Introduction

1

Carlson 2024 is application software for land development, civil engineering, surveying, construction, GIS and mining engineering which runs with AutoCAD and IntelliCAD. The CAD engine serves as the graphics engine and drawing editor for Carlson.

Carlson 2024 consists of the following programs: Survey, Civil, Hydrology, GIS, Field, GeoTech, Trenching, CAD Net, Construction, Natural Regrade, Point Clouds, Geology, Underground Mining and Surface Mining. Each of these programs can run independently or together with each other.

Carlson Directory Structure

The figure below shows the default directory structure for the Carlson program files. The EXEC, LSP, and Support sub-directories have files that are accessed by the program. You should never need to access these files directly yourself. The Carlson Projects sub-directories are the user's directories.

ROOT

\Program Files\Carlson2024

\EXEC

Executables

- Programs (.EXE, .DTA)

\Support - a set of fixed program support files that are not user-customized

Support

- Help files (.CHM, .PDF)

- Shared programs (.DLL)

\SupTemplate - a set of support files to be copied to individual user's profile

Support

- Drawing blocks (.DWG)

- Menus (.MNU, .CUI)

\LSP

Lisp & ARX

- Programs (.LSP, .DLL, .ARX, .DCL)

\UserTemplate - a set of files to be copied to individual user's profile

User setup files

- Settings files (.INI)

\Carlson Projects (customizable during installation)

User data files

- Survey files (.RW5, .CRD, etc)

Startup directory, user drawings

- Drawings (.DWG)

Each user on multi-user system gets his own copy of files from support and settings areas. Depending on your operating system the location will vary:

On Windows XP and earlier it would typically be: C:\Documents and Settings*Your User Name*\Application Data\Carlson Software\Carlson2024

On Windows Vista would typically be: C:\Users*Your User Name*\AppData\Local\Carlson Software\Carlson2024

On Windows 7 would typically be: C:\Users*Your User Name*\AppData\Roaming\Carlson Software\Carlson2024 followed by folder name specific to the version of AutoCAD or IntelliCAD you are running. Please note that by default Windows will be hiding the "Application Data" ("AppData" on Vista) location from browsing, but you can still type it in, or change viewing preferences.

Installation Guide

Workstation Installation - Step-by-step instructions. For network licensing server installation instructions, please see http://www.carlsonsw.com/support/knowledge-base/?action=display_topic&topic_id=55.

What's New - Complete list of improvements for Carlson 2024.

Registration

Documentation - For full documentation, including context sensitive help, press the F1 key at any time while running Carlson 2024.

Fixes - A complete list of fixes for Carlson 2024 can be found on at the Carlson Software Knowledge Base.

Support - List of all support resources.

System Requirements

Carlson's system requirements are no greater than that of the AutoCAD® version you are running. See your AutoCAD installation guide for the minimum system configuration. It is always recommended that you use the highest performance PC possible.

For detailed information on system requirements please see this page: <http://www.carlsonsw.com/support/system-requirement/>

64-bit Windows (for details on Windows support for specific AutoCAD version, please refer here):

Carlson 2024 will operate with the following versions of CAD:

IntelliCAD 10.0 built-in (supports Windows Vista through Windows 10)

AutoCAD 2017-2024

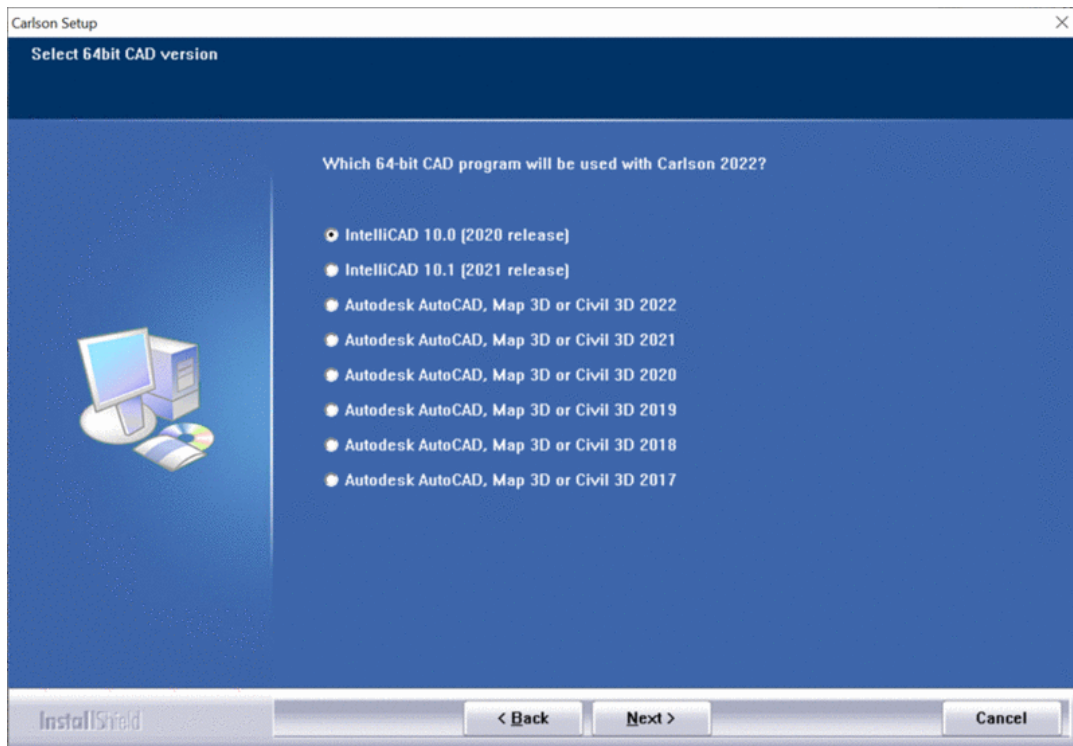

AutoCAD Map 2017-2024

Civil 3D 2017-2024

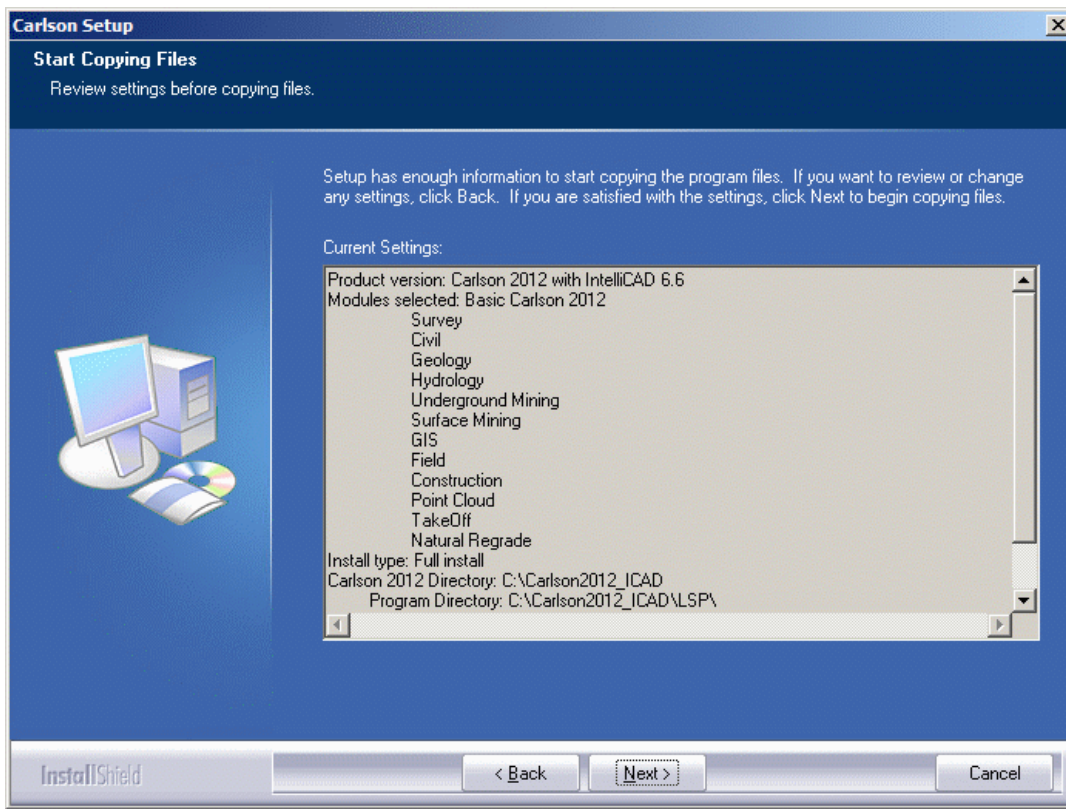

Note: Carlson requires a minimum screen resolution of 1024x768.

Workstation Installation

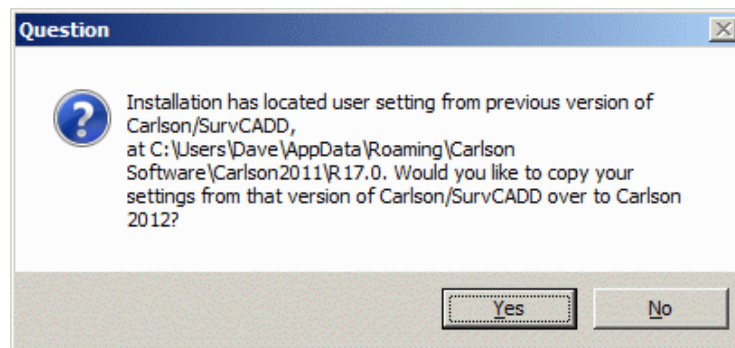

- Insert the CD and the program will initialize automatically. If the setup program does not automatically begin, click Start, select Run, type D:\Launch.exe and click OK.
- After the program begins, select Install Carlson 2024.

- Select which version of CAD you are installing Carlson 2024 on.
- During the installation process, you will be prompted for your serial number. This can be found either on the CD case or on your distribution sheet. **IMPORTANT:** Each legal copy of Carlson 2024 has its own serial number.
- Specify which folder you prefer to install Carlson 2024 in. In case of using multiple versions of AutoCAD, please select individual folders of Carlson 2024 for each version.
- Review the installation options, and click "Next" to continue:

- In the course of your installation, you may get a prompt to carry over your settings if you had SurvCADD installed on your system. Please state your preference:

- At this point, installation will start. After all the files have been copied, you have to select which copy of AutoCAD you will be using, as you may have multiple AutoCAD verticals installed on the same system.
- If you see installation take long time without any apparent activity, please make sure any other applications on computer are shutdown. This delay is caused by component registration waiting for other applications to exit.
- Installation will create a separate shortcut on your desktop for each major component of the program.

Performing Silent (Scripted) Installation

Whenever an administrator needs to install several identical computers, it may be beneficial to install once recording all the input and then deploy the rest of the computers using the input recorded when installing on the first one.

Carlson-specific Method

This method is based on creation of a plain-text configuration file and supplying this file as a command line parameter when launching the install.

If your configuration file is called setup.ini, the command line would look like this:

```
Carlson2024.64bit.exe ini=setup.ini
```

the path to the may be specified, but spaces in the path or file names are not currently supported

The contents of the setup.ini are as the following:

Entry	Description
EULAAccepted=1	Confirms that the EULA was reviewed and accepted, for example as a part of this manual. (Required)
Platform=Icad9_x64	Specifies target version of CAD. See below of acceptable values. (Required)
Serial=xxx-xxx-xxxx-xxxx	Serial number provided with purchase. (Required)
ImportProfile=Carlson2023	Name of the profile to be used to import settings (Optional)
DestDir=Path_To_Installation	Destination folder (Optional)
WorkDir=C:\Carlson Projects	Projects folder (Optional)
SettingsDir=C:\Carlson Projects\Settings	Settings Folder (Optional)
Language=en	Language code for the interface: en, win (Windows default), es, pt, cs, hr, pl, ru. (Optional)
Migration=Path_to_migration_file	Path to Carlson Settings Migrator generated zip file (Optional)

Acceptable values of the Platform parameter:

Platform Keyword	Description
Icad10_x64	IntelliCAD 10.x 64-bit
R24.3_X64	AutoCAD 2024 64-bit based products
R24.2_X64	AutoCAD 2023 64-bit based products
R24.1_X64	AutoCAD 2022 64-bit based products
R24.0_X64	AutoCAD 2021 64-bit based products

R23.1_X64	AutoCAD 2020 64-bit based products
R23.0_X64	AutoCAD 2019 64-bit based products
R22.0_X64	AutoCAD 2018 64-bit based products
R21.0_X64	AutoCAD 2017 64-bit based products

Native InstallShield Method

Carlson is using InstallShield InstallScript engine which supports this feature in the following manner:

- Start command prompt and change to the drive letter corresponding to CD-ROM drive where Carlson disc is located
- Run Carlson install with additional switches like this:

```
setup.exe /r /f1c:\some_folder\setup.iss /f2c:\some_folder\setup.log
```

where /r designates recording, /f1 response file and /f2 log file. Please note lack of space after /f switches. Apparently simple paths with no special (non-alpha) characters are required.

- Copy setup.iss to location accessible on the network
- On the target machine, run the setup as the following

```
setup.exe /s /f1network_folder\setup.iss /f2c:\some_folder\setup.log
```

where /s designates silent install, /f1 pre-recorded response file and /f2 log file

- The install runs very stealthy and does not generate any messages. The log file will contain return code of 0 on successful install.

Please note that this method will use identical Carlson serial number on all the silently installed machines. This is correct in case of network license mode, but is not proper for standalone licenses. In that case, prior to registration, please navigate to Help, About Carlson, Change registration, remove scripted number and enter proper unique serial number assigned to the workstation. After that, the new number is OK to register.

Network License Server Installation

For network licensing server installation instructions, click [here](#) or go to the Knowledge Base at www.carlsonsw.com.

Running for the first time

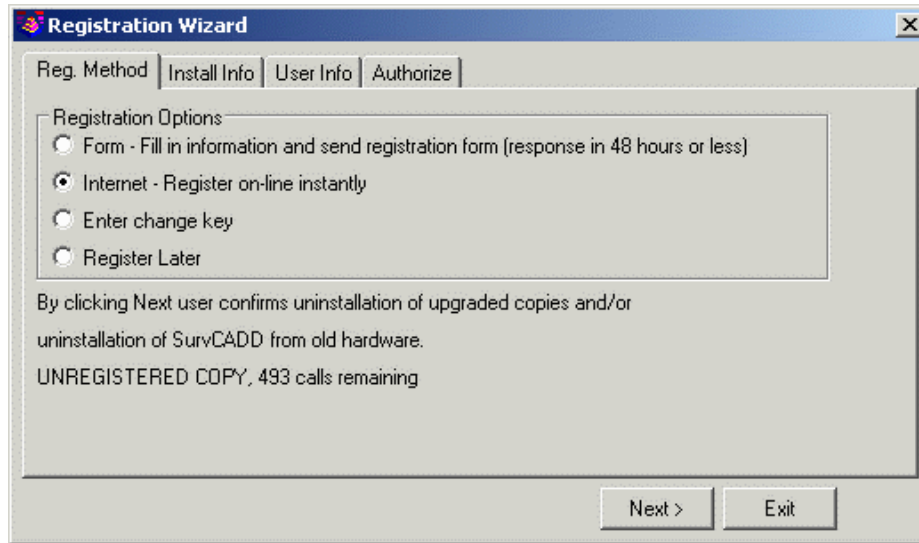

When you launch the program for the first time, it will try to connect to the updates server, to see if any program updates has been posted since the CD was created. Unless you indicate otherwise, the program will do this on a weekly basis, to make sure that your Carlson product is up to date on fixes to all known problems.

Registration

IMPORTANT ! ALL INSTALLATIONS OF THIS SOFTWARE REQUIRE A UNIQUE SERIAL NUMBER. If you are running this software on more computers than you have purchased licenses for, you must buy additional

copies.

Each Carlson program is licensed for use on **one** workstation which must be registered. The registration records your company name and AutoCAD serial number. To register your copy of Carlson, start Carlson and choose "Register Now". The following dialog will appear.

Note: Carlson Software will no longer issue change keys over the telephone. There are four registration options.

Fax: This method allows you to print out the required information on a form which you then fax to Carlson Software. The fax number is printed on the form. The change key will be faxed back to you within 72 hours.

Internet: Register automatically over the Internet. Your information is sent to a Carlson Software server, validated and returned in just a few seconds. If you are using a dial-up connection, please establish this connection before attempting to register.

Enter pre-authorized change key: If you originally chose the Fax method above, you will need to choose this method now to enter the change key that is faxed back to you.

Register Later: If you wish, you may defer registration up to 30 days. After this time, Carlson will enter demo mode which displays a message each time a Carlson command is run.

After you select the registration method, choose Next and select the type of installation you are performing. Choose Next again to review the copyright information and to fill out the required information. At this point, if you are using the Fax method, press the Print Fax Sheet button. If you are registering using the Internet method, press Next and the process will start.

If you have any problems with Internet registration, please repeat this process, and use the Fax method. There is more registration information on the Carlson Software website at <http://www.carlsonsw.com/registration.html>.

Tip: If Carlson is running, you may access the registration dialog by choosing *About Carlson* from the Help menu, then pick the Change Registration button. This also allows you to add additional serial numbers you purchased without reinstalling software. Each serial number requires separate registration.

via Discussion Groups

- Carlson Software operates user discussion groups located at <http://update3.carlsonsw.com/forum/>. You can participate in user-to-user discussion on tips, tricks and problems. Our staff monitors these groups to ensure that all the issues are addressed. Visit our website at <http://www.carlsonsw.com> for information on how to access these groups.

- You may also access the Carlson Software Knowledge Base. Visit it directly at <http://www.carlsonsw.com/support/knowledge-base/>.

via Electronic Mail

The Technical Support e-mail address is support@carlsonsw.com.

via Phone

Phone: (606) 564-5028

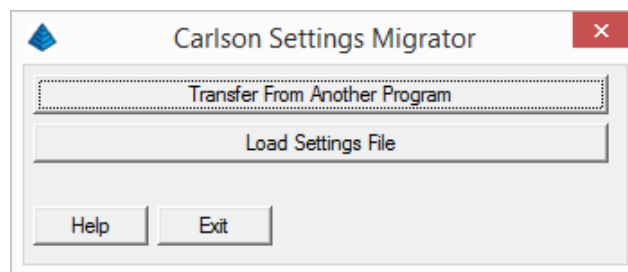

via Web Site

Check the Carlson Software Web Site at <http://www.carlsonsw.com> for:

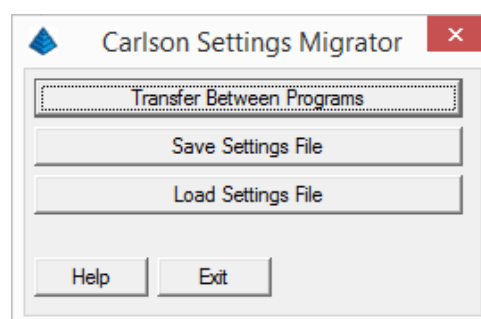

- Knowledge Base, discussion groups, technical support documents and newsletters
- Carlson Software manuals (PDF) and training movies
- Training and seminar schedules
- Step by step procedures on popular called-in topics
- Carlson Software and Autodesk downloads and updates (Feel free to register for automatic update notification of updates when you come to that area.)

Carlson Migration

When user runs the program for the first time, the Carlson Settings Migrator window will be displayed.

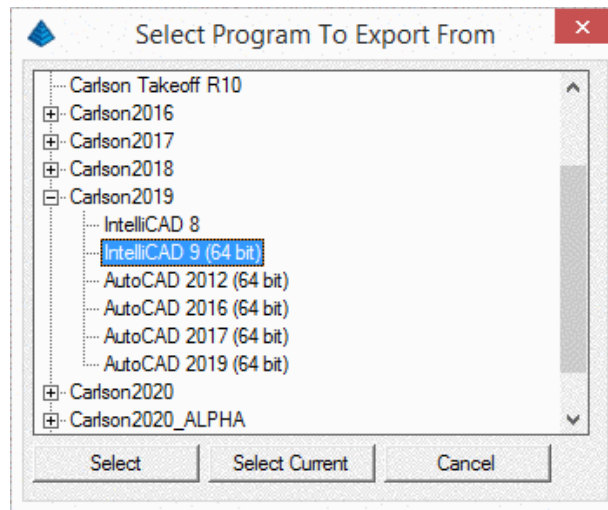

The user has an option to select another instance of Carlson product installed on the same computer to import the settings from or select a packaged import file saved on a different computer. The Settings Migrator can be copied to another computer to export the settings from there. When used internally, this interface is slightly different:

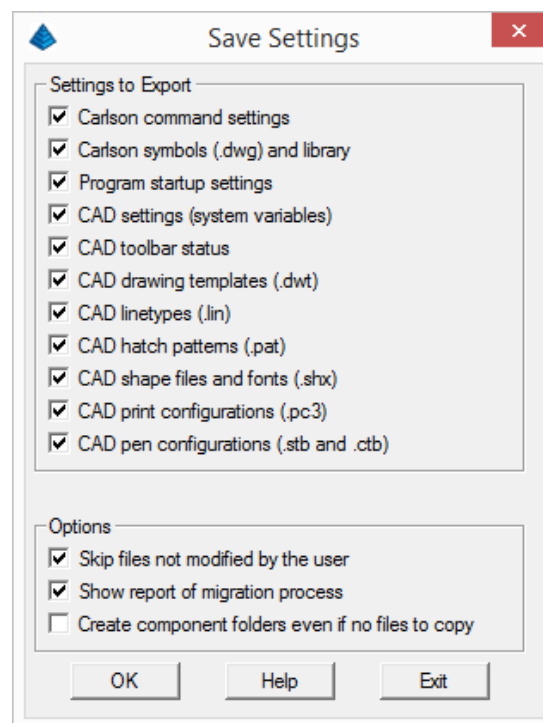

This can be used to move, export or import settings on another machine or even version of Carlson.

Select an instance to export from and click *Select*:

When an instance of the program is selected to export from, the following settings dialog is displayed:

Settings selections are fairly straightforward and most users probably will want to leave them on by default, but the options are as the following:

Skip files not modified by the user - only selected files not originally included with the program will be included. This cuts down on the migration data set size. Additionally, for some file types like fonts and hatch patterns, a care should be exercised when copying them around as they are could be protected by vendor copyrights.

Show report of migration process - displays report outlining settings and files processed

Create component folders even if no files to copy - migration data set is Zip file with sub-folders for individual file types. Most of the time, when "*Skip files not modified by the user*" toggle is used, there are no files for the particular

component to copy. This setting creates component folder anyways. This will allow an administrator to edit Zip file and included additional files in the corresponding folder. This way, by exporting from old version and adding more files, a custom initial data set can be created for the new user to hit ground running.

Additionally, the data migration file can be specified during silent installation for automatic deployment, as described in the Installation Guide.

Starting AutoCAD with Carlson

To start Carlson, use the icon which was created on your desktop and in Carlson submenu under Start > Programs (or All Programs). When you do so, CAD engine associated with Carlson is started with a customized profile, which contains all of the setting changes necessary to run Carlson. This profile prevents harmful conflicts between Carlson and other CAD based products. The changes in menus, toolbars and preferences will be saved in that profile for further use. The CAD engine associated with Carlson is selected during the installation of Carlson.

Custom Template Profile Name

The company with the internal CAD profile setup can specify the desired profile name to be used as a template for setting up Carlson 2024. The existing template will be copied and new profile for Carlson 2024 will be created, changing minimal number of settings required to run Carlson. As a result, most of the profile will match company setup and no further customization will be necessary.

Additionally, there is a way to specify the template as a property of the shortcut starting the program. Under the Target setting in the Windows Properties for the desktop shortcut, add `TEMPLATE=tempatename.dwt` to the list arguments.

Specifying which AutoCAD product is used to start the program

As already mentioned, in case when there are several AutoCAD vertical products installed for the same version of AutoCAD, user can configure which AutoCAD product is used with Carlson. However, in some cases, like having to switch between AutoCAD products based on availability of the network licenses, it may be more convenient to control this with the use of different shortcuts rather than with the program setting. Under the Target setting in the Windows Properties for the desktop shortcut, add `ENGINE=engine_name` to the list arguments. For example for AutoCAD 2019, engine name is `ACAD-2001:409` and for Civil 3D 2019 is `ACAD-2000:409`. These values change often with new releases of AutoCAD and it is best to look them up in the `scjstart.ini` located in the same folder as `scjstart.exe` pointed by the shortcut. This file will contain the value for AutoCAD product currently configured to start with Carlson.

Startup Module

The Carlson module that is loaded when the program is started is set by the desktop icon. The Carlson install program creates different desktop icons depending on how many modules are licensed in your serial number. Under the Target setting in the Windows Properties for the desktop icons, the `SCSTATE` setting controls the startup module as follows:

`SCSTATE=1` Survey

`SCSTATE=2` Civil

`SCSTATE=3` Geology

`SCSTATE=4` Hydrology

`SCSTATE=5` Underground Mining

`SCSTATE=6` Surface Mining

`SCSTATE=7` GIS

`SCSTATE=8` Field

SCSTATE=9 Construction
SCSTATE=10 Point Cloud
SCSTATE=11 GeoTech
SCSTATE=13 Trench
SCSTATE=14 Natural Regrade
SCSTATE=15 CADNet
SCSTATE=17 Civil Suite (any module Survey, Civil, GIS, Hydrology depending on last loaded)
SCSTATE=18 Mining (any module Geology, Surface or Underground depending on last loaded)

License Models

Carlson Software supports a multitude of the license models to better fit the specific needs of the customer. There are three retail license modes: regular standalone license, network license and hardware lock license. There are four additional special license modes: a demo license, not for resale license, educational standalone and educational network license. These license modes as well as their features, benefits and restrictions are described with further details below.

Standalone license model

This is the most typical license model. The user is issued a serial number containing a license to run one or more modules of Carlson application. This authorizes user to install and register software on one machine and one machine only. The exception is made for use of home or laptop computer of the same person. Both computers have to be registered online and home/laptop system is specifically designated during the registration.

Multiple serial numbers containing separate features can be combined within the same installation by entering them in Change Registration dialog, found under Help, About Carlson.

When the computer is no longer available and software needs to be moved onto the new system, the move can be performed by using hardware upgrade option during registration, which marks old system as decommissioned and allows registration on new system.

The upgrade serial numbers are tied to the original serial numbers from the older version and continued use of older version is only allowed if upgrade serial number is used on the same system as original serial number. Otherwise the use of the original serial number is terminated within 60 days of the upgrade registration on different system.

Network license model

This is the license models used by the larger companies needing flexibility of the software licensing when license is not tied to a particular machine. The company is purchasing a pool of licenses consisting of the appropriate count of individual modules to better fit the needs of its users. The pool can be expanded by adding more licenses at later date.

The licenses are loaded into the license server and software is installed locally on the workstations with a network serial number instructing software to look for the license on the network server. For details on the installation process, please refer to the Installation Guide found on CD. Procedure for requesting and installing the license on the server is outlined in the Knowledge base: http://update.carlsonsw.com/kbase_main.php?action=display_topic&topic_id=55

Even if purchased as "seat" or as a part of the Suite, the modules are treated by the license server as individual modules, allowing separate users to have simultaneous use of separate modules from the same "seat". Each

user is going to request and hold the license for the module he is currently uses. That license is held as long as the program is running. When user switches the modules, the held license is released and new module license is acquired.

The network license mode does not allow for the home/laptop license the standalone license mode has, but it allows users to use WAN or VPN software to get licenses from the remote servers over the network and it allows to commute the license from the server and install the license temporarily on the workstation. Commuting is discussed in further detail in the Administrator's guide included with the license server. The commuted license automatically returns to the server when it expires or it can be returned by user earlier when computer returns to the network. Licenses commuted from the server are not available to other users contacting the server for the license, so commuting essentially decreases the server license pool for the commute period.

Software configured to use any serial numbers with network license mode enabled can not use any serial numbers with other license models enabled - it will treat them all as network license serial numbers. Therefore it is not possible to share a module on network but have other modules in standalone mode.

Hardware lock licensing

In this model, the physical hardware key is issued. This key is an USB device which has to be plugged in to the computer in order for the computer to be able to use software. This allows a single user to setup software on multiple computers or even locations and carry his license with him in form of USB device. This is also a primary model of licensing in the countries where software-only protection is not considered sufficient protection due to rampant software piracy.

User is responsible for the cost of the device in addition to the cost of the software itself if this licensing model is employed.

Demo license model

Demo serial numbers allow full use of software within the demo period. The license is limited both by the duration and built-in use counter. Once the demo period expires, the user can get extensions from Carlson customer service in two week increments if there is a demonstrated need to continue with decision process.

Educational institutional license

Accredited institution can receive the network license for the institutional license server for the purpose of teaching course on Carlson software at a nominal cost of software maintenance instead of list price. The university will be responsible for student support and for commuting the licenses for student use in the course. For all practical purposes this is a regular network license, except for the different pricing structure.

Educational student license model

Students currently enrolled at college can purchase a significantly discounted standalone license which will run for 1 year from the date of purchase. A proof of enrollment is required and software running in this mode will be checking online weekly for license extension until 1 year runs out. After this, the additional purchase is required if enrollment remains current. Second and home computers are not allowed with this license model.

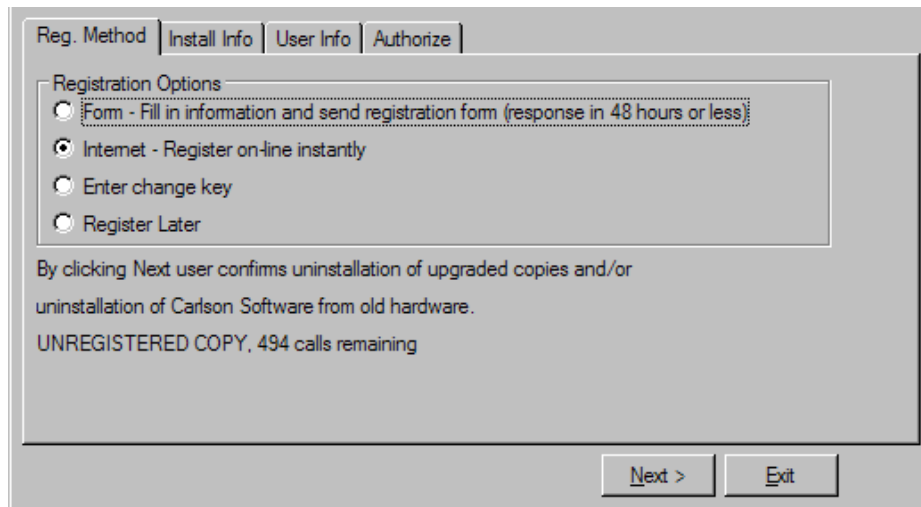

Not for resale license model

This is essentially a standalone license model governed by additional restrictions of license use. Serial numbers designated as "not for resale" are issued only to Carlson personnel and Carlson resellers. These licenses should never be installed at end-user systems or sold to the end-user. Such use constitutes a violation of Carlson agreements.

Carlson Registration

Each Carlson program is licensed for use on **one** workstation which must be registered. The registration records your company name, Carlson serial number and AutoCAD serial number. To register your copy of Carlson, start Carlson and choose "Register Now". The following dialog will appear.

Note: Carlson Software will no longer issue change keys over the telephone. There are four registration options.

Fax: This method allows you to print out the required information on a form which you then fax to Carlson Software. The fax number is printed on the form. The change key will be faxed back to you within 72 hours.

Internet: Register automatically over the Internet. Your information is sent to a Carlson Software server, validated and returned in just a few seconds. If you are using a dial-up connection, please establish this connection before attempting to register.

Enter pre-authorized change key: If you originally chose the Fax method above, you will need to choose this method now to enter the change key that is faxed back to you.

Register Later: If you wish, you may defer registration up to 30 days. After this time, Carlson will enter demo mode which displays a message each time a Carlson command is run.

After you select the registration method, choose Next and select the type of installation you are performing, choose Next again to review the copyright information and to fill out the required information. At this point, if you are using the Fax method, press the Print Fax Sheet button. If you are registering using the Internet method, press Next and the process will start.

If you have any problems with Internet registration, please repeat this process and use the Fax method. The registration form is available on the Carlson Software website at <http://www.carlsonsw.com/registration.html>.

Tip: If Carlson is running, you may access the registration dialog by choosing *About Carlson* from the Help menu, then pick the Change Registration button.

Network License Setup

The up to date version of this process is always available online at http://www.carlsonsw.com/support/knowledge-base/?action=display_topic&topic_id=55

Quick Summary of Network License Manager Installation Procedure

Install the Carlson Software product which you intend to network onto each of the workstations using the network serial number provided to you. Once you have completed that task, please do the following on the network server:

1. Download the Sentinel Server.exe from the link below and install it to the server: Sentinel Server ver. 8.2.3
2. Download the Carlson LMTools.zip from the link below to the server and extract the files in a location on your computer which is both easy to find and easy to remember. You will need these files in the future for license management purposes: Carlson LM Tools 8.2.3.zip
3. If you are existing user of Carlson and you are upgrading to a later version of Carlson Software (2010 and beyond) **You do not need to request new license files...** the network license files for older versions will work with your upgraded serial numbers and software.
4. Open the LMTools folder and run the **regclient.exe** to request license files for your new license manager (see more details below). You will receive a reply (to the e-mail address specified in your request) containing your license file.
5. Save the .txt license file (from your reply e-mail) into the LMTools folder.
6. Run the **WLMAAdmin.exe** file, also found in the LMTools folder, to point the license manager to the new license file (see more details below).
 - On the left-hand side of WLMAAdmin you will see Subnet Servers with a plus (+) beside it. Please click on the plus beside Subnet Servers to expand the list of servers.
 - Right-click on the subnet server which you intend to use for the license manager.
 - Select **ADD A FEATURE > FROM A FILE > TO A SERVER AND IT'S FILE.**
 - A Windows browser window will open within the LMTools folder to allow you to select the license file that you received in your e-mail.

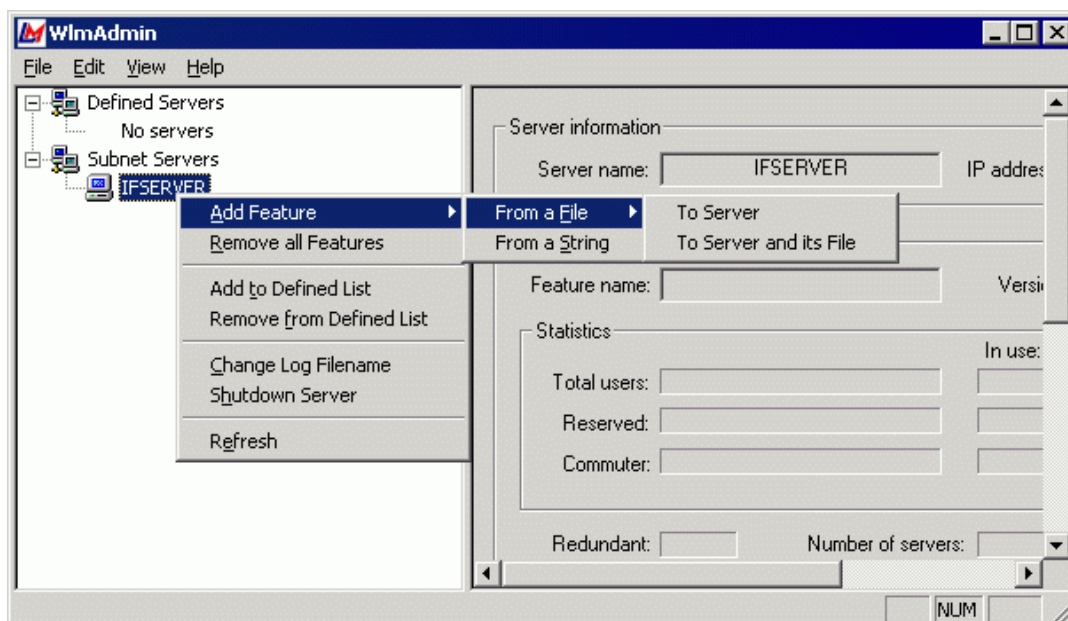

In order to **REQUEST A LICENSE FILE**, please follow these steps:

1. Download LMTools8_2_3.zip and extract it into a folder of your choice.
2. If you are planning on setting up redundant license server pool, please refer to Knowledge base Article 620.
3. One of the files found in the LmTools.zip is **regclient.exe**. Execute this program on the **SERVER** computer.

- Please fill out the entire form and provide real contact information as we will use it to contact you and provide you with your license.
- Make sure to use the **Carlson network serial number** provided to you for the product being licensed.
- Make sure to select an appropriate reason for the request.
- In the note field include sufficient information about what has lead to the problem. Provide any additional information you may have in this field (i.e. the number of seats (nodes) requested for each module).
- Click on **Submit** to transmit the request directly to the Carlson server when you are finished. Make sure that any local firewall (if present) allows the connection through. In case of transmission failure, you will be given alternative submission instructions.

Installing The License File

When you receive your license file, perform the following:

1. Run the **WlmAdmin.exe** found in the LMTools folder.
2. Click "+" before Subnet Servers, to expand the list.
3. Highlight your server name on the list.

NOTE: If the server is not on the list please verify the following:

- Sentinel Server is installed
 - SentinelLM service is running (Control Panel > Administrative Tools > Services)
 - The computer running the WlmAdmin.exe is on same computer or at least on same subnet as license server
 - The license server does not have a local software firewall or modify the firewall rules to let licensing traffic through (see Knowledgebase Article 269 for more info)
4. Right Click on the Server name and select **Add Feature > From a File > To Server AND It's File**
 5. Browse to select the license file which has been emailed to you.

NOTE: If the license has been rejected:

- Make sure original license request (regclient.exe) was originated from the SERVER computer.
 - This license was not yet added (multiple additions of the same file generate errors).
 - The Server name and IP address showing for the server (within WlmAdmin.exe) are correct
6. You can now verify licenses available by clicking "+" in front of the server name

Install The Software Being Licensed

Now, install the software being licensed on the workstations by using the serial number provided to you with the installation package. All workstations on the network will share the same serial number.

NOTE: Automatic server discovery only works if the workstations and server are located within the same subnet. In other instances an environment variable needs to be set on the workstation through the following procedure:

1. Go to Control Panel > System > Advanced Environment Variables
2. Under System Variables, click on "New"
3. Set the "Variable name" to **LSFORCEHOST**, and the "Variable value" to the name or IP address of the server (SafeNet's Support recommends using the license server IP address)
4. Click OK all the way out.

NOTE: If you intend to use commuter licenses, please refer to Knowledgebase Article 507 for additional steps to be performed on the workstation by administrator.

Verify that the licensing works on the client machine. Please note that license is not when the program starts, but after the first or second consecutive command.

Troubleshooting

For troubleshooting, please refer to Knowledgebase Article 211. The Complete Administrator's Guide has been included in the Carlson LmTools8_2_3.Zip file.

Network License Monitoring

To view the current available count of licenses on the server, you can run the WLMAdmin.exe from within the Carlson LMTools folder. These tools were used to install the license and are available for download.

The WLMAdmin.exe will not automatically refresh to show which licenses are in use. You will need to click on the View drop-down and select "Refresh allÂ".

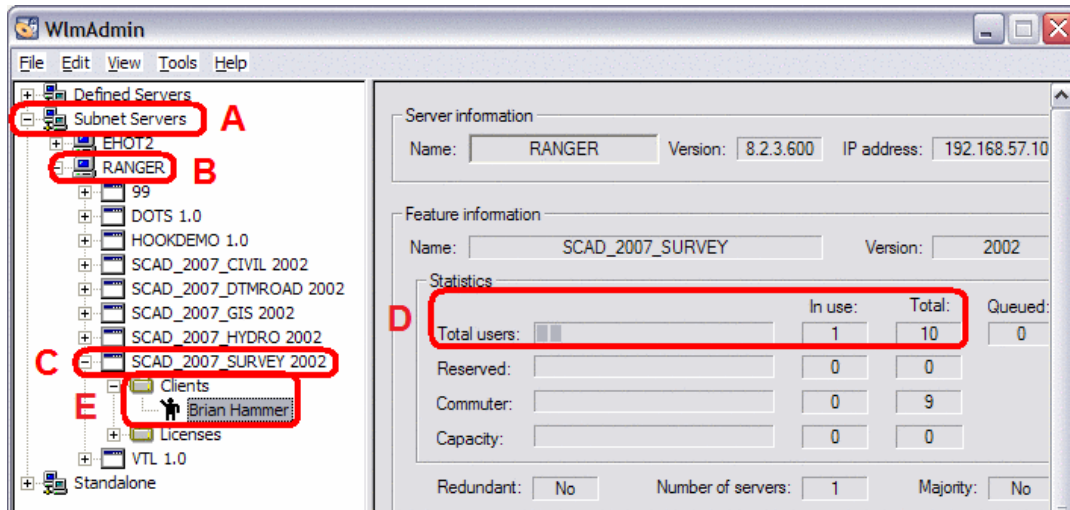

A Click on the + beside Subnet Servers to show all servers on the subnet.

B Click the + beside the Server Name to show the modules licensed to this server.

C Click on the module of your choice to highlight it.

D The total number of licenses, as well as those in use, can be found under Feature information.

E To see which user is has a particular license; click on the + beside the module name. Then, click on the + beside the Clients folder.

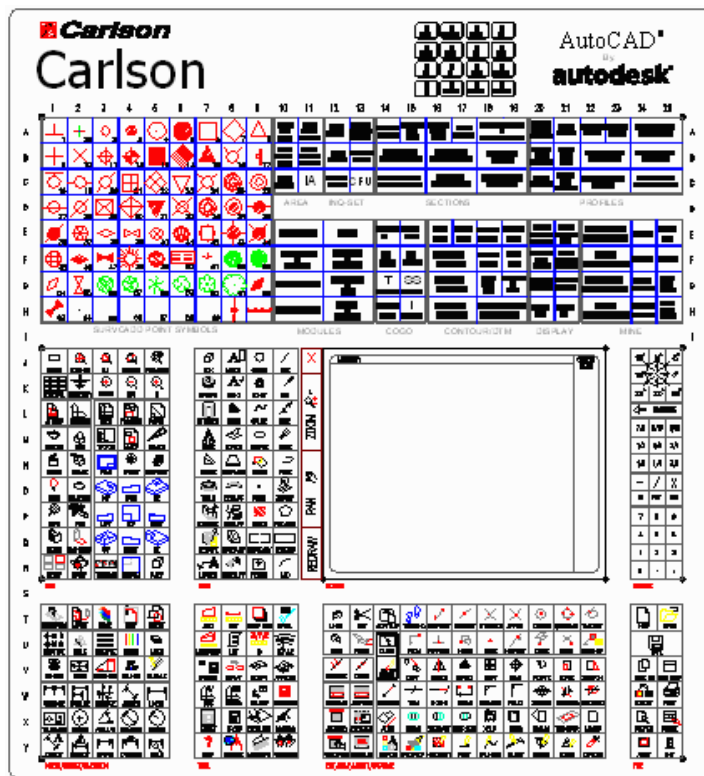

Carlson also has a set of integrated network manager functions under Help->About Carlson->Registration. Click **Network Licenses** to access the dialog which has the features which can list the features available on the server, count of the licenses and also allow the user to commit or return the license.

Tablet Template

If you have a digitizer you will probably want to plot a copy of the Carlson tablet menu. After installing Carlson, start Carlson and plot a copy of the drawing file TABLET.DWG located in the Carlson support directory (ie: \Carlson\SUP\TABLET.DWG), at a scale of 1=1. You may want to review the drawing in the drawing editor to determine layer names and colors to set up a color version of the template. You can also modify this drawing to add your own symbols and details to the tablet menu. After plotting, secure the Carlson template drawing to your digitizer. The proper scale is 1=1 for a 12" x 12" tablet. It can also be plotted at a smaller or larger scale to suit other tablet sizes.

Once you have a hard copy of the tablet, the tablet needs to be configured. Type TABLET at the command prompt. Refer to the CAD Reference Manual for details on the menu area points and number of columns and rows. The tablet template is in the standard template format which means if you are using any other templates you can easily switch between different control menus.

Troubleshooting and Customizing Setup

To install Carlson 2024 on Windows, you must have Administrator permissions to write to the system registry during the install.

Successful install of Carlson consists of four key items:

1. Windows registry settings
2. Carlson icon on desktop and in the Start menu
3. Carlson 2024 profile created in AutoCAD or IntelliCAD
4. carlson.ini configuration file in USER sub-directory of Carlson

The Carlson profile in AutoCAD/IntelliCAD is created and configured by the helper application called SCJSTART. The application is typically located in C:\ProgramData\Carlson Software\Carlson2024\ followed by subfolder specific to CAD version. Please note that ProgramData is folder hidden by default Windows Explorer settings. In this location, there is a file called scjstart.ini which is generated during install and which controls SCJSTART.EXE behavior.

If you have trouble starting the application, review the scjstart.ini contents to see if anything on the system has changed since the installation and needs to be corrected.

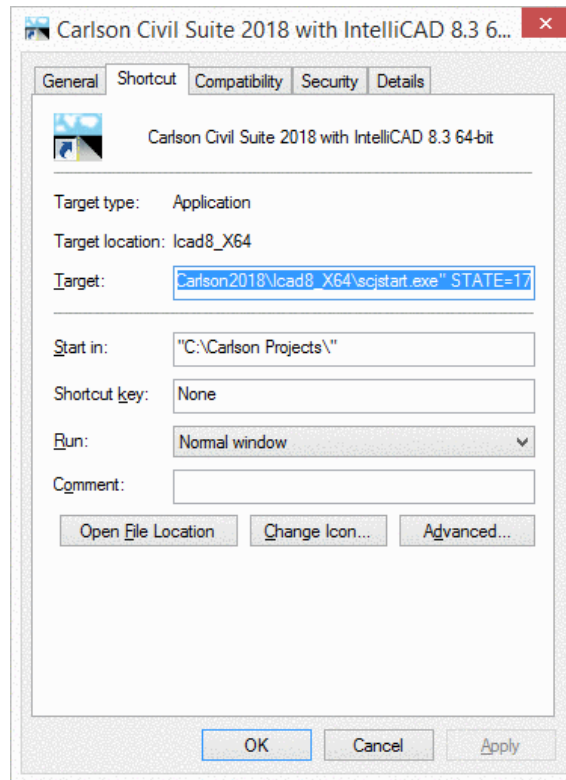

Desktop and Menu icons for Carlson 2024

A Carlson specific profile is used in order to configure Carlson correctly and start the Carlson menu when AutoCAD or IntelliCAD starts. Profiles are used by the CAD to separate different product environments. If profile is missing, the profile from old version of Carlson will be used as template to copy to new version or if that is not present, the first of the existing profiles is used instead. Once profile is copied, it is adjusted to start new version of Carlson.

Carlson shortcuts point to the scjstart.exe and command line parameter called STATE controls which module activated when the product is launched.

To verify that your Carlson icon is set up correctly, do the following:

- Right click on the Carlson icon and select Properties. Click on the Shortcut tab.
- Target field should contain the following executable **SCJSTART.EXE** (located in the Carlson\USER directory).
- Work directory defaults to the same directory where drawings are stored
- Make changes as needed and click OK.

User can control which template is used to create new drawings in the program by specifying additional command line switch to the Target field of the shortcut. Add **TEMPLATE=template_name.dwt** to the end of the input. You can create a copy of shortcut with different template name to be able to switch between templates. The template being specified should already be known to the program by being within one of the searched folders.

Checking Carlson.INI configuration file.

The last step in troubleshooting the installation is to verify the Carlson.INI file in the Carlson USER directory. Open that file using Notepad (Click Start, Programs, Accessories, Notepad) or any other editor. Then verify and/or modify the top few lines to match your setup. Save it and restart Carlson.

If the procedures outlined above did not help or you have trouble following them, please feel free to contact Carlson Software Tech Support.

Loading Carlson Menus

The Carlson programs are loaded when the Carlson menu is loaded. The Carlson menu is named cs###base.mnu (for AutoCAD 2005 and earlier) or cs###base.cui (for AutoCAD 2006 to AutoCAD 2009) or cs###base.cuix (for AutoCAD 2010 and later) where the ## is the version of AutoCAD or icadbase.mnu for IntelliCAD. For example, in AutoCAD 2014 the Carlson menu name is cs14base.cuix. The Carlson menu is located in the Carlson SUP folder. The Carlson installation and desktop icons should automatically setup AutoCAD to load the Carlson menu. To manually load the Carlson menu, first make sure that the Carlson SUP folder is listed in the Support File Search Path under AutoCAD or IntelliCAD Options. Then run the menuload or cuiload AutoCAD command or the menu IntelliCAD command and load the Carlson menu. The Carlson SUP folder is under the Windows user folder such as:

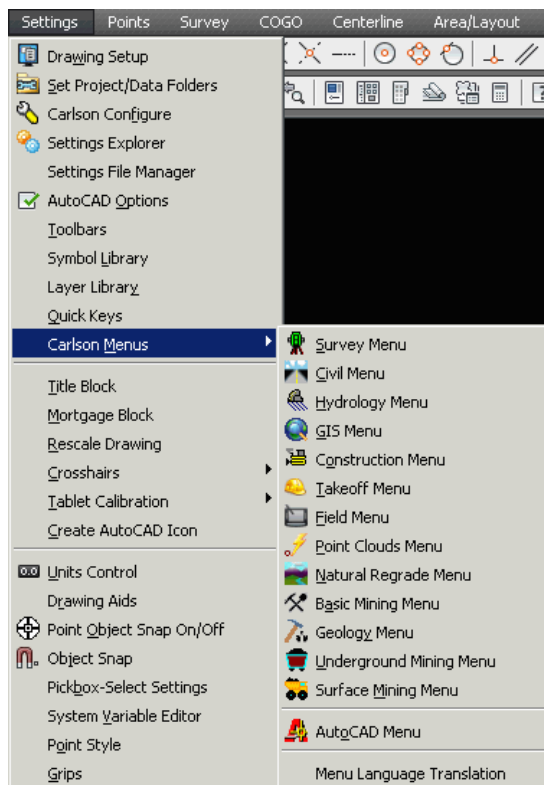

```
%appdata%\Carlson Software\Carlson_Version\CAD_Version\SUP
```

The Carlson menu has over 80 pull-down menus for the different Carlson programs. Each program has its own set of pull-down menus. The menu set for one program is active at a time. To switch current program menu, choose the menu from Settings>Carlson Menu or choose from the Modules toolbar.

By default, the Carlson menu is setup as the Main Customization File in AutoCAD. To setup the Carlson menu as the partial menu,

1. Start AutoCAD with Carlson by using the Carlson desktop icon
2. Run CUILOAD and unload all the menus. Then load your Main Customization File. Then load the Carlson menu.
3. In Carlson Configure->Startup Settings, turn on No Menu Reset.

The Carlson toolbars are defined in the Carlson menu. To turn on more toolbars, right-click in the toolbar space such as between the pull-down menus and the drawing window. This right-click menu has a list of all toolbars and you can pick on the toolbar name to activate. In AutoCAD, another way to activate toolbars is type CUI at the command prompt which brings up the Customize User Interface dialog where you can click on toolbars. In IntelliCAD, another way to turn on toolbars is type TOOLBAR at the command line which brings up a list of toolbars that you can toggle on.

For AutoCAD 2012 and higher, Carlson ribbons are available. Ribbons are like advanced toolbars. These ribbons are defined in the Carlson menu and can be accessed by setting the AutoCAD Workspace to one of the Carlson default workspaces such as Survey. Use the AutoCAD workspace command or toolbar to set this workspace. You can also use the CUI command to activate the Carlson ribbons and workspaces.

Obtaining Technical Support

via Discussion Groups

- Carlson Software operates user discussion groups located at [news://news.carlsonsw.com](http://news.carlsonsw.com). You can participate in user-to-user discussions on tips, tricks and problems. Our staff monitors these groups to ensure that all the issues are addressed. Visit our website at <http://www.carlsonsw.com> for information on how to access these groups.
- You may also access the Carlson Software Knowledge Base. Visit it directly at http://update.carlsonsw.com/kbase_main.php.

via Electronic Mail

- The Technical Support e-mail address is support@carlsonsw.com.

via Phone/Fax

- Phone: (606) 564-5028
- Fax: (606) 564-6422

via Web Site

Check the Carlson Software web site at <http://www.carlsonsw.com> for:

- Knowledge Base, discussion groups, technical support documents and newsletters
- Carlson Software manuals (PDF) and training movies
- Training and seminar schedules
- Step by step procedures on popular called-in topics
- Carlson Software and Autodesk downloads and updates (Feel free to register for automatic update notification of updates when you come to that area.)

via Training

- Basic, advanced and update training is available from Carlson College. Enroll on our webpage or call 606-564-5028 and ask for Carlson College.

Command Entry

Commands may be issued by selecting a pulldown menu, screen menu, digitizer tablet item, or by typing a command at the command prompt. Pulldown menus have a row of header names across the top of the screen. Selecting one of these header names displays the possible commands under that name. Screen menu items are shown in the screen menu (typically on the right side of the screen). The screen menu can be toggled off and on inside of the AutoCAD Options dialog. The Pulldown menus are the primary method for Carlson command selection. Each section of this manual shows the pulldown menu which contains the commands that are explained in that section. Pulldown menus are sometimes also referred to as dropdown menus.

Command availability depends on which menu is loaded. Carlson menus have a mixture of both Carlson and CAD commands. This allows you to execute the commonly used CAD commands from the menus while running Carlson.

Quick Keys are user-defined short cut names that can be typed in to start commands. To review the current set of Quick Keys, run the Quick Keys command in the Settings pulldown menu. Quick Keys are explained in more detail in the next section.

For command entry at the Command: prompt, pressing Enter repeats the last command. Also the prompt history records the sequence of previous commands, and you can run these previous commands without invoking the menu. To access the commands, use the keyboard up and down arrows. The up arrow moves backwards in the history and the down arrow moves forward. As you press the arrows, the previous command names appear at the command prompt. When you get to the command that you want to run again, press Enter.

Transparent Commands

Transparent commands can be issued at the Command: prompt while running other commands without exiting the current command. The transparent command will run and then return to the current command. To run a transparent command, you can either type in the command name or pick a button on the Transparent Command toolbar. There are nine Carlson transparent commands for point input and one for entity selection. The point commands can be used at any command prompt that is for a point location. The selection command can be used at any "Select objects" or "Select entities" prompt.

'2: Gets the 2D (x,y) coordinate by point number from the current coordinate file. You can enter a single point number or a range of points (ie 1-10).

'3: Gets the 3D (x,y,z) coordinate by point number from the current coordinate file.

'CL: Gets a point by station-offset from a centerline. The routine prompts for a centerline, station and offset left or right. The centerline can be defined by a centerline file, segment on a polyline or linework entity. The position along the centerline can be specified by entering the station, picking a point that gets projected onto the centerline, or by a distance factor. While picking the position along the centerline, the program shows the station and offset of the cursor in real-time. The 'CL command can be used as a Perpendicular From snap by picking a centerline and entering a station to come perpendicular from (the routine defaults to the station of the last point) and then entering an offset for the perpendicular distance.

'PIPT: Gets a point that is the PI position for an arc. The routine prompts to select an arc.

'CENTROID: Gets a point that is the centroid position for a closed polyline. The routine prompts for the polyline to process.

'TRAVPT: Gets a point by angle and distance from a starting point.

'TANGPT: Gets a point that is tangent to the selected centerline or polyline. The routine prompts for the centerline, station and distance. The station defaults to the position along the centerline of the last picked point.

'BBPT: Gets a point by Bearing-Bearing Intersection. The routine follows the same prompts as the Bearing-Bearing Intersect command in the COGO menu.

'BDPT: Gets a point by Bearing-Distance Intersection. The routine follows the same prompts as the Bearing-Distance Intersect command in the COGO menu.

'DDPT: Gets a point by Distance-Distance Intersection. The routine follows the same prompts as the Distance-Distance Intersect command in the COGO menu.

'FILTER: Makes a selection set of entities using an entity property filter. Available properties to filter include layer, level, type, style, linetype, size and color. For each property, you can choose whether to include or exclude from the selection using this property. When using multiple properties for the filter, they are combined using an AND operator so that all properties must match to pass the filter.

Prompts

For '2 to draw a polyline from points 100-102.

Command: *pl*

PLINE

Specify start point: '2

>>**Enter point numbers:** 100-102

Resuming PLINE command.

Specify start point: 10308.02109999,10213.95245576

Current line-width is 0.00

Specify next point or [Arc/Halfwidth/Length/Undo/Width]:

10307.46576250,10214.50318930

Specify next point or [Arc/Close/Halfwidth/Length/Undo/Width]:

10268.05722717,10245.06058831

Specify next point or [Arc/Close/Halfwidth/Length/Undo/Width]: *press Enter to end*

For 'CL to draw a polyline starting at station 200, right 50 from a centerline:

Command: *pl*

PLINE

Specify start point: 'cl

>>**CL File/Segment/<Select centerline polyline>:** *pick a polyline*

>>**Station range:** 0.00 to 256.36

>>**Factor/<Pick point on centerline or Enter Station <191.162>>>:** 200

>>**Centerline starting station <0.0>:** *press Enter to use zero*

>>**Offset (negative for left):** 50

Resuming PLINE command.

Specify start point: 5155.46856081,5271.30066060

Current line-width is 0.00

Specify next point or [Arc/Halfwidth/Length/Undo/Width]: *pick a point*

What is New

General

- AutoCAD 2024 - Added support for this new version.
- IntelliCAD 11.1 - Added support for this new version.
- IntelliCAD 10.1 - Improved speed and new features like sheet sets with the Publish command.
- Toolbars - Added over 30 new toolbar icons and a new ribbon for GeoTech.
- Open Drawings Map - Added method for custom properties for drawing records and method to store a drawing database on a shared network location. From the Map view, added function to open Windows File Explorer for the drawing's project folder.
- Settings Server - Added method to copy data files into project folders.
- Project Data Sub-Folders - Added separate Program Settings folder for settings files.
- Data Depot - Added details to the history log and the ability to restore a previous version of a data file. Adding files to Data Depot supports working from project level with controls on which files to add.
- Data Depot - Ability to log in or out of the server from the Project Setup dialog box.
- Data Depot - Ability to specify destination folder location when getting a project from the Data Depot.
- Carlson Configure - Added setting to control font used for dialogs.
- Select CAD Default Settings - New command to choose classic or modern CAD user interface settings.

- Drawing Cleanup - Added functions to remove duplicate text and to remove unused registered apps.
- Import Polyline File - Added method for locating by station/offset values from the file.
- Drawing Inspector - For polylines, added reporting of current position distance. For centerline polylines, added reporting of spiral data.
- Draw MText - In many commands that create MText, added an option to set the Text Frame to draw a box around the text.
- Translate Layers - Added method to import layer names from the drawing.
- Line Up Text - Added method to pick two points to define angle, option to respace and option to use text for alignment reference.
- Arrowhead with Line - New command to draw a two point leader with an arrowhead.
- Boundary Polyline - Added option to create 3D polyline.
- Shrink-Wrap Entities - Added options to ignore zero elevation entities for input, to elevate zero elevation vertices, and to erase the input entities.
- Add Intersection Points - Added option to average elevations at intersection within a tolerance.
- Draw Label For Companion Linework - New command for Draw To Standard to create a label using properties by layer.
- Draw Standard Item by Quick Key - New command to create entities for Draw To Standard by typing a quick key instead of dialog list selection.
- Reports - For PDF reports, added option to make PDF report files read-only. For Report Formatter, new option to put text lines at the bottom of the report and added function to sort the list of available fields.
- 3D Viewer - Added zoom extents function.
- Angle Info - Added ability to handle 3D angles.
- Layer ID - Added option to label the layer name.
- Command Search - Added reporting of toolbars for the commands.

Survey Commands

- Drone Mission Planning - New command to create a drone mission plan.
- Carlson Photo Capture - Added method to download files by file type.
- Input/Entry Distance Scale - Added method to scale distances in many COGO commands such as Enter Deed Description.
- Import Text/ASCII File - Added ability to read points from a SurvCE/Layout job database (.jdb) file. Added functions to save and load settings to a .rpnt file.
- Import Distance/Angle File - Added field for deed name for importing multiple deeds.
- Edit Process Raw Data - Added function to update the descriptions in the RW5 from a coordinate file. Added function to apply Field-to-Finish substitution codes to the descriptions in the RW5 file. Added report option for the description on the same line as the data. Added an optional warning on processing for points with a blank description. Added option to use a larger font for the spreadsheet. For processing GPS records added storing the lat/lon and RMS values to the CRDB as attributes.
- Edit Process Level Data - Added method to adjust elevations based on the number of turns.
- SurvNET - Added option to merge output point text file with control points.
- Draw Points - Added option to label elevations in inches.
- Point Group Manager - Added methods to create a point group of points unassigned to a group and to create group from point number suffix.
- Field to Finish - Added ability to run Triangulate & Contour to draw contours or make a TIN of the points and polylines. Added new utility feature. For pipe features, added ability for separate pipe feature settings per code, option to label structure names along the pipe and option to draw both pipe 3D faces and polylines. For tree features, added offset by tree symbol size as factor of text offset, added option to draw labels as MText and added settings to control order of input parameters. Added setting for annotative points per code. For GIS attributes on a line, added support for multiple attributes. Added option to match first symbol scale when creating a second symbol. New special code of OO for Offset Only that draws only the offset polyline. For OH offset horizontal special code, added method to repeat the offset multiple times. For hedge linetype, added ability to control width using OH or OFB special codes. For RECT special code, added setting for using a

third point as a rectangle corner or an offset for the rectangle width. For text attributes prefix/suffix settings, as string of [DESC] gets replaced by the point description. Added method to draw only points with GPS status of Fixed. Added option to hide the drawing under the Mtext labels. Added support for using fixed parameters with multiple codes.

- Offset Point Entry - Added option for slope stations.
- Annotation - Added option to use a custom block for endpoint leaders. For Stack Label Arc and Annotate With Leader, added option to create as MLeaders. For bearing leaders, added support for annotative leaders.
- Line/Curve Table - Added option to draw the table as MText without the grid lines.
- Stack Label Arc Auto Place - New command to automatically place the arc labels at the mid-point of the arc.
- Stack Label Arc Pick Side - Added option whether to draw leader.
- Label Angle - Added method to create an angle table. Added ability to handle 3D angles.
- Distance Table - New command to create a distance table of pairs of points and distances.
- Offset Dimensions - Added option to use CAD's current dimension style.
- Linetypes - Added method for multiple dashes between the symbol/letter such as —C—C—.
- Legal Description - Added method to report exterior angles.
- Map Check - Added support for azimuth format angles.
- Deed Correlation - Added method to screen pick points.
- Process Deed File - Added option to report using the Report Formatter.
- Area Descriptions By Interior Text - New command to tag area descriptions by automatically finding text inside polylines.
- Best Fit Line - Added method to screen pick CAD points, method to add more points to the calculation and option to set output layer.
- Convert CRD to ASCII By Folder - New command to batch process converting coordinate files to text files.

Civil Commands

- Triangulation Surface Manager - Add Point inside TIN hole has new option to fill the hole.
- Triangulation File Utilities - Added a Remove Spikes tool and added function to draw drainage low points.
- Grid File Utilities - Added export for DEM files.
- Triangulate & Contour - Added option to use linetype for depression contours.
- TIN Rebuild Inside Perimeter - Added method to apply inverse distance to adjust elevations within a perimeter. Added method to raise low points within a perimeter to fill-in low points to prevent ponding.
- 2D to 3D Polyline By Profile - New command to elevate a polyline using a profile.
- 2D to 3D Polyline By Screen - Added method to extrapolate elevations.
- Curb Ramp - Added graphic preview to dialog. Added option to taper only the first ramp section. Added method to do curb-cut only with no ramp. Added method to pick the curb position separately from the polyline selection. Added a separate curb taper method.
- Wall Polyline Editor - Added layback slope, freeboard, bury depth, output to solid model (.mdl), color/texture for 3D viewing, and report including backfill quantities and wall volume. Added double-click on the wall polyline to run the wall polyline editor. Added support for using wall polylines in Takeoff design surface modeling.
- Elevate Pads By Grade Rules - Added option to add break points to lot lines and option to create swales.
- Cut/Fill Movement - Added option to label cells.
- Stockpile Volume - Added method to use lowest elevation around perimeter as flat base elevation.
- Surface 3D FlyOver - Added support for viewing solid models (.mdl). Added settings for camera based light and shading for front, back or both sides. Add Model to the scene also draws a symbol in the drawing when the Model Library has the model defined with a CAD symbol.
- Slope At Points - Added method to use a coordinate file and two points to define the slope.
- Elevation Zone Analysis - Added method to use TIN surface and set colors in the TIN file for the elevation zones.
- [doc] Vehicle Path Tracking - Added option to draw section view of vehicle with dimensions and added vehicle section view preview to dialog.
- Polyline To Centerline File - Added method to define station at a reference point.

- Label Station Offset - Added method to label CL crossings in plan view with option to label layer names.
- Design Parking Inside Perimeter - Added ability to create islands at ends of parking rows. Added option whether to create spaces around the perimeter and option to add remainder parking space to the corner.
- Design Parking Along Alignment - Added support for alignments with multiple segments, ability to use a polyline or centerline file for the alignment, and support for angled parking. Added functions to create auto treatments and to mirror treatments between left and right sides.
- Draw Template Polylines - Added option to densify the template polylines.
- Template Series File - Added interpolation option for none.
- Shrink/Swell Table - New command to define different shrink/swell factors by station range for cut/fill and subgrade materials.
- Draw Super Elevation Color Centerline - New command to draw the centerline polyline with colors for the super elevation transition zones.
- Process Road Design - Added method to Template Point Profile to apply change in slope to another grade for a divided highway. Added method to use clip lines at the ends of the road for skewed ends.
- Road Network - Added method to create a bottom of subgrade surface. Added method to hatch the template grade areas. Added method for road template gaps by station range.
- Lot Network > Road Network - Added option to chamfer ROW intersections instead of arcs.
- Station Polyline/Centerline - Added method to store deflection angle into the point description.
- Draw Profile - Added option for fixed grid top/bottom elevations. Added option to draw horizontal line at bottom of elevation axis labels. Added option for line under label base elevations. For utility profiles, added pipe thickness and option to limit max offset for station by reference CL. For hatch, added option to label areas. For sewer profile labels above the rim, added method to place by grid top location and option for vertical labels with a leader from the rim. Added option to label manhole names using MText.
- Draw Section File - Added method to label the total section distance. For tunnel sections, added support for end areas from a single closed section. Added option to create labels as MText. Added ability to set a description for each station that can be drawn in Draw Section File and reported in Section Report. For slope labels, added filter by user-specified slope amount.
- Section File Editor - Added ability in translate elevations to use a profile to adjust the sections.
- Section Report - Added method to only report user-specified offsets.
- Set Descriptions By Offset - New command to set cross section descriptions by offset.
- Draw Mass Diagram - Added method to graph as immediate cut/fill difference instead of accumulative.

Hydrology Commands

- Rain Lookup Table - New command to store custom rain events.
- Merge Watersheds - New command to combine the polyline perimeters of neighboring watersheds.
- Time of Concentration - Added Kerby-Kirpich method.
- Channel Routing - Added Muskingom-Cunge and Modified Puls methods.
- Pond Exfiltration - Added functions to save and load parameters to a .pdx file.
- Drop Pipe Spillway - Added lookup table for entrance loss coefficient. Added functions to save and load parameters to a .drop file. Added PDF report and function to draw diagram to the drawing.
- Pipe Culvert Design - Added report option for stage-discharge graph and option to draw HGL on pipe detail graph. Added support for Muskingom-Cunge method.
- Advanced Weir Design - Added functions to save and load parameters to a .weir file.
- Orifice Design - Added functions to save and load parameters to a .outlet file.
- Multiple Outlet Design - Added PDF report method with diagram and stage-discharge graph.
- Sewer Network - Added ability to automatically set inlet as on-grade or sag based on the surface. Added support for Inlet Control Devices to limit intercepted flow. Added support for structures with underdrains. Added new yard inlet structure. For SCS rainfall lookup, added methods to choose from lookup table, rain map or NOAA. Added method to round elevations by decimal precision. For draw plan view, added setting for direction of pipe polylines as upstream or downstream. For data table, added ability to control which structures to include in the table. For Review Sewer Network Links, added a method to reassign the data files. Added pipe thickness to editor and reports. Added setting for having raised rim heights. Added a new Line

- Name field for each structure.
- Collision Check - Added option to draw 3D lines between the crossing pipes along with 3D text for 3D viewing. Added coloring of pipe portions that have conflicts. Added report of minimum horizontal and vertical clearance. Added method to check for collision with a surface model. Added option to color pipe segments with a conflict.
- Compare Sewer Networks - New command to report differences between two sewer network models.
- Draw Sewer Profile - Added ability to draw profiles for normal and critical depth lines.
- HydroNet Explorer - Added support for circular pipe reach and culverts. Added support for the Clark and Snyder hydrograph method. For draw plan view, added options to create MText labels, draw connection lines, use default symbols and save/load settings. For reports, added method to control the order of elements.
- Utility Network - For pipe labels, added settings to control offset from line and layer for labels. For creating profile at depth, added method to create streamlined profile with min number of profile points and ability to set max depth and min segment length. Added report function to check pipe depths and min/max cover. Added a description field for each utility with option to label in Draw Profile and Draw Sections. For laterals, added location by offset and slope.
- Pressure Pipe Network - Upgraded calculation engine to EPANet 2.2. Added ability to set tank level to create specified pressure. Added ability to add multiple connections or laterals at a time with a specified station interval and demand. Upgraded interface for setting up demand patterns. Added ability to draw symbols for valves in plan view.
- Pipe Network ID - New command to pick a pipe network entity and report which pipe network model it belongs to.
- Review Network Drawing Links - New command to review pipe network entities in the drawing and report network files with ability to reassign network files.
- HEC RAS - Added method to output a cross section of the water level. Added support for version 6.0.

GIS Commands

- Upgraded User-Interface - New dialogs for many commands including GIS Data Editor and GIS Data Inspector.
- Define GIS Features - Added import for StartNET, ESRI SHP and Carlson GIS .db features.
- Point GIS Editor - Added import for StartNET attributes.
- Place Camera Symbol - Added method to use points.

Geology Commands

- StrataCalc - Added new configure setting to limit pinchout by strata name range.
- Draw Geologic Column - Added complete custom control over formatting and which values to label. Added option to label bed thickness.
- Drillhole Text - Added method to create MText.
- Google Earth Drillholes - New command to tag drillhole symbols with drillhole/strata labels for viewing in Google Earth.

Surface/Underground Mining Commands

- Surface Mine Reserves - Added custom strip ratio formula. Added non-key tonnage to stored pit attributes.
- Prepare Value Block Model - Added cut surface and value calculation method tracking and grid info. Added export to text file function.
- Assign Directions - Added support to define directions by lines or leaders.
- Surface Equipment Timing - For 3D Pick, added ability to turn benches on/off. Added delay amounts to the report. Added output of period centroids to the spoil timing output file. Added option to skip non-key for timing.

- View Surface History - Added method to color surfaces by timing periods.
- Label Pit Formatter - Added options for commas in numbers and for higher order rounding.
- Block Model Viewer - Improved loading speed by over 10 times. Added option to merge matching grade blocks, option to render the outer shell of grades, option to tag blocks for inspecting in the viewer and ability to set the transparency of block by grade.
- Block Model Statistics - Added method to report by grades.
- Make Solid From Design - Added support for vertical alignments. Added option to draw cross section and template 3D polylines.
- Make Solid By 3D Triangulation - New command to create a 3D solid for a tunnel from a point cloud.
- Create Gap Points - New command to create points on a plane to fill in gaps in the point cloud.
- View Solid - Added setting for separate color for back side of 3D Faces.
- Draw 3D Mine Model - Added method to output an MDL file.

CADnet Commands

- 3D Image Viewer - Added method to download aerial image from Google Earth.

Construction/Trench Commands

- Convert Dashes to Polylines - Added individual method to trace by picking starting segment.
- Topsoil Removal - Added method to assign topsoil removal as outside of subgrade areas.
- Input Trench Line - Added option to interpolate invert elevations in case of junction without elevation label.
- Trench Network Quantities - Added option to use a user-specified TIN as the reference surface. For the plan view map, added option to label stations.

Point Cloud Commands

- Import - Added function to import cloud data from CAD points.
- Export - Added support for E57 format and RCS format.
- Bare Earth - Added option to put the ground points into a region instead of creating a new cloud. Added method to create a cloud of the non-ground points.
- Create Polyline - Added method to create polylines with tangential arcs.
- Edit Polyline - Added function to zoom scene to current polyline in editor dialog.
- Extract Slices - New function to view cross sections of cloud data and create points and polylines.
- Curb Breaklines - New method to create 3D polylines for top and bottom of curb by using edge clusters.
- Create Breaklines By Slope - New function to create 3D polylines at the boundaries of slope zones.
- Color Lines - Added new method for creating polylines that follow color lines in the cloud such as roadway paint stripes and new method to follow color boundaries such as edge between pavement and grass.
- Slope Lines - New function to create breakline polylines by following a slope grade break.
- Feature Extraction - Added batch process method to extract multiple features at a time.
- Power Lines - New function to extract overhead wires as polylines.

Data Conversions

- Geoids - Added geoids for Germany-Hessen, Thailand and Lithuania.

Setting Up a Project

Over 200 program settings can be specified in the Configure command under the Settings menu. These values are used to initialize Carlson program options when opening a new or existing drawing. Among these settings is the coordinate point number format, file and printer output options and settings for each module.

To set the drawing defaults, edit the template drawing (.DWT file). This drawing is loaded when new drawings are created. In the template drawing you can set the layers and AutoCAD /IntelliCAD variables. For example you could create your standard layers and set variables as you like such as BLIPMODE off. For Carlson, the drawing template should be set to Carlson##.dwt where the ## is the AutoCAD version number. For Carlson running in AutoCAD 2007, the template name is Carlson07.dwt. The Carlson template is located in the Carlson support directory (i.e. C:\Carlson2008\SUP\Carlson07.dwt). To customize the template, run the *OPEN* command and choose the drawing template. In the Select File dialog, set the type of file to Drawing Template (DWT) instead of regular drawings (DWG). Then make your changes and *SAVE* the drawing as Carlson##.dwt.

When starting a new drawing, one of the first steps is to run Drawing Setup under the Settings menu. Drawing Setup sets the drawing scale, the unit mode as either English or metric, and the text, symbol and linetype size scalers. The initial values for these Drawing Setup variables are set in Configure. When a drawing is saved, the Drawing Setup variables are saved with the drawing.

In Carlson, the text style height should be set to zero. The Carlson routines will set the text height according to the drawing scale and text size scaler set in Drawing Setup. For example, if the horizontal scale is set to 50 and the text size scaler is 0.1, Carlson will draw the text with a height of 5 ($50 * 0.1$). Then when the drawing is plotted at 1"=50', the text will be 0.1 inches. Use the *STYLE* command to set the text style height to zero.

The Set Data Directory command in the Settings menu can be used to specify the directory for the project data files. By default the drawing is stored in the Carlson WORK directory and the data files are stored in the DATA directory. The drawing file is the (.DWG) file. The data files are the coordinate (.CRD) file, profile (.PRO) file, grid (.GRD) file and other Carlson data files. In Configure>Project/Data Folders, there is an option to store all data files in the directory of the drawing. With this option active all the files for the drawing C:\Carlson2008\Work\JOB500\JOB500.dwg would be stored in C:\SCAD2006\WORK\JOB500.

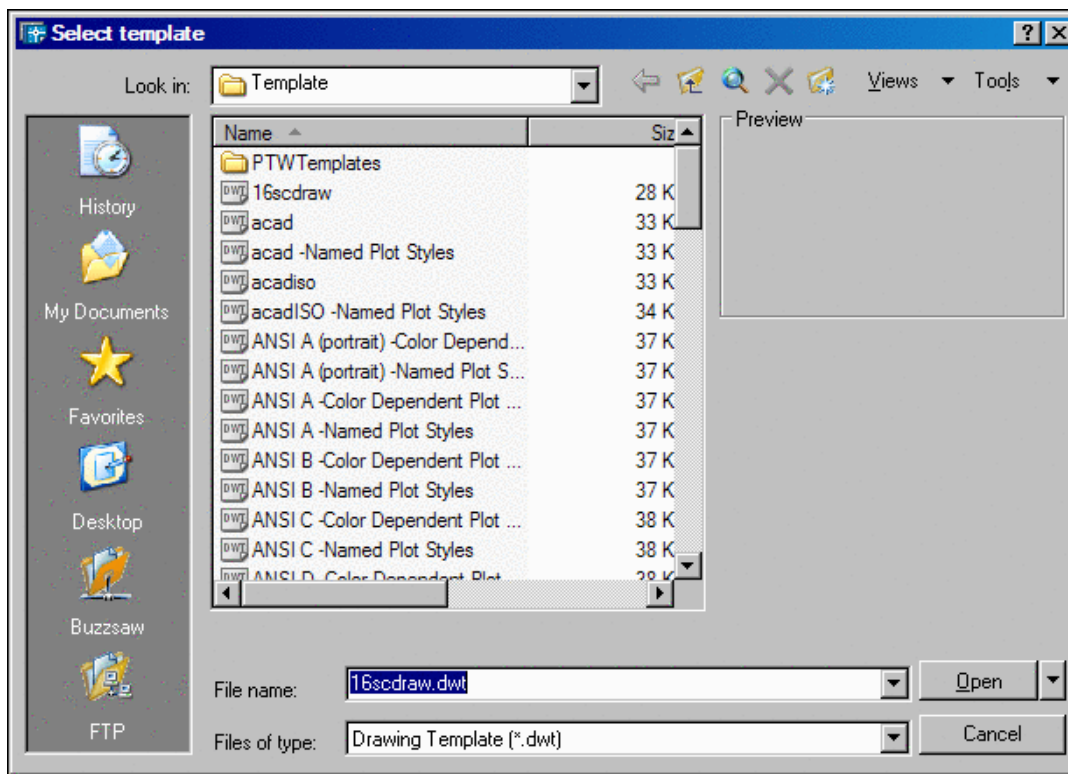

Another level of file management is the automatic project file recall. Every drawing remembers the data files that are being used for the drawing. When the drawing (.DWG) file is saved with the SAVE, SAVEAS, or QSAVE command, Carlson writes a settings file that contains all the active data file names. Then when the drawing is reopened, the data files default to their previous settings. For example, you won't have to choose which coordinate file to use unless you want to change it. The settings file is stored in the same directory as the drawing file and has the same name as the drawing with a .INI extension. For example, a drawing survey.dwg would have a settings file called survey.ini. You can turn off the INI files with the Save Drawing INI Files option in Configure under General Settings.

New/Startup Wizard

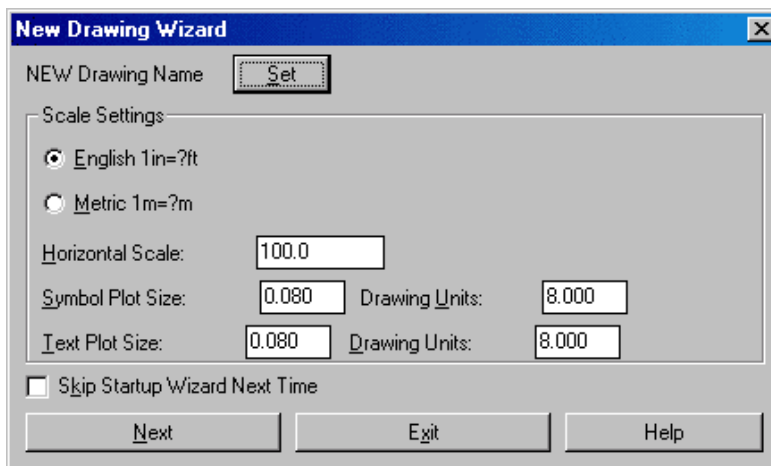

The New command is used for starting a new Carlson drawing. This page describes this New command and the Startup Wizard, along with the Carlson variables, associated with it.

Built into this routine is a Startup Wizard that can step you through and make the new Carlson drawing setup process easier. For creating a new drawing in Carlson, the Startup Wizard guides you through starting and setting up the drawing. This wizard is optional, and can be turned on or off in the Configure > General Settings command, which is part of the File pulldown. There is also a dialog box option, shown and mentioned below, that allows you to disable this feature. You can also exit out of the Startup Wizard at any time.

When the *New* drawing command is executed, you first get the standard Select template dialog box. While there are many templates to choose from, and there is an Open option, typically you want to go with choosing the Carlson drawing template (CARLSON17.DWT). The drawing template will set of some basic drawing parameters such as default layer names.

After selecting the template, the Carlson Startup Wizard begins by opening the *New Drawing Wizard* dialog box.

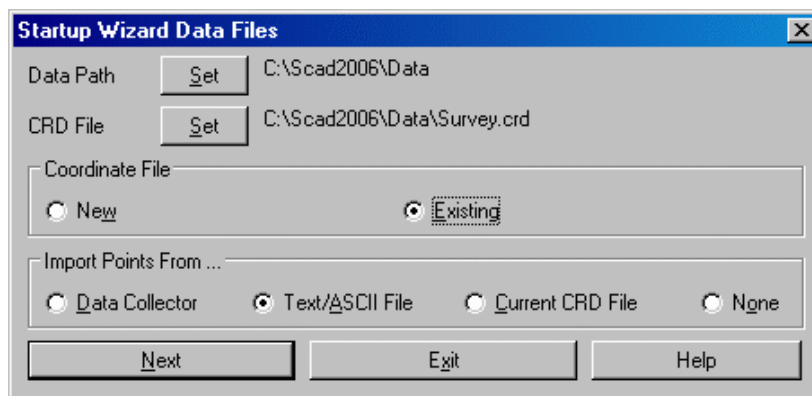

This dialog is used to set the drawing name and scale. The first step to do is set the drawing (.DWG) name by picking the *Set* button. This brings up the file selection dialog. Change to the directory/folder ("*Save in*" field) where you want to store the drawing. You can either select an existing folder or create a new folder. To select an existing folder, pull down the *Save in* field to select a folder or drive, click the Move Up icon next to the *Save in* field and/or the pick the folder name from the list. To create a new folder, pick the Create New Folder icon to the right of the *Save in* field. Then type in the drawing name in the *File name* field and click the *Save* button.

After setting the drawing name, you can set the drawing horizontal scale, symbol size, text size and unit mode (English or Metric). Notice that at the lower left corner of the *New Drawing Wizard* dialog there is an option to Skip Startup Wizard Next Time. Typically, you would leave this option unchecked, as the Wizard is a handy tool for new drawing setup. Now click the Next button.

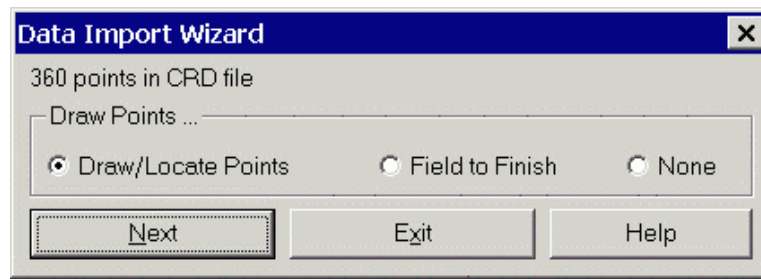

The next startup dialog sets the Data Path and CRD File. The Data Path is the folder where Carlson will store the data files such as raw (.RW5) files and profile (.PRO) files. The *Set* button for the Data Path allows you to select an existing folder or create a new folder. See the Set Data Directory command for more information. The coordinate (.CRD) File is the coordinate file for storing the point data. There is an option to create a new or existing coordinate (.CRD) file. The new option will erase any point data that is found in the specified CRD file. The existing option will retain any point data in the specified coordinate (.CRD) file. If the specified coordinate (.CRD) file does not exist, the wizard will create a new file.

The next wizard step depends on the Import Points option. The Data Collector option will start the data collection routines to download data from a collector. The Text/ASCII option will import point data from a text/ASCII file. See the Data Collection and Import Text/ASCII File commands for more information on running these routines. The Current CRD File option is a popular one to choose for bringing in coordinates. If the None option is set, then the Startup Wizard is finished.

Once point data has been imported from the data collector, text/ASCII file or CRD file, the wizard guides you through drawing the points. There are options to run Draw/Locate Points, Field To Finish or None. If None is selected, then the Startup Wizard is finished. Draw/Locate Points will import the points into the drawing using the same symbol and layer for all the points. From the Draw/Locate Points dialog, set the symbol, layer and point attributes to draw (description, elevation) and then pick the Draw All button. The Field To Finish command will import the points into the drawing using different layers and symbols depending on the point descriptions that refer to the code table defined in Field to Finish. Also Field to Finish can draw linework. See the Draw/Locate Point and

Field To Finish commands for more information on running these routines. After drawing the points, the wizard will zoom the display around the points. Then the wizard is finished.

Pulldown Menu Location: File

Keyboard Command: new

Prerequisite: None

Layer and Style Defaults

Many Carlson commands have default layers such as AREATXT for area labels and BRGTX for bearing and distance annotations. These layers can be specified in dialogs for the corresponding commands and several can be set in Configure. Sometimes you may want to use the current layer and it can be an extra step to have to open the dialog to set the layer. In this case, instead of using the default layer that set in the dialog, the default layer can be set as "CLAYER" which will use the current layer. For example, if the annotation layer is set to CLAYER then annotation will be drawn in the current layer instead of BRGTX or whatever the annotation layer used to be.

This same concept applies for text styles. Several commands have specific text styles and if you want to use the current style instead of the command style, use the name "CSTYLE" for the style name.

File Selector

Throughout Carlson Software, various commands create, utilize or interact with data in files that support the project you are working with. The *File Selector* dialog box provides a common interface for identifying new and/or utilizing existing data files.

File Selector - New File tab

File Selector - Existing Files tab

Folder: The initial default folder location for a given file type is determined through the Data Folder Setup routine. When working within a project, the program tracks file selection for each file type and this folder will default to the folder of the last selected file. Use the drop-down control to select the folder from the list of past file selections and the default folder. You can also use the **Select Folder** button to browse for another folder.

File Name: Enter the desired file name. If a file extension is not provided with the file name, the first file extension listed in the dialog box header will be utilized.

Browse: Selects the file from the standard Windows file dialog.

Control

Action

Select Folder: Browse for a desired folder location if the folder location is not displayed in the *Folder* drop-list.

Moves up a folder level from the current folder.

Carlson Community: This button launches a dialog to select a file from the Carlson Community which is a file warehouse on an on-line server. Carlson Software customers can post files to share such as a Field-to-Finish code table for a certain application.

Existing File tab only. Quickly search for file(s) that meet specific file properties. See the Find File section for additional information.

Re-assigns the currently selected folder in the *Recent Folders* drop-list as the new **Data Folder**. Use the Set Project/Data Folder > *Re-assign Data Folders* option as needed to restore the Data folder.

Removes the selected subfolder from your computer.

Renames the selected subfolder on your computer.

Allows the management of Recent and Favorite folders as described below:

Recent Folders: Displays the list of current project and recent folders.

Set as Data: Performs the same action as the Set Data Button.

Add as Favorite: Adds the currently selected folder as a *favorite* folder.

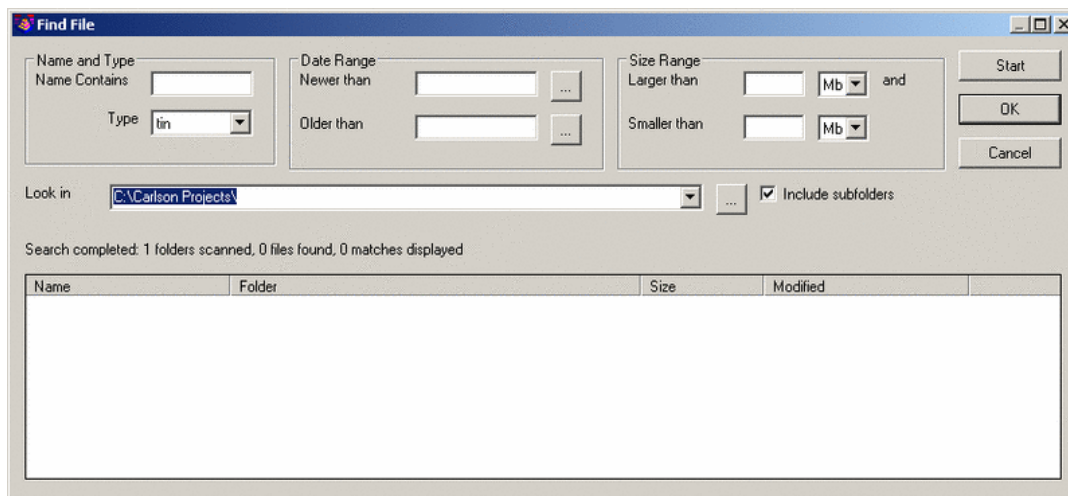

Favorite Folders: Displays the list of favorite folders (folders that are typically used or accessed repeatedly across projects).

Set as Data: Performs the same action as the Set Data Button.

Add: Allows any folder to be located and added as a favorite.

Delete: Removes the selected folder from the *Favorite Folders* list but does not delete any content found within the folder.

As the data files and folders for project(s) start to increase, the Find File option provides a mechanism to search for a particular file which meet certain file characteristics (all user-specified characteristics must met for the file(s) to be located):

Name Contains: Identify the string of characters located in the file name. For example, *Base* would return "BaseMap", "basement", "Subbase", etc.

Type: Indicate the specific file extension to be searched (the drop-list selection adjusts according to what is expected by the underlying command).

Newer than: Locate the file(s) that have been modified after the specified date.

Older than: Locate the file(s) that have been modified prior to the specified date.

Larger than: Locate the file(s) whose file size is larger than the value specified.

Smaller than: Locate the file(s) whose file size is smaller than the value specified.

Look in: Locate the file(s) in just the folder that is specified.

Include Subfolders: When enabled, the *Look in* folder is searched along with any sub-folders.

Start: Manually initiate the Find File routine.

As file(s) are located, select/highlight the desired file and click the OK button to return to the File Selector dialog box.

Note:

- In most cases, when a file name is typed into the Existing tab of the File Selector dialog box that does not exist in the *Recent Folders*, the routine will alert you the file does not exist and prompts if it should be created. If you instruct the program to create the file, it carries out the action of the New File tab.

Standard Report Viewer

Many Carlson routines display output in the Standard Report Viewer as shown below. A project name and job number can be added to the report header by filling out values for them in the Settings->Drawing Setup command. The format for the date in the upper right of the report is controlled by the Date Format setting in Settings->Configure->General Settings. The report can be edited directly in the report viewer. Report Viewer commands are described below.

Open: This allows you to open an ASCII file and display the contents in the report viewer.

Save: Save the contents of the report viewer to a text file.

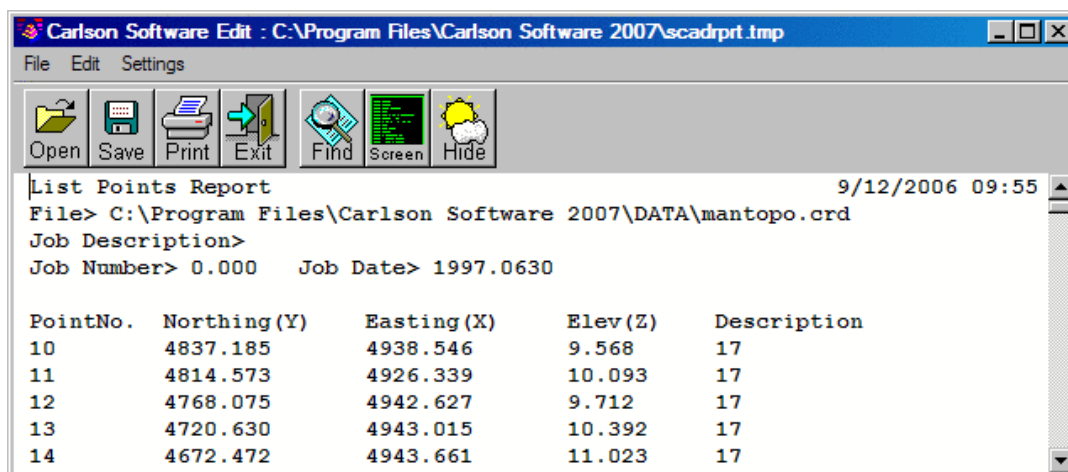

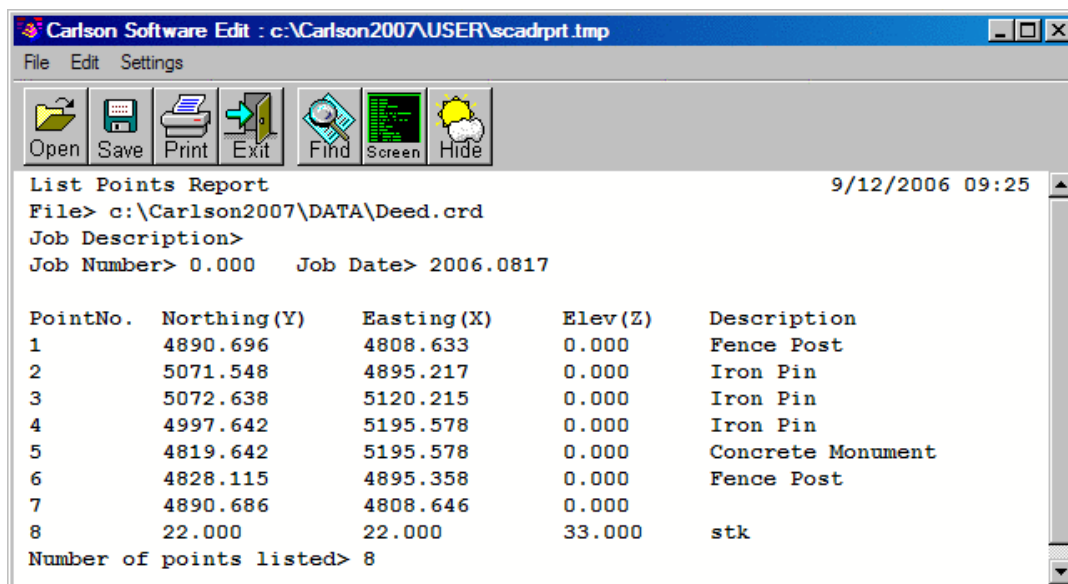

SaveAs: This allows you to save the contents of the report viewer to a file.

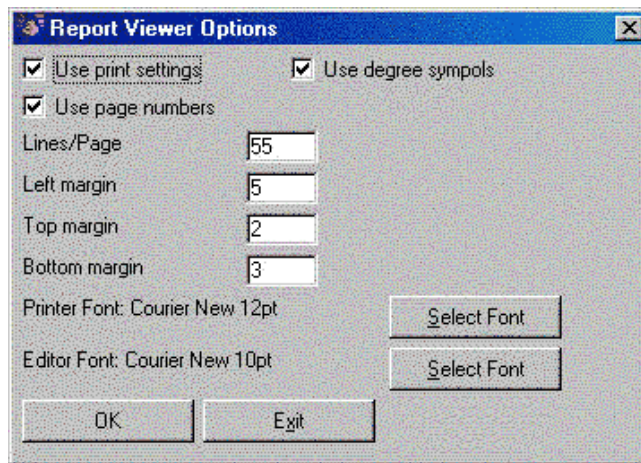

Append To: This allows you to append the contents of the report viewer to another file.

Print: Print the contents of the report viewer. This will open the standard windows Print dialog where you can choose the printer and modify any of the printer settings before you actually print.

Screen: Draws the report in the current drawing. The program will prompt you for a starting point, text height, rotation, layer and whether you want it inserted as Mtext or Text.

Undo: Reverses the effect of your last action. If you mistakenly deleted some text, stop and choose the Undo command to restore it. The key combination Ctrl+Z also performs this action.

Select All: Selects all the text in the report viewer.

Cut: Deletes the selected text and places it on the Windows® clipboard.

Copy: Copies the selected text to the Windows® clipboard.

Paste: Inserts ASCII text from the Windows® Clipboard into the report viewer at the cursor.

Search: Opens the Find Text dialog. Allows you to search for text in the report viewer.

Replace: Opens the Find and Replace Text dialog. Allows you to search for text and replace it.

Options: Opens the Report Viewer Options dialog. In this dialog, you can specify print settings, such as lines per page and margins. You can also specify the font used in the report viewer. This font is used for both the display and for printing.

Hide: This button allows you to minimize the report viewer window and give focus back to the Carlson CAD screen. This allows you to return to working on the Carlson CAD screen without closing the report. You can re-activate the report by picking on the minimized report viewer icon.

Annotative Text

For CAD systems that support the creation and use of "Annotative Objects" (e.g. AutoCAD 2008 and later), various Carlson entities can be placed into a drawing that can make use of available "Annotative Styles," including:

- Attributes of Carlson Points via Point Defaults
- Text-based Annotation Labels via Carlson Configure>General Settings

When a plot scale is needed that is different than the Horizontal Scale established under Drawing Setup, change the *Annotative Scale* as shown below.

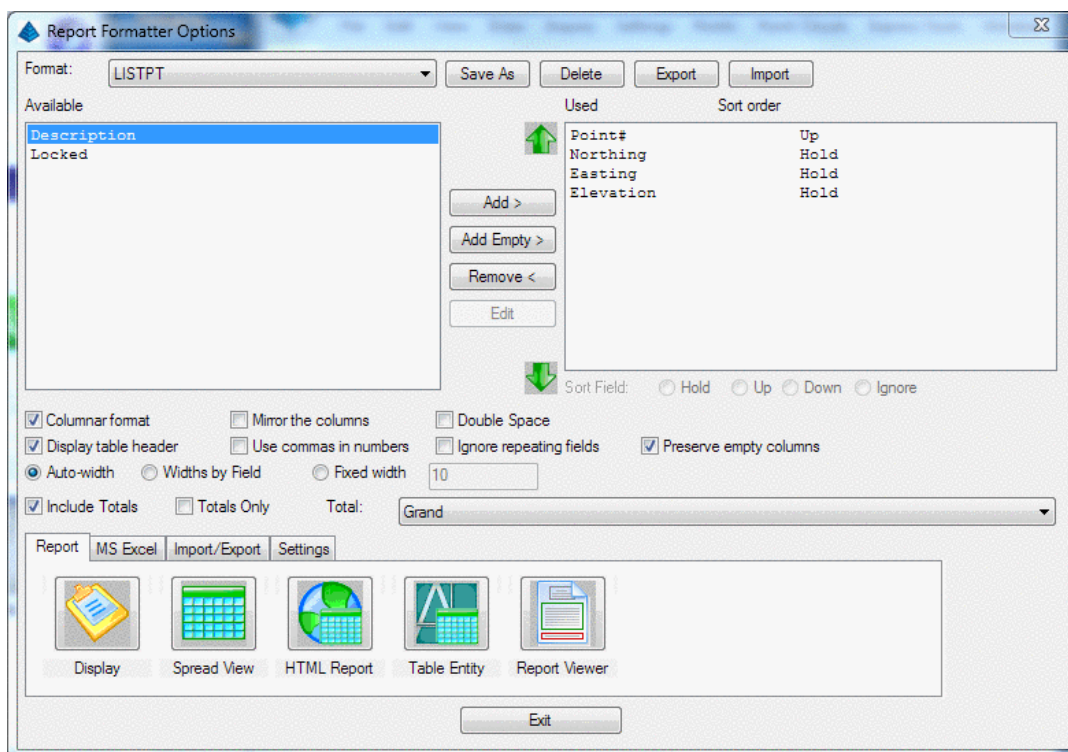

Note:

- Items placed as "annotative entities" will only make use of the annotation scales present in the drawing at the time of the entity placement.

Report Formatter Dialog

The Carlson Report Formatter routine is a highly customizable and flexible reporting engine that can be used to create a variety of output document types. A number of Carlson routines provide an option to use Report Formatter Options and allows you to specify how and which results of calculations should be presented in the report. In addition to the Standard Report Viewer, reports can be generated in web-friendly HTML format along with data formats compatible with Microsoft Excel or Microsoft Access.

Format: Select an available report format from the list of pre-established report configurations or key-in a new report format name.

Save As: Saves the current configuration of the active report format. The next time that you come to the Report Formatter from the same Carlson routine, it will recall this last format. To pick another format, select from list of formats in the left top corner and pick which format to use.

Delete: Removes the current report configuration from the listing of available report formats.

Export: Sends ALL available report formats to an XML-based "formatter style" (*.FMS) file.

Import: Imports the contents of a previously exported *.FMS file.

Control

Action

Moves the selected report option in the **Used** listing above the preceding entry until it reaches the top of the list.

Moves the currently selected item from the **Available** listing to the **Used** listing.

Removes the currently selected item from the **Used** listing and makes it selectable once again to the **Available** listing.

Moves the selected report option in the **Used** listing below the following entry until it reaches the bottom of the list.

Report Content Controls

Sort Field: For the selected "field" of data, indicate its sort method:

- **Hold:** The given field is not sorted and prohibits the sorting of subsequent columns.

- **Up:** The given field is sorted in ascending order.
- **Down:** The given field is sorted in descending order.
- **Ignore:** The given field is not sorted and permits sorting for the next column(s).

Columnar Format: When enabled, this toggle groups a given field of data into a column in the report. When disabled, each field of data is placed onto its own row in the report (the report data is output in a single column).

Mirror the Columns: (Suggested for short reports only). When enabled, this toggle transposes columns from the report into rows and vice versa.

Double Space: Adds a blank row between data rows.

Underscore Line: Adds a solid line between data rows.

Display Table Header: When enabled and exporting the report to an *HTML Report* format, the field "keys" as defined in the "Attribute Options" control are included in the report header.

Use Commas in Numbers: When enabled, this option will insert commas into numeric fields for every three digits.

Ignore Repeating Fields: When enabled, only the first occurrence of a repeating field is display in the report. Subsequent occurrences of the repeated field (*e.g.* the point description) are suppressed until a different value in the repeating field is encountered.

Preserve Empty Columns: When enabled, custom named columns can be added to the report which have no data in the rows.

Auto-width: When enabled, the width of each column is automatically set to be the wider of the column heading or the data contained within the column.

Widths by Field: When enabled, the width of each column established in the *Attrib Options* control (found in the *Settings Tab*) is used per field.

Fixed-width: When enabled, specify the width of each column.

Include Totals: When enabled, the total of each field is reported.

Totals Only: When enabled, only the total of each field is reported.

Total: Select the desired total for the *Used* field(s) of data. The summation level is defined by this "Total" pop-up list. By default, only grand total will be displayed at the bottom of the list. By picking the next item in that box, you will get subtotals added each time the value in first column is changed. It makes most sense to use this kind to summation if the corresponding column is sorted.

For example if the first column is "Area Name" and it is sorted, and "Total" is set to "Grand, Area Name" the report will have a sub-total for each distinct Area Name.

Once the desired fields of data and reporting options have been specified, the output can be generated and manipulated using one of four tabs:

1. Report
2. MS Excel
3. Import/Export
4. Settings

Choose one of the output options:

Control

Action

Sends the current report to the Standard Report Viewer command. Upon exiting the Viewer, you come back into the Report Formatter for further data manipulation as needed.

Sends the current report to a "spreadsheet" interface where it can be further exported to a variety of popular file formats. Additional information is provided in the Spreadsheet discussion.

Sends the current report to an Internet/web-ready HTML file format and displays the report using the HTML viewer that is configured on your computer.

Places the current report as a table-type of entity into the current drawing. Additional information is provided in the Table Entity discussion.

Places the current report into a special-formatted report. Additional information is provided in the Report Viewer discussion.

Report Tab Options

Spreadsheet

Export: This button has the same output options as the Export function under the Import/Export Tab. Use this option to create a variety of popular file formats, including:

- XML Format (xml)
 - Text or CSV File (txt, csv)
 - MS Excel "database" (xls, xlsx)
 - MS Access database (mdb, accdb)
 - SQLite database (db3, sqlite)
-
- ODBC Data Sources (Misc. database formats)

For commands that process reports using perimeter polylines, the Report Formatter has an option to create GIS links between the polylines and the database records when the Export to MS Access function is used. Some commands that can utilize this functionality are Surface Mine Reserves with the pit polylines and Underground Timing with the panel polylines.

When the polyline data is available for the GIS Links, there will be a report field called **Handle**. This Handle field is the entity name for the polyline and serves as the hook for the GIS link. The Handle field does not need to be put into the report **Used** list in order to create the links. When the Export function is called with the MS Access method, there is a pop-up window prompt for whether to create the GIS links. When these links are created, you can then use the GIS Data commands from the GIS module to manage and report the data.

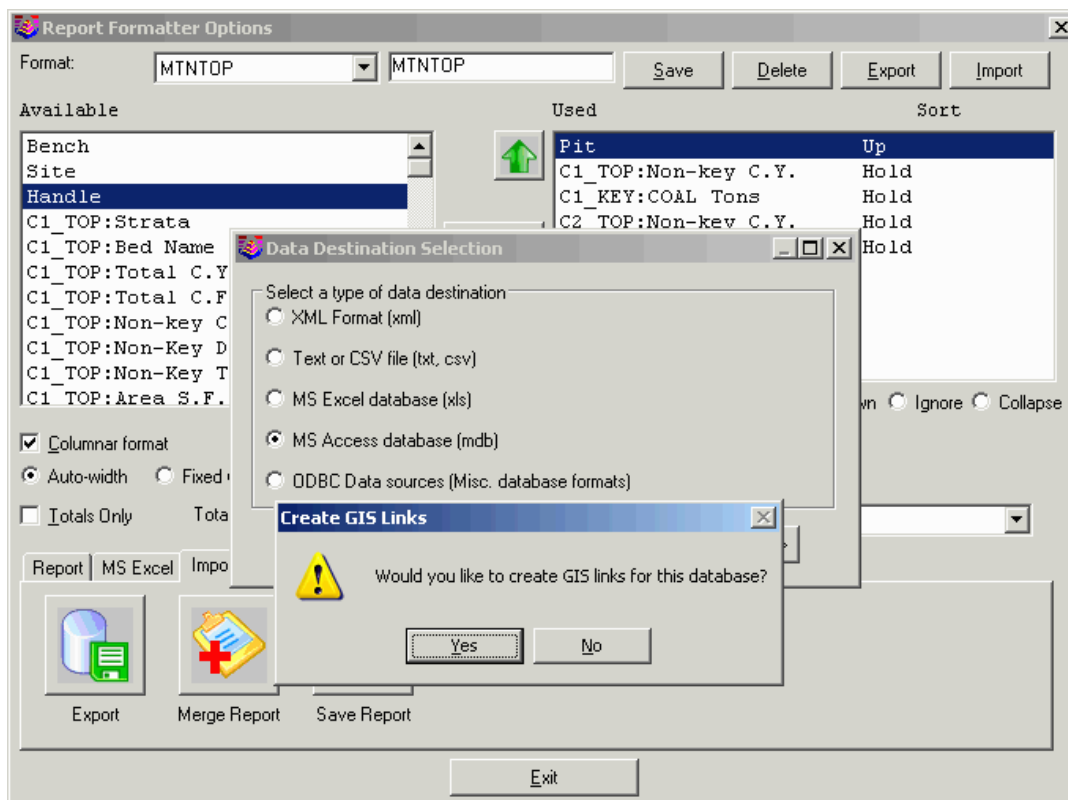

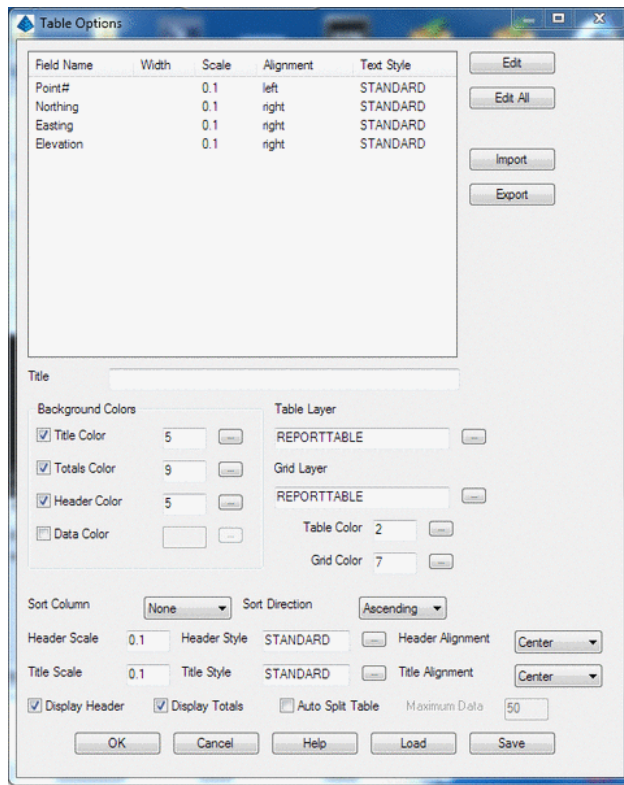

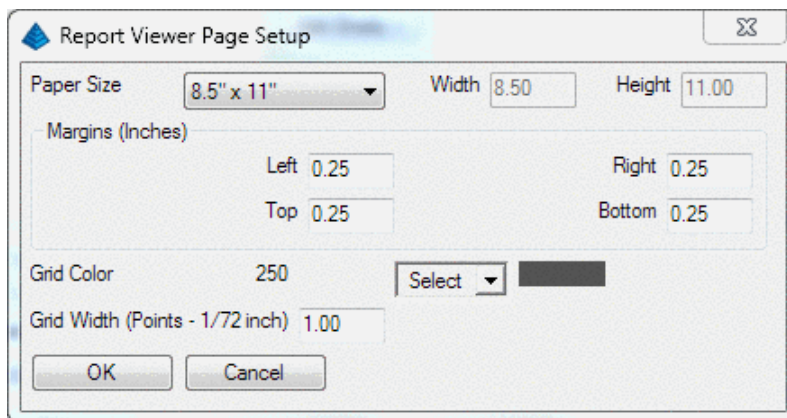

Table Entity

The data for the Table Entity is put into a queue and the table is not drawn until the Report Formatter is closed. Then the program prompts for a location to draw the table and provides options shown above to control items such as the header names, sizes, alignments, styles, colors and layers. You can also set whether to draw the table header and totals.

Report Viewer

The Report Viewer option provides the ability to produce more professional looking reports that contain horizontal and vertical dividing lines and can also be exported to a variety of common report formats.

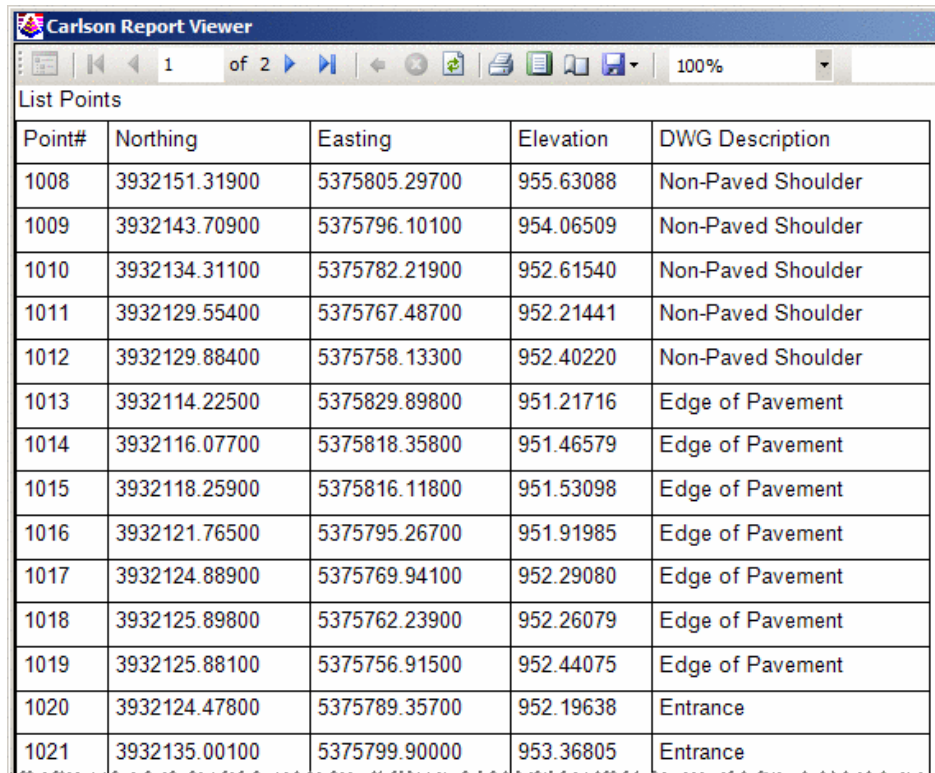

Indicate the paper size you will be printing to along with desired values for:

- Left Margin
- Right Margin
- Top Margin
- Bottom Margin

Grid Color: Used to choose the color for report grid lines.

Grid Width: Used to specify the grid line width in points (1/72 of an inch).

Upon specifying the desired values and clicking **OK**, the Report Viewer dialog box will display:

The screenshot shows the Carlson Report Viewer window. The title bar reads "Carlson Report Viewer". Below the title bar is a toolbar with navigation and utility icons. The main area displays a table titled "List Points".

Point#	Northing	Easting	Elevation	DWG Description
1008	3932151.31900	5375805.29700	955.63088	Non-Paved Shoulder
1009	3932143.70900	5375796.10100	954.06509	Non-Paved Shoulder
1010	3932134.31100	5375782.21900	952.61540	Non-Paved Shoulder

1017	3932124.88900	5375769.94100	952.29080	Edge of Pavement
1018	3932125.89800	5375762.23900	952.26079	Edge of Pavement
1019	3932125.88100	5375756.91500	952.44075	Edge of Pavement
1020	3932124.47800	5375789.35700	952.19638	Entrance
1021	3932135.00100	5375799.90000	953.36805	Entrance

Controls within the report viewer allow you to:

- navigate through the page(s) of information
- refresh the report
- send the report to a printer
- switch between print layout and print preview mode
- re-configure the page setup
- export the report to other document applications
- specify the "zoom" level while displaying the report
- searching the report for a given search criteria

Several Microsoft Excel export options are provided. You may specify a spreadsheet file to load before the export, as well as a left upper cell to start with and sheet name to use. Text lines which are reported when using built-in viewer may be skipped when using Microsoft Excel export.

Control

Action

This button contains the same export options as described in the Spreadsheet discussion.

This button allows the current report to be combined with a previous report.

This button saves all the report data values as well as all the report format settings into a single *.RPT file that can be shared with others, merged with other reports or loaded at a later time.

For commands and data that conform to the ESRI Mapping Specification for DWG/DXF (MSD), this button creates an ESRI MSD-compatible report.

Import/Export Tab Options

Control

Action

This option allows you to define new fields as equations based on existing fields. Additional information is provided in the User-defined Attributes discussion.

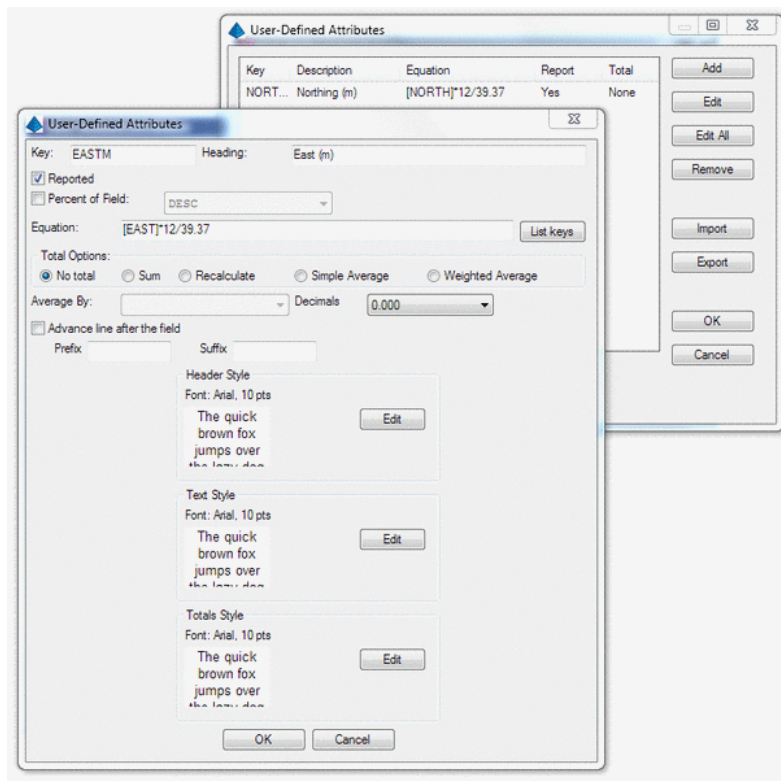

This option allows you to further customize additional content (*e.g.* Date/Time, Report Name, *etc*) into the report header, body and/or report footer. Additional information is provided in the Field Options discussion.

This option allows you to control several parameters of each field including title names, number of decimal places, *etc.* Additional information is provided in the Attribute Options discussion.

This option allows you to create more condensed reports yet still maintain easily decipherable column headings and/or permits a 2-line column heading. Additional information is provided in the Subheaders discussion.

Settings Tab Options

User-defined Attributes

You can create highly customizable fields of data using parametric equations from other fields of program-generated data... all without the use of an external spreadsheet! These User-Defined Attributes are mathematical manipulations to existing attributes. For example, if the report includes a LENGTH attribute reported in feet, you can create a User-Defined Attribute to also report this value in inches. When a User-Defined Attribute is added or edited, the above dialog will appear.

Key: This is a unique named used to identify the attribute. The Key can be used to reference the attribute in other User-Defined Attribute equations.

Heading: This is the label for the value that will show in the report. It is often useful to use a very descriptive name for the Heading.

Reported: This toggle controls whether to list this attribute as available for reporting or to only use internally as an attribute for the equation of other attributes.

Percent Of Field: This toggle defines the attribute to be a percentage of the total of another field such as the lot area percent of the total area. When this option is enabled, you will not be able to define an equation for the attribute.

Equation: This is where the attribute value is defined. To use the value of another attribute in the equation, the attribute name is entered in brackets as shown in the dialog above. The below table lists the mathematical operators that may be used in the equation.

Operation	Symbol
Add	+
Subtract	-
Divide	/
Multiply	*
Exponent	^
Grouping	()

Compare - Greater Than	>
Compare - Less Than	<
Compare - Equal To	=
Logic - AND	&
Logic - OR	—
Logic - NOT	!
Absolute Value	ABS()

Total Options: This controls how to total the attribute.

Sum: The total is a sum total of all report entries of the attribute.

Simple Average: The total is an average of all reported entries of the attribute.

Weighted Average: The total is a weighted average of the reported entries of the attribute. The attribute will be weighted based on the attribute selected in the **Average By** dropdown list.

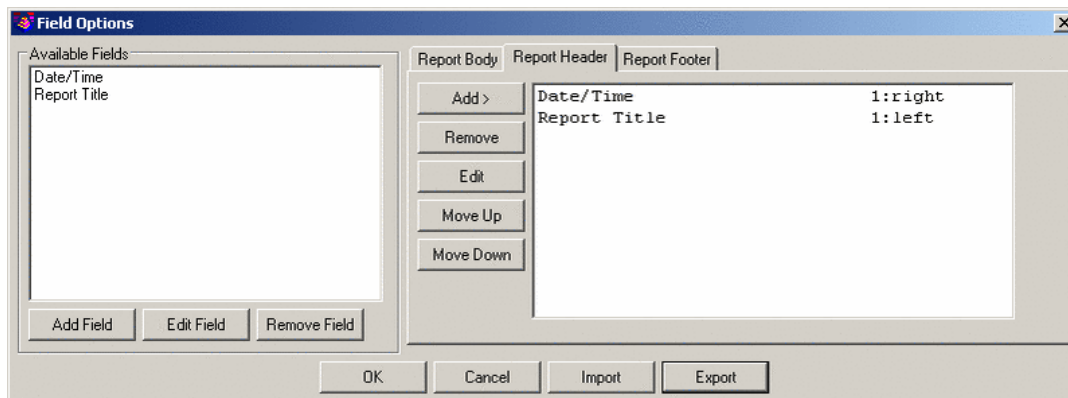

Recalculate: This total is not based on the individual entries of this attribute, but is instead recalculated based on the totals of referenced attributes. For example, consider the below report in which values A and B are naturally reported and C is a User-Defined Attribute equal to A+B. Each attribute uses a different Totaling option. In this case, the total for C is recalculated based on the totals for A and B rather than on the previous reported entries for C.

	A	B	C
	1	4	5
	3	8	11
	5	9	14
Total	3	21	24
Total by	Simple Average	Sum	Recalculate

Decimals: This dropdown lists controls the reported precision of the attribute.

Advance line after the field: This toggle adds a blank row to the report after the attribute is reported.

Field Options

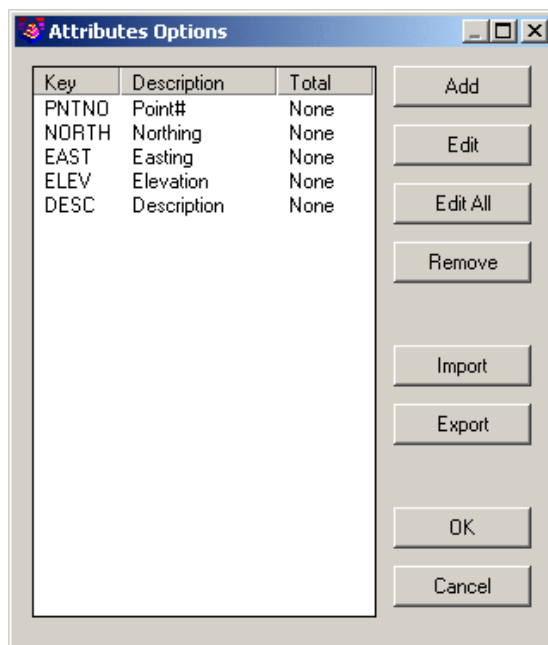

"Field Options" can be placed into one or more locations within the report:

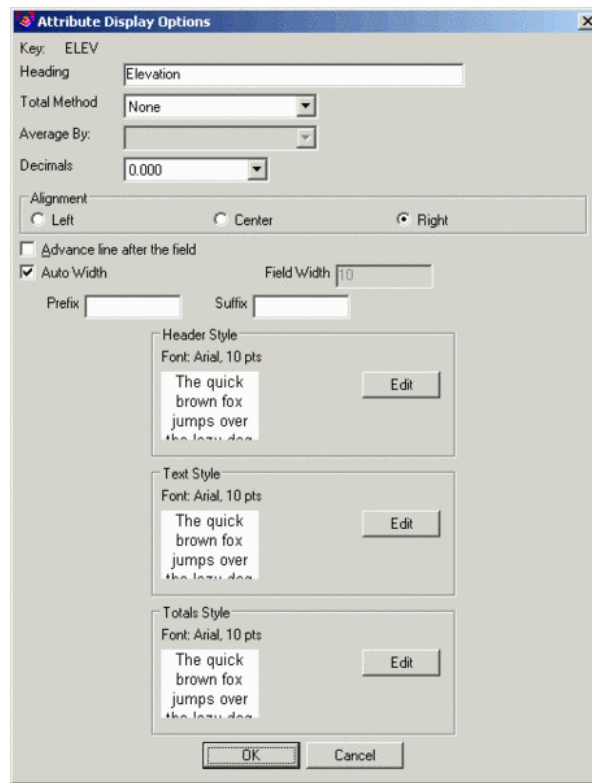

- Report Header
- Report Body
- Report Footer

Select the desired location for the field and then click on the various controls to add or remove the item from the desired location or change its formatting information.

Attribute Options

The Attribute Options dialog shows a list of all the attributes in the report. Use the Edit button to set the attribute properties.

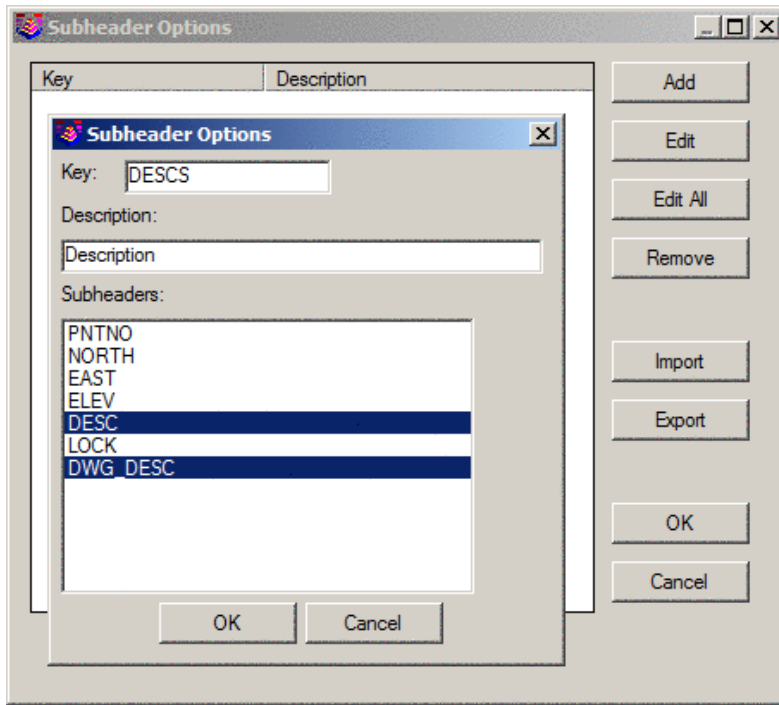

The Heading is the label to use for this attribute. The Total Method chooses between:

- Sum
- Simple Average
- Weighted Average
- No total

For Weighted Average, you can select another attribute to weight the average by such as tons for averaging a strata quality. When controlling the number of **Decimal** places, the values can also be rounded up to the nearest integer level such as when earthwork volumes need to be reported to the nearest 1000. The **Cell Format** controls the Excel cell format for this data field. The Default setting uses the cell format that the Carlson program output to Report Formatter. The **Alignment** controls the justification of the attribute. By default, numbers are right justified and strings are left justified. There is an option to **Advance Line After the Field** of the report which inserts a blank row and shifts the next attributes down to a new line in the report. The **Auto Width** option sets the attribute width to fit the attribute heading and all the values. Otherwise you can set a fixed **Field Width**. The **Prefix** and **Suffix** allow you to add to the attribute value such as adding the "ft" suffix to indicate feet units. The **Style** settings control the font to use for the header, body and total for the attribute. Use the Report Viewer output method to use the different style settings.

Subheaders

Subheaders may be created for situations where many columns of data may make the report too wide. You can use the subheaders to stack the column names. For example, a point list report with descriptions from the coordinate file also listed with descriptions from the drawing file could be setup with "Description" as a subheader (use Ctrl+Click functionality to select the desired fields that are to get a subheader). Consider (table borders added for visual clarity):

	Description	
CRD		DWG
TDC / Oak		Deciduous Tree Oak
Using Subheaders		

Contrast with:

CRD Description		DWG Description
TDC / Oak		Deciduous Tree Oak
Without Subheaders		

Instruction Manual and Program Conventions

Westwood

Italic text represent responses by the user that should be typed in and followed by the Enter key.

Number/<Pick point>:

Bold text represents prompts or questions that the computer program will ask the user.

<90.0000>

Values enclosed in corner brackets represent default values obtained by pressing Enter with a blank response.

[end on]

Lower case text enclosed in brackets in Command prompts denotes an *OSNAP* mode that is turned on by the command.

Language Localization

To run the program in another language, go to Settings->Carlson Configure->Localization Options and choose Windows Settings for the Language option.

Then set the language in Windows.

In Windows Vista, XP and earlier:

Run Start->Control Panel->Regional and Language Options. In Windows Vista, choose the language under the Formats tab. In earlier Windows, choose the language under the Regional Options tab.

In Windows 7:

Run Start->Control Panel->Clock, Language and Region. Then pick Region and Language and choose the language under the Formats tab.

There is a second Windows setup step for languages that don't use character set 1252 for English and Western languages. This second step is to run Windows Control Panel and go to the Advanced tab of Regional and Language Options and select the language. Then reboot Windows. For example, with Russian, you need to choose Russian under this Advanced tab.

After the language is set in Windows, restart Carlson to use the new language settings.

After restarting Carlson with the language setup, go to Settings->Carlson Menus->Menu Language Translation to translate the pull-down menus into the current language. This function will prompt for the source menu file to translate. For running on AutoCAD, there is only one menu file to translate which is called csXXbase.cui or .cuix where XX is the AutoCAD version. For example, for AutoCAD 2012, the menu to translate is called cs12base.cuix. For running on IntelliCAD, there is a base menu to translate and then separate menus for each module. The base menu is called icad6base.mnu for IntelliCAD 6 and icadbase.mnu for IntelliCAD 7. The menus for the modules are named after the module. For example, the survey.mnu is for the Survey module. For the IntelliCAD menus, you need to run this function multiple times to translate the multiple menus. After translating the menus, restart Carlson once more.

The language translation tables are stored in the Carlson EXEC\LANG\XX\LC.Messages folder. The XX is for the language abbreviation code. Each language has its own sub-folder with a 2 character name. There are 2 translation tables for each language called carlson-office.mo for the program prompts and carlson-office-mnu.mo for the pull-down menus.

Carlson provides tools to allow you to improve the translations by editing the source translation tables which are stored in PO files: carlson-office.po and carlson-office-menu-po. There are two methods for modifying the translations. One method is an on-line editor called POOTLE that is on the Carlson webpage, www.carlsonsw.com, under Support. Or you can use this link: <http://translate.carlsonsw.com/>. This system requires that you register with your name and email. Then you have access to edit the translation tables. After editing the translation table, you can update the translations within Carlson by rebuilding the MO files. To rebuild the MO files in POOTLE, choose the language then Carlson Office Products then Show Editing Functions. POOTLE will then list the translation tables carlson-office.po and carlson-office-mnu.po. Pick the MO function next to the table and save the MO file to the Carlson\EXEC\LANG\XX\LC_MESSAGES folder where XX is the language code such as FR for French.

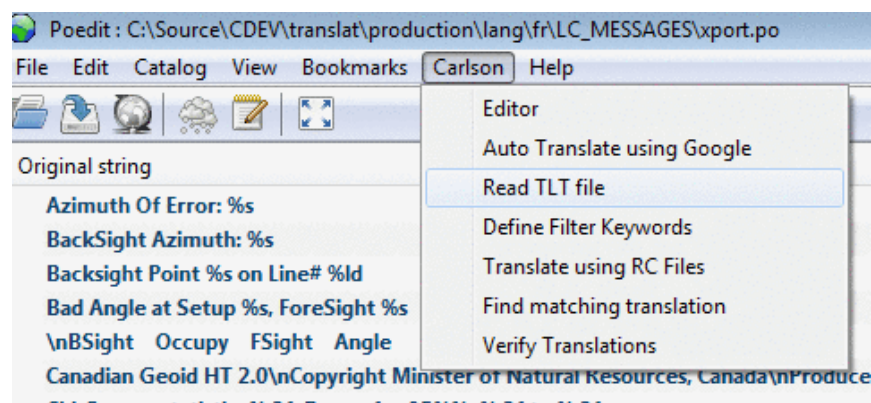

The other translation method is a desktop editor called POEdit. This desktop editor has more features than the on-line editor which could be useful if you are doing a lot of editing. This desktop editor distributed on request. When saving a PO file in POEdit, the program automatically creates the companion MO file which goes to the Carlson\Exec\LANG\XX\LC_MESSAGES folder for running. For more instructions the POEdit desktop editor, go to the Carlson webpage under Support.

After updating the MO files, the program will pick up the new translations for command prompts. The pull-

down menus are updated separately by running the Settings->Carlson Menus->Translate Menu command. You need to select the English base menu and then the translated menu is generated using the same name as the base menu with the language name added as a suffix. For the AutoCAD platform, there is a single CUI menu to translate called CSxxBASE.CUI where xx is the AutoCAD version. For example, for AutoCAD 2010 this menu is called CS10BASE.CUI. The French translated version of this menu will be called CS10BASE-FR.CUI. For the IntelliCAD platform, there is a base menu called ICADBASE.MNU as well as menus for each of the modules such as SURVEY.MNU and CIVIL.MNU. The French translated versions of these menus will be called ICADBASE-FR.MNU, SURVEY-FR.MNU and CIVIL-FR.MNU. After generating the translated menu, load it using CUILOAD command in AutoCAD and the MENU in IntelliCAD.

POEdit with Carlson Menu

Carlson has customized and added a new Menu "Carlson" to the POEdit. If the Carlson customized EXE is installed user will be able to use this menu.

The Carlson menu consists of following commands.

1. Editor

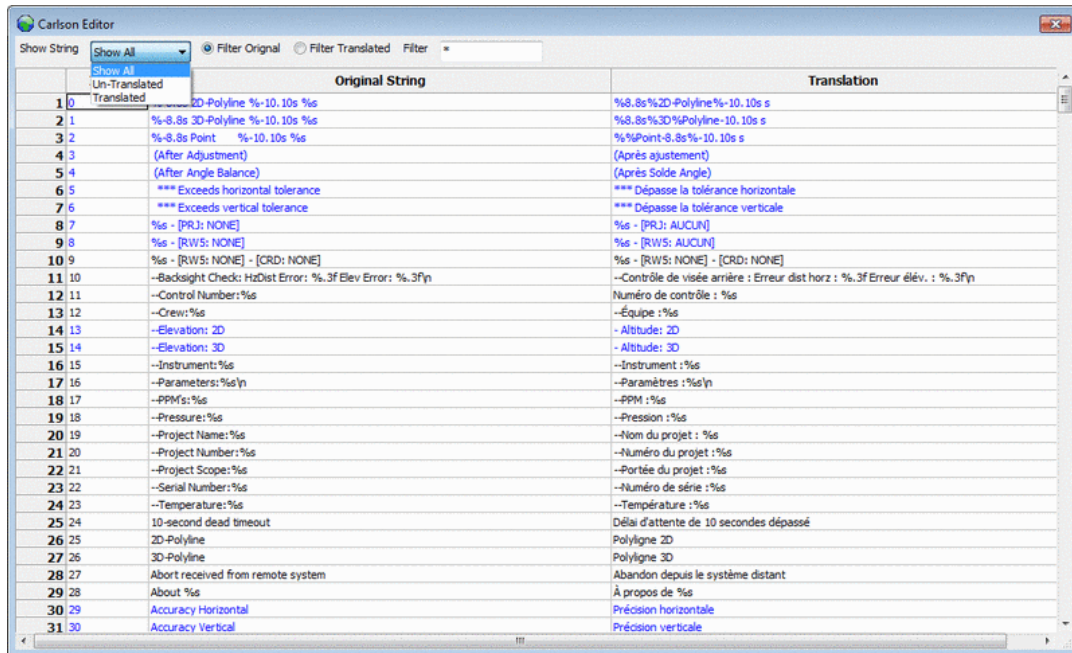

This command let user to do the translation in a spread sheet styled dialog. The PO File is divided into separate groups or ranges for the purpose reducing the amount of string user sees when doing the translation. The Carlson Editor Range dialog allows user to select the alphabetical range of strings.

The selected range is then loaded in a user friendly spread like dialog for better editing. This also provides some filtering tools to the user to be able to focus on the strings of interest. User can select to see the all, un-translated or

translated string. Also filters the original or translated strings based on the filter key words.

An un-translated string can be auto-translated using Google translation, right click the string to be translated and select Auto-Translation to fetch the translation from Google. This will work if the CURL binary files are present to the BIN\CURL folder in POEdit installation directory.

2. Auto-Translate Using Google

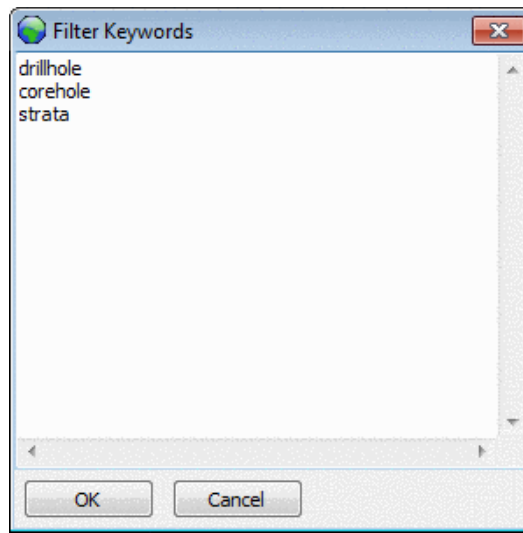

Un-translated strings can be auto-translated using Google translation using this command. This will work if the CURL binary files are present to the BIN\CURL folder in POEdit installation directory. This command does not translate strings that contain special characters used in C format i.e. string with '%' or '\\' characters.

3. Read TLT File

This command can be used to get the translations from TLT Files that already have translations, user is prompted to select a TLT file and the matching string will auto-translated if a translation was found.

4. Define Filter Keywords

This command is used for defining the filter keywords for the strings that user does not want to translate. For example translating only the Carlson survey strings user can choose to remove all the strings that contains mining words like drillhole, corehole, strata etc.

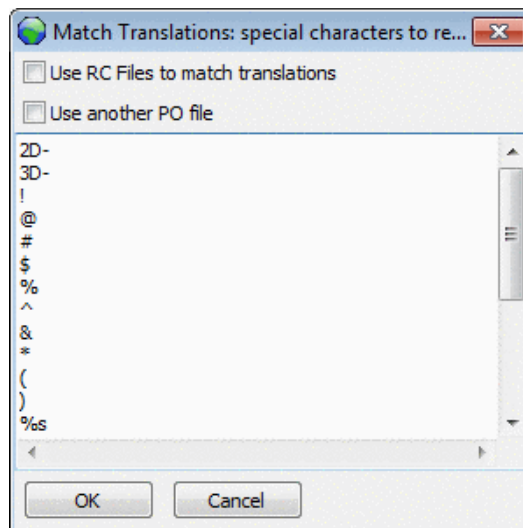

5. Translate using resource (RC) files

This command allows user to select SurvCE English and translated resource files and translates the matching strings between PO and English RC file if a translation was found in Translated RC file.

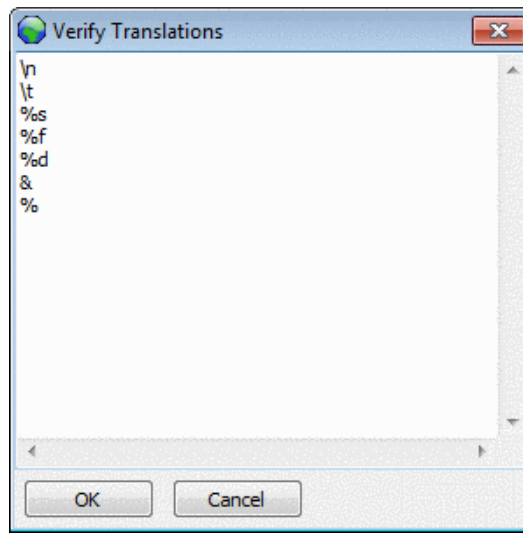

6. Find Matching Translations

This command can be used to search for matching translation in resource (RC) files and another PO File or currently loaded PO file by removing the defined special characters. For example if a string "OK" is already been translated it can look for all the strings like "&OK" etc and set the translation.

7. Verify Translation

This command can be used to verify if the equal number of special characters is present in the translated strings as there is in original string, to avoid user error in C format strings. For example if "OK\tCancel" is translated to "Acceptar\Cancele" this will prompt for user to correct the translation.

Patch Management

After the initial release of a major version, there are typically a few software service patches to fix errors. These service patches are delivered as update installs that contain only the updated program files. These update installs are not the full install and they designed to be installed onto an existing installation.

Check Patch Status

To see the software build that you are currently running, go to the Help->About Carlson command and look at the build number which is the date of the build. This number has six digits where the first two are the year, the next two are the month and the last two are the day. For example, a build on July 4, 2021 would have a build number of 210704.

Patch Notification

There are two ways to be notified of new patches. One way is that the program is setup by default to check the Carlson server once a week for new patches. This check is done when the Carlson program is started. If there is no update, the check routine displays a dialog reporting that the check didn't find a new patch. If there is a new patch, then the routine prompts for whether to install the update. If you choose to install the patch, the routine downloads the patch and steps through the install. You have the option to turn off the checking in the check status dialog by checking the "Never check again" toggle. If the checking is turned off, it can be turned on again by running Windows->All Programs->Carlson Software->Check For Updates.

The other method to be notified of new patches is to go to the Carlson website, www.carlsonsw.com, and go to Support->Downloads. Then select the product name from the product list. Then on the download page, there is a field for entering your email address for getting an email notification when updates are posted. This way you get notified immediately when an update is ready.

Manually Installing a Patch

There are two ways to manually install a patch. One is to run the Check For Updates function under the Windows->Programs->Carlson Software menu. This routine checks the Carlson server for the latest build version and

compares to your build version. If the server has a more recent build, the program downloads the patch and steps through the install.

The second method is to go to the Carlson website, www.carlsonsw.com, and go to Support->Downloads and select the software from the list of products. Then there is a list of the full install and the latest patch. The you can download and run the patch.exe.

To install the patch, you need Windows write permission to the program folder.

Managing Patches Centrally

Depending on your company administration policies, three different approaches to the central patch management can be considered:

1. Portion of the application is installed centrally, on the server, so that the files can be updated in the single central location instead of doing it on every workstation
2. Local patch downloads are disabled and instead a patch is downloaded to central location and launched on every workstation through the script
3. Local patch downloads are enforced, even if user chose to disable them manually.

Method 1: Partial central install on the server

This method involves running usual installation of Carlson product on the server as if it is a regular workstation. The installation path should be a folder which is accessible through the network share.

Next the product is installed on the workstations using the "Remote install" option:

User will then get a prompt to select the location where the program is installed on the server:

This will result in a smaller local installation with vital updatable files located centrally.

The update process is performed on the server by either installing patch manually or running "Check for updates" from Programs menu.

Methods 2 & 3: Using Windows mechanisms to control local installation of the patches by the end-users

The setting controlling whether the local install on the user workstation is automatically checking for updates is located at the following location in registry (Carlson 2024 on IntelliCAD 11.1) :

```
HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Carlson Software\SurvCADD\2024\ICAD111
```

The value name is NONET and value "1" (string) disables automatic update. Value of "0" or no value allows automatic updates.

Domain administrator can configure these settings to be changed using group policies on the domain server:

- Run "Group Policy Management" tool located in Control Panel, Administrative tools
- Navigate to your domain, Group Policy Objects
- Create new policy by right-clicking and selecting "New"
- Give policy a fitting name
- Right-click on policy and select Edit
- Right-click on Startup, select properties
- Click on Show File and copy your script (see below) into the folder which opens
- Click "Add" and select the script you copied

Other methods for running scripts on startup or login will work as well, as long as they are configured to run with administrative rights.

Save the following snippets into batch file (.bat or .cmd) and place them where your launching setup is looking for it.

Patches are delivered using InstallShield PackageForWeb tool. These packages can be installed interactively by user as long as they are launched by a script with Administrative rights. User interaction with patching process can be controlled in the following manner.

To minimize interaction, but still provide user with information on patching progress, please use the following switches:

```
Patch_file.exe -s -a minimal
```

To avoid any interaction, resulting in unconditional delivery of the patch as needed, please use the following switches:

```
Patch_file.exe -s -a stealth
```

License Agreement

Copyright 1992-2023 Carlson Software All Rights Reserved

CAUTION! READ THIS NOTICE BEFORE USING SOFTWARE

Please read the following Software License Agreement before using the SOFTWARE. Using this SOFTWARE indicates that you have accepted its terms and conditions.

Carlson 2024

END-USER LICENSE AGREEMENT FOR CARLSON SOFTWARE

IMPORTANT-READ CAREFULLY: This Carlson Software End-User License Agreement ("EULA") is a legal agreement between you (either an individual or a single entity) and Carlson Software, Inc for the software accompanying this EULA, which includes computer software and may include associated media, printed materials, and "online" or electronic documentation ("SOFTWARE PRODUCT" or "SOFTWARE"). By exercising your rights to use the SOFTWARE, you agree to be bound by the terms of this EULA. If you do not agree to the terms and conditions of this EULA, you may not use the SOFTWARE. IF YOU DO NOT AGREE TO THE TERMS AND CONDITIONS OF THIS EULA, DO NOT INSTALL OR USE ANY PART OF THE SOFTWARE.

Carlson Software, Inc., referred to as "LICENSOR", develops and/or licenses proprietary computer programs and sells use licenses for such proprietary computer programs together with or apart from accompanying copyrighted material and documentation and;

End User desires to obtain the benefits thereof and, in return for which, is willing to abide by the obligations and fee agreements applicable to LICENSOR's use licenses in LICENSOR's proprietary computer programs.

For good and valuable consideration, including but not limited to license grant in accordance with this Agreement by LICENSOR to End User's covenant regarding LICENSOR's proprietary rights, LICENSOR agrees to permit End User to utilize materials representing LICENSOR's product or products subject to the following terms and conditions:

1. License Grant: Subject to the terms, conditions and limitations of this EULA, LICENSOR hereby grants End User a personal, limited, non-exclusive, non-transferable, license to utilize the Software Product you have purchased. The license granted in this EULA creates no license, express or implied, to any other intellectual property of Licensor, except for the specific Software Product which they have lawfully purchased from LICENSOR.

This EULA grants you the following rights: You may install and use one copy of the SOFTWARE PRODUCT, or any prior version for the same operating system, on a single computer. The primary user of the computer on which the SOFTWARE PRODUCT is installed may make a second copy for his or her exclusive use on a portable computer.

Storage/Network Use. You may also store or install a copy of the SOFTWARE PRODUCT on a storage device, such as a network server, used only to install or run the SOFTWARE PRODUCT on your other computers over an internal network; however, you must acquire and dedicate a license for each separate computer on which the SOFTWARE PRODUCT is installed or run from the storage device. A license for the SOFTWARE PRODUCT may not be shared or used concurrently on different computers.

2. Exclusive Source. End User shall obtain all LICENSOR authorized product materials through LICENSOR or LICENSOR'S authorized representative and no other source. LICENSOR authorized product materials include, but are not limited to, manuals, license agreements and media upon which LICENSOR's proprietary computer programs are recorded. End User shall make no copies of any kind of any of the materials furnished by LICENSOR or LICENSOR's authorized representative, except as specifically authorized to do so in this EULA. End User is not entitled to make archival copies of those portions of LICENSOR's product(s) that are provided on a machine readable media.

3. Proprietary Rights of Licensor. End User agrees that LICENSOR retains exclusive ownership of the trademarks and service marks represented by its company name and logo and all of the documentation and computer recorded data related thereto. End User also agrees that all techniques, algorithms, and processes contained in LICENSOR's computer program products or any modification or extraction thereof constitute TRADE SECRETS OF LICENSOR and will be safeguarded by End User, but in no event shall End User exercise less than due diligence and care in accordance with the laws of the country of purchase and International Law, whichever operates to best protect the interests of LICENSOR. End User shall not copy, reproduce, re-manufacture or in any way duplicate all or any part of LICENSOR products WHETHER MODIFIED OR TRANSLATED INTO ANOTHER LANGUAGE OR NOT, or in any documentation, or in any other material provided by LICENSOR in association with LICENSOR's computer program products regardless of what manner of storage and retrieval the product exists, except as specified in this Agreement and in accordance with the terms and conditions of this Agreement which remain in force. End User agrees that in the event End User breaches this EULA, End User will be liable for damages as may be determined by a court of competent jurisdiction.

4. Restrictions. End User's rights and obligations under this EULA are nonexclusive and personal in nature, and the intellectual property Licensor grants to End User is subject to applicable law other than bankruptcy law. End User may not transfer or assign the SOFTWARE, rights under this EULA or accompanying user documentation, or any updates of the SOFTWARE which may be provided under this EULA, to a third party unless End User receives written consent from Licensor at least 30 days prior to the completion of transfer. Licensor reserves the right to deny transfer or assignment if, in its sole discretion, Licensor determines the transfer not to be a necessity. Whether or not a transfer or assignment is allowed shall be determined in Licensor's sole discretion after taking into consideration certain factors to find the existence of a necessity including, but not limited to, merger or acquisition of an entity, complete asset acquisition, change of control, severe economic hardship, severe loss of human resources or significant loss in business divisions, or winding down of entity affairs.

If Carlson consents to a transfer, such transfer shall be allowed only as a one-time permanent transfer of this EULA and Software to another end user, provided the initial End User retains no copies or previous versions of the Software. The transfer must include all of the Software, including all component parts, any media and printed materials, any upgrades, this EULA, and any associated license key. The transfer may not be an indirect transfer, such as a consignment, rental or lease. No corresponding Maintenance Agreement rights shall transfer with the SOFTWARE transfer to the subsequent end user. Prior to the transfer, the subsequent end user receiving the Software from the initial End User must agree to all terms of this EULA, with the added condition that no further

transfers to third parties are permitted for any reason whatsoever, and shall agree to the terms and conditions of a new Maintenance Agreement with Licensor.

You may not reverse engineer, decompile, or disassemble the SOFTWARE or alter the images utilized in the SOFTWARE and user documentation. The SOFTWARE PRODUCT is licensed as a single product. Its component parts may not be separated for use on more than one computer. You shall communicate to any individual user in your facility that they are bound by the restrictions of this license agreement may not copy or alter the SOFTWARE for use outside End User's facilities.

Upgrades. If you purchase an upgrade of a SOFTWARE PRODUCT and you use it on different machine from one where upgraded SOFTWARE PRODUCT was used, use of original SOFTWARE PRODUCT must be discontinued and confirmed within 30 days. If such use is not discontinued, it is a material breach of this EULA and LICENSOR shall be entitled to all remedies available to it under this EULA, and under the laws of Kentucky, USA.

5. Security Mechanisms. Licensor and its affiliated companies take all legal steps to eliminate piracy of their software products. In this context, the Software Product may include a security mechanism that can detect the installation or use of illegal copies of the Software Product, and collect and transmit data about those illegal copies. Data collected will not include any customer data created with the Software. By using the Software Product, you consent to such detection and collection of data, as well as its transmission and use if an illegal copy is detected. Licensor also reserves the right to use a hardware lock device, license administration software, and/or a license authorization key to control access to the Software. You may not take any steps to avoid or defeat the purpose of any such measures. Use of any Software without any required lock device or authorization key provided by Licensor is prohibited.

6. Audit Rights. End User agrees that LICENSOR has the right to require an audit (electronic or otherwise) of the LICENSOR Materials and the Installation thereof and access thereto. As part of any such audit, LICENSOR or its authorized representative will have the right, on fifteen (15) days' prior notice to End User, to inspect End User's records, systems and facilities, including machine IDs, serial numbers and related information, to verify that the use of any and all LICENSOR Materials is in conformance with this Agreement. End User will provide full cooperation to enable any such audit. If LICENSOR determines that End User's use is not in conformity with this EULA, End User will obtain immediately and pay for a valid license to bring End User's use into compliance with this EULA and other applicable terms and pay the reasonable costs of the audit. In addition to such payment rights, LICENSOR reserves the right to seek any other remedies available at law or in equity, whether under this Agreement or otherwise.

7. Warranty. THE PRODUCT IS PROVIDED "AS IS" WITH ALL FAULTS. TO THE MAXIMUM EXTENT PERMITTED BY LAW, LICENSOR HEREBY DISCLAIMS ALL WARRANTIES, WHETHER EXPRESS OR IMPLIED, INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND WARRANTIES THAT THE PRODUCT IS FREE OF DEFECTS AND NON-INFRINGEMENT, WITH REGARD TO THE SOFTWARE, AND THE ACCOMPANYING WRITTEN MATERIALS. YOU BEAR ENTIRE RISK AS TO SELECTING THE PRODUCT FOR YOUR PURPOSES AND AS TO THE QUALITY AND PERFORMANCE OF THE PRODUCT. THIS LIMITATION WILL APPLY NOTWITHSTANDING THE FAILURE OF ESSENTIAL PURPOSE OF ANY REMEDY. In any event, LICENSOR will not honor any warranty shown to exist for which inaccurate or incorrect identifying data has been provided to LICENSOR. The product(s) provided are intended for commercial use only and should not be utilized as the sole data source in clinical decisions as to levels of care.

8. LIMITATION OF LIABILITY. EXCEPT AS REQUIRED BY LAW, LICENSOR AND ITS DISTRIBUTORS, DIRECTORS, LICENSORS, CONTRIBUTORS AND AGENTS (COLLECTIVELY, THE "LICENSOR GROUP") WILL NOT BE LIABLE FOR ANY INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES ARISING OUT OF OR IN ANY WAY RELATING TO THIS EULA OR THE USE OF OR INABILITY TO USE THE PRODUCT, INCLUDING WITHOUT LIMITATION DAMAGES FOR LOSS OF GOODWILL, WORK STOPPAGE, LOST PROFITS, LOSS OF DATA, AND COMPUTER FAILURE OR MALFUNCTION, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES AND REGARDLESS

OF THE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH SUCH CLAIM IS BASED. THE LICENSOR GROUP'S COLLECTIVE LIABILITY UNDER THIS AGREEMENT WILL NOT EXCEED THE GREATER OF \$500 (FIVE HUNDRED DOLLARS) AND THE FEES PAID BY YOU UNDER THIS LICENSE (IF ANY).

9. Update Policy. LICENSOR may, from time to time, revise the performance of its product(s) and in doing so, incur NO obligation to furnish such revisions to any End User nor shall it warrant or guarantee that any revision to the SOFTWARE will perform as expected by the End User on End User's equipment. At LICENSOR's option, LICENSOR may provide such revisions to the End User.

10. Customer Service. Although it is the LICENSOR's customary practice to provide reasonable assistance and support in the use of its products to its customers, LICENSOR shall not be obligated to any End User to provide technical assistance or support through this Agreement and may at LICENSOR's sole election charge a fee for customer support.

11. Termination of End User License. If any one or more of the provisions of this Agreement is breached, the license granted by this Agreement is hereby terminated. In the event of such termination, all rights of the LICENSOR shall remain in force and effect. Any protected health information data of End User maintained on LICENSOR'S data base shall upon reasonable notice to End User and at the discretion of LICENSOR may be destroyed.

12. Copyright. The SOFTWARE (including, but not limited to, any images, photographs, animations, video, audio, music and or text incorporated into the SOFTWARE), and all intellectual property rights associated with it, whether exists in a tangible media or in an electronic image media is owned by LICENSOR and is protected by United States copyright laws and international treaty provisions and all other commonwealth or national laws. LICENSOR reserves all intellectual property rights in the Products, except for the rights expressly granted in this Agreement. You may not remove or alter any trademark, logo, copyright or other proprietary notice in or on the Product. This license does not grant you any right to use the trademarks, service marks or logos of LICENSOR or its licensors. You may not copy any user documentation accompanying the SOFTWARE.

13. Injunctive Relief. It is understood and agreed that, notwithstanding any other provision of this Agreement, LICENSOR has the unequivocal right to obtain timely injunctive relief to protect the proprietary rights of LICENSOR.

14. Entire Agreement. This EULA constitutes the entire agreement between the parties and supersedes any prior agreements. This EULA may only be changed by mutual written consent.

15. End User Agreement Acknowledgment. The End User hereby accepts all the terms and conditions of this Agreement without exception, deletion, alteration. End User acknowledges they are authorized to enter this agreement on behalf of any organization for which the license is sought. Any unauthorized use of LICENSOR products will be considered a breach of this Agreement, subject to liquidated damages and otherwise unlawful and willful infringement of LICENSOR's trade secrets and/or proprietary products.

16. Payment and Refund Policy. The use of the SOFTWARE herein is deemed a commercial use and under the terms of this license agreement End User shall not be entitled to any refund of purchase price. End User agrees to pay all user fees promptly. LICENSOR is authorized by End User to suspend any further access to SOFTWARE in the event fees are not fully paid. End user entity shall promptly pay any and all access and use charges incurred regardless of the end user. End user is responsible for protecting any pass word and user identity supplied to End User.

17. Loss/Theft/Misuse. End user shall promptly report to LICENSOR the theft or other loss of any password and/or user identity required to access SOFTWARE. LICENSOR shall not be responsible for maintaining the integrity of End User data in the event that end user's data base is accessed and/or altered by an unauthorized end user due to the failure of licensed End User to protect its password or user identity. End User shall be responsible for any costs incurred by LICENSOR due to the negligence or reckless disregard of End User's failure to protect its

password or user identity.

18. Civil/Criminal Investigation. End user shall fully cooperate with LICENSOR and or any person authorized by LICENSOR (including local, state, or federal law enforcement officials) to investigate any alleged theft, misuse or unauthorized use of SOFTWARE or data related thereto.

19. U.S. Government Restricted Rights. The SOFTWARE PRODUCT and documentation are provided with RESTRICTED RIGHTS. Use, duplication, or disclosure by the Government is subject to restrictions as set forth in subparagraph (b)(1)(ii) and (c) of the Rights in Technical Data and Computer Software clause at DFARS 252.227-7013 or subparagraphs (c)(1) and (2) of the Commercial Computer Software-Restricted Rights at 48 CFR 52.227-19, as applicable.

20. Governing Law. This EULA shall be governed and construed in accordance with the laws of the Commonwealth of Kentucky, USA.

General Commands

2

File Menu

All the Carlson module menus share seven of the same pull-down menus which are:

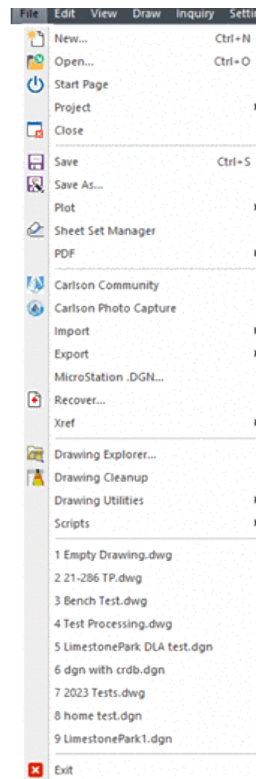

1. File
2. Edit
3. View
4. Draw
5. Inquiry
6. Settings
7. Points

These menus (along with Window and Help) form a "core" group of commands which can be accessed regardless of the Carlson module that is being used. The common pull-down menus contain general commands that are applicable within all the modules. Many of these commands are AutoCAD or IntelliCAD commands which are described in your CAD Reference manual. The Carlson commands located in the common pull-down menus are explained in the next sections.

Note:

- Within a module, other pull-down menus (typically three or four) are often specific to the module but certain commands (*e.g.* Triangulate & Contour) may be found in several modules.

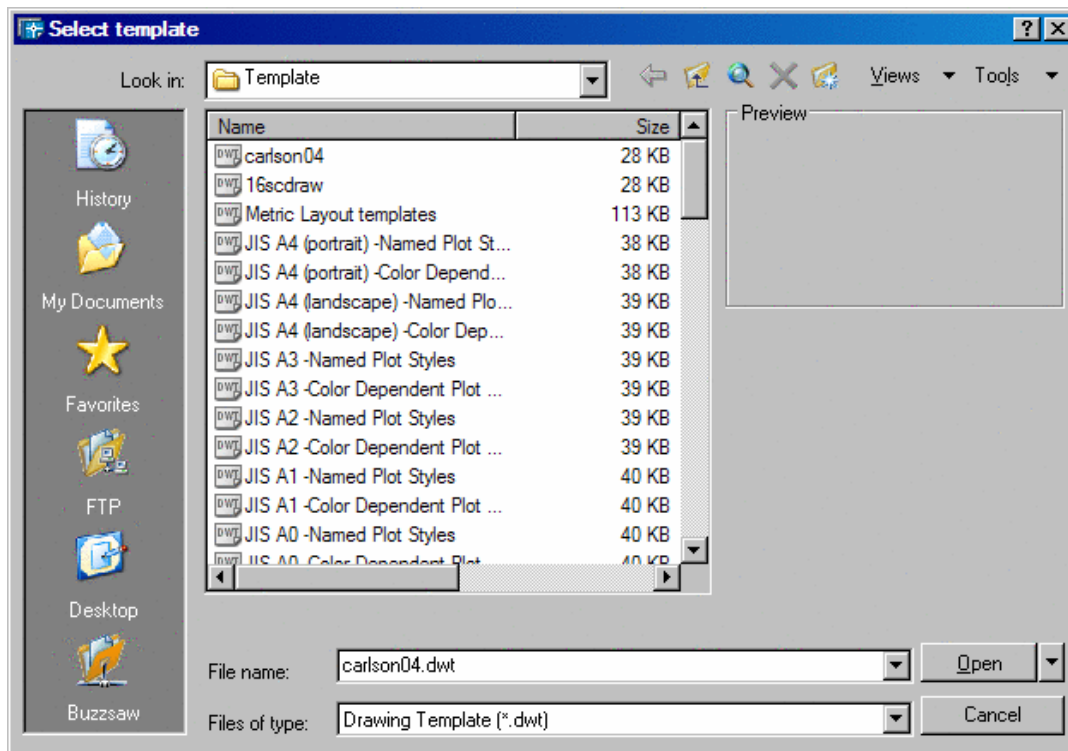

The set of commands varies slightly between the CAD platforms and versions.

New

This command allows you to create a new drawing file. This routine defines the settings for a new drawing. You can start a new drawing file by selecting New, and then picking a template file. The first dialog for the New command, called Select Template, lists all template files that currently exist in the drawing template file location. Choose a file to use as a starting point for your new drawing. A preview image of the selected file is displayed to the right.

The template file (.DWT) that you use will depend on the version of AutoCAD or IntelliCAD that you are running. After choosing the template, click the Open button at the lower-right. Next, you will either see the New Drawing Wizard dialog box, or you will be taken to a blank screen. Should you use the wizard, a new drawing name will need to be chosen in order to get to the next step.

If the wizard is in use, the following options will be available to you in the New Drawing Wizard dialog. The New command starts a new drawing using default settings defined in one of the Carlson .DWT template files, depending on the measurement system you've chosen. You cannot modify the surv.dwt or surviso.dwt templates. To start a new drawing based on a customized template, see Use a Template.

English: This option starts a new drawing based on the Imperial measurement system. The drawing is based on the surv.dwt template, and the default drawing boundary (the drawing limits) is 12 Ã- 9 inches.

Metric: This option starts a new drawing based on the metric measurement system. The drawing is based on the surviso.dwt template, and the default drawing boundary (the drawing limits) is 429 Ã- 297 millimeters.

The New command creates a new drawing, using the settings defined in a template drawing you select. Template drawings store all the settings for a drawing and may also include predefined layers, dimension styles, and views.

Template drawings are distinguished from other drawing files by the .DWT file extension. They are normally kept in the template directory. Several template drawings are included with Carlson. You can make additional template drawings by changing the extensions of drawing file names to .DWT.

Remember that there are two methods that you can use to work on a Carlson drawing. One is the New command, and the other is the more generic Open command. If you need to open an existing drawing, use Open, also found in the File menu, and then choose an existing file name.

Pulldown Menu Location: File

Keyboard Command: new

Prerequisite: None

Project Explorer

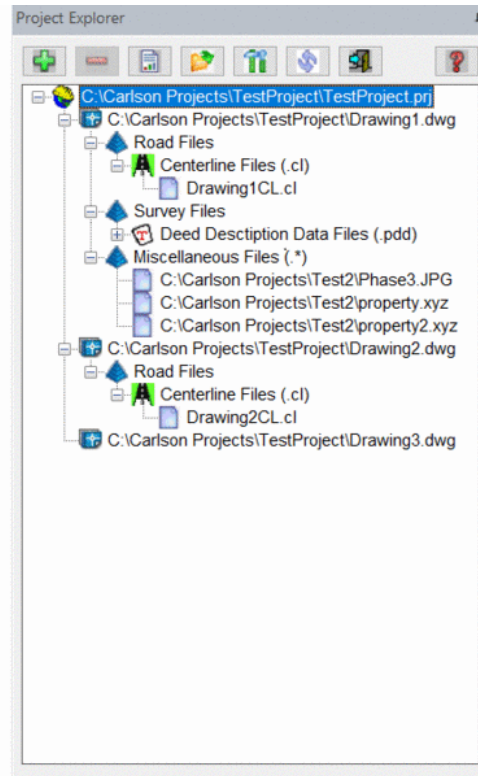

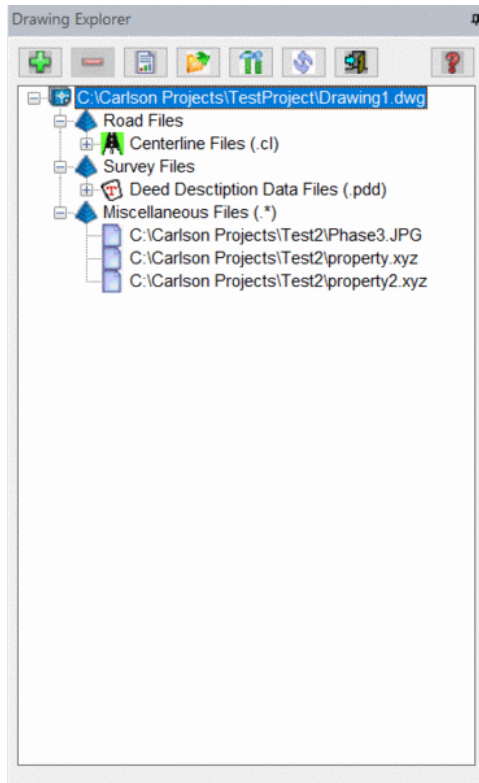

This tool is used for management of a complete project. A project can contain multiple drawings, and each drawing within that project can contain multiple associated data files.

Think of the Project Explorer as the trunk of the hierarchical tree structure that develops into a project as illustrated below:

As you work in a drawing, Carlson keeps track of the files that you create (such as TIN and coordinates files). These are related to the drawing and you can use the Drawing Explorer to manage them. The Project Explorer is used to manage multiple drawings. In the following illustration, two views of the same Project are displayed:

- *By Drawing* - shown on the left.
- *By Project* - shown on the right.

Control

Action

Adds a drawing and its data file(s) into the project.

Removes the selected file(s) along with any "child" (sub-ordinate) files from the project. Note that removing a data category or file at the "project" level also removes the category or file at the "drawing" level.

Creates a report through the Report Formatter Options dialog box. The Report Formatter can be used to move to the *Available* entries on the left to the *Used* area on the right. When coupled with the Up/Down options to control the order, highly customized reports can be generated and saved for subsequent use. Click the Display to obtain the report.

The Change Directory option allows you to instruct Carlson Software to re-direct the location for files from an old folder location to a new folder location. This option is helpful if project data files are manually moved to a new folder location.

The Settings button allows you to create Categories of file types and assign data files to a particular Category and assign how project data files are presented in the Project Explorer.

The Refresh button re-reads the current Project file along with the various Drawing file settings and updates the Project listing appropriately.

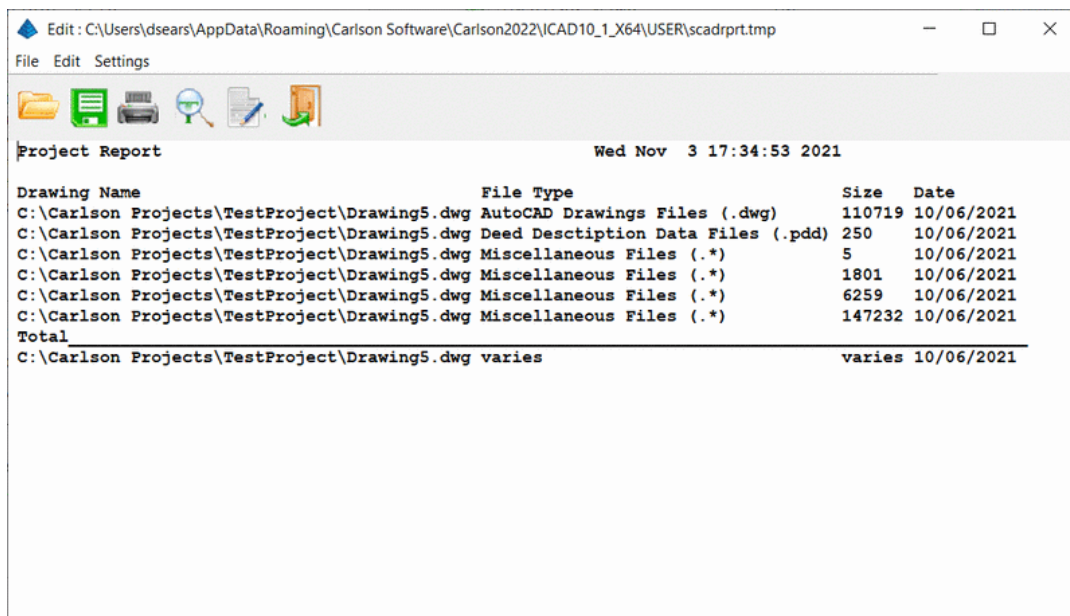

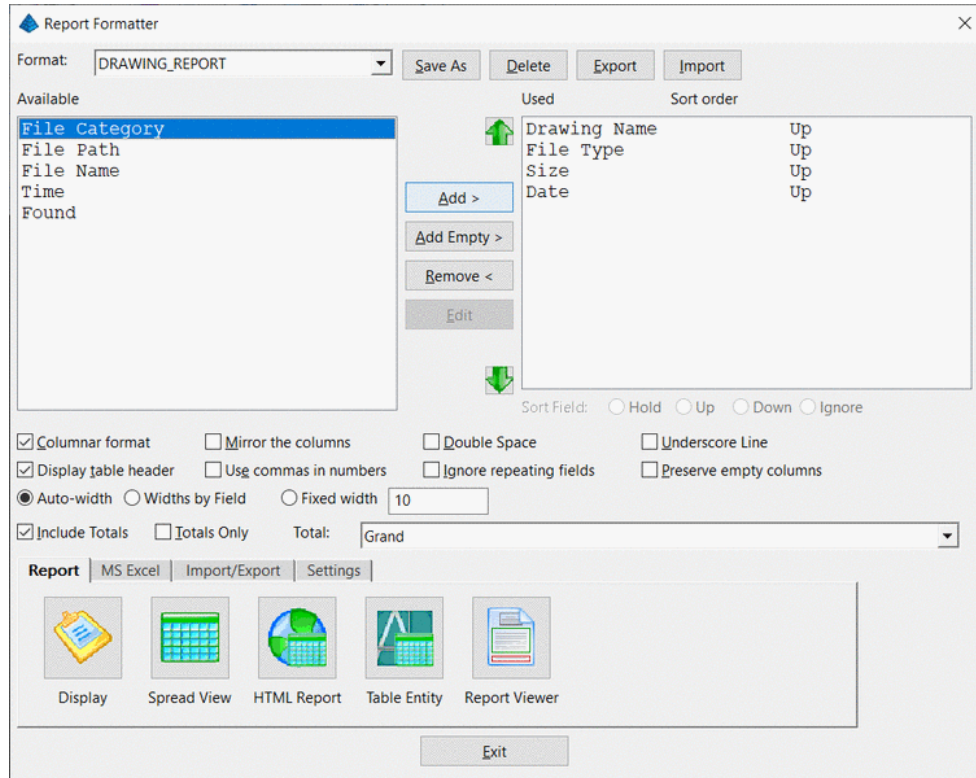

Exits from the Project Explorer command.

Displays the on-line help.

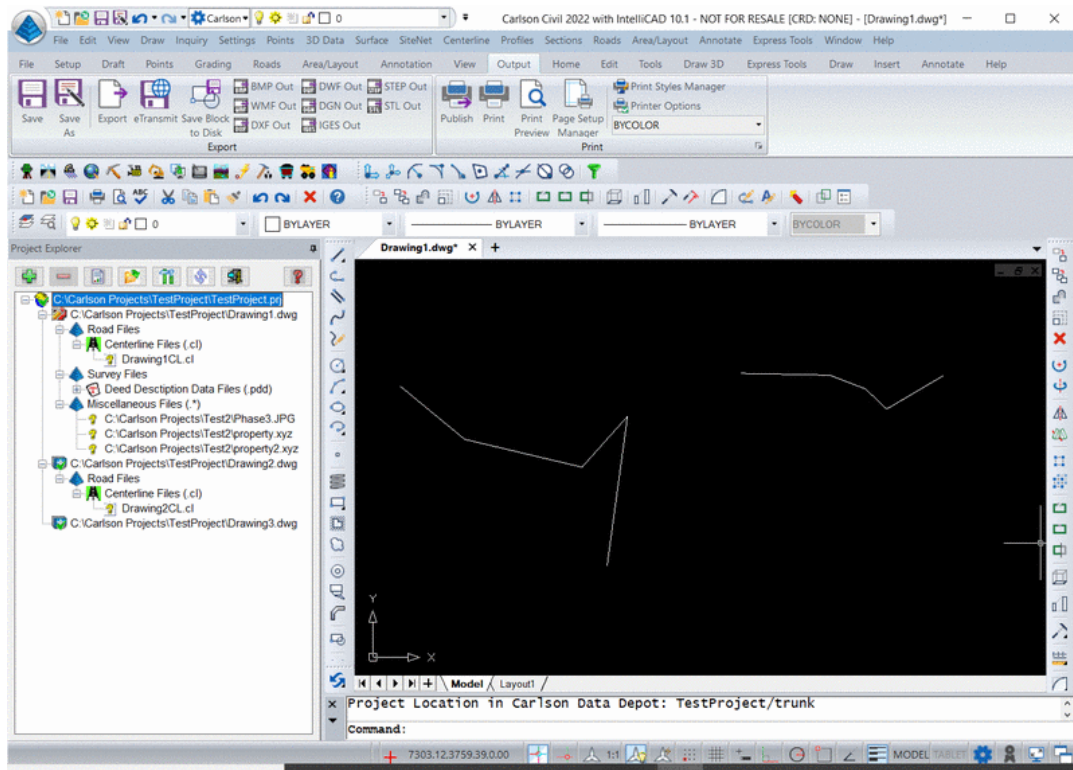

Project Explorer Controls

The project history/log report file can be generated using Report button. The Project Explorer tracks all the data files used with the project. The report function also uses the data file information logged with the Carlson Data

Depot. The program allows you to report all revisions or only the last commit on all project files from Carlson Data Depot. The information reported include project file, drawing name, file category, file path, file name, file type, date, time, size, revision, author, date committed and commit message along with project properties (i.e. company name, project name etc). Here's a sample report.

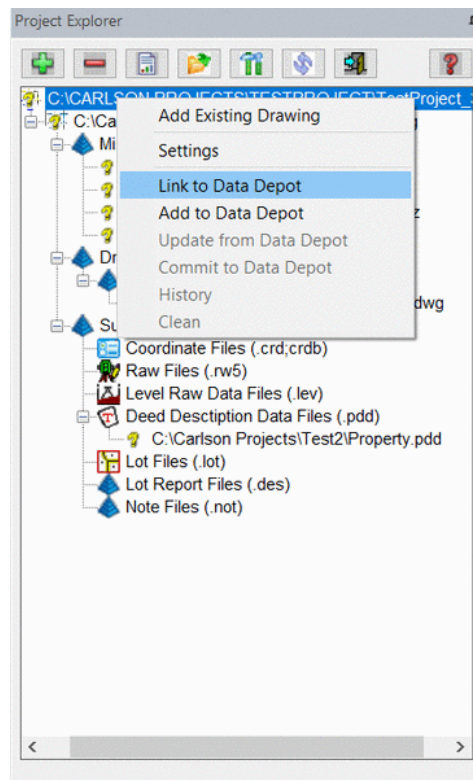

Linking a project to the Carlson Data Depot requires that you properly configure the Data Depot through the Set Project/Data Folders command and then open a drawing and assign it to a Project (.PRJ) file. If a project is not linked to the Data Depot, a question mark is overlaid on all the files and folders under that project as shown:

To link a project to the Data Depot, perform the following steps:

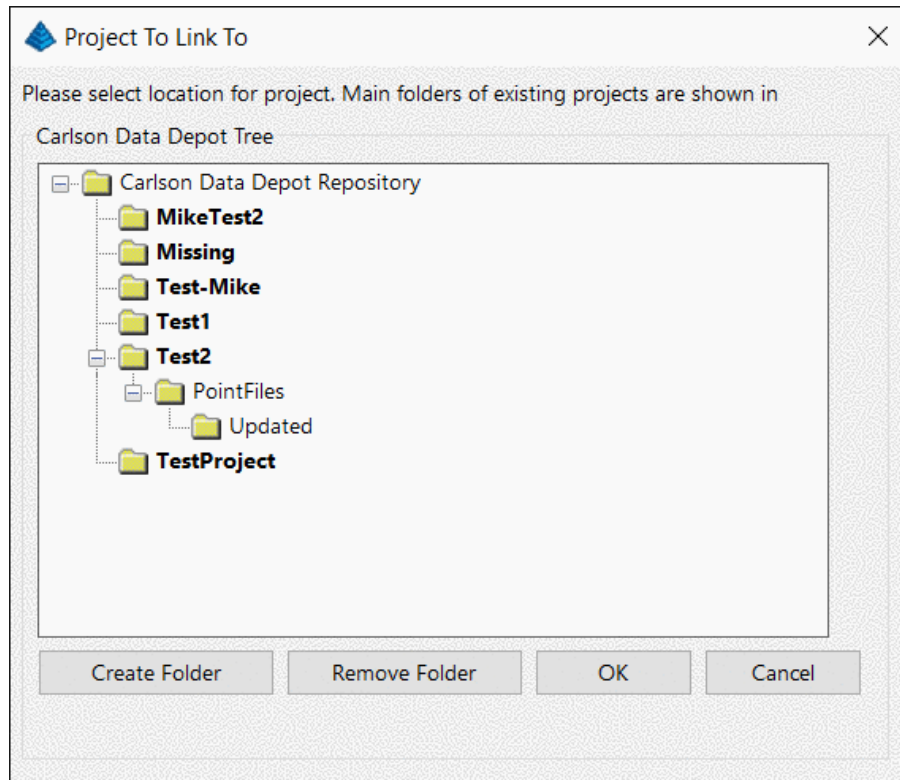

1. Right click on the Project File name (the "trunk" of the Project Explorer tree) and select Link to Data Depot command:

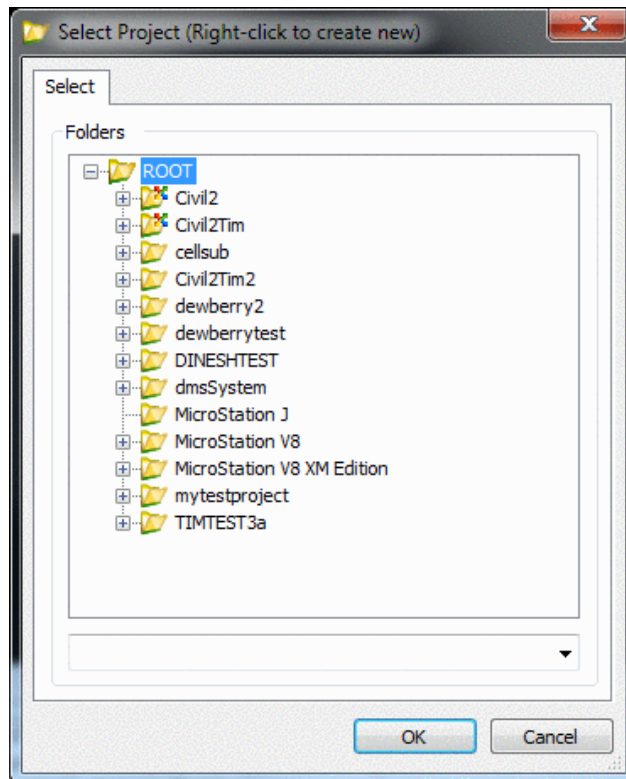

2. This will bring up the "Project to Link to" window. The window you see depends upon whether you are using SVN or ProjectWise as your Data Depot Repository.

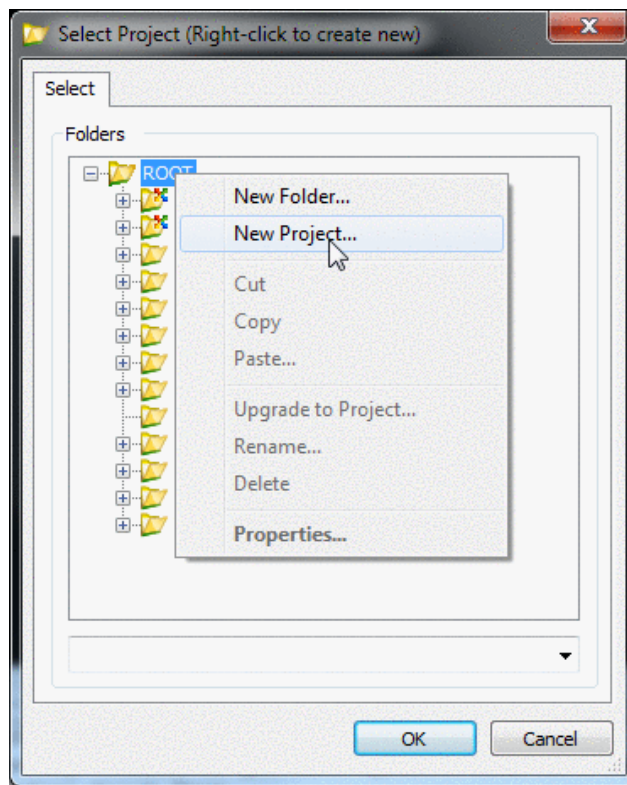

- (a) **SVN:** This window shows the existing projects under the repository, if any. A new project folder can be created under Carlson Data Depot Repository by using the Create Folder button. Sub-folders can be

created by using the Create Folder button while top folder selected. Select the folder you want to create the project under and click OK:

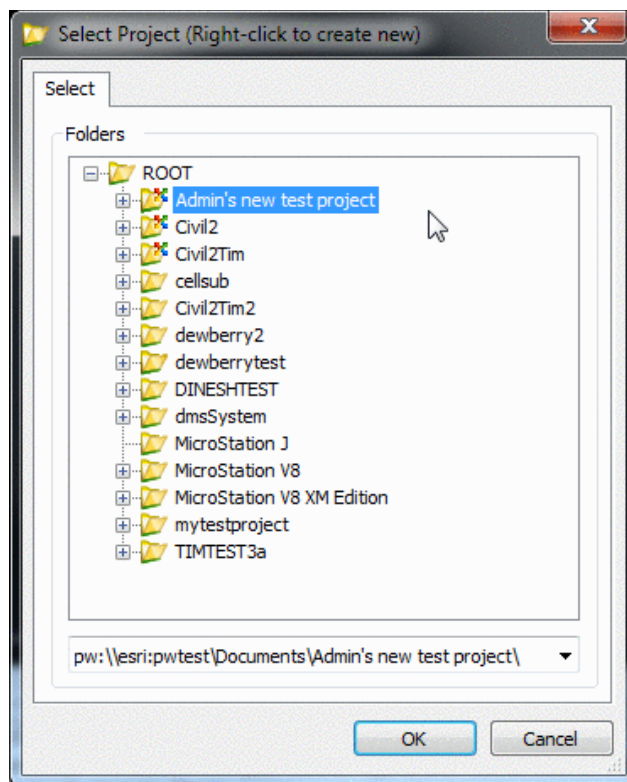

- (b) **ProjectWise - Step 1:** This window shows the existing projects under the repository, if any. A new project folder can be created by right clicking on the ROOT entry of the repository tree:

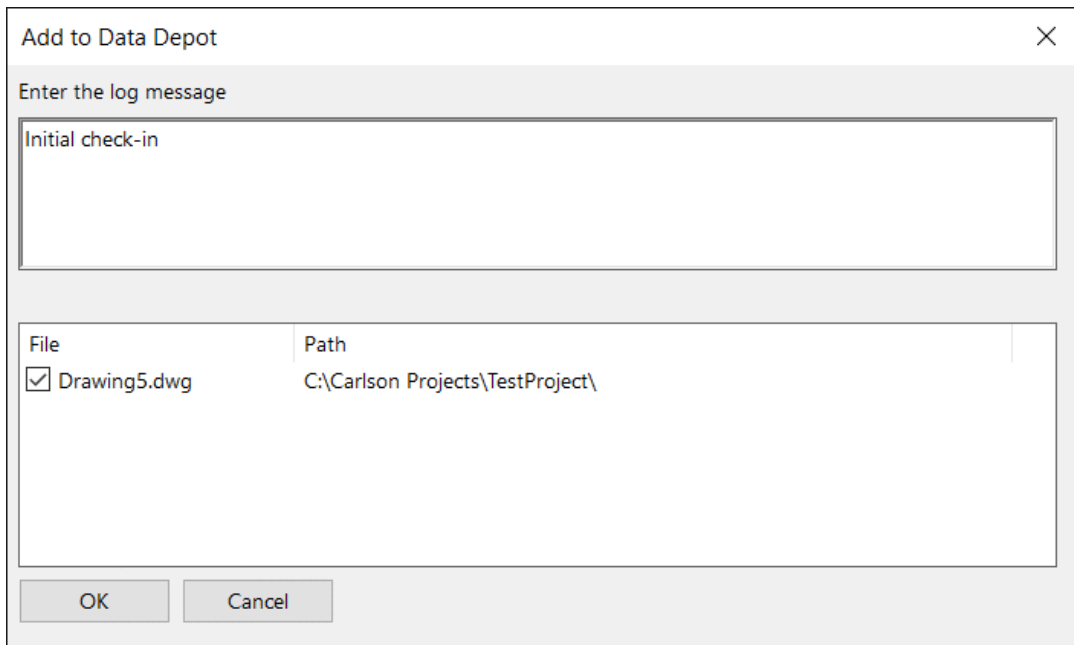

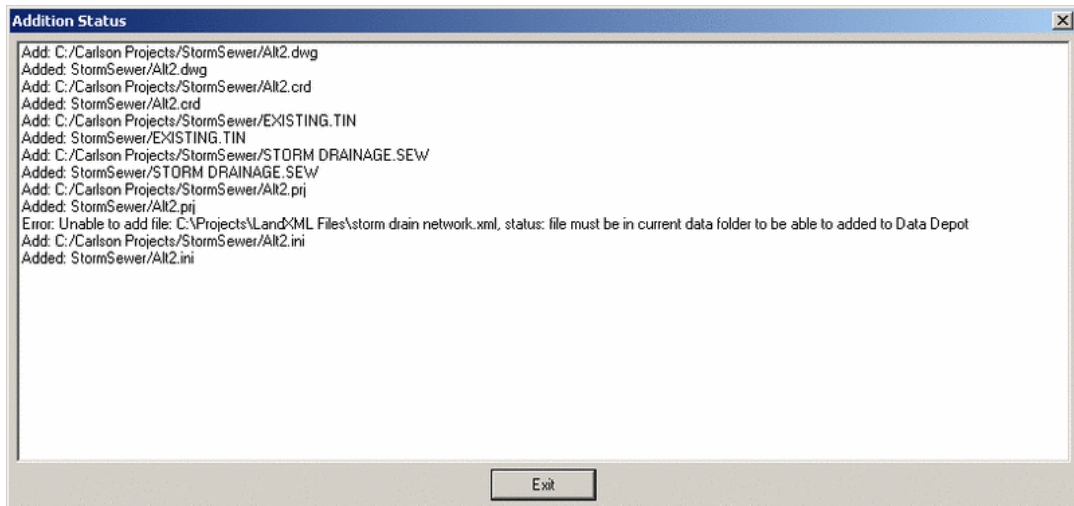

(c) **ProjectWise - Step 2:** Name the new project, select it from the list and click the OK button.

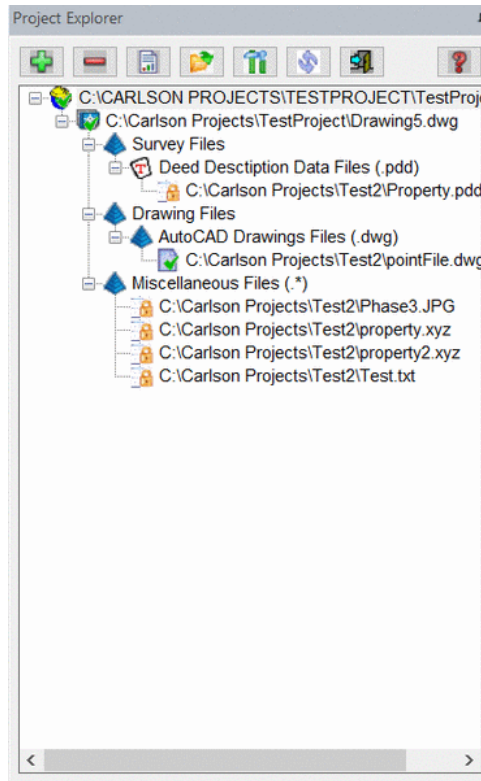

3. This will prompt you to Add to Data Depot window where you can enter a log message to identify what you are doing. This information will be added to the history log. Click OK to start adding files to the project repository:

4. A status window will appear showing the message for files that have been tasked to be added to the repository:

5. Once the files are linked to the Data Depot, the status/icon in the tree view is changed:

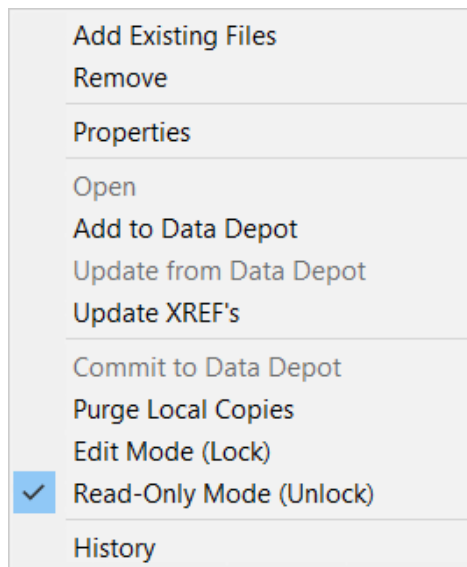

When new files are created inside the project, they are shown as not linked to the Data Depot (using the question mark icon) and can later be linked to the Data Depot by right clicking and using the Add to Data Depot command.

Data Depot File Status

The following shows the icons used in the Project Explorer tree for representing the state of files in the Data Depot:

Data Depot Commands

Add Existing Files: Allows the user to select an existing data file from local storage which will be added to the project and the Data Depot. The data file will be associated (placed under) the currently selected drawing.

Remove: Removes the selected file from the project without removing it from the Data Depot.

Properties: Brings up the system file properties dialog.

Add to Data Depot: Incorporates the selected file(s) into the Data Depot.

Update from Data Depot: Gets the last committed version of the selected file(s) from the Data Depot.

Update XREF's: Gets the last committed version of any XREF files associated with the selected drawing.

Commit to Data Depot: Incorporates locally modified/locked file(s) that are already part of the Data Depot into the Data Depot.

Purge Local Copies: Deletes the selected file from the local storage leaving it in the Data Depot and the project. The local copy can be restored later by using the "Update from Data Depot" command.

Edit Mode (Lock): Locks the selected file(s) for local editing and prevents others from modifying the file(s). If the drawing or data file is newer in the Data Depot than on local storage this command will be disabled.

Read-Only Mode (Unlock): Unlocks the selected file(s) so that they may be edited by others.

History: Displays the history log of changes made to the selected file.

Clean (project level only): "Cleans" the project of items that don't exist in both the Data Depot and local storage.

Once the project has been added to the Data Depot, it can be quickly updated or accessed by other users and be ready for use via the Get Project from Data Depot command:

Notes on locking/unlocking project files when using Subversion repository

Subversion locking of the file is specific to the specific working folder - the file in a particular checked out set of files. Same user working on another copy of file in different folder or on different computer will not own the lock. External subversion clients have additional lock functionality which not exposed through Carlson Data Depot interface for purposes of simplicity. These clients will have options for stealing lock (placing the lock on file already locked at different location or by different user) and forcing lock (unlocking a lock placed at different location or by different user). In a productive collaborative environment such design allows on one hand to prevent accidental editing of the file which is locked by another user and causing a situation when one of the users has to abandon his changes, but on the other it allows to move forward if file is locked accidentally and file needs to be re-locked elsewhere.

In the case when this design is not sufficiently strict, it is possible to override this behavior by implementing server-side hooks which change the default behavior. Here is the example of pre-unlock script for VisualSVN which limits lock overrides to original user or to user called Administrator:

```
@echo off
setlocal
set REPOS=%1
set RPATH=%2
set USER=%3
set SVNLOOK=%PROGRAMFILES%\VisualSVN Server\bin\svnlook.exe
set TMPFILE=%temp%/lockinfo
```

```
rem Creating a temporary file with output of the lock, filtering everything
except owner out
''%SVNLOOK%' lock ''%REPOS%' ''%RPATH%' | find 'Owner' > %TMPFILE%
```

```

rem Parsing the file looking for owner name only
FOR /F 'usebackq tokens=2' %%A IN (%TMPFILE%) DO set LOCK_OWNER=%%A

del %tmpfile%

if '%LOCK_OWNER%'=='' goto GOOD
if '%LOCK_OWNER%'=='%USER%' goto GOOD
rem Only Administrator can break the lock
if 'Administrator'=='%USER%' goto GOOD

echo 'Permission denied! Ask Administrator for assistance' 1>&2
endlocal
exit 1

:GOOD
endlocal
exit 0

```

Simply paste this script into the hook window by going into VisualSVN Server Manager, right-clicking over repository, All Tasks, Manage Hooks, double-click pre-unlock hook.

Pulldown Menu Location: File > Project

Keyboard Command: prjxplore

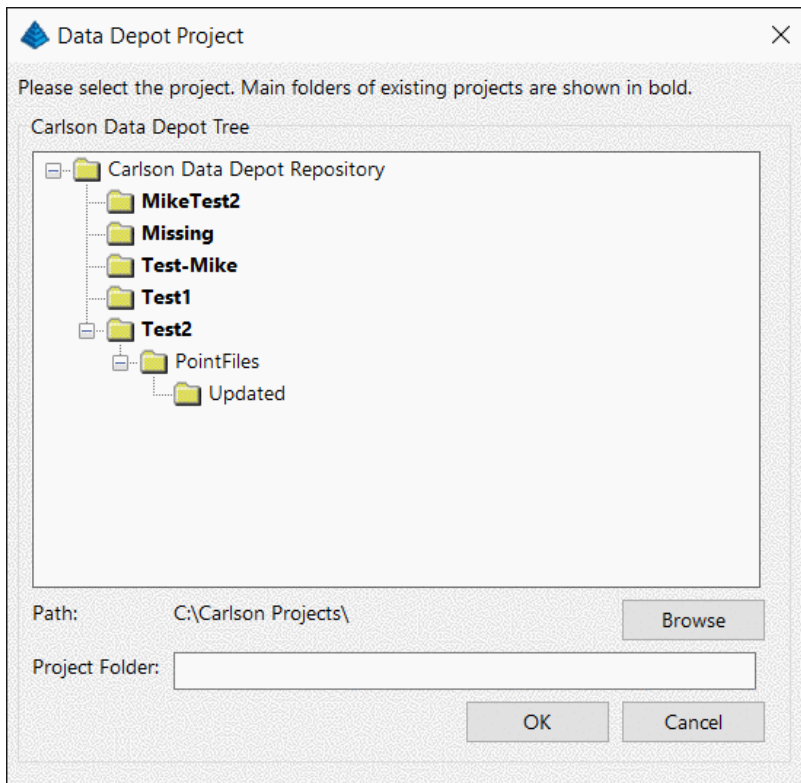

Prerequisite: None

Get Project from Data Depot

The Carlson Data Depot is a document management system to allow tracking of the changing states of files and projects over time and manage the contributions from multiple users providing data integrity, productivity and accountability for the managed products. Once a project has been successfully registered with the Data Depot using the Project Explorer, it can be retrieved through the Data Depot for subsequent editing.

Subversion Example:

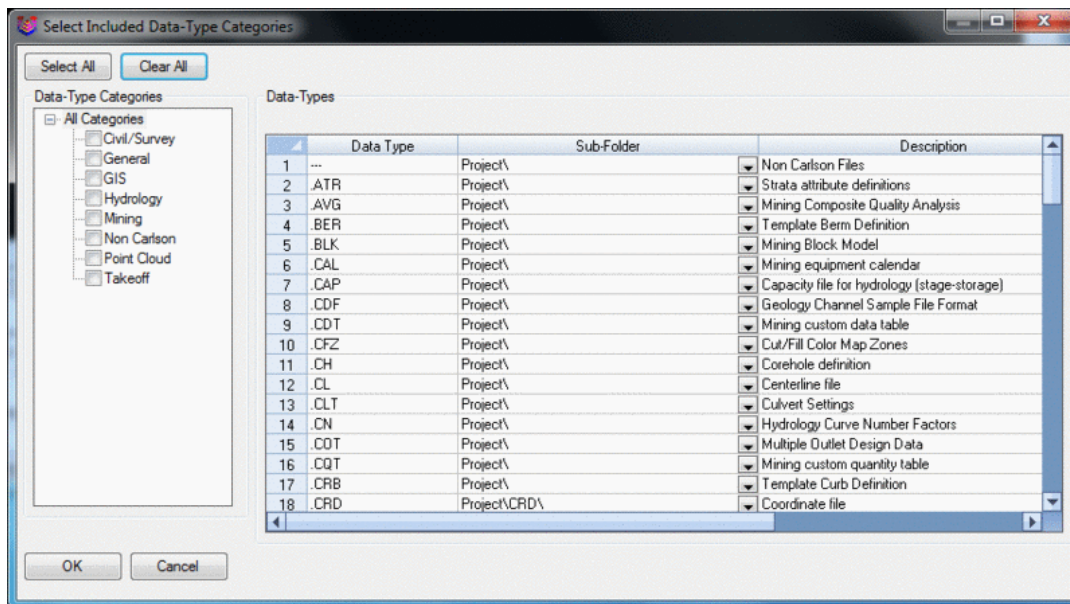

1. Select the project folder from the Repository that you wish to check out:

2. Enter the destination path to check the project out to on your local machine. You can optionally specify a project subfolder to save the project to in the desired path.

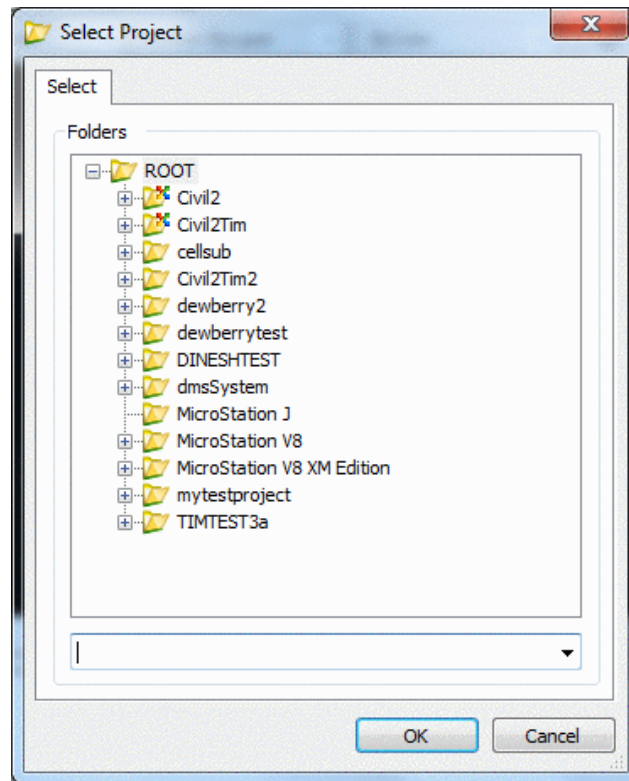

Continue below to the "Select the Project" section.

ProjectWise Example:

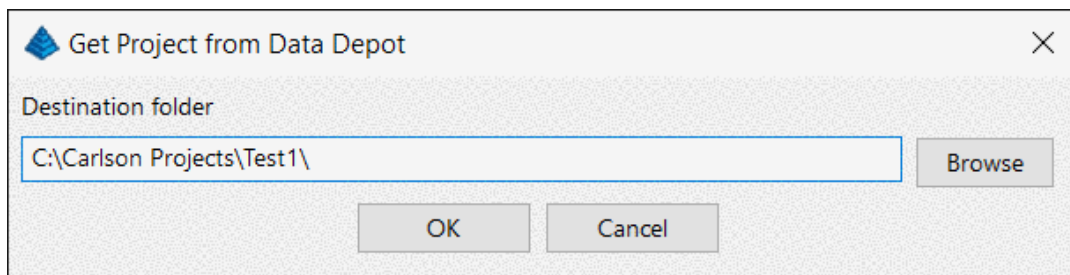

For ProjectWise the "Select Included Data Type Categories" dialog will appear. Here the user can select which types of files to download from the repository. A special category "Non Carlson" is used to determine whether files not associated with Carlson Software should be downloaded or not (e.g. Word .DOC documents or Microstation .DGN

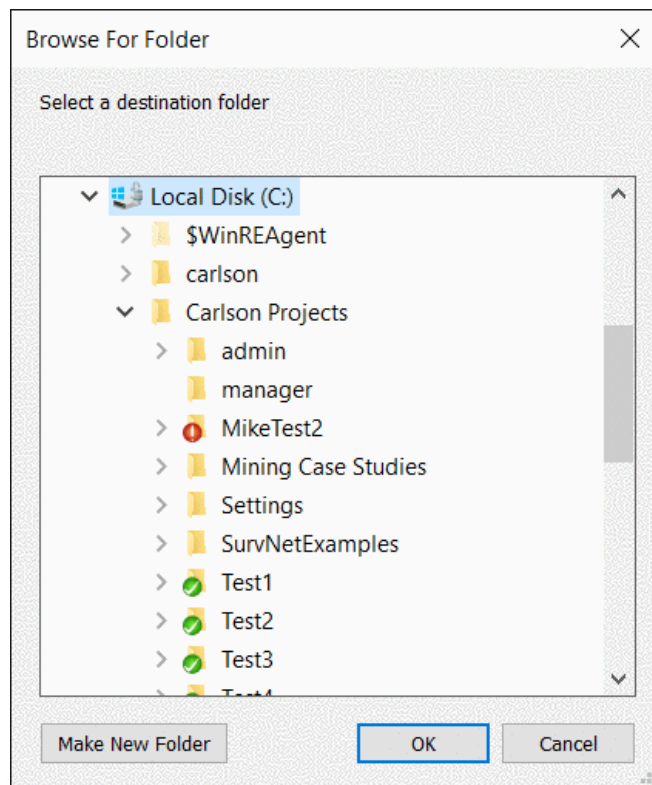

files). If the user wants even more control over what files are downloaded, say at the drawing level, he/she can use the "Clear All" button to deselect all categories. In this case, only the directory structure plus the Project File (.PRJ) will be downloaded. This allows the user to select which drawings they want to download from the repository directly from the Carlson Project Explorer.

Selecting the Project:

Select the project you would like to open and click OK. Unless you have selected "Use Automatic Project Folder Name" (see Set Project/Data Folder for more information), you will be prompted to identify a "working" folder where the checked-out copies of your project files will reside:

Identify the destination folder location and click OK. The checked-out copies of the project files will be placed into the specified folder at which point further editing can begin.

Pulldown Menu Location: File > Project

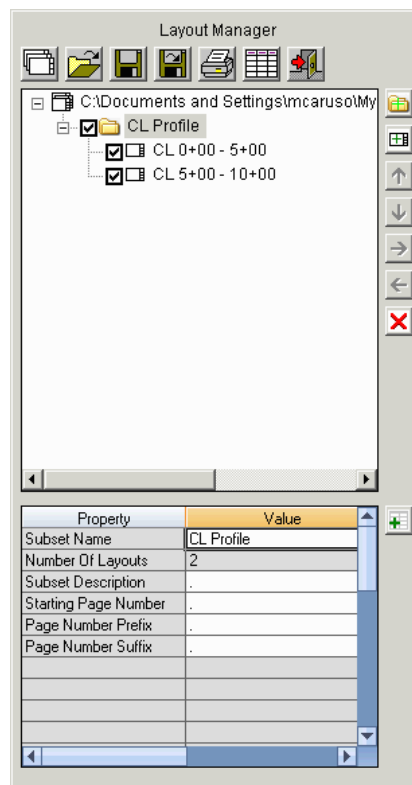

Keyboard Command: get_prj_from_depot

Prerequisite: A properly installed, configured and support content management system

Layout Manager

Note: This command is only available in AutoCAD platform

The Layout Manager is a docked dialog that displays the contents of a Layout Set. Layout Sets (.set files) contain information on layouts that come from a single or multiple drawings. Once you build a layout set, the Layout Manager facilitates printing via AutoCAD's PUBLISH functionality.

The Layout Manager contains two sections. A Treeview, which displays the items of the Layout Set. Items are the root node, which is the topmost node representing the Layout Set. Subsets, which act as folders and can contain Layouts and additional Subsets.

The bottom section contains a grid view, which will display built-in and custom properties of the selected Layout Set, Subset or Layout item. The first column shows the property name, and the second column displays its value. Some properties are read-only and are calculated by the Layout Manager.

New: Use the New button to create a new empty Layout Set. You can also specify an existing layout set to use as a Template. If a Template is specified, only the Subsets (folders) structure will be copied to your new Layout Set. This is convenient if you have a standardized Subset structure to use for all Layout Sets.

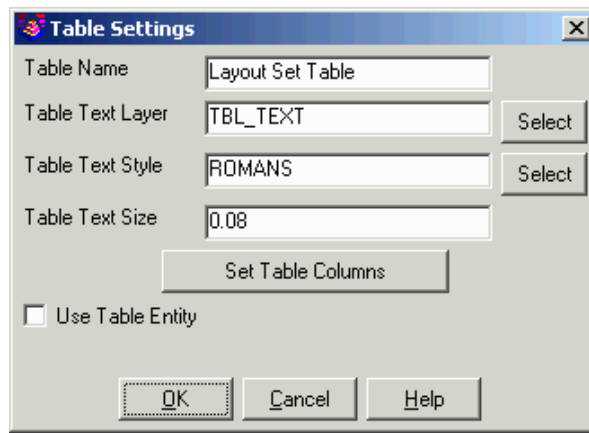

Open: Use the Open button to open an existing Layout Set. Only one Layout Set is allowed open per session. If a Layout Set is currently open in the Layout Manager, you will be prompted to save any changes if necessary.

Save: Use the Save button to save your current Layout Set file. Layout Sets are saved as .set files.

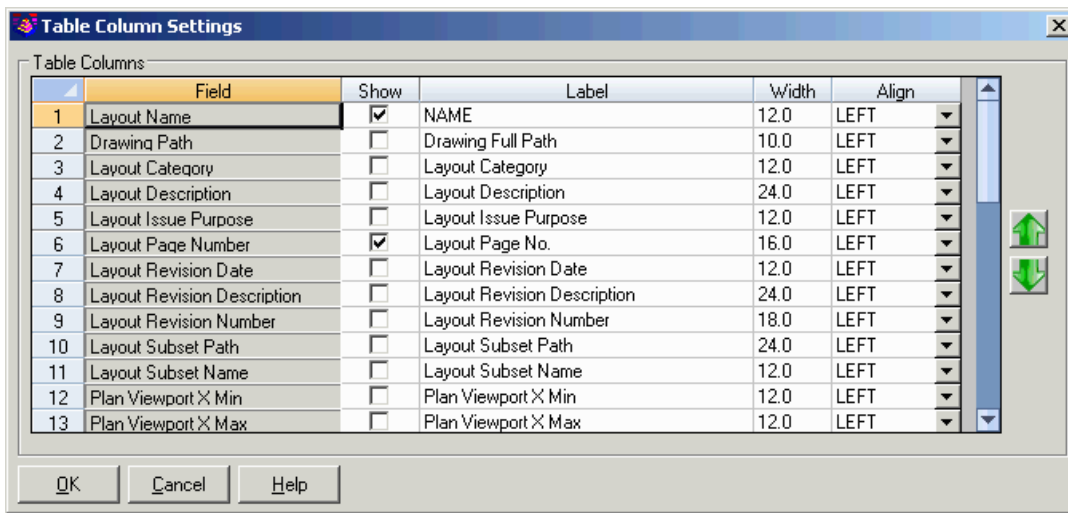

Save As: Use the Save As button to save a copy of an existing Layout Set file with a new name.

Print: Use the Print button print all checked layouts using AutoCAD's Publish functionality. All Subsets and Layouts in the Layout Manager contain a checkbox. If the Subset or Layout is checked, it will be included when the print command is run. When a user checks a Subset, all the child items of that Subset are checked. Similarly, when a Subset is unchecked, all the child items of that Subset are unchecked.

Insert Table: Use the Insert Table button to insert a Table of Contents. This feature allows you to draw a Table containing all the layouts of the Layout Set, including their file name, drawing name, page number, etc.

Use the Set Table Columns button to define which columns are to be displayed in the Layout Set table. Toggle the Use Table Entity to insert the table as a block, or leave it unchecked to draw each row as an individual block.

You can edit the Label column, which will be displayed as the column header in your table. The Width and Text Alignment can also be set for each column.

Exit: Use the Exit button to exit and close the Layout Manager.

Add Subset: Use the Add Subset button to create a new Subset folder under the selected Layout Manger item.

Add Layout: Use the Add Layout button to add a Layout to the current Layout Set file in the selected Subset or root of the Layout Set. Layouts may be selected from the current drawing, or from another drawing on your computer or network.

Move Up: Use the Save As button to move the selected Layout (or Subset and child Layouts) above the previous sibling item.

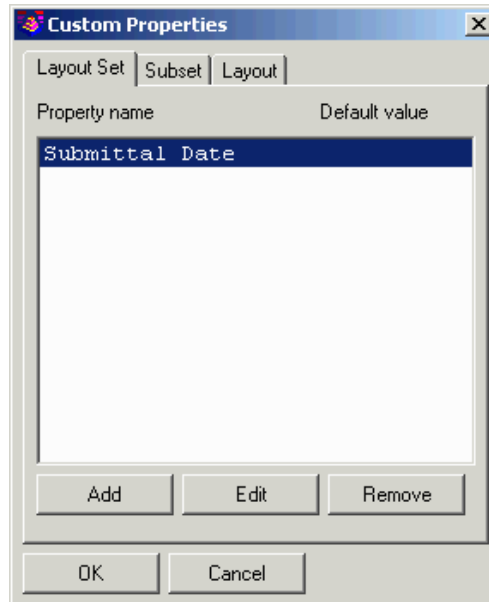

Move Down: Use the Save As button to move the selected Layout (or Subset and child Layouts) below the next sibling Subset or Layout.

Move In: Use the Move In button to move the selected Layout (or Subset and child Layouts) under the next sibling Subset.

Move Out: Use the Move Out button to move the selected Layout (or Subset and child Layouts) above the selected parent Subset.

Remove Item: Use the Remove Item button to remove the selected Layout (or Subset and child Layouts).

Custom Properties: Use the Custom Properties button to Add, Edit or Remove custom properties to a Layout, Subset or Layout Set.

Select the appropriate tab to add a custom property. Then use the Add, Edit or Remover buttons to edit properties for the selected item type.

Pulldown Menu Location: File > Plot

Keyboard Command: layoutmgr

Prerequisite: None

Output Layouts to PDF

This command creates a PDF from layouts in the current drawing. The command starts by prompting for the output PDF file to create. In the dialog, the **Title**, **Subject**, **Keywords** and **Author** are optional properties for the PDF file.

The **Print Area** controls whether to use the page size defined in the Page Setup Manager for each layout, or set the print area by zoom extents on the entities for each layout.

The **Store Layers in PDF** creates a PDF with the CAD layers.

The **Include Off Layers** outputs all layers to the PDF.

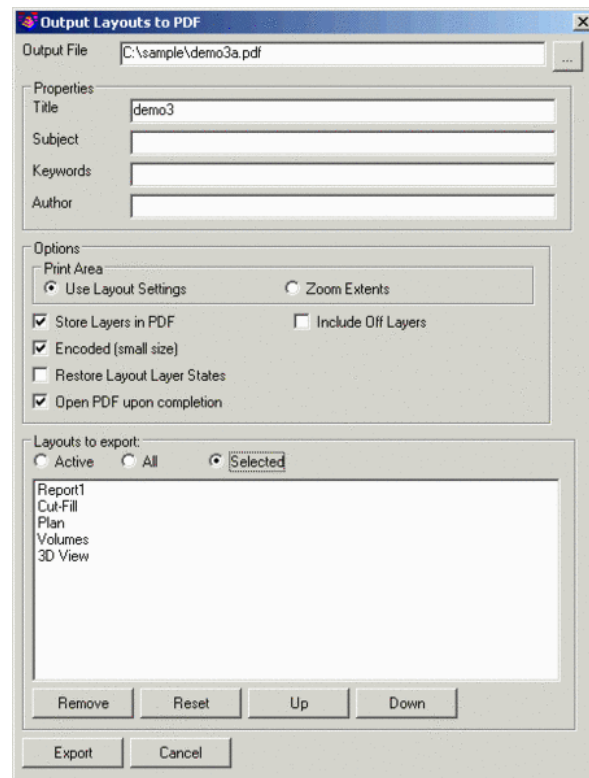

The **Encoded (small size)** option creates a PDF with encoding which should be used unless working with an old Adobe Reader.

Each layout can store the layer state for printing for which layers to thaw and which to freeze. The **Restore Layout Layer States** will set the layer state for the PDF on each layout. This option works together with the Save and Restore Layout Layer commands in the File > PDF menu.

The **Open PDF Upon Completion** option opens the PDF in the viewer for PDFs assigned in Windows which is typically the Adobe Reader.

For **Layouts to Export**, choosing Active will output the current layout to the PDF. The All option outputs all the layouts to the PDF. The Selected option lets you control which layouts to output. When in Selected mode, you can use the Remove button to remove a layout from the output. Use the Up and Down button to change the order of the layouts. The Reset button puts the list of layout back to the default.

Pick the **Export** button to create the PDF.

Pulldown Menu Location: File > PDF

Keyboard Command: pdfexport

Prerequisite: Layouts

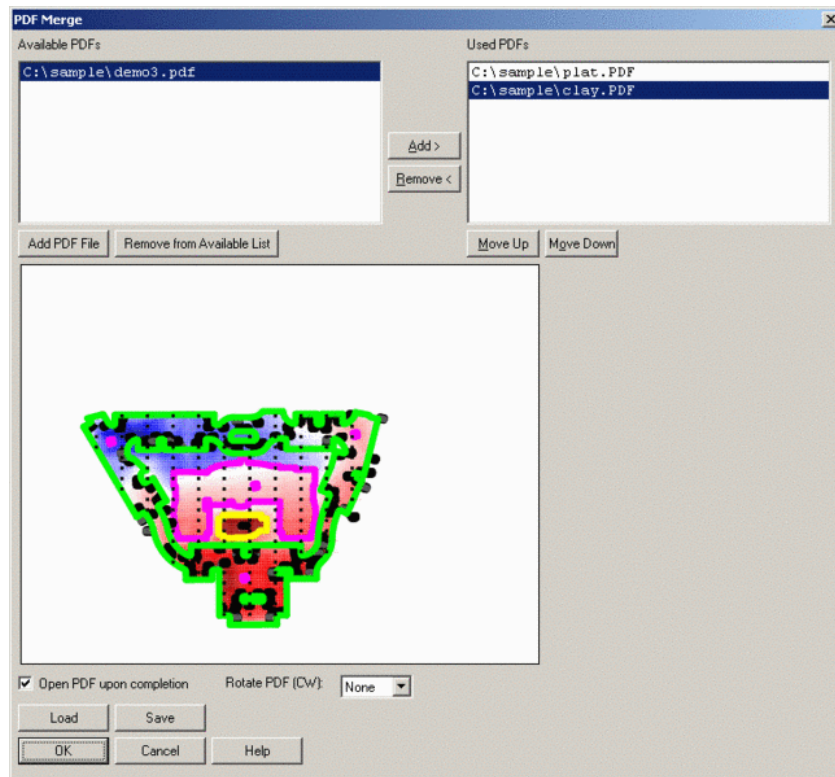

Merge PDF Files

This command combines separate PDF files into a single PDF file. The dialog has a list of available PDF files on the left and there are functions to add or remove PDF files from this list. The list of PDF files on the right and the PDFs to output to the single PDF. Use the Add and Remove buttons to move PDF files between these Available and Used lists. Use the Move Up and Down to change the order of the PDF files for the output PDF. When a PDF is highlighted in the list, a graphic preview is shown.

The Open PDF Upon Completion option opens the PDF in the viewer for PDFs assigned in Windows which is typically the Adobe Reader.

The Rotate PDF CW setting controls how much to rotate the source PDF files for the output PDF.

The Load and Save functions are for storing and recalling a set of PDF files in a .PDQ file.

Pulldown Menu Location: File > PDF

Keyboard Command: pdfmerge

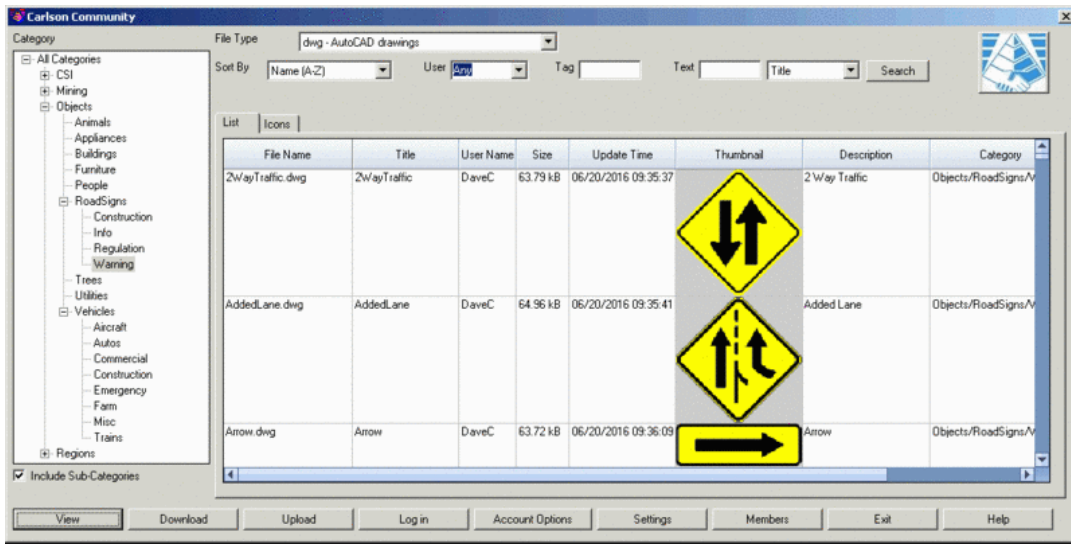

Prerequisite: .pdf files

Carlson Community

This command displays files from Carlson Community where Carlson Software customers can post files to share. This file warehouse is hosted on a Carlson Software server. Types of files on Carlson Community include 3D models for visualization (mdl), point symbol files (dwg), Field-to-Finish code tables for standards in different regions (fld), and road design templates (tpl). To view and download files, you don't need an account log in.

To find a file, first choose the File Type to search for. The files are organized by category and you can browse by category using the category tree on the left. The Include Sub-Categories option shows the files in the current category as well as any sub-categories. The results can be filtered by User, Tag and Text.

There are two views for displaying the file results. The List view shows a spreadsheet. Under the Settings button, you can control the columns to show for the List view. The Icons view shows a series of buttons with images for each file.

To see details about a file, highlight the file and pick the View button, or double-click on the file. The View file dialog shows the file name, title, image, description, tags, category, number of downloads, average rating by users, file size, user name who uploaded the file, date/time of the upload and user comments.

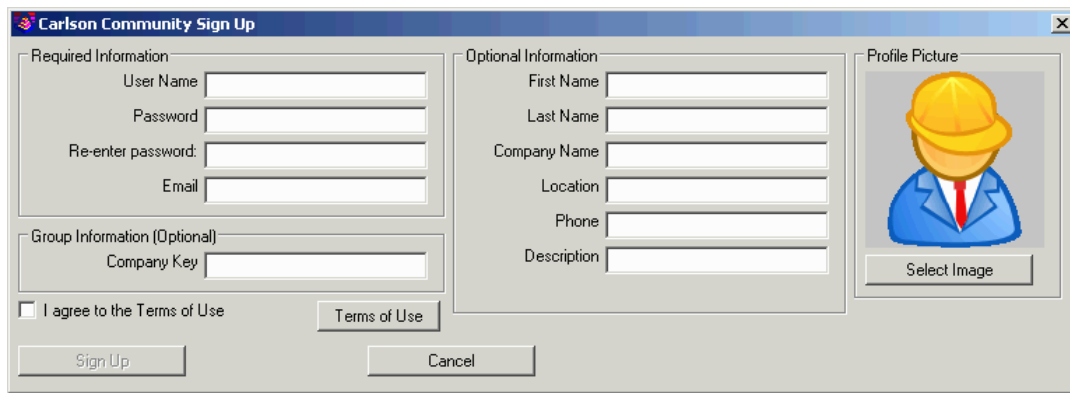

To download the file to your computer, pick the Download button on the View dialog or highlight the file on the main dialog and pick the main dialog Download button. The download routine will then prompt where to save the file on your computer.

To do more on Carlson Community, you need to have an account and log in. To log in, pick the Log In button and then enter either your User Name for Carlson Community or your email and then your password.

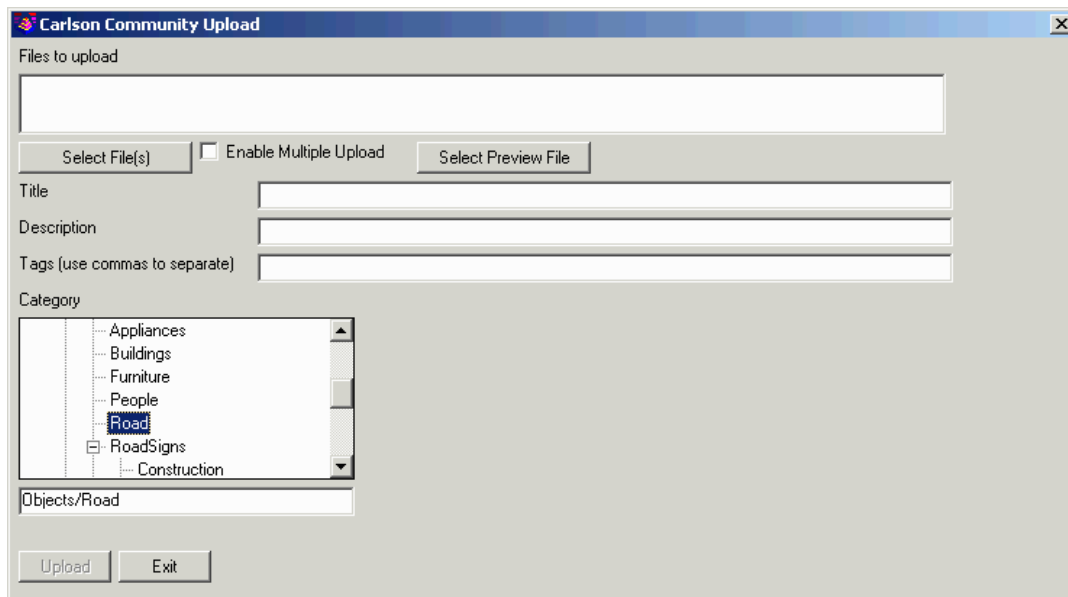

To create a new account, pick the Log In button and then the Account Sign Up button. You need to create a unique User Name for Carlson Community and a password. Your email is also required and needs to be in the Carlson Software records to create a Carlson Community account. If your email is not in the records, then you will receive an email that needs to be confirmed before your Carlson Community account is activated.

Also on the sign up, you must agree to the Terms of Use to create an account. The rest of the information is optional. The Company Key is a way to group users by company which is used by the Carlson Cloud routine for data exchange with SurvCE.

After logging in, you can upload files by picking the Upload button. On the Upload dialog, pick the Select File button and choose the file to upload. Currently the file size limit is 10mb. To upload several files at once, turn on the Enable Multiple Upload toggle before picking Select File. The Select Preview File allows you to pick an image file to use as the preview for your file. Without selecting a preview file, the program will automatically make a preview. The Title, Description and Tags are all optional but helpful ways for users to search for your file. Select a Category for the file from the list or create a new category by entering the category name in the edit box.

Under Account Options, you can update your email, image and other account settings. The List Users shows users by the Company/Group Key name. The Delete Account removes your account from Carlson Community.

The Members routine shows a list of Carlson Community accounts along with activity on uploading.

Files available on Carlson Community include:

MUTCD symbol drawings (dwg): Manual on Uniform Traffic Control Devices from FHWA.

Pulldown Menu Location: File

Keyboard Command: community

Prerequisite: None

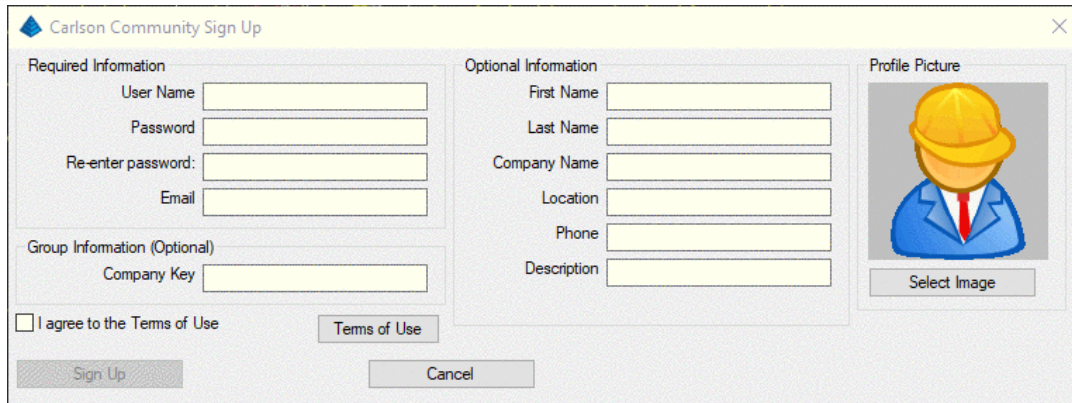

Carlson PhotoCapture

This command is used to download files from Carlson PhotoCapture directly. Found under the CAD engine "File" dropdown, clicking the command opens the Carlson PhotoCapture dialog.

If you do not have an account - these same login credentials are used for Carlson Community, Carlson Cloud, Carlson Academy and Carlson PhotoCapture - Click "Account Sign Up", fill in the information, click "Sign

Up". You will then receive a verification email that you must respond to to activate the account. Should you encounter problems with sign up, contact Carlson Support. If you have forgotten your password, click the "Forgot Password" button to reset it.

The dialog box is titled "Carlson Community Sign Up". It contains three main sections: "Required Information", "Optional Information", and "Profile Picture".

Required Information:

- User Name: [Text Field]
- Password: [Text Field]
- Re-enter password: [Text Field]
- Email: [Text Field]

Optional Information:

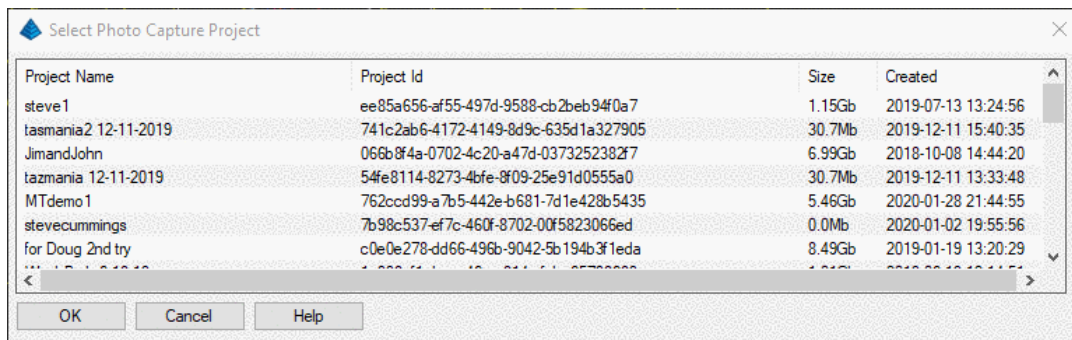

- First Name: [Text Field]
- Last Name: [Text Field]
- Company Name: [Text Field]
- Location: [Text Field]
- Phone: [Text Field]
- Description: [Text Field]

Profile Picture:

- Profile Picture: [Image of a person wearing a yellow hard hat and a blue suit]
- Select Image: [Button]

At the bottom, there is a checkbox for "I agree to the Terms of Use" and a "Terms of Use" button. Below that are "Sign Up" and "Cancel" buttons.

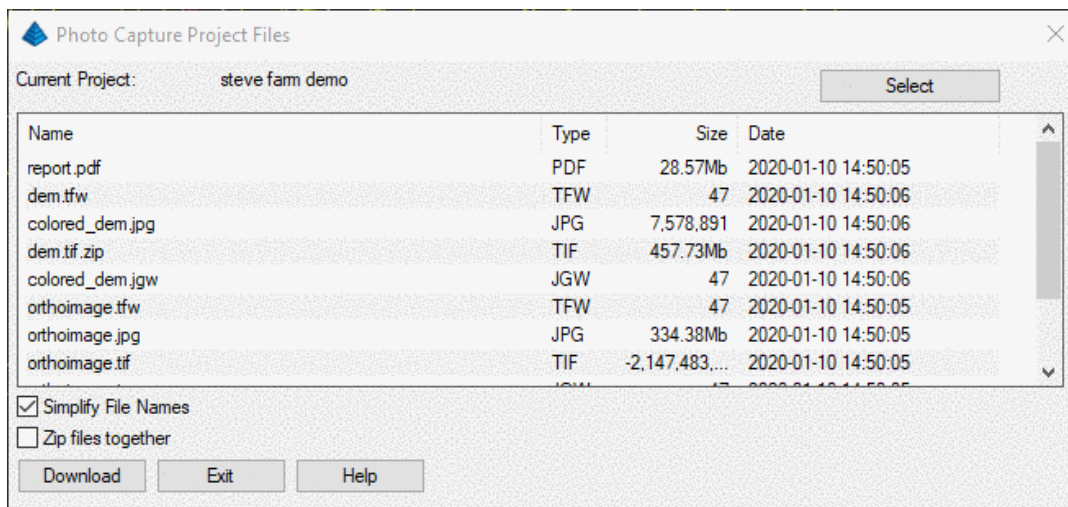

Fill in your User Name and Password, click "Remember Me" checkbox to store this for the next time or not, and click "Login". The following dialog will appear showing all jobs you have processed in Carlson PhotoCapture. Select the job you wish to download and click "OK".

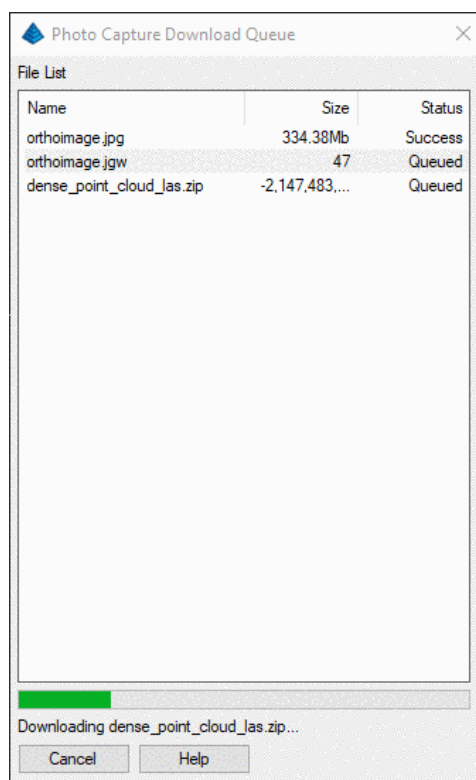

The dialog box is titled "Select Photo Capture Project". It displays a table of project information with columns for Project Name, Project Id, Size, and Created. Below the table are "OK", "Cancel", and "Help" buttons.

Project Name	Project Id	Size	Created
steve1	ee85a656-af55-497d-9588-cb2beb94f0a7	1.15Gb	2019-07-13 13:24:56
tasmania2 12-11-2019	741c2ab6-4172-4149-8d9c-635d1a327905	30.7Mb	2019-12-11 15:40:35
JimandJohn	066b8f4a-0702-4c20-a47d-0373252382f7	6.99Gb	2018-10-08 14:44:20
tazmania 12-11-2019	54fe8114-8273-4bfe-9f09-25e91d0555a0	30.7Mb	2019-12-11 13:33:48
MTdemo1	762ccd99-a7b5-442e-b681-7d1e428b5435	5.46Gb	2020-01-28 21:44:55
stevecummings	7b98c537-ef7c-460f-8702-00f5823066ed	0.0Mb	2020-01-02 19:55:56
for Doug 2nd try	c0e0e278-dd66-496b-9042-5b194b3f1eda	8.49Gb	2019-01-19 13:20:29

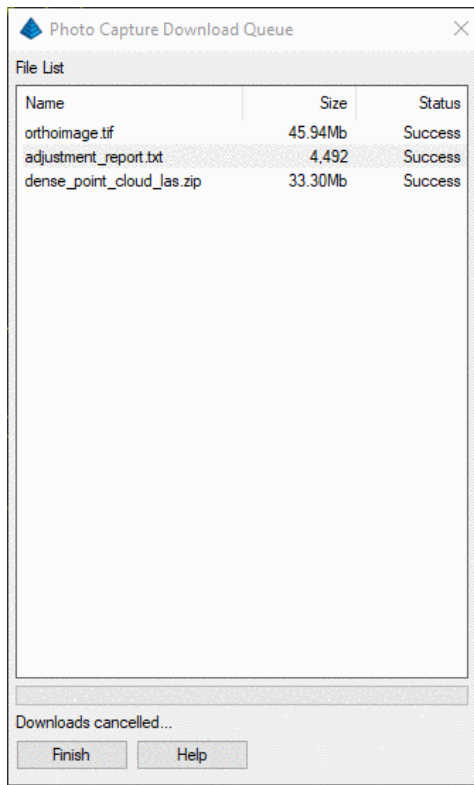

Now the Project Files dialog appears. Click "Select" to return to the Project list. Click the "Simplify File Names" checkbox to make the file names more easily readable. Click "Zip files together" checkbox to download one .zip file instead of multiple files. Using typical Windows Explorer selections tools such as click, ctrl-click, shift-click, select any or all files to be downloaded.

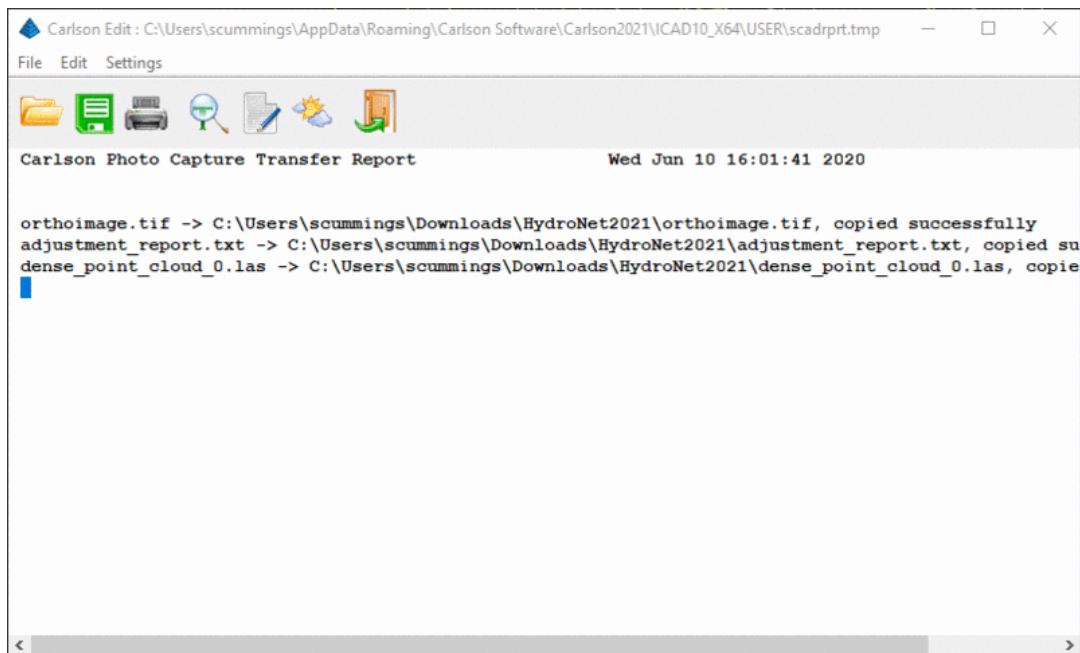

Clicking "Download" begins the download process and the Photo Capture Download Queue dialog appears. You can cancel the download process with the "Cancel" button.

Once the downloads are complete, the "Download" button is replaced by a "Finish" button.

Once the "Finish" button is clicked, a Carlson Photo Capture Download Report is generated. Note that the files are downloaded to the same location where the .DWG file is located. Now the files are available for use. Use the Red X, top right of the report dialog, to close the PhotoCapture interface.

Prerequisites: A Carlson Photo Capture account with at least one project in the account.

Import 3D Viewer File

This command selects a 3DX file and draws the objects from the scene including points, lines and 3D faces. The 3DX file can be created in 3D viewer commands including Surface 3D Flyover and 3D Viewer Drawing.

Pulldown Menu Location: File > Import

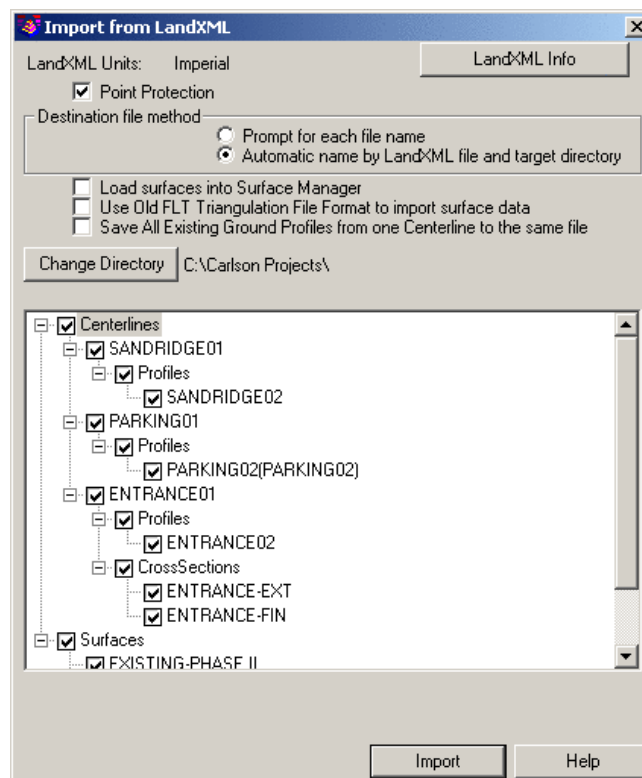

Keyboard Command: import3dx

Prerequisite: 3DX file

Import LandXML File

This command imports project data from the industry standard LandXML file format version 2.0 and earlier. Land development software applications including Carlson Software can exchange project data using LandXML. The project data in LandXML includes survey measurements, coordinates, centerlines, profiles, cross sections, surfaces, lots, plan view linework and pipe networks.

To import a LandXML file, the program first prompts to select a LandXML file to import. Then there is a dialog with import options along with a view of the contents of the LandXML file. You can toggle on which data from the file that you want to import.

LandXML Units: Indicates the Units of Measure associated with the incoming LandXML file (see the Unit Differences item below).

Point Protection: When enabled, you are prompted for a course of action if an existing LandXML file you've selected contains COGO points that have the same number(s) as those that already exist in the drawing. When disabled, existing point data in the project is updated with the values from the LandXML file.

Destination File Method: This option allows you to indicate how the incoming data file(s) are named as they are imported.

Load Surfaces into Surface Manager: When enabled, this option will automatically add surface model (TIN) data into the Surface Manager and graphically represents (draws) the surface model/contours according to the current settings found in the Triangulate & Contour command.

Skip Invisible Triangles: This option skips triangles flagged as invisible when importing a triangulation surface.

Use Old FLT Triangulation File Format to Import Surface Data: When enabled, the older ASCII-based Carlson *.FLT file format will be used in place of the newer and more efficient *.TIN file format.

Save All Existing Ground Profiles from One Centerline to the Same File: When enabled, collections of existing ground profiles associated with a particular centerline are combined into a single *.PRO file.

Draw PlanFeatures to current drawing: When the LandXML contains PlanFeatures, this option will automatically draw this linework. Otherwise, the program stores a .pln file which can be drawn using the File > Import > Polyline File routine.

Save Point Descriptions: For coordinate records, this option controls whether to use the LandXML description or code record for the coordinate file point descriptions.

Add F2F Codes to Points from PlanFeatures: When the LandXML file contains both coordinates and plan features, this option adds Field-to-Finish linework codes to the descriptions of the coordinates. For example, if a plan feature line ends at point 25, then the Field-to-Finish end linework code of END is appended to the description of point 25.

Change Directory: This option allows you to adjust the folder location where the new data files will be written.

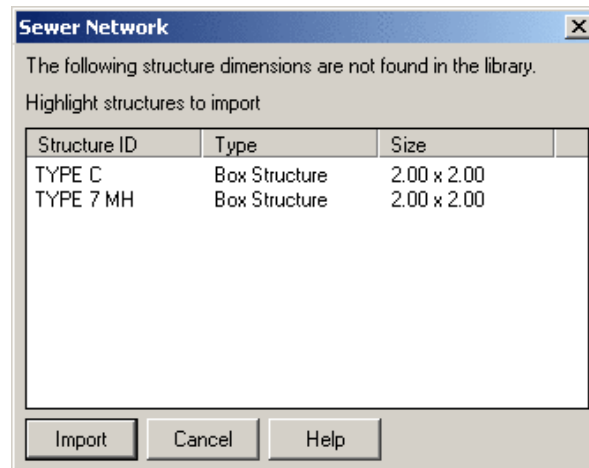

Import from LandXML: Enable or disable various entries that should be used to produce the data files found within the LandXML file.

Unit Differences: If the Units of Measure specified in the LandXML file are different than those found in Drawing Setup, you will be prompted for a course of action.

Manning's "n": If you are importing sewer data from a LandXML file and if the LandXML file does not carry Manning's "n" values, you will be prompted to specify a default Manning's "n" value for all incoming sewer entities that don't already have a Mannings "n" value.

Import Structures: If you are importing sewer data from a LandXML file and structure values specified in the LandXML file do not exist in the Structure Library, you will be prompted to indicate the structure(s) that should be imported into the Structure Library. Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select multiple structures at the same time.

Skip Invisible Triangles: This option applies to importing TIN surfaces from Civil 3D. When this option is active, triangles marked by Civil 3D as invisible or excluded are not imported.

Note:

- The LandXML initiative is being driven by the land development industry as an acceptable means to share and transfer land data rather than the traditional graphical representation of that data. It also provides an effective means for transferring a variety data (points, centerlines, profiles, surface models, sewer data, *etc*). Another advantage of LandXML is that the LandXML data structure is CAD and software vendor neutral (meaning you don't have to own or use the CAD or software product used by your data provider).
- Visit <http://www.landxml.org> for additional information on the uses and acceptance of the LandXML project.

Pulldown Menu Location(s): File > LandXML

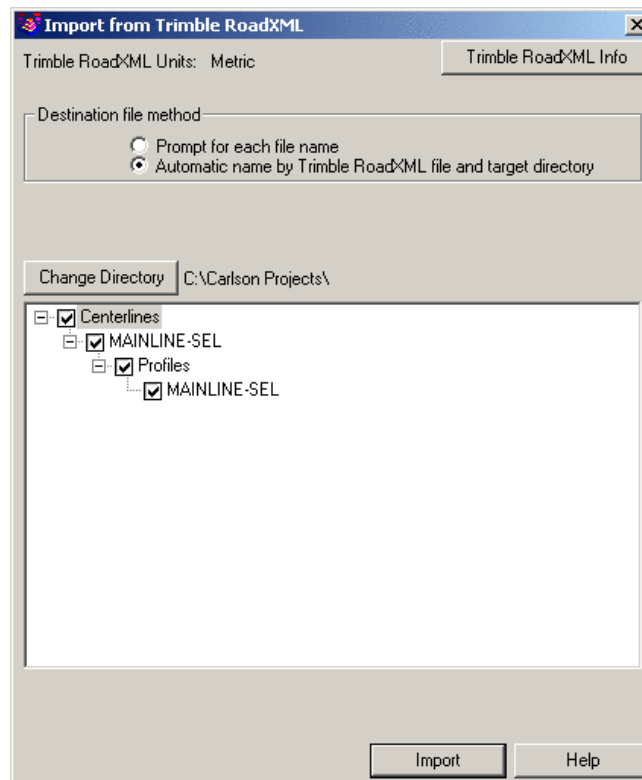

Keyboard Command: landxml_import

Prerequisite: A LandXML file to import

Import RoadXML File

The Import RoadXML File routine provides a mechanism where road-based data from other software applications (including Carlson Software) can be brought into a project and used for analysis and/or design purposes. The program supports centerline and profile data in Trimble style RoadXML format. To import a RoadXML file, a series of dialog boxes are presented:

Select RoadXML File: The standard File Selector dialog box prompts you identify an existing RoadXML (*.RXL) file you wish to import. The following dialog box is then displayed:

RoadXML Units: Indicates the Units of Measure associated with the incoming RoadXML file (see the Unit Differences item below).

Destination File Method: This option allows you to indicate how the incoming data file(s) are named as they are imported.

Change Directory: This option allows you to adjust the folder location where the new data files will be written.

Import from RoadXML: Enable or disable various entries that should be used to produce the data files found within the RoadXML file.

RoadXML Units: RoadXML files are always in metric units. If the current drawing units as set in Drawing Setup are not metric, then you will be prompted whether to apply a scale factor. Note: Visit <http://www.road-xml.org> for additional information on the RoadXML initiative.

Pulldown Menu Location: File > Import

Keyboard Command: roadxml.import

Prerequisite: A RoadXML file to import

Import 12D File

This function imports project data from the 12D modeling program into Carlson format. Linework geometry from the 12D file is drawn as polylines. The routine also draws any text, symbols and points. Project data for centerlines,

profiles, sections, pipe networks and surfaces are saved into Carlson project files.

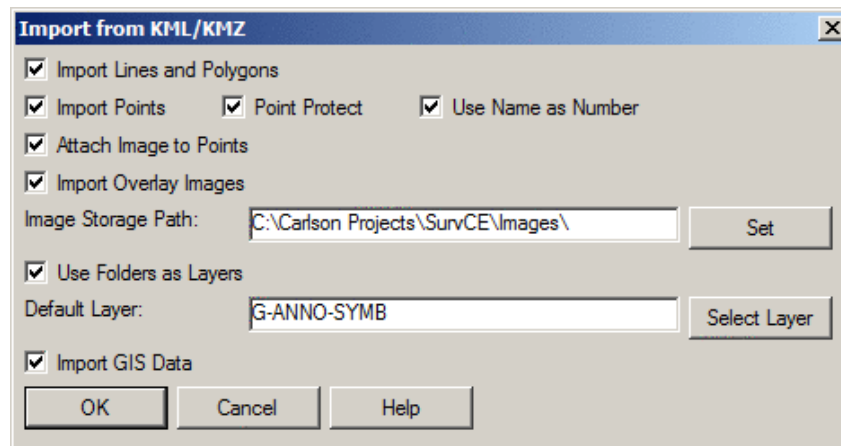

Pulldown Menu Location: File > Import

Keyboard Command: 12d_import

Prerequisite: A 12DA file to import

Import Google Earth File

The Import Google Earth File command allows you to insert a KML (Keyhole Markup Language or alternatively a KMZ) file of points (KML *Placemark*), polylines (KML *Path*) and closed polylines (KML *Polygon*) into your drawing. Throughout this discussion, *KML* will be used to also describe KMZ files unless explicitly noted.

Import Lines and Polygons: When this option is selected, KML Path and Polygon entries will be placed into the drawing as open or closed polylines, respectively.

Import Points: When this option is selected, KML Placemark entries will be placed into the drawing and active coordinate file.

Point Protect: When enabled, existing points in the active coordinate file will not be over-written.

Use Name as Number: When enabled, the names of KML Placemark entries will be utilized as Carlson point numbers.

Attach Image To Points: This option applies to KML files created by Carlson SurvCE when the points are stored together with an image. Use this option to attach the image to the point symbol. The images can be viewed using the Image/Document Inspector command. The image files are extracted from the KML and stored in the **Image Storage Path** folder.

Import Overlay Images: When enabled, any *Overlay Image* placemarks in the KML file will be inserted into the CAD drawing.

Use Folders as Layers: When enabled, KML Folder entries will be used to create layer names in CAD and the supported KML options described above will be placed onto the layer that conforms the the Folder to which they belong.

Default Layer: The supported KML options described above that are not contained in a KML folder will be placed into the specified layer.

Import GIS Data: When enabled, this routine will populate GIS data into the drawing such as that written from the drawing with the Export Google Earth File command.

Note:

- Placemarks, paths or polygon entries that have an altitude value specified will be imported at the proper "Z" elevation in the CAD drawing.
- KML or KMZ files can be specified for the import process.

Prompts

Google Earth File to Read: *Select a previously saved KML or KMZ file.*

- To import a Google Earth image into your drawing, use the Place Google Earth Image command.
- To import a Google Earth terrain data into a Carlson TIN (surface model), use the Place Google Earth Image command.
- To export content from your drawing to a KML file, use the Export Google Earth File command.

Pulldown Menu Location: File > LandXML/RoadXML/Google Earth

Keyboard Command: kmlread

Prerequisite: A KML or KMZ file with Placemark, Path and/or Polygon information, an active coordinate file with an established projection zone through Drawing Setup.

Civil 3D All

This command converts custom AEC objects from Civil 3D into standard CAD entities. The supported objects include points, surfaces, centerlines, pipe networks, feature lines and labels.

Pulldown Menu Location: File > Import

Keyboard Command: c3d_all

Prerequisite: AEC objects

Civil 3D Labels

This command converts custom AEC label objects from Civil 3D into standard CAD text entities.

Pulldown Menu Location: File > Import

Keyboard Command: c3d_text

Prerequisite: AEC label objects

Civil 3D Linework

This command converts custom AEC linework objects such as feature lines from Civil 3D into standard CAD entities.

Pulldown Menu Location: File > Import

Keyboard Command: c3d_lwork

Prerequisite: AEC linework objects

Civil 3D Pipes

This command converts custom AEC pipe and structure objects from Civil 3D pipe networks into standard CAD entities.

Pulldown Menu Location: File > Import

Keyboard Command: c3d_pipe

Prerequisite: AEC pipe objects

Import MxRoad GENIO

This command draws the linework and entities from an MxRoad GENIO file (.inp) into the current drawing. The File > Export > Polyline File command can be used to create an .inp file from the drawing.

Pulldown Menu Location: File > Import

Keyboard Command: genio_read

Prerequisite: None

Import InRoads Settings

The Import InRoads Settings routine provides a mechanism where the InRoads software application settings can be used in Carlson Software. The program currently supports Surface and Profile styles from the InRoads settings file. To import InRoads settings, the following dialog box is presented:

Select InRoads File: The standard File Selector dialog box prompts you to identify an existing InRoads (*.XIN) file you wish to import.

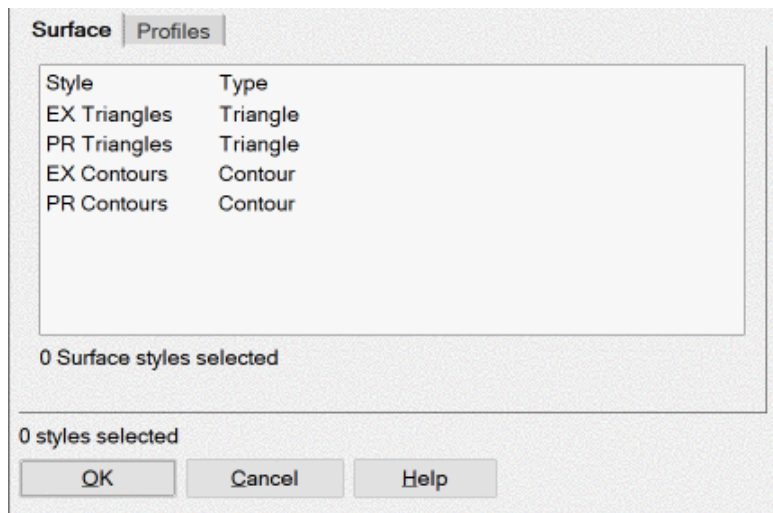

Import File: InRoads settings file to import styles from.

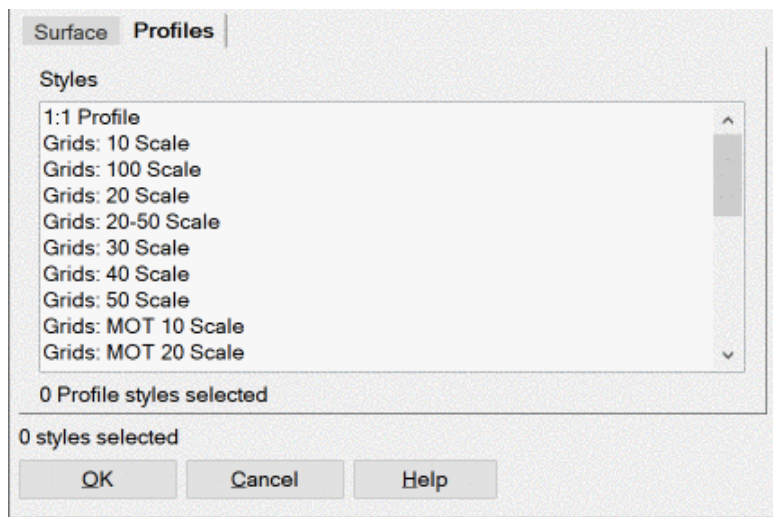

Select: Select a new InRoads settings file.

Output Folder: Output location for setting files to be created.

Select: Select a different output folder location.

Surface Style List: The Triangle and Contour settings display and are multi-selectable. Use the Select and Shift key or Select and Ctrl key for multiple selection of settings.

Profile Style List: The Profile settings display and are multi-selectable. Use the Select and Shift key or Select and Ctrl key for multiple selection of settings.

Each selected style will generate its name .TRI and/or .PFS Carlson setting file in the output folder.

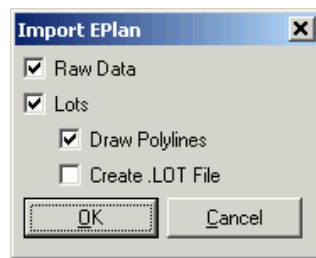

Pulldown Menu Location: File > Import

Keyboard Command: importxin

Prerequisite: An InRoads file to import

Import ePlan File

This command reads an ePlan project file and creates Carlson project files. Point data is stored to a Carlson coordinate file. There is an option to store measurements to a Carlson RW5 file. There is an option to import lot data to a Carlson LOT file and to draw the lots as polylines.

Pulldown Menu Location: File > Import

Keyboard Command: eplan_import

Prerequisite: ePlan XML file

Export LandXML File

The Export LandXML File routine provides a mechanism where data can be sent from Carlson Software into a LandXML file for use in other applications that support the LandXML data specification. LandXML version 2.0 is used which includes the ability to output triangulation surfaces with colors and materials defined for the triangles.

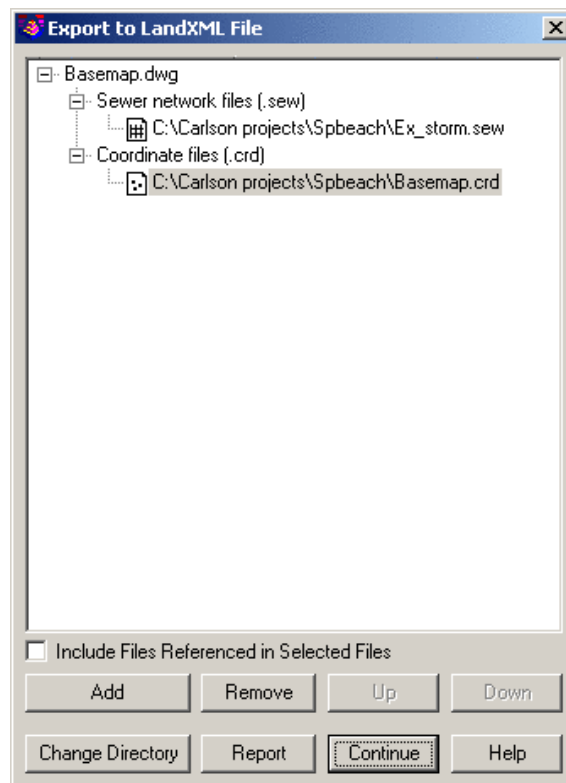

To generate a LandXML file, a series of dialog boxes are presented:

Export to LandXML: This option allows you to individually select the desired Carlson Software data file(s) that should be included in the LandXML file.

Project Data Files: This option allows you to quickly select the various data files associated with, and defined by a Carlson Project (*.prj) file.

Select LandXML File: Specify the name of a LandXML file you wish to create.

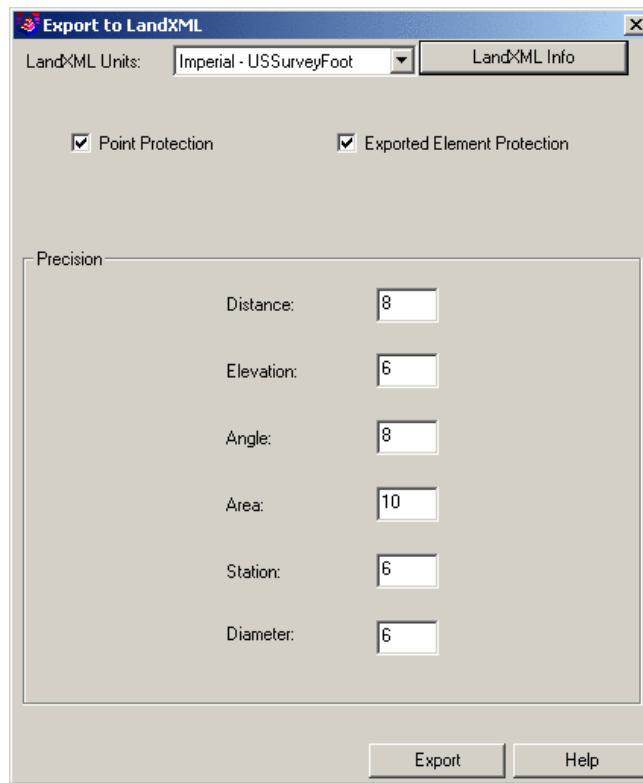

Include Files Referenced in Select Files: When enabled, this option will automatically add other files that are referenced by the selected file. As an example, the file produced by the Carlson Road Network command references TINs, Centerlines, Profiles, *etc.*, and adding the single Road Network file will also add the referenced file(s) into the Export to LandXML File dialog box.

Export to LandXML File: Add, remove (using standard Windows **click**, **shift+click** and/or **ctrl+click** functionality) or otherwise organize the data file(s) that is to be incorporated into the LandXML file.

Change Directory: This option allows you to adjust the folder location from where selected data files should be referenced (often used for project revision purposes).

Report: Create a report (suitable for file transmission or archival purposes) of the file(s) selected to be incorporated into the LandXML file.

LandXML Units: Specify the desired Units of Measure that reflect the outgoing data.

Point Protection: When enabled, you are prompted for a course of action if an existing LandXML file you've selected contains COGO points that have the same number(s) as those being selected for the LandXML file. When disabled, point data you've selected for the LandXML file are automatically written to (or updated into) the existing LandXML file.

Exported Element Protection: When enabled, you are prompted if existing data (such as a centerline) in a LandXML file should be updated with data of the same name that you have selected for the LandXML file.

Precision: Set the desired level of precision (number of decimals) for each of the various measurement categories.

Profiles:

There are two major different types of profiles in LandXML: ProfSurf and ProfAlign. ProfSurf is typically an existing surface that is usually created using existing surface data. The data for this type of profile it is stored in a series of station-elevation values as a representation of a PntList2D list. ProfAlign is for a design profile. The data for this type of profile is stored in LandXML elements starting from the simplest one: PVI element, CircCurve element, ParaCurve element, etc.

Carlson differentiates the two types mentioned above by using the profile type in the Carlson .pro file: Generic = ProSurf, Road = ProAlign.

Note:

- The LandXML initiative is being driven by the land development industry as an acceptable means to share and transfer land data rather than the traditional graphical representation of that data. It also provides an effective means for transferring a variety data (points, centerlines, profiles, surface models, sewer data, *etc*). Another advantage of LandXML is that the LandXML data structure is CAD and software vendor neutral (meaning you don't have to own or use the CAD or software product used by your data provider).

- Visit <http://www.landxml.org> for additional information on the uses and acceptance of the LandXML initiative.

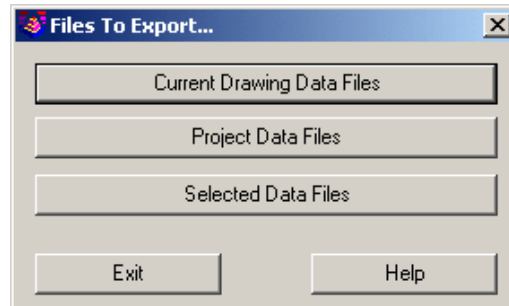

Pulldown Menu Location(s): File > LandXML

Keyboard Command: landxml_export

Prerequisite: Carlson project data files to convert

Export RoadXML File

The Export RoadXML File routine creates a RoadXML RXL file using Carlson format centerline and profile files. This RoadXML file can be used for data exchange with other applications that support the RoadXML data specification such as Trimble. To generate a RoadXML file, a series of dialog boxes are presented:

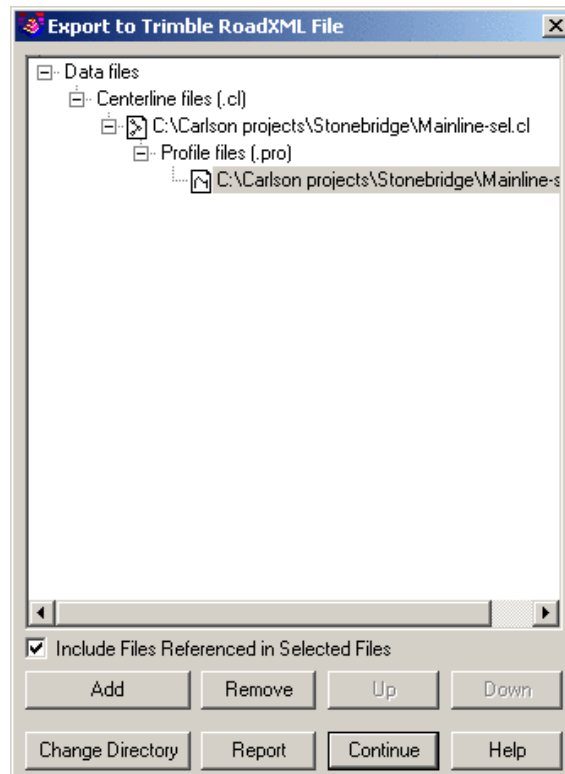

Current Drawing Data Files: This option selects the various data files associated with , and defined by the Drawing Explorer command.

Project Data Files: This option allows you to quickly select the various data files associated with, and defined by a Carlson Project (*.prj) file.

Selected Data Files: This option allows you to individually select the desired Carlson Software data file(s) that should be included in the RoadXML file. This is followed by:

Select RoadXML File: Use the standard File Selector dialog box to specify a new or append to an existing RoadXML file. This is followed by:

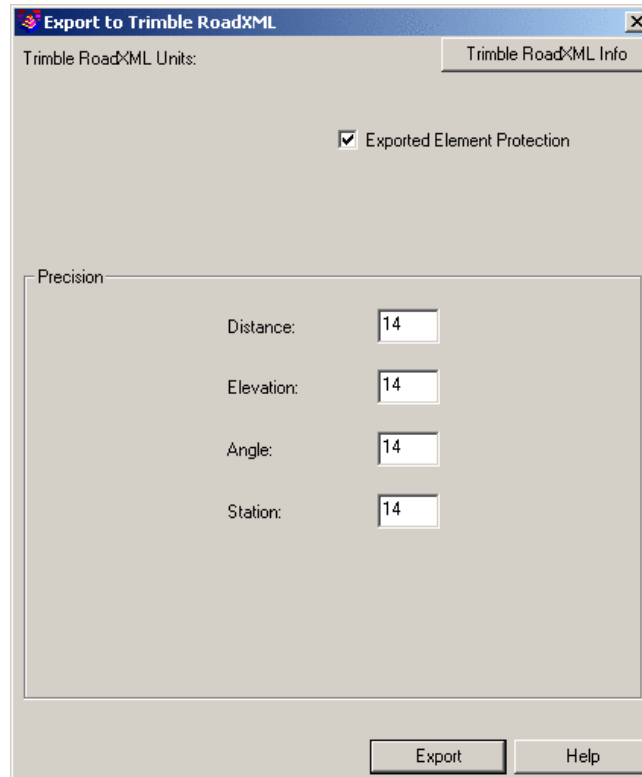

Include Files Referenced in Select Files: When enabled, this option will automatically add other files that are referenced by the selected file. As an example, the file produced by the Carlson Road Network command references TINs, Centerlines, Profiles, *etc.*, and adding the single Road Network file will also add the referenced file(s) into the Export to RoadXML File dialog box.

Export to RoadXML File: Add, remove (using standard Windows **click**, **shift+click** and/or **ctrl+click** functionality) or otherwise organize the data file(s) that is to be incorporated into the RoadXML file.

Change Directory: This option allows you to adjust the folder location from where selected data files should be referenced (often used for project revision purposes).

Report: Create a report (suitable for file transmission or archival purposes) of the file(s) selected to be incorporated into the RoadXML file.

RoadXML Units: The Units of Measure are displayed for the RoadXML file about to be created.

Exported Element Protection: When enabled, you are prompted if existing data (such as a centerline) in a RoadXML file should be updated with data of the same name that you have selected for the RoadXML file.

Precision: Set the desired level of precision for each of the various measurement categories.

Pick the Export button to complete the creation of the RoadXML RXL file.

RoadXML Units: RoadXML files are always in metric units. If the current drawing units as set in Drawing Setup are not metric, then you will be prompted whether to apply a scale factor.

Indicate the desired action of what should occur if the units of the RoadXML do not match those of the current drawing.

Note: Visit <http://www.road-xml.org> for additional information on the RoadXML initiative.

Pulldown Menu Location(s): File > LandXML/RoadXML

Keyboard Command: roadxml.export

Prerequisite: Carlson project data files to convert

Export Polyline File

This command creates a polyline file that contains the point data of the select polylines. The objects supported by this tool include polylines, arcs and lines. If you want to include text, you must use the *Text Explode To Polylines* command found in the Edit menu to convert the text to polylines before running this command. This polyline file is a text file that has three formats. The Carlson format (.PLN) is used by machine control (Carlson Grade, Dozer 2000, GradeStar) for the plan view. Each polyline begins with a line of "POLYLINE, Color number". Then the points for the polyline are listed on separate lines in X,Y,Z format. Here is a list of the available color numbers:

0 = Black	8 = Dark Gray
1 = Blue	9 = Light Blue
2 = Green	10 = Light Green
3 = Cyan	11 = Light Cyan
4 = Red	12 = Light Red
5 = Magenta	13 = Light Magenta
6 = Brown	14 = Yellow
7 = Light Gray	15 = White

The MicroStation format (.txt) can be imported into MicroStation. This format has the coordinates as space delimited for each polyline point. There is an extra column with a 1 or 0 where 1 specifies the start of a new polyline. The DTM and Idan formats create linework files for the DTM and Idan programs.

Prompts

Polyline file format [<Carlson>/DTM/Idan/MicroStation]? *press Enter for Carlson format*

Specify File to Write dialog *create a new file or append to existing*

Polyline file for Grid File Utilities macro [Yes/<No>]? *press Enter* The option will write a polyline file that can be used with Grid File Utilities for inclusion/exclusion perimeters.

Include Z coordinate in polyline file [Yes/<No>]? *press Enter* This option controls whether the polyline vertices are written in 2D or 3D.

Specify Exclusion/Warning Polylines [Yes/<No>]? *press Enter* This option applies to machine control for warning areas.

Specify WorkZone Polylines [Yes/<No>]? *press Enter* This option applies to machine control for working areas.

Reduce Polyline Vertices [<Yes>/No]? *press Enter* This option applies Reduce Polyline to the polyline vertices before writing the file.

Enter reduce offset cutoff <0.1>: *press Enter*

Decimal places for coordinates <2>: *press Enter*

Select polylines, lines and arcs to write.

Select objects: *pick the entities to process*

Done.

Sample Polyline File:

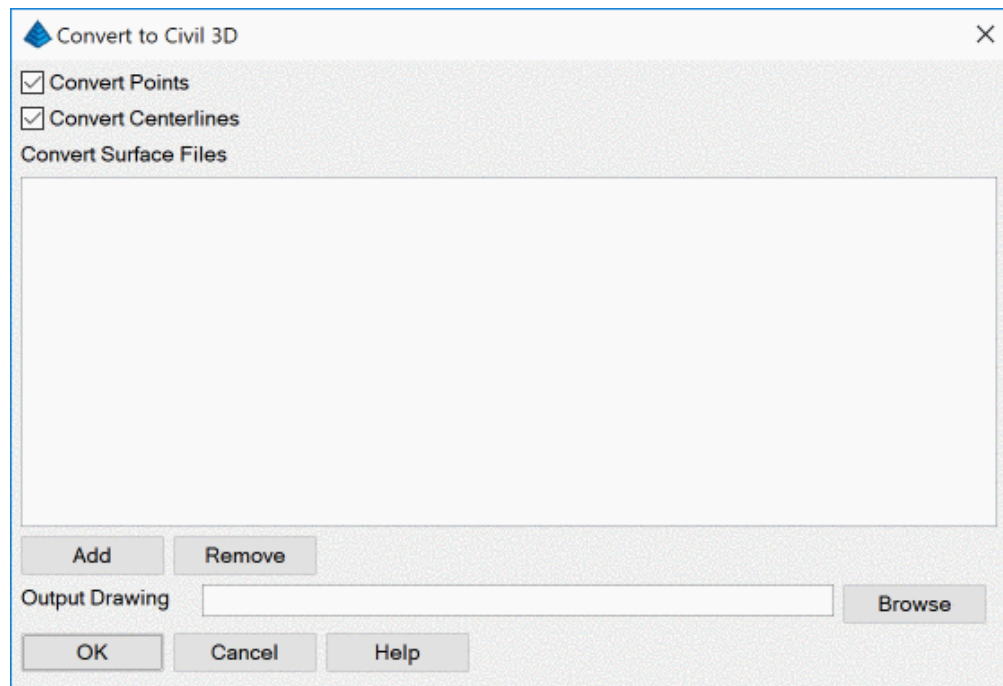

POLYLINE,15
47639.82,74540.11,0.00
47670.49,74565.79,0.00
47701.08,74591.49,0.00
49375.61,76358.47,0.00
50066.86,76846.75,0.00
POLYLINE,15
47633.24,74547.97,0.00
47663.90,74573.65,0.00
etc...

Keyboard Command: polywrite

Prerequisite: Polylines in the drawing

Export Civil 3D Drawing

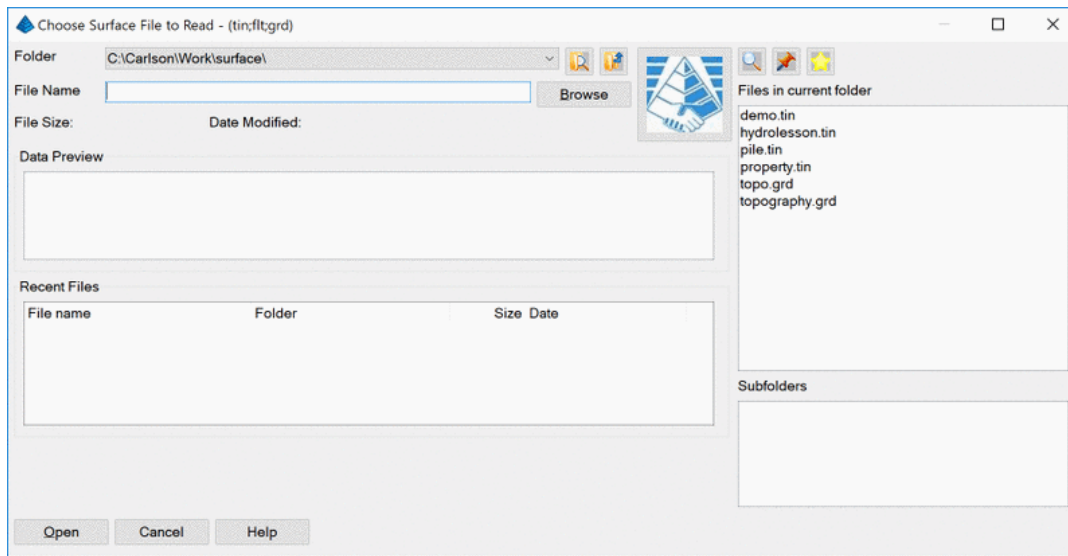

This command saves the current drawing to a dwg file and converts the optional Carlson points, Carlson centerlines and selected Carlson TIN files into Civil 3D objects.

Convert Points: When enabled, the Carlson points in the drawing will be converted into Civil 3D point objects.

Convert Centerlines: When enabled, the Carlson centerlines in the drawing will be converted into Civil 3D alignment objects.

Clicking the **Add** button yields the Choose Surface File to Read dialog box.

Clicking the **Remove** button removes the selected surface file from the list of Surface Files to convert.

Output Drawing *select a .DWG file to create Civil 3D objects within.*

Pulldown Menu Location: File > Export

Keyboard Command: convert_c3d

Prerequisite: None

Export Civil 3D Alignments

This command saves the current drawing to a dwg file and converts the Carlson centerlines into Civil 3D alignment objects.

Pulldown Menu Location: File > Export

Keyboard Command: cl_c3d

Prerequisite: None

Export Civil 3D Points

This command saves the current drawing to a dwg file and converts the Carlson points into Civil 3D point objects.

Pulldown Menu Location: File > Export

Keyboard Command: crd_c3d

Prerequisite: None

Export Civil 3D Surface

This command saves the selected TIN file to a dwg file and converts the Carlson TIN into Civil 3D surface object.

Pulldown Menu Location: File > Export

Keyboard Command: tin_c3d

Prerequisite: None

Export 12D File

This command creates a 12DA project file for the 12D modeling program. You can export drawing entities and Carlson project files. For the drawing entities, the program supports linework, text and point entities. For Carlson project files, the export handles triangulation surfaces (TIN), centerlines (CL), pipe networks (SEW), profiles (PRO) and cross sections (SCT).

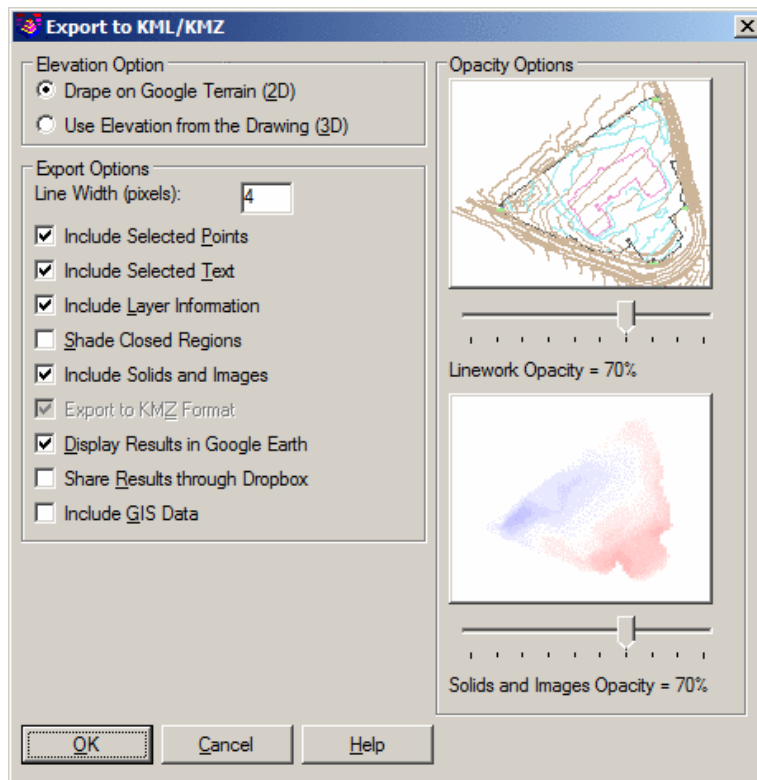

Pulldown Menu Location: File > Export

Keyboard Command: 12d_export

Prerequisite: None

Export Google Earth File

The Export Google Earth File allows you to produce a KML (Keyhole Markup Language or alternatively a KMZ) file of points, polylines, text, solids, images, lines and arcs for rendering in other mapping and GIS applications such as Google Earth and Google Maps. Throughout this discussion, *KML* will be used to also describe KMZ files unless explicitly noted.

Drape on Google Terrain (2D): When this option is selected, entities written to the KML file will have an Altitude setting of "Clamped to ground."

Use Elevation from the Drawing (3D): When this option is selected, entities written to the KML file will have an Altitude setting of "Absolute."

Line Width (pixels): Indicate how wide selected linework should be when viewed in Google Earth. The higher the value, the thicker the line.

Include Selected Points: When enabled, this option exports selected Carlson point information to the KML <Placemark><Point>...</Point></Placemark> tag structure. For the Google placemark, the **Placemark Name** chooses between using the point number, elevation or description.

Include Selected Text: When enabled, this option exports selected Text and MText entities to the KML <Placemark><Point>...</Point></Placemark> tag structure.

Include Layer Information: When enabled, this option organizes exported information based on the layer of each entity, with each CAD layer becoming a KML <Folder>...</Folder> entry with the color of the group taking the general color of the CAD layer.

Shade Closed Regions: When enabled, all closed polyline regions (*e.g.* building pads, ponds, *etc*) will be fill-shaded.

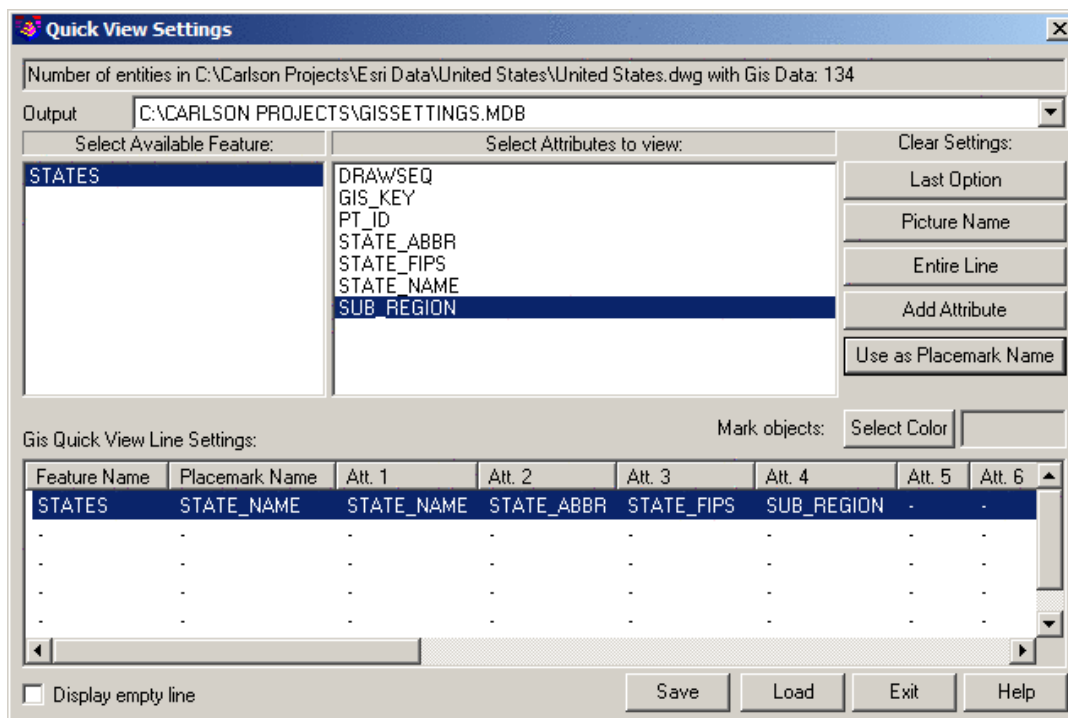

Include Solids and Images: When enabled, Solid entities and Images are included in the KML as <Placemark><Polygon>...</Polygon></Placemark> and/or <GroundOverlay>...</GroundOverlay> tags, respectively.

Export to KMZ Format: When enabled, the KML file is written to the more compact (zipped) KMZ version of the standard KML file format.

Display Results in Google Earth: When enabled, the results of the KML are passed to and automatically opened with Google Earth. To setup for running Google Earth Pro, go to Windows Start > Default Programs > Associate File Type With Program and assign KML and KMZ file types to Google Earth Pro.

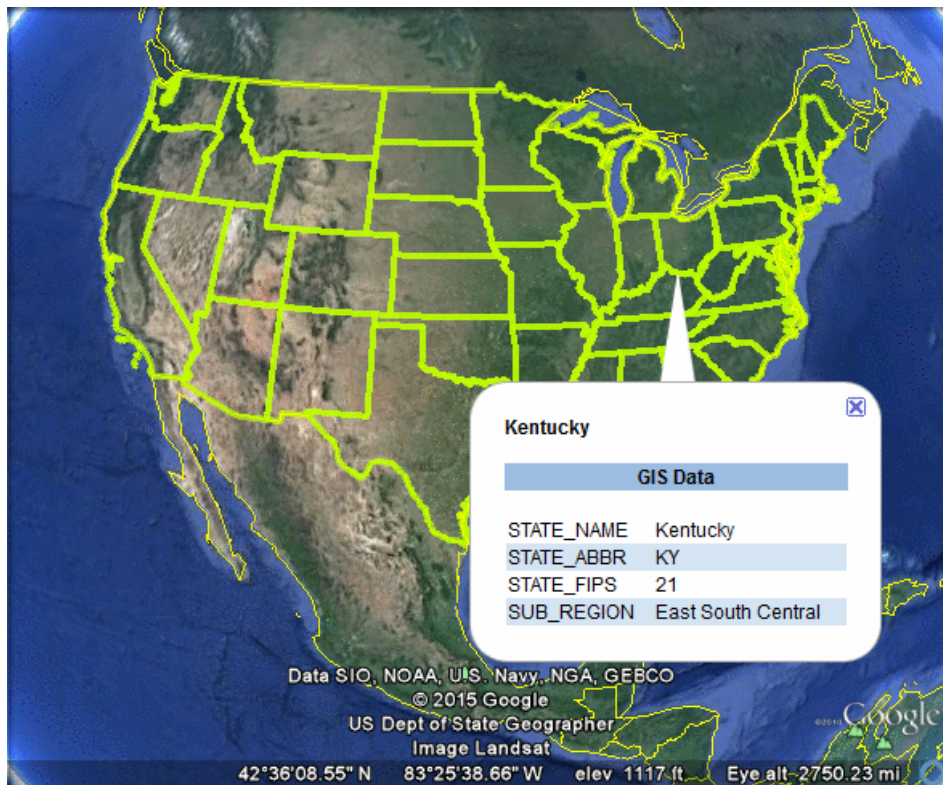

Share Results through Dropbox: When enabled, the results of the KML are passed to a personal DropBox account.

Include GIS Data: When enabled, GIS attribute data associated with selected entities will be populated into the KML file. GIS attribute data can be imported via the Import SHP File command (see the Sample Esri Data note below) or manually assigned with the GIS Data Editor command or the Set Google Tags command. Upon specifying the KML file to output, the **Quick View Settings** dialog box of the GIS Inspector command may display:

1. Select a desired GIS Feature from the upper-left of the dialog box.
2. Add the desired Attributes to the display list using a double-click action or clicking the **Add Attribute** button.
3. Indicate a desired Attribute to serve as the *Placemark Name* and use the **Use as Placemark Name** button to set it.

Upon exiting from the dialog box, available GIS Data on a per-entity basis will be populated into the KML file:

Linework Opacity: Use the horizontal slider control to indicate the desired level of opacity that should be applied to linework entities. A lower opacity results in increased entity transparency and is helpful for viewing underlying map data found in applications such as Google Earth.

Solids and Images Opacity: Use the horizontal slider control to indicate the desired level of opacity that should be applied to Solids and Image entities. A lower opacity results in increased entity transparency and is helpful for viewing underlying map data found in applications such as Google Earth.

Note:

- When the *Use Elevations from the Drawing (3D)* option is selected, be aware that elevation values lower than the Google Earth terrain may be obstructed in the Google Earth display.
- Attribute information (*e.g.* Number, Elevation, Description) of selected Carlson points are also written to the KML and will display in the "balloon" when a point is picked in the Google Earth display or data hierarchy.
- The formatting of any selected MText entities is not propagated into the KML/KMZ file.
- When the *Shade Closed Regions* toggle is enabled, note that **all** closed polyline regions will become fill shaded and may lead to undesired results for items such as closed contours.
- When *Image* entities are included, the size of the image itself is incorporated into the KMZ file and may significantly swell the size of the KMZ file which may result in lengthy load times into other applications.
- To have results posted to Dropbox, the Dropbox Application for Windows must be first installed to your PC using its default folder specification for the location of shared/synchronized folders/files.
- When prompted for the name of the KML/KMZ file to write, the appropriate KML or KMZ file extension based on the *Export to KMZ Format* toggle will be added to the file if the file extension is not specified.
- Arcs and polylines with arcs are converted into chord segments that closely approximate the arc(s).
- Other entities not supported for direct export to a KML file (*e.g.* circles, ellipses, splines, multilines, *etc.*), can be first turned into polylines with the Entities to Polylines command.
- Sample Esri data of the United States in Shape File form can be freely downloaded and explored.
- The graphical symbology of any/all items sent to the KML file can be manually modified via the Google Earth interface.
- When sending closed polylines to Google Earth, they will be sent as closed polygons.

Prompts

Select points, polylines, text, solids, images, lines and arcs to write.

FILter/⟨Select entities⟩: *Select the desired entities and press Enter when complete.*

- To import a Google Earth image into your drawing, use the Place Google Earth Image command.
- To import a Google Earth terrain data into a Carlson TIN (surface model), use the Place Google Earth Image command.
- To import KML content into your drawing, use the Import Google Earth File command.

Pulldown Menu Location(s): File > Export

Keyboard Command: kmlwrite

Prerequisite: Points, lines or polylines in the drawing with an established projection zone through Drawing Setup.

Export ePlan File

This command creates an ePlan project file from Carlson lot and coordinate files. The program prompts for the Carlson .LOT and coordinate files to read and then the ePlan .XML file to create.

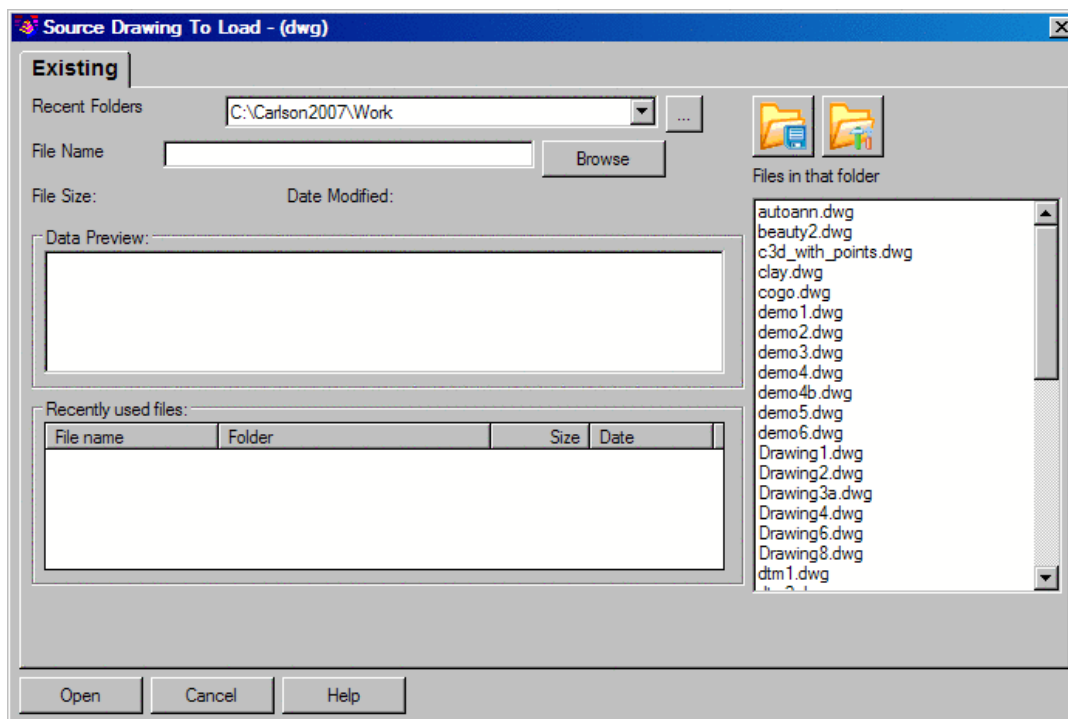

Pulldown Menu Location: File > Export

Keyboard Command: eplan_export

Prerequisite: Carlson lot and coordinate files

Export Drawing to AutoCAD 14

This command will save an existing Carlson drawing to AutoCAD R14 format. This command is for Carlson in AutoCAD 2004 and Carlson working in AutoCAD 2005.

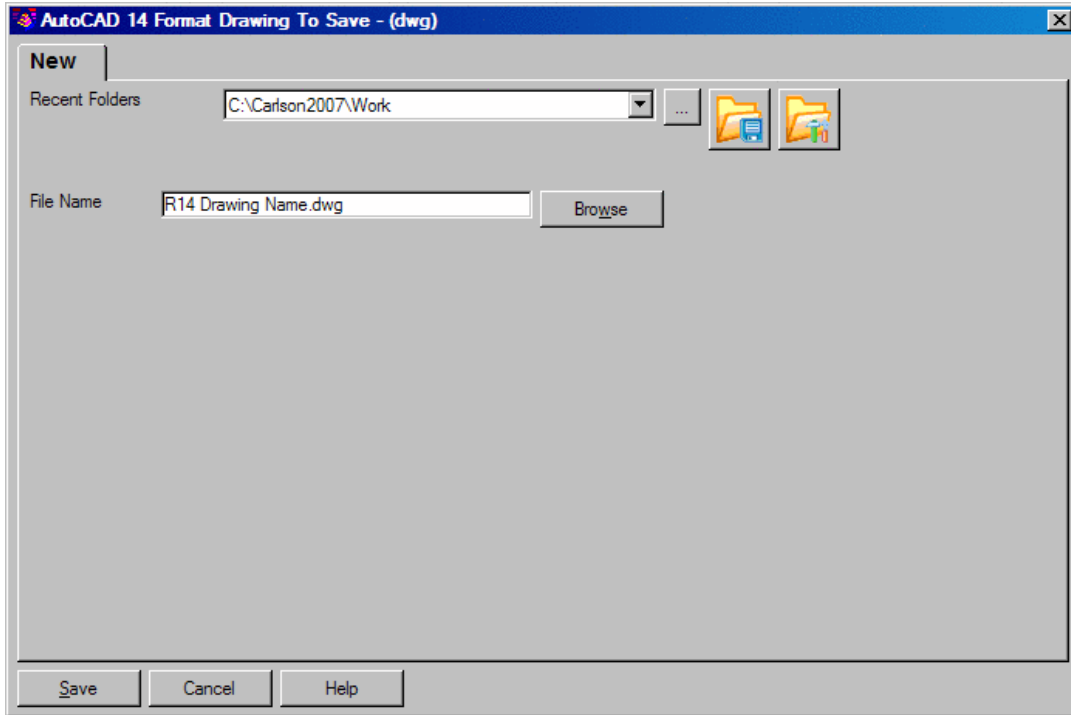

Prompts

Source Drawing To Load dialog *select a .DWG file*

AutoCAD R14 Format Drawing To Save dialog *select name for a new .DWG file*

Files saves to R14.

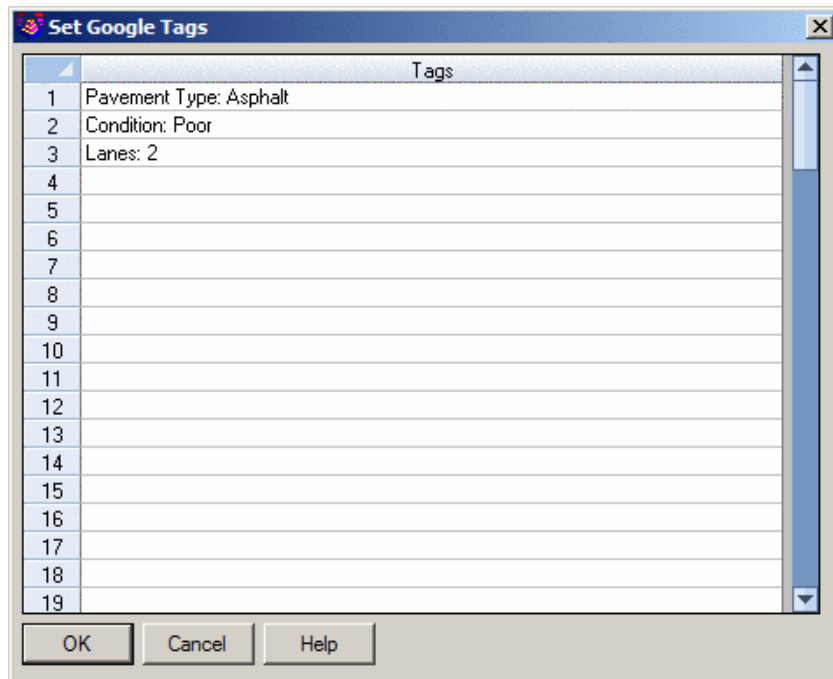

Pulldown Menu Location: File

Keyboard Command: dwg2r14

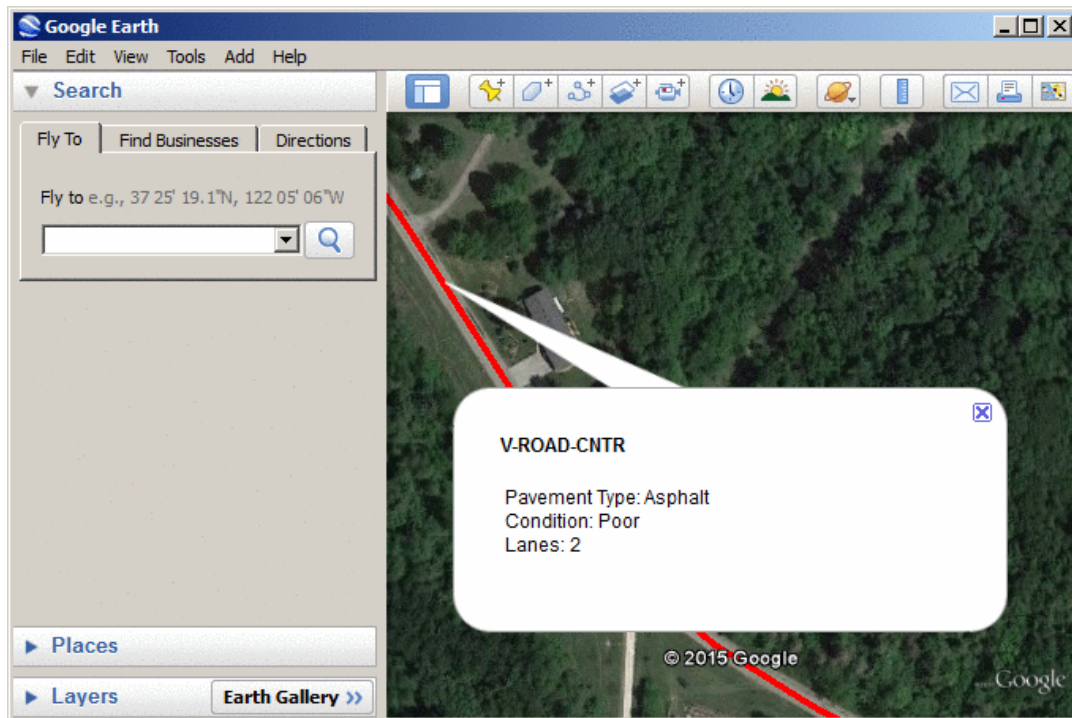

Prerequisite: An existing Carlson .DWG file, using Carlson in AutoCAD 2004 or Carlson in AutoCAD 2005

Set Google Tags

This command adds labels to drawing entities that are shown as "balloon" labels in Google Earth when the Include GIS Data option of the Export Google Earth File command is enabled.

After selecting the entity to tag, the dialog box above displays that permits various forms of tag data to be associated with the entity. An example result is shown below for reference purposes (the first "tag" being the layer upon which the entity resides):

Prompts

Select entity: *Select a point, symbol, text or linework*

Pulldown Menu Location: File > Export

Keyboard Command: tagkml

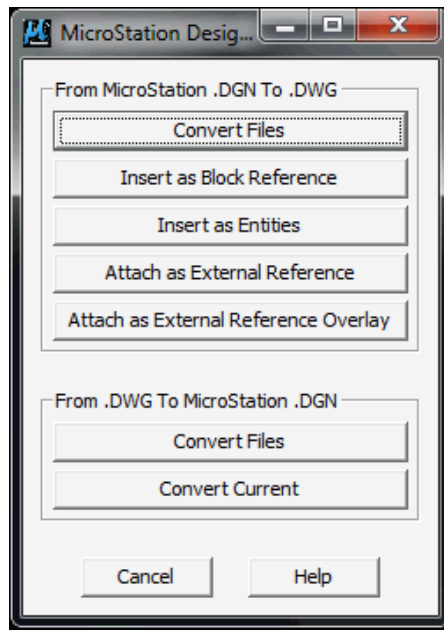

Prerequisite: Entities to attach tags

Microstation DGN

This command converts drawing files between .DWG and .DGN file formats. This command is only available when running on IntelliCAD. When running on AutoCAD, the AutoCAD Import and Export commands can be used to convert .DGN files.

When converting DGN files to DWG file format, there are several processing methods. In all cases, multiple files can be selected and processed at a time. The Convert Files method creates DWG files from the selected DGN files. The DWG files automatically have the same file name as the source DGN files except with the different file extension of .DWG. The Insert as Block Reference method inserts the selected DGN files into the current drawing as blocks. The Insert as Entities method imports the entities from the DGN files into the current drawing. The Attach as External Reference brings the selected DGN files into the current drawing as Xrefs. The Overlay option for Attach as External Reference is the same except that this method is not nested.

For converting DWG files to DGN format, the Convert Files method creates DGN files from the selected DWG files. The Convert Current exports the current drawing. In both cases, the DGN files are automatically named after the source DWG files except with the different file extension of .DGN.

Pulldown Menu Location: File

Keyboard Command: dgnio

Prerequisite: A DWG or DGN to convert

Write Polyline File

This command creates a polyline file that contains the point data of the select polylines. The objects supported by this tool include polylines, arcs and lines. If you want to include text, you must use the Text Explode To Polyline command found in the Edit menu to convert the text to polylines before running this command. Several different output formats are supported.

The Carlson format (.PLN) is a text file format that is used by some Carlson commands and by machine control (Carlson Grade, Dozer 2000, GradeStar) for the plan view. Each polyline begins with a line of "POLYLINE, Color number, etc". Then the points for the polyline are listed on separate lines in X,Y,Z format.

The DTM and Idan formats create linework files for the DTM and Idan programs.

The KOF method creates a .KOF format file.

The MicroStation format (.txt) can be imported into MicroStation. This format has the coordinates as space delimited for each polyline point. There is an extra column with a 1 or 0 where 1 specifies the start of a new polyline.

The Moss format creates a INP file for the MXROAD/MOSS Genio program.

The Peabody format is a company specific format for Peabody Energy.

The Topcon format creates a Topcon LN3 file.

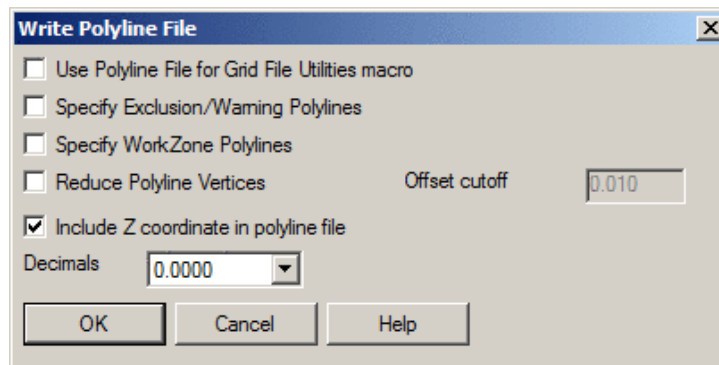

Note:

- The former **Google** (KML) output option has been moved to the dedicated Export Google Earth File command.

Prompts

Polyline file format [<Carlson>/DTM/Idan/MicroStation/MOSS/Peabody/Topcon]? Specify the desired output option by specifying the CAPITALIZED option or press Enter for the <default> option.

Polyline File to Write dialog: Create a new file or Append to Existing. If the **Carlson** option was selected, the following dialog then appears:

Use Polyline File for Grid File Utilities macro: When enabled, the option will write a polyline file that can be used with Grid File Utilities for inclusion/exclusion perimeters.

Specify Exclusion/Warning Polylines: When enabled, this option applies to machine control for warning areas.

Specify WorkZone Polylines: When enabled, this option applies to machine control for working areas.

Reduce Polyline Vertices: When enabled, this option applies the Reduce Polyline Vertices to the polyline vertices before writing the file..

Offset Cutoff: Indicate the allowable offset distance (essentially the *middle ordinate distance* of a 3-point arc) that would allow the middle vertex between two other vertex locations to be removed.

Include Z coordinate in polyline file: When enabled, this option controls whether the elevation(s) (or "Z" value) of the selected polyline vertices are written to the polyline file.

Decimals: Indicate the desired amount of precision for the coordinate values that should be written to the file.

Select polylines, lines and arcs to write.

FILter/<Select entities>: *Pick the entities to process press Enter when complete.*

Sample Polyline File:

```
POLYLINE, 51, 0, 0.0, CONT|V-STRM-PIPE  
5375168.9320, 3932304.7050, 0.0000  
5375193.3310, 3932211.6150, 0.0000  
POLYLINE, 150, 0, 0.0, CONT|V-BRKL  
5375026.8800, 3932090.0480, 962.8334  
5375062.3960, 3932105.7540, 961.5399  
5375075.5640, 3932115.7940, 961.1595  
5375079.0150, 3932128.0920, 961.1532  
5375081.6860, 3932159.7840, 961.6147  
5375086.6920, 3932195.6480, 962.6206  
etc.
```

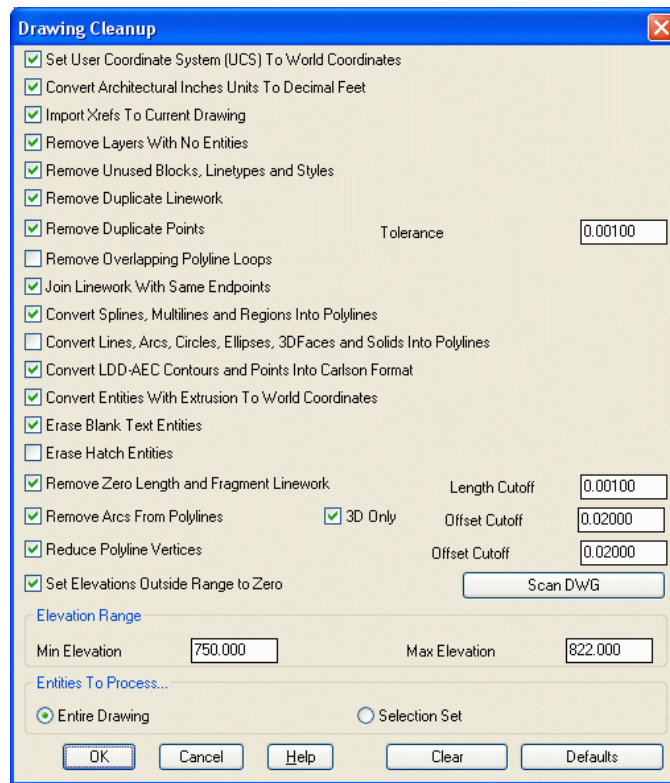

Pulldown Menu Location: File > Export

Keyboard Command: polywrite

Prerequisite: Polylines in the drawing

Drawing Cleanup

The Drawing Cleanup dialog box allows you to perform many functions that fix common errors, and it removes unnecessary data found in many drawing files. It also converts incompatible data into useful entities. This command offers many filters that audit the drawing file and allows you to select which options and settings you want to use. A report of the cleanup results will be displayed upon completion. Always save your file when the drawing cleanup routine is complete.

Set UCS to World Coordinates

This sets the UCS (user coordinate system) to the world coordinate system (WCS). Carlson works exclusively in the world coordinate system and there is no way to change this setting. In CAD, it is possible to change the coordinate system from WCS. If you receive a drawing in which the coordinate system is not set to world, click this on to restore the UCS.

Convert Architectural Inches Units To Decimal Feet

Drawings are sometimes in architectural units, i.e. inches, when the unit of measurement was intended to be in feet. This routine will change the units from inches into feet and then scale the drawing by 1/12.

Import Xrefs To Current Drawing

This routine allows you to import any 'found' external reference files (Xrefs) into the current drawing. If the path is not found, the Xref file will not be brought into the drawing. To set the Path for any unfound Xrefs, run Import Xref to Current Drawing under File.

Remove Layers With No Entities

Drawings work with a "BYLAYER" concept meaning that layer definitions define the drawing. For example, the layer named EOP might be used to display polylines at the Edge Of Pavement in the drawing. Many times extra layers get defined by a user but not used to display any objects. This function removes any layers defined in the drawing that are not being used.

Rename Layers With Wildcards

Layers with wildcard characters such as "*" can interfere with Carlson layer matching functions. This routine renames layers by replacing any wildcard characters with an underscore "_".

Remove Unused Blocks, Linetypes and Styles

This functions removes this unused information from the drawing.

Remove Unused Registered Apps

This function removes Registered Applications that are defined in the drawing but not referenced by any entities.

Remove Zero Length Linework

This function seeks out and removes any linework definition that have zero length. Point nodes are not removed.

Remove Duplicate Linework

This function finds any duplicate linework in the drawing and removes all but one set. The Tolerance setting controls how close the linework vertices must match.

Remove Duplicate Text

This function finds any duplicate text in the drawing and removes all but one set.

Remove Duplicate Points

This function searches the drawing (but not the .CRD file) for points with the same northing, easting and elevation. The tolerances for considering points to have the same coordinate are set to the right. To be counted the same coordinate, both the northing/easting and elevation must be within the tolerance distance.

Remove Overlapping Polyline Loops

Polylines that completely overlap themselves are broken into two different polylines.

Join Linework With Same Endpoint

This function finds common endpoints on linework on common layers with common elevations and joins the linework into a continuous polylines. This is very helpful for future selection sets.

Convert Splines, Multilines and Regions Into Polylines

Some CAD applications utilize Spline Object Definitions and Regions, Carlson utilizes basic polyline/polygon definitions. This function finds any Splines and/or Regions defined in the drawing and re-defines them as simple polylines or polygons.

Convert Lines, Arcs, Circles, Ellipses, 3DFaces and Solids Into Polylines

By converting Lines, Arcs, Circles, Ellipses, 3D Faces, and Solids into Polylines, you can use the variety of Polyline commands available in Carlson.

Convert LDD-AEC Contours and Points Into Carlson Format

Drawings created in the Land Development Desktop CAD program can contain special objects known as LDD-AEC contours that define their topographic contour display. This function locates those special objects and re-defines them as simple 2D polylines retaining their elevation values.

Convert Entities With Extrusion To World Coordinates

This function removes extrusion assigned to entities and puts the entities coordinates into true world coordinates.

Erase Blank Text Entities

This function removes any text boxes defined in the drawing that are not being used.

Erase Hatch Entities

Carlson offers many hatch display options, however hatch entities have no 3D value. This function removes all hatch entities in the original drawing to help reduce the size and clutter of the drawing file.

Remove Arcs From Polylines - Offset Cutoff

This function replaces arcs in polylines with a series of short chord segments. The purpose is to prepare the polylines for modeling since arcs need to be converted into segments to be part of the triangulation model. The density of chord segments is controlled by the offset cutoff. This cutoff represents how much the polyline can move horizontally. A smaller cutoff will result in more chord segments. The option for 3D Only controls whether only polylines at zero elevation or both zero and elevated polylines get processed. Sometimes you may want to leave the arcs in zero elevation polylines when these polylines represent road alignments and are not part of the surface model.

Reduce Polyline Vertices - Offset Cutoff

This function utilizes a pre determined offset amount and removes unnecessary polyline vertices that fall within the

offset amount.

Set Negative Polyline Thickness to Zero

This function sets the thickness property of polylines to zero for polylines with negative thickness.

Set Elevations Outside Range to Zero and Elevation Range

This function comes with a "Scan DWG" option that audits the elevation range in the drawing file. Once the minimum and maximum elevation range has been set, manually or by a scan, all objects that fall outside the set range are moved to elevation zero. All objects at zero elevation do not contribute to the 3D model.

Entities To Process...

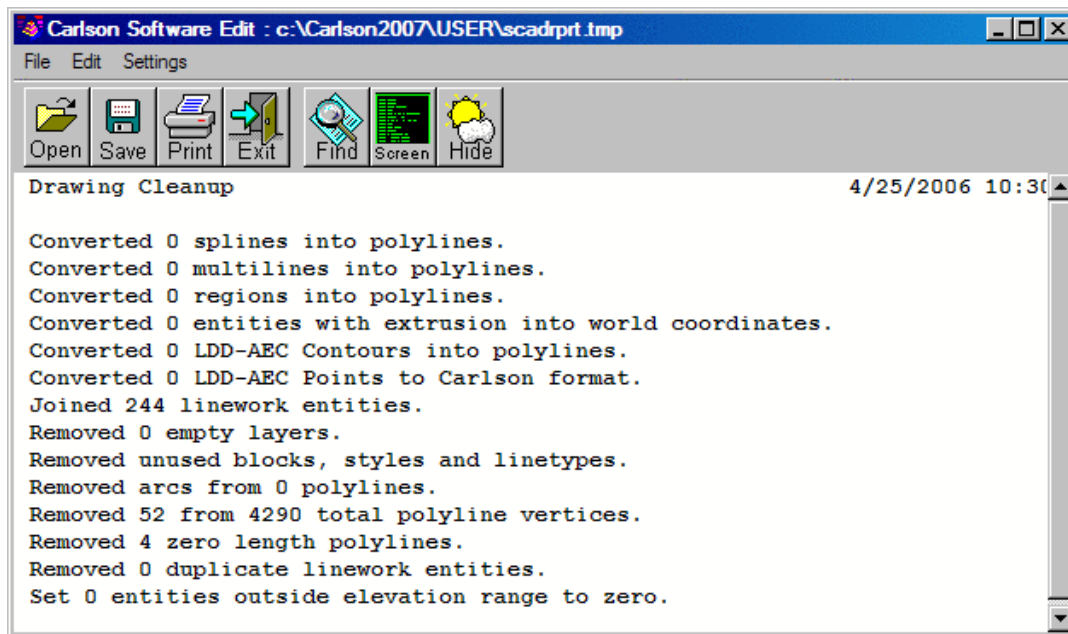

This allows you to run the command for the entire drawing or for a selected set.

Default

This allows you to return to the Carlson Drawing Cleanup default settings.

Final Report

This example report displays the results of drawing cleanup. Like all reports in Carlson, this report can be saved to a text file, sent directly to your printer, or pasted onto the screen as text entities.

Pulldown Menu Location: File

Keyboard Command: `dwg_cleanup`

Prerequisite: None

Save Drawing Named by Current Time

This command does a SaveAs of the current drawing with the dwg file automatically named using the current drawing name plus the current date and time. The date and time format is YearMonthDay.HourMinuteSecond. For example, when the current dwg is `job101.dwg` and the current time is July 4, 2020 at exactly noon, then this command will save using a file name of `job101_20200704_120000.dwg`.

Pulldown Menu Location: File > Drawing Utilities

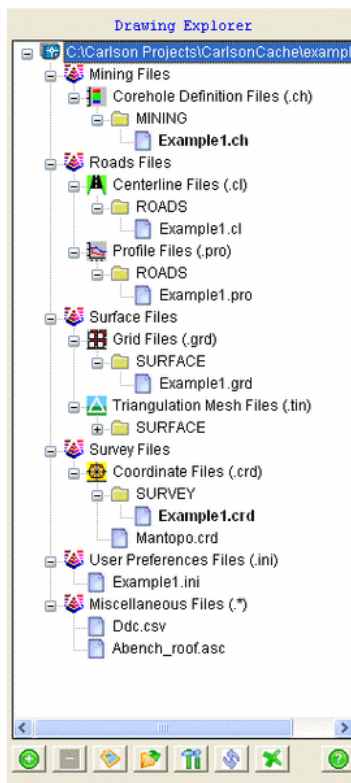

Keyboard Command: `savecurrent`

Prerequisite: None

Drawing Explorer

The Drawing Explorer command presents a list of all Carlson data files that are made in association with a drawing and are tracked in *DrawingName.ini*. If a drawing was not made in Carlson or does not have a companion .INI file, then Drawing Explorer will not display any files. The Drawing Explorer will also not show any data files if the drawing is not saved. Once data files are created such as a coordinate (.CRD) file, then Drawing Explorer will track these files. Drawing Explorer helps manage drawing-related data.

The Drawing Explorer is shown as a docked dialog on CAD window with files shown as "tree view" under different categories. These file categories are fully customizable and can contain multiple file types. The drawing name is shown as root of the tree view with file categories as its children. The file types associated with a category are listed as children of that category. The data files used with the drawing are listed under respective file type or in subfolders of the project folder specified using the Set Project/Data Folders command. The data files used as current files are shown with bold font.

The Drawing Explorer allows user to view/manage data files associated with the currently opened drawing by allowing him to add, remove, report, and change directory of these files. A mouse right-click can also be used to add and remove any data file/file type/file category from the Explorer.

The Add button allows adding a file under the category or file type that is currently selected in the tree view. If the drawing file name is selected, the user is allowed to add any type of file to the Explorer and file will be added to the corresponding category.

Removes the selected file(s) along with any "child" (subordinate) files from the drawing. The underlying file(s) are not physically deleted or removed from the hard-drive, they are merely removed from the Drawing Explorer.

Creates a report through the Report Formatter Options dialog box. The Report Formatter can be used to move to the *Available* entries on the left to the *Used* area on the right. When coupled with the Up/Down options to control the order, highly customized reports can be generated and saved for subsequent use.

Click the **Display** to obtain the report. The Change Directory option allows you to instruct Carlson Software to re-direct the location for files from an old folder location to a new folder location. This option is helpful if project data files are manually moved to a new folder location.

The Settings button allows you to create Categories of file types and assign data files to a particular Category and assign how project data files are presented in the Project Explorer.

The Refresh button re-reads the current Project file along with the various Drawing file settings and updates the Project listing appropriately.

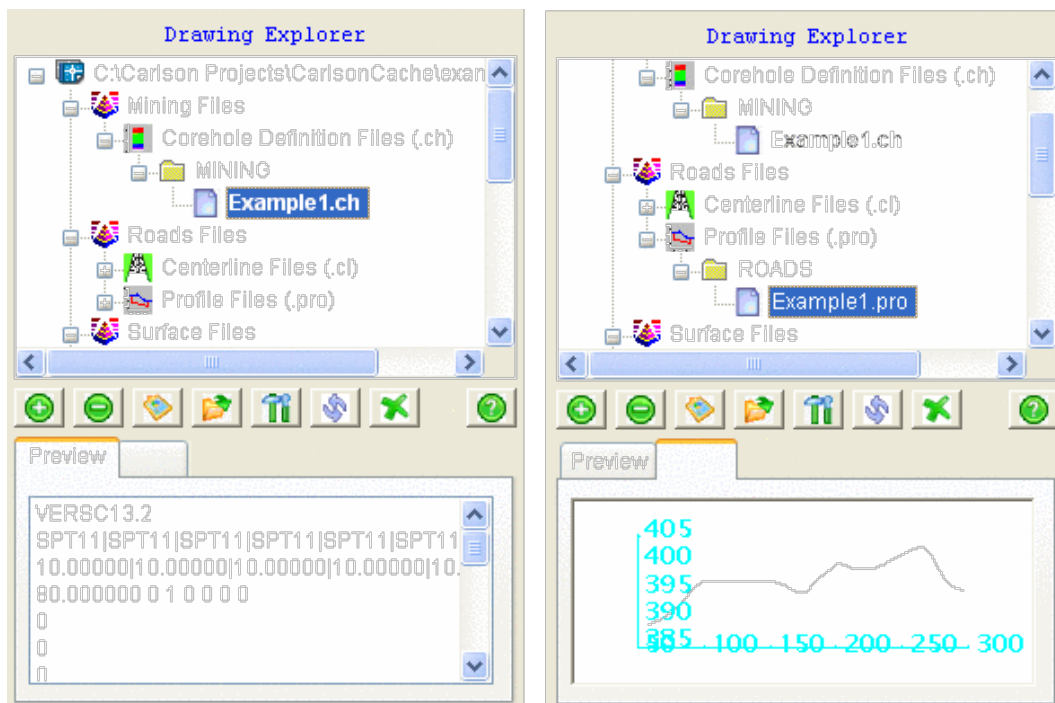

Exits from the Project Explorer command.

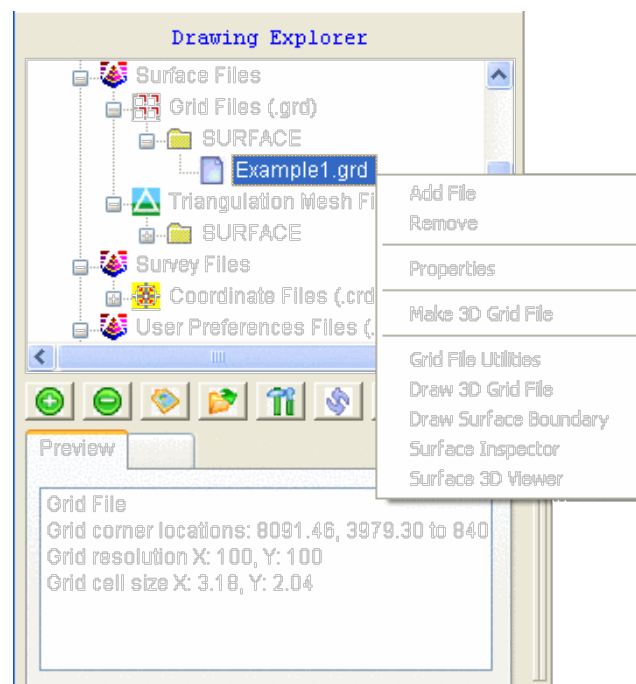

Displays the on-line help.

The option to show preview allows user to see the preview of currently selected data file in a small preview window at the bottom of the Explorer dialog.

The List Data Files settings are used in Project Explorer to list files according to drawing files in the project of by project.

Right-Click Command Execution: The Drawing Explorer also allows execution of functions associated with a file type. Right-clicking on any file type or data file brings up menu for the commands associated with that file. The right-click menu has a Zoom To function for many file types that have plan view coordinates such as centerlines. This Zoom To function zooms and pans the drawing to show the location of the highlighted file. For right-click commands that require the file during execution, the selected data file will be used to run that command. For example, in the figure below, *Example1.grd* will be used to run the Draw 3D Grid File command and the program will not prompt for the grid file to be drawn.

Double-Click Command Execution: Each file type has a default command to run when you double-click on the file. For example, TIN files run the 3D Viewer on double-click.

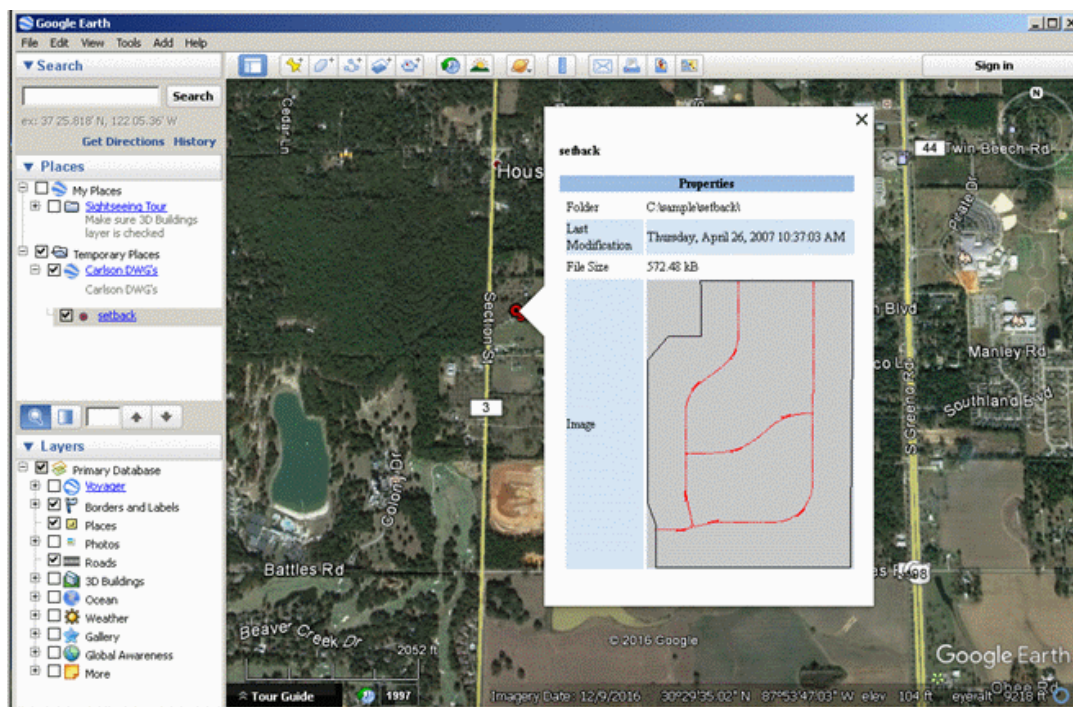

Pulldown Menu Location: File
Keyboard Command: dwgxplore
Prerequisite: None

Geolocate DWG Files

This command displays placemarks in Google Earth for DWG files. The command starts by prompting for a folder. Then all the DWG files in this folder and the sub-folders are used to make the map for Google Earth. In order to use a DWG file, the coordinate system must be set in the DWG using the Drawing Setup command. The command creates a Google Earth file called kml.dwg.kmz in the %appdata%\Carlson Software\version\platform\USER folder.

In Google Earth, the location of each DWG file is shown with a circle marker. When you click on a marker, the DWG properties are shown including the folder location, date, file size and graphic preview.

To load a DWG file from Google Earth, go to Tools > Options in Google Earth. In the Options dialog, go to the General tab and turn on Allow Access To Local Files and Personal Data. Then when you click on a placemark to open it up, you can double-click on the properties window to load that DWG file into CAD.

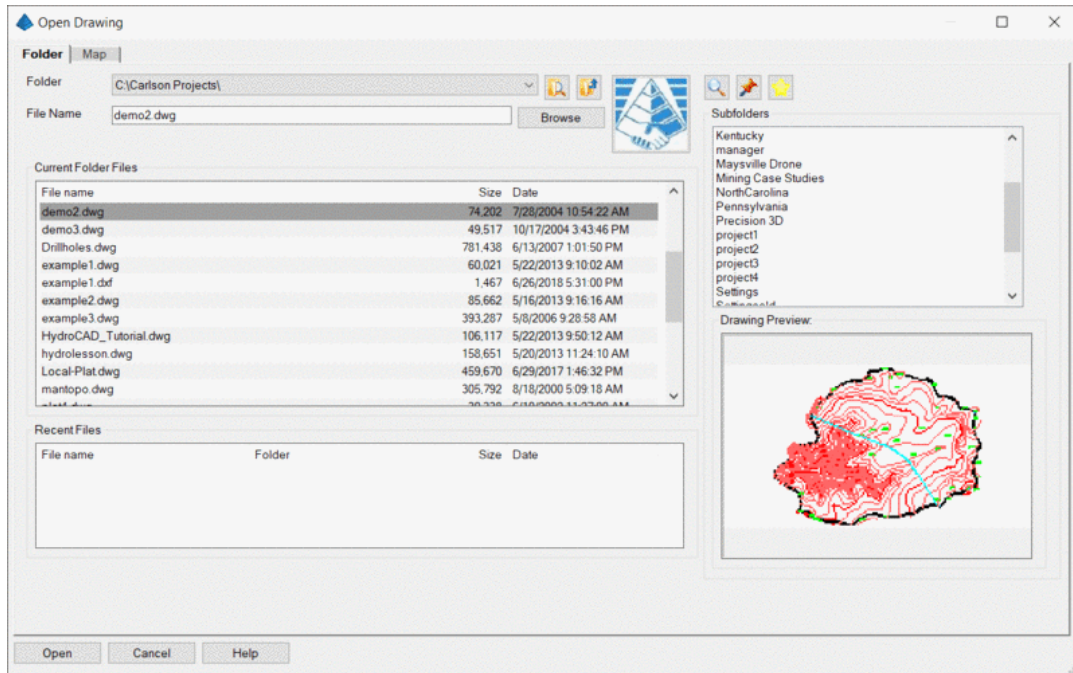

Pulldown Menu Location(s): File > Drawing Utilities
Keyboard Command: dwg2kml
Prerequisite: DWG files with defined coordinate systems

Open Drawing

This command allows you to open drawings either by browsing folders or from a map view. The map view is a visual way to select a drawing. From the map view, you can zoom into an area or type in an address into the Search

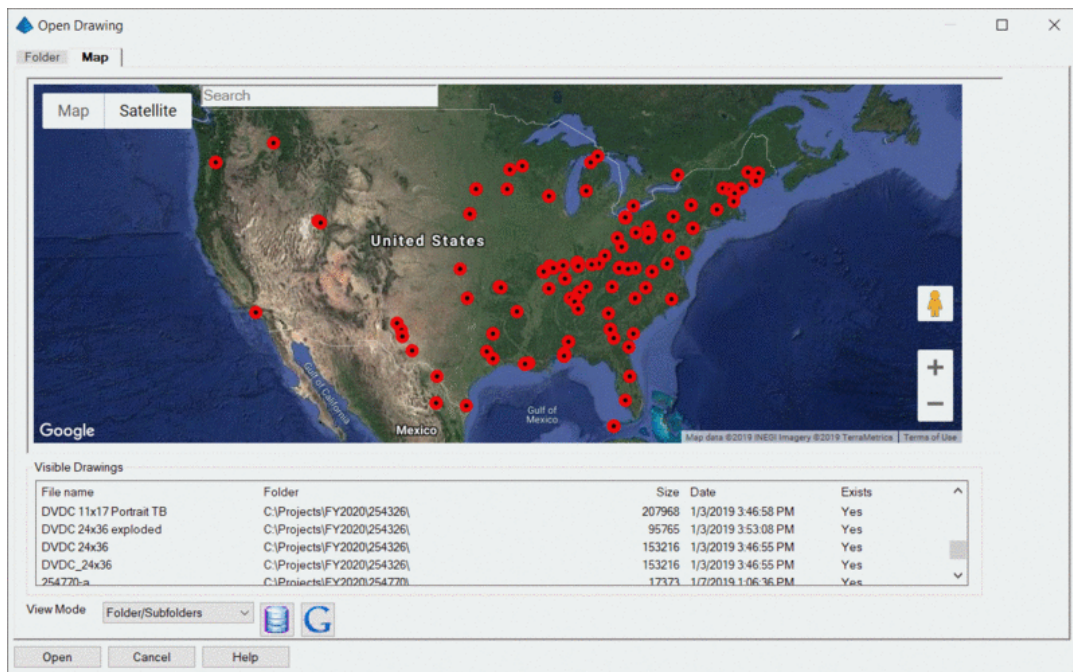

field.

Folder Tab

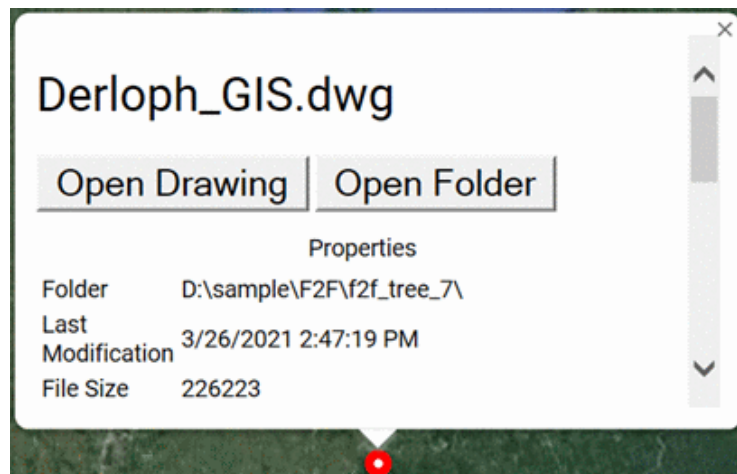

The Folder tab lets you find existing drawings by searching through folders and recent folder locations as in previous versions.

Map Tab

The Map tab displays a Map/Satellite interface that lets you pan, zoom, and browse georeferenced project drawings. In the Visible Drawings location are listed georeferenced drawing files that would appear in the current map and also follow the criteria as selected by the current View Mode listed at the bottom of the dialog box.

To select a drawing, pick on the dot icon on the map. The program will show the drawing name and properties. Pick the Open Drawing button to open the drawing in CAD or pick the Open Folder button to open the drawing folder in Windows Explorer.

For the Map tab to be available, the Use Drawing Database option in Carlson Configure > Project/Data Folders must be turned ON. Please refer to the Set Project/Data Folder command for complete information.

Data Source:

Folder: Displays georeferenced drawings in the current folder on the folder tab that also appear in the current map view.

Folder/Subfolders: Displays georeferenced drawings from the current folder (and all of its sub folders) on the folder tab that also appear in the current map view.

Drawing Database: Displays all the georeferenced drawings that would be visible in the current map display. Only georeferenced files may be added to the drawing database. If you pan or zoom the map so no georeferenced files would be visible, the last visible drawings will still display in the visible drawings list until a new drawing is found.

Recent Drawings: Displays recently opened georeferenced files that would be visible in the current map display.

Use Filter Criteria: Displays all drawings from the drawing database using the current filter criteria. (see Use Filter Criteria below)

Buttons: Next to the Data Source list, there are button icons.

Use Filter Criteria: Same as picking from the Data Source list. (see Use Filter Criteria below)

Drawing Database: Opens the Drawing Database dialog box.

Output to Google Earth: Writes database drawings out to Google Earth Pro (if installed on PC) as temporary places.

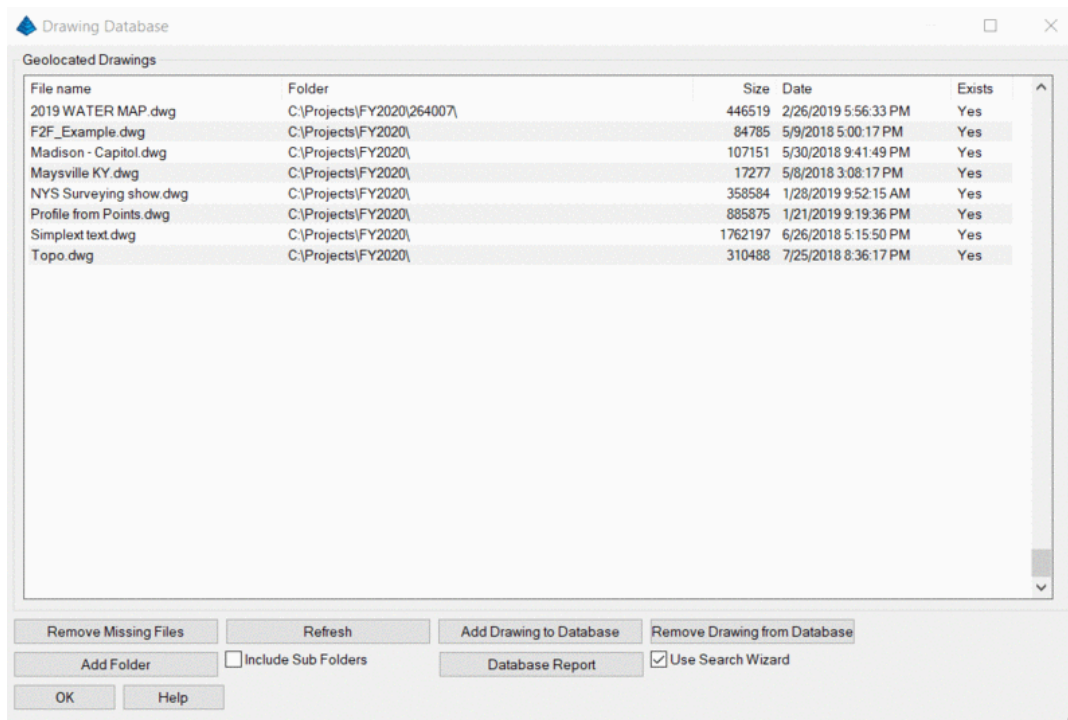

Column Options: Controls which drawing properties to display in the dialog list box.

Use Filter Criteria

Name	Folder	Size	Modified
2019 WATER MAP		446519	2/26/2019 6:56:33 PM
F2F_Example		84785	5/9/2018 6:00:17 PM
Madison - Capitol		107151	5/30/2018 10:41:49 PM
Maysville KY		17277	5/8/2018 4:08:17 PM
NYS Surveying show		358584	1/28/2019 10:52:15 AM
Profile from Points		885875	1/21/2019 10:19:36 PM
Simplext text		1762197	6/26/2018 6:15:50 PM

Drawings that have been added to the Drawing Database may be filtered down using the following criteria in addition to the current map view: Name and Type; Date (Modified) Range; and Size Range.

Drawing Database

Remove Missing Files: Removes files from the database that no longer exist in the location from whence they were added. If you want to remove a large amount of files at once, you can temporarily change the folder name of the root folder of many job files, and then run this command to remove the files, then rename the folder name change back to the original name.

Refresh: Re-reads the database and displays the current list of drawings.

Add Drawing to Database: Prompts you to browse and locate a new georeferenced file to add to the database.

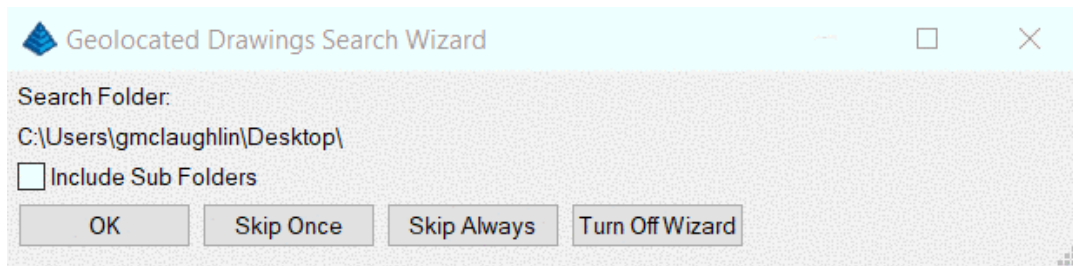

Remove Drawing from Database: Removes the highlighted drawing from the database.

Add Folder: Prompts for a folder to be selected. Any georeferenced drawings contained in that folder (and any included subfolders if this item is checked) are then added to the database. Duplicate named files from different locations or folders may reside together in the database.

Database Report: Reports on all files contained in the database. You can report items such as Full Name (Path and Drawing name); Date Modified; Size; Lat/Lon and if the file still exists in the original location.

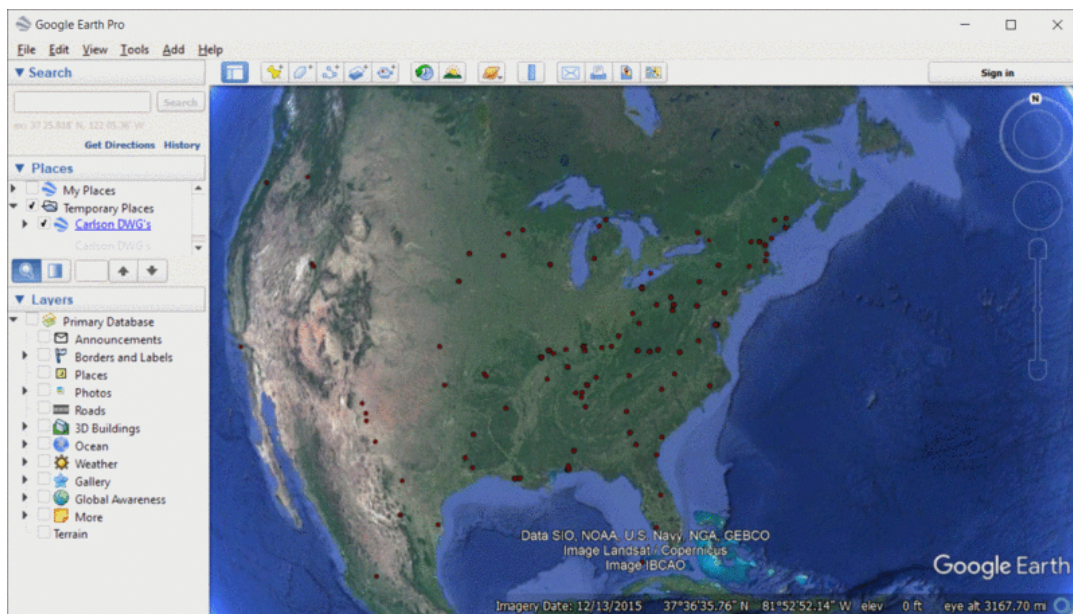

Use Search Wizard: Displays a wizard that will attempt to add georeferenced drawings from the current folder/subfolders to the database when the current folder is set to a new folder.

Geolocated Drawings Search Wizard

When you select a different folder from the folder tab to search or open drawings, then by switching back to the Map tab the Geolated Drawings Search Wizard displays if this is toggled ON in the Drawing Database. By using this search wizard, drawings will be automatically added to the database from the selected folder (and sub folders).

Output to Google Earth

Output to Google Earth writes all the database drawings out to Google Earth Pro (if installed on PC) as temporary places. These places may be added to 'My Places', be used to get directions or to display drawing information from within Google Earth.

Pulldown Menu Location: File

Keyboard Command: opendwg

Prerequisite: none

Draw Polyline File

This command draws polylines from the selected polyline file. This command supports the following formats: Carlson (.PLN), Agtek (.WRL), CAICE (.SRV), Digital Line Graph from USGS (.DLG, .OPT), Idan (.DIS), MicroStation (.TXT), MOSS (.INP, .PRN), Peabody (.PLY) and Topcon (.LN3 and .TXT). For formats that contain

only geometry without layer names, the polylines are drawn in the current layer.

Prompts

Polyline file format [`<Carlson>/Agttek/Caice/DLG/DTM/Idan/MicroStation/MOSS/Peabody/Topcon`]? *press Enter for Carlson default*

Polyline File to Read Dialog *select existing .PLN file*

Pulldown Menu Location: File->Import

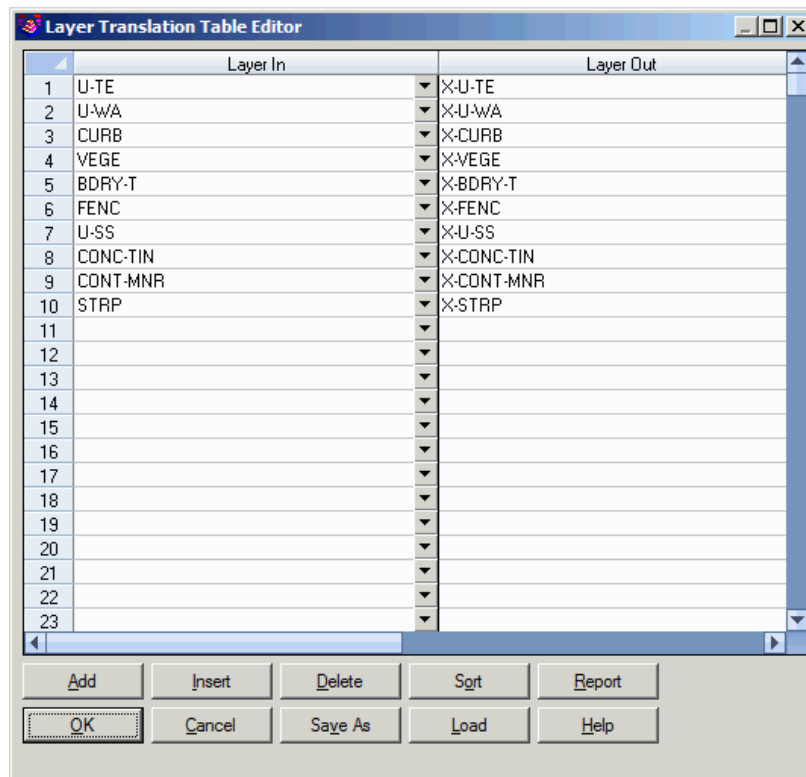

Keyboard Command: polydraw

Prerequisite: A polyline file

Translate Layers

This command renames layers using a lookup table with pairs of original and renamed layer names. This command can be used to convert the layers for a drawing from another source to match your layer standards. The layer names are entered in a spreadsheet. The Add, Insert, Delete and Sort buttons work on the spreadsheet rows. The Report button makes a report for the layer assignments. The SaveAs and Load functions store and recall the layer assignments to a .LTF file for sharing the settings or keeping different sets of layer assignments. The Add From Drawing reads the layers from the current drawing to put under the Layer In fields.

If you use Layer Library and define your target layers with their properties, then the Translate Layers command will use these layer properties. For the example below, if the X-U-TE layer is defined in the Layer Library, then X-U-TE is created using the color, line type, transparency and plot style from the Layer Library.

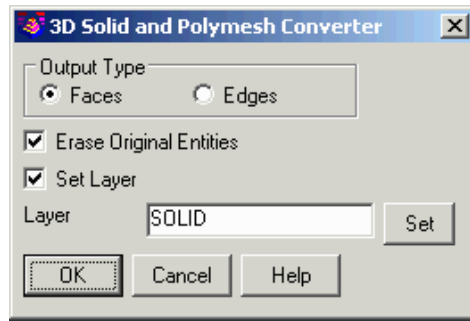

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: translayers

Prerequisite: None

3DSolid and Polymesh Converter

This command converts 3DSolid and Polymesh entities into 3D Faces or Edges. The Set Layer option allows you to put the new 3D Faces or Edges in a specified layer. Otherwise the layer of the original entities is used.

Prompts

Converter dialog

Select entities to process.

Select objects: *select 3DSolid or Polymesh*

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: solconvert

Prerequisite: 3DSolid or Polymesh entities

Remove XData

This command removes the xdata (Extended Entity Data) from the selected entities. Many Carlson routines add xdata to entities in order to add extra program specific information to them. Carlson programs use the xdata to make entities more intelligent. For example, when you draw a centerline (.cl) as a polyline, xdata is attached to the polyline that stores the reference of the .cl file name. Then if you double-click the polyline, then the program can read the xdata to know the polyline is a centerline and launch the centerline editor. By removing the xdata, the entities revert to regular CAD entities which is useful if you want to detach these entities from the program links.

Prompts

Select entities to remove extended entity data from.

Select objects: *pick the entities*

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: xxdata

Prerequisite: Entities with xdata

Remove Civil 3D Custom Objects

This command removes all Civil 3D custom objects (AEC objects) from the current drawing so that the next time the drawing is opened, AutoCAD will not load the AEC functions. The AEC objects can be either erased or exploded into standard AutoCAD entities. The cleaned drawing is saved to a new dwg file.

Prompts

Erase or Explode AEC entities during conversion [<Erase>/Explode]? *press Enter*
Save dwg selection dialog

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: aeccleaner

Prerequisite: Drawing with AEC data

Remove Reactors

This command removes the reactor links from the selected points, text, polylines and lines. This disables the links for points to the coordinate (.CRD) file, annotation with linework and linework with points. Note that in *General Settings* there is a section called Object Linking. This is the specific section that contains the options for creating these reactors to the drawing entities. Reactors can be turned off for entities created later by clicking off the four link options in *General Settings*. To get to this dialog go to *Settings > Configure > General Settings*.

Prompts

Select entities to remove reactors from:

Select objects: *pick the entities*

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: delreact

Prerequisite: Entities with reactors

Remove Groups

This command is used to "ungroup" selected entities that, prior to using this command, were part of a group. For our purposes, we might more specifically be referring to Carlson's Point Entity Grouping feature. A group is a named selection set of objects. This routine removes selected entities from groups. It is especially useful when dealing with our Carlson points.

More on Point Entity Grouping: As mentioned in the Points chapter, remember that for each point, the point attribute block, node, and symbol can be bound together. This means that if you choose to use the *Move* command (or other CAD tools) the entire collection moves together. This is done using the grouping functionality in AutoCAD or IntelliCAD. To disable this system altogether, go to *Configure*, choose *General Settings*, and turn off the toggle for Group Point Entities. If you need to temporarily disable grouping in a drawing, you can use the AutoCAD toggle for grouping, which is Ctrl-A. Holding down the Ctrl key, and pressing the letter A on the keyboard, activates this two-way toggle, with the current status echoed to the command prompt area.

Prompts

Select entities to remove from groups.

Select objects: select entities

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: rmgroup

Prerequisite: Entities in group(s)

Unlock Attributes

This command turns off the lock flag for attributes of the selected block entities.

Prompts

Select attributes to unlock.

Select objects: *pick the entities*

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: unlockatt

Prerequisite: Blocks with locked attributes

Record Script, End Script, Run Script

These commands process a sequence of commands. First, the Record Script command creates a script file (.scr). When the Record Script is active, the commands that you run and the input data is written to the script file. The End Script command stops the script recording. Then the Run Script command can be used to reprocess the commands and input from the script file. The script file is a text file that you can edit with any text editor such as Notepad or the Display-Edit File command. You can edit input data files as well as the commands.

The script supports the following commands: Draw-Locate Points, Inverse, Traverse, Sideshot, Bearing-Bearing Intersection, Bearing-Distance Intersection, Distance-Distance Intersection.

These scripts can be useful for batch processing a repetitive input. Also, the script can be used as a backup of data input for reprocessing after editing input values.

In the script file, the user-input values are after the "=>". Anything on a line that is after a ";" is a comment. The command prompts are included in the script file for easier reading. Here is a sample SCR file:

```
c:inverse ; Command: INVERSE
Traverse/SideShot/Options/Arc/Pick point or point number: =>26
Traverse/SideShot/Options/Arc/Multiple/Pick point or point number: =>24
Traverse/SideShot/Options/Arc/Multiple/Pick point or point number: =>SS
Exit/Help/Options/Points/Line/Traverse/Inverse/<Angle-Bearing Code <7>: =>
Enter Angle (dd.mmss) <90.0000>: =>45.1515
Points/<Distance>: =>59.2
Enter Zenith Angle (dd.mmss) <90.0000>: =>90.1234
Enter Point Description <>: =>IP
Exit/Help/Options/Points/Line/Traverse/Inverse/<Angle-Bearing Code <7>: =>e
```

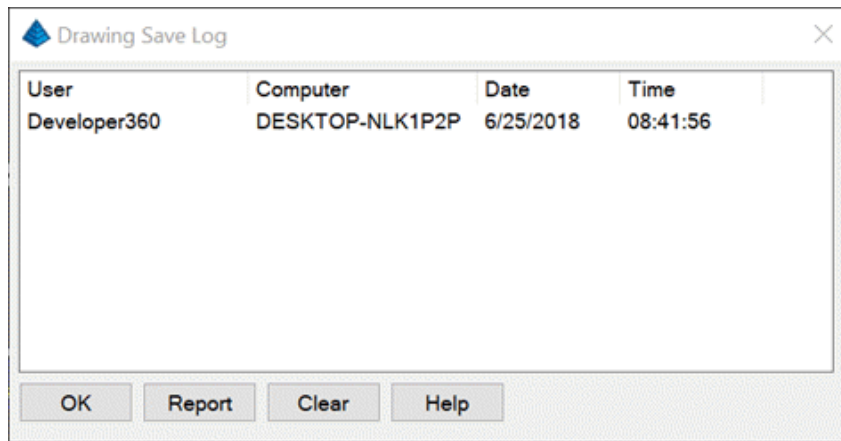

Pulldown Menu Location: File > Scripts

Keyboard Command: recscr, endscr, runscr

Prerequisite: None

Drawing Save Log

The command reports the save history for the current drawing including the date, time, user and computer name for each save. This save history is only recorded when the Generate Drawing Save Log option is turned on in the Carlson Configure > Getting Settings.

Pulldown Menu Location: File > Drawing Utilities

Keyboard Command: dwg_save_log

Prerequisite: Turn on Generate Drawing Save Log in Carlson Configure

Edit Menu

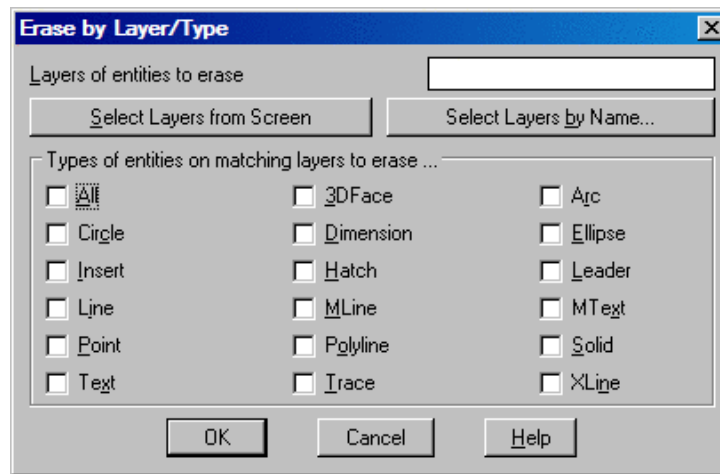

In addition to powerful CAD engine editing commands, the Carlson Edit menu has the additional commands which are explained in this section. Commands that are pure AutoCAD or IntelliCAD are not detailed here. They can be found in the CAD manual.

Erase by Layer

This command will ERASE all the entities on the specified layers but will not delete these layers from the drawing. The command prompts for the layer name to erase and then erases all entities on that layer. In addition to typing in

the layer name, you can also specify a layer to delete by picking an entity on that layer. To select layers by picking, first click the **Select Layers from Screen** button and then select the entities on the layers to be deleted. The **Select Layers by Name** button allows you to choose a layer name from a list of layers in the drawing. You can also specify which types of entities to erase. For instance, if you have both linework and points on the same layer and you want to erase only the linework, you can click off All and check Line and Polyline. The **Save** and **Load** buttons save and recall the layer names.

Pulldown Menu Location: Edit > Erase

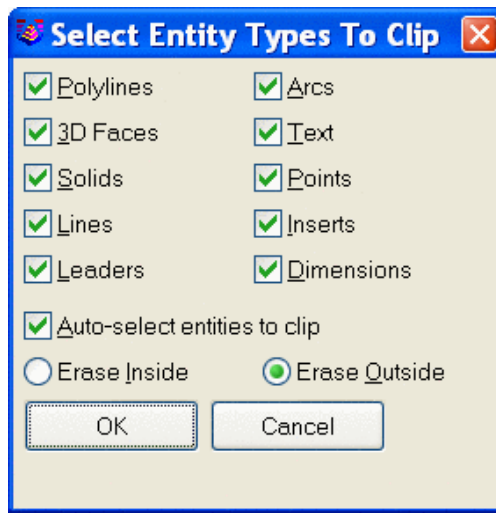

Keyboard Command: ldel

Prerequisite: Something to erase

Erase by Closed Polyline

This tool is used to clean up drawing geometry at the extents of a polyline boundary. It provides options to erase adjacent geometry as well as trim geometry crossing the fence of the polyline.

First, select the boundary polyline. Only one can be selected. Designate the desired options in the following dialog. The top section of the dialog allows you to toggle which object types should be affected by the operation. Note that some of the objects, such as text and inserts, cannot be trimmed.

In the middle of the dialog is a toggle that determines whether to prompt for objects to process. If you want to isolate the drawings contents to that of the selected polyline, turn this toggle on. Note that all geometry in the drawing is effected, even geometry that is outside of the current viewport. Many users will prefer to turn this toggle off, so that they can be prompted to manipulate the geometry.

The bottom row allows you to choose whether to erase all the entities on the inside or outside of the polyline.

Pulldown Menu Location: Edit > Erase

Keyboard Command: erasepline

Prerequisite: Entities and a closed polyline

Erase Outside

This command erases all the entities outside of a user specified window. This can be useful if you somehow place entities way outside your drawing limits and want to easily erase them.

Prompts

Pick 1st corner of window to erase outside of: *Pick point location*

Pick 2nd corner: *Pick second point location*

Pulldown Menu Location: Edit > Erase

Keyboard Command: eraseout

Prerequisite: Entities to erase

Temporary Erase

This command erases the selected entities while keeping track of their data to allow restoring them. To unerase the entities, simply run the command again. The program keeps track of the erased data only during the current drawing session. If you exit the drawing, the entities cannot be restored when the drawing is opened again.

Prompts

Select entities for temporary erase.

Select objects: *pick entities to erase*

Pulldown Menu Location: Edit > Erase

Keyboard Command: terase

Prerequisite: Entities to erase

Copy To Layer

This command is used to copy a selected entity or entities and put the copy in a specified layer. Once copied to the chosen layer the entity or entities will take on the characteristics of that layer (color, linetype, etc.).

Prompts

Select entities to copy.

Select objects: *select entities*

Select Layer dialog *select a layer from list and click OK*

Pulldown Menu Location: Edit > Copy

Keyboard Command: copy2layer

Prerequisite: Entities to be copied

Copy Polyline Section

This command is used to copy a portion of a polyline, at specified points, and put the copied portion onto another layer. The portion of existing polyline that is being copied still remains as part of the original entity (with no break), while the new portion, with its chosen layer designation, is a new polyline.

Prompts

Select polyline to copy: *Pick a polyline*

Select first break point along polyline: *Pick location on the polyline*

Select second break point along polyline: *Pick the second location on the same polyline*

Layer name <CTR>: wall

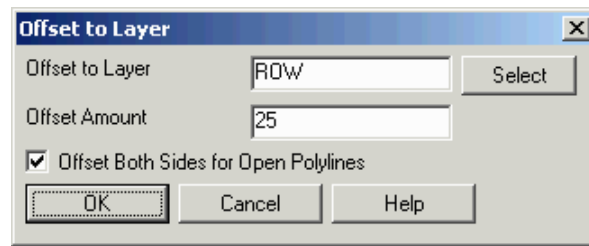

Pulldown Menu Location: Edit > Copy

Keyboard Command: copy_pl

Prerequisite: Polyline to be copied

Offset To Layer

This is a command to offset a polyline and put the offset polyline into a separate layer from the original polyline. The Offset Both Sides For Open Polylines option can be used to create easement perimeters. For example, you can pick a pipe polyline and this option will offset to both sides to create an easement around the pipeline.

Prompts

Offset To Layer dialog

Select object to offset: *pick a polyline to offset*

Specify point on side to offset: *pick a point*

Select a polyline to offset (Enter to end): *press Enter*

Pulldown Menu Location: Edit > Offset

Keyboard Command: offset_layer

Prerequisite: Linework to offset

Offset to Area

This command offsets a polyline by a distance that results in creating the specified target area. The source polyline should represent the frontage on the area. There is an option to connect the sides between the source and offset polylines to make a closed polyline.

Before and after Offset to Area

Prompts

Pick line or polyline to offset: *pick a polyline*

Select side to offset: *pick a point on the offset side*

Keep existing polyline [Yes/<No>]? *press Enter*

Create closed polyline [<Yes>/No]? *press Enter*

Acres/<Enter target area (s.f.)>: *90000*

Pulldown Menu Location: Edit > Offset

Keyboard Command: offset_area

Prerequisite: polyline to offset

Multiple Offsets

This command applies the same offset multiple times in series from the original polyline.

Prompts

Specify offset distance <20.0000>: 25

Enter Number of Repetitions <1>: 3

Select object to offset or <exit>: *pick a polyline to offset*

Specify point on side to offset: *pick a point*

Pulldown Menu Location: Edit > Offset

Keyboard Command: offset_mult

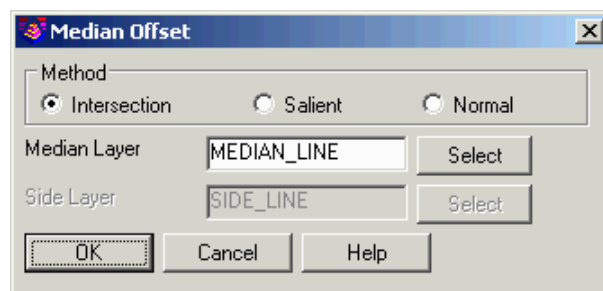

Prerequisite: Linework to offset

Median Offset

This command creates a median polyline that is offset halfway between two existing polylines. For example, this command can be used to get the center of a river given polylines for the left and right river banks. The intersection method finds where the offsets from the two reference polylines intersect. The Salient and Normal methods come from the CAPD program originally developed by the BLM.

Prompts

Select the First Polyline: *pick a polyline*

Select the Second Polyline: *pick a polyline*

Draw Chords of Parabolas [Yes/<No>]? *press Enter*

Draw Perpendiculars for Check [**<Yes>/No**]? *press Enter*

Pulldown Menu Location: Edit > Offset

Keyboard Command: medoff

Prerequisite: two polylines to offset

Variable Offset

This is a command to offset a polyline, with different offset amounts for each polyline segment of the same polyline. The offset distances can be variable, and you choose between a Line or a Point method at the command line.

Prompts

Vary offsets by line segments or at points [**<Line>/Point**]? *press Enter*

Select a polyline to offset (Enter for none): *pick polyline*

Select side to offset: *pick a point on the side to offset to*

As you go from segment to segment, you can enter in different offset values for each line segment.

Enter the segment horizontal offset **<0.000>**: 56

Enter the segment horizontal offset **<56.000>**: 33

Enter the segment horizontal offset **<33.000>**: 12

Select a polyline to offset (Enter for none): *press Enter*

Pulldown Menu Location: Edit > Offset

Keyboard Command: VOFFSET

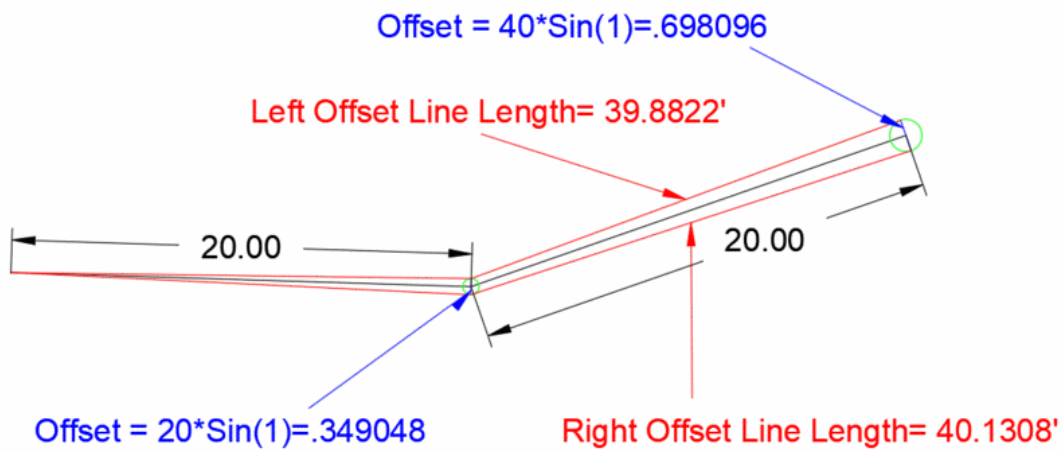

Prerequisite: A polyline to offset

Drift_Offset

This command draws two offset polylines that offset as a function of the cumulative distance of the polyline. That is, at the beginning of the original polyline, the offset distance will be zero. At the end of the polyline, the offset distance will be equal to the total length of the original polyline multiplied by an offset factor, as described by the below formula:

$$\text{Offset} = \text{Polyline.Length} * \sin(\text{angle})$$

After selecting the polyline and entering the angle, the offsets will be calculated for each vertex along the polyline. It is important to note that the offset polylines are not a simple angle rotation of the original polyline. An example is shown below.

Because the offsets are calculated only at the vertices of the original polylines, sharp angles in the original polyline will produce offset polylines that can actually get closer to the original polyline rather than farther away, as shown below. Note that the offset distances are perpendicular to the original polyline.

It is important to note that although this command can offset either a 2D or a 3D polyline, the resulting offset polylines will only be drawn as 2D polylines.

Pulldown Menu Location: Edit
Keyboard Command: offset_drift

Block Explode

This command retains the values of attributes when a block is exploded. The standard *Explode* command changes the attribute values back to the attribute type. For example, using *Explode*, a Carlson point block would become PNTNO, PNTELEV, PNTDESC. *Block Explode* would keep the point attribute values, such as 10, 1000.0, EP. The

layer names of the exploded block attributes can be either the insert layer of the parent block or the original attribute layers from the block definition.

Pulldown Menu Location: Edit

Keyboard Command: explode2

Prerequisite: A block to be exploded

Extend to Intersection

This command extends the end points of two lines and/or polylines, at the same time, to their intersection point.

Prompts

Select first line or polyline to extend: *pick a line or polyline*

Select second line or polyline to extend: *pick another line or polyline*

Before Extend to Intersection

After Extend to Intersection

Pulldown Menu Location: Edit > Extend

Keyboard Command: extint

Prerequisite: Two lines or polylines

Extend Arc

This command extends an arc entity.

Prompts

Pick arc to extend: *select an arc entity*

Break Arc at Extension [Yes/<No>]? *N* Answering *Yes* will create a new arc starting at the end of the existing arc.

Enter or pick the distance to extend: *5* This extends the arc 5 units

Enter or pick the distance to extend ('U' to Undo): *press Enter to end*

Pulldown Menu Location: Edit > Extend

Keyboard Command: extarc

Prerequisite: An arc

Extend by Distance

This command extends a line or polyline, or creates new lines or polylines off of an existing one. By specifying a distance, a new segment of the line or polyline can be drawn from the current position. The current position and direction along the line or polyline is indicated by an arrowhead. Extend by Distance starts by selecting an existing line or polyline. Initially, the current position will be the closest vertex to where the line or polyline was selected. Extending from the endpoint of a polyline will add a new point to that polyline, while extending from any other point will create a new polyline.

There are two modes of operation: draw mode (D) and move mode (M). When in draw mode, extending will draw line or polyline segments. In move mode, the current position arrowhead can be moved without drawing segments. The orientation of the current position arrowhead can be changed with the Right, Left, and Angle commands.

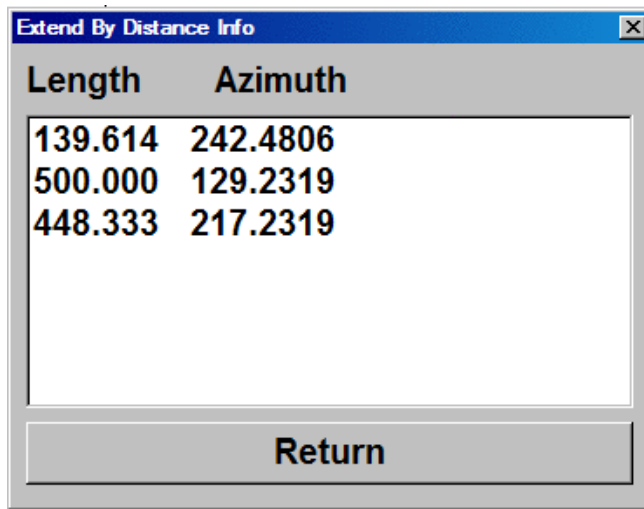

The second prompt for this command offers numerous options in the form of key letters. These key letters are listed below along with their full names and actions. The list of the Extend by Distance commands are:

- # - Number:** Distance to draw or extend
- A# - Angle change:** Rotates pointer by specified number of degrees
- A - Align:** Rotates pointer to align with segment
- B - Bearing:** Sets pointer direction by bearing in format: Qdd.mmss with Q- quadrant, d-degrees, m-minutes, s-seconds (e.g. 130.1005 is NE 30 degrees, 10 minutes, and 5 seconds)
- C - Close:** Closes the polyline
- D - Draw Mode:** Actions draw or extend the line or polyline
- E - Extend to Edge:** Extends to intersection with a selected line or polyline
- I - Input mode:** Toggles distance input between decimal feet and feet-inches
- L - Left rotate:** Rotates counterclockwise 90 degrees
- M - Move Mode:** Actions only move the pointer
- N - Next:** Moves pointer forward to next point
- O - Open:** Opens the polyline
- P - Previous:** Moves pointer backward to previous point
- R - Right rotate:** Rotates clockwise 90 degrees
- S - Switch:** Reverses pointer direction
- T# - Total distance:** Sets current segment to specified distance
- U - Undo:** Undo the last Extend by Distance command
- Z - Zoom mode:** Toggles auto-zoom between on/off
- ? - Info:** Displays lengths of current polyline

H - Help: The Help option also displays this Extend by Distance Commands list.

Press <Enter>: Ends the routine

The result of using the Info (?) feature

Prompts

Select line or polyline to extend: *select line or polyline near the place to extend*

Enter or pick distance to draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help): 50 The line is extended by 50 units.
Use the Pick option to pick a distance.

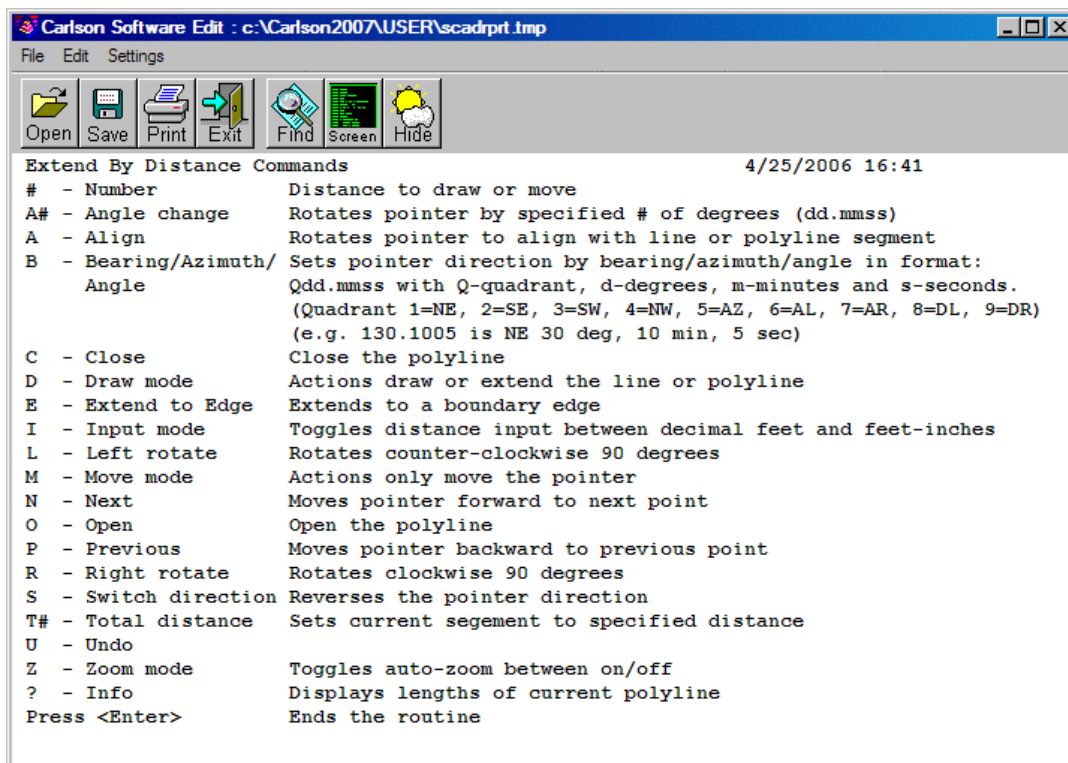

Pick/Horizontal Distance to Extend ([Enter] for new line): R Rotate right 90 degrees.

Enter or pick distance to draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help): 50 The line is extended by 50 units.
Use the Pick option to pick a distance.

Enter or pick distance to draw (A,B,C,E,I,L,M,N,O,P,R,S,T,U,Z,?,Help): *press Enter*

Extend another (<Yes>/No)? No

Note: R50 and L10 can be used to go right 50, left 10, etc.

The result of using the Help (H) option

Pulldown Menu Location: Edit > Extend

Keyboard Command: extender

Prerequisite: An existing line or polyline with at least one segment from which to start.

Break by Crossing Polyline

This tool is used to break drawing geometry at the edge of a polyline boundary. It provides options to change the layers of the interior and exterior geometry after it is broken.

First, select the boundary polyline. Only one can be selected. Then select the polylines and lines to be clipped. You will be prompted for options on specifying the layers for the newly broken geometry. Respond with a "Y" if you want to specify a new layer, then enter the new layer name. If the layer name does not exist, it will be created.

Prompts

Select the clip edge polyline: *pick a closed polyline*

Select the polylines and lines to be clipped.

Select Objects: *pick the entities to break*

Specify layer names for Inside segments (Yes/<No>)? *Yes*

Enter a layer name for the Inside segments <0>: *press Enter*

Specify layer names for Outside segments (Yes/<No>)? *Yes*

Enter a layer name for the Outside segments <0>: *Final*

Pulldown Menu Location: Edit > Break

Keyboard Command: clipline

Prerequisite: A closed polyline

Break Polyline at Specified Distances

This command allows you to pick a polyline and break it at a specified distances along the polyline. Following the prompts below, the beginning of the polyline in the illustration was broken into three 55-foot segments.

Prompts

Select polyline to break: *select polyline*

Total Distance: **779.429** This is the length of the polyline reported.

Distance Along Polyline For Break: *55.0*

Distance Along Polyline For Break (Enter to end): *110*

Distance Along Polyline For Break (Enter to end): 165
Distance Along Polyline For Break (Enter to end): *press Enter*
3 polyline breaks created.

Pulldown Menu Location: Edit > Break

Keyboard Command: breakpl

Prerequisite: A polyline

Break at Intersection

This command will break a line, arc or polyline at the intersection of another line, arc or polyline. In many cases this command is used in conjunction with the *Area by Lines & Arcs* command. In order to get the correct area of a figure, it is often necessary to break it from adjoining lines.

Prompts

Select Line, Arc, or Polyline to Break

Select object: *select object to break*

[int on] Pick Intersection to break at: *pick intersection point*

Pulldown Menu Location: Edit > Break

Keyboard Command: breakat

Break at Selected Point

This command breaks the selected linework at the cursor position where you select the linework. This break method has the minimum prompting to create a break since it has only one prompt that is used both to select the entity and specify the break point.

Prompts

Select Line, Arc, or Polyline at break point: *select linework*

Pulldown Menu Location: Edit > Break

Keyboard Command: breakat1

Prerequisite: A polyline

Chamfer By Chord Length

This command chamfers by a specified chord length. You can have a single chord or fit in a number of chords.

Before and after Chamfer By Chord Length of 25

Prompts

Select Polyline to Chamfer: *pick 1st line segment*

Select Adjoining Polyline Segment: *pick adjoining line segment*

Chord Length: 25

Number of chords <1>: *press Enter*

Pulldown Menu Location: Edit > Chamfer

Keyboard Command: chord_chamfer

Prerequisite: Two connected line segments

Change Elevations

This command will change the elevation of selected entities. It can move the entity to a specified elevation from its current elevation (absolute) or do a differential change by adding or subtracting a value from its current elevation. If Carlson points are selected, their attribute text and z axis coordinate are changed.

Prompts

Ignore zero elevations (<Yes>/No)? *press Enter* If you answer *No*, then entities with elevation 0 will be changed.

[A]bsolute or [D]ifferential Change <A>: A

Elevation to change to: 125 By using the Absolute option all entities selected are changed to the elevation 125.

Select Entities for elevation change.

Select objects: C

First corner: *pick a point*

Other corner: *pick a point*

Select objects: *press Enter*

If Carlson points are selected, the command warns:

This command DOES NOT change the elevations in the Coordinate file!

Use Coordinate File Utilities menu option F to update the file.

Pulldown Menu Location: Edit > Change

Keyboard Command: chgelev

Prerequisite: Something to change

Change Attribute Style

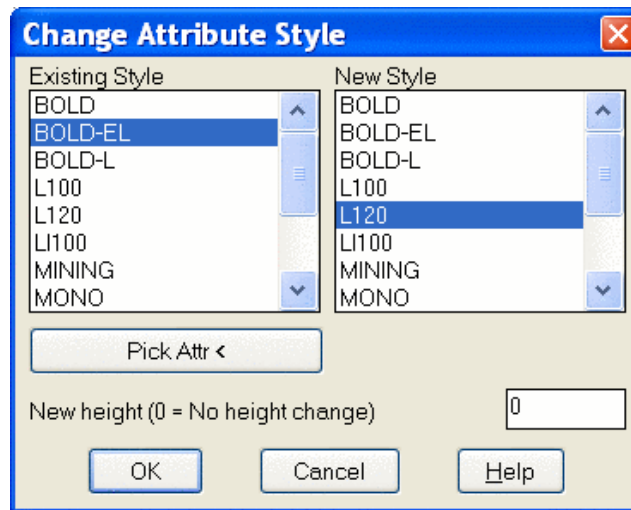

This command will globally change the text style of attributes on the drawing. This can be very useful if all the label styles (such as the point symbol attribute labels) on a drawing must be changed to accommodate a different plotting

specification. The default STYLE used for the point symbol attributes is PTXT.

Under **Existing Style**, select the style that is currently applied to the attributes you want to change. If you are unsure of the existing text style, select the **Pick Attr** button, then pick an existing attribute on the screen. When the dialog returns, the text style applied to that attribute will be selected in the list.

Select the **New Style** that you want to apply to the attributes.

Enter a **New Height** for the attributes. An entry of zero (0) will not modify the existing height.

Pulldown Menu Location: Edit > Change

Keyboard Command: chgattr

Prerequisite: You may want to use the *LIST* command to check the current Text size.

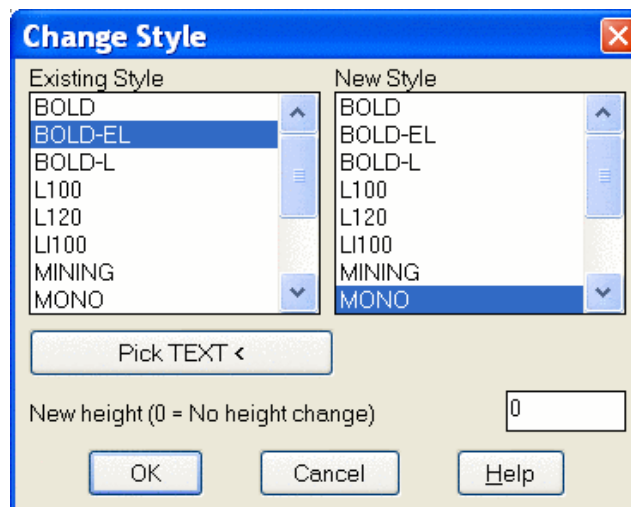

Change Style

This command will globally change the style and height of text on the drawing. This can be very useful if all the text sizes on a drawing must be changed to accommodate a different plotting scale.

Under **Existing Style**, select the style that is currently applied to the text you want to change. If you are unsure of the existing text style, select the **Pick TEXT** button, then pick an existing text entity on the screen. When the dialog returns, the text style applied to that text entity will be selected in the list.

Select the **New Style** that you want to apply to the text.

Enter a **New Height** for the text. An entry of zero (0) will not modify the existing height.

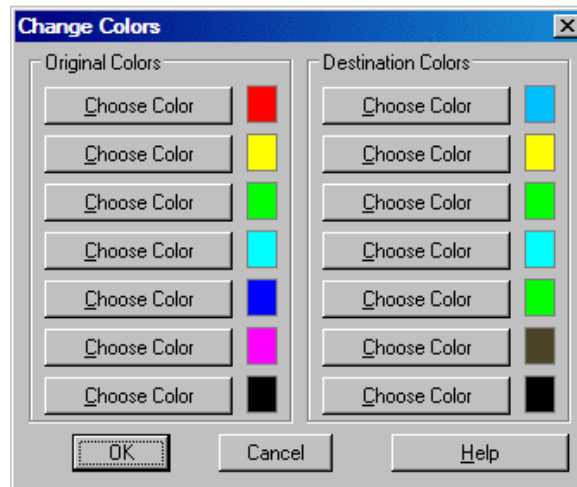

Pulldown Menu Location: Edit > Change

Keyboard Command: chgstyl

Prerequisite: Text entities

Change Colors

This command is designed to change the original color of existing entities in the drawing to a different color. This is done using the Change Colors dialog. You must match up the original colors of original entities to the preferred colors that they will change to. These "destination colors" are directly to the right of the original colors in the dialog (on the same row). You then click OK and select the specific entities on-screen that you want changed. This routine changes all entities in the drawing that you have chosen and that have an original color that has been changed. Do your dialog box color selections and matching up first, followed by *OK*. Then select the entities.

Prompts

Change Colors dialog Create your color change schemes and click OK.

Select entities to change colors.

Select objects: *select entities*

Pulldown Menu Location: Edit > Colors

Keyboard Command: chgcolor

Prerequisite: Entities whose colors are to be changed

Colors From Layer

This command sets selected entities to their current color instead of color BYLAYER. For each entity with color set to BYLAYER, this command looks up the color for the layer of the entity and sets the entity color to that layer color.

Prompts

Select entities to color from layer.

Select objects: *select entities*

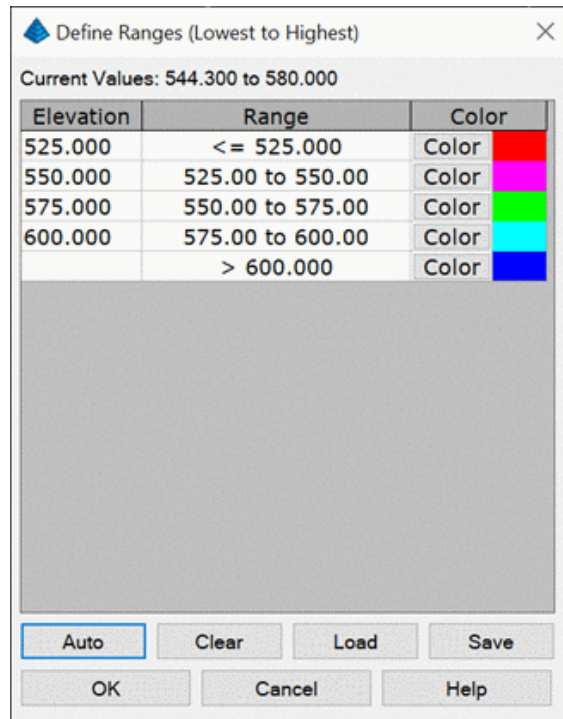

Pulldown Menu Location: Edit > Colors

Keyboard Command: layer2color

Prerequisite: Entities

Colors By Elevation

This command sets the color of entities based on the entity elevations. After selecting the entities, there's a dialog to define the colors for the different elevation ranges. The elevation range of the selected entities is shown at the top of the dialog.

Prompts

Select entities to color.

Select objects: *select entities*

Change Colors dialog Create your color change schemes and click OK.

Pulldown Menu Location: Edit > Change

Keyboard Command: ctrcolor

Prerequisite: Entities at elevation

Change Lineweight

This command sets the lineweight for the selected entities.

Pulldown Menu Location: Edit > Change

Keyboard Command: chglwt

Prerequisite: Entities

Change Block/Inserts Rotate

This is a command to set the angle of blocks by various methods. This command optionally can change the rotation of a block by twist screen angle, azimuth, entity segment or by follow polyline. It will work with Carlson point symbol blocks, or any block. For example, you may receive a drawing from another firm, insert it in, and then want to change the rotation.

Prompts

Twist by [<Twist screen>/Azimuth/Entity segment/Follow polyline]? *press Enter*

Enter angle relative to current twist screen <0.0>: 30

Select Symbols to Rotate. *pick symbol*

Select objects: 1 found

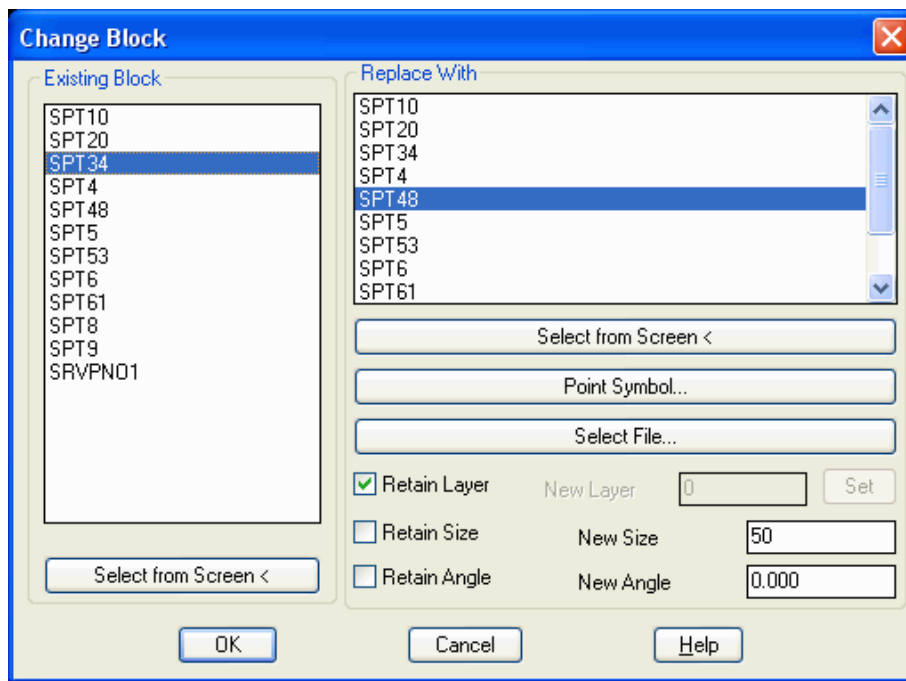

Pulldown Menu Location: Edit > Change > Block/Inserts

Keyboard Command: TWISTSYM

Prerequisite: None

Change Block/Inserts Substitute

This command is used to replace selected block(s) with a different block. The command optionally can change the size and rotation angle. This command will work with Carlson point symbol blocks, or any block. For example, you may receive a drawing from another firm and want to replace certain inserts with inserts of your own specification. In the dialog shown, we are replacing the block named NASTAR with a block named COHNORTH, which will be inserted at 50 scale and zero rotation.

Existing Block: Select the block name to be replaced. If the block name is unknown, choose the Select from Screen button, then select the block from the current drawing.

Replace With: Select the block that will replace the existing block. You may choose from the list of defined blocks, select an existing block from the current drawing, choose a point symbol from the standard Carlson point library, or select a drawing file.

Retain Size and Rotation: When checked, the new block will retain the size and rotation values from the old block.

New Size: Available if Retain Size and Rotation is not checked. Enter the size for the new block.

New Rotation Angle: Available if Retain Size and Rotation is not checked. Enter the rotation angle for the new block.

Pulldown Menu Location: Edit > Change > Block/Inserts

Keyboard Command: chgblk

Prerequisite: None

Change Block/Inserts Resize

This command resizes blocks inserts while maintaining their insertion position. When prompted to select objects, choose the inserts to resize. Note that this routine does not rescale attributes that may be associated with the selected inserts.

Prompts

Scaling Multiplier <0.5>: Enter the size scale factor.

Select symbols and blocks to scale.

Select objects: *select entities*

Pulldown Menu Location: Edit > Change > Block/Inserts

Keyboard Command: sizeblk

Prerequisite: block/inserts in drawing

Pivot Point Rotate by Bearing

This command allows you to rotate the selected entities from the drawing. The rotation angle is defined by the difference between a reference line and an entered bearing or azimuth. The reference line is defined by two points

that can be picked on the screen or entered by point number.

Prompts

Select entities to rotate.

Select objects: *select the entities*

Base pivot point ?

Pick point or point number: 2 The program then reads the coordinate value for pt#2 from the current CRD file.

Reference Bearing point ?

Pick point or point number: *pick a point*

Reference Bearing N 44d31'1" E The program then displays the reference bearing defined by the two points selected.

Azimuth/<Bearing (Qdd.mmss)>: 245.3030 Enter an A to input an Azimuth or enter the bearing. The above response is a bearing of South 45 degrees, 30 minutes, and 30 seconds East. The program then rotates the database to the new bearing.

Update viewports [Yes/<No>]? *press Enter.* This option rotates all the viewports in all the layouts of the drawing.

If Carlson Points are selected the program warns:

This command DOES NOT change the coordinates in the CoORDinate file!

Use CoORDinate File Utilities menu, Update CRD from Drawing.

This warning applies if the points entities are not linked to the CRD file. This link option is set in the Configure command.

Pulldown Menu Location: Edit > Rotate

Keyboard Command: brot

Prerequisite: None

Entity Insertion Point Rotate

This command allows you to rotate the selected entities where the rotation pivot point for each entity is the insertion point of the entity. The rotation angle will follow one of the following alignments: Twist screen, Azimuth, Entity Segment, Follow or Pick. This routine processes TEXT, MTEXT and INSERT entities only.

Prompts

Rotate by [<Twist screen>/Azimuth/Entity segment/Follow/Pick]? *F*

Select polyline to follow: *pick a polyline*

Select Entities to Rotate.

Select objects: *pick entities to rotate*

Flip text for twist screen [Yes/<No>]? *Y*

Rotating

Pulldown Menu Location: Edit > Rotate

Keyboard Command: ss_twist

Prerequisite: Entities to rotate

Select by Length

This command builds a selection set of linework objects in the drawing based on linework length. The length filter can be setup to get linework greater than or less than the specified value, or between two length values. After

specifying the length criteria, the program prompts for selecting the linework to check. The program then builds a selection set of those objects that pass the length filter. Then to use this selection set in other commands, enter "P" for previous at the "Select objects:" prompt.

Prompts

Select by greater, less or between lengths [<Greater>/Less/Between]? *press Enter*

Enter length for greater than: *1000*

Select objects to build selection set.

Select objects: *pick linework to filter*

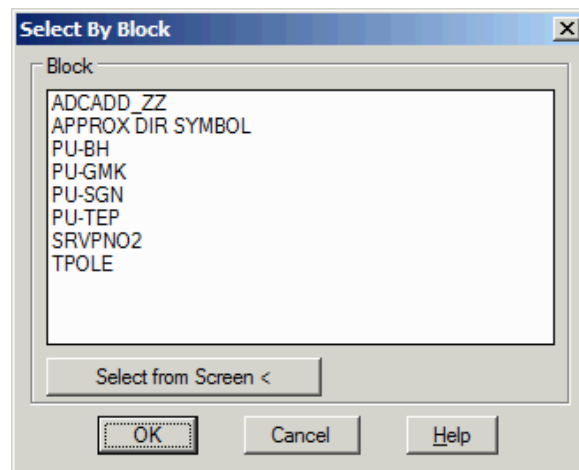

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: lenselect

Prerequisite: None

Select by Block

This command builds a selection set of blocks by using a block name filter. The block name to match is specified in a dialog with a list of all the block names in the drawing. Either pick from the list or use the Select From Screen button to get the block name by picking a block in the drawing. After selecting the block name, pick OK and the program will report how many of those blocks were found in the drawing and put into the selection set. This selection set is then ready to use at the next command with a select objects prompt. To use the selection set, type 'P' at the select objects prompt.

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: selblk

Prerequisite: Blocks

Select by Area

This command builds a selection set using inclusion and/or exclusion closed polylines. Entities within the inclusion polylines are selected and entities within the exclusion polylines are not selected. With the Window selection method, the entity must be entirely inside the inclusion area and entirely outside the exclusion area to be included in the selection set. With the Crossing selection method, an entity is added to the selection set if any part of the entity is inside the inclusion area.

Prompts

Select the Inclusion perimeter polylines or ENTER for none:

Select objects: *pick the closed polyline*

Select objects: *press Enter*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *press Enter*

Type of selection (Window/<Crossing>)? *press Enter*

Select objects to build selection set.

Select objects: *All These selected objects are checked with the inclusion/exclusion polylines.*

Select objects: *press Enter*

Built selection set with 43 objects.

Command: *Erase*

Select objects: *P* To use previous selection set created by Select by Area.

43 found

Select objects: *press Enter*

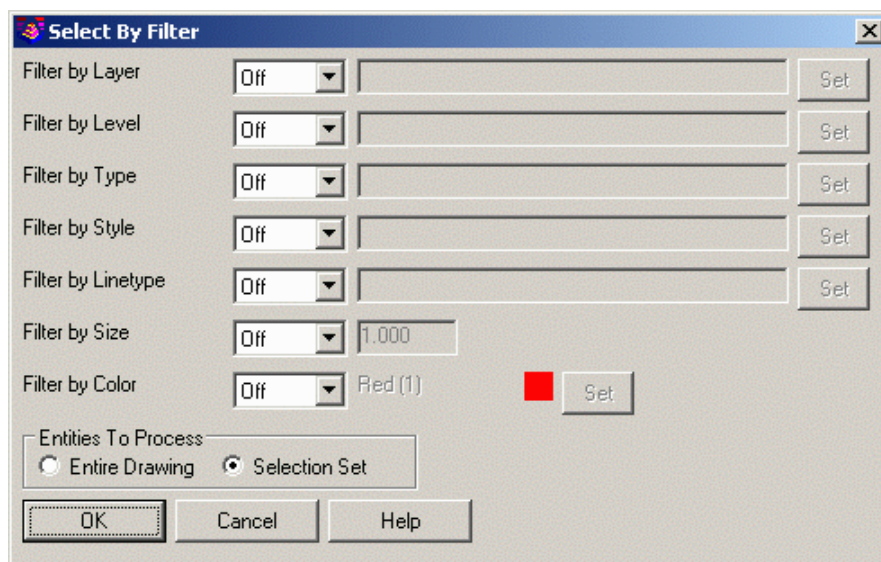

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: *ssgetarea*

Prerequisite: Closed perimeter polylines

Select by Filter

This command can be used to build a selection set of objects inside a drawing based on properties of layer, level, entity type, style, linetype, size and color. The open/closed filter applies to polylines. There is a dialog to define the filter of which properties to include and exclude. The Entities To Process option chooses between checking the entire drawing or prompting for a selection to process with the filter. The program then builds a selection set of those objects that resides on those layers. Then to use this selection set in other commands, enter "P" for previous at the "Select objects:" prompt.

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: *fsel*

Prerequisite: None

Select Similar

This command creates a selection set of all entities in the drawing with properties that match the selected entity. The properties filter uses the entity type and layer name. To use this selection set in other commands, enter "P" for

previous at the "Select objects:" prompt.

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: selectsim

Prerequisite: None

Text Enlarge/Reduce

This command will scale text entities up or down in size. The routine prompts for a scale multiplier and a selection set of text objects. If you want to enlarge the text enter a value greater than one. If you want to reduce text enter a decimal fraction such as .5. This would reduce the text size by 50%. This command is very useful if you have set up your drawing for one plotting scale and decide to change to a new plotting scale. The Change Text Size command can alternatively be used to set the text size to a specific value.

Pulldown Menu Location: Edit > Text

Prerequisite: Text entities to be changed

Keyboard Command: txtenl

Rotate Text

This command sets the rotation of the selected text to the current twist screen, an entered azimuth, or to align with a line or polyline. The text keeps the same insertion point and justification. The *Twist Screen* option sets the text rotation to align horizontal with the current twist screen. With the *Azimuth* option you can enter the angle or pick two points to define the text rotation. The *Entity segment* aligns the text with a selected line or polyline segment. The *Follow* option aligns the text with the closest polyline segment.

Prompts

Rotate by (<Twist Screen>/Azimuth/Entity segment/Follow/Pick)? *press Enter*

Enter angle relative to current twist screen <0.0>: 23

Select Text to rotate.

Select objects: *select the text*

Pulldown Menu Location: Edit > Text

Keyboard Command: twisttxt

Prerequisite: Text

Move Text

This command moves existing text entities by sliding at the text angle or perpendicular. This sliding method is equivalent to setting the crosshairs to the text angle and then moving with ORTHO on.

Prompts

Select Text to slide:

Select objects: *pick text entities*

Pick starting point for slide: *pick a point to begin sliding and then pick a second point for the new location*

Pulldown Menu Location: Edit > Text

Keyboard Command: annslide

Prerequisite: Text entity to move

Move Text with Leader

This command moves an existing text entity and creates a leader from a picked point to the new text location. The routine keeps track of the original text location and has an option to restore the text to the original without the leader. To use the Restore function, type R at the Command prompt. Also, to access the options for this command, type O for Options at the Command prompt.

Prompts

Select Label to Move (O for Options,R for Restore): pick any text entity

Pick start point for leader: pick the point where to draw the leader arrowhead

Pick end point for move: pick the end of the leader where to move the text

Select Label to Move (O for Options,R for Restore): O

When Options is chosen the "Move Text With Leader Options" dialog allows the user to customize the leader and label drawing settings:

Use MLeader: This option uses an MLeader for a combined label and leader. Otherwise a standard Leader entity is drawn with separate label.

Minimum Leader Length Scaler: If the distance of the move is less than this value, a leader will not be drawn.

Draw Horizontal Leader Tick: When checked, a horizontal leader tick will be drawn from the end of the leader towards the annotation.

Draw Arrowhead: Controls whether to draw an arrowhead at the end of the leader.

Curved Leader: Chooses between making a straight line or curved leader.

Draw Box Around Text: Creates a box around the text.

Minimum Length for Arrow Scaler: When the leader length is more than this amount, the arrowhead is drawn.

Arrow Size Scaler: Sets the size for the arrowhead.

Leader Offset Scaler: This is used to set the distance from the end of the leader and the annotation.

Leader Layer: The Use Separate Layer method places the leader on the specified layer from the dialog. The Use Current Layer method places the leader on the current drawing layer. The Use Text Layer method uses the label layer for the leader layer.

Keep Label Alignment: This option keeps the original text angle. Otherwise the leadered text is orientated horizontally to the current twist screen.

Move Multiple Labels: Use this option to select multiple text entities as a group for moving.

NOTE: The leader scaler units (Arrow Size Scaler, Minimum Length for Arrow Scaler, Minimum Leader Length Scaler and Leader Offset Scaler) are multiplied by the current horizontal scale value which is set under Drawings Setup.

Select Label to Move (O for Options,R for Restore): R

Select Label to Restore: pick a text that had been moved with the "Move with Leader" command previously. The selected label will be restored to its previous state.

Pulldown Menu Location: Edit > Text

Keyboard Command: movetext

Prerequisite: Text entity to move.

Move Attributes with Leader

This command allows you to move block attributes and to draw a dynamic leader to block insertion point. Leaders and arrowheads may be customized by selecting Options at the command line. The attributes are always justified left or right depending on which side the leader starts. The Restore option prompts to select a moved attribute label and then puts that block attribute back to the default position.

The Options dialog has these settings.

Minimum Leader Length Scaler: Specifies the minimum length, in terms of multiples of the attribute block's height, that the leader must be.

Prompt for Curved Leader Points: This option prompts for additional leader points and creates a smooth leader that goes through all the leader points.

Draw Horizontal Leader Tick: Specifies whether or not to draw a terminating tick (a short horizontal line segment sometimes referred to as a "hook line").

Draw Arrowhead: Specifies whether or not to draw an arrowhead at the end of the leader that points to the point entity.

Minimum Leader for Arrow Scaler: Specifies the minimum length of the leader, in terms of multiples of the attribute block's height, that the leader must be before an arrowhead is placed on it.

Arrow Size Scaler: A scale factor to apply to resize the arrowhead symbol.

Leader Offset Scaler: A distance indicating the desired offset from the point node to the tip of the leader.

Use Separate Leader Layer: Specifies whether or not to use a layer other than that of the identified point for the leader. Use the **Select** button to choose an alternative layer for the leader.

Block attributes before and after move with leader

Prompts

Select Label to Move [Options/Restore]: *select block attribute*

Pick label position: *pick point*

Select Label to Move [Options/Restore]: *press Enter to end*

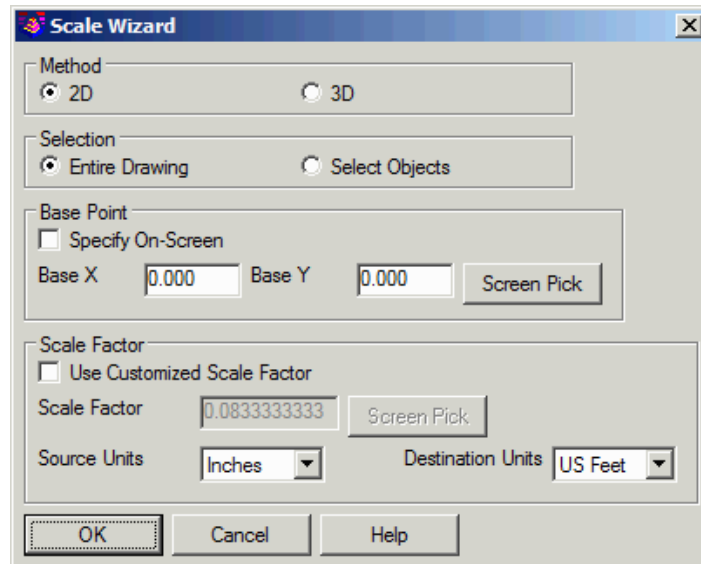

Pulldown Menu Location: Edit > Text

Keyboard Command: moveattrleader

Prerequisite: Block with attributes

2D Scale

This command will scale selected entities using a specified scale factor and base point. This 2D Scale method differs from the 3D Scale method in that it only scales the entities in the x,y coordinates and does not change the elevations of the entities. A case for using 2D Scale is when the x,y coordinates are in architectural units of inches and the elevation is in feet and you want to convert the x,y coordinates to feet. When the entities are at zero elevation, then 2D Scale makes no difference and it is better to use 3D Scale because it is faster.

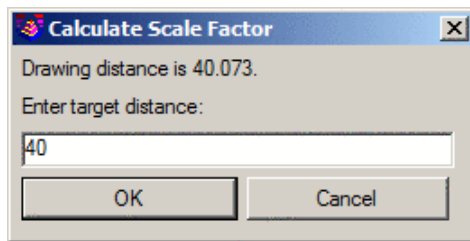

In the dialog shown here, you have the ability to determine what is scaled: the entire drawing or a selection set. If you choose Select Objects, you will be prompted to select the entities to scale after clicking the OK button. The Base Point acts as the center of the scaling operation and remains stationary. The base point you specify identifies the point that remains in the same location as the selected objects change size.

There are two methods for scaling entities: by Units Conversion or by a Customized Scale Factor. The dialog above shows one application of this routine, converting a drawing from architectural (Inches) to decimal units (US Feet) when the architectural units have the drawing x,y coordinates in inches and the elevations in feet. In this case, 2D Scale can be used to apply a 1/12 scale factor (0.08333333) to convert the inches to feet for the x,y coordinates and leave the elevations unchanged.

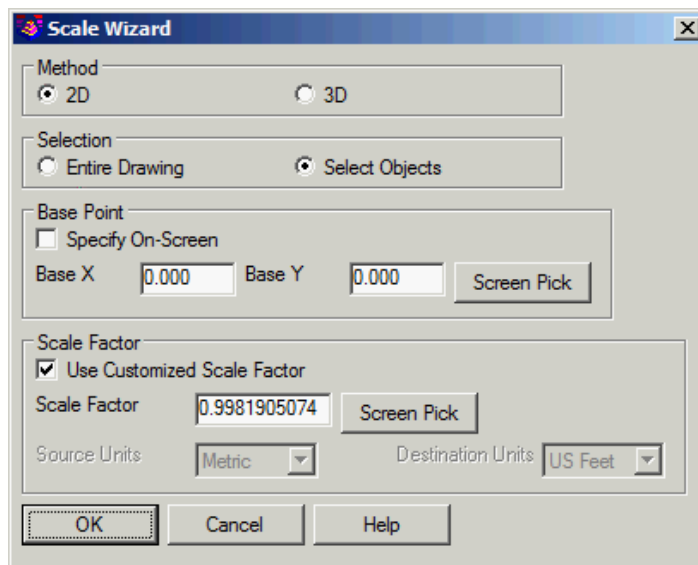

If the scale you want to apply is not a standard conversion, a manual scale can be entered by checking on the Use Customized Scale Factor checkbox. A scale factor greater than 1 enlarges the object. A scale factor between 0 and 1 shrinks the object.

To scale a drawing by a known distance on the plan (which is often the case when working with PDF imports) select the Screen Pick button. This will prompt you to pick the beginning and ending points along a known distance (like the bar scale above). The program will then report the current distance of the segment (in this example 40.073) and allow you to enter in the desired distance (which is 40 in this case).

The program will then calculate the proper Scale Factor to apply to the selection set.

Select entities to scale.

FILter/⟨Select entities⟩: *Select the entities whose size should change and press Enter to complete the selection process.*

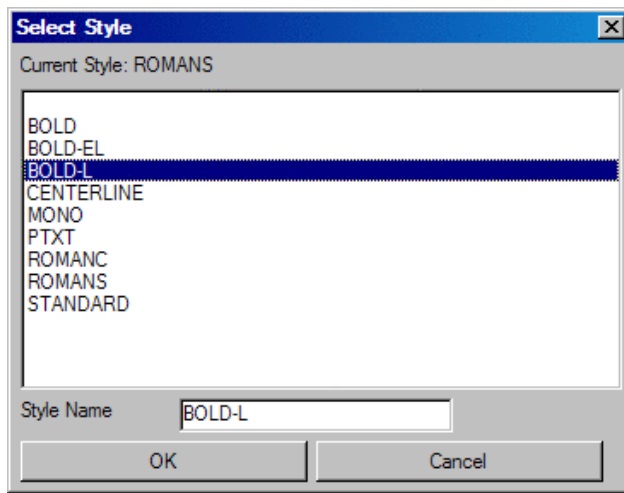

Pulldown Menu Location(s): Edit > Scale

Keyboard Command: scscale

Prerequisite: None

Change Text Font

This command can change multiple text entities to a user specified style. The routine prompts for a selection set of TEXT and/or MTEXT objects. Once the selection is made, the Select Style dialog appears. You can then select a text Style Name, such as MONO or ROMANS, that you would like to change to. Click OK. To the right on Style Name, you can enter a style name that does not exist. If you do, it will be created for you using the font with the same name.

Pulldown Menu Location: Edit > Text

Keyboard Command: chgtxtstyle

Prerequisite: Text entities to be changed

Change Text Size

This command will change the size of the selected text objects to the user specified size. The *Text Enlarge/Reduce* command also changes text size. The difference is that this routine sets the text to an absolute size whereas *Text Enlarge/Reduce* scales, or relatively changes, the text size.

Prompts

Select the text to size.

Select objects: *select the text*

Enter new text size: *enter value*

Pulldown Menu Location: Edit > Text

Keyboard Command: chgtxtsize

Prerequisite: Text entities to be changed

Change Text Width

This command changes the width of the selected text entities, after a new width factor is entered. The insertion point of each text entity is maintained as the routine lengthens or shortens the text.

Iron Pin	Text width = 1
Iron Pin	Text width = 0.75
Iron Pin	Text width = 1.5

Effect of different width factors on the same text line

Prompts

Select the text to change.

Select objects: *select text entities*

Enter new width factor <1.0>: *enter new width factor*

Pulldown Menu Location: Edit > Text

Keyboard Command: chgtxtwidth

Prerequisite: Text entities to be changed

Change Text Oblique Angle

This command allows you to change the text oblique angle on existing text in the drawing. The oblique angle for a specific text style is defined during the creation of the style. The default value for the oblique angle for text styles is 0 until defined to another value by the user. When changing the oblique angle, a minus (-) sign in front of the angle indicates a backward slant and a positive value results in a forward slant. Remember that the reference base point for the oblique change is always 0 degree. This means that if an existing text string has an oblique angle of 20, changing the oblique angle to 25 will not add 25 degrees to the existing 20 degree oblique resulting in a text oblique angle of 45 degrees, but rather a 25 degree oblique will be established by referencing 0 oblique as the base, and then slanting the text to 25 degrees. This works the same for slanting text backward as well as forward. Below is an example showing original text created with the default oblique angle of zero, then changed to a backward slant of 20 and a forward slant of 25 degrees.

Prompts

Select the text to change.

Select objects: *Select text to change oblique angle on.* Note that one or more text strings can be selected. When all desired text has been selected, press Enter.

Enter new oblique angle <0.0>: Enter the desired oblique angle.

Iron Pin	Oblique Angle = 0
Iron Pin	Oblique Angle = -20
Iron Pin	Oblique Angle = 25

Pulldown Menu Location: Edit > Text

Prerequisite: Text entities to be changed

Keyboard Command: chgtxtoblique

Convert Text To MText

This command converts regular text entities (DTEXT) into multi-line text entities (MTEXT). There are two processing methods. The Individual method converts each selected text entity into a separate MText entity. The Group method combines all the selected text entities into a single MText entity. The Group method applies to text entities that belong together such as text lines for a paragraph of text.

Prompts

Group text or process individually [Group/<Individual>]? press Enter

Select objects: *select the text entities to convert*

Pulldown Menu Location: Edit > Text

Keyboard Command: text2mtext

Prerequisite: Text entities

Fix Text Overlaps

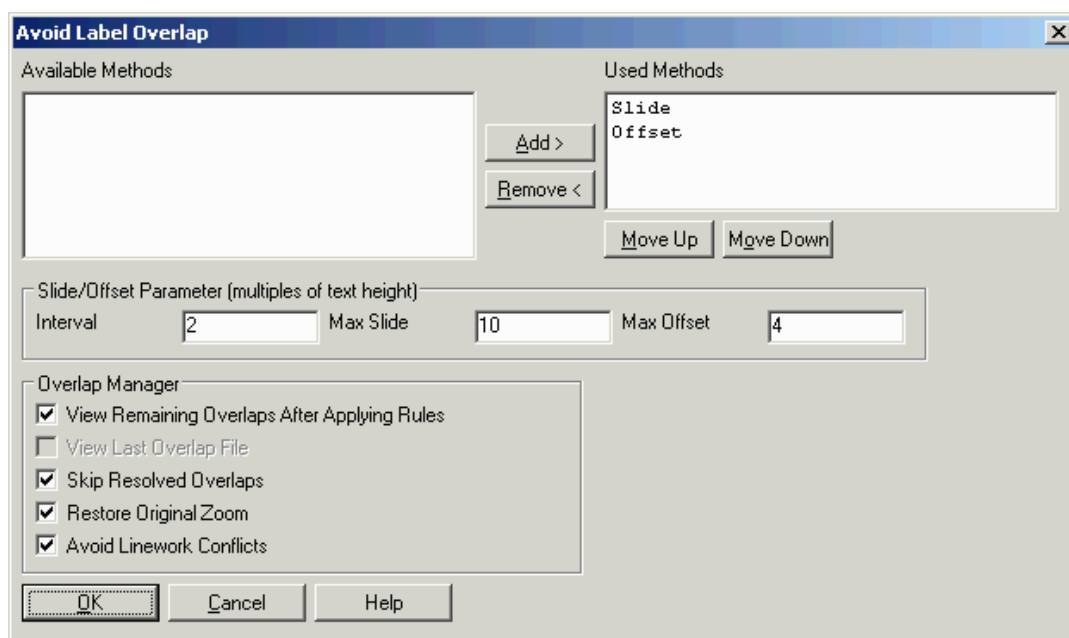

This command allows you to fix text overlaps for where different text overlap each other or where text crosses linework entities. You can either have the program automatically fix overlaps by using rules or just find the overlaps and step-through them to review and fix with CAD edits as needed.

In the options dialog, you can choose which rules to try for fixing the overlaps. The rules are applied in the order of the Used Methods list. If using a rule doesn't clear the text from overlaps, then the program tries the next rule.

The **Slide** rule moves the text parallel to text angle. The labels will not move past the **Max Slide** amount.

The **Offset** rule moves the text perpendicular to text angle. The labels will not move past the **Max Offset** amount.

The **Avoid Linework Conflicts** option checks for text overlaps with linework entities. Otherwise only overlaps with other text entities are checked.

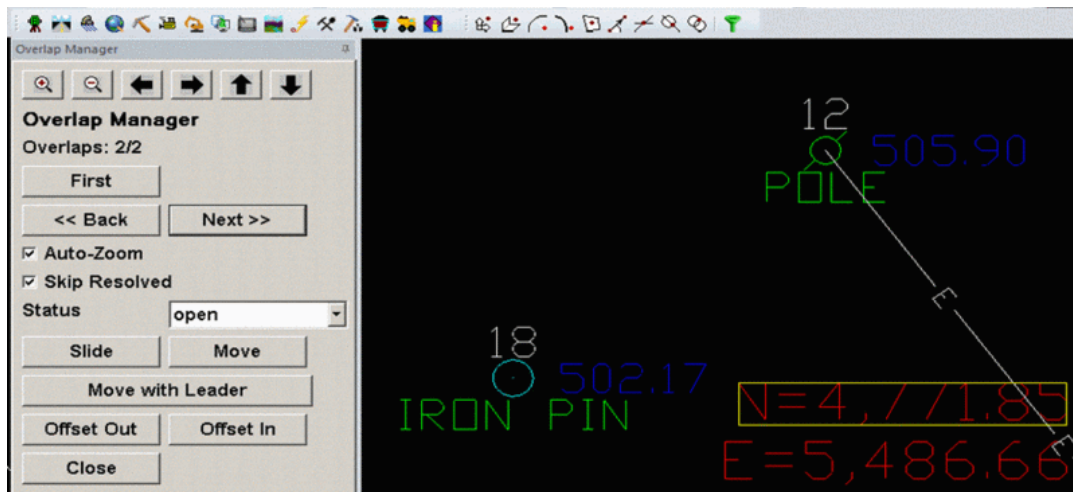

The **Overlap Manager** can be used to manually check and change label overlaps that aren't solved by the automatic rules. With the **View Remaining Overlaps After Applying Rules** option, any remaining overlaps will show in the Overlap Manager. Use the Back and Next buttons to step through each text conflict. The Auto-Zoom option zooms the dwg to show the current overlap. The Skip Resolved option shows only the unresolved conflicts. The Status option shows whether a conflict is resolved and lets you change the status. The Slide function moves text along the text angle. The Move function does an unrestricted move of the text. The Move With Leader function moves the text and creates a leader between the original and new locations. The Offset functions move the text perpendicular to the text angle.

When **View Last Overlap File** is checked, the Overlap Manager will return to the previous labels that were under review.

When **Skip Resolved Overlaps** is unchecked, the Overlap Manager will display all the labels that were moved by the command as a final check for you.

Restore Original Zoom will restore the zoom you were previously at before running the command.

Prompts

Avoid Label Overlap dialog

Select Labels for which to resolve annotation conflicts:

Select objects: *select entities*

Pulldown Menu Location: Edit > Text

Keyboard Command: textconf

Prerequisite: Text entities

Flip Text

This command will change the alignment of text entities by 180 degrees.

Pulldown Menu Location: Edit > Text

Keyboard Command: fliptext

Prerequisite: Text entities to be changed

Flip Text By Twist Screen

This command will change the alignment of text entities by 180 degrees for any selected text that are upside-down relative to the current drawing twist screen (dview twist).

Prompts

Select Text to Flip for Twist Screen.

Select objects: *pick the entities*

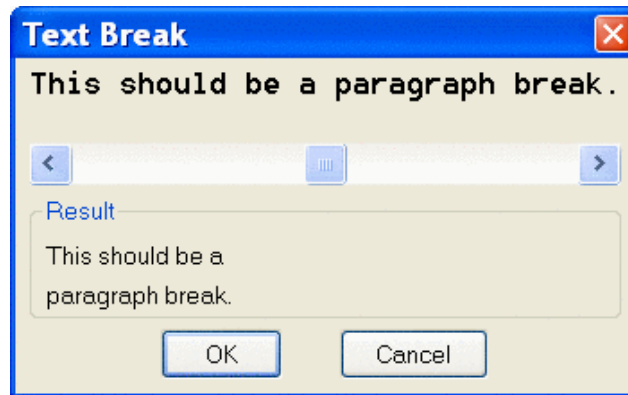

Pulldown Menu Location: Edit > Text

Keyboard Command: annflip

Prerequisite: Text entities to be changed

Split Text into Two Lines

This tool allows you to break a single line of TEXT into two separate lines. First, select the text string you would like to break. The Text Break dialog then appears. Initially, the slider is all the way to the right. Begin dragging it toward the left until it reaches the point where the split is at the desired position. Then choose OK to complete the break operation.

Pulldown Menu Location: Edit > Text

Keyboard Command: txtbrk

Prerequisite: Text entity to break

Text Explode To Polyline

This command converts the selected text into polylines. This function is generally used when preparing a plan view file for machine control, before using the *Write Polyline File* command.

Prompts

Select text to be EXPLODED.

Select objects: *select the text*

Substitute With Simple Font [<Yes>/No]? *Y*

1 text object(s) have been exploded to lines.

The line objects have been placed on layer 0.

Reading the selection set ...

Joining ...

Converting ...

Pulldown Menu Location: Edit > Text

Keyboard Command: textexp

Prerequisite: Text

Text Capitalization

This command sets the capitalization for the selected text. There are three options. The Proper method capitalizes the first character. The Upper method makes all the characters upper case. The Lower method makes all the

characters lower case.

Prompts

Set capitalization to [<Proper>/Upper/Lower]? *press Enter*

Select text to process.

Select objects: *pick text to set*

Pulldown Menu Location: Edit > Text

Keyboard Command: txtcaps

Prerequisite: Text Entities

Text Math

This command updates number labels by a math operation. After selecting the text to update, choose to add, subtract, multiply or divide, and then enter the amount.

Prompts

Select text entities.

Select objects: *pick the number labels*

Enter the operator (+ - * /): +

Enter a real number: 100

Enter number of decimals: 1

Pulldown Menu Location: Edit > Text

Keyboard Command: txtmath

Prerequisite: Text with numbers

Add Prefix/Suffix To Text

This command simply adds a prefix and/or suffix to the selected text entities. The strings to add are specified in a dialog. Then you select the text entities to update.

Prompts

Add Prefix/Suffix To Text dialog

Select text to process.

Select objects: *pick the text entities*

Pulldown Menu Location: Edit > Text

Prerequisite: Text entities to be changed

Keyboard Command: txtwrap

Remove Spaces From Text

This command removes leading and/or trailing spaces from the selected text entities.

Prompts

Trim all spaces from text on [Right/Left/<Both>]: *press Enter*

Select text to process.

Select objects: *pick the text entities to process*

Trimmed spaces from 1 text entities.

Pulldown Menu Location: Edit > Text

Keyboard Command: txtrmspace

Prerequisite: Text entities

Line Up Text

This command lines up the selected text entities along either a horizontal or vertical line position, an angle defined by two picked points, an existing text or following a polyline. There is an option to respace the text to prevent overlaps when the text is lined up.

19.80TC
19.30FS

Before and after Line Up Text

19.80TC
19.30FS

Prompts

Line up text on [Horizontal/<Vertical>/Linework/Angle/Text]: *press Enter for Vertical*

Pick vertical position: *pick a point*

Respace to clear overlaps [<Yes>/No]?: *press Enter*

Select text to process.

Select objects: *select the text to process*

Pulldown Menu Location: Edit > Text

Keyboard Command: txtlineup

Prerequisite: Text

Join Text Entities

This command combines two text entities by appending the second text to the first. The Words join method puts a space between each text. The Letter join method appends without a space.

Prompts

Select first text line: *pick a text entity*

Select text to add to first text line: *pick a text entity*

Join type as [Words/<Letters>]: *press Enter*

Pulldown Menu Location: Edit > Text

Keyboard Command: txtjoin

Prerequisite: Text entities

Replace Text

This command will replace one text string with another. For example, if the text LEGEL is on a drawing, you could use this command to replace it with LEGAL. This command has a couple method. The Copy method prompts to select an existing text label to copy and then select the text entities to replace with this copy. The Type method prompts for the old string to replace and the new string.

There is also the CAD command *Find and Replace Text* (FIND) includes more options, including replacing partial strings and searching attributes and MTEXT.

Prompts

Type in replacement string or copy another text label [<Type>/Copy]? *press Enter*

Select Text to Change

Select objects: *pick text*

Old string: *LEGEL*

New string: *LEGAL*

Replace all or prompt [All/<Prompt>]? *All*

Pulldown Menu Location: Edit > Text

Keyboard Command: chgtext

Prerequisite: Text entities to be changed

Move Attributes with Leader

This command allows you to move block attributes and to draw a dynamic leader to block insertion point. Leaders and arrowheads may be customized by selecting Options at the command line. The attributes are always justified left or right depending on which side the leader starts. The Restore option prompts to select a moved attribute label and then puts that block attribute back to the default position.

The Options dialog has these settings.

Minimum Leader Length Scaler: Specifies the minimum length, in terms of multiples of the attribute block's height, that the leader must be.

Prompt for Curved Leader Points: This option prompts for additional leader points and creates a smooth leader that goes through all the leader points.

Draw Horizontal Leader Tick: Specifies whether or not to draw a terminating tick (a short horizontal line segment sometimes referred to as a "hook line").

Draw Arrowhead: Specifies whether or not to draw an arrowhead at the end of the leader that points to the point entity.

Minimum Leader for Arrow Scaler: Specifies the minimum length of the leader, in terms of multiples of the attribute block's height, that the leader must be before an arrowhead is placed on it.

Arrow Size Scaler: A scale factor to apply to resize the arrowhead symbol.

Leader Offset Scaler: A distance indicating the desired offset from the point node to the tip of the leader.

Use Separate Leader Layer: Specifies whether or not to use a layer other than that of the identified point for the leader. Use the **Select** button to choose an alternative layer for the leader.

Block attributes before and after move with leader

Prompts

Select Label to Move [Options/Restore]: *select block attribute*

Pick label position: *pick point*

Select Label to Move [Options/Restore]: *press Enter to end*

Pulldown Menu Location: Edit > Text

Keyboard Command: moveattrleader

Prerequisite: Block with attributes

Consolidate Table

This command renumbers the first column of a table to remove any gaps in the numbering. For example, a table with rows labeled 1,3,4 would get renumbered to 1,2,3.

Prompts

Select Table to consolidate: *pick table entity*

Pulldown Menu Location: Edit > Table

Keyboard Command: crunchtbl

Prerequisite: table entity

Select by Elevation

This command builds a selection set of entities that are greater than, less than or in between a specified elevation that you enter in on the command line. Entities selected, based upon this elevation criteria, go into a selection set. With the Window selection method, the entities must be entirely inside of the inclusion area to be included in the selection set. With the Crossing selection method, an entity is added to the selection set if any part of the entity is inside the inclusion area.

Prompts

Select by greater, less or between elevations [<Greater>/Less/Between]? *press Enter*

Enter elevation for greater than: *19*

Ignore zero elevations [<Yes>/No]? *press Enter*

Select objects to build selection set. *pick objects*

Processing selection set ...

Built selection of 120 objects for elev more than 19.00.

To use type 'P' at Select objects: prompt.

Pulldown Menu Location: Edit > Selection Sets

Keyboard Command: zselect

Prerequisite: Entities

2D Align

This command will align (translate, rotate and scale) the selected objects using two pairs of source and destination control points. The difference between the first source point and first destination point determines the translation amount. The difference between the angle and distance from the first and second source points compared to the angle and distance from the first and second destination points determines the rotation and scale. The scale part of the alignment is optional. This 2D Align function is the same as the standard Align function except that this 2D Align function does not use elevations so that the alignment is always in 2D. The control points can be screen picked or entered by point numbers.

Before and after 2D Align

Prompts

Select entities to align.

Select objects: *pick entities to process*

First Source Point?

Pick point or point number: *pick point 84*

First Destination Point?**Pick point or point number:** *pick point 18***Second Source Point?****Pick point or point number:** *pick point 85***Second Destination Point?****Pick point or point number:** *pick point 19***Scale factor:** 1.00434258**Scale objects based on alignment points [Yes/<No>]?** *Y***This command DOES NOT change the coordinates in the CoORDinate file!****Use Coordinate File Utilities menu, Update CRD File from Drawing.****Pulldown Menu Location:** Edit > Align**Keyboard Command:** scalign**Prerequisite:** None

Entities to Polylines

This command converts selected lines, arcs, circles, 3DFaces, ellipses, splines, multilines, regions and solids into individual polylines. Use *Join Nearest* to convert adjoining lines and arcs into continuous polylines.

Prompts

Select lines, arcs, circles, 3DFaces, ellipses, splines, multilines, regions and solids to convert.

Select objects: *select entities***Pulldown Menu Location:** Edit > Polyline Utilities**Keyboard Command:** topline**Prerequisite:** lines, arcs or other entities to convert

Reverse Polyline

This command reverses the order of the line and/or arc segments of a *POLYLINE*. This can be useful in conjunction with the commands *Station Polyline*, *MXS by Polyline*, *Profile from Surface Model* or *CL File from Polyline*, since the polyline must be plotted in the direction of increasing stations. If it is more convenient to draft a polyline in one direction do so and then use the *Reverse Polyline* command to change its order. Temporary arrows along the polyline are drawn to graphically show the new polyline direction.

Prompts

Select the Polyline to Reverse: *pick a point on polyline*

Pulldown Menu Location: Edit > Polyline Utilities**Keyboard Command:** revpline**Prerequisite:** A polyline

Reduce Polyline Vertices

This command removes points from a polyline, without significantly changing the polyline. The offset cutoff is the maximum amount that the polyline can move horizontally and vertically when removing a point. For example, in a polyline with three points in a straight line, the middle point can be removed without changing the polyline. The

below image shows an example. If the offset cutoff were set to 0.10, the upper-left wedge would be removed, but the lower-right wedge would not.

Prompts

Enter the offset cutoff <0.1>: .5

Select polylines to reduce.

Select objects: *pick polylines*

Processed polylines: 1

Total number of vertices: 10

Number of vertices removed: 1

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: reduce

Prerequisite: A polyline

Densify Polyline Vertices

This command adds vertices to the selected polylines at the specified interval. These points are interpolated between existing points in the polyline. This command is the opposite of Reduce Polyline Vertices.

Prompts

Select polylines to densify.

Select objects: *select polylines*

Point interval <10.0>: *press Enter*

Testing Entity > 1

Added 17 points to 1 polyline.

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: densepl

Prerequisite: A polyline

Join Two Polylines

This command combines two linework entities to create a polyline. This command is simple variation of the Join Nearest command. The difference is that there is no options dialog and only two linework entities are processed. The linework entities can be polylines, lines or arcs. At the first entity prompt, you can enter Options to set the connection method for how to bridge a gap between the linework. The Direct method creates a segment across the gap. The Average method averages the endpoints into a single vertex. The Fillet method does a fillet with radius of zero.

Prompts

Select 1st entity to join [Options]: *pick polyline*

Select 2nd entity to join: *pick polyline*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: join2

Prerequisite: Linework to join

Merge Closed Polylines

This command combines two closed polylines that share a common boundary to create a single closed polyline. For example, this command can be used to merge a polyline for a lot that is too small with a polyline for a neighboring lot. There are two methods for merging. One method is to pick the two polylines to merge. The other method takes an area size and selection set of polylines and merges all the polylines with an area smaller than the specified amount.

Before and after Merge Closed Polylines

Prompts

Select polylines by individual pick or size filter [**<Pick>/Size**]? *press Enter*

Pick 1st closed polyline to merge: *pick a polyline*

Pick 2nd closed polyline to merge: *pick a polyline*

Done.

Pick 1st closed polyline to merge (Enter to end): *press Enter*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: mergepl

Prerequisite: two polylines to offset

Draw Polyline Blips

This command will draw temporary markers, "blips", at each polyline vertex. This allows you to identify the actual location of each vertex. The Blips can be drawn as temporary marks or lines. The lines method creates line entities that can be cleared from the drawing using Remove Polyline Blips. For temporary marks, any change to the viewport (pan, zoom, regen) will make the blips disappear. In later versions of AutoCAD, you can also click on the polyline to activate the grips which will remain visible during and after viewport changes.

Prompts

Draw as temporary marks or lines [**<Temporary>/Lines**]? *press Enter*

Select polylines to draw blips.

Select objects: *select polyline(s)*

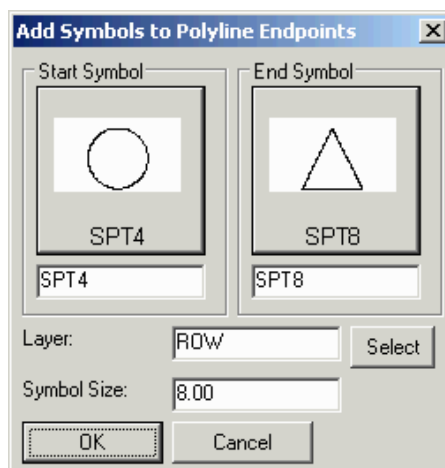

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: plblip

Prerequisite: A polyline

Draw Polyline Start/End

This command simply draws symbols at the start and end vertices of a polyline to give a visual indication of the polyline direction. The routine starts with a dialog to select the different symbols for the start and end, and to select the layer and size for the symbols. Then you select the polylines and the program draws the symbols.

Prompts

Polyline Start/End Settings dialog

Select polylines.

Select objects: *select polyline(s)*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: plends

Prerequisite: A polyline

Set Polyline Origin

This command sets the starting vertex of a closed polyline. Simply pick the polyline and then pick near the point to set as the starting point.

Prompts

Select Polyline: *pick a polyline*

Pick Near New Origin Point: *pick a point on the polyline to be the starting point*

Processing ...

Select Polyline: *press Enter*

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

Keyboard Command: plchgorg

Prerequisite: A closed polyline

Add Intersection Points

This command adds points into lines or polylines where there are intersections. This can be useful for other commands such as Auto-Annotate. For example in the drawing shown, Add Intersection Points adds points to the boundary polyline where the lot lines intersect. Then Auto Annotate for the boundary polyline will label the boundary distance along each lot. This routine does not add intersection points on arcs.

This command can also be helpful for surface modeling with breakline polylines. At crossings, breakline polylines must have the same elevations for surface modeling. This command has an option to average the elevations of the polyline vertices at the crossing when the elevation difference is smaller than the specified tolerance.

Prompts

Select lines and polylines to check.

Select objects: *pick lines or polylines*

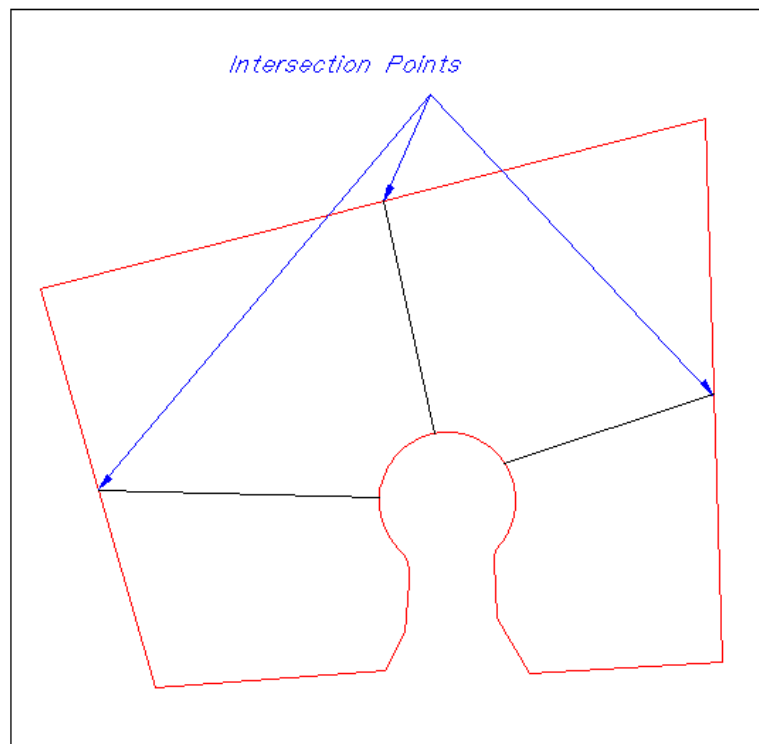

Average intersection elevations within tolerance [*<Yes>/No*]? *press Enter*

Elevation Tolerance *<0.1>*: *press Enter*

Reading the selection set ...

Adding intersection points ...

Added 3 intersection points.

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

Keyboard Command: addint

Prerequisite: Polylines or lines

Add Polyline Vertex

This command adds points into a polyline. First you select the polyline to modify. The existing polyline vertices are marked and then you can pick or enter the coordinates for the new points. A new point is inserted into the polyline at the nearest polyline segment. On a 3D polyline, the elevation of the new vertex will be calculated for you. You can continue to pick points to add or use the Undo option to remove the last point added. Press Enter when you are done.

There are two connection method. The Direct method adds the new point at the picked position. The Projected method finds the nearest perpendicular point along the polyline from the picked point and adds a vertex on the polyline segment at this projected position.

Prompts

Select polyline to add to: *pick a polyline*

Mode: Direct connection

Pick or enter point to add [Options]: *pick a point*

Pick or enter point to add (Enter to end) [Undo/Options]: *press Enter to end*

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

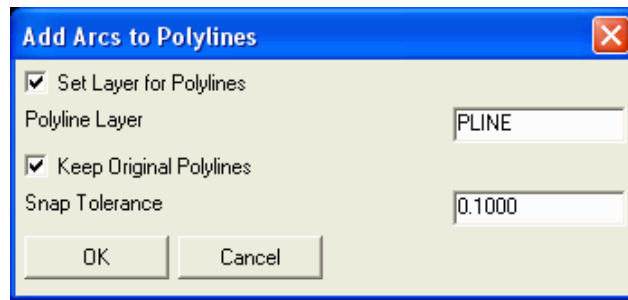

Keyboard Command: addpl

Prerequisite: A polyline

Add Polyline Arcs

This command replaces a series of short chord line segments in a polyline with an arc segment. This applies where you want to have a true arc instead of a series of line segments. In some cases, the CAD drafting has the arcs drawn as a series of short chords. Another application is to create an arc out of a series of connected survey points along the curve. The routine works by searching for a series of polyline vertices that fit within the specified tolerance with a best fit curve.

The options dialog allows you to set the layer for the new polylines. Otherwise the original polyline layer is used. There is an option whether to keep or erase the original polylines. The Snap Tolerance is the maximum offset allowed between the original points and the arc.

Prompts

Add Arcs to Polylines dialog

Select polylines to process.

Select entities: *pick the polylines*

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

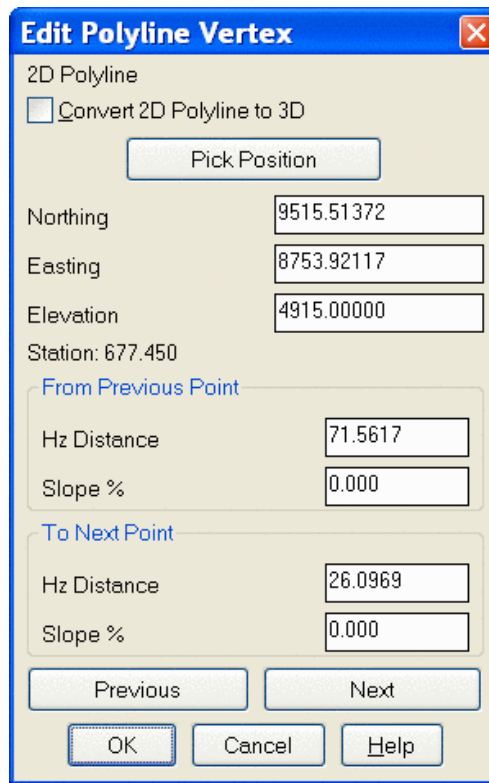

Keyboard Command: addplarc

Prerequisite: polyline

Edit Polyline Vertex

This tool allows you to make changes in the coordinates of vertices on all polyline types. Upon execution, you will be asked to select a polyline to edit. Upon selection, a temporary marker will be placed at all of the vertices of the polyline, making them easy to distinguish. You must then pick near the vertex you wish to edit. The following dialog appears.

At the top of the dialog it identifies the type of polyline as being 2D or 3D. In the case of 2D polylines, it allows you convert the polyline. You have the ability to type in new northing, easting or elevation values. You can also determine the 3D coordinate position by using distances and slope to/from adjacent points. As you change the values in the dialog, new values for derivatives are being calculated. For example, if you change the horizontal distances, the coordinates will change.

Prompts

Select polyline to edit: *pick a polyline*

Pick point on polyline to edit: *pick a point to be modified*

Edit Polyline Vertex dialog *click "Pick Position"*

Pick vertex position: *pick a new location for the vertex*

Edit Polyline Vertex dialog *click OK*

Make changes as needed. You will see the polyline vertices relocated based upon the new picked positions and coordinate changes. Use Previous and Next to move along the polyline. Note the dialog values changing.

Select polyline to edit (Enter to end): *press Enter to end*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: editpl

Prerequisite: A polyline

Edit Polyline Section

This command revises a segment of a polyline. Begin by picking a point on the polyline where you want to start editing. Then pick new points for the polyline. When finished picking new points press Enter, and then pick a point on the polyline to connect with the new points. The polyline segment between the start and end points is then replaced with the new points.

Prompts

Select polyline to edit: *pick the polyline at the place to start editing*

Pick intermediate point (Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *press Enter*

Pick reconnection point on polyline: *pick the polyline at the place to join*

Edit this contour by picking new points

Contour with segment replaced with new points

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

Keyboard Command: editpl2

Prerequisite: Polylines

Remove Duplicate Polylines

This command analyzes the selected polylines and erases any duplicate polylines found. They must be exactly the same for one to be deleted.

Prompts

Select lines, arcs and polylines to process.

Select objects: *select linework to process*

Reading the selection set ...

Removed 1 duplicate linework entities.

Pulldown Menu Location: Edit > Polyline Utilities > Remove Polyline

Keyboard Command: rmduplwork

Prerequisite: Polylines that have duplicates

Remove Polyline Arcs

This command replaces arc segments in polylines with a series of chords. Removing arcs is a prerequisite to some Carlson commands that don't handle arcs, such as *Break by Closed Polyline* and *Make 3D Grid File*. This process can add many vertices to the polyline. There are three methods to control the size of the chords and how many vertices are created. The Offset cutoff sets the maximum distance any point on the arc will be allowed to shift from the true arc to the chord position. The Length method sets the chord length. With the Length method, you can choose to create the chords entirely on the left or right side. Without setting the side, the program puts the chords

on the inside of the arcs. The Count method sets how many chords to replace each arc with.

Original polyline with reverse curve and polyline with arcs removed using Length method with chords put on top side

Prompts

Select polylines to remove arcs from.

Select objects: *pick polylines*

Use max offset or chord length method [<Offset>/Length]? *press Enter for Offset method*

Offset cutoff <0.5>: *press Enter*

Pulldown Menu Location: Edit > Polyline Utilities > Remove Polyline

Keyboard Command: rmarc

Prerequisite: polyline with arcs

Remove Polyline Segment

This command removes the user specified segment from a polyline. A polyline segment is the section between two vertices of the polyline. There are two options for removing the segment. Either the two vertices of the removed segments are averaged together to keep polyline continuous, or the segment is left missing in the polyline, which creates two separate polylines. The keywords Continuous and Break respectively identify these two options. The first image is of the Original Polyline. The second is with the Continuous Removal option. The third is using the Break Removal option.

Prompts

Break polyline at removal or keep continuous (Break/<Continuous>)? *press Enter*

Select polyline segment to remove: *pick point on polyline*

Select polyline segment to remove: *press Enter to end*

Pulldown Menu Location: Edit > Polyline Utilities > Remove Polyline

Keyboard Command: removepl

Prerequisite: A polyline

Remove Polyline Vertex

This command removes vertices from a polyline. First you select the polyline to modify. The existing polyline vertices are marked and then you pick near the vertex you wish to delete. You can continue to pick vertices to delete, press Enter when you are done.

Prompts

Select polyline to remove from: *pick point on polyline*

Pick point to remove: *pick point*

Pick point to remove (Enter to end): *press Enter to end*

Pulldown Menu Location: Edit > Polyline Utilities > Remove Polyline

Keyboard Command: rmvertex

Prerequisite: A polyline

Remove Polyline Blips

This command erases polyline blip lines created by Draw Polyline Blips.

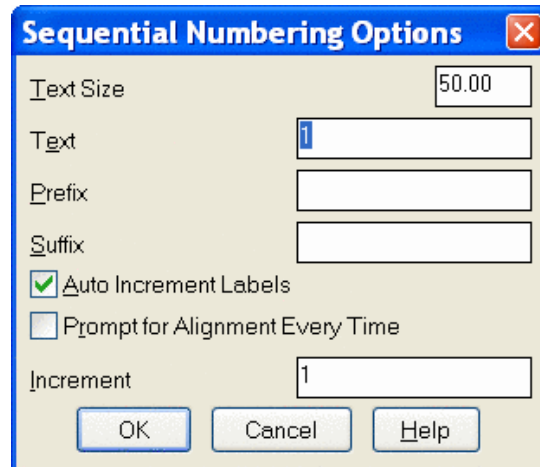

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: rmbliip

Prerequisite: Polyline blips

Create Polyline ID Labels

This command labels the selected polylines with either the entity "Handle", which can be seen with a list, or with unique text numbers, such as 1, 2, 3, 4, etc.. When using the Text option, the following window appears to choose the text settings.

Prompts

Select Polylines to label.

Select objects: *pick polyline*

Label polylines by Text or Handles [Handles/<Text>]? *press Enter*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: label_polys

Prerequisite: A polyline

Join Polyline By Trace

This command combines linework entities to create a polyline. This command is similar to Join Nearest. The difference is that this command processes a single polyline at a time instead of a selection set of polylines. This command prompts for a linework entity to start joining from. Then the program looks in the drawing at other linework to join to this polyline using the filter options from the dialog. All the options in the dialog are the same as Join Nearest except the Prompt For Linework To Join option which prompts for other linework to join to the polyline once the program has finished tracing. See the Join Nearest section of the manual for descriptions of the other options.

Prompts

Join Polyline By Trace dialog

Select line, arc or polyline to join: *pick an entity*

Select entity to join to start (Enter for none): *press Enter*

Select entity to join to end (Enter for none): *press Enter*

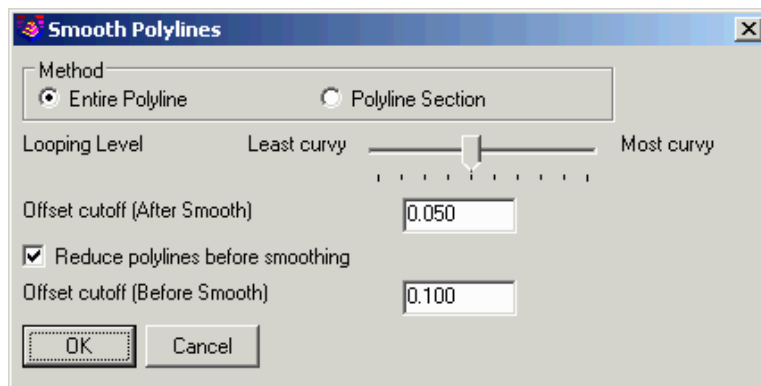

Pull-down Menu Location: Edit > Polyline Utilities

Keyboard Command: joinpoly

Prerequisite: Linework to join

Smooth Polyline

This command smooths the selected polylines using a modified Bezier method that makes the smooth polyline pass through all the original points and only smooths between the original points. Either the entire polyline can be smoothed or only a section of the polyline. When using Polyline Section, the program will prompt for points along the polyline to start and end the smoothing. The Looping Level controls smoothing amount. A higher factor gives more looping. The Offset Cutoff (After Smooth) is used to reduce the number of vertices in the final polylines. To not reduce vertices, set this Offset Cutoff to zero. The Offset Cutoff is the maximum amount that the polyline can move horizontally when removing a point. The Reduce Polylines Before Smoothing option removes extra vertices from the contours before smoothing. Removing points before smoothing gives the Bezier smoothing more freedom to make the polylines curvy.

Prompts

Smooth Polylines dialog

Select polylines to smooth.

Select objects: *pick polylines*

Smoothed 1 PolyLines

Total original vertices: 9 Total final vertices: 50

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: smoothpl

Prerequisite: A polyline

Make Arcs Tangential

This command adjusts polylines to make arcs tangential. The program holds the tangents and adjusts the radius as needed.

Prompts

Select polylines to process.

Select objects: *pick polylines*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: tang_pl

Prerequisite: Polylines with arcs

Check Elevation Range

This command analyzes a selection set of polylines, and highlights the ones that fall outside of a specified elevation range. There is an option to set the polylines that are outside of the range to zero. Every polyline vertex that is outside of the range will be highlighted with an X.

Prompts

Enter elevation range minimum: 0

Enter elevation range maximum: 4900

Select polylines to check.

Select objects: *pick polylines to process*

Found 1 polylines outside of elevation range.

Set polylines outside elevation range to zero elevation [Yes/<No>]? N

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: checkpl

Prerequisite: Polylines with elevations

Highlight Non-Perpendicular Intersections

This command highlights selected polylines that have T-intersections with other polylines that are non-perpendicular. For example, this command can be used to check that side lines for lots are perpendicular to the frontage polyline. For every non-perpendicular intersection, a temporary graphic arrow is drawn and the angle and the coordinates of the point are reported at the command line.

Prompts

Select the polylines to check.

Select objects: *pick polylines to check*

Warning: Polyline non-perpendicular by 0°00'47" at 5477.08,5047.53

Pulldown Menu Location: Edit > Polyline Utilities > Check Polylines

Keyboard Command: highlight_nonperp

Prerequisite: Polylines

Highlight Non-Tangent Polylines

This command highlights selected polylines that have non-tangent lineworks. For every non-tangent polyline, an arrow is pointed to the first non-tangent point, and the non-tangent angle and the coordinates of the point are reported at the command line.

Prompts

Select polylines to check.

Select objects: 1 found

Select objects: 1 found, 1 total

Select objects: *press Enter to end*

Polyline non-tangent by 32°15'26" at 1540.41,-182.05
Highlighted 1 non-tangent polylines.

Pulldown Menu Location: Edit > Polyline Utilities > Check Polylines

Keyboard Command: highlight_nontangent

Prerequisite: Polylines

Highlight Crossing Plines

This command highlights selected polylines that are crossing in the drawing and have different elevations at the crossing. Every intersection point where the polylines cross are marked with a temporary X. A report is provided at the end where the X and Y of the intersection points are displayed with the two Z values and the Z difference. The command has the ability to repair crossing polylines by inserting a vertex in each polyline at the intersection and assigning a common elevation at this intersection.

13	544426.2473	160413.1184	1500.0000	0.0000	1500.0000

Prompts

Select polylines to check.

Select objects: *pick polylines to process*

Ignore zero elevations [**<Yes>/No**]? *press Enter for Yes to filter out polylines at zero elevation*

Reading points ... 1677

Finding points on breaklines ...

19 crossing polylines are highlighted.

Use Report Formatter [**Yes/<No>**]? *press Enter for No.* Use the Report Formatter to customize the report layout or export to Excel.

Minimum delta Z to report **<0.0>**: 2

Add polyline vertices at intersections [**Yes/<No>**]? *Y*

Set 3D polyline to crossing contour elev or average elevs [**Set/<Average>**]? *press Enter for Average.* The Set option applies to crossing polylines where one polyline is a 3D polyline with varying elevations and the other polyline is a contour polyline with a fixed elevation. For this case, the Set method will hold the elevation of the contour polyline and set the 3D polyline elevation to match the contour. The Average method sets the elevation of the intersection point as the average of the crossing polyline elevations at that point.

Maximum delta Z to average **<1.0>**: *press Enter.* This option will only add the intersection point with the averaged elevation if the elevation difference is less than this tolerance.

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: xing_plines

Prerequisite: Polylines with elevations

Highlight Unclosed Polylines

This tool will evaluate polylines you select and highlight those that are open. It also provides options to close all or selected polylines from those found.

First select all polylines to evaluate. The tool will then display those that are open in a highlighted appearance. You will be offered an option to close all or selected polylines. If you wish to close all the open polylines, choose the All option. If you choose the Selected option you will be prompted to pick which polylines you want to close. As you pick each polyline it will be closed.

Prompts

Select the polylines to check.

Select objects: *pick polylines to process*

Open polylines are highlighted.

Close all or selected polylines [**All/<Selected>**]? *S*

Pick polyline to close: *press Enter to end or select polylines*

Pulldown Menu Location: Edit > Polyline Utilities

Keyboard Command: unclosed

Prerequisite: A polyline

Close/Open Polylines

These commands allow you close or open multiple polylines respectively. You can also use the PEDIT command to open or close polylines individually.

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

Keyboard Command: closepl, openpl

Prerequisite: A polyline

Buffer Offset

This command offsets a polyline, and maintains a fixed distance from the original polyline by placing an arc on convex corners. The standard *Offset* command can actually have a distance greater than the offset at corners. In the example shown, the distance between the corners of the original and offset polylines is 70.01, while the offset distance is 50.0. *Buffer Offset* makes an offset polyline that doesn't exceed the offset distance. This is useful when you want an offset that goes no further than the offset distance, such as wetland offsets. Later versions of AutoCAD can achieve the same effect using the standard *Offset* command by changing the system variable `OFFSETGAPTYPE` to 1.

Prompts

Enter the offset amount: 50

Select object to offset: *pick the original polyline*

Specify point on side to offset: *pick a point on the side to offset to*

Regular Offset

Buffer Offset

Pulldown Menu Location: Edit > Offset

Keyboard Command: boffset

Prerequisite: A polyline to offset

Change Polyline Width

This command sets the width of the selected polylines. In later versions of AutoCAD, the command *PEDIT* can also modify the width of multiple polylines.

Prompts

New width <1.0>: 2

Select Polylines/Contours to change width of:

Select objects: *pick polylines*

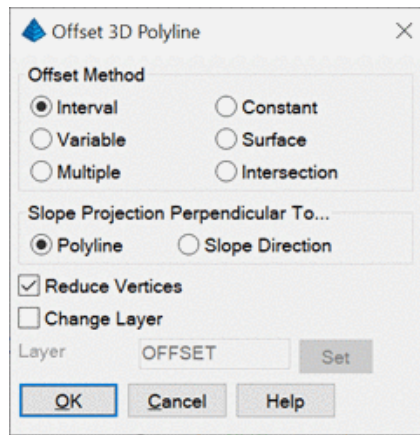

Pulldown Menu Location: Edit > Polyline Utilities > Edit Polyline

Keyboard Command: cwidth

Prerequisite: A polyline

Offset 3D Polyline

This command offsets a 3D polyline entity in both the horizontal and vertical directions. There are six offset methods.

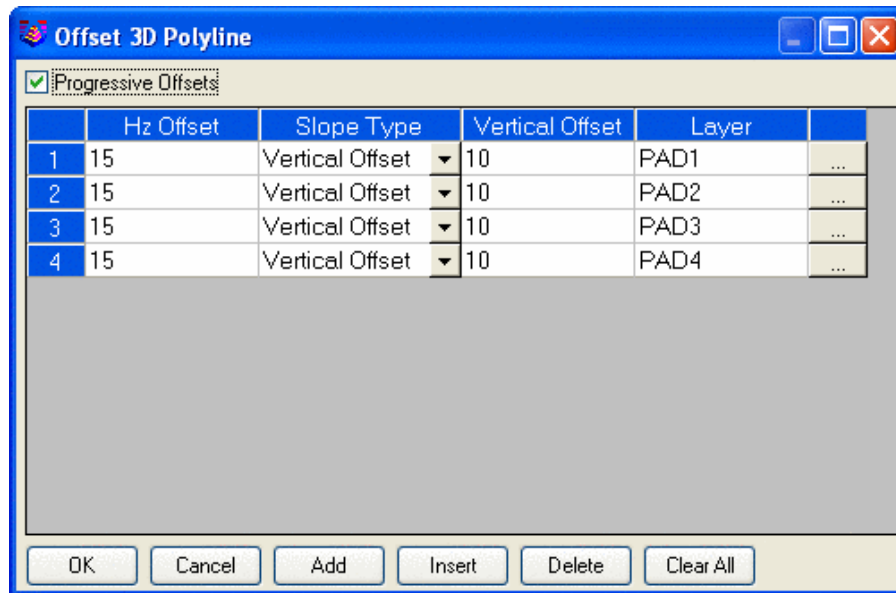

The **Interval** method applies one horizontal and one vertical offset to all the vertices of the polyline.

The **Constant** method has a horizontal offset and sets the elevation of the polyline to one constant elevation.

The **Variable** method allows you to specify each horizontal and vertical offset individually either by polyline segment or for each point. The vertical offset can be specified by actual vertical distance, percent slope or slope ratio.

The **Surface** method allows to offset/project a 3D polyline entity on to a surface (tin;flt;grd) based on cut and fill slope ratios.

The **Multiple** method allows multiple offsets of a 3D polyline with separate layers. User can add, insert and delete offsets rows and set individual layers. The option Progressive Offsets draws offsets progressively, i.e. successive offsets uses last drawn offset as base.

The **Intersection** method creates a 3D polyline at the intersection of two slopes from two reference 3D polylines.

The **Slope Projection Perpendicular To** option applies to sloping 3D polylines. The Polyline method creates the user-specified slope perpendicular to the polyline. The Slope Direction method accounts for the slope of the 3D polyline and makes the surface between the original and offset polylines to match the user-specified slope. For example, if the 3D polyline is at a 10% slope and the offset slope is at 2:1, then the Polyline method would create

surface slopes that are 2:1 perpendicular to the polyline while slightly steeper (1.96:1) for the actual slope that goes in the slope direction with the effect of the sloping 3D polyline. For the same case except with the Slope Direction method, the resulting slope perpendicular to the polyline is less steep (2.04:1) while the actual slope in the slope direction is exactly 2:1.

The **Reduce Vertices** option removes collinear points from the offset polyline.

The **Change Layer** option sets the layer for the offset polyline. Otherwise the offset polyline will use the layer of the original polyline.

Prompts

Enter the offset method [<Interval>/Constant/Variable/Surface/Multiple]: *press Enter*

Vertical/<Horizontal offset amount>: *15*

Percent/Ratio/Vertical offset amount <0>: *10*

Select a polyline to offset (Enter for none): *select a 3D poly*

Select side to offset: *pick a point*

Select a point on the graphics screen that is in the direction of the side of line to offset.

Select a polyline to offset (Enter for none): *press Enter*

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: offset3d

Prerequisite: 3D polyline

Fillet 3D Polyline

This command fillets two segments of a 3D polyline with the given radius. The standard *FILLET* command does not support 3D Polyline entities. Since 3D polylines cannot have arcs, this command draws the fillet arc as a series of short chords. The elevations along the curve are interpolated from the 3D polyline.

Prompts

Fillet corner of a polyline or intersection of two polylines [<Corner>/Intersection]? *press Enter*

Enter fillet radius <10.00>: *press Enter*

Select a corner point on polyline: *pick 3D polyline near meeting point of two segments*

Select a corner point on polyline: *pick 3D polyline near meeting point of two segments*

Select a corner point on polyline: *press Enter* (to end command)

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: fillet3d

Prerequisite: 3D polyline

Join 3D Polyline

This command joins *3DPOLY* entities into a single 3D polyline entity.

Prompts

Select the 3D polyline to join: *pick a 3D polyline*

Select the other 3D polyline to join: *pick a 3D polyline that has a common endpoint with the first 3 segments added to the polyline.*

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: join3d

Prerequisite: Plot the *3DPoly* lines to use for selection

Trim 3D Polyline

This command trims lines and polylines. The intersection for the trim location is calculated in 2D. The elevation at the intersection of the trimmed polyline is interpolated from the existing polyline vertices.

Prompts

Select trim edge polylines.

Select objects: *pick polyline for trim boundary*

Select polyline to trim: *pick polyline*

Select polyline to trim (Enter to end): *press Enter*

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: trim3d

Prerequisite: linework

Add Point by Two Slopes

This command inserts a vertex into a 3D Polyline between two points based on the slopes specified for these two points on polyline.

Prompts

Select polyline to process: *select a polyline*

Select first point on polyline: *select a point on polyline*

Enter percent slope from first point: *-1.0*

Select second point on polyline: *select a second point on polyline*

Enter percent slope from second point: *-1.0*

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: plzslopes

Prerequisite: 3D Polylines

Add Points At Elevation

This command inserts vertices into a 3D Polyline at a specific elevation, or elevation interval, by interpolating between existing elevations in the polyline.

Prompts

Add single elevation or elevation interval [Single/<Interval>]? *press Enter*

Enter Elevation Interval: 50

Select 3D polylines to process. *pick 3D polyline(s)*

Select objects: 1 found

Select objects:

Processing polylines ...

Added 10 points to polylines.

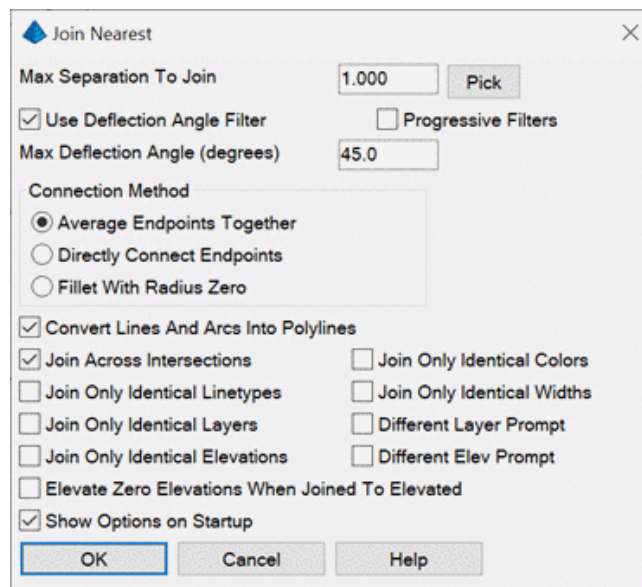

Pulldown Menu Location: Edit > 3D Polyline Utilities

Keyboard Command: addplz

Prerequisite: 3D Polylines

Join Nearest

This command joins lines, arcs and/or polylines together. While the *PEDIT-Join* command requires the endpoints to match, Join Nearest will allow you to join entities whose endpoints do not exactly meet. You specify the maximum separation distance to join, along with other options, in the dialog box shown below. Also you can join many entities at once.

Max Separation to Join: Entities whose endpoints are spaced apart greater than this value will not be joined. You may use the pick button to specify this value by picking two points on the screen.

Max Deflection Angle (degrees): This option will not join any lines if the angle between them is greater than this angle in degrees.

Progressive Filters: This option automatically runs Join Nearest multiple times with greater tolerances starting with tight tolerances and going up to the specified limits. This method helps ensure that the best matches get priority.

Connection Method: Determines how to connect the endpoints. See the illustration below.

1. **Average Endpoints Together:** New vertex will be located at midpoint between two original endpoints (see illustration below on left).
2. **Directly Connect Endpoints:** Original endpoints are connected with new segment (see the middle illustration below).
3. **Fillet with Radius Zero:** Same as the *FILLET* command using zero radius (see the illustration on right).

Convert Lines and Arcs Into Polylines: When checked, automatically converts lines and arcs into polylines. If not checked, lines and arcs are joined but remain separate entities.

Join Across Intersections: This option applies to cases where more than two linework endpoints come together such as a Y intersection. In these cases, there are multiple possible connections. When this option is on, the program will automatically choose one of the possible connections. Otherwise, the program will not connect any of them.

Join Only Identical Widths: When checked, only polylines with the same width will be joined.

Join Only Identical Layers: When checked, only entities on the same layer will be joined.

Join Only Identical Colors: When checked, only entities with the same color will be joined.

Join Only Identical Linetypes: When checked, only polylines with the same linetype will be joined.

Join Only Common Elevations: When checked, only endpoints located on the same elevation will be joined.

Different Layer Prompt: When Join Only Identical Layers is off, then this option will prompt for which layer to use when it finds a connection between two different layer names.

Different Elevation Prompt: When Join Only Common Elevations is off, then this option will prompt for which elevation to use when it finds a connection between two different elevations.

Elevate Zero Elevations When Joined To Elevated: This option applies when joining a combination of linework at elevation and linework at zero elevation. When checked, zero elevation vertices will get assigned the elevations from connected neighboring vertices.

Show Options on Startup: Controls whether to show the options dialog at the start of the command. When this option is turned off, you can type S for Settings at the command line to bring up the dialog.

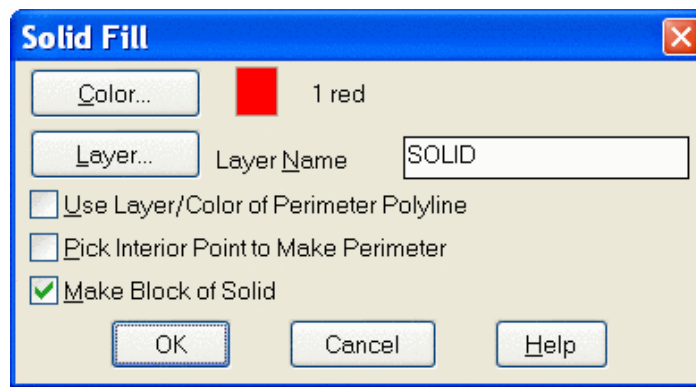

Pulldown Menu Location: Edit

Keyboard Command: nearjoin

Prerequisite: Lines or polylines to be joined

Solid Fill Polyline

This command fills the interior of closed polylines with 3D Faces to make the polyline areas appear solid. Closed polylines for exclusion areas can be used to exclude areas from the fill. Text can also be selected to exclude the text area from the fill. As an alternative, you can use the *HATCH* command, which creates an associative link between the hatch object and its boundary, interior boundary and any text that is excluded.

Prompts

Solid Fill Dialog Box

Use Layer/Color of Perimeter Polyline This option uses the layer and color of the perimeter polyline for the solid fill faces instead of those in the dialog box.

Pick Interior Point to Make Perimeter Instead of requiring a closed perimeter polyline, this option defines the perimeter by the boundary of the area around a picked point.

Make Block of Solid The solid is created by adjoining 3D faces. This option groups the 3D faces into a block.

Select Inclusion perimeter polylines.

Select objects: *pick closed polyline*

Select Exclusion perimeter polylines.

Select objects: *press Enter*

Select Text to Exclude from fill.

Select objects: *press Enter*

Pulldown Menu Location: Edit

Keyboard Command: solidfill

Prerequisite: A closed polyline

3D Entity to 2D

This command changes a 3D Line, Arc, Circle, Polyline, Hatch, Leader, Solid, 3D Face, Insert or Point to 2D. In 2D, the entity has the same Z coordinate for all vertices. When the program detects a 3D polyline with all vertices with the same elevation, there is an option to convert to a 2D polyline with this elevation. Otherwise, the entered elevation is used.

Prompts

Select/<Enter Elevation <0.00>: *press Enter*

Select entities for elevation change.

Select objects: *pick a 3D polyline*

3DPOLY to 2DPOLYLINE

Number of entities changed > 1

Pulldown Menu Location: Edit

Keyboard Command: 3dto2d

Prerequisite: None

View Menu

In addition to powerful CAD display and view commands, the Carlson View menu has some additional commands. The commands in the top section effect the screen display size and location, and the bottom section commands change layers.

Zoom Points

This command centers the screen to a user-specified point. The point can be specified by either the point number or description. The command searches the current coordinate (.CRD) file. Besides centering the screen, the magnification can also be changed. The default value is the current magnification. To zoom in, enter a smaller value and to zoom out, enter a greater value.

Prompts

Find by point number or description [<Number>/Desc]? N

Point number or range of point numbers to find <1>: 2079

We want to find point number 2079

Magnification or Height <179.50>: press Enter

Accept the default zoom magnification

Pulldown Menu Location: View

Keyboard Command: zoompnt

Prerequisite: A .CRD file

Zoom Selection

This command zooms the display to fit the selected entities. For example, if you run *Viewpoint 3D* and your viewport only shows two small dots of entities that are far apart, then you can use *Zoom Selection* to select the entities of one of these dots and quickly zoom the display to these entities.

Prompts

Select objects to zoom onto:

Select objects: *select entities*

Pulldown Menu Location: View

Keyboard Command: zoom_on

Prerequisite: Entities

Zoom Most

This command zooms to show the bulk of the entities in the drawing and avoid outliers. This zoom method is helpful when the drawing has a few entities far off and regular zoom extents results in showing small dots because it zooms out so far. When outliers are detected, there is a choice to either zoom to the bulk of the entities so you can see your main drawing, or to zoom to the outliers so you can see the entities that are far away. When no outliers are found, this command reports that none are found and does a regular zoom extents.

Prompts

Zoom to [<Most>/Outliers]? *press Enter for Most*

Pulldown Menu Location: View > Zoom

Keyboard Command: zoommost

Prerequisite: Entities

Zoom Extents on All Layouts

This command does a zoom extents for all the layouts in the drawing.

Pulldown Menu Location: View > Zoom

Keyboard Command: zoom_layout

Prerequisite: Layout

Align Paper With Model Space

This command works in paper space for a layout that has a viewport. The command aligns a point from the model view in the viewport to a point in paper space. The command prompts for the point in model space and the point in paper space. Then the command pans the model view to align with the picked point in paper space.

Prompts

Pick point in model space: *pick a point*

Pick point in paper space: *pick a point*

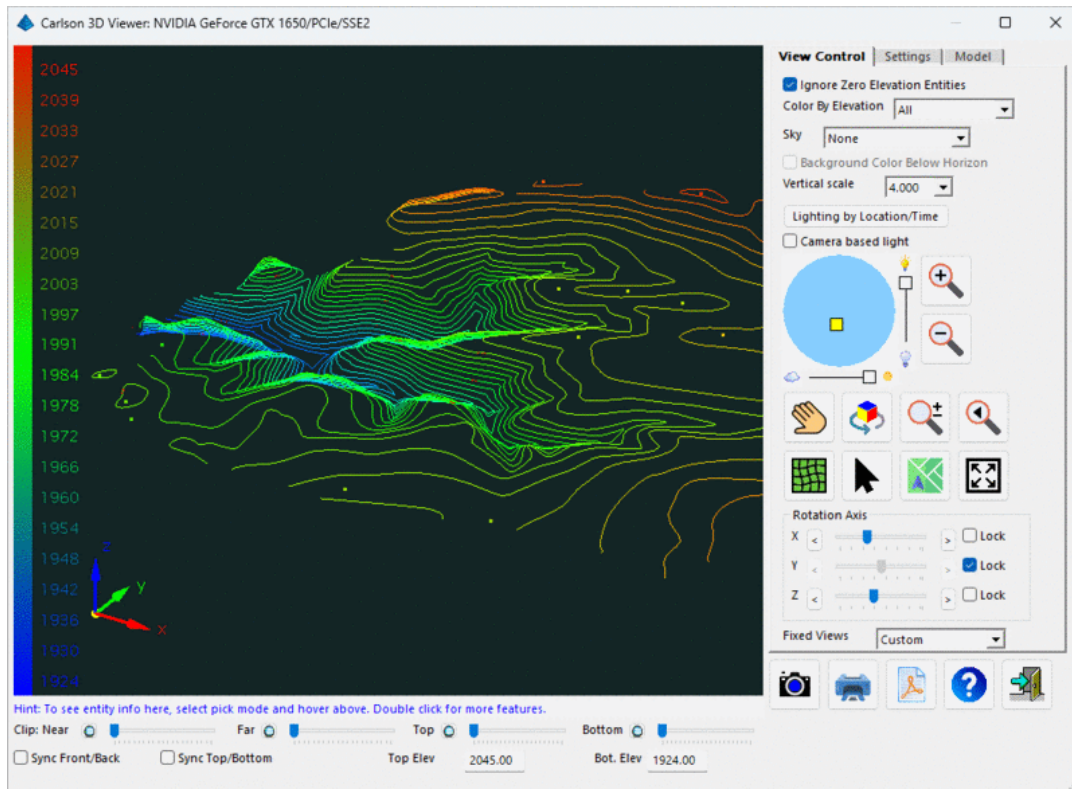

Pulldown Menu Location: View > Pan

Keyboard Command: alignps

Prerequisite: None

3D Viewer Window

This command loads the selected 3D faces, blocks, polylines, lines and points into a separate 3D Viewer window. Some of the features of this viewer include the ability to zoom in and out, pan, rotate around the X-Y-Z axes, and shade entities with user-positioned lighting.

The 3D Viewer Window has several mouse and keyboard controls that can assist with navigating the scene. These are listed below:

- Hold left-mouse button: Rotates/pans/zooms the scene based on the current mode. You can change the mode by clicking one of the control icons.
- Hold right-mouse button: Zooms in/out.
- Hold middle-mouse button: Pans around the scene.
- W key: Zooms in.
- S key: Zooms out.
- A key: Pans left.
- D key: Pans right.
- Q key: Pans up.
- Z key: Pans down.
- E key: rotates down.
- C key: rotates up.
- X key: rotates left.
- V key: rotates right.

Ignore Zero Elevations: When enabled, the 3D viewer will not display entities at zero elevation.

Color By Elevation: This will color the entities by elevation.

The *None* option will not modify the color of entities in the viewer.

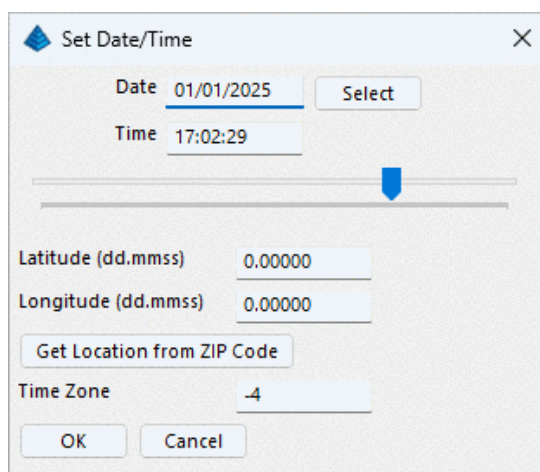

The *All* option will color all entities by elevation. The elevation color legend will be displayed on the left of the window and can be adjusted via the Color By Elevation Scale controls.

The *Surface Only* option will only color surface files by elevation. Other entities such as polylines and 3D faces will not be colored by elevation.

Sky: This option controls the background image for the 3D viewer. By default, no background image will be displayed. When a background image is displayed, you can toggle the **Background Color Below Horizon** checkbox to hide the bottom half of the background image.

Vertical Scale: This option sets the vertical scale factor for the 3D viewer.

Lighting by Location/Time: This button will display the below dialog, which allows you to set the lighting as it would appear at a specific location at a specific time.

Date/Time: These values set the date and time for the lighting. The **Select** button will allow you to pick the date from a calendar. The horizontal slider below the time will allow you to set the time of day.

Latitude/Longitude: These values set the location of the viewpoint

Time Zone: This value adjusts for the various time zones. Values should be integers representing GMT adjustments. For example, the Eastern Standard Time (EST) in the USA will use a value of -5.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display. Switch to Pan mode. Click and drag to pan.

Switch to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switch to Dynamic Zoom mode. Click and drag to zoom in and out.

Zoom Previous.

Toggle shading of 3D Faces and Surfaces. The shading of these entities is controlled by the Shading Mode control.

Switch to Pick mode. In this mode, hovering over an entity will display data such as the layer, entity type, elevation, and length. Double-clicking an entity permits additional actions to be performed on the entity including the ability to change the layer of the entity and/or setting the entity to an elevation of zero (0). When hovering over a surface, the coordinates and slope of the surface at the cursor location will be displayed. Clicking a point on the surface will set a new reference point from which the distance and slope to the cursor will be displayed (click a point, move the mouse to measure the distance/slope)

Resets the 3D view to plan.

Zooms to the extents of the view - ensuring that all objects in the viewer will be visible.

Rotation Axis: Permits the use of "slider" controls to orient the view in the X, Y and/or Z axis direction(s). Axes may be locked to prevent rotation about that axis.

Fixed Views: Permits the view to be displayed from one of six different directions:

1. Custom - This option will be displayed after manually rotating the view. Selecting this option will not return to a predefined view.
2. Plan View - Sets the view directly over the site, looking straight down. This is the same as the Reset to Plan button.
3. NE - Sets the view as shown from the Northeast looking to the Southwest in a downward direction.
4. SE - Sets the view as shown from the Southeast looking to the Northwest in a downward direction.
5. SW - Sets the view as shown from the Southwest looking to the Northeast in a downward direction.
6. NW - Sets the view as shown from the Northwest looking to the Southeast in a downward direction.

TIN Edit: This option is only available when using the Surface 3D Viewer Command and when using the Pick Mode. This allows you to modify TIN files by picking points on the surface.

Swap Tin Edge will rotate the edge of two adjacent triangles, but this is not possible for all triangles on the surface.

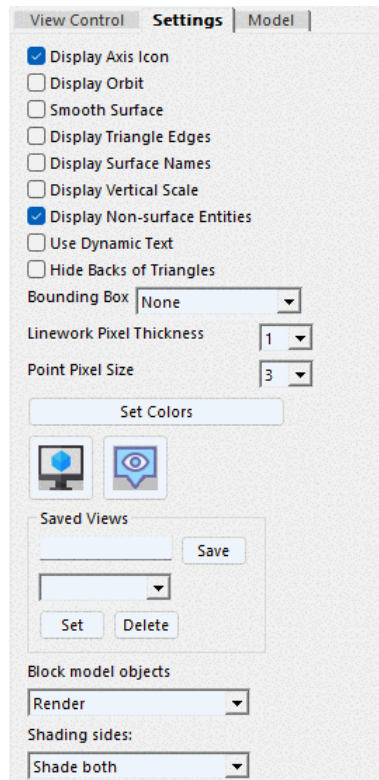

Add Breakline will add a breakline to the surface after selecting the starting and ending points on the surface.

Remove Point will remove a point on the surface and retriangulate the affected area.

Remove Triangle will remove a triangle from the surface, leaving a gap.

Set Point Elevation will allow you double-click a point on the surface and enter a new elevation for that point.

XRay Cursor: This option is only available when using the Surface 3D Viewer Command and when using the Pick Mode. This will hide the surface file near the cursor, allowing you to see objects beneath it.

Display Axis Icon: This option toggles the display of the X-Y-Z axes icon in the lower left corner of the window.

Display Orbit: This option toggles the display of a graphic guide for controlling the view angle and position using the mouse movements similar to the AutoCAD Orbit routine.

Smooth Surface: This option shades 3D faces in a way that appears to remove sharp transitions from one entity to another. This option affects both surfaces and solids.

Display Triangle Edges: This option toggles the edge lines of triangles that make up surfaces. The triangle edge color can be set with the **Set Colors** button.

Display Surface Names: This option toggles the display of the file names for the surfaces currently being viewed.

Display Vertical Scale: This options toggles the display of the vertical scale.

Display Non-Surface Entities: This option toggles the display of entities that have been tagged as "non-surface" by the Tag Non-Surface Entities/Points commands.

Use Dynamic Text: This option automatically resizes and rotates text entities so that they are always readable. When the option is first enabled, you will need to restart the viewer for the changes to take effect.

Hide Backs of Triangles: This option toggles the display of the backs of 3D Faces. When enabled, even the edges of the triangles will be hidden.

Bounding Box: This dropdown menu controls the display of a 3D box around the limits of the data.

The *None* option will not display the bounding box.

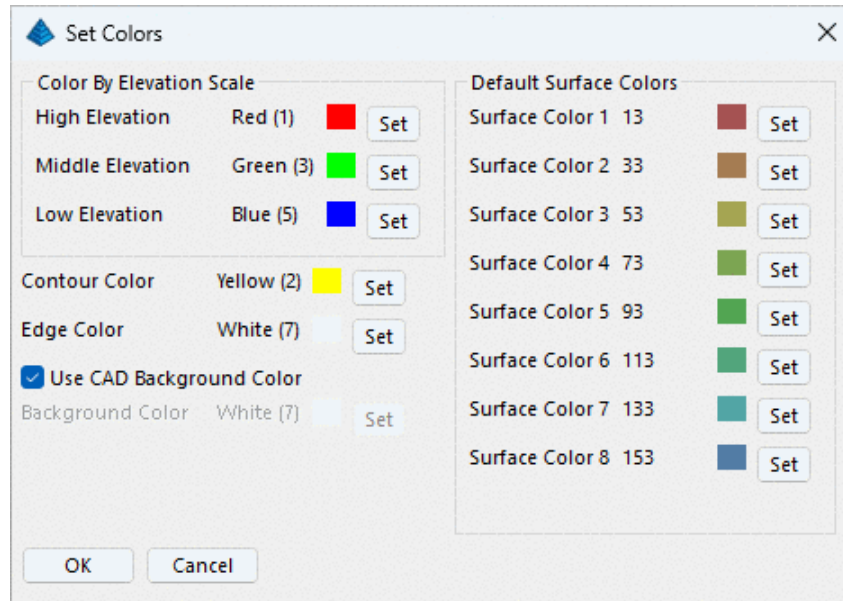

The *Box Only* option will display simple bounding box around the objects in the 3D view.

The *Box with Labels* option will display a bounding box with labels to indicate the range of X, Y, and Z values in the scene.

Linework Pixel Thickness: This value sets the display thickness for polylines.

Point Pixel Size: This value sets the display thickness for points.

Set Colors: This button opens the dialog shown below.

Color By Elevation Scale: These three colors are used for the Color By Elevation option. The program will interpolate between these colors for the color scale.

Contour/Edge color: These colors control the coloring for contours and triangle edges. Note that this does not affect the coloring of contour polylines that are loaded into the viewer, but only contours that are generated within the viewer.

Use CAD Background Color: When enabled, the background color of the 3D viewer will match the CAD background color. If this option is disabled, you can set a different background color.

Default Surface Colors: These colors set the default colors for new surfaces (Grid or TIN files) that are loaded into the 3D viewer. The colors of the surfaces may be changed after they have been loaded.

Control

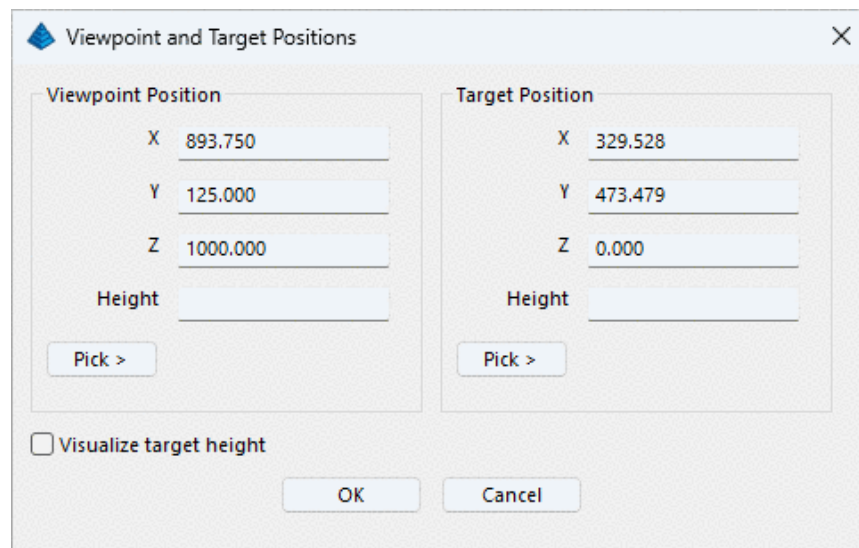

Action

Sets the drawing view to match the view shown in the 3D viewer window.

Sets the view position and target position by coordinates according to the below dialog.

Settings Controls

The positions can be entered in the edit boxes or you can use the respective **Pick >** button to pick a point in the drawing. The program will pick up the elevation of the surface for picked points and then the **Height** above the position can be entered. For example, to check sight distance the view position could be a point on a road at the driver's eye height and the target position could be the distance to check.

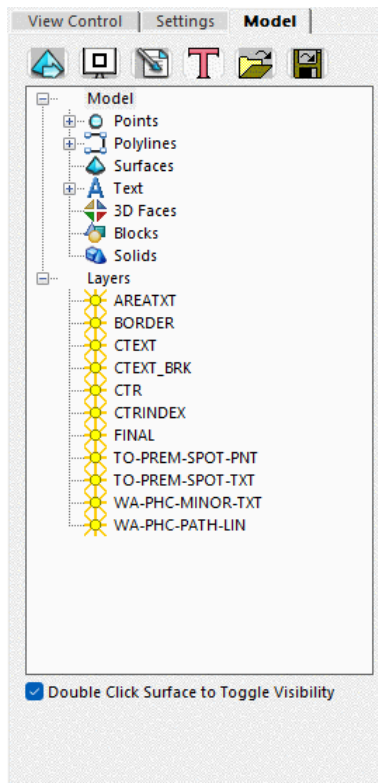

Saved Views: This option allows for naming and saving a 3D view for easy recall later. Named views can be selected from the pull-down and the active view can be deleted from the list.

Block Model Objects: This option has three choices when loading block model entities:

1. Leave as Points - this option will display blocks as points. In this mode, vertical stacks of blocks will be composited by color. For example, if 5 blocks of the same color are on top of one another, only one point will be displayed for those 5 blocks. This greatly reduces the number of points to be displayed in the viewer, but this viewing mode can be difficult to interpret for relatively homogeneous block models.
2. Render - this option will display each block as a solid.
3. Prompt Each Time - this option will prompt you to select the viewing mode each time a block model is loaded into the viewer.

Shading Mode: When the Shading control is enabled, the rendering of the shaded 3DFACE entities (usually used to represent a surface model) will vary based on:

1. Shade Front - Shades only the "positive" normal direction.
2. Shade Back - Shades only the "negative" normal direction.
3. Shade Both - Shades both the "positive" and "negative" normal directions.

Control

Action

Adds a single surface file to the 3D Viewer. You may also add one or multiple surfaces to the viewer by right clicking on "Surfaces" in the tree view.

Allows you to select more entities from the drawing to add to the 3D Viewer.

Allows you to edit properties of the currently selected entity.

Adds a text label into the scene. The program prompts for the text string, position and properties. The text can be drawn to CAD also.

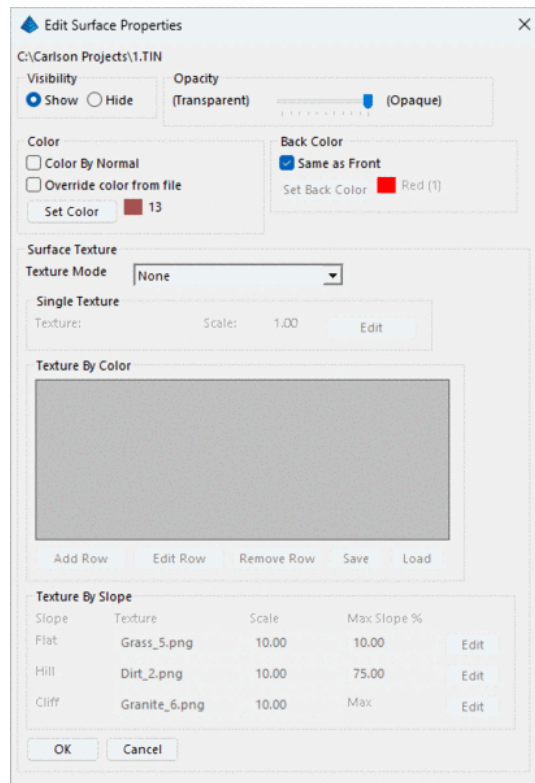

Loads a 3DX file into the viewer. This files contains all entities within a saved 3D View.

Save the entities in the 3D Viewer to a 3DX file.

Model Controls

Within the "model" tab is a "tree-view" of the various entities that comprise the view along with the listing of layers upon which the entities are found. Each "branch" in the tree view may be expanded by clicking the "+" symbol to the left of the branch. Entities may be displayed (thawed), hidden (frozen), or edited by right clicking the entity name and selecting the appropriate option. The below dialog shows the properties of a surface that may be edited.

Visibility: This option toggles the visibility of the entity.

Opacity (Surfaces/Solids): This option controls the opacity of the entity. A lower opacity results in increased surface transparency and is helpful for viewing sub-surface utilities such as Storm Sewer pipes and manholes.

Color By Normal (Surfaces/Solids): When enabled, this option will color the surface/solid by the direction perpendicular to each face. This view can be useful for identifying particularly steep areas of the surface. The Color By Elevation option must be disabled to show the designated color.

Override color from file: When enabled, this option will override any color assignments and display the entity as a single color. The **Set Color** button below this option sets the color for the entity. The Color By Elevation option must be disabled to show the designated color.

Back Color (Surfaces/Solids): This option controls the colors of the backs of triangles. If you disable the Same as Front option, you can set the backs of the triangles to a different color.

Texture Mode (Surfaces/Solids): This dropdown controls how texture images are applied to surfaces and solids.

None will not apply a texture to the surface/solid

Single Texture will apply a single texture image to the surface/solid. The texture image and the Scale of the texture may be set by clicking the Edit button.

By Color will set different texture images for each colored area of the surface. For example, surfaces output from RoadNet, may have a different color for the asphalt compared to ditches. This option will then allow you to apply one texture to the asphalt and another to the ditch. When enabled you can add a row to the Texture by Color table, first selecting a color and then specifying the texture to use in place of that color.

By Color, Single as Default is the same as the *By Color* option, but you are allowed to set a default texture for any colors not included in the list.

By Slope sets the texture of the surface according to the slope of the surface. When enabled, you will be able to set

a texture, scale, and max slope for each zone.

Shading Mode (Solids): This option controls which side of the 3D faces of the solid should be shaded.

These controls are always displayed at the bottom of the window.

Control

Action

The **Clip Plane** slider bars hide a portion of the view. Sliding the bar to the right will clip more of the view. This is helpful for producing quick "section" views of the data.

The **Near** slider bar will clip objects closer to the camera, while the **Far** slider bar will clip objects further away from the camera. Similarly, the **Top** and **Bottom** slider bars will clip higher and lower objects, respectively. Specific elevations for the **Top** and **Bottom** clipping plans may also be set by entering values in the **Top Elev** and **Bottom Elev** text boxes.

Clicking the cyan button to the left of each slider bar will allow you to pick a point in the 3D view to set the clip position.

The **Sync Front/Back** toggle will move both the **Near** and **Far** slider bars by the same amount when enabled. This can be used to hold a specific viewing width while. The **Sync Top/Bottom** toggle has a similar effect on the **Top** and **Bottom** slider bars.

This button takes a screenshot of the 3D Viewer. Several different image file formats are supported including bmp, png, jpg, xpm and gif. The image resolution and color depth may be set with this option.

This button exports the 3D Viewer to a PDF report with project information. The default project information is set under Carlson Configure > General Settings. The dialog that appears for this command is shown below.

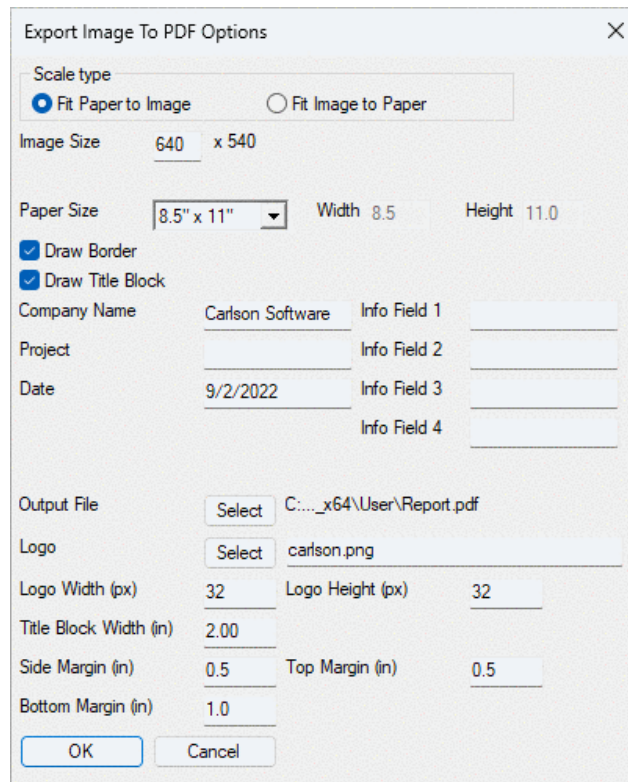

This button exports the 3D Viewer to a 3D PDF. This function is further described in the to the 3D Viewer to 3D PDF help article. Note that you must have access to the CADNET module in order to use this command.

This button opens the help documentation you are currently reading.

Exit the 3D viewer window.

Common Controls

Scale Type: This option controls how the image and the paper will be scaled to match one another. When the *Fit Paper to Image* option is selected, you will be able to manually set the **Image Size**.

Paper Size: This option sets the size of the PDF.

Draw Border: This option toggles the addition of a border around the PDF.

Draw Title Block: This option toggles the addition of a title block in the PDF. Information such as the **Company Name**, **Project**, **Date**, and **Logo** will be included in the title block. The logo may be selected by clicking the **Select** button and the dimensions may be specified in pixel dimensions.

Top/Side/Bottom Margin: These values set the margins around the PDF in inches.

Note regarding speed/performance: If the 3D Viewer Window is responding slowly to camera movements, changes to settings, etc, you may need to toggle a setting to improve performance. The setting is found under the Settings Pulldown Menu > Carlson Configure > General Settings. There you can turn off the "Use Software Rendering" setting. This setting is sometimes enabled after a program crash in an attempt to prevent further crashes. It acts a sort of "safe mode" with greatly reduced performance.

- To quickly view just a surface file, use the Surface 3D Viewer command.
- To visualize a site with animated vehicle controls, use the Surface 3D Fly-Over command.

Pulldown Menu Location: View > 3D View

Keyboard Command: cube

Prerequisite: Entities to display

3D Viewer 3DX Model File

This command selects a 3DX file to view in the 3D Viewer Window. The 3DX file contains all the elements for the scene. Use the 3D Viewer Drawing, 3D Viewer Surface File or Surface 3D FlyOver routines to create a 3DX file.

Pulldown Menu Location: View

Keyboard Command: cube_3dx

Prerequisite: .3DX file

Surface Object View Properties

This command sets the display properties for Carlson triangulation, grid and point cloud objects. The Color Style has these choices:

CAD Layer: Uses the color of the layer assigned to the surface object.

Object Colors: Uses the colors assigned to the surface object.

By Elevation: Colors by elevation range with blue for low elevations and red for high elevations.

By Normal: Colors based on the direction the surface is facing.

Pulldown Menu Location: View > 3D View

Keyboard Command: view_prop

Prerequisite: Carlson Surface Object

Draw Model View

This command draws a rectangular polyline in Model space for the outline of a selected viewport in Paper space. Before running this command, switch to a Layout that has the viewport to draw. The polyline is drawn in the drawing current layer. After drawing the polyline, the program switches to Model space.

Prompts

Pick viewport to draw:: *pick a viewport*

Pulldown Menu Location: View > Viewports

Keyboard Command: mview_draw

Prerequisite: Layout with a viewport

Set UCS to World

This command sets the UCS (user coordinate system) to the world coordinate system (WCS). Carlson command work exclusively in the world coordinate system. In AutoCAD, it is possible to change the coordinate system from WCS. If you receive a drawing in which the coordinate system is not set to world, use this command to restore the UCS.

Prerequisite: None

Keyboard Command: ucs_world

Set Level

This command assigns a level name to the selected entities. The level is an optional, additional name that can be assigned to entities and used to filter entities for making selection sets.

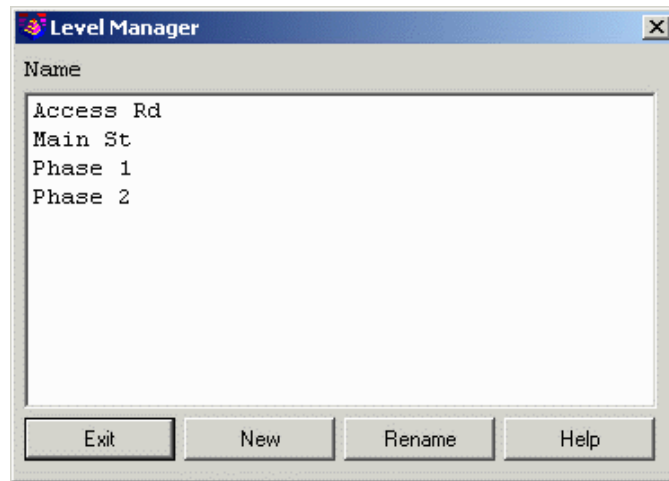

Pulldown Menu Location: View > Levels

Keyboard Command: levelset

Prerequisite: None

Level Manager

This command lists, creates and renames level names. The dialog shows the level names defined in the drawing. Use the New button to add a level name. Use the Rename button to change a level name.

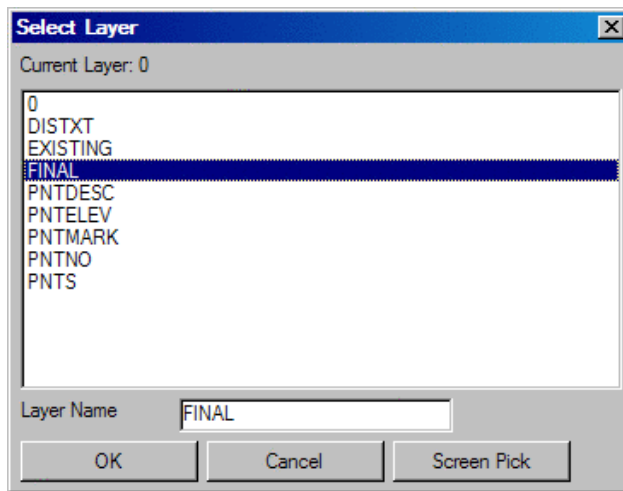

Pulldown Menu Location: View > Levels

Keyboard Command: levelmgr

Prerequisite: None

Change Layer

This command allows you to change the layer of a group of entities by selecting the group of entities. The layer name to assign can be either typed or read from an existing entity by picking an entity that is on the layer that you want to change the group to.

Prompts

Select entities to be changed.

Select objects: *pick entities*

The Select Layer dialog appears *select a layer from the list, or select Screen Pick*

If Screen Pick is chosen,

Pick entity with layer to change to: *pick another entity* This assigns the selected entities to the layer of this entity.
or

Enter new layer name or pick entity with layer (Enter/<Pick>)? *E*

Enter new layer name: *FINAL* This assigns the selected entities to the FINAL layer.

Pulldown Menu Location: View

Keyboard Command: lchg

Prerequisite: None

Freeze Layer By Selection

This command will freeze layers by picking entities on that layer. The entity selection is done by selection set for selecting one or more entities.

Prompts

Select entities on layers to be frozen.

Select objects: *pick entities*

Pulldown Menu Location: View

Keyboard Command: loff

Prerequisite: None

Restore Due North

This command twists the screen to make due north vertical. When the grid projection is specified under the Drawing Setup command, this command will prompt for whether to use grid north or geodetic north. When the grid projection is not set, this routine automatically twists to grid north.

Prompts

Twist to Grid North or True Geodetic North [<Grid>/True]? *press Enter*

Pulldown Menu Location: View > Twist Screen

Keyboard Command: twist4

Prerequisite: None

Restore Layer

This command thaws the layers that were frozen by the *Isolate Layer* command.

Pulldown Menu Location: View

Keyboard Command: restore

Prerequisite: None

Set Layer

This command allows the user to change the current layer to a different layer by picking an entity on that layer.

Pulldown Menu Location: View

Keyboard Command: lset

Prerequisite: None

Turn Off By Selection

This command will turn off layers by picking entities on that layer. The entity selection is done by selection set for selecting one or more entities.

Prompts

Select entities on layers to turn off.

Select objects: *pick entities*

Pulldown Menu Location: View

Keyboard Command: layeroffs

Prerequisite: None

Freeze Layer

This command will freeze layers by picking entities on that layer. The entity selection is done one at a time. As entities are selected, the layers are frozen.

Prompts

Pick entity on layer to be frozen: *pick an entity*

Freezing layer

Pick entity on layer to be frozen (U-Undo,Enter to end): *press Enter*

Pulldown Menu Location: View

Keyboard Command: pickoff

Prerequisite: None

Surface 3D Viewer

This command is identical to the 3D Viewer Window, except that this one loads a Carlson Grid GRD, TIN or FLT file. After the file is selected, the same viewer documented in 3D Viewer Window appears.

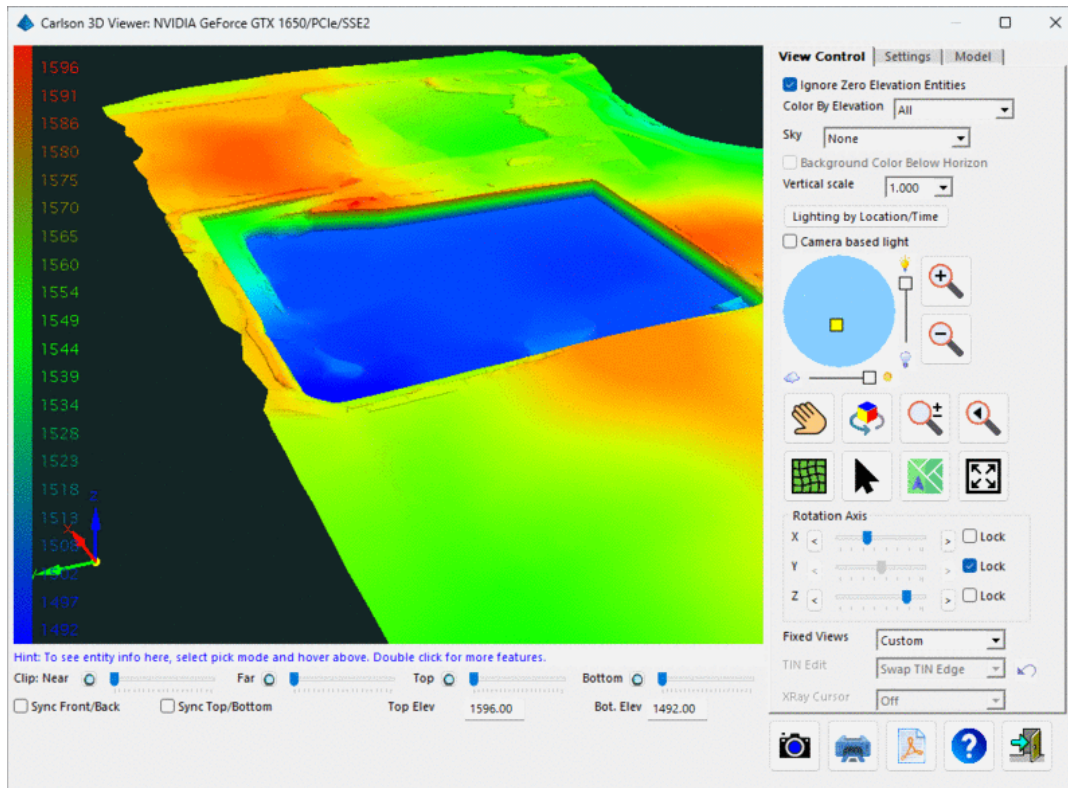

On the Model tab, the surface file is listed as an item in the model. Right-click on the surface name to access functions including:

Add Surface: Add another surface file to the scene

Add Multiple: Add many additional surfaces to the scene

Reload Surface: In case the source surface file is modified, reload the surface in the scene

Edit Surface Properties: Change display properties including colors, transparency, texture

- To view entities within the DWG file (and optionally, Carlson surface files), use the 3D Viewer Window command.
- To visualize a site with animated vehicle controls, use the Surface 3D Fly-Over command.

Pulldown Menu Location: View > 3D View, Civil > Surface > 3D Views

Keyboard Command: cube_surface

Prerequisite: Carlson surface (TIN, FLT, GRD) to display

Change Layer Color

This command changes the color of a layer. The layer is selected by picking an entity on the layer. Then the program prompts for the color to set.

Prompts

Select entity on layer: *pick an entity*
Color dialog

Pulldown Menu Location: View
Keyboard Command: lcolor
Prerequisite: A drawing entity

Add/Replace Layer Prefix

The Add Layer Prefix command adds a string to the beginning of all the layers in the drawing. The Replace Layer Prefix looks for a string at the beginning of layers and replaces this string with a new string.

Add Layer Prefix

Prompts

Layer prefix to add: PRE_

Replace Layer Prefix

Prompts

Old layer prefix to replace: PRE_
New layer prefix to add: POST_

Pulldown Menu Location: View > Layer Utilities
Keyboard Command: addLayerPrefix, replaceLayerPrefix
Prerequisite: None

Freeze Layer By Pick

This command will freeze layers by picking entities on that layer. The entity selection is done one at a time. As entities are selected, the layers are frozen.

Prompts

Pick entity on layer to be frozen: *pick an entity*
Freezing layer
Pick entity on layer to be frozen (U-Undo,Enter to end): *press Enter*

Pulldown Menu Location: View
Keyboard Command: pickoff
Prerequisite: None

Thaw Layer

This command thaws the layers frozen by the Freeze Layer command.

Pulldown Menu Location: View

Keyboard Command: lon

Prerequisite: None

Isolate Layer

This command freezes all the layers except the ones you select an entity on. The program prompts to see if you would like to retain the POINT layers which keeps the Carlson point layers from freezing. By default, these layers include PNTNO, PNTMARK, PNTDESC, and PNTELEV.

Prompts

Select objects on layers to isolate.

Select objects: *pick entities*

Retain POINT layers [Yes/<No>]? Press Enter

Isolate the wall layer by picking one wall line

Pulldown Menu Location: View

Keyboard Command: isolate

Prerequisite: None

Twist Screen: Standard

This command will twist the screen orientation to where something other than the north direction is toward the top of the screen/drawing. It does not do a coordinate rotation, the drawing coordinates remain unchanged. Use commands on the *Points* menu, such as *Rotate Points* and *Translate Points*, if you want to do a coordinate rotation or translation.

Prompts

This routine prompts for the twist angle then adjusts the screen and cross-hairs to that angle. This is a modification of the *DVIEW* command. The twist angle is always measured counterclockwise with 0 degrees being to the east/right.

Pulldown Menu Location: View > Twist Screen

Keyboard Command: twist1

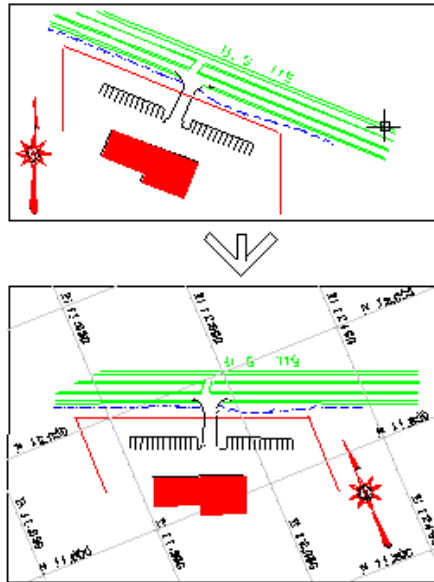

Prerequisite: None

Twist Screen: Line Pline or Text

This is a variation of the previous command that allows you to select a line, polyline, or text in your drawing that you want to be aligned parallel to the east-west direction of the graphics screen. Think of the entity you select as a pointer or arrow that will point in the east direction of the screen after you select it. Select the line, polyline, or text closest to the end point which you want to be the horizontal or east direction of the screen.

Prompts

Pick a line, polyline or text to make horizontal: *pick a line or polyline*

Pulldown Menu Location: View > Twist Screen

Keyboard Command: twist2

Prerequisite: None

Twist Screen: Surveyor

This command is another variation of twisting the screen that allows you to input an angle/azimuth that you want to be aligned parallel to the east-west direction of the graphics screen. Entering zero would align due north with respect to real world coordinates to the east or horizontal direction of the graphics screen. The Grid Projection Angle button prompts for a base point and sets the angle to the grid mapping angle. To use this option, the grid projection

must be assigned in the Drawing Setup command.

Pulldown Menu Location: View > Twist Screen

Prerequisite: None

Keyboard Command: twist3

Twist To 3D View

This command orients selected text, symbols and point attributes to face the current viewpoint. Typically, text and points are drawn to face up to plan view. When viewed in 3D from the side, this text can be hard to read. This command makes this text readable for the current view. Before running this command, the 3D view should be set by commands like Viewpoint 3D or Orbit. The entities are oriented to the current view by setting the extrusion

values for the entities.

Prompts

Select points, symbols and text to twist.

Select objects: *pick entities*

Pulldown Menu Location: View > Twist 3D Entities

Keyboard Command: twist3d

Prerequisite: Entities to view

Restore World View

This command is the companion to the Twist To 3D View command. This command resets entities so that they face up in plan view.

Prompts

Select points, symbols and text to restore.

Select objects: *pick entities*

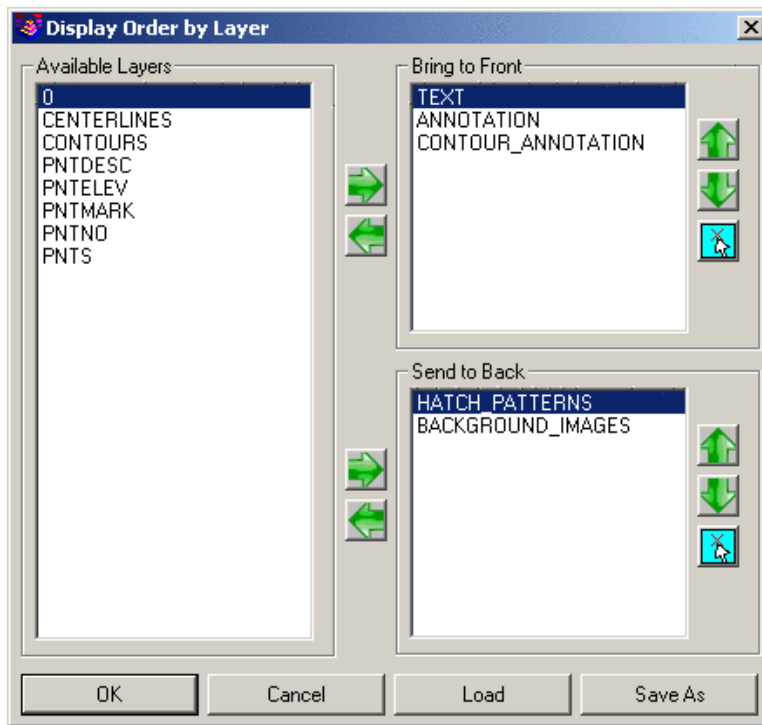

Pulldown Menu Location: View

Keyboard Command: untwist3d

Prerequisite: 3D Entities

Display Order by Layer

The Display Order by Layer command provides a handy method to quickly restore proper visibility to entities in a drawing when they become obscured by other entities (such as hatch patterns or raster image backgrounds). This command provides a combination of the popular *Send to Back* (draworderb) and *Bring to Front* (draworderf) routines (also found under the View>Display Order menu). The display order is applied to the current entities in the drawing at the time the command is run. It does not operate on newly created entities. So you need to run this command each time you want to apply the display order. The following dialog box appears:

Available Layers: The list of layers that are available in the current/active drawing.

Bring to Front: The layers to which the *Bring to Front* routine will be applied.

Send to Back: The layers to which the *Send to Back* routine will be applied.

Control

Action

Moves the selected layer(s) in the *Available Layers* group to either the *Bring to Front* group or the *Send to Back* group.

Moves the selected layer(s) from either the *Bring to Front* group or *Send to Back* group to the *Available Layers* group.

Promotes the selected layer(s) within the *Bring to Front* group or *Send to Back* group.

Demotes the selected layer(s) within the *Bring to Front* group or *Send to Back* group.

Allows the layer of a graphically selected entity to be assigned to either *Bring to Front* group or *Send to Back* group.

Navigation Controls

OK: Sets the display order to the layers in the drawing according to their rank and classification.

Cancel: Does not retain any layer rank or classification changes and does not commit any changes to entities in the drawing.

Load: Allows a previously saved Layer Order (.LO) file to be loaded into memory.

Save As: Saves the current layer rank and classification to a Layer Order (.LO) file.

Note:

- Layers that remain in the *Available Layers* category remain neutral.
- Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select multiple layers at the same time.

Pulldown Menu Location(s): View > Display Order

Keyboard Command: layer_order

Prerequisite: None

Thaw/On All Layers

This command turns on and thaws all layers in the drawing.

Pulldown Menu Location: View

Keyboard Command: loa

Prerequisite: None

Freeze Layer By Name

This command will freeze layers by entering the layer names in a dialog. Multiple layers can be frozen at the same time.

Pulldown Menu Location: View > Layer Control By Name

Keyboard Command: laz

Prerequisite: None

Thaw Layer By Name

This command will thaw layers by entering the layer names in a dialog. Multiple layers can be thawed at the same time.

Pulldown Menu Location: View > Layer Control By Name

Keyboard Command: lat

Prerequisite: Frozen layers

Isolate Layer By Name

This command will isolate layers by entering the layer names in a dialog. Multiple layers can be isolated at the same time. The layers are isolated by freezing all the other layers. Use the Restore Layers command to thaw the layers frozen by Isolate

Pulldown Menu Location: View > Layer Control By Name

Keyboard Command: lai

Prerequisite: None

Turn Off By Pick

This command will turn off layers by picking entities on that layer. The entity selection is done one at a time. As entities are selected, the layers are turned off.

Prompts

Pick entity on layer to turn off: *pick an entity*

Turning off layer

Pick entity on layer to turn off (U-Undo,Enter to end): *press Enter*

Pulldown Menu Location: View

Keyboard Command: layeroffp

Prerequisite: None

Turn Off By Selection

This command will turn off layers by picking entities on that layer. The entity selection is done by selection set for selecting one or more entities.

Prompts

Select entities on layers to turn off.

Select objects: *pick entities*

Pulldown Menu Location: View

Keyboard Command: layeroffs

Prerequisite: None

Turn On Layers

This command turns on the layers turned off by the Turn Off commands.

Pulldown Menu Location: View

Keyboard Command: layeron

Prerequisite: None

Lock Layers

The *Lock Layers* command will lock the layers for the layers of the selected entities.

The *Unlock Layers* command will unlock the layers for the layers of the selected entities.

Pulldown Menu Location: View

Keyboard Command: laylock, layunlock

Prerequisite: None

Show/Hide By Selection

This set of commands to select entities to hide, isolate or make visible.

Hide By Selection

This command prompts to select entities and then makes these entities invisible in the drawing.

Isolate By Selection

This command prompts to select entities and then makes all other entities in the drawing invisible so that only the selected entities are shown.

Show All

This command makes all the entities visible that were hidden by the Hide By Selection or Isolate By Selection commands.

Pulldown Menu Location: View

Prerequisite: None

Keyboard Command: hidess, isolatess, showss

Save/Restore Layer State

The *Save Layer State* command stores to a file all the layers in the drawing and their current status of color, freeze/thaw, on/off, and linetype. The layer state file has a .LAY extension. Later versions of AutoCAD include the ability to save and restore layer states, found in the layer dialog box.

The *Restore Layer State* command sets the drawing layers and their status from the layer information in a layer state file (.LAY file). If a layer from the layer state file does not exist in the drawing, the program will create the layer. Besides the Carlson format, the Land Desktop layer state format, which is also uses a .LAY extension, is supported by this command.

Pulldown Menu Location: View

Keyboard Command: savelay, restlay

Prerequisite: None

Draw Menu

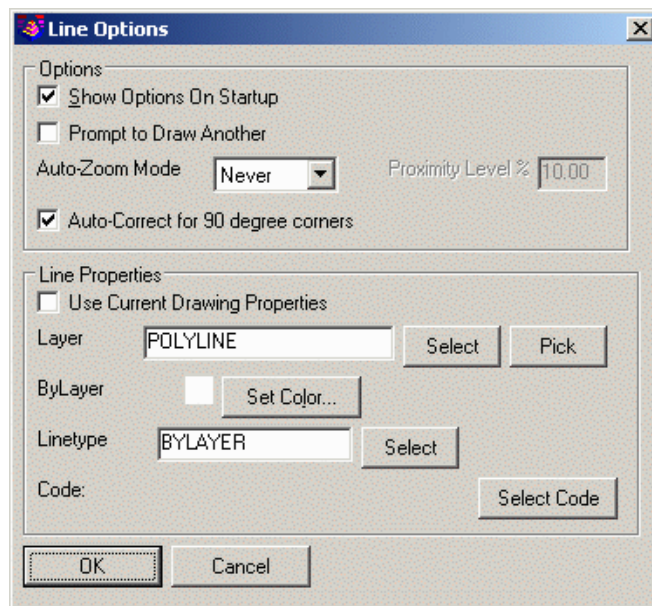

Many of the Draw Menu commands are CAD commands for creating entities in your drawing. Carlson commands that are part of the Draw menu are documented here. Any items not appearing in the Carlson manual are CAD commands that can be referenced in the AutoCAD or IntelliCAD manual.

2D Line

This command allows you to draw a line entity by picking points on the screen or by using the point number and associated coordinates stored in the current coordinate file. This command always draws 2D lines with a zero elevation. The line can also be drawn by entering distances and angles. See the 2D Polyline command for information on using the Distance and Extend input modes.

When the line is drawn using point numbers, the line is linked with the points if the Link Linework with Points option is turned on. This option is set under General Settings in the Configure command in the Settings menu. With links active, changing a point with a command like Move Points automatically updates the line.

Show Options on Startup: When this option is enabled, the dialog box will display automatically upon starting the command. If disabled, you can still get to this dialog by typing O for Options at the command prompt.

Prompt To Draw Another: This option stays in the command after completing the polyline and prompts whether you want to draw another polyline.

Auto-Zoom Mode: This setting provides 3 options for Auto-Zoom: Never, Proximity or Always. The "Never" setting requires you to manually Zoom or Pan to keep the current polyline vertex centered in the drawing screen. The "Proximity" setting will activate the "Proximity Level" setting and will automatically re-center the view only if the current polyline vertex is within a certain distance of the limits of the drawing area. The "Always" option will automatically re-center the view after each new polyline vertex is added.

Auto-Correct For 90 Degree Corners: This option will adjust two line segments to make an exact 90 degree corner when the original lines are nearly 90 degrees.

Use Current Drawing Properties: Select this option if you want the layer, color and linetype of the newly created polyline to match those currently set in the drawing.

Layer: Use this setting to manually assign the layer for the newly created polyline. You can type in the new layer name, use the "Select" button to choose an existing layer from the drawing's layer list or use the "Pick" button to select an entity in the drawing and match its layer.

Set Color: Use this button to manually specify a color for the newly created polyline.

Linetype: Use the "Select" button to manually specify a linetype for the newly created polyline.

Select Code: This option allows you to set the layer, color and linetype of a new polyline by using the properties assigned to a Field to Finish field code. The field code is selected from an existing Field Code table (.FLD) file that has been previously specified in the **Point Defaults** dialog box.

Prompts

Options/⟨Pick point or point numbers⟩: *1-3*

You may enter a single point number or a range of point numbers

Distance/Undo/⟨Pick point or point numbers⟩: *16*

Distance/Extend/Undo/Pick point or point numbers: *35*

Distance/Extend/Undo/Pick point or point numbers: *press Enter*

Pulldown Menu Location: Draw

Keyboard Command: 2DLINE

Prerequisite: None

3D Line

This command draws line entities and is the same as Draw > 2D Line except that this command uses the elevations of the points to make 3D lines.

Pulldown Menu Location: Draw

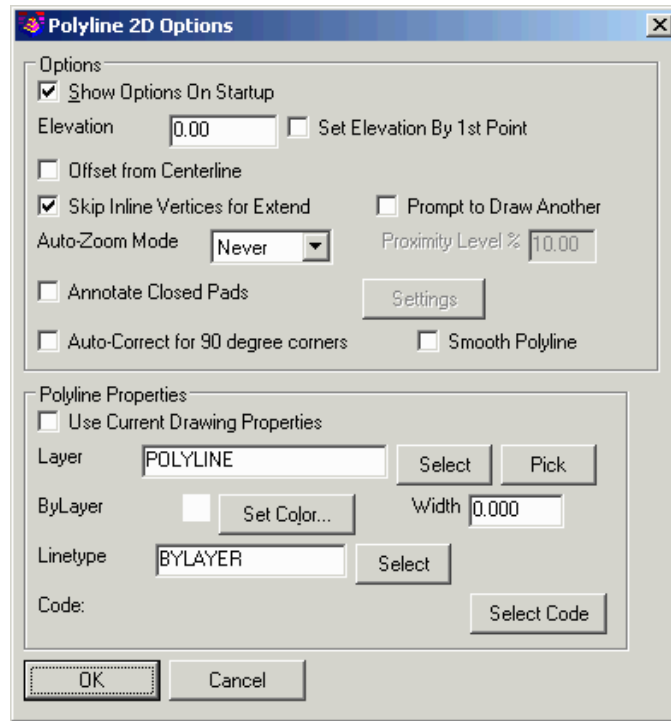

Keyboard Command: 3dline

Prerequisite: None

2D Polyline

This command creates a 2D polyline. A Polyline is a complex CAD entity comprised of one or more line or arc segments. While a 2D polyline elevation isn't necessarily zero, a 2D polyline is flat with all vertices at the same elevation.

This command is available from the **Draw** pulldown menu, from the **Draw** toolbar or at the Command: line (**2DP**) and provides many more options than the standard CAD version of the command. Unless disabled, the **Polyline 2D Options** dialog box will appear after starting Carlson's **2D Polyline** command.

Show Options on Startup: When this option is enabled, the **Polyline 2D Options** dialog box will display automatically upon starting the **2D Polyline** command. If disabled, you can still get to this dialog by typing O for Options at the command prompt.

Elevation: Set the elevation of the polyline to be drawn. The **Set Elevation By 1st Point** option will use the elevation from the first specified point for the whole polyline.

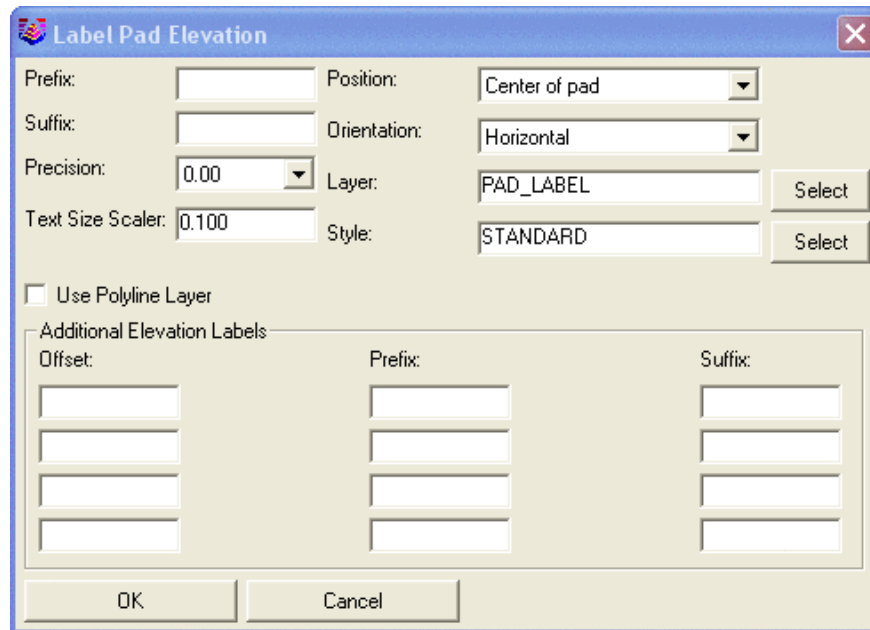

Offset from Centerline: If this option is enabled, an additional option, Offset, is available from the Command: line. Issuing the "Offset" option allows you to draw a new polyline using Station and Offset entry from an existing polyline or existing Centerline (.CL) file.

Skip Inline Vertices for Extend: This setting applies to the "Extend" option with the Total Distance Sub-Menu option. If enabled, an existing vertex will dissolve when lengthening a 2D Polyline segment.

Prompt To Draw Another: This option stays in the command after completing the polyline and prompts whether you want to draw another polyline.

Auto-Zoom Mode: This setting provides 3 options for Auto-Zoom: Never, Proximity or Always. The "Never" setting requires you to manually Zoom or Pan to keep the current polyline vertex centered in the drawing screen. The "Proximity" setting will activate the "Proximity Level" setting and will automatically re-center the view only if the current polyline vertex is within a certain distance of the limits of the drawing area. The "Always" option will automatically re-center the view after each new polyline vertex is added.

Annotate Closed Pads: Enabling this option will activate the "Settings" button. The "Settings" button displays the **Label Pad Elevations** dialog box where you can specify label settings for the pad and other vertical offset elevations. For instance, you can label both the Finished Floor Elevation and the SubGrade elevation of a building pad at the same time using this command. See additional information on the **Label Pad Elevation** command.

In the "Polyline Properties" section of the dialog box you have several alternatives for specifying the layer, color and linetype of the newly created polyline.

Auto-Correct For 90 Degree Corners: This option will adjust two line segments to make an exact 90 degree corner when the original lines are nearly 90 degrees.

Smooth Polyline: This option applies for drawing smooth polylines such as a path for a stream. The Bezier smoothing method is used which passes through all the points and smooths only between the points.

Use Current Drawing Properties: Select this option if you want the layer, color and linetype of the newly created polyline to match those currently set in the drawing.

Layer: Use this setting to manually assign the layer for the newly created polyline. You can type in the new layer name, use the "Select" button to choose an existing layer from the drawing's layer list or use the "Pick" button to select an entity in the drawing and match its layer.

Set Color: Use this button to manually specify a color for the newly created polyline.

Width: Specify the width of the newly created polyline.

Linetype: Use the "Select" button to manually specify a linetype for the newly created polyline.

Select Code: This option allows you to set the layer, color and linetype of a new polyline by using the properties assigned to a Field to Finish field code. The field code is selected from an existing Field Code table (.FLD) file that has been previously specified in the **Point Defaults** dialog box.

Prompts

Command:*2dp*

[Continue/Extend/Follow/Offset/OPTIONS/<Pick point or point numbers>]: *screen pick a point*

[Arc/Close/Distance/Follow/Offset/Undo/<Pick point or point numbers>]: *screen pick a point*

Segment length: 202.55, Total length: 202.55

[Arc/Close/Distance/Extend/Follow/Line/Offset/Undo/<Pick point or point numbers>]: *screen pick a point*

Segment length: 179.73, Total length: 382.28

[Arc/Close/Distance/Extend/Follow/Line/Offset/Undo/<Pick point or point numbers>]: *screen pick a point*

Segment length: 127.45, Total length: 509.73

[Arc/Close/Distance/Extend/Follow/Line/Offset/Undo/<Pick point or point numbers>]: *press Enter*

Command:

Options and SubMenu Options

Once all settings have been specified and the "OK" button is picked, the options shown below are available from the Command: line. To issue any of these options, simply type in the capitalized portion of the Option at the Command: line and press Enter. The default option is always shown between angle brackets < *Default* >.

Continue: This option allows you to select an existing polyline to which you'd like to add more line or arc segments. When prompted to "Select a polyline to continue or extend:", you may pick anywhere on the existing polyline and the new segment will begin at the ending vertex nearest your cursor. New line or arc segments can be added by screen-picking or using the options at the Command: line. Once finished adding segments, they are automatically joined to the original polyline.

Extend: This option gives you many ways to lengthen or shorten an existing polyline using the abbreviated SubMenu options shown below. Some of these options create additional segments at the end of the existing polyline and some allow you to change the length of the ending segment of the polyline. When prompted to "Select a polyline to continue or extend:", you may pick anywhere on the existing polyline and the "Extend" will occur at the ending vertex nearest your cursor. Once finished Extending, the new segments are automatically joined to the original polyline.

[**I / R / L / S / T / A / B / E / U / X / Help / <Enter or Pick Distance>**]

I - Input mode - This option toggles the distance input between feet & inches (will prompt first for feet, then prompt again for inches) and decimal feet.

R - Right rotate - From the ending vertex, turns the pointer 90-degrees to the right and then prompts for a distance.

L - Left rotate - From the ending vertex, turns the pointer 90-degrees to the left and then prompts for a distance.

S - Switch direction - From the ending vertex, turns the pointer 180-degrees and then prompts for a distance.

T - Total distance - Prompts you to "Enter total distance (100.00)" and displays the current length of the segment in parentheses. If a number smaller than the current distance is entered, this option will shorten the existing segment. If a number larger than the current distance is entered, this option will lengthen the existing segment. This option is also affected by the Skip Inline Vertices for Extend setting in the **Polyline 2D Options** dialog box. If "Skip Inline Vertices for Extend" is enabled, then the existing vertex will be dissolved when lengthening a segment. If the setting is not enabled, then the existing vertex will be left intact and an additional segment will be created inline.

A - Angle change - From the ending vertex, prompts you to "Enter Angle (ddd.mmss):" to turn the pointer by a specified angle and then prompts for a distance.

B - Bearing/Azimuth/Turned/Deflection - From the ending vertex, this option allows you to set the pointer direction by specifying an Angle. The Angle format is Qdd.mmss and there are a variety of ways to use the "Q" value to specify the Angle. See here for more.

E - Extend to edge - Extends current segment to another line or entity

U - Undo - Undo last action

X - Quit extend mode - Returns to normal 2D Polyline Draw mode

Help - Displays the descriptions of the Extend options

Enter or Pick Distance - Distance to extend the current segment

Follow: This option allows you to trace all or a portion of an existing polyline. After issuing the "Follow" option, you are prompted to "Select the polyline to Follow:" and then to "Specify the first follow point:". After snapping to a starting point on the polyline, you are asked whether you want to "Interpolate follow vertices elevations?". With this being a 2D Polyline, the answer to this is most likely "NO". You will then be prompted to specify the "Last follow point or follow distance:" where you can snap to another point on the polyline or type in a distance to trace the existing polyline.

Offset: With the "Offset" option, you will first be prompted to select an existing polyline or select an existing Centerline (.CL) file. Next, you will be asked to "Specify starting station:" where you will enter the station number of the first polyline vertex. Then, you will be prompted to "Enter Station" and "Enter Offset" for each vertex of the new polyline. Note: To have this option available, you must place a check next to Offset From Centerline in the **Polyline 2D Options** dialog box.

Pick Point or Point Numbers: This is the default prompt for the command. From here you can set a new polyline vertex by screen picking, entering coordinates in X,Y format or entering a point number from the associated Coordinate (.CRD) file.

Arc/Line: New polyline segments can be either an Arc or a Line segment. If the last polyline segment drawn was a LINE, then the "Arc" option will be shown as an available option; however, if the last polyline segment drawn was an ARC, then the "Line" option will be available.

When in the "Arc" mode, there are many additional SubMenu options available to you for creating an arc segment within the new polyline. The options are generated directly from the standard CAD version of the PLINE command and include Radius Point, Radius Length, Arc Length, Chord and Second Point (Point on Curve).

Close: This option will create a new Line or Arc segment back to the starting vertex of the polyline and results in a closed polyline.

Distance: This option allows you to first enter a distance for the new Line segment and then to specify the direction using one of three methods: Cursor, Line or Angle.

Cursor - This method will draw the polyline segment in the direction of your cursor position.

Line - This method prompts you to select a line or polyline segment to which it will draw a parallel segment.

Angle - This method prompts you for an Angle to determine the direction of your new polyline segment. The Angle format is Qdd.mmss and there are a variety of ways to use the "Q" value to specify the Angle. See here for more.

Undo: Undo the last drawn polyline segment.

Angle Entry Methods

The Angle format is Qdd.mmss where: Q=quadrant/angle, d=degrees, m=minutes and s=seconds.

The Quadrant/Angle can be specified as:

1=NE (NorthEast)

2=SE (SouthEast)

3=SW (SouthWest)

4=NW (NorthWest)

5=AZ (AZimuth)

6=AL (turned Angle-Left)

7=AR (turned Angle-Right)

8=DL (Deflection angle-Left)

9=DR (Deflection angle-Right)

Pulldown Menu Location: Draw

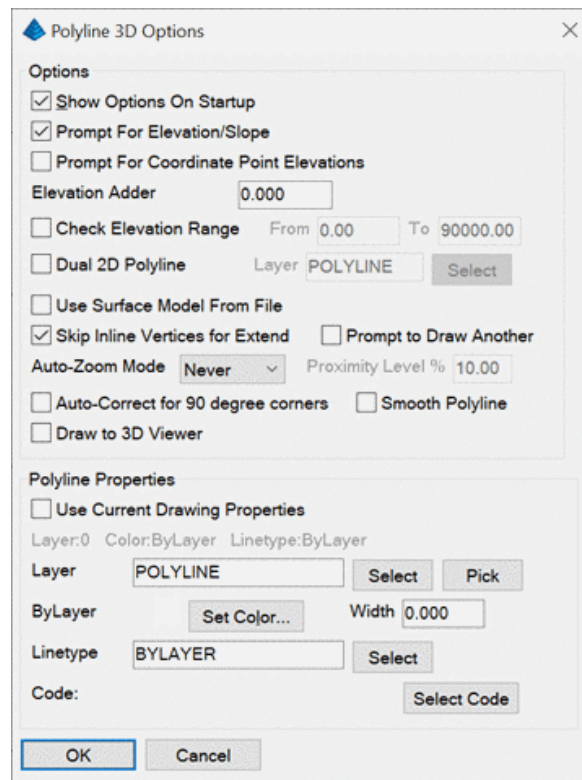

Keyboard Command: 2DP

Prerequisite: None

3D Polyline

This command creates a 3D Polyline. A 3D Polyline is a version of a polyline that can have different elevation at every vertex. 3D Polylines can not have arcs and the program will instead draw a series of short chords to closely follow an arc.

The **3D Polyline** command is available from the **Draw** pulldown menu, from the **Draw** toolbar or at the Command: line (**3DP**). Unless disabled, the **Polyline 3D Options** dialog box will appear after starting Carlson's **3D Polyline** command.

Show Options on Startup: When this option is enabled, the **Polyline 3D Options** dialog box will display automatically upon starting the **3D Polyline** command. If disabled, you can still get to this dialog by typing O for Options at the command prompt.

Prompt for Elevation/Slope: When this option is enabled, the elevation for each new vertex will be displayed as a prompt, giving you an opportunity to override that value by typing in a new elevation. When disabled, the elevation to be assigned to each new vertex is displayed but you are not given a chance to assign a different elevation.

Prompt for Coordinate Point Elevations: This option only applies if you specify a point number from an associated Coordinate (.CRD) file to establish the X,Y,Z values for a new 3D Polyline vertex. When this option is enabled, the elevation for each new vertex will be displayed as a prompt, giving you an opportunity to override that value by typing in a new elevation. When disabled, the elevation to be assigned to each new vertex is displayed but you are not given a chance to assign a different elevation.

Elevation Adder: Use this setting to add a constant elevation value to all default elevation values.

Check Elevation Range: Enabling this option allows you to monitor elevations assigned to 3D Polyline vertices and issue a warning (with options to correct) if the elevation falls outside the specified range. If the proposed elevation of a 3D Polyline vertex falls outside the range specified, the **Warning: Elevation Range** dialog box is displayed. The **Warning: Elevation Range** dialog box allows you to assign a new elevation to the vertex, adjust the acceptable range of elevations or turn OFF monitoring of elevations.

Dual 2D Polyline: This option creates a 2D polyline in addition to the 3D polyline. The 2D polyline is drawn on a separate layer, uses elevation zero and has true arcs instead of the series chord segments used for arcs in 3D polylines.

Use Surface Model From File: Selecting this option allows you to use a Surface Model (.TIN, .GRD, .FLT) file to determine the elevation for each new 3D Polyline vertex.

Skip Inline Vertices for Extend: This setting applies to the "Extend" option with the Total Distance Sub-Menu option. If enabled, an existing vertex will dissolve when lengthening a 3D Polyline segment.

Prompt To Draw Another: This option stays in the command after completing the polyline and prompts whether you want to draw another polyline.

Auto-Zoom Mode: This setting provides 3 options for Auto-Zoom: Never, Proximity or Always. The "Never" setting requires you to manually Zoom or Pan to keep the current polyline vertex centered in the drawing screen. The "Proximity" setting will activate the "Proximity Level" setting and will automatically re-center the view only if the current polyline vertex is within a certain distance of the limits of the drawing area. The "Always" option will automatically re-center the view after each new polyline vertex is added.

In the "Polyline Properties" section of the dialog box you have several alternatives for specifying the layer, color and linetype of the newly created polyline.

Auto-Correct For 90 Degree Corners: This option will adjust two line segments to make an exact 90 degree corner when the original lines are nearly 90 degrees.

Smooth Polyline: This option applies for drawing smooth polylines such as a path for a stream. The Bezier smoothing method is used which passes through all the points and smooths only between the points.

Draw to 3D Viewer: When the 3D Viewer is running during Draw 3D Polyline, then this option will draw the 3D polyline simultaneously in the 3D Viewer and the drawing. This is a way to see the 3D polyline is a 3D scene with other objects while entering the 3D polyline data.

Use Current Drawing Properties: Select this option if you want the layer, color and linetype of the newly created polyline to match those currently set in the drawing.

Layer: Use this setting to manually assign the layer for the newly created polyline. You can type in the new layer name, use the "Select" button to choose an existing layer from the drawing's layer list or use the "Pick" button to select an entity in the drawing and match its layer.

Set Color: Use this button to manually specify a color for the newly created polyline.

Width: Specify the width of the newly created polyline.

Linetype: Use the "Select" button to manually specify a linetype for the newly created polyline.

Select Code: This option allows you to set the layer, color and linetype of a new polyline by using the properties assigned to a Field to Finish field code. The field code is selected from an existing Field Code table (.FLD) file that has been previously specified in the **Point Defaults** dialog box.

Prompts

For A 3D Polyline With A Specified Elevation At Each Vertex:

Command: *3dp*

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: *screen pick a point*

Interpolate/Object/<Elevation> <0.00>: *150.50*

Z: *150.50*

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: *screen pick a point*

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *155.25*

Z: *155.25*, Hz dist: *324.63*, Slope dist: *324.66*, Slope: *1.5%* Ratio: *68.3:1*

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: *screen pick a point*

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *148.12*

Z: *148.12*, Hz dist: *272.88*, Slope dist: *272.98*, Slope: *-2.6%* Ratio: *-38.3:1*

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: *press Enter*

Command:

For A 3D Polyline With Interpolated Elevations At One or More Vertices:

Command: *3dp*

[Continue/Extend/Follow/Options/<Pick point or point numbers>]: *screen pick a point*

Interpolate/Object/<Elevation> <0.00>: *91.73*

Z: *91.73*

[Arc/Close/Distance/Follow/Undo/<Pick point or point numbers>]: *screen pick a point*

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *screen pick a point*

This point elevation will be interpolated upon completion.

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *screen pick a point*

This point elevation will be interpolated upon completion.

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *screen pick a point*

This point elevation will be interpolated upon completion.

Percent/Ratio/Elevation/Degree/Object/Osnap[.]/Next point or elevation<Interpolate>: *94.44*

Z: *94.44*, Hz dist: *79.39*, Slope dist: *122.88*, Slope: *0.8%* Ratio: *122.4:1*

[Arc/Close/Distance/Extend/Follow/Line/Undo/<Pick point or point numbers>]: *press Enter*

Command:

Note that the difference between this and the previous example is that, instead of entering an elevation for each vertex, we are screen picking another new vertex. Each time we neglect to enter an elevation we are notified that, "This point elevation will be interpolated upon completion." After we specify "94.44" as the elevation of the last vertex, the slope of the interpolated segments is calculated using the total elevation change and the total length of all interpolated segments. Now, the elevations of all vertices can be determined and set based on the resulting slope.

Options and SubMenu Options

Once all settings have been specified and the "OK" button is picked, the options shown below are available from the

Command: line. To issue any of these options, simply type in the capitalized portion of the Option at the Command: line and press Enter. The default option is always shown between angle brackets *<Default >*.

When starting a new 3D Polyline, the initial set of options assist you in setting the X,Y location of the first vertex:

Continue: This option allows you to select an existing polyline to which you'd like to add more line or arc segments. When prompted to "Select a polyline to continue or extend:", you may pick anywhere on the existing polyline and the new segment will begin at the ending vertex nearest your cursor. New line or arc segments can be added by screen-picking or using the options at the Command: line. Once finished adding segments, they are automatically joined to the original polyline.

Extend: This option gives you many ways to lengthen or shorten an existing polyline using the abbreviated SubMenu options shown below. Some of these options create additional segments at the end of the existing polyline and some allow you to change the length of the ending segment of the polyline. When prompted to "Select a polyline to continue or extend:", you may pick anywhere on the existing polyline and the "Extend" will occur at the ending vertex nearest your cursor. Once finished Extending, the new segments are automatically joined to the original polyline.

[**I / R / L / S / T / A / B / E / U / X / Help / <Enter or Pick Distance>**]

I - Input mode - This option toggles the distance input between feet & inches (will prompt first for feet, then prompt again for inches) and decimal feet.

R - Right rotate - From the ending vertex, turns the pointer 90-degrees to the right and then prompts for a distance.

L - Left rotate - From the ending vertex, turns the pointer 90-degrees to the left and then prompts for a distance.

S - Switch direction - From the ending vertex, turns the pointer 180-degrees and then prompts for a distance.

T - Total distance - Prompts you to "Enter total distance (100.00)" and displays the current length of the segment in parentheses. If a number smaller than the current distance is entered, this option will shorten the existing segment. If a number larger than the current distance is entered, this option will lengthen the existing segment. This option is also affected by the Skip Inline Vertices for Extend setting in the **Polyline 3D Options** dialog box. If "Skip Inline Vertices for Extend" is enabled, then the existing vertex will be dissolved when lengthening a segment. If the setting is not enabled, then the existing vertex will be left intact and an additional segment will be created inline.

A - Angle change - From the ending vertex, prompts you to "Enter Angle (ddd.mmss):" to turn the pointer by a specified angle and then prompts for a distance.

B - Bearing/Azimuth/Turned/Deflection - From the ending vertex, this option allows you to set the pointer direction by specifying an Angle. The Angle format is Qdd.mmss and there are a variety of ways to use the "Q" value to specify the Angle. See here for more.

E - Extend to edge - Extends current segment to another line or entity

U - Undo - Undo last action

X - Quit extend mode - Returns to normal 3D Polyline Draw mode

Help - Displays the descriptions of the Extend options

Enter or Pick Distance - Distance to extend the current segment

Follow: This option allows you to trace all or a portion of an existing polyline. After issuing the "Follow" option, you are prompted to "Select the polyline to Follow:" and then to "Specify the first follow point:". After snapping to a starting point on the polyline, you are asked whether you want to "Interpolate follow vertices elevations?". After answering Yes or No, you will then be prompted to specify the "Last follow point or follow distance:" where you can snap to another point on the polyline or type in a distance to trace the existing polyline.

Options: This will display the **Polyline 3D Options** dialog box.

Pick Point or Point Numbers: This is the default prompt for the command. From here you can set a new polyline vertex by screen picking, entering coordinates in X,Y format or entering a point number from the associated Coordinate (.CRD) file.

After setting its location, the next set of options help you calculate the elevation of the initial vertex:

Interpolate: This option will set the elevation of the vertex by calculating the slope between other vertices of known elevation.

Object: This option allows you to "Select an elevation label or a point on a polyline:" to set the elevation of the vertex. Elevation labels such as "FFE: 124.85" or "Z: 124.85" can be selected.

Adjust: This option allows you to add or subtract an amount from the elevation like for a curb offset.

Elevation: This is the default option and prompts you to type in the elevation for the vertex.

For subsequent 3D Polyline vertices, several options are added to assist you in setting the X,Y location of each new vertex:

Arc/Line: New polyline segments can be either an Arc or a Line segment. If the last polyline segment drawn was a LINE, then the "Arc" option will be shown as an available option; however, if the last polyline segment drawn was an ARC, then the "Line" option will be available.

When in the "Arc" mode, there are many additional SubMenu options available to you for creating an arc segment within the new polyline. The options are generated directly from the standard CAD version of the PLINE command and include Radius Point, Radius Length, Arc Length, Chord and Second Point (Point on Curve).

Close: This option will create a new Line or Arc segment back to the starting vertex of the polyline and results in a closed polyline.

Distance: This option allows you to first enter a distance for the new Line segment and then to specify the direction using one of three methods: Cursor, Line or Angle.

Cursor - This method will draw the polyline segment in the direction of your cursor position.

Line - This method prompts you to select a line or polyline segment to which it will draw a parallel segment.

Angle - This method prompts you for an Angle to determine the direction of your new polyline segment. The Angle format is Qdd.mmss and there are a variety of ways to use the "Q" value to specify the Angle. See here for more.

Undo: Undo the last drawn polyline segment.

After setting subsequent vertices, several more options are added to help you calculate the elevation of each new vertex:

Percent: This option allows you to specify the slope in Percent format (3%) from the previous vertex.

Ratio: This option allows you to specify the slope in Ratio format (for 3:1, enter 3) from the previous vertex.

Degree: This option allows you to specify the slope angle in decimal degree format (dd.dddd) from the previous vertex.

Osnap[.]: Using the [.] will toggle Running OSNAP settings ON or OFF.

Angle Entry Methods

The Angle format is Qdd.mmss where: Q=quadrant/angle, d=degrees, m=minutes and s=seconds.

The Quadrant/Angle can be specified as:

1=NE (NorthEast)

2=SE (SouthEast)

3=SW (SouthWest)

4=NW (NorthWest)

5=AZ (AZimuth)

6=AL (turned Angle-Left)

7=AR (turned Angle-Right)

8=DL (Deflection angle-Left)

9=DR (Deflection angle-Right)

Pulldown Menu Location: Draw

Keyboard Command: 3DP

Prerequisite: None

3 Point

This command draws an arc between three points. The first point is the PC, the second is a point on the arc and the third is the PT. The points can either be picked on-screen or specified by point number.

Prompts

Pick PC point or point numbers: *101* (For point number 101.)

Pick Second point or point number: *102*

Pick PT point or point number: *103*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 3PA

Prerequisite: None

PC, PT, Radius Point

This command draws an arc between the PC point, radius point and PT point. The points can either be picked on-screen or specified by point number. Given these points, the arc can be drawn clockwise or counterclockwise. The program shows one direction and asks if it is correct. If you need the arc to go the other direction, enter No.

Prompts

Pick PC point or point number: *101*

Pick Radius point or point number: *102*

Pick PT point or point number: *103*

Is the direction of this arc correct ? No/<Yes>: *N*

Pulldown Menu Location: Draw > Arc

Keyboard Command: pca

Prerequisite: None

PC, PT, Radius Length

This command draws an arc that is defined by the specified PC point, PT point and radius length. The points can either be picked on-screen or specified by point number. Given these points, the arc can be drawn clockwise or counterclockwise. The program shows one direction and asks if it is correct. If you need the arc to go the other direction, enter No.

Prompts

Pick PC point or point number: *pick a point*

Radius length: *300*

Pick PT point or point number: *pick a point*

Is the direction of this arc correct [<Yes>/No]? press Enter for Yes

Pulldown Menu Location: Draw > Arc

Keyboard Command: pcptr

Prerequisite: None

PC, PT, Tangent

This command fits a curve between beginning and end points (PC, PT) given a tangent-in. The tangent-in is specified by selecting a line entity. The PC and PT points are screen picked.

Prompts

Pick tangent-in: *pick a line entity*

Pick point PC: *pick a point*

Pick point PT: *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: tangpcpt

Prerequisite: Tangent line

PC, Radius, Chord

This command draws an arc, given the PC point, radius length, chord length and chord bearing. The PC point can either be picked on-screen or specified by point number. Given these points, the arc can be drawn clockwise or counter-clockwise. The program shows one direction and asks if it is correct. If you need the arc to go the other direction, enter No.

Prompts

Radius of Arc <-40.00>: 500

PC Start Point ?

Pick point or point number: *pick a point*

Chord bearing or chord endpoint (<Bearing>/Point)? Press Enter

Enter Bearing (Qdd.mmss) <90.0000>: 145.1041 (for NE 45d10'41")

Chord Length <200.46>: 200

Is this arc in the correct direction (<Yes>/No)? Press Enter

Pulldown Menu Location: Draw > Arc

Keyboard Command: srcb

Prerequisite: None

PC, Radius, Arc Length

This command draws an arc given the PC point, radius length, and arc length. The PC point can either be picked on-screen or specified by point number. Given these points, the arc can be drawn clockwise or counterclockwise.

The program shows one direction and asks if it is correct. If you need the arc to go the other direction, enter No.

Prompts

Pick PC Point or point number: *pick a point*

Pick Radius point or point number: *pick a point*

Arc length <5.00>: *150*

Is this arc in the correct direction (<Yes>/No)? *press Enter*

Pulldown Menu Location: Draw > Arc

Keyboard Command: pra

Prerequisite: None

2 Tangents, Radius

This command fits a curve between two tangent lines by entering a known radius. It prompts for the radius and then prompts to pick points on the two tangent lines.

Prompts

Radius of Arc <300.000>: *press Enter*

[nea] Pick Point on 1st Tangent Line: *pick a point*

[nea] Pick Point on 2nd Tangent Line: *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanlin

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Arc Length

This command fits a curve between two tangent lines and a known arc length. It prompts for the arc length then pick the P.I. (intersection of tangent lines) and points on the two tangent lines.

Prompts

Arc Length <100.00>: *press Enter or enter distance*

[int on] Pick P.I. of curve: *pick intersection of tangent lines*

[nea on] Pick pnt on 1st Tangent Line: *pick a point*

[nea on] Pick pnt on 2nd Tangent Line: *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanlal

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Chord Length

This command fits a curve between two tangent lines and a known chord length. It prompts for the chord length, the P.I. and points on the two tangent lines.

Prompts

Chord Length <100.00>: *press Enter*
[int on] **Pick P.I. of curve:** *pick a point*
[nea on] **Pick Point on 1st Tangent Line:** *pick a point*
[nea on] **Pick Point on 2nd Tangent Line:** *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tancl

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Mid-Ordinate

This command fits a curve between two tangent lines and a known middle ordinate. It prompts for the middle ordinate length, the Point of Intersection and points on the two tangent lines.

Prompts

Middle Ordinate <50.00>: *press Enter*
[int on] **Pick P.I. of curve:** *pick a point*
[nea on] **Pick Point on 1st Tangent Line:** *pick a point*
[nea on] **Pick Point on 2nd Tangent Line:** *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanlmo

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, External

This command fits a curve between two tangent lines and a known external secant distance. It prompts for the P.I. and points on the two tangent lines then the external distance.

Prompts

[int on] **Pick P.I. of curve:** *pick a point*
[nea on] **Pick Point on 1st Tangent Line:** *pick a point*
[nea on] **Pick Point on 2nd Tangent Line:** *pick a point*
External Distance <50.00>: *press Enter*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanlex

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Tangent Length

This command fits a curve between two tangent lines and a known curve tangent length. It prompts for the tangent length, P.I. and points on the two tangent lines.

Prompts

Tangent Length <50.00>: *press Enter*

[int on] **Pick P.I. of curve:** *pick a point*

[nea on] **Pick Point on 1st Tangent Line:** *pick a point*

[nea on] **Pick Point on 2nd Tangent Line:** *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanltl

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Degree of Curve

This command fits a curve between two tangent lines by entering a known degree of curve. It prompts for the degree of curve and then prompts to pick points on the two tangent lines.

Prompts

Degree of Curve (ddd.mmss) <5.0000>: *press Enter*

Define by [C]hord or [A]rc length <A>: *press Enter*

[nea on] **Pick Point on 1st Tangent Line:** *pick a point*

[nea on] **Pick Point on 2nd Tangent Line:** *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2tanldo

Prerequisite: Tangent lines should be drawn before execution

2 Tangents, Through Point

This command creates an arc by tangents in/out plus a pass through point on the arc.

Prompts

Pick tangent-in: *pick a line entity*
Pick tangent-out: *pick another line entity*
Pick point on the arc: *pick a point*

Pulldown Menu Location: Draw > Arc
Keyboard Command: 2tanpt
Prerequisite: 2 tangent lines

Tangent, PC, Radius, Arc Length

This command draws a curve from a perpendicular tangent line with a known radius and arc length. It prompts for the radius, the arc length and then to pick the P.C. start point of the curve (endpoint of previously drawn tangent line) and a point along the tangent line.

Prompts

Precede radius with - sign for curve to the left.

Radius of Arc <15.00>: 55

Arc Length <25.00>: 30

PC Start Point ?

Pick point/<point Number>: 14

PtNo. North(y) East(x) Elev(z) Desc

Pulldown Menu Location: Draw > Arc

Keyboard Command: sral

Prerequisite: Tangent lines should be drawn before execution

Tangent, PC, Radius, Tangent Length

This command draws a curve from a perpendicular tangent line with a known radius and tangent length. It prompts for the radius, the tangent length and then to pick the P.C. start point of the curve and a point along the tangent line.

Prompts

Precede radius with - sign for curve to the left.

Radius of Arc <300.0000>: *press Enter*

Tangent Length <236.0000>: *press Enter*

PC Start Point ?

Pick point or point number: *pick a point*

[nea on] Pick point along perpendicular tangent line: *pick a point*

(5270.39 4840.36 0.0)

Radius Point Coordinates: (5251.37 4534.71 0.0)

Pulldown Menu Location: Draw > Arc

Keyboard Command: srlt

Prerequisite: Tangent lines should be drawn before execution

Tang, PC, Radius, Chord Length

This command draws a curve from a perpendicular tangent line with a known radius and chord length. It prompts for the radius, the chord length and then to pick the P.C. start point of the curve and a point along the tangent line.

Prompts

Precede radius with - sign for curve to the left.

Radius of Arc <300.0000>: *press Enter*

Chord Length <25.0000>: *press Enter*

PC Start Point ?

Pick point or point number: *pick a point*

[nea on] Pick point along perpendicular tangent line: *pick a point*

(5142.38 4911.57 0.0)

Radius Point Coordinates: (5221.51 5209.63 0.0)

Pulldown Menu Location: Draw > Arc

Keyboard Command: SRCL

Prerequisite: Tangent lines should be drawn before execution

Tang, PC, Radius, Delta Angle

This command draws a curve from a perpendicular tangent line with a known radius and delta angle. It prompts for the radius, the delta angle and then to pick the P.C. start point of the curve and a point along the tangent line.

Prompts

Precede radius with - sign for curve to the left.

Radius of Arc <300.00>: *press Enter*

Enter Delta Angle <90.00>: *press Enter*

PC Start Point ?

Number/<Pick point>: *pick a point*

[nea on] Pick point along perpendicular tangent line: *pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: srda

Prerequisite: Tangent lines should be drawn before execution

Arc From Last Point

This command draws an arc that is tangent from the last point of the most recent linework or arc entity. The PC point of the arc is automatically set from this last point. This command only prompts for the PT point to create the

arc.

Prompts

Specify end point of arc: *DRAG pick a point*

Pulldown Menu Location: Draw > Arc

Keyboard Command: arc

Prerequisite: Linework

Compound or Reverse

This command draws a compound or reverse off an existing curve. It prompts whether the curve is reverse or compound, for the P.C. start point (endpoint of an existing arc) and the known radius. Then the user selects the other known from the choices of tangent length, arc length, chord length or delta angle and enters that value. This command can be confused and malfunction if there is another entity such as a point symbol at the P.C. (If this happens, freeze the PNTMARK layer or temporarily erase the point symbol.)

Reverse curve off an existing curve

Prompts

[end on] Select ARC at PC Start point of the curve: *pick a point*

Type of curve [<Compound>/Reverse]: *press Enter*

Enter the Radius: *300*

Define arc method [Tangent/Chord/Delta/<Length>]: *press Enter*

Enter the arc length: *236*

Pulldown Menu Location: Draw > Arc

Keyboard Command: srcr

Prerequisite: Tangent arc should be drawn before execution

3D Arc

This command draws an arc in 3D using three points for input. The points are the beginning of the arc (PC), a point along the arc, and the end of the arc (PT).

Prompts

Pick PC point or point numbers: *pick a point*

Point on arc.

Pick point or point number: *pick a point*

PT point.

Pick point or point number: *pick a point*

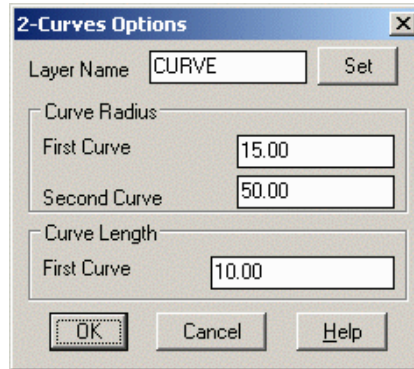

Pulldown Menu Location: Draw > Arc

Keyboard Command: 3darc

Prerequisite: None

2-Radius Curve Series

This command draws a series of two curves with different radii between 2 tangents. In the dialog, set the layer to draw, the radius for each curve and the arc length of the first curve. The program calculates the length of the second curve to fit with the tangents. After the dialog, the program prompts to pick 2 lines to define the tangents in and out.

Prompts

Pick first tangent: *pick a line*

Pick second tangent: *pick a line*

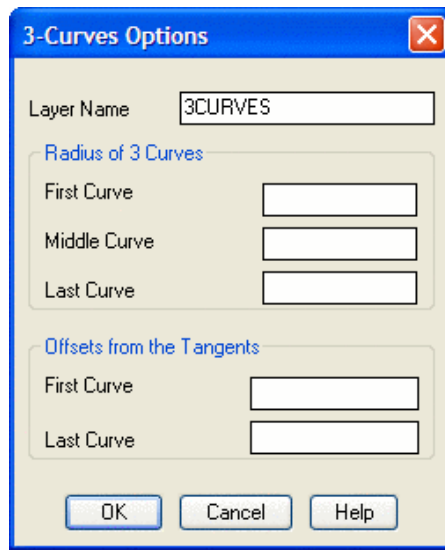

Pulldown Menu Location: Draw > Arc

Keyboard Command: 2curves

Prerequisite: Two tangents

3-Radius Curve Series

This command is used to fit a series of three curves with different radii between 2 tangents. The "Offsets from the Tangents" is the distance perpendicular to the tangent from both ends of the second curve.

Offset from the tangents is the x value

Prompts

Please pick two tangents...

Pick first tangent: *pick a line*

Pick second tangent: *pick a line*

Pulldown Menu Location: Draw > Arc

Keyboard Command: 3curves

Prerequisite: Two tangents

Best Fit Curve

This command draws an arc between two endpoints with a radius that is derived from sampling points. Least-squares is used to find the radius for the closest arc that passes through these points. The Hold End Points option applies additional weight to the end points by the specified weight factor. After specifying the points, the program calculates the best-fit arc and shows the results in the dialog show here. You can toggle each point for whether to include in the calculations. When a point is toggled off for processing, it is not used to calculate the best-fit arc but the residual is still reported. Use the Remove button to remove a point both from calculation and reporting. You can also modify the radius. After picking OK, the arc is drawn in the current layer and there is a report.

Prompts

Starting Point ?

Pick point or point number: 46

Ending point ?

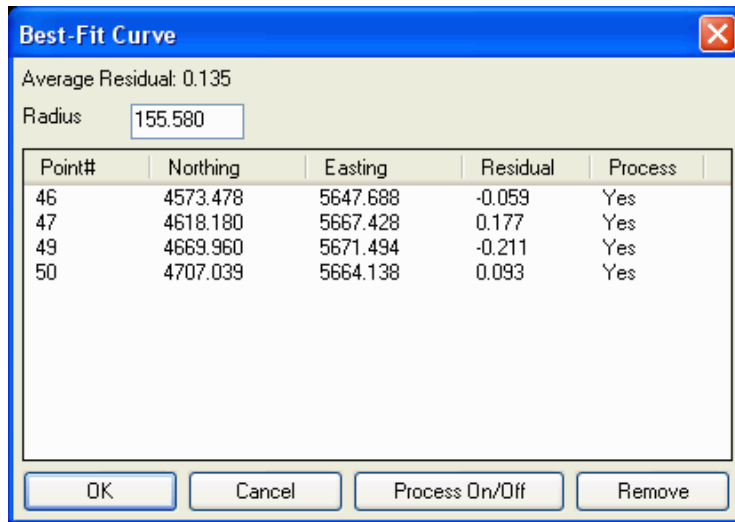

Pick point or point number: 50

Select points from screen, group or by point number [`<Screen>/Group/Number`]? *press Enter*

Select Carlson Software Points.

Pulldown Menu Location: Draw > Arc

Keyboard Command: bfitcrv

Prerequisite: Points for sampling should be drawn before execution.

Curve Calc

This Curve Calculator command displays a dialog box with a series of edit boxes that are filled in with the values of a curve. You can input two known values and the program calculates the other values. One of the known values must be the radius or the delta angle. The 3 Points option allows you to simply select three on-screen point locations. All of the fields will immediately be filled in after the picking of the third point. Optionally, you can also input point numbers from a coordinate file.

Roadway or Railroad: Allows you to choose which type of curve you would like information on. Toggling between the two, after data is entered, will reveal different values.

Select: Allows you to select an arc from the drawing. The information for the selected arc is displayed in the dialog box.

3 Points: Allows you to specify three points on the screen to define an arc. The information for this defined arc is displayed in the dialog box.

Plot: Allows you to plot the currently defined arc in the drawing.

Clear: Clears all edit boxes in the dialog.

Prompts

Curve Calculator dialog *Enter at least two values, as described above*

The dialog box first pops up without any data in the fields. The above dialog graphic is a result of entering in the radius and the arc length values of a known curve, then the *Enter* or *Tab* key.

Pulldown Menu Location: Draw > Arc

Keyboard Command: curvecalc

Prerequisite: None

Spiral Curve

This command plots a spiral curve. The user must provide the P.I. (point of intersection), the length of spiral and the radius length of the simple curve. The command will plot a symmetrical spiral or a spiral in or spiral out (choose the S option for the first prompt if you only want to plot a spiral out). If you have an unsymmetrical spiral then plot a spiral in using the T or P option then use the S option to plot the spiral out. The command plots a polyline to represent the spiral as line segments at the resolution specified by the user. You can use the *Calculate Offsets*, *Station Polyline/Centerline* or *Offset Point Entry* commands, found in the Centerline menu, to calculate points and/or stations and offsets from the spiral.

Prompts

Spiral method [TS/ST/<PI>] *press Enter*

Pulldown Menu Location: Draw > Arc

Keyboard Command: spiral

Prerequisite: For a symmetrical spiral, draw the tangent in and tangent out lines. For spiral in or out only, draw the tangent line in or out.

Text Wizard

This command creates text using a dialog to set the text properties. In the dialog, you set the text string to create, height, justification, layer, style and color. Text Rotation chooses between having the label horizontal to the current view, prompting for the label angle or at a fixed angle specified in the dialog. The Use MText setting controls whether to create the text as a regular Text entity type or as MText. The Use Current Drawing Properties option will use the current layer, style and color from the drawing instead of the dialog.

Prompts

Draw Text dialog

Text location: *pick a point*

Pulldown Menu Location: Draw > Text

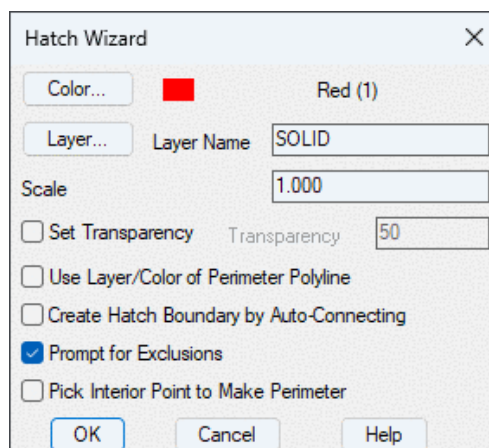

Keyboard Command: drawtext

Prerequisite: None

Hatch Wizard

This command draws a hatch. The dialog has settings for the Color, Layer, Transparency and Scale for the hatch. The **Use Layer/Color of Perimeter Polyline** option sets these properties for the hatch from the polyline used for the hatch perimeter instead of from the dialog. The **Pick Interior Point to Make Perimeter** method defines the hatch area by picking a point in the drawing and having the program find the bounding linework. Otherwise the program prompts to select the inclusion and exclusion perimeter polylines. The **Prompt For Exclusions** controls whether the program prompts to select closed polylines for areas to exclude from the hatch. The **Create Hatch Boundary by Auto-Connecting** method creates a closed area for hatching from unclosed linework by joining the selected linework at their endpoints.

After dialog and selecting the hatch area, the program prompts for the hatch pattern. Then the hatch is created.

Prompts

Pick interior point method:

Pick interior point: *pick a point*

Pick interior point (Enter to end): *press Enter*

Pick polylines method:

Select the Inclusion perimeter polylines.

Select objects: *pick closed polylines to hatch*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *press Enter*

Select Text to Exclude from fill or ENTER for none.

Select objects: *press Enter*

For selected text, the program automatically creates an exclusion box around the text to keep the hatch pattern from covering the text.

Pulldown Menu Location: Draw

Keyboard Command: hatchwiz

Prerequisite: Perimeter linework

Multileader with Text

This command draws multiple leaders to a label. The style of the leaders is controlled by the current Dimension Style.

Prompts

Beginning point of leader: *Pick point at arrowhead*

End point for leaders: *Pick point at label*

Text: *Multileader*

Text (Enter to end): *press Enter*

Beginning point of leader (Enter to end): *pick a point*

Beginning point of leader (Enter to end): *press Enter*

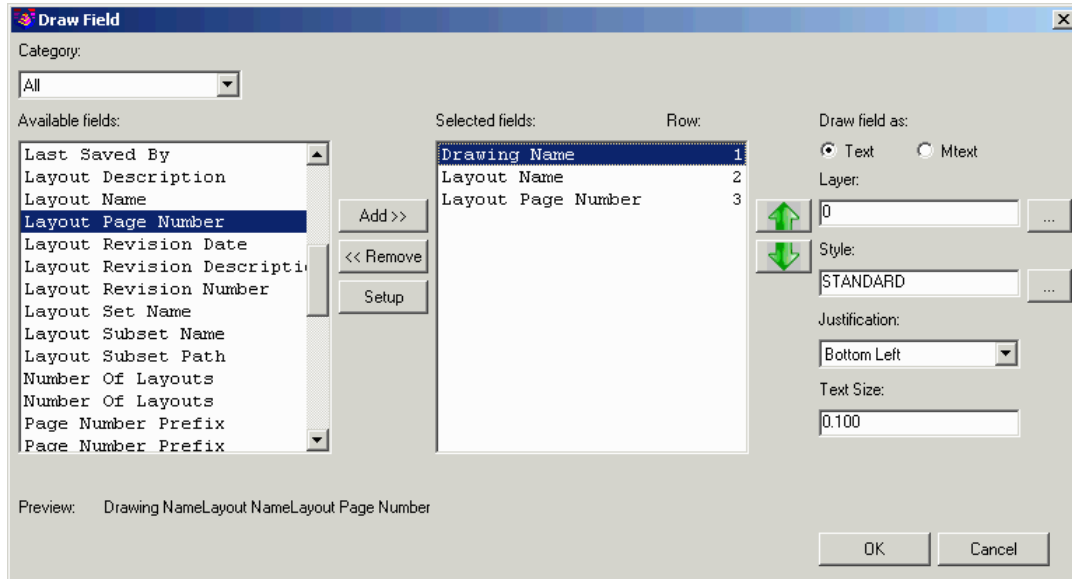

Pulldown Menu Location: Draw > Leader

Keyboard Command: mldr

Prerequisite: None

Field Text

This command adds predefined and custom text objects to your drawing that are updated when a drawing is Regenerated or Saved. Custom fields refresh their data from the Custom Properties defined in the Layout Manager. For example, one of the available fields is Layout Page Number which can be placed as a text entity on a layout. Then if the layout page number changes, the text is updated.

Category: The Category list is used to filter the Available Fields. Selecting All will show all Categories. Some Categories, such as Current Layout Set, Current Layout Subset and Current Layout will only be displayed if the current drawing is attached to a Layout Set file (.set).

Add: Use the Add button to add an Available Field to the Selected Fields list. As you add fields sequentially to the Selected Fields list, the name and row number will be displayed. You can change the row number if you would like the field to appear on a new line. See the Setup button description for more information.

Remove: Use the Remove button to remove a field from the Selected Fields list.

Setup: Use the Setup button to edit the Prefix, Suffix and other contextual properties of the field. For example, Date fields will show a Date Format option, and numeric fields may show a precision format option. Toggle the "Place on new row" checkbox to place the field on a new line. The Field Setup dialog can also be invoked by double clicking a Selected Field list item.

Move Up: Use the Move Up button to move the selected field above the previous field.

Move Down: Use the Move Down button to move the selected field below the next field.

Draw Field As: This setting controls whether the Field is drawn as Text, MText or block attribute objects. The block attribute method can be used to fill out attributes in your title block.

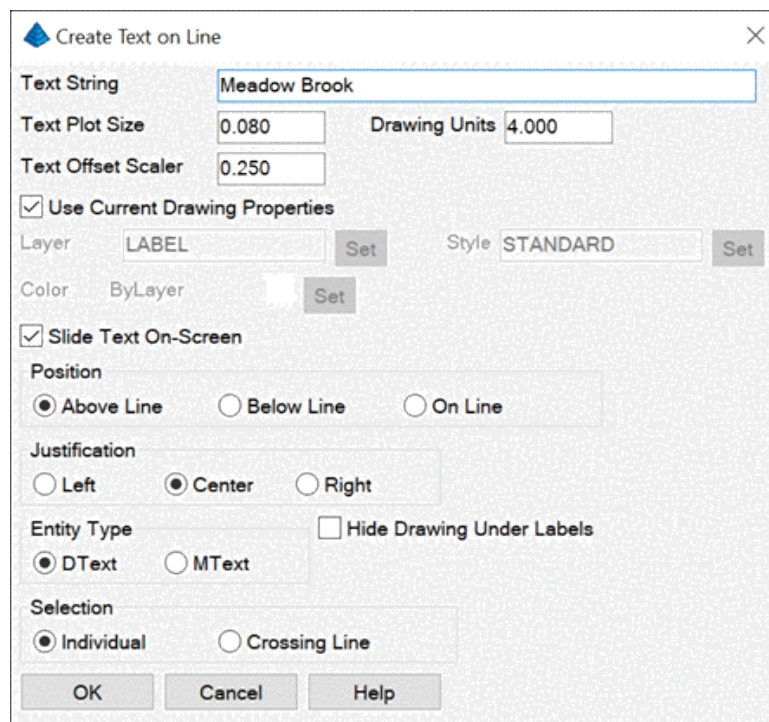

Pulldown Menu Location: Draw > Text

Keyboard Command: drawfield

Prerequisite: None

Text on Line

This command creates text aligned by the selected linework. In the options dialog, you set the text string to create, height, layer, style, color, justification and text entity type. The Text Offset controls the distance between the linework and the text. The Slide option allows you to graphically place the text. The User Current Drawing Properties option will use the current layer, style and color from the drawing instead of the dialog. The Hide Drawing Under Labels creates a Wipeout entity under the text label. The Selection method by Individual prompts for a line or polyline segment to place a single text label at a time. The Crossing Line method prompts to pick two points in the drawing and places the text label at every linework intersection along the line between the two points.

Prompts

Create Text on Line dialog

Pick line or polyline segment: *select linework entity*

Pick point for slide: *pick a point*

Pulldown Menu Location: Draw > Text

Keyboard Command: textline

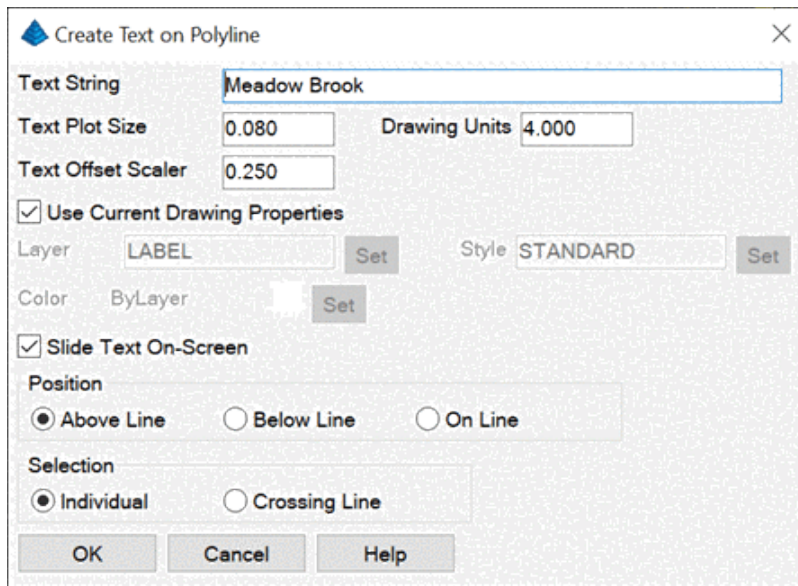

Prerequisite: polyline or line

Text on Polyline

This command creates text with each character aligned by the selected polyline. In the options dialog, you set the text string to create, height and offset. The Text Offset controls the distance between the polyline and the text. The Slide option allows you to graphically place the text. The Hide Drawing Under Labels creates a Wipeout entity under the text label. The Selection method by Individual prompts for a line or polyline segment to place a single text label at a time. The Crossing Line method prompts to pick two points in the drawing and places the text label at every linework intersection along the line between the two points.

Prompts

Create Text on Polyline dialog

Pick polyline: *select polyline entity*

Pick point for slide: *pick a point*

Pulldown Menu Location: Draw > Text

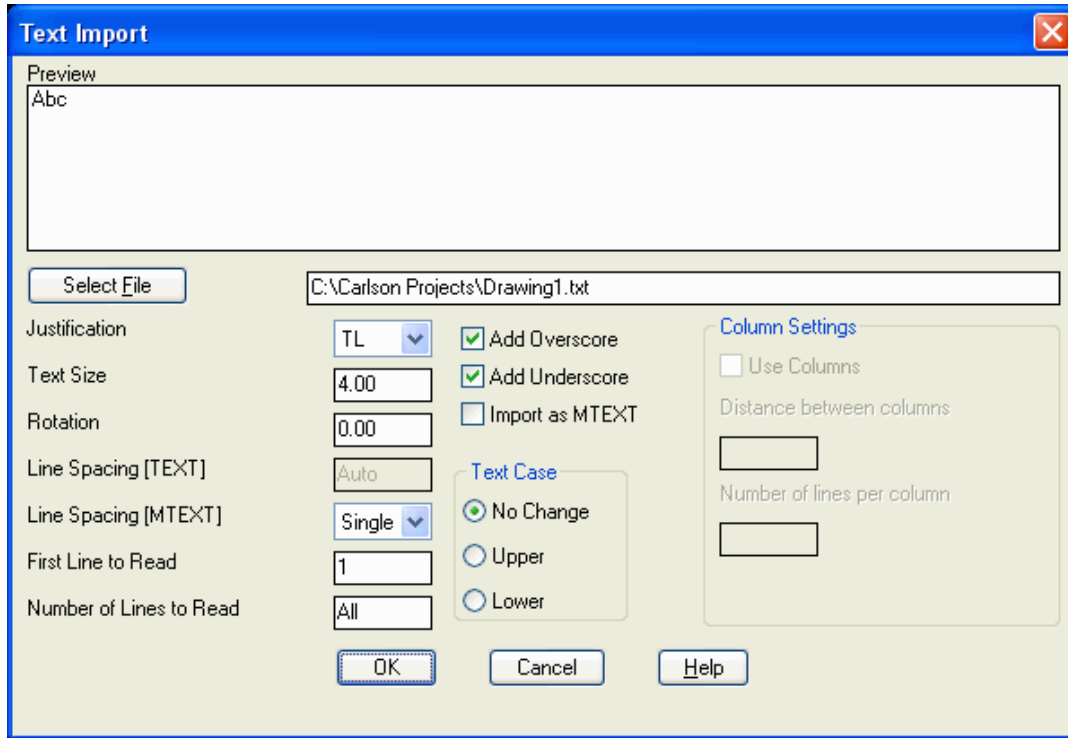

Keyboard Command: textpline

Prerequisite: polyline

Text Import

This command reads a text file and draws the contents as text entities. The file to import and the options are set in the dialog show here.

When using a Microsoft Word .doc or .docx file, the document is drawn as MText using the formatting from the document. There is an option to link the MText to the document so that the MText is updated when the document is changed. This update is done when the drawing is opened or running a REGEN.

Pulldown Menu Location: Draw

Keyboard Command: textin

Prerequisite: text file

Text Export

This command writes a text file from the selected Text and MText entities. The text is sorted to output in top to bottom order based on the entity locations.

Pulldown Menu Location: Draw

Keyboard Command: textout

Prerequisite: text entities

Text Mask

This command hides drawing entities under text by creating a wipeout entity around the text. The Offset is a distance in drawing units to create a buffer around the text.

Prompts

Select text to mask.

Select entities: *pick text*

Offset <0.100>: *press Enter*

Pulldown Menu Location: Draw > Text

Keyboard Command: textmask

Prerequisite: text

Text UnMask

This command removes text masks from the selected text entities.

Prompts

Select text to unmask.

Select entities: *pick text*

Pulldown Menu Location: Draw > Text

Keyboard Command: textunmask

Prerequisite: masked text

Draw Box Around Text

This command draws a rectangle to enclose the selected text. This rectangle is drawn as a polyline in the current layer. The options dialog has Gap Factor which controls the offset from the text to the polyline. The factor is relative to the text size. The Round Corners option fillets the corners of the box.

Prompts

[Options/<Select text>]: *pick the text to box or type O for the options dialog.*

Pulldown Menu Location: Draw > Text

Keyboard Command: txtbox

Prerequisite: Text entity

White Solid Behind Text

This command draws a white solid rectangle to highlight the selected text. The display order for the solid is set behind the text and the solid is drawn on the current layer. This command is only useful when the text itself is not white. At the command prompt, type O for Options to bring up the settings dialog for how to set the layer for the solid.

Prompts

[Options/<Select text>]: *pick the text to highlights*

Pulldown Menu Location: Draw > Text

Keyboard Command: txtwhite

Prerequisite: Text entity

Trim Linework Through Text

This command trims linework that crosses text. After selecting the text to trim with and entering a buffer offset around the text, the program automatically finds any crossing linework and trims.

Prompts

Select text: *pick the text to trim with*

Enter gap <0.5>: *press Enter*

Pulldown Menu Location: Draw > Text

Keyboard Command: txttrim

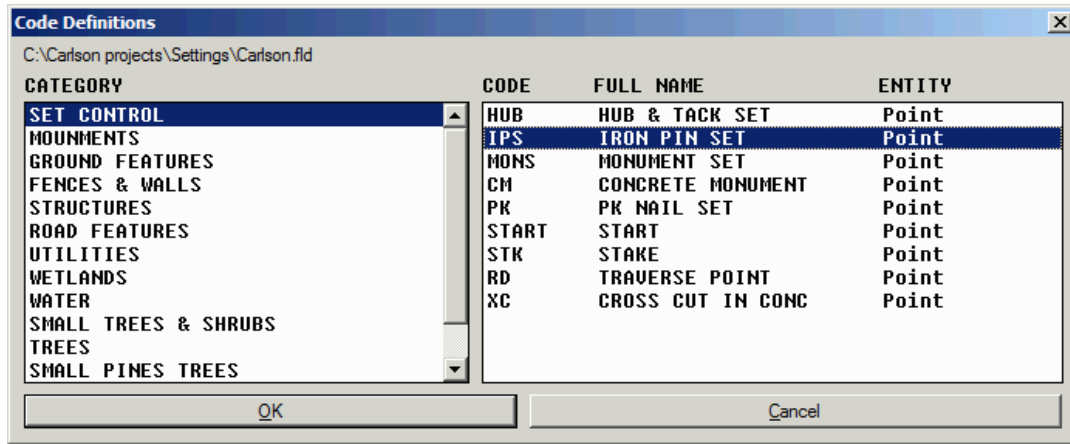

Prerequisite: Text entity and linework

Insert Symbols

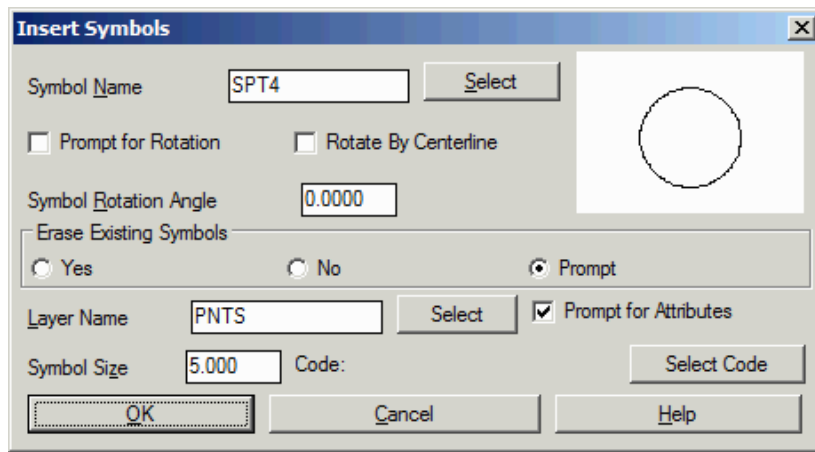

This command inserts symbols from the symbol library into the drawing. The symbol library may be edited using the *Edit Symbol Library* command.

In the Insert Symbols options dialog, choose a symbol by entering the Symbol Name or by picking the Select button which brings up the Select Symbol dialog. The default Symbol Category choices are Points, Trees and Map Symbols. You may select a category by choosing the Symbol Category dropdown list. Within each category, use the scroll bar to view all of the symbols. The Prompt For Rotation option will add a prompt for each symbol rotation. The Rotate By Centerline option will prompt to select linework and then rotate the symbols to make them parallel to the nearest linework. The Symbol Rotation Angle is applied relative to horizontal of the current twist screen or to the nearest linework angle when Rotate By Centerline is active. The Erase Existing Symbols options apply if you specify a symbol location that already has a symbol on it. There are also settings for the symbol layer name and size. The Prompt For Attributes option applies to symbols that have attribute definitions. When active, this option will prompt for the attribute values in a dialog.

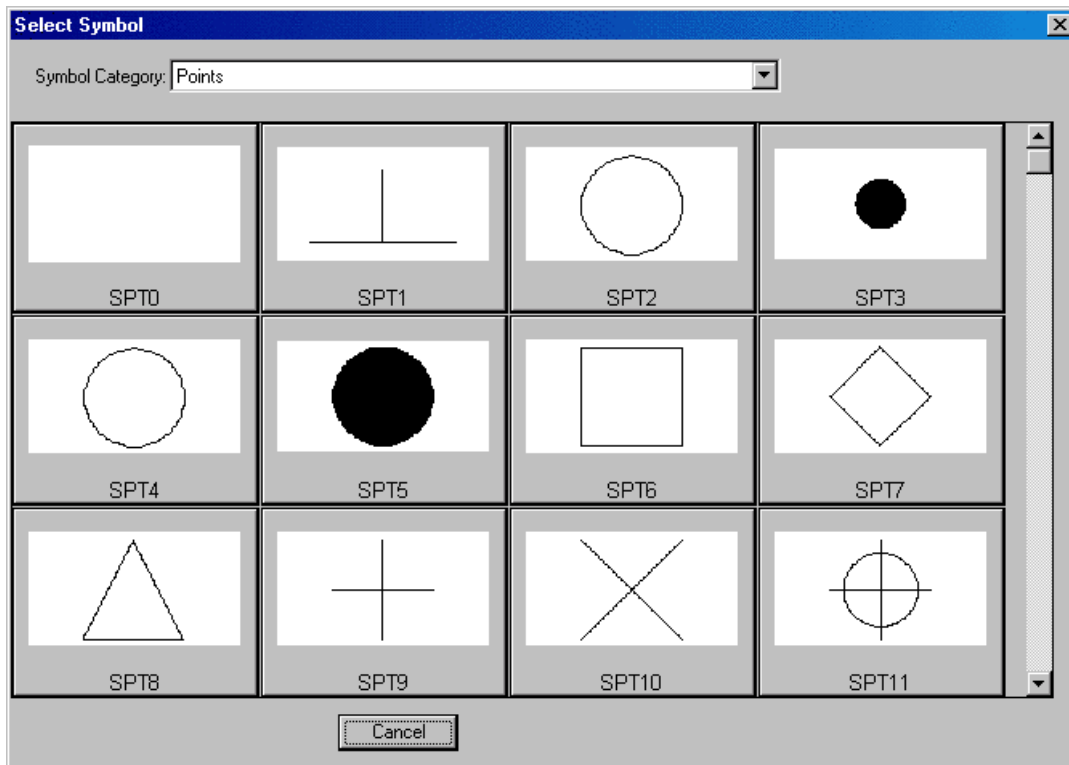

The Select Code option is an alternate way of selecting the symbol by Field-to-Finish code name. The Field-to-Finish code table to use is set with the Points->Point Defaults command. Besides setting the symbol name, the code lookup method also sets the layer. For example, instead of picking a symbol like SPT5 and setting the layer name to "TRAVERSE" for an iron pin symbol, the select code method would set the symbol name and layer by picking the code name/description of "IPS"/"Iron Pin Set" from the code list. So the code method is a way to handle drawing standards.

After the options dialog, the program prompts at the Command line for the symbol locations. The locations can be specified by picking points, specifying point numbers in the current coordinate (.CRD) file or by entering the northing and easting. Using the Select entities option, symbols can also be placed on arcs, faces, points, text, lines and polylines. Selecting the Enter coords option allows you to insert the symbol by entering a easting, northing and elevation in x,y,z order.

Appears at start of command

Appears when Select (symbol) is chosen

Select entities dialog box

Prompts

Insert Symbols dialog *Choose parameters and click OK*

Options/Select entities/Enter coords/<Pick point or point numbers>: *pick a point*

Options/Select entities/Enter coords/<Pick point or point numbers>: *5-10* Inserts symbols at points 5-10 from the current coordinate file.

Options/Select entities/Enter coords/<Pick point or point numbers>: *S*

Insert Symbols dialog

Select arcs, faces, points, text, lines and polylines. *select objects*

Options/Select entities/Enter coords/<Pick point or point numbers>: *press Enter to end*

Pulldown Menu Location: Draw > Symbols

Keyboard Command: ptsym

Prerequisite: None

Insert Multi-Point Symbols

This command allows you to locate symbols using multiple insertion points. Up to three insertion points can be defined for an individual symbol. When defining only two insertion points for a particular symbol, the symbol will be scaled and rotated. With three insertion points defined, the symbol is rotated and scaled in both the X and Y directions. The two point insertion definition will aid in the drawing of tree symbols with a specific drip line width. For instance, a surveyor could locate the tree and then locate the drip line, two shots for each tree, and allow the program to size the tree symbol accordingly so that the map will have various tree symbol sizes that reflect the actual field conditions.

The multiple insertion points are defined in the Field to Finish codes. The *Insert Multi-Point Symbols* command reads the Field to Finish code table and finds all of the codes with multi-point symbol definitions. Then you can select from these codes for the symbol to draw. Both the two and three point insertion definitions can aid with the insertion of concretes and buildings symbols during final drawing preparations and design phases of a project.

Here are the various steps to define two point and three point insertion point symbols. First, you must decide on the symbol to use for the desired code, as well as the specific placement points for the symbol. Once a symbol has been chosen, open the desired symbol drawing. To do this, identify the symbol name and then locate the symbol by its drawing name under the SUP sub-directory found under the Carlson installation directory. Next, determine the placement points for the symbol. As shown below, the placement points for the BLD code symbol, which will be explored later in this section, were determined by identifying X and Y values of the desired placement points by using the id command and specifying the end points of the lines.

Next, the symbol insertion points must be defined in the Field to Finish code table (.FLD) file. To do this, open your FLD file by choosing *Draw Field to Finish* under the Survey pulldown. Then select a particular code from the list of codes displayed in the Field to Finish dialog box. Edit it by highlighting the code and picking the Edit button, or define a new code with the Add button. Either choice will display the Edit Field Code Definition dialog. In the Edit Code Definition dialog, choose the desired symbol for the code by pressing the Set Symbol button and selecting the desired symbol. Next, select the Symbol Pts button. This brings up a dialog called Define Symbol Placement Points. Here is where you define the symbol by three points. You do this by entering an X and Y coordinate and a description for the symbol. Enter the X and Y values for each placement point into the appropriate fields. The description fields are used as the prompts when placing the symbol in the drawing. A two insertion point symbol is defined in the same way. An example is the Symbol Pnts definition for the code TREE. The placement points for the Tree code symbol were determined by opening the symbol drawing and finding the X and Y values at the insertion points. The center of the large circle was chosen for Point 1 and the East Quadrant was chosen for point 2. In both cases osnaps were used in picking the points.

Now that we have the codes defined, let's go through the *Insert Multi-Point Symbol* command and see the results. The command starts with a dialog that lists all the codes with Multi-Point Symbols defined. At this point you can select the symbol to draw. The symbol size applies only to using one point to place the symbol. When two or more points are used, the symbol is scaled to fit the points. Let's look at the BLD code three point insertion definition.

Shown below are three points that represent a building pad. We want the building to be exactly the same dimensions defined by the point locations.

The three point PAD and the tree with drip line examples follow. We start by specifying the building pad codes.

Prompts

Insert Multi-Point Symbol Dialog

Choose a symbol to draw. In this example, the Pad symbol is a 3 point multi-symbol.

Specify LTFNT PAD point.

Pick Point or Point Number (Enter to End): 15

Specify LT REAR PAD point.

Pick Point or Point Number (Enter to End): 16

Specify RT REAR PAD point.

Pick Point or Point Number (Enter to End): 17

Insert another BLD symbol [<Yes>/No]? N

Insert Multi-Point Symbol Dialog

Choose a symbol to draw. In this next example, the Tree symbol is a 2 point multi-symbol. Now specify the location of the trunk and the drip line by point number.

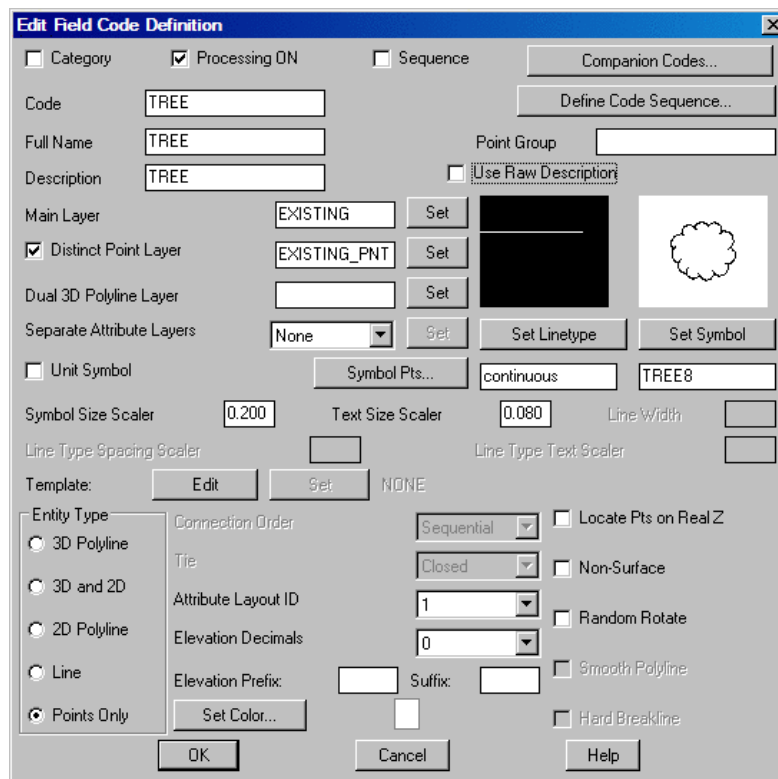

Specify Trunk Location point.

Pick Point or Point Number (Enter to End): 1

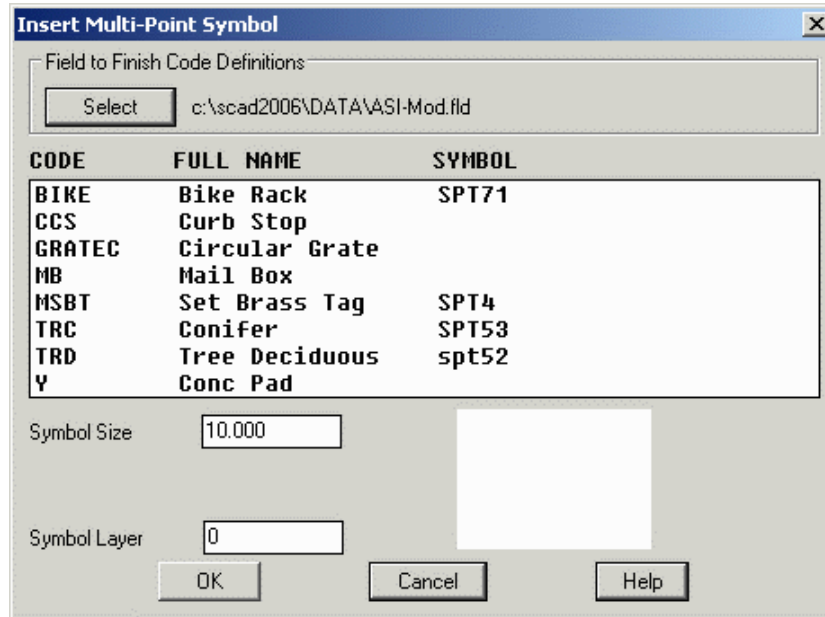

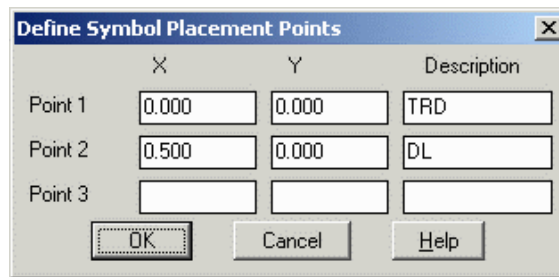

Specify Drip Line Point.

Pick Point or Point Number (Enter to End): 13

Insert another TREE symbol [<Yes>/No]? N

From the Field to Finish routine

Two points symbol placement for TREE

Three points for building PAD

Two point tree with drip line

Pulldown Menu Location: Draw > Symbols

Keyboard Command: multisym

Prerequisite: Field to Finish file (.FLD) with codes defined with Multi-Point Symbols

Draw 3D Model File

This command draws 3D faces for geometry in a 3D model file in .mdl or .obj file format. These graphic files are used in 3D viewing commands like 3D Drive Simulation. The Settings > 3D Model Library manages these graphics files. The .mdl file is also used for Solids in the Underground Mining module.

Pulldown Menu Location: Draw > 3D Solids

Keyboard Command: mdl2dwg

Prerequisite: MDL or OBJ file

Draw Table

This command creates a table entity by either reading a data file or by filling in a spreadsheet. For the input by data file, the text file must have rows of data fields separated by a delimiter such as a comma separated file (CSV). In the options dialog, set the Delimiter for the character that separates the values in the text file. Also there is an option for whether to create a totals line at the end of the table. The Link Table option will update the table in the drawing when the text file is updated. This update is done when the drawing is opened or running a REGEN.

For Manual Input method, the data is entered in a spreadsheet that starts out empty. You can manually type in data or copy/paste from the Windows clipboard.

After picking the location to draw the table, there is a dialog for formatting the table. You can control the header names, width, size, alignment and style. There are settings for the table layer, color and title.

Pick an intermediate point (U to Undo): *pick a point*

Pick an intermediate point (U to Undo): *press Enter*

Examples of Curve - Arrow

Pulldown Menu Location: Draw

Keyboard Command: carrow

Prerequisite: None

Leader With Text

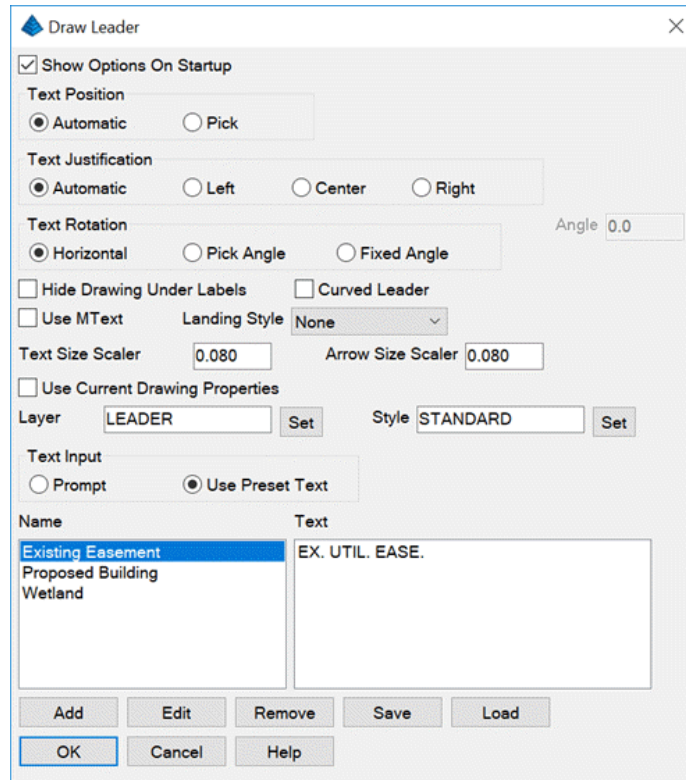

This command will draw a straight or curved leader between two points, with an arrow at one end and optional text at the other. The options dialog is displayed at the start. To skip this dialog, turn off the Show Options On Startup toggle. Then on the command line, entering *O* for Options will show the options dialog. To quickly change the label size, enter *S* for Size at the command line.

In the options dialog, Text Position chooses between automatically placing the label next to the leader end point or picking the label position. For Text Justification, you can set a specific justification or use the Automatic option which uses either Left or Right justification depending on whether the leader end is left or right of the leader start. Text Rotation chooses between having the label horizontal to the current view, prompting for the label angle or at a fixed angle specified in the dialog. The Hide Drawing Under Labels option uses a wipeout to hide drawing entities behind the leader labels. The Curved Leader option curves the leader between the start and end points. Otherwise a straight leader line is created. The Use MText option chooses between creates MText or regular Text entities. The Landing Style of Horizontal Tick draws a short horizontal line segment at the end of the leader. The Landing Style of Underline draws the leader line under the text like an underscore. The Text Size Scaler and Arrow Size Scaler are multiplied by the Horizontal Scale from Drawing Setup to set the drawing size for the label and arrowhead. There

are settings for the layer and style for the label. When the User Current Drawing Properties is on, then the current layer and current style from the drawing will be used.

The Text Input can either be entered with prompts after the leader points at the command line or selected from a prepared list. The prepared list is a way to quickly create leaders for common labels. To prepare the label list, use the Add, Edit and Remove buttons. Use the Save and Load buttons to save the preset labels to a .CALL file.

Pick callout point: *pick a point for point of leader*

Pick textbox corner: *pick a point for position of label*

Pulldown Menu Location: Draw > Leader

Keyboard Command: callout_ldr

Prerequisite: None

Bold Curve Leader

This command draws a thick curved leader with an arrowhead. This leader is created by picking three points.

Prompts

Starting point: *pick a point*

End of arrowhead: *pick a point*

Pick end point of leader: *pick a point*

Pulldown Menu Location: Draw > Leader

Keyboard Command: site_leader

Prerequisite: None

Flow Leader

This command draws a wavy leader line with an arrowhead. The size of the arrowhead is set by the symbol size scaler in Drawing Setup.

Prompts

Starting point: *pick a point for arrow end of leader*

Ending point: *pick a point for tail end of leader*

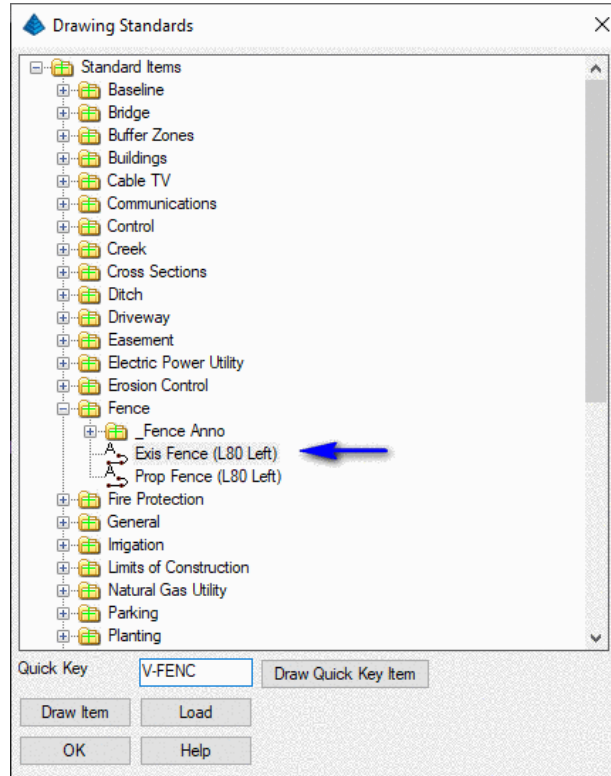

Pulldown Menu Location: Draw > Leader

Keyboard Command: flowline

Prerequisite: None

Draw Standard Item

The **Draw Standard Item** command activates the **Standards Draw** palette:

This palette is essentially the same as the **Standards Draw Manager** palette except that it does not have the Standards management commands available in the right-click short-cut menu.

Draw Quick Key Item: When a valid Standard Item key-in (essentially the layer designation of an item until changed to something more meaningful) has been keyed into the *Quick Key* edit box, you can draw the item without having to navigate for it in the list of Standard Items.

Draw Item: This option will permit you to browse for a Standard Item from the list of items (within their respective Categories, if present) and place the Standard Item into the drawing.

Load: This command will load the content of an XML-structured *.CAD file.

Carlson includes a Standards Database file (.cad) with the installation (**NCS_SurveyCivil.cad** which is a fully populated database based on the **US National CAD Standard**).

The **Draw Standard Item** command permits you to browse through you list of Standard items or draw one based on its "quick key" (essentially its layer name) designation and can be quickly accessed through the toolbar short-cut on the left shown below.

Items in the **Standards Draw** palette are organized into Categories and given commonly referred-to, descriptive names. Defining these Items and other management tasks are done through the Items Standards Manager.

A Standard Item can include any one or a combination of three types of entities:

1. Symbol
2. Linework
3. Annotation (with or without a Leader)

Next to each item in the palette is a graphic icon which indicates the type of entity(ies) defined for that Standard Item.

This icon,  is shown for a Standard Symbol Item.

This icon,  is shown for a Standard Linework Item.

This icon,  is shown for a Standard Annotation Item.

You may also see one of these icons representing a combination of entity types:

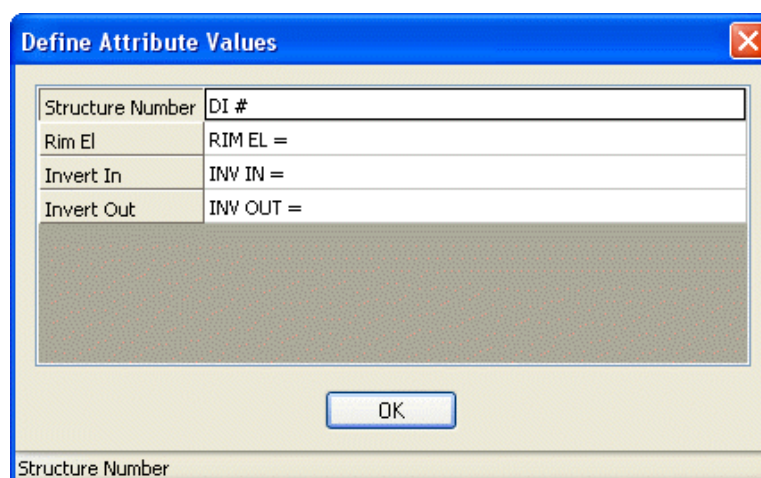

Because many Standard Items will be sized based on the scale of the drawing, it is important to set the "Horizontal Scale" in the **Carlson Drawing Setup** dialog box before drawing Standard Items into your drawing. If Standard Items are drawn and scaled according to the "Horizontal Scale", the "Horizontal Scale" setting is saved with the entity. In other words, changes to the "Horizontal Scale" of the drawing will not affect existing entities. This is true of Symbols, Annotation and Leader components.

To Draw a Standard Item using the Item menu in the palette, navigate through and left-click the Standard Item to be drawn. Assuming the Standard Item has a Symbol, Linework and Annotation component, you will see, generally, the following series of prompts. Note that, depending on the various options that have been set for each Item, the prompts may vary.

Start Point: Using the left-mouse button, select the location for the first Symbol component. This point will also be the first endpoint of the Linework for this Item. If you do not wish to have a Symbol inserted at this point and only wish to draw the associated Linework, hold the **ALT** key when specifying the Start Point to proceed on to the next Endpoint.

Rotation Angle: If you have placed a Symbol, specify its Rotation Angle. If you have set the Symbol Rotation option to "Fixed", you will not be prompted for this Rotation Angle.

If you insert a Symbol having non-Constant attribute values, you will be prompted through a dialog box to define the attribute values:

Halfwidth/Width/CLose/LEngth/Open/Undo/Arc Endpoint of line: Select the next Endpoint of the line segment or specify one of the other Polyline command options before picking the Endpoint. If you do not want to draw a

Linework segment at this time, press **Enter** to skip this step and continue on to place Annotation.

Rotation Angle: Specify the Rotation Angle for the next Symbol. Again, depending on the Symbol Rotation options you have set, you may or may not receive this prompt.

The prompts will continue to alternate between "Rotation Angle" and "Endpoint of Line" until you have reached the end of your Linework. When you have specified your final Endpoint and the Rotation Angle of your final Symbol, right-click to continue on to place Annotation.

Displacement/Identify or <\P>key in alternative text: This is the prompt for your first Annotation entity. The Item's Label is used for default Text content. To override the default Text, simply type in the alternative Text at the Command: Line. If you need a 2nd line of Text, use "\P" to designate the 2nd line of text. For instance, entering "TWO STORY\PWOOD FRAME" would result in the following Text string in the drawing:

```
TWO STORY
WOOD FRAME
```

Also, left-clicking on any other Text entity will update your current Text value to match the Text that was selected. And, holding the **ALT** key while left-clicking on any other Text entity will add the value of that Text entity as a 2nd line of Text to your current Text value.

Once you have finished entering the Text, press **Enter** to finish Text entry. Left-click in the drawing to place the Text.

Rotation angle/Identify or <\P>key in alternative text <0.0000>: Type in a Rotation Angle for the text or left-click to specify the desired angle.

Leader Start Point: Left-click to specify the location of the arrowhead part of the Leader. If you do not want a Leader, you can right-click to skip the Leader and proceed on to place the next Text entity.

Next Leader Point: Left-click to specify the next Endpoint of the Leader. You will continue being prompted for "Next Leader Point:" until you right-click or **Enter** to finish drawing the Leader. After you have finished drawing the first Annotation entity (with or without a Leader), you will continue to be prompted to place additional Annotation and Leaders. Right-click or press **Enter** to finish the command.

Pull-down Menu Location(s): Draw > Draw To Standard

Keyboard Command: drawitem

Prerequisite: Standards Database file (.cad)

Draw Label For Companion Linework

This command creates text using the text properties (layer, style, color, height, etc) defined in Item Standards Manager. This command prompts to select a linework entity from the drawing. The layer from this entity is used to lookup the text properties from the standards manager and then create text. For text items in the standards manager, there is a setting for Companion Linework Layer which needs to be defined using Item Standards Manager.

This command is a way to apply your CAD standards when adding text to linework already in the drawing. For example, if you have polylines for building perimeters drawn on your standardized layer for building perimeters, then you can use this command to add text to the buildings. In this case, you need to have a text item defined in the Item Standards Manager with a Companion Layer set to the layer for the building perimeters.

Pull-down Menu Location(s): Draw > Draw to Standard

Keyboard Command: textitem

Prerequisite: Linework on a layer defined in Item Standards Manager

Draw Standard Item by Quick Key

This command draws standard items defined in Item Standards Manager similar to the Draw Standard Item command. The difference with this command is that the item to draw is selected by typing in the quick key instead of selecting the item from the dialog. This quick key method can be faster than the dialog selection. In Item Standards Manager, each item has a field to specify a quick key.

Pulldown Menu Location(s): Draw > Draw to Standard

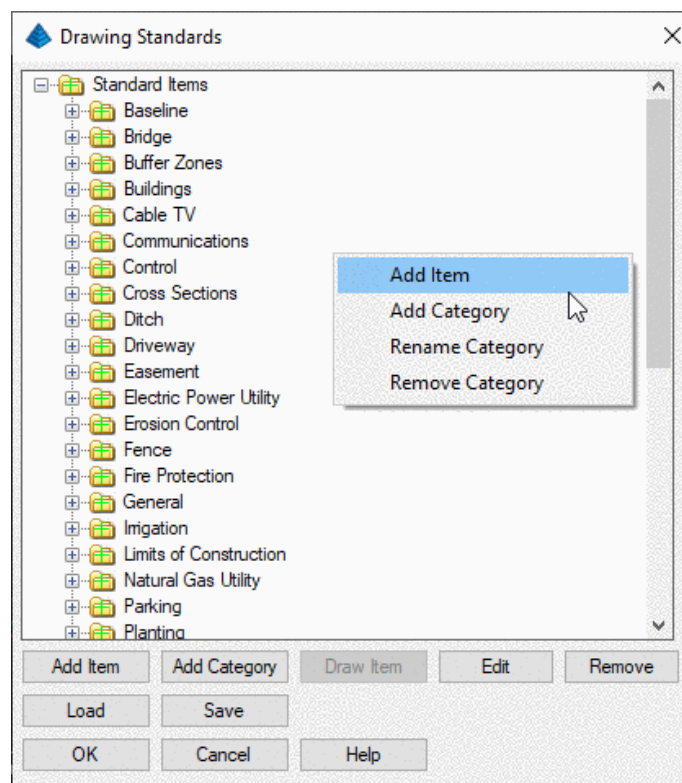

Keyboard Command: qkeyitem

Prerequisite: Items defined with quick keys in Item Standards Manager

Item Standards Manager

The **Item Standards Manager** command launches the **Standards Draw Manager** palette.

This palette has a right-click shortcut menu allowing you to Insert, Modify, Delete and otherwise manage Items stored in the Standards Database file (.cad):

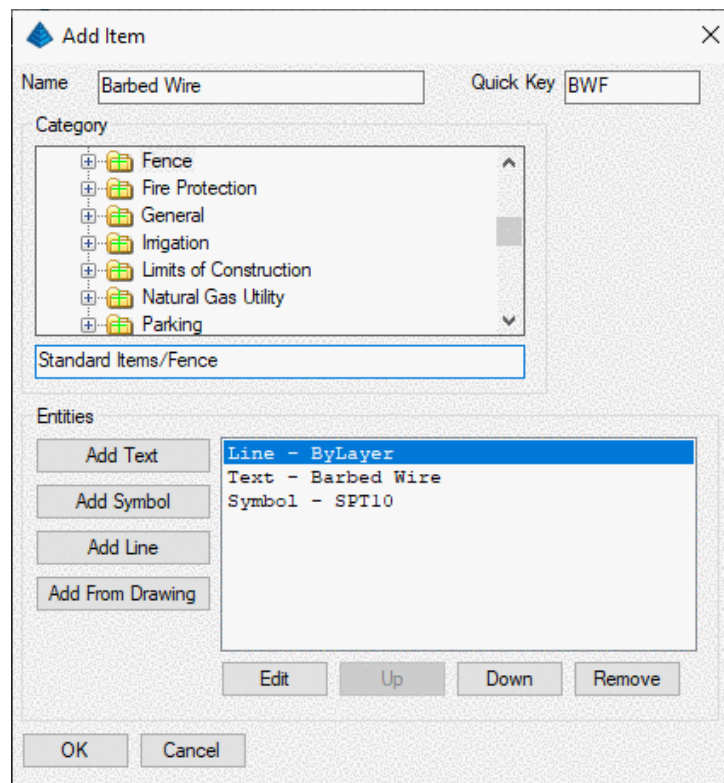

Once displayed, right-clicking inside the **Standards Draw Manager** displays a menu containing the Standards Database management commands. Other than the shortcut menu, this palette is essentially identical to the Draw Standard Item command.

The **Item Standards Manager** command permits you to browse through your list of Standard Items and manage the list of Items you can quickly place into a drawing. The command can be quickly accessed through the toolbar short-cut on the right shown below.

Add Item

When a Category has been selected/highlighted, you can add an Item into it.

Name: Provide a common name for Item in the selected Category.

Quick Key: Indicate a desired short-cut key-stroke (for example, a survey field code might be useful) that would be used to designate the Item. This value is not used or set for Categories.

Category: Select/identify the Category to which the item should belong.

Entities: Indicate the entity(ies) (and the order thereof) that comprise the Standard Item you are creating.

NOTE: The **Add from Drawing** option permits you to select a previously drawn Text, Symbol or Line/Polyline entity and add it to the Standard Item. Each item will have specific properties you can set that will permit you to control its insertion and composition into the Standard Item.

Add Category

When a Category has been selected/highlighted, you can add a sub-Category into it.

Draw Item

With an Item selected from the list, you can draw the item into the drawing. Refer to the Drawing Standard Items discussion for additional details.

Edit

This command allows you to make changes to the composition of the actively selected/highlighted Item or Category.

Remove

This command allows you to delete the the actively selected/highlighted Item or Category.

NOTE: Removing (deleting) a Category will also remove/delete the Items/Sub-Categories which are "housed" within the Category! You will be prompted for confirmation prior to deletion.

Load

This command allows you to replace the content of the current Drawing Standard library content with that of a different *.cad file.

Save

This command allows you to commit the values of the current Drawing Standard library content to a named *.cad file

Pulldown Menu Location(s): Draw – Draw to Standard

Keyboard Command: configItem

Prerequisite: None

Draw By Example

This command prompts you to pick an entity and then starts the appropriate draw command to begin creating another one of the selected type of entity. The properties such as layer and color of the original entity are used for creating the new one. For example, if you pick a polyline, this command will start the *Pline* command. Likewise if you pick text, this command will begin the *Text* command using the layer and style of the selected text.

Prompts

Pick Object for Command: *pick an entity*

The remaining prompts depend on the type of the selected entity.

Pulldown Menu Location: Draw

Keyboard Command: drawbyex

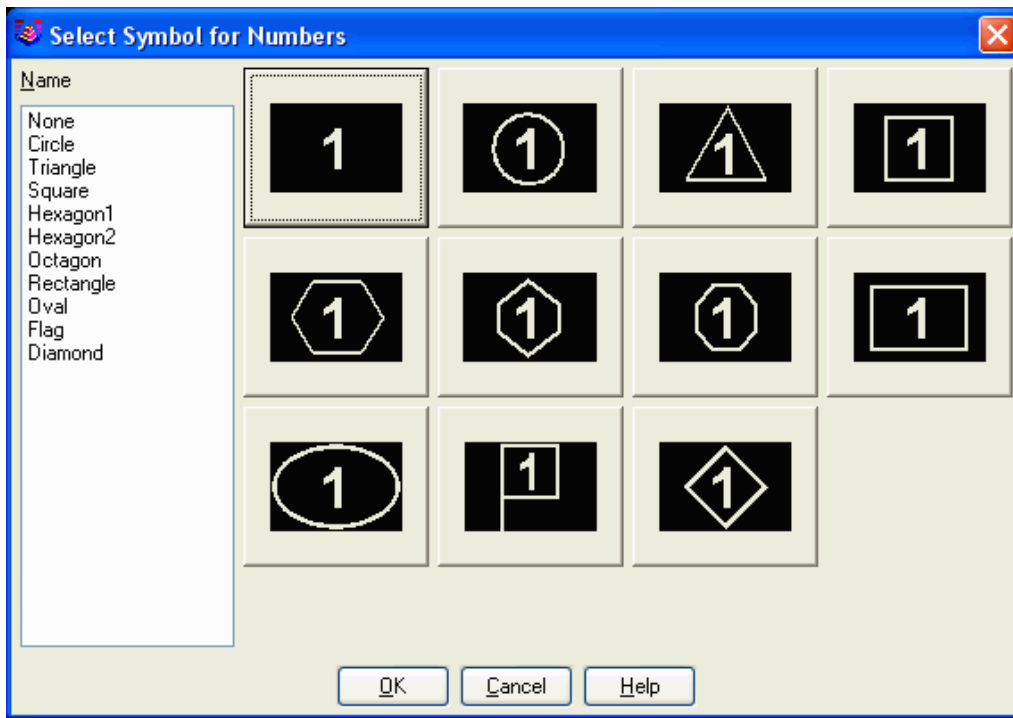

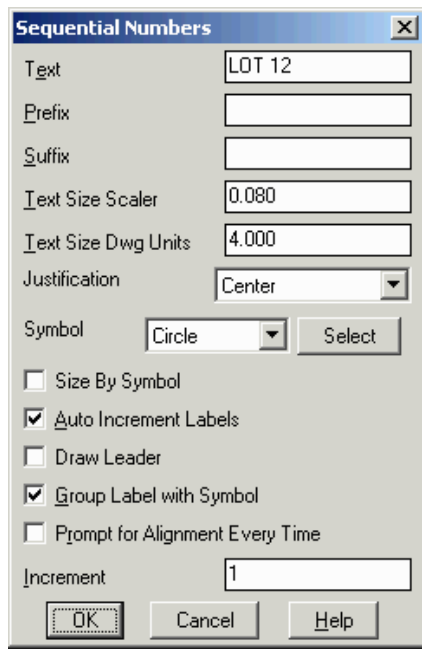

Prerequisite: Entities

Sequential Numbers

This command draws a text label and then increments to the next value for additional labels. The label can optionally be placed inside a circle, square or other symbol. The size of the symbol adjusts to fit the label size.

In the dialog, specify the **Text** label. The text **Prefix** and **Suffix** are optional. The **Text Size Scaler** is the text size in paper units that gets multiplied by the horizontal scale from Drawing Setup to set the text drawing size or **Text Size Dwg Units**. The **Justification** setting controls the text justification mode. The **Size By Symbol** method uses a fixed symbol size and sizes the label to fit within the symbol. When **Auto Increment Labels** is checked, the value entered in the Text field will be incremented by the value in the **Increment** field. The **Group Label With Symbol** option will make a group of the label text and symbol. When **Prompt for Alignment Every Time** is checked, you will be prompted for the alignment angle for each label, otherwise the alignment from the first label is automatically used for the other labels. The **Draw Leader** option creates a leader from the label to a picked point.

The label is drawn by combining the Prefix, Text and then Suffix into one text label. When placing multiple labels, the text portion of the label will increment by the value in the Increment field. For example, this command could be used to quickly label a series of boundaries by setting the Prefix to "Perimeter" and the Text field to the starting number. Then pick points inside the boundaries to label as "Perimeter 1", "Perimeter 2", etc.

Perimeter1	Perimeter5
Perimeter2	Perimeter6
Perimeter3	Perimeter7
Perimeter4	Perimeter8

Prompts

Select Symbol for Numbers dialog *select your symbol*

Sequential Numbering Options dialog *make your choices*

Pick point at beginning of label: *pick a point*

Pick point for label alignment: *pick a point to the right of the first point*

Pick point at beginning of label: *press Enter to end the routine*

Pulldown Menu Location: Draw

Keyboard Command: numbers

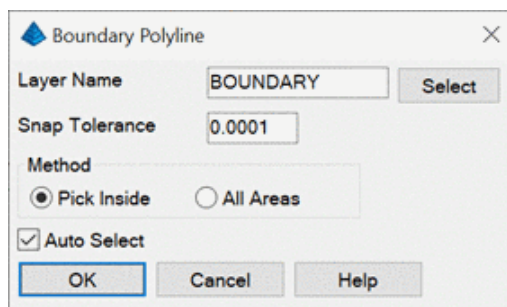

Prerequisite: None

Boundary Polyline

This is a streamlined analog of the AutoCAD command *Boundary*. The Carlson version is faster and works in many cases where *Boundary* fails. *Boundary Polyline* supports a **Snap Tolerance**, which means that you may specify a maximum gap to close when creating a closed polyline.

To create closed polylines from any existing linework, simply select all entities you would like to use and specify desired snap tolerance. There are two methods to create boundary polylines. The **Pick Inside** method creates boundary polylines one at a time. For this method, click inside openings you would like to trace and the routine will generate the corresponding closed polyline. Duplicate polylines are detected and not created, so that clicking more than once in the same area does not change anything. For the **All Areas** method, the program finds all the closed areas from the input linework and creates a boundary polyline for each area. The **Auto Select** option will automatically select the linework in the current drawing view to use for calculating the boundary. Otherwise, the program prompts for you to select the linework to use for the boundary. The **Type of Polyline** controls whether to use the elevations of the existing linework to create a 3D polyline, or ignore the elevations and create a 2D polyline at zero elevation.

These new polylines are created in the layer set in the options dialog. Layers of the original linework do not matter.

Prompts

Boundary Polyline dialog

Select polylines.

Select objects: *pick entities to be used*

Pick an internal point: *pick the points to enclose*

These three polylines are created from original linework by clicking at shown locations

Pulldown Menu Location: Draw

Keyboard Command: boundpl

Prerequisite: Entities

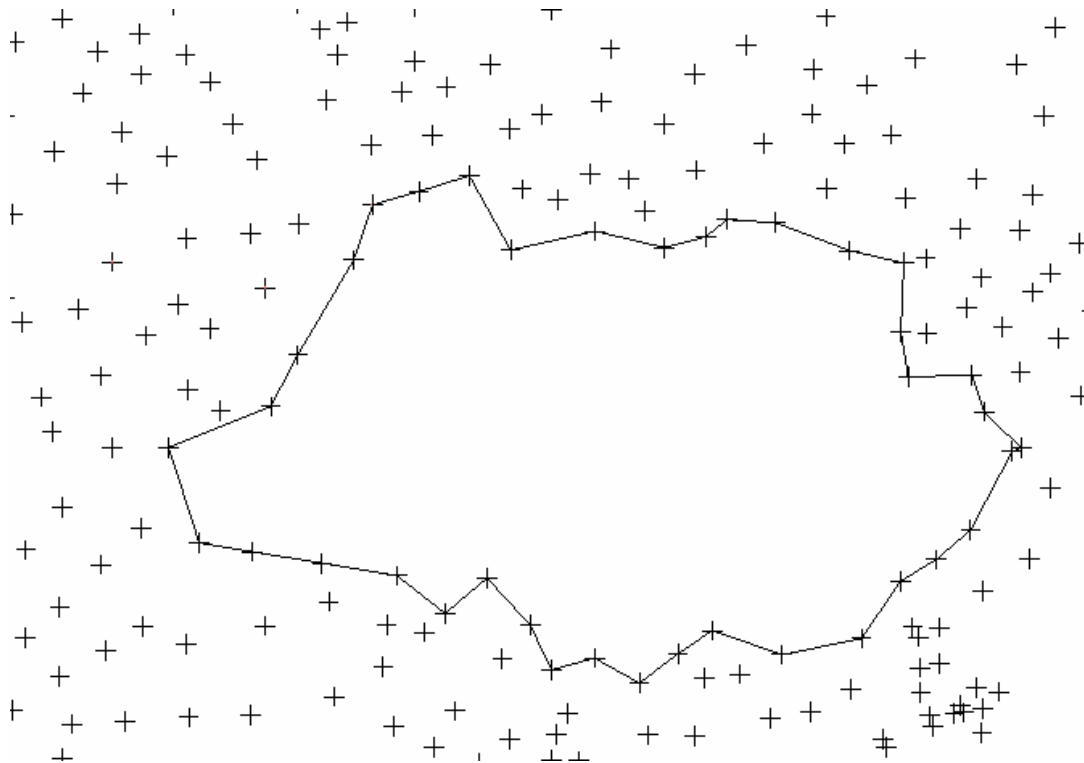

Shrink-Wrap Entities

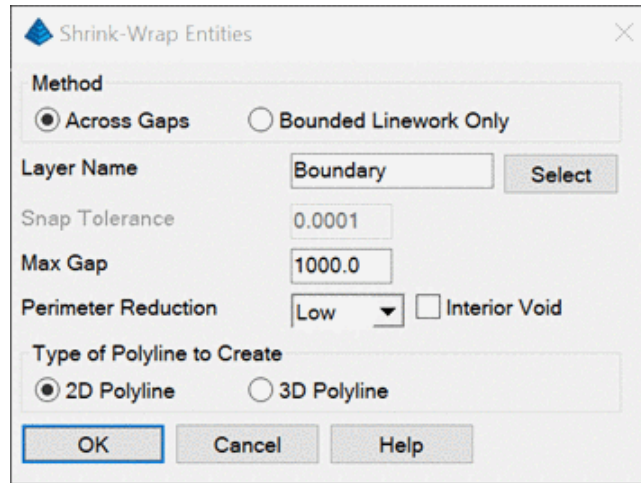

This command creates a closed polyline which encloses a given set of point and linework entities. The resulting polyline is created in the specified layer.

There are two different methods. The Across Gaps method creates a closed polyline through the points around the perimeter of the area defined by the selected entities. The Max Gap limits how far the polyline segments will connect between points. The Perimeter Reduction pulls in the shrink-wrap polyline to make a tighter fit similar to a vacuum suction effect. The 3D Polyline method uses the elevations of the input entities to create a 3D polyline. The 2D Polyline method ignores the elevations of the input entities and creates a polyline at elevation zero. For open polylines, as in the bottom figure, the Gap method works better, as it jumps across the gaps and connects the end points. The Interior Void method creates a closed boundary polyline for an empty area that is surrounded by points such as a pond. The Ignore Zero Elevations option will filter out entities at zero elevation and not use them in creating the perimeter. The Elevate Zero Elevations option will interpolate zero elevation vertices in the perimeter

polyline using other vertices with elevations.

For the Bounded Linework Only method, the shrink-wrap polyline follows the outside border of the selected polylines. The polylines that are processed have to be connected to be shrink-wrapped. The Snap Tolerance is the maximum gap that will be joined to make the closed polyline.

Prompts

Shrink-Wrap Entities dialog

Select points and linework to shrink-wrap.

Select objects: *select entities to process*

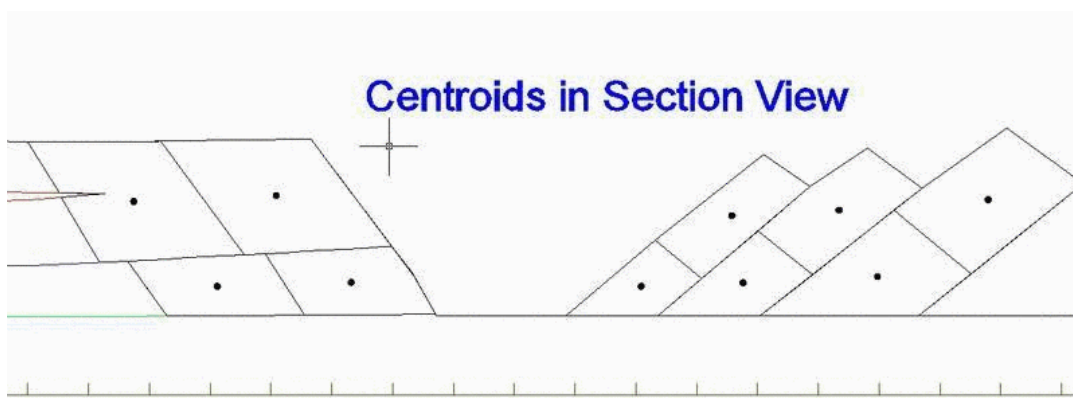

Pulldown Menu Location: Draw

Keyboard Command: swplines

Prerequisite: Entities

Centroid Point

This command draws points at the centroids of the selected polylines. In the section option, the areas need to be closed polylines representing the blocks to calculate the centroids of. This is useful for calculating haul distances and blast distances in section view. When choosing to come from a grid file, it finds the x,y position for the center of mass. Typically this grid would be the difference between existing and design surfaces, represented as a thickness grid. For example, this routine could be used to find the center of mass for a stockpile using a difference grid of the stockpile grid and base grid.

Prompts

Centroid from cross-section or grid file [<Section>/Grid]? S

Select closed polyline(s).

Select objects: 1 found

Select objects:

Center at 1462284.64,1971935.94

Pulldown Menu Location: Draw

Keyboard Command: plcenter

Prerequisite: Closed polylines for calculating the centroids

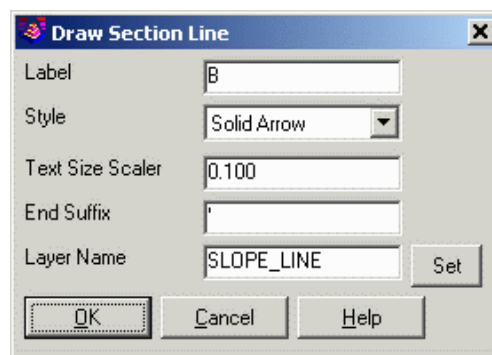

Section Line

This command creates a plan view section line with labels such as for showing the alignment for a cross section. Choose the section line properties in the options dialog. Then the program prompts for the two end points for the line and draws the section line with labels.

Three different styles of section lines

Prompts

Section Line dialog

Pick 1st point: *pick a point*

Pick 2nd point: *pick a point*

Pulldown Menu Location: Draw

Keyboard Command: sectionline

Prerequisite: None

SmarTrace

SmartTrace is an enhanced sketch routine. AutoCAD's *Sketch* command is acceptable for some tracing, but if a large contour map is sketched, it creates a huge file that loads and regenerates slowly. The problem is that the sketch command creates points at user specified increments, this small increment may be appropriate for sharp corners, however, in relatively straight stretches this is very inefficient.

SmartTrace solves this problem. The routine works by reducing the number of vertices created on polyline tracing by using a deflection angle and minimum and maximum distance. In sharp turns, it will create points at the minimum distance specified, and in relatively straight stretches it creates points at the maximum distance specified. If the angle of the polyline turns more than the specified deflection angle, SmartTrace also creates a point.

Prompts

Deflection Angle <4.0>: *press Enter* A range of 3 to 5 degrees is best.

Minimum Distance <5.0>: *press Enter* Usually 5% of map scale, or 1/20 inch.

Maximum Distance <50.0>: *press Enter* Usually 50% of map scale, or 1/2 inch.

Start point: *pick beginning point on polyline*

Begin Tracing ... Press Pick Button to End. Carefully move along polyline. *press the pick button to complete the polyline*

Pull-down Menu Location: Draw

Keyboard Command: TABLET3

Prerequisite: None

Polyline by Slope Ratio

This command allows you to draw or revise a polyline by specifying distance and slope ratio, percent of grade or pick points on the screen. The polyline could represent a section or profile which can be processed with the *Polylines End Area* or *Sections from Polyline*.

Prompts

Horizontal scale <50.0>: 20

Vertical scale <50.0>: 10

Pick point/<Starting elevation of polyline-section <100.0>>: *P* Enter the starting elevation or press Enter to use the default value in brackets and you are prompted for the starting offset or X coordinate. By entering P you are prompted to pick a starting point for the polyline/section.

Pick start point: *pick a point*

Slope ratio + for up slope - for down slope.

Undo/End/switch to Left/Pick point/<Enter Right Distance>: 130

End/Percent slope/<Slope Ratio (?:1) <2.0>>: 5 This enters a slope ratio of 5 to 1 for 130 feet to the right of the starting point.

Undo/End/switch to Left/Pick point/<Enter Right Distance>: L

Undo/End/Pick Point/<Enter Left Distance>: 110

End/Percent slope/<Slope Ratio (?:1) <2.0>>: P

Percent of grade slope: 2 This enters a slope of 2 in 100 for a distance of 110 feet to the left of the starting point.

Undo/End/Pick Point/<Enter Left Distance>: 30

End/Percent slope/<Slope Ratio (?:1) <2.0>>: 4

Undo/End/Pick Point/<Enter Left Distance>: E Entering E ends the command.

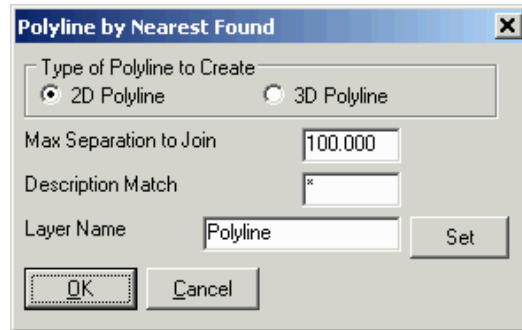

Pull-down Menu Location: Draw

Keyboard Command: PSR

Prerequisite: None

Polyline by Nearest Found

This command draws a polyline by connecting points using a nearest found method. The points to connect can be specified either by entering point numbers or picking POINT entities on the screen. The nearest found method draws a polyline by starting at one of the points and then connecting to the closest of the remaining points. Then a remaining point that is closest to one of the polyline end points is added until all points are part of the polyline.

Prompts

Polyline By Nearest Found dialog

Select point from screen or by point number (<Screen>/Number)? *press Enter*

Select points.

Select objects: *pick points*

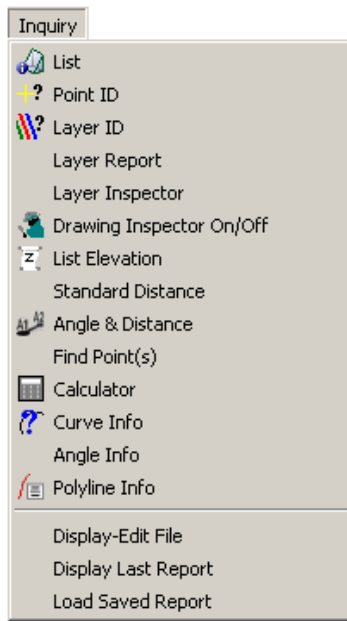

Pulldown Menu Location: Draw

Keyboard Command: plnear

Prerequisite: Points

Inquiry Menu

Shown here is the Carlson Inquiry menu. The top section contains detailed inquiry commands. The lower section of the menu includes report and file editing commands.

Point ID

This command reports complete information pertaining to a Carlson point. Although similar in function to the AutoCAD *ID* command, this routine is much more detailed. With this command, you are given the point number, as well as the northing, easting and elevation coordinates. You also are given the point description, and you are shown the name and the location of the coordinate file for the point.

Prompts

Pick point or point number: 255

```
PointNo.  Northing(Y)  Easting(X)  Elev(Z)  Description
255      4379.83      4265.48    19.01    GROUND/SHOT
N: 4379.83  E: 4265.48  Z: 19.01
PT#: 255  CRD File: c:\Carlson2008\data\mantopo.crd
```

Pulldown Menu Location: Inquiry

Keyboard Command: PT_ID

Prerequisite: None

Layer ID

This command reports the layer name of the selected entity. Under Options, you can choose to draw a label of the layer name.

Prompts

Pick entity to read layer [Options]: *pick an entity*

Layer: FINAL

Pick entity to read layer: *press Enter to end*

Keyboard Command: layerid

Prerequisite: None

Layer Report

This command generates a report containing all the layers defined in the drawing. Along with the layer names, the report includes the number of entities on each layer, and the color, linetype and lineweight for each layer.

Layer Report

Drawing: C:\sample\example1

Layer Name	Entity Count	Color	Linetype	Lineweight
0	5	White	CONTINUOUS	
AREA_PERIM	0	White	CONTINUOUS	
AREATXT	0	Magenta	CONTINUOUS	
BL	8	White	DASHED	
BL-LAB	76	Red	CONTINUOUS	

Pulldown Menu Location: Inquiry

Keyboard Command: reportlayer

Prerequisite: None

Layer Inspector

This command is used to inspect and work with layers in the drawing. This command is ideal when you are working on a very dense and complex drawing which has many layers and you want to review the entities on different layers. In some cases, there will be layers that you would want to erase. Another scenario might be that you'd like to highlight a layer that is hard to find and see.

The Layer Inspector command has a dialog that docks to the bottom of the drawing window which keeps the drawing window visible while running the command. On the left of the dialog is a list of all the layers in the drawing. To inspect a layer, highlight the layer name from this list. You can inspect multiple layers at a time by selecting multiple layers in the list using the Shift and Ctrl keys while picking in the list. When a layer is selected, the Entity Count reports how many entities in the drawing are set to that layer. The Zoom toggle will zoom the drawing window to the extents of the entities on the layer. The Isolate toggle will freeze all other layers. The Highlight toggle will highlight all the entities on the layer. The Restore View On Exit will set the drawing window to the original position when Layer Inspector was started. The magnify and arrow buttons are used to zoom in/out and pan the drawing window. The Rename button allows you to rename the layer. The Erase Entities button will erase all the entities on the layer. The Purge button will purge the layer from the drawing which is only available when there are no entities on the layer. The Current button sets the layer as the current layer for the drawing.

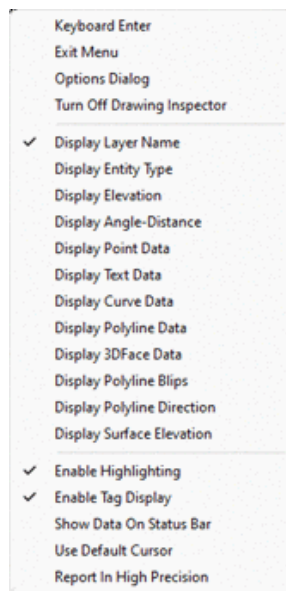

Pulldown Menu Location: Inquiry

Keyboard Command: layer_inspect

Prerequisite: None

Drawing Inspector

This command reports object properties to you as you move the cursor over an entity. You can simply move the pointer over an entity and the selected property will be displayed either in a pop-up window next to the pointer and/or on the status bar, depending on the selected option. Drawing Inspector is a transparent command that can run while other commands are running. Once Drawing Inspector is started, it will stay active even while running other commands until you turn it off. To turn off Drawing Inspector, run the command again to toggle it off by pick Drawing Inspector from the Inquiry pull-down menu or from the toolbar or by typing the command name, or right-click and choose Turn off Drawing Inspector. The options for this command are set in the menu that pops up by clicking the right mouse button. The available properties are: Layer Name, Elevation, Azimuth-Distance, Bearing-Distance, Point Data, Text Data, Curve Data, 3D Face Data, Polyline Data and Polyline Blips.

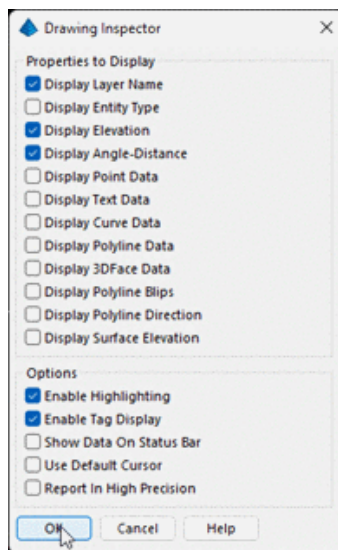

In the *Drawing Inspector* menu, you can choose one or more properties to display.

Keyboard Enter turns off the dialog box and returns to command control

Exit Menu exits the dialog box but leaves Drawing Inspector active

Options Dialog opens a separate dialog box which allows the On/Off toggle of display options. This is useful for turning on or off multiple display options at once.

Turn Off Drawing Inspector turns the routine off completely.

Display Layer Name: displays the layer name of the entity.

Display Entity Type: displays the type of the entity (ie. TEXT or POLYLINE).

Display Elevation: displays the elevation of the entity.

Display Angle-Distance: displays the direction and distance of a line. The angle mode will follow that in the Drawing Setup

Display Point Data: displays the coordinate data of point.

Display Text Data: displays the contents of text.

Display Curve Data: displays the radius, arc length, chord length and delta angle of a curve.

Display Polyline Data: displays the end point elevations, horizontal distance, slope distance, slope ratios and distance along the polyline for the current cursor position.

Display 3D Face Data: displays the Z elevations at the face corners.

Display Polyline Blips: displays temporary blip plus marks at the vertices of polylines.

Display Polyline Direction: displays temporary arrows to show the direction of polylines.

Display Surface Elevation: prompts for a TIN or grid surface file to load and displays the surface elevation at the current cursor location.

In the *Drawing Inspector* menu, you can also choose how the property information is reported.

Enable Highlighting: Allows you to highlight the object that the *Drawing Inspector* is reporting.

Enable Tag Display: Enables you to view the information next to the cursor on the screen.

Show Data On Status Bar: Enables you to view the information on the status bar, in the lower corner of the screen.

Use Default Cursor: When enabled, only the drawing cursor shows. When disabled, the mouse pointer is also shown.

Report In High Precision: When enabled, displays 8 decimals on distance and 4 decimal seconds on angles.

Example of Drawing Inspector reporting Angle-Distance using the Tag Display

Calculator

The Carlson Calculator command uses a convenient pop-up calculator with three tabs for a standard calculator, scientific calculator and conversion calculator. The standard calculator does basic math calculations using expressions such as +, -, / and *. The scientific calculator has angle and other functions. The conversion calculator has feet-metric and angle conversions including radians. The standard and scientific calculators support RPN. Here is how RPN works:

1+2 = 3
- type value 1 + Enter
- type value 2 + Enter
- type +
X = 3.

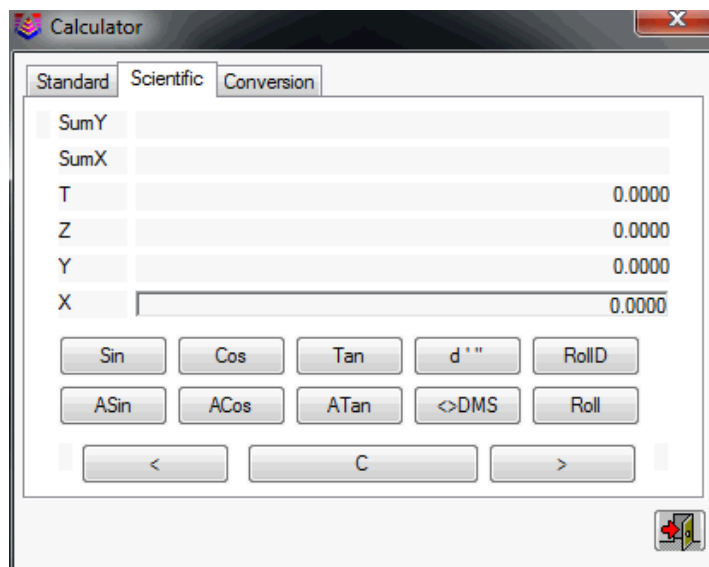

Standard Calculator

Most basic calculations can be performed using this tab in the calculator. Memory functions are also available.

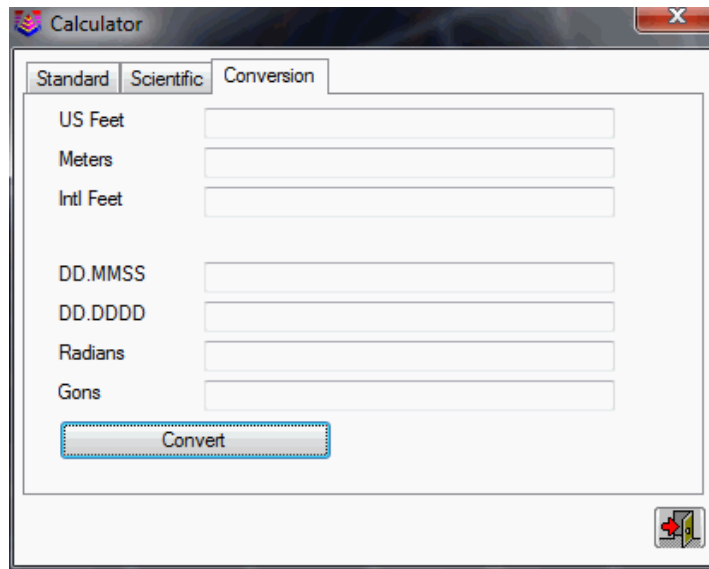

Scientific Calculator

Values can be entered on the X register. The values can be rolled up and down with the up and down arrow keys and the Roll and RollD buttons on the dialog. The Enter key finishes the entry of a number and pushes the stack. The C on the touch screen clears an entry. Additional functions on the screen can be obtained through touching the scroll [<] and [>] area of the screen.

Conversion Calculator

This mode provides for conversion between many units. Enter a value in any field and press Enter to find the conversion value. The following units are available in Feet, Meters and International Feet Degrees, Minutes, Seconds and Gons/Grads and Decimal Degrees.

Pulldown Menu Location: Inquiry

Keyboard Command: cscal

Prerequisite: None

Curve Info

This command displays information about a curve/arc. The curve can be defined by an arc entity or polyline arc segment or by selecting three points on the arc. The three points can be defined by point number or picked on the screen. The curve data is displayed in the text window with an option to be displayed in the Standard Report Viewer. Click Exit to return to the graphics window.

Prompts

Define arc by, Points/<select arc or polyline>: *select the arc entities*

Block Data Report

This command reports the number of different types of blocks in the drawing along with the block attributes. After selecting the blocks to report, the program has a dialog with all the block attributes. You can select which attributes to report. The Details option for the Report Format includes the properties for each block including the northing and easting. The Summary Report reports the number of each type of block with matching reported attributes. The Only Report Blocks With Attributes chooses whether to report blocks with no attributes.

Prompts

Select blocks to report.

Layer Report

This command generates a report containing all the styles defined in the drawing. Along with the style names, the report includes the number of entities on each style and the style properties.

Style Report

```
Drawing: C:\files\user\Project.dwg
Style      Font          Text Count Fixed Height Width Factor Oblique Angle
ROMAND     romand.shx     1198      0.0        1.0 0°00'00''
ROMANS     romans.shx     3981      0.0        1.0 0°00'00''
ROMANT     romant.shx     104       0.0        1.0 0°00'00''
```

Prerequisite: None

Angle Info

This command reports the interior and exterior angles defined by two joining line segments or by three points. The coordinates, angles and distances of the line segments are also reported. The report is display in the standard report viewer. When the input points have different elevations, there is an option to report the angle in 2D or 3D. For 2D, the elevation are ignored. For 3D, the points are projected onto a plane to report the 3D angle.

```
Angle Information
      Point#      Northing      Easting
Start Point:  11      4728.73      5660.09
Corner Point: 12      4684.89      5624.99
End Point:    13      4664.02      5690.60

      Bearing      Distance

Keyboard Command: load_report

Prerequisite: A saved report

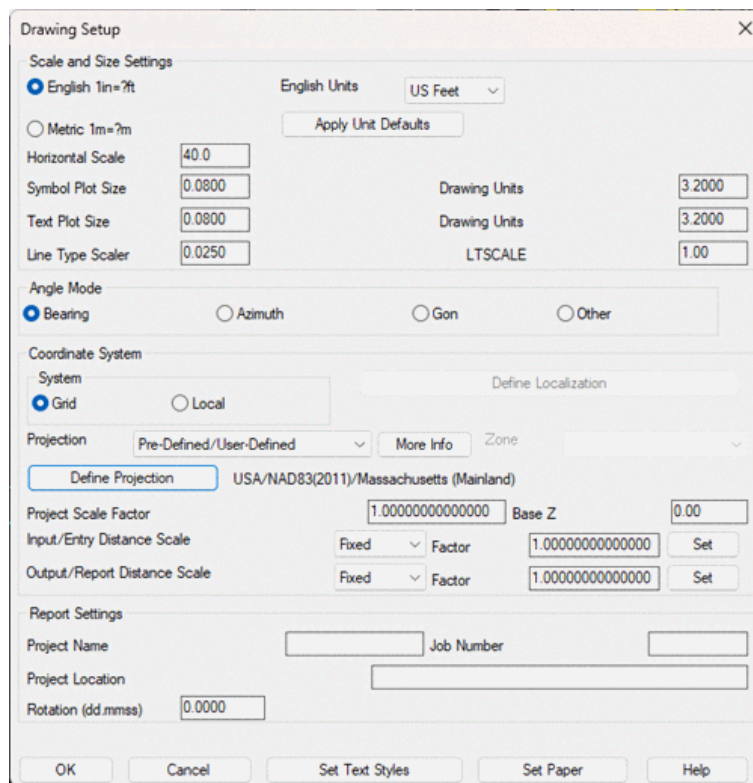

Settings Menu

Shown here is the Carlson Settings menu. The top section contains the commands most important for setting up the drawing. You should run Drawing Setup prior to starting work in your drawing. Additional setup and settings features are found in the middle section. The last section of the menu includes AutoCAD/IntelliCAD settings commands, including the System Variable Editor.

Drawing Setup

This command allows you to specify drawing parameters, including the plotting scale, size of symbols, label annotation size, and the angle mode.

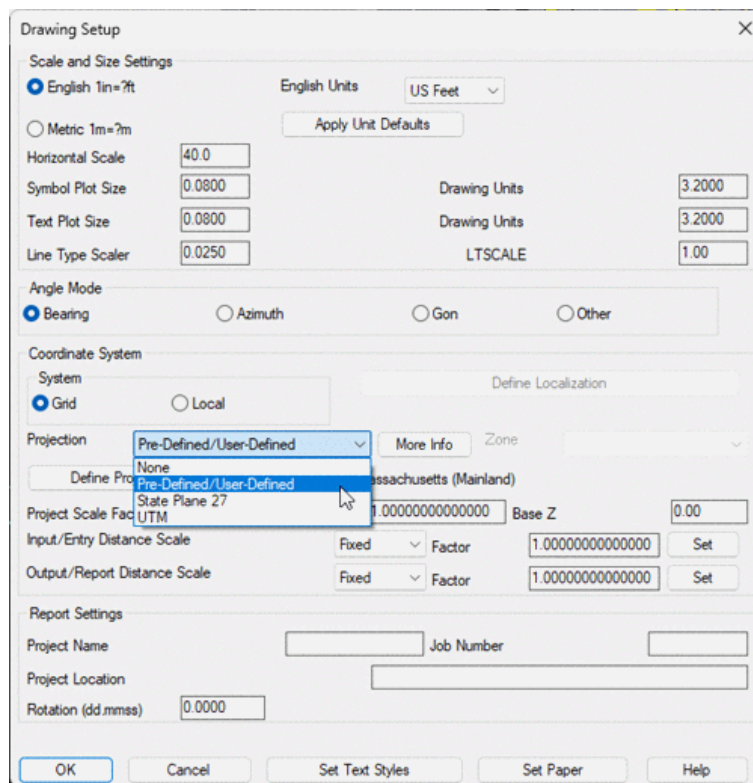

Specify **English 1in=?ft** or **Metric 1m=?m** as the unit mode to use. This affects the prompting and reports. When you are working on a drawing in English units, one unit equals one foot. In metric, one unit equals one meter.

- **Apply Unit Defaults** sets the default units for either English or Metric Units with regards to the Symbol, Text and Line Type Scalers.
- Specify the **Horizontal Scale** of the drawing. For example, if the horizontal scale is set to 50, then 1" = 50' is your drawing scale.
- The **Symbol Plot Size** value is a scaler that represents the size on the plot. The Drawing Units are determined by multiplying the scaler by the horizontal scale. In English mode the scaler represents the plotted size in inches. In Metric mode, this value is the plotted size in centimeters. The **Drawing Units** field shows the result of the Symbol Plot Size value (the scaler) multiplied by the horizontal scale.
- The **Text Plot Size** value is a scaler that represents the size on the plot. The Drawing Units are determined by multiplying the scaler by the horizontal scale. In English mode the scaler represents the plotted size in inches. In Metric mode, this value is the plotted size in centimeters. The Text Plot Size is not entered in Drawing Units. The **Drawing Units** field shows the result of the Text Plot Size value (the scaler) multiplied by the horizontal scale.
- The **Line Type Scaler** option sets the linetype scale by multiplying this scaler by the horizontal scale.
Note: For those utilizing Annotation Scales [SCALELISTEDIT], this value is typically set at 1 for all drawing scales
- **Angle Mode-Bearing** sets reporting to bearing mode for any of the inquiry commands. (Modifies the settings in the AutoCAD *UNITS* command.)
- **Angle Mode-Azimuth** sets reporting to north based azimuth mode for any of the inquiry commands. (Modifies the settings in the AutoCAD *UNITS* command.)
- **Angle Mode-Gon** sets reporting to gon mode for any of the inquiry commands. (Modifies the settings in the AutoCAD *UNITS* command.)
- **Angle Mode-Other** lets the user determine angle mode by using the AutoCAD *UNITS* command.
- **Coordinate System** is an optional setting to define the drawing coordinate system. The coordinate system settings are used in commands like List Points and Label Lat/Lon to report geodetic coordinates from the drawing coordinates. The **Grid** System setting applies to drawing coordinates that are in a grid projection

system such as state plane coordinates. The Projection list selects the grid projection from the list of supported projections. Along with the Projection, there are selections for the zone and datum to use with the projection. When the drawing setup is in English mode, there is a projection setting for whether the feet are in US Feet or International Feet units. The **Local** System setting applies to all other coordinate system beside grid projections. The **Define Localization** button has settings to define the transformation from local coordinates to grid coordinates. With a localization defined, you can work in a drawing in local coordinates and still report lat/lon. The localization definition contains pairs of local and grid coordinates that define the transformation. Once a localization has been defined, it can be saved as a .dat, .loc or gc3 file for use on other projects or exported to SurvCE/PC.

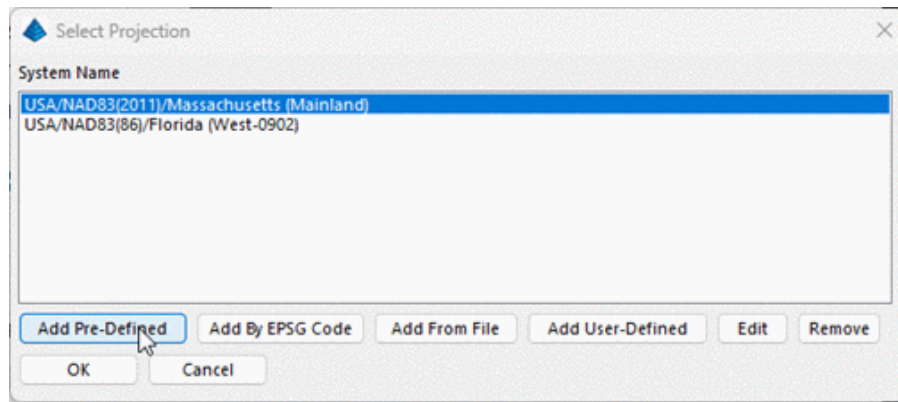

See the *Align To Local Coordinates* command in the *Field Module* for more information.

- **Project Scale Factor** is multiplied by the x,y coordinates when converting between drawing and geodetic coordinates.
- **Base Z** is used for calculating the combined scale factor for calculating geodetic areas.
- **Projection:** There are three choices for selecting a projections. If Pre-Defined/User-Defined is selected, you will be directed to a second dialog box for selecting or creating the projection. If State Plane 27 or UTM are selected, you can select the state or UTM zone respectively from the adjacent drop down menu.

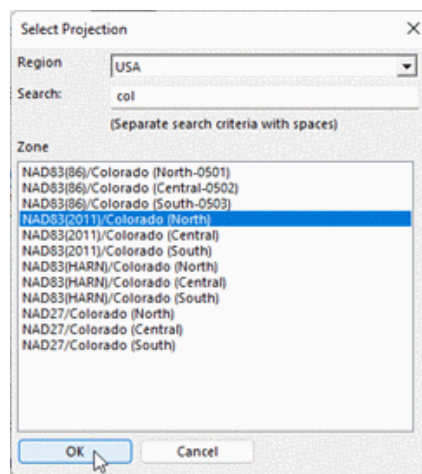

See also *Alternate Drawing Setup* for additional information regarding projections and the previous Lat/Lon datum selection.

- When you pick **Pre-Defined/User Defined**, a dialog shows a list of recently selected Pre-Defined projections.

You can pick from this recently used list, or pick the **Add Pre-Defined** to select from the built-in list.

This expanded Pre-Defined selection includes the projections used in SurvCE which has hundreds of projections including the US County projections for Indiana INDOT INGCS, Iowa Regional Coordinate System, Minnesota, Oregon and Wisconsin (WCCS and WISCRS) as well as from around the world.

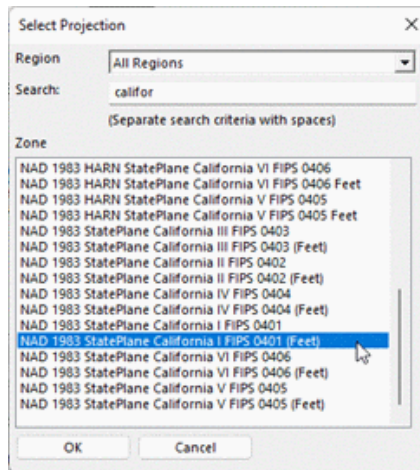

Note: Many projections in the list contain a designation in parentheses () indicating the realization date or specific projection reference. 86, 2011, and HARN are such designations. Pick the datum and realization that your project coordinates are located in. In the Continental US, the most recent realization is 2011 and is suited to most surveys. Changing the projection in the Drawing Setup **DOES NOT** alter the coordinates in the CRD/CRDB file. To transform coordinates from one projection to another, use Coordinate Transformation in the **Coordinate File Utilities**.

The **Search** field shown above, allows you to begin typing the projection name while the program filters available projections based on the entered text characters within that projection name.

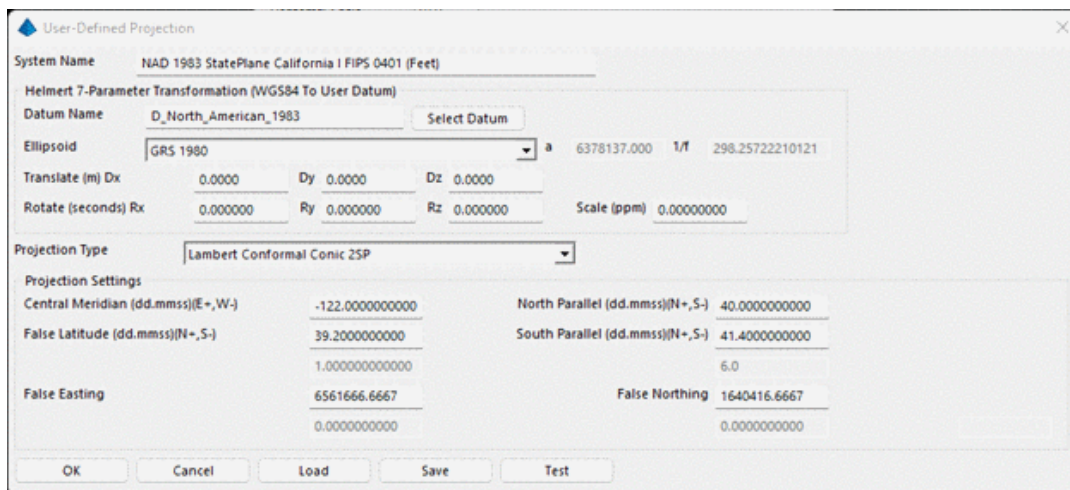

- The **Add by EPSG Code** allows the selection of existing EPSG Codes by entering in the projection number in a separate dialog box.

- The **Add From File** button reads in a projection saved to a file by this routine or by SurvCE CSL or ESRI PRJ.

- The **Add User-Defined** routine defines a projection by setting the ellipsoid, choosing the method and entering the parameters.

There are over 25 built-in ellipsoids to choose from such as Clarke 1880. You can also manually enter the ellipsoid

values. The projection definition includes the 7 parameter Helmert transformation to go from WGS-84 to the user datum. There are over 20 projection types to choose from such as Transverse Mercator. After selecting the projection type, there are edit fields for each of the parameters for the selected projection. The **Load** button allows you to browse and load predefined projections (cls, udp, prj) file formats. The **Test** button brings up a calculator to enter a lat/lon and report the projection coordinates as a way to test that the projection parameters are entered correctly and are working.

- The **Edit** button allows you to change the name or parameters of an existing projection.
- The **Remove** function removes a projection from the list of recently used projections.

Note: Besides Drawing Setup, these projections are used in the Coordinate Transformation function in Coordinate File Utilities.

Alternate Drawing Setup

In some cases, usually when opening an older project, you may be presented with a Drawing Setup dialog box with different options:

The above settings, **Perform Geodetic Lat/Lon Transformation** are a replacement to the versions previous to 2024 release. In these earlier versions, there was a drop down menu with options for a Lat/Lon datum. The default for this selection was WGS84. In the Continental US, WGS84 was equivalent to State Plane 83 *or* NAD83(1986) making this setting ambiguous which prompted its removal. When opening an existing drawing, the lat/lon transformation setting in the Drawing Setup is compared to the equivalent settings in Carlson Configure->Survey Settings. If there is a mismatch, the above options will be displayed to allow the user to confirm or correct the transformation setting.

As described above, the newer selection of datum along with any realization date is a more complete selection of a projection. In most cases, users will prefer to have their lat/lon datum on the same datum as their coordinates and not perform any transformation. However, in some cases, especially when opening older drawings, this transformation is detected, and you are prompted to make a choice to rectify these settings.

Example:

You are opening an older drawing that was set to State Plane 83 with the option to use WGS84 as a lat/lon datum. When doing so, you are presented with the following prompt:

You select NAD83 (2011). At this point your projection is not consistent with the previously selected WGS84 lat/lon datum. You will see the above options in the Drawing Setup.

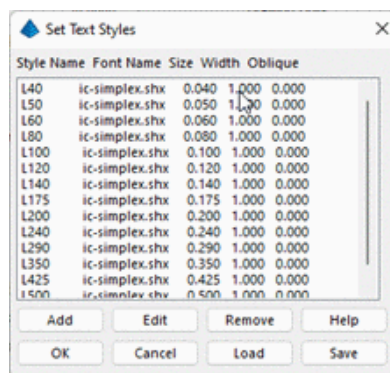

The options for this setting are:

- On - will transform lat/lon coordinates to the previously called WGS84 or other datum
- Off - will perform no transformation. (Preferred for most surveys)

- Use Survey Setting - will follow the options as set in the Survey Settings in Carlson Configure. This setting will remove the above options from the drawing setup placing control in the more global configuration settings.

Note: None of the above settings will alter the existing coordinates in a crd or crdb file. These transformation settings only apply to select routines within Carlson such as the use of geodetic bearings in reports.

- **Project Name and Job Number** are optional fields that are used in the header for reports.
- **Project Location** is used in the header for reports and used to roughly geolocate the drawing when the Projection isn't set. This location can be used in the OpenDWG command.
- **Input/Entry Distance Scale** is used to adjust distances in a second system besides the drawing units. For example, it can be used to input grid distances when the drawings is in a ground coordinate system. This factor is applied in COGO commands that use distance for input such as Enter Deed Description. The scale factor can be set to a single fixed value or set to go from ground to grid or from grid to ground on-the-fly. The fixed scale factor can be entered directly into the edit box or calculated using the Set button which has feet-meters conversions as well as combined scale factor calculations for grid-ground factors. See the Scale Points command for more information on calculating the combined scale factor. For the on-the-fly factor between grid and ground, the program calculates the combined scale factor for each distance using the two end points for the distance line.
- **Output/Report Distance Scale** is used to show distances in a second system besides the drawing units. For example, this factor can be used to report distances in meters when the drawing is in feet, or it can be used to report grid distances when the drawings is in a ground coordinate system. This factor is applied in commands that have an option to label/report a second scaled distance such as the Inverse command and Annotate Defaults that applies to the angle/distance label routines. The scale factor can be set as described under Input/Entry Distance Scale.
- **Rotation** is used to adjust the bearings and azimuths for labels and reports such as in the Inverse and Auto-Annotate routines. This setting does not affect the coordinate values in the coordinate file. It is used only to query and annotate bearings.
- The **Set Text Styles** button creates text styles in the drawing for the current drawing Horizontal Scale with the specified Font Name and list of Style Names and Text Size Scalars.

For example, when the Horizontal Scale is set to 50 and there is a Style Name of L80 with Text Size Scaler of 0.08 in the list, then this function will create a text style in the drawing called L80 with the text height of 4 ($50 * 0.08$). Besides the font and size, you can also set the width factor and oblique angle for each style. Use the Save and Load buttons to store and recall these style settings to a .FNT file for sharing with co-workers or your own use. the **Add**, **Edit** and **Remove** buttons allow you to add your own text styles, alter the settings of existing ones, or

remove unwanted styles. The **Load** and **Save** buttons allow you to load previously created styles or save the current styles to an external file.

- The **Set Paper** button allows you to draw a rectangle on the screen that represents the edge of your paper. After you have set the horizontal scale, press the Set Paper button and the Set Paper dialog appears.

- The **Layout** option lets you specify landscape or portrait paper orientation. Landscape layout is where the width of the page is greater than the height of the page. Portrait layout is the opposite.
- The **Paper Size** option allows you to specify the paper size. The numbers in parenthesis represent drawing units and will be multiplied by the horizontal scale to determine the rectangle to be drawn. If you select the Other option, you will be prompted on the command line for the horizontal and vertical sizes of the paper.

Prompts (for Set Paper)

Pick or Type lower left corner point for border <(5000.00 5000.00 0.0)>: *pick a point*

Erase existing Set Paper boundary [<Yes>/No]? *Y* This prompt only appears if there is an existing paper boundary in this drawing.

Set Limits [Yes/<No>]? *Y* If you answer Yes to Set Limits, drawing limits are enabled, and AutoCAD restricts the coordinates you can enter to within the paper boundary. Drawing limits also determines the area of the drawing that can display grid dots, and the minimum area displayed by the Zoom All command on the View menu. To turn drawing limits off, type in LIMITS on the command line and set to Off.

Drawing Setup also sets the AutoCAD dimension scale (DIMSCALE) and linetype scale (LTSCALE) to the Horizontal Scale.

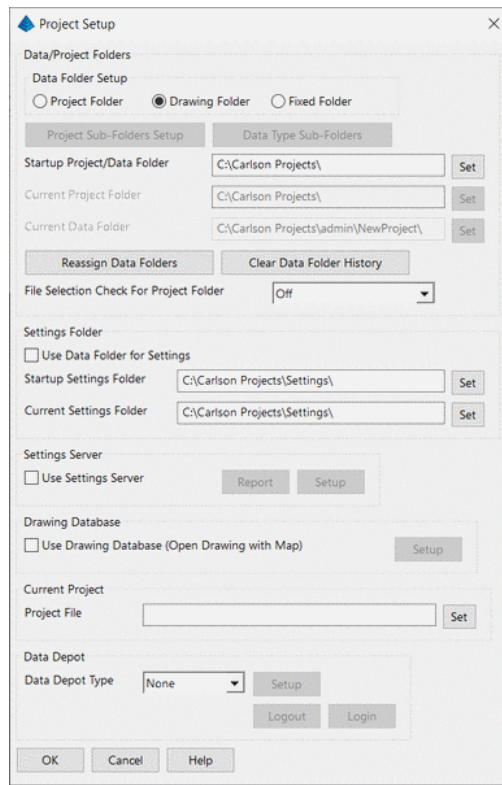

Pulldown Menu Location: Settings

Keyboard Command: setup

Prerequisite: None

Set Project/Data Folders

This command sets the project work folder, the data folder and the settings folder to use as the default folders for your Carlson drawing and data files. The PROJECT folder is the top-level folder for all the data sub-folders with all the files for the project. The DATA folder contains project specific data files such as coordinate (.CRD), profile (.PRO) and centerline (.CL) files. The SETTINGS folder contains program settings files that can apply to multiple projects such as Field-To-Finish Code Tables (.FLD) and Draw Profile Settings (.PFS). These folders are the defaults where the file selection dialogs will start in. When selecting files, you can change to another folder at any time.

Data Folder Setup: This grouping of controls provides varying levels of sophistication towards how data files associated with a given project are stored and organized on your computer system. Three options are provided:

- **Project Folder** - Data files are organized and stored (by default) into a user-definable sub-folder structure and this option is often used by larger organizations that have teams of employees working on a project. Selecting this option enables the Project Sub-Folders Setup and Data Type Sub-Folders buttons.
- **Drawing Folder** - Data files are stored (by default) into the same folder where the current project drawing has been directed and this option is often used by mid-sized or smaller organizations who seek only basic data organization.
- **Fixed Folder** - Data files are stored (by default) into a single folder and might be used by smaller organizations who do not require any type of data organization.

A note regarding file paths: When files are referenced within other files (for example, when a Centerline file is referenced in a RoadNet file), the program may store the file path in one of four ways: Relative path based on project, relative path based on reference file, relative path based on startup folder, or absolute path. As an example, consider the below files:

Startup Project/Data Folder: C:\Carlson Projects

Project Folder: C:\Desktop\Roads

Files within project folder: Road01.rdn, Centerline01.cl, Road Design.dwg

The Road01.rdn is the reference file, the Centerline01.cl file is the target file within the reference file.

Method	Variable	Source of Variable	Example of Target Notes File Path
--------	----------	--------------------	-----------------------------------

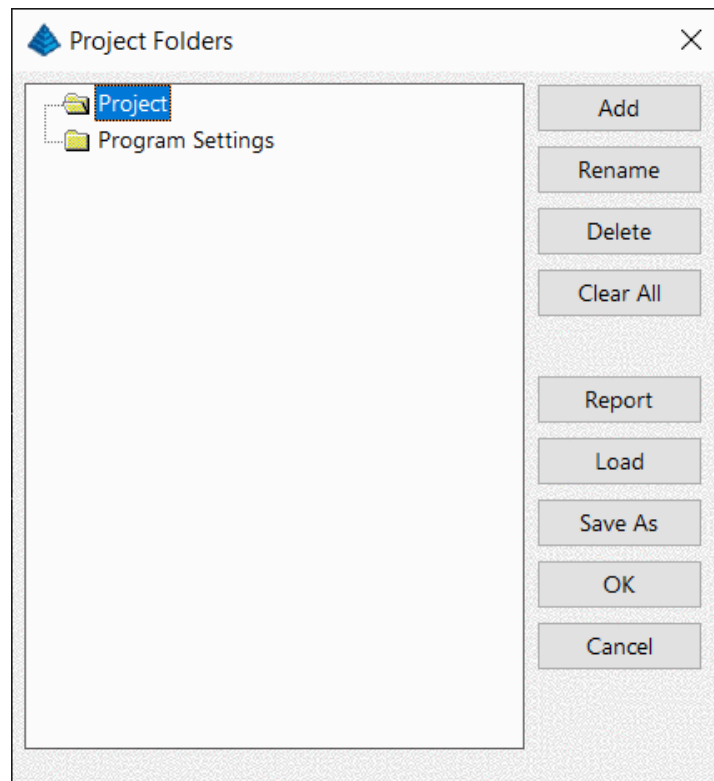

Relative path based on \$PROJECTPATH project folder	Project Folder (set \$PROJECTPATH\Centerline) according to Data Folder Setup)	This is the most commonly used method to store paths to target files. If the target file is stored in the project folder (either directly in the folder or in a subfolder), the path may use this method. The main benefit to this method is that the file paths will remain intact when the project folder is moved/copied to a new location or a different computer.
Relative path based on \$REFPATH reference file	Directory of Reference \$REFPATH\Centerline File	This method is a bit more resilient to folder reorganization. Here, the location of the target file is relative to the reference file (in this case, the RoadNet file). The benefit to this option is that the files do not necessarily have to be stored within the project folder. Therefore, if the reference file and the target file are reorganized within the project folder, or if they are moved outside of the project folder entirely, the paths will still remain intact.
Relative path based on \$WORKPATH startup folder	Startup Folder Project/Data \$WORKPATH\Centerline	This method is used when a target file is stored in the Startup Project/Data Folder.

Absolute path

C:\Desktop\Roads\Certification\ is the least resilient to change, as any degree of reorganization or renaming the folder structure will break the link to the file. This method is only used when the program cannot determine a pattern of association to either the project path or the reference path.

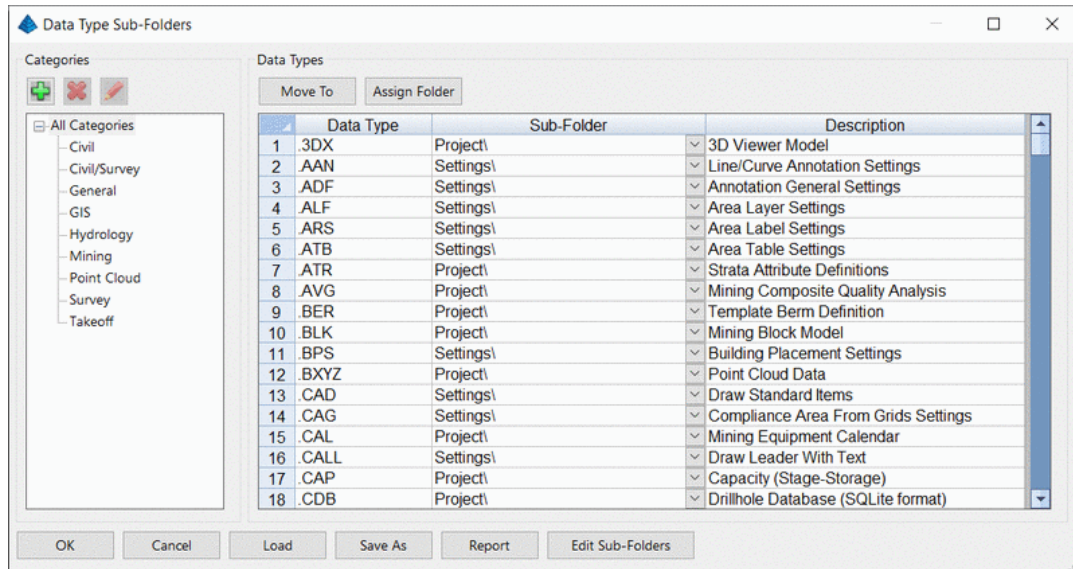

Please note that it is not recommended to manually modify these file paths within reference files. The program will automatically select the method to use for storing file paths.

Project Sub-Folders Setup: Click this button to create a folder structure (see the sample below) that is created when a new project is created. The list of project folders can be customized at any time but modifications to the folder structure will only occur on projects that are created after the modification(s) to the Project Folder list.

Data Type Sub-Folders: Clicking this button allows the various types of data files produced by Carlson to be assigned to a folder identified with the Project Sub-Folders Setup command, as illustrated below. File types set to the "Settings" sub-folder are for program settings files like Triangulate & Contour (.TRI) for settings like contour interval and layer. These settings are often stored for use across the program in the Settings Folder. Files types set to the "Project" sub-folder are for data files that are specific to the project like the Triangulate & Contour (.TIN) for the

surface data file. File types that are not assigned to a sub-folder are stored by default in the current project folder.

The following controls allow you to organize your data file types:

Control

Action

Creates a new data type sub-category.
Removes the selected data type sub-category. Any data types that have been assigned to the sub-category are subsequently migrated into the *Misc Data-Types* category.
Allows the selected data type sub-category to be renamed.

Category Controls

Move To: Associates the selected data type(s) with a data type sub-category. Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select multiple data types at the same time.

Assign Folder: Assigns the selected data type(s) to a project sub-folder. Use standard Windows **click**, **shift+click** and/or **ctrl+click** functionality to select multiple data types at the same time.

Load: Loads a previously saved Data Type Sub-Folder (.DSF) file.

Save As: Saves the current Data Type Sub-folder configuration to a Data Type Sub-Folder (.DSF) file.

Report: Allows the contents of the current Data Type Sub-folder configuration to be sent to a report.

Edit Sub-Folders: Initiates the Project Sub-Folders Setup command.

Startup Project/Data Folder: Indicate or use Set button to assign the start-up (or default) *Project Folder* location (when using the Project Folder option) or the start-up *Data Folder* location when using either the Drawing Folder or Fixed Folder option.

Current Project Folder: This setting is the top-level project folder for the current drawing.

Current Data Folder: This setting is the default data folder for the current drawing.

Reassign Data Folder: This function shows a list of all the folders used for data files associated with the current drawing. You can select a folder from this list and switch to another folder location which re-associates the data files. This function applies to projects that have been moved in the file system.

Clear Data Folder History: This function removes the association of all data files with the current drawing. The effect is to go back to defaults for data file selections.

File Selection Check for Project Folder: This option applies to the standard File Selection dialog for whenever a project data file is selected:

- **Off:** No folder checking is performed.

- **Warn Non-Project:** The program will display a warning if a project file is selected from a folder that is outside the Current Data Folder.
- **Prevent Non-Project:** The File Selection will not accept selecting a data file that is outside the Current Data Folder.

Use Data Folder For Settings: When enabled, this option sets the Settings folder to match the Data folder which, in effect, combines the Settings and Data folders into one folder.

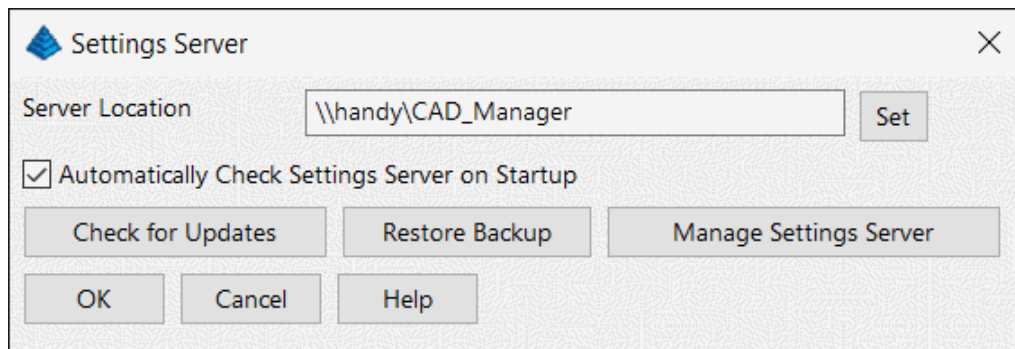

Startup Settings Folder: This folder is the default Settings folder for new drawings.

Current Settings Folder: This folder is the Settings folder for the current drawing.

Use Settings Server: The Settings Server is a system for distributing program settings and files to workstations in the office.

Report: Reports the date and time that files have been copied to your computer.

Setup: Provides an interface to configure the Settings Server as illustrated below:

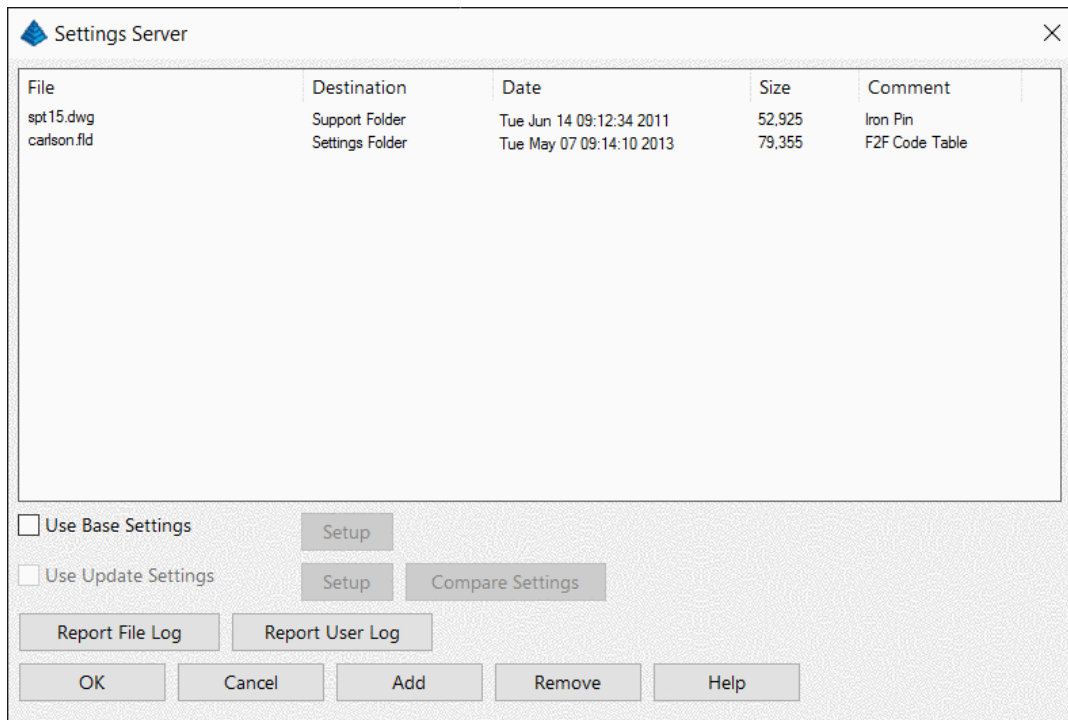

Server Location: Indicate the path to a shared folder on your office network. This folder is where the settings and files to distribute are stored.

Automatically Check Settings Server On Startup: When enabled, the settings are checked each time the program is started.

Check For Updates: This button copies any new files and settings from the Settings Server to your computer. When files are copied from the Settings Server to your computer, your existing files are backed up.

Restore Backup: This option allows you to bring back your original files.

Manage Settings Server: Use this button to setup the files and settings to distribute:

The Manage Settings Server dialog shows a list of the files to distribute. To control access to these settings and files, use Windows permissions to set the folder to *read-only* to all except the Server Manager.

Use Base Settings: Base Settings are copied to each workstation only once. After this initial setup, the workstation settings can be changed by that user. Use the **Setup** button to show the settings in the Settings Explorer command where you can review and edit the settings for each file.

Use Update Settings: Update Settings are copied to each workstation each time the workstation checks the Settings Server. These Update Settings can be used to make sure certain settings are kept set on workstations. Use the **Setup** button to show the settings in the Settings Explorer command where you can review and edit the settings for each file.

Compare Settings: This function reports the difference between the Base Settings and the Update Settings.

Report File Log: This button reports the date and time each file is distributed per user.

Report User Log: This command reports the date and time that users have checked into the Settings Server and it reports the version and build date of Carlson that they are running.

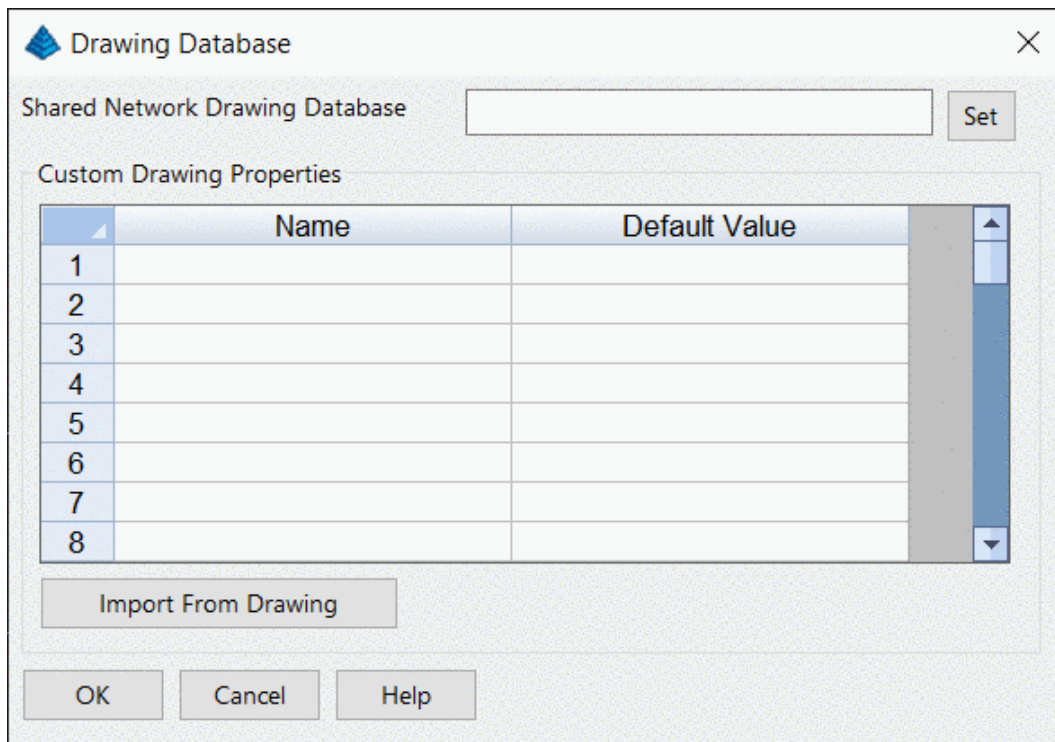

Add: This button permits you to add a file. The Add function prompts for the target folder for the file:

- **Settings Folder:** For Carlson command settings files such as Field-To-Finish code table (.fld), Draw Profile settings (.pfs) or Triangulate and Contour settings (.tri). The target Settings folder is defined in the Project Setup dialog shown above. The default Settings folder is C:\Carlson Projects\Settings.
- **Support Folder:** For CAD support files such as symbol drawings, hatch patterns (.pat) and linetypes (.lin). The target Support Folder is under the Windows AppData folder in this format: \Users\\AppData\Roaming\Carlson Software\\<CAD version>\SUP.
- **User Folder:** For Carlson program files such as Symbol Library (symbols.dta), Quick Keys (quickrun.lsp) and Report Formatter (formats.dta). The target Support Folder is under the Windows AppData folder in this format: \Users\\AppData\Roaming\Carlson Software\\<CAD version>\USER.
- **Data Folder:** For project data files that you want to include in every project. These files can be non-Carlson files such as a Word document.
- **Other Folder:** For files in a user-specified folder.

When adding files, there is an option to assign a comment to the file which is used in reporting.

Remove: This button removes the selected file from the list.

Drawing Database: Controls whether to maintain a database of drawings to use for the Map view in the Open Drawing command. This drawing database stores the drawing file names, latitude/longitude and properties. The drawing database is stored in the Carlson Settings folder and is named DrawingSQLite.db. The Setup button has a dialog with drawing database options. The Shared Network Drawing Database is for a second drawing database besides the drawing database in the Carlson Settings folder. This network drawing database can be used to track the drawing files located on the network drive and shared by your company staff with network drive access. The Drawing Properties are for user-defined properties to store in the drawing database for each drawing. The Import From Drawing buttons fills out the property names from the current drawing which you can edit using the DWGPROPS command.

Project File: Indicate or use **Set** button to specify the Project Settings (.PRJ) file associated with the current drawing. The Project Settings file is a collection of drawing names (e.g. BaseMap.dwg, Roads.dwg, Parcels.dwg, Sewers.dwg, etc) that belong to the same project. This collection of drawings is used by Project Explorer to manage the drawings and data files for the current project and must be specified if the Carlson Data Depot service is to be used. If the current drawing is not associated with a project, then this setting will be blank.

Data Depot Type: The Carlson Data Depot is a document management system to allow tracking of the changing states of files and projects over time and merge the contributions from multiple users providing data integrity, productivity and accountability for the managed products. Carlson Software supports the following *version control systems*:

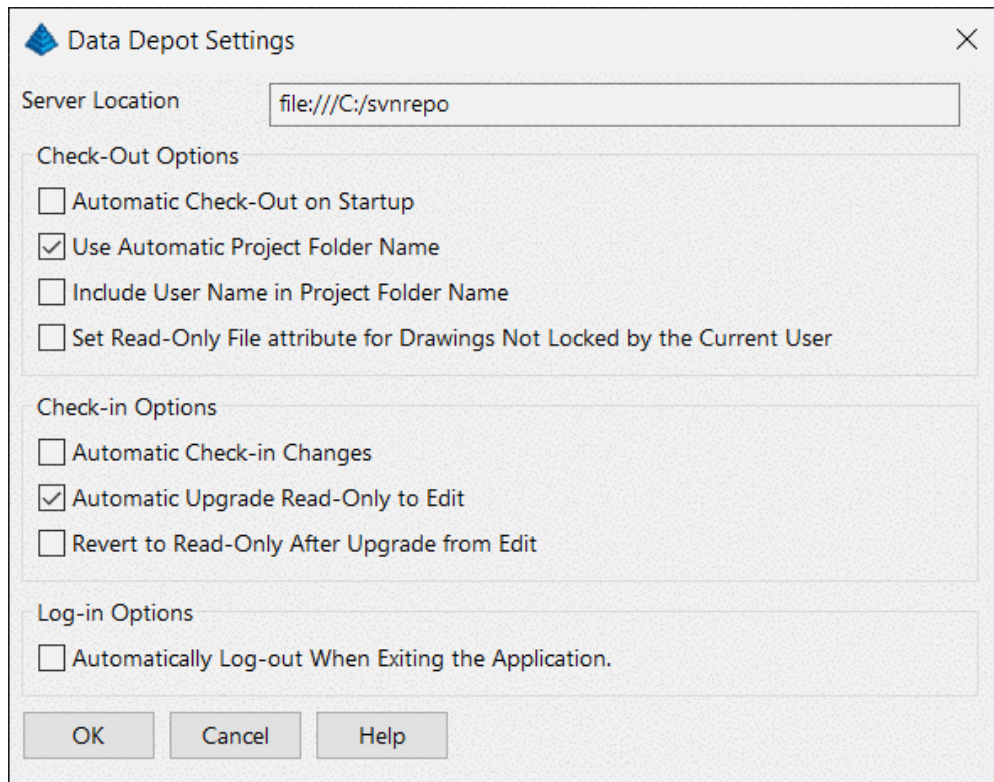

1. Subversion - a free, open-source version control system.
2. ProjectWise - software developed and produced by Bentley Systems.

Setup: Before proceeding, refer to the Carlson Data Depot section for information on how to install and properly prepare your preferred document management system. Once this has been completed, click this button to complete the *Data Depot Settings*.

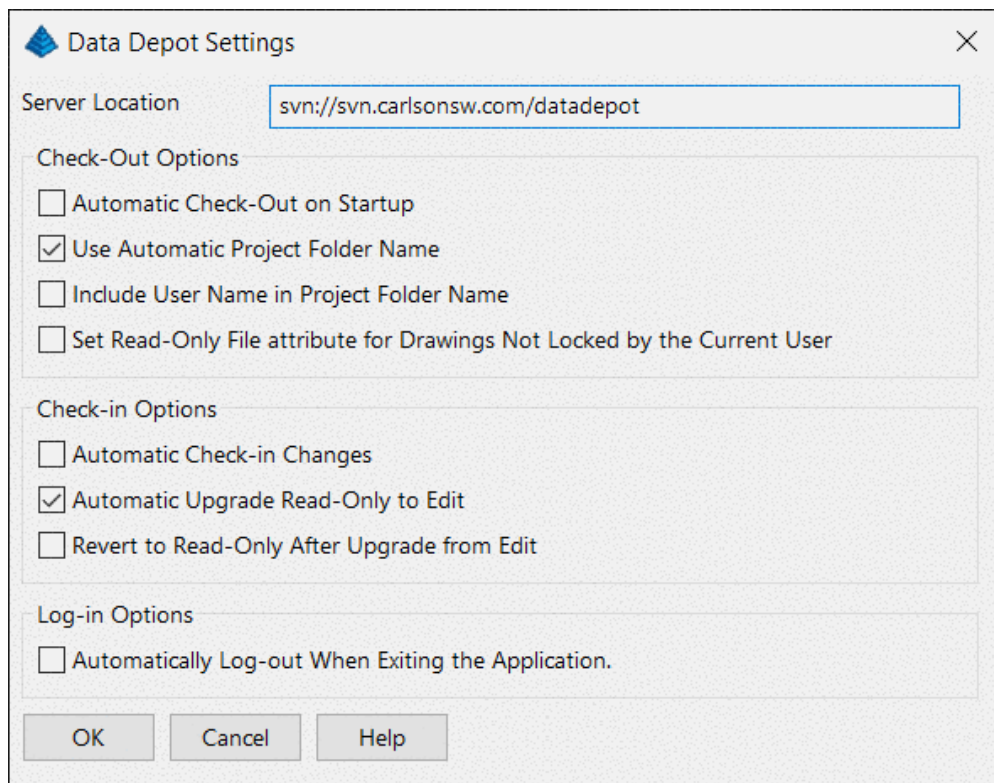

Logout: Log out of the Data Depot server.

Login: Log in to the Data Depot server.

Server Location (Subversion local): Indicate the path for the appropriate location (often a shared server drive) where the file edits and updates are tracked (*e.g.* file:///C:/svnrepo). For Windows users, note the triple-slash convention:

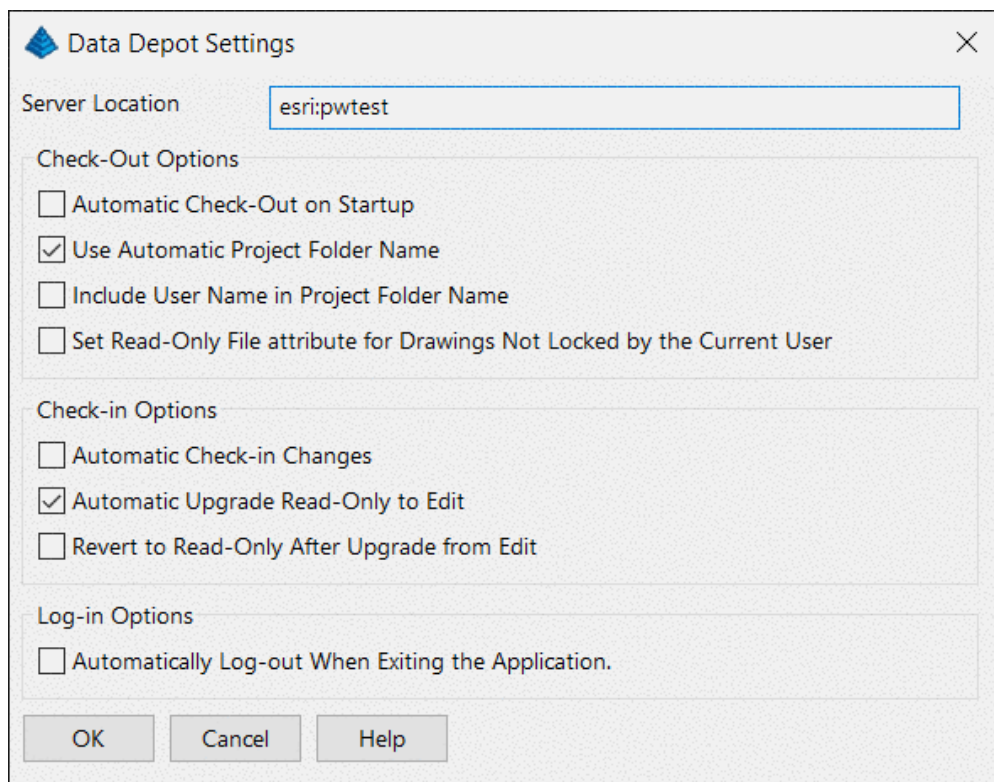

Server Location (Subversion VPN): Indicate the server (proper login name and password may be required) where the file edits and updates are tracked:

For a more extensive write-up on available options, refer to Subversion in Action - Chapter 1. Fundamental Concepts.

Server Location (ProjectWise): Indicate the ProjectWise server and datasource where the file edits and updates are tracked (format is server-name followed by a colon ":", followed by the datasource name, *e.g.* esri:pwtest). See your ProjectWise Administrator for the name of your ProjectWise servers and datasources.

Automatic Check-Out on Startup: This option will check for any updates for the project and associated file on the server while opening the drawing. If there is a new version of a file is found it is automatically updated to match the

current version on the server. User will be prompted if an older version or conflicting versions of file are found.

Use Automatic Project Folder Name: When a project is updated or initially accessed with the `get_prj_from_depot` command, this option will automatically map the project to a folder with the same name as the repository project name under your Startup Project Folder. For example, if your Startup Project Folder is named "C:\Carlson Projects\" and the repository project is named "My Test Project" the `get_prj_from_depot` will use "C:\Carlson Projects\My Test Project\" as the local Current Project Folder.

Include User Name in Project Folder Name: When "User Automatic Project Folder Name" is enabled this option will also be enabled. When a project is updated or initially accessed with the `get_prj_from_depot` command, this option will automatically map the project to a folder with the same name as the repository project name, plus your user name under your Startup Project folder. For example, if your Startup Project Folder is named "C:\Carlson Projects\", your user name is "Engr1" and the repository project is named "My Test Project" the `get_prj_from_depot` will use "C:\Carlson Projects\Engr1\My Test Project" as the local Current Project Folder.

Set Read-Only File Attribute for Drawings Not Locked by the Current User: This option will prevent the user from being able to save drawings for which he/she is not the lock owner. This prevents the user from getting into situations that may cause potential loss of data at check-in time.

Automatic Check-In Changes: If any file under project is updated or edited, it will be automatically checked-in to the repository.

Automatic Upgrade Read-Only to Edit: If a file is checked-in by the current user, the file is upgraded to Edit Mode (locked) for that user for further editing opportunity.

Revert to Read-Only After Upgrade from Edit: If a file is checked-in by the current user, the file is reverted to Read-only Mode (unlocked) so that other users can further edit the file.

Automatically Log-out When Exiting the Application: If a user is logged in to the server upon exiting the application, they will automatically be logged out.

Once the Data Depot has been configured, you can assign a project to the Data Depot via the Project Explorer command.

Pull-down Menu Location: Settings

Keyboard Command: `settmpdir`

Prerequisite: None

Store Project Archive

This command will zip and archive an entire project. The archive contains the current drawing file (.dwg) and all the associated data file such as the surfaces. The data files associated with the current project can be reviewed with the Drawing Explorer command. Besides project data files, images and xref's attached to the dwg are also included. The format of the archive file is a standard .zip file which can be used by WinZip. This file can be sent to someone who can unzip it and use all the same files. The current dwg must have a name before running this command.

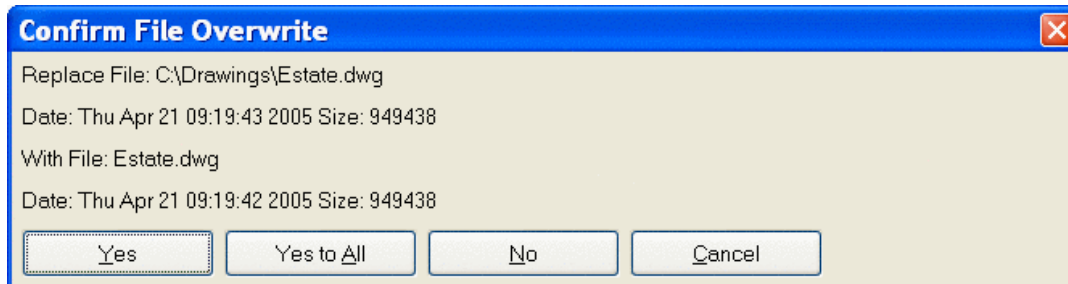

Pull-down Menu Location: Settings > Project

Keyboard Command: `zip_project`

Prerequisite: A named dwg

Extract Project Archive

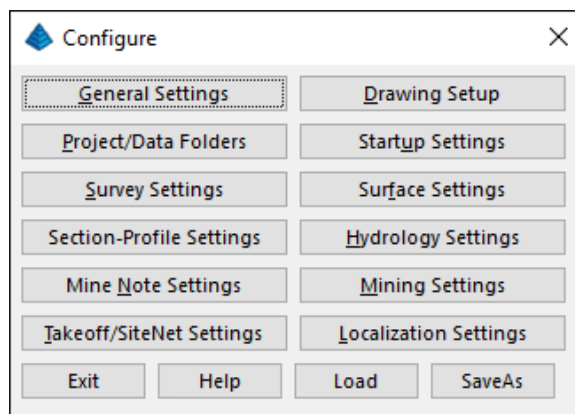

This command will unzip an archive file that has been previously created with the command Store Project Archive. It prompts for the directory to unzip to. If any of the files already exist in the folder it is extracting to, there is a window prompting to overwrite the files.

Pulldown Menu Location: Settings > Project
Keyboard Command: unzip_project
Prerequisite: A project file that has been zipped (ZIP)

Configure Carlson

This command allows you to set up the default settings that are used each time you start a new drawing, or load an existing drawing.

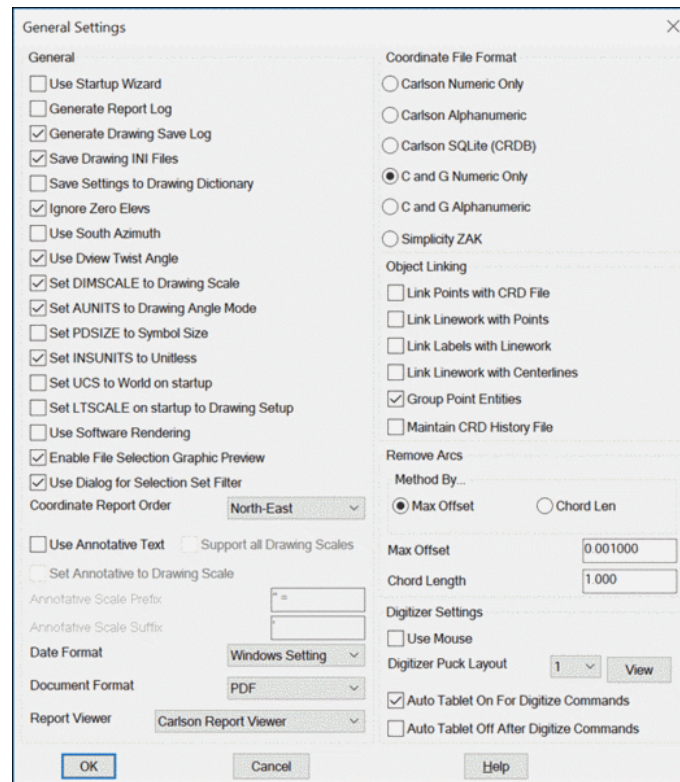

NOTE: When using Carlson products with an "embedded AutoCAD OEM engine" (e.g. *Carlson Survey with Embedded AutoCAD* or *Carlson Takeoff with Embedded AutoCAD*), only a subset of the various configuration commands will be available.

Load: This command permits a previously saved configuration (CFG) file to be loaded into the software and is useful for propagating corporate standards to groups or individuals within an organization.

SaveAs: This command "packages" up all current configuration settings and permits them to be saved to a named configuration (CFG) file that can be shared with users of Carlson Software.

General Settings	Drawing Setup
Project/Data Folders	Startup Settings
Survey Settings	Surface Settings

Table of Contents

Use Startup Wizard: When enabled, a dialog-based "wizard" interface is used for the creation of a new project

Generate Report Log: When enabled, output from several commands will be accumulated in a report buffer. Commands that output to the report log include Inverse, Traverse, Curve Info, *etc.* Also, any report that is displayed in the standard report viewer is also added to the report log. While activated, the report log resides in the lower left corner of the desktop as a minimized title bar that shows how many lines are in the report buffer. To view the report log, pick on the maximize icon on this title bar. You can also view the report log by running the Display Report Log function in the Inquiry menu. The report log can be edited, saved to a file or printed. To quickly turn the report log on and off, you can type REPORT at the command prompt.

Generate Drawing Save Log: This option stores the time stamp and user name in the DWG each time the drawing is saved. This save log can be viewed using the Drawing Save Log command.

Save Drawing INI Files: This option stores the file names of data files used with the current drawing. When enabled, an .INI with the same name as the DWG file will be created to store the data file names. These file names are used for the list of recent files when selecting data files and the Drawing Explorer command manages the list of these data files.

Save Settings To Drawing Dictionary: This option saves the settings for commands within the drawing. Commands always store settings at the program level for recall the next time the commands are run. By storing settings

with the drawing, each drawing will recall the command settings used in the drawing. For example, if you run Triangulate & Contour at an interval of 5 in Drawing_A, then use interval 1 in Drawing_B, then the next time you contour in Drawing_A it will recall interval 5 instead of using the last interval of 1.

Ignore Zero Elevs: This option will ignore any entities with a zero elevation. It is used for many commands, such as Triangulate and Contour or Make Grid File.

Use South Azimuth: Turning on this option will use a South Azimuth instead of a North Azimuth as the basis for 0 degree.

Use Dview Twist Angle: This option makes the program create text entities at an angle to match the current VIEWTWIST system variable so that the labels are horizontal to the screen twist angle. This twist angle can be set with the DVIEW command or the View > Twist Screen commands. In IntelliCAD, this option also controls the USEVIEWTWIST system variable for making MLEADER and MTEXT default rotation to be horizontal to the current screen twist angle.

Set DIMSCALE to Drawing Scale: This will set the dimension scale to match the drawing scale.

Set AUNITS to Drawing Angle Mode: This will set the DWG angular units to match the angle mode established under Drawing Setup.

Set PDSIZE to Symbol Size: This will set the PDSIZE scale to match the symbol size defined in Drawing Setup.

Set INSUNITS to Unitless: This will set the INSUNITS (Insertion Units) CAD system variable to Unitless (INSUNITS=0) when the drawing is opened.

Set MENUBAR on Startup: When enabled, the Carlson Menu associated with the Carlson icon (usually on the PC Desktop) will be loaded. Otherwise, use the Carlson Menus command to select the desired menu.

Set UCS to World on Startup: When enabled, drawings with a User Coordinate System (UCS) other than *World* will have the UCS set to **World**.

Set LTSCALE on Startup to Drawing Setup: When enabled, the *linetype scale* (LTSCALE) variable will be set to the **Horizontal Scale** defined under Drawing Setup.

Use Software Rendering: When enabled, commands that use OpenGL functionality (such as 3D Viewer Window) on computers with older video cards that don't offer extensive hardware acceleration will attempt to render the information with any available random-access memory (RAM).

Use Dialog For Selection Set Filter: For IntelliCAD, this option chooses whether to prompt for selection set filters in a dialog or command prompt at the "Select objects" prompt.

Use Annotative Scale: When enabled, text created by Carlson routines such as Annotation will use scale-able annotative properties. This setting also applies to symbols created by Draw > Insert Symbols. Carlson Points have a separate setting for annotative under the Point Defaults command.

Support All Drawing Scales: When enabled, text placed as annotative entities will make use of all annotation scales currently defined within the drawing.

Set Annotative to Drawing Scale: This option sets the annotative scale to match the Horizontal Scale set in the Drawing Setup command.

Annotative Scale Prefix/Suffix: These strings are used for naming annotative scales when the program creates new annotative scales. For example, when the program creates an annotative scale for a horizontal scale of 50, you can name the annotative scale as 1:50 or 1"=50' depending on these string settings.

Coordinate Report Order: You can choose the traditional North-East format, or reverse these in reports with an East-North format.

Date Format: You can control the display of dates in Carlson reports with this drop-down menu. The default is "*Windows Setting*" which allows you to control it with Windows Control Panel. Several other common formats are

available.

Formatted Document Type: (AutoCAD-based platforms, only) Use this option (for commands such as 3D Viewer Window to establish the type of document produced by the command.

Report Viewer: This option chooses between the Carlson Report Viewer, Windows Notepad and Microsoft Word for the viewer to use for reports that the Carlson commands generate.

Dialog Font: This option chooses which Windows font to use for Carlson dialogs.

AutoCAD Menu: (AutoCAD-based platforms, only) This option chooses which AutoCAD menu to load when picking the AutoCAD menu from the Carlson Menus toolbar or from the Settings > Carlson Menus pull-down menu. When AutoCAD Map is installed, there are different layouts of the Map menu to choose from. When Autodesk LandDesktop is installed, those menus are available.

Object Linking: The Object Linking section contains options for creating additional "intelligence" on Carlson-placed entities:

- **Link Points with CRD File** - (AutoCAD-based platforms, only) When enabled, points placed into the drawing will be given a "reactor" so that any change to the entities such as MOVE or ROTATE will update the coordinates in the CRD file.
- **Link Linework with Points** - (AutoCAD-based platforms, only) Line and polyline entities that are drawn by point number (including those placed via Draw Field-to-Finish such that a positional change to a linked point will automatically update the linework.
- **Link Labels with Linework** - (AutoCAD-based platforms, only) When enabled, direction and/or distance labels assigned to physical linework entities will get updated if the underlying line is changed.
- **Link Linework with Centerlines** - (AutoCAD-based platforms, only) For linework that has been used to create a Carlson Centerline, changes to the linework will update the corresponding centerline (CL) file.
- **Group Point Entities** - When enabled, the three entities of a Carlson point (attribute block, symbol and node) become linked as a single entity. For each point, selecting any one of these entities selects all three entities for the point. **NOTE:** This setting is *not* the same as the "Point Group" functionality as found under the Point Group Manager command.
- **Maintain CRD History File** - When enabled, changes to a point are tracked into a "history" file. These changes can be accessed via the **History** button found under the Edit Point Attributes command.

Coordinate File Format: Carlson can be configured to utilize a variety of coordinate file formats:

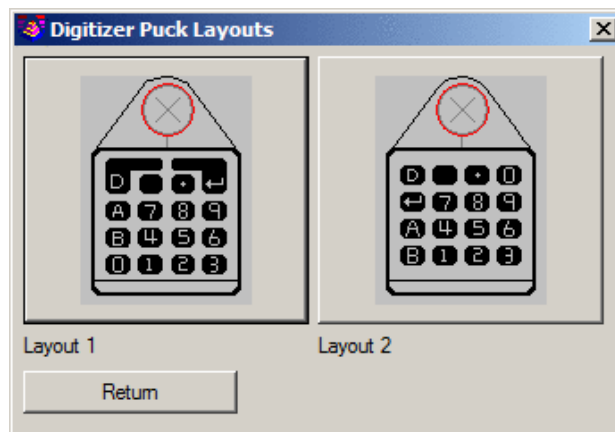

- **Carlson Numeric Only** - Point numbers cannot contain letters and must be in the range from 1 to 99999.
- **Carlson Alphanumeric** - This format allows letters in the point numbers and the point "number" can be up to 9 characters in length. Any combination of letters and numbers is acceptable.
- **Carlson SQLite** - Based on the Structured Query Language (SQL) database format, this CRDB format allows alphanumeric combinations of point number and descriptions up to 255 characters in length.
- **C&G Numeric** - This format of the C&G division supports up to 5 digits, with a 65000 point limit.
- **C&G Alphanumeric** - This format of the C&G division supports up to 10 characters, with no limit to the number of points.
- **Simplicity ZAK:** - This is the Simplicity Systems "Sight Survey" coordinate file format.
- **MS Access Database (LDT)** - This is a Microsoft Access database used by Autodesk Land Desktop. The file is typically named "*points.mdb*" and is typically found in a Land Desktop project \COGO subdirectory. The point identifier limitation is established by the database structure, which has a default of 255 characters.

Remove Arcs: Since 3D polylines do not allow true arcs, the program represents arcs in 3D polylines as a series of short chords. The Remove Arcs settings control the spacing of these arcs:

- **Max Offset** - Sets the maximum difference between the chords and the original arcs as shown in the image above. This method is similar to the Reduce Polyline Vertices command.
- **Chord Len** - Sets the length of the chord segments that replace the original arc.

Digitizer Puck Layout & View: There are two main formats for the digitizer puck. They are numbered 1 and 2. Selecting the View button brings up the window showing the two formats.

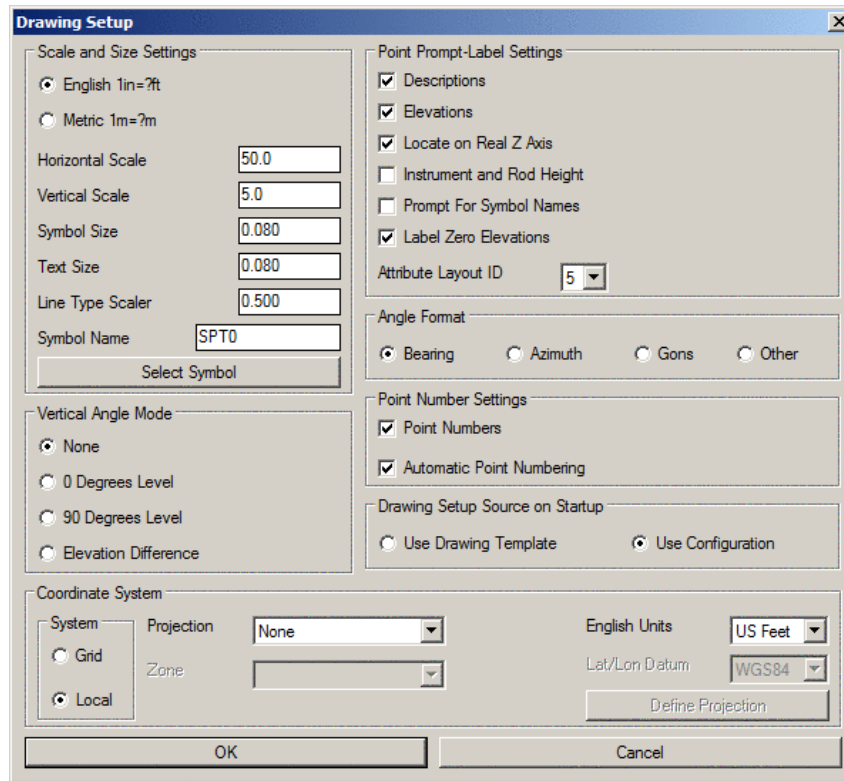

Use Mouse: This option allows you to use the mouse instead of the digitizer puck for the digitize commands.

Auto Tablet On for Digitize Commands: This option will activate the tablet when using the digitize commands.

Auto Tablet Off for Digitize Commands: This option will de-activate the tablet when using the digitize commands.

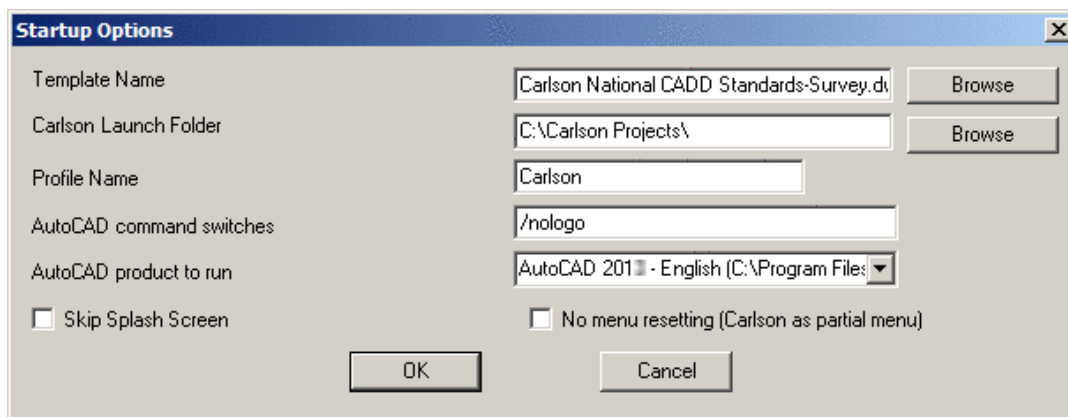

The settings under *Drawing Setup* are used to establish the initial values when creating a new drawing. Most of these settings are identical to those discussed in Drawing Setup. There are a few additional settings. The **Vertical Scale** is used by profile and cross section routines for the grid scale. The Point Prompt-Label Settings, Point Number Settings and Vertical Angle Mode settings are described in the Points > Point Defaults command. The Drawing Setup Source on Startup control the source for the initial settings for a new drawing. The **Use Configuration** option uses the settings from this dialog. The **Use Drawing Template** uses the settings stored in the drawing template (dwt). To store settings to the dwt, open the dwt and run the Drawing Setup command and then save the dwt. The settings are then automatically stored in the dwt.

There is also the ability to maintain two different sets of defaults (English and Metric). You can maintain a separate set of settings for each unit system, especially if you switch back and forth. Also added was support for meters/metres, tons/tonnes and various date representation which can be accessed via the Localization Settings button.

Please refer to the Set Project/Data Folder command for complete information.

These options are used for starting Carlson. Defaults are set here, and will be used at the beginning of each session.

Template Name: This is the drawing template file that will be used when starting a new drawing. The Browse button allows for selecting a new file.

Carlson Launch Folder: This is the folder where Carlson projects would be stored by default. The Browse button allows for selecting a new folder location.

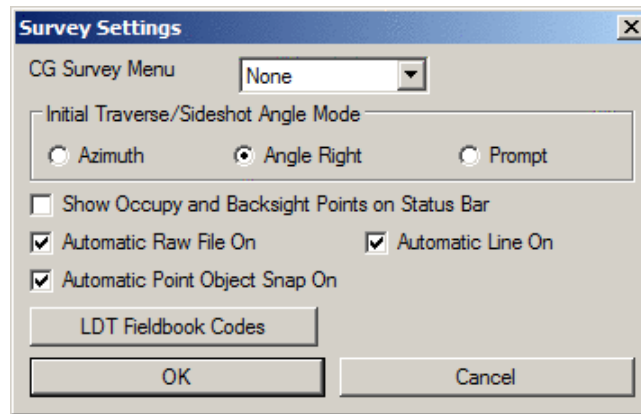

Profile Name: This is the AutoCAD/IntelliCAD Profile that will be used when working in Carlson. If you use a custom profile, be sure that the profile contains the Carlson support folder in the Support File Search path (ie. %appdata%\Carlson Software\Carlson version\CAD version\SUP), and the Carlson main menu must be loaded. If the custom profile doesn't have these requirements, then the program switches to the default Carlson profile.

AutoCAD command switches: This turns off the AutoCAD "splash" screen upon launching the program. The

/nologo takes the splash screen out of the start-up procedure. See AutoCAD documentation for other switches that are available for use.

AutoCAD product to run: (AutoCAD Only) This is the AutoCAD version and flavor (Map or LDT, *etc.*) that Carlson is installed for, and will run with.

No menu resetting: (AutoCAD Only) This controls whether to set the Carlson menu as the main customization file on startup or to keep the current main customization unchanged.

CG Survey Menu: Indicate whether to add-on the C&G Survey pull-down menus to the standard Carlson Survey menus. The Compact mode has all the C&G commands in a single pull-down menu. The Expanded mode has all eight C&G pull-down menus that C&G "stand-alone" used to have.

Initial Traverse/Sideshot Angle Mode: This sets the default angle mode for these COGO commands.

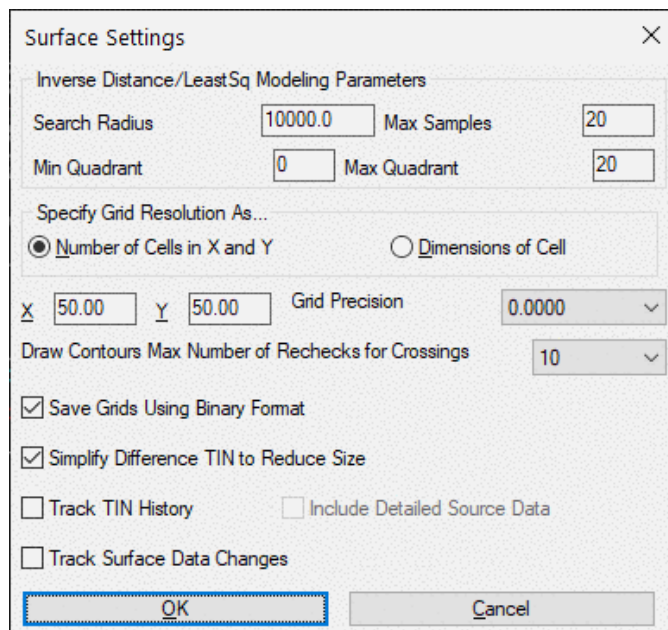

Show Occupy and Backsight Points on Status Bar: This is an option for the COGO Inverse command.

Automatic Raw File On: This is equivalent to toggling on the COGO > Raw File On/Off automatically when the drawing is opened.

Automatic Line On: This is equivalent to toggling on the COGO > Line On/Off automatically when the drawing is opened.

Automatic Point Object Snap On: This is equivalent to toggling on the Settings > Point Object Snap On/Off automatically when the drawing is opened.

Automatic Compare DWG points with Coordinate File on Startup: This option runs the Coordinate File Utilities > Compare Points routine when the DWG file is opened to report any differences between the point entities in the drawing and point coordinates in the coordinate file.

Most of the Surface/Triangulate & Contour commands will remember the settings and parameters used from drawing to drawing. There are some in this screen that will be used for gridding and modeling.

Inverse Distance/LeastSquares Modeling Parameters: The modeling methods of Inverse Distance and Least Squares are similar ways to create a grid from datapoints or drillholes. It is not recommended to use these methods for gridding contour or breaklines. Triangulation is better for that. These methods need a search radius defined. Anything past this distance from one data point to the next will be ignored for influence. The Max Samples are the number of data points that will be used to influence each data point. The area is broken into 4 quadrants. The Min and Max Quadrant are the numbers of data points that will be used in each quadrant.

Specify Grid Resolution As: There are two ways to create a grid file. Once the boundary has been selected, the cells need to be determined. Number of Cells in X and Y will divide the boundary up into the specified number of cells. These will then be odd shaped rectangles, with the size calculated by the boundary dimensions and the number of cells. The Dimensions of Cells is the more commonly used method. This will allow for a set cell size for the X and Y directions. Most of the time the grid cells should be square, where you set the size.

Grid Precision: This is the number of decimals that are stored in the grid file.

Draw Contours Max Number of Rechecks for Crossings: Routines that generate contours check for any crossings that can occur from smoothing or reduction options. When a crossing is found, the smoothing or reduction factors are reduced and then the contours are rechecked in case that adjustment causes a new crossing. This option can be used to decrease the number of rechecks in case your dataset is large and you don't want to take the time for these checks.

Save Grids Using Binary Format: This options chooses between saving .grd files as either text or binary files. This setting applies to all routines that save grid files. The advantage of the text format is the ability to view the grids using any text editor like Notepad and the ability for non-Carlson programs to easily read the grids. The advantage of the binary format is the speed of saving and loading the grids which is several times faster than the text format. Only Carlson 2015 and later versions can read the binary format. When the range of min/max grid values is small enough relative to the grid precision, the program will automatically switch to an indexed binary format which uses half the file size and loads twice as fast.

Simplify Difference TIN to Reduce Size: When difference TIN is calculated, the intersection of individual triangles is calculated. When two source TINs are large and somewhat similar, the resultant TIN can have exceedingly large number of triangles. This option seeks to limit the growth of intersection TIN by keeping the points on the breaklines and in the areas major surface changes (based on the normals) while eliminating extraneous points in flat

areas. While this results in some approximation of the difference TIN, the resulting surface has significantly fewer points and minor slivers.

Track TIN History: When this option is enabled, the information about creation of the TIN and editing operations is stored in the TIN. This allows to review the history, modify the steps and rebuild the TIN in Surface Manager -> History utility.

Include Detailed Source Data: When TIN history is enabled, this option adds additional data about entity data, allowing user to recreate the surface without original drawing or when the source entity is no longer in the drawing. Without this option, only handles (IDs) of entities are stored.

Track Surface Data Changes: When the TIN is made and added as a surface to the Surface Manager, the source selection set used to create the TIN is stored in the drawing. When this option is enabled, the changes to the source entities will be tracked and TIN will be updated accordingly, recreated with same options as originally.

Eye Height and **Object Height** are used for calculating sight distance on vertical curves.

Vertical Curve Drawing Resolution applies to Draw Profile for the segment length for drawing vertical curves.

Use Crest Sight Distance Formula for Sag:When this option is on, the Crest Vertical Curve formula is used to calculate the sight distance for sag vertical curves. Otherwise the the Sag Vertical Curve formula is used.

Parabolic Template Grade Subdivisions applies to Process Road Design and Road Network for how many 3D polylines to draw for grades defined as parabolic in the template.

Station Type controls the format of station labels. For the NO.0 type, there is a setting for the label prefix, and the Use Partial Labels for Intermediate Stations option will skip the label prefix for odd stations.

Section-Profile Settings

Eye Height: 3.500 Object Height: 0.500

Vertical Curve Drawing Resolution: 10.000

Use Crest Sight Distance Formula for Sag

Parabolic Template Grade Subdivisions: 10

Station Type:

1+00 1+000 100 NO.0

NO. Station Prefix: NO. Use Partial Labels for Intermediate Stations

OK Cancel

Stage-Storage File Format: Indicate the format of the Stage-Storage File to be used in Carlson Hydrology. Carlson method should be used as default. SEDCAD 3 and 4 is a comprehensive hydrology and sedimentology package by others that Carlson can output data files to be used.

Rainfall Amount Method: Rainmap TP-40/TP-47, NOAA Atlas 14 and Rainfall Lookup methods are available. The program defaults to the Prompt option and the rainfall amount program will show all three methods when Prompt is on. When users select a method and check the "Skip Method Prompt Next Time", the method is set to the default rainfall amount method.

Rainmap TP-40/TP-47: Get the rainfall amount on the rainfall map.

NOAA Atlas 14: Rainfall amount is download automatically from NOAA website by specifying the location.

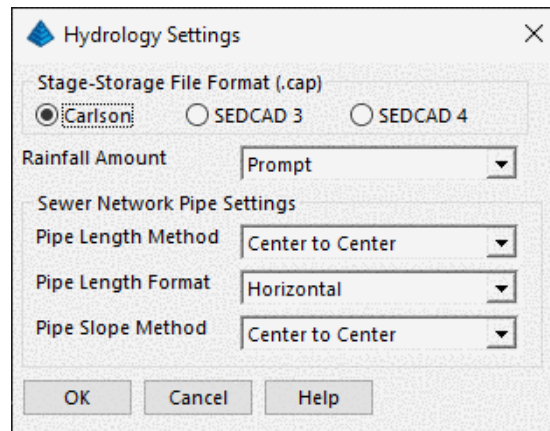

Rainfall Lookup: This is a rainfall lookup table created by users. It can be accessed for all the hydrology functions to get the rainfall amount.

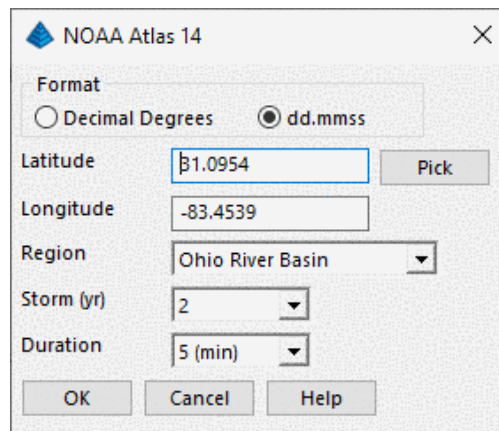

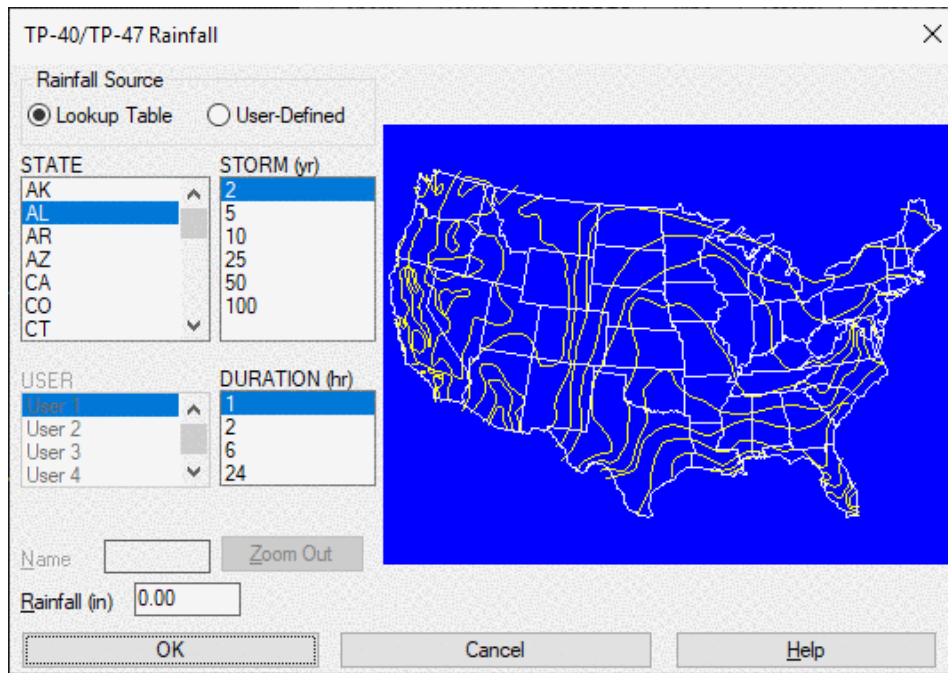

Sewer Network Pipe Settings: Specify the pipe settings based on jurisdictional requirements.

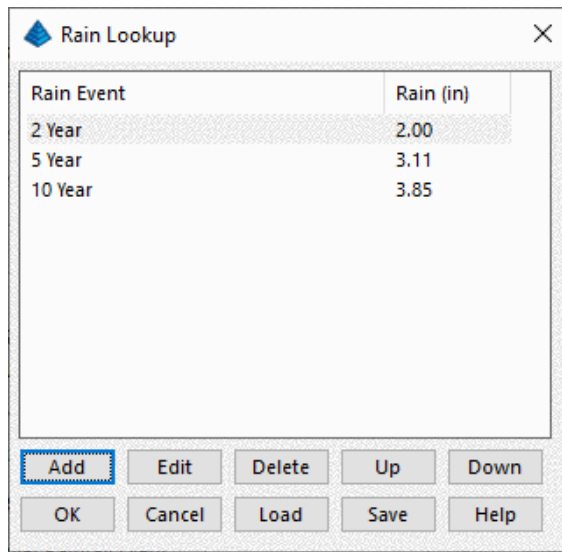

Pipe Length Method can be set for Center to Center or Actual Pipe Length.

Pipe Length Format can be set to Horizontal or Slope Length.

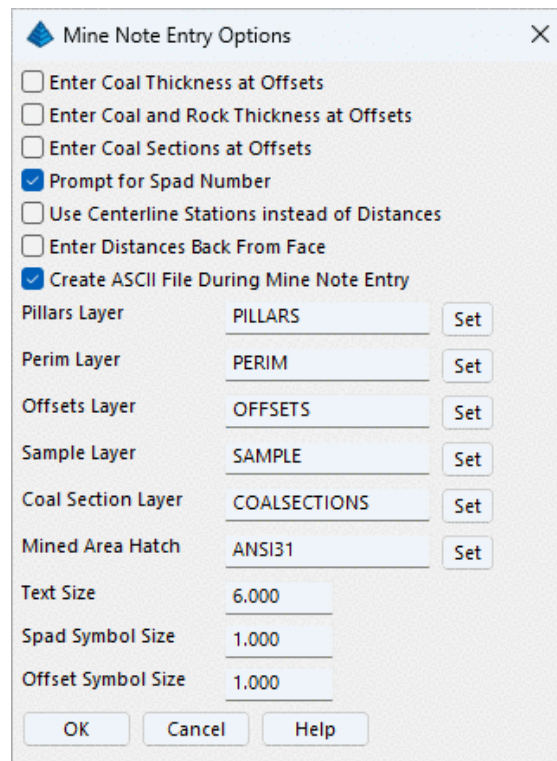

Pipe Slope Format can be Center to Center or Actual Pipe Length.

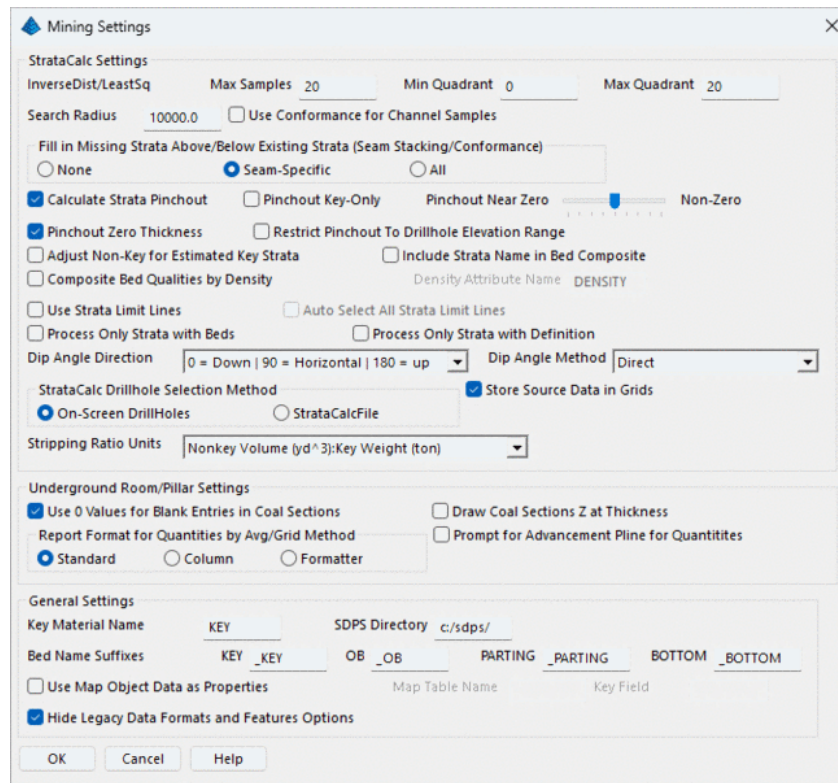

These options will toggle various prompts when entering Mine Notes in the Underground Mining module. You can also set the layers for various linework needed for geologic modeling and mine planning. These options are further described in the documentation of the the Mine Note Defaults command.

This is the configuration screen for default settings used with the Mining Modules. Each item is detailed below.

InverseDist/LeastSq Max Samples: This value sets the maximum number of data points to use to estimate the value at a grid node. If this value is set to 20, only the 20 data points nearest the grid node being calculated will be used. This option only affects the Inverse Distance and Linear Least Squares modeling methods.

Min/Max Quadrant: When the program calculates the value of a grid node, the area around the grid node is divided into four quadrants, as shown below by the blue dashed line. These Min/Max Quadrant values set the minimum/maximum number of data points to use from each quadrant. If the Min Quadrant value is set to 5, a value will only be assigned to the grid node if at least 5 data points are found within all four quadrants. If the Max Quadrant value is set to 20, only the nearest 20 data points in each quadrant will be used for estimation.

Search Radius: This value sets the maximum search radius for data points. For example, if this value is set to 10,000, any data points beyond 10,000 ft/meters from a given grid node will not be used to estimate the value of that grid node. This concept is shown in the below image.

Fill in Missing Strata Above/Below Existing Strata (Seam Stacking/Conformance): This option determines how the program handles drillholes with missing strata. An example of a data set modeled with and without the conformance option is shown below. Notice that when conformance is applied, the red and blue strata will more closely mimic the green strata, even though the red and blue strata do not occur in all three drillholes. The program does this by artificially adding data points to the drillhole with missing strata.

In the below example, consider drillhole #3. This drillhole does not contain the blue strata. To make the blue strata conform to the green strata, the program will search for the nearest drillhole that contains the blue strata (in this case, Drillhole #1). The program will then measure the elevation difference between the blue and green strata and apply that same elevation difference in drillhole #3. In this example, the bottom of the blue strata and the top of the green strata in Drillhole #1 are 800' and 705', respectively (a difference of 95'). The top elevation of the green strata in Drillhole #3 is 655'. So, when the program models the blue strata, an artificial elevation of 750' (that is, 655' + 95') will be used in Drillhole #3. In this case, the green strata is considered to be the "marker" and the blue strata is considered to be the "target".

In drillhole #2, the red strata is not present. In this case, either the blue or the green strata could serve as the "marker" strata. When the "All" option is used, the program will automatically select one of these strata to be the "marker". The program will set the "marker" strata as the strata closest to the "target" strata. In this example, the red strata is closer to the blue strata, so the blue strata will be used as the "marker". If the "Seam-Specific" option is used, you will have to manually define which strata are "markers" and which strata are "targets".

Although this example shows the result of seam stacking/conformance applied to an area with sufficient drilling depth in an area with varying topography, the same effect can be applied to drillholes that are not simply drilled deep enough to intersect all strata.

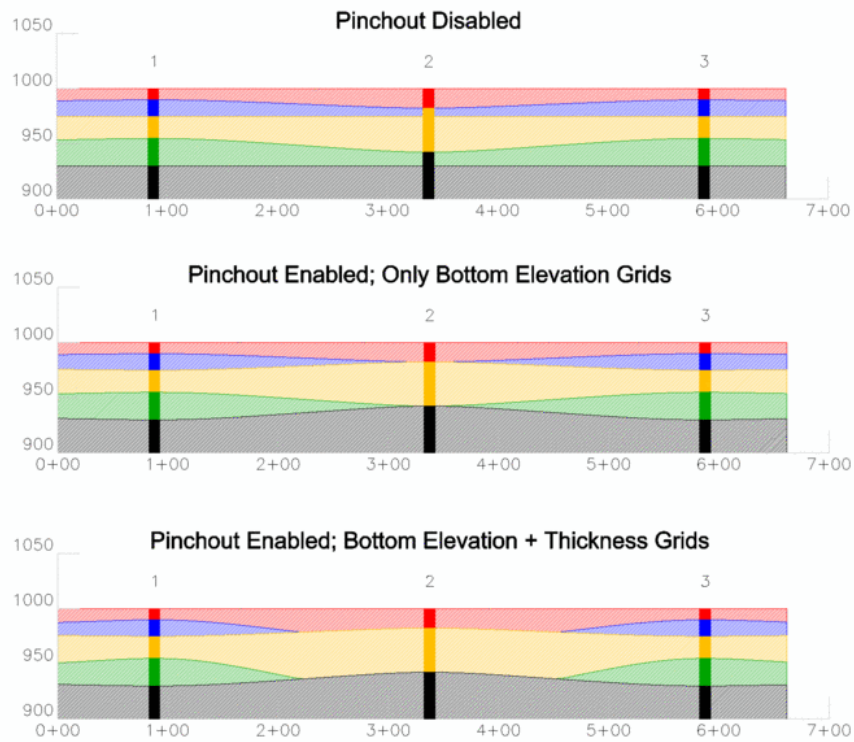

None: This option will not apply seam stacking/conformance. In this scenario, each strata layer will be modeled independently of other strata layers. Only strata data that is actually included in the drillhole will be used to make the strata grid file.

All: This option will apply conformance in any way possible. This can be a useful option when the structure of all strata are similar. However this option does not give you the option to specify which strata layers are "markers" and which strata are "targets".

Seam Specific: This option also applies conformance, but requires that you specify which strata are "markers" and which strata are "targets". The strata are tagged as "markers" and "targets" in the Define Strata/Bed command. It is important to note that when using this option, you can define the "Marker Level", which sets the priority of the marker strata (this is an optional field, but it can have a significant impact on the model when multiple marker strata are available for use).

Use Conformance for Channel Samples: This option controls whether to use channel samples as source data points for conformance of other strata.

Calculate Strata Pinchout: This option determines if the thickness of a seam is pinched out when it does not occur in a drillhole, as shown in the below image.

When pinchout is disabled, as shown in the first cross section in the above image, the middle drillhole is completely ignored when making the grids for the blue and green strata. This results in the blue and green strata suggesting a significant thickness at the location of drillhole 2. In the second cross section, pinchout has been enabled, but the results are misleading because no thickness grids were incorporated into the model. In the third cross section, pinchout has been enabled and the thickness grids have been incorporated into the model to accurately model the pinchout.

It is important to note that elevation grids will not be automatically modified to show the pinchout, although the elevation grids may in fact be adjusted somewhat. It is therefore recommended to only enable this option when making thickness grids to avoid misleading results. When the program creates a thickness grid with this option enabled, the missing strata will be modeled as having a negative thickness at the drillhole without the strata. The thickness value will be equal but opposite to the thickness of the nearest thickness data point for that strata. In the above example, the blue strata has a thickness of 10' in drillhole 1, so the program will use a value of -10' in drillhole 2 when making the blue thickness grid. By incorporating a negative thickness value, the thickness will approach a value of zero approximately halfway between the drillholes 1 and 2. The Pinchout Slider bar to the right of this toggle in the dialog controls where the strata will actually pinchout. Before the thickness grid is written, it will be modified so that all negative values are reset to zero. This results in a thickness grid that begins to decrease in value as it nears the drillhole with the missing strata, but never shows a negative thickness.

Since this option is only intended to be used when making thickness grids, you will need to create modified elevation grids before adding them to the Geologic Model. This can be done quite easily with Grid File Utilities. In the above image, notice that the blue and green strata layers only pinch out properly when the elevation grids have been modified. In this case, the top of the blue strata was created by adding the bottom elevation grid of the blue strata to the thickness grid of the blue strata. Notice that in the second diagram in which only bottom elevation grids were used, the blue strata does not pinchout between the drillholes.

Finally, it is important to note that pinchout will only affect thickness grids when two "sandwiching" strata are detected above and below the missing strata. In the above image, the blue strata is "sandwiched" between the red

and yellow strata. If drillhole 2 did not contain the red strata, then the blue strata would not pinchout. This means that the top and bottom strata in any given model will not be able to pinchout.

Pinchout Zero Thickness: This option determines if a strata with a thickness of zero will be modeled as a pinchout. Pinchout is normally only applied for strata layers that are absent in a hole.

Pinchout Key Only: This option will only apply the pinchout to the Key strata while the Non-Key strata will be modeled as if the pinchout were not applied.

Adjust Non-Key for Estimated Key Strata: This setting controls whether to adjust non-key strata to fit in key strata for pinchout or conformance.

Restrict Pinchout to Drillhole Elevation Range: This option controls where the seam will pinchout. If there is a shallow hole, and a seam is running beneath it, this setting will pinchout the seam if it is off. If it is on, then the seams will only pinchout if they pass through the elevation range of the drillhole. This is useful if it is desired to pinch out a seam that passes above or below the elevation range of the drillholes. For most applications, it is recommended to leave this option disabled.

Include Strata Name in Bed Composite: This option will add the strata name to the bed name when running the bed compositing commands, such as Split Bed by Parameters.

Composite Bed Qualities by Density: When creating grids of bed qualities from drillholes with multiple samples of the bed quality, the quality will be composited to a single data point before the grid file is made. By default, the quality will be averaged by the thickness of the sample. When this option is enabled, the qualities will instead be averaged by weight (thickness * density). The **Density Attribute Name** sets the name of the density attribute to be used for weighting. Density is always expressed as lbs/ft³ or kg/m³.

Use Strata Limit Lines: This option determines if Strata Limit Polylines will be used for modeling. If this option is disabled, you will not be prompted to select Strata Limit Lines when modeling.

Auto Select All Strata Limit Lines: This option will automatically select all Strata Limit Polylines when modeling. You will not be prompted to select the lines when this option is enabled.

Process Only Strata with Beds: This option will ignore all strata layers without a bed name when modeling. This can be useful when overburden/interburden layers are not marked with unique strata names and have not been tagged with a bed name.

Process Only Strata with Definition: This option will ignore all strata that are not listed in the current Strata Definition file when modeling. However, strata layers that are not included in the Strata Definition file will still be used to calculate conformance and pinchout.

Dip Angle Direction: This option determines how drillhole dip values are interpreted. The default option of $0 = \text{Down} - 90 = \text{Horizontal} - 180 = \text{Up}$ will treat dip values of 0 degrees as vertical in the downward direction, dip values of 90 degrees in the horizontal plane, and dip values of 180 degrees as vertical in the upward direction. The other options may be used to accommodate other dip value schemes.

Dip Angle Method: The Direct method simply applies the dip angle of the sample to the depth of the sample. The Minimum Curvature method looks at two adjacent samples at a time and calculates assuming the samples lie on a circular arc. The Min Curvature From Bottom method considers the sample point to be at the bottom of the sample and pairs this point with the dip from the previous sample. The Min Curvature From Top method considers the

sample points to be at the top of the sample and pairs this point with the dip from the next sample.

Store Source Data in Grids: This option will include the source data used to make strata grid files within the grid itself. This includes the X-Y coordinates of the data point, the value used for modeling, and the type of data source (drillhole, channel sample, etc.). This can be useful for understanding how the grid file was generated when the original source data is not available.

StrataCalc Drillhole Selection Method: This option determines how the program will prompt for geologic data when modeling. The *On-Screen Drillholes* option will prompt you to select drillholes, channel samples, etc. when making the geologic model. The *StrataCalc File* option will instead prompt you for a .stc file, which can be saved from the StrataCalc Data Sheet command. The .stc file can be useful when you need to be certain that the same information is being used to create model between iterations.

Stripping Ratio Units: This option sets the units to be used when reporting Stripping Ratio. Some commands, however, will not respect this option, and will instead report Stripping Ratio using the default units of (yd³ waste)/(ton key) or (m³ waste)/(tonne key). Commands that are hard-wired to use the default stripping ratio units are Dragline Pits, Vertical Pit Quantities, and Pit Scheduler. Also, when using Surface Mine Reserves, when the "Type of Strip Ratio Contours/Grid" is set to Accumulative, only the default stripping ratio units will be used for the contour/grid output (be cautious not to confuse the contour/grid output option with the Accumulative Stripping Ratio that is included in the report - all stripping ratio values in the Surface Mine Reserves report will respect the stripping ratio units selected in Carlson Configure).

Underground Room/Pillar Settings: These options apply to the series of commands for placing coal sections (used for calculating end of month volumes).

Use 0 Values for Blank Entries in Coal Sections: This option will replace treat blank values in coal sections as 0 rather than considering it to be null.

Draw Coal Sections Z at Thickness: This option will draw coal section symbols at the Z value of the actual thickness. For example, a coal section with a thickness of 5 feet will be drawn at an elevation of 5. This is useful for contouring or gridding the coal sections with standard commands from the Civil module.

Prompt for Advancement Pline for Quantities: This option will prompt you to select an additional advancement polyline when running the Quantities by Average / Grid / Centerline commands. This polyline represents the direction of mining in a particular area. The length of the polyline will be included in the quantity report.

Report Format for Quantities by Avg/Grid Methods: This option determines the default report format for the Quantities by Average / Grid / Centerline commands. However, each of these commands will also let you set the report format when the command is executed. The *Standard* option will use a simple text editor for the report. The *Columns* option will still use a standard text editor, but with the values aligned into columns. The *Formatter* option will send the report to the Report Formatter for user-defined formats.

General Settings:

Key Material Name: This is the name of the Key material you are mining. This name will be used in several reports to identify Key material, such as the outputs from Surface Mine Reserves and Surface Production Timing. If you have more than one type of key material, you may want to give this a more generic name such as "Key Material" to avoid confusion in the reports.

Bed Name Suffixes: KEY, OB, PARTING, BOTTOM: These suffixes are used to identify the four portions of a bed. An example is shown in the below image. When Bed names are applied to a group of strata layers, all strata layers with matching bed names are treated as a single group. This allows the program to properly correlate groups between drillholes even when the number of samples for each bed is not consistent between drillholes. Although

the strata will be treated as one group, there are four portions of the bed available for modeling. Note that not all four portions of the bed may not be present in a data set.

OB: This is the non-key portion of the bed above the first occurrence of Key strata.

Parting: This is the Non-Key portion of the bed bound between Key strata.

Key: This is the Key portion of the bed.

Bottom: This is the non-key portion of the bed below the last occurrence of Key strata.

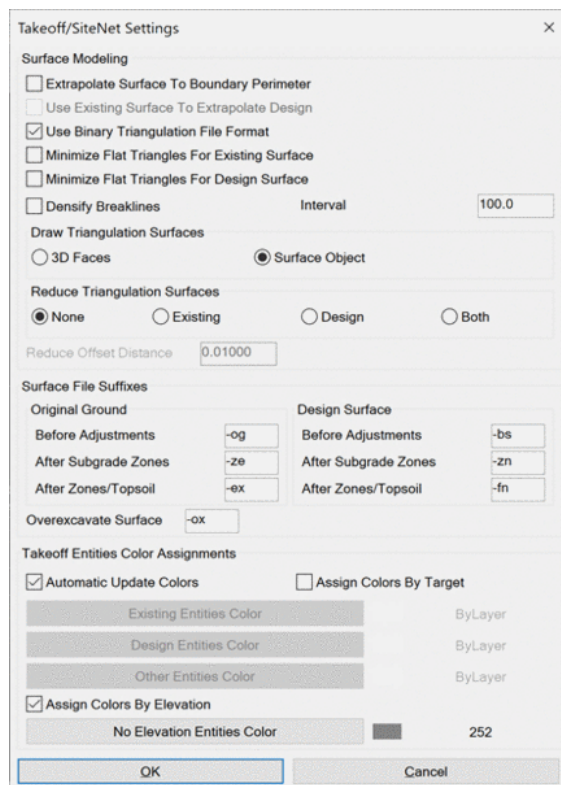

SDPS Directory: This field sets the installation directory for the Subsidence Deformation Prediction System (SDPS) program. The SDPS commands are found under the Subsidence Pulldown Menu of the Underground Mining Module.

Use Map Object Data as Properties: This option will use the AutoCAD Map data to set the Property and Owner names for reserve estimates. When this option is disabled, the program will use the Owner and Property names assigned to polylines from the Assign Property Names command.

Hide Legacy Data Formats and Features Options: When enabled, older settings and commands considered to be outdated will be hidden. The goal with this option is to simplify interfaces by hiding options users are unlikely to use. If you find that this option hides an option/feature you are still using, please contact us at support@carlsonsw.com.

These options are used for the Construction module and SiteNet commands in the Civil module.

Extrapolate Surface To Boundary Perimeter: When this is checked ON surfaces are extended and volumes are calculated out to your boundary perimeter. When this is checked OFF surfaces and calculations end at the extents of your design data.

Use Existing Surface To Extrapolate Design: When this is checked ON surfaces and volumes are calculated to the extents of your existing data.

Use Binary Triangulation File Format: This option sets the format for the surface model files as either binary or ASCII. The binary format has a .tin file name extension and loads about twice as fast and has about 50% less file size than ASCII. The ASCII format has a .flt extension and is the legacy format used by other Carlson products and Softdesk.

Minimize Flat Triangles: This option reduces the occurrence of "flat" (or more precisely, horizontal) triangles. Flat triangles often occur when creating surface models from contour data. The Minimize Flat Triangle option will swap triangulation edges when possible to switch flat triangles to sloped triangles.

Densify Breaklines: This option automatically add vertices on breakline segments for triangulation at the specified Interval.

Draw Triangulation Surfaces: This option sets how the Takeoff surfaces are drawn in the drawing. The 3D Faces option creates 3D Face entities for each triangle in the surface. The Surface Object option creates a single Carlson Surface Object for the surface which is more efficient on memory and drawing size.

Reduce Triangulation Surfaces: This causes edges within the selected surface TIN mesh to be collapsed to reduce the number of triangles, edges, and points within the mesh while having a minimal impact on the overall shape of the mesh.

Reduce Offset Distance: This setting is used by the Reduce Triangulation Surfaces command to set the reduction tolerance. Specify the maximum average distance that any point can be moved outside of the plane of any triangle that connects to that point. Values might range from .01 to .1 for most purposes.

Surface File Suffixes: These settings allow you to change the file names for the surfaces generated by the program:

- **-og** - This is the default name for the original ground surface before adjustments.
- **-ze** - This is the default name for the original ground surface after subgrade zone adjustments.
- **-ex** - This is the default name for the original ground surface after subgrade zone and topsoil adjustments.
- **-fg** - This is the default name for the initial design surface before adjustments.
- **-zn** - This is the default name for the design surface after subgrade zone adjustments.
- **-sg** - This is the default name for the design surface after subgrade zone and topsoil adjustments.
- **-ox** - This is the default name for the over-excavate surface after subgrade zone and topsoil adjustments.

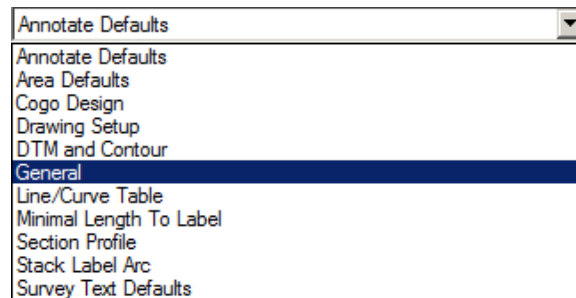

Automatic Update Colors: This refreshes colors in your drawing as they change (*i.e.* elevating entities, setting layers for different Targets, *etc*). If your drawing is very large and is slow to automatically refresh you may want to toggle this off and use the Update Colors For Set Elevations command under View when you want/need to see the color changes.

Assign Colors By Target: This option allows you to set the Existing, Design, and Other layers to any color you define.

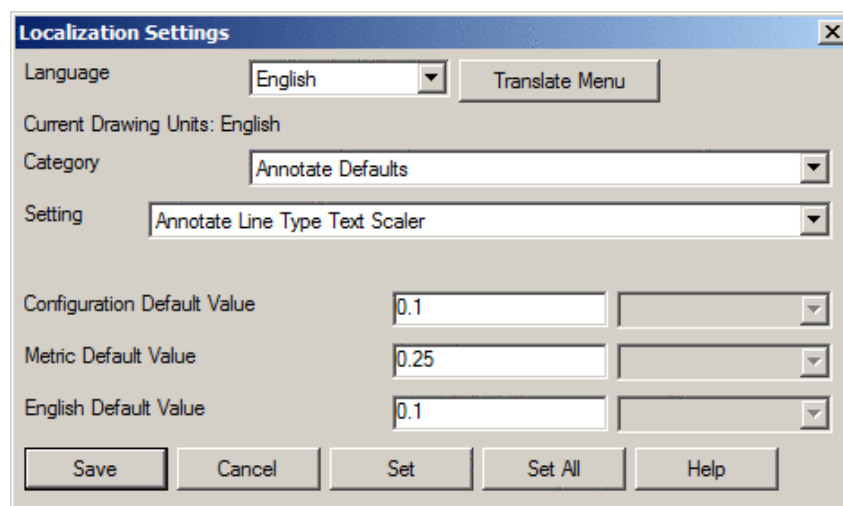

Assign Colors By Elevation: This option allows you to set the color for entities needing elevations.

No Elevation Entities Color: Indicate the color entities with no elevation ($Z=0$) should be assigned to when their layer is classified as "Original" or "Design".

There are literally hundreds of default settings that can be set with this dialog. The categories that can be selected from are:

The Settings for each Category will display all of the items that can be setup for default values. The Default value is set in the Configuration Default Value box. The corresponding Metric or English default values are set here, allowing for easy switching between the two systems.

Pulldown Menu Location(s): Settings

Prerequisite: None

Data Depot

The Carlson Data Depot is a document management system to allow tracking of the changing states of files and projects over time and merge the contributions from multiple users providing data integrity, productivity and accountability for the managed products. Also, having a central project repository helps with data back-up eliminating the fear of losing data due to local drive failures. The Carlson Data Depot protects against productivity loss due to re-implemented work, not only avoiding losses of data, but also making each user's work readily available to other users on the project. The general process for implementing your preferred document management system is:

1. Install and initialize one or more of the version control software products listed below.
2. Instruct Carlson Software to utilize one of these services by establishing the needed settings in the Set Project/Data Folder command.
3. Assign a project to the Data Depot through the use of the Project Explorer command.
4. Subsequently open or update any Data Depot project through the use of the Get Project from Data Depot command *or* the Data Depot icon on the Start-up Wizard dialog box:

Carlson Software supports the following *version control systems*:

- Subversion - a free, open-source version control system.
- ProjectWise - software developed and produced by Bentley Systems.

Subversion is a powerful revision control system which is actively evolving and is part of Apache web-server project. The home page of this project is <http://subversion.apache.org/>, with a book on setup, use and administration available in print and online at <http://svnbook.red-bean.com>.

Carlson Software supports Subversion release 1.5.6 or newer.

While there multiple ways to setup Subversion repository and connect to it, the most typical scenario is setting up Subversion server and connecting to it through the web-server. Local directory setup is also available, but not useful in group environments. Running the shared directory on the network should not be attempted since it could lead to the repository corruption and permanent data loss.

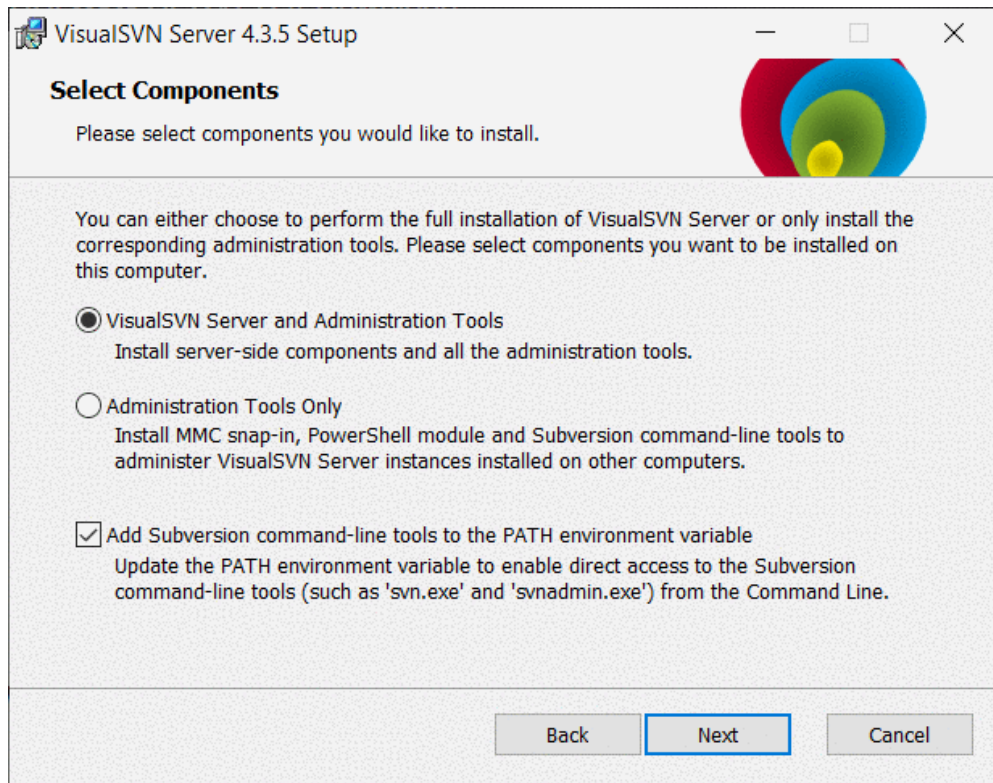

Setting up a Subversion Server on Windows Host

For users who run Windows on their host there is a nicely integrated front-end to a standard Subversion server (included): VisualSVN server (<http://visualsvn.com/server/>). There are two licenses available for commercial users:

1. a free basic edition
2. a reasonably priced enterprise edition with additional features larger sites will find attractive

This document will concentrate on install of the basic edition.

1. Download and run the VisualSVN install.
2. Select option to install VisualSVN server:

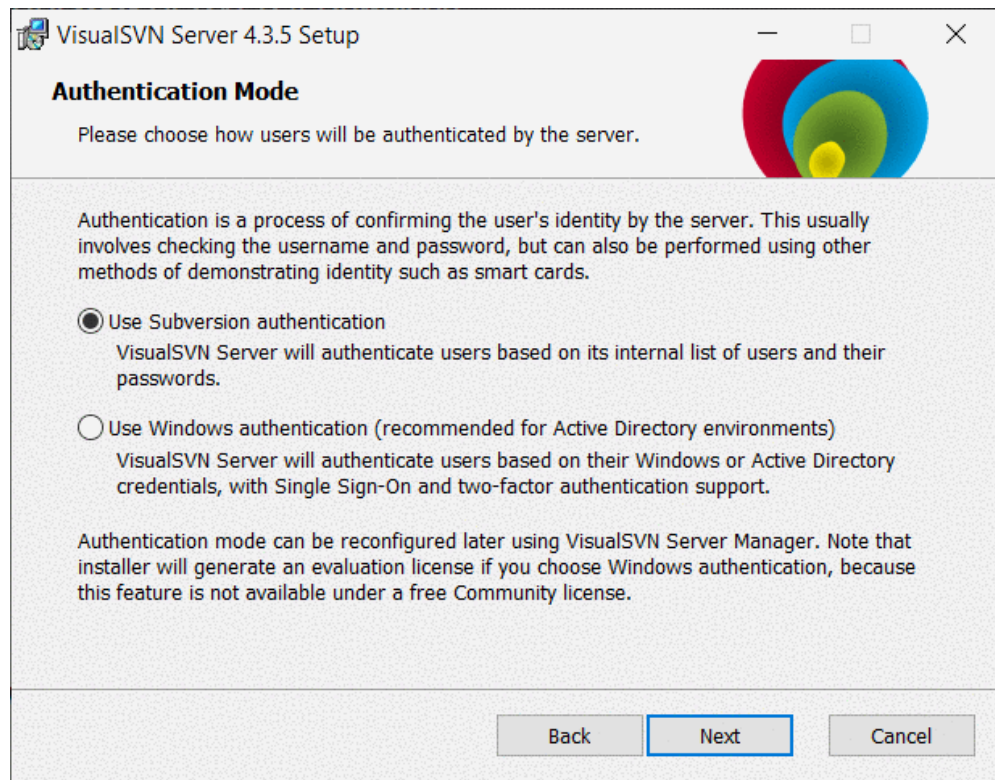

3. Specify repository directory where the data will be stored.

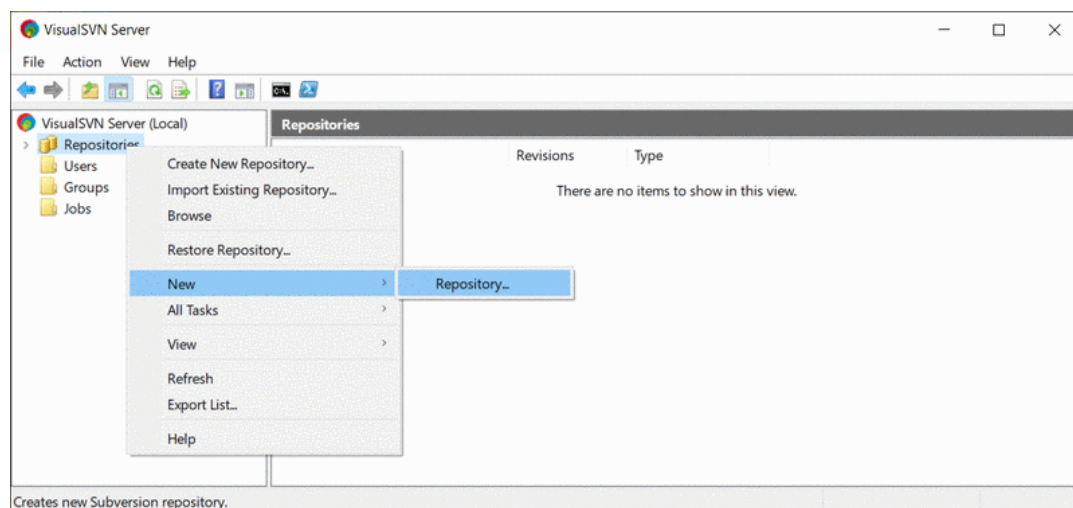

This should be a secure and backed-up location since this is where the data will be stored. The **server port** and **https://** settings are standard and most users will want to leave them alone.

4. The Authentication Mode is a matter of the site preference. Enterprise edition of VisualSVN offers additional authentication options like using Microsoft Active Directory server.

5. Upon completion of the install the manager interface will be displayed. Create a new repository by right-clicking on the Repositories:

6. Select the Repository Type:

Create New Repository ×

Repository Type
Choose the new repository type. 

Select the preferred repository type.

Regular FSFS repository
Create a regular Subversion repository based on the standard FSFS data store.

Distributed VDFS repository
Create a distributed Subversion repository based on the VisualSVN Distributed File System. The VDFS repositories act as standard Subversion repositories and allow data to be replicated between geographically distributed sites.

[Learn more about available repository types](#)

< Back Next > Cancel

7. Give new repository a name. You may choose to have several repositories, each containing data of the similar kind or covering an area of your business:

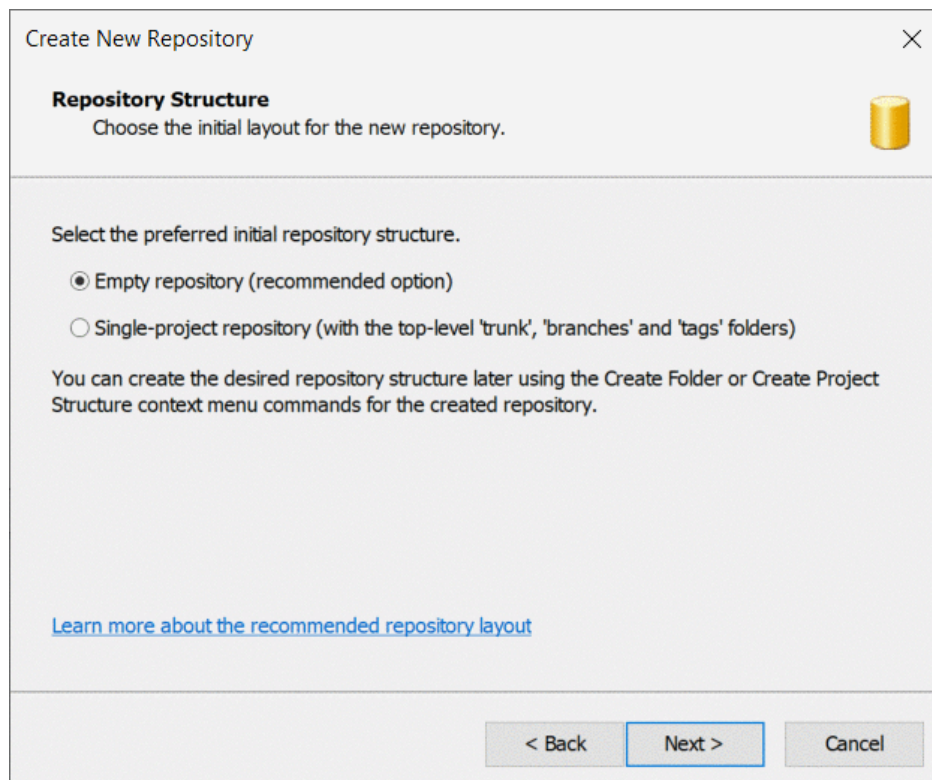

Create New Repository

Repository Name
Specify the name for the new repository.

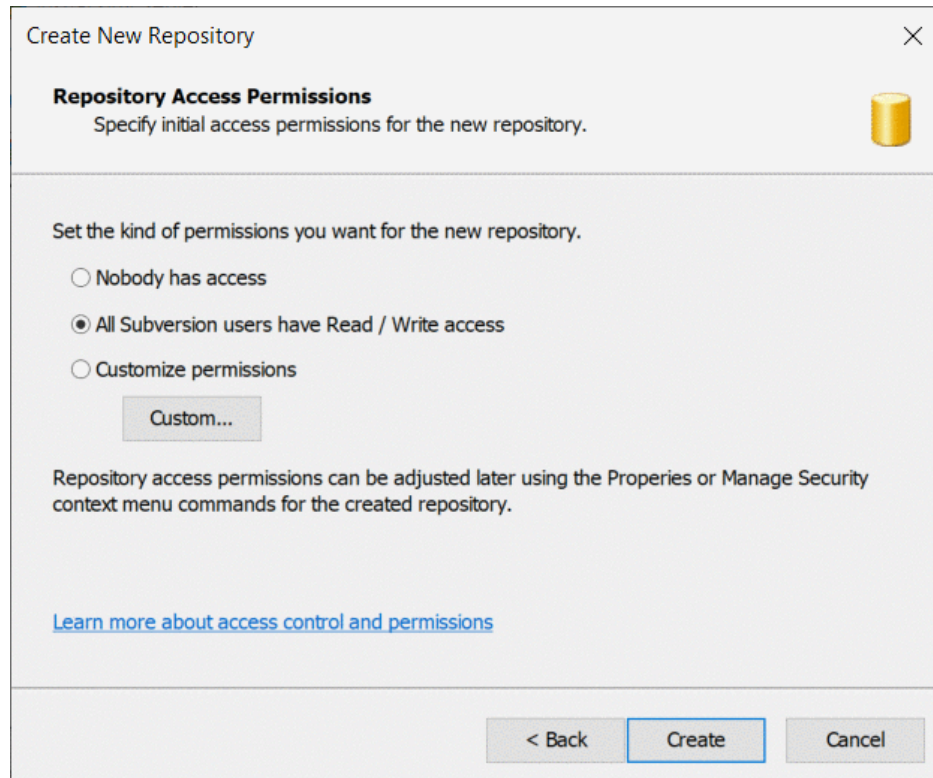

Repository Name:
Projects

< Back Next > Cancel

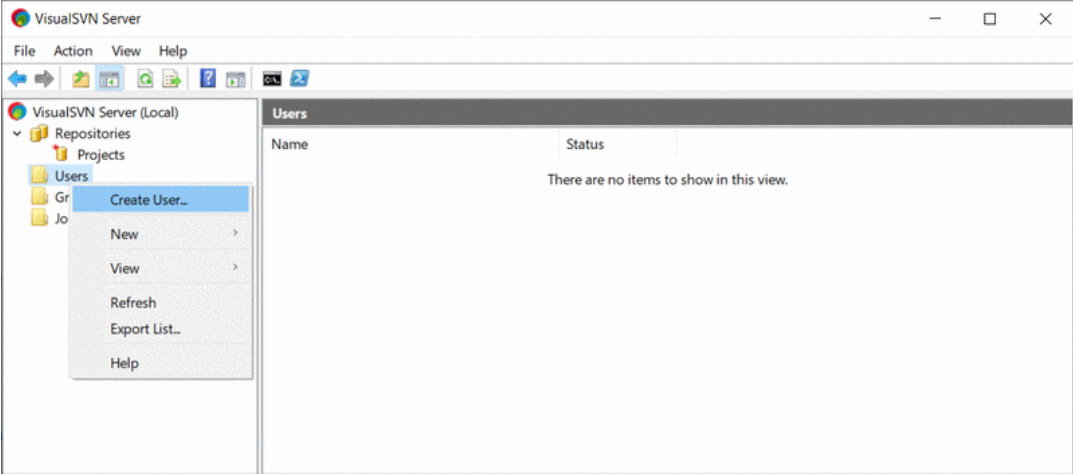

8. Select the Repository Structure:

9. Select the Repository Access Permissions:

10. Create users and set passwords (if using Subversion's own user authentication):

Create New User ✕

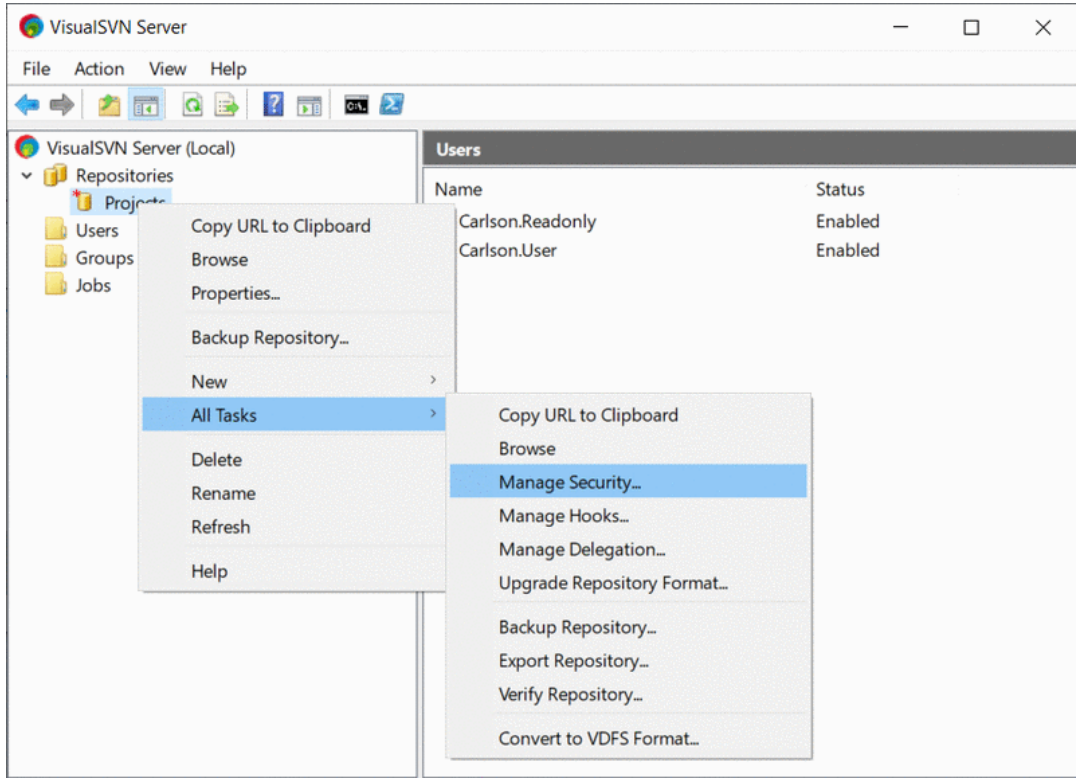

User name:

Password:

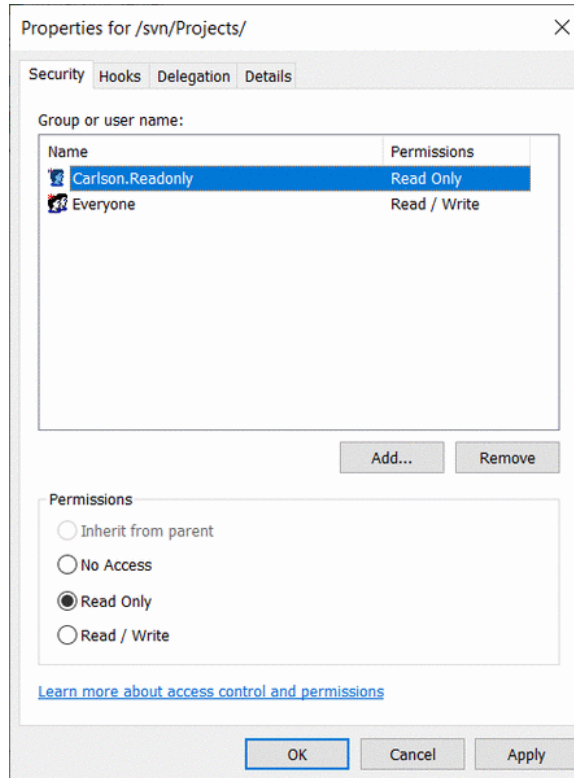

Confirm password:

i User name and password are case sensitive.

11. Run the "Manage security" command by right-clicking over whole repository to set defaults or right-clicking on specific folder to set specific permissions:

12. Add users or user-groups and set specific permissions for the folder you selected:

This completes the server side installation of Subversion.

Setting up a Subversion Server on Linux Host

Subversion is a project which was born on Unix platform, so it is fairly straightforward to set up and run on the Linux host. Specific details may vary for different distributions, but below is a quick summary of steps for Redhat or CentOS based hosts, which should at least point you in the right direction.

Install needed packages

The following packages should be installed:

- **httpd** - Apache web server for access to the subversion
- **subversion** - the Subversion command line and administration tools
- **mod_ssl** - support for secure connections
- **mod_dav_svn** - integration between the Apache and Subversion

Create repository folder

Run the following command to configure the Subversion file structure:

```
svnadmin create --fs-type fsfs /var/lib/subversion/repos
```

where 'fsfs' refers to the type of the file storage being selected and last argument is the future location of the repository data files on the system.

Configure Apache to be handle Subversion calls

The Apache configuration file httpd.conf is typically located in the /etc/httpd/conf folder. Please modify it to contain a section like this:

```
<Location /repos>
```

```
DAV svn
SVNParentPath /var/lib/subversion/repos
AuthType Digest
AuthName 'Subversion'
AuthDigestdomain /repos/
AuthUserFile /var/lib/subversion/svn_passwd
Require valid-user
SSLRequireSSL
</Location>
```

Restart Apache server. This should let you reach your Subversion server with URL like this:

```
https://server_name/repos
```

User control

The configuration above assumes the authentication for the domain "Subversion" handled by Apache itself. Much more powerful options are available, but since these are standard Apache features, plenty of documentation for is readily available.

To add new users, please use the following command:

```
htdigest -c /var/lib/subversion/svn_passwd 'Subversion' user_name
```

where -c is for "create" and only should be used first time. Supply user name for whom the password is being set. The permissions are controlled by the *svnserve.conf* file typically located in /etc/subversion directory. The equivalent configuration to the Windows example above would look like this:

```
[Projects:/]
Carlson.Readonly=r
Carlson.User=rw
```

For further documentation please refer to the book mentioned above or to the numerous Subversion resources online.

Creating a local Subversion Repository

The Windows MSI installer with the basic Win32 client binaries can be downloaded at:

<http://www.collab.net/downloads/subversion/>

Running this installation file installs the required binaries to create the Subversion *repository* on the server or local machine under "**C:\Program Files\Subversion**" using the default options.

To create the Subversion repository:

1. Click the Windows Start > Run and then type **cmd** into the resulting dialog box as shown below and click **OK**:

2. At the DOS prompt, navigate to the Subversion install directory by typing:
cd "C:\Program Files\Subversion" and press the *Enter* button to complete this step as shown above.
3. To create the Subversion repository under the "C" drive, type:
svnadmin create c:\svnrepo and press the *Enter* button to complete this step as shown above. This will create

a "svnrepo" folder under the "C" drive (c:\svnrepo); see the **Notes** section below for important information. The path and the name of the repository could be path to a network drive as well. For setting up a Subversion Repository on the server, refer to the <http://subversion.tigris.org> documentation.

4. Type the word **exit** and press the *Enter* button to dismiss the DOS window and complete the command as shown above.

NOTE: Once you have created a Subversion Repository, do not add, delete, or modify files in the Repository folder unless you know how to avoid corrupting the repository.

Setting Subversion URL in Carlson

In order to connect Carlson to Subversion repository, please go to Settings – Configure Carlson – Project/Data Folders. Set the project type to Subversion and click Setup button. Specify the server location like:

file:///c:/svnrepo

for a local example above, or:

https://server.name/repos

for a network server as described above. Other URL types supported by Subversion for the scenarios beyond the scope of this document are permitted as well.

Accessing Subversion through a GUI Client

There are various graphical-user interface (GUI) client applications available for accessing the SVN repositories on the Internet for free:

- RapidSVN
- SmartSVN
- TortoiseSVN
- ViewVC
- WebSVN

Once a supported document management system has been properly installed and configured for each computer work-station, continue with the Data Depot configuration by initiating the Set Project/Data Folder command.

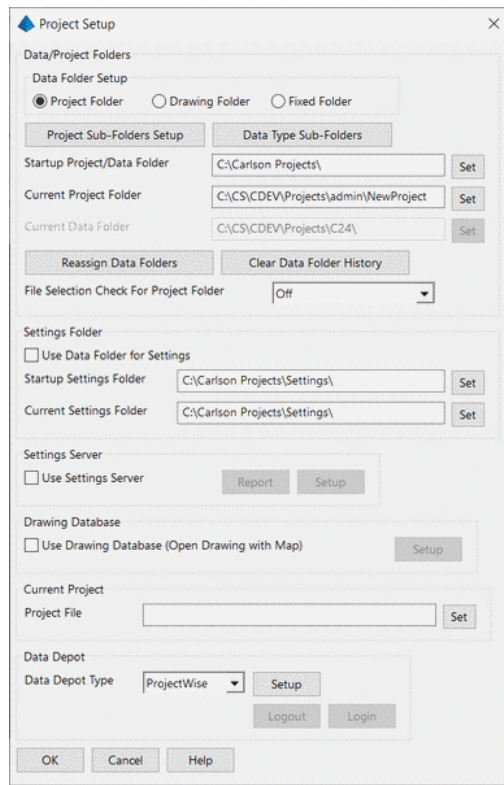

Please see your ProjectWise Administrator for instructions on configuring ProjectWise Datasources for your company. Here are steps to add a sample project to ProjectWise.

- 1) In the ProjectWise Explorer (not to be confused with the Project Explorer, which is the Carlson routine that operates inside of CAD) create a new project under the datasource that you will be connecting to in the "Documents" section (right click on Documents and use "New Project"). Name your project the same name as what you will be calling it in CAD. For example, call it "NewProject".

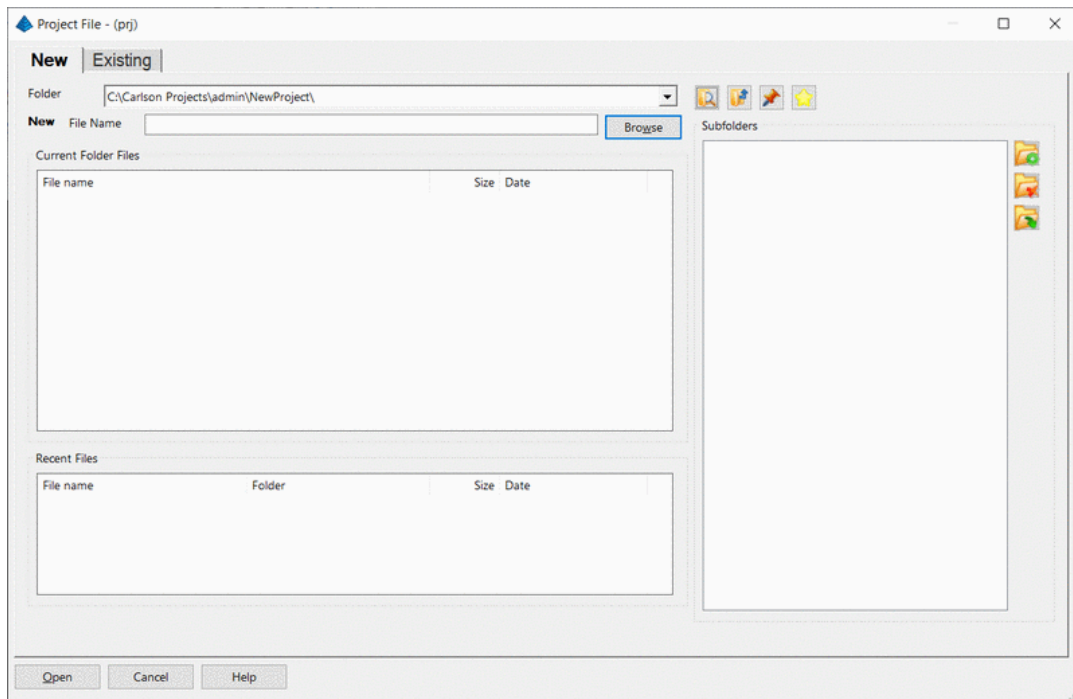

- 2) If you don't have one already, in Windows create a folder where you will store your project and related files. Place any files under that folder. You don't have to place all the files in that one folder. You can use any hierarchy layout that you want but in this sample case for illustration just uses the root folder of the project and a single drawing.

- 3) Open a drawing that belongs to this project.

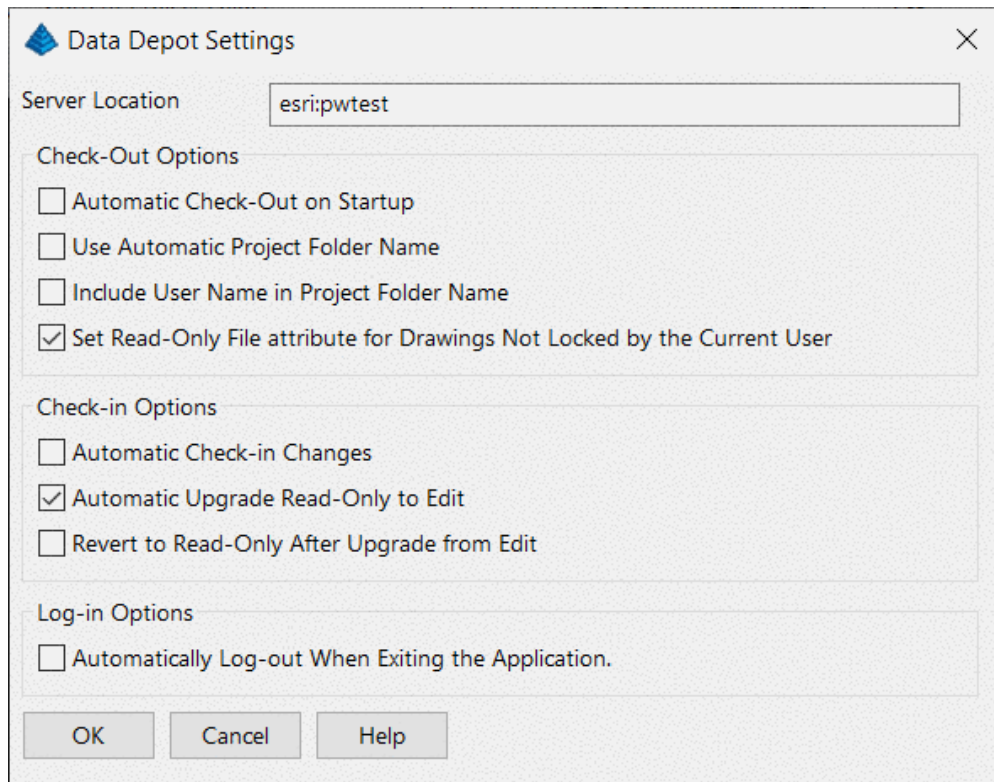

- 4) Go to the menu item Settings->Set Project Data Folders:

Your settings should look something like this. Select the "Project Folder" option. Make sure you set your Project File. When you click on Project File->Set, it will prompt you to either select an existing or create a new project:

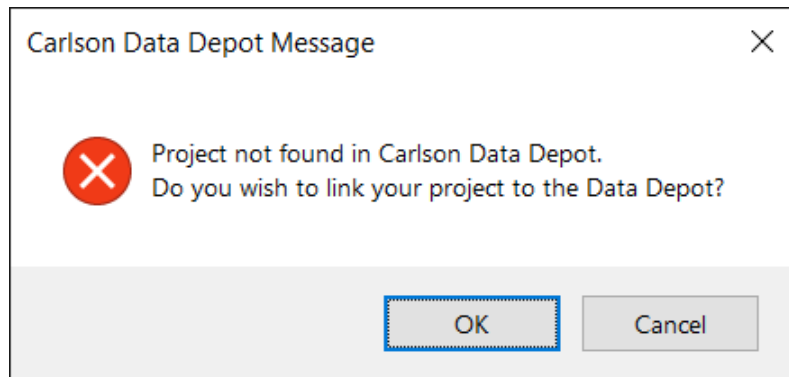

The project folder should have the same name as that you used in ProjectWise. In this case "NewProject". This name is case-sensitive. The .PRJ file name itself can be anything you want to call it. In this case it is called "newproject" as shown above. So the actual project file name is "newproject.prj". If you have multiple drawings that are part of this same project, you will want to make sure they all point to this same project file and have the same settings at this time. In this sample case, there is only the one test.dwg drawing.

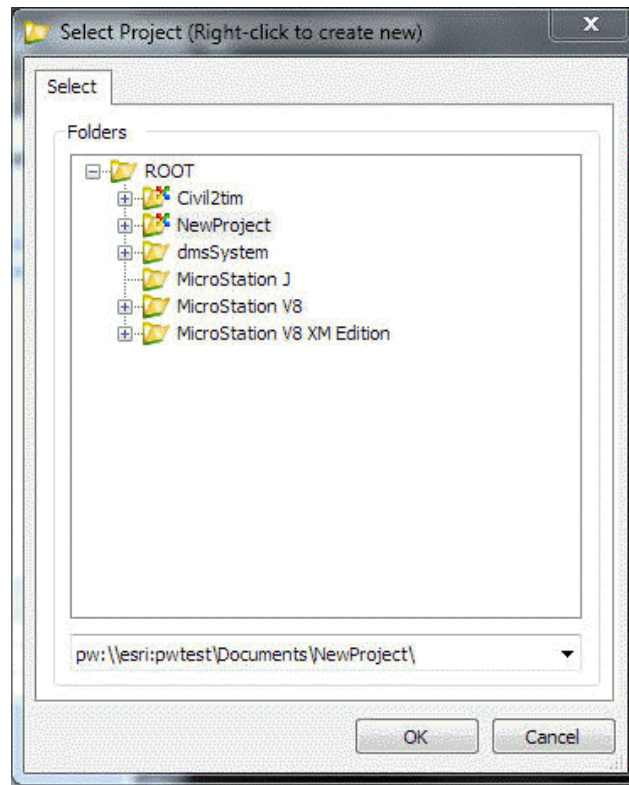

You will notice that the actual folder name shown above is C:\Carlson Projects\admin\NewProject. This is because in the Data Depot Settings the user's name is included in the folder name. In this case the user's name is "admin". This makes it easy to use a single computer with multiple users where they can store their local copy independently of other users.

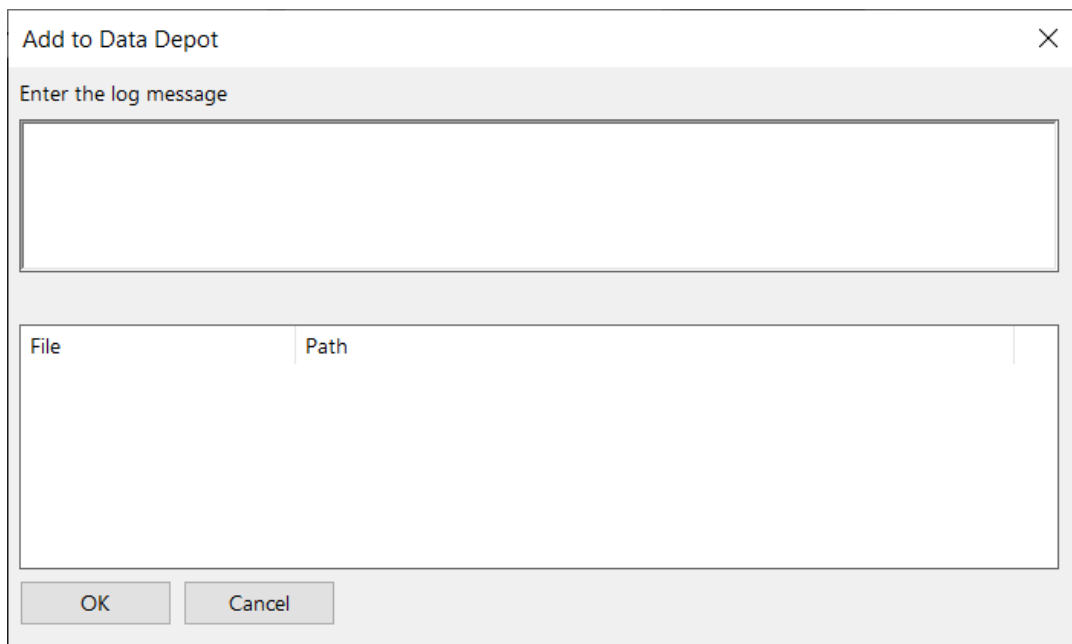

5) Open the Project Explorer in CAD (menu option File->Project->Project Explorer). You should see the following alert:

Select OK. Next you will be asked to select the project in ProjectWise that you want to store the files under:

6) Select the new project you created earlier in step 1. In this sample case it is "New Project" as shown above.

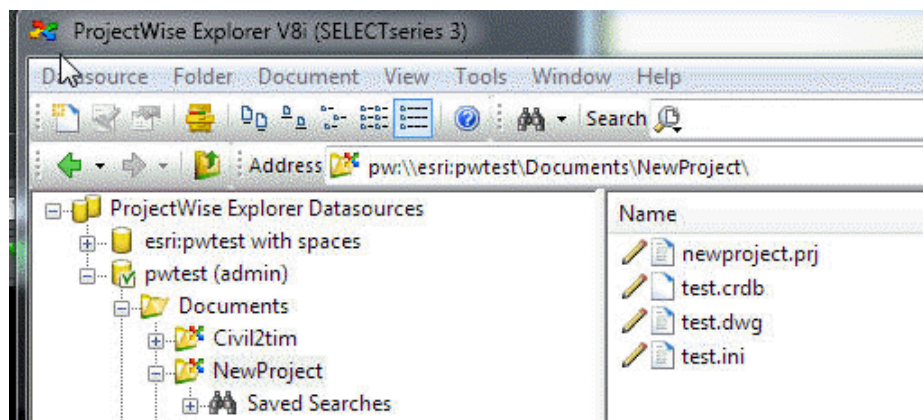

At this dialog, keep the default of "The project and all associated files". Enter any log message you want. This will appear in your ProjectWise audit trail.

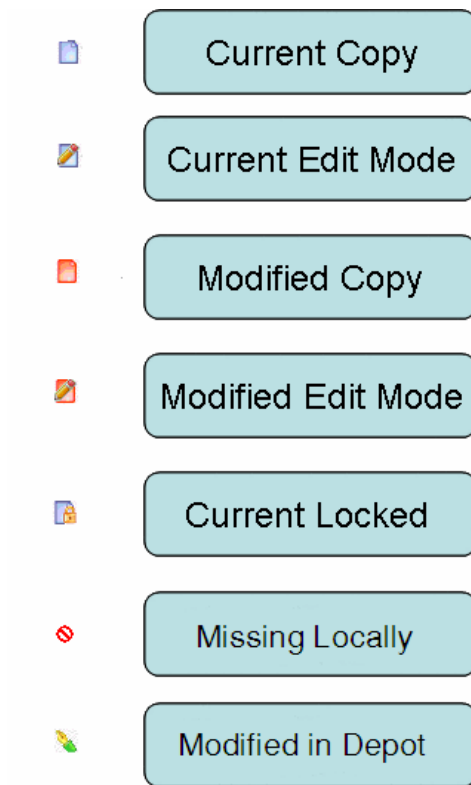

At this point it should upload all of the files that are part of this project. In this sample case that is test.dwg and associated files. If there are any XREFs that have not been uploaded they will also be uploaded at this time.

Once done uploading you will see a message showing that the project file has been uploaded (shown below). In the command window you will also see a list of all of the files that were uploaded to ProjectWise (test.dwg, test.crdp and test.ini in this sample case).

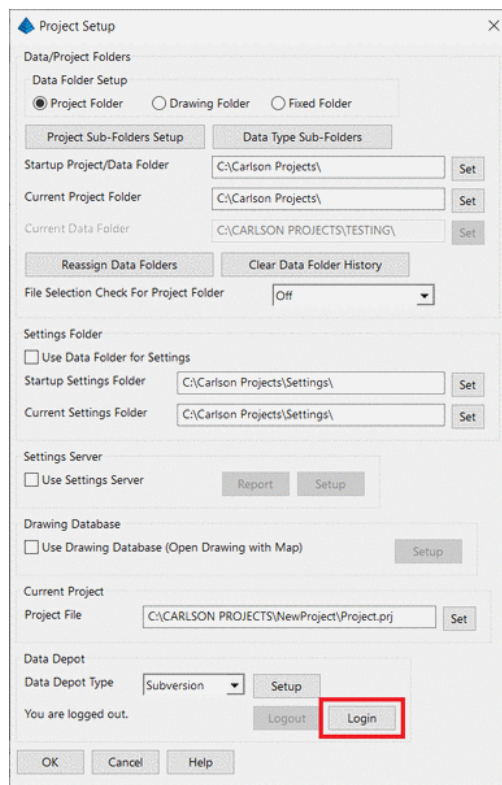

You can now go to your ProjectWise Explorer to see the results:

Logging in or Out of Data Depot in Carlson

1. Go to the menu item Settings->Set Project Data Folders:
2. Click the Login button to log in to the server located at the location specified in the "Data Depot Settings" dialog box(accessed by clicking Setup next to Data Depot Type):

3. Once logged in, the Logout button will be enabled and you will be able to log out from the server.

Pulldown Menu Location(s): None

Keyboard Command: None

Prerequisite: None

Carlson Settings Explorer

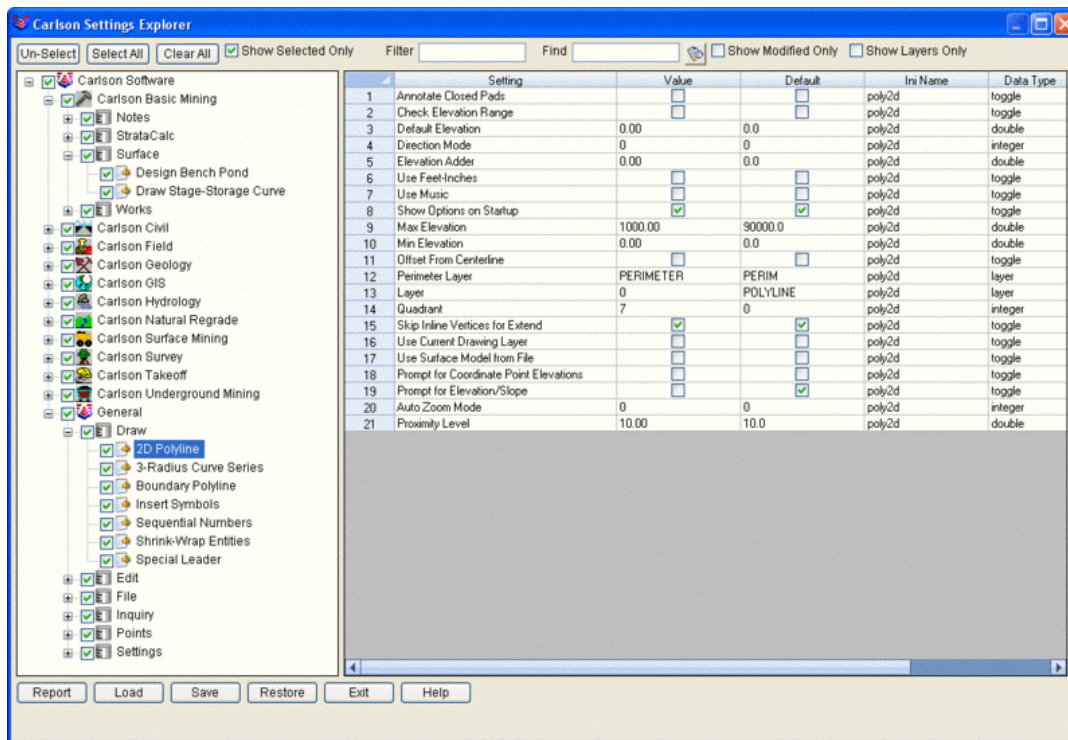

The Carlson Settings Explorer dialog box allows you to view, manage and report the values for all settings in all commands in all Carlson Software programs.

The tree-view on the left of the window shows the four levels of the command structure of Carlson Software, Program, Menu and Function. Selecting (highlighting) any one or many of these levels will show associated settings. The programs level also includes General, that includes the first six menus available in all Carlson programs.

The right-side is a spreadsheet view and is populated depending on the item(s) selected and highlighted in the tree-view. Selecting and placing a checkmark next to an item at one of the upper levels of the tree structure will select that item and all its sub-items.

The spreadsheet view shows the following columns for a command:

- Setting - Prompt for the settings in the dialog or at Command: line
- Value - Current value
- Default - Default value for the setting
- Ini Name - Carlson internal file name for the command
- Data Type - Description of the value for this setting

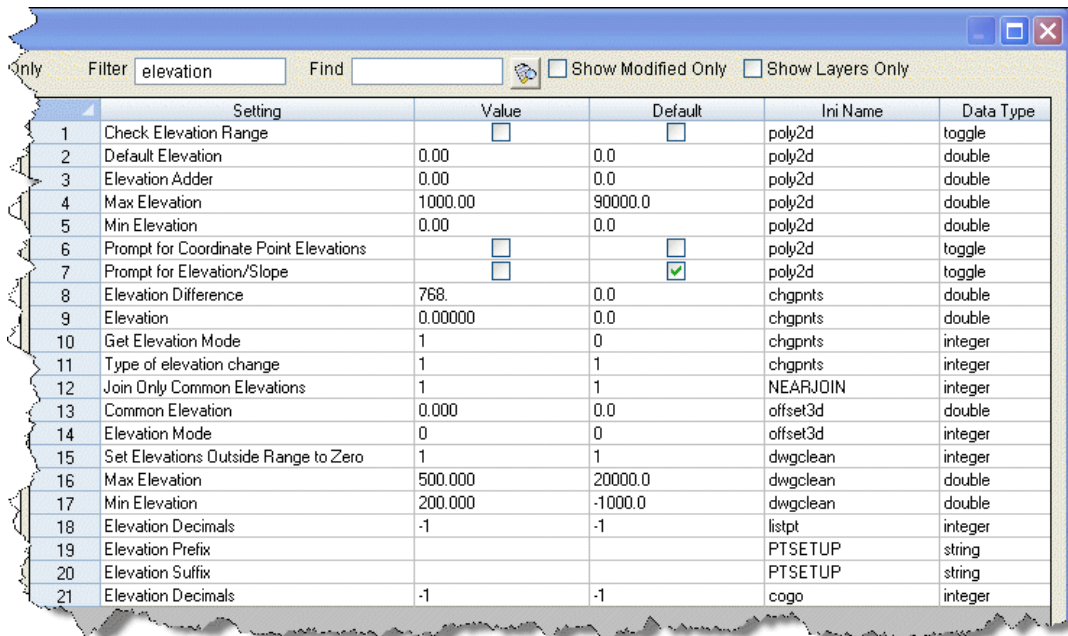

Select/Unselect: Using the square tick boxes you can click this toggle to select or unselect a unique item or all items under the hierarchical list. All ticked items will appear in the spreadsheet view to the right.

Select All: Use this button to place a checkmark next to all items and sub-items in the tree-view.

Clear All: Use this button to clear checkmarks from all items and sub-items in the tree-view.

Show Selected Only: Select this option to display, in spreadsheet view, the tree-view settings that have checkmarks on.

Filter: Using a Filter will display the settings containing the text string specified as the Filter. For instance, filtering with the word "elevation", returns the following results:

Find: Use this option to search for a string of text. First, enter the text to be found and then pick the button to the right to execute the search.

Show Modified Only: Select this option to display the settings whose current value, as shown in the "Value" column, is different from the default value shown in the "Default" column.

Show Layers Only: Select this option to display the settings whose value in the "Data Type" column is specified as "Layer".

Report: Use this button to prepare a report of all selected settings using Carlson's Report Formatter.

Load: Use this button to Load settings from a Carlson Configuration File (.cfg).

Save: Use this button to Save settings to a Carlson Configuration File (.cfg).

Restore: Use this button to Restore selected settings to their Default value.

Pulldown Menu Location: Settings

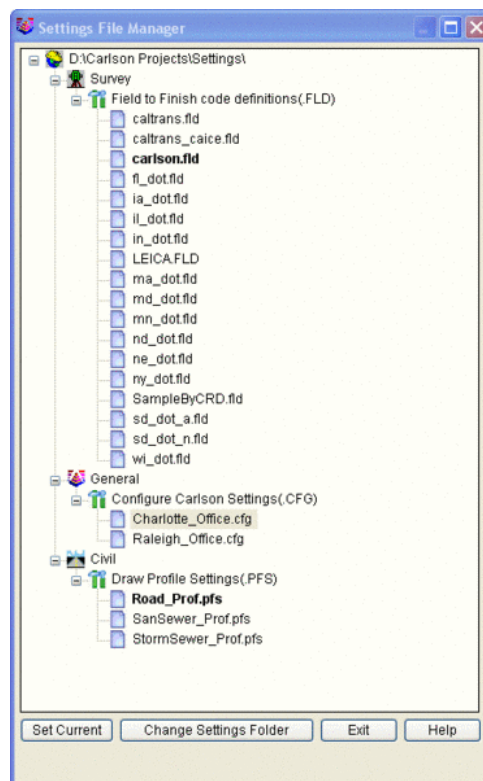

Keyboard Command: setxplore

Prerequisite: None

Settings File Manager

The Settings File Manager provides an organized view of all Carlson Software Settings files that have been saved in a specified "Settings" folder. By default, the initial folder displayed is the "Startup Settings Folder" as specified in the Project Setup dialog box.

The various Settings files are displayed in a tree structure based on their corresponding Carlson Software program. If the current Settings for any command match the Settings found in a Settings file, the file name will show up in a **Bold** font. Because Configuration Files (.cfg) are collections of many Settings files, they cannot be set Current and will not show up in Bold font.

Set Current: After selecting one of the various Settings files, use this button to set that file current. Files that have been set "Current" will show up in a **Bold** font. Only one file of any Setting type can be set Current at one time. And, because Configuration Files (.cfg) are collections of many Settings files, they cannot be set Current and will not show up in Bold.

Change Settings Folder: Use this button to browse to and select a folder in which Carlson Software settings have

been stored.

Compare: This function compares two settings files and reports differences in a spreadsheet. To run this function, select the first settings file to compare from the Settings File Manager dialog. Then pick the Compare button and the program will prompt for the second file of that type to compare with. In the Compare dialog, you can make changes to the settings and use the save buttons to save the edits.

29	Starting Station	0.	0.0	double

Pulldown Menu Location: Settings

Keyboard Command: setmanager

Prerequisite: None

Toolbar Manager

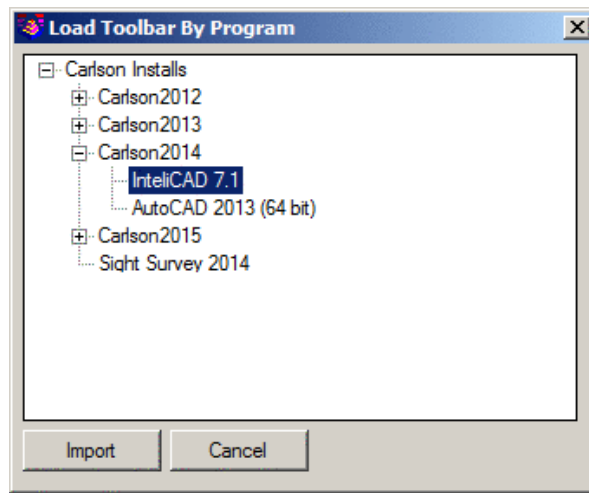

The *Toolbar Manager* command permits the saving and loading of toolbar configurations and allow migrating toolbar settings between versions.

Load Toolbar File: Restores the toolbar settings from a previously saved *.TB file.

Save Toolbar File: Writes the current toolbar settings to a *.TB file.

Load Toolbar by Program: Loads the toolbar configuration associated with an alternate version of Carlson into the current application.

Note:

- The *Load Toolbar by Program* does not allow the toolbar configuration from the current software installation to be loaded into itself.
- The files created and used by this command are stored in an Extensible Markup Language (XML) format but are assigned a *.TB extension.

Pulldown Menu Location: Settings

Keyboard Command: tb_manager

Prerequisite: None

Edit Symbol Library

This command allows you to customize the symbol library. For a printout of the default symbols, get the symbols.pdf in the Carlson Projects folder. The default library has hundreds of 2D and 3D symbols including National CAD Standard (NCS) symbols, MassDOT standard symbols and a set of symbols with wipeouts built-in to hide linework under the symbols.

Categories are a way for grouping symbols by type for your own convenience in symbol selection. There are two levels of categories: top-level and sub-category. Within each top-level category, you can have any number of sub-categories. A new category is added by clicking on the "Add Category" button. An edit field then appears in the tree view on the left and waits for you to enter the category name. The input is finished by pressing the Enter key.

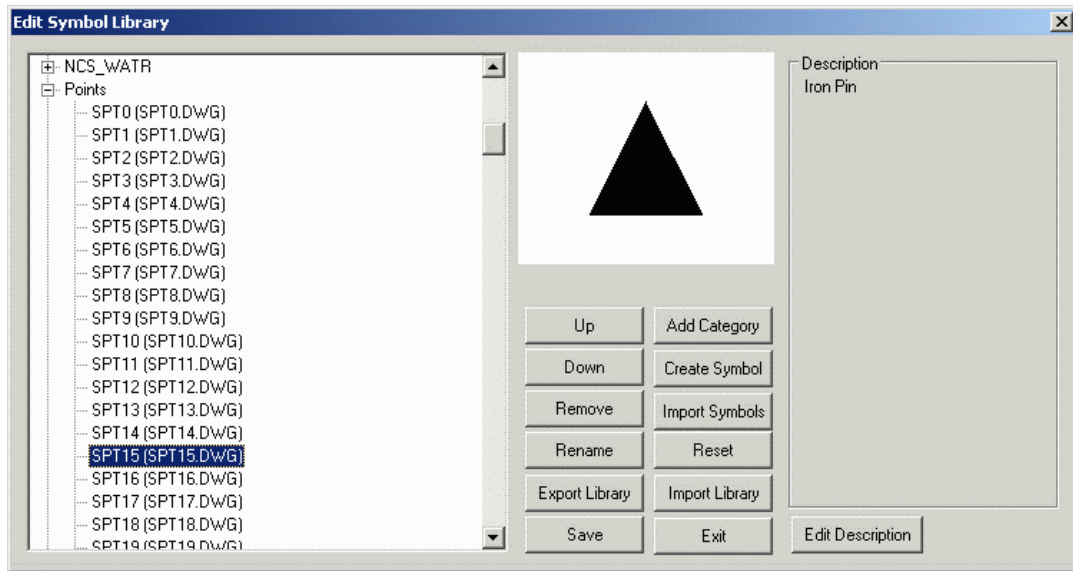

The category may be populated by creating a new symbol from selected entities in the drawing, by specifying drawing (.DWG) files, or by moving existing symbols from one category to another.

Each symbol has an optional description which is shown with the symbol to help choosing in symbol selection like in Draw > Insert Symbols. To change a description, highlight the symbol in the list and then pick Edit Description.

To create a new symbol, open a drawing which has the entities to be used in the symbol. The symbol should be drawn at unit size (scale 1:1) because Carlson will scale the symbol by the current drawing scale when the symbol is used. Highlight the category for the symbol and click on the "Create Symbol" button. A dialog appears for entering the new symbol name. Next, specify the file name for the symbol. The file name has a .DWG extension and would usually reside in the Carlson SUP directory, but you may use another path. Then the program will prompt you to select the entities from the drawing for the symbol. An insertion point for the symbol must also be picked.

The "Import Symbols" button brings up a file selection dialog which allows you to select multiple files to be added to the current category (to select multiple files use Shift or Control keys along with the mouse). If the files you select are not in the Carlson SUP directory, the program will offer an option of copying them there. There are also

Import Library and Export Library buttons.

By default, the symbol description is the same as file name. The description for the symbol or category name may be changed by highlighting that name and clicking on "Rename" button, the name being edited is then placed into edit mode. To move a symbol into a different category, select the symbol to be moved on the tree and click an "Up" or "Down" button as many times as needed to reach the desired category. The symbols are sorted alphabetically within each category, while categories are remaining in the order placed to allow the more frequently accessed categories be on top.

The Reset button adds symbols from the default symbol library into the current library.

Note: The symbol library is stored in an ASCII file named symbols.dta in the Carlson \USER directory.

Pulldown Menu Location: Settings

Keyboard Command: editptsym

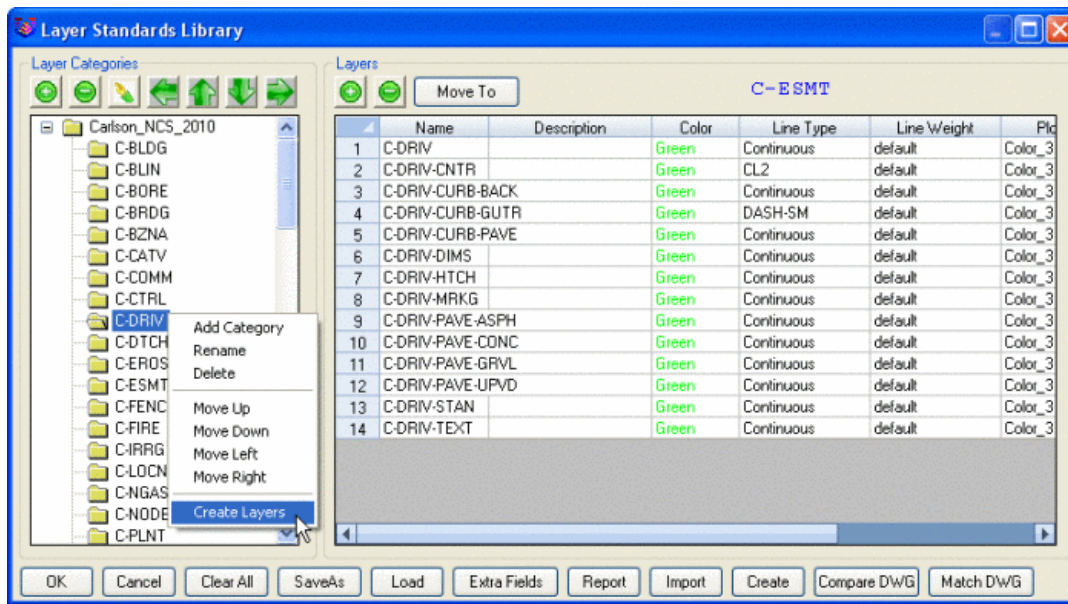

Prerequisite: None

Layer Library

This feature serves as an expanded version of the Layer Manager and also as a layer standards manager. In addition to allowing you to sort layers into easily recognizable groups called **Layer Categories**, this feature can also be used to import layers from a text file and to compare and match layers in the library to the current drawing.

Once populated, layers from the Library can be called from commands such as **2D Polyline** and **3D Polyline** for layer and property assignment.

The **Layer Library** has two areas of the dialog box: the **Layer Category** List on the left and the **Layer** List on the right.

Layer Categories: Layer Categories are shown as a list in a tree view in the left-hand pane of the dialog box.

Categories can be re-ordered by dragging and dropping to a different position in the list or by using the **Move Up**, **Move Down**, **Move Left** and **Move Right** arrow buttons. Other buttons above the Layer Category list also enable you to **Add**, **Remove** and **Rename** Categories.

Also, right-clicking on a Category in the list displays a shortcut menu allowing you to access many of the same commands as the buttons along the top and bottom of the dialog box.

Layers: Layers in a selected Category are shown as a list in spreadsheet view in the right-hand pane of the dialog box.

Layer Properties: Except for Non-Surface, all the layer properties in Layer Library correspond to the layer properties in CAD. The **Non-Surface** property is a specific flag used by the Triangulate & Contour routine to filter out entities. You can set a layer as Non-Surface when you want to exclude all entities on that layer from surface modeling.

The default column-headings for the Layer List are Name, Description, Color, Line Type, Line Weight, Non-Surface, Transparency, Plot Style and Plot/No Plot. Additional column-headings may be added using the **Extra Fields** button at the bottom of the dialog. Using the **Add Layer (plus)** and **Delete Layer (minus)** buttons, layers can be easily added and removed from a particular Category. The **Move To** button can also be used to change a layer to a different Category.

Clear All: This button removes all the Layer Category and Layer definitions.

Save As and **Load:** These buttons can be used to create and restore **Layer Library** settings using a Layer Library Settings (.LA) file. There are a few default .LA files in the Carlson Projects\Settings folder that you can load for National CAD Standard (NCS) layers and MassDOT standard layers. The current layer library definitions are stored in the USER folder in a file named **layerstd.dta**.

Extra Fields: This button allows you to define up to ten extra text fields (column headings) for a layer. These fields can then be used as import fields or displayed in a report.

Report: This button uses the Report Formatter to allow you to compile and display a report containing all Layer Categories and Layers in the Library. The Report Formatter can also be used to export the data to a Microsoft Excel

(.XLS or .XLSX) file.

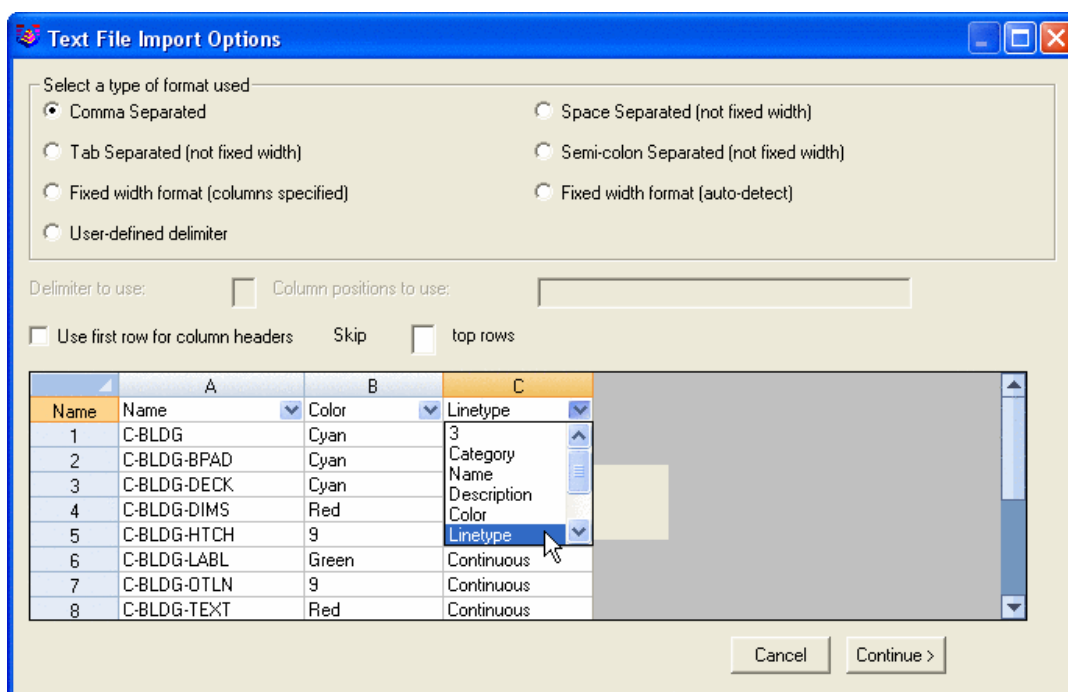

Import: This button gives you two options for Importing layers into the **Layer Library**.

The **Drawing Layers** option simply copies all layer definitions from the current drawing into the Library after prompting you to select the destination Category.

The **Text File** option allows you to select an existing Text (.TXT, .DAT, or .CSV) file containing standard layer definitions to populate the Library. Note that Microsoft Excel provides an option to save an Excel (.XLS or .XLSX) file as a Text file. Follow the steps below to Import layers from a text file.

1. Pick the **Import** button.
2. Pick the **Text File (txt;dat;csv)** button. This opens the **Text File Import Options** dialog box.

3. At the top of the **Import Options** box, select the file format type such as "Comma-Separated" or "Tab Separated".
4. If the top-line of the Text file contains column headings, pick the option to "Use first row for column headers".
5. If the Text file contains one or more lines of text above the layer and property data, use the text box next to "Skip" to specify the number of rows at the top of the text file to be "Skipped" before importing the list of layers.
6. If headers are not included in the Text file, use the drop-down at the top of each column heading in the spreadsheet view to specify the column's data type such as "Name", "Color" or "Linetype".
7. Pick the *Continue* button and specify the Category into which the new layers are to be Imported.

Create: After selecting a Layer Category, you can pick this button to create all the layers for that Category in the Drawing. When creating the layers, there is an option to create a layer group filter for the CAD Layer command.

Compare DWG: This button is used to Compare drawing layers and their associated properties such as color, linetype, lineweight and plot style to the standard Library definition for those layers. This feature will report how many layers matched exactly, how many had a different set of properties and how many non-Standard layers were found. It will also list the non-standard layers which are those defined in the drawing but not in the Library.

Match DWG: This button is used to alter the properties of drawing layers to match the properties of layers defined in the library, or vice versa. After picking the **Match DWG** button, this dialog box displays:

Pick the **Library to DWG** button to alter the drawing layers to conform to the Library definitions.

Pick the **DWG to Library** button to alter the Library definitions of the layers to conform to those set in the drawing.

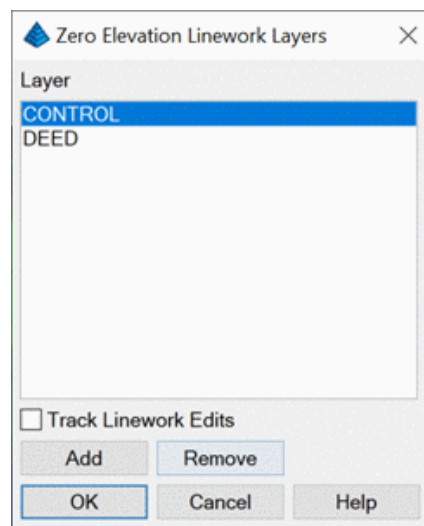

Pulldown Menu Location: Settings → Layer Library

Keyboard Command: layerlib

Prerequisite: None

2D Linework Library

This command sets lines and polylines on specified layers to zero elevation which helps solve the common drafting problem of linework getting moved to elevation such as with a grip edit snapping to a 3D point. In the dialog, you select which layers to check. When you pick OK, the program checks all linework on those layers and sets their elevations to zero. The Track Linework Edits option checks when the linework is modified to make sure the elevations are zero. When this routine prints a message to the command line whenever it moves the linework elevation to zero.

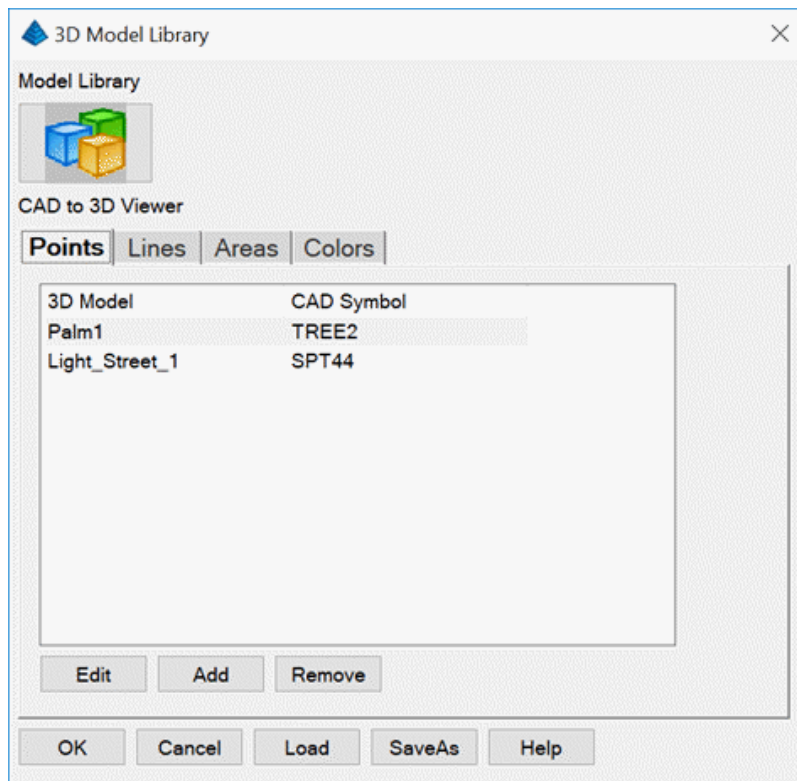

Pulldown Menu Location: Settings

Keyboard Command: 2dlworklib

Prerequisite: None

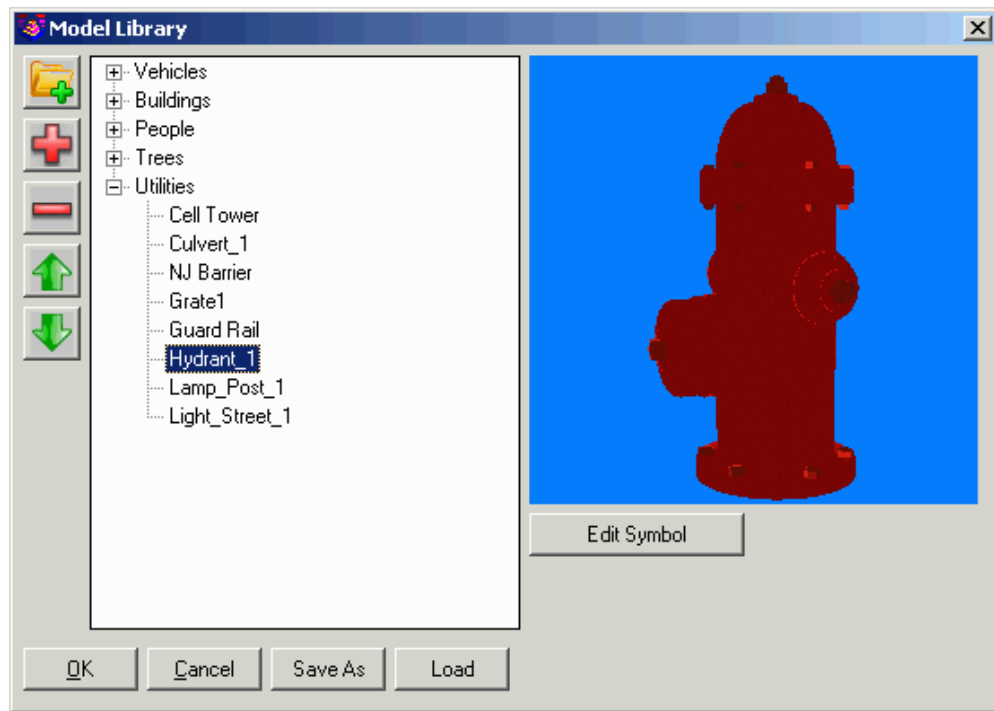

3D Viewer/Model Library

This command manages a collection of 3D graphic files and defines how to render CAD entities in the 3D Viewer. The CAD to 3D Viewer settings define how to translate different types of selected CAD entities into the 3D Viewer. The **Points** tab associates a CAD block name with a 3D model. This way you can have a simple symbol when working in CAD that is rendered as a complex 3D model with viewing in the 3D Viewer. The **Lines** tab defines a 3D model to use for linework on a specified layer. For example, a polyline on a layer of FENCE in CAD can be assigned to render using a fence 3D model. Besides defining the layer and 3D model, there is also a setting for Gap which is the distance between the 3D models along the linework. The **Area** tab defines textures to apply to the surface model by closed CAD polylines on specified layers. You can have different textures using nested closed polylines on different layers and the texture for the inner polyline is used for that inner area. For example, you can have an outer polyline on a Parking layer for a texture of asphalt and inner polylines for parking lot islands on an Island layer for a texture of grass. The **Colors** tab applies to TIN surfaces that have colors assigned to the 3D faces. This settings map TIN colors to textures for rendering the TIN.

The Model Library button has the collection of 3D model files which can be assigned to CAD symbols in the Points tab of CAD to 3D Viewer. Also, these 3D Models can be added to the scene by using the Add Model function in commands such as 3D Drive Simulation.

The files are grouped by user-defined categories. The graphic files can be either .dxf, .mdl or .obj format. SketchUp .skp files can also be selected to add to the library. The program will convert these .skp files into .obj format. The SaveAs and Load functions allow you to save the model library to .mlib files for sharing or backup. The current model library data is stored in the Carlson USER folder in models.dta.

The Edit Symbol function brings up another dialog with edit functions. In the edit dialog, the program shows the dimensions of the model and the number of data points.

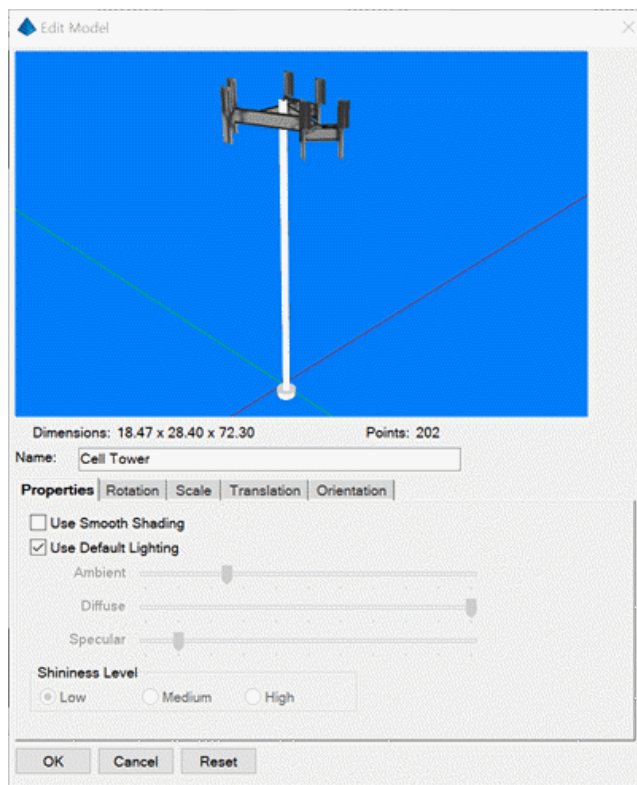

The Properties tab has controls for the lighting of the object and whether to smooth the 3D faces of the object.

The Rotation function sets the default rotation for when the object is inserted. The Random Rotate option makes the rotation random for each time the object is inserted which applies to objects like trees that are inserted multiple times and look better with different rotations.

The Scale function sets the initial insertion scale. Often a scale factor of 0.08333 is needed to convert a model in inches units into feet for inserting into a scene in feet units. The X/Y/Z axis can be scaled independently or uniformly. The scale can be set directly by factors or by entering the model dimensions which is handy for vehicle models when the dimensions of the vehicle are known.

The Translation settings control the insertion point of the model.

The Orientation setting for Force Vertical Orientation makes the model level when inserted into the scene which applies to objects like trees and buildings. Otherwise the models get inserted at the slope of the surface at their position which is good for objects like vehicles.

Keyboard Command: modellib

Prerequisite: None

Quick Keys

Quick Keys can provide an enormous time savings on initiating keyboard commands. One frustration of using CAD is when your command initialization cannot keep up with your train of thought, and you are constantly seeking the fastest way to initiate commands. Quick Keys provides numerous command aliases that are already set up for you, which you can customize easily. You can also add any new commands quickly and easily using the Quick Keys editor, without leaving CAD. The Quick Keys are so productive, that even dedicated menu users appreciate and use them.

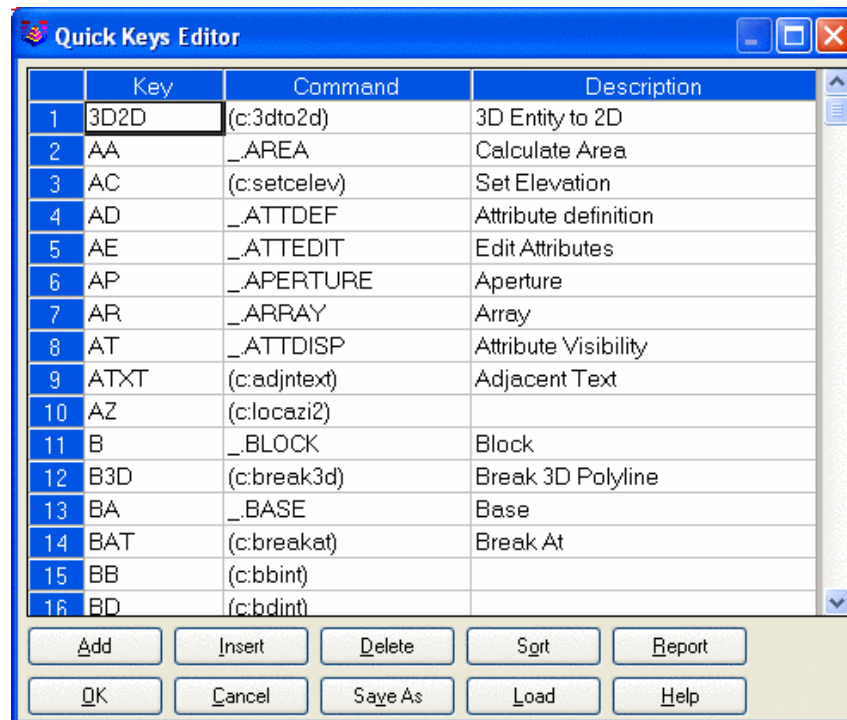

The Quick Keys Editor can be broken down into areas. The spread box at the top of the screen, spread control buttons, and program control buttons. Each area and button is explained below.

Spread Box contains a list of the loaded quick keys. Use the scroll bar to move up and down through the list or maximize the dialog to view more rows. Each item can be edited in its cell.

Each record item consists of up to a 5 character quick key (the portion typed in at the command line), and a long command or AutoLISP expression. Note that if you are adding a shortcut to a lisp function, you must use the following syntax: (C:FUNC) where FUNC is the command name. All Carlson commands use this lisp function syntax. To find the lisp function name for a Carlson command, you can run the command from the menus and look for the command name in Command window. Also, you can find the command name in the Keyboard Command field at the end of each command description in the manual. For example, enter (c:quickkey) for the command to run Quick Keys. For CAD commands, the command name can be entered directly with a prefix of "_.". For example, the CAD Area command name should be entered as _AREA. Some CAD commands will run in command line prompt mode instead of dialog mode when issued by the command name from Quick Keys. For these commands that you want to run with the dialog, enter the command with this syntax of (c:acad_command "name"). For example, enter

(c:acad_command "_plot") for the CAD Plot command in dialog mode. There are several examples of this included with the Quick Keys defaults.

If you intend to make changes in an item, use standard editing procedures, including the use of arrow keys along with the tab key and/or pointer movements to make changes. Pressing enter on either field will have no effect on the item in the list.

Changes made to items are automatically changed in the list, you must use the **OK** button to record changes to be saved.

When a new item has been created in the edit fields, you must click the **Add** or **Insert** button to add the item to the list and type in your key, command and description in respective columns.

Highlight the item you wish to delete in the list box, then press the **Delete** button to remove it from the list. In the event you accidentally delete items, simply choose Cancel to exit without saving changes.

At any time during processing of Quick Keys, you may choose the **Sort** button to sort the list of Quick Keys or left click on respective column header to sort it using key, command or description. The most common use of sort will be after adding several new items to the list.

The buttons on the bottom row are used to control files. Changes made to the Quick Keys table are stored when exiting the dialog with the OK button. The original key definition file supplied is called Carlson.QKS. However, when you make changes for the first time and use the OK button to exit the dialog, the program writes changes to a file called CUSTOM.QKS. The Quick Keys editor looks for the existence of the file CUSTOM.QKS when loading, and will use this file when available. This approach will shelter your (CUSTOM.QKS) from overwrites if you reinstall Carlson.

When all changes are complete, choose the **OK** button to save changes, which will automatically build and load the run time file. Any Quick Keys added or updated will be immediately available at the command prompt. However, if a key definition was deleted, it will not be removed from memory until another drawing is loaded or you begin a new drawing.

The **Cancel** button exits the Quick Keys dialog without making any changes to your system.

This **Report** option is used to obtain a printed list of the Quick Keys currently loaded. First consider sorting the list,

then use this option and enter a filename. The program will write the list to a file that can be brought into any editor or word processor, then printed.

The **Save As** button can be used to save the current quick keys as a QKS file that can be distributed to other computers and can be loaded using **Load** button.

Keyboard Command: quickkey

Prerequisite: None

Title Block

This command draws a border and title block for the selected sheet size. At the top of the dialog, choose your horizontal scale and sheet size. The *other* choice at the bottom of each list will allow you to add your own scale or size if yours is not listed. Anything added to these lists will be retained for future use. Next, choose either "landscape" or "portrait" format. A blue rectangle next to this choice shows you the difference. Below this, you can choose what layer to draw the border and title block on. The margins to use are specified next at the bottom of the dialog. On the right hand side of the dialog, you can choose from several title blocks. As you choose each one, a preview will be shown below this list. This routine looks for all drawings named "tblock" in the \SUP directory. If you want to add your own title block, simply create a new drawing (or copy an existing one) in the \SUP directory and give it a name that starts with tblock. Example: tblock22.dwg and tblock-Jones.dwg are both valid names for this routine, but "MyTitleblk.dwg" is not. After you have made all your decisions in the dialog box, press OK. Depending on your current zoom level, your drawing may be zoomed out to allow you to see the entire area that will be covered by the drawing border. At this point, you have the border attached to your cursor and it is waiting for you to pick a point for insertion. As soon as you do this, a secondary dialog will appear for you to fill out the attributes associated with the particular title block you selected.

Mortgage Block

This command draws a personalized title block for a mortgage survey. You may select an 8½" x 11" sheet, an 8½" x 14" sheet, or define your own sheet size. The dialog box allows the user to edit all block information and input unique data for every layout. The mortgage block drawing is called from the *mortgage.dwg* file located in the \sup directory and can be easily opened and edited within AutoCAD, allowing for the user to alter the size, text, or any other aspect of the drawing to fit the user's particular needs. However, this is usually unnecessary since the original .dwg file places this block for a standard 8½ x 11 ratio drawing. In addition to the block, the user can include the inputs and prescribed text for a Flood Note, which is placed in the bottom left hand corner of the drawing. You may also select a custom drawing file for your flood note. All inputs are saved and recalled from a *mortgage.ini* file located in the \User directory.

The *LIMITS* of the drawing can be set to the lower left and upper right corners of the border. After the title block is drawn, the contents can be edited using the *Attribute Edit* command under the Edit menu.

Keyboard Command: mortgage

Prerequisite: Set horizontal scale in *Drawing Setup*

Rescale Drawing

This command resizes selected text, symbol and block entities within the drawing by comparing the existing drawing scale factor to a new scale factor. Entities are scaled from their individual insertion points. Lines and polylines are not scaled.

Prompts

Old Horizontal Scale: 20

New Horizontal Scale: 30

Select text, symbols, dimensions and blocks to scale.

Select objects: select objects by window, crossing or by typing "all" at the command prompt, and press Enter

Number of symbols and blocks changed > 7

Testing Entity > 41

Number of text entities changed > 20

Pulldown Menu Location: Settings

Keyboard Command: scaledwg

Prerequisite: Drawing entities to be scaled

Set/Reset X-Hairs

Set X-Hairs sets the crosshairs either to align with the selected line or polyline or to a user-specified slope. *Reset X-Hairs* restores the crosshairs alignment to horizontal.

Pulldown Menu Location: Settings > Crosshairs

Keyboard Command: setxhairs, resetxhairs

Prerequisite: Line entity

Save/Load Tablet Calibration

A common problem with calibrating maps on a large format digitizer is that if you leave the current drawing session, AutoCAD forgets the tablet calibration. Tablet save can be used to save the calibration when a drawing is taped down properly. This calibration file can be restored at any time later and be accurate so long as the drawing did not move on the tablet.

Save Configuration Procedure:

- 1) Command: TABSAVE
- 2) Designate filename (*.TCF) to save configuration into.

Restore Configuration Procedure:

- 1) Command: TABREST
- 2) Select filename (*.TCF) to restore configuration from.

Pulldown Menu Location: Settings > Tablet Calibration

Keyboard Command: tablet1, tablet2

Prerequisite: None

Create AutoCAD Icon

This command will create an icon on your desktop to launch plain AutoCAD.

Many people assume that the stock AutoCAD icon will launch plain AutoCAD. This is not always true. The problem occurs because, if no profile is specified, AutoCAD always starts with the last used profile. If you run Carlson, then exit and then execute the stock AutoCAD icon (which does not specify a profile), Carlson loads anyway.

When you run this command, an AutoCAD profile called Vanilla is created, and an AutoCAD icon is created on the desktop that specifies this startup profile.

Technical Note: In its attempt to create the vanilla profile, this routine removes references to Carlson from the support file search path, and replaces the Carlson menu with the stock AutoCAD menu. If the program cannot locate the AutoCAD menu (due to it being deleted or moved), you may have to create the icon manually, as outlined in the Carlson Software Knowledge Base on-line.

Pulldown Menu Location: Settings

Point Object Snap

When this toggle is turned on, you can move your cursor near a Carlson point and snap to the actual coordinates of the point without having to use the AutoCAD *NODE* snap. Point Object Snap can be used alone to display the point information or it can be turned on and used during other commands. In the example illustration, the *2DP* command (2D polyline) has been started and the first point picked was point number 2074. As the cursor nears point number 2067, the point snap marker appears and the point information is displayed, click the mouse and the next polyline vertex will snap to the coordinates of point 2067.

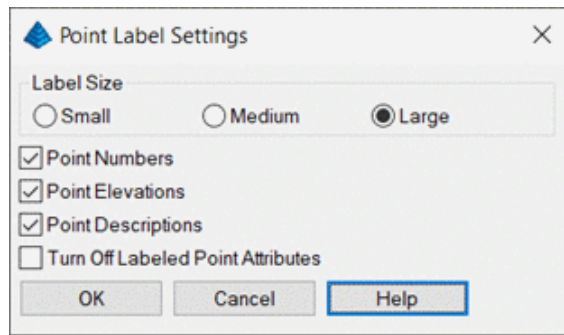

Pulldown Menu Location: Settings

Keyboard Command: 'pointsnap

Prerequisite: None

Point Label Settings

When launching this command, all Carlson points in the drawing that have attributes showing will have those attributes replaced with a dynamic label that retains its height while zooming in and out of the drawing. This is so the text is always readable regardless of what zoom level you are at. The label will display using the font based according to the drawing's current text style.

Label Size There are 3 sizes (Small, Medium and Large) that represent 1, 2 and 3% of the total height of the screen. Choose your size preference that works best for your screen when viewing the labels.

Point Numbers Check this box to hide any point number attributes and to replace with a dynamic point number label.

Point Elevations Check this box to hide any point elevation attributes and to replace with a dynamic point number label. This does not replace elevation labeled as just text.

Point Descriptions Check this box to hide any point description attributes and to replace with a dynamic point number label. This does not replace Carlson Notes.

Turn Off Labeled Point Attributes Check this box to hide the point attributes so you are only seeing one set of labels at a time - either the dynamic point label or the regular point attribute. Unchecking this box will unhide the existing point attributes.

The Point Label is used purely for viewing while in the drawing and will not affect plotting or how points print or export. Certain point attributes may be hidden while in effect, but will still plot based on your layer settings.

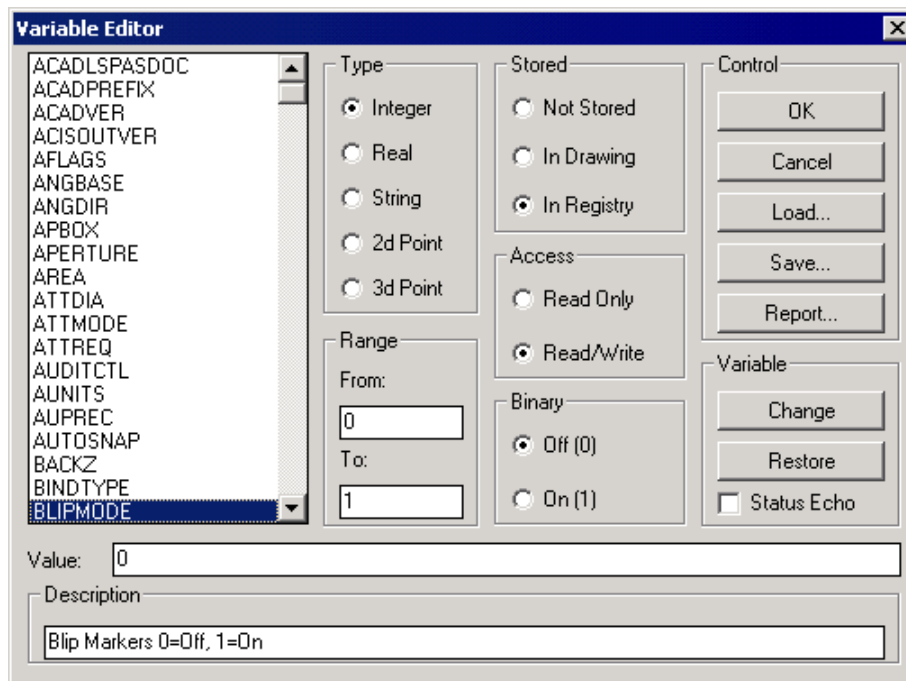

Pulldown Menu Location: Settings

Keyboard Command: pointlabel

Prerequisite: none

System Variable Editor

The AutoCAD/IntelliCAD engine stores the values for its operating environment and some of its commands in system variables. Each system variable has an associated type: integer, real, point, switch, or text string. This command allows you to list or change the values of system variables.

- **List Box:** Contains a list of the variables associated with the currently running version of AutoCAD. There are more items than will display on the list box, use the scroll bar to move up and down through the list. Picking on an item in the list box makes it the current item, causing the information about the item to be displayed, and can be affected by most of the edit commands explained below.
- **Edit Field:** When an item on the list box is picked, its current setting is displayed in the edit field. If you intend to make changes in an item, use standard editing procedures including the use of arrow keys and/or pointer movements to make changes. Once changes have been made, you must use the CHANGE options explained below to effect changes. Pressing enter at the edit field will have no effect on the item in the list. If the item selected is a read-only variable, the edit field will be grayed-out and will not allow input.
- **Description:** When an item on the list box is picked, its definition is referenced and displayed in this field. This can be a benefit in learning the uses of the assorted system variables. This is a display only field, so you can't change the description given.

Under Type Group, the type of variable will be displayed indicated by one of the radio buttons. Each of these types are explained below for your benefit. For additional information on variable types used by AutoCAD, obtain and consult a source of AutoCAD documentation.

- **Integer:** Defined as a whole number in the range from -32767 to +32768, no decimal value accepted.
- **Real:** Defined as a real number in the range from -1.797E+308 to +1.797E+308, with extreme decimal accuracy maintained.. Some real variables have a smaller range than previously stated.
- **String:** Defined as a sequential array of characters in the range from 0 to 65535 characters, with a range of ASCII (0-255). Numbers can be included in strings, even though they have no mathematical significance.
- **2D Point:** Defined as a list of two real numbers in the range from -1.797E+308 to +1.797E+308 separated by a comma, having extreme decimal accuracy maintained. Always maintain the X,Y format, one (and only one) comma must be used, separating the X and Y.
- **3D Point:** Defined as a list of three real numbers in the range from -1.797E+308 to +1.797E+308 separated by commas. While editing a 3D point, you must always maintain the X,Y,Z format, two (no less or no more), commas must be used, separating the X and Y and Z values.

Under Range Group, the variable displayed will usually have a range displayed. The FROM value indicating the minimum, and the TO value being the maximum value accepted.

Under the Store Group, depending on the type of variable, AutoCAD may store the value in the drawing or the configuration file, or it may not be stored. Each of these types are explained below for your benefit.

- **Not Stored:** Some variables, such as PLATFORM and CDATE, are not stored because they are system interdependent.
- **In Drawing:** Most variables are stored in the drawing, making the drawing format more personal than just a database of objects. This allows you to open a drawing and have it behave just as though you had never left it.
- **In Config:** These are variables that remain the same regardless of the drawing opened. APERTURE and PICK-BOX are just two examples of variables stored in the configuration file.

Under Access Group, depending on the type of variable, AutoCAD may not allow you to make changes to it. Each of these types are explained below.

- **Read Only:** Some variables, such as PLATFORM and CDATE, are read-only and therefore cannot be changed. Read-Only variables are marked and the edit field will be grayed indicating that you can't change the variable.
- **Read/Write:** Most variables are read/write and can be changed. These variables are marked and the edit field will be active so you can change the variable.

Under Binary Group, depending on the type of variable, the value may be off or on, yes or no. If the variable type is not binary, this group will be grayed out entirely.

- **Off (0):** Indicate an off condition. Some variables, such as ATTREQ, are simply on or off toggles. You may change a binary item by clicking in this group to change the variable, or changing the value in the edit field.
- **On (1):** Indicate an on condition. Binary variables are simply on or off toggles. Their range is from 0 to 1. You may change a binary item by clicking to change the variable, or changing the value in the edit field.

Control Buttons - These buttons are the main controls in the use of the Variable Editor. Each buttons purpose is explained below.

- **OK:** Used to accept the changes made during the variable editing process, returning you to the command prompt with changes in effect.
- **Cancel:** Used to cancel the changes made during the variable editing process, returning you to the command prompt without the changes in effect.
- **Load:** Used to load a saved set of system variables. This allows you to create a drawing, save the system variables, open a second drawing, and load those variables into that drawing. Read-only variables are skipped.
- **Save:** Used to save the current system variables to a disk file. All system variables are stored to the file, even those that are marked as read-only.
- **Print:** Used to print the current system variables. After choosing this option, you will prompted for an output filename, then the program will proceed to write the system variables to the file. This file can be loaded into any editor or word processor, edited and printed.

Variable Buttons - These buttons are used to control the changes in variables, while using the Variable Editor. Each buttons purpose is explained below.

- **Change:** Used to execute the changes typed into the edit field. You must use this button, simply pressing enter will not make the change.
- **Restore:** Used to cancel the changes typed into the edit field. If you make a mistake or change your mind while making changes in the edit field, press this button to restore the edit field to the value before editing.
- **Status:** Used to determine if the program will echo the status of changes being made to the command area. If this toggle is on, any changes made from the dialog will echo the change. Also if a stream of change commands is being read from a file, and the toggle is on, the changes taking place will be displayed.

Note: This command displays many more system variables than are found in the Systems Variable Chapter, which contains a list of **supported** system variables. Modification of any system variable other than the supported ones found in the Systems Variable Chapter is done at your own risk, and may result in program errors requiring a re-installation of Carlson.

Pulldown Menu Location: Settings

Keyboard Command: VAREDIT

Prerequisite: None

Select CAD Default Settings

This command sets some important CAD user-interface settings. The buttons across the top set all the settings in the dialog.

Carlson Recommended: These are the commonly used settings.

Classic Settings: These have the user-interface like the old versions of the program.

New Standard Settings: These have the new style user-interface settings.

Custom: Let's you choose each setting.

For each user-interface feature, the dialog shows the CAD variable name and value. You can type in these variable names at the Command: prompt to set that feature. Here are the settings in this dialog:

Start Page - Controls whether to use the Start Page tab when the program starts up.

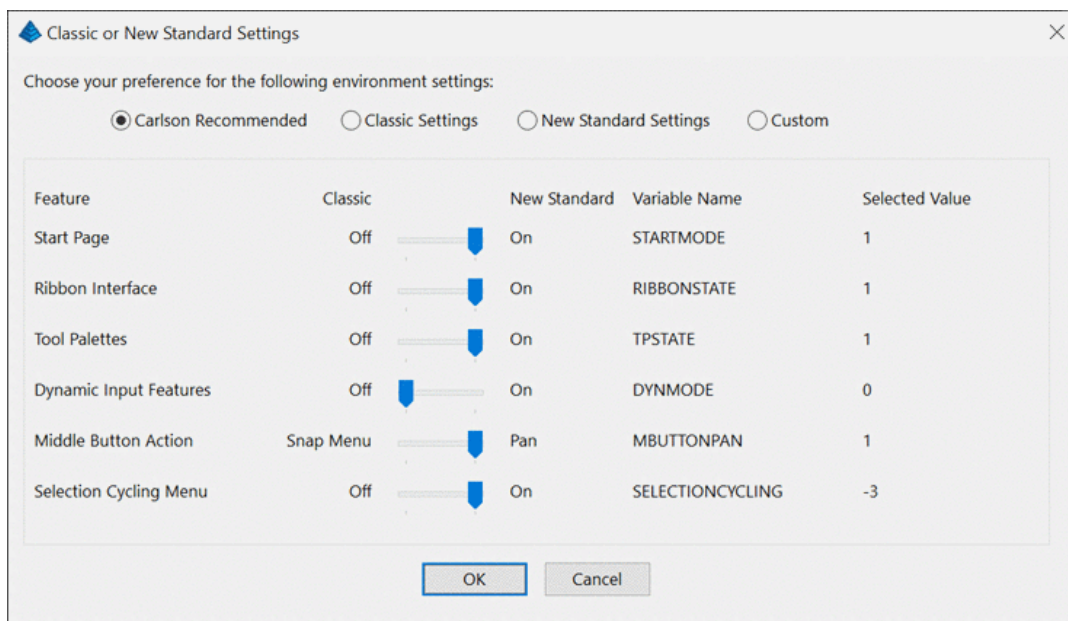

Ribbon Interface - Controls whether to show the ribbon of toolbar icons and tabs.

Tool Palettes - Controls whether to show the tool palettes interface for selecting commands.

Dynamic Input Features - Controls whether the input prompting is show in the display next to the cursor.

Middle Button Action - Choose between using the mouse middle button for the snap menu or pan action.

Selection Cycling Menu - Controls how to select entities when picking a position with multiple entities under the cursor.

Pulldown Menu Location: Settings

Keyboard Command: options_default

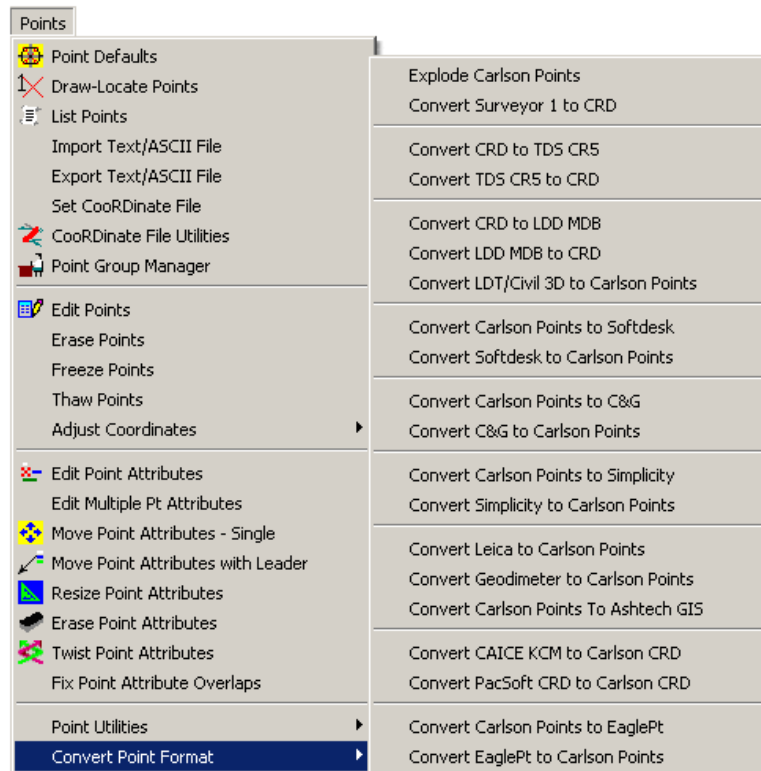

Prerequisite: None

Points Menu

All of the routines in this menu operate on points in a Carlson coordinate (.CRD) file. Coordinate files are binary files that contain point numbers, northings, eastings, elevations and descriptions. The Carlson coordinate database (.CRDB) is based on SQLite and supports point numbers and descriptions up to 255 characters. Alternately, C&G

CRD and CGC files, LandDesktop MDB files or Simplicity Systems ZAK files can be used in place of the Carlson CRD file. All routines in this menu will read from, and write to, these types of point data files. At any given time, there can only be one active coordinate file. If a command is initiated that requires a coordinate file while one is not one set, Carlson will prompt for a coordinate file name. From that point on, this is the current coordinate file. Another coordinate file can be used by choosing Set Coordinate File or *Open CRD File* in Coordinate File Utilities.

Whenever you asked for point numbers, you can enter any combination with commas and dashes or type **ALL** to use all points. For example 1-3,7,20-23 would act on points 1,2,3,7,20,21,22,23. Coordinate files have either numeric or alphanumeric point numbers. Alphanumeric point numbers consist of nine or less digits and letters (*i.e.* point# 7A). The type of point number format is set when the coordinate file is created. This setting is found under *General Settings* in Carlson Configure. This setting only affects new coordinate files.

Each point is drawn by three entities:

1. point block
2. point node
3. symbol

The point block is an INSERT entity with PNTNO, PNTLEV and PNTDESC attributes. These attributes represent the point number, elevation and description respectively. The point node is a POINT entity and is used for picking the point with the NODE snap. The point node is also used as the X, Y, Z coordinate in Triangulate & Contour. The symbol can be any symbol defined in the Symbol Library (use SPT0 for no symbol). Since points use Carlson point symbols, the CAD system variables PDMODE and PDSIZE should usually be set to 0.

The points in the drawing can be linked to their coordinates in the coordinate file. The link updates the coordinate file when a point is modified in the drawing. For example, when points are moved with the Rotate Points command, their coordinates will be automatically updated in the coordinate file. To update the coordinate file without this automatic link, you can run the command *Update CRD File from Drawing* in Coordinate File Utilities. The linking option is called *Link Points with Coordinate File* (currently only available in AutoCAD) and can be set under *General Settings* in Carlson Configure. This setting does not affect points currently in your drawing, only points drawn after you change this setting.

Each point in the coordinate file has room for a 32 character description. To have a longer description, an associated point note file can be used. The note file has the same file name as the coordinate file with a .NOT extension and is

stored in the same directory as the coordinate file. For example, **survey.note** would be the note file for **survey.crd**. The note file is a text file that stores a point number together with the additional notes for the point. There is no limit to the length of the note. Notes can be added to points using the Edit Points command. The List Points command can be used to print out the notes.

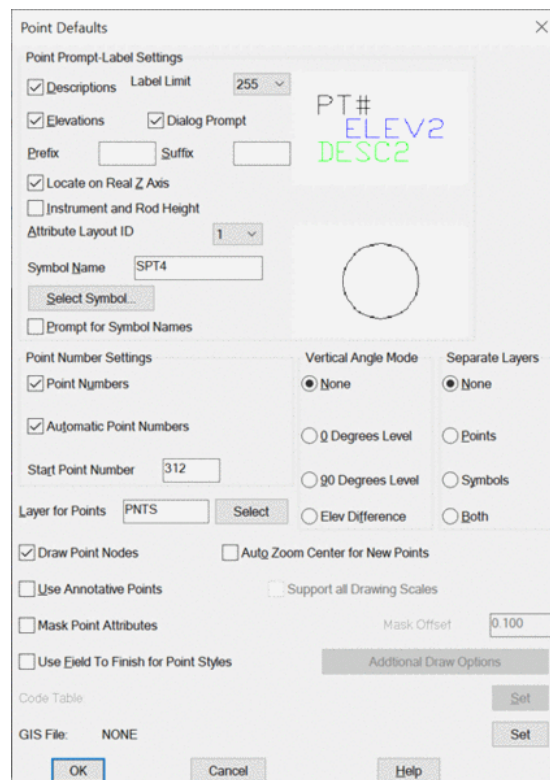

For each point, the point attribute block, node, and symbol can be bound together into a "grouped" entity. This means that if you choose to use the Move command (or other CAD tools) the entire collection moves together. This is done using the grouping functionality.

To disable this system altogether, navigate to Carlson Configure > General Settings and turn off the toggle for *Group Point Entities*. If you need to temporarily disable grouping in a drawing, you can use the AutoCAD toggle for grouping, which is *Ctrl-A* (holding down the 'Ctrl' key and then pressing the letter 'A' on the keyboard activates this two way toggle and the current status will be echoed to the Command prompt area).

Carlson points include additional information on each element that makes up the point collection (attribute block, node and symbol). This information allows Carlson to know such things as which coordinate (.CRD) the point came from. Commands like Drawing Inspector can then display the point information for the point entities. This also makes it easier for Carlson to identify which drawing objects belong to a point, making commands like Edit Point Attributes a "double-click" pick association instead of a selection set.

Point Defaults

This command sets Carlson point options for drawing point entities.

Descriptions: Specify whether you are prompted for a point description when creating points and whether the point descriptions are labeled in the point block.

Label Limit: Sets the maximum length for description attribute labels.

Dialog Prompt: When creating new points, this option controls whether to prompt for descriptions and elevations

in a dialog or at the command line.

Elevations: Specify whether you are prompted for a point elevation when creating points and whether or not the point elevation is labeled with the point.

Prefix/Suffix: Indicate a desired prefix or suffix that should be included with the elevation label.

Locate on Real Z Axis: When checked, points are drawn at their actual elevation, otherwise, points will be drawn at Z=0.

The following tables illustrate the effects of Elevation vs. Real Z settings:

	Elevations Yes	Real Z Yes
Picked Point	Labels point, Prompts for elevation	Uses elevation for z coordinate
Point Number	Labels point, No Prompt	Uses z coordinate from file
Effects of Elevation Settings - Scenario 1		
	Elevations Yes	Real Z No
Picked Point	Labels point, Prompts for elevation	Uses 0 for z coordinate
Point Number	Labels point, No Prompt	Uses 0 for z coordinate
Effects of Elevation Settings - Scenario 2		
	Elevations No	Real Z Yes
Picked Point	Labels point, No Prompt	Uses z coordinate of picked point
Point Number	Labels point, No Prompt	Uses z coordinate from file
Effects of Elevation Settings - Scenario 3		
	Elevations No	Real Z No
Picked Point	No Label, No Prompt	Uses 0 for z coordinate
Point Number	No Label, No Prompt	Uses 0 for z coordinate
Effects of Elevation Settings - Scenario 4		

Attribute Layout ID: Controls the location of the point number, elevation and description. Up to 10 attribute layouts (0 through 9) are available. See Carlson Knowledgebase Article 779 (Customized Carlson Point Attribute Layouts) for examples and steps of different attribute layout configurations.

Symbol Name: Enter the default symbol name to use. You may also pick the *Select Symbol* button to select a symbol from the Symbol Library.

Prompt for Symbol Names: When checked, you will be prompted for each symbol name instead of using the default symbol.

Point Numbers: When this toggle is OFF, no point number will be created and no points will be stored in the active coordinate file.

Automatic Point Numbers: When enabled, point numbers are numbered sequentially from the *Start Point Number*. If the Start Point Number field is set to 0, no point will be plotted. An exception to this is when you use the Draw-Locate Points command and use the Range option, then a point entity is plotted. When disabled, commands that locate new points will prompt for the point number.

Start Point Number: Specify the starting point number to use.

Layer for Points: Specify the default layer name for Carlson points.

Vertical Angle Mode: Specify how Carlson should prompt you for vertical angles. None means "Do not prompt." This applies to creating points with commands such as Traverse. The vertical angle is used to calculate the point elevation.

Separate Layers: Specify settings for point attribute layers:

- **None** - The point number, elevation and description use the layer names PNTNO, PNTELEV and PNTDESC, respectively.
- **Points** - The point number, elevation and description layers are composed by concatenating the point layer and the string NO, ELEV, and DESC. For example, if the point layer is UTIL then the attribute layers will be UTILNO, UTILELEV and UTILDESC, respectively.
- **Symbols** - The point symbol layer is composed by concatenating the point layer and the string MARK. For example, if the point layer is UTIL then the symbol layer will be UTILMARK.
- **Both** - The point symbol, point number, elevation and description layers are composed by concatenating the point layer and the string MARK, NO, ELEV, and DESC respectively. For example, if the point layer is UTIL then the symbol/attribute layers will be UTILMARK, UTILNO, UTILELEV and UTILDESC.

Auto Zoom Center for New Points: When checked, the drawing will perform a "Zoom Center" around new points to keep the display centered around the current working area during the new point creation process.

Draw Point Nodes: This option controls whether to create a CAD point entity. A full Carlson point consists of the CAD point entity, point symbol and point attribute block that has the point number, elevation and description labels. Normally the CAD point entity is part of this group but is not required.

Use Annotative Points: When enabled, points (usually placed through the Draw Field-to-Finish or Draw-Locate Points commands) will use scale-able annotative properties.

Support All Drawing Scales: When enabled, points placed as annotative entities will make use of all annotation scales currently defined within the drawing.

Mask Point Attributes: This option hides the drawing behind the point attributes when the points are drawn. The Mask Offset controls the buffer area around the point attribute. This offset value is scaled by the drawing horizontal scale. You can also leave this option off and apply the mask later by using the Mask Point Attributes command under the Points > Point Utilities menu.

Use Field to Finish for Point Styles: Allows you to use the code definitions from the designated Feature Library Definition (FLD) table specified below. For example, when creating a point with description of "FH" (for Fire Hydrant), Carlson would look up "FH" in the Field to Finish table and will use the field code definitions to establish the parameters of the point being created instead of the definitions defined in within *Point Defaults*. The Field To Finish settings under **Additional Draw Options** are described in the Field To Finish topic in the manual.

Code Table: This option lets you specify the Feature Library Definition file (FLD) used by the Use Field to Finish controls specified above.

GIS File: This option lets you specify a GIS file to be used when creating new points. The GIS file contains a list of fields to prompt for. For each point that is created, the program will prompt for these fields and store the results to the note file (.not) associated with the current coordinate file.

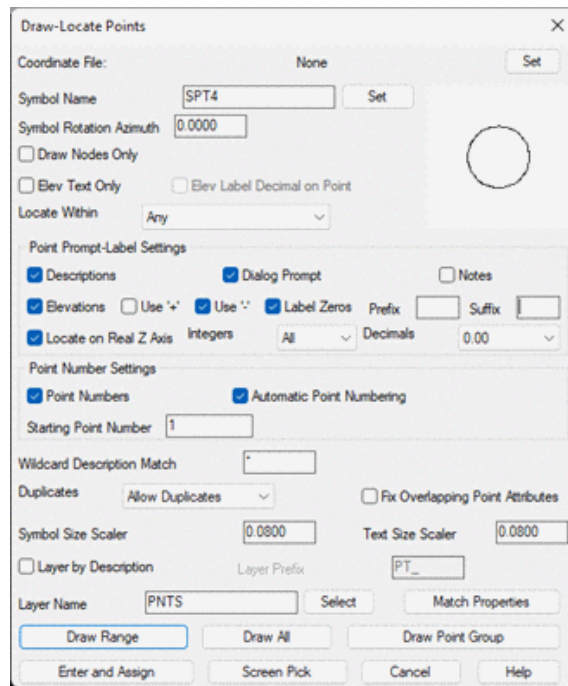

Pulldown Menu Location(s): Points

Keyboard Command: ptsetup

Prerequisite: None

Draw-Locate Points

The Draw-Locate Points dialog box allows you to insert either new or existing points into the drawing. You can create new points either by picking points on the screen, or by entering northing and easting coordinates. You can also place existing points by entering point numbers which reference the current coordinate file. You are prompted to choose a coordinate file if no coordinate file is current.

The **Coordinate File** at the top of the dialog shows the current file which can be changed with the Set button.

The name of the symbol file is displayed in **Symbol Name**. You can choose a different symbol by clicking Select. The selected point symbol is displayed on the right.

Symbol Rotation Azimuth is the rotation angle that is used for the point symbols. This angle is used in a counter-clockwise direction relative to the current twist screen.

Layer by Description inserts the points in the layer named by the point description. Using Layer by Description organizes the points by description and allows for layer management. For example, you can use the Isolate Layers command to show only points on a certain layer. If you include an invalid layer character in the description, the layer name stops at the bad character. A point description of "UP / 105" would use layer "UP", for example. The **Layer Prefix** is added to the beginning of the layer name. For example, a Layer Prefix of "PT_" and a point with the description "EP" would use the layer "PT_EP". Layer Prefix is optional. It allows all the point layers to be grouped.

Draw Nodes Only inserts only a point entity (the node) and not the point block and symbol. This option is most useful when you have a lot of points to insert, because inserting only the nodes is faster than inserting nodes with the point block and symbol. Commands such as Triangulate & Contour and Make 3D Grid File can use these points, and do not need the point block and symbol.

Selecting **Elev Text Only** draws text of the point elevation without the point block, symbol, or node. The decimal place of elevation text is placed at the northing and easting point location.

Locate within Polyline inserts only the points that are inside a closed inclusion polyline. The command prompts you to select a closed inclusion polyline and as well as an optional exclusion polyline. All the points in the current coordinate file are checked. Any points that are located within the inclusion polyline and outside the exclusion polyline are drawn.

Locate within Distance inserts only the points that are within a specified distance from a reference point. The command asks you for the reference point and the search distance. All the points in the current coordinate file are checked. Any points that are located within the search distance of the reference point are drawn.

Locate within Window/Coord Range inserts only the points that are within the specified window or range of northing, easting, and elevation. The command prompts for the minimum and maximum northing, easting, and elevations. These values default to the actual minimum and maximum in the coordinate file. Then the command prompts for the point number range of points to check. The points that fall in both the point number range and the

coordinate range are drawn.

Under **Point Prompt-Label Settings**, you determine attributes for which you will be prompted.

Descriptions determines whether you are prompted for descriptions for each point when creating new points. When you are placing both new and existing points, Descriptions determine whether this attribute is labeled with the point inserts.

Notes works with the note file (.not) associated with the current coordinate file. The note file contains unlimited point descriptions in addition to the fixed 32-character point descriptions in the coordinate file. When you create points with Notes on, the command will prompt for point notes to be stored with the point. When you draw existing points with Notes on, any notes for the points are drawn as text entities below the point description.

Elevations determines whether you are prompted for elevations for each point when creating new points. When you are placing both new and existing points, Elevations determine whether this attribute is labeled with the point inserts.

Use '+' labels the positive elevations with a leading '+'. For example, "+159.43".

Use '-' labels the negative elevations with a leading '-'.

Locate on Real Z Axis determines if the points are placed at their elevations or at zero elevation.

Label Zeros will label points with zero elevation when the Elevations option is on. Otherwise only points with nonzero elevation will be labeled.

Elevation Prefix/Suffix set the prefix and suffix labels to apply for the elevation labels.

Elevation Integers controls the number of digits to display to the left of the decimal point for the elevation label. The All setting will show the full elevation digits. The other settings allow you to limit the number of digits to display for the purpose of reducing the amount of space the elevation labels take up in the drawing. For example, if a site is in the 4000 foot elevation range, then this setting could be set to three digits (000) and an elevation of 4321 would be labeled as 321.

Elevation Decimals sets the number of decimals to the right of the decimal places for the elevation labels.

Under **Point Number Settings**, you determine how points will be numbered.

Point Numbers determines whether the complete point block is drawn or just the symbol and node. When you create new points with Point Numbers off, no points are stored in the current coordinate file, and only the point symbol and node are drawn. When you draw existing points with Point Numbers off, the point attribute block is not drawn and only the point symbol and node are drawn.

Automatic Point Numbering applies to creating new points. With this option active, the command will use the **Starting Point Number** for the first new point. The next point number is automatically incremented. Before storing the point, the command checks whether the point number is used. If the point number is used and point protect is on (set in the Coordinate File Utilities command), then the command will prompt for another point number or to overwrite the point. With Automatic Point Numbering off, the command will prompt for the point numbers.

Determine how the points are to be displayed and in what layer.

With **Wildcard match of pt description**, you can display only points with specific descriptions. This can be thought of as a filter. For example, entering IP would display only points that are labeled with the description IP, or Iron Pin. The default is the asterisk (*). This will display all points regardless of description.

Layer Name allows you to designate a layer for the points to be displayed. You can enter a new name, CLAYER, or choose an existing layer by clicking **Select Layer**. Entry of CLAYER selects the current layer. A Carlson Survey point consists of a block insert with attributes, a point symbol, and a point entity. The point entity is used for picking the point by OSNAP Node in other commands. The block insert includes a point number, elevation, and description. These attributes are in the PNTMARK, PNTNO, PNTELEV, and PNTDESC layers. The points are also in an overall layer as specified in this dialog box. This layer setup allows you to freeze a group of points by the main layer name or freeze point attributes for all the points in the drawing. For example, freezing layer "PNTS"

would freeze all the points in this layer. Freezing layer "PNTELEV" would freeze the point elevation attribute for all the points.

The **Duplicates** option for **Erase and Redraw** will erase existing point entities that match the point numbers currently being drawn. The **Allow Duplicates** option will leave any existing point entities as the specified points are drawn. The **Draw Only New** option will only draw points that don't already exist in the drawing.

Fix Overlapping Point Attributes will detect point number, elevation and description attributes that overlap with other points. Rules can be applied to rearrange the point attributes to avoid the overlaps. A point overlap manager then steps through each overlap for review or manually moving the attributes.

Symbol Size Scaler controls the size of the point symbol and **Text Size Scaler** controls the size of the point attribute labels. The scalers are multiplied by the Horizontal Scale from Drawing Setup to set the size in drawing units.

Match Properties prompts to select an existing point entity and then the program sets the settings in the dialog such as layer and symbol to match the selected point.

Draw Range will draw existing points from the current coordinate file. The Draw Range button will prompt for the point numbers to draw.

Draw All will draw all the points in the coordinate file, and then zoom the extents of the display to show the points.

Draw Point Group will draw a point group with settings that are established in the Point Group Manager.

Enter and Assign can be used to create new points using the point northing and easting. When a grid projection is defined in Drawing Setup, then there is an option to enter the points using latitude/longitude.

Screen Pick allows you to create points by picking the point coordinate on the screen. For example, you could set the Object Snap to EndPoint and pick the end point of a building polyline to create a point at the building corner.

Prompts

To create a new point:

Draw-Locate dialog *choose Screen Pick*

Pick point to create: *pick a point*

Select/<Enter Point Elevation <0.00>: *Enter elevation Press S to select text to set elevation.*

Enter Point Description <>: *Enter*

N: 5106.57 E: 4901.96 Z: 0.00

Enter/<Select text of elevation>: *Select text entity that defines elevation of point.*

To locate a point in the coordinate file (point number 3 in this example):

Draw-Locate Point dialog *choose Draw Range*

Point numbers to draw: *3*

Points Drawn> *1*

Locates point 3.

Point numbers to draw: *1-2*

Points Drawn> *2*

Locates a range of points. From 1 to 2.

Point numbers to draw: *Enter*

Keyboard Command: *lpoint*

Prerequisite: A CRD file and you may want to execute *Drawing Setup* (see the Setting menu) to set the scale and size.

List Points

This command generates a report of point numbers, northings, eastings, elevations and descriptions.

The screenshot shows the 'List Points' dialog box with the following settings:

- Selection method:** Range (selected), Area, Selection Set
- Range Settings:**
 - Highest Point Number: CP14
 - Range of Points: 1-CP14
 - Buttons: All, Point Group
 - Description Match: *
- Report Options:**
 - Report Coordinate Range
 - Report Job Header
 - List Point Notes
 - List CRDB GIS Attributes
 - List SurvCE GIS Attributes
 - Use Report Formatter
 - Include Geodetic Report (with Geodetic Options button)
 - Double Space Between Points
 - Coordinates in Inches: Off
 - Northing/Easting Decimals: 0.00
 - Elevation Decimals: 0.00
- Buttons:** OK, Cancel, Help

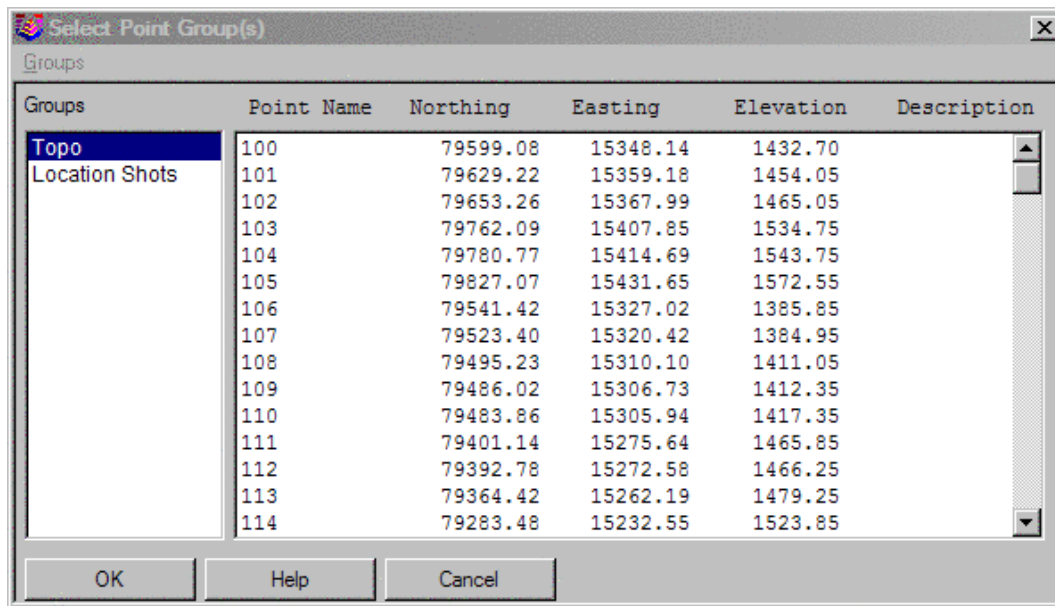

Selection Method-Range allows you to specify the points to list by point number range

Selection Method-Area allows you to select a closed polyline to list all of the points inside of that polyline.

Selection Method-Selection Set allows you to specify the points to list by selecting them from the drawing.

Range of Points: If you are using the Range method, specify the range of points to list here. To quickly specify all points, click the **All** button.

Point Group allows for the selection of a specified group or multiple groups for listing. Standard windows selection tools, ctrl and shift keys, can be utilized for selecting groups.

Description Match: Can be used to filter the point list. For example, entering "EP" for the Description Match would only list those points with a description of "EP". An asterisk (*) is the default setting, it matches any character sequence, meaning no filtering occurs.

Report Coordinate Range: When checked, the point list will include the minimum and maximum northing, easting and elevation.

Report Job Header: Includes the Job Description, Job Number and Job Date in the header of the report. These job values can be set in the Coordinate File Utilities command.

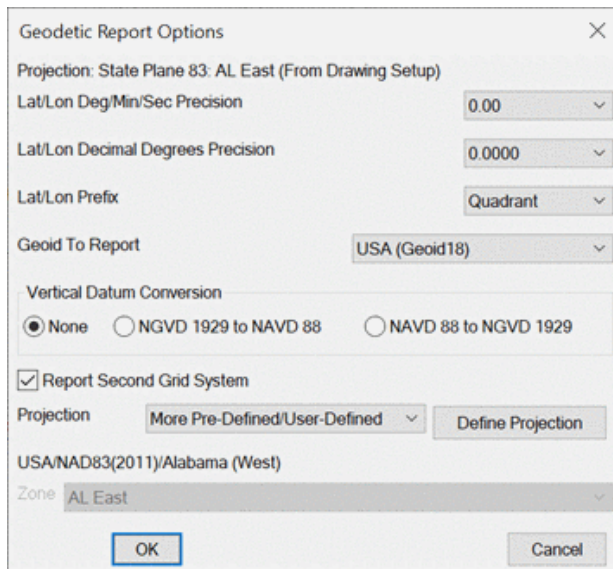

List Point Notes: When checked, any additional point notes assigned to the points will be included in the point list. Point notes can be entered using the *Input-Edit Point* command found in *Coordinate File Utilities*.

List CRDB GIS Attributes: Includes any GIS attributes from CRDB format coordinate files. Use the Point GIS Editor command to edit these GIS attributes.

List SurvCE GIS Attributes: Includes any GIS attributes from the companion VTT file from SurvCE.

Use Report Formatter: When checked, you may customize the fields and layout of the point report using the Report Formatter. The Report Formatter can also be used to export the point report to Excel or Access.

Include Geodetic Report: When Use Report Formatter is on and the Drawing Setup command has a coordinate system defined, this option handles reporting of latitude/longitude and geoids. You can also use this option to report the coordinates in a second grid system.

Double Space Between Points: When checked, the report will be double spaced.

The point list report is displayed in the Standard Report Viewer which can print, draw and save the report file. This report viewer cannot be used to edit the coordinate file. Instead use the *Edit Points* command in the Points menu.

Example of List Points Report:

```

List Points Report
File> C:\Carlson2008\DATA\POINTS.CRD
Job Description>
Job Number> 0.000 Job Date> 06/01/2002
PointNo. Northing(Y) Easting(X) Elev(Z) Description
1          5355.240    5000.000    91.8    CP2
2          5000.000    5000.000    90.0    CP2
1000       5355.236    5000.000    91.8    CK
1001       4941.911    4622.029    91.4    FPC
1002       4952.629    4642.818    90.6    FH
1003       4959.931    4634.440    89.8    TOE1

```

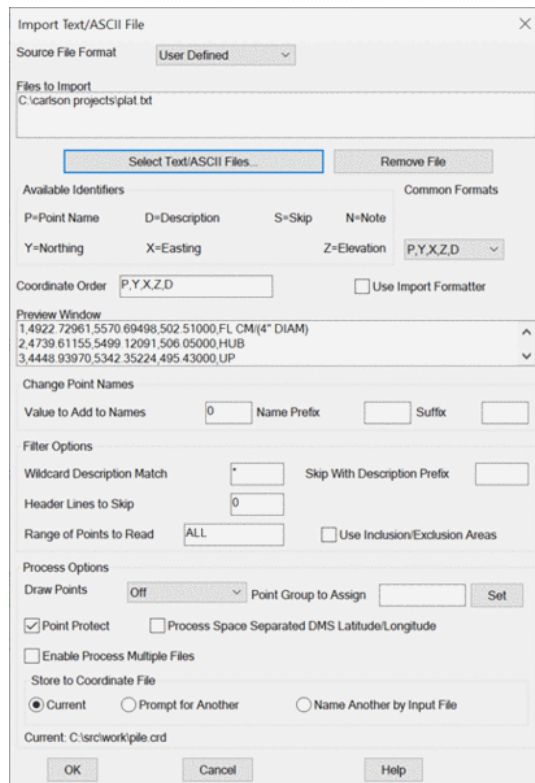

Pulldown Menu Location: Points

Keyboard Command: listpt

Prerequisite: Points in a coordinate file or on the screen

Import Text/ASCII File

This command converts point data from an ASCII text file into a Carlson coordinate (.CRD) file. Each line of the text file can contain any combination of point number, northing, easting, elevation and description. All point information should be on one line with the values separated by a comma, space or other delimiter.

Under the Source File Format setting you can choose from some specific formats or User-Defined. For User-Defined, the format of the text file is specified in the Coordinate Order field where the value identifiers are listed with the appropriate delimiters. For example:

For a text file with northing, easting, elevation and comma delimiters:

5100.0,5150.5,485.1

5127.1,5190.3,487.3

The Coordinate Order would be:

Y,X,Z

For a text file with point number, easting, northing, elevation, description and space delimiters:

1 5000.0 5000.0 490.3 TRAV

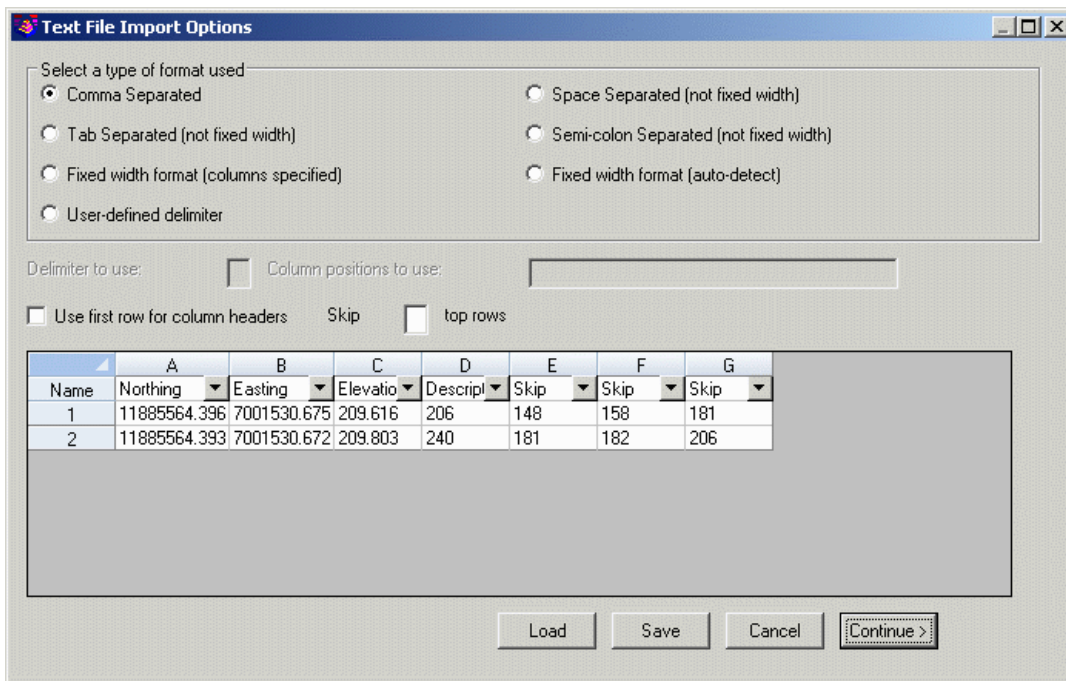

2 5030.4 4930.5 495.5 TRAV

The Coordinate Order would be:

P X Y Z D

Common formats can be selected from the Common Format List. All the lines in the text file should contain only point data and any header lines should be removed. To read the text file, pick the Select Text/ASCII File button and choose the file to read. Then the selected file is displayed in the Preview Window to help with filling out the Coordinate Order. When the Coordinate Order is set, click OK to read the text file.

The Use Import Formatter is an alternative way to define the format of the input file. This method has a heads up interface for selecting the fields for each column of data. This method also supports fixed width, user-defined delimiter and semi-colon delimited files that the Coordinate Order method doesn't handle.

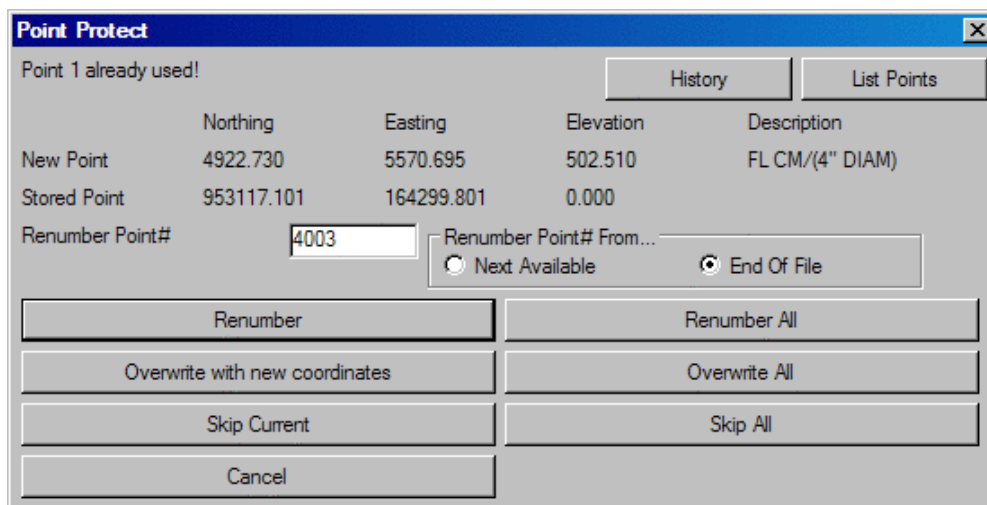

Under Change Point Names, the Value to Add to Point Numbers allows you to renumber the points as they are imported. The Name Prefix and Suffix are added to the point names as they are imported.

Under Filter Options, the Wild Card Descriptions Match allows for only point with matching descriptions to be imported. The Header Lines to Skip value is the number of lines not to be processed at the start of the text file. The Skipt With Description Prefix filters out points with a description that starts with the specified prefix string. The Range of Points to Read is a method to only import points within the specific point number range. The Use Inclusion/Exclusion Areas option prompts for selecting closed polylines to control where to import points.

The Point Group To Assign option will create a point group with the specified name for the coordinate file containing the point numbers imported with Import Text/ASCII File.

With Point Protect active, the program will check if a point number already exists in the CRD before importing the point. If a point conflict is found, you can either assign a new point number or overwrite the old point.

Multiple files can be imported at once. To do this, toggle on the Enable Process Multiple Files option. After selecting the Text/ASCII Files button, you can select multiple files by using the Shift or Ctrl keys while picking files. You can also run Select Text/ASCII Files multiple times allowing for selection of files located in different locations. The files to import are listed in the top scroll display window. The point data from all the import files can be stored to the current CRD file or to separate files for each import file. The separate file option will name the resulting CRD files with the same name as the import file with a .CRD file extension. For example, the import file job125.txt would create job125.crd. The CRD file will be created in the same location as that of the selected text file to import.

Under Process Options, there are choices for selecting the coordinate file to store the imported points. The Current option uses the current coordinate file that is active in the drawing. This coordinate file name is shown at the bottom of the dialog. The Prompt For Another option uses the standard file selection dialog to select the file. The Name Another By Input File uses a coordinate file name with the same name as the input file except for a file extension of .CRD.

The Process Space Separated DMS Latitude/Longitude handles a text file with the degrees, minutes and seconds separated by spaces. The latitude and longitude values get stored to the coordinate file in decimal degrees. Here is an example text file line with the point number (1100), latitude degrees (42), latitude minutes (6), latitude seconds (3.200), longitude degrees (70), longitude minutes (2), longitude seconds (2.090) and elevation (85.245). The Coordinate Order for this example should be set to P Y X Z.

```
1100 42 06 03.200 70 40 02.090 85.245
```

The special formats of SurvCE Job Database .jdb, SDMS .ctl, Leica .d45/.gsi/.raw files, MicroStation .TA2 files, WinCMM .cor and .lev files, TDS .cr5 files, Topobase .ro files, Geodimeter .obs/.raw/.are files, Laser Atlanta .txt files, Trimble .pos files, Zeiss .txt files, Traverse PC .trv files, Maptech, Benchmark .dat files, CAICE/Caltrans .tss files, NLS MMH360 .360 files, EMXS .xng files, and Cadvantage .cog files can be directly imported by choosing that File Format at the top of the dialog.

The Load and Save buttons are for saving and recalling the settings from the dialog using a .rpnt file.

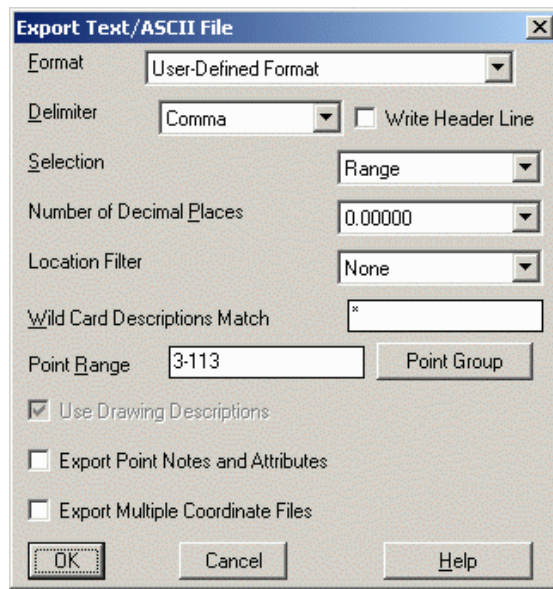

Pulldown Menu Location: Points

Keyboard Command: readpt

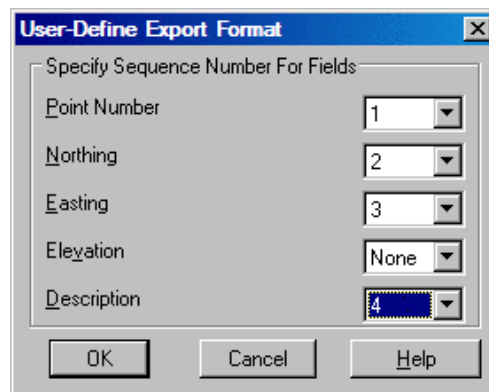

Prerequisite: A text file to read

Export Text/ASCII File

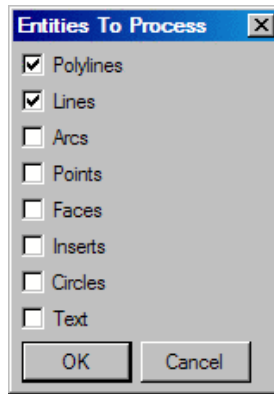

This command outputs point data from the current Carlson coordinate file to an ASCII text file formatted according to a variety of options presented in the form of a general dialog.

Format. Specify the type of file to write from the drop down list. There are several variations on point number, northing, easting, elevation and descriptions as well as specific formats for Leica, Geodimeter, Zeiss, Maptech, Idan REG, NLS MMH360, D45, Cadvantage, Multiplane and SDMS CTL formats. In addition there is a User-Defined Format option to define the order of the fields output. When using the User-Defined format, after selecting OK, the User-Define Export Format dialog will appear. On this dialog, specify the order of the fields by defining a number sequence in each field. You can skip fields and omit data in the output file by leaving None in the sequence field for this data:

Selection. There are four Selection Methods provided for the data to export. Specify either Range, Screen Points, Screen Entities or Pick Points in the Selection Field. A Range selection is a user specified range such as 1-10,30-50. A Screen Points selection is made by selecting points from the screen area. The Pick Points method prompts to select the points to export from the drawing. The Screen Entities option allows for selection of polylines, lines, arcs, points, faces, inserts and text to export point data from. When the Screen Entities option is selected, the following dialog box will display allowing for the specification of the type of entity to export data from:

Delimiter. Select the desired field delimiter of the export file as either Comma or Space from the drop down list. If a header line is to be included, enable the check box.

Number of Decimal Places. Select the desired number of digits to be included in the mantissa of all output ordinates.

Location Filter. Choose from filter methods of within inclusion perimeter polyline, by coordinate window or center within radius from a center point.

Wild Card Descriptions Match. A description filter is also available for exporting only points from the range or selection set with certain descriptions.

Export Point Notes and Attributes. Notes associated with the points may be included in the export by enabling the check box.

Export Multiple Coordinate Files. Enable this check box to specify multiple CRD files to apply the selection criteria against. If enabled, an additional dialog will be presented from which you can browse, select, and remove as many CRD files as desired. In this mode, you can use the Write To Single ASCII File to output the multiple coordinate files into one combined text file.

Point Group. Displays the Point Group manager dialog from which you may define, modify, and select one or more Point Groups to define the points to be included in the export.

After selecting the OK button, a final dialog appears that allows you to specify a new file or to append data into an existing file. The standard file selection dialog allows you to specify the export file name.

Pulldown Menu Location: Points

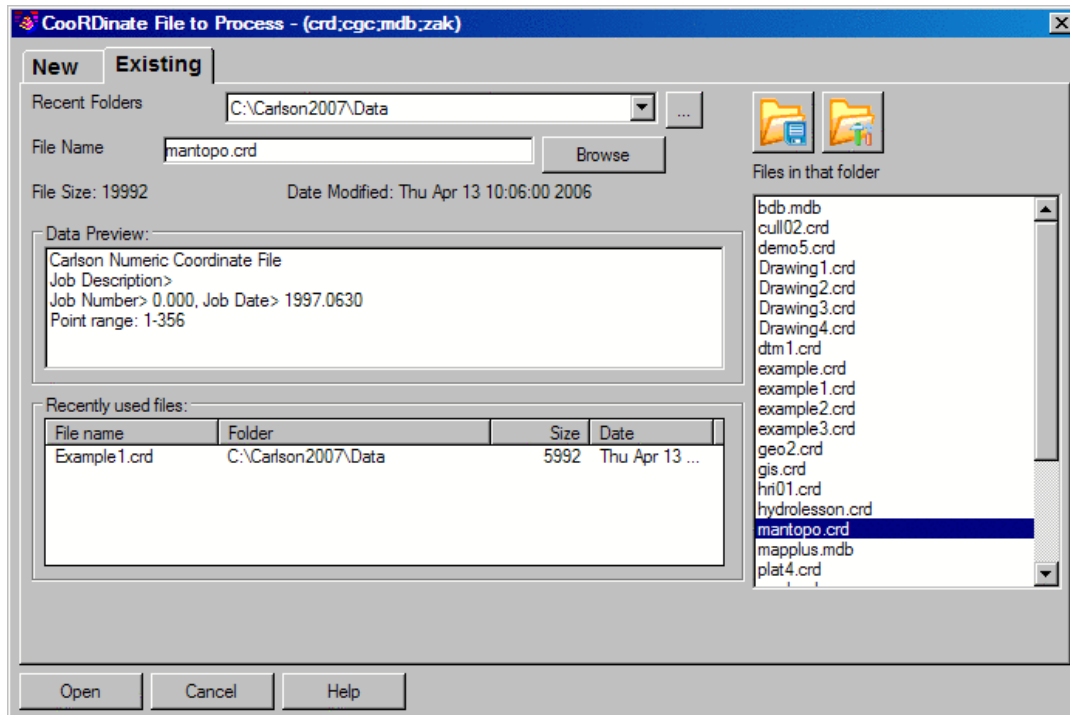

Keyboard Command: writept

Prerequisite: A Coordinate File (.CRD)

Set Coordinate File

This command allows the user to set the name of the active coordinate file. This file is used by different commands that compute, store and recall point coordinates. Carlson coordinate (.CRD) files are binary files that contain point numbers, northings, eastings, elevations and descriptions. Alternately, C&G CRD & CGC files, LandDesktop MDB files or Simplicity Systems ZAK files can be used in place of the Carlson CRD file. These files are stored by default in the configured data subdirectory. When prompted for the name, if you type in a path name the file will be stored in the specified path. If you don't specify a path then the default path that is configured in the *Configure* command, found under Settings, will be used.

When executed, the command defaults to the Existing tab for selection of an existing file. You may select a file from the list of Recent Folders, or choose the Browse button to go to a specific location on your computer. To create a new file, select the New tab and enter the name of the file in the file name field provided. Use the Browse button to specify the desired location to save the file.

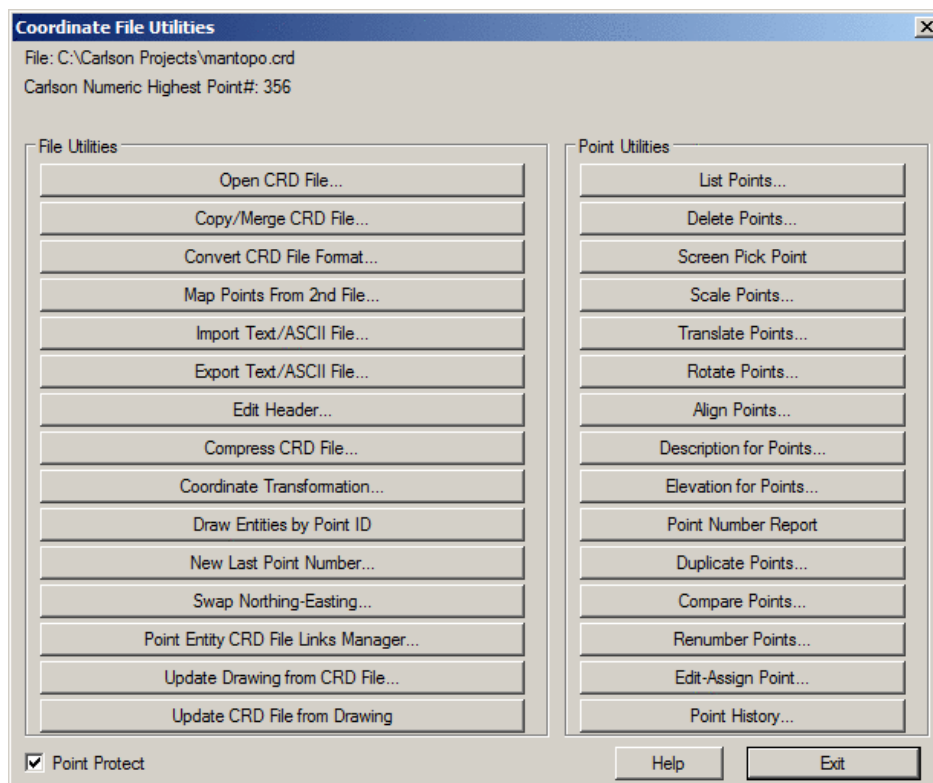

Pulldown Menu Location: Points

Keyboard Command: setcrd

Prerequisite: None

CooRDinate File Utilities

This command organizes a wide variety of coordinate file and point manipulation routines into one central location. The type of coordinate file format is displayed within the dialog box. Another increasingly popular coordinate format is the Carlson coordinate database (.CRDB) which is based on SQLite and supports point numbers and descriptions up to 255 characters in length.

In addition to running the routines through the dialog, many routines have command names that you can enter at the *Command* prompt, create a Quick Key, or put into a toolbar. The table below shows the command names and their corresponding key-in command equivalents:

	File Utilities	Point Utilities	
Open CRD File	setcrd	List Points	listpt
Copy/Merge CRD File	cfucopy	Delete Points	delpt
Convert CRD File Format		Screen Pick Point	
Map Points from 2nd File		Scale Points	scalept
Import Text/ASCII File	readpt	Translate Points	transpt
Export Text/ASCII File	writpt	Rotate Points	rotatept
Edit Header		Align Points	alignpt
Compress CRD File		Description for Points	cfudesc
Coordinate Transformation	cfutransform	Elevation for Points	cfuelev
Draw Entities by Point ID		Point Number Report	cfureport
New Last Point Number		Duplicate Points	cfuduplicate
Swap Northing-Easting		Compare Points	cfucompare
Point Entity CRD File Links Manager		Renumber Points	renumpnt
Update Drawing from CRD File	cfuupdatedwg	Edit-Assign Point	
Update CRD File from Drawing	cfuupdatecrd	Point History	cfuhistory

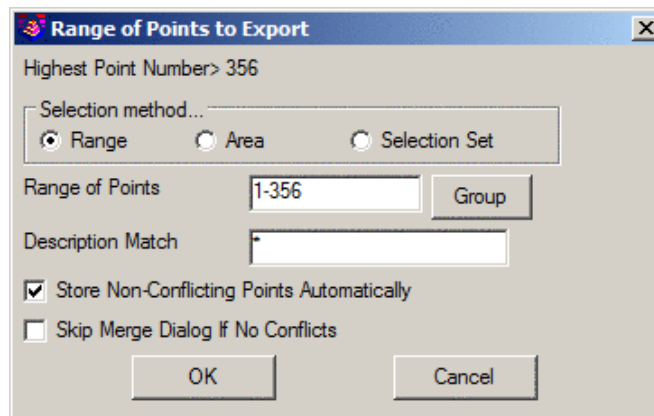

Open CRD File: Allows the user to switch to another file. See Set Coordinate File for additional information. When you exit Coordinate File Utilities this will be the current file that you work with in Carlson.

List Points: List the points stored in the active coordinate file. See List Points for additional information.

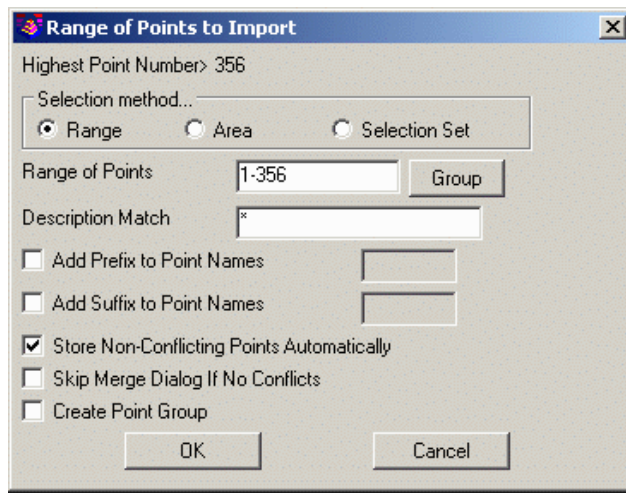

Copy/Merge CRD File: This command allows for the copying of entire CRD files, or parts of CRD files, to a new or existing files. This can be used to make a backup of your coordinate file, and it can also be very valuable in coordinate file manipulation. For example, if a certain range of points from one CRD file was also required in the active CRD file, this command would be used to simply copy the required range into the active CRD file. There are two options when first executing the command. These options are whether to import points from another file to the current (active) CRD file, or to export the current (active) coordinate file to another file.

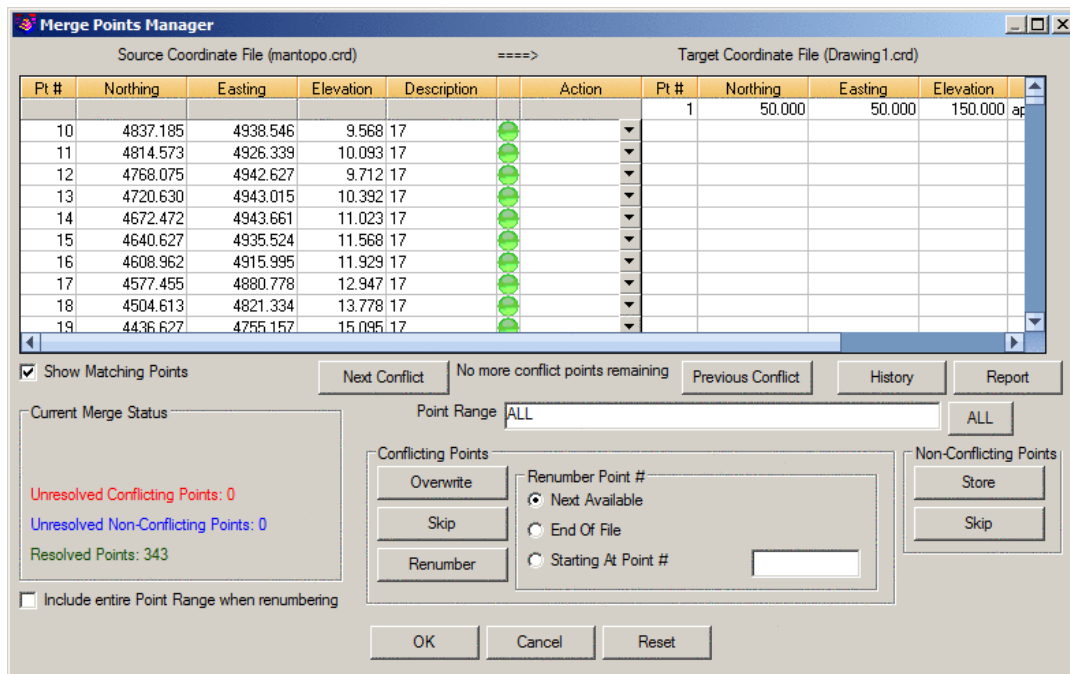

Once this option has been decided, a prompt for the file to copy From or TO, will be displayed. Here simply specify the correct file.

Next there's a dialog to specify the range of points to transfer and some options. Here specify the points to copy. Point numbers and ranges can be entered together. For example, **1-3,10,15** would result in points 1 through 3 and points 10 and 15 being copied. The Description Match can be used to filter the points to transfer only the points with matching description. The default of * will transfer all the points in the range. The Store Non-Conflicting Point Automatically will set the transfer action as Store for all transfer points that don't have a point protect conflict. The Skip Merge Dialog If No Conflicts will skip the next dialog when there are no point protect conflicts.

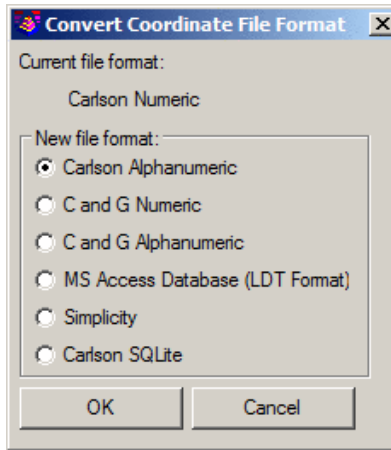

The Import dialog has a few more options than the Export dialog. The Add Prefix/Suffix To Point Names will change the point names as they are imported. The Create Point Group will make a new point group with the imported point names.

Next there's the Merge Points Manager dialog that shows the Source Coordinate File on the left (where the point data is being copied from) and the Target Coordinate File on the right (where the point data is being written to). Conflict cases are when the same point number exists in both files with different coordinates. The action choices for conflicts are to Overwrite, Skip or Renumber. For renumber, you can either renumber with the next available point number in the target file or to the highest point number in the target file plus one. Non-conflict cases are when the source point number does not exist in the target file. The action choices for non-conflicts are to Store or Skip. You can assign actions by picking on the Action field in the spreadsheet or by entering in a Point Range to apply and picking an action button. The Show Matching Points toggle will show points with matching point data in both files. Otherwise only point with differences are shown. The Next Conflict button will highlight the spreadsheet and set the Point Range to the next point that needs an action assigned. Similarly, the Previous Conflict sets focus to a lower point number that needs an action. The History button shows the point history for the selected point. The Report button creates a list points report. The Current Merge Status reports the number of unresolved and resolved points. When all the unresolved points are resolved by assigning actions, you can pick OK.

Delete Points: Deletes points from the active coordinate file. See Erase Points for additional information.

Convert CRD File Format: This allows you to convert the current coordinate file from one format (*e.g.* numeric only) to another (*e.g.* alphanumeric). This routine will also change coordinate files to and from other software formats. These formats include Carlson SQLite (.CRDB), C&G, Microsoft Access (.MDB) in same format as AutoDesk Land Desktop, and Simplicity (.ZAK). The current format of the active coordinate file will be displayed as well as the options for the new file format. This command only changes the format of the active coordinate file.

Screen Pick Point: Pick a point on the graphics screen and its coordinate value is added to the coordinate file. This command does not plot a point, point attributes or point symbol. Use Draw Field-to-Finish or Draw-Locate Points or Update Drawing from CRD File to graphically draw the point(s).

Map Points from 2nd File: This routine adds point to the current coordinate file from points stored in a second coordinate file. The points to copy are specified by numbers one at a time. Prompts for the destination point number (number to create in current coordinate file) and source point number (point number to be copied from second coordinate file) will be displayed.

Scale Points: This option multiplies the point northing, easting, and elevation by the scale conversion factor. You can use this routine for Metric-Imperial unit conversion. See Scale Points for additional information.

Import Text/ASCII File: This routine converts point data from a text file into the current coordinate file. See Import Text/ASCII File for additional information.

Translate Points: This option translates a range of points based on entered delta x and delta y, entered coordinates or translation point numbers. See Translate Points for additional information.

Export Text/ASCII Text File: This routine outputs point data from the current coordinate (.CRD) file to a ASCII Text file. See Export Text/ASCII File for additional information.

Rotate Points: This option rotates a range of points based on entered degrees or rotation, entered azimuths, entered bearings or rotation point numbers. See Rotate Points for additional information.

Edit Header: Enter or edit the job information associated with the coordinate file. The fields include Job Description, Job Number and Job Date. This information will appear on the List Point report. Non-digit characters are not allowed in the Job Number field.

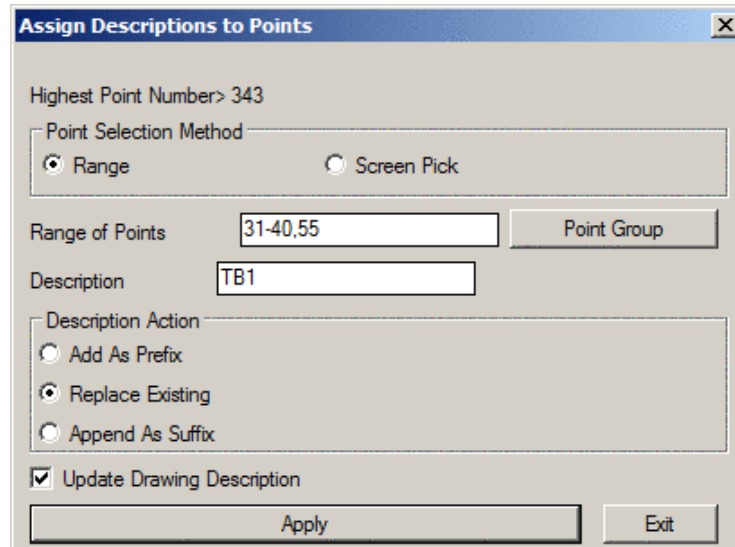

Align Points: This option does a translate based on a source point and destination point and then rotates to align the

first source point and a second source point with the first destination point and a second destination point. See Align Points for additional information.

Compress CRD File: Removes unused point numbers by renumbering high point numbers into the unused spaces. For example, for an original file with points 1,2,105,107,108,109 would be compressed to 1,2,3,4,5,6.

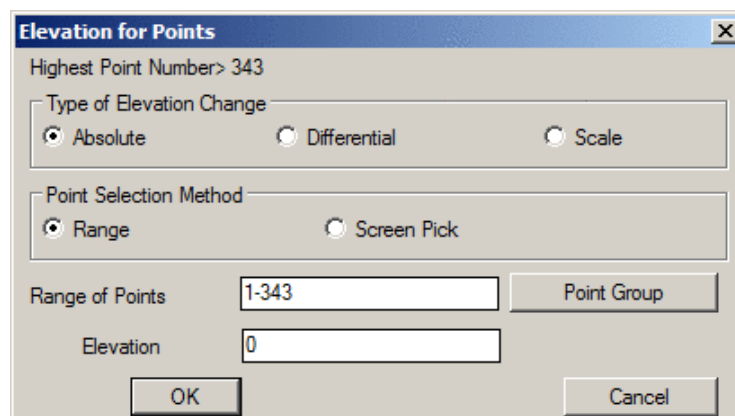

Description for Points: This routine modifies the point description field with the user-specified text for a range of point numbers. There is an option to update the description attributes of the points in the drawing in addition to updating the coordinate file.

Coordinate Transformation: Transforms coordinates between local, State Plane 27, State Plane 83, Latitude/Longitude, Universal Transverse Mercator (UTM) and many other projections, including regional and user-defined projections. This works on individually entered coordinates, by range of point numbers and with on-screen entities. See Coordinate Transformation for additional information.

Elevation for Points: This routine modifies the elevation of the specified points. The Absolute method sets the elevations to the specified value. The Differential method adds the value to the current elevations. The Scale method multiplies the current elevations by the value.

Draw Entities by Point ID: Draw Lines, Arcs, 3DLines, Polylines or 3DPolys by defining a range of point numbers.

Prompts

Plot Entities by Point Number

Type of entity, Arc/Polyline/3dpoly/2dline/Exit/ <Line>: Indicate the type of entity to draw.

Undo/ <Enter point numbers or ranges>: Indicate the point numbers through which to draw.

Example: **1-4,7,10-12,5,8** would draw the entity from point numbers 1 through 4 then to 7, to 10 through 12, then to 5 to 8 (limit 132 characters)

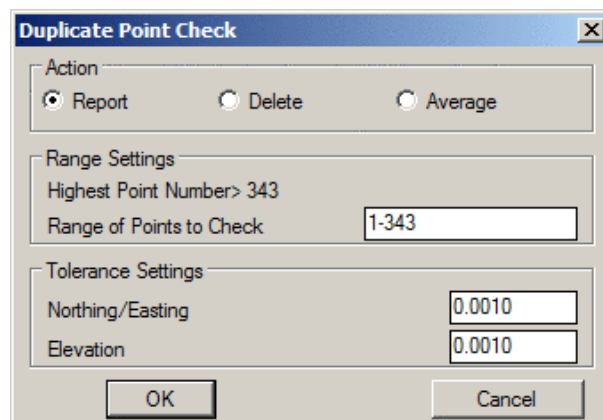

Example: **1-10,20-30** would draw the entity from point number 1 through 10 then to point number 20 through 30.

Point Number Report: This routine lists the used and the unused point numbers in the coordinate file.

New Last Point Number: This option sets the highest point number in the coordinate file. **NOTE:** All points above this number are erased!

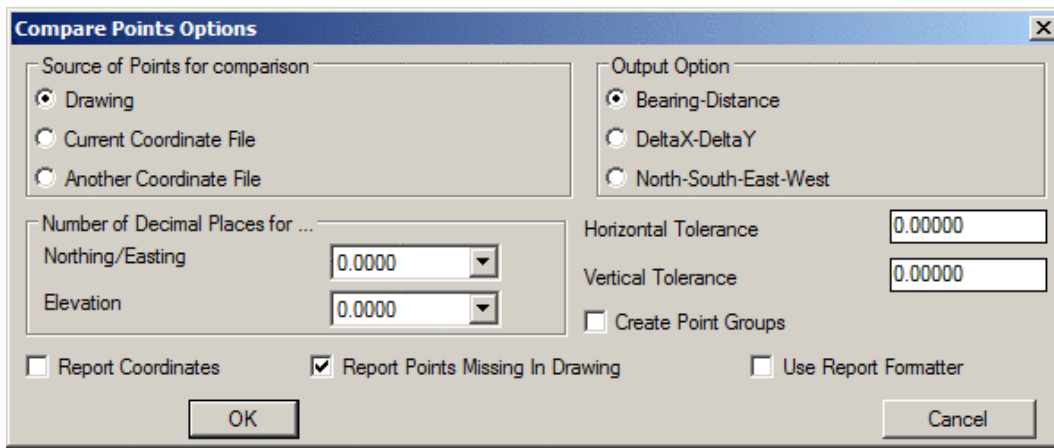

Duplicate Points: This function searches the coordinate file for points with the same northing, easting and elevation. The tolerances for considering points to have the same coordinate are set in the dialog separately for northing/easting and elevation. To be counted the same coordinate, both the northing/easting and elevation must be within the tolerance distance. The duplicate points can be reported, deleted or averaged. For the erase and average options, the first point number is kept and any higher point numbers with duplicate coordinates are processed from the coordinate file.

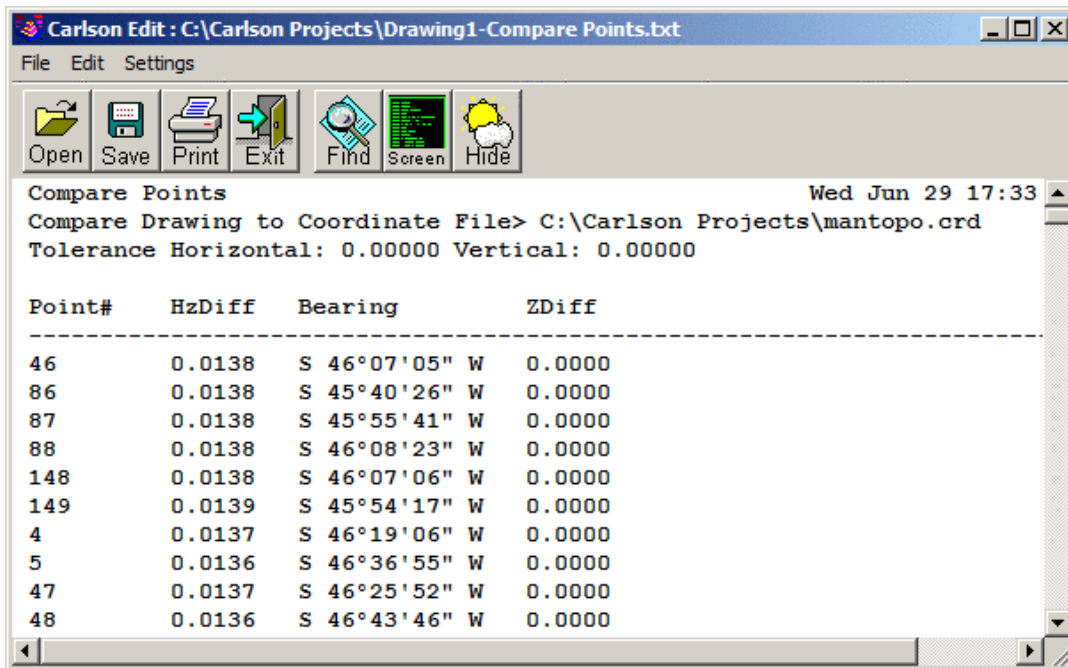

Swap Northing-Easting: This option allows you to swap northing and easting coordinates for any selected range of points. What was the northing of an existing coordinate point, or range of points, becomes the easting. And the easting(s) become the northing(s).

Compare Points: This function compares the coordinates in the coordinate file with either the coordinates for the matching point numbers in the drawing file, with matching point numbers from another coordinate file or with different point numbers from the same coordinate file. A report is created for any differences that shows the point numbers and the differences. The difference can be reported as a bearing and distance between the two points, as distance North/South and East/West or as the delta-X and delta-Y. There is an option whether to include the point coordinates in the report. The Create Point Groups option creates point groups of "Missing From Drawing" and "Changed Points" for any points that have this status. Use the Point Group Manager routine to check on these point groups.

Example Bearing-Distance format Compare Points Report:

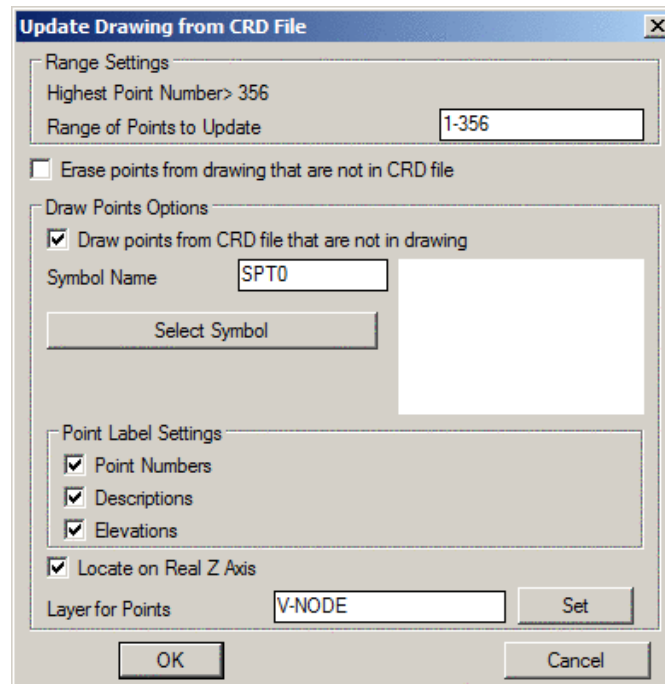

Point Entry CRD File Links Manager: When points are created in the drawing, the program records the source coordinate file for the points. The coordinate file names assigned to the point entities links the point entities back to the coordinate file. These links are used by routines that process the point entities and then need to reference the changes (*e.g.* those generated from the Rotate Points routine) back to the coordinate file. This routine checks all the point entities in the drawing and lists all the linked coordinate files. You can use the Assign button to set the coordinate file assigned to point entities which is useful when the coordinate file has been moved or manually renamed after the points were drawn. Use the Unlink button to remove the link.

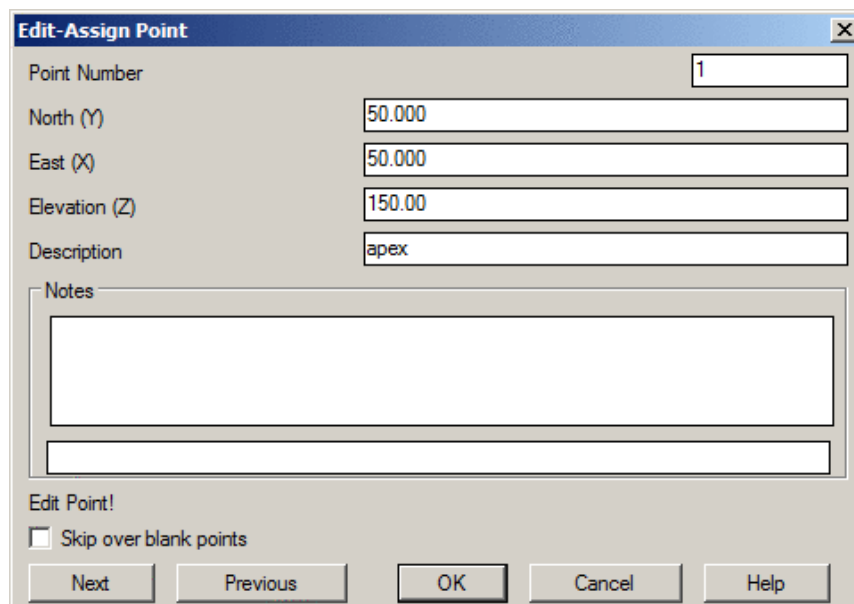

Renumber Points: This option renumbers points in the user-specified range starting from a new point number. See Renumber Points for additional information.

Update Drawing from CRD File: This function updates the position of Carlson points in the drawing to match the position stored in the coordinate file. This command also has options to erase and draw points. For the erase option, points are erased from the drawing if the point number does not exist in the coordinate file. For the draw option, if a point number in the CRD file does not exist in the drawing, then this point is drawn using the settings from the dialog. The number of points modified, erased and drawn is reported at the end of the command.

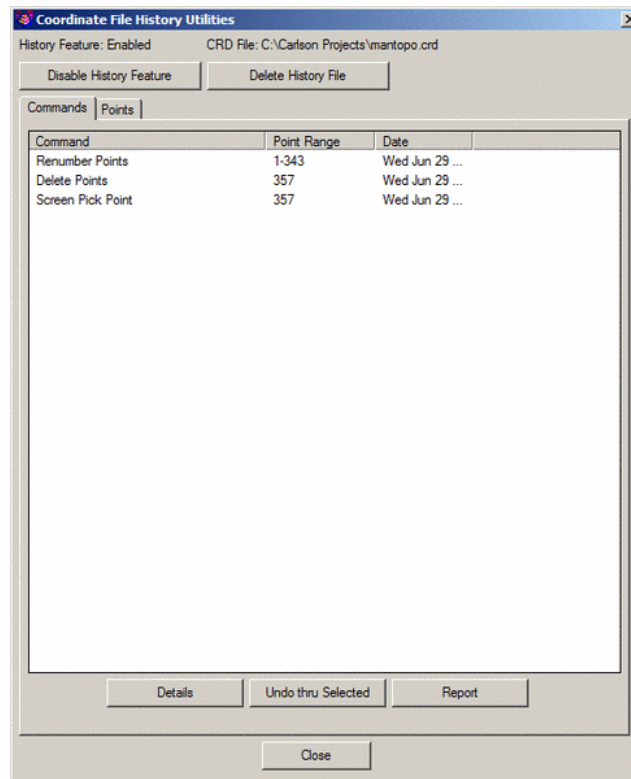

Input-Edit Point: Enter or edit the coordinate values or the description of a point. The Notes section is for adding optional point notes which are additional point descriptions. Under notes, any number of lines of text can be assigned to the point. A list box shows the lines of notes. To add a note line, pick a blank line in the list box and then type in the note in the edit box along the list box and press **Enter**. To edit a note, highlight the line in the list box and edit the text in the edit box.

Update CRD File from Drawing: This function allows you to select all or some of the points in the drawing and add or update them to the coordinate file. The points can be filtered using standard CAD entity selection and/or

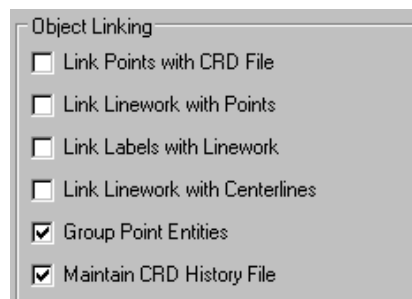

wild-card matching of the point descriptions. The Update Point Descriptions option determines whether the point descriptions from the drawing will be stored to the coordinate file. Use this command to manually update the file after a general CAD edit such as *Move*, *Rotate*, *Erase*, etc. This routine directly reads Leica (Wildsoft), Softdesk, Geodimeter, InRoads, Land Development Desktop, and Eagle Point point blocks.

Point History: All changes to the coordinate file will record the commands performed on this coordinate file and the status of the points themselves. This makes up the coordinate file history. The history can then be reported by point number or by command. All of the changes can be rolled back.

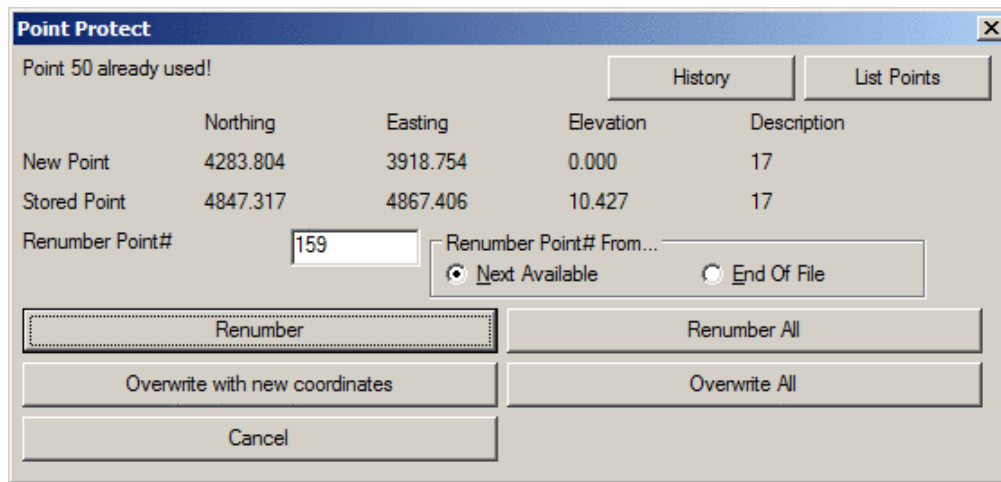

The **Disable History Feature** button at the top of the dialog shown above is a toggle device. It should be clicked if you prefer not to build the point history file. Clicking it a second time changes it back to saying **Enable History Feature**. You can also choose **Delete History File** to delete the file altogether. By clicking any point from the list, as shown in the Points tab example above, and then selecting **History**, you will be given the history for that specific point. Double-clicking on any command shows the details. Clicking on **Details** also shows the selected command details. Undo thru Selected will undo the effect of all of the commands up through and including the selected command. The changes from the undo command are themselves then added to the command list and can be undone in the future.

NOTE: It is important to note that if maintaining such a history file is your objective, make sure that *Maintain CRD History File* option is enabled within the (Carlson) Configure – General Settings command:

Point Protect: When enabled, attempting to store a point with a point identifier (point number) that already exists in the current coordinate file will display the following alert:

Overwrite with new coordinates will update the existing point number with the new location of the point.

The **Renumber Point#** field displays the point number that will be used if the Renumber Point# From – Next Available option is selected (the routine will attempt to fill in any point number gaps. To leave any existing point number gaps in the file, specify the **End of File** option.

The **Overwrite All** and **Renumber All** options apply when more than one point with the same number exists in the coordinate file. These options are helpful when importing points into existing coordinate files.

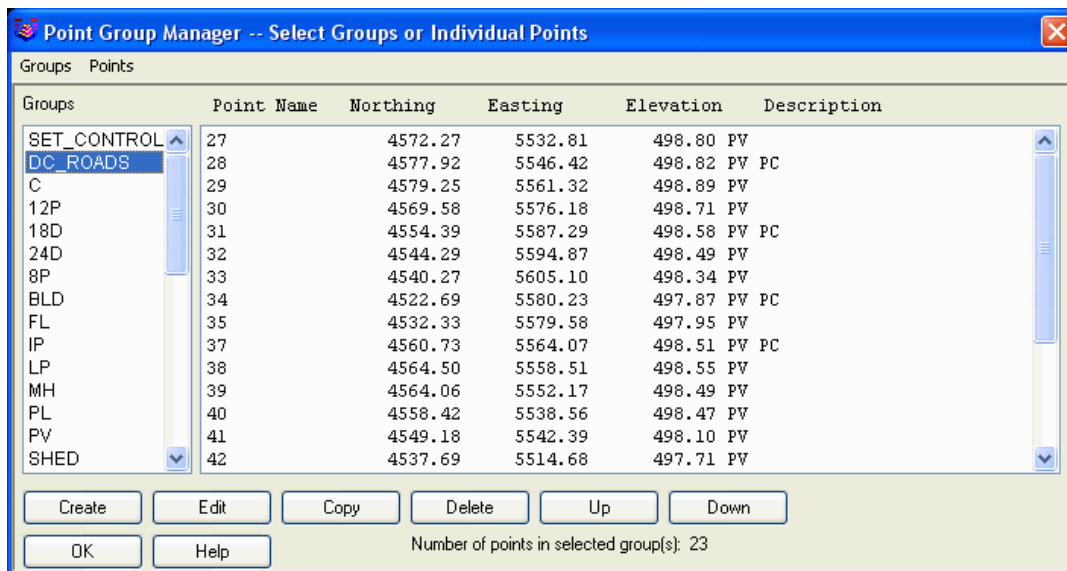

Pulldown Menu Location(s): Points

Keyboard Command: cfu

Prerequisite: None

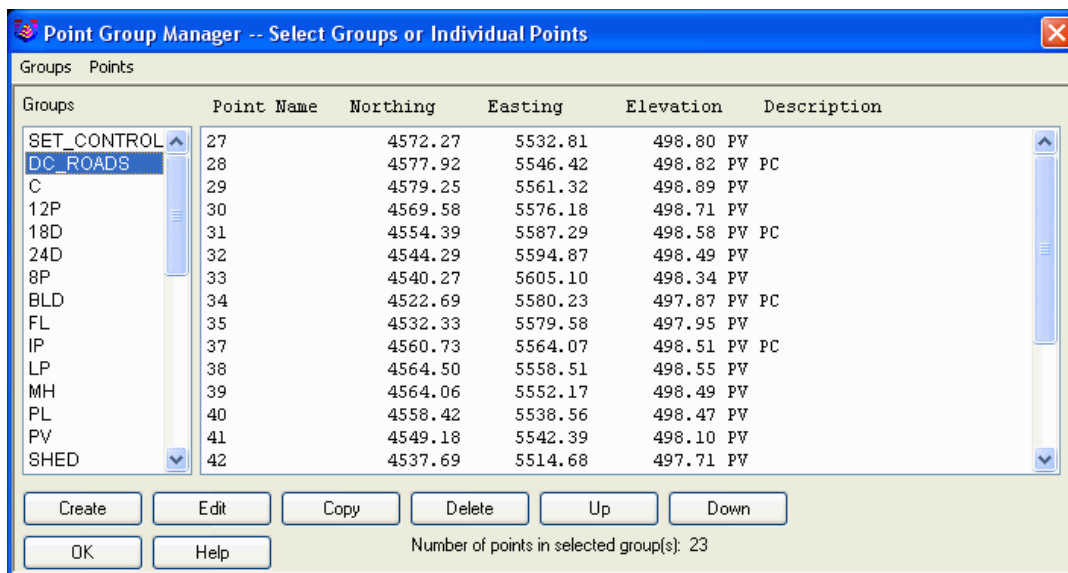

Point Group Manager

This command is used to create point groups based on inclusion and exclusion filters. The manager can perform various functions on these point groups. Also point groups can be referenced by group name in other commands such as Field to Finish and Data Collection.

Groups Pulldown

Create Point Group: This routine creates point groups. When selected, the New Point Group dialog box is displayed.

Group Name is the name of Point Group to create.

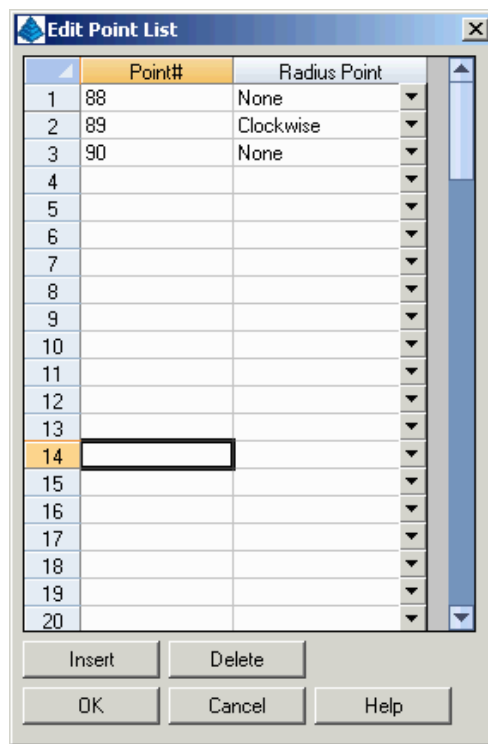

Description is the description of Point Group to create.

Use the **Include Tab** to define the filters to be applied when creating the point group. Inclusion rules are applied before the exclusion rules.

When **Include All** is toggled on, all points in the coordinate file will be included in the selection.

When **Point List** is toggled on, an option of defining the point list can be selected or the point numbers can be manually entered in the edit box. The points retain the order entered in the edit box which can be used in other point functions that process points where the order matters such as Legal Description. The Edit button brings up a spreadsheet editor for the point list and there is a flag for each point for whether the point is a radius point. This radius point flag is used in routines that process points for a polyline or perimeter such as Legal Description. The radius point is used to define an arc in the polyline. The sequence of points for the arc are PC, radius point and PT.

DWG: Select allows for manual selection of the points to include from the drawing. The points must be drawn on the screen prior to using this option. All standard AutoCAD selection tools, are available for selection of the points.

DWG: Inside Circle allows for selection of the points to include by a user defined circle. The circle is defined by specifying the center and radius of the circle. The radius can be defined by entering in a numeric value or by picking on the screen. Points must be drawn to the screen prior to using this option.

DWG: Inside Polyline allows for the selection of points to include by referencing a closed polyline. All points located within the closed polyline will be included in the selection. Prompts for the inclusion polyline and the exclusion polyline will display. The inclusion polyline limits of the selection area. The exclusion polyline defines the area to exclude within the inclusion polyline. Points must be drawn to the screen prior to using this option.

DWG: Along Polyline allows for the selection of points to include by offset from an alignment polyline. All points located within the specified offset tolerance from the polyline will be included in the selection.

CRD: Select allows for manual selection of the points to include from a point list. Standard window selection tools are available for selecting the points to include.

Name	North	East	Elevation	Description
1	4806.66	5980.63	0.00	
2	4950.61	4695.72	102.05	XCUT
3	4785.03	4716.23	96.96	XCUT
4	4852.58	5278.93	109.71	MNSET
5	5154.12	5237.54	106.49	MN-SET
6	5124.84	4999.58	104.90	MN-6
7	5287.14	5049.95	0.00	
8	5297.01	5098.97	0.00	
9	5306.88	5147.98	0.00	
10	5316.75	5197.00	0.00	
11	5326.61	5246.02	0.00	
12	5336.48	5295.03	0.00	
13	5346.35	5344.05	0.00	
14	5356.22	5393.07	0.00	
15	5366.09	5442.08	0.00	

CRD: Inside Circle allows for selection of the points to include by a user defined circle. The circle is defined by specifying the center and radius of the circle. The radius can be defined by entering in a numeric value or by picking on the screen. The points do NOT have to be drawn to the screen prior to selection.

CRD: Inside Polyline allows for the selection of points to include by referencing a closed polyline. All points located within the closed polyline will be included in the selection. Prompts for the inclusion polyline and the exclusion polyline will display. The inclusion polyline limits of the selection area. The exclusion polyline defines the area to exclude within the inclusion polyline. The points do NOT have to be drawn to the screen prior to selection.

CRD: Along Polyline allows for the selection of points to include by offset from an alignment polyline. All points located within the specified offset tolerance from the polyline will be included in the selection.

RW5 File: creates a list of points from all the point numbers used in the selected RW5 raw data file.

History Select: creates a point group by date range using the log stored in the CRD history. See Coordinate File Utility > Point History to review this information.

Point Name Prefix: creates a point group by a specified number of digits from the start of point names. This method applies when your point numbering method uses a fixed beginning string for point names. For example, if point names begin with a code for the crew, then this method can make point groups per crew.

Point Name Suffix: creates point groups using alpha characters that follow numbers in the point names.

Ungrouped: creates a point group including any points that are not already part of another group.

Non-Surface: creates a list of points that are set as Non-Surface points to be skipped in surface modeling.

Elevation Range allows for the selection of points within a specified elevation range to be included in the group. The minimum and maximum elevations can be entered manually in their respective data fields. The minimum and maximum values can also be specified by the Set By Selection and Set From List options.

Set By Selection allows for selection of points to include in the group from the drawing. The points must be drawn to the screen prior to using this selection method. Standard AutoCAD selection methods are available.

Set From List allows for selection of points to include in the group from a point list. Standard Windows selection tools are available with this option.

The **Description** option allows for a selection of points to include based upon the description of the point. The description to filter for can be entered in the data field or by using the Set By Selection and/or the Set From List options described above.

Make Point List converts the group definition to a list of point numbers that currently match the group definition.

The **Exclude Tab** allows for defining rules that pertain to the points to be excluded from the Inclusion selection. After defining the inclusion rules for the group, the options on the Exclude tab can be used to filter for points to exclude from the group. For example, if the inclusion rules call for all points within the elevation range of 8 to 12, an exclusion rule can be set to exclude the points on elevation 9 or with the description tree. The options on this tab work exactly like the options on the Include tab. Please refer to the Include tab definitions for further instruction.

Save Changes saves the point group to the group name specified based upon the Inclusion and Exclusion rules specified.

Cancel Changes discards specified rules and changes and goes back to the Point Group Manager dialog.

Edit Point Group: This function allows for editing of existing point groups. From the list of available groups, highlight the group or groups to edit. When complete with the first group, if more than one is selected, selecting the Save Changes option will save the changes to the active group and switch to the next group in the selection set.

From the Groups pulldown, select Edit Groups, the Edit Group dialog box will now appear.

See Create Point Groups for further definitions of the available options.

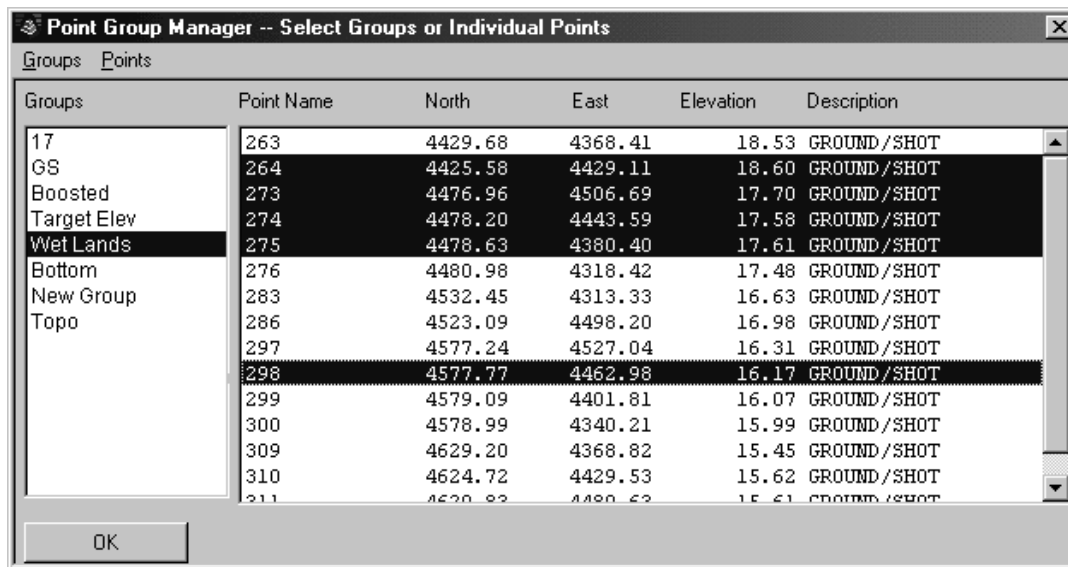

Delete Point Group: This deletes specified groups for the existing group list. One or more groups can be deleted at one time.

Copy Point Group: This routine creates a new point group by copying the currently highlighted group. This allows you to modify an existing group definition and create a new group.

Import Point Groups: This allows for importing filters from point group manager settings of other coordinate files. This is a useful option when coordinate files are going to contain same point group names with the same filters. This option only brings in the filters into the point group manager, it does not import actual points into the coordinate file by group name. Existing points in the active coordinate file that meet the filter definitions of the imported point groups will automatically be added to the corresponding group.

Points Pulldown

Insert into Drawing: This routine draws the points in the group in the drawing. Individual points or point ranges can be selected from the group to be erased from the drawing. For example points 264-275 and point 298 contained in group Wet Lands are tagged to be erased from the drawing in the following figure.

The symbol to be used and the attribute layout are determined by the Point Default Settings. The symbol size and the point attribute size are determined by the settings in the Drawing Setup routine.

Erase from Drawing: This erases specified point group/groups or specified points from within the group from the drawing.

Erase from Coordinate File and Drawing: This erases the points in the specified group/groups or specified points from within the group from the drawing and will also permanently delete the points from the CRD file. You will be prompted with a warning as follows:

Selecting **Yes** will complete the command and erase the points from the screen and also the coordinate file. Selecting **No** will cancel the command leaving the drawing and the coordinate file unchanged.

Report: The routine will generate a point list of the points contained in the selected group/groups or specified points from within the group.

Highlight: This routine highlights the specified objects in the drawing. This makes them distinguishable from the other points on the screen.

Isolate: This routine freezes all the points except for the current group.

Freeze: This routine freezes the points of the highlighted point group like the Points->Freeze Points command.

Thaw: This routine thaws the points of the highlighted point group like the Points->Thaw Points command.

Thaw All: This routine thaws all the points like the Points->Thaw Points command.

Draw 2D Line: This routine draws a 2d polyline between the points contained in the group/groups or between specified points in a group.

Renumber: Renumbers points in the current group.

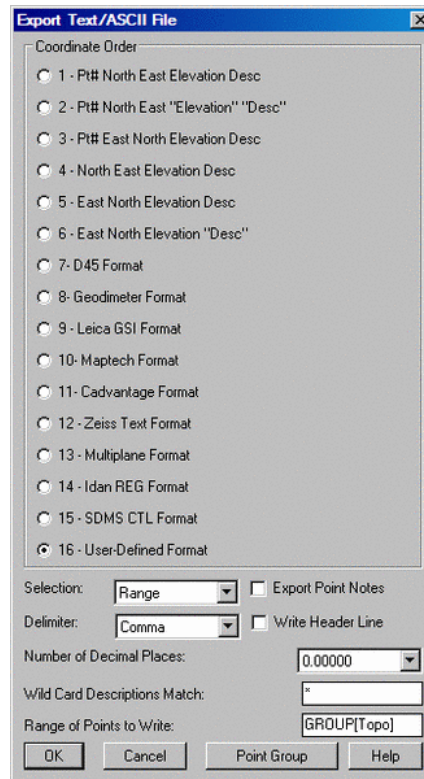

Edit Attributes: Edits the point attributes for the points entities in the drawing.

Edit Descriptions: Sets the description for the points in the current group.

Edit Elevations: Sets the elevation for the points in the current group.

Export: This command exports the selected group/groups or the specified point(s) or range of points from within the group to various formats. The available formats are ASCII/Text, Carlson Software CRD and C&G CRD files.

When **ASCII/Text** is selected, the Export Text/ASCII File dialog box will be displayed. Please refer to the Export Text/ASCII File section of the manual for more information.

The **CRD-Carlson software** command writes the selected group/groups or the specified point(s) or range of points within the group to a new Carlson formatted CRD file.

Specify the file name of the CRD file to create and press save.

CRD-C&G writes the selected group/groups or the specified point(s) or range of points within the group to a new C&G formatted CRD file.

Specify the file name of the CRD file to create and press save.

Button Functions

The series of buttons at the bottom of the main dialog do the same functions as the routines in the Groups pull-down menu except the Move Up and Move Down which are only available as these buttons. The Move **Up/Down** simply change the display order of the groups in the list. The **Import** function brings in group definitions from either another coordinate file or from a C&G Points List File. The **Sort** function sorts the groups by name or by number of points. The **Merge** function combines the definitions from two or more existing groups to create a new group.

To run Merge, highlight the groups to merge in the Groups list by clicking on them while holding the Ctrl key, and then pick the Merge button.

Pulldown Menu Location: Points

Keyboard Command: pgm

Prerequisite: A coordinate file

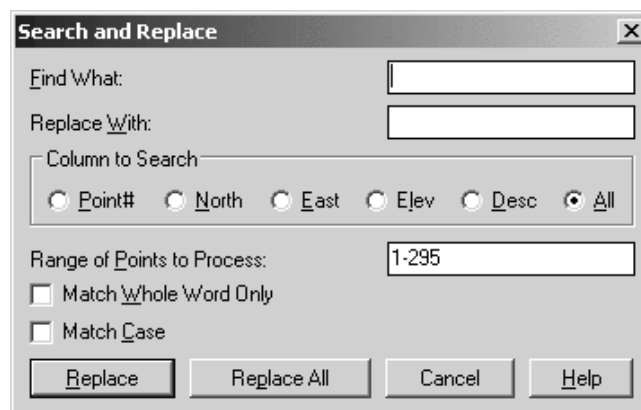

Edit Points

This command edits point data in the current coordinate file or within a point range. The current coordinate file can be set with the Set Coordinate File command. Edit Points shows all the points in the coordinate file. New points can be added and points can be deleted by using the Insert and Delete keys.

In the Edit pull-down menu, there are functions to add and remove rows from the spreadsheet. Also there are clipboard functions to copy and paste spreadsheet cell values. The **Delete Range** function allows you to delete a range of points or all the points by entering "ALL" for the range. The **Hide** function hides the selected range of spreadsheet rows and the **Show** function brings these rows back. The **Settings** function has a dialog to control the decimals to show in the spreadsheet and an option to use a large font in the spreadsheet to make it easier on the eyes to see.

In the Search pull-down menu, the **Find** function searches the spreadsheet. The **Replace** function has settings to limit the replace by point number range or by field type.

The Group > **Point Group Filter** function allows you to edit subset collection of points as defined by Point Group Manager. This Group method is a way to filter the points by point range, elevation range or description.

This tool also lets you edit notes associated with each point. While the standard point description is limited to 32 characters, the drawing notes are not. When you click on a given point, you can add numerous lines of notes about that point in the bottom of the dialog. Keep in mind that these notes are stored in a separate file with the extension ".not" having the same name as the CRD and residing in the same folder.

Point#	Northing	Easting	Elevation	Description
1	4024.91158781	5205.10767843	542.20000000	
2	4062.10394883	5173.57036672	543.10000000	
3	4126.71087104	5180.82246408	543.70000000	
4	4192.64550433	5207.19058280	544.20000000	
5	4219.67569784	5279.05437114	544.30000000	
6	4212.41921401	5369.37699554	544.20000000

Keyboard Command: editpt

Prerequisite: None

Erase Points

This command erases Carlson points inserted from the drawing. The points to erase can either be selected from the screen or specified by point number, point number range or by point group. Erasing a Carlson point will erase the three entities that make up a Carlson point: the point symbol, point attributes, and point node. There is an option to skip erasing the point symbol in case you want to leave the symbols in the drawing. The points may optionally be erased from the coordinate file. As long as the points are not deleted from the coordinate file, they can be redrawn with *Draw-Locate Points* or *Field-to-Finish*.

When the program detects linework associated with the points, there is a prompt for whether to erase this linework too. For example, when *Field-to-Finish* is used to draw both points and linework, then this linework can be erased along with the points.

Prompts

Select points from screen, group or by point number [Screen/Group/<Number>]? *press Enter*

Point numbers to erase: 1-5

Delete points from coordinate file [Yes/<No>]? *press Enter*

Delete point symbols [<Yes>/No]? *press Enter*

Erasing Carlson Points

Number of points erased > 5

Pulldown Menu Location: Points

Keyboard Command: DELPT

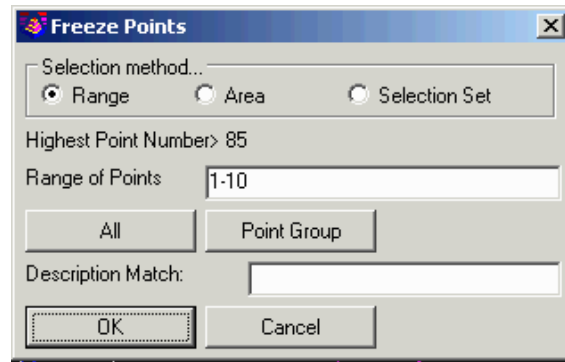

Prerequisite: Carlson points to be erased

Freeze Points

This command freezes Carlson points to hide them from view without erasing them. Use the Thaw Points command to show the points again. This command works similar on points as Freeze Layers works on layers. The points to freeze can be selected by point number range, point group, inclusion/exclusion perimeter polyline areas, or screen selection. There is a dialog to choose the method and specify a description match filter.

When the program detects linework associated with the points, there is a prompt for whether to freeze this linework

too. For example, when Field-to-Finish is used to draw both points and linework, then this linework can be frozen along with the points.

Pulldown Menu Location: Points

Keyboard Command: freezept

Prerequisite: Carlson points to freeze

Thaw Points

This command thaws Carlson points that were frozen with the Freeze Points command to show the points in the drawing again. This command works similar on points as Thaw Layers works on layers.

Pulldown Menu Location: Points

Keyboard Command: thawpt

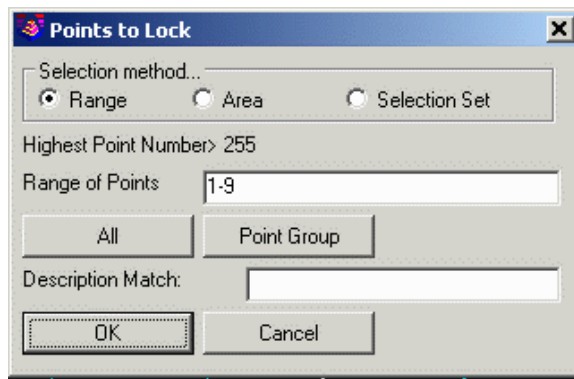

Prerequisite: Frozen Carlson points

Lock Points

This command locks points in the coordinate file so that their names, coordinates and descriptions cannot be modified. There are several types of coordinate files. Lock points only works with the CRDB format because this format is in an SQLite database which has a point attribute for lock status. To check on the format of the current coordinate file, run Coordinate File Utilities (CFU) which shows the format type at the top of the dialog. To change the current coordinate file format to CRDB, run CFU and choose the Convert CRD File Format function.

The only way to modify locked points is to first run the Unlock Points command and then run one of the point edit functions.

The points to lock can be selected by point number range, point group, inclusion/exclusion perimeter polyline areas, or screen selection. There is a dialog to choose the method and specify a description match filter.

Pulldown Menu Location: Points
Keyboard Command: lockpts
Prerequisite: CRDB coordinate file

Unlock Points

This command unlocks points from the current coordinate file that are locked. There is a dialog to choose the method to select which points from the coordinate file to unlock.

Pulldown Menu Location: Points
Keyboard Command: unlockpts
Prerequisite: CRDB coordinate file

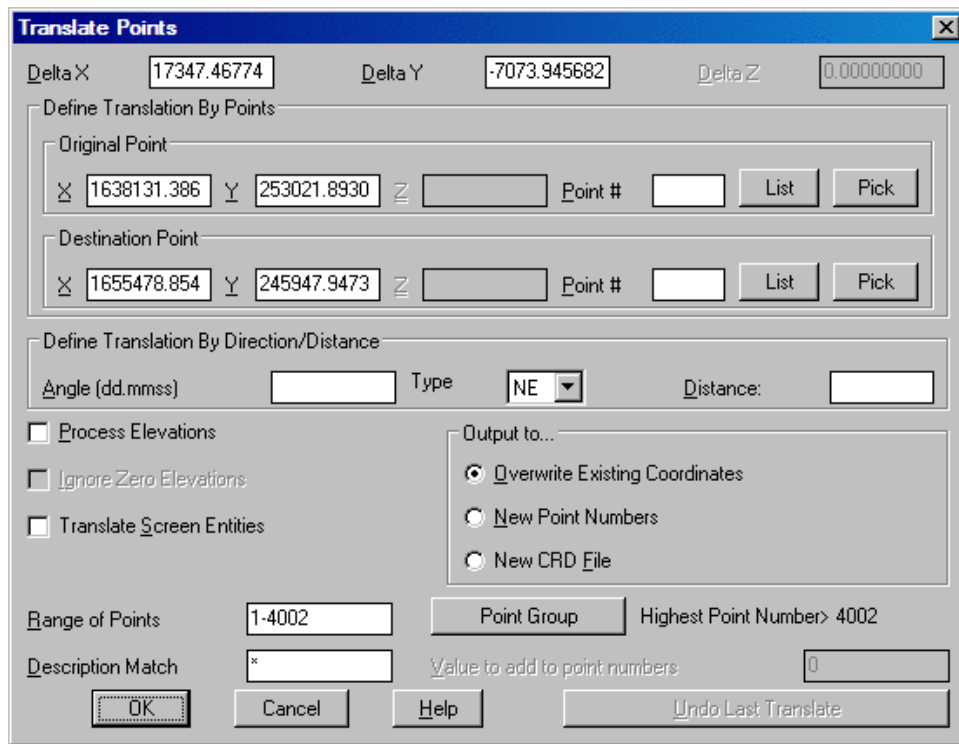

Report Locked Points

This command reports points from the current coordinate file that are locked. There is a dialog to choose the method to select which points from the coordinate file to check for the locked status.

Pulldown Menu Location: Points
Keyboard Command: reportlocks
Prerequisite: CRDB coordinate file

Translate Points

This command translates points in a coordinate file from one coordinate position to another. The delta X, Y, and Z can be entered directly or calculated from original and destination coordinates. The original and destination coordinates can be entered directly, specified by point number, selecting the point number from a point list by selecting the list icon, or selected from the screen by selecting the pick icon. Once these points have been specified, the Delta X,Y,Z, if Process Elevations is checked ON, fields will be filled in with their calculated values. Any points in the drawing will be updated automatically in addition to updating the coordinate file.

Define Translation By Angle/Distance requires a specified direction, Northeast (NE), Southeast (SE), Southwest (SW), Northwest (NW) or Azimuth (AZ) along with a specified distance in order to perform a translation. Once the direction and distance are entered, the Delta X,Y,Z will be calculated. This is a useful command when you know that the job needs to shift, for example, to the Northeast 25 degrees for a distance of 100 feet. Here you would simply type in 25 in the Angle (dd.mmss) field, choose NE in the Type field and then enter the distance of 100 in the Distance field.

With **Process Elevations** checked, all elevations will be translated by the specified or calculated Delta Z value. This option is very useful in correcting point elevations after performing a survey with assumed elevations and then later surveying into a benchmark with known true elevation. In this case only the Delta Z value, use (-) to indicate a lower correction, and the range of points to translate would be required for a translation. For example if the entire job needed to be lowered by 5', the Delta Z would be defined as -5 and the Range of Points defined as ALL.

Ignore Zero Elevations is only available when Process Elevations has been chosen. With this option checked ON, all points with an elevation of 0 will be ignored resulting in no translation taking place on these points.

With **Translate Screen Entities** checked ON, after specifying the point range or group to translate and selecting OK on the dialog box the following command line prompt is displayed:

Select objects to rotate (points excluded):

At this prompt select the objects on the screen, polylines, lines, arc, etc., to also translate and press enter. The translation of the points and screen entities will be completed.

Various **Output Options** for the translated points are available.

Overwrite Existing Coordinates will overwrite the existing coordinate points with the new translation coordinates thus changing the coordinate values in the existing crd file.

New Point Numbers will assign new point numbers to the translated coordinate points and leave the original co-

ordinate points unchanged and present in the coordinate file. When using this option, on the Range of Points to Translate dialog, there is a Value to add to point numbers field. In this field, enter the value to add to the point numbers. For example if the existing point numbers are 1-20, and the value to add is 100, the resulting new point numbers will begin at 101 and end at 120.

New CRD File will place the translated coordinates in a new crd file. After selecting OK to the range of points to translate dialog, the Coordinate File to Create dialog will appear. On this dialog enter the name of the new crd file and select save. The original crd file will remain unchanged and the new file will contain the points with the translated coordinates.

Specifying the points to be translated is accomplished either by specifying a **Range of Points** (1-20,33,36-40....) or by **Point Groups**. If using the Point Group option, the Select Point Group(s) dialog box will be displayed allowing for the selection of the Group(s) to rotate.

The **Description Match** option only translates points with the description(s) specified in this field.

Undo Last Translation restores the points to their previous location before translation. It is important to note that if Translate Screen Entities has been checked to restore the translated objects to their previous location will require the use of the undo command located in the Edit pulldown.

The AutoCAD command *MOVE* can be used to translate points on the screen but this does not update the coordinate file unless you have the option Link Points with CRD File turned ON in *Configure* . (Note: This toggle must have been turned ON prior to locating the points). If you do use the *MOVE* command and the CRD file needs updating, run the command *Update CRD file From Drawing* found in *Coordinate File Utilities*.

Pulldown Menu Location: Points

Keyboard Command: transpt

Prerequisite: points in a coordinate file

Rotate Points

This command rotates points in a coordinate file. The degrees of rotation can be entered directly or calculated from original and destination bearings or azimuths.

Rotate Points

Degrees of Rotation (dd.mmss)

Rotation Point

X: Y: Point #:

Original Bearing(Qdd.mmss)/Azimuth(dd.mmss)

Bearing Azimuth From Pt#: To Pt#:

Destination Bearing/Azimuth

Bearing Azimuth From Pt#: To Pt#:

Rotate Screen Entities

Output to...

Overwrite Existing Coords New Point Numbers

Range of Points Highest Point Number > 356

Description Match Value to add to point numbers

The **Rotation Point** will remain unchanged while the points specified for rotation rotate around it. This point can be specified by using the **List** button to pick from a list of points contained in the coordinate file, or from the screen by using the **Pick** button. The rotation point can also be defined by a coordinate value by manually entering in the X and Y values of the point. This point must be defined before the rotation will take place.

The **Original Bearings/Azimuths** and **Destination Bearings/Azimuths** can be entered directly or specified by point numbers. If using a pair of points to define the original bearing and then specifying the destination bearing by entering in the desired Bearing/Azimuth, the From and To Pt# fields should be left blank in the destination bearing/azimuth settings. Use the From and To Pt# fields in the Destination Bearing/Azimuth when you want to make a direction or Bearing/Azimuth between two existing points match the Bearing/Azimuth between two other existing points within the file. For example, to make the bearing between points 10-12 match the bearing between points 25-26, the Original Bearing/Azimuth could be defined as From Pt#10 To Pt#12 with the Destination Bearing/Azimuth defined as From Pt#25 To Pt#26.

With **Rotate Screen Entities** checked ON, after specifying the point range or group to rotate and selecting OK on the dialog box the following command line prompt is displayed:

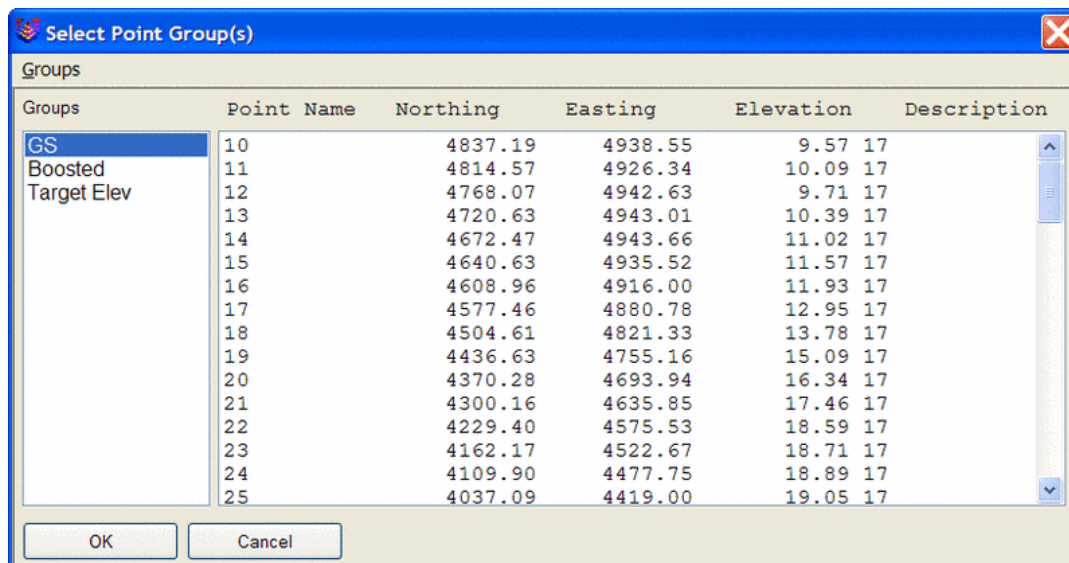

Select objects to rotate (points excluded):

At this prompt select the objects on the screen, polylines, lines, arc, etc., to also rotate and press enter. The rotation of the points and screen entities will be completed.

Various **Output** options for the rotated points are available.

Overwrite Existing Coordinates will overwrite the existing coordinate points with the new translation coordinates thus changing the coordinate values in the existing crd file.

New Point Numbers will assign new point numbers to the translated coordinate points and leave the original coordinate points unchanged and present in the coordinate file. When using this option, on the Range of Points to Translate dialog, there is a Value to add to point numbers field. In this field, enter the value to add to the point numbers. For example if the existing point numbers are 1-20, and the value to add is 100, the resulting new point numbers will begin at 101 and end at 120.

Specifying the points to be rotated is accomplished either by specifying a Range of Points (1-20,33,36-40....) or by Point Groups. If using the Point Group option, the Select Point Group(s) dialog box will be displayed allowing for the selection of the Group(s) to rotate.

The **Description Match** option only rotates points with the description(s) specified in this field.

The points that have been specified for rotation that are present in the drawing will be graphically updated to their new location in addition to an automatic update of the coordinate file.

Undo Last Rotate restores the points to their previous location before rotation. It is important to note that if Rotate Screen Entities has been checked to restore the rotated objects to their previous location will require the use of the undo command located in the Edit pulldown.

Keyboard Command: rotatept

Prerequisite: points in a coordinate file

Align Points

This command translates a specified Range of Points or Points Group(s) based on a source point and destination point and then rotates to align the first source point and a second source point with the first destination point and a second destination point. The command basically combines the Translate and Rotate Point commands. To specify a Range of Points to align, enter the range to align or select a point group(s) by selecting the Point Group button. Each of the Translation and Rotation points, both Source and Destination points, can be entered manually or picked from the point list by selecting the List button.

Align Points (Translate and Rotate)

Range of Points: 1-311 Point Group

Translation Points

First Source Point
X: 15502.93972 Y: 79257.05119 Z: 1452.000000 Point#: 2 List Pick

First Destination Point
X: 15488.99039 Y: 79547.48899 Z: 1434.600000 Point#: 45 List Pick

Rotation Points

Second Source Point
X: 15619.72502 Y: 79613.66199 Z: 1481.170000 Point#: 6 List Pick

Second Destination Point

Align Screen Entities Ignore Elevations

DX: -13.949 DY: 290.438
Rotation (dd.mmss): 1.5901

OK Cancel Help Undo Last Align

When **Align Screen Entities** is checked, after specifying the point range or group to align and selecting OK on the dialog box the following command line prompt is displayed:

Select objects to rotate (points excluded): At this prompt select the objects on the screen, polylines, lines, arc etc., to also align and press Enter. The alignment of the points and screen entities will be completed.

When **Ignore Zero Elevations** is checked, all points with an elevation of 0 will be ignored in the alignment.

Undo Last Align restores the points to their previous location before alignment. It is important to note that if Align Screen Entities has been checked to restore the aligned objects to their previous location will require the use of the

undo command located in the Edit pulldown.

Pulldown Menu Location: Points

Keyboard Command: alignpt

Prerequisite: Points in a coordinate file

Scale Points

This command scales points in a coordinate file. The northing, easting and optionally the elevation are multiplied by the specified scale factor. You can use this routine for Metric-English conversion or a specific conversion by choosing the Use Customized Scale Factor option and specifying the desired Scale Factor in the edit box.

The screenshot shows the 'Scale Points' dialog box with the following settings:

- Points and Entities To Process:**
 - Range of Points: 1-4002
 - Point Group: (button)
 - Description Match: *
 - Highest Point Number: 4002
- Output to...:**
 - Overwrite Existing Coords
 - New Point Numbers
- Scale Screen Entities
- Value to add to point numbers: (text box)
- Scale Factor:**
 - Scale Factor: (text box)
 - Calculate Combined Factor: (button)
 - Ignore Elevations
- Base Point:**
 - N(y): 0.0
 - E(x): 0.0
 - Point #: (text box)
 - List: (button)
 - Pick: (button)
- Use Customized Scale Factor
- Source Coordinates:**
 - Metric
 - US Feet
 - International Feet
- Destination Coordinates:**
 - Metric
 - US Feet
 - International Feet
- Warning: this command scales the coordinates in the CRD file.
- OK: (button)
- Cancel: (button)

Specify the **Range of Points** to scale by entering in a range or group to scale. You can access the group dialog box by typing "group" in the range of points field.

The **Description Match** option only scales points with the description(s) specified in this field.

The **Scale Factor** is to be entered in manually when using a customized scale factor. If converting from standard measurement units, feet to meters, meters to feet, US Feet to International Feet, etc., the scale factor will be calculated and entered automatically. If a combined scale factor is required for converting from ground to grid and grid to ground coordinates, this value can be calculated by using the **Calculate Combined Factor** option. The Combined Factor is the Elevation Factor times the Grid Factor. This calculation process begins with the Calculate Scale Factor dialog shown below.

The **Projection Type** must be specified as either State Plane 83 or State Plane 27 as well as what state plane **Zone** is required.

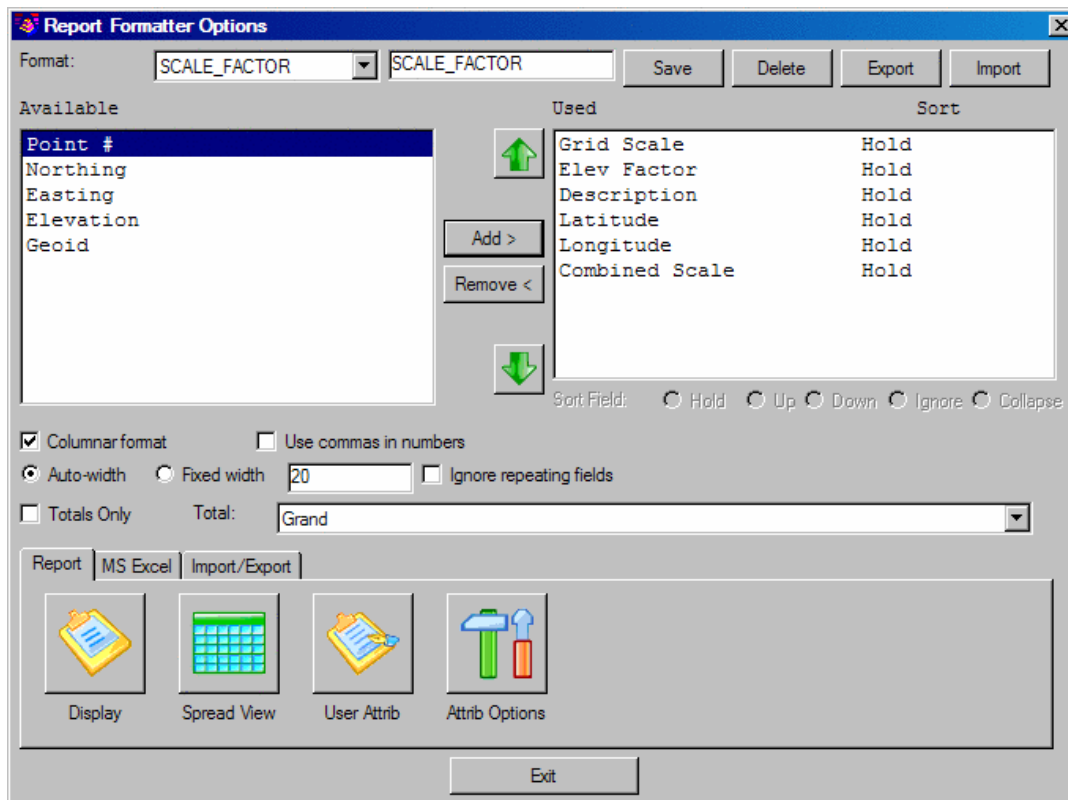

The available **Coordinate Units** are Metric, US Feet and International (Intl) Feet. The correct unit must be specified before calculating the combined scale factor.

The **Range of Numbers** to Process should be used to select the points to be used in order to calculate the combined scale factor. This does not specify what points are going to be scaled by the resulting scale factor. These points can be selected from a list by selecting the **List** button.

Scale Direction determines which way the scale factor will be calculated. A scale for **Ground to Grid** or **Grid to Ground** can be calculated and applied.

Pressing the **Calculate** button will calculate and then display the combined scale factor on the dialog box. To accept this value as the customized scale factor to use to scale the points in the coordinate file, press the **OK** button.

The **Report** option displays a report showing specified information. This information is specified by using the report formatter found throughout the program. Simply choose the information you wish to display and the order to be displayed. For further instruction and information on the Report Formatter please refer to the Report Formatter section of this manual.

With **Align Scale Entities** checked ON, after specifying the point range or group to scale and selecting OK on the dialog box the following command line prompt is displayed:

Select objects to scale (points excluded):

At this prompt select the objects on the screen, polylines, lines, arc, etc., to also scale and press enter. The points and screen entities will be now be scaled and updated graphically and in the active coordinate file.

With **Use Customized Scale Factor** Off, various conversions can be performed by specifying the Source Coordinate units and the Destination Coordinate units. This is a quick and easy way to perform Metric/English conversions.

Pulldown Menu Location: Points

Keyboard Command: scalept

Prerequisite: points in a coordinate file

Move Points

This command allows you to move Carlson points, one at a time by selecting any part of the point. Each Carlson point is made of three entities: a POINT entity, a symbol, and a point attribute block with the point number, elevation and description. This routine updates the X,Y of the point and not the Z. To update the elevation, use commands such as Edit Point Attributes or Translate Points. All these parts of the point are moved together with this routine. Any point moved using this command will result with the original source coordinate file (which is not necessarily the current coordinate file) updated with the new position of the point. Setting the Link Points with CRD File from Carlson Configure->General Settings is not necessary because the coordinate file is always updated since the Move Points command has built-in smarts to lookup the coordinate file for the selected point entity. The Link Points settings applies to generic CAD commands like the regular Move command.

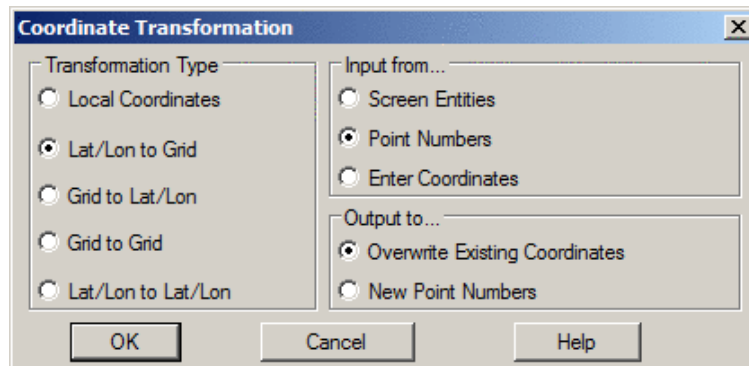

Pulldown Menu Location: Points

Keyboard Command: mpnt

Prerequisite: Carlson points

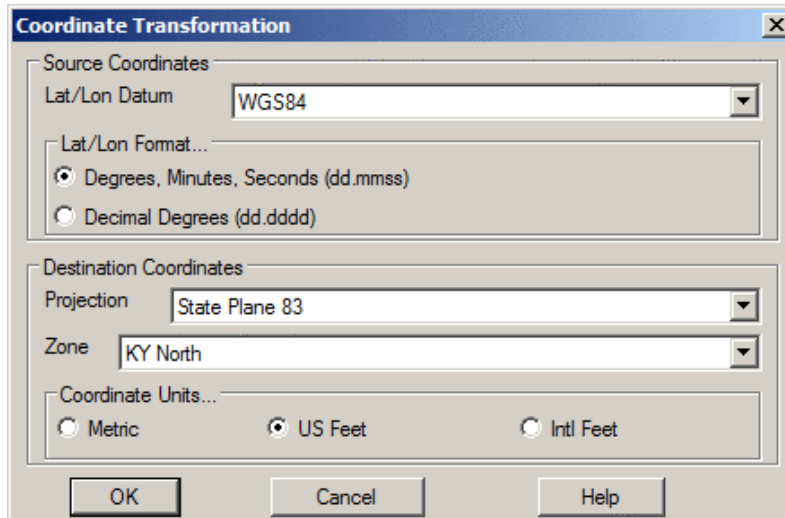

Coordinate Transformation

Transforms coordinates between local, State Plane 27, State Plane 83, Latitude/Longitude, Universal Transverse Mercator (UTM) and many other projections, including regional and user-defined projections. This works on individually entered coordinates, by range of point numbers and with on-screen entities. For converting between State Plane 27 and 83 within the USA, Carlson calls upon NADCON from the National Geodetic Survey to apply the Latitude/Longitude adjustment. Converting between NAD27 and NAD83 for Canada is supported using NTV2 grids.

The Transformation Type is used to define the Source Coordinate and Destination Coordinate formats. Settings for Lat/Long Datum, Lat/Long formats (dd.mmss or dd.dddd), Projections, State Plane Zones and coordinate units are defined in the Transformation Type dialog. The format of this dialog will change depending upon the type of transformation requested.

For Grid to Grid transformations, the program converts between state plane projections as well as other pre-defined and user-defined. When converting between pre-defined/user-defined projections, the program automatically converts the source grid coordinate to latitude/longitude and then to the destination grid coordinate. This method of using latitude/longitude works for converting between projections that share the same datum.

Example Lat/Long to Grid dialog

For all Transformation types, there are three options for inputting the data to be transformed. Data can be selected from the screen by using the **Screen Entities**. If a range of points or a particular point is desired, the **Point Numbers** option would be used. Manual entry of coordinates to transform one at a time is accomplished with the **Enter Coordinates** option. The coordinates can be typed in or use the Input Point Number option. Output Point Number is an option to store the results in the coordinate file.

For all transformations there are two output options when using point numbers as the input data. **Overwrite Existing Coords** replaces the original coordinate values with the new coordinate values after transformation. **New Point Numbers** will retain the original coordinate data and point numbers and create new point numbers with the revised coordinate data after transformation.

When transforming a **Local Coordinate System**, there are three options for defining the transformation as shown in the next dialog.

The **Enter Transformation Parameters** method prompts for the translate, rotate and scale parameters. The Base X and Y are used for the rotation and scale. The Load and Save functions store and recall the parameters to a .DXY file.

The **Align by Two Pairs of Points** option uses two pairs of source and destination coordinates. The first pair defines the translation as the difference between the source and destination northing and easting.

Local Coordinate Transformation

Translation Points

First Source Point
 Northing: 4768.07489136 Easting: 4942.62719383 Point #: 12

Second Destination Point
 Northing: 4661.03001519 Easting: 4038.39555830 Point #: 129

Scale Points Scale: 1.04034394

OK Cancel Help

This destination point is also the pivot point for rotation. Rotation can be entered directly or defined by a second pair of points where the bearing between the first and second source points is rotated to align with the bearing from the first and second destination points. There is an option to also apply scaling. The scaling holds the angle between points and adjusts the distances by the scale factor. The scale factor is calculated for each point as the elevation factor at the first source point times the grid factor at the first destination point averaged with the elevation factor at the transform point times the grid factor at the transform point.

The **Least-Squares Best-Fit** option is used when there are more than two pairs for translation points. Since two pairs of points are sufficient to define the translation and rotation, more than two pairs of points provides more than enough information.

Local Coordinate Transformation

Add Edit Delete Optimize Report Process On/Off

OK Cancel Load Save Help

Over Determination by Plane Similarity is used to find the least squares best fit transformation for all the given source and destination points. Besides doing a translation and rotation, this option will also scales the points during the transformation. The **Rigid Body Transformation** also does a best fit least squares transformation, but applies

only translation and rotation with no scale.

The **Helmert 7-Parameter** method can also be used for local transformations. The 7-Parameter Values can be calculated from control points or entered by the user. The program uses the Helmert Transformation, Strict formula:
 $[X_t \ Y_t \ Z_t] = [dX \ dY \ dZ] + M * R * [X_s \ Y_s \ Z_s]$
where R is the rotation matrix.

The Transformation Type chooses between doing a 2D transformation and 3D transformation. For the 3D transformation, the program transforms the x/y using the same method as the 2D transformation, and the z is transformed using an elevation difference model that is modeled by either a best-fit level plane or tilted plane as set by the **Vertical Transformation** setting.

The **Add** button is used to define the source and destination coordinates for the points that define the transformation. Pressing this button brings up the following dialog box.

Source Coordinate	
Point Number	34
Northing	4048.75387
Easting	4088.82307
Elevation	17.97471

Destination Coordinate	
Point Number	243
Northing	4326.12568
Easting	4377.69479
Elevation	20.10343

The **Edit** button is used to edit existing data.

The **Delete** button removes the source and destination pairing from the transformation setup.

The **Process On/Off** button allows source and destination pairings to be turned on and off. This is useful when wanting to inspect different results using different pairings.

The **Optimize** option chooses which point pairings would yield the best transformation results by turning off the processing of pairings with higher residuals. This minimizes the average residual for the control points.

The **Report** option displays a report of the transformation point pairings, their residuals, processing status, transformation scale and avg. residual.

The **Load** and **Save** options allow for saving and recalling local coordinate transformation pairings and settings.

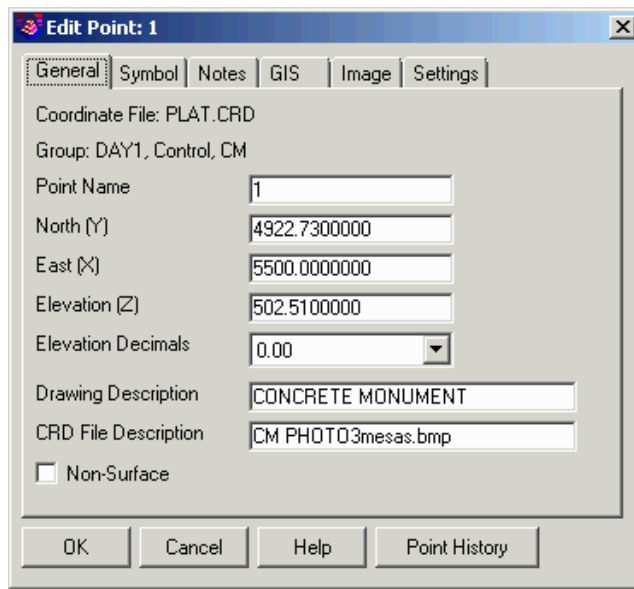

Pulldown Menu Location(s): Points

Keyboard Command: cfutransform

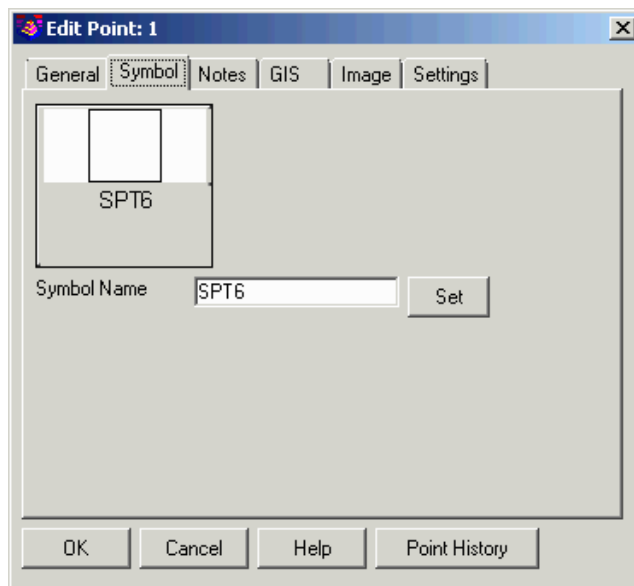

Prerequisite: Drawing entities or coordinate points

Edit Point Attributes

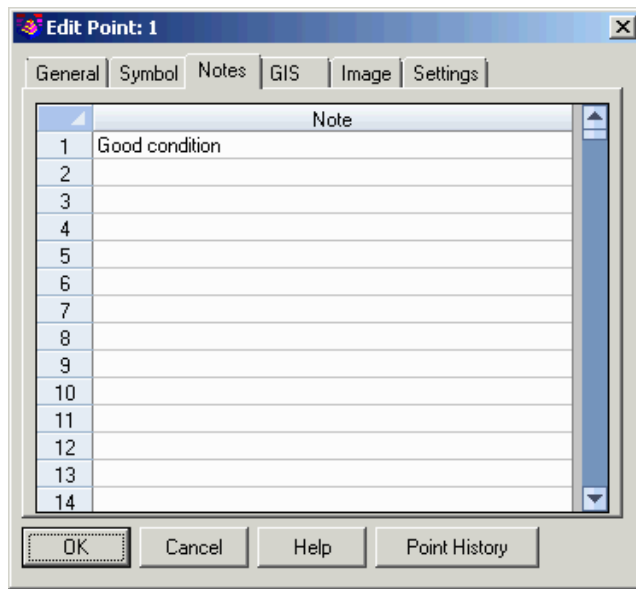

This command will edit the attributes of a Carlson point, such as the symbol type, point number, elevation and description. When this command is invoked, the command line will prompt the user: **Select point to edit (Enter to end)**. At this point, you can select any part of the point including the symbol, elevation, point number or the description. Next, a dialog will appear as shown.

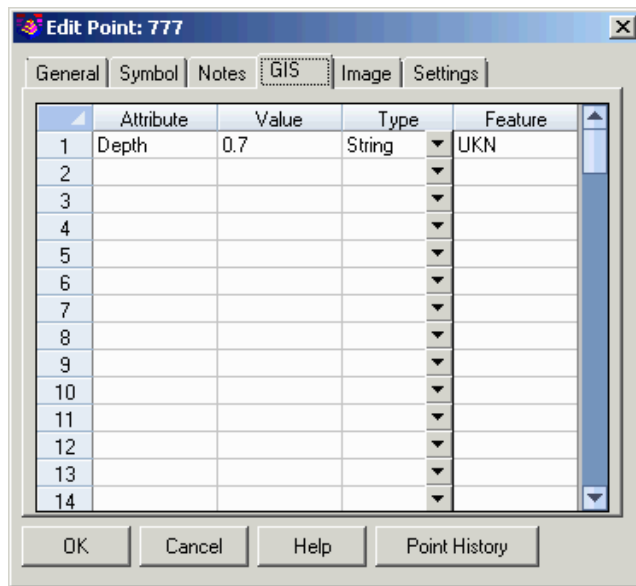

The dialog has several tabs. On the General tab, the name of the coordinate file for the point is displayed at the top along with any point groups that contain this point. The Elevation Decimals setting for the point elevation label. Both Drawing Description and CRD File Descriptions are displayed. When a change to the Drawing description is made, this change will not be reflected in the coordinate file. This allows the change of a description that is defined in the Field to Finish (fld) table for a particular code. If a change is made in the CRD File description, it will be reflected in the coordinate file. Take note that if the CRD file description is changed, running Field to Finish will change the definitions for the point changed. If you change the point number to a number that already exists in the current CRD file, and point protect is ON, you will be prompted whether to overwrite or renumber. The Non-Surface toggle controls whether this point is filtered out in surface modeling with Triangulate & Contour. This Non-Surface setting is the same that the Non-Surface Points routines use in the 3D Data menu. The properties that you modify, with the exception of Drawing Description, will update the current CRD file. All modifications will update the point screen entities. Edits to the elevation and Non-Surface setting will update any triangulation surface created by Triangulate & Contour that used the point for input.

To change the symbol, go to the Symbol tab and either type in a new symbol name in the edit box, or choose the Symbol or Set button where you can choose from a list of symbols from the Symbol Library.

On the Notes tab, you can edit notes for the point. These notes are free-form additional descriptions for the point.

On the GIS tab, you can edit GIS attributes for the point. These GIS attributes are only available for CRDB format coordinate files. See the GIS Data section of the manual for more information on the CRDB GIS data.

The Image tab shows any images assigned to the point. The Open function will open the image in the image program set in Windows for the image file type. The Add and Remove functions are to add and remove images assigned to the point. The Next and Previous buttons are for selecting different images when the point has multiple images.

The Settings tab has a control for the number of decimals to use in the dialog.

Selecting the Point History button will bring up another dialog box that displays the point history of the point chosen. A history of the point will be listed, but only if, under General Setting, the Maintain CRD History File had been set to ON (selected) for the coordinate file that you are working with. With the CRD History feature of Carlson, all point changes can be rolled back.

You may also choose to use the *CAD DDATTE* command to change the attributes of a point. If you do this, then the CRD file will not be updated and if you change the elevation attribute, the point will not change its current Z location.

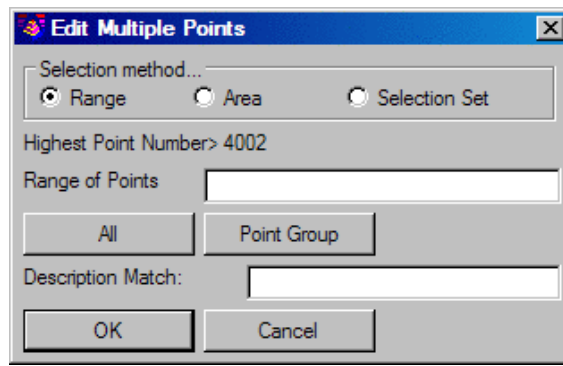

Pulldown Menu Location: Points

Keyboard Command: editpnt

Prerequisite: Carlson points

Edit Multiple Pt Attributes

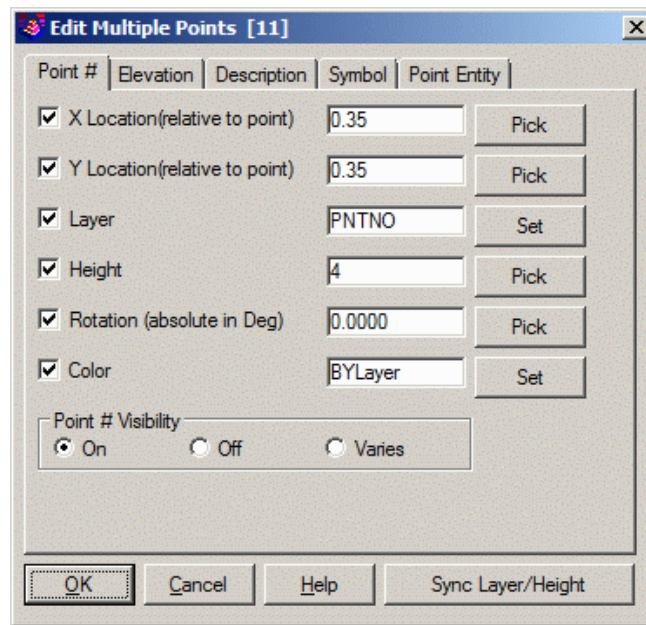

This function allows you to modify the properties of multiple point attributes at the same time. This command gives you complete control over the Carlson point attributes that are present in the drawing. Changes can be made to each attribute – the point number, elevation, description or symbol – all in one motion. For example, you could rotate the elevation text of some points to 45 degrees, change the height of the description text for all the points in the drawing, or change the layer for a particular attribute. Once this command is chosen, the entry Edit Multiple Points dialog, a smaller box, appears. Here you can determine your point selection method. There is also an option for description matching.

After the selection of the points to change, click OK, and the subsequent, larger Edit Multiple Points dialog boxes will appear. The number of points selected will be shown at the top of the dialog boxes.

Edit Multiple Points dialog

For each attribute, you can change any number of the properties, including the layer, height and rotation. These dialogs will reflect the current status of each attributes properties. If, for example, you select 10 points, and 5 of them have the elevation rotation set at 45 degrees, and the other 5 are set at 0 (zero) degrees, then the rotation edit field will say *varies* to let you know that the properties of the points you selected are not the same. Here is an example of the dialog box.

The **X location** refers to the distance in the X direction from the center (or insertion point) of the point symbol. The **Y location** refers to the distance in the Y direction from the center (or insertion point) of the point symbol.

The **Layer** refers to the layer of the individual attribute, not the entire attribute block. To change the layer of the entire attribute block, use the **Attribute Block Layer** option. The **Height** is expressed in real units (generally feet or meters), not plotted size. The **Rotation angle** is expressed in absolute decimal degrees. The **Color** can be set ByLayer or to a specific color. The **Point Entity Layer** refers to the layer that the node of the point resides. The required layers can either be typed in manually, or the Select button can be used to pick from the existing layers in the drawing. If a new layer is desired, simply type in the name of the new layer and it will be created automatically. Use the layer property manager to edit the properties of this new layer, if required. The **Visibility** setting allows for attributes to be shown or hidden in the drawing.

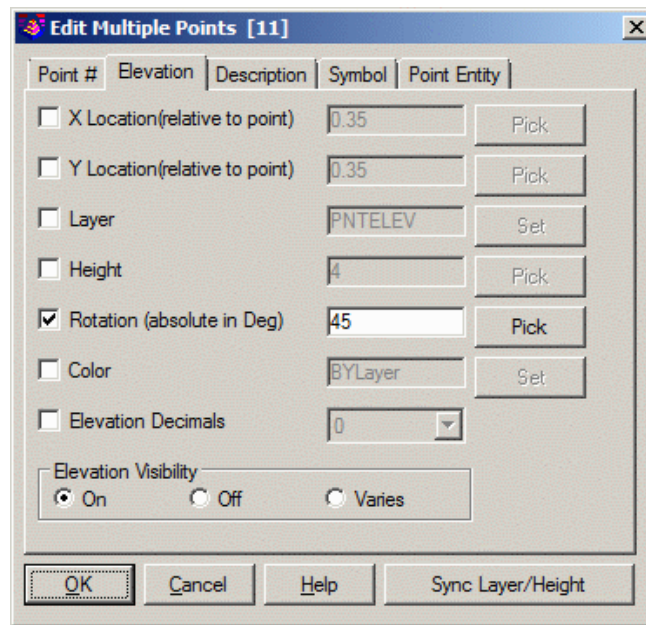

To change a point symbol, check on the **Symbol** tab and use the select button to choose the desired symbol. On the Point Entity tab, the **Attribute Layout ID** refers to the attribute layout style defined in Point Defaults or Field to Finish code definitions. This option allows you to change the particular layout with one of the other available styles or to a customized style if defined. The Pick buttons allow you to pick two points to define a distance (or angle in the case of Rotation). If you want to select a line to define a distance or angle, select two points on the line with the appropriate OSNAP.

Select the attribute to edit, make the necessary changes to this attribute and then move on to the next attribute if required. Changes made to the attributes are remember individually, which allows for switching back and forth though the attributes until the command is completed. After completion the new settings for the point attributes will be retained until changed or redrawn on the screen.

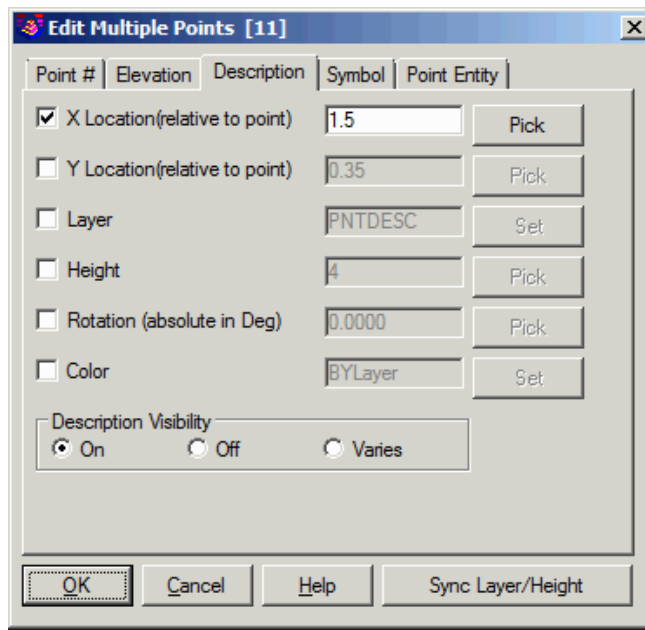

The **Sync Layer/Height** function sets the layer or height for some or all the attributes. The layer and height can be entered manually or pick an existing attribute to get the value. The **Save** and **Load** functions are a way to store and recall all the point display settings to a .PT file for having different point styles to reuse or share.

Example sequential use of Edit Multiple Points dialog

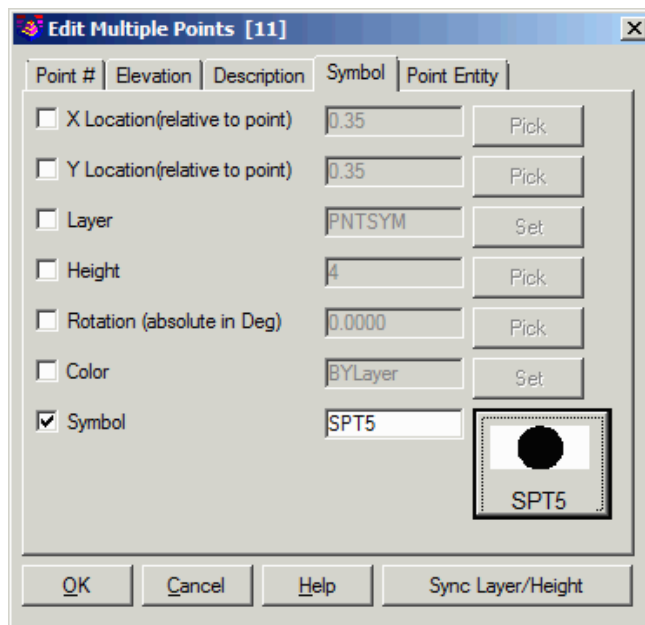

Again, the number of points selected will be shown in the dialog title. Let's now define the changes for each attribute individually. In the following example, suppose we want to rotate the elevation text to a 45 degree angle, move the description to the right and change the symbol. First, click on the Elevation for the Attribute to Edit. Now, select the Rotation option and type in 45. The dialog box should be as below.

Now, select the Description option for the Attribute to Edit. Select the X location from the Items to Change. Enter 1.50 in the box. This value makes the description line up better with the rotated elevation. The dialog should be as below:

Now, for the final change, select the Symbol for the Attribute to Edit. We want to actually change the point symbol. To do this, toggle on the option to change the symbol by clicking in the box beside the word Symbol. Next, press the Select button and select symbol SPT5. The dialog should be as below:

At this point we are ready to select the OK button to perform the changes. The following image shows the points before and after the changes.

Before and After Changes

Pulldown Menu Location: Points
Keyboard Command: modpnts
Prerequisite: Points drawn on the screen

Dynamic Point Attributes

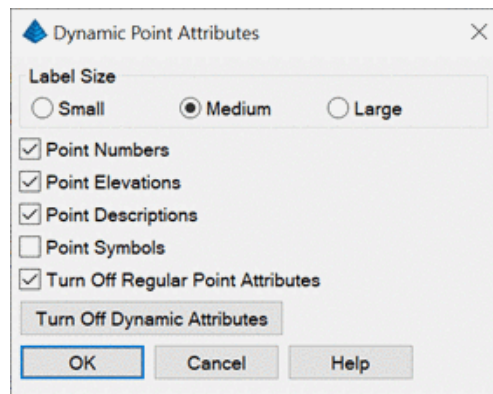

This command creates point attributes that dynamically resize to view in the current zoom level. This way the point labels appear the same size at any drawing zoom level. These point attributes are for viewing only and are not saved to the dwg file.

Label Size: Sets the label size.

Point Numbers, Elevations, Descriptions, Symbols: Choose which labels to view as dynamic.

Turn Off Regular Point Attributes: Hides the regular point entities in the drawing to make viewing the dynamic point attributes clearer.

Turn Off Dynamic Attributes: Turns off all the dynamic point attributes and returns to regular points.

Pulldown Menu Location: Points
Keyboard Command: pntlab
Prerequisite: Points in the drawing

Move Point Attributes Single

This command allows the user to move Carlson point attributes (including the point number, elevation or description) one at a time.

Prompts

Select Point Number, Elevation, or Description to Move: *select point attribute*

Pick new location: *pick point*

Pick new angle: *pick new angle or press Enter*

Pulldown Menu Location: Points

Keyboard Command: movepnt

Prerequisite: Carlson points

Move Point Attributes with Leader

This command allows you to move Carlson point attributes (including the point number, elevation or description), and to draw a dynamic leader to the point node. Leaders and arrowheads may be customized by selecting Options at the command line. If you redraw a point with Draw-Locate Points or Field-To-Finish, the program will recall the moved attribute location to redraw the attributes in the same location as long as the point coordinate is the same.

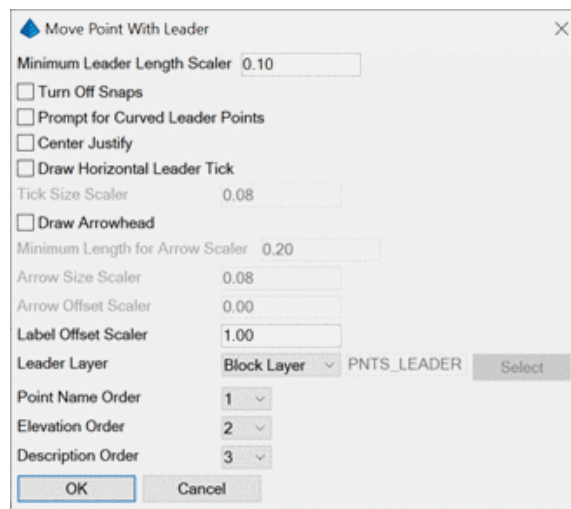

The **Options** keyword brings up the settings dialog shown below. The **Restore** function prompts to pick a point label that has been moved and puts this label back to its default position. The **Multiple** method moves all of the selected points instead of one at a time. The **Group** function selects the points to move by Point Group Name. The **Number** function selects the point to move by point number instead of screen pick.

Prompts

Select Point Label to Move [Options/Restore/Multiple/Group/Number]: *select point attribute*

Pick label position: *pick point*

Select another Point Label to Move [Options/Restore/Multiple/Group/Number]: *O*

Minimum Leader Length Scaler: Specifies the minimum length, in terms of multiples of the attribute block's height, that the leader must be.

Turns Off Snaps: Temporarily turns off any object snaps while picking the label position.

Prompt for Curved Leader Points: This option prompts for additional leader points and creates a smooth leader that goes through all the leader points.

Center Justify: This option uses center justification for the labels. Otherwise the attributes are always justified left or right depending on which side the leader starts.

Draw Horizontal Leader Tick: Specifies whether or not to draw a terminating tick (a short horizontal line segment

sometimes referred to as a "hook line").

Draw Arrowhead: Specifies whether or not to draw an arrowhead at the end of the leader that points to the point entity.

Minimum Leader for Arrow Scaler: Specifies the minimum length of the leader, in terms of multiples of the attribute block's height, that the leader must be before an arrowhead is placed on it.

Arrow Size Scaler: scale factor to apply to resize the arrowhead symbol.

Arrow Offset Scaler: distance from the point node to the tip of the leader.

Leader Offset Scaler: distance from the end of the leader and the labels.

Leader Layer: Specifies whether to use a layer other than that of the identified point for the leader. Use the **Select** button to choose an alternative layer for the leader.

Point Name Order, Elevation Order and Description Order: These settings control the sequence of the attributes for the leader.

Pulldown Menu Location: Points

Keyboard Command: movepntleader

Prerequisite: Carlson points

Scale Point Attributes

This command will scale point attribute text (number, elevation and descriptions) and point symbols up or down in size. The routine prompts for a scale multiplier and a selection set of objects. If you want to enlarge, enter a value greater than one. If you want to reduce, enter a decimal fraction such as .5. This would reduce the text size by 50%. This command is very useful if you have set up your drawing for one plotting scale and decide to change to a new plotting scale. This command has the added benefit that it will adjust the point attributes and symbols to a new screen twist angle.

Prompts

Scaling Multiplier <0.500>: 2.5 This response would enlarge the point attributes and symbols by 250 percent.

Scale symbols only, point labels only or both [Symbols/Labels/<Both>]? *press Enter*

Select points from screen, group or by point number [<Screen>/Group/Number]? *press Enter*

Resize Point Attributes

This command sets the size of the selected point attributes (point number, elevation, description) and point symbols. This command is similar to Scale Point Attributes, but instead of scaling the size by a factor, all the select points are set to the same specified size. Points can also be chosen based upon Point Groups.

Prompts

Enter point attribute and symbol size <4.0>: *press Enter*

Scale symbols only, point labels only or both [Symbols/Labels/<Both>]? *press Enter*

Select points from screen, group or by point number [<Screen>/Group/Number]? *press Enter*

Select Carlson Software points.

Select objects: *pick the point entities*

Finding Carlson Software Point Attributes

Number of entities changed > 10

Pulldown Menu Location: Points
Keyboard Command: sizepnt
Prerequisite: Carlson points

Mask Point Attributes

This command creates wipeouts behind the selected point attribute labels (point number, elevation and description) to hide other drawing entities that cross the point attributes.

Prompts

Select point attributes to mask.
Select objects: *pick points*
Offset <0.100>: *press Enter*

Pulldown Menu Location: Points
Keyboard Command: ptmask
Prerequisite: Points

Trim by Point Symbol

This command will trim lines and polylines that pass through the selected point symbols such that the lines do not appear within the symbol. This should be a last step because this routine explodes the points and modifies the lines and polylines by trimming which makes these entities unusable by some of the other COGO routines.

Prompts

Select Carlson Software point symbols to trim against.
Select objects: *select the point symbols*

Before Trim by Point Symbol

After Trim by Point Symbol

Pulldown Menu Location: Points
Keyboard Command: trimpts
Prerequisite: Carlson point symbols

Freeze Point Attributes

This command freezes the point attribute layers for all Carlson points in the drawing. The attribute layers include the point number, elevation and description. This command is a quick way to hide all point attributes from view without erasing them. Use the Thaw Point Attributes command to show the points again.

Pulldown Menu Location: Points > Point Utilities
Keyboard Command: freeze_ptattr
Prerequisite: Carlson points

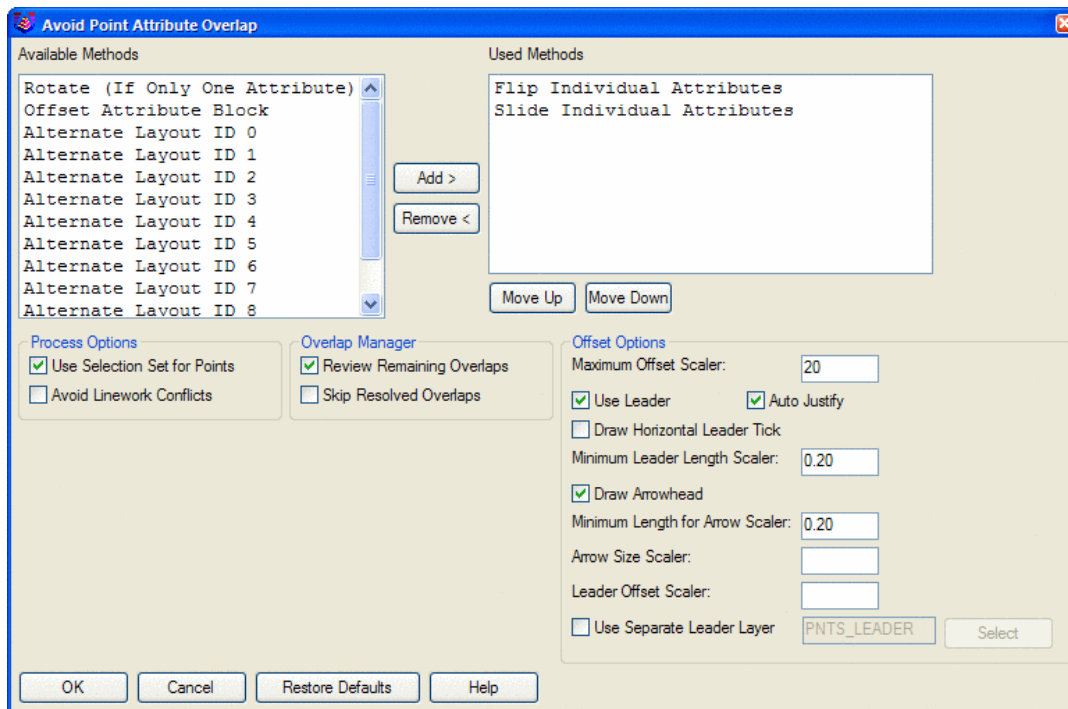

Thaw Point Attributes

This command thaws the point attribute layers for all Carlson points in the drawing to show the point number, elevation and description attributes.

Pulldown Menu Location: Points
Keyboard Command: thaw_ptattr
Prerequisite: Carlson points

Fix Point Attribute Overlaps

This command is to be used to adjust point attribute labels to avoid overlapping labels. It applies adjustment methods based upon user-specified ordering and tolerances. The command steps you through any remaining overlaps in an Overlap Manager, which includes the capability to manually move labels. This point overlap feature is also available within the Draw-Locate Point and Field To Finish commands.

Methods: There are different methods of automatically solving a point attribute overlap. The methods will be applied in order from top to bottom on the Used Methods list. Unused methods appear on the Available Methods list. The methods are:

Alternate Layout ID 0-9

These methods will simply apply the specified attribute layout ID and then check to see if the attributes of the point in question still overlap. The different attribute layout IDs can be seen in the *Point Defaults* command on the Points menu.

Flip Individual Attributes

This method tests each attribute (point #, description, and elevation) by flipping it or mirroring it the other side of the point. The mirror is the vertical axis of the text that goes through the point entity. This method is not applied to points that have a leader.

Slide Individual Attributes

This method tests each attribute (point #, description, and elevation) by sliding it back and forth. The maximum distance the attribute will be moved is the horizontal length of the text. This method is not applied to points that have a leader.

Rotate (If Only One Attribute)

This method is applied if there is only one point attribute, either point #, description, or elevation. The one attribute is rotated around the point entity to see if the point overlap can be fixed.

Offset Attribute Block

This method is arguably the most powerful method and can solve any overlap by moving the attribute block far enough. See *Offset Options* below for a description of the options that can be used with this method.

Offset Options: These are the options that apply to the Offset Attribute Block method of automatically solving point attribute overlaps.

Maximum Offset Scaler: This specifies the maximum distance, in terms of multiples of the whole attribute block's height, that the attribute block may be offset from the point entity.

Use Leader: Specifies whether or not a leader should be drawn when offsetting the attribute block.

Minimum Leader Length Scaler: Specifies the minimum length, in terms of multiples of the height of an attribute's text, that the leader must be.

Draw Arrowhead: Specifies whether or not to draw an arrowhead at the end of the leader that points to the point entity.

Minimum Leader for Arrow Scaler: Specifies the minimum length of the leader, in terms of multiples of the height of an attribute's text, that the leader must be before an arrowhead is placed on it.

Arrow Size Scaler: Specifies a scale factor to be applied to control the size of the arrowhead if drawn.

Leader Offset Scaler: Specifies the length, in terms of multiples of the height of an attribute's text, that the leader arrowhead should be offset from the point.

Use Separate Leader Layer: If enabled, allows the user to define a different layer on which to place the resultant leader.

Use Selection Set for Points: Check this checkbox to be given the option of selecting which points in drawing to fix overlaps with. If not checked, then all the points in the drawing are used.

Avoid Linework Conflicts: Check this checkbox to prevent point attributes from overlapping linework in addition to other point attributes.

Review Remaining Overlaps: Check this checkbox to have the Overlap Reviewer dockable dialog come up after the automated process finishes. The Overlap Reviewer allows for reviewing the automated fixes as well as tools for manually fixing any remaining overlaps. See Overlap Reviewer below for more information.

Skip Resolved Overlaps: Check this checkbox to skip overlaps that were automatically resolved and to only review unresolved overlaps. If not checked, then both resolved overlaps and unresolved overlaps will be available for review. This option only applies if Review Remaining Overlaps is on.

Overlap Reviewer

The Overlap Reviewer will come up after automatic overlap fixing if the Review Remaining Overlaps checkbox was checked. This tool displays how many points were found, how many overlaps were fixed, which overlap is currently being viewed, how many overlaps there were total, and the point # of the current overlap. Use the First, Last, Back, and Next buttons to navigate forwards and backwards through the list of overlaps. Use the Move Block and Move Attrs buttons to manually move either the entire attribute block or individual attributes.

Pan and Zoom Controls: Use the buttons on the top to help zoom in and out and pan the drawing around. You can also use the standard mouse controls for panning and zooming.

First, Last, Back, and Next: These buttons allow you to step through each overlap or to jump to the first or the last.

Status: This drop-down list indicates the status of the current overlap. *open* means that the overlap has not been fixed yet. *resolved* means that the overlap has been fixed. *ignore* can be chosen by you to remove the overlap from the list.

Restore: Restores the attributes of the current point to their original location and rotation from before the Fix Point Attribute Overlaps command was run.

Move Block: Allows you to move one or more attribute blocks in the drawing. See the documentation for *Move Point Attributes with Leader* command in the Points menu.

Erase Attrs: Allows you to erase selected point attributes.

Move Attrs: Allows you to move and rotate one or more individual attributes in the drawing. See the documentation for *Move Point Attributes* command in the Points menu.

Auto-Zoom: Check this checkbox to automatically zoom and pan the view as each overlap is viewed.

Prompts

The following prompt will be displayed if the Use Selection Set for Points checkbox is on and OK is pressed.

Select the points to fix overlaps with: *pick the Carlson point inserts*

Pulldown Menu Location: Points

Keyboard Command: overlapppts

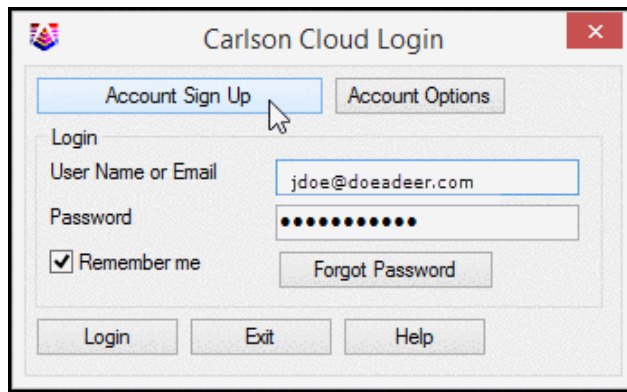

Prerequisite: Points in the drawing

Coordinate Cloud

The Coordinate Cloud command (not to be confused with the Carlson Point Cloud module) is an Internet/cloud-based routine designed to easily facilitate storing and sharing coordinate point information either publicly or privately.

Prior to using the coordinate cloud command, the user must have created a Carlson Cloud account.

Upon launching Coordinate Cloud, the user is challenged to provide login credentials as shown below:

- **Account Sign Up**
- **Account Options**

Username: Supply the user name (Case Sensitive) that you used when creating your Carlson Cloud account.

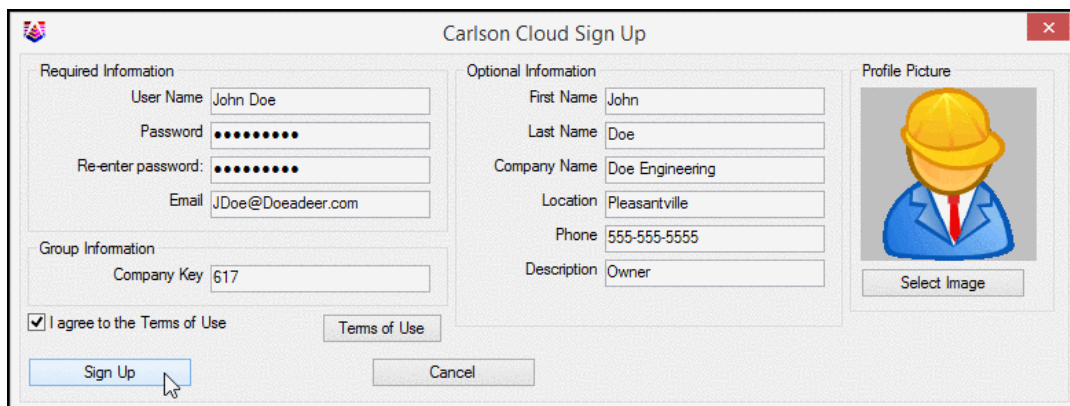

Password: Supply the password (Case Sensitive) that you used when creating your Carlson Cloud account.

Remember Me: When enabled, the last used *Username* and *Password* values are recalled for the next Carlson Cloud login session.

Forgot Password: Use if you have forgotten your password and need it emailed to you or reset.

Once logged in, refer to the Carlson Cloud - Logged In discussion.

The *Account Sign Up* command provides the ability to create a new user account and associate the user account with a "company key" (essentially, a group of people with whom you wish to network within Carlson Cloud). See the *Carlson Cloud* command for more information

Username: Supply the user name (this will be Case Sensitive) that you will want to use for your Carlson Cloud account.

Password: Supply the password (this will be Case Sensitive) that you will want to use for your Carlson Cloud account.

Email: Supply an Email address where password recovery instructions can be sent.

Optional Information: Supply your name, company, location, phone and additional description

Create Company Key: When enabled, this toggle permits you to create a new company "profile" (or communication group).

Existing Company Key: Indicate the name (Case Sensitive) of an existing company "profile" to which the new member should belong.

Read and agree to the **Terms of Use**

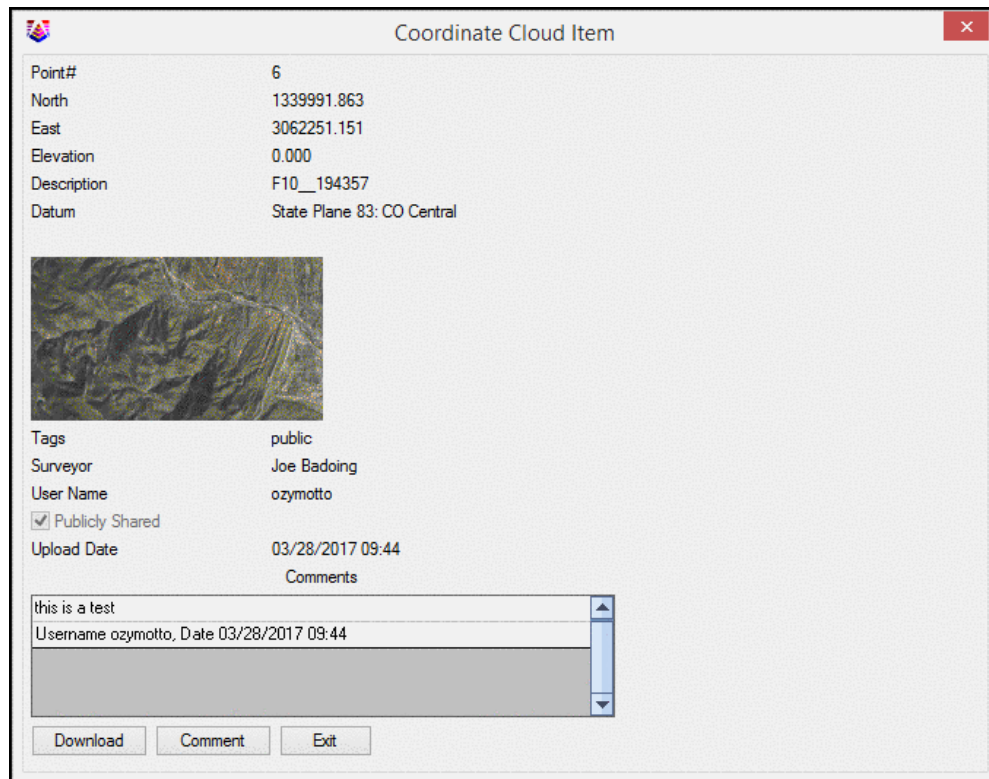

Sign Up: Click this button when complete

Show Public Points: When enabled, all points designated as public will be shown.

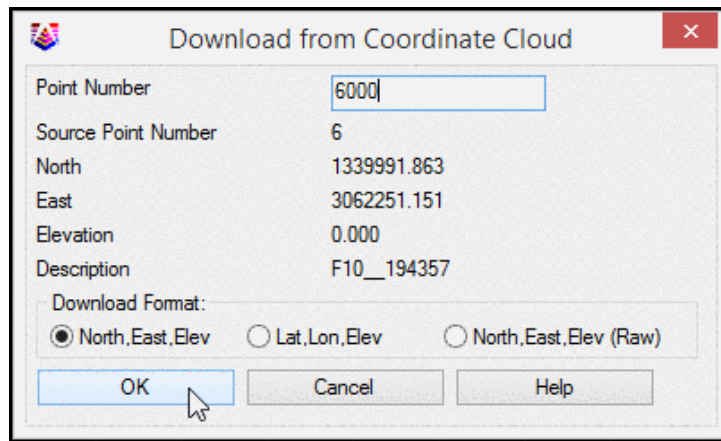

Search by Distance: Will control the search area by zip code, or distance in miles.

Select CRD File: Use this to select a coordinate file from which to upload point data.

View: Highlight a point from the display list and view the detailed information

Download: Download the point data into the current coordinate (CRD)file.

Upload: Upload point data from the current coordinate (CRD) file.

Export to Google Earth: Export the point data to Google Earth

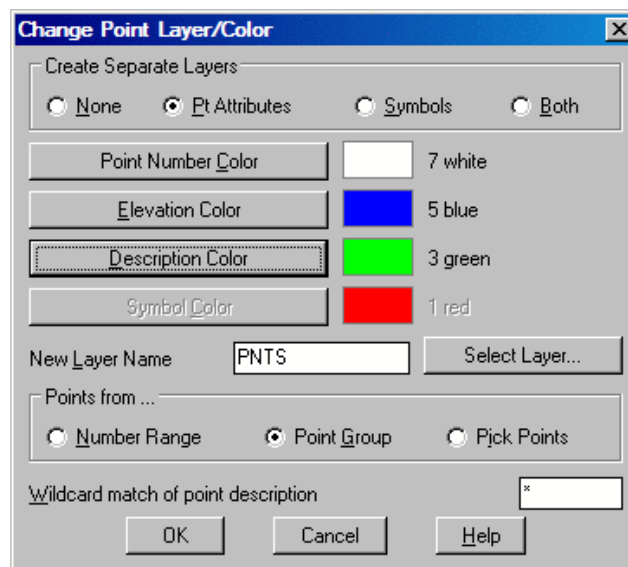

Pulldown Menu Location: Points->Point Utilities

Keyboard Command: crdcloud

Prerequisite: Internet connection, Carlson Cloud account

Change Point LayerColor

This command changes the layer and optionally the color of Carlson points. The points are initially put in the layer set in Point Defaults. The symbol, point number, elevation and description are in the layers PNTMARK, PNTNO, PNTELEV, and PNTDESC. To change the point attribute colors, this routine creates new attribute layers based on the new layer name. For example if the new layer name was TRAV, then the resulting layers would be TRAVMARK, TRAVNO, TRAVELEV and TRAVDESC. These new layers can be given different colors. To select an attribute color, pick on the color button. To permanently change attribute colors, edit the drawing SRVPNO1.DWG in the Carlson SUP directory. To permanently change a symbol color, edit the symbol drawing itself.

The selection of the points to change can be accomplished in three ways. A number range selection would require the input of the range of points to change. An example would be 1-20,25,30, 32-36. Points groups can also be used as a selection method. Simply specify the point group name to change, when prompted, and all the points included

in that group will be changed. The final selection method is that of Pick Points. Using this method a prompt to select objects is displayed. When prompted select the points to change from the screen.

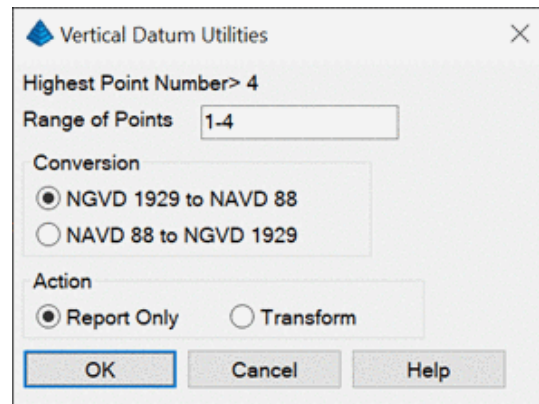

Pulldown Menu Location: Points

Keyboard Command: pntchg

Prerequisite: Carlson points displayed in the graphic drawing window

Vertical Datum Utilities

This command calculates the elevation difference between NGVD 1929 and NAVD 88 for points from the current coordinate file. Before running this command, the grid projection for the drawing must be defined in Settings > Drawing Setup so that the points can be geolocated. The Report Only option uses the Report Formatter to report the elevation differences. The Transform option updates the point elevations in the coordinate file.

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: vdatum_util

Prerequisite: Coordinate file

Link Linework With Points

This command links lines and polylines with points so that the linework updates if the points are updated. This link is the same as option under Carlson Configure > General Settings. The option in Configure is applied when the linework is created. This separate link command allows you to add links on selected linework in case the Configure link option was off when the linework was created.

In order to link points to the linework, the program matches points from the current coordinate file to the linework vertices. The Vertex Tolerance is how close the coordinate point needs to be to the linework vertex to create a link.

To remove point links, run File > Drawing Utilities > Remove Reactors.

Prompts

Enter Point to Vertex Tolerance <0.001>: *press Enter*

Select Lines and Polylines to Create reactors for.

Select objects: *pick the linework*

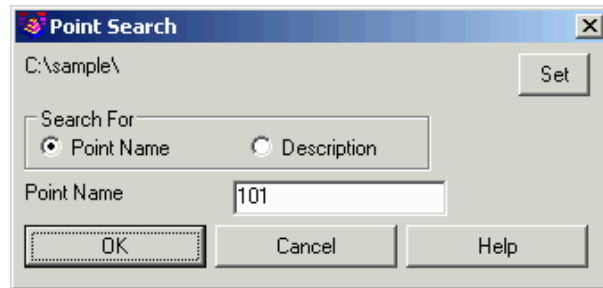

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: linkline

Prerequisite: Points and linework

Search Point Files

This command searches for a point number or description in coordinate and raw files in a folder. The program also searches in all sub-folders of the selected folder. The command reports all files that found a match.

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: ptsearch

Prerequisite: None

Point Attribute Layout Manager

This command helps manage the drawings that are used for Carlson Points for the point attributes of point number, elevation and description. To allow for up to ten different layout styles, there are ten point attribute drawings in the support folder. The support folder path is shown at the top of the dialog. The file names for the point attribute drawings are SRVPNO followed by a digit 0 to 9. For example, SRVPNO1.dwg.

The dialog shows a preview of the point attribute drawing. Select from the Attribute Layout ID list to see different drawings. The Edit function opens the point attribute drawing. Then you can make edits in CAD such as moving or rotating the attributes, and then save the dwg file. The Save and Load functions are a way to store and recall all 10 of the point attribute drawings to a single PBLK file. This provides a way to transfer custom point attribute blocks between computers.

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: pt_attr_mgr

Prerequisite: None

Geoid Utilities

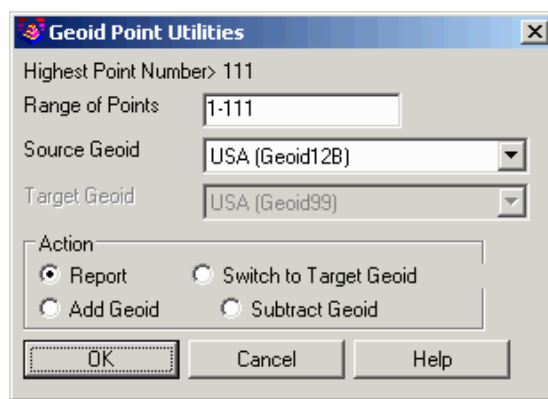

This command has functions for using a geoid with points in the current coordinate file.

Report: Reports the geoid heights at the points.

Add Geoid: Adds the geoid heights to the point elevations.

Subtract Geoid: Subtracts the geoid heights from the point elevations.

Switch To Target Geoid: Allows you to adjust the point elevations to switch from one geoid to another. The geoid used with the original point elevations is specified as the Source Geoid, and the geoid to switch to is set by the Target Geoid.

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: geoid_util
Prerequisite: Points in coordinate file

Renumber Points

This command edits point numbers. This function is also in Coordinate File Utilities. The points to renumber can be selected by point number range, point group, the area inside a closed polyline or by selecting points from the drawing. The Description Match is a way to filter which points to renumber. The Condense Points option removes any gaps in the point numbers to make the renumbered points sequential. There are five renumbering methods:

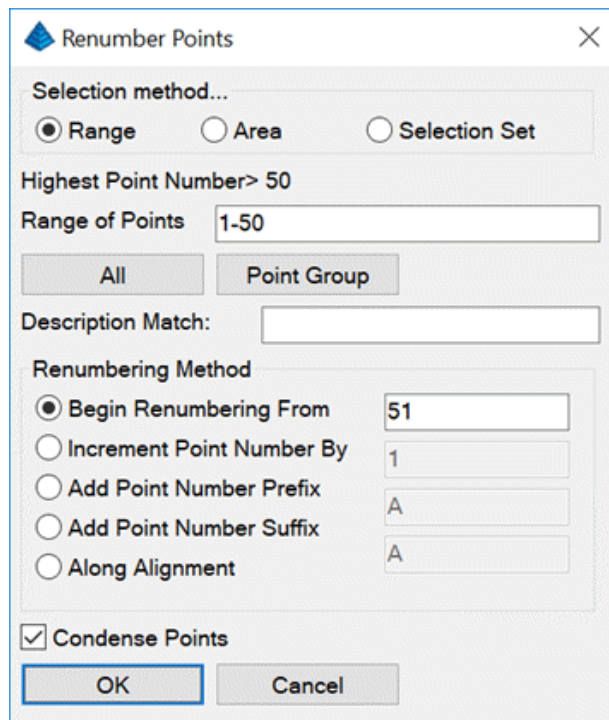

Begin Renumbering From: Points are numbered starting from the specified point number.

Increment Point Number By: Adds this number to the existing point numbers.

Add Point Number Prefix: Adds this string to the start of the existing point numbers.

Add Point Number Suffix: Adds this string to the end of the existing point numbers.

Along Alignment: Sequences the point numbers in station order along a centerline.

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: renumpnt

Prerequisite: Coordinate file

Explode Carlson Points

This command can be useful if you need to send your drawing to another firm who does not have AutoCAD/Carlson. Drawing transfer problems occur when the recipient does not have the same block/inserts defined or available. This command explodes all blocks and replaces the Carlson point attributes with TEXT entities of the same value. After the points have been selected, a prompt for the layer name for each point attribute will be displayed. Point Numbers, Point Elevations and Point Descriptions can be put on user specified layers, or the default for each prompt can be selected. **Caution:** After using this command, the link between the points and the coordinate file are destroyed and

you can no longer extract the attributes from the drawing. If you want to use this command but retain your point information, follow these steps:

1. Save your drawing
2. Run this command to explode the points
3. Execute the SAVEAS command and save the drawing as a different name (you can also choose DXF format if you wish).
4. Exit the drawing **without** saving.

Prompts

This command will explode selected Carlson Software point blocks and replot the attributes as Text entities! The resulting points will NOT be useable by most Carlson Software commands!!!!

Select Carlson Software Points to Explode. *select points*

Layer Name for Point Numbers <PNTNO>: *press Enter*

Layer Name for Point Elevations <PNTELEV>: *press Enter*

Layer Name for Point Descriptions <PNTDESC>: *press Enter*

Number of entities changed> 345

Pulldown Menu Location: Points

Keyboard Command: explode_scad

Prerequisite: Carlson points

Convert Surveyor1 to CRD

This command will convert a Surveyor1 coordinate file to the current Carlson format.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: SURVEYOR2CRD

Prerequisite: A Surveyor1 coordinate file

Convert CRD to TDS CR5/Convert TDS CR5 to CRD

These commands convert coordinate file formats between a Carlson CRD file and a TDS CR5 file. Both of these file formats are binary which require these special routines. These commands will prompt for the file names to process.

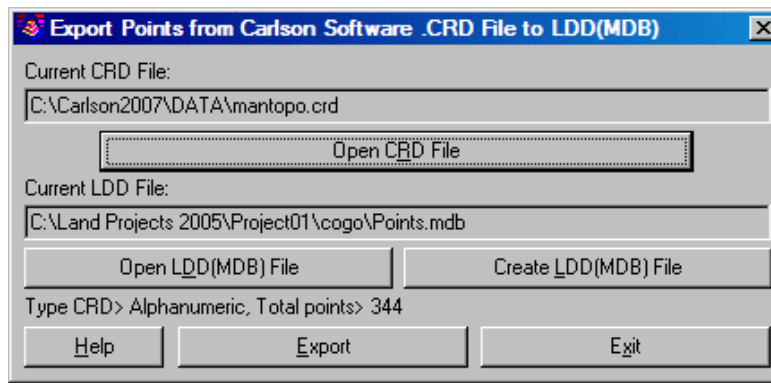

Pulldown Menu Location: Points

Keyboard Command: crd_cr5, cr5_crd

Prerequisite: A CRD or CR5 file

Convert CRD to Land Desktop MDB

This command converts a Carlson CRD file into an Autodesk Land Development Desktop (LDD) point database file in Access MDB format. The LDD point database always has the file name of POINTS.MDB. So, to specify the LDD file to create, you only need to specify the directory/path and not the file name. This path corresponds to the LDD project directory. The conversion program has point protect, so that if a point number from the CRD file already exists in the LDD file, you then will be prompted to skip or replace the point. Once the command is executed, the following dialog is displayed. On this dialog, specify the Carlson CRD file to convert as well as the LDD (MDB) file to append, if existing, or create if creating a new LDD (MDB) file.

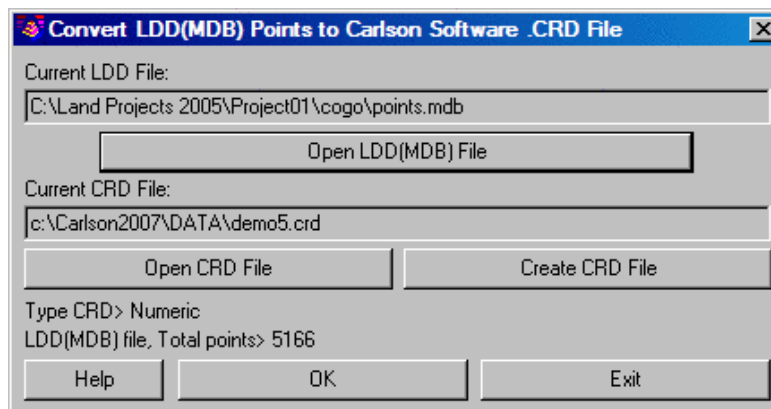

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: crd_ldd

Prerequisite: A .CRD file

Convert Land Desktop MDB to Carlson Points

This command converts an Autodesk Land Development Desktop (LDD, also referred to as LDT) point database file into a Carlson CRD file. The LDD point database always has the file name of POINTS.MDB and is stored in the LDD project directory. Once the command is executed, the following dialog is displayed. On this dialog, specify the LDD file to convert as well as the Carlson CRD file to append, if existing, or create if creating a new CRD file.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: LDD_crd

Prerequisite: An LDD point database file

Convert Civil 3D to Carlson Points

This command converts Civil 3D point entities into Carlson format point entities. When running in AutoCAD, the Civil 3D Object Enabler from Autodesk is used to read the Civil 3D point entities. This object enabler must be installed before running this routine. The installation for the object enabler is located under Support at www.autodesk.com. When running in IntelliCAD, this routine uses a conversion program from the Open Design Alliance to read the Civil 3D point entities.

If you have Civil 3D, another way to make a drawing with standard AutoCAD entities is to use the `aectoacad` command in Civil 3D which converts the custom objects into standard entities.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: c3d_crd

Prerequisite: Civil 3D points in the drawing

Convert Carlson Points to Land Desktop

This command converts a Carlson CRD file into a Land Desktop point file. To do this, you must specify the existing Carlson CRD points to convert. You have the option of selecting all points, or selecting on-screen the specific points you'd like to convert.

Prompts

Convert all or selected points [All/<Selected>]? *press Enter*

Select Carlson Software Points to convert:

Select objects: *pick first point for window selection method*

Select objects: *pick second point*

Processing Carlson Software point...

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: pt_aec

Prerequisite: A Carlson CRD file

Convert Land Desktop to Carlson Points

This command converts Land Desktop point entities into Carlson format point entities. The Land Desktop Object Enabler from Autodesk is used to read the Land Desktop point entities. This object enabler must be installed before running this routine. The installation for the object enabler is located under Support at www.autodesk.com. Be sure to match the version of the object enabler with the Land Desktop version used to create the drawing.

Prompts

Convert all or selected points [All/<Selected>]? *all.* Choose which points to convert.

Point position method [Insertion/<Database>]? *press Enter.* Choose between the drawing insertion points or the point database for the point locations.

Locate points on Real-Z Axis [Yes/<No>]? *press Enter.* Choose between creating the points at their elevation or at zero.

Convert point markers to symbols [<Yes>/No]? *press Enter.* Choose between using a point symbol or the PDMODE.

Pulldown Menu Location: Points

Keyboard Command: ldd_crd

Prerequisite: LDT points in the drawing and the LDT Object Enabler

Convert Softdesk to Carlson Points

This command converts Softdesk point blocks in the drawing to Carlson point blocks. These point block formats are similar and converting only requires reordering and renaming the attributes. Softdesk points can also be read into the current CRD file by using the command *Update CRD File from Drawing* in *Coordinate File Utilities*, this updates the CRD file without modifying the screen entities.

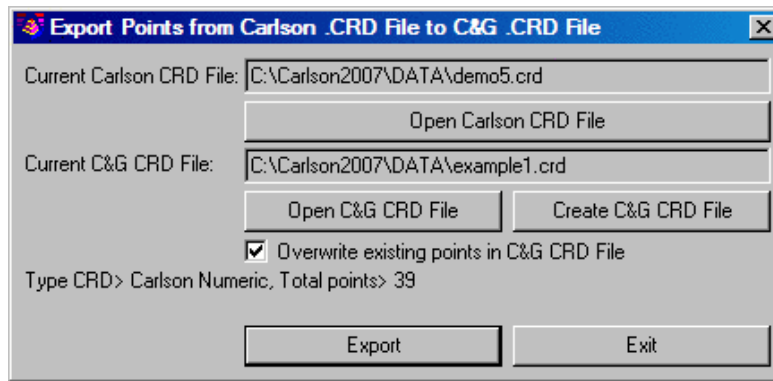

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2surv

Prerequisite: Softdesk points

Convert Carlson Points to C&G

This command converts a Carlson CRD file into a C&G Point file.

Specify the existing Carlson CRD to convert by selecting the Open Carlson CRD File button. Specify the existing C&G CRD file to write to, or the new C&G CRD file to create, by selecting either Open C&G CRD file or Create C&G CRD file. Press OK and the conversion is completed.

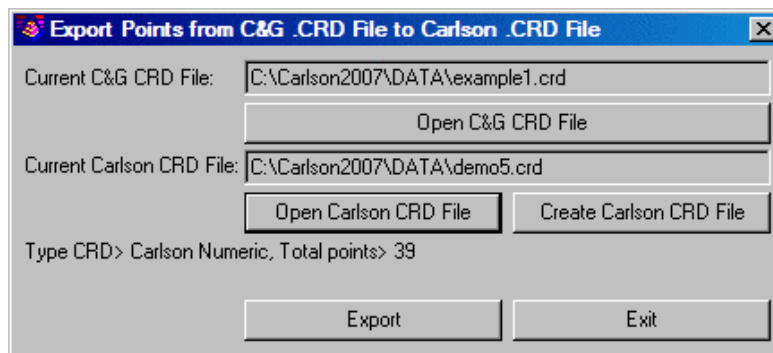

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: crd2cg

Prerequisite: A Carlson CRD file

Convert C&G to Carlson Points

This command converts C&G Points into a Carlson CRD file.

Specify the existing C&G File to convert by selecting the Open C&G CRD File button. Specify the existing Carlson CRD file to write to, or the new Carlson CRD file to create, by selecting either Open Carlson CRD file or Create Carlson CRD file. Press OK and the conversion is completed.

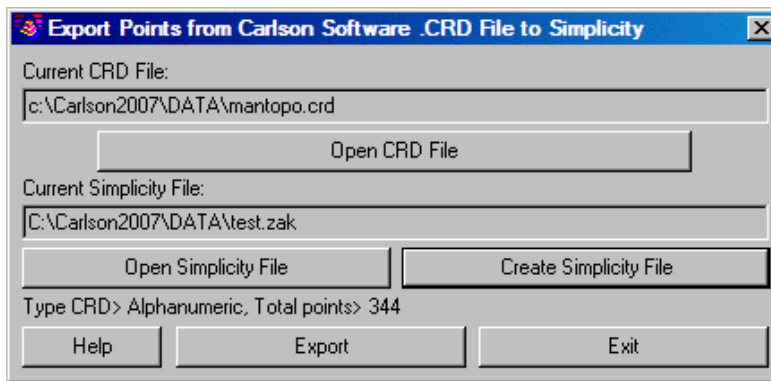

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: cg2crd

Prerequisite: A C&G point file

Convert Carlson Points to Simplicity

This command will convert Carlson points to Simplicity.

Select Carlson CRD file to convert by selecting the Open CRD file button.

Specify the existing Simplicity file to write to, or the new Simplicity file to create, by selecting either Open Simplicity File or Create Simplicity File. Press Export and the conversion is completed.

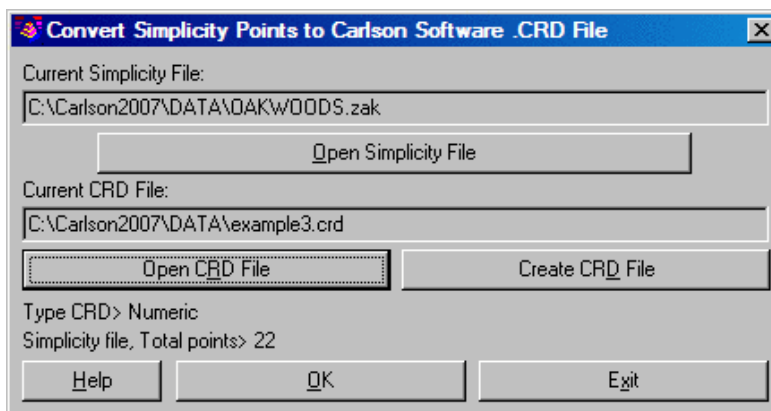

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: crd_zak

Prerequisite: A Simplicity point file

Convert Simplicity to Carlson Points

This command converts Simplicity Points into a Carlson CRD file.

Specify the existing Simplicity File to convert by selecting the Open Simplicity File button. Specify the existing Carlson CRD file to write to, or the new Carlson CRD file to create, by selecting either Open CRD File or Create CRD File. Press OK and the conversion is completed.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: zak_crd

Prerequisite: A Simplicity point file

Convert Leica to Carlson Points

This command converts LisCad or Leica point blocks in the drawing to Carlson point blocks. These point block formats are similar and converting only requires reordering and renaming the attributes. Leica points can also be read into the current CRD file by using the command *Update CRD File from Drawing* in *Coordinate File Utilities*. This updates the CRD file without modifying the screen entities.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2surv3

Prerequisite: Leica points

Convert Geodimeter to Carlson Points

This command converts Geodimeter point blocks in the drawing to Carlson point blocks. These point block formats are similar, and converting only requires reordering and renaming the attributes. Geodimeter points can also be read into the current CRD file by using the command *Update CRD File from Drawing* in *Coordinate File Utilities*. This updates the CRD file without modifying the screen entities.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2surv4

Prerequisite: Geodimeter points

Convert Carlson Points to Ashtech GIS

This command converts Carlson point blocks in the drawing to Ashtech GIS point blocks. After executing the command, you will be prompted to select the points to convert. When using this command, the setting "Group Point Entities", found under General Settings of the Configure command (Settings menu) should be unchecked (turned off).

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2ashtech

Prerequisite: Carlson Points

Convert Carlson Points to Softdesk

This command converts Carlson point blocks in the drawing to Softdesk point blocks. These point block formats are similar, and converting only requires reordering and renaming the attributes.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2soft

Prerequisite: Carlson points

Convert CAICE KCM to Carlson CRD

This command converts a CAICE .KCM point database file to a Carlson CRD file.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: kcm2crd

Prerequisite: CAICE KCM file

Convert PacSoft CRD to Carlson CRD

This command converts a PacSoft CRD file to a Carlson CRD file. PacSoft stores the point descriptions to a separate coordinate descriptor file having an extension of PTD. This file should be present in the same directory as the CRD file to convert. Prompts for the PacSoft CRD file to convert, and the Carlson CRD file to create, will be displayed. Once both files have been specified, the following dialog box will be displayed.

The **No Coordinate Conversion** option converts the file format while leaving the coordinate values unchanged.

Convert From Meters to Feet will assume the coordinates in the selected PacSoft crd file are metric, and will convert the coordinate values to US Feet.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: pacsoft2crd

Prerequisite: PacSoft crd file

Convert Carlson Points to Eagle Point

This command converts Carlson point blocks in the drawing to Eagle Point point blocks. A prompt for the Eagle Point version to convert to will be displayed.

Specify the appropriate version and then select the OK button. You will then be prompted to select the Carlson points to convert. These point block formats are similar, and converting only requires reordering and renaming the attributes.

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2eds

Prerequisite: Carlson points

Convert Eagle Point to Carlson Points

This command converts Eagle Point point blocks in the drawing to Carlson point blocks. These point block formats are similar, and converting only requires reordering and renaming the attributes. Eagle Point points can also be read into the current CRD file by using the command *Update CRD File from Drawing*, found in *Coordinate File Utilities*. This updates the CRD file without modifying the screen entities.

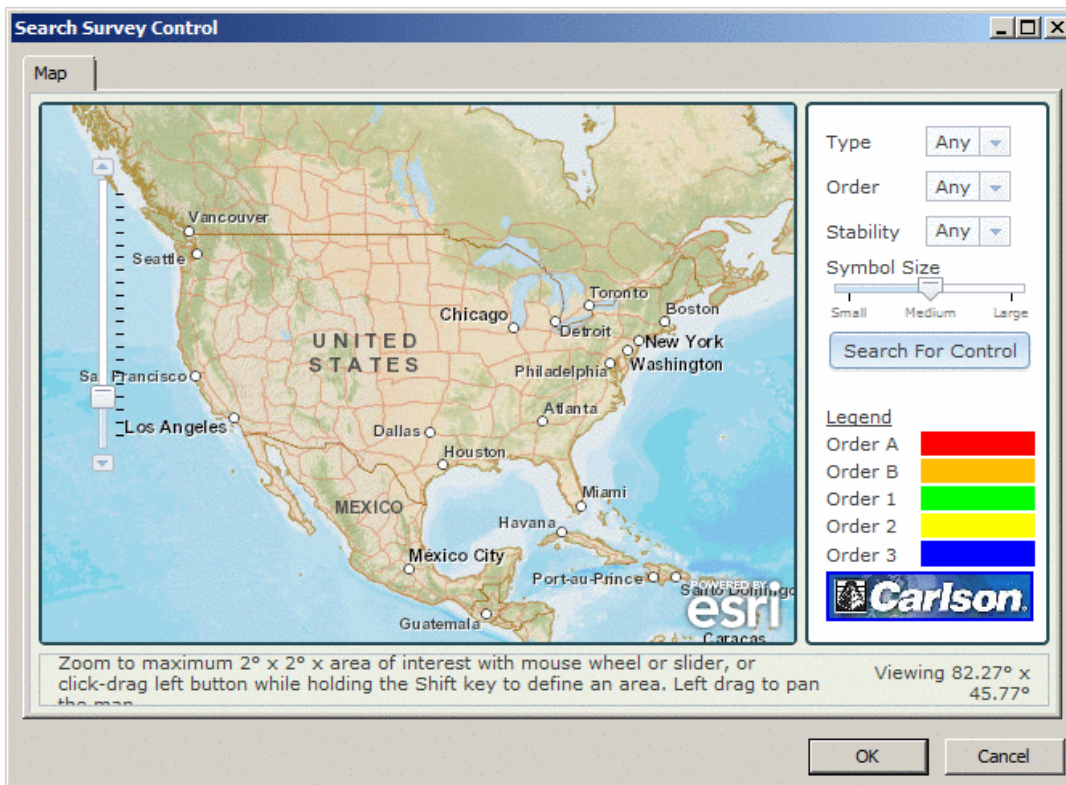

Pulldown Menu Location: Points > Convert Point Format

Keyboard Command: 2surv2

Prerequisite: Eagle Point points

Search Published Control

The Search Published Control command allows you to search published control mark data freely available on the National Geodetic Survey (NGS) web-site (<http://www.ngs.noaa.gov>) and optionally store the retrieved information to the active coordinate file.

Map Tab: Use the Map tab to navigate to a location bounded by a viewing window no greater than 2 degree of latitude by 2 degree of longitude. The limits of the current view are shown at the lower right of the Map tab (see below). To navigate to the area of interest:

- "zoom" using the slider control on the left side of the Map tab, or,
- "zoom" using the mouse wheel, or,
- "zoom window" by holding the Shift key and while left-clicking two points to define a rectangular area, or,
- "pan" by left-clicking and dragging the image to the desired position in the Map tab.

Type: Select the type of the NGS markers that are to be returned.

Order: Select the positional order of accuracy of the NGS markers that are to be returned.

Stability: Select the elevational stability of the NGS markers that are to be returned.

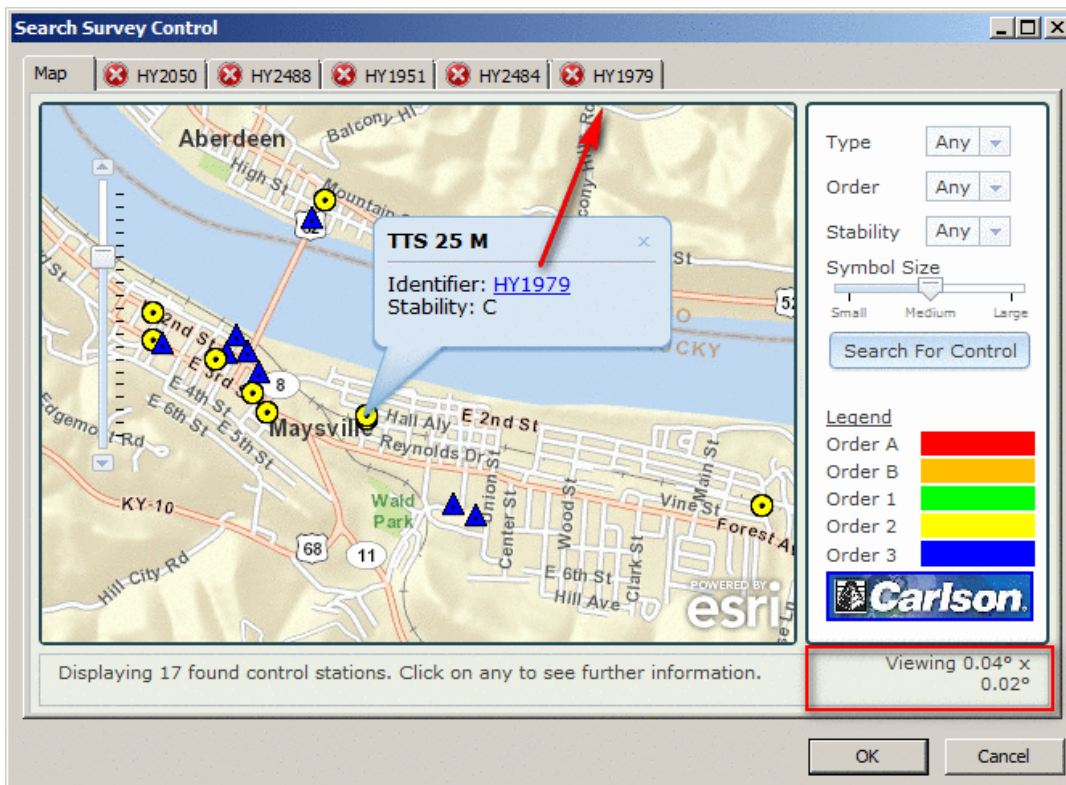

Symbol Size: Use the horizontal slider to adjust the symbol size of the NGS markers.

 Triangle = horizontal control, elevation unknown

 Circle = vertical control (benchmark), hz position usually scaled

 Triangle with circle = 3D position, all dimensions measured.

Search for Control: Click on this button to initiate the search for NGS control markers that satisfy the search criteria.

Note:

- The Search Survey Control dialog box is re-sizeable and contains re-sizeable controls.
- Order - For additional information on Order accuracy, reference <http://www.ngs.noaa.gov/faq.shtml#WhatHARN>: Horizontal A-order stations have a relative accuracy of 5 mm +/- 1:10,000,000 relative to other A-order stations. Horizontal B-order stations have a relative accuracy of 8 mm +/- 1:1,000,000 relative to other A-order and B-order stations. Additional information can also be viewed at <http://gpsinformation.net/main/ngs-accuracy.html>.
- Stability - For additional information on marker Stability, reference http://www.ngs.noaa.gov/AERO/Genspecs_A/Volume%20A_Attachment%201-6.pdf: Stability code A = expected to hold an elevation. Examples: rock outcrops; rock ledges; bedrock; massive structures with deep foundations; large structures with foundations on bedrock; or sleeved deep settings (10 feet or more) with galvanized steel pipe, galvanized steel, stainless steel, or aluminum rods.
Stability code B = probably hold an elevation. Examples: unsleeved deep settings; massive retaining walls; abutments and piers of large bridges or tunnels; unspecified rods or pipe in a sleeve less than 10 feet; or sleeved copper-clad steel rods.
Stability code C = may hold an elevation but subject to ground movement. Examples: Metal rods with base plates less than 10 feet deep; concrete posts (3 feet or more deep); large boulders; retaining walls for culverts or small bridges; footings or foundation walls of small to medium-size structures; or foundations such as landings, platforms, or steps.
- As NGS markers are retrieved, left-click on the marker itself to see summary information about the marker.
- To retrieve the NGS datasheet with additional information about the marker, left-click on the Identifier hyperlink. To close a "balloon" marker on the Map tab or an NGS datasheet, left-click on the "X" icon of the balloon or datasheet tab, respectively.
- If any NGS datasheet tabs are open and the OK button is clicked on the dialog box, you will be prompted if the open NGS markers should be saved to the current coordinate file.

Prompts

Save selected stations to coordinate file? Indicate your preference if the opened NGS control marks should be saved to the current coordinate file.

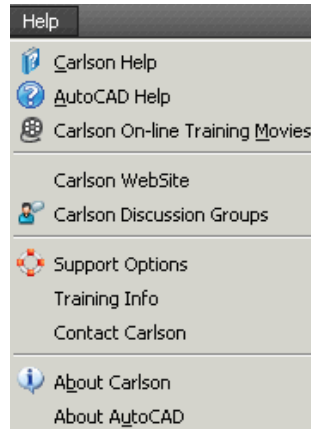

Pulldown Menu Location: Points > Point Utilities

Keyboard Command: searchcontrol

Prerequisite: Internet connection

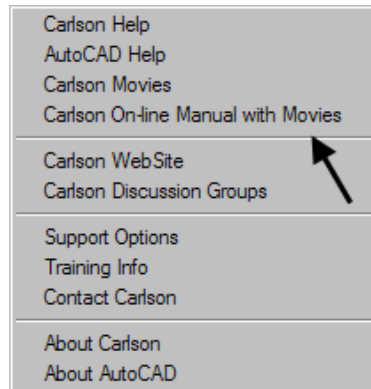

Help Menu

The Help menu has links to the manual and helpful links to on-line resources.

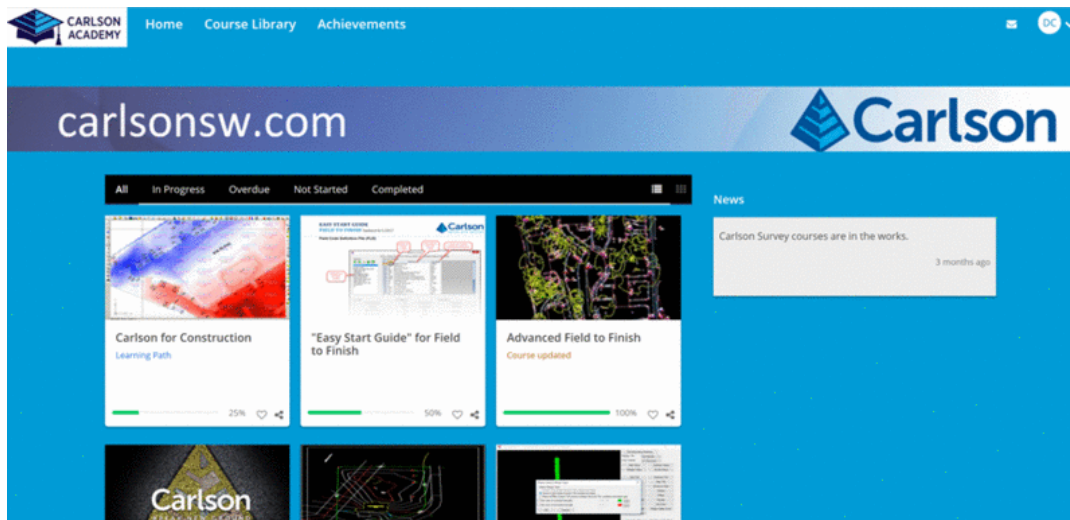

Carlson On-line Manual with Movies

This function launches the Internet browser to view the Carlson manual on-line. This on-line manual also includes training movies. You will need a fast internet connection to use this manual.

Carlson Academy

This command launches your default internet browser to bring up Carlson Academy which is an on-line learning system. There are training movies and example data files that are organized by categories.

Carlson Academy requires a login with username and password. To create an account, go to <https://account.carlsonsw.com/login> and pick Sign Up. Access to Carlson Academy requires a Carlson Software account and your company being current on the maintenance program.

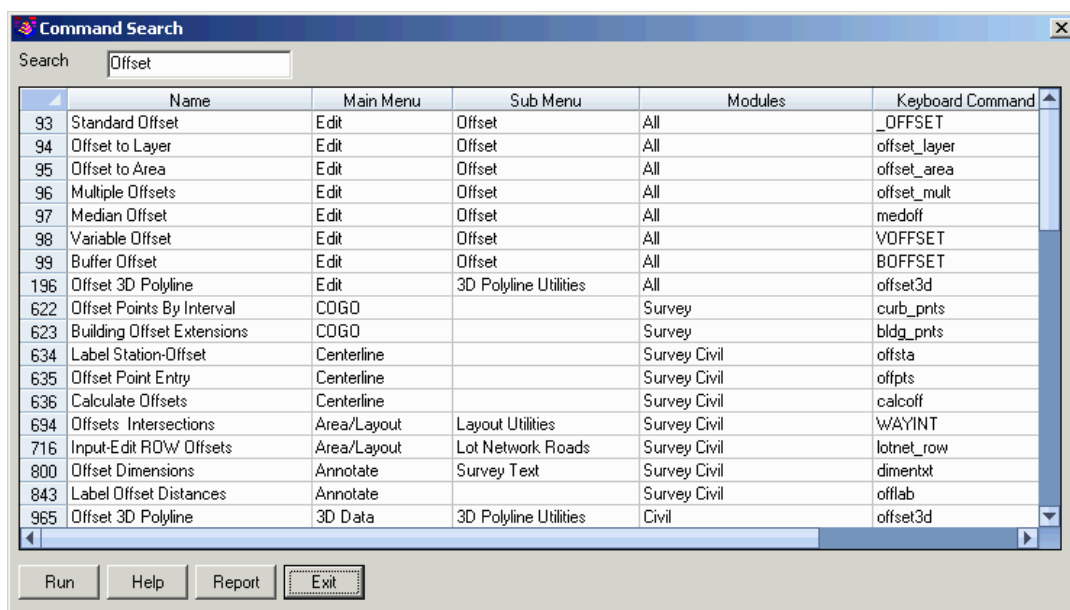

Pulldown Menu Location: Help

Prerequisite: None

Command Search

This command helps find commands in the menu. Enter a command name to search for in the Search edit box. The resulting matches are shown in the spreadsheet. Main Menu and Sub Menu are for the pop-down menu name that contains the command. Modules lists the modules that include the command. Keyboard Command is the name for running the command from the Command: line. Toolbars lists any toolbars that contain the command.

The Run button runs the highlighted command. The Help button brings up the manual help topic for the highlighted command. The Report function uses the Report Formatter to make a report for the current contents of the spreadsheet.

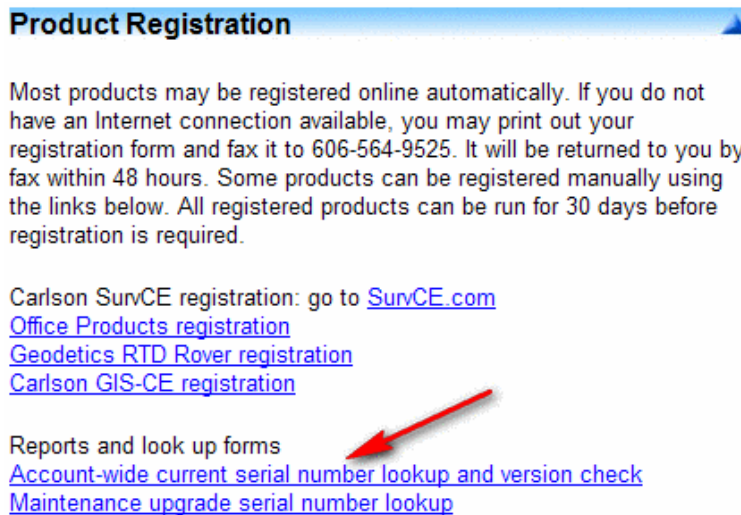

Pulldown Menu Location: Help
Keyboard Command: cmd_search
Prerequisite: None

Serial Number Report

Carlson Software is setup (by default) to check the Carlson server for periodic updated patches (*aka* "service packs"). These checks are logged so that the server collects which build versions a particular machine is running. On the www.carlsonsw.com webpage, under the Support > Product Registration, there is a link for a report of this serial number information:

http://update.carlsonsw.com/current_version_report.php

This tool generates a patch status report for all the computers at your company.

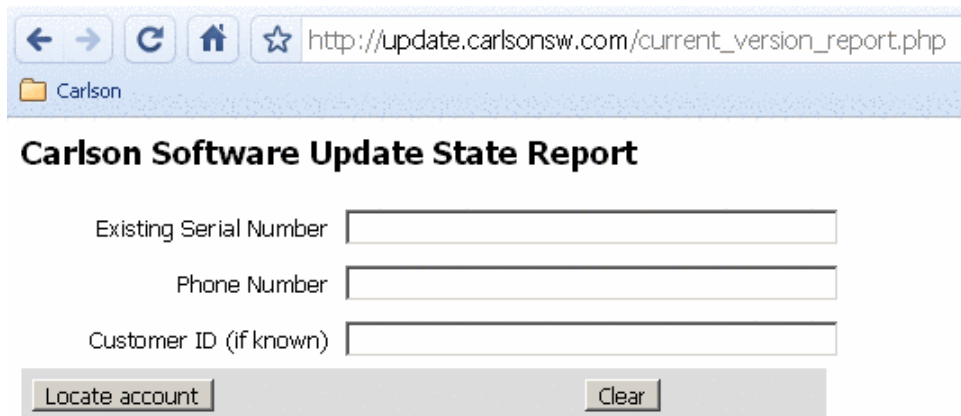

Product Registration

Most products may be registered online automatically. If you do not have an Internet connection available, you may print out your registration form and fax it to 606-564-9525. It will be returned to you by fax within 48 hours. Some products can be registered manually using the links below. All registered products can be run for 30 days before registration is required.

Carlson SurvCE registration: go to [SurvCE.com](#)
[Office Products registration](#)

Carlson

Carlson Software Update State Report

Existing Serial Number

Phone Number

Customer ID (if known)

A report is then generated with all the machines, serial numbers and current build numbers and last update check date for the identified account as shown in the sample below (parts of the serial numbers below have been blurred for security purposes).

Carlson Software Update State Report

Product Name	Serial Number	Build	Date last seen
Carlson 2010	-4F27AC0-	100713	August 25, 2010, 9:09 am
Carlson 2010	-4F27AC0-	091023	June 2, 2010, 10:40 am
Carlson 2010	-4F27AC0-	100713	August 25, 2010, 7:44 am
Carlson 2010	-4F27AC0-	091023	November 25, 2009, 1:31 pm
Carlson 2010	-4F27AC0-	091023	November 25, 2009, 12:24 pm

Carlson 2010	-4F27AC0-	Unknown	Never

- The Carlson *Build Number* is essentially identical to the release date for the build as it is in the form of **YYMMDD**.

About Carlson

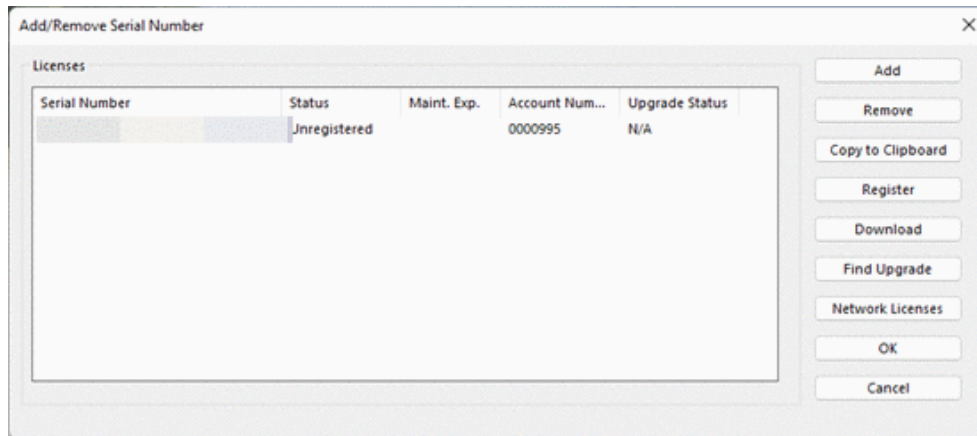

The purpose of this dialog is to inform user about currently installed version of the software, enabled features and to assist with registration and installation issues.

The list box in the dialog shows the copyright notice, when and what version was installed, patches applies and

features currently licensed based on the serial numbers enabled.

Registration - clicking button leads to a dialog containing the list of the serial numbers currently in use in software and their status:

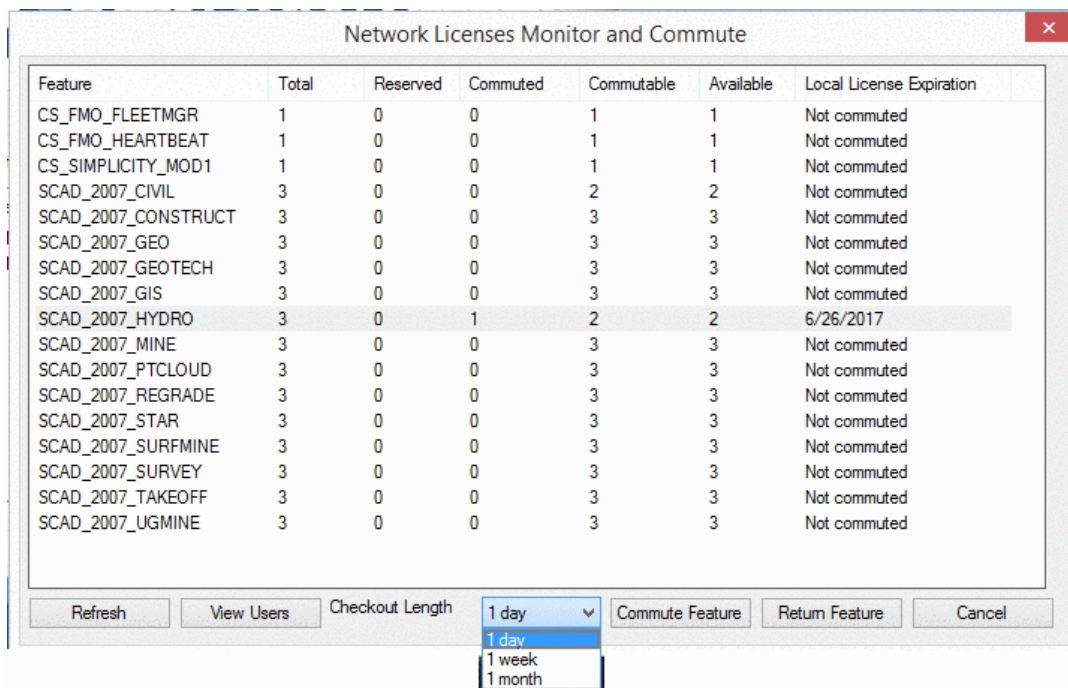

Click **Add** to put in additional serial numbers, or highlight number and click **Remove** to deactivate it. At least one serial number needs to be entered in this dialog for the program to function. Each purchased serial number needs to be registered, which is done at program startup or from this dialog, by highlighting the number and clicking **Register**.

Copy to Clipboard copies the serial number to aid in updated version installation and other applications

Download button takes user to the download page on the Carlson website.

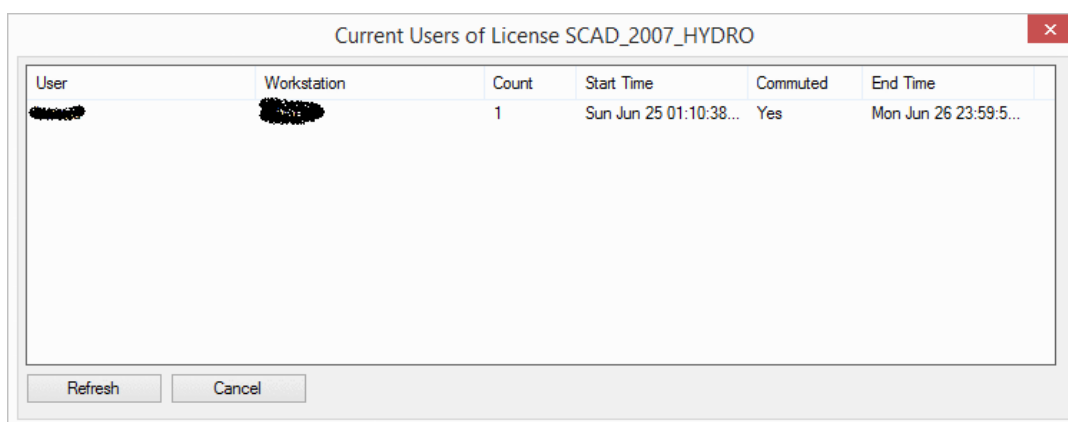

Find Upgrade function opens the page on the Carlson website to lookup the upgrade serial number to the newest version of the product, if the user is on active maintenance agreement.

Network Licenses accesses the integrated Network License Manager tools to display available licenses on the server, show users using the license; commute (borrow) or return committed license.

Refresh updates the list of licenses and license counts.

View Users displays the list of users for the selected feature, along with information on how long the license is commuted for.

user can use this feature to determine the holder of the license he needs and communicate with his coworker about the access to the license.

Commute Feature button requests the commute of the license for the selected feature for the selected length of time. If commute is successful, the display will update to reflect this.

Return Feature button returns the commuted license back to the server. Normally, the commuted license will return to server automatically upon expiration. This function allows to return the license early if it is no longer needed locally.

Extend Demo - this button is only present when software is in trial mode. This provides user with information needed to extend duration of the trial by 14 days or 2000 uses, whichever comes first. Extension is not additive,

so it needs to be performed when software expired or about to expire to give the most benefit.

Revision History - clicking this button causes software to receive the revision notes off the server and to display information about changes contained in individual updates

Prompts

Pulldown Menu Location: Help

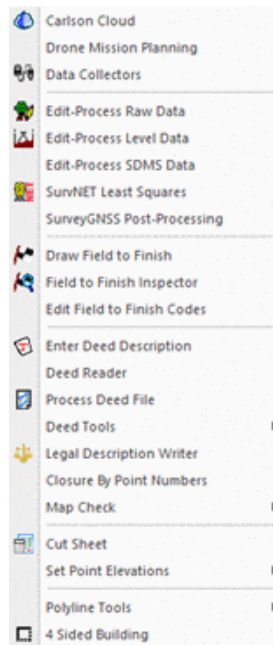

Keyboard Command: `about_scad`

Survey Module

3

Survey Menu

This chapter provides information on using the commands from the Survey pulldown menu, in order to download data from data collectors, process raw data and prepare plats. The first sections of the pulldown provide information on working with data collectors, editing and processing raw data and drawing Field to Finish. Carlson SurvNET is Carlson's Network Least Squares Reduction (NLSA) program. Below that there are complex deed creation and linework commands. The bottom portion of this menu provides features for creating cut sheets, polyline data and other survey important requirements.

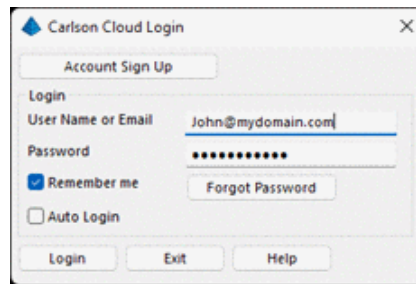

Carlson Cloud

The Carlson Cloud command (not to be confused with the Carlson Point Cloud module) is an Internet/cloud-based routine designed to easily facilitate sending messages, data files and crew locations between the office and Internet-connected field devices running Carlson SurvCE or Carlson SurvPC.

Upon launching Carlson Cloud, the user is challenged to provide login credentials as shown below:

- **Account Sign Up**
- **Account Options**

Username: Supply the user name (Case Sensitive) that you used when creating your Carlson Cloud account.

Password: Supply the password (Case Sensitive) that you used when creating your Carlson Cloud account.

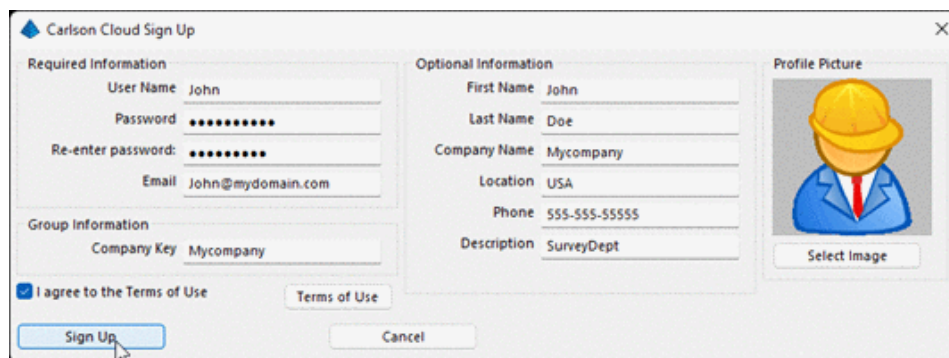

Remember Me: When enabled, the last used *Username* and *Password* values are recalled for the next Carlson Cloud login session.

Forgot Password: Password recovery instructions are sent to the specified Email address.

Auto Login: When enabled, automatically logs in to Carlson Cloud each session.

Once logged in, refer to the Carlson Cloud - Logged In discussion.

The *Account Sign Up* command provides the ability to create a new user account and associate the user account with a "company key" (essentially, a group of people with whom you wish to network within Carlson Cloud).

Username: Supply the user name (this will be Case Sensitive) that you will want to use for your Carlson Cloud account.

Password: Supply the password (this will Case Sensitive) that you will want to use for your Carlson Cloud account.

Phone: Supply your phone number.

Email: Supply an Email address where password recovery instructions can be sent.

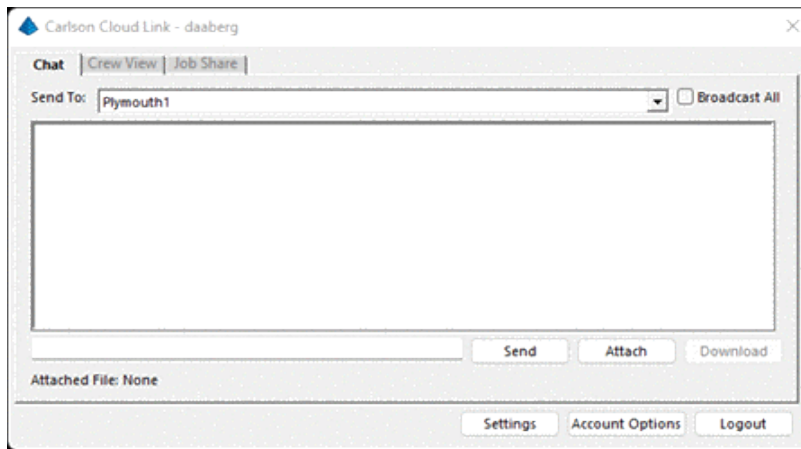

Create Company Key: When enabled, this toggle permits you to create a new company "profile" (or communication group).

Existing Company Key: Indicate the name (Case Sensitive) of an existing company "profile" to which the new member should belong.

Optional Information: Enter in the optional information of name, company, location, phone number and a description.

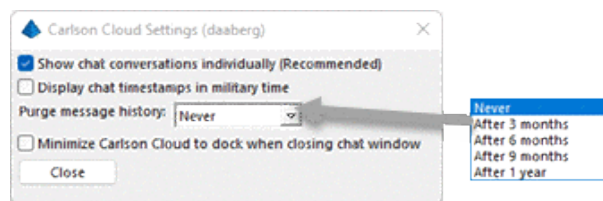

Select **Sign Up** when all information has been entered.

Upon successful login to Carlson Cloud, the user is presented with the communication aspects of Carlson Cloud.

This dialog box contains the Chat Window, Crew View and Job Share Tabs.

Settings:

This dialog box shows options for the Chat View Tab as well as other options.

Show Chat Conversation Individually shows a single conversation at a time in the view window.

Display chat timestamps in military time sets the time view to a 24 hour clock.

Purge message history controls how long to keep the chat history for each user

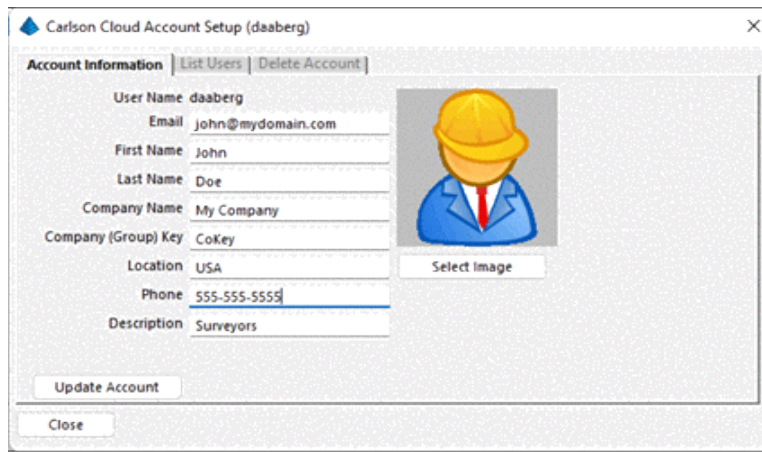

Minimize Carlson Cloud to dock when closing chat window keeps the chat window active but minimizes it to a small icon. This option allows you to keep a chat conversation active while working in the drawing editor without the distraction of the complete dialog box.

Account Options

The *Account Options* of Carlson Cloud permits you to investigate and manage certain aspects of your Carlson Cloud account(s).

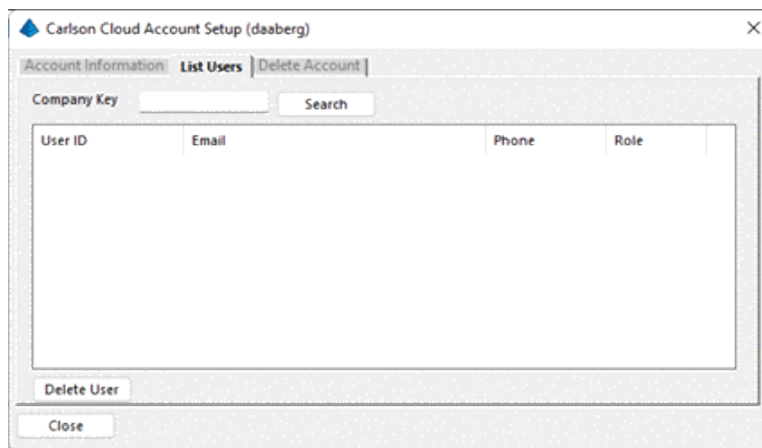

Account Information:

Allows you to review, edit and update your account information.

List Users Tab

Carlson Cloud can display the listing of users assigned to a specified *Company Key*.

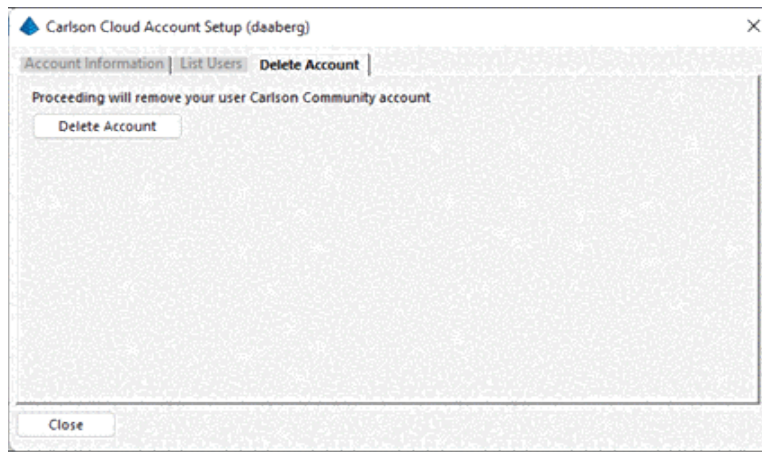

Company Key: Supply the name of the unique Company Key established for your communication group.

Search: The list of users associated with the Company Key is returned.

Delete User: Highlight an existing user and press Delete User to remove a user from the group.

Delete Account

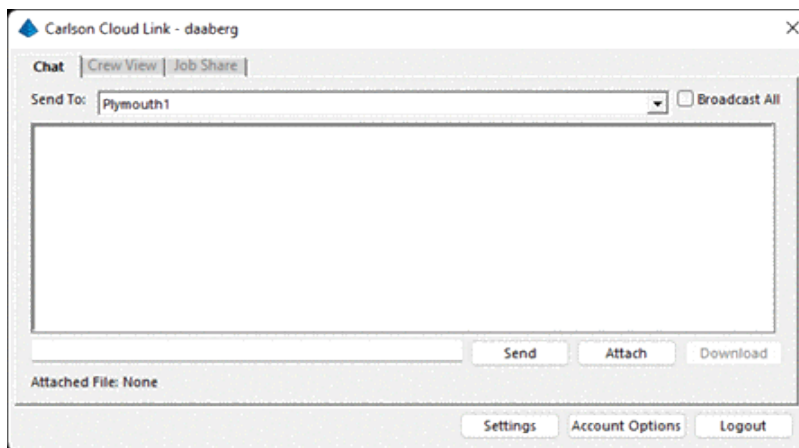

Carlson Cloud accounts that are no longer needed can be removed from the Carlson Cloud service.

Logs the active account out of the Carlson Cloud service.

Chat Tab

While logged in to Carlson Cloud, it is possible to communicate with other Carlson Cloud accounts that belong to the same "Company Key" as that of the active logged in user.

Username Drop-list: Select the individual with whom you would like to chat.

Broadcast All: When enabled, all members listed in the Username Drop-list will receive your chat (and optional attachment) at their next login.

Message Area: The listing of communication chats (both current and received since the last successful login) will appear.

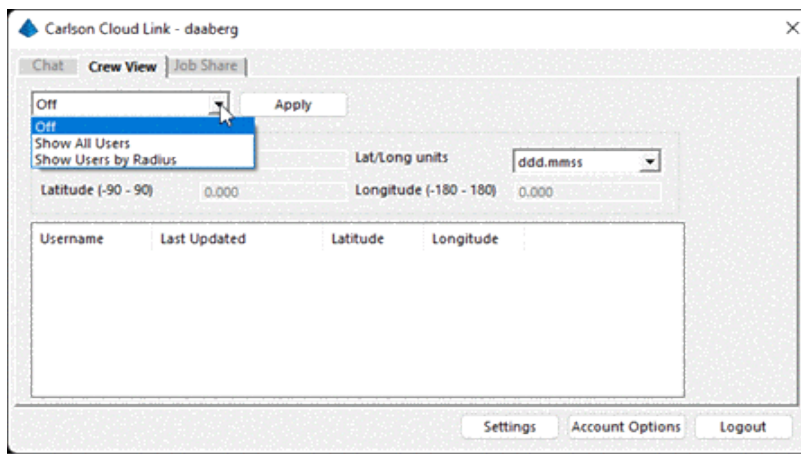

Chat Line: Supply a brief chat question or statement for the intended person or audience.

Send: Delivers the Chat Line content (and optional attachment) to the intended person or audience.

Attach: Specify a Carlson SurvCE, SurvPC or CSI Mobile compatible file (*e.g.* CRD, RW5, NOT, LOC, *etc*) that should be delivered to the intended person or audience.

Crew View Tab

Carlson Cloud permits the viewing of other crew members that can be helpful for site logistics and planning.

Crew to Show Drop-list: Indicate the crew members (if any) that should be shown:

- **Off** - No crew members will be shown.
- **Show All Users** - All crew members will be shown.
- **Show Users by Radius** - Crew members within a prescribed radius of a central Latitude/Longitude position will be shown.

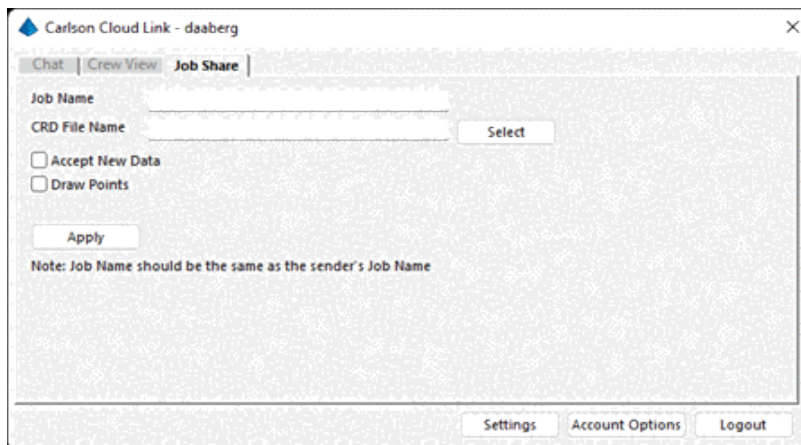

Latitude: Indicate the central latitude.

Longitude: Indicate the central longitude.

Radius: Indicate the radius value in miles from the central Latitude/Longitude position to display crew members.

Job Share Tab

Carlson Cloud permits the sharing of job data (*e.g.* field readings) with other Carlson Cloud members associated with the Company Key.

Job Name: Specify the name as it appears (Case Sensitive) from the sending device (such as Carlson SurvCE).

CRD File Name: Indicate the name of the Carlson Coordinate File that is to receive the job information. **Note:** This CRD does not need to be the same name as that used on the sending device.

Accept New Data: When enabled, incoming data will be permitted into the specified **CRD File Name**.

Draw Points: When enabled, incoming data will be placed into the drawing via the Draw-Locate Points command.

Note:

- When creating a "Company Key," consider a unique combination of your organization name with a portion of your phone number or postal code to help establish "uniqueness."
- When resetting a password, the "From" Email address will be from **customerportal@carlsonsw.com**. Please make sure you add this address to your "Safe Senders" list.
- The positions of crew members will only appear if the crew has enabled their "Allow others to view my position" toggle.
- The positions of crew members update about once every 5 minutes.
- While logged out of Carlson Cloud, any "chats" or data files sent to you are held in-transit until you next log into Carlson Cloud.

Pulldown Menu Location: Survey

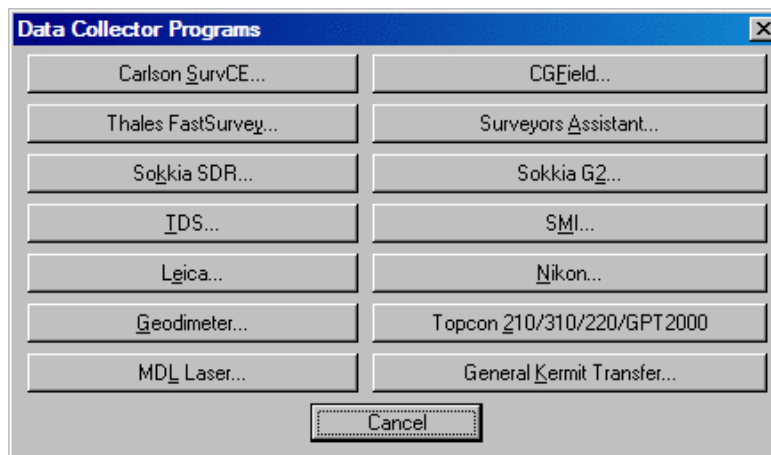

Keyboard Command: ccloud

Prerequisite: Internet connection

Data Collectors

This command does two main functions for a variety of popular data collectors. First, this command transfers (uploads and downloads) data between the data collector and Carlson. Second, this command converts data formats between the data collector format and the Carlson format. So, if you already have the data file on the computer, you can skip the transfer function and just perform the conversion function.

The transfer function does the conversion at the same time. In most cases, the download from the data collector produces a raw (.RW5) file (field notes) and/or a coordinate (.CRD) file (coordinate points). Several of the download programs have an option to automatically run the *Edit-Process Raw Data File* command after downloading raw data. You can also send, or upload, a coordinate (.CRD) file. The dialog shown here appears when the menu command is selected.

Carlson SurvCE: For Carlson Software data collection programs SurvCE and SurvStar. This button produces the SurvCOM dialog and program.

Prepare Geoid for SurvCE: Creates a subset of a geoid as a .GSF file to load into SurvCE.

CG Field: For CG Field programs.

Magellan/Thales FastSurvey: For Magellan and Thales FastSurvey data collectors.

Surveyors Assistant: For data collectors running Surveyors Assistant software (Corvallis MC2, MC5 and Pentax SC5).

Sokkia SDR: For SDR2 through SDR 33 and other collectors that have a SDR format like the Trimble.

Sokkia G2: Specifically for the SDR2.

TDS: For data collectors that use TDS software (Ranger, HP48, HP95, Husky FS-2 & FS-3, Corvallis MC-V and TOPCON FS2, FC95 and FC48).

SMI: For SMI data collectors on the HP48.

Leica: For Leica GIF-10 module, GeoCOM for older Leica and DBX for newer Leica instruments.

Nikon: For Nikon DTM and DR-48 total stations.

Geodimeter: For the Geodimeter Geodat collector.

Topcon 210/310/220/GPT2000: Supports these Topcon models.

MDL Laser: For MDL Laser instruments.

General Kermit Transfer: For general transferring using Kermit.

Carlson SurvCE

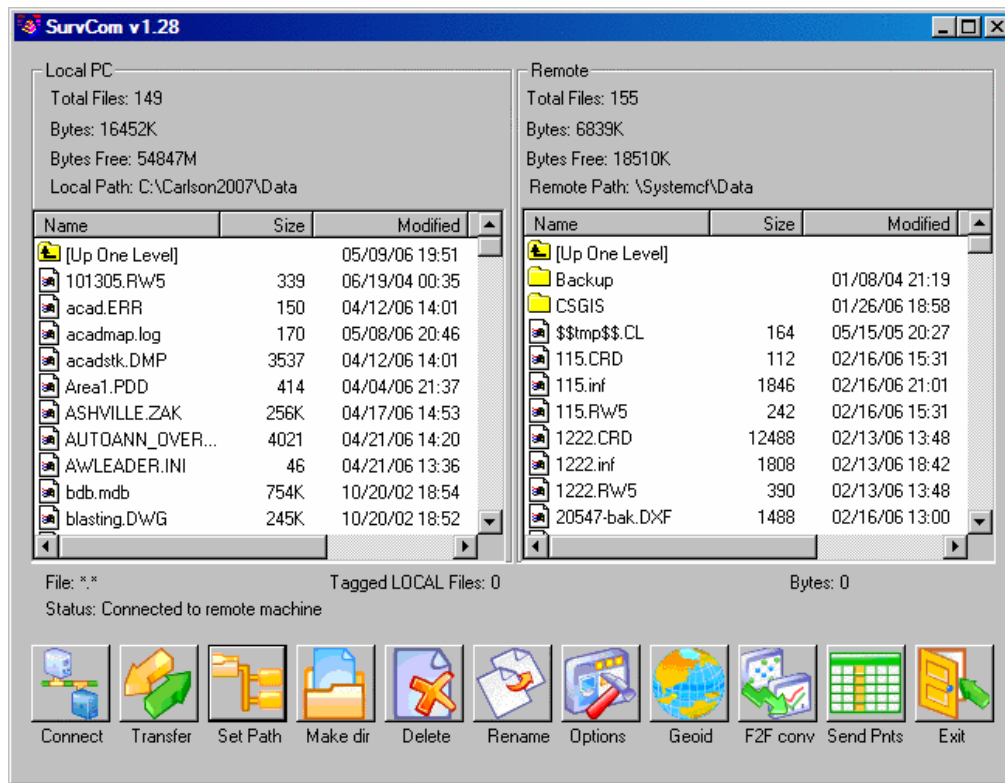

Note: In the following text, the term SurvCE will apply to SurvCE, SurvStar, and Sokkia G2

Connect the serial cable. Select Data Transfer from the on the handheld. Choose Carlson/Carlson Survey Download. This leads to a File Transfer screen on SurvCE, which says "Awaiting Connection". All the action is on the PC side. There is no time delay in this handshake. It will wait for the PC program to catch up. When you connect the cable from SurvCE to the PC, Microsoft ActiveSync may interfere and say "Connect to PC?" If you get this question, say No or otherwise terminate the Microsoft ActiveSync linkage. Start the Carlson portion of this link by choosing Survey, Data Collectors, then the SurvCE option. If connection is automatically established, SurvCE will display, "Connected to PC".

If only the left side of the screen displays data, then you do not yet have a connection. Press the Connect button located at the bottom left of the file transfer dialog. The transfer program will respond with Retrieving File List. Once the file list has been retrieved, the left side of the dialog box will show files located in the specified path on the PC and the right side of the dialog displays the files located in the designated path on the remote. You can change directories by scrolling to the top of the file list and choosing Up One Level (just like in Windows).

To transfer one or more files, simply select or highlight the desired files and select the transfer button. More than one file can be transferred from the remote to the PC or from the PC to the remote during the transfer process. Standard Windows selection options apply. For example, selecting one file and then while pressing the shift key on the PC, selecting another file deeper on the list will select all the files in between the first and last selected. You can also select the first file to transfer and press and hold down the shift key and use the down arrow to specify the range of files to transfer. Pressing and holding the control key on the keyboard allows for the selection of multiple files in any selection order, by picking the files with the left mouse button.

After the files have been selected, press the transfer button. When the transfer is complete, the program will return a "Transfer Complete" message, and will then proceed to update the file lists on the PC and the Remote.

The following information describes the buttons on the bottom row of the SurvCOM dialog box. The button name is on the left in bold:

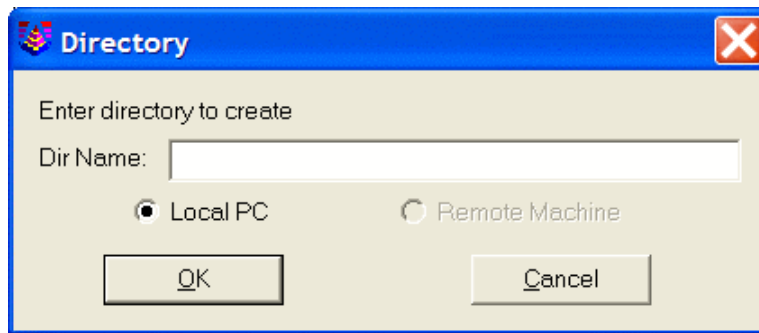

Connect: After selecting Data Transfer in SurvCE, press this button to start the connection. Once connection is made, the status line on the file transfer utility dialog box will show Connected to the remote machine.

Transfer: Pressing this button transfers selected files from either the Remote to the PC, or the PC to the Remote.

Set Path: This option allows for the specification of the desired source and destination drives and folders for both the PC and the Remote device. For example, if you were downloading, or copying files from the Remote device to the PC, to specify a source path on the remote device, select the Remote Machine toggle and then type in the desired path in the path field. To specify a destination path on the PC, select the Local PC toggle and type in the desired path the path field. When a change to either path is made, the transfer utility will retrieve a new file list from the specified paths.

Make dir: This option allows for creation of directories on both the PC and the Remote device. Specify the hardware on which to create the directory and then enter the directory name.

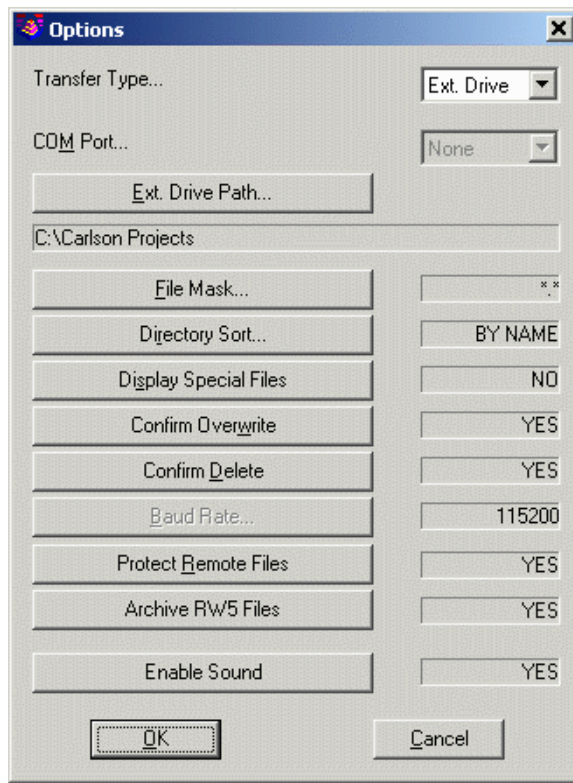

Delete: This option allows you to delete the tagged files. To delete a file, select the file to delete by clicking on the file, press the delete button at the bottom of the dialog. Confirm deletion by selecting the appropriate response on the Delete File dialog.

Rename: To rename a file, click on the file to rename and select the rename button at the bottom of the dialog. On the dialog that displays type in the new name and press the OK button.

Options: This command allows you to set various options for data transfer. The dialog shown below will appear.

Transfer Type: Choose USB for transferring over a USB cable. Choose 9-Pin for transferring over a 9-pin serial cable. Choose Ext Drive for transferring to another folder on your computer or a drive connected to your computer such as a USB storage drive or memory card.

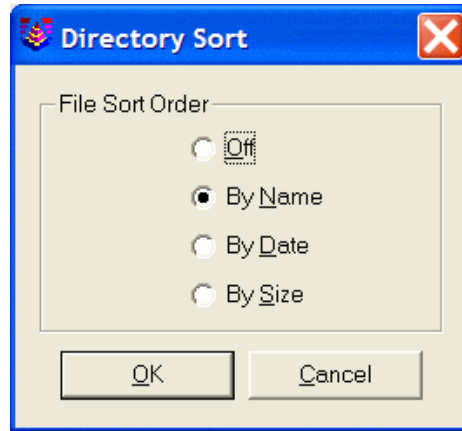

Com Port: You must select which com port on the PC to use when using the 9-Pin transfer type.

If you are transferring data via a USB port, set the com port to ActiveSync, see the Options section below for procedures to change com ports. To transfer data using an USB port a connection between the Remote and PC using ActiveSync is required. In ActiveSync verify that the "Connect Settings" have been set to "Allow serial cable or infrared connection to this Com port" and Allow USB connection with this desktop computer. This will allow for connection using an USB port or a COM port connection. Both will use ActiveSync to transfer data between devices.

File Mask: You must select a file filtering syntax. This filter allows for the setting of specific file types to display. For example if you only wanted to see CRD files the filter would be *.CRD.

Directory Sort: You must select how to sort the list of files.

Display Special Files: Toggle whether or not you should see special files.

Confirm Overwrite: Check this to confirm before overwriting files.

Baud Rate: You must choose the baud rate for transferring data.

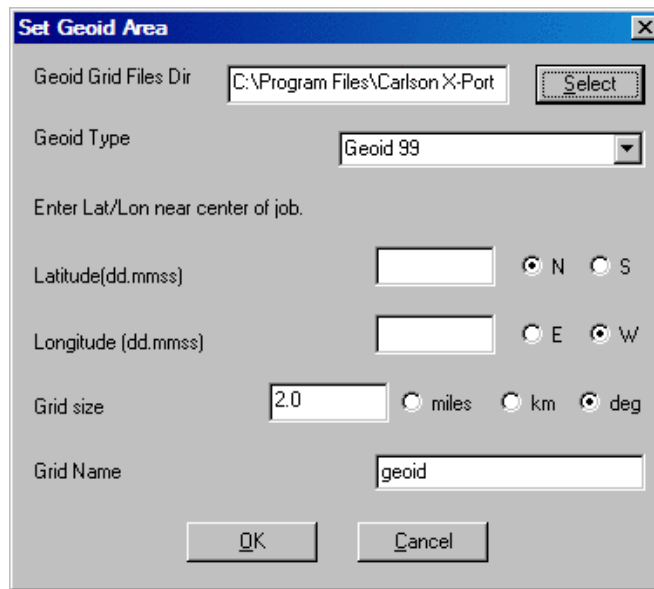

Protect Remote Files: Check this to protect files on the mobile device.

Archive RW5 Files: With this option set to YES, when downloading rw5 files, a second copy of the file will be made with a .SC5 extension to serve as an archive of the original rw5 file.

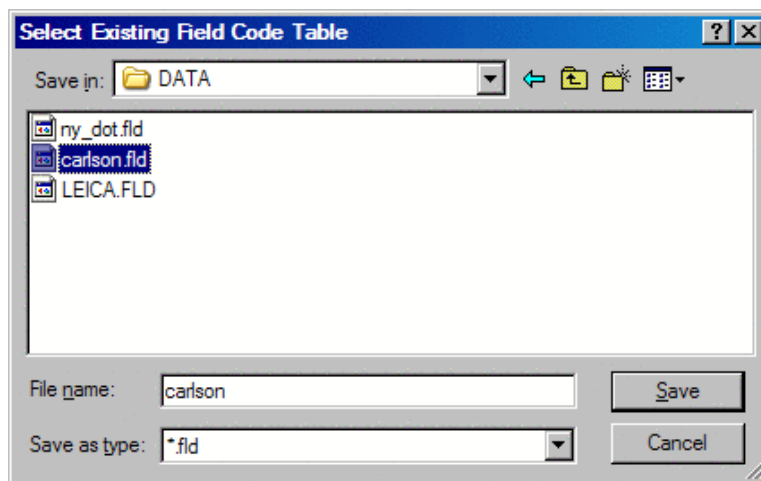

Geoid: This command will carve out a portion of the Geoid 99, EGM96, Canadian CGC2000, Canadian HT2.0, Canadian HT 1.01, Australian GDA94, Great Britain OSG-MO2 and Geoid 2003 grid files, and send it to SurvCE. Since these geoid grids are very large, this carves out a precise portion of it and avoids overloading the memory on the remote device running SurvCE. You will be prompted for the directory on the PC of the source Geoid grid file, the approximate latitude and longitude of the job, and the size of the area desired in miles, kilometers or degrees of latitude and longitude. To define a Geoid area, make sure that this criteria is met:

1. Specify the location of the geoid grid files.
2. Specify the geoid type.
3. Enter the latitude and longitude near the center of the job area.
4. Specify the Grid size either in miles, km (kilometers), or deg (degrees).
5. Name the grid file.

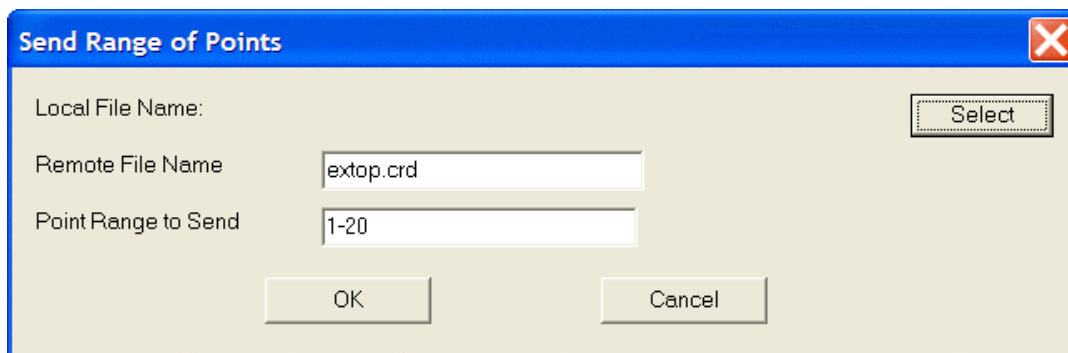

The file will be transferred to the data collector and place in the appropriate place for use.

F2F conv: This converts the more thorough and detailed Carlson field code file (for field-to-finish work, *.FLD) to the more simplified Feature Code List that runs in SurvCE (*.FCL). The Feature Code List in SurvCE (not SurvStar or Field) handles Linework (on or off), Line Type (2D or 3D), Layer (= Code) and Full Text (Description). Select the Carlson field code (*.FLD) to convert, the conversion takes place and the file is transferred and located in the correct location for use in the data collector.

Send Pnts: This option allows for the uploading of a user specified point number range out of the selected crd file to unload. Use the Select button to specify the crd file to upload. The Remote File Name will default to the name of the crd file selected to upload. You can change this name if needed. Specify the Point Range to Send and select the OK button.

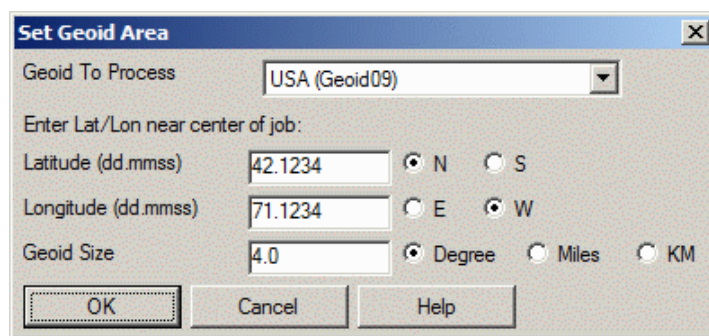

Exit: This command will exit the File Transfer Utility

The following information describes the buttons on the Data Collection Programs dialog box that come after the Carlson SurvCE button, moving from left to right and then from top to bottom. The command/button name is on the far left margin, in bold:

Prepare Geoid for SurvCE

This function creates a .GSF (Geoid Separation File) for SurvCE from a built-in geoid. Most geoids are very large and this routine carves out a subset of the geoid by specifying a center position and area size. The geoid data files are not included in the regular install since they are so large. Instead, the program automatically downloads them as needed from the Carlson server. You can also install them separately by running the CarlsonGeoidGrids.exe from the Support->Other Downloads on www.carlsonsw.com.

CG Field

To transfer data to and from data collectors using CGField software, first make sure that the Baud Rate is set to 9600 and the Parity is set to NONE then follow the steps outlined below.

Receiving a Coordinate File from CGField

CGField:

- 1) Go to the UTILS menu and select Option 1, C&G Transfer.
- 2) Select Option 4, "Send Coords"
- 3) Select the Coordinate file to send.

Stop here in CGField and go to Carlson.

Carlson:

Leave the FILE fields blank.

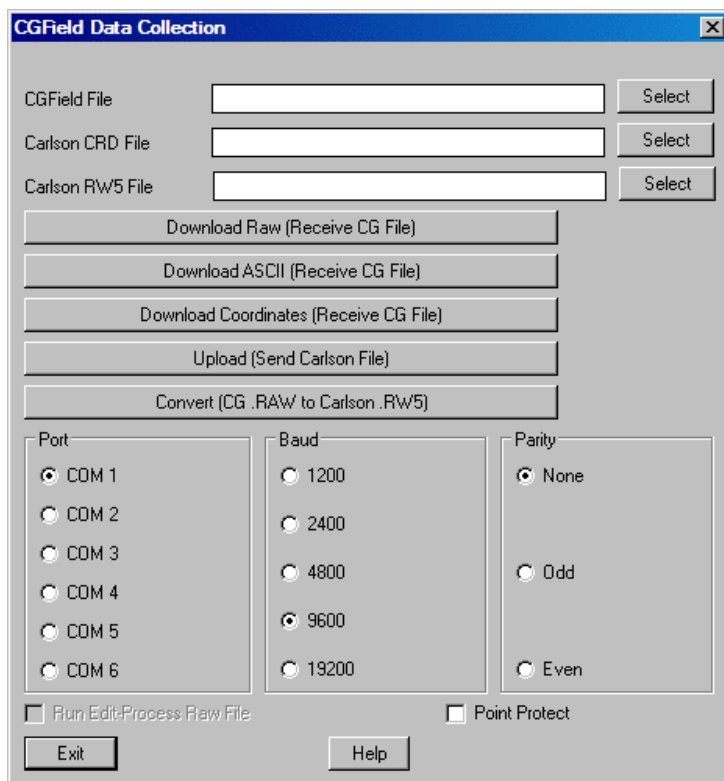

Press the "Download Coordinates" button to ready Carlson to receive the file.
Stop here in Carlson and go back to CGField to complete the transfer process.

CGField:

Select the points to send

- 1) For All points
- 2) To select Blocks of points.
- 3) From .PTS file (the set of points in a Batch Point File).

The coordinates will be transferred. After the transfer is complete, you will be asked for the CRD file name. The C&G CRD file will automatically be converted to a Carlson CRD file. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Receiving a Raw Data File from CGField

CGField:

- 1) Go to the UTILS menu and select Option 1, C&G Transfer.
- 2) Select Option 2, "Send Raw Data". Stop here in CGField and go to Carlson.

Carlson:

Leave the FILE fields blank.

Press the "Download Raw" button to ready Carlson to receive the file. Stop here in Carlson and go back to CGField.

CGField:

Select the raw data file to be sent. The transfer will begin.

The C&G .RAW file will be transferred and saved in the data folder. After the transfer is complete, you will be asked for the RW5 file name. The RAW file will be automatically converted to a Carlson RW5 file.

Receiving an ASCII file from CGField

This will allow you to transfer a C&G report file (RPT) or an ASCII NEZ file to Carlson.

CGField:

- 1) Go to the UTILS menu and select Option 1, C&G Transfer.
- 2) Select Option 6, "Send ASCII". Stop here in CGField and go to Carlson.

Carlson:

Leave the FILE fields blank.

Press the "Download ASCII" button to ready Carlson to receive the file. Stop here in Carlson and go back to CGField.

CGField:

Select the ASCII file to send.

After the transfer is complete, you will see the file in the Carlson editor. You can then select FILE and SAVE (or SAVEAS) to save the ASCII file.

Sending a Coordinate File to CGField

CGField:

- 1) Go to the UTILS menu and select Option 1, C&G Transfer.
- 2) Select Option 3, "Receive Coords" to ready the data collector. Stop here in CGField and go to Carlson.

Carlson:

Leave the FILE fields blank.

- 1) Press the "Upload (Send Carlson File)" button.
- 2) Select the Coordinate file.
- 3) Select the points to send.
- 4) Press the "Start Transfer" button.

CGField:

Carlson will send the file name to CGField and a coordinate file with the same name will be automatically created or opened in CGField.

If the file exists you will be asked how you want to handle duplicate points:

- 1) Overwrite
- 2) Don't Overwrite
- 3) Ask for each Point

The point transfer will begin.

Convert CG .RAW to Carlson .RW5

This utility allows you to convert a C&G raw data file to a Carlson raw data file. Select the C&G .RAW file to convert. Then enter the file name of the destination Carlson RW5 file.

Thales/FastSurvey You will be taken directly to the SurvCOM dialog, similar to the Carlson SurvCE process.

Surveyor's Assistant

Download

From the Surveyor's Assistant data collector, go to the Transfer routine from the main menu. Fill out the transfer screen as follows:

Direction: OUTPUT

Format: LIETZ

Data: Coordinate or All Data

Port: COM1 or COM2 Ckh Hold: NO

Protocol: NONE

You should also check the settings under the PORT menu. Typical port settings are baud=9600, parity=none, data=8, stop=1 and handshake=XON/XOFF. Now in Carlson, run *Data Collection* in the Survey menu and choose Surveyor's Assistant. Check that the COM port and baud rate are set correctly. Then click the Download button and within 10 seconds go back to Surveyor's Assistant and press GO. The file transfer should now go. If the All Data option is used, then the Leitz format will contain both coordinate and raw data. The coordinate data is converted to a Carlson coordinate (.CRD) file and the raw data is converted to a Carlson raw data (.RW5) file. When the transfer is complete, the program will ask you for the Carlson coordinate (.CRD) file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Upload

Point data from the Carlson coordinate (.CRD) file can be uploaded into the Surveyor's Assistant. First go to the Transfer routine on the main menu. Fill out the screen as follows:

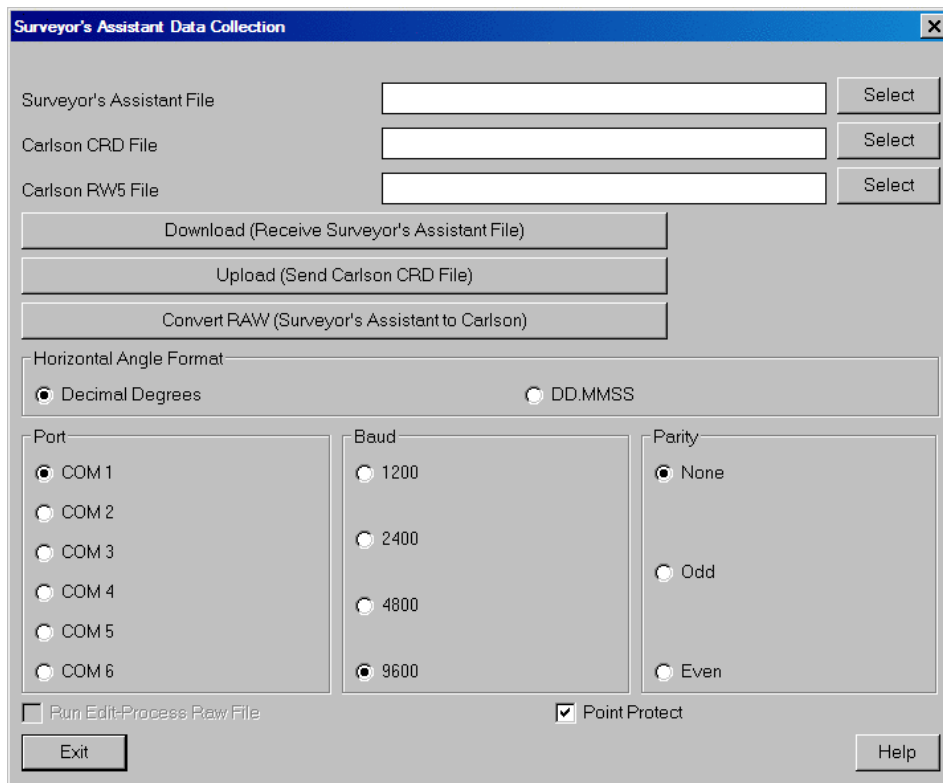

Direction: INPUT

Format: LEITZ

Port: COM1 or COM2

Protocol: NONE

Go back to Carlson and choose Surveyor's Assistant from the *Data Collection* command in the Survey menu. Check that the COM port and baud rate are set correctly. In the Carlson dialog, pick the Select File button next to the Carlson coordinate (.CRD) File edit box and choose the coordinate (.CRD) file to send. Then click the Upload button. A dialog now allows you to specify the range of point numbers to upload. Before clicking the OK button for range of points, go to the Surveyor's Assistant and hit the GO function key. The Surveyor's Assistant is now waiting to receive so return to Carlson and click OK on the range of point dialog. The file transfer should now go.

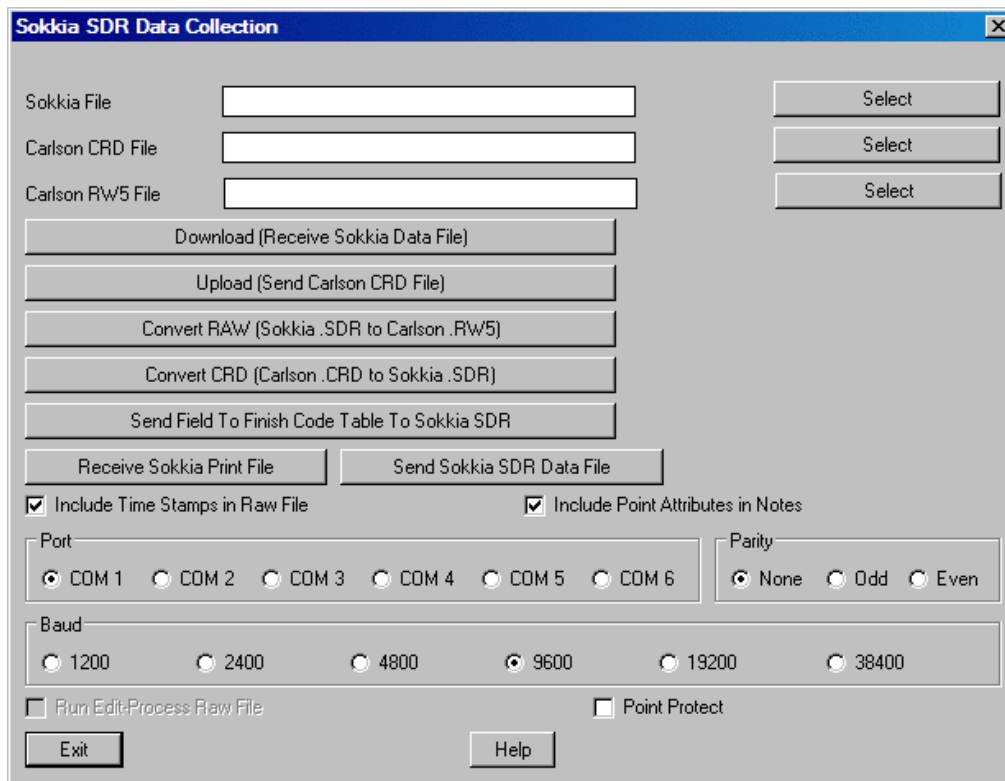

Sokkia SDR

This routine applies to the Sokkia SDR-20, SDR-22, SDR-31 and SDR-33 as well as other collectors that have SDR format transfer such as the Trimble and C & G.

Download

From the SDR data collector, go to the Communications routine from the main menu. Choose Data Format SDR. Next hit the Send function key. Then choose Select Jobs. From the list of jobs, highlight the job to transfer and set it to Yes with the arrow keys. Now in Carlson, run *Data Collection* in the Survey menu and choose Sokkia/SDR. Check that the COM port and baud rate are set correctly. Then click the Download button and within 10 seconds go back to SDR and press OK. The file transfer should now go. The SDR format contains both coordinate and raw data. The coordinate data is converted to a Carlson coordinate (.CRD) file and the raw data is converted to a Carlson raw data (.RW5) file. The original SDR transfer file is stored on the computer as a RAW file. When the transfer is complete, the program will ask you for the Carlson coordinate (.CRD) file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

The SDR-33 has different modes for storing and transferring data. In coordinate mode, the download will create points in the coordinate (.CRD) file and the raw data (.RW5) file will only contain some basic header lines. In the raw data mode, the download will create all the measurement data in the raw file and no points will be created in the coordinate (.CRD) file. For this raw data mode, you will need to run *Edit-Process Raw Data File* in the Survey menu to calculate the points from the raw data. The third mode in the SDR-33 creates both raw data in the raw data (.RW5) file and points in the coordinate (.CRD) file. The Include Time Stamps in Notes option sets whether all the date-time records for each point are put in the raw data (.RW5) file as description records. The Include Point Attributes in Notes option will store SDR code 13(AT) codes to the point note (.NOT) for the coordinate (.CRD) file.

Upload

Point data from the Carlson coordinate (.CRD) file can be uploaded into the SDR. First go to the Communications routine on the SDR main menu. Choose Data Format SDR. Go back to Carlson and choose Sokkia/SDR from the *Data Collection* command in the Survey menu. Check that the COM port and baud rate are set correctly. In the Carlson dialog, pick the Select File button next to the Carlson CRD File edit box and choose the coordinate (.CRD) file to send. Then click the Upload button. Then a Sokkia Options dialog appears for setting the job parameters for the file to be created on the collector. Be sure to choose the Distance Unit that matches your coordinate (.CRD) file (meters, US feet or international feet). Click OK and the next dialog now allows you to specify the range of point numbers to upload. Before clicking the Start Transfer button for range of points, go to the SDR and hit the Receive function key. The SDR is now waiting to receive so return to Carlson and click Start Transfer on the range of point dialog. The file transfer should now go.

Communication Settings

Besides matching the baud rate between Carlson and the collector, make sure that the collector is set to word length of 8 and 1 stop bit under the communication settings.

Print File

The Receive Sokkia Print File downloads a print report from the SDR33 data collector. This file is only used for printing report purposes in Carlson. This file is not used by Carlson to generate coordinate (.CRD) files or raw files. The first step is to choose Data format=Printed in the Communications menu of the SDR33. Next pick the Receive Print File button in Carlson. Then on the SDR33 choose the Send function and select a job to send. At this point the file is transferred. After downloading, the job report is displayed in the Carlson standard report viewer.

Example of Sokkia Printed Format:

```
SDR33 V04-04.25 (C) Copyright 1998 Sokkia May-29-80 23:39 01/29/1999
      Angle Degrees          Dist Feet
      Temp Farenht          Coord N-E-Elev
JOB      TRAV              Point Id Alpha (14)

** End of report **

```

Sokkia G2 This routine takes you directly to the SurvCOM dialog, similar to the Carlson SurvCE process.

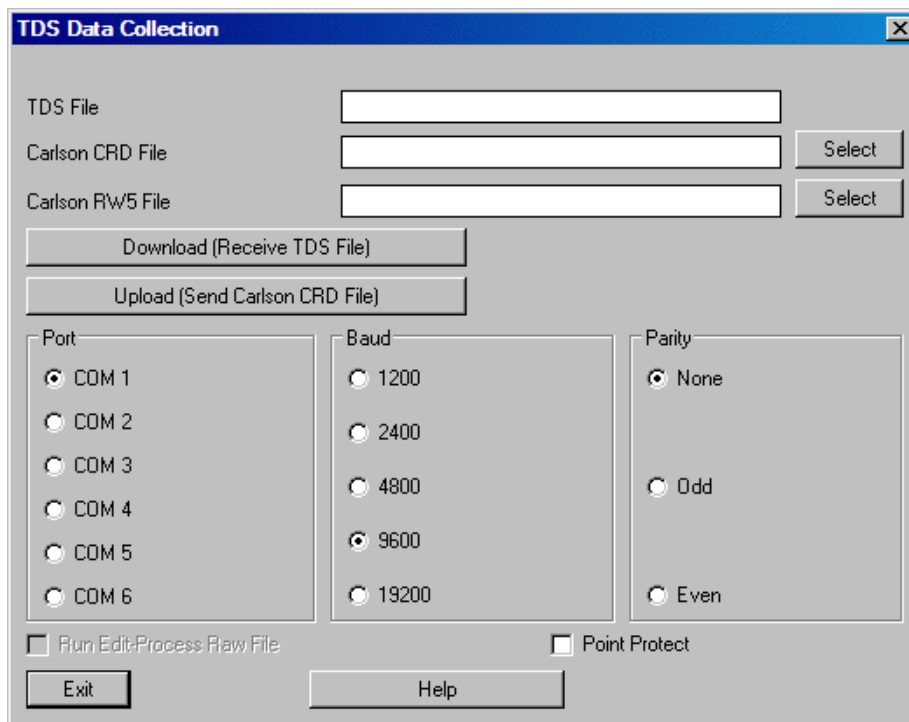

TDS

Download [HP-48 and Husky]

In the TDS program, go to the File Transfer routine. Choose the type of data to transfer (CRD or RAW). Next pick the Send function key. Stop here on the TDS and go to Carlson to run *Data Collection* in the Survey menu and pick TDS. Make sure that the COM port and baud rate are set correctly. Then pick the Download button. The Carlson program will now wait to receive the TDS file. Within 10 seconds select the file to send on the TDS. The file should be transferred now. When the transfer is complete, the program will ask you for the Carlson file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Download [Ranger and Windows CE]

In the TDS program, go to the Transfer routine and pick the Send File function. Set the "Connecting To" field to HP-48. Make sure that the COM port, baud rate and parity are set correctly and then pick OK. In the Type field of the file selection dialog, choose Coordinate Files or Raw Files. Stop here on the TDS and go to Carlson to run *Data Collection* in the Survey menu and pick TDS. Make sure that the COM port and baud rate are set correctly. Then pick the Download button. The Carlson program will now wait to receive the TDS file. Within 10 seconds select the file to send on the TDS and pick OK in the TDS dialog. The file should be transferred now. When the transfer is complete, the program will ask you for the Carlson file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Upload [HP-48 and Husky]

A Carlson coordinate (.CRD) file can be converted to a CR5 file and uploaded into TDS. Start in the TDS program, by going to the File Transfer routine. Then move back to Carlson and run *Data Collection* in the Survey menu and pick TDS. In the Carlson dialog, enter a TDS File name. This name should not include the drive and directory path or file extension. For example, if the coordinate (.CRD) file is c:\scadxml\data\simo2.crd then the TDS File name could be just SIMO2. Next pick the Select File button next to the Carlson coordinate (.CRD) File edit box and choose the coordinate (.CRD) file to send. Check that the COM port and baud rate are set correctly. Now pick the Carlson Upload button. A dialog now allows you to specify the range of point numbers to upload. Enter the range of points but before clicking the Start Transfer button go to TDS and hit the Receive function key. Within 10 seconds go back and click the OK button on the range of points. The file should then transfer.

Upload [Ranger and Windows CE]

A Carlson coordinate (.CRD) file can be converted to a CR5 file and uploaded into TDS. Start in the TDS program, by going to the Transfer routine and pick the Receive File function. Set the "Connecting To" field to HP-48. Make sure that the COM port, baud rate and parity are set correctly and then pick OK. Then move back to Carlson and run *Data Collection* in the Survey menu and pick TDS. In the Carlson dialog, enter a TDS File name. This name should not include the drive and directory path or file extension. For example, if the coordinate (.CRD) file is c:\scadxml\data\simo2.crd then the TDS File name could be just SIMO2. Next pick the Select File button next to the Carlson coordinate (.CRD) file edit box and choose the coordinate (.CRD) file to send. Check that the COM port and baud rate are set correctly. Now pick the Carlson Upload button. A dialog now allows you to specify the range of point numbers to upload. Enter the range of points and click the Start Transfer button.

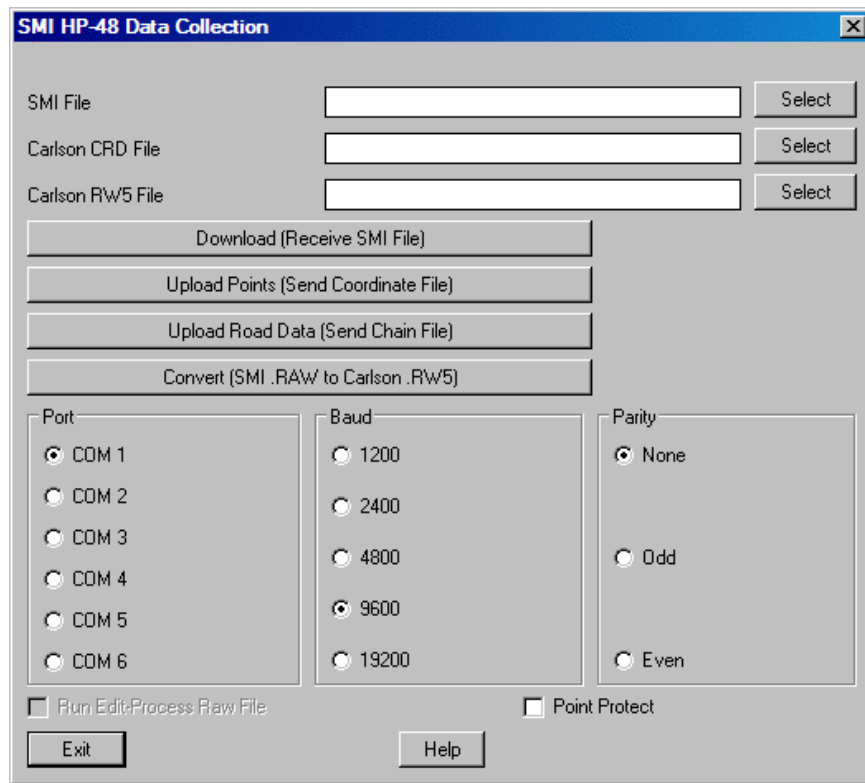

SMI

Download

To send point data from the SMI data collector, go to the file transfer routine by typing [More] [NXT] [TOPC] [COMM]. In SMI version 6 or later, type [Job][KERM][SEND]. Also in version 6, make sure that the first function key reads [NE] and not [XY] in the [Job][KERM] screen. Otherwise the coordinate northing and easting will be reversed. The [NE] stands for North-East coordinate order which is the format that Carlson expects. Also in the [Job][KERM] screen, make sure that the second function key reads [COMM] and not [SPACE]. The [COMM] stands for comma separators. Then enter the first point to send followed by the last point to send but before pressing Enter for the last point go to Carlson. Run *Data Collection* in the Survey menu and choose SMI. Check that the COM port and baud rate are set correctly. Then click the Download button and within 10 seconds go back to SMI and press Enter for the last point to send. The file transfer should now go. When the transfer is complete, the program will ask you for the Carlson coordinate (.CRD) file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector. To send raw data, use the [Print][Raw] routine in SMI along with the same Carlson procedure used for point data.

Upload

From the SMI data collector, go to the file transfer routine by typing [More] [NXT] [TO48] [COMM]. In SMI version 6 or later, type [Job][KERM][RECV]. Also in version 6, make sure that first function key reads [NE] and not [XY] in the [Job][KERM] screen. Otherwise the coordinate northing and easting will be reversed. Then enter the first point to send followed by the last point to send. Next enter the job name but before pressing Enter go to Carlson and run SMI under *Data Collection* in the Survey menu. In the Carlson dialog, specify the same job name as entered in SMI. Next pick the Select File button next to the Carlson CRD File edit box and choose the coordinate (.CRD) file to send. Check that the COM port and baud rate are set correctly. Then click the Upload button. A dialog now allows you to specify the range of point numbers to upload. Enter the same range of points as entered on the SMI. Go back to SMI and hit Enter for job name followed by clicking the OK button for range of points in Carlson. The file transfer should now go.

Leica

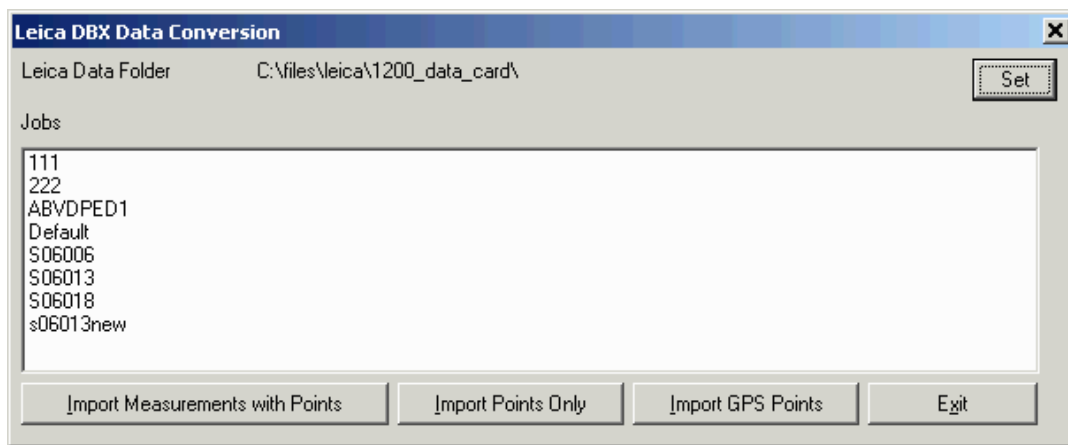

There are three types of Leica transfers: GIF-10, GeoCom and DBX.

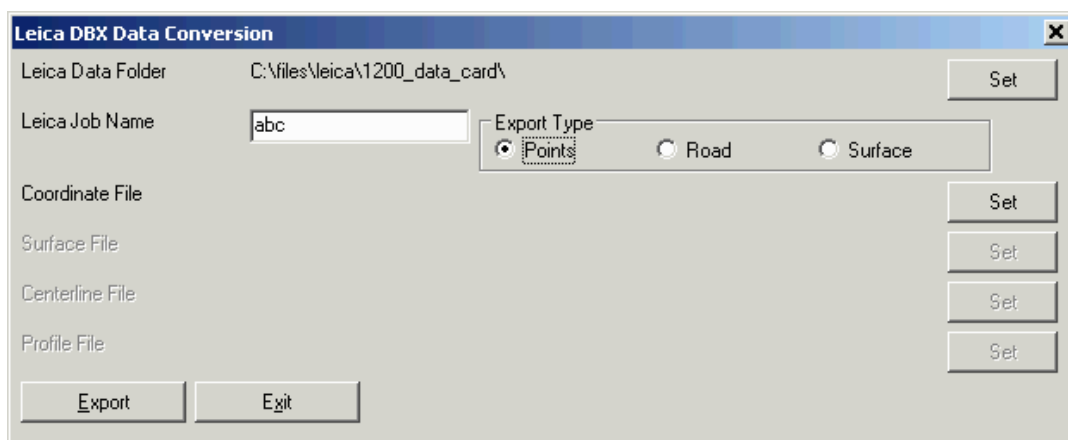

Choose newer Leica instruments, choose Leica DBX on first dialog. Then there is a choice between Import and Export.

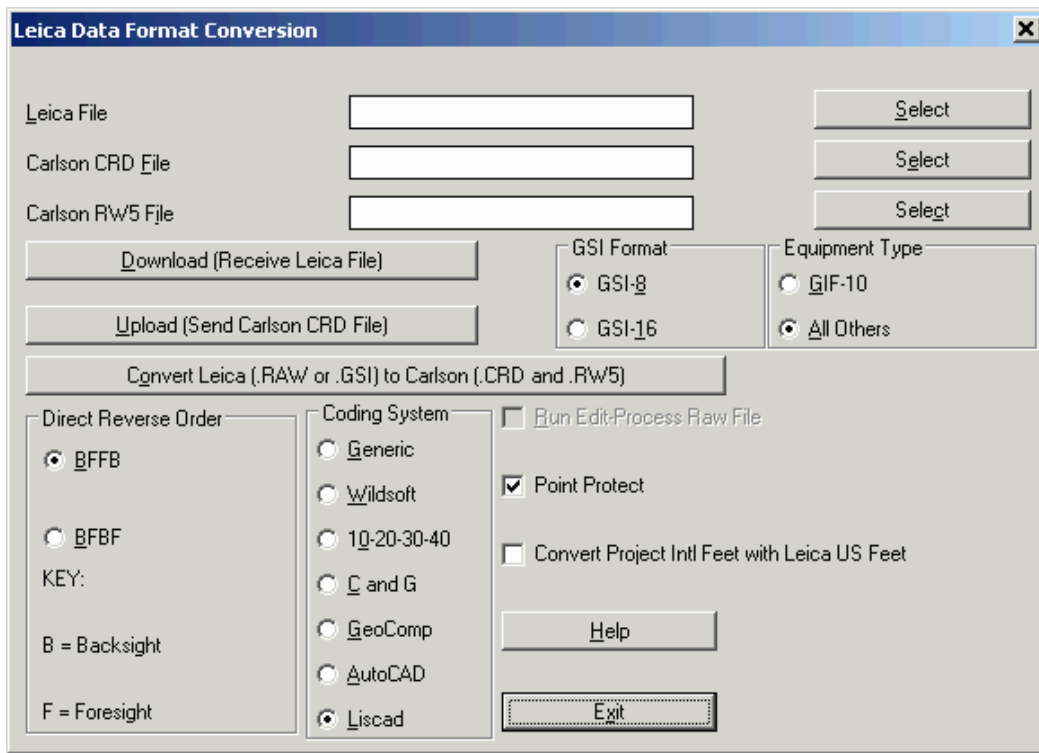

For Import, select the folder that contains the Leica DBX data. Typically the Leica DBX data is on a memory card that is inserted into the computer and gets assigned a drive name by Windows. Use the Set button to browse to this Leica DBX drive or folder. Then the program shows a list of the Leica projects in that folder. The Import Measurements With Points function reads the Leica data into Carlson CRD and RW5 files. The Import Points reads the Leica data into a Carlson CRD/CRDB file. If CRD file is chosen, then it will bring in attribute data to the Carlson NOT file. If CRDB file is chosen, then it will store attribute data to the CRDB file. The Import GPS Points function imports the Leica data into a Carlson RW5 file for GPS measurements.

For Export, select the folder to store the Leica DBX data to using the Set button. Enter in a job name for the new job in the Leica Job Name edit box. There are three types of project data that can be exported. The Points export converts a Carlson coordinate file to Leica format. The Road export converts Carlson profiles and centerlines to Leica format. The Surface export converts a Carlson TIN file to Leica format.

For GIF-10 and GeoCom, choose All Others on the first dialog Then the choice for GIF-10 or GeoCom is set in the Equipment Type field on the main dialog. For transferring with the Leica instruments, the GeoCom program shows a dialog of the available COM ports on your computer. On the first time that you transfer to an instrument, you will need to pick the Instruments button and register the instrument from the list. Pick the Port Settings button to make sure that the communication settings match the instrument.

To download a file with GeoCom, make sure that the instrument is ON and connected to the computer by serial cable. The instrument also needs to be in GeoCom mode. Then pick the Download in the Carlson dialog. In the GeoCom program, open the computer COM port that the instrument is connected to by picking the '+'. Then open the Memory Card and GSI folders. Next select the file to transfer and click the OK button. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

To upload a file with GeoCom, specify the file name to be created on the instrument in the Leica File field and pick the Upload button in the Carlson dialog. Then the program will prompt for the range of points to transfer. Fill out the range and pick the Start Transfer button. Then the GeoCom program will start. Open the computer COM port by picking the '+'. Then open the Memory Card folder and highlight the GSI folder and click OK.

The upload and download file transfer works with the GIF-10 data collector. The GIF-10 communication settings should be the following:

- Baud: 9600
- Parity: NONE
- Protocol: NONE
- Stop Bit: 1
- End Mark: CR/LF
- Connected As: Some computers use DCE and others use DTE

Download

From the GIF-10, go to the file transfer routine. Then go to Carlson and run *Data Collection* in the Survey menu and choose Leica. Check that the COM port and baud rate are set correctly. Then click the Download button and within 10 seconds go back to GIF-10 and select the file to send. The file transfer should now go. When the transfer is complete, the program will ask you for the Carlson coordinate (.CRD) file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Upload

From the GIF-10 data collector, go to the file transfer routine. Then go to Carlson and run Leica under *Data Collection* in the Survey menu. In the Carlson dialog, specify the job name in the Leica File field. Next pick the Select File button next to the Carlson coordinate (.CRD) File edit box and choose the coordinate (.CRD) file to send. Check that the COM port and baud rate are set correctly. Then click the Upload button. A dialog now allows you

to specify the range of point numbers to upload. Before clicking the OK button for range of points, go to GIF-10 and start the receive by highlighting Receive and pressing the Run button. The GIF-10 now shows the available job numbers. Choose a job to receive the transfer using the arrow buttons and then press the Run button.

Converting

Carlson supports raw and coordinate data collected using three different Leica Operation Codes: Wildsoft and 10-20-30-40 as well as the newer LISCAD. Moreover, data could be in the GSI8 format or the newer GSI16 format. Some example files are shown here.

GSI8 format data file using LISCAD Operation codes:

WILD GIF-12

Leica raw files usually have a .RAW or .GSI extension. The primary difference in the GSI8 and GSI16 formats is that information is contained in data blocks of 16 characters in the GSI16 format, while it is contained in blocks of 8 characters in the GSI8 format. Leica instruments make it possible to have both the GSI8 as well as GSI16 data formats in the same raw file. However, lines with the GSI16 format data will always start with an asterisk (*) character, to distinguish them from the GSI8 format. There is no distinction between Leica raw files collected in the Wildsoft and LISCAD operation codes.

Supported Wildsoft codes:

- 1: Start Job
- 11: Assign Coords
- 12: Coord Offset
- 13: Target Height
- 14: Add to Tgt Ht
- 15: Add to Meas Dist
- 2: Occupy Point
- 21: Occupy Saved Point
- 3: FS to Trav Pt
- 31: FS to Single Pt
- 32: Radial Sideshots
- 33: Sets of Angles
- 4: Closing Pt
- 41: Closing Angle
- 50: BS to Benchmark
- 51: FS to Turn Pt
- 52: BS to Turn Pt
- 53: FS to Benchmark
- 60: Save Point
- 61: Recall Point
- 62: Compare Point
- 63: Remark

Supported LISCAD codes:

- 1: New instrument setup
- 2: New target height
- 3: Sets of directions
- 4: Fixed azimuth
- 5: Feature code
- 6: Measured offset
- 8: Line creation for sub-codes 1 (straight string), 2 (curved string) and 6 (arc by 3 points)
- 9: Fixed coordinates
- 11: Close string
- 14: Additional description
- 20: Start of job
- 27: Feature code
- 90: Split feature code
- 100+: Descriptions

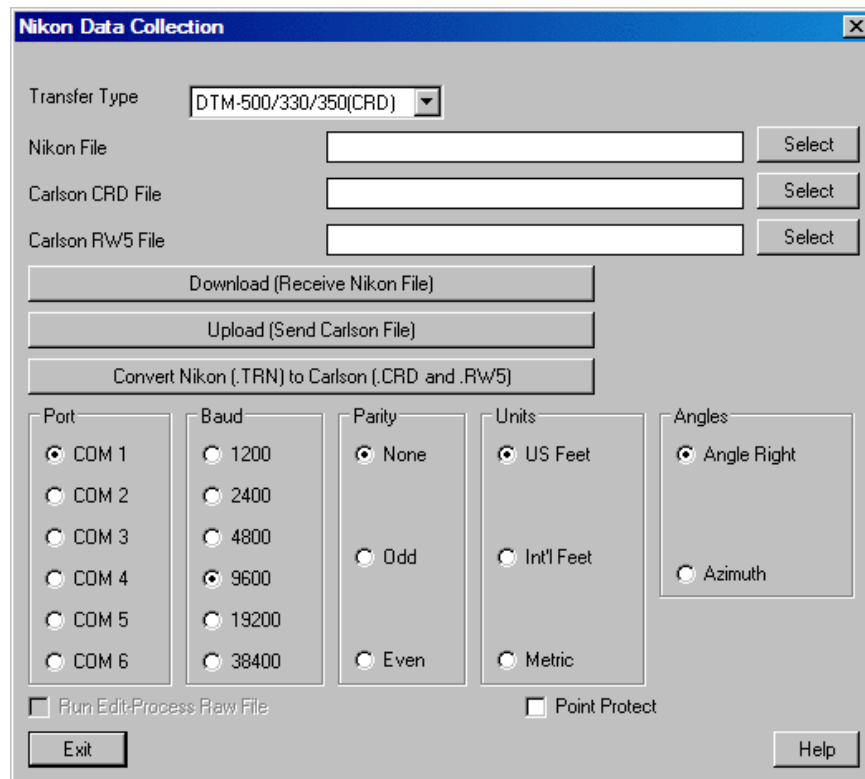

The Convert button can be used to convert any Leica format file into a Carlson format file. For example, if you have a Leica PCMCIA card then there is no serial cable transfer to do. Instead use the Convert routine to make the Carlson raw data (.RW5) and coordinate (.CRD) files. Since there is no distinction between Wildsoft and LISCAD files, the user must know in advance which format has been used in the file. Then, select that particular option (Wildsoft, 10-20-30-40 or LISCAD) under the "Coding System" option at the bottom of the dialog box, as shown in the previous page. Another option that the user needs to choose is the order in which foresight-backsight readings have been recorded in the raw file, BFFB or BFBF, as explained in the dialog box. Then, the user can simply pick the "Convert" button and the program prompts for the input "Wild/Leica File" (raw file), and the output "Carlson RW5 file" and "Carlson CRD file", if they are not already filled.

Nikon**Download**

First choose the equipment and data type under the Transfer Type list. Also check that the communication and data format settings match your collector. Then click the Download button and follow the on-screen directions. When the transfer is complete, the program will ask you for the Carlson coordinate file (.CRD) and raw file (.RW5) to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector. The original data from the collector is stored in a file name with the same name as the coordinate file except with a .TRN extension. For example, job5.crd would have job5.trn.

Upload

Pick the Select File button next to the Carlson CRD File edit box and choose the CRD file to send. Check that the COM port and baud rate are set correctly and then click the Upload button. A dialog now allows you to specify the range of point numbers to upload. Set the points and then click the Start Transfer button. The file transfer should now go.

Convert Nikon to Carlson

The Convert button will translate the Nikon raw file format (.TRN or .RAW) into Carlson coordinate (.CRD) and raw (.RW5) files.

Portion of typical Nikon file format:

```
MP,1,,5000.0000,5000.0000,0.0000,T/1
CO,31-Oct-1999 11:42:38
ST,1,,2,,0.0000,0.00000,0.00000
SS,3,0.0000,152.1510,359.59590,90.44100,11:43:38,T/2
SS,4,0.0000,127.5560,0.06040,90.40110,11:44:45,CON
SS,5,0.0000,97.1820,2.19580,90.52460,11:45:43,CON
```

Geodimeter

Download

From the Geodimeter data collector, go to the file transfer routine by pressing the PRG (Program) key and entering

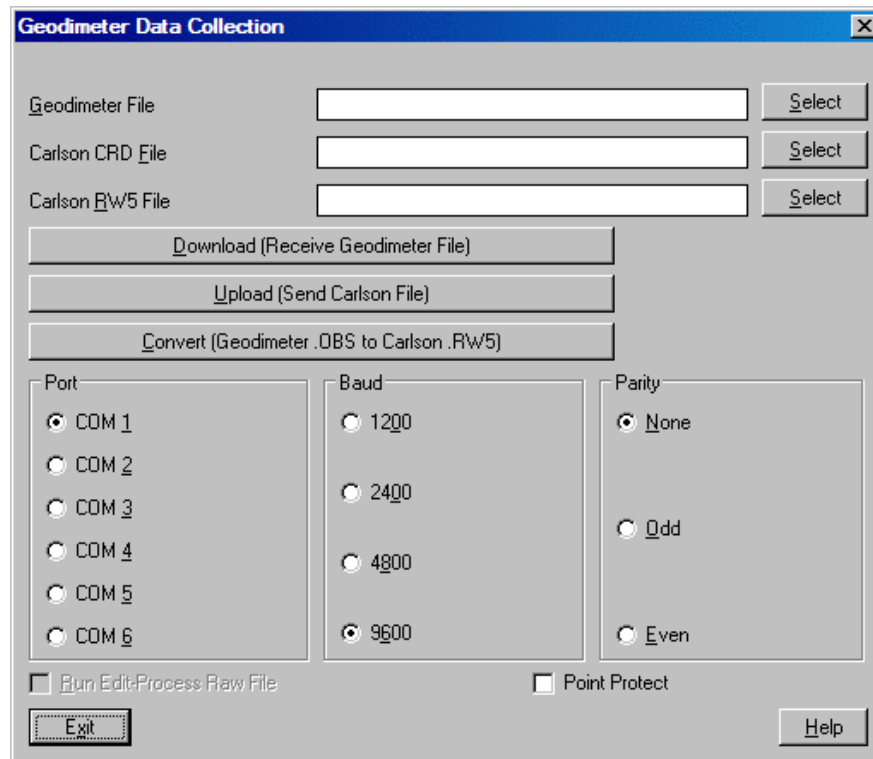

program 54. Then choose Imem (option 1) as the source. Next choose the file type to send as either Job (measurement data) or Area (point data). The Geodimeter will then prompt for the job name. Next enter Serial (option 3) as the destination. A confirmation screen appears showing the serial port settings. Here are some typical settings:

COM=1,8,0,9600

Before pressing enter (ENT key), go to Carlson and run *Data Collection* in the Survey menu and choose Geodimeter. Then click the Download button and within 15 seconds, go back to the Geodimeter and press Enter. The file transfer should now go. When the transfer is complete, the program will ask you for the Carlson coordinate file and raw file to create if you haven't already specified a file name in the dialog. With Point Protect on, the routine will check the coordinate file for existing point data before downloading the point from the data collector.

Upload

In Carlson, run Geodimeter under *Data Collection* in the Survey menu. Pick the Select File button next to the Carlson CRD File edit box and choose the CRD file to send. Check that the COM port and baud rate are set correctly and then click the Upload button. A dialog now allows you to specify the range of point numbers to upload. Enter the points to send but before clicking OK, go to the Geodimeter data collector. Start the file transfer routine by pressing the PRG key and entering program 54. Then choose Serial (option 3) as the source. The Geodimeter will display the serial port settings. Check these values and press enter. Next choose Area (option 2) as the destination. Then enter the job name. The Geodimeter is now listening for data. Quickly go back to Carlson and click OK on the points to send dialog. The file transfer should now go

Convert

The Convert button will translate the Geodimeter raw file format (.OBS) into Carlson coordinate (.CRD) and raw (.RW5) files.

Communication Settings

If the Geodimeter is not communicating with Carlson, run function 79 on the Geodimeter and make sure that it is set to 4. This setting is for the transfer message end of sequence format.

Supported Geodimeter Codes

The following Geodimeter codes are processed when converting the Geodimeter raw file. All other codes are

recorded as descriptions in the Carlson rw5 file.

0=Info

1=Data

2=Station No

3=Instrument Height

4=Point Code

5=Point Number

6=Signal Height

7=Horizontal Angle

8=Vertical Angle

9=Slope Distance

11=Horizontal Distance

17=Horizontal Angle

18=Vertical Angle

21=Horizontal Reference Angle

30=Atmospheric Correction

37=Northing

38=Easting

39=Elevation

40=Delta North

41=Delta East

42=Delta Elevation

45=Correction To Bearing

46=Standard Deviation

50=Job Number

51=Date

52=Time

53=Operator

54=Project Id

55=Instrument Id

56=Temperature

60=Shot Id

61=Activity Code

62=Reference Object

70=Entered Radial Offset

71=Entered Angle Offset

72=Calculated Radial Offset

73=Calculated Angle Offset

74=Air Pressure

Portion of typical Geodimeter file format

5=108

4=13POC

6=5.000

7=238.0708

8=89.2236

9=440.39

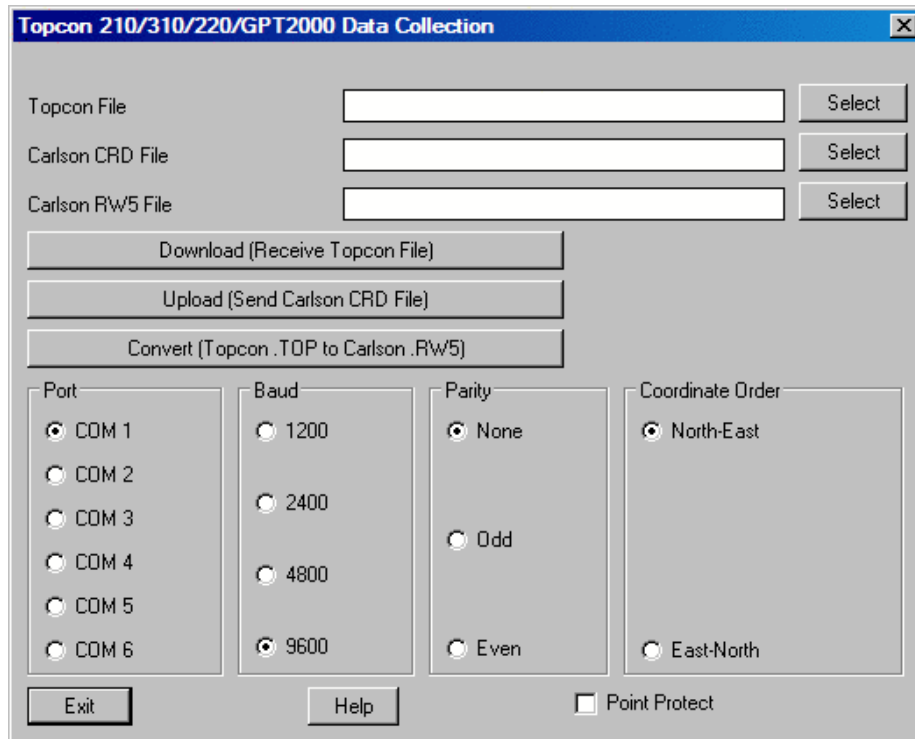

37=767.42

38=4626.07

39=699.795

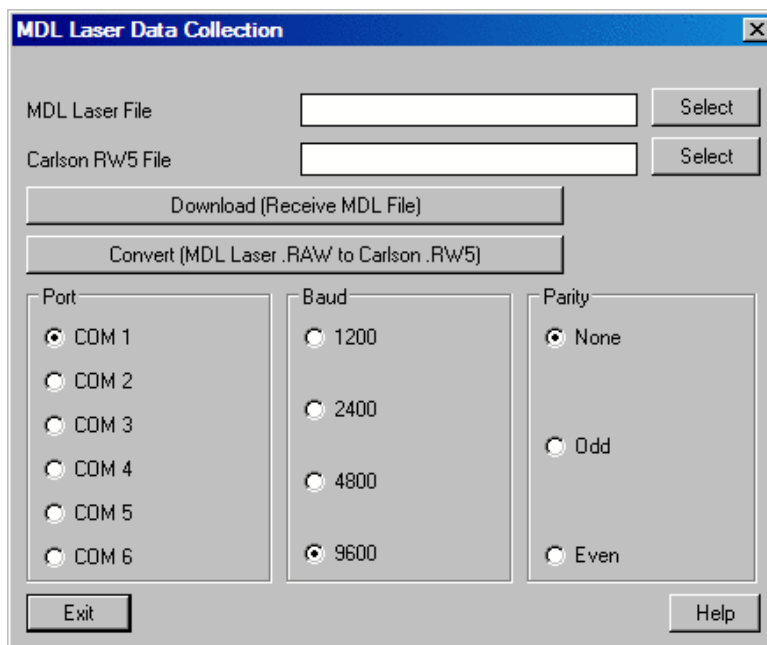

Topcon 210/310/220/GPT2000

This command supports these above Topcon models.

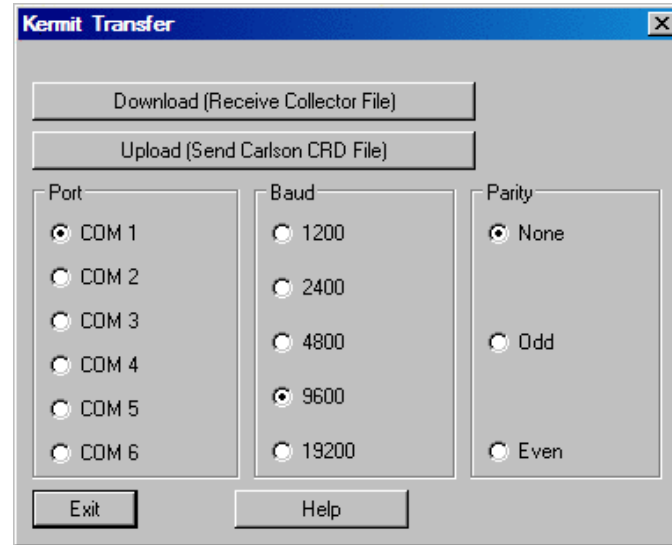

MDL Laser

The MDL Laser outputs a raw file of angles, distances and codes as one long string of data which can be converted into a Carlson raw data (.RW5) file. There is no coordinate data in the MDL raw file. So you need to run *Edit-Process Raw File* to calculate coordinates from the raw data. The Download button will transfer the MDL raw data from a BDI logger.

Kermit

Kermit can be also used for transferring files with accuracy. The dialog looks like this:

Pulldown Menu Location: Survey

Keyboard Command: datacolt

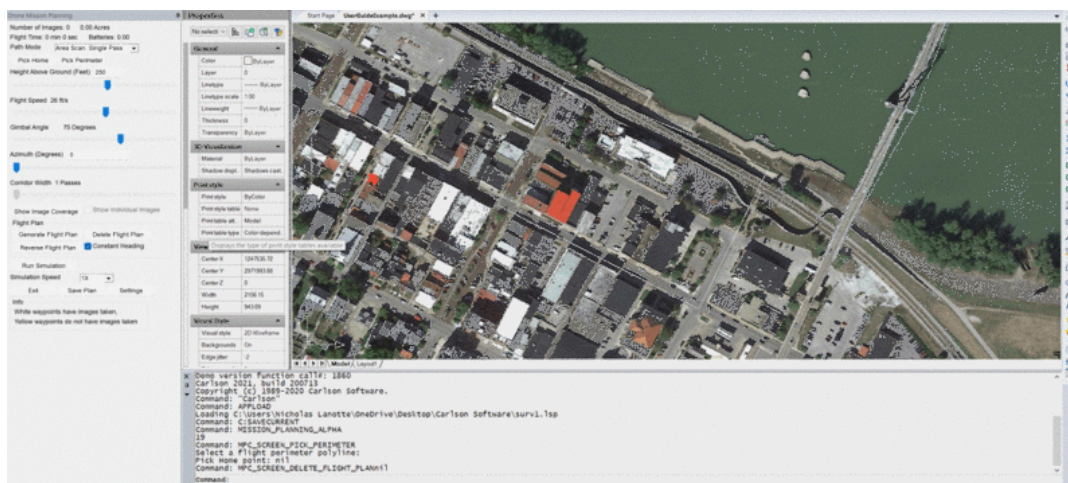

Prerequisite: None

Drone Mission Planning

This command generates a drone flight plan for taking aerial photos. Before running this command, set the Coordinate System for the drawing using the Drawing Setup command. Also before this command, you can optionally load an aerial image into the drawing using the Place Google Earth Image command.

Basic Workflow

1. When the Drone Mission Planning command starts, it places a dialog on the left side of the drawing.

2. Select a path mode. Defaults to Area Scan: Single Pass.
3. Draw a Polyline to perform the Area Scan on. The Polyline must be closed for an area scan or structure scan and must be open for a corridor scan. Structure scans and corridor scans can only be performed on polylines that do not contain arcs.
4. While Area Scan or Structure Scan is the selected Mode there will be a "Pick Perimeter" button to select the polyline. If the Path Mode is Corridor Scan this button becomes "Pick Corridor".
5. Click "Pick Home" then select the location in CAD you wish to launch the drone from. You may be asked to select a home position after selecting the scan polyline.
6. The flight plan should automatically be plotted. The number of images, estimated flight time and the area covered will be displayed at the top of the drone mission plan dialog. Use the parameter sliders to adjust the flight plan in real time. Yellow points are waypoints without images and white points are waypoints with images.
7. When the plan is satisfactory, press the "Save Plan" button to save the drone mission plan as a .plan file. These files can be read by the DJI Companion App, Drone Deploy and qGroundControl. For example, the .plan file can be loaded into Drone Deploy where the mission can be edited further and uploaded to the drone.

Features

Icons: The Mission Home position is represented by the Yellow target. The flight plan is drawn in solid White. Each location where a photo is taken will be shown as a circle with an arrowhead inside. The direction of this arrow head is the heading of the camera while taking this image.

Height Above Ground: This setting controls the height above ground level the aircraft will fly for the mission. The highest allowed height is 400 ft and the lowest allowed height is 40ft. Higher heights result in fewer images taken.

Flight Speed: This setting controls the flight speed of the aircraft. Faster speeds result in lower mission times. The lowest speed is 1ft/s and the fastest speed allowed is 50ft/s

Frontlap: This setting controls the amount of overlap in the forward direction of each image. A front lap of 60% minimum is recommended. Larger overlap results in more images.

Sidelap: This setting controls the amount of side overlap of each image. A side lap of 70% minimum is recommended. Larger overlap results in more images.

Gimbal Angle: This setting controls the Gimbal angle for the flight. 90 degrees points the camera straight down while smaller angles orient the camera closer to horizontal. The recommended Gimbal angle is 75 degrees.

Azimuth: This setting controls the angle flight lines for the Area and Structure scan will be drawn at. Adjust this setting if necessary if the generated plan does not completely cover the scan area or the drone would fly over areas that are not desired. 0 degrees points north and the degrees increase in the clockwise direction

Corridor Width: This setting only becomes active while in Corridor Scan Mode. This controls the amount of back

and forth passes the drone will take along the corridor. The more passes the wider the corridor becomes.

FOV: This setting should be sent to the FOV of the camera on the drone

Aspect Ratio X: This setting should be sent to the X portion of the aspect ratio of the camera on the drone

Aspect Ratio Y: This setting should be sent to the Y portion of the aspect ratio of the camera on the drone

Delete Flight Plan: This button will delete everything in the flight plan

Reverse Flight Plan: This button will reverse the direction of the flight plan

Constant Heading: Checking this box has the heading of the drone remain constant throughout the mission (except when not possible with a corridor scan and outer perimeter of structure scan). Unchecking the box will have the drone fly more like an airplane.

Show Image Coverage: Pressing the "Show Image Coverage" button will draw the area that the camera will capture during the mission. To see the area of each individual image, enable the "Show Individual Images" option.

Simulator: Pressing the "Run Simulation" button after a drone mission plan has been made, will run a simulation with the drone represented by a red target. It will move along the path with the path traversed highlighted in red. Use the Simulation Speed drop box to speed up or slow down the simulation. The "Run Simulation" button will become the "Stop Simulation" button while the simulation is running. Pressing this button stops the simulation. The current image count will appear next to this button and update as the drone flies over each of the image points.

Automatic Checks: While generating the drone mission plan, the routine automatically checks to ensure the entire scan area is covered by the images. If it is not, the user will be shown a warning. Use the "Show Image Coverage" features to view what area is not covered. Use the parameter sliders to adjust the drone mission plan until the full area is covered. While generating the drone mission plan, the routine automatically checks to ensure that the drone mission plan is within 400 meters of the home position so that a line of sight from the operator to the drone is possible. If the drone mission plan extends beyond 400m, the user will receive a warning.

Area Scan Single Pass: This Path Mode creates a flight plan that covers a selected perimeter, only flying the drone over the area once. The flight paths are drawn in the direction of the Flight Angle and with offsets that are a function of the Height Above Ground, Sidelap and camera parameters.

Area Scan Double Pass: This Path Mode is the same as the Single Pass mode except the drone will not fly over the area two times. The second pass will have the flight lines draw perpendicular to the previous pass.

Corridor Scan: This Path Mode will create a drone mission plan along an open polyline with each image evenly spaced out along the polyline. The spacing is a function of the Height Above Ground, Sidelap and camera parameters. Adjusting the Corridor Width slider to be larger than 1 pass will result in the scanned area being wider as each pass is made at an offset from the original.

Structure Scan: This Path Mode will create the same path as a Area Scan: Single Pass with the addition of a perimeter scan at the end. The Perimeter Scans sets the heading of the drone camera to be towards the inside of the closed polyline. This feature allows structures to be scanned with more images from better 3D models of the exterior vertical surfaces. The scan polyline can only include line segments.

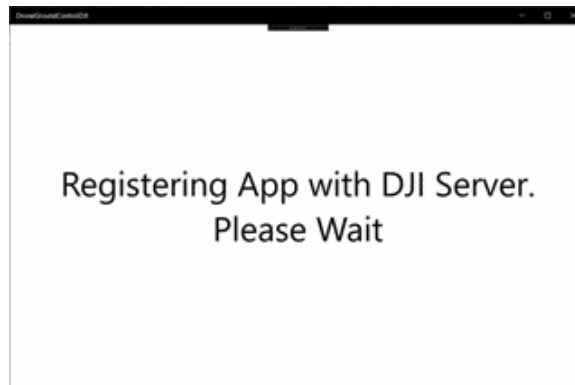

Elevation Compensation: For use on highly uneven terrain. The drone is only able to sense the height above ground level from where it was launched. Terrain that has large elevation differences can result in the camera captures too large or too small of an area, or in the presence of a large hill, cause the drone to crash. This setting retrieves the elevation at each photo point and applies an offset to the Height Above Ground level so that the drone's actual height above ground level at each photo point is the desired value.

Stop For Pictures: Enabling this setting will have the drone stop at each Geolocation to take each picture. This may result in more accurate image overlap and stability but will increase flight time and use more of the drone's battery.

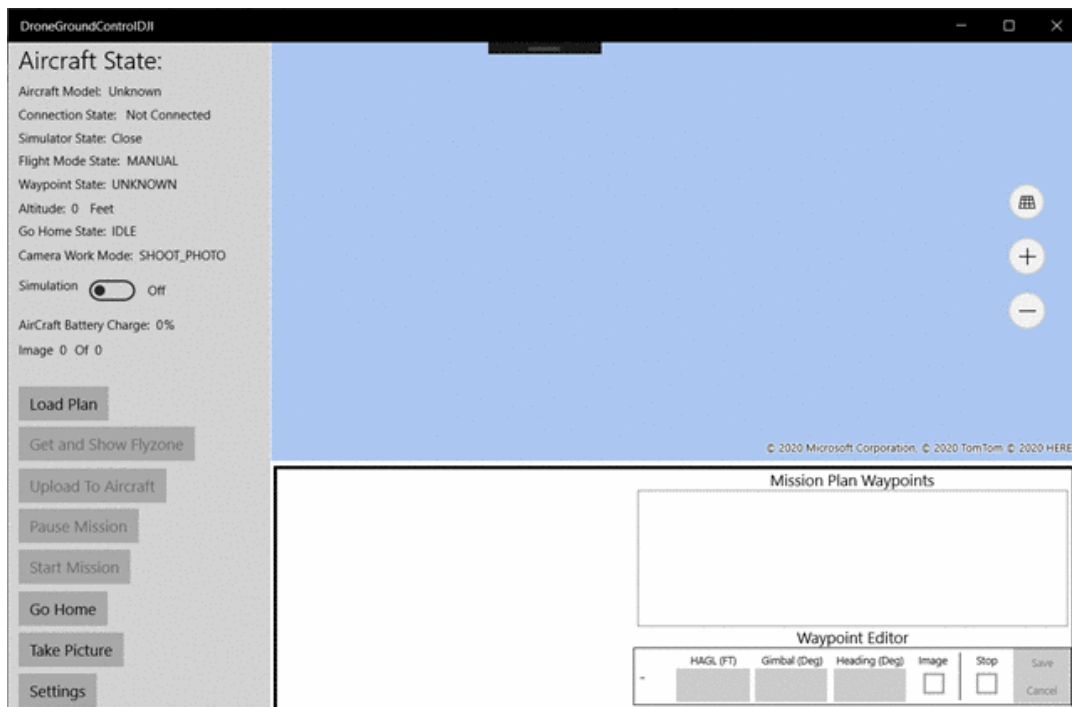

DJI Companion APP

Basic Workflow

1. After launching the app there will be a screen that say it is registering with DJI. This screen will hold itself until a response is received. If this screen gets stuck on for a while then it is something wrong with DJI's servers.

2. Upon success the main window will be shown.

3. Press load plan and select the drone mission plan created by pointcloud. The screen should look similar to this image.

4. Press upload to aircraft. Once the mission is done uploading the Waypoint State should say "READY_TO_EXECUTE" and the Start Mission button will be enabled. Sometimes the drone won't report this right away. Try uploading the plan again or restarting the app if this happens. There are a lot of background threads running within DJIs SDK and some of these errors are a result of not knowing exactly how they work.
5. Press Start Mission when ready. The mission will be executed, and the drone will auto land when completed. If the mission fails to start, an error message will be shown to the user. The Aircraft position will be shown on the map and the aircraft Altitude will be updated in real time. There is other aircraft state information displayed in the app that is mainly used for testing purposes.
6. You can pause or stop the mission at any time while it is running.

This process should result in a lot of pop-ups to be displayed. If everything is running as expected they should all report "NO_ERROR".

Features

Load Plan: This button will open the Windows File Selection Tool. Select the .plan file for the current mission. If there are no problems the application will report "NO_ERROR".

Get and Show Flyzone: This button will retrieve the nearby flyzones and display them on the map.

Upload to Aircraft: This button will upload the selected plan to the aircraft. The program should report "No Error" if the plan is possible for the drone to execute and will report errors otherwise. In some rare cases, this may return "NO_ERROR" but the Waypoint State will revert back to "READY_TO_UPLOAD" instead of "READY_TO_EXECUTE". This is an internal error with the drone firmware that the DJI SDK will not report. Making a slight modification to the drone mission plan in the Pointcloud drone mission planner should solve this issue.

Simulation: It may be useful to simulate the drone mission plan beforehand. Enabling the Simulation toggle switch will put the drone in simulation mode. The application will run as normal, but the drone will not take off. The drone must be turned off and on again to exit Simulation Mode.

Pause/Resume Mission: This button can be used while a mission is running to pause or resume the mission. There is an option to swap batteries when pausing the mission. As of writing this guide the feature does not work. Disconnecting the drone and reconnecting it causes an error with DJIs software preventing the mission from being continued. This needs to be fixed before using this feature

Start/Stop Mission: This button is used to start the drone mission plan, or if the mission is running it is used to

stop the mission.

Go Home: This button will have the drone return home and land.

Take Picture: This button will have the drone camera take a picture and save it to the SD card if enough space is available.

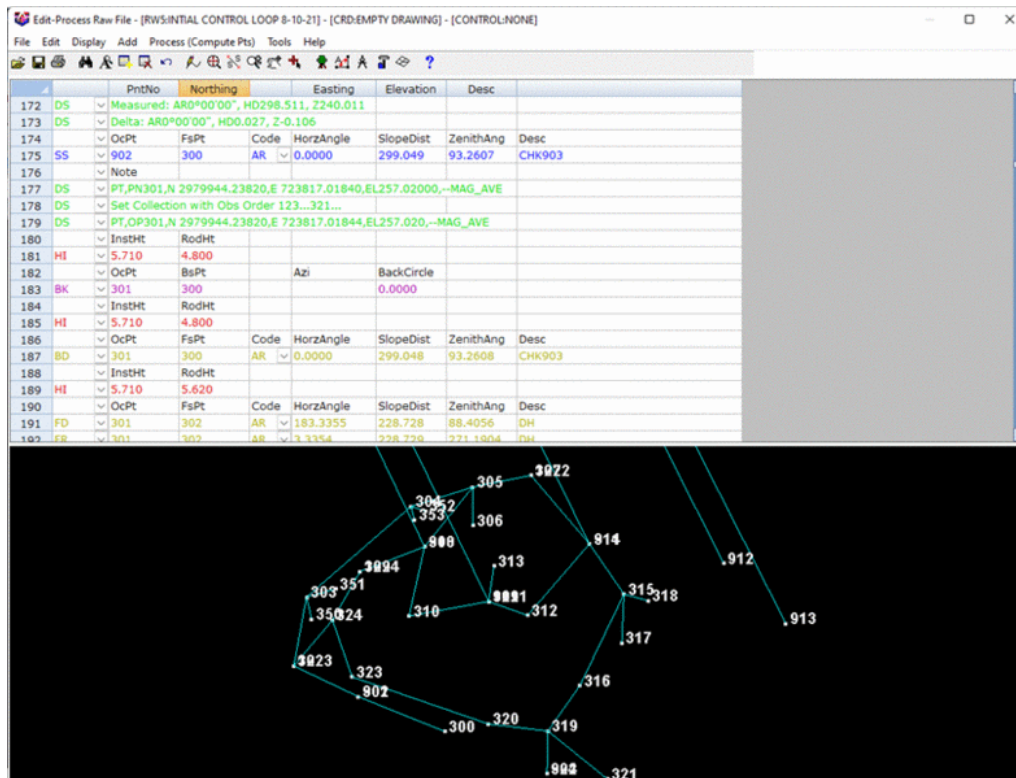

Pulldown Menu Location: Survey

Keyboard Command: mission_planning

Prerequisite: Set Coordinate System in Drawing Setup

Edit-Process Raw Data File

This program reads or creates a raw data (.RW5) file that contains various lines of data (records) that can be likened to a surveyor's field book. The RW5 file can contain both Traverse/Side Shot data from an EDM total station as well as GPS position coordinates and vector data from a GNSS receiver.

The Edit Process Raw Editor contains 7 separate pull down menus:

File

Edit

Display

Add

Process (Compute Pts)

Tools

Help

Within the Editor itself, you can specify point coordinates, job information, notes, and the angles and distances that make up traverse or sideshots records. Once the raw data is created or read it can be processed and reduced to coordinates that are stored in the current coordinate (.crd; .cgc; .mdb; .zak) file.

The raw file can also be created or appended using the *Locate Point*, *Traverse*, *Sideshot*, and *Inverse* commands in the COGO menu. To store the data inputs from these commands into a raw file, first toggle on the *Raw File ON/OFF*

command on the COGO menu. It is possible to always have the raw data file open to store data inputs. To enable this option, choose Configure from the Settings menu, then choose Survey Module, then choose General Settings. Turn on the Automatic Raw File toggle in this dialog.

Legacy raw files created by TDS data collector programs are also compatible without conversion. The command *Data Collectors* on the Tools menu has options for reading other data collectors native file formats and converting them to raw data (.RW5) format. Within the raw data editor, the File menu includes an import menu for converting raw data from other formats.

When you select the *Edit-Process Raw Data File* command you are prompted to specify the name of the raw data (.RW5) file. The current coordinate file is used automatically. To change the current coordinate file, use the Set Coordinate File command in the Points menu before starting this command. If no coordinate file is current, the program will prompt you to set the current coordinate (.CRD) file.

Edit-Process Raw Data File uses a spreadsheet for editing the raw data as shown.

174		OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng	Desc
175	SS	902	300	AR	0.0000	299.049	93.2607	CHK903

178	HI	Set Collection with Obs Order 123...321...						
179	PT	PT,OP301,N 2979944.23820,E 723817.01844,EL257.020,--MAG_AVE						
180	DS	InstHt	RodHt					
181	HI	5.710	4.800					
182		OcPt	BsPt		Azi		BackCircle	

Each row of the spreadsheet is represented by a number located at the far left side of the editor. Various messages and reports often reference possible problems with the data by this row number. Each row of the spreadsheet represents one record of data. There are 14 types of **data records**. The type of data record is shown in the first column. Different record types use different numbers of columns. Whenever the data record type changes between rows, a record header is added to the spreadsheet that describes each column of data in the following row. To edit the raw data, simply highlight the cell and type in the new value. To change the type of record, pick on the down arrow in the first column and choose a new data type from the list. To delete a row, highlight any cell in the row and hit the Delete key or choose Delete Row from the Edit menu. Records can be added pressing the Insert key, pressing the down arrow key from the last line in the spreadsheet, or by choosing one of the add records from the Add menu.

The different data record types are described below.

TR (Traverse)

The traverse record contains the occupied point number, foresight point number, angle mode, horizontal angle, distance, vertical angle and description. When processed, this record will calculate and store the coordinates for the foresight point. Traversing also moves the setup by making the traverse foresight point the next occupied point and the traverse occupied point becomes the next backsight point. The different angle codes are NE for northeast bearing, SE for southeast, SW for southwest, NW for northwest, AZ for azimuth, AL for angle left, AR for angle right, DL for deflection angle left and DR for deflection angle right. To set the angle code, pick on the Code down arrow and choose from the list. The horizontal and vertical angles should be entered as dd.mmss. For example, 45.2305 is 45 degrees, 23 minutes and 5 seconds. The vertical angle can be shown as vertical angle (0 degrees level), zenith angle (90 degrees level) or elevation difference. The vertical angle mode is set in the Display menu. The distance mode is also set in the Display menu as either slope or horizontal distance. The description field is used as the foresight point description.

SS (SideShot)

The sideshot record is the same as the traverse record except that sideshot does not move the setup.

HI (Instrument and Rod Height)

This record sets the instrument and rod heights used in elevation calculations. This record should precede any

traverse and sideshot records that you want the heights applied to.

BK (BackSight)

The backsight record contains the occupied point number, backsight point number, backsight azimuth and the set azimuth. This record should precede any traverse and sideshot records that use this setup. If no backsight point is entered, the program uses the backsight azimuth to turn angles from. The Set Azimuth is the circle reading of the instrument when sighting the backsight. A Set Azimuth of zero is the default.

PT (Store Point)

The store point record consists of a point number, northing, easting, elevation and description. When processing, this data will be stored as a point in the coordinate file. If the first Occupied point and/or the initial Backsight point are not defined in the coordinate file set for processing to, both points will need to be added to the rw5 file as PT (Store Point) records.

DS (Description)

The description record is an additional note that appears in the spreadsheet editor and printouts. This record can contain various information that is recorded in data collectors during field operations. This data can vary from user, temperature and general data to each line of data associated with "Set Collection". When "Sets" of data collected using various brands of data collection software is converted/imported into the raw editor, the actual measurements made during the spinning of the angles and distances are recorded as DS records and the mean value of the angle and distance is recorded as a SS record. The OF records are recorded by SurvCE for offset left/right, in/out and depth. DS records are not used in processing, but are a record of the values entered in the data collector for reference. SurvCE also stores names of images in the description record using AT,TN coding followed by the name of the image file. The program will create links to these images for the points. For example,
-AT,TNPHOTO1,TV.\Pictures\PN1_2208.jpg

CL (Closing Shot)

The closing shot record is the traverse record where the foresight point is the closing point for the traverse. This record is used by the adjustment commands in the Process menu. There should be only one CL record in each Traverse loop (Name Record) in the raw file. If there is no CL record, the process adjustment routines will prompt for which shot is the closing shot. The closing shot can also be define in the field by using special codes defined in the Open Settings found under the File pulldown within the editor. Please refer to the "Open Settings" documentation below for more information on these codes.

AB (Angle Balance)

The Angle Balance record is the measurement data observed that closes the angles of the traverse. Typically this record is the measurement data recorded from the closing shot to the initial backsight point. The backsight could be either external or internal to the traverse. Angle Balance routine in the Process menu uses this record and compares the angle between the occupied point and foresight point of this record with a user-specified reference angle. There should be only one AB record in the raw file. If there is no AB record, then the Angle Balance routine will prompt for which shot to use as the angle balance.

CL + AB (Closing Shot and Angle Balance)

This record is used as both the closing shot and angle balance records.

FD (Foresight Direct)

The foresight direct is a traverse record used in a direct and reverse set. When the program finds one the of direct-reverse measurement records, it will look for the other three records to complete the set.

FR (Foresight Reverse)

The foresight reverse is a traverse record used in a direct and reverse set.

BD (Backsight Direct)

The backsight direct is a traverse record used in a direct and reverse set.

BR (Backsight Reverse)

The backsight reverse is a traverse record used in a direct and reverse set.

EL (Elevation Only)

This record sets the elevation in the CRD file for the specified point number. Often used when an existing point with good vertical control is being traversed through. Using this record type for the point would keep the elevation from changing on the existing point regardless of the measurement data.

AZ (Azimuth Only)

Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

CSE (Control Standard Error)

Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

SSE (Set-up Standard Error)

Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

MSE (Measurement Standard Error)

Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

NAME (Traverse Name)

This record acts as an identifier for the group of records that make up a traverse. All the records after the NAME record belong to that traverse up to the next NAME record or the end of the file. This record allows you to have multiple traverses in one raw file. When running one of the Process commands, the program will bring up a list of all the traverse names. Simply choose which traverse to process. If you have only one traverse in the raw file, then you don't need the NAME record.

GPS (GPS Measurement)

This record contains the Latitude and Longitude of a point as measured by GPS surveying equipment using Carlson SurvCE data collection software. This record has additional information tied to it such as localization files, geoid files, coordinate projection systems etc. This record has its own processing routine in the Process pulldown within the editor. Processing procedures are discussed in the Process (Compute Pts) pulldown documentation.

BP (Base Point)

This record contains the Point Name, Latitude, Longitude, Elevation and Description of a GPS base receiver point.

G0 (GPS Vector Comment)

This record is the description for the GPS vector.

G1 (GPS Vector Deltas)

This record contains the delta x,y,z for the GPS vector.

G2 (GPS Vector Variances)

This record contains the x,y,z variances for the GPS vector.

G3 (GPS Vector Covariances)

This record contains the x,y,z covariances for the GPS vector.

File Menu

Open Raw File

This command prompts for a rw5 file to load into the editor.

New Raw File

This command clears the editor spreadsheet.

Save Raw File

This saves the rw5 file. If the file hasn't been named you will be prompted for the file name and the location to save the file. After you perform the first save, this command acts as a quick save and saves the file to the name and location specified during the initial saving of the file.

Save Raw As

This command saves the raw editor data in the spreadsheet to a rw5 file and always prompts for file name and location to save.

Open CRD File

This command prompts for an existing coordinate file to set as the active coordinate file for the raw editor.

New CRD File

This command prompts for a new coordinate file to set as the active coordinate file for the raw editor. The coordinate data will be initialized as empty.

Save CRD File

This command saves the current coordinate data in the raw editor to the current coordinate file.

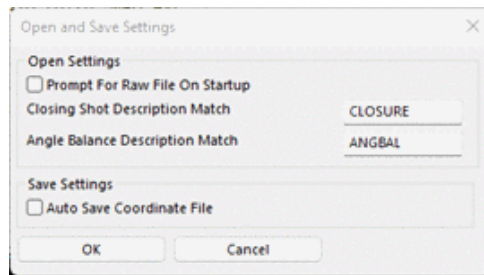

Save CRD As

This command saves the current coordinate data to a specified coordinate file name.

Note: The file format for a Coordinate File includes crd, crdb, cgc, mdb and zak

Open/Save Settings

This option allows for defining codes that represent the closing shot and angle balance shot of a traverse. These codes can be entered in the description of a point while in the field. When the rw5 is opened in the raw file editor, the measurement data containing the closing shot code will be set to a CL record and the measurement data containing the angle balance code will be set to an AB record. This allows for quick processing of the survey data and saves the time spent setting up the file for processing.

Import

These routines convert raw data from other formats into the current Carlson RW5 format. The converted raw data will be added to the end of any existing data in the editor. In many cases, the raw data file to import can be downloaded directly from the data collector or instrument using the *Data Collectors* command. The following supported formats (along with their standard file extension) are listed here.

Some Sample File Formats are listed at the end of this section.

C&G (.CGR; .RAW; .TXT; *)

CalTrans (.DMP)

Carlson (.RW5)

EFB (.RAW; .OBS) Electronic Field Book

Fieldbook (.FBK): From Softdesk, Land Development Desktop or Civil 3D. The import handles the following record types:

AD

AZ / AZM / AZIMUTH

B / BRG / BEARING

BEG / BEGIN

BS / BACKSITE / BACKSIGHT

C3

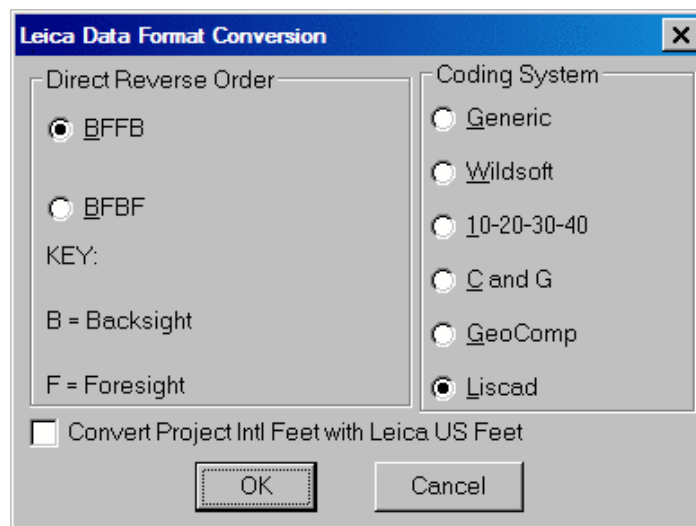

END
F1
FC1
NE / NEZ
PRISM
STN / STA / STATION
ZD

Geodimeter (.OBS; .RAW; job;*)

Horizon (.RAW)

LandXML (.XML): LandXML is the industry standard data format for exchanging project data. It can contain any number of different data types including surfaces besides raw measurements.

Leica (.GSI; .RAW; GRE): This reads the Leica raw file in Wildsoft, Liscad, 10-20-30-40, C&G, or GeoComp format. There are options to specify direct-reverse shot order if any and to convert from International Feet to Leica US Feet.

Maptech (.FLD)

MDL Laser (.CDS)

Nikon (.TRN; .RAW)

PC Cogo (.BAT)

SDMS (.prj;*)

SMI (.RAW)

Sokkia SDR (.SDR; .RAW;*)

StarNET (.DAT) The import handles the following StarNET record types: E - Elevation record

C - Coordinate record

B - Bearing / Azimuth record

M - Measurement record

SS - SideShot record

TB - Begin Traverse record

T - Traverse record

TE - End Traverse record

DV - 3D Distance Record (creates a slope distance/zenith angle record)

D - 2D Distance Record (creates a horizontal distance)

A - Horizontal Angle Record (creates an angle-only record)

V - Zenith Angle record (creates a zenith angle-only record)

When parsing these records, if a measurement, coordinate or azimuth has standard errors assigned to it, then standard error records are created in the RW5 file so none of that information is lost. The import also handles the following DOT commands:

.ORDER - Specifies point order (AtFromTo or FromAtTo) in the measurement record, and/or the order of NORTH/EAST or EAST/NORTH in control records.

.DELTA - Specifies whether the data is SlopeDist/Zenith or HDist/VDist. The default is SD/ZE.

.2D / .3D - Specifies the data format. Without this information the fields can be confused while parsing.

SurvCOGO (.RAW or .TXT)

SurvCE Archive (.SC5) When downloading a rw5 file from SurvCE using SurvCOM, there's an option to copy the rw5 file to a sc5 file as a read-only backup.

Survis (.RAW)

TDS (.RW5; RAW)

Topcon (raw;*)

Trimble (.dc)

3TA5 (.TXT)

Zeiss (.DAT)

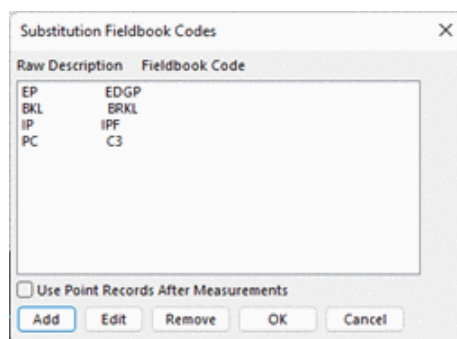

Export

These routines convert the Carlson raw data (.RW5) file to other formats. The following file formats are supported.

CalTrans (DMP)

dgDialog (.DGD)

Fieldbook (.FBK): This export routine provides an option to "Setup Fieldbook Codes". This allows the user to substitute the raw description contained in the rw5 file with the fieldbook code used in AutoDesk Land Desktop or Civil 3D.

FL DOT (.OBS)

GPS Data (.TXT;*)

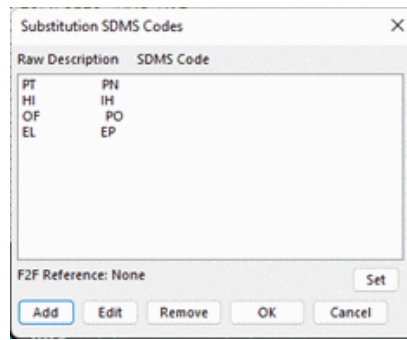

LandXML (.XML)

Leica (.GSI)

MOSS (.MOS)

RMGeo (.txt)

SDMS (.PRJ) This export routine provides an option to "Setup SDMS Codes". This allows the user to substitute the raw description contained in the rw5 file with the SDMS codes used in SDMS program.

SFN: This format is used in the Netherlands.

Sokkia (.SDR)

TDS (RW5;RAW)

Topobase (PO)

Trimble (JXL): JobXML format.

VA Dot (TOP)

WinCMM (.LSA)

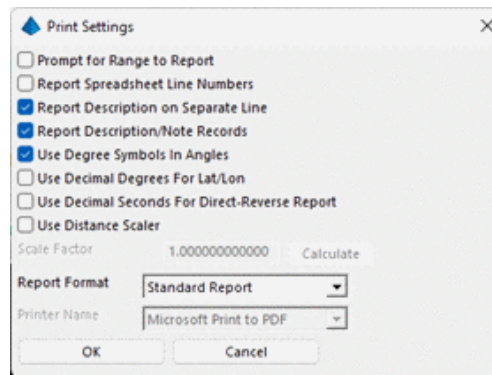

Report/Print

There are three types of reports: Raw Data, Coordinates and Summary. A sample of the raw data report is shown below. This report shows the data from the raw editor spreadsheet. The Coordinates report lists the point data (point number, northing, easting, elevation, description) from the current coordinate file. The summary report groups the traverse, sideshot and store point numbers along with a list of the setups and the shots from each setup. The summary report also groups the range of point numbers by date using the dates in the note records.

```
Raw File> c:\data\survey.rw5
CRD File> c:\data\survey.crd
Note
Survey Example

TR 7   8      AR 261.2756 387.250  91.4405  CLOSE
SS 7   19     AR 289.3456 112.450  91.3423  SS1
```

Report/Print Settings

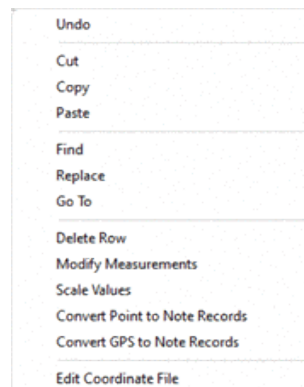

This dialog has settings for the report functions. The Use Distance Scaler allows for reporting distances in different units. For example, the survey distances could be in US Feet and then use a scale factor to report the distances in chains. For Report Format, the Report Formatter option allows for customized reports and exporting to Excel. The Spreadsheet Report option creates a report using the spreadsheet layout including the spreadsheet colors. The spreadsheet report goes directly to the specified printer.

Exit

Exits the raw file editor.

Edit Menu

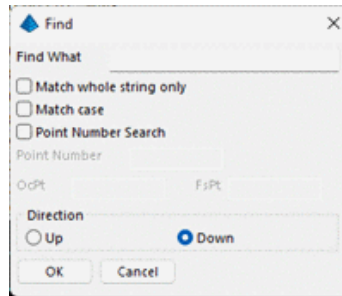

Undo: This command undoes the last data entry or the last copy, cut or delete command performed on keyboard entered data only. This will not undo a change to the Type or Code columns, nor a cut or copy command to a row.

Cut: Standard windows cut command. Removes data from editor and places it in the windows clipboard.

Copy: Standard windows copy command. Copies selected data to windows clipboard.

Paste: Pastes copied data to the row location selected

Find: Tool to search and find a particular word, letter, numeric value or a point number.

- **Match Whole String** filters search to the entire entered text string. For example, if you enter the Find What field searching for TREE, it will only find fields that match exactly TREE as opposed to just TR which will find any field beginning with TR ie. Tree, Transformer etc.
- **Match Case** only finds fields with the same capitalization setting
- **Point Number Search** searches specifically for a point record.

- The **Point Number Search** can be for a Point in the form of a Point (PT) Record, Occupied point or Foresight point.
- **Direction** allows for a Up or Down directional search from the active cell in the editor.

Replace: Tool to search and replace a particular word, letter, numeric value or point number.

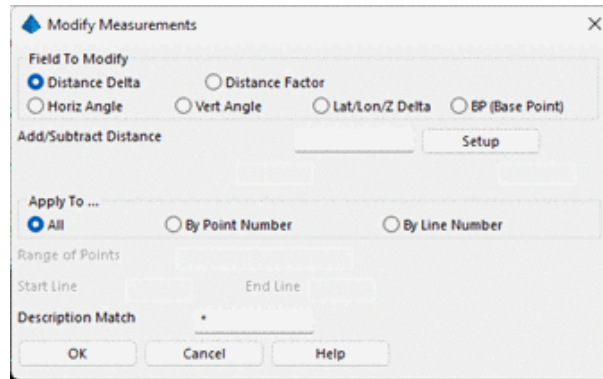

- **Match Whole String** filters search to the entire entered text string. For example, if you enter the Find What field searching for TREE, it will only find fields that match exactly TREE as opposed to just TR which will find any field beginning with TR ie. Tree, Transformer etc.
- **Match Case** only finds fields with the same capitalization setting
- **Point Number Search** searches specifically for a point record and replaces it with the one entered. This is useful when redundant measurements have been made to the same point and are to be part of a least squares network or in the case of mistaken point identification.

Go To: Tool to advance the focus of the active cell to a specified line number.

Delete Row: This command deletes the row containing the active cursor or cell. You can delete a row by placing the cursor in any of the cells in the row that you wish to delete, or by picking on the row number at the far left of the editor.

Modify Measurements: This option allows for a change in distance, horizontal angle, vertical angle or lat/lon by a specified amount for the entire file or for a specified point number or line number range.

To modify a measurement, choose which field to modify, enter the change in distance, angle (dd.mmss format), Lat/Lon, or Coordinate values followed by how to apply the change(s).

- **Distance Delta** applies a distance to add or subtract to all measurements included in the "Apply to..." This option is useful in instances where a consistent distance value was mistakenly introduced, such as the wrong prism constant. There is a helpful Setup that allows the input of Original Distance and New Distance for calculating the delta.

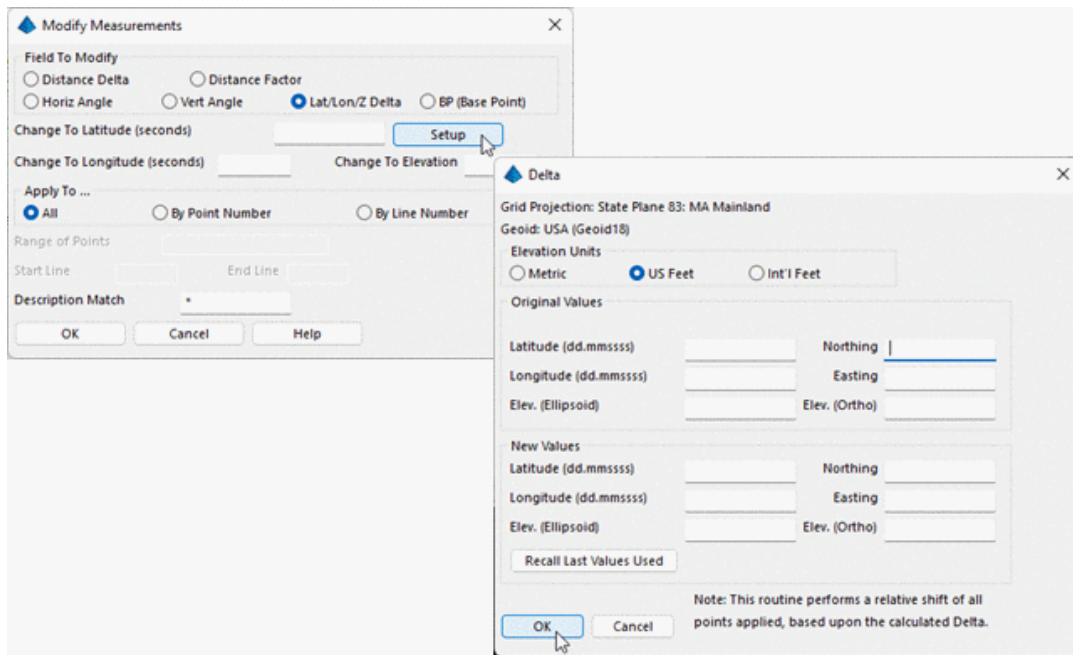

- **Distance Factor** method multiplies the distances by the specified value which can be used to convert distance units between feet and meters or to apply a scale factor. There is a helpful Setup that allows the input of Original Distance and New Distance for calculating the delta.
- **Horiz Angle** applies a horizontal angle to adjust all measurements included in the "Apply to...". This option is useful in instances where a mistaken angle was applied to multiple measurements such as an incorrect backsight. There is a helpful Setup that allows the input of Original Angle and New Angle for calculating the delta.

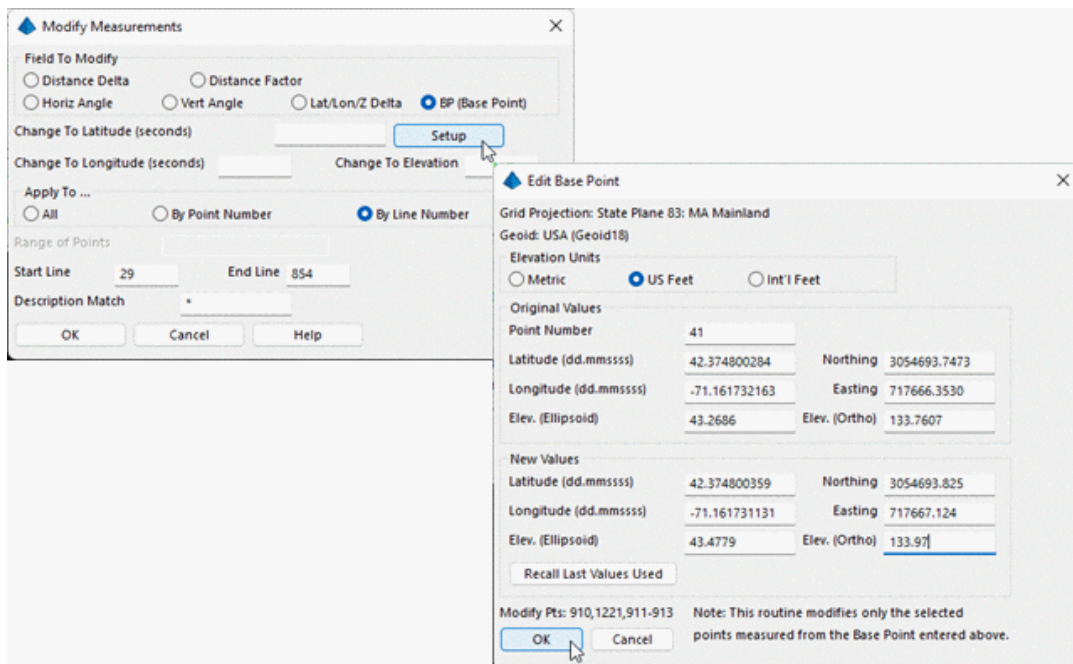

- **Vert Angle** applies a vertical angle to adjust all measurements included in the "Apply to...". Similar to Horiz. Angle, There is a helpful Setup that allows the input of Original Angle and New Angle for calculating the delta.

- **Lat/Lon/Z Delta** is used to adjust GPS records in cases where Delta "shift" is desired for all or a group of points.

The points specified in the "Apply to..." selection are moved a delta latitude, longitude, elevation or a combination of all three. The **Setup** option supplies an easy to use optional entry of direct coordinate values; Northing, Easting and Orthometric Elevation. The delta is calculated in the Setup dialog box and populates those values in the Delta change values seen in the first dialog box. This routine shifts all selected points the same value regardless of a specific base point. It is useful in cases where the entire GPS survey needs to be altered in the same direction.

- **BP (Base Point)** is used to adjust GPS records in cases where Delta "shift" is desired for a group of points measured from a specific base point.

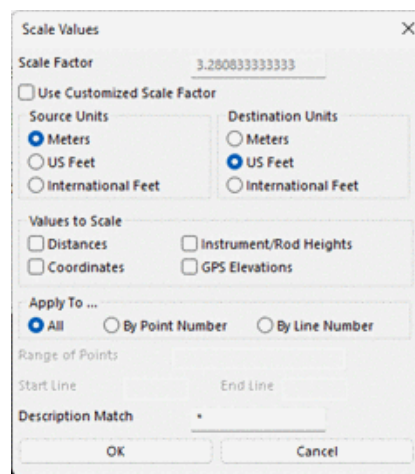

The points specified in the "Apply to..." selection are moved a delta latitude, longitude, elevation or a combination of all three. The **Setup** option supplies an easy to use entry where you can specify a base point that was used to measure points from. The routine recalls the coordinates of the base point and identifies all points measured from that base point. New values can be entered into the appropriate spaces, either Latitude, Longitude, Ellipsoid height or Northing, Easting, Orthometric height. The delta is calculated in the Setup dialog box and populates those values in the Delta change values seen in the first dialog box. This routine shifts all points measured from the specified base point but that selection can be further modified through the "Apply to..." selection.

The **Recall Last Values** Used is convenient if the base point is used multiple times within the RW5 file and the same shift is to be applied.

Apply to... controls how to apply the modification. If **All** is selected, the change will be applied to all records in the specified field. If **By Point Number** is chosen, enter the point number or range of numbers in the Range of Points field. If by **Line Number** is chosen, define the area for the change by specifying the Starting and Ending line.

Scale Values: This function scales selected values which by a specified scale factor.

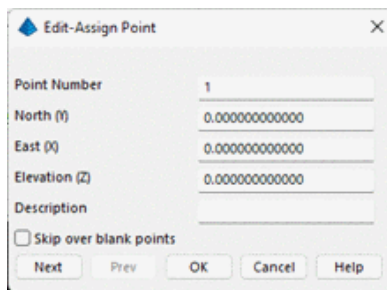

A common use of this feature is to scale measured values from meters to feet or visa versa. The Values to Scale options allow filtering for particular values to be scaled. The Apply To... section controls which records within the RW5 are to be scaled.

Convert Points To Notes Records: This function converts point (PT) records to note (DS) records. This leaves the information of the point coordinates in the rw5 file as display only. The points marked as notes (DS) records will not be used when processing the data and will not be stored in the Coordinate File upon completion. When this option is selected, you will be prompted to enter all or a range of point numbers to be included in the conversion.

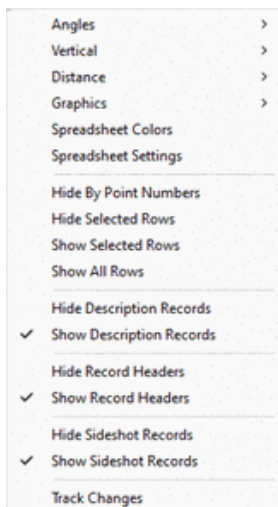

The point data in the DS records can be converted back to PT records by picking the Code field in the spreadsheet and switching DS to PT.

Convert GPS to Note Records: This function converts GPS point (GPS) records to note (DS) records. This leaves the coordinates of the GPS point, *Latitude, Longitude, Ellipsoid* in the rw5 file as display only. The GPS points marked as notes (DS) records will not be used when processing the data and will not be stored in the Coordinate File upon completion. When this option is selected, you will be prompted to enter all or a range of point numbers to be included in the conversion.

Edit Coordinate File: This option allows for editing and/or listing of the coordinate data in the active coordinate file. The active coordinate file is displayed in the Header of the raw data editor. This routine brings up the edit point dialog and allows editing of the points one at a time.

Display Menu

Angles: This option chooses the angle format between degrees/minutes/seconds (dd.mmss) and Gons-400 decimal degree circle (dd.dddd). This setting applies to the angles in the spreadsheet editor as well as the angle format for reports. There is also a separate setting to Show Decimal Seconds which use edit and process angles to the nearest tenth of a second (dd.mmsss).

Vertical: The options contained in this menu allow for specifying the type of vertical measurement information you will input or is contained in the rw5 file. The Vertical Angle selection assumes the barrel or scope of the instrument is level when reading 0 (zero). With this setting, the vertical component of a measurement record will have a header of VertAng. The Zenith Angle selection, most commonly used, assumes the barrel/scope to be level when reading 90. Using this setting results in a header of ZenithAng. Elevation difference displays the elevation difference between the occupied and foresight points. If the Distance option is specified as Slope, this elevation difference will be used to calculate the horizontal distance of the measurement. The header for this record is ElevDiff. The None selection assumes all distances are horizontal distances and removes the vertical component for a measurement from the editor. Switching modes can be performed at any time.

Distance: This option controls the display of either Slope or Horizontal Distances. Changing the display results in the distance data adjusting to reflect the correct value for the selection made. The Vertical data, VertAng, ZenithAng

or VertDiff, is used to convert the distance value when changing this display option.

Graphics: The Raw Data Editor uses an optional graphics window to display the points and traverse lines in real time. As data is entered or edited, the graphics window will be updated to show the configuration or new configuration of the traverse, sideshots or vectors.

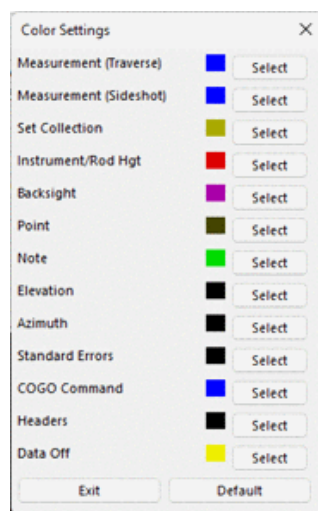

The overall graphics window is toggled On or Off and is displayed below the raw data records.

- **Show Sidehots** toggles the display of sideshots On or Off. When a cell is selected, the traverse or sideshot line in the display window will change to the color yellow for a graphical reference.

Zoom, Pan or Pick Mode sets the behavior of the left click mouse button. It should be noted that if your mouse is configured to use the middle button for Pan and it Scrolls for Zoom, the Zoom and Pan options are redundant.

- **Zoom Mode:** Within the graphics window, real time zoom is available. To zoom in press and hold the left mouse button and drag in the direction of the + symbol. To zoom out, press and hold the left button and drag in the direction of the - symbol.
- **Pan Mode:** Real time pan is available within the graphics window. To pan, set the graphics window to pan mode, then press and hold the left mouse button and then drag to desired position.
- **Pick Mode,** you can select a point from the graphics window below the data fields and the cursor will go to that point or measurement record in the data field.
- **Resize Text:** With this option on the text becomes smaller/larger in the view when you zoom in/out.
- **Fixed Text Size:** With this option on, the text stays a fixed size while zooming in and out.

Spreadsheet Colors: This option allows for the assignment of colors to record types.

From the Color Settings dialog select the record to edit by clicking on the **Select** button next to the desired record. The color slide beside the select button shows the current setting for the record.

To change the color for a data record, select the **Set** button next to the desired color.

The Default button will return all colors back to the installed defaults.

Spreadsheet Settings: This command has an option to use a larger font for the spreadsheet for easier viewing.

Hide by Point Numbers: This option hides point records by selecting the points that are to remain displayed.

Hide/Show Selected Rows: This option allows for hiding single or multiple rows. This could be used to prevent crucial information from being accidentally altered during editing of data or data entry. Hiding a record does not exclude it from processing. To hide records or rows, select the column at the far left of the editor and select **Hide Selected Rows**. Multiple rows of data can be selected by selecting the first row of data to hide then while holding down the shift key on the keyboard, select the last row to hide. When a row or rows of data are hidden, the row numbers will remain as originally assigned. Hidden rows will not display a line number. To show previously hidden rows, select the row above and below the hidden rows and select **Show Selected Row**.

Show All Rows: turns on all rows in the raw file. This resets the raw file to its' original display.

Hide/Show Description Records: This option hides all description (DS) records. Show Description Records will turn them back on.

Hide/Show Record Headers: This option controls the display of the headers just above each record, such as InstHT, RodHT, Latitude, Longitude etc.

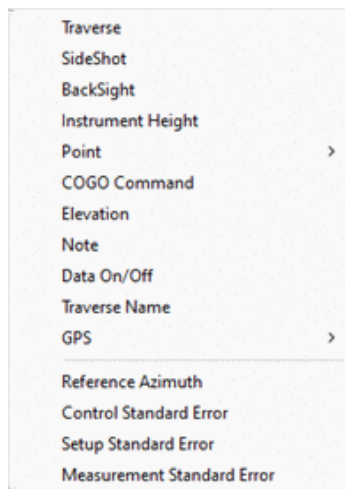

Hide/Show Sideshot Records: This option controls the display of the sideshot records themselves. This is useful in isolating traverse measurements from sideshot measurements.

Track Changes: When toggled on, this option tracks changes in the raw file by adding a note (DS) record just below the edited line. For example if a rod height was altered, a new record would be displayed in the RW5. Example:

185		InstHt	RodHt				
186	HI	5.150	6.0				
187	DS	Old RodHt: 5.100					
188		OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng
189	SS	5	56	AR	225.2329	19.871	92.5323
190	SS		57	AR	118.713	45.05	37.11

Add Menu

The add menu contains options for adding specific records and functions to the raw data editor.

Each element will be added in the raw file editor at the location of the cursor. This is important especially in situations such as adding an Instrument or Rod Height.

Traverse: Adds a traverse record (TR) to the spreadsheet editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

SideShot: Adds a sideshot record (SS) to the spreadsheet editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

Backsight: Adds a backsight (BK) to the spreadsheet editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

Instrument Height: Adds an instrument height (HI) record to the editor. This record contains both the instrument and rod height setting.

Point: Adds a point (PT) record to the editor. Provides options to either add a Blank Point Record or Import From Coordinate File.

Inserting a blank record allows for manual input to define the coordinates for the point. Import From Coordinate File imports the coordinate values from an existing point or range of points contained in the coordinate file. Enter the point number or range of points and select OK. The points will be read into the rw5 file at the top of the file.

COGO Command: Adds COGO Command (CC) record with a field to specify the command (Translate, Rotate, Scale or Align) and a field for entering the parameters. The COGO commands are executed in sequence as the rw5 file is processed from top to bottom by any of the process methods in the Process menu. The COGO commands are all transformation commands that are applied to the points in the current coordinate file. The following list is the syntax of the COGO commands:

- Translate: Range Dx Dy Dz Process_Zero_Z
- Rotate: Range Angle Base_Y Base_X
- Scale: Range Scale Base_Y Base_X Use_Z
- Align: Range From1 To1 From2 To2

All the parameters are entered into one spreadsheet cell next to the COGO function. The parameters use space separators. The following list is the parameter definitions:

Range: point numbers

Dx: delta easting (X)

Dy: delta northing (Y)

Dz: delta elevation (Z)

Process_Zero_Z: toggle for whether to process points with elevation of zero (0=No, 1=Yes)

Angle: rotation angle in dd.mmss format

Base_Y: base point northing

Base_X: base point easting

Scale: scale factor

Use_Z: toggle for whether to scale the elevations (0=No, 1=Yes)

From1: point number of first source point

To1: point number of first destination point

From2: point number of second source point

To2: point number of second destination point

For example, to translate points 1-10 by a delta Z of 6.0 while filtering out zero elevation points, set the parameters for the COGO Translate record as "1-10 0 0 6.0 0".

Elevation: Adds an elevation (EL) record to the editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

Note: Adds a note (DS) record to the editor. Note records are for information display and do not affect processing except for three particular notes which are:

- Elevation: 2D
- Elevation: 3D
- Tilt Sensor Offset

- **Elevations 2D and 3D** are special notes that set the elevation mode for processing for the records that follow the note. The raw editor starts in 3D mode. The "Elevation: 2D" note will switch processing to 2D mode and the "Elevation: 3D" note will switch the mode back to 3D. In 2D mode, the processing will not set the elevations in the coordinate file.
- **Tilt Sensor Offsets** are notes placed on GNSS receiver locations when the Tilt Sensor option is on, usually in cases where the rod is not plumb. The note record indicates the offset values between the phase center of the receiver and the bottom of the pole. These values are applied during processing.

1436		▼	Note					
1437	DS	▼	GSRD,TXD4.127,TYD-5.302,THD1.776,TDTCarlson_BRx7					
1438	DS	▼	GSAL,TEL0.025,TNL0.794,TZL0.047,T2D0.794,TTL0.049					
1439	DS	▼	GT,PN21114,SW2218,ST312264800,EW2218,ET312264800					
1440	DS	▼	HRMS:0.055, VRMS:0.082, STATUS:FIXED, SATS:26, AGE:2.0, PDOP:0.893, HDOP:0.465,					

Data On/Off: Adds a data on/off (DO) record to the editor. This record toggles the raw data between processing on and off modes. The raw data starts in processing on mode. Working from top to down, when a DO record is reached, the processing mode is turned off. Then next DO record will turn processing back on, and so on. Data records that are in processing off mode and skipped when running the routines in the Process menu.

Traverse Name: Adds a traverse name (Name) to the editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

GPS: Adds a GPS record to the editor. The new record will be insert above the row that contains the active cell unless this row is the last row in the file. If so, you will be prompted to insert above or below the current row.

Reference Azimuth: Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

Control Standard Error: Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

Setup Standard Error: Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

Measurement Standard Error: Applies to SurvNET, the optional Network Least Squares analysis and adjustment routine.

Process (Compute Pts) Menu

This menu contains tools to process raw data by various methods. The calculated coordinates, and notes if specified, are stored to the active specified coordinate file. The coordinate file can be specified using *Set Coordinate File*, under the Points pulldown within the drawing screen, or from the Tools menu of the editor, discussed later in this section.

There are several adjustment options:

No Adjust

Angle Balance

Compass Rule

Crandall Rule

Transit Rule

Least-Squares - *Note, this is a legacy adjustment routine that has been superseded by SurvNET, a comprehensive least squares adjustment program that processes EDM traverse measurements, GNSS vectors and Differential Leveling.*

Stadia

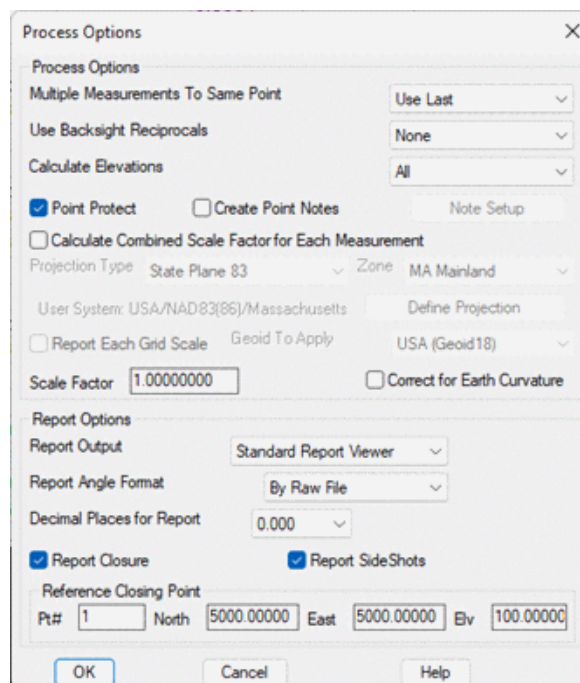

GPS

Process Settings

No Adjust, Angle Balance, Compass, Crandall, and Transit processing contain options that are accessed through a separate dialog box when each option is first selected. Many of these options are identical. The options in common are shown below:

Common Process Options

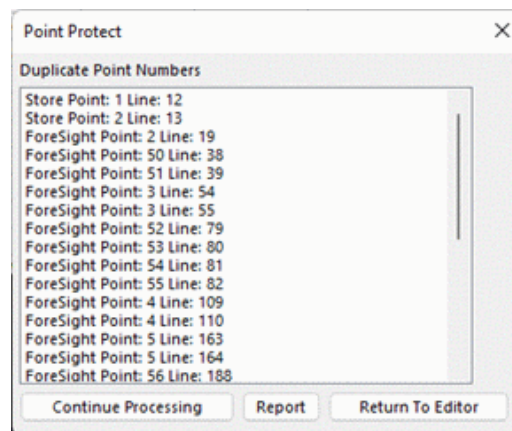

These are processing options which are common to No Adjust, Angle Balance, Compass Rule, Crandall Rule, and Transit rule.

- **Multiple Measurements To Same Point:** This option sets the method of how to handle multiple measurements to the same point (identical point name). There are three available options, Use Last, Average or Use First. **Use First** uses the first measurement to calculate the position of the point. **Average** uses the average of all the measurements for the position, and **Use Last** takes the last measurement to the to calculate the position.
- **Use Backsight Reciprocals:**This setting applies to backsight measurements that are not part of a complete direct/reverse set. Backsight measurements that are part of a direct/reverse set use the direct/reverse settings under Process Settings to reduce the measurements.

A foresight to point 15 from a setup on 14, followed by a backsight from 15 to 14, makes a pair of "reciprocal" measurements. The backsight "reciprocal" measurement can be ignored for its impact on recalculating the occupied point (None Option), or the elevation of component of the reciprocal measurements can be averaged (Average Elevation option), or both the elevation and distance can be averaged (Average Elev & Dist) to recalculate the setup (occupied point) coordinates.

- **Calculate Elevations:** This option determines whether the elevations of the points will be calculated and written to the coordinate file. Options of whether to calculate All elevations or just the Sideshots Only are provided.
- **Point Protect:** This option will check the coordinate (.CRD) file for existing point data before processing. If the foresight point number for any traverse or sideshot record already is a stored coordinate in the coordinate (.CRD) file, then the program shows a list of conflicting point numbers. You can either continue processing and overwrite the coordinate (.CRD) file coordinates with the calculated raw file coordinates or cancel the processing to go back to the editor to change foresight numbers.

A report of the conflicting point numbers can be generated to the standard report viewer in Carlson by selecting the Report option on the Point Protect dialog box. From the report viewer, the report can then be printed, sent to the screen or saved to a file.

Raw File: C:\Carlson Work Files\Workshops and Webinars\Workshop Data Files\SurvNET\Ground Traverse\Loop 1.RW5
 CRD File: C:\Carlson Work Files\Product Development\Test Files\2023 Alpha\DWG\Empty Drawing.crd

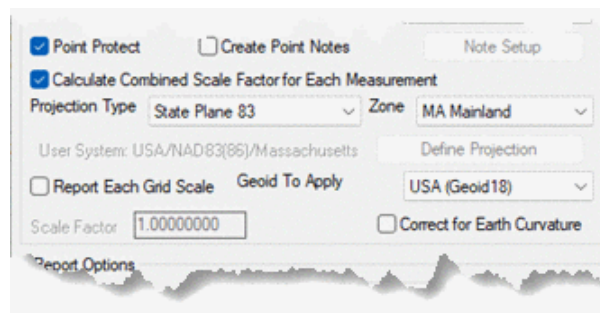

Store Point: 1 Line: 12
 Store Point: 2 Line: 13
 ForeSight Point: 2 Line: 19
 ForeSight Point: 50 Line: 38
 ForeSight Point: 51 Line: 39
 ForeSight Point: 3 Line: 54
 ForeSight Point: 3 Line: 55
 ForeSight Point: 52 Line: 79
 ForeSight Point: 53 Line: 80
 ForeSight Point: 54 Line: 81
 ForeSight Point: 55 Line: 82

Create Point Notes: This option will generate a note (.NOT) file named after the coordinate file. The note file contains additional descriptions for points. With this option active, the text from all note records (DS records) will be stored to the note file for the foresight point number preceding the note records. When this option is active, the Note Setup button brings up a dialog to set a Wildcard Match which filters the notes in the raw file

and only stores the notes that match to the note file.

- The **Prefix To Remove** option removes the specified string from the start of the note in the raw file when storing to the note file.
- **Calculate Combined Scale Factor at Each Setup:** This option will calculate a scale factor for each TR and SS record.

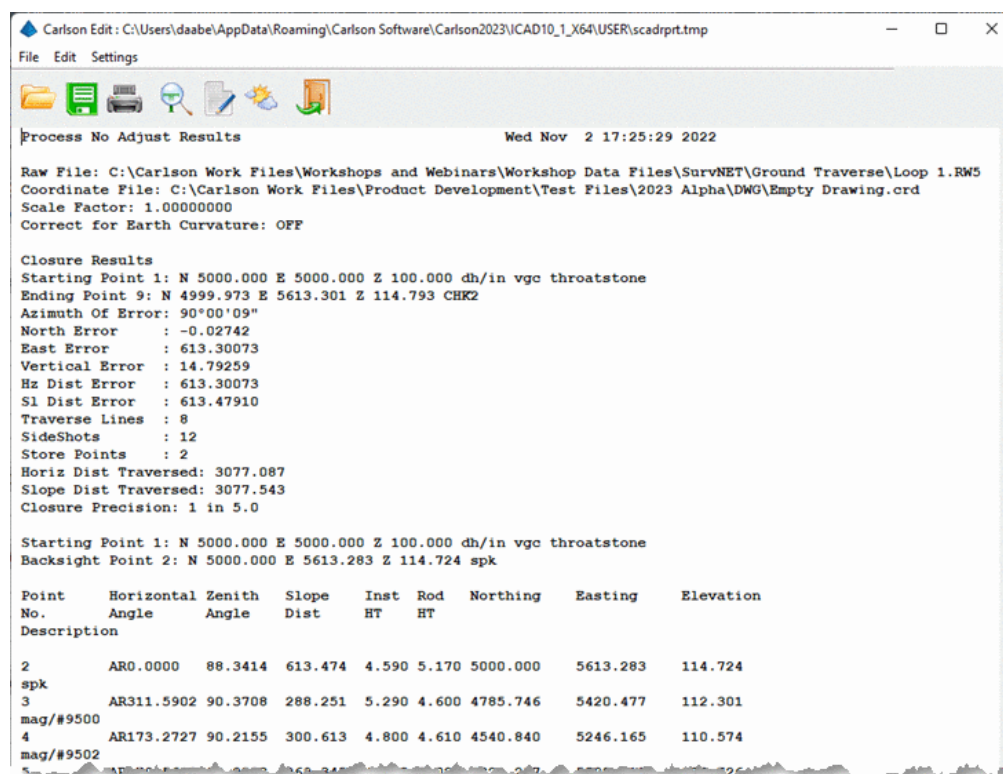

This scale factor is calculated as the average of the scale factors at the occupied and foresights points. At these points the scale factor is calculated as the projection grid factor multiplied by the elevation factor which is the earth radius divided by the elevation plus the earth radius [$SF = \text{Grid Factor} * (\text{Earth Radius} / (\text{Elevation} + \text{Earth Radius}))$]. In order to calculate these projection grid factors, the traverse coordinates must be in grid coordinates. When this option is desired, set the projection and zone to use. The elevation for the scale factor can be adjusted by the geoid height using the geoid specified in the **Geoid To Apply** list. The geoid height is added to the point elevation to adjust the elevation value used in the scale factor equation. The geoid surface files are not installed by default due to the large size of these files but will be loaded on demand as they are selected. To install the geoids manually, go to the Carlson Software web page www.carlsonsw.com and download the Geoid Grid Files from the Support->Downloads section.

- **Report Each Grid Scale:** This option becomes available if the Calculate State Plane Factor at Each Setup has been selected. With this option on, the scale factor at each point will be shown in the process results report.
- **Scale Factor:** displays the calculated combined scale factor. This can be entered directly if known.
- **Correct for Earth Curvature:** This option adjusts the calculated points for the effect of the Earth's curvature. Typically this adjustment is small and adjusts the elevation more than the horizontal values.

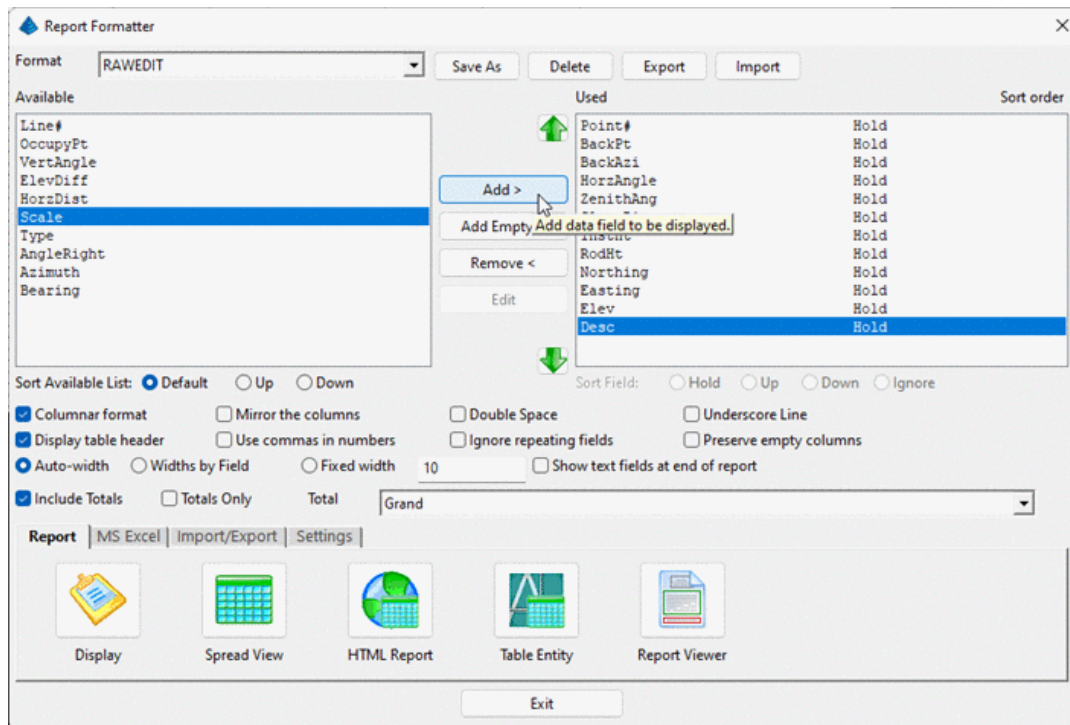

Report Options

- **Report Output:** There are three report output options contained in the raw editor, the *Standard Report Viewer*, the *Custom Report Formatter* and the *Tabular Report Viewer*. Each is documented below.

- **Report Angle Format:** This option controls the angle format displayed on the process results report. The option of **By Raw File** will display the angles in the format that is contained in the raw file. The **Bearing** option will display the angle in a bearing format. The **Azimuth** option will display the azimuth of the measurement and the **Angle Right** option will display the angle right measurement of the observation.
- **Decimal Places for Report:** This option controls the number of decimal places for the reported data.
- **Report Closure:** This option determines whether the closure report will be displayed after processing. If processing a survey where the traverse has not been closed, turn this toggle off for quick processing. To use this option, you will need to supply a **Reference Closing Point**. This is an optional field for entering the coordinates to compare the ending traverse point with. This reference closing point is used to calculate the closure. Without using this option the program will by default use the starting coordinate as the reference closing point.
- **Report Sideshots:** Controls whether the sideshot data is shown in the process report.
- The **Standard Report Viewer** is the default report viewer throughout the program. Any routine that generates a report has this option and the data contained in the report depends upon the routine executed. The report viewer is also a text editor. It allows for addition and deletion of text in order to customize the report for printing or for saving to a particular format for a file. Options to print, send to the screen in the drawing window as text or save to a file are available.

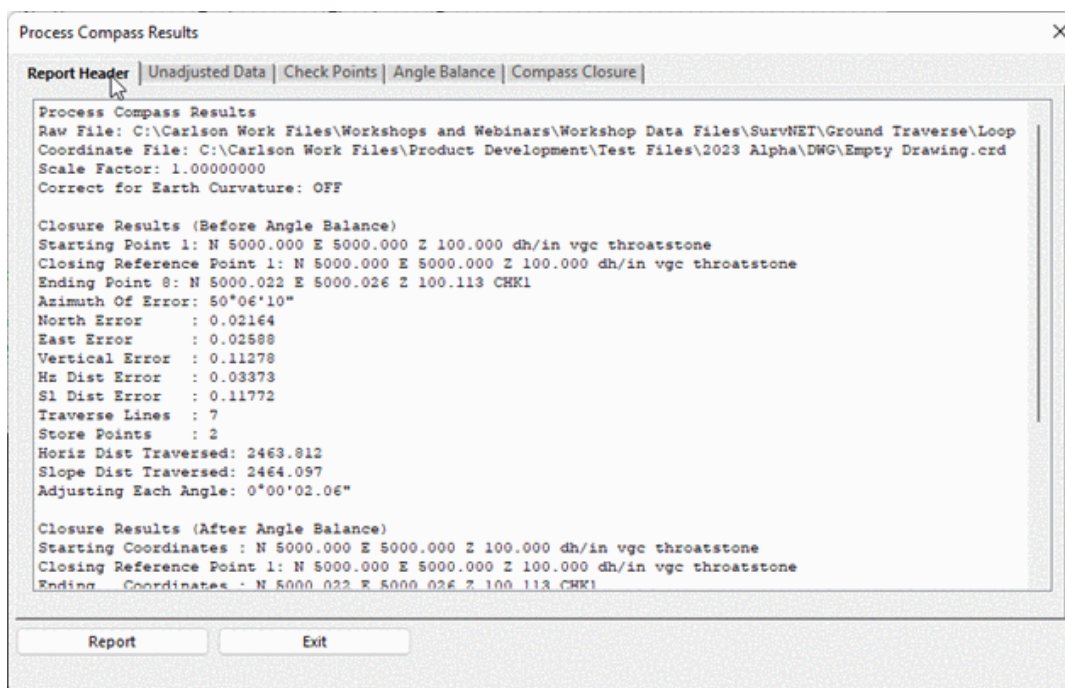

- The **Custom Report Formatter** allows for customization of the process results by selecting the fields and the layout of the fields to display. The settings can be saved to a format name and recalled when needed. Options to Delete, Export and Import saved Formats are also available.

To create a report, select data from the Available list and then select the Add button. This will populate the Used field with the selected data. Standard window selection methods can be used when selecting the data to report. Holding the ctrl key while selecting data allows for making random selections. Holding the shift key while selecting data will select the first item picked, last item picked and all items between.

For more information on the Report Formatter Dialog box, see the Help menu in the Introduction portion of the User Manual.

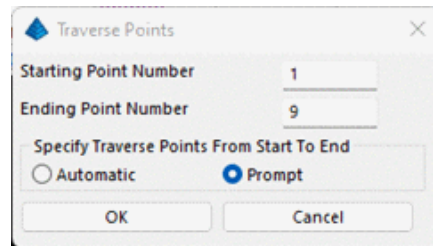

- The **Tabular Report Viewer** displays a report viewer consisting of tabs. Each tab organizes and displays different data depending upon the process options chosen. The process results using the No Adjust method results in three tabs the Report Header, Unadjusted Data and the Store Points tabs. Each of these tabs display different information which corresponds to the tab title. Using an adjustment method results in five tabs. In addition to the three listed above, an Angle Balance and Compass Closure tab is added.

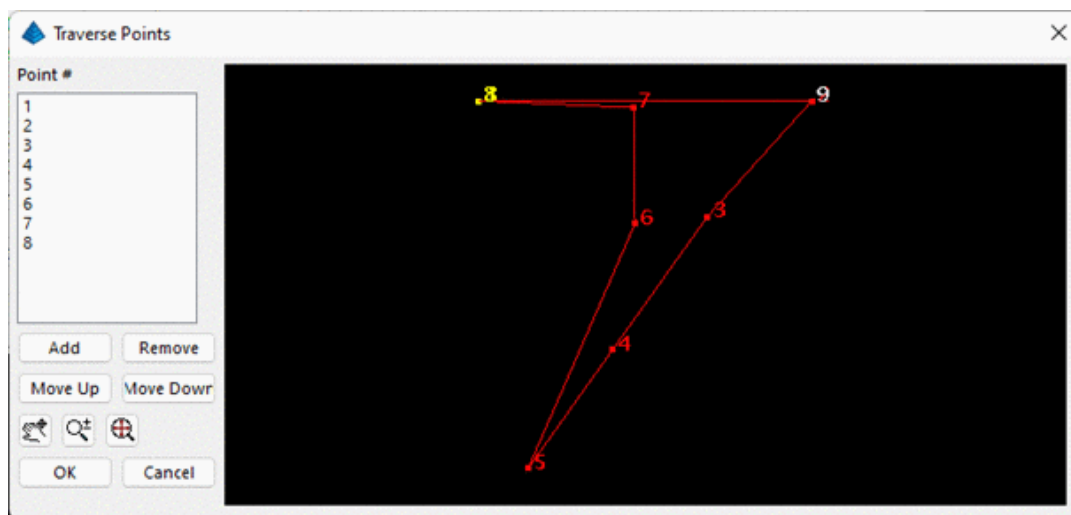

From the Tabular Report Viewer, the Standard Report Viewer can be switched to by pressing the **Report** option at the bottom of the dialog. This is useful when wishing to combine all tabs into one report for printing or saving to a file. An example of a Tabular Report for a compass rule adjustment is shown above.

Processing Methods

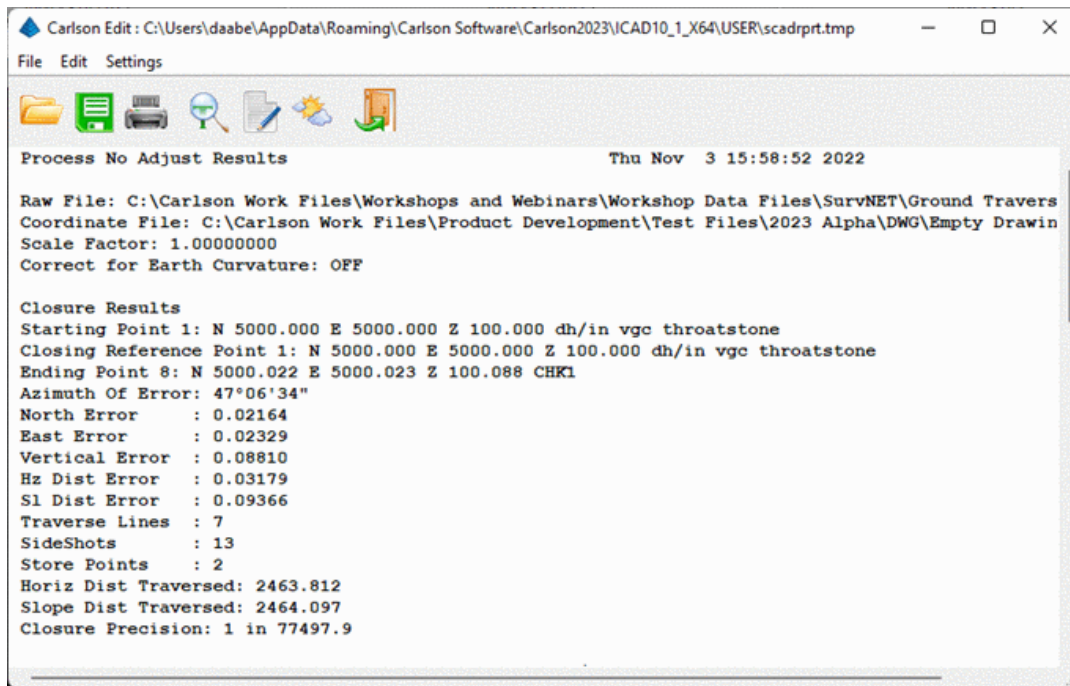

No Adjust: No Adjust means that no angle balance or traverse adjustment will be applied. Options are specified in the Process Options dialog. After picking OK, and Report Closure was NOT selected, for a process option, the program process all data records. If the Report Closure option was selected, a Traverse Points dialog box appears for entering the starting and ending point numbers.

The program reads the raw file to set the defaults for these point numbers which are used to calculate the closure. If you set the option to **Automatic**, the routine will continue to process using the numbers seen in the dialog box. If you choose the option Prompt, you will see the following graphic dialog box:

This dialog box depicts the traverse with both point numbers and a graphic display. You can examine the traverse, rearrange the order, add or remove points with the buttons on the left side of the dialog box. Once you are satisfied with the order of the traverse, click OK and the routine will calculate the results. The program starts processing the raw file from the top record down. The result is displayed in the Standard Report Viewer which can be saved, printed or drawn in the Drawing editor.

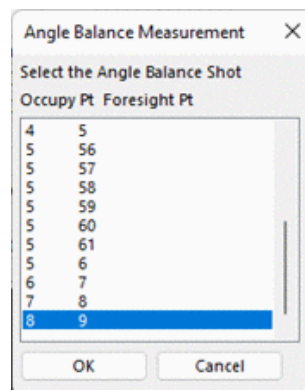

Note: The difference between the ending point and the reference closing point is the closure error and the sum of the traverse distances from the starting to the ending point is used as the total distance traversed.

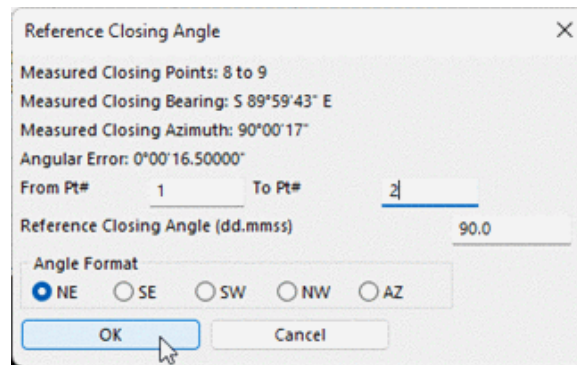

Angle Balance: This process method applies an angle balance to the traverse lines when calculating the coordinates. The angle balance takes the angular error divided by the number of traverse lines and adjusts the angle of each traverse line by this amount. The angular error is the difference between the angle balance shot and a reference angle. The angle balance shot is specified as a type AB or CL+AB record in the raw file. If no AB record is found in the raw file, then the program will prompt for which traverse shot to use as the angle balance shot. The angle from the angle balance shot is calculated as the angle from the occupied point to the foresight point. The reference angle can be specified as a bearing, azimuth or by two point numbers in the dialog shown.

The process is identical to the No Adjust method but with one or two additional prompts needed for selecting the angle balance shots.

Note: If the raw file has the Closing Point and Angle Balance Fields selected for the appropriate measurement records, these additional prompts will not be necessary.

Select the correct pair of point numbers for the Angle Balance Measurement. This is often the last leg of the traverse relocating the initial backsight and setup points.

Enter the Reference Closing Angle. This can be entered by point numbers or entering the angle. This is often the original backsight and setup points.

```

The angle balance report shows the unadjusted points, the unadjusted closure, the angular error, the adjusted points and then the adjusted closure. Typically but not always, applying the angle balance correction will improve the traverse closure.

Compass, Crandall, Transit: These processing methods apply the selected rule to the traverse lines when calculating the coordinates. After adjusting the traverse, the sideshots are also recalculated. The closure error is calculated as the difference between the closing shot and a reference point. The closing shot is specified as a type CL or CL+AB record in the raw file. If no CL record is found in the raw file, then the program will prompt for which traverse shot to use as the closing shot. The foresight point is used as the closing coordinate. The reference point can be specified by point number or by entering the northing, easting and elevation. The process results report shows the unadjusted points, closure error, adjustments to each traverse point and adjusted point.

Compass Rule: This common closure method performs a typical linear adjustment of the traverse proportional to the length of each leg, weighting both distances and angles. Beyond the *common options*, the Compass Rule Adjustment dialog box presents a few additional options:

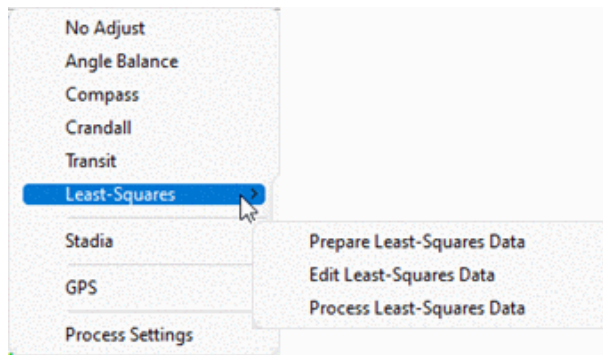

- **Apply Angle Balance** matches the Angle Balance method described above. This option performs an angle balance as part of the adjustment which negates the need to perform a separate angle balance.
- **Report Unadjusted Points** provides the option to report the original unadjusted points along with the adjusted positions.
- **Report Point Adjustments** provides the option to report the amount each individual point was adjusted.

Once these options have been selected, proceed with the traverse adjustment as shown above in the *Angle Balance* method.

Crandall Rule adjustment method performs an adjustment to a closed traverse applying error predominately on distances while heavily weighting the directions (angles). The procedure for performing this adjustment is identical to the *Compass Rule*.

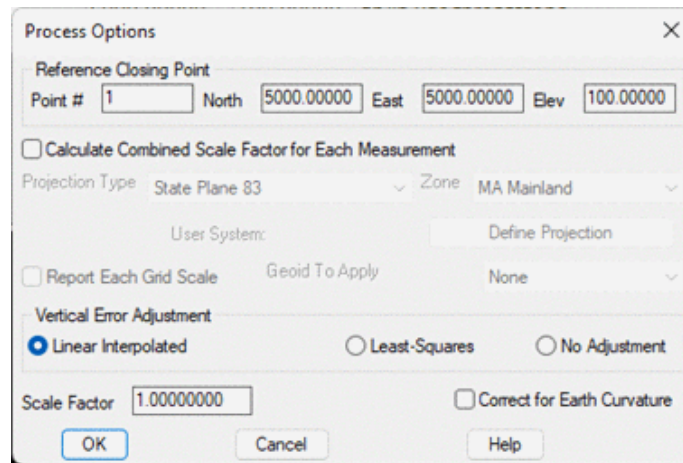

Transit Rule: This method of adjustment is similar to the *Compass Rule*. The main difference is the distribution of error is proportional to the length of the latitude and departure rather than the length of the traverse leg. The procedure for performing this adjustment is identical to the *Compass Rule*.

Least Squares: *Note, this is a legacy adjustment routine that has been superseded by SurvNET, a comprehensive least squares adjustment program that processes EDM traverse measurements, GNSS vectors and Differential Levelling.*

Within the Least Squares option, there are 3 steps to processing the data and adjusting the network.

- **Prepare Least Squares Data:** From the raw file data, this routine makes initial calculations for the coordinate points in the traverse.

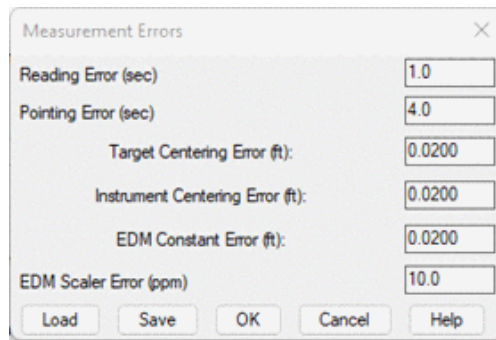

This data, along with the control point coordinates and the angle and distance measurements, is stored to a data file with the same name as the current RW5 file except with a .LSQ extension (ie: survey.lsq goes with survey.rw5). The constraints of the routine are:

- All angle readings must be in angle right mode.
- The coordinates of the starting and the ending points must be known.

The routine begins with a dialog for specifying the reference closing coordinates and any scale factors to apply to the distance measurements. The **Reference Closing Point** is the last point in the traverse, whose coordinates must be known. If an angle balance shot is used in the traverse, the Reference Angle Balance Angle must also be specified, either as a value or as the angle between known points.

When you click <OK>, a **Measurement Error** dialog box will appear.

Since angles and distances have errors of different magnitudes, they are normalized using weights, based on the accuracy and confidence with which these quantities have been measured. There is a dialog for specifying the estimated measurement errors. The Reading Error is the horizontal angular error in the instrument. For example, for a "5-second" instrument this error would be 5. The Pointing Error accounts for several factors in the horizontal angle reading including accuracy lining up the crosshairs on the target, the target size and the optical quality of the instrument. The Target and Instrument Centering Errors are the distance off the point due to faulty centering. The EDM Constant Error is the accuracy of the instrument distance measurements. The EDM Scaler Error is entered in parts per million for the increased error in longer measurements. These settings can be saved and loaded as a way to store settings for different equipment.

The program will calculate the weights for each distance and angle measurement using these measurement errors. The control points, points to adjust, distance and angle measurements with weights are reported. You can edit these measurements and weights using the Edit Least-Squares Data routine or go directly to the Process Least-Squares Data routine. You can also **Save** these settings as a .LQE file and **Load** them for future surveys. When you click <OK>, the routine calculates and reports the initial measurements.

Typical results of the initial measurement report.

```

- **Edit Least Squares Data:** Once the initial data is processed with *Prepare Lest Squares Data*, you can view

and edit the data. This routine edits the points, measurements and weights stored in the .LSQ file associated with the current RW5 file. The editor works through the dialog shown. You can edit, add or remove the control points, adjust points, angle measurements or distance measurements. The program does not check that the editing is valid. So you need to make sure that your changes keep a good set of least-squares data (i.e. don't delete a needed control point). The Distance Error button allows you to set the distance standard error weights for all the distance measurements to the same value. Likewise the Angle Error button sets the standard error weights for all the angle measurements.

Edit Least-Squares Data

Control Points

Point#	North	East
2	5000.00000	5613.28050

- **Process Least Squares Data:** This routine applies a least-squares adjustment to the data stored in the .LSQ associated with the current raw data (.RW5) file. The closing errors are distributed among the other points, using the "Method of Least Squares" (Ref : Wolf, P.R. and Ghilani, C.D., 1996, "Adjustment Computations", John Wiley and Sons, NY, Third Edition). After the adjustment, the rest of the raw file is processed to recalculate the sideshots. There is an option to draw standard error ellipses around the adjusted points. The ellipse axes are multiplied by Ellipse Scale Factor to make the ellipse larger for easier viewing.

Clicking <OK> will bring up the Error Ellipse options.

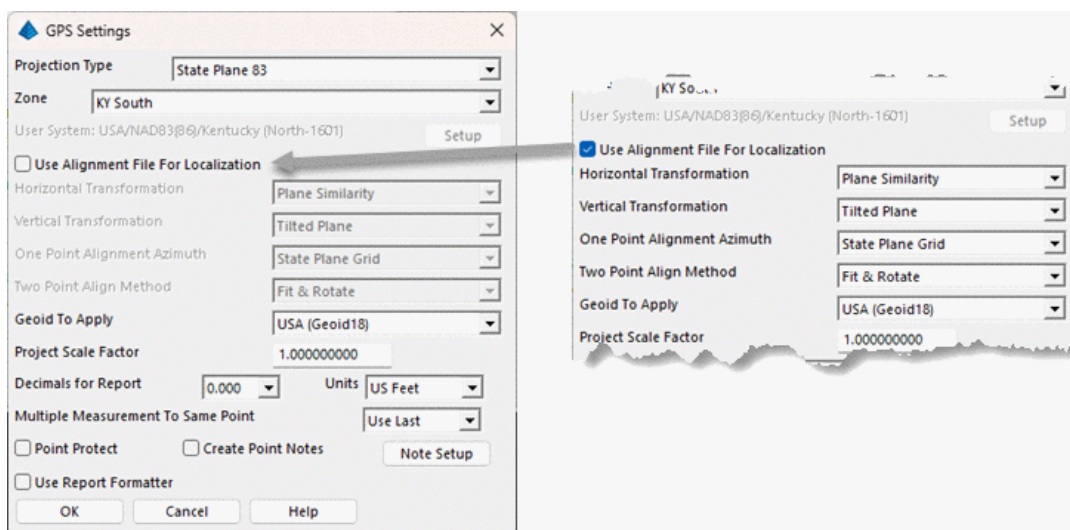

Error Ellipses are a graphic depiction of the network error for each point. The error is usually very small, so the scale factor is applied so you can visibly see the ellipses.

The least-squares process report shows the input data and the results. For each point, the amount adjusted and the standard error in X and Y are reported. The Reference Standard Deviation is based on the sum of the residuals and the initial estimated standard errors. The Chi-Squares test is a goodness-of-fit test that checks the reference standard deviation with the least-squares model. If this test fails, there may be a blunder in the measurement data or the initial estimated standard errors were too low or too high.

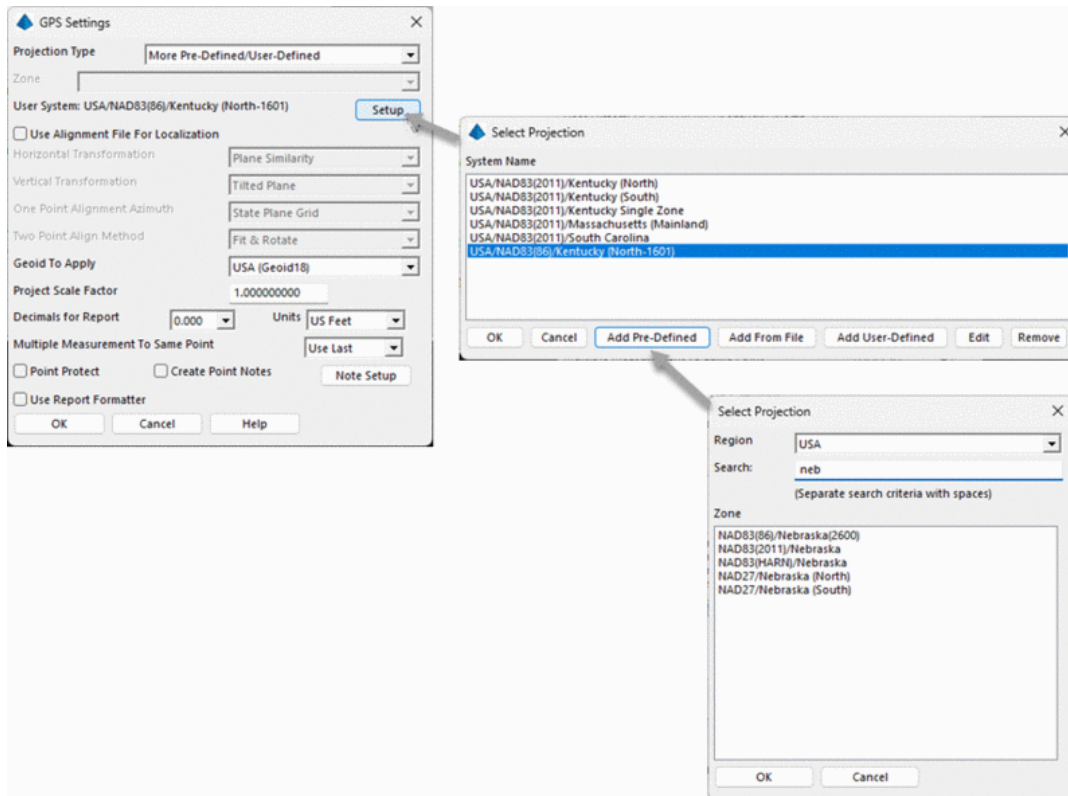

Stadia Processing Method: Provides functionality to process Stadia surveying notes. Stadia sighting depends on two horizontal cross-hairs, known as stadia hairs, within the telescope. These hairs are parallel to the horizontal cross-hair and are equally spaced above and below it. The distance between the two stadia hairs is known as the intercept. The distance from the instrument to the rod is 100 times the intercept. For example, an intercept of 3.10 would represent a distance of 310 (3.10 X 100). For entering in stadia notes, you would enter the horizontal angle, the distance (entered as the intercept X 100) and the vertical angle. The processing options for Stadia reduction are similar to the Common Options shown above.

GPS: The process GPS routine allows for reduction of GPS records that reside in a raw (*.RW5) file from latitude, longitude and WGS84 Ellipsoid Height to State Plane or local coordinates. When a DZ (Depth) record follows a GPS record, the depth value is used to adjust the GPS point elevation. When a GSAL record follows a GPS record, the position is adjusted by the record delta tilt values for the rod tilt. When using a CRDB coordinate file format, the process GPS routine stores the lat/lon and RMS values from the raw data to point attributes in the CRDB.

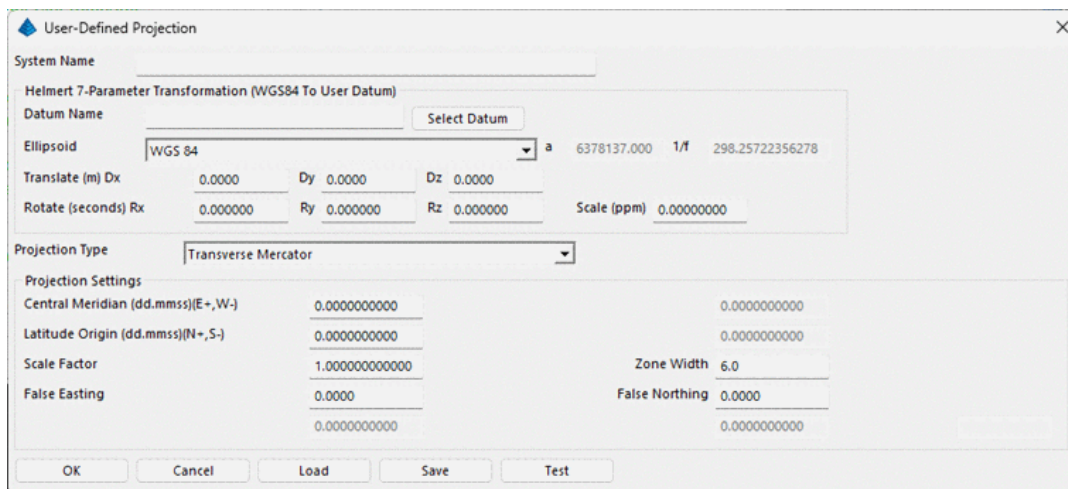

The Process GPS settings dialog is shown below.

- **Projection Type:** Defines the datum coordinate system to be used for converting the latitude, Longitude and WGS84 Ellipsoid height collected from the GPS receiver into Cartesian coordinates. The supported projection types are State Plane 83, State Plane 27, UTM, Lat/Long, Great Britain-OSGB36, Australia, New Zealand-NZGD2000, New Zealand-NZGD49, France NTF-GR3DF97A, and Barbados National Grid. A User-Defined option is also available for defining a user projection or loading More Predefined projections.

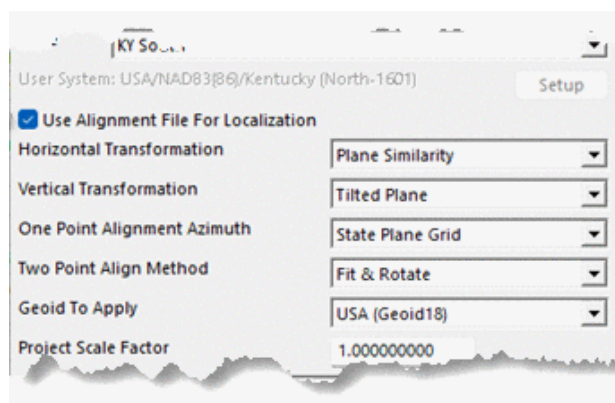

- **Zone:** for State Plane projections, you must select the correct state zone that you are working in. For UTM, the Automatic Zone option will have the program automatically use the program automatically use the correct UTM zone for your location. Otherwise for UTM, you can manually set a specific UTM zone. This manual option applies to working on the border between zones and you want to force the program to always use one of those zones.
- **Add User-Defined** is an option to define a new projection using a dialog box to populate all appropriate data.

Enter a name for your system (e.g. PRVI for Puerto Rico/Virgin Islands), then select a Projection type and enter the appropriate parameters. Note that all latitude and longitude values are in Degrees Minutes and Seconds (dd.mmss) and False Northing and False Eastings are always presented in meters. Define a Datum shift by selecting the Select Datum radial button. You may select a predefined Ellipsoid or set your own parameters by typing in a new ellipsoid name in the Ellipsoid field and entering values for a and 1/f. When you enter in a new Ellipsoid name, the Datum name field will be blank. The values for Dx, Dy, Dz, Rx, Ry, and Rz and scale are "to WGS84". If the values you have are "from WGS84", simply reverse the sign of each value (positive becomes negative and vice versa).

You may save your system to a ".udp" file. To Load a user defined coordinate system from a file, select the Load radial button. A list of user defined systems will be displayed. Select the desired system and press OK.

- **Use Alignment File For Localization:** With this option toggle on, a prompt for the Alignment File to Process will be displayed. This file is typically created by SurvCE (Carlson's Data Collection System) using the Localization routine or by Carlson Field Using the Align to Local Coordinates routine. This file (.DAT, LOC, GC3) contains the parameters to transform the derived State Plane coordinates to the defined local coordinates.

At the end of the process, the coordinates will be written to the current coordinate (*.crd) file and a report will be presented in the Carlson editor for saving or printing purposes.

- **Horizontal Transformation:** The transformation in the align Local Coordinates command can either be by plane similarity or rigid body methods. The difference is that the rigid body method does a transformation with a translation and rotation and without a scale. The plane similarity does a rotation, translation and scale. This option only applies when two or more points are used in Align Local Coordinates or the Localization routine in SurvCE.
- **Vertical Transformation:** This transformation has two options, Level Plane and Tilted Plane.
- **One Point Alignment Azimuth:** This option applies to the rotation when using one point in Align Local Coordinates or the Localization routine in SurvCE. For this alignment method, the state plane coordinate is translated to the local coordinate. Then the rotation can use either the state plane grid or the geodetic as north. No scale is applied in this transformation. The state plane and geodetic true north diverge slightly in the east and west edges of the state plane zone. This option allows you to choose which north to use.
- **Two Point Alignment Method:** There are two options when using this method, Fit & Rotate and Rotate Only. Fit & Rotate will use the second point in the localization file for direction and scaling. The Rotate Only option allows you to use the second point in the localization file for direction but not for scaling. When using the Rotate Only option, any scale factor entered in the Project Scale Factor will be used.

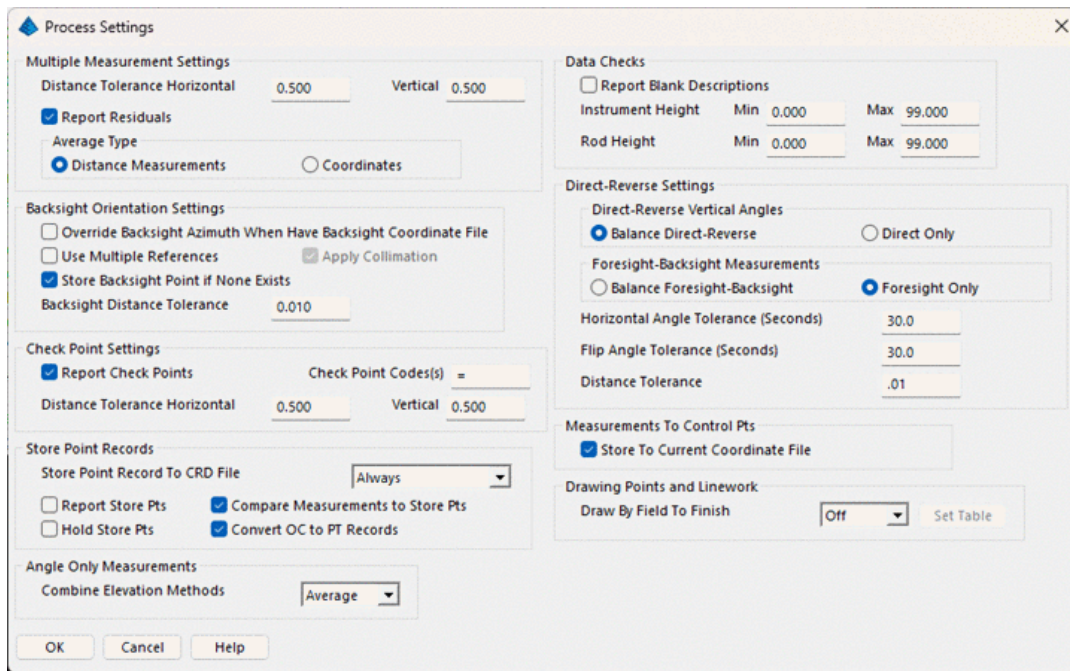

- **Geoid to Apply:** There are a vast number of supported Geoids which are available for selection using the drop down menu.

This option will account for the geoid undulation in determining the orthometric elevation of the measurement. The definition of the geoid model as currently adopted by the national Geodetic survey is the equipotential surface of the Earth's gravity field which best fits, in a least squares sense, global mean sea level. Orthometric elevation measurements are used in survey calculations. In order to convert ellipsoid heights (H_e) as measured by GPS into orthometric elevations (E_0), you must provide for a correction between the GPS-measured ellipsoid (reference ellipsoid) and a constant level gravitational surface, the geoid. This correction is the geoid undulation (U_g). The formula is $H_e = E_0 + U_g$.

Carlson applies the Geoid model by subtracting the Geoid undulation from the GPS elevation. The resulting elevation is then used and displayed. In practice, the Geoid model is most applicable to two types of alignment scenarios. One of these types is when setting up the base over a known point and having no alignment control points. The other is when there is one alignment control point. When using multiple alignment control points, the Geoid model is not as important because Carlson can model the elevation difference which can generally pick up the local Geoid undulation.

- **Project Scale Factor:** For most applications, the Scale Factor should be set to 1.0. The scale factor represents the "combined" grid/elevation factor that reduces ground distances to grid. After converting the LAT/LONG from the GPS records to state plane coordinates and applying the coordinate alignment (Localization) file, the Project Scale Factor is applied as the final adjustment to the coordinates. This adjustment is used on the X, Y, and not the Z. The Project Scale Factor is applied by dividing the distance between the coordinate and a base point by the Project Scale Factor. The coordinate is then set by starting from the base point and moving in the direction to the coordinate for the adjusted distance. The base point is the first point in the alignment (Localization) file. If there are no points specified in the alignment file, then 0,0 is used as the base point. If using an alignment file (Localization File) this value will be automatically calculated and displayed. Manual entry of a scale factor is also permitted and is often used with the Two Point Alignment Method when a scale factor is known.
- **Units:** Coordinates can be reduced into one of three available units, Metric, US Feet or International Feet.
- **Multiple Measurements to Same Point:** Specify what you would like to program to do when 2 or more points are located with the same point name. The options are Use Last, Average and Use First. the options Use First or Last will overwrite previous point locations while the Average option will perform an average of all same named points.
- **Point Protect** and **Create Point Notes** are described in the Common Process Options above.

Process Settings: This dialog box contains a large variety of settings that affect the way data will be processed. It is limited to traditional traverse methods such as EDM total stations. Processing GPS locations has a separate dialog box contained in the processing option itself.

- **Multiple Measurement Settings:** These options provide control for managing how multiple measurements to the same point are handled and reported.
- **Distance Tolerance Horizontal and Vertical:** Allows for user input of desired tolerance values for multiple measurements. Exceeded tolerances will be displayed on the process results report. With the Report Residuals option ON, the residual values of the measurements will be shown on the process results report.
- **Report Residuals:** These options control how the residual differences between multiple measurements will be displayed. The options are Distance Measurements or Coordinates.
- **Backsight Orientation Settings:** These options are specific to the back sight record.
 - **Use Multiple References** option will take multiple backsight measurements for an occupation and computes a least squares orientation for the instrument. There is also an option to compute and correct for the instrumental collimation error from the available measurements if both direct and reverse readings to one or more stations in the same set have been recorded. The program uses the BD (backsight direct) and BR (backsight reverse) records to identify the measurements to process. You can backsight different targets. The targets do need to have known coordinates either as points in the current coordinate file or as SP records in the raw file. The measurements can be complete with angles and distance, and they can be partial with only angles or only distance. When this option is active, the calculated backsight orientation will override the SetAzi field in the BK (backsight) record for the setup. The process report will include all the measurements used, the residuals and the resulting backsight orientation. The least-squares routine will also calculate the occupied station coordinate by resection if possible from the measurements and the report includes this calculated position along with the reference position and residuals. This calculation of the occupy point is used only for a check for the report and does not affect the occupy coordinate for processing. Note that if the occupied station position is unknown, there must be sufficient measurements to at least three known reference stations to support the resection and orientation solution. Here is an example of the raw data and the report.

- **Store Backsight Point if None Exists:** This option allows for the creation of a backsight point based on the the initial backsight (BD) record. The point will be created based on the measurement data from the Occupied Point which needs starting coordinates, a back sight azimuth and distance to the backsight point.

- **Backsight Distance Tolerance:** This value is a tolerance for reporting the difference between a stored point used for a backsight and the field measurement to that point.
- **Check Point Settings:** These options provide user controls for survey check points. Essentially, points located more than once intended for precision checks.
 - **Report Check Points:** When toggled ON, any point coded as a check point in the raw data file, will be reported. When selected the *Check Point Code* and Distance Tolerance fields become active and allow for editing.
 - **Check Point Code** is a user specified code entered in during the survey that tells the program to check the coordinates of a particular point with the coordinates of another point. This code is configurable by the user. An example of a point description coded as a Check Point would be as such, "trav =8". This description tells the program that the description of the point is "trav" and to check the coordinates of the this point with that of point #8.
 - **Distance Tolerance Horizontal** and **Vertical** are user specified tolerances for the check point. If either of these tolerances is exceeded it will be reported on the process results report.
- **Store Point Records:** These options control how any store point (PT) record is handled during processing of the raw data file. There are three options for storing Store Point (PT) records, *Never*, *Always*, and *When CRD Empty*. *Never* prevents any Store Point (PT) Record Report in the raw file from being written to the crd file. With this option on no existing point in the crd file would be overwritten. *Always* will write to the coordinate file and will overwrite any existing point with the same number of the Store Point (PT) records. The *When CRD Empty* option will only write Store Point (PT) records to the coordinate file when it is empty.
 - **Report Store Points** displays all store points in the process results report.
 - **Hold Store Points** option will hold the coordinate values for the store point record when measurements are taken to the store points. This will prevent the coordinates of the point from changing if measurements to the point dictate a change in coordinate position.
 - **Compare Measurements to Store Pts:** This option will add residuals to the report for field measurements to already stored PT records or points contained in the current CRD file.
 - **Convert OC to PT Records** option will convert description (DS) records to store point (PT) records when the description record contains contains an OC tag with an occupy point number and coordinates for a point number that isn't already used in another PT or SS record.
- **Angle Only Measurements:** The **Combine Elevations Method** applies to points calculated from Angle Only measurements. Angle Only points are calculated as part of the processing for the No Adjust, Compass, Crandall, Transit and Angle Balance process methods. To calculate points from Angle Only measurements, there needs to be multiple SS records with horizontal and vertical angles and no distance with the same target foresight point number from setups at different occupy points. The elevations can be set as the average from the multiple measurements, using the highest measured elevation, or using the lowest measured elevation. For example, to survey the top of a tree, you could have a SS to foresight point 99 from occupy point 1 with a horizontal and vertical angle and another SS to foresight point 99 from occupy point 2 with a horizontal and vertical angle. Then point 99 can be calculated by angle-angle intersect which determines the horizontal distances from 99 back to occupy points 1 and 2. These distances are then used with the vertical angles and occupy point elevation to calculate the elevation at point 99.
- **Data Checks:**
 - **Report Blank Descriptions** option reports any raw data records with empty descriptions. The
 - **Instrument Height** and **Rod Height** settings are used to check the instrument and rod heights when the raw file is processed. The program will report warnings if there are any heights that exceed the specified min/max ranges.
- **Direct Reverse Settings:**
 - **Direct-Reverse Vertical Angles:** This option determines how to handle direct-reverse vertical angle measurements when processing. *Balance Direct-Reverse* will take the mean of the direct-reverse

measurements and use this value when processing the file. **Direct Only** will only use the direct measurement to the point for processing.

- **Foresight-Backsight Measurements:**

- **Balance Foresight-Backsight** allows for averaging in the Foresight and backsight measurements when using direct-reverse sets. This option applies the mean angle of the Foresight and backsight to the backsight azimuth if entered.
- **Foresight Only** option will average the foresight measurements only of a direct-reverse set. This is the default setting

- **Horizontal Angle Tolerance (Seconds):** This is the tolerance that the angle measured by the direct measurements and the angle measured by the reverse measurements in a direct-reverse set must fall within.

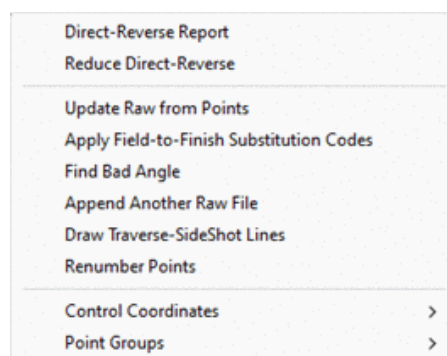

- **Flip Angle Tolerance (Seconds):** User specified value for the acceptable difference in measured horizontal angles determined from the direct (BD-FD) and reverse (BR-FR) observations.

- **Distance Tolerance:** User specified tolerance for the difference in distance measurements to the same points. When this value is exceeded on a measurement, it will be displayed on the process results report.

- **Measurements To Control Points:** The **Store To Current Coordinate File** option applies when a control coordinate file is used in addition to the active coordinate file. When processing the raw file, measurements to point numbers that are in the Control Coordinate File will not be stored into the active coordinate file when this option is disabled (off). When this option enabled (on), all control points that have a foresight measurement to them, will be stored in the active coordinate file.

- **Drawing Points and Linework:** This option controls the drawing of points and linework using Field to Finish. It differs from the draw traverse and sideshot lines under the Tools Menu of the Raw Editor by using a field to finish code table (*.fld) to define how the points and linework are to be drawn and layerized. There are three settings for this option, Manual, Auto and Prompt. Manual means that the file will not be processed using the field to finish codes and no points or linework will be drawn upon exiting the raw editor. The Auto option will use the current or last used field to finish file (*.fld) to draw the points and lines on the drawing screen when the raw editor is existed. The option of Prompt will give the option to draw the points and lines to the screen. With this setting specified, a prompt will be displayed when exiting the editor.

Tools Menu

Direct-Reverse Report: This routine creates a report of direct and reverse shots along with the resulting averaged shots. Any tolerance specified in the Process Settings>Direct-Reverse Settings section, that is exceeded will be displayed in this report. The residuals are the difference between the measurement and the final average. If the current spreadsheet display mode for distances is set to horizontal, then the report will show horizontal distances. Otherwise, the report uses slope distances.

Reduce Direct-Reverse: This routine processes the direct and reverse shots and simplifies the raw file by replacing the sets of direct and reverse shots with the resulting average traverse record. It is not necessary to perform this operation to ensure mean angles are used during the processing.

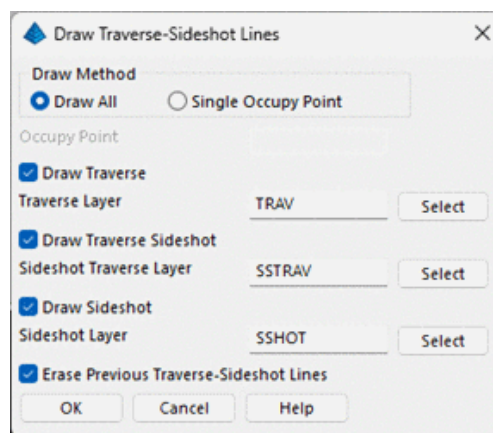

Update Raw from Points: This routine is used to update the raw data based upon the coordinates of the points contained in the coordinate file. There is a choice to update only the point descriptions in the raw data or update both the descriptions and the measurement values. An example for updating the measurements is when the raw data has been processed using the compass rule adjustment method, the points in the crd file are now adjusted. However the raw data remains unchanged. If a record of the rw5 file reflecting the angles and distances between the points after an adjustment has been ran is desired, this routine can be run thus updating the raw data to reflect the adjusted angles and distances. Another application for this routine is that of building a rw5 file for future processing and adjustment. For example if a point file or text file has been received from another engineering firm or fellow surveyor and you would like to build a rw5 file for future reference and processing this option can also be used to accomplish this. The rw5 file would be set up with the occupied points, foresight points and the desired angle type to use specified for the traverse. This would be all the manual entry of the data necessary. After creating the "shell" of the traverse then run the update raw from points routine and the raw data, as contained in the coordinate file, will be imported into the rw5 file thus filling out the horizontal angle, distance and vertical components specified.

Apply Field-to-Finish Substitution Codes: This routine updates the point descriptions in the raw data using substitutions defined in the Field-to-Finish command.

Find Bad Angle: This routine applies the angular error to each traverse record one at a time. The adjusted traverse record that improves the closure the most is reported as the Bad Angle. The angular error is the difference between the angle balance shot and a reference angle.

Append Another Raw File: This routine prompts for another raw data (.RW5) file which is read and the data added to the end of the existing raw data (.RW5) file. For example, if you are editing the raw file from the first days work and have a separate raw file with a second days work, you can use this routine to add the second raw data to the first raw file.

Draw Traverse-Sideshot Lines: This routine draws lines for all the traverse and sideshot records.

Each option has a layer selection for that particular entity. If a layer does not exist, it will be created as it is drawn.

- Draw All: draws all traverse and/or sideshot lines contained in the raw file.
- Single Occupy Point: draws traverse legs and sideshots from a specific occupied point.
- Draw Traverse: draws all traverse lines
- Draw Traverse Sideshot: draws traverse sideshot lines. Sideshot Traverses are traverses that do not lead to the closing or ending point.
- Draw Sideshot: draws sideshot lines from the occupied point to the foresight point.

This command does not process the raw file. Instead it reads the raw file and for each traverse and sideshot record, the program looks up the coordinates for the occupied and foresight points in the CRD file. So it may be necessary to run a Process Option before running this routine. With the Erase Previous Traverse-Sideshot Lines toggled on, any previous linework drawn using this method will be erased from the drawing screen before drawing the lines again.

Renumber Points: This routine renumbers points in the raw file. This applies to all point numbers including: TR, SS, and PT records. The points can be renumbered by either incrementing the number or by adding a suffix. The Renumber Duplicates Only option only renumbers points that are duplicated in the raw file.

The screenshot shows a dialog box titled "Renumber Points". It has a close button (X) in the top right corner. The dialog contains the following fields and options:

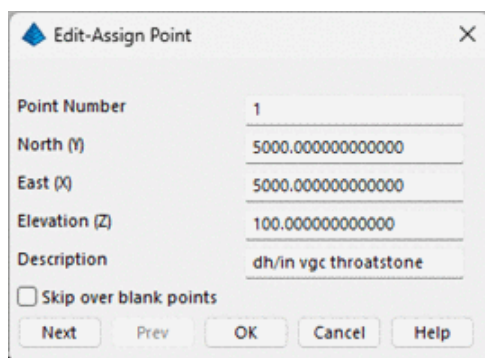

- Range of Points to Renumber:** A text box containing "100-TR100".
- Line Number To Begin Renumbering:** A text box containing "1".
- Line Number To End Renumbering:** A text box containing "670".
- Renumbering Method:** Two radio buttons are present. The first is "Increment Point Number By" (unselected). The second is "Add Point Number Suffix" (selected). To the right of the selected radio button is a text box containing "_B".
- Renumber Duplicates Only:** A checked checkbox.
- At the bottom are two buttons: "OK" and "Cancel".

- **Range of Points to Renumber:** Enter in the range of points to change, ie 1-4.
- **Line Number to Begin Renumbering:** This corresponds to the line number located at the far left of the raw data editor. Enter the line number to begin the renumbering.
- **Line Number To End Renumbering:** This also corresponds to the line number located at the far left on the raw data editor. Enter the line number to end the renumbering. If the range of numbers specified does not occur between the beginning line number and the ending line number, no changes will be made.
- **Renumbering Method**
 - **Increment Point Number By:** This number will be added to the existing point number to create the new point number. For example, if the number to add is 10 and the existing point numbers 1 and 6, the new renumber points will be 11 and 16.
 - **Add Point Number suffix:** This method adds a suffix to all points within the specified range. For example, point 1 could be renamed as 1.B

Control Coordinates: This option allows for the use of a supplemental control file for use in processing the raw file. The points in the control file will not be stored in the current (active) coordinate file unless specified to do so in the Process Settings.

Set Control Coordinate File
List Control Coordinates
Edit Control Coordinates

- **Set Control Coordinate File:** browse and select a coordinate file (CRD, CRDB, CGC, MDB, OR ZAK) to use as a Control File
- **List Control Coordinates:** Lists all points contained in the Control File
- **Edit Control Coordinates:** Opens a dialog box for displaying and editing points in the Control File:

Point Groups: This option can be used to organize the survey data into point groups.

Create All Point Group
Create Traverse Point Group
Create Sideshot Point Group

There are three options for the creation of point groups:

- **Create All Point Group:** creates a user specified group containing all of the points defined in the rw5 file.
- **Create Traverse Point Group:** creates a user specified group containing only the points defined in the traverse records (TR) of the rw5 file
- **Create Sideshot Point Group:** creates a user specified group that contains only the points defined in the sideshot records (SS) of the rw5 file

More about the format of the raw data (.RW5) file

The Carlson raw data format is a comma delimited ASCII file containing record types, headers, recorded data and comments. The format is based on the RW5 raw data specification, with the exception of angle sets. Angle sets are recorded as BD, BR, FD and FR records to allow reduction of all possible combinations. Essentially, these records are identical to a sideshot record.

Backsight Record

Record type: BK

Field headers:

CL+AB	7	8	AR	261.2756	387.250	91.4405	CLOSE

Notice that the record from point 7 to 8 is set as a CL+AB record. This tells the program that point 8 is the closing point and that the angle from 7 to 8 is the closing angle. For traverse adjustment, the closing reference point is 1 and the closure error is the difference between point 1 and point 8. For angle balance, the reference closing angle is 358d0'42" (178d0'42" + 180). The angle balance error is the difference between this reference angle and the angle from points 7 to 8.

Now let's process using Compass adjustment with Angle Balance. Choose Compass under the Process menu and fill out the dialogs as shown.

CLOSE								

Shown above is the resulting process report. The angle balance had an error of 39 seconds which was divided among the 7 traverse sides. The Compass Closure shows how each traverse point was adjusted and then the resulting adjusted angles and distances.

Here is another layout of the last example that shows an external backsight setup. In this case there are two known points. Point 1 is the starting point and point 21 is the initial backsight. The setup could also use a backsight azimuth (ie north azimuth for example) instead of a backsight point number.

The closing record setup has changed from the last example. In this example, the shot from 7 to 8 is the closing shot with point 8 as the closing point. The closing reference point is still point 1. The angle balance shot is from 8 to 9 and the reference angle is from 1 to 21.

Example of an open traverse

The traverse starts from the known point 1 and ends at the known point 14. In this case there is no angle balance shot. The closing shot is from 3 to 4 with point 4 being the closing point. Point 14 is the closing reference point.

The closing record setup has changed from the last example. In this example, the shot from 7 to 8 is the closing shot

with point 8 as the closing point. The closing reference point is still point 1. The angle balance shot is from 8 to 9 and the reference angle is from 1 to 21.

Here is an example of an open traverse.

Edit-Process Level Data

This command is for entering and calculating level data. It has a spreadsheet editor for entering the level measurements, and the level calculations are updated as the data is entered. There is also a processing and reporting feature.

Carlson Software supports two level file formats:

LEV Files: The .LEV file is the old format. You can still edit and process files in this format. The LEV format only supports differential levels, single and three-wire. The LEV file has 5 record types:

- 1) SR - Start Record. Contains the starting benchmark measurement.
- 2) TP - Turning point record, contains the backsight and foresight to the turning point.
- 3) LV - Side Shot (or level) record. Contains the foresight measurement to the point.
- 4) ER - End Record, contains the measurement to the ending benchmark.
- 5) Note/Comment - starts with two dashes

TLV Files: The TLV file format can contain Differential and/or Trig-Level data. This is Carlson's new format and is supported by SurvCE (Carlson data collection program). The TLV file has the following record types:

- 1) H1 - First header record contains project information
- 2) H2 - Second header record contains date, time, temperature and pressure information
- 3) BM - Benchmark record, contains the point number, elevation and description of the benchmark.
- 4) LS - Rod height, only used with TRIG-LEVEL data.

- 5) BS- Backsight measurement. This record contains the backsight point number and measurement:
 - a) Differential data: VD and HD - Vertical Difference (rod reading) and Horizontal Distance
 - b) Trig data: SD/ZE - Slope Distance and Zenith Angle
- 6) FS - Foresight measurement. This record contains the foresight point number and measurement.
 - a) Differential data: VD and HD - Vertical Difference (rod reading) and Horizontal Distance
 - b) Trig data: SD/ZE - Slope Distance and Zenith Angle
- 7) Note/Comment - starts with two dashes

This routine runs the *.TLV / *.LEV file editor and file report functions.

LEV File Editor:

If you are creating a new .LEV file, you must choose either single-wire or three-wire for your level format data entry preference.

Three Wire leveling, or precise leveling, is a process of direct leveling wherein three cross hairs, or threads, are read and recorded rather than the single horizontal cross hair. Note below, in the sample three-wire editor graphic, the additional columns representing top and bottom readings.

The commands starts by asking you, with a dialog box, to select an existing level file (.LEV) to process or to select a name for a new level file. The below examples are using existing files. Once this choice is made the small, Level Format dialog appears.

Format choice box

Regardless of whether you choose Single or Three Wire, the Level Editor appears in its own window. Below we see the editor displaying the contents of two existing files of level information. One is single wire and the other is three wire. The pulldown menus are the same for both, as described below in detail.

In the spreadsheet, the background color of the cells indicate the data type. White cells are for user-specified values. Blue cells are program calculated values. Black cells are data fields that aren't used by the level record for that row.

	Type	Point#	BS	HI	FS	Elevation	Code	AdjustElv	Description

Level File Editor - sample Three Wire data

Level Settings ✖

3-Wire Tolerance:

3-Wire Distance:

File->Settings

File: Standard File routines - Open, Save, Save As, Settings, Print and Exit. Settings brings up a dialog where you can adjust the 3-wire tolerance and distance values. Open will allow you to open up another existing .LEV file.

File->Import: This routine imports Carlson .LEV format, Leica level data in .GSI or .XML format, TDS .RAW format, Topcon or Trimble .DAT format into the level editor.

File->Settings: This function has a setting for whether to use the Report Formatter for the Print function. The Report Formatter allows for customized reports and output to Excel. Without the Report Formatter, the Print function creates an automatic report.

Edit: Cut, Copy, Paste and Go To. Go To will take you to the row of your choosing.

Add: These options provide the standard level run routines. Details on each and a graphic of the pull-down follow.

Tools: This pull-down is for adjusting and storing elevations.

The Add and Tools pull-downs at the top of the editor provide the following features:

Level Editor - Add pull-down menu

Level Start (SR): Starts the level run, usually with a known starting elevation or benchmark.

Level Turning Point (TP): Turning point procedure for leveling.

Level Side Shot (LV): For entering leveling side shots.

Level End (ER): Enter your value.

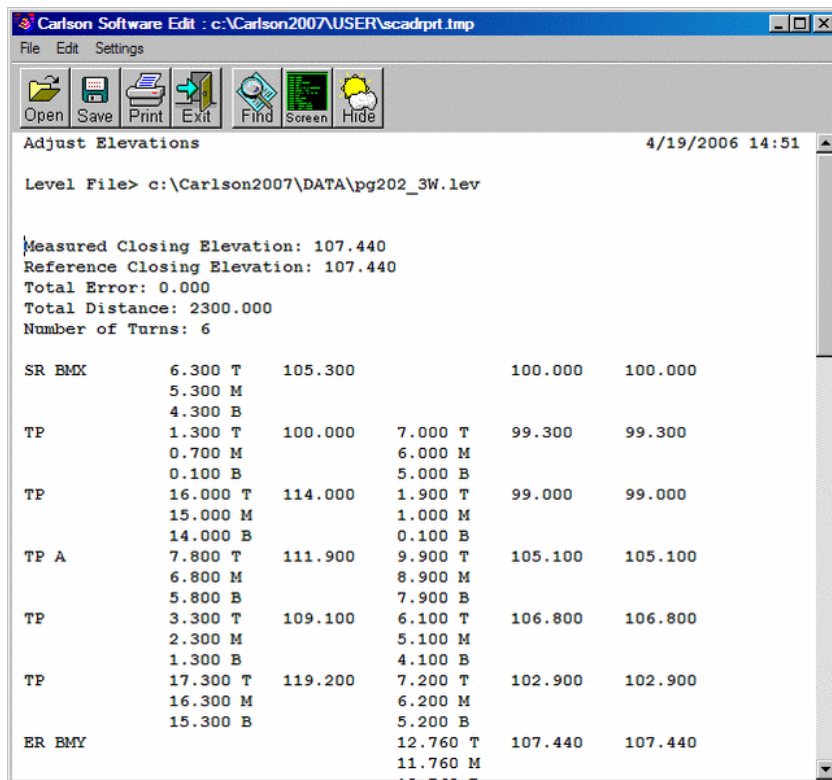

Note: You can add a note, or comments, into the editor as you move through the level run.

Level Editor - Tools pull-down menu

Adjust Elevations: This function will do a simple adjustment of your level data and place the adjusted elevations in the Adjusted Elevation column. If you are running 3 wire level loop the corrections will be inversely proportionate to the distance between the measurements. If you are running a single wire level loop, the corrections will be averaged by the number of turns.

Store Elevations to Coordinate File: If you have an active coordinate file passed to the level editor, this function will be available to store the elevations calculated in the level file to the active coordinate file by matching point numbers. The point number in the level file must match the point number in the coordinate file for an elevation to be stored. If adjusted elevations have been calculated, they will be stored. If not, the unadjusted elevations will be stored. This function shows a report of the original elevations from the coordinate file and the level elevations and reports matching or missing points numbers. After the report, there is a prompt to confirm whether to store the elevations to the coordinate file.

Selecting Print (editor File menu) provided this Level File Report sample

Editor Columns:

Type: These are small pulldown menus with two-letter level procedure choices. The two letters are abbreviations as indicated in the next dialog. These steps may be made with the Add pulldown or with this method. The options are SR, TP, ER, LV and DS. DS stands for description shot.

Point # - Point number of measurement.

BS - Backsight rod reading

HI - Calculated height of instrument

FS - Foresight rod reading

Elevation - Elevation of point

Code: The code is used by SurvNet for network least-squares processing of networked level loops. The code can be either EL or FE where EL is for calculated elevations and FE is for fixed elevations. FE should only be assigned to a START or END record (where you can enter the value for the adjusted elevation). If FE is assigned to an intermediate record it is ignored. Here is how the FE records are used. Say you run from one benchmark to another (point 1 to point 10). Point 1 and point 10 are the START and END records of the first loop and both are FE records. Then you start another loop at point 5 (halfway between 1 and 10). This is not a benchmark and can be adjusted so it should be assigned an EL code. Point 5 is the START record for the second loop. You run from point 5 to point 20 which is a benchmark. Point 20 is the END record and is assigned an FE code. When SurvNET processes the file, it will hold points 1, 10 and 20, allowing all others to be adjusted, including point 5 (even though it is a START record).

Adjusted Elevation - Adjusted elevation of point

Description - description of point

TLV File Editor:

TLV files can contain trig-level and/or differential level data. The editor will allow both type records in the same file.

Below is a sample Trig-Level TLV file:

Trig-Level Editor TLV> C:\Data\Triglev\Loop.tlv CRD>									
File Edit Add Tools Help									
		Point#	RodHt	Zenith	S.Dist	HI/Elev	AdjustElv	Description

18	FT	12	4.500	89.31000	1300.540	998.311		100+00.00 RS	

Below is a sample Differential-Level TLV file:

Trig-Level Editor TLV> C:\Data\Level formats\Trimble\Benchloop.tlv CRD>								
File Edit Add Tools Help								
		Point#		V.Diff	H.Dist	HI/Elev	AdjustElv	Description
1		Point#				Elev	AdjustElv	Description
2	BM	1				100.000	100.000	86
3		Point#		V.Diff	H.Dist	HI/Elev	AdjustElv	Description
4	BS	1		3.953	26.870	103.953		BM
5	FS	1		4.055	15.410	99.898		BM
6	BS	1		4.053	15.110	103.951		BM
7	FS	2		3.949	27.620	100.002		BM
8		Point#				Elev	AdjustElv	Description
9	BM	3				100.000	100.000	BM

Menu Options:

File Menu:

Open - Open an existing .TLV file.

New - Creates a new TLV level file.

Save - Save changes

Save As - Save as different file name

Settings - Not used with TLV files.

Import - You can import the following level file formats: Leica GSI format, Leica XML format, and Trimble DAT format.

Print - get hard copy printout of data.

Exit - Exit Level Editor Program

Edit Menu:

Clipboard: Cut, Copy, Paste

Go To - "Go To" will take you to the row of your choosing. Enter the row number.

Add Menu:

Add: These options allow you to add or insert a new record into the level editor.

Benchmark Record (BM): Point with known elevation.

Backsight Record (BS): Differential-level measurement to the backsight point.

Foresight Record (FS): Differential-level measurement to foresight point.

Backsight Record (BT): Trig-level measurement to the backsight point.

Foresight Record (FT): Trig-level measurement to foresight point.

Note: You can add a note, or comments, into the editor as you move through the level run.

Tools Menu:

Adjust Elevations: This function will do a simple adjustment of your level data and place the adjusted elevations in the Adjusted Elevation column. If you have distances, either HD or SD for all your measurements, the corrections will be inversely proportionate to the distance between the measurements. If you are running a single wire level loop (VD but no HD), the corrections will be averaged by the number of turns.

Store Elevations to Coordinate File: It is important that the point numbers in the level file match the point numbers in the coordinate file. If you have an active coordinate file passed to the level editor, this option will be available to you. The elevations calculated in the level file will be stored in the active coordinate file by matching point numbers. The point must exist in the coordinate file before an elevation will be stored. After the elevations have been stored, a report will show which points were stored and which ones were not. If adjusted elevations have been calculated, they will be stored. If not, the unadjusted elevations will be stored.

Editor columns

Measurement records will have the following columns:

Trig Level Record:

Type - Two character abbreviation that shows the record type:

BM - Benchmark

BS - Differential-level backsight record

BT - Trig-Level backsight record

FS - Differential-level foresight record

FT - Trig-Level foresight record

DS - Note or Comment

Point # - Point number of measurement.

RodHt - Rod reading

Zenith - Zenith angle

S.Dist - Slope Distance

HI/Elev - Elevation of HI if a backsight record, or the foresight point if a foresight record

Adjusted Elevation - Adjusted elevation of foresight point

Description - description of point

Differential Level Record:

Type - Two character abbreviation that shows the record type, same as above.

Point # - Point number of measurement.

V.Diff - Rod Reading

H.Dist - Horizontal Distance

HI/Elev - Elevation of HI if a backsight record, or the foresight point if a foresight record

Adjusted Elevation - Adjusted elevation of foresight point

Description - description of point

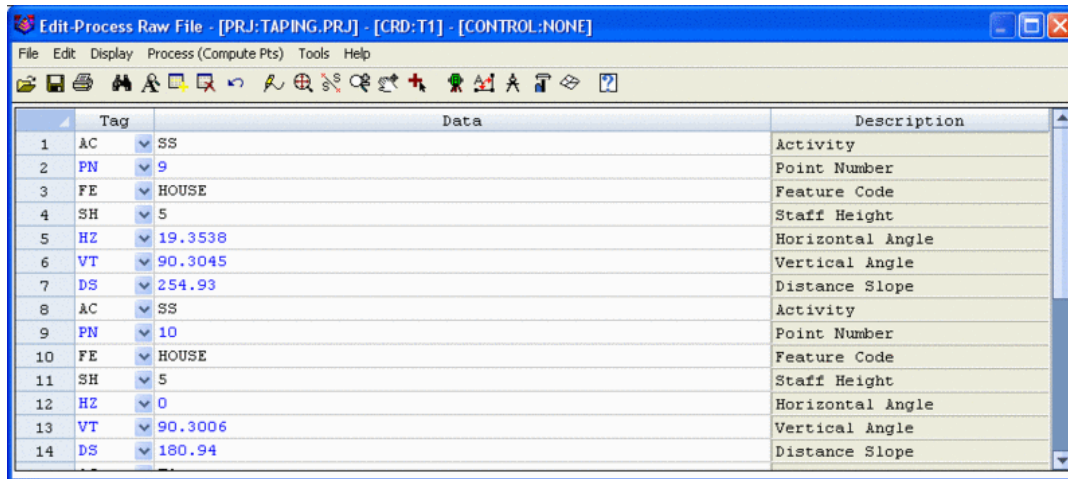

Pulldown Menu Location: Survey

Keyboard Command: diglevel

Prerequisite: .LEV (level) file to process

Edit Process SDMS File

This command processes SDMS format raw data from PRJ files. There is a spreadsheet editor with the data tag, value and description for each of the records. The processing functions are the same as the Edit Process Raw Data command. See that section of the manual for a description of the processing functions. The Edit Process SDMS command allows you to work with the SDMS raw data in its native format. Alternatively, you can run Edit Process Raw Data and convert the SDMS PRJ file into a Carlson RW5 file.

	Tag	Data	Description
1	AC	SS	Activity
2	PN	9	Point Number
3	FE	HOUSE	Feature Code
4	SH	5	Staff Height
5	HZ	19.3538	Horizontal Angle
6	VT	90.3045	Vertical Angle
7	DS	254.93	Distance Slope
8	AC	SS	Activity
9	PN	10	Point Number
10	FE	HOUSE	Feature Code
11	SH	5	Staff Height
12	HZ	0	Horizontal Angle
13	VT	90.3006	Vertical Angle
14	DS	180.94	Distance Slope

Pulldown Menu Location: Survey

Keyboard Command: sdmseedit

Prerequisite: None

SurvNET

SurvNET performs a least squares adjustment and statistical analysis of a network of raw survey field data, including total station measurements, differential level data and GPS vectors. SurvNET simultaneously adjusts a network of interconnected traverses with any amount of redundancy. The raw data can contain any combination of angle and distance measurements, and GPS vectors. SurvNET can adjust any combination of trilaterations, traverses, triangulations, networks and resections. The raw data does not need to be in a linear format, and individual traverses do not have to be defined using any special codes. **All measurements are used in the adjustment.**

SurvNET implements the standard parametric observation equation method with independent weighting for azimuths, directions, angles, distances, GPS baselines, coordinates, elevations and level data to compute least squares estimates of all unknowns in accordance with well-established reference texts: Ghilani, Charles D. & Wolf, Paul R., (2006) *Adjustment Computations: Spatial Data Analysis*. Hoboken, NJ: Wiley.

SurvNET produces a wealth of statistical information that allows an effective way to evaluate the quality of survey measurements. In addition to the least squares statistical information there is an option to compute traverse closures during the preprocessing of the raw data. Traverse closures can be computed for both GPS and total station traverses. This option has no effect on the computation of final least squares adjusted coordinates. This option is useful for surveyors who (due to statutory requirements) are still required to compute traverse closures and for those surveyors who still like to view traverse closures prior to the least squares adjustment.

For additional information, feel free to explore the introduction to SurvNET or let's get started!

Pulldown Menu Location: Survey

Keyboard Command: survnet

Introduction

- SurvNET reduces survey field measurements to coordinates in assumed, UTM, SPC83 SPC27, and a variety of other coordinate systems. SurvNET calculates the minimum necessary corrections to measured horizontal angles, slope distances and vertical angles in order to fit the desired control. **NOTE:** SurvNET can only process raw field measurements, it is not designed to process bearing or azimuth traverses. If you wish to use SurvNET to process your traverses, you must collect the angles and distances.
- In the 2D/1D model in a state plane coordinate system, a grid factor is computed for each individual line during the reduction. The elevation factor is computed for each individual line if there is sufficient elevation data. If the raw data has only 2D data, the user has the option of defining a project elevation to be used to compute the elevation factor.
- SurvNET supports a variety of map projections and coordinate systems including the New Brunswick Survey Control coordinate system, UTM, and user-defined systems consisting of either a pre-defined ellipsoid or a user defined ellipsoid and one of the following projections, Transverse Mercator, 1-Standard Parallel Lambert Conformal, 2-Standard Parallel Lambert Conformal, Oblique Mercator, and the Double Stereographic projection.
- A full statistical report containing the results of the least squares adjustment is produced and written to the report (.RPT) file. An error report (.ERR) file is created and contains any error messages that are generated during the adjustment.
- Coordinates can be stored into a variety of file types including the Carlson (.CRD) file, C&G (.CRD) file, Simplicity file (.ZAK), Carlson SQLITE (.CRDB), or an Autodesk Land Desktop (.MDB) file types. An ASCII coordinate (.NEZ) file is always created that can be imported into most any mapping/surveying/GIS program. The user has the option to compute unadjusted preliminary coordinates.
- There is an option to compute Traverse Closures during the preprocessing of the raw data. Closures can be computed for both GPS and total station traverses. Closure for multiple traverse loops in the same raw file can be computed.
- When processing Angle-Only records for triangulation, if there is a zenith angle and rod height (zero is a valid rod height), a 3D triangulation will be performed, calculating an elevation of the triangulation point. This is true in both the 3D and 2D/1D models.
- SurvNET can combine GPS vectors and total station data in a single adjustment. GPS Vector files from Leica, Thales, Topcon and Trimble can be input, as well as GPS files in the StarNet format. Additionally GPS vectors can be read from NGS G-files. There is also an option to read the G-file section of an OPUS report.
- SurvNET includes a variety of blunder detection routines. One blunder detection method is effective in detecting if the same point number has been used for two different points. Additionally this blunder detection method is effective in detecting if two different point numbers have been used for the same physical position. This method also flags other raw data problems. Another blunder detection method included in SurvNET is effective in isolating a single blunder, distance or angle in a network. This method does not require that there be a lot of redundancy, but is effective if there is only one blunder in the data set. Additionally, SurvNET includes a blunder detection method that can isolate multiple blunders, distances or angles in a network. This method does require that there be a lot of redundancy in the network to effectively isolate the multiple blunders.
- Other key features include: Differential and Trig level networks and loops can be adjusted using the network least squares program. Geoid modeling is used in SurvNET, allowing the users to choose between a variety of geoid models. The user can alternately enter the project geoid separation. There are description codes to identify duplicate points with different point numbers. The user can specify the confidence interval from 50 to 99 percent.

Least squares is very flexible in terms of how the survey data needs to be collected. Generally speaking, any combination of angles, and distances combined with a minimal amount of control points and/or azimuths are needed. This data can be collected in any order. There needs to be at least some redundancy in the measurements. Redundant measurements are measurements that are in excess of the minimum number of measurements required to determine the unknown coordinates. Redundancy can be created by including multiple GPS and other control points within a

network or traverse. Measuring angles and distances to points in the network that have been located from another setup in the survey creates redundancy. Running additional cut-off traverses or additional traverses to existing control points creates redundancy. Following are some general rules and tips in collecting data for least squares reduction:

- Backsights should be to point numbers. Some data collectors allow the user to backsight an azimuth not associated with a point number. SurvNET requires that all backsights be associated with a point number.
- There has to be at least a minimum amount of control. Control is defined as known points or azimuths. They can be held FIXED or allowed to move a designated amount. The minimum amount of control is either two points or one point and a reference azimuth. You can however have as many control points as you wish. Control points can be entered in either the raw data file or there can be a supplemental control point file containing the control point. Reference azimuths are entered in the raw data file. The control points and reference azimuths do not need to be for the first points in the raw data file. The control points and azimuths can be associated with any point in the network or traverse. The control points do not need to be adjacent to each other. It is permissible, though unusual, to have one control point on one side of the project and a reference azimuth on the other side of the project.
- Some data collectors do not allow the surveyor to shoot the same point twice using the same point number. SurvNET requires that all measurements to the same point use a single point number. The raw data may need to be edited after it has been downloaded to the office computer to insure that points are numbered correctly. An alternative to renumbering the points in the raw data file is to use the 'Pt Number substitution string' feature in the project 'Settings' screen. See the 'Redundant Measurement' section for more details on this feature.
- The majority of all problems in processing raw data are related to point numbering issues. Using the same point number twice for different points, not using the same point number when measuring the same point, misnumbering backsights or foresights, and misnumbering control points are all common problems.
- It is always best to explicitly define the control for the project. A good method is to put all the control for a project into a separate raw (RW5) file. A big source of problems with new users is a misunderstanding in defining their control for a project.
- Some data collectors may have preliminary unadjusted coordinates included with the raw data. These coordinate records should be removed from the raw file. The only coordinate values that should be in the raw file are the control points. Since there is no concept of 'starting coordinates' in least squares there is no way for SurvNET to determine which points are considered control and which points are preliminary unadjusted points. So all coordinates found in a raw data file will be considered control points.
- When a large project is not processing correctly, it is often useful to divide the project into several raw data files and debug and process each file separately as it is easier to debug small projects. Once the smaller projects are processing separately they can be combined for a final combined adjustment.

SurvNET gives the user the option to choose one of two mathematical model options when adjusting raw data, the **3D model** and the **2D/1D model**.

In the process of developing SurvNET, numerous projects have been adjusted using both the 2D/1D model and the 3D model. There are slight differences in final adjusted coordinates when comparing the results from the same network using the two models. But in all cases, the differences in the results are typically less than the accuracy of measurements used in the project. The main difference in terms of collecting raw data for the two different models is that the 3D model requires that rod heights and instrument heights need to be measured, and there needs to be sufficient elevation control to compute elevations for all points in the survey. When collecting data for the 2D/1D model, the field crews do not need to collect rod heights and instrument heights.

2D/1D Model

In the 2D/1D model, raw distance measurements are first reduced to horizontal distances and then optionally to grid distances. Then, a two dimensional horizontal least squares adjustment is performed on these reduced horizontal distance measurements and horizontal angles. After the horizontal adjustment is performed, an optional one-dimensional vertical least squares adjustment is performed in order to adjust the elevations if there is sufficient data to compute elevations. The 2D/1D model is the model that has been traditionally been used in the past by non-geodetic surveyors in the reduction of field data. There are several advantages to SurvNET 's implementation of the 2D/1D model. One advantage is that an assumed coordinate system can be used. It is not necessary to know

geodetic positions for control points. Another advantage is that 3D raw data is not required. It is not necessary to record rod heights and heights of instruments. Elevations are not required for the control points. The primary disadvantage of SurvNET 's implementation of the 2D/1D model is that GPS vector data cannot be used in 2D/1D projects.

In the 2D/1D model, it is allowed to mix 2D and 3D measurements. Elevations will be calculated only if there is enough information in the raw data file to do so. Least squares adjustment is used for elevation adjustment as well as the horizontal adjustment. To compute an elevation for the point, the instrument record must have an HI, and the foresight record must have a rod height, slope distance and vertical angle. If working with .CGR raw data, a 0.0 (zero) HI or rod height is valid. It is only when the field is blank that the record will be considered a 2D measurement. Carlson SurvCE/SurvPC 2.0 or higher allows you to mix 2D and 3D data by inserting a 2D or 3D comment record into the .RW5 file. A 3D traverse must also have adequate elevation control in order to process the elevations. Elevation control can be obtained from the supplemental control file, coordinate records in the raw data file, or elevation records in the raw data file. The "Adjust Elevations" box in the project settings must be checked to adjust the calculated elevations. If it is unchecked, elevations will still be calculated if the 3D data is available, but they will not be adjusted.

3D Model

In the 3D model, raw data is not reduced to a horizontal plane prior to the least squares adjustment. The 3-dimensional data is adjusted in a single least squares process. In SurvNET 's implementation of the 3D model, XYZ geodetic positions are required for control. The raw data must contain full 3D data including rod heights and measured heights of the instrument(s). The user must designate a supported geodetic coordinate system. The main advantage of using the 3D model is that GPS vectors can be incorporated into the adjustment.

SurvNET can also automatically reduce field measurements to State Plane coordinates in either the NAD 83 or NAD 27 coordinate systems. If a grid coordinate system is selected, the grid scale factor is computed for each individual line during the reduction. The elevation factor is also computed for each individual line if there is sufficient elevation data. If the raw data has only 2D data, the user has the option of defining a project elevation to be used to compute the elevation factor.

A full statistical report containing the results of the least squares adjustment is produced and written to the report (.RPT) file. An error report (.ERR) file is created and contains any error messages that are generated during the adjustment.

Coordinates can be written to the following formats, including:

- C&G numeric (*.crd)
- C&G alphanumeric (*.cgc)
- Carlson numeric (*.crd)
- Carlson alphanumeric (*.crd)
- Carlson SQLite (*.crdb)
- MS Access Database (Autodesk Land Desktop) (*.mdb)
- Simplicity (*.zak)
- ASCII P,N,E,Z,D,C (*.nez)

A file with the extension .OUT is always created and contains an ASCII formatted coordinate list of the final adjusted coordinates formatted suitable for printing. Additionally, an ASCII file with an extension of .NEZ containing the final adjusted coordinates in a format suitable for input into 3rd party software that is capable of inputting an ASCII coordinate file.

Starting Survnet

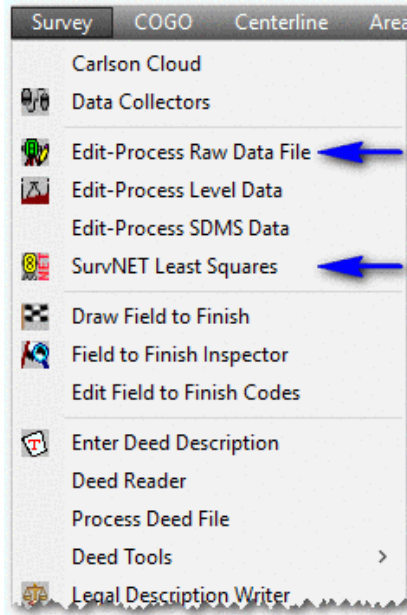

Using SurvNET Dialog Box

The dialog box version of SurvNET offers an interactive graphics user interface which utilizes the CAD drawing editor for graphics while mainlining data entry in a docked dialog box.

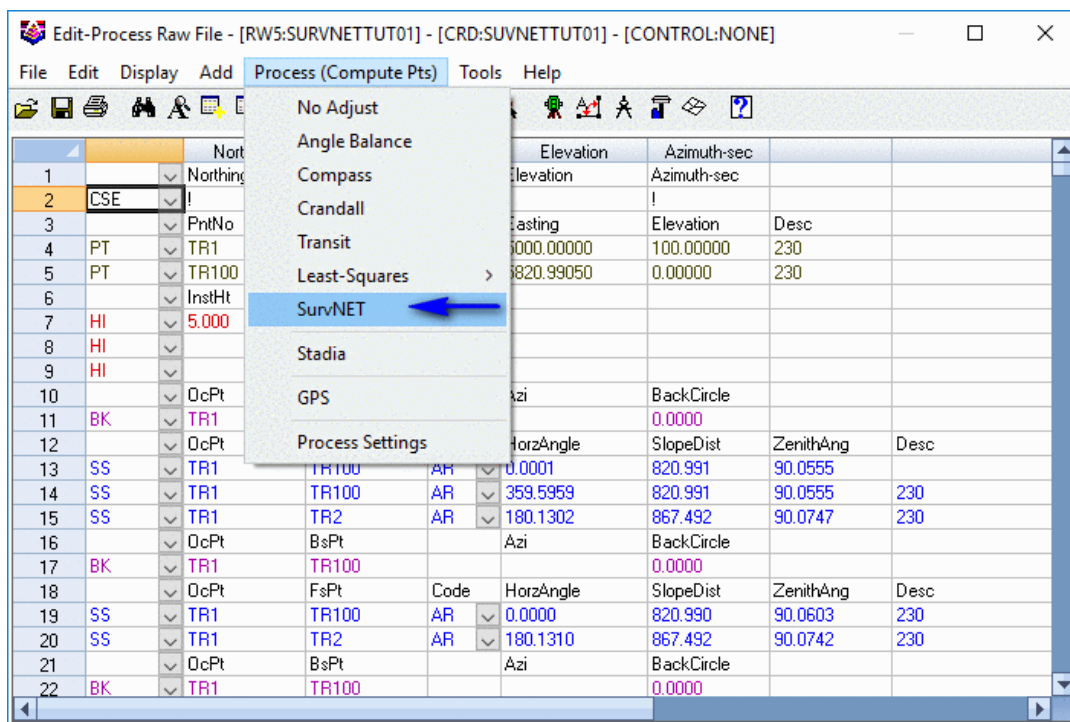

Double-click on the SurvNET icon on the desktop or use the Start menu – Programs (or All Programs) – SurvNET

Running From Carlson

Entry into the SurvNET program is easy. It can be accessed in two different ways. The easiest way to start the program is to select **SurvNET** from the **Survey** menu. The other method is to start SurvNET from within the **Raw Data File** editor. To bring up the Raw Data File editor, select **Edit - Process Raw Data File** from the **Survey** menu (see below).

To access SurvNET from within the Carlson Raw Data Editor, choose the **Process (Compute Pts)** menu then the **SurvNET** menu item (see below).

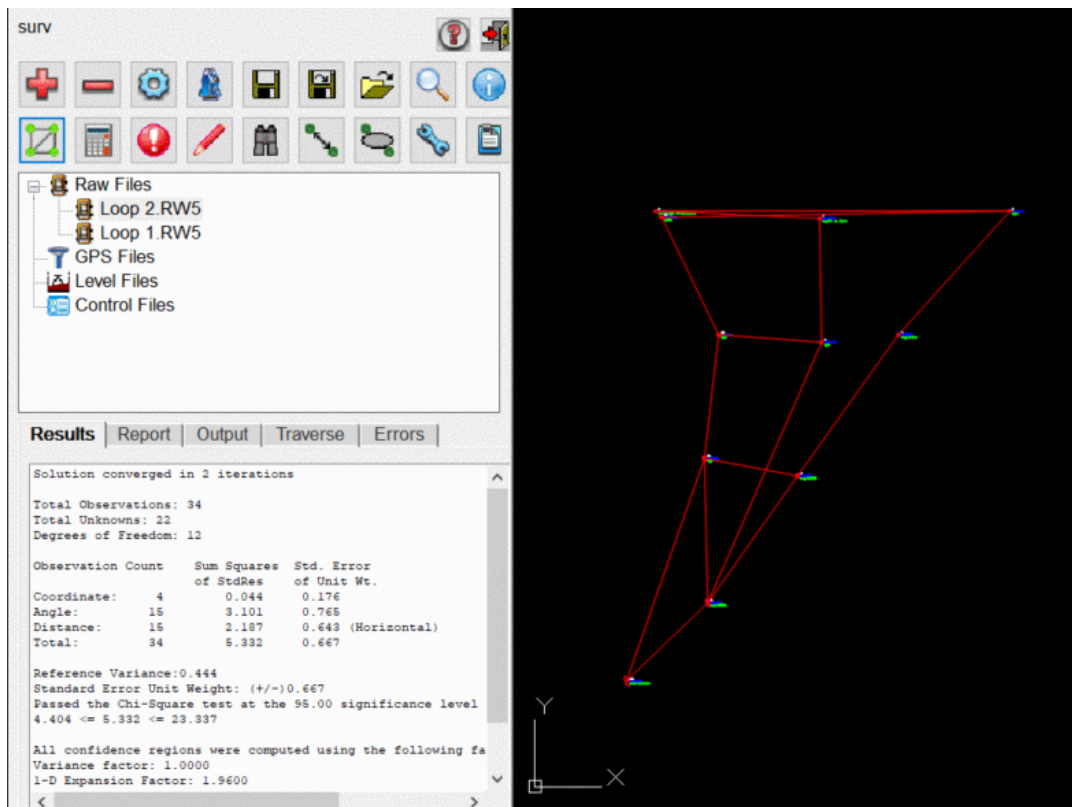

SurvNET Start-up Dialog

The **SurvNET Start-up** dialog is displayed when SurvNET is first started (see below). SurvNET is a project based program. Before performing a least squares adjustment an existing project must be opened or a new project created. This opening dialog box allows the user to open or create a project on start-up.

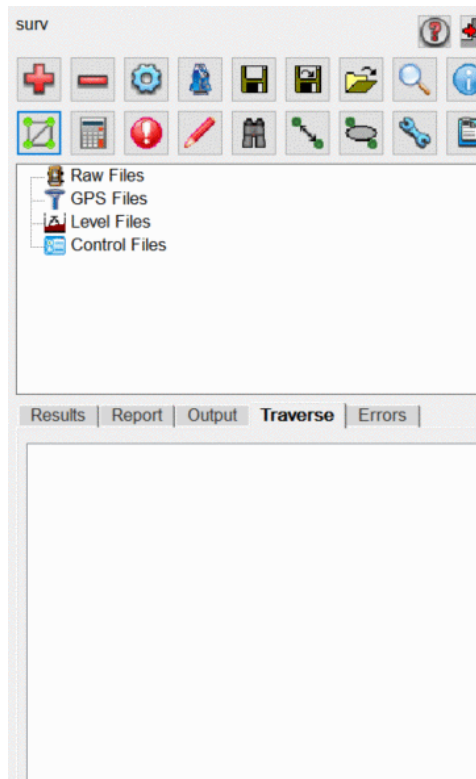

The following is a view of the SurvNET main window after an existing project has been opened and processed:

Note: The various report sub-windows within SurvNET and the SurvNET application itself can all be resized to suit specific screen "real-estate" preferences.

Menu System Overview

The following graphic shows the main SurvNET least squares interface.

Least squares operations are initiated using the menus summarized below:

Entering and Editing Raw Files

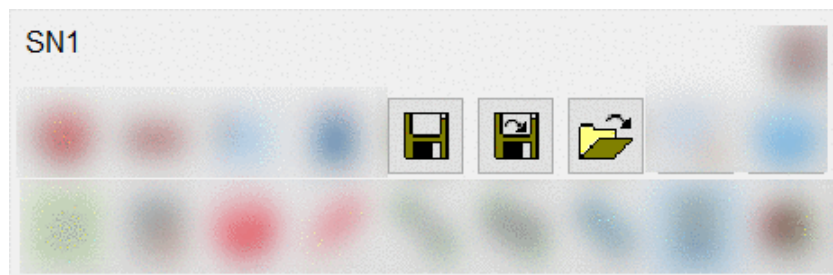

- Add and Remove Raw Files
- Review and Edit Control Points and Measurements
- Editing Raw data
- Assigning Standard Errors

Project Settings

- Coordinate System
- Input File defaults
- Pre-processing
- Default Standard Errors
- Adjustment Standards
- Output Options
- Drawing Settings
- Global Settings

Working with Project Files

- Open and Create Project Files
- Save Current
- Saveas - copy and create new file

Analyzing and Processing

- Process Network
- Pre-process Network
- Blunder Detection
- Draw Network

Tools

- EDM Calibration
- Point Search
- Inverse
- Error Ellipse
- Conversion Tools

Reports

- Main
- Output
- Errors
- Results

Exit - Exits the program

Help - launches the Carlson Help Menu

File Menu

The **File** menu consists of three main buttons.

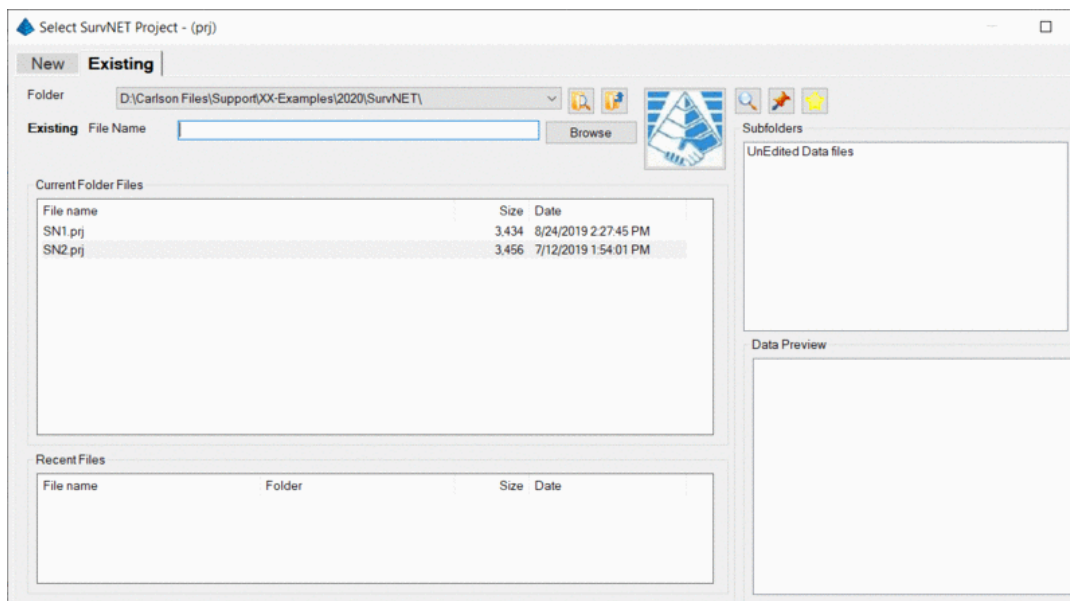

From left to right the are:

Save - saves the current file

Saveas - saves the current file as a new one, essentially making a copy.

Load/New - opens a new dialog box that allows users to select and existing project file or create a new one.

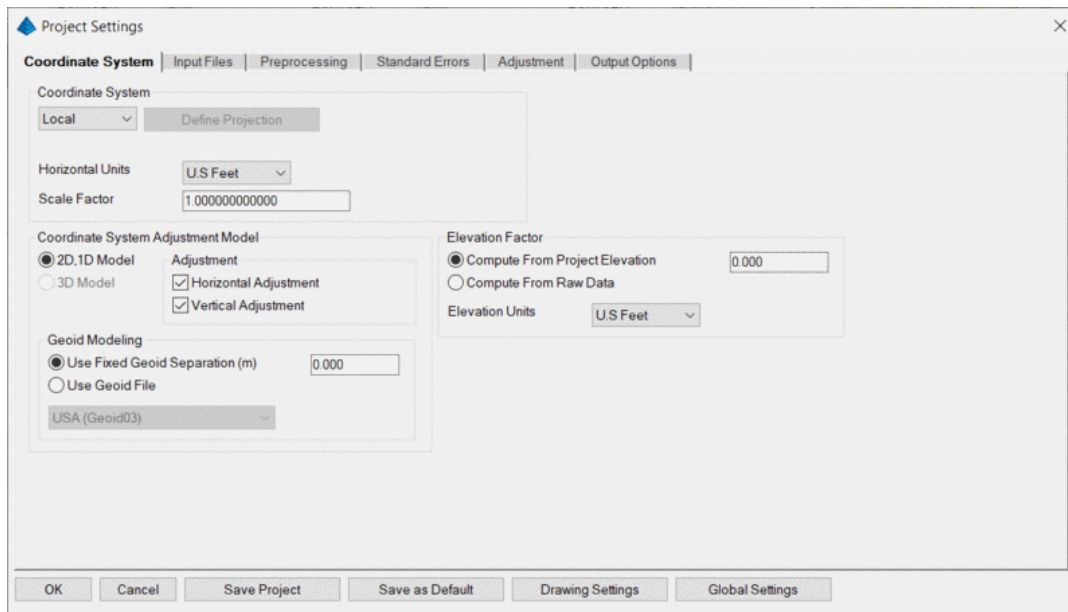

Settings Menu

Selecting the **Settings** menu opens the following menu:

Project Settings

The Project Settings dialog box has six tabbed windows:

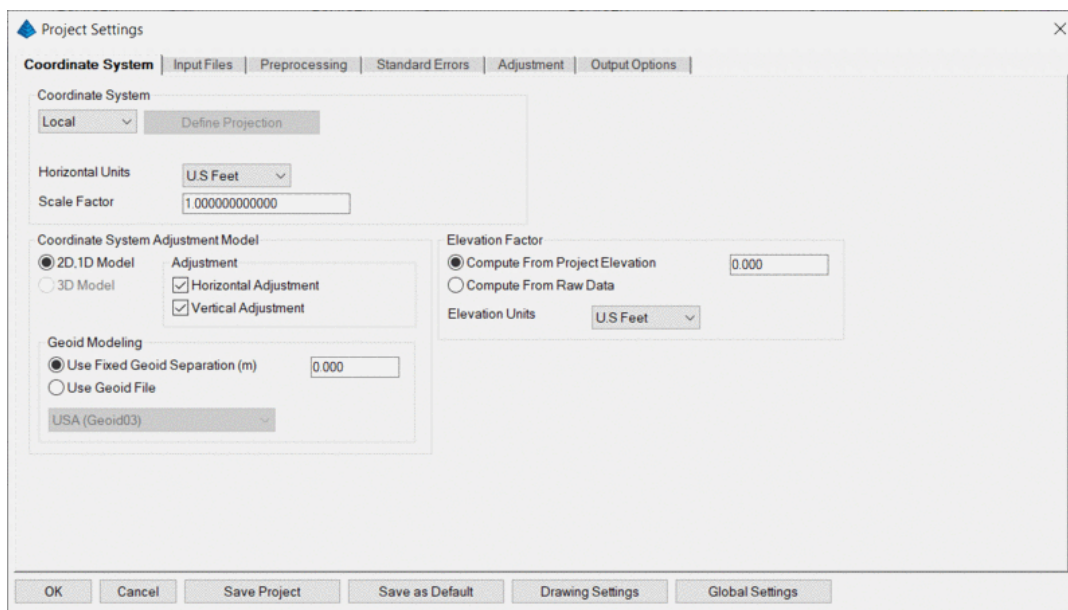

1. Coordinate System
2. Input Files
3. Preprocessing
4. Adjustment
5. Standard Errors

6. Output Options

In addition to the above tabs, there are options to

- Save Project - saves the current project
- Save as Default - saves the current settings as defaults for future projects
- Drawing Settings - opens the Drawing Settings dialog box
- Global Settings - opens the Global Settings dialog box

The Coordinate System tab contains settings that relate to the project coordinate system, the adjustment model and other geodetic settings.

You can select either the 3D model or the 2D/1D mathematical model. If you choose 2D/1D mathematical model, you can choose to only perform a horizontal adjustment, a vertical adjustment or both. In the 3D model, both horizontal and vertical are adjusted simultaneously. The 3D model requires that you choose a geodetic coordinate system. Local, assumed coordinate systems cannot be used with the 3D model. GPS vectors can only be used when using the 3D model.

If using the 2D/1D mathematical model, you can select Local (assumed coordinate system), or a geodetic coordinate system such as State Plane NAD83, State Plane NAD27, UTM, or a user-defined coordinate system as the coordinate system. When using the 3D model you cannot use a local system.

Select the "Horizontal Units" for output of coordinate values (Meters, US Feet, or International Feet). In the 3D model, both horizontal and vertical units are assumed to be the same. In the 2D/1D model, horizontal and vertical units can differ if you select "Compute from Project Elevation". The "Horizontal Unit" setting in this screen refers to the output units. It is permissible to have input units in feet and output units in meters. Input units are set in the Input Files tab.

If you choose SPC 1983, SPC 1927, or UTM, the appropriate zone will need to be indicated. The grid scale factor is computed for each measured line using the method described in Section 4.2 in the publication by: Stem, James E., (1990) *State Plane Coordinate System of 1983*. Rockville, MD: NOAA.

If using the 2D/1D model and you select a geodetic coordinate system, you have a choice as to how the elevation factor is computed. You can choose to either enter a project elevation or you can choose to have elevations factors computed for each distance based on computed elevations. In order to use the "Compute Elevation from Raw Data", all HI's and foresight rod heights must be collected for all points.

If you choose a geodetic coordinate system and are using the 2D/1D model, you will want to select "Project Elevation" if any of your raw data measurements are missing any rod heights or instrument heights. There must be enough information to compute elevations for all points in order to compute elevation factors. For most survey projects, it is sufficient to use an approximate elevation, such as can be obtained from a Quad Sheet for the project elevation.

Geoid Modeling

If you are using either the 3D or the 2D/1D adjustment model using non-local coordinate system, you must choose a geoid modeling method. A project geoid separation can be entered or the grid model can be selected from a list of models. The project must fall within the geographic range of the geoid grid files.

Geoid modeling is used as follows. Entering a 0.0 value for the separation is the method to use if you wish to ignore the geoid separation. In the 2D/1D model, it is assumed that elevations entered as control are entered as orthometric heights. Since grid reduction requires the data be reduced to the ellipsoid, the geoid separation is used to compute ellipsoid heights. The difference between using geoid modeling and not using geoid modeling or using a project geoid separation is insignificant for most surveys of limited extents.

In the 3D model, it is also assumed that elevations entered as control are orthometric heights. Since the adjustment is performed on the ellipsoid, the geoid separation is used to compute ellipsoid elevations prior to adjustment. After the adjustment is completed, the adjusted orthometric elevations will be computed from the adjusted ellipsoid elevations and the computed geoid separation for each point.

If you choose one of the geoid models from the list, the geoid separations are computed by interpolation with data points retrieved from geoid separation files. The geoid separation files should be found in the primary the installation directory. Grid files have an extension of .grd. These files can be downloaded from the Carlson website (www.carlsonsw.com). If you pick a geoid model that is not on your computer, SurvNET will automatically connect to the Carlson website and download the specific geoid file.

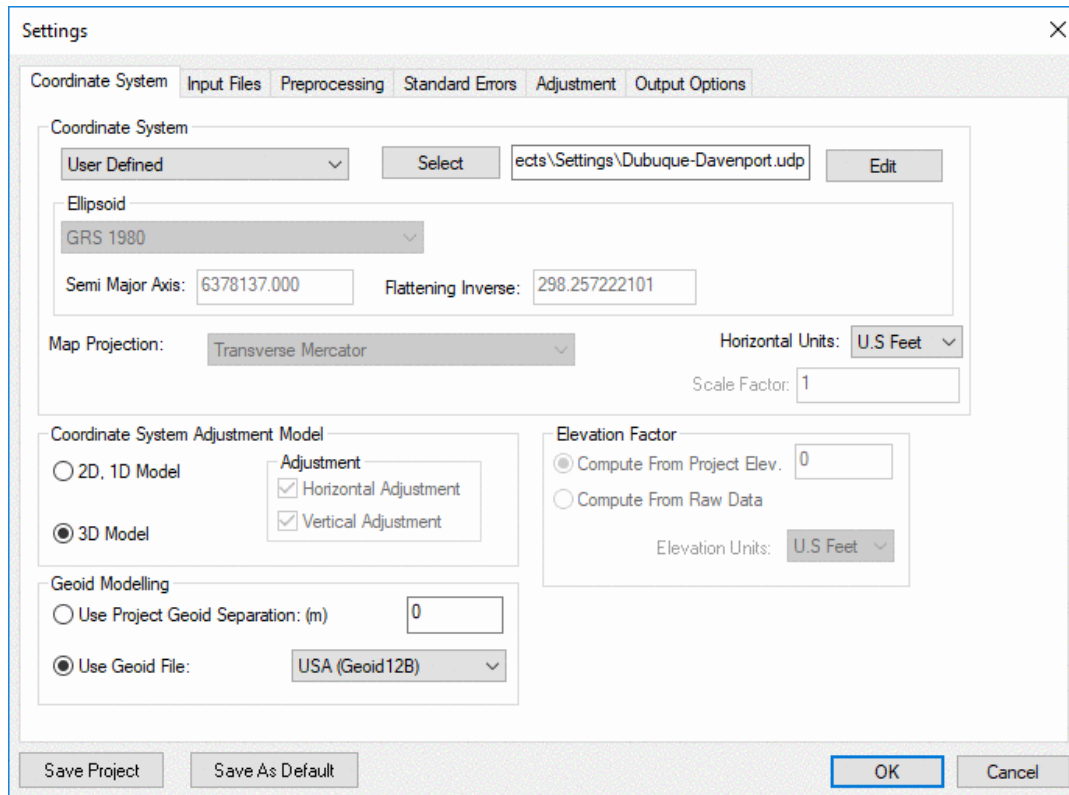

If you choose to enter a project geoid separation, the best way to determine a project geoid separation is by using the NGS on-line Geodetic Toolkit. Enter a latitude and longitude of the project midpoint and the program will output a project separation.

Working With User-defined Coordinate Systems

SurvNET allows the creation of user-defined geodetic coordinate systems (UDP). The ability to create user-defined coordinate system allows the user to create geodetic coordinate systems based on the supported projections that are not explicitly supported by SurvNET. A SurvNET user-defined coordinate system consists of an ellipsoid, and a map projection. The ellipsoid can be one of the explicitly supported ellipsoids or a user-defined ellipsoid. The supported map projections are:

- Transverse Mercator
- Lambert Conformal Conic with 1 standard parallel
- Lambert Conformal Conic with 2 standard parallels
- Oblique Mercator
- Double Stereographic projection

User-defined coordinate systems are created, edited, and attached to a project from the Project Settings 'Coordinate System' dialog box. To attach an existing UDP file, *.udp, to a project use the 'Select' button. To edit an existing UDP file or create a new UDP file use the 'Edit' button.

The following dialog box is used to create the user-defined coordinate system. The ellipsoid needs to be defined and the appropriate map projection and projection parameters need to be entered. The appropriate parameter fields will be displayed depending on the projection type chosen.

Note: *Grid Origin* values for both the Northing and Easting values need to be input in Metric values!

Test - Use the 'Test' button to enter a known latitude and longitude position to check that the UDP is computing correct grid coordinates. Following is the test UDP dialog box. Enter the known lat/long in the top portion of the dialog box then press 'Calculate' and the computed grid coordinates will be displayed in the 'Results' list box:

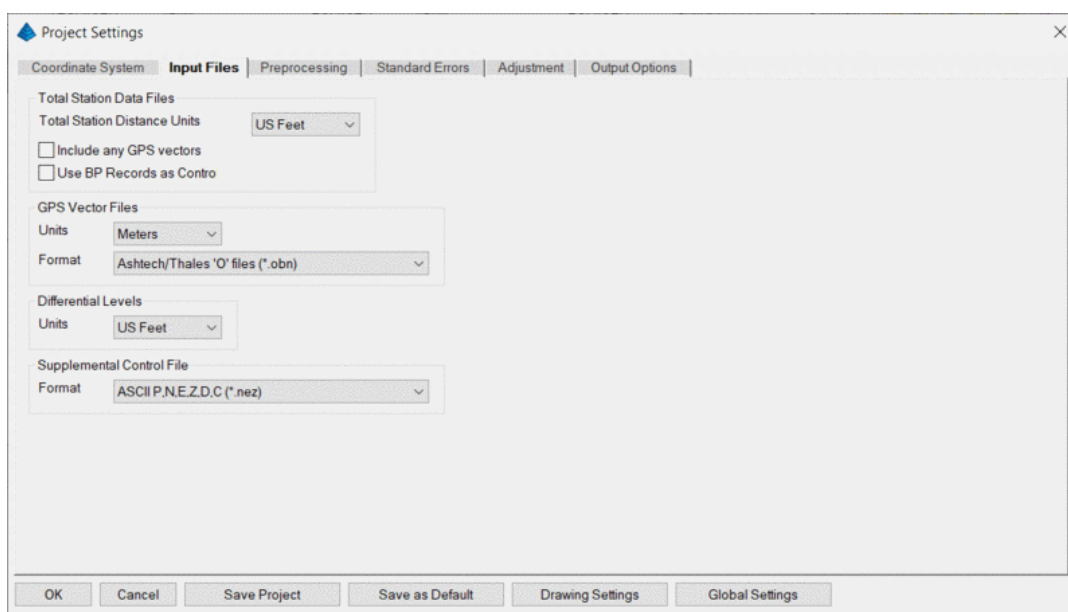

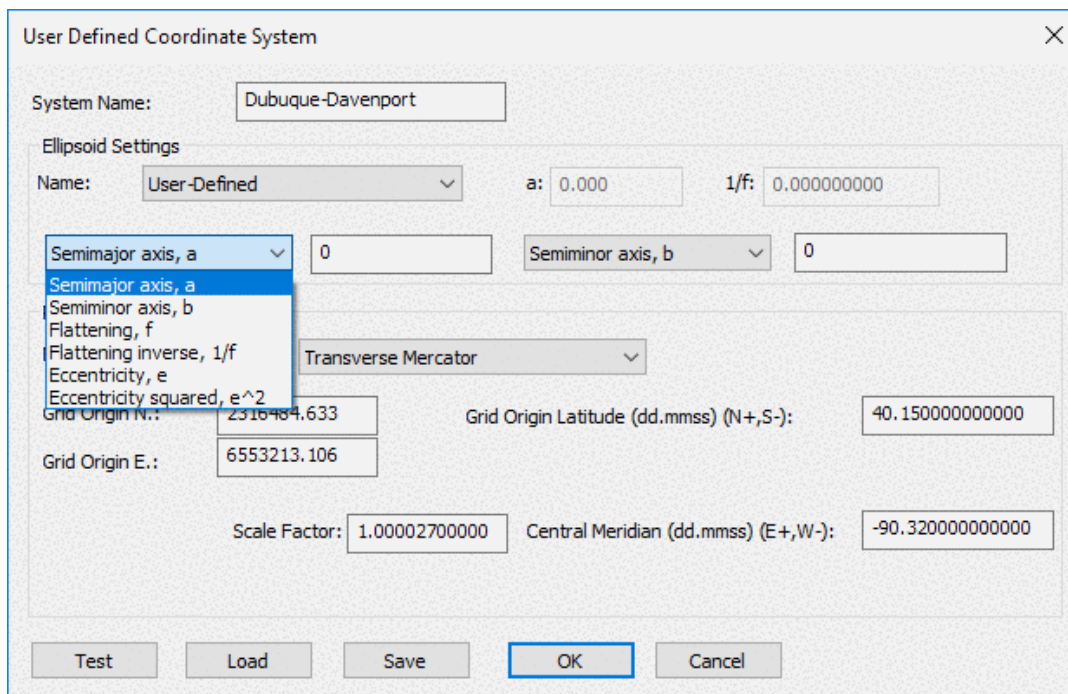

Load - Use the 'Load' to load the coordinate system parameters from an existing .UDP file.

Save - Use the 'Save' button to save the displayed UDP. The 'Save' button prompts the user to enter the .UDP file name.

OK - Use the 'OK' button to save the UDP using the existing file name and return to the 'Coordinate System' dialog box.

Cancel - Use the 'Cancel' button to return to the 'Coordinate System' dialog box without saving any changes to the .UDP file.

If you need to define an ellipsoid, choose the 'User-Defined' ellipsoid option. With the user-defined ellipsoid you will then have the option to enter two of the ellipsoid parameters.

This dialog box is used to set the default parameters for the **Input Raw** files that will be used for processing the data.

Note that if you are processing Carlson RW5 total station files, you have the option of including GPS vectors that can be collected by SurvCE/SurvPC and stored in the RW5 file. Alternatively, you can select the RW5 file in the GPS vector section. **If the "Include any GPS vectors" option in the Total Station Data Files section is checked, you will have the option to use the Base Point records in the RW5 file as control.** If "Use BP records as control" is NOT checked, or the RW5 file is selected in the GPS vector section, you must define the control in either the RW5 file as POINT records or in a Supplemental Control File.

GPS Vector Files: GPS vector files can be entered and processed. Both GPS vector files and total station raw files can be combined and processed together. **You must have chosen the 3D mathematical model in the Coordinate System tab in order to include GPS vectors in the adjustment.**

A variety of popular GPS vector file formats are supported, including (but not necessarily limited to):

- **ASCII (StarNet):** See below for more information on StarNet format. These files typically have .GPS exten-

sions.

- **Ashtech/Thales 'O' files:** Typically have .obn extensions and are binary files.
- **Carlson .RW5:** (containing GPS vectors)
- **GeoLab IOB**
- **LandXML (*.xml)**
- **Leica:** Leica files are ASCII files.
- **NGS G-File**
- **NGS G-File from OPUS report**
- **Topcon (.tvf):** Topcon .tvf files are ASCII files.
- **Topcon (.xml):** Topcon also can output their GPS vectors in XML format which is in ASCII format.
- **TDS (.raw):** TDS raw data file with vector information
- **Trimble Data Exchange Format (.asc):** These files are in ASCII format
- **Trimble data collection (.dc):** These files are ASCII.
- **Trimble LandXML (*.jxl)**

The following is a typical vector record in the StarNet ASCII format. GPS vectors typically consist of the 'from' and 'to' point number, the delta X, delta Y, delta Z values from the 'from' and 'to' point, with the XYZ deltas being in the geocentric coordinate system. Additionally the variance/covariance values of the delta XYZ's are included in the vector file.

```
.GPS WEIGHT COVARIANCE
C PRS34452 1305780.345005 -4667085.299019 4132689.544939 0.005000 0.005000 0.005000 --MON
C UCNJ 1305780.345005 -4667085.299019 4132689.544939 0.00000100 0.00000100 0.00000100 --MON
G1 UCNJ-1000 8399.71318061 -4742.15645068 -8036.07224424 --MNS
G2 3.939428e-006 2.474560e-005 1.160301e-005
G3 3.924536e-006 -3.360765e-006 -1.028503e-006
G1 UCNJ-1001 8328.15569476 -4796.59445569 -8072.25948922 --MNS
G2 9.596618e-007 1.687749e-005 1.936038e-006
G3 1.176891e-007 -8.668020e-009 -4.798408e-006
```

The first line defines what values are in the G2 and G3 records. It can be either GPS WEIGHT COVARIANCE (G2 is Variance, G3 is Covariance), or GPS WEIGHT STDERRCORRELATION (G2 is standard error, G3 is standard error correlation). This line is optional; the default is COVARIANCE.

The next two lines are coordinate control records. These records are also optional. If used, they must be Geocentric Coordinates (XYZ) in metric units. The format is as follows:

```
C PointName X Y Z StdErrX StdErrY StdErrZ --PointDescription
```

The standard errors and point description are optional.

The GO record is a comment.

The G1 record includes the 'from' and 'to' points and the delta X, delta Y, and delta Z in the geocentric coordinate system and an optional description of the rover point.

The G2 record is the variance (or standard error) of X, Y, and Z. The G3 record contains the covariance (or standard error correlation) of XY, ZX, and ZY. Most all GPS vector files contain the same data fields in different formats.

Use the 'Add' button to insert GPS vector files into the list. Use the 'Remove' button to remove GPS vector files from the list. All the files in this list will be used in the least squares adjustments. All the GPS files in the list must be in the same format. If the GPS file format is ASCII you have the option to edit the GPS vector files. The Edit option allows the editing of any of the ASCII GPS files using Notepad. Typically, only point numbers or point descriptions would be edited. The variance/covariance values are used to determine the weights that the GPS vectors will receive during the adjustment and are not typically edited.

Level Raw Files: Differential and Trig level files can be entered and processed. Differential or Trig Level raw files have a .TLV extension and are created using the Carlson Level Editor. The Carlson Level Editor has several Import options that allow you to bring in levels from different formats (*e.g.* Leica, Trimble, Topcon, *etc.*). You can process level data in the same project with the traverse and GPS vector data but the vertical measurements in the

traverse/vectors will be part of the adjustment. If you want to use the elevations calculated ONLY from the level data, you must process it in a separate project after your traverse/vector data has been adjusted. The elevations will be written to the Output Coordinate file. Make sure your point numbers in the level data match the points in the traverse/vector data.

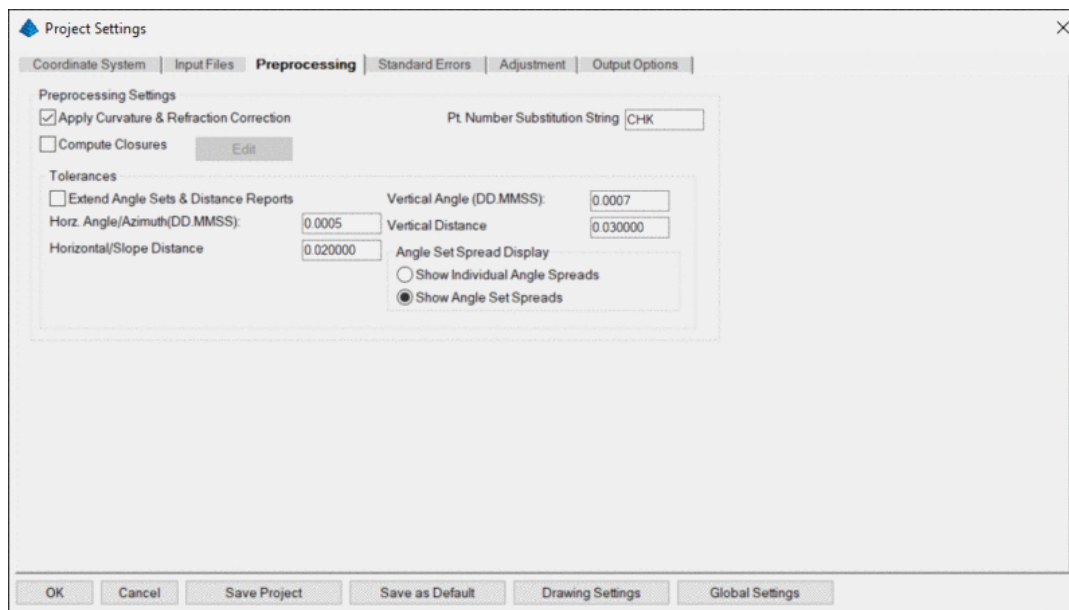

Supplemental Control File: The supplemental control file option allows the user to designate an additional coordinate file to be used as Control. The supplemental control file can be from a variety of different file types, including (but not necessarily limited to):

- **C&G or Carlson numeric (.CRD) files**
- **C&G Alphanumeric coordinate files (*.cgc)**
- **Carlson Alphanumeric coordinate files (*.crd)**
- **Autodesk Land Desktop (*.mdb)**
- **Simplicity coordinate files (*.zak)**
- **ASCII (.NEZ) file**
- **ASCII latitude and longitude (3D model only)**
- **CSV ASCII NEZ with std. errors** (only external control file that allows you to assign standard errors to specific points)
- **SDMS (.ctl) control file**
- **ASCII Geocentric (.xyz)** (Geocentric coordinates XYZ in metric units)

Note: For additional information on file format pertaining to the file formats above, refer to the Supplemental Control Files section of the documentation.

Note: You will not be allowed to use the same file for supplemental control points and for final output. Least Squares considers all points to be measurements. If the output file is also used as a supplemental control file, then after the project has been processed all the points in the project would now be in the control file and all the points in the file would now be considered control points if the project was processed again. The simplest and most straight-forward method to define control for a project is to include the control coordinates in a raw data file.

The Preprocessing tab contains settings that are used in the preprocessing of the raw data.

Apply Curvature and Refraction Corrections: Check this box if you wish to have the curvature refraction correction applied in the 2D/1D model when reducing the slope distance/vertical angle to horizontal distance and vertical distance. Curvature/refraction primarily impacts vertical distances.

Pt. Number Substitution String: This option is used to automatically renumber point names. Some data collectors do not allow the user to use the same point number twice during data collection. In Least Squares, it is common to collect measurements to the same point from different locations. If the data collector does not allow you to use

the correct point number, this option can be used to automatically renumber these points during processing. For example you could enter the string '=' in the Pt. Number Substitution String. Then if you shot point 1 but had to call it something else such as 101, you could enter '=1' in the description field and during preprocessing point 101 would be renumbered as point '1'.

Compute Closures: Traditional traverse closures can be computed for both GPS and total station traverses. This option has no effect on the computation of final least squares adjusted coordinates. This option is useful for surveyors who, due to statutory requirements, are still required to compute traditional traverse closures and for those surveyors who still like to view traverse closures prior to the least squares adjustment. This option is used to specify a previously created Traverse Closure file.

Tolerances: When sets of angles and/or distances are measured to a point, a single averaged value is calculated for use in the least squares adjustment. You may set the tolerances so that a warning is generated if any differences between the angle sets or distances exceed these tolerances. Tolerance warnings will be shown in the report (.RPT) and the (.ERR) file after processing the data.

If you check the **Extended Angle Sets & Distance Report** option, all the sets will be shown with the difference between the high angle and low angle, and the difference between the high distance and low distance. If this option is not checked ONLY the sets that exceed the tolerances will be shown in the report.

Horz./Slope Dist Tolerance: This value sets the tolerance threshold for the display of warnings if the difference between highest and lowest horizontal distance exceeds this value. In the 2D model it is the horizontal distances that are being compared. In the 3D model it is the slope distances that are being compared.

Vert. Dist Tolerance: This value sets the tolerance threshold for the display of a warning if the difference between highest and lowest vertical difference component exceeds this value (used in 2D model only).

Horz. Angle Tolerance: This value sets the tolerance threshold for the display of a warning if the difference between the highest and lowest horizontal angle exceeds this value.

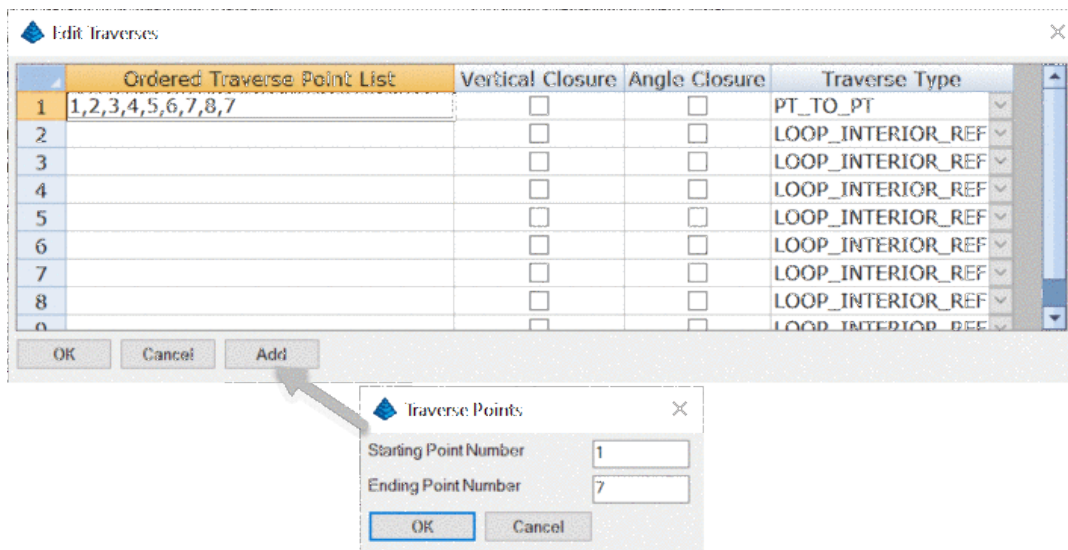

Vert. Angle Tolerance: This value sets the tolerance threshold for the display a warning if the difference between the highest and lowest vertical angle exceeds this value (used in 3D model only).

Angle Set Spread Display: You can choose to see the splits of individual angles in each set (2 per set), or just the splits of all the sets combined (high / low angle of all the sets combined).

Traverse Closure Files

Some statutes and jurisdictions still require the computation of traditional **Traverse Closures**. SurvNET gives the surveyor the ability to compute the closures of multiple traverses within a project as part of the preprocessing of the project raw data. Closures for single or multiple traverses can be computed for a single project. Additionally, GPS closures can be computed for GPS loops. To compute closures you must first create a "Closure File" (.CLS). Closure Files define the type of traverse loops that are to be computed and an ordered list of the point numbers comprising the traverse. Since the raw data for SurvNET is not expected to be in any particular order, it is required that the user must specify the points and the correct order of the points in the traverse loop. Both GPS and angle/distance traverses can be defined in a single traverse closure file.

To add a traverse closure file, select Edit from the dialog box.

1. **Add** - This command permits you to automatically add a traverse from the row file, or manually enter the order of the traverse points.

First, enter the point sequence which defines the traverse in the "edit control" portion of the dialog box. Toggle the check boxes to set whether Vertical Closure and/or Angle Closures need to be computed. Then choose what traverse type is being entered. When the values are correct, press the **Save** button and the traverse will be entered into the Traverse Closure file. Add additional traverse information via the "Record" button icon located at the upper left (you may also remove a recorded traverse via the Delete button icon also located in the upper left portion of the dialog box).

If you need to edit one of the traverses, mouse-click the traverse to be edited. Make the appropriate edit(s), then click the **OK** button to save the changes.

As an example of traverse point entry, points can be entered in the form:

10, 23, 30-35, 45, 23, 10

A comma separates the point numbers. You can select a range (e.g. 30-35) when the points are sequential.

NOTE: You must start with the first backsight point number and end with the last foresight point number for a loop traverse.

For example, if you have a simple loop traverse with angle closure using points 1, 2, 3 and 4, it will be entered as "4,1,2,3,4,1" (or 4,1-4,1) where 1 is the first occupied point and 4 is the initial backsight.

You can turn the "Angle Closure" ON or OFF. If the angle closure is ON, you will be shown the total angular error and error per angle point. If the final closing angle was not collected, you can turn "Angle Closure" OFF and only the linear closure will be computed.

You can turn the "Vertical Closure" ON or OFF. If the vertical closure is ON, you will be shown the total vertical distance closure.

In order to calculate the traverse closure, you must select the **Traverse Type**. It can be:

- **Pt. to Pt. Trav.** - A Point-to-Point Traverse is a traverse that starts at a set of known coordinates and ends at another known coordinate. This option assumes you start from **two** control points and:
 1. tie into one control point if only a linear closure is desired, or,
 2. tie into two control points if an angle closure is desired.

The first backsight distance and last foresight distance are not used in computing the linear closure. Following is an example:

100,101,2-5 (angle closure example collected)

In the above Point-to-Point list, Pt. 100 is the starting backsight point, Pt. 101 is the starting instrument point. Pt. 4 is (would be) the ending instrument point and the foresight to the angle closure point is point 5. If a closing angle was not collected, the list would look as follows:

100,101,2-4

- **Loop Trav., Int. Az. Ref.** - A closed loop traverse that begins by backsighting the last interior point on the traverse. Following is an example:

7,101,2-7,101

In the above example, closed loop with angle balance list, point 7 is the backsight point and point 101 is the first occupied point. If the closing angle 6-7-101 was not collected, the list would be entered as follows:

7,101,2-7

- **Loop Trav., Ext. Az. Ref.** - A closed loop traverse that begins by backsighting an exterior point (point not on the traverse):

100,101,2-7,101,100

In the above example loop with exterior reference and angle balance list, point 100 is the backsight point and point 101 is the first occupied point. If the closing angle 7-101-101 was not collected, the list would be entered as follows:

100,101,2-7,101

- **GPS Loop Closure** - GPS loop closures can be computed using this option

A, E, F, A

In the above example GPS loop, closure will be computed from the GPS loop going from A-E-F-A.

- **GPS Point to Point Closure** - GPS Point to Point closures can be computed using this option:

A, E, D, B

In the above example the closure will be computed from the GPS traverse going from A-E-D-B. The starting and ending points **MUST** be control points.

When the data is processed, the Closure reports will appear in the RPT and ERR files. You will notice that two Closures are shown, one with no angle balance and one with angle balance.

Following is an example of a closed loop traverse report:

Traverse Closures

=====

Traverse points:

ALTA Tolerance Reports

SurvNET provides the ability to generate reports that give the surveyor the information needed to determine if the survey is within ALTA positional tolerances. It is required that the user define which points are to be included in the ALTA testing. The points to be included for ALTA testing are defined in an .ALT file.

There are two options in the **File** menu that are used to create and edit the ALTA files:

1. **Open ALTA, Rel. Err. Ellipse File** - This command permits you to browse for and open a previously created ALTA File for editing. Once opened, it displays the dialog box below.
2. **New ALTA, Rel. Err. Ellipse File** - This command provides you the ability to create a named ALTA File in a folder of your choosing. After supplying a file name to create, the following dialog box is displayed.

The above dialog box allows the user to define the points to be included in the ALTA report processing.

Notice that you can enter points based on Descriptions in the left-hand list box. For example, if you wished to check connections between all points with TP, EIP, MON descriptions, enter the descriptions in the edit field and press the **Add by Desc.** button. If TP, EIP, and MON represented Traverse Points, Existing Iron Pipes and Monuments (respectively), then ALTA testing would be performed on those point types.

After you have created the .ALT point file, you need to set some additional **Project Settings**. The Adjustment tab within the Project Settings, has a **Relative Error Ellipses/ALTA Report** section where the ALTA report settings are located. These settings define the ALTA Tolerances, specify the .ALT file to be used, and define the type of reporting to be generated.

Note: The **Rel. Err. Points File** check box must be checked, and an .ALT file must be chosen to get an ALTA report. The .ALT file defines which points will be included in the ALTA reporting. Also note typical ALTA specifications define their positional standard as 0.07 plus 50 PPM.

Sample ALTA Report

There are two sections in the .RPT file created through the ALTA reporting. The following report shows the sections of the ALTA report generated by the data in the dialog box.

The first section of the report displays the *Relative Error Ellipses* between points in the **Specific Connection** list. All the connections will be displayed whether they pass or fail the ALTA certification. The point sequences used in this section come from the list on the right-hand side of the above dialog box.

The second section of the report performs an ALTA tolerance test on the points in the "Check all Connections" list. Every possible connection between the points listed will be checked. In this section, only the worst connections will be shown. The number of connections shown is determined by the "Max. connections to display" value in the above dialog box. The point sequences used in this section come from the list on the left-hand side of the above dialog box.

An asterisk (*) will be placed beside each connection shown in the report that **does not pass** based on the confidence interval, tolerance and PPM (parts per million) settings in the Adjustment section of the Project Settings.

The following is a sample ALTA report:

Relative Error and ALTA Tolerances

=====

SPECIFIC CONNECTIONS: Tolerance of 0.070 + 50 PPM. at the 95% CI.

Sta.	Sta.	Dist.	Actual Semi Major	Allowable Semi Major	Ratio Actual/Allowable	Semi Minor	Max. Err.
27	500	204.5030	0.0793	0.0802	0.9890	0.0588	S 85-06' 3"
500	502	66.8572	0.1132	0.0733	1.5432	0.0842	S 86-05' 0"
34	36	237.9748	0.0731	0.0819	0.8920	0.0731	N 00-00' 0"

ALL CONNECTIONS: Tolerance of 0.070 + 50 PPM. at the 95% CI.

All possible connections between the following points were checked:

505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 550, 551, 552, 553, 554, 557, 558, 559, 560

1225 connections tested, the 10 largest relative error ellipses will be shown:

Sta.	Sta.	Dist.	Actual Semi Major	Allowable Semi Major	Ratio Actual/Allowable	Semi Minor	Max. Err.
506	556	806.5402	1.0818	0.1103	9.8054	0.2586	S 86-37' 4"
507	556	827.2364	1.0832	0.1114	9.7268	0.2446	S 86-37' 0"
505	556	818.7994	1.0779	0.1109	9.7158	0.2386	S 86-48' 2"
508	556	854.9436	1.0836	0.1127	9.6108	0.2477	S 86-38' 3"
509	556	880.6338	1.0848	0.1140	9.5129	0.2489	S 86-45' 3"
521	556	798.2729	1.0387	0.1099	9.4500	0.2318	S 87-22' 5"
512	556	793.0518	1.0334	0.1097	9.4245	0.2127	S 87-21' 3"
517	556	907.2084	1.0856	0.1154	9.4106	0.2379	S 87-07' 3"
510	556	918.6572	1.0861	0.1159	9.3682	0.2525	S 86-52' 4"
516	556	935.1194	1.0885	0.1168	9.3228	0.2426	S 87-22' 2"

*** All connection combinations passed ***

The first part of the report labeled "Specific Connections" will show all selected connections whether they passed or failed. If a connection failed, an asterisk (*) will be placed at the end of the line.

The second part of the report, labeled "All Connections" will only show the connections that "failed" (we chose to see the worst 10).

If all the connections pass in the **Specific Connection** section, you will also see this message in the report:

***** All Specific Connections passed *****

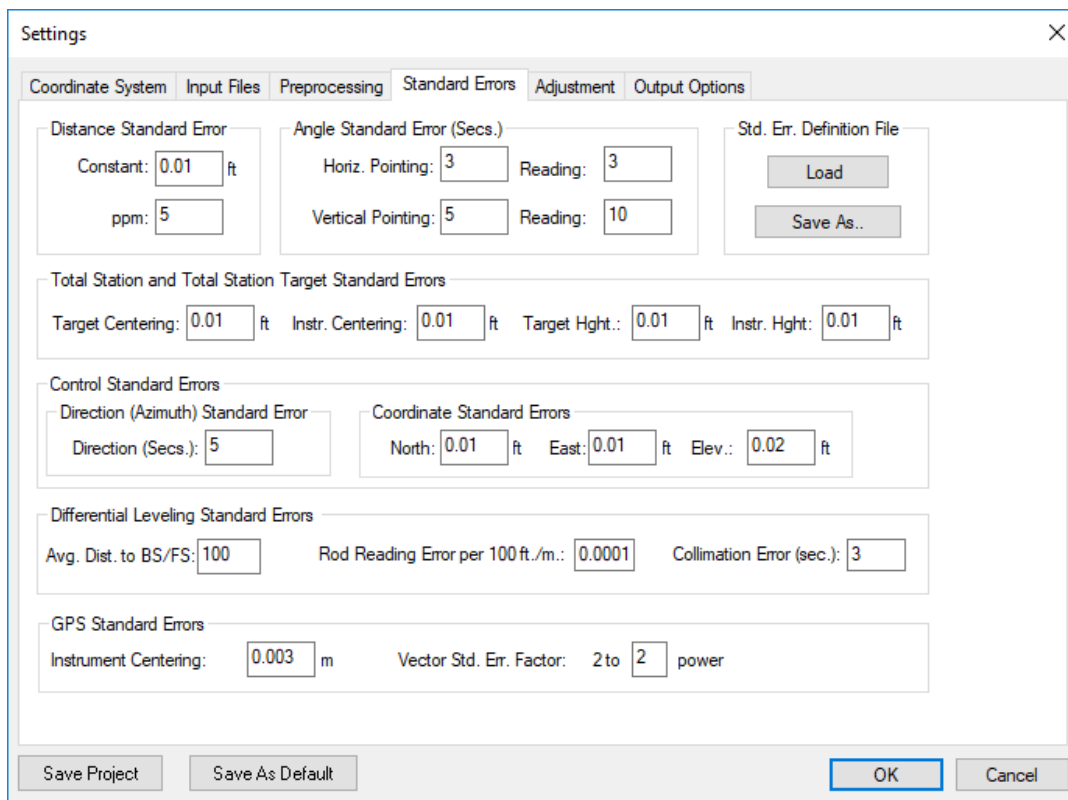

If all the connections pass in the **All Connections** section, you will not see any Error Ellipses. You will see the following message:

***** All connection combinations passed *****

Standard errors are the expected measurement errors based on the type equipment and field procedures being used. For example, if you are using a 5 second total station, you would expect the angles to be measured within +/- 5 seconds (Reading error).

The Distance Constant, PPM settings, and Angle Reading should be based on the equipment and field procedures being used. These values can be obtained from the published specifications for the total station. Or, the distance PPM and constant can be computed for a specific EDM by performing an EDM calibration using an EDM calibration baseline.

Survey methods should also be taken into account when setting standard errors. For example, you might set the target centering standard error higher when you are sighting a held prism pole than you would if you were sighting a prism set on a tripod.

The settings from this dialog box will be used for the Project Default settings. These default Standard Errors can be overridden for specific measurements by placing SE records directly into the Raw Data File.

If the report generated when you process the data shows that generally you have consistently high standard residuals for a particular measurement value (angles, distances, etc.), then there is the chance that you have selected standard errors that are better than your instrument and methods can obtain. (See explanation of report file). Failing the chi-square test consistently is also an indication that the selected standard errors are not consistent with the field measurements.

You can set the standard errors for the following:

Distance and Angle Standard Errors

Distance Constant: Constant portion of the distance error. This value can be obtained from published EDM specifications, or from an EDM calibration.

Distance PPM: Parts per million component of the distance error. This value can be obtained from published EDM specification, or from an EDM calibration.

Horizontal Angle Pointing: The horizontal angle pointing error is influenced by atmospheric conditions, optics, experience and care taken by instrument operator.

Horizontal Angle Reading: Precision of horizontal angle measurements, obtain from theodolite specifications.

Vertical Angle Pointing: The vertical angle pointing error is influenced by atmospheric conditions, optics, experience and care taken by instrument operator.

Vertical Angle Reading: Precision of vertical angle measurements, obtain from theodolite specifications.

Instrument and Target Standard Errors

Target Centering: This value is the expected amount of error in setting the target or prism over the point.

Instrument Centering: The expected amount of error in setting the total station over the point.

Target Height: The expected amount of error in measuring the height of the target.

Instrument Height: The expected amount of error in measuring the height of the total station.

Control Standard Errors

Direction (Bearing / Azimuth): The estimated amount of error in the bearing / azimuth (direction) found in the azimuth records of the raw data.

North, East, Elev: The estimated amount of error in the control north, east and elevation values. You may want to have different coordinate standard errors for different methods of obtaining control. For example, standard errors of control derived from RTK GPS would be higher than control derived from GPS static measurements.

GPS Standard Errors

Instrument Centering: This option is used to specify the error associated with centering a GPS receiver over a point.

Vector Standard Error Factor: This option is used as a factor to increase GPS vector standard errors as found in the input GPS vector file. Some people think that the GPS vector variances/covariances as found in GPS vector files tend to be overly optimistic. This factor allows the user to globally increase the GPS vector standard errors without having to edit the GPS vector file. A factor of 0 is the default value and results in no change to the GPS vector standard errors as found in the GPS vector file. Acceptable values are 0 through 9. **It is not a linear progression.** The actual multiplication factor is the number 2 raised to the power entered in the factor box. For example, if the value of 4 is entered, the multiplication factor will be 2 to the 4th power or 16.

The Vector Standard Error is 2 to the Power of x as shown below:

0 = original value from GPS

1 = x2

2 = x4

3 = x8

4 = x16

A way to determine the proper factor to use for your specific make and model of GPS equipment is to perform a GPS only survey without mixing in Total Station. Then process with a different factors and check the Chi-Square result that falls closest to the middle of the range.

Differential Leveling Standard Errors

These setting only effect level data and are not used when processing total station or GPS vector files.

Avg. Dist. To BS/FS: This option is used to define the average distance to the backsight and foresight during leveling.

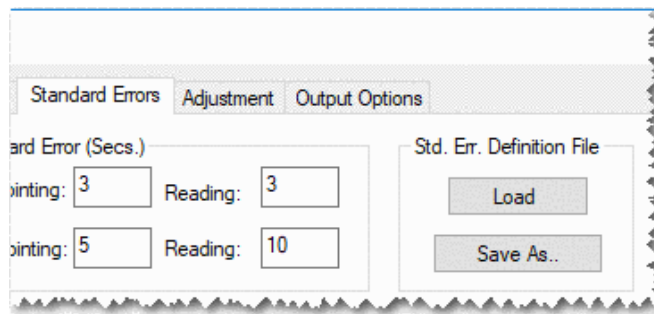

Rod Reading Error per 100 ft./m: This option is used to define the expected level reading error.

Collimation Error: This is the expected differential leveling collimation error in seconds.

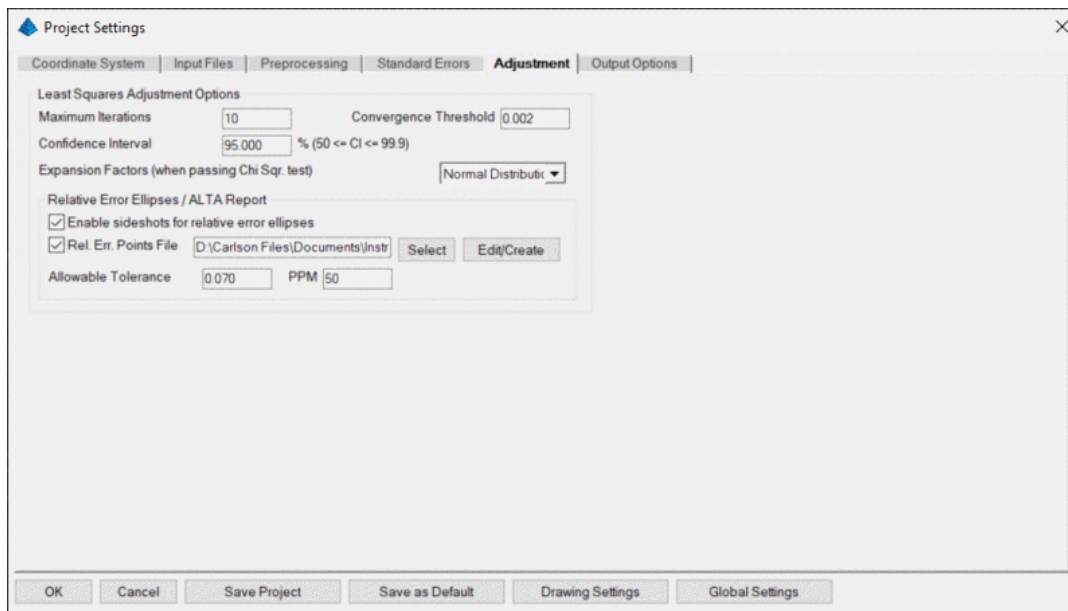

Standard Error Definition Files

The Standard error settings can be saved and then later reloaded into an existing or new project. Creating libraries of standard errors for different types of survey equipment or survey procedures is convenient method of creating standards within a survey department that uses a variety of equipment and performs different types of surveys.

Standard error library files (.sef) can be created two ways. From the 'Settings – Standard Errors' tab, the 'Load' button can be used to import an existing .SEF file into the current project. A .SEF file can also be created from the existing project standard errors by using the 'Save As..' button.

Adjustment

Maximum Iterations: Non-linear least squares is an iterative process. The user must define the maximum number of iterations to make before the program quits trying to find a converging solution. Typically if there are no blunders in the data, the solution will converge in less than 5 iterations.

Convergence Threshold: During each iteration, corrections are computed. When the corrections are less than the threshold value, the solution has converged. This value should be somewhat less than the accuracy of the measurements. For example, if you can only measure distances to the nearest 0.01' then a reasonable convergence threshold value would be 0.005'.

Confidence Interval: This setting is used when calculating the size of error ellipses, and in the Chi²; (Chi-square) testing. For example, a 95% confidence interval means that there is a 95% chance that the error is within the tolerances shown.

Expansion Factors (when passing Chi²; test): This setting allows users to choose between a normal distribution or F distribution for error ellipses on points that pass the Chi Square Test.

Enable sideshots for relative error ellipses: Check this box if you want to see the error ellipses and relative error ellipses of sideshots. This check-box must be set if you want to use the "relative error ellipse inverse" function with sideshots. When unchecked, this toggle filters out sideshots during the Least Squares processing. Since the sideshots are excluded from the Least Squares processing, error ellipses cannot be computed for these points. When this toggle is off, the sideshots are computed after the network has been adjusted. The final coordinate values of the sideshots will be the same regardless of this setting.

- **Note:** Large numbers of sideshots slow down least squares processing. It is best to uncheck this box while de-

bugging your project to avoid having to wait for the computer to finish processing. After the project processes correctly you may turn on the option for the final processing.

- **Note: Any sideshots that are selected for the ALTA report will automatically be included in the adjustment process in order to calculate the error ellipses - even if this option is turned OFF.** Even if you do not need ALTA report, this is an easy way to get statistics on only selected sideshots which can greatly speed up the adjustment process.

Relative Err. Points File: Any certification specifying "Positional Tolerance", "Positional Accuracy" or "Positional Precision" deal with the relative error between specified points. The ALTA standards require that surveyors certify to the relative positional tolerance between points. Relative error ellipses are an accepted method of determining the relative positional error required by the ALTA standards. The points that are to be included in the relative error checking are specified by the user. These points are defined in an ASCII file with an extension of .ALT. To select an .ALT file for relative error checking use the 'Select' button and then browse to the location of the file. Refer to the Creating ALTA Tolerance Reports for a discussion on creating the .ALT file.

If the Relative Err. Points File box is checked, an ALTA section will be created in the report.

Allowable Tolerance, PPM: These fields allow the user to set the allowable error for computations. Typically the user would enter the current ALTA error standards. Many States are adopting similar certifications to the ALTA standards. These certifications may have different tolerances depending on the type of survey (for example rural vs. urban). Make sure the appropriate tolerance and PPM (parts per million) values have been defined. The ALTA standards define their positional standard as 0.07' plus 50 PPM and typically require that the computations be performed to a 95% confidence. The confidence interval is set in the *Confidence Interval* edit field.

Refer to the discussion on creating and interpreting the ALTA report.

Output Options

These settings apply to the output of data to the report and coordinate files.

The screenshot shows the 'Settings' dialog box with the 'Output Options' tab selected. The 'Display Precision' section has dropdowns for North/East (4), Elev. (4), Distances (4), and Directions (0.00 sec). The 'Format' section has dropdowns for Direction (Azimuth), Angles (Degrees), and Coordinate (North, East), and a text field for Null Elevation (-9999999.0). The 'ASCII NEZ Output' section has a dropdown for Format (P, N, E, Z, CD, DESC (fixed columns)), and dropdowns for N/E Precision (8) and Elevation Precision (8). The 'Coordinate File Output' section has a checked 'Write to coordinate file' checkbox, a file path 'C:\Carlson Projects\SurvNET.crd', and 'Do not overwrite elevations' and 'Do not overwrite descriptions' checkboxes. The 'Scaled Coordinate File' section has a 'Create Scaled/Ground NEZ File' checkbox, a file path field, and a 'Scaled NEZ File Format' dropdown set to 'Coordinate File'. The 'Scale' section has a 'Scale Factor' field, a 'Pt. to Scale Around' field, a 'Use Current NE values' dropdown, and 'N:' and 'E:' text fields. At the bottom are 'Save Project', 'Save As Default', 'OK', and 'Cancel' buttons.

Display Precision

These settings determine the number of decimal places to display in the reports for the following types of data. **The**

display precision has no effect on any computations, only the display of the reports.

- Coordinates (North, East, Elevation) - Chose 0-4 decimal places.
- Distances - Chose 0-4 decimal places
- Directions (Azimuths or Bearings) - nearest second, tenth of second, or hundredth of second.

Format

These settings determine the format for the following types of data.

Direction - Choose either bearings or azimuth for direction display. If the angle units are degrees, bearings are entered as QDD.MMSSss and azimuths are entered as DDD.MMSSss. If the angle units are grads, bearings are input as QGGG.ggggg and azimuths are input as GGG.ggggg.

Angles - Choose the units you are working in: degrees or gradians.

Coordinate - Choose the order of coordinate display, either north-east or east-north.

Null Elevation - Choose the value for null elevations in the output ASCII coordinate NEZ file. The Null Elevation field defaults to SurvNET's value for NO ELEVATION. This is used to differentiate between NO ELEVATION (a true 2D point) and ZERO ELEVATION (which is a valid elevation).

Coordinate File Output

These settings determine the type and format of the output NEZ file. An ASCII .NEZ and .OUT files are always created after processing the raw data. The .OUT file will be a nicely formatted version of the .NEZ file. The .NEZ file will be an ASCII file suitable to be input into other programs. There are a variety of options for the format of the .NEZ file. Following are the different ASCII file output options.

- P,N,E,Z,CD,DESC (fixed columns); - Point,north,east,elev.,code,desc in fixed columns separated by commas.
- P,N,E,Z,CD,DESC; Point,north,east,elev.,code,desc separated by commas.
- P N E Z CD DESC (fixed columns); Point,north,east,elev.,code,desc in fixed columns with no commas.
- P N E Z CD DESC; Point,north,east,elev.,code,desc in fixed columns with no commas.
- P,N,E,Z,DESC (fixed columns); Point,north,east,elev., desc in fixed columns separated by commas.
- P,N,E,Z,DESC; Point,north,east,elev., desc separated by commas.
- P N E Z DESC (fixed columns); Point,north,east,elev., desc in fixed columns with no commas.
- P N E Z DESC; Point,north,east,elev.,code,desc separated by spaces.
- P,E,N,Z,CD,DESC (fixed columns); - Point,east,north,elev.,code,desc in fixed columns separated by commas.
- P,E,N,Z,CD,DESC; Point,east,north,elev.,code,desc separated by commas.
- P E N Z CD DESC (fixed columns); Point,east,north,elev.,code,desc in fixed columns with no commas.
- P E N Z CD DESC; Point,east,north,elev.,code,desc in fixed columns with no commas.
- P,E,N,Z,DESC (fixed columns); Point,east,north,elev., desc in fixed columns separated by commas.
- P,E,N,Z,DESC; Point,east,north,elev., desc separated by commas.
- P E N Z DESC (fixed columns); Point,east,north,elev., desc in fixed columns with no commas.
- P E N Z DESC; Point,east,north,elev.,code,desc separated by spaces.
- CSV ASCII with Standard Errors

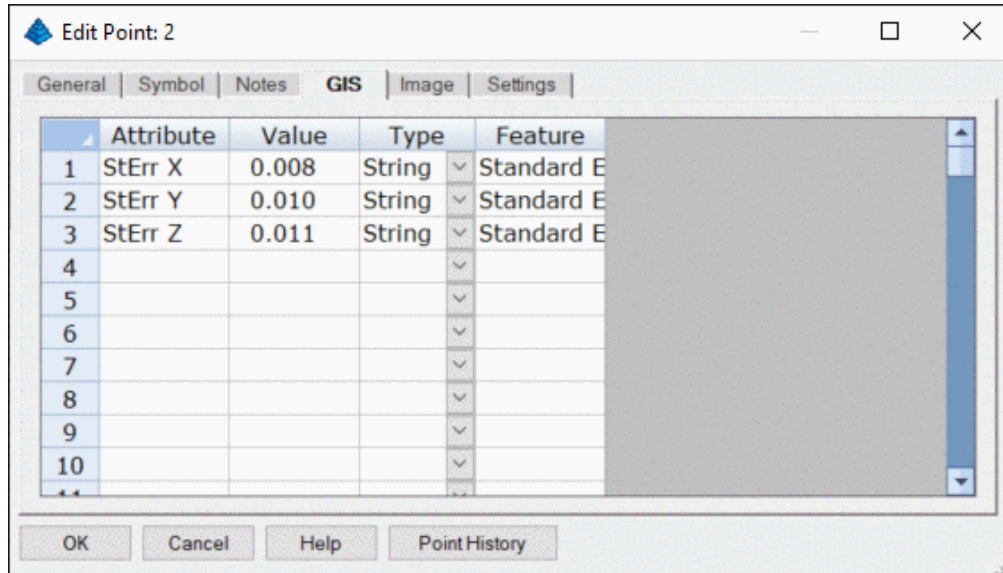

You can also set the output precision of the coordinates for the ASCII output file. This setting only applies to ASCII files, not to the C&G or Carlson binary coordinate files which are stored to full double precision.

* N/E Precision: number of places after the decimal to use for North and East values (0 – 8) in the output NEZ ASCII file.

* Elevation Precision: number of places after the decimal to use for Elevation values (0 – 8) in the output NEZ ASCII file.

Write to Coordinate File: If you want to write the calculated coordinates directly to a Carlson-supported coordinate file, check the "Write to Coordinate File" box and select the file. You can choose the type of Carlson .CRD or CRDB/C&G file to be created when you 'select' the file to be created. You may wish to leave this box unchecked until you are satisfied with the adjustment. Specifying the File Extension will govern the type of file being created.

Note: if you use the Carlson **CRDB** file format, you are allowed to store attributes for each point as well as the standard Point Number, Northing, Easting, Elevation and Description. If this option is used when processing a SurvNET least squares adjustment, the standard error results will be stored for each point.

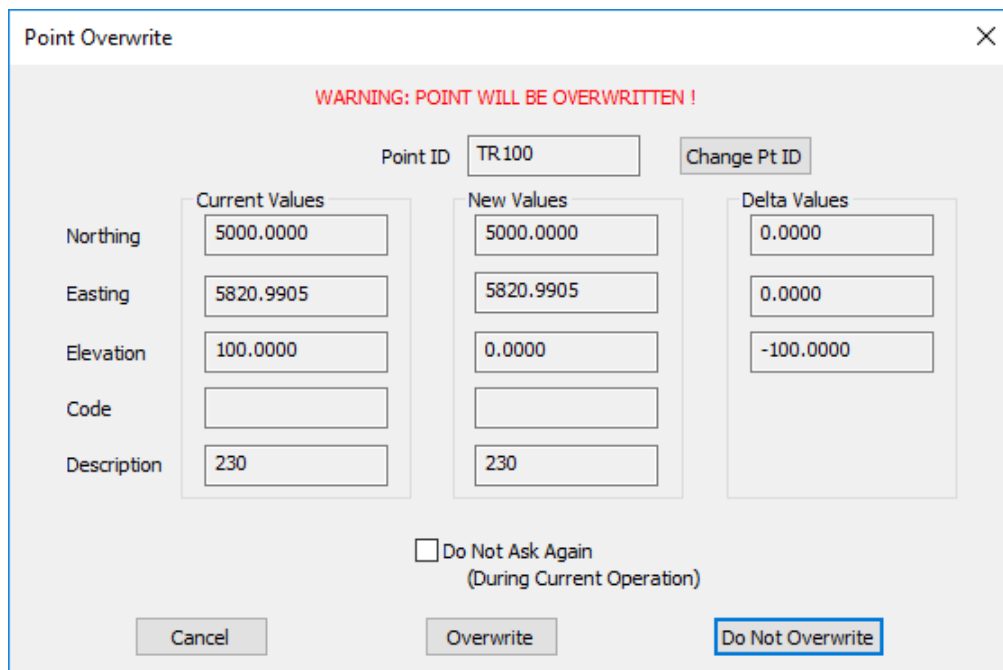

There are two check-boxes below the Output File edit box:

1. **Do not overwrite elevations** - If this is checked the existing elevations in the coordinate file will not be changed.
2. **Do not overwrite descriptions** - If this is checked the existing point descriptions in the coordinate file will not be changed.

Overwriting existing points:

* NOTE: After the adjustment the coordinates will be written to the selected output file. If coordinate points already exist in the coordinate file, before a point is written, you will see the following "Point Protection" dialog box:

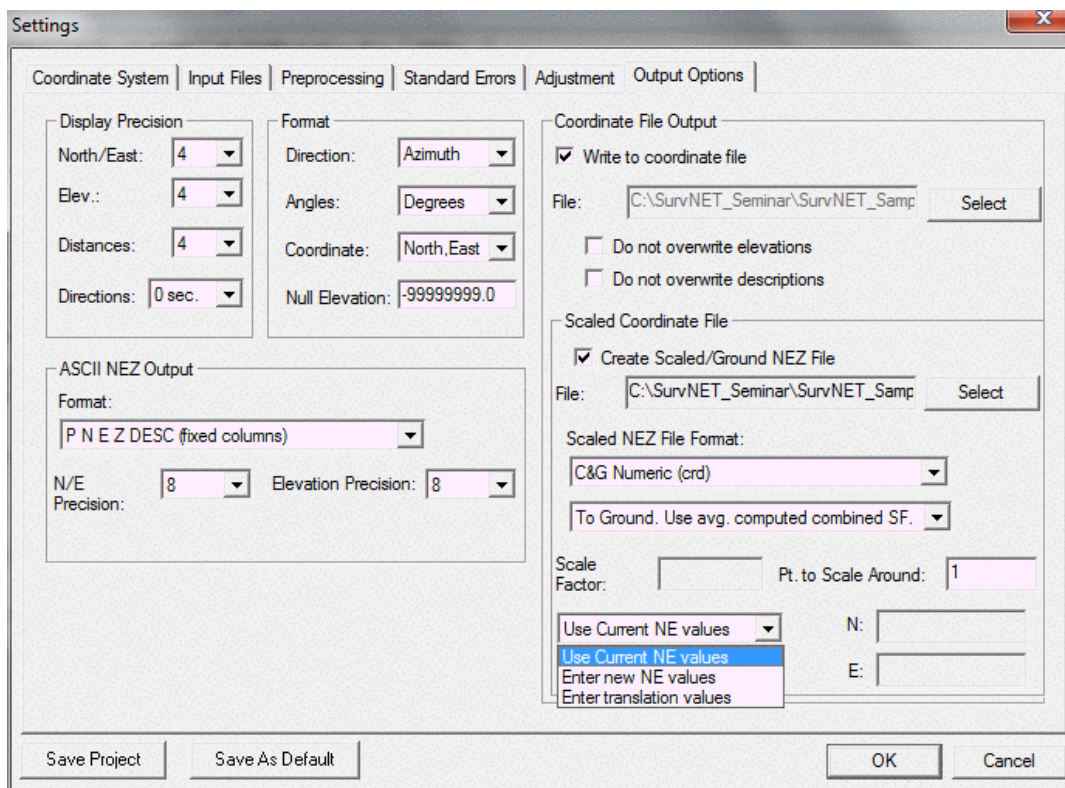

Cancel: Cancel the present operation. No more points will be written to the coordinate file.

Overwrite: Overwrite the existing point. Notice that if you check the 'Do Not Ask Again' box, all further duplicate points will be overwritten without prompting.

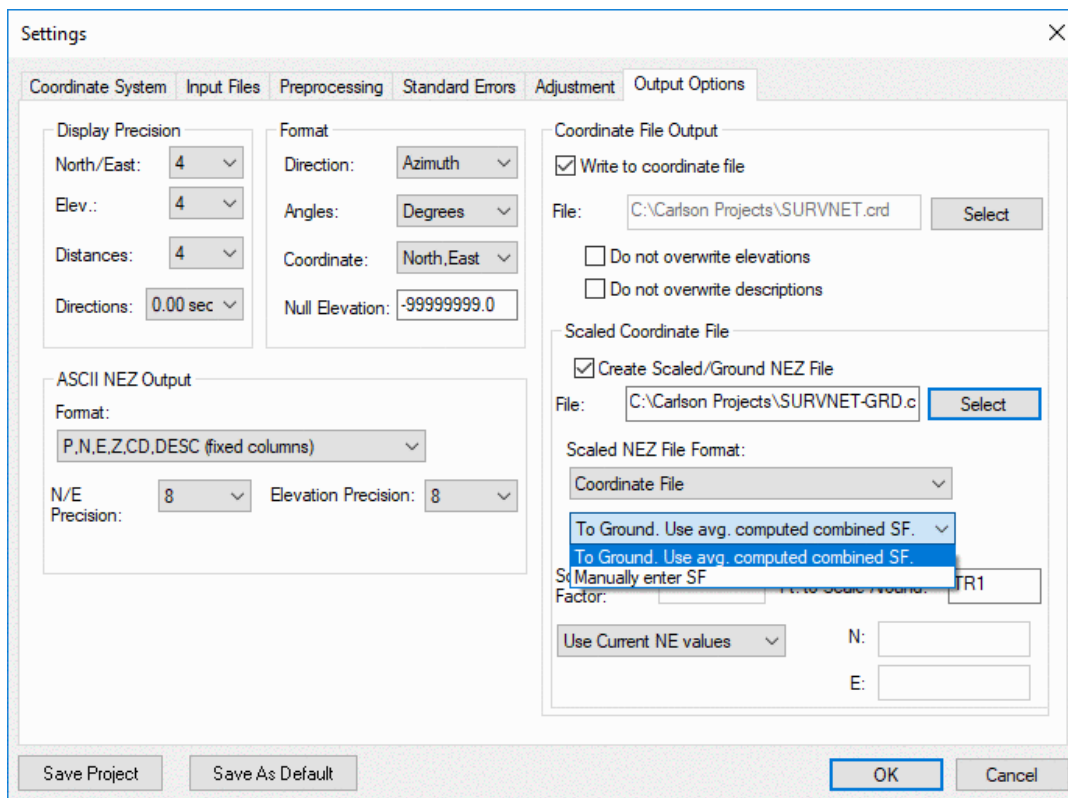

Do not Overwrite: The existing point will not be overwritten. Notice that if you check the 'Do Not Ask Again' box, all further duplicate points will automatically not be overwritten - only new points will be written.

Scaled Coordinate File: You are also allowed to output coordinates to a second, scaled or ground, coordinate file. Check the "Create Scaled/Ground NEZ file" box (see below):

If you are working with a **Local** coordinate system as defined in the Coordinate System tab, you will only be allowed to manually enter a scale factor. You can select the output file format and the output file.

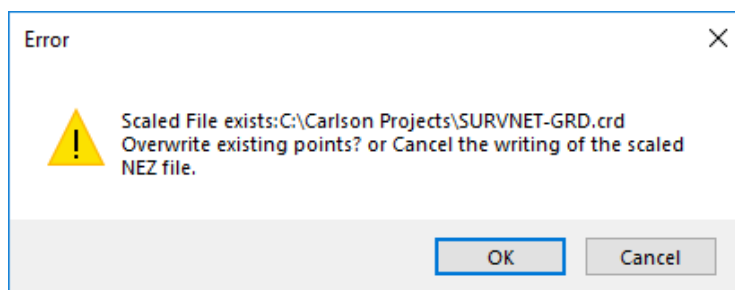

If you are working in a non-local coordinate system (*i.e.* 1983 State Plane), you will have the following scaling options:

You can either enter a scale factor or use the computed grid to ground scale factor. If you select to use the computed scale factor, SurvNET will use the "average combined scale factor" as shown in the project report file.

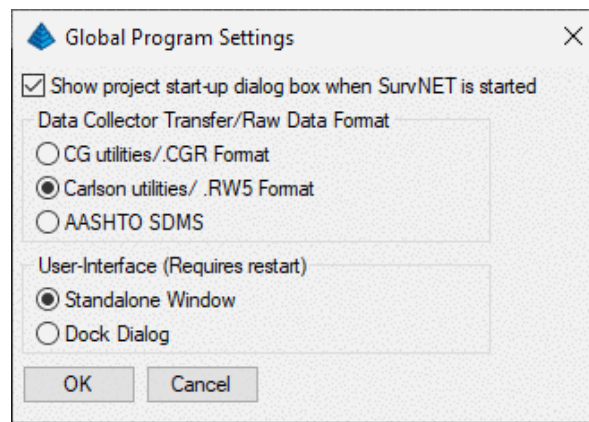

You will also be required to enter the point number of the point you will be scaling around. This function can also be used as a translation tool. You can either "Use the Current NE values" (no translation), "Enter the new NE values" (desired N and E values for the scaling point), or "Enter Translation Values" (enter the actual delta-north and delta-east values).

If the Scaled Coordinate file exists when you process the project, you will see the following warning dialog box:

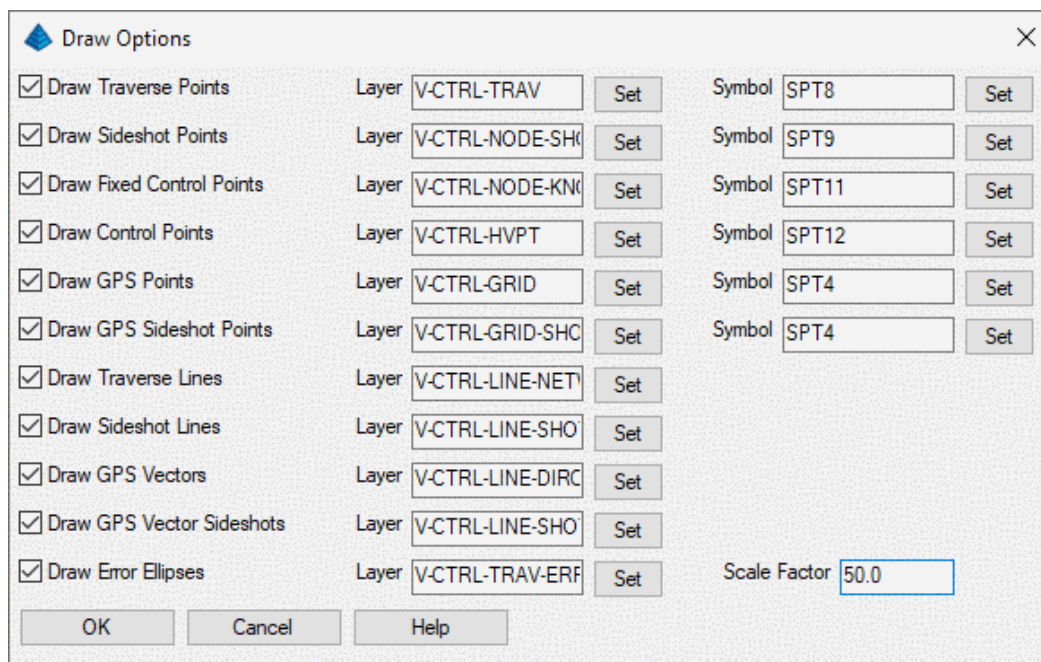

If you pick OK the points in the Scaled File will be overwritten. If you Cancel no point will be written to the Scaled File.

The menu option "Settings – Global Settings" displays the following dialog box. If the 'Use Carlson Utilities' is chosen then the .RW5 editor will be the default raw editor and Carlson SurvCom will be the default data collection transfer program. If the 'Use C&G Utilities' is chosen then the C&G .CGR editor will be the default raw editor and C&G's data collection transfer program will be the default data collection transfer program. For additional information, refer to the Raw Data Files and Raw Data Editor Functions section of this manual.

User-Interface (for CAD versions of SurvNET) - Indicate the desired graphical user interface (*gui*, "goosey") you wish to use.

If you are running SurvNET from inside Carlson Survey, you can draw the network into the active drawing file. These are the settings for the Draw Network function.

NOTE: As a reference, the following is the suggested *National CAD Standards* layer list for the Drawing Settings dialog box:

- V-CTRL-TRAV
- V-CTRL-NODE-SHOT
- V-CTRL-NODE-KNOW
- V-CTRL-HVPT
- V-CTRL-GRID
- V-CTRL-GRID-SHOT
- V-CTRL-LINE-NETW
- V-CTRL-LINE-SHOT
- V-CTRL-LINE-DIRC
- V-CTRL-LINE-SHOT
- V-CTRL-TRAV-ERRO

Check the type points and lines you want to draw. If you want to draw the error ellipse at each point check the "Draw Error Ellipses" box. You can choose a layer for all the points and lines and a symbol for all the points.

Process Menu

The Processing buttons from left to right are:

Network Adjustment - adjusts the network and creates a results report

Preprocess, compute unadjusted coordinates - processes the network, calculates positions and creates an error and coordinate report

Blunder Detection - processes the network based on three user selected parameters and creates an error report

Draw Network - draws the network in an open CAD drawing based on the Drawing Settings set in the Project Settings

When you select Process – *Network Adjustment* from the menu, the raw data will be processed and adjusted using least squares based on the Project Settings. If there is a problem with the reduction, you will be shown error messages that will help you track down the problem. Additionally a .ERR file is created that will log and display error and warning messages.

The data is first preprocessed to calculate averaged angles and distances for sets of angles and multiple distances. For a given setup, all multiple angles and distances to a point will be averaged prior to the adjustment. The standard error as set in the Project Settings dialog box is the standard error for a single measurement. Since the average of multiple measurements is more precise than a single measurement, the standard error for the averaged measurement is computed using the standard deviation of the mean formula.

Non-linear network least squares solutions require that initial approximations of all the coordinates be known before the least squares processing can be performed. So, during the preprocessing approximate coordinate values for each point are calculated using basic coordinate geometry functions. If there is inadequate control or an odd geometric situation, SurvNET may generate a message indicating that the initial coordinate approximations could not be computed. The most common cause of this problem is that control has not been adequately defined or there are point numbering issues.

Side-shots are separated from the raw data and computed after the adjustment (unless the "Enable sideshots for relative error ellipses" toggle is checked in the Adjustment dialog box). If side shots are filtered out of the least squares process and processed after the network is adjusted, processing is greatly sped up, especially for a large project with a lot of side shots.

If the raw data processes completely, a report file, .RPT, a .NEZ file, an .OUT file, and an .ERR file will be created in the project directory. The file names will consist of the project name plus the above file extensions. These different files are shown in separate windows after processing. Additionally, a graphic display of the network can be generated.

.RPT file: This is an ASCII file that contains the statistical and computational results of the least squares processing.

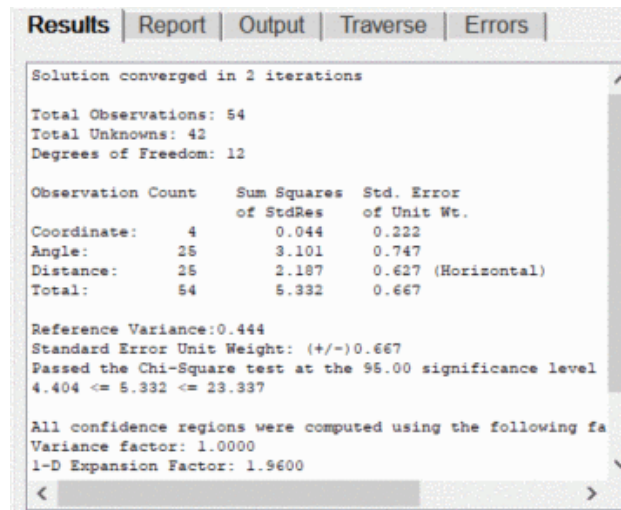

.NEZ file: This file is an ASCII file containing the final adjusted coordinates. This file can be imported into any program that can read ASCII coordinate files. The format of the file is determined by the ASCII NEZ setting in the Project Settings dialog box.

.OUT file: The .OUT file is a formatted ASCII file of the final adjusted coordinates suitable for display or printing.

.ERR file: The .ERR file contains any warning or error messages that were generated during processing. Though some warning messages may be innocuous it is always prudent to review and understand the meaning of the messages.

If you have "Write to Coordinate File" checked in the Output options dialog, the coordinates will also be written to a coordinate file (.CRD by default).

The following is an example of the initial report displayed in the dialog box showing the calculation results.

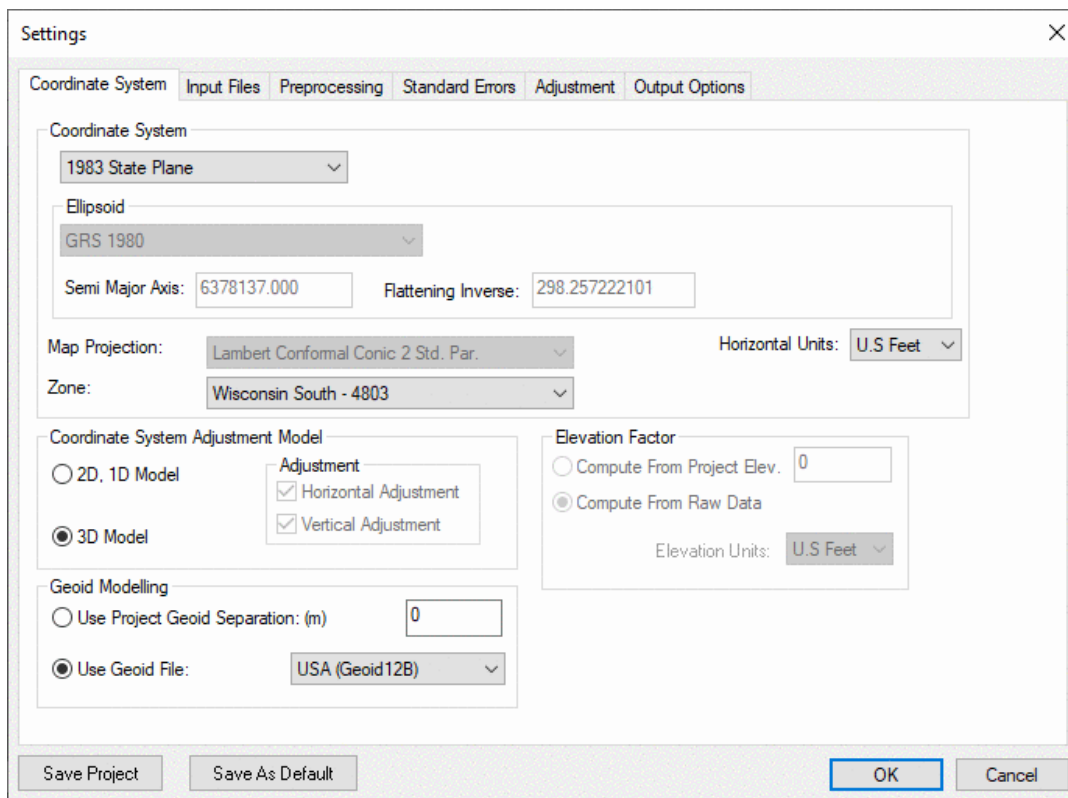

Users can see immediately the results of the Chi Square test along with other pertinent information. you can also toggle each tab to see additional information. To review and print a complete report, use the Report button.

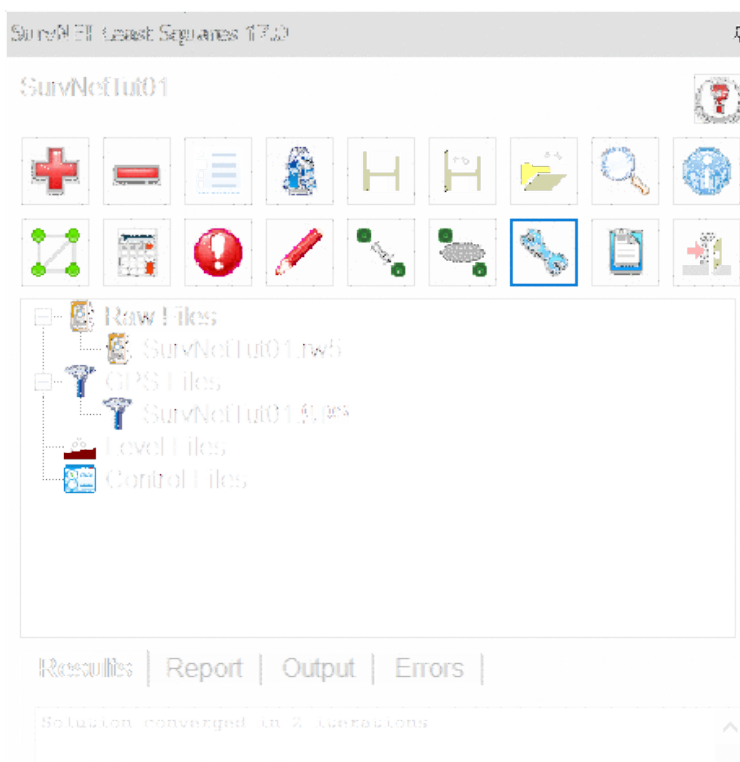

GPS vector networks can be adjusted with SurvNET. This chapter will describe the processing of a simple GPS network. Following is a graphic view of the GPS network that is to be adjusted. Points A and B are control points. The magenta lines represent measured GPS vectors. Most GPS vendor's software can output GPS vectors to a file as part of the post-processing of GPS data.

When processing GPS vectors, certain project settings are important. In the following settings dialog box, notice that the 3D-model has been chosen and SPC 1983 with the appropriate zone has been chosen. The 3-D model and a geodetic coordinate are required when processing GPS vectors. Though it is not required for GPS processing, it is in most cases appropriate to choose to do geoid modeling.

The following settings dialog box shows the raw files used in processing GPS files. A GPS vector file must be chosen. GPS vector files from various GPS vendors are supported. Select the vector files to be processed:

Coordinate control for the network can be in one of several files. The control can be located in the GPS vector file itself. More typically, the control points can be regular coordinate records in the .RW5 or the .CGR file. They also

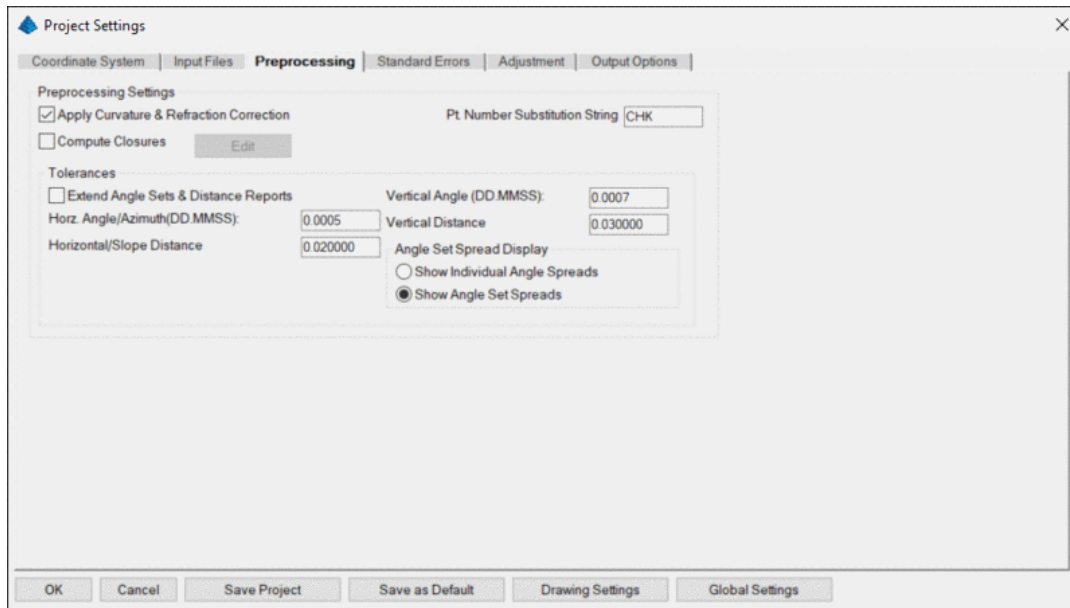

can be entered as 'Supplemental Control' in one of the available formats.

When the control coordinates are in the raw data file they are expected to be grid coordinates with orthometric heights.

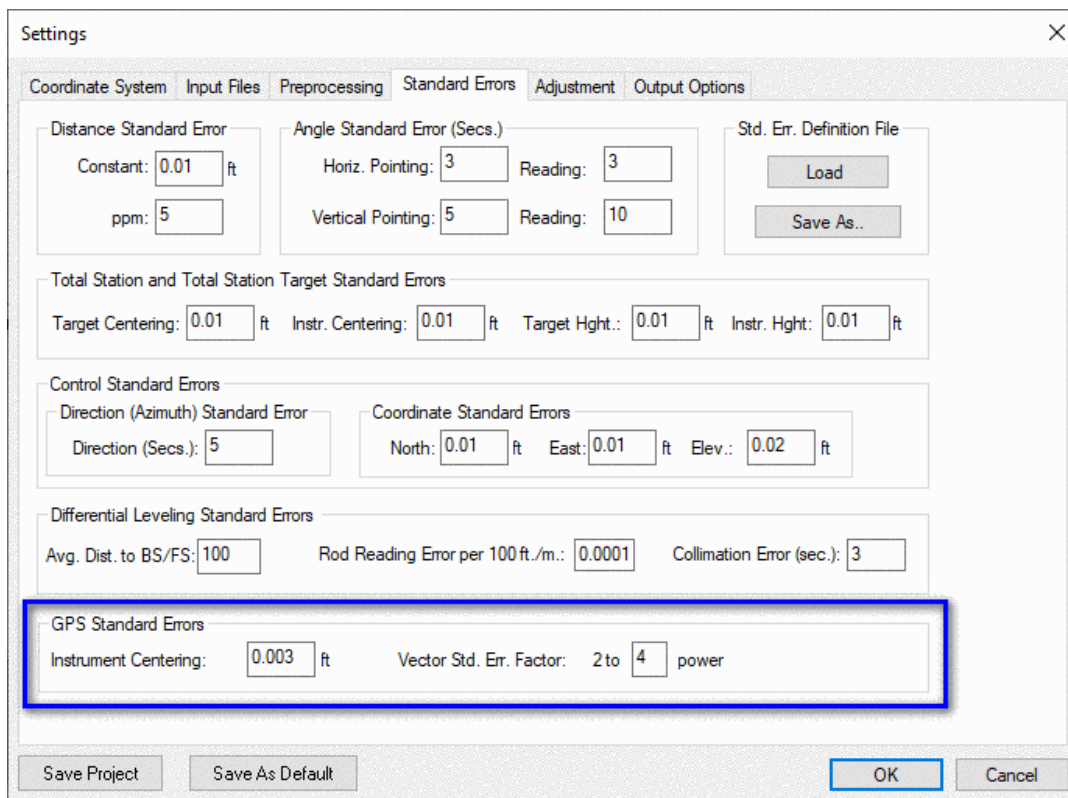

The supplemental control file formats support grid coordinates with orthometric heights, geographic coordinates with orthometric heights, or geocentric coordinates with ellipsoid heights.

If the control coordinates are found in the GPS vector file, they are assumed to be Geocentric ECEF (earth-centered-earth-fixed) XYZ coordinates. As shown in the dialog above, it is not unusual to have different distance units for GPS, total station data, and control data. GPS vector data is usually in metric units but the total station raw file can be in US Feet. So, the distance units must be specified for the different raw data types.

In the Preprocessing Settings dialog box, the only important setting is the **Compute Closures** option. If GPS loop or point-to-point closures need to be computed, the point numbers defining the loops need to be entered into a Closure File. See the discussion on traverse closures to see how to create Closure Files.

There are two GPS standard errors fields in the Standard Errors Settings dialog box. The GPS vector XYZ standard errors and covariances do not need to be defined as project settings since they are found in the GPS vector data files.

For more information, see the discussion on GPS Standard Errors.

Processing a GPS vector network together with conventional total station data is similar to processing a GPS network by itself. The only difference in regards to project settings is that a raw data file containing the total station data needs to be chosen as well as a GPS vector file. The project must be set up for the 3D model and a geodetic coordinate system needs to be chosen. **The total station data must be 3D, all rod heights and instrument heights must be measured.**

Following is a view of the Input Files Settings dialog box showing both a GPS vector file and a total station raw data file chosen in a single project. It is not uncommon to have different distance units for GPS data and total station data, so make sure the correct units are set for data types.

One of the most common problems for new users in combining GPS and total station data is not collecting HI's and rod heights when collecting the total station data. Since the 3D model is being used complete 3D data needs to be collected. If you only have 2D traverse data, you can adjust the GPS vectors first and then use the adjusted coordinates as control for the Traverse data project.

The 'Preprocess, Compute Unadjusted Coordinates' option allows the computation of unadjusted coordinates. If there are redundant measurements in the raw data, the first angle and distance found in the raw data is used to compute the coordinates. If a State Plane grid system has been designated the measurements are reduced to grid prior to the computation of the unadjusted coordinates. If the point is located from two different points the initial computation of the point will be the value stored.

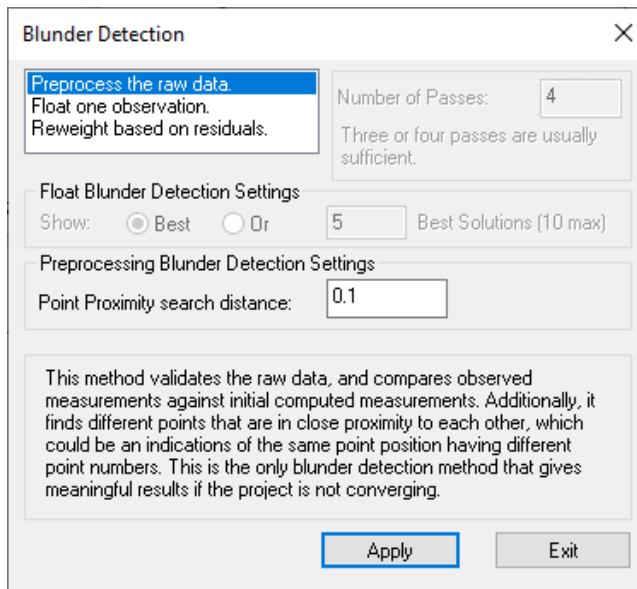

A variety of blunder detection tools are available that gives the user additional tools in analyzing the survey data and detecting blunders. The standard least squares adjustment processing and its resulting report can often be used to determine blunders. No blunder detection method can be guaranteed to find all blunders. So much depends on the nature of the network geometry, the nature of the measurements, and the intuition of the analyst. Generally, the more redundancy there is in a network the easier it is to detect blunders.

There are three different methods that can be used to track down blunders in a network or traverse:

1. Preprocess the raw data
2. Float one observation
3. Reweight based on residuals

Option 1) Preprocess the raw data:

The **Preprocess the raw data** option validates the raw data. It displays angle and distance spreads as well as checks the validity of the raw data. Traverse Closures are computed if specified. It also performs a "K-Matrix" analysis. The "K-Matrix" analysis compares the unadjusted, averaged measurements with the computed preliminary measurements (measurements calculated from the preliminary computed coordinates). This method will catch blunders such as using the same point number twice for two different points. The report will be sent to the .ERR file. The .ERR file will contain the tolerance checks, closures and the K-Matrix analysis. Following is an example of the report created using the 'Preprocess the raw data' option. Notice that the first section of the report shows the angle and distance spreads from the multiple angle and distance measurements. The second part of the report shows the 'K-matrix' analyses.

Additionally there is a 'Point Proximity Report' section that reports pairs of different points that are in close proximity to each other which may indicate where the same point was collected multiple times using different point numbers.

The 'Preprocess the raw data' option is one of the simplest and effective tools in finding blunders. Time spent learning how this function works will be well spent. If the project is not converging due to an unknown blunder in the raw data, this tool is one of the most effective tools in finding the blunder. Many blunders are due to point numbering errors during data collections, and the 'K-matrix' analysis and 'Point Proximity' search are great tools for finding this type blunders.

 Point Proximity Report:
 Points 3 and 30 are within 0.05 of each other.

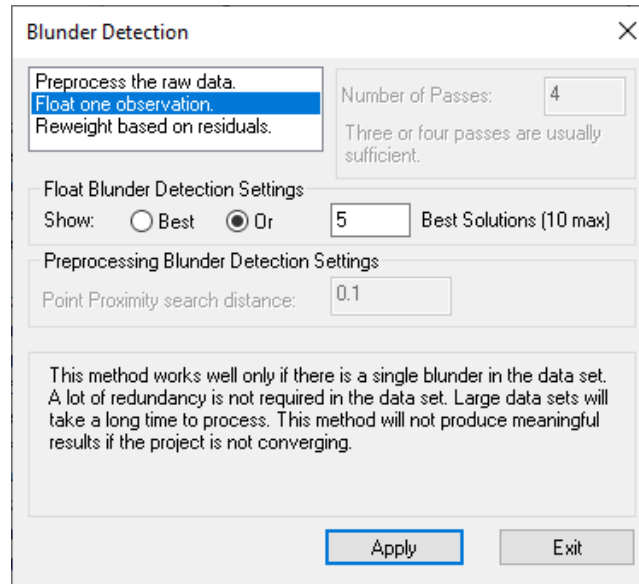

The problem with the above project was that point 6 was accidentally used twice for two separate side shots. Because of the point numbering problem the project would not converge, using the regular least squares processing. The 'Preprocess the raw data' option was then used. Notice in the K-matrix section the distance from 5 to 6 shows

a difference of 174.79' and the angle 4-5-6 shows a difference of 065-50'47.6". Then notice that the other listed differences are in the range of .02' for the distances and less than a minute for the angles. This report is clearly pointing out a problem to point 6.

Note the point proximity report section. During data collection, point number 30 was used as the point number when the point was previously collected as point 3.

In the first section of the report, notice that there are several warnings concerning whether a horizontal angle reading was collected in direct or reverse reading. The preprocessing software uses the vertical angle reading to determine the angle face of the horizontal angle reading. If the vertical angle is missing, the program makes its best guess as to whether the angle was collected in direct or reverse face. Since all horizontal angle spreads in the report are reasonable, the preprocessing software must have made the correct determination.

Option 2) Float one observation:

This option is useful in finding a single blunder, either an angle or distance, within a network or traverse. If there is more than a single blunder in the network then it is less likely that this method will be able to isolate the blunders. **If the standard least squares processing results in a network that will not converge, then this blunder detection method will not work.** Use the Preprocess the raw data blunder detection method if the solution is not converging. Also this method will only work on small and moderately sized networks. This method performs a least squares adjustment once for every non-trivial measurement in the network. So for large networks this method may take so long to process that it is not feasible to use this method.

With this method, an adjustment is computed for each non-trivial individual angle and distance measurement. Consecutively, a single angle or distance is allowed to float during each adjustment. The selected angle or distance does not "constrain" the adjustment in any way. If there is a single bad angle or distance, one of the adjustment possibilities will place most of the error in the "float" measurement, and the other measurements should have small residuals. The potentially bad angle or distance is flagged with a double asterisk (**). Since an adjustment is computed for each measurement, this method may take a long time when analyzing large data files.

The adjustments with the lowest reference variances are selected as the most likely adjustments that have isolated the blunder. You have the choice to view the best adjustment, or the top adjustments with a maximum of ten. In the above example, we asked to see the top 5 choices for potential blunders. The results are shown in the .ERR file. Following is a section of the report generated where an angular blunder was introduced into a small traverse. Notice the '**' characters beside the angle measurements. In this report the two most likely adjustments were displayed. The blunder was introduced to angle 101-2-3. Angle 101-2-3 was chosen as the 2nd most likely source of the blunder, showing that these blunder detection methods though not perfect, can be a useful tool in the analysis of survey measurements. Notice how much higher the standard residuals are on the suspected blunders than the standard

residuals of the other measurements.

The blunder is most likely in the measurement containing the largest residual and standard residual. The observation marked with ** is the observation that floated. It is also most likely the measurement containing the blunder.

Option 3) Reweight based on residuals:

This method is capable of detecting multiple blunders but one is more likely to find the blunders if there is a high degree of redundancy (network of interconnected traverses). The higher the degree of freedom the more likely this method will find the blunders. **This method will not work if the standard least squares processing will not converge.** Use the Preprocess the raw data blunder detection method if the network is not converging.

First, select the number of adjustments or passes you wish to make. Each time an adjustment is completed, the measurements will be re-weighted based on the residuals and standard errors. Hopefully, after three or four passes, the blunders will become obvious. The results are shown in the .ERR file, look for the measurements with the highest standard residuals. These measurements are more likely to contain blunders.

The theory behind this method is that after processing, the measurements with blunders are more likely to have higher residuals and computed standard errors. So, in the next pass the measurements are re-weighted based on the computed residuals, with less weight being assigned to the measurements with high residuals. After several passes it is likely that the measurements with the blunders have been reweighed such that they have little effect on the network.

As a rule of thumb, three or four passes are usually sufficient. Following is a section of the report showing the results of the 'Reweight based on residuals'. This report was generated using the same data used in the earlier example. Notice that it has flagged the same two angle measurements.

The 'Reweight based on residuals' method performs a new adjustment for each pass. So, this method will take longer than the standard least squares adjustment, but does not take near as long to complete processing as the Float one Observation method for larger networks.

The blunders are most likely in the measurements containing the largest residuals and standard residuals.

If you are running SurvNET from inside Carlson Survey with AutoCAD or IntelliCAD, you can draw the network in the DWG file. The Drawing Settings option located in the Settings Menu will determine the layers and symbols used for each point and line entity.

The Draw Network option will not be available until the network has been adjusted. After the adjustment, you can select Draw Network.

Your project will be drawn in the drawing (.DWG) file. Put focus back in the CAD program to view the network.

Once the network is drawn in CAD, you are able to use the CAD entities themselves interactively with the raw files. This allows you to make edits to data such as adding specific standard errors to points and measurements with greater ease. See Raw Data Files and Raw Data Editor Functions for more on editing raw data.

Tools Menu

There are a variety of **Tools** for working within the SurvNET project manager.

From left to right/top to bottom, the tools are:

EDM Calibration - offers an option to enter field measurements and calibrate to a published base line.

Point Search - Searches for points by name

Inverse - calculates the direction and horizontal distance between two points

Relative Error Ellipses - calculates the error ellipse between two points

Conversion Tools - converts data formats of raw input files

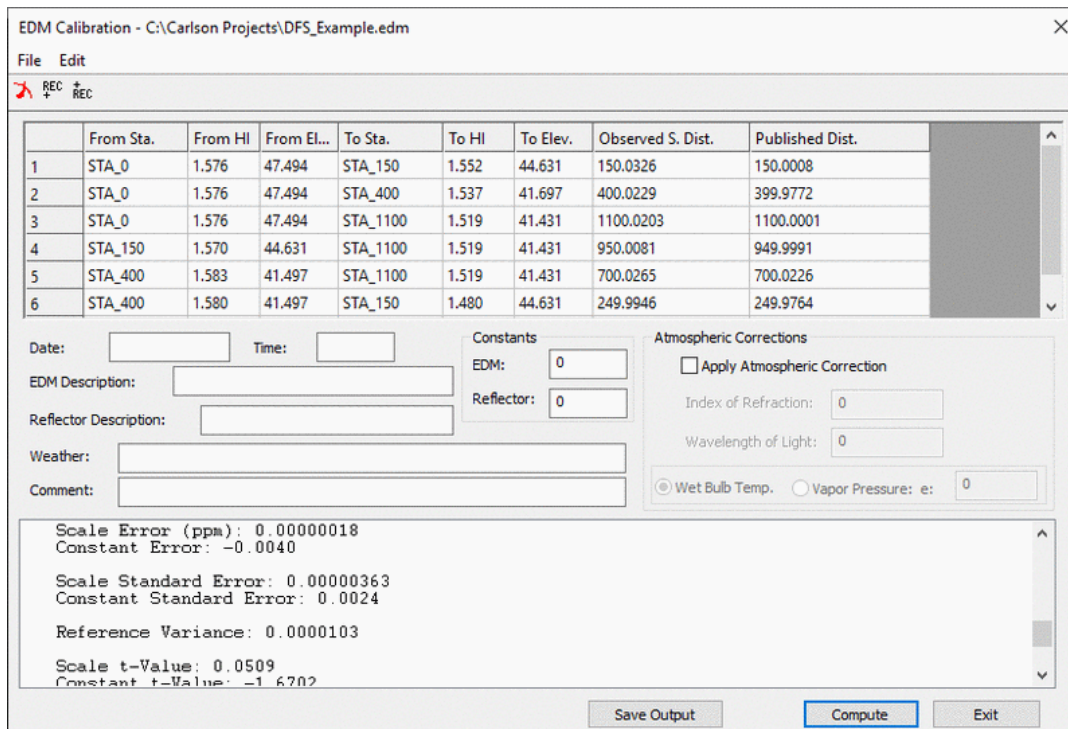

- Convert GPS/Total Station File
- Convert Level Files

The EDM Calibration program allows a surveyor to enter and process the raw data collected on an EDM calibration

baseline. The purpose of an EDM calibration is to determine if the EDM is measuring within standards. The program performs a statistical analysis of that data as outlined in "Use of Calibration Base Lines", by Charles J. Fronczek, NOAA Technical Memorandum NOS NGS-10. The NGS document can be downloaded from the NGS website. NGS maintains a webpage on EDM Calibration Base Lines. The manual and other information on EDM calibrations can be found at <https://www.ngs.noaa.gov/CBLINES/calibration.shtml>. Following is the main EDM Calibration dialog box. NGS publishes the EDM calibration data in metric units. SurvNET's EDM calibration program currently expects the data to be collected in meters.

The basic flow of this program is to first fill out the lower portion of the dialog box which contains different text fields, EDM constant values, and the optional Atmospheric Corrections settings. Next, fill out the grid in the upper portion of the dialog box. This grid contains the field data collected and also the published distances between monuments of the baseline. After this information has been filled out use the 'Compute' button. The program will then display the result of the calibration in the window in the lower portion of the dialog box as follows.

After the file is processed, the results can be stored as an ASCII text file. Use the **Save Output** or the menu option "File/Save Results File As..." to save the results. First, you will be prompted for an output file name. The input data can also be stored. Once stored it can be opened and processed again.

Following is the entire output with a brief explanation of the results. Comments about the results are inserted in **bold**:

```
EDM Calibration Report
  Observed Data
EDM Type:
Date:      Time:
Prism description:
Weather description:
Comment:
Atmosphere Correction: OFF
Constants: Refractor: 0.000    EDM: 0.000
From      From      From      To      .      To      To      Observed  Published
Sta.      Elev.      HI      Sta.      Elev.      HI      Temp.  Pressure  Slope Dist. Dist.

STA_400   41.497    1.583    STA_1100 41.431    1.519    0.0    0.0      700.0265  700.0226
STA_400   41.497    1.580    STA_150  44.631    1.480    0.0    0.0      249.9946  249.9764
STA_400   41.497    1.580    STA_0     47.494    1.526    0.0    0.0      400.0260  399.9722
```

The above section shows the input. The input consists of the observed slope distances and the measured HI's. The from and To elevations are published data from the data sheet from NGS on the particular baseline being observed. The published distances are also published data from the data sheet from NGS. In this example atmospheric pressure was turned off so the Temperature and Pressure fields are irrelevant.

Results

Null Hypothesis, H_0 : EDM scale error and EDM constant error = 0.0

If the scale error and the EDM constant are 0.0, then the EDM is without error. So the purpose of the statistical test is to test how close to 0.0 are the results.

Scale Error (ppm): -0.00000044

Constant Error: -0.0032

The two above lines show the values for the computed scale error and constant error.

Scale Standard Error: 0.00000403
Constant Standard Error: 0.0026

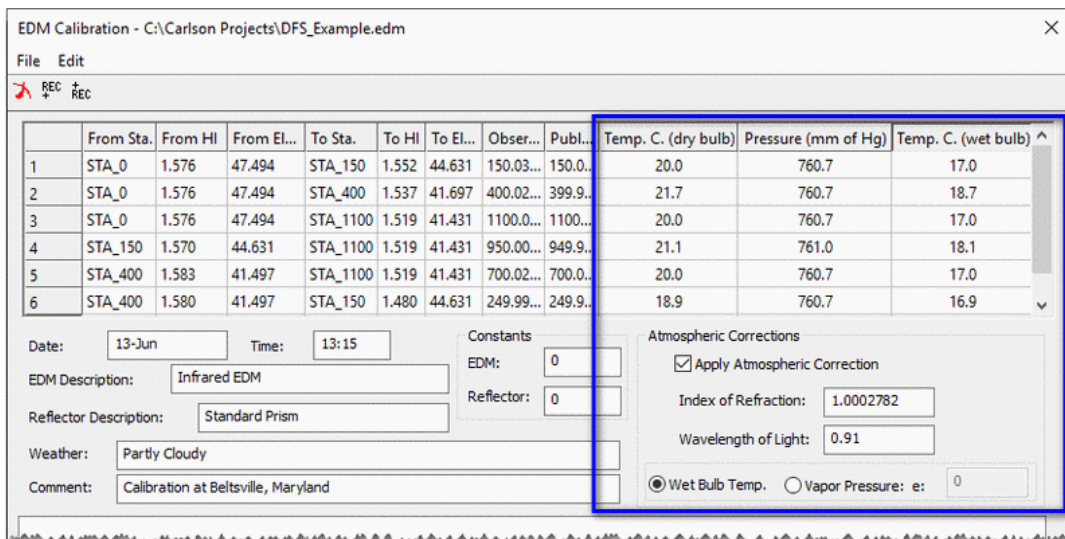

The two above lines show the values for the computed standard errors of the scale error and constant error.

Reference Variance: 0.0000126
Scale t-Value: -0.1096
Constant t-Value: -1.2110
Degrees of Freedom: 5
Critical t-Value at the 1 percent confidence level: 4.0320
Cannot reject the H0 for the scale error. (The scale factor is 0.0)
Cannot reject the H0 for the constant error. (The constant is 0.0)

The above lines show the final results of the statistical test. Since the test determined that we cannot reject the null hypothesis, this EDM is in good working order.

EDM Calibrations and Atmospheric Corrections

The atmospheric correction algorithms used in the EDM calibration are from the NGS manual. To use this method both dry-bulb and wet-bulb temperature needs to be measured, or the vapor pressure, e, and the dry bulb temperature needs to be measured. Refer to the NGS documentation for a detailed explanation of the atmospheric corrections that they use.

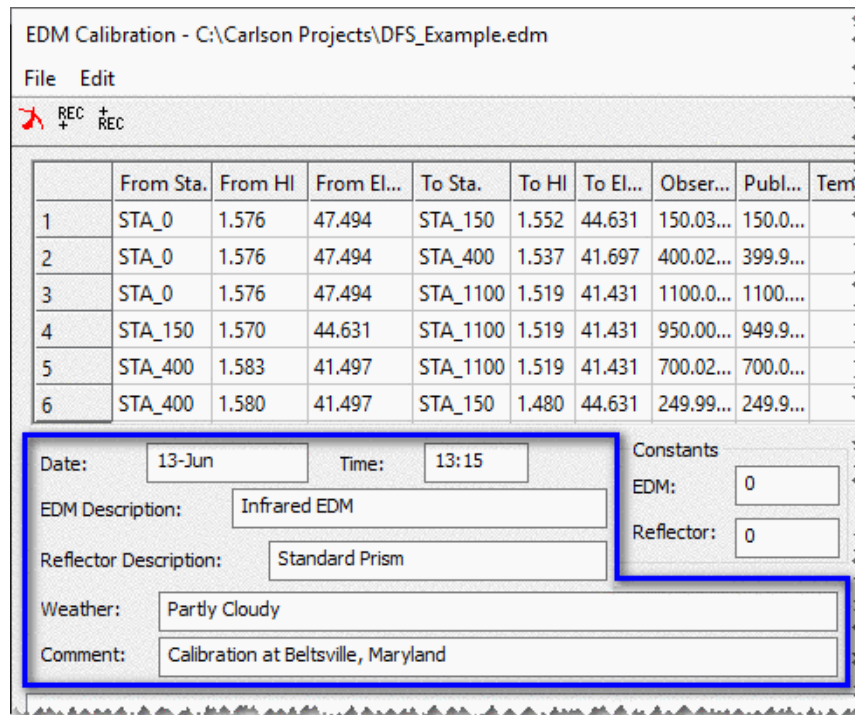

It is probably most common to turn atmospheric correction off in the calibration program, and turn atmospheric correction ON on the EDM (total station). When atmospheric correction is turned off in the calibration program, the user does not need to enter the temperature into the grid or any of the other atmospheric values. If atmospheric corrections are turned OFF then the grid input columns 'Temp. (dry bulb)', 'Pressure, (mm of Hg)', and 'Temp. (wet bulb)' will not be displayed since they are not needed.

Constants can be entered for both the EDM and the reflector. These values are added to the observed distances during processing. Typically they are set to 0.0.

The following text fields have no effect on any computations and are simply comments that can be used to document the calibration.

Entering Data Into the EDM Calibration Grid

Blank data records are inserted into or deleted from the grid using the following tool bar.

The first button deletes the current highlighted record. The second button inserts a new blank record before the current highlighted record. The third button inserts a new blank record after the current highlighted record. Alternately the 'Edit' menu options could be used to delete and insert new data records.

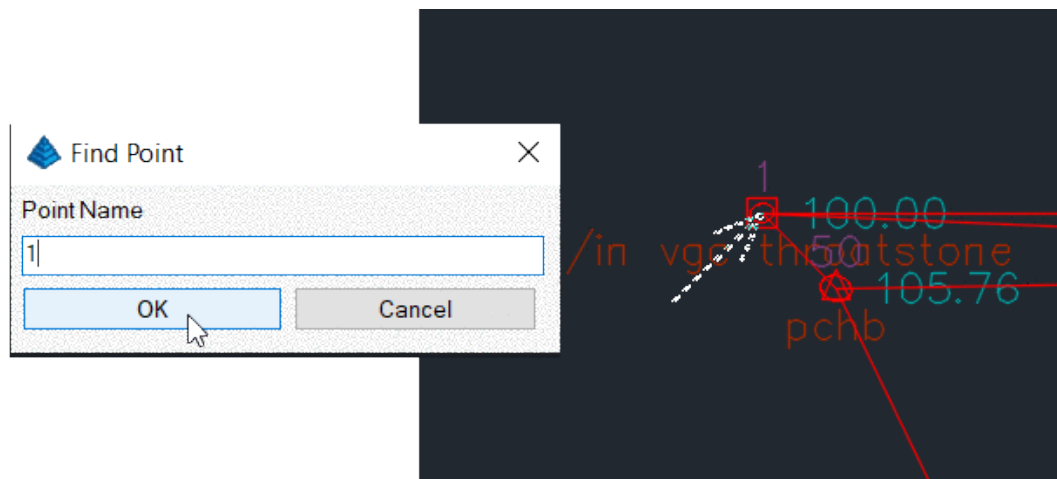

Following is a brief explanation of the fields that make up the grid.

	From Sta.	From HI	From El...	To Sta.	To HI	To El...	Obser...	Publ...	Temp. C. (dry bulb)	Pressure (mm of Hg)	Temp. C. (wet bulb)
1	STA_0	1.576	47.494	STA_150	1.552	44.631	150.03...	150.0...	20.0	760.7	17.0
2	STA_0	1.576	47.494	STA_400	1.537	41.697	400.02...	399.9...	21.7	760.7	18.7
3	STA_0	1.576	47.494	STA_1100	1.519	41.431	1100.0...	1100....	20.0	760.7	17.0
4	STA_150	1.570	44.631	STA_1100	1.519	41.431	950.00...	949.9...	21.1	761.0	18.1
5	STA_400	1.583	41.497	STA_1100	1.519	41.431	700.02...	700.0...	20.0	760.7	17.0
6	STA_400	1.580	41.497	STA_150	1.480	44.631	249.99...	249.9...	18.9	760.7	16.9

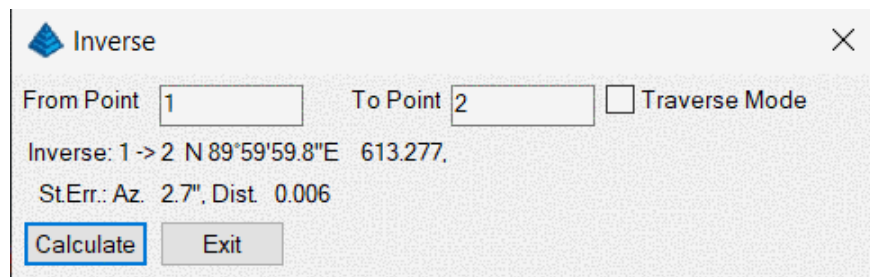

- **From Sta.** - This field represents the station name where the EDM is located. Any name can be used, but you must be consistent and used the same name whenever you occupy or measure a distance to the station.

- **From HI.** - This field represents the height of instrument of the from station. It should be in the same units as the measurements. If horizontal distances are being entered into the grid then all the HI fields should be set to a constant value such as 0.0.
- **From Elev.** - This field represents the elevation of the station. This value is published as part of the baseline calibration sheets obtained from NGS. If horizontal distances, then all the Elevation fields should be set to a constant.
- **To Sta.** - This field represents the station name where the prism is located. Any name can be used, but you must be consistent and used the same name whenever you occupy or measure a distance to the station.
- **To HI.** - This field represents the height of instrument of the to station. It should be in the same units as the distance measurements. If horizontal distances are being entered into the grid, then all the HI fields can be set to a constant value such as 0.0.
- **To Elev.** - This field represents the elevation of the station where the prism is located. This value is published as part of the baseline calibration sheets obtained from NGS. If horizontal distances, then all the Elevation fields should be set to a constant.
- **Observed S. Dist.** - This is the measured slope distance. This can be a measured horizontal distance. If it is a horizontal distance then all the HI's and elevations should be set to a constant value.
- **Published Dist.** - This field represents the published distance between the From and To station. This value is published as part of the baseline calibration data obtained from NGS for the particular baseline being observed.
- **Temp. C. (dry bulb)** - This field is only present if atmospheric corrections are turned on. Provide the dry bulb temperature in degrees Centigrade.
- **Pressure. (mm of Hg)** - This field is only present if atmospheric corrections are turned on. Provide the atmospheric pressure in millimeters of Mercury.
- **Temp. (wet bulb)** - This field is only present if atmospheric corrections are turned on. Provide the wet bulb temperature in degrees Centigrade.

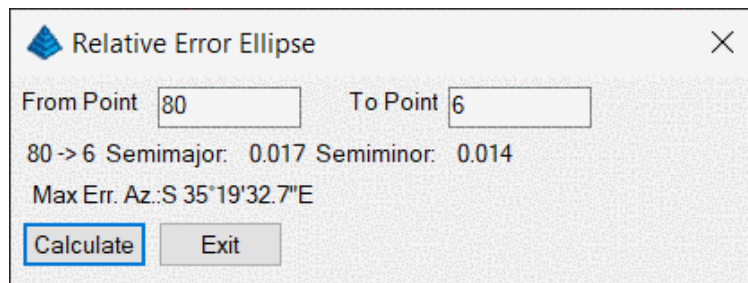

Searches and indicates the location of a point in the drawing file.

The 'Inverse' command is only active after a network has been processed successfully. This option can be used to obtain the bearing and distance between any two points in the network. Additionally the standard deviation of the bearing and distance between the two points is displayed.

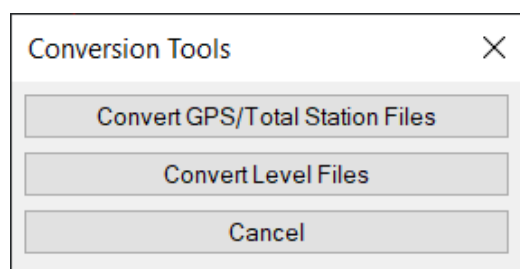

The 'Relative Error Ellipse' command is only active after a network has been processed successfully. This option can be used to obtain the relative error ellipse between two points. It shows the semi-major and semi-minor axis and the azimuth of the error ellipse, computed to a user-define confidence interval. This information can also be used to determine the relative precision between any two points in the network. It is the relative error ellipse calculation that is the basis for the ALTA tolerance reporting. If the Enable sideshots for relative error ellipses toggle is enabled, then all points in the project can be used to compute relative error ellipses. The trade-off is that with large projects, processing time will be increased.

If you need to certify as to the "Positional Tolerances" of your monuments, as per the ALTA Standards, use the **Relative Error Ellipse** inverse routine to determine these values, or use the specific ALTA tolerance reporting as you desire.

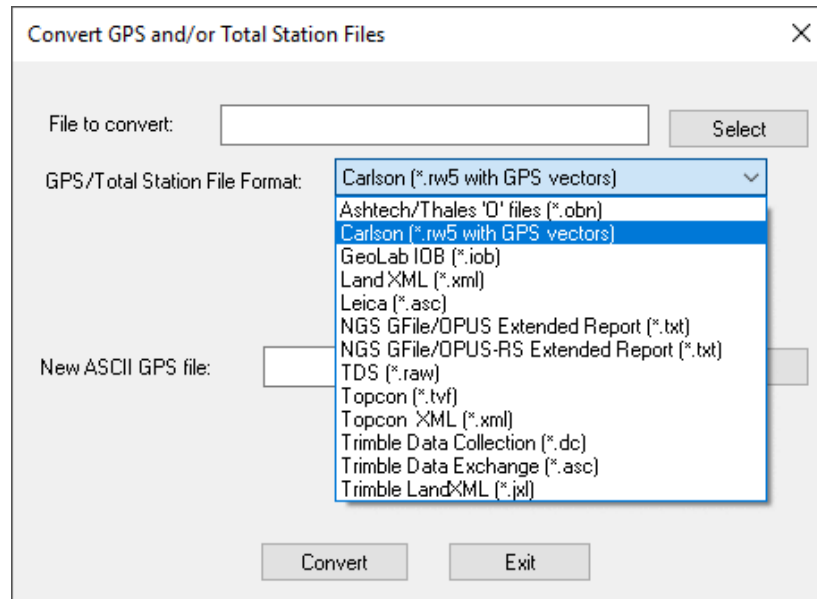

For example, if you must certify that all monuments have a positional tolerance of no more than 0.07 feet with 50 PPM at a 95 percent confidence interval. First set the confidence interval to 95 percent in the Settings/Adjustment screen. Then process the raw data. Then you may inverse between points in as many combinations as you deem necessary and make note of the semi-major axis error values. If none of them are larger than 0.07 feet + (50PPM*distance), you have met the standards. It is however more convenient to create a Relative Error Points File containing the points you wish to check and include the ALTA tolerance report. This report takes into account the PPM and directly tells you if the positional tolerance between the selected points meets the ALTA standards.

Convert GPS/Total Station Files

The purpose of this option is to convert GPS vector files that are in the manufacturers' binary or ASCII format into the StarNet ASCII file format. The advantage of creating an ASCII file is that the ASCII file can be edited using a standard text editor. Being able to edit the vector file may be necessary in order to edit point numbers so that the point numbers in the GPS file match the point numbers in the total station file.

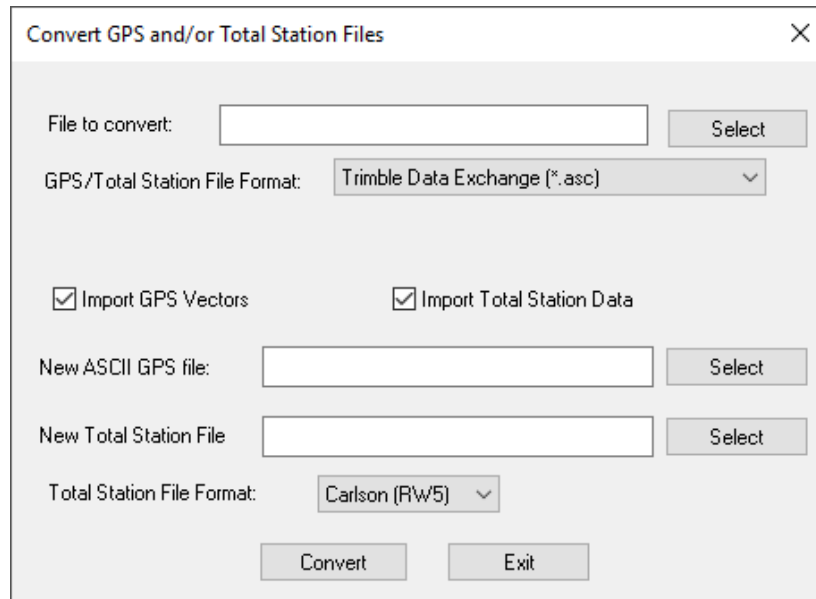

There is also a tool to convert Trimble Data Exchange total station data to either the Carlson RW5 format or the C&G CGR format. The following dialog box is displayed after choosing this option.

First choose the file format of the GPS vector file to be converted. Next use the 'Select' button to navigate to the vector file to be converted. If you are converting a Thales file you have the option to remove the leading 0's from Thales point numbers. Next, use the second 'Select' button to select the name of the new ASCII GPS vector file to be created. Choose the 'Convert' button to initiate the file conversion. Press the 'Cancel' button when you have completed the conversions. The file created will have an extension of .GPS. Following are examples of different GPS formats that can be converted to ASCII:

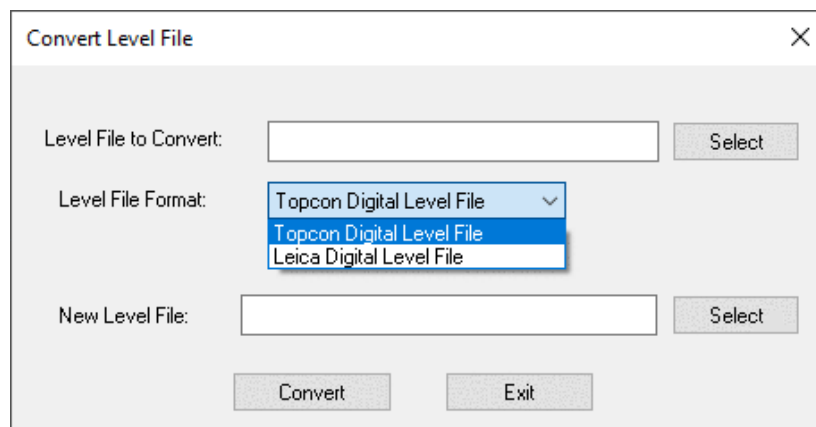

- **Ashtech/Thales 'O' files:** - Typically have .obn extensions and are binary files. Notice that you have the option to remove the leading 0's from Thales point numbers, by checking the "Remove leading 0's from Thales point numbers" check box.
- **Carlson .RW5** - (containing GPS vectors)
- **GeoLab IOB**
- **LandXML (.XML):** - The LandXML format is an industry standard format. Currently SurvNET will only import LandXML survey point records. The conversion will not import LandXML vectors.
- **Leica:** - The Leica vector file is an ASCII format typically created with the Leica SKI software. This format is created by Leica when baseline vectors are required for input into 3rd party adjustment software such as SurvNET. The SKI ASCII Baseline Vector format is an extension of the SKI ASCII Point Coordinate format.
- **NGS G-File:** - National Geodetic Survey format.
- **NGS G-File from OPUS report:** - National Geodetic Survey format as used in the OPUS report
- **TDS (.RAW):** - Import vector records from a TDS raw data file.
- **Topcon (.TVF):** - The Topcon Vector File is in ASCII format and typically has an extension of .TVF
- **Topcon (.XML):** - The Topcon XML file is an ASCII file. It contains the GPS vectors in an XML format. This format is not equivalent to LandXML format.
- **Trimble Data Exchange Format (.ASC):** - The Trimble TDEF format is an ASCII file. It is typically output by Trimble's office software as a means to output GPS vectors for use by 3rd party software.
- **Trimble Data Collection (.dc):** - The Trimble .dc format is an ASCII file. It is typically output by Trimble's data collector. It contains a variety of measurements including GPS vectors. This option only converts GPS vectors found in the .DC file.
- **Trimble LandXML (*.jxl):** This is Trimble's Land XML format.

NOTE:The Trimble Data Collection (.dc) and Trimble LandXML (.jxl) formats allow you to bring in both GPS vectors (creating a .GPS file) and Total Station data (creating a .RW5 file) at the same time.

Convert Level Files

The purpose of this option is to convert differential level files from digital levels into C&G/Carlson differential level file format. At present the only level file format that can be converted are the level files downloaded from the Topcon digital levels.

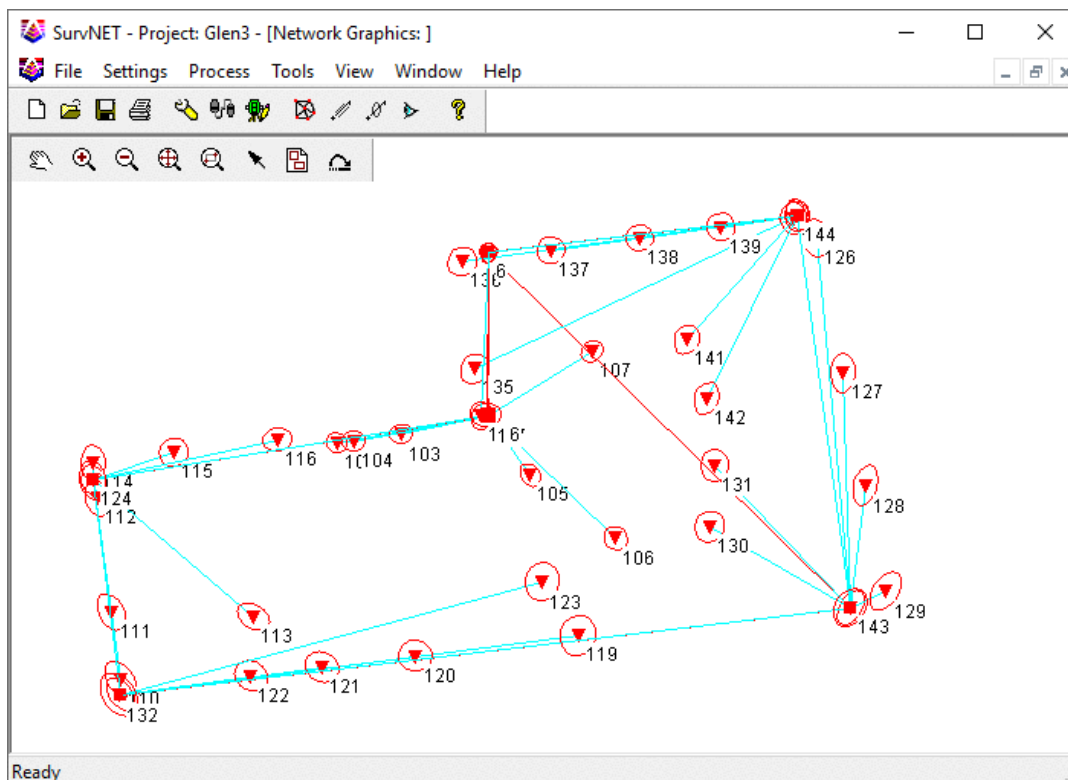

View Menu

Graphics

SurvNET provides a window that graphically displays the survey network. Additionally the user is able to display Error Ellipses, and GPS vectors. The user has much control over how the network is displayed. The graphic tool is a useful tool in debugging networks since the raw data can be displayed prior to adjustment. If there are problems with the raw data the graphics often reflect the problem. The actual graphics cannot be output or saved. The graphics can be shown independent of whether the project has been processed.

The following snapshot shows a view of the graphic window. The graphic window can be accessed using the "eye" icon on the main tool bar. A project must be opened before the graphic window can be displayed. The graphics window will only display Error Ellipses after the project has been processed.

The tool bar in the graphics window contains buttons that allow the user to pan, zoom in, zoom out, zoom extents, and zoom to a window. Additionally there is a button that allows the user to navigate to points in the .CGR raw data editor. Also, there are buttons that will refresh the graphic, and change the graphic settings.

Icon	Friendly Name	Action
	Pan	Use this button to position the graphics to a different position on the display.
	Zoom In	Use this button to increase the magnification of the graphics.
	Zoom Out	Use this button to decrease the magnification of the graphics.
	Zoom Extents	Use this button to fit the content of the entire project into the limits of the available display.
	Zoom Window	Use this button to display the content of the project within the rectangular confines defined by two corner "pick-points".
	Pick Point	This button allows the user to navigate within the (.CGR) Raw File Editor from the graphics window. It also allows you to pick points when creating a Traverse Closure file.
	Graphics Settings	This buttons is used to change the graphic display settings.

This button will refresh the graphic view. Graphics are generated from the saved raw data file. If you make changes to the raw file in the raw editor you must save the project before the changes will be reflected in the refreshed graphic screen.

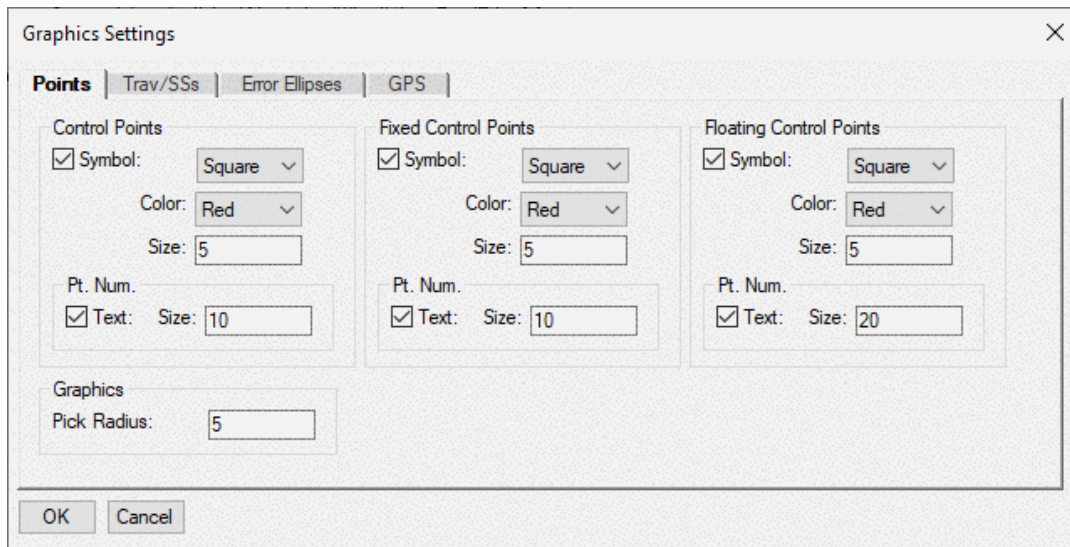

Display Controls

Following is a description of the options in the Graphics Setting dialog box.

Points Options

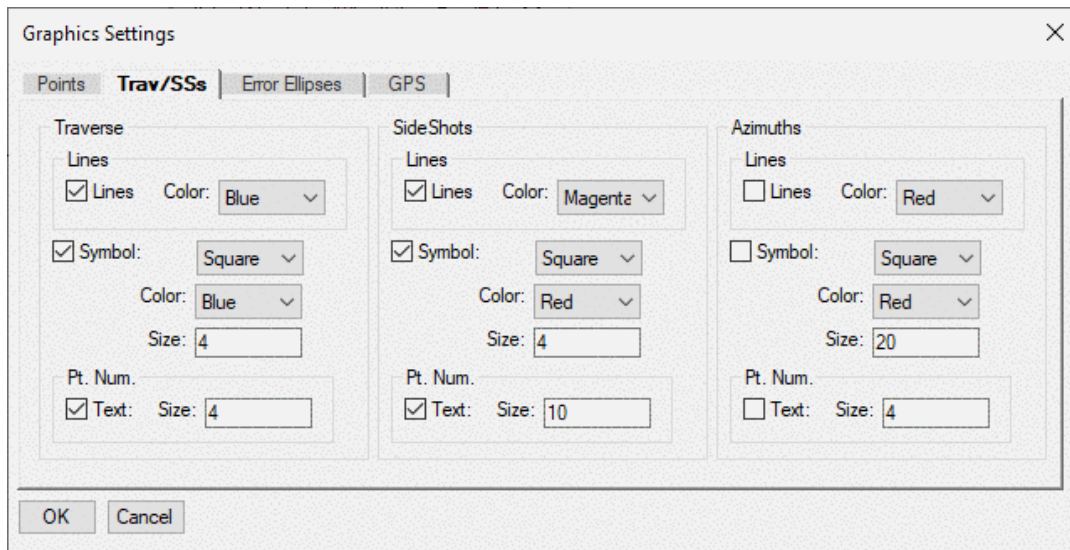

These settings determine how the different type control points are displayed in the graphics window. Different graphic settings can be applied to standard control points, fixed control points and floating control points. The symbol node display can be controlled as to symbol type, symbol color, symbol size. The control point name can be displayed and its size set from this setting dialog box.

The graphic pick radius defines a search radius. This radius is used when navigating the .CGR editor using the graphic window. You can pick a point graphically and the cursor in the editor will go to the next field containing that point number. The radius is defined in terms of the distance units of the raw data file.

Trav/SS's Options

These settings determine how the network line work will be displayed for total station raw data. There are settings for traverse data, side shot data, and azimuth control. The program considers any point that has only a single angle and distance to it a side shot. The user can control the color of the traverse lines. The symbol node display can be controlled as to symbol type, symbol color, symbol size. The point name can be displayed and its size set from this setting dialog box.

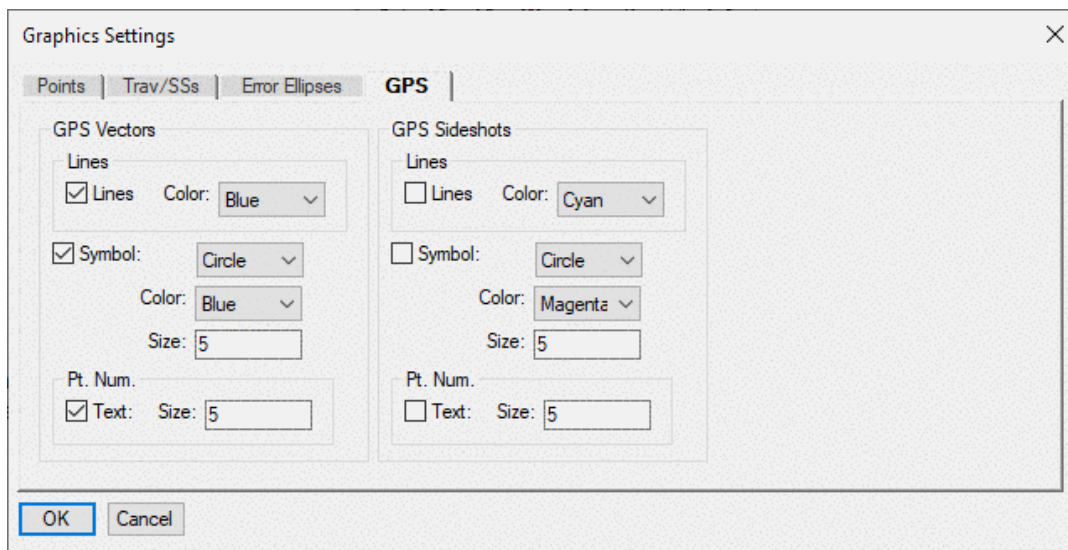

Error Ellipses Options

These settings determine how the error ellipses will be displayed in the graphic window. Error ellipses will only be displayed if there is a successful least squares adjustment. The display of the error ellipses is relative. The program automatically determines a default relative error ellipse size. The user can modify the visual size of the error ellipses using the track bar in the following dialog box. The user can also control the color of the error ellipse from the following dialog box.

GPS Options

The settings in the following dialog box determine how GPS vectors will be displayed in the graphic window. The user can control the color of the GPS vector lines. The symbol node display can be controlled as to symbol type, symbol color, symbol size. The GPS point names can be displayed and their size set from this setting dialog box. GPS side-shots (points defined by a single vector) can be controlled separately.

SurvNET Window Menu

Selecting the **Window** menu opens the following menu:

Menu Command(s)

Menu Image

- Cascade
- Tile
- Close All
- Least Squares Report
- Error Report
- NEZ Report
- Graphics

Window Menu

This command option will cause the open "reports" to cascade in sequence so that their dialog box title bars are most likely visible... permitting you to select the desired window to review the material.

This command option will cause the open "reports" to fit into a tile pattern that fills the SurVNET Window application so that all open windows are simultaneously visible at the same time.

This command option will cause all of the open "reports" close but will leave the SurVNET application (and the SurVNET project) open. To re-open the report(s), either select the desired report from the Window menu or perform a Network Adjustment.

This option opens/displays the Least Squares report.

This option opens/displays the Error report.

This option opens/displays the NEZ (Northing, Easting, Elevation) report.

This option opens/displays the Graphic result of the network.

Toolbars

Many of the more commonly used functions can be accessed using the toolbar:

Icon	Menu Location	Action
	File – New Project	Creates a New Project.
	File – Open Project	Opens an Existing Project.
	File – Save Project	Saves the Current Project.
	File – Print	Prints the Specified Output.
	Settings – Project Settings – Standard Errors	This icon initiates the Project Settings – Standard Errors tab.
	Tools – Data Collector Transfer	[Legacy Application] - This icon will initiate either the specified "handshaking" program designed to communicate with numerous field collection data collection devices thus permitting the user to directly transfer data from the field device into SurvNET (and vice versa).
	Tools – Edit Raw Files	This icon can be used to review or edit your raw data file(s). If your project has multiple raw data files, you will be shown a list and asked to select the file you wish to edit.
	Process – Network Adjustment	This icon will process the available data against the specified Project Settings and displays any pertinent results or alerts.
	Tools – Inverse	This icon will provide the ability to inverse between a pair of specified points (once the network has been adjusted) to get the angle and distance information between the specified points.
	Tools – Relative Error Ellipse	This icon will provide the ability to generate the Relative Error Ellipse information between a pair of specified points (once the network has been adjusted).
	Window – Graphics	This icon is active once a project has been opened and displays the graphical results (if any) of the traverse, sideshot(s) and GPS points.
	Help – SurvNET Help	This icon will take you to the SurvNET Help/on-line documentation.

SurvNET Toolbar Short-cuts

Raw Traverse Data

SurvNET works equally well for both Carlson users and C&G users. The primary difference between the two users is that a Carlson user will typically be using an .RW5 file for raw data and a C&G user will typically be using a .CGR file.

SurvNET is capable of processing either C&G (.CGR) raw data files, Carlson (.RW5) raw data files or SDMS (.PRJ) raw data files. If the raw data is in another format, you can use our conversion tools to create one of the supported formats. Select the desired type of raw file editor as described under Settings – Global Settings.

Measurement, coordinate, elevation and direction (Brg/Az) records are all recognized. Scale factor records in the .CGR file are not processed since SurvNET calculates the State Plane scale factors automatically.

Once raw data is entered, the network can be processed. Often it is desired to apply a standard error for a particular measurement or control point that is different than those set in the Project Settings. This can be accomplished by editing the Standard Errors of specific or groups of points or measurements.

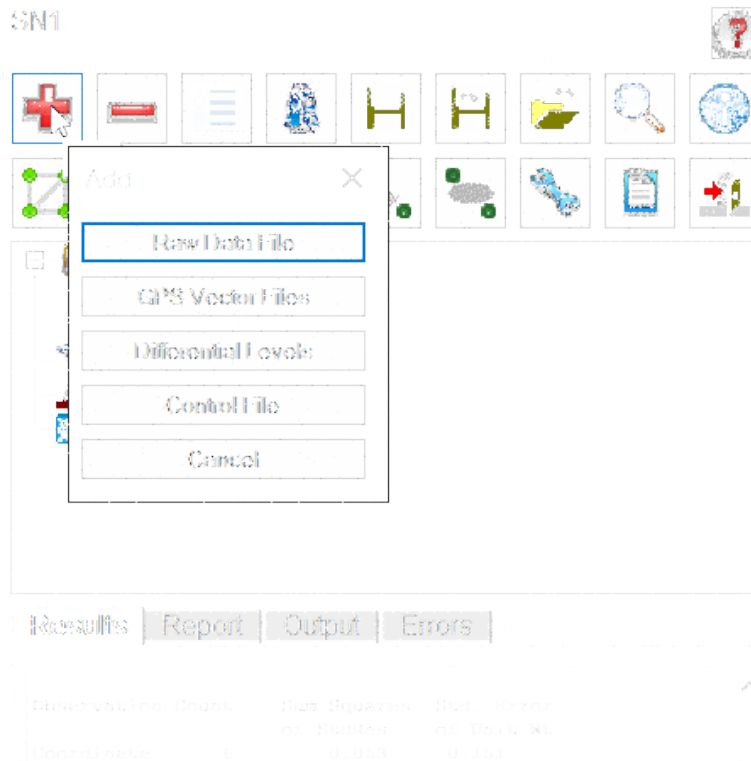

There are four types of Raw Data Files files you can add and process as part of a single network:

Raw Data File - traditional total station files (usually ground measurements)

GPS Vector File - GPS observations in the form of vector data

Differential Levels - standard differential level or Trig observations for vertical control

Control File - point records to be used as control for the network.

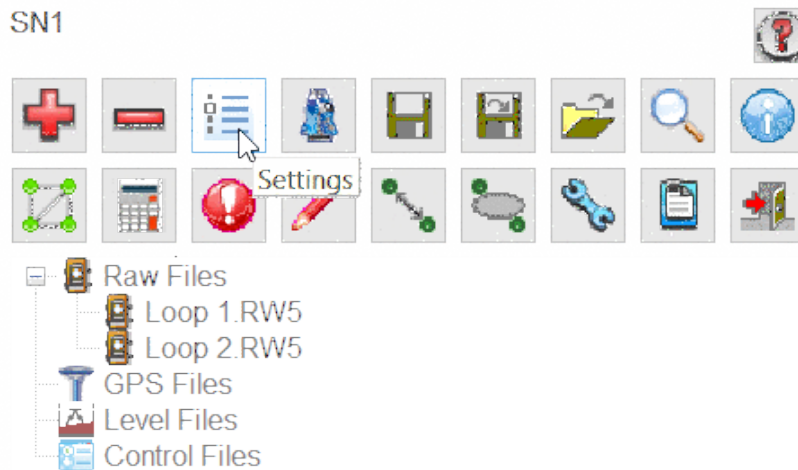

Raw Data File

To process traverse raw data, click the **Add** (red + button) and select the **Raw Data File** to insert raw total station files into the list. Use **Remove** (red - button) to remove raw files from the list. All the files in this list are included in the Least Squares adjustments. Having the ability to choose multiple files allows one to keep Control in one file and measurements in another file. Or, different files collected at different times can be processed all at one time. If you have multiple crews working on the same project using different equipment, you can have "crew-specific" raw data files with standard error settings for their particular equipment. Having separate data files is also a convenient method of working with large projects. It is often easier to debug and process individual raw files. Once the individual files are processing correctly, all the files can be included for a final adjustment. You can either enter C&G (.CGR) raw files or Carlson (.RW5) files into the list for processing. You cannot have both .CGR and .RW5 files in the same project to be processed at the same time. Notice that you have the ability to highlight multiple files when removing files from the project.

Note that if you are processing Carlson RW5 total station files, you have the option of including GPS vectors that

can be collected by SurvCE/SurvPC and stored in the RW5 file. Alternatively, you can select the RW5 file in the GPS vector section. **If the "Include any GPS vectors" option in the Total Station Data Files section is checked, you will have the option to use the Base Point records in the RW5 file as control.** If "Use BP records as control" is NOT checked, or the RW5 file is selected in the GPS vector section, you must define the control in either the RW5 file as POINT records or in a Supplemental Control File.

To set these options, select the **Settings** option from the main menu.

GPS Vector Files

GPS vector files can be entered and processed. Both GPS vector files and total station raw files can be combined and processed together. **You must have chosen the 3D mathematical model in the Coordinate System tab in order to include GPS vectors in the adjustment.**

A variety of popular GPS vector file formats are supported, including (but not necessarily limited to):

- **ASCII (StarNet):** See below for more information on *StarNet* format. These files typically have .GPS extensions.
- **Ashtech/Thales 'O' files:** Typically have .obn extensions and are binary files.
- **Carlson .RW5:** (containing GPS vectors)
- **GeoLab IOB**
- **LandXML (*.xml)**
- **Leica:** Leica files are ASCII files.
- **NGS G-File**
- **NGS G-File from OPUS report**
- **Topcon (.tvf):** Topcon .tvf files are ASCII files.
- **Topcon (.xml):** Topcon also can output their GPS vectors in XML format which is in ASCII format.
- **TDS (.raw):** TDS raw data file with vector information
- **Trimble Data Exchange Format (.asc):** These files are in ASCII format
- **Trimble data collection (.dc):** These files are ASCII.
- **Trimble LandXML (*.jxl)**

The following is a typical vector record in the StarNet ASCII format. GPS vectors typically consist of the 'from' and 'to' point number, the delta X, delta Y, delta Z values from the 'from' and 'to' point, with the XYZ deltas being

in the geocentric coordinate system. Additionally the variance/covariance values of the delta XYZ's are included in the vector file.

```
.GPS WEIGHT COVARIANCE
C PRS34452 1305780.345005 -4667085.299019 4132689.544939 0.005000 0.005000 0.005000 --MON
C UCNJ 1305780.345005 -4667085.299019 4132689.544939 0.00000100 0.00000100 0.00000100 --MON
G1 UCNJ-1000 8399.71318061 -4742.15645068 -8036.07224424 --MNS
G2 3.939428e-006 2.474560e-005 1.160301e-005
G3 3.924536e-006 -3.360765e-006 -1.028503e-006
G1 UCNJ-1001 8328.15569476 -4796.59445569 -8072.25948922 --MNS
G2 9.596618e-007 1.687749e-005 1.936038e-006
G3 1.176891e-007 -8.668020e-009 -4.798408e-006
```

The first line defines what values are in the G2 and G3 records. It can be either GPS WEIGHT COVARIANCE (G2 is Variance, G3 is Covariance), or GPS WEIGHT STDERRCORRELATION (G2 is standard error, G3 is standard error correlation). This line is optional; the default is COVARIANCE.

The next two lines are coordinate control records. These records are also optional. If used, they must be Geocentric Coordinates (XYZ) in metric units. The format is as follows:

```
C PointName X Y Z StdErrX StdErrY StdErrZ --PointDescription
```

The standard errors and point description are optional.

The GO record is a comment.

The G1 record includes the 'from' and 'to' points and the delta X, delta Y, and delta Z in the geocentric coordinate system and an optional description of the rover point.

The G2 record is the variance (or standard error) of X,Y, and Z. The G3 record contains the covariance (or standard error correlation) of XY, ZX, and ZY. Most all GPS vector files contain the same data fields in different formats.

Use the 'Add' button to insert GPS vector files into the list. Use the 'Remove' button to remove GPS vector files from the list. All the files in this list will be used in the least squares adjustments. All the GPS files in the list must be in the same format. If the GPS file format is ASCII you have the option to edit the GPS vector files. The Edit option allows the editing of any of the ASCII GPS files using Notepad. Typically, only point numbers or point descriptions would be edited. The variance/covariance values are used to determine the weights that the GPS vectors will receive during the adjustment and are not typically edited.

Differential Levels

Differential and Trig level files can be entered and processed. Differential or Trig Level raw files have a .TLV extension and are created using the Carlson Level Editor (**See Edit Process Level Data in the Survey Menu**). The Carlson Level Editor has several Import options that allow you to bring in levels from different formats (*e.g.* Leica, Trimble, Topcon, *etc.*). You can process level data in the same project with the traverse and GPS vector data but the vertical measurements in the traverse/vectors will be part of the adjustment. If you want to use the elevations calculated ONLY from the level data, you must process it in a separate project after your traverse/vector data has been adjusted. The elevations will be written to the Output Coordinate file. Make sure your point numbers in the level data match the points in the traverse/vector data.

Supplemental Control File: The supplemental control file option allows the user to designate an additional coordinate file to be used as Control. The supplemental control file can be from a variety of different file types, including (but not necessarily limited to):

- **C&G or Carlson numeric (.CRD) files**
- **C&G Alphanumeric coordinate files (*.cgc)**
- **Carlson Alphanumeric coordinate files (*.crd)**
- **Autodesk Land Desktop (*.mdb)**
- **Simplicity coordinate files (*.zak)**
- **ASCII (.NEZ) file**
- **ASCII latitude and longitude (3D model only)**

- **CSV ASCII NEZ with std. errors** (only external control file that allows you to assign standard errors to specific points)
- **SDMS (.ctl) control file**
- **ASCII Geocentric (.xyz)** (Geocentric coordinates XYZ in metric units)

Note: For additional information on file format pertaining to the file formats above, refer to the Supplemental Control Files section of the documentation.

Note: You will not be allowed to use the same file for supplemental control points and for final output. Least Squares considers all points to be measurements. If the output file is also used as a supplemental control file, then after the project has been processed all the points in the project would now be in the control file and all the points in the file would now be considered control points if the project was processed again. The simplest and most straight-forward method to define control for a project is to include the control coordinates in a raw data file.

Supplemental Control Files

In order to process a raw data file, you must have (as a minimum) a control point and a control azimuth, or two control points. Control points can be inserted into the raw data file or alternately control points can be read from a coordinate file as linked via the Input Files portion of the program.

The major advantage of putting coordinate control points in the actual raw data file is that specific standard errors can be assigned to each control point (as described in the Control Standard Errors section above). If you do not include an SE record, the standard error will be assigned from the NORTH, EAST, and ELEVATION standard errors from the Control Standard Error project default values found in the Project Settings dialog box.

The standard errors for the control points from a supplemental control file will be assigned the NORTH and EAST standard errors from the project settings dialog box.

In the ASCII .NEZ file, the coordinate records need to be in the following format:

```
Pt. No., Northing, Easting, Elevation, Description<cr><lf>
103, 123233.23491, 238477.28654, 923.456, Mon 56-7B<CR><LF>
```

Each line is terminated with the "non-printing" carriage-return <CR> and line-feed <LF> characters. When viewed in a simple ASCII file editor such as Windows Notepad, the file snippet above would resemble:

```
Pt. No., Northing, Easting, Elevation, Description
103, 123233.23491, 238477.28654, 923.456, Mon 56-7B
```

In the ASCII latitude and longitude file, the records need to be in the following format:

```
Pt. No., Latitude (NDDD.mmsssss), Longitude (WDDD.mmsssss), Elevation (Orthometric), Description<cr><lf>
FRKN,N35.113068642,W083.234174724,649.27<CR><LF>
```

Each line is terminated with the "non-printing" carriage-return <CR> and line-feed <LF> characters. When viewed in a simple ASCII file editor such as Windows Notepad, the file snippet above would resemble:

```
Pt. No., Latitude (NDDD.mmsssss), Longitude (WDDD.mmsssss), Elevation (Orthometric), Description
FRKN,N35.113068642,W083.234174724,649.27
```

In the ASCII XYZ Geocentric file, the records need to be in the following format:

```
Pt. No. X Y Z Descriptions<cr><lf>
105 1413426.6020 -4537671.2000 4239299.9360 MON<CR><LF>
```

Each line is terminated with the "non-printing" carriage-return <CR> and line-feed <LF> characters. When viewed in a simple ASCII file editor such as Windows Notepad, the file snippet above would resemble:

```
Pt. No. X Y Z Descriptions
105 1413426.6020 -4537671.2000 4239299.9360 MON
```

NOTE: It is not allowed for the supplemental control file and the final output file to be the same file. Since Least Squares considers all points to be control points, only control points should be in a supplemental control file.

Once raw data files are added to the network it can be adjusted using the parameters as set in the Project Settings. In many instances, there will be a need to assign specific standard errors for particular measurements or control points. This can be accomplished by editing individual points or measurements or by assigning a standard error to a particular raw data file.

Standard errors are estimated errors that are assigned to measurements or coordinates. A standard error is an estimate of the standard deviation of a sample. A higher standard error indicates a less accurate measurement. The higher the standard error of a measurement, the less weight it will have in the adjustment process.

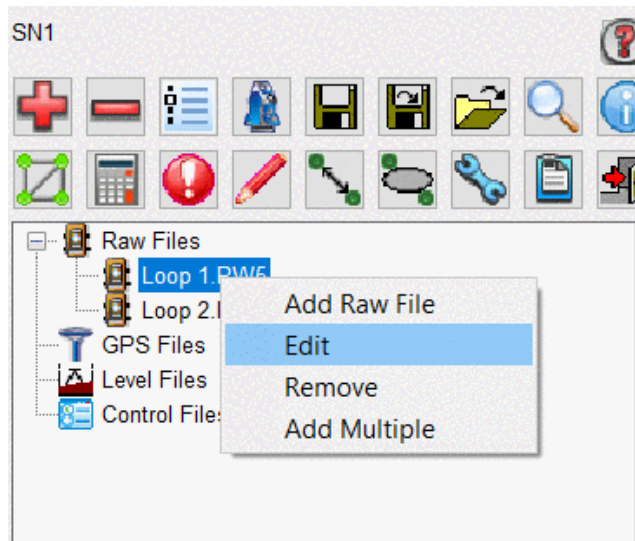

Although you can set default standard errors for the various types of measurements in the Project Settings of SurvNET, standard errors can also be placed directly into the raw data file. A standard error record inserted into a raw data file applies to all the measurements following the **SE** record. The standard error does not change until another SE record is inserted that either changes the specific standard error, or sets the standard errors back to the project defaults. The advantage of entering standard errors into the raw file is that you can have different standard errors for the same type measurement in the same job.

For example, if you used a 1" total station with fixed backsights and foresights for a portion of a traverse and a 10" total station with backsights and foresights to hand-held prisms on the other portion of the traverse, you would want to assign different standard errors to reflect the different methods used to collect the data.

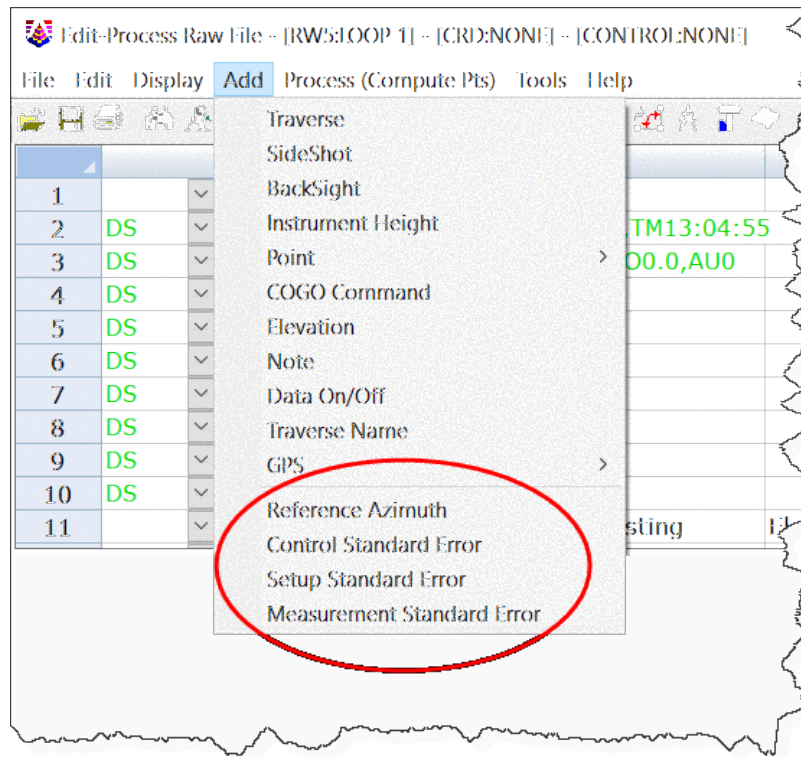

Make sure the SE record is placed before the measurements for which it applies. If you do not have standard errors defined in the raw data file, the default standard errors in the project settings will be applied to the entire file.

Editing Standard Errors

The dialog box option allows users to edit raw field data directly through a the typical Carlson data Editor by selecting a raw file and *right-clicking*:

Carlson Raw Data Editor

Note, editing standard errors in the Carlson Data Editor is described more fully in the **Standalone** version of this help menu.

Graphic CAD Editor

With the dialog box editor, users can review and edit information for points, vectors and measurement lines by

selecting the information button  or by double-clicking any entity.

Select any a graphic entity such as a traverse line or control point and *double-click* on it.

Line: 2 to 3

OK Cancel Edit Measurement Errors Edit Setup Errors Edit Raw File

CSE - Control Standard Errors

You can insert or add Control Standard Error records for a specific point by double-clicking on a control point and selecting **Control Standard Error**

Control Point

Point 1 at N: 5000.000, E: 5000.002

Pt	Northing	Easting	Elevation	Description	Control Error	File	Line
1	5000.00000	5000.00000	100.00000	dh/in vgc thro:Default		D:\Carlson Files\Support\10	

OK Cancel Edit Control Errors Edit Raw File

You can set standard errors for Northing, Easting, Elevation, and Azimuth selecting the **Edit Control Errors** option. Azimuth standard errors are entered in seconds. The North, East and Elevation standard errors affect the PT (coordinate) and EL (elevation) records.

Control Standard Errors

*=Project Settings Default
 !=Fixed
 #=Float

Northing

Easting

Elevation

Azimuth(sec)

OK Cancel

You can hold the North, East and Elevation fixed by entering an exclamation "!" symbol. You can allow the North, East and Elevation to FLOAT by entering a hash (or "pound") "#" symbol. You can also assign the North, East and Elevation actual values. If you use an asterix "*" symbol, the current standard error value will return to the control standard error project defaults.

North	East	Elevation	Azim	
!	!	!		(Fix all values)
#	#	#	30.0	(Allow the N., E. & Elevation to Float)
0.01	0.01	0.03	5.0	(assign values)
*	*	*	*	(return the control standard errors back to project defaults)

When you fix a coordinate point, the original value does not change during the adjustment and all measurements will be adjusted to fit the fixed point. If you allow a value to float, it will not be used in the actual adjustment, it will just be used to help calculate the initial coordinate values required for the adjustment process. Placing a very high or low standard error on a coordinate point accomplishes almost the same thing as setting the standard error as float or fixed. The primary purpose of using a float point is if SurvNET cannot compute preliminary values, a preliminary float value can be computed and entered for the point.

Direction records cannot be FIXED or FLOAT. You can assign a low standard error (or zero to fix) if you want to weight it heavily, or a high standard error to allow it to float.

In the example below, the first CSE record containing the '!' character and sets points 103, 204, and 306 to be fixed. The last CSE record contains the '*' character. It sets the standard errors for point 478 and any other points that follow to the project settings. The Azimuth standard error was left blank.

MSE - Measurement Standard Errors

You can set the standard errors for various types of measurements for a specific measurement by *double-clicking* on a drawing entity (line or point) and selecting **Edit Measurement Errors**

	BsPt	OcPt	FsPt	Code	HorzAngle	SlopeDist	ZenithAng	InstHt	RodHt	Description	MeasureErr	SetupErr	File	Line
1	4	5	6	AR	348.1209	492.842	90.0829	5.150	4.770	spk	Default	Default	D:\Carlson f214

Instrument Height

OK Cancel

Example:

	Rod Ctr	Inst Ctr	Inst Ht	Rod Hgt
SSE	0.005	0.005	0.01	0.01

You can enter any combination of the above values. If you do not want to change the standard error for a particular measurement type, leave it blank.

If you use an "*" symbol, it will return the standard error to the Instrument and Target Standard Errors project default values.

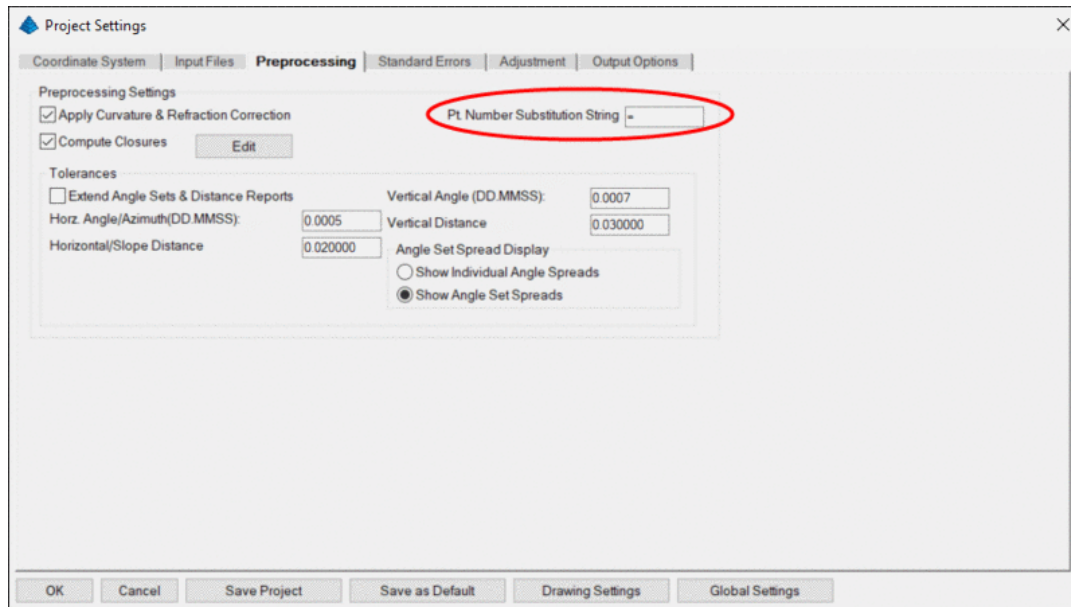

Redundant Measurements

One of the benefits of SurvNET is the ability to process redundant measurements. In terms of total station data, redundant measurement is defined as measuring angles and/or distances to the same point from two or more different

setups.

It is required that the **same point number** be used when locating a point that was previously recorded. However, since some data collectors will not allow you to use the same point number if the point already exists, SurvNET also uses the following convention for collecting redundant points while collecting the data in the field:

If the point description contains a user-defined string, for example an "=" (equal sign) followed by the original point number, SurvNET will treat that measurement as a redundant measurement to the point defined in the description field. The user-defined character or string is set in the Project Settings dialog. For example, if point number 56 has the description "=12", we will treat it as a measurement to point 12 and point 56 will not exist. Make sure the *Preprocessing Settings* dialog box has the **Pt. Number Substitution String** set to the appropriate value.

Alternately, the point numbers can be edited after the raw data has been downloaded from the data collector.

SurvNET Editor

Please refer to topic on Carlson or CGEditor raw editor.

Data Collector Transfer

Please refer to the Carlson or CG data collector transfer topic.

Example Projects

On the installation disk there are a variety of different least squares projects one can use to become familiar with least squares and SurvNET. These projects are located in the SurvNET Examples folder under the Carlson Projects folder (e.g. C:\Carlson Projects\SurvNET Examples).

NOTE: When you open a project for review, you will need to check the project settings, input data files to see if the paths are correct. If they do not, you will have to re-select them.

Simple Traverse with Traverse Closure

This project is located in \Carlson Projects\SurvNET Examples\2DTraverse. The name of the project is Traverse. This project illustrated a basic loop traverse with two control points and a known azimuth for control. This project also illustrates how to obtain traditional closure information as part of the least squares report. The program uses the 2D/1D model and uses a local coordinate system.

Traverse using State Plane Coordinates

This project is located in \Carlson Projects\SurvNET Examples\SPCTraverse. The name of the project is Trav01SPCUSft. This project illustrated a basic network with three GPS control points for control. This project is computed using the **SPC83 NC Grid** coordinate system. The project is set up to generate traditional loop closure data. The program uses the 2D/1D model. No elevations are computed or adjusted as there were no HI's or rod readings collected. Notice, that the project uses two raw data files. One file contains the raw angle & distance data. The other raw data file contains the control for the project.

Network with ALTA Reporting

The ALTA reporting project is located in \Carlson Projects\SurvNET Examples\ALTARpt. The name of the project is ALTARpt. This project illustrates how to perform ALTA tolerance testing on points within a network.

GPS Network with GPS Loop Closures

The GPS network project is located in \Carlson Projects\SurvNET Examples\GPSNetwork. The name of the project is GPSOnly. This project is a simple GPS network. In addition to the least squares computation and report, GPS loop closures were generated for various GPS loops for this project.

Level Network

The differential leveling project is located in \Carlson Projects\SurvNET Examples\LevelNetwork. The name of the project is network1. This project is a simple differential leveling network.

Basic 3D Project

The basic 3D adjustment project is located in \Carlson Projects\SurvNET Examples\3DNetwork. The name of the project is pg08. This project is a simple four point example network. Notice in the raw data that all set up records have an HI and all FS readings have valid rod heights. Also note that there are valid vertical angles for every slope distance. Since the 3D model is a true one process 3-dimensional adjustment, you must enter all valid slope distances and vertical angles. Be aware that you cannot just enter a horizontal distance and a vertical angle of 90 from reduced field notes when adjusting using the 3D model.

3D Project Combining Total Station and GPS Vectors

The total station raw data combined with GPS vectors example is located in \Carlson Projects\SurvNET Examples\GPSandTtlSta. The name of the project is GPSandTS. This project illustrates a 3D model adjustment that combines both GPS vectors and data from a total station. Since there is GPS data the 3D model must be used. Notice that the GPS vectors are in meters but the total station data is in US feet and the output coordinates are in US feet. Always make sure your units are correct for each data type, especially when using the 3D model.

Resection

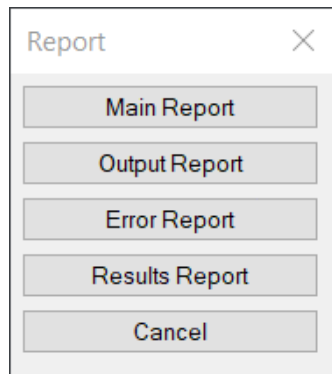

The total station raw data combined with GPS vectors example is located in \Carlson Projects\SurvNET Examples\Resection. The name of the project is ResectRaw. This project illustrates an angle and distance resection. There is no real difference in a resection project than any other angle and distance network in terms of how the data is collected or how the project is set up.

Network Processing Reports

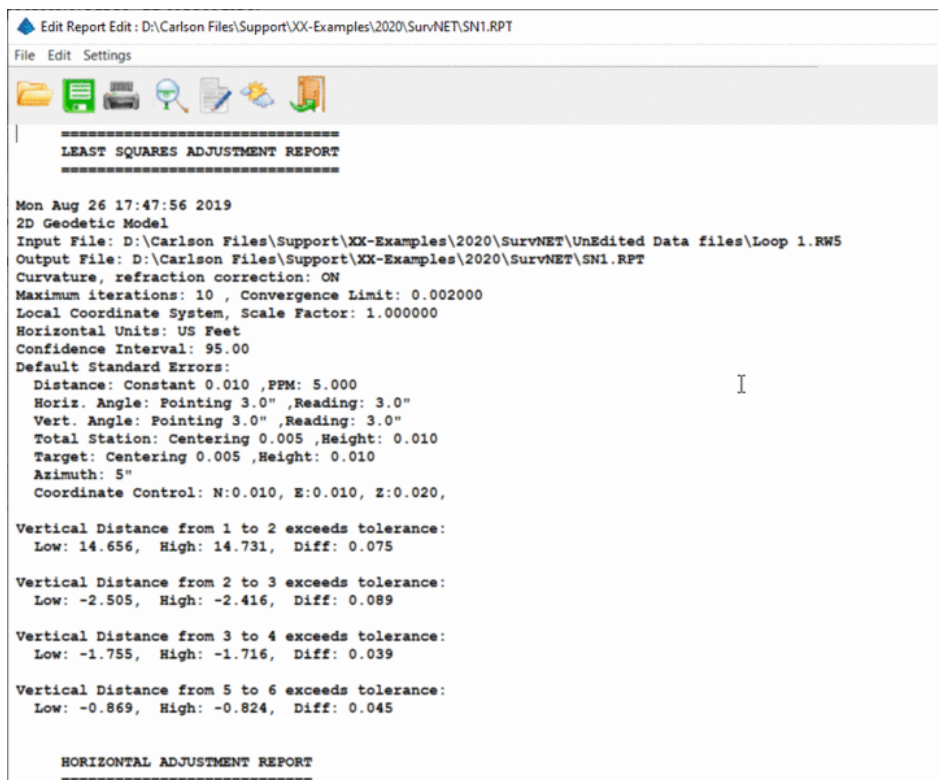

Report File: A report file consisting of the project name with an .RPT extension is generated after successfully processing the raw data. The report file will be shown in a text window so you can analyze the data.

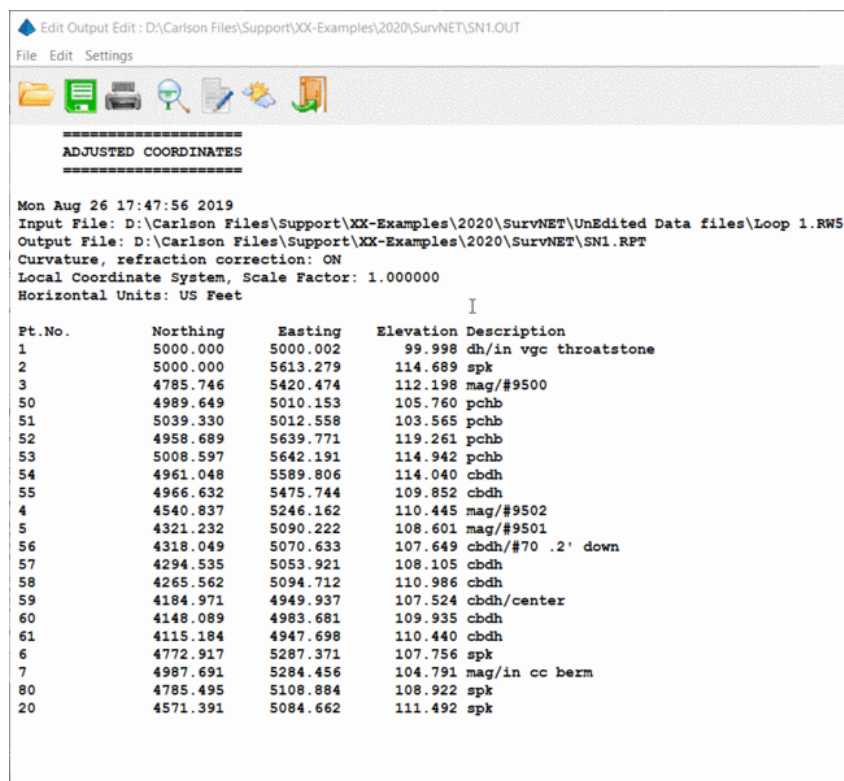

By clicking on the **Report** button, you will see several options for available reports.

This report contains essentially all of the data analysis of the network, errors, horizontal and vertical adjustments, data statistics, the optional ALTA report and the results of the chi square test are all included.

This report contains final adjusted coordinates from the network based on the options made in the Project Settings.

This report contains essential information about measurements that exceed the tolerances of standard errors set in

the Project Settings. It also contains information such as Point Aliases and traverse closure, if selected.

2D-1D Local Coordinate System

The following explanations should be used in conjunction with the report at the end of the explanatory text. The report is shown in a tabbed window.

Project Settings

The first section of the report displays the project settings at the time the project was processed.

Tolerances

The second section of the report displays warning and error messages generated during the preprocessing of the raw data. The primary messages displayed will be warnings when multiple angles, horizontal distances, and vertical differences exceed the tolerance settings as set in the project settings. The low and high measurement and the difference are displayed. It is prudent to pay attention to any messages generated in this section of the report. Some warnings may be innocuous but it is prudent to check and understand all warning messages.

The next four sections list the reduced and averaged, but unadjusted measurements that make up the network. Multiple measurements of the same angle or distance are averaged to a single measurement. The standard error of multiple averaged measurements is less than the standard error of a single measurement. When multiple measurements are used, the standard error for the averaged measurement will be computed using the average of the mean formula.

The first of the four sections lists the control coordinates used in the network adjustment. These coordinates could have been read from the .CGR raw data file, or from the .CRD or .NEZ supplemental coordinate file. Notice that the standard errors for the control points are displayed.

The second of the four measurement sections shows the control reference azimuths and azimuth standard errors used in the adjustment. Azimuths are defined in the .CGR or RW5 files (Add->Reference Azimuth).

The third of the four measurement sections shows the distances and distance standard errors used in the adjustment. These distances are horizontal distances computed from all slope distance and vertical angles for that distance, including all foresight and backsight distances. The standard error settings used to calculate the final distance standard error include the distance standard error, the PPM standard error, the target centering standard error and the instrument centering standard errors. The techniques and formulas used to calculate the final distance standard error are found in section 6.12 of the textbook "Adjustment Computations, Statistics and Least Squares in Surveying and GIS", by Paul Wolf and Charles Ghilani (Wolf, Paul, and Charles Ghilani. *Adjustment Computations, Statistics and Least Squares in Surveying and GIS*. John Wiley & Sons, 1997).

The fourth of the four measurement sections shows the angles and angle standard errors used in the adjustment. These angles are the averaged angle value for all the multiple angles collected. The standard error settings used to calculate the final angle standard error include the pointing standard error, the reading standard error, the target centering standard error and the instrument centering standard errors. The techniques and formulas used to calculate the final angle standard error are found in section 6.2 of the textbook "Adjustment Computations, Statistics and Least Squares in Surveying and GIS", by Paul Wolf and Charles Ghilani (Wolf, Paul, and Charles Ghilani. *Adjustment Computations, Statistics and Least Squares in Surveying and GIS*. John Wiley & Sons, 1997).

If you have a Traverse Closure file selected, there will be a fifth section in the Unadjusted Observations section which shows the error of closure report.

If the adjustment of the network converges the next section displays a list of the final adjusted coordinates and the computed standard X, Y standard error. An interpretation of the meaning of the X, Y standard error, is that there is a 68% probability that the adjusted X, Y is within plus or minus the standard error of the X, Y of its true value.

Also shown are the Delta N, Delta E and Delta EL values of the non-fixed control points (how much the control points moved).

The next section displays the error ellipses for the adjusted coordinates. The error ellipse is a truer representation of the error of the point than the X, Y standard error. The error ellipses are calculated to the confidence interval as defined in the settings screen. In this report the error ellipse axis is larger than the X, Y standard errors since the error ellipses in this report are calculated at a 95% probability level as set in the Settings screens. The maximum error axis direction is along the axis of the semi-major axis. The direction of the minimum error axis direction is

along the semi-minor axis and is perpendicular to the semi-major axis. If a point is located from a variety of stations, you will most likely see that the error ellipse will approach a circle, which is the strongest geometric shape.

The next three sections list the adjusted horizontal distance, horizontal angle, and azimuth measurements. In addition to the adjusted measurement the, residual, the standard residual and the standard deviation of the adjusted measurement is displayed.

The **residual** is defined as the difference between the unadjusted measurement and the adjusted measurement. The residual is one of the most useful and intuitive measures displayed in the report. Large residuals in relation to the standards of the survey are indications of problems with the data.

The standard residual is the *a priori* standard error divided by the residual of a measurement. The *a priori* standard errors are the standard errors of the measurements as displayed in the unadjusted measurement section. A standard residual of 1 indicates that the adjustment applied to the measurement is consistent with the expected adjustment to the measurement. One or a few measurements having high standard residuals, in relation to the rest of the standard residuals, may be an indication of a blunder in the survey. When all standard residuals are consistently large there is likely an inconsistency in the a priori standard errors and the adjustments being made to the measurements. In other words the standard errors defined for the project are too small, in relation to the survey methods used.

The standard deviation of the measurement means that there is a 68% probability that the adjusted measurement is within plus or minus the standard deviation of the measurement's true value.

Additionally, the root mean square of each measurement type is displayed. The root mean square is defined as the square root of the average of the squares of a set of numbers. Loosely defined, it is as an average residual for that measurement type.

Statistics

The next section displays some statistical measures of the adjustment including the number of iterations needed for the solution to converge, the degrees of freedom of the network, the Error Factor for each type of measurement, the standard error of unit weight, the reference variance and the results of a Chi²; (Chi-square) test.

- **Degrees of Freedom** - The degree of freedom is an indication of how many redundant measurements are in the survey. Degree of freedom is defined as the number of measurements in excess of the number of measurements necessary to solve the network. The higher the DOF the more meaningful the statistics are.
- **Standard Error** - The possible measurement types are:
 - Coordinates (control points - in the 2D/1D model each point counts as 2 measurements (N & E); in the 3D model each point counts as 3 measurements (N, E, & EL))
 - Elevations (elevation control - from elevation records in the raw data file)
 - Azimuths (azimuth control - from reference azimuth records in the raw data file)
 - Angles (horizontal angles)
 - Distances (horizontal in 2D/1D model and mark-to-mark in 3D model)
 - Vertical Angles (mark-to-mark, 3D model only)
 - GPS Vectors (3D model only)

The total standard error of unit weight relates to the overall adjustment and not an individual measurement. A value of one indicates that the results of the adjustment are consistent with *a priori* standard errors. The total standard error of unit weight equals the sum of all the measurement standard errors of unit weight.

- **Reference Variance** - The reference variance is the standard error of unit weight squared.
- **Chi²; Test** - The Chi²; (Chi-square) test is a test of the "goodness" of fit of the adjustment. It is not an absolute test of the accuracy of the survey. The a priori standard errors which are defined in the project settings dialog box or with the SE record in the raw data (.RW5 or .CGR) file are used to determine the weights of the measurements. These standard errors can also be looked at as an estimate of how accurately the measurements were made. The chi-square test merely tests whether the results of the adjusted measurements are consistent with the a priori standard errors. **Notice that if you change the project standard errors and then reprocess the survey, the results of the chi-square test change... even though the final adjusted coordinates may change very little.**

If the project passes the Chi Square test, the expansion factor used to calculate the confidence regions (error ellipses at say 95% confidence) will be taken from the normal distribution table. If the project fails the Chi Square test, the expansion factors will be taken from the F-Distribution table:

All confidence regions were computed using the following factors:

Variance factor: 1.0000

1-D Expansion Factor: 1.9600

2-D Expansion Factor: 2.4477

Expansion factors for 95.00 confidence regions taken from normal distribution table

The next section displays the computed sideshots of the network. Sideshots are filtered out of the network adjustment as part of the preprocessing process if the Enable Sideshots for Relative Error Ellipses toggle is off. Least squares adjustment requires a lot of computer resources. Sideshots are filtered out to minimize the computer resources needed in a large network adjustment. The sideshots are computed from the final adjusted network points. The results of the side shot computations are the same whether they are reduced as part of the least squares adjustment or from the final adjusted coordinates.

The next part of the report displays the results of the vertical adjustment. In the 2D/1D model the horizontal and the vertical adjustments are separate least squares adjustment processes. As long as there are redundant vertical measurements the vertical component of the network will also be reduced and adjusted using least squares.

The first section displays the vertical benchmarks used in the vertical adjustment. Next, is listed the points that will be adjusted as part of the vertical adjustment. The following section displays the measurements used in the adjustment. The measurements consist of the vertical elevation difference between points in vertical adjustment. The lengths between these points are used to determine the weights in the vertical adjustment. Longer length lines are weighted less in the vertical adjustment than shorter length lines.

The next section displays some statistics about the vertical control: Number of unknown elevations, number of routes, number of fixed and non-fixed benchmarks, and degrees of freedom.

The next section displays the adjusted elevations and the computed standard deviations of the computed elevations. Following the adjusted elevation section is a section displaying the final adjusted elevation difference measurements and their residuals. Finally, the computed side shot elevations are displayed.

In the Adjusted Coordinates section of the report there is a section displaying the latitude and longitude of the final adjusted points. Additionally the convergence angle, the grid factor, the elevation factor, and the

combined factor are displayed for each point. Also calculated is the Average Combined Scale Factor for the project which is useful if you want to scale the grid coordinates to ground.

 3-DIMENSIONAL ADJUSTMENT REPORT
 =====

The following section shows the unadjusted measurements that make up the network. The control coordinates are displayed first followed by the GPS vectors. The control coordinates are displayed as latitude/longitude, SPC Grid XYZ, and geocentric XYZ. If geoid modeling is set both ellipsoid and orthometric elevations are displayed, ellipsoid elevation in the latitude/longitude section and orthometric elevation in the SPC section. The GPS vector section shows the unadjusted delta XYZ, variances and covariances of the vectors.

GPS Vectors and Total Station

The following is a report generated from a project that combined GPS vectors and total station data. The 3D adjustment model **MUST** be used when processing GPS vectors. Notice that the report is very similar to the GPS vector only project report. Explanations of the report are included in the report and are in **bold, normal text**.

```

Draw Field to Finish

This command turns data collector field notes into a final drawing by matching the descriptions of the field points with user-defined codes. The points are brought into the drawing with attributes defined by the code, including the layer, symbol, size and linetype. Essentially, Field to Finish drafts a plan as you survey.

Example of a survey processed with Draw Field to Finish

Draw Field to Finish	Create/Edit a Field Code	See Some Examples
Create a Code/Point List	Use The Tree Feature	
Work with Code Tables	Use the Pipe Feature	
Use Special Codes	Use the Utility Feature	

Two main files are used in Draw Field to Finish - a coordinate file (**CRD/CRDB**) and a field code definition file (**FLD**). The coordinate file consists of point#, N,E,Z coordinates and text description fields. The description field contains the codes for the Draw Field to Finish processing. An ASCII data file can be converted into a coordinate file using the *Import Text/ASCII File* command. The field code definition file defines the layer, symbol, size and other actions to apply with each code. These file names are displayed at the top line of the Draw Field to Finish dialog box.

Field to Finish is an extremely versatile and robust program. The concept however is straight forward. Each point located in the field is coded with a description. That point description is related to a matching code in a Code Table (**FLD**) that instructs the Field to Finish program on how to process and draw it. Points can be placed in a drawing using specific symbols, on particular layers and annotated with text or block attributes. A series of points can be used to draw 2D and/or 3D polylines for use in drafting or creating surface models. Beyond a large variety of settings for each defined code in the code table, there are also Special Codes that modify the behavior of the code, such as PC (point of curvature) and PT (point of tangent).

Field to Finish is a very powerful tool but it is not required to place points from a coordinate file into a drawing. *Draw-Locate Points* provides a simpler method for drawing points but it is much less versatile.

Using a drawing template: Field-to-Finish will "layerize" the points and linework according to the code definitions. If the layers to use are not already defined in the drawing, Field-to-Finish will create any layers defined in the code table when it processes that code. It will however, randomly assign a color, linetype etc. to that layer. To provide consistency and have the same properties for these layers in all your drawings, it is recommended you use a prototype drawing, or Template (DWT). Each new drawing created can then be started using this template which contains all layers needed matching those in the Code Table (FLD) file. See Carlson Configure -> Startup Settings to select a prototype Template.

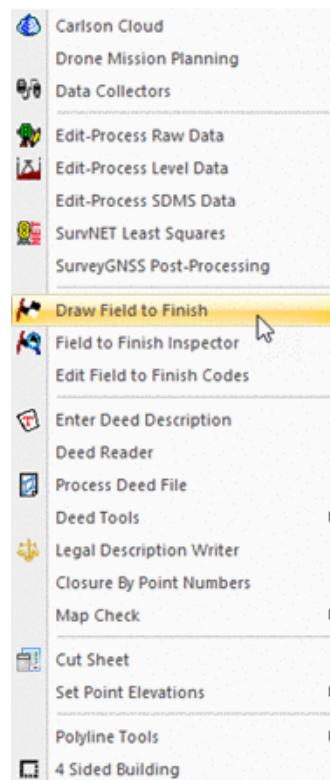

Connecting Line Work: If a code is created as a Line, 2D Polyline or 3D Polyline, all codes with that same description will be connected with no extra coding needed. For example if the code EP is defined as a 3D Polyline and points 100-110 all have EP as a description, Field to Finish will draw a 3d Polyline connecting all points 100 through 110. Stopping and starting line work is where additional coding is needed. There are basically two different methods for connecting linework and controlling the start/stop or gaps between line segments.

1. **Adding group numbers:** As described above the linetype is defined by the code as either lines, 2D polylines, 3D polylines (breaklines), or both 2D and 3D polylines. To control the connection of the linework, distinct lines with the same code are defined by adding a group number to the end of the code name in the data file. With this method, all points with the description CODE1 will be one line while points with CODE2 will be another line. Both CODE1 and CODE2 use the definition for CODE. For example, the code EP could be a code for edge of pavement that is to be connected as 3D polylines. If there are two separate edge of pavement lines on the left and right sides of a road, all the points for the left side could have the description EP1 and the points on the right side could be EP2. Besides having the number after the code, the number can be used as a prefix by defining the code with a # special character. For example, when the code is defined as #CODE, then the points with descriptions 10CODE and 20CODE get matched to this code.
2. **Adding Special Codes:** The second method is to add a special code to the end of a line segment or the beginning of a new line segment. For this method, you use the same code for all similar line segments and

just instruct Field to Finish when to stop drawing. For example the end of an edge of pavement line would be coded EP END. (The code END is the default end line special code). Alternatively, you can instruct Field to Finish to start a new line segment by adding a beginning special code IE. EP BEG. The program will realize that a new line segment should not be connected to a previous one and will create an appropriate gap.

Legacy PointCAD format: This method also connects points with the same code. The difference is that instead of using a number after the code for distinct lines, you use the same code with an additional code for starting and ending the line. For example, +0 is used to start a line and -0 to end. So the coding for a segment of edge of pavement could be EP+0, EP, EP, EP-0. Another special code that has been added to Field to Finish is +7, -7. This 7 code will use the linetype definition of line, 2D polyline or 3D polyline defined by the Draw Field to Finish code. For example, if EP is defined as a 3D polyline, then the coding EP+7, EP, EP, EP-7 will create a 3D polyline. Otherwise codes like +0, -0, which is defined as start and end line, will draw EP as a line. Other PointCAD special codes are: +4 starts a curved 2D polyline, *4 starts a closed curved 2D polyline, +1 begins a 3-point arc, +5 starts a 3D polyline, *5 starts a closed 3D polyline, +6 starts a 2D polyline, *6 starts a closed 2D polyline, +7 starts a line whose type is specified by the field code definition, -05 starts a curved 3D polyline section, -50 ends that section, +8 starts a 2D and 3D polyline combination, *8 starts a closed 2D and 3D polyline combination, -08 starts a 2D and 3D polyline combination curved section, -80 ends that section. //, followed by a field code, concatenates that field code's description on to the point's description. For example, OAK//04 might become LIVE OAK TREE 4" if the field code OAK translates to LIVE OAK TREE and the field code 04 translates to 4".

Draw Field to Finish is found in the **Survey** Pull-down Menu

Draw Field to Finish

Range of Points: Specify the range of points to draw.

Point Group: Specify the point group(s) to process.

Point List: Select points from a point list dialog box.

Entities To Draw: The Points option draws only the points and point attributes. The Lines option draws only the linework and the Symbols draws only the symbols. Any combination of these options can be processed as well as individual processing of each entity.

Draw Within: These options are methods to filter the points to draw. The Polyline method prompts for a closed polyline and only draws points inside this polyline. The Distance method uses a specified center point and distance to only draw points within this circle. The Window/Coordinate Range prompts for lower left and upper right points to define the rectangular area to draw points.

Layer Prefix: Optional layer prefix added to all entities drawn with Draw Field to Finish.

Erase Existing Draw Field to Finish Entities: When checked, this option will erase from the drawing any old entities created by previous Field-To-Finish runs before drawing the new entities.

Erase In Range: This option only erases and redraws those Draw Field to Finish entities that are within the specified range of points to process.

Preview Only: When checked, this option will temporarily draw the points and linework and allow you to review it with zoom and pan.

Fix Overlaps: This option checks the points drawn by Field-to-Finish for any point labels that overlap with other points or linework. For any overlaps, the point labels can be automatically moved or you can step through each overlap to decide how to handle it. See the command called Fix Point Attribute Overlaps in the Points chapter for more information on this feature.

Triangulate and Contour: This option uses the points and 3D polylines created by Field-to-Finish as input for

building a surface in Triangulate and Contour. Pick the Setup button for the options like contour interval and TIN file to create.

Code Table: Sets the FLD file to process which contains the code definitions.

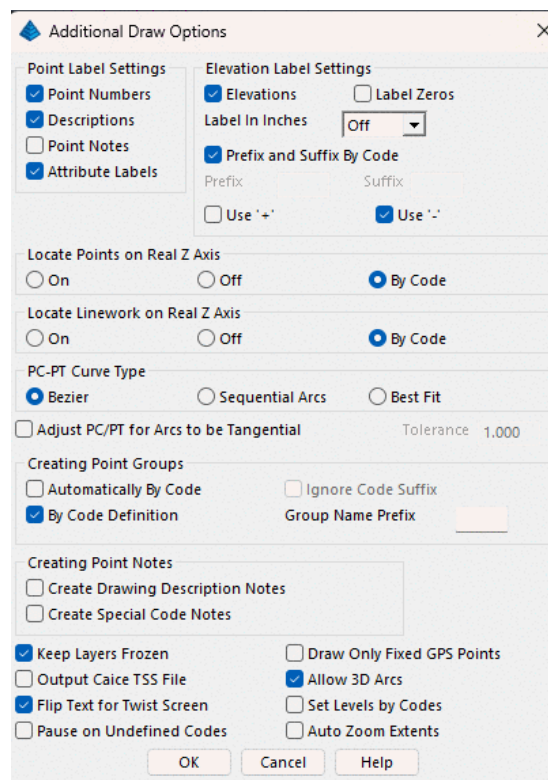

Coordinate File: Sets the CRD file to process which contains the point numbers, coordinates and descriptions.

GIS Table: Sets the GIS file which defines the GIS feature and attribute names. This file is optional and is used in GIS processing.

Edit Codes: Opens the **Field to Finish** Edit Code dialog box.

Report Codes: Opens the Report Code dialog box.

Additional Draw Options:

Point Label Settings: Specify whether you want Draw Field to Finish to label the **Point Numbers**, **Descriptions**, or **Points Notes** which are contained in the note (.NOT) file that is associated with the coordinate (.CRD) file. The **Attribute Labels** option controls whether or not to draw attribute labels. These attributes can be the description and/or additional comments in the form of block attributes or text and may or may not be associated with a GIS feature.

Elevation Label Settings: Specify the elevation labeling options. The Elevations toggle controls whether to draw the elevation attribute label for the points. The Label Zeros option will label the elevations of points with z=0. The Prefix and Suffix By Code sets whether to use the general Prefix and Suffix for all point elevation labels from this dialog or use the Prefix and Suffix defined in each code definition. Use '+' and Use '-' will place the appropriate symbol in front of the elevation. The Label In Inches option allows for elevation label in feet and inches instead of in decimals.

Locate Points on Real Z Axis: Choose between locating all the points at real Z elevation, all at zero elevation or to use the real Z setting as defined in the individual codes (**By Code**). These options can be used to override the setting contained in the FLD as part of the code and is global in nature. It is usually recommended to use the By Code option.

Locate Linework on Real Z Axis: Choose between drawing all the linework at real Z elevation, all at zero elevation or to use the 2D/3D polyline setting as defined in the individual codes (**By Code**). These options can be used to override the setting contained in the FLD as part of the code and is global in nature. It is usually recommended to use the By Code option.

PC-PT Curve Type: Sets the method for drawing curves with more than 3 points. The **Bezier** option draws a smooth polyline through all the curve points. The **Sequential Arcs** method draws multiple arcs with arc end points at each of the curve points. These arcs are tangent to the preceding line segment. The **Best Fit** method creates a single best-fit curve for all the curve points between the PC and PT.

Adjust PC/PT for Arcs to be Tangential: This option will adjust the PC and PT polyline vertices to make the curve tangential. The program will only adjust these points if the adjustment distance is less than the specified tolerance. This option applies to cases where the tangents are well defined and the PC/PT are harder to survey exactly.

Creating Point Groups: Point Groups can be created in one or two different ways. Each field code definition can specify Point Group(s) that all point numbers that use that code will be added to. Multiple field codes can use the same Point Group name. Check the By Code Definition checkbox for that option. The second method is to automatically create Point Groups for each code that is processed. Check the Automatically By Code checkbox for that option. Ignore Code Suffix, if checked, will cause the codes to be considered after removing the numeric suffix. For example, points with the EP10 and EP11 codes will both be automatically added to the Point Group named EP. No matter how the Point Group is created, the Group Name Prefix can be used to add a prefix to the group name. Note: if the Point Group already exists, it will be erased first before being created again by either of these two methods.

Creating Point Notes: These options append point notes to the coordinate file data for some of the data fields processed by Field-to-Finish. These notes can then be used by other commands like List Points to report these fields. For example, this enables List Points to report both the point coordinate file description as well as the point drawing description as generated by Field-to-Finish.

Keep Layers Frozen: This option will not thaw layers that Field-to-Finish uses for drawing entities. So when you have this option on and some layers are frozen, then you won't see the entities that Field-to-Finish creates until you thaw those layers.

Draw Only Fixed GPS Points: This option applies to coordinate files created by GPS measurements. The program checks for GPS status records and only uses points that have GPS solution status of Fixed.

Output Caice TSS File: This option creates a TSS file from the processing results.

Allow 3D Arcs: When creating polyline arcs with the PC special code, this option checks whether to create the arc in 3D for tilted or vertical arcs such as a doorway or bridge arch. Otherwise, only the 2D coordinates are used to define the curvature.

Flip Text for Twist Screen: This option will rotate the point labels and symbol by 180 degrees when needed to make them right-side up readable relative to the current twist screen drawing view. This option applies to the Rotate To Line and Rotate special code (ROT).

Set Levels By Codes: This option assigns the optional Level Names for use by selection filters.

Auto Zoom Extents: When checked, this will force a zoom extents after Draw Field to Finish is done.

Pause on Undefined Codes: When checked, Draw Field to Finish will pause if it encounters a description that is not defined in the code table.

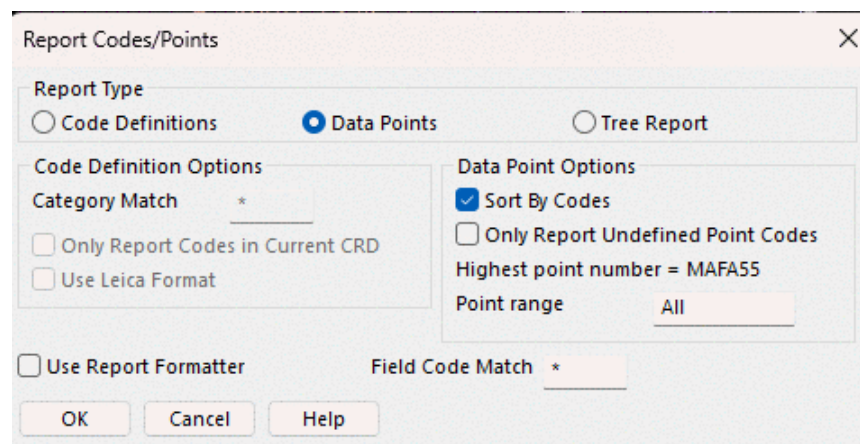

The options for handling undefended codes are:

- **Abort without drawing anything:** This stops the command. Run Draw Field to Finish again to correct the code table.
- **Use the default settings for this point:** This option draws a point using the current Point Default settings with no linework. To set your own default, define a code called "SC_DFLT" or "DEFAULT." This default code will instruct Field to Finish on how to process undefined codes.
- **Use default settings for all undefined codes:** This option will draw all undefined codes using the current Point Default settings with no linework. To set your own default, define a code called "SC_DFLT" or "DEFAULT." This default code will instruct Field to Finish on how to process undefined codes.
- **Edit Point Description:** Use this option to edit the point description or select a different code.

Report Codes/Points

This routine prints the code table or the data file to the screen, file, or printer. A useful option here is to print the data file (CRD Points) and choose Sort by Codes which will group the data points by distinct codes.

A useful option here is to print the data file (CRD Points) and choose Sort by Codes which will group the data points by distinct codes.

Report Type:

- Code Definitions: Creates a list of code definitions from the currently selected FLD file.
- Data Points: Creates a list of points grouped by codes of the current CRD (coordinate file)
- Tree Report: Creates a list of all points coded as a Tree Feature.

Code Definition Options

- Only Report Codes in Current CRD: Reports only the codes from the current FLD that are contained in the current CRD (coordinate file)
- Use Leica Format: Creates a list of code definitions using the Leica comma delineated format.

Data Point Options

- Sort by Codes: Sorts the list of points by code name
- Only Report Undefined Codes: Restricts the list to report only those points that have descriptions not contained in the code table. This is useful for reviewing a data set before processing.
- Point Range: Enter the range of points to be included in the list.

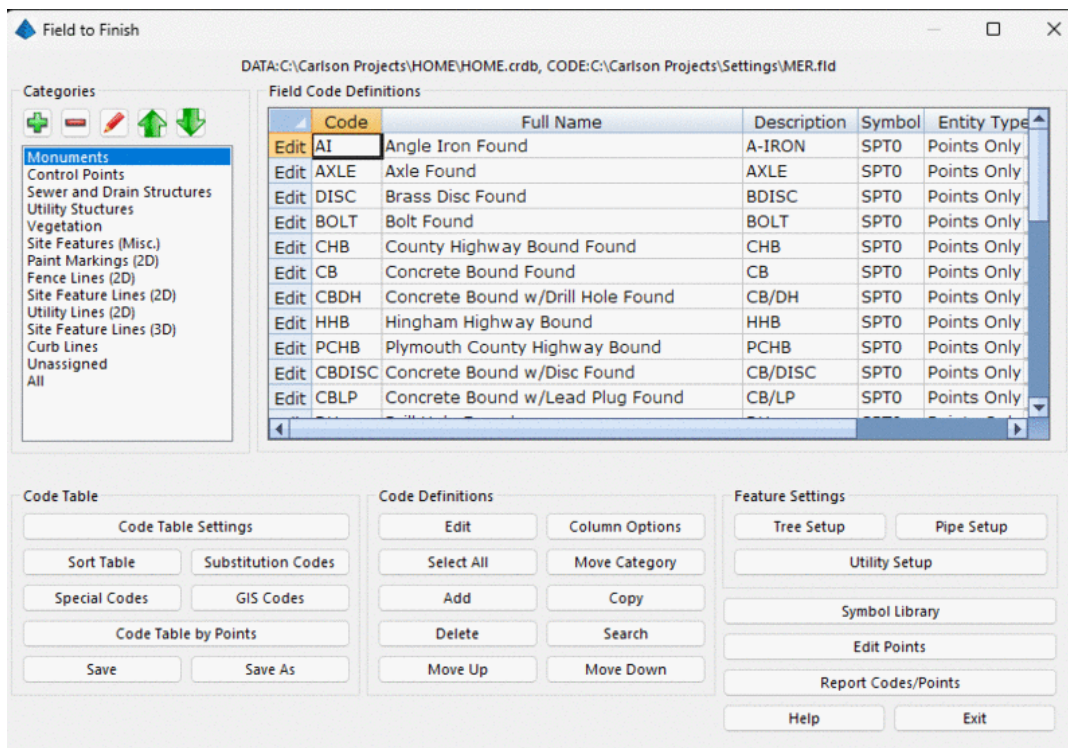

Use Report Formatter: Enables the option to use the Carlson Report Formatter for more control of the creation of the point list.

Field Code Match: Option to filter and limit the list to only select codes.

Edit Codes

Selecting Edit Codes takes you to the Field to Finish Code Table dialog box. This dialog box contains access to all of the tools and options for Field to Finish. It is the heart of this program.

The **Field to Finish** dialog box allows you to load the coordinate and field code definition file. Here you can add, view and edit the code definitions, view and edit the coordinate file, create reports, and then return to the Draw Field to Finish dialog box to process the files. The top section displays the code definitions. The bottom section has three columns of functions each pertaining to controls for different elements of the command. The **Code Table** section provides controls for settings, sorting and reporting of codes. The **Code Definitions** section provides tools for the creation and editing of codes. The **Feature Settings** section provides controls for the special tree, utility and pipe feature types.

The code table editor has a list of categories and a spreadsheet of codes with optional displays of related definitions. The spreadsheet shows the codes for the currently highlighted category. The category toolbar buttons allow you to add, remove, edit the names and change the order of the categories. There are two fixed categories. The **Unassigned** category shows any codes with blank categories. The **All** category shows all the codes. You can control which fields are visible in the spreadsheet by using the **Column Options** button. You can make edits to the fields in the spreadsheet or highlight a row and pick the **Edit** button to bring up a dialog to edit the code.

This section of the manual is separated into three categories:

Special Codes

GIS Special Codes

Code Table by Points

Code Table Settings:

These options provide tools for defining the coding method to be used for processing of the point data. Various import tools allow for the importing of codes from different software packages. Controls for handling multiple codes are located on this dialog. All special codes can be replaced to other characters defined by the user. The special codes are listed and edited on this dialog.

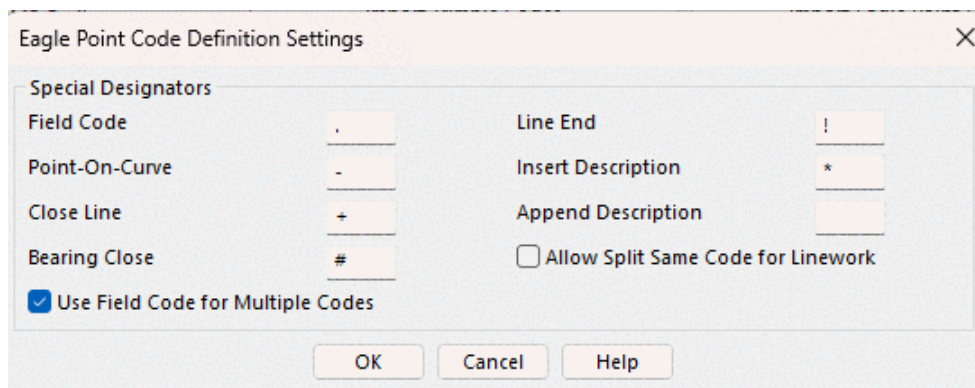

Set: Choose this button to select an existing or create a new code table. The name of the current table is shown in the field to the left of this button.

Coding Method:

Carlson Coding: When checked, this option interprets and processes coordinate files based upon the Carlson Coding method and data collection method.

LandXML Coding: This method prompts for a LandXML or Leica/Hexagon HeXML file to use with the processing. This method applies when the point descriptions do not have linework coding and the LandXML file has PlanFeatures that define how points are connected to create linework. This method reads the LandXML file to find the points that begin and end lines and curves.

Eagle Point Coding: When checked, coordinate files are processed based on the Eagle Point Data Collection method. When selected the *Eagle Point Codes* button at the bottom of the dialog box becomes available for selection and displays the following dialog. This dialog allows for customization of the eagle point special designators.

Currently the supported designators include, "Field Code", "Point-On-Curve", "Close Line", "Bearing Close", "Line End", "Insert Description" and "Append Description". Also supported is the ability to recognize overwriting of

descriptions just as Eagle Point does by using the space separator instead of the "Insert Description" designator. Examples of supported coding are as follows:

.TC Places a node and or line per the field code library.

TC Places a node and or line per the field code library.

-TC Specifies a point on a curve.

TC- Specifies a point on a curve.

..TC Stops the line.

TC! Stops the line.

.TC+ Closes the line back to the starting point.

TC+ Closes the line back to the starting point.

.TC# Typically coded on the third corner of a rectangle to close the figure with having to locate the fourth corner.

TC# Typically coded on the third corner of a rectangle to close the figure with having to locate the fourth corner.

WV.WI Places a node as specified by the code "WV" in the field code library and then begins a line as specified by code "W" in the field code library.

.TC.EP.FL Results in three lines coming together.

TC1.TC2.TC3 Results in three lines coming together. All three lines are specified by the definition of the single code "TC" in the field code library.

TC.TC1 When used in conjunction with the "Draw Field Codes Without a Suffix as Points Only" toggle, "TC" will be recognized as the node and "TC1" will be recognized as the line so that if the code "TC" in the field code library is defined as a polyline, line or 3D polyline, duplicate lines will not be unintentionally placed when this shot only pertains to a single element. Keep in mind that all line work must have a numeric suffix when using this toggle.

TREE * OAK Result on screen would be: TREE OAK

TREE OAK * Result on screen would be: OAK TREE

TREE OAK Result on screen would be: OAK

TC1!.TC2-.VLT6# Stops "TC1", continues "TC2" as a point on a curve and closes VLT6 as a rectangle using the "Bearing Close" code.

Note: The use of the "Use Multiple Codes for Linework Only" toggle is recommended when using Eagle Point Coding.

SDMS Coding: This option processes coordinate files based upon SDMS coding method. When active, the program will prompt for an SDMS .PRJ file to process.

CAiCE Coding: When checked, coordinate files are processed based on the CAiCE Data Collection method. Examples of supported coding are as follows:

169 is just the code 169.

145C10 is the code 145 and line #10.

169C25C is the code 169, line #25, and the point is on a curve.

172C12B is the code 172, line #12, and this point closes the line.

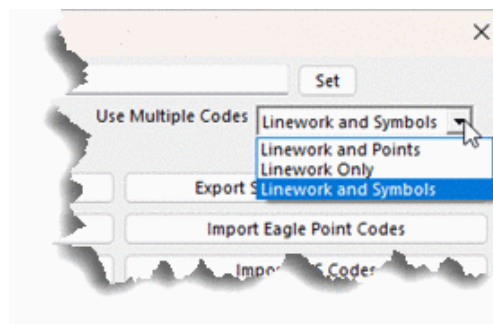

Split Multiple Codes:

Multiple codes are defined by including each code in the point description field separated by a space. A single data point can be used in different lines by assigning it multiple codes. For instance, a point might be part of both a curb line and a driveway line with a description of "CURB DRW". Field-to-Finish uses spaces as the delimiter for multiple codes. You should avoid spaces in the descriptions except for where multiple codes are intended or after the "/" character. For example, a code for light post should not be "LGT POST" but instead should be "LGTPOST".

There are three options for the handling of multiple codes when encountered. The **All** option will split all multiple codes and process each code based upon its code definition. When **None** is select the first code in the description string will be processed and the remaining characters left a part of the description (this is exclusive of any Special Codes used). If the **Prompt** option is checked on, when Field-to-Finish detects multiple codes on a point the following dialog will be displayed with options for handling the codes.

Use Multiple Codes:

Multiple Codes are simply more than one code separated by a space (default setting). Field to Finish has options to allow more control over the use of these multiple codes. This setting has three options:

- Linework and Points - Uses the space to connect multiple line codes as well as creating multiple point blocks at each location.
- Linework Only - Limits the multiple coding to be used for connecting line work only.
- Linework and Symbols - Uses the space to connect multiple line codes as well as creating multiple symbols at each location.

Import/Export Options:

Import SurvCE Codes: This option imports a SurvCE Feature Code List (fcl) into a Carlson Field to Finish (fld) code definition file.

Import Trimble Codes: This option imports Trimble .FXL file codes into the Carlson Field to Finish (fld) code definition file.

Import Land Desktop Desc Key: This option imports and converts a Land Desktop Description Key into a Carlson Draw Field to Finish (fld) code definition file. The Land Desktop Description Key file is a mdb file and is found in the Land Desktop Project file path. It is located in the under the COGO/DescKey directory.

Import C&G Description Table: This option imports C&G code tables (tbl) into the Carlson Field to Finish (fld) code definition file.

Import Civil 3D Codes: This option imports Civil 3D .fdb_xdef file codes into the Carlson Field to Finish (fld) code definition file.

Import GIS Feature Codes: This option imports features in a .GIS file from Define GIS Features into F2F codes.

Export SurvCE Codes: This option creates a SurvCE Feature Code List (fcl) from the current a Carlson Field to Finish (fld) code definition file.**Import TDS Codes:** This option imports TDS codes into the Carlson Field to Finish (fld) code definition file.

Import TDS Codes: This option imports TDS codes into the FLD code definition file.

Import Eagle Point Codes: This option imports Eagle Point codes into the Carlson Field to Finish (fld) code definition file.

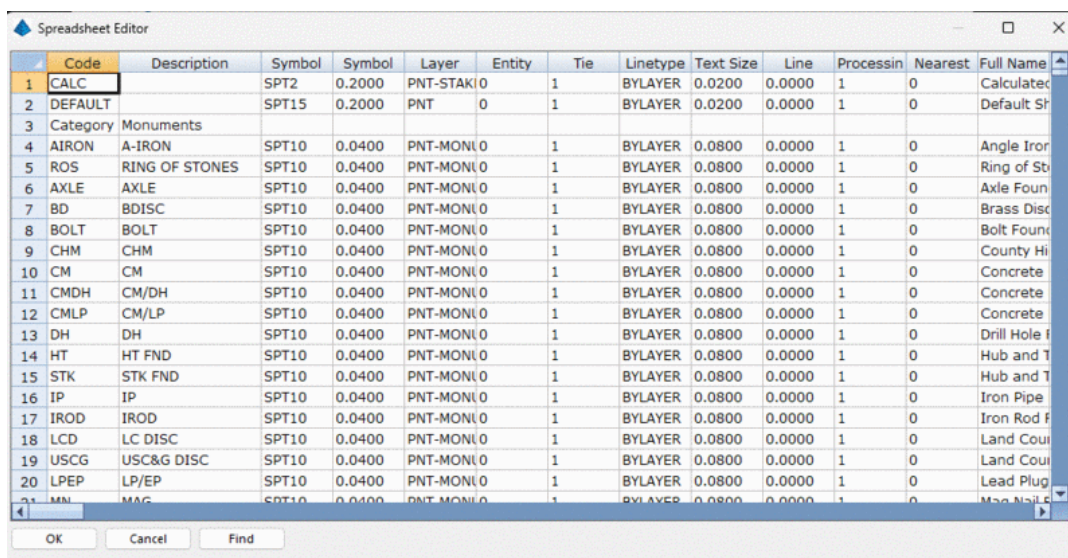

Import Topcon Codes: This function imports Topcon codes and layers from an XML file.

Merge Code File: This function adds code definitions from another (fld) code definition file into the current code table. The program shows a list of the codes from the other file that are different than the current code table. You can choose which codes to import. Any codes that conflict with an existing code definition are defaulted to not import.

Import EFB: This option imports the SDMS Electronic Field Book codes (.xml) into the Carlson Field to Finish (fld) code definition file.

Import Text/ASCII Codes: This option imports code definitions from a user-defined format. Each row in the text file should represent one code. The program will prompt for the delimiter (ie. comma separated) that is used in the text file and then for the field type for each of the columns (ie. "Layer" or "Description").

Spreadsheet Editor: This function lets you edit all the codes with all their settings in a single large spreadsheet. This method can be a handy way to use copy and paste to edit the codes. This method can also be quicker to make many changes than navigating the Edit Code dialog. This method is for expert users and you need to take care to make valid inputs.

Additional Options:

Draw Field Codes Without a Suffix as Points Only: This option is useful for when wanting to use a field code sometimes for linework and sometimes for just points but it is preferred to number the lines rather than using start

and stop codes. For example, if the field code EP is defined to use the Line Entity type, then EP25 will be drawn as a Line, however if just EP is used, no linework will connect to that COGO point. When using this option, it is required to add a numerical value after each line code.

Stop Linework At Gap In Point Numbers: This option is a method for controlling the start and stop of drawing linework. This method will automatically stop linework where there is a gap in the point numbers for the linework code. For example, if there are points with code EP then points with code CL then more points with code EP, the EP linework for the first set of EP points will stop at the last EP before the CL points and then new EP linework will start after the CL points.**Max Delta-Height for Linework:** Use this option to specify the maximum elevation difference that Draw Field to Finish should draw any section of linework. This option is for use with 3d polylines and lines.

Max Length for Linework: Specify the maximum length that Draw Field to Finish should draw any section of linework. If two codes are distant beyond this limit, no linework will be drawn between them.

Default Distinct Point Layer: These settings control the default layer for when the Distinct Point Layer option is turned on for each code definition.

Skip 1st/2nd Symbol Control When Missing 3rd Control: For multi-point symbols when the 3rd control point is missing, this option centers the symbol on the 1st point instead of using the 1st point as a control point.

Use MText for Linework Descriptions: Controls whether to create MText or regular Text entities for linework description labels.

Skip Multiple Z Labels For Linework At Same Z: This option labels only the first point elevation for points on polyline or rectangle from the RECT code when the elevation difference between the points is less than the specified **Z Tolerance** and the horizontal distance is less than the **Distance Tolerance**. For example, for points on the corners of a level utility pad, this option will label the pad elevation just once.

Stop Linework For Different Point Groups: This option applies to when you have points for the same job collected at different times or with different crews and you want to prevent linework connecting points between them. For example, this applies when you survey a job with two crews and combine their points into a single CRD and both crews used "EP1". In this case, to keep each set of "EP1" separate, you can put each set of points into a separate point group with Point Group Manager and use this Field-to-Finish option. The **Point Group Filter** is optional and is used to make the program only check groups that match the filter. A point can be in multiple groups such as "CONTROL" and "DAY1". Some groups could be used for different days such as "CONTROL". So the Point Group Filter could be set to "DAY" to filter out the common groups and only process the time related groups.

Use Preceding Special Codes: This setting tells the program to expect the special codes before the main code. For example, if "BEG" is the special code for begin linework and "EP" is a main code, then the program looks for "BEG EP". The default sequence is for the special code to come after the main code as in "EP BEG".

Interpolate No Elevation Points for 3D Polyline: For points tagged as "No Elevation" that are part of a 3D polyline, this option will interpolate an elevation for this point from the other points in the 3D polyline. Otherwise, this point will be skipped in the 3D polyline.

Sort Table

This sorts the code table by either code name or layer.

Substitution Codes:

This option defines a lookup table for translations of the raw point descriptions. This translation is done as a pre-processing step before the regular Field-to-Finish processing. For example, if you had a substitution setup for "25" = "EP", then a point description of "25" would get translated to "EP" and then this would be processed with Field-to-Finish.

This works for both numerical and alpha raw descriptions.

- The **Match With Number Suffix** option will match with a number following the string. For example, "CL" will match with "CL2". Otherwise, the strings have to be an exact match. The substitution codes are stored in a file named f2f_sub.dta in the %appdata%\Carlson...\USER folder. You can also use the **Import** and **Export** functions to load and save substitution codes to a comma separated text file.

Special Codes:

Special Codes are essentially modifiers of an original code. They perform additional operations and/or offer addi-

tional control over the original code. These special codes work with line work, point data and symbols. There are also options to control the placement of labels and add additional text to attributes.

Below shows the default dialog box containing the Special Codes. These can all be modified at the users discretion but the must be unique and not conflict with any codes defined in the code table.

A special code is placed after (or before if that option is enabled) the regular code with a space separating the code and special code. For example if an edge of pavement shot was taken at the beginning of a curve, it would be coded EP PC, whereas the PC tells Field to Finish to begin drawing an arc. Special codes may be strung together to modify a single code or added to multiple codes within the same string. For example, if a ling string ended at the PT of a curve it could be coded EP PT END whereas both PT and END are the special codes. An example of multiple codes combined with special codes could be a driveway intersecting the edge of pavement at the beginning of a curve: EP PC DRV SMO. The PC starts drawing an arc on the edge of pavement and the driveway begins with a smoothing code. It is important that any special code modifying another code must be placed immediately after the code it is modifying.

Quick Links for this Section

- General Special Codes
- Linework Special Codes
- Point Symbol/Attribute Special Codes
- 3D Face Special Codes

General Special Codes

NE: No Elevation - This special code represents no elevation. A point with this special code is located at zero elevation and the elevation attribute is set to None.

NOS: Non-Surface - This special code indicates that the point should be "non-surface"; that is, that it should be ignored when contouring or creating surfaces. This can also be controlled per-field code by turning on the Non-Surface toggle in the Edit Field Code Definition dialog box. When used, this special code tags the point to be non-surface but maintains the elevation attribute.

YZ: Yes Elevation: - This special code locates overrides the code setting for non-surface and locates the point and

maintains the elevation attribute.

ZO: Elevation Only - This special code represents elevation only (Z-Only). A point with this special code is used as part of a 3D polyline for elevating the 3D polyline without effecting the horizontal position of the polyline. For example, this code could be used on a grade break point along a curb where only the elevation should change and not the horizontal alignment.

"\": Prefix Description - This special code takes the part of the description after the "\" and puts it as the prefix before the point description. For example, a data point with the description "TR \ 24ft" and a "TR" code definition with a description of "Tree" would be drawn with a description of "24ft Tree".

"\\": Prefix Field Code Description - This special code causes text after the "\\" to be interpreted as a field code. That field code's description is then prefixed to the first field code's description. For example, if the field code 02 has the description 2" and the field code OAK has the description *oak tree*, then OAK\\02 will result in the point having the description of 2" *oak tree*.

"/": Append Description - A special character "/" (the forward slash or divide key) can be used for an unprocessed description to append. Everything after the "/" is added directly to the point description and is not considered a code and no further substitution is done on it. For example, a data point with the description "UP/#150" for a code UP that has UP for its description would be drawn "UP #150".

"/": Append Field Code Description - This special code causes text after the "/" to be interpreted as a field code. That field code's description is then appended to the first field code's description. For example, if the field code 02 has the description 2" and the field code OAK has the description *oak tree*, then 02//OAK will result in the point having the description of 2" *oak tree*. If the "/" character has been replaced with a different character, for example with a & character, then the "/" code would become "&&".

"—": End Coding - The bar separator indicates the end of coding. Everything after the bar is ignored for Field-to-Finish processing. This is useful if additional information is needed for a point but no action should be taken and no description should be added.

"/": Replace Description - This special code takes the part of the description after the "/" and uses it as the point description label.

" ": Code Separator - The default for separating multiple codes is a space. This can be modified to another character if desired. Caution should be taken when modifying special codes to be sure there are no conflicts with other codes or special codes.

MULT: Multiple Field Code - This code applies when the Split Multiple Codes under Code Table Settings is set to None and you want to override this setting and explicitly split selected codes. Multiple codes apply to points with dual code definitions for drawing two different style points or for connecting different linework to the same point. For example, if a point is both a sidewalk and driveway corner, then the point description could be "SW MULTDR".

Substitute Characters - The characters (*, -, +, /, and _) can be used and substituted in Draw Field to Finish. The way these characters are used is that when the file is processed the description field is searched for these characters. If the "+" symbol was changed to "-" then the program would look for "-" and change it to "+". This is useful when a particular data collector may not have all the symbols available. With these substitutions you can make a character that is provided on the data collector generate the symbol needed. Multiple characters can also be used. For example "-" can be used to in order to produce a "/" character or any of the characters listed above.

Linework Special Codes

BEG: Begin Linework - This special code denotes the beginning of a new line string. If a code is already designated to be a line, 2D or 3D polyline, then Field to Finish will connect like codes without the need for the BEG code. However, BEG can be used to designate the start of a new line string or can be used to force linework

between codes designated as points only.

END: End Linework - This special code denotes the end of a line string. This is used when line numbers are not being used. See Connecting Line Work for description.

PC: Start Curve - This code begins a three point arc or a curved line when used with the "PT" code (see below). The point with this special code is the first point on the arc. The next point with the code is considered a point on the arc, and third point with the code is the arc endpoint. The PT code is not necessary when coding a 3 point arc.

Example of 3 point curve:

- 10, 500, 500, 0, EP PC - start curve
- 11, 525, 527, 0, EP - second point on curve
- 12, 531, 533, 0, EP - end point of curve

For curves beyond 3 points, the **PT** code needs to be used for the last point on the curve. The routine then looks back for the PC and "fits" a curve between all intermediate points.

PT: End Curve - This code can be used with "PC" to define a curve with more than three points or a tangent two-point curve. Starting at the point with the "PC", the program will look for a "PT". If the "PT" is found, all the points between the "PC" and "PT" are used for the curve which is drawn as a smoothed polyline that passes through all points and only curves the polyline between points. If no "PT" is found, then the regular three point arc is applied as explained above. If no points are found between the "PC" and "PT", then the point prior to the "PC" and the point after the "PT" are used to create tangents for the resulting curve.

Both the PC and PT codes used for drawing arcs are subject to the PC-PT Curve Type found in the Additional Draw Options.

CTOG: Curve Toggle - This special code toggles curve mode on and off. Instead of using PC to start a curve, you can use CTOG. Likewise, instead of using PT to end a curve, you can use CTOG.

NEAR: Nearest Found - This special code sets the current polyline to Nearest Found connection order. This applies to codes that have the Connection Order set to Sequential and you want to override this setting to Nearest Found for the current polyline. This is useful in situations when a point on a polyline was taken out of sequential order.

CLO: Close - This code forces the lines drawn between a series of points with the same code to close back to the first point with the same code. For example, shots 1-4 all have the BLD description with the exception of point 4. Its description is BLD CLO. This will force the linework drawn for the BLD code to close back to point 1 which is the first point with the description of BLD.

RECT: Close Rectangular - The "RECT" special code creates a rectangle as a 2D or 3D polyline using one of two different methods.

- *2 Point Method*: Locate 2 points for one side of a structure and add the code RECT plus a dimension for the remaining dimension of the rectangle. For example, you are locating a shed with the dimensions 20x8. Take a shot at each corner on the 20' side and code the second shot with the 8' dimension. A positive dimension offsets to the right and a negative dimension offsets to the left. First code: **BLD** Second Code **BLD RECT-8**

- 3 Point Method: Locate 3 corners of the structure and code the 3rd shot as RECT. This tells Field to Finish to form a parallelogram out of the 3 shots taken by copying the 2 sides located respectively.

Offsets: OH, OV, OFL, OFB, OO

The codes "OH" and "OV" stand for offset horizontal and offset vertical. These offset codes apply to 2D and 3D polylines. A single set of offset codes can be used to offset the polyline a set amount. For example,

10, 500, 500, 100, EP OH2.5 OV-.5

11, 525, 527, 101, EP

12, 531, 533, 103, EP

This would create a polyline connecting points 10,11 and 12 and an offset polyline with a 2.5 horizontal and -0.5 vertical offset. The direction of the horizontal offset is determined by the direction of the polyline. A positive horizontal offset goes right from the polyline direction and a negative goes left. The horizontal and vertical offset amounts apply starting at the point with the offset codes until a new offset code or the end of the polyline. Only one horizontal and vertical offset can be applied to 2D polylines. For 3D polylines, multiple offset codes can be used to make a variable offset. For example,

10, 500, 500, 100, EP OH2.5 OV-.5

11, 525, 527, 101, EP OH5.5 OV-.75

12, 531, 533, 103, EP OH7.5

This would offset the first point horizontal 2.5 and vertical -0.5, the second point horizontal 5.5 and vertical -0.75 and the third point horizontal 7.5 and vertical -0.75.

Multiple Offsets: When there are multiple "OH" codes for the same point, the polyline is offset multiple times, one for each OH code.

Alternatively and in conjunction with the "OH" code, a second number after the offset amount repeats the offset by that number. For example "OH2 5" means offset by 2 and repeat 5 times. This multiple offset option is useful drawing stair steps.

The "OFL" code stands for offset left horizontal. The only difference with the "OH" code is that you don't have to enter the "-" to go left.

The "OFB" code stands for offset both left and right horizontal. For example, if the points follow the center of a ROW, the OFB code can be used to create the left and right edges of the ROW. There is a setting in Special

Codes for Offset Both for whether the offset value is for the full or half width between the two offset lines. Also, there is a setting in each code definition under the Linetype tab for whether to create a closed polyline from the left and right offset polylines. If 3D polylines are offset, they maintain the elevations of the original located 3D polyline.

The "OO" code stands for offset only. This option only draws the offset polylines and not the polyline connecting the points. The "OO" code is a companion code that can be combined with any of the other offset codes. For example, "EP OH2 OO" will offset the EP line horizontally by 2 but draw only the offset polyline.

CIR: Circle - The "CIR" special code causes the point to create a circle in one of three different ways.

- *Single Point and Radius method:* The first way uses just the current point as the center with the CIR special code followed immediately by the radius. For example "CIR7.5" will create a circle centered on this point with radius 7.5 and at the elevation of the current point.
- *Two Point method:* The second method uses two points, the first point specifying the center and the elevation, and the second point specifying the radius. Only the first point has the "CIR" special code and the second point is the next point with a matching field code. Another variation of method 2 is using 2 points that are on the perimeter and define the diameter. For the 2 point method, whether the points define the radius or diameter is defined on the Code Table Settings > Special Codes > 2-Point Circle.
- *3 Point method:* The third method uses 3 or more points that specify the perimeter of the circle in 2D with the first point specifying the elevation. For this method, the "CIR" special code is only on the first point and the rest of the points are the next points with matching field codes.

The "CIR" code can be used with all of the linetypes including "points only". The circles are always parallel to the X-Y plane unless the code linetype is set to "3D Polyline". Then the circle is drawn as a 3D polyline. Any active linework for the code is ended before processing the "CIR" special code.

Examples of drawing circles:

PointNo. Description

Method 1 (Single point at center with radius value)

82 PP CIR7.5

Method 2a (Point at center plus point at perimeter)

83 PP CIR

84 PP

Method 2b (2 Points on perimeter that define the diameter)

83 PP CIR

84 PP

See 2-Point Circle for options to designate methods 2a or 2b.

Method 3 (Points on perimeter)

85 PP CIR

86 PP

87 PP

88 PP

89 PP

Methods 1, 2a, 3

Method 2b

JPN: Join to Point Name - The "JPN" (Join to Point Name) special code joins to the point named immediately after the code. For example, "JPN205" causes a line to be drawn from the current point to the point "205". JPN is designed to work for adding a segment at the start of linework, but can be used at any point during the survey.

SMO: Smooth - This code is used to smooth the polyline. It is ideal for long winding roads or walkways that are generally curved as it prevents the need of adding PCs and PTs to define the arc segments. Tree lines and landscape areas are also good examples of utilizing this special code.

JOG: Extend By Distance - The "JOG" special code allows for additional points to be inserted into the line work at perpendicular or straight offsets. Only offsets should follow the JOG code. Positive numbers indicate a jog to the right and negative numbers indicate a jog to the left. Alternatively, "R#" and "L#" can be used where # is the distance to either the right or the left. Finally, "S#" can be used to make an offset straight ahead by using a positive # or behind by using a negative #. For example, "BLDG JOG S10.1 R5 L12.2 L5 L12.2" or equivalently "BLDG JOG S10.1 5 -12.2 -5 -12.2" advances 10.1 units and then draws a closed rectangle on the right hand side of an existing line. The offsets are always done in the X-Y plane. If the current line is vertical, an offset to the right is along the positive X-axis.

Example of building location using jog special. The command adds both a jog of 20 to the right and 10 to the left and then closes the building at point 108. **BLD JOG20 -10 CLO**

GAP: -This special code makes a single segment break in the current linework. For example, if you have a curb polyline that you want to break to skip over a driveway, then you could add the GAP code at the start of the driveway and continue the curb as normal on the other side.

LTF: Linetype Flip - This special code switches the side for the linetype. This option applies to non-symmetrical linetypes like the tree line or guard rail for when you want the linetype to face the other way.

AFIT: Fit Arc - This special code adjusts the PC/PT points for the current arc to make the arc tangential. This special code is a way to individually control this tangential arc adjustment. To adjust all arcs within a specified adjustment tolerance, use the Adjust PC/PT setting under the Additional Draw Options from the first Field-To-Finish dialog.

LTW: Line Width - This special code sets the line width. The width value is entered after the LTW code. This width is applied to lines and 2D polylines.

BFIT: Best-Fit Line - This code creates a best-fit line using the points for the linework. This feature can be used when you have multiple points on a feature that you know is a straight line such as a sidewalk and you want a single line to be drawn. Each of the points that you want to include in the best-fit need to have the BFIT code.

RAMP: Curb Ramp - This special code adjusts the 3D polylines to create a curb ramp. The routine looks for parallel 3D polylines for the bottom of curb, top of curb and back of curb. These 3D polylines can be created in Field-To-Finish by using a Template under the Code > Linetype definition, or using the offset special codes, or by having three separate 3D polylines. The ramp is centered at the point with the RAMP code. The dimensions of the ramp follow the code in order of width, depth and taper. For example, a description of "BC RAMP 3 2 1" uses "BC" for a bottom of curb code then "RAMP" for the special code and 3 for the width, 2 for the depth and 1 for the side taper.

XSCT: Template - This special code defines a template from a series of points with this special code. This template is then applied like a template defined under Linetype for a code. This XSCT code is a way to define a template in the field instead of having a template with fixed dimensions defined in the code table. For example, you could have a code for BC for back-of-curb. Then store three points with a description of "BC XSCT" for three points to cross section the curb: back-of-curb, top-of-curb and flow line. After these three "BC XSCT" points, you could have single "BC" points along the curb and the program will apply the template along these curb points and draw three parallel lines.

PARKING: Parking - This special code draws parking stall lines using three points. Points one and two are used to draw the first parking line and define the length and angle of the lines. The third point defines that position of the last parking line. On the first point, a number needs to follow the PARKING code for the number of parking lines to draw. For example, PARKING8.

Point Symbol/Attribute Special Codes

ROT: Rotate - This code is used to set the rotation of the point symbol. If a point number follows the ROT code, then angle from the current point to this point number is used for the rotation. For example, "ROT45" would rotate the symbol towards point number 45. If there is no point number after the ROT code, then the rotation point is the next point number with the same code as the current point or a companion code for the current code. ROT can also be used to rotate towards an angle clockwise from north by using '+' or '-' in front of the number. For example ROT+45 rotates the point symbol to the northeast and ROT-90 rotates the point symbol to the west.

SZ: Symbol Size - This code is used to set a different symbol size. There are several ways to use this code. It can take multiple scale factors for different dimensions by putting an ID character after the factor.

- **SZ:** If nothing follows the SZ code, then the next point with the same field code as the current point will be used to determine the size.
- **SZ#:** The value of the new symbol size is specified after the SZ. This value is the actual size in drawing units. For example, SZ2.
- **SZ#X:** The value after the SZ is used to scale the symbol in the X dimension. For example, SZ2X.
- **SZ#Y:** The value after the SZ is used to scale the symbol in the Y dimension. For example, SZ2Y.
- **SZ#Z or SZ#V:** The value after the SZ is used to scale the symbol in the Z (Vertical) dimension. For example, SZ2Z.
- **SZ#H:** The value after the SZ is used to scale the symbol in the X,Y (Horizontal) dimensions. For example, SZ2H.
- **SZ#S:** The value after the SZ is a symbol size scaler that get multiplied by the drawing horizontal scale to determine the actual drawing units. For example, SZ0.2S.

The X, Y, Z, V and H can be combined. For example, to scale a symbol by 10 horizontally and 25 vertically, use SZ10H25Z. Or to scale a symbol by 2 in the X direction and 4 in the Y direction, use SZ2X4Y.

When multiple SZ codes are used in the same point description, the symbol is drawn multiple times at the different sizes. For example, a point description of "TREE SZ5 SZ10" will draw the tree symbol twice. One symbol will be size 5 and the other size 10.

AZI & DIST

The AZI and DIST codes are used together to offset the point. The AZI sets the offset azimuth and DIST sets the distance. The values should directly follow the code. For example, AZI25 DIST4.2 would draw the point offset 4.2 at an azimuth of 25 degrees.

2ND: Multi-Point Code - When used on the first point of a multi-point symbol, the "2ND" code indicates that the second point of the sequence (i.e., the next point after the current one) should be used as the second symbol insertion point for a multi-point symbol. Please refer to Symbol Points in the Edit Field Code Definition section below.

3RD: Multi-Point Code - When used on the first point of a multi-point symbol, the "3RD" code indicates that the third point of the sequence should be used as the third symbol insertion point. The "3RD" code should be used with the "2ND" code. Please refer to Symbol Points in the Edit Field Code Definition section below.

Note: The 2nd and 3rd codes are not necessary if the Automatic Multi-Point Special Codes option is enabled. Please refer to Symbol Points in the Edit Field Code Definition section below.

PHOTO - This code attaches a photo file to the point. The name of the photo file should be right after the PHOTO code. The PHOTO Link setting controls whether the photo is attached using a Carlson-format link or a CAD Hyperlink. Use the Image Inspector command to view photos attached to points by either link method. To use the Hyperlink, you can Ctrl-click or right-click on the point entity.

In addition to the PHOTO code, Field-to-Finish will also automatically create the photo links for SurvCE photos. The program looks for the photo database from SurvCE which should have the same name as the coordinate file with an extension of .phdb. This photo database file should be in a sub-folder of the coordinate file folder and called Pictures_X where X is the name of the coordinate file. For example, if your coordinate file is C:\Projects\Job1\Job1.crd, then the program looks for C:\Projects\Job1\Pictures_Job1\Job1.phdb.

When SurvCE stores photos, it creates this photo database using this naming. So to process with Field-to-Finish, copy the coordinate file and photo files from the data collector to your computer.

LABEL - This code controls the point attribute format using a number after the code. This number uses 0=attribute block, 1=text, 2=both, 3=none. For example, LABEL1 means draw that point using text attributes.

COLOR - This code sets the entity color. The color is specified after the "COLOR" code by either a CAD color number (1 to 256) or color letter. The color letters are R=red, Y=yellow, G=green, C=cyan, B=blue, M=magenta, W=white. For example, COLOR1 means use CAD color 1 (red) and COLORB means use color blue.

PHOTO Link - Sets the option for linking the photos. Carlson format links using the process described above. Hyperlink is a CAD link that is enabled through the CAD properties dialog box. You can also double click on any point and use the image tab to add an image file.

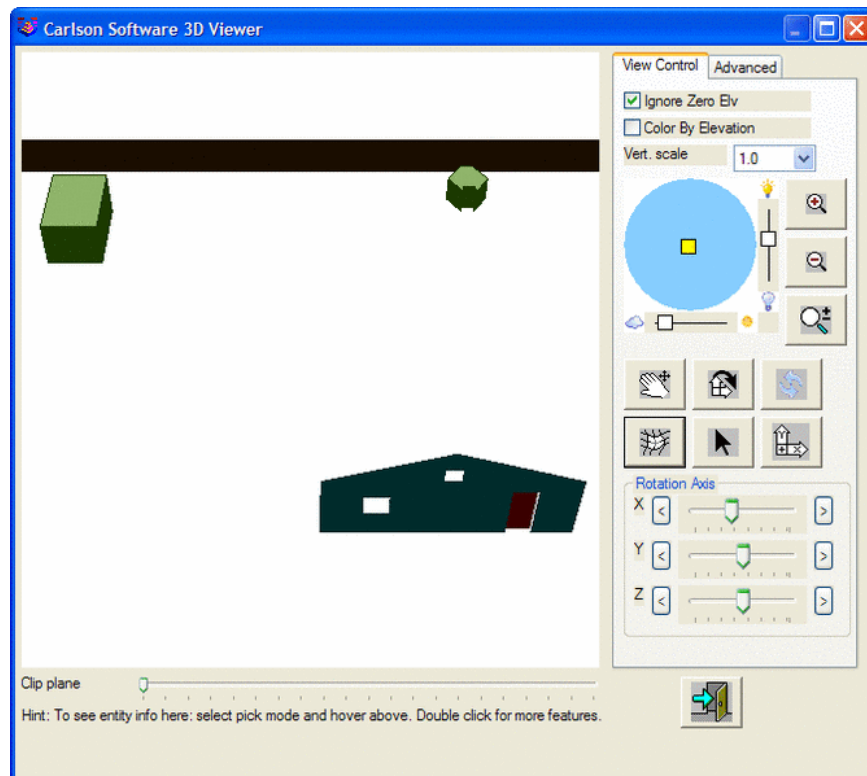

OFB Offset Width -This option works with the **OFB** special code.

- The Double option expects the user to enter half the total offset distance and the routine will double it. For example, if the total width of a pathway is 10, the OFB code will be 5.
- The Split option expects that the user will enter the total distance and the routine will split it in half. For example, if the total width of a pathway is 10, the OFB code will be 10.

2-Point Circle - This option works with the CIR special code. The radius option will use the first point with the CIR code as the radius point and the second located point as the outside of the circle. The Diameter option expects that the first point with the CIR code is one point identifying the outside of the circle and the second point another. Together they create a 2 point circle diameter.

Append Desc Auto Space -applies to the special codes that control the point description label. This option sets whether to insert a space in the description label when appending to the description.

3D Face Special Codes Below are the special codes that can be used for the easy creation of 3D surfaces. The resulting 3D face entities can be viewed in the Carlson 3D viewer by entering "cube" on the command line.

FACE3D - Makes a triangle mesh of 3D face entities by triangulating points starting with the current point and continuing until the line ends or another 3D special code is found. The points must be ordered along the perimeter. Although the mesh will be built if the points are clockwise or counterclockwise along the perimeter, the visible side in the Carlson 3D viewer, "cube", is the clockwise side by default. On the Advanced tab, the shading mode may be set to *Shade both* or *Shade back* if you would prefer to see both sides or just the counter-clockwise side.

HOLE3D - Makes an exclusion area within the triangle mesh identified by the point number following this code (e.g., "HOLE3D101" will start a hole in point # 101). If no point number is given ("HOLE3D"), the exclusion area is applied to the last mesh or if there is a mesh in the process of being constructed by the current sequence of points, it is ended and the hole is applied to it. Note that a hole can only be applied to a mesh that was created by FACE3D (not BLOCK3D or WALL3D). Note also that it can be difficult to predict what the "last mesh" was if it used a different field code since the points of the coordinate file are processed by order of field code first and then point number. There is no limit to how many holes can be applied to a FACE3D mesh. The points of the hole itself are not added to the FACE3D mesh; they are projected on to the best plane that contains the FACE3D mesh and then the hole is cut-out.

Example 1:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 VENT1 HOLE3D2500 */applies 2505-2508 as a hole to last mesh that uses point #2500. So any point in the range 2500-2504 would have the same effect.*

2506 VENT1

2507 VENT1

2508 VENT1

Example 2:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 HOUSE1 HOLE3D */stops the above mesh and applies 2505-2508 as a hole*

2506 HOUSE1

2507 HOUSE1

2508 HOUSE1

Example 3:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 WINDOW1 FACE3D HOLE3D2503 */applies 2505-2508 as a hole to above mesh 2500-2504 and starts a new mesh using the WINDOW field code.*

2506 WINDOW1

2507 WINDOW1

2508 WINDOW1

Example 4 (same result as Example 3):

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1
2504 HOUSE1
2505 WINDOW1 FACE3D /starts a new mesh using the WINDOW field code.
2506 WINDOW1
2507 WINDOW1
2508 WINDOW1 HOLE3D2504 /makes the mesh 2505-2508 also be a hole in the mesh 2500-2504.

BLOCK3D - Makes a set of 3D faces to make a 3d block using the height value entered after the code (e.g., "BLOCK3D2.3" with height 2.3). Heights can be positive or negative. With 3 points, makes a parallelogram base that is extruded up (or down if height is negative) to form a 6-sided block, including top and bottom. With 4 or more points, makes a closed polygon for the base that is then extruded by the height. The points can be laid out in clockwise or counterclockwise order around the perimeter. The perimeter or base does not have to be a convex polygon.

WALL3D - Makes a set of 3D faces above the polyline using a height value entered after the code (e.g., "WALL3D2.3" with height 2.3). This height is a signed value so you can shoot either the top of the wall or the bottom of the wall. The height can be negative if the points on the top of the wall have been shot. If no height parameter exists, then the height is determined by the distance from the current point to the next point.

After the height value, you can have a width/thickness value. If no width value is entered, then a width of zero is used. When the width value starts with a minus "-", then the width is put on the left side of the points. When the width value starts with a plus "+", then the width is put on the right side of the points. When the width value has no plus or minus, then the points go through the center of the wall width.

Both sides of the wall will have triangles and so both sides will always be visible in the Carlson 3D viewer.

Example – 6' high wall shot along the bottom:

```
2000 1000.000 1060.000 100.000 WALL1 WALL3D6.0 /wall 6'  
2001 1100.000 1060.000 100.000 WALL1  
2002 1100.000 1160.000 100.000 WALL1
```

Example – 6' high and 1.5' wide wall shot along the bottom:

```
2000 1000.000 1060.000 100.000 WALL1 WALL3D6.0 1.5 /wall 6' high and 1.5' thick  
2001 1100.000 1060.000 100.000 WALL1  
2002 1100.000 1160.000 100.000 WALL1
```

Example – 6' high wall, height specified by 1st to 2nd point, shot along the bottom:

```
2020 1100.000 1160.000 100.000 WALL2 WALL3D /height by 2nd pt  
2021 1100.000 1160.000 106.000 WALL2  
2022 1000.000 1160.000 106.000 WALL2
```

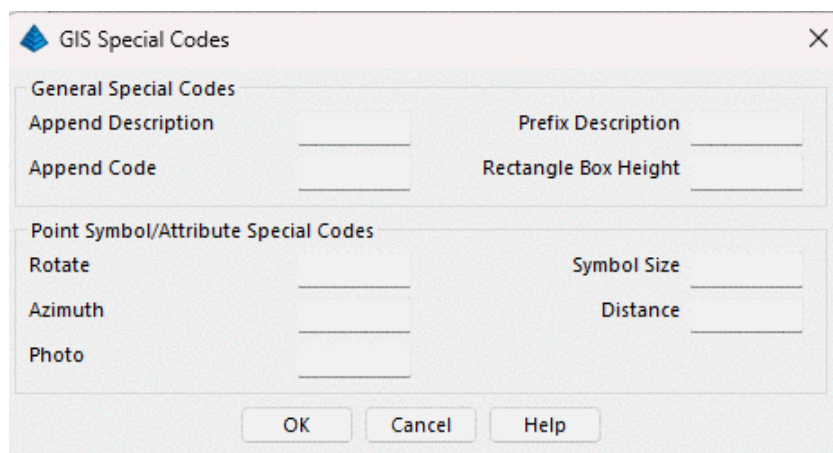

Load Default

This button sets the special codes to Carlson, Eagle Point, Geopak, InRoads or TMOSS defaults.

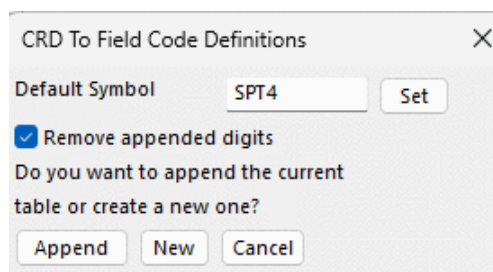

GIS Special Codes: This option allows you to use GIS attribute for Field-to-Finish special coding. For a select group of special codes, a GIS attribute can be assigned. When processing the points, if a point has GIS data for the specified attribute, then that attribute value is used for the special coding. For example, you can have a GIS attribute of COMMENT set to the Append Description special code. Then if a point has a GIS attribute for COMMENT, the value of that COMMENT will be added to the description label for that point.

The Append Code option adds the GIS code to the description code to make the code for processing. For example, for a point with description "ROAD" and a GIS attribute named "TYPE" with a value of "DIRT", then set the GIS Special Code for Append Code to "TYPE" and the program will process this point using the combined code of "ROADDIRT".

Code Table by Points - This command will create code table definitions based on the coordinate file field descriptions. This is useful when creating a code table from scratch

The options available when creating a code table from existing descriptions are:

- Default Symbol: Use the Set button to select a symbol to use for all of the codes created
- Remove appended digits: Removes the numeric group number from any code descriptions. For example EP1 would be created as EP. This avoids unnecessary duplication of code names.
- Append or New: allows you to append an existing code table or create a new one.

Save: Saves the Draw Field to Finish field code definition (.FLD) file.

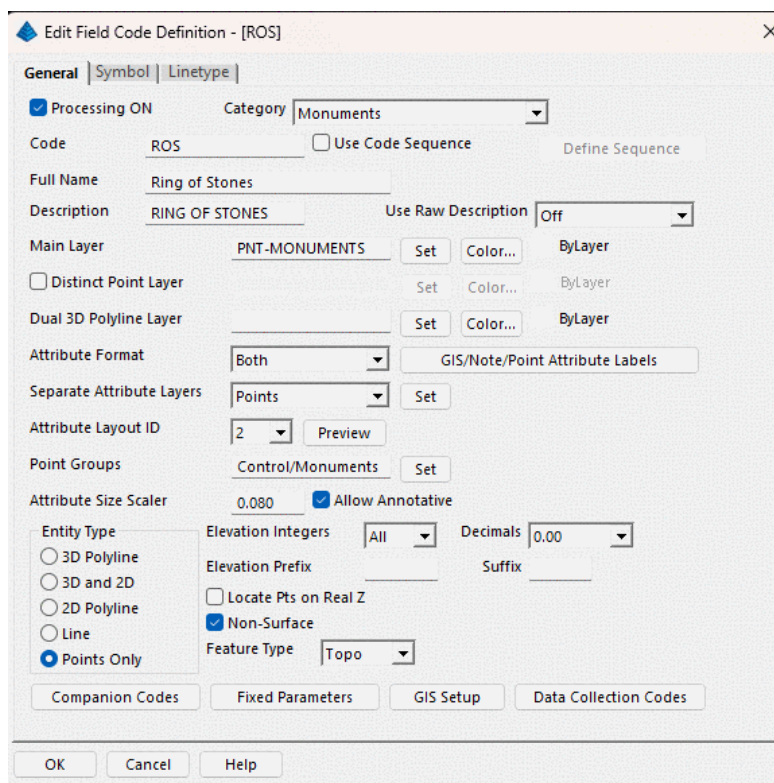

Save As: Reacts the same as Save but allows for specification of file name and location to save to.

Code Definitions

Edit: the Edit button reacts differently depending on whether a Single code is selected or Multiple codes are selected.

Edit (Single Code)

If only one field code is selected, the Edit Field Code Definition dialog box is opened.

The code definition dialog has three tabs: **General**, **Symbol** and **Linetype**. Here are the settings under General:

General Tab

Processing ON: This toggle controls whether this code will be processed. This allows you to process only specific codes if desired.

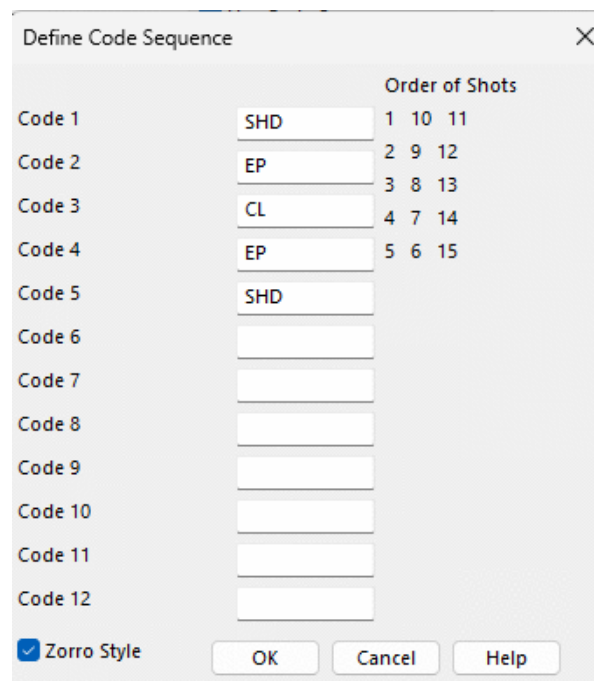

Category: Contains a "drop down" menu that displays the names of the Categories Created in the Draw Field to Finish dialog box for selection.

Code: This is the key name that identifies the code and is matched with the field data descriptions. It is important to note that the * character, used in this field, is regarded as a wildcard or "match anything" code. For example, a field code definition with the code defined as TREE* will be used for any raw description of TREE. Raw descriptions of TREEA, TREE12, TREE, etc. will match the TREE code definition. This will always be the case unless there is a more specific code is found. For example is there was a code TREEA in the code definition file, then that code would be used instead of the TREE code.

It is also important to note that the wild card is not necessary for line number grouping such as EP1, EP2 EP3 etc. The code for this example is simply EP. The program is designed to treat all codes with a numerical suffix as the code itself but separates each one into a separate line string.

Use Code Sequence: This specifies a sequence type code. Sequences are a way to simplify field entry of a sequence of codes. For example, a road cross-section could be SHD1 EP1 CL EP2 SHD2. Instead of entering these different descriptions, one sequence definition can store these descriptions in order. Then just the sequence code (such as RD) is used in the field. The cross-section can be shot in left to right then left right order, right to left then right to left order, or alternating left to right then right to left order. The alternating method is known as the Zorro style. The one restriction is that the shots always start from a right or left edge. To set up a sequence, choose the Sequence toggle in the Edit Code dialog. Then pick the Define Code Sequence button. This brings up a dialog for entering the sequence codes in order. These sequence codes should be defined as normal codes somewhere else in the Draw Field to Finish code table (ie SHD as a 3D polyline). In the field, the one template code is used for all the cross-sections shots (ie RD for all the points). Then Draw Field to Finish will substitute this template code with the sequence codes (ie substitute RD with SHD).

Define Code Sequence: This sets the code names that make up the sequence.

The image shows a dialog box titled "Define Code Sequence" with a close button (X) in the top right corner. The dialog contains a table with 12 rows, each representing a code. The first column is labeled "Code" and the second column is labeled "Order of Shots". The "Order of Shots" column contains three numbers for each code, representing the sequence order. The codes are: Code 1 (SHD), Code 2 (EP), Code 3 (CL), Code 4 (EP), Code 5 (SHD), Code 6 (empty), Code 7 (empty), Code 8 (empty), Code 9 (empty), Code 10 (empty), Code 11 (empty), and Code 12 (empty). At the bottom left, there is a checked checkbox labeled "Zorro Style". At the bottom right, there are three buttons: "OK", "Cancel", and "Help".

Code	Order of Shots
Code 1	1 10 11
Code 2	2 9 12
Code 3	3 8 13
Code 4	4 7 14
Code 5	5 6 15
Code 6	
Code 7	
Code 8	
Code 9	
Code 10	
Code 11	
Code 12	

Zorro Style

OK Cancel Help

Resulting points and linework showing Zorro style template

Full Name: This is an optional field that describes the code for viewing and printing but also works with the **Legend** command.

Description: This value is assigned to the point description attribute when the point is drawn. This description can be different than the field code. For example, the code **IP** could have a description of **IRON PIPE** which will be applied to the attribute of the point.

Note: An additional description can be added to a point by entering it after a forward slash "/" for suffix or backwards slash "\" for prefix in the data description field.

Example **IP\3"** would be **3" IRON PIPE**.

Use Raw Description: This option turns off the Description field described above. Instead the points will be drawn with their original unprocessed descriptions.

- Attribute Block: The raw description will populate the *Description Attribute* of the point block.
- Text Attribute: The raw description will add text to the drawing in accordance with the **Attribute Format** options and the respective **GIS/NOTE/Point Attribute Labels** options.
- Both: will perform both of the above options.

Main Layer: The point and line work for the code will be created and placed on this layer.

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Distinct Point Layer: When this toggle is selected, the line work is created on the layer defined in the Main Layer field and the points are created in the specified distinct point layer. For example, you could have DRIVEWAY for linework and DRIVEWAY_PNT for the points. This option allows for greater control over the placement of points and linework.

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Dual 3D Polyline Layer: Displays the layer that the 3d polyline will be drawn on when using an Entity Type of 3D and 2D. The layer name can be typed in this field. The result is the 2D and 3D polylines being drawn on separate layers. For Example, you could have the 2D polyline drawn on the layer DRIVEWAY and the 3D polyline drawn on the layer BREAKLINES.

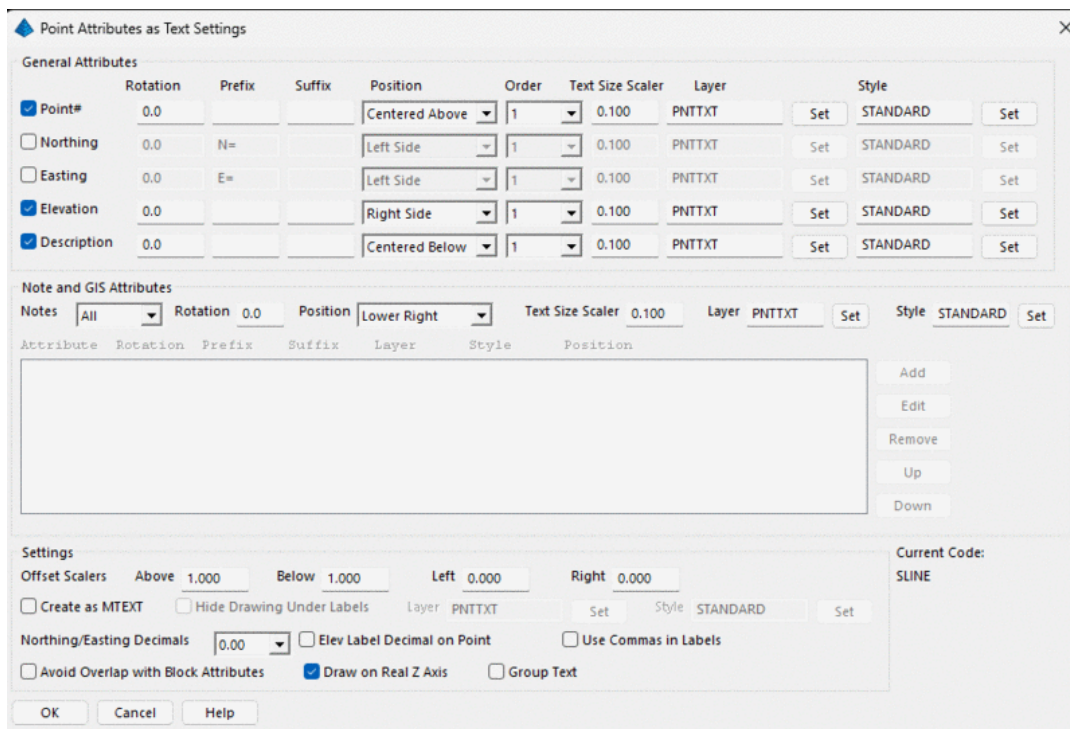

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Attribute Format:

This chooses the type of point entities to create. The **Attribute Block** format creates a Carlson point entity which is a block with attributes for point#, elevation and description. The layer of each attribute as well as the point block can be controlled by setting the Separate Attribute Layers.

The **Text Attribute** format creates text entities for each of the point attributes.

When the **Text Attribute** or **Both** format is selected, the placement, appearance, and function of each is controlled by selecting the GIS/Note/Point Attribute Labels button.

For the **General Attributes** control, there are toggles to control whether or not each attribute is displayed for the Point# (number), Northing, Easting Elevation and Description. In addition, there are controls for for each attribute that include:

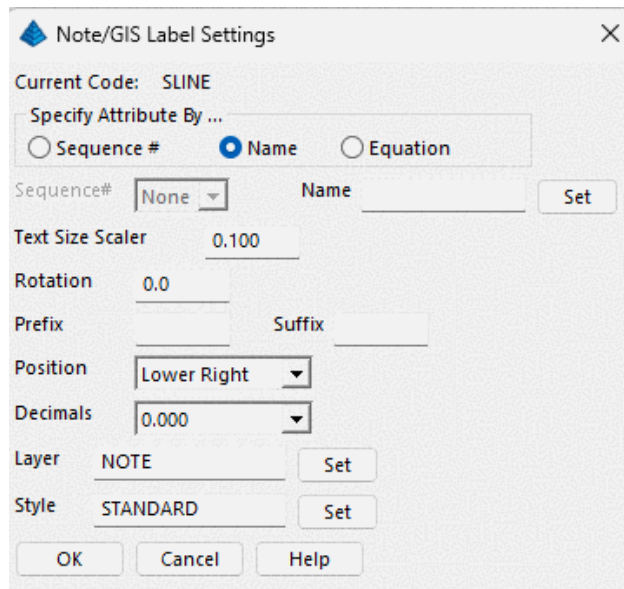

- Rotation - rotates the attribute display
- Prefix - adds a prefix to the attribute
- Suffix - adds a suffix to the attribute
- Position - controls the placement of the attribute in relationship to the point (node)
- Order - controls the order of each attributes.
- Text Size Scaler - sets the size of the attributes in relation to the drawing scale. Example 0.10 at a drawing scale of 1" = 20' will create a text size of 2.0
- Layer - sets the layer for the attribute to be placed
- Style - sets the text style for the attribute.

The **Note and GIS Attributes** section of the dialog box adds additional control over both Notes contained in the .NOT file and GIS attributes defined either by the GIS module, SurvCE/PC or other data collectors or created via Field to Finish fixed parameters. These notes/attributes are in addition to the point description but are directly related to each individual point. Making use of these additional attributes can add a great deal of power and flexibility to the Field to Finish program.

The **Notes** drop-down box allows 3 options.

- None - will not place any additional attributes into the drawing
- All (default) - will place all attributes contained in the .NOT file or created during the Field to Finish process into the drawing.
- Selected - will only place the specifically selected attributes into the drawing.

For **selected**, use the Add, Edit and Remove buttons to build the list of fields to label.

To specify the field to label, the *Sequence#* method sets the field by its order position. For example, a sequence of 3 would use the third attribute for the point. 5 Wires in the below example

9	
10	

The **Name** method sets the field to label by field name. The field name can be predefined through the GIS feature file, by SurvCE/PC in the field or can be created via the Fixed Parameters in the Edit Field Code Definition dialog box. Example of Named Attributes:

Note	
1	NUMBER=#43
2	MATERIAL=WOOD
3	WIRES=5
4	
5	
6	
7	
8	
9	
10	

The **Equation** method sets the value by the specified equation of attribute names and numbers. Besides the attribute

names, there are keywords of "X", "Y" and "Z" for the values of the current point coordinates. For example, if there is an attribute named DEPTH, then you could define a label for the invert as an equation of "Z - DEPTH".

Another example is to make a label that is 1.5 higher than the point elevation using an equation of "Z + 1.5". Besides attribute names, you can make an equation by attribute sequence using "NOTE" plus the sequence number. For example, if the depth value is the 3rd attribute, then to define a label for the invert elevation, use the equation "Z - NOTE3".

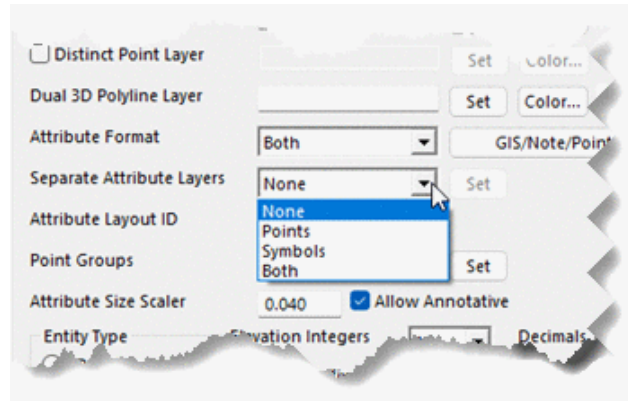

Note: Besides labeling attributes as text with this method, the Symbol > Custom Attributes feature is a way to label attributes as block attributes.

The **Settings** portion of the dialog box adds additional control of the placement and appearance of the attributes as they are placed in the drawing.

- Offset Scalers - control the distance for the text from the point for the different positions. These offset distances are calculated by multiplying the scaler by the horizontal scale for the drawing.
- Create as MTEXT - creates a Mtext entity containing all of the attributes.
 - Hide Drawing Under Labels - creates a background mask for the Mtext entity
 - Layer - with the *Create as Mtext* option enabled, all attributes will be placed on the same layer as set in this portion of the dialog box.
 - Style - with the *Create as Mtext* option enabled, all attributes will be use the same text style as set in this portion of the dialog box.
- Northing/Easting Decimals - sets the precision for the horizontal coordinates displayed
- The Elevation Label Decimal On Point option will place the elevation label so that the decimal point of the label is on top of the point location.
- Use Commas In Labels option will add commas for the thousandths place for the northing, easting and elevation labels. ie. N=1,000,000.00
- Avoid Overlap With Block Attributes option will attempt to resolve conflicts between the point block attributes and those set in this dialog box by shifting the horizontal location of the latter.
- Draw On Real Z Axis option controls whether to the text entities at the point elevation or at zero elevation.

- Group Text option creates a CAD Group for all the point labels.

Separate Attribute Layers:

This controls the layers of the point block, point attributes and/or point symbols.

- None - the point attribute layers are the default layers of, "PNTNO", "PNTELEV" and "PNTDESC", the parent layer for the point attribute block and symbol is the Main Layer designated in the Field Code definition.
- Points - allows the designation of each point block and associated attributes layers. For example if the code DWL has a layer name "DRIVEWAY", the point attributes could then be "DRIVEWAYNO", "DRIVEWAYELEV" and "DRIVEWAYDESC".
- Symbols allows the designation of the symbol associated with the point
- Both allows both of the above options.

Attribute Layout ID: Controls the location of the point number, elevation and description. These attribute layouts are defined in the drawings that are stored in the Carlson SUP directory with the file name of SRVPNO plus the ID number (i.e. SRVPNO1.DWG, SRVPNO2.DWG, etc.). If you want to change the attribute positions for a layout ID, then open and edit the associated SRVPNO drawing. Layout Ids of 1-9 are available.

Point Groups: This field is for the name of the point group that all points with this code will be added to. If the points for this code belong to multiple point groups, you can specify multiple point group names in this field separated by commas. Under Draw in Additional Draw Options, there is an option whether to automatically use the code name as the point group name or to use the name defined in the code definition. A point group does not have to exist for this option to work. It will create the designated point groups when processed.

Attribute Size Scaler: This is a scaler value that is multiplied by the horizontal scale to obtain the actual size for the point number, elevation and description attributes. This control is independent of the symbol size scaler and other text/attribute scalers allowing complete control over each element associated with the code.

Allow Annotative: This option will create the points as annotative when the annotative setting is on in the Point Defaults command.

Entity Type: This defines the line entity to be created.

- Points Only - does not connect points with any line work, however does create an option symbol is selected.
- Line - draws a CAD line entity
- 2D Polyline - creates a 2 dimensional Polyline drawn at elevation 0.

- 3D and 2D - creates both a 2D Polyline at elevation 0 and a 3D Polyline with each vertex matching the point elevation. The 3d polyline is placed on the layer specified in the **Dual 3d polyline Layer** setting and a 2d polyline in the layer identified in the **Main Layer** setting. Since 3d polylines do not display linetypes and are often difficult to draft with, this option is useful. 3D Polylines can be used for adding breaklines for surface modeling while 2d Polylines will maintain proper linetypes and can be edited through general CAD commands such as offset and fillet.

Note: The generation of Points, Symbols 2D and 3D Polylines can also be controlled through the Draw Field to Finish and Additional Draw Options.

Elevation Integers: This controls the number of digits to display to the left of the decimal point for the elevation label. The All setting will show the full elevation digits. The other settings allow you to limit the number of digits to display for the purpose of reducing the amount of space the elevation labels take up in the drawing. For example, if a site is in the 4000 foot elevation range, then this setting could be set to three digits (000) and an elevation of 4321 would be labeled as 321.

Elevation Decimals: This controls the display precision for the elevation label.

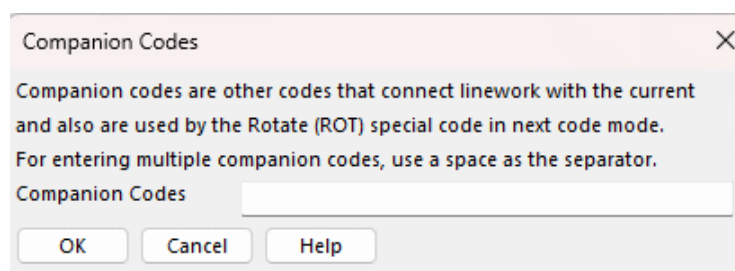

Elevation Prefix/Suffix: These set the prefix and suffix for the elevation label per code. In the Draw function under Additional Draw Settings, there is an override to set the elevation prefix/suffix for all the codes.

Locate Pts on Real Z Axis: This option will draw the points at the actual point elevation. Otherwise the points are drawn at zero elevation. For example, you could turn this option off for the FH for fire hydrant code to draw them at zero. Then the GND code could have this option on to draw the ground shots at their elevations. It is important to remember that Carlson's Triangulate and Contour routine will utilize points for creating a surface model regardless of whether they are set at Real Z or not. If the point is placed in the drawing at Real Z, Triangulate and Contour will use the point block elevation for the Z value whereas if they are drawn at zero (0), it will use the elevation from the CRD file. To ensure that a point is not used for surface modeling in Triangulate and Contour, use the Non-Surface option or utilize the NE or NOS special codes.

Non-Surface: Entities created with this flag are ignored when contouring or creating surfaces regardless of their elevation.

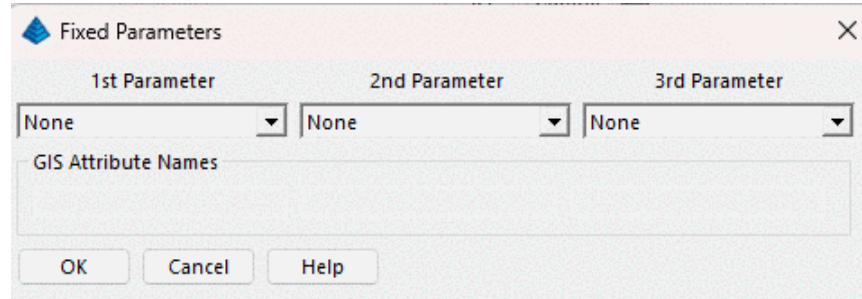

Feature Type: Controls how to process this code. The Default Feature Type is Topo. This is used for most survey work and places points using all of the above assigned settings. The Tree, Utility and Pipe Features are processed more specifically and are controlled via individual setups.

Companion Codes: This option allows different codes to connect when defined as line, polyline or 3d polyline. For example, a main line power pole code may be defined as PP while a service utility pole may be defined as UP. When processing Draw Field to Finish, it may be desired to connect all PP and UP codes together. This could be accomplished by defining a companion for UP as PP and a companion code for PP as UP. Each code needs to reference the other as a companion code.

Companion Codes can also be used in conjunction with special codes such as the Rotate (RO) code.

Fixed Parameters: This option is a coding method where you specify a sequence of parameters that follow the main code.

There can be up to three parameters each one having the options shown below:

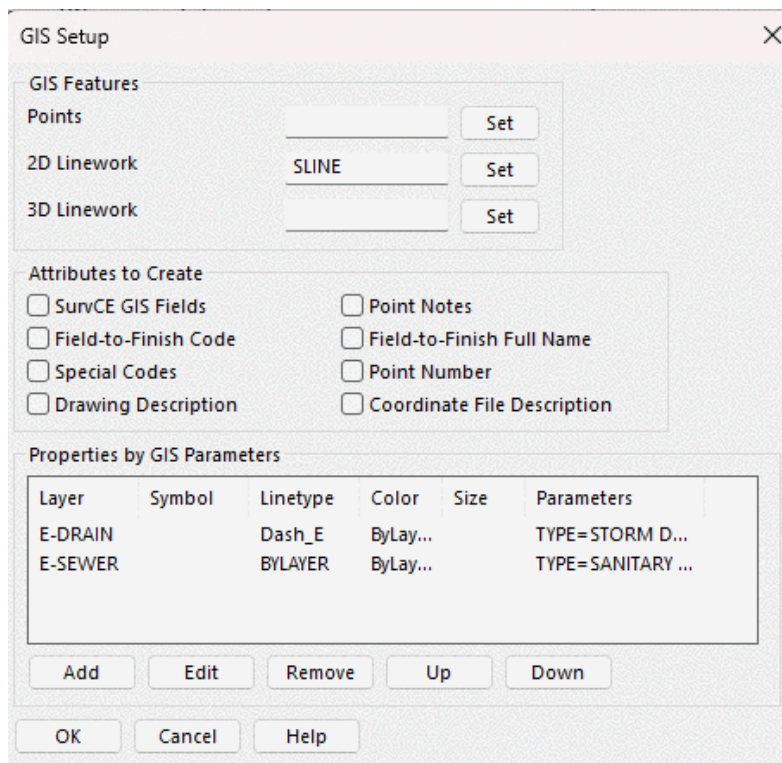

Each of these options take the place of keying in special codes in the field. Instead, the parameters can be entered directly following the main code followed by spaces.

For example: a code called CURB was used to create a consistent front and back of curb lines using the Horizontal and Vertical offset special codes. The first parameter is set as **Offset Horiz** and the second as **Offset Vert**. It would be coded in the field as **CURB 1 .5** for a horizontal offset of 1 and a vertical offset of 0.5 eliminating the need for the OH and OV special codes.

GIS attributes can also be created using Fixed Parameters by choosing the GIS Attribute parameter. This way the GIS attributes can follow the main code in the description. For example, you could have a main code of MH for manhole followed by the depth to store as a GIS attribute. The description would be "MH 4.4" which results in the creation of a named attribute, DEPTH with a value of 4.4.

GIS Setup:

With GIS processing activated, the entities created by Field-to-Finish are linked to a GIS feature name and attributes. The Features and respective attributes are contained in the .GIS file created in the GIS pull-down menu in the Survey module or within the full GIS module. There are two basic required files for using GIS, (beyond the use of Field to Finish), a .GIS file that contains the features and attributes and a database file to contain that data associated with those features and attributes. *See GIS module help for more information*

GIS processing in Field-to-Finish starts with the GIS Table setting in the initial Draw Field To Finish dialog.

Setting the GIS Table is optional but useful. The GIS Table is used as the reference in the Set functions for selecting a GIS feature name to assign to Field-to-Finish codes. Additionally, when processing the Field-to-Finish codes, any associated attributes from the GIS Table will be attached to the entities. Also, attributes generated from Field-to-Finish can be added to the GIS Table. Essentially, there is a "read/write" functionality between the FLD file and the GIS file.

GIS Features: Each Field-to-Finish code has settings to assign GIS feature names. In the Edit Field Code Definition dialog, the GIS Setup button brings up a dialog for setting the GIS feature names and attribute options for the current code.

Points - selects a GIS feature defined as a Point

2D Linework - selects a GIS feature defined as a 2D polyline

3d Linework - selects a GIS feature defined as a 3D polyline

Set - in all 3 of the above options, the Set button will open a dialog box listing the available features in the active GIS table

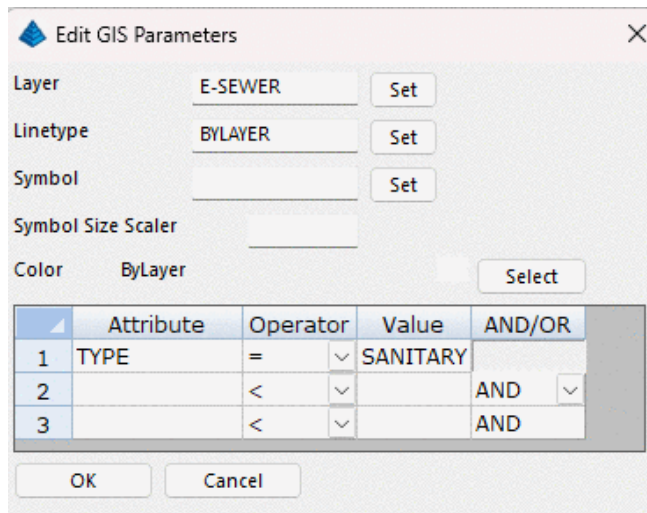

Since Field-to-Finish codes are capable of drawing both points and linework and GIS can have different features for points and linework, there are separate settings for the GIS feature names for points and linework. For example, a Field-to-Finish code UP for utility pole could be setup to draw both points with symbols at the poles and polylines between these points. Then you could have different GIS feature names for the pole points and linework with separate GIS attributes for each.

Attributes to Create: each option toggled on will create a GIS feature and add it to the .GIS file.

- **SurvCE GIS Fields:** This option uses the attribute data generated by SurvCE which is stored in a .vtt file with the same file name as the current coordinate file except with the .vtt extension.
- **Point Notes:** This option creates GIS attribute data generated by SurvCE from the .not file with the same file name as the coordinate file except with the .not extension.
- **Field-to-Finish Code:** This option creates an attribute named CODE with a value of the Field-to-Finish code name (ie. UP).
- **Field-to-Finish Full Name:** This option creates an attribute named FULL_NAME with a value of the Field-to-Finish Full Name (ie. Utility Pole).
- **Special Codes:** This option creates attributes for Field-to-Finish special codes including OH (Offset Horizontal), OV (Offset Vertical), SZ (Size), ROT (Rotation), AZI (Azimuth) and DIST (Distance).
- **Point Number:** This option creates an attribute named POINT_NAME with a value of the point number from the coordinate file.
- **Drawing Description:** This option creates an attribute named POINT_DWG_DESC with a value of the point description for the point block created in the drawing.
- **Coordinate File Description:** This option creates an attribute named POINT_RAW_DESC with a value of the point description from the coordinate file.

The Point Properties By GIS Parameters lets you control the layer, symbol, linetype, color or size of the points based on GIS attributes.

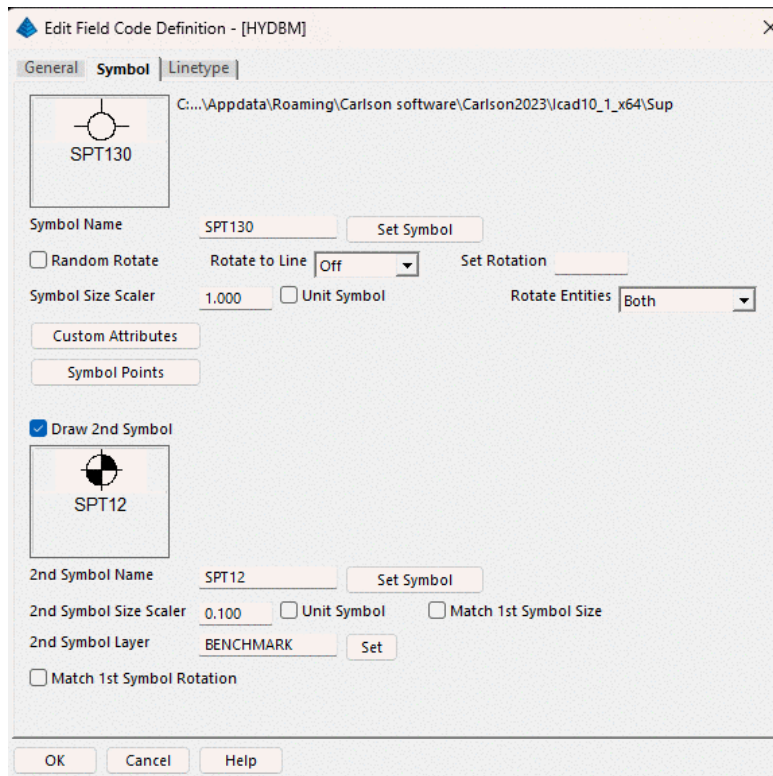

In the above example, a feature with the name SLINE (meaning sewer line) was selected. When Field to Finish finds 2 or more points with that code name and the attribute Type is set to Sanitary, it will draw a 2D polyline on the layer E-Sewer with a bylayer line type. Each code and respective feature can contain as many attributes as desired. Each attribute can then trigger different options for the placement of lines or symbols on different layers at different sizes.

Data Collection Codes: These settings apply to Carlson Field for turning on the Offset mode and Rotate mode automatically by F2F code.

Symbol Tab

Set Symbol: This is the point symbol for the code. The dialog allows you to select from the symbols defined in the Symbol Library which is setup with the Settings->Symbol Library command. Besides the symbols from the symbol library, you can also use any symbols that are defined as blocks in the current drawing by entering the block name in the symbol edit box. To have a point without a symbol, use the Carlson symbol named SPT0 which represents "no symbol". If you create a custom symbol (DWG file) and you want to process Field-To-Finish on other computers, be sure to load this symbol (DWG file) in the Settings > Symbol Library on each computer which will place it into the appropriate sub-folder. Or you can upload the symbol onto Carlson Community for the other computer to find. Field-To-Finish automatically checks the Carlson Community for any symbols that aren't found on a local computer.

Note: a great way to distribute custom symbols as well as all other custom settings and files is to use the Settings Server contained in the Project/Data Folders setup.

Random Rotate: This option will randomly rotate the symbol. For example, this option could be used for tree symbols to have the trees drawn in various orientations.

Rotate To Line: This option applies to points that are part of Field-to-Finish linework. This option will align the point attributes and symbol to the associated linework. The Middle mode uses the average angle for the line segments coming to and from the point. The Forward mode uses the line angle going from the point. The Backward mode uses the line angle coming into the point. The Ends mode uses the perpendicular angle for the line end segment and applies for culverts.

Rotate Entities: This setting controls whether to apply rotation to the symbol, the point attribute block or both.

Set Rotation: Sets a specific rotation for a symbol. This rotation is subject to the current view as set in the Twist Screen command.

Symbol Size Scaler: This is a scaler value that is multiplied by the horizontal scale to obtain the actual size in the drawing. The horizontal scale can be set in *Drawing Setup*.

Unit Symbol: This option, when enabled, will draw the point symbol at unit (1:1) scale and will ignore the horizontal drawing scale. For example, this option could be used for a symbol that is already drawn to actual dimensions such as a car symbol.

Custom Attributes: This feature allows you to use customized blocks that have customized attributes (the tag/value pairs). This feature works for both point attribute blocks and symbols. For attribute blocks, Field-to-Finish looks for attributes with the tags "PT#", "ELEV2", and "DESC2". The custom attributes feature allows you to define additional attributes in their custom blocks on a per-field code basis. The dialog shows five attributes at a time. The number of attributes is unlimited. Use the Next and Back buttons to show more attributes.

Custom Attributes

Attributes must not be Constant or Preset.

Find Custom Attributes

Tag #	Value	Set	Decimals	Prefix	Suffix
Tag #1 TYPE	Value GIS[TYPE]	Set	Decimals	Prefix	Suffix
Tag #2 SIZE	Value GIS[SIZE]	Set	Decimals	Prefix	Suffix
Tag #3	Value	Set	Decimals	Prefix	Suffix
Tag #4	Value	Set	Decimals	Prefix	Suffix
Tag #5	Value	Set	Decimals	Prefix	Suffix

OK Cancel Help Back Next Clear

For an example, the custom block could have an attribute with the tag "TREE_SPECIES" and there is a separate field code for each species of tree. Each of those field codes can specify the value that should be assigned to the attribute that has the TREE_SPECIES tag. Then when the points are drawn, the tree species is shown. Note that the custom attributes must have their Constant and Preset properties set to "no". The custom attributes settings in F2F should not use those tags that the software already handles (PT#, ELEV2, and DESC2), or the setting will be ignored.

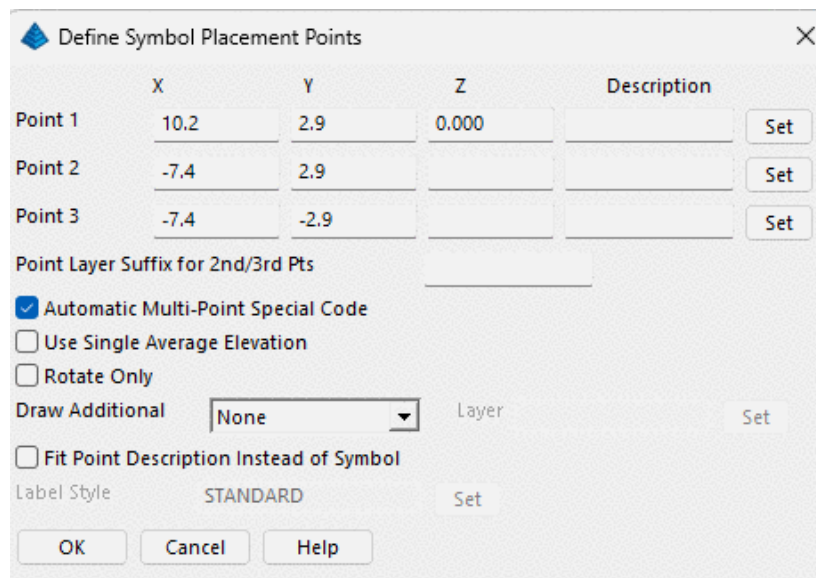

The Values for the attributes can be fixed strings that you enter in the dialog shown here. They can also be dynamic parameters including point number, northing, easting, elevation or description for the current point as well as a point note, GIS attribute or equation. The Equation type sets the value by the specified equation of attribute names and numbers. Besides the attribute names, there are keywords of "X", "Y" and "Z" for the values of the current point coordinates. For example, if there is an attribute named DEPTH, then you could define a value for the invert as an equation of "Z - DEPTH". To setup a parameter value, pick the Set button and then select the attribute. The Decimals setting applies to fields that are real values. The Prefix and Suffix fields are added to the Value for the attribute string. Available Parameter Types:

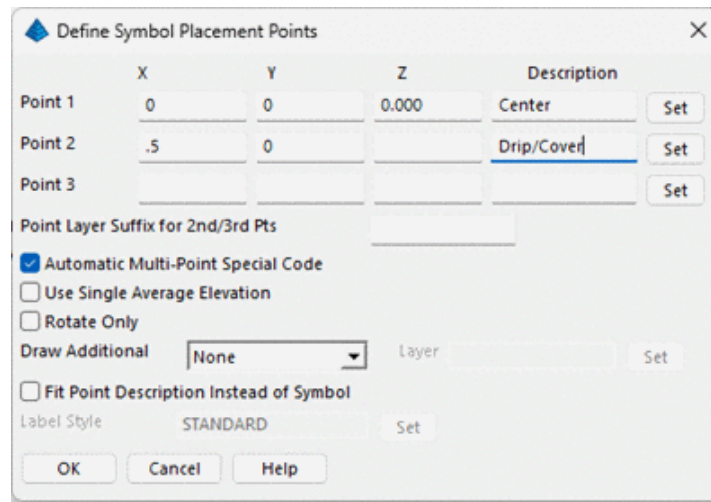

Besides labeling as block attributes, the Attribute Format method of Text mode is a way to label the attributes as text entities.

Symbol Points: For each code definition, the symbol insertion points can be defined with up to three points. To define the symbol insertion points, choose the Symbol Pts button in the Edit Code Definition dialog box. By default, the symbol insertion is defined by one point at the symbol center (0,0). A one point insertion definition can be used to insert a symbol offset from the center. With a two insertion point definitions, the program will rotate and scale the symbol. For example, two insertion points can be used to insert a tree symbol to size the tree, where the first point is for the tree center and the second is for the drip line. With three insertion point definitions, the program will rotate and scale the symbol in both X and Y. For example, three points can be used to insert a car symbol with the first point being the front drivers side, the second point as the back driver side (to rotate and scale the length) and the third as the back passenger side (to scale the width). Besides the insertion point coordinates, you can define a description for each point which is used for the drawn point description and is used for prompting in the Insert Multi-Point Symbol command and in Carlson Field data collection.

Three Point Symbol Drawing

The coordinates for the insertion point definitions are for the symbol at unit size. To figure these coordinates, you will need to open the symbol drawing (.DWG) file. By default, the symbols are located in the Carlson SUP directory. For example to make an insertion point for the tree drip line, open the tree symbol drawing and find the coordinate at the edge of the tree symbol (in this case 0.5,0.0).

Two Point Symbol Example

Not all of the symbol insertion points need to be used when drawing the points. If a code definition has a three insertion points, it is possible to use just the first two or first one. There are special codes to associate multiple points to the same symbol. The first code point is used as the first symbol insertion point. The "2ND" code is used to specify the second symbol insertion point. A point number can follow the "2ND" to identify a specific point. Otherwise without the point number, the program will use the next point with the current code. The "3RD" code is used to specify the third symbol insertion point and similar to the "2ND" code, a point number after the "3RD" is optional. The "2ND" and "3RD" codes should be assigned to the first point. For example, consider a code of "CAR" with a three point symbol insertion definition. If point #1 has a description of "CAR 2ND 3RD", then point #1 will be used as the first symbol insertion point and the next two points with the "CAR" description will be used as the second and third symbol insertion points.

Multi Point Symbol Drawing

The **Point Layer Suffix for 2nd/3rd Points** option allows for having different layers for the 2nd and 3rd points used with the multi-point symbol.

The **Automatic Multi-Point Special Code** option saves from having to enter the 2ND or 3RD special codes. This option applies when the code is always used from multi-point symbols.

The **Use Single Average Elevation** option averages the elevations of the symbol points for the point elevation label.

The **Rotate Only** option uses the symbol points only to rotate the symbol and does not scale.

The **Draw Additional** has options for drawing a 4th point or rectangle. The **Create 4th Corner Point** option draws another point when using a three multi-point symbol. This option applies when the symbol is rectangular and you shoot three corner points and want the program to draw a point at the 4th corner. The **Rectangle** option creates a rectangle to fit the 3 symbol points and applies to creating a breakline for surface modeling around the symbol.

The **Fit Point Description Instead Of Symbol** option is a method to drawing labels that are positioned by these points such as road markings. To set a custom text to label, you can use the `///` (Replace Description) special code. For example with a code called MARK, the description could be "MARK 3RD `///`BUS LANE". Or turn on the Automatic Multi-Point Special Code and then the "3RD" isn't needed and the description could be "MARK`///`BUS LANE". For the text control points, lower-left = 0,0, upper-right = 1,1, upper-left=0,1, and lower-right = 1,0.

Draw 2nd Symbol: This option creates a second symbol on each point. For example, this additional symbol can be used to add a 3D symbol to a 2D symbol used as the first symbol or simply add a second symbol to the point. Besides selecting the symbol name, there are settings for the Symbol Size Scaler Layer and Rotation which mimics the settings described for the first symbol with the addition of matching the 1st symbol size and rotation.

Linetype Tab

Set Linetype: Line work can be drawn in any of the special linetypes or with the linetype for the layer ("BY-LAYER"). There are three types of pre-defined linetypes: **CAD**, **Entity** and **Continuous**.

The type is shown as part of the linetype names in the list. The **CAD** linetypes are the default linetypes available

in AutoCAD and IntelliCAD. The **Entity** linetypes insert text or symbol entities at the linetype interval. These linetypes are the same as used with the Annotate->Polyline To Special Line command. The **Continuous** linetypes define a special linetype in CAD and create continuous polylines with that special linetype. These linetypes are the same as with the Annotate->Change Polyline Linetype command. Besides these pre-defined linetypes within Field-to-Finish, you can also use any linetype that is defined in the drawing by entering that linetype name in the linetype edit box or by picking the **Select From Drawing** button within the Set Linetype dialog. The spacing and size of the special linetypes is determined by the CAD LTSCALE system variable and by the 3 controls shown above or in the field code settings:

- Line Type Spacing Scaler - controls the spacing between the text and/or symbols inserted in the linetype for either the Entity or Continuous linetypes.
- Line Type Text Scaler - controls the size of the text and/or symbols inserted in the linetype for either the Entity or Continuous linetypes.
- Custom Text - allows text entry for the "User Defined" linetype.

Note: The special linetype "**Hedge**" is drawn with a width set by Line Width. The offset special codes of OH or OFB can also be used to control the width of the "hedge" linetype. The special linetype "**userdash**" is drawn with user specified distances for the length of the dash and the length of the gap between dashes.

Line Width: This controls the width for the linework. Only applies to 2D polylines. The LTW special code can also be used to set the line width for a specific line.

Linetype Text Style: Sets the text style created in the *Style* command in CAD

Linetype Text: This is the text that is used for the user-defined linetype. To use, Set Linetype to either Other_E or UserDef_C. Then this text will be used for the linetype. For example, if you have a code for a 8" PVC pipeline, then you could set this text to 8" PVC. This linetype text will use the font set in the **Linetype Text Style**. If this style is blank, the text will use the current font.

Linetype Spacing Scaler: This is a scaler value that is multiplied by the CAD LTSCALE system variable to give the distance between text or symbols in the line.

Linetype Text Scaler: This is a scaler value that is multiplied by the CAD LTSCALE system variable to give the size of the text or symbol in a line.

Flip Linetype: This option switches the side for the linetype which applies to non-symmetrical linetypes like the treeline or guard rail. The Special Code LTF can be added to the first code in the line sequence to accomplish this as well.

Smooth Polyline: This option applies a modified Bezier smoothing to the polyline. The smoothed polyline will pass through all the original points.

Hard Breakline: This option will tag the 3D polylines created with this code as hard breaklines. In *Triangulate & Contour*, contours are not smoothed as they cross hard barriers.

Label Lines and Arcs: This option will label the lines and arcs drawn using the specified Line/Arc and General Label Settings.

- **Line/Arc Label Settings:** *Selected Setting* Select an existing Label Settings file (AAN) by clicking the **Select** button or modify the file by clicking the **Edit** button.
- **General Label Settings:** *Selected Setting* Select an existing Label Settings file (ADF) by clicking the **Select** button or modify the file by clicking the **Edit** button.

Label Areas: This option will label closed areas within the specific tolerance. The areas will be labeled using the specified Area Label Settings.

- **Area Tolerance:** This is the tolerance used to determine if an area is closed and should be labeled. If a polyline closure is greater than this tolerance, the area will not be labeled.
- **Area Label Settings:** *Selected Setting* Select an existing Label Settings file (ARS) by clicking the **Select** button or modify the file by clicking the **Edit** button.

Separate Offset Layer: This setting uses another layer name for polylines created using an offset special code.

Label 3D Offset Elevations: This option labels the elevations and symbols of the vertices for polylines created using an offset special code. The Attribute Format must be set to Text Attribute or both and the Elevation attribute enabled for this option to take effect.

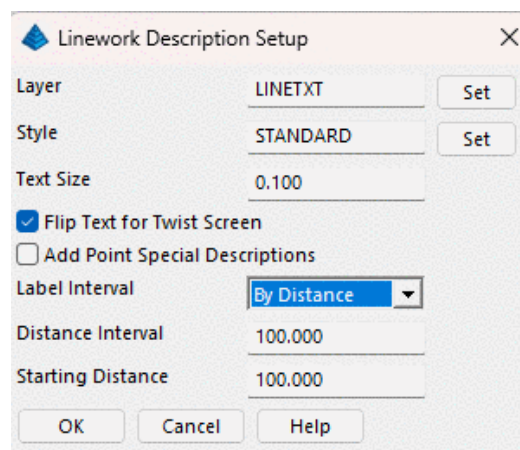

Closed Polyline for Offset Both: This option will create a closed polyline from the left and right offset polylines when the OFB (Offset Both) special code is used.

Connection Order: The points of a distinct code can be connected in their point number order, sequential, or by nearest found which creates the line by connecting each point to the next closest point.

Tie: The options for this is **Open** or **Closed**. When set to Open, the polyline created will end at the last point in the line string. When set to Closed, the last point in the line string will close back to the first. For example if you have points 1, 2, 3, and 4 with the code BLDG and Tie is set to Closed, the linework will be drawn from point 1 to 2 to 3 to 4 and then back to point 1, closing the figure.

Linework Description: This allows for an optional description which is labeled along linework created by the code.

- The **Select GIS** button chooses a GIS attribute to use for the linework description from the GIS Table. The program checks all the points used for the linework for the GIS attribute for this description. To setup the GIS attributes, the Linework Description string is formatted with "[GIS:attribute]". For example, if you have GIS attributes for "Client" and "Weather", then the string to label both attributes with prefixes could be "Client=[GIS:Client], Forecast=[GIS:Weather]" or without prefixes could be "[GIS:Client] [GIS:Weather]".
- **Description Setup** button displays a dialog to control the layer, style and size for these labels.

Layer - Sets the layer for the line text

Style - sets the text style for the line text

Text Size - sets the text size scaler for the line text

Flip Text for Twist Screen - orients the linework labels to be right side up for the drawing current twist view

Add Point Special Descriptions - adds a special description created using the prefix or suffix special codes and adds that to the description. For example if a sewer line were drawn with the Linework Description of Sewer and a prefix was added to the code of /8", the linework would be labeled as 8" Sewer

Label Interval - sets the option for the frequency of labeling the linework description. The options are from 1 to 4 labels per line string or by a Distance Interval.

- Distance Interval - sets the distance between labels in terms of drawing units.
- Starting Distance - sets the distance from the beginning of the line for the first description label.

Edit and Set Template: For 3D polyline codes, this option allows you to assign a template (.TPL) file to the code. The code points act as the base line for the template and the program will draw parallel 3D polylines for each break point (grade ID) in the template. The template file is defined in the Civil Design module or by using the Edit button. In the Edit Template dialog, there's a special setting for Field-to-Finish for the Offset Target Grade. This Offset Target Grade controls which grade in the template to use as the center line for the code points. If this field is blank, then the start of the template is used.

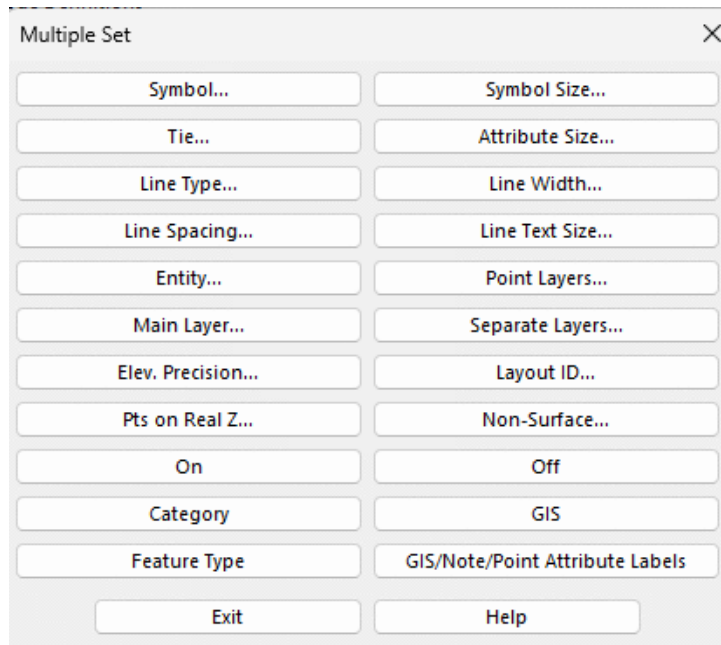

The templates are dynamic and can be adjusted along the 3D polyline by using the OH (offset horizontal) and OV (offset vertical) special codes. For example, when there is a curb template that flattens when it comes to a driveway, then an OV0 code could be used at the driveway start point and then use OV.5 at the driveway end point to restore the curb to 0.5 feet high.

Use Template IDs as Layer option will use the grade IDs from the template for the layers of the polylines created.

Hatch Closed Areas: This option applies for codes used to draw closed linework which is used as the perimeter for a hatch area. The hatch settings include the hatch pattern name, scale and layer.

Edit (Multiple Codes)

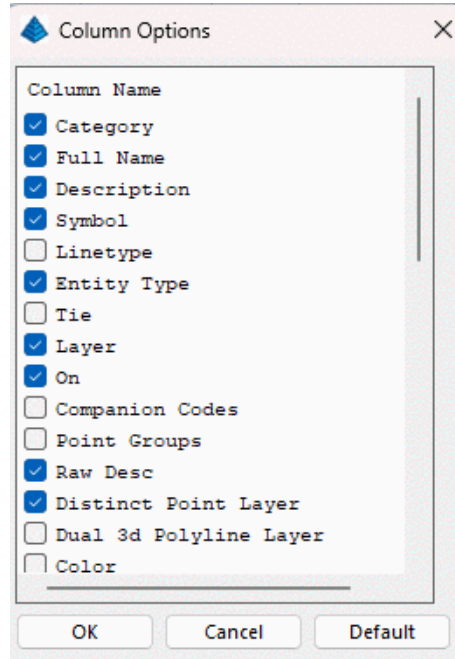

If more than a single code is selected, the Edit button will allow a limited number of "Global Edits" to the codes.

Each of these options will effect all codes selected and is a great way to make changes to a large number of codes at the same time. For example, if you wanted to set all the codes to a particular attribute size, use the Select All option and then Edit. You can then set all codes in the library to the same size attribute.

Code Definitions (continued)

Column Options: Controls the displayed columns in the display window.

Each item can be toggled on or off and the display window will update accordingly. It is important to remember that each field in each column can be modified directly from the display window. This helps greatly in the ease of editing codes in the table. Turn the columns on of interest and use copy/paste or a drop down selection as is available.

Select All: This option selects all the codes within a selected category. This can be used when only wanting to process a couple of codes. For example, use the select all option to select all the codes and then turn them off. Now select the codes for processing and turn them on. Also it can be used to make a global change to all the codes.

Move Category: Moves the selected code(s) to a predefined category.

Add: Adds a new empty code definition which is inserted in the list at the position after the currently selected one. If none are selected for positioning, the new code is placed at the top. Only one code definition may be highlighted before running this routine.

Copy: This option copies the definition of a selected code. It opens the Edit Field Code Definition dialog and copies the definition of the selected code to the appropriate settings. It does not copy the name of the code. It is a time saving tool to use when creating codes that are similar with only a couple of differences.

Delete: This command will remove the highlighted code definitions from the list.

Search: Allows you to search for a specific code in the list.

Move Up/Move Down: allows for the manual resorting of the code list by moving the selected code either up or down.

Feature Settings

Tree Setup:

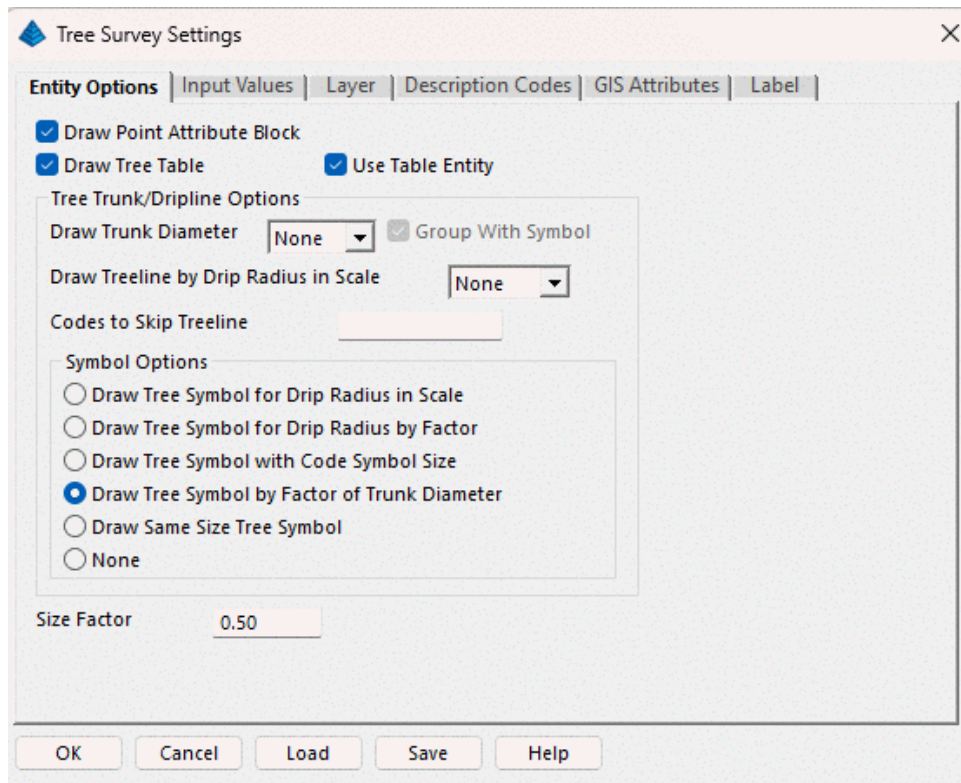

Tree surveys can be coded simply by using general Field-to-Finish coding methods such as defining a code for a tree ("OAK") with a tree symbol and using the SZ special code for sizing the symbol. The **Tree Feature** provides more power and flexibility in cases where a simple symbol is not sufficient. The tree survey works with three optional attributes for each tree: trunk, drip and tag. Trunk is the diameter of the tree trunk. Drip is the radius of the tree canopy. Tag is an id for the tree for reporting.

Tag	Trunk	Drip	Comment
T100	12"	15	MAPLE
T101	10"	10	CEDAR

Important: The Tree Survey Settings apply to codes that are set to a Feature Type of Tree. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

Entity Options Tab:

Draw Point Attribute Block -controls whether to draw the point block with the point #, elevation and description attributes.

Draw Tree Table - This option makes the program prompt for whether to draw a tree table when the program finds a couple points with tree codes. Otherwise, there must be many tree codes to have the program prompt for creating a tree table. The Use Table Entity option draws the table as a Carlson Table Entity. Otherwise the table is drawn with regular CAD lines and text.

Draw Trunk Diameter - Sets whether to create a circle or solid with the trunk diameter. The Group With Symbol option creates a CAD group to combine the tree and trunk symbols.

Draw Treeline by Drip Radius in Scale - shrink wraps the tree drip lines to get the overall treeline perimeter. The perimeter polyline can be drawn either as Bubbles or Smooth. The Bubbles creates a treeline style polyline with a series of arcs. The Smooth creates a regular polyline.

Codes to Skip Treeline - allows you to skip specific Field-to-Finish codes from using with the treeline. If you have more than a single code to skip, use either a space or comma to separate the codes.

Draw Tree Symbol for Drip Radius in Scale - draws individual symbols for each tree using the symbols defined in the code table and scaled by the drip size attribute.

Draw Tree Symbol for Drip Radius by Factor - draws individual symbols for each tree using the symbols defined in the code table and scaled by the drip size attribute and the Size Factor from this dialog.

Draw Tree Symbol with Code Symbol Size - draws individual symbols for each tree using the symbol name and size defined in the code table.

Draw Tree Symbol by Factor of Trunk Diameter - draws individual symbols for each tree using the symbols defined in the code table and scaled by the trunk size attribute multiplied by 12. For example, a 10" trunk size is drawn as a 10ft symbol.

Draw Same Size Tree Symbol - draws individual symbols for each tree using the symbols defined in the code table and at size of 6.

None - simply does not draw a tree symbol

Input Values Tab:

The screenshot shows the 'Tree Survey Settings' dialog box with the 'Input Values' tab selected. The dialog has a title bar with a close button (X) and a tabbed interface with the following tabs: 'Entity Options', 'Input Values', 'Layer', 'Description Codes', 'GIS Attributes', and 'Label'. The 'Input Values' tab contains the following settings:

- Default Tree ID to Point ID
- Begin Tree ID from: 100
- Input Trunk Value: Diameter
- Input Drip Value: Radius
- Canopy Companion Code: DRIP

At the bottom of the dialog are five buttons: 'OK', 'Cancel', 'Load', 'Save', and 'Help'.

Default Tree ID to Point ID - option uses the point number for the tree tag unless the point description contains a tree tag.

Begin Tree ID From - this is the number to start the incremental numbering of tree tags from. Each point with a tree feature code will be numbered consecutively thereafter.

Input Trunk Value - controls whether the trunk size is entered as a radius or diameter.

Input Drip Value - controls whether the canopy drip size is entered as a radius or diameter.

Canopy Companion Code - this tree coding method handles a point at the trunk and then a series of 3 or more points for the canopy. The point description coding uses separate codes for the trunk and the canopy points.

The program draws a Bezier smooth polyline thru the points for the canopy. In this example, points 1 and 6 have the tree feature code from the Field-to-Finish code table, and the rest of the points have the Canopy Companion Code.

Layer Tab:

Table Layer - sets the layer for the optional tree table to be drawn

Prefix/Suffix Type - designates whether the layer names will be added as a suffix or prefix to the Main Layer as designated in the code itself.

- Label Layer - added to the layer name for the tree label ie. Maple, Oak etc.
- Tree Trunk Layer - added to the layer name for the label of the trunk size
- Tree Drip Layer - added to the layer name for the label of the drip line size

Example: the main layer for the code DT is set to Tree. The tree labels would be placed on the layers Tree-Name, Tree-Trunk and Tree-Drip

Description Codes Tab:

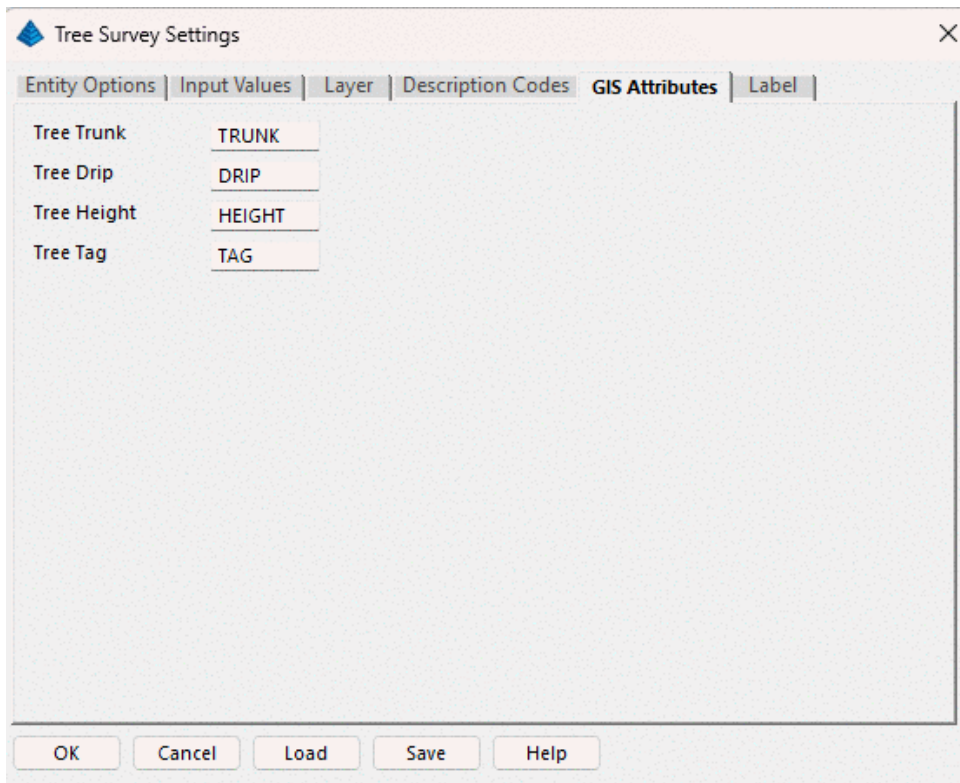

There are settings to help identify the tree attributes in the point description. The program looks for the trunk size, drip size, tag ID and height in the point description after the tree code. By default, the program expects the attributes to be in the order of trunk size, drip size, tag ID and height. Here's an example default order:

OAK 16 12 100 28

where OAK is the tree code from the code table, 16 is the trunk diameter, 12 is the drip radius, 100 is the tag ID and height is 28.

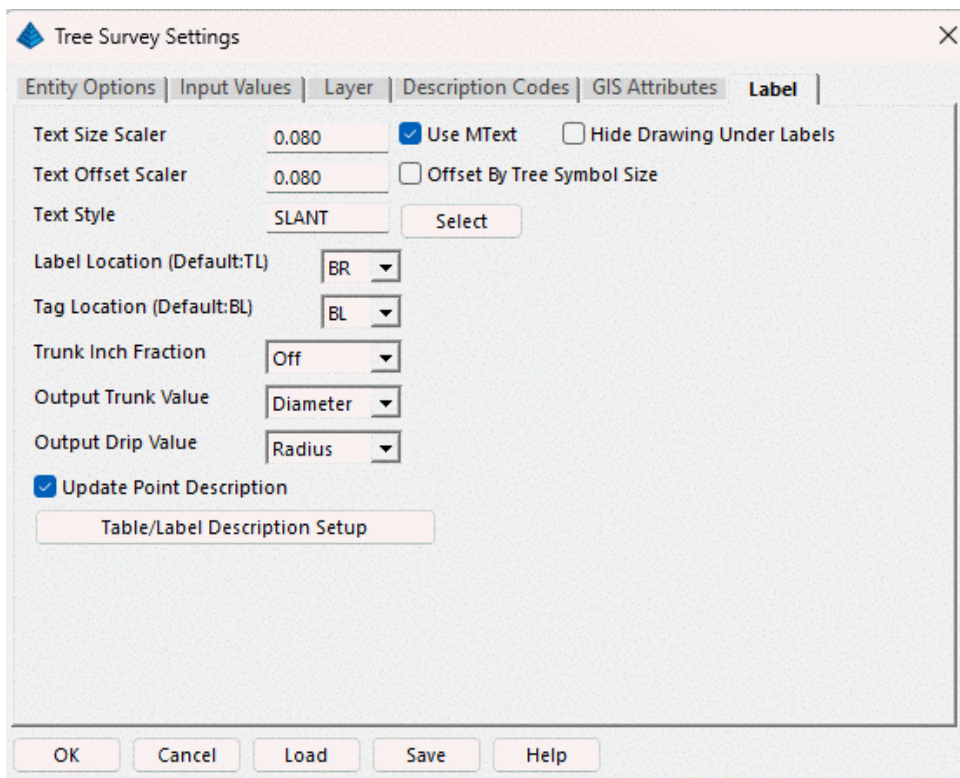

You can change the order that the program looks for the attributes by setting the Default Order numbers. Another way to change the attribute order is to use the suffix/prefix settings to identify the attributes. When the program finds a specified prefix or suffix, it tells the program which attribute to use. For example, if the Trunk Suffix is "in" and the Drip Suffix is "ft" and the Tag Prefix is "T", then OAK T100 16in 12ft means tag ID of 100, trunk diameter 16 and drip radius 12 feet.

GIS Attributes Tab:

In addition to looking for the tree attributes in the point description, the program can also read these attributes from GIS fields. On the **GIS Attributes** dialog tab, you can set the GIS field names for the tree attributes. The data collected in the field would be stored in the .vtt file which would contain the values for each of the defined attributes. Normally, this option would be used in place of adding the tree data directly to the code description.

Label Tab:

There are settings for the tree text labels for the size, offset from trunk center, style and location. When creating a tree table, only the tag text is labeled. Otherwise, the label is drawn.

Text Size Scaler - sets the scale size of the text the value of which is multiplied by the horizontal scale as set in the drawing setup. Options to **Use Mtext** and **Hide Drawing Under Labels** (applies a wipeout or text mask) are available.

Offset Scaler - applies a scale factor to control the placement of the text as it pertains to the point. **Offset By Tree Symbol Size** moves the labels beyond the tree symbol to avoid overlap between the labels and the symbol. The amount to move is factored by the Text Offset Scaler.

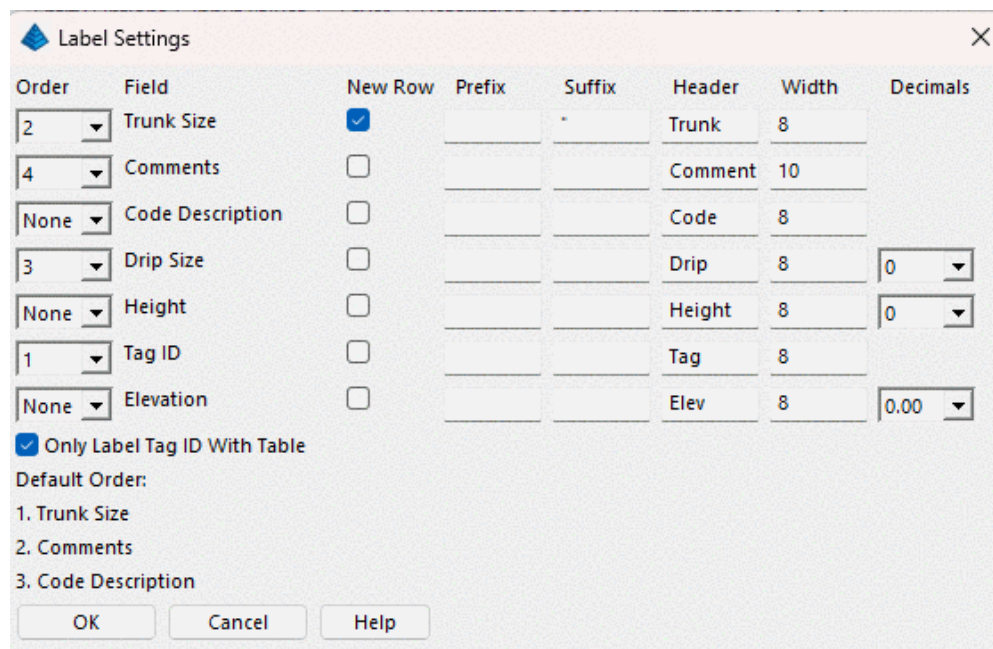

Trunk Inch Fraction - sets the precision in inches to use for the trunk size labels.

Output Trunk Value - sets whether to label the trunk size as a radius or diameter.

Output Drip Value - sets whether to label the canopy (drip line) size as a radius or diameter.

Update Point Description - sets whether to only use the label setup for the table and not the point drawing description. With this toggled on, the description attribute in the drawing will be updated to reflect the values to be used in the table as opposed to the coding as input in the field. The code description in the coordinate file is not affected by this setting.

Table/Label Description Setup - opens a Label Settings dialog box that controls the fields to be labeled in the drawing as well as included in the tree table.

For each field, there are settings to control the placement, prefix, suffix and the caption for the table columns. These settings effect both the labeling in the drawing and the table.

- Order - sets the order for the field
- New Row - when toggled on, places the field on a new row for the description label. This does not affect the tree table.
- Prefix - adds an optional prefix for the label

- Suffix - adds and optional suffix for the label
- Header - designates the caption for the top of the column in the tree table
- Width - sets the width of the field for the tree table column
- Only Label Tag ID With Table - when enabled, tree tags will only be used when the option for a tree table is enabled.

When Field-to-Finish draws entities, the program checks for codes set as tree features and applies the settings from the Tree Survey dialog. When tree features are found, the number of trees are reported along with a prompt for whether to draw a tree table. The tree table has the tag ID, code description and trunk diameter.

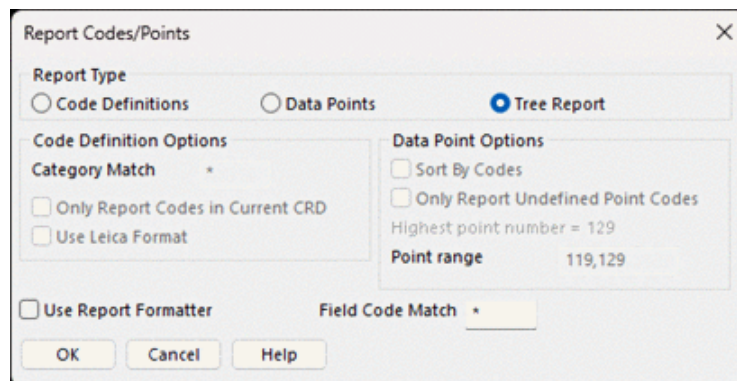

Here is an example with the following three points:

Point#	Northing	Easting	Description
1	4994.73	4923.15	OAK 24 38 301
2	5034.59	4881.40	PINE 18 24 302
3	4987.32	4975.79	PINE 12 20 303

Drip line drawn as Treeline method along with a tree table.

Another feature of Tree Survey is the **Tree Report** under the Report Codes/Points function. The Report Formatter option can be used to make a custom report and output to Excel or create a custom table in the drawing. To use this feature, use the Report Codes/Points option found in the Code Table or Draw Field to Finish dialog box.

Select the Tree Report option and click **<OK>**. Alternatively, enable the Use Report Formatter option and click **<OK>** to reveal additional options for the report.

Example Tree Table Report

Tree ID# Trunk Diameter Canopy Radius Comment
 T100 12" 15' MAPLE
 T101 10" 10' CEDAR

Pipe Setup:

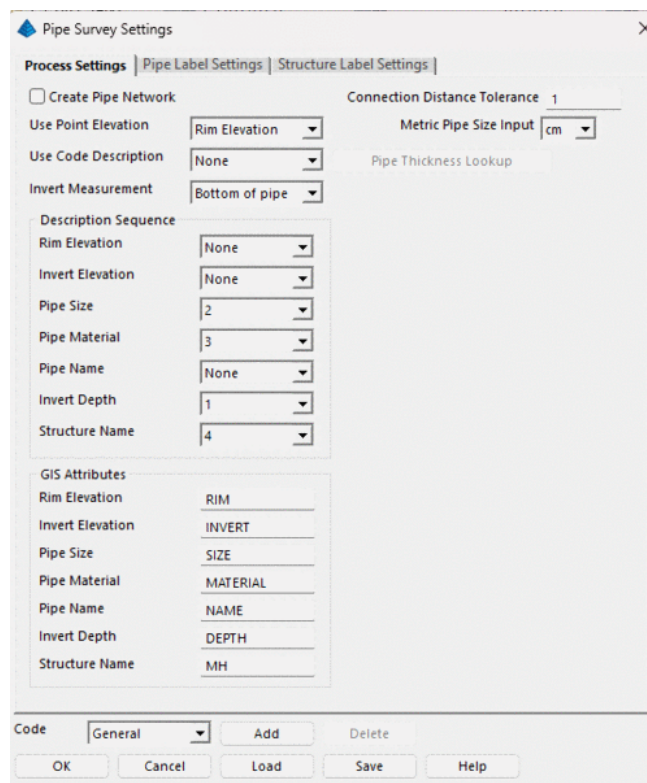

The **Pipe Feature** adds additional properties and options to the drawing a pipe line or network. Size, material and name are some of those options. in addition, the Pipe Feature allows more control over labeling of the pipe parameters and ability to draw the pipe in 3D.

Important: The Pipe Settings apply to codes that are set to a Feature Type of **Pipe**. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

When a code is tagged as a Pipe Feature, the program looks for additional parameters after the code. The parameters are separated by spaces in the point description and in the order specified in the Description Sequence in the settings dialog. For example, if code 'P' is defined as a Pipe Feature and the order of size, material and name, then a description of 'P 8 PVC 31' would define a pipe point for an 8 inch pipe of material PVC and name of 31. These pipe parameters are optional. The program will use the provided parameters and leave the rest blank. Besides using the point description, the pipe attributes can alternatively be set from GIS attributes using the attribute names setup in the dialog.

Process Settings Tab:

Create Pipe Network - when enabled, a SewerNET pipe network (.SEW) file will be created from the points connected with a pipe feature type. The **Connection Tolerance** limits the distance between points to be considered pipes belonging to the same structure. This is particularly useful when locating the actual invert for each pipe within a structure. The .SEW file can be utilized in the Sewer Network (**SewerNET**) contained in the **Hydrology** module. From there, the network can be edited, analyzed, and used for plan and profile creation.

Use Point Elevation - sets the control parameter for the point elevation. The field located point can be used as the **Rim Elevation**, the **Invert Elevation** or can be set to **None**.

Use Code Description - the code description can be used as the **Pipe Material**, **Pipe Name** or set to **None**.

Invert Measurement - when a pipe is field located directly, this control if the elevation will be used as the **Top** of Pipe or **Bottom** of Pipe.

Description Sequence - sets the order for the code descriptions as they are input into the code. The order of these setting must match the method in which the code is created. The fields that can be used and ordered are:

- Rim Elevation
- Invert Elevation
- Pipe Size
- Pipe Material
- Pipe Name
- Invert Depth
- Structure Name

For a structure with multiple inverts, pipe sizes and/or materials, the values should be in the description separated by commas. For example, for a structure with two incoming PVC pipes with sizes of 15" and 24", and inverts at depths 5.9 and 5.5, the description would be 'P 15,24 PVC 5.9,5.5'. If a value, such as the material does not change between structures, it need not be reentered.

GIS Attributes - using GIS attributes mimics the process described above. The difference is how the values are input into the pipe feature. Using the GIS attribute option requires that the data be entered as an attribute that is carried with the point coordinate file. The advantage to this method is that it does not necessitate long code description. Instead, the point attribute data can be entered in in a tabular format.

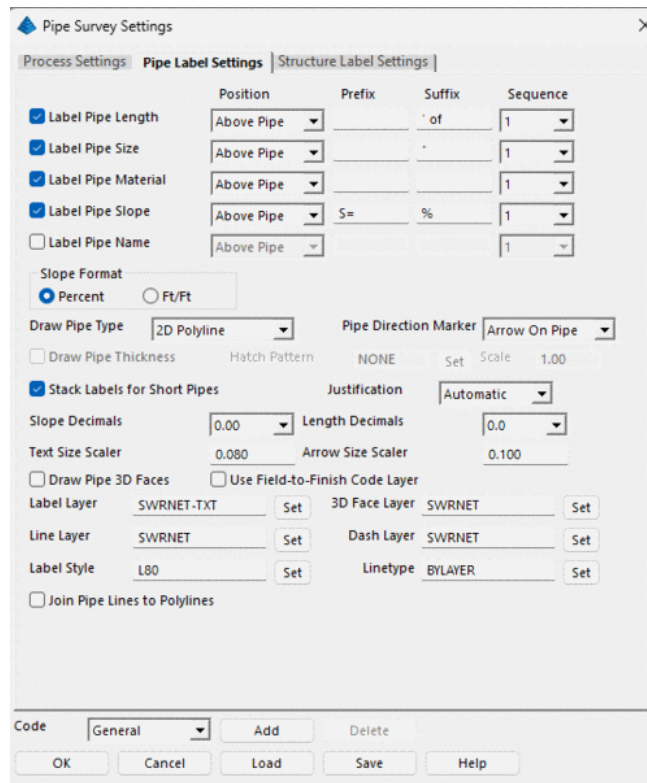

Example:

```
DEPTH=5.0  
SIZE=12  
MATERIAL=CONCRETE
```

The attributes can be created in advanced or in the field using SurvCE/PC and can be set up for prompts during the collection of the data.

Code - the Code defaults as General which would apply to all pipe feature codes. You can also Add a code that is contained in the Code Table as a Pipe Feature which can then have individual settings. For example, you could have a code called STORM for storm sewers and one called SANITARY for sanitary sewers. Each pipe network can have unique settings for layers and labels.

Pipe Label Settings Tab:

Label Pipe Length, Size, Material and Slope - all have controls over the position and content of the labels:

- Position - sets the position of the label as above or below the pipe
- Prefix - adds a prefix to the label
- Suffix - adds a suffix to the label
- Sequence - sets the sequence of the pipe label

Slope Format - can be expressed as a percentage of slope or foot per foot (ft/ft)

Draw Pipe type - sets the type of pipe to be drawn.

- 2D Polyline - draws a consistent 2D polyline at elevation 0
- 3D Polyline - draws a 3D polyline with each vertex matching the point elevation
- Double/Width - draws 2 dashed lines offset from each other the size of the pipe with no scale exaggeration.
- Dashed/Width - draws a solid and dashed line whose width is the size of the pipe with no scale

- None - does not draw line work between points
- Field-to-Finish - uses the linetype as selected in the Field to Finish Code Table

Pipe Direction Marker - draws an arrow in the direction of flow for each pipe segment. The choices are an **Arrow** on the Pipe, **Parallel** to the pipe or **None**

Draw Pipe Thickness - a pipe thickness (if available) can be drawn outside the pipe with the exception of the 2D or 3D polyline options.

- **Hatch Pattern** - an optional Hatch Pattern can be used to depict the pipe thickness. The selection and scale of the hatch pattern is also available.

Stack Labels for Short Pipes - automatically stacks the selected labels to make them look more readable.

Justification - the text justification for the labels can be set as Automatic, Left/Right or Centered.

Slope Decimals - sets the precision for the pipe slope labels

Length Decimals - sets the precision for the pipe distance labels

Text Size Scaler - sets the text size in terms of a scale factor which is applied to the horizontal scale as set in the Drawing Setup. (text scaler x horizontal scale = text size)

Arrow Size Scaler - sets the Arrow size in terms of a scale factor which is applied to the horizontal scale as set in the Drawing Setup. (text scaler x horizontal scale = text size)

Draw Pipe 3D Faces - when enabled, a 3 dimensional pipe as 3D Faces is drawn separately from the other pipe lines which can be viewed in Orbit view or Carlson's Drawing Viewer'

- **Use Field-to-Finish Code Layer** - draws the 3D pipes on the layer established in the Code Tablee

Layers for the Labels, Lines, 3D Faces and the Dashes (when using the Dashed/Width option) can be typed in or selected using the Set button.

Label Style - sets the text style for the pipe labels

Linetype - sets the linetype for the line work. This will override the linetype defined in the layer unless bylayer is selected and does not apply to the Dashed/Width option.

Join Pipe Lines to Polylines - joins all connected pipes into a single polyline. This does not work for the Double/Width or Dashed/Width pipe types

Structure Label Settings Tab:

Available/Used Labels - to setup the Pipe Structure Labels, highlight any available pipe structure labels on the left side of the dialog box and either double click or hit the Add button to move it to the Used Labels portion of the dialog box on the right.

Label Format - select the desired label format from the drop down list.

- Individual Labels - labels text at each structure location
- Data Table - creates a Data Table at each structure location. When this option is used, you are able to control the **Justification** of the table as well as the **Width** of the Labels and Values. These options only become available when the Data Table option has been selected.
- Attribute Block - adds the data for each structure to a predefined block containing the relative attributes. When this option is used, there is a Select button to select the block to be used.
- Along Pipe - labels the structure information along each respective pipe segment.

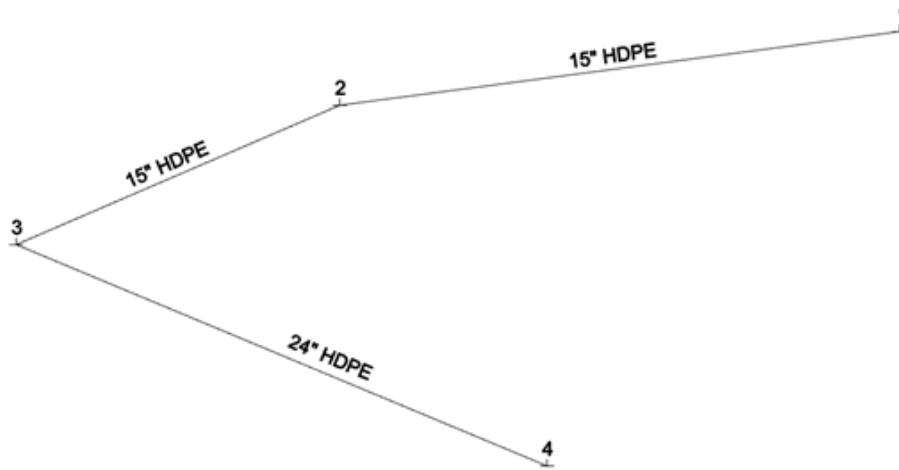

Station/Offset Decimals - sets the precision for the CL Station and Offset Labels

Elevation/Depth Decimals - sets the precision for Elevation labels of Rim, Inverts, and Depth.

Example coding of a pipe network. PIPE code is defined as a Pipe Feature. The 1st description is the pipe size. The 2nd description is the pipe material. The 3rd description is the pipe depth. Point 3 has two sizes and two depths separated by commas because two pipe connect at this point.

Point	Description
1	PIPE1 15 HDPE 4.75
2	PIPE1 15 HDPE 6.15

- 3 PIPE1 15,24 HDPE 5.96,5.5
- 4 PIPE1 24 HDPE 9.9

Example coding for 2 separate pipes using END code to separate the pipes. CUL code is defined as a Pipe Feature. 1st description is the Pipe Material and 2nd description is the pipe size. In this case, turn OFF the Create Pipe Network because the separate pipes are using the same code of CUL.

Point	Description
7	CUL RCP 18
8	CUL END RCP 18
14	CUL RCP 18
15	CUL END RCP 18

Example coding for 2 separate pipes using number suffix on codes to separate the pipes. CUL code is defined as a Pipe Feature. 1st description is the Pipe Material and 2nd description is the pipe size. In this case, the Create Pipe Network can be applied. The separate pipes are using separate codes of CUL1 and CUL2.

Point	Description
7	CUL1 RCP 18
8	CUL1 RCP 18
14	CUL2 RCP 18
15	CUL2 RCP 18

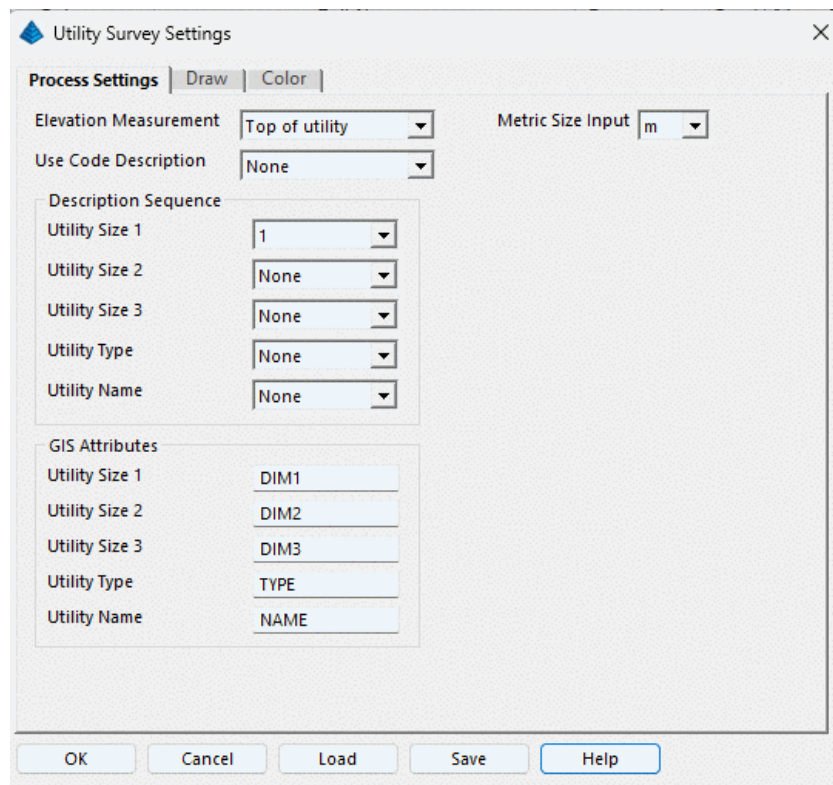

Utility Setup:

The Utility Feature works similar to the Pipe feature. The differences with utility are supporting different pipe shapes (circle, rectangle, etc), different types of utilities (gas, electric, etc), and not having manhole structures. For each utility type, there are settings for pipe shape, color, labels and drawing 2D Polylines, 3D Polylines and 3D Faces.

Important: The Utility Settings apply to codes that are set to a Utility Feature. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

Process Settings Tab:

Elevation Measurement - sets the reference for the point location as either Top or Bottom of the pipe

Description Sequence - Sets the order of the utility size in the code description

GIS Attributes - using GIS attributes mimics the process described above. The difference is how the values are input into the Utility feature. Using the GIS attribute option requires that the data be entered as an attribute that is carried with the point coordinate file.

Draw Tab:

Type - selects the type of utility for the draw settings. There is a pull down menu with include utility types of:

- Gas
- Water
- Sanitary
- Storm
- Communication
- Electric
- Irrigation
- Fire
- Utility Duct
- and Other for user defined utilities

Setup - allows the additional control of adding prefix, suffix and the size precision to the utility line label. This can also be accomplished by double clicking the label field.

Available/Used Labels - to setup the Utility Line Labels, highlight any available field labels on the left side of the dialog box and either double click or hit the Add button to move it to the Used Labels portion of the dialog box on the right.

Label Location - sets the location of the label along the utility line

- None - does not add a label to the line
- Ends - adds a label to each end of the utility line
- Interval places a label at a distance interval
 - Label Interval is the distance in CAD units to place the label
- Both - places a label at each end as well as at intervals

Label Style - controls the placement of the text label for the size and/or name of the utility.

- Parallel - places the label parallel to the utility pipe
- Horizontal - places the label horizontal to the screen view, with respect to a Twist Screen if present
- Mleader - creates a Mleader that points to the utility line

Draw Options - are toggles to select options for the entities to be drawn. One or more may be selected. The options are:

- Draw Plan View - will draw the 2D line work as set in the code table with respect to the options herein
- Draw 3D Polylines - draws a 3D polyline between points with each vertex matching the point elevation
- Draw 3D Faces - creates 3D Faces in the shape and size of the pipe shape selected

2D Polyline Linetype - sets the linetype for the 2D polyline

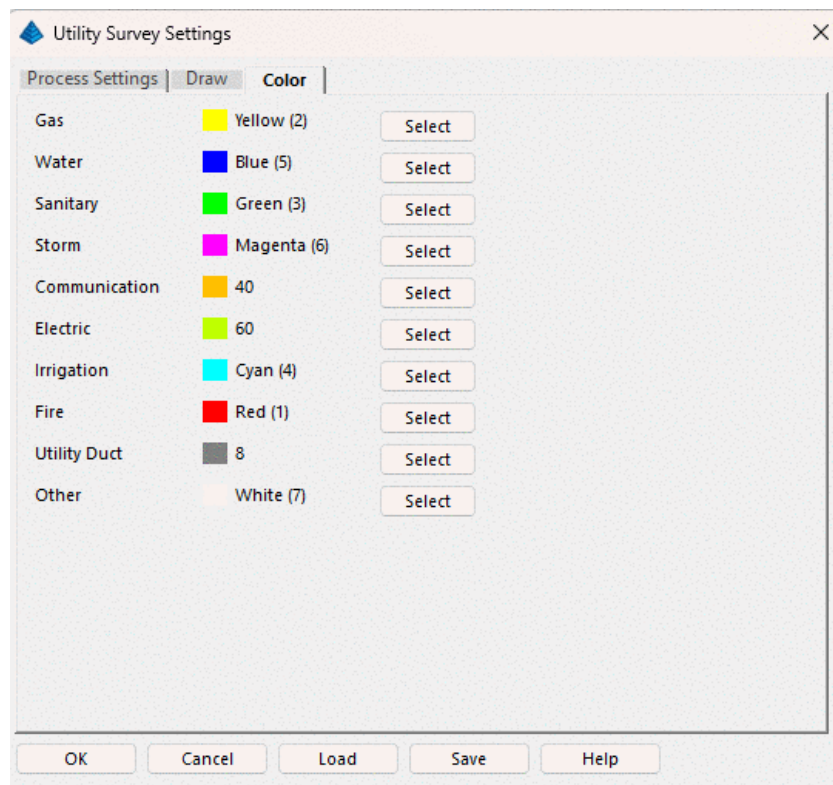

2D Polyline Layer - sets the layer for the 2D polyline to be placed

3D Polyline Layer - sets the layer for the 3D polyline to be placed

3D Faces Layer - sets the layer for the 3D faces to be placed

Pipe Shape - select the shape of the pipe to be created. These pipe shapes affect the 3D Faces created if that option is enabled.

Color Tab:

This dialog box contains the option to set individual colors for each utility type.

Symbol Library - accesses the Symbol Library also contained in the Settings Menu

Edit Points: - accesses the Edit Points Menu also contained in the Points Menu

Report Codes/Points - Option to Report Codes and Points from the current Coordinate file and/or Field Code Table

Help - accesses the Help Menu

Exit - exits the Field Code Table Editor

Coding Examples

Under the Carlson Projects folder, there is an example that shows the different ways for linework coding along with examples for many of the special codes. The examples are in **f2f_example.crd** and **f2f_example.fld**. To see this example, create a new drawing, set to the supplied coordinate file and process using the supplied field code table.

Here is a breakdown of the features that the points above illustrate.

Point 1: Point Entity by itself

Points 2-3: Using Begin code to start a line; end line using Begin code for next line

Points 4-5: Using Begin and End to start and stop linework

Point 6: Point Entity by itself after End code

Points 7-11: Linework by code defined as Polyline entity type; using End as break between linework

Points 12-15: Linework by code defined as Polyline entity type; using Begin as break between linework

Points 16-19: Linework by code defined as Polyline entity type; using # after code instead of Begin/End to separate linework

Points 20-22: Linework by code defined as Polyline entity type without using Begin/End to start/stop linework

Points 24-26: 3 point curve using on PC code

Points 27-30: 3+ point curve using PC/Point codes

Points 32-33: 2 point tangent curve using PC/Point codes

Points 35-39: reverse curve using PC/Point codes

Point 40: Regular point without extra description

Point 41: Using // to use a code description as a suffix

Point 42: Using \ to use a code description as a prefix

Point 43: Using / to append a description

Point 44: Using \ to add a description as a prefix

Point 45: Using ROT and a Point# to rotate to that Point#

Point 46: Using ROT and a value to set the rotation

Point 47: Using ROT by itself to rotate to the next Point#

Point 48: Regular point without rotation

Point 49: Using AZI and DIST codes to offset the point

Point 50: Using SZ with value to set size of symbol

Points 51-52: Using SZ by itself to size symbol by the distance to the next point

Point 53: Using SZ with 2 values to draw multiple symbols at those sizes

Points 54-55: Using 2ND code to size the symbol

Points 56-58: Using 2ND and 3RD codes to size the symbol in 2 dimensions

Points 59-62: Using CLO to close the linework

Points 63-64: Using RECT with two points and a value to create a rectangle

Points 65-67: Using RECT with three points to create a rectangle

Points 68-69: Using OH to offset right a fixed amount

Points 70-73: Using OH on multiple points to offset various amounts

Points 74-75: Using multiple OH on the same point to offset polyline multiple times

Points 76-77: Using OH with negative value for offset to left

Points 78-79: Using OFL with value for offset left a fixed amount

Points 80-81: Using OFB with value to offset both left and right a fixed amount

Point 82: Using CIR to draw circle at specified radius

Points 83-84: Using CIR to draw circle using two points for center and perimeter

Points 85-89: Using CIR to draw best-fit circle through points on perimeter

Points 90-91: Using JPN to join linework to another Point#

Points 92-95: Using SMO to create smoothed linework

Points 96-97: Using JOG to create additional linework segment extensions

Points 98-102: Using GAP to create a break in the linework

Points 103-106: Using LFT to switch linetype to left side

Points 107-109: Using WALL3D with specified height value

Points 110-112: Using WALL3D with height from 2nd point

Points 113-115: Using BLOCK3D with height and three points to define parallelogram

Points 116-123: Using BLOCK3D with height and multiple points to define perimeter

Points 124-128: Using FACE3D with multiple points to make a surface

Points 129-132: Using HOLE3D with multiple points to define the perimeter of a hole in the FACE3D surface

Point 133: Using code definition with Attribute Format set to Text and only Elevation turned on with Label Decimal

Menu Location: Survey

Keyboard Command: fld2fin

Prerequisite: A data file of points with descriptions

Field to Finish Inspector

This command reviews entities in the drawing created by Field To Finish. Point descriptions can be edited and the drawing is updated for both the point symbols and linework, using the Field To Finish coding.

Field to Finish Inspector docks a control panel dialog at the bottom of the screen which leaves the drawing view at the top.

Code: Lists the field codes that were found in the drawing. Clicking on a code causes the Instance list to show all of the linework and points that use the selected code.

Instance: Lists the linework and points of the currently selected code.

Point: Lists the points that make up the currently selected linework or point in the Instance list.

Go to Point#: Type in the point # to see in the drawing and then press this button to bring the point # into view. If the point # is not in the drawing, then a message will be printed at the top of the dialog box. If the Zoom toggle is on, then the point # will be brought to the center of the screen even if it was already visible on the screen. Likewise, if Isolate or Highlight are on, then those options will be applied, too.

Zoom: Check this checkbox to make the Field to Finish Inspector automatically zoom and pan the drawing so that the selected items in the above lists are viewable. Zoom is used on the Code and Instance lists. Pan is used for all three lists.

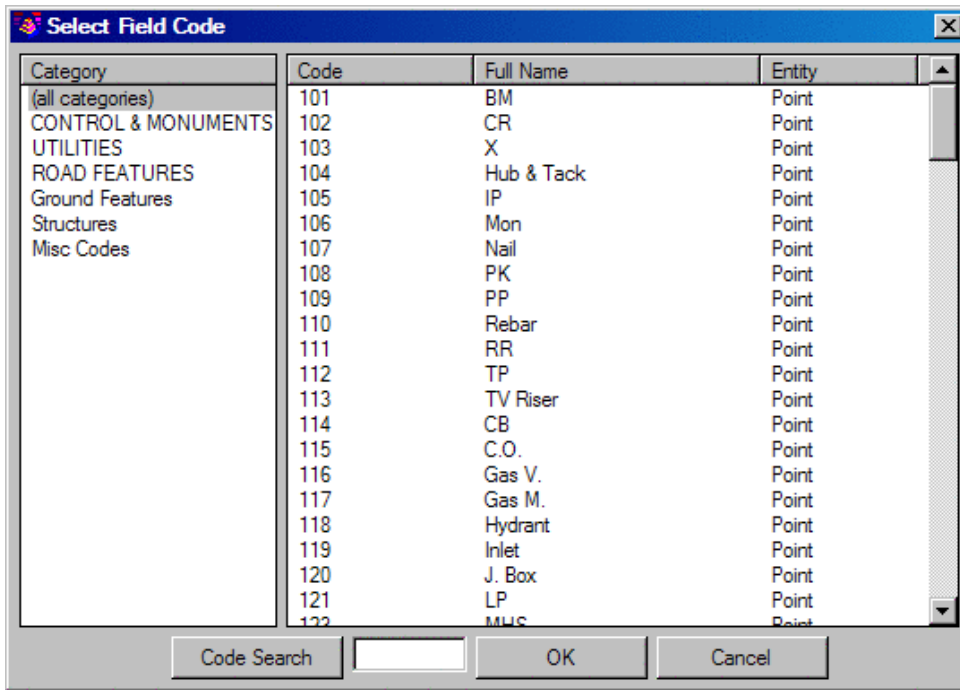

Isolate: Check this checkbox to make the Field to Finish Inspector only display the selected items in the above lists.

Highlight: Check this checkbox to make the Field to Finish Inspector highlight the selected items in the above lists.

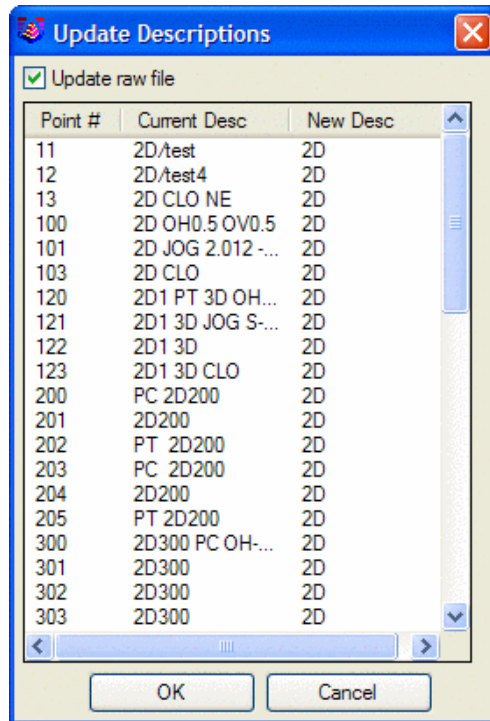

Restore View On Exit: Check this checkbox to make the Field to Finish Inspector restore the zoom and pan values when you exit.

Desc: This edit box will display the description field from the coordinate file used on the given point(s). If the points do not all have the same description in the coordinate file, **varies** is displayed instead. If you type in a new description and then click on Apply, the new description will be applied to the coordinate file and Field-to-Finish will be used to process the coordinate file and update the drawing, including linework. Press the Code button to place an existing field code into this Desc edit box.

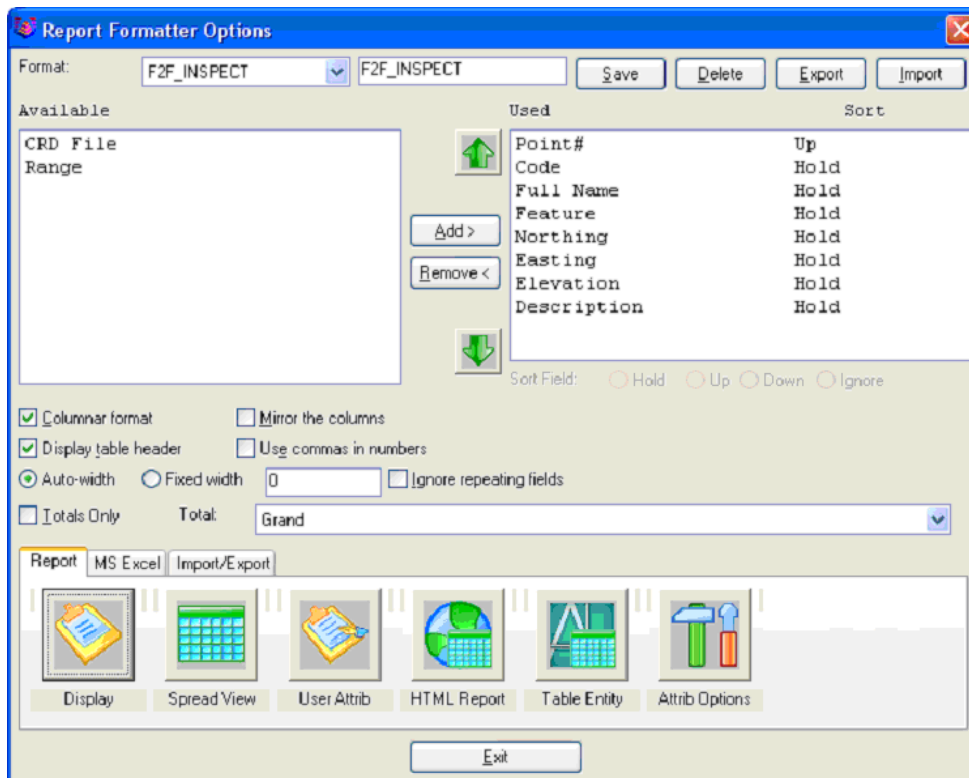

Code: Press this button to select a field code from the current field code definition (FLD) file. The following dialog box is an example of what you will see. The Categories on the left are the categories that are defined in the current field code definition file. The list on the right is all of the field codes in the selected category. Select (*all categories*) to see all of the codes in all of the categories. The selected field code will be placed in the Desc edit box.

Apply: Press this button to apply the modified description that is in the Desc edit box to the currently selected points. The below dialog box will come up that lists exactly what will be changed. Optionally, the raw file that was used to create the coordinate file will be updated as well. Press OK to continue. The description will be updated in the coordinate file and then Field-to-Finish will be used to process that coordinate file and finally the drawing will be updated to reflect the changes.

Code: This button generates a user-defined report with fields for the point number, coordinate, feature name and code. This report uses the Report Formatter to select which fields to include.

SAMPLE REPORT

Point# Code Full Name Feature Northing Easting Elevation Description

1 CM CONCRETE MONUMENT POINT 4922.730 5570.695 502.510 CM/(4" DIAM)

2 CM CONCRETE MONUMENT POINT 4739.612 5499.121 506.050 CM

5 SHED SHED POLYLINE 4794.880 5495.289 505.110 SHED

6 SHED SHED POLYLINE 4771.855 5486.661 505.530 SHED

7 SHED SHED POLYLINE 4782.648 5457.861 505.820 SHED

Pulldown Menu Location: Survey

Keyboard Command: f2f_inspect

Prerequisite: Entities created by Field-to-Finish

Edit Field to Finish Codes

This command edits a Field to Finish code table. The program prompts for the .fd file to edit and then runs the code table editor. See the Field-to-Finish section of the manual for a description of the code table.

Pulldown Menu Location: Survey

Keyboard Command: editf2f

Prerequisite: None

Enter Deed Description

This command lets you enter line and curve data which is drawn and annotated as entered. When entering in data, the bearing quadrant and bearing value is input on the same line. For example, a bearing of N45-10-30E would be entered as 145.1030, where (1) represents the NE quadrant. The numeric codes for the quadrants are 1-4 beginning

with NE as (1) and continuing sequentially in a clockwise direction to the NW quadrant (4). Distance data can be entered in Varas, Meters, Poles, Chains or US Feet. In addition to typing in the angle and distance numbers, there is a Select option at the command line which prompts to select an existing text label that the program will read to get the angle or distance.

Curve data can be entered for Non-Tangent, Reverse-Tangent and Tangent curves. Data used to define curves includes but is not limited to Tangent Out Bearing, Radius data, Chord Bearing, DeltaAng and Tangent Length. Prompting for curve data is determined by what curve definition data is used. When you are finished, the closure and area of the figure is reported.

The program has the option to Undo the previous data entry in case you need to re-enter values. Also, the program auto-saves the data entered during the command so that if the command is canceled and restarted, there's an option to resume entering data. The command starts with the dialog shown here.

Line and Curve Layer: Specify the layer name for lines and arcs.

Points Layer: Specify the layer name for the points.

Traverse by: Select between entering bearings, azimuth, gons or point numbers. The points option recalls points from the current coordinate (.CRD) file. The prompt option adds a prompt for each angle to specify the angle format.

Point Format: Choose between creating Carlson points in the coordinate (.CRD) file at each point in the figure, drawing descriptions only or having no point labels.

Apply Rotation: This option adjusts the entered bearings by the specified rotation.

Label Lines and Arcs: Specify whether the annotation should be drawn on the lines and arcs or should be added to line and curve tables. The settings for the label styles are defined by the Annotate Defaults and Auto Annotate commands. Please see those commands in the manual for a description of those settings. You can either specify specific settings files from those commands or use the current settings which is the default.

Deed Name: Specify the beginning deed name. Only available when Store to Deed File is checked on.

Draw Linework: Specify whether or not to draw linework, if this is disabled then all annotation options are disabled also.

Create Polyline: This option creates a polyline of the deed perimeter instead of individual line and curve entities.

Prompt for Descriptions: Specify whether or not the program should prompt you for point descriptions. If this is not checked, then point descriptions are blank.

Prompt for Elevations: Specify whether or not the program should prompt you for point elevations. If this is not checked, then point elevations are set to zero.

Prompt for True Point of Beginning: With this option, the traverse begins before the TPOB. When the traverse reaching the TPOB, enter the POB option at the command prompt to indicate the true point of beginning and start the traverse loop.

Plot Point Symbols: If the Point Format is set to Descriptions Only or None, this option is available. It will place point symbols without creating points in the coordinate (.CRD) file.

Create Radius Points: When checked, radius points will be created for arcs. Radius points are given the description RADPT.

Store to Raw Data (.RW5) File: When checked, data entered will also be written to a raw data (.RW5) file that can be opened using the *Edit-Process Raw Data File* command. This file can be used to perform coordinate adjustments. The Compass rule, Crandall rule, Transit rule, Angle balance adjustment and Least-square adjustment routines are all available. See *Edit-Process Raw Data File* for more information.

Store to Deed File: When checked, data entered will be written to a deed (.PDD) file. This file can be processed later to correct errors, create deed reports or to redraw the deed. To use this option, set the deed file name by picking the Specify File Name button. Also set the Deed Name field.

Prompts

Pick point or point number: 1

```
PtNo. North(y) East(x) Elev(z) Description
1      8000.00 12000.00 0.00
```

In this example the coordinate for point number one has already been stored in the current coordinate (.CRD) file with the *Draw-Locate Points* command.

Undo/Exit/Curve/Select/<Bearing (Qdd.mmss)>: 145.3035

Varas/Meters/Poles/Chains/Select/<Distance(ft)>: 210.5 Enter P to input a distance in Pole format or C for Chains format.

Undo/Exit/Curve/Select/<Bearing (Qdd.mmss)>: C Enter C to traverse through a curve.

Tangent-out/Radius: R

Radius: 1103.5

Curve direction (Left/<Right>)? press Enter for right

Non-tangent/Reverse-tangent/Chord/Delta angle/Tangent/<Arc length>: N If the curve is non-tangent to the previous leg then enter the arc length, enter C for a chord length, D to enter the delta angle or T to enter the tangent distance. In this example we have a non-tangent curve so we entered N.

Curve direction input [<Chord>/Radial]?: C

Chord Bearing (Qdd.mmss): 245.2341

Length of Chord: 201.22

Undo/Exit/Curve/Select/<Bearing (Qdd.mmss)>: 345.3218

Varas/Meters/Poles/Chains/Select/<Distance(ft)>: 209.28

Undo/Exit/Curve/Select/<Bearing (Qdd.mmss)>: 445.2348

Varas/Meters/Poles/Chains/Select/<Distance(ft)>: 200.54

Undo/Exit/Curve/Select/<Bearing (Qdd.mmss)>: E Enter E to end the prompting and calculate the closure error.

Closure error distance> 1.35251089 Error Bearing> N 70d41'35" E

Closure Precision> 1 in 607.63 Total Distance Traversed> 821.82

Pulldown Menu Location: Survey

Keyboard Command: PDD

Prerequisite: None

Draw Field to Finish

This command turns data collector field notes into a final drawing by matching the descriptions of the field points with user-defined codes. The points are brought into the drawing with attributes defined by the code, including the layer, symbol, size and linetype. Essentially, Field to Finish drafts a plan as you survey.

Example of a survey processed with Draw Field to Finish

Draw Field to Finish	Create/Edit a Field Code	See Some Examples
Create a Code/Point List	Use The Tree Feature	
Work with Code Tables	Use the Pipe Feature	
Use Special Codes	Use the Utility Feature	

Two main files are used in Draw Field to Finish - a coordinate file (**CRD/CRDB**) and a field code definition file (**FLD**). The coordinate file consists of point#, N,E,Z coordinates and text description fields. The description field contains the codes for the Draw Field to Finish processing. An ASCII data file can be converted into a coordinate file using the *Import Text/ASCII File* command. The field code definition file defines the layer, symbol, size and other actions to apply with each code. These file names are displayed at the top line of the Draw Field to Finish dialog box.

Field to Finish is an extremely versatile and robust program. The concept however is straight forward. Each point located in the field is coded with a description. That point description is related to a matching code in a Code Table (**FLD**) that instructs the Field to Finish program on how to process and draw it. Points can be placed in a drawing

using specific symbols, on particular layers and annotated with text or block attributes. A series of points can be used to draw 2D and/or 3D polylines for use in drafting or creating surface models. Beyond a large variety of settings for each defined code in the code table, there are also Special Codes that modify the behavior of the code, such as PC (point of curvature) and PT (point of tangent).

Field to Finish is a very powerful tool but it is not required to place points from a coordinate file into a drawing. *Draw-Locate Points* provides a simpler method for drawing points but it is much less versatile.

Using a drawing template: Field-to-Finish will "layerize" the points and linework according to the code definitions. If the layers to use are not already defined in the drawing, Field-to-Finish will create any layers defined in the code table when it processes that code. It will however, randomly assign a color, linetype etc. to that layer. To provide consistency and have the same properties for these layers in all your drawings, it is recommended you use a prototype drawing, or Template (DWT). Each new drawing created can then be started using this template which contains all layers needed matching those in the Code Table (FLD) file. See Carlson Configure -> Startup Settings to select a prototype Template.

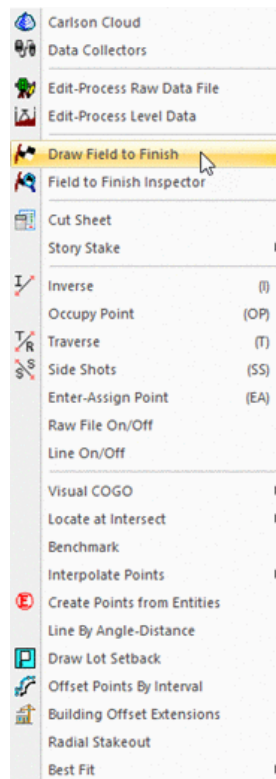

Connecting Line Work: If a code is created as a Line, 2D Polyline or 3D Polyline, all codes with that same description will be connected with no extra coding needed. For example if the code EP is defined as a 3D Polyline and points 100-110 all have EP as a description, Field to Finish will draw a 3d Polyline connecting all points 100 through 110. Stopping and starting line work is where additional coding is needed. There are basically two different methods for connecting linework and controlling the start/stop or gaps between line segments.

1. **Adding group numbers:** As described above the linetype is defined by the code as either lines, 2D polylines, 3D polylines (breaklines), or both 2D and 3D polylines. To control the connection of the linework, distinct lines with the same code are defined by adding a group number to the end of the code name in the data file. With this method, all points with the description CODE1 will be one line while points with CODE2 will be another line. Both CODE1 and CODE2 use the definition for CODE. For example, the code EP could be a code for edge of pavement that is to be connected as 3D polylines. If there are two separate edge of pavement lines on the left and right sides of a road, all the points for the left side could have the description EP1 and the points on the right side could be EP2. Besides having the number after the code, the number can be used as a prefix by defining the code with a # special character. For example, when the code is defined as #CODE, then the points with descriptions 10CODE and 20CODE get matched to this code.
2. **Adding Special Codes:** The second method is to add a special code to the end of a line segment or the beginning of a new line segment. For this method, you use the same code for all similar line segments and just instruct Field to Finish when to stop drawing. For example the end of an edge of pavement line would be coded EP END. (The code END is the default end line special code). Alternatively, you can instruct Field to Finish to start a new line segment by adding a beginning special code IE. EP BEG. The program will realize that a new line segment should not be connected to a previous one and will create an appropriate gap.

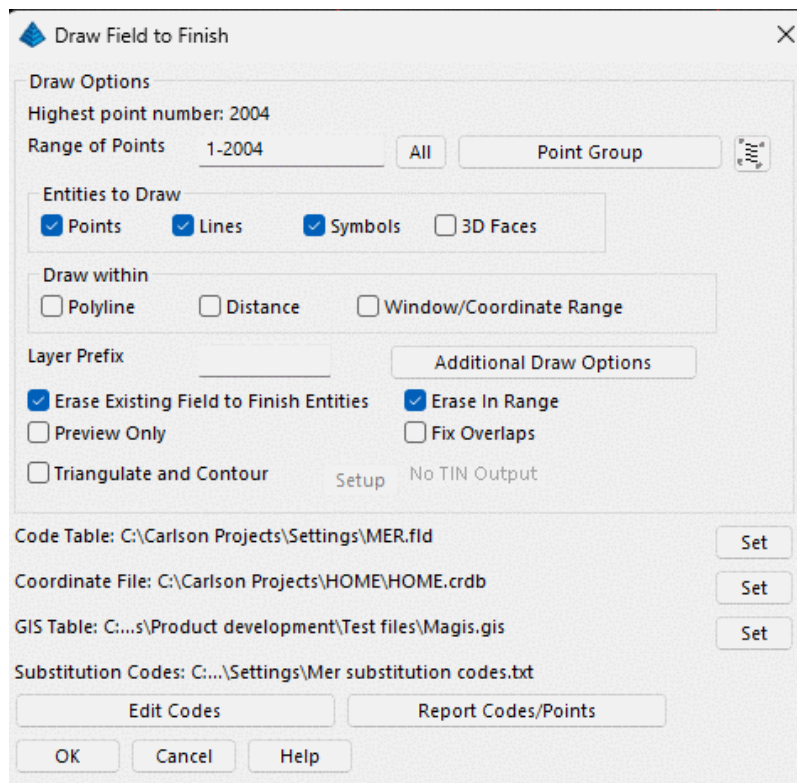

Legacy PointCAD format: This method also connects points with the same code. The difference is that instead of using a number after the code for distinct lines, you use the same code with an additional code for starting and ending the line. For example, +0 is used to start a line and -0 to end. So the coding for a segment of edge of pavement could be EP+0, EP, EP, EP-0. Another special code that has been added to Field to Finish is +7, -7. This 7 code will use the linetype definition of line, 2D polyline or 3D polyline defined by the Draw Field to Finish code. For example, if EP is defined as a 3D polyline, then the coding EP+7, EP, EP, EP-7 will create a 3D polyline. Otherwise codes like +0, -0, which is defined as start and end line, will draw EP as a line. Other PointCAD special codes are: +4 starts a curved 2D polyline, *4 starts a closed curved 2D polyline, +1 begins a 3-point arc, +5 starts a 3D polyline, *5 starts a closed 3D polyline, +6 starts a 2D polyline, *6 starts a closed 2D polyline, +7 starts a line whose type is specified by the field code definition, -05 starts a curved 3D polyline section, -50 ends that section, +8 starts a 2D and 3D polyline combination, *8 starts a closed 2D and 3D polyline combination, -08 starts a 2D and 3D polyline combination curved section, -80 ends that section. //, followed by a field code, concatenates that field code's description on to the point's description. For example, OAK//04 might become LIVE OAK TREE 4" if the

field code OAK translates to LIVE OAK TREE and the field code 04 translates to 4".

Draw Field to Finish is found in the **Survey** Pull-down Menu

Draw Field to Finish

Range of Points: Specify the range of points to draw.

Point Group: Specify the point group(s) to process.

Point List: Select points from a point list dialog box.

Entities To Draw: The Points option draws only the points and point attributes. The Lines option draws only the linework and the Symbols draws only the symbols. Any combination of these options can be processed as well as individual processing of each entity.

Draw Within: These options are methods to filter the points to draw. The Polyline method prompts for a closed polyline and only draws points inside this polyline. The Distance method uses a specified center point and distance to only draw points within this circle. The Window/Coordinate Range prompts for lower left and upper right points to define the rectangular area to draw points.

Layer Prefix: Optional layer prefix added to all entities drawn with Draw Field to Finish.

Erase Existing Draw Field to Finish Entities: When checked, this option will erase from the drawing any old entities created by previous Field-To-Finish runs before drawing the new entities.

Erase In Range: This option only erases and redraws those Draw Field to Finish entities that are within the specified range of points to process.

Preview Only: When checked, this option will temporarily draw the points and linework and allow you to review it with zoom and pan.

Fix Overlaps: This option checks the points drawn by Field-to-Finish for any point labels that overlap with other points or linework. For any overlaps, the point labels can be automatically moved or you can step through each overlap to decide how to handle it. See the command called Fix Point Attribute Overlaps in the Points chapter for more information on this feature.

Triangulate and Contour: This option uses the points and 3D polylines created by Field-to-Finish as input for

building a surface in Triangulate and Contour. Pick the Setup button for the options like contour interval and TIN file to create.

Code Table: Sets the FLD file to process which contains the code definitions.

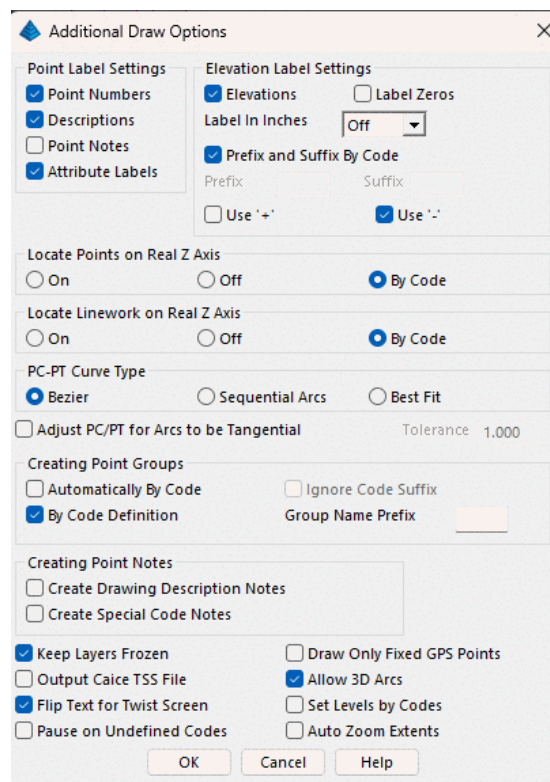

Coordinate File: Sets the CRD file to process which contains the point numbers, coordinates and descriptions.

GIS Table: Sets the GIS file which defines the GIS feature and attribute names. This file is optional and is used in GIS processing.

Edit Codes: Opens the **Field to Finish** Edit Code dialog box.

Report Codes: Opens the Report Code dialog box.

Additional Draw Options:

Point Label Settings: Specify whether you want Draw Field to Finish to label the **Point Numbers**, **Descriptions**, or **Points Notes** which are contained in the note (.NOT) file that is associated with the coordinate (.CRD) file. The **Attribute Labels** option controls whether or not to draw attribute labels. These attributes can be the description and/or additional comments in the form of block attributes or text and may or may not be associated with a GIS feature.

Elevation Label Settings: Specify the elevation labeling options. The Elevations toggle controls whether to draw the elevation attribute label for the points. The Label Zeros option will label the elevations of points with z=0. The Prefix and Suffix By Code sets whether to use the general Prefix and Suffix for all point elevation labels from this dialog or use the Prefix and Suffix defined in each code definition. Use '+' and Use '-' will place the appropriate symbol in front of the elevation. The Label In Inches option allows for elevation label in feet and inches instead of in decimals.

Locate Points on Real Z Axis: Choose between locating all the points at real Z elevation, all at zero elevation or to use the real Z setting as defined in the individual codes (**By Code**). These options can be used to override the setting contained in the FLD as part of the code and is global in nature. It is usually recommended to use the By Code option.

Locate Linework on Real Z Axis: Choose between drawing all the linework at real Z elevation, all at zero elevation or to use the 2D/3D polyline setting as defined in the individual codes (**By Code**). These options can be used to override the setting contained in the FLD as part of the code and is global in nature. It is usually recommended to use the By Code option.

PC-PT Curve Type: Sets the method for drawing curves with more than 3 points. The **Bezier** option draws a smooth polyline through all the curve points. The **Sequential Arcs** method draws multiple arcs with arc end points at each of the curve points. These arcs are tangent to the preceding line segment. The **Best Fit** method creates a single best-fit curve for all the curve points between the PC and PT.

Adjust PC/PT for Arcs to be Tangential: This option will adjust the PC and PT polyline vertices to make the curve tangential. The program will only adjust these points if the adjustment distance is less than the specified tolerance. This option applies to cases where the tangents are well defined and the PC/PT are harder to survey exactly.

Creating Point Groups: Point Groups can be created in one or two different ways. Each field code definition can specify Point Group(s) that all point numbers that use that code will be added to. Multiple field codes can use the same Point Group name. Check the By Code Definition checkbox for that option. The second method is to automatically create Point Groups for each code that is processed. Check the Automatically By Code checkbox for that option. Ignore Code Suffix, if checked, will cause the codes to be considered after removing the numeric suffix. For example, points with the EP10 and EP11 codes will both be automatically added to the Point Group named EP. No matter how the Point Group is created, the Group Name Prefix can be used to add a prefix to the group name. Note: if the Point Group already exists, it will be erased first before being created again by either of these two methods.

Creating Point Notes: These options append point notes to the coordinate file data for some of the data fields processed by Field-to-Finish. These notes can then be used by other commands like List Points to report these fields. For example, this enables List Points to report both the point coordinate file description as well as the point drawing description as generated by Field-to-Finish.

Keep Layers Frozen: This option will not thaw layers that Field-to-Finish uses for drawing entities. So when you have this option on and some layers are frozen, then you won't see the entities that Field-to-Finish creates until you thaw those layers.

Draw Only Fixed GPS Points: This option applies to coordinate files created by GPS measurements. The program checks for GPS status records and only uses points that have GPS solution status of Fixed.

Output Caice TSS File: This option creates a TSS file from the processing results.

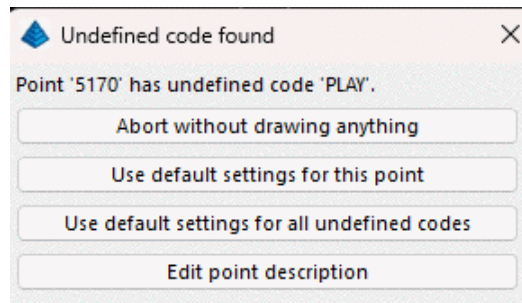

Allow 3D Arcs: When creating polyline arcs with the PC special code, this option checks whether to create the arc in 3D for tilted or vertical arcs such as a doorway or bridge arch. Otherwise, only the 2D coordinates are used to define the curvature.

Flip Text for Twist Screen: This option will rotate the point labels and symbol by 180 degrees when needed to make them right-side up readable relative to the current twist screen drawing view. This option applies to the Rotate To Line and Rotate special code (ROT).

Set Levels By Codes: This option assigns the optional Level Names for use by selection filters.

Auto Zoom Extents: When checked, this will force a zoom extents after Draw Field to Finish is done.

Pause on Undefined Codes: When checked, Draw Field to Finish will pause if it encounters a description that is not defined in the code table.

The options for handling undefended codes are:

- **Abort without drawing anything:** This stops the command. Run Draw Field to Finish again to correct the code table.
- **Use the default settings for this point:** This option draws a point using the current Point Default settings with no linework. To set your own default, define a code called "SC_DFLT" or "DEFAULT." This default code will instruct Field to Finish on how to process undefined codes.
- **Use default settings for all undefined codes:** This option will draw all undefined codes using the current Point Default settings with no linework. To set your own default, define a code called "SC_DFLT" or "DEFAULT." This default code will instruct Field to Finish on how to process undefined codes.
- **Edit Point Description:** Use this option to edit the point description or select a different code.

Report Codes/Points

This routine prints the code table or the data file to the screen, file, or printer. A useful option here is to print the data file (CRD Points) and choose Sort by Codes which will group the data points by distinct codes.

A useful option here is to print the data file (CRD Points) and choose Sort by Codes which will group the data points by distinct codes.

Report Type:

- Code Definitions: Creates a list of code definitions from the currently selected FLD file.
- Data Points: Creates a list of points grouped by codes of the current CRD (coordinate file)
- Tree Report: Creates a list of all points coded as a Tree Feature.

Code Definition Options

- Only Report Codes in Current CRD: Reports only the codes from the current FLD that are contained in the current CRD (coordinate file)
- Use Leica Format: Creates a list of code definitions using the Leica comma delineated format.

Data Point Options

- Sort by Codes: Sorts the list of points by code name
- Only Report Undefined Codes: Restricts the list to report only those points that have descriptions not contained in the code table. This is useful for reviewing a data set before processing.
- Point Range: Enter the range of points to be included in the list.

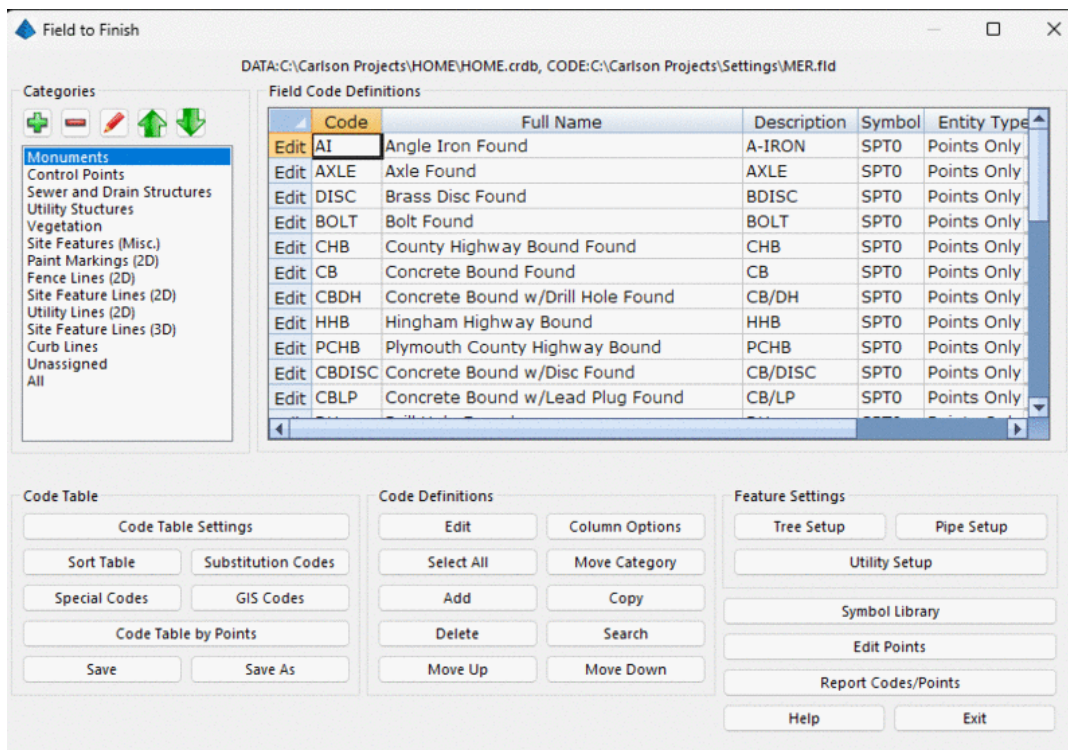

Use Report Formatter: Enables the option to use the Carlson Report Formatter for more control of the creation of the point list.

Field Code Match: Option to filter and limit the list to only select codes.

Edit Codes

Selecting Edit Codes takes you to the Field to Finish Code Table dialog box. This dialog box contains access to all of the tools and options for Field to Finish. It is the heart of this program.

The **Field to Finish** dialog box allows you to load the coordinate and field code definition file. Here you can add, view and edit the code definitions, view and edit the coordinate file, create reports, and then return to the Draw Field to Finish dialog box to process the files. The top section displays the code definitions. The bottom section has three columns of functions each pertaining to controls for different elements of the command. The **Code Table** section provides controls for settings, sorting and reporting of codes. The **Code Definitions** section provides tools for the creation and editing of codes. The **Feature Settings** section provides controls for the special tree, utility and pipe feature types.

The code table editor has a list of categories and a spreadsheet of codes with optional displays of related definitions. The spreadsheet shows the codes for the currently highlighted category. The category toolbar buttons allow you to add, remove, edit the names and change the order of the categories. There are two fixed categories. The **Unassigned** category shows any codes with blank categories. The **All** category shows all the codes. You can control which fields are visible in the spreadsheet by using the **Column Options** button. You can make edits to the fields in the spreadsheet or highlight a row and pick the **Edit** button to bring up a dialog to edit the code.

This section of the manual is separated into three categories:

Code Table

Code Definitions

Feature Settings **Quick Links for this section:**

Code Table Settings

Sort Table

Substitution Codes

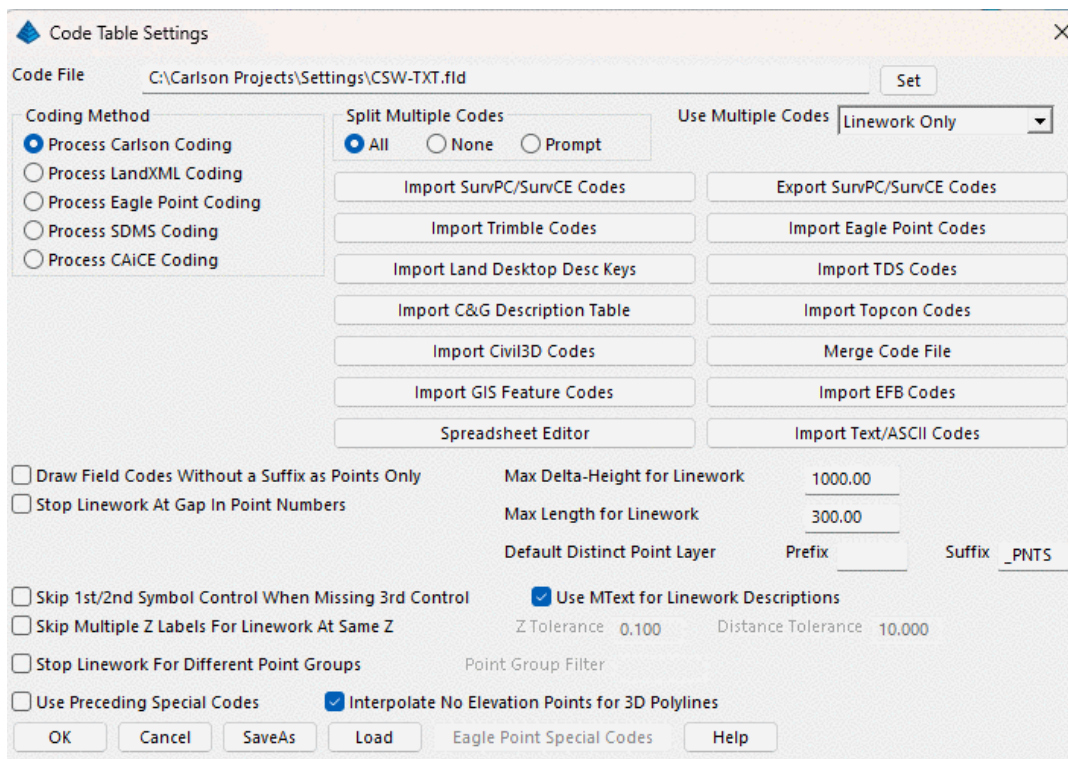

Special Codes

GIS Special Codes

Code Table by Points

Code Table Settings:

These options provide tools for defining the coding method to be used for processing of the point data. Various import tools allow for the importing of codes from different software packages. Controls for handling multiple codes are located on this dialog. All special codes can be replaced to other characters defined by the user. The special codes are listed and edited on this dialog.

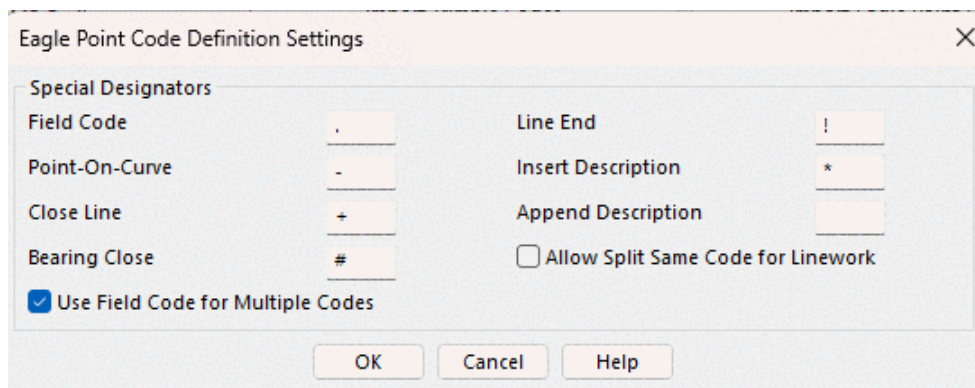

Set: Choose this button to select an existing or create a new code table. The name of the current table is shown in the field to the left of this button.

Coding Method:

Carlson Coding: When checked, this option interprets and processes coordinate files based upon the Carlson Coding method and data collection method.

LandXML Coding: This method prompts for a LandXML or Leica/Hexagon HeXML file to use with the processing. This method applies when the point descriptions do not have linework coding and the LandXML file has PlanFeatures that define how points are connected to create linework. This method reads the LandXML file to find the points that begin and end lines and curves.

Eagle Point Coding: When checked, coordinate files are processed based on the Eagle Point Data Collection method. When selected the *Eagle Point Codes* button at the bottom of the dialog box becomes available for selection and displays the following dialog. This dialog allows for customization of the eagle point special designators.

Currently the supported designators include, "Field Code", "Point-On-Curve", "Close Line", "Bearing Close", "Line End", "Insert Description" and "Append Description". Also supported is the ability to recognize overwriting of

descriptions just as Eagle Point does by using the space separator instead of the "Insert Description" designator. Examples of supported coding are as follows:

.TC Places a node and or line per the field code library.

TC Places a node and or line per the field code library.

-TC Specifies a point on a curve.

TC- Specifies a point on a curve.

..TC Stops the line.

TC! Stops the line.

.TC+ Closes the line back to the starting point.

TC+ Closes the line back to the starting point.

.TC# Typically coded on the third corner of a rectangle to close the figure with having to locate the fourth corner.

TC# Typically coded on the third corner of a rectangle to close the figure with having to locate the fourth corner.

WV.WI Places a node as specified by the code "WV" in the field code library and then begins a line as specified by code "W" in the field code library.

.TC.EP.FL Results in three lines coming together.

TC1.TC2.TC3 Results in three lines coming together. All three lines are specified by the definition of the single code "TC" in the field code library.

TC.TC1 When used in conjunction with the "Draw Field Codes Without a Suffix as Points Only" toggle, "TC" will be recognized as the node and "TC1" will be recognized as the line so that if the code "TC" in the field code library is defined as a polyline, line or 3D polyline, duplicate lines will not be unintentionally placed when this shot only pertains to a single element. Keep in mind that all line work must have a numeric suffix when using this toggle.

TREE * OAK Result on screen would be: TREE OAK

TREE OAK * Result on screen would be: OAK TREE

TREE OAK Result on screen would be: OAK

TC1!.TC2-.VLT6# Stops "TC1", continues "TC2" as a point on a curve and closes VLT6 as a rectangle using the "Bearing Close" code.

Note: The use of the "Use Multiple Codes for Linework Only" toggle is recommended when using Eagle Point Coding.

SDMS Coding: This option processes coordinate files based upon SDMS coding method. When active, the program will prompt for an SDMS .PRJ file to process.

CAiCE Coding: When checked, coordinate files are processed based on the CAiCE Data Collection method. Examples of supported coding are as follows:

169 is just the code 169.

145C10 is the code 145 and line #10.

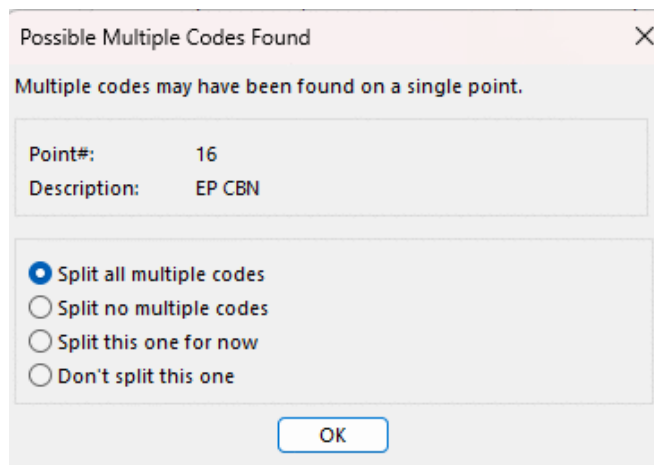

169C25C is the code 169, line #25, and the point is on a curve.

172C12B is the code 172, line #12, and this point closes the line.

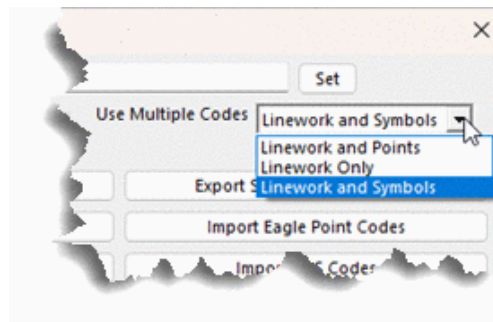

Split Multiple Codes:

Multiple codes are defined by including each code in the point description field separated by a space. A single data point can be used in different lines by assigning it multiple codes. For instance, a point might be part of both a curb line and a driveway line with a description of "CURB DRW". Field-to-Finish uses spaces as the delimiter for multiple codes. You should avoid spaces in the descriptions except for where multiple codes are intended or after the "/" character. For example, a code for light post should not be "LGT POST" but instead should be "LGTPOST".

There are three options for the handling of multiple codes when encountered. The **All** option will split all multiple codes and process each code based upon its code definition. When **None** is select the first code in the description string will be processed and the remaining characters left a part of the description (this is exclusive of any Special Codes used). If the **Prompt** option is checked on, when Field-to-Finish detects multiple codes on a point the following dialog will be displayed with options for handling the codes.

Use Multiple Codes:

Multiple Codes are simply more than one code separated by a space (default setting). Field to Finish has options to allow more control over the use of these multiple codes. This setting has three options:

- **Linework and Points** - Uses the space to connect multiple line codes as well as creating multiple point blocks at each location.
- **Linework Only** - Limits the multiple coding to be used for connecting line work only.
- **Linework and Symbols** - Uses the space to connect multiple line codes as well as creating multiple symbols at each location.

Import/Export Options:

Import SurvCE Codes: This option imports a SurvCE Feature Code List (fcl) into a Carlson Field to Finish (fld) code definition file.

Import Trimble Codes: This option imports Trimble .FXL file codes into the Carlson Field to Finish (fld) code definition file.

Import Land Desktop Desc Key: This option imports and converts a Land Desktop Description Key into a Carlson Draw Field to Finish (fld) code definition file. The Land Desktop Description Key file is a mdb file and is found in the Land Desktop Project file path. It is located in the under the COGO/DescKey directory.

Import C&G Description Table: This option imports C&G code tables (tbl) into the Carlson Field to Finish (fld) code definition file.

Import Civil 3D Codes: This option imports Civil 3D .fdb_xdef file codes into the Carlson Field to Finish (fld) code definition file.

Import GIS Feature Codes: This option imports features in a .GIS file from Define GIS Features into F2F codes.

Export SurvCE Codes: This option creates a SurvCE Feature Code List (fcl) from the current a Carlson Field to Finish (fld) code definition file.
Import TDS Codes: This option imports TDS codes into the Carlson Field to Finish (fld) code definition file.

Import TDS Codes: This option imports TDS codes into the FLD code definition file.

Import Eagle Point Codes: This option imports Eagle Point codes into the Carlson Field to Finish (fld) code definition file.

Import Topcon Codes: This function imports Topcon codes and layers from an XML file.

Merge Code File: This function adds code definitions from another (fld) code definition file into the current code table. The program shows a list of the codes from the other file that are different than the current code table. You can choose which codes to import. Any codes that conflict with an existing code definition are defaulted to not import.

Import EFB: This option imports the SDMS Electronic Field Book codes (.xml) into the Carlson Field to Finish (fld) code definition file.

Import Text/ASCII Codes: This option imports code definitions from a user-defined format. Each row in the text file should represent one code. The program will prompt for the delimiter (ie. comma separated) that is used in the text file and then for the field type for each of the columns (ie. "Layer" or "Description").

Spreadsheet Editor: This function lets you edit all the codes with all their settings in a single large spreadsheet. This method can be a handy way to use copy and paste to edit the codes. This method can also be quicker to make many changes than navigating the Edit Code dialog. This method is for expert users and you need to take care to make valid inputs.

Code	Description	Symbol	Symbol	Layer	Entity	Tie	Linetype	Text Size	Line	Processin	Nearest	Full Name

Additional Options:

Draw Field Codes Without a Suffix as Points Only: This option is useful for when wanting to use a field code sometimes for linework and sometimes for just points but it is preferred to number the lines rather than using start

and stop codes. For example, if the field code EP is defined to use the Line Entity type, then EP25 will be drawn as a Line, however if just EP is used, no linework will connect to that COGO point. When using this option, it is required to add a numerical value after each line code.

Stop Linework At Gap In Point Numbers: This option is a method for controlling the start and stop of drawing linework. This method will automatically stop linework where there is a gap in the point numbers for the linework code. For example, if there are points with code EP then points with code CL then more points with code EP, the EP linework for the first set of EP points will stop at the last EP before the CL points and then new EP linework will start after the CL points.**Max Delta-Height for Linework:** Use this option to specify the maximum elevation difference that Draw Field to Finish should draw any section of linework. This option is for use with 3d polylines and lines.

Max Length for Linework: Specify the maximum length that Draw Field to Finish should draw any section of linework. If two codes are distant beyond this limit, no linework will be drawn between them.

Default Distinct Point Layer: These settings control the default layer for when the Distinct Point Layer option is turned on for each code definition.

Skip 1st/2nd Symbol Control When Missing 3rd Control: For multi-point symbols when the 3rd control point is missing, this option centers the symbol on the 1st point instead of using the 1st point as a control point.

Use MText for Linework Descriptions: Controls whether to create MText or regular Text entities for linework description labels.

Skip Multiple Z Labels For Linework At Same Z: This option labels only the first point elevation for points on polyline or rectangle from the RECT code when the elevation difference between the points is less than the specified **Z Tolerance** and the horizontal distance is less than the **Distance Tolerance**. For example, for points on the corners of a level utility pad, this option will label the pad elevation just once.

Stop Linework For Different Point Groups: This option applies to when you have points for the same job collected at different times or with different crews and you want to prevent linework connecting points between them. For example, this applies when you survey a job with two crews and combine their points into a single CRD and both crews used "EP1". In this case, to keep each set of "EP1" separate, you can put each set of points into a separate point group with Point Group Manager and use this Field-to-Finish option. The **Point Group Filter** is optional and is used to make the program only check groups that match the filter. A point can be in multiple groups such as "CONTROL" and "DAY1". Some groups could be used for different days such as "CONTROL". So the Point Group Filter could be set to "DAY" to filter out the common groups and only process the time related groups.

Use Preceding Special Codes: This setting tells the program to expect the special codes before the main code. For example, if "BEG" is the special code for begin linework and "EP" is a main code, then the program looks for "BEG EP". The default sequence is for the special code to come after the main code as in "EP BEG".

Interpolate No Elevation Points for 3D Polyline: For points tagged as "No Elevation" that are part of a 3D polyline, this option will interpolate an elevation for this point from the other points in the 3D polyline. Otherwise, this point will be skipped in the 3D polyline.

Sort Table

This sorts the code table by either code name or layer.

Substitution Codes:

This option defines a lookup table for translations of the raw point descriptions. This translation is done as a pre-processing step before the regular Field-to-Finish processing. For example, if you had a substitution setup for "25" = "EP", then a point description of "25" would get translated to "EP" and then this would be processed with Field-to-Finish.

This works for both numerical and alpha raw descriptions.

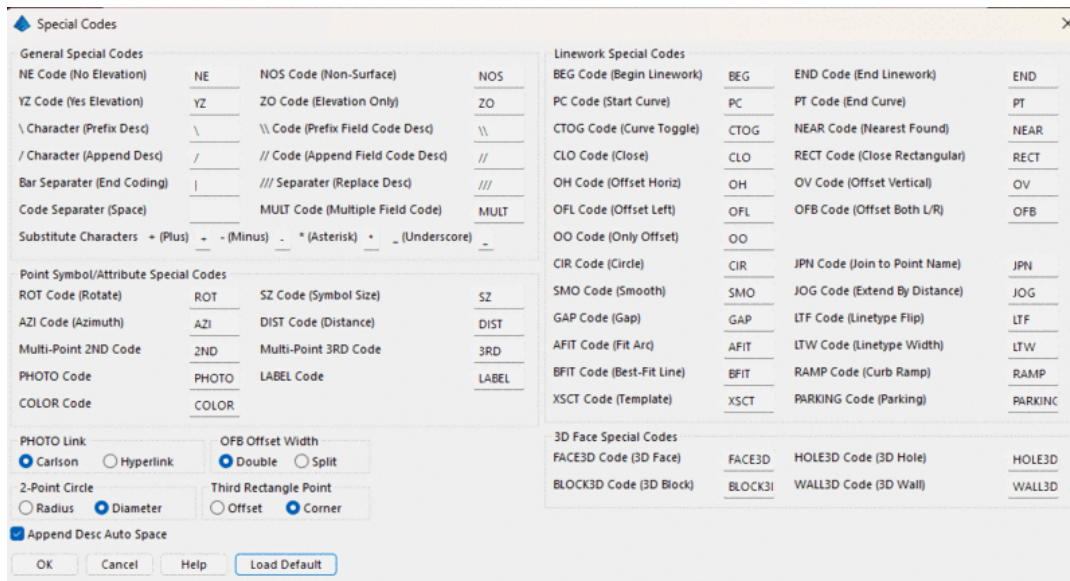

- The **Match With Number Suffix** option will match with a number following the string. For example, "CL" will match with "CL2". Otherwise, the strings have to be an exact match. The substitution codes are stored in a file named f2f_sub.dta in the %appdata%\Carlson...\USER folder. You can also use the **Import** and **Export** functions to load and save substitution codes to a comma separated text file.

Special Codes:

Special Codes are essentially modifiers of an original code. They perform additional operations and/or offer addi-

tional control over the original code. These special codes work with line work, point data and symbols. There are also options to control the placement of labels and add additional text to attributes.

Below shows the default dialog box containing the Special Codes. These can all be modified at the users discretion but the must be unique and not conflict with any codes defined in the code table.

A special code is placed after (or before if that option is enabled) the regular code with a space separating the code and special code. For example if an edge of pavement shot was taken at the beginning of a curve, it would be coded EP PC, whereas the PC tells Field to Finish to begin drawing an arc. Special codes may be strung together to modify a single code or added to multiple codes within the same string. For example, if a ling string ended at the PT of a curve it could be coded EP PT END whereas both PT and END are the special codes. An example of multiple codes combined with special codes could be a driveway intersecting the edge of pavement at the beginning of a curve: EP PC DRV SMO. The PC starts drawing an arc on the edge of pavement and the driveway begins with a smoothing code. It is important that any special code modifying another code must be placed immediately after the code it is modifying.

Quick Links for this Section

- General Special Codes
- Linework Special Codes
- Point Symbol/Attribute Special Codes
- 3D Face Special Codes

General Special Codes

NE: No Elevation - This special code represents no elevation. A point with this special code is located at zero elevation and the elevation attribute is set to None.

NOS: Non-Surface - This special code indicates that the point should be "non-surface"; that is, that it should be ignored when contouring or creating surfaces. This can also be controlled per-field code by turning on the Non-Surface toggle in the Edit Field Code Definition dialog box. When used, this special code tags the point to be non-surface but maintains the elevation attribute.

YZ: Yes Elevation: - This special code locates overrides the code setting for non-surface and locates the point and

maintains the elevation attribute.

ZO: Elevation Only - This special code represents elevation only (Z-Only). A point with this special code is used as part of a 3D polyline for elevating the 3D polyline without effecting the horizontal position of the polyline. For example, this code could be used on a grade break point along a curb where only the elevation should change and not the horizontal alignment.

"\": Prefix Description - This special code takes the part of the description after the "\" and puts it as the prefix before the point description. For example, a data point with the description "TR \ 24ft" and a "TR" code definition with a description of "Tree" would be drawn with a description of "24ft Tree".

"\\": Prefix Field Code Description - This special code causes text after the "\\" to be interpreted as a field code. That field code's description is then prefixed to the first field code's description. For example, if the field code O2 has the description 2" and the field code OAK has the description *oak tree*, then OAK\\O2 will result in the point having the description of 2" *oak tree*.

"/": Append Description - A special character "/" (the forward slash or divide key) can be used for an unprocessed description to append. Everything after the "/" is added directly to the point description and is not considered a code and no further substitution is done on it. For example, a data point with the description "UP/#150" for a code UP that has UP for its description would be drawn "UP #150".

"/": Append Field Code Description - This special code causes text after the "/" to be interpreted as a field code. That field code's description is then appended to the first field code's description. For example, if the field code O2 has the description 2" and the field code OAK has the description *oak tree*, then O2//OAK will result in the point having the description of 2" *oak tree*. If the "/" character has been replaced with a different character, for example with a & character, then the "/" code would become "&&".

"—": End Coding - The bar separator indicates the end of coding. Everything after the bar is ignored for Field-to-Finish processing. This is useful if additional information is needed for a point but no action should be taken and no description should be added.

"/": Replace Description - This special code takes the part of the description after the "/" and uses it as the point description label.

" ": Code Separator - The default for separating multiple codes is a space. This can be modified to another character if desired. Caution should be taken when modifying special codes to be sure there are no conflicts with other codes or special codes.

MULT: Multiple Field Code - This code applies when the Split Multiple Codes under Code Table Settings is set to None and you want to override this setting and explicitly split selected codes. Multiple codes apply to points with dual code definitions for drawing two different style points or for connecting different linework to the same point. For example, if a point is both a sidewalk and driveway corner, then the point description could be "SW MULTDR".

Substitute Characters - The characters (*, -, +, /, and _) can be used and substituted in Draw Field to Finish. The way these characters are used is that when the file is processed the description field is searched for these characters. If the "+" symbol was changed to "-" then the program would look for "-" and change it to "+". This is useful when a particular data collector may not have all the symbols available. With these substitutions you can make a character that is provided on the data collector generate the symbol needed. Multiple characters can also be used. For example "-" can be used to in order to produce a "/" character or any of the characters listed above.

Linework Special Codes

BEG: Begin Linework - This special code denotes the beginning of a new line string. If a code is already designated to be a line, 2D or 3D polyline, then Field to Finish will connect like codes without the need for the BEG code. However, BEG can be used to designate the start of a new line string or can be used to force linework

between codes designated as points only.

END: End Linework - This special code denotes the end of a line string. This is used when line numbers are not being used. See Connecting Line Work for description.

PC: Start Curve - This code begins a three point arc or a curved line when used with the "PT" code (see below). The point with this special code is the first point on the arc. The next point with the code is considered a point on the arc, and third point with the code is the arc endpoint. The PT code is not necessary when coding a 3 point arc.

Example of 3 point curve:

- 10, 500, 500, 0, EP PC - start curve
- 11, 525, 527, 0, EP - second point on curve
- 12, 531, 533, 0, EP - end point of curve

For curves beyond 3 points, the **PT** code needs to be used for the last point on the curve. The routine then looks back for the PC and "fits" a curve between all intermediate points.

PT: End Curve - This code can be used with "PC" to define a curve with more than three points or a tangent two-point curve. Starting at the point with the "PC", the program will look for a "PT". If the "PT" is found, all the points between the "PC" and "PT" are used for the curve which is drawn as a smoothed polyline that passes through all points and only curves the polyline between points. If no "PT" is found, then the regular three point arc is applied as explained above. If no points are found between the "PC" and "PT", then the point prior to the "PC" and the point after the "PT" are used to create tangents for the resulting curve.

Both the PC and PT codes used for drawing arcs are subject to the PC-PT Curve Type found in the Additional Draw Options.

CTOG: Curve Toggle - This special code toggles curve mode on and off. Instead of using PC to start a curve, you can use CTOG. Likewise, instead of using PT to end a curve, you can use CTOG.

NEAR: Nearest Found - This special code sets the current polyline to Nearest Found connection order. This applies to codes that have the Connection Order set to Sequential and you want to override this setting to Nearest Found for the current polyline. This is useful in situations when a point on a polyline was taken out of sequential order.

CLO: Close - This code forces the lines drawn between a series of points with the same code to close back to the first point with the same code. For example, shots 1-4 all have the BLD description with the exception of point 4. Its description is BLD CLO. This will force the linework drawn for the BLD code to close back to point 1 which is the first point with the description of BLD.

RECT: Close Rectangular - The "RECT" special code creates a rectangle as a 2D or 3D polyline using one of two different methods.

- *2 Point Method*: Locate 2 points for one side of a structure and add the code RECT plus a dimension for the remaining dimension of the rectangle. For example, you are locating a shed with the dimensions 20x8. Take a shot at each corner on the 20' side and code the second shot with the 8' dimension. A positive dimension offsets to the right and a negative dimension offsets to the left. First code: **BLD** Second Code **BLD RECT-8**

- 3 Point Method: Locate 3 corners of the structure and code the 3rd shot as RECT. This tells Field to Finish to form a parallelogram out of the 3 shots taken by copying the 2 sides located respectively.

Offsets: OH, OV, OFL, OFB, OO

The codes "OH" and "OV" stand for offset horizontal and offset vertical. These offset codes apply to 2D and 3D polylines. A single set of offset codes can be used to offset the polyline a set amount. For example,

10, 500, 500, 100, EP OH2.5 OV-.5

11, 525, 527, 101, EP

12, 531, 533, 103, EP

This would create a polyline connecting points 10,11 and 12 and an offset polyline with a 2.5 horizontal and -0.5 vertical offset. The direction of the horizontal offset is determined by the direction of the polyline. A positive horizontal offset goes right from the polyline direction and a negative goes left. The horizontal and vertical offset amounts apply starting at the point with the offset codes until a new offset code or the end of the polyline. Only one horizontal and vertical offset can be applied to 2D polylines. For 3D polylines, multiple offset codes can be used to make a variable offset. For example,

10, 500, 500, 100, EP OH2.5 OV-.5

11, 525, 527, 101, EP OH5.5 OV-.75

12, 531, 533, 103, EP OH7.5

This would offset the first point horizontal 2.5 and vertical -0.5, the second point horizontal 5.5 and vertical -0.75 and the third point horizontal 7.5 and vertical -0.75.

Multiple Offsets: When there are multiple "OH" codes for the same point, the polyline is offset multiple times, one for each OH code.

Alternatively and in conjunction with the "OH" code, a second number after the offset amount repeats the offset by that number. For example "OH2 5" means offset by 2 and repeat 5 times. This multiple offset option is useful drawing stair steps.

The "OFL" code stands for offset left horizontal. The only difference with the "OH" code is that you don't have to enter the "-" to go left.

The "OFB" code stands for offset both left and right horizontal. For example, if the points follow the center of a ROW, the OFB code can be used to create the left and right edges of the ROW. There is a setting in Special

Codes for Offset Both for whether the offset value is for the full or half width between the two offset lines. Also, there is a setting in each code definition under the Linetype tab for whether to create a closed polyline from the left and right offset polylines. If 3D polylines are offset, they maintain the elevations of the original located 3D polyline.

The "OO" code stands for offset only. This option only draws the offset polylines and not the polyline connecting the points. The "OO" code is a companion code that can be combined with any of the other offset codes. For example, "EP OH2 OO" will offset the EP line horizontally by 2 but draw only the offset polyline.

CIR: Circle - The "CIR" special code causes the point to create a circle in one of three different ways.

- *Single Point and Radius method:* The first way uses just the current point as the center with the CIR special code followed immediately by the radius. For example "CIR7.5" will create a circle centered on this point with radius 7.5 and at the elevation of the current point.
- *Two Point method:* The second method uses two points, the first point specifying the center and the elevation, and the second point specifying the radius. Only the first point has the "CIR" special code and the second point is the next point with a matching field code. Another variation of method 2 is using 2 points that are on the perimeter and define the diameter. For the 2 point method, whether the points define the radius or diameter is defined on the Code Table Settings > Special Codes > 2-Point Circle.
- *3 Point method:* The third method uses 3 or more points that specify the perimeter of the circle in 2D with the first point specifying the elevation. For this method, the "CIR" special code is only on the first point and the rest of the points are the next points with matching field codes.

The "CIR" code can be used with all of the linetypes including "points only". The circles are always parallel to the X-Y plane unless the code linetype is set to "3D Polyline". Then the circle is drawn as a 3D polyline. Any active linework for the code is ended before processing the "CIR" special code.

Examples of drawing circles:

PointNo. Description

Method 1 (Single point at center with radius value)

82 PP CIR7.5

Method 2a (Point at center plus point at perimeter)

83 PP CIR

84 PP

Method 2b (2 Points on perimeter that define the diameter)

83 PP CIR

84 PP

See 2-Point Circle for options to designate methods 2a or 2b.

Method 3 (Points on perimeter)

85 PP CIR

86 PP

87 PP

88 PP

89 PP

Methods 1, 2a, 3

Method 2b

JPN: Join to Point Name - The "JPN" (Join to Point Name) special code joins to the point named immediately after the code. For example, "JPN205" causes a line to be drawn from the current point to the point "205". JPN is designed to work for adding a segment at the start of linework, but can be used at any point during the survey.

SMO: Smooth - This code is used to smooth the polyline. It is ideal for long winding roads or walkways that are generally curved as it prevents the need of adding PCs and PTs to define the arc segments. Tree lines and landscape areas are also good examples of utilizing this special code.

JOG: Extend By Distance - The "JOG" special code allows for additional points to be inserted into the line work at perpendicular or straight offsets. Only offsets should follow the JOG code. Positive numbers indicate a jog to the right and negative numbers indicate a jog to the left. Alternatively, "R#" and "L#" can be used where # is the distance to either the right or the left. Finally, "S#" can be used to make an offset straight ahead by using a positive # or behind by using a negative #. For example, "BLDG JOG S10.1 R5 L12.2 L5 L12.2" or equivalently "BLDG JOG S10.1 5 -12.2 -5 -12.2" advances 10.1 units and then draws a closed rectangle on the right hand side of an existing line. The offsets are always done in the X-Y plane. If the current line is vertical, an offset to the right is along the positive X-axis.

Example of building location using jog special. The command adds both a jog of 20 to the right and 10 to the left and then closes the building at point 108. **BLD JOG20 -10 CLO**

GAP: -This special code makes a single segment break in the current linework. For example, if you have a curb polyline that you want to break to skip over a driveway, then you could add the GAP code at the start of the driveway and continue the curb as normal on the other side.

LTF: Linetype Flip - This special code switches the side for the linetype. This option applies to non-symmetrical linetypes like the treeline or guard rail for when you want the linetype to face the other way.

AFIT: Fit Arc - This special code adjusts the PC/PT points for the current arc to make the arc tangential. This special code is a way to individually control this tangential arc adjustment. To adjust all arcs within a specified adjustment tolerance, use the Adjust PC/PT setting under the Additional Draw Options from the first Field-To-Finish dialog.

LTW: Line Width - This special code sets the line width. The width value is entered after the LTW code. This width is applied to lines and 2D polylines.

BFIT: Best-Fit Line - This code creates a best-fit line using the points for the linework. This feature can be used when you have multiple points on a feature that you know is a straight line such as a sidewalk and you want a single line to be drawn. Each of the points that you want to include in the best-fit need to have the BFIT code.

RAMP: Curb Ramp - This special code adjusts the 3D polylines to create a curb ramp. The routine looks for parallel 3D polylines for the bottom of curb, top of curb and back of curb. These 3D polylines can be created in Field-To-Finish by using a Template under the Code > Linetype definition, or using the offset special codes, or by having three separate 3D polylines. The ramp is centered at the point with the RAMP code. The dimensions of the ramp follow the code in order of width, depth and taper. For example, a description of "BC RAMP 3 2 1" uses "BC" for a bottom of curb code then "RAMP" for the special code and 3 for the width, 2 for the depth and 1 for the side taper.

XSCT: Template - This special code defines a template from a series of points with this special code. This template is then applied like a template defined under Linetype for a code. This XSCT code is a way to define a template in the field instead of having a template with fixed dimensions defined in the code table. For example, you could have a code for BC for back-of-curb. Then store three points with a description of "BC XSCT" for three points to cross section the curb: back-of-curb, top-of-curb and flow line. After these three "BC XSCT" points, you could have single "BC" points along the curb and the program will apply the template along these curb points and draw three parallel lines.

PARKING: Parking - This special code draws parking stall lines using three points. Points one and two are used to draw the first parking line and define the length and angle of the lines. The third point defines that position of the last parking line. On the first point, a number needs to follow the PARKING code for the number of parking lines to draw. For example, PARKING8.

Point Symbol/Attribute Special Codes

ROT: Rotate - This code is used to set the rotation of the point symbol. If a point number follows the ROT code, then angle from the current point to this point number is used for the rotation. For example, "ROT45" would rotate the symbol towards point number 45. If there is no point number after the ROT code, then the rotation point is the next point number with the same code as the current point or a companion code for the current code. ROT can also be used to rotate towards an angle clockwise from north by using '+' or '-' in front of the number. For example ROT+45 rotates the point symbol to the northeast and ROT-90 rotates the point symbol to the west.

SZ: Symbol Size - This code is used to set a different symbol size. There are several ways to use this code. It can take multiple scale factors for different dimensions by putting an ID character after the factor.

- **SZ:** If nothing follows the SZ code, then the next point with the same field code as the current point will be used to determine the size.
- **SZ#:** The value of the new symbol size is specified after the SZ. This value is the actual size in drawing units. For example, SZ2.
- **SZ#X:** The value after the SZ is used to scale the symbol in the X dimension. For example, SZ2X.
- **SZ#Y:** The value after the SZ is used to scale the symbol in the Y dimension. For example, SZ2Y.
- **SZ#Z or SZ#V:** The value after the SZ is used to scale the symbol in the Z (Vertical) dimension. For example, SZ2Z.
- **SZ#H:** The value after the SZ is used to scale the symbol in the X,Y (Horizontal) dimensions. For example, SZ2H.
- **SZ#S:** The value after the SZ is a symbol size scaler that get multiplied by the drawing horizontal scale to determine the actual drawing units. For example, SZ0.2S.

The X, Y, Z, V and H can be combined. For example, to scale a symbol by 10 horizontally and 25 vertically, use SZ10H25Z. Or to scale a symbol by 2 in the X direction and 4 in the Y direction, use SZ2X4Y.

When multiple SZ codes are used in the same point description, the symbol is drawn multiple times at the different sizes. For example, a point description of "TREE SZ5 SZ10" will draw the tree symbol twice. One symbol will be size 5 and the other size 10.

AZI & DIST

The AZI and DIST codes are used together to offset the point. The AZI sets the offset azimuth and DIST sets the distance. The values should directly follow the code. For example, AZI25 DIST4.2 would draw the point offset 4.2 at an azimuth of 25 degrees.

2ND: Multi-Point Code - When used on the first point of a multi-point symbol, the "2ND" code indicates that the second point of the sequence (i.e., the next point after the current one) should be used as the second symbol insertion point for a multi-point symbol. Please refer to Symbol Points in the Edit Field Code Definition section below.

3RD: Multi-Point Code - When used on the first point of a multi-point symbol, the "3RD" code indicates that the third point of the sequence should be used as the third symbol insertion point. The "3RD" code should be used with the "2ND" code. Please refer to Symbol Points in the Edit Field Code Definition section below.

Note: The 2nd and 3rd codes are not necessary if the Automatic Multi-Point Special Codes option is enabled. Please refer to Symbol Points in the Edit Field Code Definition section below.

PHOTO - This code attaches a photo file to the point. The name of the photo file should be right after the PHOTO code. The PHOTO Link setting controls whether the photo is attached using a Carlson-format link or a CAD Hyperlink. Use the Image Inspector command to view photos attached to points by either link method. To use the Hyperlink, you can Ctrl-click or right-click on the point entity.

In addition to the PHOTO code, Field-to-Finish will also automatically create the photo links for SurvCE photos. The program looks for the photo database from SurvCE which should have the same name as the coordinate file with an extension of .phdb. This photo database file should be in a sub-folder of the coordinate file folder and called Pictures_X where X is the name of the coordinate file. For example, if your coordinate file is C:\Projects\Job1\Job1.crd, then the program looks for C:\Projects\Job1\Pictures_Job1\Job1.phdb.

When SurvCE stores photos, it creates this photo database using this naming. So to process with Field-to-Finish, copy the coordinate file and photo files from the data collector to your computer.

LABEL - This code controls the point attribute format using a number after the code. This number uses 0=attribute block, 1=text, 2=both, 3=none. For example, LABEL1 means draw that point using text attributes.

COLOR - This code sets the entity color. The color is specified after the "COLOR" code by either a CAD color number (1 to 256) or color letter. The color letters are R=red, Y=yellow, G=green, C=cyan, B=blue, M=magenta, W=white. For example, COLOR1 means use CAD color 1 (red) and COLORB means use color blue.

PHOTO Link - Sets the option for linking the photos. Carlson format links using the process described above. Hyperlink is a CAD link that is enabled through the CAD properties dialog box. You can also double click on any point and use the image tab to add an image file.

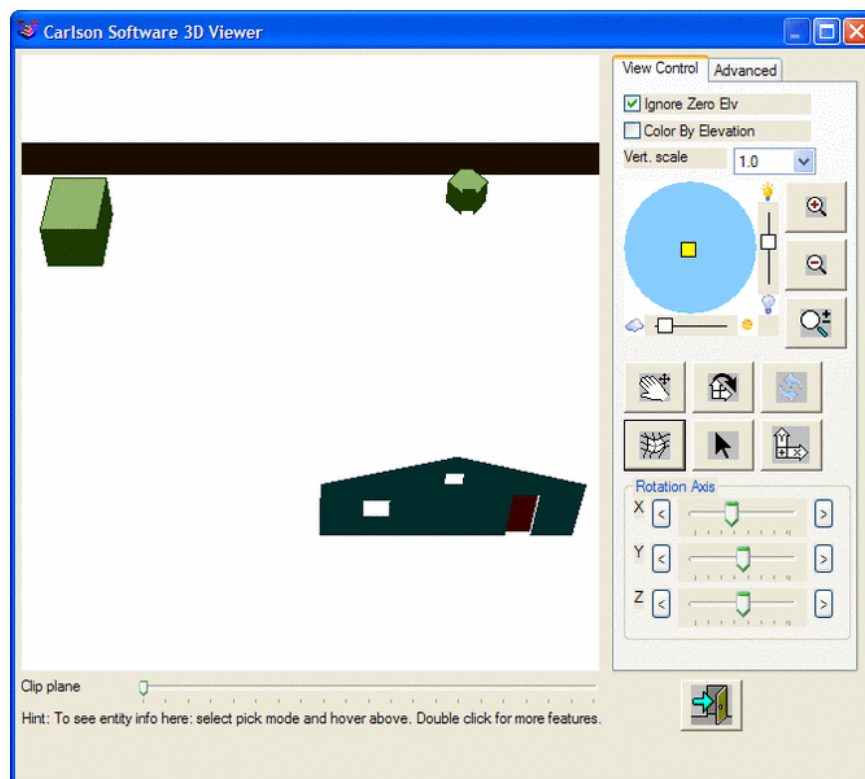

OFB Offset Width -This option works with the **OFB** special code.

- The Double option expects the user to enter half the total offset distance and the routine will double it. For example, if the total width of a pathway is 10, the OFB code will be 5.
- The Split option expects that the user will enter the total distance and the routine will split it in half. For example, if the total width of a pathway is 10, the OFB code will be 10.

2-Point Circle - This option works with the CIR special code. The radius option will use the first point with the CIR code as the radius point and the second located point as the outside of the circle. The Diameter option expects that the first point with the CIR code is one point identifying the outside of the circle and the second point another. Together they create a 2 point circle diameter.

Append Desc Auto Space -applies to the special codes that control the point description label. This option sets whether to insert a space in the description label when appending to the description.

3D Face Special Codes Below are the special codes that can be used for the easy creation of 3D surfaces. The resulting 3D face entities can be viewed in the Carlson 3D viewer by entering "cube" on the command line.

FACE3D - Makes a triangle mesh of 3D face entities by triangulating points starting with the current point and continuing until the line ends or another 3D special code is found. The points must be ordered along the perimeter. Although the mesh will be built if the points are clockwise or counterclockwise along the perimeter, the visible side in the Carlson 3D viewer, "cube", is the clockwise side by default. On the Advanced tab, the shading mode may be set to *Shade both* or *Shade back* if you would prefer to see both sides or just the counter-clockwise side.

HOLE3D - Makes an exclusion area within the triangle mesh identified by the point number following this code (e.g., "HOLE3D101" will start a hole in point # 101). If no point number is given ("HOLE3D"), the exclusion area is applied to the last mesh or if there is a mesh in the process of being constructed by the current sequence of points, it is ended and the hole is applied to it. Note that a hole can only be applied to a mesh that was created by FACE3D (not BLOCK3D or WALL3D). Note also that it can be difficult to predict what the "last mesh" was if it used a different field code since the points of the coordinate file are processed by order of field code first and then point number. There is no limit to how many holes can be applied to a FACE3D mesh. The points of the hole itself are not added to the FACE3D mesh; they are projected on to the best plane that contains the FACE3D mesh and then the hole is cut-out.

Example 1:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 VENT1 HOLE3D2500 */applies 2505-2508 as a hole to last mesh that uses point #2500. So any point in the range 2500-2504 would have the same effect.*

2506 VENT1

2507 VENT1

2508 VENT1

Example 2:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 HOUSE1 HOLE3D */stops the above mesh and applies 2505-2508 as a hole*

2506 HOUSE1

2507 HOUSE1

2508 HOUSE1

Example 3:

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1

2504 HOUSE1

2505 WINDOW1 FACE3D HOLE3D2503 */applies 2505-2508 as a hole to above mesh 2500-2504 and starts a new mesh using the WINDOW field code.*

2506 WINDOW1

2507 WINDOW1

2508 WINDOW1

Example 4 (same result as Example 3):

2500 HOUSE1 FACE3D */front of house*

2501 HOUSE1

2502 HOUSE1

2503 HOUSE1
2504 HOUSE1
2505 WINDOW1 FACE3D /starts a new mesh using the WINDOW field code.
2506 WINDOW1
2507 WINDOW1
2508 WINDOW1 HOLE3D2504 /makes the mesh 2505-2508 also be a hole in the mesh 2500-2504.

BLOCK3D - Makes a set of 3D faces to make a 3d block using the height value entered after the code (e.g., "BLOCK3D2.3" with height 2.3). Heights can be positive or negative. With 3 points, makes a parallelogram base that is extruded up (or down if height is negative) to form a 6-sided block, including top and bottom. With 4 or more points, makes a closed polygon for the base that is then extruded by the height. The points can be laid out in clockwise or counterclockwise order around the perimeter. The perimeter or base does not have to be a convex polygon.

WALL3D - Makes a set of 3D faces above the polyline using a height value entered after the code (e.g., "WALL3D2.3" with height 2.3). This height is a signed value so you can shoot either the top of the wall or the bottom of the wall. The height can be negative if the points on the top of the wall have been shot. If no height parameter exists, then the height is determined by the distance from the current point to the next point.

After the height value, you can have a width/thickness value. If no width value is entered, then a width of zero is used. When the width value starts with a minus "-", then the width is put on the left side of the points. When the width value starts with a plus "+", then the width is put on the right side of the points. When the width value has no plus or minus, then the points go through the center of the wall width.

Both sides of the wall will have triangles and so both sides will always be visible in the Carlson 3D viewer.

Example – 6' high wall shot along the bottom:

```
2000 1000.000 1060.000 100.000 WALL1 WALL3D6.0 /wall 6'  
2001 1100.000 1060.000 100.000 WALL1  
2002 1100.000 1160.000 100.000 WALL1
```

Example – 6' high and 1.5' wide wall shot along the bottom:

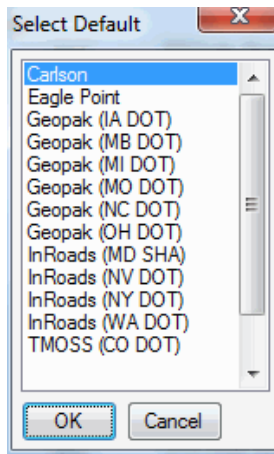

```
2000 1000.000 1060.000 100.000 WALL1 WALL3D6.0 1.5 /wall 6' high and 1.5' thick  
2001 1100.000 1060.000 100.000 WALL1  
2002 1100.000 1160.000 100.000 WALL1
```

Example – 6' high wall, height specified by 1st to 2nd point, shot along the bottom:

```
2020 1100.000 1160.000 100.000 WALL2 WALL3D /height by 2nd pt  
2021 1100.000 1160.000 106.000 WALL2  
2022 1000.000 1160.000 106.000 WALL2
```

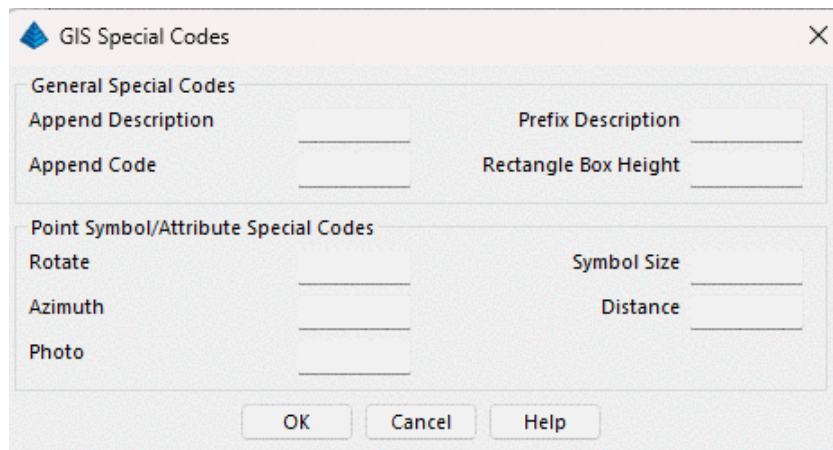

Load Default

This button sets the special codes to Carlson, Eagle Point, Geopak, InRoads or TMOSS defaults.

GIS Special Codes: This option allows you to use GIS attribute for Field-to-Finish special coding. For a select group of special codes, a GIS attribute can be assigned. When processing the points, if a point has GIS data for the specified attribute, then that attribute value is used for the special coding. For example, you can have a GIS attribute of COMMENT set to the Append Description special code. Then if a point has a GIS attribute for COMMENT, the value of that COMMENT will be added to the description label for that point.

The Append Code option adds the GIS code to the description code to make the code for processing. For example, for a point with description "ROAD" and a GIS attribute named "TYPE" with a value of "DIRT", then set the GIS Special Code for Append Code to "TYPE" and the program will process this point using the combined code of "ROADDIRT".

Code Table by Points - This command will create code table definitions based on the coordinate file field descriptions. This is useful when creating a code table from scratch

The options available when creating a code table from existing descriptions are:

- Default Symbol: Use the Set button to select a symbol to use for all of the codes created
- Remove appended digits: Removes the numeric group number from any code descriptions. For example EP1 would be created as EP. This avoids unnecessary duplication of code names.
- Append or New: allows you to append an existing code table or create a new one.

Save: Saves the Draw Field to Finish field code definition (.FLD) file.

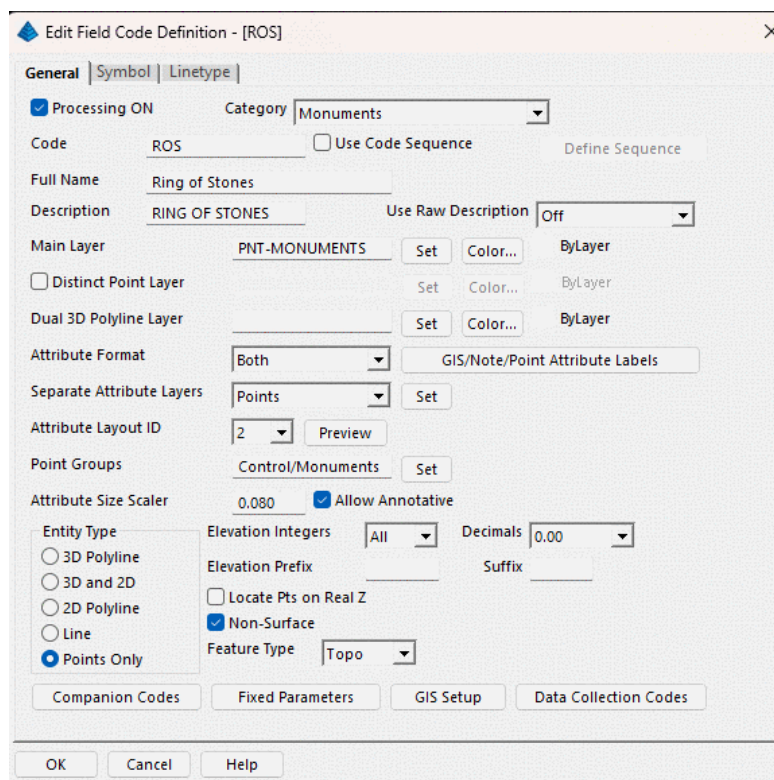

Save As: Reacts the same as Save but allows for specification of file name and location to save to.

Code Definitions

Edit: the Edit button reacts differently depending on whether a Single code is selected or Multiple codes are selected.

Edit (Single Code)

If only one field code is selected, the Edit Field Code Definition dialog box is opened.

The code definition dialog has three tabs: **General**, **Symbol** and **Linetype**. Here are the settings under General:

General Tab

Processing ON: This toggle controls whether this code will be processed. This allows you to process only specific codes if desired.

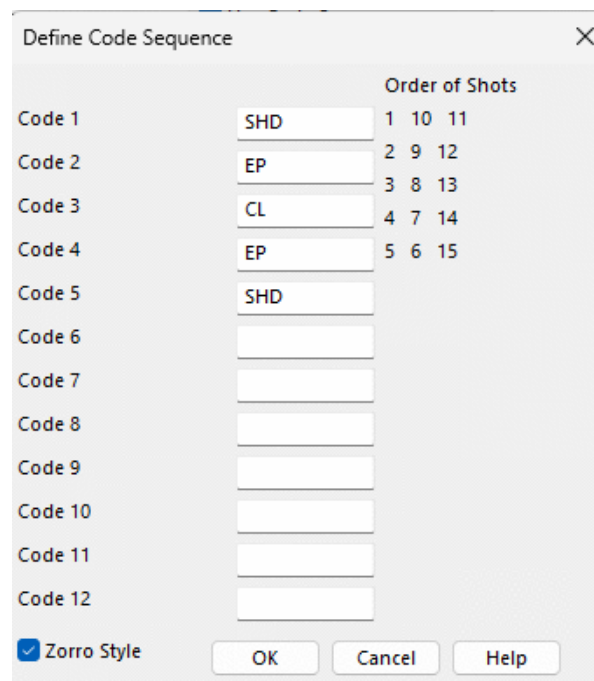

Category: Contains a "drop down" menu that displays the names of the Categories Created in the Draw Field to Finish dialog box for selection.

Code: This is the key name that identifies the code and is matched with the field data descriptions. It is important to note that the * character, used in this field, is regarded as a wildcard or "match anything" code. For example, a field code definition with the code defined as TREE* will be used for any raw description of TREE. Raw descriptions of TREEA, TREE12, TREE, etc. will match the TREE code definition. This will always be the case unless there is a more specific code is found. For example is there was a code TREEA in the code definition file, then that code would be used instead of the TREE code.

It is also important to note that the wild card is not necessary for line number grouping such as EP1, EP2 EP3 etc. The code for this example is simply EP. The program is designed to treat all codes with a numerical suffix as the code itself but separates each one into a separate line string.

Use Code Sequence: This specifies a sequence type code. Sequences are a way to simplify field entry of a sequence of codes. For example, a road cross-section could be SHD1 EP1 CL EP2 SHD2. Instead of entering these different descriptions, one sequence definition can store these descriptions in order. Then just the sequence code (such as RD) is used in the field. The cross-section can be shot in left to right then left right order, right to left then right to left order, or alternating left to right then right to left order. The alternating method is known as the Zorro style. The one restriction is that the shots always start from a right or left edge. To set up a sequence, choose the Sequence toggle in the Edit Code dialog. Then pick the Define Code Sequence button. This brings up a dialog for entering the sequence codes in order. These sequence codes should be defined as normal codes somewhere else in the Draw Field to Finish code table (ie SHD as a 3D polyline). In the field, the one template code is used for all the cross-sections shots (ie RD for all the points). Then Draw Field to Finish will substitute this template code with the sequence codes (ie substitute RD with SHD).

Define Code Sequence: This sets the code names that make up the sequence.

The dialog box titled "Define Code Sequence" contains a table for defining sequence codes. The table has three columns: "Code", "Code", and "Order of Shots". The "Order of Shots" column is further divided into three sub-columns with values 1, 10, and 11. The "Zorro Style" checkbox is checked. At the bottom are "OK", "Cancel", and "Help" buttons.

Code	Code	Order of Shots
Code 1	SHD	1 10 11
Code 2	EP	2 9 12
Code 3	CL	3 8 13
Code 4	EP	4 7 14
Code 5	SHD	
Code 6		
Code 7		
Code 8		
Code 9		
Code 10		
Code 11		
Code 12		

Zorro Style

OK Cancel Help

Resulting points and linework showing Zorro style template

Full Name: This is an optional field that describes the code for viewing and printing but also works with the **Legend** command.

Description: This value is assigned to the point description attribute when the point is drawn. This description can be different than the field code. For example, the code **IP** could have a description of **IRON PIPE** which will be applied to the attribute of the point.

Note: An additional description can be added to a point by entering it after a forward slash "/" for suffix or backwards slash "\" for prefix in the data description field.

Example **IP\3"** would be **3" IRON PIPE**.

Use Raw Description: This option turns off the Description field described above. Instead the points will be drawn with their original unprocessed descriptions.

- Attribute Block: The raw description will populate the *Description Attribute* of the point block.
- Text Attribute: The raw description will add text to the drawing in accordance with the **Attribute Format** options and the respective **GIS/NOTE/Point Attribute Labels** options.
- Both: will perform both of the above options.

Main Layer: The point and line work for the code will be created and placed on this layer.

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Distinct Point Layer: When this toggle is selected, the line work is created on the layer defined in the Main Layer field and the points are created in the specified distinct point layer. For example, you could have DRIVEWAY for linework and DRIVEWAY_PNT for the points. This option allows for greater control over the placement of points and linework.

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Dual 3D Polyline Layer: Displays the layer that the 3d polyline will be drawn on when using an Entity Type of 3D and 2D. The layer name can be typed in this field. The result is the 2D and 3D polylines being drawn on separate layers. For Example, you could have the 2D polyline drawn on the layer DRIVEWAY and the 3D polyline drawn on the layer BREAKLINES.

- The **Set** button allows the selection of an existing layer contained in the current drawing.
- The **Color** button allows the selection of a color from the CAD color selection dialog box.

Attribute Format:

This chooses the type of point entities to create. The **Attribute Block** format creates a Carlson point entity which is a block with attributes for point#, elevation and description. The layer of each attribute as well as the point block can be controlled by setting the Separate Attribute Layers.

The **Text Attribute** format creates text entities for each of the point attributes.

When the **Text Attribute** or **Both** format is selected, the placement, appearance, and function of each is controlled by selecting the GIS/Note/Point Attribute Labels button.

For the **General Attributes** control, there are toggles to control whether or not each attribute is displayed for the Point# (number), Northing, Easting Elevation and Description. In addition, there are controls for for each attribute that include:

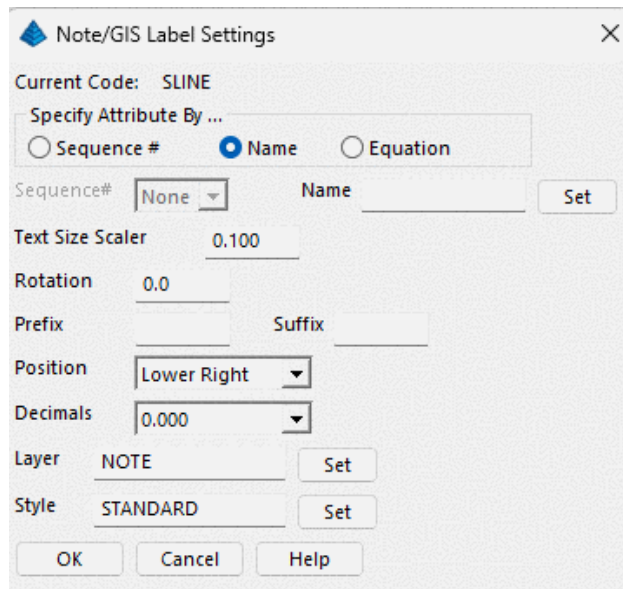

- Rotation - rotates the attribute display
- Prefix - adds a prefix to the attribute
- Suffix - adds a suffix to the attribute
- Position - controls the placement of the attribute in relationship to the point (node)
- Order - controls the order of each attributes.
- Text Size Scaler - sets the size of the attributes in relation to the drawing scale. Example 0.10 at a drawing scale of 1" = 20' will create a text size of 2.0
- Layer - sets the layer for the attribute to be placed
- Style - sets the text style for the attribute.

The **Note and GIS Attributes** section of the dialog box adds additional control over both Notes contained in the .NOT file and GIS attributes defined either by the GIS module, SurvCE/PC or other data collectors or created via Field to Finish fixed parameters. These notes/attributes are in addition to the point description but are directly related to each individual point. Making use of these additional attributes can add a great deal of power and flexibility to the Field to Finish program.

The **Notes** drop-down box allows 3 options.

- None - will not place any additional attributes into the drawing
- All (default) - will place all attributes contained in the .NOT file or created during the Field to Finish process into the drawing.
- Selected - will only place the specifically selected attributes into the drawing.

For **selected**, use the Add, Edit and Remove buttons to build the list of fields to label.

To specify the field to label, the *Sequence#* method sets the field by its order position. For example, a sequence of 3 would use the third attribute for the point. 5 Wires in the below example

Note	
1	#43
2	WOOD
3	5 WIRES
4	
5	
6	
7	
8	
9	
10	

The **Name** method sets the field to label by field name. The field name can be predefined through the GIS feature file, by SurvCE/PC in the field or can be created via the Fixed Parameters in the Edit Field Code Definition dialog box. Example of Named Attributes:

Note	
1	NUMBER=#43
2	MATERIAL=WOOD
3	WIRES=5
4	
5	
6	
7	
8	
9	
10	

The **Equation** method sets the value by the specified equation of attribute names and numbers. Besides the attribute

names, there are keywords of "X", "Y" and "Z" for the values of the current point coordinates. For example, if there is an attribute named DEPTH, then you could define a label for the invert as an equation of "Z - DEPTH".

Another example is to make a label that is 1.5 higher than the point elevation using an equation of "Z + 1.5". Besides attribute names, you can make an equation by attribute sequence using "NOTE" plus the sequence number. For example, if the depth value is the 3rd attribute, then to define a label for the invert elevation, use the equation "Z - NOTE3".

Note: Besides labeling attributes as text with this method, the Symbol > Custom Attributes feature is a way to label attributes as block attributes.

The **Settings** portion of the dialog box adds additional control of the placement and appearance of the attributes as they are placed in the drawing.

- Offset Scalers - control the distance for the text from the point for the different positions. These offset distances are calculated by multiplying the scaler by the horizontal scale for the drawing.
- Create as MTEXT - creates a Mtext entity containing all of the attributes.
 - Hide Drawing Under Labels - creates a background mask for the Mtext entity
 - Layer - with the *Create as Mtext* option enabled, all attributes will be placed on the same layer as set in this portion of the dialog box.
 - Style - with the *Create as Mtext* option enabled, all attributes will be use the same text style as set in this portion of the dialog box.
- Northing/Easting Decimals - sets the precision for the horizontal coordinates displayed
- The Elevation Label Decimal On Point option will place the elevation label so that the decimal point of the label is on top of the point location.
- Use Commas In Labels option will add commas for the thousandths place for the northing, easting and elevation labels. ie. N=1,000,000.00
- Avoid Overlap With Block Attributes option will attempt to resolve conflicts between the point block attributes and those set in this dialog box by shifting the horizontal location of the latter.
- Draw On Real Z Axis option controls whether to the text entities at the point elevation or at zero elevation.

- Group Text option creates a CAD Group for all the point labels.

Separate Attribute Layers:

This controls the layers of the point block, point attributes and/or point symbols.

- None - the point attribute layers are the default layers of, "PNTNO", "PNTELEV" and "PNTDESC", the parent layer for the point attribute block and symbol is the Main Layer designated in the Field Code definition.
- Points - allows the designation of each point block and associated attributes layers. For example if the code DWL has a layer name "DRIVEWAY", the point attributes could then be "DRIVEWAYNO", "DRIVEWAYELEV" and "DRIVEWAYDESC".
- Symbols allows the designation of the symbol associated with the point
- Both allows both of the above options.

Attribute Layout ID: Controls the location of the point number, elevation and description. These attribute layouts are defined in the drawings that are stored in the Carlson SUP directory with the file name of SRVPNO plus the ID number (i.e. SRVPNO1.DWG, SRVPNO2.DWG, etc.). If you want to change the attribute positions for a layout ID, then open and edit the associated SRVPNO drawing. Layout Ids of 1-9 are available.

Point Groups: This field is for the name of the point group that all points with this code will be added to. If the points for this code belong to multiple point groups, you can specify multiple point group names in this field separated by commas. Under Draw in Additional Draw Options, there is an option whether to automatically use the code name as the point group name or to use the name defined in the code definition. A point group does not have to exist for this option to work. It will create the designated point groups when processed.

Attribute Size Scaler: This is a scaler value that is multiplied by the horizontal scale to obtain the actual size for the point number, elevation and description attributes. This control is independent of the symbol size scaler and other text/attribute scalers allowing complete control over each element associated with the code.

Allow Annotative: This option will create the points as annotative when the annotative setting is on in the Point Defaults command.

Entity Type: This defines the line entity to be created.

- Points Only - does not connect points with any line work, however does create an option symbol is selected.
- Line - draws a CAD line entity
- 2D Polyline - creates a 2 dimensional Polyline drawn at elevation 0.

- 3D and 2D - creates both a 2D Polyline at elevation 0 and a 3D Polyline with each vertex matching the point elevation. The 3d polyline is placed on the layer specified in the **Dual 3d polyline Layer** setting and a 2d polyline in the layer identified in the **Main Layer** setting. Since 3d polylines do not display linetypes and are often difficult to draft with, this option is useful. 3D Polylines can be used for adding breaklines for surface modeling while 2d Polylines will maintain proper linetypes and can be edited through general CAD commands such as offset and fillet.

Note: The generation of Points, Symbols 2D and 3D Polylines can also be controlled through the Draw Field to Finish and Additional Draw Options.

Elevation Integers: This controls the number of digits to display to the left of the decimal point for the elevation label. The All setting will show the full elevation digits. The other settings allow you to limit the number of digits to display for the purpose of reducing the amount of space the elevation labels take up in the drawing. For example, if a site is in the 4000 foot elevation range, then this setting could be set to three digits (000) and an elevation of 4321 would be labeled as 321.

Elevation Decimals: This controls the display precision for the elevation label.

Elevation Prefix/Suffix: These set the prefix and suffix for the elevation label per code. In the Draw function under Additional Draw Settings, there is an override to set the elevation prefix/suffix for all the codes.

Locate Pts on Real Z Axis: This option will draw the points at the actual point elevation. Otherwise the points are drawn at zero elevation. For example, you could turn this option off for the FH for fire hydrant code to draw them at zero. Then the GND code could have this option on to draw the ground shots at their elevations. It is important to remember that Carlson's Triangulate and Contour routine will utilize points for creating a surface model regardless of whether they are set at Real Z or not. If the point is placed in the drawing at Real Z, Triangulate and Contour will use the point block elevation for the Z value whereas if they are drawn at zero (0), it will use the elevation from the CRD file. To ensure that a point is not used for surface modeling in Triangulate and Contour, use the Non-Surface option or utilize the NE or NOS special codes.

Non-Surface: Entities created with this flag are ignored when contouring or creating surfaces regardless of their elevation.

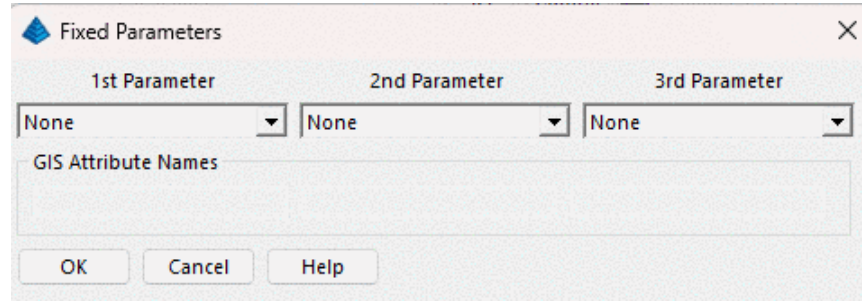

Feature Type: Controls how to process this code. The Default Feature Type is Topo. This is used for most survey work and places points using all of the above assigned settings. The Tree, Utility and Pipe Features are processed more specifically and are controlled via individual setups.

Companion Codes: This option allows different codes to connect when defined as line, polyline or 3d polyline. For example, a main line power pole code may be defined as PP while a service utility pole may be defined as UP. When processing Draw Field to Finish, it may be desired to connect all PP and UP codes together. This could be accomplished by defining a companion for UP as PP and a companion code for PP as UP. Each code needs to reference the other as a companion code.

Companion Codes can also be used in conjunction with special codes such as the Rotate (RO) code.

Fixed Parameters: This option is a coding method where you specify a sequence of parameters that follow the main code.

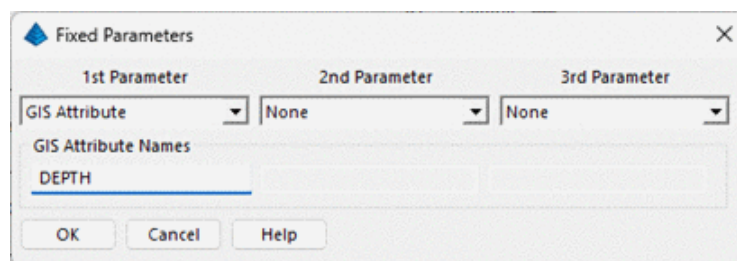

There can be up to three parameters each one having the options shown below:

Each of these options take the place of keying in special codes in the field. Instead, the parameters can be entered directly following the main code followed by spaces.

For example: a code called CURB was used to create a consistent front and back of curb lines using the Horizontal and Vertical offset special codes. The first parameter is set as **Offset Horiz** and the second as **Offset Vert**. It would be coded in the field as **CURB 1 .5** for a horizontal offset of 1 and a vertical offset of 0.5 eliminating the need for the OH and OV special codes.

GIS attributes can also be created using Fixed Parameters by choosing the GIS Attribute parameter. This way the GIS attributes can follow the main code in the description. For example, you could have a main code of MH for manhole followed by the depth to store as a GIS attribute. The description would be "MH 4.4" which results in the creation of a named attribute, DEPTH with a value of 4.4.

GIS Setup:

With GIS processing activated, the entities created by Field-to-Finish are linked to a GIS feature name and attributes. The Features and respective attributes are contained in the .GIS file created in the GIS pull-down menu in the Survey module or within the full GIS module. There are two basic required files for using GIS, (beyond the use of Field to Finish), a .GIS file that contains the features and attributes and a database file to contain that data associated with those features and attributes. *See GIS module help for more information*

GIS processing in Field-to-Finish starts with the GIS Table setting in the initial Draw Field To Finish dialog.

Setting the GIS Table is optional but useful. The GIS Table is used as the reference in the Set functions for selecting a GIS feature name to assign to Field-to-Finish codes. Additionally, when processing the Field-to-Finish codes, any associated attributes from the GIS Table will be attached to the entities. Also, attributes generated from Field-to-Finish can be added to the GIS Table. Essentially, there is a "read/write" functionality between the FLD file and the GIS file.

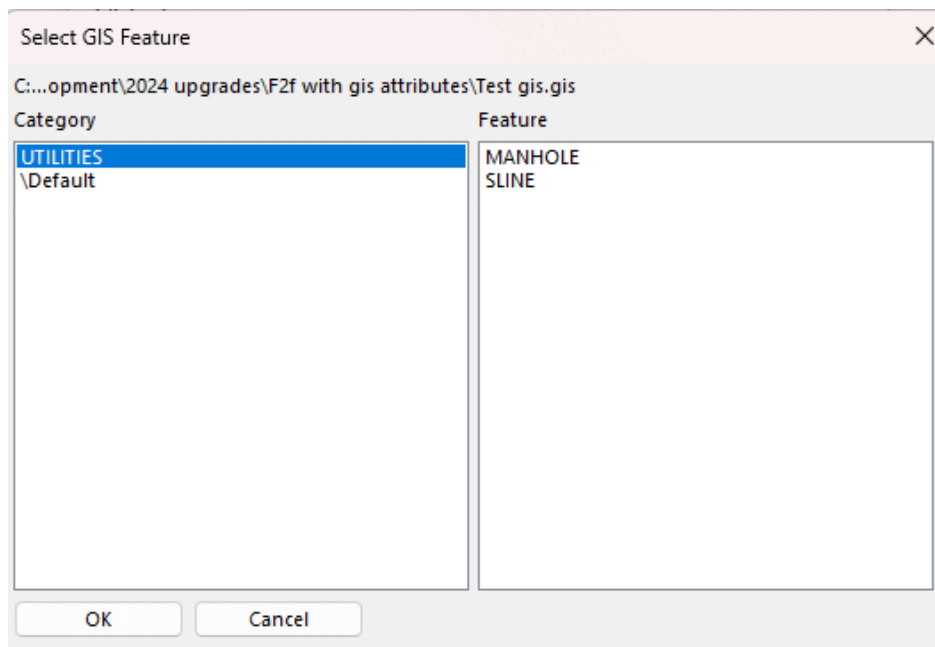

GIS Features: Each Field-to-Finish code has settings to assign GIS feature names. In the Edit Field Code Definition dialog, the GIS Setup button brings up a dialog for setting the GIS feature names and attribute options for the current code.

Points - selects a GIS feature defined as a Point

2D Linework - selects a GIS feature defined as a 2D polyline

3d Linework - selects a GIS feature defined as a 3D polyline

Set - in all 3 of the above options, the Set button will open a dialog box listing the available features in the active GIS table

Since Field-to-Finish codes are capable of drawing both points and linework and GIS can have different features for points and linework, there are separate settings for the GIS feature names for points and linework. For example, a Field-to-Finish code UP for utility pole could be setup to draw both points with symbols at the poles and polylines between these points. Then you could have different GIS feature names for the pole points and linework with separate GIS attributes for each.

Attributes to Create: each option toggled on will create a GIS feature and add it to the .GIS file.

- **SurvCE GIS Fields:** This option uses the attribute data generated by SurvCE which is stored in a .vtt file with the same file name as the current coordinate file except with the .vtt extension.
- **Point Notes:** This option creates GIS attribute data generated by SurvCE from the .not file with the same file name as the coordinate file except with the .not extension.
- **Field-to-Finish Code:** This option creates an attribute named CODE with a value of the Field-to-Finish code name (ie. UP).
- **Field-to-Finish Full Name:** This option creates an attribute named FULL_NAME with a value of the Field-to-Finish Full Name (ie. Utility Pole).
- **Special Codes:** This option creates attributes for Field-to-Finish special codes including OH (Offset Horizontal), OV (Offset Vertical), SZ (Size), ROT (Rotation), AZI (Azimuth) and DIST (Distance).
- **Point Number:** This option creates an attribute named POINT_NAME with a value of the point number from the coordinate file.
- **Drawing Description:** This option creates an attribute named POINT_DWG_DESC with a value of the point description for the point block created in the drawing.
- **Coordinate File Description:** This option creates an attribute named POINT_RAW_DESC with a value of the point description from the coordinate file.

The Point Properties By GIS Parameters lets you control the layer, symbol, linetype, color or size of the points based on GIS attributes.

In the above example, a feature with the name SLINE (meaning sewer line) was selected. When Field to Finish finds 2 or more points with that code name and the attribute Type is set to Sanitary, it will draw a 2D polyline on the layer E-Sewer with a bylayer line type. Each code and respective feature can contain as many attributes as desired. Each attribute can then trigger different options for the placement of lines or symbols on different layers at different sizes.

Data Collection Codes: These settings apply to Carlson Field for turning on the Offset mode and Rotate mode automatically by F2F code.

Symbol Tab

Set Symbol: This is the point symbol for the code. The dialog allows you to select from the symbols defined in the Symbol Library which is setup with the Settings->Symbol Library command. Besides the symbols from the symbol library, you can also use any symbols that are defined as blocks in the current drawing by entering the block name in the symbol edit box. To have a point without a symbol, use the Carlson symbol named SPT0 which represents "no symbol". If you create a custom symbol (DWG file) and you want to process Field-To-Finish on other computers, be sure to load this symbol (DWG file) in the Settings > Symbol Library on each computer which will place it into the appropriate sub-folder. Or you can upload the symbol onto Carlson Community for the other computer to find. Field-To-Finish automatically checks the Carlson Community for any symbols that aren't found on a local computer.

Note: a great way to distribute custom symbols as well as all other custom settings and files is to use the Settings Server contained in the Project/Data Folders setup.

Random Rotate: This option will randomly rotate the symbol. For example, this option could be used for tree symbols to have the trees drawn in various orientations.

Rotate To Line: This option applies to points that are part of Field-to-Finish linework. This option will align the point attributes and symbol to the associated linework. The Middle mode uses the average angle for the line segments coming to and from the point. The Forward mode uses the line angle going from the point. The Backward mode uses the line angle coming into the point. The Ends mode uses the perpendicular angle for the line end segment and applies for culverts.

Rotate Entities: This setting controls whether to apply rotation to the symbol, the point attribute block or both.

Set Rotation: Sets a specific rotation for a symbol. This rotation is subject to the current view as set in the Twist Screen command.

Symbol Size Scaler: This is a scaler value that is multiplied by the horizontal scale to obtain the actual size in the drawing. The horizontal scale can be set in *Drawing Setup*.

Unit Symbol: This option, when enabled, will draw the point symbol at unit (1:1) scale and will ignore the horizontal drawing scale. For example, this option could be used for a symbol that is already drawn to actual dimensions such as a car symbol.

Custom Attributes: This feature allows you to use customized blocks that have customized attributes (the tag/value pairs). This feature works for both point attribute blocks and symbols. For attribute blocks, Field-to-Finish looks for attributes with the tags "PT#", "ELEV2", and "DESC2". The custom attributes feature allows you to define additional attributes in their custom blocks on a per-field code basis. The dialog shows five attributes at a time. The number of attributes is unlimited. Use the Next and Back buttons to show more attributes.

For an example, the custom block could have an attribute with the tag "TREE_SPECIES" and there is a separate field code for each species of tree. Each of those field codes can specify the value that should be assigned to the attribute that has the TREE_SPECIES tag. Then when the points are drawn, the tree species is shown. Note that the custom attributes must have their Constant and Preset properties set to "no". The custom attributes settings in F2F should not use those tags that the software already handles (PT#, ELEV2, and DESC2), or the setting will be ignored.

The Values for the attributes can be fixed strings that you enter in the dialog shown here. They can also be dynamic parameters including point number, northing, easting, elevation or description for the current point as well as a point note, GIS attribute or equation. The Equation type sets the value by the specified equation of attribute names and numbers. Besides the attribute names, there are keywords of "X", "Y" and "Z" for the values of the current point coordinates. For example, if there is an attribute named DEPTH, then you could define a value for the invert as an equation of "Z - DEPTH". To setup a parameter value, pick the Set button and then select the attribute. The Decimals setting applies to fields that are real values. The Prefix and Suffix fields are added to the Value for the attribute string. Available Parameter Types:

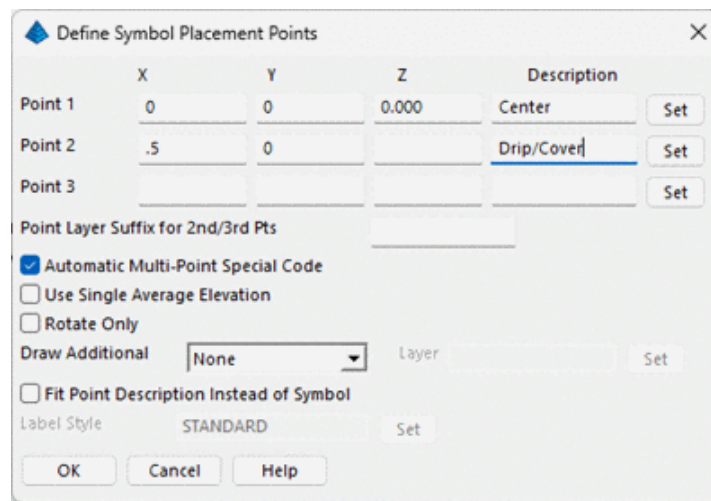

Besides labeling as block attributes, the Attribute Format method of Text mode is a way to label the attributes as text entities.

Symbol Points: For each code definition, the symbol insertion points can be defined with up to three points. To define the symbol insertion points, choose the Symbol Pts button in the Edit Code Definition dialog box. By default, the symbol insertion is defined by one point at the symbol center (0,0). A one point insertion definition can be used to insert a symbol offset from the center. With a two insertion point definitions, the program will rotate and scale the symbol. For example, two insertion points can be used to insert a tree symbol to size the tree, where the first point is for the tree center and the second is for the drip line. With three insertion point definitions, the program will rotate and scale the symbol in both X and Y. For example, three points can be used to insert a car symbol with the first point being the front drivers side, the second point as the back driver side (to rotate and scale the length) and the third as the back passenger side (to scale the width). Besides the insertion point coordinates, you can define a description for each point which is used for the drawn point description and is used for prompting in the Insert Multi-Point Symbol command and in Carlson Field data collection.

Three Point Symbol Drawing

The coordinates for the insertion point definitions are for the symbol at unit size. To figure these coordinates, you will need to open the symbol drawing (.DWG) file. By default, the symbols are located in the Carlson SUP directory. For example to make an insertion point for the tree drip line, open the tree symbol drawing and find the coordinate at the edge of the tree symbol (in this case 0.5,0.0).

Two Point Symbol Example

Not all of the symbol insertion points need to be used when drawing the points. If a code definition has a three insertion points, it is possible to use just the first two or first one. There are special codes to associate multiple points to the same symbol. The first code point is used as the first symbol insertion point. The "2ND" code is used to specify the second symbol insertion point. A point number can follow the "2ND" to identify a specific point. Otherwise without the point number, the program will use the next point with the current code. The "3RD" code is used to specify the third symbol insertion point and similar to the "2ND" code, a point number after the "3RD" is optional. The "2ND" and "3RD" codes should be assigned to the first point. For example, consider a code of "CAR" with a three point symbol insertion definition. If point #1 has a description of "CAR 2ND 3RD", then point #1 will be used as the first symbol insertion point and the next two points with the "CAR" description will be used as the second and third symbol insertion points.

Multi Point Symbol Drawing

The **Point Layer Suffix for 2nd/3rd Points** option allows for having different layers for the 2nd and 3rd points used with the multi-point symbol.

The **Automatic Multi-Point Special Code** option saves from having to enter the 2ND or 3RD special codes. This option applies when the code is always used from multi-point symbols.

The **Use Single Average Elevation** option averages the elevations of the symbol points for the point elevation label.

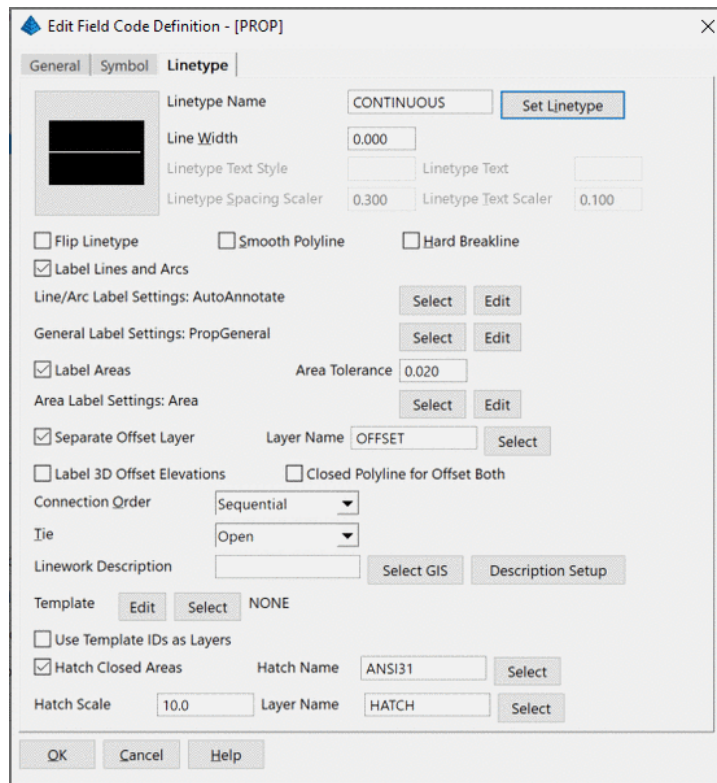

The **Rotate Only** option uses the symbol points only to rotate the symbol and does not scale.

The **Draw Additional** has options for drawing a 4th point or rectangle. The **Create 4th Corner Point** option draws another point when using a three multi-point symbol. This option applies when the symbol is rectangular and you shoot three corner points and want the program to draw a point at the 4th corner. The **Rectangle** option creates a rectangle to fit the 3 symbol points and applies to creating a breakline for surface modeling around the symbol.

The **Fit Point Description Instead Of Symbol** option is a method to drawing labels that are positioned by these points such as road markings. To set a custom text to label, you can use the `///` (Replace Description) special code. For example with a code called MARK, the description could be "MARK 3RD `///`BUS LANE". Or turn on the Automatic Multi-Point Special Code and then the "3RD" isn't needed and the description could be "MARK`///`BUS LANE". For the text control points, lower-left = 0,0, upper-right = 1,1, upper-left=0,1, and lower-right = 1,0.

Draw 2nd Symbol: This option creates a second symbol on each point. For example, this additional symbol can be used to add a 3D symbol to a 2D symbol used as the first symbol or simply add a second symbol to the point. Besides selecting the symbol name, there are settings for the Symbol Size Scaler Layer and Rotation which mimics the settings described for the first symbol with the addition of matching the 1st symbol size and rotation.

Linetype Tab

Set Linetype: Line work can be drawn in any of the special linetypes or with the linetype for the layer ("BY-LAYER"). There are three types of pre-defined linetypes: **CAD**, **Entity** and **Continuous**.

The type is shown as part of the linetype names in the list. The **CAD** linetypes are the default linetypes available

in AutoCAD and IntelliCAD. The **Entity** linetypes insert text or symbol entities at the linetype interval. These linetypes are the same as used with the Annotate->Polyline To Special Line command. The **Continuous** linetypes define a special linetype in CAD and create continuous polylines with that special linetype. These linetypes are the same as with the Annotate->Change Polyline Linetype command. Besides these pre-defined linetypes within Field-to-Finish, you can also use any linetype that is defined in the drawing by entering that linetype name in the linetype edit box or by picking the **Select From Drawing** button within the Set Linetype dialog. The spacing and size of the special linetypes is determined by the CAD LTSCALE system variable and by the 3 controls shown above or in the field code settings:

- Line Type Spacing Scaler - controls the spacing between the text and/or symbols inserted in the linetype for either the Entity or Continuous linetypes.
- Line Type Text Scaler - controls the size of the text and/or symbols inserted in the linetype for either the Entity or Continuous linetypes.
- Custom Text - allows text entry for the "User Defined" linetype.

Note: The special linetype "**Hedge**" is drawn with a width set by Line Width. The offset special codes of OH or OFB can also be used to control the width of the "hedge" linetype. The special linetype "**userdash**" is drawn with user specified distances for the length of the dash and the length of the gap between dashes.

Line Width: This controls the width for the linework. Only applies to 2D polylines. The LTW special code can also be used to set the line width for a specific line.

Linetype Text Style: Sets the text style created in the *Style* command in CAD

Linetype Text: This is the text that is used for the user-defined linetype. To use, Set Linetype to either Other_E or UserDef_C. Then this text will be used for the linetype. For example, if you have a code for a 8" PVC pipeline, then you could set this text to 8" PVC. This linetype text will use the font set in the **Linetype Text Style**. If this style is blank, the text will use the current font.

Linetype Spacing Scaler: This is a scaler value that is multiplied by the CAD LTSCALE system variable to give the distance between text or symbols in the line.

Linetype Text Scaler: This is a scaler value that is multiplied by the CAD LTSCALE system variable to give the size of the text or symbol in a line.

Flip Linetype: This option switches the side for the linetype which applies to non-symmetrical linetypes like the treeline or guard rail. The Special Code LTF can be added to the first code in the line sequence to accomplish this as well.

Smooth Polyline: This option applies a modified Bezier smoothing to the polyline. The smoothed polyline will pass through all the original points.

Hard Breakline: This option will tag the 3D polylines created with this code as hard breaklines. In *Triangulate & Contour*, contours are not smoothed as they cross hard barriers.

Label Lines and Arcs: This option will label the lines and arcs drawn using the specified Line/Arc and General Label Settings.

- **Line/Arc Label Settings:** *Selected Setting* Select an existing Label Settings file (AAN) by clicking the **Select** button or modify the file by clicking the **Edit** button.
- **General Label Settings:** *Selected Setting* Select an existing Label Settings file (ADF) by clicking the **Select** button or modify the file by clicking the **Edit** button.

Label Areas: This option will label closed areas within the specific tolerance. The areas will be labeled using the specified Area Label Settings.

- **Area Tolerance:** This is the tolerance used to determine if an area is closed and should be labeled. If a polyline closure is greater than this tolerance, the area will not be labeled.
- **Area Label Settings:** *Selected Setting* Select an existing Label Settings file (ARS) by clicking the **Select** button or modify the file by clicking the **Edit** button.

Separate Offset Layer: This setting uses another layer name for polylines created using an offset special code.

Label 3D Offset Elevations: This option labels the elevations and symbols of the vertices for polylines created using an offset special code. The Attribute Format must be set to Text Attribute or both and the Elevation attribute enabled for this option to take effect.

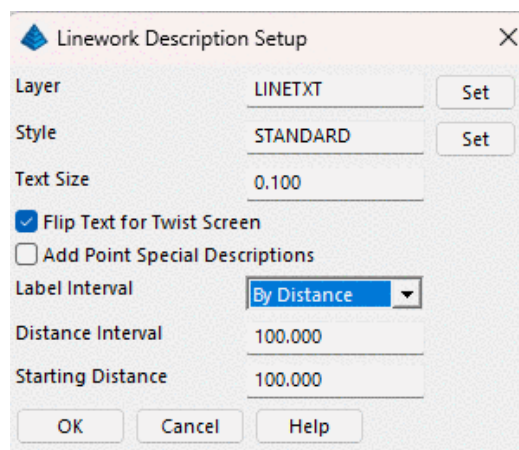

Closed Polyline for Offset Both: This option will create a closed polyline from the left and right offset polylines when the OFB (Offset Both) special code is used.

Connection Order: The points of a distinct code can be connected in their point number order, sequential, or by nearest found which creates the line by connecting each point to the next closest point.

Tie: The options for this is **Open** or **Closed**. When set to Open, the polyline created will end at the last point in the line string. When set to Closed, the last point in the line string will close back to the first. For example if you have points 1, 2, 3, and 4 with the code BLDG and Tie is set to Closed, the linework will be drawn from point 1 to 2 to 3 to 4 and then back to point 1, closing the figure.

Linework Description: This allows for an optional description which is labeled along linework created by the code.

- The **Select GIS** button chooses a GIS attribute to use for the linework description from the GIS Table. The program checks all the points used for the linework for the GIS attribute for this description. To setup the GIS attributes, the Linework Description string is formatted with "[GIS:attribute]". For example, if you have GIS attributes for "Client" and "Weather", then the string to label both attributes with prefixes could be "Client=[GIS:Client], Forecast=[GIS:Weather]" or without prefixes could be "[GIS:Client] [GIS:Weather]".
- **Description Setup** button displays a dialog to control the layer, style and size for these labels.

Layer - Sets the layer for the line text

Style - sets the text style for the line text

Text Size - sets the text size scaler for the line text

Flip Text for Twist Screen - orients the linework labels to be right side up for the drawing current twist view

Add Point Special Descriptions - adds a special description created using the prefix or suffix special codes and adds that to the description. For example if a sewer line were drawn with the Linework Description of Sewer and a prefix was added to the code of /8", the linework would be labeled as 8" Sewer

Label Interval - sets the option for the frequency of labeling the linework description. The options are from 1 to 4 labels per line string or by a Distance Interval.

- Distance Interval - sets the distance between labels in terms of drawing units.
- Starting Distance - sets the distance from the beginning of the line for the first description label.

Edit and Set Template: For 3D polyline codes, this option allows you to assign a template (.TPL) file to the code. The code points act as the base line for the template and the program will draw parallel 3D polylines for each break point (grade ID) in the template. The template file is defined in the Civil Design module or by using the Edit button. In the Edit Template dialog, there's a special setting for Field-to-Finish for the Offset Target Grade. This Offset Target Grade controls which grade in the template to use as the center line for the code points. If this field is blank, then the start of the template is used.

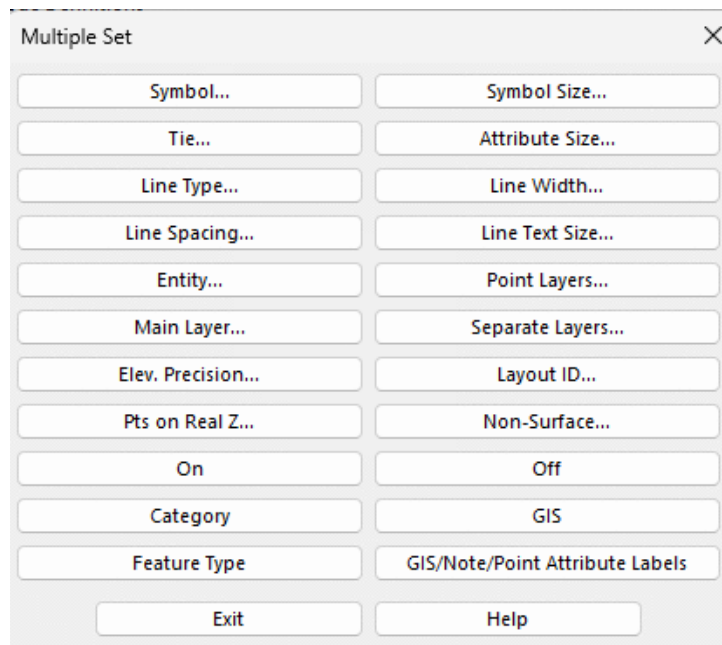

The templates are dynamic and can be adjusted along the 3D polyline by using the OH (offset horizontal) and OV (offset vertical) special codes. For example, when there is a curb template that flattens when it comes to a driveway, then an OV0 code could be used at the driveway start point and then use OV.5 at the driveway end point to restore the curb to 0.5 feet high.

Use Template IDs as Layer option will use the grade IDs from the template for the layers of the polylines created.

Hatch Closed Areas: This option applies for codes used to draw closed linework which is used as the perimeter for a hatch area. The hatch settings include the hatch pattern name, scale and layer.

Edit (Multiple Codes)

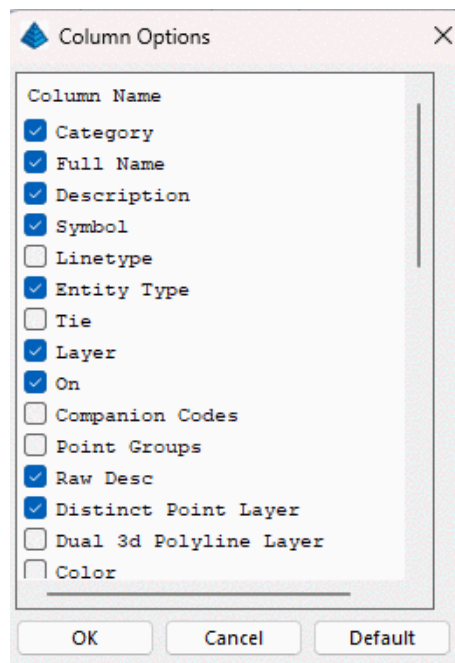

If more than a single code is selected, the Edit button will allow a limited number of "Global Edits" to the codes.

Each of these options will effect all codes selected and is a great way to make changes to a large number of codes at the same time. For example, if you wanted to set all the codes to a particular attribute size, use the Select All option and then Edit. You can then set all codes in the library to the same size attribute.

Code Definitions (continued)

Column Options: Controls the displayed columns in the display window.

Each item can be toggled on or off and the display window will update accordingly. It is important to remember that each field in each column can be modified directly from the display window. This helps greatly in the ease of editing codes in the table. Turn the columns on of interest and use copy/paste or a drop down selection as is available.

Select All: This option selects all the codes within a selected category. This can be used when only wanting to process a couple of codes. For example, use the select all option to select all the codes and then turn them off. Now select the codes for processing and turn them on. Also it can be used to make a global change to all the codes.

Move Category: Moves the selected code(s) to a predefined category.

Add: Adds a new empty code definition which is inserted in the list at the position after the currently selected one. If none are selected for positioning, the new code is placed at the top. Only one code definition may be highlighted before running this routine.

Copy: This option copies the definition of a selected code. It opens the Edit Field Code Definition dialog and copies the definition of the selected code to the appropriate settings. It does not copy the name of the code. It is a time saving tool to use when creating codes that are similar with only a couple of differences.

Delete: This command will remove the highlighted code definitions from the list.

Search: Allows you to search for a specific code in the list.

Move Up/Move Down: allows for the manual resorting of the code list by moving the selected code either up or down.

Feature Settings

Tree Setup:

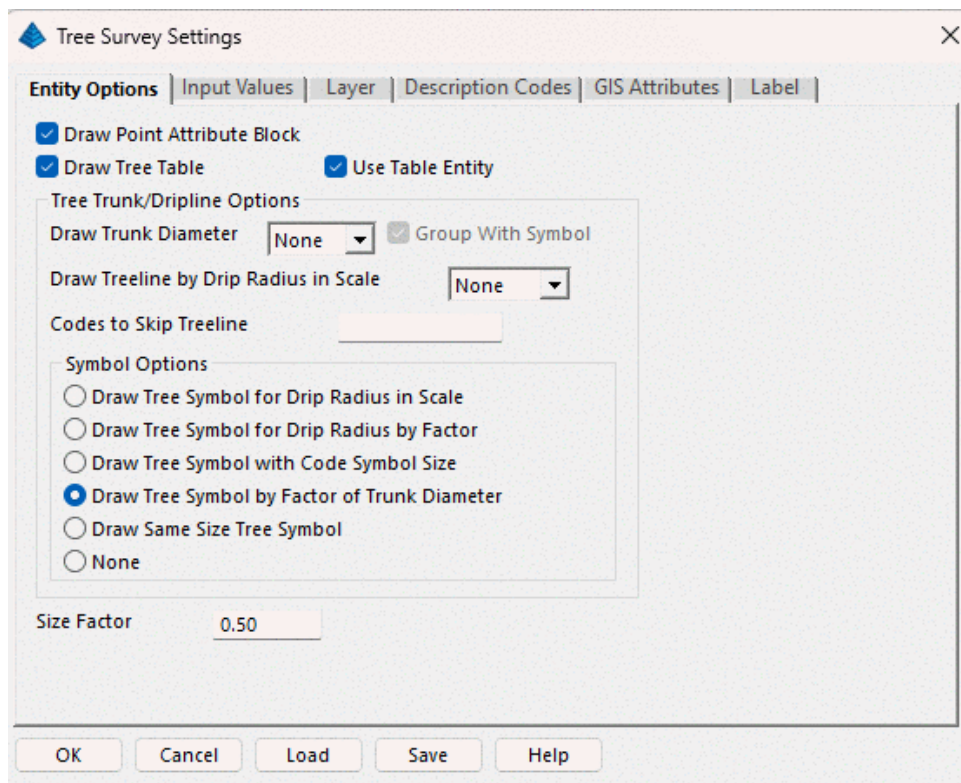

Tree surveys can be coded simply by using general Field-to-Finish coding methods such as defining a code for a tree ("OAK") with a tree symbol and using the SZ special code for sizing the symbol. The **Tree Feature** provides more power and flexibility in cases where a simple symbol is not sufficient. The tree survey works with three optional attributes for each tree: trunk, drip and tag. Trunk is the diameter of the tree trunk. Drip is the radius of the tree canopy. Tag is an id for the tree for reporting.

Tag	Trunk	Drip	Comment
T100	12"	15	MAPLE
T101	10"	10	CEDAR

Important: The Tree Survey Settings apply to codes that are set to a Feature Type of Tree. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

Entity Options Tab:

Draw Point Attribute Block -controls whether to draw the point block with the point #, elevation and description attributes.

Draw Tree Table - This option makes the program prompt for whether to draw a tree table when the program finds a couple points with tree codes. Otherwise, there must be many tree codes to have the program prompt for creating a tree table. The Use Table Entity option draws the table as a Carlson Table Entity. Otherwise the table is drawn with regular CAD lines and text.

Draw Trunk Diameter - Sets whether to create a circle or solid with the trunk diameter. The Group With Symbol option creates a CAD group to combine the tree and trunk symbols.

Draw Treeline by Drip Radius in Scale - shrink wraps the tree drip lines to get the overall treeline perimeter. The perimeter polyline can be drawn either as Bubbles or Smooth. The Bubbles creates a treeline style polyline with a series of arcs. The Smooth creates a regular polyline.

Codes to Skip Treeline - allows you to skip specific Field-to-Finish codes from using with the treeline. If you have more than a single code to skip, use either a space or comma to separate the codes.

Draw Tree Symbol for Drip Radius in Scale - draws individual symbols for each tree using the symbols defined in the code table and scaled by the drip size attribute.

Draw Tree Symbol for Drip Radius by Factor - draws individual symbols for each tree using the symbols defined in the code table and scaled by the drip size attribute and the Size Factor from this dialog.

Draw Tree Symbol with Code Symbol Size - draws individual symbols for each tree using the symbol name and size defined in the code table.

Draw Tree Symbol by Factor of Trunk Diameter - draws individual symbols for each tree using the symbols defined in the code table and scaled by the trunk size attribute multiplied by 12. For example, a 10" trunk size is drawn as a 10ft symbol.

Draw Same Size Tree Symbol - draws individual symbols for each tree using the symbols defined in the code table and at size of 6.

None - simply does not draw a tree symbol

Input Values Tab:

The screenshot shows the 'Tree Survey Settings' dialog box with the 'Input Values' tab selected. The dialog has a title bar with a close button (X) and a tabbed interface with the following tabs: 'Entity Options', 'Input Values', 'Layer', 'Description Codes', 'GIS Attributes', and 'Label'. The 'Input Values' tab contains the following settings:

- Default Tree ID to Point ID
- Begin Tree ID from: 100
- Input Trunk Value: Diameter
- Input Drip Value: Radius
- Canopy Companion Code: DRIP

At the bottom of the dialog are five buttons: 'OK', 'Cancel', 'Load', 'Save', and 'Help'.

Default Tree ID to Point ID - option uses the point number for the tree tag unless the point description contains a tree tag.

Begin Tree ID From - this is the number to start the incremental numbering of tree tags from. Each point with a tree feature code will be numbered consecutively thereafter.

Input Trunk Value - controls whether the trunk size is entered as a radius or diameter.

Input Drip Value - controls whether the canopy drip size is entered as a radius or diameter.

Canopy Companion Code - this tree coding method handles a point at the trunk and then a series of 3 or more points for the canopy. The point description coding uses separate codes for the trunk and the canopy points.

The program draws a Bezier smooth polyline thru the points for the canopy. In this example, points 1 and 6 have the tree feature code from the Field-to-Finish code table, and the rest of the points have the Canopy Companion Code.

Layer Tab:

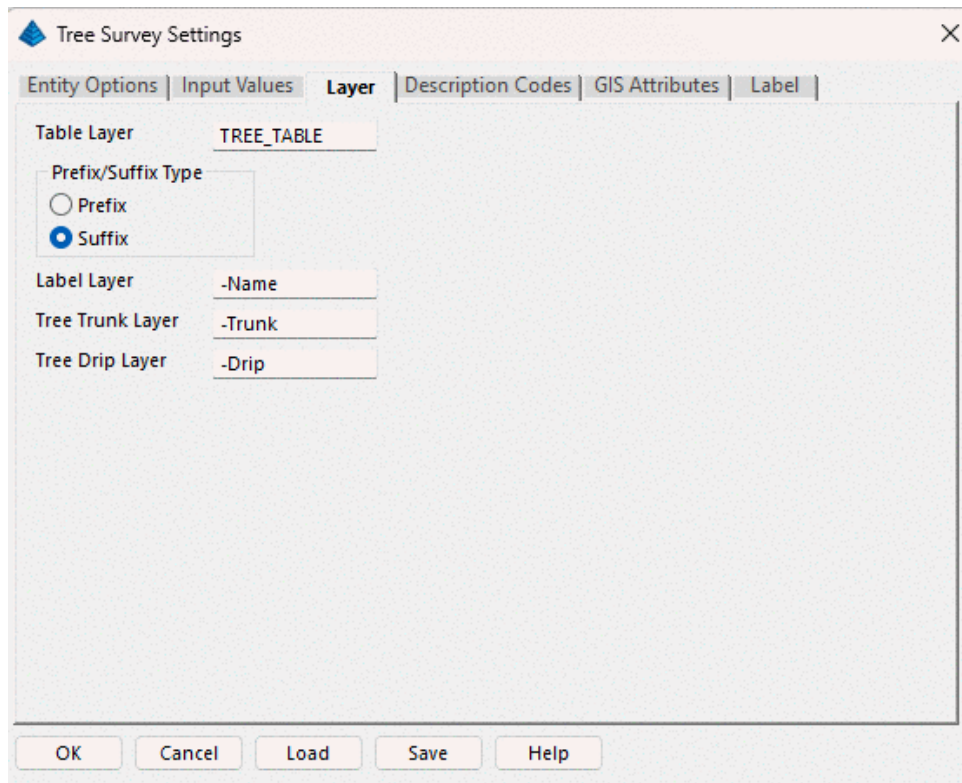

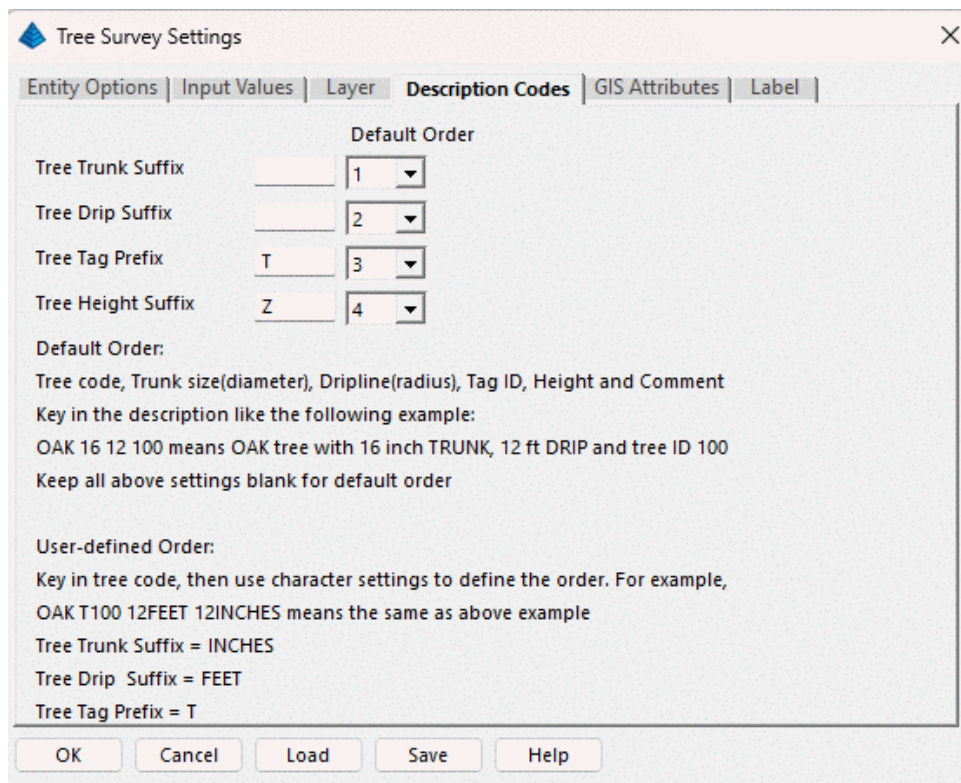

Table Layer - sets the layer for the optional tree table to be drawn

Prefix/Suffix Type - designates whether the layer names will be added as a suffix or prefix to the Main Layer as designated in the code itself.

- Label Layer - added to the layer name for the tree label ie. Maple, Oak etc.
- Tree Trunk Layer - added to the layer name for the label of the trunk size
- Tree Drip Layer - added to the layer name for the label of the drip line size

Example: the main layer for the code DT is set to Tree. The tree labels would be placed on the layers Tree-Name, Tree-Trunk and Tree-Drip

Description Codes Tab:

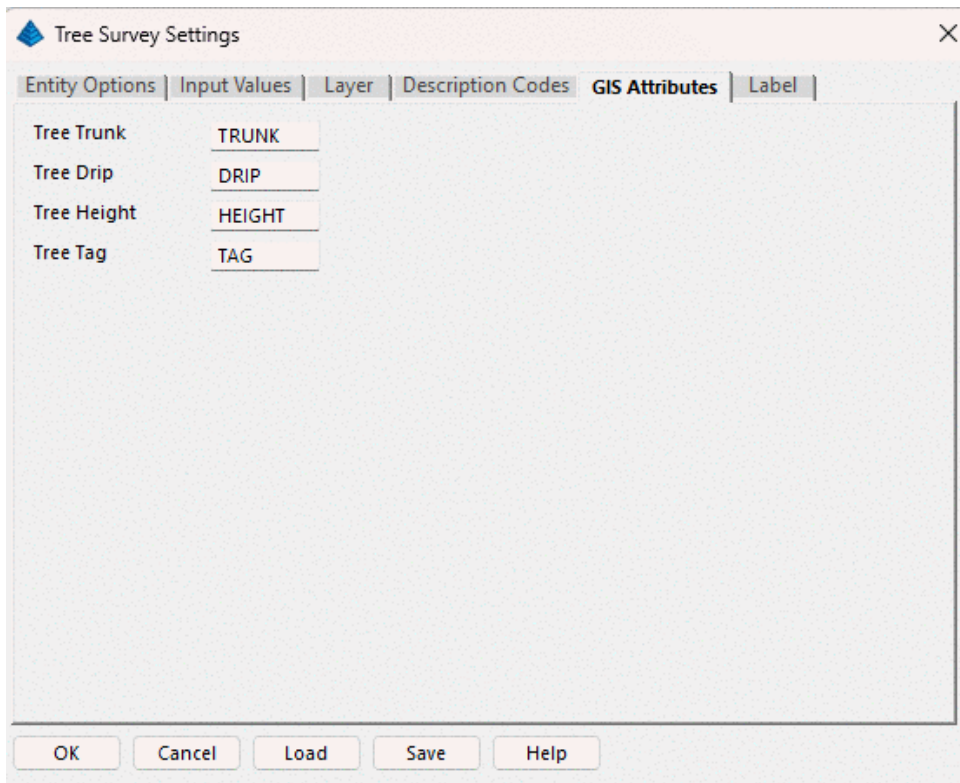

There are settings to help identify the tree attributes in the point description. The program looks for the trunk size, drip size, tag ID and height in the point description after the tree code. By default, the program expects the attributes to be in the order of trunk size, drip size, tag ID and height. Here's an example default order:

OAK 16 12 100 28

where OAK is the tree code from the code table, 16 is the trunk diameter, 12 is the drip radius, 100 is the tag ID and height is 28.

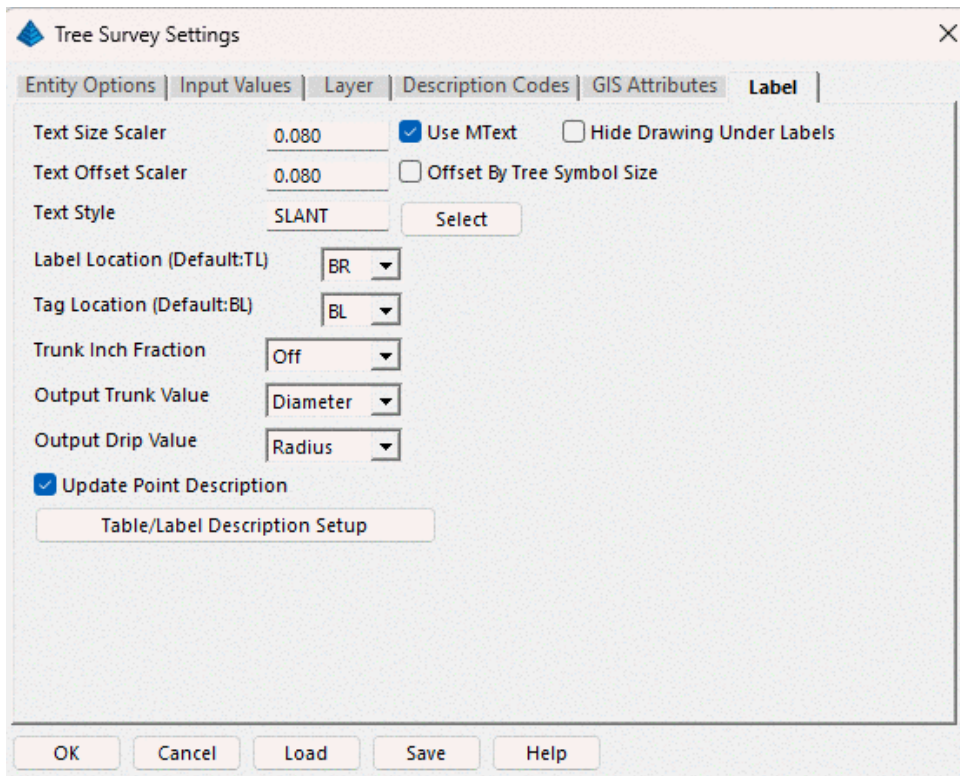

You can change the order that the program looks for the attributes by setting the Default Order numbers. Another way to change the attribute order is to use the suffix/prefix settings to identify the attributes. When the program finds a specified prefix or suffix, it tells the program which attribute to use. For example, if the Trunk Suffix is "in" and the Drip Suffix is "ft" and the Tag Prefix is "T", then OAK T100 16in 12ft means tag ID of 100, trunk diameter 16 and drip radius 12 feet.

GIS Attributes Tab:

In addition to looking for the tree attributes in the point description, the program can also read these attributes from GIS fields. On the **GIS Attributes** dialog tab, you can set the GIS field names for the tree attributes. The data collected in the field would be stored in the .vtt file which would contain the values for each of the defined attributes. Normally, this option would be used in place of adding the tree data directly to the code description.

Label Tab:

There are settings for the tree text labels for the size, offset from trunk center, style and location. When creating a tree table, only the tag text is labeled. Otherwise, the label is drawn.

Text Size Scaler - sets the scale size of the text the value of which is multiplied by the horizontal scale as set in the drawing setup. Options to **Use Mtext** and **Hide Drawing Under Labels** (applies a wipeout or text mask) are available.

Offset Scaler - applies a scale factor to control the placement of the text as it pertains to the point. **Offset By Tree Symbol Size** moves the labels beyond the tree symbol to avoid overlap between the labels and the symbol. The amount to move is factored by the Text Offset Scaler.

Trunk Inch Fraction - sets the precision in inches to use for the trunk size labels.

Output Trunk Value - sets whether to label the trunk size as a radius or diameter.

Output Drip Value - sets whether to label the canopy (drip line) size as a radius or diameter.

Update Point Description - sets whether to only use the label setup for the table and not the point drawing description. With this toggled on, the description attribute in the drawing will be updated to reflect the values to be used in the table as opposed to the coding as input in the field. The code description in the coordinate file is not affected by this setting.

Table/Label Description Setup - opens a Label Settings dialog box that controls the fields to be labeled in the drawing as well as included in the tree table.

For each field, there are settings to control the placement, prefix, suffix and the caption for the table columns. These settings effect both the labeling in the drawing and the table.

- Order - sets the order for the field
- New Row - when toggled on, places the field on a new row for the description label. This does not affect the tree table.
- Prefix - adds an optional prefix for the label

- Suffix - adds and optional suffix for the label
- Header - designates the caption for the top of the column in the tree table
- Width - sets the width of the field for the tree table column
- Only Label Tag ID With Table - when enabled, tree tags will only be used when the option for a tree table is enabled.

When Field-to-Finish draws entities, the program checks for codes set as tree features and applies the settings from the Tree Survey dialog. When tree features are found, the number of trees are reported along with a prompt for whether to draw a tree table. The tree table has the tag ID, code description and trunk diameter.

Here is an example with the following three points:

Point#	Northing	Easting	Description
1	4994.73	4923.15	OAK 24 38 301
2	5034.59	4881.40	PINE 18 24 302
3	4987.32	4975.79	PINE 12 20 303

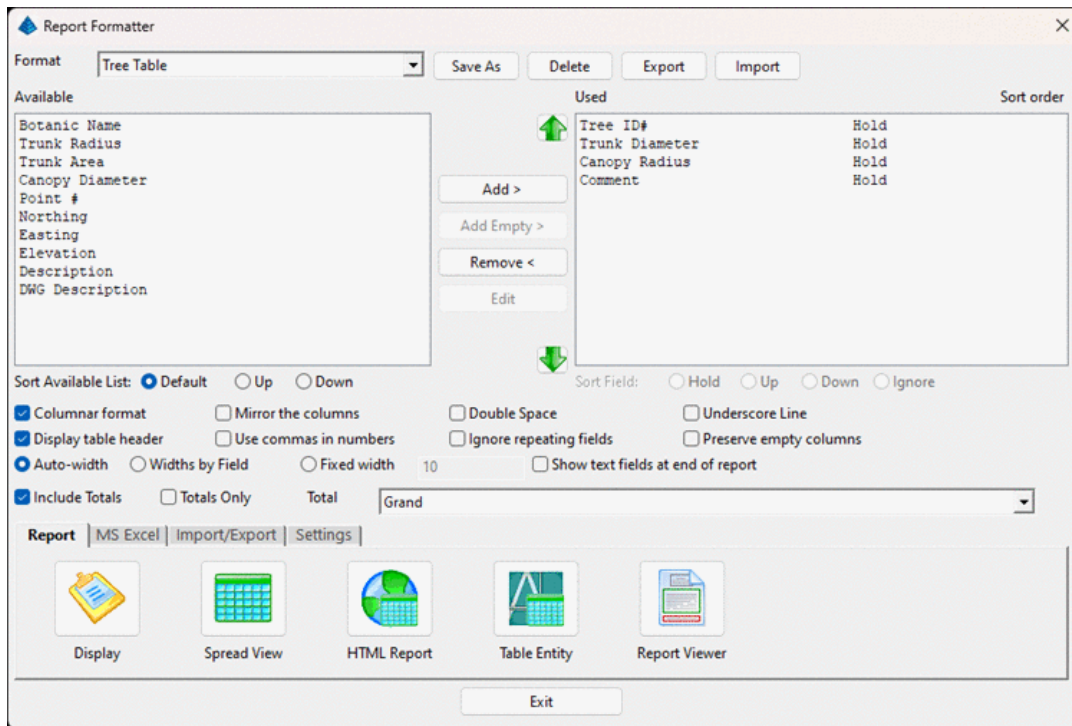

Drip line drawn as Treeline method along with a tree table.

Another feature of Tree Survey is the **Tree Report** under the Report Codes/Points function. The Report Formatter option can be used to make a custom report and output to Excel or create a custom table in the drawing. To use this feature, use the Report Codes/Points option found in the Code Table or Draw Field to Finish dialog box.

Select the Tree Report option and click <OK>. Alternatively, enable the Use Report Formatter option and click <OK> to reveal additional options for the report.

Example Tree Table Report

Tree ID# Trunk Diameter Canopy Radius Comment
 T100 12" 15' MAPLE
 T101 10" 10' CEDAR

Pipe Setup:

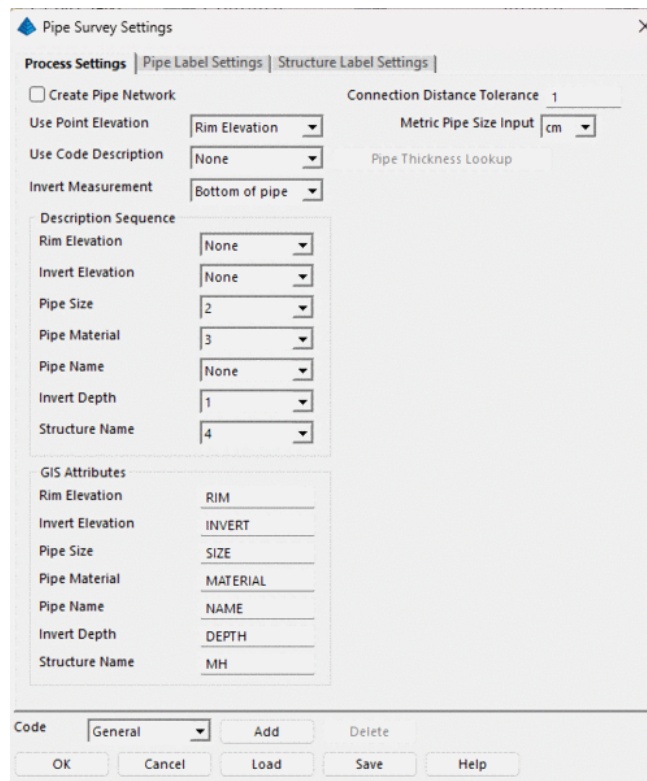

The **Pipe Feature** adds additional properties and options to the drawing a pipe line or network. Size, material and name are some of those options. in addition, the Pipe Feature allows more control over labeling of the pipe parameters and ability to draw the pipe in 3D.

Important: The Pipe Settings apply to codes that are set to a Feature Type of **Pipe**. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

When a code is tagged as a Pipe Feature, the program looks for additional parameters after the code. The parameters are separated by spaces in the point description and in the order specified in the Description Sequence in the settings dialog. For example, if code 'P' is defined as a Pipe Feature and the order of size, material and name, then a description of 'P 8 PVC 31' would define a pipe point for an 8 inch pipe of material PVC and name of 31. These pipe parameters are optional. The program will use the provided parameters and leave the rest blank. Besides using the point description, the pipe attributes can alternatively be set from GIS attributes using the attribute names setup in the dialog.

Process Settings Tab:

Create Pipe Network - when enabled, a SewerNET pipe network (.SEW) file will be created from the points connected with a pipe feature type. The **Connection Tolerance** limits the distance between points to be considered pipes belonging to the same structure. This is particularly useful when locating the actual invert for each pipe within a structure. The .SEW file can be utilized in the Sewer Network (**SewerNET**) contained in the **Hydrology** module. From there, the network can be edited, analyzed, and used for plan and profile creation.

Use Point Elevation - sets the control parameter for the point elevation. The field located point can be used as the **Rim Elevation**, the **Invert Elevation** or can be set to **None**.

Use Code Description - the code description can be used as the **Pipe Material**, **Pipe Name** or set to **None**.

Invert Measurement - when a pipe is field located directly, this control if the elevation will be used as the **Top** of Pipe or **Bottom** of Pipe.

Description Sequence - sets the order for the code descriptions as they are input into the code. The order of these setting must match the method in which the code is created. The fields that can be used and ordered are:

- Rim Elevation

- Invert Elevation
- Pipe Size
- Pipe Material
- Pipe Name
- Invert Depth
- Structure Name

For a structure with multiple inverts, pipe sizes and/or materials, the values should be in the description separated by commas. For example, for a structure with two incoming PVC pipes with sizes of 15" and 24", and inverts at depths 5.9 and 5.5, the description would be 'P 15,24 PVC 5.9,5.5'. If a value, such as the material does not change between structures, it need not be reentered.

GIS Attributes - using GIS attributes mimics the process described above. The difference is how the values are input into the pipe feature. Using the GIS attribute option requires that the data be entered as an attribute that is carried with the point coordinate file. The advantage to this method is that it does not necessitate long code description. Instead, the point attribute data can be entered in in a tabular format.

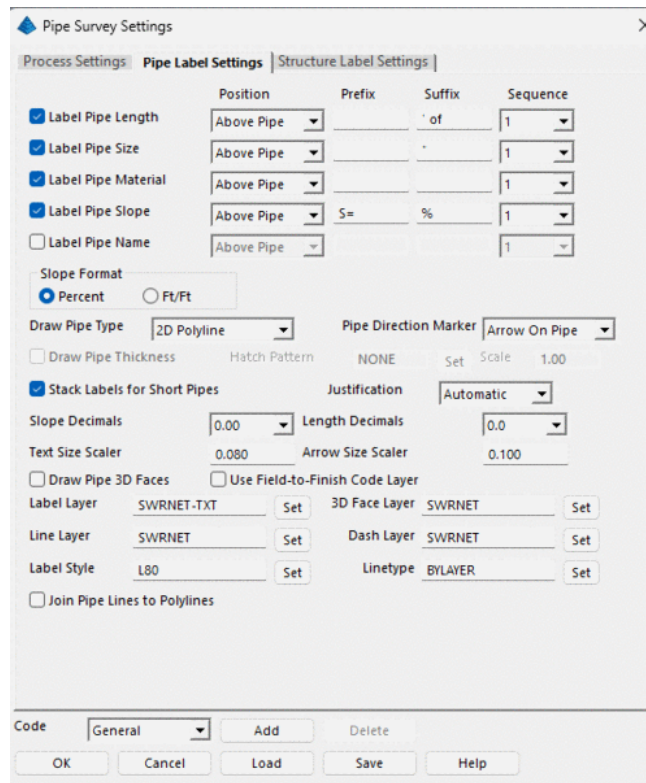

Example:

```
DEPTH=5.0  
SIZE=12  
MATERIAL=CONCRETE
```

The attributes can be created in advanced or in the field using SurvCE/PC and can be set up for prompts during the collection of the data.

Code - the Code defaults as General which would apply to all pipe feature codes. You can also Add a code that is contained in the Code Table as a Pipe Feature which can then have individual settings. For example, you could have a code called STORM for storm sewers and one called SANITARY for sanitary sewers. Each pipe network can have unique settings for layers and labels.

Pipe Label Settings Tab:

Label Pipe Length, Size, Material and Slope - all have controls over the position and content of the labels:

- Position - sets the position of the label as above or below the pipe
- Prefix - adds a prefix to the label
- Suffix - adds a suffix to the label
- Sequence - sets the sequence of the pipe label

Slope Format - can be expressed as a percentage of slope or foot per foot (ft/ft)

Draw Pipe type - sets the type of pipe to be drawn.

- 2D Polyline - draws a consistent 2D polyline at elevation 0
- 3D Polyline - draws a 3D polyline with each vertex matching the point elevation
- Double/Width - draws 2 dashed lines offset from each other the size of the pipe with no scale exaggeration.
- Dashed/Width - draws a solid and dashed line whose width is the size of the pipe with no scale

- None - does not draw line work between points
- Field-to-Finish - uses the linetype as selected in the Field to Finish Code Table

Pipe Direction Marker - draws an arrow in the direction of flow for each pipe segment. The choices are an **Arrow** on the Pipe, **Parallel** to the pipe or **None**

Draw Pipe Thickness - a pipe thickness (if available) can be drawn outside the pipe with the exception of the 2D or 3D polyline options.

- **Hatch Pattern** - an optional Hatch Pattern can be used to depict the pipe thickness. The selection and scale of the hatch pattern is also available.

Stack Labels for Short Pipes - automatically stacks the selected labels to make them look more readable.

Justification - the text justification for the labels can be set as Automatic, Left/Right or Centered.

Slope Decimals - sets the precision for the pipe slope labels

Length Decimals - sets the precision for the pipe distance labels

Text Size Scaler - sets the text size in terms of a scale factor which is applied to the horizontal scale as set in the Drawing Setup. (text scaler x horizontal scale = text size)

Arrow Size Scaler - sets the Arrow size in terms of a scale factor which is applied to the horizontal scale as set in the Drawing Setup. (text scaler x horizontal scale = text size)

Draw Pipe 3D Faces - when enabled, a 3 dimensional pipe as 3D Faces is drawn separately from the other pipe lines which can be viewed in Orbit view or Carlson's Drawing Viewer'

- **Use Field-to-Finish Code Layer** - draws the 3D pipes on the layer established in the Code Tablee

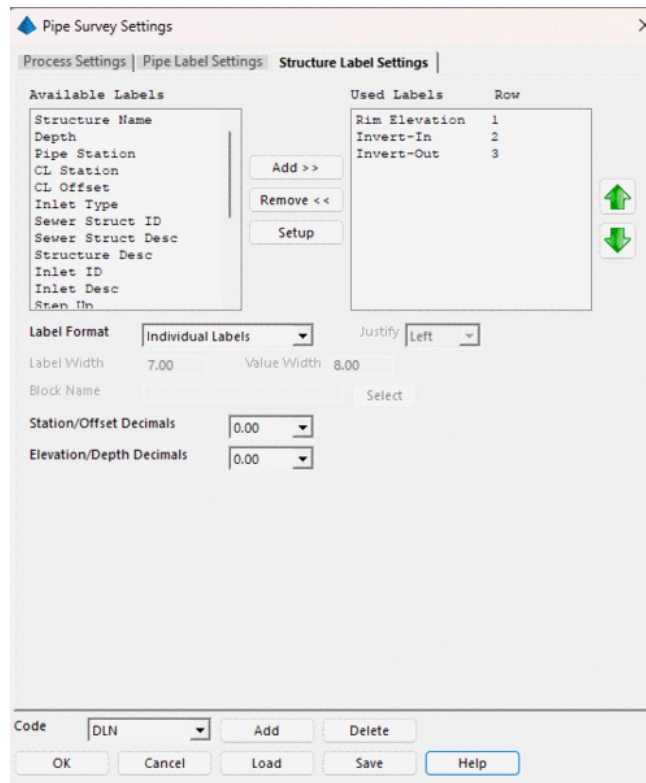

Layers for the Labels, Lines, 3D Faces and the Dashes (when using the Dashed/Width option) can be typed in or selected using the Set button.

Label Style - sets the text style for the pipe labels

Linetype - sets the linetype for the line work. This will override the linetype defined in the layer unless bylayer is selected and does not apply to the Dashed/Width option.

Join Pipe Lines to Polylines - joins all connected pipes into a single polyline. This does not work for the Double/Width or Dashed/Width pipe types

Structure Label Settings Tab:

Available/Used Labels - to setup the Pipe Structure Labels, highlight any available pipe structure labels on the left side of the dialog box and either double click or hit the Add button to move it to the Used Labels portion of the dialog box on the right.

Label Format - select the desired label format from the drop down list.

- Individual Labels - labels text at each structure location
- Data Table - creates a Data Table at each structure location. When this option is used, you are able to control the **Justification** of the table as well as the **Width** of the Labels and Values. These options only become available when the Data Table option has been selected.
- Attribute Block - adds the data for each structure to a predefined block containing the relative attributes. When this option is used, there is a Select button to select the block to be used.
- Along Pipe - labels the structure information along each respective pipe segment.

Station/Offset Decimals - sets the precision for the CL Station and Offset Labels

Elevation/Depth Decimals - sets the precision for Elevation labels of Rim, Inverts, and Depth.

Example coding of a pipe network. PIPE code is defined as a Pipe Feature. The 1st description is the pipe size. The 2nd description is the pipe material. The 3rd description is the pipe depth. Point 3 has two sizes and two depths separated by commas because two pipe connect at this point.

Point	Description
1	PIPE1 15 HDPE 4.75
2	PIPE1 15 HDPE 6.15

- 3 PIPE1 15,24 HDPE 5.96,5.5
- 4 PIPE1 24 HDPE 9.9

Example coding for 2 separate pipes using END code to separate the pipes. CUL code is defined as a Pipe Feature. 1st description is the Pipe Material and 2nd description is the pipe size. In this case, turn OFF the Create Pipe Network because the separate pipes are using the same code of CUL.

Point	Description
7	CUL RCP 18
8	CUL END RCP 18
14	CUL RCP 18
15	CUL END RCP 18

Example coding for 2 separate pipes using number suffix on codes to separate the pipes. CUL code is defined as a Pipe Feature. 1st description is the Pipe Material and 2nd description is the pipe size. In this case, the Create Pipe Network can be applied. The separate pipes are using separate codes of CUL1 and CUL2.

Point	Description
7	CUL1 RCP 18
8	CUL1 RCP 18
14	CUL2 RCP 18
15	CUL2 RCP 18

Utility Setup:

The Utility Feature works similar to the Pipe feature. The differences with utility are supporting different pipe shapes (circle, rectangle, etc), different types of utilities (gas, electric, etc), and not having manhole structures. For each utility type, there are settings for pipe shape, color, labels and drawing 2D Polylines, 3D Polylines and 3D Faces.

Important: The Utility Settings apply to codes that are set to a Utility Feature. To set the Feature Type, go to Edit Codes and then the General tab of the Edit Field Code Definition dialog.

Process Settings Tab:

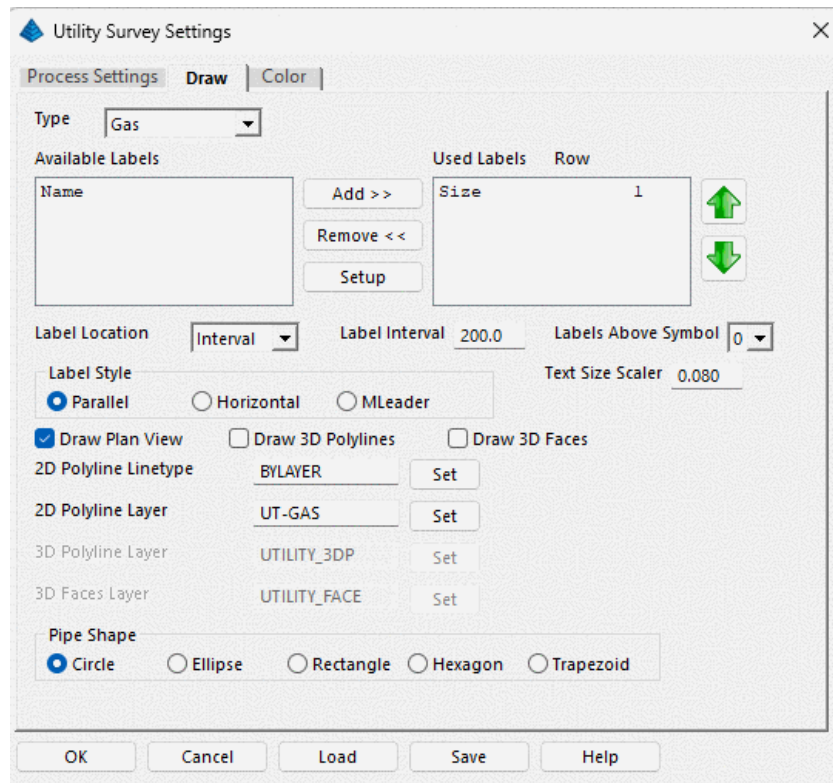

Elevation Measurement - sets the reference for the point location as either Top or Bottom of the pipe

Description Sequence - Sets the order of the utility size in the code description

GIS Attributes - using GIS attributes mimics the process described above. The difference is how the values are input into the Utility feature. Using the GIS attribute option requires that the data be entered as an attribute that is carried with the point coordinate file.

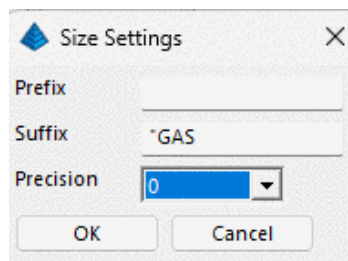

Draw Tab:

Type - selects the type of utility for the draw settings. There is a pull down menu with include utility types of:

- Gas
- Water
- Sanitary
- Storm
- Communication
- Electric
- Irrigation
- Fire
- Utility Duct
- and Other for user defined utilities

Setup - allows the additional control of adding prefix, suffix and the size precision to the utility line label. This can also be accomplished by double clicking the label field.

Available/Used Labels - to setup the Utility Line Labels, highlight any available field labels on the left side of the dialog box and either double click or hit the Add button to move it to the Used Labels portion of the dialog box on the right.

Label Location - sets the location of the label along the utility line

- None - does not add a label to the line
- Ends - adds a label to each end of the utility line
- Interval places a label at a distance interval
 - Label Interval is the distance in CAD units to place the label
- Both - places a label at each end as well as at intervals

Label Style - controls the placement of the text label for the size and/or name of the utility.

- Parallel - places the label parallel to the utility pipe
- Horizontal - places the label horizontal to the screen view, with respect to a Twist Screen if present
- Mleader - creates a Mleader that points to the utility line

Draw Options - are toggles to select options for the entities to be drawn. One or more may be selected. The options are:

- Draw Plan View - will draw the 2D line work as set in the code table with respect to the options herein
- Draw 3D Polylines -draws a 3D polyline between points with each vertex matching the point elevation
- Draw 3D Faces -creates 3D Faces in the shape and size of the pipe shape selected

2D Polyline Linetype - sets the linetype for the 2D polyline

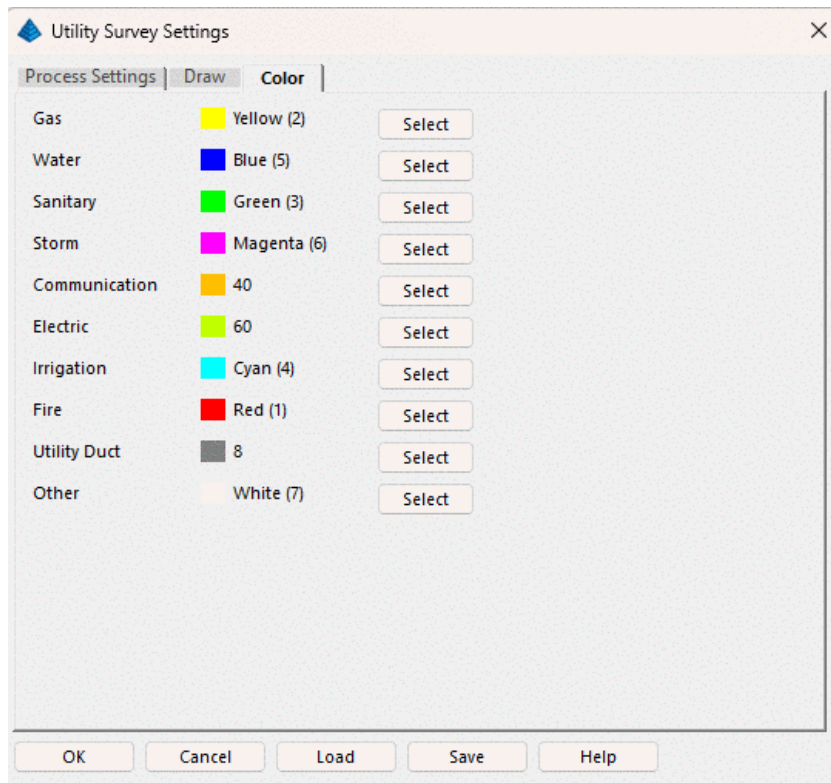

2D Polyline Layer - sets the layer for the 2D polyline to be placed

3D Polyline Layer - sets the layer for the 3D polyline to be placed

3D Faces Layer - sets the layer for the 3D faces to be placed

Pipe Shape - select the shape of the pipe to be created. These pipe shapes affect the 3D Faces created if that option is enabled.

Color Tab:

This dialog box contains the option to set individual colors for each utility type.

Symbol Library - accesses the Symbol Library also contained in the Settings Menu

Edit Points: - accesses the Edit Points Menu also contained in the Points Menu

Report Codes/Points - Option to Report Codes and Points from the current Coordinate file and/or Field Code Table

Help - accesses the Help Menu

Exit - exits the Field Code Table Editor

Coding Examples

Under the Carlson Projects folder, there is an example that shows the different ways for linework coding along with examples for many of the special codes. The examples are in **f2f_example.crd** and **f2f_example.fld**. To see this example, create a new drawing, set to the supplied coordinate file and process using the supplied field code table.

Here is a breakdown of the features that the points above illustrate.

Point 1: Point Entity by itself

Points 2-3: Using Begin code to start a line; end line using Begin code for next line

Points 4-5: Using Begin and End to start and stop linework

Point 6: Point Entity by itself after End code

Points 7-11: Linework by code defined as Polyline entity type; using End as break between linework

Points 12-15: Linework by code defined as Polyline entity type; using Begin as break between linework

Points 16-19: Linework by code defined as Polyline entity type; using # after code instead of Begin/End to separate linework

Points 20-22: Linework by code defined as Polyline entity type without using Begin/End to start/stop linework

Points 24-26: 3 point curve using on PC code

Points 27-30: 3+ point curve using PC/Point codes

Points 32-33: 2 point tangent curve using PC/Point codes

Points 35-39: reverse curve using PC/Point codes

Point 40: Regular point without extra description

Point 41: Using // to use a code description as a suffix

Point 42: Using \ to use a code description as a prefix

Point 43: Using / to append a description

Point 44: Using \ to add a description as a prefix

Point 45: Using ROT and a Point# to rotate to that Point#

Point 46: Using ROT and a value to set the rotation

Point 47: Using ROT by itself to rotate to the next Point#

Point 48: Regular point without rotation

Point 49: Using AZI and DIST codes to offset the point

Point 50: Using SZ with value to set size of symbol

Points 51-52: Using SZ by itself to size symbol by the distance to the next point

Point 53: Using SZ with 2 values to draw multiple symbols at those sizes

Points 54-55: Using 2ND code to size the symbol

Points 56-58: Using 2ND and 3RD codes to size the symbol in 2 dimensions

Points 59-62: Using CLO to close the linework

Points 63-64: Using RECT with two points and a value to create a rectangle

Points 65-67: Using RECT with three points to create a rectangle

Points 68-69: Using OH to offset right a fixed amount

Points 70-73: Using OH on multiple points to offset various amounts

Points 74-75: Using multiple OH on the same point to offset polyline multiple times

Points 76-77: Using OH with negative value for offset to left

Points 78-79: Using OFL with value for offset left a fixed amount

Points 80-81: Using OFB with value to offset both left and right a fixed amount

Point 82: Using CIR to draw circle at specified radius

Points 83-84: Using CIR to draw circle using two points for center and perimeter

Points 85-89: Using CIR to draw best-fit circle through points on perimeter

Points 90-91: Using JPN to join linework to another Point#

Points 92-95: Using SMO to create smoothed linework

Points 96-97: Using JOG to create additional linework segment extensions

Points 98-102: Using GAP to create a break in the linework

Points 103-106: Using LFT to switch linetype to left side

Points 107-109: Using WALL3D with specified height value

Points 110-112: Using WALL3D with height from 2nd point

Points 113-115: Using BLOCK3D with height and three points to define parallelogram

Points 116-123: Using BLOCK3D with height and multiple points to define perimeter

Points 124-128: Using FACE3D with multiple points to make a surface

Points 129-132: Using HOLE3D with multiple points to define the perimeter of a hole in the FACE3D surface

Point 133: Using code definition with Attribute Format set to Text and only Elevation turned on with Label Decimal

PointCAD Coding

Field-to-Finish supports an early Carlson style of linework coding called PointCAD. The PointCAD codes use numbers with +,-,* symbols as follows:

- +0 Starts a regular 2D line (not a polyline) that is open.
- *0 Starts a regular 2D line that is closed.
- +4 Starts a curved 2D polyline that is open.
- *4 Starts a curved 2D polyline that is closed.
- +1 Begins a 3-point arc.
- 0 or -1 or -3 or -4 or -5 or -6 or -7 Ends a line.
- +5 Starts a 3D polyline that is open.
- *5 Starts a 3D polyline that is closed.
- +6 Starts a 2D polyline that is open.
- *6 Starts a 2D polyline that is closed.
- +7 starts line whose type (2D line, 2D polyline, 3D polyline) is specified by the point's field code definition. If the field code definition is to use points, then a 2D line is started.
- +2 Middle point of 3 point arc
- 05 starts a curved 3D polyline section.
- 50 ends a curved 3D polyline section.
- +8 starts a 2D and 3D polyline combination that is open.
- *8 starts a 2D and 3D polyline combination that is closed.
- 8 ends a 2D and 3D polyline combination.
- 08 starts a 2D and 3D polyline combination curve that is open.
- 80 reverts back to a straight 2D and 3D polyline combination.

PointCAD linework coding examples

Menu Location: Survey

Keyboard Command: fld2fin

Prerequisite: A data file of points with descriptions

Deed Reader

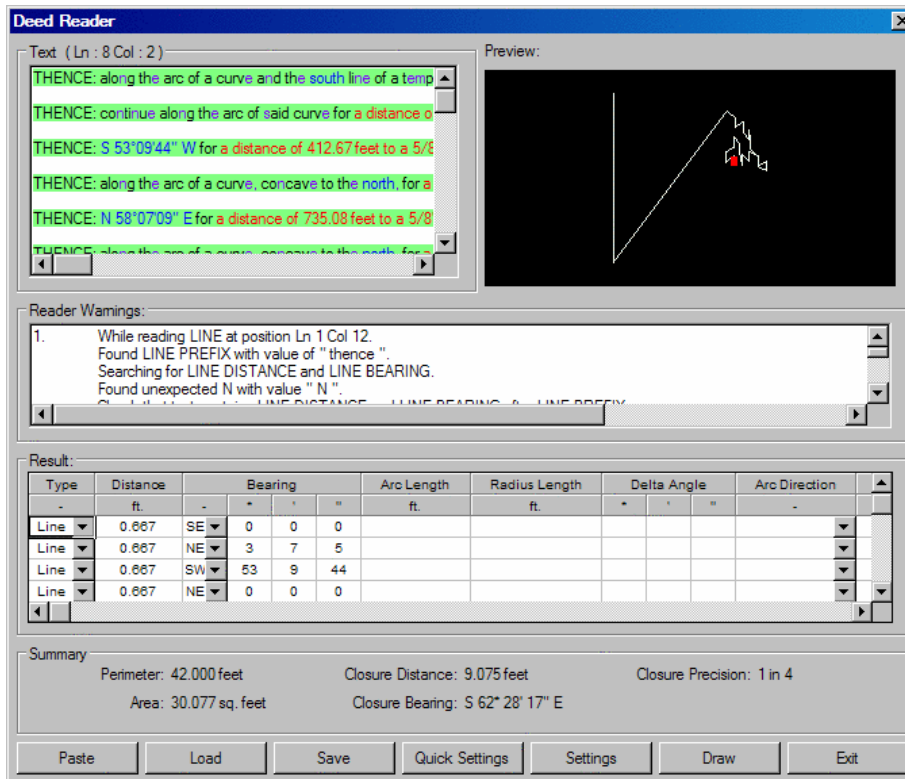

This command is used to extract deed line and curve data from the text of a deed. It shows the deed data in a spreadsheet and also graphically. The deed data can be saved to a deed file, drawn and reported. A blank Deed Reader dialog box appears as soon as the command is chosen.

The **Text** section is for entering in ASCII/TXT data for the deed. This can be accomplished by using the Paste button at the bottom of the dialog, or loading a filing using the Load button. You can also type information directly into this screen. **Reader Warnings** indicates irregularities in the deed text. The **Result** section is below that. This section will give you a detailed, editable spreadsheet of the deed, which can be saved. At the very bottom of the dialog is a section called **Summary**. Here is where you will see the mathematical and closure data for this deed displayed.

Paste: This is for pasting in copied information.

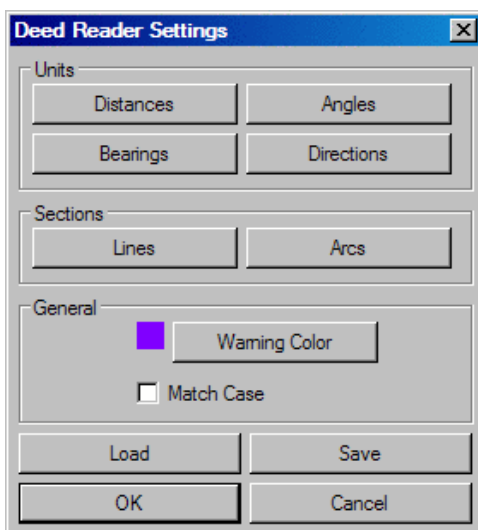

Load: This option will load an existing deed text (.TXT) file. Here is an example.

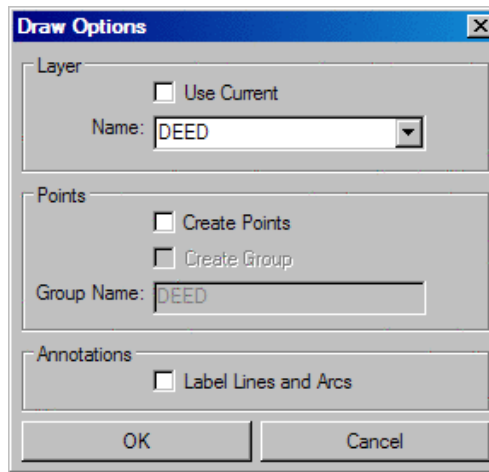

Quick Settings: This option allows you to set up, in a speedy fashion, the detailed criteria for this *Deed Reader* command.

Settings: A more formal settings feature, which is more methodical and dialog box driven.

Draw: This option will provides you choices as to how the date will be translated to the drawing screen.

It is in the Draw Options dialog that you can make decisions as to how detailed and involved your drawing will be. The Points section is key if you desire to have points created to a new coordinate file, or if you want to append an existing one. In the Annotations section, if Label Lines and Arcs is clicked on, the next dialog that you see, after choosing a point of origin, will be Auto-Annotate. Finally, click OK.

Prompts

Deed Reader dialog: *enter in or load the deed text*

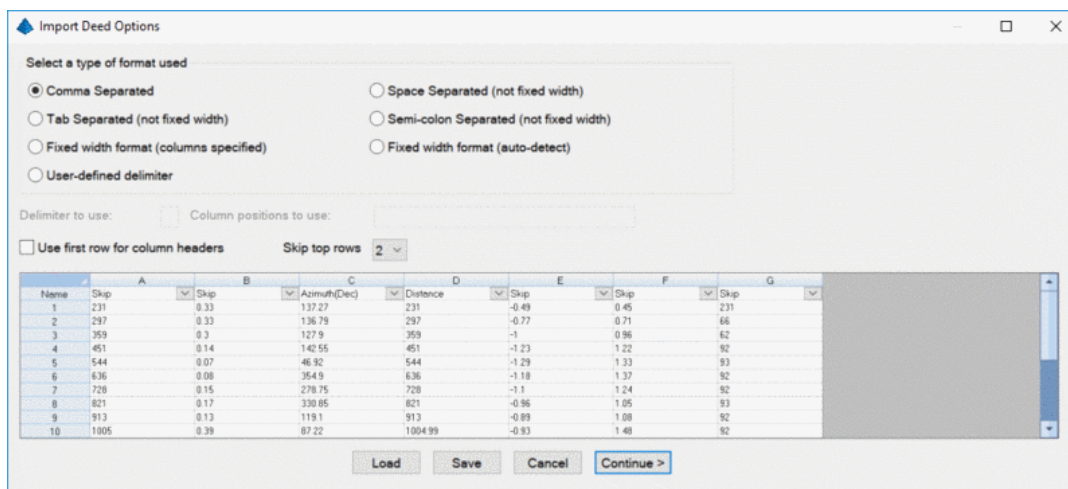

Pulldown Menu Location: Survey

Keyboard Command: read_legal

Prerequisite: Deed text

Import Angle/Distance File

This command creates a Deed File (PDD) using the angles and distances from a text file. The text file must have one set of angle and distance on each row with the values separated by a delimiter such as a comma. After selecting the data file to import and the deed file to output, the program has a dialog to define the format of the input file. Choose the file delimiter and select the columns for the Azimuth and Distance.

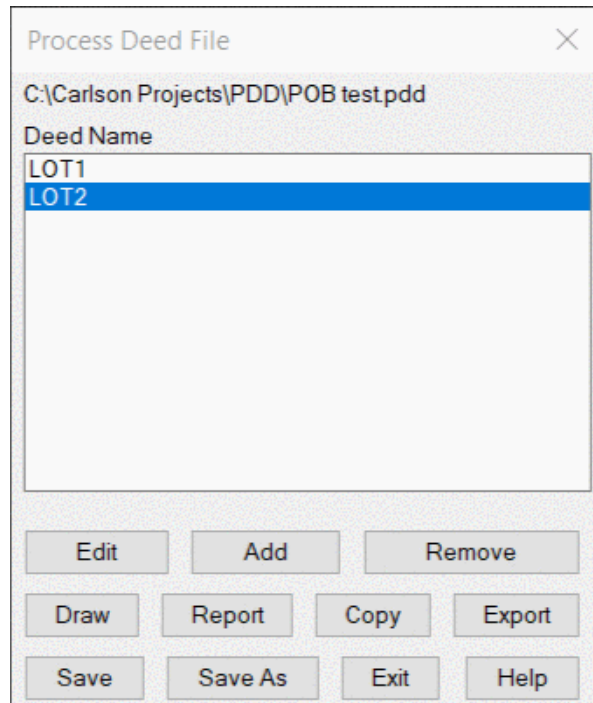

Pulldown Menu Location: Survey > Deed Tools

Keyboard Command: csv2pdd

Prerequisite: File to import

Process Deed File

This command contains several functions for deed (.PDD) files. A deed file consists of one or more deed descriptions. Each deed description includes a deed name, starting coordinate and line/curve data. This deed data can be created with the *Enter Deed Description* command. This command begins with the Process Deed File dialog.

Edit Opens the Edit Deed dialog where you can view or modify the deed name, starting coordinates, or line/curve data. Within this dialog the following commands are available.

Add Opens the Edit Deed dialog where you can add a new deed.

Remove Removes the currently highlighted deed.

Draw Draws the currently highlighted deed in the drawing and returns to the main dialog. The actual geometry will not appear in the drawing until you exit *Process Deed File*. There is an option to label the deed using the settings from the Annotate Defaults and Auto-Annotate commands.

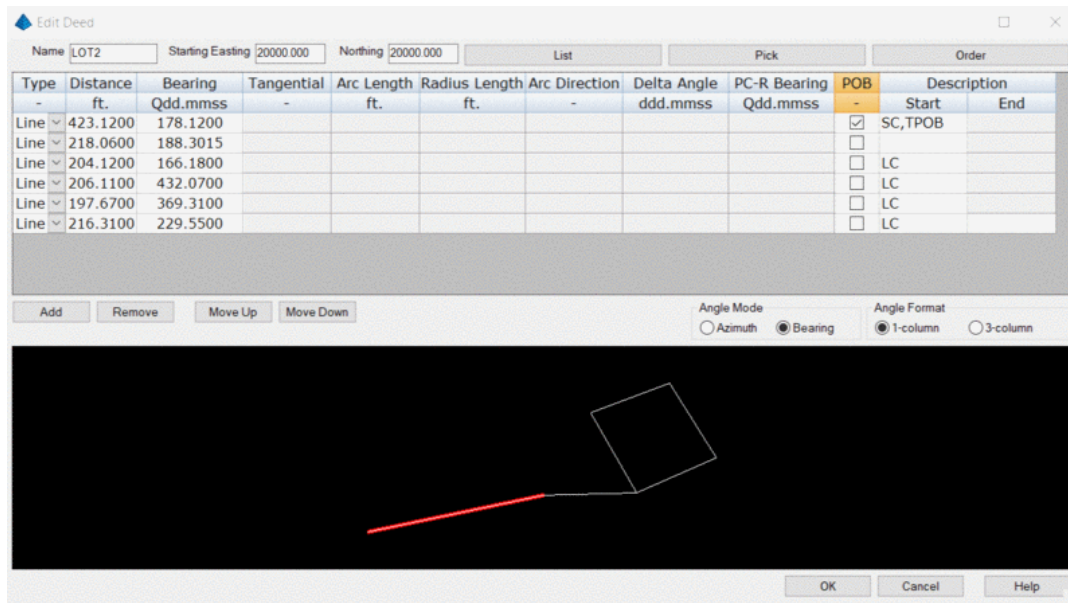

Report Generates a report for the currently highlighted deed. The report is displayed in the Standard Report Viewer unless Use Report Formatter is active which allows for customized reports and Excel output using the Report Formatter. For the Report Closure, the Start-End Coordinates option uses the difference between the POB (point of beginning) and the coordinates of the last call to calculate the closure error. The Angle-Distance Precision option determines the closure error by starting with the POB and calculating each point in the deed using the angle and distance values entered. Distance values are further affected by the precision in the report settings.

Copy Creates a new deed by copying the geometry of the highlighted deed.

Export Saves the selected deed data (.PDD) in raw file format (.RW5) that can be used with Edit-Process Raw File.

Save Saves the currently loaded deed (.PDD) file.

SaveAs Allows you to save the currently loaded deed (.PDD) file to another file name.

List Selects the starting coordinate from a point selection list from the current coordinate file.

Pick Allows you to screen pick the starting coordinate.

Order Allows you to set the sequence of the columns in the spreadsheet editor.

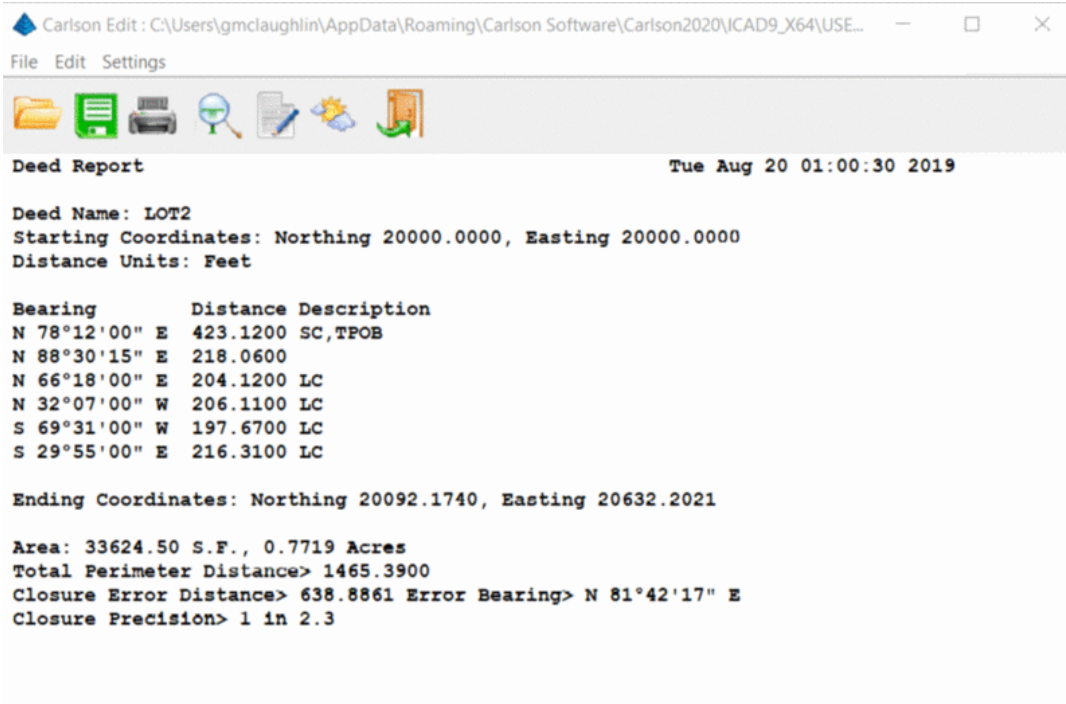

Add Allows you to add a new deed call (line or curve).

Remove Removes the highlighted deed call.

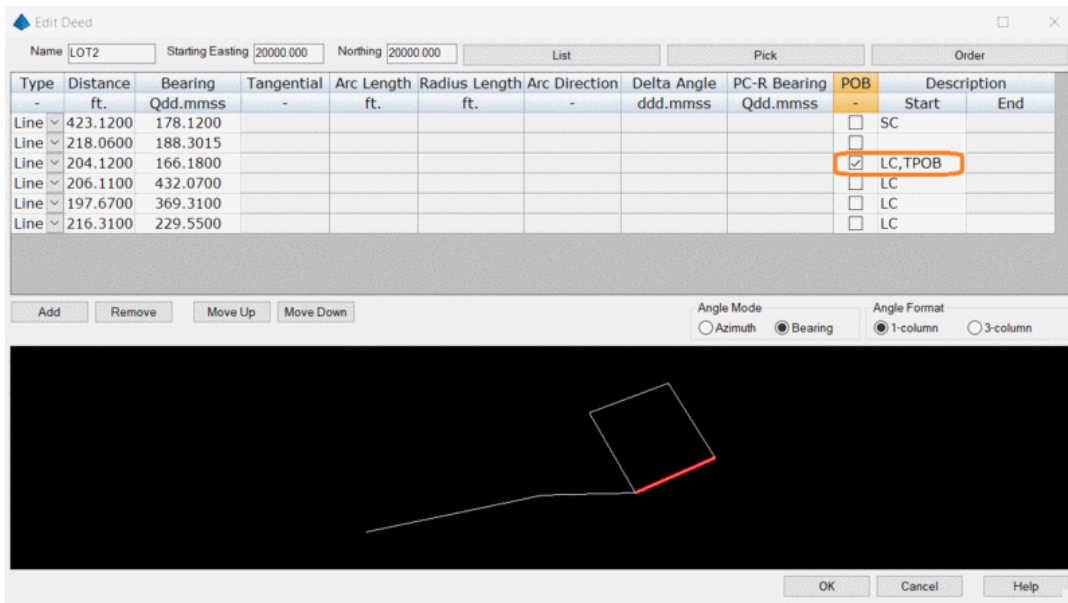

Move Up/Down Change the list order of the data records for the currently highlighted row.

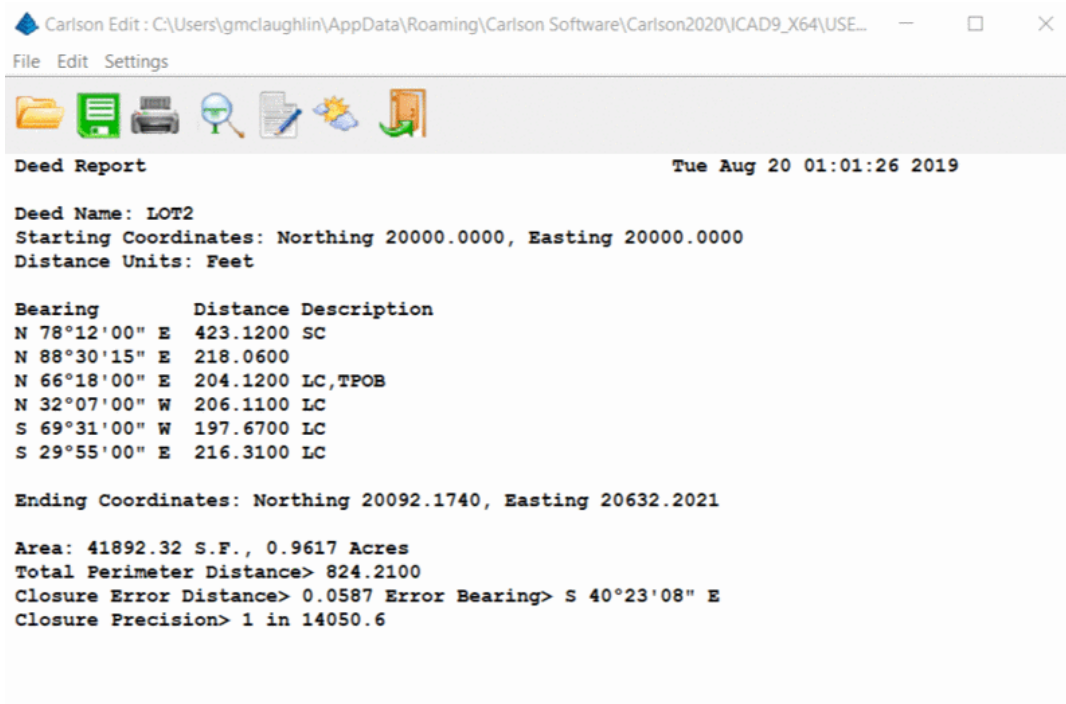

Angle Mode Choose between Azimuth or Bearing inputs.

Angle Format Choose between using one spreadsheet cell for the angle in dd.mmss format or using three cells with dd, mm and ss in separate cells for easier editing.

The POB location is variable on the deed. This means when entering or editing a deed, you may select any call in the deed to be the POB (Point of Beginning). The total perimeter, closure error and precision are determined from this point to the last call of the deed. Other calls leading up to the POB may be included in the deed as reference or commencement calls but not used in the closure calculations.

Pulldown Menu Location: Survey

Keyboard Command: deed

Prerequisite: none

Deed File By Interior Text

This command stores deed data to a deed file (.pdf) using linework boundaries around selected text of the deed names. You can create a single deed or process multiple deeds at once. From the selected linework, the program finds all the closed areas and then looks in the closed areas for text to use as the deed name. The deed boundaries can be defined by any combo of lines, arcs and polylines.

In the options dialog, the Clockwise Point Order option chooses between creating the deed points in clockwise or counter. The Combine Common Angles option will join sequential boundary line segments together that have the same angle.

Prompts

Deed File to Process dialog: choose .pdd file to save deed data

Deed File By Interior Text options dialog

Select deed linework and text.

Select objects: *pick the deed labels and surrounding linework*

Pull-down Menu Location: Survey > Deed Tools

Keyboard Command: txt2pdd

Prerequisite: Deed labels surrounded by linework

Deed Linework ID

This command is used to report the deed name associated with selected linework. Since the Carlson deed commands that draw deeds attach the deed name to the linework, this command will extract that information and list it out. You can choose to select more than one deed linework entity before ending out of the command.

Prompts

Select deed linework to identify: *select deed linework*

Deed Name: Out Lot3 - Carlson Property

Select deed linework to identify (Enter to end): *select Enter*

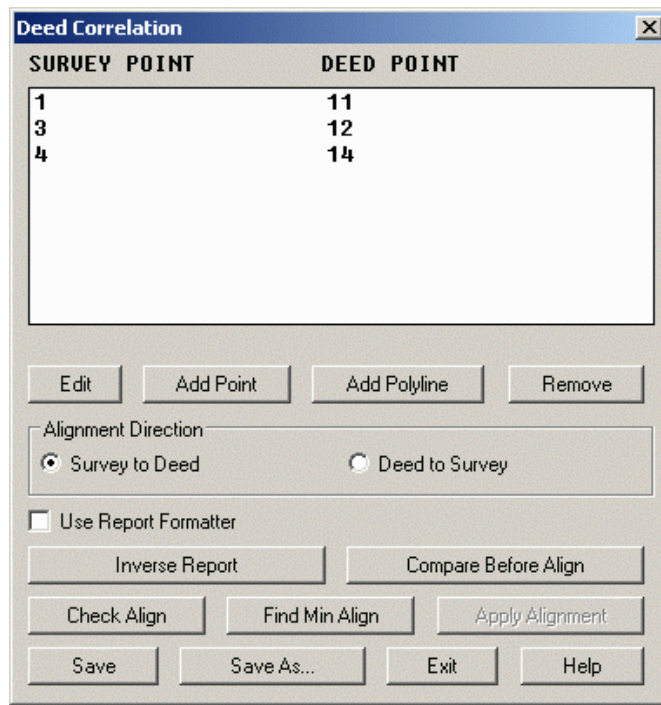

Pull-down Menu Location: Survey

Keyboard Command: deed_id

Prerequisite: A deed name assigned to the entity

Deed Correlation

This command takes a set of field and design/deed points and creates an inverse report, such as radial stakeout, for each pair of points. The Align functions combine a translation and rotation. The Alignment Direction settings controls whether to go from the survey points to the deed points, or vice versa. The command includes a routine to find the best point to hold and the best point to rotate to. This command provides tools for the correlation of surveyed points with that of deed input points. Different points can be specified as hold points, or rotation points, and provide a report showing the bearing and distance of all sides of the traverse/deed, based upon the hold and rotation points. This allows for the review of different scenarios based upon hold and rotation points. Perhaps two points in the field are in good shape, and seem to meet all the descriptions thereof. You decide to hold these two points as good, but you would like to see what holding these points will do to each side/call of the tract/description. This is what this routine is designed to do. In addition to allowing user specified trials of different hold and rotation points, the routine also provides a Find Minimum Rotation option that will report which points specified as the hold and rotation points will result in the minimum rotation of all sides of the tract/description. All points must be contained in the same coordinate file, and the points to be used in the correlation must be specified as either Survey points or Deed points. The Use Report Formatter option chooses between a fixed, automatic report, or a user-defined report format.

Edit: Edits the highlighted Survey and Deed point. Once selected the dialog above is displayed allowing for changes to be made.

Add Point: Click this button to specify the points as either Survey or Deed points. Then fill out the Edit Points dialog as desired or use the **Screen Pick** button to pick point entities in the drawing.

Add Polyline: This function prompts to select polylines for the survey and deed perimeters and uses the polyline vertices for the survey and deed points.

Remove: Removes the highlighted Survey and Deed points from the correlation setup. This does not delete the points from the coordinate file.

Inverse Report: This generates a report showing the inverse data from each point, both survey and deed, to every other point specified in the correlation set up. For example if there were four points in the survey points (1-4) then the report would show inverse data from 1 to 2, 3,4; from 2 to 1,3,4; from 3 to 1,2,4 and from 4 to 1,2,3. This would be the same for the corresponding deed points.

Compare Before Align: This option compares the survey information to the deed information.

Check Align: This option that allows for user specified hold and rotation points, and then reports the inverse data of each side of the tract/description. The hold point and rotation point must be points from the specified survey point group.

Find Min Align: Determines the hold and rotation points that would result in the minimum rotation to each side of the tract/description. When selected the Minimum Deed Rotation Report is displayed.

Apply Alignment: This option can be issued after the Min Align criteria is set.

Save: Saves the point list to the current dcf file.

Save As: This option prompts for a user specified file name and allows for a user specified location to save the file. The file extension for the deed correlation file is dcf. When executing the program you have the option of using an existing file or creating a new file for the deed correlation.

After specifying the hold and rotation points, the deed correlation report will display again, showing the bearing and distance of each side of the tract/description.

Legal Description Writer

The *Legal Description Writer* gives you the ability to create a detailed legal description from a polyline. This description consists of calculated calls, point descriptions from Carlson points, and numerous user defined terms. The programs values for these terms are easily replaced, and are stored as defaults with each use. When a scale factor is specified under Drawing Setup, the Legal Description distances will apply the scale factor which is a way to report grid distances from ground drawing coordinates or vice versa.

In addition to this command, you can also generate legal descriptions by point numbers with the Report function within the Lot File Manager command.

Legal Description Writer Dialog

This initial and primary dialog box is shown above, and described below.

Pick Boundary Polyline: This button is used to designate the polyline boundary used. The boundary should be a closed polyline. Tools are provided in the Edit menu if you need to reverse the polyline or change its origin point. You can also select multiple polylines to process at the same time by entering M for Multiple at the Select Boundary Polyline prompt in this routine.

Pick Inside Boundary: This button is another way to designate the polyline boundary. With this method, the boundary can be defined by multiple linework entities. You pick inside the boundary area and the program will figure the boundary perimeter from the surrounding linework. This method uses the same technique as the Draw->Boundary Polyline command. The boundary perimeter that the program finds is highlighted for visual confirmation.

Deed File: This method selects the deed to report from a deed file (.pdd).

Pick Reference Lines: Used to select lines that tie into the polyline boundary used for the legal description. These should be LINE objects that have one endpoint exactly the same as the beginning point of the boundary polyline. If a Carlson point exists at the end of the line away from the boundary, the routine will pick up its description, otherwise you will be prompted for the description. You can choose any number of reference lines, simply press enter to conclude the selection of reference lines.

Point Group: This method defines the perimeter by a series of points from a group defined by the Point Group Manager command. In Point Group Manager, a group can be defined as a point list including the ability to have radius points.

Header File: This button and edit field are used to designate the optional header text file. If a valid file is selected

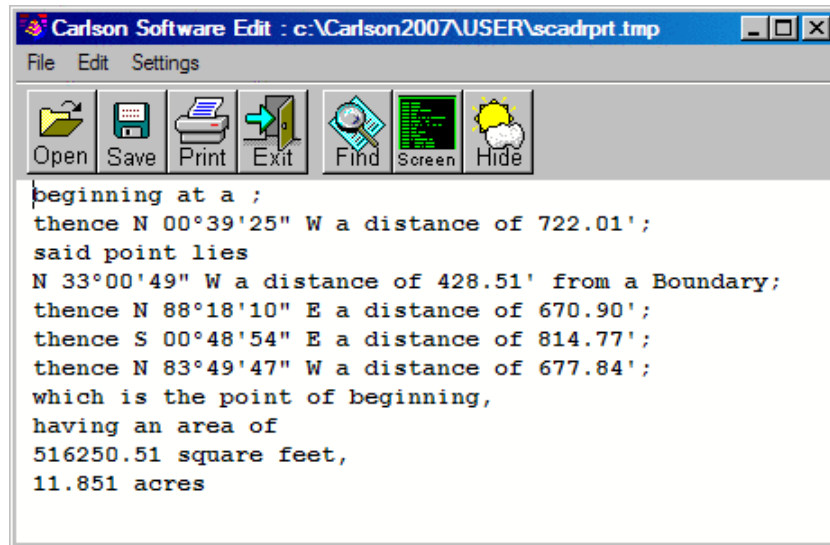

it will be written into the top of the output.

Footer File: This button and edit field are used to designate the optional footer text file. If a file is selected it will be written at the end of the output.

Centerline File: This allows you to set an optional reference centerline for reporting station/offset for each point in the boundary.

Output Options allows you to select where Legal Description Writer should send the output.

Report Viewer: The output is sent to the report viewer specified under Configure Carlson->General settings: Carlson Standard Report Viewer, Windows Notepad or Microsoft Word.

Text File: The output is sent to an external text file as designated in the output file section described below.

Mtext Object: This creates a mtext object in the current drawing. Upon choosing OK you will be prompted for a starting point (which is the upper left corner) and well as a second point that determines the width and angle. By default ortho is turned on for this second point. Press the F8 key to toggle its status.

Output File: This button and edit field are used to designate the necessary output text file. This file can then be brought into your word processor and finalized. Note that the appearance of the output file can be affected by the status of the 'Use Paragraph Format' toggle in the Legal Description's General settings.

Angle Specifications

This section is used to establish the appearance of the bearings that are output with the description, and allows detailed control over each aspect.

Angle Format: The Format chooses between Bearing, Azimuth, Decimal and Fraction. Designate the character or word used in each bearing direction. Standard values are the letters N, S, E, or W. One possible option is the entire words NORTH, SOUTH, EAST, and WEST. It is important to keep in mind that spaces are literal, meaning that if you don't have a literal space after N/S, and before E/W, a space will not be formatted into the bearing. To use Azimuth, place a check in the Use Azimuth box and the General Prefix will be set to AZ.

Cardinal Angles: For example bearings that are due NORTH, the default is to generate N 00_ 00' 00 E. If the Label Cardinal Angles toggle is turned on, the program will substitute the single word (which you can change) for the direction, these usually being NORTH, or DUE NORTH.

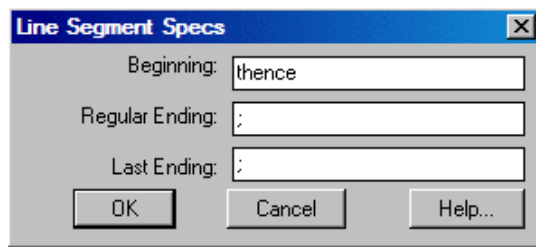

Interior/Exterior Angles: Controls whether to report the interior and exterior angles at corners.

Quad Directions: These names are used for the Concave Direction for curves and for the direction when using the Report Interior Angle option.

Symbols: This section allows you to designate the precision for bearings, as well as the symbols used. Turn on/off the toggles for degrees, minutes, and seconds to control the precision. For example, if you wish to round to the nearest minute, simply clear the toggle from the second field. For each field (degrees, minutes, seconds), you can supply the character or word to be used. You can quickly fill in these fields with the two buttons to the right.

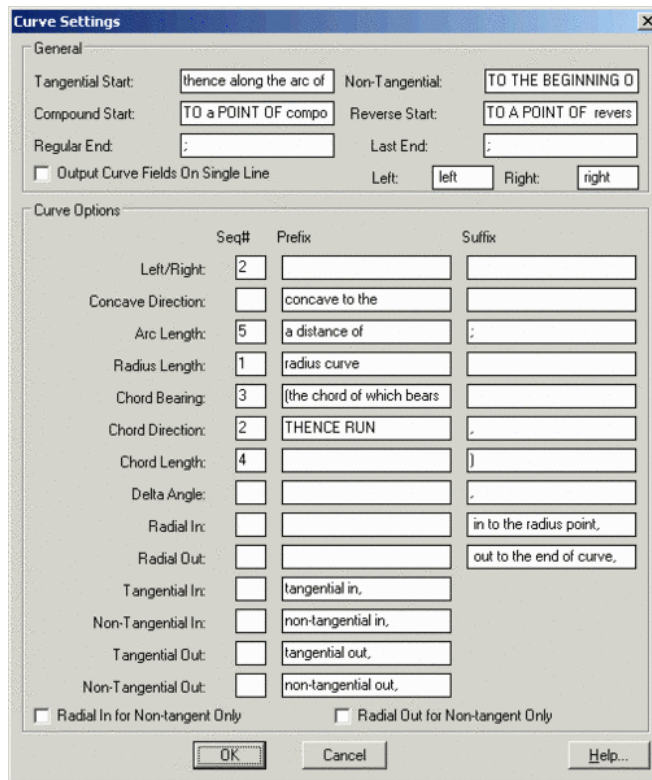

Line Segment Specifications

This section is used to establish the terms used when the course of a call is a line segment, as is often the case. Simply supply the beginning and ending terms for these line calls.

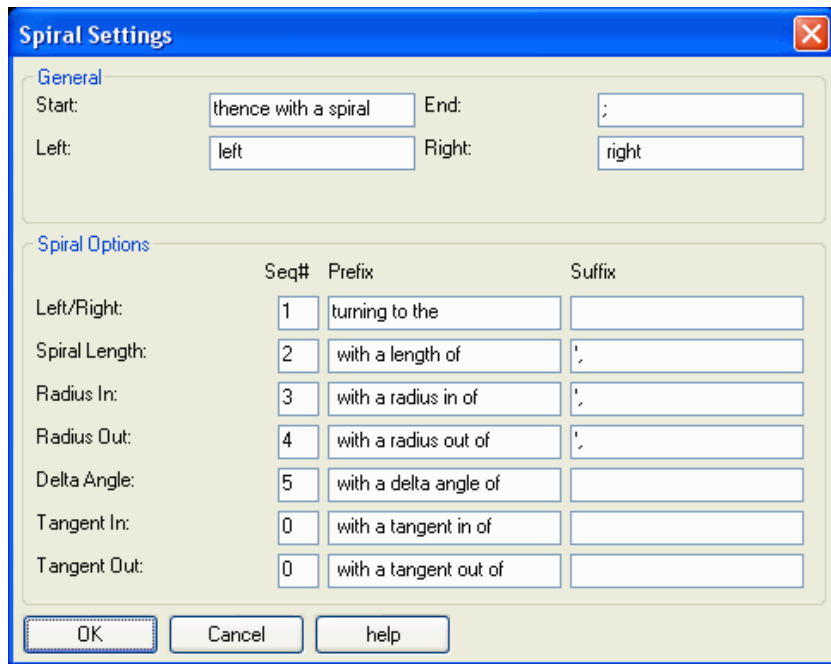

Curve Segment Specifications

This large dialog is used to establish the terms and options used when creating the course of a curve. Basic options include beginning and ending terms, as well as the words for left and right if chosen. In the large table of curve options, you can choose the items you wish to report, in the order you want them to appear. Simply place a number in the sequence field indicating the items you wish to report, making sure that there are no duplicate numbers. In the example below, the program would output the curve direction, arc length, radius length, chord bearing, and chord length, radius length, chord bearing, and chord length, and in that order. Each field can also have a unique prefix/suffix. There are four different possible phrases for the start of the curve description for whether the curve is tangential, non-tangential, compound or reverse. The Radial In/Out for Non-tangent Only option applies to the Radial In/Out fields and tell the program to only use these fields when the curve is non-tangent. Otherwise, these fields are always used when the Radial In/Out fields are in the sequence.

Spiral Specifications

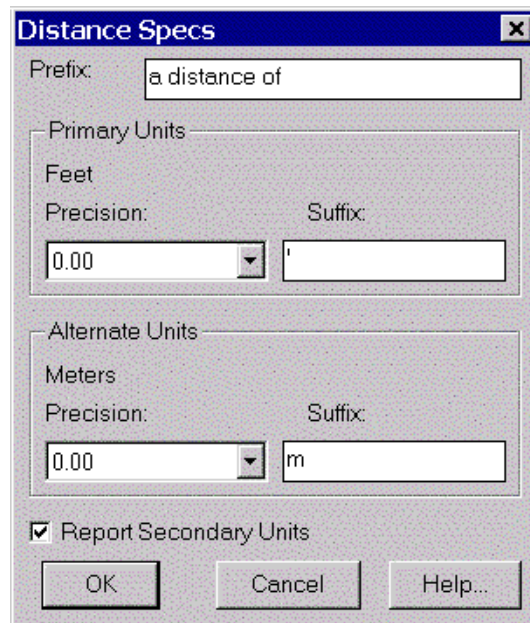

This dialog has the setting for reporting spiral portions of the boundary. In order to pick up the spiral, a centerline (.CL) containing the spiral must be drawn using the Draw Centerline File command. Then the program will pick up the spiral definition for any portion of the legal description boundary that follows the spiral on the centerline.

Distance Specifications

This dialog is used to establish the terms and precision used when creating a distance for the course of a call. The precision and suffix apply to curves as well. Simply choose the desired distance precision from the popdown, and supply the beginning and ending terms for the line calls.

Note the availability of dual distance reporting. If you would like to report dual distances such as feet/metric, turn on the toggle in the lower left corner of the dialog. Note that the primary units are the units set in the Settings menu, Drawing Setup. If you have English set as your units in Drawing Setup, then the alternate units will be metric. The opposite also applies. If your units in Drawing Setup is set to metric, then the alternate units will be English.

Point Specifications

In the process of following the polyline definition for a boundary, the legal description writer can look for descriptions of the points at the endpoints of the polyline. These can be extracted by setting the data source to the corresponding point from the coordinate (.CRD) file, meaning the points do not have to be plotted on the screen. A second option is point block, in which the program will read the information from the drawing, and not require the presence of a coordinate (.CRD) file.

Besides point descriptions, you can also report the point coordinates.

Prefix: General term applied before the actual description.

Suffix: General term applied after the actual description.

Unknown: The text designated here will be placed in the description if the program does not find a valid description at that coordinate location. The words 'Unknown Point' may be used.

Tolerance: The point must be within this distance of the polyline vertex to use the description.

Report Coordinates: Choose whether to report coordinates and the order for the northing and easting.

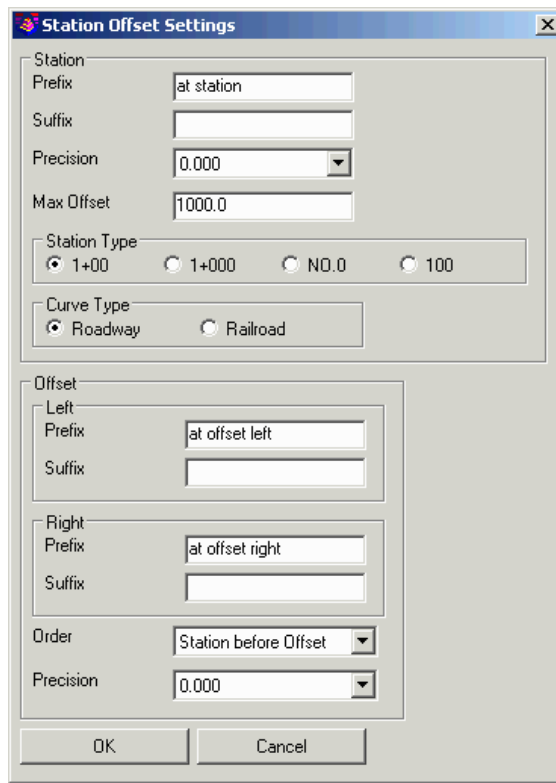

Northing Prefix/Suffix: Strings to report before and after each northing value.

Easting Prefix/Suffix: Strings to report before and after each easting value.

Precision: Number of decimals for the northing and easting values.

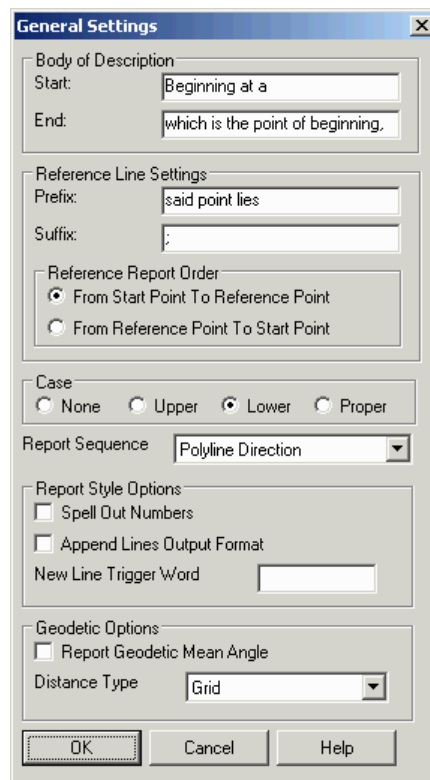

Station/Offset Specifications

When using a reference centerline file, the report will include the station and offset for each of the points in the boundary. The settings in this dialog control the format of these values. The program will skip reporting the station/offset for points with an offset more than the specified **Max Offset**.

General Specifications

This dialog controls general specifications which can affect the entire description. Each group of items are explained in detail below.

Body of Description: Enter the beginning and ending terms for the description.

String Case: Choose the button corresponding to the string case conversion desired. If you want no changes made, choose none. Choosing upper, lower, or proper case conversion will affect the case of all text throughout the description, except bearing letters.

Report Sequence: This option controls the sequence to report the boundary segments either in the direction of the polyline, clockwise or counter-clockwise.

Spell Out Numbers: This option writes numbers as words instead of digits. For example, a distance of 123 would be written as one hundred twenty three.

Append Lines Output Format: If this toggle is on, the program will output the description without carriage returns after each line. This approach makes a nice paragraph style when brought into a word processor with word wrap. If the toggle is cleared, the program will place carriage returns at the end of each call.

Geodetic Options: In order to use these options, the grid projection for the drawing must be set using the Settings > Drawing Setup command. The **Report Geodetic Mean Angle** option reports the geodetic mean angle which is the average of the geodetic bearings at the two point instead of reporting the direct coordinate bearing between two points. **Distance Type** controls whether to report grid distances or geodetic distances at zero or mean elevation.

Report Course Numbers adds a number that increments for each course in the legal description. There are settings for the Prefix and Suffix for this number.

Area Specifications

The legal description writer can output several types of areas. Basic options include beginning and ending terms. In the large table of area options, you can choose the items you wish to report, in the order you want them to appear. Simply place a number in the sequence field indicating the items you wish to report, making sure that there are no duplicate numbers. You can edit the prefix/suffix for each and control decimal precision of each field output. For geodetic areas, the grid projection needs to be defined in the Settings > Drawing Setup command.

	Seq#	Prefix	Suffix	Precision
Sq. Feet	1		Square Feet.	0.0
Sq. Yards	0		Square Yards	0.00
Sq. Miles	0		Square Miles	0.000
Acres	2		Acres	0.000
Sq. Meters	0		Square Meters	0.0
Sq. Kilo	0		Square KM	0.00
Cuerdas	0		Cuerdas	0.00
Hectares	0		Hectares	0.00
Geodetic Sq. Feet	0		Geodetic Sq. Feet	0.0
Geodetic Sq. Meters	0		Geodetic Sq. Mete	0.0
Geodetic Acres	0		Geodetic Sq. Acre	0.00

Reset: This option will reset all settings to their original default values.

Save: This option saves the legal description settings to a file. The file will be saved with an extension of (LGL).

Load: This option loads previously saved legal description (*.LGL) files.

Pulldown Menu Location: Survey

Keyboard Command: legal

Prerequisite: Polyline boundary

Closure by Point Numbers

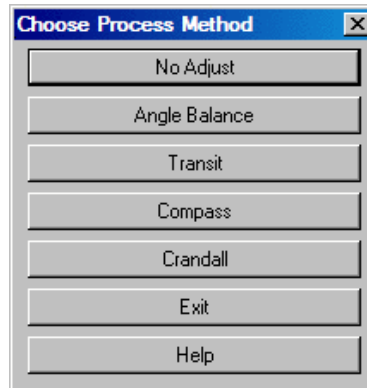

This command allows for traverse entry by point numbers, reports the closure and supports traverse adjustments. Using an existing coordinate file, the traverse is defined by a series of point numbers. The angle and distance for each traverse segment is calculated using the coordinates of the points. The traverse can be processed using all adjustment routines. Refer to the *Edit-Process Raw Data File* command for more detail on adjustment procedures. After selecting *Closure By Point Numbers* from the Survey menu, the Closure By Point Numbers dialog will appear.

Point#	North	East	Elevation	Desc
1	5000.000	5000.000	0.000	
2	4950.156	4692.914	2.716	XCUT
3	4783.049	4713.613	-1.716	XCUT
4	4851.222	5281.506	11.852	MNSET
5	5155.546	5239.733	8.928	MN-SET
6	5126.433	4999.524	7.655	MN-6
7	5000.056	4999.506	3.414	MN-1

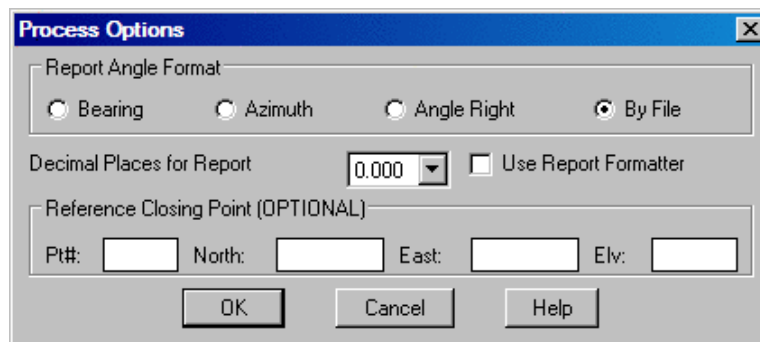

Point Number(s)

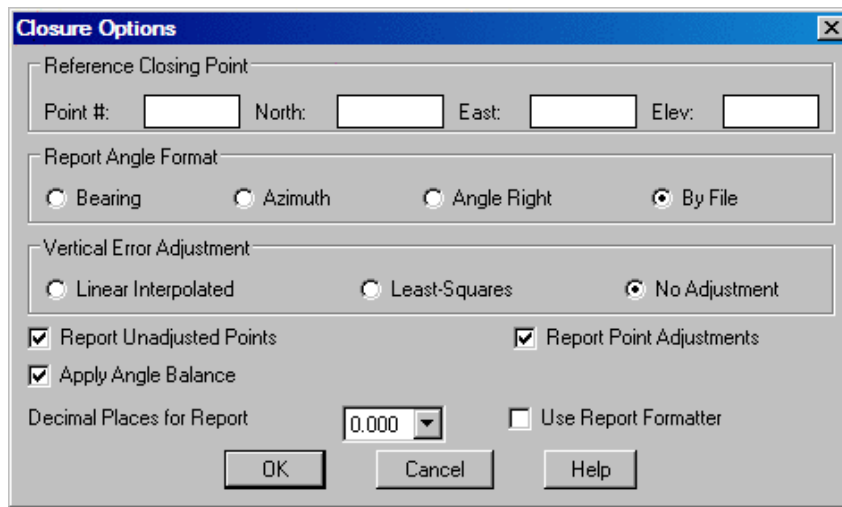

In this dialog shown above, add the point numbers that make up the traverse. This can be done by entering the point number, a range of points, or a point group into the Point Number(s) field. You can also choose points from a list by clicking the List button. Once each point, or group of points, is entered, click the Add button. Continue in this fashion until all of the point numbers are entered in. Clicking the Process button will display the Choose Process Method dialog. Choose the desired process method.

After selecting the process method for any of the adjustment methods, the dialogs and prompts will follow. They all start out with an "options" dialog box. These dialogs are titled either Process Options or Closure Options, depending on which process method you chose. The prompts that follow for any of the methods are subset of, and are very similar to, the prompting found in the *Edit-Process Raw Data File* command. After you have made your selections within these dialog boxes, click OK.

When you choose No Adjust of Angle Balance

When you choose Transit, Compass or Crandall

Each of the process methods will display a report that details the closure before the adjustment, and after the adjustment. Options to save and print this report are available. After a review of the report, pressing Exit will remove the report from the screen. At this point a Process Results dialog, prompting whether to Update points in CRD file with adjusted coordinates, will appear. If you choose Yes, the active coordinate (.CRD) file will be updated with the adjusted coordinates. Choosing No will leave the active coordinate (.CRD) file in its existing state, with the coordinates unchanged. It is important to remember that the starting and ending point in this routine must be a different point number. For example, if the traverse starts at point 1 and ends at point 1, then another point number should be used for the tie in shot to point 1. This logic is different in *Edit-Process Raw Data File*, where the starting and ending point can be the same point number.

Pulldown Menu Location: Survey

Keyboard Command: ptrawedit

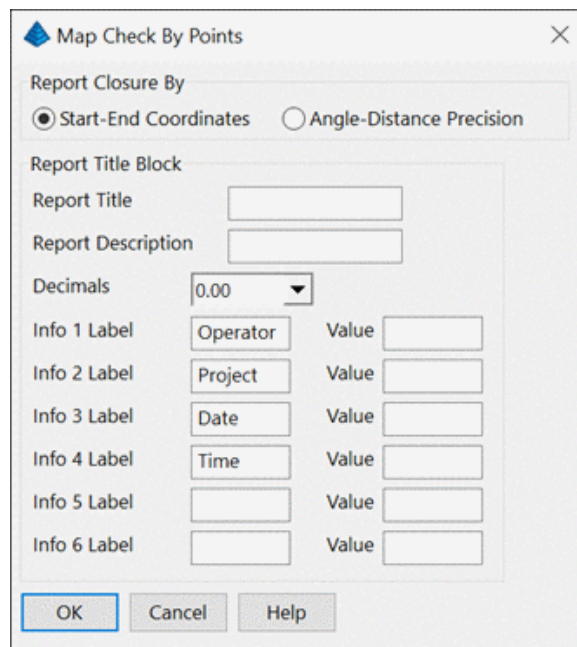

Prerequisite: Coordinate (.CRD) file

Map Check by Pnts

This command allows you to check the closure of a figure and produce a report. The points used for the map check should already be stored in a coordinate (.CRD) file, by using commands such as *Traverse*, *Locate by Bearing*, *Curves* menu, *Locate by Angle* – or perhaps a file from an electronic data collector.

In the dialog, you can set the labels for the report and the closure method.

Report Closure By: For the Start/End Coordinates method, the closure error distance is the distance between the start and end points which is 0 (perfect closure) if starting and ending at the same point number. For the Angle/Distance Precision method, the actual bearings and distances in the report are used, and the rounding used in the report will result in small closure errors.

Mapcheck by Screen Entities

This command allows you to check the closure of a figure, and produce a report from the Distance and Bearing labels in the drawing. The command works by prompting for a polyline and a sample of the text labels. Then the program looks for text on the sample layer and matches the text labels to the polyline segments. The text to process can be selected manually or automatically using an offset factor from the polyline. In addition to labels along the polyline, line or curve tables can also be used when the table are created using the Table Entity method in Table Defaults. The *Deed Reader* command is used here also, for extracting the deed line and curve data from the text of the deed. This polyline can be an open polyline in which case it's like doing an open traverse. The closure is based on the length of the polyline compared to the difference between the ending coordinate of the polyline and the ending coordinate from the label angles and distances. The deed data can then optionally be saved to deed file.

The report includes the line and curve data for every segment along with the starting and ending coordinates, the area and the closure. The format for the area values is set by the Area Defaults command.

Prompts

Select linework to process: *select polyline for the figure*

Select sample text: *select a label*

Keyboard Command: textdeed

Prerequisite: Distance and Bearing labels

Cut Sheet

This command creates a report of the horizontal distance and elevation difference between points and a design. The design elevation can be defined by a grid file, triangulation file, 3D polyline, section file, note file, road template file, runway airway clearance or design points. The station and offset of the points can also be reported when a centerline is applied.

The data for the cut sheet is shown in a spreadsheet. You can edit or enter data in all the fields except for the Cut/Fill and Hz Error fields which are calculated. The cut sheet data can be saved and loaded with a .CUT file. The functions for processing the data are in the pull-down menus. Here's an outline of a typical workflow:

1. Import the survey data using Import > Points, or Import > SurvCE.
2. Assign the target design elevation using a method from the Grade menu.
3. If station-offset are needed, use a method from the Centerline menu.
4. Run Report > Create Report.

5. Run File > SaveAs to save the cut sheet data.

Point#	Description	Survey Z	Design Z	Cut/Fill	Station	Offset	Comment	Ht Error	Survey Northing	Survey Easting	Design Northing	Design Easting	Design PII

File > Open: Loads data from a .CUT file.

File > New: Clears the spreadsheet.

File > Save: Saves the spreadsheet data and report format settings to the current .CUT file.

File > SaveAs: Prompts for a .CUT file and saves the data.

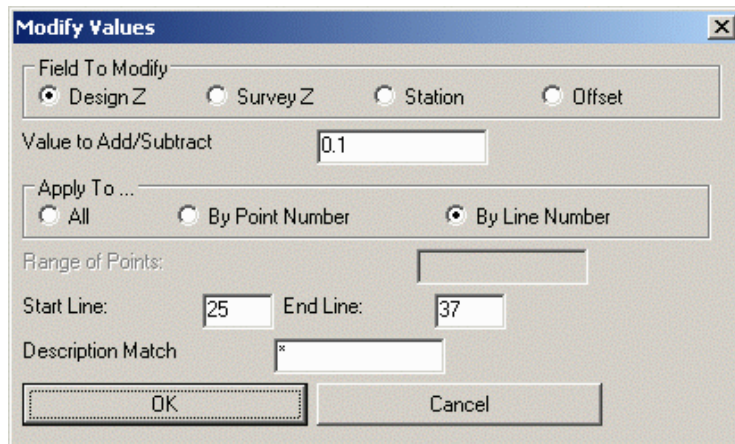

File > Exit: Quits the program.

Edit > Undo: To under the last edit in the spreadsheet.

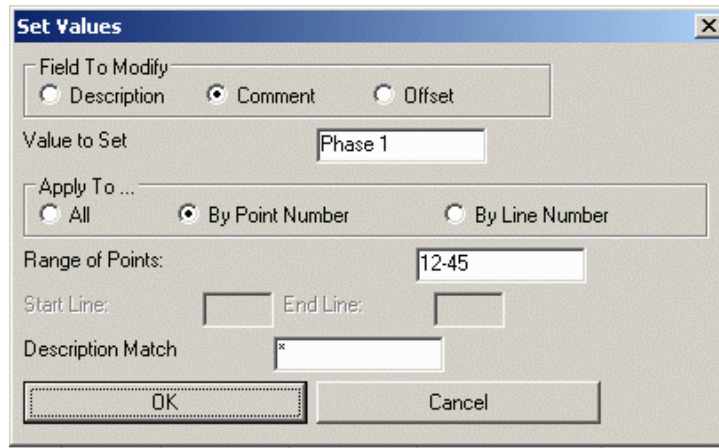

Edit > Delete Row: Deletes the currently highlighted spreadsheet row. You can also use the Delete key to delete the current row.

Edit > Insert Row: Inserts a new row above the current row. You can also use the down arrow key from the last row to add rows to the bottom of the spreadsheet, and use the Insert key to add a row above the current row.

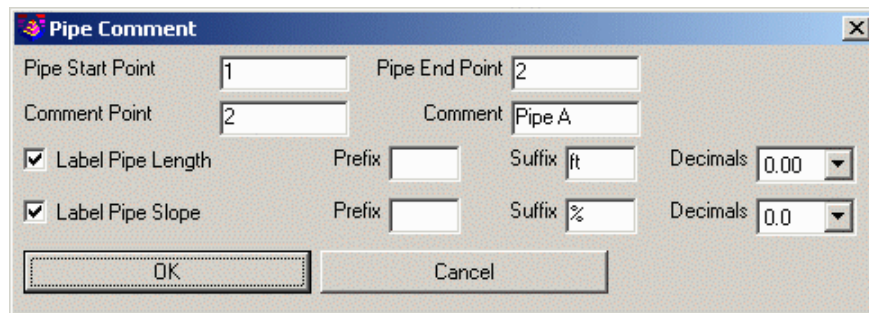

Edit > Modify Values: Changes values in the spreadsheet for the elevation, station or offset. In the dialog, set the amount to add or subtract (use negative value to subtract) and set which field to modify. There are controls for whether to update all the values or by point number range or by line number range. The Description Match is a way to filter which values to update.

Edit > Set Values: Sets values in the spreadsheet for the description, comment or offset field. In the dialog, choose the field to set, the value and which rows to set.

Edit > Set Pipe Command: This function fills in a Comment record of length and slope (ie "81.00ft - 15" RCP @ 2.4%") using the distance and slope between two points. The two points to use and the formatting options are set in this dialog.

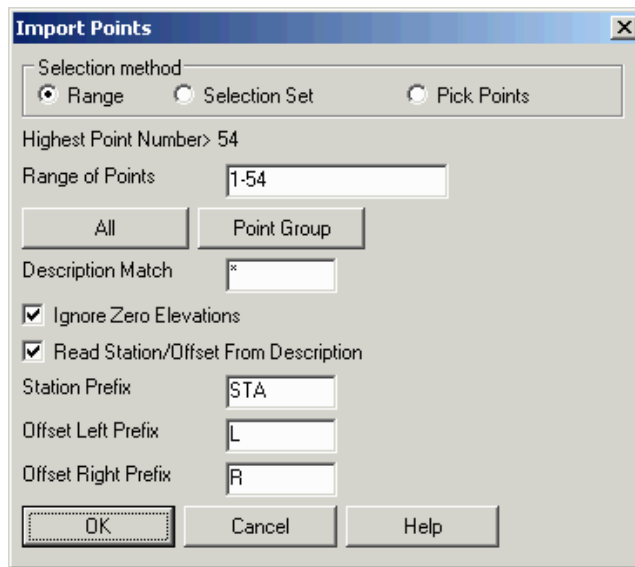

Edit > Cut: Blanks out the data for the currently highlighted cells and puts this data into the Windows clipboard.

Edit > Copy: Copies the data for the currently highlighted cells into the Windows clipboard.

Edit > Paste: Puts data from the Windows clipboard into the spreadsheet starting at the currently highlighted cell.

Import > Coordinate File: Imports survey data from a coordinate file for the Point#, Northing, Easting, Survey Z and Description fields of the spreadsheet. This function first prompts for the coordinate file to import. Then there is a dialog to choose whether to select the points by point number range, by selecting point entities from the drawing, or by screen picking points. The Description Match and Ignore Zero Elevations are options for filtering out points.

Besides reading the coordinate data, this import function can also read station/offset data from the point descriptions by looking for values after the prefixes defined in this dialog.

Import > Point Text File: This method is similar to Import by Coordinate File except a text file is used instead of a CRD file. The text file should have one point per row with fields for the northing, easting, elevation, description and point number.

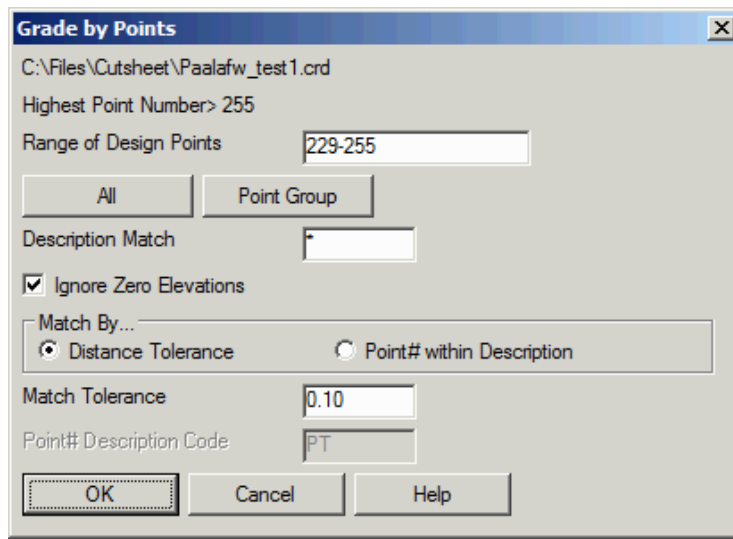

Import > Note File: This method reads the survey data along with the grade elevation from the note (.NOT) file that is associated with a coordinate file. For example, if the coordinate (.CRD) file is job3.crd then the note file name is job3.not. In Carlson Software's data collection programs (SurvCE and Field), there is an option to store stakeout data to the note file under the Stakeout options. When storing a point in the stakeout routines (using SurvCE or Field), the target point number, coordinates and elevation can be stored to the note file. This results with the as-staked coordinate stored in the coordinate (.CRD) file and the target coordinate stored in the associated note file. The Cut Sheet report can display this stakeout data using the Stakeout Point Comparison report option. The horizontal difference between the staked point and the target point can be reported in Bearing-Distance, Delta X-Y or North-South-East-West format. Also, in SurvCE and Field, the elevation difference routines can record the design grade elevation and station-offset to the note file when a point is stored to the coordinate (.CRD) file. This grade data can be reported using the Grade Elevation Report option. The note file records that the Cut Sheet report uses are TARGET_X, TARGET_Y, TARGET_Z, TARGET_DESC, TARGET_PT, STATION, OFFSET, VOFF1 and VOFF2.

Import > RW5 File: This method imports cut sheet data from a RW5 file of measurement data created by SurvCE. The stakeout functions in SurvCE store all the data needed to fill out the whole cut sheet including the survey data, design data and station-offset.

Import > SurvCE Cut Sheet: Imports data from a SurvCE Cut Sheet file (.CSV or .TXT). The setup for these cut sheet files in SurvCE is under File > Job Settings > Stake > Cut Sheets.

Import > TDS Raw: Imports data from a TDS RAW or RW5 file by reading the TDS stakeout records.

Grade > Points: The reference points to compare can be in the same coordinate file or a separate file. The reference/design points need to be matched with the survey points. The Match By Distance Tolerance method matches the design point that is closest to the survey point and within the specified Match Tolerance. The Point# Within Description method looks for the specified Point# Description Code in the descriptions of the design points and gets the survey point number from the suffix of the description code. When the Point# Description Code is found, the number after this code is used as the point# to match from the other file. For example, if description code is "PT" and the description for point# 101 in the first coordinate file is "CURB PT303", then point# 303 from the second coordinate file is used for the match. For the separate file option, there is a third method to match points between the files which is to use point numbers to match points between the files. The Match By Manually method has a dialog for picking pairs of point numbers for the survey and design to add. The list of available survey points to match with comes from points in the spreadsheet that have Point#, Survey Northing and Survey Easting but not the design data.

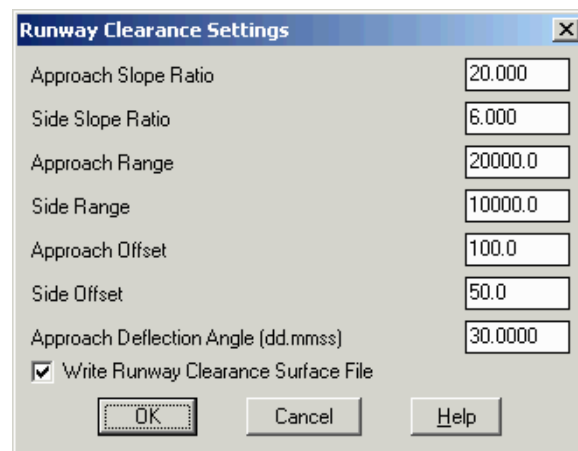

Grade > Triangulation File: the design elevation is determined by the elevation of the triangulation surface at each point.

Grade > Grid File: the design elevation is determined by the elevation of the grid surface at each point.

Grade > 3D Polyline: When using a **3D Polyline** for the grade elevation, the program calculates the elevation along the 3D polyline at the position perpendicular from the point selected. This calculated elevation is then compared to the point(s) selected to determine the cut/fill values.

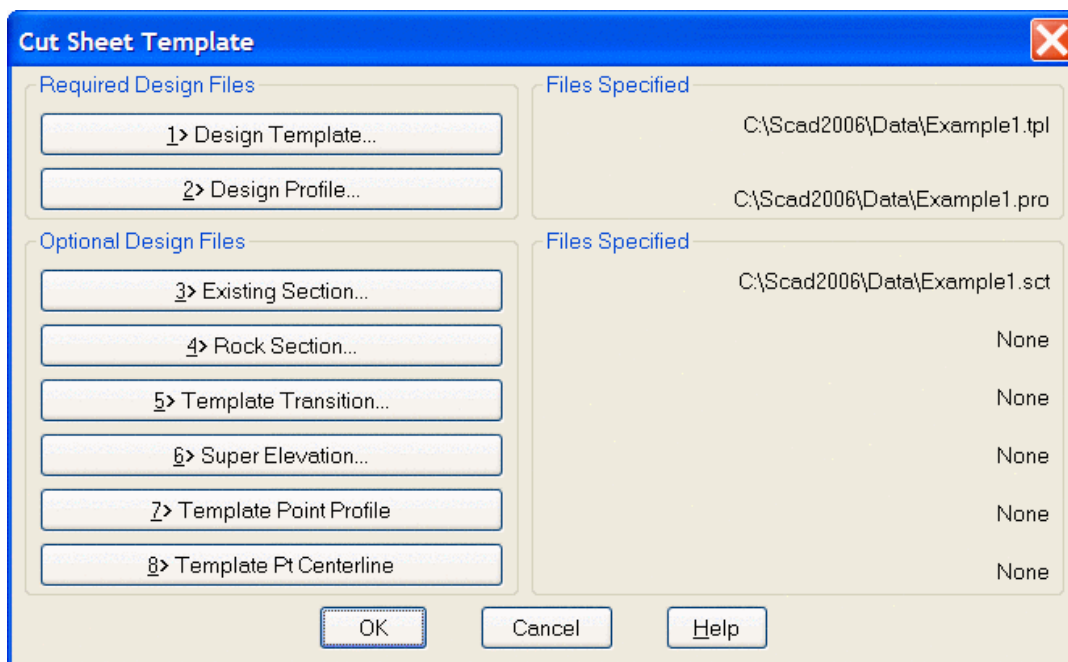

Grade > Cross Sections: With **Section Files**, the grade elevation is interpolated from the offset-elevation data in the section file based on the station-offset of the point along the centerline. When using this method, a centerline file (*.cl) must be specified for station-offset data.

Grade > Runway Clearance: This option defines the target surface as the airway clearance around a runway. This method is for clearance reports for tree and building tops by comparing points to this runway clearance surface. The runway surface is built from a 3D perimeter polyline of the runway along with slopes for the approach lanes and runway sides. The runway sides are offset level from the runway perimeter for the specified distances before starting the slopes. The parameters for the runway are defined in the dialog and illustrated in the graphic shown here. The Write Runway Clearance Surface File creates a triangulation surface file that you can draw or inspect for verification of a correct target surface.

Grade > Road Design: This option defines the grade elevation using road design files. For each point, the program finds the station-offset for the point along the centerline and then applies the road design at that station to determine the grade elevation. **Grade to Process** is used to define the surface to use for the cut sheet comparison. These grades are defined as Top Surface, usually final grade, or subgrades and correspond to the defined grades and subgrades within a template file. The required design files include a centerline (.CL) file, a template (.TPL) file, and a profile (.PRO) file. There are also several optional design files such as Superelevation, Template Point Profile and Template Point Centerline. The design files are created in the Civil Design module. Using the design files in *Cut Sheet* is similar to the *Process Road Design* command.

Centerline > Centerline File: This function assigns the Station and Offset fields in the spreadsheet by prompting for a centerline file (.CL) and locating each point along the alignment.

Centerline > Polyline: This function assigns the Station and Offset fields in the spreadsheet by picking a polyline, entering the starting station, and locating each point along the alignment.

Centerline > Points: This method defines the alignment by entering two points to define a line.

Report > Create Report: This function display a report of the cut sheet data using the current report settings. When Use Report Formatter is off, the report is shown directly in the standard viewer. Otherwise, the Report Formatter dialog is shown for customizing the report and outputting to different formats such as Excel.

Report > Report Settings: There are several settings for the report including decimal precision, prefix for cut and fill and distance units. For the Horizontal and Vertical Tolerance, the report highlights any points that exceed these tolerances. The **Distance Format** chooses between Angle-Distance, Delta X/Y, and North-South-East-West deltas. The **Cut/Fill Direction** chooses whether to report cut/fill as Survey relative to Design or vice versa.

The **Report Zero Elevations** option controls whether to skip or report points with zero elevation.

The **Report Statistics** option reports the min, max, average and standard deviations of the deltas at the bottom of the report.

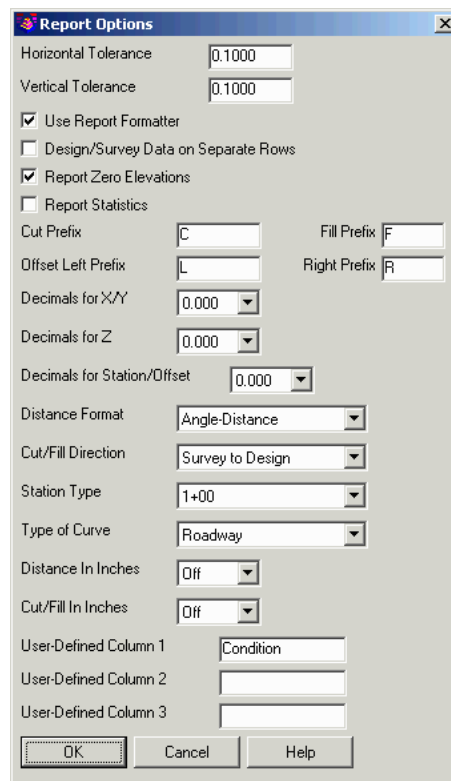

The **Design/Survey Data on Separate Rows** option creates two rows in the report for each record with the Design coordinate on one row and the deltas on the second row as shown here.

```
Point# Northing Easting Elevation Description Comment
229 499.997 1000.001 3.027
201 -0.005 -0.002 0.004 A

230 507.120 1000.158 2.929
202 -0.006 -0.003 0.001 B

231 515.694 1000.304 2.875
203 -0.005 -0.006 0.002
```

There are options for up to three **User-Defined Columns** which add extra fields to the spreadsheet and report.

Draw > Draw Labels: This function uses the cut sheet data and draw settings to create labels in the drawing.

Draw > Label Settings: There are three types of labels to draw. The Mark Points Outside Tolerance draws a symbol at each point that exceeds the tolerances setup in Report Settings. The Colors Labels Outside Tolerance sets the color for points outside the tolerance. Otherwise these points are labeled using BYLAYER for the color.

The Draw Delta Symbol has three styles. The DX/DY style draws a symbol to show the direction of the delta X and delta Y along with the values. The deltas are due north-south and due east-west. The Rotate Deltas By

Centerline style draws the same DX/DY symbol but this style prompts for a centerline to align the deltas. The Delta Distance style draws an arrow from the design towards the survey point.

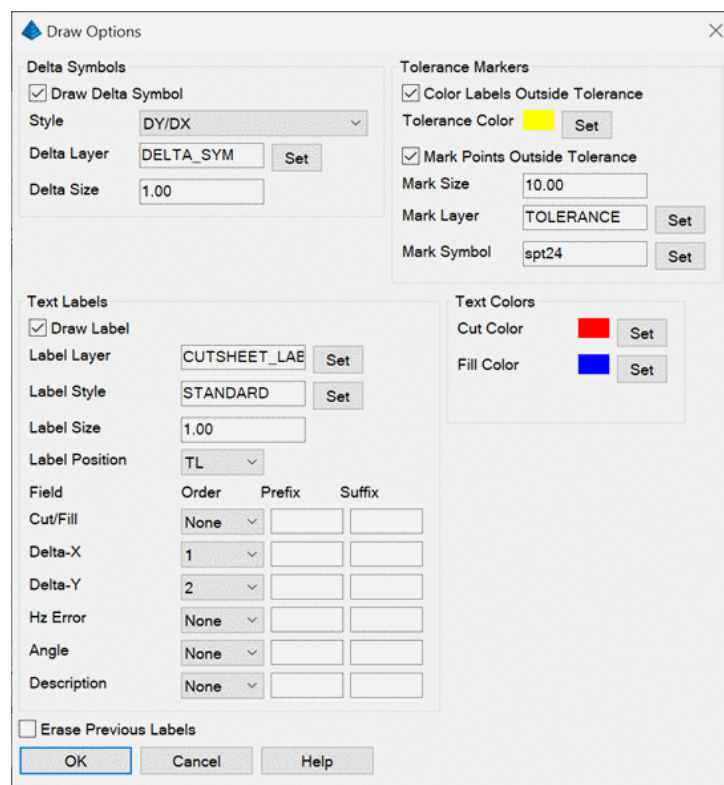

DX/DY symbol style

Delta Distance symbol style with Hz Error text label

The Text Labels creates text labels for cut/fill, delta-x, delta-y, horizontal distance error or description. There are settings for the sequence order, prefix, suffix, layer, style, color, size and position.

View > Zoom Plan View: This function zoom centers the drawing on the currently highlighted point.

View > Profile: Creates profiles connecting the survey and design points. The profiles are shown in a graphic preview dialog which has functions to save the profiles to .PRO files.

View > Hide By Point Numbers: This function is a way to filter the spreadsheet by point numbers. The function prompts for a range of point numbers and then only displays those points in the spreadsheet.

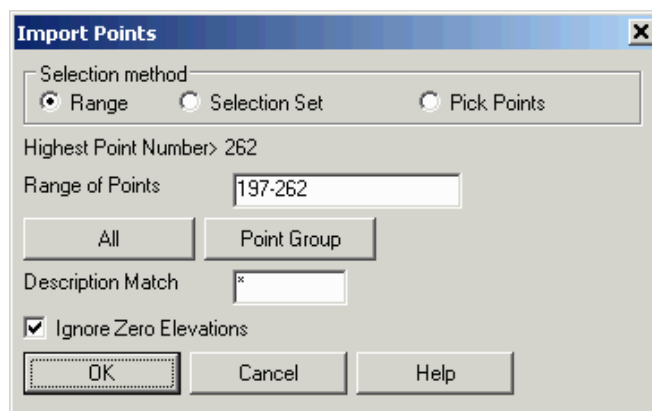

View > Hide By Description: This function is a way to filter the spreadsheet by description. Wildcard matching applies to the user-defined description filter.

View > Show All Rows: This function shows all the spreadsheet rows including those hidden by the above functions.

Examples of Cut Sheet reports comparing points are shown next.

Example 1: Cut Sheet comparing points to surface and using Report Viewer for report

1) Run Import > Points and select sample_cusheet.crd from Carlson Projects. Select the points to import by range as shown.

2) Run Grade > Triangulation File and choose sample_cutsheet.tin from Carlson Projects.

3) Run Centerline > Centerline File and choose sample_cutsheet.cl from Carlson Projects. Now all the data is ready for reporting.

	Point#	Description	Survey Z	Design Z	Cut/Fill	Station	Offset	Comment	Hz Error	Survey Northing	Survey Easting

Type of Curve

Cut/Fill In Inches

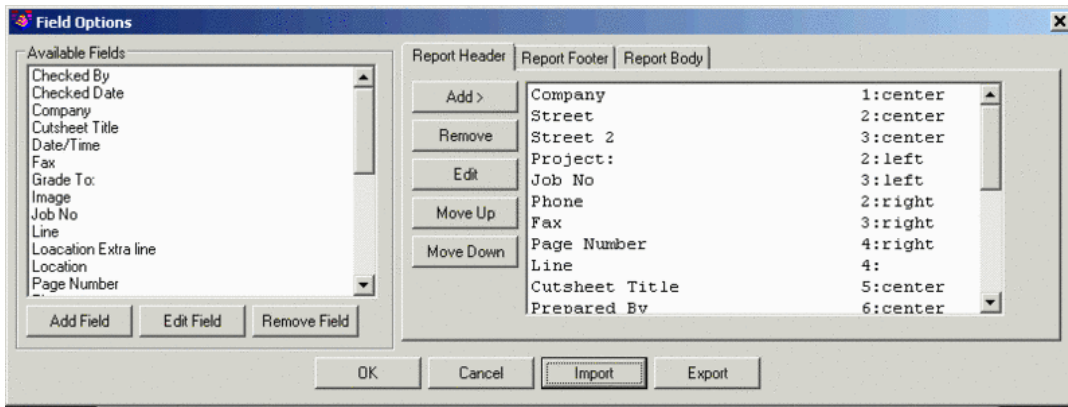

5) The next steps will format the report. Run Report > Create Report which brings up the Report Formatter. Move the Available fields over to the Used fields list as shown. Also, be sure that Widths by Field is toggled on.

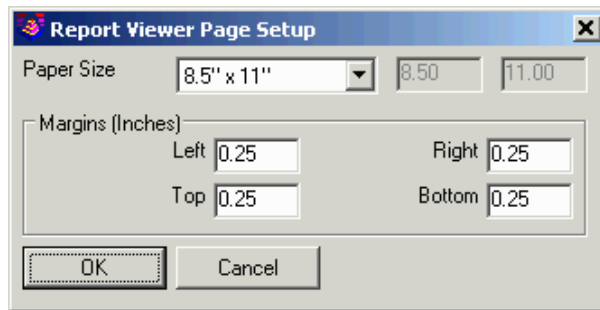

6) On the Report Formatter dialog, pick the Settings tab and then the Attrib Options button which controls how the values are formatted in the report. Then on the Attribute Options dialog, highlight Description and pick the Edit button. On the Attribute Display Options dialog for Description, turn off Auto Width and set the Fixed Width to 18. Then pick OK. Next highlight Comment in the list and pick Edit. Set the Fixed Width to 21 for Comment. Then pick OK on the Attribute Options to finish the attribute edits.

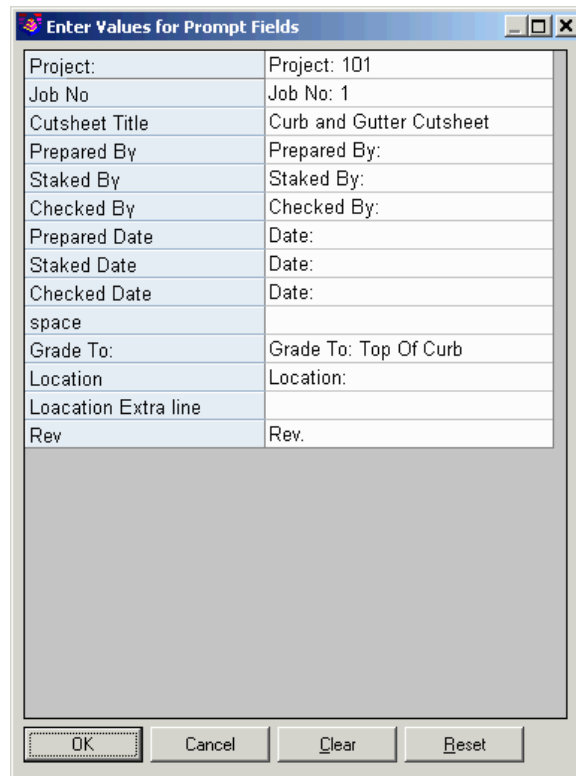

7) On the Settings tab for Report Formatter, pick the Field Options button which setups up the report header and footer. On the Field Options dialog, pick Import and select sample.cutsheet.fds from the Carlson Projects\Settings folder. Then pick OK.

8) On the Report tab for Report Formatter, pick the Report Viewer button. There is a dialog for setting the report page size. Pick OK.

Next is a dialog for entering report fields for the report header as setup in the previous step with the Field Options. Fill in the report fields and then pick OK.

Now the report is displayed in the Report Viewer which can be printed or saved to PDF, MS Word or Excel.

Example 3: Cut Sheet Report comparing points from Another Coordinate file, reporting coordinates for the points.

Example 4: Steps for Comparing Points in Current Coordinate file and using Report Formatter Option to customize report output to user preference.

- 1) Check on Use Report Formatter on the Cut Sheet Report dialog.
- 2) Specify points to compare by one of the four methods described above for comparing points within the current coordinate file.
- 3) Select report content by highlighting the desired data from the Available list on the left side of the dialog box and then pressing the Add button to place the selected data in the Used list. Standard window selection methods using the Ctrl and Shift keys can be used to select more than one item at a time. After moving the selected data to the Used window it may be necessary to move data up or down to obtain the desired order of your report. To do this use the up and down arrows located on the left of the Used window.

4) When the desired data has been specified in the Used window press the Display button at the bottom left of the dialog. For more detailed information on using the report formatter see the Report Formatter section of this manual.

Set Point Elevations by 3D Polyines

This command assigns elevations to points by referencing 3D polyines. The station-offset is calculated for each point to the nearest reference 3D polyline. The point must be within the specified Max Offset Tolerance in order to be elevated. The elevation is calculated from the elevation of the reference 3D polyline at the station combined with the specified percent slope times the offset plus the vertical offset. The Decimals setting is for the elevation label of the point. The elevation for the coordinate file always uses full precision. The option to Link Elevations To Polyines will update the point elevations when the reference polyline is changed.

Prompts

Polyline Report

This command generates a report of data in the selected polylines. After starting the command, press O for Options to set various report options. When the Report Points option is active, the report includes the coordinates, angle-distance and curve data for all the points. With Report Points turn off, the report includes just the perimeter, area and layer names of the polylines. The closure can be reported between the starting and ending points of the polyline. The polyline area can also be reported. With the Multiple Polylines option, you can report a selection set of polylines with their total length at the end of the report.

Crandall Polyline Adjustment

This command applies a crandall adjustment to a perimeter defined by a polyline. This is a way to distribute rounding errors on perimeters without altering the record dimensions. The command draws a new polyline of the adjusted perimeter and creates a report. The closure error is the difference between the end point of the polyline and the specified closing point that the program prompts for. For a closed loop adjustment, the closing point is the starting point of the polyline.

Here is an example report for a closed loop.

Compass Polyline Adjustment

This command applies a compass adjustment to a perimeter defined by a polyline. After selecting the polyline, the program displays arrows to show the polyline direction and you have an option to reverse the polyline. The command draws a new polyline of the adjusted perimeter and creates a report. The closure error is the difference between the end point of the polyline and the specified closing point that the program prompts for. In the dialog, you can set the Traverse Type as Open or Closed. For a closed loop adjustment, the closing point is the starting point of the polyline. For an open traverse, the program will prompt for the closing point.

For the Geodetic Report option, the program reports the geodetic distances and angles. To use this option, the grid

projection must be define in Settings > Drawing Setup.

Here is an example report for a closed loop.

Prerequisite: A polyline

Grant Boundary Adjustment

This command applies a Grant Boundary Adjustment by rotating and scaling a polyline. Before running this command, the grid projection must be set in Drawing Setup and a polyline must be drawn.

The Grant Boundary method is used to set lost corners on perimeters within public lands. Distances between the record and measured are compared to define a ratio for adjustments. A rotation is defined by the difference between the record and measured bearings to preserve the angular relationship at the lost corners and to adjust the distance at the same ratio through each lost corner.

Prompts

Pick polyline for Grant Boundary Adjustment: *pick polyline*

Layer name for adjusted polyline <GRANT>: *press Enter*

Reverse polyline [Yes/<No>]? *press Enter*

Pick new closing point: *pick point*

Pulldown Menu Location: Survey > Polyline Tools

Keyboard Command: grantadj

Prerequisite: A polyline

4 Sided Building

Often only one or two sides of a building are surveyed in the field. This routine completes the building by drawing the other sides. *4 Sided Building* creates a parallelogram given two connecting lines, or given a polyline with two segments. With two lines, there is an option to make the parallelogram as a polyline or as four lines. When only one side is defined, the program will prompt for the building width. Besides using linework to define the sides, you can use points by entering P at the prompt to switch to points mode.

Prompts

Options/Points/<Pick a line or polyline>: *pick a line*

Pick another side (Enter for none): *pick a line*

Convert the lines into a polyline [<Yes>/No]? *press Enter*

Options/Points/<Pick a line or polyline>: *press Enter*

Entering O for options lets you choose whether or not to be prompted to set the new polyline width, and for whether to default the width to make a square building with one sided input.

Pulldown Menu Location: Survey

Keyboard Command: 4sided

Prerequisite: A polyline with two segments or two adjoining lines

CAPD Command Reference

Cadastral Automated Plat Drafting System (CAPD) was developed by the BLM. Here are a list of command names from CAPD and the equivalent commands in Carlson. This list is to help CAPD users find these functions within Carlson.

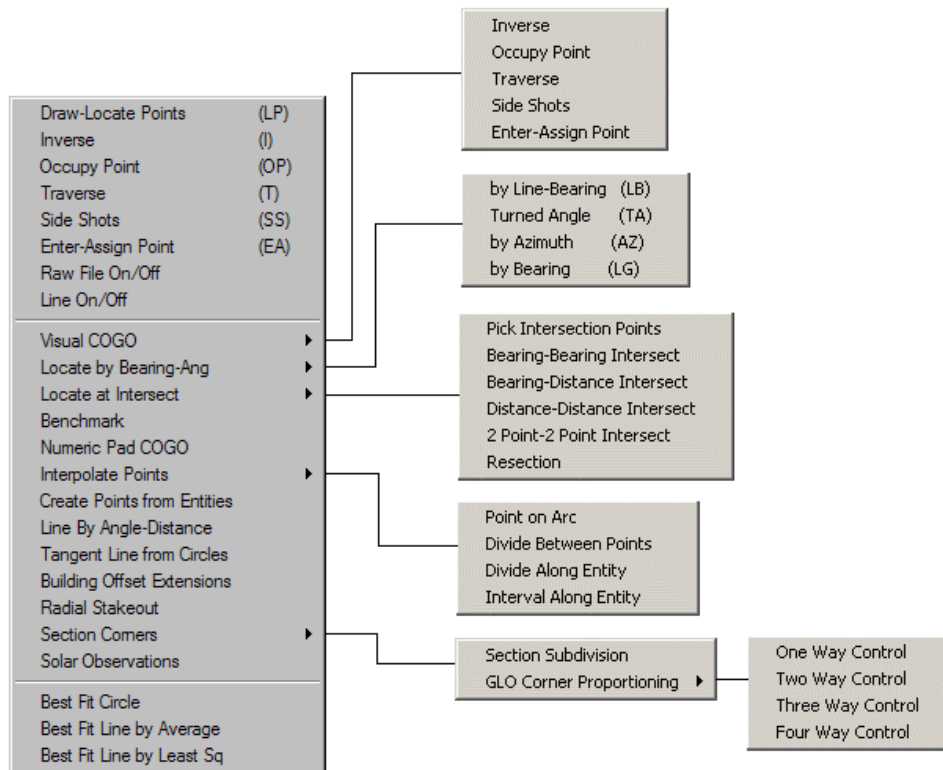

CAPD Command	Carlson Command	Menu Location	Description
ALIGN	TXTLINEUP	Edit > Text > Line Up Text	Used to align text
BAREA	DEFAREA, PLAREA	Area/Layout > Area De- faults, Area By Closed figure Polyline	Computes area of a closed figure

TRAV	GEOTRAV	COGO > Geodetic > Geodetic traverse for input Geodetic Traverse	of bearings and distances

COGO Menu

This chapter provides information on using the commands from the COGO menu to perform coordinate geometry operations in your drawing. The top section provide basic COGO routines, with optional quick keys. The bottom section provides numerous survey functions, including the easy-to-use Visual COGO and also Numeric Pad COGO.

Inverse

This command reports the bearing/azimuth and horizontal distance between two points. The command prompts for a series of points. Use the appropriate object snap mode to select the points from the screen, or use the point numbers to reference coordinates stored in the current coordinate (.CRD) file. The results are then displayed. This command is also used in conjunction with the *Traverse* and *Sideshot* commands to occupy and backsight two points. The last two points you Inverse to are the Backsight and the Occupied point for the Traverse and Sideshot commands. An

attractive feature of *Inverse* is that you can enter T or SS within the command and go directly to *Traverse* or *Sideshot*. Even a single S will transmit to *Sideshot*. Hotkeys are not case sensitive. Press [Enter] at the point prompt to end the command.

You can also inverse around an arc by inverting to the Point of Curvature (PC), and then entering an A for Arc option. The program will ask for the radius point, the curve direction left or right and the PT point. The curve data is then reported. There is an unequal PC-Radius and PT-Radius distance check. The tolerance for this is set in the *Area Label Defaults* command.

After picking the first point, there is a keyboard option for Multiple which will prompt for a range of point numbers to report as a sideshot inverse.

There are several input options for *Inverse* that are set by entering O for Options on the command line. Sideshot inverse holds the current occupied point and calculates the bearing/distance to each entered point. The Pairs option reports the bearing/distance between pairs of points and not for every entered point. For example, if points 1,2,11,12 were entered, the bearing/distance would be reported for 1,2 and 11,12 but not 2,11. The Auto Increment option uses the next point number by just pressing Enter. To exit the routine with Auto Increment active, End must be entered.

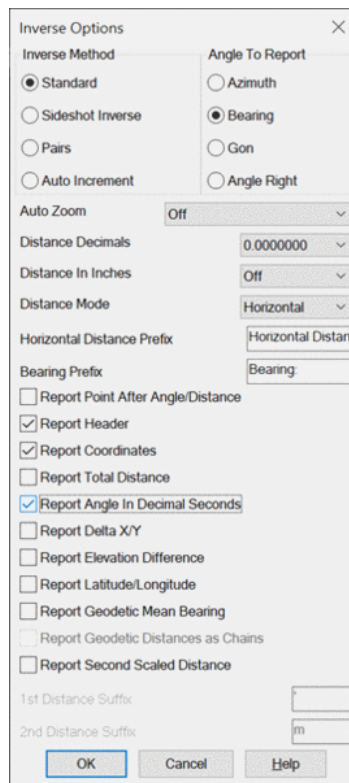

The *Auto Zoom* settings under Inverse Options will zoom the display as needed to have the occupied point or both the occupied and backsight points visible. The *Report Total Distance* option displays a running total of all inversed distances during the current run of the routine.

The Report Geodetic Mean Bearing option reports the geodetic bearing at the to point (forward), at the from point (back) and the mean bearing. The geodetic distance is also report for the geodetic distance at zero elevation and at ground elevation. The coordinates are converted to lat/lon using the projection setup under the Drawing Setup command. The program reports that lat/lon, convergence angle and grid scale factor at the from and to points. Here's an example for SP83 VT,
Northing(Y) Easting(X) Elev(Z)

Bearing: S 84°33'28" E Horizontal Distance: 1942.6941325
Lat: 43°01'05.81806" Long: -76°49'09.53807"
Convergence: N 02°56'59" E Scale: 1.0014892493
Lat: 43°01'04.98404" Long: -76°48'43.45145"
Convergence: N 02°56'41" E Scale: 1.0014841465
Geodetic Forward Bearing: S 87°30'28" E
Geodetic Back Bearing: S 87°30'09" E
Geodetic Mean Bearing: S 87°30'18" E
Geodetic Distance: 1942.984 Zero Elev, 1942.984 Ground Elev

There are also several angle output options that are set at the second prompt in Options. The angle can be reported as either Bearing, Azimuth, Gon or Angle Right. You can also specify to report angles with decimal seconds. The distance settings include the number of decimals for distances, whether to report slope or horizontal distance and whether to report distances in feet and inches format. The Report Total Distance option will report the cumulative distance for all the inverses. The Report Delta X/Y will distances as delta north-south-east-west instead of angle and distance. For Report Latitude/Longitude, the grid projection must be set in Drawing Setup. The Report Point After Angle/Distance controls whether the point coordinates are reported before or after the angle and distance. The Report Header controls whether to have a header label line for the point data. The Report Coordinates option choose whether to report the northing, easting and elevation of the points. The Report Elevation Difference option will report the delta Z between the pairs of points. The Report Second Scaled Distance option will report a second

distance value that is scaled from the first distance value using the scale factor defined in Drawing Setup. When the Second Scaled Distance option is on, there are settings for the suffix to use for both the first and second distance to help identify them separately in the report.

For instruction on how to insert either new or existing points into the drawing, see Draw-Locate Points in the Points Commands section of the General Commands chapter.

Prompts

Pulldown Menu Location: COGO

Keyboard Command: inverse, i

Prerequisite: None

Occupy Point

This command sets the occupied point and backsight angle for other COGO commands such as *Traverse*. For setting the occupied point, you have the option of picking a point on the screen, entering coordinates at the command line or typing in a point number that will be read from the current coordinate (.CRD) file. Four options are available for determining the backsight direction: Azimuth, Bearing, None and Point. For the default Point option, you may pick

a point on the screen, input coordinates, or type a point number that will be read from the current coordinate file. For the Azimuth and Bearing option, you enter the backsight angle in the selected format. The None option sets the backsight to an azimuth of 0 (zero) or North. You can also set the occupied point by using the *Inverse* command. If you inverse from point 3 to point 1, you have set point 1 as the occupied point and point 3 as the backsight. For more information, see the *Inverse* command.

The current occupied point and backsight are shown in the lower right hand corner of the AutoCAD status bar just below the command line.

Prompts

Set Occupied Point

Set backsight method [Azimuth/Bearing/None/<Point>]? *press Enter*

Set Backsight Point

Pick point or point number: *pick a point (5184.76 5381.3 0.0)*

For instruction on how to insert either new or existing points into the drawing, see Draw-Locate Points in the Points Commands section of the General Commands chapter. This feature can be found in the Points pulldown of all menus.

Pulldown Menu Location: COGO

Keyboard Command: occpoint, op

Prerequisite: None

Traverse

This command allows the user to input any combination of turned angles, azimuths or bearings to define a traverse or figure. The command prompts for an Angle-Bearing Code which defines the angle or bearing type. This command always occupies the last point it calculated and backsights the point before that.

Codes 1 through 4 define the bearing quadrants:

- 1 = Northeast
- 2 = Southeast
- 3 = Southwest
- 4 = Northwest

The remaining codes define as follows:

- 5 = Azimuth
- 6 = Angle turned to the left
- 7 = Angle turned to the right
- 8 = Deflection angle left
- 9 = Deflection angle right

For both the Angle-Bearing Code and the Distance prompt, the user can enter point-defined responses: two points separated by an asterisk, as in 2*3 for the bearing (or distance) defined by 2 to 3. You can also add math expressions. For angles, 2*3+90 would deflect 90 degrees right from 2 to 3. For distances, 2*3/2 would mean half the distance of 2 to 3. You do not need to enter N before entering a number-defined distance. Just bring up the number inverse prompt. For distances, the # symbol can also be used to indicate point numbers like in SurvCE. So 2#3 means the distance between points 2 and 3.

The command draws lines between located points (if the Line On/Off in the COGO menu is set to on) and plots the points calculated and stores them in the current coordinate (.CRD) file if point numbering is On. The point settings

are defined in the *Point Defaults* command. If Point Protect is turned on, *Traverse* checks if the point numbers are already stored in the file. Point Protect is set in the *Coordinate File Utilities* command.

There are Angle-Bearing code input options for *Traverse* that are set by entering O for Options. The Angle Right option prompts for the angle right and skips the angle-bearing code prompt. The Azimuth option prompts for the azimuth and skips the angle-bearing code prompt.

Prompts

Occupied Point ?

Pick point or point number: *pick a point*

You will only be prompted for the occupied point the first time you use the command.

Use the *Inverse* command to set the occupied and backsight points.

Exit/Options/SideShot/Inverse/Enter Azimuth (ddd.mmss) <>: o

Angle prompt angle right or azimuth only [Right/Azimuth/Prompt]? p

Exit/Options/Arc/Points/Line/SideShot/Inverse/Angle-Bearing Code <5>: *press Enter* Pressing Enter uses the default angle right code.

Enter Angle (dd.mmss) <90.0000>: *88.1324* You can also enter L or R to define an angle 90 degrees Left or Right.

Backsight Point ?

LEFT & RIGHT

Select Coordinate (.CRD) File This dialog only appears if there is not a current coordinate (.CRD) file.

Exit/Options/Line/Side Shot/Inverse/<Angle-Bearing Code <7>>: *14*9-45.2045* Uses the bearing defined by point numbers 14 & 9 and subtracts the angle 45 degrees, 20 minutes, and 45 seconds. You can use a + or - in this type of entry.

Number inverse/<Distance>: *N* (*note: you can enter 14*9/2 here, as well*)

Point number inverse (i.e. 10*20): *14*9/2* This causes the command to recall the distance from point number 14 to 9 and divide it by 2.

Exit/Options/Line/Side Shot/Inverse/<Angle-Bearing Code <7>>: *L*

Select Line or Polyline that defines Bearing: *select line that defines bearing*

Number inverse/<Distance>: *100*

Exit/Options/Line/Side Shot/Inverse/<Angle-Bearing Code <7>>: *E* Enter E to end the command. Enter S or SS to execute the *Side Shots* command or I to execute the *Inverse* command.

For instruction on how to insert either new or existing points into the drawing, see Draw-Locate Points in the Points Commands section of the General Commands chapter. This feature can be found in the Points pulldown of all menus.

Pulldown Menu Location: COGO

Keyboard Command: T, Traverse

Prerequisite: None

Side Shots

This command allows the user to input any combination of turned angles, azimuths or bearings while remaining on an occupied point. The command prompts for an Angle-Bearing Code which defines the angle or bearing type. Codes 1 through 4 define the bearing quadrants; 1 being North-East, 2 South-East, 3 South-West, and 4 North-West. Code 5 is a north-based azimuth, 6 an angle turned to the left, 7 an angled turned to the right, 8 a deflection angle left and 9 a deflection angle right. The command plots the points calculated and stores them in the current coordinate (.CRD) file if point numbering is On. If Point Protect is turned On, *Side Shots* checks if the point numbers are already stored in the file. All points calculated radiate from the occupied point. Use the *Traverse*, *Inverse*, or *Occupied Point* commands explained previously to define the occupied and backsight points. Options allows you to select your angle entry method.

Prerequisite: None

Visual COGO

This command contains COGO routines for Inverse, Occupy Point, Traverse, Side Shots, Bearing-Bearing Intersect, Bearing-Distance Intersect, Distance-Distance Intersect and Enter-Assign Point. Choosing Visual COGO from the COGO pull-down menu provides you with quick access to any of the Visual COGO routines.

A dialog for command input docks on the side of the graphic window when any of the five options from the pulldown menu are selected. Points are drawn to the screen as they are created. Linework can also be drawn. CAD and Carlson commands can be activated with the Visual COGO dialog active. This allows for quick switching between Visual COGO commands and any other command. You can also switch between Visual COGO commands within the dialog by entering the 2 character function name in any edit box. For example, from Visual COGO Inverse, you can enter SS in the point number field to switch to Side Shots.

The function names OC, EA, IN, BB, BD, DD, TR and SS are also available as function buttons across the top of the dialog. The second row of buttons are functions for zooming in/out and panning. The final button brings up Visual Cogo options. The **Use Sound** option is for whether to have sounds cues. The Prompt for **Bearing/Azimuth Rotation** adds an additional angle input in the Sideshot and Traverse functions. This angle is added to the bearing or azimuth angle input and is a way to handle North rotation where the orientation of the angles that your entering is different than the target coordinate system.

Prompts

When in Visual COGO, you will have a very different user interface from other areas of Carlson. This user-friendly screen will guide you through various COGO data entry procedures such as Inverse, Occupy Point, Traverse, Side Shots and Enter-Assign Point. You will still be able to follow the command on the command line at the bottom of your Carlson screen. Using Visual COGO is an alternative and easy method to entering in such information. The top half of the COGO pulldown menu offers you the more traditional Carlson data entry method. Your results will be the same.

IN (Inverse): This command reports the bearing/azimuth and horizontal distance between two points. The points can be entered manually or by picking from a point list by picking on the list button. The resulting report of bearing/azimuth is dependent upon the Angle Mode setting in the drawing setup options.

OC (Occupy Point): Used to specify the point number of the instrument setup point. The point can be specified by manually entering in the point number in the Occupied Point data field, or by selecting the List button and choosing from the list of points contained in the coordinate file.

Backsight Method can be either by Point Number or by Azimuth. If angle right/left or deflection right/left is being used for traverse or sideshot entry, a backsight method must be specified. If using Bearing or Azimuth entry, no backsight method is required. The Backsight Point can be specified by manually entering in the point number in the Backsight Point data field, or by selecting the List button and choosing from the list of points contained in the coordinate file.

Instrument Height: Use this field to set the height of the instrument.

Accept (F2): Selecting this button or pressing the F2 function key accepts the data entered in the fields above. After accepting the data, until changed, the points specified will remain the occupied and backsight points. If the dialog is exited without Accepting the settings the Occupied and Backsight points will have to be specified when the OC dialog is revisited.

Exit: Cancels the command

TR (Traverse): This command allows data entry using any combination of turned angles, deflections, azimuths or bearings to define a traverse or figure. This command always occupies, moves up to, the last point it calculated and backsights the point before, or the previous occupied point.

Point Number: This is the number of the point to be created.

Rod Height: Height of target to be located.

The horizontal angle component can be input in various formats. The format label will change with the option chosen. Choose the format by selecting the down arrow and picking from the list.

NE=Northeast
SE=Southeast
SW=Southwest
NW=Northwest
AZ=Azimuth
AL=Angle Left
AR=Angle Right
DL=Deflection Left
DR=Deflection Right

The vertical angle component can be input in various ways (the format label will change with the option chosen). Choose the format by selecting the down arrow and picking from the list.

VA=Vertical Angle. Zero (0) degrees is level.

ZE=Zenith Angle. Ninety (90) degrees is level.

DZ=Elevation Difference. The difference in elevation either plus or minus from the instrument setup to the target.

The distance component can be entered as either Slope or Horizontal Distance. Choose the format by selecting the down arrow and picking from the list.

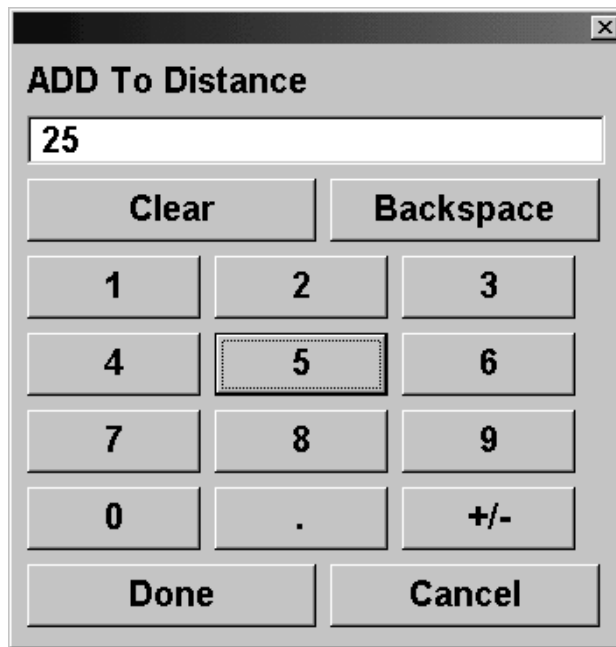

SD=Slope Distance

HD=Horizontal Distance

Distance can be defined by Point Numbers by selecting the calculator button to the far right of Angle Right and Slope Distance.

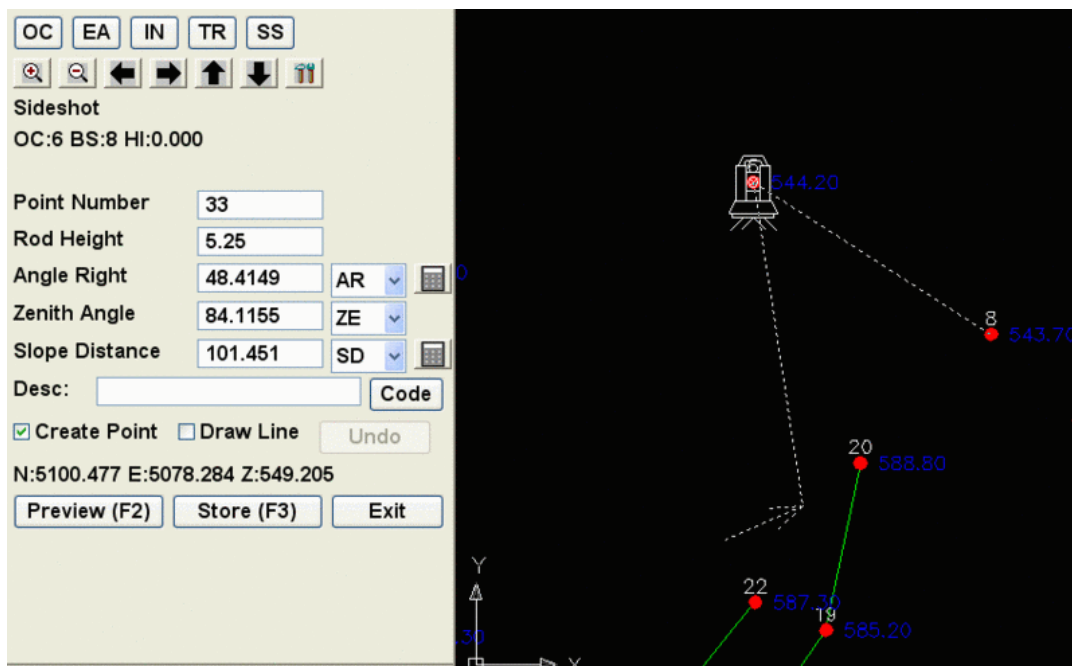

Additional mathematical calculations of addition, subtraction, multiplication and division can be performed on the input distance by selecting the appropriate button and filling out the function dialog.

For example to add 25 to the Slope distance value on the traverse dialog, select the + button, enter 25 and then select Done. The same steps apply to any of the other mathematical functions.

Side Shots: This command works in the same way as the traverse command. All the available options contained in the traverse command are available in this command. The only difference in the commands is that the side shot command does not move the setup point to last shot input. Refer to the traverse command for further details.

Desc: Defines the description for the point to be created.

Create Point: Option whether to store the point to the CRD file and draw a point.

Draw Line: Option to draw line to the traverse point.

Preview (F2): Previews the traverse point location, without storing the point to the coordinate file.

Store (F3): Stores the traverse point based upon the entered data to the coordinate file.

Undo: After storing the point, the point can be deleted from the screen and coordinate file by selecting the undo button.

Exit: Exits the Visual COGO command and closes the dialog box.

EA (Enter Assign): Use this function to enter and assign coordinate values for new and existing points.

BB (Bearing-Bearing Intersect): Enter two base points along with the angles from each and the routine calculates the bearing-bearing intersection point. The dialog has fields for the output point number and description.

BD (Bearing-Distance Intersect): Enter two base points along with the angle from the first and distance from the second and the routine calculates the bearing-distance intersection point. The dialog has fields for the output point number and description.

DD (Distance-Distance Intersect): Enter two base points along with the distances from each and the routine calculates the distance-distance intersection point. For the two possible solutions of the intersecting circles, the intersection clockwise from the first point is used. The dialog has fields for the output point number and description.

Zooming and panning functions are also available from the Visual COGO dialog box:

Plus (+) magnifier: Zooms the display window in. Use to view an area up close.

Minus (-) magnifier: Zooms the display window out. This shows more of the drawing.

Left arrow: Pans the display window to the left.

Right arrow: Pans the display window to the right.

Up arrow: Pans the display window up.

Down arrow: Pans the display window down.

Pick near solution or Enter [A] or [B]: *pick a point*

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: DD

Prerequisite: None

Bearing-Distance Intersect

The Bearing-Distance Intersect command prompts the user for a base point from which the known bearing intersects. It then defines the bearing by one of three methods. The bearing can be defined by picking two points, selecting a line with the same bearing or by typing in the bearing in the form of Qdd.mmss (similar to the *Locate by Bearing* command). Next the user is prompted for a base point from which the known distance radiates. After entering the known distance a circle is drawn radiating from the selected base point, and a line defined by the bearing is extended to intersect the circle. The user then picks the correct point for the solution desired and a point symbol is located at the selected intersection. The command then erases the temporary circle and line. The Options choice allows you to be prompted for angle method or for offsets, or both.

When a grid projection for the drawing is defined under Drawing Setup, this command will prompt for whether to use the grid bearing or geodetic mean, forward or back bearing. Also, the program will prompt for whether to use the grid or geodetic distance.

Prompts

[Enter] to use preview point or select known Bearing base point

When Options (O) is selected

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: bdint

Prerequisite: None

Perpendicular Intersect

This command creates a point at the perpendicular intersection from an offset point to a line. This command prompts for a base point from which the known bearing intersects. Then the bearing is defined by typing in the bearing in the form of Qdd.mmss (similar to the *Locate by Bearing* command). Next the user is prompted for an offset point.

Prompts

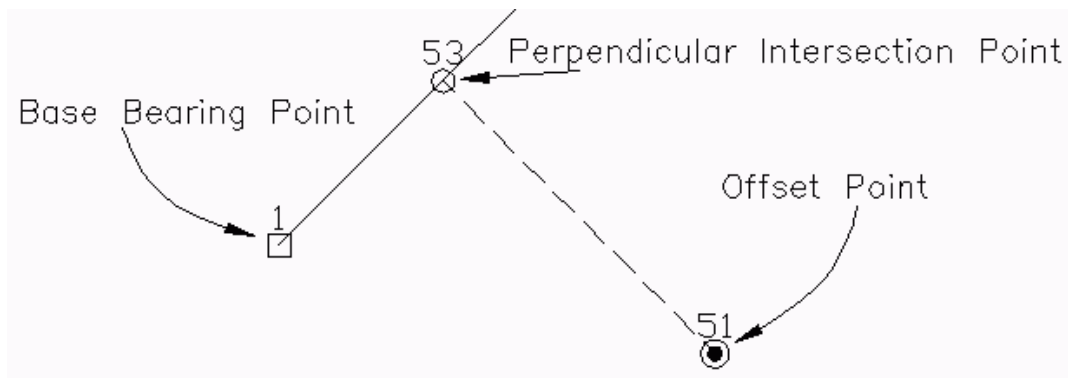

[Enter] to use preview point or select known Bearing base point

Pick point or point number: 1

Bearing (Qdd.mmss): 145.0000

Offset point.

Pick point or point number: 51

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: perpint

Prerequisite: None

Tangent Intersect

This command creates a point at the tangential intersection from a point to another point and distance. This command prompts for a base point and then the distance. Next there is a prompt for the second point. Since there are two possible tangential solutions on the circle from the base point, the program displays the two possible solutions and prompts for which one to use. To choose the solution, pick close to the solution point.

Prompts

Pick point or point number: 1

Points/<Enter Distance>: 25

Second point.

Pick point or point number: 51

Pick tangent point solution: *pick a point*

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: tangint

Prerequisite: None

2 Point - 2 Point Intersect

This command is similar to Bearing-Bearing Intersect except that in this command bearings are defined by specifying two point numbers. In the example shown below, the first two points specified are 3838 and 3839, the second pair are 3841 and 3840. Point 3842 is located at the intersection.

Prompts

Specify 1st base point.

Pick point or point number: 3838

Specify 2nd point that defines 1st direction.

Pick point or point number: 3839

Specify 2nd base point.

Pick point or point number: 3841

Specify 2nd point that defines 2nd direction.

Pick point or point number: 3840

Select/<Enter Point Elevation>: *Enter value*

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: bbint2

Prerequisite: None

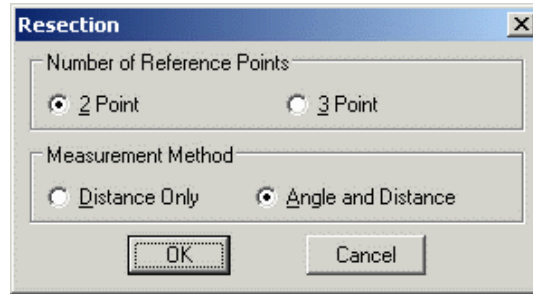

Resection

This command calculates point coordinates given the angle and distance from two or three reference points. The Z coordinate can also be calculated in addition to the X,Y. If you only need the 2D solution, then enter the instrument and rod heights as 0.0, the zenith angle as 90 and the distance as the horizontal distance. The reference points are specified by point number. These reference points need to be stored in the current coordinate (.CRD) file before running this command.

After entering the reference point, there is a dialog to enter the horizontal angle, zenith angle and slope distance. The horizontal angle is the horizontal azimuth or angle right from the unknown point to the reference point. In the example, the backsight azimuth is 0 (due north), but this is not a requirement since the backsight can be any angle. The program calculates the coordinate by averaging the distance-distance and angle-angle solutions. Since there is redundant data, the final calculated coordinate will differ slightly from the individual measurements. For example, in a 3-point resection, there are two different distance-distance solutions (between the first-second point and between the second-third points). The program reports the difference between the final coordinate and the

individual solutions as the residuals which act as an indicator whether the data is good. High residuals suggest a problem with the input data. In the dialog that displays the final coordinates and residuals, there is a button to store the coordinates to the current coordinate (.CRD) file with a specified point number.

In the first Resection dialog box, you can choose to use two or three reference points.

In the second Resection dialog box, you assign the reference point.

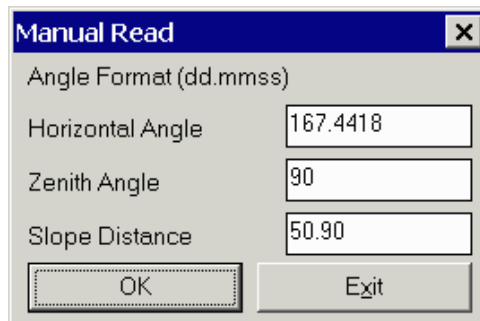

Point: You must enter the point number of your reference point. These reference points need to be stored in the current coordinate file before you run this command.

Inst. Height: You must enter the instrument height.

Target Height: You must enter the target height.

If you need only the 2D solution, then enter the instrument and target heights as 0.0.

In the Manual Read dialog box, you must specify parameters for the calculation.

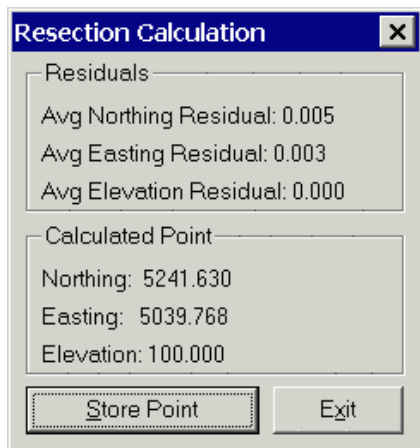

Horizontal Angle: You must enter a horizontal angle from the resection to the reference points. The horizontal angle is the horizontal azimuth, or angle right, from the unknown point to the reference point.

Zenith Angle: You must enter a zenith angle. For a 2D solution, set the zenith angle to 90 degrees.

Slope Distance: You must enter a slope distance from the reference points to the resection.

You are prompted for additional reference points and parameters.

The Resection Calculation dialog box that displays the final coordinates and residuals. You can select the option to store the coordinates in the current coordinate file with a specified point number.

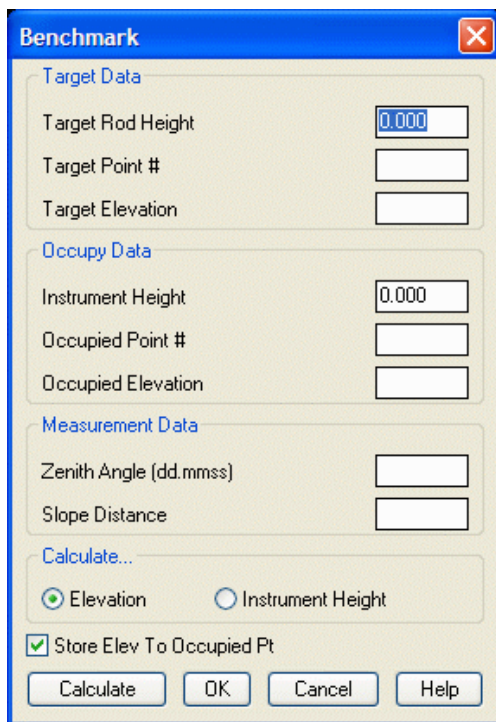

Pulldown Menu Location: COGO > Locate at Intersect

Keyboard Command: cresection

Prerequisite: Two or three reference points

Benchmark

This command is similar to the data collector routine, where a measurement with a total station is taken from an unknown elevation to a known elevation foresight. The unknown elevation of the occupied point is then calculated based on the measurement. Either the Occupied Elevation or the Instrument Height can be calculated. Note that a check box is located at the bottom of the dialog box to "Store Elev To Occupied Pt". This will automatically change the elevation of the occupied point.

Prompts

Coordinate File to Process dialog If required, this dialog will appear and you must select a file.

Benchmark dialog *Fill in variables, click Calculate*

Pulldown Menu Location: COGO

Keyboard Command: benchmark

Prerequisite: None

Numeric Pad COGO

Using only the keys on the numeric pad, this command does several COGO commands. The program cycles through six prompts. Only respond to the prompts that apply and the program will perform the correct action. The prompts are: First point? First angle? First distance? Second point? Second angle? Second distance?

To *inverse*, give a first point and second point.

To *traverse*, give a first point, first angle and first distance.

To do *bearing-bearing intersect*, give a first point, first angle, second point and second angle.

To do *bearing-distance intersect*, give a first point, first angle, second point, and second distance. Or give a first point, first distance, second point, and second angle. The point is calculated at the closer intersection.

To do *distance-distance intersect*, give a first point, first distance, second point, and second distance. The point is calculated at the first intersection going clockwise from the first point's distance circle.

Points can be screen picked or entered as point numbers that reference the current coordinate file. The last point is used as a default when you press Enter at the prompt for the first point. Which point is being used is indicated by a ghost arrow pointer.

Angles can be specified by picking two points or entering an angle code which begins with a single digit code followed by the degrees and the minutes and seconds after a decimal point. The digits codes are (1 - Northeast, 2 - Southeast, 3 - Southwest, 4 - Northwest, 5 - Azimuth). For example, Northwest 50d10'2" would be *450.102*.

Distances can be specified by picking two points or entering the distance value.

Prompts

Enter coords/Quit/<Pick 1st point or point number>: 5

Pick or Type 1st Direction by 2 Points: *145.0135* (Northeast 45d1'35")

Pick or Type 1st Distance by 2 Points: *50.0*

A point is created from the values for this traverse. The prompts for the second point don't appear because all the information for this action is entered.

Enter coords/Quit/<Pick 1st point or point number>: *press Enter* to use the point created by the traverse.

Pick or Type 1st Direction by 2 Points: *50.0*

Enter coords/Quit/<Pick 1st point or point number>: 4

Enter/Pick 2nd Direction by 2 Points: *press Enter*

Enter/Pick 2nd Distance by 2 Points: *75.0*

This creates a point by distance-distance intersect.

Enter coords/Quit/<Pick 1st point or point number>: *Q*

Pulldown Menu Location: COGO

Keyboard Command: ccogo

Prerequisite: None

Line by Angle-Distance

This command draws a line from an occupied point at a given angle and distance, where the angle format supports the standard 1-9 angle-bearing codes. It holds the current occupied point and calculates a line by angle-distance to each entered point. As for the angle formats, the Options choice allows for angle right, azimuth only or prompt entry (Right/Azimuth/Prompt) methods. The Prompt method allows you to enter the 1-9 angle-bearing codes.

Tangent Line from Circles

This command draws a line that is tangent to two circles or arcs. The circles can be defined either by picking the radius point and entering the radius, or by selecting circle or arc entities. The tangent line can be drawn to either outside on the left or right side, or across the middle between the circles from left to right or from right to left. The line and the circles are drawn in the current layer. There is also an option to create two points at the ends of the tangent line.

Keyboard Command: linecircle

Prerequisite: None

Geodetic Traverse

This command creates points by traversing by bearing and distance. The program starts by prompting for a starting point. Then the bearing is entered as either grid bearing or geodetic bearing for mean, forward or backward. Then the distance is entered either as grid distance or geodetic distance at mean elevation or zero elevation, and the distance units can be either feet, meters or chains. The resulting point is then drawn using the point settings from the Point Defaults command. Before running this command, the grid projection for the drawing must be defined in the Drawing Setup command.

Geodetic Double Proportion Line Division

This command is used to restore a lost corner from new measurements between four known corners with two measurements each on intersecting meridional and latitudinal lines. The program prompts for the four known corner points to establish the retracement. Plus the program prompts for the four sets of record bearings and distances from the known points to the lost corner. The report then shows the calculated point along with the input data.

Irregular Boundary Adjustment

This command adjusts angle/distance courses between two control points. This adjustment applies to boundaries that are not established as straight lines and are termed "irregular". A modified form of single proportionate measurement is used by this method to restore the lost corners. To apply the geodetic lengths and angles with this adjustment, the grid projection must be set under Drawing Setup before running this command.

For input, this command takes reference coordinates for the starting and ending points either by screen pick or by point number. Then the record angles and distances between these two reference points are entered. The program reports the input data, the recalculated points and the adjusted angles and distances.

GLO Corner Proportioning

The GLO Corner Proportioning commands calculate section and 1/4 section corners by one, two, three or four way control. GLO plats are the official plats of the U.S. Government Land Office (GLO) executed after July 1946. The Department of the Interior, Bureau of Land Management (BLM) is the successor agency to the GLO.

Section Subdivision

This command calculates and stores unknown Section corners that can be calculated given the data specified. The calculated points will be plotted on the screen and saved to the coordinate file.

A screenshot of the 'Section Subdivision' dialog box. It contains several input fields and groups. The 'Section Location' group has fields for Section (3), Township (67), and Range (18). The 'Specify Field Located Corners' group has radio buttons for 'Section & Quarter Corners' (selected) and '1/16th Corners'. The 'Section Linework' group has a checked 'Draw Section Lines' box and dropdown menus for 'Section Lines' (V-PROP-SECT), 'Quarter Section Lines' (V-PROP-QTRS), and 'Sixteenth Section Lines' (V-PROP-SXTS). The 'Government Chainages' group has input fields for 'A to H' (39.15) and 'C to D' (39.98). A grid of 12 input fields is arranged in a 3x4 grid, labeled C, B, A, D, H, E, F, G. The top row contains 5744, 5745, and 4386. The bottom row contains 5764, 5765, and 5766. 'OK' and 'Cancel' buttons are at the bottom.

Section Location Group: Input the required Section number, Township and Range.

Specify Field Located Corners Group: Indicate whether Section & Quarter Corners were located in the field or if 1/16th corners were located in the field.

Section Linework Group: Indicate whether the calculated Section lines should be drawn and indicate the desired layer(s) for the Section Lines, Quarter Section Lines and Sixteenth Section Lines.

Inputs A - H: Specify the point IDs of corners that have been located in the field.

Government Chainages Group: Specify the government chainages as documented/required.

Note:

- The choices in the **Specify Field Located Corners** section of the dialog merely make it more convenient to enter the Section & Quarter corners and the 1/16th corners. This choice allows you to enter the corners in order by just typing the point ID of a corner then just press Enter to move to the next corner. You may enter any type of corner located in the field by changing the types of corners selection in the **Specify Field Located Corners** section.

For each calculated corner, the **Saving Point** dialog box will be displayed. Depending on the Point Default settings, this dialog may allow you to accept or change the default point ID. Also, depending on the Point Default settings, the description and elevation may also be changed or accepted.

Pulldown Menu Location(s): COGO > Section Corners

Keyboard Command: cg_section_subd

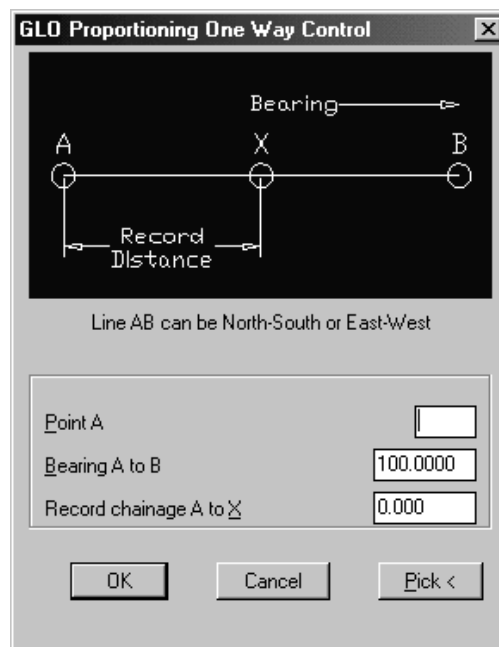

Prerequisite: Coordinate File with at least eight points

One Way Control

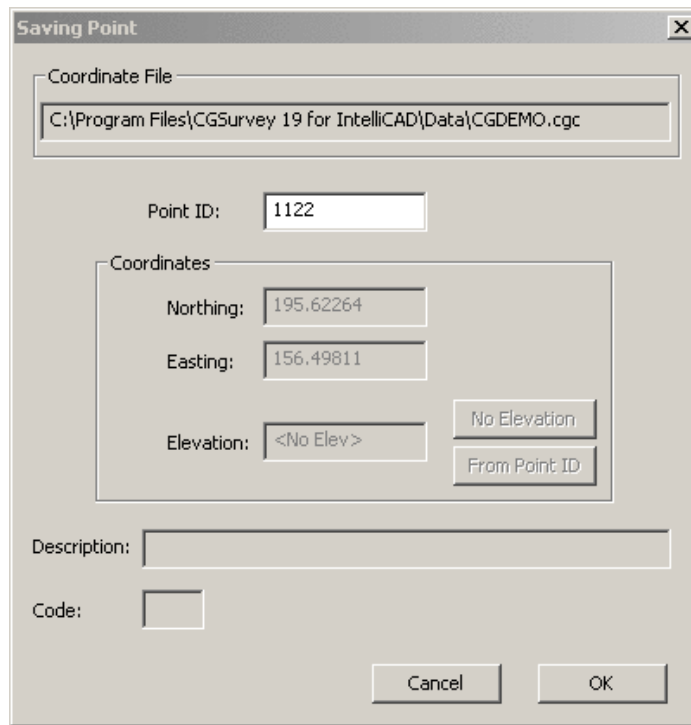

This routine calculates section and 1/4 section corners by one way control. First, enter the point number for Point A. This number can be entered in manually or picked from the screen by selecting the Pick radial button at bottom right. In a like manner, the Bearing from A to B can be entered manually or by using the Pick radial button to pick from the screen. The distance from A to X can be specified in the same manner as above. After selecting OK, a dialog box will display where the Point number, description and elevation can be edited. The point default settings determine the available data for editing. For example, if the option for Automatic Point Numbering is turned off in the Point Defaults, then the field for the point number will be grayed out. If elevations are turned off in the point defaults, then the elevation field will be grayed out. This also applies to the description of the point as well.

Three Way Control

This routine works as the previous GLO Proportioning methods described. Fill out the required data fields on the dialog box and select OK. After selecting OK, a dialog box will display where the Point number, description and elevation can be edited. The point default settings determine the available data for editing. For example, if the option for Automatic Point Numbering is turned off in the Point Defaults, then the field for the point number will be grayed out. If elevations are turned off in the point defaults, then the elevation field will be grayed out. This also applies to the description of the point as well. GLO is an acronym for Government Land Office.

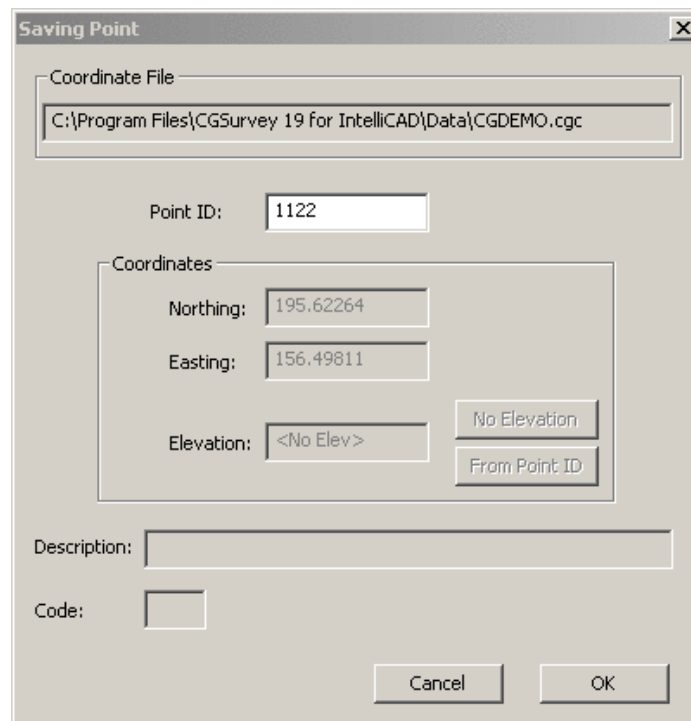

Prompts

GLO Proportioning Three Way Control dialog

The dialog box titled "GLO Proportioning Three Way Control" features a diagram at the top showing a horizontal line segment AB and a vertical line segment CD intersecting at point X. A dashed line connects point X to point C. Below the diagram, the text "Line AB can be North-South or East-West" is displayed. The "Point numbers" section contains three input fields: "Point A", "Point C", and "Point D". The "Bearing" section has a "Bearing A to B" input field with the value "100.0000". The "Record Chainages" section includes three input fields: "A to X" (0.000), "C to X" (0.000), and "C to D" (0.000). At the bottom are "OK", "Cancel", and "Pick <" buttons.

Saving Point dialog

The "Saving Point" dialog box shows the "Coordinate File" path as "C:\Program Files\CGSurvey 19 for IntelliCAD\Data\CGDEMO.cgc". The "Point ID" is "1122". The "Coordinates" section includes "Northing" (195.62264), "Easting" (156.49811), and "Elevation" (<No Elev>). There are "No Elevation" and "From Point ID" buttons. The "Description" and "Code" fields are empty. "Cancel" and "OK" buttons are at the bottom.

Solar Observations

This feature calculates true north and/or grid north bearings by solar observation. It uses the Local Hour Angle (LHA) method. The routine calculates Ephemeris data, thus alleviating the necessity of obtaining a Solar Ephemeris. The True North option calculates the true north bearing to mark. This option requires no zone/ellipsoid information. The True North & Grid North option calculates both true north and grid north bearings to north. The convergence angle is also shown.

Note: There is a description of solar observation field procedures at the end of this section.

True North Prompts

Calculate true north, or true north and grid bearing (<True north>/Grid Bearing): type T, press Enter

Choose field method (Leading edge/Trailing edge/<Center>): choose method, press Enter

If a Roelofs prism is being used, the Center Method should be selected. If not, select one of the other options. The Trailing Edge Method is the more popular of the two remaining methods.

Date of observation as MM/DD/YY or MM-DD-YYYY: For example 04/08/03.

Enter latitude of instrument point as DD.MMSS: For example 36.0545

Enter longitude of instrument point as DD.MMSS:

The following input loop will begin:

Obs. #1 - Time of observation as HH.MMSS: For example 15.3030

Enter angle to mark as DD.MMSS: Angle in the instrument when backsighting the mark.

Enter angle to sun as DD.MMSS: Clockwise angle from mark to sun.

The angle to the mark always has a default value of the last entered Angle to Mark. Each observation is numbered and the true bearing to the mark will be calculated. There is not limit as to the number of observations that can be made from a setup. After data entry is complete, press Enter.

The following options appear:

[Edit/Ok/Quit] <O>:

If you choose Edit, you will have the following options:

ADD/Change/Delete/eXit:

Add: Allows for addition observation data entry.

Change:

Allows editing of existing data. When selected a prompt for Enter observation to change will be displayed. Choose which observation number to edit. You will then be prompted with the initial input prompts for the observation again. The original input values will be the default values for each prompt. To change the value, simply enter new data.

Once Delete: This will delete the specified observation data. Choose the observation number to delete.

eXit: This exits the change routine.

If you type 0 and Enter or just enter for **OK**, the bearings from all the observations will be averaged and shown as well as the True Bearing. For example:

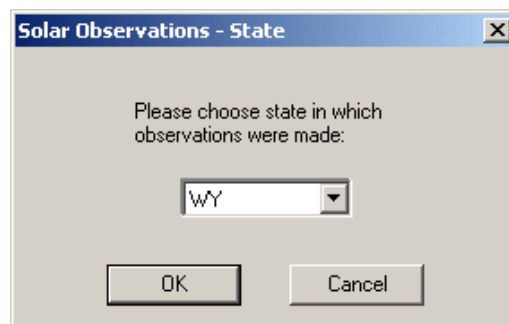

No. Time Angle-@-Mark Angle-to-Sun True-Brg-to-Mark

1 12.3030 0°00'00" 20°00'00" N 73°05'43"E
2 12.4456 0°00'00" 21°00'00" N 74°17'15"E
Average True Bearing: N 73°41'29"E

True North & Grid Bearing Prompts

Type of calculation [True-north/true-north-and-Grid-bearing] <T>: G

The following dialog will be displayed.

Select the state in which the observations were made. All fifty states are available, as well as PR for Puerto Rico and UTM for Universal Transverse Mercator.

If the state is divided into zones, you will be prompted for the zone you are working in.

Enter zone (N,S): Enter the zone.

If you are using a UTM , you will see the following prompt:

Enter ellipsoid to use [GRS-1980/Other] <G>:

Type "R" and Enter or just Enter for Reciprocal flattening, "S" and Enter for Semi-minor axis, or "E" and Enter for ellipsoid ECC squared.

if you typed O and Enter for **Other**, you will see the following prompt:

Ellipsoid constant [Reciprocal flattening/Semi-minor axis/ellipsoid ECC squared] <R>:

Depending on what was entered at the last prompt you will see one of the following prompts: **Enter reciprocal flattening constant:** Type the constant.

Enter semi-minor axis: Enter the axis.

Enter ellipsoid ECC squared constant: Enter the constant.

After entering the zone and ellipsoid information (if applicable) the date, latitude, longitude and time input loop will begin (as described above for the True North calculation).

After data entry is completed the **[Edit/Ok/Quit] <O>:** prompt will be displayed (see the True North section for more details on this prompt).

If you type 0 and Enter or just Enter for Ok, the information for all the observations is displayed along with the Average True Bearing, Average Grid Bearing and the Convergence Angle as follows:

No. Time Angle-@-Mark Angle-to-Sun True-Brg-to-Mark

1 12.2222 0°00'00" 20°00'00" N 72°57'31"E

2 12.4444 0°00'00" 22°00'00" N 74°20'51"E

Average True Bearing: N 73°39'11"E

Average Grid Bearing: N 72°15'12"E

Convergency Angle: 1°23'59"

Field Procedures for the Local Hour Angle (LHA) method

This section explains Universal Time and then explains two ways of pointing, Trailing Edge Tangency and Roelofs Prism.

Universal Time

The Universal Time can be obtained on certain radio bands. On the radio channel there will be a signal beep every minute. Set a watch to the Universal Time or, when in the field, start a stopwatch at the beep (for a known Universal Time).

In order for the solar observation method to produce accurate results, it is essential that you record the precise Universal Time for an observation. Thus, when making the field observations, record the stopwatch elapsed time in order to calculate the Universal Time or, if you set your watch to Universal Time, record the time directly.

Trailing Edge Tangency

While pointing at the ground mark, set the horizontal circle to read about 00-00-30, perfect pointing. With the scope direct, record the horizontal circle reading to the mark.

Attach the eyepiece filter and sight the sun. After locating the sun, do the following:

Set the horizontal reticle line near the center of the sun's image with the vertical reticle line leading the trailing edge of the sun (slightly right for a direct image).

Clamp the horizontal motion and watch the image of the sun as the trailing edge approaches tangency with the vertical reticle line.

Stop the timer at the time of tangency.

Record the time and the horizontal circle reading.

Repeat the pointing for a total of four pointings in the direct position.

Unclamp the horizontal motion, rotate the instrument 180 degrees, plunge the scope, and then obtain data for four reverse readings.

Unclamp the horizontal motion, point at the ground mark with the instrument reverse and record the horizontal circle.

The timer must be checked-in on a radio signal. Some quartz regulated electronic watches are accurate for extended periods of time, allowing several hours of check-in to check-out on the radio. Otherwise, most timers should be started and stopped on a radio signal at the beginning and ending of the observation set.

Roelofs Prism

Attach Roelofs prism and sight the sun (you can center the shadow of the telescope between the standards as an aid in locating the sun). Be sure that the hinged tube is closed when pointing at the sun. After locating the sun through the scope, do the following:

Rotate the prism until the four overlapping images of the sun are symmetrical with the instrument's reticle lines.

Point on the ground mark with the instrument direct and the Roelofs prism tube swung open, perfect pointing on the ground mark. Record the horizontal circle reading to the mark.

Point at the sun with the prism closed. After locating the sun, do the following:

Set the horizontal reticle line near the center of the sun's pattern with the vertical reticle line leading the center of the moving pattern (slightly to right of the sun for direct optics).

Clamp the horizontal motion and watch the pattern move to the point of coincidence. This is the intersection of the vertical reticle line with the apex of the small dark square formed in the center of the pattern by the overlapping parts of the four images formed of the sun.

Stop the timer at the moment of coincidence.

Record the time and the horizontal circle reading.

Repeat the pointing for a total of four readings in the direct position.

Unclamp the horizontal motion, rotate the instrument 180 degrees, plunge the scope, and then obtain data for four reverse readings.

Unclamp the horizontal motion, point on the ground mark with the instrument reversed and record the angle on the horizontal circle.

The timer must be checked-in on a radio signal. Some quartz regulated electronic watches are accurate for extended periods of time, allowing several hours of check-in to check-out on the radio. Otherwise, most timers should be started and stopped on a radio signal at the beginning and ending of the observation set.

Prerequisite: None

Triangle Solutions

Triangle Solutions solves for the remaining sides and angles of a triangle given the known side and angles. The upper case letters A, B and C represent the distances. The lower case letters a, b and c represent the angles. Distance A is the leg of the triangle opposite the angle 'a'. Likewise, distance B and C are the legs opposite the angles of 'b' and 'c', respectively. Enter any three known values of the six possible parameters and the three unknowns will be calculated and displayed. If you enter three angles, you will be shown proportional distances since there is an infinite number of distances that would solve a three angle triangle.

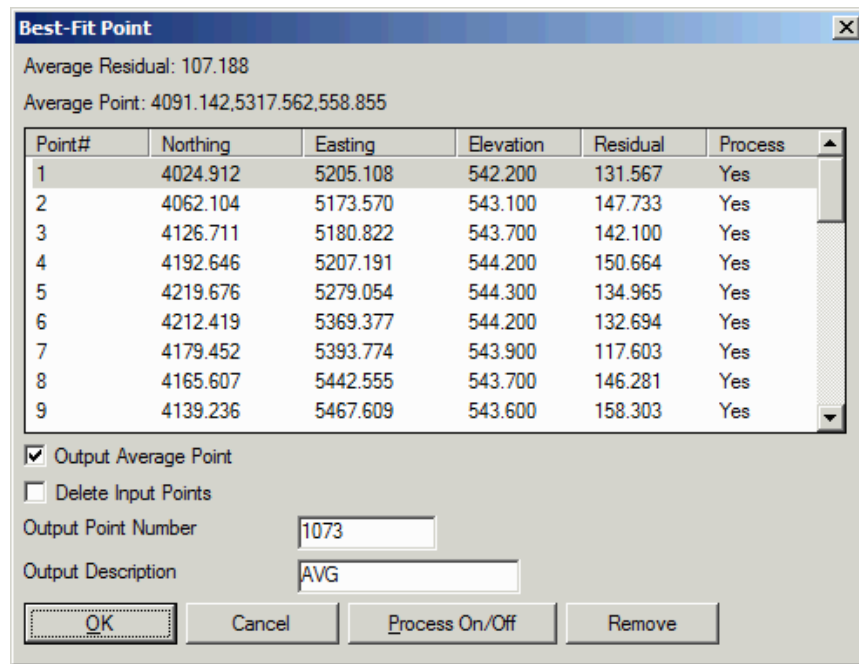

In this example, The sides A & B are known as is angle 'a'. After entering the three parameters, press the Solve button and the remaining three will be calculated and shown. The area in acres or hectares and feet or meters will also be calculated and shown. Press clear to enter data on a new triangle after the triangle has been solved. The solution for each triangle area is then displayed at the command line. You may press F2 to display the command line window and view the results

```
Side A Side B Side C Angle a Angle b Angle c
45.00 85.00 88.40 30°00'00" 70°48'43" 79°11'17"
Area = 1878.550 sq. ft. (0.043 acres)
```

Prerequisite: None

Best Fit Point

This command calculates the average point from a selection of input points and reports the residual statistics. The input points can be specified by point number, by point group or by screen selection. The program displays the input points with residuals in a dialog where you can toggle on/off whether to include points in the point average using the Process On/Off button. The Remove button removes a point from the average and the residual report. There is an option whether to output the average point to the current coordinate file. The option to delete all the input points applies when there are several points that are meant to be the same point and you want to replace them with a single averaged point. The command shows a report of the input points, residuals and average point.

Best Fit Circle

This command draws a least-squares best-fit circle based on points on the perimeter. The program handles four or more perimeter points. A design point for the circle center can optionally be specified as a reference to compare with the best-fit center in the report. The report shows the residuals for each point, the residuals standard deviation, the difference between the design point and the circle center, and the circle parameters. The residuals are calculated as the perpendicular distance from the point to the circle. The best-fit circle can be calculated in 2D or 3D. In 2D mode, the elevation of the points is not used. In 3D mode, a best-fit plane is calculated for the points. Then the points are projected onto the plane and the best-fit circle is calculated on this plane. Then the resulting circle

is projected back into world coordinates and drawn as a 3D polyline with short chords to represent the 3D circle since CAD doesn't support a 3D circle entity. Applications for 3D circles are tunnel sections and architectural arches.

After specifying the points, the program calculates the best-fit circle and shows the results in the dialog show here. You can toggle each point for whether to include in the calculations. You can also modify the radius.

Best Fit Centerline

This command processes a group of points to compute the best fitting centerline by least squares. The points can be input from Carlson points or from vertices of a polyline. For points input, the points can be selected by screen selection or point number range. Each line segment in the centerline is calculated by the best-fit line method and each arc segment is calculated by the best-fit arc method.

In the process options dialog, the **Snap Tolerance** is the max offset from the point to the line or arc segment in order to be counted as part of that segment. The **Polyline Layer** is used for the output polyline. The **Max Radius** controls the maximum radius for arc segments that the program will fit to the data. The **Create Tangents Only** option skips the step of calculating the best-fit arcs and outputs only the lines. Arcs can be added later using routines like Fit Curve in the Centerline Editor command. The **Make Curves Tangential** option fits the line and arc segments to be tangential. The **Remove Outliers** applies when the input data is noisy. This option will remove points that seem too far off the centerline to improve the centerline match with the remaining point. The **Min Points For Arc** setting controls how many points are required to calculate an arc. If this number is low that makes is more likely to create an arc where some points vary from linear but there really isn't meant to be an arc. If this number is high that makes is more possible to miss creating an arc in case the arc only has a few points on it.

The residual for each point is the perpendicular distance from the point to the best-fit centerline. The results are shown in a dialog and you can toggle each point for whether to include in the calculations. Points that are toggled off are not used for calculating the centerline but are still used in the residual report. The Remove function removes the point from both calculation and residual reporting.

Northing	Easting	Residual	Process

Best Fit Line by Average

This command will fit a line from a starting point by sampling a group of points. The routine averages the coordinates of the sampling group then draws the best-fit line. The program generates a report of the residuals, standard deviation, line bearing and line distance. The perpendicular distance from each point to the line is reported as the residual.

Best Fit Line by Least Squares

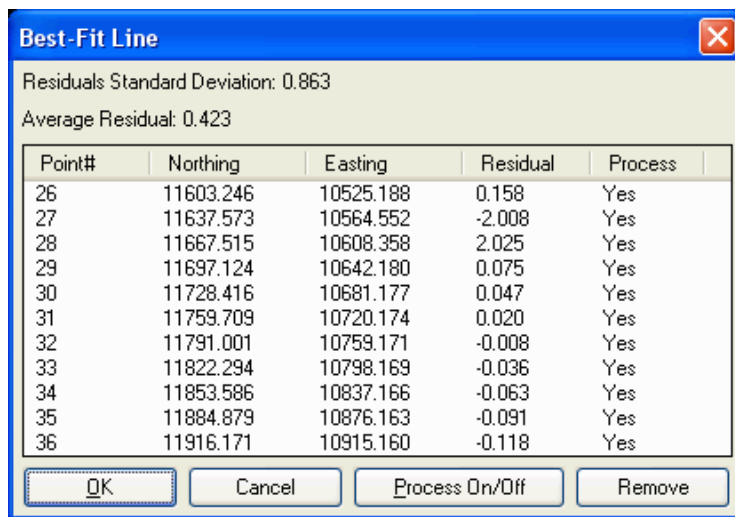

This command will process a group of points to compute the best fitting line by least squares. The points can be selected by screen selection of point entities, point number, point group name, screen pick or polyline vertices. The program can calculate either a 2D or 3D line. There are options to best fit with nothing held (None), to best fit by holding a point, and to best fit by holding a bearing. All three options are shown below in the graphic. When holding a point, you are prompted to enter the weight for the point. In this example, a weight of 1000 caused the line to pass to within 0.025 of point 111. With a weight of 5000, the line passed to within 0.005 of point 111. Increase the weight accordingly to obtain the desired precision. When holding a bearing such as N45E, you are prompted to enter the bearing in the form QDD.MMSS (e.g. 145.0000 or just 145). The program generates a standard report. The residual for each point is the perpendicular distance from the point to the best-fit line.

After specifying the points, the program calculates the best-fit line and shows the results in the image shown here. You can toggle each point for whether to include in the calculations. Points with Process set to No and not used for calculating the line but are still included in the report of residuals. Use the Remove button to remove a point both from calculation and reporting. Use the Add button to add another point into the calculations.

The Create Two Parallel Lines option applies when the points are for two line that are meant to be parallel such as a right-of-way. The program takes input for the distance between these two lines and then automatically sorts the points between the two lines, reports the residuals for the two lines and draws the two lines.

Point on Arc

This command locates a point on an arc. You can select an arc entity, an arc polyline segment or enter three points to define an arc. After the arc is defined, the screen preview arrow shows the occupied point and the distance to solve

for is entered. The command then displays the curve information and locates/inserts a point symbol at the computed point. When prompted for the distance, use a positive value if the distance is from the 1st endpoint (PC the one highlighted by the screen preview arrow) and a negative value if from the 2nd endpoint (PT).

Prompts

Define arc by, Points/<select arc or polyline>: *pick arc or polyline arc segment* Pick a point on the arc somewhere near it's midpoint. The preview arrow points to the 1st endpoint.

Precede distance with minus sign if distance from 2nd endpoint.

Distance along arc from 1st point: *100*

The command then plots a point at the computed distance.

If a positive distance is entered for the distance then the point is measured from the occupied point. If a negative value is entered the point is measured from the opposite endpoint of the arc.

Pulldown Menu Location: COGO > Interpolate Points

Keyboard Command: ptarc

Prerequisite: None

Divide Between Points

This command divides the distance between two points and inserts one of the point symbols at the specified distances. It can also interpolate elevations (to interpolate the elevations, the points picked must be at their real Z axis elevation).

Prompts

Keyboard Command: ptintpt

Prerequisite: None

Interval Along Entity

This command creates points at a specified distance along an entity such as a line, arc, spline or polyline. The points are listed out on the text screen, stored in the current coordinate (.CRD) file and drawn on the screen. For example, you might use this command to locate lot corner points along a frontage line. When Break Entity at Points is checked, the selected entity will be broken at every located point. The Create Points At Endpoints option locates points at the starting and ending points of the entity. When Create Point at Vertices is checked, points will also be located at each vertex of the selected entity. Horizontal Distance Between Points allow you to specify the distance between located points. There is also an option to create points on curved portions of the centerline at a different interval than on tangent portions (to reduce chord lengths, a shorter interval may be suitable for curves).

There is an option in this dialog allowing you to determine whether or not to label elevations on the new points. And for the purposes of describing the points, there is an option that allows you to set the same description to all of the points. For more options related to points, see *Point Defaults* under the Points pulldown.

Create Points from Entities

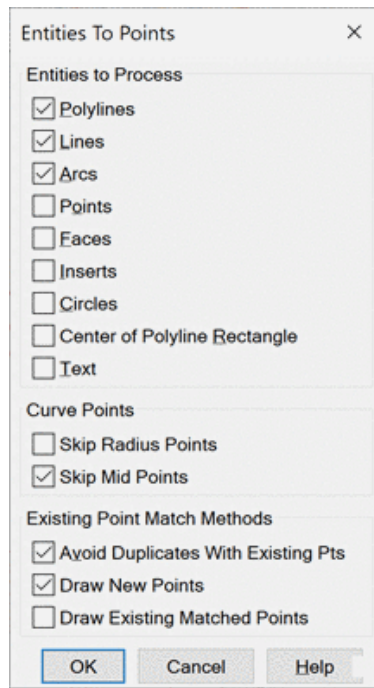

This command will create Carlson points on selected entities. The points are stored in the current coordinate (.CRD) file and drawn on the screen. For arcs and polylines with arc segments, points are created at the radius points of the

arcs as well as the PC and PT.

In the first options dialog, there are settings for the point attributes. To have points obtain their elevation from the selected entities, unselect the **Prompt for Elevations** toggle and select the **Locate on Real Z Axis** toggle. After you have specified the point options, a secondary dialog appears which allows you to specify the entity types to process. The **Point Order** setting controls the sequence of the new point numbers to be in the order of selection or in a direction like left to right. Under the **Description Settings**, **Prompt for Description At Each Point** will prompt you at the command line for a description for each individual point. **Prompt Per Entity** will ask you for a description per each highlighted entity. **Use Entity Layer for Description** will assign the layer name to the description. When Entity Layer for Description is checked, the layer name of the entity will be used as the description for the created point. **Same Description For All Points** will prompt you for a single description for all points. The **Use Text as Description** applies to points from Text entities where the description is set to the text string. The **Use Block Name as Description** applies to points from Insert entities and the program sets the point description to the block name.

The second options dialog has processing settings. When **Avoid Duplicates with Existing Pts** is checked, this routine will not create a point if a point with the same coordinates already exists in the current coordinate (.CRD) file. The **Draw New Points** option creates point entities in the drawing. Otherwise, the new points are only stored to the coordinate file. The **Draw Existing Matched Points** option applies to the Avoid Duplicates option for the case when a duplicate is found in the coordinate file and not yet drawn.

Offset Points By Interval

This command creates offset points along an alignment which can be used for creating curb stakeout points. The alignment can be defined by either a 2D polyline or a centerline file (.cl). The options dialog has three tabs for the General, Description and Draw settings.

Offset Distance: Sets the offset distance from the alignment to the points. Use a positive value for offset right and negative for offset left.

Reference Elevation: This setting controls the point elevations. The **3D Polyline** method prompts to select a 3D polyline. The offset points get the elevations from the position of the nearest perpendicular offset on the 3D polyline. The **Profile** method prompts to select a profile file. The stations of the profile must match the alignment stations. The **Constant** method sets the point elevations to a fixed elevation. The **Surface Model** method uses a triangulation (.tin) or grid (.grd) surface model file.

Delta Z: Adjusts the point elevations from the reference elevations.

Create Interval Points: Creates points along the alignment at the specified interval. There are separate intervals for line and curve segments.

Space Points Evenly: For each segment, this option figures how many points fit at the interval and then adjusts the interval to make that number of points evenly spaced. For example, if the interval is 10 and the segment length is 48, then 4 points fit and this option will space them at an interval of 12.

Create Vertex Points: Creates points offset from the points in the alignment.

Create Radius Points: Creates radius points for curve segments in the alignment.

Offset Side Only: Applies to radius points and only creates the radius point when it is on the same side of the alignment as the offset direction.

Max Radius: Applies to radius points to only create the radius point when the radius of the curve is less than this amount.

Create Only Radius Points on Small Curves: When the curve radius is less than the **Min Radius**, only the radius point is created and not the PC, PT or mid points.

Create Curve Midpoints: Creates a point midway along the curve when the curve length is greater than the specified **Min Curve Length**.

Minimum Deflection Angle: At an alignment vertex between two line segments, when the deflection between the line in and line out is greater than this value, only a single offset point is created. Otherwise two offset points are

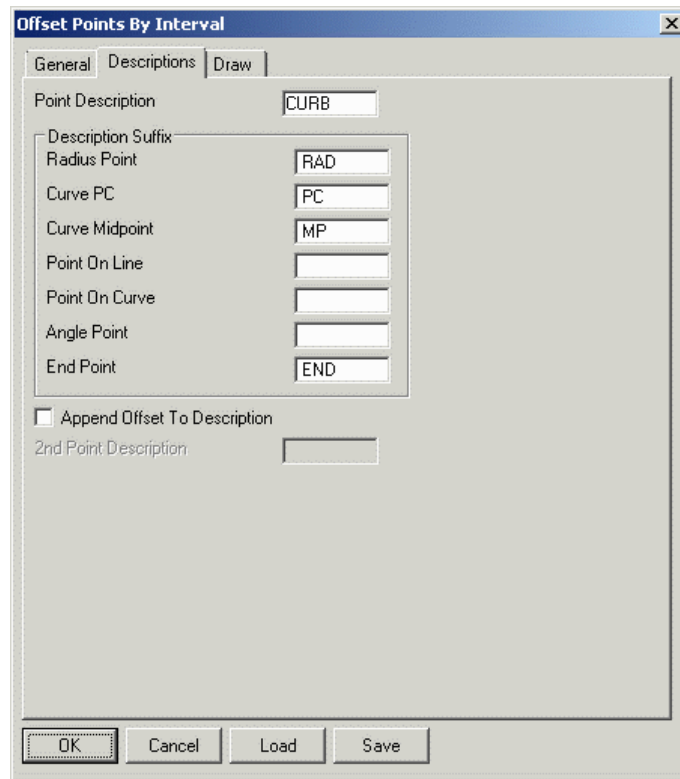

created, one for the line in and one for the line out. Set this value to 0 to always have only a single offset point. Set this value to 180 to always have two offset points.

Deflection Distance Tolerance: Sets how close together two offset points should be set on vertex deflection points. When the vertex point is set to get two offset points, but the offset points are within this tolerance of each other, then only a single offset point is created instead of two.

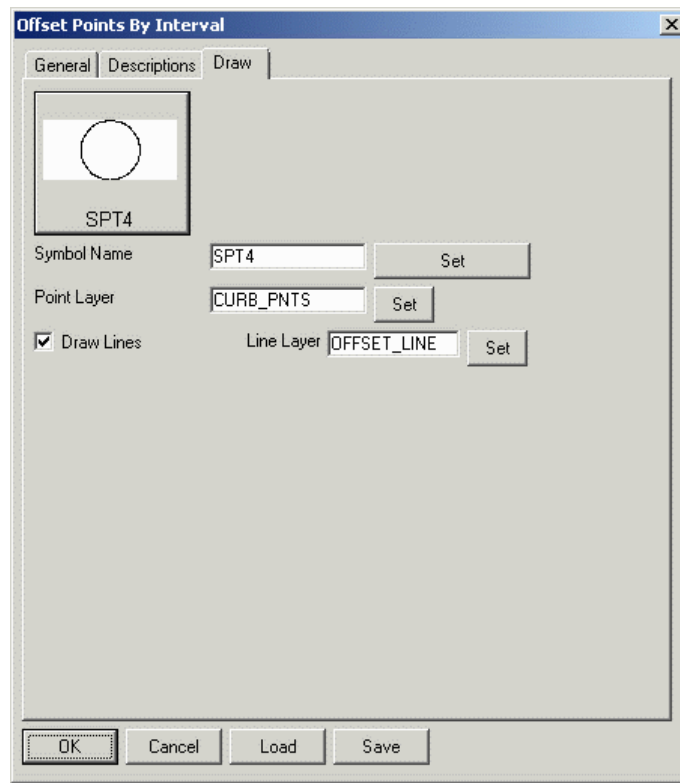

Starting Point Number: The new point numbers will increment starting from this number.

Point Group to Assign: Creates a point group for the new points created by this command.

Create 2nd Offsets: Creates a second set of points at the **2nd Offset Distance**.

The Description settings control the point descriptions for the various types of new points. The **Append Offset To Description** option adds the offset amount to the description of each point.

The Draw settings have the symbol and layer for the points. The **Draw Lines** option is for drawing lines between the alignment and the points.

Building Offset Extensions

This command is used to calculate building corner offset points that are extensions of the building faces. This command uses building perimeters that are drawn as closed polylines. The points are stored to the current coordinate file and drawn on the screen. There is a dialog for setting the parameters. The **Offset Amount** is the distance that the offsets are extended past the end of the building line. The **Starting Point Number** is the point number to begin storing from. The **Point Description** and **Elevation** are assigned to all the new points and the **Point Layer** is used for all the drawn points. The **Create Extension Points** controls whether offset points are created as extensions of the building lines at the corners. The **Create Perpendicular Points** applies to the extension points for creating a pair of perpendicular points at the corners. The **Create Diagonal Points** method creates points at the diagonals of corners. The **Create Across Building Points** creates points across to the other side of the building for inside corners. The **Create Envelope Points** calculates a rectangle that encloses the building and creates points at the four rectangle corners. The **Create Polyline Vertex Points** creates points at each vertex in the building perimeter. The **Create 2nd Offset** option makes a second point for each point at another offset and with another description.

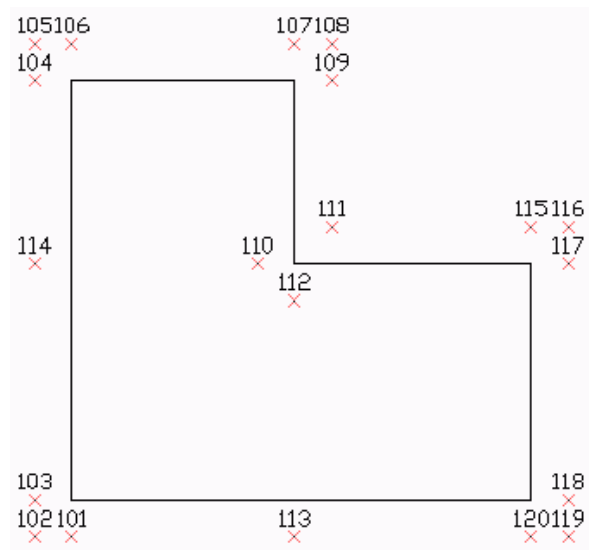

The screenshot shows the 'Building Offset Extensions' dialog box with the following settings:

- Offset Distance: 10.000
- Starting Point Number: 201
- Point Description: (empty)
- Point Elevation: 0.000
- Point Layer: BLDG_PNTS (with a 'Set' button)
- Create Extension Points
- Create Perpendicular Points
- Create Diagonal Points
- Create Across Building Points
- Create Envelope Points
- Create Polyline Vertex Points
- Create 2nd Offsets
- 2nd Offset Distance: 15.000
- 2nd Point Description: (empty)

Buttons at the bottom: OK, Cancel, Help.

In the first example shown here, Create Perpendicular Points is on. Points 101, 103, 104, 106, 107, 109, 110, 112, 115, 117, 118 and 120 are corner extension offset points. Points 102, 105, 108, 111, 116 and 119 are diagonal points. Points 113 and 114 are across building points.

In the second example, Create Perpendicular Points is off and the program only creates points on one side. Also on this example, the Create 2nd Offsets option is on.

Area/Layout Menu

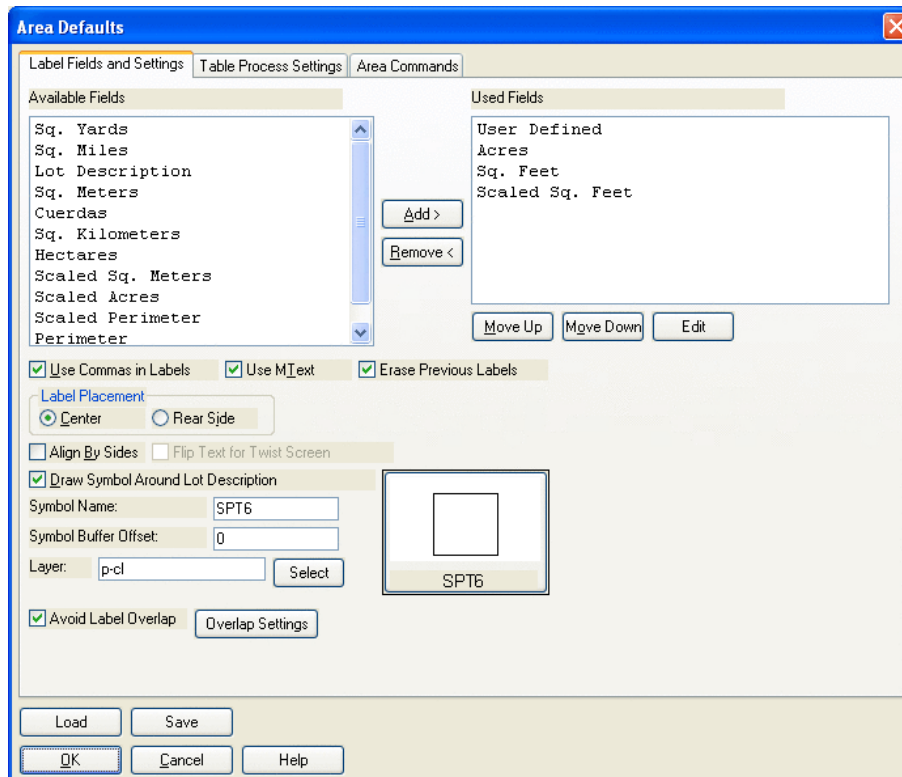

This chapter provides information on using the commands from the Area/Layout menu to calculate and label areas, and also to set and define lots. Commands for designing and drawing more complex configurations, such as cul-de-sacs and intersections, are available here as well.

Area Defaults

This command allows you to specify default settings for area labeling. The Area Defaults dialog is divided into 3 tabs. The first is the Label Fields and Settings tab. The top portion of the Label Fields and Settings tab contains two listboxes which are used to control which of the possible ten area fields will be used for area labeling. You use the Add and Remove buttons to control which fields will be included in area labels. You can also add to the Used Fields list by double-clicking on items in the Available Fields list. The area label will include the values in the order as specified in the Used Fields listbox. To change the order you use the Move Up and Move Down buttons.

When a grid projection is defined in Drawing Setup, the Available Fields will include geodetic areas where the areas are adjusted by the projection. The Base Z from Drawing Setup is used for the elevation factor for this adjustment.

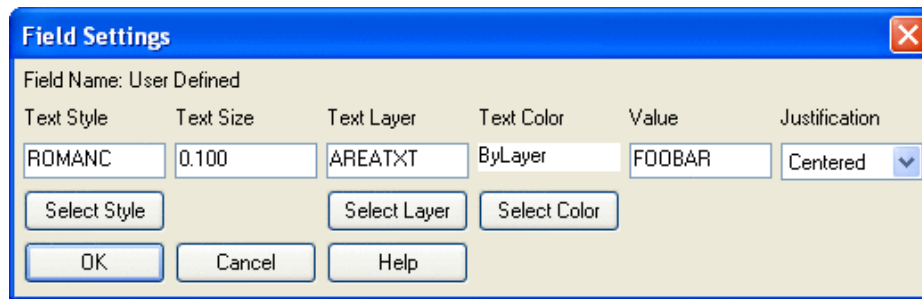

Field Settings Dialog: To control the appearance of the fields in the drawing, use the Edit button to edit the highlighted item in the Used Fields list, or double click on a field in the same list. This will call up the Field Settings Dialog.

User Defined: The Field "User Defined" can be added to place a custom fixed label in all areas. To control the value and appearance of the custom label in the drawing, use the Edit button to edit the "User Defined" item in the Used Fields list, or double click on a field in the same list. This will call up the Field Settings Dialog. In this case the "Value" setting becomes the custom label.

Scaled labels: The "Scaled Sq. Feet", "Scaled Sq. Meters", "Scaled Acres" and "Scaled Perimeter" fields can be used to include area labels that are scaled based on Drawing Setup "Report Scale Factor".

Text Style: This allows you to set a text style for the area labels. You can enter the name manually or use the Select Style button to call up a dialog which presents a list of known text styles.

Text Size: This value is multiplied by the horizontal scale to obtain the actual text size.

Text Layer: This allows you to assign a layer for the area text. You can enter the name manually or use the Select Layer button to call up a dialog which presents a list of known layers.

Text Color: This allows you to assign a color for the area text. Use the Select Color button to call up the standard color picker dialog. To use the default for the Text Layer, select ByLayer.

Prefix and Suffix: Although most area labeling uses the suffix, as in 1.25 Acres or 3.515 Hectares. But for those who prefer a prefix, as in Ac: 1.25, this routine can create that area labeling style automatically (see below for example of results of using a prefix with square feet and acres).

Justification: Use this to control whether the label field is left, centered or right justified.

+/-: This allows you to display + or - in the Prefix or Suffix of the area labels, or choose None.

Precision: Choose precision level for the currently selected field.

Below the Available and Used Fields lists the following items for further controlling area label generation:

Use Commas in Labels: This allows you to use commas in the area labels.

Use MText: Check this box to turn on the use of MText for area labels. If this is checked all area labels will be grouped into as few MText entities as possible. Area labels with different text styles, justification or layers will not be combined into the same MText entity.

Erase Previous Labels: When checked, previous area labels for the area being relabeled will be erased.

Label Placement: When auto placement of area labels is used, the labels can be placed either at the centroid of area or at the rear side. This is accomplished by selecting either the Center or Rear Side radio button, respectively. When Center is selected the user can choose to have the labels oriented according to the side lines of the area by checking the Align By Sides checkbox. When either Align By Sides or Rear Side is selected, the checkbox Flip Text for Twist Screen can be selected to have the label rotated 180 degrees to present it in the best reading orientation relative to the current Twist Screen rotation setting.

Draw Symbol Around Lot Description: When the Lot Description field is included in the Used Fields list, the user can check this checkbox to have a symbol drawn around the Lot Description field. When this box is checked, you specify the symbol name in the **Symbol Name** field or click on the current symbol (drawn to the right) to graphically choose the desired symbol. You specify the layer by entering the name in the **Layer** box or by clicking on the **Select** button to choose from a dialog that presents all known layers.

Symbol Buffer Offset: By default, the symbol will be automatically scaled according to the text length and size of the Lot Description value for the area. For additional control of symbol scaling, the user can enter a number in text size units in the Symbol Buffer Offset box. This value will be added to the automatically generated default scaling value.

Avoid Label Overlap: If this box is checked the area labels will be checked for overlaps after they are generated. Please see the Overlap Manager documentation for more information.

Overlap Settings: Click this button to go to the Avoid Label Overlaps dialog where you can review or modify the Overlap Manager settings. Please see the Overlap Manager documentation for more information.

Table Process Settings Tab:

Use Area Tables: Use this control to determine whether area labels are sent to a table or not. Options are "Never", "Always", "By Scaler" or "Both". The By Scaler method uses the area table for areas less than the specified To Table Area. The Both method creates a table and also draws the labels within the area.

To Table Area: When the user has selected "By Scaler" in the "Use Area Tables" list this item is enabled. When "By Scaler" is selected and the area is less than this minimum, the area label is sent to a table.

Area Reference Numbering: There are three different methods for setting the reference number: **Next Available** will automatically use the lowest available number. **Specified With Prompt** will prompt you for a number for each area. **Specified with Auto Numbering** will automatically use the lowest available number starting with the specified number.

Auto Place Table References: When checked, will automatically place the area reference label according to the settings for the area labels as specified in the Label Field and Settings tab (see above). Otherwise you will be prompted to pick each label location manually.

Area Commands Tab:

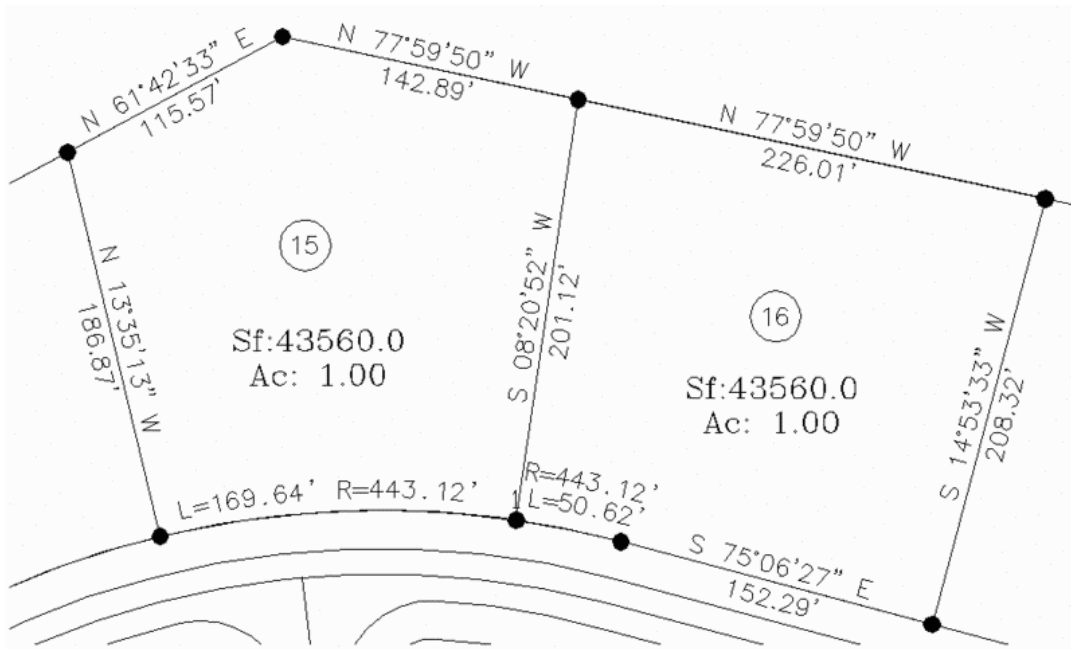

Max gap to join: You use this option during *Area by Lines & Arcs* command. When connecting lines and arcs that define the perimeter, the program will join endpoints if the distance between the two points is less than the specified gap. Otherwise the program will report an error and will not report an area.

Prompt whether to retain polylines created by Area by Interior Point: When checked the user will be asked whether to retain the polylines created by the "Area by Interior Point" command.

Polyline Layer: Will be enabled when "Prompt whether to retain polylines created by Area by Interior Point" is checked to allow the user to select the layer that any such created polylines will be placed in.

Load/Save: These buttons save and recall all the Area Default settings to a .ARS settings file.

Tip: Keep in mind that changes in Area Defaults, if changed from the Area/Layout pulldown menu, only apply to that work session. If changed within the Configure command, the changes apply to all new work sessions as well.

The results of using a prefix with square feet and acres

Pull-down Menu Location: Area/Layout

Keyboard Command: defarea

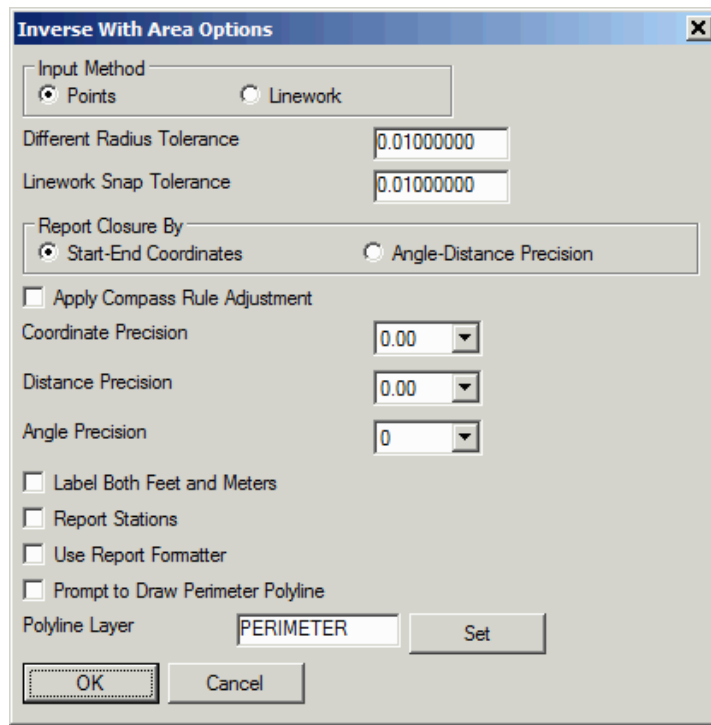

Prerequisite: None

Inverse with Area

This command generates a report of the angle and horizontal distance between a series of points and calculates the area of the closed figure defined by the points. The points can be entered individually or by selecting a point group or linework entities. To use a point group, type G for Group at the first prompt. To use a linework, type L for Line at the first prompt. For linework, a single closed polyline can be used or a series of connected lines, arcs and polylines that are selected one at a time.

Curve data can also be entered and reported. The points can be either picked on the screen, or entered by point number. You can also enter a range of point numbers (i.e. 1-9). The closure is reported using the total distance inversed, and the difference between the starting and ending points, as the closure error.

At the first command prompt, you can enter O for Options to bring up the command options. The **Input Method** determines the default input mode for the first command prompt. The **Different Radius Tolerance** checks that the distance between the PC and radius point and the PT and radius point match for curves. The **Linework Snap Tolerance** applies to the linework input mode and is used to check the distance between end points when connecting two linework entities. The Report Closed By choosing between using the difference between the starting and ending coordinates to calculate the closure error or angle and distance values in the report. The **Apply Compass Rule Adjustment** will adjust the perimeter as a closed loop for the closure error. The **Label Both Feet And Meters** is an option to report the distances in both feet and meters. The **Report Stations** option adds stations for each point into the report. The **Use Report Formatter** chooses between the standard report or customizing the report. You can also set the decimal precisions for the report and whether to report stations for the distances along the perimeter. This command creates a polyline of the figure which can be erased or kept in the drawing. The **Prompt To Draw Perimeter Polyline** and **Polyline Layer** settings apply to this polyline.

The area can be labeled in the drawing using the settings from the *Area Defaults* command. If you don't want to label the area, press Enter at the pick label point prompt.

AREA: 74664.6 SQ METERS

Pulldown Menu Location: Area/Layout

Keyboard Command: ia

Prerequisite: None

Area by Lines & Arcs

This command allows you to calculate the area of a perimeter or lot defined by lines, arcs, or polylines. Default settings for this command are set in *Area Defaults*. One of these settings is Max gap to join. If there is a gap greater than this value, the area is not reported, and the program will show where the gap is with a temporary X symbol. The area data shows up on the text screen. You can then choose to plot the area information to the drawing, or, by hitting *Enter*, just read it from the text screen.

Prompts

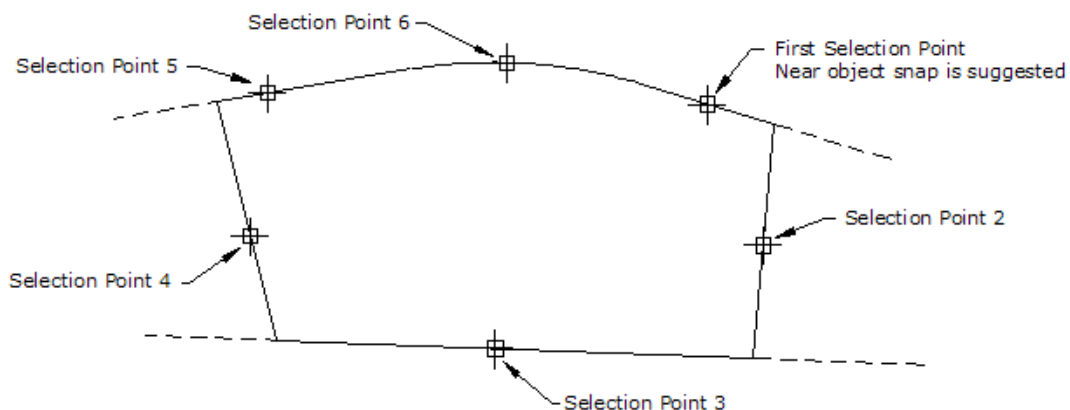

Select lines & arcs or polylines of perimeter for area calculation.

Select Objects: *select lines and arcs or polylines*

Lines and arcs are then joined together and the area calculated.

Pick area label centering point (Enter for none): *pick a point*

The area is then plotted at the point selected.

Pulldown Menu Location: Area/Layout
Keyboard Command: joinarea
Prerequisite: Lines, arcs, or polylines to define the area

Area by Interior Point

This command calculates and labels the area of the perimeter surrounding a picked interior point. The *Boundary Polyline* command is used to find the perimeter. Generally, this command will only work on closed or overlapping objects. Use *Area by Lines & Arcs* for other applications. The settings for the area label and for whether to prompt to create a closed polyline for the area are under the *Area Defaults* command.

Prompts

Pick point inside area perimeter: *pick a point*

Pick area label centering point (Enter for none): *pick a point*

The area is then plotted at the point selected.

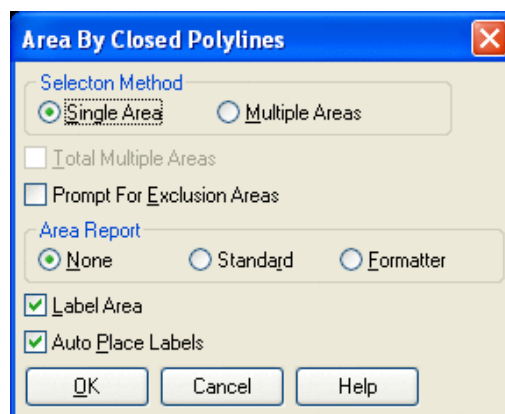

Pulldown Menu Location: Area/Layout

Keyboard Command: ptaarea

Prerequisite: Set Area Defaults

Area by Closed Polylines

This command will calculate and report the area of single area and multiple area closed polylines. In the case of multiple areas, the user can choose to have the areas totaled (**Total Multiple Areas**) into a single result or to generate data for each area separately. Area by Closed Polyline will also automatically find special Carlson attributes attached to the polyline, in addition to capturing the area itself. These attributes will appear in the report, which can be the standard report or which can be presented in the Report Formatter, which itself links to Excel and Access. For example, property names and owner names, as applied to a polyline using the Mine modules, will report out automatically using Area by Closed Polyline. The command "Draw Lots from File..." will apply "extended entity data" to the lot polylines, which includes the lot name, and this will also report out when using Area by Closed Polyline. In addition, lot names, or any interior text whatsoever, can be captured and included in the report. The plot of the area on-screen can be canceled if only the report is desired.

Prompts

Select Area Polyline: *select the area polyline*

SQ. FEET: 64862.9 SQ. YARDS: 7207.0 SQ. MILES: 0.0

ACRES: 1.5 PERIMETER: 1018.7

Pick area label centering point (Enter for none): *pick a location*

When auto-placing labels at the rear of lots or when aligning labels by the sides of the lot the user will also be prompted to pick one or more centerlines (**Select the Centerline Polyline**s). The routine will find the closest centerline and use this to determine the location of the front and back corners of the area.

When additional interior text is selected, the standard report will include that text:

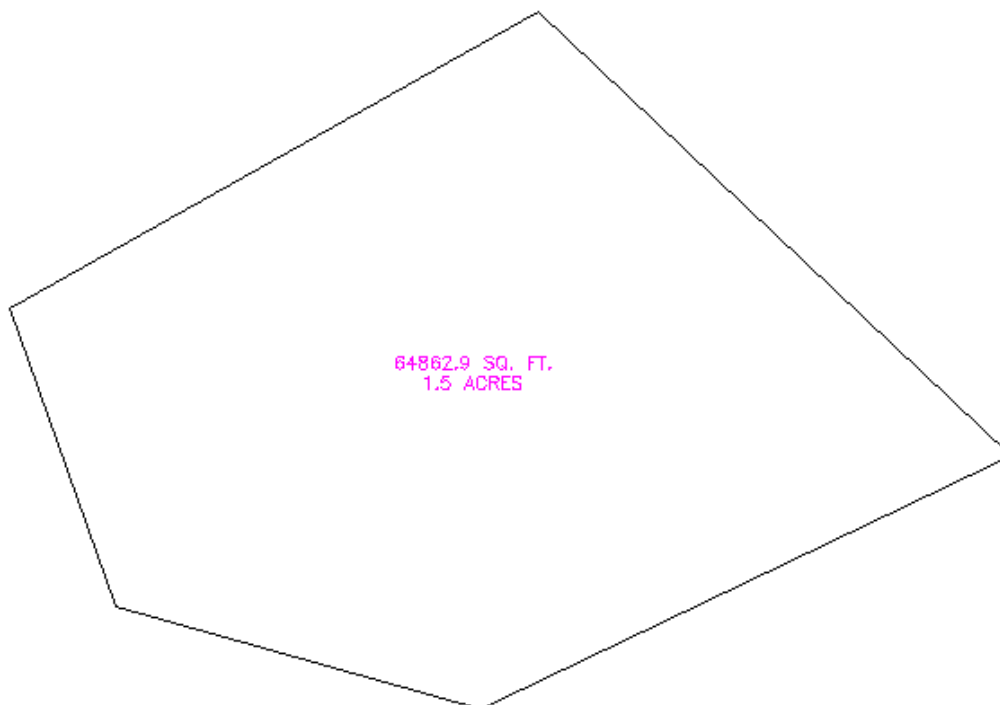

Polyline Area 11/17/2004 12:49

Polyline Area: 43560.0 sq ft, 1.00 acres

Polyline Perimeter: 838.35 ft

Text: 16 Sf: 43560.0; Ac: 1.00

In this case, the "16" refers to Lot 16, and appears in the report because the lot number and existing area labeling were selected along with the polyline for the lot.

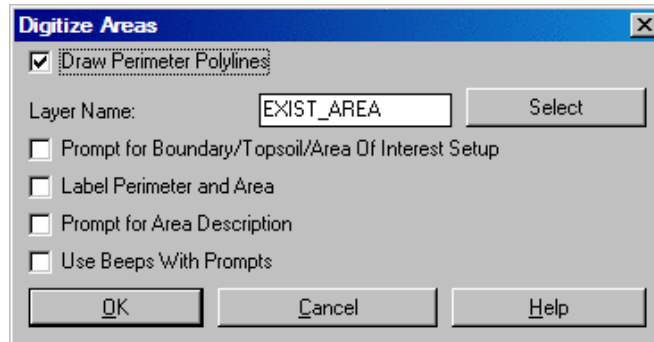

Pulldown Menu Location: Area/Layout

Keyboard Command: plarea
Prerequisite: Set Area Label Defaults

Digitize Areas

This command allows for digitizing areas. This routine includes an option for drawing perimeter polylines.

Pulldown Menu Location: Area/Layout
Keyboard Command: dig_area
Prerequisite: A digitizer

Label Last Area

This command will label the last area calculated with one of the Area commands in the manner defined in the *Area Defaults* dialog. The command prompts for a point where the label will be centered.

Prompts

SQ. FEET: 50265.3 SQ. YARDS: 5585.0 SQ. MILES: 0.0
ACRES: 1.2 PERIMETER: 889.4
Lot Description <2>: 1
Pick area label centering point (Enter for none): *pick a point*

Pulldown Menu Location: Area/Layout
Keyboard Command: lastarea

Prerequisite: Set *Area Defaults*, and use one of the Area commands to calculate an area.

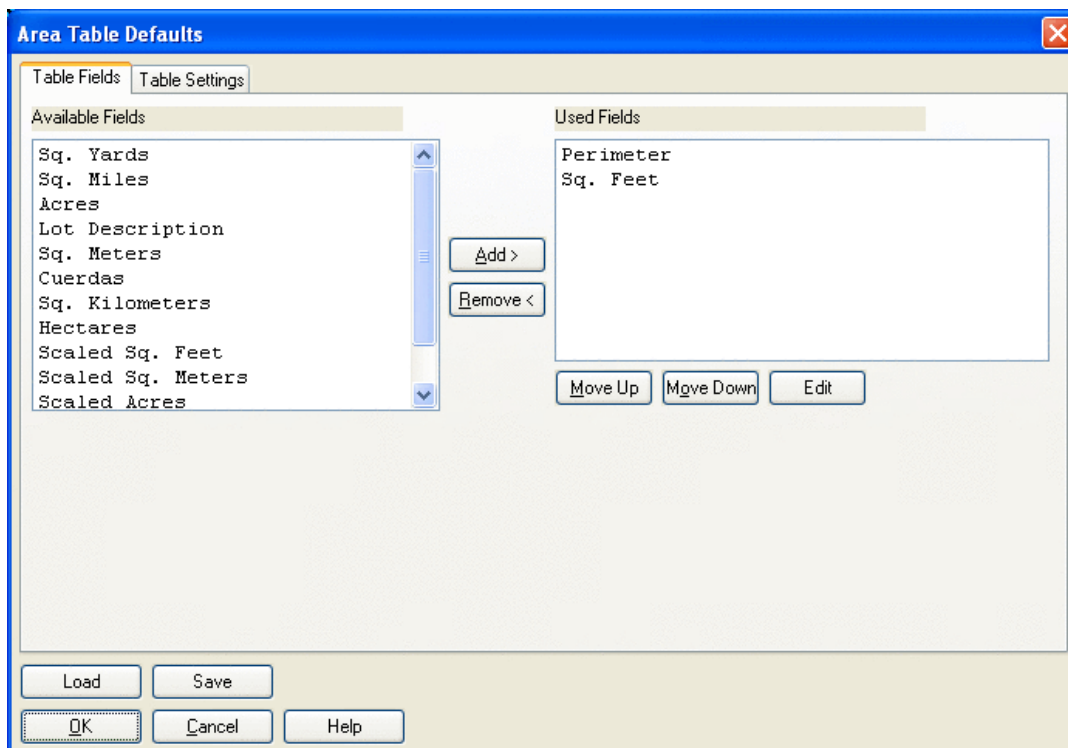

Area Table Defaults

This command allows you to specify table fields and format settings for area tables. Whether the Area Commands create an area table or label within the area is controlled by the Area Defaults command by the Use Area Tables setting. With the Area Defaults and Area Table Settings prepared, the various Area Commands will create tables according to the settings. When the Area By Closed Polyline routine is used to create the area table and the Link Linework With Labels option is on under Configure Carlson->General Settings, then the area table values are automatically updated when the polyline geometry is modified. Also, when using the Area By Closed Polyline command with the Lot Description field active for the table, the program prompts for an area description for each polyline. The rest of the area table fields are calculated from the polyline geometry.

Area	Perimeter	Sq. Feet	Acres	Lot Description
A1	574.43	20212.71	0.46	Park
A2	835.85	41989.21	0.96	Lot 404
A3	910.72	50710.66	1.16	Lot 405

The Area Table Defaults dialog is divided into 2 tabs. The **Table Fields** tab brings up the Table Settings panel shown below. The area table option puts the area data in a table that is typically drawn outside the area and contains area data for multiple areas. Each row in the table has the data for one area and includes a reference number. The reference number is also labeled inside the area.

The **Table Fields** tab contains two listboxes which are used to control which of the area fields will appear in any table rows that are generated for areas. You use the Add and Remove buttons to control which fields will be included in area tables. You can also add to the Used Fields list by double-clicking on items in the Available Fields list. The area table will include the values in the order as specified in the Used Fields listbox. To change the order you use the Move Up and Move Down buttons.

Field Settings Dialog: To control the appearance of the fields in the table, use the Edit button to edit the highlighted item in the Used Fields list, or double click on a field in the same list. This will call up the Field Settings Dialog.

Column Title: This will be the tile name used for the field's column in the area table.

Text Style: This allows you to set a text style for the area labels. You can enter the name manually or use the Select Style button to call up a dialog which presents a list of known text styles.

Text Size: This value is multiplied by the horizontal scale to obtain the actual text size.

Text Layer: This allows you to assign a layer for the area text. You can enter the name manually or use the Select Layer button to call up a dialog which presents a list of known layers.

Text Color: This allows you to assign a color for the area text. Use the Select Color button to call up the standard color picker dialog. To use the default for the Text Layer, select ByLayer.

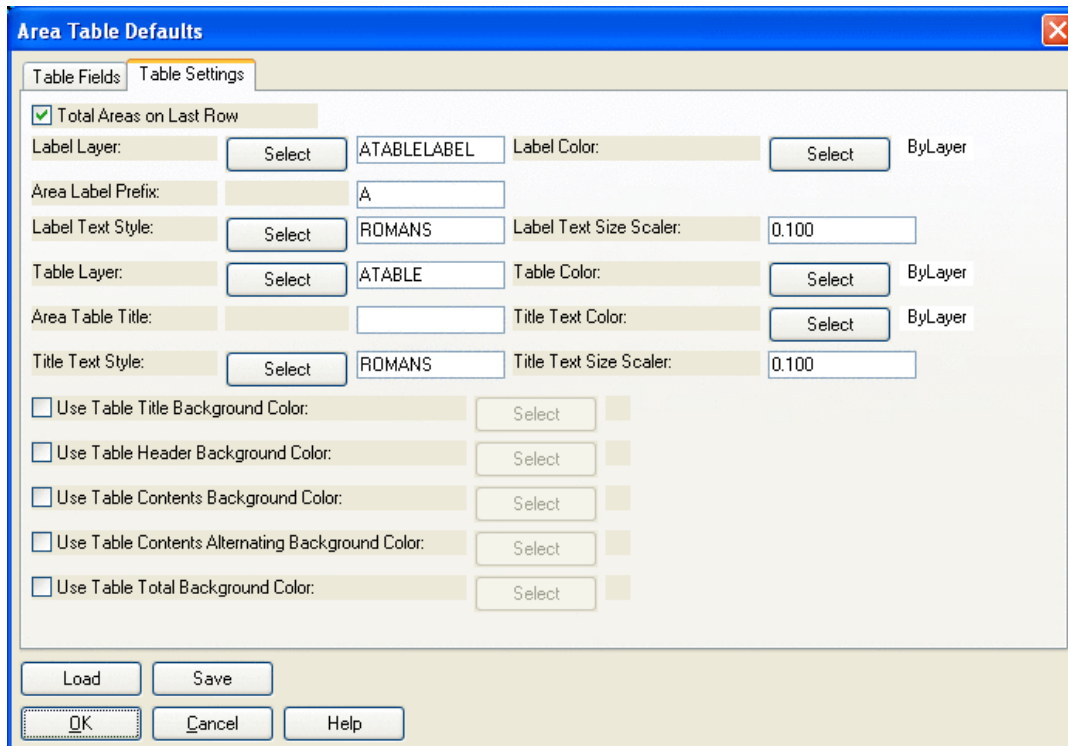

Prefix and Suffix: Although most area labeling uses the suffix, as in 1.25 Acres or 3.515 Hectares. But for those who prefer a prefix, as in Ac: 1.25, this routine can create that area labeling style automatically.

Justification: Use this to control whether the label field is left, centered or right justified.

+/-: This allows you to display + or - in the Prefix or Suffix of the area labels, or choose None.

Precision: Choose precision level for the currently selected field.

Column Width/Auto: The default behavior is that the column width is automatically set for best fit. The user can override this value by unchecking the Auto checkbox and setting the column with in text size units.

The **Table Settings** tab brings up the Table Settings panel shown above. The area table option puts the area data in a table that is typically drawn outside the area and contains area data for multiple areas. Each row in the table has the data for one area and includes a reference number. The reference number is also labeled inside the area.

Table Parameters:

Total Area on Last Row: Select this to have a total row placed at the bottom of the table which will contain the sum of all relevant table fields.

Label Layer: Use this to control the layer that the area table reference will be placed in. Use the **Select** button to pick from a list of all known layers.

Label Color: Use this to control the color of the area table reference. Use the **Select** button to pick from a color picker dialog. Select **ByLayer** to use the default color of the label layer.

Area Label Prefix: Use this to control the prefix of the area table references. Add a space after the prefix to have the prefix and the reference number separated by a space if desired.

Label Text Style: Use this to set the text style of the area table reference. Use the **Select** button to pick from a list of all known text styles.

Table Layer: This allows the user to set the layer that the table will be placed in. Use the **Select** button to pick from a list of all known layers.

Table Color: This allow the user to set the color of the grid lines of the table. Use the **Select** button to pick from a color picker dialog. Select **ByLayer** to use the default color of the table layer.

Area Table Title: To add a title row as the first row of the area table, enter a table title here.

Title Text Color: This allow the user to set the color of the table title. Use the **Select** button to pick from a color picker dialog. Select **ByLayer** to use the default color of the table layer.

Title Text Style: Use this to set the text style of the table title. Use the **Select** button to pick from a list of all known text styles.

Title Text Size: Use this to control the size of the table title text.

Background Colors: The area table is broken into 5 zones in respect to background color. Each zone can have its

own unique background color. The zones are Title, Header, Contents1, Contents2 and Total. To set a background color for each zone, first the respective "Use Table...Background Color" box must be checked. This enables the **Select** button, which is used to pick the respective background color from a color picker dialog. For the Contents zone all contents rows can either have the same background color, or by setting up an "Alternating Background Color", rows will have alternating colors.

Pulldown Menu Location: Area/Layout->Area Tables

Keyboard Command: defatab

Prerequisite: None

New Area Table

This command draws the column header labels for the Area Table commands. When prompted for the starting point, the user may enter a coordinate or pick a point on the screen. This table becomes the active area table. Any new area table entries will be added to this table until another table is created or the active table is changed with the atabset command (menu item Area/Layout> Area Tables> Set Active Table).

Area	Perimeter	Sq. Feet	Acres	Lot Description
------	-----------	----------	-------	-----------------

Prompts

Starting point of area table: *pick point*

Pulldown Menu Location: Area/Layout> Area Tables> Create New Table

Keyboard Command: atabnew **Prerequisite:** None

Set Active Area Table

This command allows the user to change the active area table. The table selected becomes the active area table. Any new area table entries will be added to this table until another table is created or the active table is changed with another invocation of this command.

Prompts

Select active Table: *pick area table*

Pulldown Menu Location: Area/Layout> Area Tables> Set Active Table

Keyboard Command: atabset

Prerequisite: None

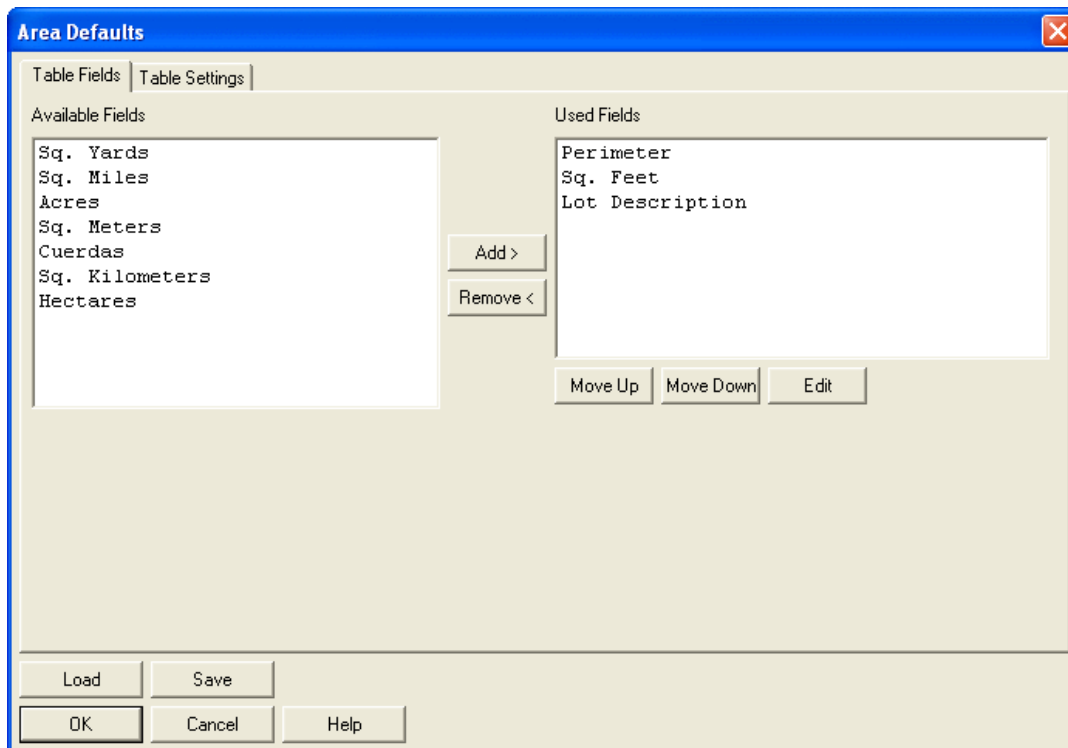

Edit Area Table Properties

This command allows the user to edit the properties of an area table.

Prompts

Select an area table to modify: *pick an area table*

After picking an area table the Area Defaults dialog will be displayed. Here you can change the settings of the selected table. The changes will be reflected once the user selects the OK button.

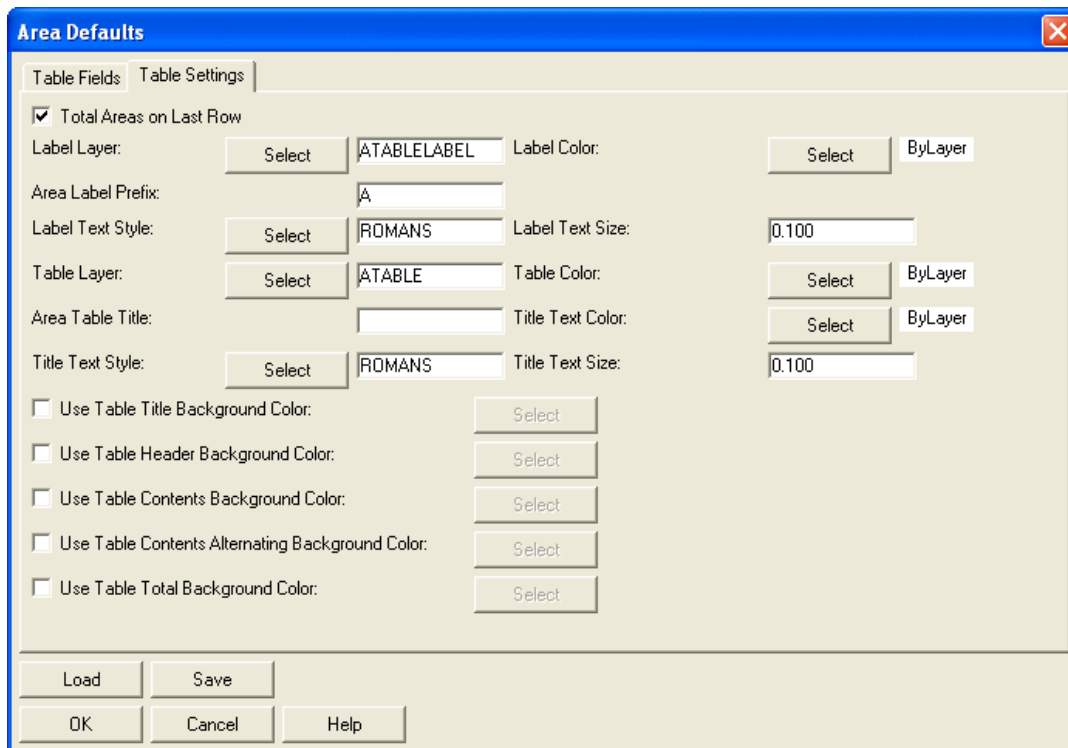

The Table Fields tab contains the Available Fields and Used Fields listboxes which are used to control which of the possible ten area fields will be used in the area table. You use the Add and Remove buttons to control which fields will be included in the table. You can also add to the Used Fields list by double-clicking on items in the Available Fields list. The area label will include the values in the order as specified in the Used Fields listbox. To change the order you use the Move Up and Move Down buttons.

Field Settings Dialog: To control the appearance of the fields in the table, use the Edit button to edit the highlighted item in the Used Fields list, or double click on a field in the same list. This will call up the Field Settings Dialog.

- Column Title:** This will be the tile name used for the field's column in the area table.
- Text Style:** This allows you to set a text style for the area labels. You can enter the name manually or use the Select Style button to call up a dialog which presents a list of known text styles.
- Text Size:** This value is multiplied by the horizontal scale to obtain the actual text size.
- Text Layer:** This allows you to assign a layer for the area text. You can enter the name manually or use the Select Layer button to call up a dialog which presents a list of known layers.
- Text Color:** This allows you to assign a color for the area text. Use the Select Color button to call up the standard color picker dialog. To use the default for the Text Layer, select ByLayer.
- Prefix and Suffix:** Although most area labeling uses the suffix, as in 1.25 Acres or 3.515 Hectares. But for those who prefer a prefix, as in Ac: 1.25, this routine can create that area labeling style automatically.
- Justification:** Use this to control whether the label field is left, centered or right justified.
- +/-:** This allows you to display + or - in the Prefix or Suffix of the area labels, or choose None.
- Precision:** Choose precision level for the currently selected field.
- Column Width/Auto:** The default behavior is that the column width is automatically set for best fit. The user can override this value by unchecking the Auto checkbox and setting the column with in text size units.

The **Table Settings** tab brings up the Table Settings panel shown below.

Total Area on Last Row: Select this to have a total row placed at the bottom of the table which will contain the sum of all relevant table fields.

Label Layer: Use this to control the layer that the area table reference will be placed in. Use the **Select** button to pick from a list of all known layers.

Area Label Prefix: Use this to control the prefix of the area table references. Add a space after the prefix to have the prefix and the reference number separated by a space if desired.

Label Text Style: Use this to set the text style of the area table reference. Use the **Select** button to pick from a list of all known text styles.

Table Layer: This allows the user to set the layer that the table will be placed in. Use the **Select** button to pick from a list of all known layers.

Table Color: This allow the user to set the color of the grid lines of the table. Use the **Select** button to pick from a color picker dialog. Select ByLayer to use the default color of the table layer.

Area Table Title: To add a title row as the first row of the area table, enter a table title here.

Title Text Color: This allow the user to set the color of the table title. Use the **Select** button to pick from a color picker dialog. Select ByLayer to use the default color of the table layer.

Title Text Style: Use this to set the text style of the table title. Use the **Select** button to pick from a list of all known text styles.

Title Text Size: Use this to control the size of the table title text.

Background Colors: The area table is broken into 5 zones in respect to background color. Each zone can have its own unique background color. The zones are Title, Header, Contents1, Contents2 and Total. To set a background color for each zone, first the respective "Use Table...Background Color" box must be checked. This enables the **Select** button, which is used to pick the respective background color from a color picker dialog. For the Contents zone all contents rows can either have the same background color, or by setting up an "Alternating Background Color", rows will have alternating colors.

Load/Save: These buttons save and recall all the Area Default settings to a .ARS settings file.

Tip: Keep in mind that changes made here only apply to the selected table. If properties are changed within the Configure command, the changes apply to all new work sessions as well

Pulldown Menu Location: Area/Layout> Area Tables> Edit Properties

Keyboard Command: atabedit

Prerequisite: An area table

Remove Area Table Rows

This command allows the user to remove rows from an area table. The routine will remove both the table row and the table reference label from the drawing.

Prompts

Select a table row to delete: *pick area table row*

Consolidate table [<Yes>/No]? If consolidation is chosen, row numbers will be renumbered to close up the gap created by this deletion. Consolidation will also update all relevant area table references in the drawing. If the user chooses not to consolidate the table at this time, the atabfix command (menu item Area/Layout> Area Tables> Consolidate Table) can be used at any time to perform consolidation.

Area	Perimeter	Sq. Feet
A1	470.70	9157.63
A2	629.20	15572.47
A3	542.18	16810.50
Total		41540.60

The drawing above shows the table before row removal. In the drawing below, row 2 has been deleted without table consolidation.

Area	Perimeter	Sq. Feet
A1	470.70	9157.63
A3	542.18	16810.50
Total		25968.13

The drawing below shows the results of deleting the same row 2, only this time the user has chosen to perform table consolidation.

Area	Perimeter	Sq. Feet
A1	470.70	9157.63
A2	542.18	16810.50
Total		25968.13

Pulldown Menu Location: Area/Layout> Area Tables> Remove Row

Keyboard Command: atabel

Prerequisite: None

Consolidate Area Table

This command allows the user to renumber area tables to eliminate numbering gaps left as the result of row deletions or other means.

Prompts

Select a table to consolidate:: *pick area table*

Row numbers will be renumbered to close up the gaps in the selected area table. Consolidation will also update all relevant area table references in the drawing.

Area	Perimeter	Sq. Feet
A1	470.70	9157.63
A3	542.18	16810.50
Total		25968.13

The drawing above shows the table before row removal. The drawing below shows the results of consolidating this table.

Area	Perimeter	Sq. Feet
A1	470.70	9157.63
A2	542.18	16810.50
Total		25968.13

Pulldown Menu Location: Area/Layout> Area Tables> Consolidate Table

Keyboard Command: atabfix

Prerequisite: None

Tag Area Descriptions

This command is used to assign a description to a closed polyline. The description is stored with the polyline in the drawing. This description is used for reports in routines like Area By Closed Polyline.

Prompts

Select polyline for area description: *pick a polyline*

Area description <AREA1>: *West Pond*

Pulldown Menu Location: Area/Layout > Area Descriptions

Keyboard Command: tag_area_desc

Prerequisite: A closed polyline.

Identify Area Descriptions

This command reports area descriptions for the selected polylines. There are two methods. The Pick method reports the area description for one selected polyline at a time. The Search method scans the whole drawing and highlights polylines with area descriptions.

Prompts

Pick polylines to check or search drawing [<Pick>/Search]: *press Enter*

Select area description polyline: *pick a polyline*

Description: West Pond

Select area description polyline (Enter to end): *press Enter*

Pulldown Menu Location: Area/Layout > Area Descriptions

Keyboard Command: id_area_desc

Prerequisite: A polyline with a tagged area description.

Untag Area Descriptions

This command removes an area description that has been assigned to a polyline.

Prompts

Select polylines to remove area description from.

Select entities: *pick area polylines*

Cleared 10 area descriptions.

Pulldown Menu Location: Area/Layout > Area Descriptions

Keyboard Command: untag_area_desc

Prerequisite: A polyline with a tagged description.

Area Descriptions By Interior Text

This command is used to assign a description to a closed polyline. The description is stored with the polyline in the drawing. This description is used for reports in routines like Area By Closed Polyline.

The program prompts to select closed polylines and text. For each closed polyline, the program looks for a text label inside the polyline and assigns that text as the description for the polyline.

Prompts

Select area polylines and text.

Select objects: *pick a polyline and text*

Pulldown Menu Location: Area/Layout > Area Descriptions

Keyboard Command: area_desc_text

Prerequisite: Text and closed polyline

Hinged Area

This command can be used to determine the dimensions of a figure when the area is fixed and three or more sides are known. The figure can be defined by a closed polyline or by picking the known points and curves. The command then prompts for the area to be solved for (in square units and acres).

Prompts

Define area by points or closed polyline [Points/<Linework>]? press Enter

Select polyline segment to adjust: *select a polyline segment*

Select hinge point [endp]: Move the cursor around to find a hinge point.

Keep existing polyline [Yes/<No>]? N

Area: 47104.31 S.F, 1.0814 Acres

Remainder/Acres/<Enter target area (s.f.)>: 48000

Polyline method

Pulldown Menu Location: Area/Layout

Keyboard Command: harea

Prerequisite: A closed polyline or at least one known side. Two direction lines should be drawn.

Sliding Side Area

This command adjusts one side of a polyline to meet a specified area. The existing area can be defined by a closed polyline or by picking each point in the perimeter. The desired area can be entered in either square feet or acres. The area to adjust must be represented by a closed polyline. The program moves the selected segment of the polyline in or out. There are a few methods for defining the direction of the adjusted segment. With the Selected method, the original direction of the segment is maintained. The Line method prompts to pick another line segment to define the direction. The Angle method uses an entered angle for the direction. The Points method prompts for two points to define the direction.

Prompts

Define area by points or closed polyline [Points/<Linework>]? press Enter

Select polyline segment to adjust: *pick a point on a closed polyline*

Keep existing polyline [Yes/<No>]? press Enter

Define new line by selected line, another line, angle or points [<Selected>/Line/Angle/Points]? press Enter

Area: 176044.14 S.F, 4.0414 Acres

Remainder/Acres/<Enter target area (s.f.)>: 17800

Linework Polyline method:
Original perimeter polyline on left, adjusted perimeter on right

Points method

Pulldown Menu Location: Area/Layout

Keyboard Command: ssarea

Prerequisite: A closed perimeter polyline

Area Radial from Curve

This command swings a line radial from a curve to reach a predetermined area. The existing area can be defined by polylines or by picking each point on the perimeter. For the point method, the curve to radiate from should be the last entity selected when defining the figure. For the polyline method, front and back polylines are used. The computed line goes perpendicular from the front polyline and intersects the back polyline. This line is moved to find the target area. Both ends of the front and back polylines are connected to close the area. The options for the polyline method are set in the dialog shown.

Prompts

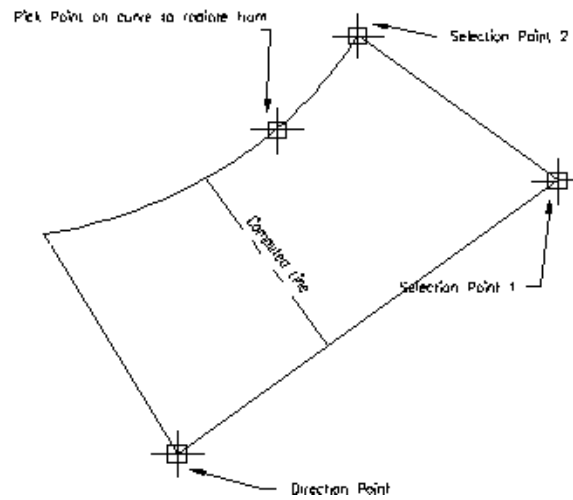

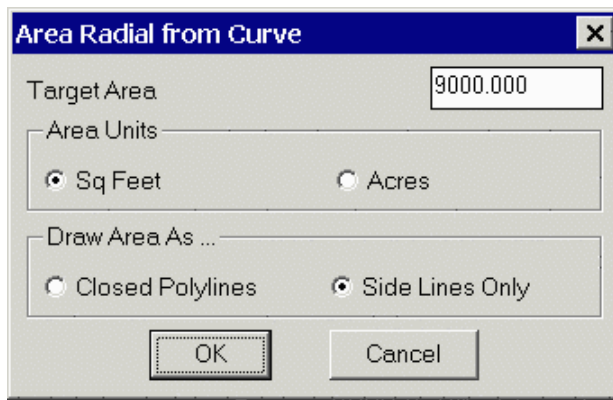

Define area by points or closed polyline [Points/<Linework>]? press Enter

Area Radial from Curve dialog Make choices and click OK.

Select curve to radiate from: *pick the curve*

Select back polyline: *pick the back polyline*

Lot Area: 9000.00 S.F., 0.2066 Acres

Point Method

Polyline Method

Pulldown Menu Location: Area/Layout
Keyboard Command: arearc

Prerequisite: An existing area defined by points or polylines

Bearing Area Cutoff

This feature allows you to cut a predetermined area from a closed figure using a cut-off line having a specified bearing. The boundary intersected by the cut-off bearing line can be either a straight line or arc.

Enter area in ACRES [Sq. Feet/Done] <0.000000>: Enter the number of acres contained within the cut-off area.

To change from acres to square feet, type S and <Enter>.

Note: if units are set to meters, the prompt will be:

Enter area in HECTORS [Square meters/Done].

Enter bearing of cutoff line <100.000000>: Enter the bearing of the cut-off line through the property using Qdd.mmsss format.

where:

Q = quadrant (1 = NE, 2 = SE, 3 = SW, 4 = NW)

dd = degrees

mm = minutes

sss = seconds (The third s indicates that, if desired, you can optionally specify seconds to the nearest 0.1 second)

Note: Trailing zeros need not be entered.

Place area to right or left of bearing line [Right/Left] <R>:

"Looking" in the direction of the cut-off bearing allows you to determine which side is left or right. Type R and <Enter> or just <Enter> for right. Type L and <Enter> for left.

Method of defining the overall area to be divided [C&G Point-group/Manual-entry] <M>:

Type "P" and Enter if you wish to use a point group to specify the overall area or type "M" and Enter (or just press Enter) to specify the overall area interactively.

Defining the overall area using a C&G Point Group:

If you have a C&G Point Group that defines the area to be divided and you choose to use the point group option, you will then be asked to use a file dialog to browse to the point group file and select it.

Defining the overall area manually:

If you choose to type or pick the points defining the overall area individually, you will see the prompt:

Enter point ID or pick graphically [cLockwise/ccW/Polyline]: Specify a point ID or begin a curve by typing L or W. Type P and enter to pick a polyline.

Note: if you choose to pick a polyline, it must be a closed polyline and all its vertices must have coordinates matching points found in the coordinate file.

When specifying individual points, move around the parcel and pick or type in the points, in order, to define the overall area involved.

After all points have been entered, press Enter to end point input.

Calculate the Cut-off Line

No matter which method you use to specify the property being divided, once the overall tract is specified, the cut-off line is calculated and the points at which the cut-off line intersects the tract boundaries are saved.

The **Saving Point** dialog (below) will be shown for each intersection point.

The image shows a 'Saving Point' dialog box with the following fields and buttons:

- Coordinate File: C:\Program Files\CGSurvey 19 for IntelliCAD\Data\CGDEMO.cgc
- Point ID: 1122
- Coordinates:
 - Northing: 195.62264
 - Easting: 156.49811
 - Elevation: <No Elev>
- Buttons: No Elevation, From Point ID
- Description: (empty field)
- Code: (empty field)
- Buttons: Cancel, OK

Click the **OK** button to save the intersection point.

Depending on your settings for **Auto Line Plot** and **Auto Point Plot** on the **Graphics** tab of the **C&G Options** dialog box, you may see both the points and the cut-off line drawn on the screen.

This process can be repeated as many times as is necessary to further divide the overall area or to divide another area.

Press <Esc> or "D" at the **Enter area...** prompt to end the command.

Prompts

Enter area in ACRES [Sq. Feet/Done] <0.000000>:

Enter the number of acres contained within the cutoff area or type "S" and Enter to use square feet or "D" and Enter when done.

Enter bearing of cutoff line <100.000000>: Enter the bearing of the cut-off line through the property.

Place area to right or left of bearing line [Right/Left] <R>:

Type "R" and Enter or just Enter for right of line. Type "L" and Enter for left. The direction of the cut-off bearing determines which side is left or right.

Method of defining the overall area to be divided [C&G Point-group/Manual-entry] <M>:

Type "P" and Enter if you wish to use a point group to specify the overall area or type "M" and Enter (or just press Enter) to specify the overall area interactively.

for Manual entry:

Enter point ID or pick graphically [cLockwise/ccW/Polyline]: Specify the point ID or begin a curve by typing L or W. Type P and enter to pick a polyline.

Pulldown Menu Location: Area/Layout

Keyboard Command: baco

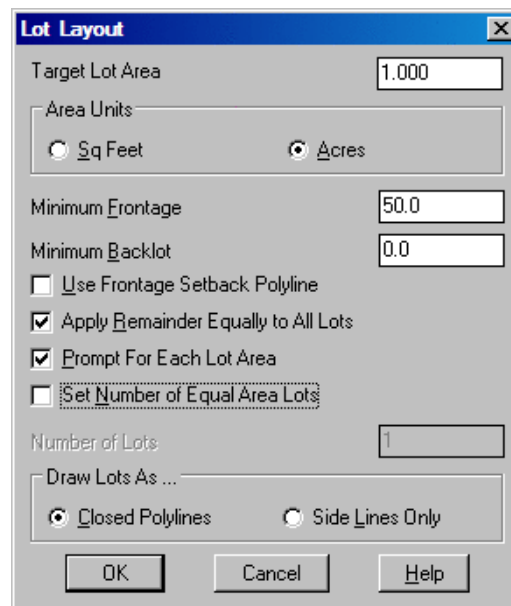

Prerequisite: Coordinate file.

Lot Layout

This command draws lots based on a front and back polyline. Starting from the front polyline, the program calculates two lot side lines perpendicular from the front polyline that intersect the back polyline and create the specified lot size. Lots are created along the front polyline in the order that the front polyline is drawn. If the front polyline needs to be reversed, use the *Reverse Polyline* command found on the Edit menu. The direction of the back polyline does not matter. The lots can be drawn as closed polylines or just the lot sides can be drawn. There is also an option to automatically create all the possible lots at the specified area between the front and back polylines or to prompt for each 0.4 acre lot.

In prompt mode, the program reports the remaining area between the front and back polylines and then asks for the lot size. The lot size can be specified either by area or frontage along the front polyline.

The lots are sized to meet the specified area and also meet the minimum frontage and backlot distances. The program starts by checking the lot area at the minimum distances. If this area is greater than the target, then the lot is drawn at the minimum distance and the resulting lot area will be greater than the target area. Otherwise the program will increase the frontage until the lot reaches the exact target area. The Use Frontage Setback Polyline option allows you to use another polyline besides the actual frontage polyline for the minimum frontage indicator. Typically, this Frontage Setback Polyline would be offset a set amount from the actual frontage polyline.

Prompts

Lot Layout dialog

Select front polyline: *pick a polyline*

Select back polyline: *pick a polyline*

With prompt for each lot active:

Area remaining: 160326.88 S.F, 3.6806 Acres
Quit/Frontage/Enter lot area (Acres) <1.2269>: I
Area remaining: 116766.88 S.F, 2.6806 Acres
Quit/Frontage/Enter lot area (Acres) <1.0000>: F
Enter Frontage <50.00>: 75
Lot Area: 37807.50 S.F., 0.8679 Acres
Area remaining: 78959.38 S.F, 1.8127 Acres
Quit/Area/Enter frontage <50.00>: A
Quit/Frontage/Enter lot area (Acres) <1.0000>: press Enter
Area remaining: 35399.38 S.F, 0.8127 Acres
Quit/Frontage/Enter lot area (Acres) <1.0000>: Q

Polylines for Lot Layout
 The Front Polyline goes from right to left

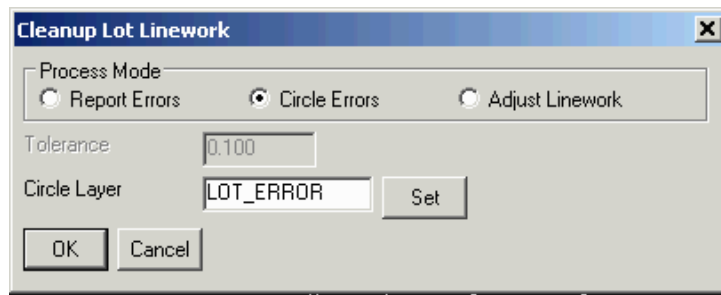

Resulting lots numbered using Sequential Numbers

Pulldown Menu Location: Area/Layout
Keyboard Command: lotlay
Prerequisite: A frontage polyline and a backlot polyline.

Cleanup Lot Linework

This command finds any overshoots or undershoots in the lot linework. The Report Errors mode will report the location of the errors in the standard report viewer. The Circle Errors mode will draw circles on the specified layer around the errors. Then you can use CAD functions to review these errors and make edits. The Adjust Linework mode makes the program automatically adjust the linework coordinates to remove the errors as long as the coordinates move less than the specified Tolerance.

Example of overshoot where lot line goes past intersection

Example of undershoot where lot line falls short of intersection

Prompts

Cleanup Lot Linework dialog

Select polylines to process.

Select objects: *pick polylines*

Pulldown Menu Location: Area/Layout > Lot Layout Utilities

Keyboard Command: lotclean

Prerequisite: Linework

Set Linework Angles To Nearest Second

This command adjusts the coordinates of lines and polylines to set their bearings to the nearest second. This routine eliminates decimal seconds for the linework. Here's an example inverse showing decimal seconds on a line before running this routine.

```
Northing(Y) Easting(X) Elev(Z)
7054276.3676 11519401.0186 0.0000
7054104.6344 11519556.5360 0.0000
Bearing: S 42d09'47.5207" E Horizontal Distance: 231.6850115
```

Here's the inverse showing the bearing to the nearest second on the line after running this routine:

```
Northing(Y) Easting(X) Elev(Z)
7054276.3673 11519401.0182 0.0000
7054104.6344 11519556.5360 0.0000
Bearing: S 42d09'48.0000" E Horizontal Distance: 231.6850115
```

Prompts

Select lines and polylines to process.
Select objects: *pick lines and polylines*
Adjusted 1 polylines.
Maximum distance shift 0.000538

Pulldown Menu Location: Area/Layout > Lot Layout Utilities
Keyboard Command: pl2sec
Prerequisite: Linework

Set Linework Intersections To Perpendicular

This command processes a set of polylines to find any T-intersections and adjusts the polyline coordinates for any polylines that are not exactly perpendicular. A use for this routine is to select a right-of-way polyline and connected lot polylines that are meant to be perpendicular. To check polylines without adjusting, use the Edit > Polyline Utilities > Check Polylines > Highlight Non-Perpendicular Intersections command.

Prompts

Select polylines to check.
Select objects: *pick polylines*
Adjusted 1 polylines to make perpendicular.

Pulldown Menu Location: Area/Layout > Lot Layout Utilities
Keyboard Command: pl2perp
Prerequisite: Polyines

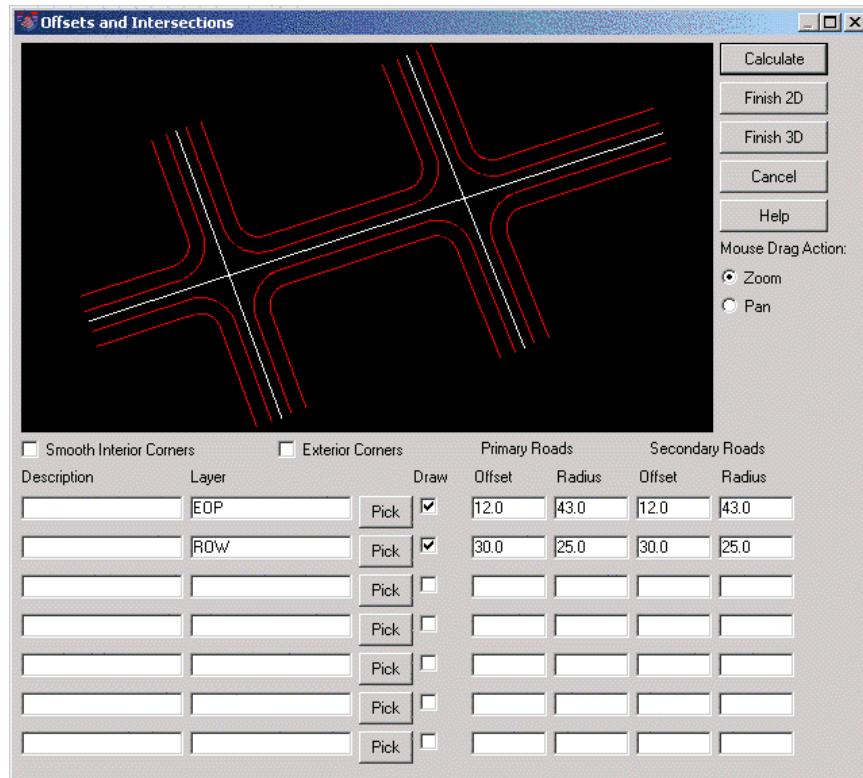

Offsets & Intersections

This command takes a set of centerline polylines and calculates the series of offset polylines using the user defined offset and fillet radius values. The function recognizes primary and secondary roadways which allows for different

offsets and fillet radii to be specified for each. Up to seven sets of offsets and radii can be defined for different features such as edge of pavement, right-of-way, sidewalk, etc.. Each set also has a layer name and description. The Pick button lets you set the layer name by picking an entity with that layer in the drawing. The description is for your own information and is not used by the program.

Multiple centerline polylines can be processed together which allows for the creation of an entire set of roadway offset polylines in one step. Intersections are calculated based on the centerlines selected and the fillet radii are applied at the intersections. The Smooth Interior and Exterior Corner options will fillet bends in the offset polylines. Otherwise turns without an arc in the original centerline will become straight corners in the offset polylines. The results of the calculations for the given parameters may be previewed in the dialog. Zoom and pan are available by clicking and dragging mouse on the preview image (zoom or pan mode is selected by a toggle). Once the satisfactory offsets are calculated, they are inserted into the drawing by clicking on Finish2D button. The Finish 3D button opens the *Elevate 2D Polylines* command, described in this chapter.

If it is preferable to handle intersections manually, you may run the command multiple times on non-intersecting centerlines. Another alternative is to use the *Offset* command in the Draw menu and the *Fillet* command in the Edit menu.

Prompts

Select all PRIMARY road polylines.

Select objects: *select polylines*

Select objects: *Enter*

Select all SECONDARY road polylines.

Select objects: *select polylines*

Select objects: *Enter*

Calculating offsets for layer EOP...

Calculating offsets for layer ROW...

Pulldown Menu Location: Area/Layout

Keyboard Command: wayint

Prerequisite: Centerline polylines

Cul-de-Sacs

This command uses a polyline centerline and the offset polylines to create a cul-de-sac. These offset polylines can be generated by the *Offsets & Intersections* command, or with the standard *Offset* command. The layer names of the offset polylines must match the layer names set in the dialog.

To run this command, pick a set of polylines and point on roadway centerline where the cul-de-sac center is. For cul-de-sacs with an offset center, pick a projection of that center onto the centerline and specify an offset distance (positive value is offset to the right, negative - to the left). Like the *Offsets and Intersections* command, a preview is shown of the cul-de-sac being designed. Any of the cul-de-sac parameters may be modified and reviewed before the cul-de-sac is applied and the drawing is modified with the Finish 2D button. The Finish 3D button opens the *Elevate 2D Polylines* command described in this chapter.

Bend cul-de-sacs are created by selecting offset entities on one side of the centerline.

Prompts

Select all offset polylines to end with cul-de-sac.

Select objects: *make selections*

Pulldown Menu Location: Area/Layout

Keyboard Command: stdcul

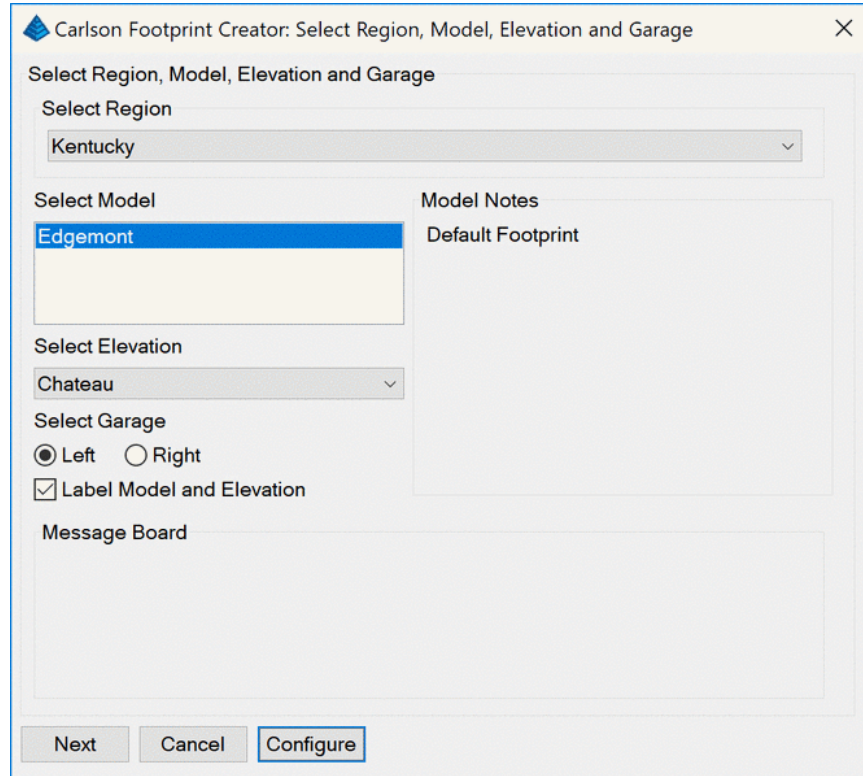

Prerequisite: A set of offset polylines and roadway centerlines.

Footprint Creator

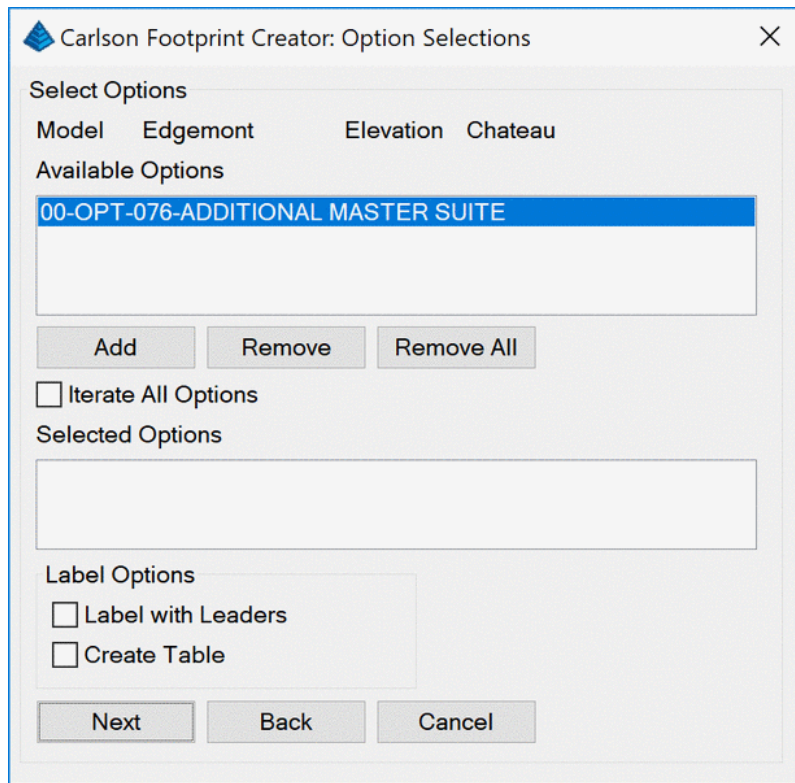

Footprint Creator is a command that allows for the creation of a library and placement of building footprints. The command is run from the Area/Layout menu and found in the Layout Utilities sub menu. The command inserts footprint drawings and uses the layering scheme in them to place the footprints with options. *Footprint Creator* allows the person producing plans to include optional aspects of designs such as; locating the garage left or right and including details such as driveways. Labeling tools are provided should it be desired that elements of the

footprints are called out in the plans.

Command Operation

The command starts with a dialog that allows for the selection of a footprint by a number of characteristics. These are region, model and elevation. Placement of the garage is able to be left or right. Labeling of model and elevation can be enabled or disabled. There is also a message board function that allows for team members to share information with each other about use and updates to footprints. For operation of the command select Next.

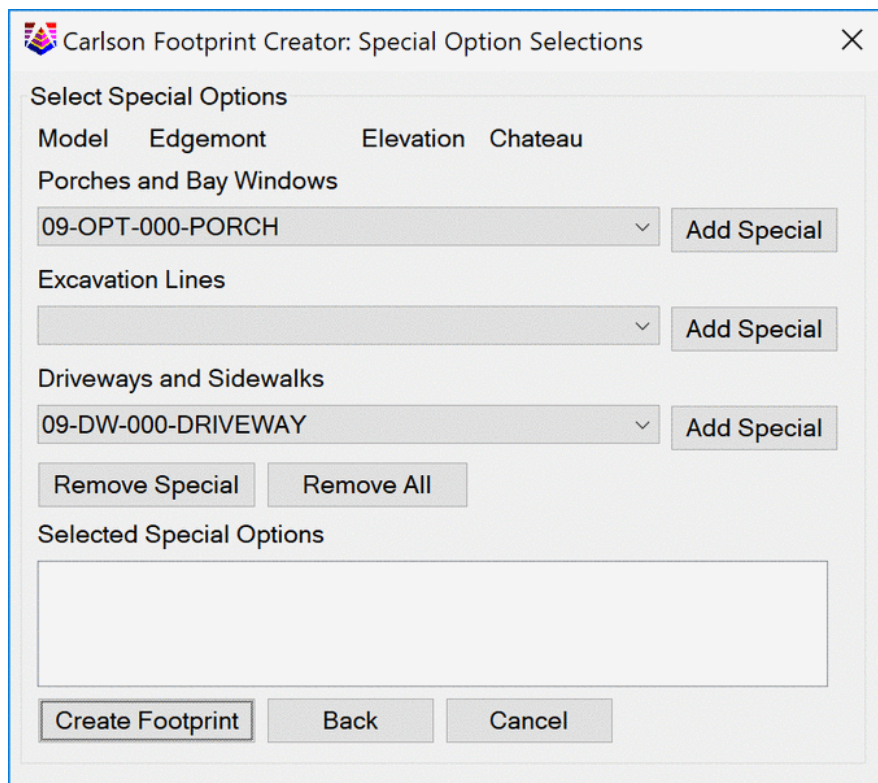

Footprint drawings may contain optional elements to be included upon placement. In this case an option is a master suite. This is read from the source drawings layering convention, layers containing "-OPT" display as options. To place an option select it by single clicking and choose the Add button. To remove it select it from the Selected Options pane and then select the Remove button. The Remove All button does just that and allows you to restart the selection of options.

Additionally, Iterate All Options if toggled along with the final creation method of Place on Building Pads will place and all options and combinations of all options. This option only has an effect if Place on Building pads is chosen.

The Label Options toggles will annotate the options either by leader, create table or both.

Use the Back button should you realize a different footprint is needed.

Select the Next button to select further options.

Porches and Bay Windows

The source drawing's layering scheme is used to allow for the placement of porches and bay windows. The command reads the drawing and displays any porches or bay windows available. The layer schemes for porches and bay windows are any of the following: "##-OPT-000-COVERED LANAI", "##-OPT-000-PORCH" "##-OPT-155" or "##-OPT-156". If none are included this pull down will be blank.

Excavation Lines

Excavation lines are also read from the source drawing. The layer scheme for excavation lines is "##-EXC". If none are included this pull down will be blank.

Driveways and Sidewalks

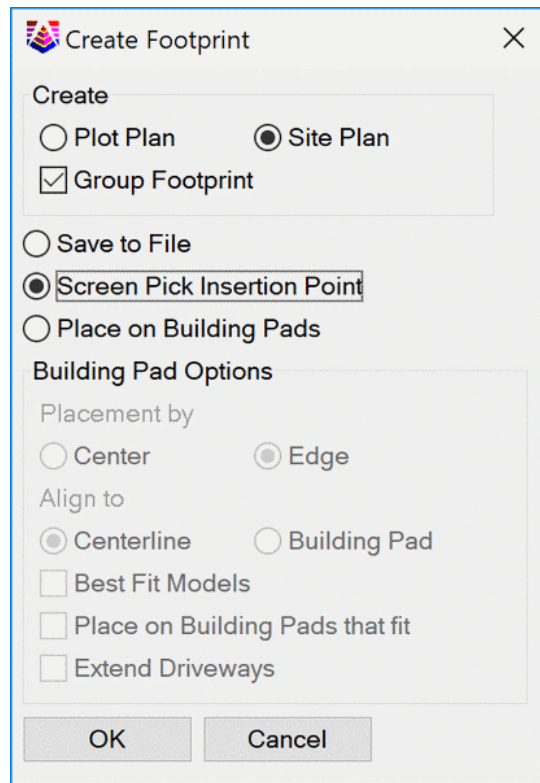

The source drawing can also include driveways. The layer scheme for driveways is "##-DW" and for sidewalks is "##-SW". Again, if none are present in the drawing this pull down will be blank.

Add Special, Remove Special, Remove All

The Add Special, Remove Special and Remove All buttons will add the option selected for the corresponding list. Remove them individually or remove them all.

Create Footprint

When ready to place the footprint select Create Footprint. You will be prompted to select the method for creation.

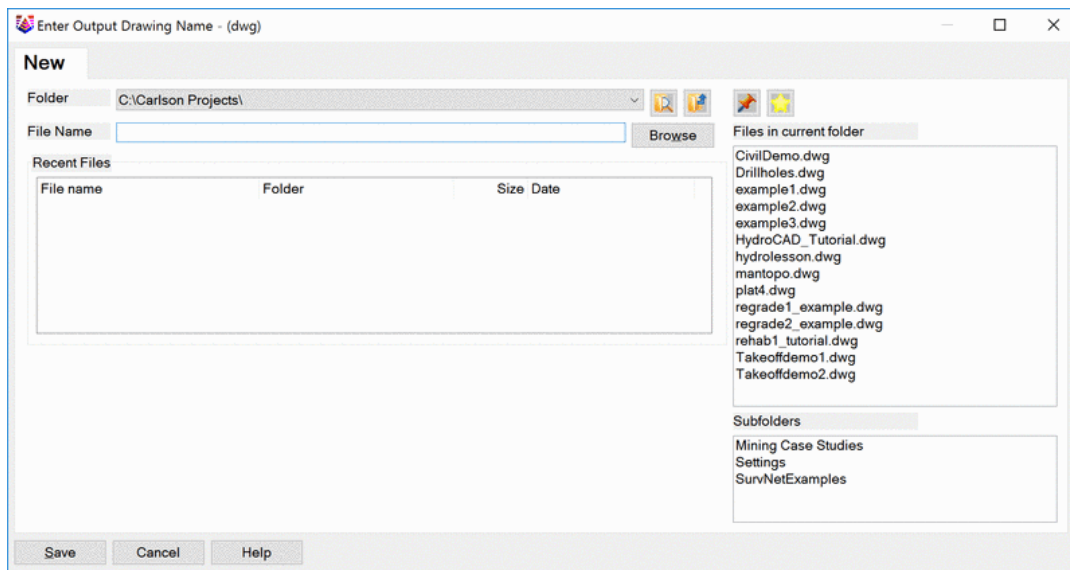

Create

Choose the option for placement. The footprint will include an enclosure line "Plot Plan" or simply place the footprint as drawn in the source drawing "Site Plan". The Group Footprint if selected will group the Footprint entities together.

Save to File

Enter Output Drawing Name

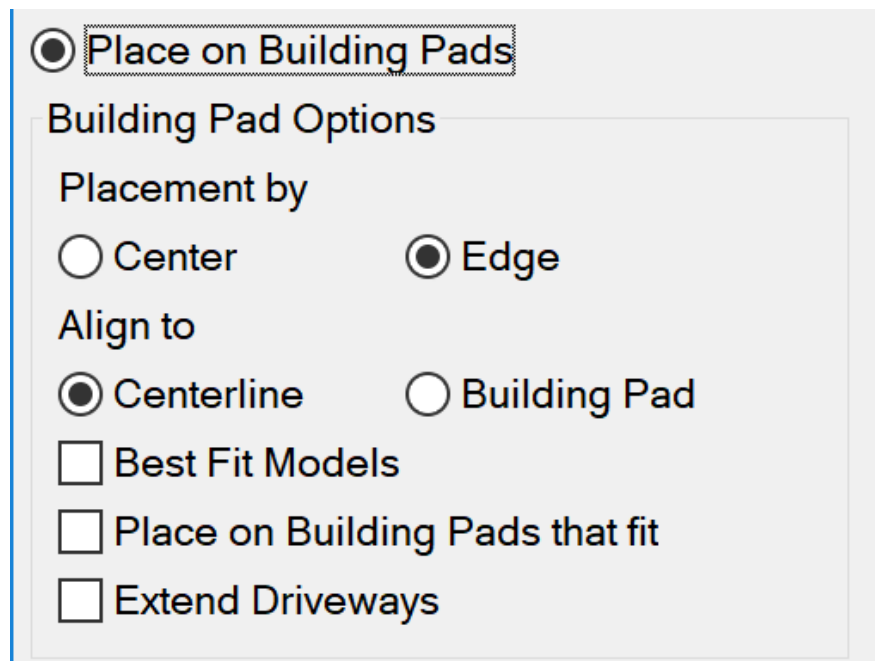

Screen Pick Insertion Point

Pick an insertion point and the rotation for the footprint. The command will continue to prompt for insertion points until canceled allowing for multiple placements of the same model, elevation and options within the same command execution.

Place on Building Pads

For the Place on Building Pads to work properly, the footprint source drawing must be laid out properly. The insertion point of the footprint should be the front most point of the footprint with the garage on the left side. This option will prompt for the selection of Building Pads, these should be closed polylines. After selecting the building pads, the selection of Centerlines or Targets for Building Alignment will be prompted. Multiple targets may be selected and the tool will use these targets for determining the footprint front orientation.

Footprints will be placed in each building pad selected and rotated toward the selected alignment option. The footprints will be placed by edge (driveway side) or centered on the building pad. When the alignment is by centerline, the footprint will be placed perpendicular to the centerline. When alignment is by building pad it will rotated the footprint along the edge of the building pad.

Placement Center
Align to Centerline

Placement Edge
Align to Building Pad

Placement Center
Align to Building Pad

Placement Edge
Align to Centerline

Optional Toggles

If no option is selected, all Models and Elevations selected on the initial Select Region, Model, Elevation and Garage page will be placed within every Building Pad.

Best Fit Models

This option will adjust the footprint forward and back as well as side to side until the footprint fits within the building pad. If multiple models are selected on the initial Select Region, Model, Elevation and Garage page this will attempt to fit the highest priority model/elevation on each Building Pad. Once a footprint has placed on a building pad the building pad will no longer be processed. This is used to place the highest priority models in the selected building pads.

Place on Building Pads that fit

Like the Best Fit Models, this will only place footprints that fit within each building pads. This option will continue to process building pads that footprint have been placed in resulting with multiple footprints within any building pad that the footprint fits within.

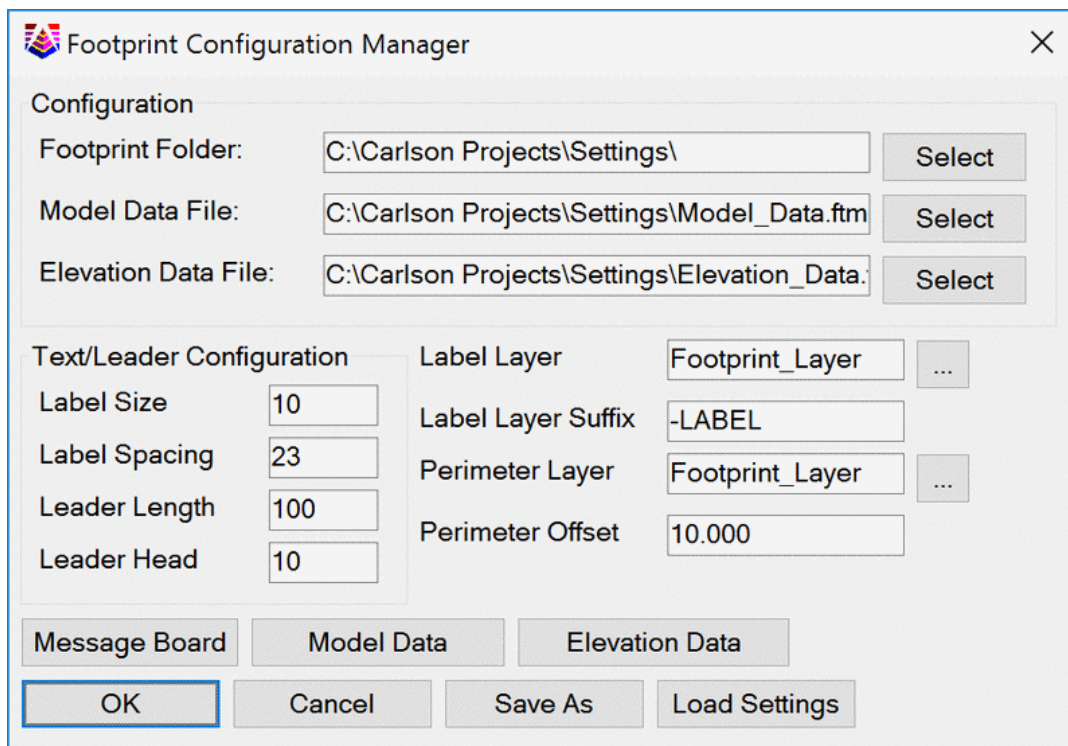

Extend Driveways

This option will prompt for Edge of Pavements for Driveway Extensions. Multiple targets may be selected, and the tool will use these targets while extending closed polylines representing the driveway. The layer scheme for the driveway extension must contain "DRIVEWAY" or "-DW". This includes the Special Optional Selections of driveways and sidewalks.

Configure

To configure *Footprint Creator*, select the Configure button on the first dialog. This must be coordinated with the drawings and directory structure for them for the command to work properly.

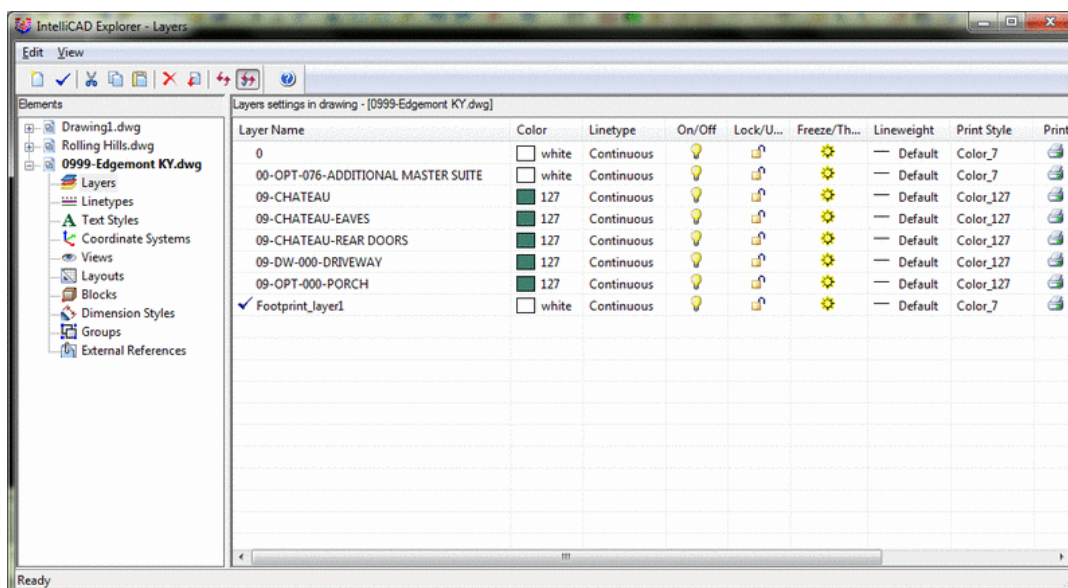

Footprint Configuration Manager

The Footprint Folder is the folder where all the sub folders for footprints will be located. The Model Data and Elevation Data Files by default will be in your Settings folder. Each footprint is stored in a folder with a name that corresponds to elements of the footprint. A footprint is included with the Carlson installation. It is 0999-Edgemont KY.dwg and is in a folder named 0999-Edgemont KY under the settings folder.

An additional model 0998-Remington KY.dwg is also included in the Carlson installation and is in a folder named 0998-Remington KY. This model has multiple elevations defined and can be accessed by choosing the Add_Model.ftm and Add_Elevation.fte files. The additional model and elevation files also include the Edgemont model and elevations.

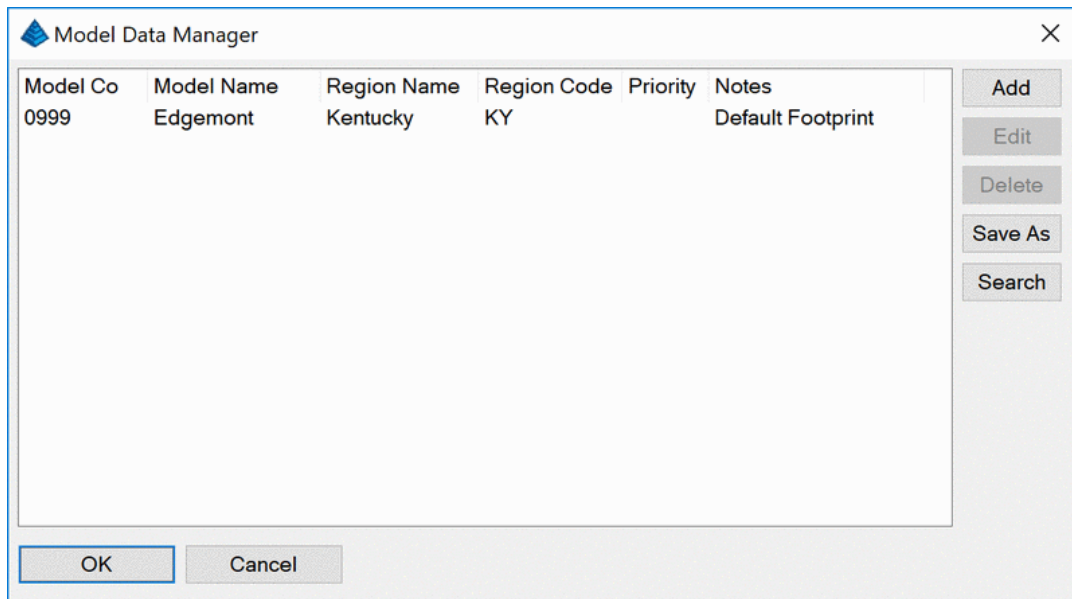

Layers are included that are read by the command to determine which elements of the drawing are placed when the command is run.

Other layers that can be used are those related to excavation. Layers with OPT are standard Options, they must be preceded by 00- as shown "##-OPT". Layers that include the Elevation name can be selected during command operation.

Model Data

To create or edit Models select the Model Data button.

The Model Code is a four-digit code that will be the first four characters of the folder and drawing file name. This is followed by a dash and then the Model Name which is followed by a space and then the Region Code. The command matches the Region Code to the Region Name for display in the dialog box for Region. The Notes are purely descriptive.

Add Model Data

To add a model select the Add button.

The 'Enter Fields' dialog box is a standard Windows-style window with a title bar containing a logo and the text 'Enter Fields' and a close button (X). The main area contains six labeled input fields stacked vertically: 'Model Code', 'Model Name', 'Region Code', 'Region Name', 'Priority', and 'Model Notes'. Each label is to the left of a rectangular text box. At the bottom of the dialog are two buttons: 'OK' and 'Cancel'.

The Model Code is four numeric characters. The Model name can be alpha or numeric. The Region Code is a two-character designation. The Region Name matches up with the Region Code and can be alpha or numeric. The notes are descriptive and are there purely to help understand information about the Model. To edit an existing model, select the Model and then select the Edit button. To save a model for modification, select the model and then select the Save As button. Should the list of models become extensive, use the Search button to locate the model desired.

Elevation Data Manager

To create or edit Elevation Data select the Elevation Data button.

The 'Elevation Data Manager' dialog box has a title bar with a logo and the text 'Elevation Data Manager' and a close button (X). The main area contains a table with the following data:

Code	Name	Abbreviation	Color Code
09	Chateau	CHAT	127

To the right of the table are five buttons: 'Add', 'Edit', 'Delete', 'Save As', and 'Search'. At the bottom of the dialog are two buttons: 'OK' and 'Cancel'.

The operation of this dialog is nearly identical to the Model Data Manager dialog. The Code and Name relate to layers in the source drawing.

Pulldown Menu Location: Area/Layout - Layout Utilities

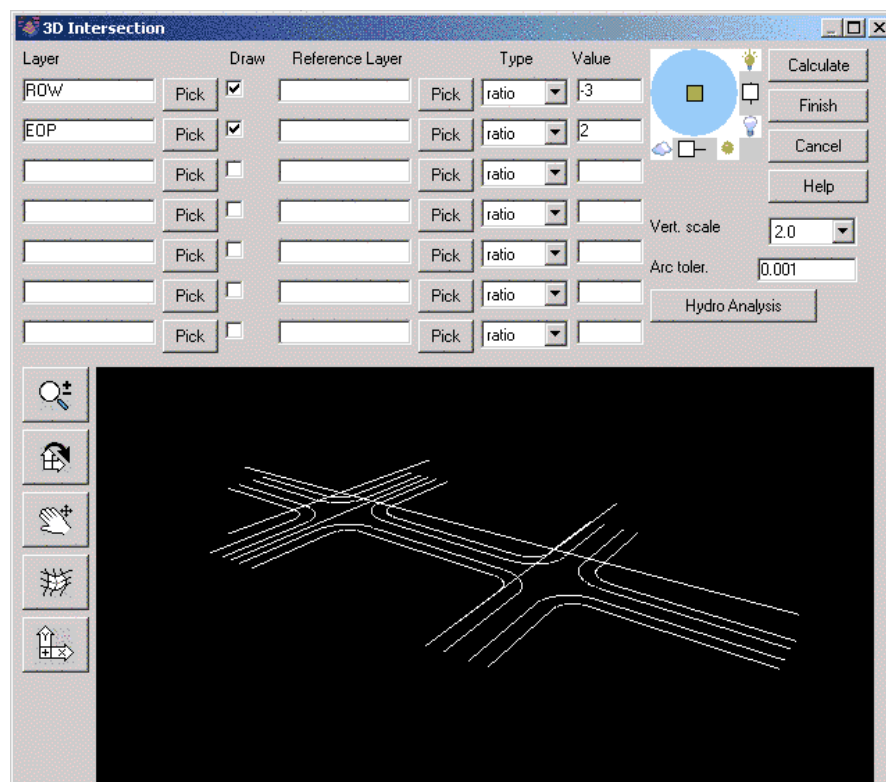

Keyboard Command: createfp

Prerequisite: Footprint drawings in properly named folders with layering convention matching the command configuration.

Elevate 2D Polylines

This command allows to assign elevations to a selection of polylines based on elevations along supplied 3D centerline and user-defined slopes. This routine calculates a distance from each vertex of 2D polyline to a specified 3D reference polyline and uses that distance and slope to calculate a 3D offset to a corresponding point on 3D polyline.

You can specify either the original centerline to be a reference 3D polyline or use another set of offset polylines. For example, you could specify the edge of pavement elevation to be relative to the curb elevation, while curb elevation is calculated based on the centerline elevation. You can view the resulting road/intersection design in 3D, making changes and updating picture on-the-fly. Local sink points can be reported instantly by evaluating a resulting triangulation to predict low points in the design leading to water retention.

After selecting entities

Another road/intersection design, this time in 3D

Prompts

Select all offset polylines for the intersection.

Select objects: *select entities*

Select all 3D profile polylines.

Select objects: *select entities*

Pulldown Menu Location: Area/Layout

Keyboard Command: 3dintersect

Prerequisite: A set of offset polylines and roadway centerlines

Parking

This command draws a series of parking stalls. The command prompts for stall width and length, stall parking angle, and side for stalls. Stalls can be located by the number of stalls in a direction, as many as fit between two points, or along a polyline.

Stall Layout Method: The Number of Stalls method creates the specified number of stalls at a fixed stall width along an alignment. The Fit By Width creates as many stalls as can be fit on an alignment between the specified Min and Max Stall Width. The Fit By Number is the same as Number of Stalls except the stall width is adjusted to span the full alignment with the stalls.

Min Stall Width: Indicate the minimum width a stall can be when the Fit on Alignment option is specified.

Max Stall Width: Indicate the maximum width a stall can be when the Fit on Alignment option is specified.

Stall Width: Indicate the stall width when the Number of Stalls option is specified.

Number of Stalls: Indicate the desired number of stalls when the Number of Stalls option is specified.

Stall Length: Indicate the desired length of each stall.

Angle of Parking: Controls the angle of the stalls from the alignment.

Line Width: Sets the line width property of the parking lines. Using a Line Width helps with viewing the parking lines in the 3D Viewer.

Adjust Length for Angle Method: When the stalls are not perpendicular, this setting controls whether the stall length is measured along the stall line or as the perpendicular offset from the curb alignment.

Side for Stalls: Indicate the side to which the stall lines should be placed. The Left and Right sides are relative to the direction of the baseline. Use the Pick option to screen pick the side for the stalls.

Stall Placement Method: Indicate the method by which the stall direction should be determined whether it be between two picked points or along an existing graphical alignment.

Draw Baseline: This option draws a baseline in addition to the stall side lines.

Draw Handicap Marker: This option draws a handicap symbol.

Locate on Real Z Axis: Controls whether the stall lines are created at zero elevation or the elevation of the alignment.

Draw Label: This option labels the number of stalls using the Text Size Scaler, Label Prefix and Suffix settings.

Layer: Specify the layer on which parking lines should be placed or click the Set button to choose an existing layer.

Prompts

Starting Point?

Pick point or point number: *Pick a point*

Ending Point?

Pick point or point number: *Pick a point*

Created 10 stalls.

Pulldown Menu Location: Area/Layout > Layout Utilities

Keyboard Command: parking

Prerequisite: None

Set Back Measure-Move

This command can be used to measure the perpendicular distance of 1 or 2 points to 1 or 2 lines. This can be helpful in placing buildings for proper setback from lot lines. After selecting the lot lines and the building, the command allows you to drag the building while a real time display on the side-bar menu shows the perpendicular distances to the lot lines. After experimenting you can press T to type in the values to move to. The second line and point are optional.

Prompts

Select 1st Lot line to measure perpendicular from.

Select object: *select line*

Select 2nd Lot line to measure perpendicular from ([Enter] for none).

Select object: *select line*

Select entity to move at 1st point to measure from:

Select object: *ENDPOINT of (Pick a point on polyline.)*

Pick a 2nd point on entity to measure from ([Enter] for none). *END of (Pick a point.)* Pick another endpoint of the polyline representing the building.

Drag-Pick new Location or [T]ype in Move distance(s) [C] to Cancel: *T* Either drag the building to a location and press the pick button on your pointing device or press T to enter the distances.

You may have to use a negative distance to move to the proper side of lot line!

Distance from 1st line: *10*

Distance from 2nd line: 20

The building is then moved to your specification.

Pulldown Menu Location: Area/Layout

Keyboard Command: setback

Prerequisite: Lot lines and polyline representing the building should be plotted.

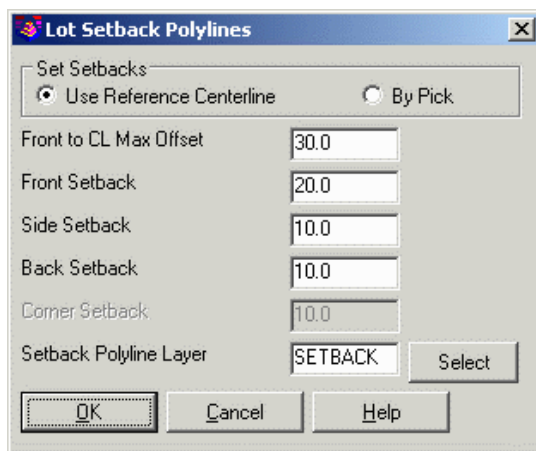

Draw Lot Setback

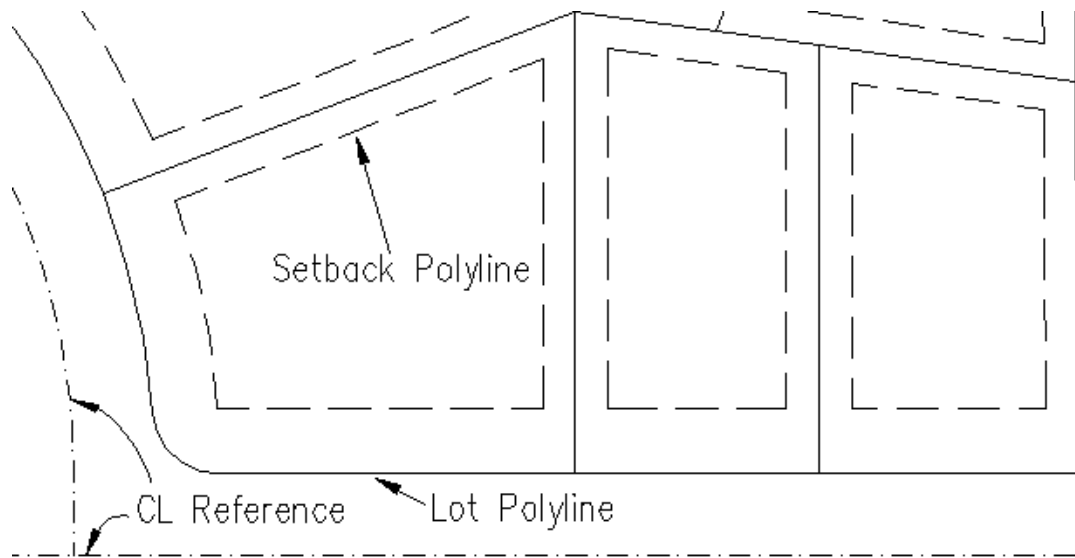

This command draws closed polylines inside lots to represent the building setback offsets. Before running this command, the lots need to be drawn as closed polylines. The command starts with a dialog for entering the setback offsets and the layer for the new setback polylines.

There are two methods for the program to define the edges of the lot as front, side, back or corner. For the Use Reference Centerline method, the Front to CL Max Offset is used to determine which lot edges are frontage. The program will prompt to select CL reference polylines and lot edges that are within this offset from these CL polylines are considered frontage edges. For the By Pick method, the program prompts to select the setback type for each lot edge. Only the By Pick method has the option for the Corner Setback type.

The Round Corners option will round the setback polyline using a radius of the setback offset amount for corners with an interior angle over 180 degrees.

The Front Setback is applied to the lot frontage edges. The Side Setback offset is applied to lot edges that have only one of their ends within the frontage offset. The Back Setback offset is applied to all other lot edges.

Prompts

Lot Setback Polyline dialog

Select reference centerline polylines.

Select objects: *pick the polylines*

Select lot polylines to setback.

Select objects: *pick the polylines*

Pulldown Menu Location: Area/Layout

Keyboard Command: lot_setback

Prerequisite: Lot and CL polylines

Fit Structure

The purpose of the Fit Structure feature is to place a structure (or the footprint) within a bounding polygon. For example, a house foundation - the footprint - within the limits of the setback lines of a lot - the bounding polygon.

The user can easily insert a structure footprint within a lot or bounding polygon near its final location. The footprint then it can then be conveniently rotated and/or translated, in user definable increments, to the exact position desired.

Footprint Templates

The template, a full scale definition of a structure's footprint, must be defined prior to placing it within the bounding polygon.

Templates are not AutoCAD drawings but they can be imported from AutoCAD drawings.

The data specifying the dimensions of a template is stored in a binary format and cannot be manipulated without using the Template Manager. Once a template is placed in the drawing, it becomes a C&G footprint polyline. Since

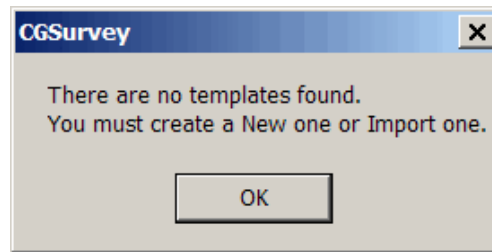

it is a C&G polyline, it can be queried and manipulated using ordinary AutoCAD and CGSurvey commands.

Template Manager

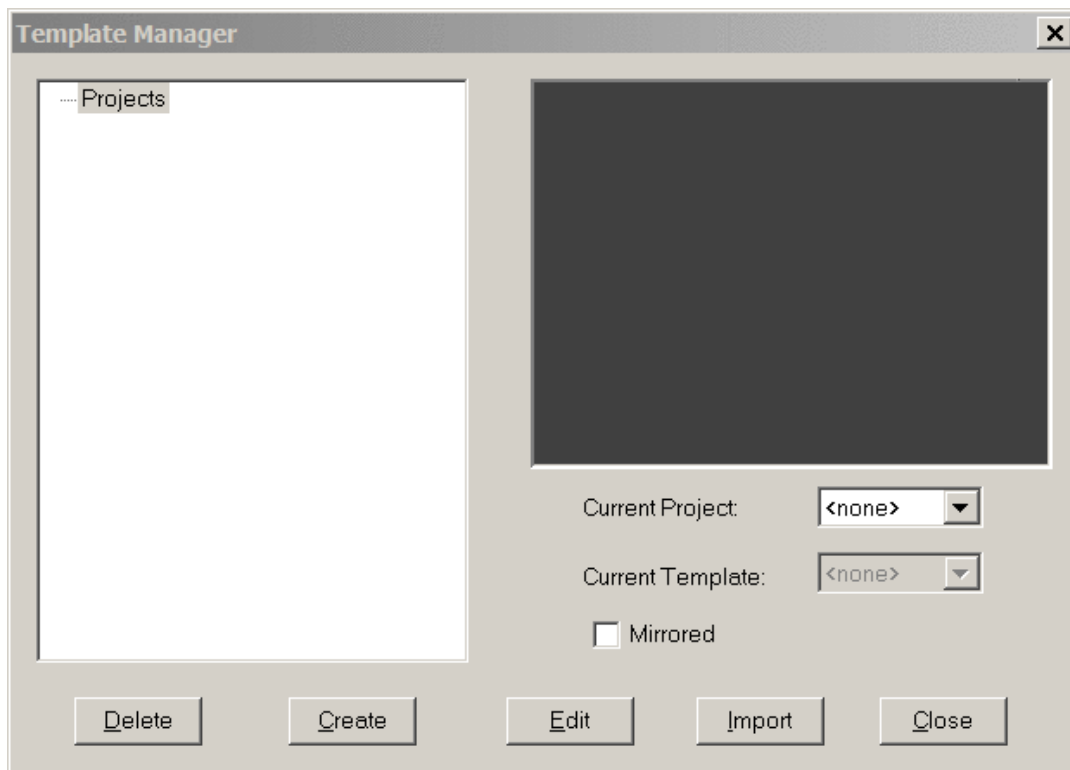

The Template Manager is used to manage the templates for the various projects you work on. For example, the various house footprints used in a given subdivision can be defined as templates. The templates can then be placed in a lot in an "as" or "reverse" orientation and reused as many times as necessary. You can use the Template Manager to define templates directly or import the templates from existing AutoCAD drawings.

The Template Manager allows you to organize your templates within projects. You can name the projects in a meaningful way then import the templates into the project "folder".

When you choose the Fit Structure feature from the Cogo menu for the first time, a dialog warns you that you have no templates defined then brings up the Template Manager.

In the dialog below you will notice that there is nothing listed under the Projects item. This means that you will have to either create a template or import one from an existing drawing.

Creating a Template:

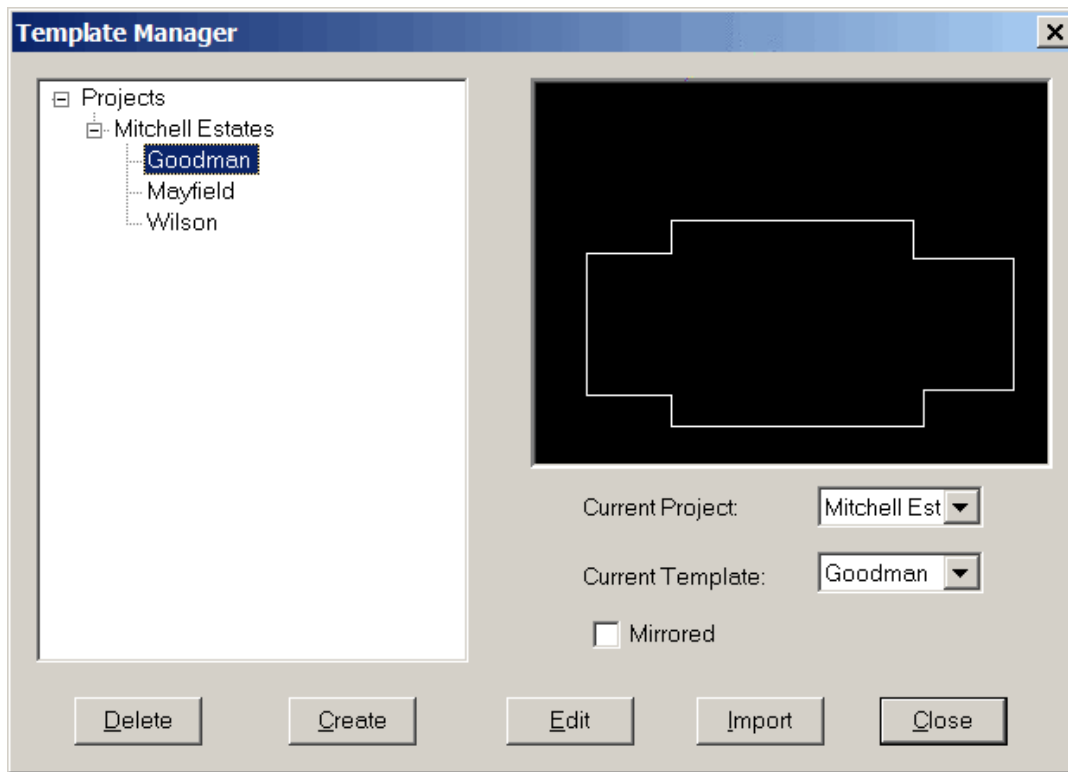

To create a new template, click the Create button. This brings up a dialog that allows you to configure the simple drawing in which you will create a template. This dialog allows you to specify the name of the project, the name of the template and asks about the approximate overall size of the template. If the structure template is made up of right angle segments you may want to specify a snap grid to aid you in laying out the template. You should be

aware that the create template method should only be used for very simple templates and that it does not allow you to edit the structure once it is added to the Template Manager.

The screenshot shows the 'Add a Template' dialog box. The title bar is blue with the text 'Add a Template' and a close button (X). The main area is light gray. It contains the following elements:

- 'Name of Project:' dropdown menu with 'Morristown' selected.
- 'Name of Template to Add:' dropdown menu with 'bldg 3' selected.
- A section titled 'Approximate Overall Dimensions of Template' containing:
 - 'Length:' input field with '125'.
 - 'Width:' input field with '75'.
- A section titled 'Grid' containing:
 - A checked checkbox labeled 'Use grid to aid in drawing the template'.
 - 'Grid interval:' input field with '5'.
- 'Cancel' and 'OK' buttons at the bottom.

When you are done configuring the create template drawing interface, click OK and you will see an empty AutoCAD screen upon which you can draw the template. The template is merely a closed polyline. The C&G Polyline by Points interface is used but in this case there will only be normal AutoCAD points picked (also known as graphic points designated as GR-PT). The polyline must be closed - so use the C for Close command line option for the last line segment in the template. Once you enter the Close option keyword for the polyline you are working on, the drawing window closes and the template is imported into the Template manager as shown below.

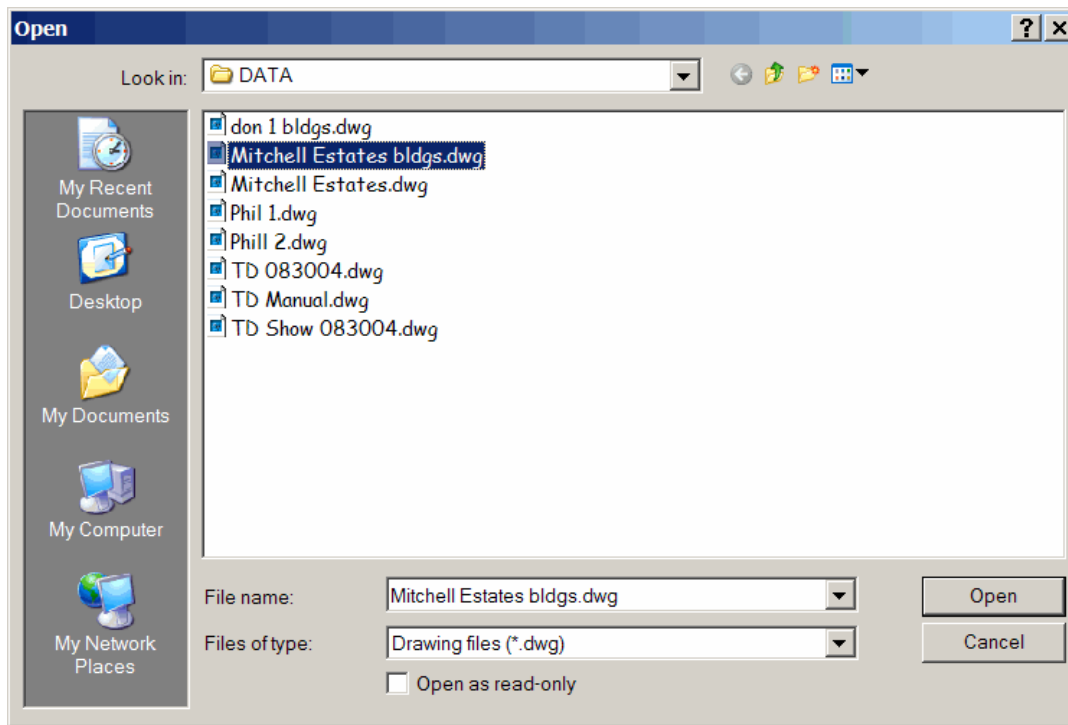

Note: You must click on the template name in order to see its shape in the window on the right and to choose it as the current template.

Importing a Template

The Create template method is only useful for very simple templates. For more complicated templates and projects with multiple structures, it is recommended that you use the Import method. To import a template you must create a separate drawing, then draw all of your templates at full scale on the layer specified for templates (see **Fit Structure Setup**).

Create a separate template drawing

Begin the importing of a template by creating a new drawing file as a repository for all the structure template drawings used in a specific project. For this example we will create a new drawing named Mitchell Estates bldgs.dwg. This file will only contain the structure template drawings for this project. Select the CAD **File** menu then select the menu **New** item

You may be asked to choose a drawing template (not to be confused with the structural template polylines you are about to create). It is generally easiest to use the default acad.dwt drawing template but you may also specify one of your own choosing.

In this new drawing create a layer having the name specified in **Fit Structure Settings** and make this layer current. You can accomplish this by using the CAD Layer Manager. To open the Layer Manager, from the Format menu choose the Layer menu item.

In the new drawing, draw the templates (house footprints for example) you will be using in your project. A structure template must be a closed polyline and may contain arc segments.

Draw the individual house footprints. It is recommended that you use either the C&G **Polyline by Points** feature or use the standard CAD PLINE command - on the Draw menu choose 2D Polyline.

You could also use the C&G **Quick Traverse** feature to traverse around the building. However, if you use **Quick Traverse** to create the footprint you must then convert the C&G lines created by Quick Traverse to polyline. To do this you can use a utility on the CGTools menu, Join Nearest.

Once you have created the templates needed, close and save the template drawing file. You can come back to this drawing at anytime and add or modify templates as needed.

Note: If you change a template in the original template drawing, you must be re-imported using the Template Manager. First, use the Template Manager's **Delete** feature to delete the old template, then re-import the changed template from your template drawing file.

Placing a Footprint:

Return to the original drawing into which you wish to insert the footprint. In this example Mitchell Estates.dwg will be used to place structure footprints within lot setbacks.

Select the **Fit Structure** menu item.

If this is the first time you have run the command and no templates have been specified, you will be informed of this by a warning dialog. Click **OK** in the warning dialog and the **Template Manager** will come up.

If you have inserted a template prior to running this command, the following prompt will be seen at the command line:

Choose a structure template

[Set template/Current-template (Wilson)/Mirror-current/Done] <C> :

Select "S" for **Set template** to bring up the **Template Manager**.

The Template Manager

As mentioned earlier, the **Template Manager** is used to manage the structure templates you use for your various projects. In the left hand pane the projects and their associated templates are arranged similar to the directories in the Windows Explorer. On the right pane is a drawing showing an unscaled representation of the shape of the currently highlighted template. The highlighted template becomes the current template when you Close the Template Manager. The following describes the Template Manager functions in more detail.

Delete button: This allows you to delete a Project or an individual template.

Create button: This allows you to generate a template "on-the-fly" while in the current drawing file. This method of creating templates should only be used for the simplest of templates. In most cases it is recommended that you import pre-drawn templates from other existing drawings.

When the **Create** button is selected, the **Add A Template** dialog appears (shown earlier).

Name of Project: enter a new name or press the down arrow to select from existing projects.

Name of Template to Add: enter a new name or press the down arrow to select from existing projects.

Approximate Overall Dimensions of Template:

enter an approximate length and width. Make sure this overall dimension will include the entire template so you will be given enough room to draw the template - too large is better than too small.

Grid:

If you wish to have a snap grid as a drawing aid when you create a template, check the **Use grid to aid in drawing the template** checkbox and set the grid interval. You need not use a grid but it is useful in creating simple rectangular templates.

Click **OK** to begin creating the template. To create the template, pick the desired locations for the various building corners. Be sure to close the structure perimeter by typing C and Enter. After closing the template polyline you will be returned to the **Template Manager**.

Import button:

clicking this button allows you to import the template from another drawing file. As described earlier, you should create a separate template drawing. In that drawing draw the required templates as closed polylines. The templates may contain arcs.

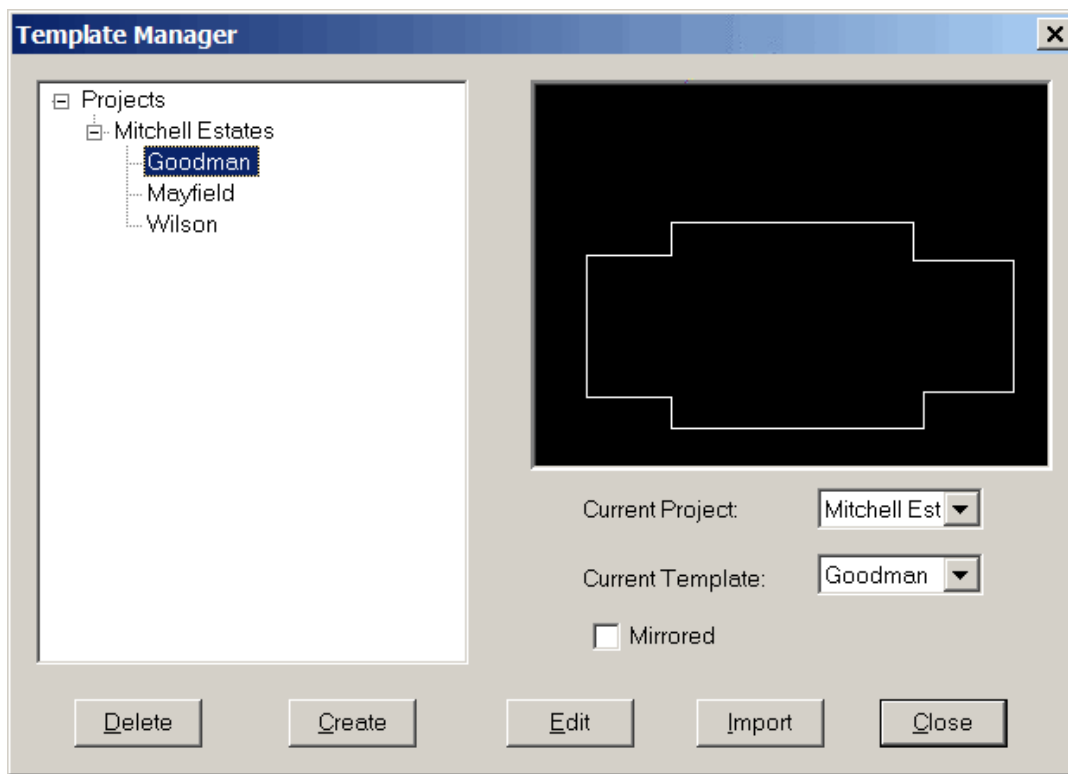

When you select the Import button a dialog (shown earlier) comes up asking you to enter or select a **Project Name** and to specify the **Name of Template to Add**.

The **Project Name** can be anything you wish but is often the name of the subdivision or the client name. The template name can also be anything you wish. It should generally reflect the type or style of structure the template represents.

After filling out the project and template names and clicking **OK**, a file dialog will be displayed. Choose the drawing file you created earlier containing the template(s) you wish to import.

After closing the file dialog the template drawing will be shown and you will be asked to choose the template polyline. When you pick the template polyline its geometry is stored in a special file reserved for template information and you will be returned to the **Template Manager**.

If you highlight the newly imported template on the left hand pane it becomes the current template and you should see it displayed in the right hand pane.

If you wish to import another template just repeat these steps as many times as necessary.

By highlighting the template name it is made the current template. You may choose to mirror the current template on the Y axis by checking the Mirrored checkbox. All you need do now is click the **Close** button to close the **Template Manager** and place the footprint in the drawing.

Fit Structure Example

The following file names will be used when describing the following example:

Coordinate File: Mitchell Estates.crd

Drawing File: Mitchell Estates.dwg

Template Drawing File: Mitchell Estates bldg.dwg

Note: The template drawing file may have several templates in the same drawing file. For example you may have a subdivision with many different house footprints.

Import the templates

Open the subdivision drawing file, in this case; Mitchell Estates.dwg, and the associated coordinate file: Mitchell Estates.crd.

The subdivision drawing should already exist and you should have already defined the bounding polygons within which the structures are to be placed. These bounding polygons can be defined either by polylines (arcs are allowed) or lines and arcs. The lots and setbacks (bounding polygons) can also be defined using a C&G Point Group or Groups.

Once the subdivision drawing is open and has been prepared for the placement of structures choose **Fit Structure** from the menu.

If you have not run the **Fit Structure** command and set a current template in this drawing session, the **Template Manager** dialog will appear.

The first task will be to create a project and import templates from the template drawing file, Mitchell Estates bldg.dwg.

Select the Import button and fill in the project name and template name.

In this example the subdivision name is Mitchell Estates and the house model being added to the template list is the Wilson.

Next a drawing file dialog will be displayed. Highlight the template drawing file (in this case Mitchell Estates bldg.dwg) and click the **Open** button and use the cursor to choose the polyline representing the template to be imported.

After choosing the template polyline, you will be returned to the **Template Manager**. You will notice that the template you just chose has been added to the template manager under the project you selected. To see its shape and make it the current template, click the template name under the current project.

You may continue to add templates as required. Click **Close** to begin placing the template in the subdivision drawing.

After the Template Manager closes you will return to the main drawing and see the following prompt:

Pick the lot within which the structure will be placed [cg-Point-group/Done] <pick>:

Pick a polygon or a series of lines that define a closed lot boundary or setback within which you wish to place the structure. Type P and Enter to use a C&G point group file to define the bounding polygon.

Place the structure in the bounding polygon

Once you have specified the bounding polygon you will be asked to place the structure near its final location in the bounding polygon. Move the structure near its desired location using the mouse and click the left mouse button to place it at that location. Once you have picked the approximate location for the structure you will then be allowed to rotate and move the structure to its exact final location.

Note: If you need to adjust a template further once it has been placed within the bounding polygon and you have exited the Fit Structure command, you can run the Fit Structure command again and pick the existing structure instead of using a template.

Adjust the structure

After placing the structure in the bounding polygon you will see the following prompt at the command line:

Adjust structure [Move/Step-move/step-Rotate/rotate/Ninety/Parallel/On-boundary/setup/Done] <D>:

You are now at the stage where the structure can be adjusted to its final desired location with relationship to the setback lines and its orientation with respect to the street and other features.

In all the commands used to adjust the structure, the distances to the bounding polygon may be displayed at the appropriate corners of the template (see example below). You may turn this distance display on or off or view or change other fit structure parameters using the setUp option (type U and Enter at various the prompts).

Move:

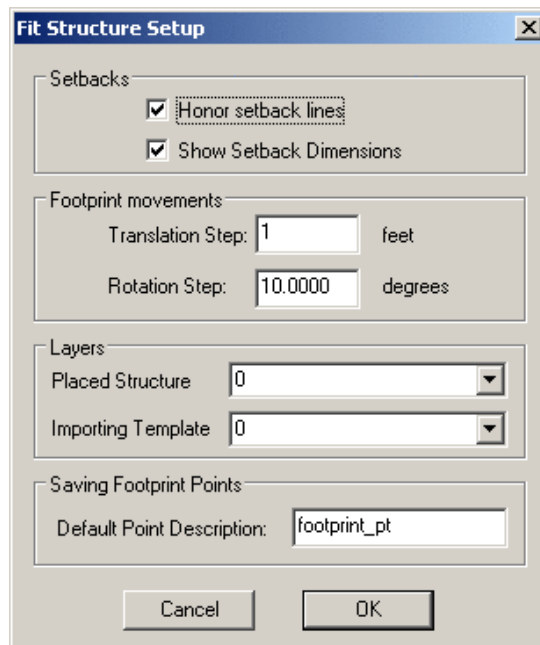

Type M and Enter to "drag" the structure around using the mouse cursor - similar to when you first placed the structure in the bounding polygon. This option is only meant for moving the structure in a gross, imprecise way and thus allow you to place it near its final location. After using this option the structure can be more finely adjusted using one of the other options described here.

Step-move:

To move the structure up, down, left or right, using the arrow keys on the keyboard, type S and Enter. The following prompt will appear:

Press arrow keys to move 1.000 dwg units [setUp/Done] <D>:

Now you can use the arrow keys on your keyboard to move the structure by steps in the X and Y directions. The distance moved per keystroke is indicated at the command line - in this case the structure moves 1 unit each time you press an arrow key. To change the per step increment, type U for setUp. This brings up the **Fit Structure Setup** dialog, allowing you to change the **Translation Step** setting (see below).

Click **OK** to return to the **Adjust Structure** command line.

Step-Rotate:

If you type R and Enter for **step-Rotate** you can then use the up and down arrow keys on the keyboard to rotate the structure by small rotational steps.

The following prompt will appear:

Use down/up arrow keys to rotate 10°00'00" clockwise/ccw [setUp/Done] <D>:

Rotate:

To rotate the structure, type R and Enter. The following prompt will appear:

Rotate structure to desired orientation: [setUp] <pick>:

Use this option to rotate the structure by moving the mouse. Left clicking will place the structure at the current rotated orientation. This method of rotation is not precise and is thus useful only for gross rotational movements.

rot-Ninety: Type N and Enter to rotate the structure 90 degrees in a clockwise direction.

Parallel:

Type P and Enter to rotate the structure so that one of its sides is parallel to a specified line segment on the bounding polygon.

First, select the side of the bounding polygon that you wish to be parallel to a selected side of the structure.

Next, select the side of the structure that is to be parallel to the previously selected line on the bounding polygon.

After picking the side on the structure the structure will be rotated into position.

Note: If the rotating the structure about its geometric center to make the selected sides parallel to one another will cause an encroachment, an error message will be displayed, no changes will be made, and you will return to the **Adjust Structure ...** prompt.

On-boundary:

Type O and Enter to choose a point on the structure that is to touch a selected point on the bounding polygon. This is accomplished by translation only.

Pick the point on the bounding polygon where you want the structure to touch: Pick the point where the structure touches the bounding polygon.

Choose the point on the structure that you want to touch the bounding polygon: Pick the point on the structure that touches the bounding polygon.

If choosing a structure corner as the point to touch the bounding polygon, you should use the end point snap. If you do not use end point snap, the translation of the point picked to the bounding polygon will likely cause the corner of the structure to encroach. You can specify end point snap when picking the point on the structure by typing in "end" and Enter at the prompt, then you merely need to pick a point on the structure near the desired corner to actually specify the corner point.

Note: If the translating the structure to make the selected point touch the bounding polygon at the selected point would cause an encroachment, an error message will be displayed, no changes will be made, and you will return to the **Adjust Structure ...** prompt.

Completing the adjustment process

Once you are satisfied with the location of the structure type D and Enter and you will see the following prompt:

Creating structure coordinate points:

Enter description for structure corner points <footprint_pt>:

You can accept the default description shown in brackets by pressing Enter or you may type in a description that will help you identify this particular structure and lot.

The corner and any radius points for the current location of the structure are stored in the current coordinate file and, if **Auto plot points** is ON, the points are drawn.

After storing the points for the previously placed structure you will see the following prompt:

Choose a structure template [Set template/Current Template/Mirror current/Done] <C>:

Press Enter or C and Enter if you wish to repeat the process and place the current structure template in the same or another bounding polygon.

If you wish to place a mirrored ("reverse") version of the current structure template in a bounding polygon, type M and Enter.

If you wish to place a different structure in a bounding polygon, type S and Enter to bring up the Template Manager, allowing you to pick a new template.

If you are done placing templates for now, type D and Enter for Done.

At any time you may adjust an existing structure by choosing **Fit Structure**. If there are existing structures in the drawing, it will be detected and the following the prompt will appear at the command line:

Pick existing structure to adjust or choose a structure template.

[Set-template/Current-template(Wilson)/Mirror-current/Done] <C>:

At this prompt you can use the mouse to pick an existing structure to adjust. You can now use any of the adjustment methods described above to further refine the location of the structure. After the adjustment process is complete the coordinate file is updated to reflect the adjusted locations of the structure's corner and radius points.

Note: When you pick an existing structure, any plotted corner point symbols are temporarily removed to facilitate the adjustment process. Once you are done adjusting the existing structure, these points are re-plotted at their new adjusted locations

At this prompt you may also choose to place a new structure in a bounding polygon. To use a different template, type S and Enter to bring up the **Template Manager** and allow to choose the desired template. If you

have already placed a template in the current drawing session, the prompt will indicate the current template. By typing C and Enter or just pressing Enter you can choose to place the current template in a bounding polygon or you can type M and Enter to place a mirrored version of the current template:

Prompts

Template Manager dialog: create or choose a template to place within a bounding polygon (a lot)

Add a Template dialog: Used in conjunction with the Template Manager dialog to add a template to a given project.

if you have already specified a template to use but no templates have been placed in the drawing:

Choose a structure template

[Set template/Current template (Wilson)/Mirror-current/Done] <C> : Type "S" and Enter to bring up the Template Manager dialog. Type "C" and Enter or just Enter to use the current template. Type "M" and Enter to mirror the current template. Type "D" and Enter when done placing templates.

if a structure/template exists in the drawing or you have already specified a template to use:

Pick existing structure to adjust or choose a structure template.

[Set-Template/Done] <S> : To adjust an existing structure pick it on the screen. Type "S" and Enter or just Enter to bring up the Template Manager dialog to choose a new template. Type "D" and Enter when done.

after you set a new template or chose to use the current one:

Pick the lot within which the structure will be placed [c&g-Point-group/Done] <pick> : pick the polyline or a series of lines that define a closed polygon within which the structure template will be placed. Type P and Enter to specify the bounding polygon using a C&G Point Group file.

Place the structure near its final location in the bounding polygon <pick> : Drag the structure template to the desired location and click the left mouse button to place the structure.

after you place a template or pick one to adjust:

Adjust structure [Move/Step-move/step-Rotate/roTate/rot-Ninety/Parallel/On-boundary/setUp/Done] <D> : Type "M" and enter to move the structure. Type "S" and Enter to use the arrow keys to move the structure in predefined steps. Type "T" and Enter to use the cursor to rotate the structure. Type "R" and Enter to rotate the structure template a predefined number of degrees using the up and down arrow keys. Type "N" and Enter to rotate the structure 90 degrees clockwise. Type "P" and Enter to translate and rotate the structure template parallel to a side of the bounding polygon. Type "O" and Enter to move the structure template so a chosen point on the structure touches a chosen point on the bounding polygon. Type "U" and enter to use the Setup dialog to change the step sizes, layer names and other configuration items for the fit structure command.

when saving the structure coordinate points:

Enter description for structure corner points <footprint_pt> : Specify a description for the structure template corner points to be saved in the coordinate file or just press Enter to use the default description.

Pulldown Menu Location: Area/Layout > Layout Utilities

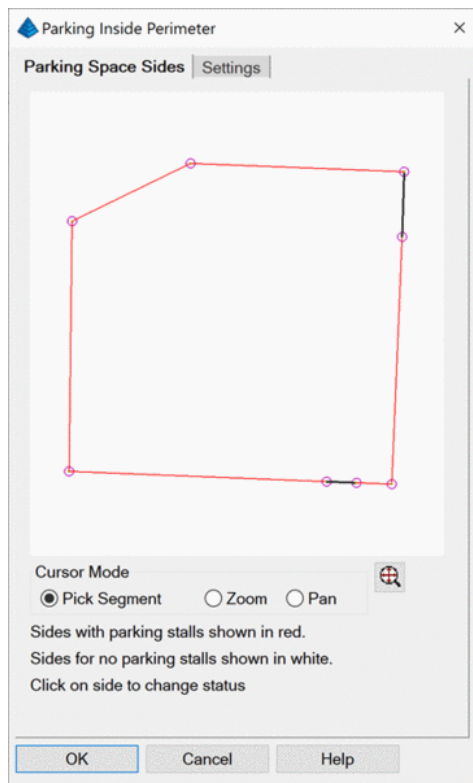

Keyboard Command: cg_fit_structure

Prerequisite: coordinate file, pre-drawn bounding polygon (lines and arcs or a polyline)

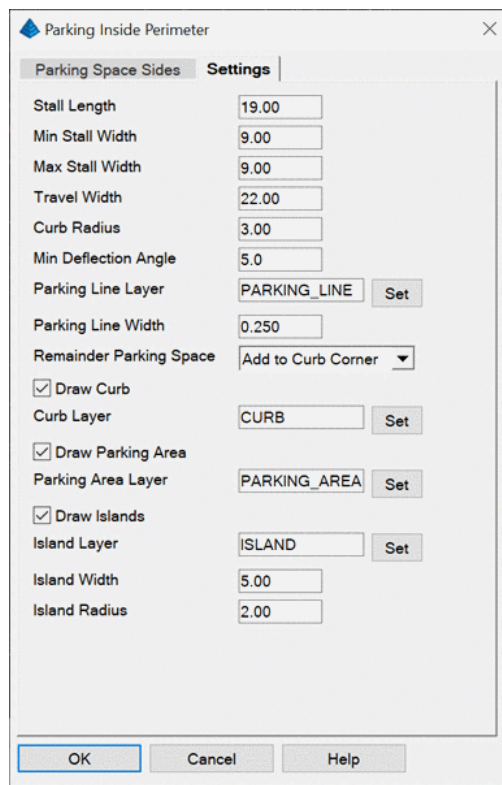

Design Parking Inside Perimeter

This command creates a parking lot layout inside a closed polyline. The program draws parking stalls along the perimeter and creates interior parking stalls. Before starting the command, create a closed polyline that has vertices for any locations along the perimeter where to skip creating stalls. For example, the part of the perimeter where the parking lot entrance is located should have vertices on either side of the entrance.

The command starts by selecting the parking perimeter. Then the dialog shows the selected perimeter. Pick on the perimeter segments for skipping parking stalls. In this example, the segments on the bottom-right and top-right are set for no parking stalls. Use the Create Parking Spaces Along Sides option to turn off all parking spaces around the perimeter and only create interior parking spaces.

The dialog has a Settings tab to set the dimensions of the parking stalls. The Min Stall Width and Max Stall Width set a range for the program to best fit the stalls along the perimeter. Set these widths to the same value to hold a fixed width. The Travel Width is the space between the rows of interior parking stalls. The Curb Radius is used for the fillet radius on interior corners. The Parking Line Layer and Parking Line Width are used for the parking stall lines. Using the Parking Line Width makes the lines show like paint stripes in the 3D Viewer command. When the parking stalls don't exactly fit a perimeter edge and there is left over space, the Remainder Parking Space setting chooses between leaving the space empty or making the curb corner larger to use up the space. The Draw Curb option draws a polyline around the perimeter with the interior corners and excluding the skip parking segments. The Draw Parking Area creates a closed polyline that makes the perimeter of the parking area. The Draw Islands option creates polylines for islands at the end of the parking space rows.

After the dialog, the program draws the parking lines and reports the number of parking stalls. The interior parking stalls are automatically created in the direction that makes the longest rows.

Prompts

Pick perimeter polyline: *pick driveway polylines*

Parking Perimeter dialog

Created 128 parking spaces.

Pulldown Menu Location: Area/Layout > Parking Utilities

Keyboard Command: park_perim

Prerequisite: Closed polyline

Edit Parking Inside Perimeter

This command adjusts the perimeter polyline and recreates the parking layout from the Design Parking Inside Perimeter command. To start the command, pick any entity from the parking design. The program shows symbols along the parking perimeter. Pick near the plus symbol to adjust a single vertex and pick near a triangle to adjust a segment. After picking the vertex or segment to adjust, the program shows the new layout in real-time as you move the cursor to pick the new position. After picking the new position, the parking layout is redraw and the program reports the number of parking spaces and new parking area.

Prompts

Pick parking linework: *pick any entity from the parking design*

Pick perimeter point to adjust: *pick point on perimeter to adjust*

Created 127 parking spaces in area 38787.0 sf.

Pick perimeter point to adjust (Enter to end): *press Enter*

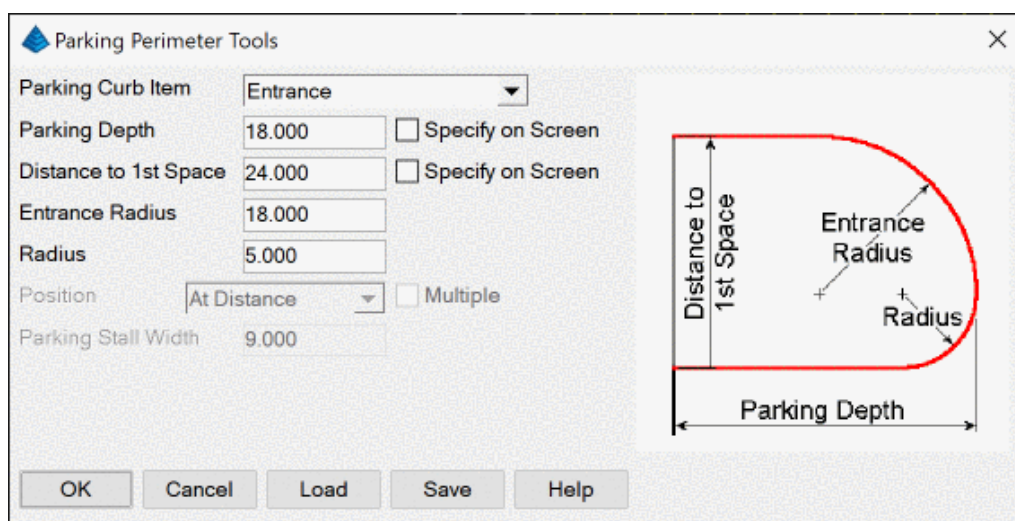

Pulldown Menu Location: Area/Layout > Parking Utilities

Keyboard Command: park_adj_perim

Prerequisite: Parking design

Parking Perimeter Tools

Parking Perimeter Tools are a set of tools to assist in the design of parking area curb linework.

Parking Curb Item: Tool items; Entrance, Half-Island, Bump-Out, Exterior Corner, , Extend Corner and Interior Corner

Depth: Depth of the curb item **Specify on Screen** Value will be input by prompt

Width: Width of the curb item **Specify on Screen** Value will be input by prompt

Exterior Radius: Radius on the exterior of the curb item

Interior Radius: Radius on the interior of the curb item

Position: Options for placement; By Pick, At Stall Count or At Distance

Parking Stall Width: Width of parking each stall

The **Save** and **Load** buttons save and recall the curb item settings to a .PARK file.

Parking Perimeter Tool dialog

Select Parking Perimeter Polyline: *Select the entity to attach the parking curb item to. The command will use this initially selected polyline as the perimeter polyline through out the command.*

Entrance

Select end point to attach Entrance: *Select an end point of the entity. The entrance will be located at the closest end point of the point selected.*

Select polyline to align Entrance (Enter for None): *Select another polyline to align the entrance. If selected the entrance will join to the selected polyline.*

Pick side: *Pick a point for the entrance, the entrance will be drawn toward the point selected.*

Half-Island

Optional for By Pick

Pick center point for Half-Island: *Pick a point for the placement of the half-island.*

Pick Side: *Pick a point for the side of the half-island, the half-island will be drawn toward the point selected.*

Optional for At Stall Count and At Distance

Pick reference point for Half-Island: *Pick the point where the distance or stall count is calculated from along the*

entity selected.

Pick side and direction: Pick a point for the side of the half-island, the half-island will be drawn on the side of the perimeter toward the point selected.

Optional for At Distance

Half-Island Spacing: Graphically pick or input the distance to the half-island.

Optional for At Stall Count

Parking Stall Count: Input the number of parking stalls fit before the half-island.

Bump-Out

Pick center point for Bump-Out: *Pick a point for the placement of the bump-out.*

Pick Side: *Pick a point for the side of the bump-out, the bump-out will be drawn toward the point selected.*

Exterior Corner

Pick a to attach Exterior Corner: *Pick a point, the corner will be located at the closest vertex of the point selected.*

Extend Corner

Pick a point to attach Extend Corner: *Pick a point, the corner will be located at the closest vertex of the point selected.*

Pick Side: *Pick a side point for the corner to be extended.*

Interior Corner

Pick a to attach Interior Corner: *Pick a point, the corner will be located at the closest vertex of the point selected.*

Pick a point to attach *last curb item* or (Enter to End)[Options/Undo]:

Options will allow you to return to the Parking Perimeter Tool to change curb item or parameters.

Undo will undo the previous *curb item* placed.

Depth: *Graphically pick or input the depth of the curb item.*

Width: *Graphically pick or input the width of the curb item.*

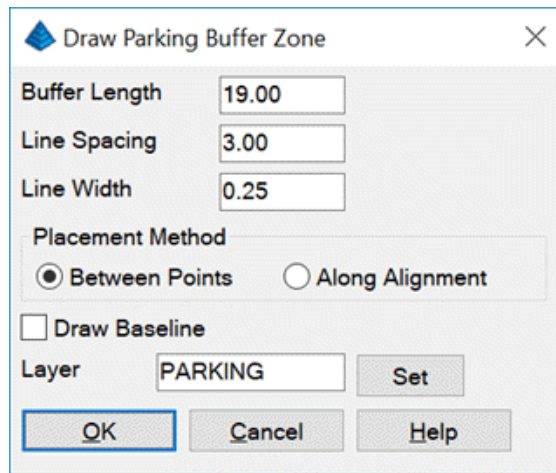

Pulldown Menu Location: Area/Layout > Parking Utilities > Parking Perimeter Tools

Keyboard Command: park_tool

Prerequisite: Parking perimeter linework

Parking Buffer Zone

This command draws a striped buffer zone for next to parking stalls.

Buffer Length: Sets the depth for the buffer which is typically the same as the parking stall length.

Line Spacing: Sets the interval for the stripes.

Line Width: Sets the line width property of the buffer lines. Using a Line Width helps with viewing the buffer lines in the 3D Viewer.

Placement Method: Indicate the method to set the baseline for the buffer zone which controls the buffer width and alignment. The Along Alignment method prompts to select a line, arc or polyline and supports an alignment that changes direction including a curve.

Draw Baseline: This option draws a baseline in addition to the buffer side lines.

Layer: Specify the layer on which parking lines should be placed or click the Set button to choose an existing layer.

Prompts

Starting Point?

Pick point or point number: *Pick a point*

Ending Point?

Pick point or point number: *Pick a point*

Pulldown Menu Location: Area/Layout > Layout Utilities

Right Add selected treatment to the right side of design

Right Treatments List of parking treatments assigned to right side

Up/Down Reorder the selected parking treatment

Remove Remove the selected parking treatment

Edit Edit selected parking treatment

Mirror Mirror right parking treatments to the left

Treatment Setup/Edits

Treatment edit is the same for edit of a side's treatment and setup of available treatments.

Entrance

The screenshot shows a dialog box titled "Parking Treatment" with a close button (X) in the top right corner. The dialog is divided into two main sections. On the left, there is a list of settings for the "Entrance" parking treatment:

Parking Treatment	Entrance
Parking Depth	18.000
Distance to 1st Space	24.000
Entrance Radius	12.000
Radius	5.000

On the right, there is a diagram of a parking stall with a semi-circular entrance. The diagram is outlined in red. Labels with arrows point to various parts of the diagram: "Distance to 1st Space" (the vertical distance from the entrance to the start of the parking space), "Parking Depth" (the horizontal distance from the entrance to the end of the parking space), "Entrance Radius" (the radius of the semi-circular entrance), and "Radius" (the radius of the inner curve of the entrance).

At the bottom of the dialog, there are five buttons: "Add Left", "Add Right", "OK", "Cancel", and "Help".

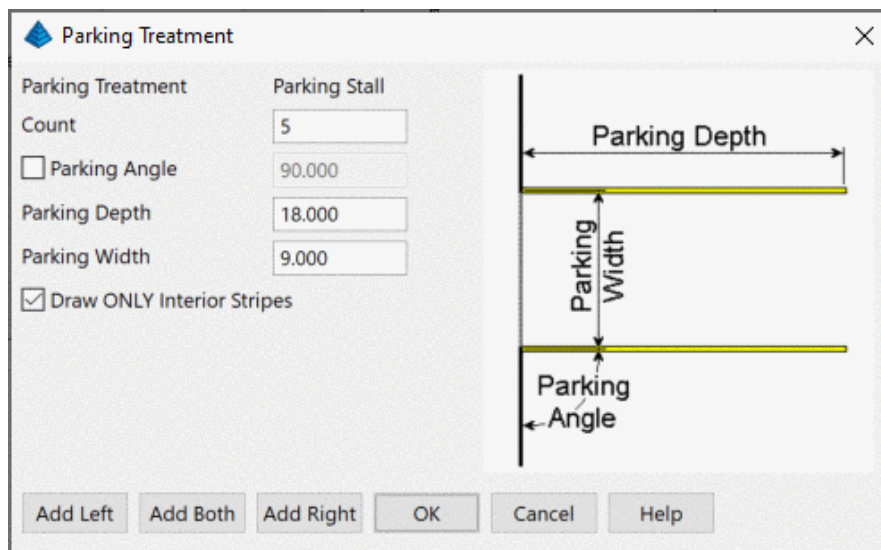

Parking Depth: Distance from parking perimeter to inside of entrance.

Distance to 1st Space: Distance from entrance to start of parking treatments.

Entrance Radius: Radius on the outside of entrance.

Radius: Radius on the inside of entrance.

Parking Stall

Count: Number of parking stalls.

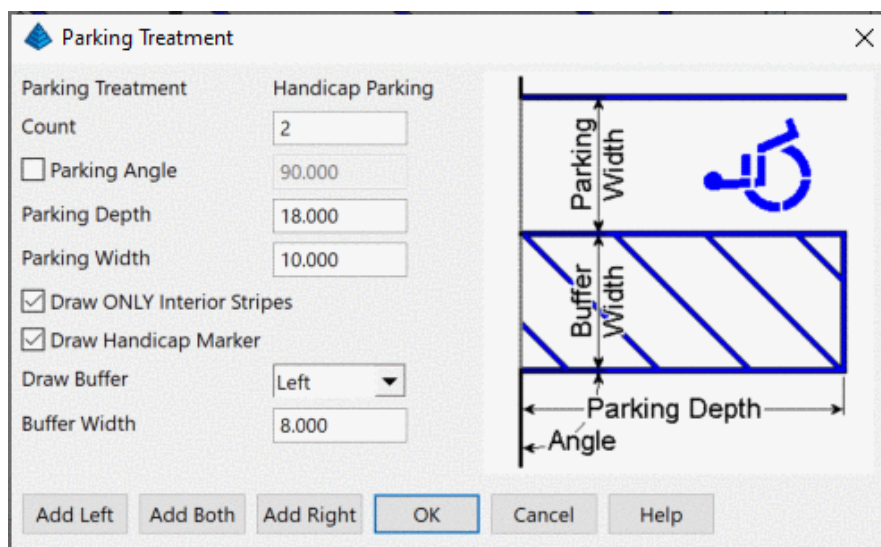

Parking Angle: Toggle to set the angle of parking stall.

Parking Depth: Depth of parking stall.

Parking Width: Width of parking stall.

Draw ONLY Interior Stripes: Include or exclude first and last stripe lines.

Handicap Parking

Count: Number of handicap parking stalls.

Parking Angle: Toggle to set the angle of parking stall.

Parking Depth: Depth of handicap parking stall.

Parking Width: Width of handicap parking stall.

Draw ONLY Interior Stripes: Include or exclude first and last stripe lines.

Draw Handicap Marker: Draw the handicap marker in the parking stall.

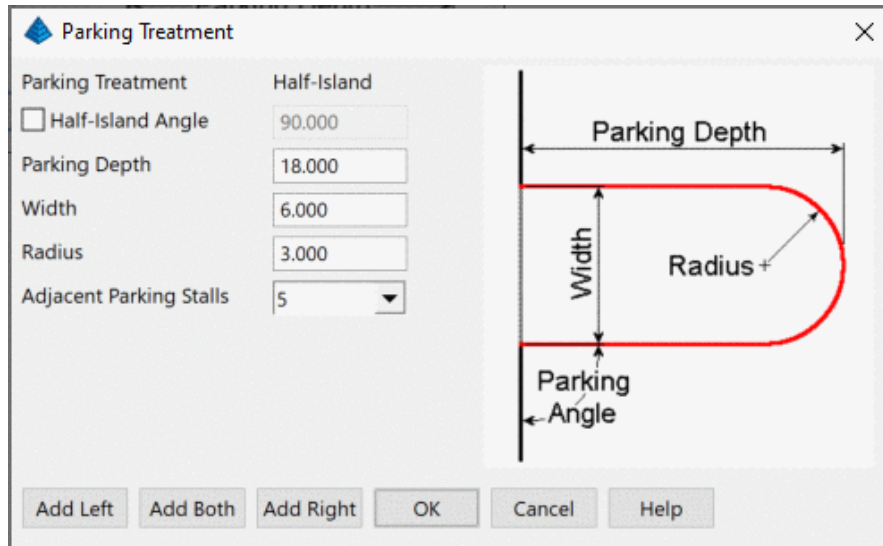

Draw Buffer: Location of parking buffer **None** No buffer is drawn

Left Buffer is drawn on the left side of stall

Right Buffer is drawn on the right side of stall

Both Buffer is drawn on both sides of stall
Buffer Width: Width of parking buffer.

Half-Island

Half-Island Angle: Toggle to set the angle of half-island.

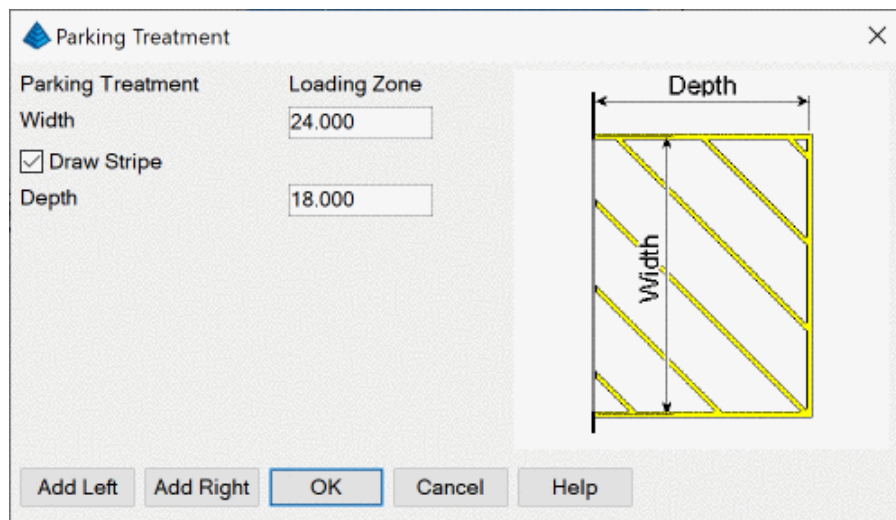

Parking Depth: Distance from parking perimeter to inside of half-island.

Width: Width of half-island.

Radius: Radius on inside of half-island.

Adjacent Parking Stalls: (Optional for Available Treatment's Edit) Number of parking stalls to add if none are adjacent to half-island.

No Parking Zone/Loading Zone/Emergency Zone

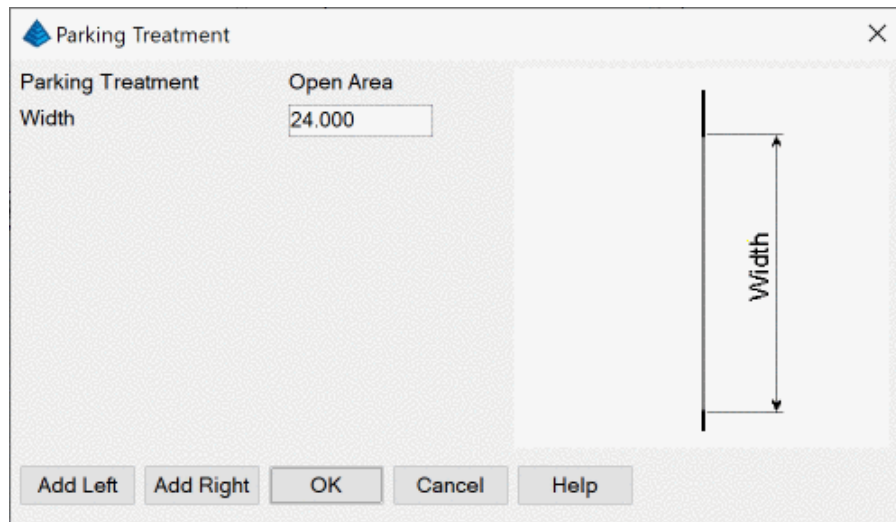

Width: Width of parking treatment.

Draw Stripe: Draw the Stripe for parking treatment.

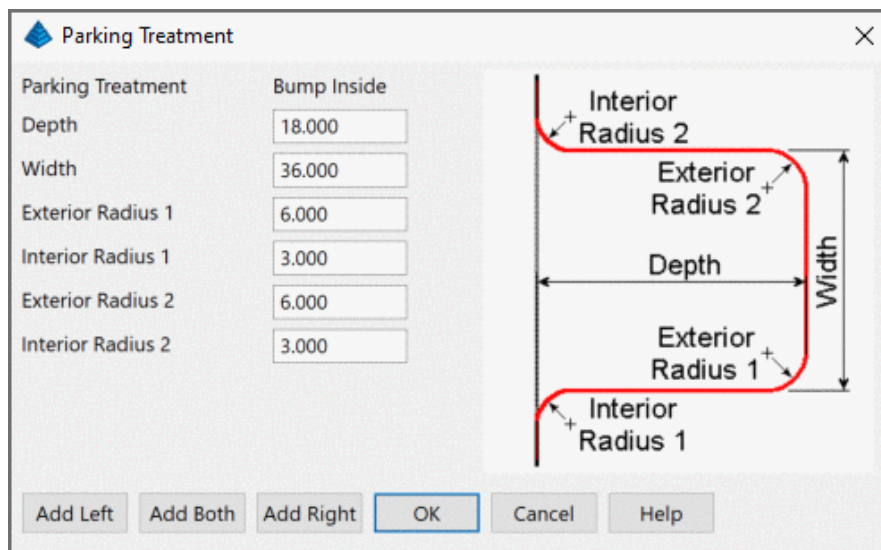

Depth: Distance from parking perimeter to inside of treatment.

Open Area

Width: Width of open area.

Bump Inside

Depth: Distance from parking perimeter to inside of bump inside.

Width: Width of bump inside.

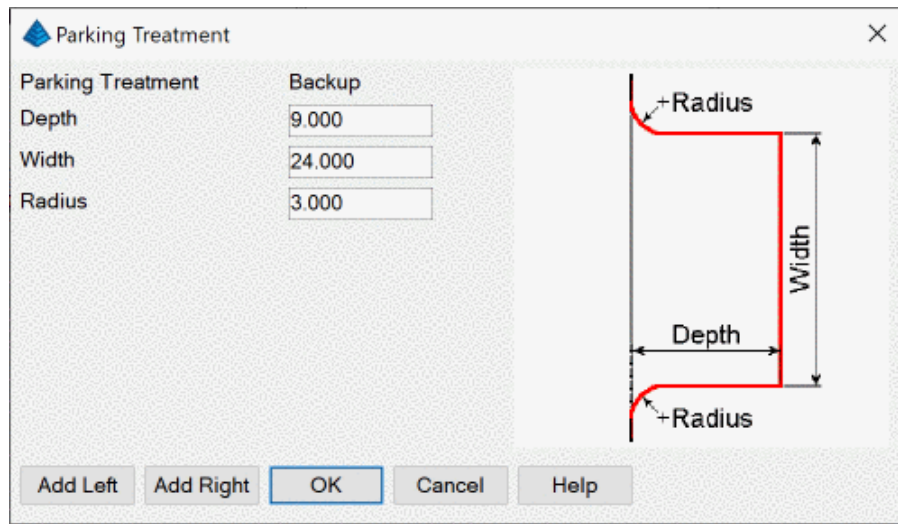

Exterior Radius 1: Radius of first side on the inside of bump inside.

Interior Radius 1: Radius of first side on the outside of bump inside.

Exterior Radius 2: Radius of second side on the inside of bump inside.

Interior Radius 2: Radius of second side on the outside of bump inside.

Backup

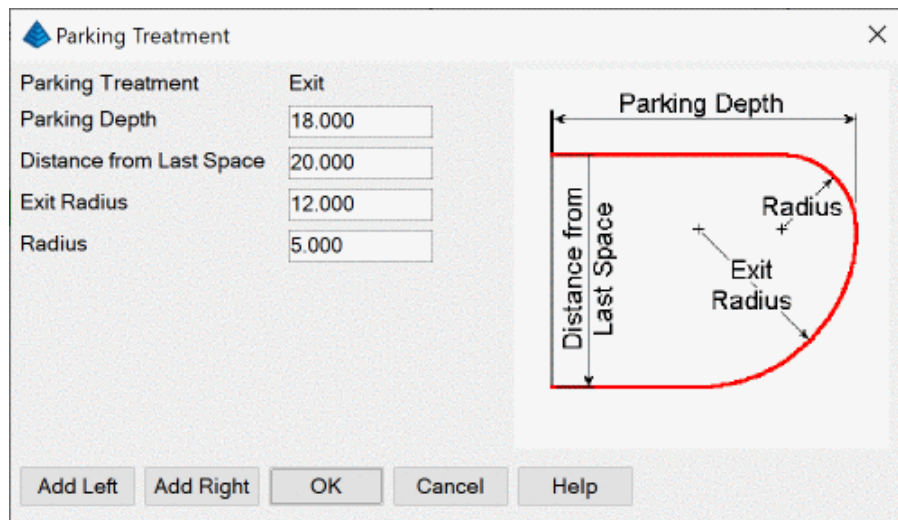

Depth: Distance from parking perimeter to inside of backup.

Width: Width of backup.

Radius: Radius on the outside of backup.

Exit

Parking Depth: Distance from parking perimeter to inside of exit.

Distance from Last Space: Distance from last parking treatment to exit.

Exit Radius: Radius on the outside of exit.

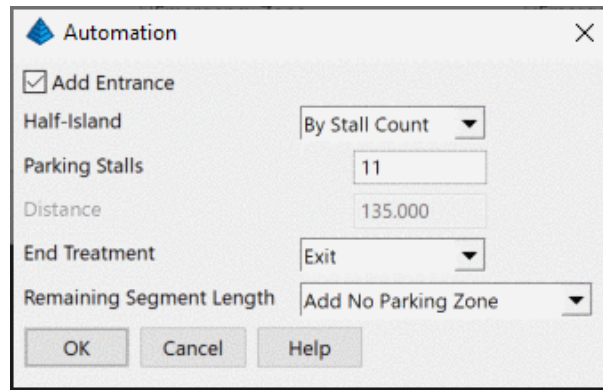

Radius: Radius on the inside of exit.

Add Left: (Optional for Available Treatment's Edit) Adds the treatment to the left list.

Add Right: (Optional for Available Treatment's Edit) Adds the treatment to the right list.

Automation dialog

The Automation dialog can automatically generated based of selected parameters. When placing treatments it will use the defaults of the treatment from the Layout tab. Various options can be selected to get a start of a parking design based on the initial selected length.

Add Entrance: If the default Entrance is added to both the left and right sides of the automatic design.

Half-Island: Method for adding half-islands to the automatic design.

None No half-islands will be automatically added to the automatic design.

By Stall Count Half-islands will be added after a number of stalls.

By Distance Half-islands will be added after a specified distance.

End Treatment: Type of end treatment to use when generating an automatic design.

None No end treatment will be automatically added to the automatic design.

Backup A backup is added to the design to allow for vehicles to backup and exit.

Exit An exit is added to both the left and right sides.

Remaining Segment Length: The way that the remaining length is used for treatment generation.

Add No Parking Zone Add no parking zone of remaining length.

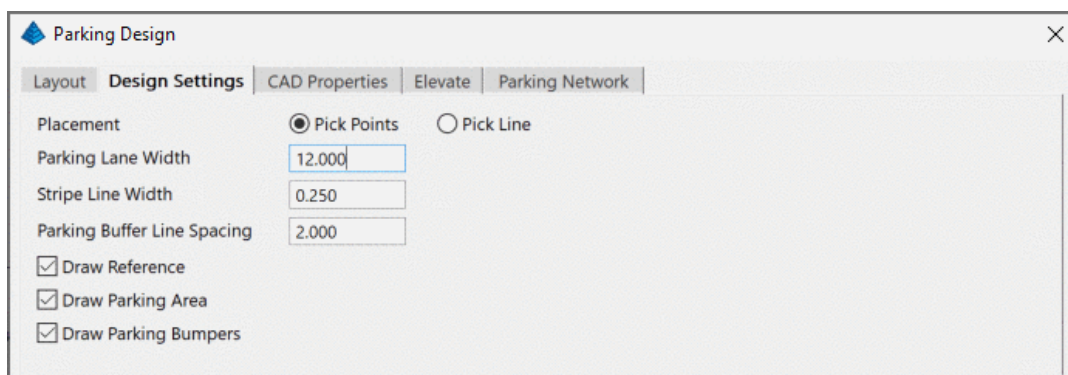

Add Open Area Add open area of remaining length.

Distribute Distribute the remaining length among last treatment.

Append to End Treatment Add remaining length to the segment end treatment.

OK Automatically generate the parking design based on the parameters specified.

Design Settings tab

Placement:

Pick Points Graphically select the start and end points for parking alignment.

Pick Line Graphically select a line for parking alignment.

Parking Lane Width: Width of the drive lane of parking.

Stripe Line Width: Line width of the parking stripes.

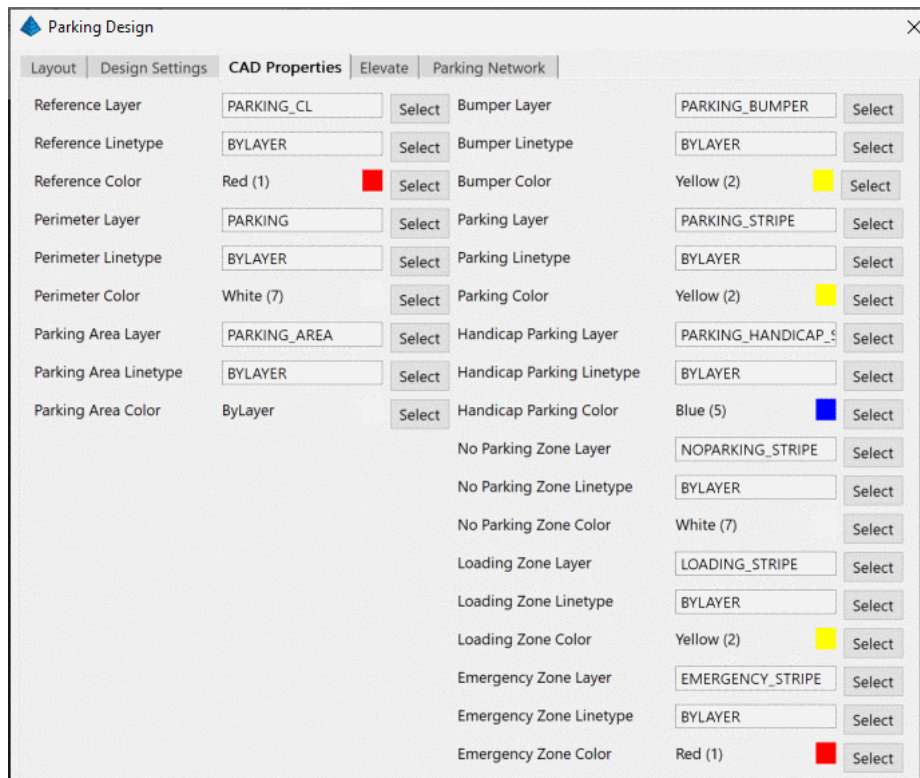

Parking Buffer Line Spacing: Distance between buffer line stripes.

Draw Reference: Toggle to draw the reference alignment.

Draw Parking Area: Toggle to draw the closed parking area.

Draw Parking Bumpers: Toggle to draw the parking bumpers on angled stalls.

CAD Properties tab

Reference Layer: Layer to draw the reference CL.

Reference Linetype: Linetype to draw the reference CL.

Reference Color: Color to draw the reference CL.

Perimeter Layer: Layer to draw the perimeter.

Perimeter Linetype: Linetype to draw the perimeter.

Perimeter Color: Color to draw the perimeter.

Parking Area Layer: Layer to draw the parking area.

Parking Area Linetype: Linetype to draw the parking area.

Parking Area Color: Color to draw the parking area.

Bumper Layer: Layer to draw the parking bumpers.

Bumper Linetype: Linetype to draw the parking bumpers.

Bumper Color: Color to draw the parking bumpers.

Parking Layer: Layer to draw the parking stripes.

Parking Linetype: Linetype to draw the parking stripes.

Parking Color: Color to draw the parking stripes.

Handicap Parking Layer: Layer to draw the handicap parking stripes, buffer and marker.

Handicap Parking Linetype: Linetype to draw the handicap parking stripes, buffer and marker.

Handicap Parking Color: Color to draw the handicap parking stripes, buffer and marker.

No Parking Zone Layer: Layer to draw the no parking zones.

No Parking Zone Linetype: Linetype to draw the no parking zones.

No Parking Zone Color: Color to draw the no parking zones.

Loading Zone Layer: Layer to draw the loading zones.

Loading Zone Linetype: Linetype to draw the loading zones.

Loading Zone Color: Color to draw the loading zones.

Emergency Zone Layer: Layer to draw the emergency zones.

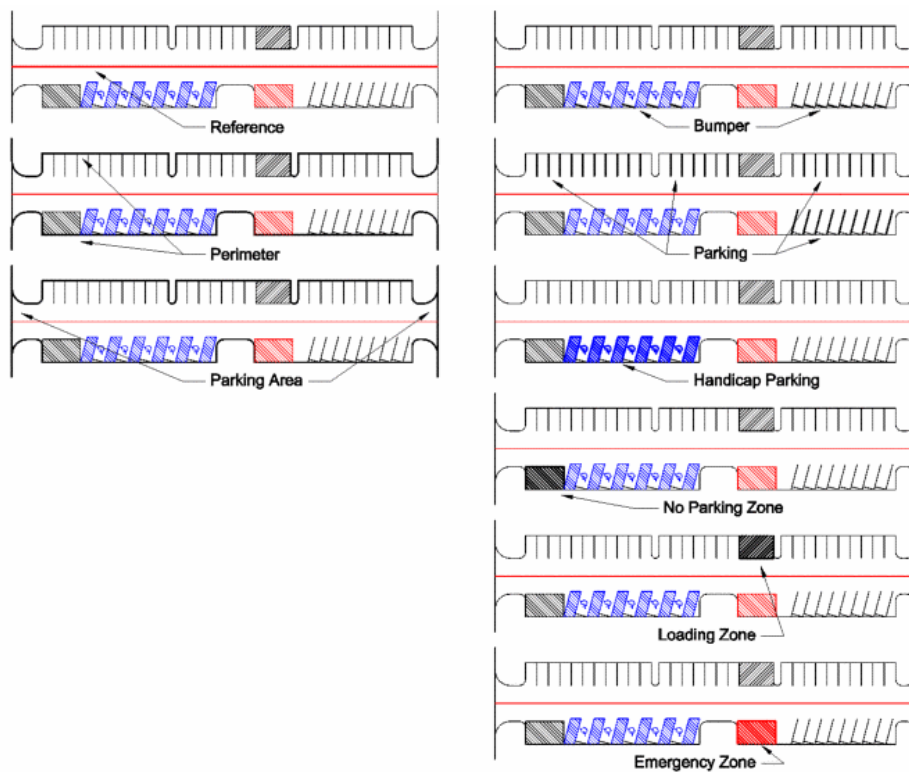

Emergency Zone Linetype: Linetype to draw the emergency zones.

Emergency Zone Color: Color to draw the emergency zones.

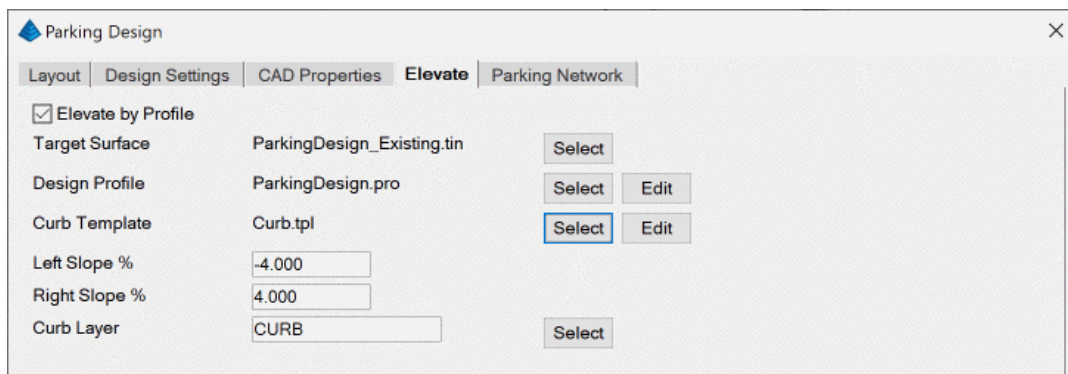

Select: (Layer) Select the corresponding layer from list.

Select: (Linetype) Select the corresponding linetype from list.

Select: (Color) Select the corresponding color from list.

Elevate tab

Elevate by Profile: Elevate the perimeter linework by the profile and side slopes.

Target Surface: Existing Surface to target. **Select:** Use this button to browse to and select the Existing Surface file to be used for the Road Network. Either a TIN or FLT triangulation file are accepted as valid surfaces, both of which can be made within the command Triangulate and Contour. For speed, it is recommended that the binary TIN file format be selected.

Design Profile: Design Profile of parking alignment. **Select:** Select the design profile file. **Edit:** Edit the design profile.

Curb Template: Curb Template to draw along perimeter. **Select:** Select the curb template file. **Edit:** Edit the curb template.

Left Slope %: Left slope from profile.

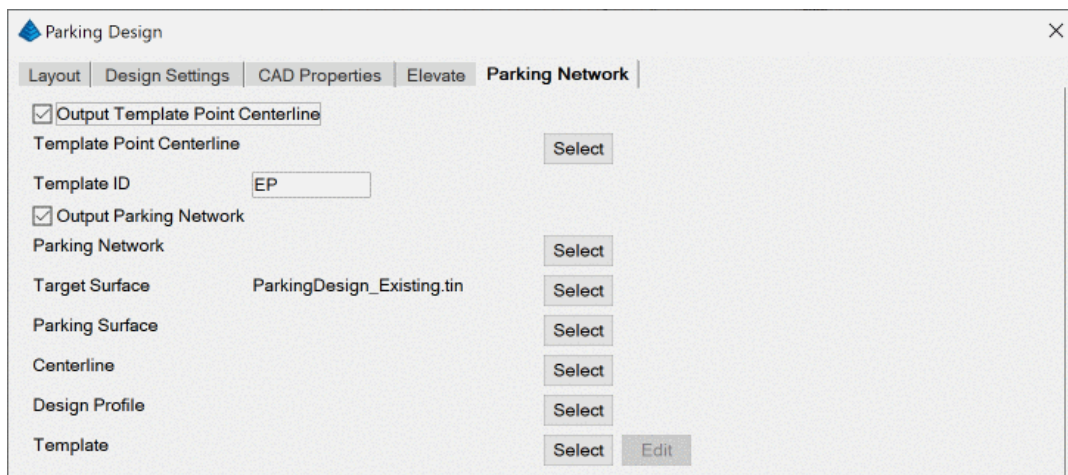

Right Slope %: Right slope from profile.

Curb Layer: Layer to draw the curb linework.

Parking Network tab

For integration with Road Network the parking design command can create the necessary data files to process with Road Network.

Output Template Point Centerline: Toggle for creation of a Template Point Centerline.

Template Point Centerline: Specified Template Point Centerline TPC file to create from the parking design.

Template ID: ID to use within the TPC file.

Output Parking Network: Toggle for creation of a Road Network RDN file from the parking design.

Parking Network: Specified Road Network RDN file to create from the parking design.

Target Surface: Existing Surface to target. **Select:** Use this button to browse to and select the Existing Surface file to be used for the Road Network. Either a TIN or FLT triangulation file are accepted as valid surfaces, both of which can be made within the command Triangulate and Contour. For speed, it is recommended that the binary TIN file format be selected.

Parking Surface: Parking Surface to create. **Select:** Use this button to browse to and select the Parking Surface file to be output from Road Network. Either a TIN or FLT triangulation file are accepted as valid surfaces For speed, it is recommended that the binary TIN file format be selected.

Centerline: Parking alignment centerline to create. **Select:** Use this button to browse to and select the Centerline file to be output for Road Network.

Design Profile: Parking alignment centerline's profile to create. **Select:** Use this button to browse to and select the Profile file to be output for Road Network.

Template: Template to use for the Road Network. **Select:** Select the template file. **Edit:** Edit the template.

The **Save** and **Load** buttons save and recall the parking design settings to a .PKD file.

Pick Start Point [CL-Centerline/P-Polyline] (Enter for none): Pick the start point for the parking alignment.

Pick Next Point: Pick the next point of the parking alignment.

Pick Next Point (enter to end): Pick additional points of the parking alignment or enter to end point selection.

Centerline Select the centerline file to use for the parking alignment.

Polyline Select the line for the parking alignment. The parking design will start at the line start point draw the direction that the line is drawn.

Optional Prompts

Select polyline to align Entrance (Enter for None): Select another polyline to align the entrance. If selected the entrance will join to the selected polyline.

Select polyline to align Exit (Enter for None): Select another polyline to align the exit. If selected the exit will join to the selected polyline.

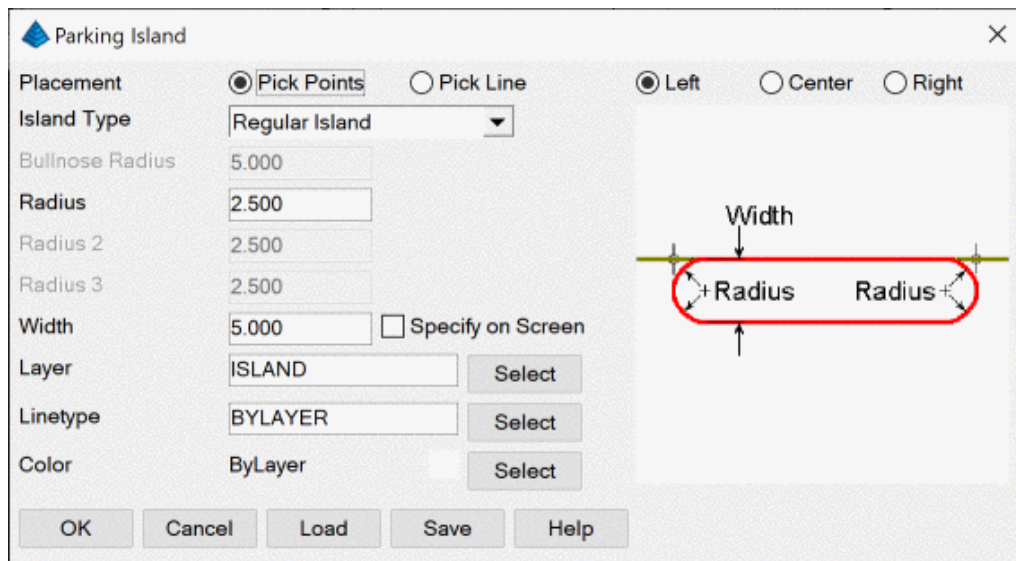

Pulldown Menu Location: Area/Layout > Parking Utilities > Design Parking Along Alignment

Keyboard Command: park_design

Prerequisite:

Parking Island

Parking Design is a set of tools to create a network of parking treatments.

Placement:

Pick Points Graphically select the start and end points for parking island.

Pick Line Graphically select a line for parking island.

Left The island will be aligned to the left of the selection.

Center The island will be drawn centered on the selection.

Right The island will be aligned to the right of the selection.

Island Type Type of island to create

Regular Island Regular cegar shaped island.

Bullnose Island Bullnose shape island.

Wedge Island Wedge shaped island.

Bullnose Radius Optional large radius on the bullnose island.

Wedge Radius Optional large radius on the wedge island.

Radius Radius on the regular island, smaller radius of bullnose island.

Radius 1 Optional radius 1 of the wedge island.

Radius 2 Optional radius 2 of the wedge island.

Radius 3 Optional radius 3 of the wedge island. **Width** Width of island.

The **Save** and **Load** buttons save and recall the parking island settings to a .ISLAND file.

Pick Start Point:

Pick End Point: *Pick the start and end points for the parking island.*

Select Line for Island: *Select the line for the parking island. The parking island will start at the line start point and be drawn the length of the line.*

Width: *Graphically pick or input the width of the island.*

Repeat prompt [**Options/Undo**] (**Enter to End**):

Options will allow you to return to the Parking Island to change type or parameters.

Undo will undo the previous island placed.

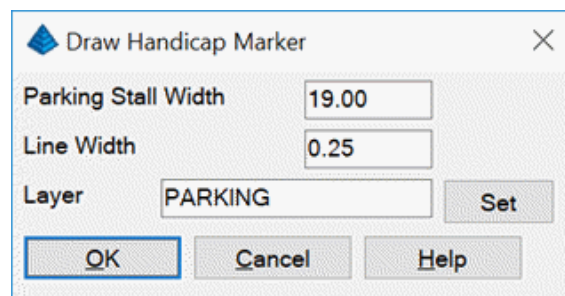

Pulldown Menu Location: Area/Layout > Parking Utilities > Parking Island

Keyboard Command: park_island

Prerequisite: None

Handicap Marker

This command draws a handicap symbol for parking stalls.

Parking Stall Width: Indicate the stall width which is used to size the marker.

Line Width: Sets the line width property of the parking lines. Using a Line Width helps with viewing the parking lines in the 3D Viewer.

Layer: Specify the layer on which parking lines should be placed or click the Set button to choose an existing layer.

Prompts

Pick point: *Pick a point for the marker center*

Pick rotation: *Pick a point*

Pulldown Menu Location: Area/Layout > Layout Utilities

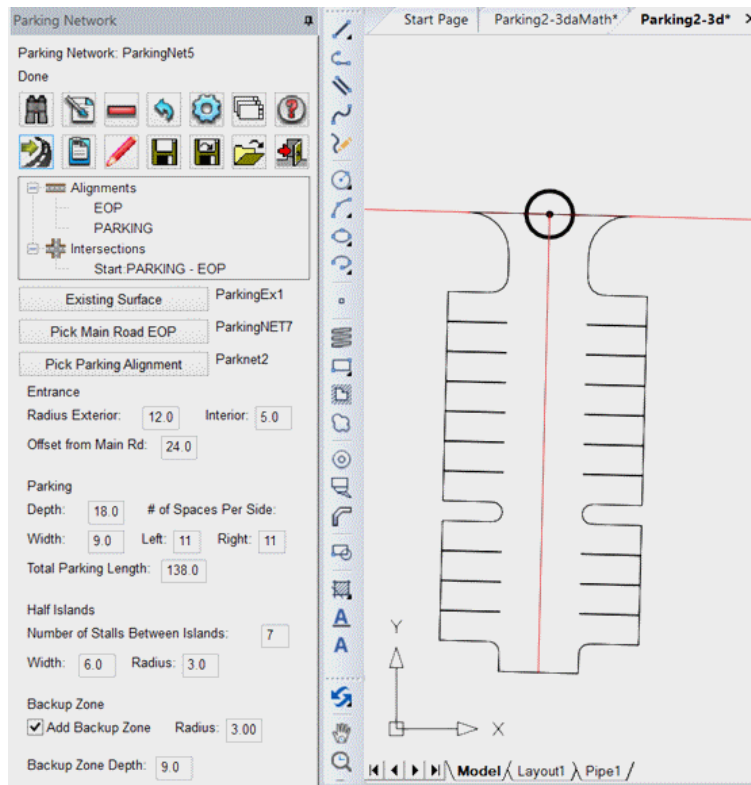

Keyboard Command: handicap_marker

Prerequisite: None

Parking Network

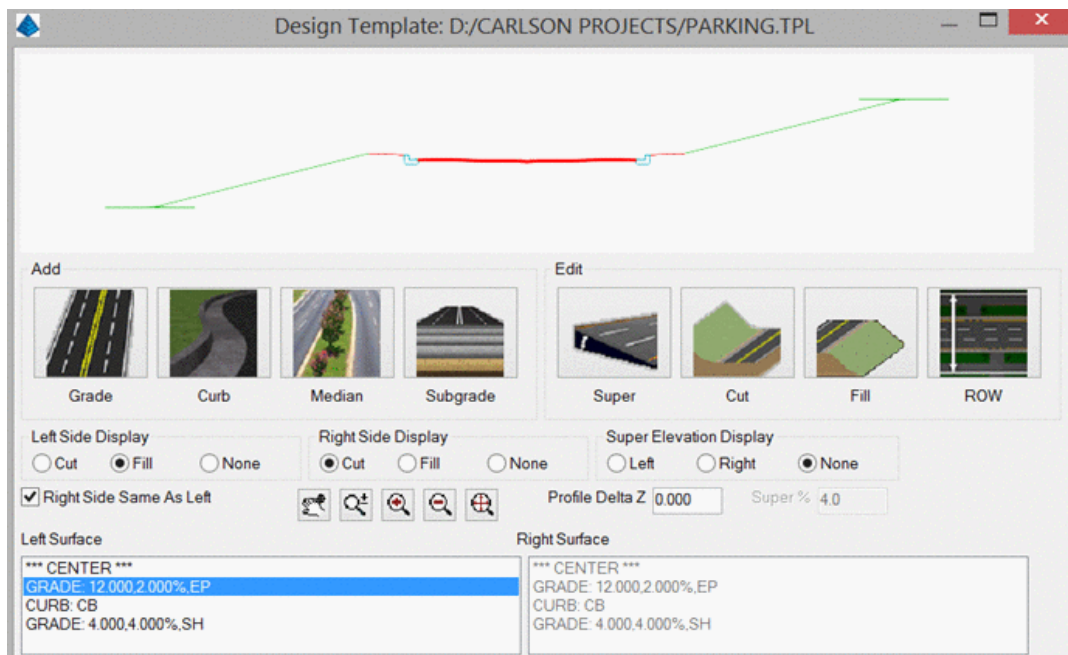

This command quickly designs parking based on a 2-point parking alignment connecting to a main road edge-of-pavement alignment. The typical application is to use a curb-based template for the parking, with dimensions for the parking stalls set within the main dialog.

A dialog pops up immediately that is similar to Roadnet, in which you work your way top to bottom starting by selecting the Existing Surface. After you complete the 3 items highlighted in red below, the Edit Alignment dialog appears, where you can review your Parking template (as well as the alignment data). The program automatically defaults to using the Parking.tpl file for the template, which sets the grade to the center of the driving lanes for the parking. You need to check the current default values set in the remainder of the dialog. These defaults recall your last use of the command. Then you launch the calculation by clicking the Process button as also highlighted in red.

There are a number of default assumptions used in ParkingNet:

1. The Parking Alignment is a 2-point polyline.
2. Both the main road EOP alignment and the Parking alignment are given default names, "EOP" and "Parking"
3. Curb and Gutter parking perimeters are assumed.
4. The Main Road EOP (edge-of-pavement) is used primarily to transition the parking curb and gutter perimeter in an "apron" effect as shown above and below. For this, the "Zero" template is used automatically by the program, and provided to the user as Zero.tpl.
5. A Parking Template is used for the parking which assigns the width of the driving lane, and the slopes of the driving lanes. The default that is provided is designed to slope the water to the middle of the road, so that center of parking storm drain inlets can be used. If the parking profile slopes downhill, pipe lengths are minimized from end-of-parking drain to outlet as shown below. The template can be revised by the user by double-clicking "Parking" (default name for the parking alignment) and editing the template as shown below:

6. The Parking Profile defaults to a straight line from the point of connection to the Main Road EOP to the interpolated elevation of the end of the parking alignment, as derived from the selected existing TIN. You can add PVI elevations and vertical curves to the parking lot centerline profile by double-clicking "Parking" and editing the profile, as shown below:

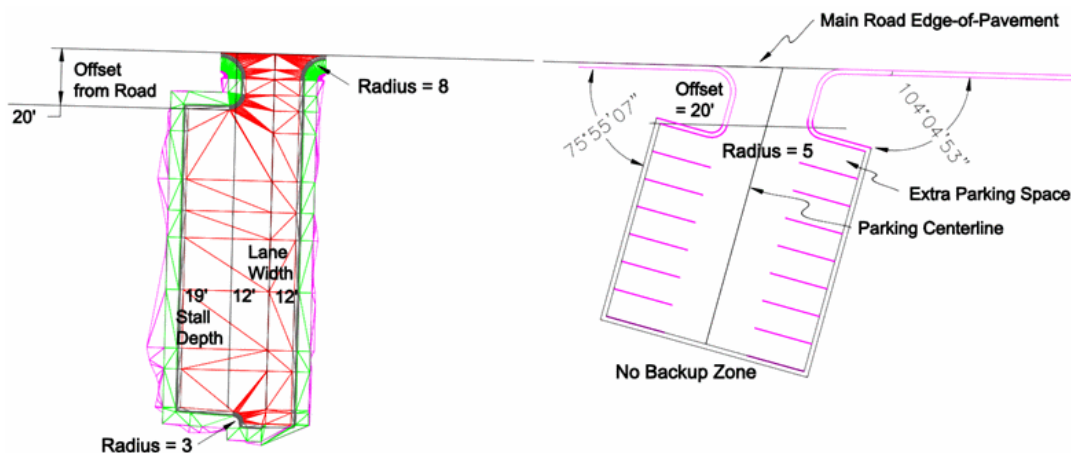

You can click the Settings button in the main dialog and save an Output TIN, merged with the existing surface. When this output TIN is viewed in the 3D Surface Viewer or in Precision 3D Topo/Hydro as below, you can see that the output TIN contains intelligent texturing:

When brought up in P3D Hydro (by running Dynamiccad with the TIN set in Surface Manager or by loading the output TIN in P3D), you can see the concrete curb and gutter and the typically asphaltic parking lot surface. Note that with a sloped template to the middle, the minimum length of pipe can be used (here, 15.3') to drain from the mid-point of the backup zone of the parking lot. As shown above, "half islands" can break up the parking for landscape purposes. Many counties and municipalities have rules for the spacing of half islands, with maximum distances between half islands of 150 feet being a typical maximum. In this case, a half island was placed after only 7 parking spaces to illustrate its use on a small parking lot example.

Show below are additional examples of output based on revised entries.

The Offset from Road prompt in the dialog sets how far from the main road EOP the first parking stall is placed. In the example above left, with an 8' radius to the main EOP and a 5' radius for the curve into the first parking space, that total of 13' leaves 7' additional for the tangent between the 2 curves, totaling a 20' offset from the road. The example parking alignment at left is perpendicular to the main EOP and calls for only parking to right of the Parking Alignment, as drawn from the main road EOP. This produces one-side only parking. (The parking stripe layer has been frozen in this case).

In the example at right, the alignment angles from the main road edge-of-pavement. An offset of 20' from the main road has been set for the first parking space. This offset is applied to the side that is closest to the main road. If the angle of parking alignment allows for an extra parking space as it does in the example above right, the user is prompted whether to place that extra parking space. If Yes, it appears as above. If no, the first parking

stall on the right would align with the first parking stall on the left, which was controlled by the minimum offset to the main road. Parking stalls and striping always line up on the left and right side in the ParkingNet command as designed. Note above, no backup zone was specified.

The "Binoculars" icon in the upper left of the dialog allows you to draw the 3D parking lines without grading the TIN, so they in effect preview things before you click the Process icon. The polylines drawn will all be erased with the next process or next use of the Binoculars or preview. You would need to Undo or erase these entities to remove them from the drawing.

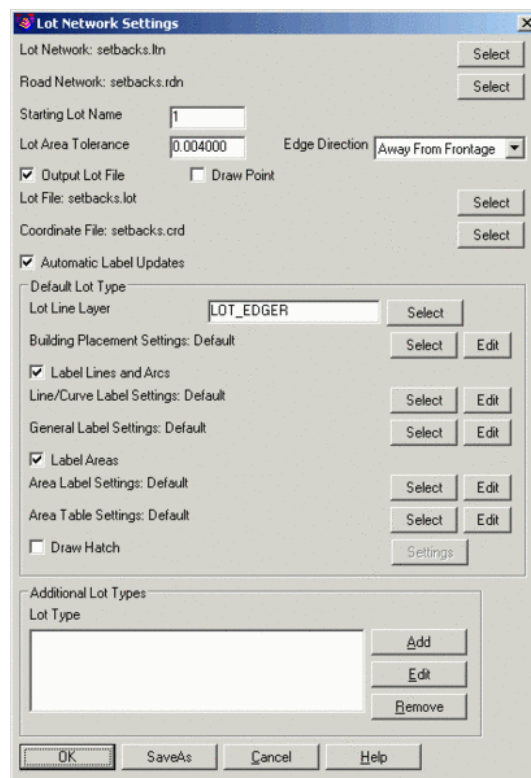

Pulldown Menu Location: Area/Layout > Parking Utilities

Keyboard Command: parkingnet

Prerequisite: TIN surface model

Lot Network Settings

This command displays a dialog for the current Lot Network Settings which specifies the lot network name, road network name, label settings, setback settings, hatch settings, building placement settings, lot type settings and lot area tolerance.

Lot Network: Click Select for the Lot Network name and choose the Lot Network file (.ltn).

Road Network: Click Select for the Road Network name and choose the Road Network file (.rdn).

Starting Lot Name: Indicate the starting Lot Name. As Lots are created, the trailing digit will be incremented by a value of 1.

Lot Area Tolerance: When creating lots to a target area, the program will finish adjustments when the area is within this tolerance of the target.

Edge Direction: Select an option to have new Lot lines drawn either *Away From Frontage* or *Toward Frontage*.

Output Lot File: This option automatically outputs a Lot file (.lot) from the Lot Network. When this option is enabled, set the Lot and Coordinate files to create. There is also an option to draw the lot file points. The settings

from Points > Point Defaults are used for drawing these points.

Automatic Label Updates: Enable this option if Lot labels should automatically update themselves if a Lot is altered or adjusted.

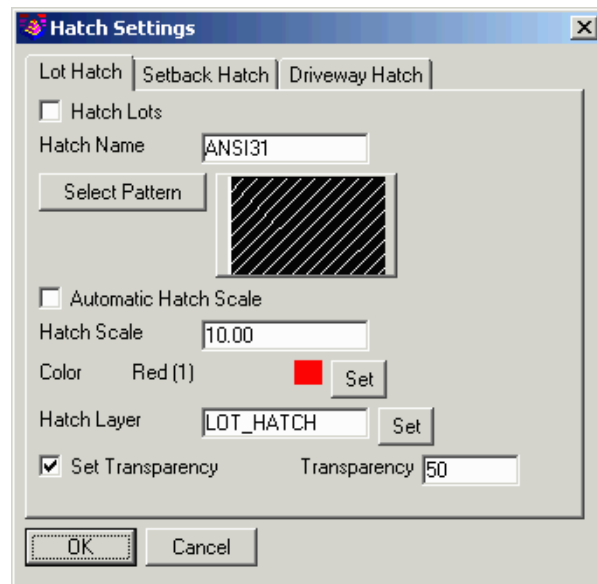

Default Lot Type: Settings in this section of the dialog box will be applied to all new Lots created using the "Default" Lot type.

Lot Line Layer: Specify a new layer or click Select to choose an existing layer for newly created Lot lines

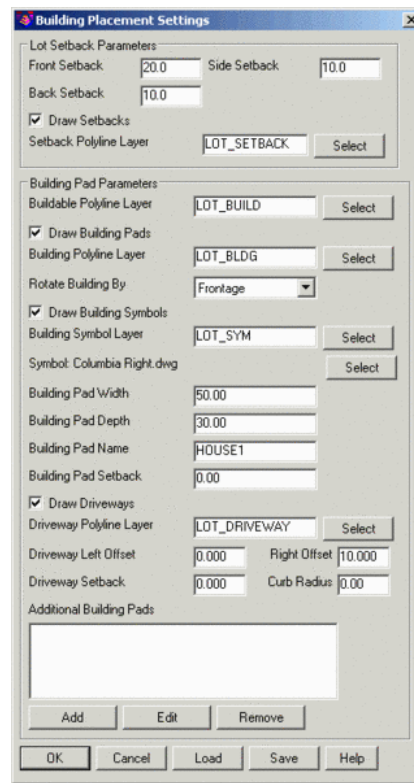

Label Lines and Arcs: Enable this option if you want this routine to label the newly created lines and arcs at the time new Lots are generated. For Line/Curve Label Settings, you can click Select to specify the Auto Annotate settings file (.aan) or click Edit to make changes to the Auto Annotate settings. For General Label Settings, you can click Select to specify the Annotation General Settings file (.adf) or click Edit to make changes to the Annotate Defaults settings.

Label Areas: Enable this option if you want this routine to label the areas at the time new Lots are generated. For Area Label Settings, you can click Select to specify the Area Defaults file (.ars) or click Edit to make changes to the Area Defaults settings. For Area Table Settings, you can click Select to specify the Area Table Settings file (.atb) or click Edit to make changes to the Area Table Defaults settings.

Draw Hatch: Enable this option if you want this routine to draw a Hatch pattern inside Lots at the time new Lots are generated. Click Settings to adjust the Hatch Settings as desired. In addition to hatching the lot area, you can also hatch the setback and driveway areas. Each area has separate hatch property settings.

Building Placement Settings: Click the Building Placement Settings button to specify the values that should be followed when building pads are placed using the Lot Network routines.

Front Setback: Sets the amount of setback for lot segments that are along the frontage.

Side Setback: Sets the amount of setback for lot segments that are partially along the frontage.

Back Setback: Sets the amount of setback for lot segments that are not along the frontage.

Draw Setbacks: Enable this option if you want this routine to draw Setback lines at the time new Lots are generated.

Buildable Polyline Layer: The Lot Network Report looks for closed polylines on this layer within the lots for reporting the buildable width and depth. This buildable area is a separate reporting option from the setback.

Draw Building Pads: Enable this option to draw building pad polylines.

Building Polyline Layer: Specify the layer on which building pad polylines should be drawn or click the Select button to choose an existing layer.

Rotate Building By: This setting controls whether to align the building pads to be perpendicular with the frontage or to be parallel with the lot edges.

Draw Building Symbols: Enable this option to draw building symbols (blocks).

Building Symbol Layer: Specify the layer on which building pad symbols should be placed or click the Select button to choose an existing layer.

Symbol: Click the Select button to specify the name of the building symbol.

Building Pad Width: Specify the width of the building pad polyline.

Building Pad Depth: Specify the depth of the building pad polyline.

Building Pad Setback: Specify the distance behind the Setback line at which to place building pad polylines. Enter "0" to have building pad polylines placed directly on the Setback.

Draw Driveways: Creates driveways as closed polylines between the building pad and lot frontage.

Driveway Polyline Layer: Sets the layer for the driveway polylines to create.

Driveway Left Offset: Facing the building pad from the front, this setting positions the left side of the driveway on the building pad.

Driveway Right Offset: Facing the building pad from the front, this setting positions the right side of the driveway on the building pad.

Driveway Setback: Sets the offset of the driveway from the building pad.

Driveway Curb Radius: Sets the curb return radius for where the driveway connects to the frontage.

Additional Building Pads: Click the Add button to create additional building pads, the **Edit** button to modify existing building pads and the **Remove** button to delete building pads.

Note:

- When building pad creation is enabled, the initial Building Pad dimension will be attempted. If the initial building pad cannot be placed due to Lot size/placement restrictions, subsequent building pads in the Additional Building Pad list will be attempted.

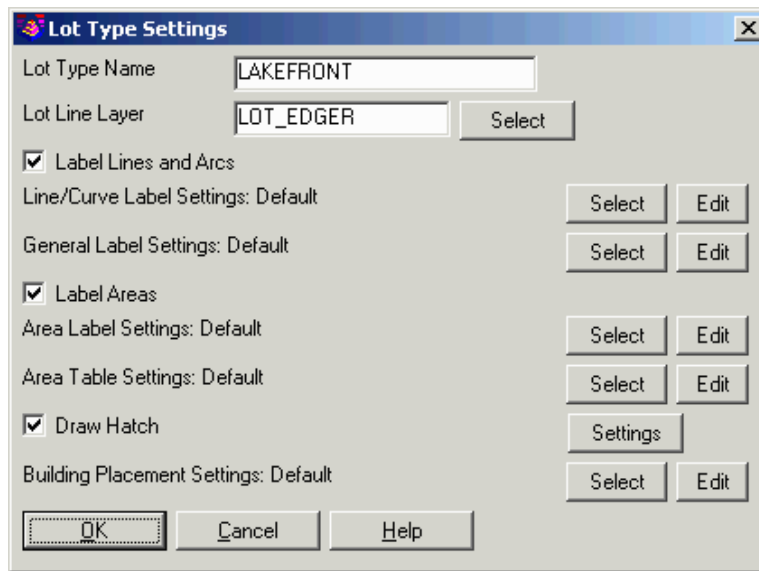

LotNet sample showing setbacks and examples of varying building sizes.

LotNet sample showing 3D building symbol.

Additional Lot Types: Settings established in this section of the dialog box allow you to create additional types of Lots in order to apply different Line/Curve, Area, Area Table, Setback, Hatch and Building Placement Settings according to their specified Lot Type. Additionally, running a Lot Network Report will break out Lot data based on Lot Type and Lot Network Inspector will display Lot Type.

Add, Edit and Remove: Use these buttons to create additional Lot types, edit or remove existing Lot types.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_config

Prerequisite: None

Lot Network Boundary

These are a collection of commands to assign and verify the site boundary for lot network.

Set Boundary: Sets the site boundary. It must be a closed polyline.

Highlight Boundary Perimeter: Indicates the boundary to the user by highlighting it.

Hatch Boundary Perimeter: Indicates the boundary to the user by hatching it.

Erase Hatch Boundary: Erases the hatched boundary for the user.

Clear Boundary: Deletes the boundary designation from the polyline.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_limit, lotnet_highlight_limit, lotnet_hatch_limit, lotnet_hatch_erase, lotnet_untag_limit

Prerequisite: None

Tag Sub-Area

This command provides the ability to establish "exclusion" areas (such as wetlands or drainage ponds) that limit where Lots or Lot Setbacks from the Lot Network routines can be created.

Prompts

Select polyline for sub-area: *Pick a closed polyline that defines the sub-area.*

Area Category: *Provide the name of a general category for the sub-area.*

Area Description: *Provide a more specialized description for the sub-area.*

Note:

- If a Sub-Area is created after a Lot Network has been processed, the existing Lot lines are kept and any associated setback lines are updated to honor the Sub-Area.
- If a Lot Network is processed after a Sub-Area has been created, the newly created Lots will honor the Sub-Area(s).

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: tag_subarea

Prerequisite: A closed polyline

Untag Sub-Area

This command removes the from the selected polyline(s) the Sub-Area Category and Description information placed with the Tag Sub-Area command.

Prompts

Select sub-area polylines to remove sub-area tag.

Select objects: *Pick the polyline(s) whose Sub-Area information you wish to clear and press Enter when complete.*

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: untag_subarea

Prerequisite: A closed polyline with appropriate Sub-Area data.

Identify Sub-Area

This command displays the Sub-Area Category and Description information found on polylines tagged with the Tag Sub-Area command and reports it to the Command prompt.

Prompts

Pick polylines to check or search drawing [<Pick>/Search]: Press Enter to individually select Sub-Area polylines or Type S and press Enter to search the entire drawing.

Select sub-area polyline: Pick the polyline whose Sub-Area information you wish to identify and press Enter when complete.

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: id_subarea

Prerequisite: A closed polyline with appropriate Sub-Area data

Report Sub-Area

This command displays the Sub-Area Category and Description information found on polylines in the drawing that have been tagged with the Tag Sub-Area command and reports the information to the standard Report Viewer.

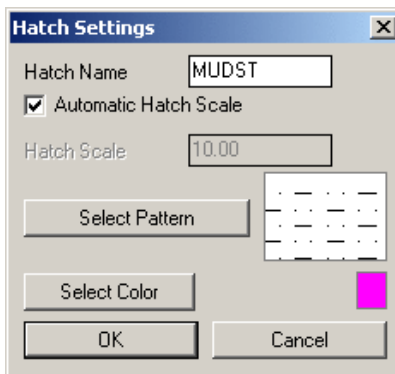

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: report_subarea

Prerequisite: A closed polyline with appropriate Sub-Area data.

Hatch Sub-Areas

This command places a hatch pattern into polylines in the drawing that have been tagged with the Tag Sub-Area command.

Prompts

Hatch Name: Type in the name of a valid hatch pattern. A sample of the pattern will appear near the "Select Pattern" control.

Automatic Hatch Scale: Disable this toggle to manually control the size/density of the hatch pattern.

Hatch Scale: Specify the size of the hatch pattern. Larger Scale values create a less dense pattern.

Select Pattern: Use a visual dialog box approach to select a hatch pattern. The name of the hatch pattern selected displays in the Hatch Name control.

Select Color: Use a visual dialog box to specify the color of the hatch pattern.

Note:

- Any previous hatch patterns placed by the Hatch Sub-Areas command are first erased from the drawing.
- Hatch patterns are placed onto the LOTNET_HATCH.SUBAREA layer.

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: hatch_subarea

Prerequisite: A closed polyline with appropriate Sub-Area data

Erase Sub-Areas Hatch

This command removes the hatch pattern(s) placed with the Hatch Sub-Areas command.

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: erase_subarea_hatch

Prerequisite: A Sub-Area with an appropriately placed hatch pattern

Label Sub-Areas

This command displays the Sub-Area Category and Description information found on polylines tagged with the Tag Sub-Area command and uses the current text style to place the information as text into the drawing.

Prompts

Text Size <4.00>: *Press Enter accept the specified text size or Type an alternate numeric text size and press Enter.*

Label area size [Yes/<No>]?: *Choose whether or not the area of the Sub-Area(s) should be labeled in the drawing.*

Layer name <LOT.SUBAREA>: *Press Enter to accept the layer name specified or type in the desired layer name and press Enter when complete.*

Note:

- To remove Sub-Area Labels from the drawing, use the Lot Network Settings command.

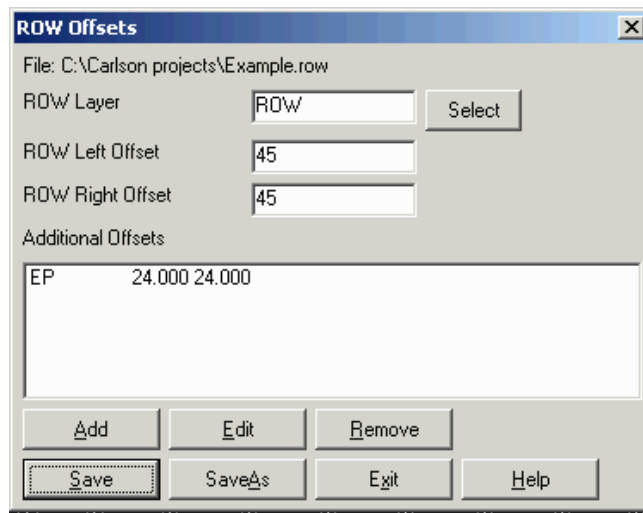

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Sub-Areas, Survey > Area/Layout > Lot Network Sub-Areas

Keyboard Command: label_subarea

Prerequisite: A closed polyline with appropriate Sub-Area data

ROW Offsets Editor

This command defines the ROW offsets for the Road Network for Lot Networks. The ROW offsets are for the frontage polylines to the left and right of the centerlines. Besides the ROW, you can also define additional offset polylines to be drawn. These additional offset polylines do not affect the lot network.

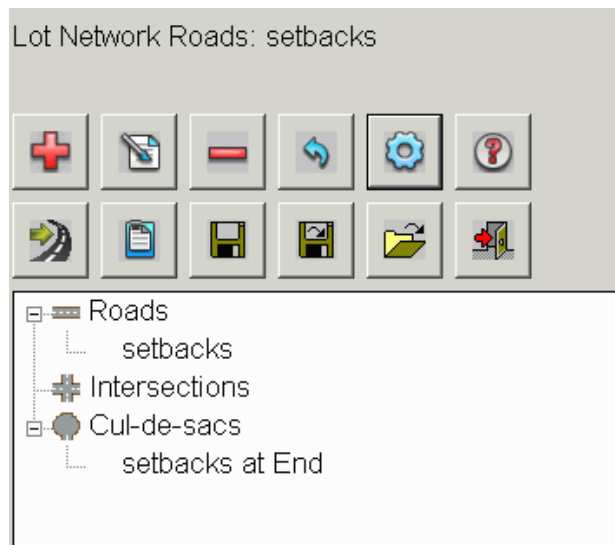

Pulldown Menu Location: Area/Layout > Lot Network Roads

Keyboard Command: lotnet_row

Prerequisite: None

Lot Network Road Network

This command develops the linework, geometry and labeling for subdivision, commercial and industrial sites by using the familiar Road Network interface and pre-defined settings. The program docks a dialog on the left of the screen identifying the geometry settings and all road files and leaves an active CAD screen and command line. You can save drawings and run virtually any standard AutoCAD command while within the docked dialog. Once you identify centerlines for the road network, the program detects intersections and end segments suitable for cul-de-sacs, and through input of design parameters for offset criteria, cul-de-sac dimensions and intersection transitions, the program will process the complete geometry layout, with output options including creating Lot files for later reference and a variety of labeling options for such items as Areas, Distances and Bearings. The road network settings are saved in a .RDN file.

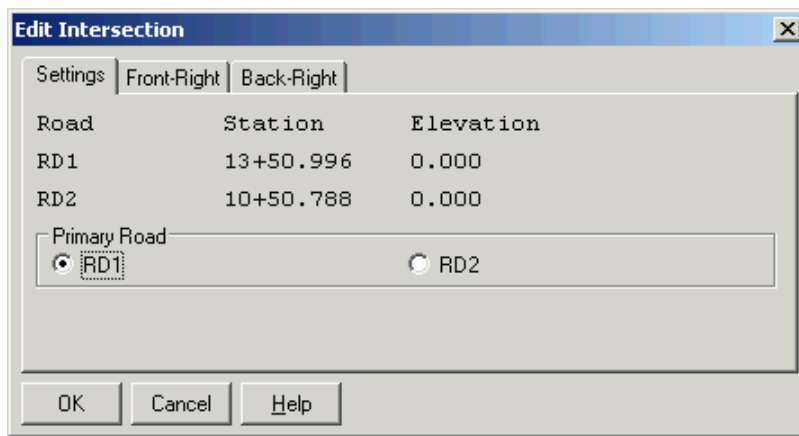

Before running the Road Network, use the following procedure to setup the lot labeling settings and site boundary.  Click the Lot Network Settings button. Note that you can use the Area/Layout Menu pulldown to access these commands as well. Select or create a lot network settings file.  Next, select the Set Boundary icon. Select a closed  polyline for the boundary around your site.  Next select the Road Network icon. When prompted,

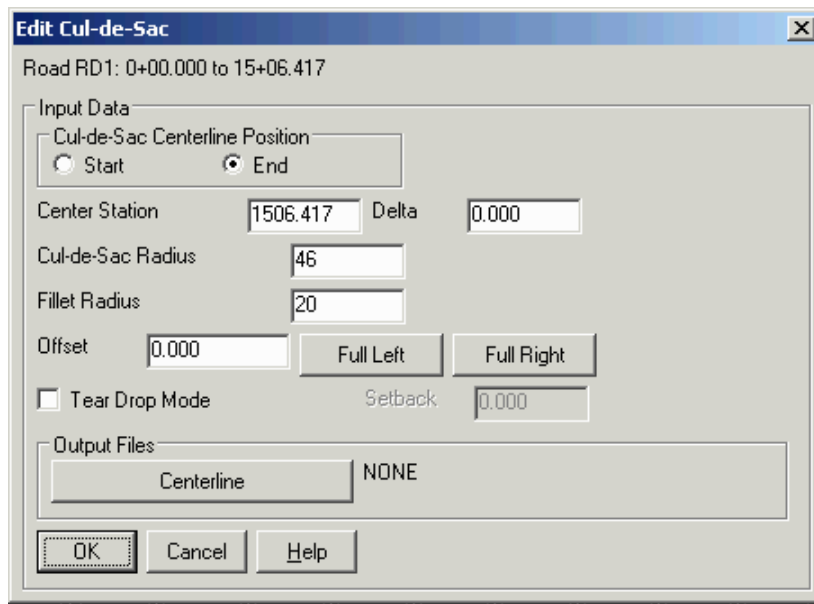

select the .RDN file from the Existing tab. This is where the centerlines involved for the subdivision will be defined and added to the Road Name area of the panel. These centerlines are standard Carlson .CL files. Click a centerline and choose Edit. If a CRD file is requested choose or create a .CRD file. The Edit Road dialog appears. The centerline can be selected here and these centerlines can be edited on the fly if needed. For ROW Offsets, we are using the Row-OFF-a.Row file. Click Edit. The ROW offsets dialog displays. Use the defaults of 45' left and right and note that additional graphics can be automatically generated by hitting Add and entering additional values, names and layers. Hit Exit.

Note also that Optional Input files can be attached to the process for roadway widenings based on the standard Carlson Road design tools of the same name. This is where a polyline indicating where the roadway template ID's should be tapered or widened is developed into a Centerline file and attached to the roadway template involved. Refer to the Road Design documentation for this information. Hit OK to close the Edit Road dialog. These settings can be set and altered for each road in the network.

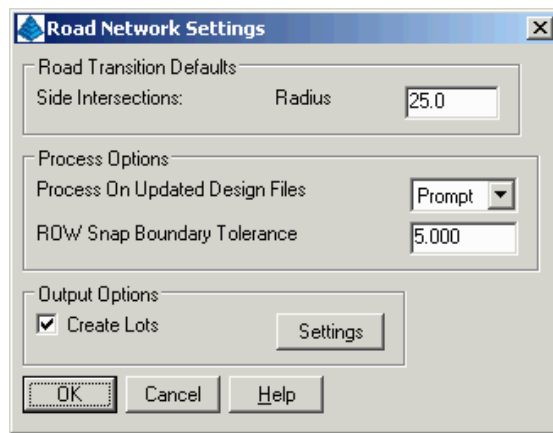

Next click on one of the intersections you may have and select Edit Intersection. In the Edit Intersection dialog, the intersection's radii can be set. Click on the Front Left or Front Right to verify this.

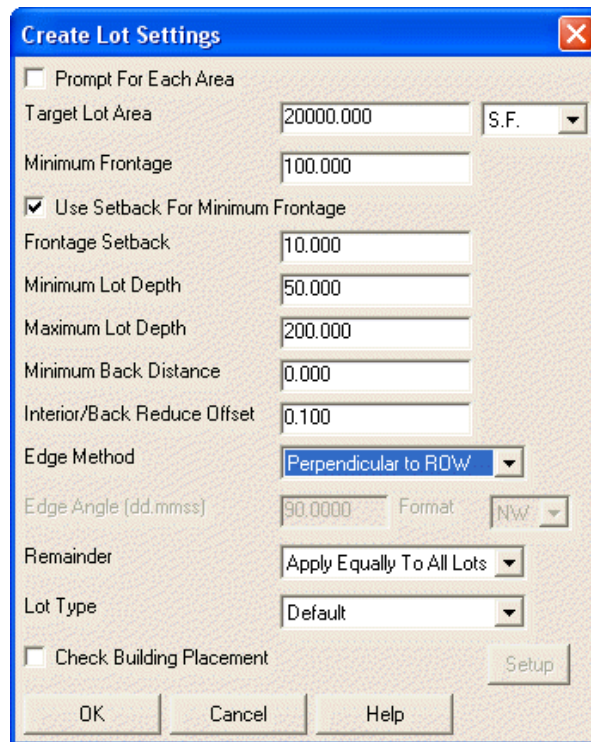

The program can also develop cul-de-sacs for the subdivision, although this example doesn't require one. To see how it works, click Add under Cul-de-sac's area of the panel. The Select Road for Cul-de-sac dialog appears. Select the road for the Cul-de-sac and the Edit Cul-de-sac dialog opens. Then as shown in the figure, choose whether the cul-de-sac occurs at the beginning or ending of the roadway, provide a cul-de-sac radius and file radius and any other criteria to develop the graphics as desired. Since we do not have a cul-de-sac in this example we will skip this step.

Next select Settings at the bottom of the Road Network panel.

The **Radius** is the default for new intersections. The radius for any existing intersection can be modified by selecting the intersection in the list and picking the Edit button. The **Process On Updated Design Files** controls whether to automatically run the Process function when an element of the road network is edited. The **ROW Snap Boundary Tolerance** is used to snap the ROW linework onto the Lot Network Boundary which is useful to clean up any undershoots between the ROW and boundary in case the centerline is not perfectly perpendicular to the boundary. The **Create Lots** setting draws linework for lots for the specified geometry parameters. Otherwise, only the ROW polylines are drawn. Use a radius of 25.0 and turn on the Create Lots toggle and click Settings. Set the values as shown in the Create Lot Settings dialog below. Then hit OK and OK to exit.

Prompt For Each Area: This option will pause to prompt for the target area as each lot is created.

Target Lot Area: The new lots will have this area +/- the Lot Area Tolerance under Lot Network Setting plus any effect from handling the Remainder.

Minimum Frontage: Controls the minimum lot perimeter length along the ROW.

Use Setback For Minimum Frontage: This option bases the Min Frontage check at the specified Frontage Setback from the ROW.

Minimum Lot Depth: This setting is the min distance from the ROW to the back of the lot for the lot side lines.

Maximum Lot Depth: This setting is the max distance from the ROW to the back of the lot for the lot side lines.

Minimum Back Distance: This setting is the min distance along the back of the lot perimeter between the two lot side lines.

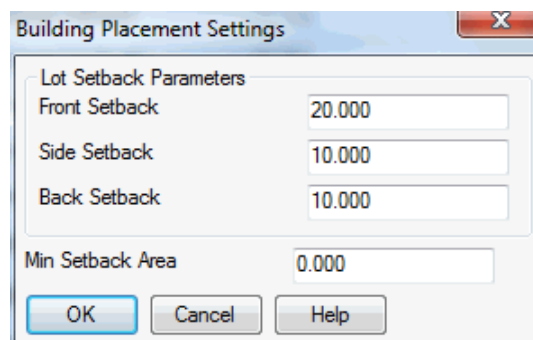

Interior/Back Reduce Offset: For interior boundaries generated by the program between lots, this option reduces the number boundary vertices. A vertex is removed if it doesn't affect the boundary by more than the specified offset amount. This method is similar to the Reduce Polyline Vertices command.

Edge Method: The lot sides can be created perpendicular to the frontage ROW, back boundary or at a specific angle.

Remainder: This option determines how to handle any remaining area that is less than the target area after fitting as many lots as possible. The **Create Separate End Lot** will make a lot with this remainder area. The **Apply Equally to All Lots** will spread the extra area to all the lots. The **Add To Last Lot** will add the remainder to the last lot created making it larger than the target area. The **Create Back Lot Edge** makes a back lot edge that meets the target area at min frontage.

Lot Type: Sets the lot type for the new lots.

Check Building Placement: Checks that the building footprints fit within the lots for the specified setbacks.

Lot Setback Parameters: These setting offset the lot perimeter inward for different sides of the lot.

Min Setback Area: This option checks that the lot area within the setbacks is at least this much.

In the Road Network panel click Save or Saveas to save these settings for your own experimentation.

Now Click Process to begin the lot layout. You will notice the ROW's and EOP's being generated, followed by the lot lines. Then areas are labeled and setbacks are created. Finally, the lotlines are labeled with distances, bearings and arc data.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_rdn

Prerequisite: centerlines and a site boundary polyline

Lot Network Linework

The following commands allow for the Lot Network to be manipulated after the processing. The commands allowing this are:

Adds a ROW polyline into the model. By clicking this command, the software asks for the user to select the new ROW polyline. It then reprocesses the site based on this new ROW data and relocates the EOP for this portion of the roadway.

This command adds a lot edge to the model. The software may request a Lotnet Settings file and if so create or select it. The software prompts with: Select Edge linework to add to model: Select the polyline you drew in the lot representing the new lot edge. The software reprocesses the site based on this new data and redevelops the lot layout accordingly.

This takes a property line out of the model. Select the edge in question when prompted.

This command allows for adding a new property corner to an existing lotline. Simply select the lot edge in question and then pick the point to be added using a snap or other means.

This command allows for moving a lot corner.

This command allows for eliminating a lot corner. Simply select the lot edge in question and then the corner to be removed.

Pulldown Menu Location: Area/Layout

Keyboard Command: Lotnet_Add_Row, Lotnet_Add_Edge, Lotnet_Remove_Edge, Lotnet_Point_Add, Lotnet_Point_Edit, Lotnet_Point_Remove

Prerequisite: None

ID Linework

This command identifies the type of Lot Network linework and which Lot Network it belongs to. For example, you can identify whether a line is a lot edge or ROW.

Prompts

Select Lot Network linework: *pick an entity*

Lot Edge: SETBACKS

Select Lot Network linework (Enter to end): *press Enter*

Pulldown Menu Location(s): Area/Layout > Lot Network Linework

Keyboard Command: lotnet_id

Prerequisite: Lot network linework

Untag Linework

This command removes entities from the Lot Network model by removing the Extended Entity Data (Xdata) related to Lot Network. You can use this command to remove a lot edge or ROW polyline that you no longer want to be part of the Lot Network.

Prompts

Select Lot Network linework to untag.

Select objects: *pick entities to untag*

Remove Lot Network tags for 2 entities

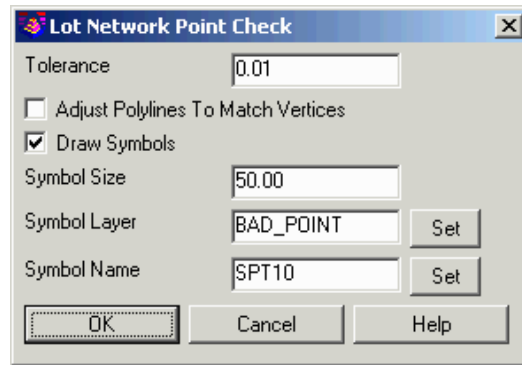

Pulldown Menu Location(s): Area/Layout > Lot Network Linework

Keyboard Command: lotnet.untag

Prerequisite: Lot network linework

Point Check

This command checks for points that are close together in the Lot Network. Any points that are within the specified Tolerance are reported. The command has an option to Draw Symbols at these points which helps with finding these points in the drawing. Also, the Adjust Polylines To Match Vertices option combines the close points to a single point by averaging them together and updates the linework entities. The Check T-Intersections option finds any points with the tolerance of a line segment.

Pulldown Menu Location(s): Area/Layout > Lot Network Linework

Keyboard Command: lot_pt.check

Prerequisite: Lot network linework

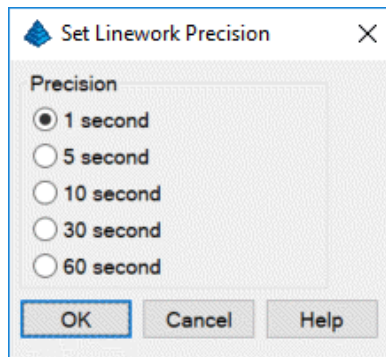

Set Lot Edge Angles To Nearest Second

This command adjusts the coordinates of Lot Network lines and polylines to set their bearings to the nearest specified precision between 1 and 60 seconds. This routine eliminates decimal seconds for the linework. Here's an example inverse showing decimal seconds on a line before running this routine.

```
Northing(Y) Easting(X) Elev(Z)
7054276.3676 11519401.0186 0.0000
7054104.6344 11519556.5360 0.0000
Bearing: S 42d09'47.5207" E Horizontal Distance: 231.6850115
```

Here's the inverse showing the bearing to the nearest second on the line after running this routine:

```
Northing(Y) Easting(X) Elev(Z)
7054276.3673 11519401.0182 0.0000
7054104.6344 11519556.5360 0.0000
Bearing: S 42d09'48.0000" E Horizontal Distance: 231.6850115
```

Prompts

Set Linework Precision dialog

Select lot edges to process.

Select objects: *Pick lot lines to adjust*

Pulldown Menu Location: Area/Layout > Lot Network Utilities

Keyboard Command: edge2sec

Prerequisite: A lot network

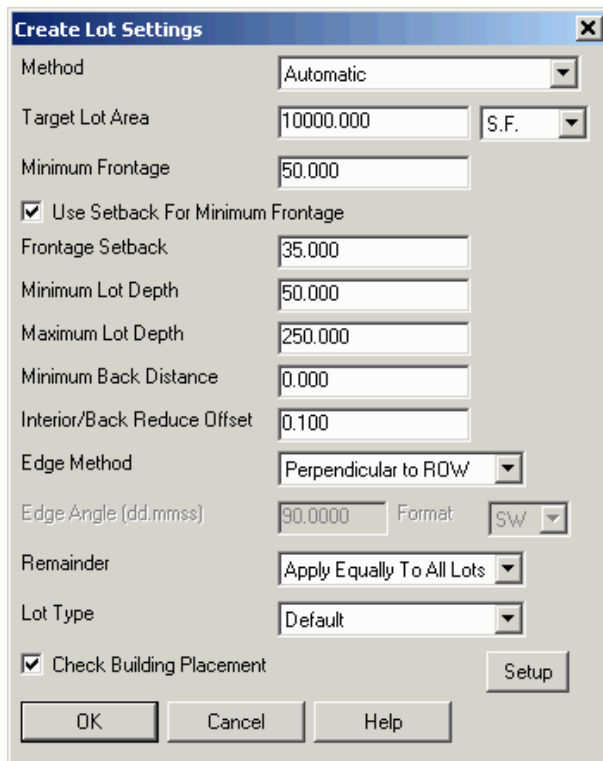

Lot Network Subdivide Area

This command subdivides an area into smaller parcels. The command displays the Create Lot Settings dialog. Once all settings are values have been entered, *click on the OK button.*

Next you are prompted to *Pick inside area to subdivide:*

Next, the right-of-way adjacent to your area to subdivide is highlighted. You are prompted to *Pick end of frontage to start lots:* . Use your left mouse button to pick a point near one end of the highlighted right-of-way. New lots will be created starting from this end of the right-of-way.

Note: All previously created lots will be re-drawn and re-labeled if the setting for "Automatic Label Updates" has been toggled ON in the LotNet Settings dialog box.

Method: The **Automatic** method will create the lots within the area according to the parameters in the dialog. The **Prompt For Each Area** method will prompt you to specify the area for each lot as it is created. The **Prompt For Each Frontage** will prompt you to specify the frontage for each lot as the method to size the lots.

Target Lot Area: This setting establishes the minimum lot area for each lot created using this command. Target Lot Area can be specified using Acres or Square Footage.

Minimum Frontage: This setting establishes the minimum width, along the front Right of Way, of the newly created lots.

Use Setback for Minimum Frontage Enabling this option measures the minimum frontage at the setback location instead of along the front Right of Way.

Frontage Setback: This setting establishes the distance off the front right-of-way for the front setback.

Minimum Lot Depth: This setting establishes the minimum depth of new lots created with this routine.

Maximum Lot Depth: This setting establishes the maximum depth of new lots created with this routine.

Minimum Back Distance: This setting establishes the minimum width of the rear lot line. Setting this to "0" allows for a pie-shaped lot.

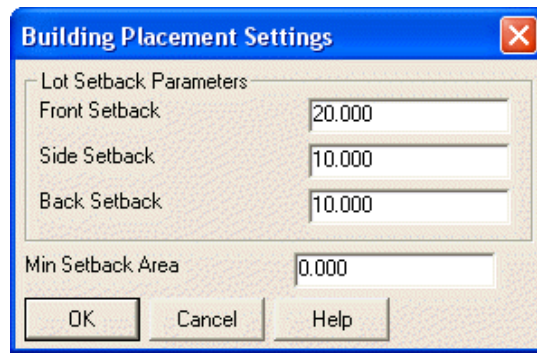

Interior/Back Reduce Offset: This setting establishes the maximum distance interior or back lot lines can be shifted or trimmed in order to meet other setback rules.

Edge Method: This setting establishes the angle between the front right-of-way and new lot lines. You are able to specify that new lot lines be drawn: Perpendicular to ROW, Perpendicular to Back Lot Line or at a Specific Angle.

Remainder: This setting allows you to distribute the area that is left over after creating new lots. The remaining area can be distributed using one of several methods: Apply Equally to all Lots, Create Separate End Lot, Add to Last Lot and Create Back Lot Edge.

Lot Type: This setting allows you to specify the Lot Type for new lots created using this routine. Lot Types are defined in the LotNet Settings dialog box.

Check Building Placement: This setting allows you to establish front, side and back setback distances for building placement along with a minimum allowable area for front setback. Building sizes are defined in the LotNet Settings dialog box.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_subdivide_area

Prerequisite: None

Size Lot by Frontage

This command provides the ability to resize a Lot associated with the current Lot Network .LTN file based on a user-specified amount of Lot Frontage.

Prompts

Pick inside lot to adjust: *Identify the interior portion of a Lot whose Frontage is to be adjusted.*

Select lot edge to adjust: *Choose a side Lot edge that is common to two Lots. The Current Area and Current Frontage of the selected Lot is reported.*

Frontage (ft): *Type in the new Frontage amount and press the Enter button.*

Note:

- To specify an alternate .LTN file, use the Lot Network Settings command.
