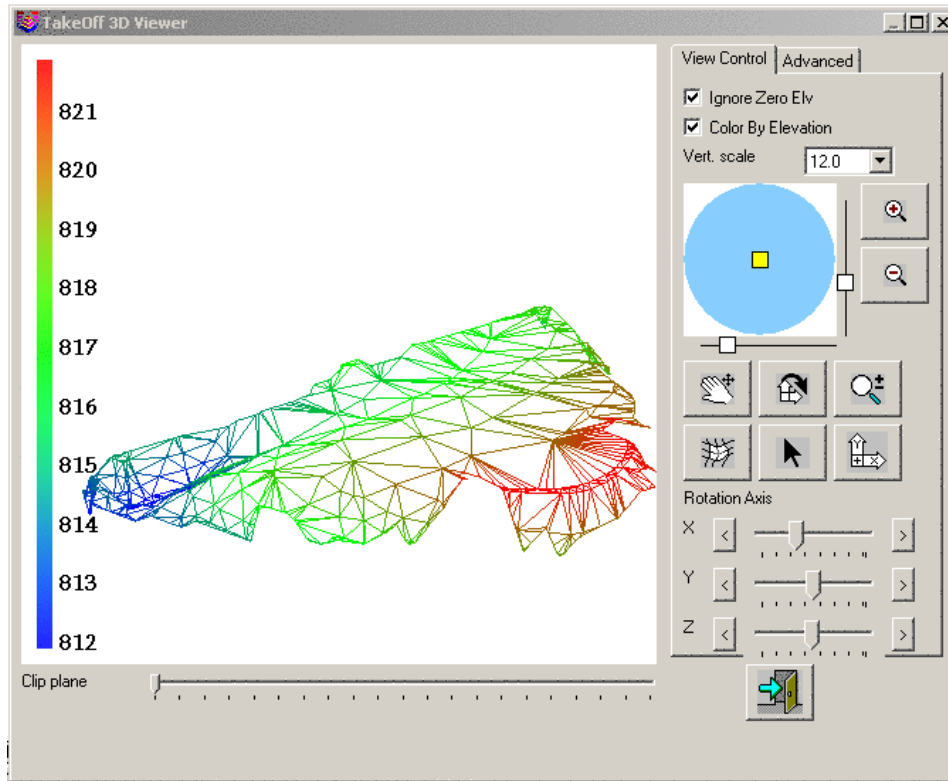

The  icon restores the surface viewpoint to flat. The  icon exits 3D Driver Simulation.

Rotation Axis: These three control bars rotate the surface around the x, y, and z axis. Clip plane trims the size of the surface shown in the viewer.

Prerequisite: a design surface
Keyboard Command: cube_design

Existing Surface 3D Viewer

This command allows you to view the existing surface in 3D mode.

In the top right of the control bar you can check to Ignore Zero Elev and Color By Elevation and change the Vertical Scale. If you increase the Vertical Scale than elevation differences can be seen easier. Ignore Zero Elev does not display elevations of zero in the 3D viewer. Color By Elevation shows elevation change with the change of colors. Note: Color By Elevation is used in the above example. To adjust the color use the color circle on the right.

The magnify glass icons can be used to zoom in and out. Click on the plus magnify glass to zoom in and

the minus magnify glass to zoom out. With the  icon click and drag up to zoom in and drag down to zoom out. The hand icon below the color circle allows you to pan around the viewer. Click and drag the direction you want

to move. The  icon can be used to rotate the vantage point of the viewer by the x, y, or z axis. When you move the cursor to the screen it will change into a x, y symbol or a z symbol. Move the cursor around to move it from one to the other. If you have the x, y cursor move right or left to change the x axis view, or to change the y move the cursor up or down. If you have the z cursor than move it in a circular fashion to rotate the view point according

to the z axis. The  icon toggles on and off the shading of the surface. The arrow icon reports the elevations

at the bottom of the screen as you move around the surface. The  icon restores the surface viewpoint to flat.

The  icon exits 3D Driver Simulation.

Rotation Axis: These three control bars rotate the surface around the x, y, and z axis. Clip plane trims the size of the surface shown in the viewer.

Prerequisite: an existing surface

Keyboard Command: cube_exist

Import MicroStation DGN

This command takes a MicroStation DGN file and imports the MicroStation elements into your current DWG drawing. After selecting the DGN file you want to import, you will receive a conversion report like the one below:

```
Element
Type Name Encountered Converted
3 Line3d 273 273
4 LineString3d 48 48
6 Shape3d 1 1
12 ComplexString 321 321
17 Text3d 131 131
-1 Model 1 1
775 total 775 converted elements in 1 seconds.
```

After the command has imported the DGN file, run View > Zoom > Extents to see the converted entities.

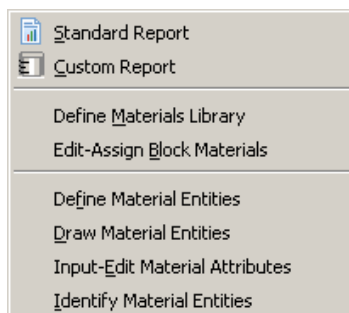

Pulldown Menu Location: Tools > Import/Export

Prerequisite: a MicroStation DGN file

Keyboard Command: dgn_in

Material Quantities

The Material Quantities flyout shown here offers many options for quantity reporting including standard and custom report options. User-defined attributes can also be drawn, edited, and identified from the different command options.

Material Quantities draws heavily from the command Define Layer Target/Material/Subgrade found in the Takeoff and SiteNET pull-down menus. Material Quantities are calculated from the entities in the drawing. Several entity properties can be reported including entity count, length, area, and volume. The type of material for each entity is determined by the layer for the entity. Use Define Layer Target/Material/Subgrade, to assign the material types by layer before running the Material Quantities Standard or Custom Report.

Standard Report

Use this command to display all or a selected set of material quantities in present in the drawing. Quantities can be limited by the established boundary polyline(s) or can look outside your boundary area for materials that might be outside of your Cut/Fill limits.

The command will then report out the materials found in the drawing based off of settings made in Define Layer Target/Material/Subgrade. This text report can be edited, printed, or put onto the screen.

Road Agg	\$14.00/Ton	140.00
Sand	\$8.00/Ton	120.00

Prerequisite: Defined materials

Keyboard Command: materials_report2

Custom Report

Use this command to customize or "user define" the reporting options. This command first prompts whether to report quantities for all the entities in the drawing or selected entities. Then if the drawing contains Areas Of Interest polylines, there is an option report quantities by these areas which adds the area name to the available report fields to allow sorting and grouping by area name. The Report Formatter Options dialog box shown here offers a variety of output options. You can choose the fields to report from the Available list and put them in report order under the Used list.

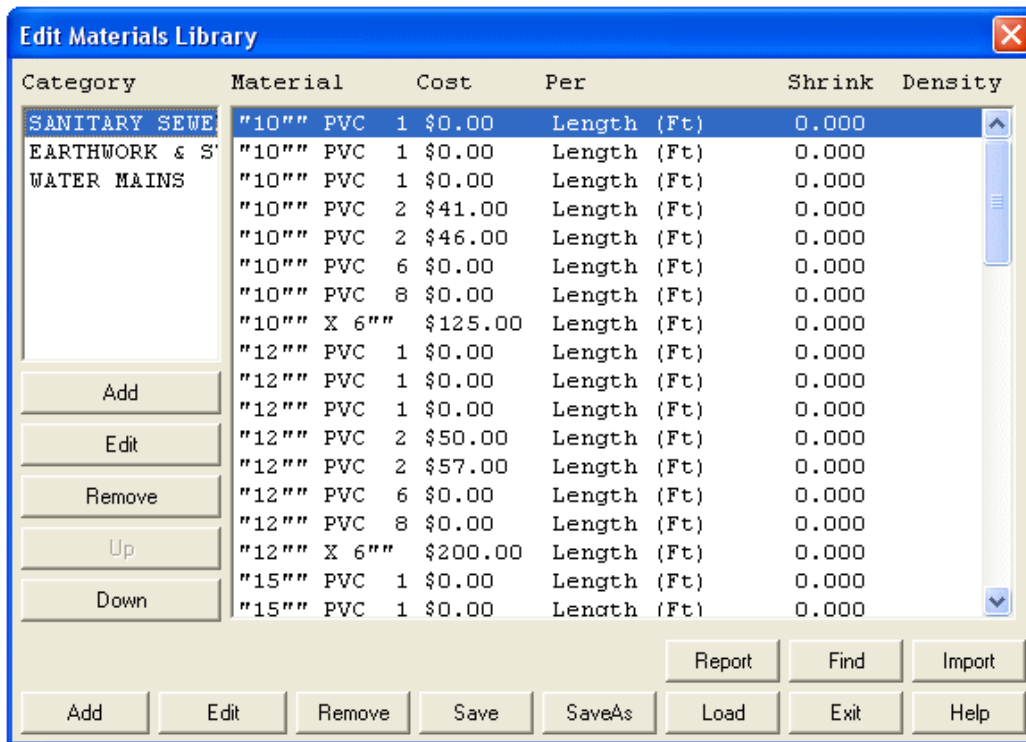

Selecting the Display option shows the report in the standard Carlson Takeoff report viewer. Reports can be exported to an Excel spreadsheet as well.

Prerequisite: Defined materials

Keyboard Command: materials_report

Define Materials Library

Define Materials Library allows you to Add, Remove, Load, Save, and Report a list of material costs. Costs can be set per area, count, volume, ton, or length by using the Edit function at the bottom of the dialog. The left side of the dialog can be used to set categories for different material costs. Material costs can also be Imported from user-specified text files (.txt, .dat, or .csv). Once this library is defined, the items can be used in Define Layer Target/Material/Subgrade and reported out with the Material Quantities standard and custom reports.

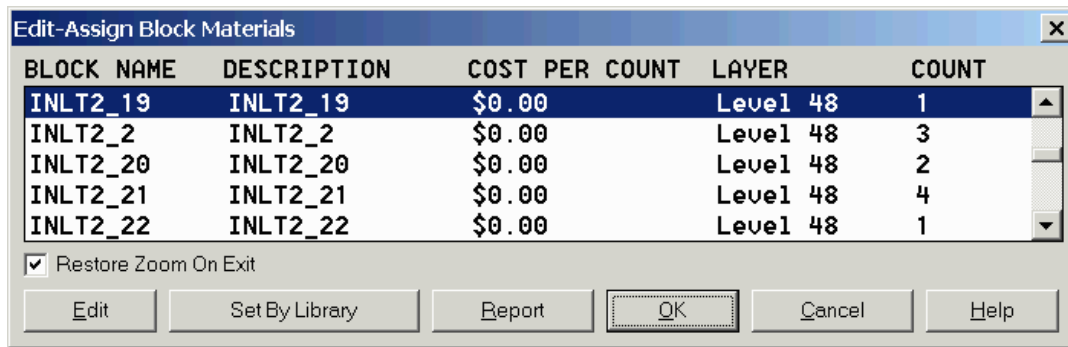

Prerequisite: pricing for materials

Keyboard Command: define_tk_materials

Block Materials Editor

This command scans the current drawing to find and report block/symbol names and their count. For example, when the drawing contains different symbols for different types of utilities, this command identifies each type of symbol and the number.

From this command, you can set the Description and Cost of the block by using the Edit button. You can also set the Description and Cost by predefined Materials by using the Set By Library button. When a block name is highlighted from the list, the drawing is zoomed to the location of one of those blocks so that you can see what it looks like. To Report these materials as part of the Standard Report, check on Include Materials Quantities Report in the Edit Materials dialog of the block layer found in the Define Layer Target/Material/Subgrade command. You can also just click on the Report button for a simple report.

Prerequisite: Blocks

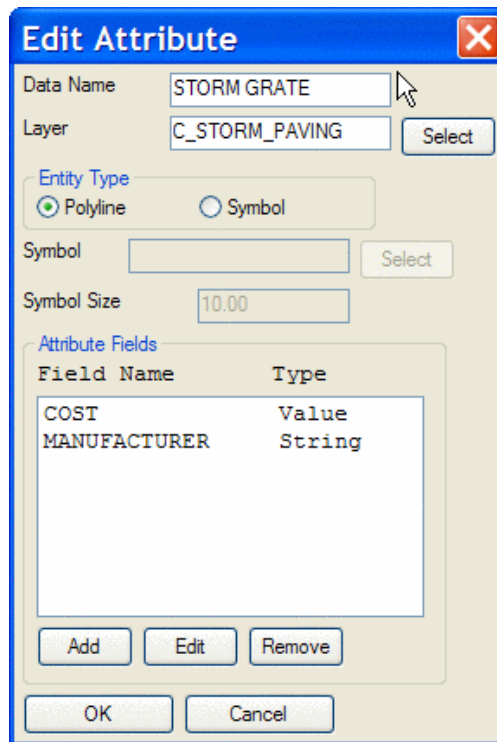

Keyboard Command: edit_all_blocks

Define Material Attributes

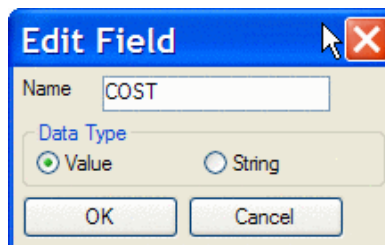

Use this command to create user-defined attributes that can be assigned to objects in the drawing. Once attributes have been defined, use Material Entities Editor to add the attributes to existing linework or Draw Material Entities to create new linework. For reporting, the material attributes defined in this command will be shown as Available items in the Material Quantities Custom Report command.

The Define Attribute dialog box shown here allows the user to "Add", "Edit", or "Remove" attributes and save the definitions for later use. Simply "Load" a saved attribute definition file with the "tkd" extension for future use.

Selecting the Add or Edit options produce the edit attribute dialog box shown here. Use this command to define the Data name and the layer the objects currently reside on and the layer that future objects will be drawn on. Two entity types can be used, polyline data or point data. If the symbol option is selected the user has the option of which symbol will represent the object. Attribute fields must be defined for material reporting.

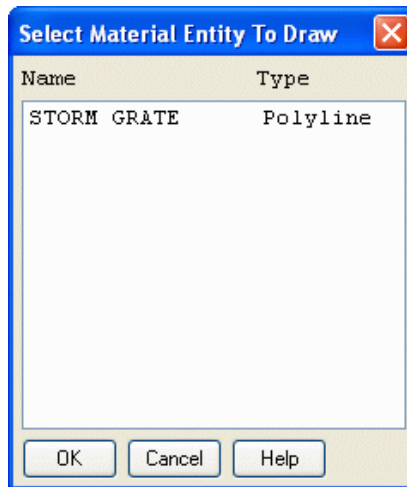

Selecting the Add or Edit button on the Edit Attribute dialog box brings up the Edit Field dialog box shown here. Use this dialog to define the field name and type. If the Value option is selected, only numeric values will be allowed when prompted. If the String option is selected, the user will have the ability to type in a text message when prompted.

Prerequisite: attributes

Keyboard Command: define_tk_data

Draw Materials Entities

Use this command to apply attribute data to objects as you draw or digitize them. Select the predefined attribute type to draw from the list available in the Select Attribute to Draw dialog box shown here.

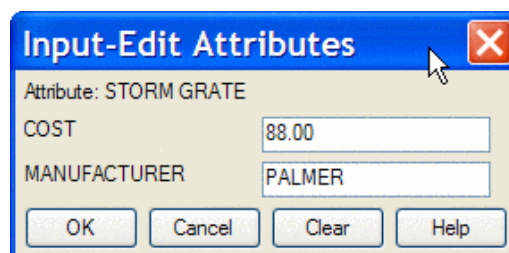

The command line will prompt the user to pick the points of the desired location of the object and allow the attribute data fields to be filled out upon completion or each "enter".

Prerequisite: defined attributes

Keyboard Command: draw_tk_data

Material Attributes Editor

Use this command to assign predefined attribute information to an object already existing in the drawing. The command line prompt will require the user to select the object that attribute information is to be applied, and offer the Attribute dialog box shown here. This dialog box will display all predefined fields for that particular attribute type.

Prerequisite: predefined attribute information

Keyboard Command: edit_tk_data

Identify Materials Entities

Use this command to display all the objects that have attribute data assignments. The user will have the options of selecting the objects by picking them individually or by searching the entire drawing database. The objects that have attribute information assignments will "highlight" on the screen and the command line will display the attribute information.

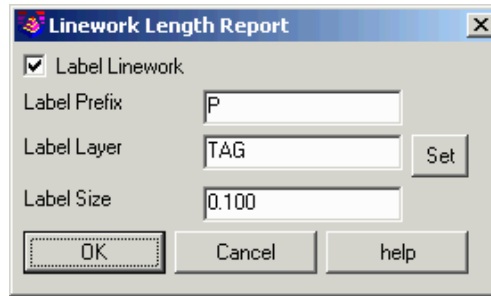

Prerequisite: attributes

Keyboard Command: id_tk_data

Linework Length Report

This command reports the length and properties of selected linework. When the layer for the linework is defined with a linear cost in the Define Layer Surface/Material Subgrade command, then the report will report costs. The Material name for the report also is defined in Define Layer Surface/Material Subgrade.

This command has an option to draw labels next to the linework. The dialog has settings for the label layer, prefix and size.

Length Report

Tag	Material	Length	Cost	Layer
P1	Edge	235.1	\$775.79	PRLCST
P2	Building Base	920.3	\$2300.63	PAD
P3	Parking Curb	1273.0	\$2864.20	PR-FC-CURB
P4	Parking Curb	1817.6	\$4089.61	PR-FC-CURB
P5	Parking Curb	84.7	\$190.59	PR-FC-CURB
P6	Parking Curb	107.6	\$242.00	PR-FC-CURB
Total		4438.2	\$10462.81	

Pulldown Menu Location: Takeoff > Material Quantities

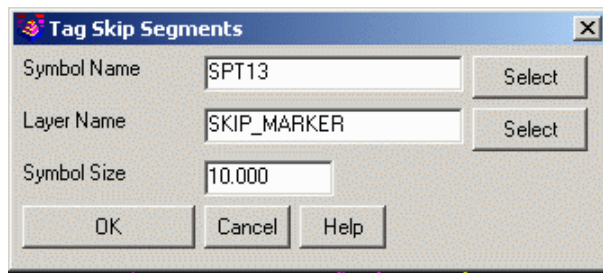

Keyboard Command: length_report

Prerequisite: linework

Tag Segments To Skip Linear

This command tags segments of polylines to skip for material linear quantities. This command applies to materials that are both used for volume/area and linear quantities. In this case, the polyline needs to be closed for the volume/area quantities but when there is a portion of the polyline to exclude from the linear quantities, then this command can be used. For example, curb quantities can use a closed polyline for reporting the pavement volume/area and the length of the polyline for reporting the length of curbing. When there is an entrance for pavement area, there is a gap in the curb but the closed polyline goes across any gaps. So the segments across gaps can be tagged to exclude for the linear curb length report.

The program draws a symbol on these segments to skip. The program prompts for the symbol name, layer and size to use for the tags. Then the Material Quantities report commands will automatically pick up these tags.

Two segments tagged to exclude from linear quantities for curb polyline at entrances to parking area

Prompts

Tag Skip Segments

Pick segment to skip: *pick a point on the polyline*

Pick segment to skip (Enter to end): *press Enter*

Pulldown Menu Location: Takeoff > Material Quantities

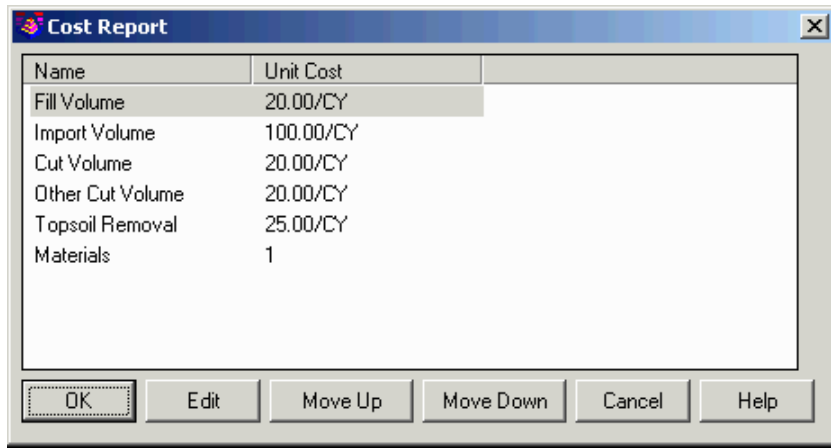

Prerequisite: a closed polyline

Keyboard Command: tag_skips

Cost Summary Report

This command reports the combined costs from the quantities from the Calculate Total Volumes and Material Quantities routines. For the volume quantities, there are separate costs for the different types of volumes. For the material quantities, the report just has the total material cost. For detail material costs, use the Material Quantities routines.

In the dialog, use the Edit button to set the unit cost and the report name. Use the Move Up and Down functions to change the report order. After picking OK, the report data is shown in the Report Formatter for setting the report style and output method such as Excel.

Cost Summary

Name	Cost	Amount	Rate
Fill Volume	\$88,173.85	4,408.7	\$20.00/CY
Import Volume	\$103,218.02	1,032.2	\$100.00/CY
Cut Volume	\$67,530.25	3,376.5	\$20.00/CY
Other Cut Volume	\$141,351.69	7,067.6	\$20.00/CY
Topsoil Removal	\$106,025.27	4,241.0	\$25.00/CY
Materials	\$70,144.21		
Total	\$576,443.29		

Pulldown Menu Location: Takeoff

Keyboard Command: tk_cost

Prerequisite: Calculate Total Volumes or Material Quantities

Make Layout

This command creates a layout with a title block and optionally creates a model view. In the dialog, choose the **Printer/Plotter** and **Paper Size** that the program will use to set the print area on the layout.

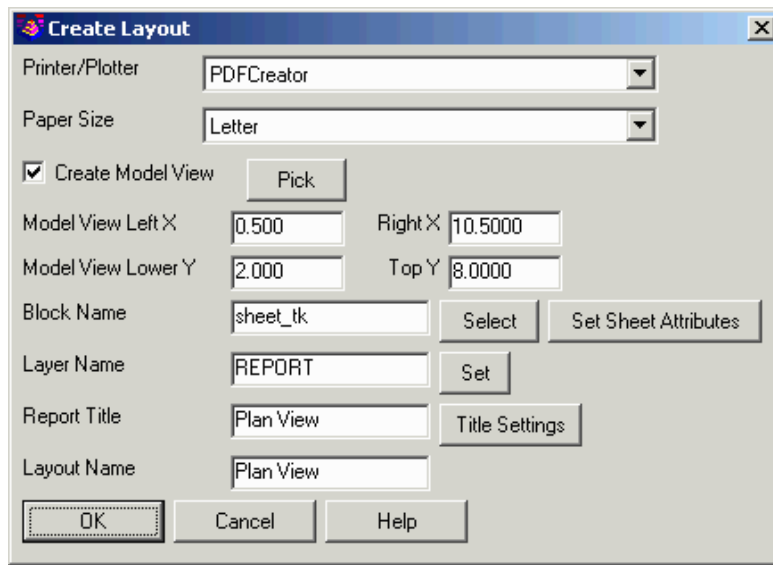

The **Create Model View** option makes a viewport on the layout. The Model View X/Y settings are in paper units and define the borders of the model view window. For the model view, the program will automatically size the drawing to fit in the viewport by using the boundary polyline from the Set Boundary Polyline command.

The **Block Name** sets the title block to use. You can use a custom drawing that has your company logo and title block. The **Set Sheet Attributes** defines how to fill out any block attributes defined in the block drawing.

The **Layer Name** is used for the layer of the block and report title label in the layout.

The **Report Title** is the label to draw in the layout at the position defined under Title Settings.

The **Layout Name** is the name for the new layout to create.

Pulldown Menu Location: Takeoff > Graphic Reports

Keyboard Command: make_layout

Prerequisite: None

Place Image On Layout

This command inserts an image in the drawing to fit within a view window. The image is cropped to fit the window. This command is a way to handle an image with a different aspect ratio than the window area for a report. The image is sized to fill the whole window area. For example, you can use the screen shot function in the 3D Viewer Window to make an image of your surface model and then use this command to fit this image onto a report.

After selecting the image file, the program prompts to pick the corners of the window for the image in the drawing. Then the dialog shows the image and four white boxes for the corner points for cropping. Click and drag the corner points to move and resize these corner points. When you click in the middle, all the corners move together. When you click near a corner that corner point can be moved in or out to resize.

The program creates a new image file for the adjusted image. This file is named after the original file name with ".fit" added. The original image file is not changed.

Prompts

Select Image File

Pick 1st corner for image: *pick a point*

Pick other corner for image: *pick a point*

Fit Image dialog

Pulldown Menu Location: Takeoff > Graphic Reports

Keyboard Command: image_layout

Prerequisite: Image file

Save Layout Layers

This command saves the current freeze/thaw status of the layers for the current layout. When the Output Layouts To PDF command generates the PDF for the layout, the saved layout layer settings are used for the PDF output. The Restore Layout Layers command can also be used to reset the freeze/thaw status for the layout.

This command is useful when making a layout using certain layers and then later making new layers in the drawing and you want the layout to use only the original layers.

Pulldown Menu Location: Takeoff > Graphic Reports

Keyboard Command: save_layout

Prerequisite: None

Restore Layout Layers

This command sets the freeze/thaw status of the layers for the current layout using the settings stored by the Save Layout Layers command.

Pulldown Menu Location: Takeoff > Graphic Reports

Keyboard Command: restore_layout

Prerequisite: Save Layout Layers

Convert Dashes To Polylines

This command connects sequential dashes into polylines. There are two processing methods. The Individual method creates one polyline at a time. The Selection method processes a selection set of dashes and creates multiple polylines. The program will prompt you to select a sample and adjacent dash line. This identifies the layer and approximate gap between dash lines. It is helpful to isolate this layer before running the command. Next, select the dash lines to process and press enter. Below are typical results of the conversion.

Before Conversion

After Conversion

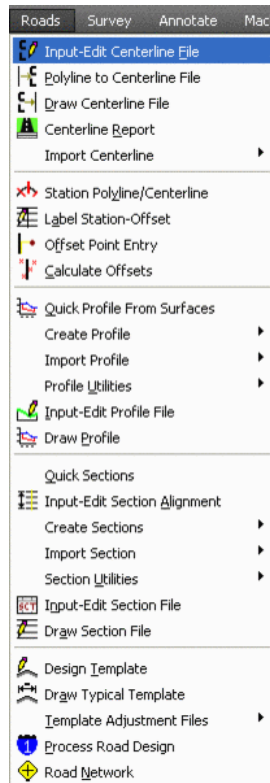

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: dash2pl

Prerequisite: Dashed linework to convert into continuous polylines.

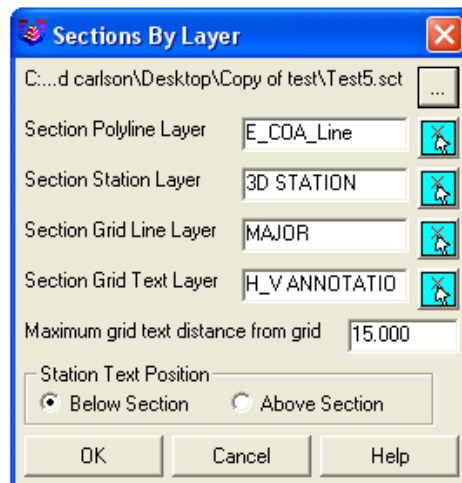

Roads Menu

The Roads pull-down is a composite of commands taken from Carlson Civil. The pull-down includes centerline, vertical profile, cross-sectioning, and Road Network functions for estimating, plan view representation, and the 3D modeling of roads and highways. All of the commands for Roads are described in the manual under the Civil chapter.

Sections From Polylines On Section Grids

Section From Polylines By Layer command can be used to automatically import section data from drawing entities by selecting samples of the different section elements. When running the command, you will first be prompted to name and save the section file you are about to create. The next dialog shown below will ask you to select the layers that represent different elements of the section. Use the mouse pick on the right side to pick the layer in the plan view, or type in the layer name in the middle column.

Here is an example of the linework needed for Section From Polylines.

The "Maximum grid text distance from grid" allows you to determine how far from the grid linework the routine searches in order to find text. The program uses the grid linework and the text associated with the linework to calculate the scale of the grid. Station Text Position tells the routine to assign stationing from text either Above or Below the section linework. After saying okay to this dialog, the routine will prompt you to select the entities to process. You can pick on linework, window around a group of linework or type in All.

Pulldown Menu Location: Roads > Create Sections

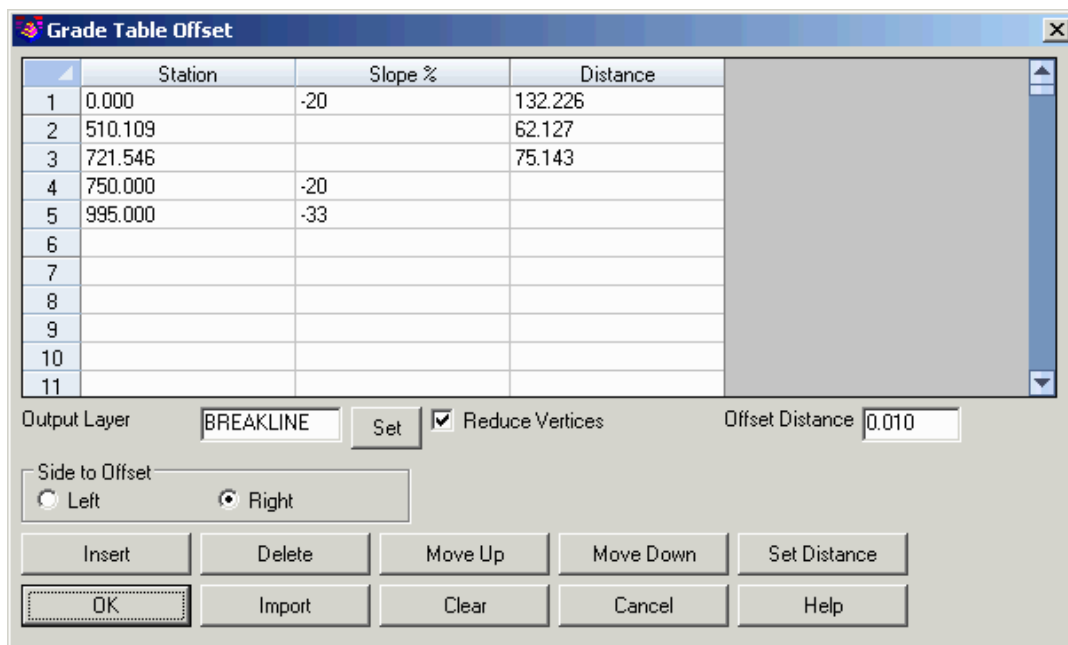

Prerequisite: dwg with section grids

Keyboard Command: scfsct

Offset 3D Polyline By Grade Table

This command creates a 3D polyline that is offset from a reference 3D polyline using the distances and slopes from a Grade Table file. This command provides a simple and easy way to handle complex offsets for features like bottom of ditch polylines offset from the road edge-of-pavement in a road design with transitions.

The Grade Table defines the slopes and offset distances at different stations along the reference polyline. Slopes and offsets for polyline segments between defined stations in the list are interpolated. For example, if the distance at station 0 is 10 and the distance at station 100 is 14, then the offset distance for a polyline vertice at station 50 would be 12. Then slopes and distances are interpolated separately. So if there is a slope change at a station but the distance doesn't change at that station, then you only need to make an entry in the table with the station and slope and leave the distance blank.

The **Output Layer** is used for the offset 3D polyline that is created. The **Side To Offset** controls the offset direction from the reference polyline. The **Reduce Vertices** is used to reduce the number of vertices in the offset polyline. The **Offset Distance** is the maximum amount that the polyline can move horizontally when removing a point. To not reduce vertices, set this Offset Distance to zero.

The **Set Distance** function has several methods for filling out the distance in the table.

Polyline method: prompts to pick the reference and target polylines and then figures the different distances between them. This method applies when there is a 2D polyline for the target location of the 3D offset.

Profile method: prompts for the reference 3D polyline and a target profile. The slope must already be defined in the Grade Table. This method uses the elevation difference between the reference 3D polyline and a profile plus the slope to fill out the distances.

Surface method: prompt for the reference 3D polyline and the target surface. The slope must already be defined in the Grade Table. This method finds the intersection of the surface from the reference 3D polyline at the slope to fill out the distances.

Section method: prompt for the reference 3D polyline and a cross section file. The reference polyline should be at offset zero of the cross sections. The slope must already be defined in the Grade Table. This method finds the intersection of the cross section from the reference 3D polyline at the slope to fill out the distances.

The **Import** function reads in station, slope and distance data into the table. The data can come from either a text file, drawing graphics or superelevation file. For the text file, the format should have station, slope% and distance separated by a delimiter such as a comma. For the drawing graphics, the import reads a polyline on a superelevation diagram grid to set the transition slopes. For superelevation file method, the import reads the transition slopes from a .sup file.

Pulldown Menu Location: Roads

Prerequisite: 3D Polyline

Keyboard Command: tgotffset

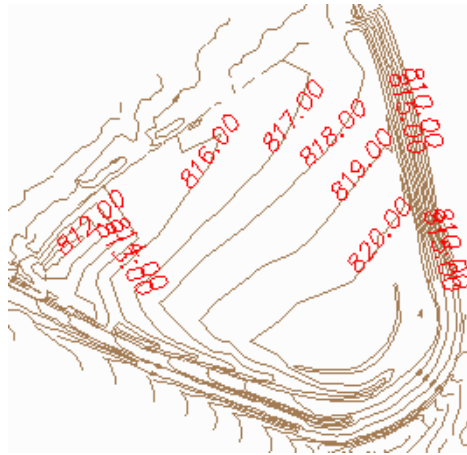

Display Menu

The Display menu commands are quick controls for the drawing view.

Existing Drawing

This command allows you to display all the entities on the layers that are grouped as part of the Existing Drawing.

Carlson Takeoff allows you to assign layers into three different "Target" surface groups: Existing, Design, and Other. For more about assigning layers to different "Target" surface groups see Define Layer Target/Material/Subgrade under the tools menu. Once layers have been assigned, the display menu allows for easy viewing of each "Target" surface. When Existing Drawing is checked then the existing drawing will be displayed. If it is not checked it will not be displayed. You can check on and off the other "Target" surfaces to view the existing drawing in isolation or in accordance to the other drawings.

Keyboard Command: set_display_exist_dwg

Prerequisite: Define Layer Target/Material/Subgrade

Existing Contours

This command displays all the contours that represent the existing surface (For contouring options see Display Options). Clicking on Cut/Fill Labels from the menu runs the command and puts a check mark on the menu. Picking again turns it off.

When Existing Contours is checked than all the contours for the existing surface will be displayed. If it is not checked they will not be displayed.

Prerequisite: existing surface

Keyboard Command: set_display_exist_ctr

Existing Surface

This command allows you to display the surface triangulation for the existing drawing.

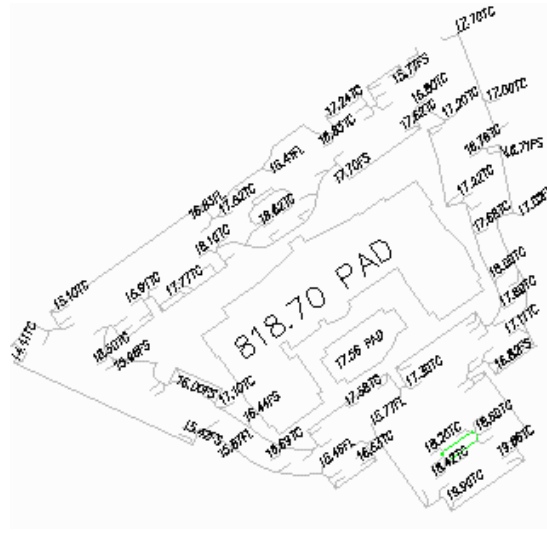

When Existing Surface is checked than all the triangulation for the existing will be displayed. If it is not checked, they will not be displayed.

Keyboard Command: set_display_exist_grd

Prerequisite: an existing surface

Design Drawing

This command allows you to display all the entitles on the layers that are grouped as part of the Design Drawing.

Carlson Takeoff allows you to assign layers into three different "Target" surface groups: Existing, Design, and Other. For more about assigning layers to different "Target" surface groups see Define Layer Target/Material/Subgrade under the tools menu. Once layers have been assigned, the display menu allows for easy viewing of each "Target" surface. When Design Drawing is checked than the design drawing will be displayed. If it is not checked it will not be displayed. You can check on and off the other "Target" surfaces to view the Design drawing in isolation or in accordance to the other drawings.

Keyboard Command: set_display_final_dwg

Prerequisite: Define Layer Target/Material/Subgrade

Design Contours

This command displays all the contours that represents the design surface (For contouring options see Display Options). Clicking on Cut/Fill Labels from the menu runs the command and puts a check mark on the menu. Picking again turns it off.

When Design Contours is checked than all the contours for the design will be displayed. If it is not checked they will not be displayed.

Keyboard Command: set_display_final_ctr

Prerequisite: design surface

Design Surface

This command allows you to display the surface triangulation for the design drawing.

When Design Surface is checked than all the triangulation for the design will be displayed. If it is not checked, they will not be displayed.

Keyboard Command: set_display_final_grd

Prerequisite: a design surface

Cut/Fill Contours

This command compares the existing and design surfaces and shows the cut/fill contours in blue for fill and red for cut. There is a Draw Only Cut/Fill Daylight option and Draw Labels option as part of the Display Options command (See Display Options for more information). Clicking on Cut/Fill Contours from the menu runs the command and puts a check mark on the menu. Picking again turns it off.

Keyboard Command: set_display_cf_ctr

Prerequisite: elevation differences between existing and design

Cut/Fill Labels

This command displays the design elevation, the existing elevation, and the amount to either cut or fill right on the screen (See Display Options for information about labeling options). Picking on Cut/Fill Labels from the menu runs the command and puts a check mark on the menu. Picking again turns it off.

Keyboard Command: set_display_cf_txt
Prerequisite: existing and design surfaces

Cut/Fill Color Map

This command compares the existing and design surfaces and shows the cut/fill regions in blue for fill and red for cut (See Display Options for information on pixel resolution). Clicking on Cut/Fill Color Map from the menu runs the command and puts a check mark on the menu. Picking again turns it off.

Keyboard Command: set_display_cf_map
Prerequisite: existing and design surfaces

Other Drawing

This command allows you to display all the entities on the layers that are grouped as part of the Other drawing.

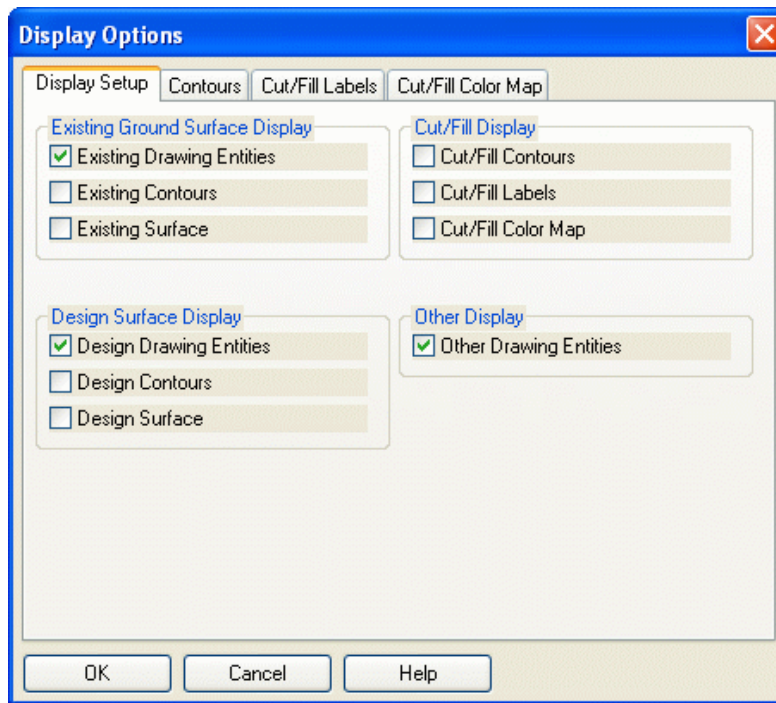

Carlson Takeoff allows you to assign layers into three different "Target" surface groups: Existing, Design, and Other. For more about assigning layers to different "Target" surface groups see Define Layer Target/Material/Subgrade under the tools menu. Once layers have been assigned, the display menu allows for easy viewing of each "Target" surface. Typically, most layers are listed under Other before they are assigned to Existing or Design. Some layers, like perimeter, are neither apart of the Existing or the Design drawing so they remain under Other. When Other Drawing is checked than the entities grouped under Other will be displayed. If it is not checked it will not be displayed. You can check on and off the other "Target" surfaces to view the Other surface in isolation or in accordance to the other surfaces. In this example, Existing, Design, and Other are all shown.

Keyboard Command: `set_display_other_dwg`

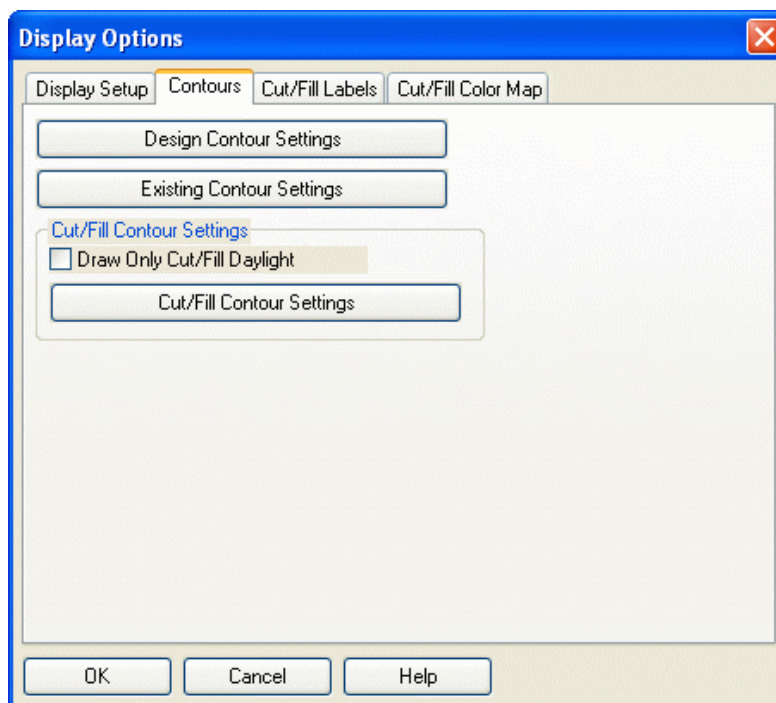

Prerequisite: Define Layer Target/Material/Subgrade

Display Options

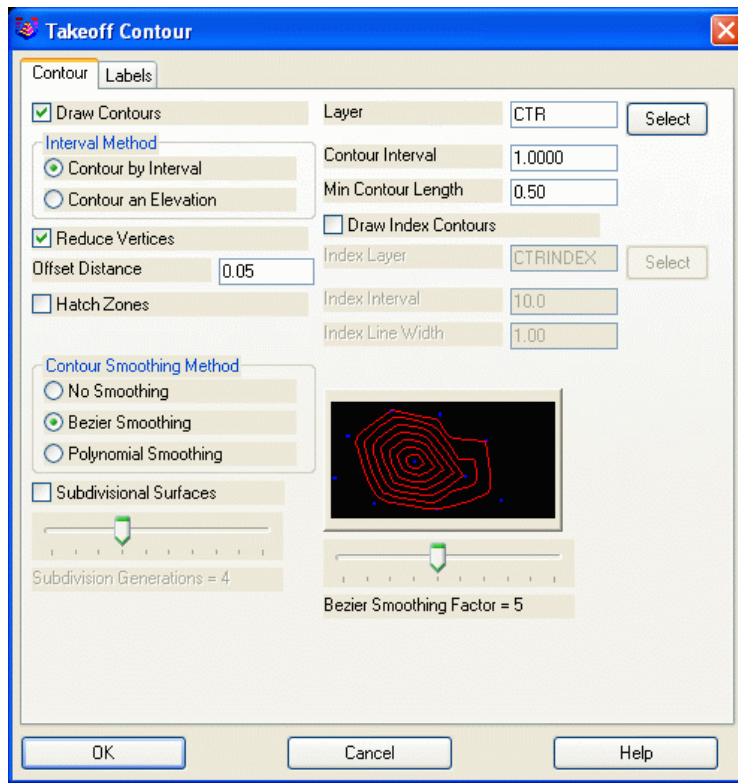

This command allows you to change the features of the different display commands. Note: You can toggle on/off the Existing, Design, and Other surfaces by right clicking with your mouse. To activate this feature type in "short-cutmenu" in the command line and then <1>. To turn off the feature type in <0>.

Display Setup: Here is the master list for the major things you can display, including: the Entities, Contours, and Surface for both the Existing and Design, Cut/Fill Displays, and Other Drawing Entities.

Contour Options: Here you can set the interval, the elevation difference between each contour, for the Existing, Design and Cut/Fill by clicking on their Contour Settings. You can also choose to draw only the daylight line between Existing and Design instead of the Cut/Fill contours at an interval.

Draw Contours

When this box is checked, the program will draw contour lines after triangulating. Otherwise, only the designated triangulation operations are performed. Specify the layer for contours in the edit box to the right.

Contour by Interval or Contour an Elevation

Select whether to contour by interval (ie: every 10 feet) or to contour a certain elevation. The elevation option allows you to contour specific values. For example, if you want just the 100ft contour, then select elevation and enter 100. The default mode is by interval.

Contour Interval

Specify the interval to contour. Note: If the above option is set to Contour an Elevation, then this field is used to specify the elevation to contour.

Minimum Contour Length

Contour lines whose total length is less than this value will not be drawn.

Reduce Vertices

This option attempts to remove extra vertices from the contour polylines which has the advantages of a faster drawing and smaller drawing size. Default is ON

Offset Distance

When the Reduce Vertices option is enabled, This value is the maximum tolerance for shifting the original contour line in order to reduce vertices. The reduced contour polyline will shift no more than this value, at any point, away from the original contour line. A lower value will decrease the number of vertices removed and keep the contour line closer to the original. A higher value will remove more vertices and allows the contour line to shift more from the original.

Hatch Zones

When activated, this option will allow you to hatch the area between the contours sequentially. A secondary dialog will load allowing the user to specify the hatch type and color.

Draw Index Contours

This option creates highlighted contours at a specified interval. When enabled, the fields for Index Layer, Index Interval and Index Line Width are activated.

Contour Smoothing Method

Select the type of contour smoothing to be performed. Bezier smoothing holds all the contour points calculated from the triangulation and only smooths between the calculated points. Polynomial smoothing applies a fifth degree polynomial for smooth transition between the triangulation faces. The smoothing factor described below affects the smoothing bulge.

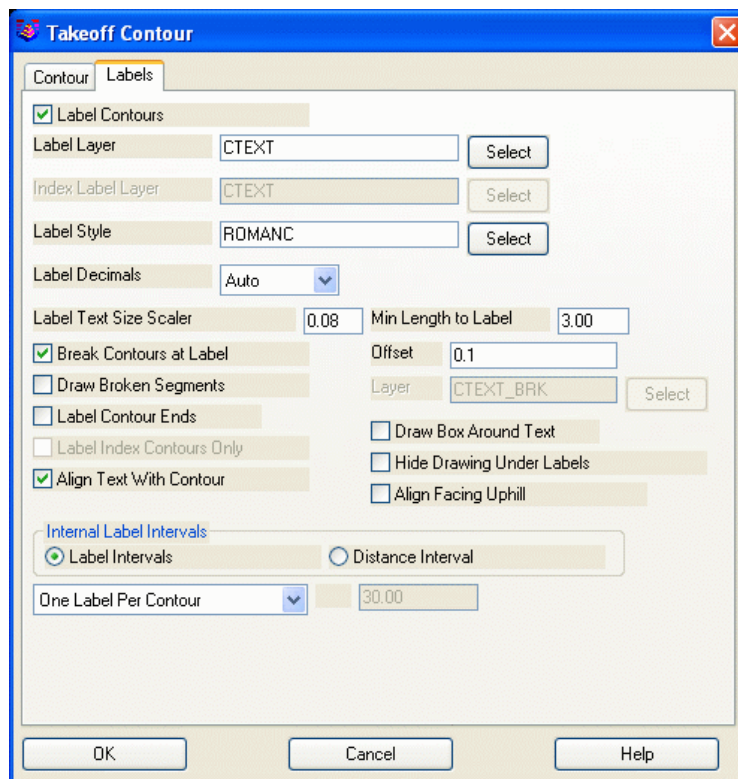

Bezier Smoothing Factor

The contour preview window shows you an example of how much smoothing can be expected at each setting. Sliding the bar to the left results in a lower setting which have less looping or less freedom to curve between contour line points. Likewise, moving the slider to the right results in a setting that increases the looping effect.

Subdivisional Surfaces / Subdivisions Generation

This option causes each triangle in the triangulation surface model to be subdivided into an average of three smaller triangles per subdivision generation, with the new temporary vertices raised or lowered to provide smoother contours. More generations increases the smoothness of the algorithm at a cost of increased processing time. If Straight Lines are chosen as the contouring drawing method, then the contours are guaranteed never to cross. The original points of the surface model are always preserved. These modifications to the surface model are only for contouring purposes and are not written to the triangulation (.FLT) file or inserted into the drawing. If some contour movement is too small for appearance's sake, consider enabling Reduce Vertices.

Label Tab

Label Contours

When activated, contours will be labeled based on the settings below.

Label Layer

Specifies layer name for intermediate contour labels.

Index Label Layer

Specifies layer name for index contour labels.

Label Style

Specifies the text style that will be used for the contour label text.

Label Text Size Scaler

Specifies the size of the contour labels based on a multiplier of the horizontal scale.

Min Length to Label

Contours whose length is less than this value will not be labeled.

Break Contours at Label

When checked, contour lines will be broken and trimmed at the label location for label visibility. When enabled, the Offset box to the right activates. The Offset determines the gap between the end of the trimmed contour line and the beginning or ending of the text.

Draw Broken Segments

When checked, segments of contours that are broken out for label visibility will be redrawn as independent segments. Specify the layer for these broken segments in the box to the right of this toggle.

Label Contour Ends

When checked, contour ends will be labeled.

Draw Box Around Text

When checked, a rectangle will be drawn around contour elevation labels.

Label Index Contours Only

When checked, only the index contours will be labeled. This option is active only when "Draw Index Contours" has been selected in the Contour tab of the main dialog.

Hide Drawing Under Labels

This option activates a text wipeout feature that will create the appearance of trimmed segments at the contour label, even though the contour is fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels, and the contour lines themselves remain contiguous. This feature will also hide other entities that area in the immediate vicinity of the contour label.

Align Text with Contour

When checked, contour elevation labels will be rotated to align with their respective contour lines. This option also activates the Align Facing Uphill feature explained below.

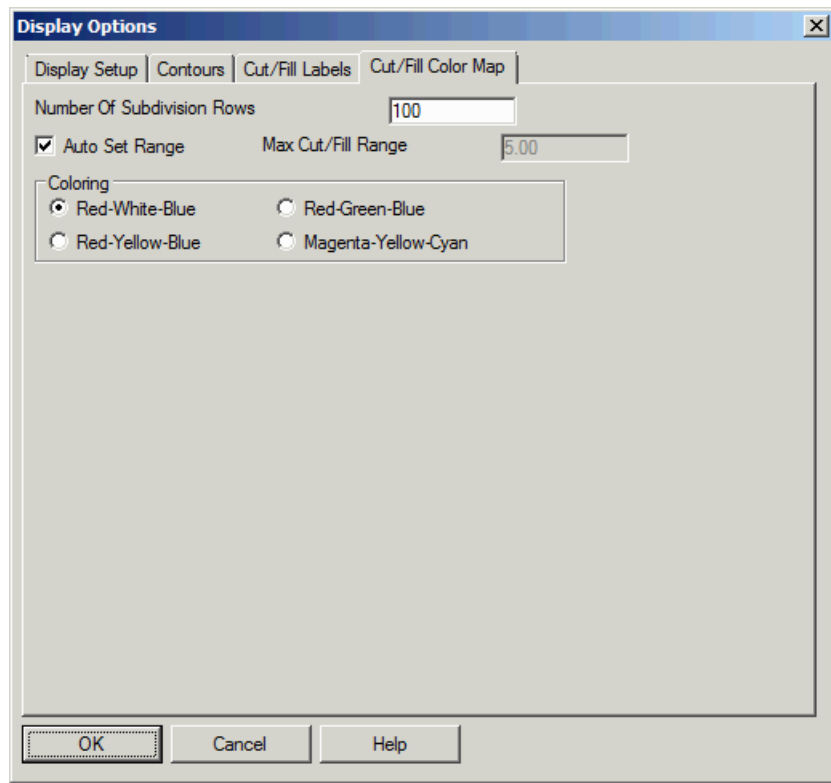

Align Facing Uphill

When checked, contour elevation labels will still be rotated to align with their respective contour lines, but the labels will be flipped in such a manner that the bottom of the text label will always be toward the downhill side of the contours. So as the labels are read right side up, you are always facing uphill.

Internal Label Intervals

Choose between label intervals or distance interval. Label intervals will label each contour with a set number of labels. Distance interval lets you specify a distance between labels.

Cut/Fill Label Options: Here you can customize the Cut/Fill labels. Text can be added either before or after the Cut/Fill amount, the Existing elevation, and the Design elevation with the Prefix and Suffix fields. You can also choose whether or not to display the Existing Surface elevations, the Design Surface elevations and Strata Cut Thickness. The colors for the Cut, Fill, Existing Elevation, and Design Elevation text are all customizable. Carlson Takeoff gives you the option to draw a marker symbol for where each label represents. You can also hide the drawing under the labels so that you can read the labels clearly. Text Size chooses the text size for each line of the label. Text Style allows you change the Font Style displayed in the labels. Decimal Places sets to how many decimal places the labels will report. The Spacing of the labels can be determined by intervals or by a selected number of spaces. The size of each space is determined by the Text Size.

Cut/Fill Color Map Options: Number Of Subdivision Rows is the number of blocks both horizontally and vertically in the Color Map. If the box reads 100 that means 100 blocks left to right and 100 blocks up and down or 10,000 total pixels. A higher the Number Of Subdivision Rows will make the Color Map sharper, however too high number can cause Carlson Takeoff to run slower. Auto Set Range will automatically set the red to blue scale for your cut/fill levels. However, if you desire greater contrast, then use Max Cut/Fill Range to manual set the range. Use lower numbers for greater contrast. There are several coloring schemes with different Cut-Daylight-Fill colors. For example, the Red-White-Blue scheme means red for cut, white for daylight and blue for fill.

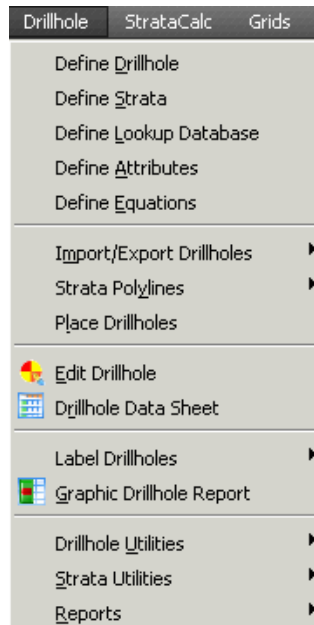

Keyboard Command: tk_display_options

Prerequisite: a drawing

GeoTech Module

9

The GeoTech module is a combination of drillhole routines from the Geology module, surface routines from the Civil module and mapping routines from the Survey module. The GeoTech functions focus on geotechnical tools for civil and environmental firms. The GeoTech menus have commands for drillholes, strata modeling and mapping. Commands that are not covered in the GeoTech chapter are found in the Geology, Survey or Civil chapters.

Drillhole Menu

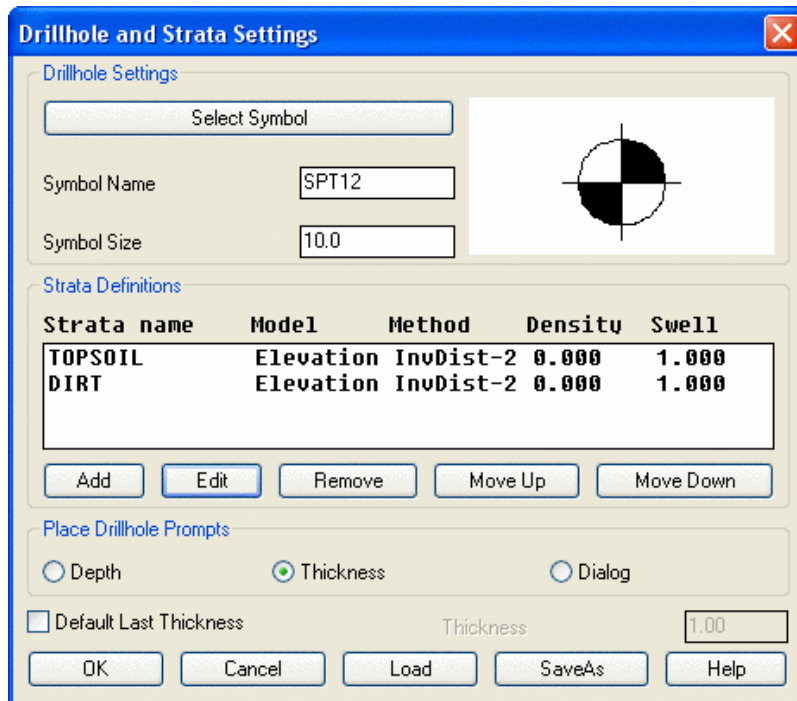

This chapter provides information on using the commands from the Drillhole menu to produce, import and edit drillhole strata settings, place drillholes and report drillholes.

Drillhole Strata Settings

This command selects drillhole symbols, defines strata, and determines how you place drillholes.

Note: The order in which the Strata are defined in the Strata Definitions list will be the default order for the strata when you create new drillholes through **Place Drillhole**.

The dialog box below shows the layout of the Drillhole and Strata Settings.

- **Select Symbol:** Select a symbol to represent the drillhole location on the screen.
- **Symbol Name:** This name corresponds to the symbol selected.
- **Symbol Size:** This field can be edited to adjust the symbols size displayed on the screen.
- **Strata Definitions:** This is not directly editable. Select the Strata you are interested by highlighting it, then select the Edit button.

- **Add:** This option adds additional strata to the available Strata name list. See Edit Strata dialog box below.
- **Edit:** Similar to Add, this option is available to make changes to the Strata, including adding a swell factor.
- **Strata Name:** The name of the strata.

Density (lbs/ft³): The Strata Density field is the default density used to calculate strata tons. Density is strata-specific.

- **By Depth:** This option will generate a strata surface by modeling the strata depth values in the drillholes. This strata surface will follow the existing ground surface at the model depth.

- **By Strata Elevation:** This option will generate a strata model that connects strata irrespective of the upper surface elevation changes.

- **Strata Modeling Method:** There are three ways to model strata by Inverse Distance to the 2nd power, 3rd power, or by linear least squares.

Inverse Distance (Power 2 and Power 3) Modeling Method

Inverse distance calculates the strata model by assigning weights to the drillholes. The strata model calculated by inverse distance are a weighted average of the drillhole data. Inverse distance will not carry trends and the calculated surface model will never be higher than the highest drillhole elevation. Likewise the calculated strata model will never be lower than the lowest drillhole elevation. The weights are proportional to the inverse of the distance between the point to be estimated and a drillhole. Closer drillholes are weighted more than points farther away. The inverse distance can be calculated to the second or third power which are $(1/d^2)$, and $(1/d^3)$ respectively. Inverse Distance - Power 3 will weigh drillholes less that are further away.

Linear Least Squares Modeling Method

The linear least squares method finds the least squares best fit plane across the surface model. The least squares routine weights each drillhole by inverse distance so that closer points are weighted more than points farther away.

So the best fit plane varies at different points on the surface. The linear least squares method extrapolates trends very well. Least squares will trend and allows for data points that are new highs and lows, that don't appear in the original drillhole data.

- **Remove:** This will remove a strata name from the available strata.
- **Move Up:** This option will move the selected strata name up one place in the strata name list.
- **Move Down:** This option will move the selected strata name down one place in the strata name list.
- **By Strata Elev:** This method will generate a strata surface by modeling the strata elevation values from the drillholes. This strata surface is independent of the existing ground surface.
- **Place Drillhole Prompts:** If Depth is selected, then when you run Place Drillholes you will be prompted for the depth of each strata in your drillhole. If Thickness is selected, you will be prompted for the thickness of each strata. If Dialog is selected, you will go straight into the Place Drillhole dialog when you create a drillhole.
- **Default Last Thickness:** Will set the thickness of your bottom strata to the same amount for all your drillholes.

Keyboard Command: tk_chdef

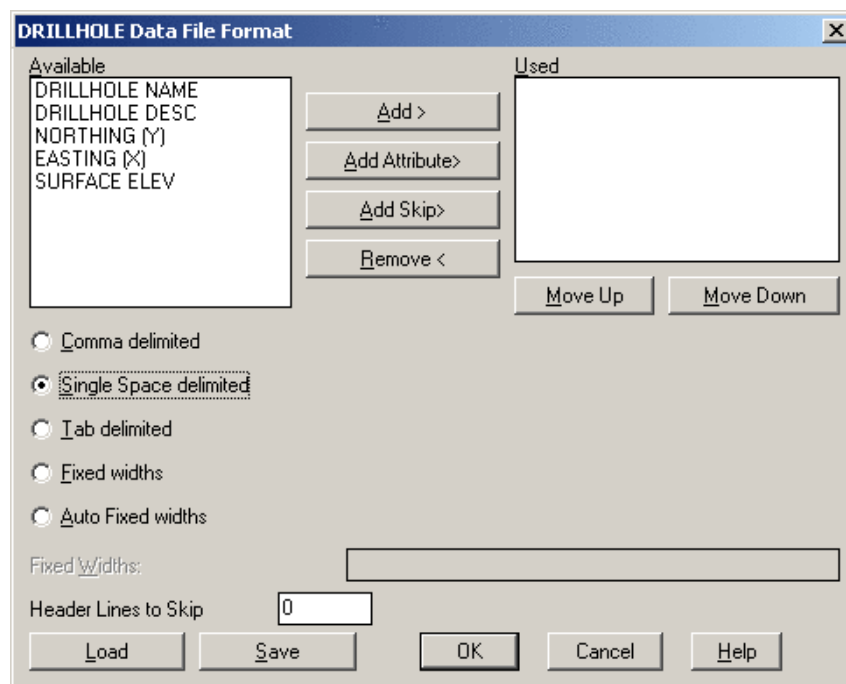

Prerequisite: strata information

Drillhole Import

This command allows you import existing drillhole files. When you select Drillhole Import from the Drillhole menu, a command prompt shows:

"Use separate drillhole and strata files [Yes/<No>]?" If you have two separate files, one with strata info, and the other file has drillhole locations, select Yes. If you enter Yes, the dialog box below appears.

This command creates drillholes from the data contained in text files. Currently there are many company-specific formats. A Drillhole Data File Formatter that is flexible to handle almost any drillhole text file format is below. The format to use is chosen in the dialog shown here.

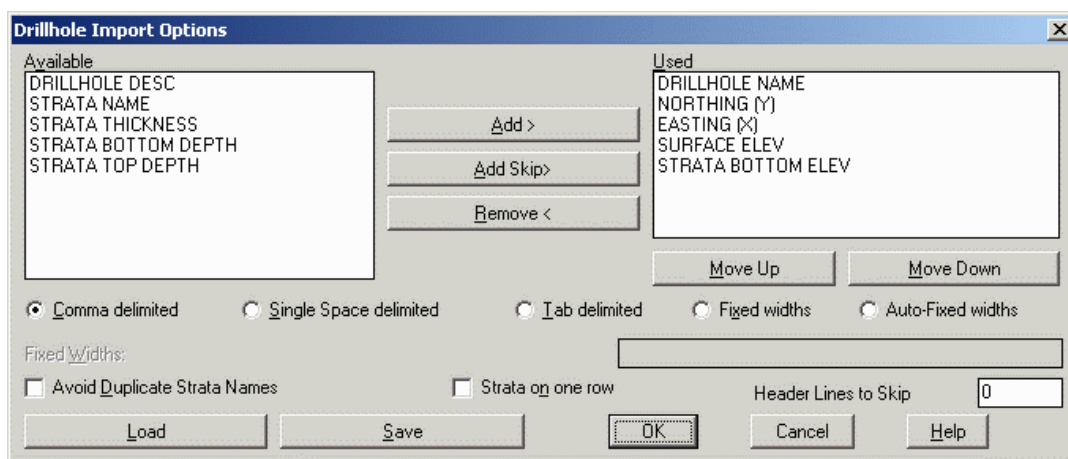

The import text can have comma delimited, space delimited or fixed width columns of data. All the data for a record should be on one row. For the fixed width format, choose the Fixed Width toggle and then enter the column numbers separated by spaces in the edit box. For example, "8 15 24 32".

The Custom format can import all the drillhole and strata data from one text file or the drillhole data from one file and the strata data from another file. The method to use is set at the Use separate drillhole and strata files prompt.

Use the following commands to prepare a file format that will match the *.imp imported file.

- **Add:** Moves the selected entry from Available to Used.
- **Add Attribute:** Allows user input attributes into the Used section.
- **Add Skip:** Adds a "Skip" place holder in the Used List
- **Remove:** Moves a selected item from Used to Available list.
- **Move Up:** Moves the selected item up one place in the list.
- **Move Down:** Moves the selected item down one place in the list.
- **Comma Delimited:** Select this if your *.imp file has commas separating each field.
- **Single space delimited:** Select this if your *.imp has a space separating each field.
- **Tab delimited:** Select this if your *.imp file has tabs separating each field.
- **Fixed widths:** Select this if your *.imp has a defined width of space separating each field.
- **Auto Fixed widths:** Select this to automatically determine the fixed widths that separate each field in the *.imp file.
- **Header Lines to Skip:** If your *.imp file has header lines, enter the number of header lines here.
- **Load:** Takes you to select/brows for your *.imp file.
- **Save:** This command will save your imported file as a *.imp file.

The dialog box below details the drillhole import options.

In addition to the previously listed import commands above, this dialog box also has the following prompts:

- **Avoid Duplicate Strata Names:** Select this to prevent have more than one strata with the same name.

- **Strata on one row:** Select this option if all of your strata info is on one row.

Keyboard Command: tk_chimport

Prerequisite: drillhole files

Place Drillhole

This command allows you to screen pick, enter coordinates or, locate by station-offset the placement of a drillhole.

Go to **Drillhole/Strata Settings, Place Drillhole Prompts**, to determine how you would like to be prompted. When you select **Place Drillhole** from the **Drillhole menu**, the command line prompt shows:

"Station/<Pick Drillhole Location>:" Type in x-y coordinates or move your pointer around the screen to pick the placement of the drillhole. To load a centerline file, press S, select the centerline file to reference, then type in the desired Station and Offset amount. If you are in Dialog Mode defined in **Drillhole/Strata Settings**, once a location has been selected, the following dialog box appears:

STRATA NAME	DEPTH	BOTTOM ELU	THICKNESS
LOOSE LOAM	0.00	0.00	0.00
GLATIAL TILL	0.00	0.00	0.00
SHALE	0.00	0.00	0.00
SEDIMENT	0.00	0.00	0.00

Place Drillholes generates drillholes in the drawing that are required to run strata surface application routines. Each drillhole consists of a surface elevation, strata, and optional description(s). Every strata has a name, bottom elevation, thickness. Within a drillhole, the strata names must be unique, but each real-world strata should have the same strata name across all the drillholes. This is because strata surface applications connects together the strata with the same name.

The drillhole data can be entered in the dialog shown here, or if Depth or Thickness Mode is selected under **Drillhole/Strata Settings**, then the data can be entered in on the command line when you place each drillhole. Make sure to specify the surface elevation and drillhole description. While in Dialog Mode or to change data, use the Edit and Insert/append buttons to enter strata data. The symbols are defined in DrillHole/Strata Settings and drillhole may be changed in Edit DrillHole. Pick Save when done and a drillhole symbol is drawn.

- **Edit:** Make changes to the highlighted strata name. Thickness, Bottom Elevation, Depth.

When placing drillholes, every strata must be assigned a bottom elevation and a thickness. The bottom elevation is the elevation of the bottom of the strata. There are different methods for entering this information.

- **Insert Above:** To add a Strata above the highlighted strata name.
- **Append to Bottom:** To add a strata to the bottom of the available strata name list.
- **Remove:** Removes a strata from the available Strata Name list.
- **Surface Elevation:** This field can be set by you to establish the surface elevation of the drillhole.
- **Drillhole Name:** The name of the drillhole
- **Description:** Drillhole descriptions are intended for storing of drillhole specific information in the drillhole. One general drillhole description is predefined and user may define any number of specific drillhole descriptions. Typical additional descriptions are DRILLER, DATE, TOWNSHIP, and etc. You will be prompted for values of these descriptions in Place DrillHole.
- **Adjust Bottom Elevations:** Will make adjustments to the bottom elevation based on thickness changes.
- **Adjust Next Thickness:** Will adjust the next thickness to hold the bottom elevation unchanged.
- **Save:** This command saves this drillhole as listed.
- **Zoom In:** This increases the magnification of the black view window, cross-section view of the drillhole.
- **Zoom Out:** This decreases the magnification of the black view window, cross-section view of the drillhole.
- **Cancel:** Ends Drillhole placement routine without making changes.

Keyboard Command: tk_chplace

Prerequisite: drillhole information

Edit Drillhole

This command allows you to screen pick an existing drillhole and edit its properties. When you select **Edit Drillhole** from the **Drillhole menu**, a command prompt shows:

"Select Drillhole to edit:" Move your pointer around the screen to pick the drillhole you want to edit. Once a drillhole is picked on the screen, the following dialog box appears:

STRATA NAME	DEPTH	BOTTOM ELV	THICKNESS
DIRT	2.00	815.70	2.00
ROCK	27.00	790.70	25.00

- **Edit:** Make changes to the highlighted strata name. Thickness, Bottom Elevation, Depth.

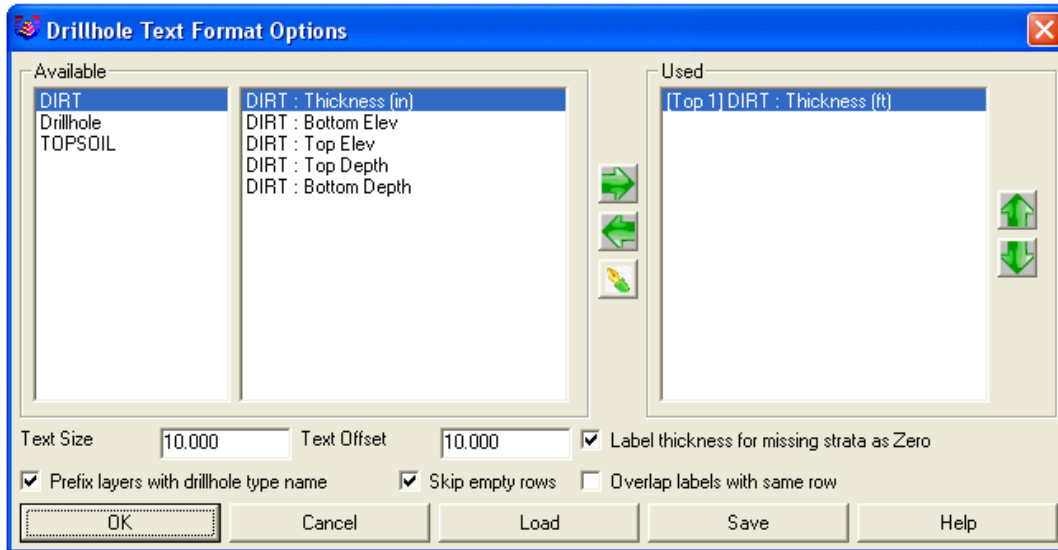

- **Insert Above:** To add a Strata above the highlighted strata name.
- **Append to Bottom:** To add a strata to the bottom of the available strata name list.
- **Remove:** Removes a strata from the available Strata Name list.
- **Surface Elevation:** This field can be set by you to establish the surface elevation of the drillhole.
- **Water Table Elevation:** This elevation is used for modelling the water table surface.
- **Drillhole Name:** The name of the drillhole
- **Description:** The screen display description of the drillhole
- **Adjust Bottom Elevations:** Will make adjustments to the bottom elevation based on thickness changes.
- **Adjust Next Thickness:** Will adjust the next thickness to hold the bottom elevation unchanged.
- **Save:** This command saves this drillhole as listed.
- **Zoom In:** This increases the magnification of the black view window, cross-section view of the drillhole.
- **Zoom Out:** This decreases the magnification of the black view window, cross-section view of the drillhole.
- **Cancel:** Ends Drillhole placement routine without making changes.

Keyboard Command: tk_chedit

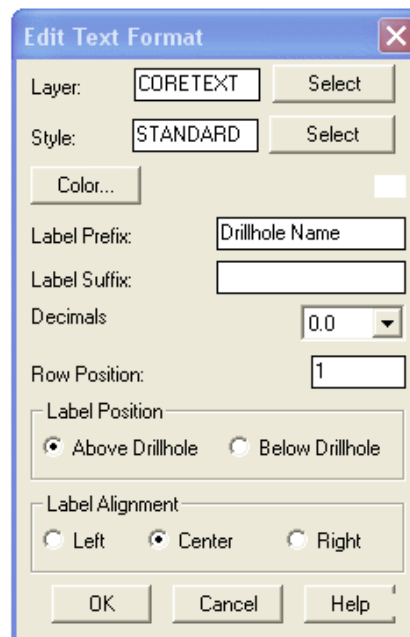

Prerequisite: drillhole information

Label Drillhole

Label Drillhole can be used to label selected properties from drillholes in the current drawing. The first prompt will ask you to select the drillholes you wish to label. To do this, either window around the drillholes you wish to label or type in "all" enter to select all the drillholes in the drawing. Next, a dialog will appear that gives you control on what is displayed in the Labels.

On the left side of this dialog are the Available label options for the drillholes. You have control what is shown for each strata surface as well as general drillhole information such as the name and coordinates. Use the arrows in the middle of the dialog to move an Available label option into the Used column on the right. When you do this, the below dialog will appear with more options.

In the Edit Text Format dialog, you can control the Layer, Style, Color, Prefix/Suffix, Decimals, Row Position, and Alignment of text. These items when changed become default the next time the dialog is opened. Here is an example of Drillhole Labels.

Pulldown Menu Location: Drillhole
Prerequisite: Place Drillhole
Keyboard Command: chtext2

Strata Polylines

Strata Polylines define strata elevation or thickness along linework instead of a single point like Place Drillhole. Linework defined as Strata Polylines are incorporated with Drillhole Data to create surface models. Note: Strata surface models can not be made exclusively from Strata polylines, some drillholes need to be placed as well.

Tag Strata Polylines

This command allows the user to select polylines that define a Strata. Pick the Strata from the list or type in the name in the Enter Name field. Any Strata you enter in must match a strata defined in Drillhole/Strata Settings in order for the surface to be created.

After selecting a Strata and pressing enter you will be prompted for the type of polyline.

Type of strata polyline [<Elevation>/Thickness]?

Elevation signifies that the Z value for the polyline(s) you are about to select represent the bottom elevation of the previously selected strata. Thickness means that the Z value represents thickness of the strata. Choose one of these options and select the polylines.

Prerequisite: Drillhole/Strata Settings, desired polylines

Keyboard Command: stratatag

Highlight Strata Polylines

This command allows users to identify Strata Polylines by either picking on a polyline(s) or by searching the entire drawing. The command will then dash the polyline in the plan view.

Prerequisite: Tag Strata Polylines

Keyboard Command: highlight_strata_pl

Identify Strata Polylines

This command allows users to identify topsoil polylines by picking on a polyline. The command will then report the Strata name and Type (either Elevation or Thickness).

Prerequisite: Tag Strata Polylines

Keyboard Command: strataid

Untag Strata Polylines

This command allows the user to remove previously tagged Strata Polylines so that they are not included in the strata model.

Prerequisite: Tag Strata Polylines

Keyboard Command: stratauntag

Drillhole Reports

This command allows you to generate a report of selected drillholes. When you select **Reports** from the **Drillhole** menu, a sub-menu choice of **Standard Drillhole Report** or **Custom Drillhole Report**, is displayed.

Standard Drillhole Report

If this is selected, several prompts are asked at the command line. They are as follows:

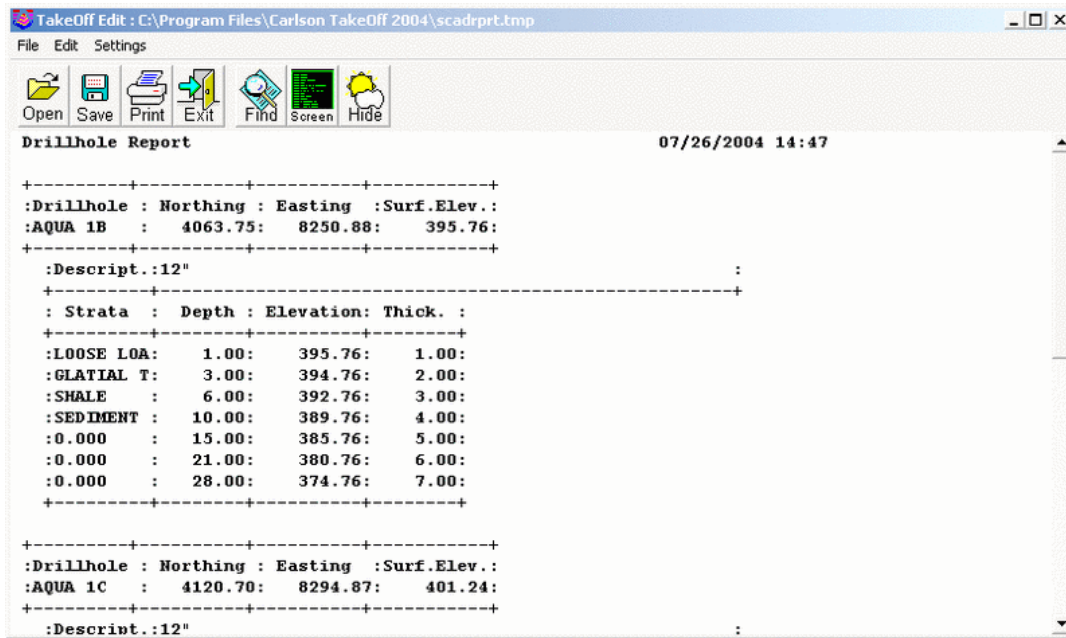

Select objects:

Add Page break between drillholes [Yes/<No>]?

Report Strata depth to [Top/<Bottom>]?

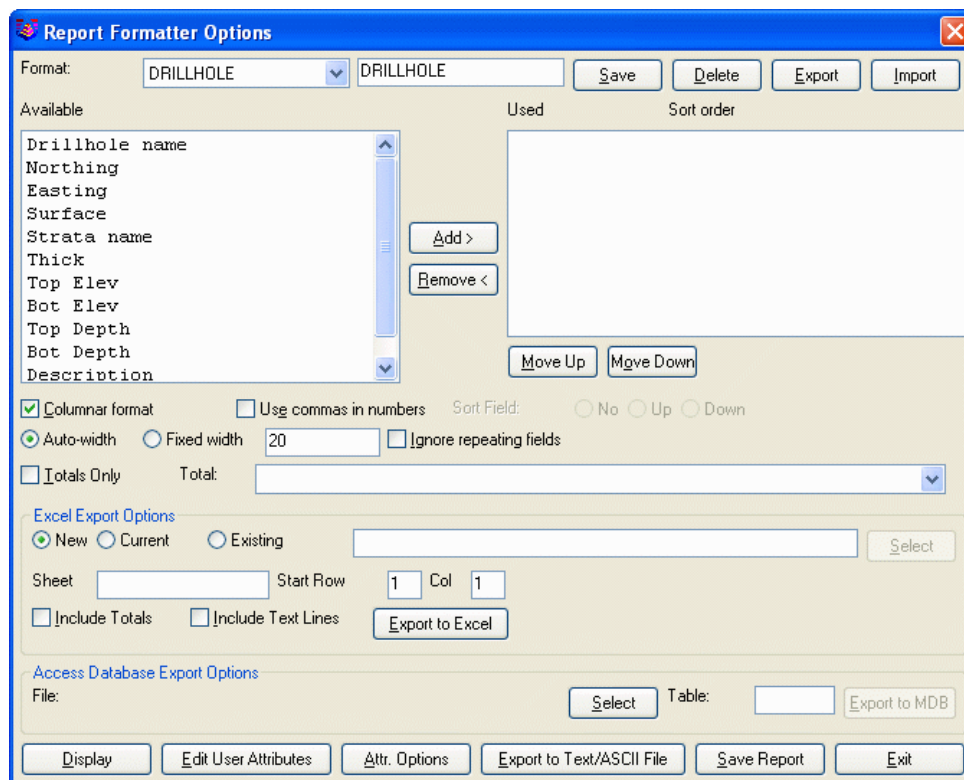

Report Strata elevation of [Top/<Bottom>]?

The report is then displayed accordingly.

Custom Drillhole Report

This function allows you to customize your report format.

Prompts:

Command: tk_chreport2

Select the Drillholes for report.

Select objects: Specify opposite corner: 271 found

262 were filtered out.

Keyboard Command: tk_chreport, tk_chreport2

Prerequisite: drillholes

Make Strata Surface

This command generates multiple strata surfaces based on strata definitions and placements of drillholes. Strata surfaces are generated at the bottom of each strata. These strata surfaces can then be used in other Takeoff commands like **Calculate Total Volumes**. They can be viewed on screen, through the command **Draw Strata Surface**.

This command also builds the water table surface when the drillholes have water table elevations specified. The water table surface is independent of the strata surfaces. When you have a water table surface, you can use it in other commands such as **Draw Strata Surface**. The water table surface is also used in **Calculate Total Volumes** to report cut quantities below the water table.

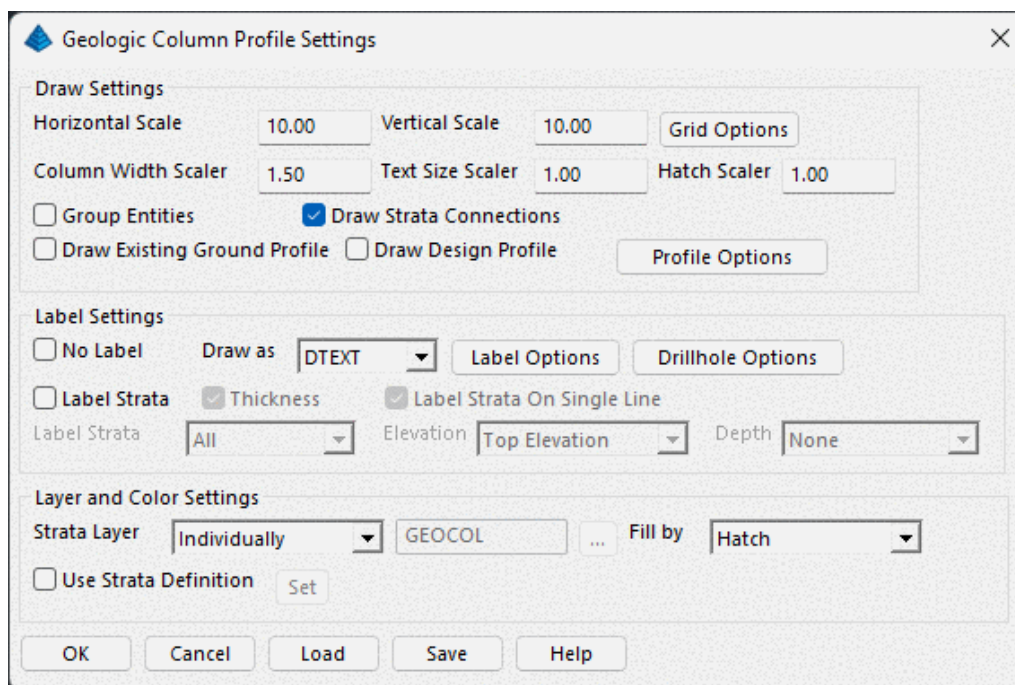

Note: By observing the command line, one can see the status of each strata surface generation.

Keyboard Command: tk_chgrid

Prerequisite: Define Drillhole/Strata Settings, Place Drillhole

Geologic Column Profile

This command will draw drillholes in a profile view, projected along a centerline. Prior to running this command, you must draw a polyline through (or close to) the drillhole symbols. Note that all of these settings may be saved to a geologic column settings file (.gcl).

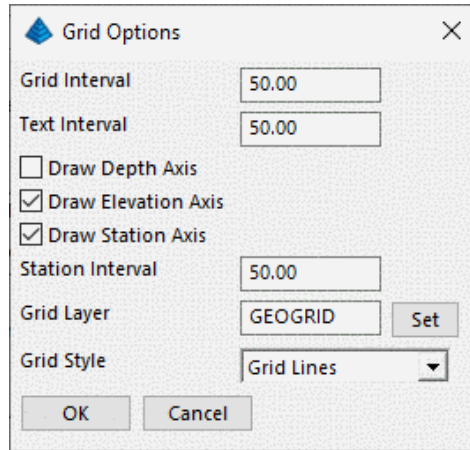

Horizontal Scale: This value sets the overall drawing scale that many other options in the dialog reference

for scaling. This allows you to quickly change the size the geologic columns with a single value.

Vertical Scale: This value, relative to the Horizontal Scale, determines the vertical exaggeration. For example, a Horizontal Scale of 50 and a Vertical Scale of 10 will produce a 5X vertical exaggeration.

Grid Options: This button will open the below dialog. These settings adjust the axis lines drawn behind the drillhole itself.

Grid Interval: This value sets the grid line spacing for the Elevation and Depth axes. For example, a Interval of 25 will draw a tick/grid line every 25 ft/m of elevation change.

Text Interval: This value sets the text intervals for the Elevation and Depth axes. For example, a Text Interval of 100 will draw an elevation/depth label every 100 ft/m of elevation change.

Draw Elevation Axis: This option will draw an elevation axis for the background grid.

Draw Depth Axis: This option will draw a depth axis (vertical line) through the individual drillholes.

Station Interval: This value sets the grid line spacing for Station axis. For example, a Interval of 25 will draw a tick/grid line every 25 ft/m along the length of the fence polyline.

Grid Layer: This option sets the layer for the background grid.

Grid Style: This option controls how the grid will be drawn.

The *Grid Lines* option will draw a true grid with lines spanning the appropriate axes.

The *Ticks Only* option will draw the grid axes, but instead of full lines spanning the axes, small tick marks will be placed along each axis.

The *Ticks and Dots* option will draw tick marks along each axis, as well as points where true grid lines would intersect.

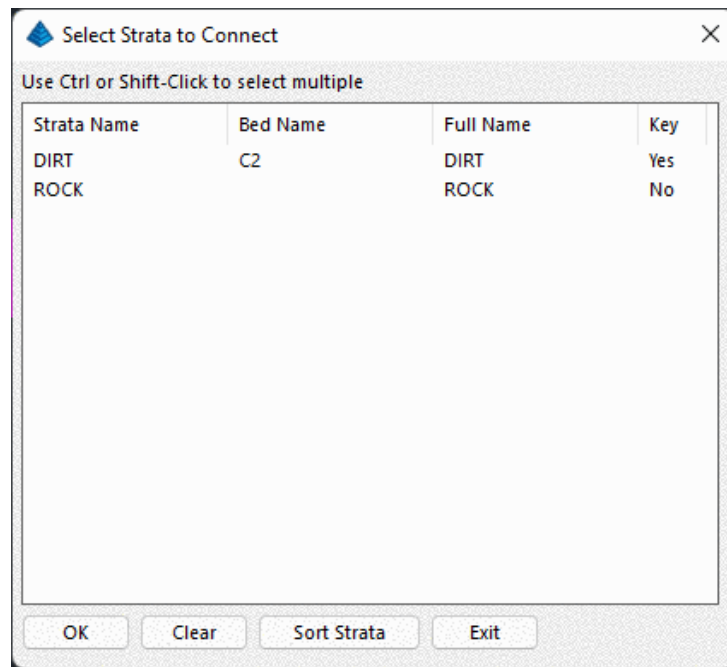

Column Width Scaler: This value, relative to the Horizontal Scale, determines the width of the geologic column. For example, a Column Width Scaler of 0.15 and a Horizontal Scale of 100 will produce a column with a width of 15 drawing units. **Text Size Scaler:** This value, relative to the Horizontal Scale, set the text size labels for strata labels.

Hatch Scaler: This value is only used when the *Fill by Hatch* option is selected. This value, relative to the hatch scales in the current Strata Definition File, determines the hatch scale of each strata's hatch pattern. For example, a Hatch Scaler of 5 and a strata with a defined hatch scale of 2 will produce a hatch pattern with a scale of

10. If a strata is not found in the Strata Definition File, the Hatch Scaler will be multiplied by a value of 5 to set the hatch scale of the strata.

Group Entities: This option will draw each column as a group of entities (not to be confused with a block entity).

Draw Strata Connections: This option will draw polylines connecting similar strata between drillholes. Note that if a strata pinches out between columns, this pinchout will not be drawn. After clicking OK on the dialog, you will be prompted for the strata to connect, as shown below. Note that the bed names are not usable by the Geotech module and may be ignored.

Sort Strata: This button will sort the list alphabetically by Strata Name.

Draw Existing Ground Profile: This option will draw a profile of the existing ground.

Draw Design Profile: This option will draw a profile of the design surface.

Profile Options: This button will display the below dialog to set the layers for the Existing Ground and Design Profiles.

No Labels: This option will turn off labeling for the drillholes and will also ghost out all labeling options in the

dialog.

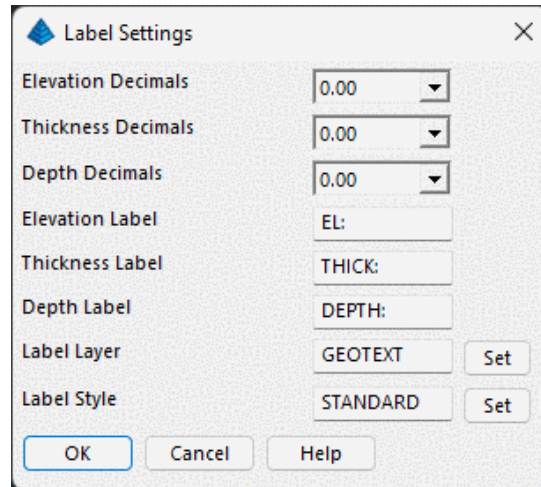

Draw Labels as: This option controls the type of text that is used for labels.

The *DText* option will use a standard text entity for labels.

The *MText* option will use MText (multi-line text) entities for labels.

The *MLeader* option will use Multileader entities for labels, which are simply MText entities attached to a leader line.

Label Options: This button will open the below dialog to control labels specific to each strata layer.

Elevation/Thickness/Depth Decimals: These options control the number of decimals to display for elevation, thickness, and depth labels, respectively.

Elevation/Thickness/Depth Prefix: These text strings set the prefix for elevation/thickness/depth labels, respectively.

Label Layer: This option sets the layer for the strata labels. Clicking the **Set** button will display the list of existing layers in the drawing.

Label Style: This text string sets the text style for the labels. The **Set** button may be used to select a pre-existing text style. Text styles may be edited via the STYLE command.

Drillhole Options: This button will display the below dialog to control labels about the drillhole itself.

Label Northing and Easting: This option will draw a label of the Northing and Easting coordinates for each column.

Label Surface Elevation: This option will draw a label of the Surface Elevation for each column.

Label Drillhole Name: This option will draw a label of the Drillhole Name for each column.

Label Drillhole Descriptions: This option will draw a label of the Drillhole Description for each column.

Label Drillhole Depth: This option will draw a label of the maximum depth for each column.

Label Offset Distance for Projected Method: This option is only applied when the Horizontal Alignment is set to the *Projected* option. This option will draw a label indicating the perpendicular distance from the column to the alignment polyline.

Label Water Level: This option will draw a label of the water table elevation in the column. When this option is selected, the **Water Level Attribute** must match the name of the water level attribute defined in the drillhole. Note that the water level is an attribute of the drillhole itself; it should not be listed as an attribute of a particular strata.

Northing Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Northing coordinate.

Easting Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Easting coordinate.

Elevation Prefix/Suffix: These two text strings will set the prefix and suffix for the label of the column Surface Elevation.

Offset Prefix/Suffix: This option will only be applied when the Horizontal Alignment is set to the *Projected* option. These two text strings will set the prefix and suffix for the label of the column Offset from the fence alignment polyline.

Label Position: This option determines where the drillhole label is drawn.
If the *Above Drillhole* option is selected, the label will be center justified above the column.
If the *On Side* option is selected, the label will be drawn to the right of the column.

Drillhole Text Layer: This option sets the layer for the drillhole labels. The **Set** button may be used to select a pre-existing layers.

Drillhole Text Style: This text string will set the text style for the drillhole label. The **Set** button may be used to select a pre-existing text style. Text styles may be edited via the STYLE command.

Drillhole Text Size Scaler: This value, relative to the Horizontal Scale, set the text size labels for the drillhole labels. For example, a Text Size Scaler of 0.15 and a Horizontal Scale of 100 will produce a label with a height of 15 drawing units.

Label Strata: This option will draw labels for each strata found in the drillhole. All strata label options will be ghosted when this option is not selected.

Strata to Label: This option will determine which strata are labeled.
The *All* option will label all strata.
The *Selected* option will prompt you to select the strata to label.
The *Fit-Only* option will only draw a label if the strata is thick enough to place a label without having to adjust the label position to avoid overlaps.

Elevation Label: This option determines which elevation will be labeled for each strata.
If the *None* option is selected, no elevation label will be drawn.
If the *Top Elevation* option is selected, the top elevation of each strata will be labeled.
If the *Bottom Elevation* option is selected, the bottom elevation of each strata will be labeled.

Depth Label: This option determines which depth will be labeled for each strata.
If the *None* option is selected, no depth label will be drawn.
If the *Top Depth* option is selected, the depth to the top of each strata will be labeled.
If the *Bottom Depth* option is selected, the depth to the bottom of each strata will be labeled.

Strata Layers: This option will determine which CAD Layers are used for each strata in the column.
If the *Individually* option is used, each strata will be drawn on the CAD Layer specified in the Strata Definition File.
If the strata is not found in the Strata Definition File, each strata will be drawn on a CAD Layer matching the name of the strata.
If the *All Same* option is selected, all strata will be drawn on the CAD Layer specified just to the right of this option.
The ellipsis button may be used to select a pre-existing CAD Layer.

Fill by: This option determines the hatch pattern for each strata.
If the *Outline Only* option is selection, no hatch pattern will be drawn.
If the *Hatch* option is selected, the strata will be filled with the hatch specified in the Strata Definition File. If a strata is not found in the Strata Definition File, the strata will be hatched with the ANSI31 pattern.

If the *Solid Fill* option is selected, all strata will be hatch with the SOLID hatch pattern.

Use Strata Def: This option allow the use of a different Strata Definition File (which controls layering, colors, hatching, etc.) other than the one associated with the drawing. Note that if you leave this option unchecked, the program will use the settings defined in the Define Drillhole and Strata Settings command. The ellipsis button will prompt you for this Strata Definition File.

Pull-Down Menu Location: StrataCalc

Keyboard Command: geocol_profile

Clear Strata Surface

This command clears the strata surfaces previously generated with **Make Strata Surface**. This removes the strata surfaces from processing in other takeoff commands.

Note: This command will not remove the surface from the screen view. You must use the command **Erase Strata Surface** to remove them from view.

Keyboard Command: tk_chclear

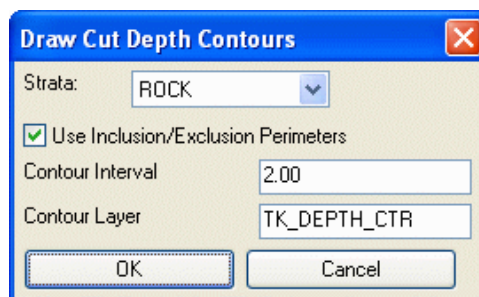

Prerequisite: Make Strata Surface

Draw Strata Cut Depth Contours

This command will draw the **Strata Cut Depth Contours**. This command creates contours for the cut depth between the design surface and strata.

You must have created Strata Surfaces through the **Make Strata Surface** command.

Then select **Draw Strata Cut Depth Contours** from the **Drillhole menu**. You will be prompted to select the Strata from the dialog box below.

You can assign a contour interval and contour layer for the contours to be drawn. If **Use Inclusion/Exclusion Perimeters** is checked on you will be prompted for an Inclusion polyline and an Exclusion polyline if needed, otherwise the drawing's Boundary linework will be used.

Keyboard Command: tk_chdepth

Prerequisite: Make Strata Surface

Erase Strata Cut Depth Contours

This command will erase the Strata Cut Depth Contours from the screen display.

Keyboard Command: tk_chdepth2

Prerequisite: Strata Cut Depth Contours

Draw Strata Cut Color Map

This command will generate a map of areas where the design surface cuts into the selected strata.

Prompts

Select point for color legend: - Use your pointing device to select the top left corner of where you want the cut color legend to be displayed.

Legend size <10.0>: Screen display size.

Label all zones or summary [All/<Summary>]? This pertains to the number of elevation labels on the legend.

Keyboard Command: tk_chmap

Prerequisite: Make Strata Surface

Erase Strata Cut Color Map

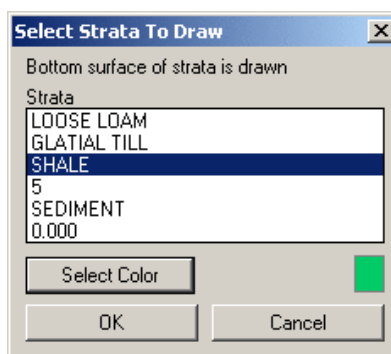

This command will erase all Strata Cut Color information from the screen display.

Keyboard Command: tk_chmap2

Prerequisite: Draw Strata Cut Color Map

Draw Strata Surface

This command will display the selected strata surfaces as 3D faces. The bottom elevation of the strata is drawn.

A color can be selected to distinguish each strata.

Keyboard Command: tk_chplot

Prerequisite: Make Strata Surface

Erase Strata Surface

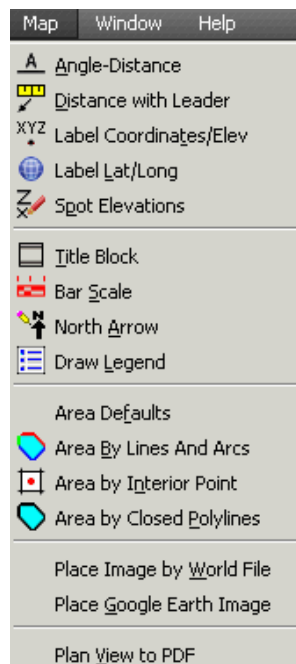

This command will erase all strata surface 3D faces from the screen display.

Keyboard Command: tk_chplot2

Prerequisite: Draw Strata Surface

Map Menu

The Map menu commands are for annotating the plan view. Most of these commands are described in the Annotate section of the Survey module.

Plan View To PDF

This command is a quick and simple way to create a PDF of drawing. The command prompts for the page size and two points to window the area from the drawing to output. Then the program generates and displays the PDF which can be printed as saved to a file. On the dialog for the page size, there is an option to draw a title block which has settings for the margins and contents for the title block. For more control and advanced output to PDF, create the title block in the drawing and then use the File > Plot command.

Prompts

Plot Plan dialog

Pick Lower Left corner: *pick a point*
Pick Upper Right corner: *pick a point*

Pulldown Menu Location: Map
Keyboard Command: plotwindow
Prerequisite: None

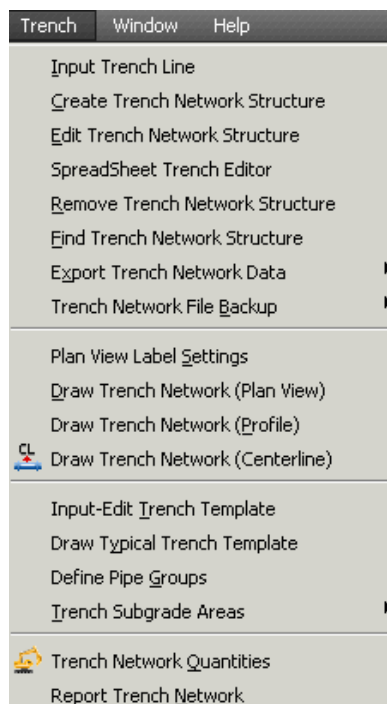

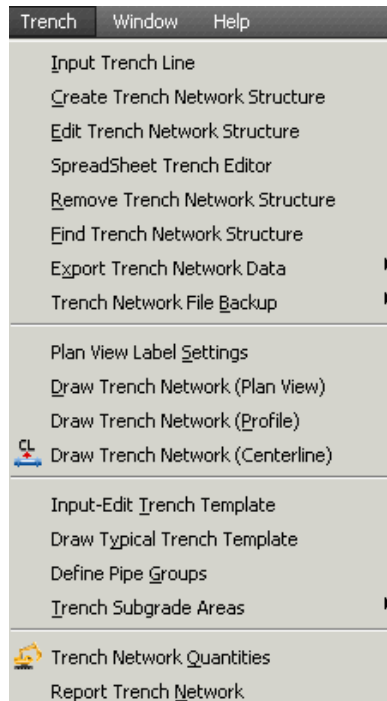

Trench Module

10

Trench Menu

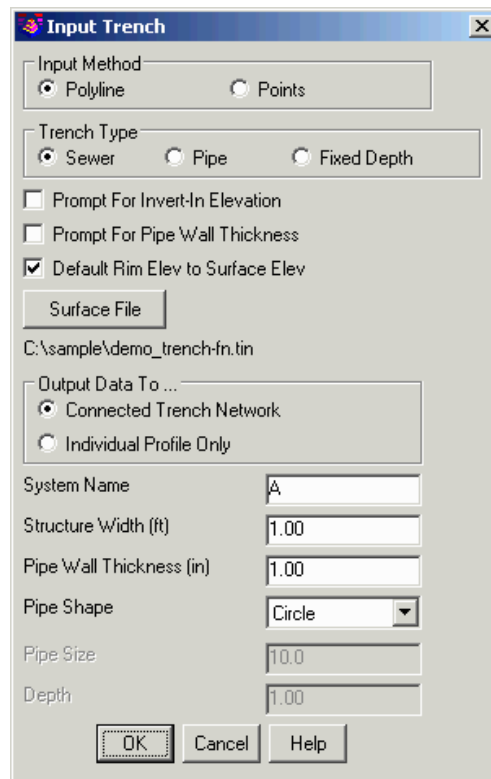

The Trench menu commands layout trench networks and calculate trench quantities.

Input Trench Line

This command allows you to input a trench sewer network structure from polylines or points. It first prompts you the **Input Trench Line Dialog** where you specify the Trench Type, Trench System, and the System Name. The Fixed Depth method automatically assigned the trench elevations at a specified depth from the surface. The Individual

Profile option lets you input one trench reach at a time and save its information to a profile (.pro). The Connected Network option lets you input all the trench polylines on the drawing, merge them into a trench network structure and save the whole structure to a .sew file. For trenching or utilities without Invert-Ins, uncheck Prompt For Invert-In Elevation. If you want to set the Rim Elevation to any surface elevations, check on Default Rim Elev to Surface Elev and then use the Surface Button to select the desired .tin or .flt surface file. Prompt For Pipe Wall Thickness allows you to enter in the pipe thickness that will be used in calculating backfill quantities in two prompts: 1) the interior pipe size and, 2) the thickness of the pipe wall. If this is check off, the value in Pipe Wall Thickness will be automatically added to the Pipe Size for backfill volumes. You can also enter in a Structure Width to be considered in the Cut volumes. Pipe Shape determines the prompting so that you can create Circular, Elliptical, or Rectangular pipe. Click OK to start inputting trench structures.

There are two different types of Input Methods in this command: Polyline or Points. Points allows you to pick freely the location of each sewer structure. With the polyline method, Takeoff extracts the coordinates of all the vertices of the polyline to determine the location of the structures. With both methods you are prompted for the starting station number. Takeoff computes the station values based on the starting station number. Next, you are prompted to enter the Manhole ID (Sewer Trench) or Station ID (Pipe Trench), Invert Elevation, Manhole Elevation (Sewer Trench), and Pipe Size or Pipe Group for every station. You can either enter the values manually or select the texts that represent these values on the drawing. When you finish inputting a polyline, the command would ask you for a profile name to store the profile data if you are doing Individual Profile; otherwise the command would ask you to pick next polyline that is in the same trench network.

Prompts:

Pick a polyline that represents a trench reach: *pick a polyline on your drawing*

Starting Station of trench reach <0.0>: *press Enter to accept 0.0 as the starting station or enter a value*

For station 0.00 ...

Enter/<Select text of Manhole ID>: *select the Manhole ID text on the drawing or enter Enter on the keyboard to enter the Manhole ID value manually*

Enter/⟨Select text of invert elevation⟩: *select the invert elevation text on the drawing or enter Enter on the keyboard to enter the invert elevation value manually*

Enter/⟨Select text of manhole elevation⟩: *select the manhole elevation text on the drawing or enter Enter on the keyboard to enter the manhole elevation value manually*

For station 270.22 ...

Enter/⟨Select text of Manhole ID⟩: *select the Manhole ID text on the drawing or enter Enter on the keyboard to enter the Manhole ID value manually*

Enter/⟨Select text of invert elevation⟩: *select the invert elevation text on the drawing or enter Enter on the keyboard to enter the invert elevation value manually*

Enter/⟨Select text of manhole elevation⟩: *select the manhole elevation text on the drawing or enter Enter on the keyboard to enter the manhole elevation value manually*

Undo/Select/Group/⟨Enter Pipe Size <0.0000⟩: *select the pipe size text on the drawing or enter Enter on the keyboard to enter the pipe size value manually or select Group to enter in a Pipe Group*

For station 425.02 ...

Enter/⟨Select text of Manhole ID⟩: *select the Manhole ID text on the drawing or enter Enter on the keyboard to enter the Manhole ID value manually*

Enter/⟨Select text of invert elevation⟩: *select the invert elevation text on the drawing or enter Enter on the keyboard to enter the invert elevation value manually*

Enter/⟨Select text of manhole elevation⟩: *select the manhole elevation text on the drawing or enter Enter on the keyboard to enter the manhole elevation value manually*

Undo/Select/Group/⟨Enter Pipe Size <0.0000⟩: *select the pipe size text on the drawing or enter Enter on the keyboard to enter the pipe size value manually or select Group to enter in a Pipe Group*

For station 649.73 ...

Enter/⟨Select text of Manhole ID⟩: *select the Manhole ID text on the drawing or enter Enter on the keyboard to enter the Manhole ID value manually*

Enter/⟨Select text of invert elevation⟩: *select the invert elevation text on the drawing or enter Enter on the keyboard to enter the invert elevation value manually*

Enter/⟨Select text of manhole elevation⟩: *select the manhole elevation text on the drawing or enter Enter on the keyboard to enter the manhole elevation value manually*

Undo/Select/Group/⟨Enter Pipe Size <0.0000⟩: *select the pipe size text on the drawing or enter Enter on the keyboard to enter the pipe size value manually or select Group to enter in a Pipe Group*

Another Polyline [⟨Yes⟩/⟨No⟩?] *enter Yes to input another trench reach from a polyline or enter No to finish*

At the end of the command, a file opening dialog would be prompted to you to specify a .sew file name to store the trench network structure.

Prerequisite: A drawing with one or more polylines that represent the trench structure.

Keyboard Command: pline_trench

Create Trench Network Structure

This command allows you to create or modify a trench network structure on a drawing. Before you are able to locate the trench structure, the drawing has to be open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. You can locate the trench structure by one of three methods: picking points on the drawing, entering the point number, or specifying the station and offset of a centerline. If you use centerline method, you need to specify a centerline file. After you locate a point on the drawing, you are prompted the **Sewer Structure Data Dialog** for entering the sewer structure information, such as Structure Name, System Name, Symbol Name, and Elevations. Take a look at the list of the trench points that have been defined. If there is any point that is connected upstream to the current point, you add it to the Upstream Connections list. The Invert Elevation and the Pipe Size fields will be filled with the information of the upstream point. Use Pipe Group allows you to set multiple pipes for the trench run by using an existing or new Pipe Group. Click OK to finish entering the trench structure data. The command will repeatedly ask you to pick a structure point until you hit **Enter** to finish. The trench network structure data is saved in a .sew file.

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface.

Keyboard Command: locate_trench

Edit Trench Network Structure

This command edits the existing trench structure data on the drawing. There has to be a trench network structure that has been created beforehand and its data is store in a .sew file whose name is as same as the drawing name. The command first prompts you to pick a sewer structure on the drawing. If there is no such structure in the .sew file, you would get an error message like this: "Error: unable to locate structure in file C:\temp\takeoff\SANI1x.sew, otherwise this command will restore the trench structure data from the corresponding .sew file and display it on the Sewer Structure Data Dialog for editing. Click OK to confirm your modification. You are prompted to edit another structure point until you press Enter to finish. All modifications are saved in the .sew file.

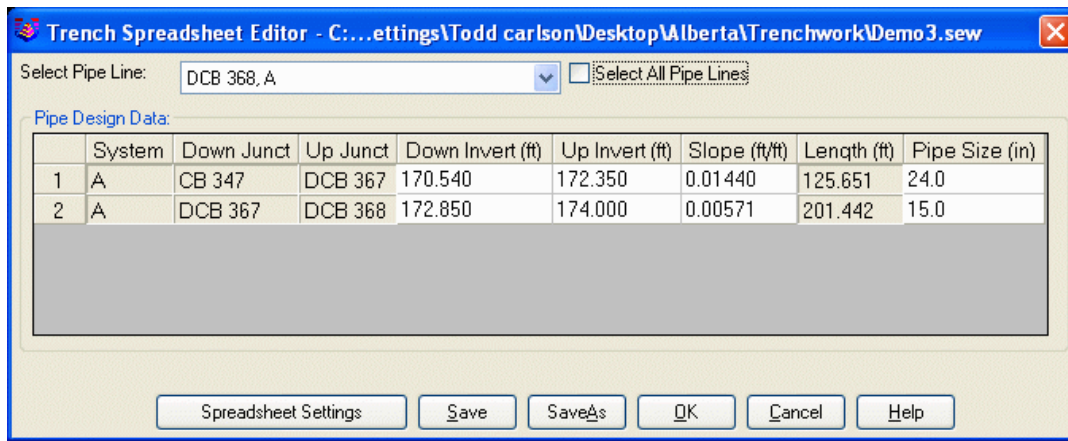

Set Location will return you to the plain view and prompt you for a new location for the structure by either typing in the coordinates or picking on the screen. In the dialog you can change the Structure Name, Symbol, Width, Depth, and Type. Setting a Structure Template will allow you to set the dimensions of the Structure with a .tch file. See Trench Template Editor for details on creating a .tch file. Here you can also manage how the Structure is connect to other Structures. Under Upstream Connections you will see the Structure(s) currently connected to upstream and a list of available Structures on the right. Pick Add to connect to a Structure you have selected under Available, and Remove to disconnect to any selected Structures. Other options are to edit the Rim Elevation, Invert In and Out, as well as Pipe information between your Structure and the highlighted Upstream Connection. Use Pipe Group allows you to set multiple pipes for the trench run by using an existing or new Pipe Group. Min Cover shows you the depth between the Design Surface and top of pipe. Set Min Cover will adjust your Invert In and Out elevations so that you have at least the value you enter as the Min Cover.

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. Trench structure data has been stored in a .sew file, whose name is as same as the drawing name.

Keyboard Command: edit_trench

Trench Spreadsheet Editor

This command allows you to view and edit existing trench network data in spreadsheet form. Upon running the command, the program will open the .sew file associated with the drawing, or if one has not been established, you will be prompted to select one.

The Trench Spreadsheet Editor allows you to select the Pipe Line you want to edit, or view all the Pipe Lines at once by checking on "Select All Pipe Lines". After selecting a Pipe Line, each segment of the Pipe Line will be displayed as: the downstream connection (Down Junct), upstream connection (Up Junct), the invert in of the downstream manhole (Down Invert), the invert out of the upstream manhole (Up Invert), and the Slope, Length and Pipe Size between the two. Any value between two manholes can be edited except for the Length. Spreadsheet Settings allows you to choose what elements of a segment are displayed.

Click OK to confirm your modification. All modifications are saved in the .sew file.

Prerequisite: Sewer Network File

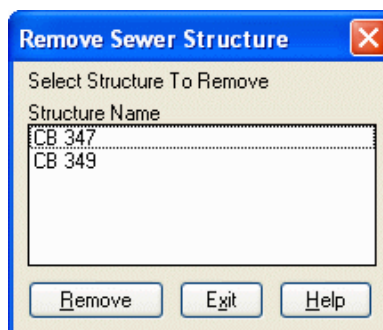

Keyboard Command: edit_trench2

Remove Trench Network Structure

This command removes the existing trench structure data. There has to be a trench network structure that has been created beforehand and its data is store in a .sew file whose name is as same as the drawing name. The command first prompts you to pick a sewer structure on the drawing or to select from a List of your Sewer Structures. If there is no such structure in the file, you will get an error message like this: "Error: unable to locate structure in file C:\temp\takeoff\SANI1x.sew, otherwise this command removes the structure from both the drawing and the .sew file immediately. You are prompted to remove another structure point until you press **Enter** to finish. The removed trench structure points would no longer be found in the .sew file.

Prompts

Select structures to erase by screen pick or name list [<Pick>/List]? Pick to choose from the screen, or List to choose from the below dialog.

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. Trench structure data has

been stored in a .sew file, whose name is as same as the drawing name.

Keyboard Command: remove_trench

Find Trench Network Structure

This command will center the screen and draw an arrow to the structure you specify.

Prerequisite: a Trench Network

Keyboard Command: findswr

Import Trench Network Data - Utility Network

This command imports a sewer network file (.sew) into the current trench network model.

Pulldown Menu Location: Trench

Keyboard Command: import_swrnet

Prerequisite: .sew file

Import Trench Network Data - Utility Network

This command imports a utility network file (.util) into the current trench network model.

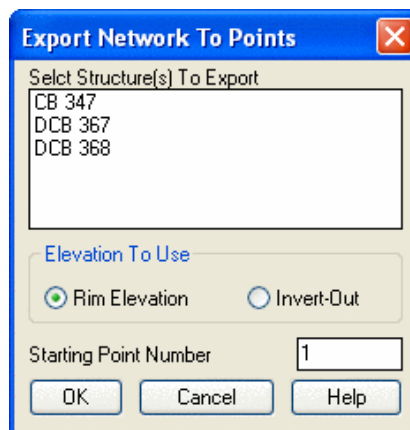

Pulldown Menu Location: Trench

Keyboard Command: import_utilnet

Prerequisite: .util file

Export Trench Network Data

Export to Points

This command will add points at your trench structures and add them into your coordinate file by either the Rim Elevation or the Invert-Out.

Export to Profiles

This command will create a profile file (.pro) of your trench either going Upstream or Downstream. The (.pro) file can then be drawn under Roads->Draw Profile.

Prerequisite: a Trench Network

Keyboard Command: swr2pts, swr2pro

Trench Network File Backup

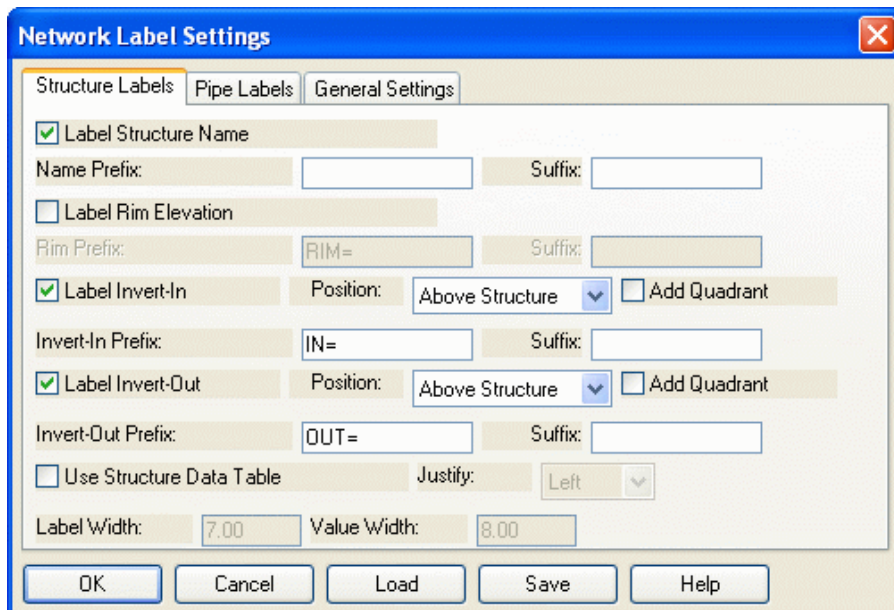

Save Trench Network File saves your trench network as a (.sew) file. *Load Trench Network File* loads a previously saved (.sew) file.

Prerequisite: none

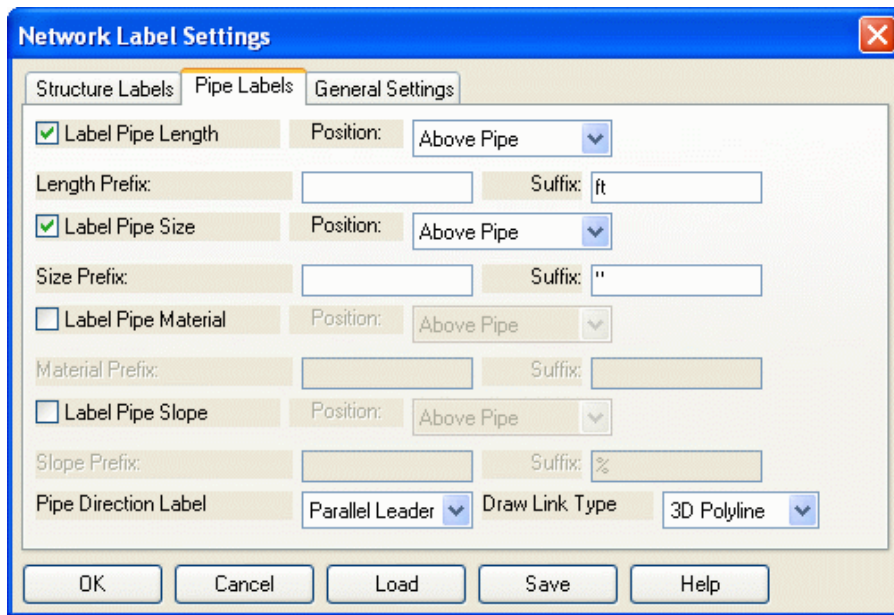

Keyboard Command: save_trench, load_trench

Plain View Label Settings

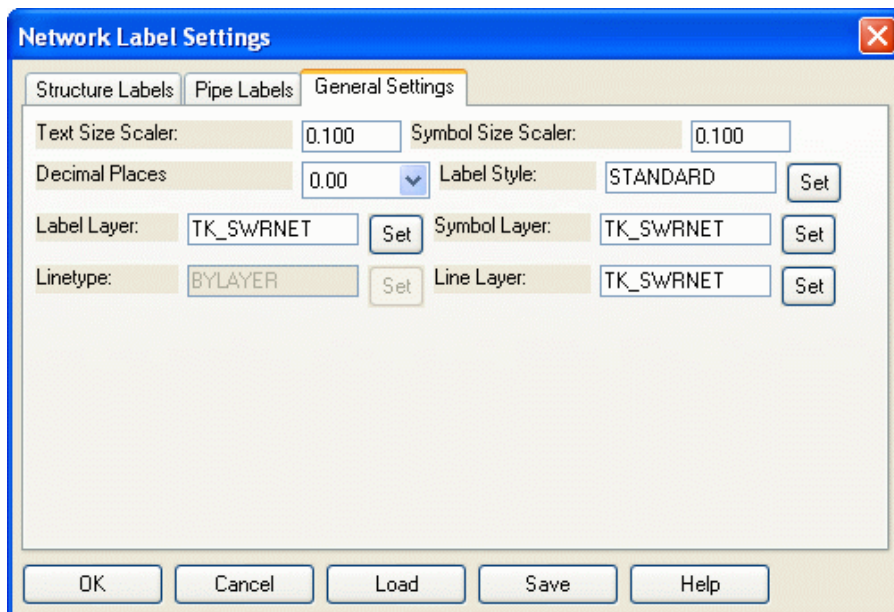

This command allows you to set the labeling for your structures and piping. The below dialog box gives you the option to display the Structure Name, the Rim Elevation, the Invert-In, and Invert-Out. In addition, you can set the Prefixes, Suffixes and labeling location as you so desire. The Use Structure Data Table will create linework around each Structure's labeling.

This below dialog box gives you the option to display the Length, Size, Material, and Slope for you Piping. In addition, you can set the Prefixes, Suffixes and labeling location as you so desire. To specify to which structure the label is meant for, select Arrow On Pipe, Parallel Leader, or None. You can also set the type of linework to draw.

In this dialog you can set the properties for your Symbol and Linework as well as the decimal places to report.

Prerequisite: a trench network

Keyboard Command: swrsetup

Draw Trench Network - Plan

This command draws trench network structures, pipes, and labels on the screen, based on the Plan View Label Settings command and the trench network structure data in the .sew file whose name is as same as the drawing name. Pipe linework will automatically be displayed as 3D faces in the command 3D Viewer Window. If Takeoff can't find a .sew file in the same directory where the drawing is located, nothing would be drawn on the screen.

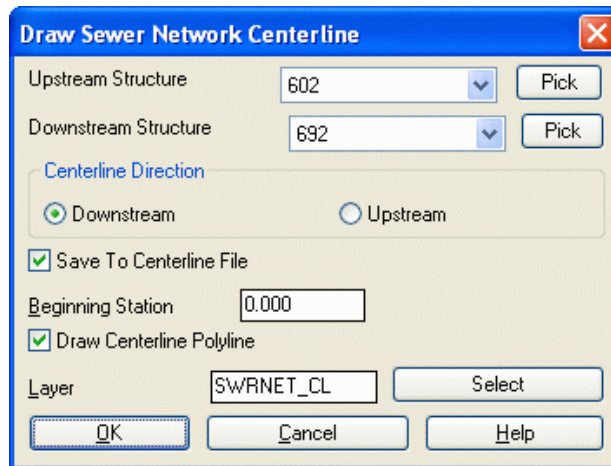

Prerequisite: A open drawing

Keyboard Command: plan_trench

Draw Trench Network Centerline

This command allows you to draw a branch of the trench network structure as a centerline. There has to be a trench network structure that has been created beforehand and its data is store in a .sew file whose name is as same as the

drawing name, otherwise you would get an error message like "Error: no data in sewer network file". The command first prompts you the **Draw Sewer Network Centerline Dialog**. Select the Upstream and Downstream Structure for the centerline you are about to create. The Centerline Direction determines from which structure the polyline is drawn. You can also choose to save the centerline data to a .cl file with the option of entering in the Beginning Station. In this dialog is the ability to set the Layer name as well. Click OK to draw.

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. Trench structure data has been stored in a .sew file, whose name is as same as the drawing name.

Keyboard Command: drwswrcl

Draw Trench Network - Profile

This command allows you to draw a branch of the trench network structure as a sewer/pipe profile. There has to be a trench network structure that has been created beforehand and its data is store in a .sew file whose name is as same as the drawing name, otherwise you would get an error message like "Error: no data in sewer network file". The command first prompts you the Draw Sewer Network Dialog. Select the Upstream and Downstream Struct that you want to draw. If you want to draw the existing and final design surface, as well as Strata Surfaces, toggle on Draw Existing Ground Surface, Draw Final Design Surface, and Draw Strata Surfaces options. If your profile is from upstream to downstream, then select the Profile Direction as Downstream, otherwise Upstream. You can also choose to save the profile data to a profile file. Click OK to draw.

Initializing Draw Profile command ...

OK Cancel

Use the Manhole tab to define what manhole information is labeled in your trench profile.

Use the Pipe tab to define what piping information is labeled in your trench profile.

The command will find the elevation range of your profile and display it at the top of this dialog. Here you can set the elevation top and bottom of the profile's grid.

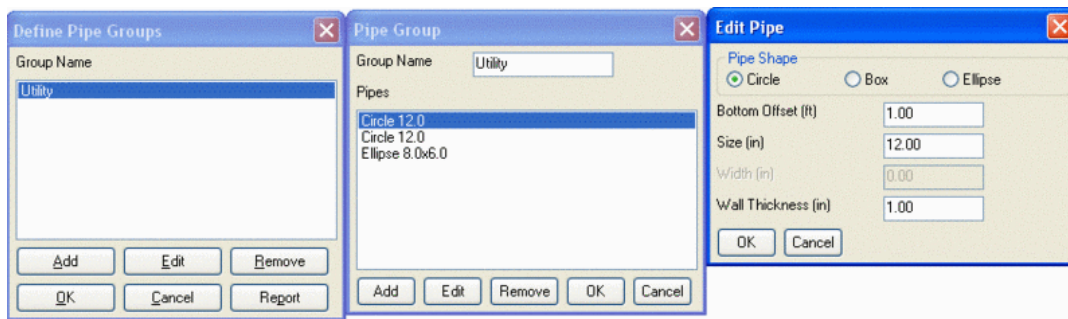

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. Trench structure data has been stored in a .sew file, whose name is as same as the drawing name.

Keyboard Command: profile_trench

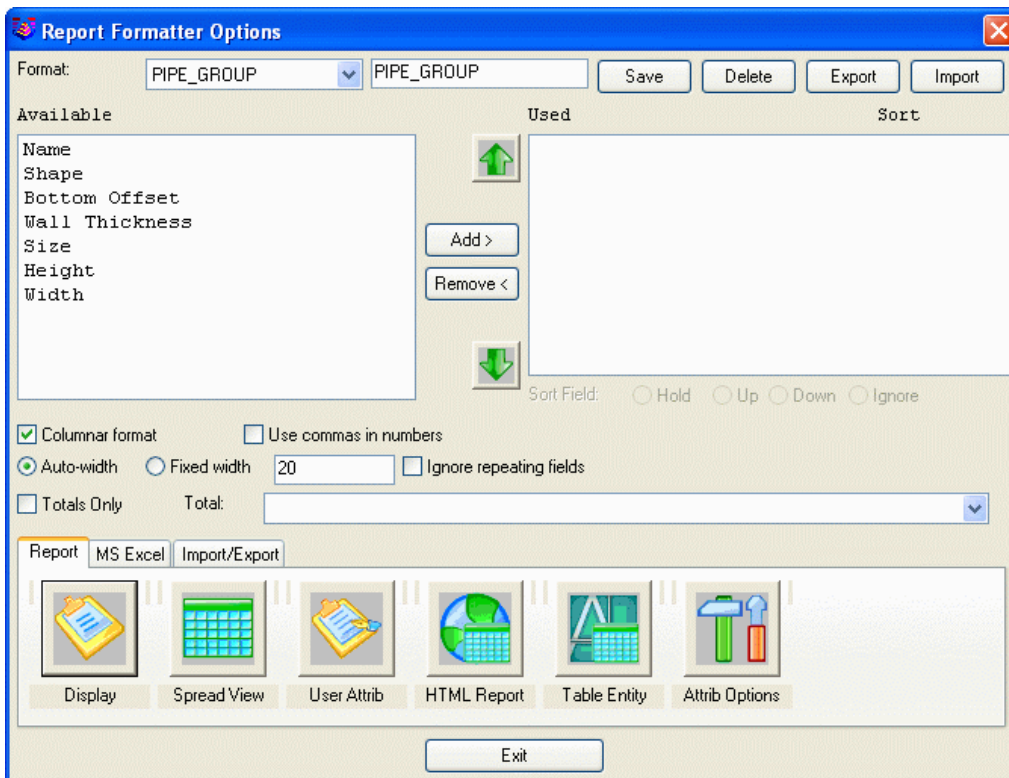

Define Pipe Groups

Pipe Groups allow users to define multiple pipes inside a single trench. Pipe Groups can be applied to a Trench Run during the creation of a Trench Network or after the fact with Edit Trench Structure. In the Define Pipe Groups dialog you can Add, Remove, Edit, or Report different Pipe Groups.

Click Add and a blank Pipe Group dialog will appear. Here you can enter in a Name for the Group and Add different types of pipes into the Group. Clicking Edit or Add in the Point Group dialog will bring up the Edit Pipe dialog. Here you can specify the Pipe Shape, Bottom Offset (from the bottom of the Trench), the Size, Width (when needed), and the Wall Thickness of the pipe.

Report in the Define Pipe Groups dialog will bring up the below dialog:

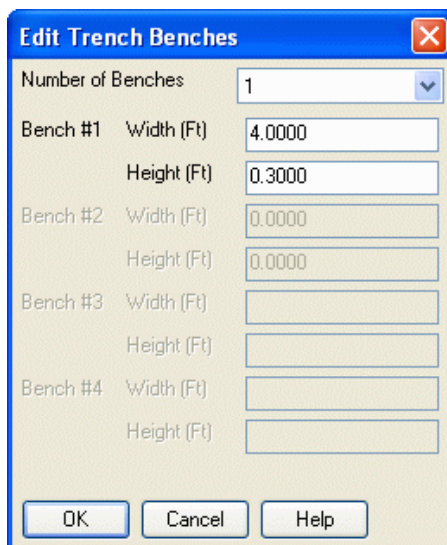

From this dialog you can pick on what you want to report and view it or export it into Excel.

Prerequisite: none

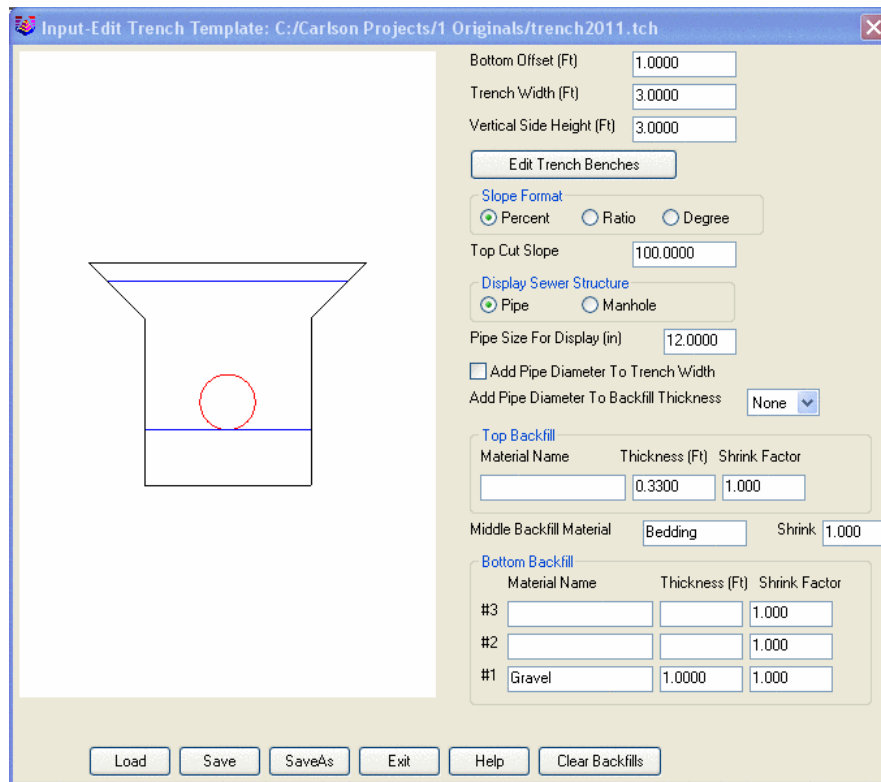

Keyboard Command: define_pipe_grp

Trench Template Editor

This command lets you create a new trench template or modify an existing trench template. It prompts you the **Trench Template Editor Dialog**. If you are modifying a trench template, click the **Load** button on the dialog to open a trench template file and display the template data on the dialog. Enter the dimensions of the trench: bottom offset, trench width and vertical side height. The Edit Trench Benches button will bring up the below dialog, and allows you to enter in up to four benches into your trench.

There are three methods for entering the cut slope, Percent, Ratio and Degree. Choose one of the methods and enter the slope value. Display Sewer Structure allows you to see your pipe or manhole as part of the trench. This is for display purposes only, calculations will be drawn from the pipe size you set in the Trench Network Structure commands. Add Pipe Diameter To Trench Width will increase the size of your trench by the diameter of your different pipe sizes. The Add Pipe Diameter To Backfill Thickness will increase the thickness of backfill material either by half the pipe diameter or the full pipe diameter. For example, when set to Half #1, the backfill thickness for #1 material is increased by half the pipe diameter.

If there is a Top Backfill, enter the Material Name, Thickness and if needed Shrink Factor. The thickness of the Top Backfill is assessed from the top of the trench down. There are three trench Bottom Backfill layers that can be defined. Enter the layer label in the material name field, the depth of the layer in the thickness field. The thickness of these values are assessed from the bottom of the trench up. The Middle Backfill Material is any volume between the Top and Bottom Backfills and can fluctuate depending on the depth of the trench. No set thickness can be applied to the Middle Backfill. Click Save or SaveAs to save the template information in a .tch file, and Click Exit to quit this command.

Prompts:

Trench Template Editor Dialog

Enter the dimensions of the trench template, save the information to a template file (.tch).

Pulldown Menu Location: Trench

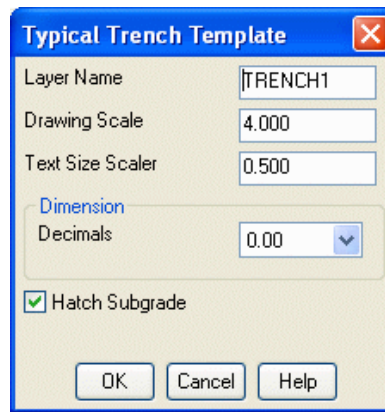

Prerequisite: None

Keyboard Command: make_trench_tpl

Draw Typical Trench Template

This command draws a trench template on the screen. After you select a trench template file (.tch) to draw, a **Typical Trench Template Dialog** is prompted for entering the layer name, drawing scale, text size scaler and selecting how many decimal points you want. You can also hatch the backfill on the drawing. Click OK to draw the

template at the position that you pick on the screen.

Prompts

Pick position to draw template: *pick a position on the screen*

Prerequisite: None.

Keyboard Command: draw_trench_tpl

Trench Subgrade Areas

The purposes of Trench Subgrades is to assign a different type of trench template when a trench passes under a road, building pad, etc.

Set Trench Subgrade Polylines

Choose a closed polyline that defines the area that you want a different trench template for, ie a building pad polyline.

Prerequisite: None.

Keyboard Command: tag_trench_subgrade

Clear Trench Subgrade Polylines

This command untags selected polylines for trench subgrade use.

Prerequisite: Trench Subgrade Polylines

Keyboard Command: untag_trench_subgrade

Hatch Trench Subgrade Area

This command hatches trench subgrades for easy viewing.

Prerequisite: Trench Subgrade Polylines

Keyboard Command: hatch_trench_subgrade

Erase Trench Subgrade Hatch

This removes previous made trench hatching.

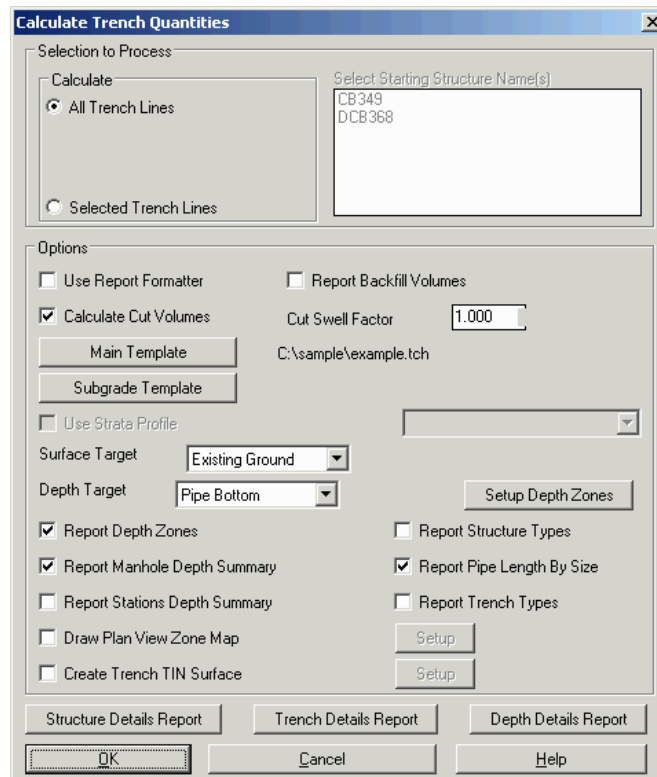

Prerequisite: Trench Subgrade Hatching

Keyboard Command: erase_trench_subgrade

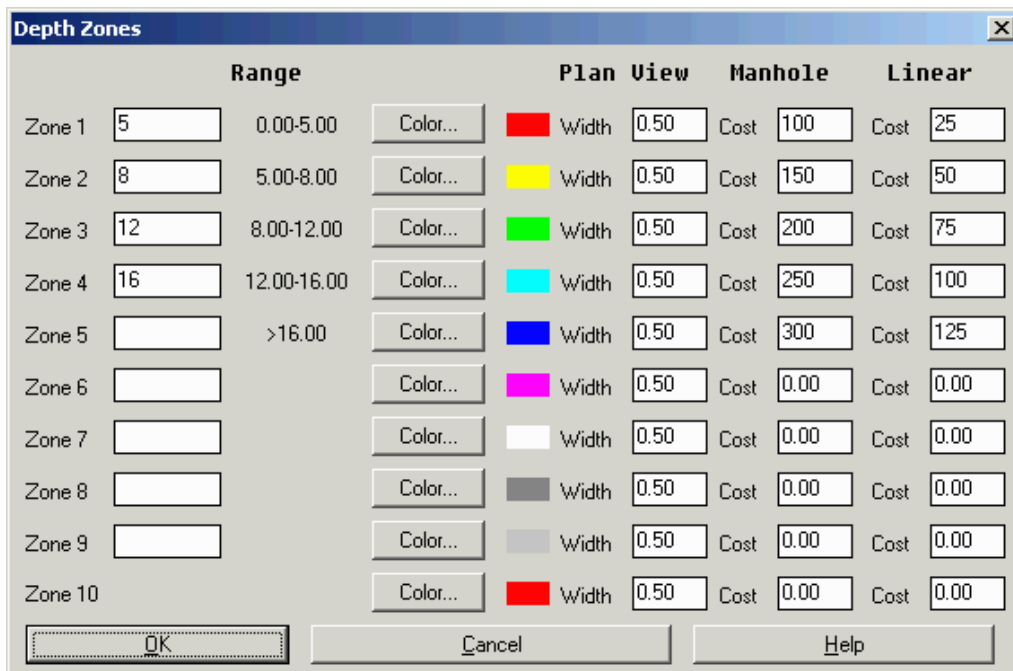

Trench Network Quantities

This command calculates the trench volumes. There has to be a trench network structure that has been created beforehand and its data is store in a .sew file whose name is as same as the drawing name, otherwise you would get an error message like "Error: no data in sewer network file".

The command loads the trench network data and splits them into individual trench lines and displays them on the **Calculate Trench Quantities Dialog**. You can choose to calculate the trench volume of one trench line or several trench lines at a time. You need to set a **Main Template** in order to calculate volumes. To create a template, run Trench> **Trench Template Editor**. The trench cut volume is multiplied by the Cut Swell Factor. Surface Target determines the Surface that the bottom of the trench is compared to, either: the Existing Surface, the Design, the Existing and Design to minimize cut, or simply to the Rim Elevations (no surface required). Trench Depths can be reported by either the bottom of the trench or bottom of the pipe by using the Depth Target pull-down. If you have Strata Surfaces defined then the program can calculate cut volumes for a strata you select. For more comprehensive reports you can customize, click on the Structure, Trench, and Depth Details Reports buttons. For the Standard Report, click the OK button.

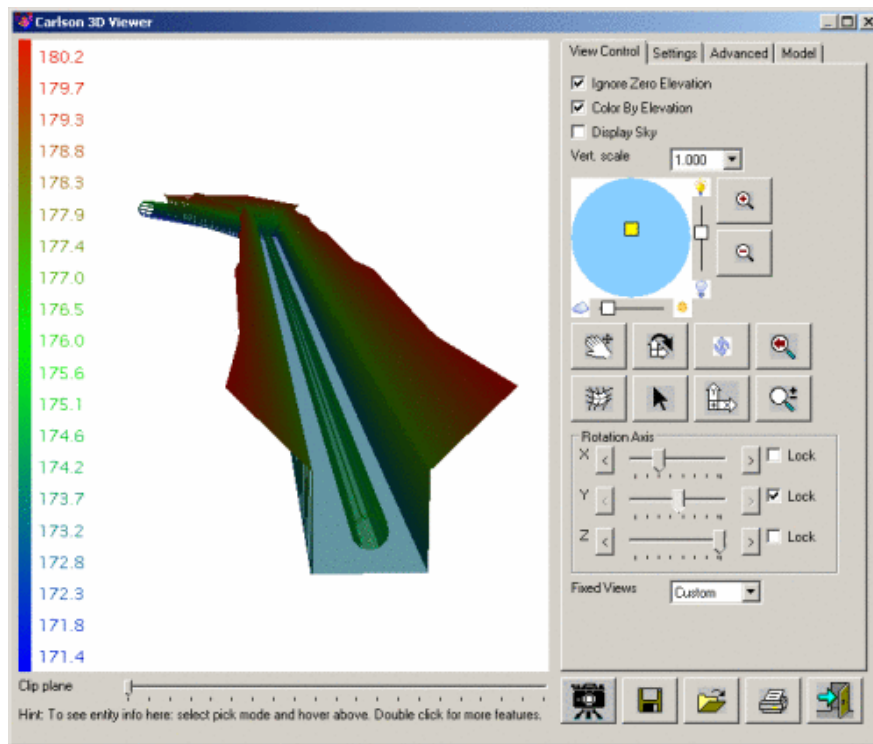

Setup Depth Zones will breakout your trench cut volumes according to user-defined "depth zones" of the trench. You can also color the trench in the drawing by these defined zones. The Width value is used with the Draw Plan View Zone Map for the width of the trench lines. The Manhole Cost is for reporting the structure cost by zone depth. The Linear Cost is for reporting the linear cost for the trench lines by zone depth.

Create Trench TIN Surface will create a triangulation surface of the trench. Under the Setup dialog, the Write Triangulation File option will have the program prompt for a TIN file to create for the trench surface. The Draw Triangulation Faces option creates 3D faces in the drawing on the Layer Name from this dialog. Use "View > 3D Viewer Window" to display the new 3D faces in 3D. Note: Pipes are automatically displayed in 3D from the linework created in "Draw Trench Network (Plan View)". To turn 3D pipes off in the viewer, freeze the layer created with "Draw Trench Network (Plan View)". By default this layer is "SWRNET".

Click OK to compute the template volumes. Backfill quantities take into account pipe size. A report would be shown after the calculation and any depth zone linework and 3D faces will be drawn in the plan view.

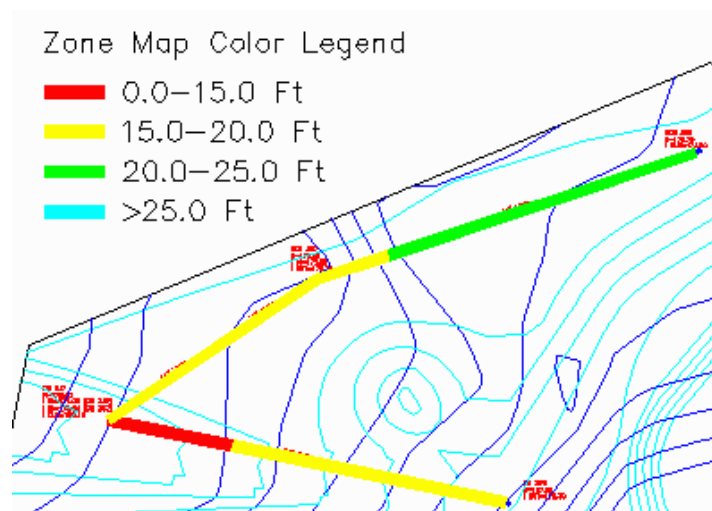

Prompts

Trench Quantities Report Window

Draw zone map color legend on the screen [Yes/No]: *y for Yes*

Pick a point for color legend: *pick a point away from site*

Legend size <10.00>: *Press <Enter> for the default*

Pulldown Menu Location: Trench

Prerequisite: Your drawing is open, has been cleaned up and pre-processed by such commands as Define Layer Target, Set Boundary Polyline, Make Existing Ground Surface and Make Design Surface. Trench structure data has been stored in a .sew file, whose name is as same as the drawing name.

Keyboard Command: calc_trench

Trench Quantities By Profiles

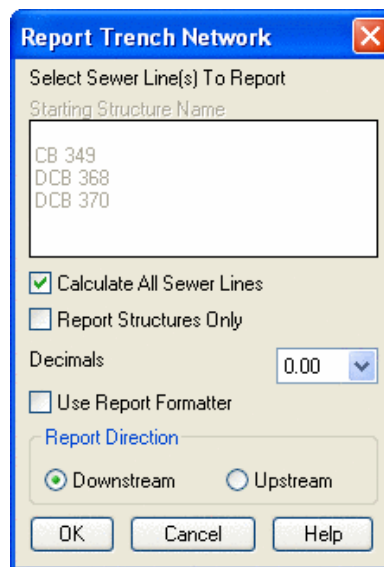

This command calculates trench quantities using two profiles that define the ground surface and the pipeline. See the Pipe Depth Summary command in the Profiles chapter for more information.

Pulldown Menu Location: Trench

Prerequisite: Two profiles

Report Trench Network

This command will a report the Name, Station Distance, Invert-In Slope, Invert-Out Width, the Rim Elevation, Trench Type, Manhole Depth, and the Area Direction for the selected Trench. You may also choose to report the Trench Network from Downstream or Upstream, or just the Structures.

Keyboard Command: reportswr

CADnet Module

11

Digitize Menu

The Takeoff menu commands create drawing entities by digitizing on paper plans or on-screen raster images.

Tablet On

Executes AutoCad's TABLET command to set the tablet on. Refer to the AutoCad Reference manual for further information.

Note: Function key [F4] can toggle on/off tablet.

Keyboard Command: tablet

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

Tablet Off

Executes AutoCad's TABLET command to set the tablet on. Refer to the AutoCad Reference manual for further information.

Note: Function key [F4] can toggle on/off tablet.

Keyboard Command: tablet

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

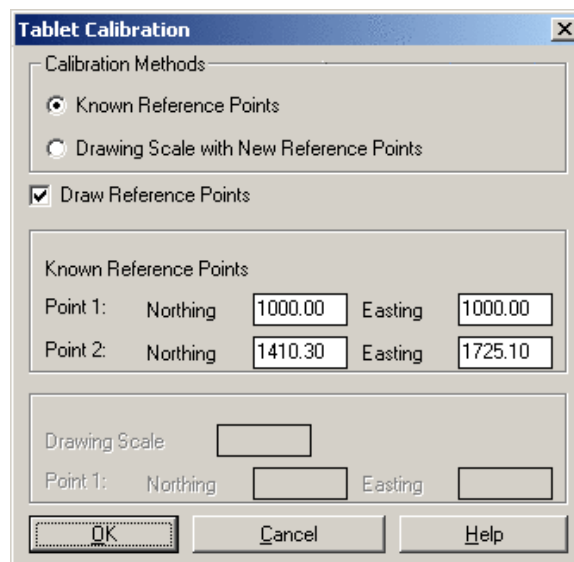

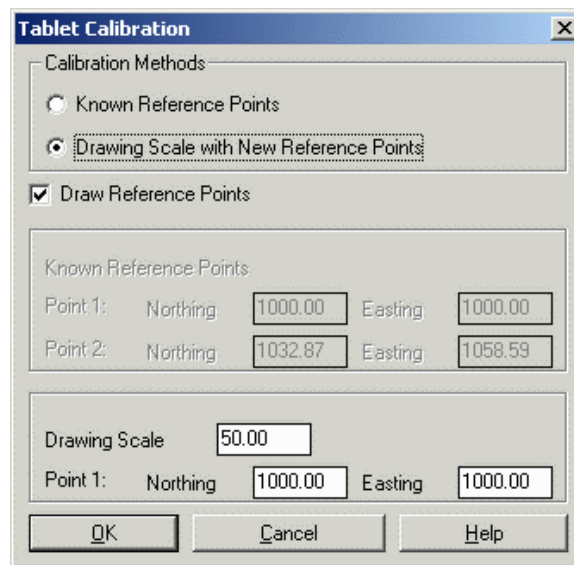

Tablet Calibrate

You can calibrate the tablet/digitizer in one of two ways: **Known Reference Points** or **Drawing Scale with New Reference Points**. Reference points are the foundations of whatever data you digitize into the computer. Takeoff bases everything from drawing location to drawing scale on the reference points you digitize.

Drawing Scale with New Reference Points method is very convenient when you don't know the precise coordinates of the entities on your drawing. As long as you can obtain the drawing scale from your plan, this method can establish a coordinate system relative to the position of the plan on the digitizer board. In addition to the drawing scale, you are required to enter a random coordinate for the first reference point, the default coordinate is (1000,1000). Takeoff would computer the coordinate of the second reference point that you pick based on the first point. The coordinates of these two reference points would be saved and will be display on the **Tablet Calibration Dialog** next time when you calibrate the tablet, so you can digitize back to the previous coordinates using **Know Reference Points** method if you are working on the same drawing, though you might have moved or rotated your drawing on the digitize board..

If you know the precise coordinates of two points, you can select **Known Reference Points** method, which establishes a coordinate system that is exactly match the coordinates in the field or on your drawing. Furthermore, Takeoff saves the coordinates of the two reference points from previous calibration and displays them on the **Tablet Calibration Dialog** next time when you calibrate the tablet. If you want to continue to work on the same drawing, you can use the **Know Reference Points** method with the saved coordinates to digitize back to your previous coordinates although you might have moved or rotated your drawing on the digitizer board.

For accurate takeoff calculations, choose two points that can be easily found in the field and are farther apart rather than closer together.

Prompts

Tablet Calibration Dialog

Specify the Calibration Methods. If you select Drawing Scale method, enter the drawing scale and the coordinate of the first reference point. Otherwise enter the exact coordinates of the first and second reference points.

Pick first reference point: *pick a point on the drawing*

Pick second reference point: *pick another point on the drawing*

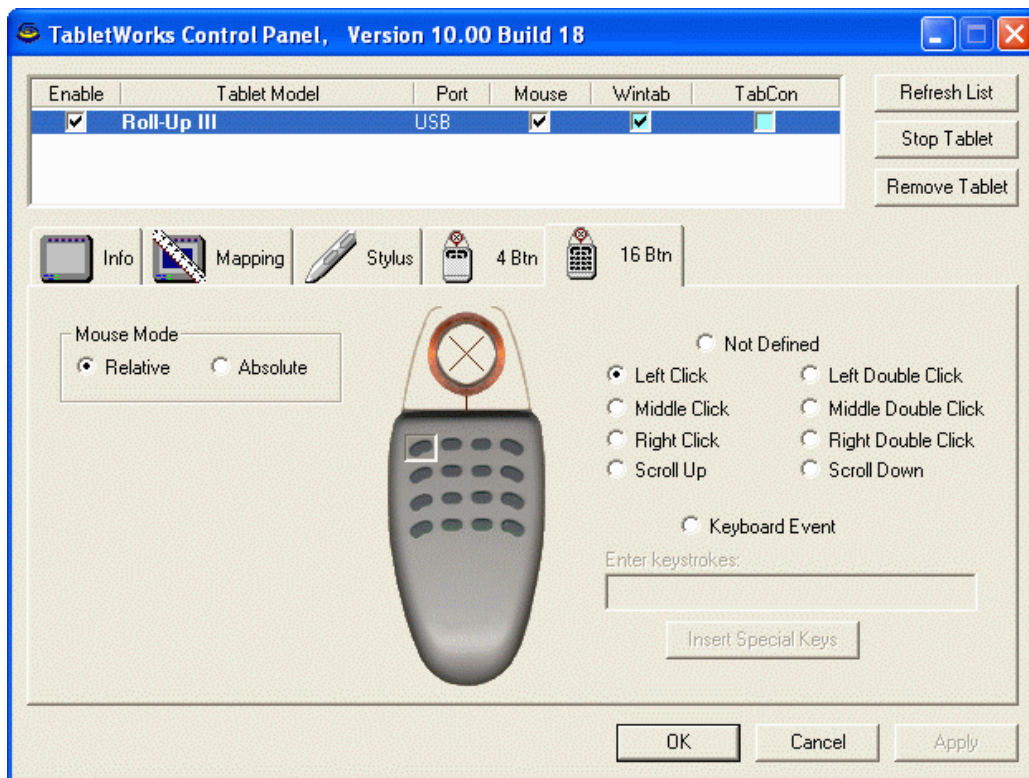

Keyboard Command: digsetup

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

Digitizer Setup

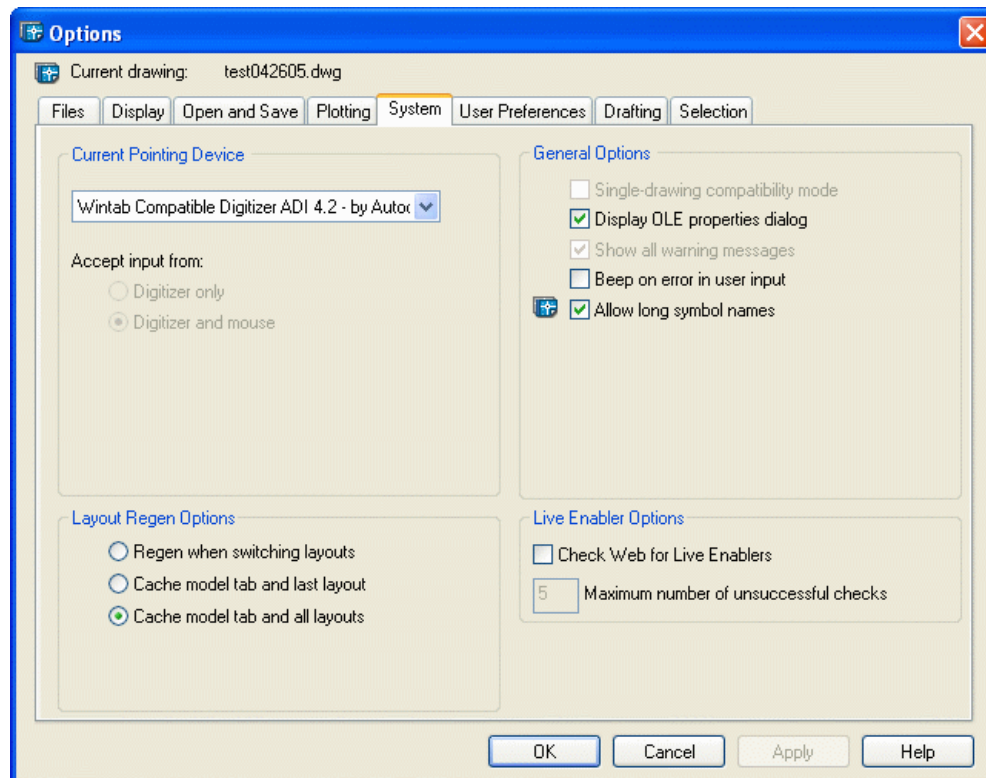

Digitizing is the act of inputting data into the computer by tracing the data from a plan sheet. You need to have a digitizer board, puck, Carlson Takeoff, your computer and your plan to do digitizing. Wintab is a digitizer driver that lets you to use the digitizer cursor as both a digitizer cursor and a mouse. You need to install Wintab when you install Carlson Takeoff. Wintab can be downloaded from GTCO web site: <http://www.gtcocalcomp.com/supportgtcosoftware.htm>. Select the driver version that suits the type of your digitizer board well.

After you installed Wintab driver on your computer, you set up you digitizer to the correct point mode. In Windows 2000/XP, go to **Start->Settings->Control Panel->TabletWorks**, high light the **16-Btn Cursor**, and select **Mouse** as the **Pointing Mode**, which lets the digitizer cursor moves relatively to the screen coordinates. This step is indicated in the following **TabletWorks Control Panel** dialog.

The next is to set up the pointing device in Carlson Takeoff. Open up Takeoff and go to pull-down **Settings-**

>**Preferences**, click tab **System**, select **Wintab Compatible Digitizer** as **Current Pointing Device**, and set the **Accept input from** to **Digitize and mouse**. Please refer to the following **Options** dialog.

Now, you are ready to use your digitizer. On the bottom of the screen, there is a tray icon **TABLET** on the right side of **MODEL**. You can use accelerator key **F4** to toggle on/off the tablet.

Save Tablet Calibration

This command saves current tablet calibration to a file. You are prompted to enter a file name.

Keyboard Command: tablet1

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Load Tablet Calibration

This command restores the tablet calibration parameters from a file and load it into the current drawing. You are prompted to specify a file name.

Keyboard Command: tablet2

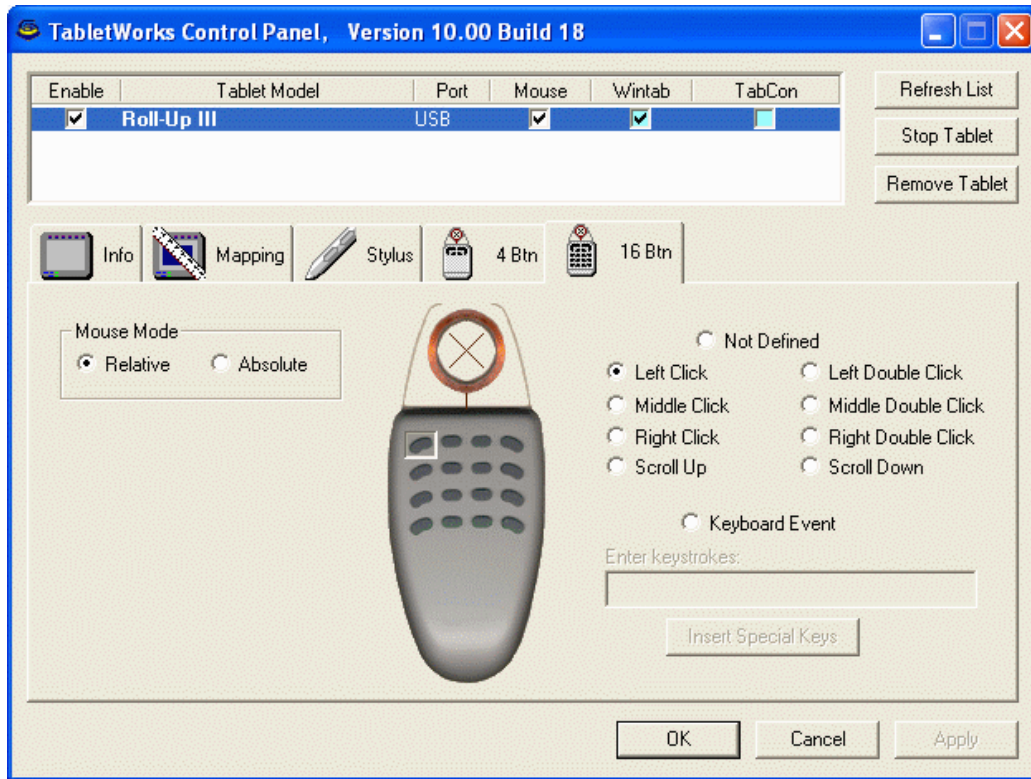

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. The calibration file should be associated to the current drawing, and the current drawing shouldn't have been moved on the digitizer board since last calibration.

Digitize

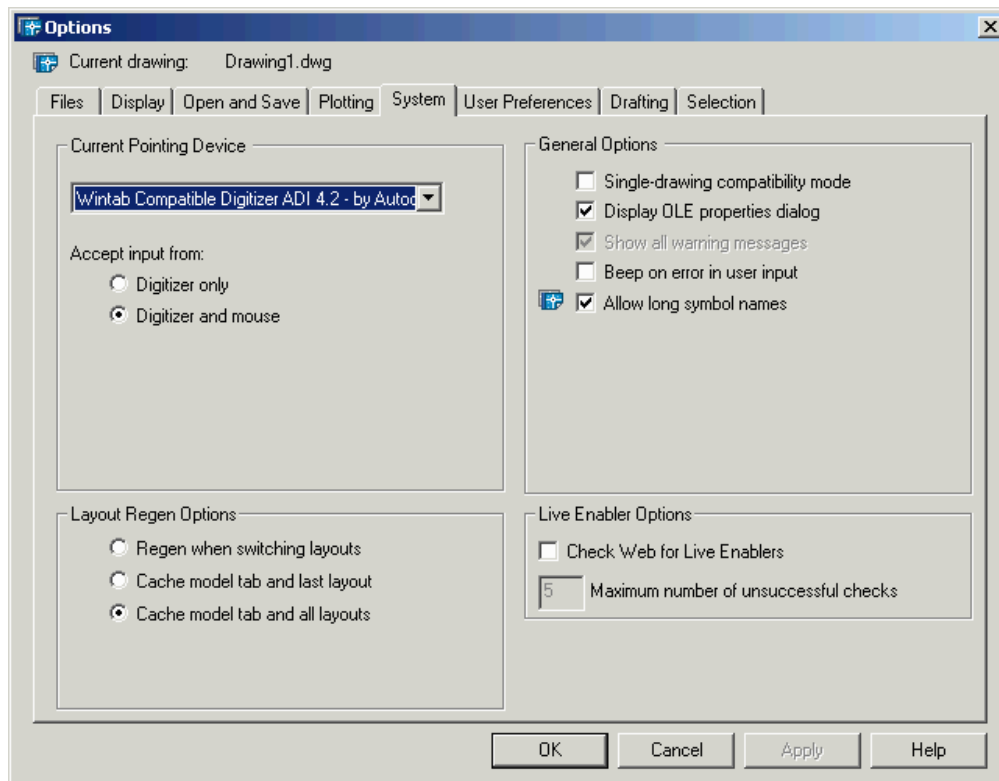

Digitizing is the act of inputting data into the computer by tracing the data from a plan sheet. You need to have a digitizer board, puck, Carlson Takeoff, your computer and your plan to do digitizing. Wintab is a digitizer driver that lets you to use the digitizer cursor as both a digitizer cursor and a mouse. You

need to install Wintab when you install Carlson Takeoff. Wintab can be downloaded from GTCO web site: <http://www.gtcocalcomp.com/supportgtcosoftware.htm>. Select the driver version that suits the type of your digitizer board well.

After you installed Wintab driver on your computer, you set up you digitizer to the correct point mode. In Windows 2000/XP, go to **Start->Settings->Control Panel->TabletWorks**, high light the **16-Btn Cursor**, and select **Mouse** as the **Pointing Mode**, which lets the digitizer cursor moves relatively to the screen coordinates. This step is indicated in the following **TabletWorks Control Panel** dialog.

The next is to set up the pointing device in Carlson Takeoff. Open up Takeoff and go to pull-down **Settings->Preferences**, click tab **System**, select **Wintab Compatible Digitizer as Current Pointing Device**, and set the **Accept input from** to **Digitize and mouse**. Please refer to the following **Options** dialog.

Now, you are ready to use your digitizer. On the bottom of the screen, there is a tray icon TABLET on the right side of MODEL. You can use accelerator key **F4** to toggle on/off the tablet.

The 16-button puck can be used as either a mouse or a digitizer. It's very important to understand how the 16 buttons are mapped in both modes.

Mouse Mode:

When the tablet is off, the puck is in Mouse Mode. The top-left button is the left mouse click, and the top-right button is the right mouse click. The labels on the other buttons do not mean anything. All buttons are mapped as same as the buttons of the default pointing device in AutoCad . Please refer to AutoCad Reference manual for further information.

Digitize Mode:

When tablet has been calibrated and is on, the puck is in digitize mode. It is mapped as a small keyboard, which enables you to enter numerous values such as elevation, thickness and offset etc., and also provide you some functionality to digitize various entities. Currently there are two puck layouts in Takeoff, shown in the figure below. After you install Carlson Takeoff and finish setting up the digitizer, you go to the pull-down menu **Digitize->Puck Layout** to select a 16-button puck layout. A button mapping would be created and Takeoff would recognize the buttons as represented.

Layout 1 is Carlson Puck Layout, which is the most common layout used in Carlson Takeoff. Layout 2 is for users who don't have a Carlson Puck. If your puck is different than these two layouts, please contact Technical Support for help setting the mapping for your 16 button puck.

Prompts:

Digitizer Settings Dialog

Specify the Digitizer Puck Layout to layout 1 or 2

Keyboard Command:

dig_config

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

Function:

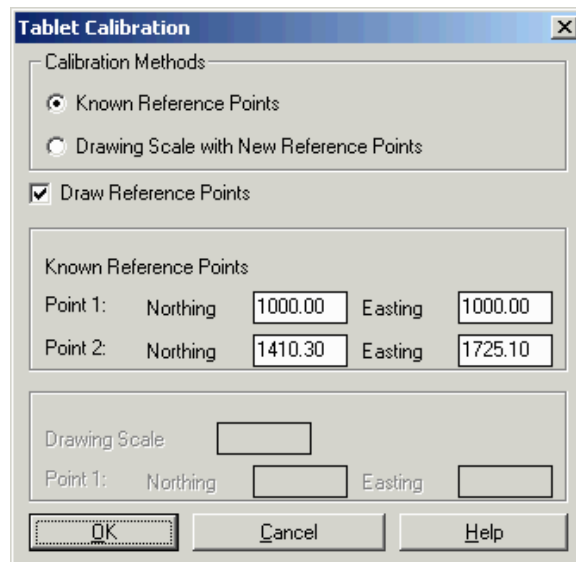

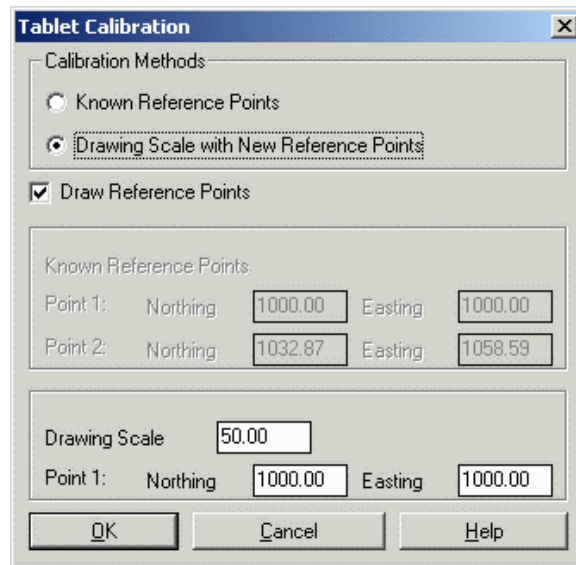

You can calibrate the tablet/digitizer in one of two ways: **Known Reference Points** or **Drawing Scale with New Reference Points**. Reference points are the foundations of whatever data you digitize into the computer. Takeoff bases everything from drawing location to drawing scale on the reference points you digitize.

Drawing Scale with New Reference Points method is very convenient when you don't know the precise coordinates of the entities on your drawing. As long as you can obtain the drawing scale from your plan, this method can establish a coordinate system relative to the position of the plan on the digitizer board. In addition to the drawing scale, you are required to enter a random coordinate for the first reference point, the default coordinate is (1000,1000). Takeoff would computer the coordinate of the second reference point that you pick based on the first

point. The coordinates of these two reference points would be saved and will be display on the **Tablet Calibration Dialog** next time when you calibrate the tablet, so you can digitize back to the previous coordinates using **Know Reference Points** method if you are working on the same drawing, though you might have moved or rotated your drawing on the digitize board..

If you know the precise coordinates of two points, you can select **Known Reference Points** method, which establishes a coordinate system that is exactly match the coordinates in the field or on your drawing. Furthermore, Takeoff saves the coordinates of the two reference points from previous calibration and displays them on the **Tablet Calibration Dialog** next time when you calibrate the tablet. If you want to continue to work on the same drawing, you can use the **Know Reference Points** method with the saved coordinates to digitize back to your previous coordinates although you might have moved or rotated your drawing on the digitizer board.

For accurate takeoff calculations, choose two points that can be easily found in the field and are farther apart rather than closer together.

Prompts:

Tablet Calibration Dialog

Specify the Calibration Methods. If you select Drawing Scale method, enter the drawing scale and the coordinate of the first reference point. Otherwise enter the exact coordinates of the first and second reference points.

Pick first reference point:*pick a point on the drawing*

Pick second reference point:*pick another point on the drawing*

Keyboard Command:

digsetup

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

Function:

Executes AutoCad's TABLET command to set the tablet on. Refer to the AutoCad Reference manual for further information.

P.S. Function key [F4] can toggle on/off tablet.

Keyboard Command:

tablet

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up.

Function:

Executes AutoCad's TABLET command to set the tablet on. Refer to the AutoCad Reference manual for further information.

P.S. Function key [F4] can toggle on/off tablet.

Keyboard Command:

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Function:

This command allows you to label points with their elevation. The point can either be digitized from a drawing, picked on a screen or specified by a point number. The command first prompts you the **Label Spot Elevation Dialog** for entering layer name, label prefix and suffix and symbol types etc. Click OK to start. After specifying the point, the command prompts you to enter the elevation if its elevation is unknown and then pick an angle from the location of the point to label the elevation. You can repeat labeling points until you press **Enter** to finish.

Prompts:

Label Spot Elevation Dialog

Specify a layer name, label prefix and suffix and select the spot symbol.

Point to Label ?

Pick point or point number: 2 (enter a point number)

PointNo. Northing(Y) Easting(X) Elev(Z) Description

2 1231.16 1099.17 30.00 bb

Note: if the point number you entered is not in the drawing, you will be prompted again to pick point or enter a point number.

Elevation <30.000>: *press enter*

Pick angle for label: *pick an angle from the spot*

Point to Label (ENTER to End)?

Pick point or point number: *pick a point on the drawing*

Elevation <0.000>: *enter elevation*

Pick angle for label: *pick an angle from the spot*

Point to Label (ENTER to End)?

Pick point or point number: *press enter to finish*

Keyboard Command:

labspot

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Function:

2D polyline is a line of connected points that have the same elevation. This command lets you digitize a 2D polyline by picking points along the lines on the drawing. It prompts you first the **Polyline 2D Options Dialog** for entering the layer name. **Prompt For Polyline Elevation** option allows you to enter the elevation for each polyline, otherwise all 2D polylines have 0.0 elevation. **Auto-Zoom** mode would automatically zoom the display to center around the last point when you get near the edge of the screen while picking points. There are three ways to enter a layer name, **Use current drawing layer**, **Select** from a list of layer name, or **Pick** an entity on the screen to get its layer name. While digitizing a polyline, the command keeps prompting you to pick next point until your **press Enter** to finish digitizing, or **press A** on the puck or **enter Close** on the keyboard to close the polyline on itself. If you make a mistake, **press B** on the puck or **enter Undo** on the keyboard to remove the mistake and then continue to digitize. After finishing a polyline, the command prompts your to digitize another polyline until you **press B** or **enter No**.

Prompts:

Polyline 2D Options Dialog

Enter the layer name and select the options of Prompt For Polyline Elevation and Auto-Zoom mode etc.

Enter default elevation <0.00>: 100

First point: *pick a point on the drawing using puck*

Segment length: 0.00, Total length: 0.00

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 119.03, Total length: 119.03

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 121.76, Total length: 240.80

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 115.23, Total length: 356.03

Close[A]/Undo[B]/Pick next point (Enter to end): *press enter to finish digitizing or press A to close the polyline*

Digitize Another FINAL Polyline [Yes(A)/<No(B)>]?: *press A on the puck or enter Yes on the keyboard to digitize next 2D polyline, press B on the puck or enter No on the keyboard to finish digitizing 2D polyline.*

Keyboard Command:

dig_2dp

Pull-Down Menu Location:

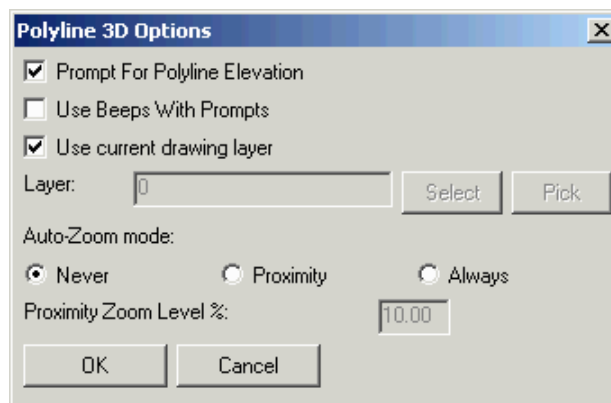

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Function:

3D polyline is a line of connected points that have various elevations, and the slope between points is constant. It can be used in defining pads, excavations, drainage ditched and slopes from proposed design features to meet existing site conditions. This command lets you digitize a 3D polyline by picking points along the lines on the drawing. It prompts you first the **Polyline 3D Options Dialog** for entering the layer name. **Prompt For Polyline Elevation** option allows you to enter the elevation for each point you pick. If you don't select this option, all points have 0.0 elevation and you get a 2D polyline. There are four ways to enter elevations: known elevation of the point, slope from previous point, ratio from previous point and degree from previous point. You can choose one of the methods between picking points. **Auto-Zoom** mode would automatically zoom the display to center around the last point when you get near the edge of the screen while picking points. While digitizing a polyline, the command keeps prompting you to pick next point until your **press Enter** to finish digitizing, or **press A** on the puck or **enter Close** on the keyboard to close the polyline on itself. If you make a mistake, **press B** on the puck or **enter Undo** on the keyboard to remove the mistake and then continue to digitize. After finishing a polyline, the command prompts your to digitize another polyline until you **press B** or **enter No**.

Prompts:

Polyline 3D Options Dialog

Enter the layer name, toggle on Prompt For Polyline Elevation and select the Auto-Zoom mode.

First point: *pick a point on the drawing*

Elevation <0.00>: *12 (enter the elevation)*

Z: 12.00, Hz dist: 0.00, Slope dist: 0.00, Slope: 0.0% Ratio: 0.0:1

Close[A]/Undo[B]/Pick next point (Enter to end): *pick a point on the drawing*

Slope/Ratio/Point/Degree/<Elevation> <0.00>: *S (switch to entering Slope)*

Ratio/Point/Elevation/Degree/<Slope> <-8.24>: *12 (enter the slope)*

Z: 29.47, Hz dist: 145.56, Slope dist: 146.61, Slope: 12.0% Ratio: 8.3:1

Close[A]/Undo[B]/Pick next point (Enter to end): *pick a point on the drawing*

Segment length: 153.14, Total length: 257.41

Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Segment length: 104.89, Total length: 362.30

Close[A]/Undo[B]/Pick next point (Enter to end): press Enter to finish the perimeter, or press A to close the perimeter

Digitize Another PERIMETER Polyline [Yes(A)/<No(B)>]? press A or enter Yes to continue digitizing another perimeter, press B or enter No to finish digitizing perimeters.

Keyboard Command:

dig_perim

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

A contour is a line of points with a constant elevation, representing the natural contour of the site. In Takeoff, there are two layer targets: **Existing Ground Surface** and **Design Surface**. Contour Polyline has two sub-command to digitize contour lines into Existing Contour and Final Contour layers directly for assigning them easily into Existing Ground Surface and Design Surface in the future analysis.

There are two ways to digitize contour lines: sketch mode or point mode.

Sketch Mode:

In sketch mode, you press the digitize button on the puck and release it to make the digitizer ready to sketch the contour lines. Then you move the digitizer cursor along the lines on your drawing. If you make a mistake, you first release the digitizer by press the **Enter** button on the puck if you are using a Carlson Puck Layout, otherwise you need to press the top-right button. Next you press B on the puck or enter Undo on the keyboard to remove your mistake, keep doing this step until you remove all you mistake. After that, you move your cursor to the position that you want to continue digitizing on the same line, press and release the digitize button, and trace the contour line by moving the cursor. You can always stop digitizing by pressing **Enter** button of a Carlson Puck (or top-right button for all other pucks) or keyboard, and then press the digitize button again to start tracing. When you finish digitizing, your first put the pen down by pressing **Enter** on the Carlson Puck (or top-right button for all other pucks) or keyboard, then press **Enter** on the puck to finish the contour line, or **press A** on the puck or **enter Close** on the keyboard to close the contour on itself.

Usually sketch mode uses more points then point mode. But you can reduce the number of points by specifying larger increment in sketch mode. Choosing smaller increment if your contour lines have more curved parts, otherwise choosing larger increment. Also Takeoff will automatically reduce the number of points on the straight parts of lines. Sketch mode digitizing is fast and accurate. You might need a little practice in order to get familiar with the command line prompts.

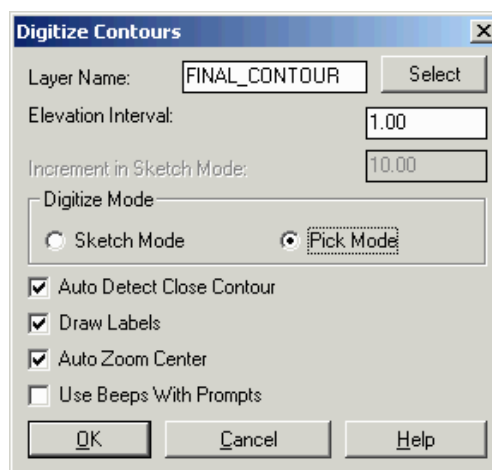

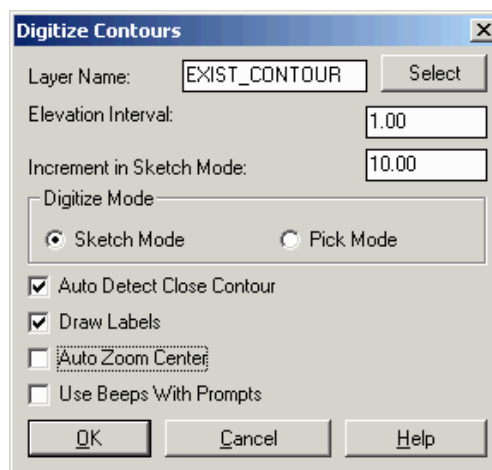

Pick Mode:

Pick mode digitizing allows your to digitize a contour line one point at a time. This method creates a new data point each time you press and release the digitize button. If you make a mistake, you can **press B** on the puck or **enter Undo** on the keyboard to remove the mistake, and then continue to digitize by picking point along the line on the drawing. In general, we recommend using pick mode to digitize because it reduces the number of points and speeds up Takeoff's calculations.

Function:

This command lets you digitize contours as polylines one at a time. The first time it prompts you the **Digitize Contours Dialog**. Enter the layer name or select it from a list of existing layer. Look at your plans and determine an elevation interval that is between most of the contours and enter it in the Elevation Interval field. You are able to modify both the value and the direction of the elevation interval between digitizing contour lines, using the buttons on the puck. If you decide to do Sketch mode digitizing, you need to enter the increment field. To have Takeoff automatically close contours whose beginning and ending points are within a specified range, check the Auto Detect Close Contour. Draw Labels would draw the elevation at the starting point of the contour. In Pick mode, if you want the Takeoff to automatically zoom the display to center around the last point when you get near the edge of the screen while picking points, check the Auto Zoom Center. Click OK to start digitizing.

Place your cursor at one end of the contour line and begin digitizing the line. While digitizing a line, you can force a contour to close on itself by **pressing A** on the puck to end the contour and connect the last point to the first point, or remove a mistake by **pressing B** on the puck. At the end of the contour line, **press Enter** on your puck or keyboard. The contour is completed, and the elevation for the next contour is automatically incremented. You would be asked to digitize next contour. If you **press A** on the puck or **enter Yes** on the keyboard, you can digitize another contour, or **press B** on the puck or **enter No** on the keyboard to finish digitizing contours.

Digitize Contour in Sketch Mode Digitize Contour in Pick Mode

Prompts:

Sketch Mode:

Digitize Contours Dialog

Enter Layer Name, Elevation Interval, Increment in Sketch Mode if select Sketch Mode, and toggle on/off Auto Detect Close Contour etc.

Increment(1.00)[A]/Direction(+)[B]/Elevation <573.00>: 450 (*enter elevation or press Enter to accept current value*)

Pick and drag to digitize (Enter to finish): <Pen down> <Pen up> (*press Enter on the puck or keyboard to finish sketching*)

1 polyline with 243 edges recorded.

Note:

If you are using puck layout 2, Takeoff would prompt you differently here.

Pick and drag to digitize (Press [0]/Enter to finish): <Pen down> <Pen up> (*press 0 on the puck or press Enter on the keyboard to finish sketching*)

1 polyline with 243 edges recorded.

Close[A]/Undo[B]/Pick to continue (Enter to finish): *press Enter on the puck or keyboard to finish the contour line*

Digitize Another Contour [<Yes(A)>/No(B)]? A (*press A to digitize next contour line*)

Increment(1.00)[A]/Direction(+)[B]/Elevation <451.00>: A

(Elevation is automatically incremented. Press A on the puck or keyboard to increase it by the Increment again.)

Increment(1.00)[A]/Direction(+)[B]/Elevation <452.00>: *press Enter on the puck or keyboard to start digitizing*

Pick and drag to digitize (Enter to finish): <Pen down> <Pen up> (*press Enter on the puck or keyboard to finish sketching*)

1 polyline with 234 edges recorded.

Note:

If you are using puck layout 2, then Takeoff would prompt you differently here.

Pick and drag to digitize (Press [0]/Enter to finish): <Pen down> <Pen up> (*press 0 on the puck or press Enter on the keyboard to finish sketching*)

1 polyline with 234 edges recorded.

Close[A]/Undo[B]/Pick to continue (Enter to finish):

Digitize Another Contour [<Yes(A)>/No(B)]? A (*press A to digitize next contour line*)

Increment(1.00)[A]/Direction(+)[B]/Elevation <453.00>: B

(Elevation is automatically incremented. Press B on the puck or keyboard to change the increment from positive to negative.)

Increment(1.00)[A]/Direction(-)[B]/Elevation <452.00>: A (*Press A on the puck or keyboard to increase it by the Increment again.*)

Increment(1.00)[A]/Direction(-)[B]/Elevation <451.00>: A (*Press A on the puck or keyboard to increase it by the Increment again.*)

Increment(1.00)[A]/Direction(-)[B]/Elevation <450.00>: A (*Press A on the puck or keyboard to increase it by the Increment again.*)

Increment(1.00)[A]/Direction(-)[B]/Elevation <449.00>: A (*Press A on the puck or keyboard to increase it by the Increment again.*)

Increment(1.00)[A]/Direction(-)[B]/Elevation <448.00>: *press Enter on the puck or keyboard to start digitizing*

Pick and drag to digitize (Enter to finish): <Pen down> <Pen up> (*press Enter on the puck or keyboard to finish sketching*)

1 polyline with 109 edges recorded.

Note:

If you are using puck layout 2, then Takeoff would prompt you differently here.

Pick and drag to digitize (Press [0]/Enter to finish): <Pen down> <Pen up> (press 0 on the puck or press Enter on the keyboard to finish sketching)

1 polyline with 109 edges recorded.

Close[A]/Undo[B]/Pick to continue (Enter to finish): *press Enter on the puck or keyboard to finish the contour line*

Digitize Another Contour [<Yes(A)>/No(B)]? B *(press B to finish digitizing contour line in sketch mode)*

Pick Mode:

Digitize Contours Dialog

Enter Layer Name, Elevation Interval, Increment in Sketch Mode if select Sketch Mode, and toggle on/off Auto Detect Close Contour etc.

Increment(1.00)[A]/Direction(+)[B]/Elevation <458.00>: *press Enter on the puck or keyboard to start digitizing*

First point:

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

(You can force a contour to close on itself by pressing A or remove mistake by pressing B.)

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *press Enter to finish picking*

Digitize Another Contour [<Yes(A)>/No(B)]? A *(press A to digitize next contour line)*

Increment(1.00)[A]/Direction(+)[B]/Elevation <459.00>: *press Enter on the puck or keyboard to start digitizing*

First point:

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Close[A]/Undo[B]/Pick next point (Enter to end): *press Enter to finish picking*

Digitize Another Contour [<Yes(A)>/No(B)]? B *(press B on the puck or enter No on the keyboard to finish digitizing contour line in pick mode)*

Keyboard Command:

digcont_exist, digcont_final

Pull-Down Menu Location:

Digitize

Prerequisite:

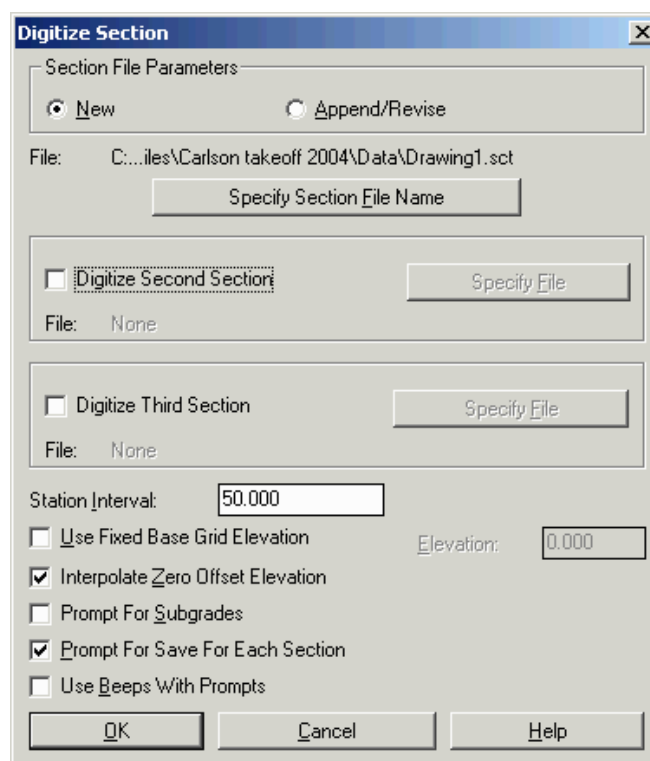

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Functions:

This command allows you to digitize section lines and store the section data in the section file you have specified. The command first prompts you the **Digitize Section Dialog**. Enter the section file name and determine if you want to digitize second and third sections at the same station. Look at your plans and determines the station interval,

which is used to automatically default to the next station value when digitizing a series of stations. If the grids at all the stations have the same base elevation, toggle on Use Fixed Base Grid Elevation. You can also toggle on Interpolate Zero Offset Elevation, Prompt for Subgrades, Prompt for Save for Each Section and Use Beeps with Prompts. Click OK to start digitizing.

Takeoff prompts you to calibrate the section sheet before you digitize the section lines. You pick three points and specify their offsets to the centerline and elevations in order to determine the horizontal and vertical intervals. Corners on the section grid are preferred reference points. Place your cursor at one end of the section line and begin digitizing the line. While digitizing a line, you can remove a mistake by **pressing A** on the puck or **entering Undo** on the keyboard. At the end of the section line, **press Enter** on your puck or keyboard. The station is completed, and the station value is automatically incremented. The command would prompts to digitize next section. You can **press A** on the puck or **enter Exit** on the keyboard to finish digitizing. If you want to continue to digitize next section, **press Enter** or enter the new station number. For every station after the first one, you can calibrate the grid sheet by picking one reference point and specify its offset and elevation. After you digitize the section lines on your drawing, all the section data would be saved in a section file (.sct).

Prompts:

Digitize Section Dialog

Enter Section File Name, Station Interval, and toggle on/off Use Fixed Base Grid Elevation etc.

Section station to digitize <0.000>: *press Enter to start with station 0.0 or enter a station number*

Calibrate section sheet

Pick First section sheet reference point: *pick a grid point of this station on your drawing*

Enter offset <0.0>: *press Enter to accept the offset or enter the offset of the point to the centerline*

Enter elevation: 1030 *(enter the Elevation of the reference point)*

Pick Second section reference point: *pick the second grid point*

Enter offset: 0 *(enter the offset of the point to the centerline)*

Enter elevation: 1040 *(enter the Elevation of the reference point)*

Pick Third section reference point: *pick the third grid point*
Enter offset: 50 (*enter the offset of the point to the centerline*)
Enter elevation: 1040 (*enter the Elevation of the reference point*)

Keyboard Command:

digxsec

Pull-Down Menu Location:

Digitize

Prerequisite:

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Functions:

There are two types of end areas: cut area and fill area. This command allows you to digitize both cut area and fill area on the drawing and writes data to a .ew file. The command first prompts you to calibrate the section sheet by picking three points and specify their offsets to the centerline and elevations in order to determine the horizontal and vertical intervals. Corners on the section grid are preferred reference points. Then it prompts you to digitize the cut area and fill area respectively. Place your cursor at one end of the end area and begin digitizing the outline of the area. At the end of the section line, **press Enter** on your puck or keyboard. The end area is completed, and its area is printed on the command line, and you are prompted to digitize next end area. After you finish all the end area at one station, accumulated cut area and fill area are computed and printed out on the screen. All data of cut area and fill area at every station would be saved in the area file (.ew) that you have specified.

Prompts:

Calibrate section sheet

Pick First section sheet reference point: *pick a point on the drawing*

Enter offset <0.0>: *press Enter to accept the offset (or enter the offset of the point to the centerline)*

Enter elevation: 1020 *(enter the Elevation of the reference point)*

Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitizer Settings

This command allows you to select the puck layout and set Auto On/Off features.

Auto Tablet On For Digitize Commands means after you select a digitize command your puck will automatically be put in Digitize Mode. If this is toggle off, then you will need to turn Tablet on separately from running a digitize command.

Auto Tablet Off After Digitize Commands means you will return to Mouse Mode after running a digitize command. Read below for more on Mouse and Digitize Mode.

Puck Layout

The 16-button puck can be used as either a mouse or a digitizer. It's very important to understand how the 16 buttons are mapped in both modes.

Mouse Mode

When the tablet is off, the puck is in Mouse Mode. The top-left button is the left mouse click, and the top-right button is the right mouse click. The labels on the other buttons do not mean anything. All buttons are mapped as same as the buttons of the default pointing device in AutoCad . Please refer to AutoCad Reference manual for further information.

Digitize Mode

When tablet has been calibrated and is on, the puck is in digitize mode. It is mapped as a small keyboard, which enables you to enter numerous values such as elevation, thickness and offset etc., and also provide you some functionality to digitize various entities. Currently there are two puck layouts in Takeoff, shown in the figure below. After you install Carlson Takeoff and finish setting up the digitizer, you go to the pull-down menu **Digitize->Puck Layout** to select a 16-button puck layout. A button mapping would be created and Takeoff would recognize the buttons as represented.

Layout 1 is Carlson Puck Layout, which is the most common layout used in Carlson Takeoff. Layout 2 is for users who don't have a Carlson Puck. If your puck is different than these two layouts, please contact Technical Support for help setting the mapping for your 16 button puck.

Prompts

Digitizer Settings Dialog

Specify the Digitizer Puck Layout to layout 1 or 2

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed.

Keyboard Command: dig_config

Digitize Existing

This sets the layer target to existing. Set this prior to running any digitizing command and anything you digitize will be assigned for your existing surface. Checkout the Define Layer Target/Material/Subgrade command under Tools for more on targets.

Keyboard Command: set_digit_exist

Prerequisite: none

Digitize Design

This sets the layer target to design. Set this prior to running any digitizing command and anything you digitize will be assigned for your design surface. Checkout the Define Layer Target/Material/Subgrade command under Tools for more on targets.

Prerequisite: none

Keyboard Command: set_digit_final

Digitize Other

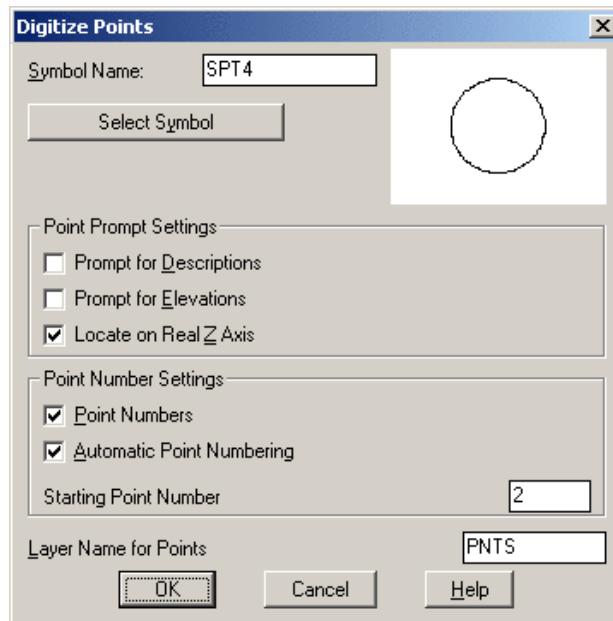

This sets the layer target to other. Set this prior to running any digitizing command and anything you digitize will be assigned to the Other target. Checkout the Define Layer Target/Material/Subgrade command under Tools for more on targets.

Keyboard Command: set_digit_other

Prerequisite: none

Digitize Point

This command allows you to digitize individual points one at a time. The first time it prompts you the **Digitize Points Dialog** for entering point symbol styles, point prompt settings and number settings, starting point number and layer name. If you want to enter the elevation and description for each point, select **Prompt for Descriptions** and **Prompt for Elevations**. After having digitized a point, you can continue to digitize next point by picking the point on the drawing. The command defaults to the last layer name, point symbol, elevation, description and the last point number plus 1. If you have finished digitizing points, press **Enter** to finish.

Prompts

Digitize Points Dialog

Specify a layer name and select the point symbol, point prompt settings and number settings.

Pick point to create (Enter to end): *pick a point on the drawing*

Select/<Enter Point Elevation <>>: *enter the elevation or type <Select> to select the elevation text on the screen*

Enter Point Description <>: *enter the point description*

Result like "N: 1231.16 E: 1099.17 Z: 30.00" would be display on the command line, and a point would be drawn on the screen with the text of its number, elevation and description.

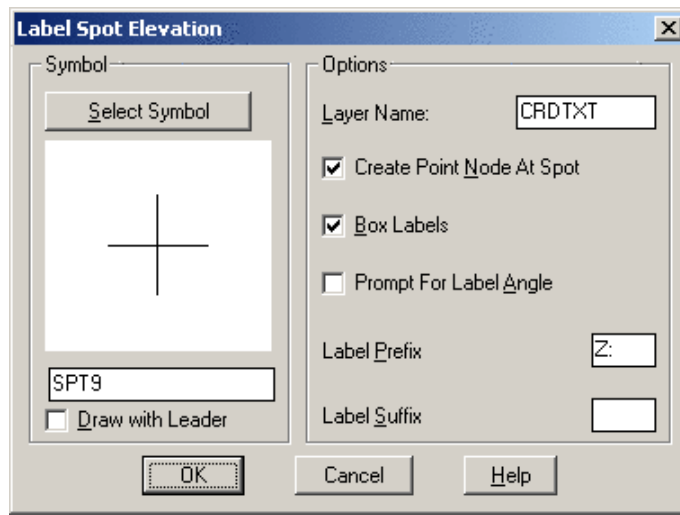

Pick point to create (Enter to end): *pick next point or press Enter to finish digitizing points*

Keyboard Command: dig_pt

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitize Spot Elevation

This command allows you to label points with their elevation. The point can either be digitized from a drawing, picked on a screen or specified by a point number. The command first prompts you the **Label Spot Elevation Dialog** for entering layer name, label prefix and suffix and symbol types etc. Click OK to start. After specifying the point, the command prompts you to enter the elevation if its elevation is unknown and then pick an angle from the location of the point to label the elevation. You can repeat labeling points until you press **Enter** to finish.

Prompts

Label Spot Elevation Dialog

Specify a layer name, label prefix and suffix and select the spot symbol.

Point to Label ?

Pick point or point number: 2 (*enter a point number*)

PointNo. Northing(Y) Easting(X) Elev(Z) Description

2 1231.16 1099.17 30.00 bb

Note: if the point number you entered is not in the drawing, you will be prompted again to pick point or enter a point number.

Elevation <30.000>: *press enter*

Pick angle for label: *pick an angle from the spot*

Point to Label (ENTER to End)?

Pick point or point number: *pick a point on the drawing*

Elevation <0.000>: *enter elevation*

Pick angle for label: *pick an angle from the spot*

Point to Label (ENTER to End)?

Pick point or point number: *press enter to finish*

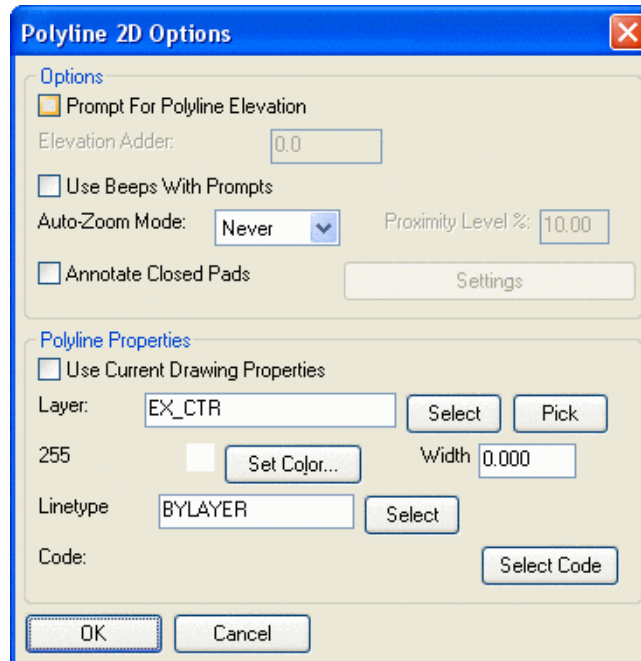

Keyboard Command: labspot

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitize 2D Polyline

A 2D polyline is a line of connected points that have the same elevation. This command lets you digitize a 2D polyline by picking points along the lines on the drawing. It prompts you first the **Polyline 2D Options Dialog** for entering the layer name. **Prompt For Polyline Elevation** option allows you to enter the elevation for each polyline, otherwise all 2D polylines have 0.0 elevation. **Auto-Zoom** mode would automatically zoom the display to center around the last point when you get near the edge of the screen while picking points. There are three ways to enter a layer name, **Use current drawing layer**, **Select** from a list of layer name, or **Pick** an entity on the screen to get its layer name. While digitizing a polyline, the command keeps prompting you to either pick the next point or **press 0** to create an Arc until your **press Enter** to finish digitizing. **Press A**

on the puck or **enter Close** on the keyboard to close the polyline on itself. You can define an **Arc** by Radius, Arc length, Chord length, Delta angle, or by simply picking 3 points along the arc. If at any point you make a mistake, **press B** on the puck or **enter Undo** on the keyboard to remove the mistake and then continue to digitize. After finishing a polyline, the command prompts you to digitize another polyline until you **press B** or **enter No**.

Prompts

Polyline 2D Options Dialog

Enter the layer name and select the options of Prompt For Polyline Elevation and Auto-Zoom mode etc.

Enter default elevation <0.00>: 100

First point: *pick a point on the drawing using puck*

Segment length: 0.00, Total length: 0.00

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): *pick next point*

Segment length: 119.03, Total length: 119.03

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): *pick next point*

Segment length: 115.23, Total length: 234.26

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): *press 0*

[Radius[0]/Second pt[A]/Undo[B]/<Pick Endpoint>]: *press A*

Second point or point number: *pick a point along the arc*

Endpoint or point number: *pick the last point along the arc*

Segment length: 500.82, Total length: 735.08

Arc[0]/Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): *pick next point*

Segment length: 115.23, Total length: 850.31

Close[A]/Undo[B]/Pick next point (Enter to end): *press enter to finish digitizing or press A to close the polyline*

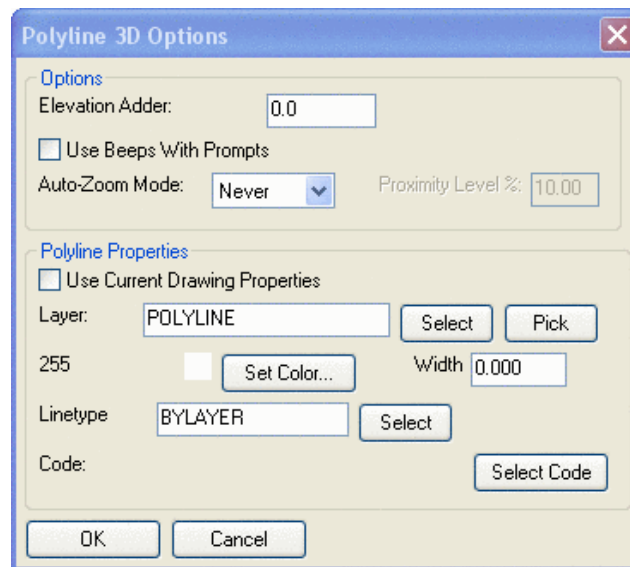

Digitize Another FINAL Polyline [Yes(A)/<No(B)>]? *press A on the puck or enter Yes on the keyboard to digitize next 2D polyline, press B on the puck or enter No on the keyboard to finish digitizing 2D polyline.*

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Keyboard Command: dig_2dp

Digitize 3D Polyline

A 3D polyline is a line of connected points that have various elevations, and the slope between points is constant. It can be used in defining pads, excavations, drainage ditched and slopes from proposed design features to meet existing site conditions. This command lets you digitize a 3D polyline by picking points along the lines on the drawing. It prompts you first the **Polyline 3D Options Dialog** for entering the layer name. **Elevation Adder** allows you to truncate the elevations you have to enter in by add a given amount to them. There are five ways to enter elevations: known elevation of the point, interpolate, slope from previous point, ratio from previous point and degree from previous point. You can choose one of the methods between picking points. **Auto-Zoom** mode would automatically zoom the display to center around the last point when you get near the edge of the screen while picking points. While digitizing a polyline, press **A** to interpolate the elevation or **B** to enter it in. The command keeps prompting you to either pick the next point or **press 0** to create Arc cords until you **press Enter** to finish digitizing. **Press A** on the puck or **enter Close** on the keyboard to close the polyline on itself. You can define **Arc cords** by Radius, Arc length, Chord length, Delta angle, or by simply picking 3 points along the arc. You can also use the OSNAP command to pick points by pressing the decimal [.] button on the digitizer puck. If you make a mistake, **press B** on the puck or **enter Undo** on the keyboard to remove the mistake and then continue to digitize. After finishing a polyline, the command prompts your to digitize another polyline until you **press B** or **enter No**.

Prompts

First point:

Interpolate[A]/screen Pick/<Elevation[B]> <0.00>: 256

Z: 256.00

Arc[0]Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): Pick point

Slope/Ratio/Interpolate[A]/Degree/screen Pick/<Elevation[B]> <256.00>: A

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: Pick point

This point elevation will be interpolated upon completion.

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: 279

Z: 279.00, Hz dist: 30.01, Slope dist: 37.81, Slope: 76.6% Ratio: 1.3:1

Arc[0]Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): Pick point

Slope/Ratio/Elevation[B]/Degree/screen Pick/Osnap[.]/Next point or elevation<Interpolate>: Press Enter

Z: 279.00, Hz dist: 24.18, Slope dist: 24.18, Slope: 0.0% Ratio: 0.0:1

Arc[0]Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): A

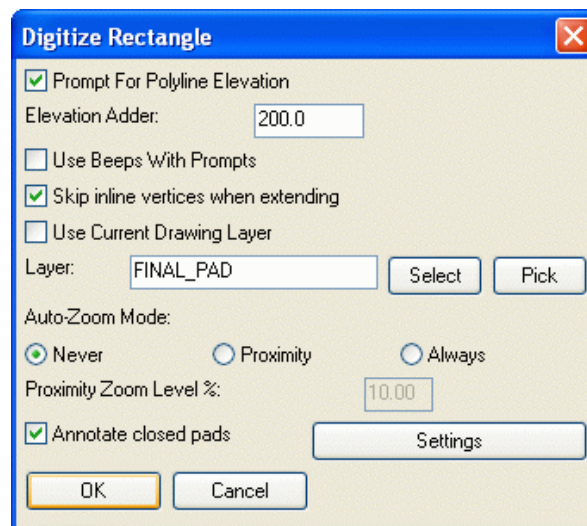

Digitize Another EXIST_PLINE Polyline [Yes(A)/<No(B)>]? B
<Tablet Off>

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

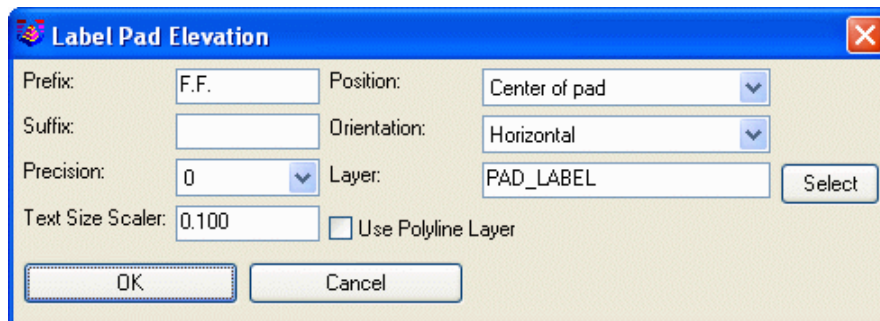

Keyboard Command: dig_3dp

Digitize Rectangle

This command enables you to quickly create rectangles while digitizing. In the dialog, you can pick to set elevations to the rectangles, otherwise all rectangles will have 0.0 elevation. The Elevation Adder will be added to the value you enter in for the prompt "Enter polyline elevation <0.00>:". For example, if you know all the rectangles you are creating are in the 200s for elevation, you can put in this value for the Elevation Adder and simply put 46, 54, 57, etc. when prompted, and your rectangles will end up with the elevations of 246, 254, 257 etc. There are three ways to enter a layer name, Use current drawing layer, Select from a list of layer name, or Pick an entity on the screen to get its layer name. Auto-Zoom mode would automatically zoom the display to center around the last point when you get near the edge of the screen while picking points.

Annotate closed pads will label your rectangles according to the Settings button/dialog shown below:

In this dialog, you can enter in a Prefix or a Suffix to the elevation, and determine the labels position, orientation, precision out to 5 decimal places, its layer, and text size.

Prompts

Target surface: Design

Digitize Rectangle Dialog Make any changes you desire in the above dialogs.

Enter polyline elevation <0.00>: 200

First point: *pick a point on the drawing using puck*

Segment length: 0.00, Total length: 0.00

Close[A]/Undo[B]/Osnap[.]/Pick next point: *pick next point*

Segment length: 1105.96, Total length: 1105.96

Close[A]/Undo[B]/Osnap[.]/Pick next point: *pick next point*

Segment length: 426.83, Total length: 1532.79, Area: 236021.59

Close[A]/Undo[B]/Osnap[.]/Pick next point (Enter to end): *After 3 points you can press (A) for Close to create a rectangle*

Digitize Another FINAL_PAD Polyline [Yes(A)/<No(B)>]? *B for No*

Prerequisite: a digitizer

Keyboard Command: DIG_RECT

Digitize Perimeter

Perimeter is a 2D polyline that all points on it have the same elevation. It can be used as boundary polyline of your targets on your drawing. This command allows you to digitize a perimeter by picking points on the drawing. While digitizing a polyline, the command keeps prompting you to pick next point until you **press Enter** to finish digitizing, or **press A** on the puck or **enter Close** on the keyboard to close the polyline on itself. If you make a mistake, **press B** on the puck or **enter Undo** on the keyboard to remove the mistake and then continue to digitize. After finishing a perimeter, the command prompts you to digitize another polyline until you **press B** or **enter No**.

Prompts

First point: *pick a point on the drawing using puck*

Segment length: 0.00, Total length: 0.00

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 104.27, Total length: 104.27

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 153.14, Total length: 257.41

Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Segment length: 104.89, Total length: 362.30

Close[A]/Undo[B]/Pick next point (Enter to end): *press Enter to finish the perimeter, or press A to close the perimeter*

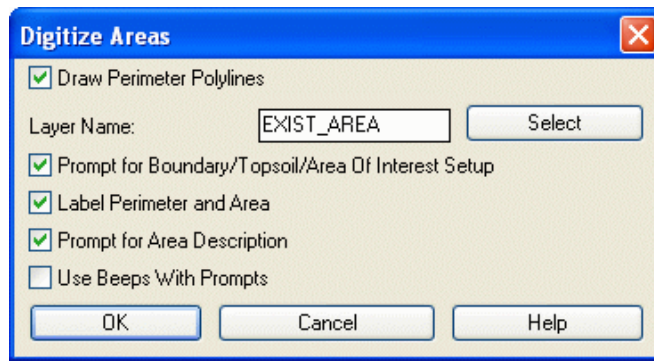

Digitize Another PERIMETER Polyline [Yes(A)/<No(B)>]? *press A or enter Yes to continue digitizing another perimeter, press B or enter No to finish digitizing perimeters.*

Keyboard Command: dig_perim

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitize Areas

This command allows you to find an area in digitize mode. With the puck, pick around the area you wish to calculate. If Draw Perimeter Polyline is toggled on then the linework of your perimeter will be displayed. You can then set the Layer Name and choose to label the Perimeter and Area and enter in an Area Description. You can also set the area you created as a Boundary, Topsoil, or Area of Interest.

Prerequisite: a digitizer

Keyboard Command: dig_area

Digitize Contour Polyline

A contour is a line of points with a constant elevation, representing the natural contour of the site. In Takeoff, there are two layer targets: Existing Ground Surface and Design Surface. Contour Polyline has two sub-command to digitize contour lines into Existing Contour and Final Contour layers directly for assigning them easily into Existing Ground Surface and Design Surface in the future analysis.

There are two ways to digitize contour lines: sketch mode or point mode. You can start digitizing a contour with one mode and switch to the other during digitizing the contour. Sketch mode uses more points than pick mode. In general, we recommend using pick mode to digitize the straight parts of lines because it reduces the number of points and speeds up Takeoff's calculations, but using sketch mode to digitize the curved parts because it is fast and accurate.

This command lets you digitize contours as polylines one at a time. The first time it prompts you the Digitize Contours Dialog. Enter the layer name or select it from a list of existing layer. Look at your plans and determine an elevation interval that is between most of the contours and enter it in the Elevation Interval field. You are able to modify both the value and the direction of the elevation interval between digitizing contour lines, using the buttons on the puck. To have Takeoff automatically close contours whose beginning and ending points are within a specified range, check the Auto Detect Close Contour. Draw Labels would draw the elevation at the starting point of the contour. In Pick mode, if you want the Takeoff to automatically zoom the display to center around the last point when you get near the edge of the screen while picking points, check the Auto Zoom Center. Click OK to start digitizing.

If this is your first time digitizing a contour, you are defaulted to the Pick Mode digitizing, otherwise you would be defaulted to the last digitize mode. If you want to use the other digitize mode, press 0 on the puck or enter 0 from the keyboard. Place your cursor at one end of the contour line and begin digitizing the line. While digitizing a line, you can force a contour to close on itself by pressing A on the puck to end the contour and connect the last point to the first point, remove a mistake by pressing B on the puck, or switch to the other digitize mode by pressing 0. During Sketch Mode digitizing, you can stop digitizing by pressing Pick or Enter button on the puck, take some rest or changes, and start sketching again. At the end of the contour line, **press Enter** on your puck or keyboard. The contour is completed, and the elevation for the next contour is automatically incremented. You would be asked to digitize next contour. If you press A on the puck or enter Yes on the keyboard, you can digitize another contour, or press B on the puck or enter No on the keyboard to finish digitizing contours.

Prompts

Digitize Contours Dialog

Enter Layer Name, Elevation Interval, and toggle on/off Auto Detect Close Contour etc.

Increment(1.00)[A]/Direction(+)[B]/Elevation <573.00>: 450 (*enter elevation or press Enter to accept current value*)

Start Digitizing...

Sketch[0]/Pick the first point: *pick a point to start Pick Mode digitizing (press 0 to switch to Sketch Mode)*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): 0 (*press 0 on the puck or enter 0 on the keyboard to use Sketch Mode*)

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): pick and drag

Drag to digitize (Pick or press Enter to stop sketching)... pick or press Enter to stop sketching

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): B (undo the last point)

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): B (undo the last point)

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): pick and drag again

Drag to digitize (Pick or press Enter to stop sketching)... pick or press Enter to stop sketching

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): 0 (*press 0 on the puck or enter 0 on the keyboard to use Pick Mode*)

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): pick next point

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): press Enter to finish digitizing

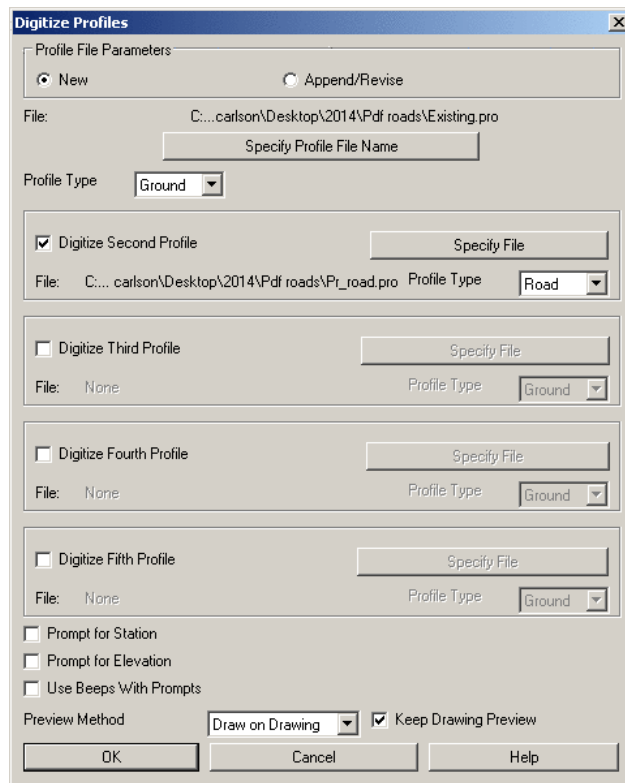

Digitize Another Contour [<Yes(A)>/No(B)]? B (*press B to finish digitizing*)

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Keyboard Command: digcont_exist, digcont_final

Digitize Profiles

This command allows you to digitize profile lines and store the profile data into the profile file (.pro) you have specified. The command first prompts you the **Digitize Profile Dialog**. Enter the profile file name and determine if you want to digitize up to five profiles from the same grid. Next, determine the **Profile Type**: Ground, Road, or Pipe. Selecting Road will prompt you for a "Vertical Curve" to be applied between the current point and previous profile point. If no Vertical Curve exists, type "0"; entering without specifying any Vertical Curve will turn off the VC prompt on subsequent profile points. Selecting Pipe will prompt you for a "Step up for the pipe" and "Enter the Pipe size" at each profile point. With Ground, there are no additional prompts.

Towards the bottom half of the dialog, there are toggles for **Prompt for Station** and **Prompt for Elevation**. These will show you a preview value for the Station and Elevation based on the point that you picked. Press Enter to except or type in a new value in manually. This is most useful for accurate import of Road and Pipe data. Also at the bottom, **Preview Method** offers 2 ways to view the profiles as you digitize. "Graphic Dialog" displays the profile data in a grid dialog and is best when digitizing from paper plans. "Draw on Drawing" draws 2D polylines in your CAD drawing and is best when digitizing over an Image in your drawing. "Keep Drawing Preview" will leave the 2D polylines in your CAD drawing (having this checked off will erase the 2D polylines after each station).

After clicking OK in the main dialog, Takeoff prompts you to **calibrate the profile sheet** before you digitize the profile lines. You will pick three points and specify their station and elevations in order to determine the horizontal and vertical scales. Corners on the profile grid are preferred reference points. Once calibrated, place your cursor at one end of the profile line and begin digitizing the line. While digitizing a line, you can remove a mistake by **pressing A** on the puck or **entering Undo** on the keyboard. At the end of the profile line, **press Enter** on your puck or keyboard. The command then prompts you to digitize the next profile. You can **press A** on the puck or **enter Exit** on the keyboard to finish digitizing. After you digitize the profile lines on your drawing, all the profile data would be saved in a profile file (.pro).

Prompts

Calibrate profile sheet

- Pick First profile sheet reference point:** *pick a grid point of a station on your drawing*
- Enter station <0.0>: 1000** *press Enter to accept the station or enter a new station value*
- Enter elevation: 95** *(enter the Elevation of the reference point)*
- Pick Second profile reference point:** *pick a second grid point*
- Enter station: 1200** *(enter the grid's station)*
- Enter elevation: 110** *(enter the Elevation of the reference point)*
- Pick Third profile reference point:** *pick a third grid point*
- Enter station: 1500** *(enter the grid's station)*

Enter elevation: 105 (*enter the Elevation of the reference point*)

Digitize break point (Undo[A],Enter to end): *pick a point on the profile line*

Station: 1440 Elev: 100.49

Digitize break point (Undo[A],Enter to end): *press Enter to finish*

Keyboard Command: digprof

Prerequisite: For "on-screen" digitizing, have an image loaded and Digitizer Settings set to "Use Mouse". For paper plans, have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitize Sections

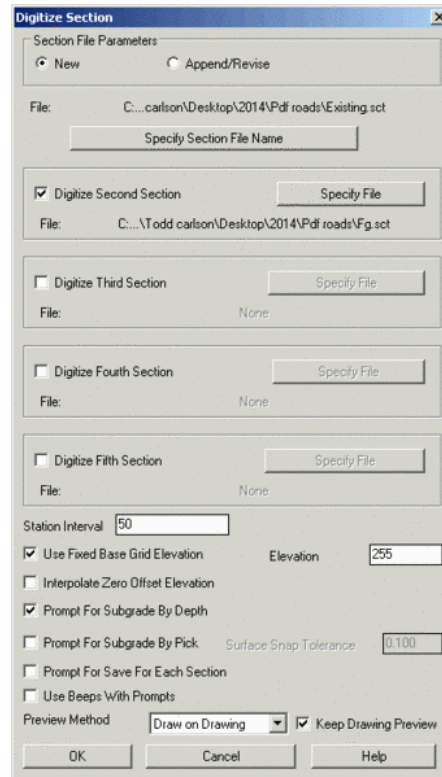

This command allows you to digitize section lines and store the section data in the section file you have specified. The command first prompts you the **Digitize Section Dialog**. Enter the section file name and determine if you want to digitize second and third sections at the same station (i.e., for existing, finish grade, unsuitable, etc.). Look at your plans and determines the station interval, which is used to automatically default to the next station value when digitizing a series of stations. If the grids at all the stations have the same base elevation, toggle on **Use Fixed Base Grid Elevation**. The **Interpolate Zero Offset Elevation** option calculates a section point at the zero offset when the zero offset point isn't digitized. The **Prompt for Save for Each Section** option can be used to save the SCT file after completing each station. The **Use Beeps with Prompts** option gives audio feedback to help keep your eyes on the sheet. **Surface Snap Tolerance** sets the maximum distance that the program will automatically snap the tie back point between the subgrade and design surface. The **Prompt For Descriptions** option will prompt for a description for each digitized section point.

There are two ways to account for Subgrades. **Prompt For Subgrade By Depth** will ask you for a subgrade depth while you are digitizing a section file and apply that subgrade depth below each point you pick for that section. If no subgrade linework is shown on the plans, but the depth is known, this is a good option. **Prompt For Subgrade By Pick** allows you to digitize in the subgrade linework after initial section has been digitized. This option is best when your Subgrade Depth is not uniform.

Preview Method offers 2 ways to view the sections as you digitize. "**Graphic Dialog**" displays the section data in a grid dialog and is best when digitizing from paper plans. "**Draw on Drawing**" draws 2D polylines in your CAD drawing and is best when digitizing over an Image in your drawing. "Keep Drawing Preview" will leave the 2D polylines in your CAD drawing (having this checked off will erase the 2D polylines after each station). Click OK to start digitizing.

Takeoff prompts you to calibrate the section sheet before you digitize the section lines. You pick three points and specify their offsets to the centerline and elevations in order to determine the horizontal and vertical intervals. Corners on the section grid are preferred reference points. Place your cursor at one end of the section

line and begin digitizing the line. While digitizing a line, you can remove a mistake by **pressing A** on the puck or **entering Undo** on the keyboard. At the end of the section line, **press Enter** on your puck or keyboard. The station is completed, and the station value is automatically incremented. The command would prompts to digitize next section. You can **press A** on the puck or **enter Exit** on the keyboard to finish digitizing. If you want to continue to digitize next section, **press Enter** or enter the new station number. For every station after the first one, you can calibrate the grid sheet by picking one reference point and specify its offset and elevation. After you digitize the section lines on your drawing, all the section data would be saved in a section file (.sct).

Prompts

Digitize break point for DRAWING1 section 200.000 (Undo[A],Enter to end): *pick a point on the section line*

Offset: 27.86 Elev: 1030.02

Digitize break point for DRAWING1 section 200.000 (Undo[A],Enter to end): *pick a point on the section line*

Offset: 50.33 Elev: 1035.80

Digitize break point for DRAWING1 section 200.000 (Undo[A],Enter to end): *press Enter to finish*

Save changes to DRAWING1 section 200.000 [<Yes(A)>/No(B)>]? A** *(press A or B)***

Exit[A]/Section station to digitize <250.000>: A *(press A to finish or enter the station number to continue)*

Keyboard Command: digxsec

Prerequisite: For "on-screen" digitizing, have an image loaded and Digitizer Settings set to "Use Mouse". For paper plan digitizing, have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Digitize End Areas

There are two types of end areas: cut area and fill area. This command allows you to digitize both cut area and fill area on the drawing and writes data to a .ew file. The command first prompts you to calibrate the section sheet by picking three points and specify their offsets to the centerline and elevations in order to determine the horizontal and vertical intervals. Corners on the section grid are preferred reference points. Then it prompts you to digitize the cut area and fill area respectively. Place your cursor at one end of the end area and begin digitizing the outline of the area. At the end of the section line, **press Enter** on your puck or keyboard. The end area is completed, and its area is printed on the command line, and you are prompted to digitize next end area. After you finish all the end area at one station, accumulated cut area and fill area are computed and printed out on the screen. All data of cut area and fill area at every station would be saved in the area file (.ew) that you have specified.

Prompts

Calibrate section sheet

Pick First section sheet reference point: *pick a point on the drawing*

Enter offset <0.0>: *press Enter to accept the offset (or enter the offset of the point to the centerline)*

Enter elevation: 1020 *(enter the Elevation of the reference point)*

Pick Second section reference point: *pick a point*

Enter offset: 0 (enter the offset of the point to the centerline)
Enter elevation: 1030 (enter the Elevation of the reference point)
Pick Third section reference point: pick a point
Enter offset: 50 (enter the offset of the point to the centerline)
Enter elevation: 1030 (enter the Elevation of the reference point)
3 calibration points
Transformation type: Orthogonal Affine Projective

Outcome of fit: Success Exact Impossible

RMS Error: 11.69

Standard deviation: 2.40

Largest residual: 14.29

At point: 2

Second-largest residual: 14.29

At point: 3

Digitize cut area (Enter to end): pick a point that is on the outline of the cut area, 0*(0.211129 1030.76)

Digitize cut area (Enter to end): pick a point that is on the outline of the cut area, 1*(11.5804 1030.49)

Digitize cut area (Enter to end): pick a point that is on the outline of the cut area, 2*(17.8643 1030.73)

Digitize cut area (Enter to end): pick a point that is on the outline of the cut area, 3*(19.0216 1032.35)

Digitize cut area (Enter to end): pick a point that is on the outline of the cut area, 4*(-0.777246 1030.75)

Digitize cut area (Enter to end): press Enter to finish

End area: 17.2312

Accumulated Cut Area: 17.2312

More Cut Areas [Yes(A)/<No>(B)]? press A to digitize more Cut Areas, or press B to finish digitizing Cut Areas.

Accumulated Cut Area: 17.2312

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 0*(-18.9614 1029.65)

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 1*(-18.1315 1030.75)

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 2*(-11.9592 1030.49)

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 3*(-2.06761 1030.72)

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 4*(-10.0082 1030.01)

Digitize fill area (Enter to end): pick a point that is on the outline of the fill area, 5*(-18.531 1029.67)

Digitize fill area (Enter to end): press enter to finish

End area: 8.64646

Accumulated Cut Area: 8.64646

More Fill Areas [Yes(A)/<No>(B)]? press A to digitize more Fill Areas, or press B to finish digitizing Fill Areas.

Accumulated Cut Area: 8.64646

Total Cut Area: 17.2312

Total Fill Area: 8.64646

Store data to file [<Yes>(A)/No(B)]? press A or B

Opened file: C:\Program Files\Carlson Takeoff 2004\DATA\Drawing1.ew

Station Number: 1 (enter Station Number)

Data Stored in file: C:\Program Files\Carlson Takeoff 2004\DATA\Drawing1.ew

Digitize another station [<Yes>(A)/No(B)]? B (press A or B)

Prerequisite: Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Have done tablet calibration for current drawing.

Keyboard Command: digendar

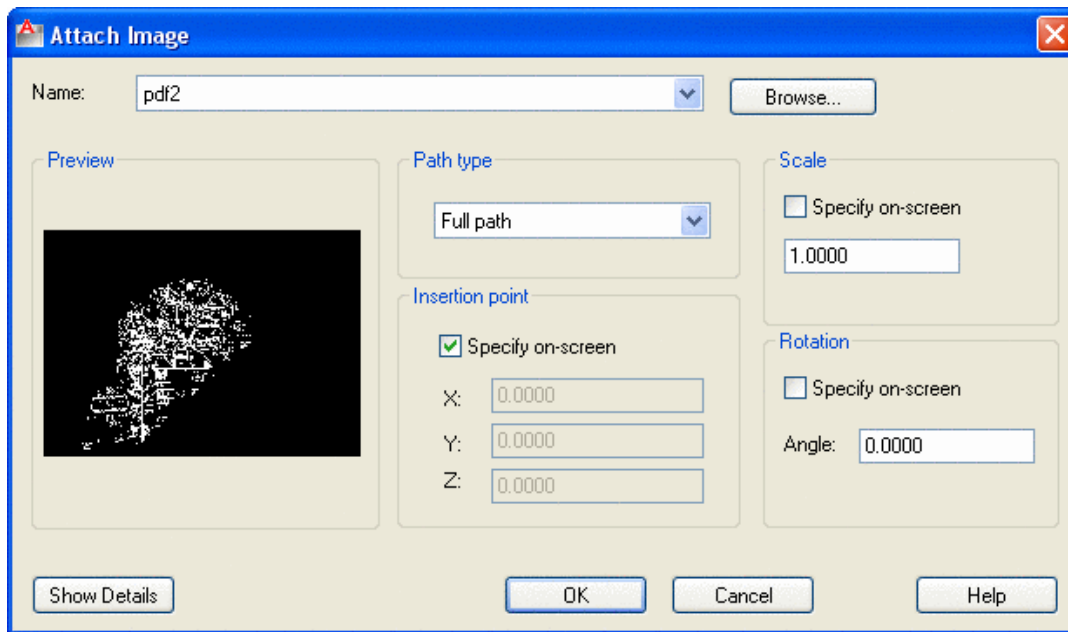

Raster Menu

The Raster menu commands convert raster images into drawing entities.

Draw Raster Image

This command inserts an Image file into your current drawing. After selecting the file you wish to draw, the following dialog is shown:

The name of the file is shown at the top with a preview of the file shown below. To select a different file, click on the Browse button. Path Type can be set to the full (absolute) path, the relative path to the image file, or No Path, the name of the image file (the image file must be located in the same folder as the current drawing file). If the scale factor is known, you can enter it under Scale.

If the scale factor is unknown, it is recommended to use the default scale factor of 1 and adjust the Scale with Edit > 2D Scale once the Image is inserted and a scale factor can be determined. Specify On-Screen allows you to input the scale at the Command prompt. Insertion Point specifies the insertion point for the selected image file. Specify On-Screen is the default. The default insertion point is 0,0,0.

Specify On-Screen Directs input at the Command prompt or the pointing device. If Specify On-Screen is unchecked, enter the insertion point as X, Y, and Z coordinate values. Rotation specifies the rotation angle of the selected image. If Specify On-Screen is selected, you may wait until you exit the dialog box to rotate the object with your pointing device or enter a rotation angle value at the Command prompt. If Specify On-Screen is unchecked, enter the rotation angle value in the dialog box. The default rotation angle is 0.

Below is list of Images that can be inserted into the drawing. For PDF files, use the Import PDF File (loadpdf) command available in Carlson Takeoff.

Prompts

Specify the insertion point: pick on the screen or typing in a coordinate (Example: 1000,1000).

Specify rotation angle: To accept the default value displayed, press Enter, or enter the rotation angle (Example: 90).

Specify scale <1.0>: To accept the default value displayed, press Enter, or enter a scale factor. If the scale factor is not known, which is typical, accept the defaults to this prompt. The proper scale factor can be determined by running Inquiry>Standard Distance on a known distance on the site (ie, the side of a building or the distance across the road). If the side of a building is labeled as 60' and Standard Distance reports it is at 120', then the Scale factor is 0.5 (60/120). Run Edit>2D Scale, select the imported objects, specify a base point of 0,0 and use the Scale Factor you determined with Standard Distance to scale the entities correctly.

After the command has imported the Image file, run View > Zoom > Extents to see the converted entities.

Pulldown Menu Location: Raster > Draw Raster Image

Keyboard Command: imageattach

Prerequisite: None

Set Raster Image

The Raster pull-down has several commands for manipulating images. These commands work with one image at a time. Set Raster Image determines which image in a drawing is "current" to edit. Simply run the command and select the image.

Prompts

Select image: Pick on the image (often you will need to pick on the boundary of the image to select it)

Image selected. Image file: pdf1.bmp

Pulldown Menu Location: Raster

Keyboard Command: rassel

Prerequisite: an image in the drawing

Save As Raster Image

This command saves the current image to a file. This command is a way to make a backup of the image before doing image adjustment commands. Also this command is a way to change the format of the image file such as .bmp to .jpg.

Pulldown Menu Location: Raster > Set Raster Image

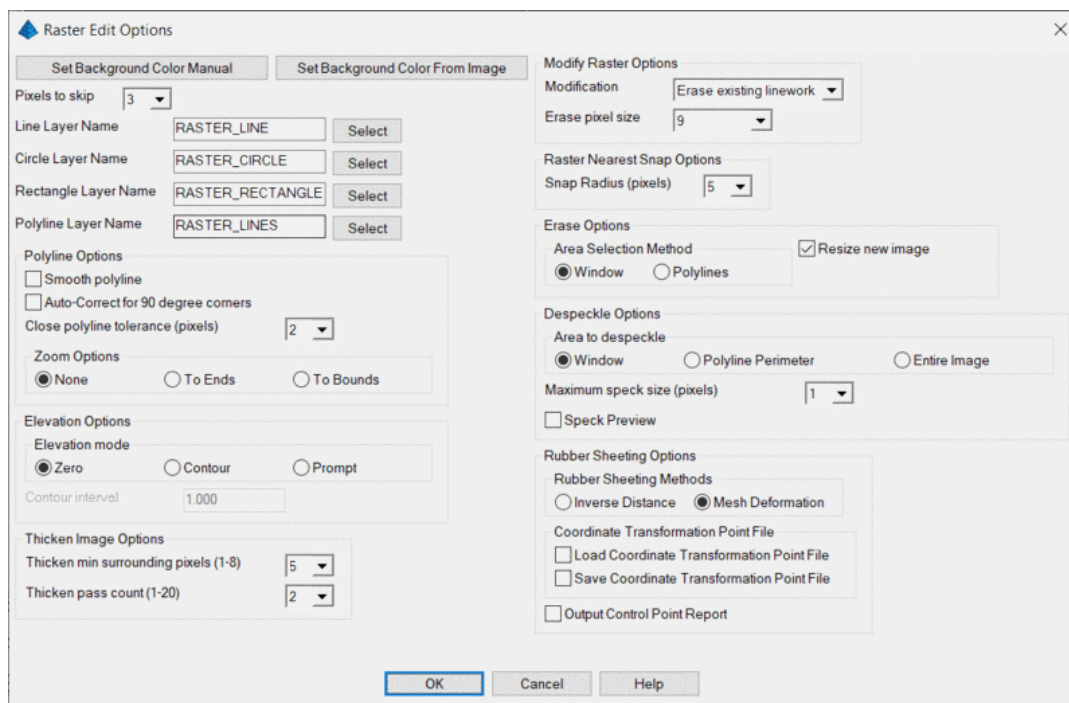

Keyboard Command: rassaveas

Prerequisite: Set Raster Image

Raster Edit Options

General Settings for working with images can be found in the command Raster Edit Options. Defaults are shown below.

Raster Edit Options Menu:

Set Background Color Manual/From Image: These settings apply to the Trace Line, Trace Rectangle, Trace Circle, and Trace Polyline routines. Methods to specify "background" color in image. Pixels in image similar to the "background" color will be considered part of the "background" of an image, as opposed to part of the linework of an image.

Pixels to skip: This setting applies to the *Trace Line* and *Trace Polyline* routines. As the program determines where to draw the new linework, it can "skip" or pass over a given amount of pixels who's color does not match the rest of the linework that is being processed. This allows for longer length polylines to be created on poor quality images. A larger amount of pixels to skip will typically create longer length new linework.

Line Layer Name: determines layer on which to draw lines when using the *Trace Line* routine.

Rectangle Layer Name: determines layer on which to draw rectangles when using the *Trace Rectangle* routine.

Circle Layer Name: determines layer on which to draw circle entities when using the *Trace Circle* routine.

Polyline Layer Name: determines the Layers for new linework in various *Trace Polyline* routine.

Polyline Options: Options specific to the *Trace Polyline* routine.

- **Smooth Polyline:** Interpolates between nodes of the polyline currently being traced to create interstitial nodes in the current polyline that give the current polyline a smoother
- **Auto-Correct for 90 degree corners:** Attempts to determine if a section of line work represents a 90 degree corner. If so, creates a 90 degree corner in the current polyline traced over line work.
- **Close polyline tolerance (pixels):** Sets the close polyline distance tolerance (in pixels, 0-25) for *Trace Polyline*. If the beginning and end of the current polyline are closer than the close polyline distance tolerance then *Trace Polyline* will determine the current polyline to be closed, geometry will be automatically added to the poyline to connect the beginning and end of the polyline. Any redundant nodes created by connecting the beginning and end of the polyline will be removed.
- **Zoom Options:** Specifies how to update view after new geometry is added to the polyline being traced.
 - *To Ends:* Zooms view to the end nearest the most recently added polyline geometry. This end is set as the currently active end)
 - *To Bounds:* Zooms view such that the entirety of the geometry of the currently traced line work is visible.
 - *None:* View does not change after the addition of new geometry.

Elevation Options: Options specifying how polyline geometry is elevated in the *Trace Line*, *Trace Circle*, *Trace Rectangle*, and *Trace Polyline* routines.

- **Elevation mode:**
 - *Zero:* All polyline geometry is drawn with its z value set to 0.0.
 - *Contour:* Sets polyline geometry z values based on elevation set by the *contour prompt* When enter is pressed, or the currently active polyline is closed, the user is prompted to update contour information (again, using the
 - *Prompt:* Prompts user to enter z value of traced polyline geometry. If enter is pressed or polyline is closed, user is again prompted to enter z value of traced polyline geometry.
- **Contour Interval:** When in contour mode, specifies amount to increment elevation after a polyline is ended or closed in *Trace Polyline* routine.

Thicken Image Options: Options used to specify how *RASTHICKEN* routine (command line only, not in pull-down menu) will update modify selected imagery.

- **Thicken min surrounding pixels (1-8):** When running the *RASTHICKEN* command, the routine looks at the surrounding pixels of an individual pixel and will change the color of that individual pixel to the surrounding pixels if minimum amount is met. The lower the number, the more "thickening" or "densifying" will occur.
- **Thicken pass count (1-20):** This is the number of times the *RASTHICKEN* command will run on a selected area. The greater number of passes, the more "thickening" or "densifying" will occur.

1. *No modification, do not modify the "current" image.*

2. *Erase existing linework,* Sets pixels on "current" image to the current background color up to a distance of 'Pixel size' from the current polyline geometry.

3. *Draw new linework,* First erases existing linework (See: Erase existing linework), then draws a 1 pixel wide line

using the color of the current linework on the "current" image.

Modify Raster Options: Options for modifying selected imagery when running any of the Trace routines (*Trace Line*, *Trace Circle*, *Trace Rectangle*, or *Trace Polyline*)

- **No modification:** do not modify the "current" image.
- **Erase existing linework:** Sets pixels on "current" image to the current background color up to a distance of 'Pixel size' from the current polyline geometry.
 - **Pixel Size:** Specifies the number of pixels to set to background color around current polyline geometry.
- **Draw new linework:** First erases existing linework (See: Erase existing linework), then draws a 1 pixel wide line using the color of the current linework on the "current" image.

Raster Nearest Snap Options: Snap Radius, tolerance factor for selecting line work. If line work is found at a distance less than 'Snap Radius' away from most recent user selected pick point, that line work will be added to the geometry of the current polyline.

Erase Options: Options specifying how manipulate imagery using the *Cut Image* and *Crop Image* routines.

- **Area Selection Mode:** Specify method for selecting area of image for cut or crop
- **Resize new Image:** Specifies whether or not to resize image in drawing after cut or crop.

Despeckle Options: Options specific to the *Despeckle* routine.

- **Area To Despeckle:** Specify method for selecting area of image to despeckle.
- **Maximum Spec Size:** Maximum size of a cluster of pixels to consider a speck.
- **Speck Preview:** Specifies whether or not to generate a preview for approval before despeckling image.

Rubber Sheeting Options: Options specific to the *Rubber Sheet* routine.

- **Rubber Sheeting Methods:** Methods for deforming image. *Inverse Distance* method weights the delta x/y from each control point as the inverse of the distance to the control point. This way the closer control points have a higher weight. The *Mesh Deformation* method uses an affine transformation.
- **Coordinate Transformation Point File:** If *Load Coordinate Transformation From Point File* is toggled, control points are specified based on crd file selected by user, otherwise user will be prompted to specify control points. If *Save Coordinate Transformation To Point File* is toggled, user will be prompted to specify crd file to save control points to after transformation.
- **Output Control Point Report:** Toggle on to generate control point report after selecting control points.

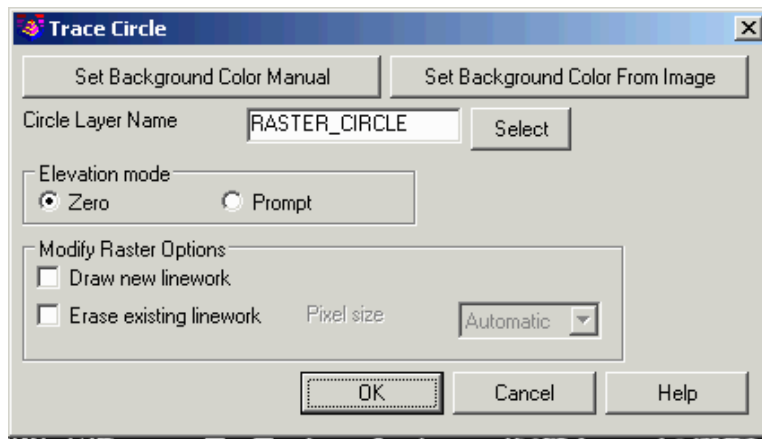

Pulldown Menu Location: Raster > Raster Edit Options

Keyboard Command: rasopts

Prerequisite: none

Trace Circle

This command draws a circle by following a circle in the image. The Draw New Linework option draws the circle in the image as well as the drawing. The Erase Existing Linework option removes the circle in the image by setting the circle pixels to the background color.

Prompts

Trace Circle dialog

Select a point on the circle [Options/Undo] (Enter to exit): *pick a point on the image circle*

Select a point on the circle [Options/Undo] (Enter to exit): *press Enter*

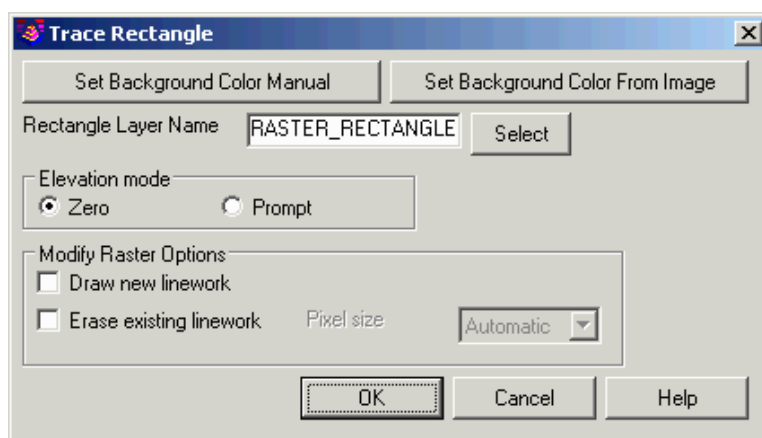

Pulldown Menu Location: Raster

Keyboard Command: rascircle

Prerequisite: an Image

Trace Rectangle

This command draws a rectangle by following a rectangle in the image. The Elevation Mode to Prompt is useful for cases like building pads and you want to set the pad elevations. The Draw New Linework option draws the rectangle in the image as well as the drawing. The Erase Existing Linework option removes the rectangle in the image by setting the rectangle pixels to the background color.

Prompts

Trace Rectangle dialog

Select a point on the rectangle [Options/Undo] (Enter to exit): *pick a point on the image rectangle*

Select a point on the rectangle [Options/Undo] (Enter to exit): *press Enter*

Pulldown Menu Location: Raster

Keyboard Command: rasrect

Prerequisite: an Image

Trace Line

Trace Line will convert a line in an image into a single CAD polyline. If an image is "current" through the **Set Raster Image** command, simply run **Trace Line** and click on a line in the image. In the command line, you will see the **Line Length**, **Angle**, and **Thickness** reported for the new polyline. The command line will also prompt you to change the **Angle**, **Length** or **Reverse** the direction the new polyline if desired. To accept the new line press Enter. To cancel, type C or press Esc.

Different images have different resolutions or quality to them. To account for this, you can adjust the parameters that the program tries to recognize linework in an image with **Edit Raster Options**. Here is also where the default **Layer** for the new polyline is determined.

Prompts

Pick a point for line (Enter to end): Select a line in the image

Line Length=780.00 Angle=269°32'47'' Thickness=5

Enter to accept line or [Angle/Reverse/Length/Cancel]: Type in the first letter in a word to adjust that element of the new polyline. For example, typing in "A" would allow you to adjust the Angle.

Pulldown Menu Location: Raster > Trace Line

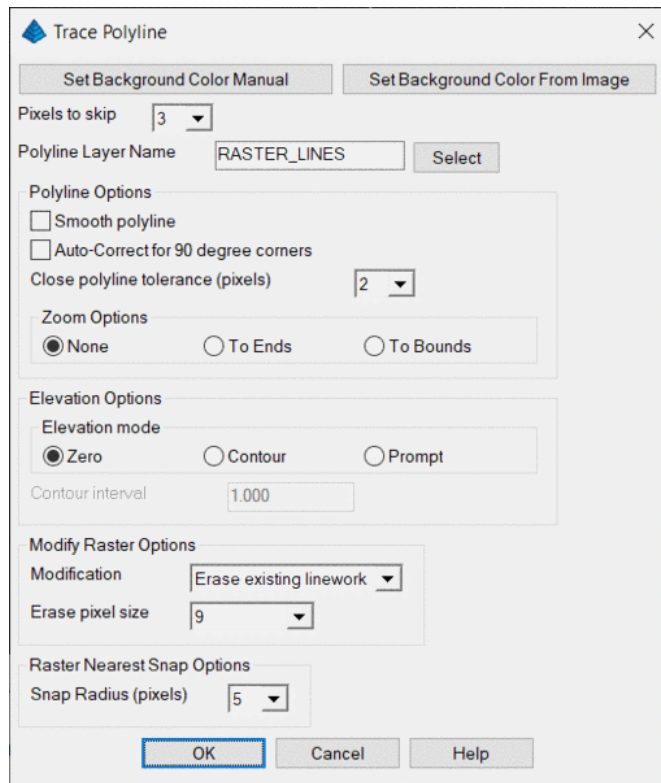

Keyboard Command: rasline

Prerequisite: Set Raster Image

Trace Polyline

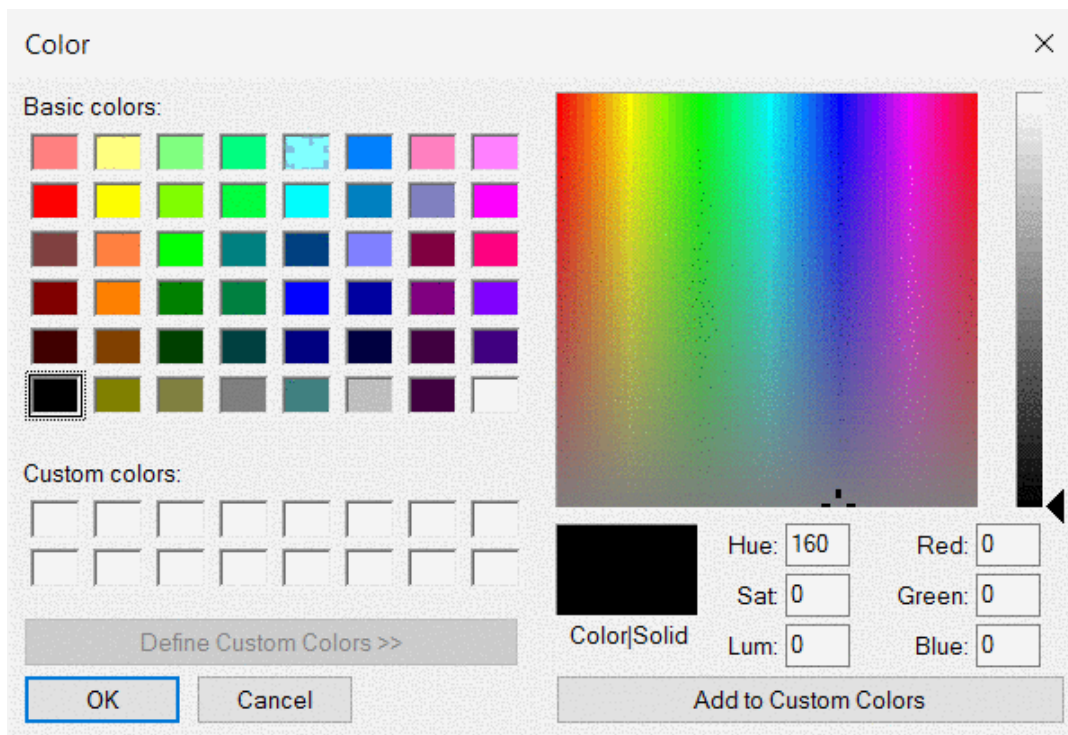

Trace Polyline will convert linework in an image into a CAD polyline with multiple vertices. Trace Polyline requires that an image is "current" this can be accomplished either by using the **Set Raster Image** command or if only one image exists in the drawing, running **Trace Polyline** will automatically set the lone image in the drawing as the "current" image.

Trace Polyline options menu:

Set Background Color Manual/From Image: These settings apply to the Trace Line, Trace Rectangle, Trace Circle, and Trace Polyline routines. Methods to specify "background" color in image. Pixels in image similar to the "background" color will be considered part of the "background" of an image, as opposed to part of the linework of an image.

Trace Polyline currently works best if the image being processed has a distinct background color that pervades most of the image and is easily distinguished from the color of the line work of the image. Set Background Color Manual allows the user to set the color that **Trace Polyline** interprets as the background color manually, by selecting a color from the Color dialog (shown below). Alternately The user can select the background color From Image.

Pixels to skip:

Sets the number of pixels (0-25) that **Trace Polyline** will "skip" (pass over) in order to connect two groups of pixels of the same color. This allows for longer length polylines to be created on poor quality images that contain gaps in between traceable line work. A larger number of pixels to skip will typically create longer length CAD line work. However, if the image line work contains few gaps, then the *Pixels to skip* should be set lower to avoid incorrectly connecting traced line work between unrelated traceable line work.

Smooth Polyline:

Interpolates between nodes of the polyline currently being traced to create interstitial nodes in the current polyline that give the current polyline a smoother appearance.

Auto-correct for 90 degree corners:

Attempts to determine if a section of line work represents a 90 degree corner. If so, creates a 90 degree corner in the current polyline traced over line work.

Close polyline tolerance (pixels):

Sets the close polyline distance tolerance (in pixels, 0-25) for **Trace Polyline**. If the beginning and end of the current polyline are closer than the close polyline distance tolerance then **Trace Polyline** will determine the current polyline to be closed, geometry will be automatically added to the polyline to connect the beginning and end of the polyline. Any redundant nodes created by connecting the beginning and end of the polyline will be removed.

Zoom Options:

1. *To Ends*, zooms view to the end nearest the most recently added polyline geometry. This end is set as the currently active end (see *switch ends*).
2. *To Bounds*, zooms view such that the entirety of the geometry of the currently traced line work is visible.
3. *None*, view does not change after the addition of new geometry.

Elevation Mode:

1. *Contour*, sets polyline geometry z values based on elevation set by the *contour prompt*. When enter is pressed, or the currently active polyline is closed, the user is prompted to update contour information (again, using the *contour*

prompt).

2. *Prompt*, prompts user to enter z value of traced polyline geometry. If enter is pressed or polyline is closed, user is again prompted to enter z value of traced polyline geometry.
3. *Zero*, all polyline geometry is drawn with its z value set to 0.0.

Contour Interval:

When in contour mode, specifies amount to increment elevation after a polyline is ended or closed in Trace Polyline routine.

Modify Raster Options:

1. *No modification, do not modify the "current" image.*
2. *Erase existing linework*, Sets pixels on "current" image to the current background color up to a distance of 'Pixel size' from the current polyline geometry.
3. *Draw new linework*, First erases existing linework (See: Erase existing linework), then draws a 1 pixel wide line using the color of the current linework on the "current" image.

Raster Nearest Snap Options:

Snap Radius, tolerance factor for selecting line work. If line work is found at a distance less than 'Snap Radius' away from most recent user selected pick point, that line work will be added to the geometry of the current polyline.

Prompts: Pick segment or [Options/Manual point/cross line Pick/Undo/Close/Switch active end/Exit] (Enter to end polyline):

(Select pick point to continue tracing polyline.)

(O)-Options, opens the Trace Polyline options dialog.

(M)-Manual point, allows user to contribute additional geometry to current polyline manually, ie not automatically traced.

(P)-cross line Pick, allows user to select pick point by crossing line work to be added with a cross line.

(U)-Undo, undoes previously drawn geometry.

(S)-Switch active end, switches the end to which geometry will be added (given new geometry begins near active end).

(E)-Exit, exits **Trace Polyline**.

*(C)-Continue, if no geometry has been traced, continue allows user to select on screen polyline geometry and use that as the basis for new line work.

Pick manual point or [enable snap Nearest/Switch active end/Exit] (Enter to end):

(Pick manual point to add to polyline geometry.)

(N)-enable snap Nearest, see **raster Nearest Snap Options**.

(S)-Switch active end, switches the end to which geometry will be added.

(E)-Exit, exits **Trace Polyline**.

Enter elevation or [Increment 1.00/Direction +/-/Exit] Elevation <0.00>:

(Enter elevation in contour mode.)

(I)-Increment, increment the elevation according to "direction" (either + or -).

(D)-Direction, toggles incremental direction from + to - or vice versa.

(E)-Exit, exits **Trace Polyline**.

Enter elevation or [Exit] Elevation <0.0>:

(Enter elevation in Prompt mode.)

(E)-Exit, exits **Trace Polyline**.

Pulldown Menu Location: Raster > Trace Polyline

Keyboard Command: raspline

Prerequisite: Set Raster Image

Raster Nearest Snap

Similar to the standard Object or Entity Nearest Snap with CAD entities, **Raster Nearest Snap** will snap to the nearest point on a linework segment or point in an Image. This command can be used with Draw commands such as Draw > 2D Polyline.

Pulldown Menu Location: Raster > Raster EndPoint Snap

Keyboard Command: rnea

Prerequisite: most Draw commands

Raster EndPoint Snap

Similar to the standard Object or Entity EndPoint Snap with CAD entities, **Raster EndPoint Snap** will snap to the closest endpoint of a point or linework segment in an Image. This command can be used with Draw commands such as Draw > 2D Polyline.

Pulldown Menu Location: Raster > Raster EndPoint Snap

Keyboard Command: rend

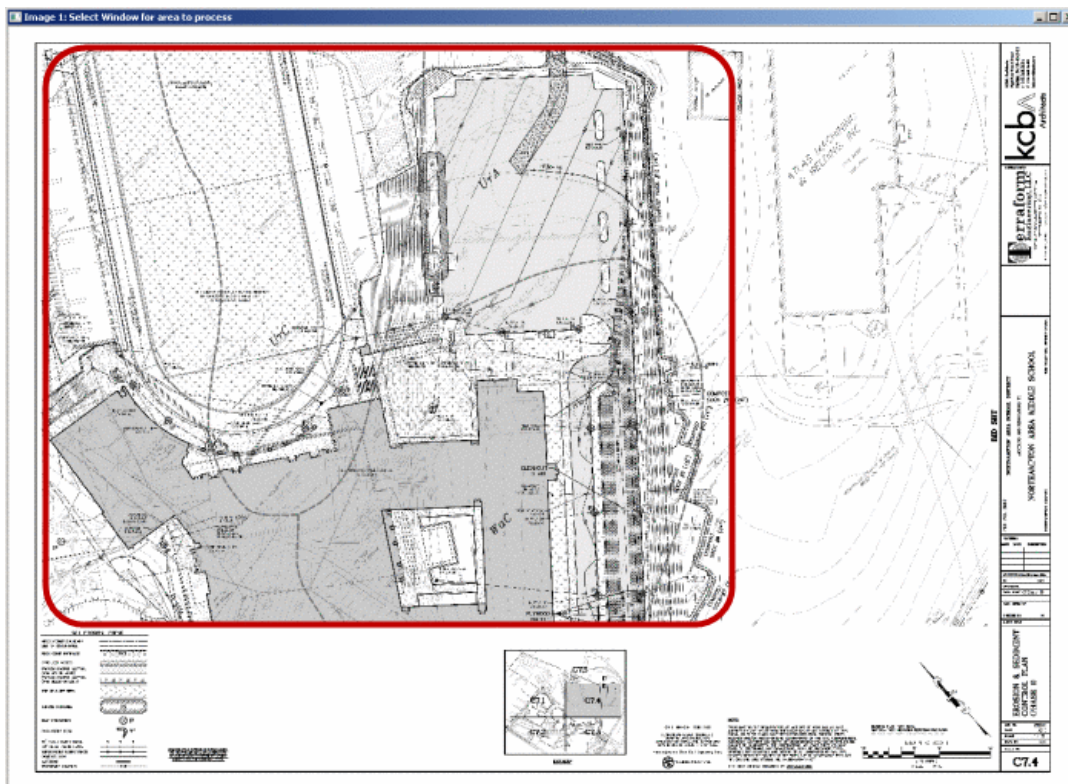

Prerequisite: most Draw command

Merge Raster Files

This commands merges bitmaps or other images (not pdf-based, unless the pdf has been turned into an image). There are two different methods for merging raster files: Automatic and Manual.

Automatic Merge

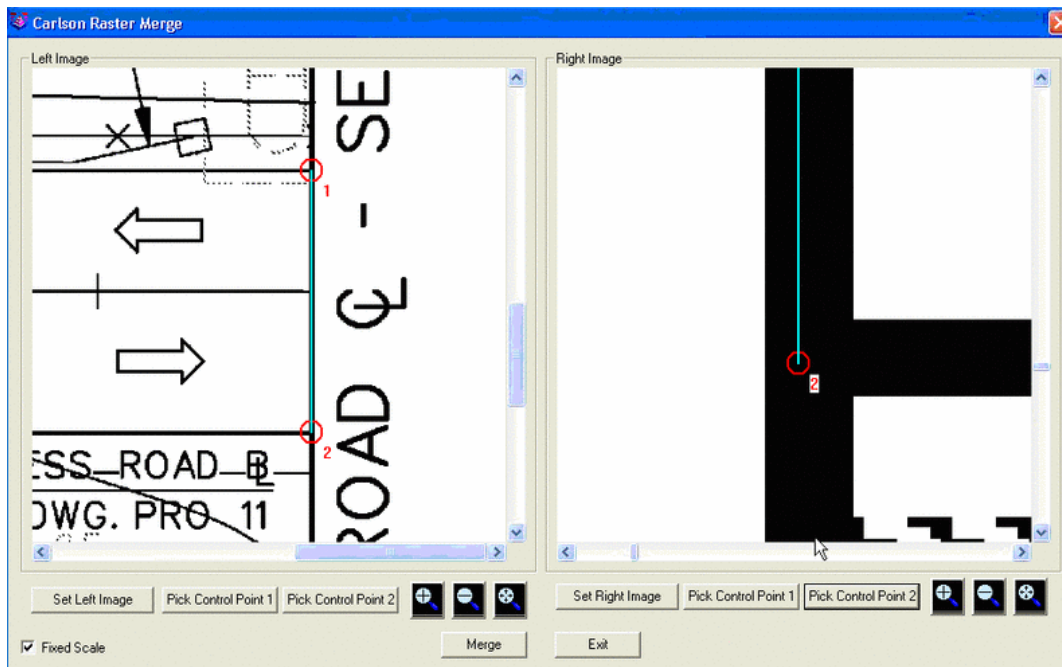

The program will first prompt you for the two existing files to merge and then for a new file name to create of the results. After picking and naming these files, the program will bring up a preview of each file to merge. Here, you will be prompted to "Select Window for area to process":

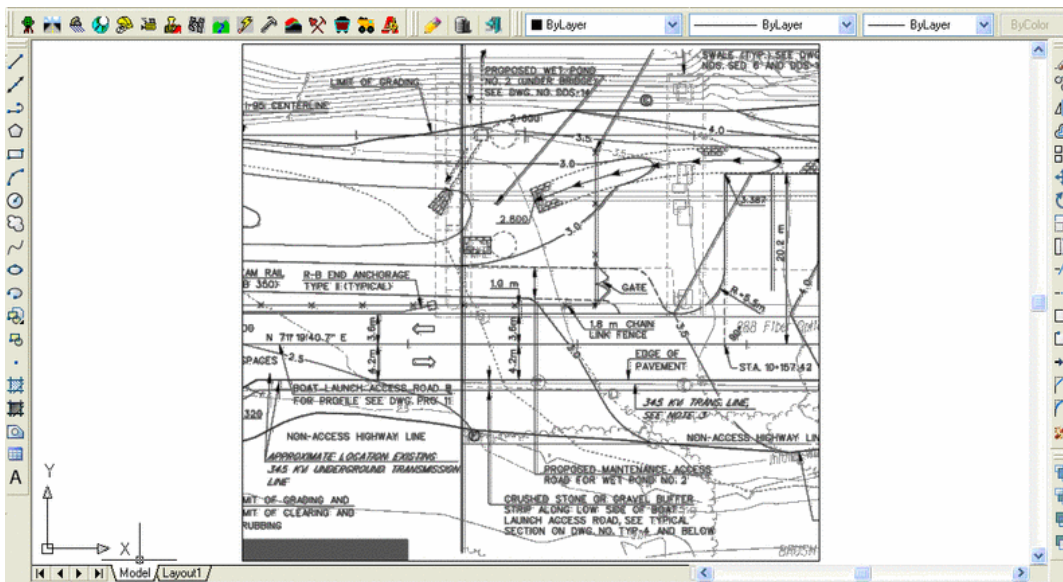

Create a Window along the given or approximate match lines (shown above in red), excluding elements like the title box. After doing this on both images, the program will perform a best-fit match and crop out any unneeded linework. The results will be shown in a preview window with a prompt: "Select Window for area to output". This allows you to select the whole or a smaller area of the preview to create the final image from. After Windowing the desired area, the new image will be created and the command will exit out.

Manual Merge

First, run "Set Left Image" and "Set Right Image" to determine the files to merge. Next, pick identical control points on the left side and right side. Zoom in and pick the best that you can. This establishes the scale, rotation, and alignment for the merge. Note: the preview windows are labeled "Left Image" and "Right Image", but the program will merge images "Top" to "Bottom" if the control points are aligned in that orientation.

After establishing control points, click the Merge button and it merges the left with the right side. When you click Save Image, you can save it in a number of distinct forms (typically as a .bmp is sufficient). Notice the program automatically removed the match line text, with no overlap. The key is that your two reference points for scale and rotation, which match, must be at the linear overlap line, because everything to either side is removed automatically. Originally, the two images overlapped, but now that has been removed.

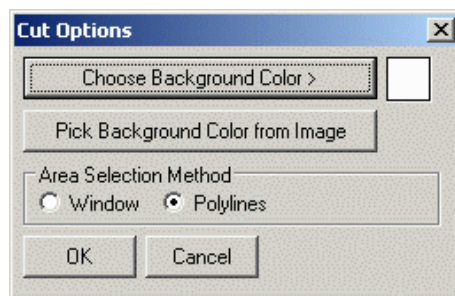

Pulldown Menu Location: Raster > Merge Raster Files

Keyboard Command: rasmerge

Prerequisite: Two or more Images you'd like to combine

Cut Image

This command wipes out an area of an image using the specified Background Color and is used to clean up an image. The area to cut can be selected either by picking a window or selecting closed inclusion polylines. Everything in the image to the inside of the area is removed. Warning: this command will update the image seen on the screen as well as the source Image.

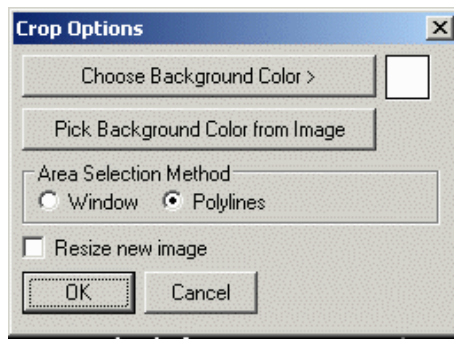

Pulldown Menu Location: Raster

Keyboard Command: rascut

Prerequisite: an Image and a closed polyline

Crop Image

This command is used to clean up an image. Everything in the image to the outside of crop area is wiped out using the specified Background Color. The area is defined either by picking a window or selecting closed inclusion polylines. The Resize New Image option will make the image file smaller to remove the cropped out area. Warning: this command will update the image seen on the screen as well as the source Image.

Pulldown Menu Location: Raster

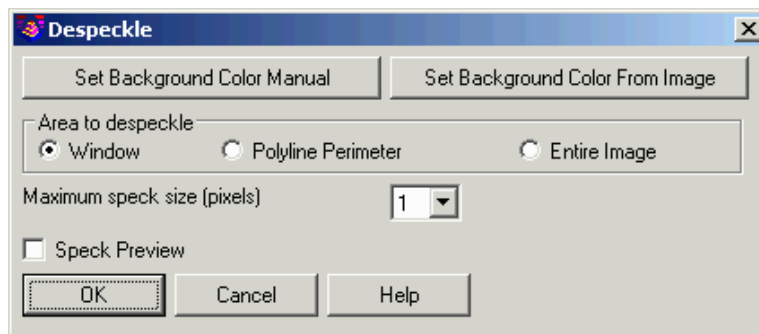

Keyboard Command: rascrop

Prerequisite: an Image and a closed polyline

Remove Speckles

Images that have been scanned in from paper plans often have unwanted black dots or "speckles" that can be removed with this command. Depending on the image, there is a max speck size that can be set. The larger the size indicated, the more specks will be removed. You can specify the area to remove specks from based on the entire image, a window area or by a closed inclusion polyline. The Speck Preview option will highlight the specs to be removed for confirmation before the removal.

Warning: this command will update the Image seen on the screen as well as the source Image.

Pulldown Menu Location: Raster > Adjust Image

Keyboard Command: rasdespeckle

Prerequisite: an Image

Mirror Image

This command flips an image either top to bottom or left to right.

Prompts

Mirror direction [**<Left-right>/Up-down**]? *press Enter*

Pulldown Menu Location: Raster

Keyboard Command: rasmirror

Prerequisite: Set Raster Image

Decompress Image

This command changes the format of a TIF image from the compressed TIF format to the uncompressed TIF format. First the program prompts for the input image file to read and then the output image file to create. The program handles LZW compression.

Pulldown Menu Location: Raster

Keyboard Command: rascompress

Prerequisite: Image File

Deskew Image

This command rotates an image. To do the rotation, this command defines a line by picking two points on the image and the image is rotated to make this line horizontal.

Prompts

Pick point 1 of the horizontal: *pick point 1*

Pick point 2 of the horizontal: *pick point 2*

Crop deskewed image [Yes/<No>]? *press Enter*

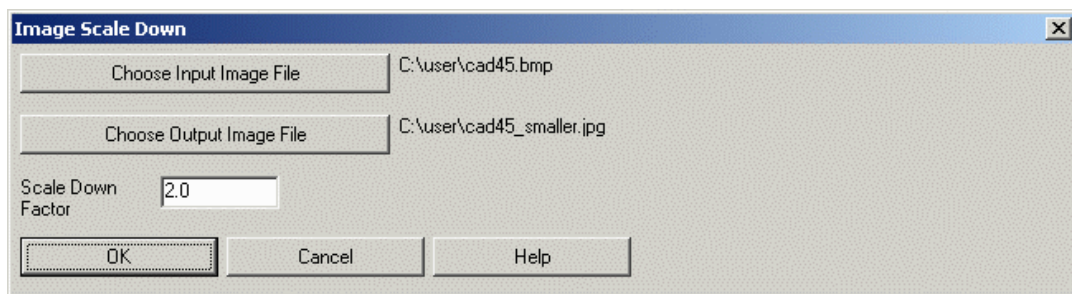

Pulldown Menu Location: Raster

Keyboard Command: rasdeskew

Prerequisite: Set Raster Image

Shrink Resolution

This command decreases the resolution of an image file. This feature applies when an image resolution is too dense to process in some other routines or you simply want to make the file size smaller to save space. This command prompts for the input image file to read and the output image file to write. The Scale Down Factor sets how many times smaller to make the output file.

Pulldown Menu Location: Raster

Keyboard Command: rasres

Prerequisite: Set Raster Image

Black/White By Threshold

This command makes the current image binary by assigning grays and colors to either black or white based on a brightness threshold. A binary image is easier to process in commands like Raster To Text and Raster To Vector. The Calculate Threshold function analyzes the image using the specified Threshold Method to estimate a good threshold value.

Pulldown Menu Location: Raster

Keyboard Command: rastreshold

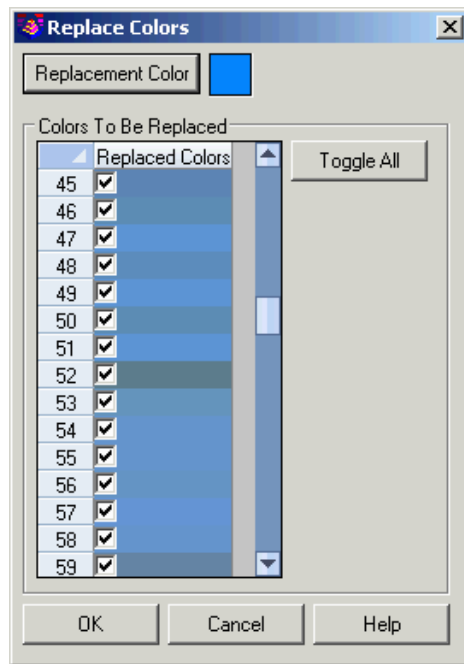

Prerequisite: Set Raster Image

Replace Color

This command replaces colors in the image with a specified new color. You can specify the area to get colors by window area or by a closed inclusion polyline. The program makes a list of all the colors from the selected area. From this list, toggle which colors that you want to be replaced and pick the Replacement Color button to select the new color.

Warning: this command will update the Image seen on the screen as well as the source Image.

Pulldown Menu Location: Raster > Adjust Image

Keyboard Command: rascolorsub

Prerequisite: an Image

Brighten/Darken Image

This command changes the brightness of the current image and applies to color images. Enter a positive number to brighten and negative to darken.

Prompts

Enter brightness change from -255 to +255: 64

Pulldown Menu Location: Raster

Keyboard Command: rasbright

Prerequisite: Set Raster Image

Negative Image

This command inverts the colors of an image. For example, black pixels are changed to white.

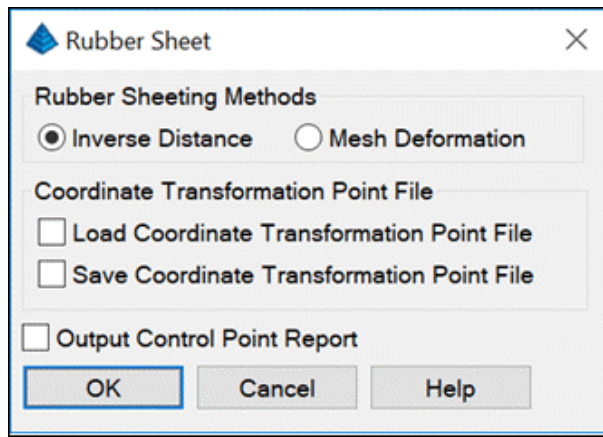

Pulldown Menu Location: Raster

Keyboard Command: rasnegative

Prerequisite: Set Raster Image

Rubber Sheet

This command adjusts an image to fit control points. This image adjustment applies when the image distortion varies and requires more than a single translate, rotate and scale transformation. This command changes the image file. The original image file is backed up to a separate file with a .bak extension.

There are two methods to model the adjustment from the control points. The Inverse Distance method weights the delta x/y from each control point as the inverse of the distance to the control point. This way the closer control points have a higher weight. The Mesh Deformation method uses an affine transformation. The control points can be either loaded from a file stored previously by Rubber Sheet, or by screen picking. With picking, the control points are defined by screen picking a point on the image and then the point to move this point on the image to. In the example shown here, the roads in the image don't line up with the road linework. After picking the road points on the image and the corresponding points on the linework, the image is adjusted to fit the road linework. The Output Control Point Report generates a report of the control point coordinates.

Image before Rubber Sheet showing control points

Image after Rubber Sheet

Prompts

- Pick origin of control point 1:** *pick point 1*
- Pick destination of control point 1:** *pick point 2*
- Pick origin of control point 2:** *pick point 3*
- Pick destination of control point 2:** *pick point 4*
- Pick origin of control point 3 (Enter to end):** *pick point 5*
- Pick destination of control point 3:** *pick point 6*
- Pick origin of control point 4 (Enter to end):** *pick point 7*
- Pick destination of control point 4:** *pick point 8*
- Pick origin of control point 5 (Enter to end):** *press Enter*

Pulldown Menu Location: Raster

Keyboard Command: rasrubber

Prerequisite: an Image

Undo Raster Edit

Undo Raster Edit will revert an Image back to its original form (both on-screen and source) from changes made by: Image Cut, Image Crop, Remove Speckles, Trace Line or Trace Polyline. It will not remove any polylines created by Trace Line or Trace Polyline.

Pulldown Menu Location: Raster > Undo Raster Edit

Keyboard Command: rasundo

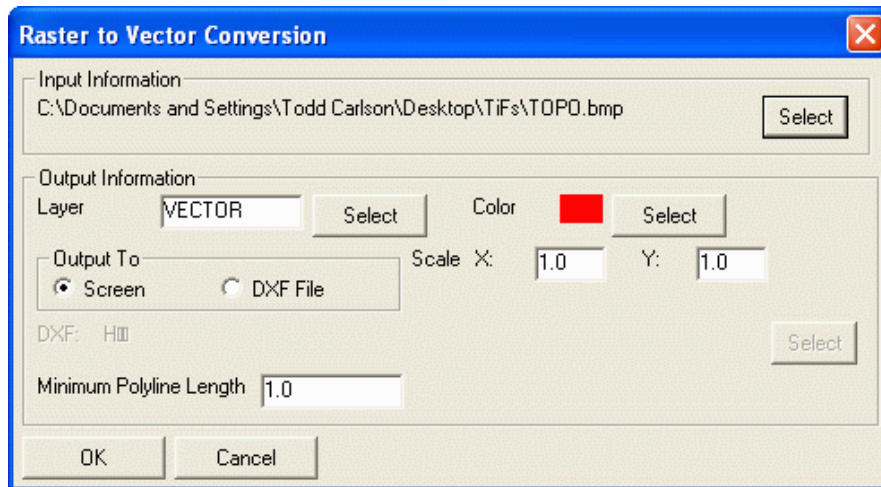

Prerequisite: an Image that has been edited

Import Raster To Vector

This command creates polylines from a raster image. The image can be either an external .bmp file or an image inserted in the drawing.

For the external file to process other file types, such as .tif or .jpeg, open the image up in Microsoft Paint and Save As the file as a monochrome .bmp. In the dialog below, you can specify the Layer, Color, Scale, and whether to draw the entities on the screen or write a .dxf file. Minimum Polyline Length will reduce the amount of line segments created from the conversion.

For an image in the drawing, you can process the entire image or limit the area to process by window or inclusion polylines. The Erase Selection option wipes out the image with the specified Background Color in the area that is processed.

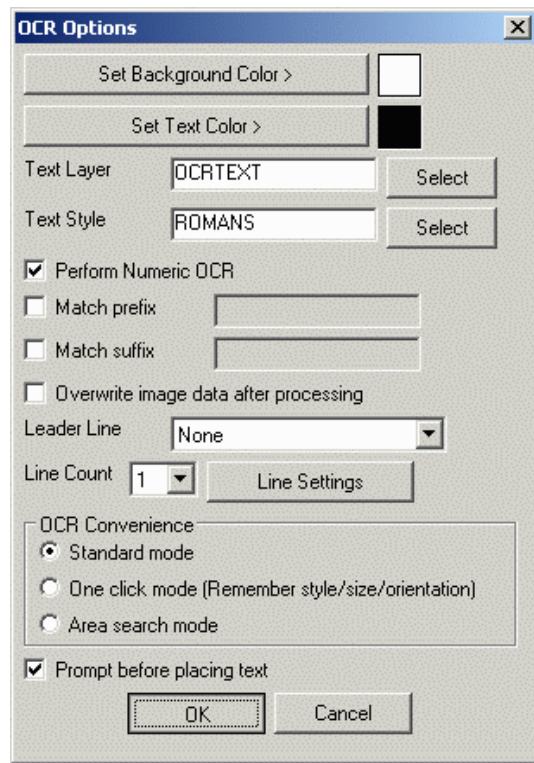

Pulldown Menu Location: Raster

Keyboard Command: ras2vec

Prerequisite: a monochrome .bmp file

Raster To Text

This command will create text from an image in your drawing generated from commands such as PDF Import, Raster Import, Attach Image, etc. one line at a time. From the OCR (**Optical Character Recognition**) Options dialog, you have the ability to identify the Background and Text Color of the image being used. The Text Layer and the font Style the text will appear on once converted can also be set here.

Perform Numeric OCR will limit the text recognition to only numeric values. By default, this command attempts to convert to alphabetic characters as well. When dealing with only numeric text, turn this feature on so that no alphabetic characters are accidentally used during the conversion. Use the Match Prefix or Match Suffix to help the recognition when the numbers have an alpha prefix or suffix like "TC 123.4".

The **Overwrite Image** option will erase the raster text from the image after it has been converted to CAD text.

The **Leader Line** option draws a leader along with converting the text.

For the OCR Mode, the **Standard Mode** prompts to pick two points across the raster text for each text to convert. These points define the area of the image to process. The **One Click Mode** converts the first text like Standard Mode and gets the text size and angle properties from this first text. Then for the additional text to convert, you only need to pick a single point on the text instead of two points. For the **Area Search Mode**, the first text is again processed the same as Standard Mode and then you window an area and the program looks for other raster text with the same size and angle as the first text.

The **Prompt Before Placing Text** shows the conversion results in a dialog with a chance to review, edit or cancel.

After clicking OK to the OCR Options dialog, you will be prompted for a "start of strike-line" then "end of strike-line". Pick left to right through the text you want to convert. A **Replacement Text dialog** will appear. Here you can review the values that the program has converted and change them if needed before accepting them by clicking OK. You will then be prompted to "strike-through" another line of text. Press Enter to end.

Prompts

OCR dialog

Pick start of stike-line or [Options] (Enter to end): *pick 1st point*

Pick end of stike-line (Enter to end): *pick 2nd point*

Pick start of stike-line or [Options] (Enter to end): *press Enter*

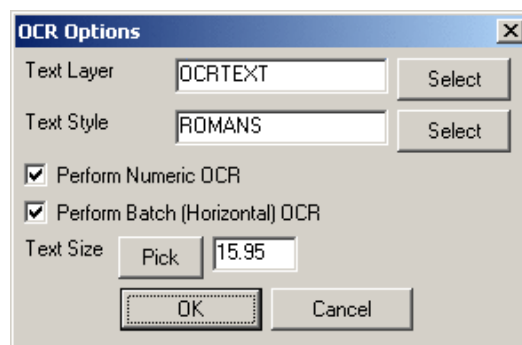

Pulldown Menu Location: Raster

Keyboard Command: RASOCR

Prerequisite: An image in the drawing

Vector To Text

This command will create text from linework in a drawing. From the OCR (**Optical Character Recognition**) Options dialog, set the Text Layer and the font Style the text will appear on in drawing once converted. **Perform Numeric OCR** will limit the text recognition to only numeric values. By default, this command attempts to convert to alphabetic characters as well. When dealing with only numeric text, turn this feature on so that no alphabetic characters are accidentally used during the conversion.

By default, this command converts one line at a time. **Perform Batch (Horizontal) OCR** allows you to convert multiple line at once as long as the text is aligned horizontally. Choosing a **Text Size** helps the program to distinguish text linework vs. standard linework. "Pick" allows you to pick two points in the plan view to set the text height to be used.

After clicking OK to the "OCR Options" dialog (with "Perform Batch (Horizontal) OCR" checked off), you will be prompted for a "start of stike-line" then "end of stike-line". Pick left to right through the linework you want to convert. With "Perform Batch (Horizontal) OCR" checked on, you will be prompted to "Select objects", which can be individually picked linework or windowing around a group of linework. After making your selection, a **Replacement Text dialog** will appear. Here you can review the values that the program has converted and change them if needed before accepting them by clicking OK. You may also Skip the conversion altogether or OK All the conversions at once in this dialog.

Pulldown Menu Location: Raster

Keyboard Command: vecocr

Prerequisite: Linework to convert to text

Set Text Color

This command sets which color to use as the text color for other Raster commands such as Raster To Text. For example, one image could have a black background and white text, and another image could have the opposite with a white background and black text. The Raster commands need to know which type of text color the image has.

This command uses the current image. If the current image isn't already set, then the program prompts to select the image. Then the program reports the current text color and prompts to pick a point on the image. The program reads the color from the image at the picked point to set the text color.

Prompts

Select image: Pick on the image (often you will need to pick on the boundary of the image to select it)

Current text color: red=0 green=0 blue=0

Pick a point in the image to set the text color: *pick point*

Text color changed to: red=201 green=234 blue=157

Pulldown Menu Location: Raster

Keyboard Command: ocrtextcolor

Prerequisite: an image in the drawing

Set Background Color

This command sets which color to use as the background color for other Raster commands such as Trace Line. For example, one image could have a black background and white lines, and another image could have the opposite with a white background and black lines. The Raster commands need to know which type of background the image has.

This command uses the current image. If the current image isn't already set, then the program prompts to select the image. Then the program reports the current background color and prompts to pick a point on the image. The program reads the color from the image at the picked point to set the background color.

Prompts

Select image: Pick on the image (often you will need to pick on the boundary of the image to select it)

Current background color: red=255 green=255 blue=255

Pick a point in the image to set the background color: *pick point*
Background color changed to: red=232 green=232 blue=232

Pulldown Menu Location: Raster

Keyboard Command: ocrbgcolor

Prerequisite: an image in the drawing

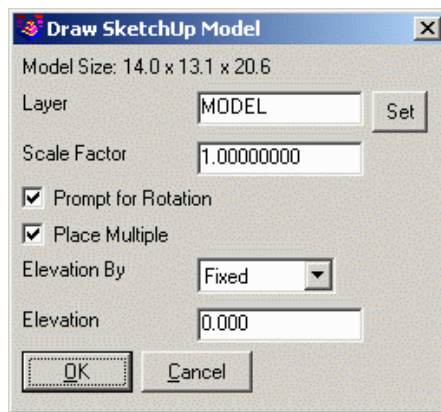

BIM Menu

The BIM menu commands are for exchanging Carlson project data with BIM.

Import SketchUp File to Drawing

This command creates a CAD block from a SketchUp model and inserts this block into the drawing.

After selecting the .skp file to import, the options dialog shows the dimensions of the model at the top of the dialog.

Layer: Sets the layer for the block in the drawing.

Scale Factor: Allows resizing the model. For example, when the SketchUp model is in inches and the drawing in feet, use a scale factor of 0.0833333.

Prompt For Rotation: This option prompts to pick a second point for rotation of the block in the drawing.

Place Multiple: Sets whether to place a single block in the drawing or allow for drawing multiple copies.

Elevation By: The Pick method uses the elevation of the picked points. The Fixed method uses the **Elevation** from the dialog. The Surface method prompts for a grid or triangulation file to use for the elevation.

See <http://www.sketchup.com/> for information on SketchUp and see <https://3dwarehouse.sketchup.com/> for a collection of available SketchUp models.

Prompts

Select SketchUp File

Draw SketchUp Model dialog

Pick position: *pick a point*

Pick rotation: *pick a point*

Pick position (Enter to end): *press Enter*

Pulldown Menu Location: BIM

Keyboard Command: skp2dwg

Prerequisite: .skp file

Import Architectural IFC File to Drawing

The **Import Architectural IFC File to Drawing** permits architectural information stored in an "open IFC" format (see <http://www.buildingsmart.org/standards/ifc> for additional information regarding Industry Foundation Classes) to be imported into the current drawing. Common uses of this routine are to permit the graphical representation of a building (or its component entities) within the Carlson environment for construction staking.

Note:

- In the event the data represented by the IFC file needs to be scaled to better align with the units found within Drawing Setup, consider using the Scale Wizard command.
- In the event the data represented by the IFC file needs to be aligned to better fit the coordinates of the project, consider using the 2D Align command.
- In the event the data represented by the IFC file needs to be elevated for better visualization within the project, consider using the Change Elevations command.
- Quick visualizations of the imported IFC file can be viewed via the 3D Viewer Window command (experiment with the **Clip Plane** control along the bottom of the Viewer window to slice through the model).
- As entities are imported from the IFC file, they are assigned to a layering convention based on the IFC entity type. A template drawing (Carlson_ifc.dwt, set-able via Carlson Configure is available that contains an introductory layer scheme for many of the classifications found within IFC files.
- Various sample IFC files abound on the Internet and can be found at locations such as:
 - <http://www.ifcwiki.org/index.php/Examples>
 - <http://download.bimserver.org/ifc-examples/>
 - <http://openifcmodel.cs.auckland.ac.nz/Model>

Prompts

IFC File to Read: *Navigate to and select an IFC 2x or later file and click Open.*

Pulldown Menu Location(s): BIM

Keyboard Command: ifc2dwg

Prerequisite: IFC 2x or later file

Import Architectural IFC File to Model

Similar to the procedure found within the Import Architectural IFC File to DWG command, the **Import Architectural IFC File to Model** command imports and converts an architectural IFC file into:

- *.OBJ - An "object" geometry file
- *.MLT - A "material" file

This command is useful for larger IFC data sets that might otherwise tax the performance of the CAD engine or clutter a drawing file.

Note:

- The OBJ and MLT file(s) are created with the same file name as that of the IFC file.

- The representation of the OBJ file can be viewed with the Model 3D Viewer command.

Prompts

IFC File to Read: *Navigate to and select an IFC 2x or later file and click Open.*

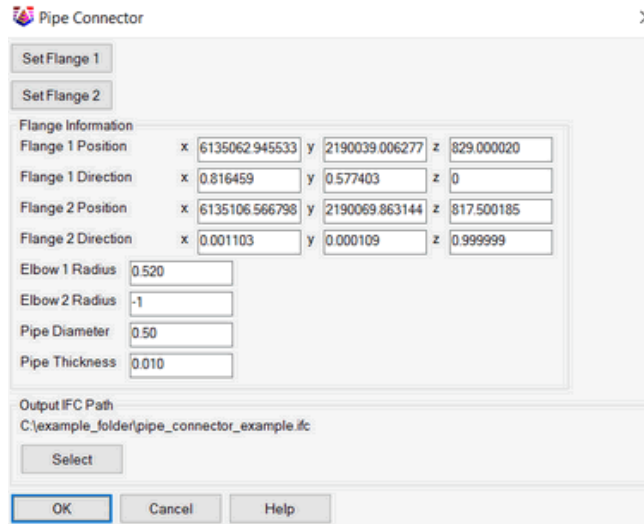

Pulldown Menu Location(s): BIM

Keyboard Command: ifc2obj

Prerequisite: IFC 2x or later file

Pipe Connector

This command draws the geometry of the connector pipe between two points in the current drawing, and outputs the connector pipe geometry to an IFC file.

Set Flange 1 & 2:

Allows you to select groups of points representing the first and second (start and end) points to be connected. Groups of points are expected to be laid out in a pattern resembling a circle. The best estimate of the center of this group of points will be the first or second connection point respectively¹. Using Set Flange 1 or 2 will also set flange direction 1 and 2 such that the first point is "facing" the second point and the second point is "facing" the first point.

Flange 1 & 2 Position:

Position of the first and second point that the connector pipe will join.

Flange 1 & 2 Direction:

Direction from which the beginning and end of the connector pipe will emanate.

Elbow 1 Radius:

Radius of the 1st elbow in the connector pipe geometry. This will be -1 if no pipe geometry is feasible².

Elbow 2 Radius:

Radius of the 2nd elbow in the connector pipe geometry. This will be -1 if only 1 elbow is needed to connect the start and end points of the connector pipe, or if no pipe geometry is feasible².

Pipe Diameter:

Diameter of connector pipe².

Pipe Thickness:

Thickness of the connector pipe².

Output IFC Path:

Output file path for the IFC file. Can be set using the "Select" button.

1. Pipe Connector performs various calculations when determining the geometry of the connector pipe. Because of this, the actual point that is determined by Set Flange 1 & 2 may not be the center of the group of points selected by the user. For example, if the two points can be joined by a pipe with only one elbow if one of the points is altered "slightly" Pipe Connector will alter the two points to simplify the pipe connector geometry in this way.

2. The feasibility of the connector pipe geometry depends on many variables. The two most common:

A) set flange 1 and 2 will attempt to set the the direction of the first and second point such that they face each other. However as the direction is editable, it is possible to set the point and direction of the first and second points of the connector geometry that cannot be connected.

B) Given a pipe Diameter and thickness it may be impossible to curve a pipe such that it connects the first point of the connector pipe to the second point of the connector point. If a larger radius is feasible, Pipe Connector will automatically compute this value, otherwise radius 1 and 2 will be set to -1.

Example

In this drawing the points (1, 2, 3, 4) and (5, 6, 7) will be used to specify the start and end point of the connector pipe. After being selected by Set Flange 1 and Set Flange 2 respectively and pressing okay, an ifc file will be written to the output IFC path and the connector geometry will be drawn in the drawing "demo3." (see below).

Pulldown Menu Location: BIM

Keyboard Command: pipe_connector

Prerequisite: Points on connections

Model 3D Viewer

Similar to the functionality offered by the Surface 3D Viewer command, the **Model 3D Viewer** permits the viewing of 3D models (such as those produced by the Import Architectural IFC File to Model command).

Note:

- Please reference the Surface 3D Viewer command for the functionality regarding the various controls available in the **Model 3D Viewer** command.

Prompts

Select Model to View: *Navigate to and select the desired model file and click Open.*

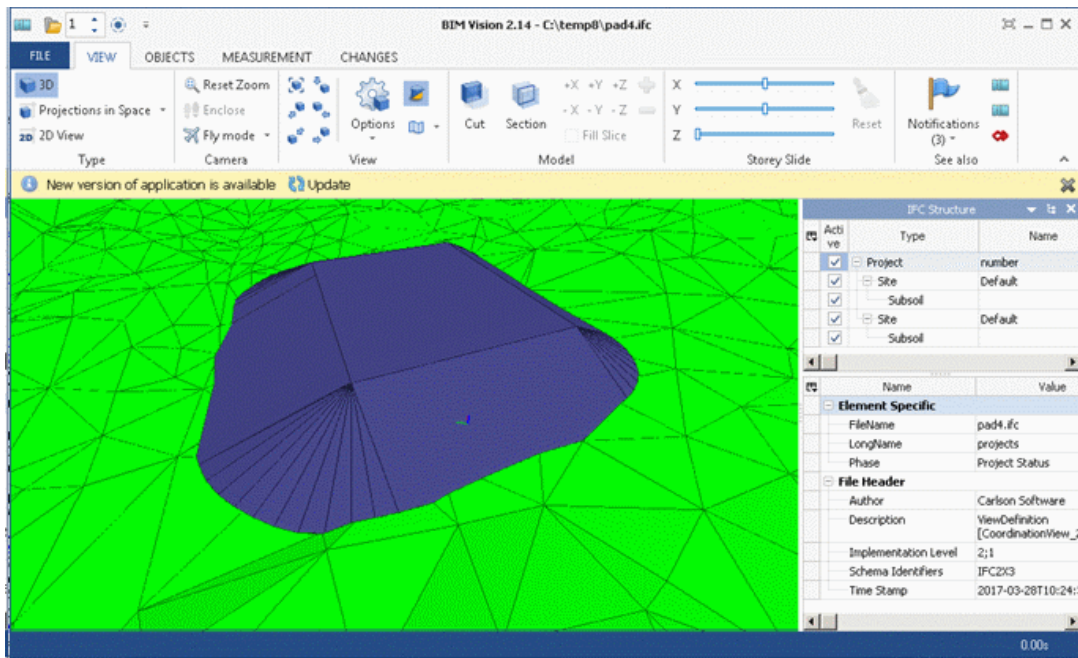

Pulldown Menu Location(s): BIM

Keyboard Command: viewmdl

Prerequisite: A valid 3-D MDL, DXF or OBJ file

Export Surface Architectural IFC File

This command outputs a Carlson triangulation surface model (.tin) to an "open IFC" format (see <http://www.buildingsmart.org/standards/ifc>) and subsequently shared with other applications that make use of IFC-structured files (typically, architectural-oriented products). When the Carlson triangulation surface uses different colors, the IFC file is created with separate models for each color which is a way to create separate models for each different type of surface area.

Prompts

Select Triangulation File to Read: *Navigate to and select the desired Carlson surface model file and click Open.*

IFC File to Write: *Navigate to the desired folder location and indicate the desired IFC file name to write and click Save.*

Pulldown Menu Location(s): BIM

Keyboard Command: tin2ifc

Prerequisite: A Carlson surface model (TIN or FLT) file

Export Solid Model IFC File

This command creates an IFC model file from a Carlson Solid model file (.MDL). For example, you can use Takeoff to create solid models of the pavement subgrades and then create IFC models to load into a site model. First the program prompts for the MDL file to read and then prompts for the IFC file to create.

Pulldown Menu Location: BIM

Keyboard Command: mdl2ifc

Prerequisite: A Carlson solid model (.MDL)

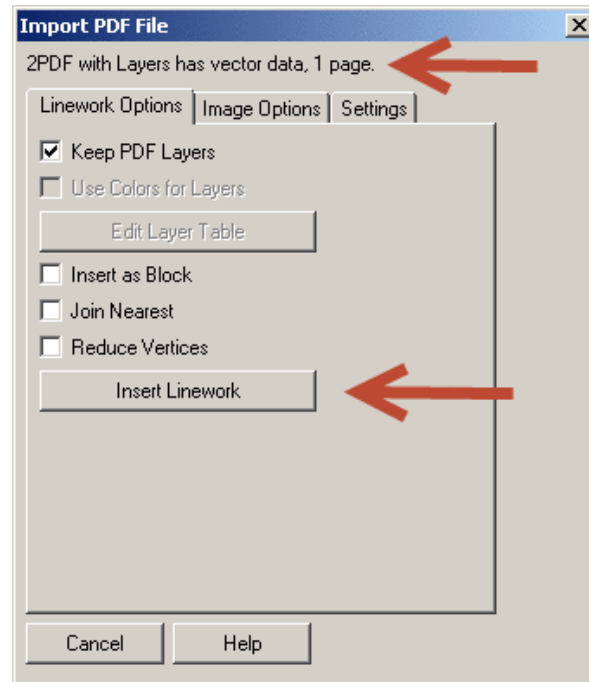

PDF Menu

The PDF menu commands are for importing from PDF.

Import PDF File

This command allows you to bring in an Adobe .PDF file and convert it into CAD linework or an image file. First the program prompts to select the file you want to convert. Next, the below dialog will open. The first line in the dialog will show important information about the PDF, including the file name, data type (Vector or Raster), and the number of pages. It will also display "Layers" or "3D" if those elements are found in the file. Vector vs Raster data is an important distinction. Vector PDFs are typically of higher quality and can be brought in with the "Linework Options". Raster PDFs are lower quality and it is recommended to bring them in with the "Image Options".

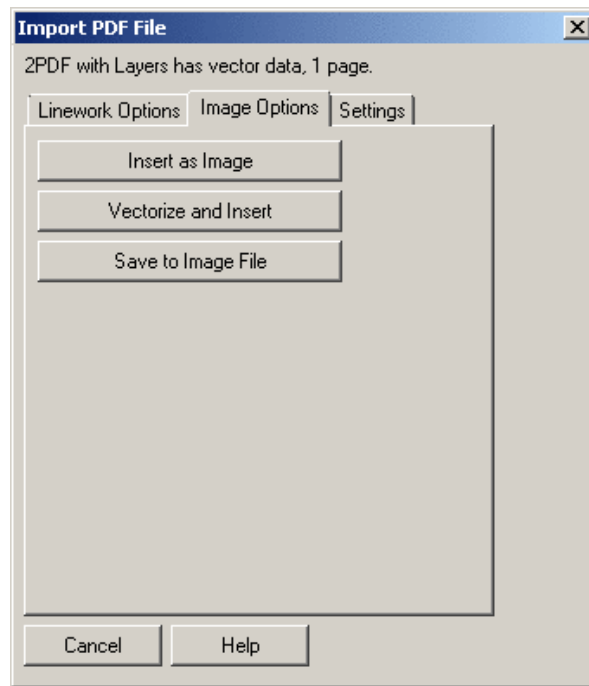

Linework Options

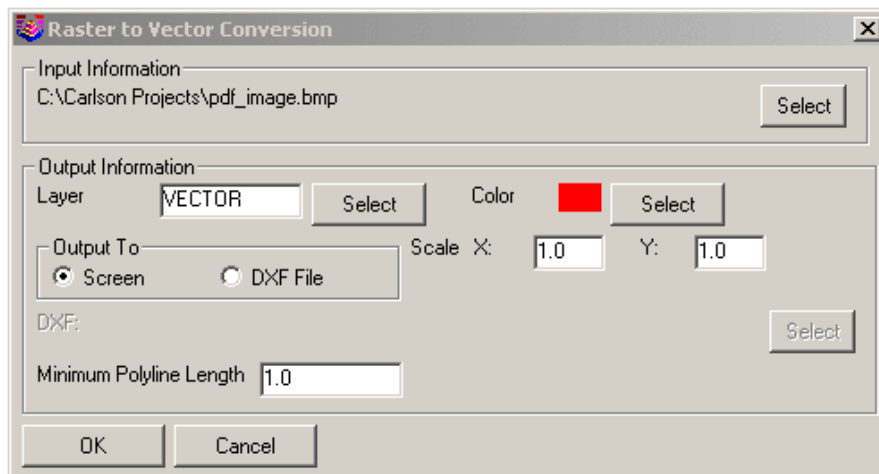

The "Insert Linework" button shown above will convert the PDF file into usable CAD polylines. If layers are present in the PDF file, "Keep PDF Layers" will import the PDF layers into CAD layers. If there are not layers in the PDF file, "Use Colors for Layers" will parcel out the converted polylines onto layers based on the linework's color, gray scale, width, horizontal and vertical orientation. "Insert as Block" will create one block entity for all the linework. "Join Nearest" can be used to clean up the converted linework by combining adjacent linework but requires longer processing time. The "Reduce Vertices" simplifies the linework by removing extra vertices. The "Use Zero Linewidth" option creates linework with the line width set to zero. Otherwise the linewidth will be set from the linework properties in the PDF. The "Skip Tiny Lines" option doesn't draw any super short lines which is helpful for handling a PDF that has a dense hatch pattern made of tiny lines.

Image Options

In some cases, it may be preferred to bring in the PDF as an Image. "Image Options" shown below has three different methods for working with the converted Image. "Insert as Image" will convert the PDF into a Image file that is then inserted into the drawing. When inserted, the Image is visible on the screen, but unusable as CAD linework. "Save to Image File" simply saves the Image file without inserting it into the drawing.

"Vectorize and Insert" can be used to convert raster PDFs into CAD linework. If the program recognizes "vector data", indicated in the status section of the dialog, then it is recommended to use the "Linework Options" to produce CAD linework. Using "Vectorize and Insert" on "raster data", you will receive this additional dialog:

In this dialog, you can specify the Layer, Color, Scale, and whether to draw the entities on the screen or write a .dxf file. Minimum Polyline Length will reduce the amount of line segments created from the conversion.

Inserting the Converted PDF

When you are inserting the converted PDF into the drawing, will you receive the following prompts:

Pick point to insert PDF: Specify the insertion point for the PDF converted linework by either picking on the screen or typing in a coordinate (Example: 1000,1000).

Specify rotation angle: To accept the default value displayed, press Enter, or enter the rotation angle (Example: 90).

Specify scale <1.0>: To accept the default value displayed, press Enter, or enter a scale factor. If the scale factor is not known, which is typical, accept the defaults to this prompt.

Note: The proper scale factor can be determined by running Edit>Scale Wizard after inserting the PDF.

After the command has imported the PDF file, run View > Zoom > Extents to see the converted entities.

Settings

The program has two different conversion engines available, "Visual Integrity" and "Ghostscript". "Visual Integrity" is recommended and the default. In order for Ghostscript to work you need to download and install it from the website <http://sourceforge.net/projects/ghostscript/>. Click on the "View all files" button to the right of the "Download Now!" button. A list of Ghostscript versions will appear below (i.e., 9.23, 9.22). Choose the 9.23 or newer version. After downloading the .exe to your computer double click on it to install. Ghostscript is a free software and should only take a few minutes to install. Once it is installed, Carlson Takeoff will automatically utilize this software when Ghostscript is selected as the PDF Import Engine.

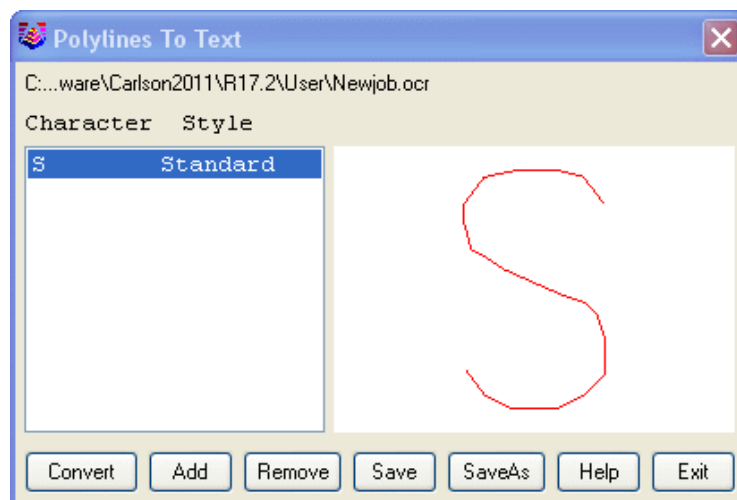

Pulldown Menu Location: Tools > Import/Export

Prerequisite: a PDF file, Ghostscript installed

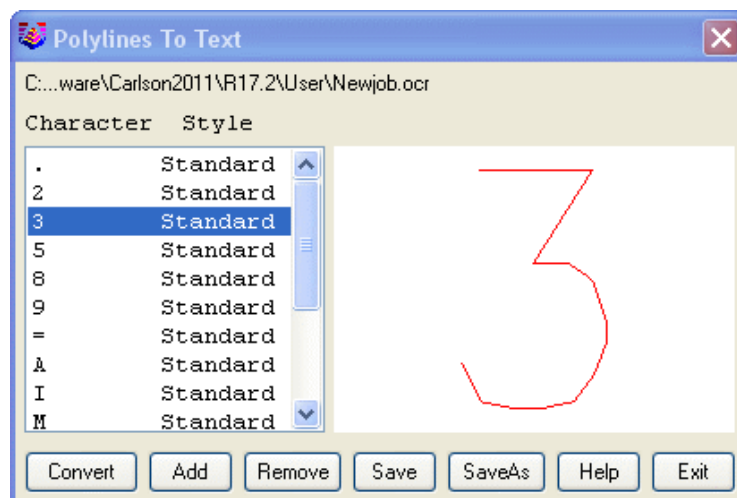

Keyboard Command: loadpdf

Convert Polylines To Text

This command will create text from polylines generated by a PDF or raster import. When you run the command you will be prompted to load or create a Character file (.ocr). This file acts as a library that associates polylines in your drawing with a particular character (A, B, C, 1, 2, 3, etc.) to convert into text. From the Polyline To Text dialog, you have the ability to modify the Character library and to Convert selected linework in the drawing.

To build the Character library, pick on the Add button. Here you type in the character you'd like to add, choose the font style the text will appear on, and then select the polyline(s) that comprise the character.

After the desired library has been compiled, Convert will prompt you to select the linework you wish to process from the library into text. Below is an example of PDF linework convert from polylines into text.

Run Save or Save As to use the Character file (.ocr) on future projects.

Pulldown Menu Location: PDF

Keyboard Command: pl2txt

Prerequisite: Polylines to convert

Convert Dashes To Polylines

This command connects sequential dashes into polylines. There are two processing methods. The Individual method creates one polyline at a time. The Selection method processes a selection set of dashes and creates multiple polylines. The program will prompt you to select a sample and adjacent dash line. This identifies the layer and approximate gap between dash lines. It is helpful to isolate this layer before running the command. Next, select the dash lines to process and press enter. Below are typical results of the conversion.

Before Conversion

After Conversion

Pulldown Menu Location: PDF

Keyboard Command: dash2pl

Prerequisite: Dashed linework to convert into continuous polylines.

Drawing to 3D PDF

This command creates a PDF file from 3D entities in the drawing. The elevations of the entities are used to make the PDF a "3D PDF" that can then be opened and oriented in 3D with a standard PDF viewer such as Adobe Acrobat Reader.

Note:

- See the 3D Viewer to 3D PDF command for a complete description of the 3D PDF Options controls.
- Additional controls can be exposed in the 3D PDF via a "right mouse click" while the 3D PDF is open.

Prompts

Select entities for 3DPDF.

<Select entities>: *Select the entities that should be written to the 3D PDF file.*

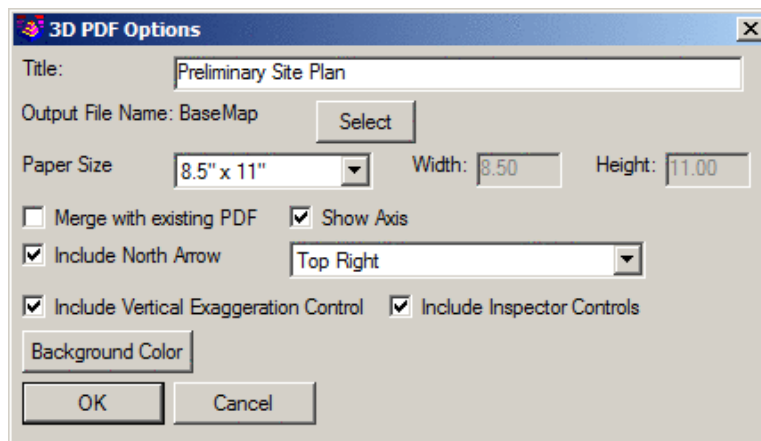

Pulldown Menu Location: PDF

Keyboard Command: dwg2pdf3d

Prerequisite: Entities in a drawing

3D Viewer to 3D PDF

This command creates a PDF file from 3D viewer files (.3DX) which are created in commands such as 3D Viewer Window and Surface 3D Viewer. The PDF file is a "3D PDF" that can then be opened and oriented in 3D with a standard PDF viewer such as Adobe Acrobat Reader.

Title: Indicate a title (if any) that should appear at the top of the PDF file you are about to create.

Output File Name: Use the **Select** button to supply the desired PDF file name to which the drawing content shall be written.

Merge with existing PDF: Use this option with the Template File Name to add the 3D PDF onto an existing PDF. This option is a way to have your own title block as a template PDF and then insert in the 3D PDF.

Paper Size: Indicate the desired PDF paper size.

Append with existing PDF: When enabled, the new PDF output will be appended as a new page to the **Output File Name** if the file already exists.

Plan View Margins: Controls the margins around the 3D view window and the border of the page.

Background Color: Controls the background color for the PDF.

Show Axis: When enabled, the X,Y,Z axis directions will be displayed in the PDF.

Include North Arrow: When enabled, a North Arrow will be displayed in the PDF.

Include Vertical Exaggeration Control: When enabled, a Vertical Exaggeration control will be available in the PDF.

Include Inspector Controls: When enabled, an inspection (Signature) control is provided in the PDF.

Background Color: Indicate the desired background color of the PDF.

Note:

- To create a 3D PDF from entities directly selected from a drawing, see the Drawing to 3D PDF command.
- Additional controls can be exposed in the 3D PDF via a "right mouse click" while the 3D PDF is open.

Prompts

3DX File to Create PDF: *Select the *.3DX file that should be written to the 3D PDF file.*

Pulldown Menu Location: PDF

Keyboard Command: 3dx2pdf

Prerequisite: A *.3DX file

Convert LDD Contours

This command allows you to convert LandDesktop contours (known as AECC_CONTOUR objects) into polylines. You must have the AEC Object Enabler installed before using this command. If you do not have the object enabler installed, download the latest version from www.autodesk.com.

You can use the *List* command to determine if contours are polylines or AECC_Contour objects. Here is an example listing:

AECC_CONTOUR Layer: "CONT-MJR"

Space: Model space

Handle = 429

Major Contour Interval

Elevation: 1005.00

Smoothing: None

Number of Vertices: 48

Open

Length: 560.25

Constant width: 0.00

Style Name: Standard

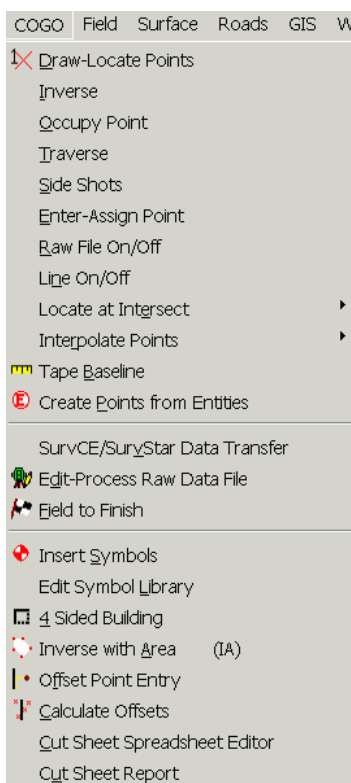

Field Module

12

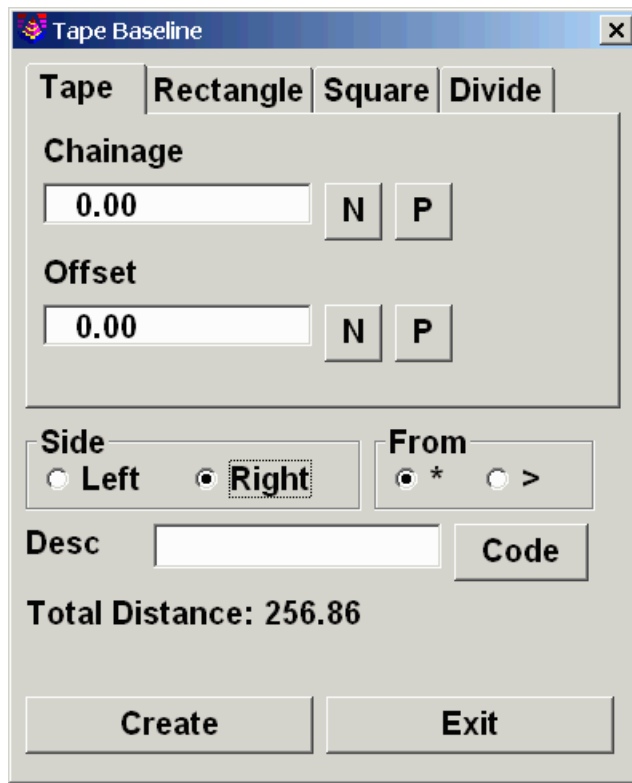

COGO Menu

The most of the commands in the COGO pull-down menu are described in the Survey manual. Only the few commands that are specific to Field are described here.

Tape Baseline

This command creates points or linework along a baseline that is defined by two points. After specifying the baseline start and end points by either entering point numbers from the coordinate file or screen picking points, the program has a dialog with different methods for creating the points. The Tape method creates points at the specified chainage (distance) and offset from the baseline. reports the cut or fill between your current position and a design surface. The design surface can be one flat elevation, a grid file, a triangulation file, a road design file, or a section file. The Rectangle method draws a rectangle as a closed polyline using two points specified by chainage and offset from the baseline. The Square method draws a square as a closed polyline with a starting point at a baseline endpoint and the other corner specified by a distance along the baseline. The Divide method creates points at an interval between the baseline endpoints.

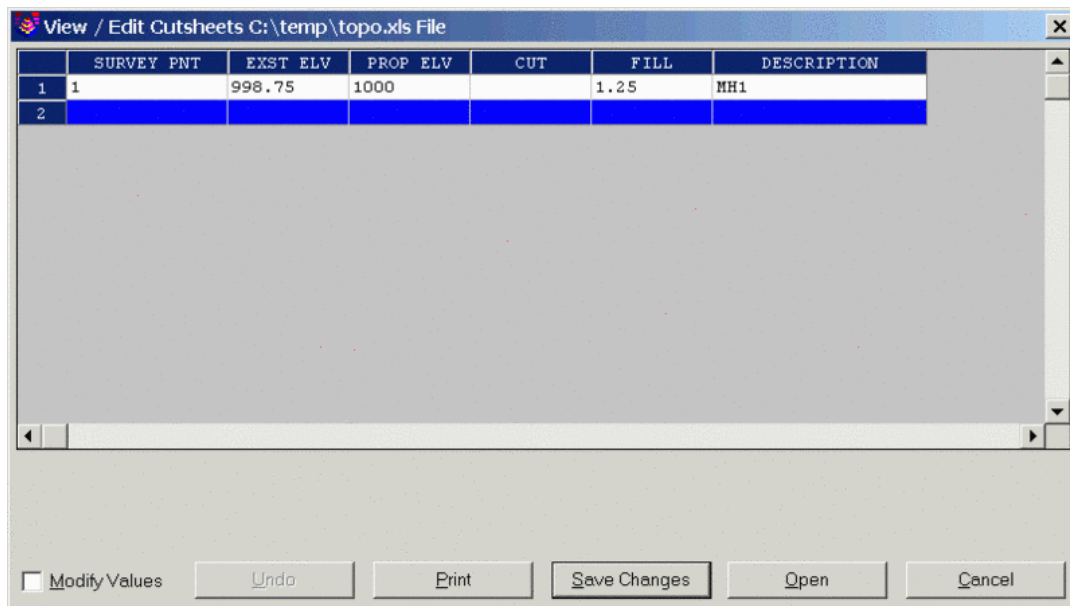

Pulldown Menu Location: COGO

Prerequisite: None

Keyboard Command: tape.blinc

Cutsheet Spreadsheet Editor

This command edits and reports cut sheet data that is stored in an Excel (.xls) file. To create this data with Field stakeout routines, the option to Store Cutsheet Data In Spreadsheet must be set active in Configure Field->Stakeout Settings.

Pulldown Menu Location: COGO

Prerequisite: None

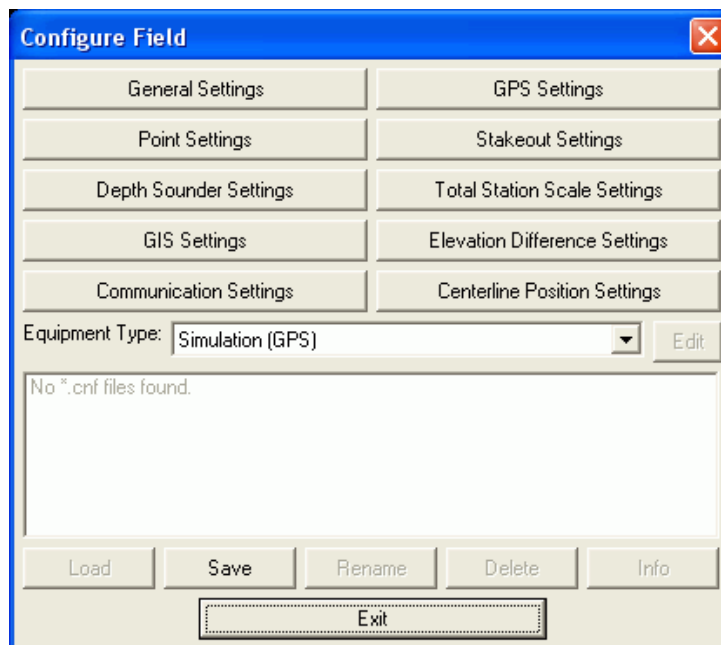

Field Menu

The Field pull-down menu has the main functions for Field including equipment setup, storing points and stakeout.

Configure Field

This command sets the equipment type, communication parameters and other Carlson Field options. Make sure the *Equipment Type* box shows the correct GPS or Total Station equipment that you'll be using. The down triangle button to the right of this box brings up a list of the equipment types to choose from. There are ten *Settings* buttons to bring up the dialog boxes which are used to change Carlson Field's default settings. Explanations for each are shown below.

General Settings

If you are using a total station, *Rod Height* is the distance from the prism to the ground. For GPS, *Rod Height* is the distance from the center of the GPS antenna to the ground.

The *Show Carlson Field Startup Icon* controls whether the Carlson Field Startup Icon is displayed in the lower right of the screen. This startup icon brings up the Carlson Field function menu for launching Carlson Field commands without having to pick them from the pull-down menu.

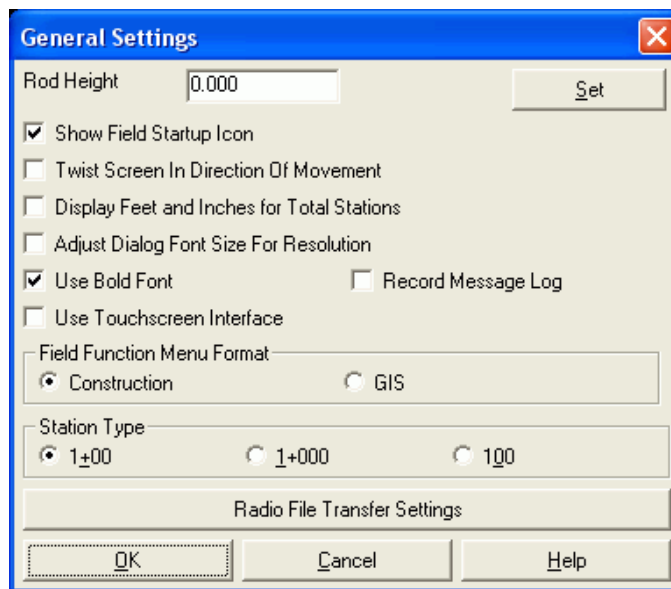

The *Twist Screen In Direction Of Movement* will rotate the drawing view so that your current direction of movement is facing straight up in the view. This rotate is for the view only and does not change the coordinates. This option only applies to GPS and robotic total stations in commands that show the arrow icon such as Track Position.

The *Display Feet and Inches for Total Stations* will use a feet and inches display format (1'2 3/4") in most routines when using a total station.

The *Adjust Dialog Font Size For Resolution* will attempt to adjust some dialogs to better fit the resolution you are using.

The *Use Bold Font* toggles between using standard or bold font for the Carlson Field dialogs.

The *Station Type* chooses the format of centerline station labels. Typically 1+00 is used for feet units, 1+000 is used for metric and 100 has no plus symbol in the number.

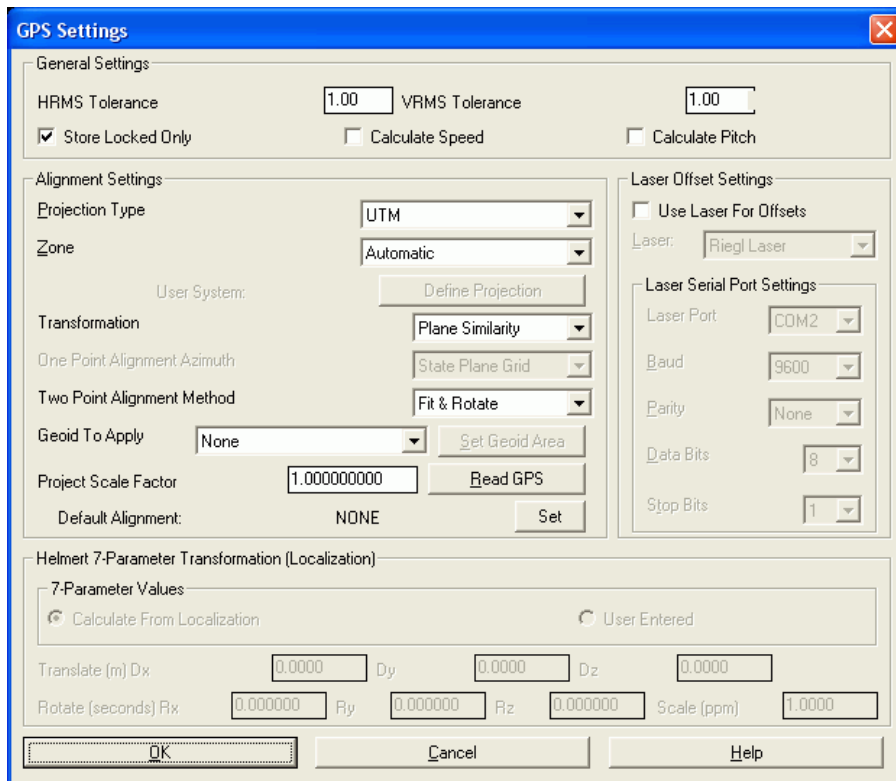

GPS Settings

The *RMS Tolerance* checks the RMS values when reading GPS positions. The RMS is the accuracy value reported by the GPS receiver. There are separate settings for the horizontal and vertical RMS values. The RMS (root mean square) value means that the reported coordinate is within +/- the RMS value of the true coordinate to a certain confidence level. The confidence level depends on the GPS receiver. Typically it is a 98% confidence. If either RMS value exceeds the user-defined tolerance while storing points, Carlson Field will default to "No" when it asks if you want to store the point. You are required to choose yes to override the tolerance check and store the point.

Suggestion: When GPS RTK systems loose lock and go "Float", both the horizontal and vertical RMS values typically jump up to sub-meter (1' or higher) values. In Carlson Field, one foot is the default for the *GPS RMS Tolerance*. Some operators set the *GPS RMS Tolerance* low to 0.2 to check for high RMS values while still "Fixed".

Store Locked Only - The position of the GPS rover is considered either "Autonomous", "Float" or "Fixed" based on the solution status from the GPS base corrections. When you are storing points and the *Store Locked Only* box is checked, Carlson Field will only store points if your position is "Fixed". We suggest you leave this box checked. It ensures that you do not record inaccurate points.

Suggestion: When walking in light to heavy canopy, the rover might remain "Float" and display RMS accuracies of over a foot, sub-meter or more. Setting your *GPS RMS Tolerance* high and turning off *Store Fixed Only* will allow storing wetland and LOD (limits of disturbance) points under canopy that require only sub-meter tolerances. (USCG beacon DGPS sub-meter RTK GPS will always use these settings.)

Projection Type - defines the datum coordinate system to be used for converting the latitude/longitude from the GPS receiver into cartesian coordinates. For the United States two separate horizontal control systems have been developed by the Federal Government: State Plane 1927 and State Plane 1983. For international use the UTM (Universal Transverse and Mercator System) should be selected. The Lat/Lon option will convert the latitude/longitude from degrees minutes seconds format into decimal degrees. This option is useful when working in a decimal degrees lat/lon coordinate system.

Zone - For State Plane projections, you must select the correct state zone that you are working in. For UTM, the Automatic Zone option will have the program automatically use the correct UTM zone for your location. Otherwise for UTM, you can manually set a specific UTM zone. This manual option applies to working on the border between zones and you want to force the program to always use one of those zones.

Important: Coordinates of surveyed points will be inaccurate if the Projection Type and Zone settings are wrong. If you have done survey work and then realize that they are set wrong, then your point coordinates are wrong, but your work is not wasted. Carlson Field records the latitude, longitude and height of every point in a *.RW5 file. You can input the correct projection zone settings later and reprocess your data using the Edit-Process Raw File command.

Model - For UTM, this option sets the ellipsoid constants for converting the lat/lon to UTM coordinates. The following is a list of the models:

Model Earth Radius(m) Flattening factor

Airy 1830 6377563.396 0.00334085064038

Transformation - The transformation in the Align Local Coordinates command can either be by plane similarity or rigid body methods. Both methods use a best-fit least squares transformation. The difference is that the rigid body method does a transformation with a translation and rotation and without a scale. The plane similarity does a rotation, translation and scale. This option only applies when two or more points are used in Align Local Coordinates.

One Pt Align Azimuth - This option applies to the rotation when using one point in Align Local Coordinates. For this alignment method, the state plane coordinate is translated to the local coordinate. Then the rotation can use either the state plane grid or the geodetic as north. No scale is applied in this transformation. The state plane and geodetic true north diverge slightly in the east and west edges of the state plane zone. This option allows you to choose which north to use.

Two Point Align Method - This option applies only two point alignments. Possible values are *Fit & Rotate* and *Rotate Only*. *Fit & Rotate* (the default) will use the second alignment point for rotation, translation, and scale (depending on the value set for *Transformation*). The *Rotate Only* option will use the second point of a two point alignment for rotation only.

Geoid To Apply - This option will account for the geoid undulation in determining the orthometric elevation of the measurement. The definition of the geoid model as currently adopted by the National Geodetic Survey is the equipotential surface of the Earth's gravity field which best fits, in a least squares sense, global mean sea level. Orthometric elevation measurements are used in survey calculations. In order to convert ellipsoid heights (H_e) as measured by GPS into orthometric elevations (E_o), you must provide for a correction between the GPS-measured ellipsoid (reference ellipsoid) and a constant level gravitational surface, the geoid. This correction is the geoid undulation (U_g). The formula is $H_e = E_o + U_g$.

The Geoid models are essentially large elevation difference models in grid format. Carlson Field has two geoid models available. Geoid99 covers the United States at 1 minute grid intervals. EGM96 covers the entire globe at 15 minute intervals. These Geoid models are huge and take a lot of disk space and memory. The Geoid model files are not installed automatically and instead need to be installed by going to the Geoid folder on the Carlson Field installation CD. Once installed onto Carlson Field, you then need to specify your location by lat/lon so that the program only needs to load a local portion of the Geoid model. To set your local Geoid area, pick the *Set Geoid Area* button. Setting the Geoid area will carve out a Geoid model around the specified lat/lon covering a square area of 2 degrees by 2 degrees which is about 100 miles by 100 miles.

Carlson Field applies the Geoid model by subtracting the Geoid undulation from the GPS elevation.

The resulting elevation is then used and displayed. In the Monitor function, the Geoid undulation is displayed.

In practice, the Geoid model is most applicable to two types of alignment scenarios. One of these types is when setting up the base over a known point and having no alignment control points. The other is when there is one alignment control point. When using multiple alignment control points, the Geoid model is not as important because Carlson Field can model the elevation difference which can generally pick up the local Geoid undulation.

Project Scale Factor - After converting the LAT/LONG from the GPS to the state plane coordinates and applying the Align Local Coordinates, the Project Scale Factor is applied as the final adjustment to the coordinates. This adjustment is used on the X,Y and not the Z. The Project Scale Factor is applied by dividing the distance between the coordinate and a base point by the Project Scale Factor. The coordinate is then set by starting from the base point and moving in the direction to the coordinate for the adjusted distance. The base point is the first point in Align Local Coordinates. If there are no points specified in Align Local Coordinates, then 0,0 is used as base point. The Project Scale Factor can be entered directly or calculated using the grid factor and elevation for the current position. When using the current position, the program will read the LAT/LONG from the GPS receiver. The scale

factor is then calculated as: (State Plane Grid Factor - (Elevation/Earth Radius)).

Default Alignment - This option sets the alignment file to use by default for new drawings. This feature applies when you will keep working at the same site with the same base receiver setup.

Helmert 7-Parameter Transformation - These settings apply when the Transformation is set to Helmert. The Helmert 7-parameters can either be calculated by the program using the control points in the localization or user-entered.

Laser Offset Settings - There is an option to use a laser for reading the distance and angle for offset points. When this option is enabled, you can choose the laser equipment type and communication parameters. The serial port for the laser must be different than the GPS which requires at least two serial ports on the computer. When using a laser for offsets, the program will read the current position from the GPS and then read the laser for the distance and angle to the point. This combination allows you to calculate points that cannot be directly reached by the GPS. There are two methods in the Point Store command to use the laser when this option is enabled. The Point Store dialog will have a new Laser button which will bring up another dialog that allows you to take multiple shots from the laser. The other method is to click on the Offset toggle in the Point Store dialog. Then when you do the Read function, the program will read the GPS position and then pop-up a dialog for taking one offset shot.

Point Settings

Beep for Store Point - This option will make a triple beep to indicate when a point is stored in the coordinate file.

User-Entered Point Notes - Point Notes are additional descriptions that can be stored with a point. A regular point consists of a point number, northing, easting, elevation and 32 character description. These points are stored in a .CRD file. Point Notes are a way to add an unlimited number of lines of text to a point number. With Point Notes ON in the Store Point command, the program will prompt for notes after collecting a point. The notes are stored in a file that uses the name of the coordinate file with a .NOT extension. For example, a coordinate file called JOB5.CRD would have a note file called JOB5.NOT.

Point Settings

- Split Multiple Codes
- Check Descriptions With Code Table

Code File:

Coordinates in Point Notes - When storing a point, this option will store the point number, northing, easting, elevation and description in the point notes as well. This may be used as a backup or reference to coordinate data as it was originally stored.

GPS RMS in Point Notes - When storing a point, this option will store the horizontal and vertical RMS values in the note field for the point. This offers a good check on the quality of the shot.

GPS DOPs in Point Notes - When storing a point, this option will store the DOP (dilution of precision) values as reported from the GPS receiver.

Rod Height in Point Notes - When storing a point, this option will store the rod height value in the note field for the point.

Project Scaler in Point Notes - When storing a point, this option will store the project scale factor in the note field for the point.

Time/Date in Point Notes - This option will store the time and date that the point was stored in the note file. Carlson Field will read the time from the computer.

Drawing Options control how points are drawn by default. It controls the layer, symbol number and whether points will be drawn with descriptions and elevations. Carlson Field's Field to Finish code table can override these defaults.

The symbol used for default points is displayed. You can choose another symbol by changing the *Symbol* name or by selecting one from the table that the *Select Symbol* button brings up. Default point settings are used for points whose descriptions don't correspond to any category on the Field to Finish code table.

Label Descriptions and *Label Elevations* Control whether these two items of information appear on your drawing next to each point.

Locate on Real Z Axis will record points with their true elevations. If this setting is off, all points recorded will have an elevation of zero.

Layer for Points indicates the layer where all default points will be drawn. For points using a code on the code table, the code table will determine their layer.

Number of Readings specifies how many times Carlson Field will read from the instrument in the Read function of the *Point Store* command. This applies to both GPS and total stations. The readings will be averaged to find a more accurate position.

Direct-Reverse Tolerances are used with total stations to check the pairs of direct and reverse horizontal angles, vertical angles and distances. When these values are off by more than the tolerance, the program will display a warning.

Field to Finish is explained fully in the Field to Finish command definition. Basically it uses a code table which holds information on types of points (ie. Man Hole or Edge of Pavement). When the settings *Use Code Table* is selected, Carlson Field will look to the code table for how to draw points of a particular code description.

The file containing the active code table appears after *Code File*: You can change this with the button *Select File*.

The *Split Multiple Codes* option will draw multiple points from the same point when that point description has multiple codes. For example, a point with description "EP DR" will draw the point twice: once with the properties of code EP and a second time using code DR. When this option is off, the program will use the first code and draw the point once.

The *Check Descriptions With Code Table* option will display a warning before storing a point if that point description is not found in the code table. With this option off, the program will go ahead and store the point and the point will be drawn using the default point properties.

Stakeout Settings

Display GPS RMS in Stakeout causes Carlson Field to report the constantly updating horizontal RMS accuracy values while staking a point. The only disadvantage to having this option active is that it slows down a little the stakeout position update.

Draw Trail displays a line in the stakeout screen showing where you've been as you move towards the stakeout point. This option only applies to GPS.

Prompt For Snap On Screen Pick controls whether you are prompted to select an object snap when picking points from the screen during stakeout.

Auto Zoom will zoom the drawing display in or out so that both your current position and stakeout target are visible on the screen.

Zero Horizontal Angle To Target will set the horizontal angle of the total station to zero in the direction towards the stakeout point. When stakeout is completed, the horizontal angle is set back to the original value. This option only applies to total stations.

Automatic Turn To Point Type For Robotic Total Stations does two things. First, it controls whether or not stakeout automatically turns to the stakeout point. Second, it allows the user to select what type of turn is performed: Horizontal Angle only, or Horizontal and Vertical Angle.

Default Stakeout Mode allows the user to select a default stakeout mode to be used when entering the stakeout routine. Choices include the stakeout modes: Station-Offset, Point Number, and Pick Point. If Pick Point is selected as the default stakeout mode, the user can also define the default object snaps.

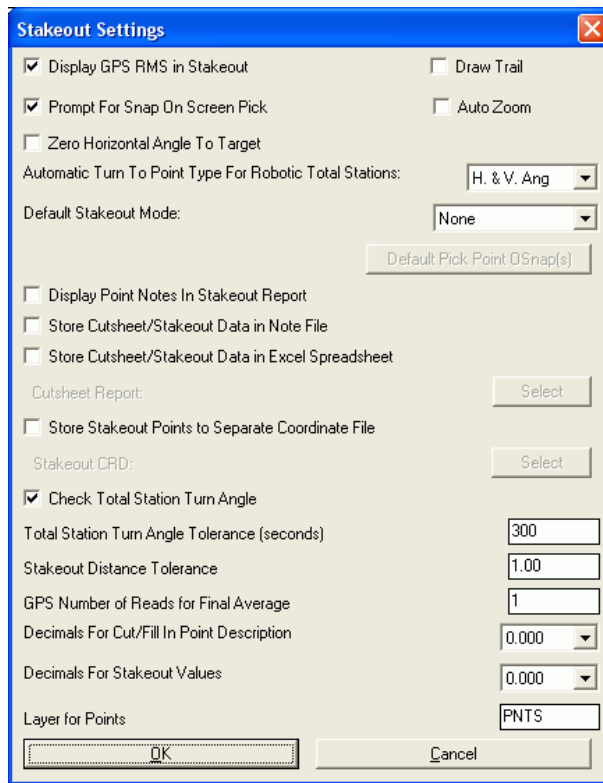

Store Cutsheet/Stakeout Data in Note File will store stakeout data in the note file (.NOT) for the current coordinate file. At the end of staking out a point, there is an option to store the staked coordinates in the current coordinate file. This stakeout note file option allows you to store more stakeout data in addition to the staked coordinates. This additional data includes the target coordinates and horizontal and vertical difference between the staked and target points. This stakeout note data can be used in reports with the List Points or CutSheet Report commands.

Store Cutsheet/Stakeout Data in Excel Spreadsheet will display a cutsheet report in an Excel spreadsheet. The spreadsheet will pop-up at the end of each point stakeout. The report can be saved in Excel format and processed by Excel.

Store Stakeout Points To Separate Coordinate File will store the staked points to a different coordinate file besides the current coordinate file. This allows you to use the same point number for the target and staked points. The staked point coordinate file can be specified by picking the Select Coordinate File button.

Check Total Station Turn Angle will compare the angle from the instrument and the angle to the target point. If this difference is greater than the specified tolerance, then Carlson Field will display a warning message.

Stakeout Tolerance controls the maximum difference between the target location and actual staked point. When the staked point is beyond the tolerance, Carlson Field displays a warning dialog.

GPS Number of Reads for Final Average specifies how many times Carlson Field will read the GPS receiver position for the final staked point. These readings are averaged. Averaging several readings while occupying one point yields a more accurate result, but inevitably takes longer.

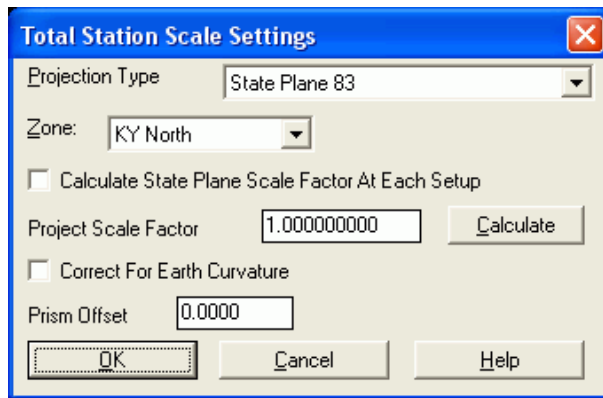

Total Station Scale Settings

These settings apply only to total stations. The *Project Scale Factor* is multiplied by the measured distance from the total station when calculating the foresight point coordinates. A typical project scale factor for working in state plane coordinates is slightly less than one. Factors greater than 2.0 or less than 0.5 are not allowed. The Project Scale Factor can be entered directly or choose the Calculate button. The Calculate function takes a state plane coordinate and calculates the project scale factor as the state plane grid factor minus the elevation factor (Grid Factor - elevation/earth radius). The state plane coordinate is specified by a point number from the current coordinate file.

The *Calculate State Plane Scale Factor At Each Setup* option will calculate the scale factor for each shot as the combined grid and elevation factors (see above equation). The scale factor is calculated at both the occupied and foresight points and then averaged. To use this option, you must be working in state plane coordinates and set the state plane zone in this dialog.

The *Correct For Earth Curvature* option adjusts the horizontal distance and vertical difference to the foresight point to account for the earth curvature.

Prism Offset is for use with total stations to account for the offset (in mm) of the prism in use. It is recommended to keep this at zero, and set the prism offset in the instrument.

Depth Sounder Settings

Carlson Field can use depth sounders in combination with GPS to collect points of underwater surfaces. Carlson Field supports depth sounders that output standard NMEA data. There are several models to choose from: Hydrotrac, Horizon, Odom Digitrace, InnerSpace, and Generic. For the Odom Digitrace and InnerSpace models, you also need to specify the depth unit mode that the instrument is set to.

The *Store Depth In Notes* option will record the water depth in the current note file (.NOT) when a point is stored to the coordinate file.

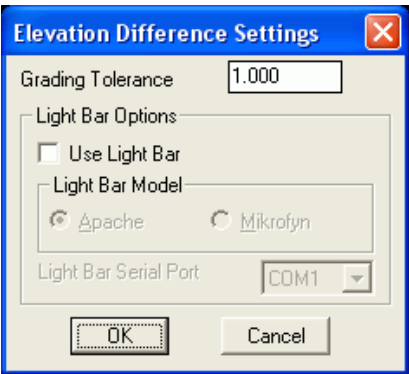

The *Debug* toggle can be used when contacting technical support to diagnose communications issues between the depth sounder and Carlson Field.

The depth sounder must be connected to a separate serial port than the GPS. The *Baud Rate* between the computer serial port and the depth sounder is also specified here.

Elevation Difference Settings

These settings apply to the Elevation Difference command. Grading Tolerance is the target difference between the actual elevation and the design surface. Carlson Field can use an external Light Bar to indicate whether your current position is in cut, fill or on-grade. Currently Carlson Field supports light bars made by Apache and Mikrofyn. The Light Bar must be connected to a separate serial port than the GPS.

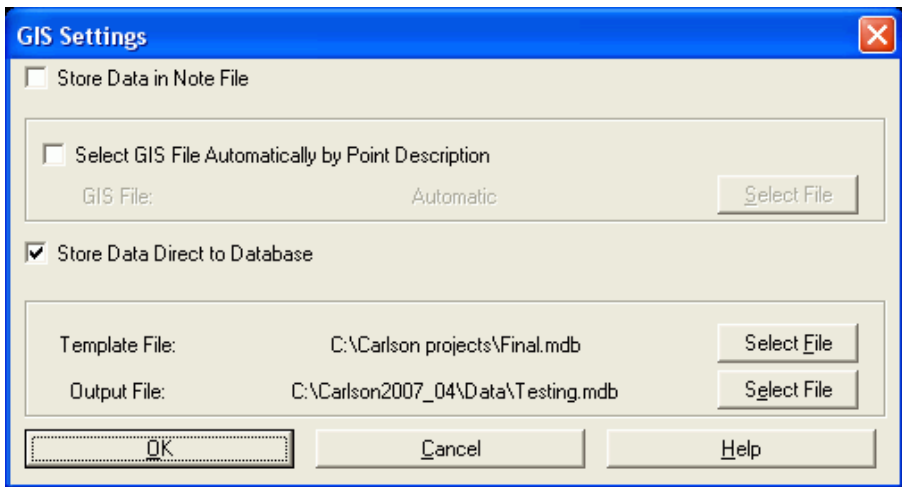

GIS Settings

A standard point is stored in the coordinate file with a maximum 32 character description. The GIS Settings allow you to store more data with each point.

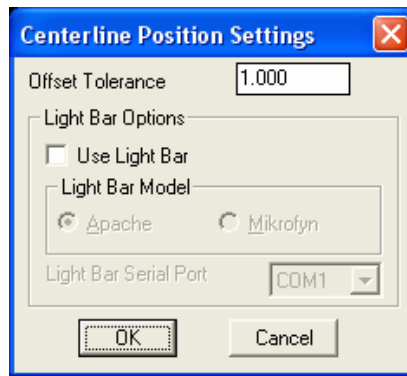

The *Store Data In Note File* option will record additional fields for each point in the note file. The note file has the same name as the current coordinate file except with a .NOT instead of .CRD file extension. The fields that are recorded are defined by the GIS File (.GIS). This file defines a sequence of field names and prompts. For example, a GIS file for manholes could contain Location, Depth and Condition fields. Choose the Select File button to choose the GIS file to use. Or use the *Select GIS File Automatically by Point Description* to use different GIS files depending on the point description. With this option, the program will look for a GIS file with the same name as the point description. For example, if the point description is MH, then the GIS file will be MH.GIS. See the Define Note File Prompts command for more information.

The *Store Data Direct To Database* option will store additional fields for each point in a Microsoft Access database. The database to store the data is set in the Output File line. The Template File is a database that defines the fields to record. See the Define Template Database command for more information.

Centerline Position Settings

Similar to Elevation Difference Settings only for the Centerline Position command.

Communication Port Settings

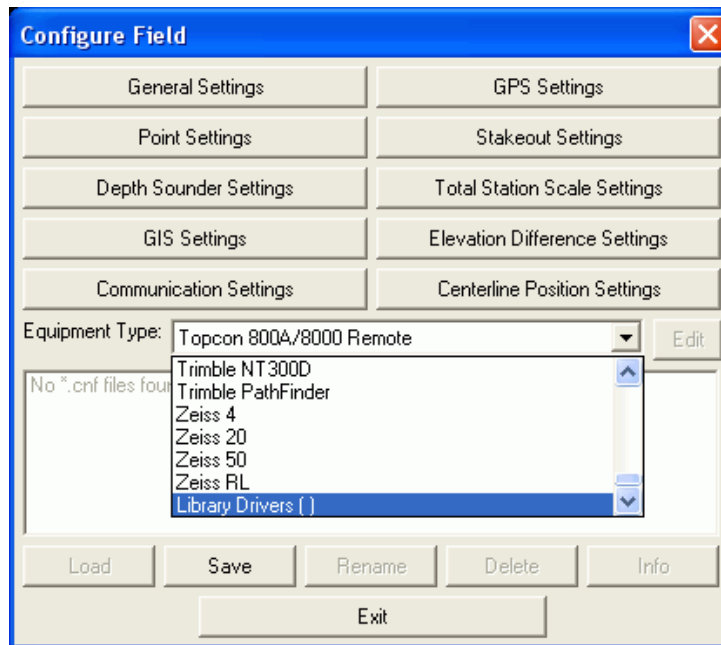

Serial COM Port - The GPS receiver or total station attaches to your Carlson Field computer using a serial cable. This cable is plugged into a serial COM port on your computer called 1, 2, 3 or 4 . Check the circle denoting the COM Port to be used.

The *Baud Rate*, *Parity*, *Char Length* and *Stop Bits* are the serial port communication parameters for the Carlson Field computer. These parameters need to match the parameters on the instrument that you are using. The Defaults button will set these communication parameters to the standard parameters for the current equipment type.

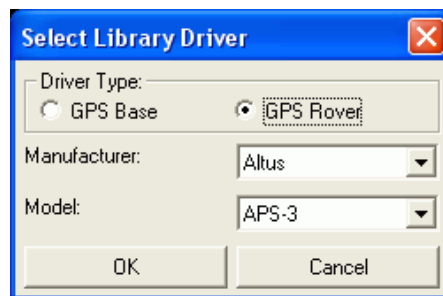

Equipment Type

The *Equipment Type* droplist allows the user to select the instrument driver to use. The very last entry is for "Library Drivers" which are instrument drivers that follow a new Carlson architecture and support many advanced features (ex. NTRIP). These "Library Drivers" are different from the legacy Carlson Field instrument drivers; they are shared with other Carlson products (ie. SurvCE and Carlson Grade). To select a "Library Driver", select that item and press the *Edit* button. Please note, that the *Edit* button is only active for "Library Drivers".

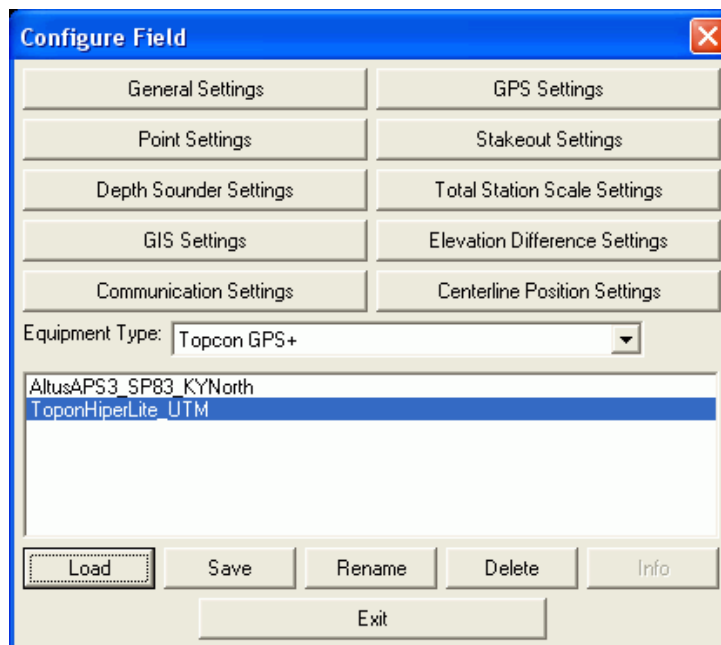

Selection of a "Library Driver" is split into two types: *Base* and *Rover*. After selecting the *Driver Type*, select the proper manufacturer and model to match the equipment being used.

Carlson Field also allows the user to save and recall equipment configurations. If you use the same equipment in different configurations, saving the configuration is an easy way to recall it later without missing a setting. First, select the *Equipment Type* you wish to save a configuration for. Next, make sure all the instrument settings are as desired by running through *Equipment Setup*. Finally, press the *Save* button and enter a description configuration name that will help remind you what the configuration is used for. Keep in mind, saving a configuration will also save the current *GPS Settings* (ie. projection type, etc).

To recall a saved configuration, just select the configuration and press the *Load* button.

Equipment Setup

Function with Total Stations

Selecting the Equipment Setup command will send the user directly to a settings window that corresponds with the instrument selected in Configure Field. Equipment Setup for total stations will be discussed first, followed by GPS equipment.

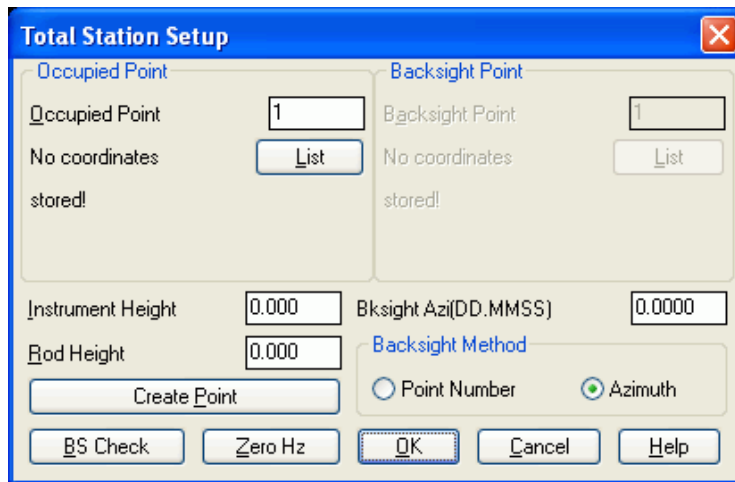

This function for Total Stations lets you tell Carlson Field how you have positioned your total station. The setup information in this command is required before taking shots. Besides running this command from the Field pull-down menu, you can also reach this command with the Setup(F3) button from many of the other Carlson Field functions.

Occupied Point refers to the point your total station is setup on. This point is defined by a point number that references the current coordinate file. The coordinates and description of this point are displayed below the point number. The *List* button will bring up a list of the points in the coordinate file which you can review or select from. If the coordinates for the occupied point are not yet in the coordinate file, then you can pick the *Create Point* button to enter these coordinates.

The backsight can reference either a point or an azimuth. *Backsight Point* is only used if *Point Number* is selected as your *Backsight Method*. If you want to use an azimuth instead of a backsight point, select the *Azimuth* toggle and specify the azimuth in the *Bksight Azi* box.

Set the *Instrument Height* and *Rod Height*. These values will use whatever units your drawing uses: feet or meters.

Carlson Field expects the instrument to have the horizontal angle zeroed on the backsight. Part of the station setup procedure needs to include zeroing the instrument on the backsight. To do this, first specify the occupy point and backsight in this dialog. Then orient the instrument to the backsight and pick *Zero Hz* to zero the gun.

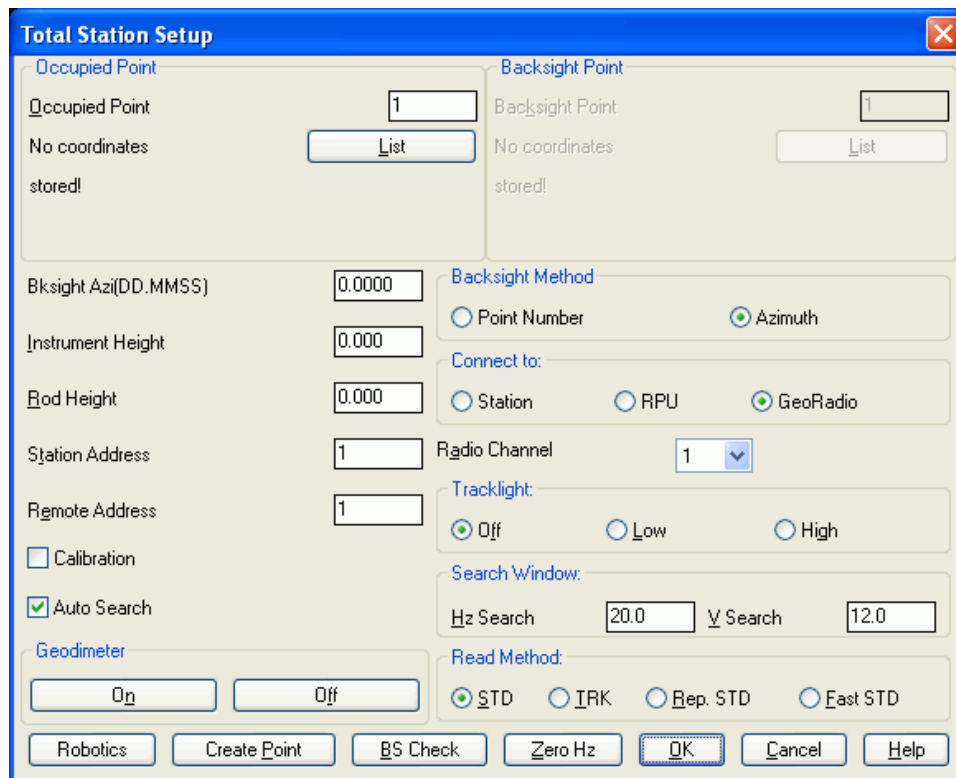

The *BS Check* button runs a backsight check. The program will take a shot and compare the calculated point to the expected backsight point and report the results to you. This will help you establish if the point you are using as the backsight point is really the point that you think it is. For some robotic total stations, the Backsight Check routine has an option to automatically turn the instrument to the backsight. Then after the check is done, the instrument can be automatically turned back to the previous direction. The purpose of this auto turn is to speed up the steps to check the backsight in the middle of surveying points in a different direction.

For some types of total stations, the Total Station Setup dialog will also contain different options that are specific to that type of total station.

Geodimeter Total Station Setup

The three methods of connecting to the Geodimeter include: *Station*, *RPU* and *GeoRadio*. The *Station* option is for connecting directly to the instrument. The *RPU* is a remote control panel. The *GeoRadio* is a radio for remote control of the instrument. For the *GeoRadio*, the *Station Address* and *Remote Address* set the radio addresses and the *Radio Channel* sets the radio channel.

The intensity of the instrument Tracklight can be set to Off, Low or High.

The Geodimeter *On* and *Off* buttons are for putting the instrument in sleep mode to save power.

There are four different read methods. STD mode has a 3.5 second measurement time for each point. It is usually used when a normal degree of angle and distance accuracy is required. TRK mode uses automatic, measured values that are updated 0.4 seconds after making a contact with the prism. Rep STD mode measures distance automatically every 4 seconds. Fast STD mode measures distance in 1.3 seconds. It is used when the demands on precision are low.

Leica Total Station Setup

The *Connection Mode* chooses between connecting Carlson Field directly to the instrument or to a radio for remote control.

The *EDM Mode* sets the instrument distance measurement mode for standard shots. All the possible modes are listed in this dialog including tracking and reflectorless. Be sure to choose a mode that is supported by your instrument. When using the reflectorless mode, the Rod Height should typically be set to zero. When tracking is selected in Carlson Field functions, the program will automatically put the instrument in IR Rapid Tracking mode during tracking and then return to the specified EDM Mode when tracking is done.

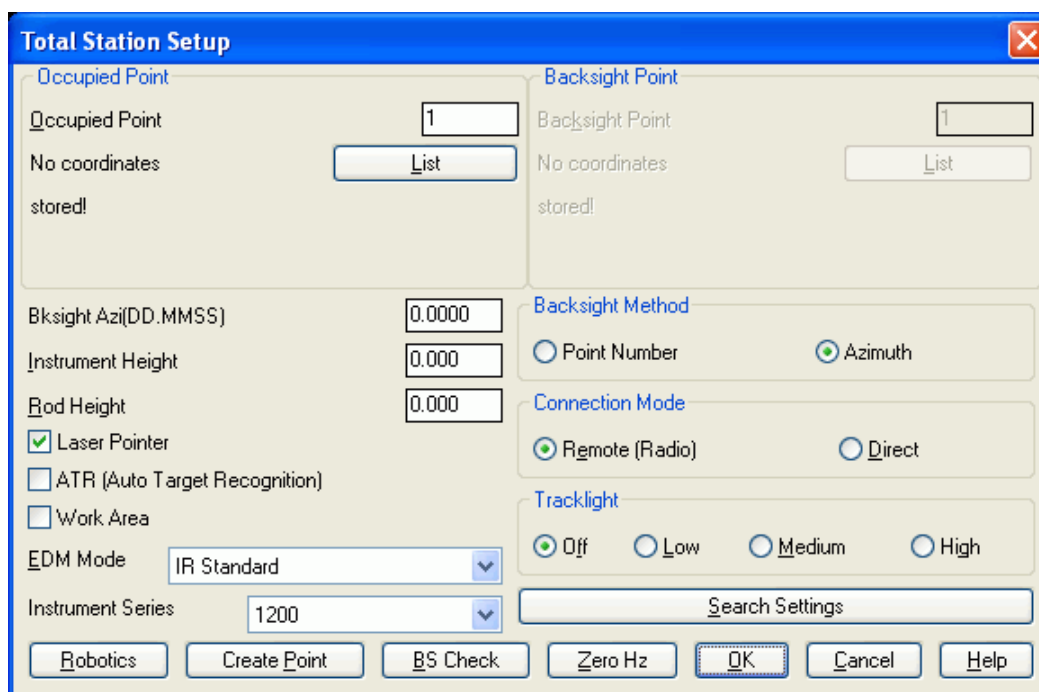

The intensity of the instrument *Tracklight* can be set to Off, Low, Medium or High.

Laser Pointer allows the user to toggle the instrument's laser pointer on and off, if the instrument is so equipped.

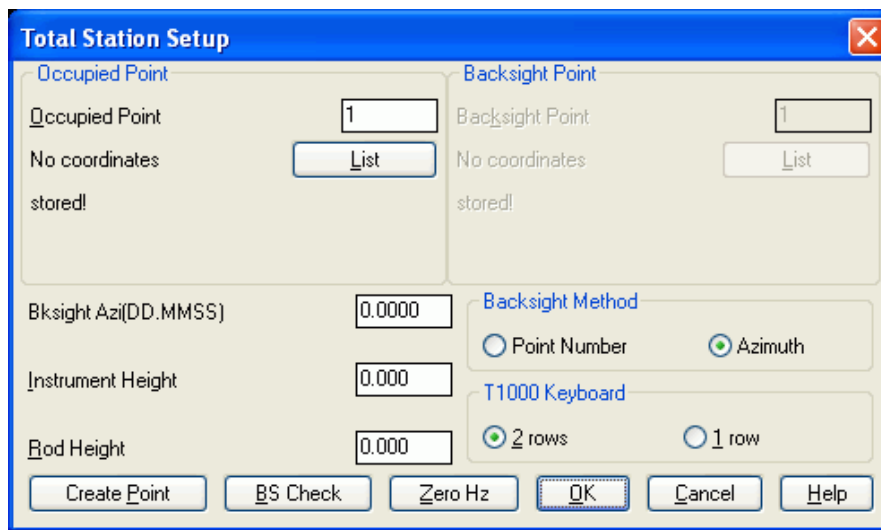

ATR (Auto Target Recognition) allows the user to choose whether or not to use the instrument's ATR system, if the instrument is so equipped. This option is not available when using a reflectorless EDM mode.

Use *Instrument Series* to select the proper Leica TPS model you are using. There are only two choices: *1200* (which uses the GeoCOM protocol) or *100/300/400/700/800/1000/1100* (which uses the GSI protocol).

The *Robotics* button can be used to access the joystick screen, where the user can access convenient controls for robotic total stations.

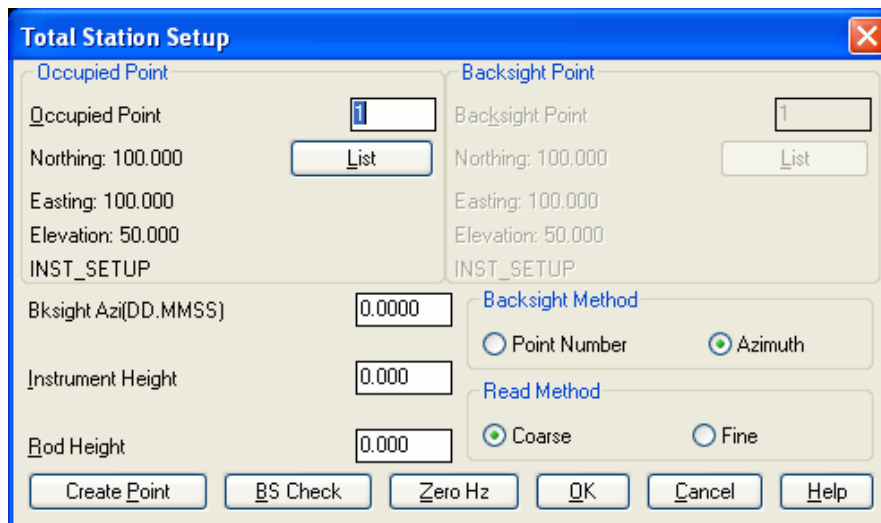

The older Leica total station driver allows the user to select what type of keyboard emulation to use, 1 or 2 row.

Topcon 800A/8000 Direct Total Station Setup

The *Read Method* sets the instrument distance measurement mode for standard shots. When tracking is selected in Carlson Field functions, the program will automatically put the instrument in Coarse mode during tracking and then return to the specified EDM Mode when tracking is done.

Topcon 800A/8000 Remote Total Station Setup

The *Radio Type* can either be Satel 3AS, Satel 2AS, RC-2, Stream, or Other. With Other, Carlson Field does not send any radio setup commands. So these radios must be configured before running Carlson Field. For the Satel 3AS radios, you can set the radio frequency by Channel ID or by manually typing a frequency between 468.5 and 470.5. Stream can be used in any situation where Other would be used. However, Stream is different in that the instrument streams measurements to Carlson Field thereby decreasing the probability of a failed reading. It should be noted, if Stream is used over a very poor radio connection, it is possible for Carlson Field to get out of sync with the instrument and fail to stop streaming when needed.

The *EDM Mode* sets the instrument distance measurement mode for standard shots. When tracking is selected in Carlson Field functions, the program will automatically put the instrument in Coarse mode during tracking and then return to the specified EDM Mode when tracking is done.

Wait Time is switched on when the instrument cannot track a prism due to an obstruction. If after the wait time have elapsed the instrument does not switch back to tracking mode, then searching mode is set.

Vertical range and Horizontal range set the search area. Vertical range can be anywhere from 0-90 degrees, and horizontal range can be anywhere from 0-180 degrees.

Track Indicator On if checked turns on the light which is mounted below the telescope.

Joystick Speed sets the instrument turning speed from the arrow keys in Robotic control.

Topcon APL1/APL1A Total Station Setup

The *Radio Type* can either be Satel 3AS, Satel 2AS or Other. With Other, Carlson Field does not send any radio setup commands. So these radios must be configured before running Carlson Field. For the Satel 3AS radios, you can set the radio frequency by Channel ID or by manually typing a frequency between 468.5 and 470.5.

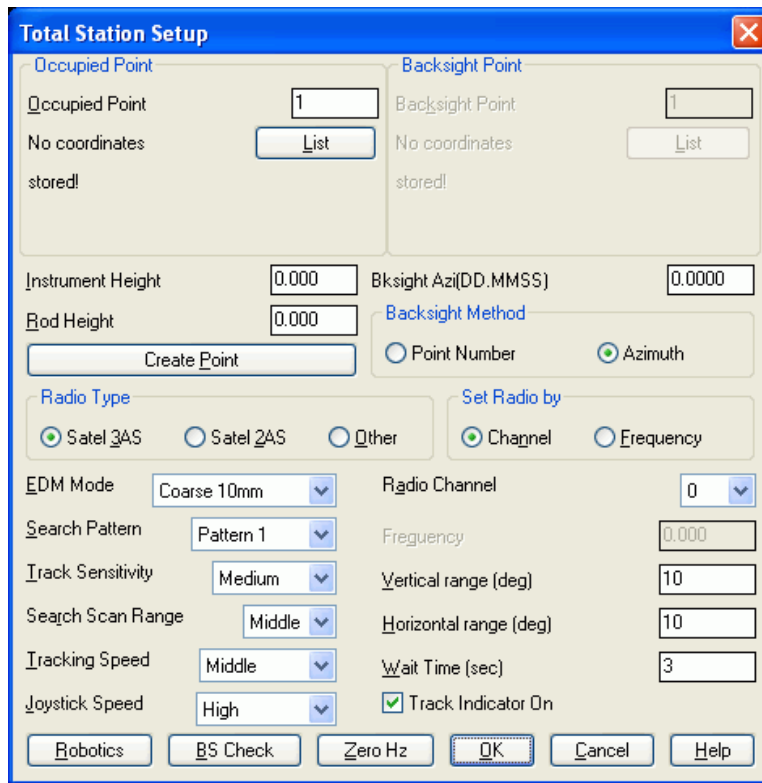

The *EDM Mode* sets the instrument distance measurement mode for standard shots. When tracking is selected in Carlson Field functions, the program will automatically put the instrument in Coarse mode during tracking and then return to the specified EDM Mode when tracking is done.

Wait Time is switched on when the instrument cannot track a prism due to an obstruction. If after the wait time have elapsed the instrument does not switch back to tracking mode, then searching mode is set.

Vertical range and Horizontal range set the search area. Vertical range can be anywhere from 0-90 degrees, and horizontal range can be anywhere from 0-180 degrees.

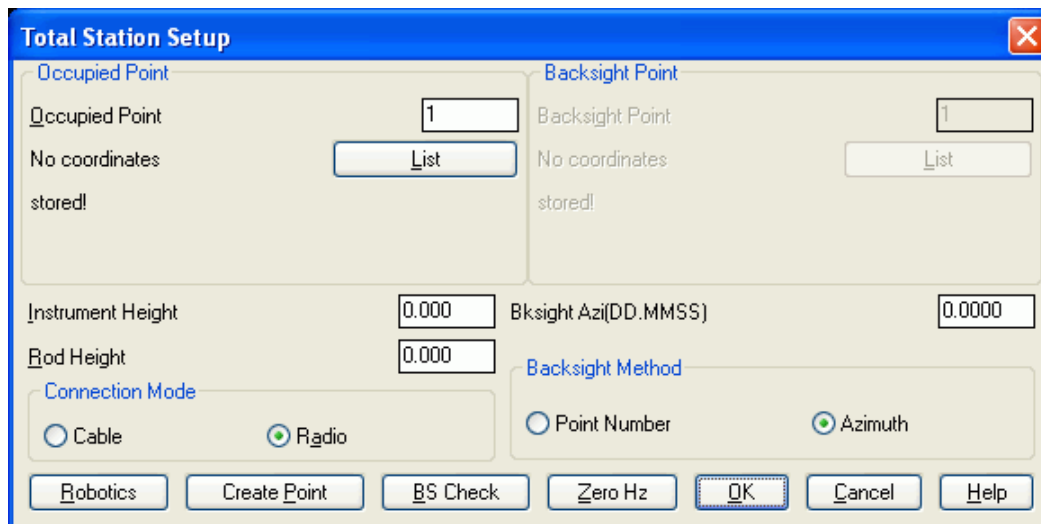

Track Indicator On if checked turns on the light which is mounted below the telescope.

Joystick Speed sets the instrument turning speed from the arrow keys in Robotic control.

Zeiss20 Total Station Setup

The *Connection Mode* chooses between connecting Carlson Field directly to the instrument (cable) or to a radio for remote control.

Equipment Setup with GPS

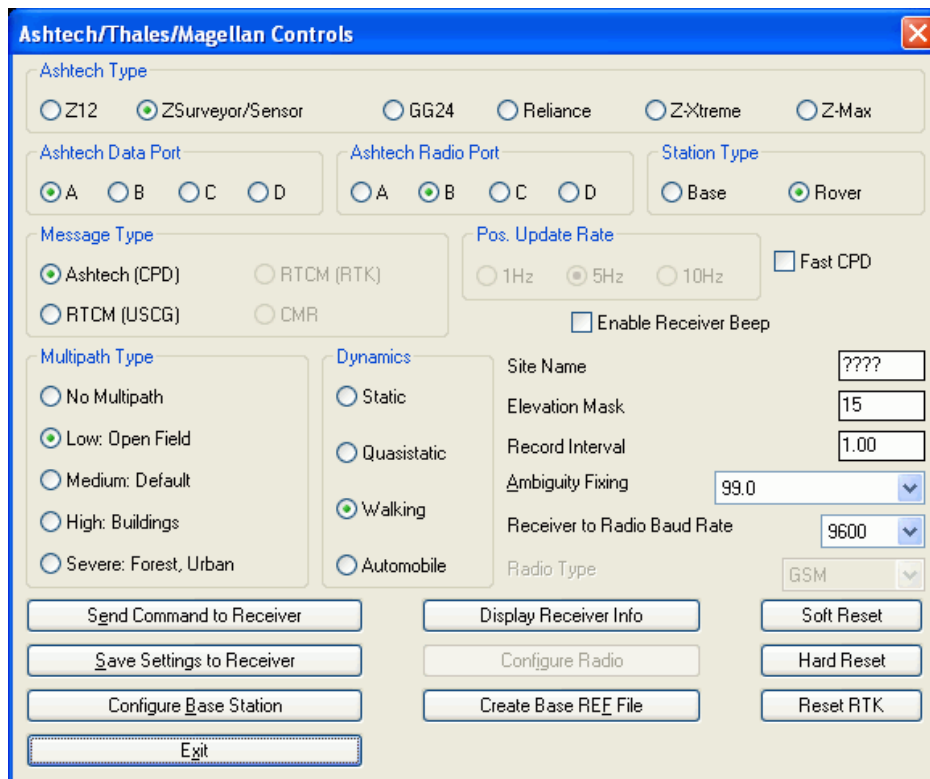

Carlson Field works with the following RTK GPS manufacturers: Ashtech, Javad, Leica, Novatel, Sokkia and Trimble. Each RTK GPS brand has its own GPS Setup control window. To get the window which matches the GPS equipment you are using, go to Configure Field and under the Equipment Type pulldown menu select the correct equipment. A brief explanation is given below for each brand's controls.

For RTK (real-time kinematic) GPS work, the base sends GPS corrections to the rover. To setup a base receiver, you should attach the computer running Carlson Field to the base receiver and run the Equipment Setup. After this is done and the base is outputting corrections, you should detach the base receiver and attach the rover receiver and do Equipment Setup again.

If your base radio has a TX light, it should be flashing while it's sending out corrections. This is a convenient way to tell if the base is configured.

Ashtech GPS Setup

The *Ashtech Type* specifies the model of Ashtech equipment to be used. Carlson Field works with the following Ashtech high precision, centimeter accurate RTK GPS equipment: Z12, Z-Surveyor/Sensor, GG24, Z-Extreme, and Z-Max. Carlson Field also works with the Ashtech Reliance USCG/DGPS RTCM sub-meter RTK GPS receivers.

The previous Ashtech Control settings are default. Changing these settings will change the internal settings of the Ashtech receiver.

Ashtech Data Port is the port on the GPS receiver where the Carlson Field computer is connected, usually Port A.

Ashtech Radio Port is the port on the receiver where the radio modem is connected, usually Port B. For the Z-Extreme, Port D is usually used for the radio port.

Message Type for high precision centimeter RTK GPS set message type to Ashtech (CPD). If you are using the USCG/RTCM DGPS message type for sub-meter accuracy then set the message type to RTCM (USCG).

Multipath Type is used to filter out interference in the satellite signals caused by nearby objects. The choices are No Multipath, Low: Open Field, Medium: Default, High: Building and Severe: Forest, Urban.

Dynamics settings are Static, Quasistatic, Walking and Automobile. Static is selected only when the Rover receiver is stationary. The default is Walking.

Elevation Mask is the cutoff vertical angle above the horizon. Any satellites below this angle will be left out of calculations.

Site Name and *Record Interval* are all setting for post processing use only, not for use with RTK GPS. Site Name is the Point ID name for post processing. Record Interval is the epoch interval to record post processing information. RTK GPS updates every second but post processing epochs are usually 5, 10, 15, 20 or 30 second intervals.

Ambiguity Fixing Parameter (90 - 99.9): controls the confidence level of fixed positions. The default is 99.0. At a lower confidence interval the system solves much faster. If the system incorrectly solves the position, then the position error will be much greater than the reported RMS value.

Position Update Rate is the frequency that GPS positions are calculated and reported.

Fast CPD is a toggle On or Off. Fast CPD toggled On will allow approximating the rover's position if your position is lost briefly. Off is the default. Fast CPD is generally toggled on when Dynamics is set to Automobile.

When Carlson Field functions start, the program uses the settings specified in Equipment Setup to configure the GPS receiver. The *Save Settings to Receiver* uploads the settings in the Carlson Field dialog to the receiver so that the next time the receiver is turned on these settings are still set even without connecting to Carlson Field. Otherwise, Carlson Field must be connected to the receiver to setup these options.

Send Command to Receiver allows experienced users to type in commands using Ashtech GPS receiver commands to set or report internal settings. (See the Ashtech operations manuals for a complete list of Ashtech GPS receiver commands.)

Reset Sensor Memory will reset the receiver memory, reinitialize the communications ports and reset the modem. Saved settings on the receiver will be returned to their default values.

Radio Baud Rate allows you to change Pacific Crest radio baud settings through the receiver. The default baud rate is 9600. (Note: If there are communication problems with either port A or B on the Ashtech ZSurveyor receiver, turn off receiver and turn it back on with both keys depressed to reset receiver to factory defaults.)

For the Z-Extreme, the *Configure Internal Radio* button allows you to change the radio channel and settings. This function will attempt to establish a connection with the internal radio, reporting an error if it is unable to do so. Otherwise, it will open a dialog which will display the current radio channel as well as the valid range of radio channels. Enter the desired radio channel in the edit box and then click on "Program Radio" to set the changes to the radio. Carlson Field will communicate with the radio for a few seconds, and will then request that you power the receiver down, then turn it on again before continuing. It is very important that this is done, or else Carlson Field will be unable to communicate with the ZExtreme. Also note that if the programming of the radio is canceled for any reason, the receiver will still need to be powered down, then powered up again in order for Carlson Field to be able to communicate with it.

Create Base REF File takes a reading from the GPS receiver and stores this lat/lon to a reference file (.ref) that can be used later in Configure Base Station. The purpose is to allow moving the base station based on the current base setup. In this case, Create Base REF File would be run from the rover receiver while in "fixed" position. Then the base could be moved to this point without having to redo the local coordinate alignment.

Configure Base Station initiates the receiver connected to Carlson Field to be a base and begin broadcasting its stationary position and satellite corrections to the rover. (See Configure Base Station for All GPS Brands at end of this section.)

Topcon GNSS/Javad GPS Setup

Radio Port on the Javad base and rover receiver is usually C. Data Port is always A. When using Pacific Crest radios, Javad recommends the new PDL Pacific Crest radios. These must be set to 38,400 baud rate. Javad also uses Spread Spectrum radios which work at 119,200 baud rate.

Receiver Model selects between *Legacy*, *Odyssey* and *Regency*. Currently the Receiver Model does not affect the Carlson Field interface except to determine the default Antenna Type.

Position Update Rate sets the frequency that the receiver calculates and reports position. The faster rates are an option that must be purchased for the receiver.

Antenna Type chooses between an internal and external GPS antennas. This option applies to receivers with built-in antennas.

The *RTK Message Type* determines the format of the GPS correction message that is used from the base to the rover.

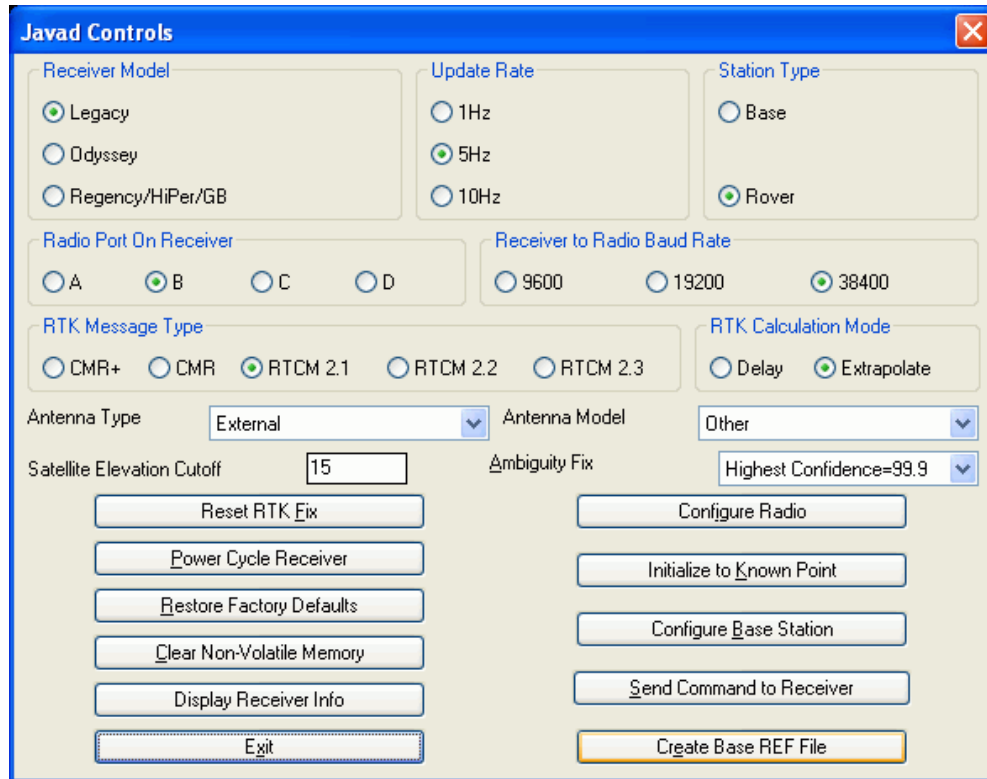

RTK Calculation Mode chooses between Delay and Extrapolate. The Extrapolate mode is needed for fast Position Update Rates.

Satellite Elevation Cutoff is the cutoff vertical angle above the horizon. Any satellites below this angle will be left out of calculations.

Ambiguity Fixing Parameter (95 - 99.9): controls the confidence level of fixed positions. The default is 99.0. At a lower confidence interval the system solves much faster. If the system incorrectly solves the position, then the position error will be much greater than the reported RMS value.

Power Cycle Receiver is the same as turning the Javad receiver off and then on.

Restore Factory Defaults resets the Javad receiver to factory settings the receiver stops acting as base or rover. The baud rate of Port A will be set to 115,200. Reset this to 9600 by turning the receiver off and then on while holding down the FN button. Watch the REC light go from orange to green to red and then let up the FN button. This method can be used if Carlson Field cannot establish communications at any time.

Clear Non-Volatile Memory does everything *Restore Factory Defaults* does and also wipes out the almanac data that tells it where to look for the satellites. The receiver then downloads a new almanac from the satellites.

Send Command to Receiver allows experienced users to type in commands using Javad GPS receiver commands to set or report internal settings. (See the Javad operations manuals for a complete list of Javad GPS receiver commands.)

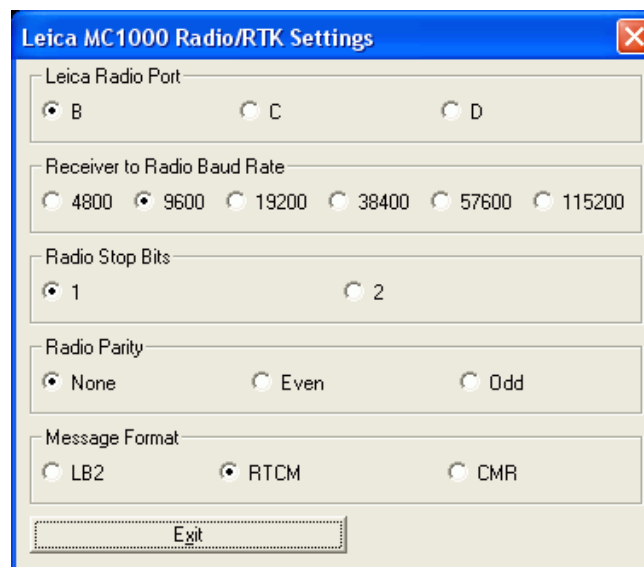

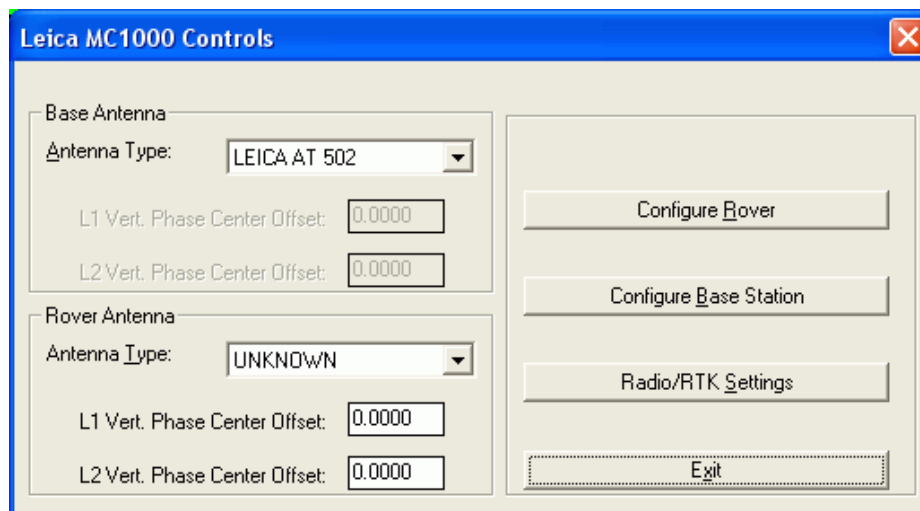

Create Base REF File takes a reading from the GPS receiver and stores this lat/lon to a reference file (.ref) that can be used later in *Configure Base Station*. The purpose is to allow moving the base station based on the current base setup. In this case, *Create Base REF File* would be run from the rover receiver while in "fixed" position. Then the base could be moved to this point without having to redo the local coordinate alignment.

Configure Base Station initiates the receiver attached to be a base and begin broadcasting its stationary position and satellite corrections to the rover. (See *Configure Base Station for All GPS Brands* at end of this section.)

Leica GPS Setup

Carlson Field works with the following Leica GPS receivers: System 500, GS50, MC1000 and MK31. The type of Leica receiver is set in the *Configure Field* command. The options available in the *GPS Setup* dialog depend on the current type of receiver.

Leica Radio Port is the port on the receiver where the radio is attached, usually 2 or 3. Port 1 is usually the one attached to the computer. For the System 500 receivers, you can also set the radio baud rate, stop bits and parity parameters.

For the system 500 receivers, you need to specify the antenna types used at both the base and rover receivers. This antenna type sets the phase center offsets for the antennas which can affect the reported elevations by as much as 0.25 foot if not set properly.

Cell phones can also be used with Leica GPS equipment instead of radios for RTK work.

For GS50 receivers, you can choose between US Coast Guard or Racad for the corrections.

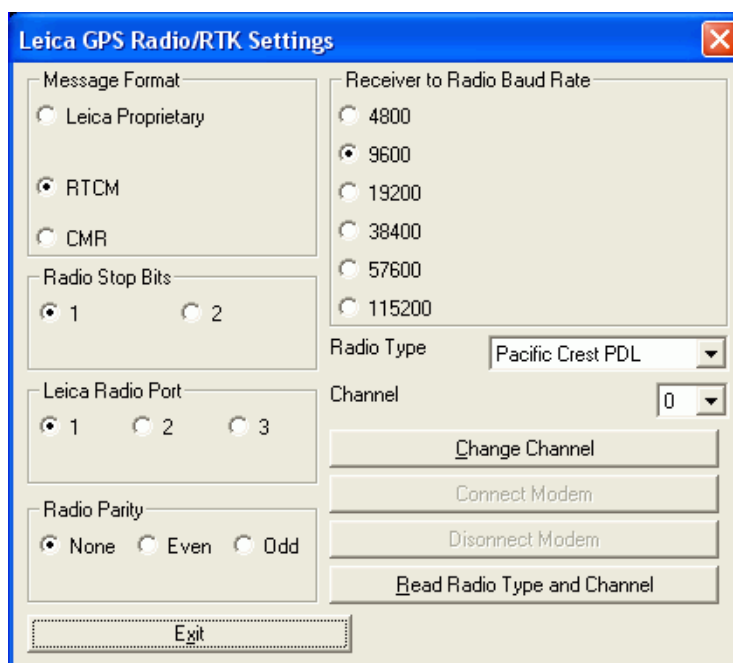

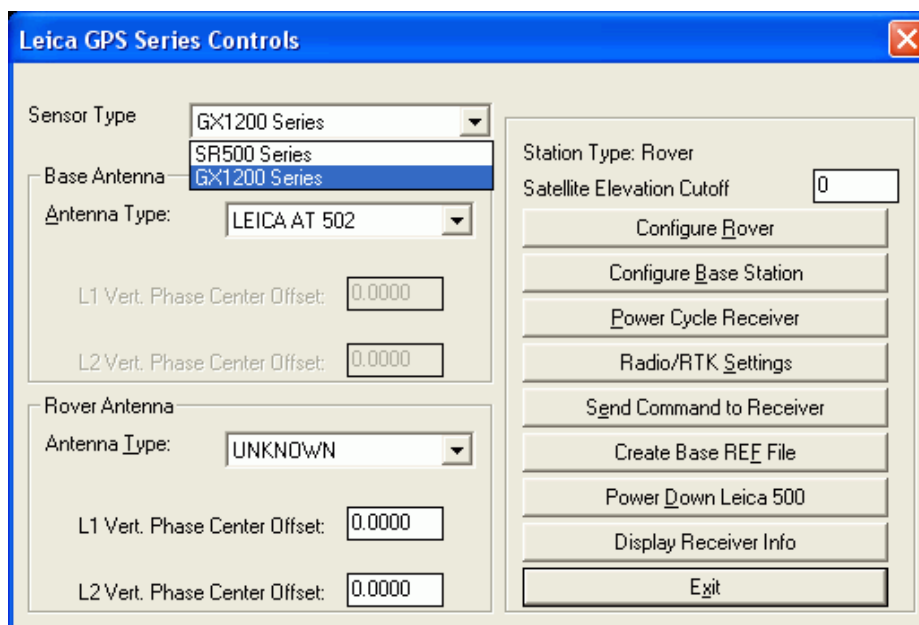

Power Cycle Receiver shuts the receiver off and turns it back on. This forces the receiver to reinitialize tracking satellites and the position solution. This routine is useful if the receiver is stuck in float solution.

Send Command to Receiver allows experienced users to type in Leica commands or send a file to set or report internal settings. (See the Leica operations manuals for a complete list of Leica GPS receiver commands.)

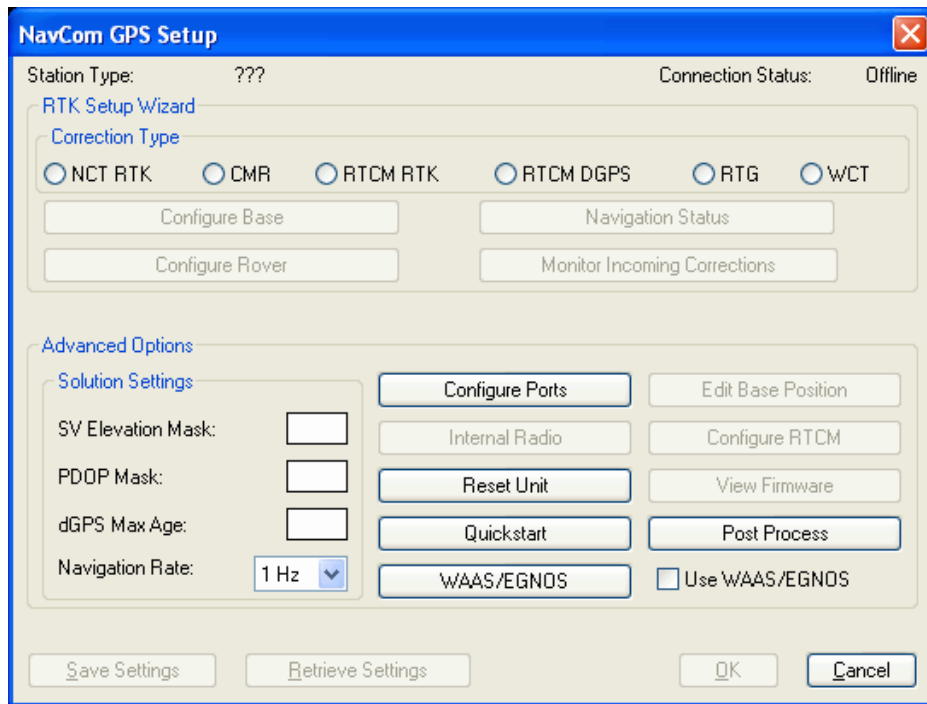

Create Base REF File takes a reading from the GPS receiver and stores this lat/lon to a reference file (.ref) that can be used later in Configure Base Station. The purpose is to allow moving the base station based on the current base setup. In this case, Create Base REF File would be run from the rover receiver while in "fixed" position. Then the base could be moved to this point without having to redo the local coordinate alignment.

Configure Rover sets the receiver to rover mode.

Configure Base Station initiates the receiver attached to be a base and begin broadcasting its stationary position and satellite corrections to the rover. (See Configure Base Station for All GPS Brands at end of this section.)

Navcom GPS Setup

Novatel GPS Setup

Carlson Field works with the original Novatel Outriders and the just released Outrider DL's including the centimeter accurate RT-2 RTK receivers and the sub-meter accurate Gismo USCG/satellite RTCM/DGPS beacon receivers.

Radio Port for external radio connection is typically COM 2 on the receiver. The Data Port connected to Carlson Field is typically COM 1.

Differential Mode toggles the Novatel GPS receiver to use RTCA, RTCM or CMR message types. RTCA is proprietary to Novatel and is used only for centimeter accuracy RTK GPS surveying. RTCM can be used with USCG/DGPS beacon signals for sub-meter accuracy. Novatel receivers work with Trimble CMR proprietary message signal type and can be either a base or rover working with Trimble RTK GPS receivers.

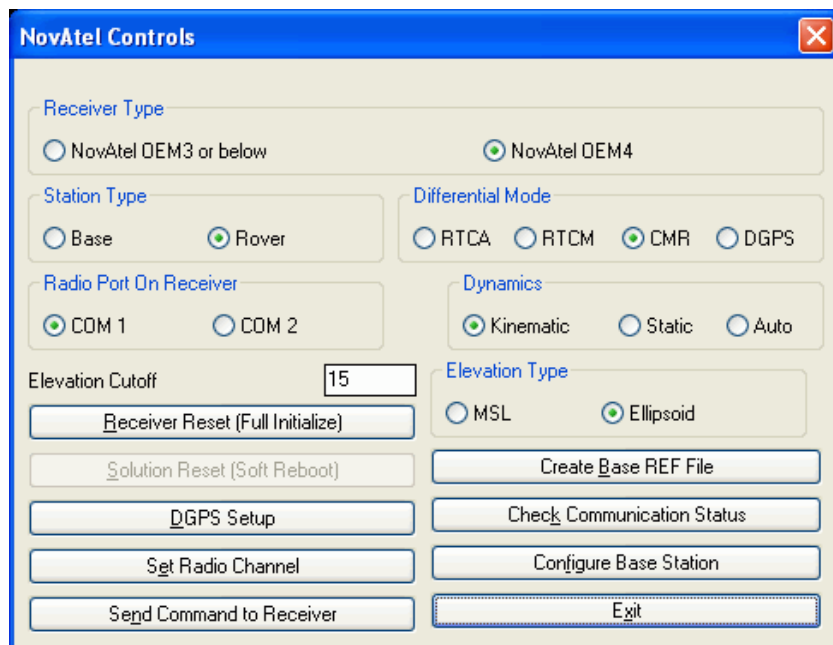

Dynamics toggles the rover between Kinematic or Static. The base is always in Kinematic mode. Kinematic is used for surveying while walking with the receiver. Static is for stationary use only at the rover and gives better accuracies. Since Static mode is for more precise measurements, it can be used for GPS alignment points and for any control points. The receiver should not be moved while in Static mode.

Elevation Cutoff is the vertical cut-off angle above the horizon. Any satellites below this limit will be ignored in calculations. 15 is a common setting.

Elevation Type chooses between Mean Sea Level or Ellipsoid for the elevation model used by the receiver.

Solution Reset (Soft Reboot) resets the Novatel receiver in a few seconds. This is used when the rover receiver is locked up or not properly reporting its position in the Monitor function.

Receiver Reset (Full Initialize) essentially does a factory reset and a power off and on cycle.

A Receiver Reset (Full Initialize) takes three to five minutes to get back on line and become fixed after a full initialize.

Set Radio Channel allows you to change Pacific Crest radio channels through the receiver. The base and rover must operate using the same radio channel.

Send Command to Receiver allows experienced users to type in commands using Novatel GPS receiver commands to set or report internal settings. (See the Novatel operations manuals for a complete list of Novatel GPS receiver commands.)

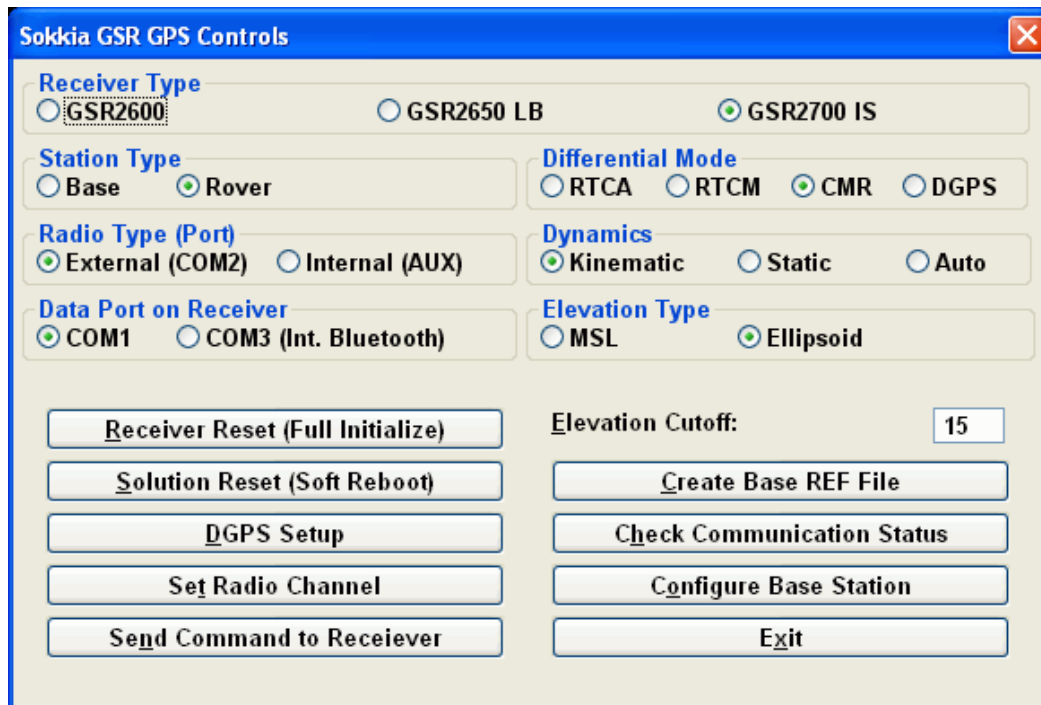

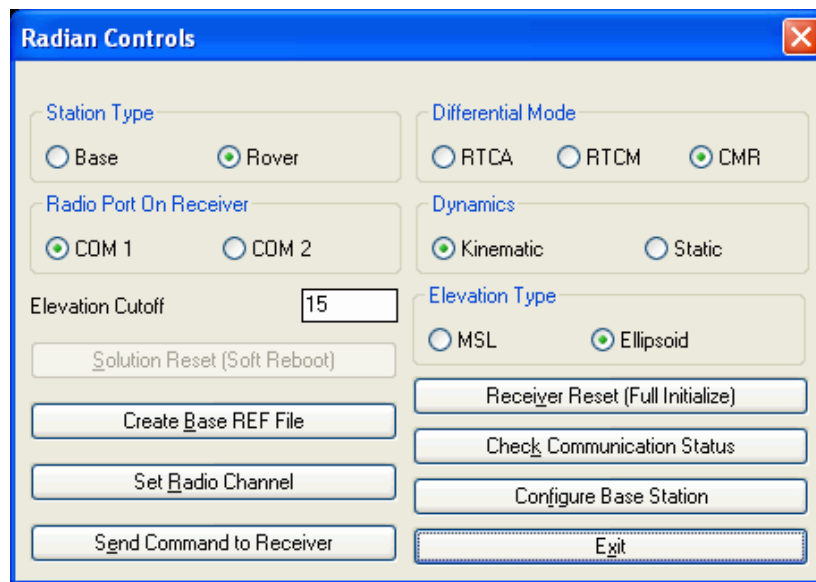

Check Communication Status checks the radio port operation and reports the status as working or not communicating.

Configure Base Station initiates the receiver connected to be a base and begin broadcasting its stationary position and satellite corrections to the rover. (See Configure Base Station for All GPS Brands at end of this section.)

Sokkia Radian GPS Setup

Radio Port for external radio connection is typically COM 2 on the receiver. The Data Port connected to Carlson Field is typically COM 1.

Differential Mode toggles the Sokkia GPS receiver to use RTCA, RTCM or CMR message types. RTCA is proprietary to Sokkia and is used only for centimeter accuracy RTK GPS surveying. RTCM can be used with USCG/DGPS beacon signals for sub-meter accuracy. Sokkia receivers work with Trimble CMR proprietary message signal type and can be either a base or rover working with Trimble RTK GPS receivers.

Dynamics toggles the rover between Kinematic or Static. The base is always in Kinematic mode. Kinematic is used for surveying while walking with the receiver. Static is for stationary use only at the rover and gives better accuracies. Since Static mode is for more precise measurements, it can be used for GPS alignment points and for any control points. The receiver should not be moved while in Static mode.

Elevation Cutoff is the vertical cut-off angle above the horizon. Any satellites below this limit will be ignored in calculations. 15 is a common setting.

Solution Reset (Soft Reboot) resets the Novatel receiver in a few seconds. This is used when the rover receiver is locked up or not properly reporting its position in the Monitor function.

Receiver Reset (Full Initialize) essentially does a factory reset and a power off and on cycle. A Receiver Reset (Full Initialize) takes three to five minutes to get back on line and become fixed after a full initialize.

Set Radio Channel allows you to change Pacific Crest radio channels through the receiver. The base and rover must operate using the same radio channel.

Send Command to Receiver allows experienced users to type in commands using Sokkia GPS receiver commands

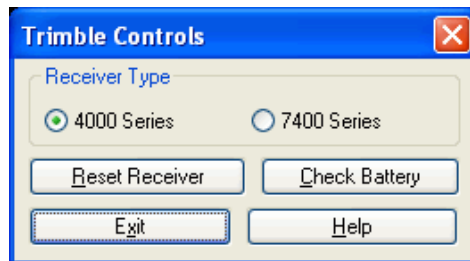

to set or report internal settings. (See the Sokkia operations manuals for a complete list of Sokkia GPS receiver commands.)

Check Communication Status checks the radio port operation and reports the status as working or not communicating.

Configure Base Station initiates the receiver connected to be a base and begin broadcasting its stationary position and satellite corrections to the rover. (See Configure Base Station for All GPS Brands at end of this section.)

Trimble GPS Controls

Carlson Field works with the following Trimble receivers: 4000 series, 4700, 4800, 7400, NT300D, GeoExplorer and Pathfinder. The type of receiver is set in the Configure Field command. The options available in the GPS Setup dialog depend on the current type of receiver.

For the Pathfinder and GeoExplorer, the *Altitude Measurement Type* chooses between using Ellipsoid or Mean Sea Level as the elevation model in the receiver.

With the Pathfinder, Carlson Field will activate the receiver when the first Carlson Field command is run and the receiver will stay active until Carlson Field is exited. The reason is that the Pathfinder will turn off as soon as the COM port is turned off. If you need to make Carlson Field turn off the receiver, then use the Close Communication

With Pathfinder button.

With the Pathfinder, *DGPS Correction Source* selects whether the Pathfinder will get its Corrections from a local Coast Guard Radio Beacon or from the Racal Satellite Correction service. Note that the Racal option must be enabled on the receiver in order to use Racal satellite corrections. (See your dealer for details as to how to do so). If *Racal Service* is selected as the correction source, the *Racal Region* selection will be enabled. The region corresponding to the relative location of the receiver should be selected to ensure proper reception of corrections.

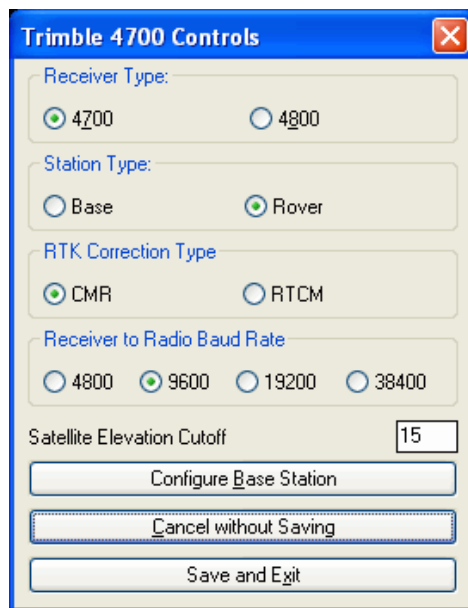

The screenshot shows the 'Trimble GPS Controls' window with the following settings:

- Station Type:** Base, Rover
- Receiver Type:** 4700, 4800, 5700/5800, MS Series
- Data Port:** 1, 2 Serial, 3, 4 BT
- Position Update Rate:** 1Hz, 5Hz, 10Hz
- Antenna Parameters:** Antenna Type: 4800 Internal; Antenna Height: 0.0000; Height Measured To: Hook By 4800 Tape
- RTK Type:** RTCM, CMR, CMR+
- Radio Parity:** Odd, None, Even
- Radio Port On Receiver:** Port 2, Channel 1
- Receiver to Radio Baud Rate:** 4800, 9600, 19200, 38400
- Satellite Cutoff:** 15
- PDOP Cutoff:** 7

Buttons at the bottom: Set Radio Station, Configure Base Station, Reset Receiver, Power Receiver On/Off, Cancel without Saving, Save and Exit.

The Pathfinder and 4700/4800 also feature the ability to select a *Satellite Elevation Cutoff*. All satellites with elevations below this setting will not be used in the final position calculations, even if they are otherwise visible to the receiver.

For 4700/4800 series receivers, the *Receiver Type* option must be set to the correct model in order for Carlson Field to communicate with the receiver. *RTK Correction Type* selects what format of RTK corrections between the Base and Rover receivers. CMR and RTCM formats are available. *Radio Baud Rate* should be set to the same setting as the communication port of the radio connected to the receiver. 4800 bps, 9600 bps, 19,200 bps and 38,400 bps rates are supported. *Configure Base Station* will configure the receiver as a base and begin transmitting corrections via the radio.

Library Drivers - GPS

For library drivers, unlike the legacy Carlson Field GPS drivers, you select a Base or Rover driver from the Configure Field command (instead of inside the Equipment Setup dialog). A GPS Base Equipment Setup dialog is shown below.

General receiver options are configured under the *Receiver* section. There are input boxes for *Antenna Height* and *Elevation Mask*. The antenna height is the rod height of the GPS receiver. The elevation mask is specified in whole degrees (above the horizon, or 0 degrees). The *Position Rate* specifies the rate at which the GPS receiver will output positions or corrections. The available position rates vary from receiver to receiver.

The *RTK* section is used to setup the RTK configuration. First, select the *RTK Device* to be used, and click the *Configure* button next to it if you need to configure the radio (ie. channels, etc). Next, select the *RTK Network* (if applicable). If available, select the correct *RTK Port* and *RTK Baud* to define the connection between the receiver and the RTK device. Then, select the desired *Message Type* (correction type). Finally, enter a *Base ID*, or leave it blank for 'any base', and continue by. In the example below, the base receiver will be configured to output *CMR* corrections (*Message Type*) through the *Internal Radio* (*RTK Device*). The *RTK Port* and *RTK Baud* are grayed out because these are known values when using the internal radio on the Altus APS-3. *RTK Network* is not available in the example because it doesn't apply to the chosen RTK device. The Rover would be configured similarly to accept CMR corrections on it's internal radio.

Altus APS-3 Base Setup

Receiver

Antenna Type: Internal

Antenna Height: 0.000

Elevation Mask: 7

Position Rate: 10 Hz

RTK

RTK Device: Internal Radio

RTK Network: None

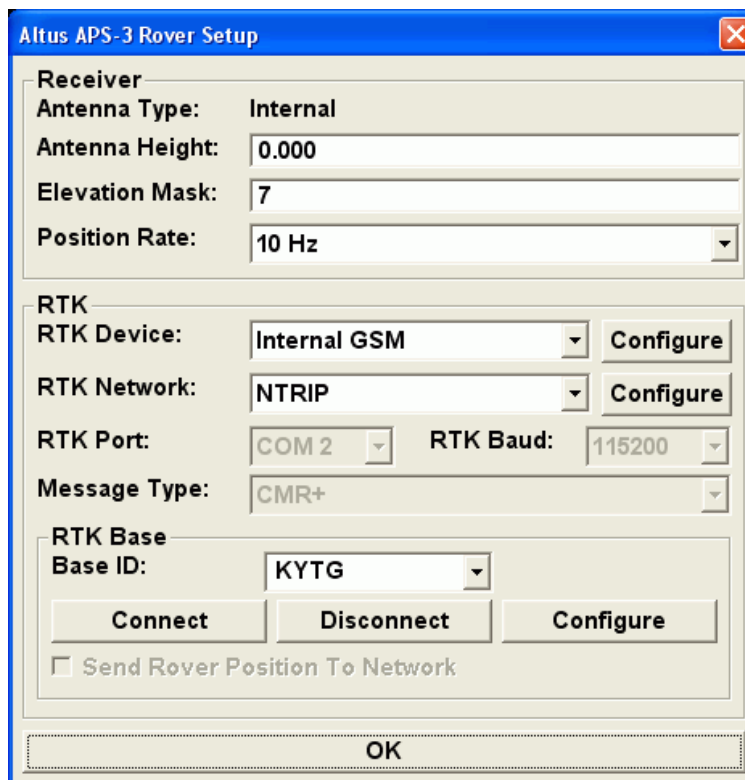

RTK Port: COM 2 RTK Baud: 115200

Message Type: CMR

RTK Base

Base ID:

To switch to the Rover, you must return to Configure Field > Equipment Type > Library Drivers and select the GPS Rover Manufacturer and Model. Similar to configuring a Base, general receiver options are configured under the *Receiver* section. In the example below, the rover receiver will be configured to receive *CMR+* corrections from the *KYTG NTRIP base* over an internet connection using the receiver's *Internal GSM* modem (PLEASE NOTE: This is a separate example from configuring a GPS Base. The examples are not intended to show how to configure the same Base/Rover pair to work in a differential configuration, but are intended to show two entirely different types of configurations.). The *RTK Port* and *RTK Baud* are grayed out because these are known values when using the internal GSM modem on the Altus APS-3. The *Message Type* is grayed out because this is the only message type available from the *KYTG NTRIP base*. Also, in the example below, the user would be required to click the *Connect* button before exiting the Rover setup to actually connect to the *NTRIP base* and start receiving corrections.

Normally, the *Configure* button next to the *RTK Network* is grayed out, and the *Configure* button in the *RTK Base* section is used to configure any details about the Base that the Rover is receiving corrections from. However, *NTRIP* is slightly different. When using *NTRIP* as the *RTK Network* the *Configure* button next to the *RTK Network* is used to configure the *NTRIP Broadcaster*. The *NTRIP Broadcaster* is the server that actually broadcasts it's available *NTRIP* bases and their information. *Save and Exit* will connect to the displayed *NTRIP Broadcaster* and download the base list. *Exit* will keep the broadcaster you have selected, but will attempt to load the base list from memory and will not attempt to connect to the broadcaster to download the base list.

When using an *NTRIP RTK Network*, the *Configure* button in the *RTK Base* section will display *NTRIP Base* information to help the user select the best base choice. As shown below, *NTRIP Base* information usually contains a short name (*Name*), a descriptive name (*Identifier*), the *NTRIP Base* type (*Type*), available *RTK* message type (*Format*), and approximate *NTRIP Base* location (*Position*). The *Send Rover Position To Network* toggle is always grayed out, but displays whether or not the selected *NTRIP Base* requires the Rover position to be sent back (ex. this is typically required by virtual base systems). Once the preferred *NTRIP Base* is selected, click the *Connect* button to actually connect to the base to begin downloading corrections. After a successful connection is created, exit the Rover Setup dialog using the *OK* button. It is recommended to goto the *Monitor/Skyplot* routine to verify that the Rover is receiving corrections. The Rover's status will be *Float* or *Fixed/Locked* if receiving corrections.

Configure Base for All RTK GPS Brands

Within Equipment Setup, the Configure Base Station button is the command that starts the base receiver broadcasting GPS corrections to the rover. You must click the *Configure Base Station* button in Equipment Setup while your are connected to the base receiver. The base needs a set of coordinates to use as its stationary position. There are five methods to set the stationary base position: Read from GPS, Enter Lat/Lon, Enter State Plane Coord, and Read From Reference File and Read From Alignment File.

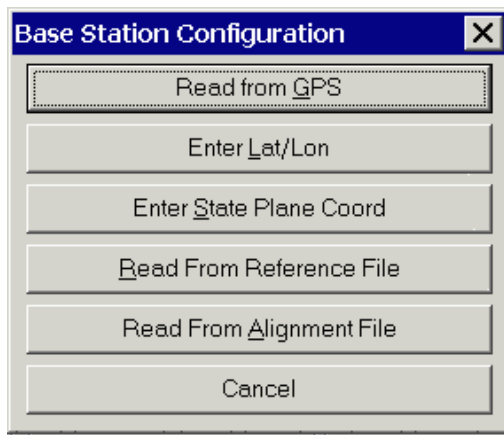

Read from GPS - This method takes one GPS reading from the base receivers autonomous position and uses it as its "true" position. The autonomous position can be off of the actual position by 200 feet. The base will calculate corrections based on this autonomous position. If you set up the base with this method, the rovers must be aligned since the corrections they are using are based on a "true" position that is not really true.

Enter Lat/Lon - requires you to enter the latitude and longitude for the position of the base antenna. This is useful if you are setting up over a USGS monument whose lat/lon you know. It can also be used over a control point whose position is known from GPS post-processing.

Enter State Plane Coord - requires you to enter the State Plane northing and easting for the point that the base is occupying. This is useful if you are setting up over a USGS monument whose coordinates you know.

Read From Reference File - reads a previously saved base position file. All of the other methods of setting up the base let you save the base position at the end of setup. If you return to a site, set up the base in exactly the same position, use Read From Reference File to use the same base position and you don't have to re-align the rover: the old alignment is still valid.

Read From Alignment File - reads a position file from one of the control points in an alignment file. This allows you to setup the base on one of the control points from the alignment. Then you don't have to re-align the rover: the old alignment is still valid.

Method 1 - Read from GPS

Step 1

Pick *Read from GPS* Step 2 - Station ID (Optional)

If you plan on doing post-processing, you can input a Station ID for the base GPS Antenna location. Otherwise just hit *OK*.

Reminder Pop-Box

You are reminded to connect the radio to the correct port.

Base GPS receiver's autonomous position

Carlson Field takes a reading and displays the latitude, longitude and ellipsoid height. This is the position that the base will use as its "true" position. The base is now configured. If you are using Pacific Crest radios, the TX light on the radio should begin blinking.

Error Message if incorrect

If the GPS receiver is not properly connected, is turned off, or hasn't determined a position yet, you will see an error message. Check all connections and try again.

Step 3 - Save Settings to File?

You have the option to save this base position as a file. You'll be able to use this file if you set up in the same spot in the future.

Method 2 - Enter Lat/Lon

Step 1

Pick *Enter Lat/Lon*.

Step 2 - Enter Lat/Long/Ellipsoid Height

Input the Latitude, Longitude and Ellipsoid Height for the base position. Pick North or South for the Latitude and East or West for Longitude. Important Note: The Latitude and Longitude entered must be within 100 meters of its true location on the globe. Ideally the entered base position should be a Latitude, Longitude and Ellipsoid Height from an accurate post processed static GPS point or a published NGS monument.

Step 3 - Station ID (Optional)

If you plan on doing post-processing, you can input a Station ID for the base GPS Antenna location. Otherwise just hit *OK*.

Reminder Pop-Box

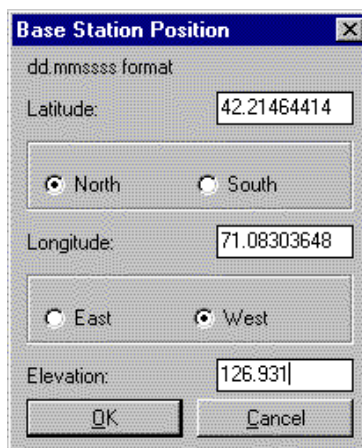

You are reminded to connect the radio to the proper port.

Base's Lat/Lon/Hgt position

The Lat/Long and Ellipsoid Height for the base position are displayed. These will be used for corrections and broadcast to the rover. If your radio has a TX light, it should begin flashing.

Step 4 - Save Settings to File?

You have the option to save this base position as a file. You'll be able to use this file if you set up in the same spot in the future.

Method 3 -Enter State Plane Coord Step 1

Pick *Enter State Plane Coord*.

Reminder Pop-Box - Current Zone & Datum

You are reminded what State Plane Zone and Datum is loaded. If this is incorrect, exit Equipment Setup and input correct State Plane Zone and Datum in Configure Field>GPS Settings.

Step 2 - Enter Northing/Easting/Elevation

Input the State Plane coordinates (northing, easting and elevation) for the base position. Important Note: The State Plane coordinates entered must be within 100 meters of its true location on the globe. Ideally, the entered State Plane coordinates (N,E,Z) should be from an accurate post processed static GPS survey point or from a published NGS monument data sheet.

Step 3 - Station ID (Optional)

If you plan on doing post-processing, you can input a Station ID for the base GPS Antenna location. Otherwise just hit *OK*.

Reminder Pop-Box

You are reminded to connect the radio to the correct port.

Base's Lat/Lon/Hgt position

The Lat/Long and Ellipsoid Height for the base position are displayed. This position will be used for the corrections that are sent to the rover. If your radio has a TX light, it should begin flashing.

Step 4 - Save Settings to File?

You have the option to save this base position as a file. You'll be able to use this file if you set up in the same spot in the future.

Method 4 - Read From Reference File

Step 1

Pick *Read From Reference File* to select an existing base position REF file.

Step 2 - Select Base Reference File to Load

Pick the base position REF file to be loaded. Use the up arrow folder to browse elsewhere for the REF file.

Position as Read from File

The latitude, longitude and elevation are read from the selected file and displayed.

Step 3 - Base Antenna Height

Enter the vertical height of the base antenna.

Step 4 - Station ID (Optional)

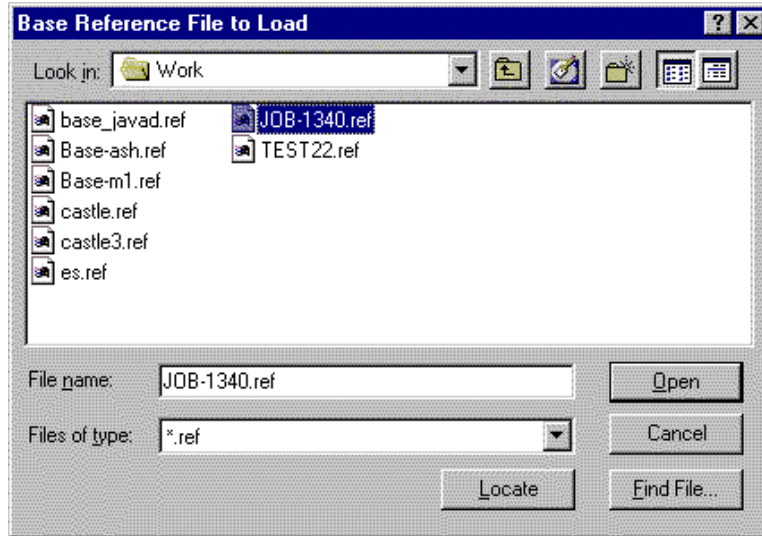

If you plan on doing post-processing, you can input a Station ID for the base GPS Antenna location. Otherwise just hit *OK*.

Reminder Pop-Box

You are reminded to connect the radio to the selected port.

Base's Lat/Lon/Hgt Position

The Lat/Long and Ellipsoid Height for the base position are displayed. This position will be used to calculate the correction that are sent to the rover. If your radio has a TX light, it should begin flashing.

Method 5 - Read From Alignment File

Step 1

Pick *Read From Alignment File*.

Step 2 - Select Alignment File to Load

Pick the alignment DAT file to be loaded. Use the up arrow folder to browse elsewhere for the DAT file.

Step 3 - Select Alignment Point

The program will display a list of points in the alignment file. Pick the point from this list.

Step 4 - Base Antenna Height

Enter the vertical height of the base antenna.

Step 5 - Station ID (Optional)

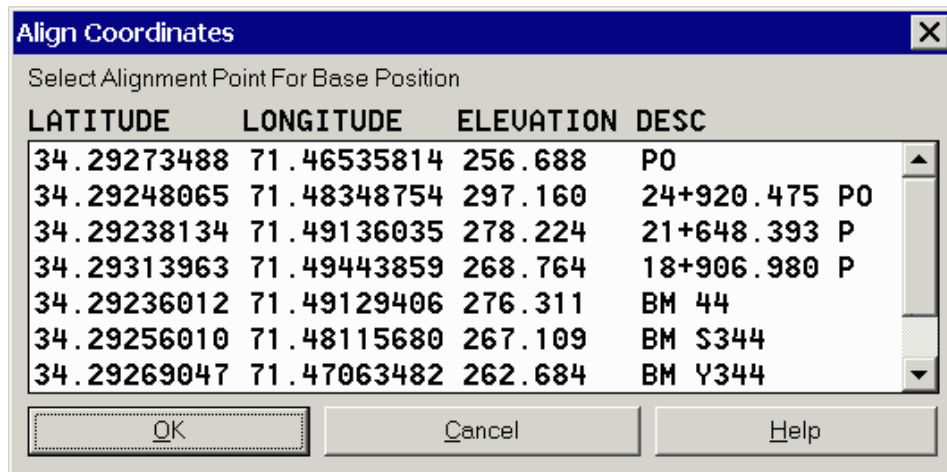

If you plan on doing post-processing, you can input a Station ID for the base GPS Antenna location. Otherwise just hit *OK*.

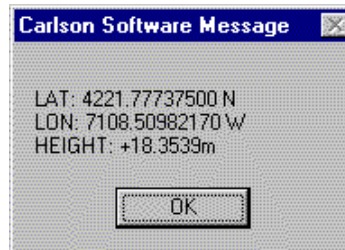

Reminder Pop-Box

You are reminded to connect the radio to the selected port.

Base's Lat/Lon/Hgt Position

The Lat/Long and Ellipsoid Height for the base position are displayed. This position will be used to calculate the correction that are sent to the rover. If your radio has a TX light, it should begin flashing.

Saving Base Settings to a File

It is always recommended to save the base position to a file if you are going to return to the same site survey again. You can setup on the same base position, recall the base REF file and enter the new antenna height. Then you can use the alignment file from the first day in the rover and not have to re-align.

When you save the base antenna position to a file it is stored with a REF extension denoting base reference file. By default, it goes in the Data directory. Input reference filename and pick *Save* and *OK*.

Configuring the Rover

After the base is configured, unplug the base receiver from the Carlson Field computer and plug in the rover receiver. In Equipment Setup, toggle the *Station Type* from *Base* to *Rover*. Then pick *Exit*. This will configure the receiver as a rover.

From the Field drop-down, pick the command Monitor GPS Position. The Status is reported as either Autonomous, Float or Fixed.

If the rover is Autonomous, it is not getting any corrections from the base.

If the status is Float, the rover is receiving corrections, but has not found the fixed solution. Once the solution becomes Fixed, the rover is locked on to the base corrections and is calculating an accurate position.

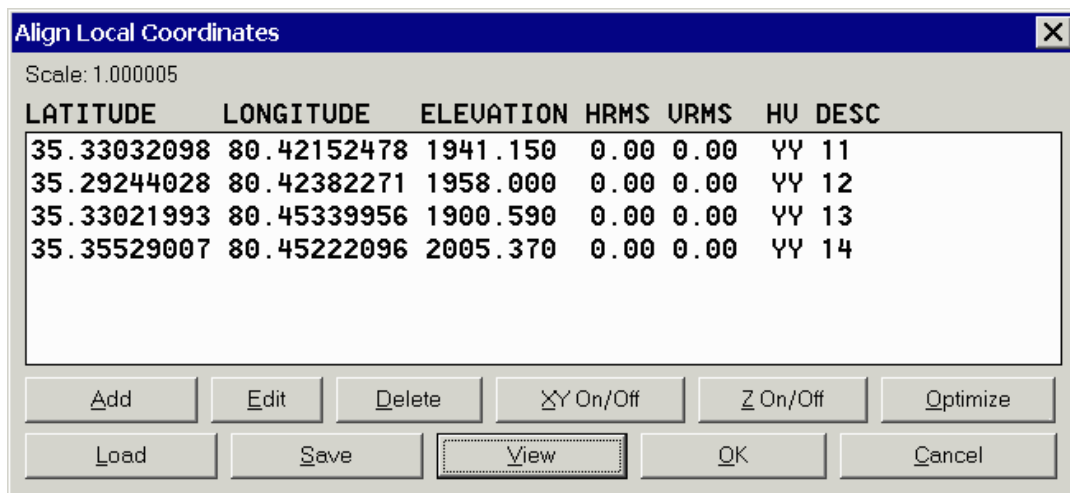

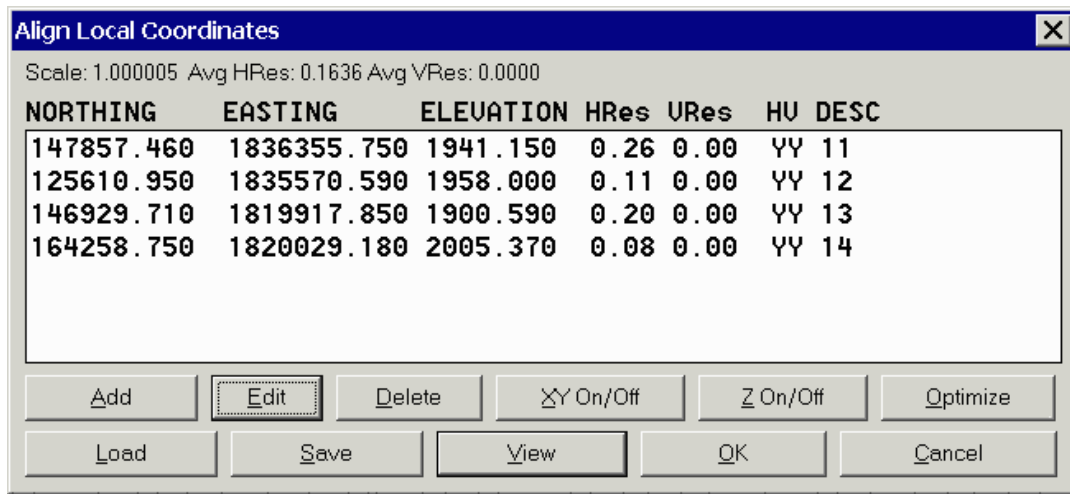

Align GPS To Local Coordinates

Carlson Field reads a latitude, longitude and height position from the GPS rover receiver and converts these values to State Plane or UTM coordinates for the current zone as set in Configure Field. Using local coordinates and their corresponding GPS position, Align Local Coordinates applies a transformation to convert the state plane or UTM

coordinate to the local. Carlson Field can operate in three different modes depending on the Align Local Coordinate settings:

- 1) No points - No Adjustment
- 2) One point - Translation Only
- 3) Two or more points - Translate, Rotate and Scale

Without any alignment points set, Carlson Field will operate with no alignment which directly uses the state plane or UTM coordinates. In order for the coordinates to be the true state plane coordinates in this alignment mode, the GPS base receiver must be set up over a known point and the true Lat/Long for the point must be entered in the base as the base position. Otherwise, if the base is set over an arbitrary point, then the coordinates will not be true state plane.

In one point alignment mode, one pair of GPS and local coordinates is specified. The differences between the GPS and local northing, easting and elevation for these points are used as the translation distances in the transformation. The rotation will use either the state plane grid or the geodetic as north. No scale is applied in this transformation.

A two or more point alignment is used to align to an existing local coordinate system. At least two pairs of local and GPS coordinates must be entered.

In addition to the northing and easting transformation, SurvStar will also translate the elevation from the GPS system to the local. The elevation difference between the two systems is modeled by a best-fit plane.

An alignment is only valid if the base receiver setup has not changed since the alignment points were recorded. In order to use an alignment when returning to a site, you must set up the base receiver in the same position and enter

the same LAT/LONG coordinates for the base.

The *Align GPS to Local Crds* menu item brings up the alignment dialog box. There is more information than to fit in one window, so use the *View* button to switch between viewing the local coordinates and the GPS Lat/Lon.

Each line in the box represents one alignment point. Each point in an alignment file relates a specific Lat/Lon/Elv to a specific Northing/Easting/Elevation for your local coordinate system. Carlson Field will use the current alignment file every time that the GPS is read. It provides the necessary adjustment to properly convert that position to your coordinate system.

In the local points view, the HRes column shows the horizontal residual and the VRes column shows the vertical residual. The residual is the difference between the actual point and the point calculated using the alignment transformation. In GPS points view, the HRMS and VRMS columns show the horizontal and vertical RMS values when that point was recorded.

The *On/Off* buttons allow you to switch whether the highlighted point is used for the horizontal and/or vertical alignment. The *HV* column shows a 'Y' if this point is used in the calculations. Otherwise it shows an 'N'. The H column represents horizontal control and the V column vertical control. For example, you may wish to use 2 points for horizontal alignment and one for vertical.

The *Optimize* button will find the combination of turning alignment points on/off for horizontal and vertical such that the horizontal and vertical residuals are minimized.

The *Desc* field shows an optional description of the alignment points.

The scale factor and average horizontal and vertical residuals appear at the top of the window. These values serve as a check that the alignment is valid. The scale factor should be closed to 1.0 (in range of 0.9 to 1.1). The average residuals should be less than 0.2.

XY On/Off toggles the highlighted alignment point horizontal component off or on. Alignment points with the horizontal component toggled off will not use the northing and easting of that point for adjustment calculations.

Z On/Off toggles the highlighted alignment point vertical component off or on. Alignment points with the vertical component toggled off will not use the elevation of that point for adjustment calculations.

Note: When you toggle either the XY or Z component off or on for any alignment point the scale factor and Horiz/Vert residuals are recalculated automatically. Briefly toggling XY or Z components off or on and reviewing the scale factor and residuals changes is a quick approach to finding the best alignment points. Carlson Field can handle an unlimited number of alignment points.

Highlight an existing alignment point entry and pick *Delete* to delete that alignment point.

Pick the *Add* button to create an alignment point. The Add Alignment Point dialog box appears. There are two ways to enter the local coordinate points: by entering the N, E, Z, or by using an existing point number stored in the current coordinate CRD file. The GPS values can also be specified by two methods: by entering in the Latitude, Longitude and Height or by occupying the control point with the rover and taking a GPS reading at this location. Manually entering the Lat/Lon can only be done when the base is setup on a known location using a true lat/lon position. Otherwise Carlson Field needs to use the Read GPS method. For this method, the base can be setup with a lat/lon that only needs to be close (within 100 feet) of the actual lat/lon. This type of position can be read from an autonomous GPS position. With the base setup on this approximate lat/lon, go with the rover to the control points and use the Read GPS option in the Add function. The rover GPS solution must be in "fixed" status when the alignment point is added. By reading the rover GPS position for the alignment points, the alignment will transform the coordinates from the GPS system of the current base setup to your local coordinate system.

Load allows you to open an existing alignment file. Only one alignment file can be open at a time. Alignment files have a DAT extension and stored in the Data directory by default. This function also loads .LOC files from SurvCE, .DC files from Trimble and .GC3 files from Topcon.

Save stores alignment files (DAT extensions) to a file. Files are by default stored to the Data subdirectory.

The *OK* button will set the current alignment to the settings in the dialog.

Alignment Methods

Carlson Field can operate by the following Alignment methods:

Alignment Method 1) - No alignment points

Alignment Method 2) - One point alignment

Alignment Method 3) - Two or more alignment points

Alignment Method 1

With no alignment of the rover, Carlson Field will report Northing and Easting as State Plane or UTM coordinates. In order for this method to give accurate State Plane or UTM coordinate values, the GPS base receiver must be set up over a known point and configured using the true Lat/Long/Hgt or true State Plane coordinates. If the base is set up over an arbitrary point, configured by reading the GPS, the RTK GPS stored coordinates will be translated up to a 200 feet but accurate in relation to each other.

When using this method, you can skip *Align GPS to Local Crds* and start surveying immediately once the base is configured and transmitting its position and the rover is fixed.

In most cases, you cannot use Method 1 because you will not have setup the base on a point whose exact true position you know. Therefore the base corrections are going to be off a certain distance north/south and a certain distance east/west. This is why you want to do an alignment. You are showing Carlson Field how to correct for the north/south and east/west offsets. Any points surveyed with the alignment file active will be translated to their proper position.

To gather alignment points, you put the GPS antenna over a point with known coordinates and Carlson Field records the GPS Lat/Lon/Elv and the Northing/Easting/Elevation you give it. This point can be a local coordinate, for example a stake you are calling 5000,5000. It can also be a true State Plane point. Using one or more State Plane points will give you an alignment to true State Plane (even if your base is not using its own true position.)

Alignment Method 2

This method uses one alignment point to translate the GPS coordinates to local or true State Plane coordinates.

Remember that if the base is set up over an arbitrary point, the GPS coordinates can be off from true state plane by up to 200 feet. This alignment method can be used to correct for this by translating the system onto true state plane coordinates.

You can choose if you want the coordinate system North to be Geodetic North or State Plane Grid North under *Configure Field>GPS Settings*. If you specify a scale factor in that dialog box, it will be applied to all points recorded.

One point alignment is useful for data collection on a new site. In this case you can set up the GPS base receiver anywhere convenient. Then position the rover over a point (preferably one you can find again) and add this point as your one alignment point by reading the GPS point and entering a local coordinate like 5000,5000,100. Now the local coordinate system is set around this first point at 5000,5000,100.

This method is commonly used for small topo or stockpile RTK GPS surveys. When collecting or staking data at distances greater than 2 miles from the base, both the horizontal and vertical errors will begin to increase gradually. Therefore, you should use a multiple point alignment for large projects.

Alignment Method 3

This method is useful if you are arriving on a job which has already been surveyed. It assures that your survey is in the same coordinate system as the original survey.

Using control points, this method transforms the GPS coordinates to an existing local coordinate system. This method takes pairs of GPS coordinates and the corresponding local coordinates to define the translation, rotation and scale of the alignment.

In *Configure Field>GPS Settings*, there is a choice for the transformation as Plane Similarity or Rigid Body. Plane Similarity will apply a scale factor to the transformation. The scale factor will be based on the alignment points and should always be very near 1.0 to be correct. The Rigid Body option will align by translate and rotate but no scale. Any difference in scale between the GPS and local coordinate systems will be distributed equally between the two alignment points. These differences will appear as horizontal residuals in the Alignment dialog.

Two pairs of points are sufficient to define the translation, rotation and scale for the transformation. But adding more alignment points yields the most accurate results for aligning to existing coordinate systems. Since two pairs of coordinates are sufficient to define the transformation, there is extra data when there are three or more pairs. The program uses a least-squares best-fit routine to find the transformation that minimizes the residuals. This one best-fit transformation is used to convert from the GPS to the local coordinate system for all the points. The residuals are the differences between the transformed GPS coordinates and the actual local coordinates.

A multiple point alignment is especially helpful on a survey which covers a large area. The error in raw GPS coordinates increases as you get farther from the base. Taking alignment points around the perimeter of your job site as alignment points will give you the best geometry for the alignment.

Point Store

This function creates points by reading from GPS or total station equipment. The new points are stored in the current coordinate and simultaneously drawn in the drawing. The measurement data is also stored to the current raw file which has the same name as the coordinate file except with a .RW5 instead of .CRD file extension.

The Point Store dialog docks on the side of the drawing window. This allows you to see the drawing view as you collect points. You can use the arrow keys to pan the drawing and the Page Up/Page Down keys to zoom out and in. There are also icons for the pan and zoom functions at the top of the dialog. Also, besides clicking the function buttons, most buttons have an associated function key such as F1 that you can use to run the routine.

Before taking measurements, make sure that the rod height is correct.

To take a measurement from the survey equipment, pick the *Read* button. The calculated northing, easting and elevation will be displayed in the dialog and a temporary icon will be shown in the drawing at the point location.

Point Store dialog for GPS

Point Store dialog for GPS with a Laser

Point Store dialog for non-robotic total station

Point Store dialog for robotic total station

Before storing the point, make sure that the point number and description are set in the *Point Number* and *Description* fields. The point number is a required field for storing to the current coordinate file. If the point number specified

already exists in the coordinate file, then a dialog will pop-up with options to overwrite the existing point number, to use another point number or to cancel storing the new point. The *Point Number* field will automatically increment after storing the point.

The *Description* is an optional field for identifying the point. The maximum length of the description is 32 characters. Besides naming the point, the description can also be used to with Field-To-Finish to draw linework and to determine the symbol of the point in the drawing. When the Field-To-Finish option is set on in *Options*, the program will lookup the description in the current code table. If the description matches one of the codes, then the code can determine the symbol, layer, format of the point when it is drawn. Otherwise the defaults in the Point Setting section of the Options dialog are used for the point symbol, layer and format.

To store the new point to the coordinate file and draw the point, pick the Store button. At the time that Store is applied, the program uses the point number, description, linework options and special options currently set in the dialog.

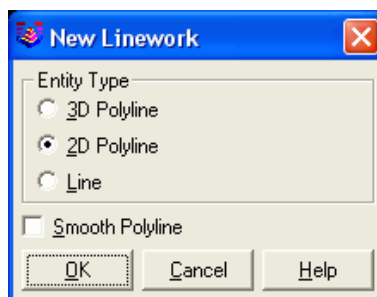

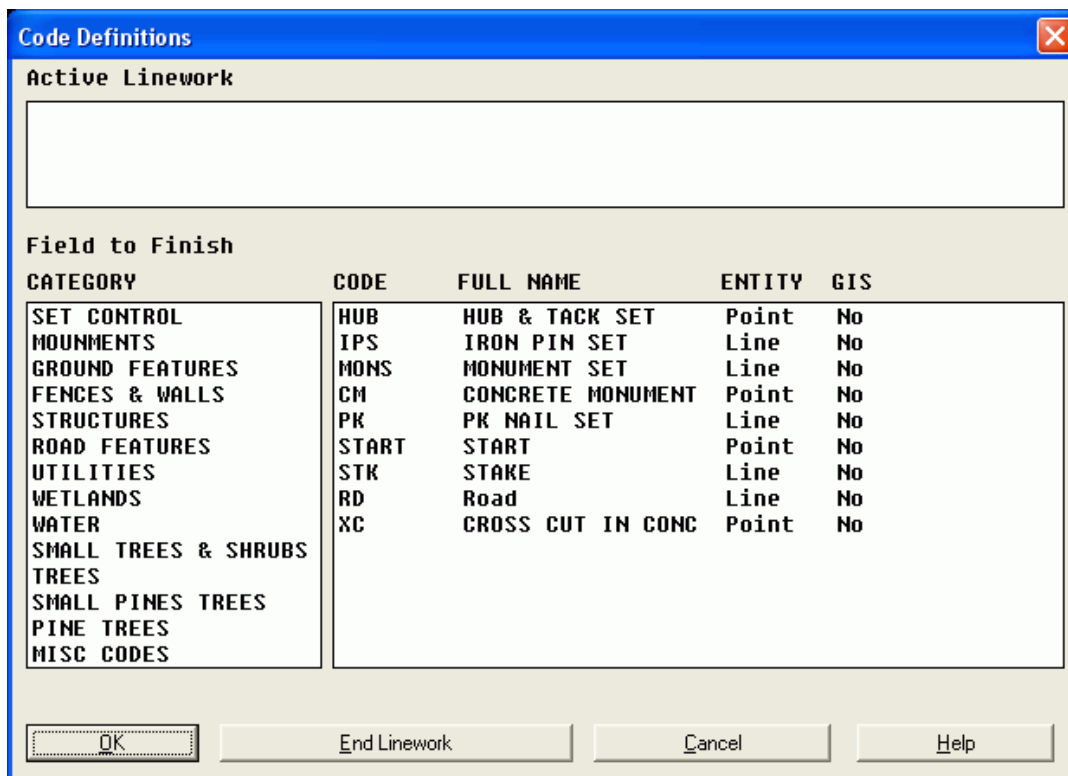

You can also use the *Read & Store* button to do both functions in one step. With this method, the program will take a measurement and if the measurement is successful, then the point will be stored immediately.

The *Code* button brings up a list of point descriptions from the current Field-To-Finish code table. You can select a code from the list to set this code as the current point description. This function also shows a list of all the descriptions of currently active linework. You can end a currently active linework by highlighting the linework description from the Active Linework list and pressing the End Linework button.

Many of the options for storing points can be set in the Configure Field>Point Settings command. The *Options* button in this dialog is a shortcut to these point settings.

If you want lines or polylines to connect the points that you are about to record, select the *Start* button under *Linework*. After the first point, the *Linework* selection will change itself to *Cont* meaning continue. Leave this selected while you are recording points in the same line. Before shooting the last point in your line, change it to *End*. If you want the line to close itself onto its first point, check the *Close* button.

The Field-To-Finish Linework option is an automatic way to start linework. The program will lookup the point description in the code table. If the description matches a code and the code is defined to create linework, then the *Start* toggle in the *Linework* options is turned on. Otherwise you can begin new linework by toggling on *Start* manually.

When a point is stored and *Start* is on, Carlson Field pops-up a dialog for choosing between a line, 2D polyline or 3D polyline. A 3D polyline can contain points with different elevations, but a 2D polyline always has an elevation of zero. The *Smooth Polyline* option will create Bezier smooth polyline through the points.

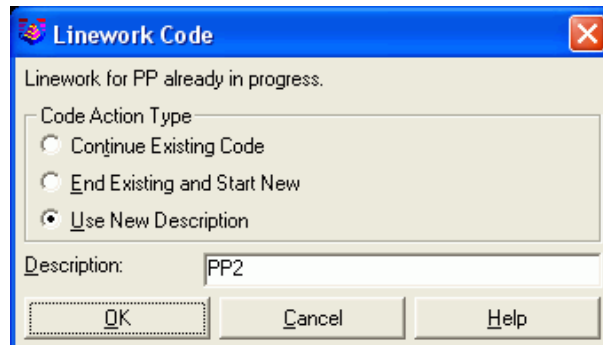

Carlson Field can keep track of several lines being drawn at once. Each line corresponds to a set of points with a different description. Let's say you are shooting a line of points called "fence" and you want to shoot some points on a curb, but you're not finished with the fence. You change the *Desc* box from "fence" to "curb". Carlson Field lets the fence line go for now. It changes the *Linework* selection to *No*. You want a line for your curb, so you select *Start*. The points you shoot now will form a new curb line. To go back to recording fence points, change the description back to "fence". The fence line you were working on will continue to include any new fence points you shoot. If you want to end this fence line, select *End* under *Linework* and Carlson Field will not connect any future "fence" points to this line. If you start a new linework with a description that already has linework, then Carlson Field pops-up a dialog with three options as shown. The *Continue Existing Code* option is the same as using *Cont* instead of *Start*. The *End Existing and Start New* option will end the active linework and start the new linework with the same description. The *Use New Description* option will keep the existing linework and start another linework with another description. For example if you are surveying two edge of pavement lines, you can have one with the description "EP" and the other with "EP2".

The *PC* and *PT* options are for drawing curves. If you want to plot a curve, check the *PC* box before recording the first point on your curve. Shoot as many points along the curve as you need. Carlson Field can handle compound curves as well as simple curves with this function. Before shooting the last point on the curve, check the *PT* button. If you don't specify a *PT*, Carlson Field will assume a three point curve.

Similar to Field-To-Finish linework, when looking up the point description in the code table, if the description matches a code and the code is defined to use data collection codes, then the *Offset* and/or *Rotate* toggles in the *Special* options are turned on. Otherwise you can create an offset and symbol rotation by toggling them on manually. *Offset* is for defining a left/right offset or an azimuth based offset. It also has the option for a vertical offset. *Rotate* will control the rotation angle of the symbol that is drawn when the point is stored; if enabled, the drawn symbol will be rotated based on the current heading of movement.

The *Undo* button will remove the last point number created. The point is removed from both the coordinate file and the drawing.

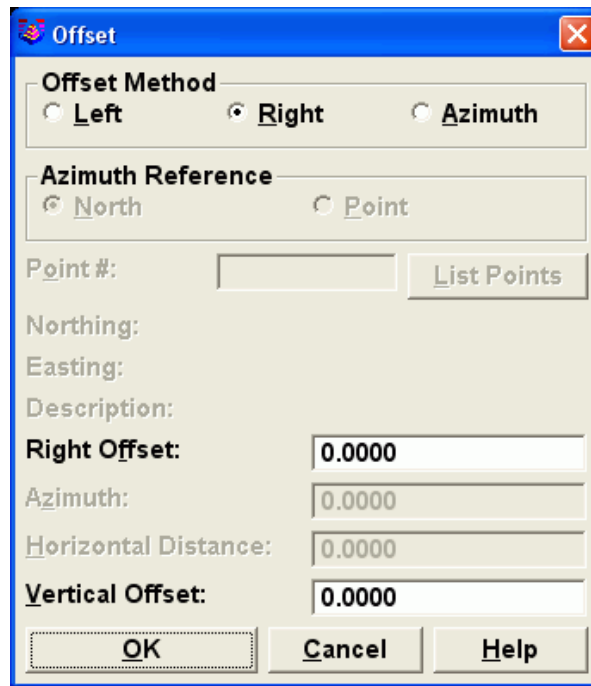

For GPS and tracking total stations, there is a *Start Continuous* button which makes Carlson Field continuously read from the instrument. The coordinates are displayed in the dialog and your position is shown with an arrow icon in the graphics view. To store a point, you can use the *Store* button without using the *Read* button first. Once continuous reading is active, the button changes to *Stop Continuous* which will put you back in standard reading mode.

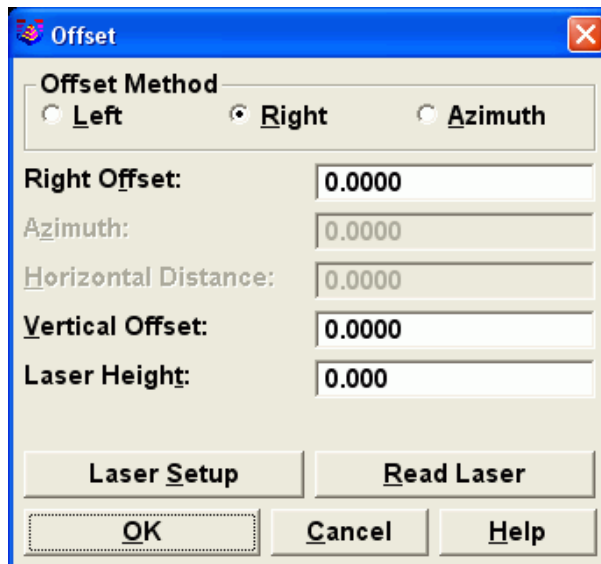

Point Store with GPS

When using GPS equipment, Carlson Field will also report the RMS values and solution status when you take a reading. If Carlson Field gives you a message that your RMS values are too high when you try to read a point, you can click on the *Monitor* button to bring up the *Monitor* window which will give you information on how accurately your position is determined and how many satellites you are tracking. The *Skyplot* button will bring up the window showing you where in the sky the satellites are.

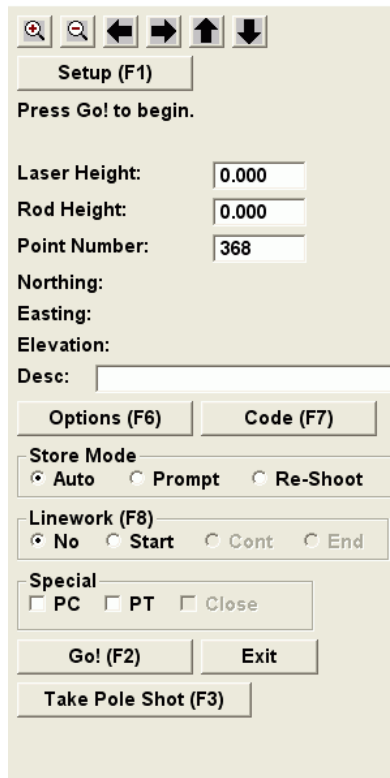

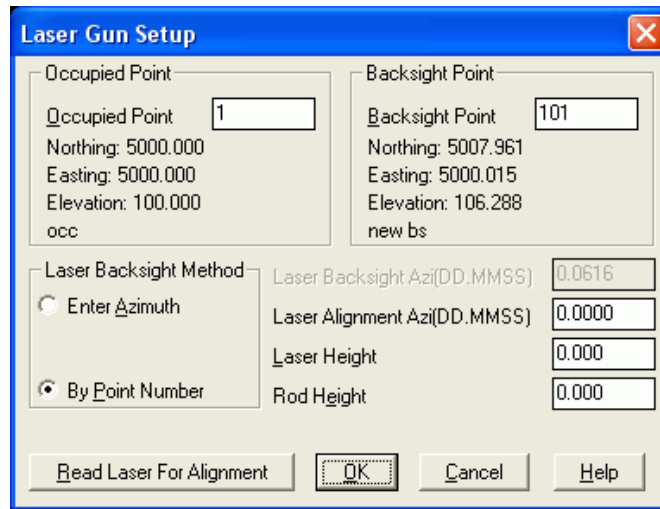

For points that are hard to reach directly by GPS, you can use the *Offset* option. This option can be used in areas of limited satellite communication such as high walls or under a tree. This allows you to setup the rover in a clear area and read the coordinate. The point that is actually stored is offset from the rover position. To create an offset point, turn on the *Offset* toggle and then choose *Read*. The offset direction can be entered as left, right or azimuth. The left and right offset is relative to the rover position at the previous read. The offset distance is entered in the dialog. A Vertical Offset can also be specified. Choose *Store* to store this point after the offset is done.

Offsets can also be done with laser guns when the laser option is setup in Configure Field>GPS Settings. There are two methods for taking laser offsets. One method is to use the *Offset* toggle and the *Read* button. In the Offset dialog, there is button for Read Laser for using the laser measurement for the offset distance and/or angle. This method creates a single offset point.

The other method is to use the *Laser* button which can create many offset points. This method brings up another dialog. The Setup button can be used to set the *Laser Alignment Azimuth*. This alignment applies to laser guns that use a magnetic compass for the horizontal angle. The magnetic north can vary from the north of your coordinate system. The *Laser Alignment Azimuth* is added to the measured laser azimuth to adjust for the difference. To set the alignment azimuth, specify a reference backsight direction by either entering an azimuth or by point number. Then choose the *Read Laser For Alignment* button and take a laser shot towards the backsight. The program will compare the azimuth from the laser with the reference backsight to figure the alignment azimuth. When the alignment azimuth is set, pick the *Go* button. Carlson Field then listens for measurements on the laser gun port. To take a shot, sight the target point and press the laser trigger. Carlson Field will read the laser measurement and read the GPS position. The laser angle and distance are combined with the GPS position for the new point coordinates. To return to regular GPS Point Store, choose the *Exit* button.

Point Store with Total Stations

Before taking measurements with total stations, you need to specify the occupied point coordinates of the instrument, the backsight and the height of the instrument. This current setup data is shown in the "OC:# BK:# HI:#" line in the dialog. Also icons are draw to show the occupied point and backsight direction in the drawing view

The *Setup* button at the top of this dialog brings up the *Total Station Setup* dialog, where you can change your occupied point, backsight and instrument height.

For robotic total stations, there is also a *Joystick* button to turn the instrument, search for the prism and set tracking or standby mode.

Carlson Field can shoot points with offsets. To shoot a point with an offset, check the *Offset* button on the Point Store dialog box. Click Read or press F1. A window appears to let you choose the type of offset to shoot. The choices are Distance/Angle and Enter Offset Distances. The *Offset Vertical* option will prompt for an elevation difference to apply to the point.

To do a Distance/Angle offset, you first take a distance shot and then angle shot. For the distance measurement, have the rodman stand to the side of the point. The prism and the point should both be the same distance from the total station. Carlson Field takes the first shot and gets the distance from it. It then prompts you to read the angle. Turn the gun so that it is aimed at the point. The prism is not needed for this step. Click OK and Carlson Field reads the horizontal angle from the gun and combines this with the distance from earlier to calculate the coordinates of the point. Also for combining these shots, there is an option whether to use the vertical angle from the distance or from the angle shot.

With the Enter Offset Distances method, you can supply both a left/right offset and an in/out offset. To do a In/Out offset, have the rodman stand a measured distance in front of or behind the point. The total station will take the shot and then Carlson Field will ask you how to move the point: in or out and the distance. If the prism is in front of the point, choose out. If it's behind the point, choose in. To do a Left/Right offset, have the rodman stand a measured distance to one side of the point. After taking the shot, Carlson Field will ask whether to offset right or left. If you are at the total station, looking at the prism, and the point you are after is to the right of the prism as you're looking at them, choose right offset. Otherwise, choose left offset.

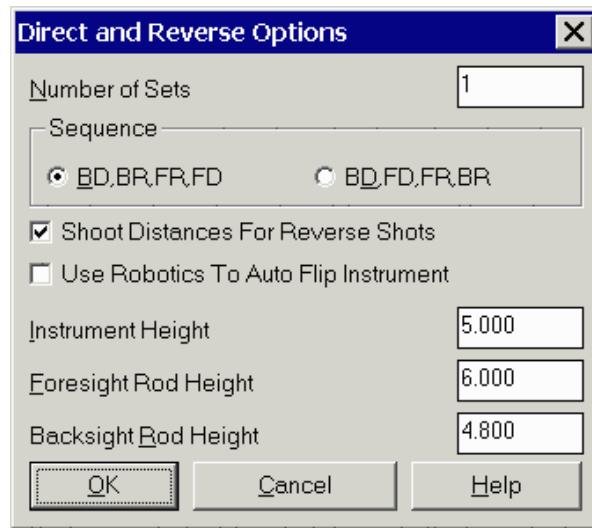

Choose *Store* to store this point after the offset is done.

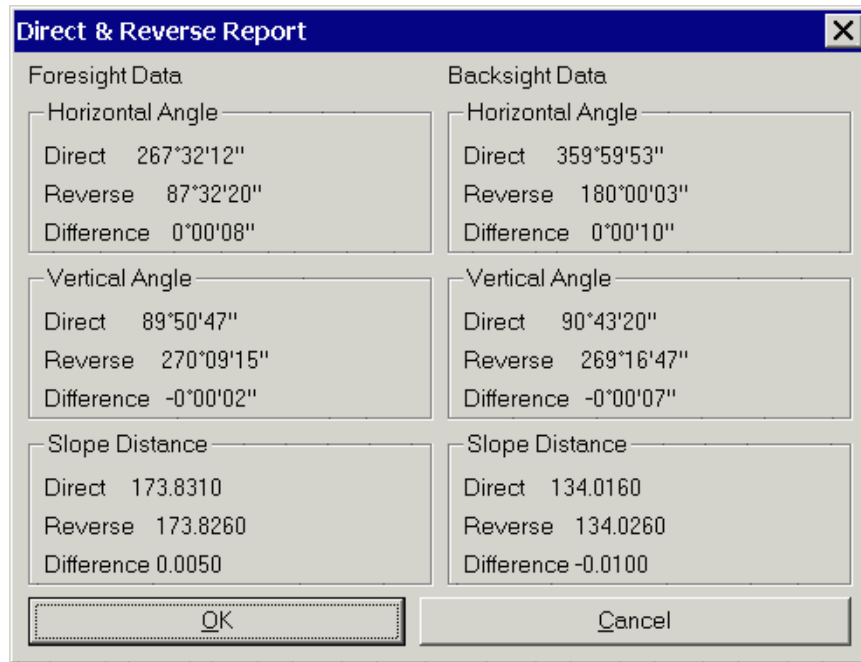

The *D&R* option stands for Direct and Reverse. When this box is checked, Carlson Field will take sets of four shots to determine the coordinates of the next point. Two shots are taken for both the backsight point and the foresight point: one direct shot, one shot with the total station reversed. This yields a more accurate reading. Two options are available for the order of shots when doing a D&R. The first is Backsight Direct, Backsight Reverse,

Foresight Reverse, Foresight Direct. The other option is Backsight Direct, Foresight Direct, Foresight Reverse, Backsight Reverse. Carlson Field also offers the option of shooting multiple sets of Direct & Reverse for even greater accuracy. The *Shoot Distances For Reverse Shots* option determines whether to take distance measurements on the foresight reverse and backsight reverse shots. When this option is off, the program will still use the reverse shots to mean the angles. Otherwise the program will also use the reverse shots to mean the distances. The *Use Robotics To Auto Flip Instrument* option applies to robotic total stations to have the program automatically turn the instrument for reverse shots.

To shoot a point as a Direct & Reverse, check the *D&R* box and click on *Read*. A dialog box appears, offering the choice of orders for the shots. Before each shot, Carlson Field tells you what kind of shot is being taken. After each shot, Carlson Field reports the measurements and allows you to confirm the measurement or to re-shoot. After all four shots are taken, Carlson Field does the math and reports the accuracy of each part of the measurement.

Choose *Store* after completing the Direct & Reverse to store this new point.

StakeOut

The Stakeout function is used to find a specific point in the field. Once you tell Carlson Field the point that you are looking for, pick *Start* and the program draws an X-marks-the-spot bullseye on that point in the drawing. Carlson Field also draws a triangle on the drawing for where you are currently standing. These icons help to guide to the target point graphically. Carlson Field also reports in the dialog box how far you need to move to reach the point.

There are several options for Stakeout defined in Configure Field>Stakeout Settings. These options should be set by Configure Field before running Stakeout. See the Configure Field section of the manual for a description of the stakeout options.

There are four ways to define the target point for stakeout. The first method is to specify a point number from the current coordinate file. To do this, click on the *Point Number* button and type in the point number in the dialog. The second method is to give a station and an offset from a centerline. The program will prompt for a centerline file (.CL) and then the station and offset. You can also specify the station interval for automatically incrementing to the next stakeout point. See the Roads section of this manual for how to create centerline files. The third method is to graphically pick the point from the drawing. Select *Pick Point* and a dialog box allows you to pick different snaps: endpoint, midpoint, center, node (point), or intersection. This will help you pick your desired point more accurately. For example, you can select endpoint and then pick on a polyline corner to stakeout that the polyline endpoint. See the Object Snap command in this manual for more on snaps. The fourth method is to simply type in the target point coordinates in the *Northing*, *Easting* and *Elevation* fields.

Once the stakeout point is set, click the *Start* button and Carlson Field begins the stakeout routine. The format of the stakeout screen that appears depends on whether you are using total stations or GPS as described below.

When you reach the target point, click the *Store* button. Carlson Field reports the difference between your current position and your target position. At this point you can choose to store this staked-out point as a new point in the coordinate file.

Draw Stakeout Point

OK Cancel

When the target stakeout point has an elevation, Carlson Field also reports the elevation difference between the target and current elevations. This cut/fill is also in an edit box that allows you to change the value for labeling. For example, you may want to round the cut/fill number to an even number to label on the stake with a mark to indicate where this even number occurs. When you change the cut/fill label from the original value, Carlson Field will report the offset for this mark. For total stations, Carlson Field will also report the zenith angle for locating this mark. There are also fields in the report dialog for entering vertical offsets to get additional cut/fill values. For example, if the target point is for the road surface and you want to also get the cut/fill to an 18 inch subgrade, then enter -1.5 as the vertical offset.

GPS Stakeout

After you click *Start* to begin staking the point, Carlson Field changes the dialog box to the one shown below. The dialog shows the target point, the current position northing, easting and elevation and the GPS HRMS/VRMS. The distance, azimuth and cut/fill from the current position to the target are also reported. Carlson Field also breaks down this distance into how far north/south and how far east/west to go. Finally based on your current heading, the program tells you whether to turn right, turn left or that you are on-line.

In the graphics view, the large "X" shows the point being staked-out and the triangle represents your position. A temporary line is drawn between your current position and the target. In Configure Field>Stakeout Settings, there is an option to auto zoom in as you approach the target point. Otherwise you can use the arrow keys to pan the display and the Page Up/Down keys to zoom out and in.

Total Station Stakeout

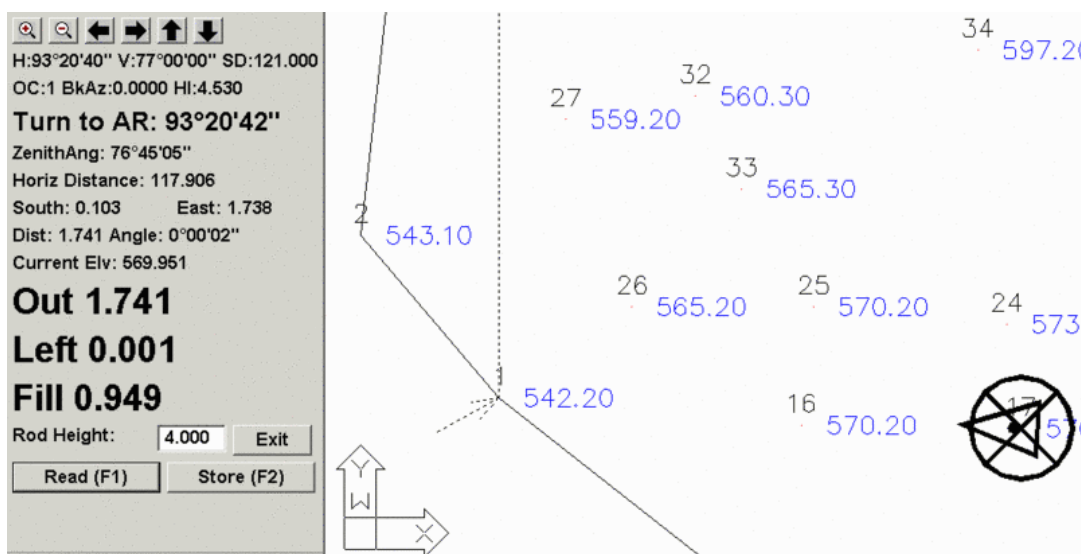

Before starting the stakeout, be sure that the instrument is setup with correct occupied point, backsight and instrument height. This setup data is displayed in the third line of the dialog. You can pick the Setup button to change the instrument setup.

After you click *Start* to begin staking the point, Carlson Field changes the dialog box to the one shown below. The dialog shows the angle to turn the gun and the horizontal distance to the target. Turn the instrument to this angle and position the rodman at this angle and distance. Then pick the Read button to take a measurement. Carlson Field will then report the horizontal distance and cut/fill from the current position to the target. This distance is also reported as how far north/south and how far east/west to go and as how far in/out and left/right to go. To in/out and left/right distances are relative to the rodman facing the instrument. Keep moving the rodman and picking the Read button until you reach the point. Then pick the Store button.

For robotic total stations operating remotely, there is a Continuous button that puts the instrument in tracking mode with continuous measurements.

In the graphics view, the large "X" shows the point being staked-out and the triangle represents your position. Also the location of the instrument is shown with an icon and the backsight is shown as temporary line.

Auto Points at Interval

This command stores a point whenever the distance or time from the previous point exceeds the user-specified interval. This command only applies to GPS and robotic total stations. If you will be collecting a large number of points at once, *Auto Points at Interval* can be a useful tool. For example, you may want to plot the edge of a road. Once you start *Auto Points*, you can walk along that edge of road and let Carlson Field record your position automatically.

The *Auto Points at Interval* dialog box resembles the *Point Store* dialog box with the addition that you can set the interval to record points. You can set it to store a point every time you move a certain distance by selecting *Distance* and entering the distance you choose in the *Interval* box. The distance will be taken in feet if your project is using English units, or meters if your project is in Metric. If you select *Time*, the number in the *Interval* box will refer to

the number of seconds between creating points.

Check the *Draw Linework* box to have your points connected by a line or polyline. You can enter a description or choose from the code table just like in *Point Store*.

The *Offset* toggle will apply an offset to the calculated coordinates. The horizontal offset is applied perpendicular either left or right to the direction of movement. There is also an option for a vertical offset.

The *Rotate* toggle will rotate each drawn symbol in reference to the current heading.

If the description contains a Field-to-Finish code, the *Offset* and *Rotate* toggles will be selected/unselected automatically based on that code's Data Collection Code settings.

Pick *Start* to begin storing points. Carlson Field will take a reading and store the first point. Then Carlson Field will continuously read the GPS or total station. For distance interval method, as each point is read the distance from the last point is calculated. When the distance is greater than the specified interval, a point is created and the point number is displayed in the dialog. In practice, the actual distance between stored points will be greater than the distance interval. For example, if the distance interval is 10 and the current distance is 8.9, then no point is stored. Then you keep moving and the next distance is 11.4 which will store a point.

For time interval point storing, after reading and storing the first point, Carlson Field will wait for the interval time to pass, then read and store again.

The screenshot displays the Carlson Field software interface. At the top, there are two buttons: "Monitor (F3)" and "SkyPlot (F4)". Below these are navigation controls: "Menu(F11)", a magnifying glass icon, a minus sign icon, left and right arrow icons, and up and down arrow icons. The main area contains several input fields: "Point Number:" with the value "359", "Rod Height:" with "0.000", "Northing:", "Easting:", "Elev:", and "Desc:". Below these are two buttons: "Options (F6)" and "Code (F7)". The "Interval Type" section has two radio buttons: "Distance" (selected) and "Time (sec)". Below this are two more input fields: "Interval(x/y):" with "5.000" and "Interval(z):" with "10.000". At the bottom, there are three checkboxes: "Offset", "Rotate", and "Draw Linework", all of which are currently unchecked. Finally, there are three buttons at the very bottom: "Start (F1)", "Stop (F2)", and "Exit".

The new points are both stored to the current coordinate file and drawn in the drawing.

When using GPS, if the RMS values of the position read are above the tolerance set in Configure Field, then the point will not be stored.

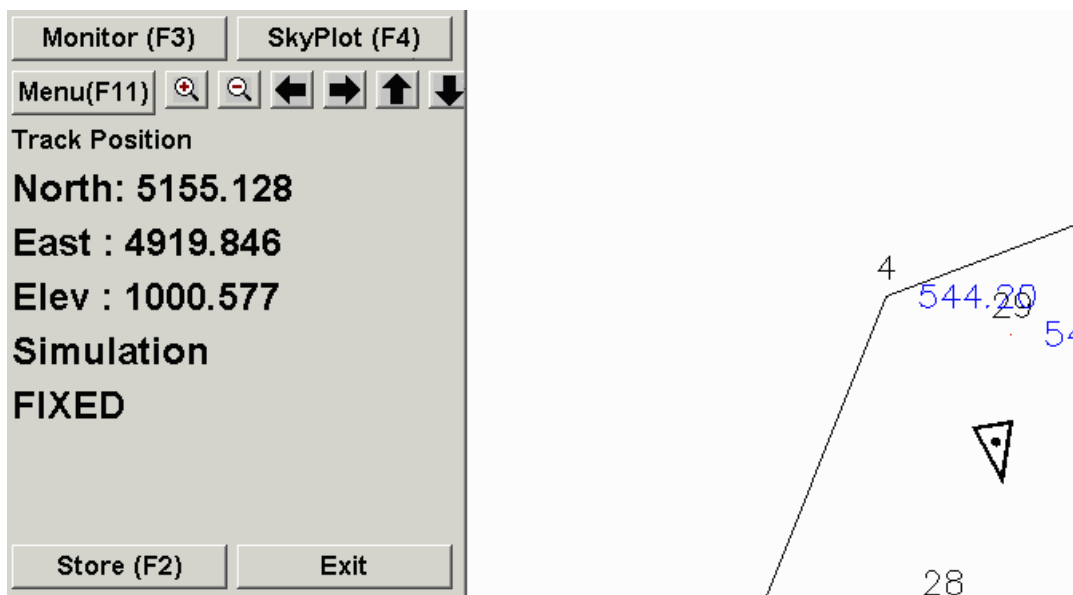

Carlson Field will continue to record points until you click on *Stop*.

Track Position

This command shows your current position in either the drawing view or a 3D view. For the drawing view, the coordinates of your current position are shown in a dialog and an arrow icon is shown in the drawing view. For the 3D view, use the Run button to get position updates and use the Stop button to stop updates and use the viewer controls to change to view. When the tablet computer has tilt and compass sensors, the 3D view uses these sensors to control the view direction.

This command only applies to GPS and robotic total stations. As you move along, the arrow icon will move through your drawing showing your position in real-time. If the arrow icon gets near the edge of the screen, Carlson Field will automatically pan over.

A dialog box also appears in Track mode. The dialog shows your current northing, easting and elevation. For GPS mode, the dialog displays the *HRMS* and *VRMS* values and solution status. There are buttons to take you to *Monitor* and *Skyplot*. There is also a *Store* button which will store your current location as a point and plot it, similar to the *Point Store* function.

Track Position in Drawing view mode

Track Position in 3D view mode

Satellite SkyPlot

When using GPS, it is important to know how many satellites you are tracking and their position in the sky. *Satellite Skyplot's* visual and graphical screen aids in identifying when satellites are being masked by surrounding structures, trees and mountains. Satellites close to the horizon, under fifteen degrees, are less helpful resolving the rover position because of extra atmospheric interference. If there are too few satellites present, the receiver will be unable to resolve its position. Typically five satellites are required to resolve position and four are needed to maintain locked solution. *Satellite Skyplot* can be an invaluable tool to help you monitor the current satellite configuration.

The skyplot screen appears at left. The top half of this window displays the visible satellite information in chart form. *PRN* is the satellite identification number. *Azi* is an abbreviation for azimuth; the horizontal angle from due north, in degrees measured clockwise, to the satellite position (0 to 360 degrees). *Elv* is an abbreviation for elevation; the vertical angle above the horizon where the satellite can be found (0 to 90 degrees). One entry appears for each satellite that the receiver is tracking.

The image on the lower half of the window displays the same information graphically. It shows a map of the sky with North at the top, East to the right. The centerpoint, where the lines cross, is straight up. Each satellite appears as a symbol resembling an "H". As you can see, most of the visible satellites were in the Northeast when this image was captured. The inner circle represents an elevation of sixty degrees. The outer circle is the horizon. Roughly speaking, any "H" touching this circle is too low in the sky to be of much use. For GPS receivers that support GLONAS satellites, Skyplot will show these satellites with a "G" symbol.

For some types of GPS receivers, the receiver will report which satellites are being used for calculating the position and which are only being tracked. A satellite might be only tracked and not part of the solution if the satellite is too low on the horizon or when the signal is not clear. The skyplot will highlight the satellites that are part of the calculations.

Monitor GPS Position

This command reports the current GPS Lat/Lon, local coordinates and GPS solution status. The latitude and longitude are reported in the DD.MMSSSSSS format. In this example, the latitude is 42 degrees, 21minutes, 46.4414 seconds north. The longitude is 71 degrees, 8 minutes and 31.5699 seconds west. Negative longitudes indicate longitudes west.

The next three items are state plane or local coordinates depending on the transformation in the Align Local Coordinates command. The *HRMS* and *VRMS* are measures of the reliability of the position that the receiver has calculated. They correspond to the position horizontally and vertically, respectively. If the receiver is autonomous, not receiving corrections from a base, the RMS can be up to a few hundred feet. If this rover is computing a "Fixed" position, the RMS values should be less than one foot, probably close to a tenth of a foot. If the receiver loses the fix and becomes "Float", the RMS values will jump to between one and ten feet.

Depending on the type of GPS receiver, the Monitor screen will also show more values like radio link status and receiver battery status.

The *Skyplot* button will jump you to that window so you can see the satellites the receiver is using.

Benchmark

This command takes a measurement to a benchmark point with a known elevation in order to calculate the elevation at the occupied point. This command only applies to total stations.

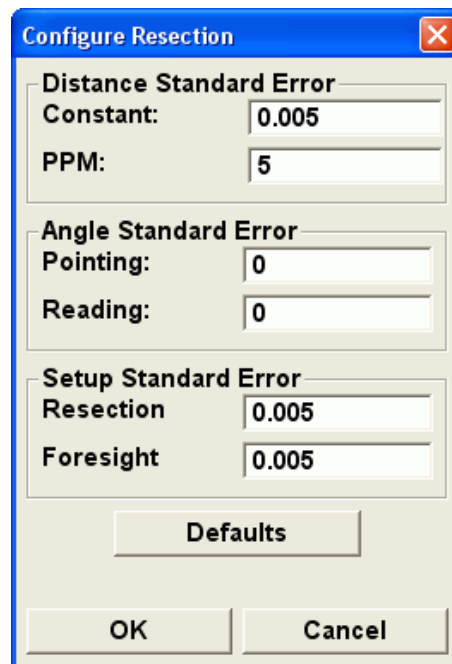

In the Benchmark dialog, fill in the instrument and rod heights. The benchmark elevation is specified in the Target Elevation field. This field can be filled out by entering a target point number which reads the elevation from the current coordinate file for the specified point. Or you can simply type in the target elevation directly. There is a choice between calculating the occupied point elevation or the instrument height. For calculating the instrument height, you need to enter the occupied point elevation. When calculating the occupied point elevation, there is an option to store this elevation to the coordinate file for the occupied point number. When all the options are set and the target benchmark is sighted, pick the Read button to take a measurement. After the reading, the program will display in the dialog the calculated occupied point elevation or instrument height depending on the calculation mode.

Resection

Resection is used when setting up a Total Station on an unknown point. The occupied point coordinates are calculated from two or more angle and distance measurements to known reference points. This command only applies to total stations.

The dialog above has options for *EDM Mode* and *Robotics*. These options will only show up for supported total stations (ie. robots, etc).

Configure Std Errors can be used to set standard errors for the measurements, as shown below. These settings allow you to take advantage of network least squares and weighting in the resection calculation. The default values are shown below:

Distance Standard Error	
Constant:	0.005
PPM:	5

Angle Standard Error	
Pointing:	0
Reading:	0

Setup Standard Error	
Resection	0.005
Foresight	0.005

Defaults

OK Cancel

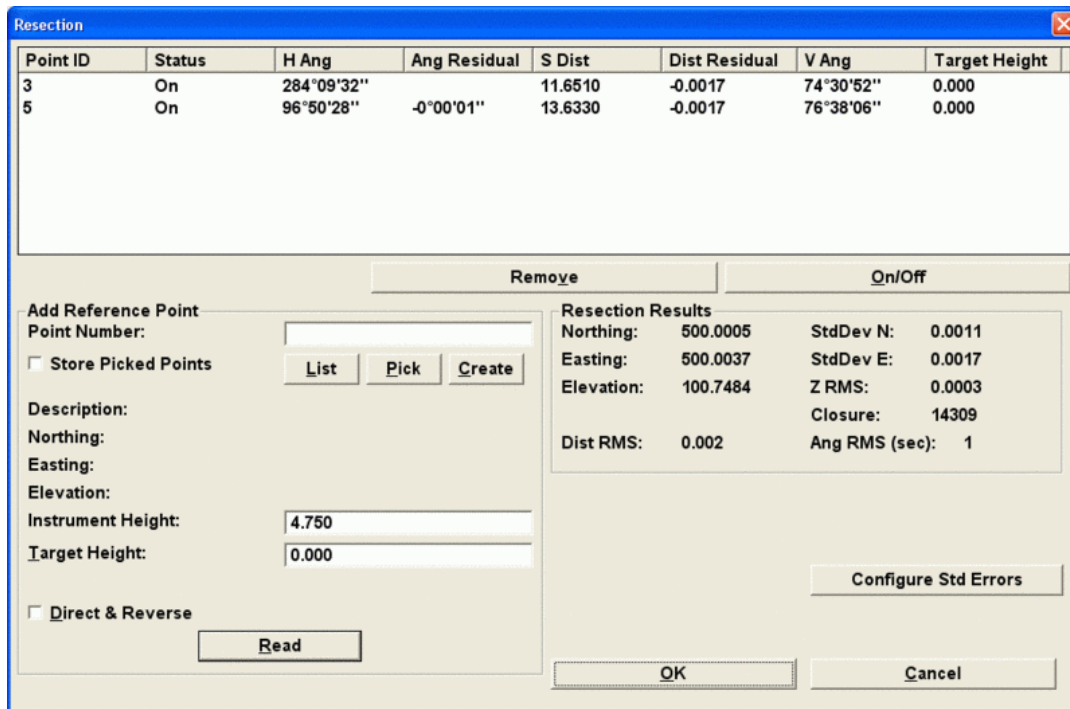

Reference points are distinct known points that are measured to calculate the unknown occupied point. Direct and Reverse measurements are optional by using the toggle *Direct and Reverse* located in the *Add Reference Point* section.

Reference points can be specified in several ways:

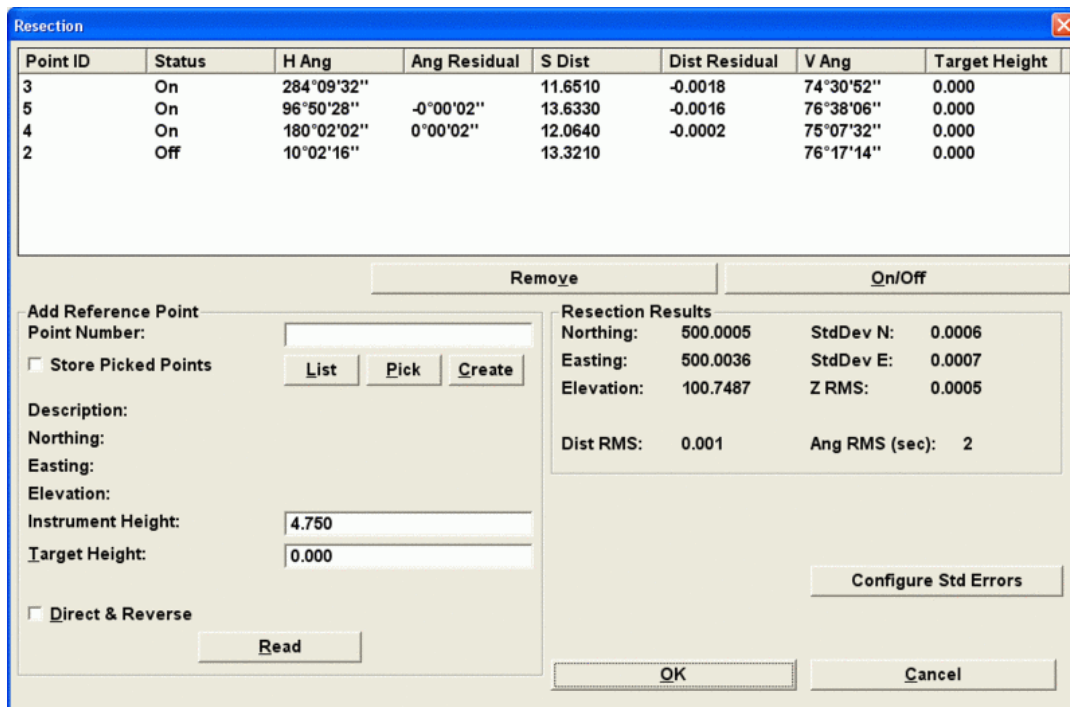

1. Manually entered point number
2. Selected from a list of points stored in the coordinate file (via *List* button)
3. Picked from the CAD screen (via *Pick* button)
4. Manually entered coordinates (via *Create* button)

There are input boxes for the target (or rod) height, and instrument height. The *Store Picked Points* toggle controls whether or not the user is prompted to store screen picked points that are not found in the coordinate file.

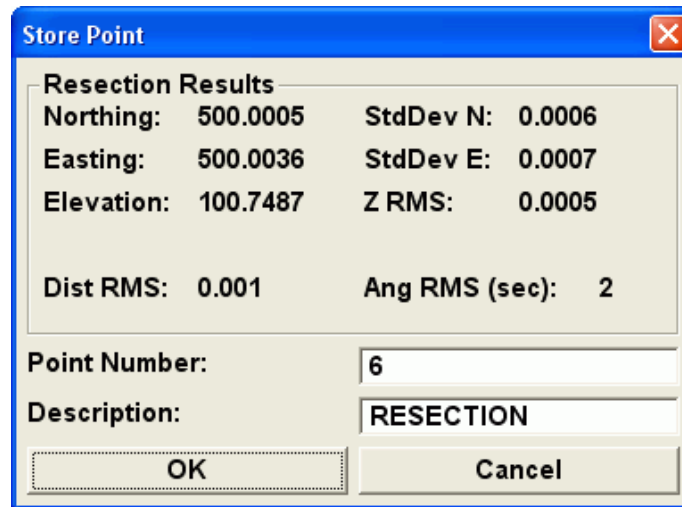

After a reference point is chosen, it's description and coordinate information are displayed. Press the *Read* button to initiate the measurement for the currently displayed reference point. After a successful measurement, the user will be prompted to verify the measurement information. This gives the user a chance to verify the target (or rod) height, and the option to discard the data and take another measurement. The user will be prompted to determine whether or not to zero the instrument on the first reference point.

A minimum of two distinct reference points and measurements are required to calculate the occupied point. The calculated occupied point information is displayed in the *Resection Results* section. The input data is displayed in a list structure and the user has the option to turn certain measurement on or off using the *On/Off* button or remove an unwanted measurement using the *Remove* button. The resection results are calculated automatically anytime a reference point measurement is added, a list item is removed, or a list item is toggled on or off. A resection with three inputs 'on' and one input 'off' is displayed below:

The *Resection Results* section shows the calculated occupied point's northing, easting, and elevation and the difference between the calculated coordinate and the individual solutions as the residuals. The residual indicate the quality of the data. High residuals suggest a problem with the input data. When you press the *OK* button, you will be prompted to verify the calculated occupied point. If accepted, the calculated point will be stored to the coordinate file and you will be setup on the calculated point backsighting the first point shot in the resection.

The 'Store Point' dialog box displays the following information:

Resection Results			
Northing:	500.0005	StdDev N:	0.0006
Easting:	500.0036	StdDev E:	0.0007
Elevation:	100.7487	Z RMS:	0.0005
Dist RMS:	0.001	Ang RMS (sec):	2

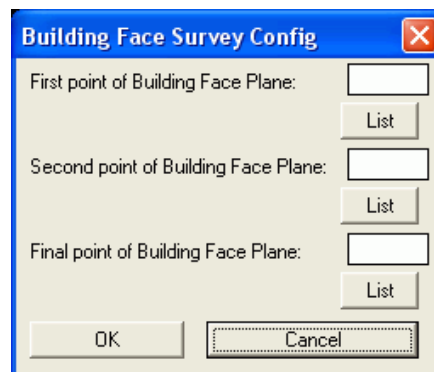

Point Number:

Description:

Buttons: OK, Cancel

Building Face Surface

Used to project all points onto a surface or plane. Upon executing the function, a menu will open, prompting the selection of three points to define the plane/surface. Note that there must already be three points along the plane in the CRD file in order for this function to work properly. After selecting the three points (the "List" buttons will bring up a list of available points), select "OK" to proceed. A screen similar to the Store Points dialog will now open. Every point which is read will be plotted along the plane defined by the three points selected, even if it is at a different distance. When finished, simply exit out of the menu as with any other function.

The 'Building Face Survey Config' dialog box contains the following fields and buttons:

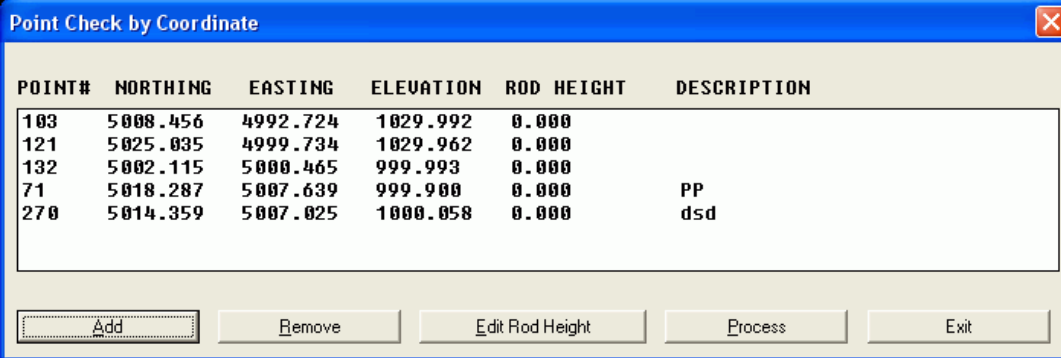

- First point of Building Face Plane: List
- Second point of Building Face Plane: List
- Final point of Building Face Plane: List
- Buttons: OK, Cancel

Pattern Point Survey

Used with a reflectorless Total Station. This function is used to shoot a regular, rectangular "pattern" of points across an area. It is useful when periodic measurements of an area are required. Upon starting the function, a query box will ask for two point defining a rectangle, the lower left corner and the upper right corner. For each of these, aim the gun at the corner of the area to be scanned and click "Read". After reading both points, a menu will prompt for several other parameters. Enter the first point number to shoot, as well as any desired description for the points, and both horizontal and vertical increments. These are angle increments, given in seconds. Once all of the above is entered, select "OK" to begin the survey. The total station will now begin turning automatically to the bottom-left corner of the area, and will begin shooting points. Upon reaching the right-hand limit of the area, it will begin a new row of points, starting at the left.

Point Check By Robotics

This command works with robotic Total Stations made by Leica, Topcon or Geodimeter. This function is used to shoot and record a series of known target points. Before running this command, the instrument setup must be set (occupy point, backsight) with the Equipment Setup commands. After selecting Point Check by Robotics you will be prompted with a dialog box. Choose the points you want to check and click process. The Total Station will then go from point to point and take new measurements. When it is all done, a report will be given with the new measurements and any deviation.

POINT#	NORTHING	EASTING	ELEVATION	ROD HEIGHT	DESCRIPTION
103	5008.456	4992.724	1029.992	0.000	
121	5025.035	4999.734	1029.962	0.000	
132	5002.115	5000.465	999.993	0.000	
71	5018.287	5007.639	999.900	0.000	PP
270	5014.359	5007.025	1000.058	0.000	dsd

Pipe Network

This set of commands is to measure pipe networks and store as-built values. The pipe network model is created by the Carlson Hydrology module and is stored in a .sew file.

Set Model

This command selects the pipe network model file (.sew) to process.

Prerequisite: Pipe network model file .sew

Keyboard Command: set_sew

Plan View Label Settings

This command defines how to draw the pipe network. See the Hydrology chapter for a description of these options. All the options for the Field version of this command are the same except a few on the General Settings tab. The Use As-Built Values option uses the measured values for the labels instead of the design values from the original .sew file. The Measured Color sets the label color for values that have been measured. The Unmeasured Color sets the label color for values that are not yet measured.

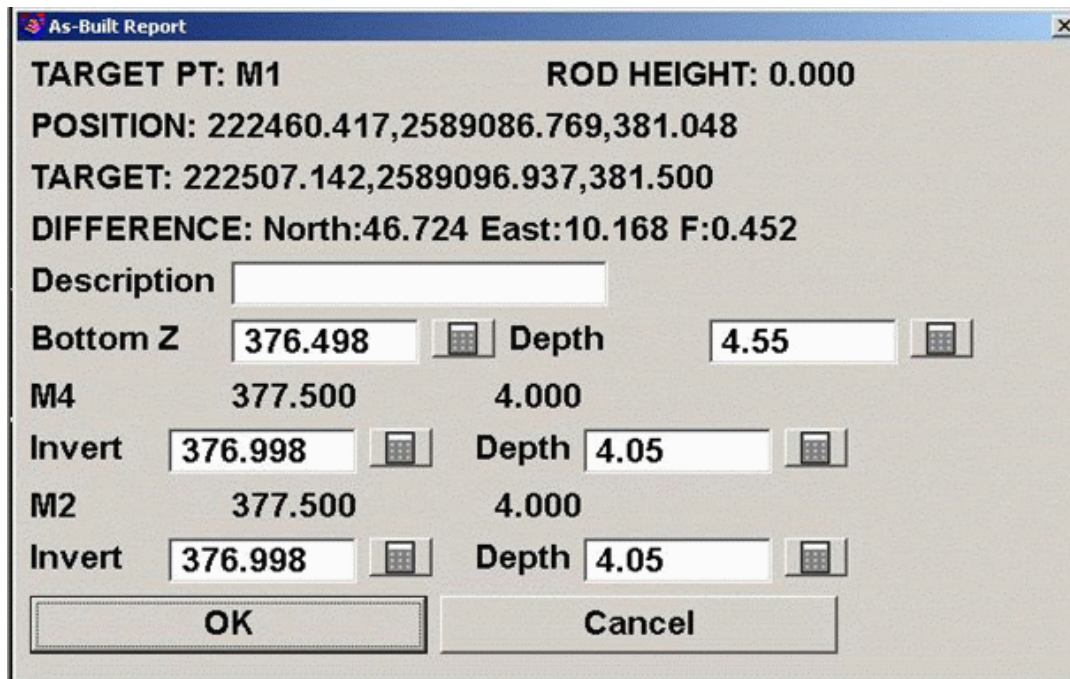

Prerequisite: None

Keyboard Command: setup_sew

Measure

This command measures as-built structures. On the first dialog, select the structure to measure by either Screen Pick where you pick on the drawing or from the pull-down list of structure names. Then pick the Start button to begin measuring. Then the program takes readings from the instrument and reports the difference and direction to the structure like the Stakeout command. Once at the structure, pick the Store button. Then the As-Built Report

dialog shows the difference between the structure design and measured positions. In this dialog, you can measure the bottom of the structure either by entering a depth or bottom elevation. Likewise you can measure the inverts for pipe connection by either depth or bottom elevation.

Prerequisite: set_sew

Keyboard Command: stake_sew

Edit

This command allows to edit the bottom elevation and inverts of a structure. After selecting the structure to edit, the As-Built Report dialog is shown for making the edits.

Prerequisite: stake_sew

Keyboard Command: edit_sew

Report Structures

This command reports structure parameters including the design and measured positions and differences.

Prerequisite: stake_sew

Keyboard Command: report_struct_sew

Report Pipes

This command reports pipe parameters including the design and measured slopes.

Prerequisite: stake_sew

Keyboard Command: report_pipe_sew

Draw Plan View

This command draws lines, labels and symbols for the pipe network. See the Hydrology chapter for more info.

Prerequisite: set_sew

Keyboard Command: plan_sew

Draw 3D

This command draws the pipes and structures as 3D Faces. See the Hydrology chapter for more info.

Prerequisite: set_sew

Keyboard Command: 3d_sew

Carlson Field Icon Menu

The Carlson Field Icon Menu lets you select Carlson Field functions by pressing a function key F1-F10 or by picking the icon button. The set of commands that are available in this menu depends of the type of survey equipment that you are configured to. Before running these Carlson Field functions, you need to run Configure Field to set the equipment type and communication parameters.

There are two ways to bring up the icon menu. One way is by picking the Start Carlson Field icon. This start icon is displayed in the lower right of your screen when the Show Startup Icon option is on as set in Configure Field under General Settings. You can close the Start Carlson Field icon for the current drawing session by clicking the X in the icon title bar. To bring back the Start Carlson Field icon you can use the F11 key. The Start Carlson Field icon is only displayed when no commands are running. The other way to show the Carlson Field function menu is to pick the Menu(F11) button while running other Carlson Field commands. This method allows you to switch between Carlson Field functions without having to exit back to the CAD menu. For example, you can switch from

Point Store directly to Stakeout.

This is the function menu when using GPS equipment:

Typical Alignment Scenarios

Scenario: New site. In this case, there are no established coordinates on the site.

Alignment: Choose a point on site and do a one point alignment. For the local alignment point, enter the coordinates that you would like to use (ie 5000,5000,100). Under Configure Field>GPS Settings, The One Pt Align Azimuth option chooses between using true north (geodetic) or state plane north (grid). To use real world ground distances, set the Project Scale

Factor under Configure Field>GPS Settings. Otherwise the default scale factor of 1.0 will collect points on state plane distances.

Scenario: One known state plane coordinate and you want to work in the state plane coordinate system.

Alignment: Either setup the base over the known state plane coordinate or do a one point alignment on this known state plane point. In Configure Field>GPS Settings, set the One Point Align Azimuth to Grid and set the scale factor to 1.0.

Scenario: Multiple known control points.

Alignment: Choose two or more control points to align to. It is best to use control points around the perimeter of the site. Use as many control points as are available or enough to envelope the site. In Configure Field>GPS Settings, set the Transformation to Plane Similarity to fit the GPS points onto the control points and set the Project Scale Factor to 1.0. After making the alignment, stake out another control point (ideally one the is not used in the alignment) to make sure the alignment is good.

Surface Menu

The Surface pull-down menu has Elevation Difference and surface creation commands that are described in the Civil Design manual.

Elevation Difference

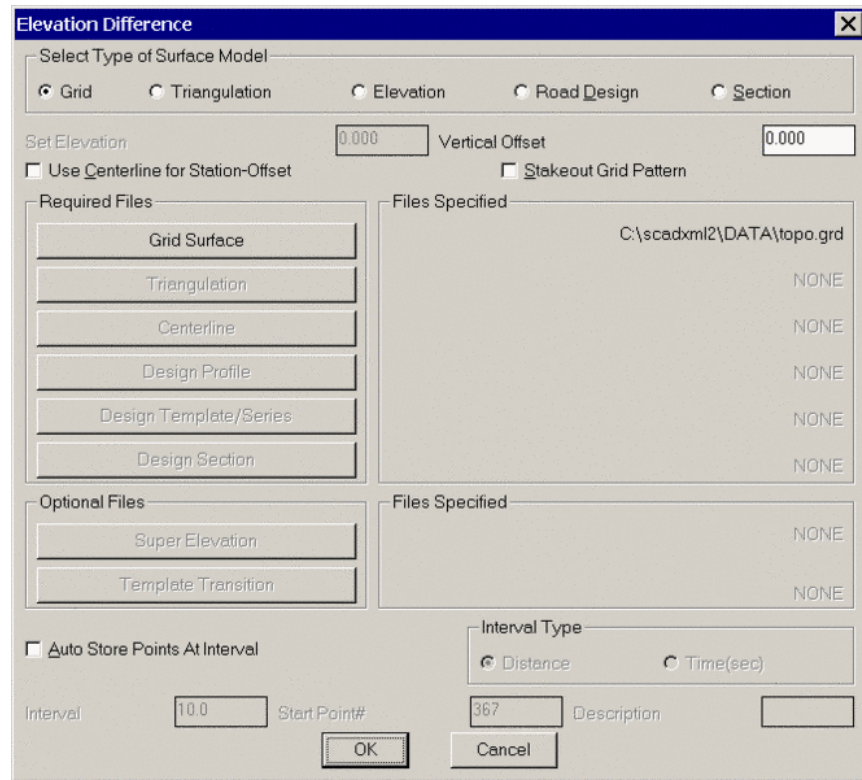

This command reports the cut or fill between your current position and a design surface. The design surface can be one flat elevation, a grid file, a triangulation file, a road design file, or a section file.

The type of design surface is set in the dialog shown. The Vertical Offset in this dialog can be used to modify the design surface by adding this value to the design surface. For example, if you have a design surface for the top of a road and you want to get cut/fill values to a 1.5 subgrade, then enter -1.5 in the Vertical Offset field. The Use Centerline For Station-Offset option will report the station-offset of your current position in addition to the cut/fill. When this option is active, the program will prompt you for the centerline file (.CL) to reference. For GPS and robotic total stations, the Auto Store Points At Interval will creates points whenever your position moves by more than the specified distance or time interval. This option is similar to the Auto Points At Interval command with the addition that the default description will include to cut/fill to the design surface. When all the options are set, pick OK and the program will then prompt you for a grid file or triangulation file if you have selected these types of design surface.

Elevation Difference with GPS

Carlson Field will continually read your current position from the GPS receiver. A dialog box appears displaying your current position. Carlson Field finds the design elevation for this point and compares it to the elevation being reported by the GPS receiver. It then tells you how much cut or fill is required to reach the design elevation from your current position. An arrow icon will appear on the drawing showing your location. You can move around the

site while in *Elevation Difference* mode and Carlson Field will report the necessary cut or fill in real-time. If you move off the area covered by the design surface, then the program will stop reporting cut/fill and instead will report "Off Surface". When using a grid or triangulation surface, the bottom of the dialog shows a profile of the surface in real-time in the direction of your movement.

The Store button will create a point at the current position. The default description will include the current cut/fill. When Store is selected, a dialog box will appear for entering the point number and description.

Elevation Difference with Total Stations

Elevation Difference uses a dialog box that is very similar to the *Point Store* dialog. Under the Setup button, make sure that the occupied point, backsight and instrument height are set. Then have your rodman set the prism over the point you are interested in. Pick *Read(F1)* or *Read & Store(F5)* and the total station will take a shot.

After the shot is taken, the dialog box looks like the one at right. Carlson Field found the design elevation for this point (557.535) and compared it to the actual current elevation (530.0). Based on the current and design elevations, Carlson Field reports to how much cut or fill is required to get to design elevation. In this case, it is fill 27.535. The cut/fill also appears in the *Desc* box. If you click *Store*, Carlson Field will record this point and plot it on the drawing, including the *Desc* as a label.

Prepare Story Stake

This command creates points with cut/fill information stored in the note fields for the points. Beginning at a point and facing a specified direction, the cut/fill information describes a design surface that is defined by contours and 3D polylines in the drawing. The program prompts you to pick the starting point followed by a direction point. Then the intersections for all the contours and 3D polylines between these two points are calculated and the resulting horizontal distances and slopes are shown in a dialog. In this dialog, you can edit, add or remove these slopes descriptions. The Point Description can also be specified. When OK is clicked, a point in the coordinate file is created at the starting point with this information stored in the note file. An offset point is also created at the specified offset distance back from the starting point. At the end of Prepare Story Stake, a report of all the created points and the corresponding cut/fill data is shown if the Create Report option was set. Prepare Story Stake does not draw the points in the drawing. These points can be drawn using the Draw-Locate Points command.

The cut/fill information in the note file can be used in the Stakeout routine. In Configure Field>Stakeout Settings there is an option to Display Point Notes in Stakeout Report. With this option active, the cut/fill data in the note file will be displayed when the point is staked out.

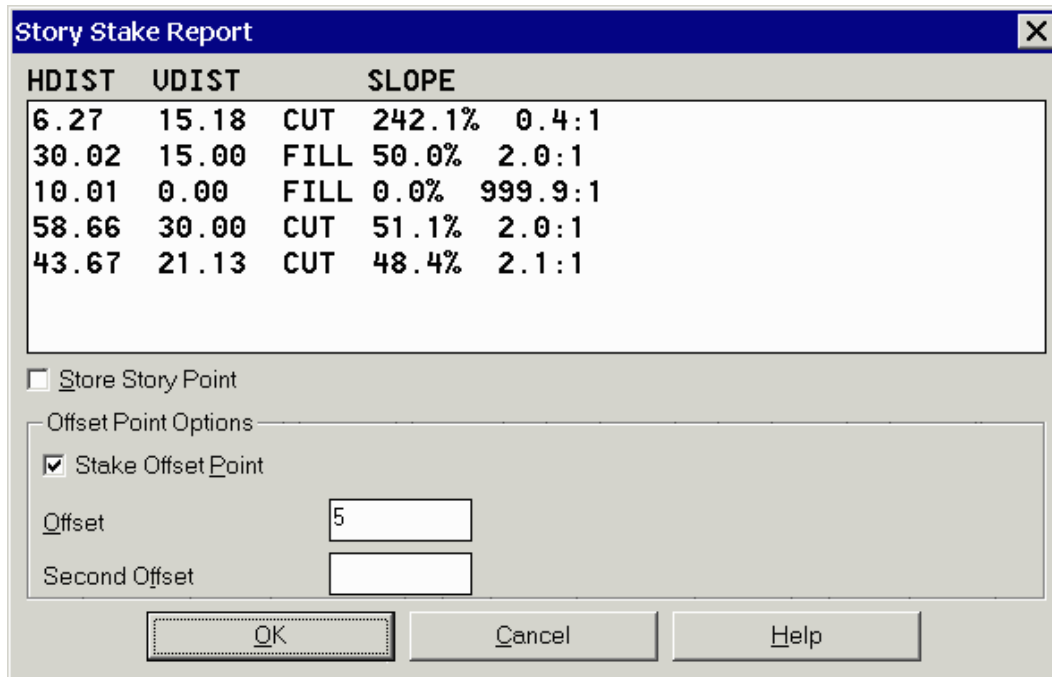

Prepare Story Stake is not a prerequisite for Story Stake By Points or Story Stake By Polyline. In fact, working in

combination with Stakeout, Prepare Story Stake is an alternative to these other routines.

Story Stake By Points

This command creates a report of cut/fill slopes and distances of a design surface from a starting point. First you move to the starting point and then take a reading from the instrument to get the starting point coordinates. This starting position is shown in the drawing. Next you pick a point in the drawing to define the direction. The drawing should contain the design surface entities. The program will then calculate all the intersections with contours and 3D polylines between these two points. The resulting horizontal distances and slopes are shown in a report dialog. From this dialog, there is an option to stakeout one or two offset points set back from the starting point at the specified offsets.

Story Stake Along Polyline

This command creates a report of cut/fill slopes and distances of a line across a design surface. The line is defined as perpendicular from a polyline starting at a specified station and going a specified distance. The drawing should contain design surface entities. The program will calculate all the intersections with drawing contours and 3D polylines along the line. For example, the polyline could be a toe of slope and this routine would be used to create story stakes at an interval along this polyline.

The routine starts by selecting a 3D polyline from the drawing. Then there is a dialog to specify the settings. The Station is the distance along the polyline for the starting point of the story stake. The Next Interval is used to increment the station for the next default station. The Story Offset is the length of the story stake line from the starting point. To have the story stake line go perpendicular right from the polyline, enter a positive offset value. To go left, enter a negative offset. The Read Current Position button will take a measurement from the instrument to find the station of your current position. This current station is put in the Station field. The Pick Point button will prompt you to pick a point in the drawing view. The station of this point is used to fill out the Station field.

After specifying the stakeout station and story offset, then program runs the stakeout routine to guide you to that station on the polyline. When that point is staked, the program calculates the story stake and the resulting horizontal distances, cut/fill and slopes are shown in a report dialog. From this dialog, there is an option to stakeout one or two offset points set back from the starting point at the specified offsets.

Second Offset

Roads Menu

The Roads pull-down menu has commands for road stakeout and preparing the road design files. Most of these commands are described in the Civil Design manual.

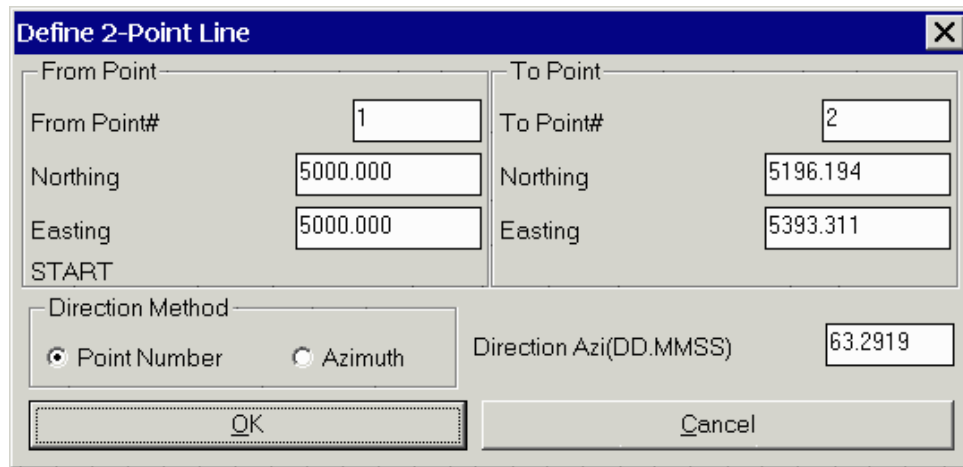

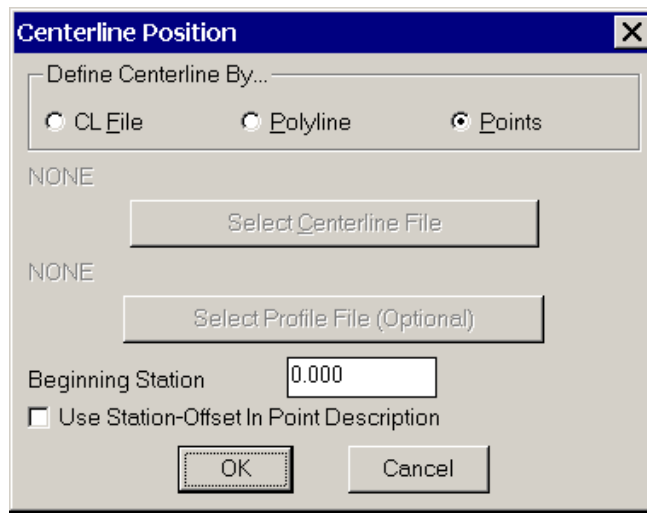

Centerline Position

This function determines the station and offset relative to a centerline for a point. The centerline can be defined by a centerline file (.CL), a points, or by a polyline. The centerline file can be created with commands in the Roads menu. One advantage of centerline files is that it allows you to use profile files which can report cut/fills. For the points method, you can either give two points or a starting point and azimuth. The points can be defined by a point number from the current coordinate file or by simply entering the northing and easting. The first dialog for Centerline Position has the choice for centerline file or points method. With the centerline file option, the dialog shows the last centerline file name used. If this file is correct, then click OK. Otherwise use the Select button to choose the centerline file name.

Light bars are useful for left-right guidance. To enable the light bar option go to Configure Field, then to Centerline Position Settings and pick Use Light Bar.

Centerline Position with GPS

Carlson Field will continually read your current position from the GPS receiver. A dialog box appears displaying your current position. Carlson Field finds and displays in the dialog the station/offset for this point.

An arrow icon will appear on the drawing showing your location. You can move along the centerline and Carlson Field will report the station/offset in real-time. If you move beyond the ends of the centerline, then the program will stop reporting station/offset and instead will report "Off CL".

The Store button will create a point at the current position. The default description will include the current sta-

tion/offset. When Store is selected, a dialog box will appear for entering the point number and description.

Centerline Position with Total Stations

Centerline Position uses a dialog box that is very similar to the *Point Store* dialog. Under the Setup button, make sure that the occupied point, backsight and instrument height are set. Then have your rodman set the prism over the point you are interested in. Pick *Read(F1)* or *Read & Store(F5)* and the total station will take a shot.

After the shot is taken, the dialog box looks like the one at right. Carlson Field reports the current coordinates and the station/offset. The station/offset also appears in the *Desc* box. If you click *Store*, Carlson Field will record this point and plot it on the drawing, including the *Desc* as a label.

The screenshot shows a dialog box titled "Setup (F3)". At the top, there is a "Menu(F11)" button and a set of navigation icons (magnifying glass, zoom out, left arrow, right arrow, up arrow, down arrow). Below these are several lines of text: "H:12°00'00" V:90°00'00" SD:90.000", "OC:1 BkAz:0.0000 HI:0.000", "Point Number: 1131", "Rod Height: 0.000", "Northing: 5088.033", "Easting: 5018.712", "Elevation: -0.000". A "Desc:" field contains the text "1+43.115 L5.681". Below the description are two buttons: "Options (F6)" and "Code (F7)". Further down, it shows "Station: 1+43.115" and "Offset: L5.681 IN: 11.299". At the bottom, there are four buttons: "Read (F1)", "Store (F2)", "Read & Store (F5)", and "Exit".

Pulldown Menu Location: Roads

Prerequisite: None

Offset Stakeout

This function stakeouts a point at a given station and offset of a centerline and reports the cut or fill to a design elevation. The centerline and design elevation can be defined by four methods as set in the dialog show. The Design Files method uses a centerline file (.CL) for the horizontal alignment and a profile file (.PRO) for the vertical alignment. A template file (.TPL) for the design cross section is optional for the cross slope. Without a template file, the program will use the elevation of the profile along the centerline. A superelevation file (.SUP) and a template transition file are optional. These design files can be created with the routines in the Roads menu. The Section File method uses a centerline file for the horizontal alignment and a section file (.SCT) for the design elevation. The section file consists of cross sections of offset/elevation points for a series of stations. Section files can be used instead of the Design Files method when a road design is too complicated to model using design files. For example, if the road contains special ditches at various offsets and varying lane widths, then it may be easier to enter a final section file than to define the template and template transitions. The Points method uses two points to define both the horizontal alignment and design elevations. The design elevation is linearly interpolated between the points. The points to used are specified in the next dialog by entering point numbers from the current coordinate file or by directly entering the coordinates. The 3D Polyline method uses a 3D polyline for both the horizontal and vertical alignment. With this method, the program will prompt you to select the 3D polyline from the drawing. For both the Points and 3D Polyline methods, you can specify the starting station of the horizontal alignment. When using the Design Files and Section File methods, the horizontal alignment starting station comes from the centerline file.

OK Exit Help

After specifying the offset stakeout method, Carlson Field prompts for the station and offset to stakeout as shown in the dialog. The station should be entered as a number without the "+" symbol. The Next Interval field is used to increment the stakeout station for the next stakeout point. In addition to incrementing to the next interval, Carlson Field will also pick up special profile or centerline points between intervals. Centerline special points include: start point, end point, curve (PC, PT) and spiral (TS, SC, CS, ST). Profile special points include: start, end, vertical curve (VC, VT), high points and low points. For example, if the current station is 100 and the interval is 50 and there is a centerline PC at 112.4, then the next station after 100 will be 112.5 followed by 150. The Station List button brings up a list of all the station intervals and special stations. You can select a station to stakeout by selecting the station from the list and pressing OK.

There are two offsets to allow for separate offsets for the design elevation and stake location. The Side For Stakeout toggle selects between left and right offsets. The Design Offset is where the stake point elevation is calculated. The Stake Offset determines X,Y position of the stakeout point by finding this offset at the stakeout station along the horizontal alignment. Having Design and Stake offsets applies, for example, to staking the back of a curb, where the Design Offset is 12, but the stake offset is 17 (5' behind the back of curb, with the elevation reference to the actual back of curb design elevation). The Stake Offset can be specified either as an offset from the design point or as an offset from the centerline. There is also an optional vertical offset that applies to the elevation of the design point. With the Design Files and Section File methods, the vertical offset works as an offset from the template or cross section surface. For example, a vertical offset of -0.5 could be used to stakeout the bottom of a 0.5 subgrade. With the 3D Polyline and Points methods, the vertical offset adjusts the elevation from the along the centerline at the stakeout station.

The Read Current Position button will take a measurement from the GPS or total station to find the station of your current position. This current station is put in the Station field.

The Pick Point button will prompt you to pick a point in the drawing view. The station and offset of this point are used to fill out the Station and Offset fields.

After specifying the stakeout stations and offsets, Carlson Field uses the same stakeout function as used in the Stakeout command. This stakeout function guides you to the stakeout point and reports the cut/fill to the design elevation. You can store the stakeout point. When the stakeout is done, the station/offset dialog appears for staking the next point. Either enter the next station/offset or pick Exit to end Template Stakeout.

For total stations, you should run the Equipment Setup command before Template Stakeout to set the occupied point, backsight and instrument height.

Stakeout dialog for GPS

Stakeout dialog for total stations

Pulldown Menu Location: Roads

Prerequisite: None

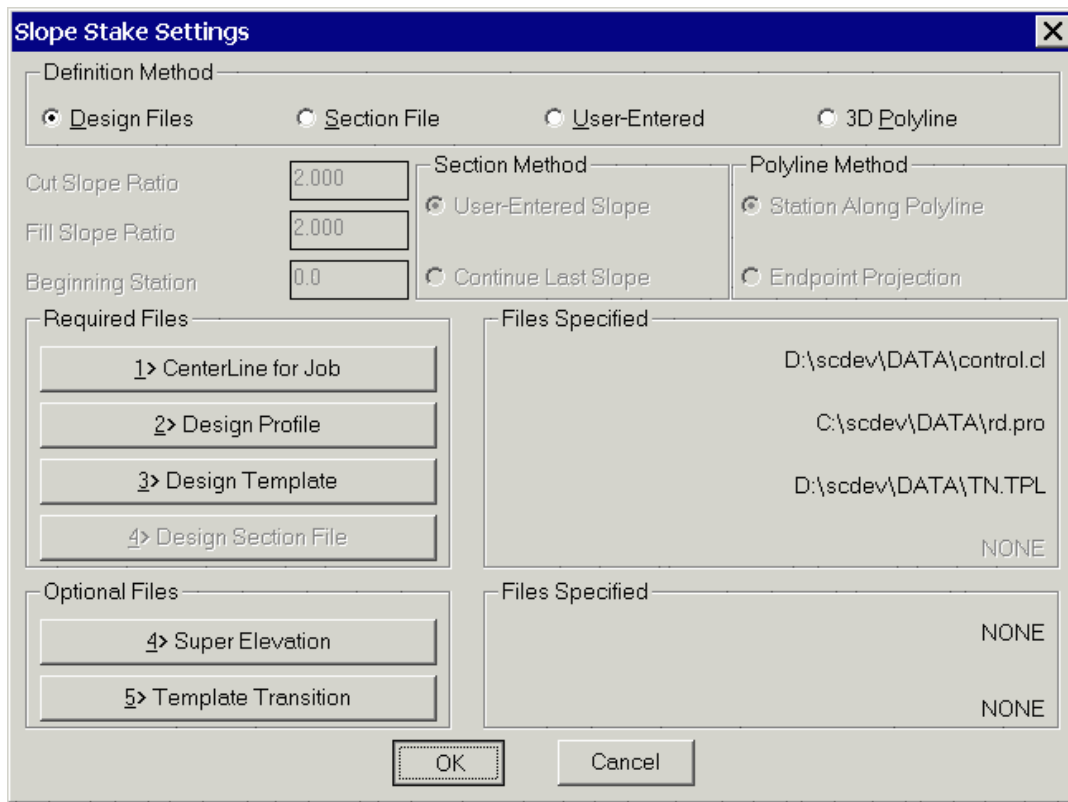

Slope Staking

This command guides you to the catch point where the cut/fill slope intersects the existing ground. Coordinates from the GPS receiver or total station are used to model the existing ground. There are four methods for defining the cut/fill slopes:

- Design Files
- Section File
- User Entry
- 3D Polyline

Design files include a centerline file (.cl), profile file (.pro) and template file (.tpl). The centerline defines the horizontal alignment, the profile defines the vertical alignment and the template defines the cross slopes and cut/fill slopes. Superelevation (.sup) and template transitions (.tpt) files can also be used. Using the design files, any station along the centerline can be slope staked. These design files can be created with commands in the Roads menu.

Section files (.sct) can be used instead of design files when the road is too complicated to model using design files. For example, if the road contains special ditches at various offsets and varying lane widths, then it may be easier to enter a final section file than to define the template and template transitions. A section file consists of offset-elevation points at different stations. At a minimum, each station should contain the pivot point offset-elevations. The slope staking routine will start the cut/fill slope from the furthest offset point in the section.

For example, when staking the right side, the right most offset will be used as the pivot point. The section file can optionally contain additional offsets such as centerline and edge of pavement. The program can then report the horizontal and vertical distances from the catch point to these additional offsets. The section pivot offsets can also be assigned a description which the program reports before starting the slope staking. For example, a pivot offset could be "2:1 from flat bottom ditch" which is reported to the operator. When using section files, a centerline file is also required to establish the horizontal alignment. Any station along the centerline can be slope staked because the program will interpolate between entered section stations. The cut/fill slopes from the section can be either User-Entered or Continue Last Slope. The User-Entered option will use the cut/fill slope ratios as entered in the dialog. The Continue Last Slope option will use the last two points in the section file as the cut/fill slope. This Continue Last Slope option applies to section files that contain pivot point to ground segments whereas the User-Entered option is for section files that end at the pivot points.

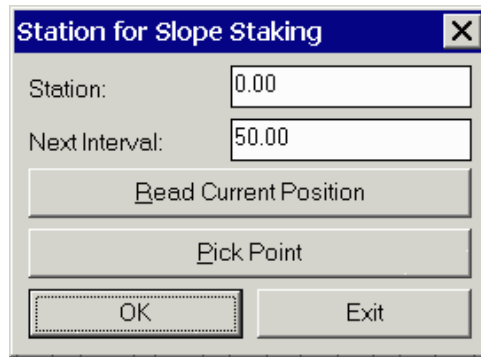

User entry is a simple method for slope staking that only requires a centerline file. With this method, the program prompts for the cut/fill slopes and the pivot offset and elevation. The program finds this offset-elevation for the stake station along the centerline and begins the cut/fill slope from this point.

The 3D Polyline method uses a 3D polyline for both the horizontal and vertical alignments. The program will prompt you to select the 3D polyline from the drawing. There are two polyline methods. The Station Along Polyline method does slope staking perpendicular to the polyline like the other slope staking methods. The Endpoint Projection is a special method that slope stakes from the selected end of the polyline. This method is described at the end of this section.

The first dialog in Slope Staking chooses the design method. For Design Files method, the files are specified in this dialog. For the other methods, the cut and fill slope ratios are also defined in this dialog.

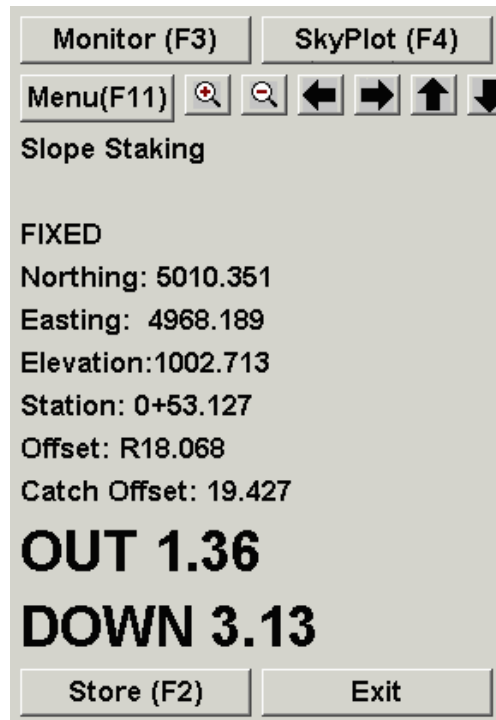

The next dialog sets the station to slope stake. The station should be entered as a number without the "+" symbol. For the 3D Polyline method, the starting station of the polyline is specified in the first dialog. For all the other methods, the starting station of the alignment is set in the centerline file. The Next Interval field is used to increment the stakeout station for the next stakeout point. The Read Current Position button will take a measurement from the GPS or total station to find the station of your current position. This current station is put in the Station field. The Pick Point button will prompt you to pick a point in the drawing view. The station of this point is used to fill out the Station field. For the User-Defined method, this dialog also contains the offset and elevation of the pivot point. For the 3D Polyline method, this dialog also contains the pivot point offset and vertical offset from the 3D polyline to

the pivot point.

The dialog box titled "Station for Slope Staking" contains the following elements:

- Station: 0.00
- Next Interval: 50.00
- Read Current Position button
- Pick Point button
- OK button
- Exit button

- DOWN 3.13**
- Store (F2) Exit

For the design file method, the centerline elevation at the stakeout station is calculated using the design profile and then the template is applied to calculate the pivot point. For the section file method, the pivot offset is interpolated from the section file. For example, if the stakeout station is 75 with offset right and the section file has offset-elevation of 18.0 right, 100.0 elevation at station 50 and has 20 right, 102.0 elevation at station 100, then the pivot offset for station 75 would be 19.0 right, 101.0 elevation. For the user entry and 3D polyline methods, the pivot point is specified Station For Slope Stake dialog.

After the slope stake station and pivot point are specified, Carlson Field begins to read the GPS receiver or total station to get the current position. The existing surface to tie into is defined by the elevations from these current position coordinates. The point where the cut or fill slope from the pivot point intersects the existing ground is called the catch point. As each coordinate is read, an existing surface cross section is built and the catch point is calculated. Carlson Field will automatically determine whether to find the catch point on the right side or left side of the centerline depending on the side of your current position. The program displays, in real-time as you move, the northing-easting and station-offset-elevation of your current position and the offset of the catch point. The distance from the current position to the catch point is reported as the offset difference as either "IN" or "OUT". The OUT means you should move out from the centerline. The IN means that the catch point is closer to the centerline. Based on this offset difference, you move perpendicular to the centerline either towards or away from the centerline to reach a new offset from the centerline while maintaining approximately the same station. The difference between your current station and the stakeout station is reported as the "UP" or "DOWN" distance. The UP means that your

current station is less than the stakeout station and you should move up the centerline. Likewise, the DOWN means that your current station is greater than the stakeout station and you should move back down the centerline.

When the catch point is located, press the Store button to end the slope staking. A report dialog is then displayed. The Catch Pt is the actual station, offset and elevation of the target catch point. The Stake Pt is the as-staked station, offset and elevation of your current position. The dialog also reports the horizontal and vertical distances from the catch point to the pivot point and the other template points. The Store Catch Point option will record the as-staked coordinates of the catch point to the current coordinate file. The Stake Offset Point is an option to locate an offset point. The offset to stake can be entered as a distance from the catch point or as an offset from the centerline.

	Station	Offset	Elevation
CATCH PT:	50.00	18.07	1002.04
STAKE PT:	51.22	16.26	1002.04

Stake to Pivot PIVOT
H: 4.26 U: 3.04 CUT

Store Catch Point

Offset Point Options

Stake Offset Point

Station: 50.00

Offset Type: CL Offset Delta Distance

Offset: 5.00

OK Exit

	Station	Offset	Elevation
OFFSET PT:	99.83	23.42	1000.15

	HDIST	UDIST	SLOPE
OFFSET to CATCH	4.46	2.33	FILL 52.3% 1.9:1
CATCH to PIVOT	6.96	3.48	CUT 50.0% 2.0:1

OK

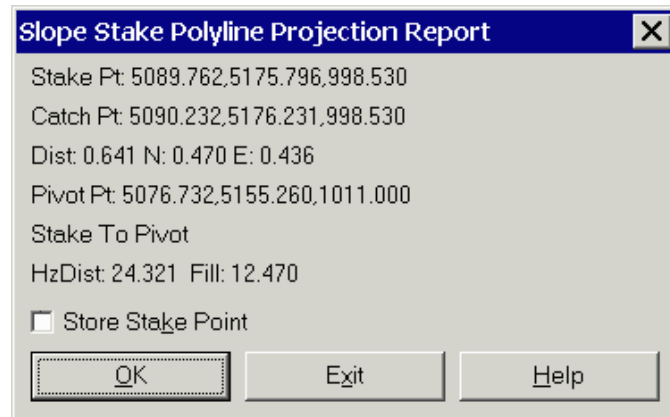

To locate the offset point, the same stakeout function from the Stakeout command is used. This function will guide you to the offset point. When the offset is reached, pick the Store button. Then an Offset Point Report dialog pops up containing the station, offset and elevation of the offset point and the horizontal distance, vertical distance and slopes from the offset point to the catch point, from the catch point to the pivot point and from the pivot point to the template points.

After locating the offset point, the station to stakeout dialog appears. You can enter the next station to stakeout or pick the Exit button to end Slope Staking.

Endpoint Projection

This is a special case of the 3D Polyline method that slope stakes from the end of the polyline. The program will prompt to pick a polyline and the end to stake from is the end nearest to the pick position. The direction of slope staking is in the direction of the polyline as if extending the polyline. The program prompts for the elevation of the pivot point which defaults to the elevation at the polyline endpoint. There is also an option to offset the pivot point along the polyline back from the endpoint.

After the pivot point is specified, the program starts the stakeout routine to guide you to the catch point. Then there is a report to show the difference between the staked and the calculated catch point.

Pulldown Menu Location: Roads

Prerequisite: A centerline file or 3D polyline

Slope Inspector

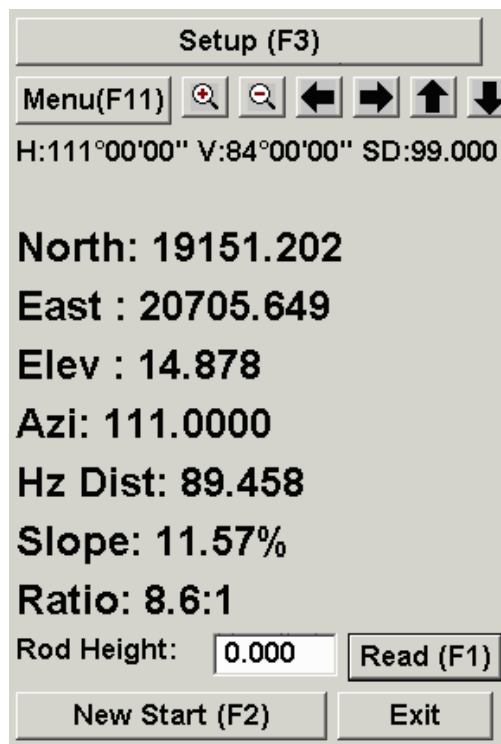

This command reports the azimuth, distance and slope between your current position and a starting point. The command starts by prompting you to move to the starting point and take a reading. This sets the starting point.

Slope Inspector with GPS

Carlson Field will continually read your current position from the GPS receiver. A dialog box appears displaying your current position and the azimuth, distance and slope from the starting point to your current position. An arrow icon will appear on the drawing showing your location. Pick the New Start button to set a new starting point.

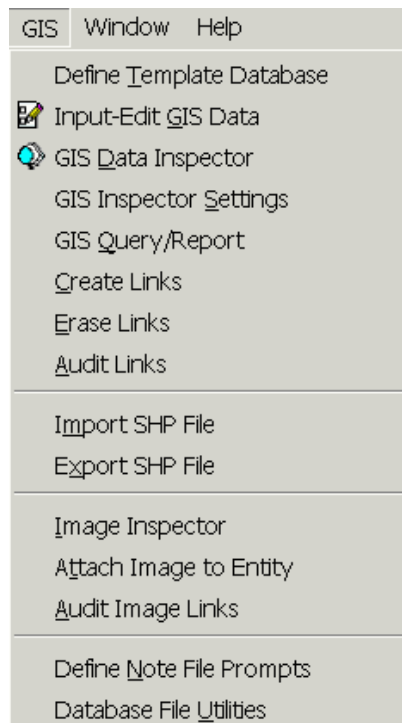

Slope Inspector with Total Stations

Before running Slope Inspector, make sure that the occupied point, backsight and instrument height are set correctly in the Equipment Setup command. Then start Slope Inspector and read a measurement for the starting point. A dialog box appears displaying your current position. Pick the Read button to take another measurement. Carlson Field will calculate the new point and report the azimuth, distance and slope from the starting point to the new point. An arrow icon will appear on the drawing showing your location. Pick the New Start button to set a new starting point.

GIS Menu

The GIS menu commands for Field are described in the GIS manual.

Equipment Menu

Apache Lightbar

Carlson Field can use an external Light Bar for determining elevation differences and centerline offsets.

Light Bars can indicate whether your current position is in cut, fill or on-grade when set vertically. When set horizontally, Light Bars can give centerline left/right offsets. Currently Carlson Field supports a light bar made by Apache, as well as by Mikrofyn, that has arrows for up/down, or left/right, and a row of lights for on-grade. The Light Bar must be connected to a separate serial port than the GPS.

CSI GBX Pro

Hardware Setup

1. Connect the receiver to the antenna by coaxial antenna cable if it is not already connected, and ensure that the receiver has ample power.
2. Ensure that the antenna is tracking corrections from an MSK Radio Beacon. The easiest way to do this is to use the antenna's automatic frequency scanning when first powering on the receiver
 - a) To do this, enter the [SETUP] menu, and select the option [AUTO BX SEARCH]

Note: The beacon automatically selected by this scan will be saved to the receiver's memory and used automatically in the future, until either the scan is executed again, or until a new beacon is specified manually. Thus, it is not necessary to scan each time the beacon is used, provided it is still operating in the same general area.

- b) A scan can be performed again in the event that the beacon is lost to scan for the next nearest beacon.
3. Enter the [Setup] menu, then select [Options] then [NMEA ON/OFF]. This menu allows the enabling or disabling of various NMEA messages. The only ones which are necessary are the GGA, GSV and GSA messages. All others should be disabled.

Software Setup

4. In Carlson Field, no further setup is necessary to make use of the CSI GBX Pro. Simply use the other Carlson Field functions as normal. Note however, that the elevations reported by the CSI GBX Pro are MSL (Mean Sea Level).

Depth Sounder

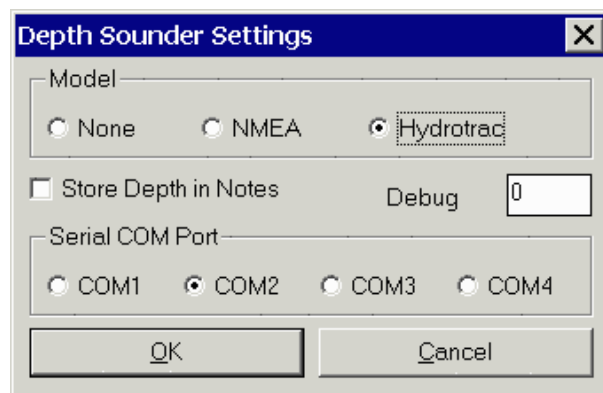

Carlson Field data collection can be used in conjunction with a depth sounder to survey the beds of rivers and lakes. Carlson Field takes input from both a GPS receiver and a depth sounder to determine and record the elevation of the terrain directly below the surveying boat or barge.

All of Carlson Field's routines work with the depth sounder to let you collect points on the underwater terrain. The elevation stored for each point is the elevation of the bed. Modeling of the bed surface works as easily as modeling any surface using Carlson Software. Carlson Field can be a powerful tool for marine surveying and construction.

Settings

To modify the Field depth sounder settings, go to the Field menu and select *Configure Field*. Choose the *Depth Sounder Settings* button.

The *Depth Sounder Settings* menu appears. At this point, Hydrotrac by Odom is the only equipment-specific depth sounder interface. Carlson Field works with other depth sounders that have NMEA standard interface. If you want to use Carlson Field without the depth sounder, make sure the Model is set to None.

For the Hydrotrac model, the depth sounder should be set so it outputs message DESO25 I/O. This is done using the Hydrotrac software. Odom should be contacted with any problems involving setting this message (www.odomhydrographic.com or 225-769-3051). The draft setting on the Hydrotrac should also be set. This will account for the height difference between the water surface and the working sensor of the Hydrotrac.

On the next line appears a box labeled *Store Depth in Notes*. Carlson Field saves point data in a coordinate file and in a text note file. By checking this box, the note file will record the water depth at each reading along with the other information about that point. (Settings to control the rest of the information saved in this file can be found in the menu *Configure Field > Point Settings*.)

The window labeled *Debug* should be set to zero for normal use.

The row of buttons labeled *Serial COM Port* refer to the COM port on your computer where the depth sounder is plugged in. Carlson Field requires two serial points on the computer when working with a depth sounder (one for the GPS and the other for the depth sounder). The depth sounder serial port must be separate from the GPS serial point.

Starting Out

Before working with the depth sounder, we suggest that you make sure the GPS system is working properly with Carlson Field. De-activate the depth sounder by setting the Model to None in the *Depth Sounder Settings* dialog box. Set up the GPS system that you are using and plug the rover receiver into the COM port for the GPS. Go to *Monitor GPS Position* under the *Field* menu. Check that the information being output is correct: Are the latitude and longitude readings what they should be? Are the north and east coordinates aligned to your job coordinate grid? Are the HRMS and VRMS low enough (less than one)? Is the status fixed? If it's autonomous or float, this rover

could be having trouble receiving the radio corrections the base receiver should be broadcasting. If everything is working properly, exit the monitor screen and start the depth sounder setup.

Measure the vertical distance from the GPS antenna to the surface of the water. This distance will be called the rod height. Go to the *Configure Field>General Settings* window and enter this measurement in the *Rod Height* box.

Plug the depth sounder into the depth sounder COM port on your computer. Go to the *Configure Field>Depth Sounder Settings* window and set the depth sounder Model. Set the rest of these settings as you want them and click OK.

Go back to *Monitor GPS Position*. Everything should appear as before, except there should be a new entry called *Depth* and *Elevation* should have changed to *Bottom Elv*. The correct depth should be showing and the *Bottom Elv* should be showing the elevation of the bed.

The usual Carlson Field functions will all work with the depth sounder active. The windows for *Monitor*, *Point Store* and *Auto Points at Interval* will display the depth when the depth sounder is set as active.

Geodimeter

Geodimeter 600 For Remote Mode

Note: Firmware version 696-03.xx or higher is required on the instrument. To check the version, pick MNU-5-4-1.

SET-UP

1. Connect the instrument to the battery pack. There is no need to connect the keyboard to the battery if it is going to be turned off, or attached to the unit.
2. Connect the prism to the top port of GeoRadio.
3. Connect the bottom port of the GeoRadio to Carlson Field. Then turn on the radio.
4. Turn on the Geodimeter. The Geodimeter starts with the screen for leveling the instrument. When the instrument is leveled press [ENT] key to continue to the next step. Now the instrument starts compensator calibration. You can wait for calibration to finish or turn it off. To turn calibration off press on [F] 22, enter 0 for comp. This needs to be done when the instrument is turned on and before [ENT] is pressed.
5. Next Geodimeter will ask for different values for pressure, offset, etc. They can either be left like they are by pressing on [ENT] or they can be changed.
6. Press [F] 79, it is the End of Transfer character, which should be set to 4.
7. To set radio, and station channels, press [MNU], and enter 1 for "Set". After set press 5, which will give the user opportunity to change channel, station, and remote address.
Note: The channel, station and remote address on the Geodimeter should match the channel, station and remote address in Carlson Field.
8. To set the Geodimeter for remote mode, press on RPU, then 3 for remote and 1 for ok, you can answer [NO] to "Define Window?" If [ENT] is pressed, the instrument will ask "Aim to A Press Ent", for which the user have aim to upper/lower left boundary and press [ENT], for "Aim to B Press Ent", aim to the upper/lower right boundary and press [ENT]. For "Measure ref obj?" press [ENT] if you want a reference object, otherwise press [NO]. Than the instrument is going to say remove keyboard however the keyboard can stay on.
9. After Geodimeter display screen turns itself off, it's ready for Carlson Field.

CARLSON FIELD

1. In Configure Field, under equipment type there should be Geodimeter. In Communication Settings Baud Rate should be set to 9600.
2. After Configure Field go to Equipment Setup and make sure GeoRadio is checked, and the channel, station and remote address is the same as it is in the total station.
Note: We recommend using channel 3.
3. If calibration box is checked the instrument will calibrate, to turn of calibration the box should be unmarked.
4. In setup there is also an option to turn on/off-tracking lights.

Geodimeter 600 For Direct Connection

1. Connect the instrument to the battery pack, and the control unit to Carlson Field.
2. Under Field go to Configure Field and place Geodimeter in Equipment type.
3. Click on General Settings make sure that the baud rate is set to 9600.
4. Exit Configure Field.
5. Go to Equipment Setup and check Connect to Station and click OK.

Now you are ready.

InnerSpace Tech depth sounder

The communication settings for the InnerSpace Tech depth sounder are 9600-N-8-1.

Laser Atlanta

To setup Laser Atlanta select Menu on the instrument, then Serial, and set Baud rate to the same as Carlson Field's and Format to Laser Atlanta.

Leica Disto

The communication settings for the Leica Disto are 9600-E-7-1.

Leica GPS System 500

Setting Up a 500 Series Receiver

1. Connect the antenna cable to the ANT Port on the front of the receiver, and to the antenna.
2. If you are using the PacCrest radio module, screw it in place over Port 1 on the receiver and attach its antenna cable. Otherwise, connect any radio being used to Port 1, 2 or 3.
3. If an external power source is being used, be sure to plug it into the PWR Port on the front of the receiver.
4. If external power is not being used, ensure that there are batteries in one or both of the batter slots on the bottom of the receiver.
5. Plug the 9 pin serial connection cable into the serial port of the computer running Carlson Field and into the Terminal Port on the front of the receiver.

Configuring Carlson Field for Use With a 500 Series Receiver

1. Select "Configure Field" from the Field pull-down menu. This will open a new window with several buttons on it, as well as a pulldown list labeled "Equipment Type." Select "Leica 500 Series" in the Equipment Type menu, then select "Communication Settings."
2. Ensure that the COM port is set to the one that the serial cable is plugged into, and that the Baud Rate is 9600, the Char Length 8, the Stop Bits 1, and the Parity None. Close this menu and the Configure Field menu.
3. In the Field pull-down menu, select "Equipment Setup." This will open another menu with several selectable options and several buttons.
4. Use the radio buttons on the top right to select whether the receiver will be a rover or a base station. Also be sure to select the antenna types being used from the pulldown menu at left.
5. Enter the desired Satellite Elevation Cutoff in the text box above the column of buttons. All satellites with elevations less than this number will not be used in position calculation(receiver default is 15).
6. Select the "Radio Settings" button. This will open another window with several selectable settings. Select the Port number the radio is attached to on the front of the receiver, the baud rate of the radio, number of radio stop bits and radio parity. These last three settings should be listed in the documentation for the radio being used. Also, select the desired format to use for sending and receiving messages from the bottommost option. Exit this menu.
7. If the GPS receiver is being configured as a base station, select the "Configure Base Station" button from the Equipment Setup menu, and proceed with step 8. Otherwise, the receiver is ready for use.

8. There will now be a menu with a few buttons to select a method of determining the base station's present location. The options are:

Read From GPS- Read one or more position readings from the GPS and use this position or the average of several positions for the base station corrections.

Enter Lat/Lon- This option will bring up a menu to enter the exact Latitude, Longitude, and elevation of the receiver's position by hand.

Enter State Plane Coord- This option will bring up a menu to enter the coordinates of the position of the base station according to the state plane coordinate system.

Read from File- This option will read a coordinate set from a file already saved to the computer.

Select whichever method will be used, and enter any necessary data. The receiver is now configured and ready for use.

Other Buttons In the Setup Menu:

1. Power Cycle Receiver will shut the receiver down and then power it up again. Used to clear the receiver's memory.
2. Power off Receiver shuts the receiver down. Note that if this button is pressed, any settings changes made while in this menu will not be saved to the receiver.
3. Send command to receiver allows for sending messages to the receiver. The user must enter the message by hand. This feature is only intended for use in conjunction with the technical support provided with Carlson Field.

Troubleshooting the Leica 500 Series in Carlson Field

Several possible errors can occur in the course of using a 500 Series Leica receiver with Carlson Field. Carlson Field will use all its standard error messages to report usual types of error messages, such as an inability to communicate with the satellites that are being tracked. In addition, the Leica 500 Series of receivers will have their own set of error messages unique to themselves. This type of error message is reported if there is an error during the transmission of various configuration messages to the receiver to set up the base station settings. Such messages will say "Set Port Message Rejected", or "Set Base Antenna Message Rejected" or "Set Antenna Height Message Rejected" or "Set RTK Message Rejected." Each indicates which particular facet of the configuration failed. If one of these messages is rejected, it is likely a momentary transmission error. If, on the other hand, several (or all) are rejected, it is possible there is a problem in the communication line between the computer and the receiver, which should be checked.

Leica TC Series

Leica TC Series Instrument Setup

On the instrument, make sure that the communication settings have CR/LF for the terminator.

Remote Mode

1. Turn on Leica
2. Connect Leica to rover radio, and connect the radio to the larger battery.
3. Connect the base radio to Carlson Field, and the smaller battery.
4. In the Field menu go to Configure Field, and under equipment type put Leica TC
5. To make sure the baud rate matches, under the Field menu go to Configure Field and click on Communication Settings and check if the baud rate is 19200. When Leica is turned on under Main Menu enter 5 for "Configuration", and 2 for "Communication Mode", then enter 1 for "Gsi parameters", and check if the baud rate is also set 19200.
6. Line Terminator in "Gsi parameters" should be set to CR/LF
7. Press [F1] for "cont" when done.
8. When back in Communication Mode screen enter 5 for "RCS (Remote) ON/OFF" and make sure it's NOT set for remote mode.
9. In Main Menu press [F6] for "meas" when ready to measure.

10. In the Field menu go to Equipment Setup and for Connection Mode check remote.

11. When done click on OK.

To put Leica in Tracking: On Gun press "FNC" then ATR+ and LOCK+

TCA 1800

1. Turn on Leica

2. Connect Leica to Carlson Field

3. In Field go to Configure Field, and under equipment type put Leica TC

4. To make sure the baud rate matches, under the Field menu go to Configure Field and click on Communication Settings and check the baud rate. When Leica is turned on press [F3] for "conf", then enter 3. The baud rate can be changed by pressing [F6] for "list", when done enter [CONT]. In addition to baud rate parity, char length, and stop bits should also match.

Note: Default in Carlson Field is not the same as default in Leica.

Leica 1100

To set up the Leica 1100 total station select the following commands on the instrument: Main Menu>Configuration>communication mode> GSI parameters. In the GSI parameters command copy the following settings: (baud=to Carlson Field's, protocol=GSI, parity=to Carlson Field's, Terminator=CR/LF, Data Bits=to Carlson Field's, Stop Bit=1), Geocom Param (baud=Field's) RCS Param (baud=Field's). Also, make sure RCS mode is OFF.

Leica 700

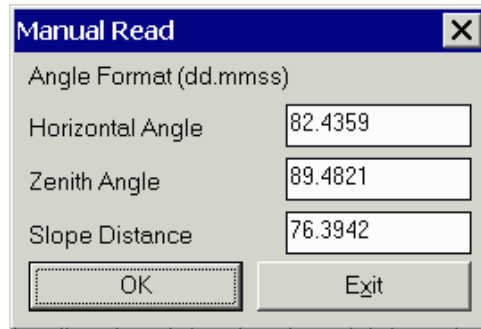

To set communication settings for **Leica 705s**, go Shift key then Prog (Menu) key and then to All Settings and last to PC Comm.

Manual Total Station

This method allows you to run Carlson Field in total station mode without being connected to equipment. The program will prompt you to enter the horizontal angle, zenith angle and slope distance. This method can be used for demonstration purposes or to work with total stations that cannot connect to Carlson Field. For these total stations, instead of the automatic connection, you can take a shot, read the instrument and then manually enter the data into Carlson Field.

As with other total stations, the first step is to run Equipment Setup to establish the occupied point, backsight and instrument/rod heights before running Carlson Field functions. Then in Carlson Field functions, when you pick the Read button, the program will bring up a dialog for entering the angles and distance. The angles should be entered in dd.mmss format (degrees.minutes seconds).

Manual Read	
Angle Format (dd.mmss)	
Horizontal Angle	82.4359
Zenith Angle	89.4821
Slope Distance	76.3942
OK	Exit

Mikrofyn Lightbar

Carlson Field can use an external Light Bar for determining elevation differences and centerline offsets. Light Bars can indicate whether your current position is in cut, fill or on-grade when set vertically. When set horizontally, Light Bars can give centerline left/right offsets. Currently Carlson Field supports a light bar made by Mikrofyn named RD-4 1137551, as well as by Apache, that has arrows for up/down, or left/right, and a row of lights for on-grade. The Light Bar must be connected to a separate serial port than the GPS.

Navcom Configuration Guide

This guide will walk you through the setup process for your Navcom units. It covers individual unit setup as well as base/rover setup under the simplest possible configuration. If you want to customize the configuration, consult the reference manual

A) Preliminary setup steps

Perform the following preliminary steps to initialize your computer for communication with your Navcom units:

- 1) Startup the Carlson product you intend to use.
- 2) Select CONFIGURE FIELD, from the FIELD Menu.
- 3) Select NAVCOM from the EQUIPMENT TYPE dropdown
- 4) Click the COMMUNICATION SETTINGS button. Verify that the SERIAL COM PORT is set to the port you intend to use to communicate with your Navcom unit. (usually COM1).
- 5) In the COM PORT SETTINGS box, click DEFAULT, and verify that baud rate=19200, parity=NONE, char length=8, and stop bits=1.
- 6) Click OK, and then click the GPS SETTINGS button.
- 7) Under GPS SETTINGS, set your HRMS and VRMS tolerance. For single-unit setup, these numbers should be at least 10. For base/rover configuration, they should be around 0.01.
- 8) Under PROJECTION TYPE, select the coordinate plane you wish to use. For state plane, make sure you choose the proper ZONE.
- 9) Click OK and then click EXIT

B) Single-unit setup (no corrections)

Before attempting a multi-unit setup, it is recommended that you first try setting up your Navcom unit to output an uncorrected position. The steps to do so are explained here:

- 1) Mount your GPS Antenna on a tripod in a place where its view of the sky is not obstructed.
- 2) If your antenna is separate from your receiver, connect your antenna to your receiver's AN TENNA port. (This step can be skipped for the RT-3010S, and other all-in-one models)
- 3) Plug your receiver into a power supply, or insert fully charged batteries into the battery ports. (Not all units have battery ports).
- 4) Turn your receiver on by holding down the power button for a few seconds, or until the status lights flash on.
- 5) Use the serial port cable to connect your computer to port A of your Navcom unit. Make sure the port on your computer that you use corresponds to the one you chose during preliminary setup.
- 6) Under the FIELD menu, choose EQUIPMENT SETUP.
- 7) If a PORT SETUP window pops up, set CONTROL PORT to PORT A, and RTK DATA PORT to RADIO PORT.
- 8) Setup is now complete. Steps that follow are optional.
- 9) Click the NAVIGATION STATUS button. From here you can monitor the progress of your Navcom unit as it calculates its position. Click AUTOREFRESH to view continuously updated status reports.
- 10) It may take a few minutes for the unit to calculate its position, if the unit was reset, or recently turned on. When the calculation is complete, VALID NAVIGATION will read YES. When this occurs, the Navcom unit is ready for use. Click CLOSE, then click CANCEL WITHOUT SAVING.
- 11) To monitor your position, choose MONITOR GPS POSITION from the FIELD menu, and you will see your current position. All Carlson Field GPS functions should now work.

C) Multi-unit setup (using corrections from a base)

- 1) Base Setup
 - a) Perform the preliminary and single-unit setup steps described above.
 - b) Attach the radio antenna to the radio port of your base unit.
 - c) Select EQUIPMENT SETUP from the FIELD menu.
 - d) Select a CORRECTION TYPE. We recommend NCT RTK.
 - e) CLICK the CONFIGURE BASE button.
 - f) When prompted to enter a position, enter the exact position of the base unit. Note that the accuracy of your rover's calculation depends on this position being completely accurate.
 - g) Enter a station ID of 0. The station ID is only used in RTCM mode.
 - h) Verify that STATION TYPE now reads BASE.
 - i) Base station setup is complete. Click SAVE SETTINGS AND EXIT.
- 2) Switch the device you're plugged in to:

After configuring the base, unplug your serial cable from your base's port A, and plug it into your rover's port A. Note: Whenever you switch the device you're plugged into be sure to close the Equipment Setup window first.

- 3) Rover Setup

- a) Perform the preliminary and single-unit setup steps described above.
- b) Attach the radio antenna to the radio port of your rover unit.
- c) Select EQUIPMENT SETUP from the FIELD menu.
- d) Select a CORRECTION TYPE. We recommend NCT RTK. Note that this selection must match the selection made during base setup.
- e) CLICK the CONFIGURE ROVER button.
- f) Verify that STATION TYPE now reads ROVER.
- g) Rover setup is complete. Steps that follow are optional.
- h) You can verify that the rover is receiving correction by clicking the MONITOR INCOMING CONNECTION, and then clicking AUTOREFRESH. The open window shows the time since each correction type was last received (delta time). In NCT RTK mode, the delta time of 5b, should stay around 1 second, and the delta time of message 5c should not go above 30 seconds. If these numbers are high, or if they read NEVER, try repeating the setup process or calling Carlson Software technical support.
- i) Click SAVE SETTINGS AND EXIT, and then choose MONITOR GPS

POSITION from the FIELD menu. The STATUS display should eventually go to LOCK.

Troubleshooting Base/Rover Configuration:

If you've configured a base to output corrections, and your rover does not appear to be receiving the corrections, try each of the following in order:

- 1) Verify that your BASE and ROVER are both set to the same correction type.
- 2) Under *Configure Radio*, check that your ROVER is set to slave, and that your BASE is set to master.
- 3) Under *Configure Ports*, check that both your base and your rover's RTK Data Ports are set to the proper value (Usually *Radio Port*).
- 4) Under the *Edit Base Position*, check that your BASE is set to a valid position. Note that if the given position is too far away from the position the BASE is reading, the BASE will not send corrections.
- 5) If you're trying to use RTCM, make sure the BASE and ROVER have the same station ID's.
- 6) Try increase the RTK Max Age constraint.
- 7) Under *Navigation Status*, verify that the Navigation is valid on both units. If either unit does not have a valid position solution, correction will not work.
- 8) Under *Monitor Corrections*, verify that the corrections you're using are arriving regularly. If they aren't you may need to reset both units.
- 9) Try configuring the BASE and ROVER again.
- 10) If all else fails, *Soft Reset* both units through the *Reset Unit* menu. After doing so, you will have to reconfigure the port settings of each device through the *Configure Ports* menu, and wait a few minutes for the devices to recalculate their position.
- 11) If none of these steps work, contact Carlson Software Technical Support.

Navcom GPS Setup

Carlson Field supports Navcom's NCT-2000D GPS message protocol, firmware versions 2.6 and later. If your Navcom unit has an earlier firmware version, contact Navcom for a free upgrade. Carlson Field has been tested extensively with Navcom models RT-3010S and RT-3020M.

From the Navcom GPS setup menu, or any of its submenus, the current device settings can be obtained by clicking the *Retrieve Settings* button. New settings can be saved by clicking the *Save Settings* or the *Save Settings and Exit* button. To cancel your changes, click *Cancel without Saving*.

By changing the *SV Elevation Mask*, you can prevent the Navcom Unit from using any satellite below a specified elevation angle (Range: 0-90).

By changing the *PDOP Mask*, you can prevent the Navcom Unit from using any GPS solution with a PDOP above a specified value (Range: 1-25).

By changing the *RTK Max Age*, you can prevent the Navcom Unit from using any RTK corrections older than a specified number of seconds. (Range: 0-1275, Multiple of 5).

By changing the *Base Station ID* on a base, you can provide your base with a unique identifying number so that rovers can specify which base they want to use for corrections. By changing this setting on a rover, you can specify which base unit you want to use. If 0 is specified, the rover will use any base station it can find. The base station ID only applies when using the RTCM correction format. (Range: 1-1023)

You can choose between 4 different *Correction Types*: NCT (Navcom Proprietary), CMR (Trimble's format), RTCM RTK (Messages 18-22), or RTCM DGPS (Message 1 and 9). When configured to BASE, changing the correction type changes the type being sent. When configured to ROVER, changing the correction type changes the type the unit is listening for. A ROVER will ignore all incoming correction messages except those of the type specified.

Configure Ports Submenu:

The *Control Port* should be configured to *Port A* or *Port B*, depending on which of the Navcom units' ports you are plugged into. Note that the *Control Port* refers to the number of the port on the Navcom unit, NOT the number of the COM port on your computer. If the *Control Port* is configured improperly, you will not be able to communicate with your Navcom unit.

The *RTK Data Port* refers to the device port out of which RTK corrections will be sent. This value should be set to *Radio Port*, unless you want to set up a non-wireless Base/Rover connection through Port A or Port B. The *RTK Data Port* cannot be the same as the *Control Port*.

Configure Radio Submenu:

The *Radio ID* is the value used to identify a unit on a wireless network of Navcom units. Make sure that no other Navcom unit in your vicinity shares the same *Radio ID*. By default, the *Radio ID* is the same as your Navcom unit's serial number. This value can be changed, although there isn't usually any need to do so.

The *Local Radio Type* can be set to either *Master* or *Slave*. Radio communication will only work between *Masters* and *Slaves*. Only one unit on your network should be set to *Master*. It makes sense to make the base unit a *Master*, and all rovers *Slaves*. These settings will be handled automatically by the *Configure Base* and *Configure Rover* routines. So there generally isn't any reason to set the *Local Radio Type* manually.

The *Local Antenna Power Level* allows you to configure your radio to use more or less power. The less power the radio has, the less it will be able to communicate over longer distances. It may be useful to change the power level if you're rover is not traveling far from your base, and you're trying to conserve battery power.

Within the *Navcom Radio Setup* menu, you will be able to access the following status information for all visible Navcom units on the network:

External Power: Indicates whether the unit is plugged into an external power source (On or Off).

Battery A: Indicates whether a well charged battery is plugged into Battery Port A (On/Good or Off/Low)

Battery B: Indicates whether a well charged battery is plugged into Battery Port B (On/Good or Off/Low)

Status: Indicates whether the unit is sending out corrections. (BASE or ROVER)

If more than two units are present, you can access this information for the additional units by selecting the desired unit's radio ID from the *Remote Radio ID* dropdown menu.

Configure RTCM Submenu:

Note: To access this menu, first configure the unit as a BASE and set the *Correction Type* to either *RTCM RTK* or *RTCM DGPS*.

Choose *message 18/19* to make your RTCM RTK base broadcast RTCM message types 18/19.

Choose *message 20/21* to make your RTCM RTK base broadcast RTCM message types 20/21.

Choose message 1 to make your RTCM DGPS base broadcast RTCM message type 1.

Choose message 9 to make your RTCM DGPS base broadcast RTCM message type 9

Edit Base Position Submenu:

Note: To access this menu, first configure the unit as a BASE.

If your BASE already has a GPS position set, it will be shown here. (If you don't see it, trying pressing Retrieve.) To edit this value, change the displayed number and press the *Lock* button.

Click *Survey* to read a new GPS position from the Navcom unit.

Click *Empty*, to clear the GPS position from the unit.

Reset Unit Submenu:

Click *Soft Reset* to send a reset command to the Navcom unit. If the command is successful, all three status lights on the unit should go solid temporarily. After performing a soft reset, you will have to go to the *Configure Port* Submenu to reconfigure the control port.

Click *Factory Reset* to send an emergency reset command to the Navcom unit. However, in nearly all cases, it is only necessary to use the *Soft Reset* button. After performing a factory reset, you will have to go to the *Configure Port* Submenu to reconfigure the control port.

View Firmware Submenu:

This submenu displays the Navcom firmware version your unit is using, along with the hardware serial numbers and the hardware model name.

Navigation Status Submenu:

If *Valid Navigation* reads *Yes*, your unit has successfully solved its position. If it reads *No*, the unit's position has not yet been calculated, and an error message explaining why will be displayed in the *Error* field. A rover will not try to use RTK corrections unless its navigation is valid. Similarly, a base will not broadcast correction unless its navigation is valid.

Navigation Status will read *AUTONOMOUS* if it is not receiving the type of corrections it has been configured to use. It will read *FLOAT* if it is receiving the right kind of corrections, but hasn't finished using them to calculate its position. It will read *LOCK* when it is receiving corrections and has successfully used them to calculate its position.

Navigation Mode displays the specific type of correction that is currently being used.

of Satellites Used shows the number of satellites the unit is able to use in its solution.

All *DOP* values are also shown here (GDOP, PDOP, HDOP, VDOP, and TDOP).

Click *Refresh* to load the latest values from the device.

Monitor Incoming Corrections Submenu:

Note: To access this menu, the local unit must be configured as a ROVER.

This menu displays the number of seconds since the arrival of each RTK correction type. At the top, the correction type currently being used is displayed.

In *NCT Correction Mode*, the relevant messages are 5B (correction), which should be arriving every second, and 5C (base position), which should be arriving every 16 seconds.

In *CMR Correction Mode*, the relevant messages are cmr0 (correction), which should be arriving every second, and cmr1(base position), which should be arriving every 30 seconds.

In *RTCM RTK Correction Mode*, the relevant messages are RTCM message 22, and either messages 18 and 19, or messages 20 and 21, depending on your base's RTCM setup. Messages 18-21 should be arriving every second. Message 22 should be arriving every 6 seconds.

In *RTCM DGPS Correction Mode*, the age of correction messages (1 and 9) cannot be monitored here.

Click *Refresh* to load the latest values from the device.

Configure Base Submenu:

Before clicking *Configure Base*, first choose the type of corrections you want to use. When you click *Configure Base*, all steps necessary to configuring a base will be performed. You will be prompted for a Base Position and a Radio ID. Upon completion, the unit status should read BASE. If it does not, or if an error occurs during base configuration, try again, or consult the Base/Rover configuration troubleshooting section below.

Configure Rover Submenu:

Before clicking *Configure Rover*, first choose the type of corrections you want to use. When you click *Configure Rover*, all steps necessary to configuring a base will be performed. Upon completion, the unit status should read ROVER. If it does not, or if an error occurs during rover configuration, try again, or consult the Base/Rover configuration troubleshooting section below.

Switching the device you're plugged in to:

Whenever you switch the device you're plugged into be sure to either close the Equipment Setup window, or click *Retrieve Settings* from the top level Equipment Setup menu.

Troubleshooting Invalid Navigations:

If the *Navigation Status* menu reports an invalid navigation, you're unit has not yet been able to calculate it's position. The unit may need more time, if less than 4 satellites are visible, or an error is reported. If you can't get a valid solution for a few minutes, try raising the PDOP mask, or lowering the Satellite elevation mask.

Troubleshooting Base/Rover Configuration: If you've configured a base to output corrections, and you're rover does not appear to be receiving the corrections, try each of the following in order:

1. Verify that your BASE and ROVER are both set to the same correction type.
2. Under *Configure Radio*, check that your ROVER is set to slave, and that your BASE is set to master.
3. Under *Configure Ports*, check that both your base and your rover's RTK Data Ports are set to the proper value (Usually *Radio Port*).
4. Under the *Edit Base Position*, check that your BASE is set to a valid position. Note that if the given position is too far away from the position the BASE is reading, the BASE will not send corrections.
5. If you're trying to use RTCM, make sure the BASE and ROVER have the same station IDs.
6. Try increase the RTK Max Age constraint.
7. Under *Navigation Status*, verify that the Navigation is valid on both units. If either unit does not have a valid position solution, correction will not work.
8. Under *Monitor Corrections*, verify that the corrections you're using are arriving regularly. If they aren't you may need to reset both units.
9. Try configuring the BASE and ROVER again.
10. If all else fails, *Soft Reset* both units through the *Reset Unit* menu. After doing so, you will have to reconfigure the port settings of each device through the *Configure Ports* menu, and wait a few minutes for the devices to recalculate their position.
11. If none of these steps work, contact Carlson Software Technical Support.

Troubleshooting when you cannot establish communication with the unit:

If all of your commands in the Equipment Setup menu are failing, try opening the *Configure Ports* submenu, selecting the proper Control Port, and saving the new settings. Make sure that you're plugged into the port you have chosen to be the control port.

If this does not work, issue a soft reset command. If this fails, try a factory reset command. If even this fails, call Carlson Software Technical Support.

Nikon Total Stations

Nikon A-Series

Nikon A-Series includes the A5LG/A5, A10LG/A10 and A20LG/A20. Also the C-100 and D-50 have the same communication as the A-Series and should be used in the SET mode.

Nikon 500 Setup

1. Turn on Nikon

2. Turn it Horizontally and Vertically to set it.

3. Connect Nikon to Carlson Field

Note: 9-pin serial cable from Nikon to Carlson Field should be NGT type and not SOKTOP.

4. In Field go to Configure Field, and under equipment type put Nikon 300,400,500 series.

5. To make sure the baud rate matches, under the Field menu go to Configure Field and click on Communication Settings and check the baud rate. On Nikon press [MENU], then 3 for "sett", and 6 for "comm". The baud rate can be changed using the arrow keys.

6. Exit the Configure Field menu.

7. To check if units (Ft /M) matches for correct results, in Carlson Field under Settings go to Drawing Setup and select the appropriate button. On Nikon, press [MENU] and 3 for "sett" again, but now press 5 for "unit".

Nikon 310

Set the same baud rate in the Nikon 310 station as you did in Carlson Field and set the Nikon instrument to the record format by selecting on the instrument Fnc->5(Set)->6(other)->3rd screen.

OmniStar Otto

In Field go to Configure Field and under equipment type select CSI GBX/OmniStar Otto and in Communication Settings set the baud rate to 9600.

Simulation GPS

Simulation GPS mode is for demonstration purposes to show or practice Carlson Field functions. This mode allows you to run Carlson Field without being hooked up to any equipment. The program will automatically generate a position. This position is the first point in the alignment. If there is no alignment, then the starting point is 5000,5000,1000. There are keyboard commands to control the simulation position during continuous read commands such as Stakeout and Track Position.

Here are the Keyboard Command:

L - Turn Left
R - Turn Right
F - Go Faster
S - Slow Down
U - Up
D - Down
W - Switch Direction

Sokkia

Sokkia Radian IS

Hardware Setup

1. Make sure that the Radian IS has fully charged batteries installed, as described in the receiver documentation.
2. Connect the Radian IS serial cable to "COM1" on the Radian IS, plugging the other end into the controlling computer's serial port.
3. If the Radian IS is to be used as a base, connect a PDL base radio to the "COM2" port of the receiver. If the IS is to be used as a rover, connect a PDL rover radio to the "COM2" port of the receiver.
4. Power the Radian IS on with its external power switch.
5. Once the receiver finishes its self-initialization (when all the lights on the side panel go out and then the battery light lights in just one position), it is ready for use with Carlson Field. However, positions will not be able to be logged until the receiver has acquired a few satellites. The receiver has enough satellites when the center light is at the second or higher level (when it is orange instead of red).

Software Setup

6. To configure the IS for use, select "Equipment Setup" from the Field pulldown menu. This will open a menu with several options:
 - a) Radio Baud Rate: This radio button sets the baud rate for COM2, the radio COM port. Make sure this number and the number the PDL's are set for is the same.
 - b) Station Type: This sets whether the Radian IS is to be configured as a base station or a rover.
 - c) Elevation Type: This allows selection of Geoid (MSL) or Ellipsoidal measures for height/altitude.
 - d) RTK Dynamics: This sets the dynamics mode of the receiver. In general, this setting should be set to "Dynamic/Kinematic".
 - e) Message Type: This sets what format of corrections this receiver will send/receive for RTK.
 - f) Motion Dynamics: This is used to set the receiver's calculations appropriate to the motion of the receiver.
 - g) Elevation Mask: This is the satellite elevation cutoff. No satellites with elevation less than this number will be used in corrections. This allows filtering out of satellites close to the horizon, which provide less accurate calculations for positions.
 - h) Send Command to Receiver: This allows a specific user-entered command to be sent to the receiver. Mostly used for troubleshooting with Technical support.
 - i) Configure Base: This configures the parameters of a base station for the receiver (Ex: Current position, etc.)
 - j) Power Cycle Receiver: This powers the receiver down and then turns it back on, clearing the main memory.
 - k) Save and Exit: This saves all settings changes and exit this menu.
 - l) Cancel: This restores original settings and exit this menu.

To set the Radian IS up as a Rover:

7. Select "Rover" for Station Type, and set the Radio Baud to match the PDL's which are being used. Also, set "RTK Dynamics" to "Dynamic/Kinematic", and set Motion Dynamics to the appropriate option.
8. Select "Exit and Save". The receiver is now ready for use as a rover.

To set the Radian IS up as a Base:

9. Select "Base" for station type, and set the Radio Baud to match the PDL's which are being used.

For most jobs, set RTK Dynamics to "Dynamic/Kinematic" (unless you are *sure* that static is more appropriate-even small fluctuations from wind on the pole can cause problems in Static mode). Set motion dynamics to Foot/Walking, and then select "Configure Base Station"

10. In the menu dialog that opens, there are a few buttons:

- a) Read from GPS: Read a position from the GPS and fix to that position
- b) Enter Lat/Lon: Fix to a manually entered Lat/Lon position
- c) Enter State Plane Coord: Fix to a manually entered State Plane Northing/Easting position
- d) Read From File: Fix to a position read from a *.ref file.
- e) Cancel: Cancel base setup

If Read From GPS is selected, the software will read once from the GPS receiver, and then fix to that position. If Enter Lat/Lon is selected, a dialog box will open and a Latitude and Longitude must be input manually. If Enter State Plane Coord is selected, a dialog box will open allowing the input of a set of Northing/Easting coordinates by hand.

Read from File will open a File>Open dialog and ask for the file name of the file to open.

Regardless of which option is selected, after the position is determined, this position will be displayed, and dialog boxes will open to enter a station id and the measured base antenna height. Once these values are entered, base setup is complete and the "Exit and Save" button can be selected to exit the Equipment Setup menu.

Sokkia 500 Series

1. Turn on Sokkia
2. Turn it Horizontally and Vertically to set it.
3. Connect Sokkia to Carlson Field
4. In Field go to Configure Field, and under equipment type put Sokkia
5. To make sure the baud rate matches, under the Field menu go to Configure Field and click on Communication Settings and check the baud rate. On Sokkia press [ESC], then [CNFG]. Scroll down or enter 4 for "Comms setup." The baud rate can be changed using the arrow keys, when done press [ESC].

6. Exit the Configure Field menu.

7. To check if units (Ft /M) matches for correct results, in Carlson Field under Settings go to Drawing Setup and select the appropriate button. On Sokkia, in [CNFG] scroll to or enter 5 for "unit" and select appropriate unit using the arrow keys.

Topcon Total Stations

The Topcon instrument must have CR/LF (carriage return/linefeed) turned on for communication with Carlson Field.

Topcon 200 Series

To set CR/LF with 200 series:

1. Turn instrument off
2. Turn instrument on while holding F2 key
3. Choose F3 (Others set)
4. Press F4 (Page down)
5. Choose F3 (CR/LF) and set it on

To set this with 700 series:

1. Choose Parameter from the main screen
2. Scroll down until you find CR/LF and set it on

Topcon ITS

The command echo on the instrument must be turned off to work with Carlson Field.

Topcon GTS-A4

To setup the instrument hold down F-2 as you switch it on. This will bring up a parameters menu, press F-3 for Data Out. Hit Select to browse through the settings options, and make sure CR, LF: is ON and that Echo back: is OFF. Setup is complete.

Topcon GTS-700

To set the instrument to work with Carlson Field, press [F2] for "std" on the instrument.

Topcon 800-A Remote Setup

Topcon Setup:

Note: The instrument needs to be set to REC-A, not REC-B mode

1. Turn on the Topcon
2. Connect the Topcon to one of the radios, and the other radio connect to Carlson Field
3. Under Field menu go to Configure Field, and under equipment type select Topcon800A-Remote.
4. To set Topcon for external mode Press [F1] for "prog", then [F6] for "more". This will lead to more programs. Enter [F2] for "Ext.Link."
5. To select the radio channel, in External Link enter 2 for "settings" and 4 for "parameter (radio modem)", then 3 for "set channel". Using the arrow keys change the channel. When done press for [F1] for set, then press [ESC] until get back to External Link Menu.

Note: Channel on the Topcon should match the channel set in Carlson Field.

6. After channel is set press 1 for "Execute"
7. Topcon is ready.

Note: If the batteries are low either in Topcon or the radios, communication problems will arise.

Carlson Field Setup:

1. In Configure Field, under equipment type there should be Topcon800A-remote. In Communication Settings Baud Rate should be set to 9600.
2. After Configure Field go to Equipment Setup and make sure the radio channel or radio frequency matches the channel and frequency in Carlson Field. Press Ok when done.

Topcon 800A Quick Lock

1. Dismount the handle from the Topcon, and mount RC-2H. Secure it with the fixing screw.
2. Attach RC-2R to the prism, and turn it on.
3. Using the Y cable attach the RC-2H to the radio and Carlson Field.

4. In Joystick click on Quick Lock and Topcon will do angle turn until it finds a prism in which it will lock to, and will start tracking.

5. If RC-2H is not attached to the radio with Y cable, when Quick Lock is pressed the big yellow button on RC-2H needs to be pressed in order for the Topcon to search for the prism.

Trimble

Trimble NT300D

1. In order to properly configure the NT300D to work with Carlson Field, it must first be powered up in Setup mode (by holding down the [Setup] button on the front panel of the receiver while powering it on) so that the advanced setup options are available. Once the NT300D is powered up in this mode, bring up the Setup menu via the [Setup] button. Page down using the *More* menu option until the *I/O* menu item is available, and select it.

a) In the *I/O* menu, select whichever port is to be used to interface the receiver with the computer running Carlson Field (Port 1 by default). Next, set both the input and the output to transmit/receive in *NMEA*, at *9600* baud rate. The final option, Remote Select, should be set to *Primary*.

b) Now the *NMEA* sentences must be configured. From the *I/O* menu, enter the *NMEA Sentences* submenu. Disable all sentences, save for the *GGA* sentences and the *GSA* sentences. Ensure the Talker ID is *GP*. From here, *Return* to the *I/O* menu.

c) The *NMEA Control* menu item, reachable from the *I/O* menu, has three options. The Output Rate here should be set to *1 second*, the Position Output Rate set to *Output Rate*, and the *NMEA Output Version* to *2.1*.

Next, the *GPS* settings must be configured, and can be found in the *GPS* menu under the main *Setup* menu.

The *GPS* Mode should be set to *3D*, and the *DGPS* mode set to *Auto*. The *DGPS* source should be toggled to *Internal*, and the Pos/Vel Filter should be *Off*. Mask Values should be left at *Default*, and the SNR at *M*.

Finally, the Beacon Receiver configuration (under *Beacon Receiver* on the Setup Menu) needs to have its Search Mode set to *Auto-Dist* Mode. All other values in all menus ought to either be left at their default settings, or configured as necessary to the local conditions (in the case of antenna height, etc.).

2. The RMS value reported in Carlson Field is the RMS value of the standard deviation of the range inputs to the navigation process including pseudoranges and *DGPS* corrections.

The NT300D is now properly configured, and if connected to a computer running Carlson Field, will transmit position fix data to the computer automatically. Before using it, however, it is best to power it down and then turn it back on normally, as running it in Setup Mode is not recommended.

Trimble 4000 Series

Hardware Setup

1. Setup the antenna and GPS receiver as normal. The radio should be on I/O Port 2.
2. Connect the Computer that Carlson Field is running on to I/O Port 1 by the appropriate cable.

Front-Panel Configuration:

Base Station:

1. After powering on the receiver, press the [Control] Button. From the selections available, select **MORE**. This will bring up a second page of options. Select **MORE** again. The front panel screen should now be on **RECEIVER CONTROL "3 of 7"**.
2. Select **BAUD RATE/FORMAT**, and from the menu that this creates, select **SERIAL PORT 1 SETTINGS**.
3. Ensure that the port is set to 38400 baud, 8-Odd-1 Format, with no flow control.
4. Similarly, make sure that the settings for I/O Port 2 agree with those of the type of radio being used (typically 9600 8-None-1).
5. Return to the **RECEIVER CONTROL** menu, and go to page 4 of 7. Select **REFERENCE POSITION**.
6. Enter the Lat/Lon of the position the base is located at. Alternately, select **HERE** to have the GPS unit read the current position and use that as the base reference point.
7. On page 1 of the **RECEIVER CONTROL** menu, select **RTK OUTPUT CONTROL**.
8. Set the **RTK OUTPUTS** to Port 2, and the **ANTENNA HEIGHT** to the measured height of the antenna.
9. Ensure that all other forms of output (Cycled Output, 1PPS output, Event Markers, etc.) are disable. These options may all be accessed with the submenus accessible through the [Control] button.
10. Ensure that the Synch time of the Rover and Base are the same. This setting may be accessed by first pressing [Control] and then cycling through the menus until the **MASKS/SYNCH TIME** option is available.

Rover Station:

1. After powering on the receiver, press the [Control] Button. From the selections available, select **MORE**. This will bring up a second page of options. Select **MORE** again. The front panel screen should now be on **RECEIVER CONTROL "3 of 7"**.
2. Select **BAUD RATE/FORMAT**, and from the menu that this creates, select **SERIAL PORT 1 SETTINGS**.
3. Ensure that the port is set to 38400 baud, 8-Odd-1 Format, with no flow control.
4. Similarly, make sure that the settings for I/O Port 2 agree with those of the type of radio being used (typically 9600 8-None-1).
5. Return to the **RECEIVER CONTROL** menus, and go to page 2.
6. Select **RTK ROVER CONTROL**.
7. Toggle the **ENABLE** setting to **L1/L2**.
8. Push the [Status] button, and select **POSITION**. There should now be an **RTK** option. Select it. This will bring up a screen displaying delta Northing/Easting, correction status, etc.
9. Ensure that the **STATIC** option appears at the right. This means you are in kinematic/rover mode. If instead the **ROVE** option is available, select it.
10. Ensure that all other forms of output (Cycled Output, 1PPS output, Event Markers, etc.) are disable. These options may all be accessed with the submenus accessible through the [Control] button.
11. Ensure that the Synch time of the Rover and Base are the same. This setting may be accessed by first pressing [Control] and then cycling through the menus until the **MASKS/SYNCH TIME** option is available.

Trimble 4700/4800

Hardware and Equipment:

1. Make sure that the computer's serial port is connected to the 4700/4800 in it's COM1 port (typically the port that a data collector is normally plugged into). Power should be supplied on COM2, and any radio used for RTK should

be plugged into COM3.

2. All other equipment (antenna, wires, etc.) should be set up as normally directed by the manuals.

Software Configuration:

1. After selecting the Trimble 4700 equipment type from the "configure field" menu, open up "Equipment Setup."

This should bring up a new window/dialog box with the following options:

- a. Receiver Type: Select whether you are using a 4700 or 4800 receiver.
- b. Station Type: Choose what type of RTK station you are setting this receiver up as a base or rover.
- c. RTK Correction type: Select the type of Corrections you would like a base station to transmit. Note that CMR messages should be used for most precision applications, as RTCM is only capable of producing less-accurate floating precision positions
- d. Radio Baud Rate: The baud rate of the radio port. This should be left at the default setting of 9600 in general
- e. Satellite Elevation Cutoff: All satellites with elevation from the horizon of less than this number will *not* be used in calculating a position. This allows less accurate low elevation satellite to be factored out of a position.
- f. Configure Base Station: Will configure the receiver to act as a base. See "Configuring Base Station" below.
- g. Cancel without saving: Will exit this menu without saving any changes that have been made.
- h. Save and Exit: Will save these settings to the receiver and to Carlson Field's setup and exit out of this menu.

Configuring Rover:

No real configuration is necessary, aside from setting up the equipment and setting the appropriate Receiver Type, Station Type, and Satellite Elevation Cutoff.

Configuring Base Station:

1. After selecting all the appropriate settings in "Configure GPS," click on the "Configure Base Station" button.
2. In the menu dialog that opens, there are a few buttons:
 - a) Read from GPS: Read a position from the GPS and fix to that position
 - b) Enter Lat/Lon: Fix to a manually entered Lat/Lon position
 - c) Enter State Plane Coord: Fix to a manually entered State Plane Northing/Easting position
 - d) Read From File: Fix to a position read from a *.ref file.
 - e) Cancel: Cancel base setup

If Read From GPS is selected, the software will read once from the GPS receiver, and then fix to that position. If Enter Lat/Lon is selected, a dialog box will open and a Latitude and Longitude must be input manually. If Enter State Plane Coord is selected, a dialog box will open allowing the input of a set of Northing/Easting coordinates by hand. Read from File will open a File>Open dialog and ask for a file name of a reference file (*.REF) to open for use in corrections.

Regardless of which option is selected, after the position is determined, this position will be displayed, and dialog boxes will open to enter a station id (used by the base to identify itself to the rover(s)) and the measured base antenna height. Once these values are entered, base setup is complete and the "Exit and Save" button can be selected to exit the Equipment Setup menu. At this point, whenever looking at a menu that displays the connection status, "REFERENCE" will be displayed, instead of Float, Fixed, or Autonomous.

Trimble 5800

Carlson Field Configuration:

In Configure Field, set the Equipment Type to Trimble Generic.

In Equipment Setup, be sure to set the Data Type to match your receiver setup. This Data Type is the port on the receiver that communicates with Carlson Field. Typically, the Data Type should be set to 2 for the serial connection and to 4 for Bluetooth.

When configuring the Base receiver, use a base station id number in the range from 1 to 32.

Point Clouds Module

13

Point Cloud Recommended Specifications

The most important aspect for processing Point Clouds is RAM: for 250 million points about 12GB of RAM is needed (the cloud itself is half that but the user will want to be able to hold a source and a destination). More RAM allows more clouds to be held in the memory.

A SSD (solid state disk) instead of an HDD (hard disk drive) allows clouds to load faster. If the SSD on your computer doesn't have a large capacity, it is recommended to have an additional drive or backup server for extended storage.

As for processing power required, Point Cloud is primarily a single-core program but some select routines are multi-threaded. Therefore, you can focus on buying a processor with more speed (GHz) rather than the number of cores if you are only using the Point Cloud software and other applications such as Survey and Civil. Now then, if you are or will be using Carlson PhotoCapture for drone image processing, you are better off buying a multi-core processor computer as PhotoCapture is a multi-threaded application and more cores are better.

It is necessary to have a 64-bit operating system. Windows 7, 8, 8.1, 10 or 11 are all fine but please note that XP is no longer supported.

It is recommended to have a separate graphics card, preferably nVidia GeForce.

Summarized Specifications:

1. 64-Bit Operating System - Windows 7, 8, 8.1, 10, 11
2. Single/Multi Core Processor - preferred higher GHz and number of cores
3. 32GB RAM or greater - for photogrammetry and point cloud processing
4. SSD Drive
5. Optional additional HDD/SDD for storage

Point Clouds Getting Started

Carlson Point Cloud (not to be confused with Carlson Coordinate Cloud) is an application designed to run alongside IntelliCAD or AutoCAD and offers processing tools for large point datasets. It provides several methods to reduce, clean, extract from, and manipulate Point Cloud datasets so that they can be processed within CAD software without the typical memory limitations found in CAD applications.

Carlson Point Cloud comes in two varieties - Basic and Advanced.

Point Cloud Basic - designed to work within a CAD environment to manipulate and extract data from a point cloud. It has a very large capacity (up to a billion points) and is a great program for performing a "virtual survey" directly in a cloud. It allows the creation of Carlson points and 3D polylines utilizing a typical Carlson Field to Finish code table (FLD file) and draws entities directly into an open CAD drawing with no additional export function. A notable feature is Survey by Grid which sets points at any specified grid spacing.

Point Cloud Advanced - contains all of the functionality of Carlson Point Cloud Basic plus the ability to extract features such as curbs, parking lot stripes, road markings, power lines, trees, hydrants and poles. It also allows the creation of TIN/Grid files, solids, and utilizes typical Carlson cross section alignments (mxs files) to extract cross sections and profiles. You can also calculate volumes between surfaces. Cloud data can be selected by color or

elevation enabling you to create regions for isolating portions of a cloud for editing or extracting features. A notable feature is the ability to simplify a TIN and create smoother looking contour lines.

All actions performed in Point Cloud are initiated through the Point Cloud **Project Manager**. This manager can be brought up from your CAD application (assuming that the Point Cloud module is loaded) via the **Point Clouds -> Point Cloud Project Manager** menu option or with the **PC_PROJECT_MANAGER** command. Work in Point Cloud is arranged into projects and each project maintains a tree structure of all the data it contains.

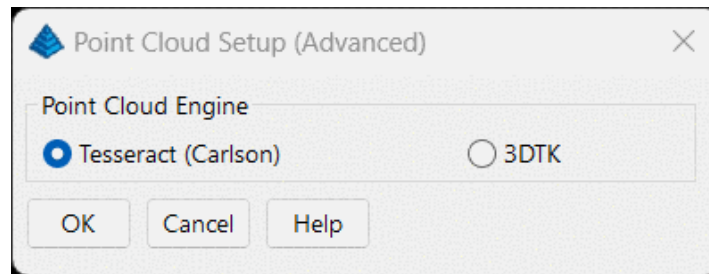

If you have not used Point Cloud before, you may want to go through the **Point Cloud Step By Step Tutorial**.

If you need to activate one of the legacy engines you can do so in the Point Cloud Setup via the **Point Clouds -> Point Cloud Setup** menu option.

Please view the Recommended Specifications.

Point Cloud Setup

The Point Cloud application comes with two point cloud engines: **Tesseract (Carlson)** and **3DTK**. Point cloud setup, located in the Point Cloud menu in CAD, allows the user to choose which point cloud engine to use.

Tesseract (Carlson): The Tesseract engine is the recommended Carlson engine for all projects. All automated feature extraction tools including paint stripes, parking lines, and color edges, and new bare earth tools require the Carlson Tesseract engine. The Tesseract engine is the default engine for the Point Cloud application.

3DTK: The 3DTK engine is a legacy engine that should only be used when working on older projects that were created using this engine. Other limitations include the fact that it doesn't support the Leica .pts or .ptx formats.

Note: When opening a point cloud legacy project created with the 3DTK engine, with the **Tesseract (Carlson)** engine active, you will be prompted to upgrade the project to use the Tesseract engine.

Menu Location: Point Clouds > Point Cloud Setup

Keyboard Command: pc_setup

Prerequisite: None

Point Clouds Step-by-Step Tutorial

Tutorial Setup

This is an introductory tutorial for Carlson Point Clouds. If you wish to follow along with the tutorial by using the same Scan files, you can download them from the Carlson website at http://update.carlsonsw.com/tutorials/Carlson_Office.laz

You can also follow along with any other scans that have proper target points and control points.

Launch Point Cloud Manager

Work done in Carlson's Point Cloud module is done on a per-project basis. To create a new project, you must first have a CAD drawing open in AutoCAD or IntelliCAD. To enable Point Clouds, on the top toolbar click **Settings** => **Carlson Menus** and select **Point Clouds Menu**. This will display the Point Clouds menu on the top toolbar. Click on **Point Clouds** and then select **Project Manager**.

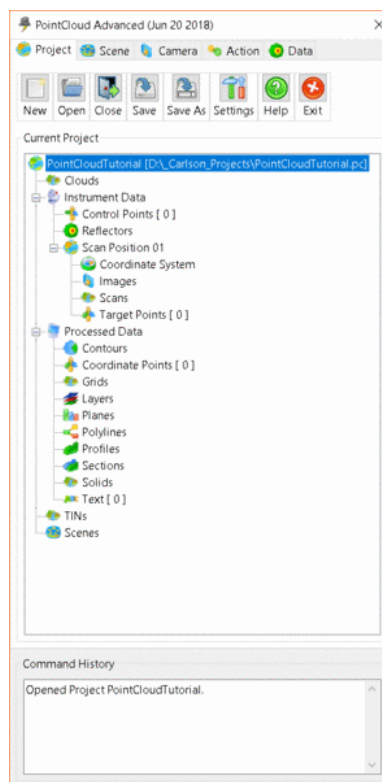

Alternatively, on the top toolbar click **Settings** and select **Toolbar Setup**. In the **Select Toolbars** window, ensure the **PointCloud** option is checked. This will now display the **Lightning Bolt** icon on the toolbar. Click the **Lightning Bolt** icon to launch Point Cloud Manager.

Project Setup

To create a new project, in the Point Cloud Advanced window, click **New**. In the New PointCloud Project window, select the file location to save the new project, enter in a File Name and then click on **Save**.

Your initial project should look like the following image. In the tree structure you will see your Project with various defaults.

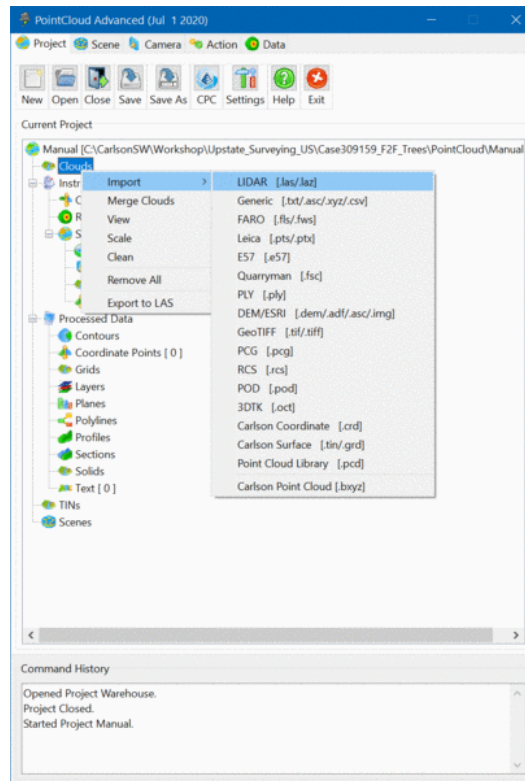

The program will attempt a recovery in the case of an error, but it is still recommended to **Save** often using the Save button at the top of the **Project Tab**.

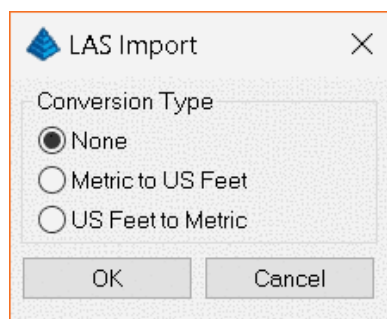

For more information see the **PointCloud Project Manager** entry.

Cloud Import

Let's begin by importing a Point Cloud. From the Project tree, right click on **Clouds** > **Import** > **LIDAR**.

Find and select the TutorialData.laz file, or use any other .las or .laz file. The program will ask if you want to convert units. This data is in feet, so if you want to work in Metric, select the third option. Otherwise leave this as "None" and click **OK**.

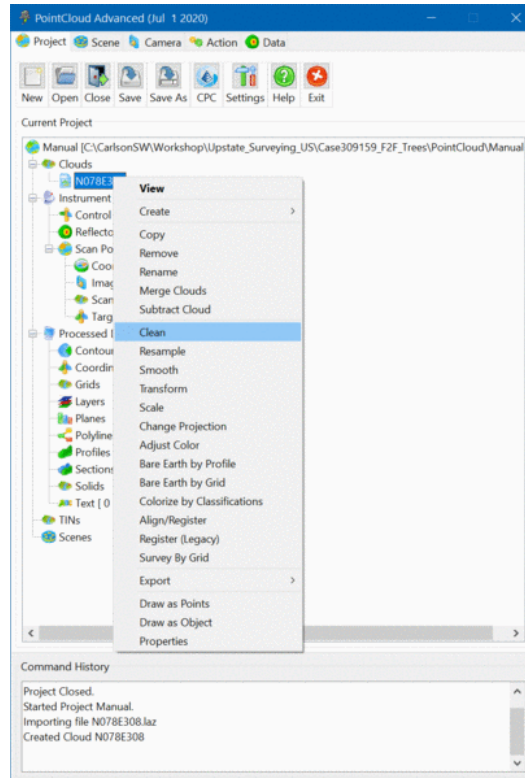

A new Cloud will now be displayed in the Project Tree.

For more information see **Import Cloud**.

Clean Cloud

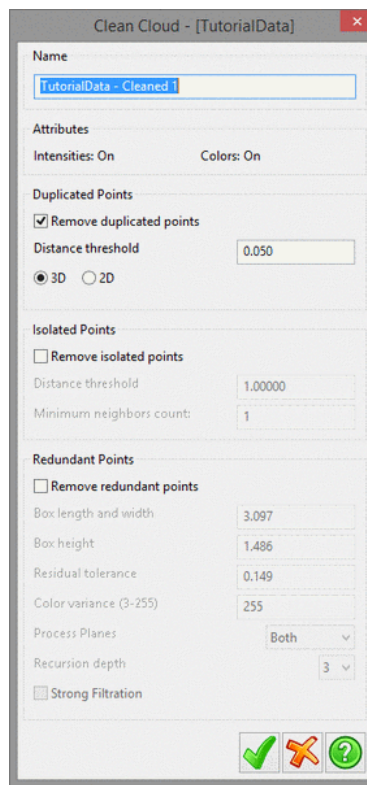

Many clouds which are imported directly from a laser scanner or exported from the manufacturer's software contain unnecessary points which can be removed.

Right-click on the newly-imported Cloud and select **Clean**.

For this type of scan, there are more points than necessary close to the scanner, so we remove them via the "Remove Duplicated Points" method.

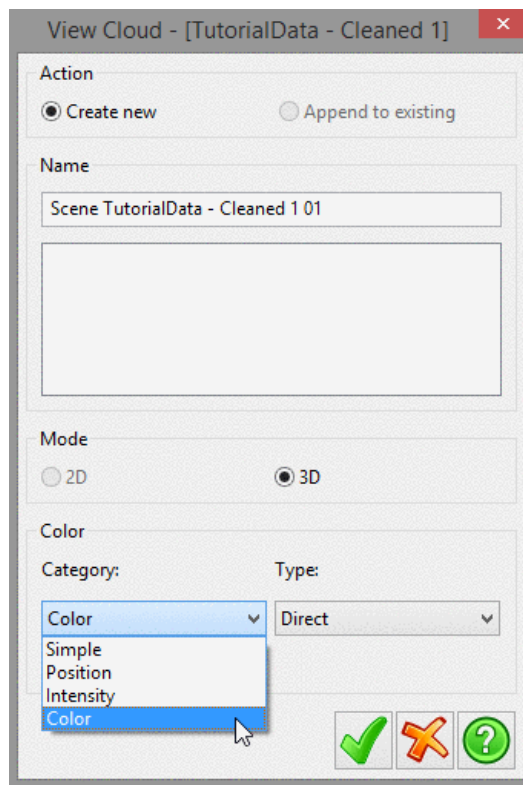

For this Cloud, we want to make sure that the "Remove Isolated Points" method is not enabled. Click the **Green Tick** to run the Clean operation.

For more information see **Clean Cloud**.

View Cloud

A new "Cleaned" Point Cloud will be available in the Project Tree. Double-click on the new Cloud or right-click and go to **View**.

This Cloud has color in it so we will choose **Color category: Color** and **Type: Direct** for our color mode. If this viewing mode is not available it may indicate that the Cloud does not have color in it. Click on the **Green Tick** to open the **View** window.

For more information, see **Scenes**.

For this screenshot, the Orbit has been displayed (via the Viewer Settings section of the **Project Settings Manager**).

By default, a left-click-and-drag within the bounds of the Orbit will change the y-angle of the scene, relative to the red pivot point.

A left-click-and-drag outside of the Orbit will rotate the scene relative to the z-axis and the pivot point.

A middle-click-and drag will pan the scene.

The mouse scrollwheel can be used to zoom in and out.

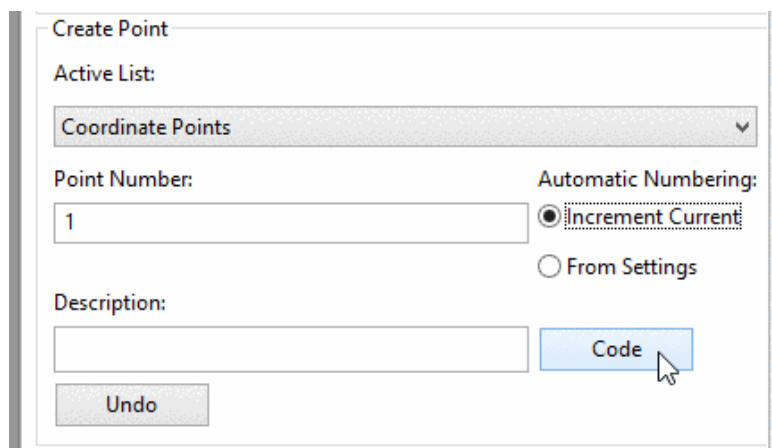

Virtual Survey

To enter the Create Point mode, select **Point** under **Create** on the **Action** tab of the **Project Manager**.

PointCloud will read your current .fld Code Table into a dialog which allows you to graphically select the code to apply to the next point.

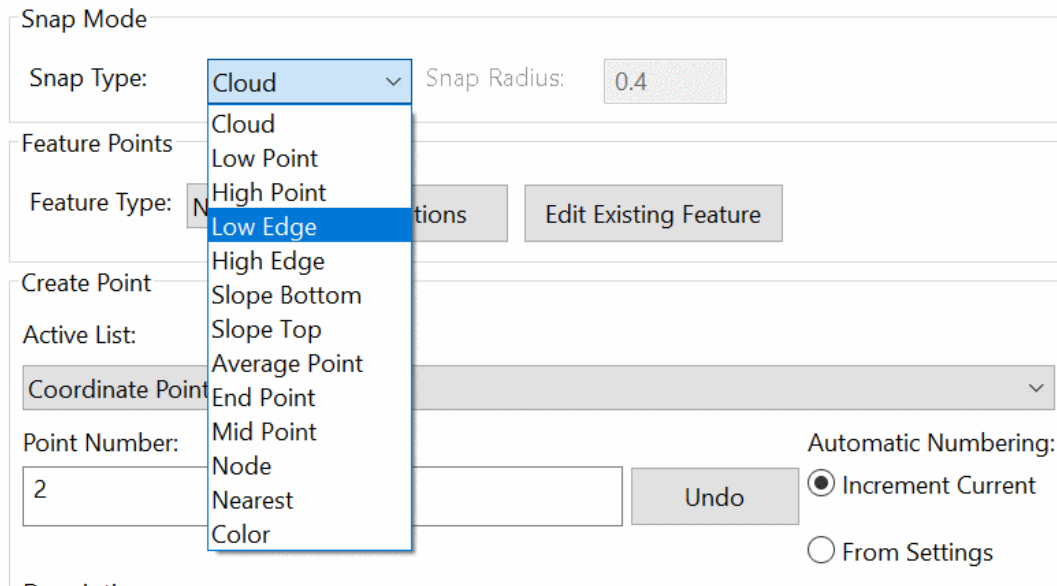

This dialog can be accessed via the **Code** button.

If the **Code Table** dialog is empty you may need to select a FLD File. To select a FLD File, click the **Code** button. In the **PointCloud - Code Table** window, click the **Pick FLD File** button at the top of the dialog then navigate to your FLD file and click **Open** to populate the data.

You can change the Snap Mode depending on what you are attempting to shoot a point of. In this example

we will select the **Low Edge** snap type in order to create some points for the bottom of the curb. The Snap Radius should be changed from 0.25 to 0.5 feet (if you are using meters, use a Snap Radius of 0.15 instead).

The code to use for this will vary depending on your code table, but it is important to pay attention to the Entity Type, as this controls whether a selected point shows up as an isolated point or as part of a polyline.

When the red pick dot appears at the bottom of the curb, hold down the **Ctrl** key and click the left mouse button to create a point. The program will automatically label this point as the start of the line and subsequent points with the same code continuing the line, until you end the line with **End Linework** or Ctrl-E.

Sending to CAD

After you are done with the Virtual Survey you may want to add the created points to your current CAD drawing.

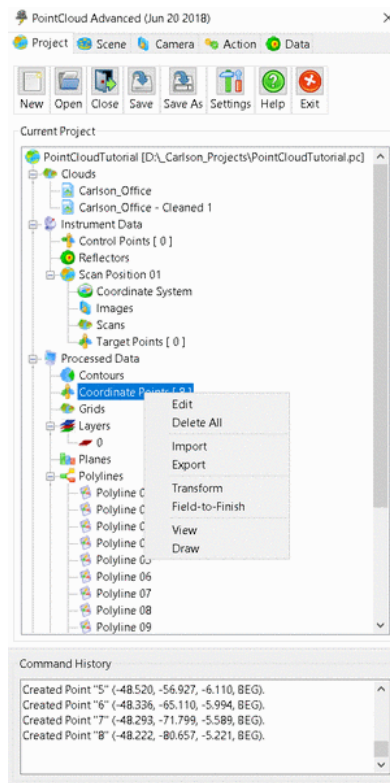

Return to the **Project** tab and select the entry for **Coordinate Points** from **Processed Data**.

To edit the points or view their coordinates you can right-click and select **Edit**, or double-click to open the editor window.

Right-clicking gives a few more options:

Field-to-Finish will use your Carlson F2F settings for styles and colors when sending to CAD.

Draw will simply send the points to CAD as points, based on the settings of the chosen Layer.

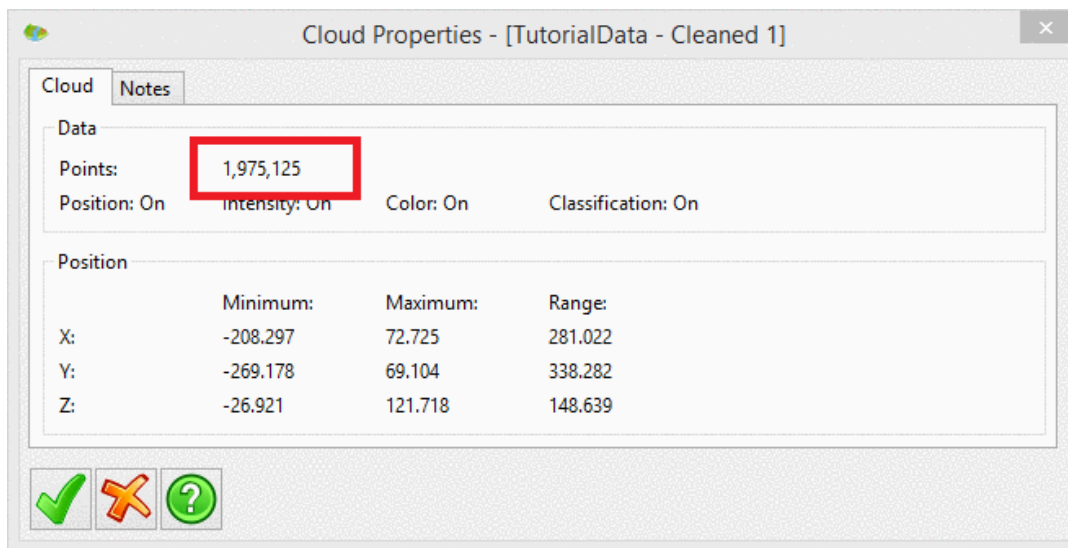

For more information see **Coordinate Points**.

TIN Creation

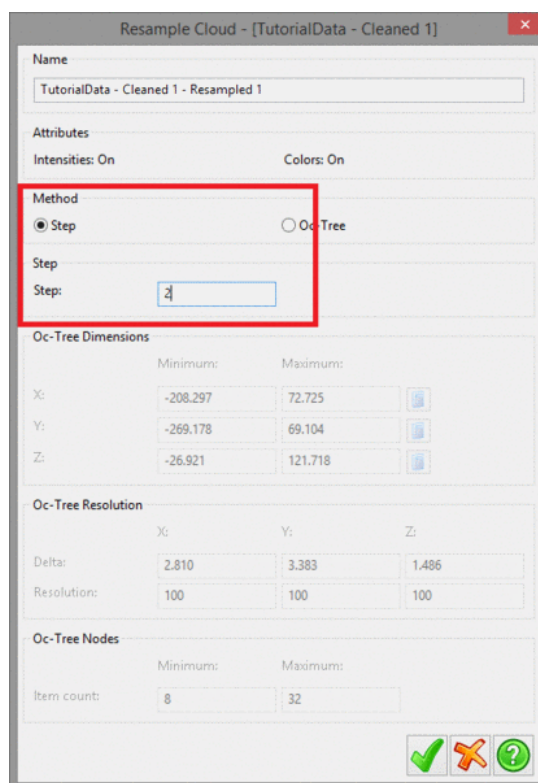

TIN files work best with about 1,000,000 or less points, and in most cases where they are used, this is more than enough points to be useful. So it can be helpful to reduce the number of points in a Cloud before creating a TIN.

First, right-click on the already-cleaned Cloud file in the Project Tree and click **Properties**.

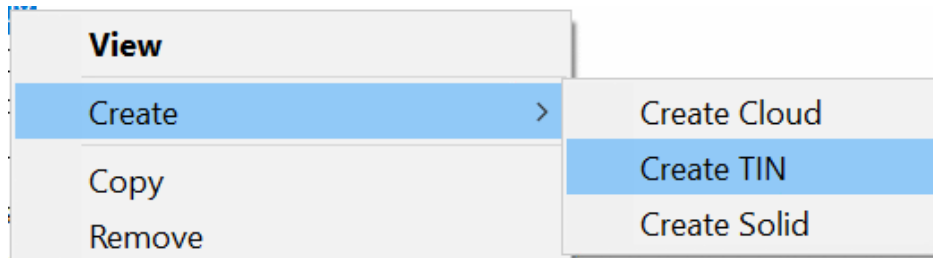

Here you can see the number of points in the current Cloud so you know how many need to be removed. Click the **Green Tick** to exit the **Properties** window.

Right-click on the Cloud again and select **Resample**. We are using a step size of 2 because we have approximately 2 million points, and having already Cleaned the Cloud we assume the density is relatively even. Click on the **Green Tick** to run the Resample operation.

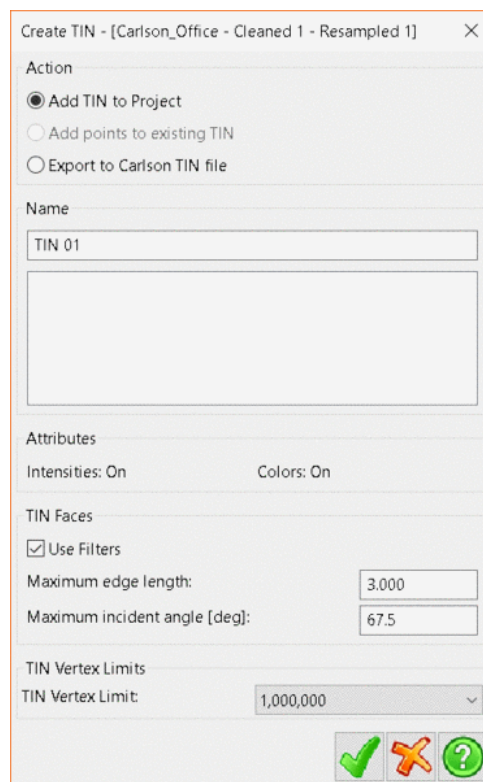

Now that we have created a more manageable Cloud, we are ready to create a TIN. Right-click on the Resampled Cloud in the Project Tree and select **Create > Create TIN**.

The maximum edge length should be a few times longer than the normal distance between points in your Cloud. The incident angle controls how tilted a triangle in the TIN can be relative to the Normal. In this Cloud, setting this below 90 will cut off the sides of buildings.

Click the **Green Tick** to create the TIN. You can also choose to Export the TIN at this stage.

The newly-created TIN can be used in other functions which work on triangulated data.

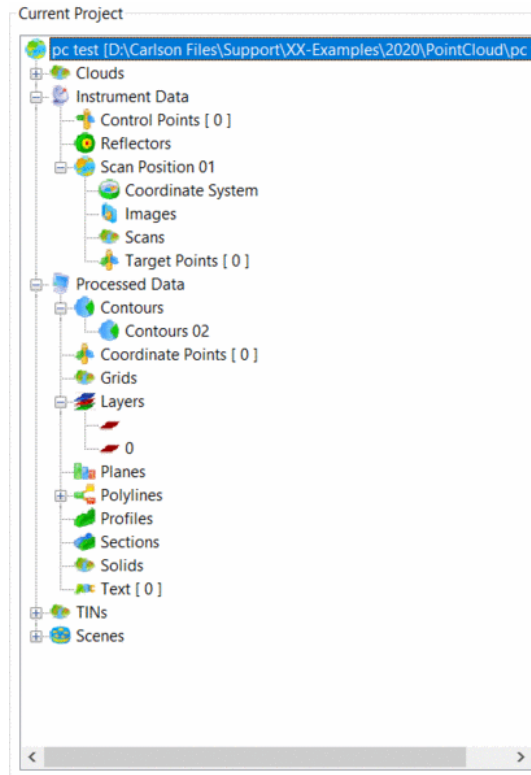

This completes the tutorial, but this is only as small sample of the functionality available in Carlson Point-Cloud.

If you would like further assistance, please contact support@carlsonsw.com.

Point Clouds Project Manager

The project manager is the central place of operations for Carlson Point Cloud. To bring up the Project Manager, first ensure that the Point Cloud module is loaded by clicking on the lightning bolt icon in your CAD application. The manager can be brought up by either clicking the **Point Clouds > Project Manager** or by entering the command **PC_TOOLBAR1** into your CAD applications command window. The title bar of the Point Cloud Manager window will display the version, build date of the software and the active Point Cloud engine. Tesseract (Carlson) is the default Point Cloud engine.

Every function and operation that can be performed in Point Cloud is accessed through the Project Manager. These functions are divided up among five major categories represented as tabs in the project manager: **Project, Scene, Camera, Action, and Data**.

Most Point Cloud features require you to have a Point Cloud Project open. These are stored as .pc files. You can manipulate them on the **Project Tab**.

Command History

The **Command History** panel maintains a list of all major functions used since execution of Point Cloud began, and is also the central place where information regarding the results of all functions is posted, much like the command window in AutoCAD or IntelliCAD. For instance, after execution of the TIN simplification function has finished, details about the number of faces removed from the TIN will be appended to the Command History.

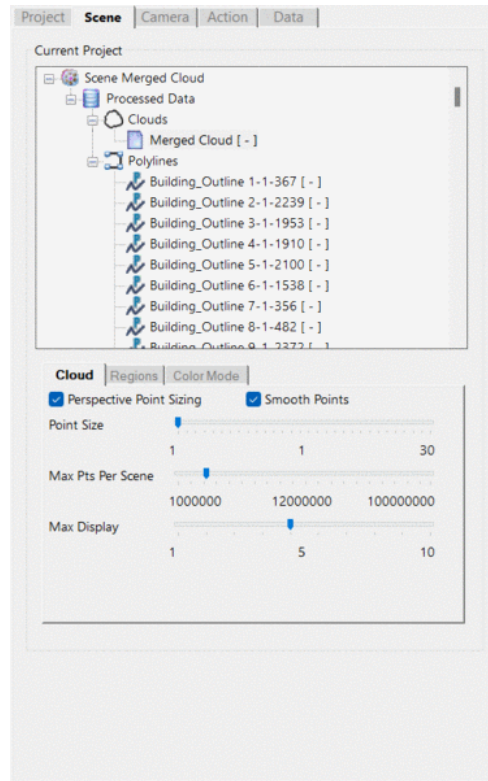

Pulldown Menu Location(s): Point Clouds

Keyboard Command: pc_toolbar1

Prerequisite: None

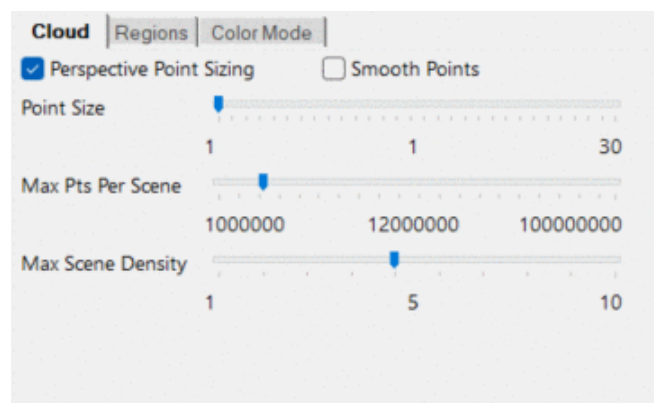

Scene Tab

The **Scene Tab** allows you to customize the active scene's display options. The **Scene Tab** will be blank until you open a scene from the **Project Tab** using the *View* command. It is important to note that the controls in the Scene Tab vary depending on whether objects are selected in the Current Project tree or selected in the active scene window.

To display the cloud controls, **select a cloud** from the **Current Project** tree. Using the cloud controls you can set the point size and display, hide/show regions (classifications), and set the color mode to display the cloud in the scene (direct color, intensity, elevation, etc).

Point Size

Perspective Point Sizing: will make points farther from the camera appear smaller than points closer to the camera when the Scene viewer is set to *Perspective Mode*.

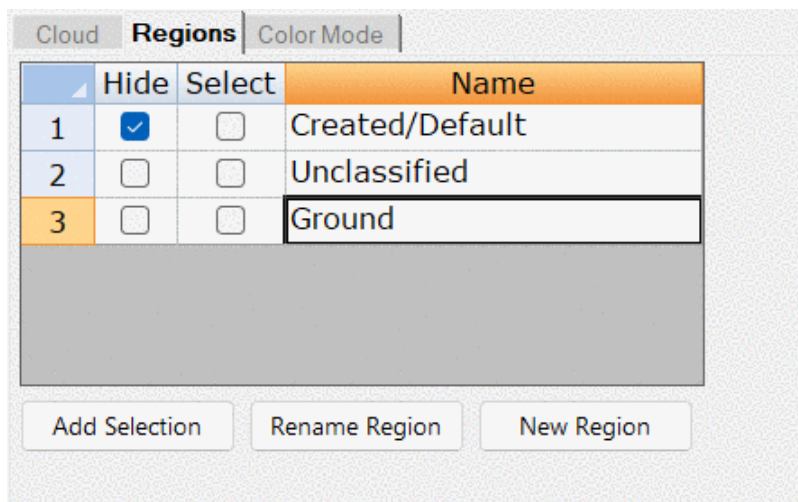

Smooth Points: Changes the way the points are displayed from a square to a circular appearance which makes the point display on screen appear fuller. The default is on. If you prefer viewing the points at standard size, uncheck Smooth Points.

Point Size: **Point Size** controls the size of points in the Scene viewer and can be set from 1-30. Default is set to 3, if you prefer displaying the points at standard size, set the size to 1.

Max Pts Per Scene: Controls the maximum number of points that can be displayed in the scene allowing to cull the cloud display and improve the graphic performance.

Max Scene Density: Controls the density of points in the view prior to limiting the overall scene. If the density is low, the cloud may appear thinner but will display faster. If the density is high, the display will show more points in the denser areas but it may reach the *Maximum Points Per Scene* quicker.

Regions

Hide: toggle on/off to hide or display the classified region.

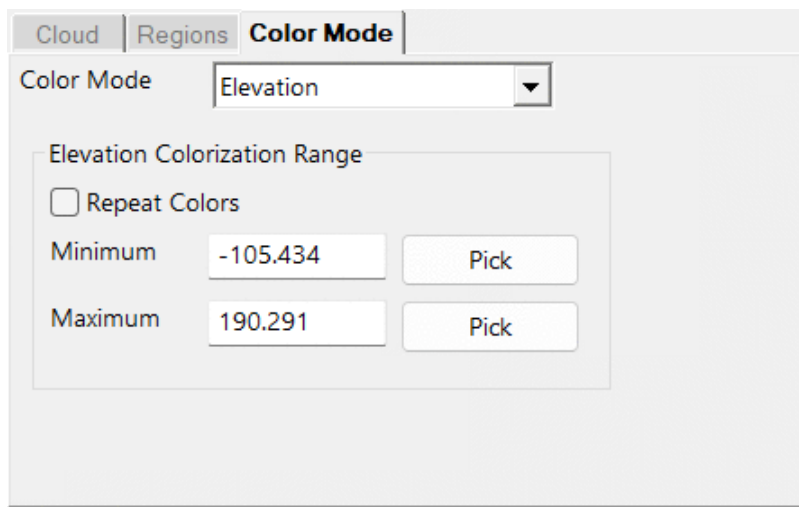

Select: toggle on/off to select all the points in the region.

Add Selection: adds the selected points in the scene to the highlighted region. Point that were in a different classification will be moved to the target region.

Rename Region: renames the highlighted region.

New Region: a new region can be created by first making a selection from one or more existing regions, or by selecting a portion of the cloud from the Action tab and then creating a region from that selection. If no points are selected, the new region will contain no points.

Color Mode

The **Color Mode** determines the mode to color the data in. There are eight modes that are contextually available depending on the type of data and selected mode to be drawn in. These color modes are divided into categories based on how the colors are determined, these categories are: **Single Color**, **Elevation**, **Intensity**, **Colorized Intensity**, **Direct Color**, and **None**.

Single Color: will color the entire dataset in the same color. **Click** the **Select** button to choose the color. Default is white.

Elevation: colors each point based off its elevation data in a range from blue being the minimum elevation to red being the maximum elevation. By default, the program will scan the cloud to determine the minimum and maximum elevations and apply the colorization. You can enter a **Minimum** and **Maximum** elevation by typing the values in the corresponding fields or by clicking the **Pick** button to select points in the cloud to affect the colorization. Toggle **Repeat Colors** to allow the software to repeat the color bands.

Intensity colors each point based off its single intensity value. Points with a low intensity will be colored pure black while colors with high intensity will be colored pure white. The **Set Range to** options allow you to customize the intensity range to be applied. **Full** will set the Min value to 0 and Max to 255. **Cloud** will analyze the cloud for the lowest and highest intensity values and automatically set the Min/Max values. **Optimized** will analyze the cloud for the lowest and highest intensity values and then apply a Min/Max set of values that will emphasize the intensity differences the most. **Custom** will allow you to enter the Min/Max values. Note that some ground scanner clouds may only have low/high intensity values therefore the range will be limited.

Colorized Intensity: colors each point based off its single intensity value using red, green, and blue col-

orization. The **Set Range to** options allow you to customize the intensity range to be applied. **Full** will set the Min value to 0 and Max to 255. **Cloud** will analyze the cloud for the lowest and highest intensity values and automatically set the Min/Max values. **Optimized** will analyze the cloud for the lowest and highest intensity values and then apply a Min/Max set of values that will emphasize the intensity differences the most. **Custom** will allow you to enter the Min/Max values. Note that some ground scanner clouds may only have low/high intensity values therefore the range will be limited.

Direct Color: colors the points based off the color information in the imported cloud data.

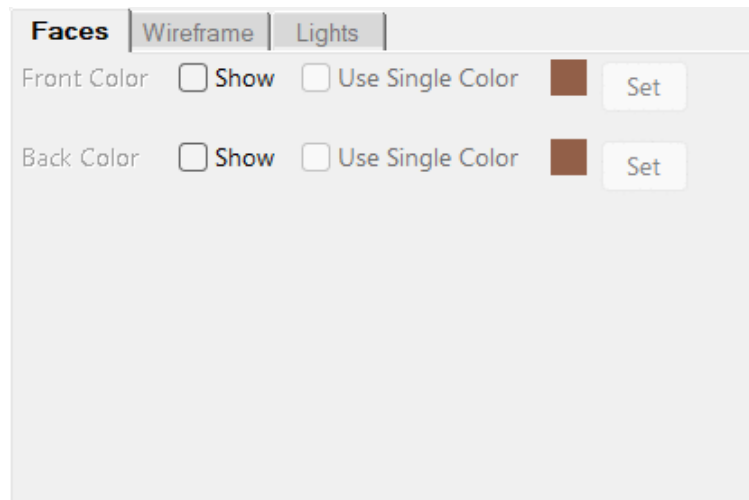

None: removes colors.

To display the TIN controls, **select** a **TIN** from the **Current Project** tree. Using the TIN controls you can set how to display the TIN faces, wireframe, and lights.

Faces

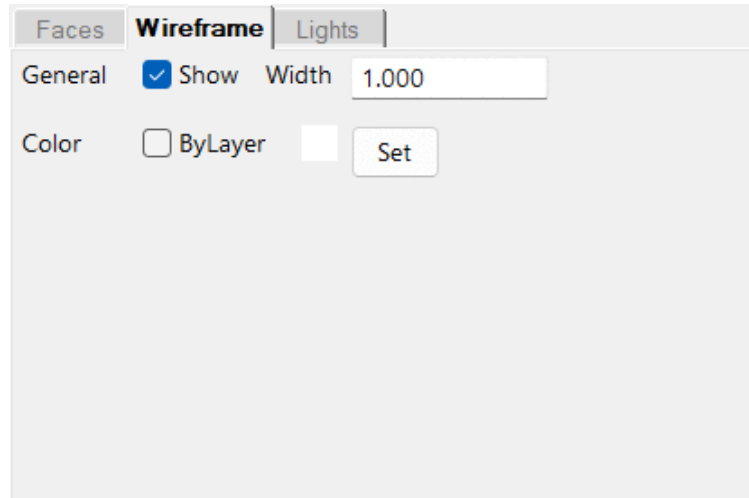

Show Front: toggles the display of the front TIN faces in the active scene viewer.

Show Back: toggles the back (or underneath) faces of the TIN in the active scene viewer.

The **Front** and **Back** colors can be set separately and different colors can be selected when toggling **Use Single Color** and then **clicking** the **Set** button.

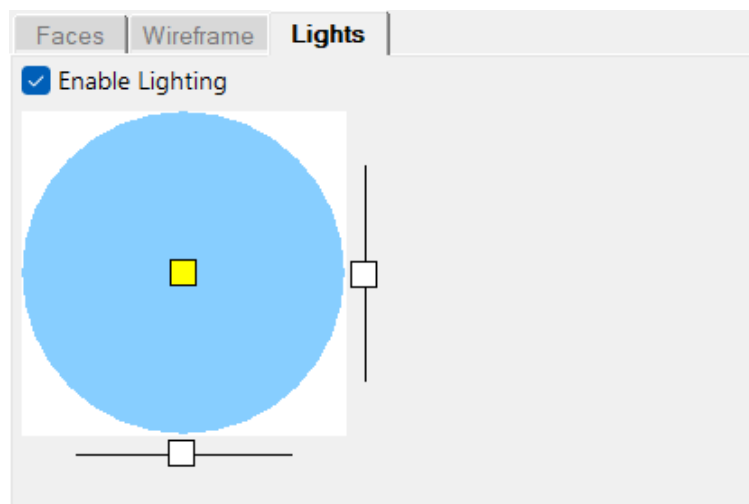

Wireframe

Show: Toggles on/off the display of the TIN wireframe (or mesh).

Color: Allows you to set the wireframe color whether to a single color or multiple colors based on elevation ranges.

Lights

The two sliding scales control the Light Intensity (vertical control) and the Ambient Intensity (horizontal control).

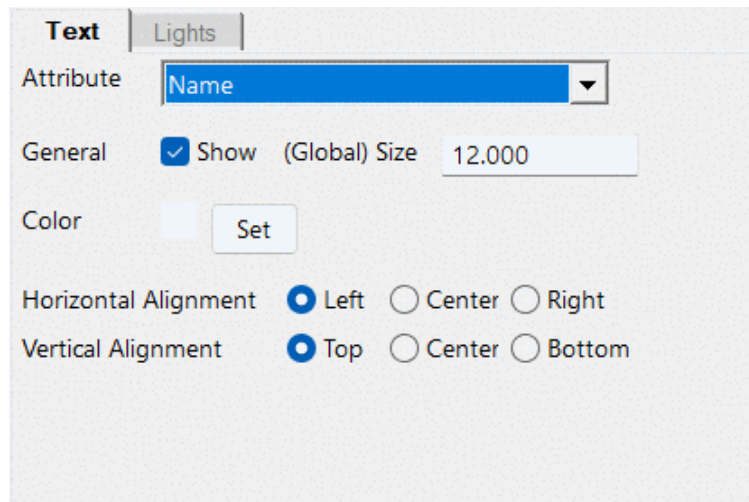

Light Intensity: Controls the intensity of the directional light, which is a light, positioned to simulate the effect of a distant light source like the sun.

Ambient Intensity: Controls the intensity of the ambient lighting, which is the base light level that affects everything

regardless of the surface normal.

Center Light control can be moved freely to change the position of the light source.

To display the Carlson Point Attribute controls, **select Coordinate Points** from the **Current Project** tree under **Processed Data**. You can set to display the attributes, their text size, color, and justification.

Attribute: use the pull-down menu to select **Name**, **Description**, or **Elevation**.

Show: toggle on/off to set if the attribute will be displayed in the scene.

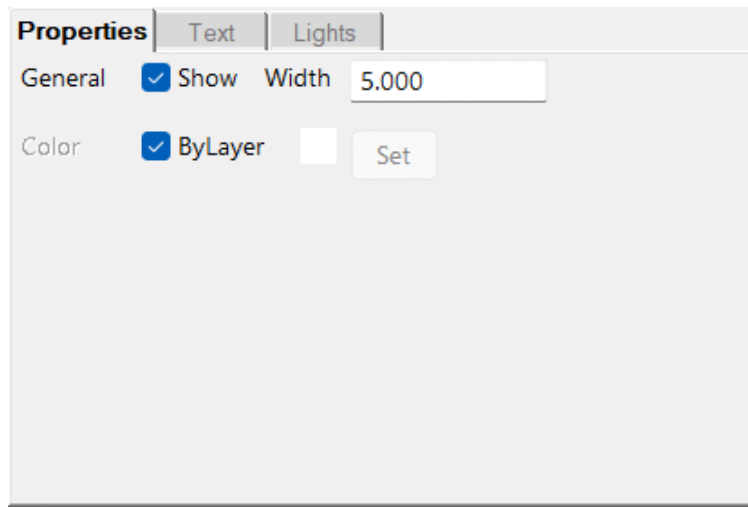

Global Size: adjust the attribute text size.

Color: set the attribute color by **clicking Set**.

Horizontal Alignment: set the attribute's horizontal justification.

Vertical Alignment: set the attribute's vertical justification.

To display the Polyline controls, **select Polylines** from the **Current Project** tree under **Processed Data**. You can turn on/off the polylines, set the line width, and set the polyline colors.

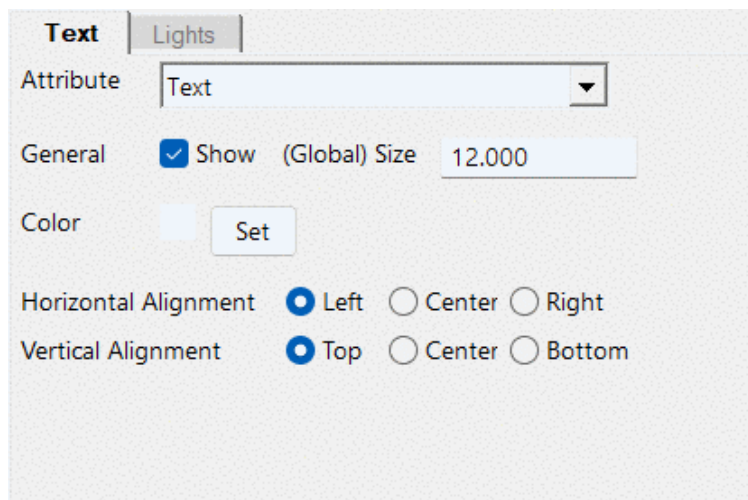

Show: toggle on/off the display of the polylines.

Width: set the line width.

Color: you can set a color to display the polylines.

To display the Polyline controls, **select Text** from the **Current Project** tree under **Processed Data**. You can turn on/off the text, set the text size, color, and justification.

Show: toggle on/off to set if the attribute will be displayed in the scene.

Global Size: adjust the attribute text size.

Color: set the attribute color by **clicking Set**.

Horizontal Alignment: set the attribute's horizontal justification.

Vertical Alignment: set the attribute's vertical justification.

Camera Tab

The **Camera Tab** is the third tab in the Project Manager and has several functions that govern the current Scene's camera behavior and positioning as well as functions that allow access to some camera presets. The Camera Tab will only be active if there is a Scene currently opened, otherwise all of its controls will be greyed out.

The Mouse Motion Panels

The **Left Motion**, **Middle Motion**, and **Right Motion** panels control the behavior of the left, middle and right mouse buttons, respectively. The options in the pull-down menu are Cub Orbit, Orbit, Pan, Swivel and Zoom.

Cube Orbit rotates the camera around the center of the scene's bounding box, the default behavior for the left mouse button.

Orbit will orbit the camera around the pivot, and the pivot's behavior can be defined in the **Pivot** panel.

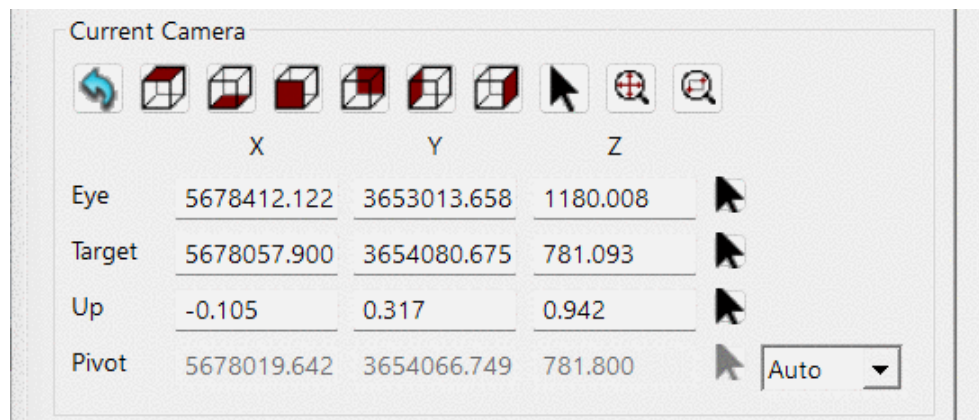

Pan pans the camera, moving the camera laterally or vertically from its perspective, the default behavior for the middle mouse button.

Swivel rotates the camera view direction around its current position.

Zoom will zoom the camera, moving the mouse up will zoom in, moving the mouse down will zoom out. This is the default behavior for the right mouse button.

The Current Camera Panel

The **Current Camera** panel has options for manually modifying each of the camera's position and view direction properties. Each option features a target button which, when pressed, will allow you to CTRL+click into the scene to set that property to a value from the scene. The preset views for the Camera are accessed by clicking the icons along the top of the panel. From left to right they are; Reset View, Top, Bottom, Front, Back, Left, Right, Pick, Zoom Extents, and Zoom Window.

Eye is the position of the current camera.

Target is the current facing direction of the camera.

Up is the current camera's up vector.

Normal is the 90 degree vector to the current view plane.

The **Pivot** determines the behavior of the pivot point when in **Orbit** mode. Use the drop-down menu to select the different Pivot behaviors.

Auto, the default behavior, moves the pivot to the valid data nearest to the cursor whenever orbit mode is activated.

Center will move the pivot point to the center of the scene's bounding box.

User will enable the **Position** controls and allow entry of the Pivot point manually (or via a CTRL+click in the scene if you press the green target button).

Origin will move the pivot point to the origin of the scene's coordinate system.

Target will place the pivot point at the nearest valid data to the center camera's view.

The Projection Panel

The **Projection** panel determines the projection mode of the current camera.

Orthographic projection

mode will not apply perspective distortion (to simulate the effect of a real-world camera lens) and the **View Height** option will determine the height of the view (in world units).

Perspective projection mode will apply a perspective distortion, and the **Field of View** option determines the vertical viewing angle of the cone that defines the camera's visibility.

The Clipping Panel

The **Clipping** options allow the user to manually set up of the view's clipping planes. Clipping planes will cut out any objects in the Scene closer than the front clip plane and any objects further than the back plane. **Note:** By default, custom clip planes are disabled.

In some cases, it may be useful to manually manipulate the clip planes.

Front defines the distance from the front of the Bounding Box that the camera clip will hide. Adjust the **Front** slider to clip more or less of the Scene, starting from the front.

Back defines the distance from the back of the Bounding Box that the camera clip will hide. Adjust the **Back** slider to clip more or less of the Scene, starting from the back.

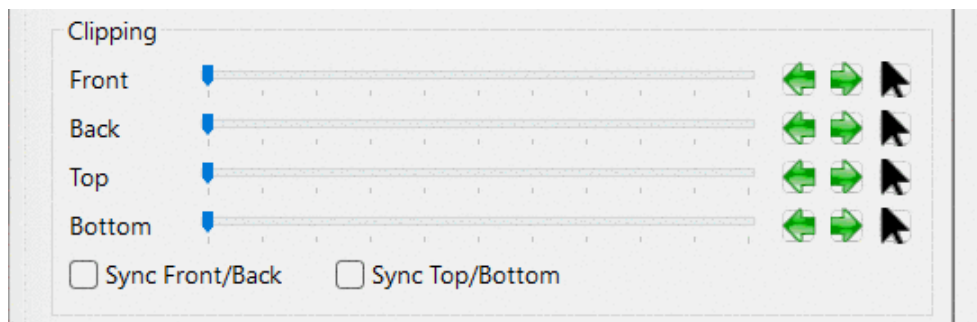

Top defines the distance from the top of the Bounding Box that the camera clip will hide. Adjust the **Top** slider to clip more or less of the Scene, starting from the top.

Bottom defines the distance from the bottom of the Bounding Box that the camera clip will hide. Adjust the **Bottom** slider to clip more or less of the Scene, starting from the bottom.

Sync Front/Back - clicking in the check box will mean that as the Front or the Back slider is adjusted, the opposite value will move in the opposite direction by the same amount.

Sync Top/Bottom - clicking the check box will that as the Top or the Bottom slider is adjusted, the opposite value will move in the opposite direction by the same amount.

The **Target** buttons next to each value can be used to define the value of each clip by clicking directly into the Scene.

Polyline Cross Section

This clipping method uses an existing polyline to clip the point cloud. Select the desired polyline using the **Polyline** drop-down menu. To undo the Cross Section view, select the **Blank** option from the drop-down menu and click anywhere in the Scene.

Station - Increase or decrease the **Station** value to move the cross section through the Cloud.

Width - Increase or decrease the **Width** value to widen or narrow the cross section.

Camera Actions

Additionally, there is an option to save the current camera settings to the current scene (which can later be accessed through the scene page) using the **Save Camera** button and an option to save an image of the current contents of the viewer using **Save Screen**, which will bring up a save file dialog. Pressing **Save Screen** will bring up the standard Carlson save file dialog and you can choose where to save the image as a BMP file. The final option is to Save to PDF. Pressing the **Save to PDF** button opens the PDF options. The user can choose size of image, Border and title block fields to be included in the PDF file. The current view in the scene is written to the PDF.

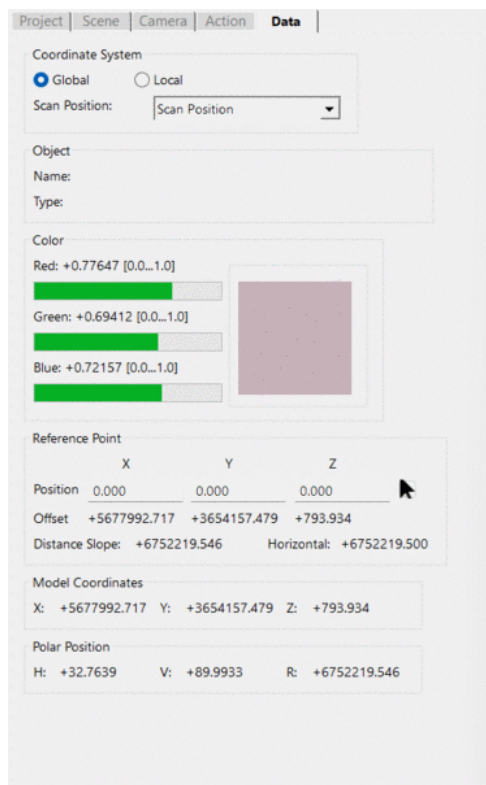

Tab Location(s): Camera Tab

Prerequisite: Open Scene

Data Tab

The Point Cloud Data tab is useful for visual inspection of data in the current scene. It allows the user to examine, color, range, and position values in the scene's coordinate system as well as in coordinate systems relative to the scanner positions or a reference point.

The **Coordinate System** panel displays the Cartesian coordinates (in the currently selected coordinate system) of the point under the cursor if it is a valid data point. By default, all data inspection is done in the Scene's global coordinate system. However, it is also possible to work in coordinate systems relative to the scanner positions by clicking the **Local** radio button and choosing a scan position to use as basis for the coordinate system.

The **Object** panel displays the name and object type of the current object under the cursor.

The **Color** panel displays the color values of the pixel under the cursor, if valid. Keep in mind that this value will not be the exact color value of the dataset if lighting is enabled or if the object under the cursor is selected.

The **Reference Point** panel displays options for placing the reference point and information about the point under the cursor's relative position to the reference point. This is useful for rough estimation of range values without having to create a polyline in the project. Clicking the small green target icon will put the current Scene into reference point positioning mode. CTRL+Click in the Scene to place the reference point at the valid data nearest to where the user clicks.

The **Polar Position** panel displays the current polar coordinates of the point under the cursor if it is a valid data point.

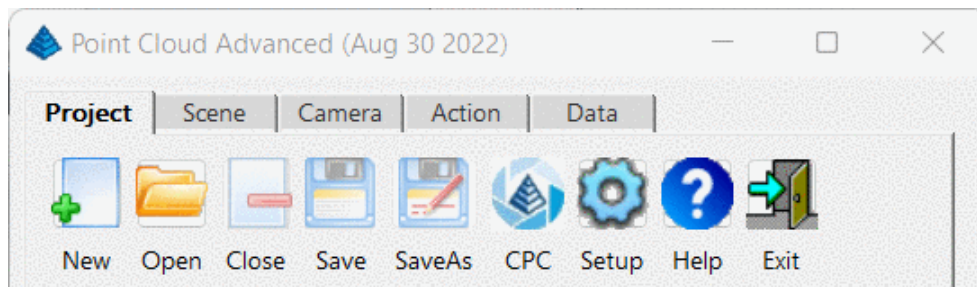

Project Tab

The **Project Tab** is the main tab of the Point Cloud Project Manager, and should be the first thing you see after pulling up the Project Manager. It is from here that you can manage your project files, as well as perform most of the operations on your datasets that affect them in their entirety. Interaction with items in the project is done by right-clicking them to bring up a contextual menu with all the actions that can be performed on them.

The Project Files Panel

This group of buttons all relate to the current working project. If there is no current working project the **Close**, **Save** and **Save As** buttons will be inactive.

New Begins a new project. If there is already a project open the user will be prompted to save changes, close it, or cancel.

Open Opens an already existing project. If there is already a project open the user will be prompted to save changes, close it, or cancel.

Close Closes the current open project. If there are any unsaved changes, the user will be prompted if they wish to save them.

Save Saves the currently open project.

Save As Saves the currently open project to a new name specified by the user. Take note, this will not create new copies of the TIN, Scan, and Cloud files.

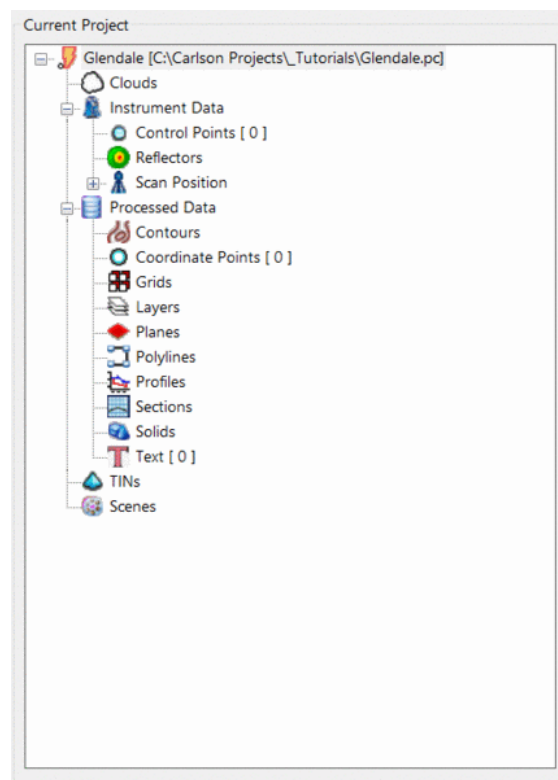

CPC opens Carlson Photo Capture online, Carlson's photogrammetry program that will process image files from a drone into a point cloud. CPC will also generate an orthoimage, DEM, DTM, and project quality report.

Settings Opens the settings dialog box - See **Settings** for further information

Help Opens the Help files for Point Cloud

Exit Leaves the Point Cloud manager

The Project Tree

Projects in Carlson Point Cloud are arranged into a tree structure. Items in projects are divided into two separate

categories: **Instrument Data** and **Processed Data**. **Instrument Data** consists of data in its raw form directly from the scanner that needs to be registered to a common coordinate system. This largely consists of raw **Scans** and the data associated with them (**Target Points**, **Control Points**, **Reflectors**, **Images**, etc). **Processed Data** is data that has been registered to a common coordinate system. **Clouds**, **Contours**, **Coordinate Points**, **Grids**, **Layers**, **TINs**, **Planes**, **Polylines**, **Profiles**, **Sections** and **Text** all fall under this category. **Clouds** are the central data objects to Carlson Point Cloud and upon which most operations are performed.

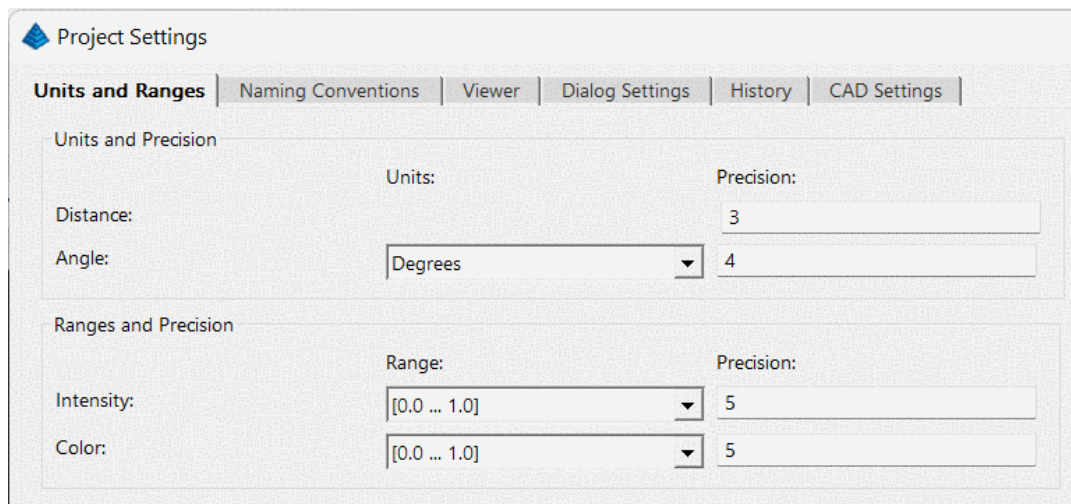

If you have not done anything else yet, you will need to **Import** a point cloud to get started.

Project Settings

The Project Settings dialog allows the user to modify various project-wide settings that fall under several categories: Units and Ranges, Naming Conventions, Viewer, Dialog Settings, History, and CAD Settings. It is usually best upon creation of a project to first go to this dialog and make sure that these settings are ideal for the work to be done.

Units and Ranges

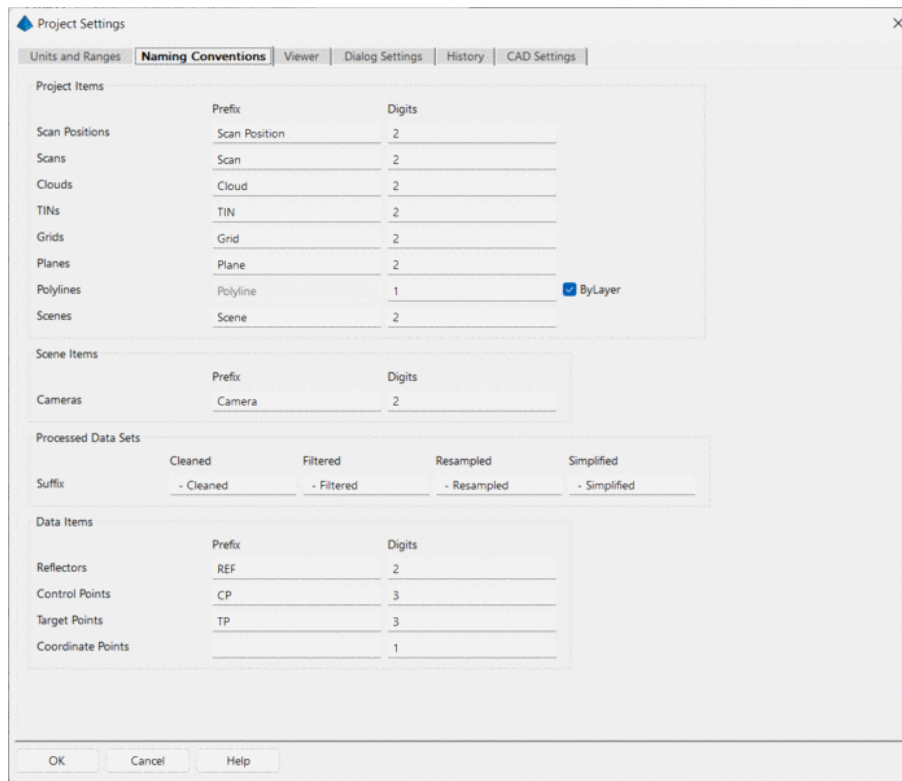

The Units and Ranges page of the Project Settings dialog allows the user to specify their desired working units and their desired ranges and precision for color values retrieved by the scanner.

These values will be internally used by Point Cloud and any values exported from Point Cloud or drawn to any CAD software will be in these units. Point Cloud no longer differentiates between feet and meters because most scanners do not include this information in their exported scans making it impossible to automatically convert. If you need to convert between distance units, use the **Scale Cloud** command.

Naming Conventions

The Naming Conventions page of the Project Settings dialog allows the user to specify the default naming behavior for each of the major item types in Point Cloud.

By default, when objects are created they will be given the names specified in the Naming Conventions dialog followed by the smallest number with the specified number of digits that will give it a unique name. For instance, using the above settings, if a project already has "TIN 01" and "TIN 02" objects and the user creates a third TIN, this third TIN will be given the default name of "TIN 03". Additionally, the user can also specify suffixes to be added to datasets after they have been processed in some manner. Given the above settings, if a TIN, "TIN 01", were simplified with the above settings its simplified TIN would be given the default name of "TIN 01 - Simplified 01". In most cases where new objects are created, the user will have the option to change the new object's name from the one automatically generated from these settings.

Viewer

The Viewer page of the Project Settings dialog allows the user to customize various settings of how the Point Cloud viewer window looks.

General

General settings allow you to define the background and selection colors. Toggling View Multiple Scenes will allow you to have multiple scene viewer windows open simultaneously - default is off which will keep a single scene window open which makes it easier to know which point cloud is being edited at any time. Show Warnings will enable displaying messages (default is on).

Orientation Axes

The Axes options specify the size of the orientation axis as well as its relative position in the viewer. The axes show the orientation of the three axes with respect to the current camera's view direction. Its size is in pixels, so the axes will not scale with the window size.

Bounding Box

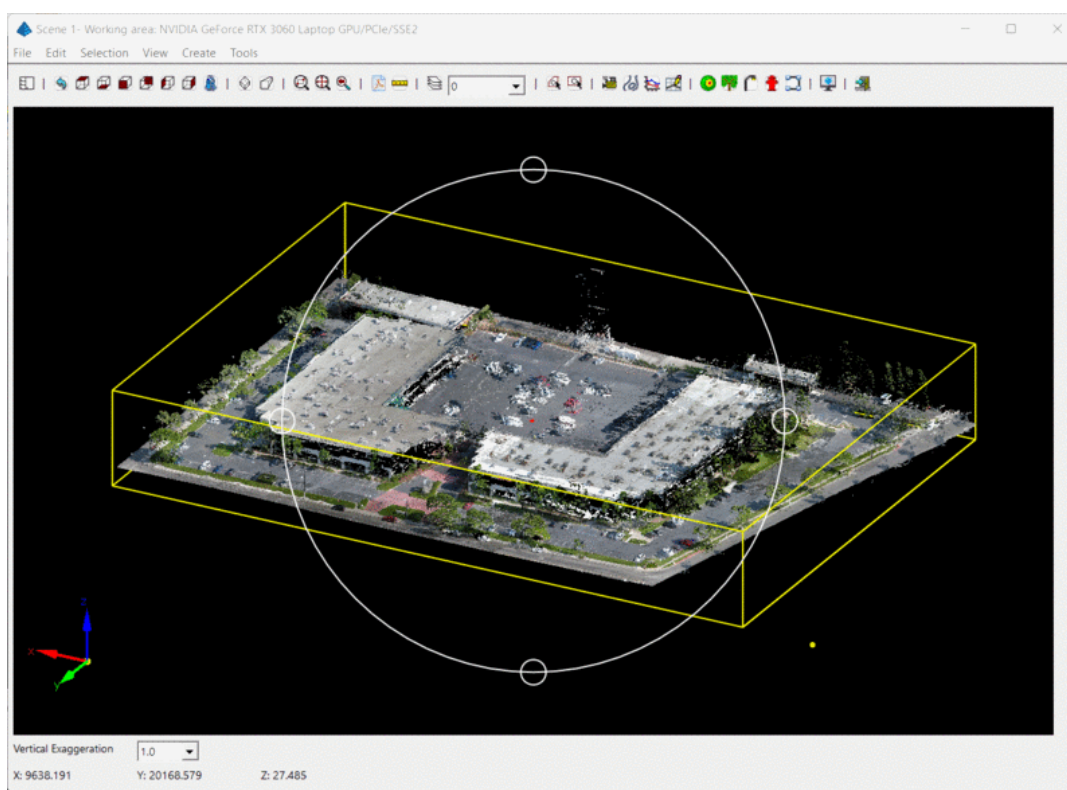

The bounding box options specify the size of the lines (in pixels) that outline the extents of the current object in the viewer as well as their colors.

TIN with its Bounding Box

Orbit

The Orbit options are for drawing a graphical orbit on screen, which is useful for restricting camera movement along a specific axis. When working with the orbit control, dragging with the mouse starting in the small circles on the left and right locks the camera to the x axis, while starting in the circle on the top and bottom locks it to the y axis. Starting a mouse drag outside the big circle locks the camera to the z axis.

Scene with the Orbit Control Enabled

Pivot Point

The Pivot Point and Reference Point settings specify the size and color of the points drawn to represent the current pivot and the current reference point, respectively. The pivot is the current pivot for the camera, which the camera rotates around in Orbit mode and the reference point is the current point of reference which is used in the data page for relative distance checks and some other functions.

Elevation / Range Legend

The Elevation / Range Legend options specify whether to draw the legends for these values (if the current dataset being viewed consists of Elevation or Range data). These legends show the elevation / range values associated with colors values for objects colored by elevation / range. Enable Selection Tooltips are helpful tips that appear when selecting data.

CTRL Key Settings

Ability to choose to use the CTRL key or not with mouse clicks. Three options: Use CTRL Key to Pick, Use CTRL Key to Navigate or Do not use CTRL Key (default). Sound Alert for Failed Snap will warn of missed snaps (default is on)

Default Cloud Point Size

Ability to set the default size of each point cloud node. Value from 1-100. Default Polyline Width allows you to set the polyline width.

Active Polyline Highlight

Ability to display active polyline as either Dashed, Thickened or None (normal). You can also set the Elevation Label and Index Label colors.

Cloud Display Limits

Ability to set the Maximum Cloud Points Per Scene and Maximum Display Density which may improve the software performance for large datasets.

Dialog Settings

Allows you to save and reload settings.

History

Allows you to track and save a history of commands and data with timestamps. You can also auto save at your

desired time interval.

The image shows three stacked settings panels. The top panel, titled 'Command History', contains two checkboxes: 'Log Command History to File' and 'Show Timestamp in Command History Panel'. The middle panel, titled 'Data Objects', contains two checkboxes: 'Show Cloud Timestamps' and 'Sort Clouds by Time'. The bottom panel, titled 'Autosave', features a text input field with the value '15' and the label 'minutes'.

Cad Settings

Allows you to draw all points, polylines, and text to the CAD automatically. Note that if you are planning on creating a large amount of data toggling on this feature will slow you down. If that is the case, use the draw polylines and draw using field-to-finish options from the project tree for faster results. Toggling on Draw Polylines in 2D will force the polylines to zero elevation.

Toggling on Use CAD's CRD for Point Cloud's Coordinate Points will link the CAD project coordinate file (CRD) with the point cloud project. This is practical when you have existing points in the CAD file as it will prevent the need to renumber points and accidentally overwriting point data.

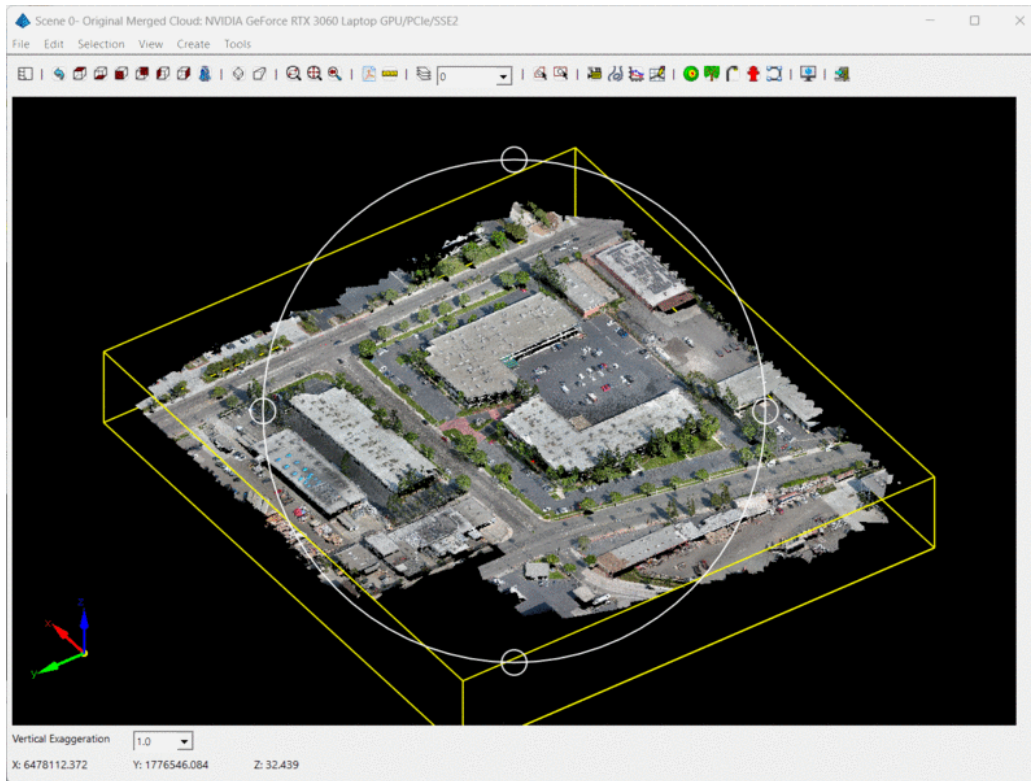

The image shows two stacked settings panels. The top panel, titled 'Auto Draw', contains two checkboxes: 'Automatically Draw All Points, Polylines, and Text to CAD' and 'Draw Polylines in 2D'. The bottom panel, titled 'CAD CRD', contains one checkbox: 'Use CAD's CRD for Point Cloud's Coordinate Points'.

Tab Location(s): Project Tab

Prerequisite: Open Point Cloud project

PointCloud Viewer

The Carlson Point Cloud viewer is where all virtual surveying and visual inspection of data is done. It has both 2D view mode functionality for viewing images and scans (as a flat image) as well as 3D view mode for viewing three dimensional data. Drawing in the viewer is divided into two different modes, dynamic and static. Dynamic mode draws a greatly reduced version of the current scene to improve draw speeds, while static mode will draw the full detailed scene. Typically, the viewer will run in dynamic mode when the user is attempting to do something interactive that involves camera, such as rotating the scene or zooming in, and it will draw in static mode when the camera isn't being manipulated. Options that pertain to how much detail is drawn in the current scene in dynamic and static mode can be changed in the Scene page of the Project Manager.

By default, the left mouse button operates in an orbit mode similar to the 3D viewer in the Carlson Civil Suite, the middle mouse button pans, and the right mouse button zooms. Mouse behavior for the current viewer can be changed in the **Camera Tab** of the Project Manager.

The toolbar and the menu at the top of the viewer have several shortcuts to functions commonly used in the Camera page. These icons and their functions are as follows (from left to right):

Tile Windows will align the Project Manager window with the Viewer window next to each other on screen.

View Reset will reset the view to its original extents and camera position.

View Top places the camera directly above and set to the extents of scene's bounding box.

View Bottom places the camera directly below and set to the extents of scene's bounding box.

View Front places the camera directly in front (negative Y axis) and set to the extents of scene's bounding box.

View Back places the camera directly in the back (positive Y axis) and set to the extents of scene's bounding box.

View Left places the camera directly to the left (negative X axis) and set to the extents of scene's bounding box.

View Right places the camera directly to the right (positive X axis) and set to the extents of scene's bounding box.

Scanner position moves the camera to the position of a scan in the scene, if there is more than one scan this button will cycle through each of the scanner positions. If the project has no scanned positions, the scene will not change.

Orthographic Projection sets the camera to parallel, orthographic, projection mode.

Perspective projection sets the camera to perspective projection mode. When in this mode, you can set the points to be displayed using *Perspective Point Sizing* from the Scene tab > Cloud. This will make the points closer to the camera look larger than those farther away.

Zoom To Window allows the user to select an area to zoom into. First click will place the first vertex of the zoom window and the second click will complete it and zoom the viewer to fit the window.

Zoom extents moves the camera to show the extents of the full scene, if in parallel projection mode, changes the width of the projection to fit the scene.

Zoom Previous resets the Point Cloud viewer to the previous view limits and orientation.

Save PDF will save the current view to a PDF format with borders and user specified title block information.

Distance Click this icon to check distances between points. Distances will be reported in Command history window. Click this icon a second time to end the distance function.

Layer Manager button opens the **Layer Properties Manager** dialog box.

Layer Selector Allows the user to select which layer to display.

Select Window Inside instigates the *Selection Set by Window* action using inside cloud points method. You will be prompted to pick the first and second point for the window and the selected cloud points will be highlighted when completed.

Select Perimeter Inside instigates the *Selection Set by Perimeter* action using inside cloud points method.

Extract Bare Earth opens the *Extract Bare Earth* window. You can choose from three different methods: *By Expansion, By Grid, or By Profile*. For more information open the **Bare Earth Extraction** help page.

Extract Contours opens the *Extract Contours* window. For more information open the **Extract Contours** help page.

Extract Profile starts the profile extraction tool. For more information open the **Extract Profile** help page.

Extract Sections starts the cross section extraction tool. For more information open the **Section Extraction** help page.

Create Point starts the create point tool. For more information open the **Point Creation** help page.

Extract Tree starts the extract tree feature tool - under the *Point Creation* actions. For more information open the **Point Creation** help page.

Extract Pole starts the extract pole feature tool - under the *Point Creation* actions. For more information open the **Point Creation** help page.

Extract Hydrant starts the extract hydrant feature tool - under the *Point Creation* actions. For more information open the **Point Creation** help page.

Create Polyline starts the create polyline tool. For more information open the **Polyline Creation** help page.

Set CAD view to current view will set your CAD drawing view to match the current scene view.

End Action will end or exit any active tools. Note that some modes can also be ended via right-click and/or the Escape key.

File Menu

- **Save PDF** Exports the current onscreen view to a PDF.
- **Exit** Closes the current viewer window only. To close the point cloud project and all open windows use the Exit button on the *Project tab* of the *Point Cloud Project Manager* window.

Edit Menu

- **Show All** shows any points which have been hidden via the Hide command.
- **Hide** hides selected points.
- **Delete Selected** deletes selected points from a Cloud or TIN.
- **Crop to Selection** crops the cloud the cloud to the selected points.
- **Transform Wizard** will open the *Transform Cloud* where transformations including translations and rotation can be applied.
- **Scale** grows or shrinks selected items.

Selection Menu

All of the same functions that can be found on the **Action Tab** along with the ability to show more information about the current selection by clicking on **Information**.

View Menu

Shows all of the available options to change the current view - similar to the options in the *Toolbar* along with the option to open the **Layer Properties Manager**.

Create Menu

In here the user has all of the functions that can be found in the Shortcuts Toolbar along with options that are found in the Create Panel within the **Action Tab**.

Tools Menu

- **Distance** Click on this to check distances between points. Slope, Horizontal and Vertical Distances will be reported on screen and in the Command history window. Click this icon a second time Right click to end the distance function.
- **Cloud**
 - **Clean** Will open the **Clean Cloud** dialog.
 - **Resample** Will open the **Cloud Resample** options.
 - **Bare Earth** Changes the mode to **Bare Earth Extraction**. Hold the Ctrl key while clicking on the scanner position to start extraction. Bare Earth works only in Plan View (viewing from Top).
- **TIN** - See **TINs** for more information
 - **Clean** To remove spikes from a TIN or noise points from a cloud
 - **Simplify** Reduces the size of the TIN surface so that it can be transferred over to CAD software
 - **Smooth** Allows the user to create a new TIN or modify the existing TIN
 - **Image** Ability to import an existing Geo-referenced image (bmp, jpg, tiff, tiff) onto a TIN

Orbit

The Orbit guide displays a primary circle with circles at the cardinal directions. These circles help guide the user when performing three dimensional rotations of the scene.

The Bounding Box

The scene bounding box is an axis-aligned box that encompasses the full range of the data currently in the scene. The bounding box is used indirectly in several functions that affect the entire scene.

The Pivot Point

The current camera pivot is represented by a point in the scene, which is red by default. When the camera is working in Orbit mode, this point is the point that the camera orbits around when you drag the mouse. By default, this point moves to the valid data nearest to your cursor when you press the left mouse button in Orbit mode, but this behavior can be changed in the **Camera Tab**.

The Reference Point

The current reference point is represented by a point in the scene, which is yellow by default. It is used for preliminary data checking without having to create any objects in the project itself. All functionality that uses the reference point can be found on the **Data Tab**.

The Elevation and Range Legend

The elevation and range legends display the range of elevation/range colors and the values associated with those colors in the current scene. The values associated with each color are not absolute and can change from scene to scene. Elevation coloring ranges from Blue, as the minimum elevation, to Red, as the maximum elevation, while range coloring ranges from white being the closest point to black for the furthest. The ranges for range coloring are calculated from the distance between the origin to the current point in clouds and TINs, while for scans the scanner position is used.

The Orientation Axes

The orientation axes are the red, blue, and green arrows that are located in the bottom left of the viewer by default. These show how the current camera's view direction relates to the world axes and can be useful when determining what direction the camera is looking in. The red arrow is the x axis, the green arrow is the y axis, and the blue arrow is the z axis. The size and position of the orientation axes can be changed in the **Project Settings** dialog.

Vertical Exaggeration

You can select different vertical exaggeration values from the pull-down menu to affect the display of vertical distances in the scene viewer.

The Status Bar

At the bottom of the viewer is a status bar that is divided up into four blocks. The leftmost three of these blocks display the x, y, and z position information of the data under the cursor (if it is valid data), and the fourth block displays any prompts to the user that may be important.

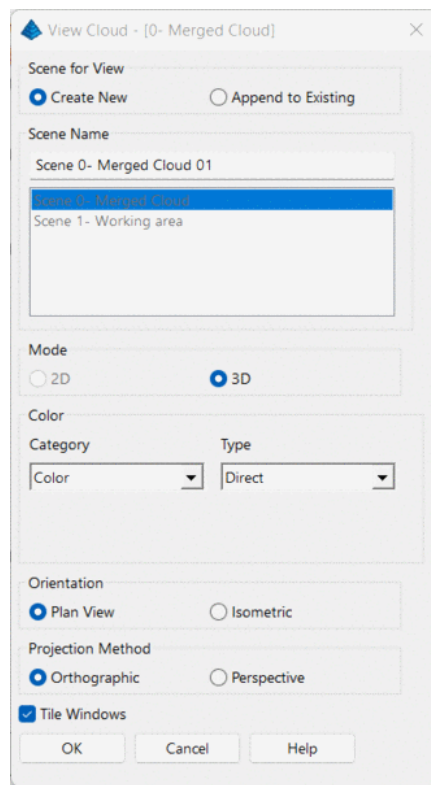

Customizing the Viewer

There exists several options for customizing the Point Cloud viewer; these options can be found in the **Project Settings** dialog, which can be accessed from the **Project Tab** of the **Project Manager** at the top of the window. See documentation on the Project Settings for more information about these options.

Scenes

Scenes are 2D or 3D displays of various data types in the viewer. Multiple objects can be viewed in a single scene or you can set each item is an independent scene. To create a scene:

- **Right-click** the object you want to view in the new scene.
- **Select View** and the View window will open.

note: If a scene already exists for the selected object, you will be prompted to view the existing scene or create a new one. The program will prompt to close the currently open scene before opening the new scene. These options can be changed in Project Settings.

The Scene for View panel determines whether to create a new scene or to append the selected object to an existing scene.

Create New: with this option selected, you will need to enter the **Scene Name**. The program will suggest scene name using the conventions found in Project Settings.

Append to Existing: with this option selected, you will append the selected object to an existing scene. Select the target scene from the list.

The **Mode** panel determines the dimensions to view the data in, **2D** or **3D**. Viewing the data in **2D** mode will only be available if the dataset can be laid out on a two dimensional plane (scans, profiles, and images). Additionally, selecting **2D** mode will not add a new scene to the project, it will only create a temporary scene to view the data in, because there is no reason to view multiple objects in the same 2D view (the objects would all obscure each other).

The **Color** panel determines the mode to color the data in. There are eight modes that are contextually available depending on the type of data and selected mode to be drawn in. These color modes are divided into categories based on how the colors are determined, these categories are: **Simple**, **Position**, **Intensity**, and **Color**. Selecting **Simple** will color the entire dataset in the same color, **Position** colors each point based off its world positioning data, **Intensity** colors each point based off of its single intensity value, **Direct** colors the points based off their color information.

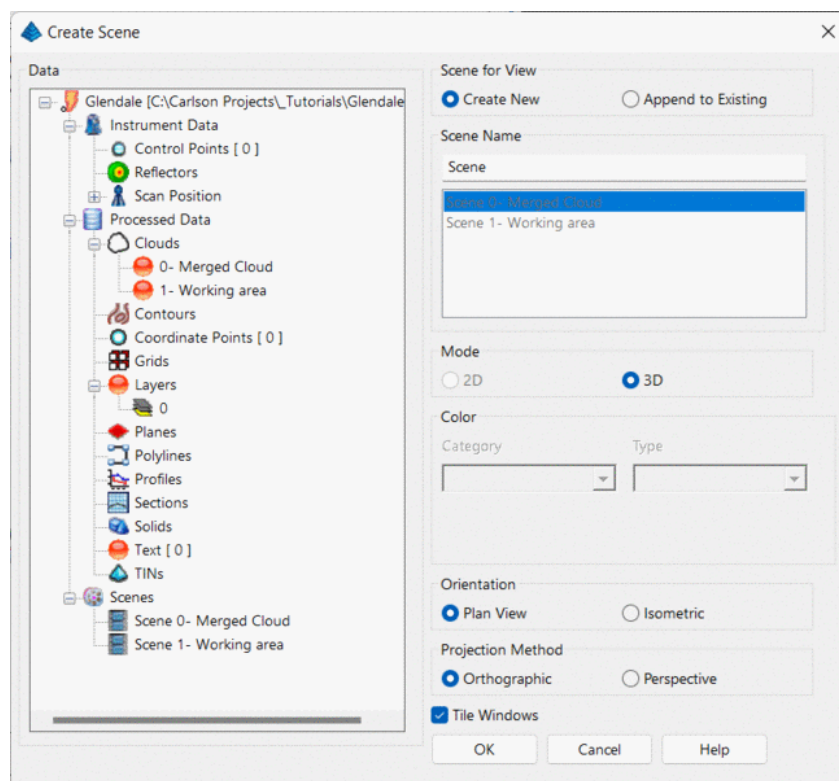

The **Simple** category only has the **Direct** color mode which colors the entire dataset a single color. Once the scene has been created, you can choose the color from the Scene tab of the Project Manager, under the Color Mode options.

The **Position** color category has three color modes: **Elevation** which colors each point in a range from blue being the minimum elevation value to red being the maximum color value, **Range** which colors each point based off its distance from the origin (or scanner if the current object being viewed is a scan), black being the minimum distance and white being the maximum, and **Normal** which colors each point based of the normal of the surface at that point. In the **Normal** mode, each color dimension (red, green, and blue) are assigned a spatial dimension (x, y, and z) to represent that direction in the objects finally color. Note that some of these options are dependent on the data set containing pertinent information.

The **Intensity** color category has three color modes: **Direct** will color each pixel in the range from black to white based off its intensity value, **Scaled** will scale the range of intensities so that the minimum intensity in the data set matches up with zero and the largest intensity in the data set will match up with the maximum possible intensity value, which can make minor changes in intensity more noticeable, and **Equalized** will perform a similar scaling operation but do it in a manner that will equalize the histogram of the intensity values, making it so that all intensity values occur equally often, this method can also make minor changes in the intensity much more noticeable.

The **Color** category has two color modes: **Direct**, which colors each point directly by its internal color value, and **Grayscale** which colors each point by the grayscale representation of its internal color value.

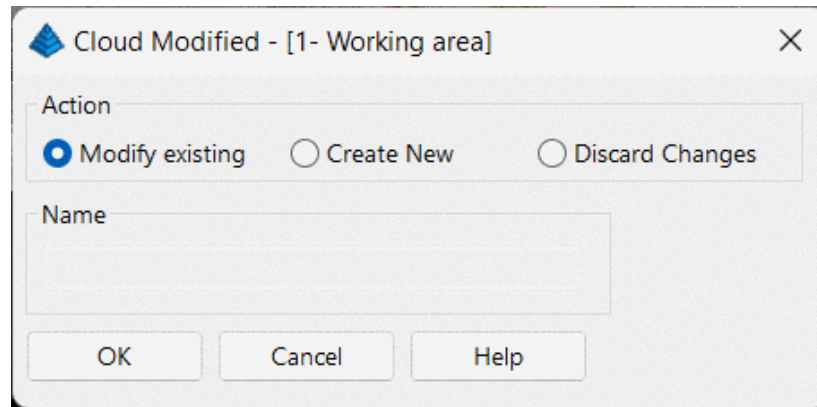

In addition to the above method of scene creation, you may also create a scene by right clicking the scenes folder and selecting **Create New** from the menu. This method will allow you to create a scene with multiple objects in it without having to go through the dialog several times.

The right half of the dialog is the same as single object viewing, but the left half of the dialog shows a tree structure representing objects in the project that can be added to the scene. Click on the red/green bubble icon next to an object to toggle on/off the inclusion of that object in the scene.

When viewing any of the large object types (scans, TINs, and clouds) there is only one copy of that object retained

in memory at all times. This is done to preserve memory as much as possible when opening up multiple views of the same object. This also means that any changes made to the object in one view will be reflected in all other views of that object. For instance, if you're viewing a scan in two views and wish to clean up its data, deleting points from the scan in one view will change the scan in any other views of it. When all views of an object have been closed, the object modified dialog will be displayed prompting the user for an action to perform with the modified data.

This dialog is very similar to the action panel found in many other dialogs. **Modify existing** will save the changes to the original object and **Create new** will allow the user to specify a name for a new object of that type with the modified data. **Discard Changes** will close the scene without saving changes.

Data Objects

There are several data types in Carlson Point Cloud including instrument and processed data. These items are organized into a tree structure in the project tree and can be manipulated by right clicking to bring up a menu specific to that item type. Depending on the complexity of the selected object, a menu may not pop up or a menu with several options may pop up.

There are several functions that are shared among these object types. For brevity, these functions are listed here.

Object Action Panel

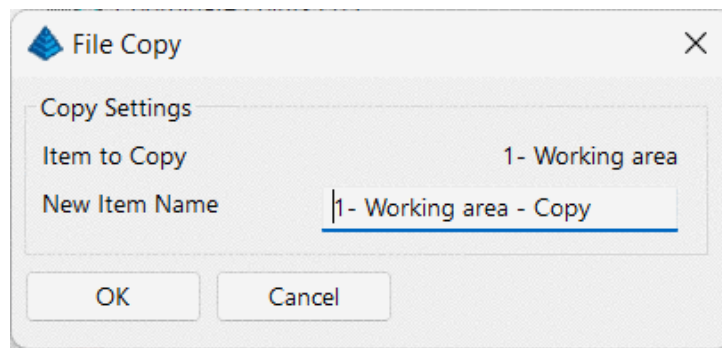

In functions that can manipulate the dataset, for example clean, resample, and bare earth point cloud filters, the topmost set of options in the dialog will allow you select whether you want to create a new point cloud or modify the point cloud or specific object as well as chose a name for the new data set when create new is selected.

Modify Existing will modify the current underlying object in the project, while the **Create New** will add a new object to the project in the same folder as the object being manipulated, with the **Name** option specifying the name of the new object.

Copying an Object

If an object has external data, such as a cloud, scan, or TIN, it may be useful to preserve the original data in case changes are made to it that are unrecoverable. Selecting **Copy** will bring up the copy object dialog.

The new item will be added to the same folder as the source item, with the name chosen.

Removing an Object

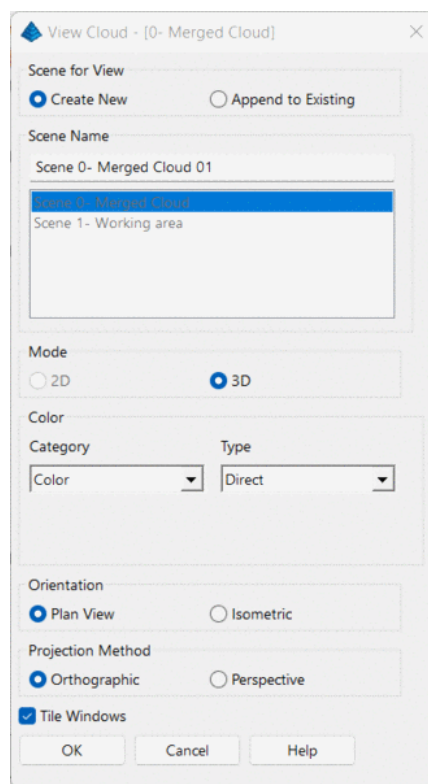

If an object can be removed from the project, there will be a **Remove** option in the right-click menu for that object. If the object has external files (scans, TINs, and clouds) you will be prompted if other files associated with this item are to be deleted or not.

Renaming an Object

To rename an object, right-click it and select **Rename**. If you try to assign that object a name that already exists elsewhere in the folder that object is in, Point Cloud will revert the change back to its old name.

Viewing an Object

If an item has data that can be viewed (in either two dimensions or three dimensions), there will be a **View** option in the right-click menu for that object. Upon clicking **View**, the **View Object** dialog will be displayed.

With **Create new** selected, you can input the name for the new scene in the **Scene Name** field. After clicking **OK**, the program determines whether a scene is already associated to that object. If none is found, the new scene window will open. If a scene is already associated to the object, you will be prompted whether to open the existing scene or

create a new one - if you do not want to be prompted this can be changed under Settings. If **Append to existing** is selected, the list of scenes in the project will become enabled allowing you to select the existing scene unto which the object will be added.

The **Mode** panel determines if the data will be viewed in 2D or 3D dimensions - defaults is 3D. Viewing the data in **2D** mode will only be available if the dataset can be laid out on a two dimensional plane (scans, profiles, and images). Additionally, selecting **2D** mode will not add a new scene to the project, it will only create a temporary scene to view the data in, as there is no reason to view multiple objects in the same 2D view (the objects would all obscure each other).

The **Color** panel determines the mode to color the data in. There are eight modes that are contextually available depending on the type of data and selected mode to be drawn in. These color modes are divided into categories based on how the colors are determined, these categories are: **Simple**, **Position**, **Intensity**, and **Color**. Selecting **Simple** will color the entire dataset in the same color, **Position** colors each point based off its world positioning data, **Intensity** colors each point based off of its single intensity value, **Direct** colors the points based off their color information.

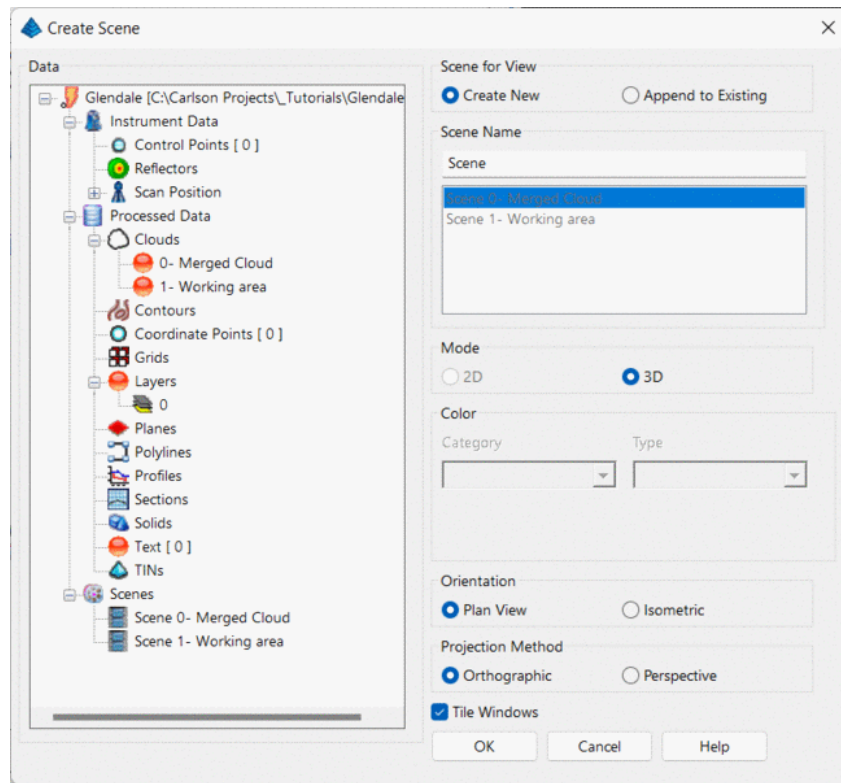

The **Simple** category only has the **Direct** color mode which colors the entire dataset a single color. Once the scene has been created, you can choose the color from the Scene tab of the Project Manager, under the Color Mode options.

The **Position** color category has three color modes: **Elevation** which colors each point in a range from blue being the minimum elevation value to red being the maximum color value, **Range** which colors each point based off its distance from the origin (or scanner if the current object being viewed is a scan), black being the minimum distance and white being the maximum, and **Normal** which colors each point based of the normal of the surface at that point. In the **Normal** mode, each color dimension (red, green, and blue) are assigned a spatial dimension (x, y, and z) to represent that direction in the objects finally color. Note that some of these options are dependent on the data set containing pertinent information.

The **Intensity** color category has three color modes: **Direct** will color each pixel in the range from black to white based off its intensity value, **Scaled** will scale the range of intensities so that the minimum intensity in the data set matches up with zero and the largest intensity in the data set will match up with the maximum possible intensity value, which can make minor changes in intensity more noticeable, and **Equalized** will perform a similar scaling operation but do it in a manner that will equalize the histogram of the intensity values, making it so that all intensity values occur equally often, this method can also make minor changes in the intensity much more noticeable.

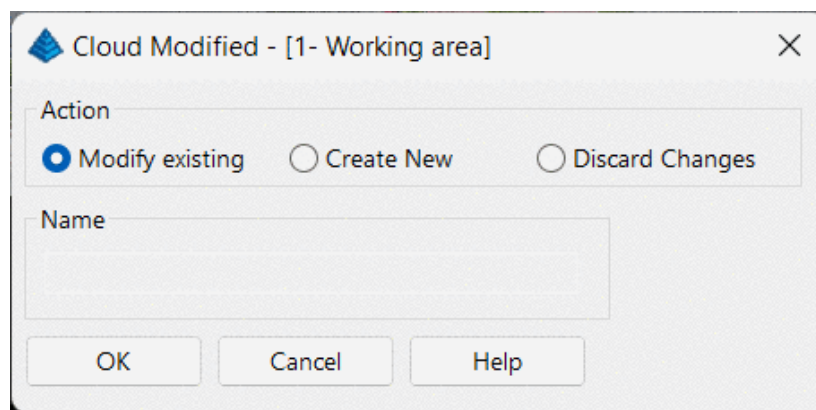

The **Color** category has two color modes: **Direct**, which colors each point directly by its internal color value, and **Grayscale** which colors each point by the grayscale representation of its internal color value.

In addition to the above method of scene creation, you may also create a scene by right clicking the scenes folder and selecting **Create New** from the menu. This method will allow you to create a scene with multiple objects in it without having to go through the dialog several times.

The right half of the dialog is the same as single object viewing, but the left half of the dialog shows a tree structure representing objects in the project that can be added to the scene. Click on the red/green bubble icon next to an object to toggle on/off the inclusion of that object in the scene.

When viewing any of the large object types (scans, TINs, and clouds) there is only one copy of that object retained in memory at all times. This is done to preserve memory as much as possible when opening up multiple views of the same object. This also means that any changes made to the object in one view will be reflected in all other views of that object. For instance, if you're viewing a scan in two views and wish to clean up its data, deleting points from the scan in one view will change the scan in any other views of it. When all views of an object have been closed, the object modified dialog will be displayed prompting the user for an action to perform with the modified data.

This dialog is very similar to the action panel found in many other dialogs. **Modify existing** will save the changes to the original object and **Create new** will allow the user to specify a name for a new object of that type with the modified data. **Discard Changes** will close the scene without saving changes.

Drawing an Object to CAD

If an object can be drawn to the CAD, there will be a **Draw** option in the right-click menu for that object. Clicking **Draw** will bring up options specific to the selected object. For example, if points are selected, you will have an

option to use Field-to-Finish or Draw points; if Draw is selected, options for point range, to add to the Carlson project CRD file and to renumber will be displayed. If polylines are selected, a layer selection dialog will display allowing you to select the layers that contain the polylines to be drawn in CAD. Objects will be drawn in their current coordinate system (if two scans are properly registered, they will be properly aligned with each other when drawn to the CAD engine).

Points

There are three kinds of point item types in Carlson Point Cloud: control points, target points, and coordinate points.

Target points always exist as a sub-item of a scan position and are in that scan position's local coordinate system. This means that a project can have several sets of target points (one for each scan position).

Control points are the global positions of the target points, and are a sub-item of the **Instrument Data** folder. There can be only one set of control points for a project.

Coordinate points are points extracted from the final registered data sets and are a sub-item of the **Processed Data** folder. Coordinate point positions are in the same coordinate system of the data from which the extraction is performed on.

All point types have the same right-click menu options.

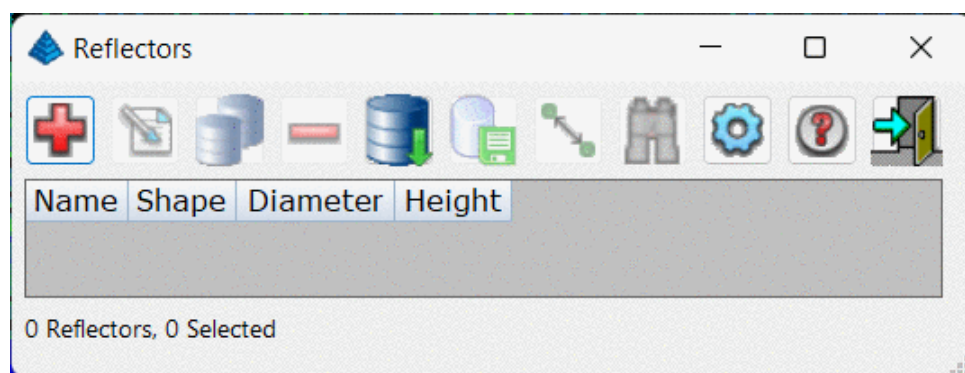

Polylines

Polylines are usually extracted from the registered data, but they can also be imported or manually entered with the **Import** and **Edit** commands. Polyline importation is very similar to importing a set of points; see the documentation for data points for more information. The edit brings up the Point Editor; see the documentation on the point editor for more information.

Reflectors

Reflectors in a Point Cloud project represent a disk, sphere, or cylinder reflector within the set of scans for the current project. Each reflector can be linked to a control point which will enable Point Cloud to account for the shape of target points that are to be linked with that control point during the scan registration process.

These reflectors can either be imported from an ASCII text file with the **Import** command or entered in manually with the **Edit** command. Pressing **Edit** will bring up the point editor dialog with some specialized options for reflectors.

The only difference between this point editor and the one used for the various point objects is that the **Add Reflector** button will bring up a different dialog that allows you to specify the properties of the new reflector.

Name will specify a unique name to be used for the reflector in the registration process.

Shape is a dropdown with three options relating to the three reflector shape types (disk, cylinder, and sphere).

Diameter allows you to specify the diameter of the sphere, cylinder, or disk objects.

Height is accessible only for the cylinder reflector type and specifies the height of the cylinder.

After all the reflectors have been added to your project, linking them to their corresponding control points is done through the control points editor. See the documentation for the Point Editor for more information.

Images

Images are stored in a folder as a sub-item of a scan position. There can be multiple images per scan-folder, and typically are pictures taken from the position of the scanner. Images can only be viewed in 2D mode.

Coordinate System

The Coordinate System is the current transformation applied to a Scan Position. This transformation is applied to any scans that belong to the current scan position. Typically, manual modification of the coordinate system should not be necessary, as the proper coordinate system to align scans properly should be determined during the registration process. To modify the coordinate system for a scan position, right-click it and select edit. This will bring up the Coordinate System editor.

The transformation panel displays the transformation matrix that is applied to the scan position. The two buttons along the bottom are **Import**, and **Export**. See the documentation on the Point Editor for information about these functions.

Contours

A contour item consists of several contour polylines that have been extracted from a TIN. Contour objects can only be viewed in 3D mode and drawn to the CAD engine. Contour extraction is done through the Action Tab, for more information on how to extract contours, see the documentation for Extract Contours in the Action Tab.

Grids

Grids are rectangular representations of a cloud typically used to instead of TIN. The grid file that is created by Point Cloud has a PCG extension. Point Cloud grids are saved to the Grids folder under Processed Data in your project folder. To share grids created in Point Cloud with other Carlson modules right-click the grid you want and select export. A GRD file will be exported. Grids created in other Carlson modules can be imported into Point Cloud by right-clicking Grids and selecting **Import**. For more information on how to create a grid, see the documentation for Create Grid in the Action Tab.

Profiles

A profile consists of a set of height values and distances taken along a polyline extracted from a cloud. Profiles can be viewed in 2D and 3D mode and drawn to the CAD engine. Additionally, profiles can be extracted to the .pro file format. Profile extraction is done through the Action Tab of the Project Manager. For more information on how to extract profiles, see the documentation for Extract Profile in the Action Tab.

Sections

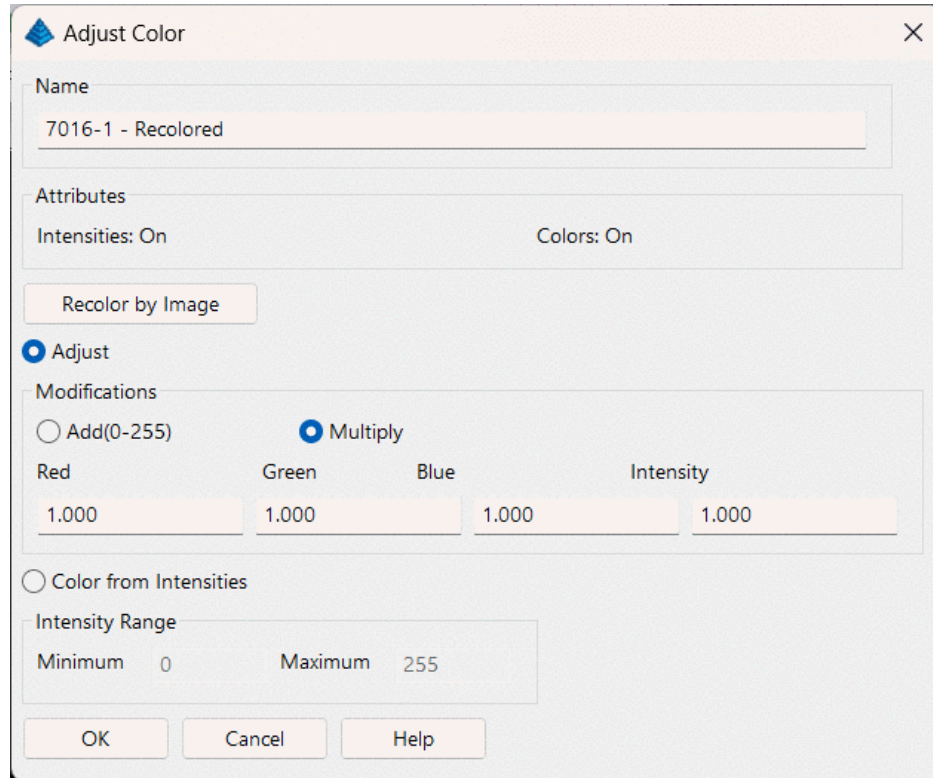

A section object consists of a list of profiles taken at certain distances along a polyline. Sections can be extracted from a cloud using the Action Tab in the Project Manager. Sections can only be viewed in 3D mode and can also be drawn to the CAD engine. Additionally, sections can be extracted to the .sct file format. See the Extract Section documentation in the Action Tab for more information about how to extract sections.

Scenes

Scene objects maintain a list of objects that are in the scene, graphics properties for those objects, and camera information for the scene. If a scene is closed and then reopened, these properties should still be the same.

Adjust Color

To adjust the color, **right-click** on a Cloud in the project tree and select **Adjust Color**. This will open the **Adjust Color** window.

Enter a name for the new Cloud.

By clicking on **Recolor by Image**, the software will ask the user to select a Geo-referenced image to use to color the pointcloud. If the image does not have an associated georeferenced world file, the software will use a best guess method to drape the image over the points. **Note:** doing this will amend existing RGB values or assign an RGB value to each point.

Under the **Modifications** panel, the user can select **Add** or **Multiply**. By selecting **Add**, Red, Green, Blue and/or the Intensity values can be altered by adding the entered value to each entity. By choosing the **Multiply** option, the existing values will be magnified by the values entered.

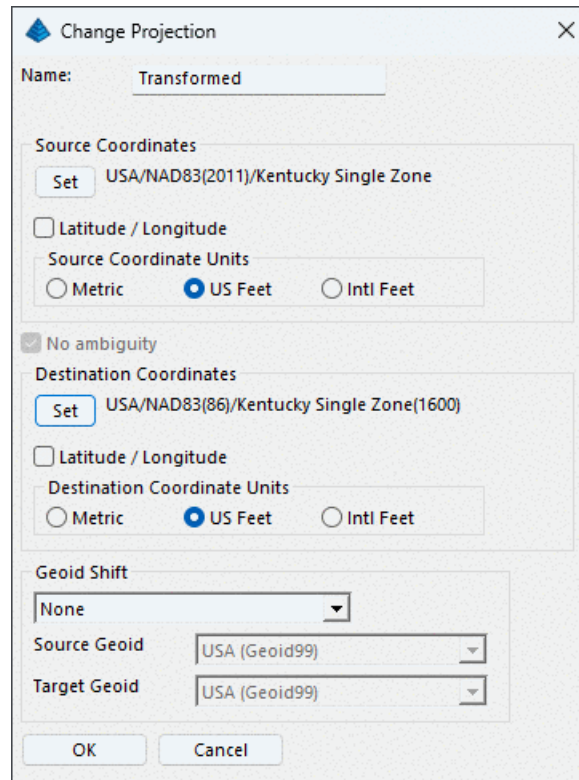

By selecting **Color from Intensities**, you can adjust the point cloud color by a **Minimum** and **Maximum** intensity range.

Click the **OK**. The new cloud will be added under the Clouds section in the project tree.

If you have an open **Scene**, the program will prompt if you want to view the newly created cloud and then prompt if you want to close the current Scene window. You can change the prompts in the Display Settings from the main Project tab.

Change Projection

To create a new Cloud using a different Coordinate projection, **right-click** on the cloud you want to change, select **Transform** then chose **Change Projection**.

Enter a name for the new cloud.

To specify **Source Coordinates**, click the **Set** button to select the **Projection**. If the source coordinate are not loaded, you will need to add a predefined system, add a project from a file, or enter a user-defined system. Alternatively, you can select using Latitude/Longitude. Make sure to select the appropriate **Source Coordinate Units**.

Then, in the **Destination Coordinates** panel, click the **Set** button to select the destination **Projection**. Similarly, if you the destination coordinates are not loaded, you will need to add a predefined system, add a project from a file, or enter a user-defined system. Alternatively, you can select using Latitude/Longitude. Make sure to select the appropriate **Destination Coordinate Units**.

Click the **OK**. The new cloud will be added under the Clouds section in the project tree.

If you have an open **Scene**, the program will prompt if you want to view the newly created cloud and then prompt if you want to close the current Scene window. You can change the prompts in the Display Settings from the main Project tab.

Control Point Editor

Control points are the global positions of the target points, and are a sub-item of the **Instrument Data** folder. There can be only one set of control points for a project. There are two ways to manipulate Control Points: the **Right-Click menu** or the **Control Point Editor**.

Note: Several commands are available in both the **Right-Click menu** and in the **Control Points Editor**. A command in the Right-Click menu operate on all control points. The Control Points editor commands operate on only the selected Control Points. If no control points are selected the users is asked if they wish to perform the operation on all control points.

Edit
Delete All
Import
Export
Transform

View

Draw

Launches the Control Point Editor

Deletes all Control Points. The user is prompted via a dialog box to confirm the deletion.

Launches the ASCII file import dialog box.

Launches the ASCII file export dialog box.

Launches the Transform dialog box to allow the user to define a transformation sequence to apply to the control points.

Launches the Scene creation dialog box to create a scene for viewing the control points.

Draws the Control Points in CAD. The user is prompted via a dialog box for the layer to draw the Control Points on.

To open the **Control Point Editor**, right-mouse click on **Control Points** under **Instrument Data** in the **Current Project** tree and then select **Edit**.

Along the top is a toolbar with several icons:

Activate Control Point toggles the selected control point(s) to be active in the current project.

Deactivate Control Point toggles the selected control point(s) to be inactive in the current project.

New Control Point brings up a dialog that allows users to specify the properties of a new control point to add.

Edit Control Points brings up the point edit dialog which allows users to change properties of the currently selected **Control Point**.

Copy Control Points allows users to copy the currently selected Control points to another point set (such as from the control points to the target points of a scan).

Delete Control Points deletes the currently selected control points.

Import Control Points brings up the ASCII file import dialog.

Export Control Points brings up the ASCII file export dialog.

Transform Control Points allows users to define a transformation sequence to apply to the control points.

View Control Points brings up the scene creation dialog to create a scene for viewing the current control point set.

Settings allow users to configure what properties of the control points are visible in the spreadsheet control.

Help brings up help documentation.

New Control Point

Name will specify a unique name to be used for the Control Point in the Project.

X, **Y** and **Z** are the coordinates of the Control Point.

Description allows users to add information that describes the new Control Point.

Target Points allows the user to specify **Target Points** from any **Scan** to be referenced to the new **Control Point**.

Add adds a new reference **Target Point**.

Edit allows the user to edit the selected reference **Target Point**

Delete deletes the selected reference **Target Point**

Import Control points

Clicking the **Import** button opens the **Import Control Points** window. Navigate to the correct file and click **Open**.

Currently supported file import types are **TXT**, **CSV**, **CRD** and **CRDB**.

Once the file has been opened, the **Import Control Points** dialog will display.

Click on the **Preset** drop-down to select the format that matches coordinates in the control points file you will import. Once a preset is selected, you will see the column headers populate with the corresponding titles. Verify that the **Delimiter Type** is set correctly if the data fields/columns are not populated correctly. Click on the **Import** check mark on the left to select or deselect points, then click **OK** to import the selected control points.

On the **Import Control Points** window, selecting **Rename all items** will rename all imported points to the settings specified in the **Naming Conventions** settings. If the **Rename all items** toggle is not selected the names listed in the file being imported will be used. If there are no names in the file being imported and **Rename all items** is not selected, the control points will be named using the settings in **Project Settings** naming conventions. The **Duplicate Entries** panel allows users to specify the action to take when a point being imported has a name that already exists in the set of points being imported to. Click **OK** to import the points.

Exporting Points

Clicking the **Export Points** button will open the **Export Control Points** window, which allows users to export the data to several different file formats.

In the **Columns** panel, click on the check boxes to include or exclude the data elements. To change the order of the data elements in the file, click on the element and then click the up or down arrows to adjust its position.

The **File** panel determines which file format to export to and also allows you to specify an extension other than the default for a given file format.

The **Text** panel contains options when exporting to the different text file types, **ANSI Text** or **Unicode Text**. The **Delimiter Type** determines the divider between data elements in the file. The **Write header** option specifies whether to write a header line to the file detailing the data ordering of the file.

Microsoft Excel allows the user to define the name of the Excel worksheet that the points will be exported to. **Note:** only available when exporting as **Format: Microsoft Excel**.

XML allows users to define the **Root** and **Collection** values and choose to **Format data**. **Note:** only available when exporting as **Format:XML**.

GCP - when exporting as GCP, click on the **Set** button to choose the Coordinate Projection. Users can choose to select a Pre-Defined projection, add a projection from a file or create a User-Defined projection on the fly. Click **OK** to select and return to the previous window. Users can select to export the coordinates in Latitude/Longitude format and also to select the appropriate units; **Metric**, **US Feet** or **International Feet**.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organize the elements into the desired order and then click the **Green Plus** button next to the drop-down. The new preset will be added to the drop-down menu for

future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** button next to the **Presets** drop-down menu.

Transform Points

The **Transform** button opens the **Transform Coordinate Points** window where users can define a selection of transformation parameters to apply to the selected Coordinate Points.

Initially, the dialog will have no transformations specified. To add a transformation, press the **Add** button, which will open the **New Transformation** window. Use the Type drop-down menu to select one of the four Transformation types:

Translate allows the user to define a translation of the current data set by specifying offsets in X, Y and Z.

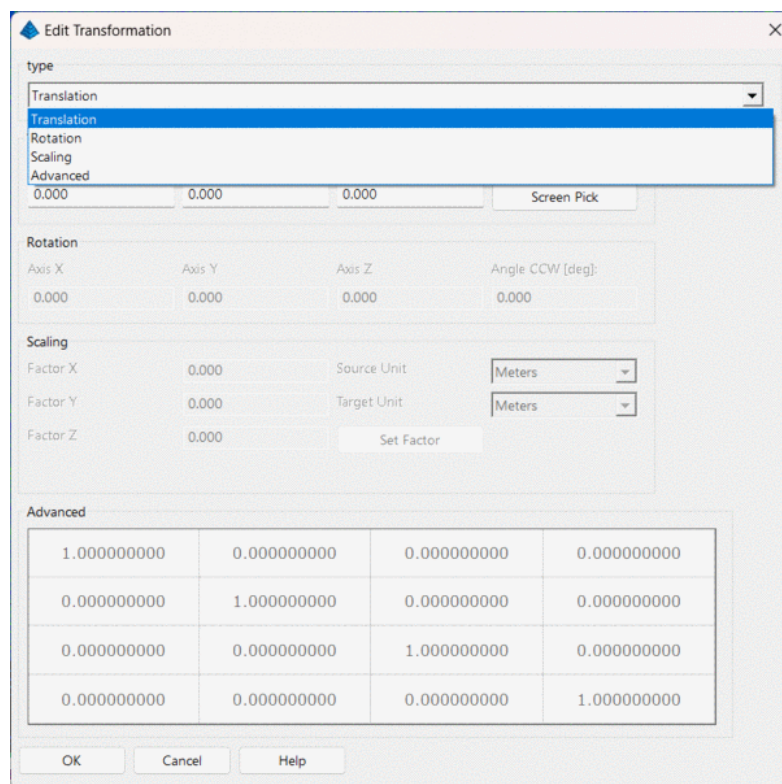

Rotation allows the user to rotate the current selection set by specifying rotations around the X Y and Z axis.

Scaling allows the user to scale the current selection by a set Factor in the X, Y and Z axis.

Advanced allows the user to specify a transformation matrix to be applied to the data.

After clicking the check button, users will be taken back to the **Transform Control Points** window. From here users can add more transformations, modify the currently selected one by pressing the **Edit** button, delete them by pressing the **Delete** button, or change their order of application to the data using the **Up/Down** buttons. Press the **OK** to apply the transformations.

Note: Transformations are applied in top-to-bottom order.

Settings

The Settings button will bring up the **Control Point Editor Settings** window, which allows the user to configure which data elements of the current point set are visible, as well as the order that they are displayed in.

To turn off a data element so it will not be displayed, click in the check box next to that element in the **Columns** panel. To change the order that data elements are displayed, select the element to move and then click the green up and down arrows to adjust the elements position.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organize the elements into the desired order and then click the **Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use. To delete a preset, select it from the **Presets** drop-down menu and then click the **Dash** button next to the **Presets** drop-down menu.

Tab Location(s): Project Tab

Panel and Button: Current Project and Control Points

Prerequisite: None

Coordinate Points

Coordinate points are points extracted from the point cloud data sets - it could be a registered scan data set, LiDAR or the result of photogrammetry processing - and are a sub-item of the **Processed Data** folder. There can be only one set of coordinate points for a project. There are two ways to manipulate Coordinate Points:

1. The Right-Click menu
2. Coordinate Point Editor

Edit

Launches the Coordinate point Editor

Delete All

Deletes all Coordinate Points. The user is prompted via a dialog box to confirm the deletion.

Import

Launches the ASCII file import dialog box.

Export

Launches the ASCII file export dialog box.

Transform

Launches the Transform dialog box to allow the user to define a transformation sequence to apply to the Coordinate points.

Field-to-Finish

Draws all Coordinate Points in CAD. The user is prompted to select a Field-to-Finish (.FLD) file.

View

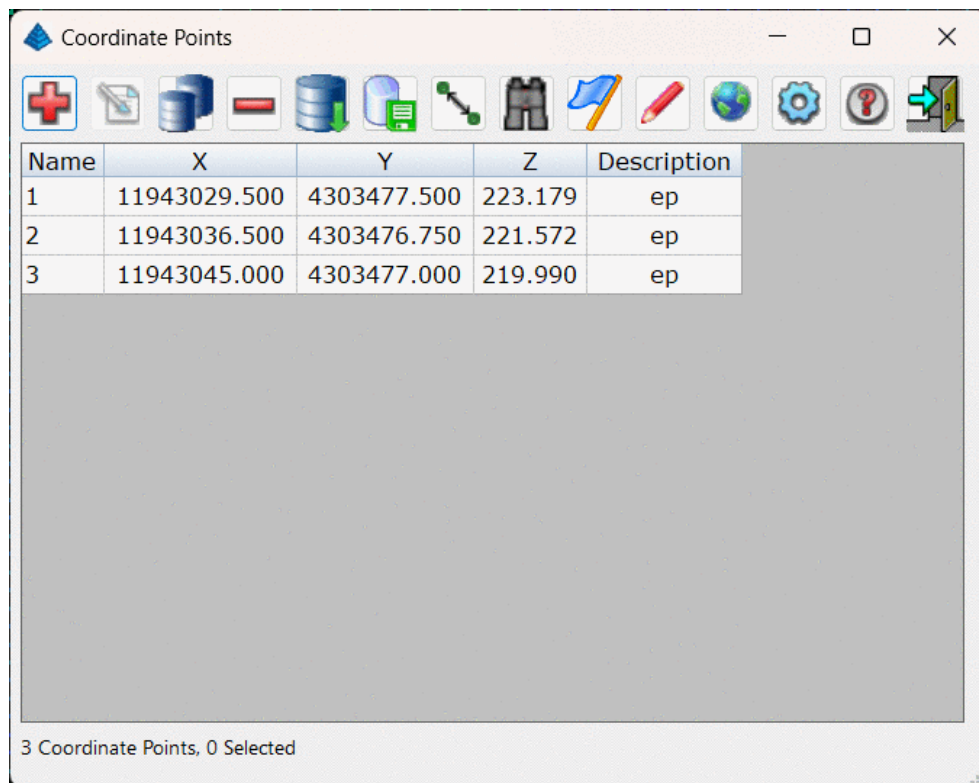

Launches the Scene creation dialog box to create a scene for viewing the Coordinate points.

Draw

Draws the Coordinate Points in CAD. The user is prompted via a dialog box for the layer to draw the Coordinate Points on.

Notes: Several commands are available in both the Right-Click menu and in the Coordinate Points editor. The difference between a command in the Right-Click menu and in the Coordinate Points editor is the Right-Click menu commands operate on all Coordinate points. The Coordinate Points editor commands operate on only the selected Coordinate Points. If no Coordinate points are selected the users is asked if they wish to perform the operation on all Coordinate points.

The Point Editor can be opened by right-mouse clicking on a set of points in the **Current Project**tree and selecting **Edit** or by double clicking on a set of points. In the **Coordinate Points** window, there are several base functions that are shared across all point types, with some extended options added for certain points types.

Along the top toolbar are several option buttons:

Add Point brings up a dialog that allows you to specify the properties of a new point to add.

Edit brings up the point edit dialog which allows you to change properties of the currently selected point.

Copy Points allows you to copy the currently selected points to another point set (such as from the control points to the target points of a scan).

Delete deletes the currently selected points.

Import Points brings up the ASCII file import dialog.

Export Points brings up the ASCII file export dialog.

Transform allows you to define a transformation sequence to apply to the points.

View brings up the scene creation dialog for viewing the current point set.

Field to Finish Draws the selected points in CAD using the current FLD file and field to finish settings.

Draw to CAD brings up the Point Draw Settings dialog specify a layer to draw the selected points on in CAD and specify if the points should be added to the current CRD file.

Coordinate System allows you to choose the coordinate system the positions values are in (Global or any current scan positions).

Settings allow you to configure what properties of the points are visible in the spreadsheet control.

Help brings up help documentation.

Adding Points

Clicking the **Add Point** button will open the **New Coordinate Point** window.

Name is a unique name for the point to be used to identify it in Point Cloud.

X, **Y**, and **Z** are the x, y, and z coordinates values for the new point to be added.

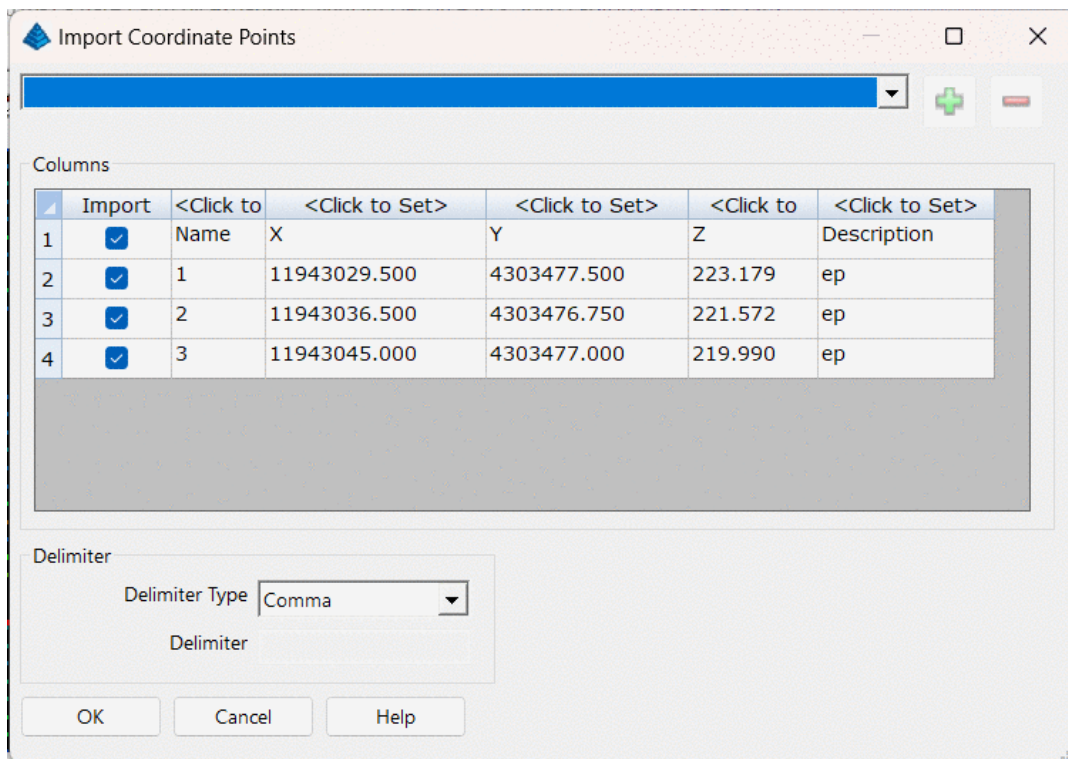

Description is a description for the point.

The image shows a dialog box titled "New Coordinate Point". It has a title bar with a blue diamond icon and a close button. The main area contains the following fields and controls:

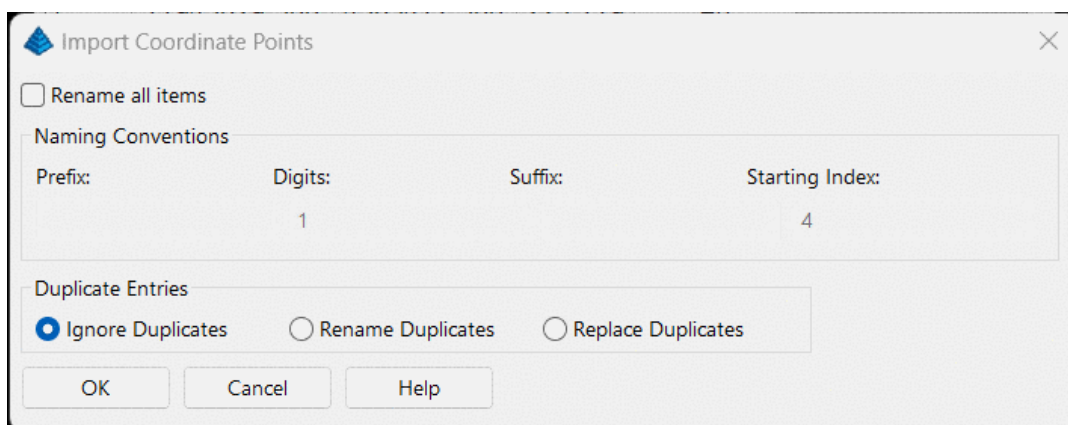

- Coordinate Point** (Section Header)
- Name:** 1001
- Description:** GCP
- X:** 0
- Y:** 0
- Z:** 0
- Screen Pick** button
- Dropdown menu: All
- OK** button
- Cancel** button
- Help** button

Importing Points

Clicking the **Import Points** button will open the **Import Coordinate Points** file selection dialog. The file formats currently supported for import are **TXT**, **CSV**, **CRD** and **CRDB**. Navigate to the correct file and click **Open** to display the **Import Coordinate Points** window.

Selecting **Rename all items** will rename all imported points to the settings specified in the **Naming Conventions** settings. The **Duplicate Entries** panel will specify the action to take when a point being imported has a name that already exists in the set of points being imported to. Click **OK** to import the points.

Exporting Points

Clicking the **Export Points** button will open the **Export Coordinate Points** window, which allows users to export the data to several different file formats.

In the **Columns** panel, click on the check boxes to include or exclude the data elements. To change the order of the data elements in the file, click on the element and then click the up or down arrows to adjust its position.

The **File** panel determines which file format to export to and also allows you to specify an extension other than the default for a given file format.

The **Text** panel contains options when exporting to the different text file types, **ANSI Text** or **Unicode Text**. The **Delimiter Type** determines the divider between data elements in the file. The **Write header** option specifies whether to write a header line to the file detailing the data ordering of the file.

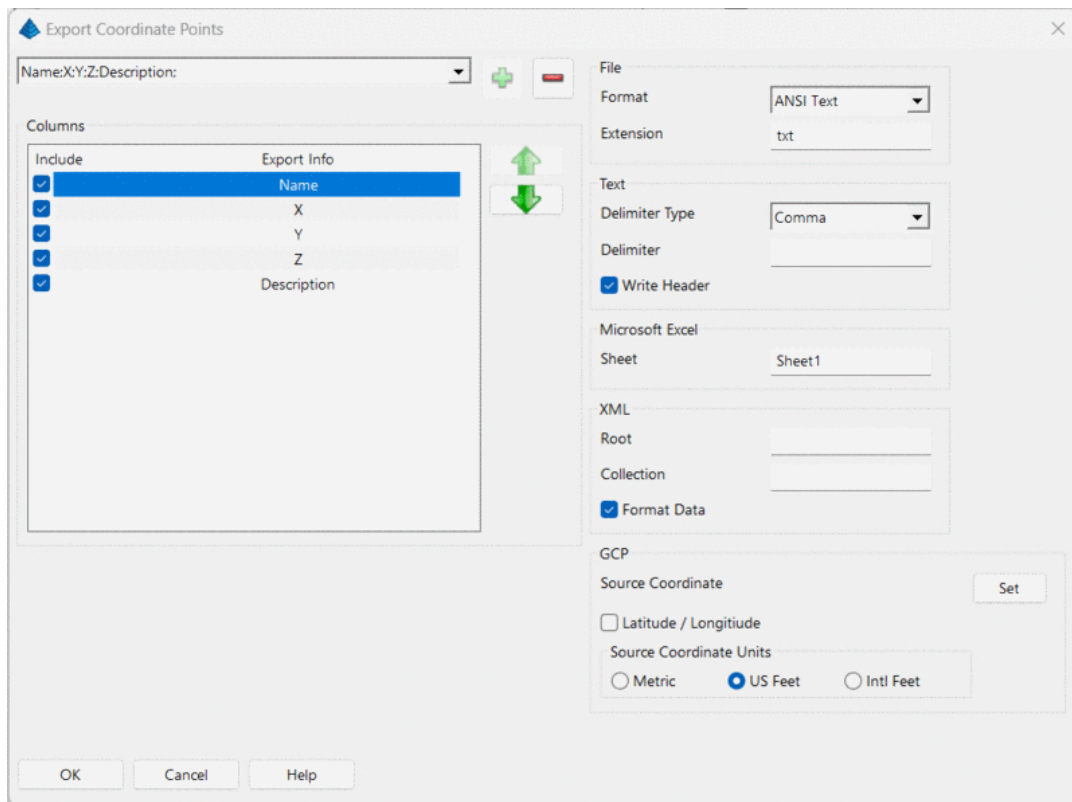

Microsoft Excel allows the user to define the name of the Excel worksheet that the points will be exported to. **Note:** only available when exporting as **Format: Microsoft Excel**.

XML allows users to define the **Root** and **Collection** values and choose to **Format data**. **Note:** only available when exporting as **Format:XML**.

GCP - when exporting as GCP, click on the **Set** button to choose the Coordinate Projection. Users can choose to select a Pre-Defined projection, add a projection from a file or create a User-Defined projection on the fly. Click **OK** to select and return to the previous window. Users can select to export the coordinates in Latitude/Longitude format and also to select the appropriate units; **Metric**, **US Feet** or **International Feet**.

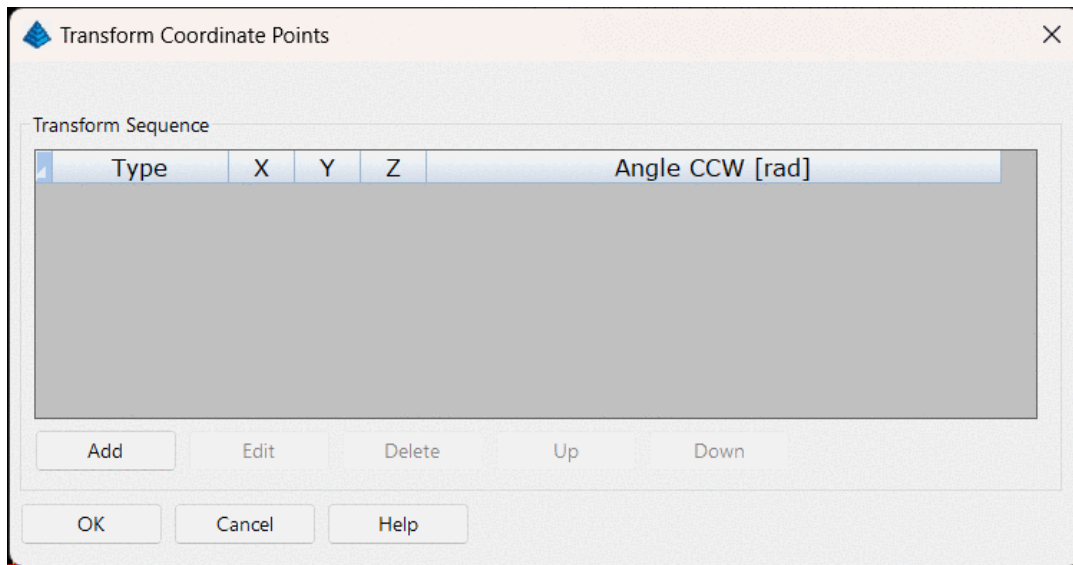

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organize the elements into the desired order and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** button next to the **Presets** drop-down menu.

Transform Points

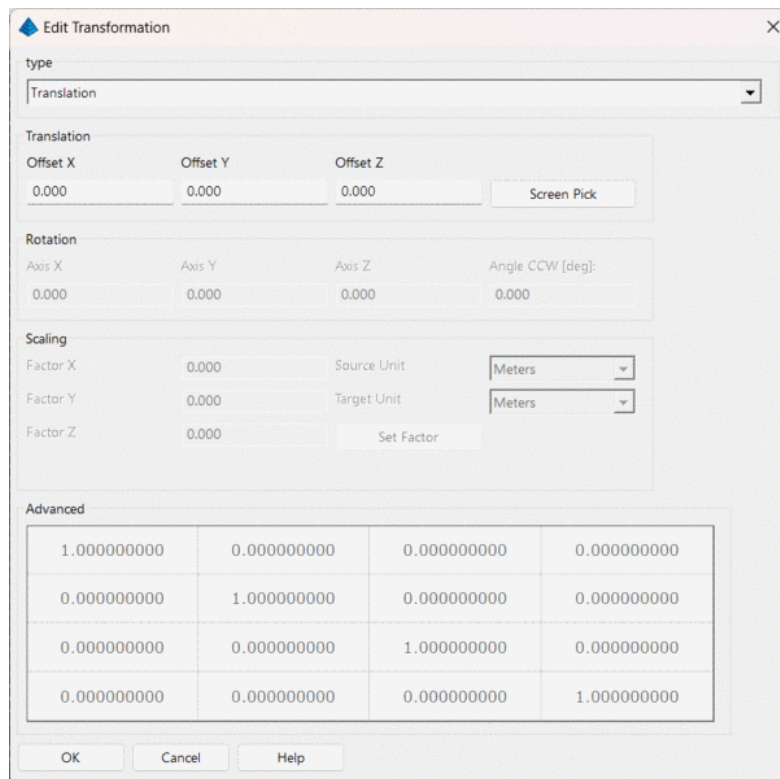

The **Transform** button opens the **Transform Coordinate Points** window where users can define a selection of transformation parameters to apply to the selected Coordinate Points.

Initially, the dialog will have no transformations specified. To add a transformation, click the **Add** button which will open the **New Transformation** window.

Use the **Type** drop-down menu to select one of the four Transformation types:

- **Translate** allows the user to define a translation of the current data set by specifying offsets in X, Y and Z.
- **Rotations** allow the user to rotate the current selection set by specifying rotations around the X Y and Z axis.
- **Scaling** allows the user to scale the current selection by a set Factor in the X, Y and Z axis.
- **Advanced** allows the user to specify a transformation matrix to be applied to the data.

After clicking the **OK** button you should be taken back to the **Transform Coordinate Points** window. From here users can add more transformations, modify the currently selected one by pressing the **Edit** button, delete them by pressing the **Delete** button, or change their order of application to the data using the **Up / Down** buttons. Press the **OK** button to apply the transformations.

Note: Transformations are applied in top-to-bottom order.

Settings

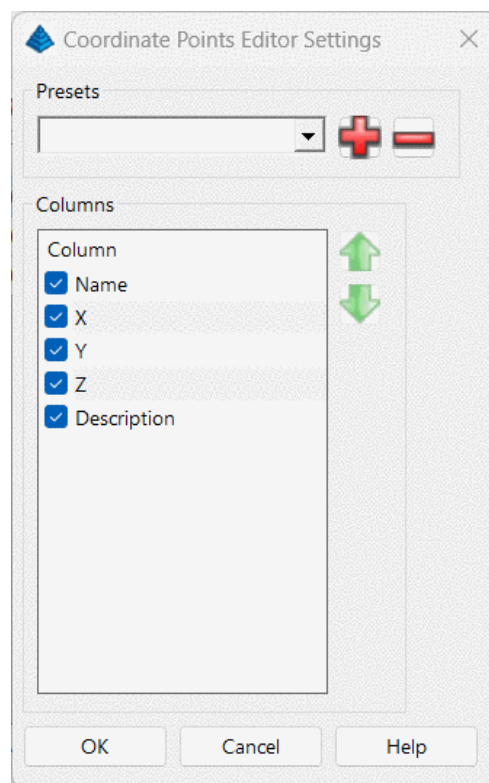

The Settings button will bring up the **Coordinate Point Settings** window, which allows the user to configure which data elements of the current point set are visible, as well as the order that they are displayed in.

To turn off a data element so it will not be displayed, click in the check box next to that element in the **Columns** panel.

To change the order that data elements are displayed, select the element to move and then click the green up and down arrows to adjust the elements position.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organise the elements into the desired order and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** button next to the **Presets** drop-down menu.

Tab Location(s): Project Tab

Panel and Button: Current Project and Coordinate Points

Prerequisite: None

Target Points

Target points always exist as a sub-item of a **Scan Position** and are in that scan position's local coordinate system. This means that a project can have several sets of target points (one for each scan position). There are two ways to manipulate Target Points:

1. The Right-Click menu
2. Target Point Editor

Edit

Delete All

Import

Export

Transform

View

Draw

Launches the Target Points Editor

Deletes all Target Points. The user is prompted via a dialog box to confirm the deletion.

Launches the ASCII file import dialog box.

Launches the ASCII file export dialog box.

Launches the Transform dialog box to allow the user to define a transformation sequence to apply to the target points.

Launches the Scene creation dialog box to create a scene for viewing the target points.

Draws the Target Points in CAD. The user is prompted via a dialog box for the layer to draw the Target Points on.

Notes:

Several commands are available in both the Right-Click menu and in the Target Points editor. The difference between a command in the Right-Click menu and in the Target Points editor is the Right-Click menu commands operate on all target points. The Target Points editor commands operate on only the selected Target Points. If no target points are selected the users is asked if they wish to perform the operation on all target points.

The Target Point Editor is activated when the user *right-clicks* **Target Points** and selects **Edit**. In the **Target Point** editor there are several base functions that are shared across all point types.

The title bar will display the scan position that the target points are part of. Just below that is a toolbar with several icons. The icons and their corresponding functions are as follows:

Activate Target Point toggles the selected target point(s) to be active in the current project.

Deactivate Target Point toggles the selected target point(s) to be inactive in the current project.

Add target Point brings up a dialog that allows you to specify the properties of a new target point to add.

Edit Target Point brings up the target point edit dialog which allows you to change properties of the currently selected target point.

Copy Target Points allows you to copy the currently selected points to another point set (such as from the target points to the control points of a scan).

Delete Target Points deletes the currently selected target points.

Import Target Points brings up the ASCII file import dialog.

Export Target Points brings up the ASCII file export dialog.

Transform Target Points allows you to define a transformation sequence to apply to the target points.

View Target Points brings up the scene creation dialog for viewing the current target point set.

Settings allow you to configure what properties of the points are visible in the spreadsheet control.

Help brings up help documentation.

New Target Point

Name will specify a unique name to be used for the Target Point in the project.

X, Y and Z may be in feet (ft) or Meters (m). These are the coordinates of the Target Point.

Description allows you to optionally add information that describes the new Target Point.

Control Point allows the user to specify a **Control Point** for the new **Target Point**.

Import Target points

The settings of the import dialog must be configured to match the data ordering of the file being imported. First, ensure that the **Delimiter** is set to the correct value, if it is there should be multiple columns in the dialog, if it isn't, all of the data should only be in one column. After the delimiter is properly set, the data values for each column must be set. This can be done by clicking the header of each column (which say *Click to Set* by default) to bring up a menu with all the available values that can be set for that column. After setting these values toggle the importing of lines you wish to leave out by clicking the green buttons in the Import column to turn them red. At the top of the dialog is the presets panel, which will allow you to save the current settings if you wish to use them again later. After configuring the dialog to match your data, click the OK to import and continue to the next step. The next dialog displayed will allow you to configure the naming conventions for the target points to be imported.

Selecting **Rename all items** will rename all imported points to the settings specified in the options. The **Duplicate Entries** panel will specify the action to take when a point being imported has a name that already exists in the set of points being imported to. If the **Rename all items** toggle is not selected the names listed in the file being imported will be used. If there are no names in the file being imported and **Rename all items** is not selected, the control points will be named using the settings in **Project Settings** naming conventions.

Exporting Target Points

Clicking the export button will bring up the Export Target Points dialog, which will allow you to export the data to several different file formats.

Simply click the check boxes next to the data elements that you wish to export. To change the order of the data elements in the file, select the data element you wish to move and click the up or down arrow to move it.

The **File** panel determines which file format to export to and also allows you to specify an extension other than the default for a given file format.

The **Text** allows you to specify the **Delimiter** to be used as the divider between data elements in the file and whether to use the **Write header** to specify whether to write a header line to the file detailing the data ordering of the file.

Transform Target Points

The Transform Target points dialog box allows specifying a sequence of transformations to apply to the currently selected target points.

Initially the transformation list is empty. Press the green plus button to add a new transformation, which will bring up a new dialog.

There are three types of transformations, as well as an advanced transformation where the user can specify the transformation matrix to apply.

1. **Translation** transformations move the points linearly along the offset values specified.
2. **Rotation** transformations rotate the points around the axis specified the angle specified.
3. **Scaling** transformations scales the selected points (using the global origin as the origin for the scaling) in each dimension by the amount specified.

After the transformation's settings have been configured, pressing the green check mark will add it to the current list of transformations. In the Transformation sequence dialog the following functions apply:

Add will allow you to add transformations.

Edit will allow you to edit the currently selected transformation.

Delete will delete the currently selected transformation.

Up / Down will change the order of applications of the transformations. Transformations are applied in top-to-bottom order.

Settings

The Settings button will bring up the Point Editor settings dialog, which will allow the user to configure which data elements of the current point set are visible, as well as the order that they are displayed in.

Display of a property can be changed by toggling the check box next to that property, changing the order can be done by first selecting the property to move and then pressing the green up or down arrows to move the selected property up or down. Saving the current settings can be done clicking the plus button in the **Presets** panel.

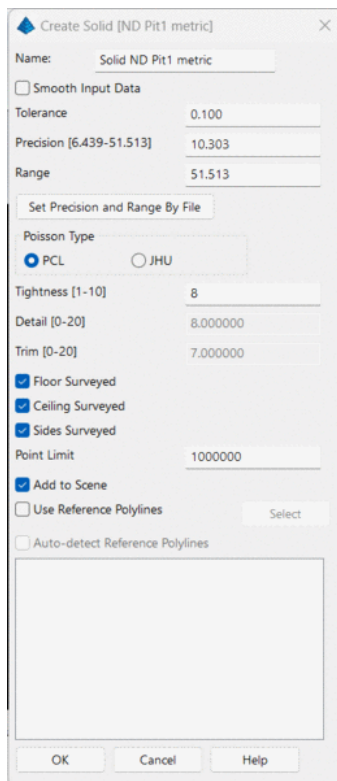

Tab Location(s): Project Tab

Panel and Button: Current Project and Target Points

Prerequisite: None

Create Solid

You can create a solid model from data objects such as point clouds and tins. The program uses Poisson surface reconstruction techniques that will create watertight surfaces from the point data. To create a Solid from a cloud, right-click the cloud you want to create a solid from the project tree and select **Create > Create Solid**. If only the floor, ceiling, or sides have surveyed, a 2D solid model can be created.

Smooth Input Data: The program applies an smoothing algorithm to remove some of the noise in the point data to facilitate flatter surfaces.

Tolerance: Helps remove outlier points. If the resulting surface is too spiky, adjust this value higher.

Precision: Uses tighter calculations for pre-processing for tighter grid.

Range: If the mesh does not span over expected gap areas, raise this value higher. If the surface spans over unexpected areas, lower the value.

Set Precision and Range By File: will calculate the precision and range values from by scanning the file.

Poisson Type: **PCL** (industry standard Point Cloud Libraries) or **JHU** (Johns Hopkins University) method can be selected. Program defaults to the PCL method.

Tightness: Used for determining the density of the triangles when the PCL method is selected. The higher the value, the smaller the triangles of the resulting solid. Note that tightness will not be used if a 2D solid model triangulation is done.

To generate a watertight 3D solid model **check** the **Floor Surveyed**, **Ceiling Surveyed**, and **Sides Surveyed** boxes.

Note: High Tightness can lead to banding in certain situations. If the resulting cloud exhibits banding, consider reducing the Tightness setting.

Point Limit ensures that the resulting 2D or 3D solid model does not have more points than the value entered in this field, with a default of 1,000,000.

Add to Scene will create and open a Scene window displaying the resulting solid model.

As the the Poisson surface generation process is highly sensitive to the normals of the points in the cloud, **Use Reference Polylines** and **Auto-detect Reference Polylines** provide a method to to set the normals for the cloud based on a set of reference polylines such that all the point normals in the cloud face away from the nearest reference polyline prior to creating the solids. **Use Reference Polylines** allows you to **Select** your drawn polylines. By checking **Auto-detect Reference Polylines**, you will allow the program will automatically calculate a group of reference polylines. As an example, when creating a 3D solid model for a tunnel, it is possible that not all the point normals will be facing away from center, by drawing custom polylines or using auto-detect, the program will ensure that all the normal are aligned away from center.

Click **OK** to create the solid. Once created, a **View Solid** dialog will display. Confirm the settings and click **OK** to view the new solid in a Scene. The new Solid will be added under the **Solids** menu in the **Current Project** tree.

Cloud Objects

Clouds are the most basic of the three large dataset objects supported by Carlson Point Cloud. Point clouds consist of a large amount of points with positions that can also contain color, intensity, and classification associated with each point.

Point Cloud has several functions that can help reduce (decimate), clean, and generally prepare clouds to be manageable in a CAD application. In the **Current Project** tree structure, clouds are categorized under their own folder, **Clouds**. Clouds have a couple of unique functions that make them distinct from other data objects, in addition to the general actions common to other data elements with 3D data.

Import a Cloud
(from an external file)

Create a Cloud
(from a selection of points, etc)

Clean a Cloud
(eliminate noise points and duplicated points)

Resample a Cloud
(to reduce total point count)

Smooth a Cloud

Transform a Cloud
(rotate, translate, etc)

Scale a Cloud
(from feet to meters etc)

Change the Projection
(Lat/Long to State Plane etc)

Adjust Color
(brighten, darken, or drape image)

Bare Earth by Grid
(keep only the low points from the cloud)

Register a Cloud
(match pre-entered control points to hand-picked target points)

Merge Clouds

Subtract Clouds
(remove one cloud's area from another cloud)

Export Cloud
(to LAS, ASCII, or PDF)

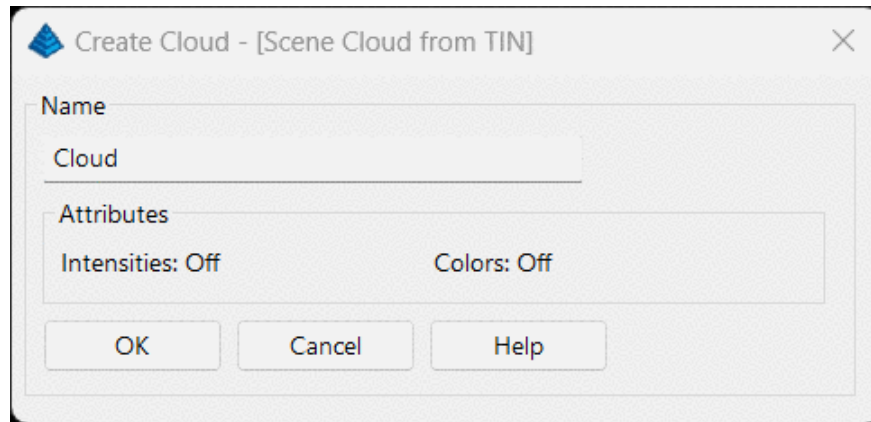

Create a Solid

Create Cloud

New clouds can be created many ways, for example, new clouds are created as the result of applying filters including the Clean and Bare Earth algorithms. Clouds can also be created from TINs and Scans by **right-clicking** on the TIN or Scan in the project tree and selecting **Create** then choosing **Cloud**. A new cloud can also be created by selecting a cloud in the project tree, the resulting cloud is copy of selected cloud.

Commonly and more practically, a new cloud can be created by selecting a section of another cloud using the **Selection Set** tools in the **Action tab** when a Scene is open. Once the data is selected in the Scene view, click **Cloud** in the **Create panel** under the **Action tab**.

In the Create Cloud window, enter the **Name** of the new cloud.

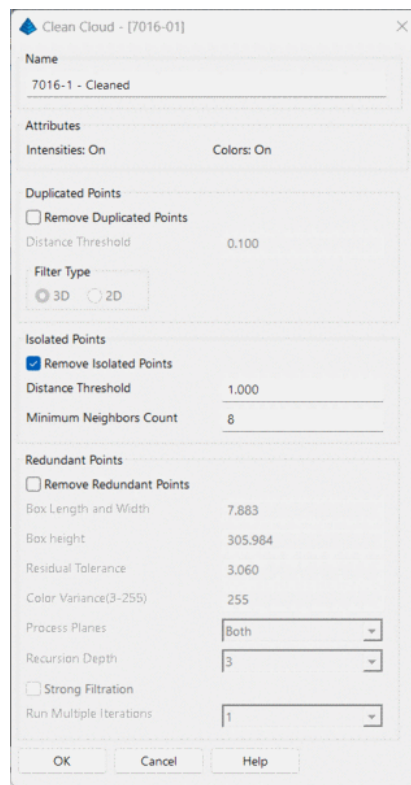

Click the **OK**. The new cloud will be added under the Clouds section in the project tree.

If you have an open **Scene**, the program will prompt if you want to view the newly created cloud and then prompt if you want to close the current Scene window. You can change the prompts in the Display Settings from the main Project tab.

Clean Cloud

Cleaning or decimating the cloud can be helpful to reduce the size of the point cloud that you are working with and make it easier to use any of the extraction tools, create TINs, calculate volumes, and extract profiles and sections. You can clean a complete cloud, a selection within the cloud, or multiple clouds at the same time.

To clean the complete cloud, **right-click** the cloud in the project tree and select **Clean**. To clean a portion of the cloud, open the cloud scene. Then, select the part of the cloud that you want to clean using any of the tools in the **Selection Set** panel of the **Action** tab; then, click **Clean** from the **Edit** panel in the **Action** tab. To clean multiple clouds, right-click **Clouds** in the project tree, then select **Clean**; the **Select Clouds to Clean** window will be displayed allowing you to select multiple clouds and then **click OK**.

The Clean function offers three different cleaning methods: Duplicate Points, Isolate Points, and Redundant Points. Note that the Duplicate Points and Isolate Points routines may be used in combination. Redundant Points must be used individually. It is also important to note that the size of the cloud or clouds being filtered and the options that are selected will affect the execution time for this routine.

Remove Duplicated Points method will search for any places where two or more points in the cloud are within the **Distance threshold** of each other. If any such points are found, they are deleted from the cloud. This method is to help remove redundant data that, for all intents and purposes, are the same given the current data set (say a data set that spans several miles having two points within inches of each other) and reduce the size of the data set. This can be carried out on a 2D or 3D basis. The 3D method runs faster. Usually clouds that are produced by stationary scanners have more points than necessary right next to the scanner, and need this kind of cleaning.

Remove Isolated Points method will search for any points in the cloud that have less than the **Minimum Neighbors Count** points within the **Distance Threshold** from them and delete them. This will remove points that are likely to be outliers, which could be a result of bad data such as the beam on a ground scanner hitting a dust particles in the air.

Redundant Points method uses a series of user parameters to clean points from the cloud. This is most useful before creating a TIN, because it will reduce flat parts down to one point. Using a box of user defined size, points are checked for fitting the plane and/or color match. If no points match the box is subdivided and the check repeated. These sub-boxes will again be subdivided if no points match. If points are found that meet the criteria a point closest to the average of those in the box is copied to the clean cloud. If no match is found, all the points from that box are copied into the clean cloud unless Strong Filtration is on.

- **Box Length and Width** Sets the horizontal distance to search for points to compare. In general a small values will produce best results.
- **Box height** Sets the vertical component completing a 3D cube search area for points to compare. In general a small values will produce best results.
- **Residual tolerance** is the measure of how far from a best fit plane points can be. A typical value would be 1/10 of the smallest box dimension.

- **Color variance** determines how much the color of a point can vary. When set to 255 color variance is not used.
- **Process Planes** allows the user the ability to choose to clean vertical or horizontal data only or to clean both.
- **Recursion depth** is the number of times the initial box is subdivided to find points that meet the parameters. Typical values used would be 3 or 4.
- **Strong Filtration** when checked on, the program will copy the point closest to the average for plane and/or color to the new cloud even if no exact plane or color match was established.

Click the **OK**. The new cloud will be added under the Clouds section in the project tree.

If you have an open **Scene**, the program will prompt if you want to view the newly created cloud and then prompt if you want to close the current Scene window. You can change the prompts in the Display Settings from the main Project tab.

Import Cloud

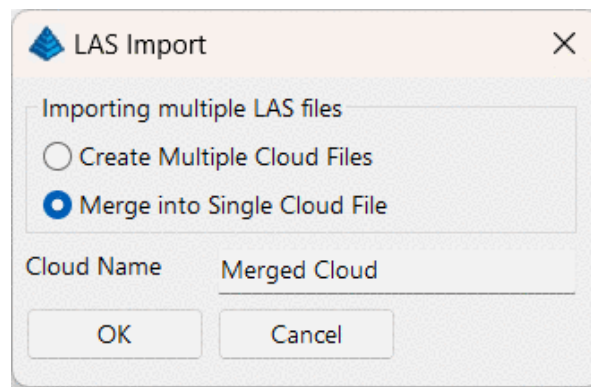

To import a **Cloud** from a file right-click the **Clouds** folder in the **Current Project** tree and select **Import**. Carlson Point Cloud supports file formats generated by multiple manufacturers. Formats include:

- LiDAR (.las/.laz)
- Generic (.txt/.asc/.xyz/.csv)
- FARO (.fls/.fws)
- Leica (.pts/.ptx)
- E57 (.e57)
- Quarryman (.fsc)
- PLY (.ply)
- DEM/ESRI (.dem/.adf/.asc/.img/.tif)
- GeoTIFF (.tif/.tiff)
- PCG (.pcg)
- RCS (.rcs)
- POD (.pod)
- 3DTK (.oct)
- Carlson Coordinates (.crd/.crdb)
- Carlson Surface (.tin/.grd)
- Point Cloud Library (.pcd)
- Points from CAD
- Carlson Point Cloud (.bxyz)

Notes: the 3DTK engine does not support .pts or .ptx files. Carlson Quarryman [.fsc] can be imported directly from a Carlson Quarryman system. Choosing **Points From CAD** allows the user to select any points in their CAD environment to import into the Point Cloud project.

After selecting a format, the **Select Clouds to Import** window will open. Browse to the folder with you point cloud files. You can select multiple files at a time for some file types. Click **Open** to import the data.

If multiple files were selected a new **Import** window will open prompting if you want to **Create Multiple Cloud Files** - each file selected will be displayed as a separate object in the project tree - or **Merge into Single Cloud File**. If merging the cloud files, you will need to enter a **Cloud Name** for the combined point cloud. Click **OK**.

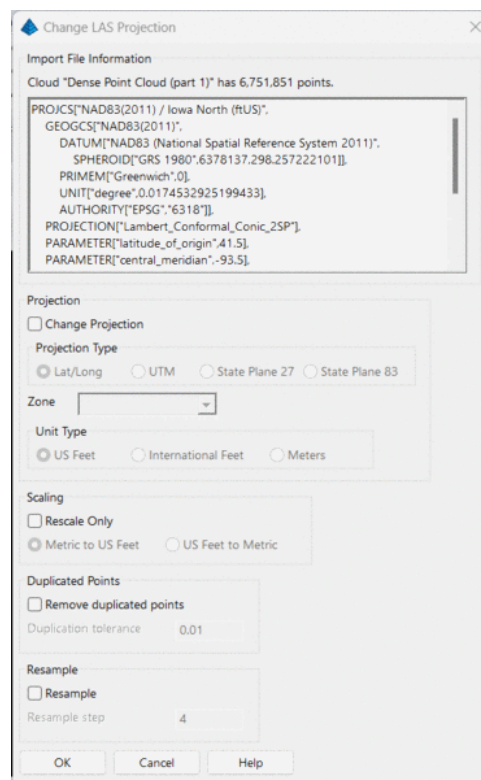

The **Change Projection** window will open. The **Import File Information** panel will display the projection information found in the file(s) that will be imported. You can use **Change Projection** to change the projection of the imported file to match your Carlson project system.

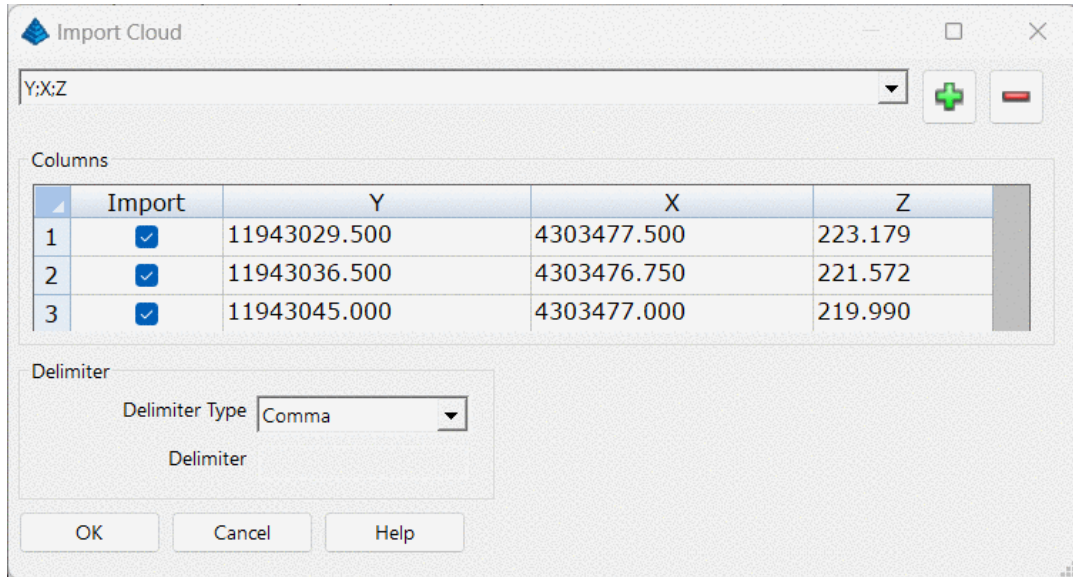

Use **Rescale Only** to convert the file from **Metric to US Feet** or **US Feet to Metric**. Note that commonly the software used to register the ground scanner clouds will export the data in metric units, therefore this tool is very handy if your project is set in feet.

Use **Remove duplicated points** to clean (decimate) the file to be imported. The program will search for any places where two or more points in the cloud are within the **Duplication tolerance** of each other. If any such points are found, they are deleted from the cloud. For example, this is recommended when the cloud was created using a ground scanner as the density of points in close proximity to the scanner will be large and unnecessary. By using this filtering tool, you can reduce the size of the cloud significantly without affecting the accuracy.

Using **Resample** will also reduce the size of the imported point cloud. The resample method though is a fast but naive method as it will reduce the cloud to 1/**Step** its current size by keeping only one out of every nth point found. Click **OK** to import the file.

Note: If a Generic format (ASCII) is selected, the **Import Cloud** window will be displayed. In order for the data to be imported correctly the user must define what **Delimiter Type** is used within the ASCII file. If the data is not shown organized in columns (all the data is in one column for example); another delimiter will need to be chosen. Clicking the header of each column will bring up a menu with all the possible values that can be assigned to it, click each column's header to set its proper value. At the top of the dialog is the **Presets Panel**, which allows users to save the current column assignments to be used in the future. The import column is used to determine whether to import that particular column (often files will have text or header information that isn't actually part of the data set). Save the current configuration by clicking the + button in the panel, presets can also be removed by clicking - button. Presets are saved in the global program settings so they can be used across multiple projects. Click the **OK** to begin the import.

After importing a cloud, you will have access to multiple methods to decimate the cloud, from the tools found in the **Clean** options to the bare earth filters to the automated feature extraction actions. r

Menu Location: Right click on Clouds entry in Project tree >Import

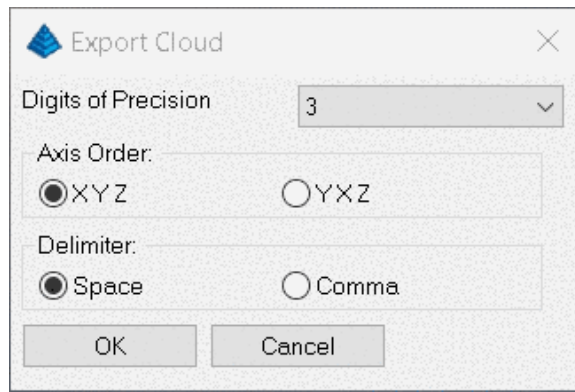

Keyboard Command: No **Prerequisite:** Supported cloud file available, a project open in the Project Tab

Export Cloud

Clouds can be exported to a variety of formats, accessed by right-clicking on the cloud to export in the project tree, then selecting **Export** and choosing the format for the exported file. Options include: **ASCII**, **LAS**, **E57**, **RC5**, **PDF**, and **PCD**.

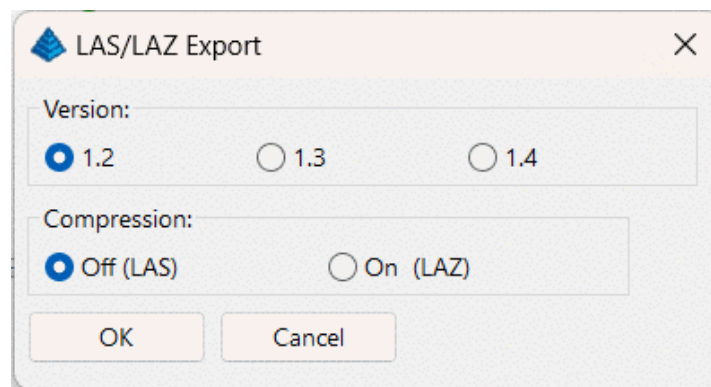

Export to ASCII - Creates a space or comma delimited text file (.txt) of the point cloud.

Select **Export to ASCII**. Enter the name for the ASCII file and click **Save**. In the **Export Cloud** window, you can set the **Digits of Precision**, the **Axis Order**, and the **Delimiter format**. Click **OK** to export.

Export to LAS - Creates an .las or .laz file.

Select **Export to LAS**. Select the version for the exported file and whether it should be uncompressed (LAS) or compressed (LAS). Click **OK** and then enter the name for the new file. Click **Save** to export the file.

Export to E57 - Creates an .e57 file. e57 files are generic and can be read by most if not all applications that support point clouds.

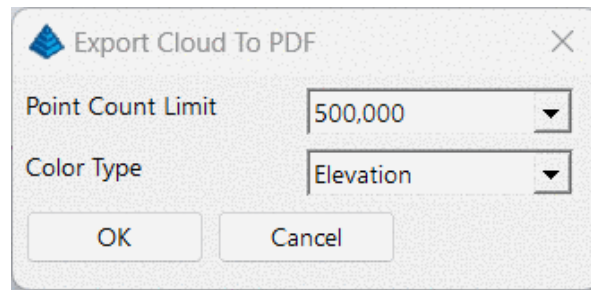

Select **Export to E57**, enter the name for the new file. Click **Save** to export the file.

Export to RCS - Creates an .rcs file. RCS the file format used by Autodesk ReCap.

Select **Export to RCS**, enter the name for the new file. Click **Save** to export the file.

Export to PDF - Creates a 3D PDF of the cloud that can be opened in Adobe Acrobat Reader.

Select **Export to PDF**, enter the name for the new file. Click **Save**. In the Export Cloud to PDF window, select the **Point Count Limit** and **Color Type**. The **Point Count Limit**, limits the number of points to be used to create the 3D PDF by resampling the selected cloud - values range from 250,000 to 2,000,000. The **Color Type** can either be Automatic (which will use the RGB values for each point in the cloud), Intensity, or by Elevation. Click **OK** to export the file.

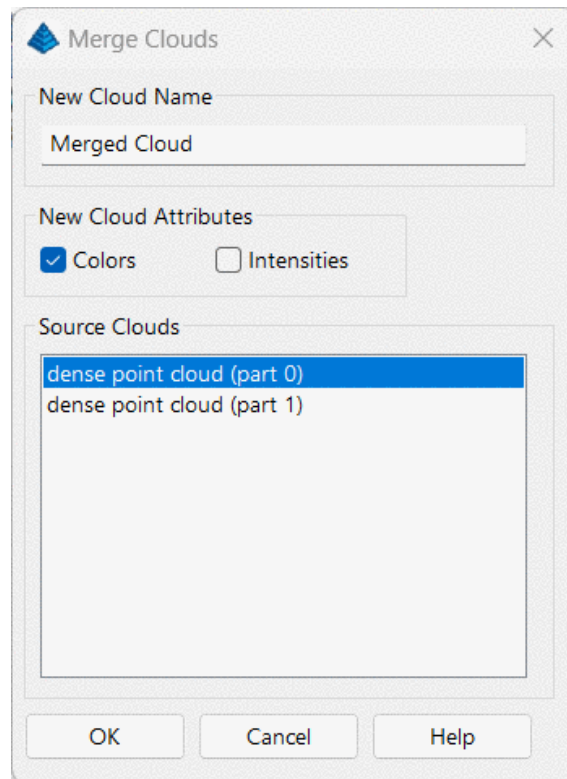

Export to PCD - Creates a .pcd file

Select **Export to PCD** to open the file selection window. Enter a name for the PCD file and click **Save** to export.

Merge Clouds

Two or more existing clouds can be merged into a single cloud. **Right-click** on one of the clouds in the **Current Project** tree and then select **Merge Clouds**.

In the **Merge Clouds** window, enter the **New Cloud Name**. Select whether to keep and merge the **Color** and **Intensity** values from the existing clouds. Under the **Source Clouds** panel, use the CTRL and SHIFT keys to select the remaining clouds to merge. Note that a maximum of 20 clouds can be merged together in a single operation. Click **OK** to begin the merge. The new cloud will be displayed in the **Clouds** sub-menu in the **Current Project** tree. You will be prompted if you would like to view the new cloud and if you want to close any opened Scene windows.

Tab Location(s): Project

Tree Folder: Clouds

Prerequisite: Existing Clouds

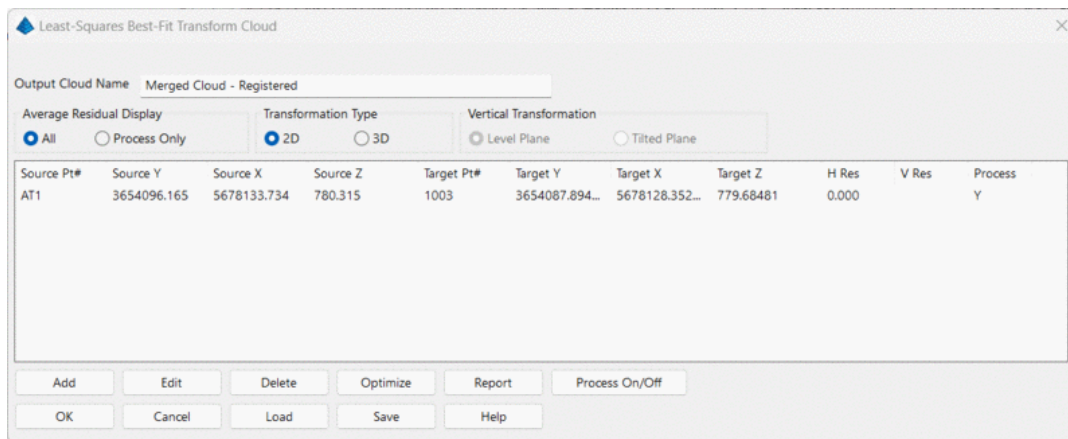

Register Cloud

Using **Align/Register** transforms coordinates between local, State Plane 27, State Plane 83, Latitude/Longitude, Universal Transverse Mercator (UTM) and many other projections, including regional and user-defined projections.

To align the cloud, **right-click on** the cloud in the **Current Project** tree and select **Align/Register**. Enter a name for the new, registered Cloud. You will be prompted to select the Alignment/Registration method.

Least-Squares Best-Fit

The **Least-Squares Best-Fit** option is used when there are more than two pairs for translation points. Since two pairs of points are sufficient to define the translation and rotation, more than two pairs of points provides more than enough information. You will need to enter the **Output Cloud Name** for the resulting cloud.

Over **Determination by Plane Similarity** is used to find the least squares best fit transformation for all the given source and destination points. Besides doing a translation and rotation, this option will also scales the points during the transformation. The **Rigid Body Transformation** also does a best fit least squares transformation, but applies only translation and rotation with no scale.

The **Helmert 7-Parameter** method can also be used for local transformations. The 7-Parameter Values can be calculated from control points or entered by the user. The program uses the Helmert Transformation, Strict formula:
 $[X_t \ Y_t \ Z_t] = [dX \ dY \ dZ] + M * R * [X_s \ Y_s \ Z_s]$
where R is the rotation matrix.

The Transformation Type chooses between doing a 2D transformation and 3D transformation. For the 3D transformation, the program transforms the x/y using the same method as the 2D transformation, and the z is transformed using an elevation difference model that is modeled by either a best-fit level plane or tilted plane as set by the **Vertical Transformation** setting.

The **Add** button is used to define the source and destination coordinates for the points that define the transformation. Pressing this button brings up the following dialog box. Clicking the **List** button will allow you to select points from the Point Cloud **Coordinate Points**, Drawing Coordinate Points (.crd/.crdb), **Control Points** (presumed to be correct in World Space), and Scan Position lists.

Source Coordinate	
Point Number	MH1
Northing	3654106.651
Easting	5678167.63
Elevation	779.756

Target Coordinate	
Point Number	1002
Northing	3654099.5742
Easting	5678179.7620
Elevation	779.49481

The **Edit** button is used to edit existing data.

The **Delete** button removes the source and destination pairing from the transformation setup.

The **Process On/Off** button allows source and destination pairings to be turned on and off. This is useful when wanting to inspect different results using different pairings.

The **Optimize** option chooses which point pairings would yield the best transformation results by turning off the processing of pairings with higher residuals. This minimizes the average residual for the control points.

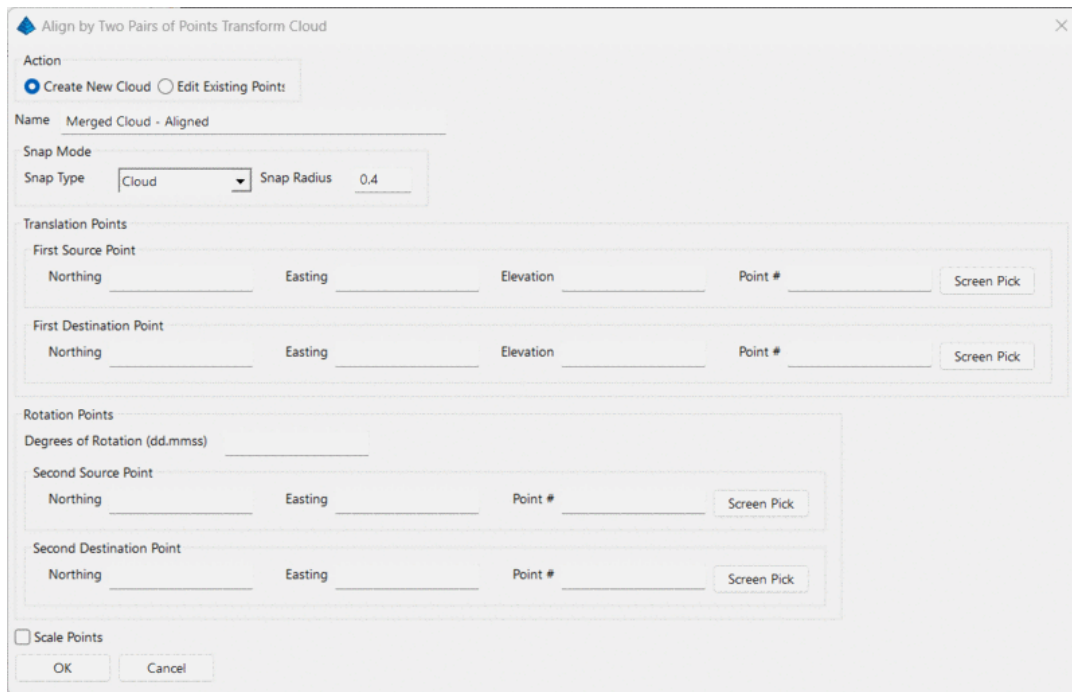

The **Report** option displays a report of the transformation point pairings, their residuals, processing status, transformation scale and avg. residual.

The **Load** and **Save** options allow for saving and recalling local coordinate transformation pairings and settings.

Align by Two Pairs of Points

The **Align by Two Pairs of Points** option uses two pairs of source and destination coordinates. The first pair defines the translation as the difference between the source and destination northing and easting. You will have the option to **Create New Cloud** or **Edit Existing Points**.

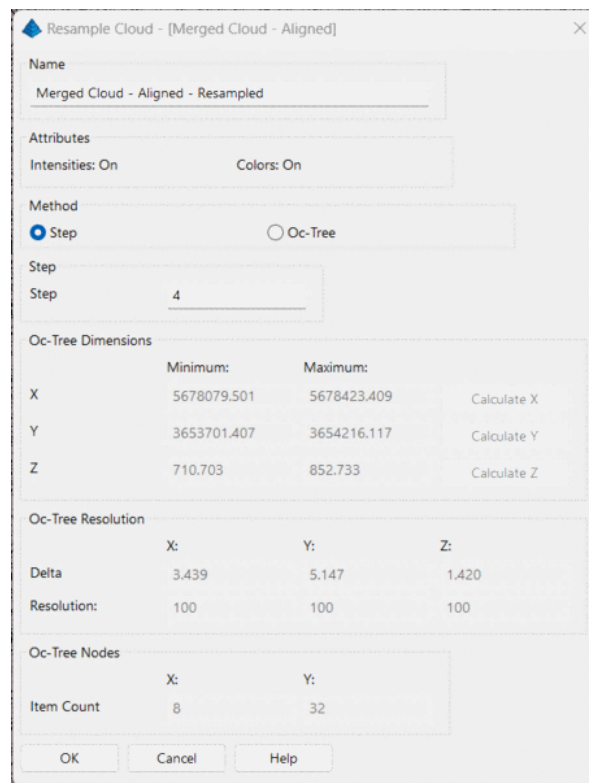

This destination point is also the pivot point for rotation. Rotation can be entered directly or defined by a second pair of points where the bearing between the first and second source points is rotated to align with the bearing from the first and second destination points. There is an option to also apply scaling. The scaling holds the angle between points and adjusts the distances by the scale factor. The scale factor is calculated for each point as the elevation factor at the first source point times the grid factor at the first destination point averaged with the elevation factor at the transform point times the grid factor at the transform point.

Resample Cloud

Point Cloud has two methods of cloud reduction **Step** and **Oc-Tree**. There is a fast, naive method, and a slower, more intelligent method.

To resample a Cloud, **right-click** the cloud in the **Current Project** tree and select **Resample**. This will open the **Resample Cloud** dialog.

Step Method

The **Step** method is much faster at the cost of being less intelligent. It will simply reduce the cloud to 1/Step its current size by only keeping one out of every nth vertices. For example, a step size of four, Resample will traverse the cloud and only keep every fourth vertex, deleting three for each one it keeps.

Oc-Tree Method

The **Oc-Tree** method is a more intelligent process, but it can have significantly longer run times than the Step method. The Oc-Tree creates a bounding box based on the **Oc-Tree Dimensions** settings. This bounding box is then subdivided into blocks (nodes) based on the **Oc-Tree Resolution** settings. The points in each block (node) in the Oc-Tree is then filtered according to the **Oc-Tree Nodes** settings.

- **Oc-Tree Dimensions:** The extents ("Minimum" <-> "Maximum") in the x,y, and z dimension of the Oc-Tree's bounding box.
- **Oc-Tree Resolution:** Defines the number of blocks (nodes) included in the Oc-Tree such that resolution*delta=extents (in x,y, or z dimension).
 - **Delta:** Extents of one of the Oc-Tree's blocks (nodes) in the x,y, or z dimension.
 - **Resolution:** Number of blocks (nodes) in the x, y, or z dimension.
- **Oc-Tree Nodes:** Specifies how the Oc-Tree filters points. If a block (node) in the Oc-Tree contains fewer than "Minimum" number points, the contents of that block (node) will be deleted. If a block (node) has more than "Maximum" number points, random points within that block (node) will be removed until it has "Maximum" number points inside it.

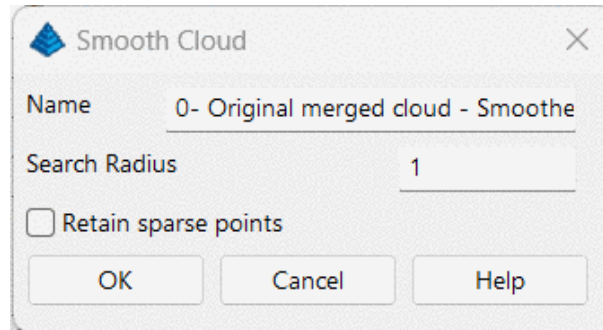

Click the **OK** to resample the Cloud. The new Cloud will be displayed in the **Clouds** sub-menu of the **Current**

Project tree.

See also: **Clean Cloud**

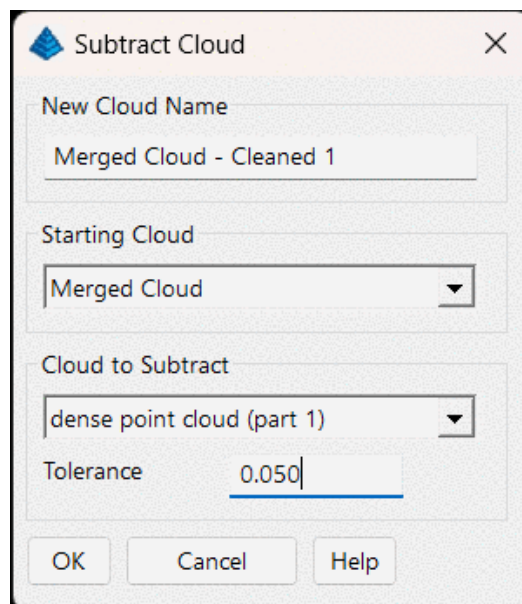

Smooth Cloud

The Smooth Cloud command moves each point to be closer in height to its neighbors within the search radius. If a point doesn't have any neighbors within the radius, it will be removed, unless "Retain sparse points" is checked.

Subtract Cloud

A cloud that is part of a combined or merged cloud, can be subtracted from another. **Right-click** on the combined or merged cloud in the **Current Project** tree and select **Subtract Cloud**. Enter the **New Cloud Name**. Use the **Starting Cloud** drop-down menu to select the original cloud. Use the **Cloud to Subtract** drop-down menu to select the cloud that is to be subtracted from the original. A **Tolerance** can be entered - recommended value of 0.05 will normally be sufficient. Click **OK**. The new cloud will be displayed under the **Clouds** sub-menu in the **Current Project** tree.

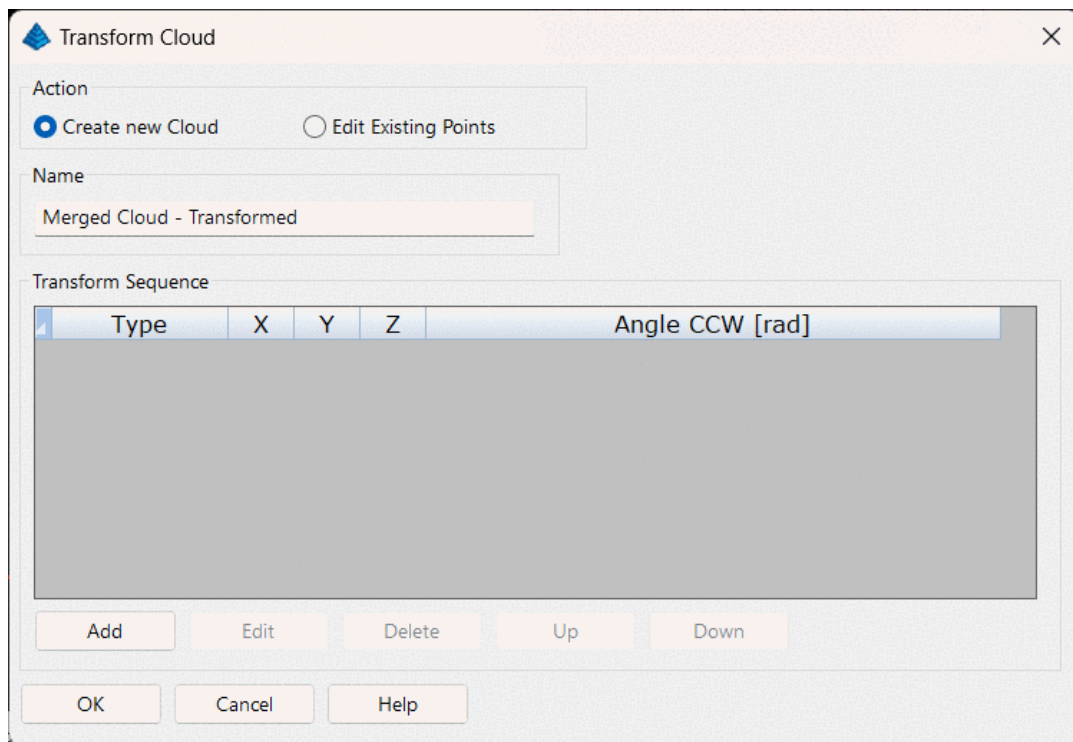

Transform Cloud

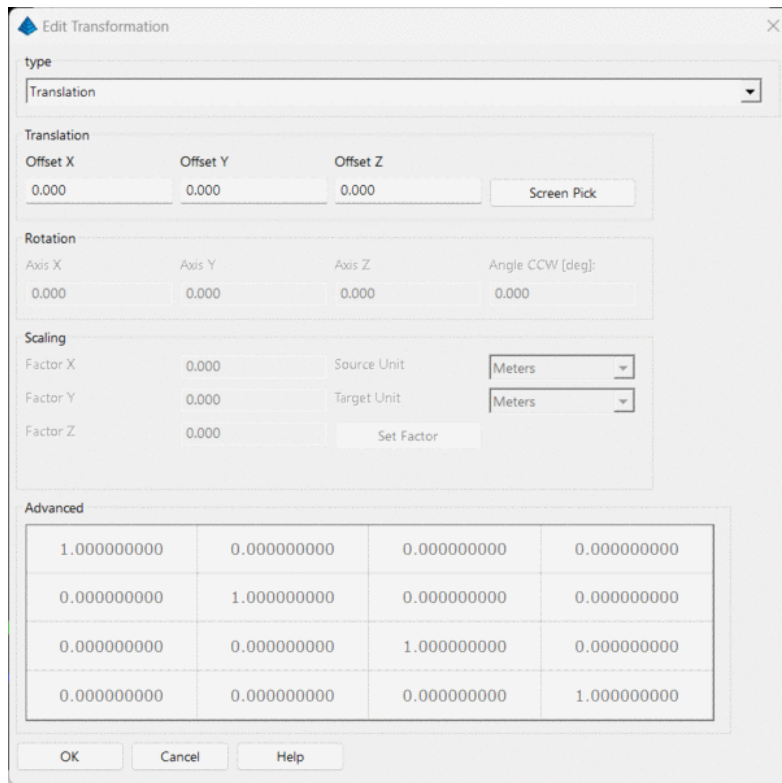

You can apply various transformations to the point cloud:

- **Translate** allows the user to define a translation of the current data set by specifying offsets in X, Y and Z.
- **Rotations** allow the user to rotate the current selection set by specifying rotations around the X Y and Z axis.
- **Scaling** allows the user to scale the current selection by a set Factor in the X, Y and Z axis.
- **Advanced** allows the user to specify a transformation matrix to be applied to the data.

Right-click on the cloud in the **Current Project** tree, select **Transform**, then chose **Transformation Wizard**. In the **Action** panel, you can choose to **Create New Cloud** or to **Edit Existing Points**. If you select **Create New Cloud**, you will need to enter the **Name** for the new cloud.

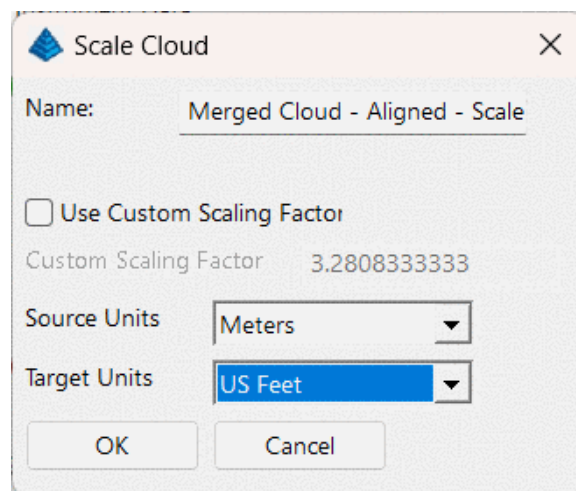

Initially, the dialog will have no transformations specified. To add a transformation, click the **Add** button which will open the **Edit Transformation** window. Use the **Type** drop-down menu to select one of the four transformation **Types**. Enter the appropriate parameters and click **OK**.

You can add more transformations to the list, modify the currently selected one by clicking the **Edit** button, **Delete**, and change their order of application to the data using **Up/Down** buttons. Press the **OK** button in the **Transform Cloud** window to apply the transformations to the selected data.

Scale Cloud

To scale a cloud from Metric to US Feet and vice versa, **right-click** on the cloud in the **Current Project** tree, select **Transform**, and choose **Scale**. This will display the **Scale Cloud** dialog. Enter a **Name** for the new Cloud. Select the **Source Units** and **Target Units** from the pull-downs. Alternatively, check **Use Custom Scaling Factor** and enter the **Custom Scaling Factor** you want to apply. Click **OK** to begin the scaling. The new Cloud will be displayed under the **Clouds** sub-menu in the **Current Project** tree.

Instrument Data Project Items

There are two data types in Carlson Point Clouds. These are Instrument Data and Processed Data. Within each data type there are various items and objects that can be added, edited or created. These Data types and items are organized into a tree structure and each can be manipulated by right clicking to bring up a menu specific to that item type. The menu options presented when an item is right-clicked will depend on what the item is. The data types listed here are specific to the Instrument Data type. Common functions can be found in the Data Objects section.

Points

There are three kinds of point item types in Carlson Point Clouds:

- Control Points
- Target Points
- Coordinate Points

Coordinate Points are processed data and are discussed in the Processed Data section.

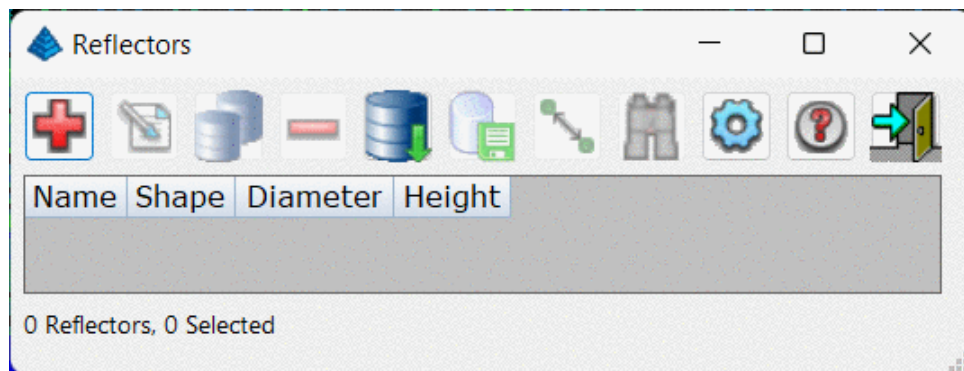

Target points always exist as a sub-item of a **Scan Position** and are in that scan position's local coordinate system. This means that a project can have several sets of target points (one for each scan position).

Control points are the global positions of the target points, and are a sub-item of the **Instrument Data** folder. There can be only one set of control points for a project.

Reflectors

Reflectors in a Point Clouds project represent a disk, sphere, or cylinder reflector within the set of scans for the current project. Each reflector can be linked to a control point which will enable Point Clouds to account for the shape of target points that are to be linked with that control point during the scan registration process.

These reflectors can either be imported from an ASCII text file with the **Import** command or entered in manually with the **Edit** command. Pressing **Edit** will bring up the Reflectors editor dialog box.

Below is a list of the Reflectors Editor options:

New Reflector brings up a dialog that allows you to specify the properties of a new reflector to add.

Name will specify a unique name to be used for the reflector in the registration process.

Shape is a dropdown with three options relating to the three reflector shape types (**Disk**, **Cylinder**, and **Sphere**).

Diameter allows you to specify the diameter of the sphere, cylinder, or disk objects.

Height is accessible only for the cylinder reflector type and specifies the height of the cylinder.

Edit Selected Reflector brings up the Reflectors edit dialog which allows users to change properties of the currently selected reflector.

Copy Reflectors will copy the reflectors.

Delete Selected Reflector deletes the currently selected reflectors.

Import Reflectors will import reflector information in text (ASCII) format.

Export Selected Reflectors will export the reflectors. When pressed, it will bring up the ASCII file export dialog for options.

Transform Reflector will transform the reflector.

View Reflector will display the reflector.

Settings allow users to configure what properties of the reflectors are visible in the spreadsheet control.

Help opens the help documentation.

Exit will close the Reflectors dialog.

After all the reflectors have been added to the project, linking them to their corresponding control points is done through the Control Points Editor.

Coordinate System

The Coordinate System is the current transformation applied to a Scan Position. This transformation is applied to any scans that belong to the current scan position. Typically, manual modification of the coordinate system should not be necessary, as the proper coordinate system to align scans properly should be determined during the registration process. To modify the coordinate system for a scan position, *right-click* it and select **View**. This will bring up the Coordinate System editor.

The transformation panel displays the transformation matrix that is applied to the scan position. Use **Import** to import a coordinate system file (.dat). Use **Export** to export the coordinate system from the point cloud project.

Images

Images are stored in a folder as a sub-item of a scan position. There can be multiple images per scan-folder, and typically are pictures taken from the position of the scanner. Images can only be viewed in 2D mode.

1. *Right-Click* **Images** in the **Current Project** tree.
2. Select **Add > Existing**.

3. In the **PointCloud - Add Image** window, select an existing image to add and click **Open**. Current supported file types are **BMP, GIF, JPG, JPEG, PNG, TIF** and **TIFF**.
4. The **Transfer File** dialog specifies if a copy of the image is to be save to the target location or move the source file and whether to use an existing target file if available or replace target file.

The **Action** panel allows the user to choose to copy the selected image to the target location or move the selected image. Moving the image will delete it from the source location and it will only be available in the target location.

The **If target file exists** panel determines what to do if the file name of the image being added already exists in the project folder.

Processed Data Project Items

There are two data types in Carlson Point Clouds. These are Instrument data and Processed data. Within each data type there are various items and objects that can be added, edited or created. These Data types and items are organized into a tree structure and each can be manipulated by right clicking to bring up a menu specific to that item type. The menu options presented when an item is right-clicked will depend on what the item is. There are several functions that are shared among multiple object types. These common functions are discussed under Data Objects. This section deals with Processed Data objects. The following data types are considered Processed Data:

- Clouds
- Contours
- Coordinate Points
- Grids
- Layers
- TINs
- Planes
- Polylines
- Profiles
- Sections
- Text

Clouds

Clouds can be created several ways.

1. You can *right-click* a scan and select **Create** > Cloud.
2. You can *right-click* **Clouds** and select Import > then select point cloud format.
3. You can *right-click* **on a Cloud** and select Create > Create Cloud.
4. You can right-click on a Cloud and select Copy.

5. You can *right-click* on a Cloud and select Merge.
6. When applying some filters to a point cloud, you can select to create new cloud.

Contours

A contour item consists of several contour polylines that have been extracted from a TIN or cloud. Contour objects can only be viewed in 3D mode. Contour objects can be drawn to the CAD engine. Contour extraction is done through the **Action Tab** of the project manager.

Coordinate Points

There are three kinds of point item types in Carlson Point Clouds:

1. Control Points

2. Target Points
3. Coordinate Points

Control Points and Target Points are Instrument Data and are discussed in the Instrument Data section.

Coordinate points are points extracted from the final registered data sets and are a sub-item of the **Processed Data** folder.

Grids

Grids are a rectangular representation of a TIN. They are created from Cloud scenes or imported. For more information about creating Grids see Create Grid under the **Action Tab**.

Layers

Layers allow the user to control visibility and color for entities drawn in the Point Cloud scenes. For additional information see Layer Properties Manager under Common Utilities.

TINs

TINs are used to extract profiles, sections and can be exported as .TIN files for use with other Carlson modules. For more information about TINs see TINs under Processed Data.

Planes

Planes may be created as part of the process of Contour extraction, Sections and/or Profiles. Planes may also be created by right-clicking **Planes** on the Project tree and selecting **Add > New**. Planes created from the Project Tree will need to be edited to establish location and normal direction. To edit a Plane **double click it** in the project tree or **right-click it** and select **edit**. Planes created by extracting data can also be edited.

Plane extraction may also be initiated by selecting **Plane** from the **Extract Panel** of the **Action Tab**. These planes are a best fit of cloud or scan point data based on user entered parameters and can be used to illustrate wall positions with the draw polyline option.

Polylines

Polylines are usually extracted from the point cloud data working through the Action tab, but they can also be imported from CAD or manually entered with the **Import** and **Add** commands. If you **Add** a polyline it will appear under **Polylines** in the project tree. To edit the new polyline you can **double click it** or **right-click it** and select **Edit**.

Polyline > Import opens the file selection dialog. Users can select TXT, PLN (Carlson polyline file) or CL (Carlson centerline) files to import. The **Edit** option brings up the Polyline Editor; see the documentation on the Polyline Editor for more information.

Profiles

A profile consists of a set of height values and distances taken along a polyline extracted from a cloud, scan or TIN. Profiles can be viewed in 2D and 3D mode and drawn to the CAD engine. Additionally, profiles can be extracted to the .PRO file format. Profile extraction is done through the **Action Tab** of the project manager.

Sections

A sections object consists of a list of profiles taken at set intervals or distances along a polyline. Section extraction is done using the **Action Tab** in the project manager. Sections can only be viewed in 3D mode and can also be drawn to the CAD engine. Additionally, sections can be extracted to the .SCT file format.

Scenes

Scene allow you to visualize the point cloud project data. Scenes maintain a list of objects that are visible in the view that you have selected, for example a point cloud with imported polylines from CAD, graphics properties for those objects, and camera information for the scene. If a scene is closed and then reopened, these properties should still be the same.

Scans

Scans represent the raw data taken from a scanning device. In addition to the position, intensity, color and normal values found in a Cloud, a Scan also maintains the scanner position, a mapping of scanner pixels to points in the cloud, and a mesh structure that creates each point in the scan with its neighbors. Each Scan is associated with one scanner position, which defines the location of the scanner when the scan was taken.

Scan Positions

A scan position encapsulates the entirety of the information needed to match scans taken from a single position with the control points of a project. This data includes any scans taken from that position, the target points associated with that position, any images taken from that position, and the current coordinate system for that scan position.

Importing a Scan

Each of the point engines that are included with Point Cloud support a variety of formats for importing.

To import a scan, right-mouse click on an existing scan position in the **Current Project** tree and select **Import** then click **Scan**. The **Import Scan** file selection dialog will be displayed. Currently **TXT** is the supported file import type.

Navigate to the desired file and click **Open**. The **Import Scan** window will be displayed.

Note: If importing a non ASCII file, the file will be converted to Point Cloud's internal format and saved to the project.

The settings in this **Import Scan** must be configured to match the properties of the scan being imported. First, verify that the correct **Column Delimiter** is being used.

Next, clicking the header of each column to open a menu with possible values that can be assigned to that column. Click on the correct value in the menu to assign it to that column.

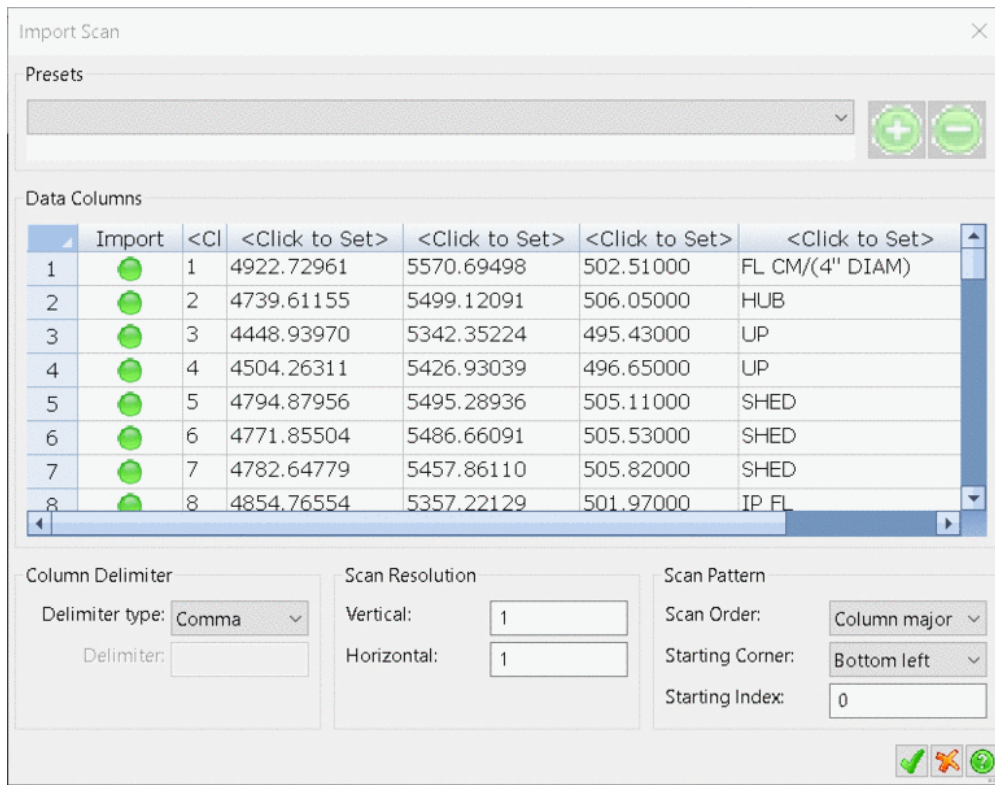

Note: Typically these values can be found in the header of the text file or in a file accompanying the text file.

Scan Resolution allows a user to define the **Vertical** and **Horizontal** resolution for the new scan.

The **Scan Pattern** options determine the ordering method of the scan's data, as well as the starting corner of the scan's data, the data for these values can often be found in the same place as the scan's resolution information, but if not, the default, or the default with the starting corner set to Top Left are the most common scan pattern types.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, define all of the **Import Scan** options as required including the column values and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** button next to the **Presets** drop-down menu.

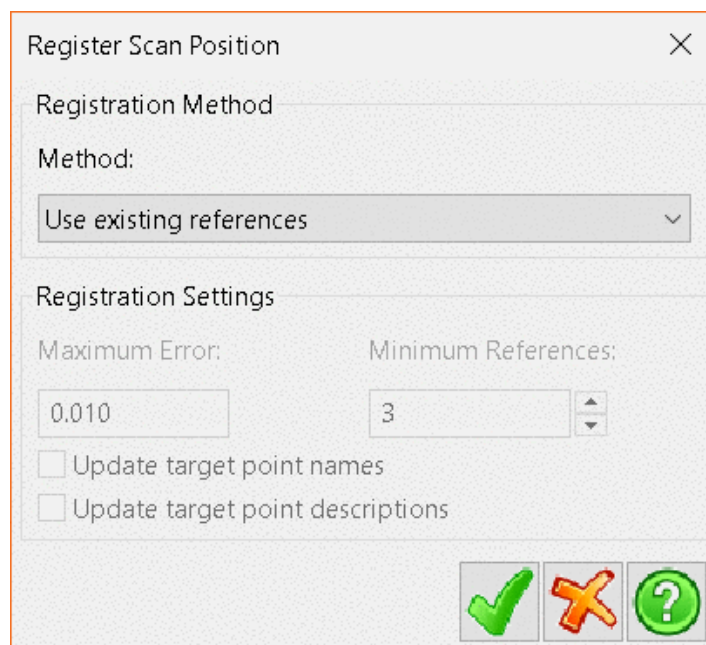

Importing Target Points

Target points can be manually entered or imported via a similar process to scan importing. To enter the target points in manually, right-click the target points object belonging to the scan position to modify and select **Edit**. This will bring up the **Edit Points** dialog for the target points.

Registering Target Points

The scan registration process begins with pressing the **Register** button in the toolbar of the **Target Points Editor**.

Carlson Point Cloud supports four different methods of scan registration:

Use existing references will make Point Cloud only use the references that already exist to perform the registration process (these references can be set manually in the Points Editor, or could have been set in a previous registration process).

Match point names will match target points up with control points with the same name.

Match point description will match target points with control points with the same description.

Minimize position error will attempt to automatically transform the current target points so that they match up with the control points, creating control point-target point pairs. If such a transformation that meets these conditions exists, the target points will have their reference control points set to the control point they were paired with.

Once satisfied, click the **Green Tick**. A dialog will display informing the user if the registration was successful. After all scans have been registered, verify the registration visually by viewing the scans together in the same Scene.

Creating a Scan

Unlike clouds and meshes, Scans can only be created from other Scans. This is due to extra information required for the indexing of the cloud data into the scanner's image.

To create a new scan from an existing one, right-mouse click the source Scan in the **Current Project** tree and select **Create > Scan**. This will display the **Create Scan** window.

Create Scan from single source

Note: Typically, the default options give the best results.

Scan Dimensions determines the height and width (in angles) of the new scan to create:

From Scan will just the ranges from the original scan

Specify will allow the user to specify their own custom angles.

Scan Resolution determines the data density of the new scan, smaller **Delta Angle** values will give denser data, while larger resolutions values will do the same.

From Scan will just the ranges from the original scan

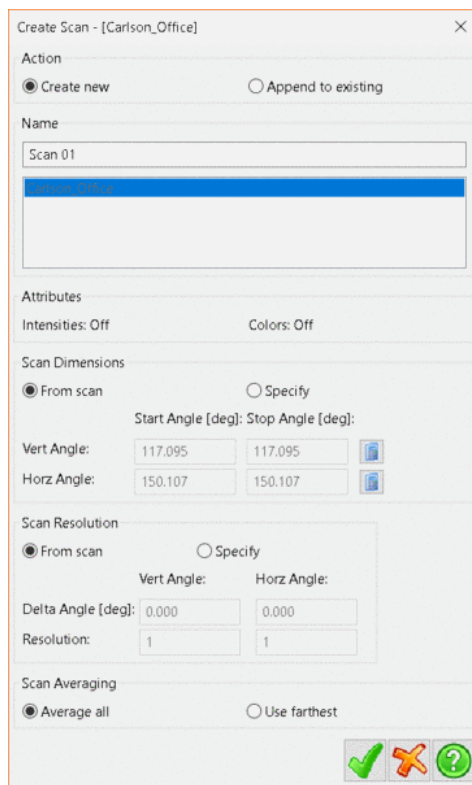

Specify will allow the user to specify their own custom angles

The **Scan Averaging** determines the action to be taken when it is found that multiple scan points in the source data set fall under the same scan pixel in the new scan data set.

Average All will average all color, position, and intensity values, discarding the original data.

Use Farthest will only use the data point furthest from the scanner and discard all other data points.

Click the **Green Tick** to create the new scan.

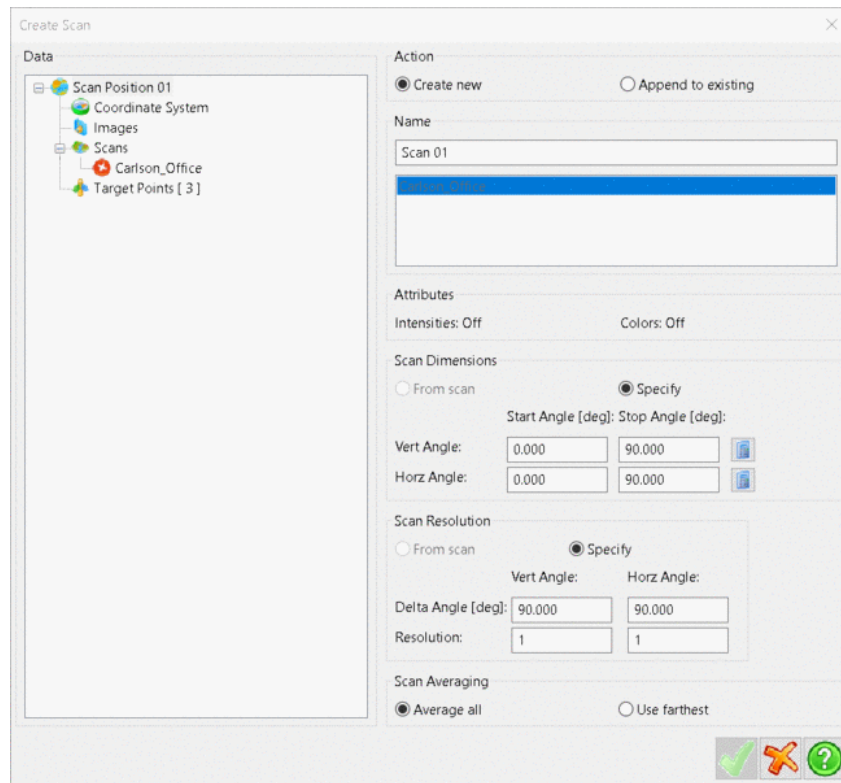

Create Scan from multiple sources

To create a scan from multiple source scans, right-mouse click on the **Scan Position** in the **Current Project** tree and select **Add > New**.

The options on the right side of the **Create Scan** window have the same functionality as the single source dialog. The tree structure on the left side of the dialog allows the user to choose the source scans to use for data. Clicking the **red x** next to a scan will turn it into **green circle**, signifying to use that scan as a data source.

Click the **Green Tick** to create the new scan.

Cleaning a Scan

To clean up scanner data to make it more uniform and remove possible outliers, right-mouse click the scan in the **Current Project** tree and select **Clean**.

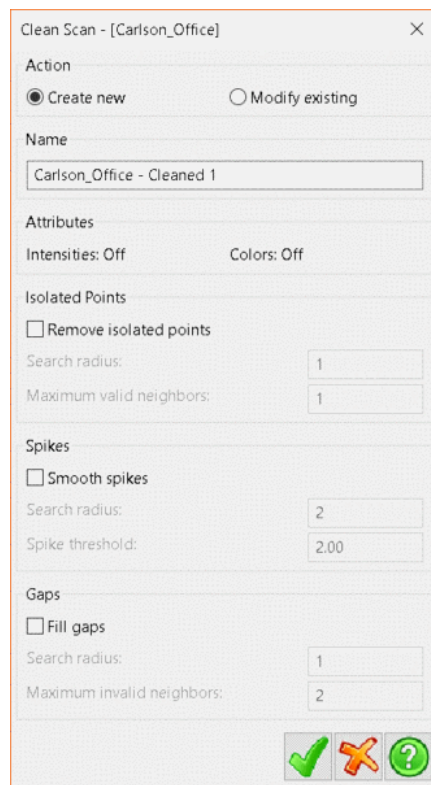

Carlson Point Cloud has three separate methods of cleaning scans:

Remove Isolated Points searches all neighbor data points within a square with a side length of **Search radius** pixels around each pixel in the scanner image for valid data. If less than the maximum amount of valid neighbors specified is found, the point is deleted.

Smooth Spikes reduces spikes in the mesh by finding any points whose distance from the scanner is larger than **Spike threshold** standard deviations from the average of the pixels in the search radius.

Fill gaps searches each invalid point's neighbor's for the specified amount of invalid neighbors. If less than the specified amount is found, then the invalid reading is changed to a valid reading with a range equal to the average of the neighbor points and color values equal to the average color values.

Click the **Green Tick** to clean the scan.

Resampling a Scan

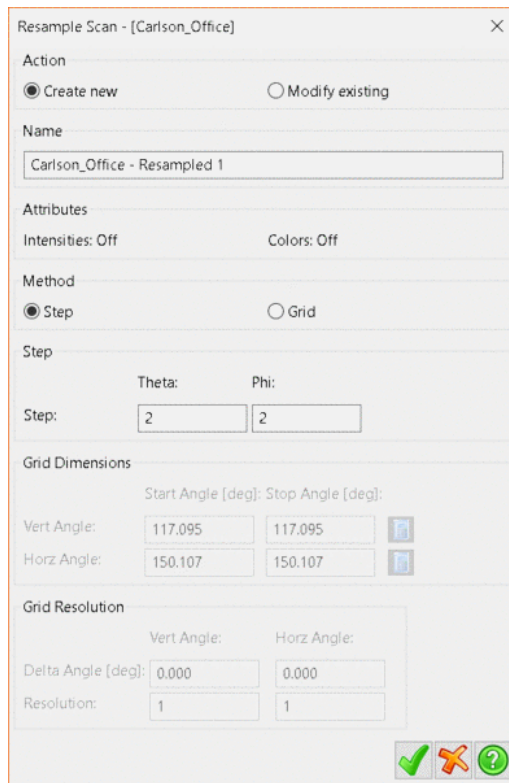

To resample a scan, right-mouse click on the scan in the **Current Project** tree and select **Resample**.

There are two methods of resampling:

The **Step** method of resampling steps through the scan using the step values provided for the step size. With a **Theta** and **Phi** value of 2 each, the scan will be reduced to 1/4th of its original size.

The **Grid** method divides the scan up into a grid where each grid block is of the specified size. It then averages the values found inside each block to a new single value for that entire grid block.

Click the **Green Tick** to resample the scan.

Tab Location(s): Project Tab

Prerequisite: Scanner Data

TINs

A TIN or Triangulated Irregular Network is the final result of processing a scan or cloud and are the basis upon which most data extraction is performed. The TIN structure itself is a set of vertices and a set of edges and faces that connect those vertices as well as any color or intensity values that were in the cloud or scan that the TIN was created from.

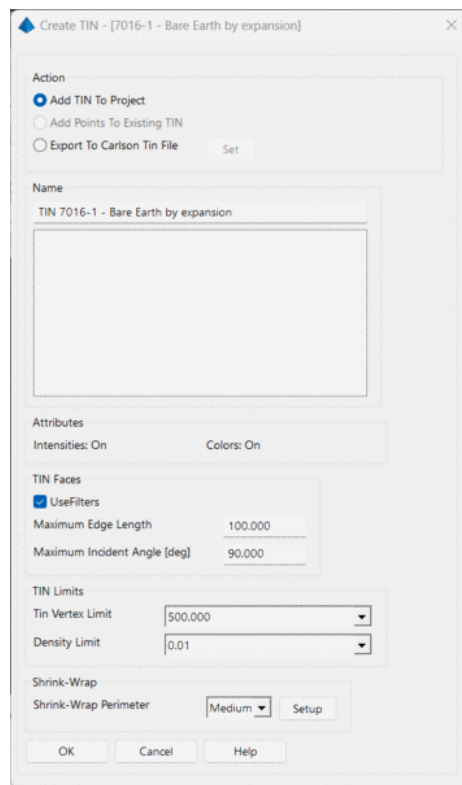

Importing a TIN

One can import a .tin file simply by right-clicking the **TINs** folder and selecting **Import** and navigating to the .tin on disk.

Creating a TIN

There are several methods for creating a TIN, but all of these methods use one of two cloud creation dialogs. The most common and direct method of creating a TIN is to right click the source data object (either another TIN, a cloud or a scan) and select **Create > Create TIN**. You can also access the **TIN** dialog from the **Action Tab**. Creating a TIN from another TIN will re-triangulate the points in that TIN based on the new normal information provided in the **Create TIN** dialog, so it is entirely possible that your new TIN can look completely different.

This dialog operates in two different modes: multiple source mode and single source mode. The single source mode is typically the result of right-clicking a data object in the Point Cloud tree structure and selecting **Create TIN** or from the **Action Tab**, this mode only allows the TIN to use the originally selected data as its source.

The **Action** panel gives you options to **Add TIN to Project**, adding a TIN to point cloud manager project, **Add Points to Existing TIN**, and **Export to Carlson TIN File** to save a .TIN file that can be read by other Carlson programs including Survey, Civil, Takeoff, Mining.

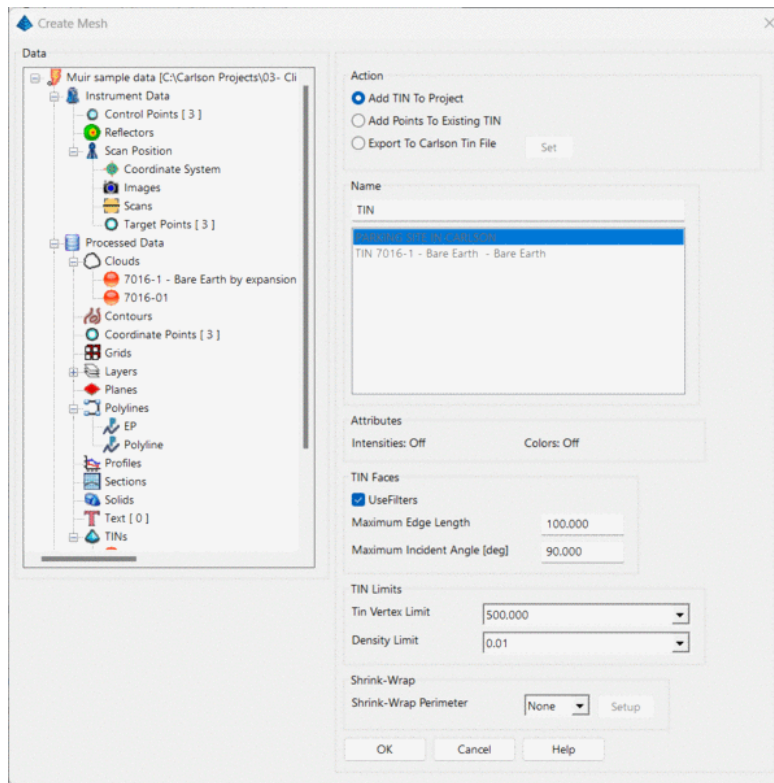

In the **Name** panel you can enter the name for the new TIN. If Add Points to Existing TIN is selected, you can choose the TIN to edit from the panel's list.

The **TIN Faces** panel allows you to set restrictions on the triangulation process. **Use filters** determines whether or not to filter out vertices based on **Maximum Edge Length** and **Maximum Incident Angle [deg]**. No edge in the TIN will be created if it will exceed the **Maximum edge length** or if the angle between the two faces it connects exceeds the **Maximum incident angle**.

In the **TIN Limits** panel, **TIN Vertex Limits** specify the maximum number of TIN vertices that will be used in a TIN. Setting this value too low may result in no TIN being created. **Density Limit** will limit the size of the smallest triangles.

In the case of scans, there will be a **From Scan** radio button that you can use, which will automatically use the scanner position information from the scan as the normal. The **Normal** is the direction to use for the Delaunay TIN triangulation; typically you want to use an axis that is representative of the direction that the data was taken from, such as the view direction of the scanner.

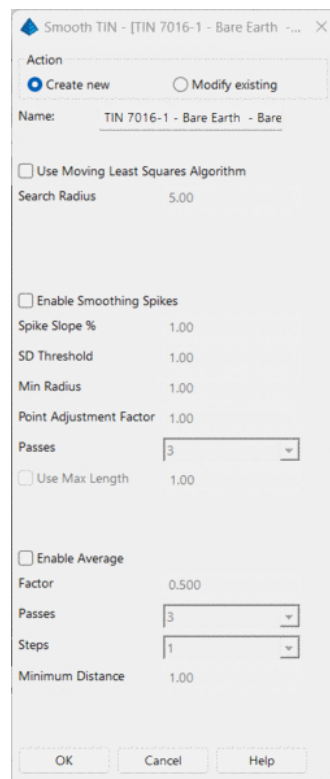

One can also create a TIN with multiple sources by **right-clicking** the **TINs** folder and selecting **Create New**, this will bring up a dialog similar to the one above with an extra tree control to the left.

All of the controls on the right half of the dialog are the same, but you can now toggle inclusion of objects into the TIN by clicking the **red ball** next to their name in the tree, turning the icon to a **green ball**.

Smooth TIN

Smooth TIN allows you to create a new TIN or modify the existing TIN. There are three methods for smoothing which may be used separately or in combination

Use Moving Least Squares - If toggled on, create a Moving Least Squares (MLS) approximation of TIN. The MLS algorithm fits a curved surface using least-square to each vertex of the TIN based on the neighbors within the **Search Radius** of that vertex. Each vertex is then projected onto its least-squares curved surface.

The **Search Radius** is a unit-less dimension used to determine how many neighbors a point has when generating a least-squared surface approximation for the TIN at that vertex. Any other vertices within the search radius distance of a vertex are considered neighbors.

Enable Smoothing Spikes - If toggled on, the routine will iterate over every vertex of the TIN and delete vertices that are considered spikes based off of the profiles in the xz and yz planes at that vertex and the smoothing settings.

Spike Slope % is the angle, in degrees, of the profile slope along the the xz and yz planes after which a vertex will be considered a spike. A value of 90% will disable this test

SD Threshold is the unit-less distance from the average plane of the neighbor points past which qualifies a vertex as a spike.

Min Radius is the unit-less distance from a vertex on the TIN to search for neighbor vertices.

Point Adjustment Factor specifies how far a point should move toward the the average plane of its neighbors. 1.0 meaning "move vertex's position to the plane" and 0.0 meaning "Do not change the vertex's position at all".

Passes are the number of times to apply the spike smoothing algorithm to TIN. Value 1-9.

Use Max Length, if toggled on, use "Max Length" alternative to the "Minimum Radius" option. Should only be used is there are a significant number of breaklines in the TIN.

Enable Average - If toggled on, smooths vertices of TIN by moving them towards the average elevation of their neighbor vertices' positions.

Factor is the factor to adjust a vertex's elevation by. 1.0 meaning "make vertex's elevation equal to the average of its neighbors' elevation), 0.0 meaning "do not change vertex's elevation".

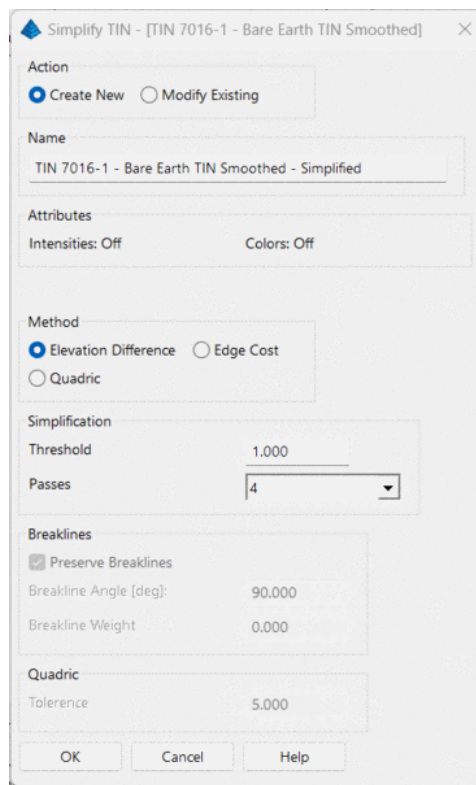

Passes is the number of times to apply "averaging" algorithm to TIN. Value 1-9.

Steps is used to specify the vertices considered neighbors of a vertex when applying the "averaging" algorithm to that vertex. Any vertex connected to the a base vertex (by an edge) is considered a 1-step-neighbor vertex to that base vertex. Any vertex connected to any of those 1-step-neighbor vertices that is not a 1-step-neighbor vertex or the base vertex is a 2-step-neighbor-vertex. In total, n-step-neighbor vertices will be used in the "averaging" algorithm for a base vertex.

Minimum Distance is the minimum elevation change that can be applied to a vertex's position when "averaging." If the distance from a vertex's elevation to its neighbors' average elevation is less than "Minimum Distance" it will not be moved.

Simplify TIN

Simplifying a TIN is one of the key ways to reduce data down to a state that it can be transferred over to the CAD software or to make it more manageable in Point Cloud without losing much surface quality. **Right-click** the TIN to simplify and select **Simplify**. This will open the **Simplify TIN** dialog.

There are three methods of TIN simplification available. Elevation Difference, Edge Cost, and Quadric.

The **Elevation Difference** method will loop over all the vertices in the TIN a number of times based on the number of **Passes**. The program will delete vertices whose deletion would not lead to a deviation in the current TIN of less than the **Threshold** value entered. Note that this method may be slower than the others.

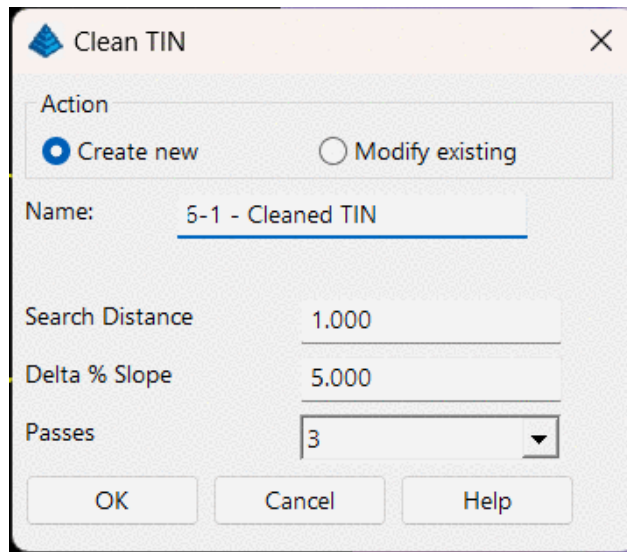

The **Edge Cost** method determines the total deviation in the TIN that result from each edge removal by merging its two vertices and removes all edges whose removal would result in a deviation of less than the **Threshold** value entered. In addition, the preserve breaklines options for the **Edge Cost** method will multiply the deviation value calculated by the **Breakline Weight** if the angle between the two faces it borders is greater than the **Breakline Angle**, this can be used to help preserve corners.

The Elevation Difference method is best used in largely flat data (such as a scan of a large open area), while the Edge Cost method is best for complex data with lots of corners. Additionally there is a memory trade off, the Elevation Difference method is generally slower at higher numbers of passes (which gives better results), while the Edge Cost method consumes more memory.

Clean TIN

To remove spikes from a TIN, **right-click** the target TIN and select **Clean**. Vertices that meet the parameters of this dialog will have their positions adjusted to meet the shape of the vertices around them, smoothing out the TIN.

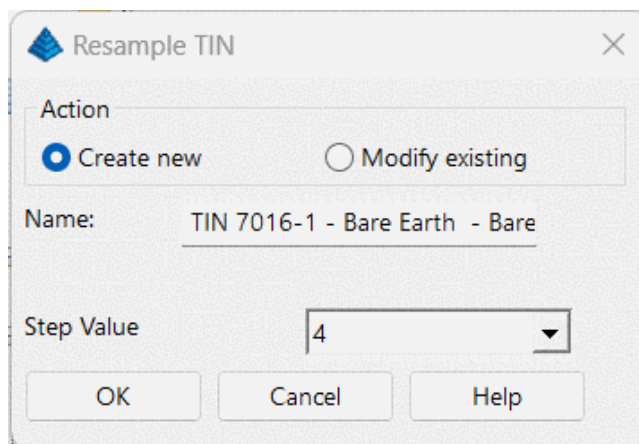

Search Distance determines the distance for a vertex to search for vertices that exceed the Delta % Slope. **Delta % Slope** is the maximum change in slope that is allowed. Vertices that exceed this value are removed. **Passes** determines the number of passes to make over the TIN.

Resample TIN

Resampling a TIN goes through the list of points in a TIN and takes one out one point at the **Step Value** interval. Therefore the number of points in the resulting TIN will be $(1 / \text{Step Size})$ times the original number of points in the TIN.

To run this command, **right-click** on the existing TIN and select **Resample**. In the Resample TIN window, the user can either choose to modify the existing TIN or create a new TIN with the resampled data. The **Step Value** can be varied from 2 to 10, depending on the final size of the output.

For example:

Original TIN

Cloud	Mesh	Notes
Data		
Vertices:	171,226	
Edges:	913,652	
Faces:	342,427	

10Mb

TIN Resampled Step 2

Cloud	Mesh	Notes
Data		
Vertices:	85,612	
Edges:	296,801	
Faces:	171,190	

5Mb

TIN Resampled Step 10

Cloud	Mesh	Notes
Data		
Vertices:	17,122	
Edges:	51,302	
Faces:	14,211	

1Mb

Approximate File Sizes of Exported TIN

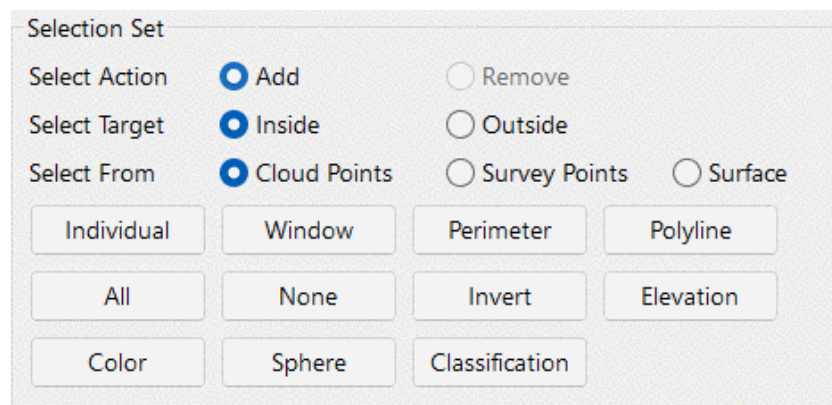

Tab Location(s): Project Tab
Tree Folder: TINs
Prerequisite: An Existing TIN

Action Tab

The **Action Tab** is the fourth tab in the **Point Cloud Manager**. All data extraction, as well as virtual surveying, is done here. A Scene with 3D data must be currently opened for the controls in the Action tab to be enabled.

The Action functions that can be used on the objects in a scene are broken up into five different Panels: **Selection Set**, **Edit**, **Transform**, **Create**, and **Extract**.

The group of radio buttons at the top of the **Selection Set** panel operate as a group to determine the behavior of the *Individual*, *Window*, *Perimeter*, and *Polyline* selection modes.

Add/Remove determines whether the objects that are selected in the view are to be added or removed from the current selection set.

Inside/Outside determines whether to perform the selection operation on entities inside or outside the boundary of the current selection set.

The next set of three radio buttons determines whether the entities to be selected are *Cloud Points*, *Survey Points*, or *Surface*.

There are four selection modes: **Individual**: every mouse click attempts to select the object currently under the cursor - useful for precision selection of individual points.

Window: you will be prompted to pick a base point and then pick a second point that defines the opposite corners of a selection window.

Perimeter: you will be prompted to pick several times on the scene to define the shape of the perimeter and then right-clicks to close the perimeter.

Polyline: you will be prompted to select an existing polyline in the scene. The polyline(s) can be drawn using the *Create Polyline* command or can be *Read from CAD*.

There are also seven global selection buttons:

All: selects all entities in the scene.

None: deselects all entities in the scene.

Invert: inverts the current selection set in the scene.

Elevation: you can specify maximum and minimum elevation values to build the selection set in the scene.

Color: selects all points with a matching RGB value to the point selected. Adjust the *Color Tolerance* to also select points with closely-matching RGB values from the base color. Users also have the ability to click on the **Screen Pick** button to set the tolerance by clicking **Screen Pick**, then choosing a first and second points to calculate the tolerance. Within the action, you can use the *Add/Remove*, *Inside/Outside* parameters as well as *Invert the Selection* and *Create a Region* from it.

Sphere: selects any points within a radius of the *Specified Point Position*.

A **Region** of selected Points can be saved to be hidden or to re-select at a later stage. See the Scene Tab page for more information.

The **Edit** panel contains controls for modifying the currently visible set of points.

Information button displays a properties dialog with some general statistical information about the current selection set, including the number of points selected, ranges of their positions, color ranges and intensity values. Click **Show Advanced** to display the Mean and Standard Deviation.

Delete button deletes the selected points from the scene and from any objects that contained them. The User will be prompted to confirm whether to Delete selected entities.

Hide button temporarily hides the current selection set, isolating the current area of interest without making permanent changes to the dataset.

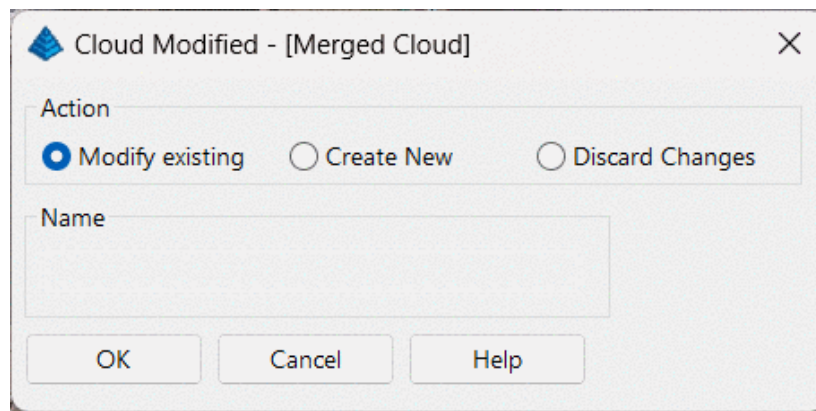

Show All will display all hidden points in the scene.

Image allows the user to drape an image over a TIN.

Smooth and **Clean** will act on the Cloud or TIN in the current Scene. See Smooth Cloud, Clean Cloud, or the TINs entry.

Crop deletes any points outside of the current selection.

As you make edits to the cloud, it is recommended that you Save the project. If you close the Scene viewer and haven't saved the changes yet, the program will prompt if you want to **Modify existing** cloud, **Create New** cloud, or **Discard Chnages**. If you select **Create New**, you will need to enter the **Name** for the new cloud.

The Transform panel contains two functions that allow you to apply translate, rotate, and scale adjustments to the selection set.

The **Create Panel** allows a user to manually create new project items including points, polylines and text, or by creating a new data set from the currently selected data points such as clouds, TINs and grids.

Create Point: will open the Point Creation action panel.

Create Polyline: will open the Polyline Creation action panel.

Create Cloud: will bring up the Point Cloud creation dialog. Enter the *Name* for the new cloud and click *OK* to create the new point cloud from the selected data in the current scene.

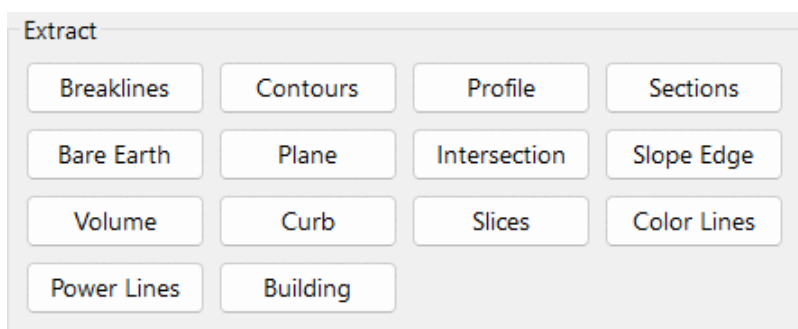

Create TIN: will bring up the TIN Creation dialog to create a TIN from the selected cloud data in the current scene.

Create Text: will open the Text Creation action panel.

Create Grid: will open the Grid Creation dialog to create a grid from the selected data in the current scene.

Create Solid: will bring up the Create Solid dialog to create a solid from the selected data in the current scene.

In the Extract Panel you will find functions to automatically extract features from point clouds such as curbs, parking lines, road markings, color edges, building and roof footprints, and power lines. Also in this panel are the bare earthing routines and tools to obtain profiles, cross sections, contours, and run volume calculations.

For more information on the specific extract tools, click on the links below to open the corresponding help entry:

- Breaklines
 - Contours
 - Profile
 - Sections
 - Bare Earth
 - Plane
 - Intersection
 - Slope Edge
 - Volume
 - Curb
 - Slices
 - Color Lines
 - Power Lines
-
- Building

Note that extracted features can be easily transferred to CAD. *Points* can be drawn in CAD using the **Field-to-Finish** routine or drawn using **Locate Points** by **right-clicking** on the **Coordinate Points** from the **Current Project Tree**. *Polylines* can be drawn by **right-clicking** on **Polylines** from the **Current Project Tree**.

Bare Earth

Clicking the **Bare Earth** button from the **Extract** panel in the **Action tab** will display the Bare Earth options. It can also be accessed by right-clicking on the point cloud in the Project Tree.

There are three methods for Bare Earth extraction, **Expansion**, **Grid** and **Profile**.

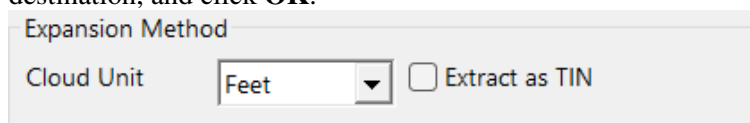

Expansion mode works by inspecting the cloud by dividing it into small cells, resolving the ground plane for individual cells from the bottom up, and then clustering the cells. Once it has determined what is most likely to be ground it will expand the point clusters to other cells. Lastly, it will create a TIN from the ground clusters to resolve isolated points. Benefit of this mode is that it has no parameters that need to be entered.

Grid mode works by inspecting the cloud as a grid to find the lowest valid points in each grid cell and keeping only those points.

Profile mode works by drawing a 3D line away from the scanner and seeing if it slopes upwards too sharply, removing any vertical segments and keeping any flat segments.

Expansion Method

Select the **By Expansion** radio button. This method only requires confirmation that the units are correct, choose the destination, and click **OK**.

Expansion Method

Cloud Unit: Feet Extract as TIN

Extract Destination: Can create either a new **Bare Earth Cloud**, a **Non-Ground Cloud** or **Bare Earth Region**. The Regions option creates regions within the current Cloud instead of creating a new Cloud. Regions are usually slower than creating a new Cloud.

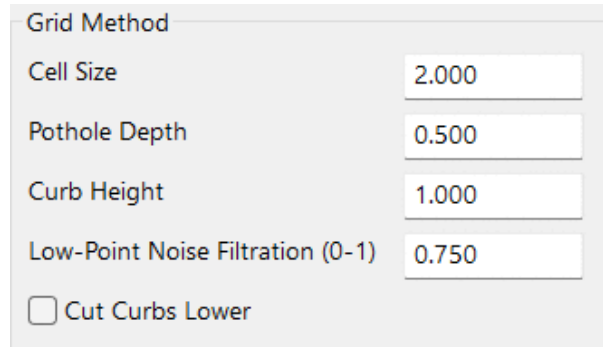

Name: Name for the newly created cloud

Cloud Unit: as the parameters for this method are internal, make sure that the selected unit matches the point cloud units.

Extract as TIN: will bare earth the point cloud and save the results as a TIN file rather than a new point cloud.

Grid Method

Select the **By Grid** radio button. Enter the desired cell size, pothole depth, curb height, and low-point noise filtration values. To begin the **Grid Method** Bare Earth extraction, click the **OK** button.

Grid Method	
Cell Size	2.000
Pothole Depth	0.500
Curb Height	1.000
Low-Point Noise Filtration (0-1)	0.750
<input type="checkbox"/> Cut Curbs Lower	

Extract Destination: Can create either a new **Bare Earth Cloud**, a **Non-Ground Cloud** or a **Bare Earth Region**. The Regions option creates regions within the current Cloud instead of creating a new Cloud. Regions are usually slower than creating a new Cloud.

Name: Name for the newly created cloud

Cell Size: Determines the grid size when analyzing the point cloud. It is recommended to use small cell size values.

Pothole Height: The tolerance for a point to be considered within the level that is to be kept for each grid cell.

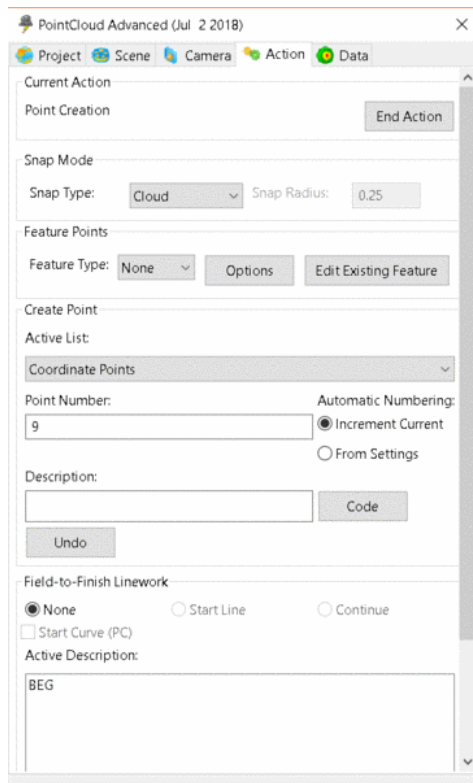

Curb Height: The tolerance between adjacent cell elevations to determine which cells should be kept.

Low-Point Noise Filtration: Filters out points below the level for each grid cell. A value of 0 will just accept the lowest point in each cell even if it's an outlier due to noise.

Cut curbs lower: When this is checked, doesn't take adjacent cells into account when deciding which points to take from each grid cell.

Profile Method

Select the **By Profile** radio button. Move the cursor to the Scene window and CTRL+click to specify the "scanner" position or center of the Bare Earth extraction. The scene must be in **Plan** view (View from Top) to run the Profile Method Bare Earth extraction. Points are examined and either included or excluded for the Bare Earth Cloud based on the extraction parameters.

Snap Mode Panel

The Snap Mode Panel offers twelve different options for snapping to points in the cloud in the open scene.

Cloud - No snap function is active. The vertex of the polyline will be placed at the cloud point nearest to the selected location.

Low - The point is placed at the lowest point (smallest z value) within the Snap Radius.

High - The point is placed at the highest point (largest z value) within the Snap Radius.

Low Edge - Snaps to the low edge of a feature, like a curb. A dynamic window in the upper left of the scene displays a cross section of the area within the Snap Radius and displays the high and low edge as red squares.

High Edge - Snaps to the high edge of a feature, like a curb. A dynamic window in the upper left of the scene displays a cross section of the area within the Snap Radius and displays the high and low edge as red squares.

Slope Bottom - Snaps to the bottom edge of a slope that is less than 45 degrees. This is useful for finding low edges on mountable curbs and other non-vertical features.

Slope Top - Snaps to the top edge of a slope that is less than 45 degrees. This is useful for finding upper edges on mountable curbs and other non-vertical features.

Average Point - This snap averages Northing, Easting and Elevation for all points within the Snap Radius and uses the averaged values for the coordinates for the new point.

End Point - Snaps the new point to the endpoint of an existing polyline.

Mid Point - Snaps the new point to the midpoint of an existing polyline.

Node - Snaps the new point to points placed in the drawing using Carlson Point Cloud Create Point.

Nearest - Snaps the new point to the point on an existing polyline nearest to the cursor location.

Feature Points Panel

Feature Points

Feature Type:

Feature points are specific types of features that Carlson Point Cloud can automatically extract. These points are extracted as 3D elements to reflect the feature selected and display the general shape in the Point Cloud scene. The screen captures below show the various 3D elements for each feature type. There are six options in the Feature point drop list.

None - No Feature type is selected.

Tree - The user picks a point near the bottom of a tree in the scene and the trunk diameter, height, and drip line diameter are extracted and displayed as the description for the point.

Pole - The user picks near the base of a pole in the scene and the diameter and height are extracted and displayed as the description for the point.

Hydrant - The user picks near the base of a hydrant in the scene and the diameter and height are extracted and displayed as the description for the point.

Circle - The user picks anywhere on a vertical structure such as a pole and the diameter of the pole is extracted. The program then prompts for an elevation and the user can pick a second point for the actual elevation of the pole. This is useful when the bottom of the pole is obscured.

Corner - This feature places a point at the intersection of two building faces. The user picks the first flat building face followed by the second. The program then prompts for a third location to use as an elevation. The result is a point set at the intersection of the two building faces at the elevation picked such as the actual ground.

Clicking **Options** from the **Feature Points** panel will display the **Feature Options** window.

Hide Feature Points - When toggled on this command will "hide" or remove from the scene the points that make up the feature selected. For example, if feature type Pole is active and you select the base of a pole, the points that display as the pole in the scene will be hidden. A coordinate point is placed showing the diameter and height of the pole.

Use SZ Code - When toggled on this command will change the description displayed in the scene and stored in the Coordinate list. The new description is coded to take advantage of special codes in Field to Finish to more accurately display the features. Size or height, rotation and diameter or width. By setting up the Field to Finish file (.FLD) to place 3D blocks and use the special codes placed in the description by Point Cloud a more realistic and accurate 3D view can be created in CAD. **Draw Solid Feature** - draws the item as a solid

For the **Tree, Pole, Hydrant, Fence, Building, Circle, Corner** settings, fill them out to suit the scene.

Note: If the Hide Feature Points is toggled on and features are selected the user will be prompted to update the cloud, save a new cloud or discard changes when closing the scene.

Create Point

The Create Point panel displays options for creating a point.

Create Point

Active List:

Coordinate Points

Point Number: Automatic Numbering:

Increment Current

From Settings

Description:

In the Create Point panel you can choose the destination of points created using the Active List drop list. Points created will be added to the list displayed in the Active List. Three options are available.

- Control Points
- Scan Position
- Coordinate Points

Point Number determines the number to be assigned to the point. There are two options for numbering.

Increment Current will follow the standard numbering convention of Carlson Civil Suite (increment the number without any filler digits).

From Settings will use the prefixes and digits from the naming Conventions in the **Project Settings**

Clicking **Code** will bring up the **PointCloud - Code Table** dialog.

PointCloud - Code Table

FLD File
C:\Carlson Projects\Settings\carlson.fld

Categories

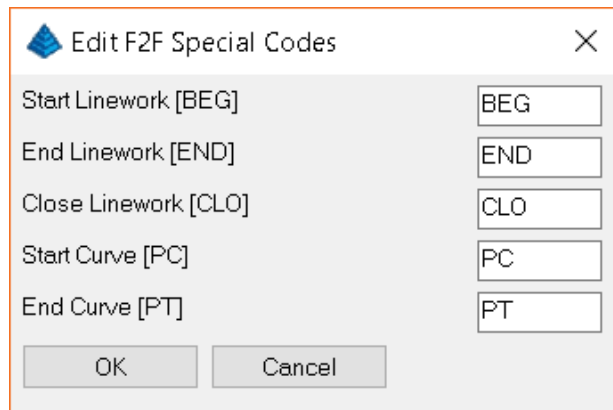

- FENCES & WALLS
- GROUND FEATURES
- MISC CODES

- UTILITIES

Codes

Code	Full Name	Enti
2D	2"	Point
2P	2" PINE	Point
4D	4"	Point
4P	4" PINE	Point
6D	6"	Point
6P	6" PINE	Point
8D	8"	Point
8P	8" PINE	Point
9P	9" PINE	Point
10D	10"	Point
10P	10" PINE	Point
12D	12"	Point
12P	12" PINE	Point
14D	14"	Point

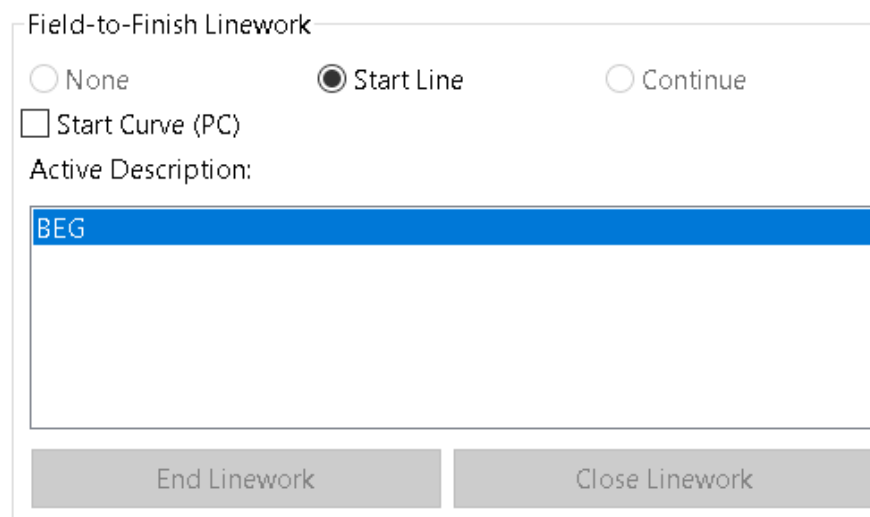

Pick FLD File allows the user to set the current field-to-finish file (.FLD). Once an FLD file is open the user can select a code to use to create points by click the desired code and then clicking the Green check mar.

Special Codes allows the user to adjust the F2F Special Codes used for Start, End and Close of Linework and the Start and End of Curves.

Field-to-Finish Linework

The Field-to-Finish Linework panel allows you to specify properties of the next field-to-finish linework segment (if the current code table entry has linework associated with it). If your code does not specify linework you will receive a message that your code does not have linework associated. Once you clear the message dialog your point will be placed and the linework options will be set to **None**.

Once a code is selected from the Create Point panel the user may select one of the Field-to-finish Linework radio button options.

None no linework is created. This is the default when a Point code without linework is selected.

Start Line Begins a line using the parameters in the code table. Lines are only created for point codes that have linework associated with them.

Continue is selected as you continue adding points to the current field-to-finish linework.

Start Curve (PC) Sets the starting point for an arc. The arc will be drawn using the parameters in the code table.

Prompts

Specify Vertex Position: Places a point at the selected location. If the point Code is associated with line work the point is connected to the previous point with a line.

Survey by Grid

The survey by Grid command sets points throughout the entire cloud at a preset interval. ie. 25' grid.

Point Code - Specify a single code for all grid points

Starting Point Number - Specify the point number to begin numbering sequence with

Cell Size - Enter the size of the grid spacing

Point Within - Specify the radius for the program to consider for the Elevation Method Snap setting

Elevation - Similar to above, specify the snap settings for elevations within the radius specified.

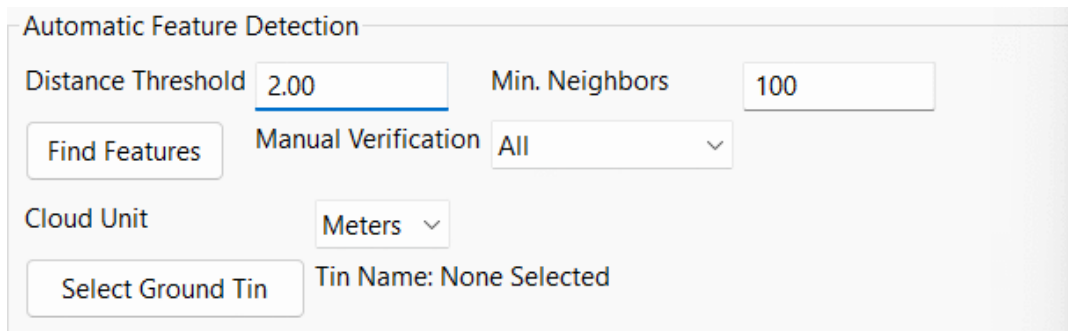

Example: The above settings would set points at the lowest elevation found within a 0.25 radius. (The drawing units are considered ie. meters, feet)

Automatic Feature Detection - *Experimental Feature* -

This requires a lot to setup - all of the Features listed above (tree, pole, etc) need to have their Settings set correctly in order for this to run correctly.

NOTE: the objects to be extracted need to be, in general, not touching each other. So a tree touching a fence would probably not work. Fences touching a building are OK. **The features in the cloud need to be well separated and isolated from one another.**

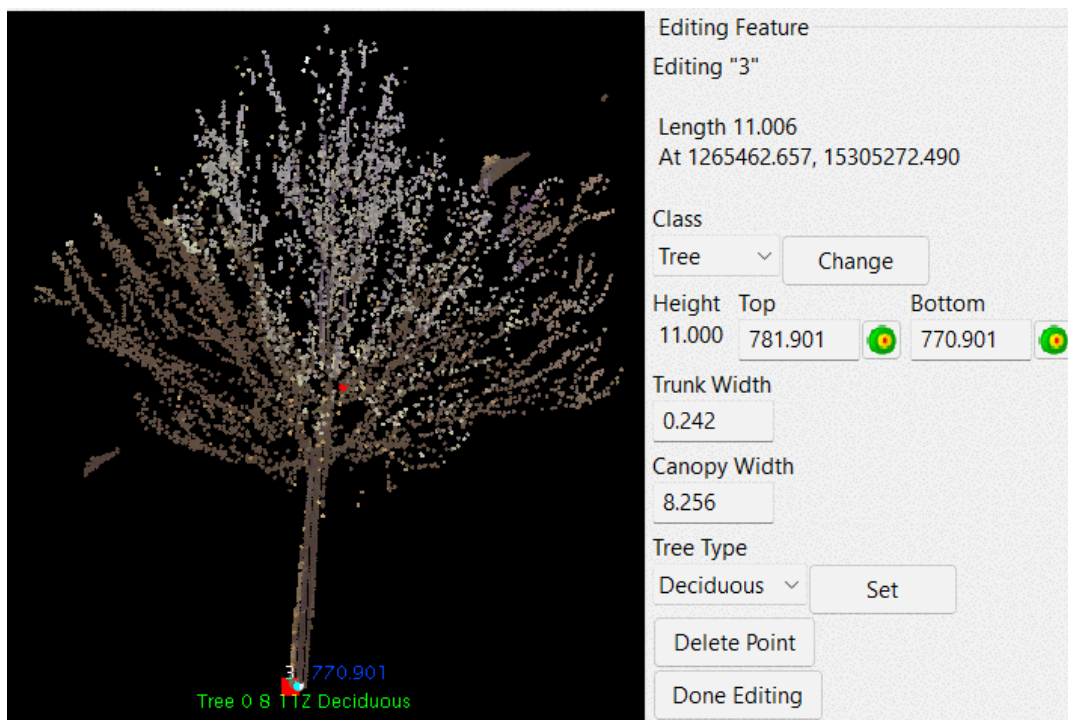

In most cases, it would be worth extracting the bare earth and creating a non-ground cloud. Then create a TIN ground surface that can be used in this routine. By having a TIN set as the ground reference, it will allow the software to better differentiate between the ground and the feature. The TIN can be turned off when loaded into the scene - with the **Show Front** unchecked, then TIN will be hidden but still used in the routine.

Manual Verification being set to ALL forces the user to run through each feature that has been found to confirm that they are indeed correct. If set to **Low Confidence** it will only pause on items that are uncertain.

Once all the settings for each feature has been configured, click on **Find Features**. It ask for the TIN file then run through the routine finding all the features.

It will now run through each feature for confirmation (if set to **All**).

When editing, the **Class** can be changed along with the **Top** and **Bottom** elevation of the tree. Click on the icon to the right of each box to pick the point on screen.

NOTE: this

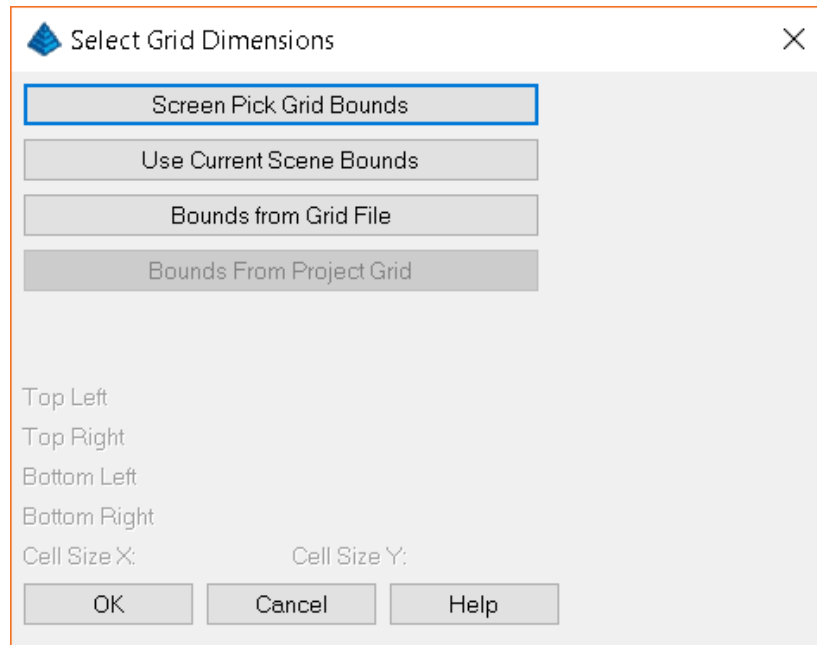

Tab Location(s): Action Tab

Panel and Button: Create and Point

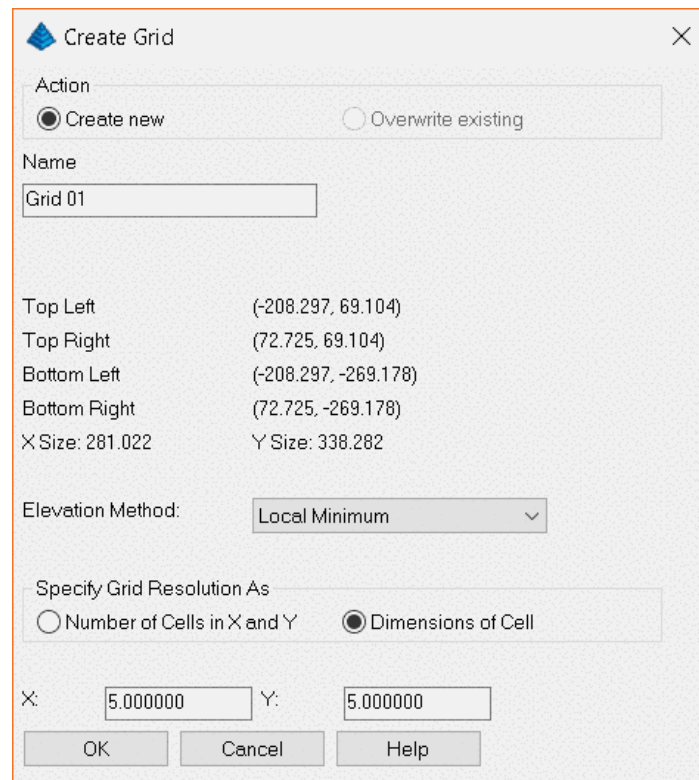

Prerequisite: An open scene of a point cloud

Create Grid

Selecting the **Grid** button from the Create panel in the **Action Tab** will open the **Select Grid Dimensions** window. Users can define the desired Grid manually onscreen, by using the boundary extent of the current scene or by selecting a Grid file (.grd).

To define the extent of the Grid onscreen, click **Screen Pick Grid Bounds**. The Scene will default to a Top-down view. Click once to pick the first corner, move the mouse to expand the box and click again to pick the other corner. The **Create Grid** window will now be displayed.

Name

The default name of the new grid is controlled through **Settings** on the **Project** panel. Statistical information about the selected area will be shown below the name field. For best results work in Plan view with the X axis pointing to the right and the Y axis pointing up.

Elevation Method

Elevation Method:

Local Maximum - Uses the maximum elevation within a grid cell as the cell elevation.

Local Minimum - Uses the minimum elevation within a cell as the cell elevation.

Cell Average - Uses the average of the cell elevation as the elevation for the cell.

Specify Grid Resolution As

Specify Grid Resolution As

Number of Cells in X and Y Dimensions of Cell

X: Y:

The grid Resolution may be specified in either the number of cells in the X and Y direction or by the size of each cell. After selecting a method you may adjust the values for X and Y. The total number of cells that will be created is shown below the X and Y values.

Note: If the size of your cell is less than the distance between points in your cloud you will have holes or void areas in your grid. If this occurs you can select the same area and create a grid with larger cell dimensions or a fewer number of cells.

To end the Grid Creation mode click the End Mode button at the top of the Action tab.

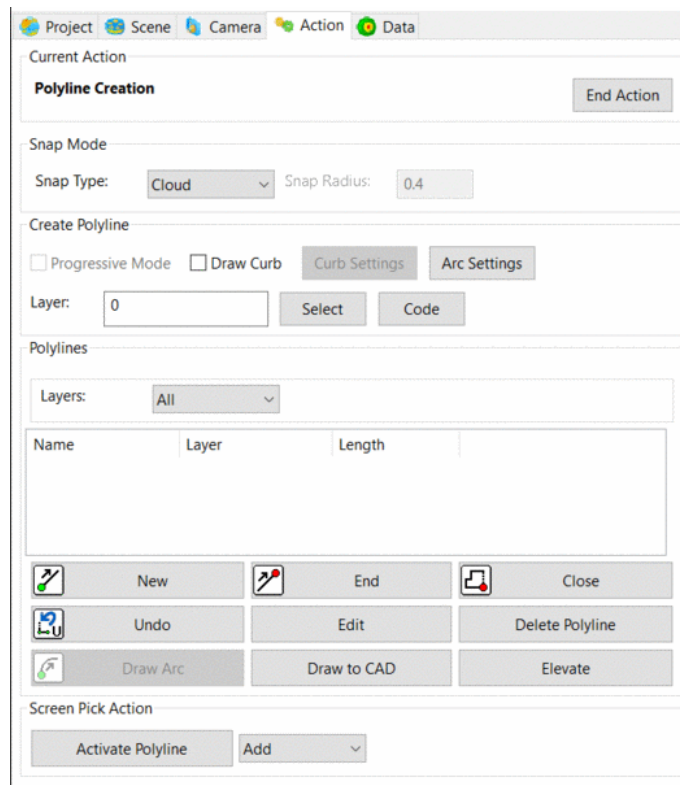

Tab Location(s): Action Tab

Panel and Button: Create and Grid

Prerequisite: An open scene of a point cloud

Create Polyline

Selecting the **Polyline** button from the **Create** panel in the **Action** tab will open the **Polyline Creation** dialog.

Snap Mode Panel

The Snap Mode Panel offers twelve different options for snapping to points in the cloud in the open scene.

Cloud - No snap function is active. The vertex of the polyline will be placed at the cloud point nearest to the selected location.

Low Point - The polyline vertex is placed at the lowest point (smallest z value) within the Snap Radius.

High Point - The polyline vertex is placed at the highest point (largest z value) within the Snap Radius.

Low Edge - Snaps to the low edge of a feature. A dynamic window in the upper left of the scene displays a cross section of the area within the Snap Radius and displays the high and low edge as red squares.

High Edge - Snaps to the high edge of a feature. A dynamic window in the upper left of the scene displays a cross

section of the area within the Snap Radius and displays the high and low edge as red squares.

Slope Bottom - Snaps to the bottom edge of a slope that is less than 45 degrees. This is useful for finding low edges on mountable curbs and other non-vertical features.

Slope Top - Snaps to the top edge of a slope that is less than 45 degrees. This is useful for finding upper edges on mountable curbs and other non-vertical features.

Average Point - This snap averages Northing, Easting and Elevation for all points within the Snap Radius and uses the averaged values for the coordinate for the new polyline vertex.

End Point - Snaps the new polyline vertex to the endpoint of existing polylines.

Mid Point - Snaps the new polyline vertex to the midpoint of existing polylines.

Node - Snaps the new polyline vertex to points placed in the drawing using Carlson Point Cloud.

Nearest - Snaps the new polyline vertex to the point on an existing polyline nearest to the cursor location.

Color - Snaps the new polyline vertex to the selected color.

High/Low Edges - Snaps to the high and low edges of a vertical curb or wall simultaneously drawing two polylines.

Create Polyline Panel

The Create Polyline Panel sets options for creating polylines from the Point Cloud. Each option is discussed below.

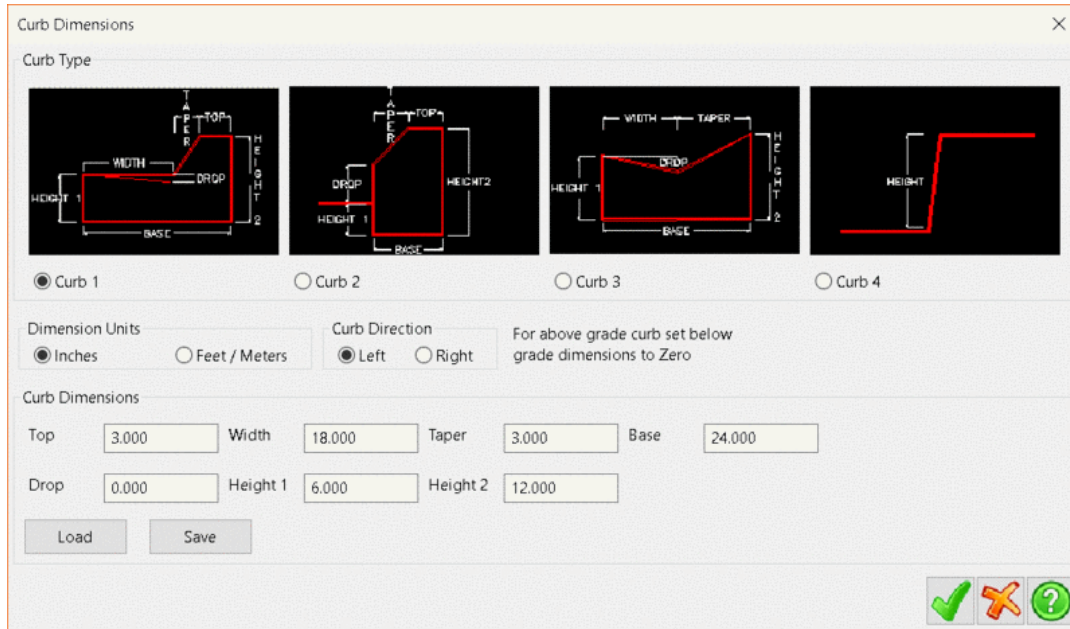

Progressive Mode - Note: Progressive mode can only be used when the Snap Type is set to High Edge or Low Edge. Progressive Mode creates a best fit polyline between the two selected points by breaking the distance into smaller segments with length equal to the snap radius. A point is found at each new segment location and a best fit line created through the resulting points.

Polyline Layer - Users can specify the layer to draw the new polyline on by typing a name in the Polyline layer field. Users may also click the Select button and select any layer currently in the scene or they may create a new layer to be used by typing it at the bottom of the Select Polyline layer dialog box.

Draw Curb - The draw curb toggle when selected activates the Curb Settings Button

Curb Settings window

There are four curb types to choose from by clicking the radio button below the desired type. The dimensions for each curb can be specified using either feet or inches. The curb direction is relative to the direction you select the curb points in.

The polyline created from the picked points will be named like any other polyline. The additional polylines created from the draw curb routine will include the name of the main polyline and a suffix number. Below is an example of polylines created using Curb Type 1.

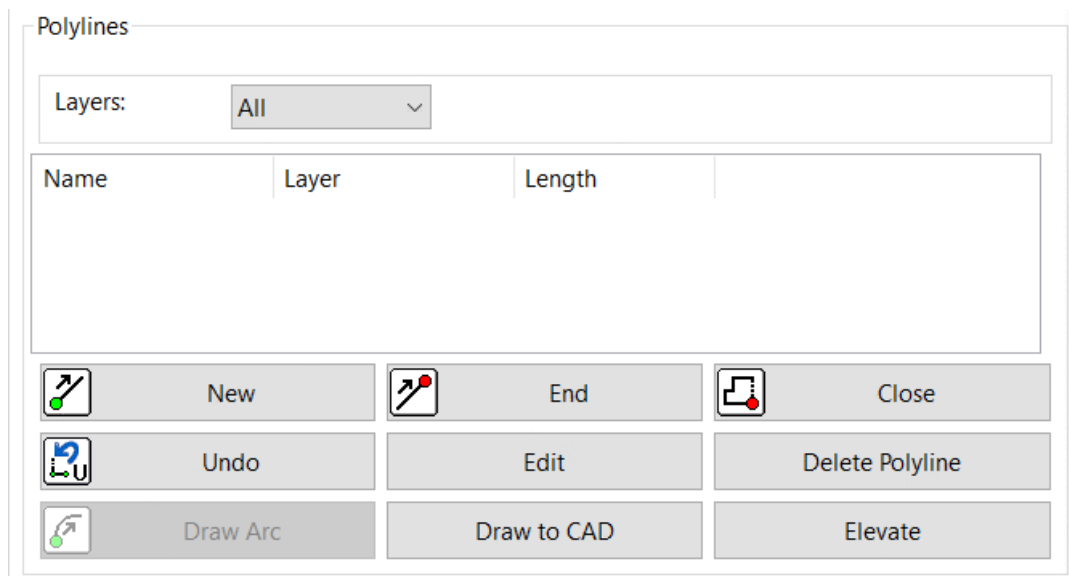

Arc Settings

Allows the creation of polylines with tangential arc. If selected, a tolerance can be set.

Polyline Control Panel

New - Starts a new polyline

End - Ends the polyline that is highlighted in the list of Active Polylines

Close - Closes the current polyline to its starting point

Undo - Removes the last polyline segment drawn and allows the user to continue the polyline creation from the previous endpoint.

Edit - Opens the Polyline Editor dialog box. The Polyline Editor dialog box can also be accessed by double clicking a polyline in the **Current Project** tree.

Delete Polyline - Deletes the selected polyline

Draw Arc - Draws a three point arc in the current polyline using the last point selected as the PC. The user is prompted to specify second point on arc. A line will display for the PC to the POC. After selecting the second point the user is prompted to specify end point of arc. The arc is drawn and the line from the PC to POC is gone.

Draw to CAD - Draws the active polylines into the current CAD file.

Elevate - elevates the selected polyline to:

Cloud

Reference Cloud

ground and road - Cleaned 2

Minimum point spacing: 10.000000

Point Within: 0.250000

Elevation Method: Lowest

Enable Simplification

Window: 8.000000

Threshold: 0.100000

Enable Smoothing

Window: 8.000000

Factor: 0.250000

OK Cancel

Reference Cloud - Specifies the cloud to use for elevating the polyline.

Minimum point spacing - sets the spacing to add vertices along the polyline as it intersects the point cloud

Point Within - specifies the radius of that the command will consider for the snap selection

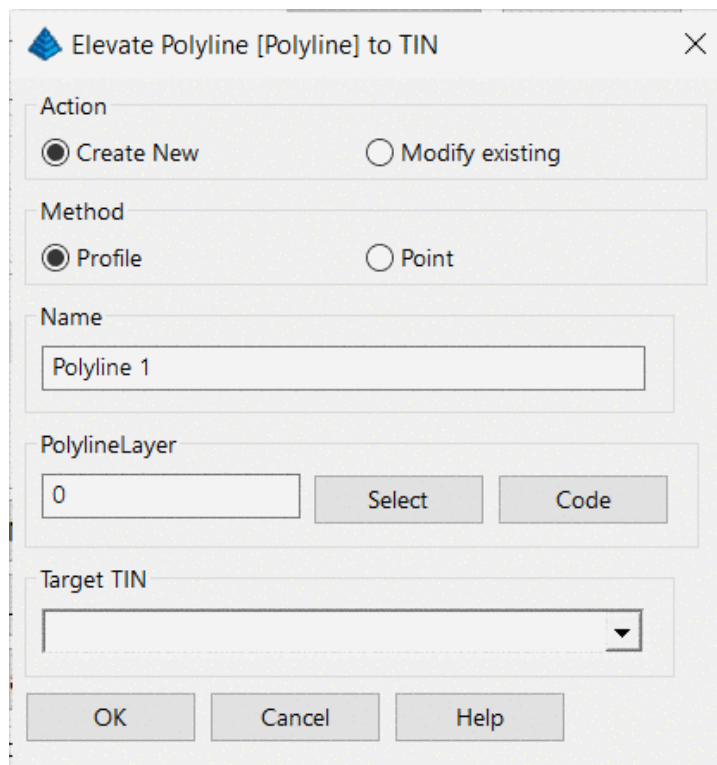

Elevation Method - sets the snap to one of four options for the elevation

- Lowest
- Highest
- Average
- Median

Enable Simplification - Sets controls to simplify the polyline as it is elevated to reduce the amount of vertices

Enable Smoothing - Sets controls to smooth the polyline as it is elevated.

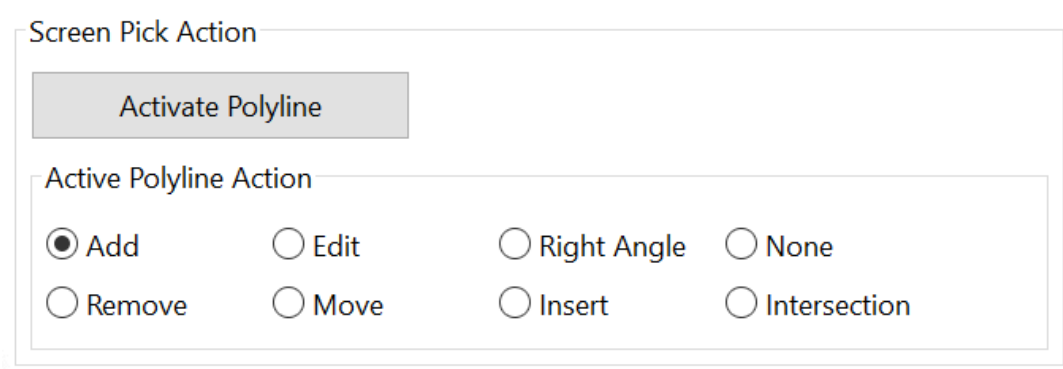

TIN

Can **Create new** or **Modifying existing** polyline using either the **Profile** or **Point** method.
Target TIN - choose the target TIN file

Screen Pick Action

The **Screen Pick Action** Panel provides options for editing polylines in the active scene. Each option is discussed below.

Activate Polyline - Allows the user to select the polyline to activate for the editing process. The Activate button can be used to make a polyline previously drawn active again so you can add on to that polyline. The user is prompted to select the polyline to activate. Multiple polylines can be activated. Click the End Activate button before trying to work with one of the activated polylines.

Add - appends (or continues) the currently selected Polyline.

Keyboard Shortcuts:

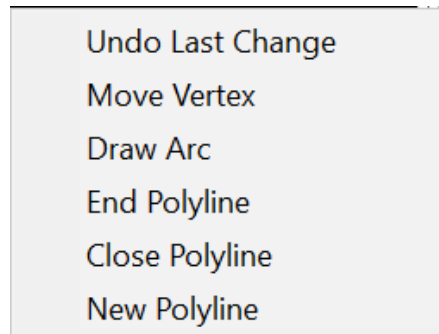

a Start point selection for arc drawing (Same as "Draw Arc" button).

c Make currently active polyline closed and deactivate currently active polyline (same as "Close" button).

e Deactivate currently active polyline (same as "End" button).

ctrl+z Undo most recent change to currently active polyline (same as "Undo" button). Note: This will only work when picking points for a polyline.

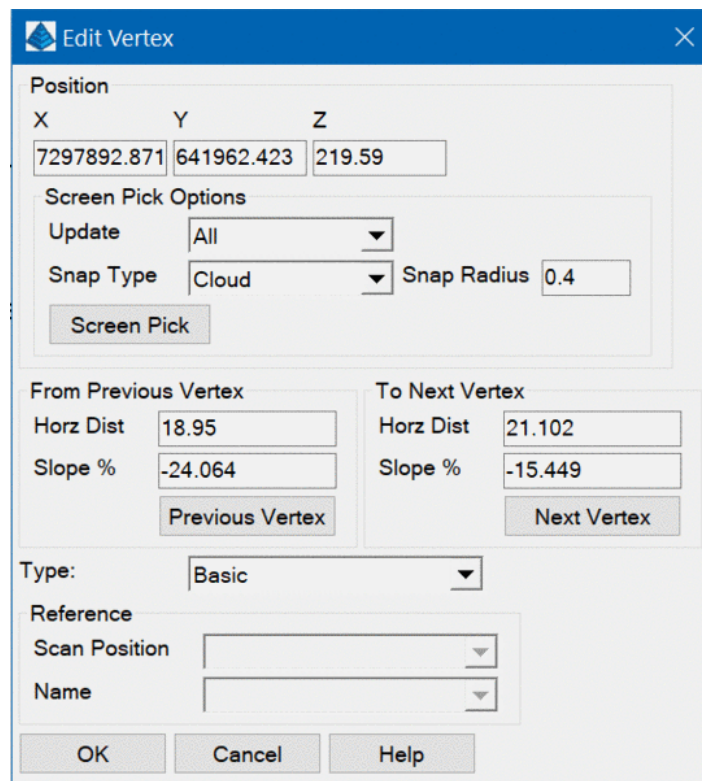

Right-Click Options:

New in 2024 is the ability to right-click while the Polyline Creation is active to choose a range of different options, listed above.

Edit - The user selects the polyline to be edited by clicking on it in the current Scene. After selecting a polyline the user is prompted to pick point on polyline to edit by clicking on the point. The dialog box below is presented to the user.

The user can change the coordinates by typing in the X, Y or Z fields or by clicking on a new position in the current Scene (click the Screen Pick button). There are buttons to advance to the Next vertex or return to the previous vertex along the polyline. The user can also change the point type from Basic to Coordinate Point reference.

Right Angle - Forces a vertex to be at a 90 degree angle from two Polyline segments. The user selects the vertex and the command will create a right angle at that point in the polyline

None - sets the Edit Mode to none to prevent unintended edits being made

Remove - Removes selected point from polyline

Move - Allows the user to select a vertex and move it to a new position

Insert - Inserts a new point into the polyline

Intersection - creates a vertex at the point of intersection of two polyline segments and modifies the polyline with the new location.

Tab Location: Action

Panel and Button: Create Polyline

Text Size Alignment Top Left

Snap Mode

The Snap Mode Panel offers twelve different options for snapping to points in the cloud in the open scene.

Snap Mode

Snap Type: Snap Radius:

- **Cloud** - No snap function is active. The text will be placed at the cloud point nearest to the selected location.
- **Low** - The text is placed at the lowest point (smallest z value) within the Snap Radius.
- **High** - The text is placed at the highest point (largest z value) within the Snap Radius.
- **Low Edge** - Snaps to the low edge of a feature. A dynamic window in the upper left of the scene displays a cross section of the area within the Snap Radius and displays the high and low edge as red squares.
- **High Edge** - Snaps to the high edge of a feature. A dynamic window in the upper left of the scene displays a cross section of the area within the Snap Radius and displays the high and low edge as red squares.
- **Slope Bottom** - Snaps to the bottom edge of a slope that is less than 45 degrees. This is useful for finding low edges on mountable curbs and other non-vertical features.
- **Slope Top** - Snaps to the top edge of a slope that is less than 45 degrees. This is useful for finding upper edges on mountable curbs and other non-vertical features.
- **Average Point** - This snap averages Northing, Easting and Elevation for all points within the Snap Radius and uses the averaged values for the coordinate for the text.
- **End Point** - Snaps the text to the endpoint of existing polylines.
- **Mid Point** - Snaps the text to the midpoint of existing polylines.
- **Node** - Snaps the text to points placed in the drawing using Carlson Point Cloud.
- **Nearest** - Snaps the text to the point on an existing polyline nearest to the cursor location.

Create Text Panel

The Create Text Panel sets options for creating text in the current Scene. Each option is discussed below.

Create Text

Text Leader Segments

Text Size Alignment

Text - This is the text that will be placed in the scene. The text will be a single line.

Leader Segments - This value specifies the number of segments a leader will have. The text is placed at the segment endpoint.

Text Size - text size is a fixed unit. This means that as the user zooms in and out the text is always the same size on the screen and not relative to the cloud.

Alignment - There are nine alignment options for the text relative to the text location picked.

- Top Left
- Top Center
- Top Right
- Middle Left
- Middle Center
- Middle Right
- Bottom Left
- Bottom Center
- Bottom Right

Tab Location: Action

Panel and Button: Create and Text

Prerequisite: Open Point Cloud Scene

Extract Breaklines

PointCloud has an automatic breakline extracting function to help facilitate the processing of a dataset.

Breakline extraction is available by clicking the **Breaklines** button under the **Extract** panel in the **Action** tab.

In order to extract breaklines, a TIN must be open in a Scene and a user should first select the area from which to extract the breaklines using a **Selection** button.

Note: For best results, it is recommended to view the TIN in a Scene using the **Color** settings of **Category**: Position and **Type**: Normal.

Click the **Breaklines** button a new panel should be displayed at the bottom of the Action Page which displays all the options for configuring PointCloud's breakline extraction utility. Additionally, the viewer window will remove the coloring of the current selection to prevent it from interfering with the zone flag specification process, the viewer still internally keeps track of the area of the TIN that you have selected.

The screenshot shows the 'Breakline Extraction' panel with the following settings:

- Current Action:** Breakline Extraction (Buttons: Show, Extract, End Action)
- Direction - Color Zones:** X - R, Y - G, Z - B, Color (with a 3D coordinate system icon)
- Active Directions - Colors:** Use X - Red, Use Y - Green, Use Z - Blue
- Extraction Method:** By Vertex, By Face
- Vertex Method Settings:** Use Local Smoothing
- Join Nearest:** Enable, Maximum Distance: 1,000
- Minimum Breakline Length:** Enable, Min Length: 1,000
- Polyline Simplification:** Enable, Window: 8, Factor: 0.10
- Polyline Smoothing:** Enable, Window: 8, Factor: 0.25

To add color zones, *Ctrl + Click* in the 3d view window on the TIN at a location that has the color/normal you want to define your zone. This will add the color to the Color Zones table, and you can manually modify the value if it isn't quite what you want it to be. You can choose which directions you want to be considered when zone classification is being performed using the **Use X**, **Use Y**, and **Use Z** check boxes. Restricting directions can yield better results in certain situations. For instance, if you're trying to extract edges along a curb, it would be best to turn off **Use X** and **Use Y** and only use the **Z** direction of the normal to determine the zone, due to the fact that curbs are usually a corner with a vertical surface and a horizontal surface.

There are two methods of breakline extraction: **By Vertex** and **By Face**.

Extraction Method by Vertex

Note: This method is the default method and generally gives better results in datasets that have hard edges (such as corners of buildings).

Extraction Method

By Vertex By Face

Vertex Method Settings

Use Local Smoothing

Join Nearest

Enable Maximum Distance:

Minimum Breakline Length

Enable Min Length:

Polyline Simplification

Enable Window: Factor:

Polyline Smoothing

Enable Window: Factor:

In this method, each vertex of the current selection is assigned a zone based on the normal at that vertex. PointCloud then creates new polyline vertices on each edge that connects vertices belonging to different zones. These polyline vertices are positioned based on how the vertex normal's compare to the normal that defines its zone.

Simple example of the Vertex Method

The Vertex method has one unique setting, **Use Local Smoothing**, which averages the normal at each vertex with the normals of its neighbors to provide a smoother set of normals to work with. This helps to give more continuous breakline edges by accommodating for places in the TIN that may be distorted due to missing or outlying data.

Extraction Method by Face

To extract breaklines using the Face Method, select the **By Face** radio button under the **Extraction Method** panel.

Extraction Method	
<input type="radio"/> By Vertex	<input checked="" type="radio"/> By Face
Zone Minimum Size	
Minimum Area:	Minimum Number of Triangles:
<input type="text" value="0.000"/>	<input type="text" value="1"/>
Join Nearest	
<input type="checkbox"/> Enable	Maximum Distance: <input type="text" value="1.000"/>
Minimum Breakline Length	
<input checked="" type="checkbox"/> Enable	Min Length: <input type="text" value="1.000"/>
Polyline Simplification	
<input checked="" type="checkbox"/> Enable	Window: <input type="text" value="8"/> Factor: <input type="text" value="0.10"/>
Polyline Smoothing	
<input checked="" type="checkbox"/> Enable	Window: <input type="text" value="8"/> Factor: <input type="text" value="0.25"/>

In this method, each face of the current selection is assigned a zone based on its normal. Polylines are created from the edges that touch faces belonging to a different zone. The face method has unique options of minimum area and triangle count values for each zone area. This is to prevent a common problem where a single or a small number of faces near the border will be classified as belonging to a zone other than the one they currently reside in, creating an extremely small zone.

The **Join Nearest** option will join any polylines whose endpoints are within the threshold distance of each other. This can help to bridge gaps in the TIN that could arise from parts of a scan being in shadow.

The **Polyline Simplification** option will remove each vertex that is within a certain distance to the least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Threshold is a positive number that determines the distance under which vertices will be removed from the polyline.

The **Polyline Smoothing** option will smooth each vertex in the polyline using a least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Factor is a number between 0.0 and 1.0, 0 being no smoothing performed and 1 being fitting each vertex to it's respective least squares line (usually makes the polyline extremely linear given a window size greater than 8).

Pressing the **Show** button at the top of the **Breakline Extraction** page will only show the zones in the viewer given the current configuration, but will not create the polyline at this stage. **Show**

This gives you a chance to review your settings and make sure that the zones are configured properly without adding any extra objects to the project.

Pressing **Extract** will extract the breaklines with the given settings. Each breakline polyline will be added to the project with the a name generated from the current project settings.

Prompts

Specify Zone Flag Position Ctrl-Click in the viewer to select the color zone for breakline extraction

Tab Location(s): Action Tab

Panel and Button: Extract and Breaklines

Prerequisite: Open scene of a TIN with color by Normal

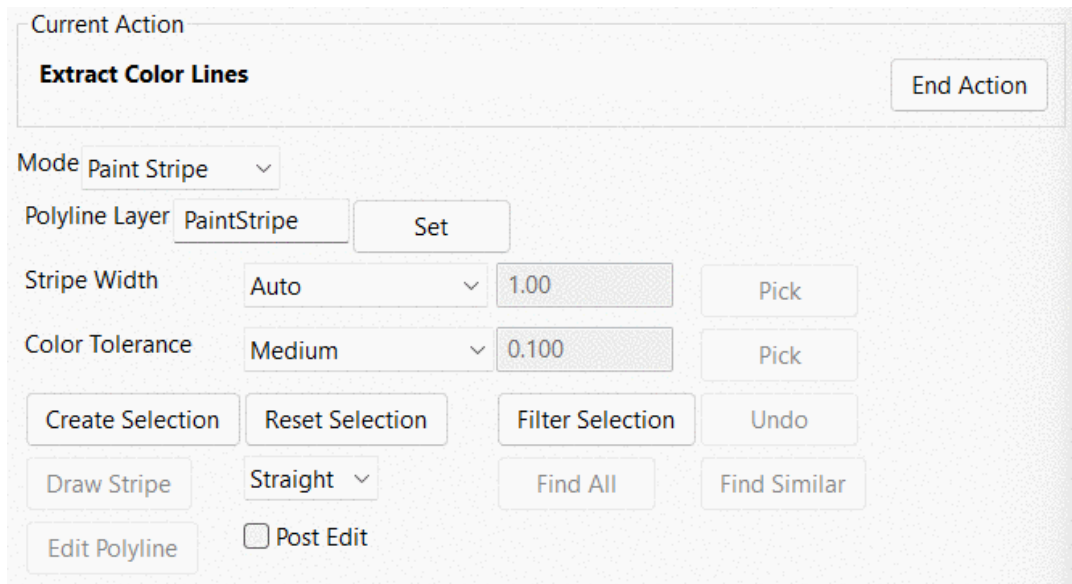

Extract Color Lines

Clicking the **Extract Color Lines** button in the **Extract** panel of the **Action Tab** will put the current mode into Extract Color Lines. There are 4 options to choose from, listed below.

Note - for point clouds that have a high density, the time taken to process using these features could be quite considerable so it is advised that the cloud is **Cleaned** prior to running these routines. For most clouds, the **Duplicated Points Distance Threshold** could be set to 0.04 (which is approx. 0.5 inches) or if using a metric cloud, set the value to 0.012.

Paint Stripe

Used to extract painted lines from a cloud.

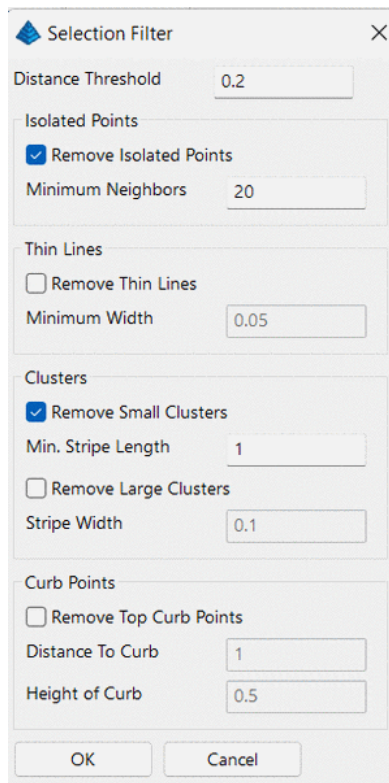

Polyline Layer sets the layer that the newly created data will go into. Click on **Set** to bring up the layer manager. **Strip Width** - setting to **Auto** is best used when using the **Draw Stripe**. Setting this to **Custom** will allow the user to enter in an approximate width of the lines they would like to select. By clicking on **Pick** to the right of this, it allows the user to choose two points in the cloud to populate the Stripe Width value

Color Tolerance will set the color tolerance of the points to be selected. Click on **Pick** to choose two points in the cloud to set this value.

Create Selection chooses the points in the cloud. Click on this then the tooltip in the scene will state "Pick a point to sample color". Once a color has been selected, it will select all of the same colored points in the cloud.

Filter Selection allows the user to filter out the points.

Distance Threshold is the distance between the points in the cloud. This will cluster all the points together. Try to go slightly larger here. For example, if the points are 0.1 to 0.2 apart, set this to 0.3.

Remove Isolated Points will remove any points that are less than the set **Minimum Neighbors**. That is, any cluster of points that contain less than this value won't be selected.

Remove Thin Lines will remove any lines that have a width of less than the value nominated here

Remove Small Clusters - by setting the **Min Stripe Length**, it will remove any clusters that are less than this value. For example, if the lines are parking lines, they're going to be quite long so can set this value to something near the average length.

Remove Large Clusters will do the opposite of the **Remove Small Clusters** - set the **Stripe Width** to the width of the stripe; be conservative on this as this will remove any clusters that are larger in width than this.

Curb Points will remove Selected Points that are a Curb Height higher (specified by the **Height of Curb** parameter) than other points that are less than the **Distance To Curb** away. The idea is that paint stripes will not go over a curb in the majority of cases so if there are some points selected that are on top of a curb then this filter will remove them.

Once the desired filters have been set, click on **OK**. This will remove the points using the filters that were originally selected using the **Create Selection** routine.

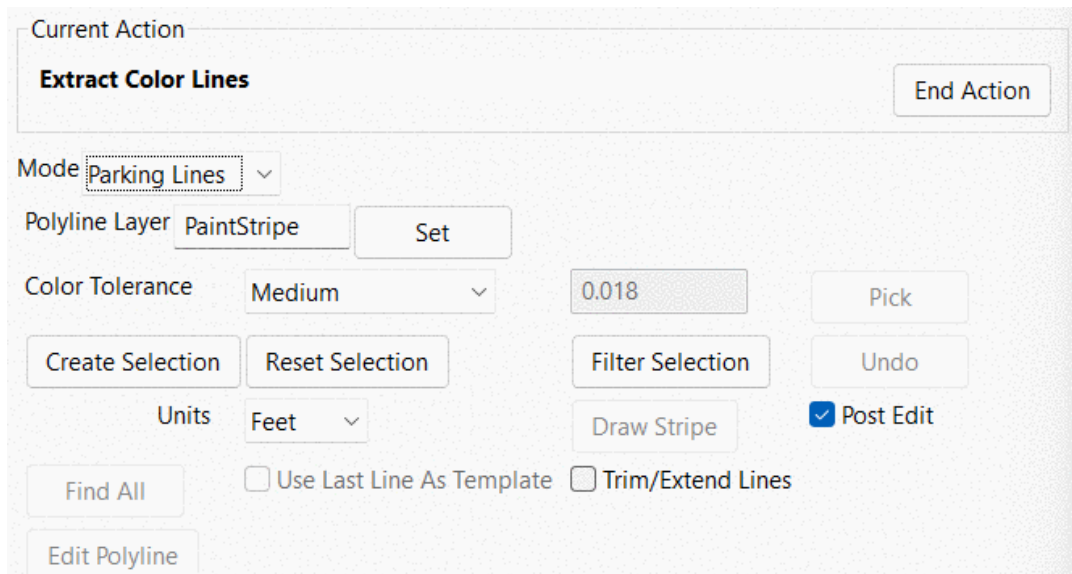

Now that the points have been selected, the option **Draw Stripe** will be available. Set **Stripe Width** to **Auto** then click on a section of straight line in the scene. It should then draw a polyline of this stripe. Repeat for others. For any curved lines, change the stripe type to **Curved** then click a point on the curve (not too close to an intersection of a straight and the curved line).

Find All is an automated process to find and create polylines for any paint stripe using the **Stripe Width** variable; it would be worth setting this to **Manual** and either entering in the width or use the Pick option to set the width.

Edit Polyline allows the user to modify polylines created using this routine.

Parking Lines

Specialized routine for extracting parking stripes. Some of the options are the same that appear in **Paint Stripe**. This routine works best when there is a clear distinction between the parking lines color and the color of the surrounding surface.

Units - this is critical. By choosing **Feet**, it looks for parking lines that are about 18 feet long, which is the typical length of parking lines. The **Metric** option does the same but in meters.

To start the routine, click on **Create Selection** then click on the parking lines in the scene. Multiple points can be selected if necessary. If there is a good distinction between the parking lines and the road surface, the **Tolerance** of **Medium** should work fine. Alternatively, change the value to another per-configured setting or choose **Custom** then click on **Pick** and select 2 points that best show the parking lines to set the tolerance value.

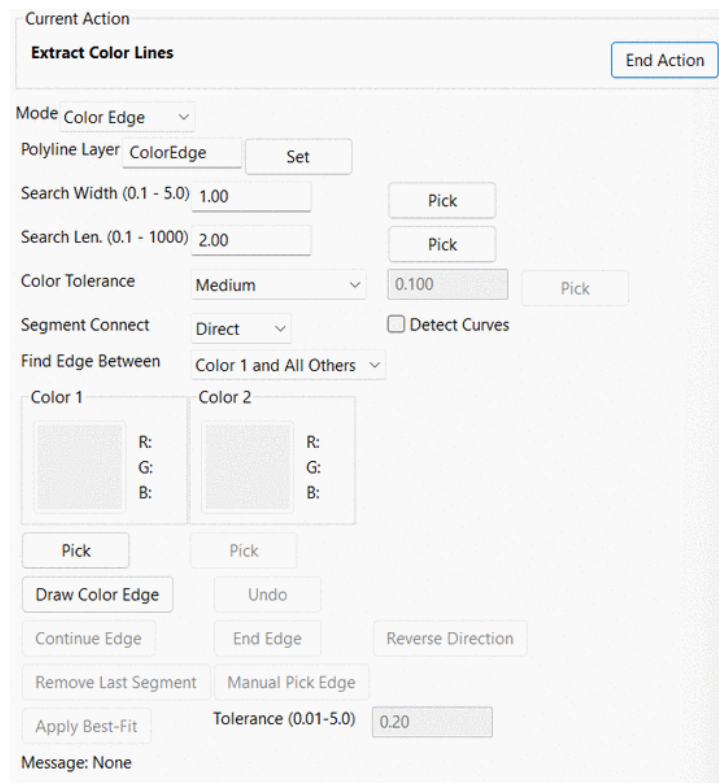

If the routine picks some points that are not parking lines (i.e. an object that is close to the color of the lines) this is OK. Click on **Find All** to draw the polyline for each parking line. The Command History will show the lines being created then the total number of Stripes found.

Note: this routine will normally draw two-point lines if the terrain is flat. However, if there are some bumps in the terrain, the lines will actually have a few points in them so that better follow the curvature of the ground.

Draw Stripe is used when the parking stripe lines are not the pre-configured 18' (or 5.5m) long. First, run **Create Selection** and choose the parking stripes. Next, choose **Draw Stripe** and click anywhere on a well-defined parking stripe. If the user is satisfied with the selection, tick the option **Use Last Line As Template** then click on **Find All**.

Color Edge

This routine extracts an edge of an object. For example, between a roadway and the grass verge. Some of the options are the same that appear in **Paint Stripe**.

Search Width is the width across the two different features in which the routine will examine the points. Users can either enter in a width or click on **Pick** and pick a point on either side of the edge.

Search Length is the length of the search area that the routine will examine. Clicking on **Pick** will allow this value to be populated via picking on two points in the scene.

Note: If either of these values are too small, and not enough points are being examined, the software will warn the user about this.

Segment Connect is how the segments will be joined; **direct, intersect** or **rounded**.

Detect Curves will try and detect the edge at an angle other than the original line.

Find Edge Between - two options: **Color 1 and All Others** allows the user to pick 1 color then tries to find an edge between that color and all other colors while **Color 1 and Color 2** allows the user to pick two colors to compare.

Draw Color Edge runs the routine based on the parameters entered in. Click on a point on the edge and it will create a starting point for the line. Click a second point on the edge to get the line started. The routine will run for as long as it can based upon the values entered.

Continue Edge can be used while within the **Draw Color Edge** routine to continue a line. If the line does not continue as far as it could, the colors may need to be selected again then continue the line work.

Reverse Direction will start the routine looking in the opposite direction to the initial starting point.

Apply Best-Fit will apply a best fit line through the segments. If it does not work, use **Undo Best-Fit** and adjust the tolerance.

Color Polyline

The **Extract Polyline** command "traces" a new Polyline from points within a Cloud, based on color and intensity. Polylines are extracted by holding down the CTRL key and clicking the line in the cloud to extract. Line sets are parallel polylines of equal length such as parking stripes. Line sets can be created by holding down the ALT key while clicking the lines to be extracted to the line set. The polyline length and direction are based on the first line extracted.

Current Action
Polyline Extraction End Action

Evaluation radius:

Chromaticity variance threshold(0-255):

Intensity variance threshold(0-100):

Maximum gap allowed:

Straight line Dynamic base color

Number of intermediate lines:

Undo
Edit Vertex

Polyline Layer: Select

Use CTRL-click to create a polyline
 Use ALT-click to create a line set

Evaluation Radius: specifies the radial distance to use to locate points to evaluate against the remaining criteria.

Chromaticity variance threshold (0-255): specifies how much the color can vary with 0 being an exact match (this almost never occurs) and 255 turning off the color match. The default value of 2 is a good starting value.

Intensity variance threshold (0-100): specifies how much the intensity value can vary from point to point. Zero (0) would be an exact match and 100 would turn off the intensity match. The default value of 3 is a good starting value.

Maximum gap allowed: Applies only to straight lines. The Maximum Gap Allowed is the maximum gap distance that a straight line may have. The value will depend on the data set being used.

Straight line: This option should be toggled on when extracting straight lines. Points are tested for variation based on the point clicked.

Dynamic base color: When toggled on this option will test points for variation based on the last point deemed to be on the line. This option is more useful when extracting curves.

Number of intermediate lines: This option is strictly for straight line extraction. To activate hold down the ALT key and left click when in the Polyline Extraction mode. The program will use the last line extracted as a guide. Polylines are then created parallel to the last polyline extracted. The new polylines are the same length as the last polyline extracted. The new polylines are placed equidistant from each other and a final polyline is placed on the point selected with the ALT-Click.

Undo will undo only the last command used.

Edit Vertex edits the vertices of the last polyline extracted. Use the CTRL or ALT key in combination with left-click to pick a new location for a vertex. The vertex nearest the location selected will be moved. In some cases you may need to select intermediate locations to move the desired vertex.

Polyline Layer specifies the layer to draw the extracted polyline on. A layer name may be enter directly in the edit box or a layer may be selected from the layer list by click the **Select** button.

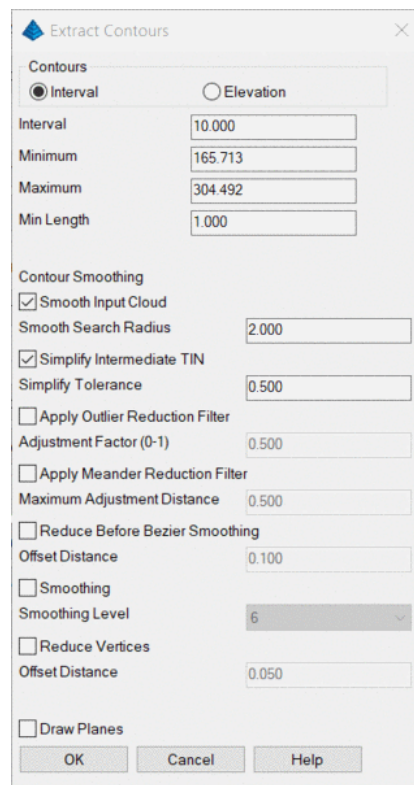

Tab Location(s): Action Tab

Panel and Button: Extract

Prerequisite: Open scene of a scan, cloud or TIN

Extract Contours

The **Extract Contours** window can be reached by clicking the **Contours** button in the **Extract** panel of the **Action Tab**, or by selecting **Create Contours** from the menu bar in a Scene Window. The only requirement for contour extraction is that the data, either a point cloud, a TIN, Solid or a scan is currently opened in a Scene.

The **Interval** extraction method extracts contours at every multiple of the specified interval between the minimum and maximum elevation values (a minimum of 2.5 and an interval of 5.0 would have the first contour elevation be at 5.0).

The **Elevation** method only extracts the contours at the specified elevation value.

By default, the **Minimum** and **Maximum** elevation values are the minimum and maximum elevations of the current scene.

Min Length determines the minimum length of a contour line to be drawn. Upon extraction, contours will be given an automatically generated name and added to the **Contours** folder in the project tree.

Contour Smoothing offers an option to smooth the cloud data prior to creating the contours. The Smooth Radius specifies how far from each point the program will look for neighbors. If a point does not have at least 3 neighbors within that radius, it will not be included in the algorithm.

Simplify Intermediate TIN removes spikes which might cause small circles or jagged edges in contours. The Simplify tolerance is the maximum adjustment distance a point will move to be closer to the same level as its neighbors.

Apply Outlier Reduction Filter reduces spikes in contours from outlier points.

Apply Meander Reduction Filter - leaving this at 0.5 default is often a reasonable choice to assist with contour smoothing but may be adjusted based upon trial and error with the data set.

Reduce Before Bezier Smoothing works in a manner similar to reduce vertices using its own Offset Distance

Smoothing (1-10) - Using the drop-down menu, users can lower the Smoothing setting which will have less looping or less freedom to curve between contour line points. Likewise, increasing the smoothing increases the looping effect. Note: too much smoothing applied in some situations can result in crossing contours. This setting affects the contour lines themselves, not the underlying data.

Reduce Vertices removes vertices from the contour polylines provided the removed vertex is not further away from the new line than the Offset Distance

If **Draw planes** is enabled, plane objects will be added to the project and the scene that cut through the scene at each extracted elevation level. The planes will be horizontal and extend to the limits of the cloud. While this can be useful for a single elevation contour that is extracted, it creates many planes when used with an interval extraction.

Tab Location: Action

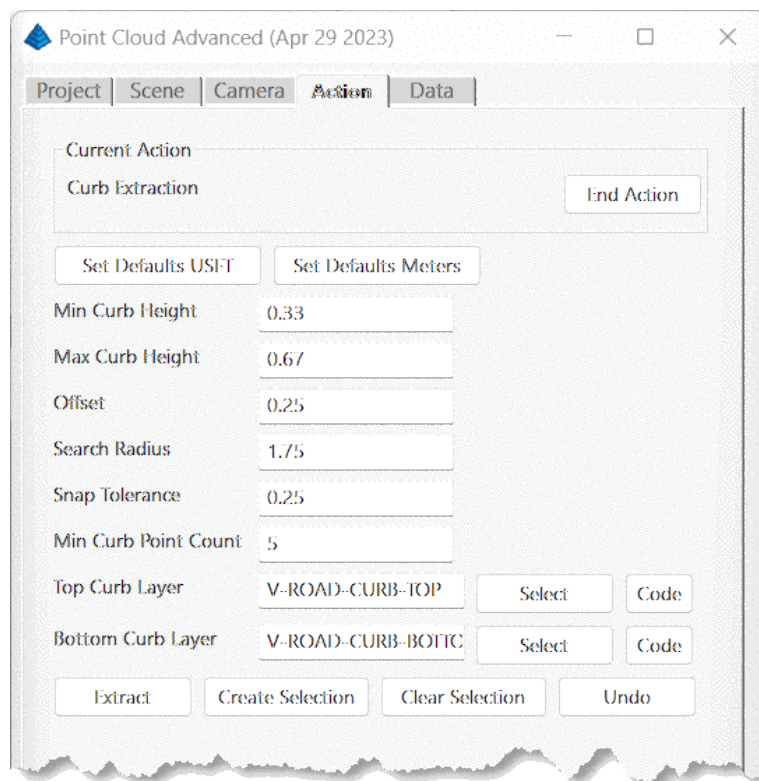

Panel and Button: Extract and Contours

Prerequisite: Open Point Cloud Scene of a scan, cloud or TIN

Extract Curb

The Extract Curb command can automatically generate top of curb and flowline polylines along the curb edges from point cloud data generated by a ground or aerial LiDAR or by photogrammetric processes. The algorithm uses edge clustering based on typical curb heights to find top of curb and bottom of curb points to find and draw the edges.

From the **Action tab**, click **Curb** under the **Extract** panel. Enter the minimum and maximum curb height parameters, flowline offset, search radius, snap tolerance, and minimum curb point count values. Click the **Create Selection** button to select the point cloud points along the curb area. Note that the points will be selected along the reference polyline drawn using the Search Radius as left and right offset range. Click **Extract** to begin the polyline extraction.

Set Defaults USFT: sets all the parameters to default values in feet.

Set Defaults Meters: sets all the parameters to default values in meters.

Min Curb Height: sets a minimum height for points to be used to determine the curb edge.

Max Curb Height: sets a maximum height for points to be used to determine the curb edge.

Offset: sets an offset range to find the bottom of curb edge.

Search Radius: sets the offset distance from the reference polyline when creating a selection set when Create Selection is used.

Snap Tolerance: specifies the radius for the program to consider for the elevation snap setting.

Min Curb Point Count: a low value helps resolve the curb edges better along curves. Click **Select** to choose from existing layers in the project. Click **Code** to select a layer based on field code table codes.

Top Curb Layer: sets the layer to draw on the top of curb polyline. Click **Select** to choose from existing layers in the project. Click **Code** to select a layer based on field code table codes.

Bottom Curb Layer: sets the layer to draw on the bottom of curb polyline. Click **Select** to choose from existing layers in the project. Click **Code** to select a layer based on field code table codes.

Extract: begins the extraction process.

Create Selection: starts a point cloud point selection mode. Click on the cloud and a reference polyline will be drawn. Points will be selected within an offset range along the polyline based on the Search Radius distance.

Clear Selection: clears the selection set.

Undo: will remove the polylines created by the last curb extraction.

Using the values shown above, below you can see an example of an extracted curb. The point cloud was generated by Carlson PhotoCapture from a drone flight with a ground sampling distance (GSD) of 0.03 ft. If you are working with ground scanner data, it is recommended that you decimate the point cloud first to reduce the number of point cloud points by using any of the methods found in the Clean or Resample filters.

Tab Location: Action tab.

Panel and Button: Extract and Curb.

Prerequisite: Point Cloud Scene open.

Extract Intersection

Extract Intersection creates a polyline based on the intersection of two selected planes. Planes can be drawn when extracting Planes, Contours, Profiles or Sections.

To extract intersections, click on the **Intersection** button under the **Extract** panel in the **Action** tab. There are two options to select the planes to be used to extract the intersection.

Use CTRL-click to select a plane Use this option to select the first plane to use to extract an intersection.

Use ALT-click to intersect two planes Use this option to select the planes to intersect with the plane selected using option one. You can also select the first plane using this option. Once the first plane is selected using either method, multiple intersecting planes may be selected using the ALT-click method.

Note:

- The 3D polyline(s) of the intersection is added to the **Project Tab**.

Tab Location(s): Action Tab

Panel and Button: Extract and Intersection

Prerequisite: Open scene with two or more planes

Extract Plane

Clicking the **Plane** button in the **Extract** panel of the **Action Tab** will put the current mode into Plane Extraction mode.

Current Action
Plane Extraction End Action

Evaluation radius:

Standard deviation threshold:

Create shrink-wrap:

Plane points:

Use CTRL-click to create a plane
Use ALT-click to expand the last plane

Note: Planes can be extracted in any rotation of the scene. The scene may be of a Cloud or Scan.

The size of the plane is controlled by two parameters.

Evaluation radius: the distance around each point that PointCloud will search for other points that meet the Standard Deviation Threshold.

Standard deviation threshold: how far a point can be away from the plane for the plane to be considered flat. A value of about 20% of the Evaluation Radius is typical.

The **Create shrink-wrap** droplist has three options.

Full: creates a 3D polyline that encloses the points used to create the plane.

Bottom: creates a 3D polyline

None: No polyline is created. This is the default option.

The **Plane points** droplist has three options.

Select: Adds the points used to create the plane to the active selection set. The points are highlighted in red. This is the default option.

Hide: removes the points used to create the plane from visibility in the scene.

Leave: The plane is created without highlighting or hiding the points used.

The **Undo** option undoes the last function performed only. For example, creating a plane having selected the **Hide** option, Undo would restore the points to being visible and the plane would still be in the Scene. Undo only performs one operation, it cannot undo multiple steps.

After these options have been set to the preferred values, the user can extract the plane by left clicking in the viewer while holding down the CTRL key. The plane is displayed in the active Scene and can be drawn in CAD as a closed 3D polyline from the **Project** tab.

Prompts

Use CTRL-click to create a plane Left-click in the viewer while holding down the CTRL key to create the plane.

Use ALT-click to expand the last plane Left-click in the viewer while holding down the ALT key to expand the last plane created.

Tab Location(s): Action Tab

Panel and Button: Extract and Plane

Prerequisite: Open scene of a scan or cloud

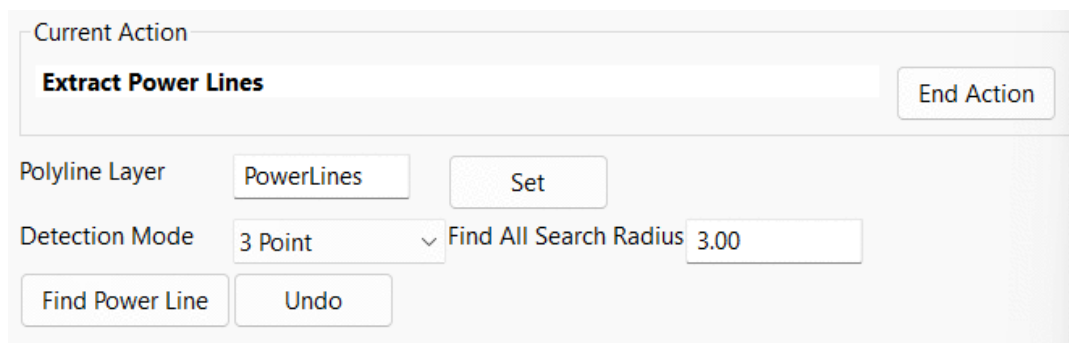

Extract Power Lines

Clicking the **Extract Power Lines** button in the **Extract** panel of the **Action Tab** will put the current mode into Extract Power Lines.

Notes:

1. For point clouds that have a high density, the time taken to process using these features could be quite considerable so it is advised that the cloud is **Cleaned** prior to running these routines. For most clouds, the **Duplicated Points Distance Threshold** could be set to 0.04 (which is approx. 0.5 inches) or if using a metric cloud, set the value to 0.012.

2. This routine works best when working with Non-ground points. To quickly do this, use the **Extract Bare Earth** routine. Under the **Extract Destination** heading, choose **Non-Ground Cloud**. This will reduce the number of points in the cloud making it easier to work with.

Polyline Layer sets the layer that the newly created data will go into. Click on **Set** to bring up the layer manager.

Detection Mode sets the type of routine used to extract the power line.

3 Point uses more manual entry, but is generally more reliable.

1. Specify the wire position on the first pole
2. Specify a point on the wire in between the poles (can be anywhere along the wire, but works best if a point in the middle is chosen)
3. Specify a point on the second pole

A polyline should now be generated that follows the curvature of the power line.

1 Point allows a user to click on a point in the middle of the line. This routine looks in both directions and it can find the power line on its own with just one point. Try and pick a point in the middle that has a good amount of data for the algorithm to look for. This works best where there is a lot of data on the lines and no holes in the data.

1 Point Find All is the same as **1 Point** mode except it uses the search radius parameter to try to identify several power lines all at once. **Find all Search Radius** needs to be large enough to span in between the power lines.

Tab Location(s): Action Tab

Panel and Button: Extract Power Lines

Prerequisite: Open scene of a scan or cloud

Extract Profile

The **Profile Extraction** functionality can be activated by going to the **Action Tab** and clicking the **Profile** button in the **Extract** panel. The only requirement for profile extraction is that the data, either a point cloud, or a TIN is being viewed in a Scene. Pressing the **Extract Profile** button also puts the current viewer into profile extraction mode. A tooltip with instructions on how to extract the profile will display when the cursor is in the scene. Left clicking in the viewer will establish the profile location. To exit profile extraction mode, click the **End Mode** button.

Polyline Simplification
 Enable Window: 8 Threshold: 0.10

Polyline Smoothing
 Enable Window: 8 Factor: 0.25

Planes
 Draw planes

Extract Along Centerline

Profiles can be extracted in two kinds of coordinate systems: **Real-World** and **Camera View**.

Top-Down is the most commonly used method and extracts the profile in the current scene's coordinate system. The z values, or elevation values, are those found in the surface the profile is being extracted from.

Camera View is much less commonly used and uses the current camera as the origin instead of the scene's origin, and elevation values are effectively distances from the camera. This mode can be useful if you're trying to extract a profile out of a vertical surface such as a wall or are trying to get the profile of an object from a direction other than the z axis. **Camera View** mode gives the best results if the current camera is in parallel projection mode (perspective mode will distort the profile).

Interval specifies the spacing between points to be added to the profile. The **Point Within** option specifies the search radius for the Elevation Method which is essentially a cloud Osnap function. The **Elevation Method** can be set to Lowest, Highest Average or Median elevations found within the specified *Point Within* radius.

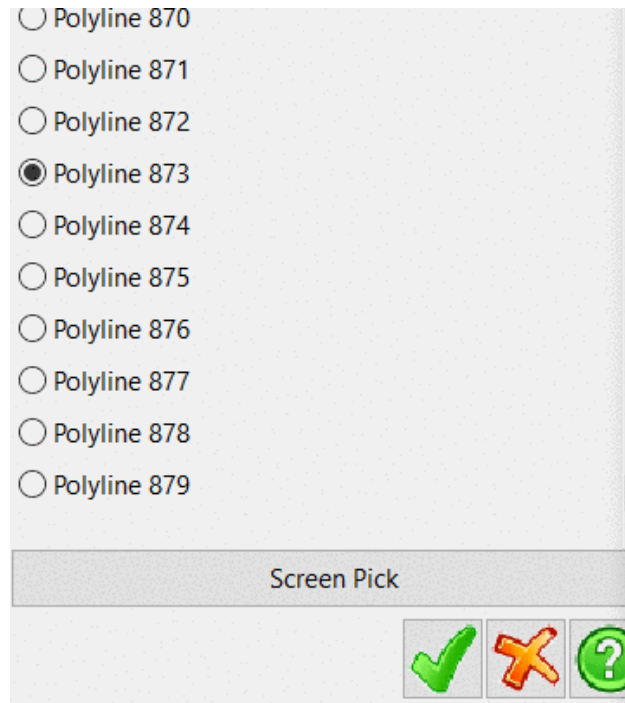

The **Profile Simplification** option will remove each vertex that is within a certain distance, **Threshold**, to its least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Threshold is a positive number that determines the distance under which vertices will be removed from the polyline.

The **Profile Smoothing** option will smooth each vertex in the polyline using a least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Factor is a number between 0.0 and 1.0, 0.0 being no smoothing performed and 1.0 being fitting each vertex to its respective least squares line (usually makes the polyline extremely linear given a window size greater than 8).

If **Draw Planes** is enabled, plane objects that follow the path of the initial selection polyline will be drawn into the viewer after the profile is extracted. The planes will extend vertically to the low and high elevation matching the limits of the Bounding box. Each plane drawn will also be added under the Planes heading in the Project Tree.

Extract Along Centerline when clicked the user is prompted for the .CL file to use. The horizontal location of the centerline is extracted from the Cloud or TIN.

Extract Along Polyline when clicked the user is prompted to select an existing polyline from the project or Screen Pick a polyline

After extracting a profile by polyline or .CL file, a dialog will open asking for an action to perform with the extracted profile, this gives you a chance to review the profile and the option to save it to the project or save it to a file.

Dynamic base color: When toggled on this option will test points for variation based on the last point deemed to be on the line. This option is more useful when extracting curves.

Number of intermediate lines: This option is strictly for straight line extraction. To activate hold down the ALT key and left click when in the Polyline Extraction mode. The program will use the last line extracted as a guide. Polylines are then created parallel to the last polyline extracted. The new polylines are the same length as the last polyline extracted. The new polylines are placed equidistant from each other and a final polyline is placed on the point selected with the ALT-Click.

Undo will undo only the last command used.

Edit Vertex edits the vertices of the last polyline extracted. Use the CTRL or ALT key in combination with left-click to pick a new location for a vertex. The vertex nearest the location selected will be moved. In some cases you may need to select intermediate locations to move the desired vertex.

Polyline Layer specifies the layer to draw the extracted polyline on. A layer name may be enter directly in the edit box or a layer may be selected from the layer list by click the **Select** button.

Tab Location(s): Action Tab

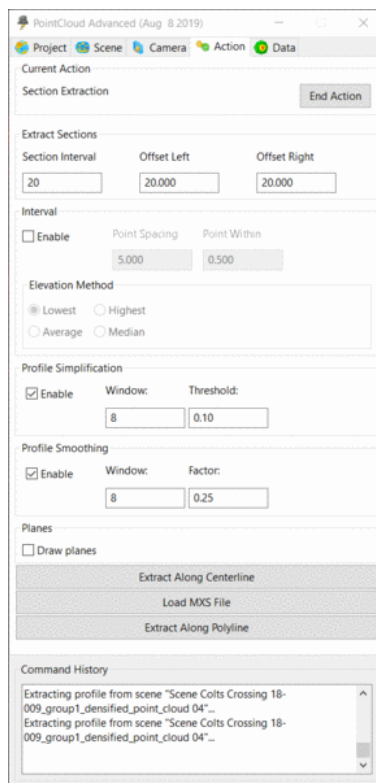

Panel and Button: Extract and Polyline

Prerequisite: Open scene of a cloud

Extract Sections

Extract Sections

Clicking the **Sections** button in the **Extract** panel of the **Action Tab** will put the current mode into Section Extraction mode.

The width of the sections and the frequency, or interval, at which they are extracted along the designated path are controlled by three parameters.

Left Offset is the distance left of the path the sections will extend. Left is determined based on the direction the extraction path was drawn or "up station".

Right Offset is the distance right of the path the sections will extend. Right is determined based on the direction the extraction path was drawn or "up station".

Interval is the value that determines the distance along the path between sections.

The **Elevation Method** sets a cloud "snap" value to specify which point elevations to use for each profile vertex. The **Point Spacing** and **Point Within** options control the search parameters for points to consider for the Elevation Method. The options are Lowest, Highest, Average and Median.

The **Profile Simplification** option will remove each vertex that is within a certain distance to its least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Threshold is a positive number that determines the distance under which vertices will be removed from the polyline.

The **Profile Smoothing** option will smooth each vertex in the polyline using a least squares approximation. Window is the number of neighbor vertices to use when generating the least squares approximation. Factor is a number between 0.0 and 1.0, 0.0 being no smoothing performed and 1.0 being fitting each vertex to its respective least squares line (usually makes the polyline extremely linear given a window size greater than 8).

If **Draw Planes** is enabled, Plane objects will be added to the project and the scene that follow each section line. The planes will extend from the upper to the lower extents of the cloud. These limits are the same as used with the bounding box option in the viewer.

Extract Along Centerline when clicked the user is prompted for the .CL file to use. The horizontal location of the centerline is used and the sections are extracted perpendicular to the centerline.

Load MXS File loads a Multiple Cross Sections file. These can be created using the "Section Alignment Editor" command under the Sections menu in Carlson Civil.

Extract Along Polyline allows users to select an existing polyline from the project or Screen Select a polyline.

After these options have been set to the preferred values, the user can extract the sections by left clicking in the

viewer to draw the path polyline and right clicking to end it. The sections are saved to the project and can be drawn in CAD or exported to a .SCT file from the **Project Tab**.

Prompts

Left-click to create polyline Left-click in the viewer to create the polyline for the profile, Right-click to end the polyline.

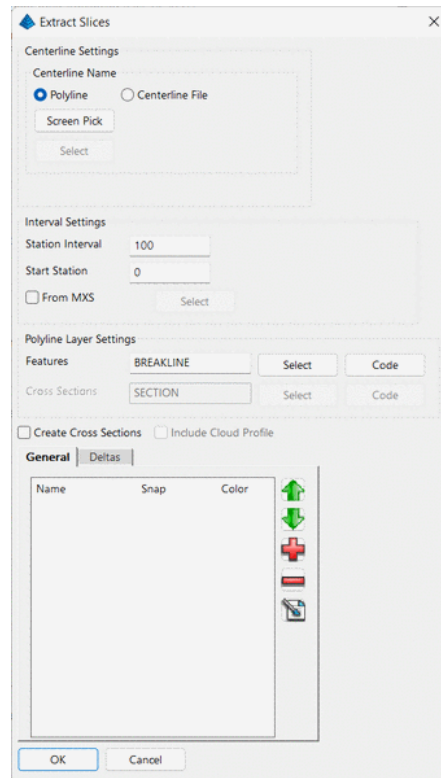

Tab Location(s): Action Tab

Panel and Button: Extract and Sections

Prerequisite: Open scene of a scan, cloud or TIN

Extract Slices

Clicking the **Extract Slices** button in the **Extract** panel of the **Action Tab** will put the current mode into Extract Slices.

Centerline Name has two options;

Polyline which uses an existing polyline in the scene via the **Screen Pick** option and

Centerline File which will load in an existing Carlson centerline (.CL) file

Station Interval is the space between each slice.

Start Station allows a starting station to be set.

Polyline Layer Settings sets the layer that the newly created data will go into. Click on **Select** to bring up the layer manager and **Code** to open the PointCloud Code table.

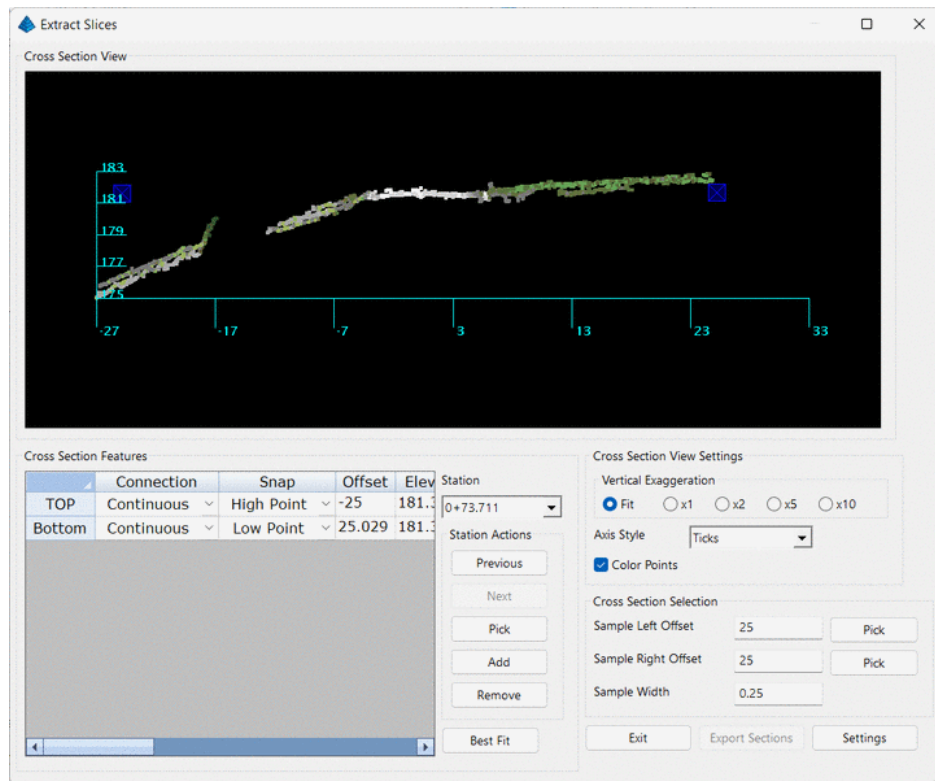

Create Cross Sections enabling this allows the Cross Sections layer to be set along with being able to set the accompanying code.

Include Cloud Profile includes the cloud points in the selection.

General is where Features can be entered in. Click on the red Plus icon to add.

Once OK is selected, the routine runs and the **Extract Slices** dialog box appears. In here, there are a number of options where the user can step through the slices to view data from the loaded scene. By using the **Cross Section Features** ongoing polylines can be created using the different Snap settings available.

The **Sample Offset** can be modified along with the **Sample Width**.

If the option **Create Cross Sections** was enabled, once the user exits out of the **Extract Slices** routine, the cross sections will be available to view in the Project Tree under the **Sections** heading. There is also the option **Export Sections** to save the sections as a Carlson xsct or sct file.

Tab Location(s): Action Tab

Panel and Button: Extract Slices

Prerequisite: Open scene of a scan or cloud

Extract Slope Edge

Clicking the **Extract Slope Edge** button in the **Extract** panel of the **Action Tab** will put the current mode into Extract Slope Edge.

Note: For point clouds that have a high density, the time taken to process using these features could be quite considerable so it is advised that the cloud is **Cleaned** prior to running these routines. For most clouds, the **Duplicated Points Distance Threshold** could be set to 0.04 (which is approx. 0.5 inches) or if using a metric cloud, set the value to 0.012. **Polyline Layer** sets the layer that the newly created data will go into. Click on **Set** to bring up the layer manager.

Segment Connect is how the segments will be joined; **direct**, **intersect** or **rounded**.

Search Len is the length at which the routine will search on each slope. When set to **Auto** it tries a wide range of search lengths and then tries to pick the best one to extract data. By setting it to **Custom** you can force the search length. Normally, **Auto** works well but it depends on the clarity of the edge.

Draw Slope Edge

1. The tooltip will ask to pick a point on the face of the 1st slope - pick a point that will contain a number of points for the routine to use
2. Pick a point on the edge of the two slopes - for example, the edge of a cliff
3. Pick a point on the face of the second slope, again ensuring that enough data is included
4. The lines need to be long enough so that the routine considers a decent amount of points along this Cliff edge; we're defining slope one and then slope two with each line respectively
5. Lastly, pick a second point along the edge of the Cliff just to indicate direction
6. It will now search for the edge between the two slopes

If it stops due to an object in the way (or goes off course) use the **Undo Last Segment** button to remove a number of segments then use **Continue Edge** and redefine the template further along.

Reverse Direction will continue the linework in the opposite direction from the initial starting point.

Apply Best Fit can create a line of best fit through the created segments. Once done, click **End Edge**.

If the profile of the slopes change too much, the routine will stop. If it goes around a curve, tick the option **detect curves**. Note: this option works best on well defined edges.

Tab Location(s): Action Tab

Panel and Button: Extract Slope Edge

Prerequisite: Open scene of a scan or cloud

Extract Volume

Extract Volume will let you calculate volumes from a point cloud selection set. Besides the volume report, you can also create triangulation files (TIN) for the resulting surface and the base elevation that can be used in other Carlson desktop programs including Civil, Takeoff, and Mining.

Before you start the Extract Volume action, use the Create Polyline action to draw a closed polyline representing the area where the volume will be calculated. Note that you can also import polylines from the CAD drawing if you have the desired boundaries.

In the **Action Tab**, under the **Extract** panel, **click Volume**.

Current Action
Volume Extraction End Action

Extract Volume

Keep Selection

Use Base Elevation Screen Pick

Save Base TIN View Base TIN

Save Scan TIN View Scan TIN

Extract Units

Feet Meters

Select incision polyline to begin

Keep Selection: When toggled, the program will keep the point cloud points selected after the volume has been calculated.

Use Base Elevation: Toggle it to enter a desired base elevation for the calculation. **Click** the **Screen Pick** button to select a point to set the base elevation.

Save Base TIN: By toggling it, the program will save the calculated base surface TIN both to the Current Project Tree, under TINs, and to the Carlson project directory.

View Base TIN: By toggling it, the program will add the base surface TIN to the current scene view.

Save Scan TIN: By toggling it, the program will save the calculated surface TIN both to the Current Project Tree, under TINs, and to the Carlson project directory.

View Scan TIN: By toggling it, the program will add the surface TIN to the current scene view.

Extract Units: Point cloud files are generally unit-less, use this setting to confirm the project units for the report.

To calculate the volume, **select** the **closed polyline** representing representing the outermost perimeter of the desired area. The program will highlight the points inside selected area and calculates the volume. If you **click Continue**, the **Report Formatter** window will open allowing you export the report to a text file, PDF, and insert a table in CAD.

Prompts

Left-click to select polyline

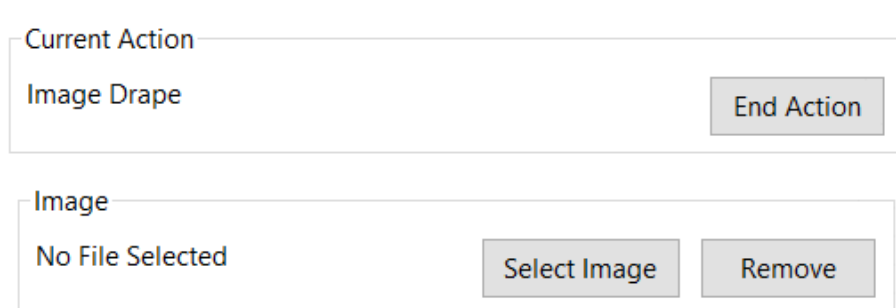

Tab Location(s): Action Tab

Panel and Button: Extract Volume

Prerequisite: Open scene of a scan, cloud or TIN and existing closed polyline.

Image Drape

The Image Drape mode is accessed by clicking the **Image** button in the Edit panel of the **Action Tab**. Two Panels make up the Image Drape dialog box.

Current Action

The Current Action panel displays the current mode, in this case Image Drape. The **End Action** button ends the Image Drape mode and closes the dialog box. The user is returned to the **Action Tab** default dialog box.

Image

If an image is currently draped in the scene, its file name will be listed in the Image panel. The two functions of the Image panel are:

Select Image - This button opens the Select Overlay Image dialog box allowing the user to browse for the image they wish to use. Supported image formats include; BMP, JPG, JPEG, TIF and TIFF.

Remove - This button removes the current image from the scene. If there is no image in the current scene this button has no effect.

Tab Location: Action Tab

Panel and Button: Edit and Image

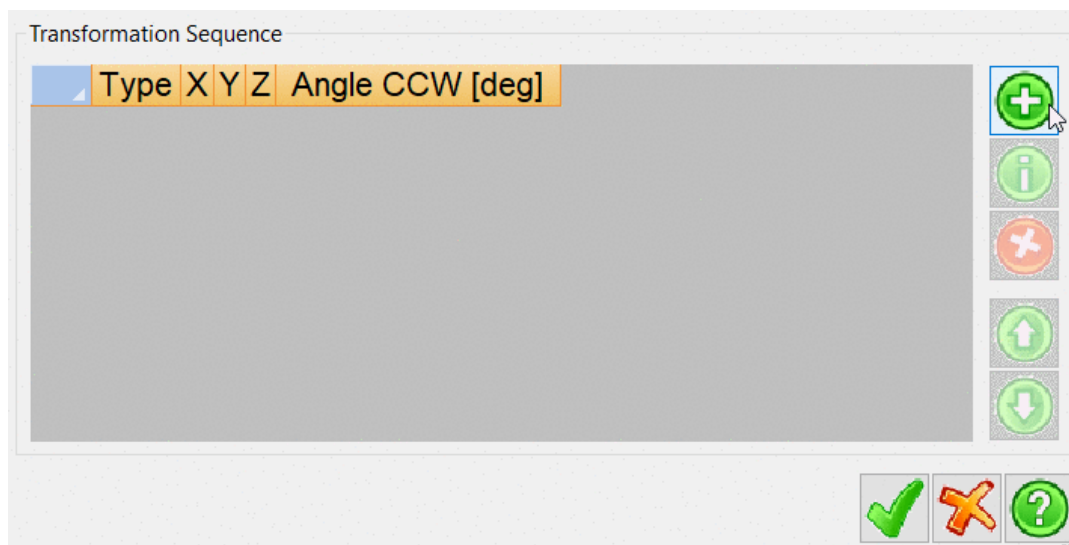

Prerequisite: Open scene of a TIN and an image file that is georeferenced

The Transformation Panel

The **Transform** panel contains three functions that allow for minor adjustments to be made to the selection set if required:

Transform will display the **Transform Cloud** window.

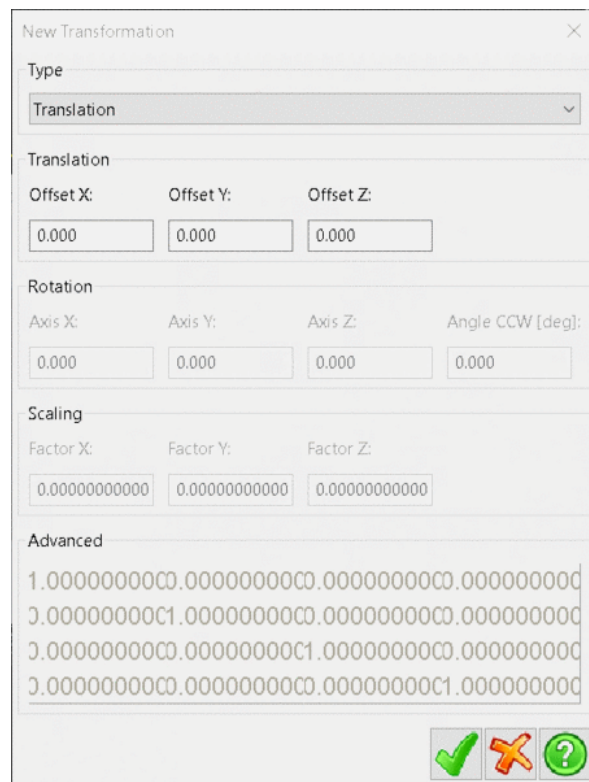

Initially, the dialog will have no transformations specified. To add a transformation, press the **Green Plus** button, which will open the **New Transformation** window.

Use the **Type** drop-down menu to select one of the four Transformation types:

Translate allows the user to define a translation of the current data set by specifying offsets in X, Y and Z.

Rotations allow the user to rotate the current selection set by specifying rotations around the X Y and Z axis.

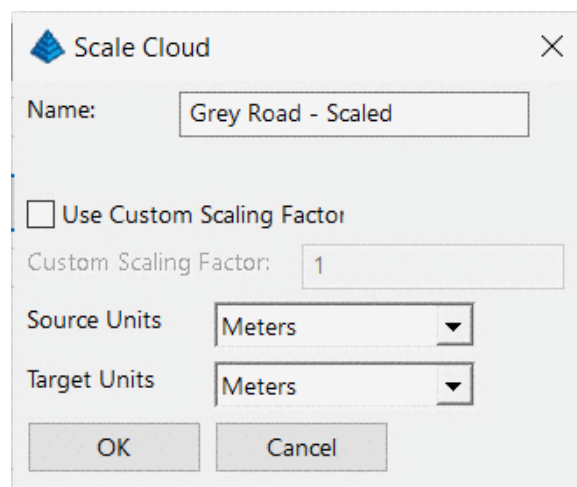

Scaling allows the user to scale the current selection by a set Factor in the X, Y and Z axis. **Advanced** allows the user to specify a transformation matrix to be applied to the data.

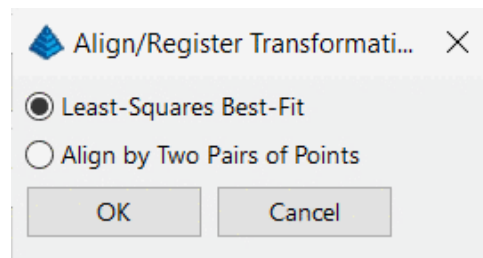

After clicking the check button you should be taken back to the **Transform Cloud** window. From here you can add more transformations, modify the currently selected one by pressing the **Green i** button, delete them by pressing the **Red X** button, or change their order of application to the data using the **Green arrow** buttons. Press the **Green Tick** button in the **Transform Cloud** window to apply the transformations to the selected data.

The transformation will be applied and, if **Create New Cloud** was selected, a new Cloud created in the **Project Tree** - the original Cloud will be unaffected. If **Edit Existing Points** was selected, then the cloud selected will be transformed.

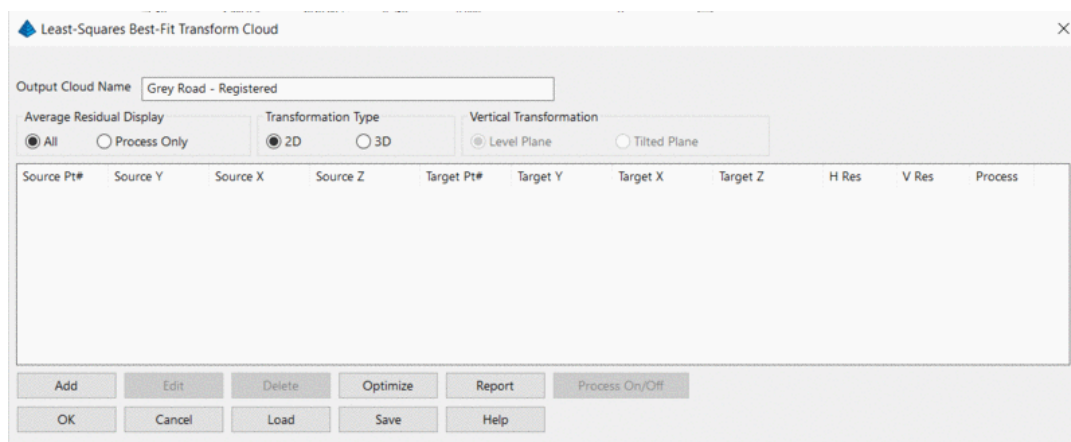

Scale allows the user to **Use Custom Scaling Factor** or to convert between Meters, US Feet and International Feet.

Align/Register performs either a **Least Squares Best-Fit** or **Align by Two Pairs of Points**

Least Squares Best-Fit is used when there are more than two pairs for translation points. Since two pairs of points are sufficient to define the translation and rotation, more than two pairs of points provides more than enough information. A Rigid Body transformation is used for the horizontal aspect.

The **Transformation Type** chooses between doing a 2D transformation and 3D transformation. For the 3D transformation, the program transforms the x/y using the same method as the 2D transformation, and the Z is transformed using an elevation difference model that is modeled by either a best-fit level plane or tilted plane as set by the **Vertical Transformation** setting.

The **Add** button is used to define the source and destination coordinates for the points that define the transformation. Pressing this button brings up the following dialog box.

The dialog box is titled "Add Alignment Point" and features a close button (X) in the top right corner. It is organized into two primary sections: "Source Coordinate" and "Target Coordinate".

Source Coordinate Section:

- Point Number:** An input field with a "List" button to its right.
- Northing:** An input field with a "Screen Pick" button to its right.
- Easting:** An empty input field.
- Elevation:** An empty input field.

Target Coordinate Section:

- Point Number:** An input field with a "List" button to its right.
- Northing:** An empty input field.
- Easting:** An empty input field.
- Elevation:** An empty input field.

At the bottom of the dialog, there are three buttons: "OK", "Cancel", and "Help".

The **Edit** button is used to edit existing data.

The **Delete** button removes the source and destination pairing from the transformation setup.

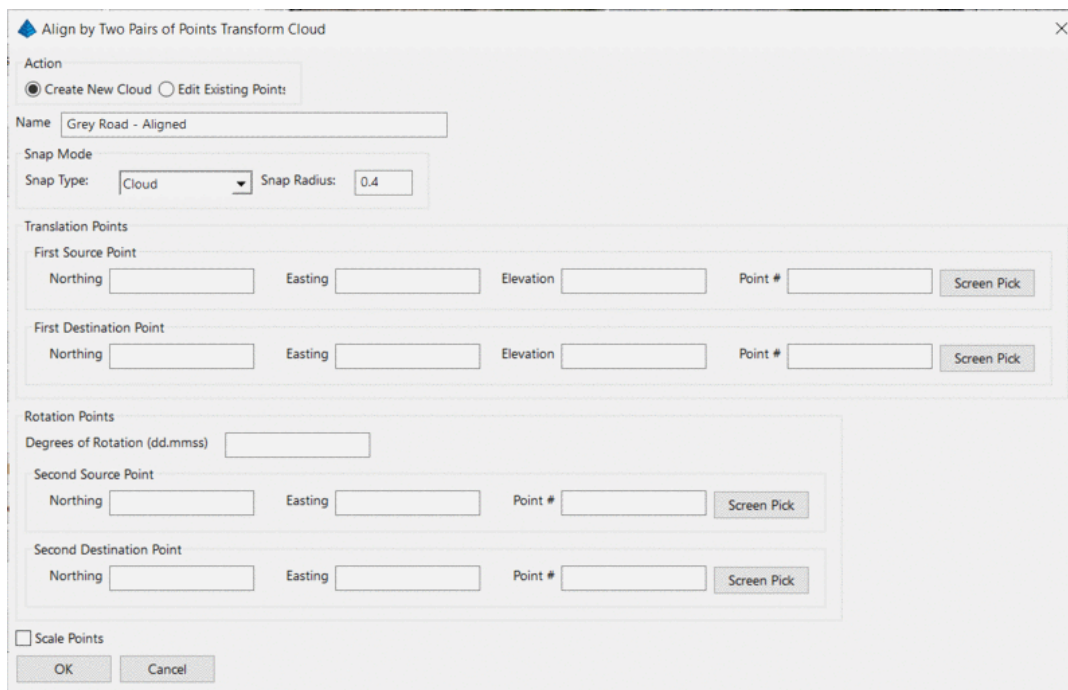

The **Process On/Off** button allows source and destination pairings to be turned on and off. This is useful when wanting to inspect different results using different pairings.

The **Optimize** option chooses which point pairings would yield the best transformation results by turning off the processing of pairings with higher residuals. This minimizes the average residual for the control points.

The **Report** option displays a report of the transformation point pairings, their residuals, processing status, transformation scale and avg. residual.

The **Load** and **Save** options allow for saving and recalling local coordinate transformation pairings and settings.

Align by Two Pairs of Points option uses two pairs of source and destination coordinates.

A new cloud can be created via **Create New Cloud** or the existing cloud can be modified using **Edit Existing Cloud**.

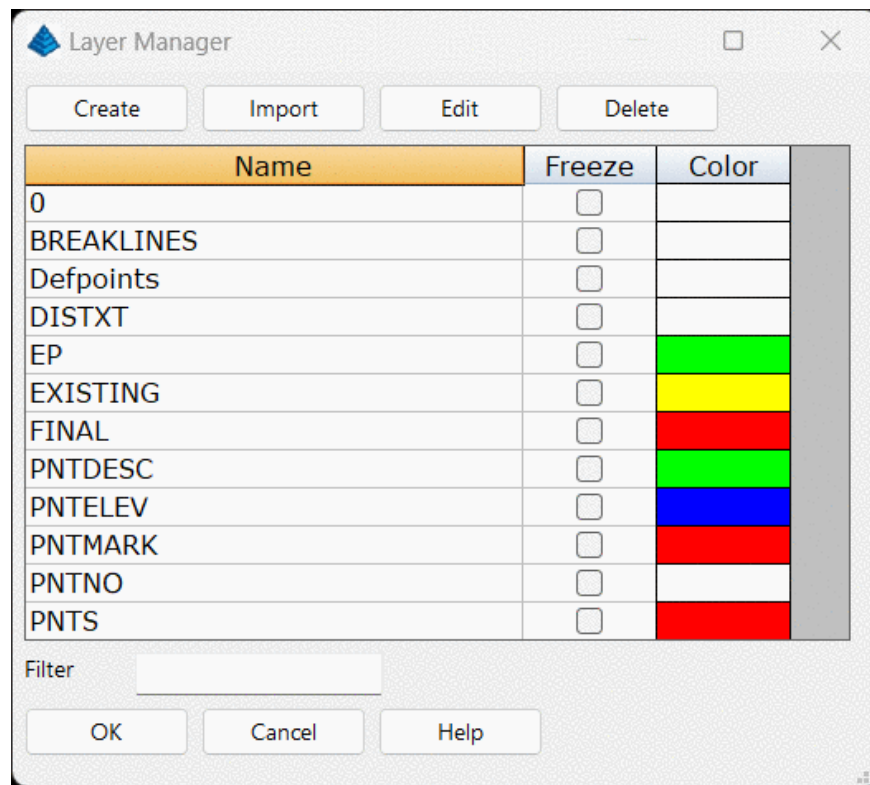

Snap Type sets the type of snap to be used when using the **Screen Pick** option.

The first pair defines the translation as the difference between the source and destination northing and easting. This destination point is also the pivot point for rotation. **Rotation** can be entered directly or defined by a second pair of points where the bearing between the first and second source points is rotated to align with the bearing from the first and second destination points. There is an option to also apply **scaling**. The scaling holds the angle between points and adjusts the distances by the scale factor. The scale factor is calculated for each point as the elevation factor at the first source point times the grid factor at the first destination point averaged with the elevation factor at the transform point times the grid factor at the transform point.

Common Utilities

Layer Properties Manager

The **Layer Properties Manager** can be accessed from the **Project Tab** by **right-clicking** on **Layers** and selecting **Edit**. It can also be opened from the menu bar in an opened **Scene** by selecting **View** and then **Layer Manager** or the toolbar by clicking the **Layer Manager** button.

Create adds a new layer to the list. The default new layer name is Layer # where # begins at 1 and increments as new layers are added.

Import allows you to import the layer names from the CAD project drawing or layer standards file.

Drawing Layers will read the layers in your drawing and open a **Select Layers** window. You can select one or multiple layers in the panel. Click **OK** to import the layers. The program will import the layer name and the layer color.

Layer Standards File will open a file selection window. Browse and select the Layer Standards File (.la) and click **Open**.

Edit Places the cursor in the **Name** field of the *highlighted layer* to allow editing of the layer name. Users can also edit layer names by double-clicking on the layer name field. **Note:** if no layer is highlighted, the cursor will select the first layer in the list.

Delete deletes the currently selected layer. **Note:** users can not delete a layer that has objects drawn on it.

The **Layer Properties** panel

Name - Shows the layer name.

Freeze - Toggles the freeze mode on and off. When toggled on, the objects on that specific layer will not be displayed.

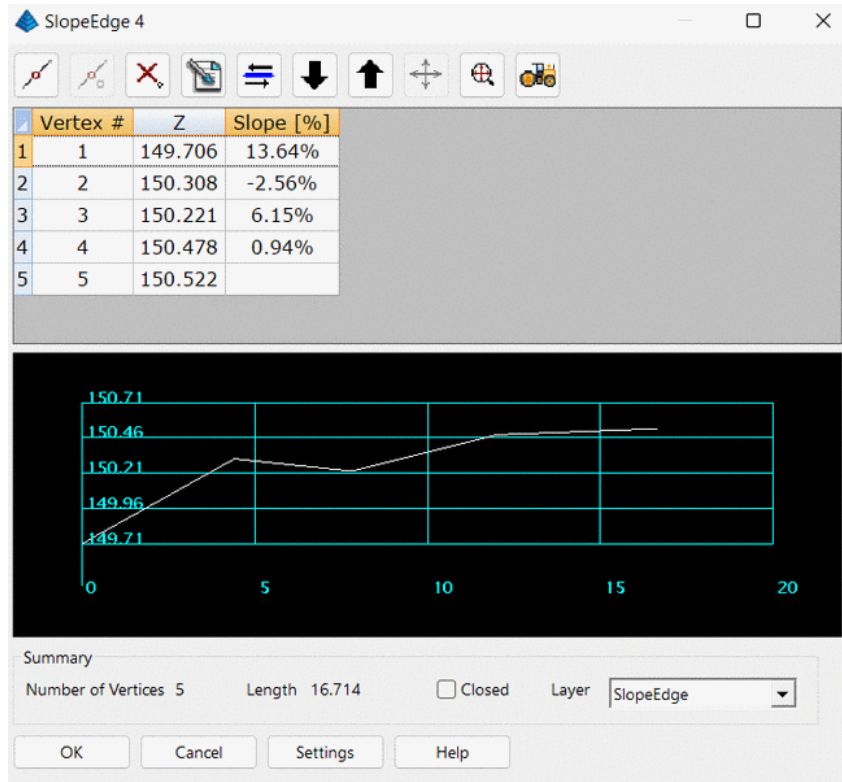

Color - Shows the color assigned to each layer. Click in the **Color** box to select a different color.

Tab Location(s): -Project Tab or Scene Viewer-

Prerequisite: -None-

Polyline Editor

Use the **Polyline Editor** to make changes to the polylines in the point cloud project. The **Polyline Editor** window can be opened by **right-clicking** on a polyline and selecting **Edit** or by **double clicking** on a polyline in the **Current Project** tree. The **Polyline Editor** can also be accessed when creating a new polyline from the **Action** tab. Under the **Active Polyline** panel, highlighting a polyline and clicking the **Edit** button.

Along the top is a toolbar with several icons. The icons and their corresponding functions are as follows:

New Vertex brings up a dialog that allows you to specify the properties of a new vertex to add.

Edit Vertex brings up the edit vertex dialog which allows you to change properties of the currently selected vertex.

Delete Vertices deletes the currently selected vertex or vertices.

Rename Polyline renames the currently selected polyline.

Reverse Polyline reverses the direction.

Import Polyline brings up the Carlson file selection dialog.

Export Polyline brings up the ASCII file export dialog.

Transform allows you to define a transformation sequence to apply to the vertices.

Zoom Extents zooms to the polyline in the current scene.

Flatten allows you to flatten the polyline.

Adding Vertices

Clicking the **New Vertex** button will bring up the **New Vertex** dialog.

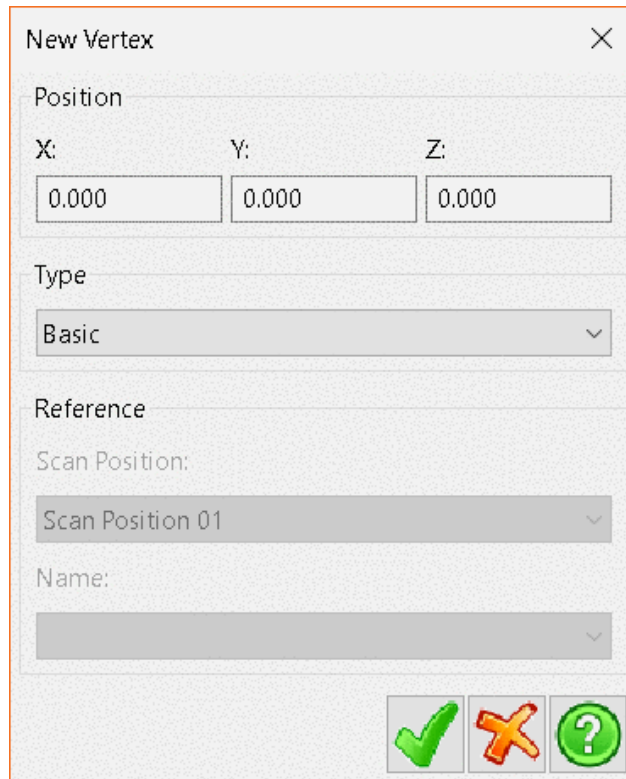

X, **Y**, and **Z** are the x, y, and z coordinates values for the new vertex to be added.

Type can be either **Basic**, **Target Point Reference** or **Coordinate Point Reference**.

The **Reference Panel** is activated when the vertex type is set to **Target** or **Coordinate Point Reference**.

When using **Target Point Reference**, select the desired scan position from the drop-down menu and then select the correct target point from those available in the **Name** drop-down menu.

When using **Coordinate Point Reference**, select the desired coordinate point from those available in the **Name** drop-down menu.

The image shows a 'New Vertex' dialog box with the following fields and options:

- Position:** X: 0.000, Y: 0.000, Z: 0.000
- Type:** Basic
- Reference:** Scan Position: Scan Position 01, Name: (empty)

At the bottom right, there are three icons: a green checkmark, an orange X, and a green question mark.

Importing Polyline

Clicking the **Import** button will bring up the **Import Polyline** file selection window. The currently supported file types for polyline import are **TXT**, **PLN** and **CL**.

Navigate to the correct polyline file and click **Open**.

Exporting Polyline

Clicking the **Export** button will open the **Export Polyline Vertices** dialog, which allows users to export the polyline to several different file formats.

In the **Columns** panel, click on the check boxes to include or exclude the data elements. To change the order of the data elements in the file, click on the element and then click the up or down arrows to adjust its position

The **File** panel determines which file format to export to and also allows you to specify an extension other than the default for a given file format.

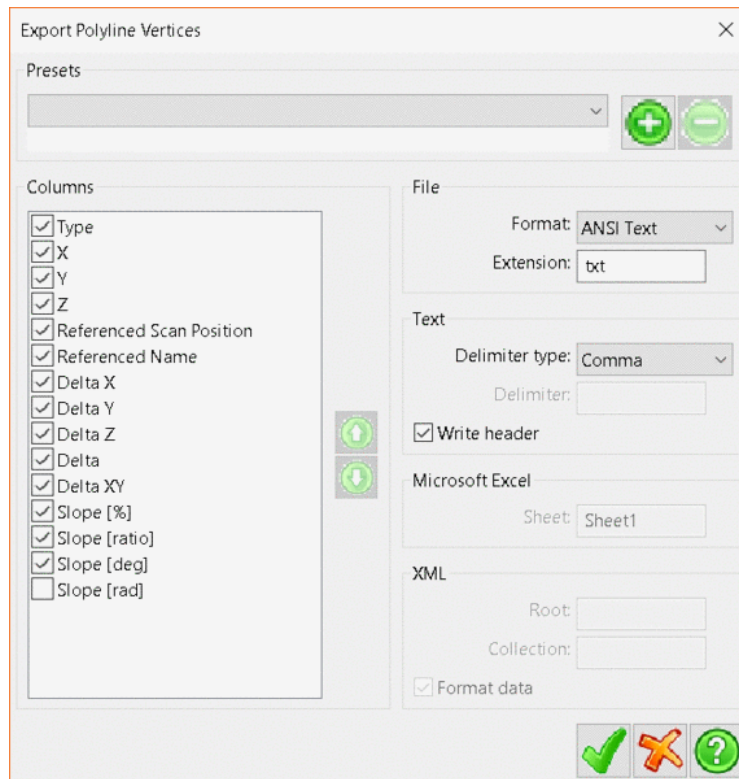

The **Text** panel contains options when exporting to the different text file types, **ANSI Text** or **Unicode Text**. The **Delimiter Type** determines the divider between data elements in the file. The Write header option specifies whether to write a header line to the file detailing the data ordering of the file.

Microsoft Excel allows the user to define the name of the Excel worksheet that the points will be exported to.

Note: only available when exporting as **Format Microsoft Excel XML** allows users to define the **Root** and **Collection** values and choose to **Format data**

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organise the elements into the desired order and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

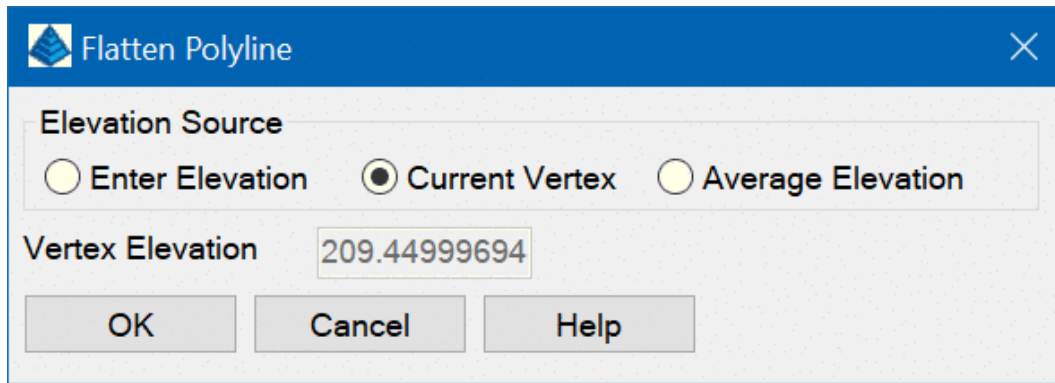

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** button next to the **Presets** drop-down menu.

Flatten Polyline

Clicking on the **Flatten Polyline** button will bring up the Flatten Polyline dialog box. There are three available methods to flatten the polyline:

- **Enter Elevation** - allows the user to enter in a constant value to be used for all of the vertices.
- **Current Vertex** - sets the polyline elevation to the currently-selected vertex.
- **Average Elevation** - will average all of the vertices. This value is displayed in the box underneath for confirmation.

Settings

The Settings button will bring up the **Polyline Editor Settings** window, which allows the user to configure which data elements of the current vertex set are visible, as well as the order that they are displayed in.

To turn off a data element so it will not be displayed, click in the check box next to that element in the **Columns** panel.

To change the order that data elements are displayed, select the element to move and then click the green up and down arrows to adjust the elements position.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organize the elements into the desired order and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Green Dash** next to the **Presets** drop-down menu.

Tab Location(s): Project Tab and Action Tab

Access Command: Right-Click Points and select Edit (Project Tab) Click Edit button (Action Tab - Polyline Creation mode)

Prerequisite: Scene with a polyline

Point Editor

The Point Editor allows you to edit the points in the point cloud project. **Right-clicking** on **Coordinate Points** in the **Current Project** tree and select **Edit** or by double clicking on a set of points. In the **Coordinate Points** window, there are several base functions that are shared across all point types, with some extended options added for certain points types.

Name	X	Y	Z	Description
1001	5678168.022	3654106.694	779.725	MH BEG

36 Coordinate Points, 0 Selected

Along the top toolbar are several option buttons:

Add Point brings up a dialog that allows you to specify the properties of a new point to add.

Edit brings up the point edit dialog which allows you to change properties of the currently selected point.

Copy Points allows you to copy the currently selected points to another point set (such as from the control points to the target points of a scan).

Delete deletes the currently selected points.

Import Points brings up the ASCII file import dialog.

Export Points brings up the ASCII file export dialog.

Transform allows you to define a transformation sequence to apply to the points.

View brings up the scene creation dialog for viewing the current point set.

Field to Finish Draws the selected points in CAD using the current FLD file and field to finish settings.

Draw to CAD brings up the Point Draw Settings dialog specify a layer to draw the selected points on in CAD and specify if the points should be added to the current CRD file.

Coordinate System allows you to choose the coordinate system the positions values are in (Global or any current scan positions).

Settings allow you to configure what properties of the points are visible in the spreadsheet control.

Help brings up help documentation.

Adding Points

Clicking the **Add Point** button will open the **New Coordinate Point** window.

Name is a unique name for the point to be used to identify it in Point Cloud.

Description is a description for the point.

X, **Y**, and **Z** are the x, y, and z coordinates values for the new point to be added. Or click on **Screen Pick** to select from the cloud.

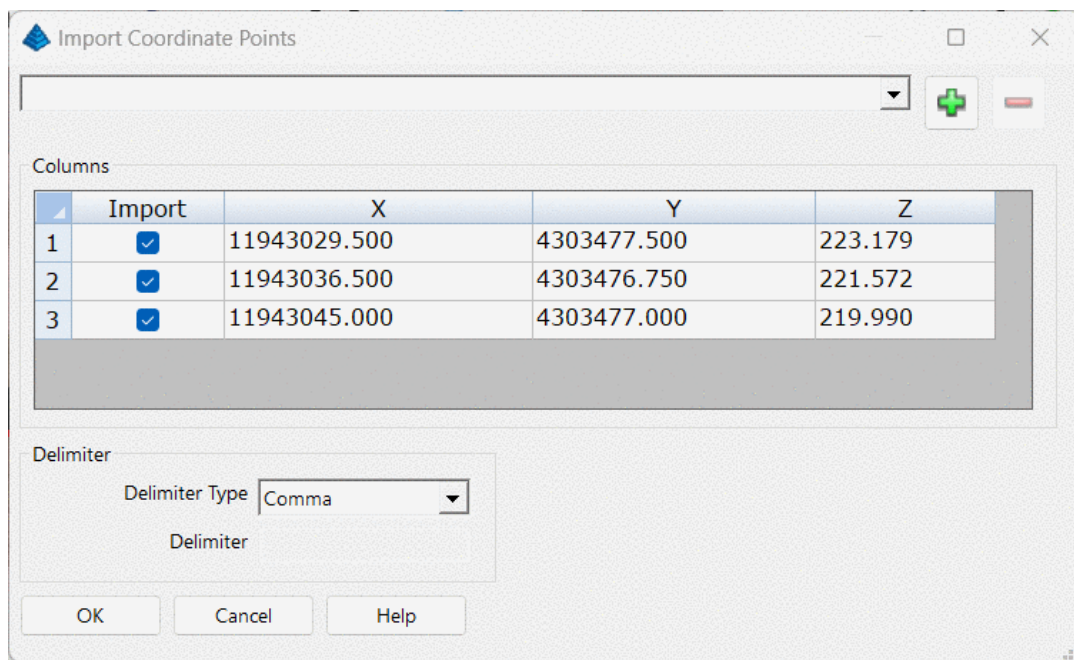

X	Y	Z
5678133.716	3654096.467	780.441

Importing Points

Clicking the **Import Points** button will open the **Import Coordinate Points** file selection dialog. The file formats currently supported for import are **TXT**, **CSV**, **CRD** and **CRDB**. Navigate to the correct file and click **Open** to display the **Import Coordinate Points** window.

Selecting **Rename all items** will rename all imported points to the settings specified in the **Naming Conventions** settings. The **Duplicate Entries** panel will specify the action to take when a point being imported has a name that already exists in the set of points being imported to.

Click the **Green Tick** to import the points.

Exporting Points

Clicking the **Export Points** button will open the **Export Coordinate Points** window, which allows users to export the data to several different file formats.

In the **Columns** panel, click on the check boxes to include or exclude the data elements. To change the order of the data elements in the file, click on the element and then click the up or down arrows to adjust its position.

The **File** panel determines which file format to export to and also allows you to specify an extension other than the default for a given file format.

The **Text** panel contains options when exporting to the different text file types, **ANSI Text** or **Unicode Text**. The **Delimiter Type** determines the divider between data elements in the file. The **Write header** option specifies whether to write a header line to the file detailing the data ordering of the file.

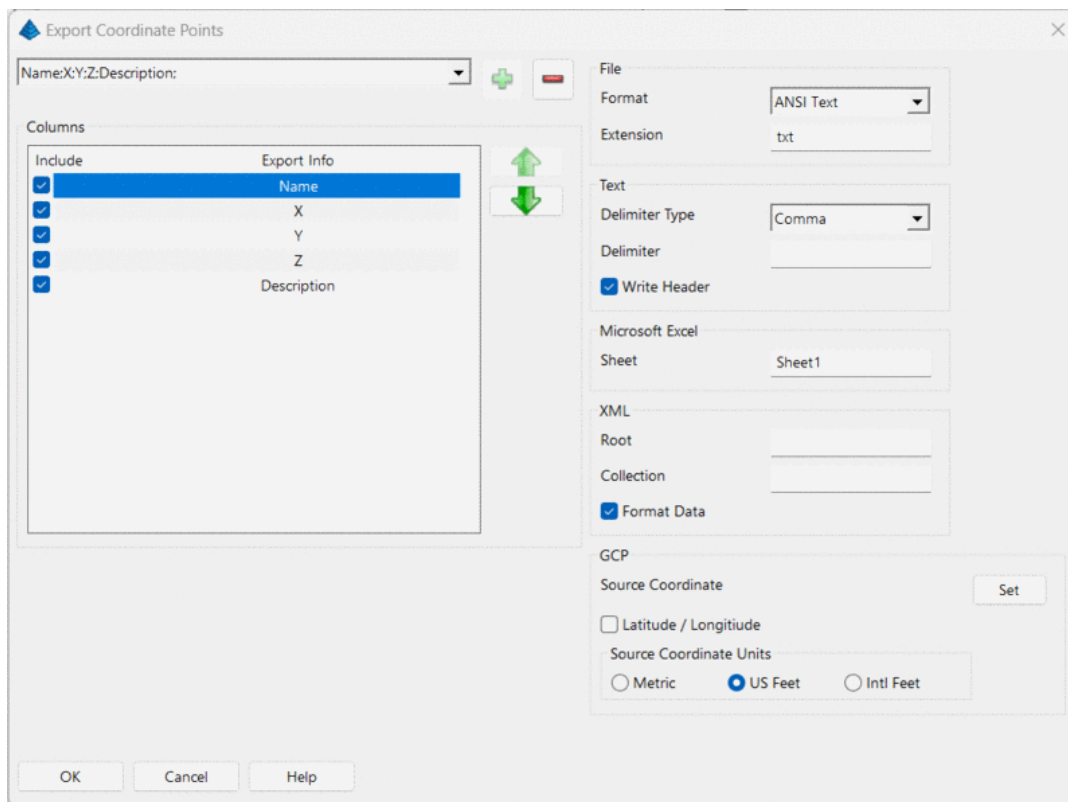

Microsoft Excel allows the user to define the name of the Excel worksheet that the points will be exported to. **Note:** only available when exporting as **Format: Microsoft Excel**.

XML allows users to define the **Root** and **Collection** values and choose to **Format data**. **Note:** only available when exporting as **Format:XML**.

GCP - when exporting as GCP, click on the **Set** button to choose the Coordinate Projection. Users can choose to select a Pre-Defined projection, add a projection from a file or create a User-Defined projection on the fly. Click **OK** to select and return to the previous window. Users can select to export the coordinates in Latitude/Longitude format and also to select the appropriate units; **Metric**, **US Feet** or **International Feet**.

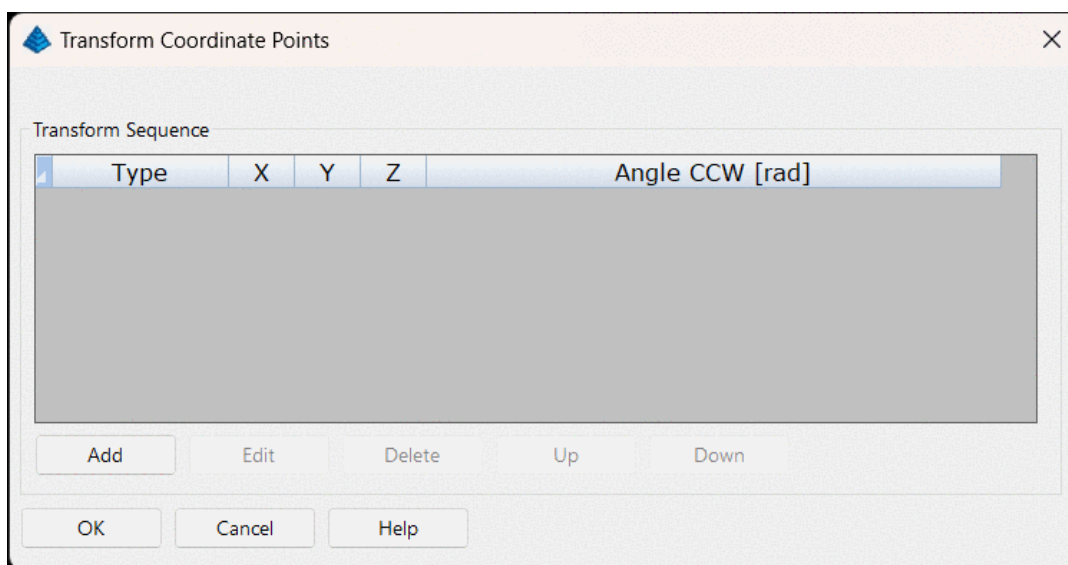

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organise the elements into the desired order and then click the **Green Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Red Dash** button next to the **Presets** drop-down menu.

Transform Points

The **Transform** button opens the **Transform Coordinate Points** window where users can define a selection of transformation parameters to apply to the selected Coordinate Points.

Initially, the dialog will have no transformations specified. To add a transformation, press the **Add** button, which will open the **New Transformation** window.

Use the **Type** drop-down menu to select one of the four Transformation types:

Translate allows the user to define a translation of the current data set by specifying offsets in X, Y and Z.

Rotations allow the user to rotate the current selection set by specifying rotations around the X Y and Z axis.

Scaling allows the user to scale the current selection by a set Factor in the X, Y and Z axis.

Advanced allows the user to specify a transformation matrix to be applied to the data.

After clicking the check button you should be taken back to the **Transform Coordinate Points** window. From here users can add more transformations, modify the currently selected one by pressing the **Edit** button, delete them by pressing the **Delete** button, or change their order of application to the data using the **Up / Down** buttons. Press the **OK** button to apply the transformations.

Note: Transformations are applied in top-to-bottom order.

Advanced			
1.000000000	0.000000000	0.000000000	0.000000000
0.000000000	1.000000000	0.000000000	0.000000000
0.000000000	0.000000000	1.000000000	0.000000000
0.000000000	0.000000000	0.000000000	1.000000000

Settings

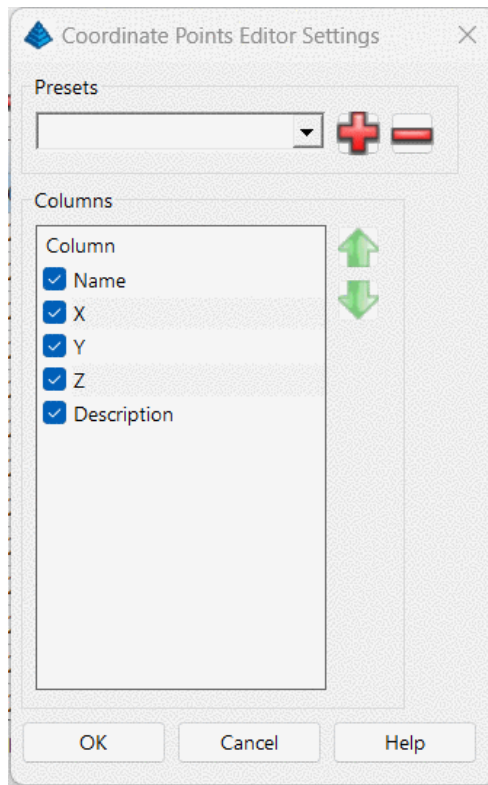

The Settings button will bring up the **Coordinate Point Settings** window, which allows the user to configure which data elements of the current point set are visible, as well as the order that they are displayed in.

To turn off a data element so it will not be displayed, click in the check box next to that element in the **Columns** panel.

To change the order that data elements are displayed, select the element to move and then click the green up and down arrows to adjust the elements position.

Users can select a preset export format by selecting it from the **Presets** drop-down menu. To define a new preset, include or exclude the desired data elements in the **Columns** panel, organize the elements into the desired order and then click the **Red Plus** button next to the **Presets** drop-down. The new preset will be added to the drop-down menu for future use.

To delete a preset, select it from the **Presets** drop-down menu and then click the **Red Dash** button next to the **Presets** drop-down menu.

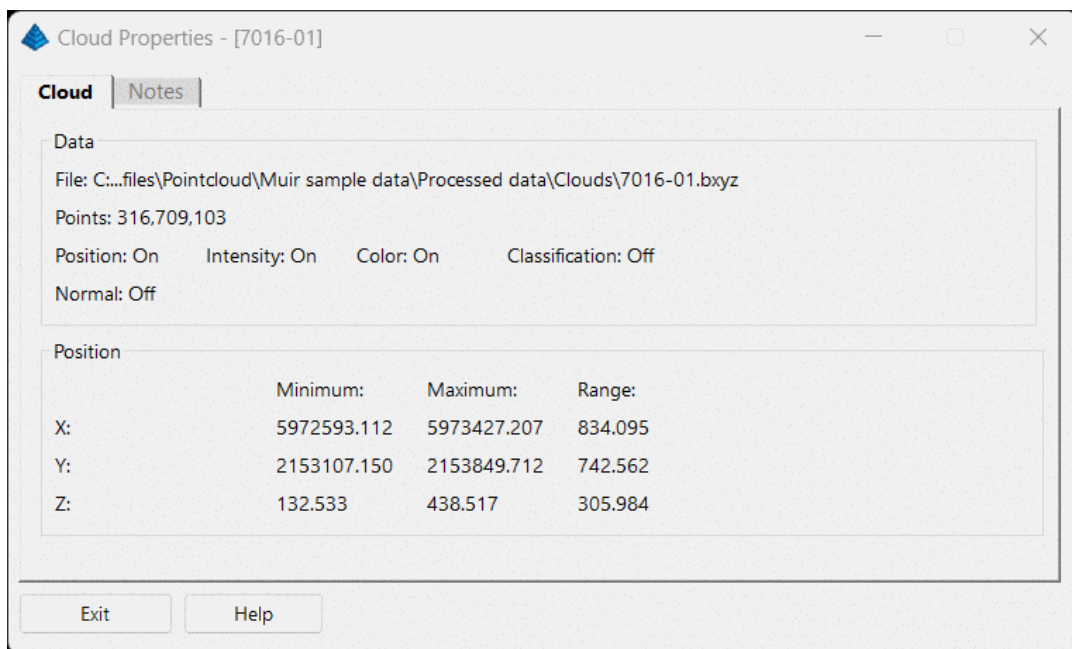

Tab Location(s): Project Tab

Access Command: Right-Click Points and select Edit

Prerequisite: Control Points or Target Points or Coordinate Points

Item Properties

To see statistics and information about the size of Scans, Clouds, TINs, or Scenes, **right-click** the object in the **Current Project** tree and select **Properties** to open the **Properties** window.

The Properties window can have different tabs depending on the data object selected. For example, when a cloud is selected as in the above image, the Properties window will display **Cloud** and **Notes** tabs. In the Cloud tab you will see the location of the cloud file on your drive or network, the number of points found in the cloud, and the minimum, maximum, and range of coordinates.

The **Scan** properties adds a **Scan** tab and a **Preview** tab. The **Preview** tab found in **Scan Properties** will show a small preview of the scan data in 2D.

The **TIN** properties adds a **TIN** tab.

The **Notes** tab features a textbox where users can add notes to the object for future reference.

Tab Location(s): Project Tab

Prerequisite: A Scan, TIN or Cloud

Natural Regrade Module 14

Traditional landscape design is often based on the subjective judgment of landscape appearance or desired land use with little consideration for proper hydrologic function for balanced conveyance of water and sediment from the land surface. Alternately, traditional design methods might use engineering principles to create structural controls for water and sediment conveyance (Bugosh, 2000). Over the last several decades, fluvial geomorphic research has identified distinct relationships among several important factors including climate, discharge, slope, and earth materials that define stable stream channels (Bloom, 1978) (Dunne and Leopold, 1978) (Williams, 1986). The Carlson *Natural Regrade* module applies fluvial geomorphic principles to upland landforms through computer software (GeoFluv™). GeoFluv™ creates a landscape design that mimics the functions of the natural landscape that would evolve over time under the physical and climatic conditions present at the site to convey the water and sediment from the land surface in a stable hydrologic equilibrium.

The following sections summarize why GeoFluv™ benefits reclamation landform design and description of how computerizing the approach provides a value multiplier by allowing detailed designs to be made and evaluated quickly. The "Problems Addressed by *Natural Regrade*" section discusses limitations of conventional approaches to disturbed-land reclamation design. "The Fluvial Geomorphic Solution" section discusses how and why *Natural Regrade's* GeoFluv™ approach solves the problems inherent in the conventional approaches. The "Description of Software" section explains fundamental concepts and terminology used in GeoFluv™ approach, and how and where these are used in the *Natural Regrade* module.

The remaining sections are as follows. The "Links with other Software" section describes other software that the user can use along with *Natural Regrade* to achieve even greater efficiency when constructing the GeoFluv™ design (or any other construction project). The "Software Compatibility" section describes the CAD software that *Natural Regrade* is designed to work with.

Highlight Tractive Force Zones

This Natural Regrade command allows the user to identify zones of tractive force values in the GeoFluv design channels above a user-specified threshold value. This is useful when editing a draft design to reduce tractive force values to meet the designer's criterion for channel 'steady-state' stability, i.e., adequate stream competence to transport sediment through the system and not cause problematic deposition while also not accelerating channel bank and bed erosion. When the user can see the zone where tractive forces exceed the project threshold value criterion, they can consider design edits, e.g., lowering reach slope, reducing reach discharge, that can lower those tractive forces to target values.

The command collects input values from the design in the drawing and uses them in the tractive force calculations. Zones in the drawing on each channel reach that exceed the specified threshold are highlighted by a linework polygon enclosing the zone's upper and lower ends. The user can specify the width of the zone, hatching within the zone, and zone color for both bankfull and flood prone values.

Double-clicking on the Highlight Tractive Force Zones command button on DWG tab causes the Highlight Tractive Force Zones Above Threshold dialog box to appear on the screen.

Bankful Highlight Settings	
<input checked="" type="checkbox"/> Draw zones of bankful tractive force above threshold	
Threshold Value (lbs/sq.ft.)	1,290
Check Interval (ft.)	2,000
Highlight Width (ft.)	5,000
Layer	GF_ThresholdBankfull
Hatch Style	SOLID
Hatch Scale	0.100
Zone Color	Red (1)
Hatch Transparency (0-100)	50

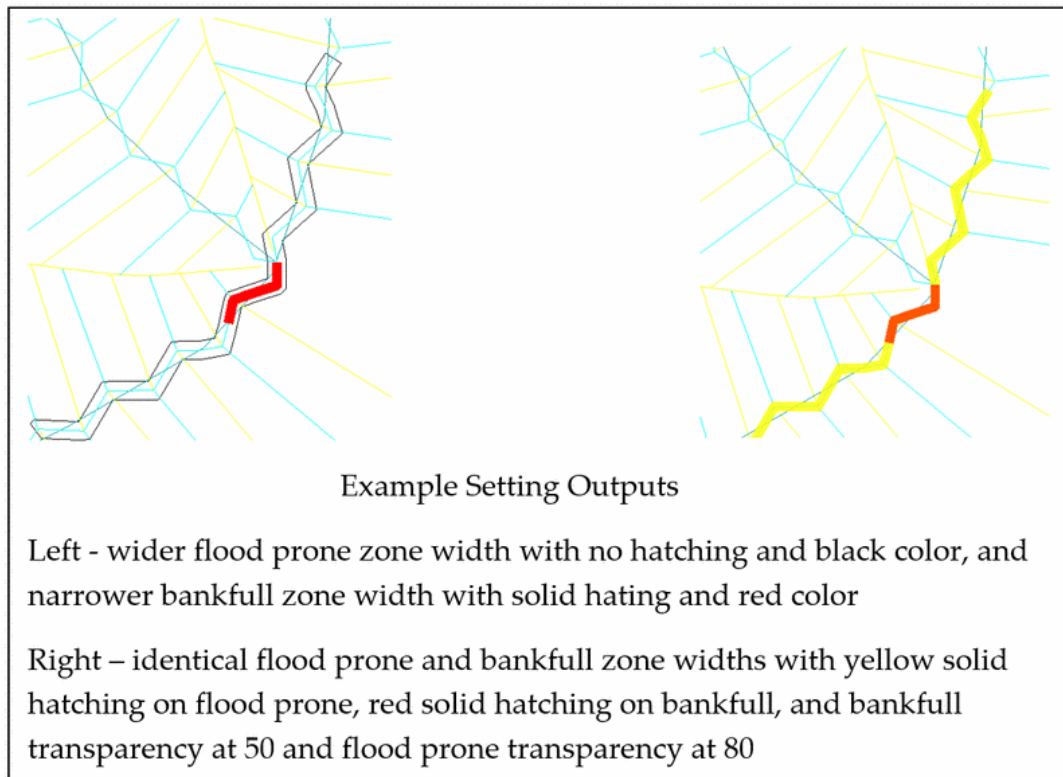

Flood Prone Highlight Settings	
<input checked="" type="checkbox"/> Draw zones of flood prone tractive force above threshold	
Threshold Value (lbs/sq.ft.)	1,290
Check Interval (ft.)	2,000
Highlight Width (ft.)	10,000
Layer	GF_ThresholdFloodProne
Hatch Style	SOLID
Hatch Scale	0.100
Zone Color	Yellow (2)
Hatch Transparency (0-100)	80

Draw zone of bankfull/flood prone tractive force above threshold: The user clicks the appropriate toggle box to specify if they want to draw tractive force zones for bankfull or flood prone or both discharges. The edit boxes in the bankfull and flood prone fields become active when their boxes are toggled on.

Threshold Value: The user enters the tractive force value above which they want identified on the GeoFluvTM design drawing. This and greater values will be located in the highlighted zones.

Check Interval Distance (ft or m): The user enters a distance value for Natural Regrade to collect input values from the design surface for the tractive force calculation. The value must be greater than or equal to 2 ft.

[Note: The tractive force values are calculated from variables measured from the design surface TIN file, which in turn is made from the input coordinate data, so that small irregularities in the resulting surfaces can result in jumps in the calculated variable values, that in turn affect the tractive force calculations over very small distances. We have observed these jumps in testing different drawings based on data sets of varying x, y, and z resolution and density. The value jumps present themselves as breaks within the zone above the threshold value. The user can eliminate any resulting breaks in the tractive force zones by increasing the check interval values until the breaks disappear. Our testing indicated that for many data sets the presented values should be considered accurate within about five percent for this reason.]

Highlight Width (ft/m): The user can specify the width of the polygon enclosing the zone above the specified threshold value. Specifying different widths for the bankfull and flood prone values can make them easier to see when both are selected (left example in settings output figure).

Layer: The tractive force above threshold zone polygon linework is drawn on GF_ThresholdBankfull and GF_ThresholdFloodProne layers by default. These layers are erased by default when leaving "Edit design surface in drawing" mode and returning to "Edit GeoFluv inputs" mode. The user can enter a different name in the edit box window if saving the zone polygons to a different layer is desired.

Hatch Style: The user can select a hatch style pattern from the example icons or by scrolling through the list of hatch styles. Selecting "None" from the list will color the polygon linework a single, color without any design pattern inside the polygon. Selecting "Solid" from the list will color the polygon linework and the area inside the polygon a single, color without any design pattern. The hatch style can be specified for both bankfull and flood prone tractive force above threshold zones, e.g., selecting "Solid" for bankfull and "None" for flood prone zones can display a flood prone outline surrounding a solid bankfull zone (left example in settings output figure).

Hatch Scale: The user can vary the size of the hatch pattern by entering larger and smaller values in the edit box.

Zone Color: The user can specify the zone color by clicking on the box next to the edit box, selecting the

desired color from the pop-up palette, and clicking "OK". The specified zone color will then be displayed on the settings dialog box.

Hatch Transparency: The user can 'see through' an overlying layer to an under-lying layer by entering a relative value on a scale of 0 to 100 for lesser or greater transparency. For example, if the bankfull and flood prone zones have the same width and the bankfull zone lies entirely within the flood prone zone, transparency would cause the bankfull zone to not be entirely obscured by the overlying flood prone zone, but instead both zones could be seen simultaneously (right example in settings output figure).

After entering all the command settings the user clicks "OK" and the command starts running and displays "Calculating and drawing tractive force zones..." at the command prompt line until completed. Complex data sets with tighter Check Interval Distance settings may take some time to complete drawing the zones; the user will know when the command is done when the command prompt line reads 'Done'.

Problems Addressed by Natural Regrade with GeoFluv

Conventional land-shaping practices are often based on conveying or capturing runoff from an extreme event. These conventional practices include grading slopes to a uniform gradient, building gradient terraces across slope faces, and constructing rip-rapped down drains to convey runoff as shown in Figure 1.

Use and Cost Limitations of Conventional Approach

Conventional designs often do not address the hydrologic balance during less extreme flow conditions. This results in problems with reclamation success for vegetation, livestock, and wildlife post-disturbance land uses, high maintenance costs, and reclamation bond complications.

Figure 1. Conventional steep slope reclamation with uniform slope gradient, gradient terrace, and rip-rap lined down drain

The unnatural configuration of these designs does not provide the terrain diversity that creates spatial variation in water harvesting and slope aspect. The result is that vegetation tends toward a monoculture and animal habitat is minimized. The native land in the foreground of Figure 1 has forbes and shrubs growing near minor gullies, whereas the uniformly-graded slopes above them do not favor these plants, despite having been seeded with them.

Conventional land-shaping practices have high construction, maintenance, and liability costs. Terraces can be difficult and expensive to grade on steep side slopes. The rip-rap material may have to be procured off site and transported to the site. After construction, regular maintenance is often required as the terraces and ditches sized for extreme flows become clogged with sediment at lower flows, or are penetrated by burrowing animals. Clogged or burrowed terraces can result in catastrophic diversions of runoff from the terraces straight down the slope, often requiring major repairs.

Bonding Limitations of Conventional Approach

The conventional approach to reclamation landform design affects reclamation bonding liability and costs. The damage to the slope from a blowout and related repair work can result in a reclamation bond clock being restarted, which prolongs the operator's period of liability. The expense of creating land form designs has often limited an operator's ability to propose incremental reclamation bonding for various stages of a project's disturbance. For example, an operator may determine that their greatest disturbance will occur at year four of a five-year permit and they may post a bond for that maximum disturbance, even though their liability will be lower for the first four years. This creates an unnecessary financial burden for the operator.

The Fluvial Geomorphic Solution

This fluvial geomorphic landscape computer-design software (GeoFluv™) uses an algorithm based on fluvial geomorphic principles. The essence of this approach is to identify the type of drainage network, i.e., stream channels and valleys, which would tend to form over a long time given the site's earth materials, relief, and climate to achieve a stable landform, and to design and build that landform. The resulting slopes and stream channels are stable because they are in balance with these conditions (Rosgen, 1996). They are a reclamation alternative to uniform slopes with terraces and down-drains. Rather than fight the natural forces that shape the land, the algorithm helps the user create a landscape that harmonizes with these forces.

The channel and swales in the foreground, and the steep slope ridges, valleys, and channels in the center of Figure 2., are examples of portions of a 115-acre coal mine reclamation project completed using this innovation fluvial geomorphic approach.

Figure 2. Steep slope reclamation using the fluvial geomorphic approach shown during the second growing season

Natural Stability

Over the last thirty-some years hydrologists have observed and measured stable natural streams and determined mathematical relationships that describe these stable stream types. Essential among these determinations is that channel morphology is directly related to a relatively small, but frequently recurring annual flood event. The natural channel is shaped to keep its sediment load and stream flow in balance during these low-flow events, as well as during extreme events. *The GeoFluv™ fluvial geomorphic approach to land reclamation relates the upland landforms to the stream channel form.* Both can be formed similarly by flowing water. Reclamation landscapes created using fluvial geomorphic principles provide stability against erosion with runoff waters capable of meeting water quality criteria, and support a diverse vegetative community. These landscapes offer the benefits of lower initial cost, no long-term maintenance costs, and they promote bond release (Bugosh, 2002, 2003).

Promotes Bond Release

The GeoFluv™ fluvial geomorphic approach provides a high degree of confidence that reclamation projects will demonstrate long-term stability against erosion similar to adjacent undisturbed lands because the reclamation channels are designed to maintain the hydrologic balance, as the natural channel does. This means that the reclaimed land does not have to be regularly disturbed to repair erosion problems. Additionally, the varied landform provides niches for different plants, wildlife, and livestock. These benefits demonstrate to regulatory authorities that the site will remain stable and productive; that demonstrated stability can promote bond release.

Benefits of Computerizing the Fluvial Geomorphic Approach

Previous application of alternative land-shaping practices may have been limited for several reasons, including the limited extent of training in fluvial geomorphic principles of the designers, the complexity of the design calculations to create a thoroughly integrated landform, and the difficulty of guiding the heavy equipment operators to build more sophisticated designs. The *Natural Regrade* module addresses all these potential limitations. GeoFluv™ creates a draft landform based on empirically determined fluvial geomorphic mathematical relationships. The draft landform is an idealized solution that uses the input parameters to create a stable landform. The designer can then modify this idealized draft landform to conform to special site conditions, such as an archaeological site, landmark, or other feature, or to create a more natural appearance.

User Friendly

Existing computer software for earth-moving designs does not incorporate this innovative approach, is often not "user friendly", and does not have the broad applications for landscape designs that are stable against erosion offered by *Natural Regrade*. GeoFluv™ makes "user friendly" computer design software available to a large body of users that do not have advanced training in fluvial geomorphology, as well as to those who do have this background. *Natural Regrade* has been designed to be as "user friendly" as possible; the program commands are organized following a left-to-right and top-to-bottom format that follows the project design work sequence, with minimal input needed and with guidance provided in the "Help" resource and documentation.

Minimizes Training

The *Natural Regrade* module minimizes the training necessary to immediately use the fluvial geomorphic approach for reclamation at disturbed sites, or when evaluating proposed reclamation designs. Users can compress design time and build reclamation landscapes from disturbed earth to seeded reclamation. GeoFluv™'s developer has successfully introduced this reclamation approach to the largest mining company in the world at truck-and-shovel and dragline operations. The *Natural Regrade* module is designed to quickly make the GeoFluv™ design approach available to the widest range of users including professional hydrologists, environmental scientists, and engineers responsible for reclamation design at disturbed sites, and for regulatory personnel responsible for evaluating reclamation designs.

Simplifies numerous complex calculations

An important advantage of the *Natural Regrade* module's GeoFluv™ computerized approach is the ease by which the user can create landscapes that are functional, stable against erosion, low-maintenance, aesthetically pleasing, and cost-effective. The GeoFluv™ computer design software offers several options for developing input parameters from climatic and hydrologic data, and several options for creating landscape features, e.g., ephemeral, intermittent and perennial stream channels, complex slopes, ridges and valleys, and calculating material balances and centroids, and optimum material movement routes, for the resulting design. The user can design channels with appropriate characteristics, including channel patterns, sinuosity, longitudinal profiles, cross sectional areas, width to depth ratios, etc. and their contiguous uplands as functional components of a stable topography for tens of acres of land in minutes. GeoFluv™ allows the user to view topographic maps and three-dimensional images of the resulting landscape design. The GeoFluv™ approach replaces lengthy and tedious manual calculations and allows rapid evaluation of many landscape design alternatives. This allows the user to select the optimum landscape design for his needs.

Promotes Bonding Alternatives

The ability to quickly create and evaluate alternative reclamation designs provides great utility for both industry and regulatory personnel working on reclamation bonds. Because designing a reclamation surface has been such a lengthy and expensive process, often only a 'worst case scenario' design has been created for setting a reclamation bond. For example, this 'worst case scenario' may have been based on the disturbance in year four of a five-year mine permit. The ability to quickly create design surfaces and conduct mass balance comparisons makes it practical for the *Natural Regrade* module user to propose bonds for several stages of mine development, i.e., incremental bonding, that can reduce bond costs and promote release of more acres from bond.

Interface with GPS and Machine-control Software

This software also is ideal for integrating with Global Positioning System and laser machine control to simplify and speed construction and reduce costs. Construction of the complex landforms that are characteristic of stable natural landscapes, and which GeoFluv™ helps the user design, is facilitated by GPS and machine guidance technologies. The need to survey and stake the designs in the field is eliminated using these technologies, as is the need for the construction team to constantly provide guidance to the equipment operators.

Description of Software

GeoFluv™ requires only minimal input parameters to produce a draft surface and the material balance associated with creating that surface. The software outputs a draft landform that provides a solution for a stable landform that satisfies the input parameters. The software also displays the cut/fill balance achieved when building the draft landform, and centroids of material and void for material movement planning.

The *Natural Regrade* module helps the user through the design process by conveniently organizing all the commands that design a draft landform using the GeoFluv™ approach on a 'dockable dialog box' that is activated by the Design GeoFluv Regrade command. When this command is selected from the *Natural Regrade* menu, the dockable dialog box appears on the screen with all the GeoFluv™ design steps organized in a generally left-to-right and top-to-bottom sequence that leads the user through the design process. As a further aid to design sequencing, subsequent GeoFluv™ design inputs/commands are inactive on the dockable dialog box until the prerequisite step has been made. Finally, the commands automate and integrate as many of the calculations as possible to relieve the user of the burden of repetitive command steps.

The user can focus his design energy on testing alternative designs for enhanced suitability to site-specific conditions. Those site-specific conditions can include post-disturbance land use considerations, community relations, equipment constraints, material constraints, bond costs, visual aesthetics, etc. The resulting three-dimensional surface map can be exported in a variety of electronic formats to other programs, or printed as two-dimensional hard copy. The completed design can be taken to the construction site using survey and stakes, or output electronically to GPS and laser-guided construction equipment to further promote project efficiency. The designed topography can then be constructed with available equipment and earth materials.

Discussion of Input Parameters

GeoFluv™ helps the user create a stable landform based on minimal local input variables. These include site elevations (from a survey grid), a GeoFluv™ project boundary, a local stream base level to which the area within the GeoFluv™ boundary drains, a desired drainage density, design maximum discharge velocity, precipitation from the 2-yr, 1-hr and 50-yr, 6-hr storms, and runoff coefficient. The user will also select a desired cut/fill balance tolerance. Figure 3 shows an example of the minimal input data needed for the software to design the landform using this fluvial geomorphic approach.

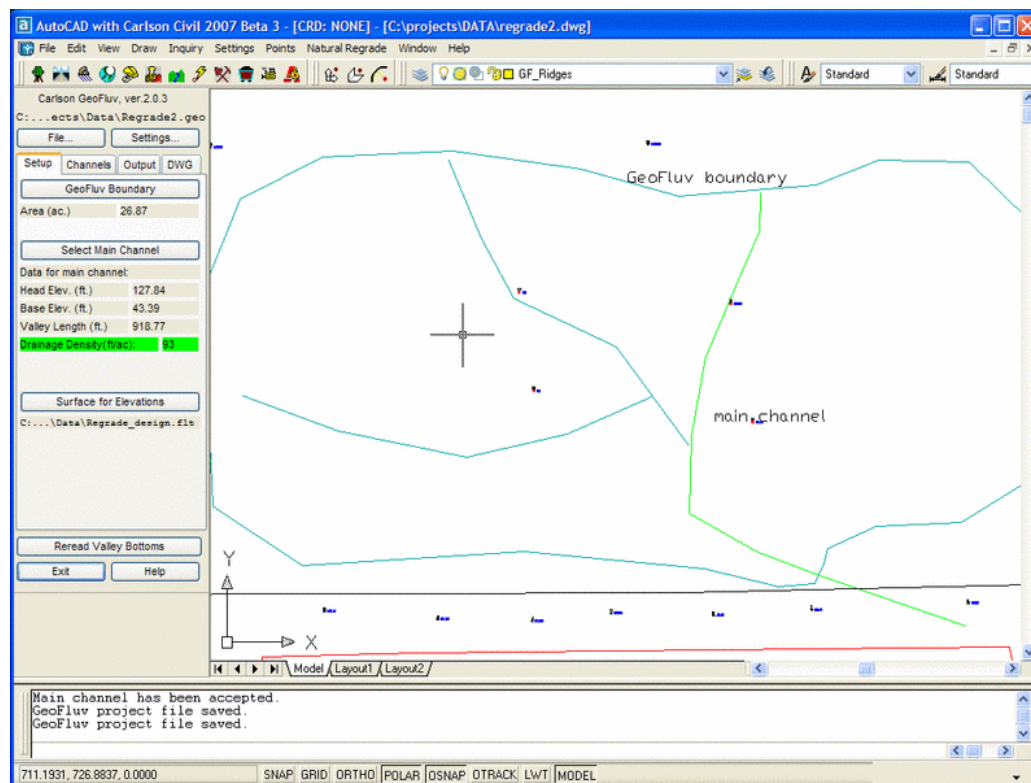

Figure 3. Example of Setup tab input dialog box

The user can then edit this idealized landform for any number of reasons. The site may have boundaries that must be avoided. The user may want to bend a channel around an archaeological or historic site, or local landmark. The user may want to alter slope aspects to promote vegetation diversity, wildlife niches, or to harvest moisture by retaining snow. Aesthetic considerations, such as view sight line, may prompt the user to edit the draft landform. Material movement planning may require the user to evaluate factors including the cut/fill balance and haul distances associated with various alterations of the draft landform. The user may wish to create several interim landform

designs leading to the final design for submission for incremental reclamation bonding. The ease and speed by which the software creates a draft design solution facilitates these and other edits. The *Natural Regrade* module frees the user to focus on site-specific design considerations and finding an optimal solution to creating a stable site landform, rather than being immersed in ponderous calculations for each subwatershed. Following the discussion of input parameters below, the Settings button default settings on the Setup tab will be explained. These settings are one way that the draft landform can be edited.

Drainage Density and Channel Pattern

The drainage density input is the valley length (without meanders) divided by the subwatershed area (Dunne and Leopold, 1978). Its units are length over area (L/L^2). Convenient U.S. units for landscape design work are feet/acre. This value will vary depending on factors such as earth materials, slope aspect, storm intensity, and vegetation type and coverage.

Drainage density is important because it represents the subwatershed size that will be stable for the local conditions. Drainage density and the ridges that form between channel meanders work together to break up the landform into many small subwatersheds, as can be seen in the natural subwatershed shown in Figure 4. The subwatersheds minimize both slope length and catchment area and thereby minimize erosion.

Figure 4. Natural "A" channel meanders and ridges break slope length into a series of subwatersheds

The drainage density is an expression of the amount of erosion that has occurred in the watershed. In a stable watershed, it represents the state at which sediment supply and water runoff are balanced in a state of dynamic equilibrium. Designing the landform using an appropriate drainage density for the project area conditions is an important first step toward achieving a stable landform design.

Watersheds may be disturbed in different ways and those affect reclamation planning differently. For example, mining may break up consolidated rock in the watershed and replace it with unconsolidated material. The result of this change on watershed reclamation design is often a marked change in channel pattern. Channels exploit weak portions of consolidated rock and tend not to form on more resistant portions, that is, the channel pattern has structural control. In the disturbed, unconsolidated material, the channels may form anywhere. Streams that previously had patterns that followed cracks in the consolidated rock can now form a more random pattern in the unconsolidated material. A different drainage pattern with greater drainage density may be expected in the unconsolidated, disturbed material for these reasons.

The effects of land leveling, whether for road building, urbanization, agriculture, or other purpose, may be nearer to the land surface and may not affect structural rock as much as an activity like mining might. The adverse effects of these land disturbances can still be unacceptable. Often these activities result in a decrease in drainage density and associated diversion of runoff from several watersheds into another watershed that is not adjusted to that flow. Runoff water may accumulate in undesirable parts of the leveled land and an undersized receiving watershed may respond to an increased flow with erosion and excess sediment production. Reclaiming these lands disturbed by leveling with an appropriate channel pattern and drainage density can mitigate the effects of the prior disturbance.

GeoFluv™'s default drainage pattern is a dendritic pattern, because this "branching tree" pattern is the type that typically forms in unconsolidated materials (Bloom, 1978; Dunne and Leopold, 1978), such as those existing at a disturbed site. Drainage patterns other than the dendritic pattern generally express structural controls related to

rock (or soil) mineralogy. Streamflow will not tend to maintain variation from the dendritic pattern when reclaiming unconsolidated materials without reestablishment of a structural control, e.g., rock-lined stream banks. Installing structural controls will add cost, will establish a point of weakness subject to attack by flowing water, and can cause disruption in the flow regime up- and downstream of the structure that will require compensation in the channel designs there.

Determining appropriate reclamation drainage density

GeoFluv™ suggests a default drainage density value, but the user can, and must, determine site-specific values to achieve landform stability comparable to surrounding natural land. By using empirically determined drainage density values in GeoFluv™'s input, the user can have a very high degree of confidence that the resulting design will behave similar to the areas from which the drainage density measurements were taken.

The user can determine a desired range of site-specific drainage density values. Local drainage density measurements taken from the undisturbed land with earth materials similar to the project area, and from nearby areas with earth materials that are similar to the project's disturbed earth materials, can define the range. The drainage density measured on undisturbed earth materials provides a lower end-of-range value, while the drainage density measured on nearby areas similar to the project's disturbed materials provides an upper end to the range of desirable drainage density input values.

The recommended procedure for determining drainage density values is to visit the field site with a map and to mark the location and length of each valley feature that, if it were to erode into a finished reclamation landscape, would be large enough to be considered undesirable. Many of these features that will be identified in the field would not be apparent when examining a 7.5 minute quadrangle. It is important to recognize that when different individuals determine drainage density values for the same stable watershed, their results will vary. One individual may map a slightly smaller feature and generate a greater drainage density value than another observer, or vice versa. For this reason, it is recommended that the same individual make all the determinations for design consistency.

Entering Drainage Density Values

The user draws a GeoFluv Boundary and sketches a draft channel pattern inside the boundary. The appropriate pattern for unconsolidated, disturbed material is typically a dendritic pattern. The channels should be spaced so as to divide the GeoFluv™ work area into roughly equal portions. The user then identifies the GeoFluv Boundary in the Setup tab by pressing the Select GeoFluv Boundary button and then selecting the boundary on screen with the cursor. The software calculates and displays the watershed area.

The user then clicks on the Select Main Channel button to identify which channel segment in the drainage pattern will collect discharge from all the tributary channels and convey it out of the watershed at the watershed's base level. Regrade will display on the Output tab the length of the main channel selected and calculate the GeoFluv™ work area drainage density that the user has sketched. If the reclamation drainage density is too low, the natural watershed response would be to erode material until the appropriate drainage density is achieved. If the software's indicated value is too low as compared to the desired design value, the user can lengthen or add channel segments until the desired drainage density is attained. Conversely, if the indicated value is too high, the user can shorten or remove channel segments. If the design drainage density is too high, erosion is not likely, the landform may even be more resistant to erosion, but earthwork costs would increase beyond that which is necessary to create a landform as stable as surrounding natural lands.

Sinuosity

Sinuosity is the ratio of channel length to valley length. A stream flowing in unconsolidated material will typically begin to meander as it flows down slope. Because of this, the distance that the stream flows is greater than the straight line distance from the stream's head to its mouth. Sinuosity is calculated using units of length over length (L/L) and is a dimensionless value greater than 1.0 when any meandering is present. After the user has input the channel pattern and accepted a pattern with the desired drainage density, this software will then draw a draft channel pattern with suggested sinuosity appropriate to the channel slope. Channels on steeper slopes generally are less sinuous than those on lower gradients in stable land forms. The user may edit the draft channel's sinuosity value

using the Channels tab's 'Current Channel Settings...' button.

Channel Longitudinal Profile

Following the development of the channel pattern with sinuosity, GeoFluv™ calculates channel longitudinal profiles for each channel in the draft drainage pattern. The longitudinal profile of a natural channel is typically concave (Dunne & Leopold, 1978), steeper gradient in the headwater reaches and lower gradient near the channel mouth. That is because the headwaters of the watershed have less area, and therefore generate less runoff and erosive energy than the reaches near the channel mouth. Steeper channel gradients can be stable in the upstream reaches and lower channel gradients are appropriate in the downstream reaches for this reason. Stable slope profiles also tend toward this profile as can be seen in Figure 5.

Figure 5. Concave longitudinal profiles in stable natural slopes

Determining appropriate channel reclamation longitudinal profile

GeoFluv™ designs the longitudinal profiles for the draft landform to grade concave profiles to each local base level. For example, the main valley bottom channel in the draft GeoFluv Boundary work area grades to the user-input local base level (the lowest elevation in the design's main channel, typically where all runoff leaves the GeoFluv Boundary). GeoFluv™ grades each valley wall channel, at its confluence with the main valley bottom channel, to the main valley bottom channel slope at their confluence. The headwater slope for the design profile can be automatically determined by the elevation of the design's GeoFluv™ Boundary and a default distance from that boundary over which the ridgeline can have a convex profile and be stable, or can be user specified using the Channels tab's 'Current Channel Settings...' button.

Entering Longitudinal Profile Values

When the user identifies the GeoFluv Boundary in the Setup tab by pressing the Select GeoFluv Boundary button and then selecting the boundary on screen with the cursor, GeoFluv™ uses the boundary elevation to calculate a channel head elevation for each channel in the watershed from the Surface for Elevations file. The user specifies the three dimensional surface file that GeoFluv™ will use as a beginning surface from which to create its fluvial geomorphic landform design using the Surface for Elevations button. Examples of Surface for Elevations include existing post-disturbance topography designs or pre-disturbance topography. The user can type in the file path and name or use the browse button to help locate the desired file. The user may also enter Head Elevation and Base Elevation values using the Channels tab's 'Current Channel Settings...' button manually to gain accuracy; this is highly recommended for the base level elevation. The base level elevation has great effect on watershed response and an interpolated elevation may vary by several feet from the actual elevation. If the sketched channel begins beyond the default maximum distance from the GeoFluv Boundary, a pop-up warning will advise the user of this condition. The user may then either extend the channel to be within the default value or reset the default distance using the Settings button if local conditions permit a greater distance without erosion. The result of GeoFluv™'s longitudinal gradient solution is a network of sinuous channels that have concave profiles and smoothly transition from steeper headwater gradients to the gradient at the design watershed's local base level elevation. Figure 6 shows

an example of a natural stable network of slopes and channels with concave longitudinal profiles graded together from steeper ground to a lower gradient valley bottom.

Figure 6. Stable natural channels and slopes grade from steep to flatter gradient by a network of concave longitudinal profiles

The Profile button allows the user to review the design longitudinal profile for the current channel. It displays the beginning and ending channel elevations, the profile, and by moving the cursor, stationing is depicted along the profile along with the elevation and slope at that station. The viewer allows for vertical exaggeration to aid work on lower relief channels. The viewer also has toggle settings for pan/zoom and tick mark options. The *Natural Regrade* drop-down menu has powerful editing commands for channel and slope longitudinal profiles for special situations.

Channel Cross-section

GeoFluv™ calculates the channel cross-sectional profiles for channel reaches. The bankfull width (Dunne and Leopold, 1978) (Rosgen, 1996) for the mean annual flow is used to create a hydrologically balanced cross section. GeoFluv™ uses the input runoff coefficient, maximum water velocity, 2-yr, 1-hr storm precipitation, and width to depth ratio values to create this cross section. As the watershed area increases downstream, more water is present in the channels and the channel cross sectional area must increase to convey the discharge within the user-specified design velocity range. Other channel pattern dimensions, i.e., meander length, meander belt width, radius of curvature, related to the bankfull discharge (Williams, 1986) increase concurrently. GeoFluv™'s cross sectional area increase occurs simultaneously with the other channel dimensions. Channel flood-prone area has been related to a 50-year recurrence interval event (Rosgen, 1996) and GeoFluv™ uses this value to design the flood-prone area of the channel. The resulting dimensions define the channel banks for the draft landform. The designer can get cross section information by station for any channel in the GeoFluv design using the Channels tab's Report button. The range of design dimensions can also be seen using the Output tab's Summary Report button. A reviewer can get cross section information by station for any channel in the GeoFluv™ design from a completed drawing using the *Natural Regrade* dropdown menu's GeoFluv™ Channel Cross-section Report command.

Ridges, Slopes, and Volumes GeoFluv™ designs ridgelines between the channels at elevations that create side slopes less than a default 5:1 gradient for the draft landform. The Preview button in the Output tab will display the location of the main ridges, and the subridges and subridge valleys that form around the channel bends. The user may alter the elevation and placement of the ridgelines to adjust slope gradient and material balance. The Draw Design Surface button in the Output tab is used to contour the ridgelines and channels to reveal the draft landform. The Save Design Surface button in the Output tab saves the landform drawing as a file.

Figure 7 shows a reclamation project midway through construction that used this fluvial geomorphic approach. The mine pit highwall that ends at the graded gray spoil used to continue trending to the right of the figure and then turned ninety degrees toward the lower right of the figure. The steep slope reclamation with four subwatersheds immediately to the right of the end of the pit is the same slope shown in Figure 2 above. This project was designed over a period of months without the benefit of the computerized software; using *Natural Regrade* with GeoFluv™, the design time would be measured in hours.

Figure 7. Fluvial geomorphic reclamation is underway at the 115-acre Cottonwood Reclamation Project, Farmington, New Mexico. Gray colored material is mine spoil being graded using fluvial geomorphic approach. The U.S. Department of the Interior awarded San Juan Coal Company "National" and "Best of the Best" reclamation awards for 2004 for this project.

GeoFluv™ calculates and displays the material balance needed to create the draft landform. The GeoFluv™ design's material balance is calculated by comparing the GeoFluv™ design surface to the surface file identified as the Comparison Surface. The user could compare the Design Surface to the pre-disturbance surface, another post-disturbance reclamation surface design, the existing disturbed surface, or other surface file. Figure 8 is an example output dialog box that compares the cut to the fill needed to create the landform.

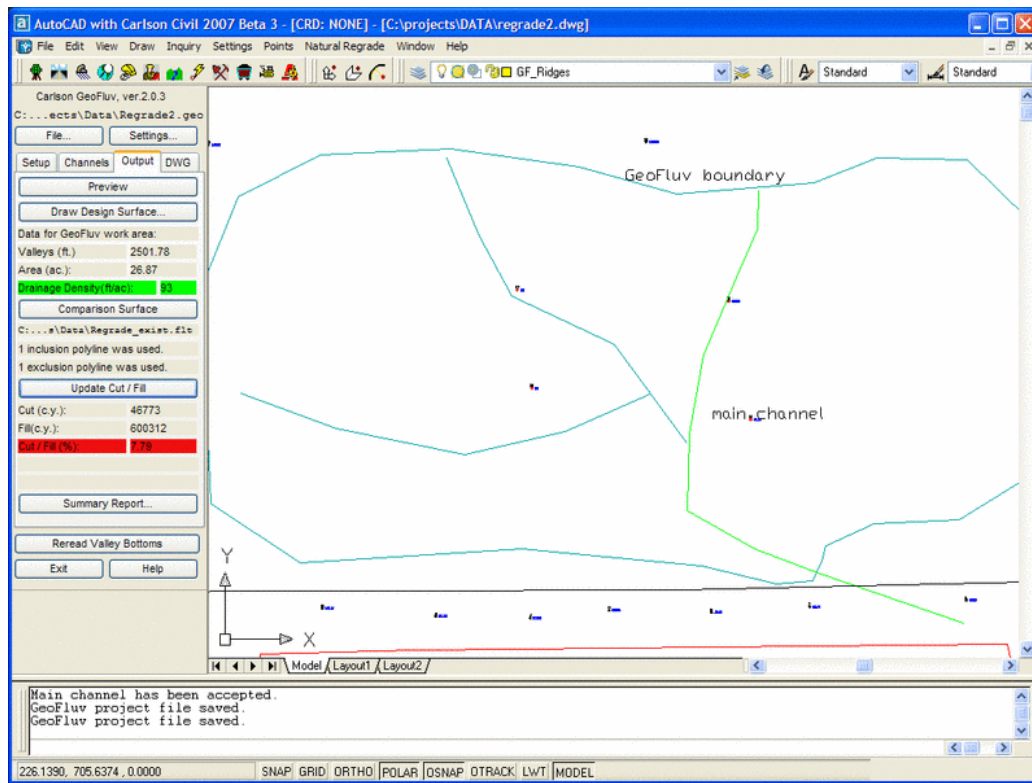

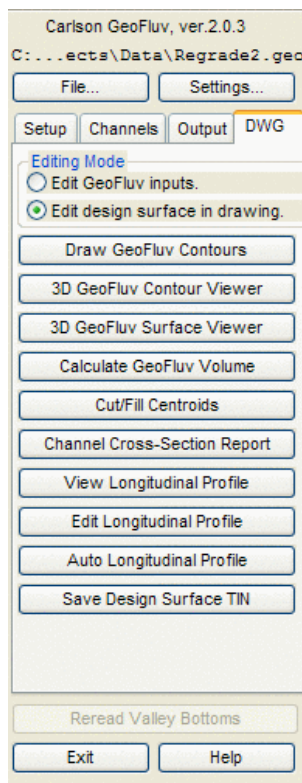

Figure 8. Output dialog box gives immediate cut/fill balance to guide landform design editing

Note that the Output tab also displays the overall drainage density with the GeoFluv work area, which can be compared with the current channel drainage density. The user can compare the drainage density that is displayed in the Channels tab for each channel's subwatershed to the overall watershed drainage density to verify that the drainage density is uniform throughout the watershed. Subwatersheds that have too great or small drainage density values can be corrected by editing ridges or channels to vary areas or channel lengths.

The Output tab and the Summary Report show whether or not the balance is within the user-specified tolerance. The Summary Report button in the Output tab generates a report for the channel showing the design parameter values of the channel and valley slopes. The report also displays the parameter values for natural channel types in the Rosgen stream classification scheme for ready comparison.

The draft landform is an idealized solution to creating a stable landform according to fluvial geomorphic principles based on the user-specified input values. The user may modify the draft landform, for example to reduce the fill volume by lowering a ridgeline using the Edit Longitudinal Profile or Auto Longitudinal Profile commands, and the software can almost instantaneously recalculate the cut/fill balance to meet the user's design.

The DWG tab lists the tools for analyzing the Design Surface as it is represented in the drawing in the channels and ridges layers (GF_Channels and GF_Ridges by default). These are the same commands that are in the Natural Regrade menu plus the addition of Save Design Surface TIN. The Save Design Surface TIN command will save a TIN file of the current Design Surface (as it is represented in the drawing) and is simply the built channels and ridges within the GeoFluv boundary. The Editing Mode toggle helps to clarify the difference between editing a GeoFluv input and editing a Design Surface in the drawing.

The Fluvial Geomorphic Characteristics of the Draft Landform

The fluvial geomorphic characteristics of the draft landform are those that are compatible with unconsolidated materials placed at various slopes, subject to particular storms, and considering special limitations of typical reclamation sites. Those special limitations include a relatively thin topsoil veneer over mixed earth materials (spoil), equipment limitations (e.g., equipment grading capability versus design grading requirements, ability to traverse steep slopes), and desire to minimize cost and maintenance.

The GeoFluv™ fluvial geomorphic approach to building stable reclamation landforms is centered on creating a network of ephemeral drainage channels and associated slopes that are in a state of quasi-equilibrium, i.e., that are "stable." Natural ephemeral channels are the landscape's response to runoff events. By definition, they flow now only in response to direct precipitation. However, they may have formed in response to greater precipitation during wetter climatic conditions, including glacial periods, when they may have flowed as intermittent or even perennial streams. Considering that, their water and sediment transport characteristics would be expected to be consistent with streams that flow perennially in the present climate.

For this discussion, we will use the Rosgen classification scheme for natural channels. The Rosgen scheme classifies perennial streams according to major types based on slope, width to depth ratio, entrenchment ratio, and sinuosity (see glossary for definitions), and stream bed material particle size (1 through 6, where 1=bedrock and 6=silt/clay). The Rosgen classification scheme describes natural channels as major types A through G using characteristics of multiple and single thread channels that form in different geologic settings.

Slope is generally considered the dominant characteristic, and only the type A and A+ channels are associated with

slopes greater than -0.04. For this reason, the A and A+ channel types have a place in many reclamation landscape designs.

Some of these channel types, such as the multiple-thread D and single-thread F and G, are associated with high bank erosion rates and sediment transport and deposition. They tend to exist as transitional channel forms as the channel moves towards a more stable type and for this reason are not favored for use in a stable reclamation landscape design.

The B type is a step-pool stream with low sinuosity, with the steps typically formed by resistant rock strata and narrow rock canyon walls limiting sinuosity. Because both of these structural elements are typically gone in a reclamation landscape, the B type channel is not favored in stable reclamation landscape design either.

The remaining major types, the C and E, differ mainly in their width to depth ratios and sinuosities, and the stable E type's association with dense bank vegetation. The low width to depth ratio of the E-type develops where the combination of cohesive bank material and a dense network of roots from bank vegetation are present. The E type channel is stable, but is very sensitive to disturbance of its bank material and vegetation. The C type has a tendency toward lateral migration through the process of erosion at the cut bank and deposition on the point bars, a tendency that is also exacerbated by bank material and vegetation disturbance.

From this discussion, it can be concluded that the characteristics of the A, C, and E major types have advantages for stable reclamation channel design. Further, the major channel types do not exist as distinct and separate entities, but in an evolutionary continuum from one type to another. For example, a B5c stream would have the major characteristics of a B channel with dominantly sand-size material, but its flatter slope, greater sinuosity, and width-to-depth and entrenchment ratios, would be tending toward those associated with type C streams. The flatter slope of this stream type combined with its greater sinuosity can allow it to transport and balance its water and sediment loads by channel geometry and not require the structural drops associated with the major B-type's step/pool sequences. Its width-to-depth and entrenchment ratios are such that all but extreme events may remain within a flood prone area within its channel banks. When its hydraulic design is correct and its banks are sufficiently protected by vegetation, natural appropriate channel roughness, and bank protection such as rock deflectors or J-hook vanes, this channel type can convey water and sediment discharge with minimal changes to the channel pattern. In other words, the channel can maintain its course and not erode into its banks and through the relatively thin veneer of topsoil because sediment transport and deposition occurs within the channel. When floods greater than the flood-prone capacity (based on entire 50-year, 6-hr recurrence interval precipitation introduced to the channel instantaneously in the GeoFluv™ approach) occur, the additional discharge energy can be rapidly dissipated on an adjacent floodplain.

The default channel-type settings create type A and A+ channels at slopes greater than -0.04 and type Bc channels for slopes less than -0.04 using lower-range channel geometry values for these types. The user can also optionally choose to randomly vary the channel geometry values within the acceptable range using the Channels tab's 'Current Channel Settings...' button. GeoFluv™ displays the channel geometry values for all channels and reaches of longer channels in the watershed in the Summary Report. The user can then edit the channel settings within the ranges of value appropriate to the default channel types or vary the settings to use different channel types.

Links with Other Software

The *Natural Regrade* with GeoFluv™ computerized landform design can further improve operational efficiency by interfacing with computerized machine guidance software. The GeoFluv™ landform design can literally be sent from the designer's computer screen to the machine operator's guidance screen by radio transmission and the designs can be implemented "on the fly". Design editing can also be done expeditiously. For example, if unforeseen conditions emerge, such as shallow bedrock near the edge of disturbance that hinders a dozer cut, the designer can keep the operator working elsewhere, adjust the channel's and related subwatershed design during the shift, and return the operator to work on the revised design.

Additional efficiency can be achieved by integrating the computerized landform design with software, such as Carlson Software's *Productivity Tools*, that provide real-time equipment monitoring and data capture during construction.

This software determines material movement volumes and distances over time for associated equipment. The information that this software provides to decision makers was previously not available and can help them identify the most efficient operational methods for maximum cost savings. *Carlson Telescope* and *Starnet* are two office monitoring products that allow for viewing heavy equipment in real-time, as well as enabling two-way real-time file transfer.

GPS guidance and machine control software can virtually eliminate the need for survey stakeout in the field and greatly enhance production efficiency. The machine operators can follow the project design and complete it to grade on their own as they work. Carlson Software makes *Carlson Dig* for excavators and shovels, *Carlson TruckPro* for haul trucks, *Carlson Autograde* for dozers, loaders, compactors, motorgraders, scrapers, foreman trucks, etc., *Carlson Drillstar* for drills, and *Carlson Grade* that allows cross-platform, multi-equipment functionality.

The link to the RIVERMorph two-dimensional data collection and channel design software allows for near instantaneous conversion of the RIVERMorph user's design into a three-dimensional design. The RIVERMorph two-dimensional software follows natural channel design methods, as developed and taught by Dave Rosgen. The user can render and view the three-dimensional channel design made in *Natural Regrade* with all the Carlson capabilities, rotating, tilting, quick volume calculations of earthwork or pools, etc. The RIVERMorph designs are made into .tin files by default and can be also be made into .flt or grid file formats. The .flt and .tin file formats are commonly used by machine control software, so the *Natural Regrade* design is ready to load into machine control equipment; construction can begin without additional surveying or staking! The RIVERMorph designs can be inserted into any GeoFluvTM design to produce an integrated natural river and upland landform design.

Software Compatibility

The *Natural Regrade* module with GeoFluvTM is a module of the Carlson Civil / Survey family. As such, it functions in tandem with the widely-used AutoCAD drafting software. Carlson Civil / Survey is application software for the civil engineering, surveying, mine engineering, and GIS disciplines that use AutoCAD as the graphics engine and drawing editor. Carlson Civil / Survey's system requirements are no greater than that of the AutoCAD version with which it operates and will work with any AutoCAD-based product from AutoCAD 2000 through AutoCAD 2009 as well as IntelliCAD.

Data Entry

The Carlson Civil / Survey software accepts data downloads from any data collector, or other data file. Once the data are imported, they are stored as a coordinate (.crd) file. The entire *Natural Regrade* module project can then be designed from the .crd files without leaving Carlson Civil / Survey.

DWG Tab

The DWG tab functions to help the user separate tasks that are done using the GeoFluv method in Natural Regrade from other tasks that are done in a CAD environment that do not relate to the GeoFluv method. For example, the user may make minor edits to ridgelines and not upset the projects hydrologic balance whereas editing channel profiles can result in knickpoints and immediate erosion consequences. The command buttons are ordered from top to bottom in logical sequences for working with a draft GeoFluv design that is made when running the Draw Design Surface button in Output tab.

Check Ridgeline Slope: The Check Ridgeline Slope command allows the user to inspect the sub-watershed ridge and swale toe slopes in the entire design. This is useful because it is possible that the user input settings: the Surface for Elevations, GeoFluv boundary line, valley input lines, Global settings and Current Channel Settings may result in areas where the resulting valley wall slopes do not drain into the channels, but instead the storm water runoff runs sub-parallel to the channel for some distance. This could result in rill or gully erosion. The

Check Ridgeline Slope command helps the user identify areas where this may be happening and determine why it is happening so that the design may be edited to correct the problem.

When the command is run, a pop-up dialog gives the user the options to generate a report, draw symbols corresponding to the slope values in the report, and to specify the type of symbol used and the layer it is drawn on, and to scale the symbol. After the user specifies the preferences and clicks, OK, the command runs and displays the specified information.

The naming convention for the lines is to identify the sub-watershed, e.g., main L2R1 (note L and R are capitalized when identifying channels and their subwatersheds), followed by the sub-watershed ridge or swale line identification where lower case 'r' indicates a sub-watershed ridge line and a lower case 's' indicates a sub-watershed swale line. The sub-watershed ridge or swale line letter is followed by a number indicating its sequential order from the head of the sub-watershed. Using this convention, the 'main L2R1 r1' designation identifies the first sub-watershed ridge on the right valley wall (r1) of the sub-watershed that holds the first tributary entering from the right valley wall (R1) of the second tributary entering from the left valley wall (L2) of the main channel.

Summary

Computerization of this fluvial geomorphic approach to land reclamation makes the applied science from a relatively obscure body of knowledge available to a wide range of users. The approach helps the designer to build the landform that would tend to form under the existing physical conditions. The benefits of this approach include stability against erosion, hydrologic function and plant and animal habitat that are similar to undisturbed natural lands, lower construction cost for steep slopes, mitigation of maintenance concerns, and improved aesthetics. This approach also links with machine control and management software to further improve the efficiency of land reclamation. Table 1 summarizes the advantages gained by using the *Natural Regrade* software with GeoFluv™ to reclaim disturbed lands.

Old method	<i>Natural Regrade</i> software with GeoFluv™
Based on conveying a single extreme discharge event	Based on all discharges
Conveys only water discharge effectively at lower Q	Natural channel morphology conveys water and sediment discharge; hydrologic balance
Requires expensive off-site earth material, e.g., rip-rap	Built with on-site materials
Expensive on steep slopes	Cost is significantly lower than gradient terraces and down drains on steep slopes
Requires long-term maintenance	Self-maintaining
Requires maximum backfill to lower slopes	Can reclaim steep slopes in stable and suitable configurations, save money on material moving
Provides minimal slope aspect diversity	Increased slope aspect diversity promotes vegetation success and animal habitat
Visual affront	Natural beauty
Rigid design sideboards limit landscape alternatives	Landscape designs can vary and provide alternatives
Regulatory agencies not satisfied	Regulatory agencies embrace*

Table. 1. Comparison of old methods of reclamation to landscape designed using this computer-aided fluvial geomorphic design method.

*Approach is award-winning: New Mexico *Innovative Practices- 2001*, US Dept. of Interior "*National*" and "*Best of the Best*" reclamation for 2004.

These benefits will be realized for those designing mine reclamation, subdivisions, golf courses, ski areas, parks,

etc.; any site where the land surface has been disturbed. For example, storm water catchments do not have to be a rectangular pond surrounded by a chain link fence, but can serve the storm water control purpose and also be a hydrologically functioning and esthetically pleasing park. This technology will help designers, developers, and regulators evaluate more options, help companies save production and bond dollars, and promote better land reclamation and use.

Natural Regrade Menu

Design GeoFluv Regrade

The Design GeoFluv Regrade command on the *Natural Regrade Menu* is used to open the dockable dialog box and access the main GeoFluv™ design commands.

The main GeoFluv™ input edit boxes, buttons, and commands are arranged in GeoFluv™'s main dockable dialog box in four tabs, Setup, Channels, Output, and DWG. The edit boxes and buttons are arranged in the input and operational sequence that the user will usually follow to make a GeoFluv™ design. The general order is left-to-right through the tabs and top-to-bottom within each tab. Prerequisite commands are further noted in the GeoFluv™ dockable dialog box by making prerequisite commands/inputs active (clear image) while subsequent command/inputs remain inactive (faded image) until the prerequisite step is performed.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gf

Prerequisite: Polyline perimeter

Natural Regrade File

The File button at the top of the Design GeoFluv Regrade dockable dialog box provides a convenient way for the user to save GeoFluv™ projects. The File button can be clicked at any time. When the user left-clicks on the File button, the Open and Save Projects dialog box appears.

This dialog box gives the user the options to create a "New" GeoFluv™ project file, "Open" an existing GeoFluv™ project file, or "Save As..." a new project file. Saving the various designs as separate project files allows the user to store and retrieve each design alternative with all of its settings intact. If the user creates a project file, either with the New button or the Save As button, then all changes made to that design will be saved automatically to the project file. If a project file is never selected, then the settings are lost when the drawing is closed or when the dockable dialog box is closed and a new drawing is opened.

Every line and point (and in general, "entity") has a name in AutoCAD. The GeoFluv™ project file remembers the names of the GeoFluv Boundary polyline and the valley bottom polylines that are in the drawing rather than storing complete copies of all the coordinates in those polylines. The advantage of this method is that when the GeoFluv Boundary or the valley bottoms change, the GeoFluv™ design will reflect the changes automatically and will never be inconsistent with the drawing.

Natural Regrade gives the user the ability to rapidly create many design alternatives according to fluvial geomorphic principles for a stable landform. The user can then compare the various GeoFluv™ landform design alternatives considering the how well the designs satisfy land use objectives, and practicality and overall material handling costs.

From these comparisons the user can decide on an optimal design. Saving the design alternatives as projects using the File button saves the user from having to repeat data entries.

Natural Regrade Global Settings

These settings include variables that will remain constant for a GeoFluv™ design, e.g., precipitation event values, and other detail settings specific to a GeoFluv™ design area that the user will typically not change for each design iteration.

The Settings button at the top of the Design GeoFluv Regrade dockable dialog box provides a convenient way for the user to access all these settings in one place. The Settings button is accessible at any time. Left-clicking on the Setup tab's Settings button opens the Natural Regrade Global Settings dialog box. Each of the settings is described below.

Maximum distance between connecting channels (ft.): This is a drawing setting that defines a maximum separation of polylines that Natural Regrade will recognize as channel polylines. The maximum distance should be set as small as the user can comfortably draw. The user types this value into the edit box. Some users may be able to hold and click the cursor more accurately than other users and this setting accommodates those differences.

Maximum distance from ridge line to channel's head (ft.): This is an essential local variable in the GeoFluv™ approach. It is the shortest distance from a ridgetline to the head of a stable channel. The user will determine this value, in the vicinity of the GeoFluv project, for stable landforms that developed in earth materials similar to the disturbed earth materials within the GeoFluv™ boundary. The value is a function of local factors including soil cohesiveness, vegetation canopy, cover, and root density, storm intensity and other climatic factors, and topographic relief. The user types this value into the edit box. The 80-foot default value is for an erosive semi-arid, high-altitude desert region in the southwestern United States.

Maximum Distance for Subridge: The user can vary the Global sub-watershed ridge length in the Natural Regrade Global Settings dialog. The sub-watershed ridges and swale valleys form by similar processes of erosion as do the channel-containing valleys, but the watershed area above them is not great enough to generate discharges that form defined channels. This means that in some areas the landform dimensions of these smaller features may have greater convex lengths than in channel-sized valleys. The user can input a maximum convex length for the sub-watershed ridges that will be applied globally in the GeoFluv design by typing the desired value in the edit box; the remainder of the profile will be concave when possible. The swale distance setting is not changed when the sub-watershed ridge setting is manually input.

Maximum Distance for Swale: The user can vary the Global sub-watershed swale length in the Natural Regrade Global Settings dialog. The sub-watershed ridges and swale valleys form by similar processes of erosion as do the channel-containing valleys, but the watershed area above them is not great enough to generate discharges that form defined channels. This means that in some areas the landform dimensions of these smaller features may have greater convex lengths than in channel-sized valleys. The user can input a maximum convex length for the sub-watershed swales that will be applied globally in the GeoFluv design by typing the desired value in the edit box; the remainder of the profile will be concave when possible. The sub-watershed ridge distance setting is not changed when the swale setting is manually input.

Slope at the mouth of the main valley bottom channel (%): This setting, along with the Channels tab's "Advanced...Specify mouth elevation." setting, may be the most critical value to creating a stable final landform design using the GeoFluv™ approach. The GeoFluv™ design must integrate with upstream and downstream areas to achieve stability. That means that GeoFluv™ channel reaches must have longitudinal profiles that blend smoothly with up-and downstream channel reach profiles. The user will determine the slope downstream of the mouth of the main valley bottom channel by survey, e.g., a point every 25 feet for about 400 feet. The user can plot a longitudinal profile from these points and select an input value for the channel slope upstream that will blend smoothly into the downstream profile. The user types this value into the edit box.

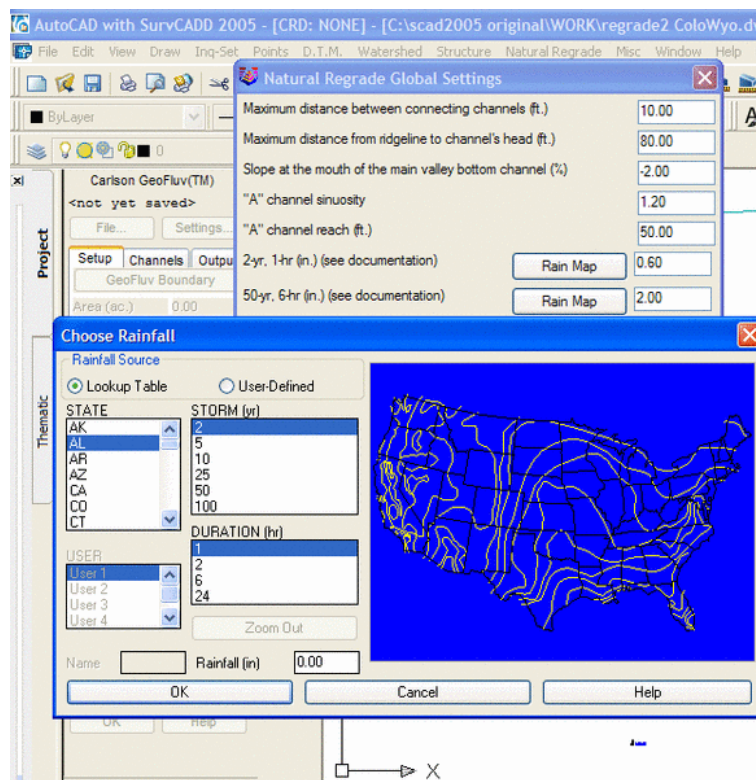

In some cases, disturbance may continue for a great distance downstream of the GeoFluv™ boundary. In those

cases, the user must determine the slope at the eventual downstream, undisturbed tie-in point, extend that profile upstream to the GeoFluv™ boundary, and specify a smooth tie-in slope value.

"A" channel sinuosity: This setting applies to channel reaches with slopes >0.04 . The channel types that form in these steeper reaches have low sinuosity, <1.2 . Steeper reaches may be expected to have lower sinuosity still. Sinuosity will typically increase as slope decreases (inversely proportional). This setting allows the user to specify a maximum sinuosity <1.2 , which may be desirable in certain cases, e.g., for very steep, short channels the user may want to specify a lower value. The user types this value into the edit box.

"A" channel reach (ft.): This is an essential local variable in the GeoFluv™ approach, and reflects many of the same local variables as does "Maximum distance from ridge line to channel's head" above. It is one-half of a meander length. The user will determine this value for stable landforms, in the vicinity of the GeoFluv™ project, that developed in earth materials similar to those within the GeoFluv™ boundary. The user types this value into the edit box.

2-yr, 1-hr (in.) (see documentation): This is where the user inputs the precipitation value for the storm event that determines the bankfull channel dimensions and plan-view channel geometry. This is an essential local variable in the GeoFluv™ approach. The GeoFluv™ approach uses a 2-yr, 1-hr storm event to design these features for ephemeral upland channels, and it can be used for ungauged intermittent and perennial channels as well. The value can be typed into the edit box, or entered by using the Rain Map button for sites in the U.S. and Puerto Rico.

Clicking on the Rain Map button produces a dialog box in which the user will select the state or territory of interest, and the storm frequency and duration using dropdown menus. When the user selects a state or territory, Rain Map zooms in to that selection. The user then moves the cursor to the GeoFluv™ project area, left-clicks on it, and the interpolated value is entered into the "Rainfall (in.)" field in Rain Map. When the user clicks on the OK button at the bottom of the Rain Map dialog box, the dialog box closes and the rainfall value is automatically entered into the Natural Regrade Global Settings precipitation event edit box (next to the Rain Map button).

If the user has data from a stream gauging station sufficient to determine the discharge associated with an annual recurrence interval (bankfull) event, they can directly enter that value into GeoFluv™ using the "Channels" tab's "Advanced . . ." button and "Use manual Qpk.". The user is cautioned that increasing these values beyond the actual event value will not create a "design safety factor", but rather will create a channel that is not competent to transport

sediment during more frequent, lower-discharge events, i.e., it will cause sediment deposition in the channel that can cause channel blockage, etc.

50-yr, 6-hr (in.) (see documentation): This is where the user inputs the precipitation value for the storm event that determines the flood-prone channel dimensions. This is an essential local variable in the GeoFluv™ approach. The user can input the value using methods discussed in the "2-yr, 1-hr" section above.

The dominant channel morphology has been shown to be related to about a 50-year recurrence interval event, rather than some extreme 100-year, 200-year, probable maximum, or other event. The GeoFluv™ approach uses an intense 50-year event to design the flood prone area of the channel and places the entire amount of the 6-hour storm into the channel instantaneously to calculate a peak discharge associated with extreme channel-forming events. All this discharge is contained within the channel banks in Natural Regrade's default GeoFluv™ channel design. The user can also design a floodplain or terrace adjacent to the channel to accommodate greater discharges; when these are relatively wide the tremendous increase in cross sectional area allows the additional discharge to spread across the surface without causing undesirable erosion.

Target drainage density (ft./ac.): This is an essential local variable in the GeoFluv™ approach. It is the total valley length divided by the area within the GeoFluv™ boundary. The user will determine this value for stable landforms, in the vicinity of the GeoFluv™ project, that developed in earth materials similar to those within the GeoFluv™ boundary. (Refer to Introduction section for more detail.) It is a function of local factors including soil cohesiveness, vegetation canopy, cover, and root density, storm intensity and other climatic factors, and topographic relief. It is the extent to which a drainage network will develop given those local factors to achieve a stability comparable to surrounding land areas. The user types this value into the edit box.

Target drainage density variance (%): This is an essential local variable in the GeoFluv™ approach. It captures the range of acceptable drainage density values for the GeoFluv™ project area based on the range of locally-measured drainage density measurements as described above and in the Introduction section. For example, if the lowest drainage density value that the designer has determined can be stable is 80 feet/acre and the highest drainage density value that is measured in similar local earth materials is 120 feet/acre, the user could set a target drainage density value of 100 feet/acre and a target drainage density variance at 20 percent to capture that locally-determined range of 80 to 120 feet/acre. The user types this value into the field.

Force ridges to be lower than GeoFluv boundary: This toggle setting allows the user to specify if any point on a main ridge line can be higher than where the ridge line meets the GeoFluv™ boundary. A main ridge line in the GeoFluv™ approach is a ridge that defines a subwatershed divide within the GeoFluv™ boundary. When this box is checked (toggled on), the elevations on the main ridgeline will all be lower than the elevation on the GeoFluv™ boundary where the main ridgeline intersects the GeoFluv™ boundary. When this box is left blank (toggled off), a ridgeline may have a high point of greater elevation than the GeoFluv™ boundary, e.g., creating a knob or butte feature. In this case all runoff will still remain within the GeoFluv™ boundary and exit at the mouth of the main valley bottom channel. The feature allows the user to create a topographic feature within the GeoFluv™ boundary that may vary from the pre-disturbed surface, but is still a stable landform. This can be used to minimize the movement of piles of earth material when creating a stable landform design.

Angle from subridge to channel's perpendicular, upstream (deg.): This is a local variable in the GeoFluv™ approach. This is the angle that subridgelines make in the upstream direction from the valley bottom to the main ridgeline. The user will determine this value for stable landforms, in the vicinity of the GeoFluv™ project, that developed in earth materials similar to those within the GeoFluv™ boundary. Setting this value similar to surrounding stable landforms will help the GeoFluv™-designed landform blend harmoniously with surrounding natural landforms. Natural Regrade will automatically create all the subridges in the draft landform using this value. The user can edit individual ridgeline orientations from the draft landform to suit site-specific design needs, however, Natural Regrade's ability to create the subridges and subridge valleys saves the user a tremendous amount of design time when producing draft landform designs. The user types this value into the edit box.

North or East straight-line slopes (%): This setting allows the user to specify a global target for a maximum ridge-to-toe slope profile steepness on the north- and east-facing slopes (between 315 and 135 degrees). The north and east-facing slopes are generally steeper in natural landforms because they get less sun and can retain more moisture, factors that favor tree growth and its associated root-binding of slope soils. Because the slope faces can contain an

infinite degree of aspects in the GeoFluv™ approach, Natural Regrade does not produce the identical slope angle for all north or east-facing slopes with this setting; it is rather a best-fit slope adjustment toward the specified target value. The user should remember that changing the slope on one side of a ridgeline will affect the slope on the other side of the ridgeline. The user types this value into the edit box.

Maximum straight-line slopes (%): This setting allows the user to specify a global target for a maximum ridge-to-toe slope profile steepness on all slopes within the GeoFluv™ boundary. As in "North or East straight -line slopes" above, it is impractical for Natural Regrade to control every area of the design with this setting; it is a best-fit slope adjustment toward the specified target value. The user should remember that changing the slope on one side of a ridgeline will affect the slope on the other side of the ridgeline. The default value is 33 percent because agricultural machinery commonly in use for land reclamation has difficulty working across steeper slopes. The user types this value into the edit box.

Maximum cut & fill variance (%): This setting allows the user to specify a global maximum for the cut and fill material balance for the GeoFluv™ design surface as compared to another surface, e.g., Pre-disturbed surface. A value of 100 percent means cut and fill are balanced. A value of 125 percent means that there is 25 percent more material that needs to be removed to create the surface than there are areas requiring fill. The user types this value into the edit box.

Minimum cut & fill variance (%): This setting allows the user to specify a global minimum for the cut and fill material balance for the GeoFluv™ design surface as compared to another surface, e.g., Pre-disturbed surface. A value of 100 percent means cut and fill are balanced. A value of 80 percent means that there is 20 percent less material that needs to be removed to create the surface than there are areas requiring fill. The user types this value into the edit box.

Cut swell factor: This setting allows the user to specify a global swell factor for cut material from bank volume to loose volume. A value of 1.000 means that the loose volume is the same as the bank volume. A value of 1.120 means that the excavated loose material fills 12 percent greater volume than did the same material in place before excavation. The user types this value into the edit box.

Fill shrink factor: This setting allows the user to specify a global shrink factor for fill material from loose volume to fill volume. A value of 1.000 means that the fill volume is the same as the loose volume. A value of 0.900 means that the filled and settled/compacted material fills 10 percent less volume than did the same loose material after excavation. The user types this value into the edit box.

Channel head elevation tolerance: Natural Regrade alerts the user via pop-up dialogs when channels designed from the user-input valley lines on the Surface for Elevations would require changes in elevation or slope to make smooth concave profiles. The alerts can be very precise, to decimal point values, but the user may not be concerned to be alerted for extremely small variances. The channel head elevation tolerance setting allows the user to input an elevation variation that the user finds significant, for example if the user is concerned about lowering or raising the channel elevation by 0.3 units, they would enter 0.3 in the edit window and pop-up alerts will only appear when greater variances exist. Note: When the project area is relatively large, even small differences in elevation over the area can result in significant changes in material volumes.

Channel head slope tolerance: Natural Regrade alerts the user via pop-up dialogs when channels designed from the user-input valley lines on the Surface for Elevations would require changes in elevation or slope to make smooth concave profiles. The alerts can be very precise, to decimal point values, but the user may not be concerned to be alerted for extremely small variances. The channel head slope tolerance setting allows the user to input a head slope variation that the user finds significant, for example if the user is concerned about starting the channel at plus or minus two percent from the specified head slope value, they would enter 2.0 in the edit window and pop-up alerts will only appear when greater variances exist.

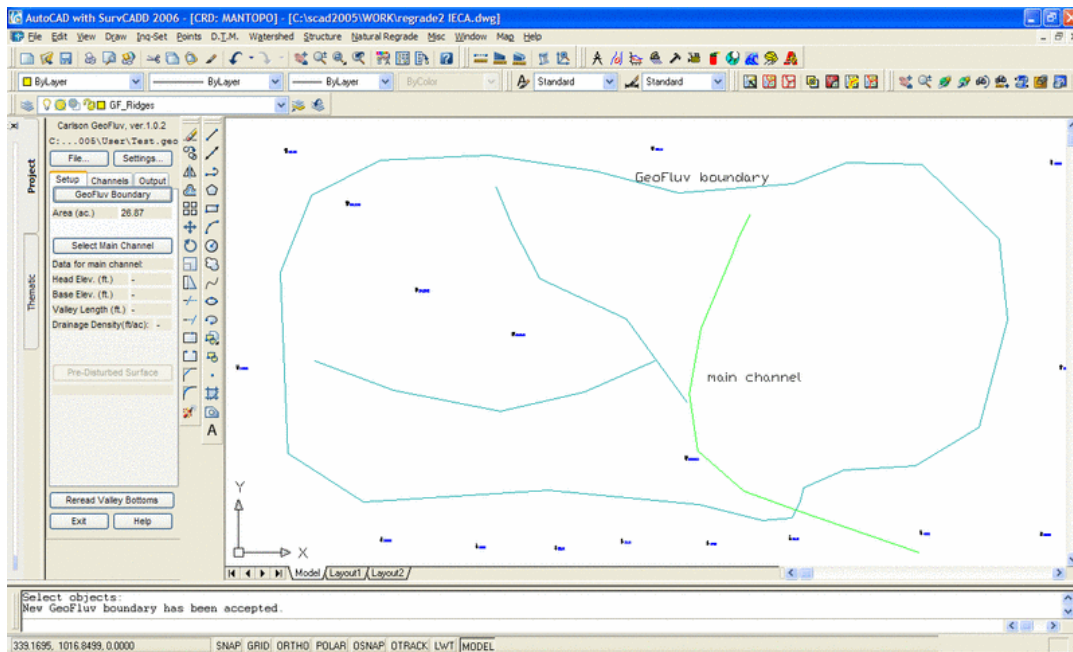

Setup Tab

The Setup tab is used for work that defines the watershed boundary, establishes the general channel pattern, calculates the watershed drainage density, channel head and mouth elevations, channel slopes, and defines the three

dimensional surfaces that GeoFluv™ will use to create the stable draft design watershed and calculate the material balances for the design.

Select GeoFluv Boundary

The user defines the boundary polyline that they have drawn to outline the GeoFluv™ design area on the drawing. GeoFluv™ will automatically calculate and display the watershed area inside the defined boundary. (This area is only the area to which the GeoFluv™ design will be applied. If additional undisturbed or previously reclaimed area lies upstream of the GeoFluv™ design area, runoff from that additional area can be added into the design in the Channels tab using the Add Area window.) The default area units are acres, but metric units can be selected in the Carlson Drawing Setup dialog box accessed through the Carlson toolbar at Settings/Configure /Drawing Setup (use of consistent units in a drawing is recommended).

Command Prompt:

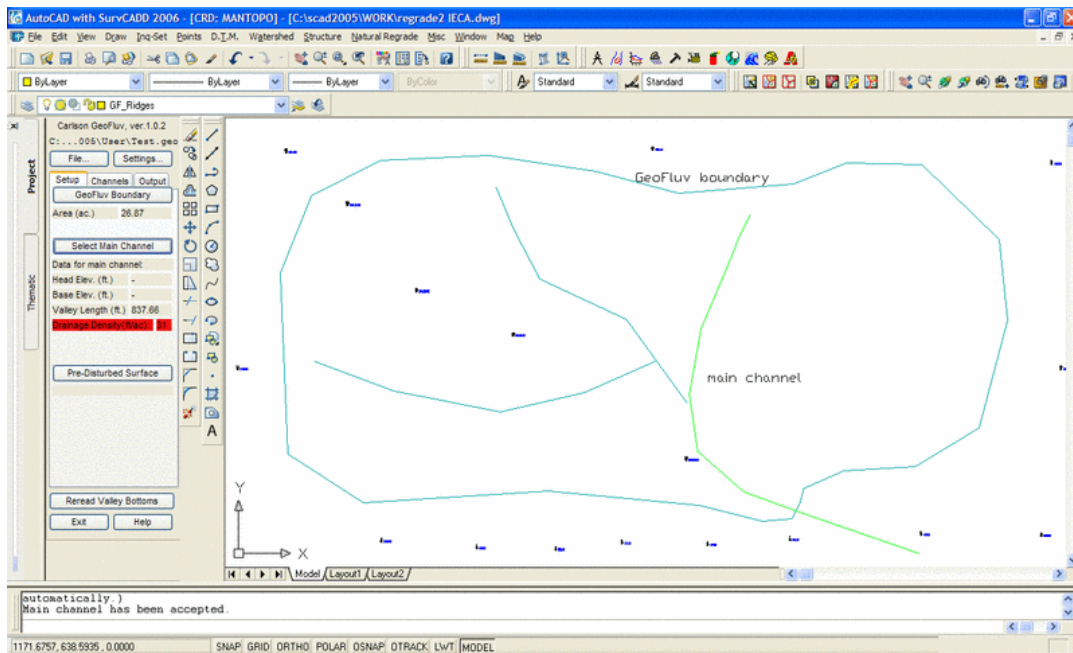

Select GeoFluv boundary polyline. Select objects

The user moves the cursor to cross the GeoFluv Boundary polyline anywhere along its length and left-clicks to define the GeoFluv Boundary to the Natural Regrade module.

The command prompt reads, "New GeoFluv boundary has been accepted.", if the cursor has clicked on a closed polyline, the watershed area is calculated and displayed, and the Select Main Channel button on the Setup tab becomes active. The command prompt reads, "GeoFluv boundary polyline must be closed." if the polyline the user selected is not closed, and the watershed area is not calculated and displayed, and the Select Main Channel button remains inactive.

Select Main Channel

The user defines the channel that is the main valley bottom channel draining all discharge to the watershed's base level. The user also specifies the point at which the main valley bottom channel makes its transition from a lower gradient (<0.04) channel type to a steeper gradient (>0.04) channel type. The Select Main Channel button becomes active after the user has selected the GeoFluv Boundary polyline.

Command Prompt

Select main valley bottom channel polyline. Select objects: The user moves the cursor to cross the main valley bottom channel polyline anywhere along its length and left-clicks to define the main valley bottom channel to GeoFluv™.

When executed correctly, the **command prompt** reads, "**Choose the forced transition point between channel types. (Press Enter to find automatically.)**" if the cursor has covered and left-clicked a closed polyline. The user then either specifies the forced transition point between channel types (reaches with >-0.04 and <-0.04 slope) by placing the cursor crosshairs on the valley bottom polyline and left-clicking, or presses enter to allow GeoFluv to find a transition point based on the Pre-Disturbed Surface file elevations.

Command Prompt:

Choose the forced transition point between channel types: The user moves the cursor crosshairs to the point at which he wants the main valley bottom channel to transition to its steeper (A/Aa+ type) reach and left-clicks to select that point. Alternately, the user can press the Enter key and GeoFluv will determine a transition point using the Pre-disturbed file data. When executed correctly, the main channel length and drainage density for that channel in the entire GeoFluv Boundary area are calculated and displayed in the "Data for main channel:" fields and the reads, "Main channel has been accepted." GeoFluv will compare this drainage density to the target value in Settings and, will highlight the value in red if it is too low or will highlight the value in green if it is within the acceptable range. If the value is too low, the user can lengthen the main channel, decrease the GeoFluv Boundary area, or add more channels using the Channels tab's Add button.

The command prompt reads, "Main channel polyline must not be a closed polyline" if the polyline the user selected is closed, and the channel length is not calculated and displayed. The command prompt reads, "Main channel must cross watershed boundary" if the user has clicked on a segment that does not leave the watershed at its base level, and the channel length is not calculated and displayed.

Data for Main Channel

The "Data for main channel" fields display information that GeoFluv™ will use to create the main valley-bottom channel that conveys all runoff from within the GeoFluv Boundary downstream to the base level elevation. The GeoFluv™ design is built headwards from the base elevation.

Head Elev. (ft.) displays the elevation at the head of the main valley bottom channel. GeoFluvTM can determine a head elevation from the three-dimensional surface entered using the Pre-Disturbed Surface button. The head elevation will appear in this field when the user enters a three-dimensional surface file. Alternatively, the user may specify an elevation using the Channels tab's Advanced button to access the "Specify head elevation" option on the 'Channel "main" Advanced Settings' dialog box.

Base Elev. (ft.) displays the elevation at the that is the local base level for the main valley bottom channel. GeoFluvTM can determine an approximate base-level elevation from the three-dimensional surface entered using the Pre-Disturbed Surface button. The approximate base-level elevation will appear in this field when the user enters a three-dimensional surface file. **This elevation is adequate for creating draft GeoFluvTM designs, but the user must use an accurate field-surveyed base-level elevation for the final design.** The user may specify the field-surveyed base-level elevation using the Channels tab's Advanced button to access the "Specify mouth elevation" option on the 'Channel "main" Advanced Settings' dialog box. (See also Settings tab's "Natural Regrade Global Settings", Slope at the mouth of the main valley bottom channel (%) for this related critical setting.)

Valley Length (ft.) displays the length of the main channel that the user has identified using the Setup tab's Select Main Channel button. After the user inputs the transition point from the main channel's headwater reach (slope >-0.04) and its valley bottom reach (slope <-0.04), GeoFluvTM will display the length of the selected main channel in this field and use the value to calculate the main channel subwatershed drainage density.

Drainage Density displays the drainage density value for the main valley bottom channel subwatershed as determined from the main channel Valley Length (ft.) and the GeoFluv Boundary Area (ac.). The drainage density is displayed in units of feet/acre in U.S. units, a convenient unit for landform design work.

If the drainage density is within the variance that the user specified in the Design Natural Regrade dockable dialog box's Settings button, Natural Regrade Global Settings, "Target drainage density variance (%)", then the value will be highlighted in green; if the value is outside the user-specified variance it will be highlighted in red. A red warning can mean that the drainage density is too high or too low. If too high, the channel can be shortened or the GeoFluv Boundary area decreased. If the value is too low, the main channel can be lengthened or more channels can be added using the Channels tab's Add button.

Pre-disturbed Surface

The user defines a three-dimensional surface file that GeoFluv™ will use as the reference surface from which the fluvial geomorphic surface will be designed. This surface file could be an existing Approximate Original Contour map, a pre-disturbance map, or any other surface from which the user wants to begin the design.

When the user clicks on the Surface for Elevations button, the Use Existing TIN or Create New TIN? Pop-up dialog box appears to give the user the options, by clicking on radio buttons, for entering a 3-D surface file. The user can type the file name into the File Name field or browse for the file by left-clicking the Browse button to the right of the File Name field. Left-clicking the browse button will open another dialog box that will display file selections and the directory path. The user can search for the surface file in various directories and left-click the Open button when the desired 3-D surface file is found.

When Open is clicked in the file search dialog box, the search dialog disappears and the Carlson Software 3D Viewer window will appear showing the .tin for the area that the user has defined. The user can rotate, fill in the .tin triangles, etc. to preview the .tin to be sure that it is satisfactory, i.e., no unwanted holes, elevation spikes, etc. When the user is satisfied that the .tin correctly represents the comparison surface, the user closes the 3D viewer window and the file name is entered into the File Name field in the Select Surface for Elevations TIN File - (tin;flt) dialog box, the file name appears below the Surface for Elevations button, details of the file loading will be listed on the command line: Loadings edges . . . , the number of points and triangles that were loaded will be listed. Regrade will also conduct an automatic save of the file and the path will be stated. The user is then ready to continue to Channels tab.

Alternatively, the user can click the radio button for Create new TIN file by selecting entities in the drawing. When the user selects this option and clicks OK, the cursor changes to a selection box that the user can use to define an area with a crossing window. (Note: it is very important that this area encompass the entire GeoFluv project .tin surface. If areas outside the GeoFluv boundary area may be used for material borrow and incorporated into the cut / fill balance, the .tin area should include those areas also.) After the user defines the .tin area and hits the enter key, the Carlson Software 3D Viewer window will appear as above. The remaining steps are also as described above.

When the Surface for Elevations file has been accepted, the file name is listed below the Surface for Elevations button, and GeoFluv™ reads the head and base level elevations from the Surface for Elevations file for the main channel that the user has sketched and displays these elevations in the "Data for main channel:" fields above the Surface for Elevations button. GeoFluv™ designs the main channel from this information and the settings on the Channels tab. The elevation at the heads of all other channels have their defaults set by the Surface for Elevations. The elevations along the GeoFluv Boundary are also set from this surface. This in turn sets the elevations of the main ridges and subridges and subridge valleys that intersect the GeoFluv Boundary.

Channels Tab

The Channels tab is used to input variables that GeoFluv™ will use to design channel geometry dimensions (including radius of curvature, meander length, meander belt width, sinuosity, and channel cross sections that are sized for bankfull and more extreme flood events), to add or delete channels from the design, to name channels, to view channel longitudinal profiles, and to design related upland landforms, and to generate reach-scale reports of the design characteristics of channels.

GeoFluv™'s draft design will have concave longitudinal channel profiles that join together in a smooth hydraulic transition. GeoFluv™ will automatically design drainage-divide ridges between the channels that form subwatersheds for each channel using this information. GeoFluv™ will also automatically design the sub-ridges and sub-ridge valleys in each subwatershed, and calculate and display the subwatershed area, subwatershed channel valley length, and subwatershed drainage density.

Channel Add

The Add button is used to add each channel to the watershed design.

Command Prompt:

Select tributary channel polyline. *Select objects*

The user selects the polyline that represents the valley bottom for a channel that is to be added to the GeoFluv™ design. The selected polyline must meet the following criteria:

- One end must be near another valley bottom polyline that has already been added to the design.
- The other end must be near the GeoFluv Boundary.
- It must not cross the GeoFluv Boundary.
- It must not cross any valley bottom polyline.
- It must not cross itself.
- It must not be closed.

When executed correctly, the command prompt reads, "Creating final design surface . . . DONE", GeoFluv™ adds the channel to the design, lists it in the Current Channel menu, retains the input settings from the previously added channel, designs the channel based on those input settings, and recalculates and displays the channel length, subwatershed area, and subwatershed drainage density. The user can view the channel's vertical curve profile and edit any of the channel design input settings. When the user left-clicks on a channel name in the Current Channel field, GeoFluv™ draws an arrow on the design pointing to that channel.

GeoFluv™ uses a consistent naming convention for channels, because this has been found to be a very important attribute for communication when taking designs to the field. Everyone involved with the project, from the designers to surveyors to equipment operators can clearly know what part of the project is being discussed when following this consistent naming convention, and this minimizes the chances of miscommunication and mistakes. GeoFluv™ uses the main valley bottom channel that drains to the watershed's local base level for the primary name, for example "Carlson Arroyo". The channels tributary to "Carlson Arroyo" have alphanumeric names that follow the hydrologic right- and left-bank convention, that is, right and left bank when facing downstream. The first tributary downstream of the headwaters entering "Carlson Arroyo" on its right bank is labeled "Carlson R1" and the first tributary entering on the left bank is "Carlson L1". This convention is applied to the tributaries themselves, so that the first tributary entering "Carlson R1" on its left bank is labeled "Carlson R1L1", and so on. GeoFluv™ will revise the naming

sequence so that when all the channels in the watershed have been added, each channel will be named correctly following this convention.

To name the channels differently, simply type the preferred name into the edit box in the Change Channel Name dialog box accessed using the Channels tab's Name button.

Channel Delete

The Delete button is used to delete the "Current Channel" from the watershed design.

First, the correct channel must be chosen in the dropdown list on the Channel tab. The user can change the current channel by left-clicking on the menu arrow to the right of the Current Channel list-box and selecting the name of the channel that is to be deleted. The user then left-clicks on the Delete button.

GeoFluv™ deletes that channel name from the list, deletes that channel's input settings, deletes any tributaries that connect to this channel, adjusts the names of the remaining channels according to GeoFluv™'s naming convention, recalculates the ridges and subwatersheds and other aspects of the GeoFluv™ design, and makes the main valley bottom channel to be the "Current Channel."

Channel Name

The Channels tab's Name button allows the user to change the name of a channel within the GeoFluv Boundary that has been named according to GeoFluv™'s default automatic naming convention.

Left clicking on the Name button causes the Change Channel Name dialog box to appear on the screen. The user types the new channel name into the "Channel's name:" edit box and left-clicks the OK button to apply the new name.

The user can toggle the Change Channel Name dialog box's option to "Update tributary channel names" on or off. This option will automatically rename all channel's that are tributary to the channel named in the "Channel's name:" edit box using that new name. Note that if the toggle is off, the selected channel will be renamed, but the channel tributary to it will not, but may need to be manually renamed if its name includes a GeoFluv™ alpha-numeric portion, i.e., if Moose Creek RE1 is renamed Spruce Creek, its tributary's name, Moose Creek R1R1, will still include the now meaningless R1R1.

If the user does not want to use the default GeoFluv™ channel naming convention, they can rename the channels simply by toggling off the Update tributary channels names option and typing in any name.

Channel Transition

This button allows the user to change the transition point from a reach greater than -0.04 slope to less than -0.04 slope in a channel's longitudinal profile.

Command Prompt:

Choose the forced transition point between channel types. (Press Enter to find automatically.)

When the user left-clicks on the Transition button, the cursor changes to a crosshair that the user can place on the valley line to specify a new transition point. The user can elect to allow GeoFluv™ to determine this point automatically based on the elevation data supplied in the Pre-Disturbed Surface file by pressing the Enter key.

Current Channel

The Current Channel list-box displays the name of the current GeoFluv™ channel that the user is designing. The main valley bottom channel was specified in the Settings tab and this channel is the first listed in the Current Channel tab. Channels that are tributary to the main valley bottom channel are added in the Channels tab using the Add button. The user can see a listing of all channels that are built by left-clicking on the down arrow to the right of the list-box. Then left-clicking on a channel name will make that channel be the "current channel".

Current Channel Settings

This button allows the user to specify settings that will vary the channel discharge and the related channel geometry and upland ridge and subridge morphology specific to the subwatershed active in the Channels tab current channel name box. The settings are organized on two tabs, Geometry and Watershed. The Geometry tab has settings for maximum velocity, upstream slope, downstream slope, width to depth ratio, sinuosity, random scale factors on sinusoidal channel, subridge spacing on sinusoidal channel, and channel head and mouth elevation. The Watershed tab has settings for runoff coefficient when using the Rational Runoff Method (the default method), or to allow input of discharge computed by an alternate method, and to add runoff from contiguous land areas.

Left-clicking on the "Settings" button brings up the "Channel 'xxxx' Settings" dialog box that gives the user the options shown below. The optional settings made in the "Channel 'xxxx' Settings" dialog box will apply only to the Channel 'xxxx' subwatershed. The blue subject bar at the top of the dialog box displays the name of the channel's subwatershed to which the Settings will apply. The user will select a different channel in the "Current Channel" window of the "Channels" tab and then left-click on "Settings" to make these changes to other channels and their subwatersheds, e.g., 'Channel yyyy', 'Channel zzzz,' etc. After specifying the settings in the dialog box, the user can apply them by left-clicking the "OK" button at the bottom of the dialog box.

Geometry Tab

Maximum Water Velocity (ft./s.): The user can specify a maximum water velocity for the channel by typing the desired value into the edit box. Velocity is inversely related to channel cross-sectional area for a given discharge according to the relationship $Q/a=v$, where Q is discharge (cubic feet per second), a is area (square feet), and v is velocity (feet per second).

Upstream slope %: The user can specify the upstream slope for the channel using this edit box. This feature can be used to vary the channel's longitudinal profile that will join to a mouth slope dictated by the receiving channel slope at their confluence. It can also be used to tie into the upstream slope when the headwaters of the channel are at the GeoFluv Boundary and join with an upstream channel slope draining "Additional watershed area."

Downstream slope % (Only adjustable on main channel.): The user can specify the mouth slope for the main channel at the GeoFluv Boundary to join smoothly to the downstream channel slope by typing the desired slope into the edit box. If the Channel's tab Settings dialog box is open for any tributary to the main channel, the edit box will read "n/a."

Width-to-Depth, slope > -0.04: xx.xx , < -0.04: xx.xx: The user can specify width-to-depth ratios for channels with slopes greater and less than -0.04 by typing the desired width-to-depth ratio into the edit box. The default values are 10.00:1 for channels with greater than -0.04 slope and 12.5:1 for channels with less than -0.04 slope.

Sinuosity, slope > -0.04: xx.xx , < -0.04: xx.xx: The user can specify sinuosity for channels with slopes greater and less than -0.04 by typing the desired sinuosity into the edit box. The default values are 1.15 for channels with greater than -0.04 slope and 1.48 for channels with less than -0.04 slope.

Random scale factors on sinusoidal channel: The meander pattern of the idealized draft valley bottom channels (<-0.04) will be determined by mathematical constants and thus will be very uniform, changing (enlarging) as a function of flow (related to discharge) and valley bottom orientation. Checking the 'Random scale factors on sinusoidal channel' box will randomly vary the constant values, within their acceptable ranges for stable channels, such that radius of curvature, meander length, and meander belt width vary. This random variation produces a more natural appearance for the channel and related upland landforms.

Subridge spacing on sinusoidal channel: This setting applies to channels with slopes <-0.04. The lower-gradient channels, with slopes <-0.04, may have an adjacent floodplain (or terrace) area and the uplands landform may begin some distance from the channel banks. The user can use this setting to create some of this open floodplain or terrace area by increasing the spacing between subridges. A subridge spacing setting of 3, for example, will create a subridge on every third meander bend of the channel with an opening for the floor of the subridge valley between these subridges.

Note: The user must select odd-number spacing; specifying even number spacing will result in all subridges and subridge valleys being on opposite sides of the valley. Even spacing can be made with manual Carlson editing.

The user can also manually add or delete subridges, or vary subridge longitudinal profiles using Natural Regrade's longitudinal profile editors, to introduce more variation to the draft GeoFluv's landform.

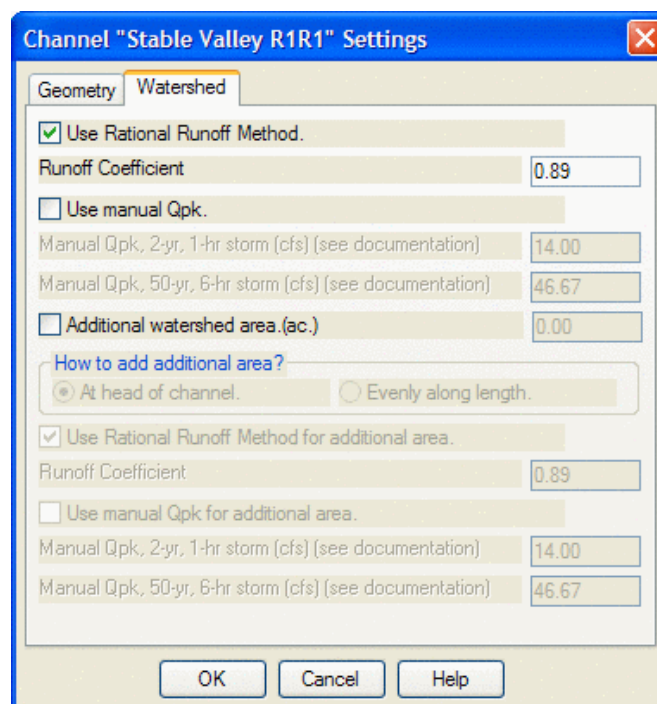

Specify head elevation: The user can specify the head elevation for any channel, rather than accepting an elevation that is automatically determined from the Pre-disturbance file specified in the Settings tab. The user checks the box to select this option and then proceeds in one of two ways. The user can type a desired headwater elevation into the Specify Head Elevation field. Alternately, the user can left-click on the Pick button and then identify a (COGO) point of the desired elevation on the drawing. To use the Pick method, the user left-clicks the cursor near the desired point and then, by moving the cursor diagonally, creates a box around the point. The user left-clicks again to define the opposite corner of the box surrounding the desired point and the point elevation is entered into the Specify Head Elevation field.

Specify mouth elevation: The user can (and should) specify the mouth elevation for the main channel only. This setting becomes inactive on the tributary channels because their mouth elevation is controlled by the main channel's longitudinal profile. The procedures for setting the elevation are the same as in Specify Head Elevation above.

Note: The user should specify the mouth elevation of the main channel in the GeoFluv's project area because this elevation and the channel slope immediately downstream of this point may be the most critical variables for assuring a stable landform design. The elevations that Natural Regrade interpolates from the 'Pre-disturbed surface' specified in the Settings tab are appropriate for creating and comparing draft design alternatives, but a channel mouth elevation interpolated from a map surface can vary from the actual elevation on the order of feet. A channel will be expected to adjust to elevation and slope inaccuracies by erosion.

Specify sub-ridge/swale distance: The user can vary the sub-watershed ridge and swale length for each project sub-watershed in the Natural Regrade Channel's tab's Current Channel/Geometry tab settings dialog. The sub-watershed ridges and swale valleys form by similar processes of erosion as do the channel-containing valleys, but the watershed area above them is not great enough to generate discharges that form defined channels. This means that in some areas the landform dimensions of these smaller features may have greater convex lengths than in channel-sized valleys. The user can input a maximum convex length for the sub-watershed swales and ridges that will be applied to all the design lines in the subwatershed by typing the desired value in the edit box; the remainder of the profile will be concave when possible. The sub-watershed ridge distance setting is not changed when the swale setting is manually input.

Watershed Tab

Use Rational Runoff Method: This is the default setting for calculating runoff to the GeoFluv boundary; channels in Natural Regrade and is the setting that will be used when the box is checked. The Rational Runoff Method calculates a peak discharge using the formula $Q_{pk} = CIA$, where C is the runoff coefficient, I is the rainfall intensity, and A is the acreage. The user enters the appropriate runoff coefficient for the area within the GeoFluv boundary in the Runoff Coefficient field and Natural Regrade does all the related calculations.

Use manual Qpk: The user can choose to input a peak discharge value calculated by some other method by checking the 'Use Manual Qpk' option. When the user checks this box, the runoff coefficient field in the Use Rational Runoff Method setting (and use of that method) becomes disabled. The user then types in the peak discharges to use for the two storm events.

Note: The GeoFluv approach uses the 2-yr, 1-hour storm event to calculate bankfull discharge and the 50-yr, 6-hr event to calculate a flood-prone discharge. Reclamation landforms constructed using the GeoFluv approach that use these inputs have been stable in a very harsh and erosive high-altitude desert environment through extreme storm events. Using other input values may give unsatisfactory results.

Additional Watershed Area: This setting allows the user to incorporate runoff from contiguous lands into the GeoFluv Boundary. When the user checks the Additional Watershed Area box, the fields below become active and offer a choice of how the additional runoff will enter the GeoFluv Boundary. If the head of the GeoFluv channel is downstream of the Additional Watershed Area, as when joining to an upstream channel reach, the user should select the "At head of channel" option. The GeoFluv channel's headwater dimensions will then be sized to accommodate the runoff from the area above the channel headwaters within the GeoFluv Boundary and the Additional Watershed Area upstream of that. If the Additional Watershed Area is subparallel to the GeoFluv channel, checking "Evenly along length" will introduce the runoff from the Additional Watershed Area gradually along the GeoFluv channel reach and the channel dimensions will increase proportionately along the reach. The remainder of the settings are as described above in "Use Rational Method" and "Use manual Qpk."

Data for Current Channel

These are the data that GeoFluv™ uses to calculate the drainage density for the subwatershed containing the channel in the Current Channel field above, and a display window that informs the user if discharge from additional area outside the GeoFluv Boundary is entering the subwatershed. These are not input fields, but real-time displays of the values being used in the GeoFluv™ design for the Current Channel. GeoFluv™ calculates these values from the subwatershed boundary it has built and the drainage pattern that the user sketched, and user-input additional area by the Channels tab's "Advanced . . ." button.

Valley Length (ft.) This value is the straight-line length of the valley (in feet in U.S. units), not the sinuous length of the channel.

Reach Area (ac.) This value is the area (in acres in U.S. units) draining water to that channel or channel reach.

Add'l Area (ac.) This field displays any additional area outside the GeoFluv™ boundary that is draining into the GeoFluv™ Current Channel. This could be contiguous undisturbed land or land that has already been reclaimed. The Channels tab's "Advanced . . ." button allows the user to add additional area.

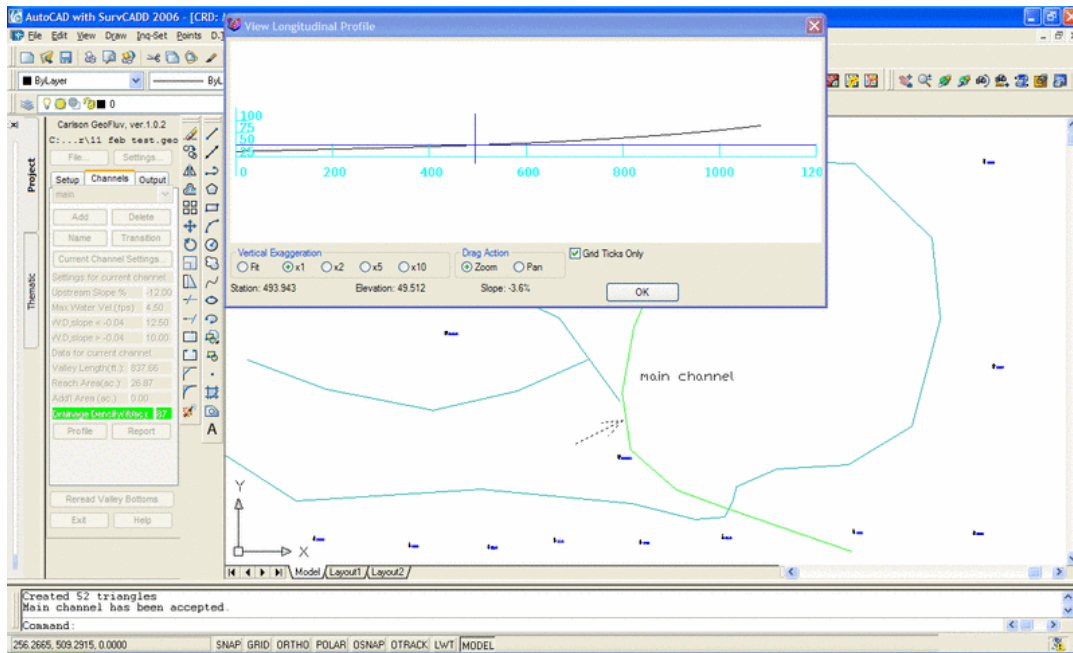

Drainage Density (ft/ac) This value is the ratio of Valley Length to Reach Area in U.S. units of feet per acre, a convenient unit for this parameter in landform design work.

If the drainage density is within the variance that the user specified in the Design Natural Regrade dockable dialog box's Settings button, Natural Regrade Global Settings, "Target drainage density variance (%)", then the value will be highlighted in green; if the value is outside the user-specified variance it will be highlighted in red. A red warning can mean that the drainage density is too high or too low. If too high, the channel can be shortened or the Current Channel's subwatershed area increased. If the value is too low, the Current Channel can be lengthened, or a tributary channel can be drawn in the Current Channel subwatershed and then added using the Channels tab's Add button, or the subwatershed area can be decreased.

If the GeoFluv Boundary polyline or the valley bottom polylines are modified in the drawing, clicking on the Reread Valley Bottoms button will cause the above data to be updated.

Profile

This button activates a popup view window, Profile Viewer, which allows the user to see the Current Channel's longitudinal profile graphically. Moving the viewer cursor along the profile allows the user to obtain the station, elevation, and slope at any point indicated by crosshairs along the profile.

Vertical Exaggeration This toggle button setting allows the user to select profile views at fit, 1x, 2x, 5x, and 10x vertical exaggeration.

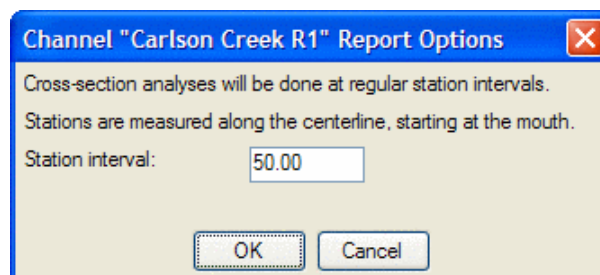

Drag Action This toggle button setting allows the user to select either zoom or pan drag action. Then the user selects the Zoom button, holding down the left-click button on the mouse as the mouse is moved will zoom in and out on the profile display. Similarly, when the user selects the Pan button, holding down the left-click button on the mouse allows the user to pan the profile in the display. Whether in Zoom mode or Pan mode, the middle mouse button can be held down to pan the profile in the display. Thus, if the user has a middle mouse button, staying in the Zoom mode and using the middle mouse button to pan is most efficient.

Grid Ticks Only This toggle button setting allows the user to select either the default x and y grid lines across the profile, or tick marks only on the axes.

Report

The Report button is used for detailed inspection of the GeoFluv™ Current Channel's design characteristics.

The report is for the channel as it would be incorporated into the design after using the Draw Design Surface button on the Output tab. Note that the channels with slopes > -0.04 do not have the meandering channel geometry relationships that lower slope channels do. Their different characteristics are designed differently in the GeoFluv™ approach and because of this radius of curvature, meander length, meander belt width, and meander width ratio are not listed.

The user left-clicks on the Report button and the "Channel 'xxxx' Report Options" dialog box opens. The user can type in the desired station interval for the report in the "Station Interval:" window. The user then left-clicks on the OK button and the report for that channel is generated according to the user-specified stationing.

```
Cross-section reports are done every 50.00(ft.).
Stations are measured along the centerline, starting from the headwaters.
Stations are only reported when there is a real cross-section
formed by the four polylines of the built channel.
The length of the centerline is 908.85(ft.).
Left and right are from the point of view of looking downstream.
```

```
-----
station (ft.):          0.00
slope at station:      -0.12
flood prone width (ft.): 0.39
flood prone depth (ft.): 0.04
flood prone area (sq.ft.): 0.01
bankfull width (ft.):  0.17
bankfull depth (ft.):  0.02
bankfull area (sq.ft.): 0.00
bottom width (ft.):    0.03
Shields shear stress, bankfull width (lbs/sq.ft.): 0.07
Shields shear stress, flood prone width (lbs/sq.ft.): 0.17
right side slope (%):  25.00
left side slope (%):   25.00
-----
```

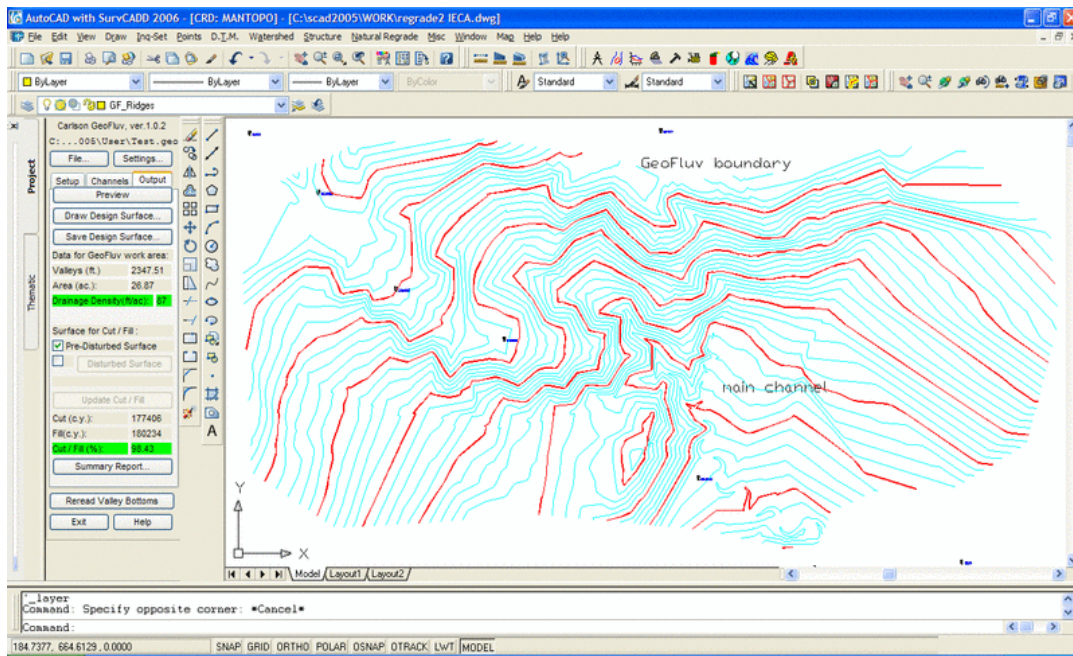

```
-----
station (ft.):          50.00
slope at station:      -0.12
flood prone width (ft.): 1.45
flood prone depth (ft.): 0.17
-----
```

The report gives summary design information for the Current Channel and lists channel-reach detailed information at the user-specified station intervals. The stationing increases in the downstream direction with station 00 being the channel head.

Output Tab

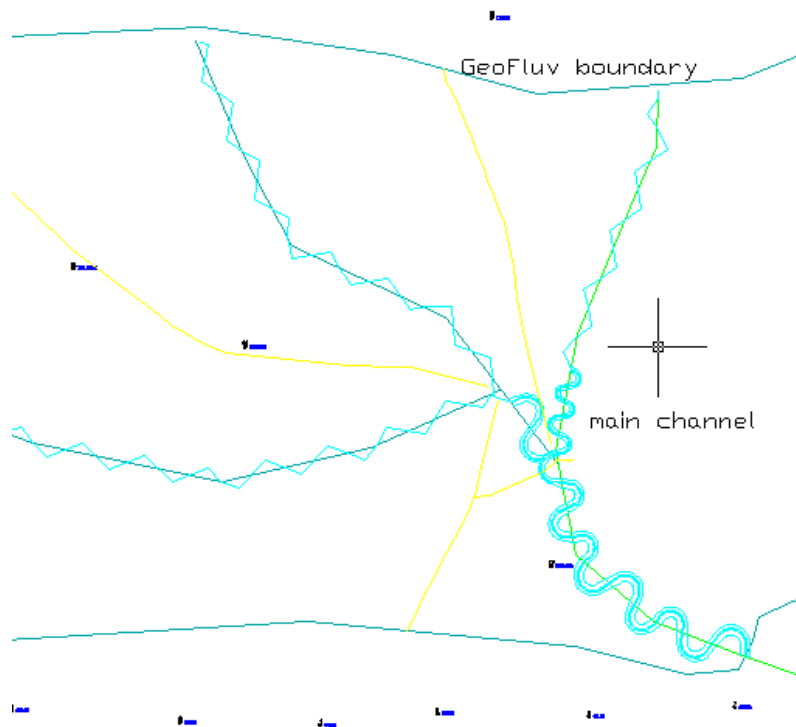

Function

The Output Tab allows the user to preview the channels and ridgelines that will be contoured to reveal the draft GeoFluv™ design landform, to draw and contour the surface, to save the design, to verify the average drainage density within the GeoFluv Boundary, to compare the cut and fill volumes needed to create the design and to verify that the cut and fill volumes balance within a user-specified limit, and to create and view a summary report of the channel settings and design dimensions.

Preview

The Preview button displays the channel and main ridgelines from which GeoFluv™ will base its draft landform design.

Command Prompt:

The command reads, "Preview. Use View menu commands to change views. Press Enter to continue." when the Preview button is left-clicked.

Left-clicking on the Preview button draws the main GeoFluv™ channel and ridge design lines on the drawing. The A and A+ channel reaches (>-0.04 slope) are displayed as zig-zag lines. The valley bottom channel reaches (<-0.04 slope) are displayed as sinuous curved lines. The main ridgelines are shown between the tributary channels and are

sub-parallel to the channels.

Data for GeoFluv Work Area

These are the data that GeoFluv™ uses to calculate the drainage density for the entire area within the GeoFluv Boundary. These are not input fields, but real-time displays of the values being used in the GeoFluv™ design for overall project area within the GeoFluv Boundary. GeoFluv™ calculates these values from the GeoFluv Boundary that the user has drawn and the drainage pattern that the user sketched.

Valleys (ft.) This value is the combined straight-line length of all the valleys (in feet in U.S. units), not the sinuous length of the channel, that the user has sketched within the GeoFluv Boundary.

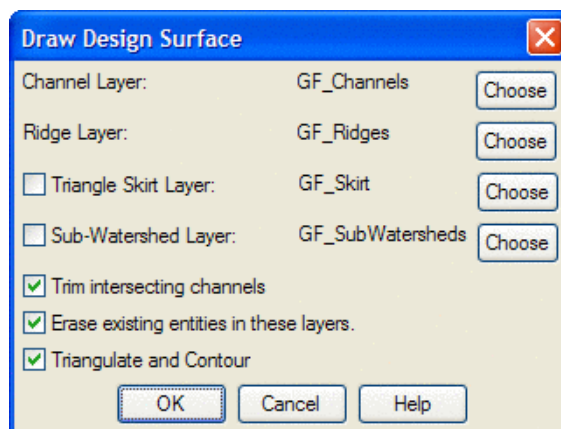

Area (ac.) This value is the area (in acres in U.S. units) within the GeoFluv Boundary.

Drainage Density (ft/ac) This value is the ratio of Valley Length to Reach Area in U.S. units of feet per acre, a convenient unit for this parameter in landform design work.

If the drainage density is within the variance that the user specified in the Design Natural Regrade dockable dialog box's Settings button, Natural Regrade Global Settings, "Target drainage density variance (%)", then the value will be highlighted in green; if the value is outside the user-specified variance it will be highlighted in red. A red warning can mean that the drainage density is too high or too low. If too high, channels can be deleted or shortened, or the area within the GeoFluv Boundary can be increased. If the value is too low, valleys can be lengthened, or a tributary channel can be drawn within the GeoFluv Boundary and then added using the Channels tab's Add button, or the area within the GeoFluv Boundary can be decreased.

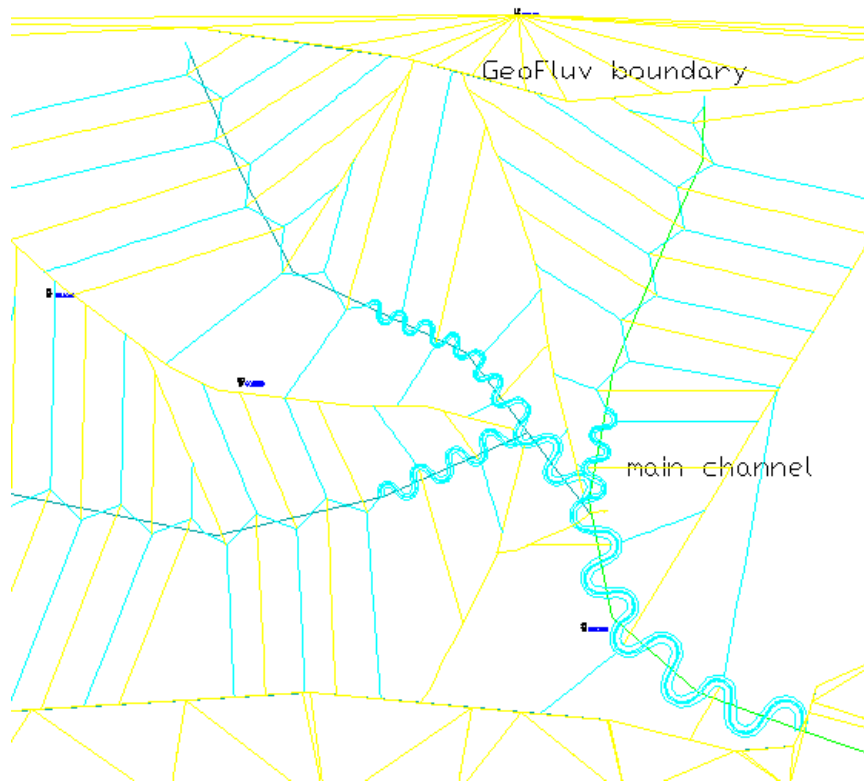

Draw Design Surface

Draw Design Surface integrates all of the GeoFluv™ landform design data that the user has input and outputs it to the drawing.

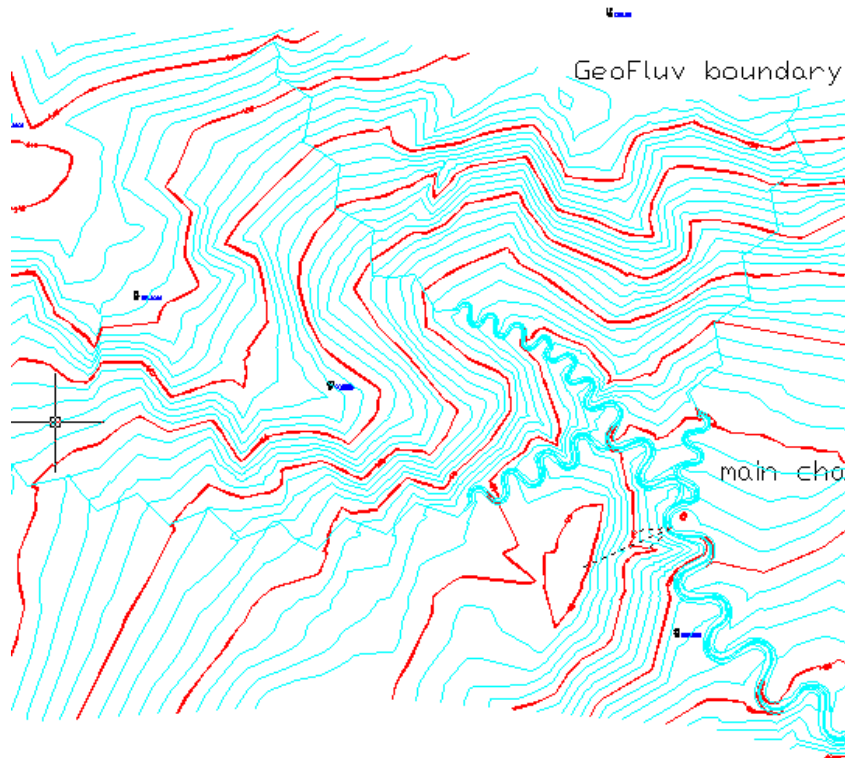

Left-clicking on the Draw Design Surface button causes the Draw Design Surface dialog box to appear. This dialog box allows the user to choose the layer name to which *Natural Regrade* will save the channel and ridge polylines, the triangle skirt layer, and the Sub-Watersheds. Toggles in the dialog box also allow the user to specify:

- If the triangle mesh outside the GeoFluv™ boundary will be drawn.
- If the 2D outlines of subwatersheds will be drawn.
- If intersecting built tributary channels are trimmed at the point of intersection or if they continue all the way to the confluence.
- If existing entities in these layers are erased.

Clicking the OK button in the Draw Design Surface dialog box will capture these settings for the GeoFluv™ design. If the settings are valid, *Natural Regrade* will insert the subwatershed subridge and subvalley breaklines into the drawing, regardless of how many are needed to create the stable draft design and the Triangulate and Contour from TIN dialog box will pop up. The user can edit the settings on the dialog box tabs or accept the default settings. The user clicks OK to begin contouring.

Natural Regrade will draw the draft GeoFluv™ landform contours on the drawing and a pop-up Carlson Edit dialog box will appear that lists any instances of 'crossing barrier lines', if the triangulate and contour settings were

appropriate. The user can use this edit box to review the drawing for possible errors; typically the crossing barrier lines reported in this edit box are intersections of channel and valley lines. (See also the Draw GeoFluv Contours command for more detail about this feature.)

If the 'maximum triangle mesh line length' setting in the Triangulate tab of the Contour selection in the Carlson DTM Triangulate and Contour menu is set to a value less than the required triangle mesh line length for portions of the design, the command line will read "Ignored 'xxx' triangulation lines that exceeded maximum tmesh line length" and only those portions of the design, if any, that did not exceed the maximum tmesh line length will be contoured. If this occurs, the user can reset the maximum triangle mesh setting in the DTM menu to be greater than the 'xxx' distance reported in the command line and then repeat the Draw Design Surface command sequence as described above. GeoFluv™ will then contour the entire drawing as described above. (See also the Draw GeoFluv Contours command for more detail about this feature.)

The subridgelines and the valleys between them extend from the main ridgelines to the channels. The slopes have default settings that create concave slopes, rather than constant gradient or convex slopes that are subject to rill and gully formation.

Save Design Surface

The Save Design Surface button provides a quick means to save the triangulation mesh file of the GeoFluv™ draft design surface. The draft design surface is virtual and is not necessarily represented in the drawing at the moment. The draft design surface is created using the inputs of the 2D valley bottom polylines, the GeoFluv Boundary, the Pre-Disturbed Surface, and the various settings of the current GeoFluv project. The draft design surface is the same one that would be created by the Draw Design Surface button.

Any modifications to ridge or subridge or channel polylines in the drawing using tools such as Edit Longitudinal Profile are not a part of the draft design surface. To create a triangulation mesh file of the design surface in the drawing, use the Draw GeoFluv Contours command in the Natural Regrade dropdown menu and select the Write Triangulation File option on the Triangulate tab.

The user left-clicks on the Save Design Surface button and the Save Design Surface - (.FLT; .TIN) dialog box appears on the screen. The user is offered three options to name and save the surface file. The user can type in the name of a new or existing file in the File Name window, or left-click on the Browse button to the right of the window to get a list of surface files related to the project. If the user wants to save surface file as an existing file (overwrite the file), they can highlight the file name in the Recently Used Files: window at the bottom of the dialog box or in the "Files in that folder" window at the right of the dialog box. The user then left-clicks on the Open button at the bottom of the dialog box to save the file with the selected name.

Update Cut/Fill

The Comparison Surface button is used to enter a three-dimensional surface file (.flt or .tin) for determination of cut and fill volume differences between the comparison surface and the GeoFluv landform design that the user has made.

When the user clicks on the Comparison Surface button, the Use Existing TIN or Create New TIN? Pop-up dialog box appears to give the user the options, by clicking on radio buttons, for entering a 3-D surface file. By clicking OK when the radio button is on Search for existing TIN file, the user can browse through existing files to select

the file to import, or select the file from a list of recently used files. When the user highlights the desired file and clicks the Open button, the file name appears below the Comparison Surface button and the user is ready to begin the Update Cut / Fill command.

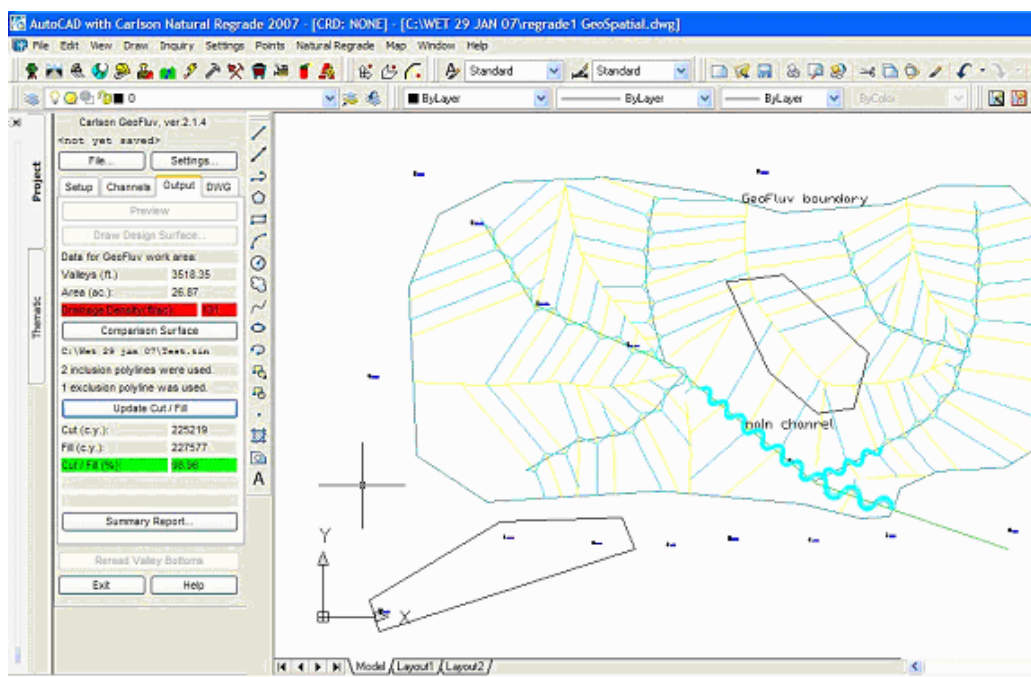

Alternatively, the user can click the radio button for Create new TIN file by selecting entities in the drawing. When the user selects this option and clicks OK, the cursor changes to a selection box that the user can use to define an area with a crossing window. (Note: it is very important that this area encompass the entire GeoFluv project .tin surface. Areas outside the work area that are the same in both the comparison surface and the GeoFluv design will not affect the volume balance so the user does not have to be concerned with defining a slightly larger area.) After defining the new .tin area, the user hits the Enter key and the Select Comparison Surface TIN file - (.tin;.flt) dialog box appears.

The user can choose an existing .tin file by browsing folders or choosing from recently used files, or click on the New tab to create the new .tin file. The user can click on the New tab, enter a name for the new .tin file, and click OK.

The Carlson Software 3D Viewer window will appear showing the .tin for the area that the user has defined. The user can rotate, fill in the .tin triangles, etc. to preview the .tin to be sure that it is satisfactory, i.e., no unwanted holes, elevation spikes, etc. When the user is satisfied that the .tin correctly represents the comparison surface, the user closes the 3D viewer window and the command prompt line reads Select Inclusion Polylines.

The Select Inclusion Polylines option allows the user to define area boundaries for use in the Cut / Fill balance with polylines. By default Natural Regrade will use the GeoFluv boundary polyline as an inclusion boundary to compare against the specified Comparison Surface. Inclusion area boundaries are useful if the user wants to add an adjacent stockpile volume to the calculations, for example. The user clicks on any additional desired inclusion area polylines, including the GeoFluv boundary polyline as needed, that Natural Regrade will use in the calculation. If no inclusion boundary lines other than the GeoFluv boundary are needed, or when all selections are made, the user can hit Enter and is prompted to select Exclusion polylines.

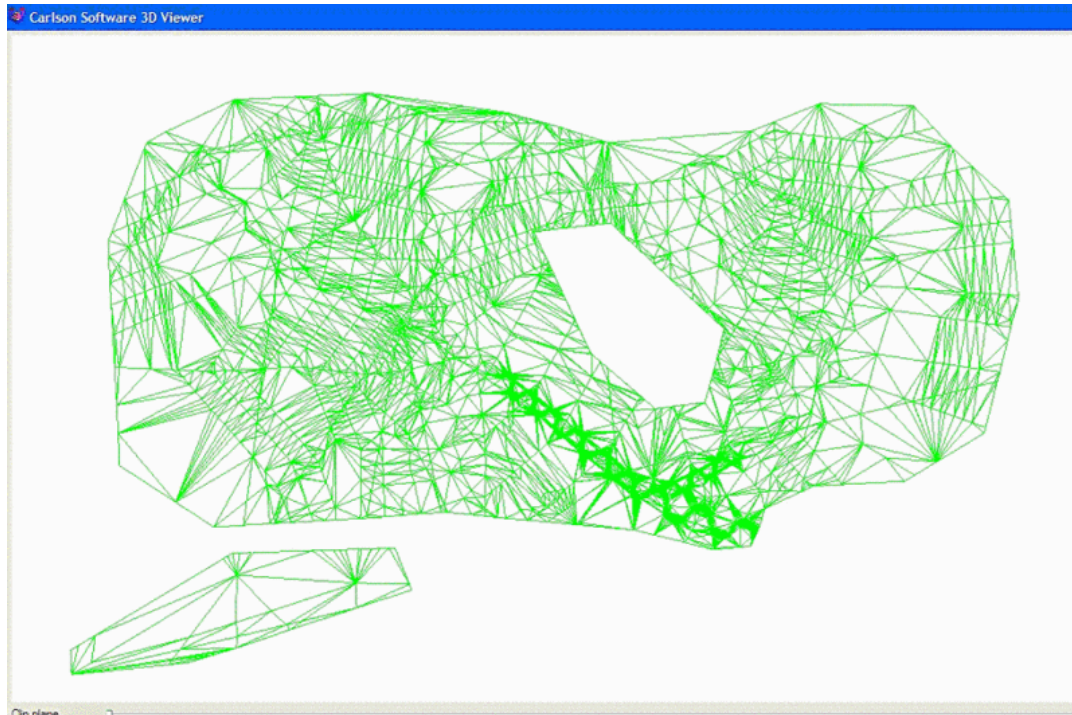

Exclusion polylines are the inverse of inclusion polylines. They can be used to exclude an area like a home-site that is surrounded by the GeoFluv project. If no exclusion boundary lines are needed, or when all selections are made, the user can hit Enter and is prompted to select Exclusion polylines. Natural Regrade will then display the number of inclusion and exclusion polylines that will be used in the cut / fill calculation. The user is then ready to proceed to the Update Cut / Fill button to make the calculation.

In the example, the user has selected two inclusion boundaries, the GeoFluv boundary and a boundary line around a stockpile southwest of the GeoFluv boundary, and one exclusion boundary on top of a ridge near the middle of the GeoFluv design.

The Update Cut / Fill button makes the calculation of the cut and fill needed to make the GeoFluv design from the comparison surface that the user has specified.

When the user clicks on the Update Cut / Fill button, the Carlson Software 3D Viewer window appears showing the .tin that will result from the user's specified file and any inclusion and exclusion boundaries. This helps the user to quickly verify that the specified areas are as desired. The user may also find it helpful to use the 3D Viewer's Toggle shading of surfaces button to fill in the triangle mesh spaces when inspecting the .tin.

When the user closes the 3D viewer, the calculation results are displayed below the Update Cut / Fill button.

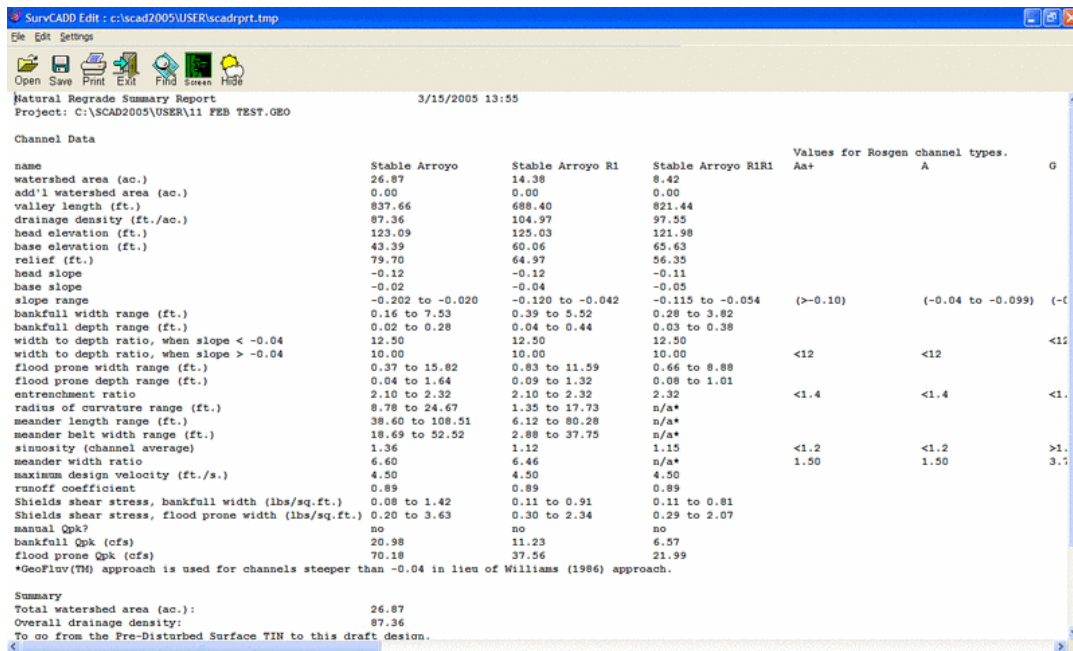

The calculation respects any inclusion and exclusion areas that the user has specified. When the result is within the balance range that the user specified in the Natural Regrade Global Settings (accessed via the Settings button), the Cut / Fill (%) is highlighted in green to give the user quick feedback; conversely, if the result is outside the user-specified range the result is highlighted in red.

Summary Report

The Summary Report button provides the user with a quick summary report of the input parameters and resulting dimensions and material volumes that *Natural Regrade* used to design each GeoFluv™ channel within the project's GeoFluv Boundary.

The user left-clicks on the Summary Report button and the GeoFluv Summary Report dialog box appears on the screen. The dialog box gives the user the options of creating a custom report by checking the "Use report formatter" box (toggle on) and presenting characteristics of Rosgen channel types by checking the "Show Rosgen example channels" box (toggle on; this is the default setting).

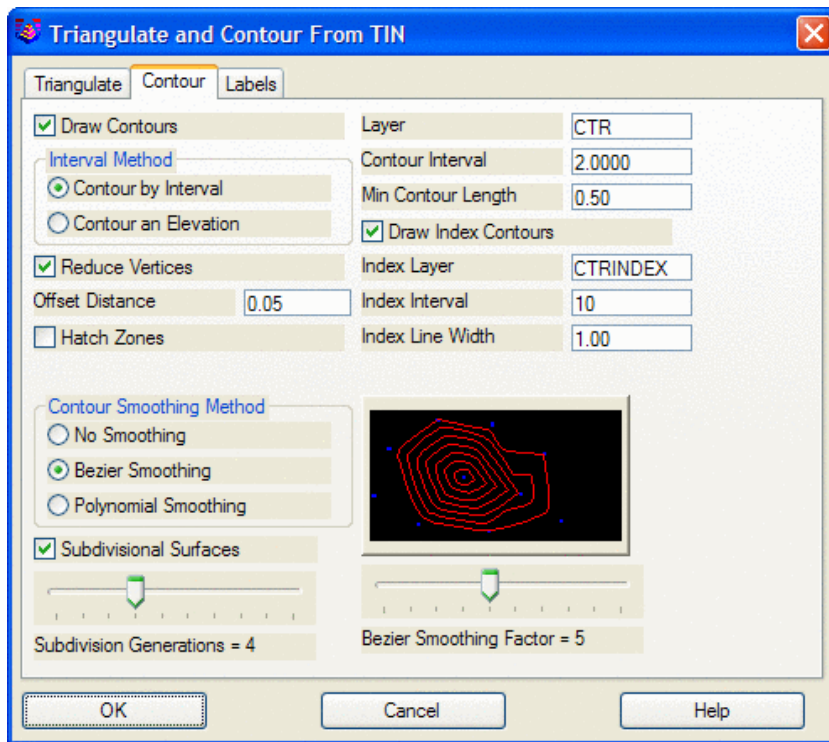

This information can be useful to compare the channels' morphology with other natural channel types when editing the draft GeoFluv™ design to verify that changes to the channel do not exceed the range established for that stable channel type. The summary report information can also be useful for estimating if the user may want to increase channel roughness, install additional bank protection or channel weirs to augment step-pool sequences, etc. Fields that contain information that is not used in the GeoFluv™ approach for designing A and Aa+ channels (>0.04 slope) are marked n/a. Many of the channel characteristics occur within a range at any particular reach in stable natural channels, rather than as a specific value. The dimensions also change in the up-and downstream directions as a function of discharge. The Summary Report presents the range of these values that are applicable to the entire length of each channel. The user can report channel reach-specific information by using the Channels tab's Report button.

DWG Tab

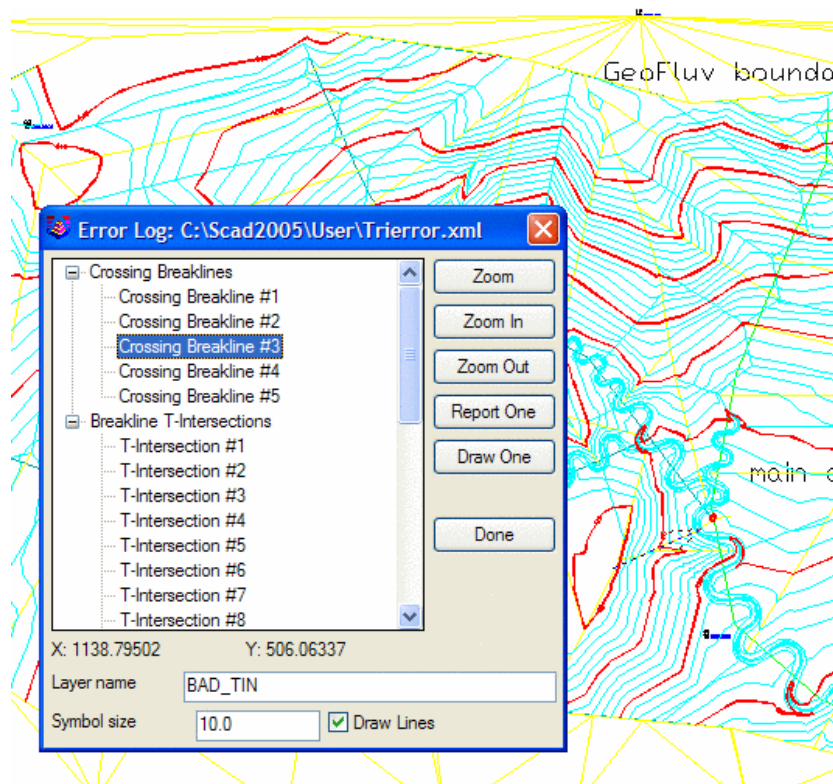

Draw GeoFluv Contours

This command gives the user single-click access to the "Triangulate and Contour from TIN" dialog box via the *Natural Regrade* drop-down menu.

After the user has used the Design GeoFluv Regrade dockable dialog box/Output tab's Draw Design Surface button to create the GeoFluv™ design in the drawing, the user can left-click on the Draw GeoFluv Contours command and produce the Triangulate and Contour from TIN dialog box to contour revisions to the polylines in the layers that the GeoFluv™ design was drawn to.

When the contours have been drawn, the **Error Log: C:\Scad2005\User—Trierror.xml** dialog box will appear. The user can review this error log, or close the box and proceed with the contouring if precise detail is not yet required at this design stage. This Error Log reports any potential errors that Carlson has detected when contouring the drawing.

For example, if the report has a Crossing Breaklines (two polylines with different elevations) field, the user can left-click on that field and a list of the detected crossing breaklines will appear. The user can then left-click on each detected crossing breakline and its x and y coordinates will be displayed at the bottom of the dialog box. The user may choose to report or draw all the detected potential problems using the **Report All** and **Draw All** buttons, or may highlight to select a single potential problem. If the user selects a single problem, the buttons change to **Report**

One and Draw One.

The user can left-click on the **Zoom** button to inspect the suspected problem; this will zoom to the relevant area of the drawing and place an arrow that points to the suspected problem on the drawing. Left clicking on the **Zoom In** button will allow closer inspection of the area of concern, and the **Zoom Out** button will return the user to the previous view.

For example, if only one entity was selected as a problem of concern, the "Report . ." button will indicate Report One and left-clicking on the **Report One** button brings up the Carlson Edit: c:\scad2005\USER\scadrprt.tmp dialog box that displays a Crossing Breaklines Report with the x and y coordinates of the problem, and the elevation difference between the crossing breaklines. Left clicking on the **Draw One** button draws the selected potential problem breakline on the drawing and brings up an AutoCAD dialog box that tells the user that one feature has been processed.

When the user closes the Error Log dialog box by left-clicking on the X in the upper right corner or on the **Done** button, the Error Log dialog box disappears and the contoured GeoFluv™ design remains on the screen. The user can then choose to edit the drawing using tools in the *Natural Regrade* menu, or any other Carlson menu tools, or can reopen the Design GeoFluv Regrade dockable dialog box to edit any of the GeoFluv™ settings there.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfContour

Prerequisite: Design geofluv

3D GeoFluv Contour Viewer

This Natural Regrade menu gives the user single-click access to the *3D GeoFluv Contour Viewer* that displays, in 3D, the surface created from the contours of a GeoFluv™ design. Viewing the contours is more representative of how the landform will look after grading than the surface produced by the *3D GeoFluv Surface Viewer*. The *3D GeoFluv Surface Viewer* shows you the surface based on the GeoFluv™ design, before using Triangulate and Contour. This resulting surface tends to be angular and faceted, and it is also the surface used for volume calculations. The *3D GeoFluv Contour Viewer* shows you the surface based on the GeoFluv™ design after using Triangulate and Contour, and therefore has more and smaller triangles, lending a smoother appearance to the 3D image.

Note that these commands use linework from particular layers in the drawing. This means that any editing the user makes to the linework in these layers will be reflected in the resulting 3D image.

The prerequisite to using the 3D GeoFluv Contour Viewer is that the contours must already exist. To create contours, the user can select the Triangulate and Contour option after clicking on the Draw Design Surface button on the Output tab of the Design GeoFluv Regrade command. Alternatively, the user can use the Draw GeoFluv Contours command on the Natural Regrade drop-down menu, which will create the contours based on the GeoFluv™ design that exists in particular layers in the drawing.

Clicking on the 3D GeoFluv Contour Viewer command first shows a dialog box asking the user to verify the layers in the drawing that the contours are in. There is also an option for saving the surface created from the contours into a TIN file, which can then be used with other tools in other *Carlson Civil / Survey* modules. Clicking on the OK button causes the contours in the selected layers to be "triangulated" into a solid surface, or TIN, and then opens the Carlson Software 3D Viewer with the GeoFluv™ design surface displayed.

The user has many options for viewing the image available in the View Control tab dialog box on the right side of the 3D Viewer screen. The 3D project view can be rotated on the x, y, and z axes using the sliding **Rotation Axis** controls to the right of the view. By left-clicking and dragging the slider control below the image, the user can clip off forward portions of the view. The viewer has the ability to add vertical exaggeration to aid inspection of lower-relief areas by left-clicking on the arrow to the right of the "**Vert. scale**" edit box and selecting a factor from the dropdown menu. The viewer can also change the position of the sun on the project to evaluate sunny and shady areas throughout the day, a very useful tool for identifying optimal areas for different plantings. The user can either left-click on the 'sun' (**yellow box in the blue circle**) and drag it across the 'sky' from the west (the blue circle is the sky) or move the slider buttons surrounding the blue circle. The 3D viewer has the ability to **color the view by elevation** layers by a toggle setting at the top of the dialog box. These views are helpful for construction to help workers visualize how the final project surface can be built in a series of lifts, for example by using GPS-guided truck dumping.

The toggle buttons on the dialog box below the blue and yellow 'sun and sky' indicator control:

Pan The user holds down the left-click button and moves the mouse across the drawing to pan the drawing in the 3D Viewer.

Rotation The 3D project view can be rotated on the x, y, and z axes by left-clicking the rotation toggle button and then holding down the left-click button while moving the mouse on the drawing.

Dynamic Zoom The user can zoom in and out of the 3D view by holding down the left-click button and moving the mouse up and down on the drawing.

Shading The user can toggle to fill with shading (color) between the TIN file's triangular edges to give the drawing a solid surface appearance.

Average Elevation The user can toggle to have an arrow appear on the drawing surface that indicates the average elevation at the point at which the arrow points.

Reset to Plan The user can left-click on this button to cancel all rotation settings and return to plan view.

The Carlson Software 3D Viewer's Advanced tab has options to block model objects, shade the view, export the view image, and save the view that are fully described in the General Commands/View Commands documentation.

The user can **exit the 3D Viewer** by left-clicking on the X at the upper right or the door at the bottom of the dialog box.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfViewC

3D GeoFluv Surface Viewer

This *Natural Regrade* command gives the user single-click access to a 3D GeoFluv™ surface viewer that is based on the GeoFluv™ design. The 3D GeoFluv Surface Viewer displays, in 3D, the surface created from the linework that was drawn by the Design GeoFluv Regrade command. This resulting surface is the same one that is used for volume calculations. Alternatively, the 3D GeoFluv Contour Viewer displays, in 3D, the surface created from the contours of a GeoFluv™ design which has more and smaller triangles lending a smoother appearance to the 3D image.

Note that these commands use linework from particular layers in the drawing. This means that any editing the user makes to the linework in these layers will be reflected in the resulting 3D image.

The prerequisite to using the 3D GeoFluv Surface Viewer is that the linework for a GeoFluv™ design must already exist in the drawing. To create the GeoFluv™ design in the drawing, the user can click on the Draw Design Surface button on the Output tab of the Design GeoFluv Regrade command.

Clicking on the 3D GeoFluv Surface Viewer command causes the 3D Surface Viewer dialog box to appear on the screen.

The user has many options for viewing the image available in the View Control tab dialog box on the right side of the 3D Viewer screen. The 3D project view can be rotated on the x, y, and z axes using the sliding **Rotation Axis** controls to the right of the view. By left-clicking and dragging the slider control below the image, the user can clip off forward portions of the view. The viewer has the ability to add vertical exaggeration to aid inspection of lower-relief areas by left-clicking on the arrow to the right of the "**Vert. scale**" edit box and selecting a factor from the dropdown menu. The viewer can also change the position of the sun on the project to evaluate sunny and shady areas throughout the day, a very useful tool for identifying optimal areas for different plantings. The user can either left-click on the 'sun' (**yellow box in the blue circle**) and drag it across the 'sky' from the west (the blue circle is the sky) or move the slider buttons surrounding the blue circle. The 3D viewer has the ability to **color the view by elevation** layers by a toggle setting at the top of the dialog box. These views are helpful for construction to help workers visualize how the final project surface can be built in a series of lifts, for example by using GPS-guided truck dumping.

The toggle buttons on the dialog box below the blue and yellow 'sun and sky' indicator control:

Pan The user holds down the left-click button and moves the mouse across the drawing to pan the drawing in the 3D Viewer.

Rotation The 3D project view can be rotated on the x, y, and z axes by left-clicking the rotation toggle button and then holding down the left-click button while moving the mouse on the drawing.

Dynamic Zoom The user can zoom in and out of the 3D view by holding down the left-click button and moving the mouse up and down on the drawing.

Shading The user can toggle to fill with shading (color) between the TIN file's triangular edges to give the drawing a solid surface appearance.

Average Elevation The user can toggle to have an arrow appear on the drawing surface that indicates the average elevation at the point at which the arrow points.

Reset to Plan The user can left-click on this button to cancel all rotation settings and return to plan view.

The Carlson Software 3D Viewer's Advanced tab has options to block model objects, shade the view, export the view image, and save the view that are fully described in the General Commands/View Commands documentation.

The user can **exit the 3D Viewer** by left-clicking on the X at the upper right or the door at the bottom of the dialog box.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfView3D

Prerequisite: Design geofluv

Calculate GeoFluv Volume

This *Natural Regrade* drop-down menu command is used to calculate the cut and fill volume difference between the GeoFluvTM design surface in the drawing and another surface, the Comparison Surface. The Comparison Surface is specified on the Output tab. Possible sources for the Comparison Surface may be pre-disturbed, such as the natural landsurface or an earlier reclamation design, or may be disturbed, such as a mine pit or construction site.

If the valley bottom or GeoFluv Boundary polylines have been moved, or any setting in the GeoFluv project has been changed that can affect volumes, then the design surface in the drawing will be out-of-date. The "Draw Design Surface" button must be used to create a new surface in the drawing to reflect the changes.

When the user clicks on the command, a dialog box appears with the cut and fill required to transform the first surface into the current design surface (layers GF_Channels and GF_Ridges). The first surface is the Comparison Surface. The cut and fill are calculated wherever the two surfaces overlap unless an inclusion polyline is given in which case the cut and fill are calculated within the inclusion polyline.

The results are displayed in cubic yards in the English system of units and cubic meters in the metric system.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfVolume

Prerequisite: Design geofluv

Cut/Fill Centroids

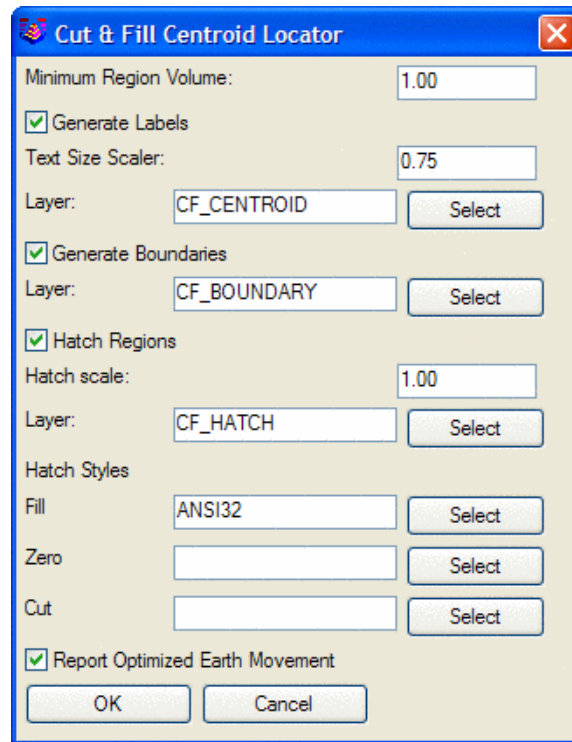

This *Natural Regrade* dropdown menu command is designed to show the amounts and locations of cut and fill that are required to transform the Comparison Surface (typically the disturbed surface) into the design surface. The Comparison Surface is specified in the current GeoFluvTM project on the Output tab. The design surface for this command is the result of combining the GeoFluvTM design in the layers in the drawing **within** the GeoFluv Boundary plus the Surface for Elevations (specified on the Setup tab) **outside** the GeoFluv Boundary.

After comparing these two surfaces, this command identifies the centers of earth-material volumes that need to be moved and the centers of voids that need to be filled to create the GeoFluv™ design. The command includes the option to identify optimal straight-line material movement paths.

Note that this command uses linework from particular layers in the drawing. This means that any editing the user makes to the linework in these layers will be reflected in the results.

The prerequisites for using the Cut Fill Centroids command is that the linework for a GeoFluv™ design must already exist in the drawing and the Comparison Surface must be set. To create the GeoFluv™ design in the drawing, the user can click on the Draw Design Surface button on the Output tab of the Design GeoFluv Regrade command. The Comparison Surface file can be entered by clicking on the Comparison Surface button on the Design GeoFluv Regrade Output tab.

Clicking on the Cut Fill Centroid command causes the Cut & Fill Centroid Locator dialog box to appear, if the prerequisites have been met. The Cut & Fill Centroid Locator dialog box gives the user several options.

Minimum Region Volume allows the user to type a minimum cut / fill centroid region volume for the calculations into an edit box.

Generate Labels is a toggle setting that allows the user to have the centroid region number, cut or fill, and volume value labeled on the drawing next to a crosshair that indicates the centroid coordinates.

Text Size Scaler: Allows the user to type a scale factor into an edit box to enlarge or reduce the size of label text. This command is inactive when Generate Labels is toggled off.

Layer: Allows the user to specify the layer on which the labels will be drawn by either typing them into an edit box or by left-clicking on the Select button which produces a dropdown list of existing layers from which to choose. The user can highlight a layer name on the list and click OK at the bottom of the dropdown menu to select a layer.

Generate Boundaries is a toggle setting that allows the user to specify if *Natural Regrade* shall create cut / fill boundaries and, if so, to what layer the boundaries should be saved. If toggled off, the edit window is inactive. When toggled on, the user may accept the default boundary layer name, type a different boundary layer name into the edit box, or left-click on the Select button to choose from the list of layers.

Hatch Regions is a toggle setting that allows the user to have the centroid regions covered with hatching to make it easier to discriminate from other parts of the drawing.

Hatch Scale: Allows the user to type a scale factor into an edit box to enlarge or reduce the size of hatching. If the user specifies a scaler that causes the hatch spacing to be too dense or the dash size too small, this error will be reported on the Command Line. [Tip: Before drawing a different scale, erase the previous iteration using Edit/Erase/Erase by layer.] This command is inactive when Hatch Regions is toggled off.

Layer: Allows the user to specify the layer on which the hatching will be drawn by either typing the layer name into an edit box or by left-clicking on the Select button which produces a dropdown list of existing layers from which to choose. The user can highlight a layer name on the list and click OK at the bottom of the dropdown menu to select a layer.

Hatch Styles: Allows the user to specify hatch styles to differentiate among Fill, Zero elevations between Fill and Cut, and Cut material by either typing them into an edit box or by left-clicking on the Select button which produces a dropdown list of existing layers from which to choose. The user can highlight a layer name on the list and click OK at the bottom of the dropdown menu to select a layer.

Report Optimized Earth Movement is a toggle setting that allows the user to specify if *Natural Regrade* shall not only calculate and identify the cut and fill centroids, but also determine the shortest straight-line haul distances to distribute the material from cut to fill regions.

```

Cut & Fill Centroid Report

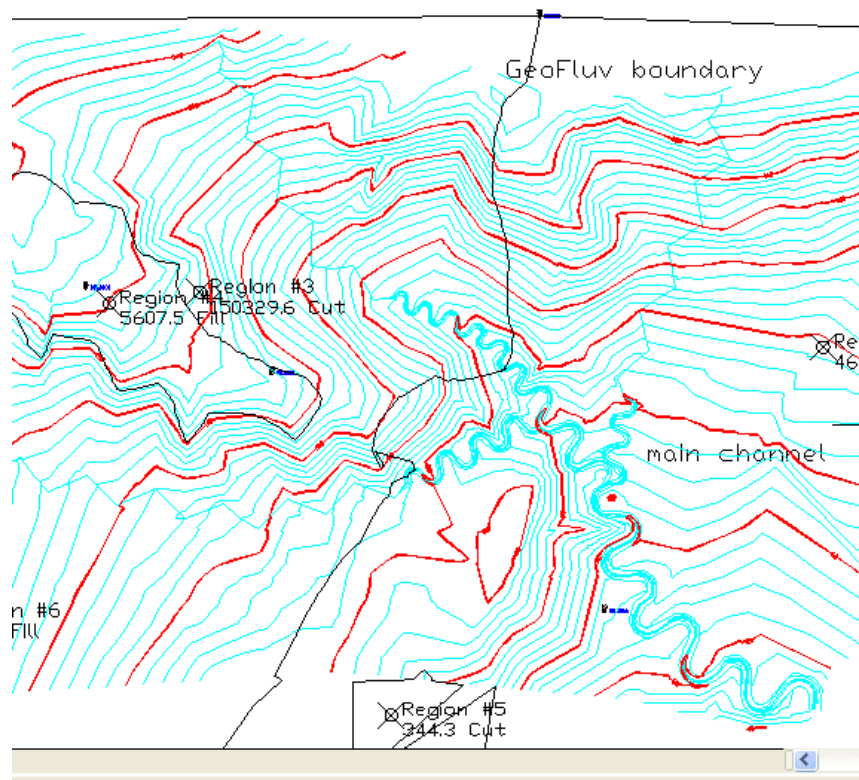

Original Ground: C:\SCAD2005\DATA\REGRADE_EXIST.FLT
Design Surface:  \sa4.2.tin

Region  Volume(C.Y.)  Northing  Easting
1       1103732.3  Cut   -361.15   1137.23
2       463494.4  Fill    697.46   1407.06
3       150329.6  Cut    763.14    660.70
4        5607.5  Fill    750.09    552.55
5        344.3   Cut    257.18    890.03

Total Internal Volume * Distance: 461685727.13
Total External Volume: 785270.89

```

When the user is satisfied with the settings on the Cut & Fill Centroid Locator dialog box, left-clicking on the OK button at the bottom will cause the centroid command selections to be executed and the Cut & Fill Centroid Report to appear on the screen. This report lists the three-dimensional surfaces that were compared to make the calculations, the material and void centroid regions that were identified, the volume of material or void in each region, whether the region identifies a cut or fill area, and the northing and easting of each centroid.

If the user toggled on Report Optimized Earth Movement, the report will be appended with the Earth Movement Report which lists the volume in cubic yards of material that has to be removed from region x to region y and the straight-line haul distance for the material movement, when such a solution can be found.

GeoFluv Channel Cross-Section Report

The *Natural Regrade* dropdown menu's GeoFluv Channel Cross-Section Report gives the user single click access to the detailed-by-station GeoFluv™ channel cross section Report that the user can create using the Channel's tab in the Design GeoFluv Regrade dockable dialog box when not actively working in the design. A user can select any GeoFluv™-designed channel in a drawing without any other files and generate this report.

Natural Regrade Summary Report on Channel "Carlson Creek R1"1/14/2005 18:
(If it were to be drawn using the Draw Design Surface command.)
*GeoFluv(TM) approach is used for channels steeper than -0.04 in lieu of 1

Cross-section reports are done every 50.00(ft.).
Stations are measured along the centerline, starting from the headwaters.
Stations are only reported when there is a real cross-section
formed by the four polylines of the built channel.
The length of the centerline is 1035.84(ft.).
Left and right are from the point of view of looking downstream.

station (ft.): 500.00
slope at station: -0.04
flood prone width (ft.): 4.74
flood prone depth (ft.): 0.48
flood prone area (sq.ft.): 1.34
bankfull width (ft.): 2.38
bankfull depth (ft.): 0.19
bankfull area (sq.ft.): 0.31
bottom width (ft.): 0.84
Shields shear stress, bankfull width (lbs/sq.ft.): 0.21
Shields shear stress, flood prone width (lbs/sq.ft.): 0.76
right side slope (%): 32.82
left side slope (%): 19.78

station (ft.): 550.00
slope at station: -0.04

Refer to the Channels tab's Report button description for details of the report.

Select any channel polyline created by GeoFluv. Select objects:

Pulldown Menu Location: Natural Regrade

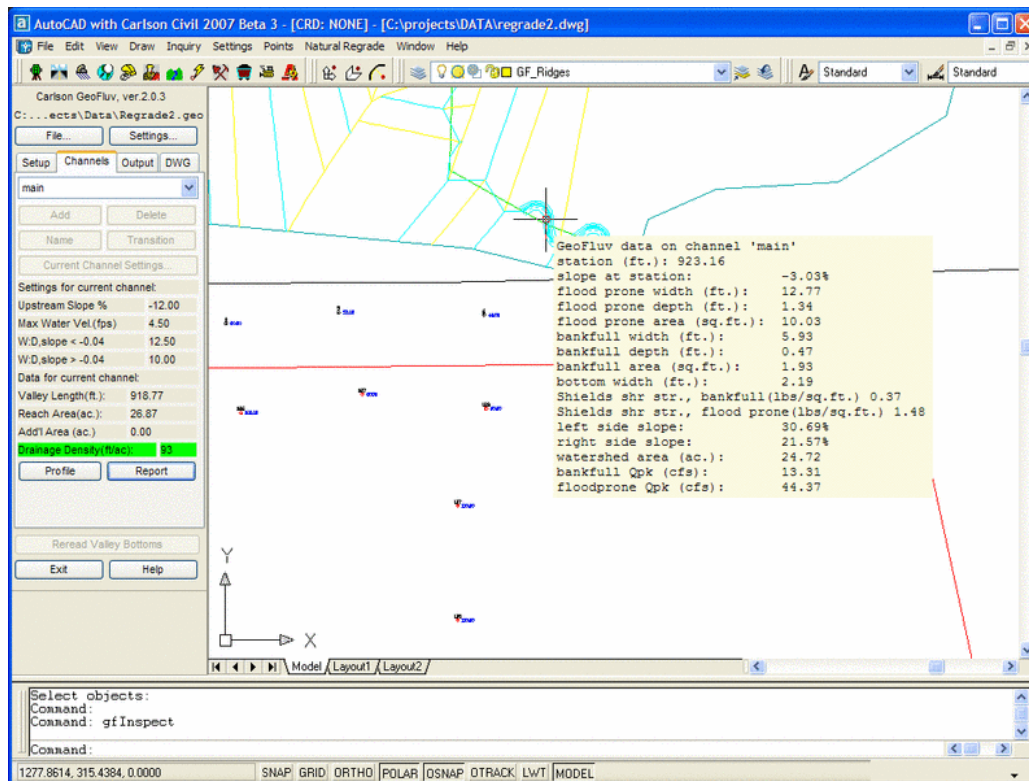

Keyboard Command: gfReport

Prerequisite: Design geofluv

GeoFluv Channel Inspector

This command allows the user to obtain detailed design information from the *Natural Regrade* drawing by passing the cursor over the point of interest (on a polyline in the drawing).

When the user left-clicks once on the GeoFluv Channel Inspector command in the *Natural Regrade* dropdown menu, a check mark appears to the left of the command signaling the user that the command is toggled on. Then when the user passes the cursor over any polyline in the drawing, detailed GeoFluv design information for that point on the polyline appears on the screen next to the cursor. The command remains active until the user left-clicks on the command in the dropdown menu to toggle it off.

The GeoFluv Channel Inspector works on ridge, valley, and contour polylines also, but obviously does not present channel design information for those polylines. This convenient and powerful feature allows the user to inspect designs without having to refer back and forth from a database to the drawing, but instead read directly from the drawing. Note that the information displayed is not an average for the entire line, but is specific to location on the line and can vary even in very small distances.

There are some limitations to be aware of. First, to inspect the zig-zag A-channel, the GeoFluv project that was used to create that channel must currently be open in the Design Geofluv Regrade tool. Secondly, using almost any command, including Edit Longitudinal Profile and Auto Longitudinal Profile, to modify a channel polyline causes the extended entity data to be removed which prevents the GeoFluv Channel Inspector from having certain information that it needs.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfInspect

Prerequisite: Design geofluv

View Longitudinal Profile

This Natural Regrade dropdown menu command allows the user to view the longitudinal profile of any polyline in the GeoFluv design and obtain the elevation and slope at any point along the profile.

Command prompt:

Select objects

The user places the cursor over the polyline that they want to inspect and left-clicks. The profile viewer appears on the screen. The user can move the cursor along the profile and the station, elevation, and slope information are displayed along the bottom of the dialog box at the position indicated by the cursor. Simultaneously, an arrow moves along the channel in the drawing pointing to the location along the longitudinal profile that the cursor is covering on the profile viewer.

Radio buttons for Vertical Exaggeration settings aid the user in evaluating low relief profiles.

Radio buttons also allow the user to toggle back and forth between Zoom and Pan drag action for the mouse. When set to Zoom, holding the mouse left-click button down while moving the mouse up and down will cause the viewer

to zoom in and out on the longitudinal profile. When set to Pan, holding the mouse left-click button down while moving the mouse across the viewer will allow the user to pan around the longitudinal profile. Whether in Zoom mode or Pan mode, the middle mouse button can be held down to pan the profile in the display. Thus, if the user has a middle mouse button, staying in the Zoom mode and using the middle mouse button to pan is most efficient.

The Grid Ticks Only toggle allows the user to see a grid on the profile display or to see only tick marks on the axes.

The GeoFluv design made using Natural Regrade typically has many sub-watershed ridge and swale lines. The lines are 3D polylines and their profiles are generated from the user inputs (based on project area field work). The blue bar at the top of the View Longitudinal Profile pop-up dialog box will display the name of the line the user is viewing to supplement the visual dot-within-a-triangle that tracks along the line on the drawing.

The naming convention for the lines is to identify the sub-watershed, e.g., main L2R1 (note L and R are capitalized when identifying channels and their subwatersheds), followed by the sub-watershed ridge or swale line identification where lower case 'r' indicates a sub-watershed ridge line and a lower case 's' indicates a sub-watershed swale line. The sub-watershed ridge or swale line letter is followed by a number indicating its sequential order from the head of the sub-watershed. Using this convention, the 'main L2R1 r1' designation identifies the first sub-watershed ridge on the right valley wall (r1) of the sub-watershed that holds the first tributary entering from the right valley wall (R1) of the second tributary entering from the left valley wall (L2) of the main channel.

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfViewPro

Prerequisite: Design geoflucv

Edit Longitudinal Profile

The Natural Regrade dropdown menu's Edit Longitudinal Profile command gives the user quick access to a powerful longitudinal profile editing tool that can change the entire longitudinal profile of a 3D polyline or just a portion of the profile.

Examples of tasks that this profile editor is well suited for is creating saddles on a long ridge line to further dissect topography and creating a 'hump' on the ridge profile where the user might want to leave excess material.

When the user left-clicks on Edit Longitudinal Profile, the command line directs the user to Select 3D Polyline and the command prompt reads, "Select objects:." The user moves the cursor to the 3D polyline that they wish to edit and left-clicks on the polyline. The "Edit Longitudinal Profile – Double Click to Adjust Profile" pop-up dialog box appears on the screen. The dialog box has a profile viewer similar to the View Longitudinal Profile command viewer. The user can move the cursor along the profile and the station, elevation, and slope information are displayed along the bottom of the dialog box at the position indicated by the cursor. Simultaneously, an arrow moves along the channel in the drawing locating the point along the longitudinal profile that the cursor is covering.

The dialog box gives the user toggle settings for the following options:

Adjust connecting linework, when toggled on (the default setting) by left-clicking on the box, will cause Natural Regrade to automatically change all connecting linework, e.g., connecting ridges, to smoothly fit the new longitudinal profile. To update contours to reflect the modified surface, the Draw GeoFluv Contours command can be used.

Grid Ticks Only toggle allows the user to see a grid on the profile display or to see only tick marks on the axes.

Radio buttons give the user the following options:

Vertical Exaggeration settings aid the user in evaluating low relief profiles.

Zoom and Pan drag action for the mouse - When set to Zoom, holding the mouse left-click button down while moving it up and down will cause the viewer to zoom in and out on the longitudinal profile. When set to Pan, holding the mouse left-click button down while moving it around the viewer will allow the user to pan around the longitudinal profile. Whether in Zoom mode or Pan mode, the middle mouse button can be held down to pan the profile in the display. Thus, if the user has a middle mouse button, staying in the Zoom mode and using the middle mouse button to pan is most efficient.

A slider button on the Blend 'x' % control allows the user to specify the percentage of the polyline to which they want to apply the profile change. As the user holds down the mouse left-click button on the slider button and moves the slider button left to right, the percentage of the line that will be affected by the edit is displayed above the slider.

When the user has specified the settings that they want to use for the edit, they move the cursor above or below the longitudinal profile in the display to the elevation that they want to raise or lower the profile at that point and double left-click on the mouse. The profile will raise at that point to the specified elevation and the line will blend from that elevation to the remaining profile over the distance specified using the "Blend 'x' %" slider control. The user can make multiple adjustments to the longitudinal profile in this fashion until the desired profile is achieved. The user then left-clicks on the OK button to apply the changes. Left clicking on the Cancel button will close the dialog box without applying the changes.

The user can toggle on the 'Original Line' option that will display the original profile in a different color to help the user see the effect of the proposed profile edits

The GeoFluv design made using Natural Regrade typically has many sub-watershed ridge and swale lines. The lines are 3D polylines and their profiles are generated from the user inputs (based on project area field work). The blue bar at the top of the Edit Longitudinal Profile pop-up dialog box will display the name of the line the user is viewing to supplement the visual dot-within-a-triangle that tracks along the line on the drawing. The Edit Longitudinal Profile command allows the user to make an irregular profile that can vary from a smooth convex to concave profile, for example when the user wants to make dips in a ridgeline profile to make saddle features. (Note: Because it can make irregular profiles it is not recommended for use on stream channels as knickpoints subject to erosion could be designed.)

The naming convention for the lines is to identify the sub-watershed, e.g., main L2R1 (note L and R are capitalized when identifying channels and their subwatersheds), followed by the sub-watershed ridge or swale line identification where lower case 'r' indicates a sub-watershed ridge line and a lower case 's' indicates a sub-watershed swale line. The sub-watershed ridge or swale line letter is followed by a number indicating its sequential order from the head of the sub-watershed. Using this convention, the 'main L2R1 r1' designation identifies the first sub-watershed ridge on the right valley wall (r1) of the sub-watershed that holds the first tributary entering from the right valley wall (R1) of the second tributary entering from the left valley wall (L2) of the main channel.

Command Prompt:

Select objects:

Pull-down Menu Location: Natural Regrade

Keyboard Command: gfEditPro

Prerequisite: Design geofluv

Auto Longitudinal Profile

The Natural Regrade dropdown menu's Auto Longitudinal Profile command gives the user quick access to a powerful longitudinal profile editing tool that can change the entire longitudinal profile of a 3D polyline or just a portion of the profile in a smooth curve by specifying starting and ending slopes.

When the user left-clicks on Auto Longitudinal Profile, the command line directs the user to Select 3D Polyline and the command prompt reads, "Select objects:". The user selects the 3D polyline that they wish to edit and left-clicks on it. The Auto Longitudinal Profile pop-up dialog box appears, which gives the user the following options.

Top Slope can be user-specified by typing a value into the edit box, or the default value, which is the present value for the selected 3D polyline, can be accepted. When the user exits the edit box, e.g., with Tab key, an entered slope value is applied to the profile and the user can inspect the revision on the profile viewer. The user can make multiple adjustments to the longitudinal profile in this fashion until the desired profile is achieved. This setting will be the slope at the upper end of the longitudinal profile.

Bottom Slope can be user-specified by typing a value into the edit box, or the default value, which is the present value for the selected 3D polyline, can be accepted. When the user exits the edit box, e.g., with Tab key, an entered slope value is applied to the profile and the user can inspect the revision on the profile viewer. The user can make multiple adjustments to the longitudinal profile in this fashion until the desired profile is achieved. This setting will be the slope at the lower end of the longitudinal profile.

Connect to Ridge allows the user to allow a longitudinal profile, e.g., on a ridgeline, to have an extended convex profile before beginning its concave longitudinal profile. When toggled off (the default setting with the "Convex curve length (ft.)" edit box inactivated), the GeoFluv approach will design a longitudinal profile between the upper and lower elevations of the 3D polyline by constructing a vertical curve using the specified bottom and top slope percents. When toggled on, the "Convex curve length (ft.)" edit box is activated and the user can type in a desired distance value that the upper end of the profile can remain convex before the vertical curve is applied using the specified Top Slope percentage. This feature can be used to place extra material in a hump, for example on a ridgeline, and still have the face of the material grade in a concave profile toward the valley bottom.

When Adjust connecting linework is toggled on (the default setting) by left-clicking on the box, Natural Regrade will automatically change all connecting linework, e.g., connecting ridges, to smoothly fit the new longitudinal profile. To update contours to reflect the modified surface, the Draw GeoFluv Contours command can be used.

The dialog box has a profile viewer similar to the Edit Longitudinal Profile command viewer. The user can move the cursor along the profile and the station, elevation, and slope information are displayed along the bottom of the dialog box at the position indicated by the cursor. Simultaneously, an arrow moves along the channel in the drawing pointing to the point along the longitudinal profile that the cursor is covering.

Radio buttons for Vertical Exaggeration settings aid the user in evaluating low relief profiles.

Radio buttons also allow the user to toggle back and forth between Zoom and Pan drag action for the mouse. When set to Zoom, holding the mouse left-click button down while moving it up and down will cause the viewer to zoom in and out on the longitudinal profile. When set to Pan, holding the mouse left-click button down while moving it around the viewer will allow the user to pan around the longitudinal profile. Whether in Zoom mode or Pan mode, the middle mouse button can be held down to pan the profile in the display. Thus, if the user has a middle mouse button, staying in the Zoom mode and using the middle mouse button to pan is most efficient.

Grid Ticks Only toggle allows the user to see a grid on the profile display or to see only tick marks on the axes.

The user can toggle on the 'Original Line' option that will display the original profile in a different color to help the user see the effect of the proposed profile edits.

The GeoFluv design made using Natural Regrade typically has many sub-watershed ridge and swale lines. The lines are 3D polylines and their profiles are generated from the user inputs (based on project area field work). The blue bar at the top of the Auto Longitudinal Profile pop-up dialog box will display the name of the line the user is viewing to supplement the visual dot-within-a-triangle that tracks along the line on the drawing. The Auto Longitudinal Profile command allows the user to make a smooth profile between the upper and lower line elevations by varying the upper (Top Slope) and lower (Bottom Slope) profile-starting slope values. The user sets either the Top Slope or Bottom Slope value in the appropriate edit box and then clicks on the other box to update the slope profile. (Note: Because it can make profiles based on slope values other than the user's field-determined upstream and downstream values, it is not recommended for use on stream channels as knickpoints subject to erosion could be designed.)

The naming convention for the lines is to identify the sub-watershed, e.g., main L2R1 (note L and R are capitalized when identifying channels and their sub-watersheds), followed by the sub-watershed ridge or swale line identification where lower case 'r' indicates a sub-watershed ridge line and a lower case 's' indicates a sub-watershed swale line. The sub-watershed ridge or swale line letter is followed by a number indicating its sequential order from the head of the sub-watershed. Using this convention, the 'main L2R1 r1' designation identifies the first sub-watershed ridge on the right valley wall (r1) of the sub-watershed that holds the first tributary entering from the right valley wall (R1) of the second tributary entering from the left valley wall (L2) of the main channel.

When the user has specified the settings that they want to use for the edit, they then left-click on the OK button to apply the changes. The new vertical curve will be applied to the GeoFluv design.

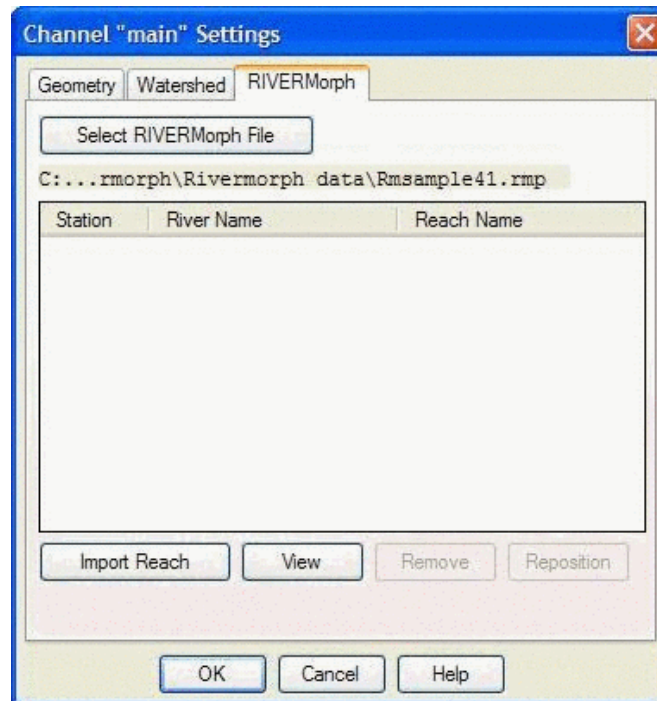

Pulldown Menu Location: Natural Regrade

Keyboard Command: gfAutoPro

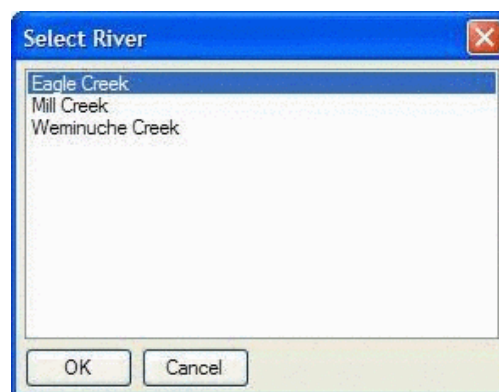

Prerequisite: Design geofluv

RIVERMorph tab

The RIVERMorph tab provides for importation of stream reach design files from the 2-dimensional RIVERMorph program into *Natural Regrade* to produce a 3-dimensional design. The resulting 3-dimensional design is in a .tin format that can be directly exported to machine-control programs like Carlson Grade that guide heavy equipment operators to build the design without the need for additional field survey and staking work.

The Select RIVERMorph File button accesses the Open RIVERMorph Project - (rmp) file selection dialog box. The user can browse through RIVERMorph files to select the file to import, or select the file from a list of recently used files. When the user highlights the desired file and clicks the Open button, the file name appears below the Select RIVERMorph File button and the user is ready to begin importing the desired RIVERMorph reach.

When the user clicks on the Import Reach button, the Select River dialog box pops up; the user highlights the desired stream file and clicks OK to select the stream.

The Select Reach dialog box then pops up and the user highlights the desired reach and clicks OK. *Natural Regrade* will advise the user by a pop-up dialog if there is a mismatch in slopes or, if the slope range is valid, will display the Place RIVERMorph Reach pop-up dialog box.

The Place RIVERMorph Reach dialog box gives the user options for *Natural Regrade* to place the reach at appropriate locations based on design .tin elevations, or at user-specified points of known elevation. If the user selects a point with a slope mismatch, *Natural Regrade* will place the reach at the nearest matching point.

When the reach has been placed, it will be displayed in the reach list on the RIVERMorph tab in the Channel "(name)" Settings dialog box. The user can highlight any reach on the list and click on the View button to get a summary of the reach details. The Remove button allows the user to select a reach from the list and delete it from the current GeoFluv project. The Reposition button allows the user to revise the RIVERMorph reach location in the GeoFluv project.

When the user clicks the OK button at the bottom of the RIVERMorph tab dialog box, the RIVERMorph reach design data are imported into the GeoFluv design input data in *Natural Regrade*. The user can use the Preview

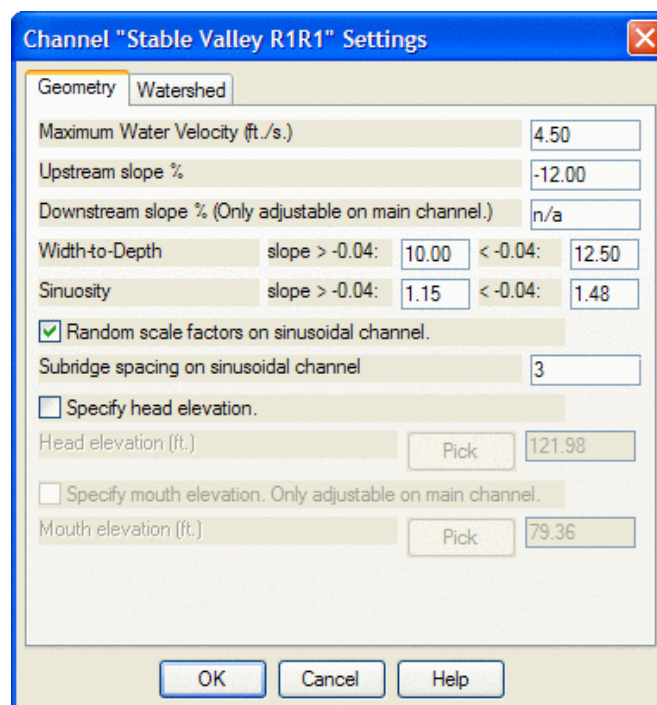

button on Output tab to verify the reach location. When the user clicks the Draw Design Surface button on the Output tab, the RIVERMorph data are made into a 3-dimensional design in the GeoFluv project.

Settings

This button allows the user to specify settings that will vary the channel discharge and the related channel geometry and upland ridge and subridge morphology specific to the subwatershed active in the Channels tab current channel name box. The settings are organized on two tabs, Geometry and Watershed. The Geometry tab has settings for maximum velocity, upstream slope, downstream slope, width to depth ratio, sinuosity, random scale factors on sinusoidal channel, subridge spacing on sinusoidal channel, and channel head and mouth elevation. The Watershed tab has settings for runoff coefficient when using the Rational Runoff Method (the default method), or to allow input of discharge computed by an alternate method, and to add runoff from contiguous land areas.

Command Prompt: (blank, dialog box appears)

Left-clicking on the "Settings" button brings up the "Channel 'xxxx' Settings" dialog box that gives the user the options shown below. The optional settings made in the "Channel 'xxxx' Settings" dialog box will apply only to the Channel 'xxxx' subwatershed. The blue subject bar at the top of the dialog box displays the name of the channel's subwatershed to which the Settings will apply. The user will select a different channel in the "Current Channel" window of the "Channels" tab and then left-click on "Settings" to make these changes to other channels and their subwatersheds, e.g., 'Channel yyyy', 'Channel zzzz,' etc. After specifying the settings in the dialog box, the user can apply them by left-clicking the "OK" button at the bottom of the dialog box.

Maximum Water Velocity (ft./s.): The user can specify a maximum water velocity for the channel by typing the desired value into the edit box. Velocity is inversely related to channel cross-sectional area for a given discharge according to the relationship $Q/a=v$, where Q is discharge (cubic feet per second), a is area (square feet), and v is velocity (feet per second).

Upstream slope %: The user can specify the upstream slope for the channel using this edit box. This feature can be used to vary the channel's longitudinal profile that will join to a mouth slope dictated by the receiving channel slope at their confluence. It can also be used to tie into the upstream slope when the headwaters of the channel are at the GeoFluv Boundary and join with an upstream channel slope draining "Additional watershed area."

Downstream slope % (Only adjustable on main channel.): The user can specify the mouth slope for the main channel at the GeoFluv Boundary to join smoothly to the downstream channel slope by typing the desired slope into the edit box. If the Channel's tab Settings dialog box is open for any tributary to the main channel, the edit box will read "n/a."

Width-to-Depth, slope > -0.04: xx.xx , < -0.04: xx.xx: The user can specify width-to-depth ratios for channels with slopes greater and less than -0.04 by typing the desired width-to-depth ratio into the edit box. The default values are 10.00:1 for channels with greater than -0.04 slope and 12.5:1 for channels with less than -0.04 slope.

Sinuosity, slope > -0.04: xx.xx , < -0.04: xx.xx: The user can specify sinuosity for channels with slopes greater and less than -0.04 by typing the desired sinuosity into the edit box. The default values are 1.15 for channels with greater than -0.04 slope and 1.48 for channels with less than -0.04 slope.

Random scale factors on sinusoidal channel: The meander pattern of the idealized draft valley bottom channels (<-0.04) will be determined by mathematical constants and thus will be very uniform, changing (enlarging) as a function of flow (related to discharge) and valley bottom orientation. Checking the 'Random scale factors on sinusoidal channel' box will randomly vary the constant values, within their acceptable ranges for stable channels, such that radius of curvature, meander length, and meander belt width vary. This random variation produces a more natural appearance for the channel and related upland landforms.

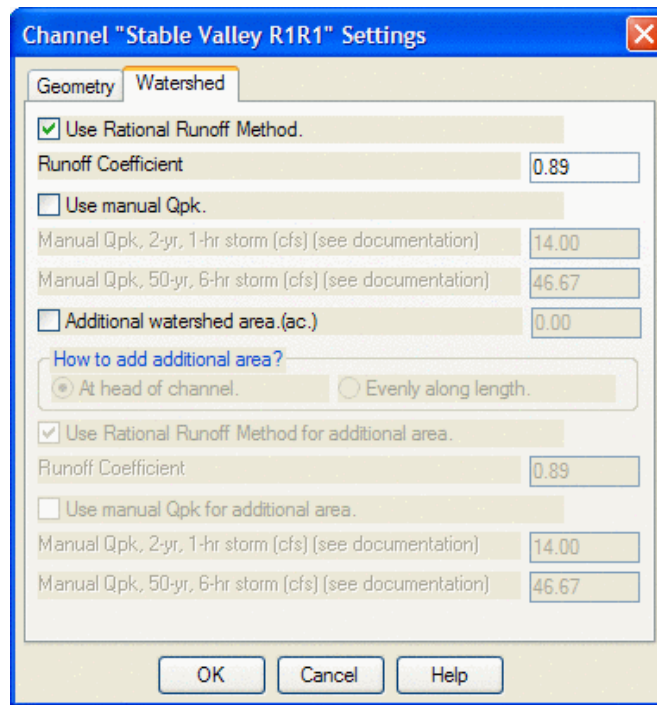

Subridge spacing on sinusoidal channel: This setting applies to channels with slopes <-0.04. The lower-gradient channels, with slopes <-0.04, may have an adjacent floodplain (or terrace) area and the uplands landform may begin some distance from the channel banks. The user can use this setting to create some of this open floodplain or terrace area by increasing the spacing between subridges. A subridge spacing setting of 3, for example, will create a subridge on every third meander bend of the channel with an opening for the floor of the subridge valley between these subridges.

Note: The user must select odd-number spacing; specifying even number spacing will result in all subridges and subridge valleys on opposite sides of the valley. Even spacing can be made with manual SurvCADD editing. The user can also manually add or delete subridges, or vary subridge longitudinal profiles using *Natural Regrade's* longitudinal profile editors, to introduce more variation to the draft GeoFluvTM landform.

Specify head elevation: The user can specify the head elevation for any channel, rather than accepting an elevation that is automatically determined from the Pre-disturbance file specified in the Settings tab. The user checks the box to select this option and then proceeds in one of two ways. The user can type a desired headwater elevation into the Specify Head Elevation field. Alternately, the user can left-click on the Pick button and then identify a (COGO) point of the desired elevation on the drawing. To use the Pick method, the user left-clicks the cursor near the desired point and then, by moving the cursor diagonally, creates a box around the point. The user left-clicks again to define the opposite corner of the box surrounding the desired point and the point elevation is entered into the Specify Head Elevation field.

Specify mouth elevation: The user can (and should) specify the mouth elevation for the main channel only. This setting becomes inactive on the tributary channels because their mouth elevation is controlled by the main channel's longitudinal profile. The procedures for setting the elevation are the same as in Specify Head Elevation above.

[Note: The user should specify the mouth elevation of the main channel in the GeoFluvTM project area because this elevation and the channel slope immediately downstream of this point **may be the most critical variables** for assuring a stable landform design. The elevations that *Natural Regrade* interpolates from the 'Pre-disturbed surface' specified in the Settings tab are appropriate for creating and comparing draft design alternatives, but a channel mouth elevation interpolated from a map surface can vary from the actual elevation on the order of feet. A channel will be expected to adjust to elevation and slope inaccuracies by erosion.]

Use Rational Runoff Method: This is the default setting for calculating runoff to the GeoFluvTM channels in *Natural Regrade* and is the setting that will be used when the box is checked. The Rational Runoff Method calculates a peak discharge using the formula $Qpk = CIA$, where C is the runoff coefficient, I is the rainfall intensity, and A is the acreage. The user enters the appropriate runoff coefficient for the area within the GeoFluvTM boundary in the Runoff Coefficient field and *Natural Regrade* does all the related calculations.

Use manual Qpk: The user can choose to input a peak discharge value calculated by some other method should he wish by checking the 'Use Manual Qpk' option. When the user checks this box, the runoff coefficient field in the Use Rational Runoff Method setting (and use of that method) becomes disabled. The user then types in the peak discharges that he wants to use for the two storm events.

[Note: The GeoFluvTM approach uses the 2-yr, 1-hour storm event to calculate bankfull discharge and the 50-yr, 6-hr event to calculate a flood-prone discharge. Reclamation landforms constructed using the GeoFluvTM approach that use these inputs have been stable in a very harsh and erosive high-altitude desert environment through extreme storm events. Using other input values may give unsatisfactory results.]

Additional Watershed Area: This setting allows the user to incorporate runoff from contiguous lands into the GeoFluv Boundary. When the user checks the Additional Watershed Area box, the fields below become active and offer a choice of how the additional runoff will enter the GeoFluv Boundary. If the head of the GeoFluvTM channel is downstream of the Additional Watershed Area, as when joining to an upstream channel reach, the user should select the "At head of channel" option. The GeoFluvTM channel's headwater dimensions will then be sized to accommodate the runoff from the area above the channel headwaters within the GeoFluv Boundary and the Additional Watershed Area upstream of that. If the Additional Watershed Area is subparallel to the GeoFluvTM channel, checking "Evenly along length" will introduce the runoff from the Additional Watershed Area gradually along the GeoFluvTM channel reach and the channel dimensions will increase proportionately along the reach. The remainder of the settings are as described above in "Use Rational Method" and "Use manual Qpk."

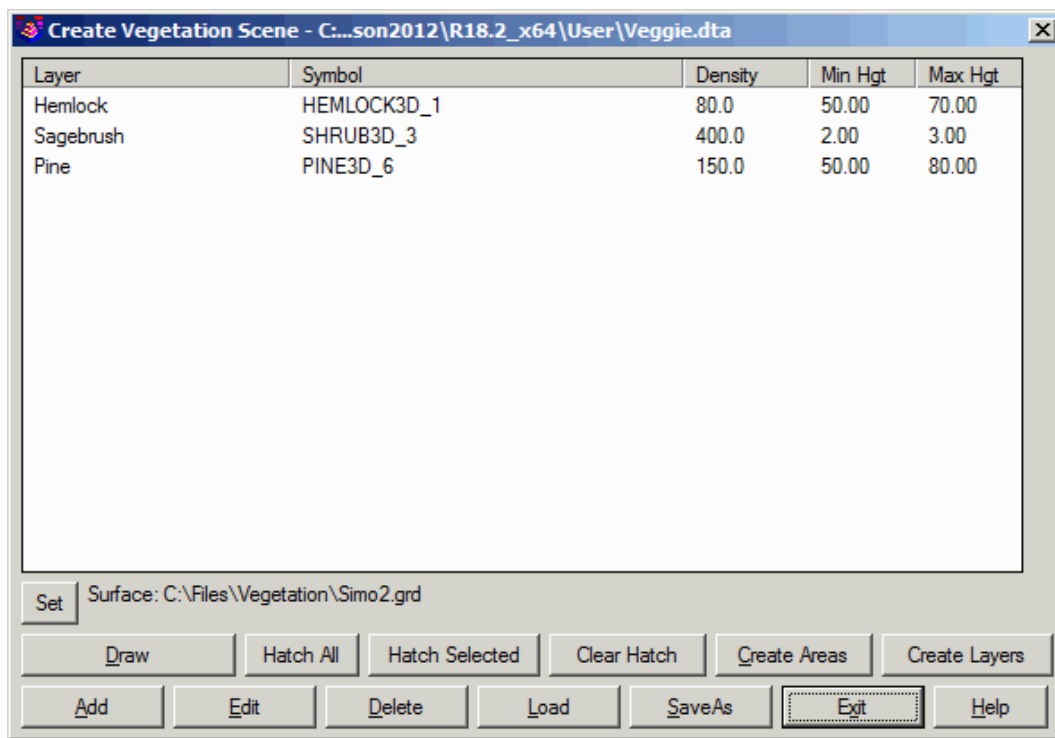

Reread Valley Bottoms

This command updates GeoFluv with information about changes to the valley bottom polylines (or GeoFluv Boundary polyline).

The valley bottom and GeoFluv Boundary 2D polylines are user inputs for fundamental values to the GeoFluv program. They are used to directly calculate valley length, subwatershed area, and drainage density, and affect discharge calculations and channel dimensions. All commands that need to use these input polylines always check the drawing first and use the current version of these polylines in the drawing. The primary use of this command is to quickly update the data displayed on the Setup tab, the Channels tab and the Output tab after a change has been made in the drawing to either the GeoFluv Boundary polyline or any valley bottom polyline.

Create Vegetation Scene

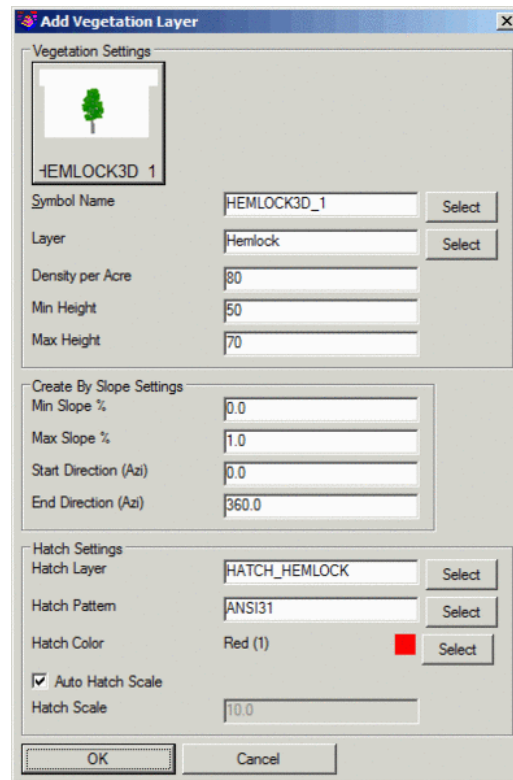

This command places 3D symbols for vegetation for visualization by commands such as 3D Viewer Window and Surface 3D Flyover. This command is layer based where closed polylines on different layers are used to different types of vegetation. The vegetation layers are defined in the dialog shown here. The list shows the layer name, symbol name and parameters for each vegetation type. Use the Add, Edit and Delete functions to manage the list of vegetation. The SaveAs and Load functions store and recall the vegetation definitions to a .veg file. The Draw function creates symbols in the drawing within closed polylines on the vegetation layers using the vegetation parameters for symbol name, size and density. The Hatch functions hatch the closed vegetation polylines as a way to visualize that the vegetation areas are correctly defined. The Create Areas function creates closed polylines on the vegetation layers using the vegetation parameters for slopes and the specified surface model. The Create Layers function creates the vegetation layers in the drawing if they don't already exist.

The Add and Edit functions define the vegetation parameters in the dialog shown here. A preview of the 3D symbol is shown along with the symbol name. To change the symbol, type in a name or pick the Select button to pick from the Symbol Library. There are several 3D symbols for vegetation included in the default install under the 3D Trees category in the symbol library. To add your own symbol to the library, run the Settings->Symbol Library command. The symbols should be created at unit height (height=1) so that the program can scale to the target height. The Layer is used both for the closed polyline for the vegetation area and for the vegetation symbols. Density Per Acre controls how many vegetation symbols to draw with the area. The Min/Max Heights define the range of heights for the vegetation symbols. The program will randomly size the symbols within this range.

The Create By Slope Settings apply to the Create Areas function. The Min/Max Slopes control the range of surface slopes that the vegetation exists. The Start/End Directions control which slope facing directions that the vegetation exists. The directions should be entered in clockwise order. For example, for vegetation that only occurs on south facing slopes, the Start Direction could be set to 90 and the End Direction set to 270.

The Hatch Settings apply to the Hatch functions. These hatch settings include the pattern, layer, color and scale. The Auto Hatch Scale option sets the scale to fit within the area.

When viewing with the 3D Viewer Window or Flyover, use the Apply Surface Smooth, Apply Texture and Display Sky options to improve the image.

Pulldown Menu Location: Natural Regrade

Keyboard Command: vegdef

Prerequisite: Closed polylines and surface file

Geology Module

15

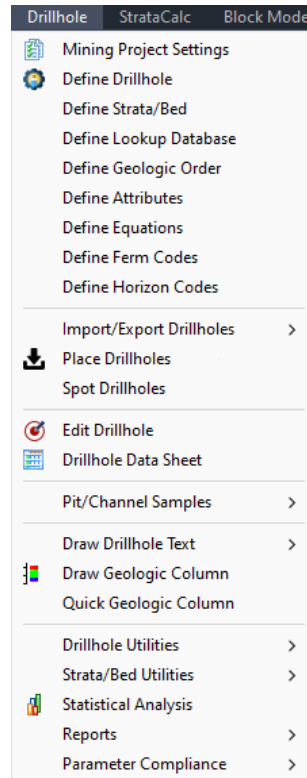

The Geology Module consists of various commands for defining the geologic deposit. Major features include

drillhole analysis and visualization, strata correlation, block modelling, cross section extraction, reserve calculation, and more! Commands are accessible from the Drillhole, StrataCalc, Block Model, and Grids pulldown menus.

Drillhole Menu

The Drillhole menu commands define, input, edit and report drillhole data.

Mining Project Settings

This command sets the current file names used for several Carlson definition files. For example, this command assigns the Drillhole Configuration file (.ch file) to be used for drillhole placement in other routines such as Place Drillhole and Drillhole Data Sheet. The Mining Project Manager lets you set up different groups of definitions. For example, if you work with two mines, then you can have two sets of strata definitions (strata1.sdf and strata2.sdf), two sets of attribute definitions (attrib1.atr and attrib2.atr), etc. When switching between the projects, you can load the .mpj file to instantly update all of your relevant settings.

Whenever a command is executed that creates one of the below files, it will be automatically added to the Mining Project Manager. However, you can also specify the file names directly from this command.

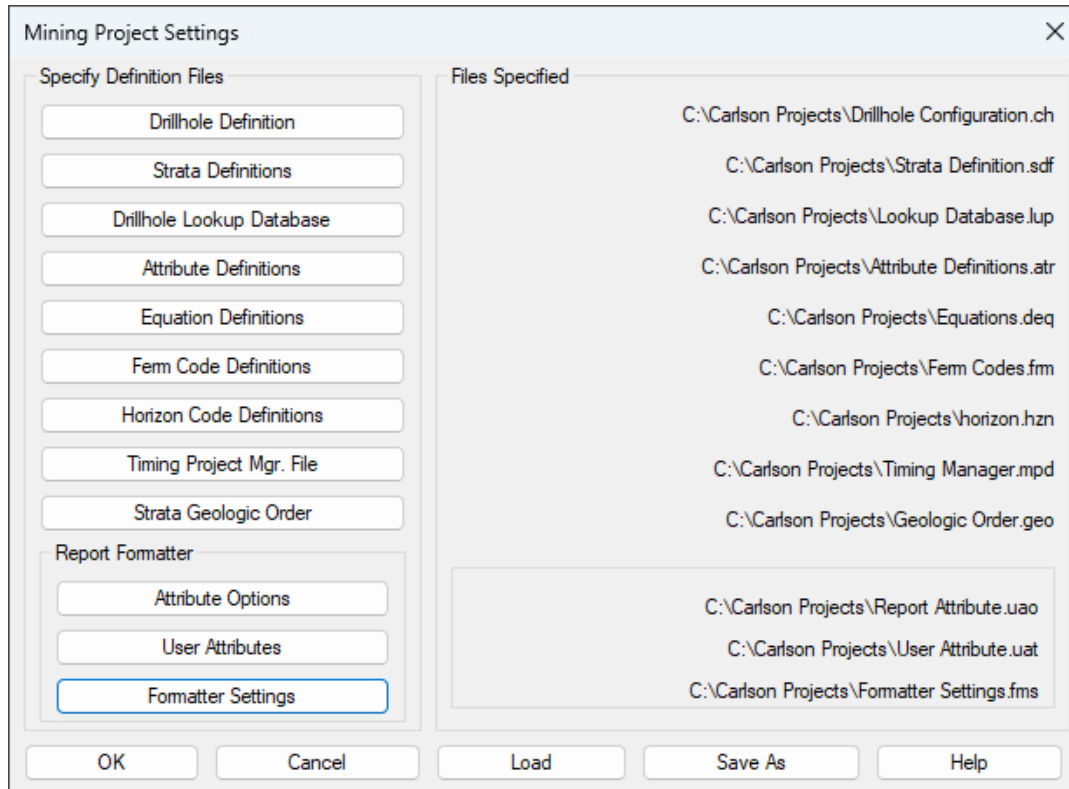

All the file names in Mining Project Manager are saved with the drawing in the drawing .INI file. You can also save this set of file names to a mining project file (.mpj) by picking the Save button. The Load button will then recall the set of file names from the selected .MPJ file.

Following is a list of commands that will create the files shown in the Mining Project Manager. The extensions of the files are shown in the dialog window below.

1. Drillhole Definition: Define Drillhole
2. Strata Definitions: Define Strata/Bed
3. Drillhole Lookup Database: Define Lookup Database
4. Attribute Definitions: Define Attributes

5. Equation Definitions: Define Equations
6. Ferm Code Definitions: Define Ferm Codes
7. Horizon Code Definitions: Define Horizon Codes
8. Timing Project Mgr. File: Underground Timing, Surface Equipment Timing, Solids Timing

9. Strata Geologic Order: Define Geologic Order
10. Attribute Options: In the Report Formatter, Attribute Options
11. User Attributes: In the Report Formatter, User Attributes.
12. Formatter Settings: In the Report Formatter, Export

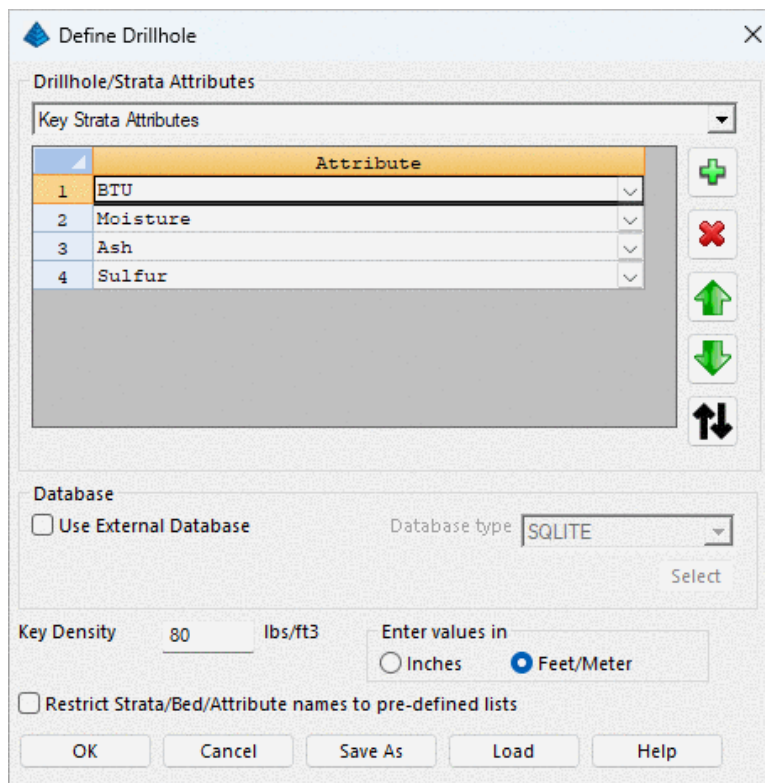

Pulldown Menu Location: Drillhole

Keyboard Command: mproject

Define Drillhole

Define Drillhole is a prerequisite to creating, importing, and processing drillholes. This is a configuration file containing settings for manual drillhole entry, data storage, predefined attributes and the default key density. There is no geologic data stored in this .CH file. The dialog for this command is shown below.

Drillhole/Strata Attributes: This dropdown menu displays the attributes that have been defined in the spreadsheet below this option. Any attributes defined in this spreadsheet will be applied to all drillholes/strata, regardless if the drillholes have a value associated with the attribute. Attributes may be relate to the drillhole itself (e.g. date drilled, drilling company), or to key/non-key strata within the drillhole(e.g. density, assay). You may also define attributes as combinations of other attributes by writing an equation. The equation must start with an equal sign (=) and can include standard mathematical operators (+ - * /). Three examples of attribute equations are given below.

=LBS*SULF/(10⁶*BTU)

=MOIST/LBS

=BTU/1000

Attributes may be added, removed, and reordered with the use of the green icons to the right of the spreadsheet. Attributes may be sorted alphabetically with the use of the sort button. If an attribute has already been defined with the Define Attributes command, it will be available in the dropdown menu to the right of each attribute name. Drillhole attributes may also be defined in the Define Lookup Database command. Strata Attributes may also be defined in the Define Attributes command. However, it is not necessary to predefine drillhole or strata attributes - they may simply be imported directly with the drillholes or added to the drillholes manually with the Edit Drillhole command.

Use External Database: Drillholes may be stored in one of two methods. The default method is leave this option disabled. In this case, the drillholes will be stored directly in the drawing file as extended entity data within the CAD Dictionary. This method is recommended for most projects as there is no requirement to maintain an external file. However, if your project contains thousands of drillholes, the drawing may become exceedingly large and sluggish. In this case, you may wish to enable this option, as the drillhole data will then be stored in a separate file and referenced when needed. Any changes made to the drillholes in the drawing will update the external database, and vice-versa. When enabled, you must select a **Database Type** to set the format of the external database. The four types of databases are:

- **SQLITE** - Data will be stored as a .cdb (Carlson Database) or an .sqlite file. The SQLITE format is open-source and can be viewed/maintained with a variety of free programs. Common web browsers even offer extensions for viewing these files.
- **MDB** - Data will be stored as a .mdb (Microsoft Database - used with older versions of Microsoft Access). Please note that Microsoft now offers a new .accdb format which replaces the .mdb format. As a result, the MDB format is not fully supported and may not function properly on 64-bit computers. If your drillhole data is already stored in this format, it is recommended to save it as an .accdb file within Microsoft Access.
- **ACCDB** - Data will be stored as an .accdb (Microsoft Access Database) file.
- **ODBC** - Data will be stored in one of a variety of other formats such as Excel files or customized database formats.

After selecting a database format, you will need to click the **Select** button to create a new database file or select an existing one. It is important to note that you will still need to import the drillholes after creating this file. If you need to import drillhole data directly from a database file, you can do so through the Drillhole Import command.

Key Density: This field is the default density used to calculate the weight of key strata. The units are lbs/ft³ or kg/m³, depending on the drawing unit system. In addition to this option, there are other ways to specify the density of strata. When calculating reserves, you can select which method to use. By default, if the density is not defined anywhere else, the value set in this dialog will be used.

1. Define Drillhole
2. Define Strata
3. DENSITY grid in a Geologic Model
4. Define Grade Parameters (sets density of each block within a block model)

Restrict Strata/Bed/Attribute Names to Predefined Lists: This option will not import or use any names that don't match up with the predefined names set here, in the Drillhole/Strata Attributes. This allows you to easily filter out drillhole data that is not needed.

Define Strata/Bed

Define Strata serves several purposes. It is an optional settings/configuration file that defines strata and bed hatch patterns, Key status, density, conformance modeling settings, and bed splitting settings. Without the strata definitions predefined, StrataCalc commands will use defaults.

Strata Definitions: C:\Desktop\Current\Simple Geology\Settings\Strata Def.sdf

Strata/Bed Name	Full Name	Key	Color	Hatch	Density	Layer	Draw Legend

Buttons: Edit, Edit Multiple, Add, Remove, Move Up, Move Down, Sort, Draw Legend, Column Options, Read Drillholes, Read Model, Clear, Load, Save, Save As, Help, Exit

Define Strata is a dialog based spreadsheet editor for strata definitions. The first window shows a list of all of the currently defined strata. If no strata are yet defined, this table will be empty. This command is used to define both Strata, such as COAL and Beds, such as C.KEY. To add a new strata definition, click on the Add button. This brings up the Strata Definition dialog. To edit an existing strata definition, highlight the corresponding line in the table and then click on Edit button which also brings up the Strata Definition dialog. To edit the same property for multiple strata such as the Hatch Scale, highlight multiple rows in the spreadsheet by picking with the Ctrl and/or Shift keys, and then pick the Edit Multiple button. You can also use the standard Windows Copy and Paste functions to edit cells in the spreadsheet. To remove a definition, highlight the corresponding line and then click on the Remove button. The Sort button will sort the strata either by name alphabetically, or by following the Geologic Order file that is created with the Define Geologic Order command.

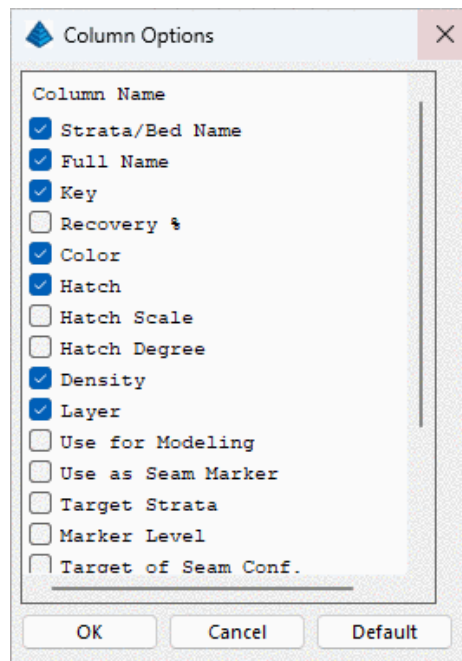

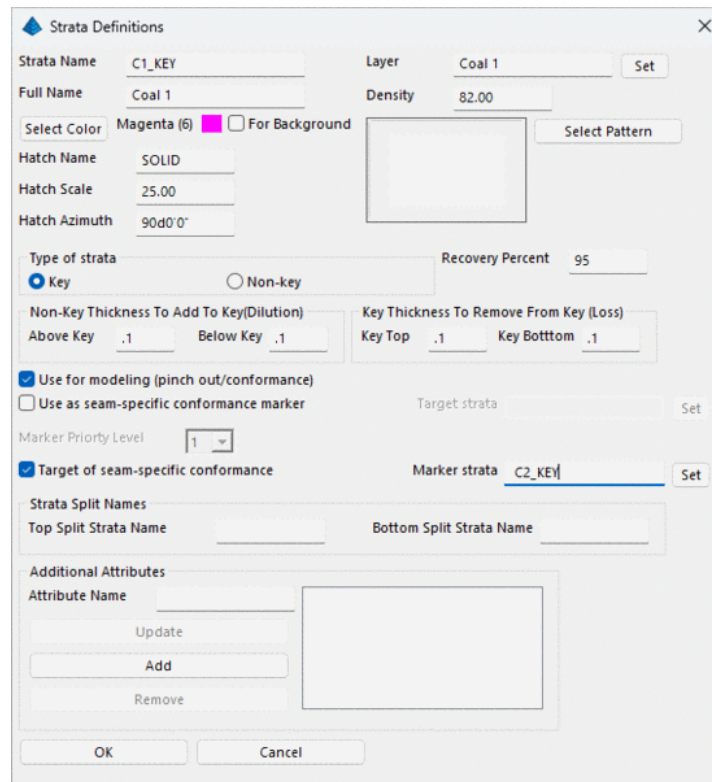

The Draw Legend button will draw a legend of the selected strata. The Read Drillholes button will read the selected drillholes and add a default definition for any strata names found in the drillholes that are not already in the table. The Read Model button will search the Geologic or Mining Model for strata names and put them on the list. The Save and Save As buttons exit Define Strata after saving all the changes in the current session to the strata definition file (.sdf file). The Exit button exits Define Strata without saving.

Draw Legend brings up the selection window to choose which items to display in the legend. Then the legend location is selected.

The Column Options button displays the window to select which columns appear in the main Define Strata Screen.

- **Strata Name:** This is the strata or bed name that is used to match up with the names in the drillhole. Enter in the strata names exactly as they appear in the drillhole. For bed names, there are four extensions or suffixes that must be added to the bed name to match up with the interval of the bed in the drillhole. They are as follows: `_OB`, `_KEY`, `_PARTING`, and `_BOTTOM`, but these options may be modified in Carlson Configure. These must also be entered below, in the target and marker strata windows, and in the strata split names when using bed names. The strata name may use wildcards. This allows fewer strata definitions. The strata list is automatically sorted to place the most general matches in the end of the list. This concept is illustrated in the following example:

Strata definitions: C1, C?, C*, *

Strata in drillhole: COAL, SAND, C2, C1, C12

Applied Matches:

COAL C* This is the least general match to the COAL. '*'=anything

SAND * This word begins with 'S' and all other keys begin with 'C'

C2 C? '?'=any one symbol, so C? is less general than C*

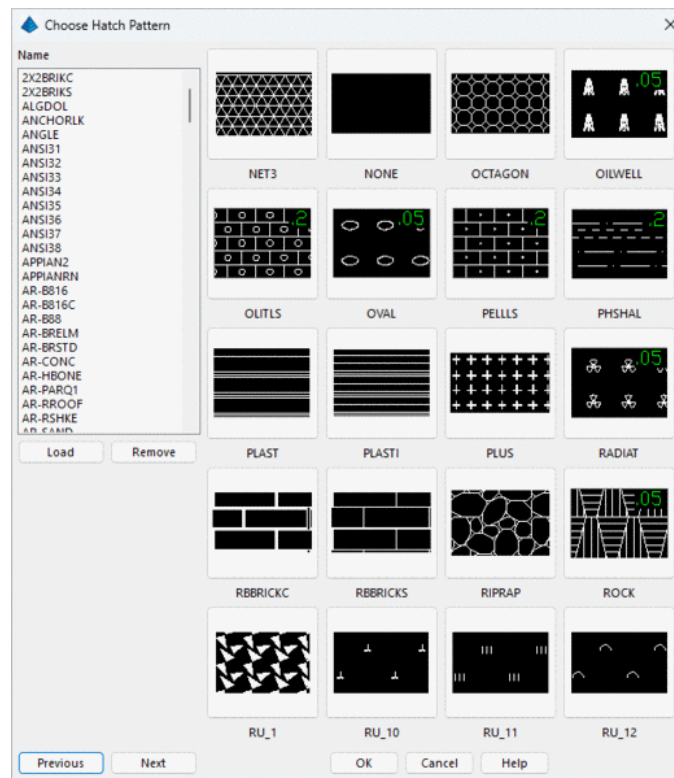

C1 C1

C12 C* C? does not match because of extra symbol on the end.

- **Full Name:** This is the name that will appear as an option in reports and other strata selection windows.
- **Layer:** This is the AutoCAD layer that will be created and used for this strata or bed.
- **Select Color:** This is the color that the solid or hatch pattern will be drawn in for the layer entered above.
- **For Background:** If this is checked, then the background will be a solid fill in the color specified. The hatch

pattern will appear on top of it in a black color.

- **Hatch Name:** This is the name of the selected hatch. A preview of it shows up next to the Select Pattern button. Clicking the Set button will open the dialog of available hatch patterns.
- **Hatch Scale:** This is the scale factor used to size the hatch pattern.
- **Hatch Azimuth:** To rotate a hatch pattern, enter in an azimuth. 90 is horizontal and the default.
- **Density:** Enter in the strata density in pounds per cubic foot or in kg/cubic meter. This is used in Mine Reserves. If no density is set in the strata definition, the program displays "BY_DRILLHOLE" which means that key-strata density of the drillhole will be used. This key-strata density is set by Define Drillhole and can be viewed or modified with Edit Drillhole.
- **Select Pattern:** This button brings up the predefined 127 geologic hatch patterns of Carlson. Each screen with 20 patterns is shown below. Just click on the one to select for each strata or bed.

- **Type of Strata:** The Key or NonKey status can be set here, by strata or bed, which is used by Place Drillholes to determine the type of the user-specified strata name. Also, while entering strata names in Place Drillholes, the strata definitions are checked to see that the strata names are already defined. If the strata name is undefined, the user can define it from there, leave it undefined, or re-enter the name. This check avoids typos and ensures that the strata names match since they should be consistent for the same strata across the drillholes.
- **Recovery Percent:** A recovery can be set for each strata or bed here. It is used in reserves and scheduling.
- **Non-Key Thickness To Add To Key (Dilution):** These values apply to the Use Strata Definitions option in the Surface Mine Reserves and Geologic to Mining Model commands.
- **Key Thickness To Remove From Key (Loss):** These values apply to the Use Strata Definitions option in the Surface Mine Reserves and Geologic to Mining Model commands.
- **Use for modeling (pinch out/conformance):** Turn on this option if the seam is to be used in modeling the drillholes for pinch out and conformance.

- **Use as seam-specific conformance marker:** Turn on this option if this is a "dominant" marker seam that other seams should conform to if needed.
- **Target strata:** Specify the "target" strata to conform to this marker bed. Enter the strata names, with spaces between the names. If they are beds, use the extensions `_TOP`, `_KEY`, `_PARTING` and `_BOTTOM`.
- **Select:** This will bring up a strata/bed list dialog box for easy selection.
- **Marker Priority Level:** This is the priority level for the marker bed. For example, the main marker bed A will have a priority of 1 for Seam C. Seam B is the next dominant, so seam B will have a priority level of 2 for seam C.
- **Target of seam-specific conformance:** This is defining the current seam as a target seam for a different marker seam. Meaning this is not the dominant seam, it will conform to another seam.
- **Marker strata:** Just as in Target Strata above, but the opposite applies; enter in the Marker seam for the current seam to conform to.
- **Strata Split Names (Top and Bottom):** Strata can be defined to split from parent into children strata for modeling. For example, if A splits into A1 and A2, they should be entered in the Top and Bottom Split windows. When modeling, the drillhole that has A will correlate to A1 and A2, with the parting pinching out as it models its way closer to the hole with A. To make sure it is working properly, the seam A should not appear on a list of strata to process. There will only be A1 and A2 for modeling. In case there are more splits, the program allows children strata to split again. For example, the strata definition for A2 can split into A2A and A2B. In Surface Mine Reserves, quantities for the children seams (ie. A1 and A2) are reported for areas that the split exists and quantities for the parent seam (ie. A) are reported for areas without a split. Also, Grid file utilities and other functions such as limit lines can be used to bring children strata "back" together to get a full parent seam.
- **Additional Attributes:** This function will define any attributes specific to that strata, which do not apply to other strata and therefore would be misplaced in the Define Drillhole. The list of attributes for particular strata will be combined from the attributes defined for define Drillhole (key or non-key attributes, depending on the strata type) and attributes defined in Define Strata. In addition the attributes specific for a strata in some drillhole may be added directly to that strata in Edit Drillhole or Drillhole Data Sheet. The equation attributes described in Define Drillhole may be used in this dialog as well.

Define Lookup Database

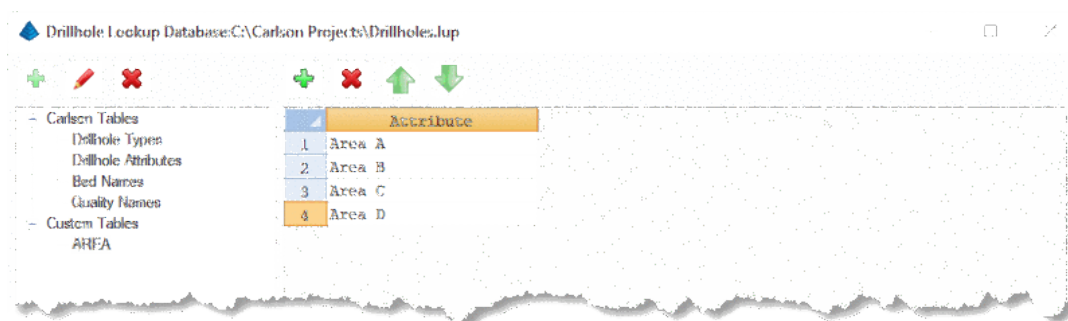

Define Lookup Database is a way to predefine drillhole fields such as drillhole type, attributes, descriptions and survey quality. Any other custom tables can be defined here for future queries and use.

Examples of the Carlson Tables are:

- **Drillhole Types:** This can be used to mark different types of drillholes, as used in the Import Drillhole command. Each can have a different layer, symbol and color for easy viewing on the map.
- **Drillhole Attributes:** Examples for this can be Drillers Name, Date Drilled, County, Mine Area. Drillhole Attributes differ from Strata Attributes in that they apply to the entire drillhole instead of a single strata.
- **Bed Names:** Bed Names can be predefined for easier selection in the Edit Drillhole command. Please note this is not required for importing Bed Names.
- **Quality Names:** This is simply a way to indicate how the coordinates of the drillhole were measured. When using the Import Drillhole command, you may specify an XY Quality and a Z quality for the drillhole to indicate how the Northing, Easting, and Surface Elevations were measured.

Custom Tables are added to represent any other fields that can have a predefined lookup fields, such as Mine Area, or Lab Company, so they can be easily selected from the list.

Define Geologic Order

This command is to assist the program when partial drillholes are encountered. While this is not a required routine, if many partial drillholes are encountered and the program reports that some strata are out of order, that may be an indication that this routine will help with the correlation. A reference list for strata order is created that all drillholes check to verify the order is correct.

Pulldown Menu Location: Drillhole

Keyboard Command: geo_order

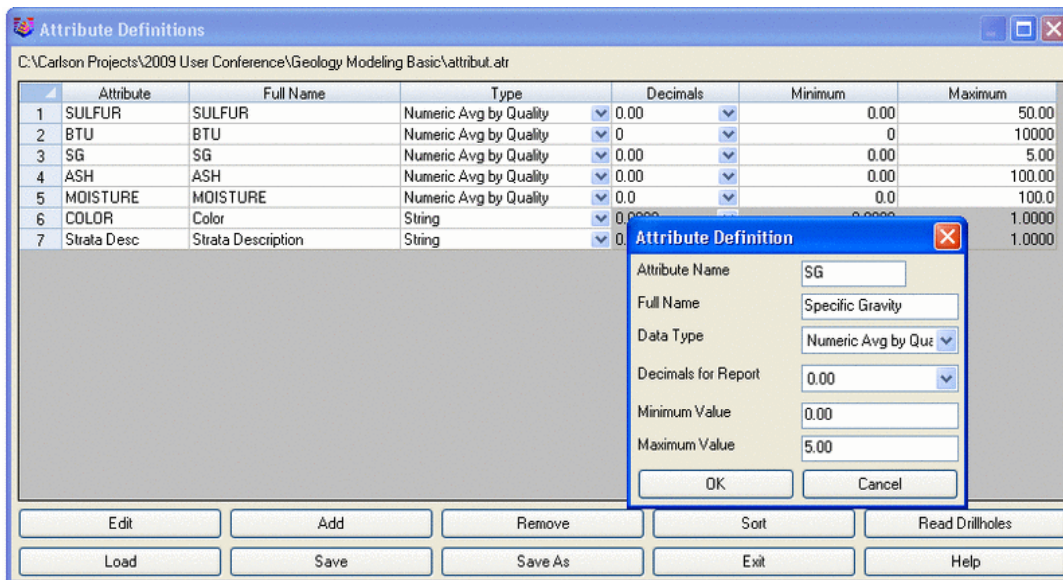

Define Attributes

This command defines the full name, value range and value type of attributes. This allows StrataCalc commands to identify invalid attributes that fall outside the minimum and maximum value range. Incorrect data entry is detected in *Place Drillhole* and *Drillhole Data Sheet*. Use the Attribute Validation Report command under Drillhole, to detect invalid attributes in the existing drillholes.

This routine also defines the data type as numeric or strings. Strings are for non-numerical attributes such as color name. String attributes need to be defined as such before importing the drillholes, otherwise the attribute values, such as green or red, will not import correctly.

For numeric attributes, there are settings to Average By Quantity or Average By Area which apply to *Surface Mine Reserves* for calculating the average attribute values. The default is to average by quantity which uses the strata quantities to calculate the weighted average. The average by area method uses the strata area as the weighting factor for the average. The average by quantity applies to attributes that you want to average by the strata volume such as BTU. For example, when the strata is thicker you pick up more quantities and the attribute value in these thicker areas should be weighted more. The average by area applies to attributes that count for the presence and not their volume. For example, for an attribute of thickness, you should average by area.

The Number of Decimal Places is used in the *Draw Drillhole Text* command and for the reports in *Surface Mine Reserves*. The attribute definitions are stored in a file with an .ATR extension.

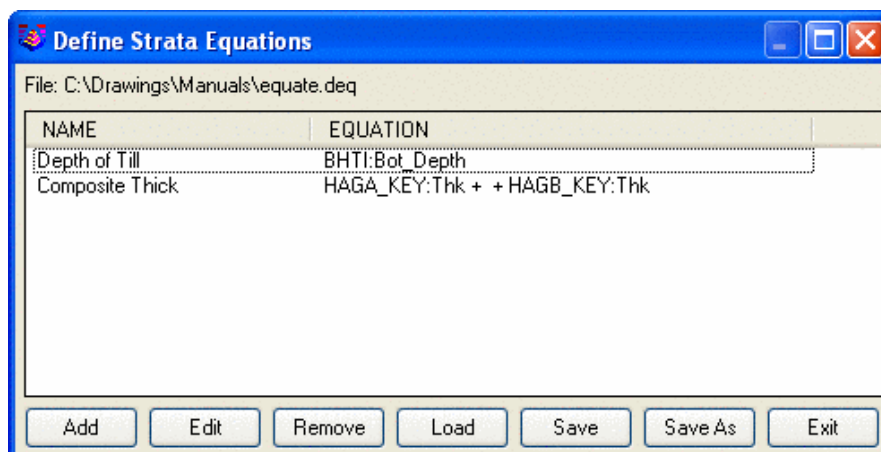

Pulldown Menu Location: Drillhole

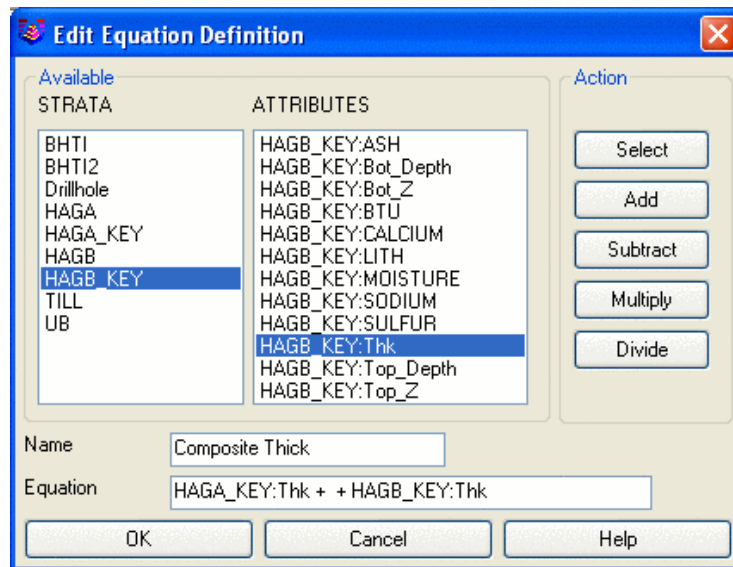

Keyboard Command: attrdef

Define Equations

This command defines equations using any existing strata attributes and data points as variables. These equations allow you to create new attributes based on a combination of strata data and values. The new attributes can then be used as data models in many routines such as *Make Strata Grid* or *Strata Isopach Maps*. This routine is useful for compositing or diluting thickness grids, or generating delivered quality grids in the initial modeling process. Any attribute that is attached to the drillhole attributes, such as water table elevation, or base of weathered zone (horizons that don't belong in the geologic column) can be put into an equation and then gridded to create the surface. After selecting the drillholes, the Define Strata Equations window appears. The selected drillholes are read to find all the available strata and attribute names for the equations. The Define Strata Equations dialog is for adding or removing equations, editing existing ones and loading and saving the equations to a .DEQ file.

User-defined drillhole attributes can now be modeled, such as water table, transgressive horizons or total depth of hole. The first step is to define a drillhole attribute in the drillhole definition file. After the holes have been assigned values for the drillhole attribute, they will appear on the list for Define Equations. If just that one value is selected and added, then it will appear on the list as an equation, capable of being isopached or gridded.

The window for the equation editing and selection has a list of all available equation variables. Equations can also contain values in addition to the drillhole variables. After defining the *.deq file, all routines that list the available strata attributes will have "EQUATIONS" at the top of the list. Selecting that will bring up a dialog window with a list of the user-defined equation names.

Define Ferm Codes

This command defines the table of Ferm codes. Each ferm code is assigned a full name and drawing options. These settings are user-definable and additional Ferm codes can be added. The drawing settings are used to hatch the strata in *Draw Geologic Column* by matching the strata Ferm code with the Ferm code definitions. Ferm codes are assigned to strata as a strata attribute. To use Ferm codes, each strata should have an attribute called "FERM". The FERM attribute needs to be defined in Define Attributes as a Non-Numeric attribute so that the Ferm code definitions are not limited to just numbers. A Non-Numeric Ferm attribute (a string) allows for Ferm codes containing letters such as 100A. The Ferm code definitions are stored in a file with a .FRM extension. If the window is empty on the initial screen, simply choose load and load the default FRM file from the Carlson DATA folder.

Ferm Codes are lithologic descriptions listed by numeric rock codes (found at <https://www.uky.edu/KGS/coal/coal-core-using-ferm-code.php>), as well as English names. The Ferm codes are derived from the core-logging manual, Cored Rocks of the Southern Appalachian Coal Fields, (<http://www.uky.edu/KGS/pubs/SappCoreBook/SAPP.html>) by J. C. Ferm and G. A. Weisenfluh from the University of Kentucky.

File: C:\scad2005\DATA\ferm.frm

Code	Description	Strata	Fill	Lauer	Color	Scale	Anale

Keyboard Command: fermdef

Define Horizon Codes

This command defines the table of horizon notes. Each horizon note is assigned a unique note number, name, description and processing options. These settings are user-definable and additional horizon notes can be added. The horizon definitions are stored in a file with a .HZN extension.

Horizon notes provide additional information about strata. To assign horizon notes to strata, the strata should have a horizon note attribute. The name of the horizon note attribute is defined in this command at the bottom of the dialog. By default this name is HORIZON, but may be changed. The horizon note from the definition file is matched with the strata by looking up the strata horizon note attribute value in the table. The attribute can be either a number to match by horizon note or a string to match with the horizon name. For example, a strata with an attribute HORIZON and a numeric value of 16 would use Questionable Structure from the table shown below. A strata with a HORIZON attribute of a string value QST would also use the Questionable Structure.

Besides using horizon notes as additional strata descriptors, horizon notes are also applied to strata processing in routines such as Strata Isopach Maps. When reading in the drillholes, if a strata has a horizon note with the Thickness option off, then this strata data will not be used for thickness modeling of this strata. Likewise if a strata has a horizon note with the Elevation option off, then this data point will not be used for elevation modeling of this strata. An application of horizon notes could be with coal section data where you have strata thickness value but the elevation is unknown. In this case, the strata in these drillholes could have a horizon note with the Thickness on and the Elevation off.

Pulldown Menu Location: Drillhole

Keyboard Command: hordef

Import Drillhole

This command imports drillholes into the drawing from a text file or database. There are many company-specific drillhole file formats available, but the Custom Import Formatter is flexible enough to handle almost any drillhole text file format. There are also two Carlson Standard Text formats and a Carlson Standard Database format that can be used to import from. The Mineral Drillholes format is similar to the Custom Import Formatter, but is intended for working with drillhole formats commonly associated with metal deposits. When the command is first executed, the below dialog will appear.

The Custom Import Formatter is the most flexible option. This option will allow you to select one or two files to define the drillhole locations and the strata information. If all both the collar and strata information are in a single file, choose "no" at this prompt. Note that if you choose "yes", the program will prompt you to select two files to import and will require you to configure two import dialogs.

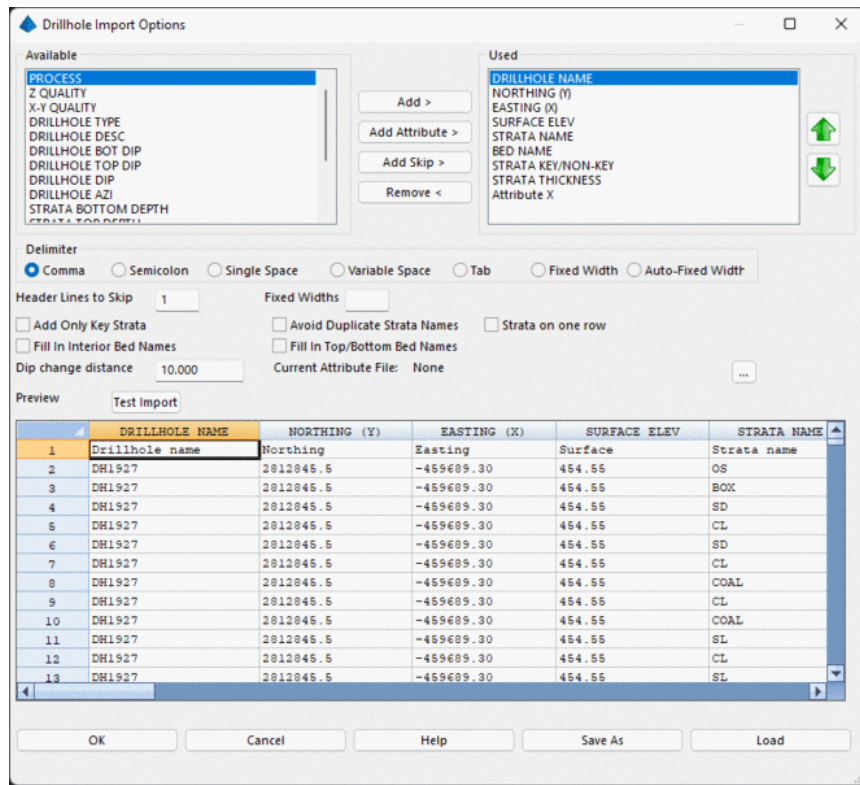

The text files may be in a .txt, .asc, .dat, or .csv file format. It is very common to store the drillhole data in a spreadsheet, then export the data to one of these formats. The text files may be comma delimited, single space delimited, tab delimited, fixed width, or Auto-Fixed width. An example set of drillhole data in a spreadsheet is shown below.

	A	B	C	D	E	F	G	H	I
1	Drillhole name	Northing	Easting	Surface	Strata name	Bed name	Key	Thick	Attribute X
2	DH1927	2812845.5	-459689.30	454.55	OS		NO	15.00	355
3	DH1927	2812845.5	-459689.30	454.55	BOX	BOX	YES	0.01	357
4	DH1927	2812845.5	-459689.30	454.55	SD		NO	11.09	152
5	DH1927	2812845.5	-459689.30	454.55	CL		NO	2.90	456
6	DH1927	2812845.5	-459689.30	454.55	SD		NO	2.00	150
7	DH1927	2812845.5	-459689.30	454.55	CL		NO	5.00	183
8	DH1927	2812845.5	-459689.30	454.55	COAL	MM	YES	3.00	21
9	DH1927	2812845.5	-459689.30	454.55	CL		NO	1.30	190

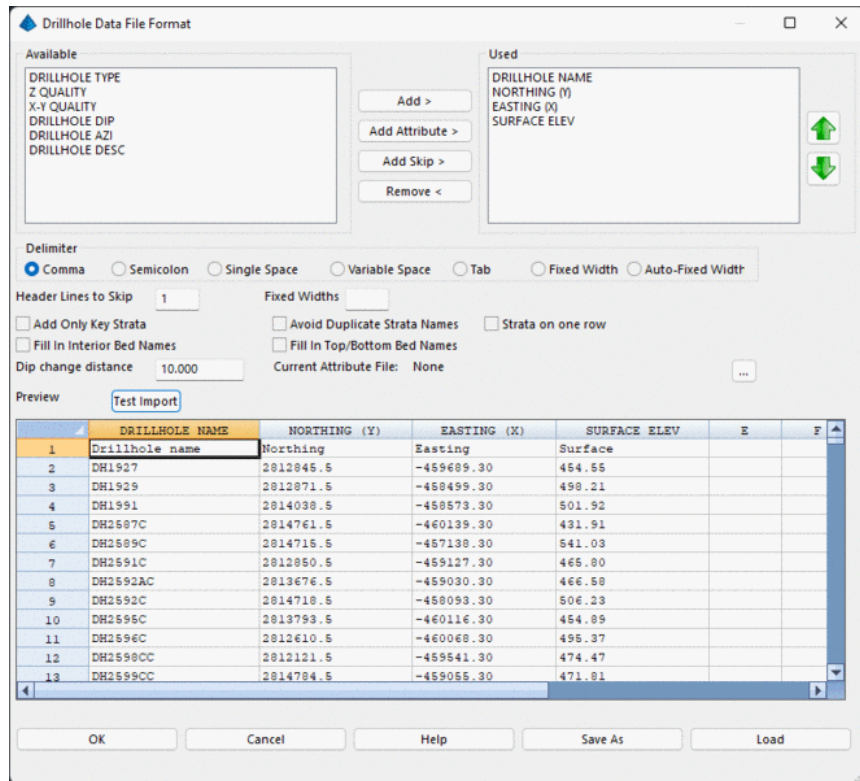

Here it is important to note that a single drillhole is normally expected to span multiple rows in the spreadsheet. Here each sample in the drillhole is represented on a new row. There is an option to import drillholes with each drillhole spanning a single row (with additional columns specified for each strata type). Note that when a drillhole spans multiple rows, data relating to the collar should not change down the rows (northing, easting, and surface elevation), whereas any data relating to the strata should change down the rows (strata name, thickness, elevation, etc.).

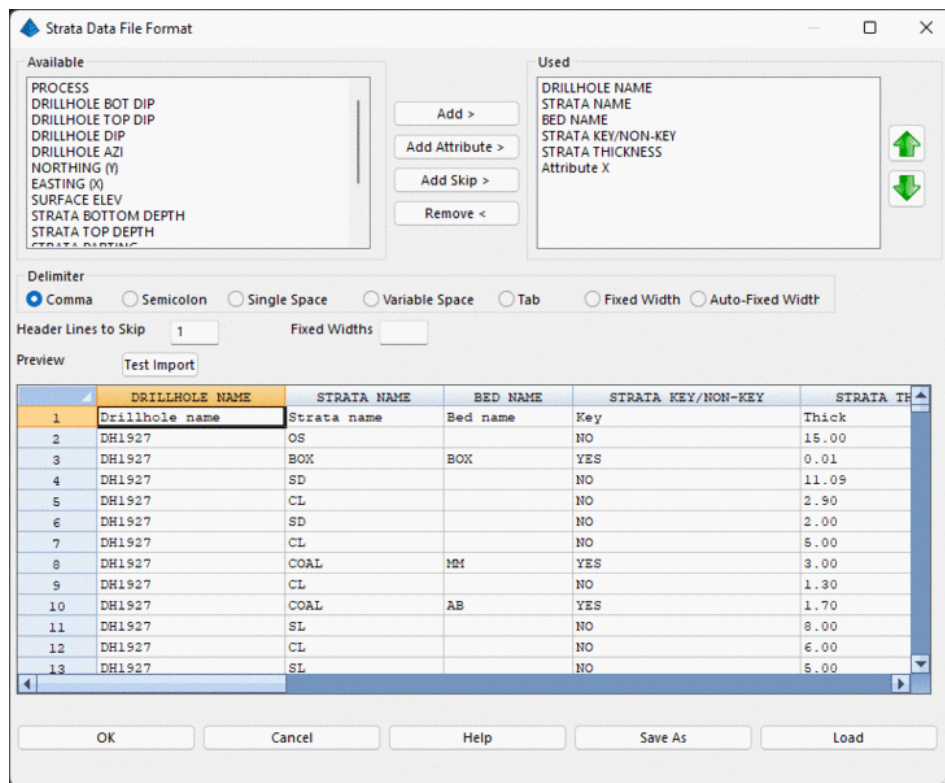

After selecting the file(s) to import, the below dialog will appear. Note that if all of the data is imported in a single file, the first dialog shown below will appear. If two files are specified (one for the collar data, one for the strata data, the following two dialogs will appear).

Single File Imported

Two Files Imported

This dialog is divided into two columns: Available and Used. The idea is to move relevant items from the Available column to the Used column in the order they appear in the drillhole file. Note that the names used in the Available and Used columns do not need to match the header names used in the drillhole file (Carlson always uses a predefined name of "DRILLHOLE NAME", but the header in your file can be something else such as "Drill ID" if you prefer). Not all items are needed, but the ordering of the items is very important. In the above example, the Drillhole Name is the first item in the Used column. You will notice that the Preview Window at the bottom of the dialog shows a spreadsheet-style preview of the file to be imported. Here you can see that the Drillhole Name is the first column of the data, and therefore it must be the first item in the Used list. The second item, Northing, is the second column in the data file. Items that are not properly ordered will result in drillhole data not importing properly.

Items may be moved between the columns by double-clicking them, or by using the **Add** and **Remove** buttons. Custom attributes (assays of the strata, date drilled, water table elevation, etc) may be defined by clicking the **Add Attribute** button. Note that when adding a custom attribute, you will need to specify the attribute as a Drillhole attribute (meaning it doesn't change with depth) or a strata attribute (meaning it will have a unique value for each strata sample in the drillhole). In the above example, Attribute X has been defined as a strata attribute at the bottom of the Used column. Any data that does not need to be imported may be omitted by placing a SKIP in the Used column. This is added by clicking the **Add Skip** button. Items in the used list may be reordered by clicking the green up/down arrows to the right of the list.

When importing drillhole data, you may import elevations, depths, or thicknesses of each sample. You may use any combination of top/bottom elevations, depth, and thickness to specify the sample thickness. Note that if a thickness or depth is specified, they are assumed to be along the length of the drillhole (very important if the holes are angled). If you only import thickness or depth, elevations will be automatically calculated on import (dip angles will be used when determining elevation)

Delimiter: This option specifies the delimiter symbol used to mark columns in the data. For the fixed width format, choose the Fixed Width toggle and then enter the column numbers separated by spaces in the edit box. For example, "8 15 24 32". The Auto-Fixed width will scan entire file first and detect columns if you have some fixed width format - it will detect where breaks between columns are.

Header Lines to Skip: This option allows you to specify how many rows are simply headers for the actual data. These header lines should not be imported as data.

Add Only Key Strata: This option will only import strata tagged as "key". Any gaps between key strata will be filled in with a generic nonkey layer name.

Avoid Duplicate Strata Names: This option will append a number to duplicate strata names within a drill-hole if these strata names do not have bed names. For example, if there are three SH strata names, then they would be imported as 'SH', 'SH2' and 'SH3'.

Strata on one row: This option applies to text files where the entire drillhole is on one row. Each strata is identified by a unique name which is combined with the strata field name. This allows you to have multiple strata value fields such as thickness and name on the same row. For example, consider two strata named COAL_A and COAL_B. When you click the Add button to add the Strata Name, a dialog appears for entering the strata identifier. In this example, you could enter COAL_A. Then click the Add button again for Strata Name and enter id as COAL_B. This creates two strata name fields called COAL_A:Strata Name and COAL_B:Strata Name. Without the Strata on one row option, you can only have one Strata Name per row.

Fill In Interior or Top/Bottom Bed Names: These options will set the bed name for strata that have no bed name to the first bed name found in a strata below the missing bed name strata. If no bed name is found in lower strata, then the program will look for a bed name in the higher strata. In this way, all the strata are assigned bed names. Otherwise only the strata with bed names from the import text file will have bed names in the drillholes.

Dip Change Distance: This value is only needed when the Drillhole Top Dip and the Drillhole Bottom Dip attributes are imported (most users don't use this option). With these two attributes, it is assumed that the drillhole dip angle is only measured at the top and the bottom of the drillhole, rather than on a regular interval down the drillhole. When these top/bottom dip values are imported, the program will distribute the change in dip angle down the hole on this interval. For example, if this value is set to 10, the program would calculate a new dip angle every 10 down the length of the hole. It is important to note that there are three methods that can be used to determine how the angle varies. These three options for the Dip Angle Method are described in Carlson Configure.

Current Attribute File: This option lists the current .atr file associated with the drawing. Clicking the ellipsis button will open the Define Attributes dialog. It is important to note that in order to import String attributes (anything other than a numeric value), you will need to pre-define the attribute as a string entity in the .atr file.

Test Import: This button will check that you have added necessary attributes to the Used column. If any of these attributes are left out, the program will fail to create the drillholes properly. It is important to note that this button does not check for all possible errors in the data; it only checks for the following conditions:

- Drillhole name must be specified
- Drillhole coordinates (X,Y,Z) must be specified
- Strata name must be specified
- Strata length must be specified (using some combination of top/bottom elevations, thickness, and from/to depths)
- Strata intervals cannot overlap

It is worth mentioning that three checks are automatically applied to the drillhole import.

- When both sample thickness and from/to depths are imported, the depths will take precedence over the thickness (depth intervals suggesting an interval of 5.00 feet vs. a thickness value suggesting an interval of 5.02

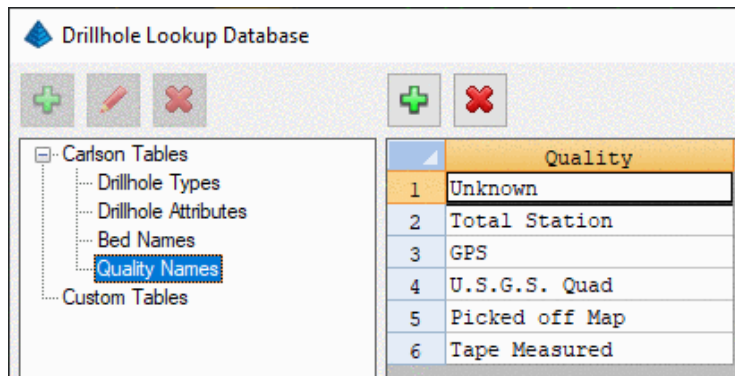

feet would result with an actual interval of 5.00 feet)

- When dip/azimuth values are specified for individual sample intervals as well as the entire drillhole, the sample intervals will take precedence

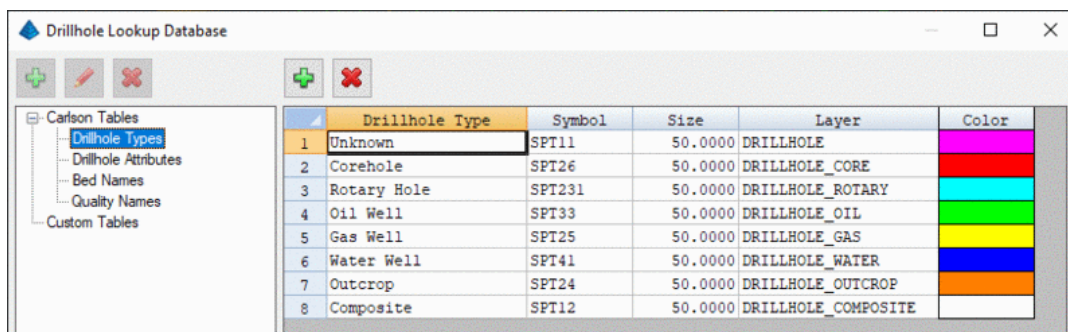

The **Load** and **Save** buttons allow you to save and recall the Custom Import Formatter settings to a settings file with a .IMPT file extension. Note that this file previously used an .IMP extension, but the actual format of the file has not changed. If you have a .IMP file that needs to be loaded, you may simply change the extension to be .IMPT.

Notes on specific attributes to be imported are listed below. Again, it is important to note that not all of these attributes are required, but the attributes that are required are marked with an asterisk (*). For each of these attributes, special characters such as exclamation points (!), pound signs (#), etc. are not recommended (though some are supported)

- *DRILLHOLE NAME - The identifier of the drillhole. Alphanumeric names with spaces are supported
- *NORTHING (Y) - Y coordinate for the drillhole collar
- *EASTING (X) - X coordinate for the drillhole collar
- *SURFACE ELEV - Elevation coordinate for the drillhole collar
- *STRATA NAME - Name of the strata type. These names may be abbreviations or full names (example: OB or Overburden are acceptable). It is common to use this name to identify the type of material (clay, coal, shale, etc.). If bed names are not used, strata names should not repeat down the length of the hole.
- BED NAME - Although not required for all projects, most users will need to specify bed names to handle repeating strata types. For example, if three beds of coal exist in the drillhole (or if each bed were sampled multiple times), the bed name is used to uniquely identify each bed. It is common to use the local name of the formation for the bed name (example: Pittsburgh Seam, Minnekahta Limestone, etc.)
- *STRATA KEY/NON-KEY - This identifies the strata as Key material that is potentially profitable for sale, or Nonkey material that will only ever be treated as waste. If the profitability of a strata is dependent on the quality/assay, it should be tagged as Key. When imported Key/Nonkey values, you may use "Yes" or "1" to identify Key strata. You may use "No" or "0" to identify Nonkey strata.
- *STRATA THICKNESS - Thickness of the sample down the length of the core.
- *STRATA BOTTOM DEPTH - Depth to the bottom of the sample measured from the collar elevation.
- *STRATA TOP DEPTH - Depth to the top of the sample measured from the collar elevation.
- *STRATA TOP ELEV - Top elevation of the sample.
- *STRATA BOTTOM ELEV - Bottom elevation of the sample.
- PROCESS - This sets the Processing option for the drillhole. This is assumed to be on when it is not specified. Note that any drillholes with this option turned off will not be used for any calculations.
- Z QUALITY - Identifies the method in which the collar elevation was measured. The predefined list may be configured in the Drillhole Lookup Database command. Note that when importing this data, an integer value should be used to specify the row on the predefined list. For example, a value of 2 relates to the second method on the predefined list (in the below example, this tells the program that the elevation was measured with a Total Station). If this is not specified, the program will default to the Unknown method.

- X-Y QUALITY - Same as the Z Quality, but specifies the method of measurement for the X and Y coordinates for the drillhole collar.
- DRILLHOLE TYPE - Specifies the type of drillhole, according to the Drillhole Types specified in the Drillhole Lookup Database command. When importing, an integer value should be used to specify the row on the predefined list. For example, a value of 3 tells the program that the drillholes is a Rotary Hole. If this is not specified, the program will default to the Unknown drillhole type.

- DRILLHOLE DESC - A text description of the drillhole.
- DRILLHOLE BOT DIP - The Drillhole Dip (degrees) measured at the top of the hole.
- DRILLHOLE TOP DIP - The Drillhole Dip (degrees) measured at the top of the hole.
- DRILLHOLE DIP - The Drillhole Dip (degrees) for the full length of the drillhole (note there is no variation in dip when this option is used). Note that the definition of 0 dip is defined in Carlson Configure > Mining Settings. By default, the program assumes that a dip value of zero is straight down.
- DRILLHOLE AZI - The Azimuth of the Drillhole Dip.
- STRATA AZI - The Azimuth of the Strata Dip (expected to vary with each strata sample)
- STRATA DIP - The Dip (degrees) of the drillhole at each strata sample (expected to vary with each sample).

It is important to note that if the dip/azimuth measurements are in a separate text file, this information can later be applied to the drillholes with the Import Dip/Azimuth command.

The Carlson Standard Text formats include a complete format that has all the drillhole data options and a simple format that contains the necessary fields. These Carlson format drillhole text files can be created with the Drillhole Export routine. Both formats are shown below. This standard format uses key-coded lines with comma separated entries. String entries are enclosed in single quotes. The first line of the file is a keyword VERSC13.2 to recognize the version of the data file.

The Carlson Standard Database option is the only format that is a database file and not a text file. This database format is an Access MDB or ACCDB file with several specific tables, listed below. When importing with this option, all of the below tables must be present in the database, even if they are empty. When importing from the Carlson database, you can filter by drillhole name, polyline area or query. To import all the drillholes, use the drillhole name option with a name of "*" for everything (this filter will be set by default). The polyline area option will only import drillholes within the selected closed polylines. The query option filters the drillholes by the specified SQL query using the drillhole database fields.

Table	Field	Data Type
DH_DESC	DESCID	Long Integer
	DRILLHOLEID	Integer
	NAME	Short Text
	VALUE	Short Text
DH_DIPAZI	DIPAZIID	Long Integer
	DRILLHOLEID	Integer
	ALONGCHDEPTH	Double
	DIP	Double
	AZI	Double
DH_STRATA	STRATAID	Long Integer
	DRILLHOLEID	Integer
	NAME	Short Text
	ELEVATION	Double
	KEY	Integer
	BED_NAME	Short Text
DRILLHOLE	DRILLHOLEID	Long Integer
	NAME	Short Text
	DESCRIPTION	Short Text
	NORTHING	Double
	EASTING	Double
	ELEVATION	Double
	KEY_DENSITY	Double
	PROCESS	Integer
	DH_TYPE	Integer
	XY_QUALITY	Integer

Z_QUALITY		Integer

DRILLHOLE_INTERVAL	ATTRINTERVALID	Long Integer
ATTRID		Integer
DRILLHOLEID		Integer
ATTR_NAME		Short Text
ATTR_FROM		Double
ATTR_TO		Double
ATTR_VALUE		Short Text
ATTR_TYPE		Short Text
STRATA_ATTR	ATTRID	Long Integer
STRATAID		Integer
NAME		Short Text
VALUE		Short Text
TYPE		Short Text

Other Specific Formats are hard-coded imports for data from specific mines or other software formats. Most of the time, the Custom Formatter is used, but if the holes are already in one of these formats, then they can be imported directly. If there is a format that doesn't follow a pattern that the Custom Formatter can use, then the import can be done by custom programming with these Other Formats.

DHDB is a format used by many mining companies. It is an Access file that is produced by the Highland Geocomputing company (<http://www.highlandgeocomp.com>). The ACCDB file contains 3 tables where the formats are shown here for Header, Lithology and Quality.

DHID	Northing	Easting	Collar	Total Depth	Hole Type	Township	Range	Meridian	Section	Qtr Sect	Qtr S
0001L	674,110.92	2,459,227.13	6,896.33	240.00							
0001N	673,403.30	2,460,280.06	6,867.42	260.00							
0002L	671,565.87	2,462,517.18	6,855.30	500.00							
0002N	672,691.51	2,461,522.65	6,863.71	260.00							
0002S	665,135.81	2,458,972.12	7,084.33	430.00							

Drill Hole ID	Easting	Northing	Collar	Named Ur	Bench	From	To	Thickness	Adj From	Adj To	Adj Thick	RQ	Hardne	Shac	Unit Col	GS
0001L	2,459,227.13	674,110.92	6,896.33			0.00	25.00	25.00	0.00	25.00	25.00					
0001L	2,459,227.13	674,110.92	6,896.33	BOX		25.00	240.00	215.00	25.00	240.00	215.00					
0001N	2,460,280.06	673,403.30	6,867.42			0.00	27.47	27.47	0.00	27.47	27.47					
0001N	2,460,280.06	673,403.30	6,867.42	BOX		27.47	27.47	0.00	27.47	27.47	0.00					

Drill Hole ID	Sample Num	Northing	Easting	Collar	seam	bed	Screen Size	Screened Pc	Sample Type	Sample Weig	Sample Date	Sampled By
0004L	0004L_01	671,635.89	2,461,702.16	6,882.31					Incremental			
0014L	0014L_01	670,215.86	2,461,827.15	6,872.30					Incremental			
0014L	0014L_02	670,215.86	2,461,827.15	6,872.30					Incremental			
0014L	0014L_03	670,215.86	2,461,827.15	6,872.30					Incremental			
0014L	0014L_04	670,215.86	2,461,827.15	6,872.30					Incremental			

The Import Mineral Drillholes option is very similar to the Custom Import Formatter, with a few exceptions:

- Dip and Azimuth must be specified
- Strata Names are not required, but a Rock Code must be specified
- Drillhole Length must be specified

Prompts

Select Drillhole Configuration File .ch file created by Define Drillhole. This dialog appears once. To change Configuration file use Mining Project Manager.

Choose Format Dialog

The prompting for other import formats may be different.

Pulldown Menu Location: Drillhole > Import/Export Drillholes

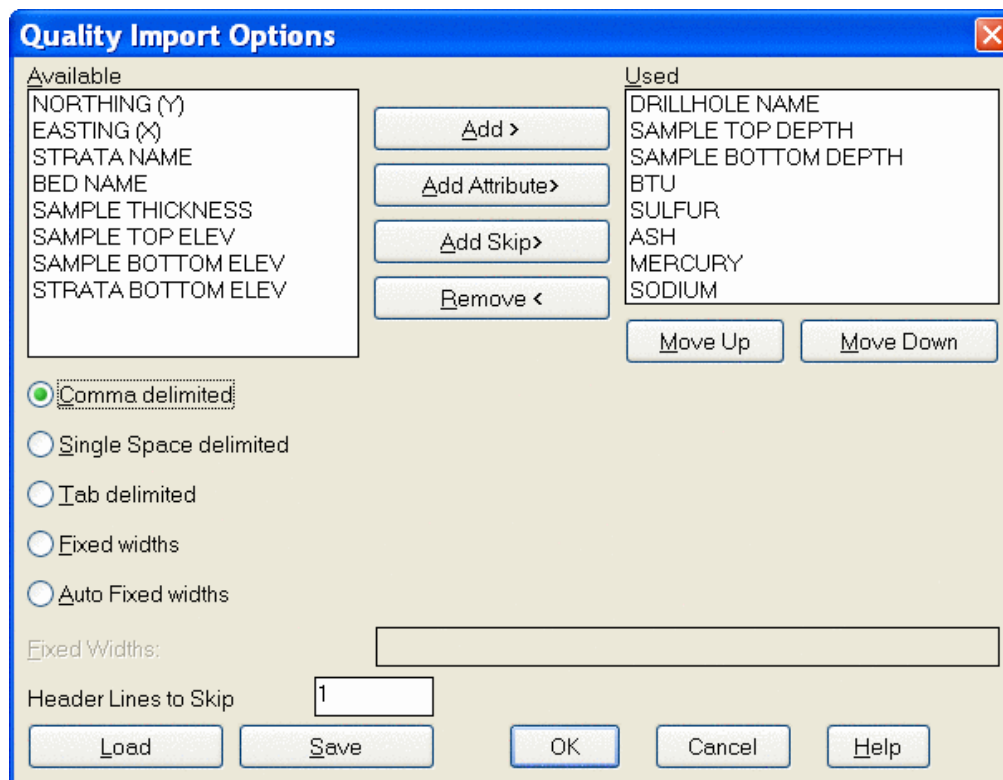

Keyboard Command: chimport

Import Qualities

Many times the lab analysis is received long after the structure data for new drillholes has been entered. This command imports attribute data from a text file into drillholes that are already existing in the drawing. Besides the attribute values, the text file must include the drillhole name or the drillhole northing and easting and a strata or bed name, from and to, or elevations. These values are used to locate where to assign the attribute values.

The order of the columns is set in the dialog shown below. To add one of the standard column types, highlight the name from the Available list and click Add. To add an attribute, click the Add Attribute button. Another dialog will appear for entering the attribute name.

To assign qualities to the drillhole by strata elevation, the program needs both the top and bottom elevation of the sample. This can be done by 2 elevations, by 2 depths or by elevation and thickness. If the sample doesn't match up with what is in the drillhole, it will split the strata and beds to match up with the sample interval from the quality file. To alleviate this, just use bed name instead of an interval to match up.

Prompts

Select the Drillholes to update.

Select objects: *pick the drillholes*

Choose Quality Text file to read

Added 30 quality values.

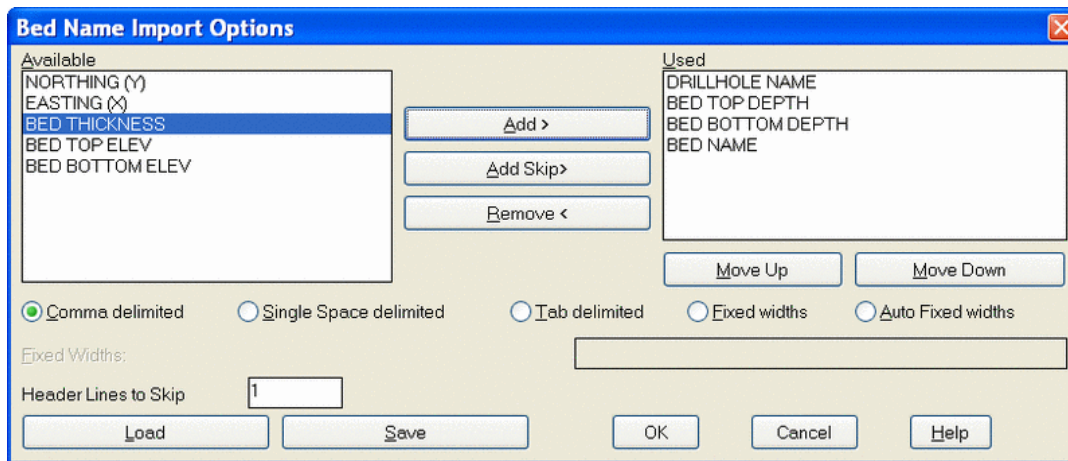

Pulldown Menu Location: Drillhole

Keyboard Command: chimport2

Import Bed Names

This command imports bed names from a text file into drillholes that are already existing in the drawing. Sometimes when importing drillhole information, there is a separate file for lithology. This will bring that file into the holes as a bed name. Besides the bed names, the text file must include the drillhole northing and easting and a strata identifier of thickness, depth, or elevation. These values are used to locate where to assign the bed names. The text file should have comma separated columns of data with each row containing all the data for the strata attributes.

The order of the columns is set in the dialog shown below. To add one of the standard column types, highlight the name from the Available list and click Add. To add an attribute, click the Add Attribute button. Another dialog will appear for entering the attribute name.

Prompts

Select the Drillholes to update.

Select objects: *Pick the drillholes*

Added 107 bed names.

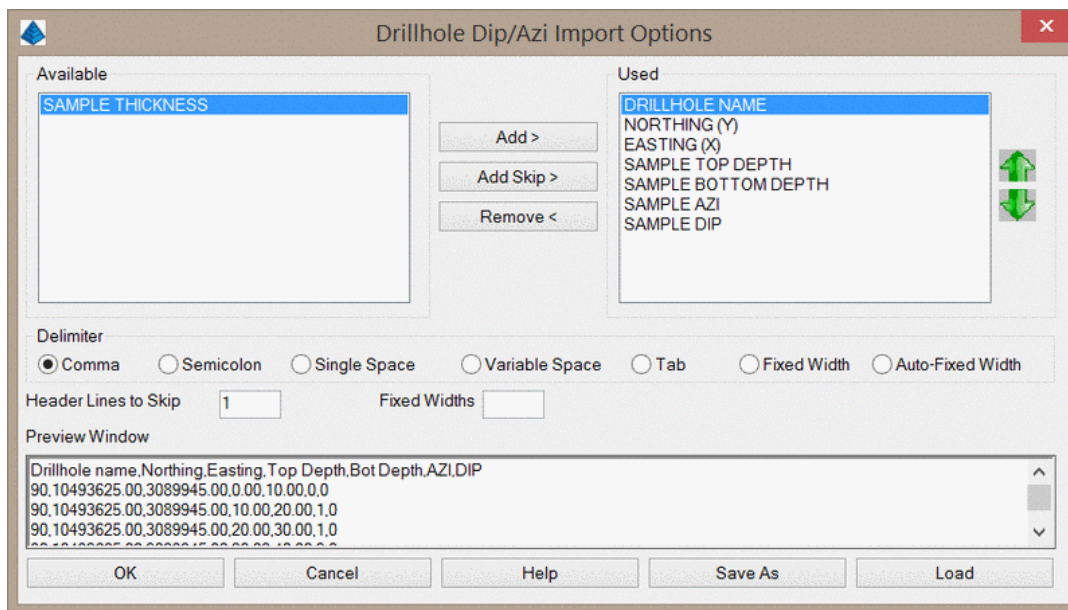

Pulldown Menu Location: Drillhole > Import/Export Drillholes

Keyboard Command: chimport3

Import Dip/Azimuth

This command imports dip and dip azimuth survey data that does not match the strata sample interval. For example, if a limestone core is quality sampled on 2' intervals, but the dip and azimuth readings are taken on a 5' interval, this command can be used to keep track of the drillhole dip without modifying the sample interval. This command will import the dip/azimuth information to each drillhole's Dip/Azimuth Table rather than applying the dip/azimuth values as new strata attributes.

When the command is executed, you will be prompted to select the drillholes to update. After selecting the drillholes, you will be prompted to select a text file containing the dip/azimuth data. The file must include the drillhole name or the drillhole Northing/Easting. After selecting the file, the below dialog will appear. Here you can specify which keyword matches each column in the text file. To add the dip/azi information, you must specify the top/bottom depth values or thickness values for each sample.

Pulldown Menu Location: Drillhole

Keyboard Command: chimport4

Coal Section to Drillhole
