Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Areas, Survey > Area/Layout > Lot Network Areas

Keyboard Command: lotnet_ssfront

Prerequisite: A processed set of Lots and their graphical entities created by the Lot Network routines.

Lot Network Sliding Side Area

In this routine a lot side can be altered to reflect a new target area. It will hold its angle and slide along the front and back lot lines until it has achieved the desired area. When running the routine, Select the lot in question when asked to pick inside lot to adjust and then select the lot edge to adjust. Then the prompt asks Acres/<Enter Target Area(sf)>: Type in the desired area you are trying to obtain and the system computes it.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_ssarea

Prerequisite: None

Lot Network Hinged Area

In this routine a lot side can be altered to reflect a new target area. It will hold a lot corner and pivot, or rotate until it achieves the desired area. The procedure is as follows:

Pick inside lot to adjust: Select a point inside the lot to modify.

Select lot edge to adjust: Select the edge that will move.

The routine will report the current area to you and then ask for your desired area.

Current Area: 22494.5 SF 0.516 Acres

Acres/<Enter Target Area (sf)>: 10000

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_harea

Prerequisite: None

Lot Network Labels

These are a collection of commands to draw lot network area, line and arc labels.

Deletes the labels in the model and re-labels the linework based on the LTN file settings.

Deletes the labels in the model and re-labels the linework.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_update, lotnet_redraw

Prerequisite: None

Lot Network Report

This command generates a report with a summary of the areas and number of lots in the lot network model. When the **Summary Only** option is off, the report also include the area, perimeter and frontage for each lot. For a detailed report of the lot data including the lot corner coordinates, output the lot network to a .lot file and run the Report function inside Lot File Manager. The **Use Report Formatter** option allows for customized reports and output to different formats such as Excel. Otherwise a standard report is generated.

To get a report of buildings that fit within lots, first setup the different building dimensions under Building Placement Settings in the Lot Network Settings command. Then in this report, turn off Summary Only and the report will include the list of buildings for each lot.

Plan A	
Lot	Buildings
1	HOUSE1,HOUSE2,HOUSE3
2	HOUSE2,HOUSE3
3	HOUSE2,HOUSE3
4	HOUSE2,HOUSE3
5	HOUSE2,HOUSE3
6	HOUSE2,HOUSE3
7	HOUSE2,HOUSE3
8	HOUSE1,HOUSE2,HOUSE3

Lot Network Report

File: C:\Carlson Projects\Clearwater Oaks.ltn

Total Area: 20.520 acres, 893839.8 sf

Lot Area: 17.600 acres, 766648.4 sf

ROW Area: 2.920 acres, 127191.3 sf

Other Area: 0.000 acres, 0.0 sf

Number of Lots: 50

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet_report

Prerequisite: None

Lot Number Report

This command reports the range of lot numbers used in the current lot network and any gaps in the numbers. Here's a sample report:

Lot Number Report

File: C:\sample\setbacks.ltn

Used Numbers

1,26-37,39-52

Number of used numbers: 27

Unused Numbers

2-25,38

Number of unused numbers: 25

Pulldown Menu Location: Area/Layout > Lot Network Utilities

Keyboard Command: lotnet_number_report

Prerequisite: A Lot Network

Lot Network Inspector

This command shows a dynamic report of the lots as the cursor passes over them. The program has a small dialog that shows the lot number, area, perimeter, frontage and Lot type.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotnet.inspector

Prerequisite: a lot network

Check Lot Network Parameters

This command compares area and frontage of Lots associated with the current Lot Network file (.ltn) against user-specified area and frontage values.

Enabling the "Check ROW Offsets" option will also check for proper right-of-way distances using a specified centerline file (.cl) or (.rdn) file.

A detailed report is generated that displays the Lots that meet or do not meet the area and frontage minimums along with the coordinates of points along Lot frontage that violate the right-of-way value specified.

Minimum Lot Area: Specify the smallest acceptable area a Lot can be to "pass the test" and the appropriate unit of measure.

Minimum Frontage: Specify the smallest allowable amount of street frontage the Lot must have in order to "pass the test."

Check ROW Offsets: This setting allows you to specify the full right-of-way width for the road defined by the centerline file (.cl) you specify.

Note:

- To specify an alternate .LTN file, use the Lot Network Settings command.
- To "browse" over lots already in a drawing, use the Lot Network Inspector command.

Pulldown Menu Location: Area/Layout > Lot Network Utilities

Keyboard Command: lotnet.check

Prerequisite: A processed set of Lots created by the Lot Network routines

Find Lot Name

This command displays a temporary indicator in the drawing showing the location of a Lot associated with the current Lot Network .LTN file.

Note:

- To specify an alternate .LTN file, use the Lot Network Settings command.
- To "browse" over lots already in a drawing, use the Lot Network Inspector command.

Prompts

Lot Network File to Process dialog *Locate an existing .LTN file*

Lot name to find: *Type in the Name (usually the Lot Number) of the Lot you wish to locate and press Enter*

Pulldown Menu Location(s): Civil > Area/Layout > Lot Network Utilities, Survey > Area/Layout > Lot Network Utilities

Keyboard Command: lotnet_find

Prerequisite: A processed set of Lots created by the Lot Network routines

Lot Network Renumber Lots

This command allows you to renumber the lot number for selected lots. The program prompts for the Starting Lot Name: where the new value can be types, such as 200 for the new starting number. It then says Pick point inside lot to start renumbering: so you would pick inside the desired lot. The routine then asks for the Next direction point for renumbering: and you must pick into the next lot to continue or cross over several lots in one pick to include all of those lots in the renumbering process.

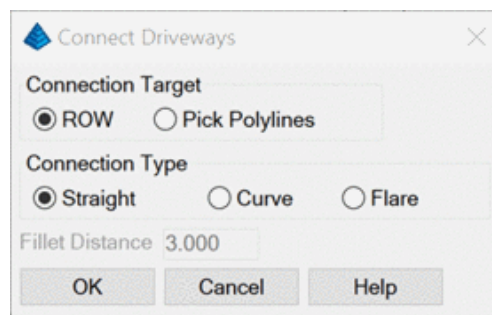

Pulldown Menu Location: Area/Layout

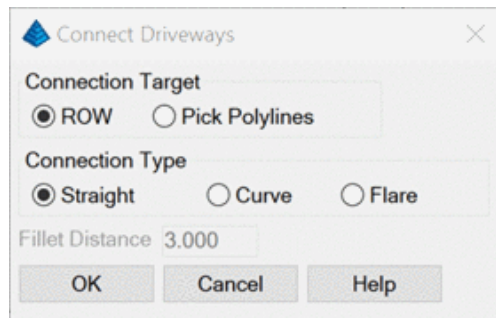

Keyboard Command: lotnet_renum

Prerequisite: a lot network

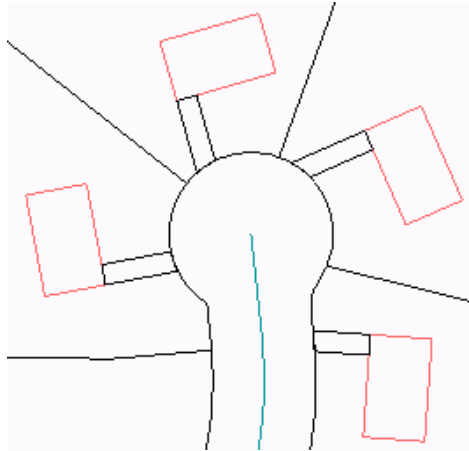

Connect Driveways

This command adjusts driveway polylines to connect them with a selected frontage polyline or the Lot Network ROW. The driveway polylines need to be closed polylines. The program will extend or trim the driveway to the frontage polyline and make the driveway follow the frontage for the width of the driveway. To run this routine, first select the driveway polylines to adjust. Then there is a settings dialog. Use the **Connection Target** to connect to either a selected polyline or the Lot Network ROW. The **Connection Type** controls how the driveway connects to the frontage polyline.

Before Connect Driveways

After Connect Driveways

Prompts

Select driveways to connect.

Select objects: *pick driveway polylines*

Connect Driveway dialog

Select polylines for driveway connections.

Select objects: *pick frontage polyline*

Pulldown Menu Location(s): Area/Layout > Lot Utilities

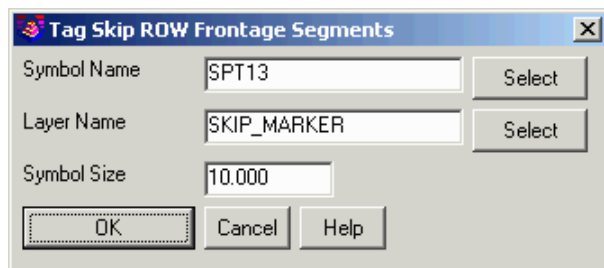

Keyboard Command: connect_driveways

Prerequisite: Driveway and frontage polylines

Tag ROW Segments to Skip Frontage

This command tags lot lines along the ROW to not use as frontage. When calculating setback, the program figures if a lot line is on the frontage based on whether the lot line is on the ROW. This command lets you tell the program not to use a lot line as frontage even when the lot line is on the ROW. This applies in cases of a corner lot where the lot side is on the side road ROW and you want this lot side to be considered as a side setback instead of front setback.

The tags are done by placing a symbol on the lot line. The program prompts for the symbol name, size and layer. Then the program prompts to pick the lot edges to tag. The symbol is drawn on the lot mid-point.

Prompts

Pick segment to skip: *pick a lot edge*

Pick segment to skip (Enter to end): *press Enter*

Pulldown Menu Location: Area/Layout > Lot Network Utilities

Keyboard Command: 3darc

Prerequisite: Lot lines

Tag No-Building Area

This command tags a polyline as a no-building area that Lot Network will avoid when placing building pads.

Pulldown Menu Location(s): Area/Layout > Lot Network Utilities

Keyboard Command: tag_no_build

Prerequisite: closed polyline

Untag No-Building Area

This command removes the no-building tag from selected polylines. You can use this command to update a polyline area that you no longer want to be counted as non-buildable.

Pulldown Menu Location(s): Area/Layout > Lot Network Utilities

Keyboard Command: untag_no_build

Prerequisite: tagged no-building polyline

Lot Network - Assign Lot Type

This command allows you to assign a new Lot Type to Lots in a Lot Network by dragging a line across the Lots to be re-assigned.

Note: Lot Types must have already been defined through the LotNet Settings dialog box.

Prompts

Set Lot Type dialog: Select the "Default" or other pre-defined Lot Type.

Pick a point inside lot to start re-assigning: Use the left-mouse button to drag a multi-segmented line across all the Lots to be re-assigned to the selected Lot Type. *Press Enter to finish.*

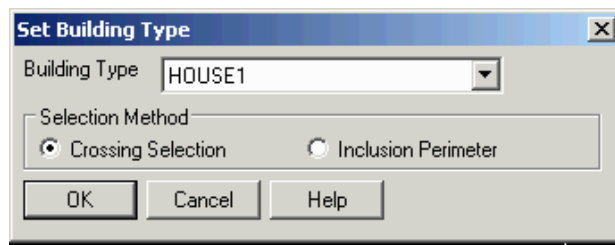

Pulldown Menu Location: Area/Layout → Lot Network Utilities

Keyboard Command: lotnet_type

Prerequisite: A lot network and pre-defined Lot Types

Assign Building Type

This command lets you change the building type within selected lots. The available building types are defined in the Lot Network Settings command under Edit for Building Placement Settings.

To run this routine, select the Building Type to use from the pull-down list in the dialog. Then select the lots to use this building type. The Crossing Selection method selects lots by picking within the lots to update. To update a single lot, pick a single point in that lot. To update a series of lots, pick a point in the first lot and another point in the last lot. Then every lot that crosses this line is updated. For the Inclusion Perimeter method, draw a closed polyline around the lots to update before running this command and pick this polyline as the inclusion and all lots inside are updated.

Pulldown Menu Location: Area/Layout > Lot Network Utilities

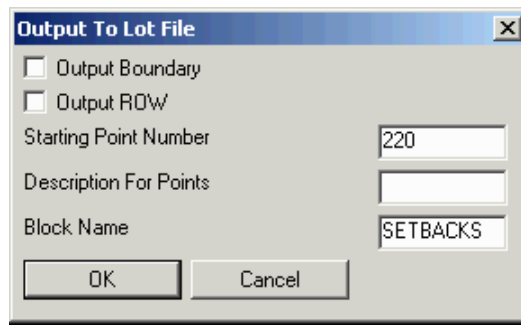

Keyboard Command: lotnet_bldg

Prerequisite: Lot network lots

Lot Network Output To Lot File

This command will create a .LOT file containing the points to define the lots. The points are stored into the specified coordinate file. The Output Boundary option creates a lot for the overall site perimeter. The Output ROW option creates lots for the ROW areas.

The .LOT file is used by the collection of Lot File commands including Lot File Manager.

Pulldown Menu Location: Area/Layout > Lot Network Utilities

Keyboard Command: lotnet_lotfile

Prerequisite: a lot network

Set Lot File

This command sets the lot (.LOT) file name that other lot routines will automatically reference. The lot (.LOT) file stores a list of lots with each lot being a list of point numbers which reference coordinates stored in a coordinate (.CRD) file.

Pulldown Menu Location: Area/Layout

Keyboard Command: setlot

Prerequisite: None

Design Lot

This command creates lot definitions that are stored in a lot (.LOT) file. The lots are defined by entering a sequence of point numbers. The point numbers reference coordinates from the current coordinate (.CRD) file. Each lot has a lot name and block name. The lots are not required to be closed perimeters and can also be used to represent other linework such as centerlines. Curves are entered by first specifying the PC point number, then type R for radius and enter the radius point number followed by the PT point number.

Prompts

Lot Name <1>: 105

Block Name <1>: *press Enter*

Lot Starting Station <0.0>: *press Enter*

If the figure that you are entering is a centerline, then you could use this as the starting station of the centerline.

Starting point number: 17

Point number (R-RadiusPt,U-Undo,Enter to end): 18

Point number (R-RadiusPt,U-Undo,Enter to end): 19

Point number (R-RadiusPt,U-Undo,Enter to end): R

Radius point number: 20

Use large included angle for curve (Yes/<No>)? *press Enter*

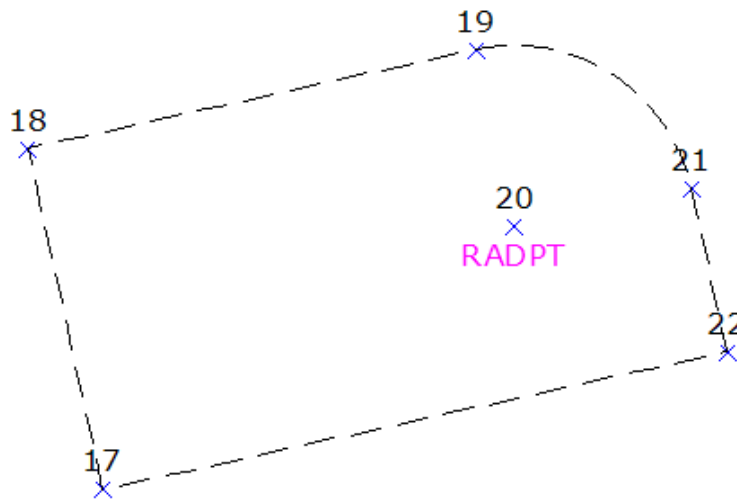

End of curve point number (R-RadiusPt,U-Undo,Enter to end): 21

Point number (R-RadiusPt,U-Undo,Enter to end): 22

Point number (R-RadiusPt,U-Undo,Enter to end): 17

Point number (R-RadiusPt,U-Undo,Enter to end): *press Enter*

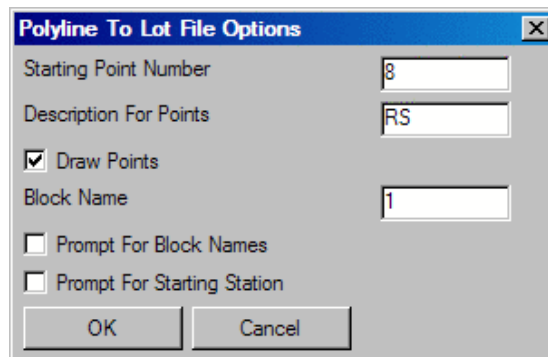

Enter another lot (<Yes>/No)? N

Pulldown Menu Location: Area/Layout > Create Lots
Keyboard Command: mklot
Prerequisite: Points in a coordinate (.CRD) file

Polyline to Lot File

This command will create lot (.LOT) files from selected polylines. The lots are defined by the series of point numbers. This command will create point numbers in the current coordinate (.CRD) file for each point in the polylines. Before creating a point number, the program will check to see if the point coordinates are already in the coordinate (.CRD) file and will use the existing point number if found. Each lot has a lot name and block name. Lots are not required to be closed perimeters and can also be used to represent other linework such as centerlines.

Prompts

Polyline To Lot File Options Dialog *enter in values*

After entering in the Starting Point Number, points will be automatically numbered starting from this value.

Select lot polyline: *pick a polyline*

Select lot polyline:

Lot Name <LOT 19>:

Created 3 lot points.

Select lot polyline (Enter to end):

Lot Name <LOT 20>:

Created 3 lot points.

Select lot polyline (Enter to end):

Lot Name <LOT 21>:

Created 3 lot points.

Select lot polyline (Enter to end):

Select lot polyline: *pick a polyline*

Lot Starting Station <0.0>: *press Enter*

Lot Name <106>: *press Enter* This defaults to the next available name.

Block Name <1>: *press Enter*

Lot Starting Station <0.0>: *press Enter*

Created 7 lot points.

Select lot polyline (Enter to end): *press Enter*

Pulldown Menu Location: Area/Layout > Create Lots

Keyboard Command: pl2lot

Prerequisite: A polyline

Lot File by Pick Interior

This command is used to create a lot by picking a point, and having the program figure the enclosing linework. The linework do not need to be closed themselves but selected together they should define closed areas. All the lots will have the same block name as entered and all lots will be assigned a starting station of 0.0.

The lots are defined by the series of point numbers. This command will create point numbers in the current coordinate (.CRD) file for each point in the bounding polylines. Before creating a point number, the program will check to see if the point coordinates are already in the coordinate (.CRD) file and will use the existing point number if found.

This command works well in conjunction with *Lot File Manager*. Once a lot (.LOT) file containing 1 or more lots is created, all lots can be redrawn automatically, with annotation, using *Lot File Manager*. Furthermore, since the lots are drawn from point numbers, if the point numbers for the lot corners are moved, the lots can be redrawn to the new point positions using *Lot File Manager*. If a point number is at the corner of four lots, moving that one point number will update all four lots.

Linework areas to convert into 3 lots

Prompts

Lot File By Pick Interior dialog

Pick point inside lot perimeter: *pick an interior point*

Lot Name <1>: *enter name for lot*

Pick point inside lot perimeter (Enter to end): *press Enter*

Pulldown Menu Location: Area/Layout > Create Lots

Keyboard Command: pt2lot

Lot File by Interior Text

This command creates lot definitions from the selected polylines and text. For each text entity, the program finds the bounding polyline around the text. The text is used as the lot name. The polylines do not need to be closed themselves but selected together they should define closed areas. Multiple lots can be created at once with this command. All the lots will have the same block name as entered and all lots will be assigned a starting station of 0.0.

The lots are defined by the series of point numbers. This command will create point numbers in the current coordinate (.CRD) file for each point in the bounding polylines. Before creating a point number, the program will check to see if the point coordinates are already in the coordinate (.CRD) file and will use the existing point number if found.

This command works well in conjunction with *Lot File Manager*. Once a lot (.LOT) file containing 1 or more lots is created, all lots can be redrawn automatically, with annotation, using *Lot File Manager*. Furthermore, since the lots are drawn from point numbers, if the point numbers for the lot corners are moved, the lots can be redrawn to the new point positions using *Lot File Manager*. If a point number is at the corner of four lots, moving that one point number will update all four lots.

Polylines and text to convert into 3 lots

Prompts

Lot File By Interior Text dialog

Select lot lines, polylines and text.

Select objects: *select the polylines and text*

Select objects: *press Enter*

Created 3 lots.

Pulldown Menu Location: Area/Layout > Create Lots

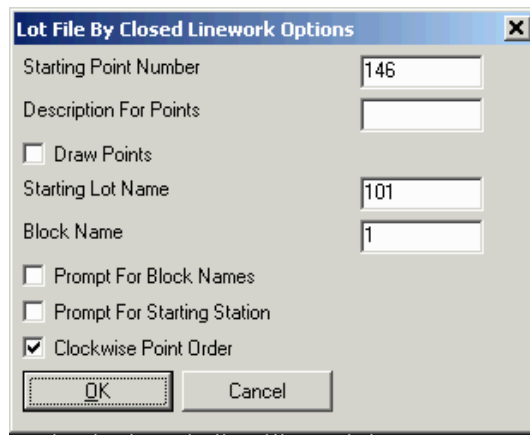

Keyboard Command: txt2lot

Prerequisite: Polylines and text

Lot File by Closed Linework

This command creates lot definitions from the selected polylines, lines and arcs. This command is similar to Lot File By Interior Text. The difference is that this routine does not process text for the lot names. Instead this command finds all the closed areas from the selected linework and then automatically names the lots.

For each lot, the program stores a series of points to the lot file. In the options dialog, there are settings for the point number, point description and whether to order the points clockwise around each lot. The Draw Points option will create point entities besides storing the points to the current coordinate file. The Starting Lot Name is used for assigning the lot names which then get incremented by one for each other new lot.

Prompts

Lot File By Closed Linework dialog

Select lot lines and polylines.

Select objects: *select linework*

Created 3 lots.

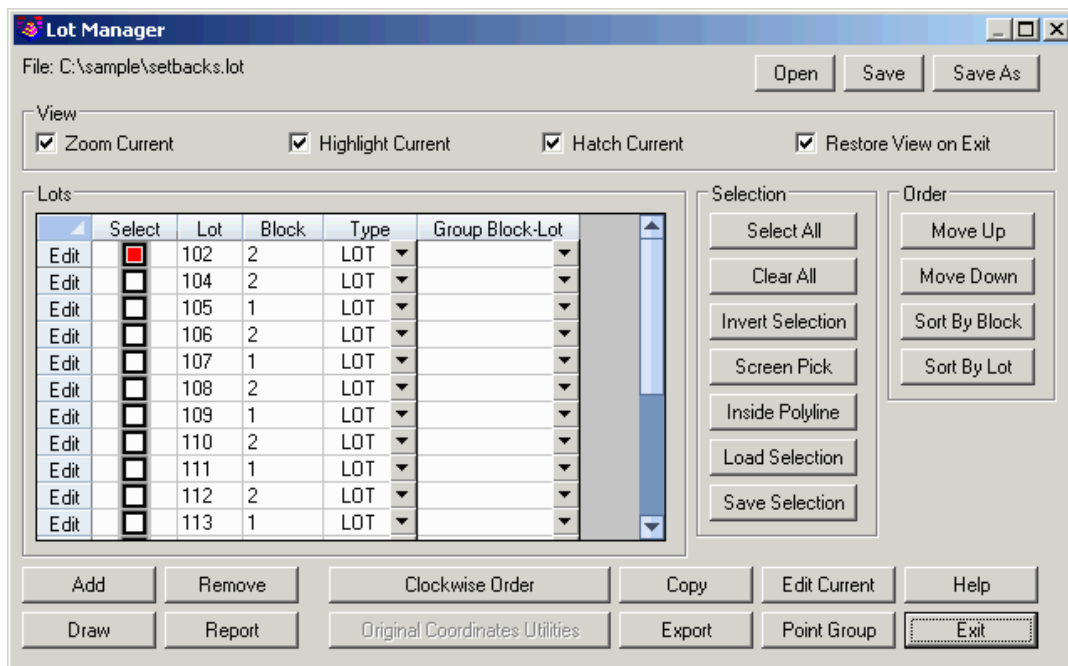

Pulldown Menu Location: Area/Layout > Create Lots

Keyboard Command: lwork2lot

Prerequisite: Polylines, lines or arcs

Lot Manager

This command combines input, edit, draw and report lot capabilities into one command.

Main Dialog

In the main dialog, there is a spreadsheet list for the lot names along with the block name, lot type and group assignment for each lot. You can edit these values directly in the spreadsheet. There are also function buttons as follows:

Open: selects another Lot File to process.

Save: saves the lot data to the current lot file.

SaveAs: prompts for another file name to save the lot data to.

View: The View options control drawing effects when you highlight lots in the spreadsheet list.

Zoom Current: zooms the display view to include the selected lot.

Highlight Current: highlights the perimeter of the selected lot as a dashed line.

Hatch Current: fills in the selected lot with a hatch.

Restore View on Exit: on leaving Lot Manager, this option sets the display to the original position before running Lot Manager.

Lot Selection: Many of the functions such as Draw process only the lots that are in selected mode. You can toggle which lots are selected with the buttons in the Selection spreadsheet column. You can also use the buttons in the Selection section to select the lots to process.

Select All: marks all the lots as selected.

Clear All: unselects all the lots.

Invert Selection: flips currently selected lots to unselected status and currently unselected to selected status.

Screen Pick: selects lots by picking inside the lots

Inside Polyline: prompts to select a closed polyline and then selects all the lots within this polyline

Load Selection: sets the current selection status from a .LSS file.

Save Selection: saves the current selection status to a .LSS file.

Add: creates a new lot. The new lot name is automatically generated by incrementing from the highest lot name.

Remove: deletes the currently selected lots.

Copy: creates new lots as copies of the currently selected lots.

Edit Current: brings up a dialog editor for the highlighted lot (see below).

Move Up/Down: changes the order of the highlighted lot in the list.

Sort By Block: sorts the lots by block name order first and then by lot name within each block.

Sort By Lot: sorts the lots by lot name only without using the block name.

Clockwise Order: sets the order for the lot points for the selected lots as either clockwise or counter-clockwise.

Point Group: creates a point group for the lot points of the selected lots.

Draw: draws the selected lot perimeters and annotation (see below).

Report: reports the selected lots (see below).

Original Coordinates Utilities: has methods for tracking lot coordinate transformations of the current coordinates relative to the original coordinates.

Export: output selected lots to a new lot file as a way to make a subset lot file.

Edit

This dialog allows you to edit the lot name, block name, group, coordinate file, starting station, ending station and the point numbers that define the lot. A curve is specified by the PC, radius point and PT point numbers. The Large Arc option indicates a curve with an included angle greater than 180 degrees. The Select button allows you to specify a new name or location for the coordinate file associated with the lot.

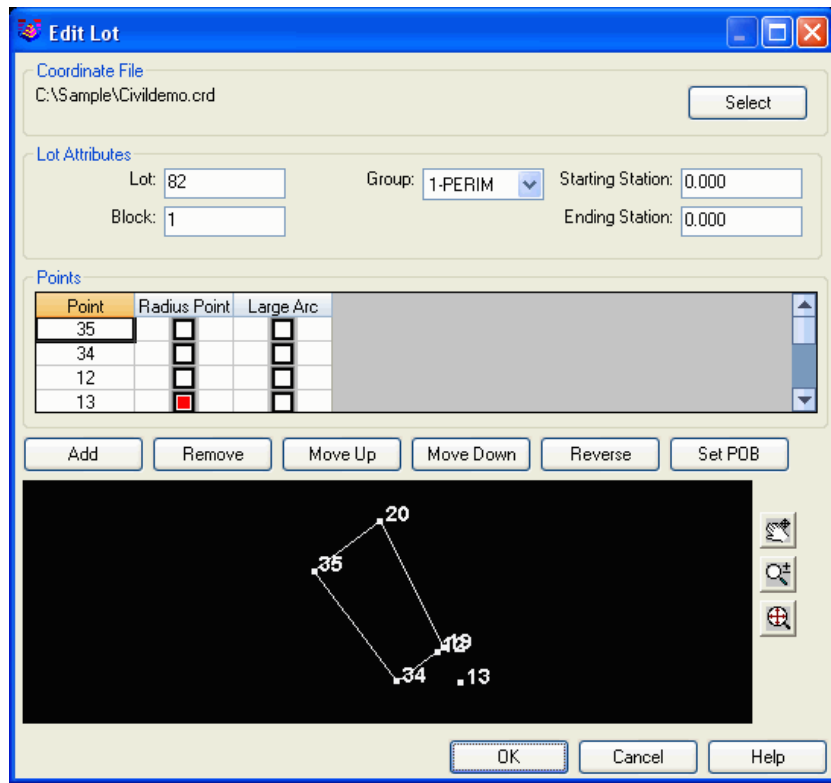

Add: adds a new point to the lot.

Remove: removes the highlighted point from the lot.

Move Up/Down: changes the order of the highlighted point in the list.

Reverse: reverses the order of the points.

Set POB: sets the point of beginning, starting point, to the currently highlighted point.

Draw

The Draw routine allows you to draw polylines for the lot perimeters as well as annotate the lot linework and areas.

Draw Lot Polylines: The Closed Polylines method creates a closed polyline for each lot. The Lines and Arcs method draws the sides of the lots as a series of lines and arcs. The advantage of the Closed Polylines method is that each lot is completely defined by the closed polyline. The advantage of the Lines and Arcs method is that there are no overlapping entities for common borders between lots. With the Lines and Arcs method, the program draws the common border entities only once. The layer for the polylines is set by the Lot Type which is defined in Define Lot Attributes. If the Lot Type is not defined, then the polylines are drawn in the current layer.

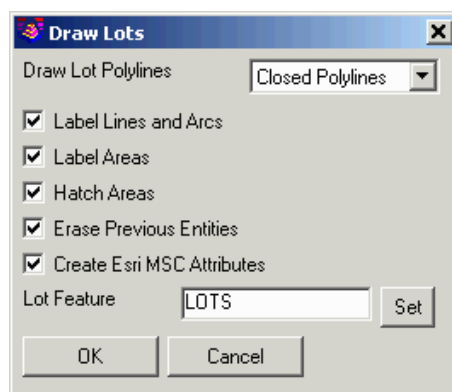

Label Lines and Arcs: Labels the bearing, distance, and curve data using the *Auto-Annotate* command. See *Auto-Annotate* for more details.

Label Areas: Labels the area, and optionally the name of the selected lots using the Area Settings dialog. See *Area Defaults* for more details.

Hatch Areas: Hatches the lot areas.

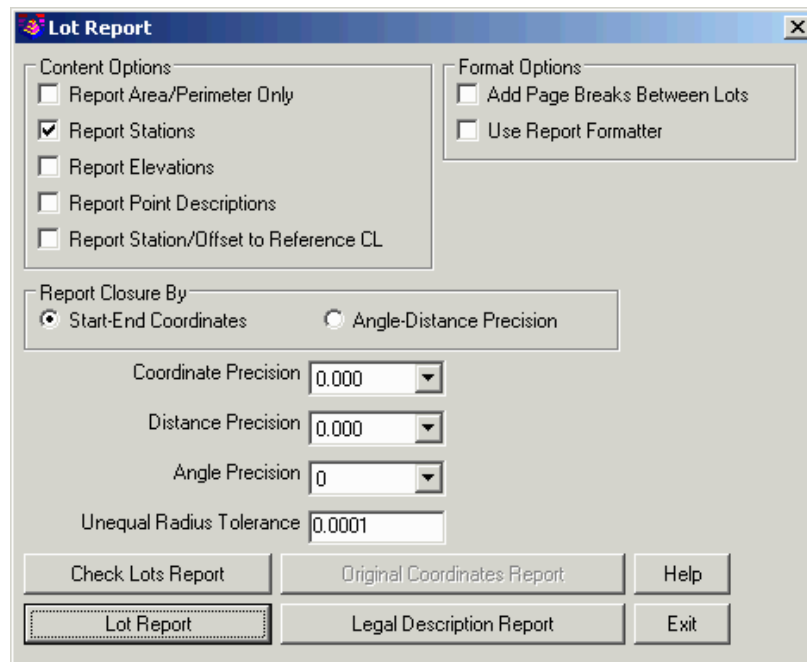

Create Esri MSC Attributes: Defines an Esri MSC format lot feature in the drawing with the lot attributes.

Erase Previous Entities: Erases lot polylines and labels from earlier runs of Draw to avoid duplicates.

Report

The Report routine has several types of reports.

Report Areas Only: When checked only the lot name, block name, and area are included in the report.

Report Stations: Controls whether to report the distance along the lot perimeter.

Report Elevations: Controls whether to report the elevation from the coordinate file for each lot point.

Report Point Descriptions: Controls whether to report the description from the coordinate file for each lot point.

Report Station/Offset To Reference CL: This option prompts for a CL file that is used to calculate stations and offsets for each of the lot points to include in the report.

Add Page Break between Lots: Formats the report so that each lot definition begins on a new page when printed.

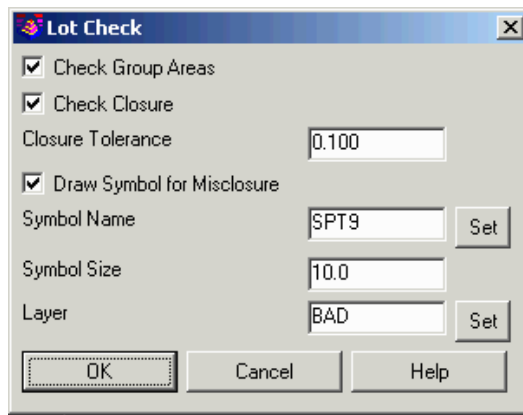

Use Report Formatter: When checked, the report is output to the *Report Formatter* where it can be customized as well as exported to Microsoft® Excel or Microsoft® Access. See *Report Formatter* in for more details.

Report Closure By: For the Start/End Coordinates method, the closure error distance is the distance between the start and end points which is 0 (perfect closure) if the lot starts and ends at the same point number. For the Angle/Distance Precision method, the actual bearings and distances in the report are used, and the rounding used in the report will result in small closure errors.

Report Precision: Specify the decimal precision for reporting coordinates, distance and angles on the report. The precision for the areas is defined in the Area Defaults command.

Unequal Radius Tolerance: When reporting the curve data for a lot, the two radial lengths are compared. If the difference in their length is more than this value, it is noted on the report.

Check Lot Report: The Check Group Areas method will check that the area for all the lots assigned to a Group Block-Lot add up to the area of the area of the enclosing group lot. The Check Closure method reports any lots where the beginning and ending coordinates are different than the specified tolerance. This closure check has an option to draw a symbol at the end point for lots outside the tolerance.

Lot Report: Creates a report using the report settings.

Legal Description Report: Writes a legal description using the same routine as the Legal Description Writer command. See the Legal Description Writer section of the manual for more details.

Pulldown Menu Location: Area/Layout

Keyboard Command: editlot

Prerequisite: None

Lot Inspector

This command activates a small pop-up window that when you place your pointer into a lot file area, the details of that lot file will be displayed in the Lot Inspector window.

Prompts

Move pointer inside lots (Pick to edit, Enter to End) hover crosshairs above lot(s)

Pulldown Menu Location: Area/Layout

Keyboard Command: lotinspector

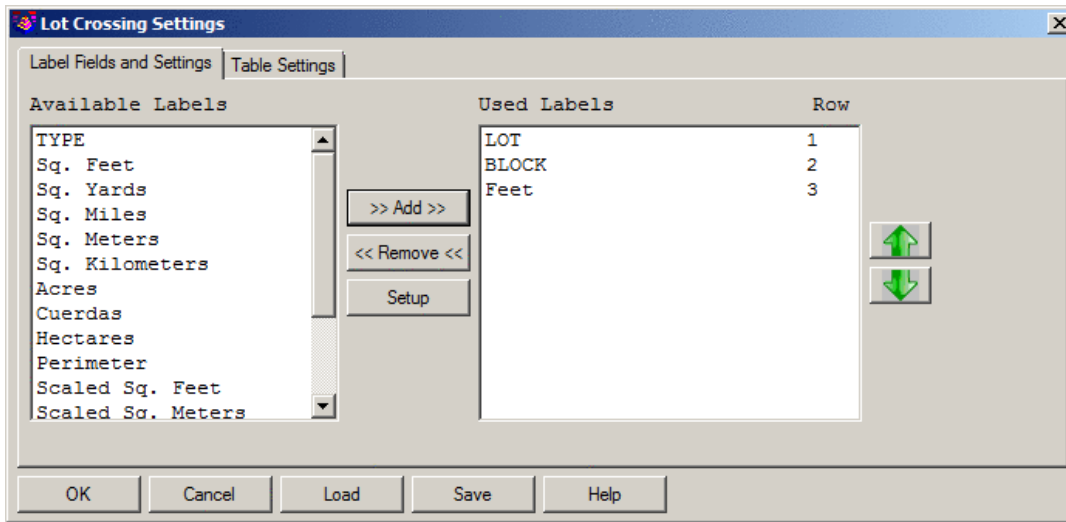

Prerequisite: None

Right-of-Way Crossing Table

This command will create a table using user selected information and user defined table features. A polyline is selected that crosses one or more lots. Lots must be defined in a Lot file prior to running the command. In the following example the polyline is labeled as a Pipeline.

When the command is started the user is presented with the Lot Crossing Settings dialog box. There two tabs; Label Fields and Settings and Table Settings.

Available Labels: This is the list of information that may be included in the table.

Used Labels: These are the items that have been selected to be in the table. They are placed in the table in the order listed. The green up and down arrows will move used labels up or down in the list.

Add: Clicking the Add button will add the highlighted labels in the available list to the used list.

Remove: Clicking the Remove button will remove labels highlighted in the used list and display in the available list.

Setup: Setup opens the Field Settings dialog for the Used Label that is highlighted.

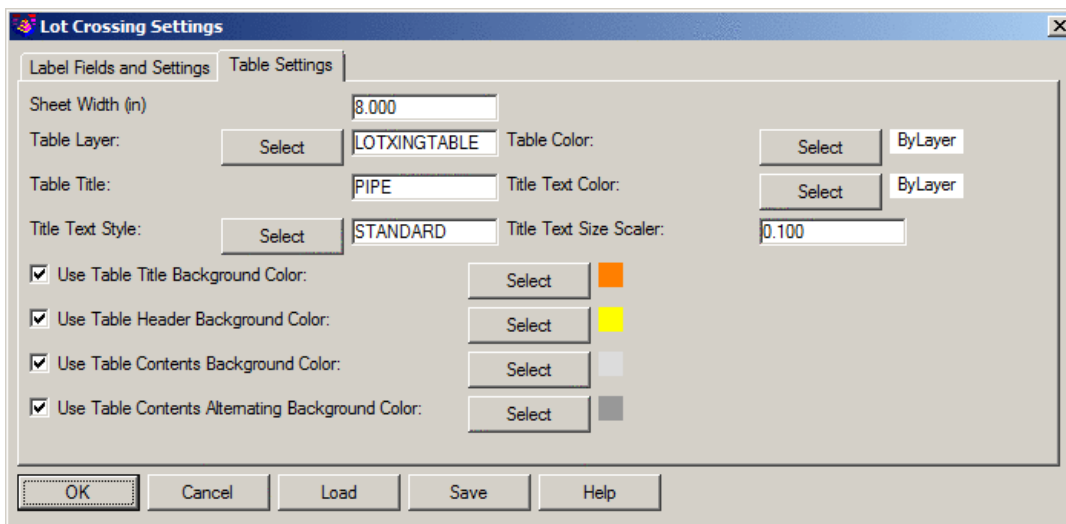

OK: Clicking the OK button will proceed to the selection of the crossing polyline.

Cancel: ends the command with no table being created.

Load: Loads previously saved settings so table created match previous tables.

Save: Saves the settings as currently displayed for use on future tables.

Help: Load this file.

Include Header: This draws a header row with the field names.

Include Horizontal Lines: This draws horizontal lines between the rows of the table.

Sheet Width (in): This value defines the width of the table. If set too small the text in the table will overlap.

Table Layer: Select an existing layer to draw the table on using the **Select** button or use a new layer by typing the name in the edit field.

Table Color: The user can specify a color for the table gridlines using the **Select** button. Bylayer will use the color assigned to the Table Layer for the grid lines.

Table Title: A title can be specified for the table by typing the desired title in the Table Title field. See example below.

Title Text Color: This specifies the color for the Table Title text.

Title Text Style: This specifies the text style for the Table Title text. Be sure the style specified is defined in your drawing.

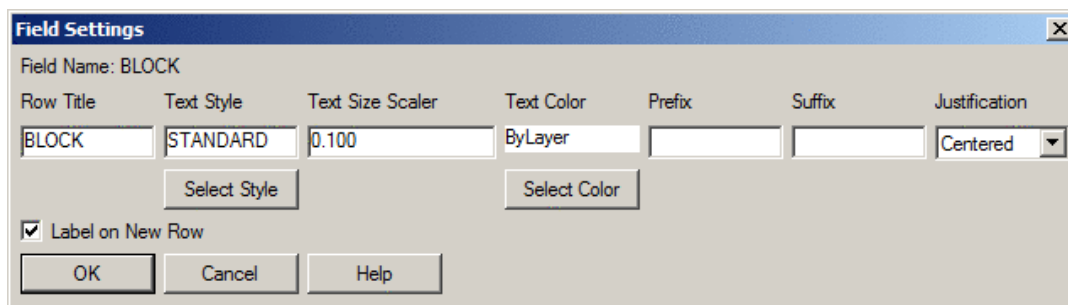

Title Text Size Scaler: This specifies the plotted height of the Table Title text. The table is drawn in model space. The height of the text in model space is the Text Size Scaler multiplied by the horizontal scale in Drawing Setup.

Use Table Title Background Color: This option allows the user to specify a background color for the Table Title.

Use Table Header Background Color: This option allows the user to specify a background color for the Table Header row.

Use Table Contents Background Color: This option allows the user to specify a background color for body of the table.

Use Table Contents Alternating Background Color: If the Table Contents Background color is being used, This option allows the user to specify a second color to use on alternating rows of the table body.

The Field Settings dialog box is opened by double-clicking a Used Label or highlighting a Used Labels and clicking the **Setup** button.

Row Title: Row Titles are the Used Labels that were selected Label Fields and Settings tab.

Text Style: This specifies the text style to be used for the current row text. You may use the **Select** button to choose a text style. Be sure the selected text style is loaded in the drawing.

Text Style Scaler: This specifies the plotted height of the current row text. The table is drawn in model space. The height of the text in model space is the Text Size Scaler multiplied by the horizontal scale in Drawing Setup.

Text Color: This specifies the color for the current row text. You can use the **Select Color** button to choose the color from a pallet. Bylayer uses the color of the Table layer for the text.

Prefix: This places the user provided prefix text with the row entries. An example would be prefixing lot numbers with the word Lot.

Suffix: This places the user provided suffix text with the row entries. An example would be using ft for feet as a suffix for a length.

Justification: Users can specify, Left, Center or Right text justification.

Calculated Numeric Values

Table numeric values that are calculated, like area or lengths, have the two following controls in addition to those listed above.

+/-: Users may specify a +/- be used as a prefix or suffix. The default is None, not used.

Precision: Decimal precision for calculated numeric values can be set to zero and up eight decimal places.

OK: Saves changes and closed the Field Setting dialog box.

Cancel: Closes the Field Settings dialog box without saving changes.

Help: Accesses this documentation.

PIPE					
LOT	Lot 16	Lot 15	Lot 14	Lot 13	Lot 12
BLOCK	1	1	1	1	1
Feet	219.14 Ft	203.93 Ft	176.67 Ft	143.92 Ft	172.48 Ft

Prompts

Pick a polyline for lot crossings: Select polyline crossing lots

Starting Station <0.0 >: Enter desired starting station

Ending Station <1642.88> Accept full length or enter ending station to process a part of the polyline.

Pick location for report table: Select location in drawing for table

Pulldown Menu Location(s): Survey Module: Area/Layout > Lot File Utilities > Right of Way Crossings Table

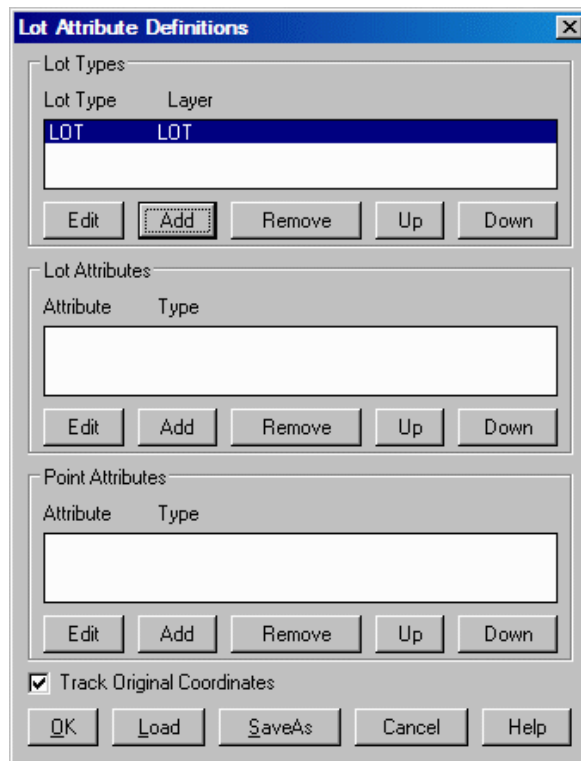

Keyboard Command: lotcross

Prerequisite: Polyline and Lot File

Define Lot Attributes

This command allows the user to define the Lot Type, Lot Attributes and Point attributes. With the use of the opening Lot Attribute Definitions dialog box, shown below, this routine allows you to edit, add, remove or reposition all of these definition types. You can save the selected data to a new Lot Attribute Definition file (LTD). You are also able to load an existing LTD file to work with.

The **Lot Types** section of the dialog lists out the Lot Type and the layer associated with it.

You can set up different lot types and a layer. When the lots are drawn, the layer name is used per lot type. Also, Lot Types are used in the lot report. There are also Lot Attributes, which are additional fields that you can define for the lots, such as deed number. And there is also Point Attributes.

Edit/Add: Both the Edit and the Add buttons bring up the same Lot Type dialog, shown here. You can edit an existing lot or add a new one.

The **Lot Attributes** section asks for the Name and to enter the Data Type.

Edit/Add: Edit or add the name of the lot attribute. Choose from one of the four options for Data Type: Real, Integer, String or Document.

Similarly, the **Point Attributes** section also asks for the Name and to enter the Data Type.

Remove: Any of the Remove button will remove a lot type, lot attribute or point attribute from the list above it, depending upon which Remove button you use.

Up/Down (all three): Types and attributes can be repositioned.

Track Original Coordinates: This option will track the original coordinates of the lot so that this record may be kept for your future usage and needs.

Load: A Lot Attribute Definition file (LTD) can be loaded.

SaveAs: A new Lot Attribute Definition file (LTD) can be saved.

Pulldown Menu Location: Area/Layout

Keyboard Command: lotattr

Prerequisite: None

Import Lot File From MDB Database

This command will import a lot file from a Microsoft Access database file (.MDB) format.

Prompts

Database File to Import dialog *select existing .MDB file*

Lot File to Write dialog *select existing or create a new .LOT file*

Pulldown Menu Location: Area/Layout > Lot File Utilities

Keyboard Command: lotimport

Prerequisite: A lot (.LOT) file

Export Lot File to MDB Database

This Lot File Utilities command will export a lot file to a Microsoft Access database file format.

Prompts

Lot File to Export dialog *select existing .LOT file*

Database File to Write dialog *select existing or create a new .MDB file*

Pulldown Menu Location: Area/Layout > Lot File Utilities

Keyboard Command: lotexport

Prerequisite: A lot (.LOT) file

Export Lot File To Old SurvCADD

This Lot File Utilities command will export a Carlson lot file to SurvCADD .LOT file format.

Prompts

Source Lot File to Export dialog *select existing .LOT file*
Destination Lot File To Write dialog *create a new .LOT file*

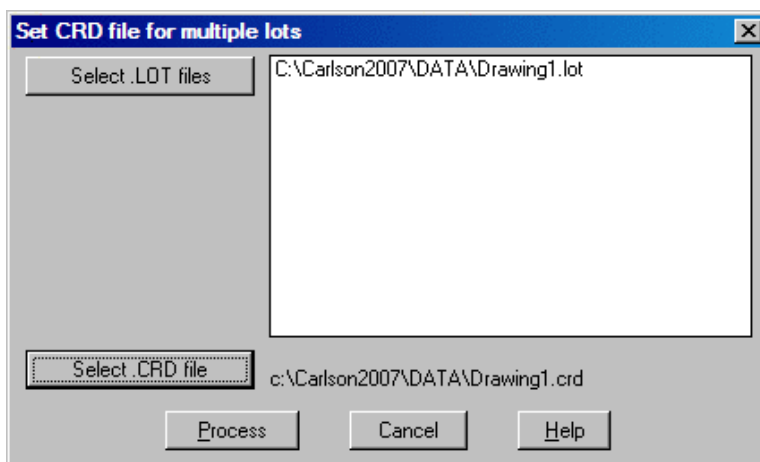

Pulldown Menu Location: Area/Layout > Lot File Utilities

Keyboard Command: lotexport2

Prerequisite: A lot (.LOT) file

Set CRD File for Lot Files

This command allows you to set the coordinate (.CRD) file that is associated with any number of lot (.LOT) files. This can be useful if the name or location of the coordinate (.CRD) file is changed. In the Set CRD for Multiple Lots dialog, press the Select .LOT files button to select any number of lot (.LOT) files. They are added to the list. Next, press the Select .CRD file button. After you have selected the files, press the Process button.

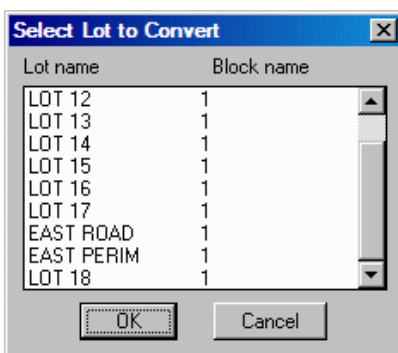

Pulldown Menu Location: Area/Layout > Lot File Utilities

Keyboard Command: lotscrd

Prerequisite: Existing lot (.LOT) file(s)

Lot File to Centerline

This command creates a centerline (.CL) file from a lot (.LOT) file. Since the lot definitions contain a series of points and a starting station, the lot (.LOT) file contains the necessary data to create a centerline. The Select Lot to Convert dialog lists the available lot names in the current lot (.LOT) file. Select a single lot to process, then specify the centerline (.CL) file name to create.

Prompts

Centerline File to Write dialog *enter new centerline (.CL) file name*

Select Lot to Convert dialog *select a lot from the list*

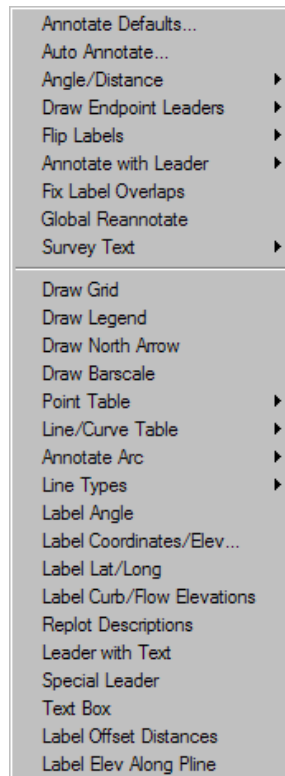

Pulldown Menu Location: Area/Layout > Lot File Utilities

Keyboard Command: lot2cl

Prerequisite: None

Annotate Menu

These menus include commands for labeling lines with bearing/azimuth and distances, special lines, coordinates, curves, curve tables and line tables. The precision of labeled distances and coordinates are set and controlled with the *Annotate Defaults* command.

Angle/Distance

The Angle/Distance sub-menu contains many commands for labeling the angle and/or distance of line segments. The line segments can be defined by picking a line, picking a polyline segment, entering two point numbers or picking two points. The angles can be labeled in bearing, azimuth or gon format. In the command names, the "_" indicates which side of the line label will appear. For example, "Bearing_" will label the bearing above the line and "_Bearing" will label below the line. There is also a Custom Label Formatter option. When this command is used and Option is chosen, there will appear a Custom Line Label dialog with various settings.

Prompts

Define bearing by, Points/type in Bearing/<select line or polyline>: P

1st Point ?

Pick point or point number: 11

PtNo. North(y) East(x) Elev(z) Description

11 4869.06 4390.31 0.00

2nd Point ?

Pick point or point number: 2

PtNo. North(y) East(x) Elev(z) Description

2 4610.89 4078.44 0.00

Bearing Distance

Stacked DistanceBearing

BearingDistance

Pulldown Menu Location: Annotate > Angle / Distance

Keyboard Command: Bearing and distance or bearing only or distance only: brg-, bbrg, brg_dis, dis_brg, brgdis-, bbrgdis, dis-, bdis, bbrgdis; Stacked labels: stackbd, stackdb2, stackdb3, stackdb4; Azimuth: AZI-, BAZI, AZI2-, AZI3-, azidist2, azidist3, azidist4, dist_azi; Gon: gonlab, gonlab2, gonlab3, gonlab4.

Prerequisite: None

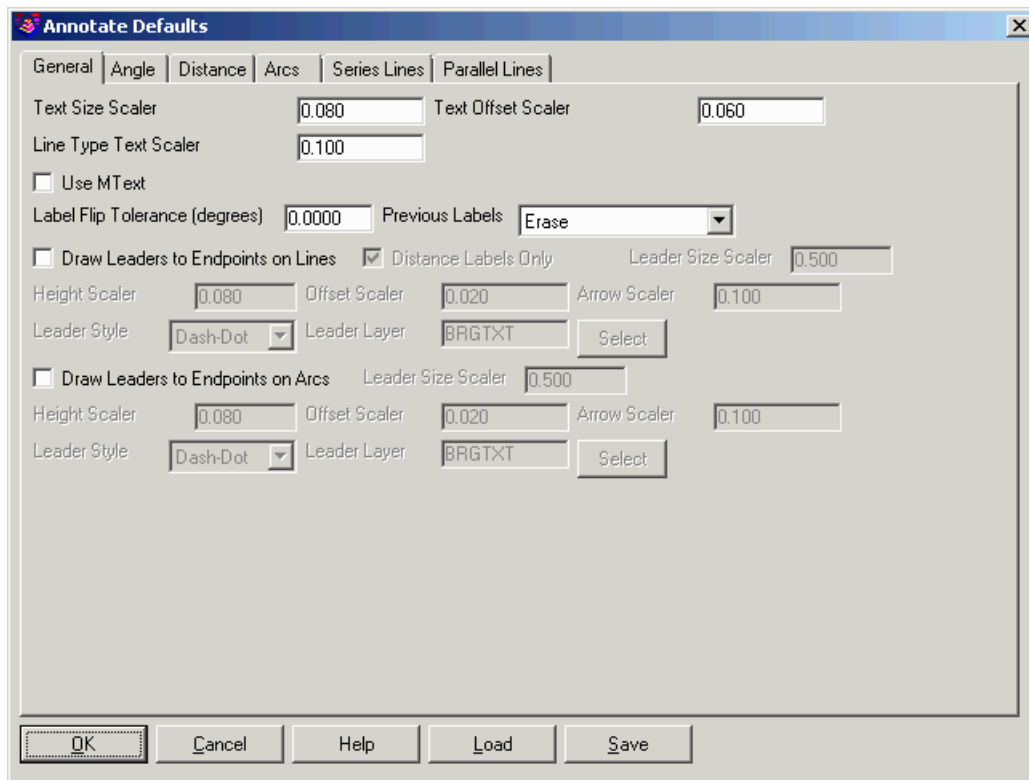

Annotation Defaults

This command sets the defaults for the annotation menus and controls the way various annotation commands work. Some of these defaults can be changed globally by running *Configure* command, which changes the file *COGO.INI* so that every time you start Carlson, the new defaults are set. When this menu option is selected the Annotate Defaults dialog appears.

This dialog is broken into 5 tabs: General, Angle, Distance, Serial Lines and Parallel Lines.

General Tab

This tab is used for settings that apply to all annotation types.

Text Size Scaler: This value is multiplied by the horizontal scale value to set the text size units. The Horizontal Scale is set in the Drawing Setup command.

Text Offset Scaler: This value multiplied by the horizontal scale defines the distance that an annotation label is placed from its defining line.

Line Type Spacing: Specifies the distance between the symbols on special line types.

Line Type Text Scaler: This value multiplied by the horizontal scale specifies the size of the symbols of special line types.

Use MText: This option creates the labels as MText instead of standard Text entities.

Label Flip Tolerance (degrees): Gives extra tolerance for label flipping for readability. Labels draw in the north-west quadrant that are within this number of degrees to due-north will be drawn upside down.

Spaces Between Bearing and Distance Labels: Controls number of spaces between labels when bearing and distance are labelled on the same row.

Previous Labels: Specifies if previous labels for the for the set of linework being annotated are kept or deleted. Setting values are Retain, Erase, Prompt Before Erasing.

Draw Leaders to Endpoints on Lines: This option creates leader lines (crow's feet) between the distance annotation and the line segment endpoints as shown below. These leaders are used to help identify the endpoints that were used to create the distance label.

Distance Labels Only: When checked, leaders will not be drawn unless the label includes a distance.

Leader Size Scaler: This option determines the maximum length for leaders. The size in drawing units will be the Leader Size Scaler multiplied by the Horizontal Scale (for example, $0.5 \times 50 = 25$). If the line segment is too short, the leader is shortened to fit.

Height Scaler: This option controls the height of the leader.

Offset Scaler: This option controls the distance between the line endpoints and the leader endpoints.

Arrow Scaler: This option controls the arrowhead size for leader styles with arrows.

Leader Style: This option determines which of the five styles of endpoint leaders to use. The styles are: Arrow-Arc, Arc-Arrow, Arc-Only, Dash-Dot, Dashed, Arrow-Line, Perpendicular and Custom. For custom, the program draws a block specified in the Block field of this dialog.

Leader Layer: This option determines the layer for drawing the leader.

Draw Leaders to Endpoints on Arcs: This option creates leader lines (crow's feet) between the arc segment endpoints as shown below. These leaders are used to help identify the endpoints that were used to create the arc label.

Leader Size Scaler: This option determines the maximum length for leaders. The size in drawing units will be the Leader Size Scaler multiplied by the Horizontal Scale (for example, $0.5 \times 50 = 25$). If the arc segment is too short, the leader is shortened to fit.

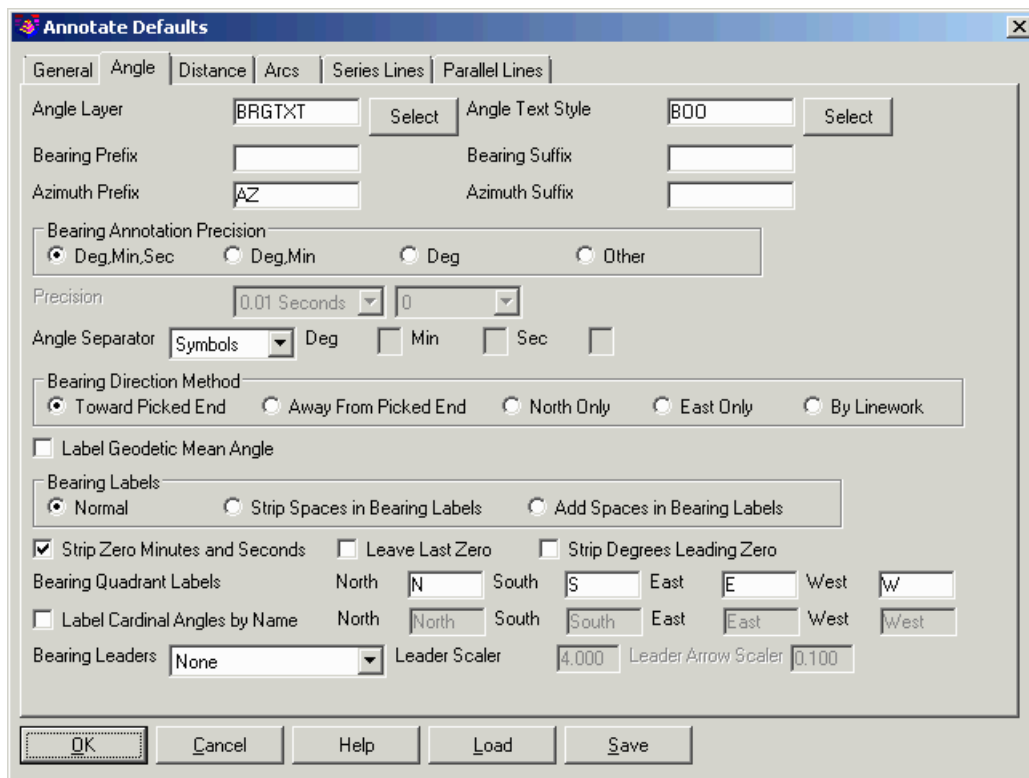

Offset Scaler: This option controls the distance between the arc endpoints and the leader endpoints.

Leader Style: This option determines which of the five styles of endpoint leaders to use. The styles are: Arrow-Arc, Arc-Arrow, Arc-Only, Dash-Dot, Dashed and Arrow-Line.

Leader Layer: This option determines the layer for drawing the leader.

Angle Tab

This tab is for settings that apply to angle labels:

Angle Layer: This specifies the layer to be used for angle labels.

Angle Text Style: This specifies the text style to be used for angle labels.

Bearing Prefix and Suffix: Specifies the prefix and suffix text for bearing labels.

Azimuth Prefix and Suffix: Specifies the prefix and suffix text for azimuth labels.

Bearing Annotation Precision: Specify the display precision for bearing labels.

Angle Separator: Choices are Symbol, Hyphen, Space, Other. When Other is chosen the Deg. Min. and Sec. fields are enable to allow the user to enter custom angle separators.

Bearing Direction Method: Choose the orientation of the bearing. This controls how lines selected for bearing or azimuth annotations will be referenced.

Toward Picked End: If this option is chosen, the line will be labeled in the direction of the endpoint that is closest to the point where you selected the line.

Away from Picked End: This labels the line in the direction away from the closest endpoint.

North Only: This option controls whether bearing annotations will always be labeled in the north quadrants (NE or NW) and never in the south quadrants.

East Only: This option controls whether bearing annotations will always be labeled in the east quadrants (NE or SE) and never in the west quadrants.

By Linework: This option labels the line in the direction that the line was drawn.

Label Geodetic Mean Angle: Instead of labeling the direct coordinate bearing between two points, this option labels the geodetic mean angle which is the average of the geodetic bearings at the two points. This method converts the drawing coordinates to lat/lon and calculates the convergence angles for both points. The projection must be defined under Settings->Drawing Setup.

Strip Spaces in Bearing Labels: This option causes the spaces in bearing labels to be removed.

Add Spaces in Bearing Labels: This option puts spaces between the degree, minutes, and seconds numbers.

Strip Zero Minutes and Seconds: This option shortens the label by dropping either seconds and or minutes and seconds when they are equal to zero. The Leave Last Zero will keep a single zero in the label.

Strip Degrees Leading Zero: This option removes any extra leading zeros on angle degrees.

Bearing Quadrant Labels: These settings control the labels for the north/south prefix and east/west suffix for bearing labels.

Label Cardinal Angles by Name: When checked, the user is allowed to enter the labels that will be used for each of the four cardinal angles.

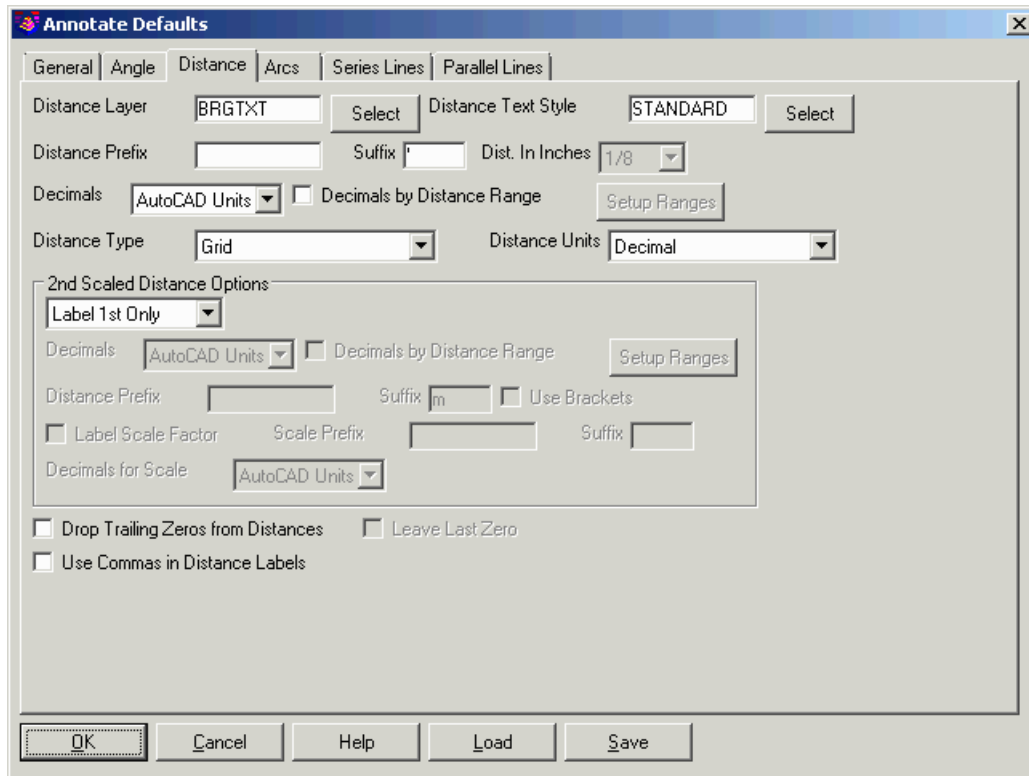

Bearing Leaders: The **Leader Scaler** controls the length for the leader. The **Offset Scaler** controls the distance between the bearing label and leader. The **Leader Arrow Scaler** controls the size of the arrowhead. The **Leaders To Side** option creates a direction arrow with the bearing annotation as shown below. The **Leaders After Bearing** option is similar to the Leaders To Side. The difference applies when having both the bearing and distance labels together. The Leaders To Side option puts the leader after the distance label. The Leaders After Bearing puts the leader between the bearing and the distance labels.

Leaders After Bearing method draws the bearing leader to the right side of the bearing label.

Distance Tab

This tab is for settings that apply to distance labels:

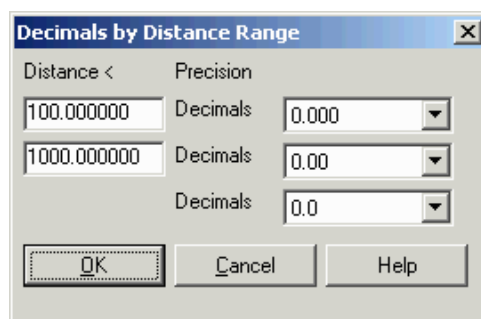

Distance Layer: This specifies the layer to be used for distance labels.

Distance Text Style: This specifies the text style to be used for distance labels.

Distance Prefix and Suffix: These specify the prefix and suffix that are added to distance annotations.

Decimals: The decimal places can be set to a specific number or set to match the CAD units which are set by the LUPREC system variable. The decimal settings with "5" round to the nearest half.

Decimals by Distance Range: This option uses different decimals depending on the distance amount. Pick the Setup button to define these decimals. In this dialog, distances less than 100 will have 3 decimals, distance between 100 and 1000 will have 2 decimals, and distance more than 1000 will have 1 decimal.

Distance In Inches: This controls the precision for inches from 1/2 to 1/256th of an inch when the Distance Units is set for inches.

Distance Type: This controls whether to label grid distances or geodetic distances at zero or mean elevation. The geodetic distances require the grid projection to be set in Drawing Setup.

Distance Units: This specifies the units used for distance labels. Choices are Decimal, Chains, Rods, Varas, "Feet and Inches" and Both.

2nd Scaled Distance Options: This option labels determines if a 2nd scaled distance is included in distance labels. This 2nd distance is scaled by the Report Scale Factor set in the Drawing Setup dialog. Choices for this option are "Label 1st Only" (label distances in current drawing units only), "Label 1st and 2nd" (label distances in both current drawing units and scaled by the Report Scale Factor) and "Label 2nd Only" (label distances scaled by the Report Scale Factor Only). There are separate settings for the 2nd Distance for the label prefix and suffix and decimal places. There is an option for labeling the scale factor used for the 2nd distance.

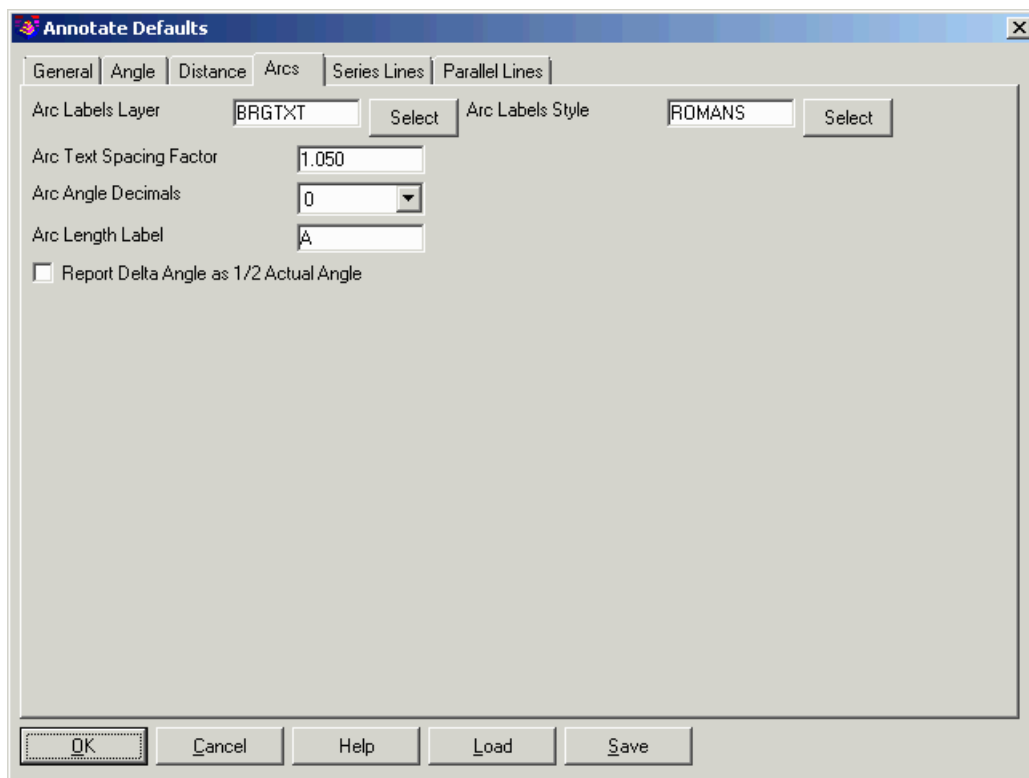

Label: This variable will be assigned as a suffix to the second scaled distance label.

Drop Trailing Zeros in Distances: This option allows you to drop trailing zeros on distance labels. **Leave Last Zero** will strip all except the decimal for tenths.

Use Commas in Distance Labels: This option formats the distances over 1000 with a commas (ie. 1,234.0).

Arcs Tab

This tab has settings for arc labels.

Arc Labels Layer: This specifies the layer to be used for arc labels.

Arc Labels Style: This specifies the text style to be used for arc labels.

Arc Angle Decimals: Controls the number of decimals for arc angle labels.

Arc Length Label: Specifies the prefix label for arc length labels.

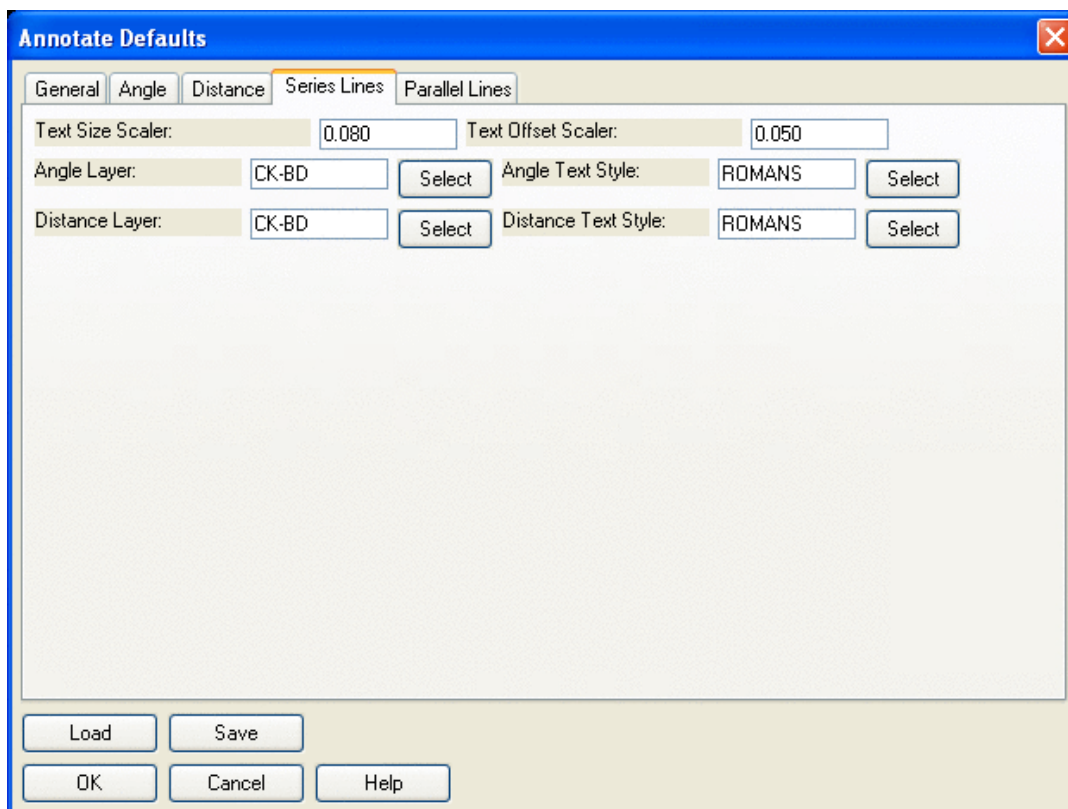

Arc Text Spacing Factor: This variable controls how close letters will be spaced when labeling arcs. The lower the number, the closer the spacing. The higher, the farther apart. (The suggested range between 0.8 and 1.5)

Report Delta Angle as 1/2 Actual Angle: The angle value in the label will be 1/2 the actual angle.

Strip Degrees Leading Zero for Delta Angle: Controls whether to have a leading zero which applies to delta angles under 100 degrees. For example, "054" verses "54".

Series Lines Tab

This tab is for settings that apply to Series Lines labels (See the section "Auto Annotate" for a detailed description of series line handling).

Text Size Scaler: This value is multiplied by the horizontal scale value to set the text size units for serial lines.

Text Offset Scaler: This value multiplied by the horizontal scale defines the distance that an annotation label is placed from its defining line for serial lines.

Angle Layer: This specifies the layer to be used for angle labels on serial lines.

Angle Text Style: This specifies the text style to be used for angle labels on serial lines.

Distance Layer: This specifies the layer to be used for distance labels on serial lines.

Distance Text Style: This specifies the text style to be used for distance labels on serial lines.

Parallel Lines Tab

This tab is for settings that apply to Parallel Lines labels (See the section "Auto Annotate" for a detailed description of parallel line handling).:

Text Size Scaler: This value is multiplied by the horizontal scale value to set the text size units for parallel lines.

Text Offset Scaler: This value multiplied by the horizontal scale defines the distance that an annotation label is placed from its defining line for parallel lines.

Angle Layer: This specifies the layer to be used for angle labels on parallel lines.

Angle Text Style: This specifies the text style to be used for angle labels on parallel lines.

Load/Save: Choose these functions to load an existing annotation defaults file (.ADF) or save a new one, which will contain your current selections.

Pulldown Menu Location: Annotate

Keyboard Command: LDEF

Prerequisite: None

Auto Annotate

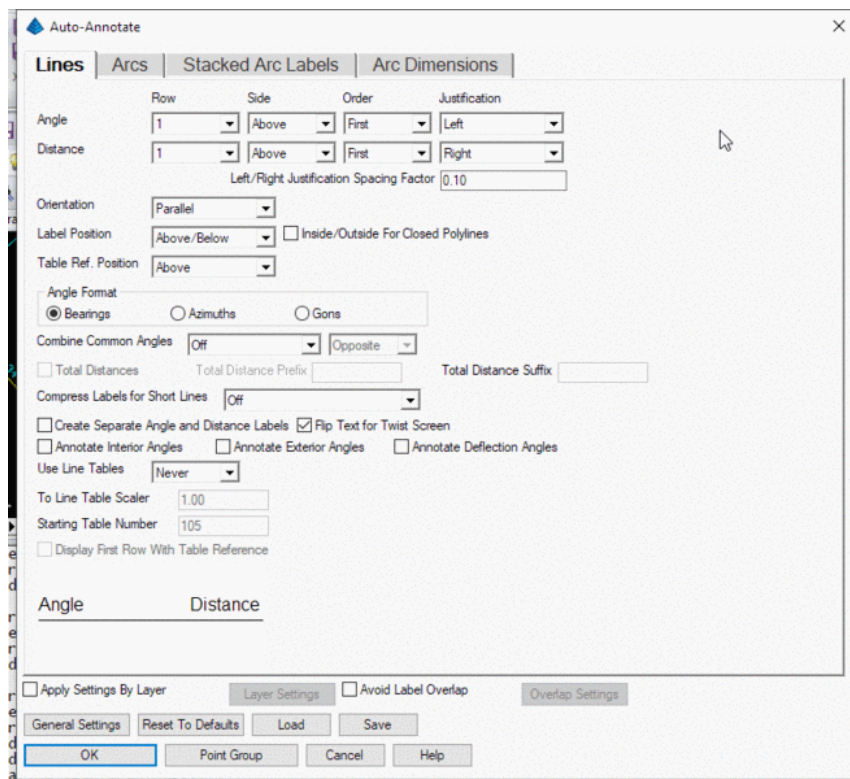

This command allows you to select a group of lines, arcs and/or polylines to be labeled. It allows for any combination of line and distance labeling, and also any combination of arc labeling.

You can position the features of the labels, once in the Auto-Annotate dialog, by using the Row, Side, Order, Orientation and Position Types options, all found under Lines tab. For Arcs, you can select the Arcs tab and determine the type of auto-annotating you would prefer for arc entities. As you select different options, you can see the changes in the preview display of the entry dialog. You will select the Angle Format in terms of Bearing, Azimuths and Gons and there is an important feature that allows you to avoid label overlaps. This is done by applying specific, user-defined settings. When labeling arcs, there are options to set the label prefixes for curve annotation. The Settings button will bring you to the Annotation Defaults dialog, as explained in a previous section. Defaults will restore the prior settings.

Apply Label Settings by Layer brings up another dialog box which allows you to import from file, or load, predetermined configurations. There is an option to have different label settings applied by layer. Apply Label Settings By Layer allows you to set, load, and save your preferred variables.

The Avoid Label Overlap option can bring up a special dialog called the Overlap Manager. This screen, which contains extra tools for, as an example, sliding or stacking the labels that are overlapping and conflicting with drawing entities, gives you the real-time ability to move along the plan and make your corrections. This also will help you to avoid overlapping with other labels, text, symbols and linework – including fence and utility lines. In this Overlap Manager, docked on the left side of the screen. it is recommended that you use the Back and Next button frequently in order to review, adjust and correct your drawing.

Auto-Annotate dialog starts with the Lines (tab).

Angle/Distance: Allows you to enter the what row the Angle label is on, what side and the order of the label on the linework. The same applies for Distance labels. Notice the preview display changing.

Row: Using numbers (1 or 2), or choosing None, you can determine the order and appearance of the descriptions.

Note the change in the preview display.

Side: Choose inside or outside of the line.

Order: If you determine that the annotations are to be on the same row and same side of the line, then you must pick the order in which they will appear, from left to right.

Justification: This option gives the ability to left or right justify labels at ends of line or center justify the labels.

Left/Right Justification Factor: This value specifies, in percent, how far right (for left justified) and how far left (for right justified) the labels will be moved along the annotated line. This gives you fine control over the justification behavior.

Orientation: This offers this choice between parallel or perpendicular with regards to the labels' orientation to the line being labeled.

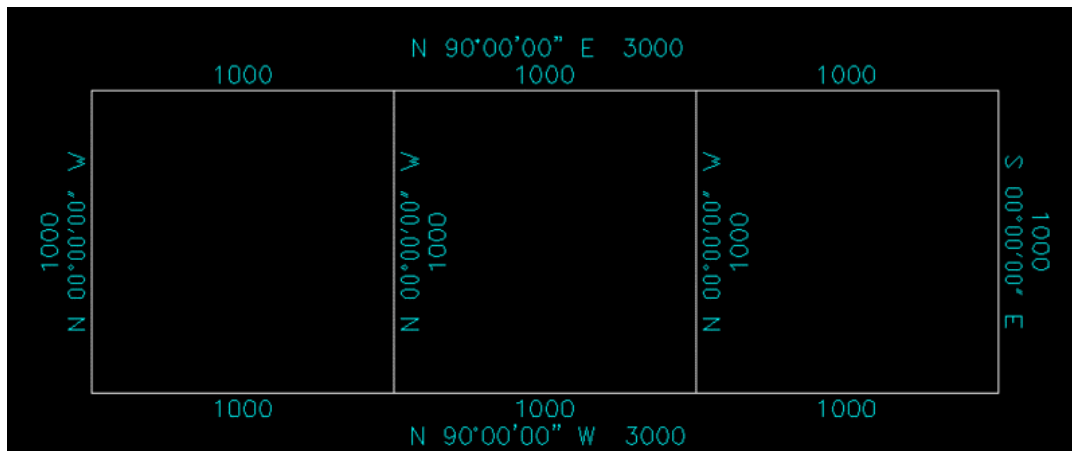

Position Types: Determined how each label is placed in relationship to the line and the other label. The **Inside/Outside For Closed Polygons** treats the first position type as the inside position and the second as outside for labeling closed polygons which applies when labeling lot polygons that are closed and you want a style like distances on the inside of the lots and bearings on the outside.

Angle Format: Bearing, azimuths or gons are the choices.

Combine Common Angles: This allows the user to reduce label clutter by minimizing labeling of serial and parallel linework. Choices are Off, Series, Parallel and "Series and Parallel". Series common angles are those where serially connected linework share the same angle. Common series angles are labeled at the mid-point of the series of connected line segments. When series common angles are selected they may be drawn stacked on the same side as the distance labels or on the opposite side from the distance labels. Also, for serial common angles the total distance may be included in the label. Parallel common angles are those where adjacent areas share parallel lines that include the line that bisects the areas. In this case, only the outer-most lines of the set of parallel lines will be labeled with the angle.

The common angle labels have separate settings for layer, style, size and offset. Please see the section "Annotate Defaults" for information on how to control these settings.

The following example shows the results of combining common serial labels, including totaling of the distances:

The following example shows the results of combining common serial and parallel labels:

Compress Labels for Short Lines: When angle and distance labels are being placed on the same side and row, this feature allows the user to place the label on different rows in the case that the label will not fit on the line otherwise. The options are Off, "Angle Above, Distance Below", "Distance Above, Angle Below", "Stacked Angle-Distance" and "Stacked Distance-Angle".

Add Space Between Angle and Distance Labels: When angle and distance labels are being placed on the same side and row, this feature allows the user to have the angle and distance labels spread apart from each other as allowed by the length of the line being annotated.

Reduce Space Between Angle and Distance Labels: When angle and distance labels are on the same row, this option puts a single space between them. Otherwise, there are two spaces.

Create Separate Angle and Distance Labels: When the angle and distance labels are on the same row, this option creates them as separate text entities. Otherwise, the labels are combined in a single text entity as long as their text styles match from Annotation Defaults.

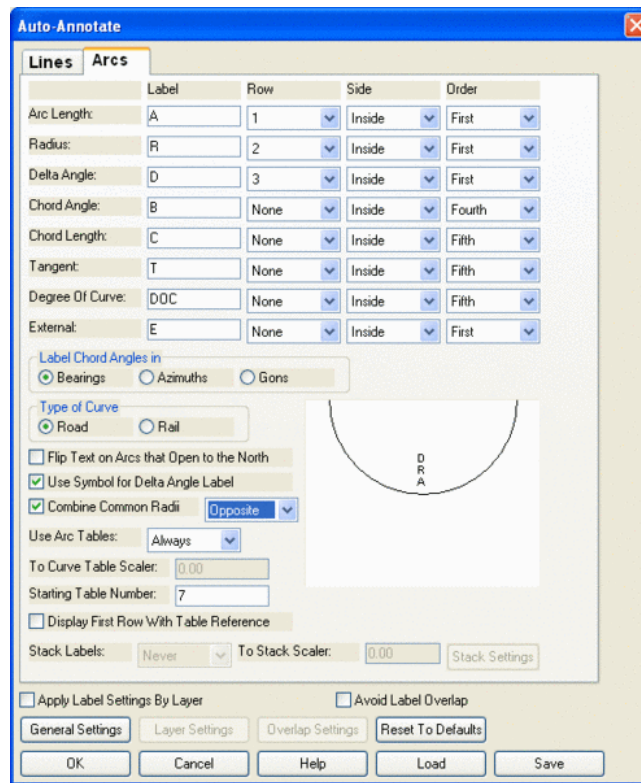

Flip Text for Twist Screen: This option automatically flips the labels when needed to make them right-side up.

Use Line Tables: Line tables are sometimes preferred as they keep the drawing linework clean and free of labeling. Choices are Always, Never or By Scaler. If By Scaler is chosen "To Line Table Scaler" is enabled.

To Line Table Scaler: If the length of the line is less than this minimum, the line is labeled as a line table entry. The To Line Table Scaler is relative to the current horizontal scale and represents the length of the line in plotted inches.

Starting Table Number: User choice. You might change this because perhaps you have another group of line labels, in table form, in the drawing. Line table entries are numbered sequentially beginning at the line Starting Table Number. The location for the line table can be picked if there is no current table. Otherwise, Auto Annotate will add to the end of the current line table. To set the location for the current line table, run the Table Header command in the Annotate > Line/Curve Table menu.

Auto-Annotate dialog box, by selecting the **Arcs tab**, displays the options for auto-annotating arcs. The columns are described, followed by the rest of the options.

Label: Here you might alter slightly the defaults by entering a letter or acronym that will represent to type of calculation. Or you could leave it alone.

Row: Using numbers, or choosing None, you can determine the order of the descriptions, and determine whether or not some might be left off altogether.

Side: Choose inside or outside of the arc.

Order: If you determine that the annotations are to be on the same row and same side of the curve, then you must pick the order in which they will appear, from left to right.

Label Chord Angles in: Bearing, azimuths or gons are the choices.

Type of Curve: Choose between Road and Rail.

Flip Text on Arcs that Open to the North: Clicking here might make for a easier to read finished plan. User preference.

Use Symbol for Delta Angle Label: The popular and traditional triangle-shaped symbol can be used, instead of the letter D, or any other letter(s).

Combine Common Radii: This allows the user to reduce label clutter by minimizing labeling of connected arc segments that share a common radius and center point. When selected, only one radius label will be generated for such arc segments. The following shows an example where a curve made of three arc segments is labeled with only one radius label. The radius label is placed offset to the mid-point of the combined arcs.

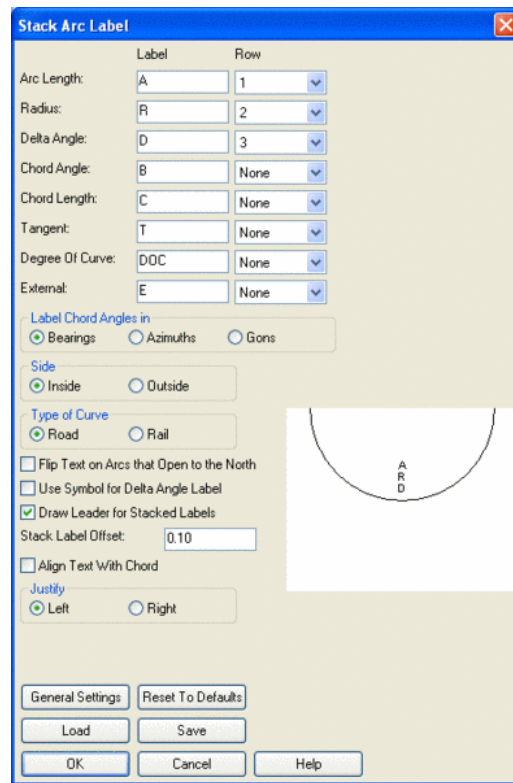

Use Arc Tables: Curve tables are sometimes preferred as they keep the drawing linework clean and free of labeling. Choices are Always, Never or By Scaler. If By Scaler is chosen "To Curve Table Scaler" is enabled.

To Curve Table Scaler: The To Curve Table Scaler applies when the Type of Arc label options is not set to Curve Table. If the length of the arc is less than this minimum, the arc is labeled as a curve table entry. The To Curve Table Scaler is relative to the current horizontal scale and represents the length of the arc in plotted inches.

Starting Table Number: The Starting Table Number is the starting number for the first line entered in the Curve Table. Curve Table entries are numbered sequentially from the curve Starting Table Number. The location for Curve Tables can be picked if there is no current table. Otherwise, Auto Annotate will add to the end of the current Curve Table. To set the location for the current Curve Table, run the Table Header command in the Annotate > Line/Curve Table menu.

Stack Labels: Stacked labels are sometimes preferred as they can help reduce label overlapping. Choices are Always, Never or By Scaler. If By Scaler is chosen "To Stack Scaler" is enabled.

To Stack Scaler: When Stack Labels is set to "To Stack Scaler" this control is enabled. If the length of the arc is less than this minimum, the arc is labeled as a stacked label. The To Stack Scaler is relative to the current horizontal scale and represents the length of the arc in plotted inches. The Stack Settings button is enabled when Stack Labels is set to Always or By Scaler. This button brings up the Stack Arc Labels which displays the options for creating stacked arcs labels. The columns are described, followed by the rest of the options.

Label: Here you might alter slightly the defaults by entering a letter or acronym that will represent to type of calculation. Or you could leave it alone.

Row: Using numbers, or choosing None, you can determine the order of the labels, and determine whether or not some might be left off altogether.

Label Chord Angles in: Bearing, azimuths or gons are the choices.

Side: Choose inside or outside of the arc.

Type of Curve: Choose between Road and Rail.

Flip Text on Arcs that Open to the North: Clicking here might make for a easier to read finished plan. User preference.

Use Symbol for Delta Angle Label: The popular and traditional triangle-shaped symbol can be used, instead of the letter D, or any other letter(s).

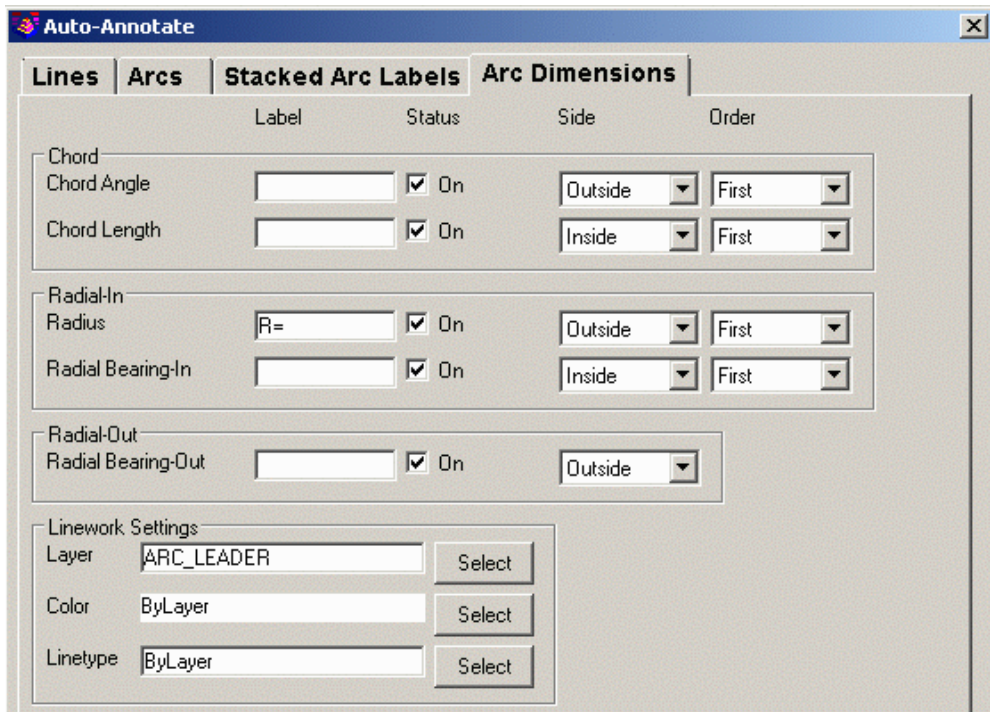

Draw Leader for Stacked Labels: When checked, a leader will be drawn from the stacked label to the mid-point of the arc.

Stack Label Offset: This value multiplied by the horizontal scale defines the distance that an annotation label is placed from its defining arc.

Align Text With Chord: Determine whether the stacked label is oriented horizontally (unchecked) or in the direction of the chord (checked).

Arc Dimensions

The Arc Dimensions style draws and annotates lines for each arc for the chord and radial lines. To use the Arc Dimensions label style, turn on **Use Arc Dimension Labeling** on the Arcs tab. On the Arc Dimensions tab, there are settings for the label prefix and position for the chord angle, chord length, radius and radial angles. You can also set the layer, color and linetype for the arc dimension lines.

Auto-Annotate dialog commands, common to both Lines and Arcs.

Apply Label Settings By Layer: See the Label By Label Settings dialog and details below.

Avoid Label Overlap: See dialog and details below.

General Settings: Brings you to the A ate Defaults dialog.

Layer Settings: Apply Label Settings By Layer option must be clicked in order to activate. You will then see the Label By Layer Settings dialog.

Overlap Settings: Avoid Label Overlap option must be clicked in order to activate. Brings up the Avoid Label Overlap dialog.

Reset to Defaults: This returns you to the default label values.

Point Group: This function prompts for a point group to use for the input data to annotate. The program uses the series of points to define the lines and arcs to annotate.

Load: You can load an existing .AAN file.

We will now say, for example, that with linework only to label in the drawing we run this routine. We first decide to go without the Avoid Label Overlap feature. This can be done by unclicking this option in the Auto-Annotate dialog. We will say that there is a fence line cutting through our property line, the property lines being the lines that we want to auto-annotate. In going without Auto Annotate's overlap protection, we perform Auto Annotate and we see that there is an overlap, with the labels running into the property lines and the fence line.

Panning and zooming the screen shows the problems we confront. Now, run Auto annotate again, but this time click ON the Avoid Label Overlap feature. Then click Overlap Settings button which brings up a dialog as shown below. This program and this specific dialog box has many different methods for fixing the overlaps. We will choose the different methods to apply.

First, we will choose Slide. This slides the labels along the linework. We can even choose a maximum amount of slide and other related parameters. We will also turn on the Stack method. The Avoid Linework Conflicts feature pertains to that fence line we have. Finally, click OK. Now can pick the linework. Note that you do not need to erase the existing auto annotate labels ahead of time. This command will remember that those labels were created with this command. It will simply replace the entire group of labels with the new auto annotate labels.

The result, with overlap detection on, is that this routine fixed 7 out of 7 of the conflicts. It slid some of the labels over and stacked others. You can also run Auto Annotate Overlap with manual mode. To do this, remove the automatic options (such as Stack, Slide, etc.) and click View Remaining Overlaps After Applying Rules ON. Say OK. It docks the Overlap Manager on the left side of the screen.

You can then fix the conflicts with this Overlap Manager by using the different methods presented in this new window. This manager will highlights the conflicts, it will, for example, slide to the next conflict and allow you to pick a new position. Hit the Next several times. Again, stack one, slide another over, and perform other changes. Then choose Close.

Also, remember that depending on the linework layer, you can even have different annotation styles. There is also an option to have different label settings "by layer". These decisions are made by using the Label By Layer Settings dialog options. To get to this dialog, click on the Layer Settings button at the bottom of the Auto-Annotate dialog.

Label By Layer Settings option and dialog.

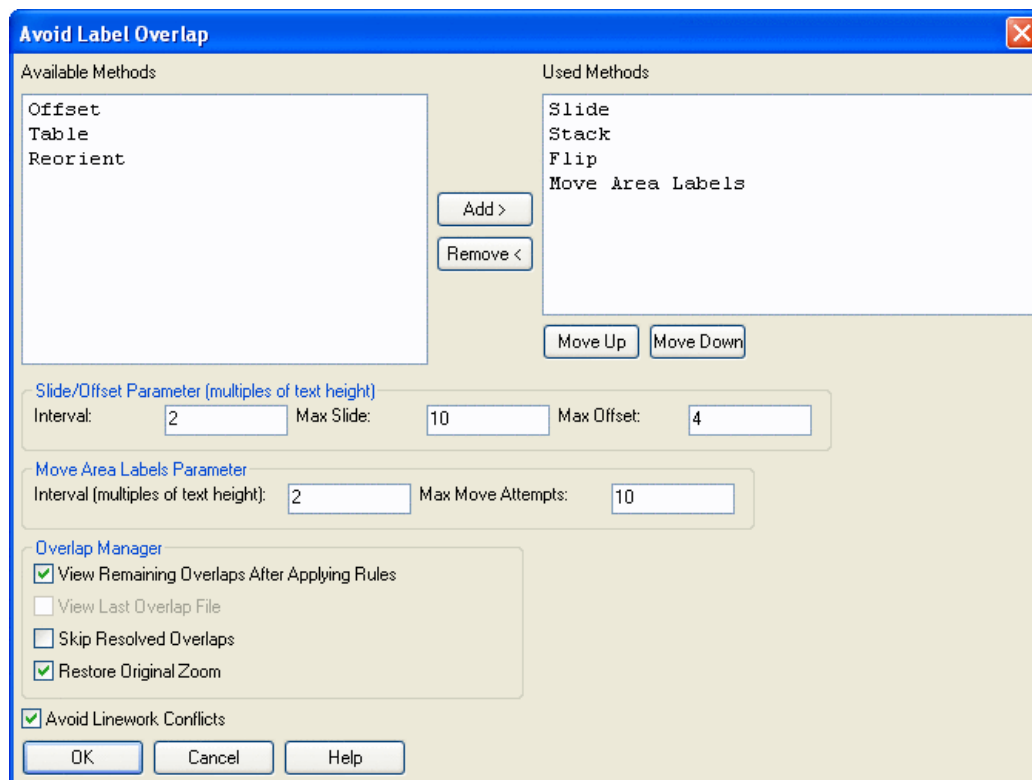

Layer: Select a layer from the existing list of layers. If the linework you select and to be labeled is on this layer, the parameters that you set in this dialog will be reflected in all labels.

Auto-Annotation Settings: Select an existing Annotation Settings file (AAN) by clicking the **File** button on the right. Or stick with the defaults.

Auto-Defaults Settings: Select an existing Default Settings File (ADF) by clicking the **File** button on the right. Or stick with the defaults.

Load: Select this option in order to load an existing layer file (LAY) to load.

Avoid Label Overlap option and dialog.

Overlap Settings dialog

Available Methods: Your choices. Pick from these.

Used Methods: Different ways in which this routine attempts to resolve the label overlaps. The overlap resolution attempt methods are applied in the order listed here.

Slide: If this is selected then the labels will be moved parallel to your linework until they do not overlap. The labels will not move past the end of the linework or the Max Slide which you determine.

Offset: will move your labels perpendicular to your linework as far as you set the Max Offset.

Table: Replaces your labels with a numbers and create a table of the numbers with the corresponding labels.

Reorient: If chosen, the labels will change orientation in the plain view to avoid overlapping.

Flip: It will flip your label onto the other side of the linework.

Stack: It will stack or unstack the text of your labels to avoid overlapping.

Move Area Labels: This method, which only applies to area labels, will attempt to move the area label to the closest place within the area that doesn't overlap with any other labels. You can control the move interval (distance between move attempts) and total number of move attempts by setting the values "**Interval (multiples of text height)**" and "**Max Move Attempts**" in the "**Move Area Labels Parameter**" section:

You can use any combination of these commands by using the add/remove button. You can also determine the order in which the command tries a method by using the **Move Up** and **Move Down** buttons. If a solution is not found by using the first method then the next method is used in descending order.

Add/Remove: Some methods you might prefer not to use.

Slide/Offset Parameter (multiples of text height): These are variable that help you to slide or offset the label(s) in question.

View Remaining Overlaps After Applying Rules: This option will help you to see what still needs treatment.

View Last Overlap File: When it is checked, the Overlap Manager will return to the previous labels that were under review.

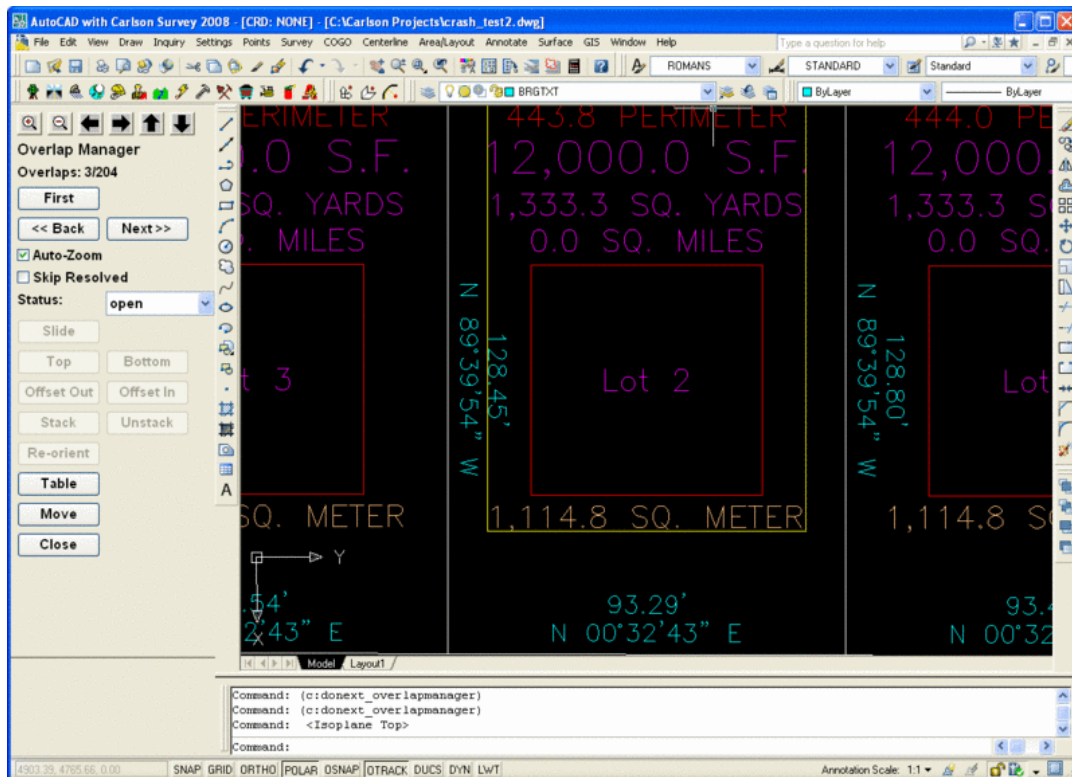

Skip Resolved Overlaps: When it is unchecked, the Overlap Manager will display all the labels that were moved by the command as a final check to you.

Restore Original Zoom: This will restore the zoom you were previously at before running the command.

Avoid Linework Conflicts: This is an extra precaution for when linework conflicts exist.

If there is a conflict, the following Overlap Manager dialog appears on the screen. It zooms to the conflict and provides you with the necessary tools to resolve the issues that need to be addressed. Many of the choices selected in the earlier dialog boxes can be modified yet again in the Overlap Manager, in your quest for a clean looking drawing. Within this special window you can zoom, pan, move to the next conflict, and perform many other tasks.

The **Overlap Manager** screen appears as a docked dialog window to the left of the main screen.

The Overlap Manager can be used to manually check and change label overlaps. The current overlap item will be have a yellow box drawn around it to help make it clear which item is the one currently being worked on. If you check on "View Remaining Overlaps After Applying Rules" then any remaining overlaps will be zoomed in on and you will have the ability with the Overlap Manager to flip through and fix or ignore the unresolved labels. When the current overlap item is an area label, only the Move and Table button will be enabled as these are the only two manual methods that can be applied to these types of labels. For line and curve labels, all methods will be enabled.

Prompts

Auto Annotate Dialog Choose settings and click OK.

Select Lines, Arcs, and/or Polylines to Annotate.

Select Objects: *pick entities*. Select the group of lines, arcs and/or polylines you want to annotate.

Pulldown Menu Location: Annotate

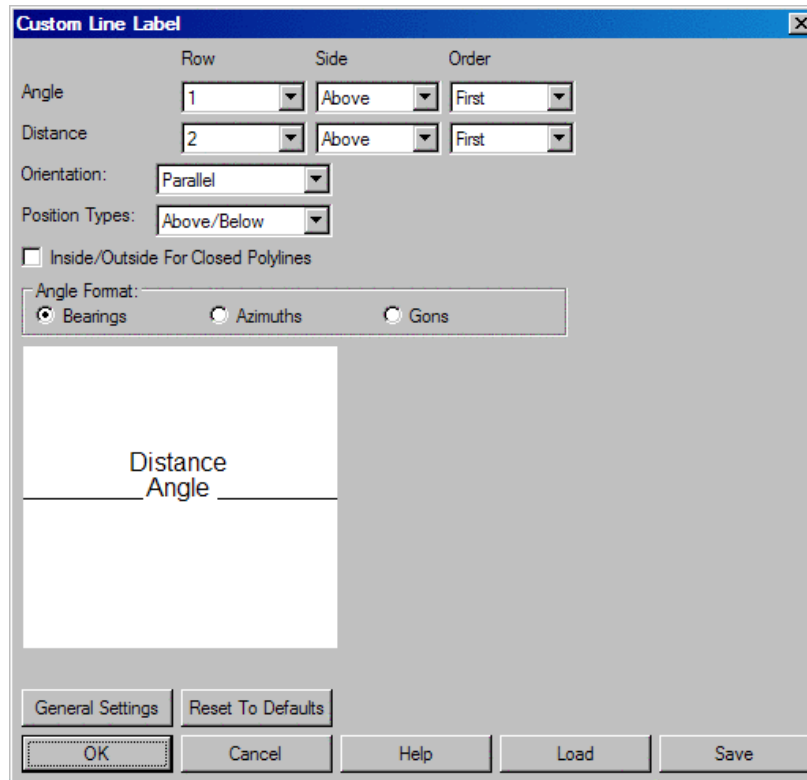

Keyboard Command: autoann

Prerequisite: Lines, arcs or polylines to annotate

Custom Label Formatter AD

This command allows you to customize the labeling for lines and polylines. You are first prompted to select a line or polyline to label, given the existing defaults currently set. The linework is shown as labeled on the screen. The

command line, shown below, also offers you an important choice called Options. When you type 'O' for options the below dialog box appears. In this dialog, there are three columns at the top of the dialog, along with other features. On the command line, there is also a choice called Format (F), which allows you to enter quick-key style keywords for quickly changing the label format. See below for these

Row: This column allows you to stack the data in different ways. You can place more than one item in the same row. If *None* is selected, then that item will not be displayed.

Side: This column allows you to place each item either inside or outside of the line or polyline.

Order: This column determines the order of items when they are placed in the same row.

General Settings: This button brings you to the Annotate Defaults dialog, see 'Annotate Defaults' for more.

Reset To Defaults: This button restores the default settings shown above.

Load/Save: You may also Load and Save different label configurations with the corresponding buttons.

Prompts

Options/Format/Points/<Select line or polyline>: *select entity*

Options/Format/Points/<Select line or polyline>: O

Custom Line Label dialog *choose your preferences and click OK*

You can decide to go into the Option dialog at the start of the command, or after your initial labeling. If you use the Format command line option, you will be asked to enter the Format command. The choices are:

B = bearing

A = azimuth

G = gon

D = distance

R = next row

_ = switch side of line

Pulldown Menu Location: Annotate > Angle/Distance

Keyboard Command: annline

Prerequisite: An arc to label

Draw End Point Leaders

These three commands draw a pair of leaders (crow's feet) at the ends of the line or polyline segment. The segment can be selected from a line, polyline or pair of points. The leaders are drawn above or below the line or polyline, or you can pick a side, depending on which Endpoint Leader command is run. The Pick Side command gives you the ability to place the crow's feet on a selected side of the line or polyline. Controls to customize the look of the endpoint leaders are accessed through the *Annotate Defaults* command in the Annotate menu. The Leader Size Scaler determines the maximum length of the leader. If the line segment is too short, the leader is shortened to fit. The actual length of the leader in drawing units is calculated by multiplying the leader scaler by the drawing horizontal scale (i.e., $0.5 * 40 = 20$). The Offset Scaler sets the distance that the leader head is off the line endpoint. There are four leader styles to choose from: Arc with Arrow, Arc Only, Dash-Dot-Dash and Dashed. Endpoint leaders can be drawn together with bearing/distance annotation by having the Draw Leaders to Endpoints option on under *Annotate Defaults*. This Draw End Point Leaders command allows you to add the leaders as another step.

Prompts

Define line by [Points/<select line or polyline>]: *Select a line or polyline.*

If you wish to define by points, enter "P" at this prompt and pick points on the screen, or type in point numbers. If a coordinate (.CRD) file has not been previously loaded, a dialog will open to allow you to select a coordinate (.CRD) file to process. While using the Point selection method, the last point picked in the selection is stored in default brackets. So if you are working around a boundary, simply press enter to accept the defaults for the first point and move ahead to the next point.

Arc with Arrow Endpoint Leader

Dashed Endpoint Leader

Pulldown Menu Location: Annotate

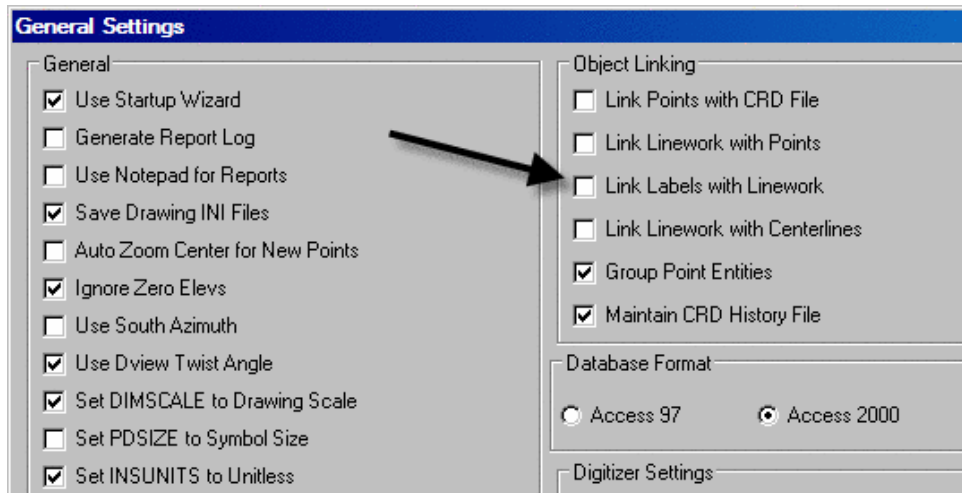

Keyboard Command: crowft

Prerequisite: None

Dynamic Annotation Note

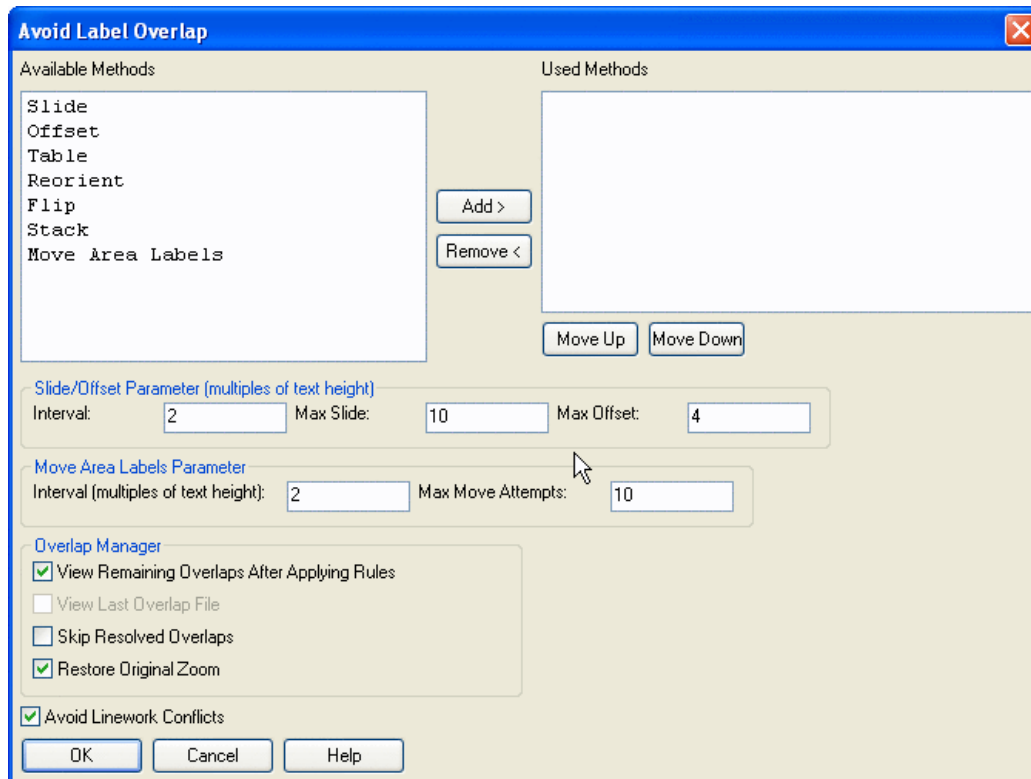

Bearing and distance annotations can be linked to the linework, such that the annotations will automatically update if the linework is changed. For example, if a line is moved with the AutoCAD *Move* command, the bearing label will update. This link can be found, and toggled on and off, under Object Linking in Configure > General Settings. Configure is in the Settings menu. The link is established between the label and the line, or polyline, when the label is created by commands such as *Auto Annotate*, *Line Table* or *Bearing Distance*. There are no links for annotation created using the Points option. To update bearing annotation without using the dynamic annotation, use the *Global Reannotate* command in the Annotate menu. To remove the links between the annotation and the linework entities,

use the *Remove Reactors* command, found under File > Drawing Utilities.

Fix Label Overlaps

This command allows you to fix label overlaps, where a conflict exists, for lines, arcs and polylines. You are immediately taken to the Avoid Label Overlap dialog. Here you can realign your labels by using a variety of optional methods. When the settings are to your liking, click OK. The command line then prompts you to select the entities for which to resolve annotation conflicts. Once you have selected your entities and hit Enter, this routine finds the conflicts and fixes the label overlaps.

If **Slide** is selected then the labels will be moved parallel to your linework until they do not overlap. The labels will not move past the end of the linework or the Max Slide which you determine.

Offset will move your labels perpendicular to your linework as far as you set the Max Offset.

Table will replace your labels with a numbers and create a table of the numbers with the corresponding labels.

If **Reorient** is selected then the labels will change orientation in the plain view to avoid overlapping.

Flip will flip your label onto the other side of the linework.

Stack will stack or unstack the text of your labels to avoid overlapping.

Move Area Labels will attempt move overlapping area labels to the closest place to the original position that does not overlap with other labels. The distance between move attempts and the number of move attempts is controlled by the **Interval** and **Max Move Attempts** settings of the **Move Area Labels Parameter** section.

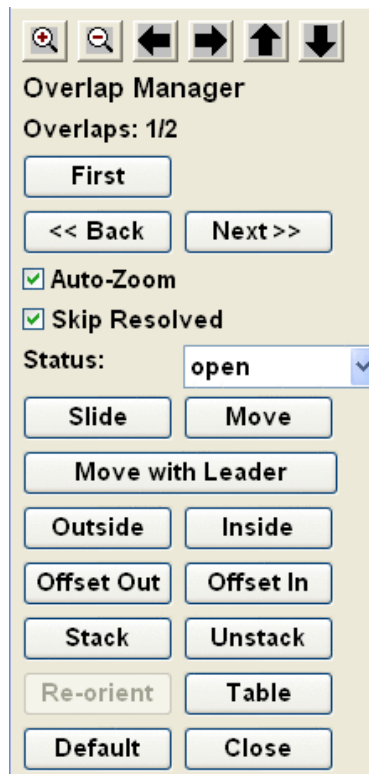

You can use any combination of these commands by using the add/remove button. You can also determine the order in which the command tries a method by using the **Move Up** and **Move Down** buttons. If a solution is not found by using the first method then the next method is used in descending order.

The **Overlap Manager** can be used to manually check and change label overlaps. If you check on "View Remaining Overlaps After Applying Rules" then any remaining overlaps will be zoomed in on and you will have the ability with the Overlap Manager to step through and fix or ignore the unresolved labels. When the current overlap item is an area label, only table and move buttons will be enabled as these are the only methods that apply. For line and curve label overlaps, the buttons for all methods will be enabled. Once a label is moved with the "Move with Leader", only Table, Default and "Move with Leader" will be enabled. The Default button can be used to restore the label back to its original state.

When **View Last Overlap File** is checked, the Overlap Manager will return to the previous labels that were under review.

When **Skip Resolved Overlaps** is unchecked, the Overlap Manager will display all the labels that were moved by the command as a final check to you.

Restore Original Zoom will restore the zoom you were previously at before running the command.

Prompts

Select Lines, Arcs, and/or Polylines for which to resolve annotation conflicts:

Select objects: *select entities*

Pulldown Menu Location: Annotate

Keyboard Command: annconf

Prerequisite: Annotation conflicts

Switch Bearing/Azimuth Quadrant

This command switches the Bearing quadrant label or adds 180° to an Azimuth label. For example, N90°32'16"E would be replaced with S90°32'16"W or AZ 78°17'18" would be replaced with AZ 258°17'18". This routine changes bearing text to read as if the bearing were in the opposite direction.

Prompts

Pick Bearing or Azimuth Text: *pick text*

Pick Bearing or Azimuth Text: *press Enter to end*

Examples of switch bearing/azimuth quadrant

Pulldown Menu Location: Annotate > Flip Labels

Keyboard Command: brgquad

Prerequisite: bearing or azimuth label

Mirror Selected Labels

This command rotates a group of text 180 degrees and maintains the same text position. Use this command to rotate any text. Ignores all entities in the selection set except text.

Before Mirror Labels

After Mirror Labels

Pulldown Menu Location: Annotate > Flip Labels

Keyboard Command: flipset

Prerequisite: Text to rotate

Mirror and Flip Selected Labels

This command mirrors the label to the other side of the labeled segment. At the new location, it then flips the label back to its original orientation. Use this command to manipulate any text. It ignores all entities in the selection set except text.

Before Mirror & Flip Labels

After Mirror & Flip Labels

Pulldown Menu Location: Annotate > Flip Labels >

Keyboard Command: MFLIP_LABELS

Prerequisite: Text to rotate

Flip Last Label

This command flips the last text drawn 180 degrees. Use this command to rotate your last annotation.

Pulldown Menu Location: Annotate > Flip Labels

Keyboard Command: flip

Prerequisite: Text to flip

Flip ON/OFF

When activated, the bearing and distance text will be rotated 180 degrees when drawn.

Pulldown Menu Location: Annotate > Flip Labels

Keyboard Command: flp

Prerequisite: None

Move Label with Leader

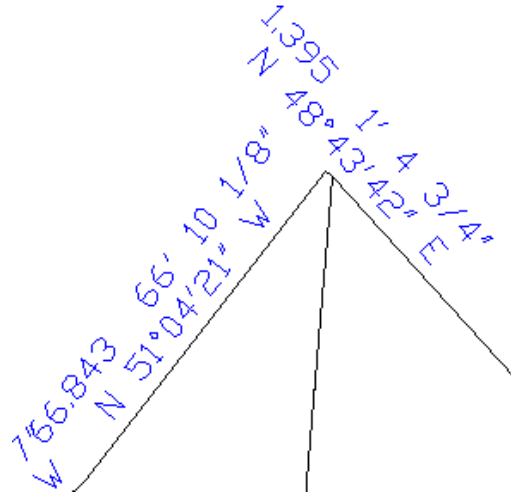

This command allows the user to make a leader label out of a selected angle/distance label.

Prompts:

Select Label to Move (O for Options,R for Restore): pick an angle or distance label.

Pick end point for move: pick the end point of the move (end of leader).

Select another Label to Move (O for Options,R for Restore,Enter to End): pick another angle or distance label if desired.

Before Move

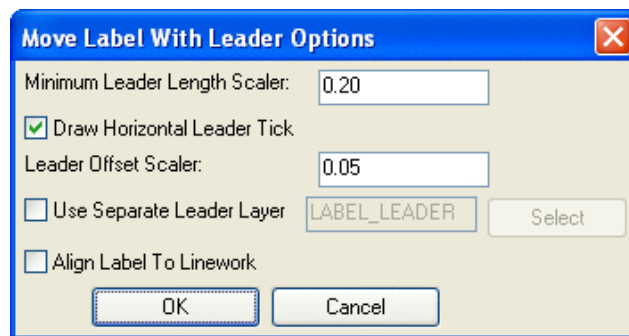

While moving the label, the user is shown where the leader and label will be drawn

After Move is Completed

Select Label to Move (O for Options,R for Restore): O

When Options is chosen the "Move Label With Leader Options" dialog allows the user to customize the leader and label drawing settings:

- Minimum Leader Length Scaler:** If the distance of the move is less than this value, a leader will not be drawn.
 - Draw Horizontal Leader Tick:** When checked, a horizontal leader tick will be drawn from the end of the leader towards the annotation.
 - Leader Offset Scaler:** This is used to set the distance from the end of the leader and the annotation.
 - Use Separate Leader Layer:** This allows the user to place the leader on a separate layer from the annotation.
 - Align Label to Linework:** When selected the orientation of the label will be parallel to the linework. Otherwise the label is orientated horizontally.
- NOTE: The leader scaler units (Minimum Leader Length Scaler and Leader Offset Scaler) are multiplied by the current horizontal scale value, which was set in the auto annotation dialog.

Select Label to Move (O for Options,R for Restore): R

Select Label to Restore: pick an angle or distance label that had been moved with the "Move with Leader" command previously.
The selected label will be restored to its previous state.

Pulldown Menu Location: Annotate > Annotate with Leader

Keyboard Command: annlead

Prerequisite: Angle or distance label to move.

Bearing with Leader

This command places the bearing of a line or polyline segment at a point, then plots a user specified leader line to point to the defining line or polyline. There is the ability for multi-segment leaders, and the option to align the label horizontal to the current view or parallel to the linework.

Prompts

Options/Points/⟨Select line or polyline⟩: *select entity*

Pick point to start leader: *pick a point near the entity*

Label Position: *pick a point* Select the point where to place the label.

Options/Points/⟨Select line or polyline⟩: *O*

When Options (O) is chosen

Pulldown Menu Location: Annotate > Annotate with Leader

Keyboard Command: brglead

Prerequisite: None

Distance with Leader

This command labels the distance of a line or polyline segment at a point then draws a user specified leader line to point to the defining line. There is the ability for multi-segment leaders, and the option to align the label horizontal to the current view or parallel to the linework.

Prompts

Define distance by, Points/⟨Select line or polyline⟩: *select a line*

Pick point to start leader: *pick a point near the line*

Label Position: *pick a point*

Define distance by, Points/⟨select line or polyline⟩: *press Enter to end*

Pulldown Menu Location: Annotate > Annotate with Leader

Keyboard Command: distlead

Prerequisite: None

Bearing-Distance with Leader

This command places the bearing and distance labels of a line or polyline segment at a selected position and draws a leader line to the defining line or polyline.

At the command prompt, type O for Options to bring up the options dialog. There is the ability for multi-segment leaders and the option to align the label horizontal to the current view or parallel to the linework.

Prompts

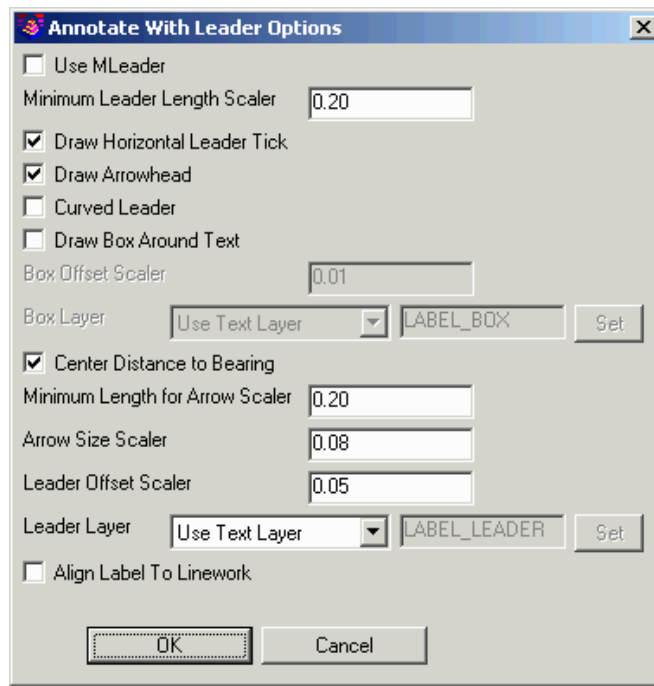

Options/Points/⟨Select line or polyline⟩: *select entity*

Pick point to start leader: *pick a point near the entity*

Label Position: *pick a point* Select the point where to place the label.

Options/Points/⟨Select line or polyline⟩: *O*

Pulldown Menu Location: Annotate > Annotate with Leader

Keyboard Command: bdlead

Prerequisite: None

Distance-Bearing with Leader

This command labels the distance and bearing of a line at the end of a user-specified leader which points to the defining line. The line can be specified by two points or by selecting a line or polyline entity. There is the ability for multi-segment leaders and the option to align the label horizontal to the current view or parallel to the linework.

Prompts

Options/Points/<Select line or polyline>: *select entity*

Pick point to start leader: *pick a point near the entity*

Label Position: *pick a point*Select the point where to place the label.

Pulldown Menu Location: Annotate > Annotate with Leader

Keyboard Command: dblead

Prerequisite: None

Azimuth-Distance with Leader

This command places the azimuth and distance label of a line or polyline at a point, and then plots a user specified leader line which points to the defining line or polyline. There is the ability for multi-segment leaders and the option to align the label horizontal to the current view or parallel to the linework.

Prompts

Options/Points/<Select line or polyline>: *pick entity*

Pick point to start leader: *pick point*
Label Position: *pick location*
Options/Points/<Select line or polyline>: *O*
Label Leader Settings dialog *make selection*

When Options (O) is chosen

Pulldown Menu Location: Annotate > Annotate with Leader
Keyboard Command: azilead
Prerequisite: None

Flip Selected Labels

This command rotates a group of text 180 degrees. Use this command to rotate any text. The command ignores all entities in the selection set except text.

Before and After Flip Labels

Pulldown Menu Location: Annotate > Flip Labels
Keyboard Command: flip_labels
Prerequisite: Text to rotate

Global Reannotate

This command updates bearing and/or azimuth labels for when the lines and polylines associated with the labels have been rotated after the bearings and/or azimuths were labeled.

Prompts

Select One Bearing/Azimuth Text Before Rotation: *pick a bearing or azimuth label*

Pick line associated with old bearing/azimuth: *pick the line or polyline for the selected label*

Select All or specific objects to reannotate (<All/Objects)? *press Enter to update all text*

Pulldown Menu Location: Annotate

Keyboard Command: globalre

Prerequisite: Bearing or azimuth labels and lines or polylines

Survey Text Defaults

This dialog box routine sets up the defaults for the Building Dimensions, Offset Dimensions and Adjoiner Text commands. The Load and Save functions allow you to store and recall the settings using a .svt settings file.

The screenshot shows the 'Survey Text Defaults' dialog box with the following settings:

- Building Dimensions:** Layer: BLDGTX, Text Style: STANDARD, Text Size Scaler: 0.080, Decimal Places: 0.0, Drop Trailing Zeros: unchecked, Use MText: unchecked, Distance in Inches: Off, Characters To Append: (empty), Offset From Line: 0.030, Auto Label Placement: None selected.
- Adjoiner Text:** Layer: ADJNTX, Text Style: Anno, Text Size Scaler: 0.100, Justification: BR, Use MText: unchecked, Label Flip Tolerance (degrees): 0.000.
- Offset Dimension Text:** Layer: DIMENTX, Text Style: STANDARD, Text Size Scaler: 0.040, Arrow Size Scaler: 0.080, Decimal Places: 0.0, Use EndPoint Snap For 1st Point: checked, Drop Trailing Zeros: unchecked, Use MText: unchecked, Distance in Inches: Off, Suppress Dim Extension Lines: unchecked, Characters To Append: (empty), Offset From Line: 0.040, Text Alignment: Horizontal selected, Position: Auto selected, Dimension Line Type: Single Arrow Line selected, Use Current Dimension Style: checked.

Building Dimensions allows you to set text specifications for building dimensions.

Layer: Allows you to set the layer for the building text.

Text Style: Allows you to set the text style for the building text.

Text Size Scaler: This value multiplied by the horizontal scale determines the actual text size.

Decimal Places: Allows you to set the display precision for the building dimensions. The AutoCAD Units option sets the decimals to match the current drawing precision (LUPREC system variable).

Drop Trailing Zeros: Allows you to truncate trailing zeros from dimensions.

Characters To Append: Allows you to set characters to add to reported dimensions.

Offset From Line: Allows you to set the offset distance from the line to the dimension text.

Auto Label Closed Plane allows you to choose between automatically labeling the Interior or Exterior or closed polylines. You may also choose none.

Offset Dimension Text allows you to set text specifications for offset dimensions.

Layer: This option allows you to set the layer for the offset text.

Text Style: This option allows you to set the text style for the offset text.

Text Size Scaler: This value multiplied by the horizontal scale determines the actual text size.

Arrow Size Scaler: This option allows you to set the arrow scaler to determine arrowhead size.

Decimal Places: This option allows you to set the precision for the offset dimensions. The AutoCAD Units option sets the decimals to match the current drawing precision (LUPREC system variable). The Annotation Defaults option uses the distance decimal settings from the Annotation Defaults command including the option to set the decimals by the distance range.

Drop Trailing Zeros: This option allows you to truncate trailing zeros from dimensions.

Distance In Inches: This option allows you to use feet and inches.

Suppress Dim Extension Lines: This option skips drawing extension lines.

Characters To Append: This option allows you to set characters to add to reported dimensions.

Offset From Line: This option allows you to set the offset distance from the line to the dimension text.

Text Alignment allows you to align text either parallel to the line or horizontally in the drawing.

Position allows you to determine if you are to pick the location of the text, or if the text is automatically positioned in the drawing.

Dimension Line Type allows you to determine the line style to use for dimensions.

Single Arrow Line: Draws a line with an arrowhead from the dimension text to the figure.

Dual Arrows Line: Draws dual arrowhead.

Standard Line: Draws a line with no arrowhead from the dimension text to the figure.

Curved Leaders: Draws a curved line with an arrowhead from the dimension text to the figure.

Dimension Only: Draws the dimension text with no line.

Use Current Dimension Style: Chooses whether to use the current dimension style set in the DIMSTYLE command or define a new dimension style using the settings in this dialog.

Adjoiner Text allows you to set text specifications for adjoiner text.

Layer: Allows you to set the layer for the adjoiner text.

Text Style: Allows you to set the text style for the adjoiner text.

Text Size Scaler: Allows you to set the text scaler to determine text size.

Justification: Allows you to set the text justification. See the AutoCAD Reference Manual for details on each justification choice.

Use MText: Chooses between creating MText and regular Text entities.

Pulldown Menu Location: Annotate > Survey Text

Keyboard Command: svtextdf

Prerequisite: None

Offset Dimensions

This command labels the perpendicular distance between a point and a line or polyline. The point can be a building corner or other object. The endpoint snap is on by default for picking this point, although you may choose another snap mode manually. There is also an option for arrow only on end of line. The text layer, size, style and the dimensioning method are set in the *Survey Text Defaults* command, found in Settings > Configure > Survey Settings.

Prompts

[end on] **Pick Bldg/Object Corner:** *pick a point*

Pick Line To Offset From: *pick a line or polyline*

Offset Dimensions showing perpendicular distances from corners to property lines

Pulldown Menu Location: Annotate > Survey Text

Keyboard Command: dimentxt

Prerequisite: Line or polyline

Building Dimensions

This command labels the length of line and polyline segments. The label is located in the middle of the line or polyline segment. The options for Building Dimensions are set in the *Survey Text Defaults* dialog. This dialog is found in Settings > Configure > Survey Settings. One option in *Survey Text Defaults* labels all the segments of a closed polyline with one pick of the polyline. Otherwise, the procedure is to pick a line or polyline segment and then choose an alignment. Depending where the alignment point is picked, the label is drawn either perpendicular or parallel, above or below the line.

Prompts

Pick Line or Polyline: *pick line or polyline segment to label*

Pick Alignment: *pick point as shown*

Pulldown Menu Location: Annotate > Survey Text

Keyboard Command: bldgtext

Prerequisite: Line or polyline

Adjoiner Text

This command draws text that is aligned with the selected line or polyline segment. The layer, style, size and justification for the text is set in the *Survey Text Defaults* command, found in Settings > Configure > Survey Settings. To align text that is already drawn, use the *Rotate Text* command found in the Edit menu.

Prompts

Pick Line or Polyline: *pick a line or polyline for alignment*

Starting point: *pick a point to start the text*

Text: *MAIN STREET*

Adjoiner Text aligns text with a line or polyline

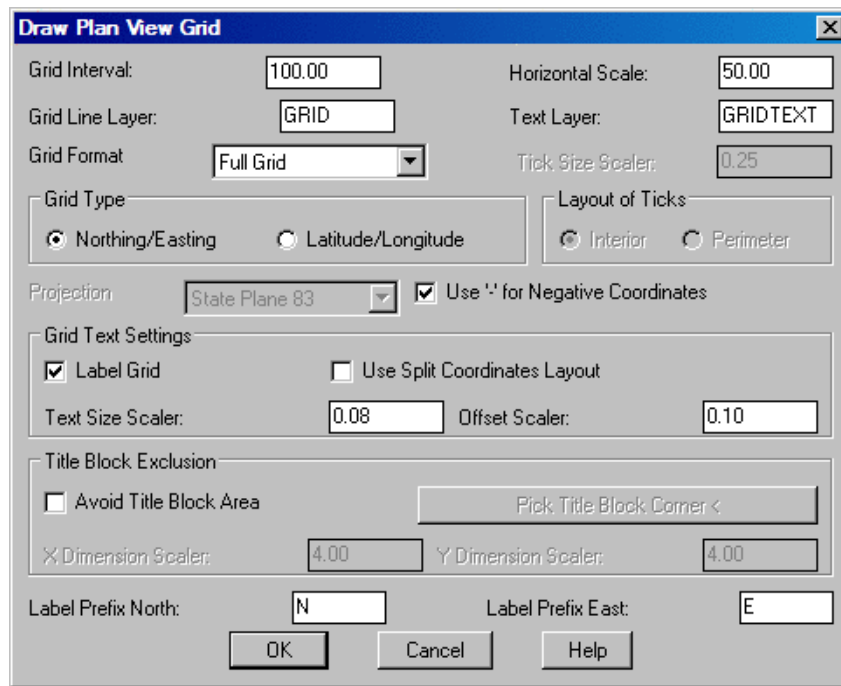

Pulldown Menu Location: Annotate > Survey Text

Keyboard Command: adjntext

Prerequisite: Line or polyline

Draw Grid

This command will plot a plan view grid at a user specified distance and optionally label the northing and easting coordinates of the grid. This command takes in consideration the current screen twist angle in which case it prompts for three corner points. After selecting the corner points the dialog below will appear. The title block is assumed right justified to the lower right corner of the grid definition points. After changing any of the settings select the *OK* button to plot the grid.

Grid Interval: The distance between each grid line.

Horizontal Scale: Reports the scale of the current drawing. This can also be set using the Drawing Setup command in the Settings menu.

Grid Format: The Ticks Only option will draw tick marks instead of grid lines. Selecting the Ticks Only option activates the Tick Size option for sizing the tick marks. There is also a Full Grid and Perimeter option.

Layout of Ticks: This option places the ticks throughout the interior of the grid work or just on the perimeter of the grid boundary.

Use '-' for Negative Coordinates: This option labels the negative grid coordinates with a '-'.

Label Grid: Selecting this Grid Text Setting option labels the grid coordinates.

Use Split Coordinates Layout: Puts the thousands digits above the grid line and the hundreds digits below the grid line

Text Size Scaler: This scaler, multiplied by the Horizontal Scale, determines text size.

Offset Scaler: This scaler, multiplied by the Horizontal Scale, determines the offset for text.

Avoid Title Block Area: This Title Block Exclusion option will allow you to not draw grid lines or tick marks in the title block area. It is for making sure that the grid does not overwrite the title block.

Pick Title Block Corner: This option prompts you to pick the corner of the title block to determine where the grid lines and ticks will be omitted.

X Dimension Scaler: This is the horizontal dimension of the title block. This option is automatically filled in when the Pick Title Block Corner option is selected.

Y Dimension Scaler: This is the vertical dimension of the title block. This option is automatically filled in when the Pick Title Block Corner option is selected.

Label Prefix North: This option is for assigning a prefix to the northing grid line and tick mark coordinates.

Label Prefix East: This option is for assigning a prefix to the easting grid line and tick mark coordinates.

Prompts

Pick or Type Lower Left Corner Point: *endp of (pick point)*

Pick or Type Upper Right Corner Point: *endp of (pick point)* Select the corners of your border in which you want the grid plotted.

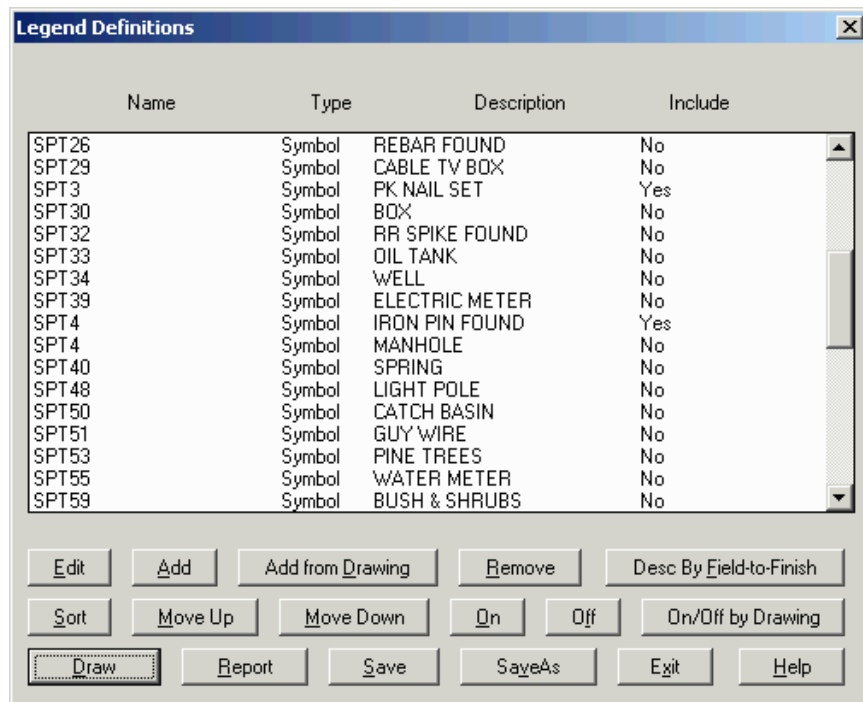

Draw Plan View Grid Dialog

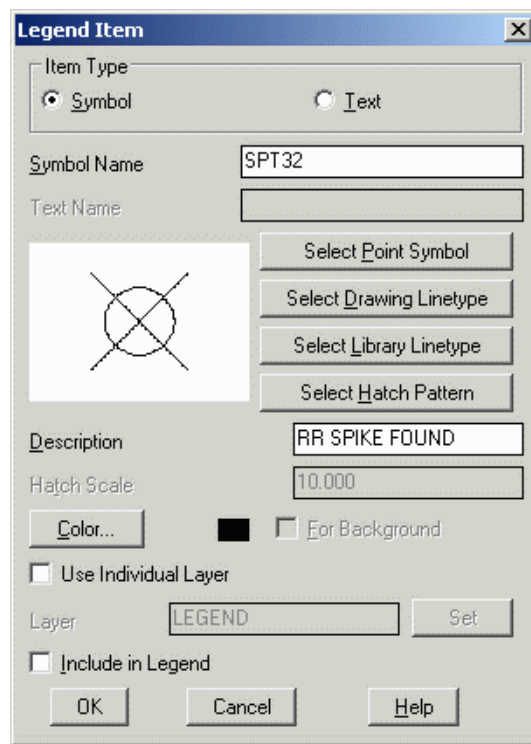

Pulldown Menu Location: Annotate
Keyboard Command: dgrid
Prerequisite: None

Draw Legend

This command draws a legend based on a legend definition file. After choosing the legend definition (.LGD) file to use, a dialog displays the current definitions. The legend definition file consists of descriptions assigned to text, symbols, linetypes and hatch patterns. The default legend that is included with Carlson is called legend.lgd.

Edit edits a definition, select it and then click on the Edit button. This brings up the Symbol Definition dialog box.

- **Item Type:** Each item can be either a simple text label or a symbol from the drawing.
- **Text Name:** This is the legend label associated with the specified Description.
- **Symbol Name** designates the symbol to draw in the legend. You can either type in the symbol name or choose it from a slide library by picking the appropriate Select button.
- **Description** is the name of the symbol.
- **2nd Description** is an optional additional name for the symbol
- The **Hatch Scale and Color** options are used if the symbol uses a hatch pattern.
- **Include in Legend:** This option corresponds to the Include column on the Legend Definitions dialog box. Not all the defined entries need to be drawn. An entry will be drawn (shown as Yes) if the Include in Legend box in the Symbol Definition dialog box is checked.
- **Use Individual Layer:** This option allows for drawing the legend item on a separate layer besides the layer from the Draw function.
- **Select Point Symbol:** This option displays a slide library of point symbols to choose from.
- **Select Drawing Linetype:** This option displays a linetype name list to choose from.
- **Select Library Linetype:** This option displays a slide library of linetypes to choose from.
- **Select Hatch Pattern:** This option displays a slide library of hatch patterns to choose from.

Add inserts a new definition to the definitions. To insert a new definition, pick an existing definition and click on the Add button. The new definition is added immediately following the existing definition.

Add from Drawing adds entries to the legend table for each different symbol that is selected from the drawing.

Remove removes the selected definition.

On switches the Include field in the selected definition to Yes.

Off switches the Include field in the selected definition to No.

On/Off by Drawing prompts you to select symbols from the drawing. Symbols found will be turned on, all others will be turned off. This helps you create a legend that includes only symbols found in the drawing.

Description by Field-to-Finish uses the description from the Field-to-Finish code definition for symbols that match

the code symbol.

Sort sorts the definitions alphabetically and numerically.

Draw draws the included definitions as a legend.

Report uses the Report Formatter to make a customized report of the names and descriptions in the legend.

Move Up: This option moves the selected definition up one row. Legend entries are drawn in the order that they are defined.

Move Down moves the selected definition down one row. Use the Move Up and Move Down buttons to change the order that the symbols will be drawn.

Save saves the legend file as its original file name.

Save As saves the legend file to a new file name.

Exit exits the command back to the drawing window.

Draw opens the Draw Legend dialog.

Draw Legend dialog box showing settings for text size, symbol size, hatch size, line size, layer name, style name, and checkboxes for drawing options like 'Draw 2nd Description', 'Draw Legend Title', 'Draw Header', and 'Draw Grid Lines'. The layout is set to 'Right Justified'.

- **Text Size** sizes the text in the legend. It defaults to the value from Drawing Setup in the Setting menu.
- **Symbol Size** defaults to the value from Drawing Setup in the Settings menu.
- **Hatch Size** sizes the hatch pattern scaler.
- **Line Size** sizes the lines in the legend.
- **Layer Name** defines the layer for the legend.
- **Style Name** sets the style for the legend labels.
- **Draw 2nd Description** creates another column with the 2nd descriptions for the symbols.

- **Draw Legend Title** draws the text from the Name, Title Line 1 and 2 fields.
- **Draw Header** adds a header row with the Symbol, Desc and 2nd Desc fields at the top of the columns.
- **Draw Grid Lines** creates a legend table with lines for the rows and columns

- **Layout Left Justified** has the symbol on the left and then the labels left-justified.
- **Layout Right Justified** has the symbols on the left and the labels right-justified.

- **Layout Right Symbol** has the labels on the left and the symbols on the right.

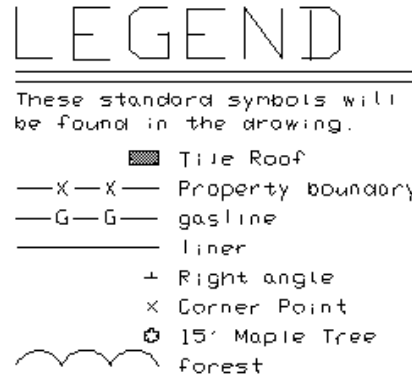

Prompts

Specify Legend Definition File Dialog *choose the file to process*

Legend Definitions Dialog

Draw Legend Dialog

Enter or pick upper left point for legend: *pick a point*

Sample legend created by Draw Legend

Pulldown Menu Location: Annotate

Keyboard Command: legend

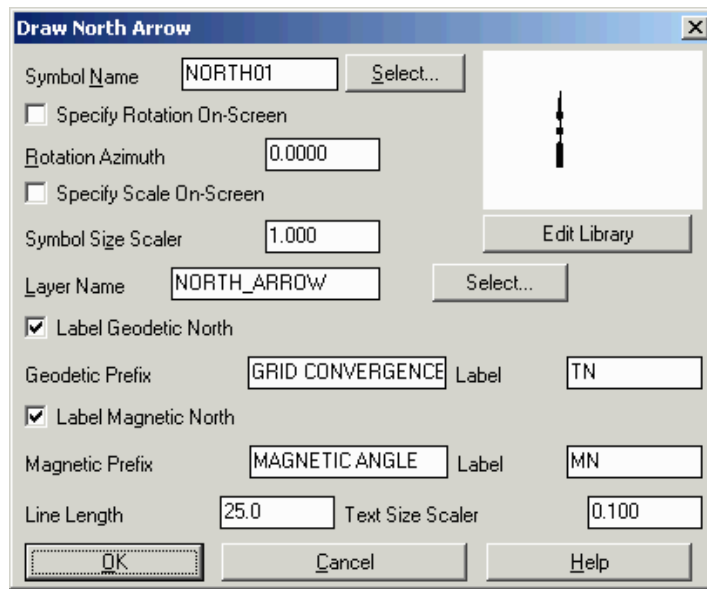

Prerequisite: None

Draw North Arrow

This command inserts a north arrow symbol. You can select from several styles of arrows, and you can add your own by using the Edit Library button which is similar to the Symbols Library command. The north arrow symbol library is stored in the narrow.dta file in the USER folder.

The Label Geodetic North option draws a line for geodetic north and labels the convergence angle between grid and geodetic north.

The Label Magnetic North option draws a line for magnetic north and labels the angle.

Prompts

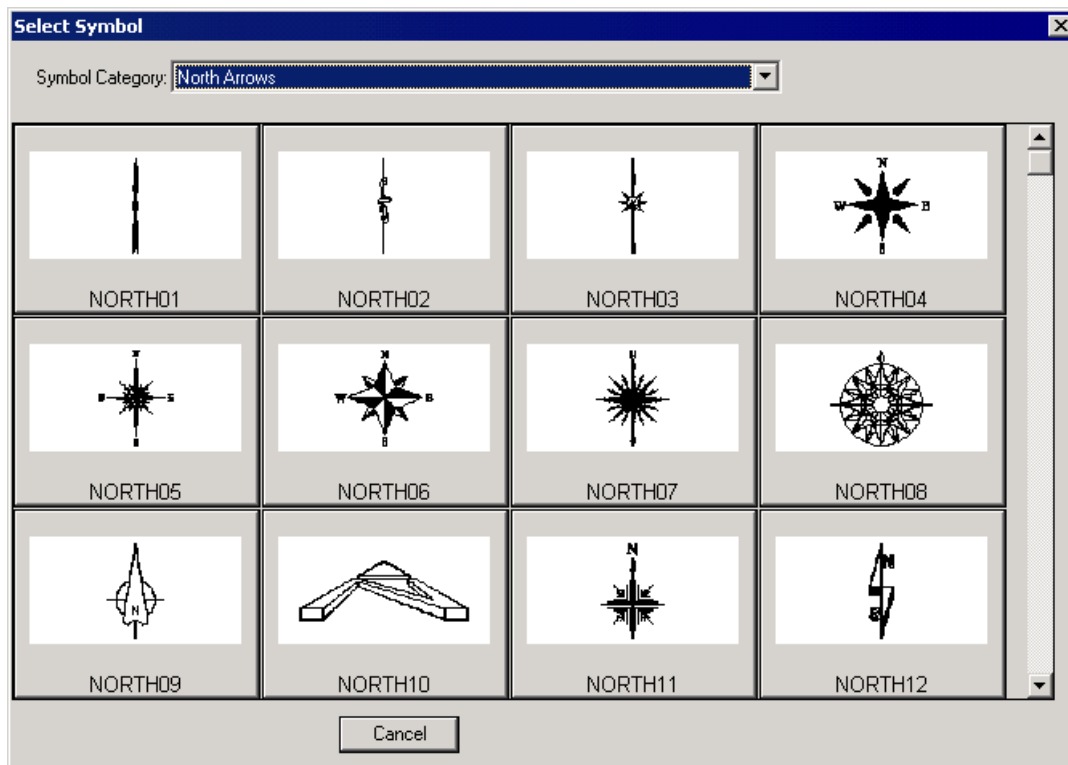

Draw North Arrow Dialog *choose an arrow symbol, layer and other variables*

Specify insertion point: *pick a point*

X scale factor <1> / Corner / XYZ: *press Enter*

Y scale factor (default=X): *press Enter*

Rotation angle <0d0'0">: *press Enter*

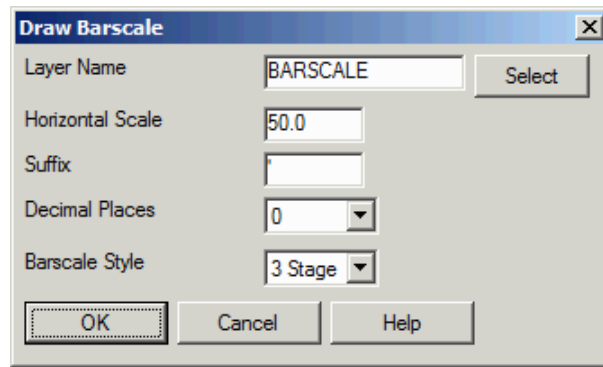

Pulldown Menu Location: Annotate

Keyboard Command: narrow

Prerequisite: None

Draw Barscale

This command draws a barscale at the user-specified scale. The command options are set in the dialog shown here. The Horizontal Scale controls the size and labels for the barscale. For example, enter 50 for 1 inch = 50 feet in English mode. The Barscale Style chooses between different barscale formats.

Prompts

Keyboard Command: barscale

Prerequisite: None

Distance Table

This command creates a distance table for all the combinations of distances between the Reference Points and Tie Points. The points are defined in the dialog by filling out the spreadsheets. Use the Add From List to select a point from the current coordinate file. Use Screen Pick to pick a position from the drawing. The Create Table function draws the table. Use the Report to use the Report Formatter to make a custom report.

AS-BUILT TIES		IP 1	IP 2
Point	Description	4	20
23	BLDG NW	196.28	89.28
24	BLDG SW	189.22	117.03

Keyboard Command: distable

Prerequisite: None

Create Point Table

This command draws a table of the coordinate data of the points from the current coordinate (.CRD) file using different methods displayed at the top of the dialog. The command displays the dialog shown below for setting all of the point table options. At the top of the dialog enter the range of point numbers to label, do a Screen Pick or select a Point Group(s). You can also specify the order and format of the table columns. If you do

not want to include a data type, set the Sequence number to blank. The Northing/Easting Format can be set to Degree/Minutes/Seconds for when the coordinate file contains latitude and longitude. The Max Rows Per Column setting makes the program start a new table when the specified max points is reached. The Use Table Entity option create a Carlson Table entity which has more formatting options and can be adjusted with the Edit > Table functions.

Typical Point Table

Pulldown Menu Location: Annotate > Point Table

Keyboard Command: pointtbl

Prerequisite: A coordinate (.CRD) file

Update Point Table

This command prompts you to select an existing point table. The program then reads the settings from this table and displays these settings in the same dialog used in *Create Point Table*. You can change any of the table format options. The program will also update the table to reflect any changes to the coordinate (.CRD) file.

Prompts

Select existing point table: *pick anywhere on the point table or select points from the screen*

Point Table Generator Dialog

Pulldown Menu Location: Annotate > Point Table

Keyboard Command: pointtblupd

Prerequisite: An existing point table, .CRD file

Point To Point Table

This command creates a course table of the angle and distance between pairs of points. The table data is entered in a spreadsheet. Fill in the From and To point numbers. The program reads the coordinates for the points from the current coordinate file and fills out the Angle and Distance. There are settings for the Angle Format as either Bearing or Azimuth, Decimals and Suffix for the distance, and Header labels for the table.

The Add From List button selects points from the current coordinate file. The Screen Pick button prompts to pick the points from the drawing.

Once the data is entered, use either the Create Table or Report buttons. The Create Table function draws the table in the drawing. The Report function uses the Report Formatter to create a user-specified report.

	From Point	To Point	Angle	Distance
1	17	20	S 50°38'52" W	180.225
2	19	21	S 42°15'18" W	100.559
3	48	49	N 42°10'20" W	57.474
4	102	106	S 35°03'37" E	205.985

Keyboard Command: p2ptable

Prerequisite: Points in current coordinate file

Table Defaults

This command sets the format for line and curve tables. Line and curve tables are commonly used in situations where:

1. The amount of line/curve annotation in the drawing itself makes the drawing look too "cluttered," and/or
2. The length(s) of the line(s)/curve(s) are too short for the annotation label being placed

You specify the label and table attributes in the Line/Curve Table Defaults dialog:

Combine Line and Curve Tables: This option makes a single table with both line and curve data. When this option is active, the curve settings govern and the line settings aren't used. For line segments, the chord length and chord bearing fields are used for the line length and bearing. Typically the chord length and chord bearing would be set to Sequence numbers 1 and 2. Also, under Curve Table Labels you can set the headers for curve number to "ID", chord length to "Length" and chord bearing to "Bearing" to make the headers apply for both lines and curves.

ID	LENGTH	BEARING	RADIUS	ARC LENGTH	DELTA ANGLE
C1	163.32'	N 66°32'02" E			
C2	142.12'	S 78°41'24" E	124.59'	151.24'	69°33'07"
C3	209.36'	N 77°30'20" W	189.20'	221.85'	67°11'00"
C4	120.27'	N 51°07'27" E			

Label Text Layer: Click the Set button or specify the layer of the annotation which is applied to the line/curve itself.

Label Text Style: Click the Set button or specify the text style of the annotation which is applied to the line/curve itself.

Label Text Size: Specify the text size of the annotation which is applied to the line/curve itself.

Line Label Prefix: Specify a prefix which should be inserted prior to each line number. The prefix can be an alpha-numeric string.

Line Table Title: Specify a caption for the line table.

Table Text Layer: Click the Set button or specify the layer of the annotation which is inserted to the line/curve table.

Table Text Style: Click the Set button or specify the text style of the annotation which is inserted to the line/curve table.

Table Text Size: Specify the text size of the annotation which is inserted to the line/curve table.

Row Height Factor: Indicate a positive, non-zero multiplier of the Table Text Size to help adjust spacing for each row in the table.

Curve Label Prefix: Specify a prefix which should be inserted prior to each curve number. The prefix can be an alpha-numeric string.

Curve Table Title: Specify a caption for the curve table.

Set Line Table Labels: See the expanded Set Line Table Labels section below.

Set Curve Table Labels: See the expanded Set Curve Table Labels section below.

Draw Text Only: Creates a table as MText without drawing grid lines.

Prompt for Label Location: When enabled, this option prompts you to pick the location for the label placed onto the line/curve itself. If this is disabled, the location is chosen automatically.

Label Symbol: Select a geometric shape that is placed around the label that is applied to the line/curve itself.

Distance Format: Indicate how distances for the lines are reported:

- **Horizontal:** The distance displayed is only the horizontal distance, even if the selected entity has different "Z" values at either end of the line.
- **Slope:** The distance measured is the slope distance, used mostly for 3D polylines to get their true length.
- **None:** For a table of angles only.

Total Distances: Adds a row at the bottom of the line table to label the total distance for the table.

Label Angles in: Indicate how the line direction is labeled:

- **Azimuth:** The angles are reported as azimuths.
- **Bearings:** The angles are reported as bearings.
- **Gons:** The angles are reported as gons.
- **None:** For a table of distances only.

Automatic Table Update: Indicate if labels in the table should be re-sequenced:

- **On:** This option renumbers the other table entries and the associated labels in the drawing if a new (but previously used number) is specified for the table. For example, if a line table contained lines #1-5 and a line

#4 was added, the new line #4 would be inserted into the table and the previous lines #4 and #5 would be updated to #5 and #6. The L4 and L5 labels on the lines would also be updated to L5 and L6.

- **Off:** You must manually pick the entry location and update the labels.

Label Alignment: Indicate the method by which the label is oriented on the line/curve itself:

- **Horizontal:** This option places the label horizontal to the current screen alignment, as defined by the various *Twist Screen* commands (Standard, Line, Polyline or Text, Surveyor or Restore Due North).
- **Parallel:** This option will orient the label parallel to the line or curve chord.

Use Table Entity: When enabled, Line and Curve Tables can be further manipulated with the Split Table, Merge Tables and Edit Table Values commands. The **Row Height Factor** controls the height of the table rows.

Combine Equal Rows: When enabled, lines or curves that share identical geometry with other lines and curves can assume the number of the equivalent line/curve. As an example, if a line *100 feet* long on a bearing of *N 90d00'00" E* is assigned a label of *L3* and additional lines with this geometry are labeled, you will have the option of re-using the *L3* label for these additional lines. In other words, a single label reference in the table can correlate to many identical entities in the drawing and can keep the overall length of the line/curve table to a minimum.

Append First Table Item To Line/Curve Label: When enabled, an additional reference item from the Line/Curve Table will be placed alongside the label number assigned to the line/curve itself.

Curve Options: Indicate the order in which curve labels shall be inserted into the curve table. Entries left blank (empty) will not be listed in the curve table.

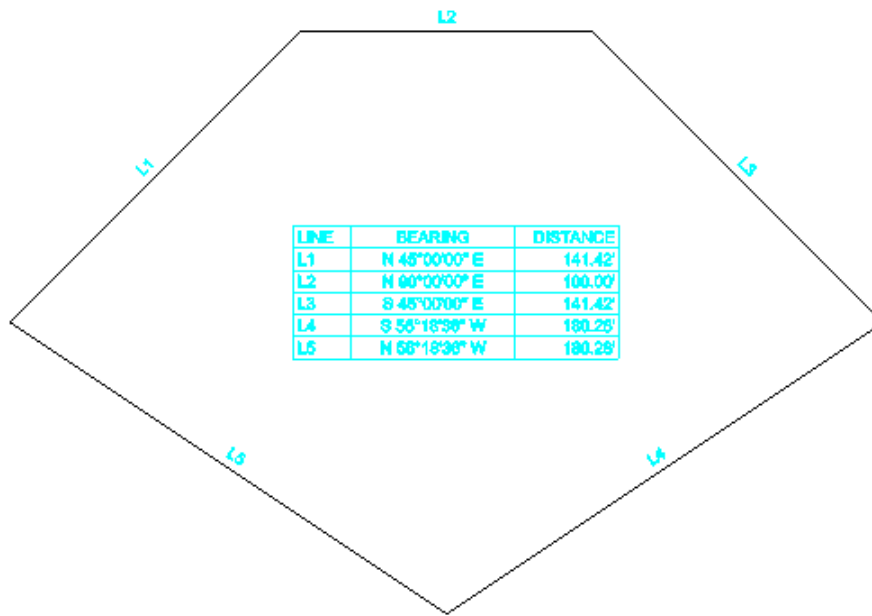

Load: Loads a previously saved collection of Line/Curve Table Default values (*.LCT) into memory.

Save: Saves the current Line/Curve Table Default values to a *.LCT file.

Selecting the **Set Line Table Labels** option allows you to control the label, column width, text justification and displayed precision for the options selected in the Line Table Distance and Label Angles In controls.

Field	Label	Scaled Label	Width	Justification	Precision
Line Number	LINE		6.250	LEFT	
Bearing	BEARING		14.000	LEFT	
Azimuth	AZIMUTH		14.000	LEFT	
GDN	GONS		14.000	LEFT	0.00
Horiz Distance	DISTANCE	DISTANCE2	11.500	RIGHT	
Slope Distance	SLOPE DIST	SLOPE DIST2	11.500	RIGHT	0.00

With the above settings, you might find the Line Table more aesthetically pleasing as it produces the following example:

The prefix flexibility and the fact that the text used for the column header can be changed, means that line and curve tables can be plotted in any language. For example, in Puerto Rico survey plats are typically submitted in bearings, in meters and in Spanish. For that location, the table could be reconfigured as shown here:

Field	Label	Scaled Label	Width	Justification	Precision
Line Number	LINEA		6.250	LEFT	
Bearing	RUMBO		14.000	LEFT	
Azimuth	AZIMUTH		14.000	LEFT	
GON	GONS		14.000	LEFT	0.00
Horiz Distance	DISTANCIA	DISTANCE2	11.500	RIGHT	
Slope Distance	SLOPE DIST	SLOPE DIST2	11.500	RIGHT	0.00

Buttons: OK, Cancel, Help

This would lead to the following line table (see the Notes section below for additional information):

Essentially identical to the *Set Line Table Labels* command, the **Set Curve Table Labels** command allows you to control the label, column width, text justification and displayed precision for the options selected in the Curve Options control.

Field	Label	Scaled Label	Width	Justification	Precision
Curve Number	CURVE		8.000	LEFT	
Radius	RADIUS	RADIUS2	9.000	LEFT	0.00
Arc Length	ARC LENGTH	ARC LENGTH2	14.000	LEFT	0.00
Chord Length	CHORD LENGTH	CHORD LENGTH2	14.000	LEFT	0.00
Chord Bearing	CHORD BEARING		15.000	LEFT	
Chord Azimuth	CHORD AZIMUTH		15.000	LEFT	
Chord GONS	CHORD GONS		15.000	LEFT	
Delta Angle	DELTA.ANGLE	TANGENT2	13.000	LEFT	0.00
Tangent	TANGENT		10.000	LEFT	
Degree Of Curve	DEGREE OF CURVE		17.000	LEFT	
Radial Bearing-in	RADIAL BEARING-IN		19.000	LEFT	
Radial Bearing-out	RADIAL BEARING-OUT		19.000	LEFT	

Note:

- Changing the distance suffix to "m" (or omitting any suffix by making it blank) is accomplished in the more general command of Annotate Defaults.
- Reporting distance units in a unit of measure different from that of the current project is accomplished via the Drawing Setup > Report Distance Scale Factor option and the Annotate Defaults command.
- Physical changes to the lines/curves will trigger label updates if the **Link Labels with Linework** option (if available) is enabled under Carlson Configure > General Settings.

Pulldown Menu Location(s): Annotate > Line/Curve Table

Keyboard Command: tdef

Prerequisite: None

Table Header

This command draws the column header labels for the *Curve Table* and *Line Table* commands. When prompted for the starting point, the user may enter a coordinate or pick a point on the screen. The starting point location that the curve or line table command defaults to is one row below the start of the header labels.

CURVE	RADIUS	ARC LENGTH	CHORD LENGTH	CHORD AZIMUTH	DELTA ANGLE
-------	--------	------------	--------------	---------------	-------------

Curve table header (C option)

Prompts

Type of table [Line/<Curve>]? C

Starting point of Curve table text <(6585.0 -704.0 0.0)>: pick point

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: tabhead

Prerequisite: None

Set Table Position

This command sets the position for adding line table entries. The next line table rows will start from this point. To add to an existing table, pick a point at the lower left of the existing table.

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: set.tbl

Prerequisite: None

Curve Table

This command will compute curve data and draw it in tabular form using the settings specified in *Table Defaults*. The program computes the curve data from an arc entity, an arc segment of a polyline or from specified points on an arc. The curve data includes radius, length of curve, chord length, chord bearing, tangent and delta or included angle. The current curve table numbers are remembered between drawings. The user is prompted for curve number (default is sequential starting with 1) and the starting point of the table. The curve is labeled with a C#, where # is the sequential curve number. After picking the starting point of the table, the placement point for the other table entries will default to the next position and you can just press Enter unless you want to relocate the table. The Auto Annotate command can also create curve tables. Use the *Table Header* command to draw the column header of the curve data names.

Prompts

Define arc by, Points/<Select arc or polyline>: *pick an arc*

Enter curve number <1>: *press Enter*

Starting point of curve table text <(5000,5000)>: *pick a point in a clear area of the drawing*

Define arc by, Points/<Select arc or polyline>: *pick another arc*

Enter curve number <2>: *press Enter*

Starting point of curve table text <(4030,4490)>: *press Enter to use next position*

Define arc by, Points/<Select arc or polyline>: *press Enter to end*

CURVE	RADIUS	ARC LENGTH	CHORD LENGTH	CHORD BEARING	DELTA ANGLE	TANGENT
C1	89.44'	60.73'	59.57'	S 70°32'53" W	38°54'14"	31.59'
C2	107.82'	76.59'	74.99'	N 71°26'44" E	40°41'57"	39.99'
C3	110.31'	94.29'	91.45'	S 63°43'00" E	48°58'35"	50.24'

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: arctabl

Prerequisite: None

Line Table

This command will compute line data and draw it in tabular form, using the settings specified in *Table Defaults*. The program computes the bearing and distance from a line, polyline segment or between points. The current line table numbers are remembered between drawings. The line is labeled with a L#, where # is the sequential number of the line picked. The bearing and distance will then be drawn in tabular form similar to the previous Curve Table

command. The Auto Annotate command can also create line tables. Use the Table Header command to draw the column header of the line data names.

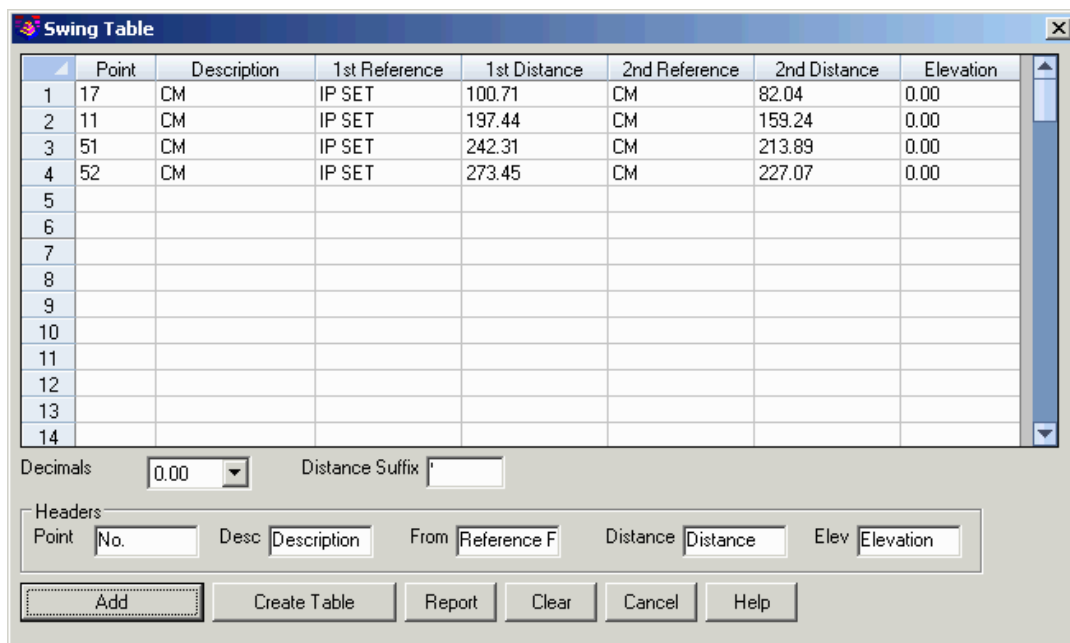

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: linetabl

Prerequisite: None

Swing Table

This command creates a swing table. From two reference points, the table reports the two distances to target points. Use the Add function to fill in the spreadsheet. The Add function prompts for two reference points and then the target points. You can also edit the spreadsheet directly. When the data is ready, use the Create Table function to draw the table. Use the Report to use the Report Formatter to make a custom report.

No.	Description	Reference From	Distance	Reference From	Distance	Elevation
17	CM	IP SET	100.71	CM	82.04	0.00

Prerequisite: None

Railroad Curve Table

This command is exactly like Curve Table, except the curve data is calculated for Railroad curves. See the Curve Table command for more details.

Pulldown Menu Location: Annotate > Line/Curve Table

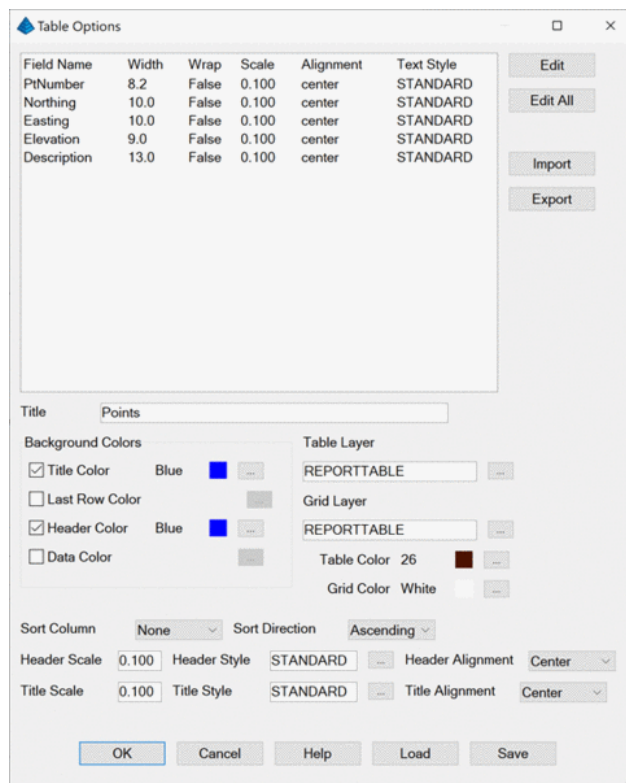

Keyboard Command: rr_curvetbl

Prerequisite: None

Edit Table Properties

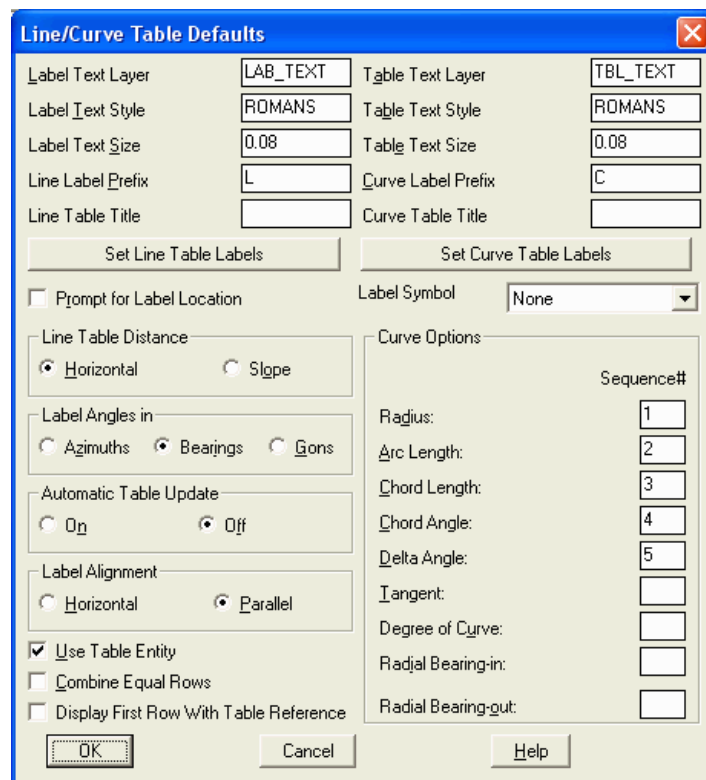

This command allows you to edit the properties of an entity based table.

For general tables, the Edit Table Options dialog is shown. In the dialog, you can change the header labels, width, word wrap, size, alignment and style. The text size is set by the Scale multiplied by the Horizontal Scale from Drawing Setup. The Wrap option automatically makes multi-line rows for long text strings. There are settings for the table colors, title and layer.

For line and curve tables, the Line/Curve Table Defaults dialog will be displayed. Here you can change the settings of the selected table. Change the settings for either line or curve tables depending upon the type of table selected. The changes will be reflected once the user selects the OK button.

Text Layer and Text Style determine the layer and style of the line/curve table text. The distance for line tables can be labeled in horizontal or slope distance. The Automatic Table Update option will automatically insert the entry into the line or curve table. The auto update will renumber the other table entries and the associated labels in the drawing. For example, if a line table had lines #1-5 and a line #4 was added, then the new line #4 would be inserted into the table and the previous lines #4 and #5 would be updated to #5 and #6. The L4 and L5 labels on the lines would also be updated to L5 and L6. Without the automatic update option, the entry location must be picked and the labels updated manually. The Label Alignment determines the orientation of the L# or C# that is labeled on the line or curve. Horizontal will make the label horizontal to the current twist screen and Parallel will draw the label parallel with the line or curve chord. The Line and Curve Label Prefix sets the text before the number that is drawn in the table and on the line or curve (i.e. "L3" or "Line3"). The Curve Options specifies which curve data to include in the table and the order. You specify the label and table attributes in the Line/Curve Table Defaults dialog.

Label Text Layer: determines the layer of the line/curve text.

Label Text Style: determines the style of the line/curve text.

Label Text Size: determines the size of the line/curve text.

Line Label Prefix: determines the prefix for each line.

Line Table Title: draws a title row at the top of the line table with this string.

Table Text Layer: determines the layer of the line/curve table text.

Table Text Style: determines the style of the line/curve table text.

Table Text Size: determines the size of the line/curve table text.

Curve Label Prefix: determines the prefix for each curve.

Curve Table Title: draws a title row at the top of the curve table with this string.

Prompt for Label Location: prompts you to pick the location to label each line or curve. If this is not selected, the location is chosen automatically.

Under **Line Table Distance**, the method for measuring distance is specified.

Horizontal: The distance measured is only horizontal, even if the line is a 3D polyline.

Slope: The distance measured is the slope distance, used mostly for 3D polylines to get their true length.

Under **Label Angles in**, the type of angle is selected.

Azimuths: The angles are reported as azimuth.

Bearings: The angles are reported as bearings.

Gons: The angles are reported as gons.

Under **Automatic Table Update**, the option automatically inserts the entry into the line or curve table. The auto update rennumbers the other table entries and the associated labels in the drawing. For example, if a line table contained lines #1-5 and a line #4 was added, then the new line #4 would be inserted into the table, and the previous lines #4 and #5 would be updated to #5 and #6. The L4 and L5 labels on the lines would also be updated to L5 and L6. If you set the Automatic Table Update to Off, you must manually pick the entry location and update the labels. If Automatic Table Update is set to On, the table is updated automatically whenever the line is modified.

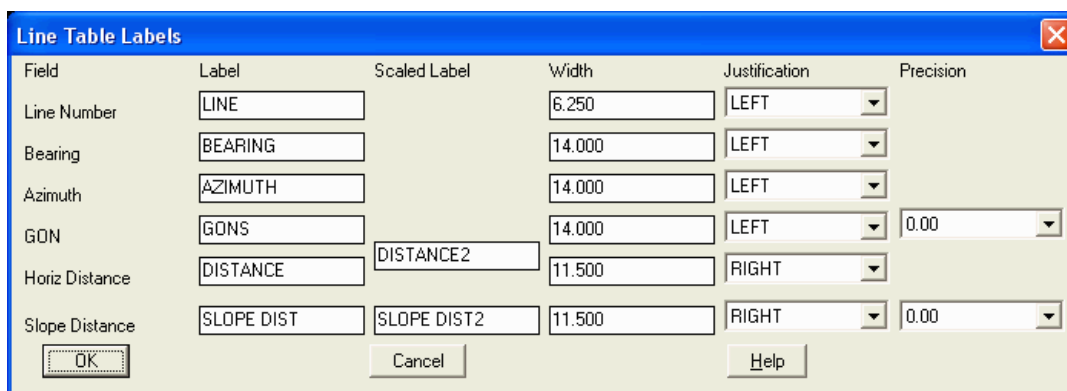

Label Alignment determines the orientation of the L# or C# that is labeled on the line or curve. Horizontal will make the label horizontal to the current screen alignment, Parallel will draw the label parallel to the line or curve chord. Under Curve Options, you specify which curve data to include in the table and the order.

Use Table Entity: will use single block for the whole table. Otherwise, each row is a separate block.

Combine Equal Rows: will use the same line or curve number when the data exactly matches an existing row in the table. For example, if two line segments have the same bearing and distance, then they would both get the same line# (ie. "L5").

Display First Row With Table Reference: When there is room on the line or arc, this option will label both the number and the first column data value from the table on the line or arc. For example, if the first curve table column is for radius and the arc length is big enough to fit the label, then the program would label both the curve # and the radius (ie. "C5 R=100.0").

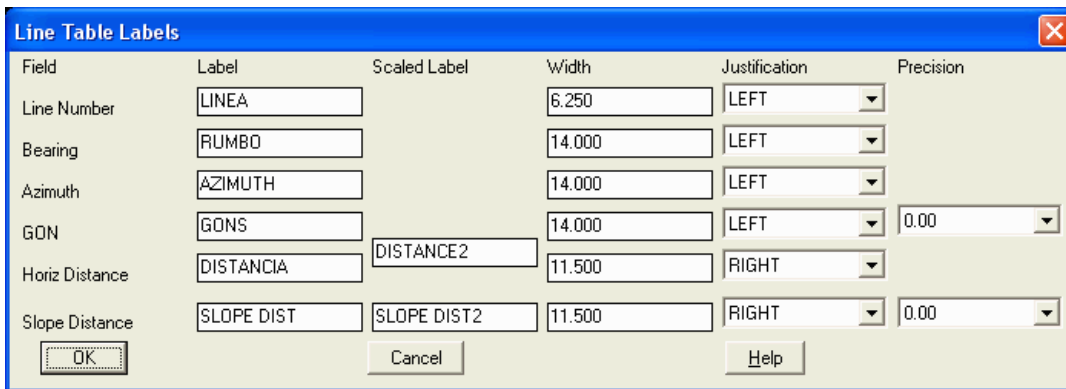

Selecting "Set Line Table Labels" will lead you to the Line Table controls, as "Set Curve Table Labels" (see graphic at end of this command page) leads to the Curve Table controls. For fields that apply to the Report Scale Factor from Drawing Setup, there is a second Scaled Label name for the table header. This scale factor can be used for reporting both grid and ground or both english and metric distances. The options in "Set Line Table Labels" are shown below:

With the above settings, for example, the Line Table appears as shown below. For improved "aesthetics", you might prefer to change the Bearing justification to "Center", for example.

LINE	BEARING	DISTANCE
L1	S 58°18'48" W	87.33'
L2	S 75°06'27" E	148.57'
L3	N 88°27'07" E	63.44'
L4	N 58°40'01" W	63.44'

To save space, you can reduce the size of the "Distance" column from 11.5 to 10. Note that using the Line Label Prefix option, L1 and L2, for example, can read Line1 and Line2, and for that, you may want to expand the "Width" setting for the Line column. The prefix flexibility, and the fact that the text used for the column header can be changed, means that line tables and curve tables can be plotted in any language. In Puerto Rico, for example, surveys are typically conducted in bearings, in meters and in Spanish. For that location, the table could be reconfigured as shown here:

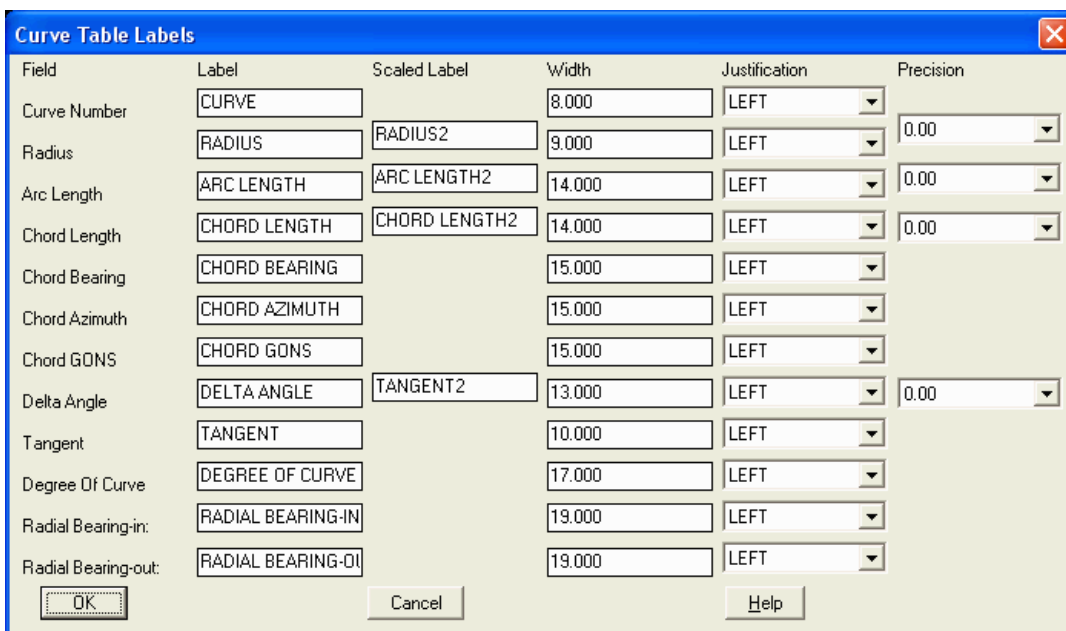

This would lead to the following line table:

LINEA	RUMBO	DISTANCIA
L1	S 58°18'48" W	87.33m
L2	N 88°27'07" E	63.44m
L3	N 58°40'01" W	63.44m

Note that changing the distance suffix to "m" (or omitting any suffix by making it blank) is accomplished in the more general command Annotation Defaults.

Finally, below we see the dialog that appears when you choose Set Curve Table Labels.

Prompts

Select a line or curve table to modify: *pick an entity based line or curve table.*

Pulldown Menu Location: Annotate > Line/Curve Table, and Edit > Table

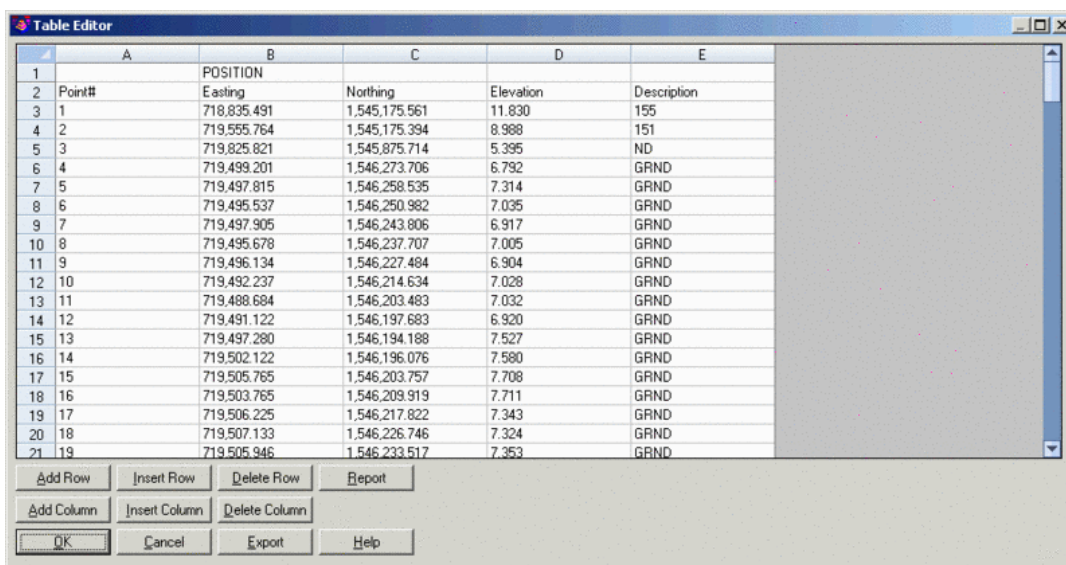

Keyboard Command: tabedit

Prerequisite: An entity based line or curve table.

Edit Table Values

The **Edit Table Values** permits the modification of any of the text labels found within a Carlson table entity. A Carlson table can be created using the Report Formatter, the Draw > Table command, or by Line or Curve table created with the Use Table Entity option enabled under Line/Curve Table Defaults.

To sort the table, you can pick on the header in the spreadsheet for the column to sort by.

	A	B	C	D	E
1		POSITION

15	13	719,497.280	1,546,194.188	7.527	GRND
16	14	719,502.122	1,546,196.076	7.580	GRND
17	15	719,505.765	1,546,203.757	7.708	GRND
18	16	719,503.765	1,546,209.919	7.711	GRND
19	17	719,506.225	1,546,217.822	7.343	GRND
20	18	719,507.133	1,546,226.746	7.324	GRND
21	19	719,505.946	1,546,233.517	7.353	GRND

Add Row: Adds a blank line to the end of the spreadsheet control.

Insert Row: Inserts a blank line immediately preceding the currently selected line in the spreadsheet control.

Delete Row: Removes the currently selected line from the spreadsheet control.

Add Column: Adds a blank column to the end of the spreadsheet control.

Insert Column: Inserts a blank column immediately preceding the currently selected column in the spreadsheet control.

Delete Column: Removes the currently selected column from the spreadsheet control.

Report: Sends the current content of the spreadsheet control to the Standard Report Viewer.

Export: Exports the current content of the spreadsheet control to an XLS file compatible with most spreadsheet applications, including Microsoft Excel (R).

Through the use of the Insert and Delete commands along with standard Windows Copy (Ctrl+C) and Paste (Ctrl+V) functionality, it is possible to return the list above into a normal-order list as illustrated below:

	A	B	C
1	LINE	BEARING	DISTANCE
2	L1	N 45°00'00" E	141.42'
3	L2	N 90°00'00" E	100.00'
4	L3	S 45°00'00" E	141.42'
5	L4	S 56°18'36" W	180.28'
6	L5	N 56°18'36" W	180.28'

Note:

- Changes to the direction or length values **DO NOT** change the direction or length of the corresponding line or curve entity in the drawing!

Prompts

Select an entity table to modify: Graphically select any portion of a table that is to be edited

Pulldown Menu Location(s): Annotate > Line/Curve Table

Keyboard Command: edittbl

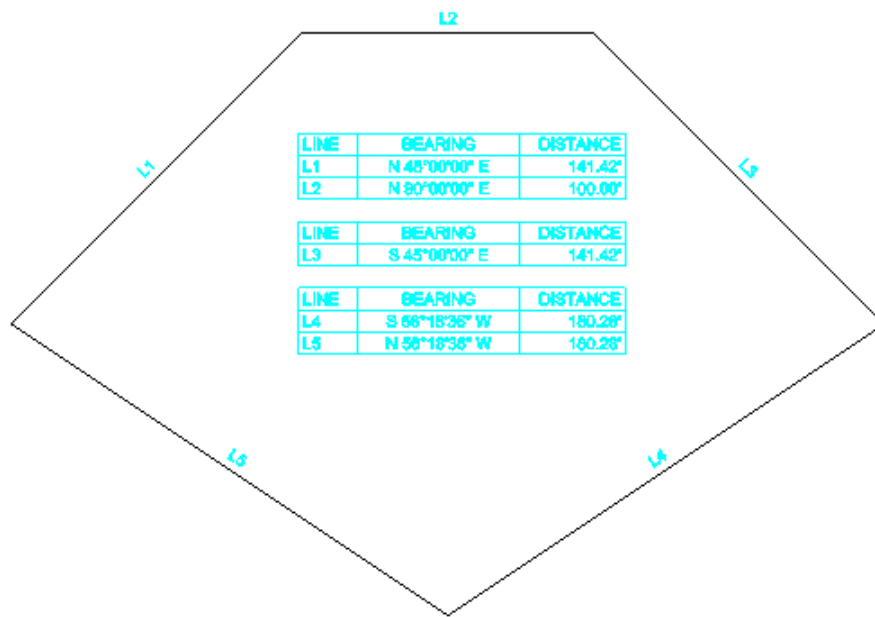

Prerequisite: A line or curve table created with the Use Table Entity option enabled under Line/Curve Table Defaults

Split Table

The **Split Table** command allows you to break a Line or Curve table created with the Use Table Entity option enabled under Line/Curve Table Defaults. This is commonly desired when a table is too lengthy to fit in its entirety on a plat. Splitting the table into two or more smaller tables allows the tables to be independently positioned on the plat. For example:

Becomes:

Note:

- In the example above, the initial table was first split at "L2" and then again at "L3".
- Split tables can be re-assembled through the use of the Merge Tables command.

Prompts

Select row of table to perform split on: *Graphically select the last row of the table that is to be retained in the original table*

Pulldown Menu Location(s): Annotate > Line/Curve Table

Keyboard Command: splittbl

Prerequisite: A line or curve table created with the Use Table Entity option enabled under Line/Curve Table Defaults

Merge Tables

The **Merge Tables** command allows you to combine two Line tables or two Curve tables into a single table. Both tables in the merge must have been created with the Use Table Entity option enabled under Line/Curve Table Defaults. For example:

Can become:

Note:

- In the example above, table "L1" was merged with table "L4" and then the modified "L1" table was merged with table "L3".
- Table numbers can be re-ordered through the use of the Edit Table Values command.

Prompts

Select first table of merge: Graphically select the first of two tables that should be combined together

Select second table of merge: Graphically select the second of two tables that should be combined together

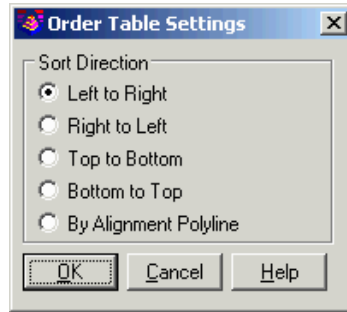

Pulldown Menu Location(s): Annotate > Line/Curve Table

Keyboard Command: splittbl

Prerequisite: Two or more line or curve table created with the Use Table Entity option enabled under Line/Curve Table Defaults. Each table in the merge must contain the same number of columns as the other table.

Order Table

This command orders the tags for line or curve tables to make the tags easier to reference in the drawing. To run this command, simply pick the line or curve table to order. At the command prompt, type O for Options to select the ordering method. The Alignment Polyline method lets you pick a polyline such as a centerline to have the tag order follow the polyline.

Prompts

Select table to order (O for Options): *pick table*

Select table to order (O for Options): *press Enter*

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: order.tbl

Prerequisite: line or curve table

Delete Table Elements

This command erases rows from line or curve tables. The table entries following the removed rows are automatically repositioned and renumbered. The line or curve labels on the linework in the drawing are also updated.

Pulldown Menu Location: Annotate > Line/Curve Table

Keyboard Command: del.tbl

Prerequisite: Line or curve tables

Label Arc

This command labels the arc data along the arc between the endpoints of the arc. The curve information is also displayed. The format for the label is set in the dialog shown here. For each arc data value, you can specify the label, the row number, and the side of the arc it will appear on. If a row number is left blank, then that value is not labeled. There is a choice of labeling inside or outside of the arc. Annotation is drawn as a block. The advantage of this is that the characters, rather than being individual entities, are plotted as a single entity that can be moved and edited as a unit. You would need to explode the "blocked" text in order to edit the text. A toggle button determines whether the user wants to flip the text on arcs that open to the top of the drawing.

Prompts

Define arc by, Points/<select arc or polyline>: *select arc*

After selecting the arc or polyline arc segment the command displays the dialog below. Select the OK button and the arc is labeled with the current settings of the dialog.

Label Arc Settings ✖

Label Options

	Label	Row	Side
Arc Length:	L=	1	Inside

Examples of Label Arc (above and below)

Example of Stack Label Arc

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: labarc

Prerequisite: Arc or polyline should be drawn before execution

Stack Label Arc Auto Place

This command is similar to Stack Label Arc Pick Side. The difference is the labels are automatically drawn at the middle of the arc. The command prompts to select an arc, define the arc by three points, or type O for Option to display the dialog shown here. See the Stack Label Arc Pick Side topic for a description of the options.

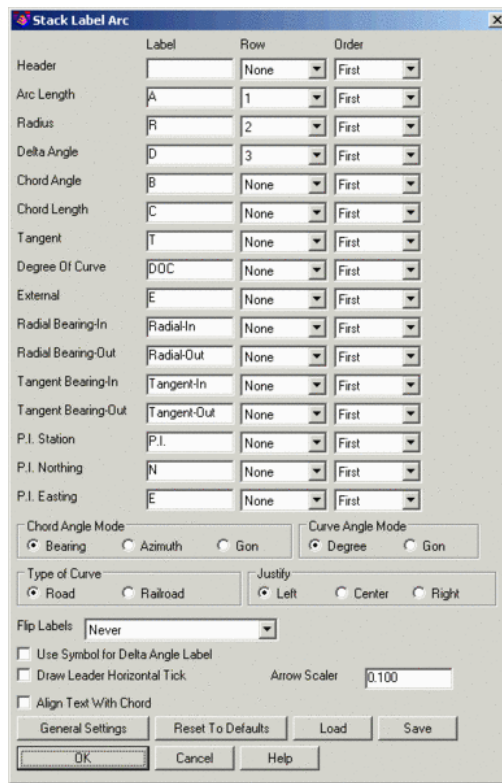

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: arcstack

Prerequisite: an arc entity or arc points

Stack Label Arc Pick Side

This command draws a small table of curve data. Unlike the command *Label Arc*, instead of fitting the text on the arc, this command lines the data up in rows. The command prompts to select an arc, define the arc by three points, or type O for Option to display the dialog shown here. For each type of arc value, you can specify the label and the sequence number. Under Label Options, the Stack Label Arc data table will display the values in the order by sequence number. There are also settings to justify label left or right.

Under Label Options, the data table will display the values in order based upon sequence number. For each of the arc properties, you can set the **Label** prefix, **Row** and **Order**. For multiple labels on the same row, the Order controls the label sequence for that row. The Header field is just the specified label and doesn't have an arc value. To display the special C/L label, enter \U+2104 in the label.

Chord Angle Mode allows you to set how the chord and radial angles are labeled as azimuth, bearing or gon.

Curve Angle Mode allows you to set how the delta angle and degree of curve are labeled as degree/minute/second or gon.

The **Type of Curve** option determines the type of curve.

Roadway: The length is determined as the true length of the curve.

Railroad: The length is adjusted based on 100-foot chord segments.

Justify sets the alignment for the text as left, center or right.

Flip Labels controls whether the text is drawn upside down in the current twist screen view.

The **Use symbol for Delta Angle** option uses a delta triangle symbol for the prefix.

Draw Leader Horizontal Tick draws a short horizontal line at the label end of the leader.

Align Text With Chord sets the angle of the text to match the chord angle. Otherwise, the text is draw horizontal to the current twist screen.

General Settings shows Annotation Defaults which has settings such as Text Size Scaler which apply to this routine.

Reset To Defaults puts the settings back to built-in defaults.

Load and **Save** functions store and recall the settings to an .ANS file. This is a way to share a label style with others or manage different styles.

Prompts

Options/Points/<Select arc>: P The P option causes the command to prompt for points on the arc. This can be

useful for labeling sub-arcs such as lot corners of a cul-de-sac.

Pick point or point number for Endpoint of arc: *pick a point*

Pick point or point number for Radius: *pick a point*

Pick point or point number for Other Endpoint: *pick a point*

Direction of curve [Left/<Right>]? *press Enter for right*

Pick stack label point (Enter for none): *pick a point*

Pick point to start leader at ([Enter] for none): *pick a point*

To point: *pick a point*

Options/Points/<Select arc> (Enter to end): *press Enter to end*

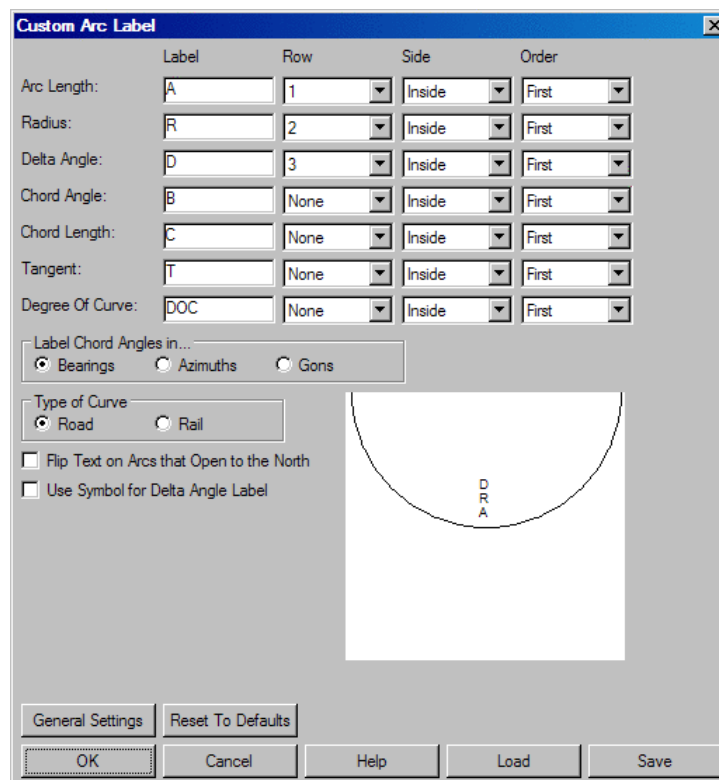

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: slabarc

Prerequisite: an arc entity or arc points

Custom Label Formatter

This command allows you to customize the labeling for arcs. You are first prompted to select an arc to label, given the existing defaults currently set. The arc is shown as labeled on the screen. The command line, shown below, also offers you an important choice called Options. When you type 'O' for options the below dialog box appears. There are four columns at the top of the dialog along with other features.

Label: This first column allows you to set the prefix that will go before your arc data.

Row: This column allows you to stack the data in different ways. You can place more than one item in the same row. If *None* is selected then that item will not be displayed.

Side: This column allows you to place each item either inside or outside of the arc.

Order: This column determines the order of items when they are placed in the same row.

Flip Text on Arcs that Open to the North: When this is checked text will be orientated according to the open side of your arcs instead of being orientated according to the plain view.

Use Symbol for Delta Angle Label: Allows you to use the triangle symbol for delta as the label instead of plain alphabetic or numeric representation.

General Settings: This button brings you to the Annotate Defaults dialog, see 'Annotate Defaults' for more.

Reset To Defaults: This button restores the default settings shown above.

Load/Save: You may also Load and Save different label configurations with the corresponding buttons.

Prompts

Options/⟨Select arc⟩: *select entity*

Options/⟨Select arc⟩: *O*

Custom Arc Label dialog *choose your preferences and click OK*

You can decide to go into the Option dialog at the start of the command and after your initial labeling.

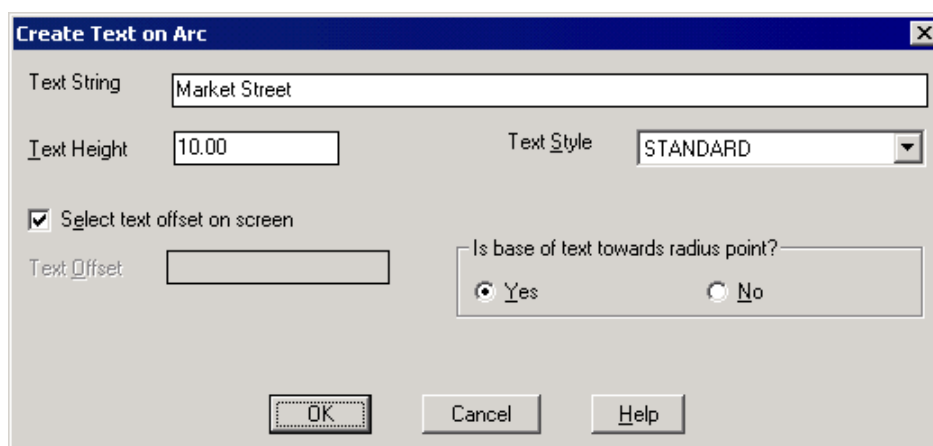

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: annarc

Prerequisite: An arc to label

Draw Text On Arc

This command draws text that aligns with an arc or polyline arc segment. Each letter of the text is drawn as a separate text entity that is rotated to align with the arc at that point. These text letters are automatically grouped together as an anonymous block. This command starts with the Create Text on Arc dialog. This command draws text that aligns with an arc, beginning at a picked point. Each letter of the text is drawn as a separate text entity that is rotated to align with the arc. These text letters are automatically grouped together as a block. The text string, text height, and text style are set in the Create Text on Arc dialog box.

Text String: Specify the text to label on the arc.

Text Height: Specify the text height. The default value is obtained from the text height specified in Drawing Setup. The value set here is retained throughout the drawing session.

Text Style: Choose an existing text style from the list of defined styles.

Select text offset on screen: When checked, the program will prompt you for offset. You can set the text offset from the arc by graphically picking the offset point on the screen. When this option is not checked, the Text Offset field described below becomes available to specify a known offset distance.

Text Offset: If the above setting is not selected, specify the Text Offset here. A positive value denotes an offset distance inside the arc, while a negative value denotes an offset distance outside the arc.

Is base of text towards radius point?: This option determines whether the base of the text should face the radius point of the arc. It orients the text to the curve. Examples showing the results of different settings follow.

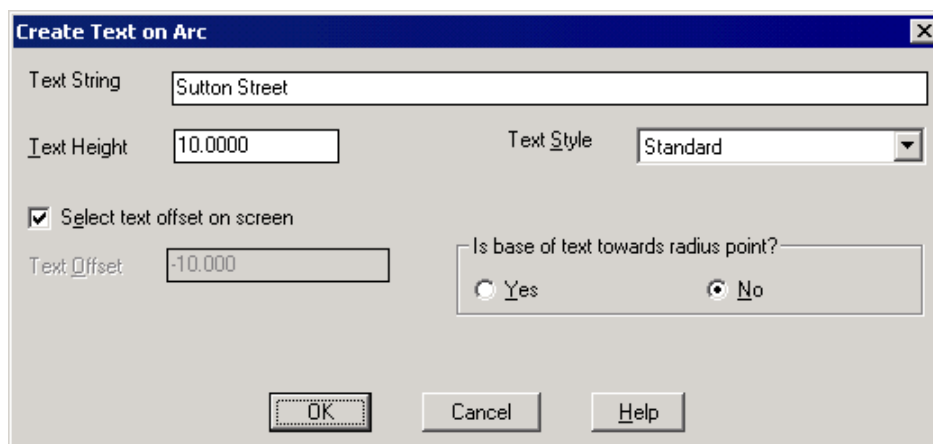

Example 1 - Offset distance specified on screen and base of text away from radius point.

Select Arc or Polyline segment: **pick Arc or Polyline segment** to place text on.

Select Text Offset: **pick the desired offset distance from arc**

Select Text Placement: **pick a point**, select the desired position to draw the text. Note that the text remains visible on the screen and attached to the "rubber banding cursor" so that various positions can be inspected before specifying the placement point. The graphic below shows this aspect of the command.

Note that the ghosted text is located along the mid point of the arc. If no offset distance is specified or picked from the screen, the text will be placed at this point. An offset of zero puts the text directly on the arc.

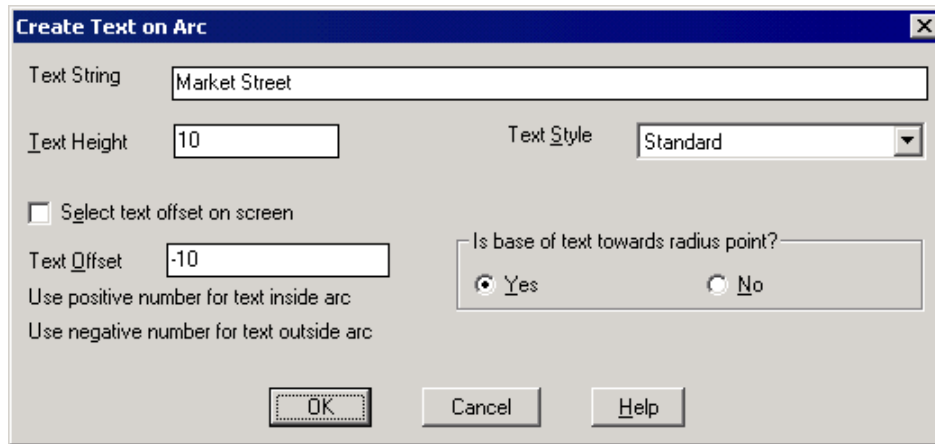

Example 2 - Offset distance specified in dialog and base of text towards radius point.

Select Arc or Polyline Arc Segment: **pick Arc**

Select Text Placement: **pick point**

Note that the prompt for offset distance was skipped because the offset distance was input on the dialog box. Simply select the text placement point resulting in the graphic below.

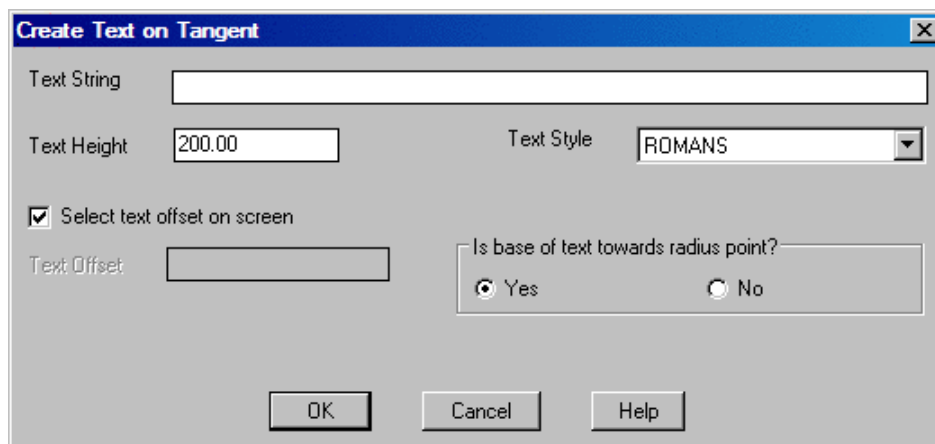

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: textarc

Prerequisite: An arc entity

Draw Text on Tangent

This command is identical to *Draw Text on Arc*, except that the text is not curved to fit the arc. You are presented with this dialog box. Fill in the text, decide on the other options, click *OK*, and then follow the prompts.

Pulldown Menu Location: Annotate > Annotate Arc

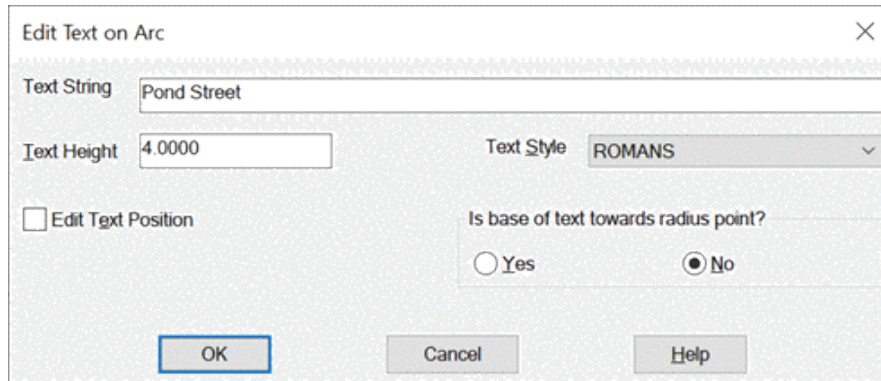

Keyboard Command: textarctan

Prerequisite: Arc or polyline arc segment

Edit Text on Arc or Tangent

This command allows you to edit text created by the *Draw Text on Arc* or *Draw Text on Tangent* command. You can change the text string, text height and text style. Use Edit Text Position to slide the text along the arc. The Towards Radius Point option can be used to flip the text.

The program prompts you to select the Text on Arc entity, then displays the same dialog used in *Draw Text on Arc*.

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: editarctext

Prerequisite: text entity as described above

Fit Text Inside Arc

This command fits text between two points picked along an arc. Text is curved to fit the arc using individual text entities, which can only be edited one at a time. The *Draw Text on Arc* command creates a text entity that can be edited using *Edit Text on Arc or Tangent*. It will optionally display information about the selected arc. If you choose to display the curve data, you will be prompted to pick the endpoints of the arc in a clockwise manner. When prompted, enter the text you want drawn inside the arc.

Prompts

Pick points in a clockwise direction.

[nea on] Start Point on arc for text: *pick point on arc to start text* Notice that the Nearest snap is turned on by default.

[nea on] End Point on arc for text: *pick point on arc to end text* Notice that the Nearest snap is turned on by default.

Enter text for inside of arc: MEADOWVIEW LANE

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: inarc

Prerequisite: An arc entity

Fit Text Outside Arc

Same as the previous command except this command fits text on the outside of the arc.

Pulldown Menu Location: Annotate > Annotate Arc

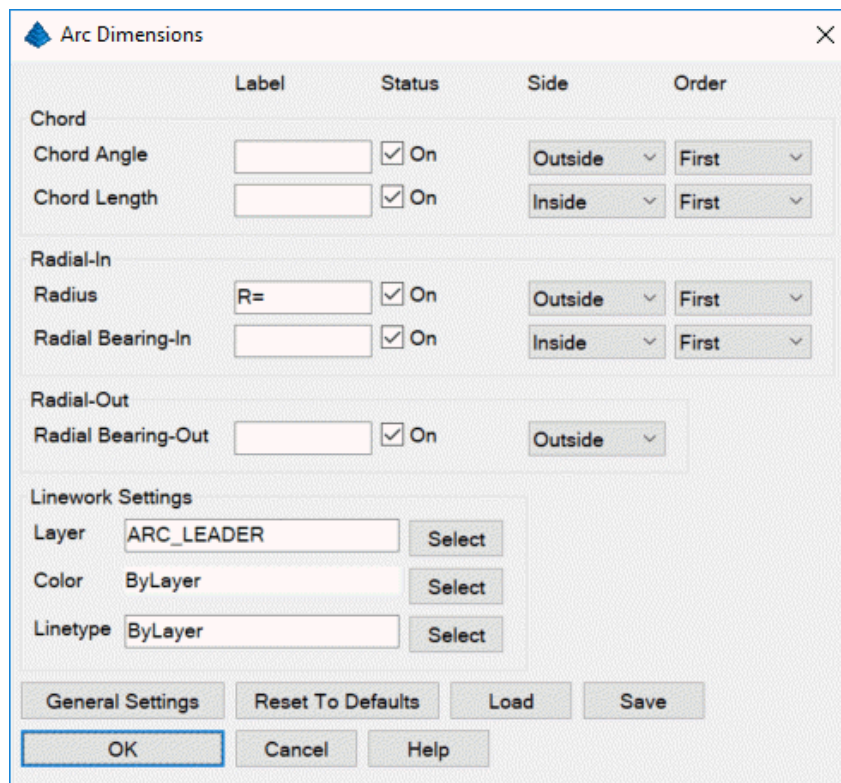

Keyboard Command: OARCT

Prerequisite: An arc entity

Arc Dimensions

This command labels dimensions of an arc including the chord angle, chord length, radius and radial bearing in and out. Besides creating the labels, this command also draws the chord line and radial lines. In the options dialog, choose which labels to draw, the label prefix and label position. The arc can be defined by selecting an arc entity, selecting an arc segment of a polylines or by entering points for the arc.

Prompts

Options/Points/⟨Select arc⟩: *pick an arc*

Pulldown Menu Location: Annotate > Annotate Arc

Keyboard Command: arcdim

Prerequisite: None

Change Polyline Linetype

This command changes the linetype of polylines or lines to the linetype selected from the dialog. True AutoCAD linetypes are created and applied to the selected entities, compared to other commands, such as *Polyline to Special Line* and *Special Line/Entity*, which break the polyline into segments. The spacing between linetype symbols and the symbols size are controlled by the Line Type Spacing and Symbol Size Scaler settings in the dialog. The Extra Dash is used for linetypes that have a symbol or letter between dashes. This setting controls how many dashes to draw between the symbol or letter. For example with the Electric2 linetype and Extra Dash set to 1, the linetype would have "- - E - - E - -". The Gap Size Scaler controls the size of the break in the line for the linetypes that have a break like UserDef and Arrow_B. The Gap Size Scaler is multiplied by the symbol size to get the gap size in drawing units. The Text Style is used for linetypes that use letters like "E" in Electric2.

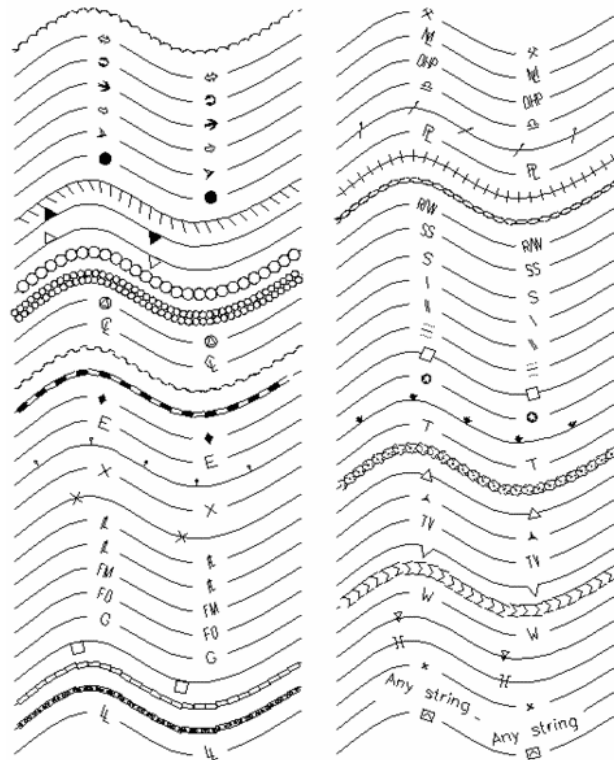

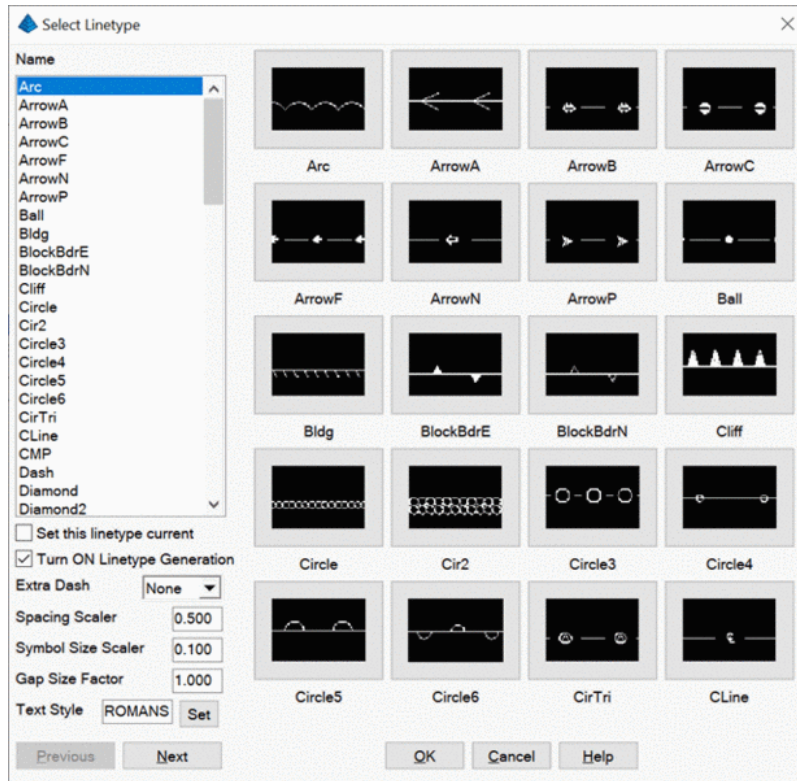

To select a linetype from the dialog, pick on the linetype image. Use the Next button to see more linetypes. At the end of the list of linetypes, there are two special choices. The UserDef choice lets you enter your own text string into a linetype, and the Wingdings choice lets you insert any Wingdings font character into a linetype. Consult Windows® documentation for a listing of Wingdings characters.

Prompts

Select Linetype dialog *select linetype and adjust other variables*

Select items to change.

Select objects: pick the polylines

Linetype styles available using Change Polyline Linetype

Pulldown Menu Location: Annotate > Line Types

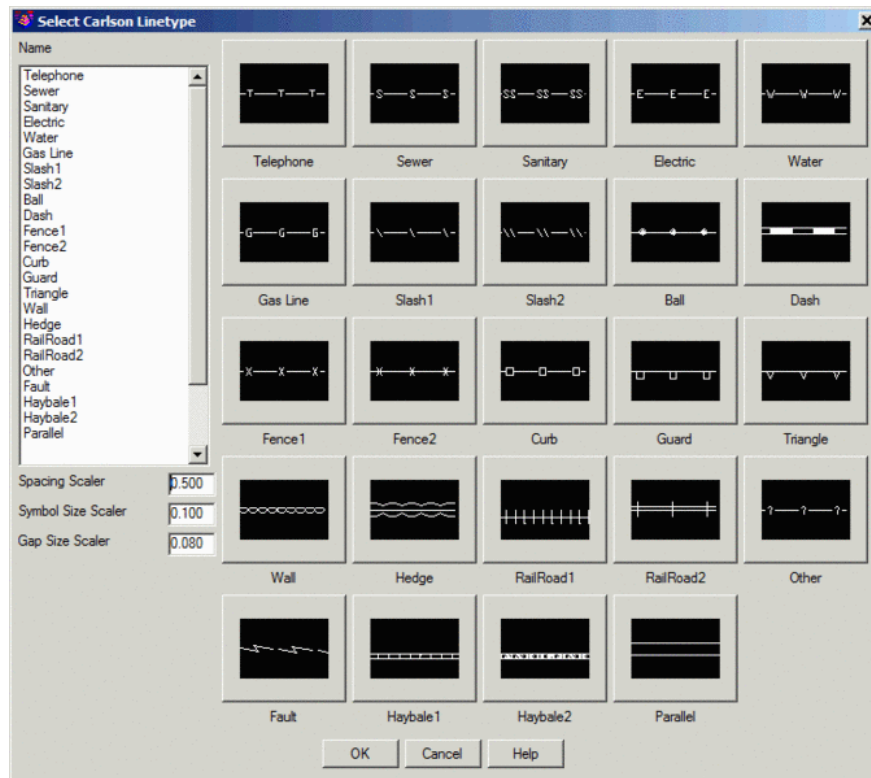

Keyboard Command: pltype2

Prerequisite: Polylines

Polyline to Special Line

This command converts polylines into special lines by adding the appropriate symbol onto the polyline, such as railroad, hedge, stonewall or telephone lines. Carlson has defined several line types as shown below. You can create custom lines by selecting the Other '?' which then prompts you for the text label to use. The size and spacing are set by the **Spacing Scaler** and **Symbol Size Scaler** settings. For some of the linetypes, this routine breaks the polyline using the **Gap Size Scaler** in order to fit in the symbol. Broken polylines cannot be used by the *Area* command, and are difficult to edit.

The *Change Polyline Linetype* command is another linetype method that creates actual AutoCAD linetypes that are applied to the selected entities.

Prompts

Select Carlson Linetype dialog

Select the polyline(s) to convert.

Select objects: *pick the polylines*

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: pltype

Prerequisite: Polylines

Polyline to Tree Line

This command changes a polyline into a series of semicircles for representing a tree line.

Prompts

Side for arcs on polyline direction? (<Left>/Right) *press Enter*

Enter the segment distance <10.0>: *press Enter*

Select the polylines to convert.

Select objects: *pick one or more polylines*

Before and After Polyline to Tree Line

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: maketree

Prerequisite: Polyline

Add Zig to Polyline

This command draws a [not-to-scale] style zig to a polyline. First pick the polyline and then pick a position on the polyline to draw the zig.

Prompts

Zig size <4.0>: *press Enter*

Select polyline to add zig: *pick a polyline*

Pick or enter point to add zig: *pick a point along the polyline*

Select polyline to add zig: *press Enter to end*

A zig in a polyline

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: addzig

Prerequisite: Polyline

Add Culvert to Polyline

This command adds culvert style brackets to both ends of the selected polylines.

Prompts

Culvert symbol size <4.0>: *12*

Select polylines to add culvert symbols.

Select objects: *pick the polylines*

Culvert symbols added to polyline

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: drwcvert

Prerequisite: Polyline

Sketch Tree Line

This command draws a tree line as you move the cursor. in the drawing editor. At the first prompt, you can type **O** for **Options** and set the Interval Scaler which controls the spacing of the arcs (bubbles) as well as the option to invert the arcs. In addition, you can select an existing polyline to convert to a tree line by typing **P** for **Polyline** at the Command Line Prompt. At the conclusion of sketching a treeline there will be a prompt and option to reverse the direction of the polyline. Choosing **Yes** results in the arcs being drawn on the opposite side of the polyline.

The resulting tree line after you pick point to end

Example of Treeline with Inverted Arcs

Prompts

Pick First Point [Options/Polyline]: *pick a point*

Sketch treeline (pick point to end): *slowly move the cursor and pick a second point to end the routine*

Reverse direction [Yes/<No>]?: *press Enter*

Options

Pick First Point [Options/Polyline]: O

Interval scaler <0.150>: *press Enter*

Invert Arcs Direction [Yes/<No>]?: N

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: treeline

Prerequisite: None

Special Line/Entity

This command breaks a line, arc or polyline and inserts a string of text or a block at an interval. It can be used to draw fence lines, utility lines, tree lines or any line which can be constructed by inserting a text or block entity. The command prompts to select an entity then the distance between inserts. Next, the user selects whether to insert text or a block, and whether to enter the distance or length to be broken out of the entity. If the user enters a 0 distance for the break distance, then the entity is not broken. If a distance greater than 0 is entered, then this distance is divided in half and broken out of the entity on both sides of the point at which the insert distance measures the entity.

If the user elects to insert text, the command prompts for the text to be inserted. Next, choose whether you want the text Middle or Center aligned, and whether you want to have the text flipped so it does not appear upside down. See the AutoCAD Reference Manual for more information on justification options. The size of the text is controlled by the text size setting in *Drawing Setup*.

If the user elects to insert a block, the command prompts for the block name. The size of the block is controlled by the symbol size setting in *Drawing Setup*. Considering that almost anything can be made into a block, such as raster images, wipeout entities, etc., this is a very powerful command.

Alternatives to this command are *Polyline to Special Line* and *Change Polyline Linetype*.

Pulldown Menu Location: Annotate > Line Types

Keyboard Command: speent

Prerequisite: None

Guard Rail

This command adds box symbols along a polyline to generate a guard rail. See the command *Change Polyline Linetype* also.

Prompts

Pick Polyline/Last: *pick a polyline*

Left/Right: *L for Left*

Pulldown Menu Location: Annotate > Line Types

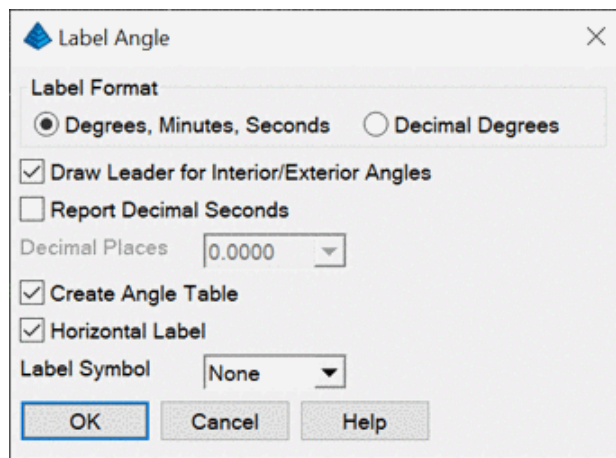

Keyboard Command: grail

Prerequisite: Polyline

Label Angle

This command will label and report the interior, exterior and deflection angles between two directions. The angles can be defined by three points, or by two line or polyline segments that have a common endpoint. An example of labeling interior and exterior angles is shown below. The Both option will label interior and exterior angles simultaneously. When the input data has different elevations, the program prompts whether to label the 2D or 3D angle. For 2D angle, the program ignores the elevations. For 3D angle, the program projects the data onto a 3D plane and calculates the angles on this plane.

At the Command line, type O for Options to bring up the options dialog. There are settings for the angle format as degrees, minutes and seconds, or as decimal degrees. You can also control the number of decimals and choose whether to draw dimension leaders for the interior angle labels. The Create Angle Table option will prompt to type in a Reference Label (ie. "A1") to draw in place of the angle value. Then at the end of the command, the program draws a table of the reference labels and angle values. The Horizontal Label option controls whether to draw the Reference Label horizontal or at the angle. The Label Symbol option sets the type of symbol to draw around the Reference Label.

Prompts

Define angle by [Options/Points/<select line or polyline>]: *pick a polyline segment*

Select adjoining line or polyline: *pick another polyline segment*

Interior: 64d15'01" Exterior: 295d44'59" Deflection: 115d44'59"

Angle to label [<Interior>/Exterior/Both/Deflection/None]? *press Enter*

Typing B for Both labels both the interior and exterior angles.

Define angle by, Points/<select line or polyline>: *press Enter to end*

Pulldown Menu Location: Annotate

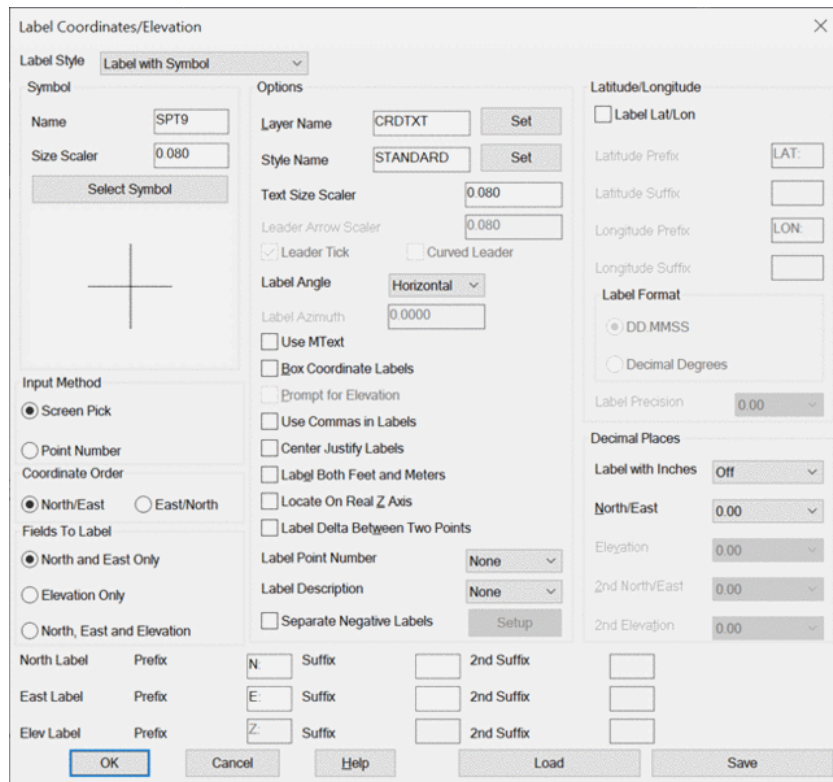

Keyboard Command: labang

Prerequisite: None

Label Coordinates/Elevation

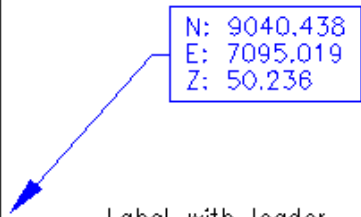

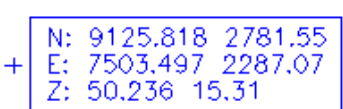

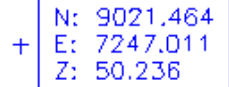

This command will label a coordinate on the screen. You can choose to label the northing and easting, or the elevation, or all three properties. The point can be picked on screen, or specified by point number or point group from the current coordinate (.CRD) file. Options include drawing a box around the label, labeling both feet and meters, setting the layer name for the label, setting the display precision, deciding whether or not to use a leader and selecting a change in the symbol used to mark the point. You can also set the text prefix and suffix for the label. Additionally, you can locate a label on Real Z Axis. The **Label With Inches** option labels with whole feet

and inches for the decimal part. The **Integers** controls how many decimals to label to the left of the decimal. The **Label Point Number** option uses the point number from the coordinate file. The **Label Description** option is for including a description with the label. There is a choice for placing this description as a header or footer. The program will prompt for the description. The **Use MText** option chooses between creating the labels as MText or regular text entities. The **Label Angle** setting chooses between having the labels horizontal, at a fixed azimuth or prompting to pick the angle for each label. The **Label Style** chooses between labeling with a leader, with a symbol, as an MLeader entity or along the x/y axis. The **Separate Negative Labels** option has prefix and suffix settings for negative coordinates that can be used for South and West labels. The **Label Lat/Lon** adds latitude and longitude labels to the coordinate labels. To use this option, the coordinate system must be defined in the Drawing Setup command.

N: 4066.66
 E: 5099.26

Label Along Axis

 <p>Label with leader</p>	 <p>Label both feet and meters</p>
 <p>Label without leader</p>	 <p>Label elevation only</p>

There is also an option to label the Delta X, Y and/or Z between two points, which is called **Label Delta Between Two Points**. When this option is clicked On, and after the prompt, you will first click two points locations. The label, with the delta value(s), will then be placed precisely in between these two pick locations. If, for example, the North, East and Elevation button is chosen, the resulting label will show the N, E and Z delta values.

The Save and Load buttons save and recall all the settings for this command to .LCE files. This is a way to manage different label styles for different mapping standards and to share between users.

Prompts

Point to Label ?

Pick point or point number: *pick a point*

Point to Label (ENTER to End)?

Pick point or point number: *press Enter*

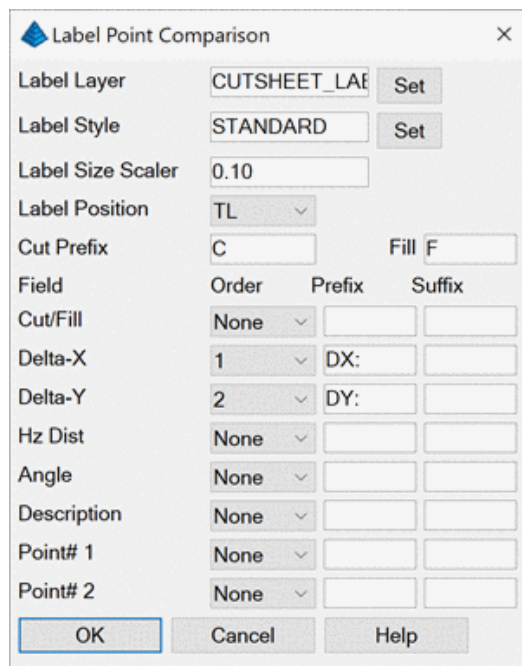

Pulldown Menu Location: Annotate

Keyboard Command: labcoor

Prerequisite: None

Label Point Comparison

This command labels the difference between two points. The points can be entered by point number or screen picked. The label is located between the points. The label layer, style, size and justification is set in the dialog along with which properties to label.

Prompts

Pick point or point number for 1st point: *pick point*

Pick point or point number for 2nd point: *pick point*

Pulldown Menu Location: Annotate

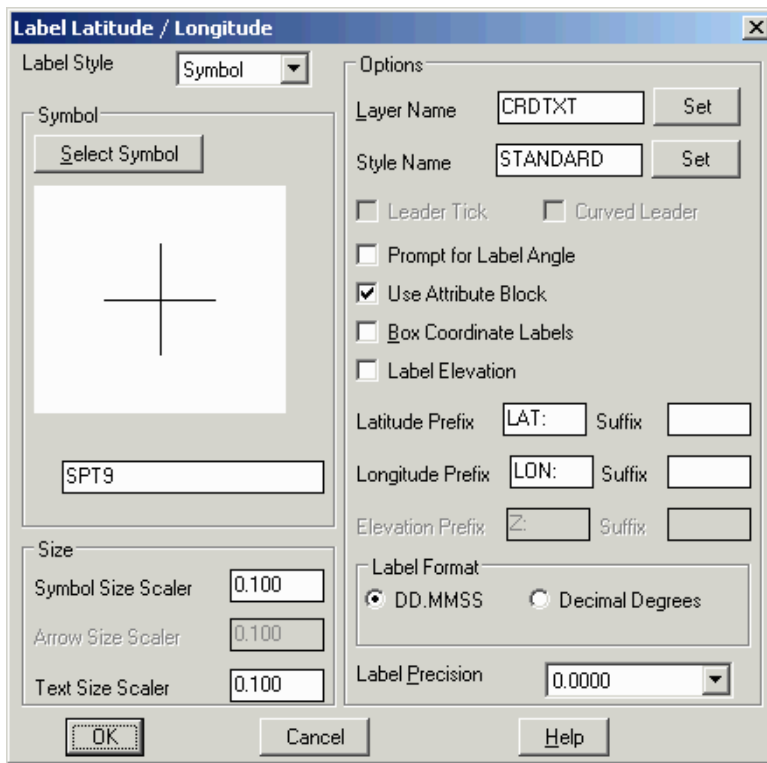

Keyboard Command: ptdiff

Prerequisite: None

Label LatLong

This command will label the latitude and longitude of a selected point. The program will convert the northing and easting of the input points to latitude and longitude. There is an option to include elevation in the labels. The coordinate system for the drawing coordinates must be defined in Drawing Setup before running this command. First, the program displays a dialog box with options to set the sizes, to set label prefixes, to set the display precision, to draw a box around the label and to change the symbol used to mark the point. The **Prompt For Label Angle** option prompts for the label rotation instead of automatically drawing the label horizontal. For the **Use Attribute Block** option, the symbol must be a block with three attributes for the latitude, longitude and elevation that the program will place and fill out the attributes instead of creating text labels. After the options dialog, the program prompts for the points to label. As you move the cursor, the program display the latitude/longitude in real-time.

For **Label Style**, the Leader and MLeader styles prompt for the point to label and then the label location and draws a leader or mleader between these points. For the Symbol style, the specified symbol is drawn at the point and the label is drawn automatically to the size.

Prompts

Label Latitude / Longitude dialog

Pick point or point number: *pick a point*

Pick point or point number: *press Enter to end*

Pulldown Menu Location: Annotate

Keyboard Command: lablat

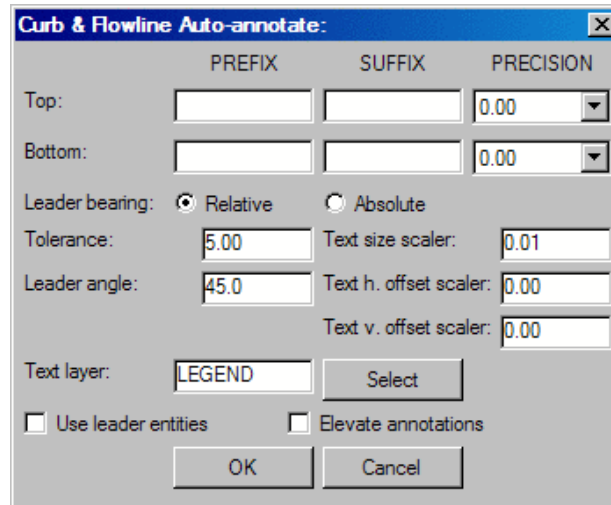

Prerequisite: Define coordinate system in Drawing Setup

Label Curb Flow Elevations

This command labels top of curb and/or bottom of curb (flowline) elevations with a leader along an alignment. The data to label comes from Carlson points and alignment is defined by a selected polyline. The program reads all the points in the drawing and then you select which descriptions to use the top of curb labels and which to use for the bottom of curb labels.

There are separate settings for the top and bottom to control the label prefix, suffix and decimals. The Tolerance setting is the maximum distance between a point to label and the polyline. The Leader Bearing determines how the Leader Angle is applied: Relative adds the angle to the alignment polyline and Absolute means based on the orientation of the screen. The Text Horizontal Offset Scaler controls the distance between the alignment polyline and the label. The Text Vertical Offset Scaler controls the buffer offset between the leader line and the label. The User Leader Entities option chooses between drawing the leaders as polylines or as leader entities. The Elevate Annotations setting controls whether the labels are created at their elevation or at zero.

Prompts

Top Curb Descriptions pick descriptions to label for top of curb

Bottom Curb Descriptions pick descriptions to label for bottom of curb

Pick a polyline to annotate (Enter to End): *pick a polyline*

Pick side for flowline (Enter to End): *pick a side*

Pulldown Menu Location: Annotate

Keyboard Command: cfelev

Prerequisite: points with elevations and descriptions, and alignment polyline

Replot Descriptions

This command will create user specified text entities at the location of selected point descriptions.

Prompts

This command will Search for a certain Point Description and plot

New text on the current layer with current style.

Attribute Text to Search for <>: *STK*

New Text to plot <>: *Stake Fnd*

Select objects: *Select Carlson points*

Select objects: *press Enter*

Number of Text Entities Plotted: 4

Found four STK descriptions and created four text entities

Pulldown Menu Location: Annotate

Keyboard Command: plotdesc

Prerequisite: Points with descriptions must be plotted. Set the layer and text style that you require.

Textbox

This command allows you to draw a shaded, shadow text box around a selection of Text or Mtext. The size of the shading and the optional leader are determined by the height of the text that is selected.

Pulldown Menu Location: Annotate

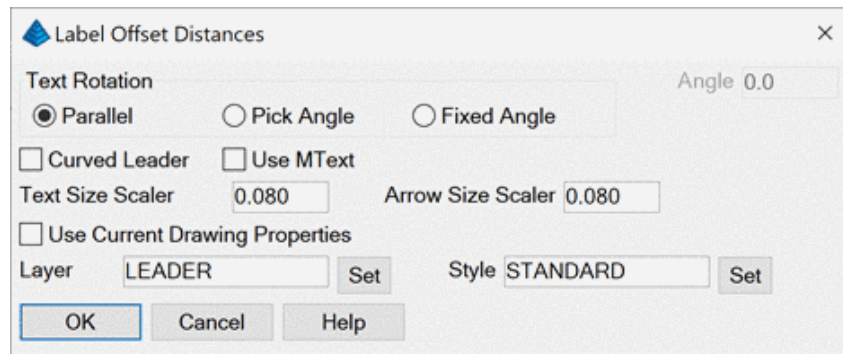

Keyboard Command: textbox

Prerequisite: Text or Mtext entities

Label Offset Distances

This command labels the distances of a point to one or two lines. The first distance is between the point and an east-west line. This distance is labeled as either north or south of the line. The second distance is between the point and a north-south line. This distance is labeled as either east or west of the line. The distances are labeled with a leader and a description of the point.

The settings dialog controls the label rotation, leader style, label size, layer and style.

Prompts

Pick 'E-W', Left to Right Property Line (if any)

Pick Line or Polyline (Enter for None): *pick the polyline*

Pick 'N-S', Top to Bottom Property Line (if any)

Pick Line or Polyline (Enter for None): *pick the polyline*

Pick Offset Point, (N) for Number, <E> to Exit: *pick a point*

Pick point to start leader at: *pick a point at or near the offset point*

To point: *pick an alignment point for the label*

To point: *press Enter*

Pick Offset Point, (N) for Number, <E> to Exit: *press Enter to End*

Pulldown Menu Location: Annotate

Keyboard Command: offlab

Prerequisite: Polyline or Line

CGSurvey Module

CGFile

Current Information

The Current Information Dialog Box contains information on:

Drawing: displays the current drawing file Path, Name, Scale, and Units

Coordinate File: displays the current coordinate file path and names.

File Type: This will display the current Coordinate file type.

The file types are:

C&G Numeric (.CRD) (PT #: 126)

C&G Alpha-Numeric (.CGC) (PT #: RW126)

Carlson Numeric (.CRD) (PT #: 126)

Carlson Alpha-Numeric (.CRD) (PT #: RW126)

Description Length: Numbers of character in the description

Total Points: Total number of points in the file

High Point: The highest point number stored

Points Used and Points Available: displays the block or blocks of points used or available in the coordinate file currently open.

Other Files: Displays the files that are currently open:

Data Path: displays the current default path and coordinate file name

Description Table: displays the current default path and description table

Print: displays the current default path and Print file name

Raw: displays the current default path and RAW file name

Map Check: displays the current default path and Map Check file name

Cross Section: displays the current default path and Cross Section file name

TIN: displays the current default path and TIN file name

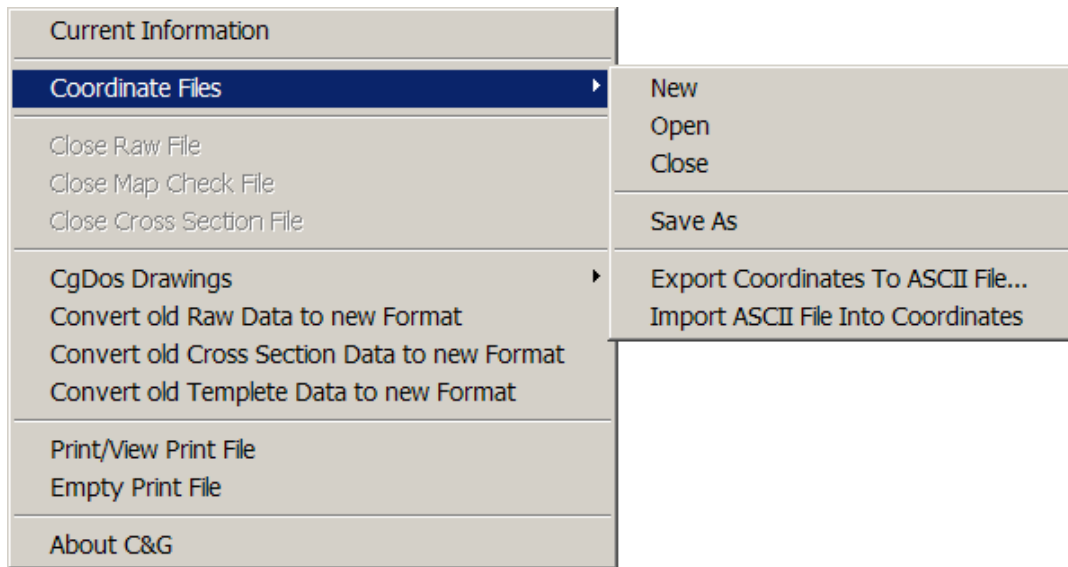

Pulldown menu Location:CG-Survey > File

Keyboard Command:INF, cg_current_info

Prerequisite: None

Coordinate Files

Choose Coordinate Files from the CGFile pull-down menu.

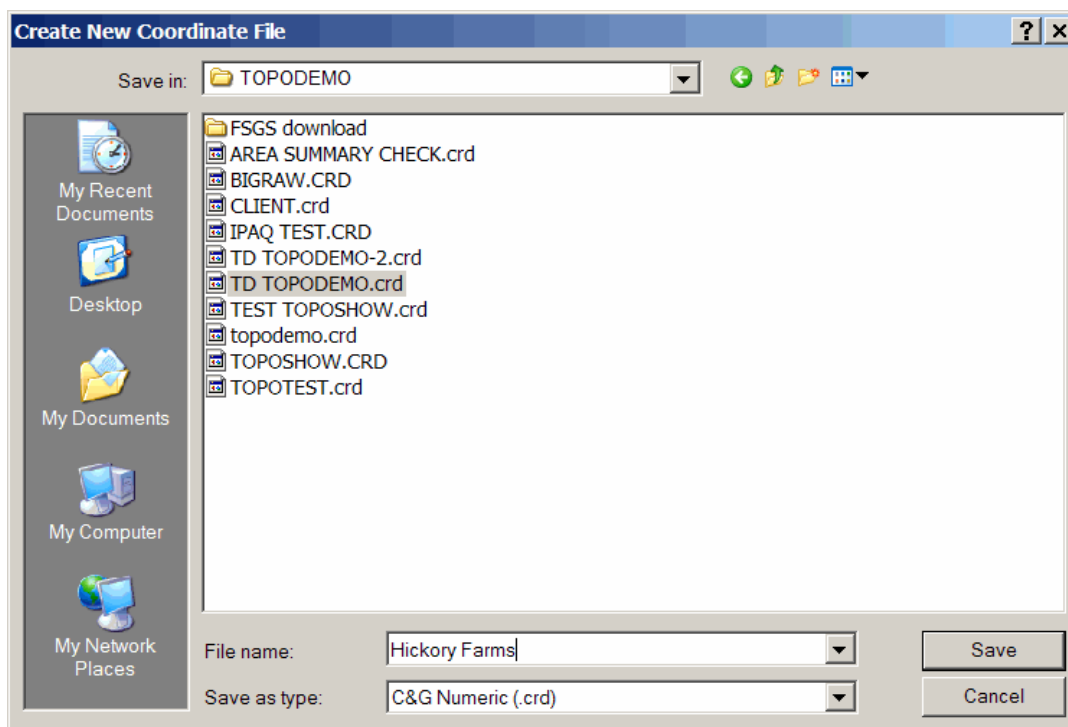

New

The New allows you to create a new coordinate file.

Prompts

Follow these steps: CGFile > Coordinate Files > New Coordinate File

Save in: Browse to folder location

Enter the name of the coordinate file you wish to create: File Name: Hickory farms

Press enter or press Save Button

NOTE: The directory displayed is the Data Path is the directory as set from the tool bar:

CG-Tools > CG Options > Data Path Options

NOTE: The description length for the new file just created will be set based on the current description length setting in the:

CG-Tools > CG Options > General

NOTE: You will not be able to change the description length once the new file is created. You must set the description length prior to creating the new file. You can however move the points to another file that has a longer description length

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: OPNC, CG_NEW_COORD

Prerequisite: None

Open

The Open menu item allows you to open an existing .CRD or .CGC file. Only one coordinate file can be open at a time in a given drawing.

Prompts

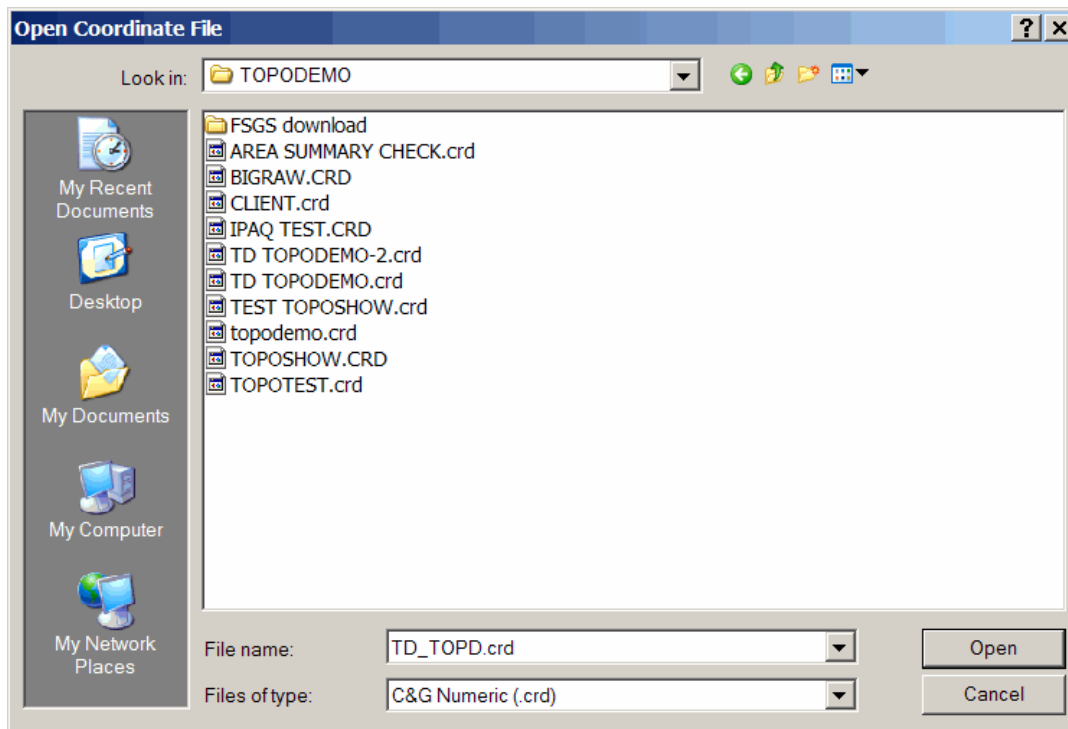

To open an existing coordinate file follow these steps:

In the file dialog box (Shown below),

Browse to folder location

select or Highlight the coordinate file you wish to open by clicking on it

Click the Open button

NOTE: The default directory is the "Data" directory below the directory where CG-SURVEY was installed. You can change the default directory by choosing:
 CG-Survey > Tools > CG Options... - Data Path tab.

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: OPC, CG_OPEN_COORD

Prerequisite: an existing coordinate file

Close

To close an open coordinate file

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: OPC, CG_OPEN_COORD

Prerequisite: Coordinate File Open

Save As

As new points are stored in a coordinate file, the file is automatically updated. If you are concerned that the changes to be made to the coordinate file may not be correct, you should use the Save As option to make an extra copy of the file before making any changes. This option allows you to save the open coordinate file under a different name. The new file becomes the current file. The original file will remain unchanged.

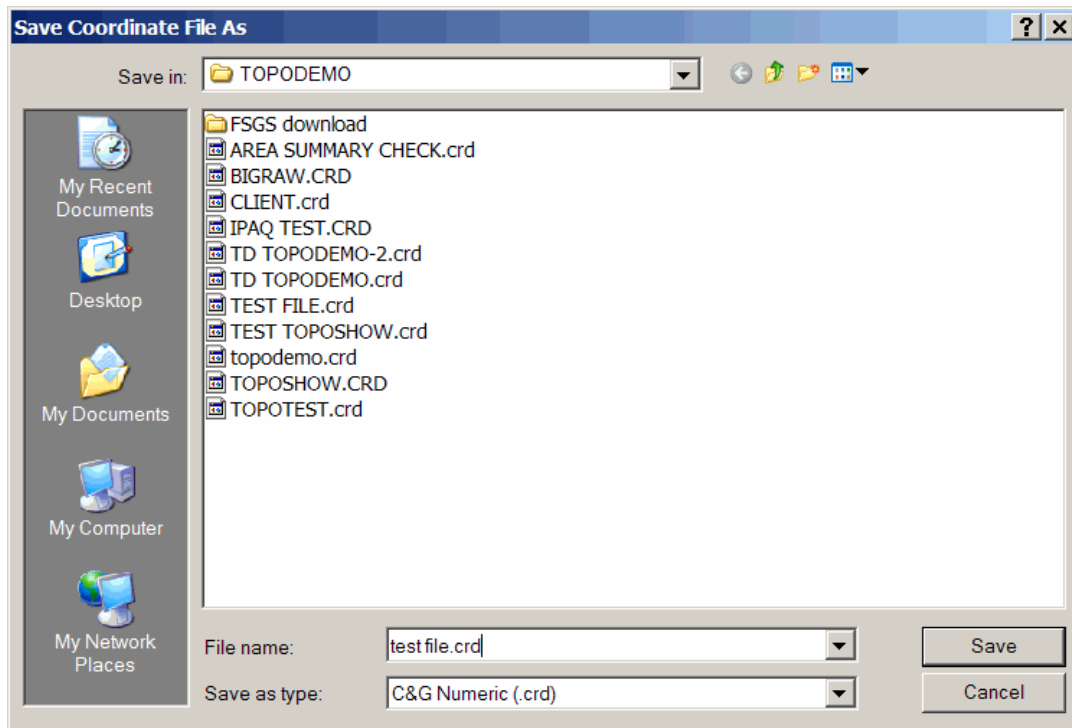

Prompts

To Save As the open coordinate file under a new name, select: > CGFile > Coordinate File > Save As

Browse to Folder Location:The Save Coordinate File As dialog box will display the default directory as set in the Data Path Options,

Enter the name : of the new file for the coordinates to be saved to.

Press Save Button: Save or Press enter

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: SCF, CG_FILE_SAVEAS

Prerequisite: None

Export Coordinates to ASCII

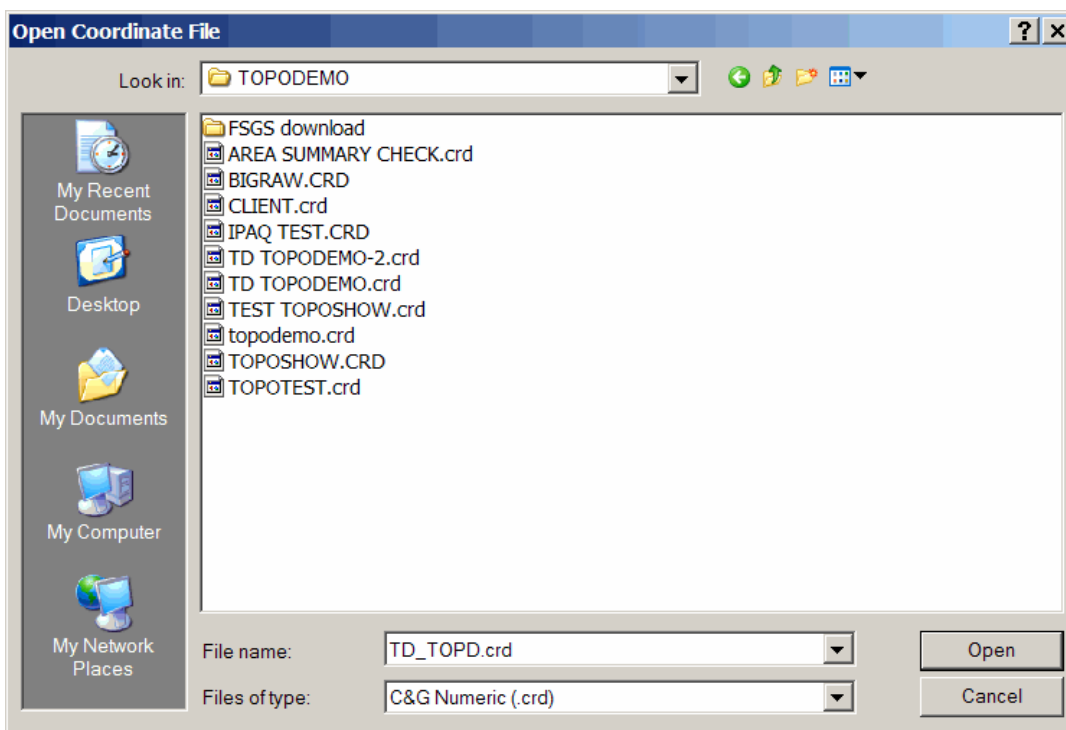

This menu item allows you to export coordinate files to an ACSII (American Standard Code for Information Interchange) file format. ASCII files are a simple text format and can be read by almost all word processors and text editors.

Prompts

To export coordinates to an ASCII file, follow these steps: > CGFile > Coordinate File > Export Coordinates to ASCII File

If a coordinate file is not currently open, the Open Coordinate File dialogue box will appear., select the file.

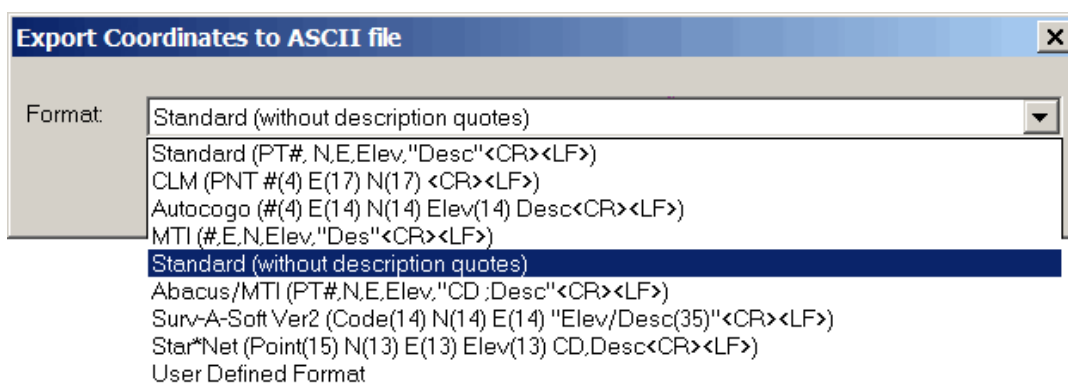

You will be prompted at the command line to select the points you wish to export:

Add points from coordinate file. (Enter When Done) (All/Block/Code/Desc/Elev/ Pt-group/Limits/Radius/Select):
 After choosing the set or sets of points you wish to export, press until the following dialogue box appears.

Enter a new file name or select an existing ASCII file and click the Save button. Next, select an ASCII file format (see the ASCII File Formats section of this chapter for an explanation of each format):

Select the OK button to export your coordinate points.

ASCII FILE CONVERSION FORMATS

NOTE: In the following formats the point code can be placed in the first two characters of the description field, followed by a semicolon. The description will follow the semicolon. You can export and import ASCII files in the following formats:

STANDARD (Point #, North, East, Elevation, "Desc")

```
2,5054.76393,9777.75761,103.70000,"gs"
3,5098.69743,9783.82411,105.20000,"gs"
4,5158.78043,9773.74111,105.67000,"gs"

```

CLM (PNT Point # Easting Northing)

```
PNT 2 9777.75761 5054.76393
PNT 3 9783.82411 5098.69743
PNT 4 9773.74111 5158.78043
PNT 5 9777.40661 5205.11493
```

Autocogo (Point # Easting Northing Elevation Desc)

2 9777.75761 5054.76393 103.70000 gs
3 9783.82411 5098.69743 105.20000 gs
4 9773.74111 5158.78043 105.67000 gs
5 9777.40661 5205.11493 106.25000 gs

MTI (Point #, Easting, Northing, Elevation,"Desc")

2,9777.75761,5054.76393,103.70000,"gs"
3,9783.82411,5098.69743,105.20000,"gs"
4,9773.74111,5158.78043,105.67000,"gs"
5,9777.40661,5205.11493,106.25000,"gs"

Standard (without description quotes) (Point #, North, East, Elevation, Desc)

2,5054.76393,9777.75761,103.70000,gs
3,5098.69743,9783.82411,105.20000,gs
4,5158.78043,9773.74111,105.67000,gs
5,5205.11493,9777.40661,106.25000,gs

Abacus/MTI (Point #, Northing, Easting, Elevation)

2,5054.76393,9777.75761,103.70000,"12;gs"
3,5098.69743,9783.82411,105.20000,"12;gs"
4,5158.78043,9773.74111,105.67000,"12;gs"
5,5205.11493,9777.40661,106.25000,"12;gs"

Surv-A-Soft (Code Northing Easting: Desc/Elevation")

6 0 "VER 2"
-1 0.00000 0.00000 " "
2 5054.76393 9777.75761 "103.70000"
2 5098.69743 9783.82411 "105.20000"
2 5158.78043 9773.74111 "105.67000"
2 5205.11493 9777.40661 "106.25000"
2 5253.39243 9779.12911 "110.47000"

The Surv-A-Soft file structure is as follows:

The first line of the file is a header line with the following information:

The total number of points is placed in the code field.

Zero (0) is placed in the northing field.

"VER 2", etc. is placed in the easting field.

After the header line each line specifies a coordinate point. The line number minus one is the point number.

The code field has three possible values:

Value Explanation

-1 no coordinate point

2 elevation (in description field)

1 description (in the description field)

Since .CRD and .CGC files can have both an elevation and description, when converting them to an ASCII Surv-A-Soft file one of the following will occur depending on the elevation value:

If the point has an elevation it will be placed in the description field. If there is no elevation, the description will be placed in the description field.

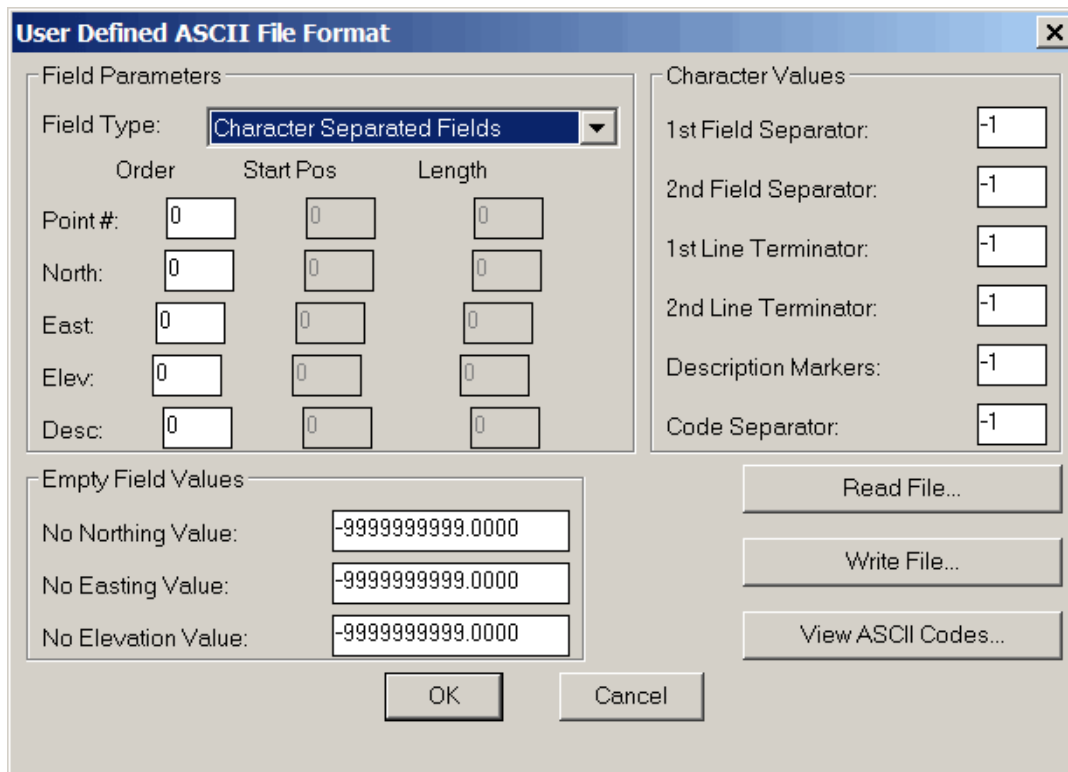

Star*Net (Point # Northing Easting Elevation Desc)

2 5054.76393 9777.75761 103.70000, gs

3 5098.69743 9783.82411 105.20000, gs
4 5158.78043 9773.74111 105.67000, gs
5 5205.11493 9777.40661 106.25000, gs

USER DEFINED

Upon selecting User Defined format, the following dialog box will appear:

The dialog box is titled "User Defined ASCII File Format" and contains the following sections:

- Field Parameters:** A dropdown menu for "Field Type" is set to "Character Separated Fields". Below it is a table with columns "Order", "Start Pos", and "Length".

	Order	Start Pos	Length
Point #:	0	0	0
North:	0	0	0
East:	0	0	0
Elev.:	0	0	0
Desc.:	0	0	0
- Character Values:** Five input fields for separators, all containing "-1":
 - 1st Field Separator: -1
 - 2nd Field Separator: -1
 - 1st Line Terminator: -1
 - 2nd Line Terminator: -1
 - Description Markers: -1
 - Code Separator: -1
- Empty Field Values:** Three input fields, all containing "-999999999.0000":
 - No Northing Value: -999999999.0000
 - No Easting Value: -999999999.0000
 - No Elevation Value: -999999999.0000
- Buttons:** "Read File...", "Write File...", "View ASCII Codes...", "OK", and "Cancel".

As the name implies you can create a format specific to your conversion needs.

Using an Existing User Defined Format To select an existing User Defined format, do the following: Press the Read File button. Select an existing user defined format from the dialog. The fields in the dialog box will automatically be updated. Select OK to accept the format.

Creating a User Defined Format: There are 5 basic pieces of information that can be defined in a user defined format. Point number Northing (required) Easting (required) Elevation Description (Code can also be part of the description field) There are two types of user defined formats " Character Separated Fields Character Separated Fields means that each field of information is separated by a character, often times a comma, but any ASCII character can be used. Fixed length Fields Fixed length fields means that you define the number characters for each field item. The fields can be in any order

Field Order

Point Number 4

North 3 (required)

East 2 (required)

Elevation 1

Description 5

NOTE: Coordinate values will be rounded based on the setting in the Rounding Options dialog box.

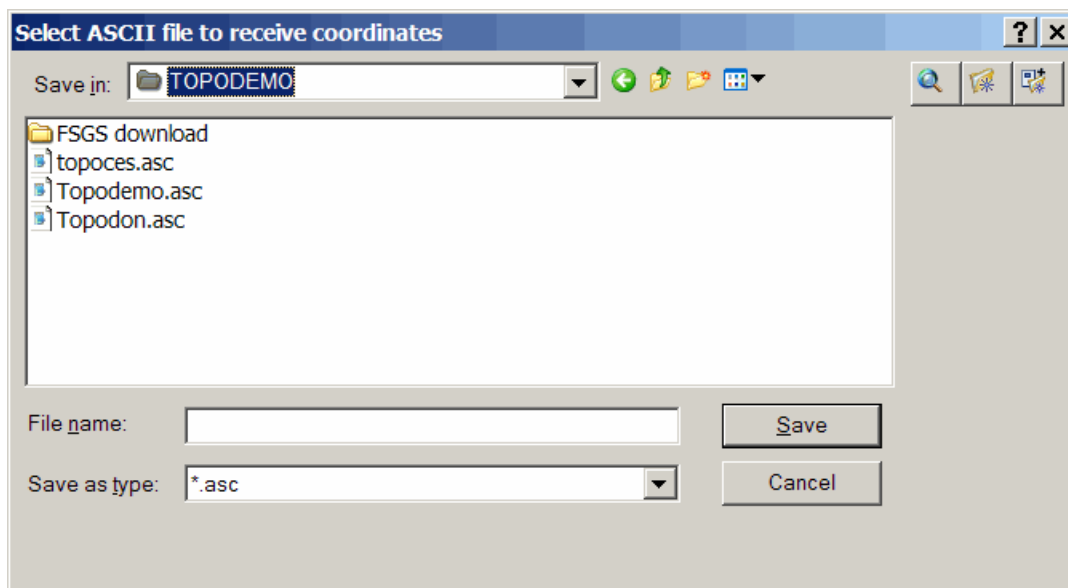

If the point number field is not assigned a value, the line number will be the point number. Select the Field Type (Character Separated or Fixed Length) and follow the appropriate instructions below:

Character Separated User Define Export File

>Go to CGFile >Select Coordinate files >Select Export to ASCII At the command line you will be prompted to select points:

Add points from coordinate file. (Enter when Done) (All/Block/Code/Desc/Elev/ Pt-group/Limits/Radius/Select):

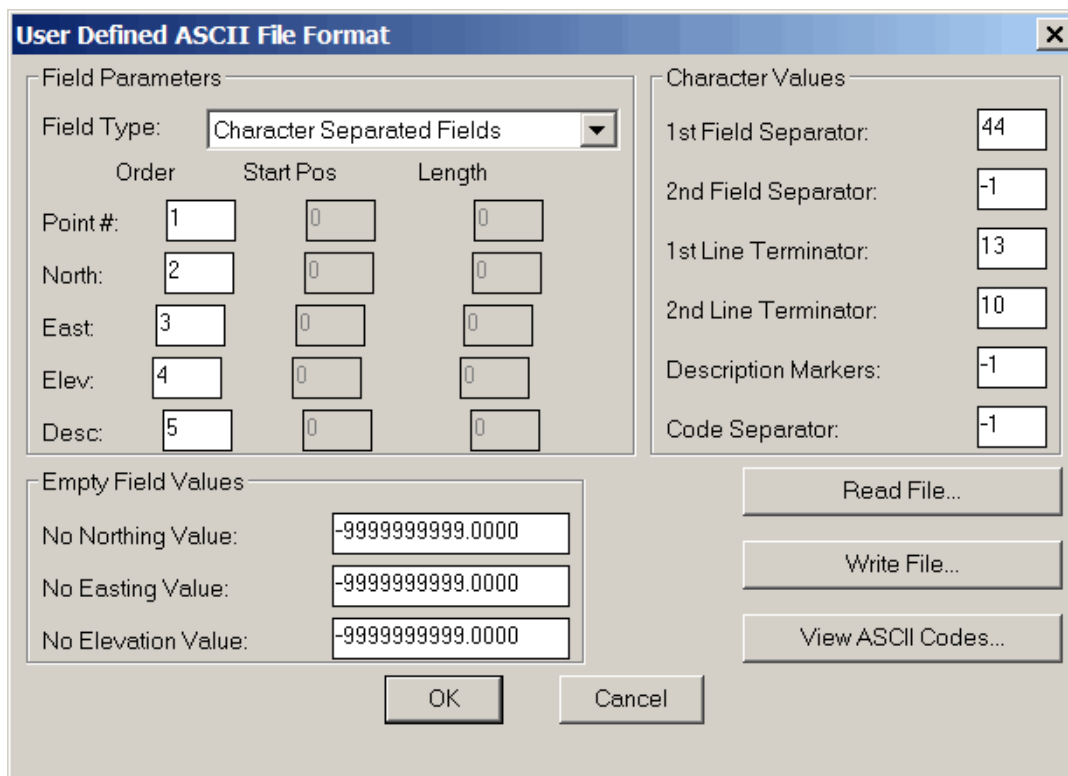

After selecting the point set or sets to export press return

Select or name the file to store the converted points.

Set the conversion format to "User Defined Format" The following dialog box allows you to define the attributes of the points being converted.

For this example Character Separated Fields has been chosen as the Field Type.

Points..... -> 1
 North..... -> 2
 East..... -> 3
 Elevation..... -> 4
 Description -> 5

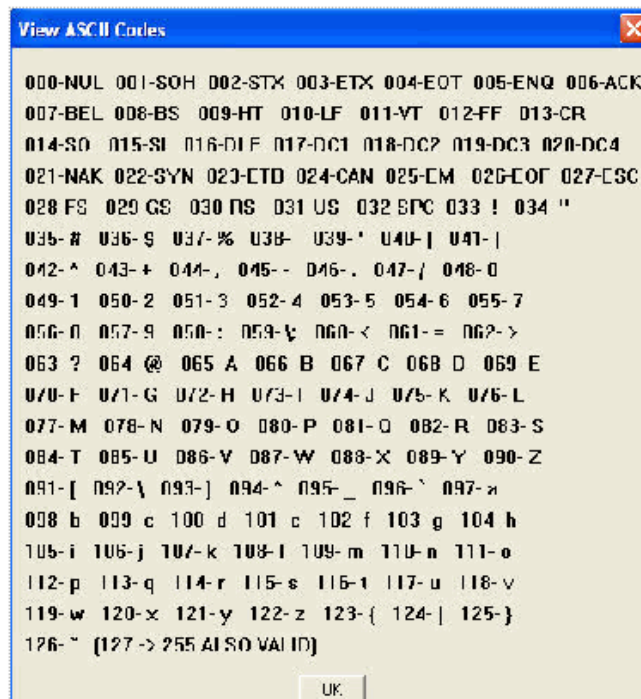

So the line data will be: Point # , North, East, Elevation, Description

Empty Field Values: It's necessary to distinguish between a field that has no value and a field that has "0" as a value. In coastal areas "0" is a valued elevation and in some cases "0" could actually be a coordinate value. By defining empty field values with a value that cannot be miss-understood for a valid value, a conversion process will not produce invalid data.

Character Values:

1st & 2nd Field Separators, these are the ASCII characters that define the fields within a line.
 1st & 2nd Line Terminator; these are the ASCII characters that define separate lines
 Description Markers; An ASCII character that surrounds the description such as quotation marks.
 Code Separator; Allows you to designate the ASCII character that separates the Code information from the Description information. In the example above the Character values are set as follows:
 1st Field Separator: 44 (which is a comma)
 2nd Field Separator: -1 (none used)
 1st Line Terminator: 13 (carriage return)
 2nd line Terminator: 10 (line feed)
 Description Marker: -1 (none used) Code Separator: -1 (none used)

This example would read as follows: 1,5000.0000,10000.0000,954.63,MH
 The following is a list of all of the ASCII codes and the respective values.

2nd Field Separator: You may however define two separators. For example, you can use a carriage return and line feed if you wish to have each field on its own line: 1 <CR> <LF> (Point number)
 1000.000 <CR> <LF> (Northing)
 1000.000 <CR> <LF> (Easting)
 954.56 <CR> <LF> (Elevation)
 MH <CR> <CF> (Description)

NOTE: Do not use a character as a separator if it appears in any of the fields. For example, if your record looks like this:

1 1000.000 1000.000 954.56 MH <CR><LF>

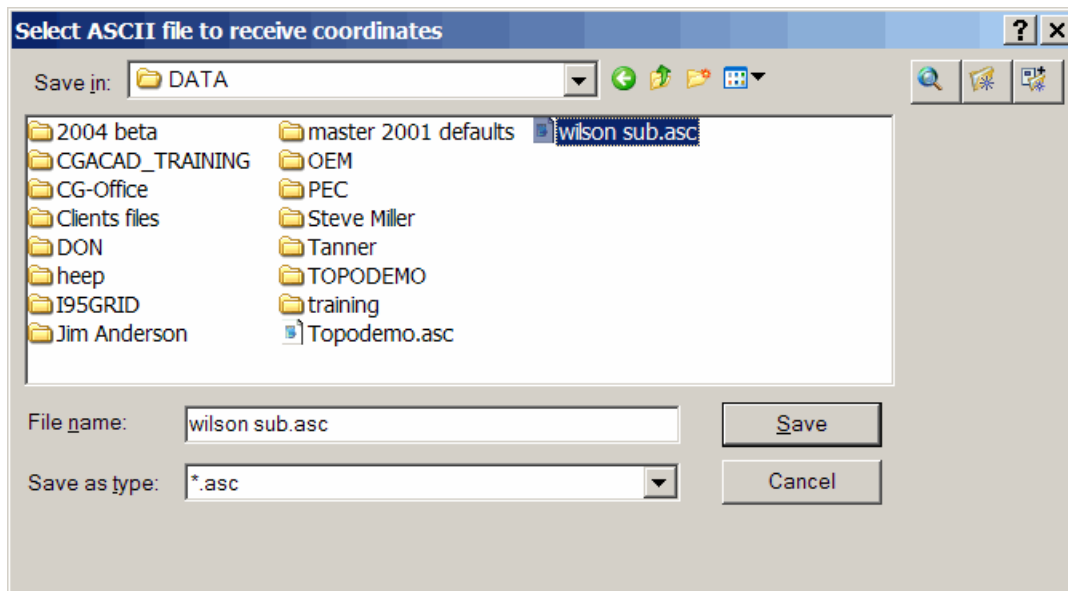

Then the period (.) character cannot be used as a separator because it is used in the northing, easting and elevation fields. Pressing the View ASCII Codes button will show you the 256 valid characters that can be used in an ASCII file. The table shows each character, with its integer value to the left of it.

NOTE: Character number 26 cannot be used as a field separate because it marks the End of File (EOF).

Fixed Length Field User Define Export File:

>Go to CGFile >Select Coordinate files
 >Select Export to ASCII Select points. (Enter When Done) (All/Block/Code/Desc/Elev/ Pt-group/Limits/Radius/Select):

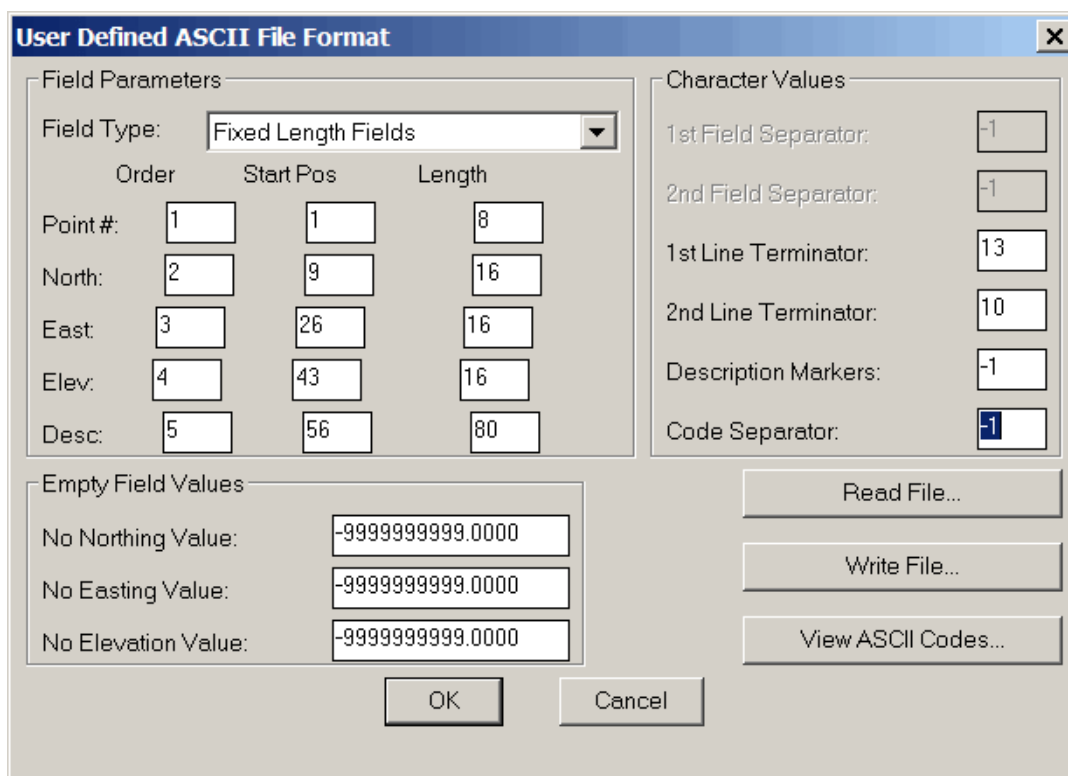

At the command line you will be prompted to Select Points After selecting the point set or sets to export press return Select or name the file to store the converted points.

Set the conversion format to "User Defined Format"

The dialog box below allows you to define the attributes of the points being converted.

For this example Fixed Length Fields has been chosen. In this case the order is set at:

Points..... -> 1
North..... -> 2
East.....-> 3
Elevation..... -> 4
Description -> 5

So the line data will be:

Point # - North-East-Elevation-Description But unlike Character Separated Fields, the information sets will be defined by their placement on the text line, rather than a separating character.

Empty Field Values: It is necessary to distinguish between a field that has no value and a field that has "0" as a value. In many cases around coast lines "0" is a contour elevation and in some cases "0" could actually be a coordinate value. By defining empty field values with a value that cannot be miss-understood for a valid value, any conversion process will not produce questionable data.

Character Values: 1st & 2nd Field Separators, do not apply, separators are defined by spacing.

1st & 2nd Line Terminator; do not apply, separators are defined by spacing.

Description Markers; An ASCII character that surrounds the description such as quotation marks.

Code Separator; Allows you to designate the ASCII character that separates the Code information from the Description information. In the example above the Character values are set as follows:

1st Field Separator: Do not apply

2nd Field Separator: Do not apply

1st Line Terminator: 13 (carriage return)

2nd line Terminator: 10 (line feed)

Description Marker: -1 (none used)

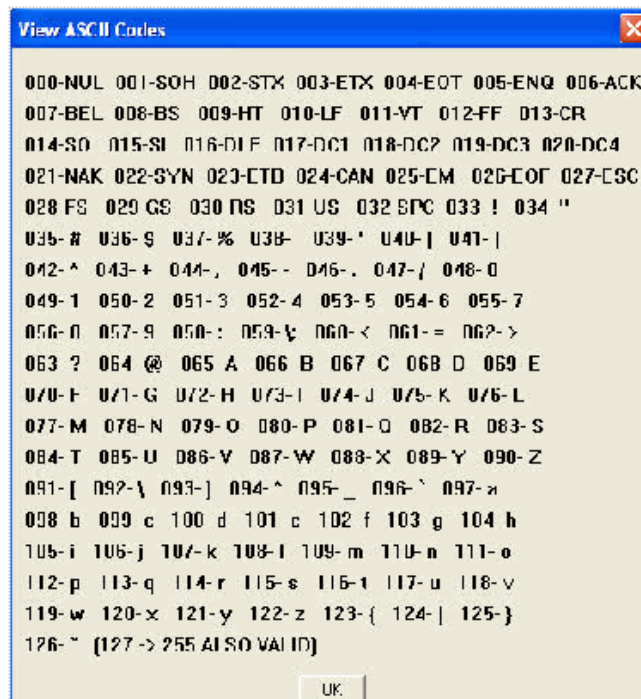

Code Separator: -1 (none used)

This example would read as follows:

1 5000.0000 10000.0000 954.63 MH <CR> <LF>

The first 8 spaces are the reserved for the point number The next 16 are reserved for the northing The next 16 are reserved for the easting The next 16 are reserved for the elevation The next 20 are reserved for the description Then a (carriage return) and a (line feed)

The following is a list of all of the ASCII codes and the respective values.

NOTE: Do not use a character as a separator if it appears in any of the fields.

Description Markers: If you have a description field, you may wish to use a Description Marker. This is a character that surrounds the description. For example, a description surrounded by quotes: 23,1056.789,2345.769,982.345,"MH" <CR> <LF>

If you are not using a description marker, enter -1 in the Description Marker box

Code Separator: If you have a description field, and want the first characters of the description field to be a C&G point code, you can enter the decimal value of the character that separates the point code from the description. This allows you to transfer both the point code and the description to an ASCII file. For example, using a semicolon as a code separator: 23,1056.789,2345.769,982.345,"MH; Inv Elev -9.23" <CR><LF>

If you are not using a code separator, enter -1 in the Code Separator box.

No Northing Value and No Easting Value

If the ASCII file does not have a point number field, the No Northing and No Easting values are mandatory. The record number will be used as the point number. This means that skipped point numbers will be filled with false northing, easting and elevation values.

Here is an example of a file with a record that has no point number field (assume you entered -999999 in the No Northing, No Easting and No Elevation boxes):

```
1056.789,2345.769,982.345,MH<CR><LF>Point 1
-999999, -999999, -999999, <CR><LF> No Point 2
2356.679,2455.645,992.678,MH<CR><LF>Point 3
2786.799,5645.789,984.234,MH<CR><LF>Point 4
```

No Elevation Value You must place a value in this box. When converting a C&G point to an ASCII point, this value will be placed in the elevation field of the ASCII point if a C&G point with "No Elevation" is encountered. When converting an ASCII point to a C&G point, if "No Elevation" is encountered in the ASCII point then "No Elevation" will be placed in the elevation field of the C&G Point.

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: EXC, CG_EXPORT_COORDS

Prerequisite: None

Import ASCII File into Coordinates

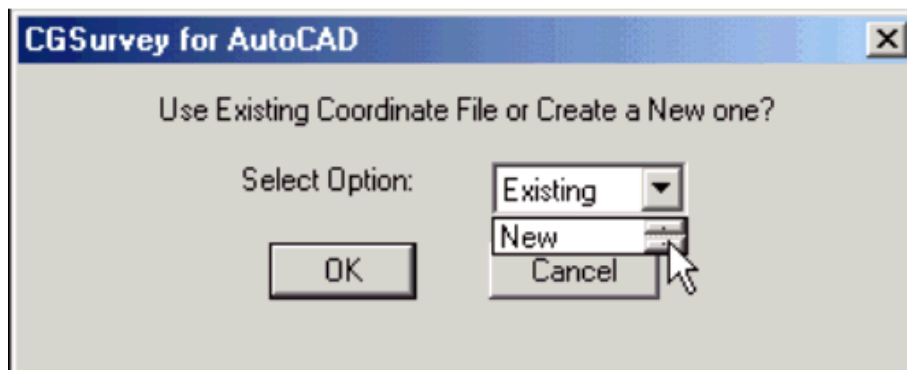

This option allows you to import the contents of an ASCII file into a coordinate file.

Prompts

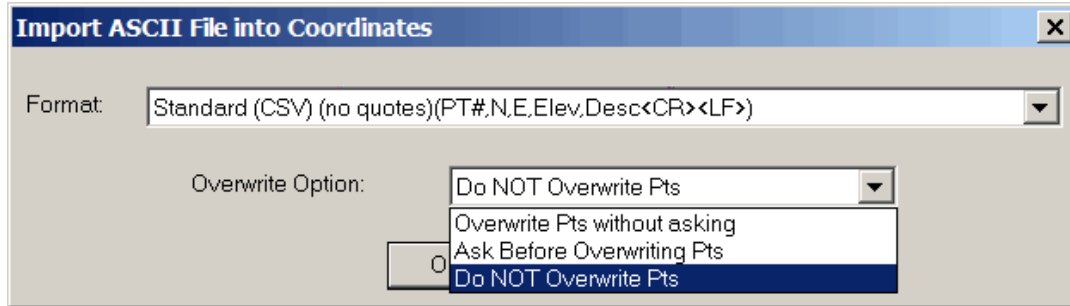

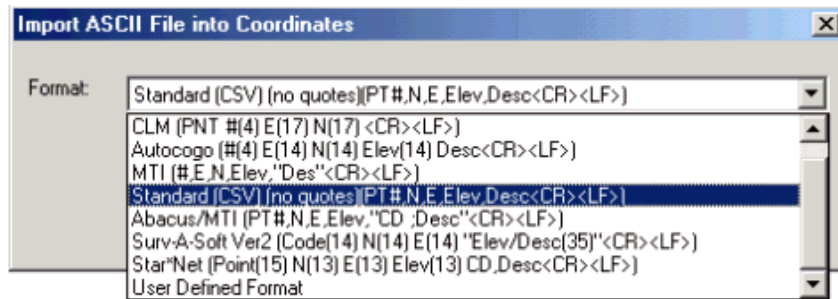

Follow these steps: > CGFile > Coordinate Files > Import ASCII File Into Coordinates

If a coordinate file is already open, the ASCII file will be imported into it, if a coordinate file is not open you will be prompted to open an existing file or create a new coordinate file.

Select the ASCII format that is being imported and how to handle duplicate points.

The points will be imported and displayed on the screen.

Pulldown Menu Location: CG-Survey > File > Coordinate Files

Keyboard Command: IMC, CG_IMPORT_COORDS

Prerequisite: None

Close Raw File

To close the current raw data file, select CGFile from the main menu and then select Close RAW File.

Pulldown Menu Location: CG-Survey > File

Keyboard Command: CLR, CG_CLOSE_RAW

Prerequisite: Raw File OPEN

Close Map Check File

To close the current map check file, select CGFile from the main menu and then select Close Map Check File.

Pulldown Menu Location: CG-Survey > File

Keyboard Command: CLM, CG_CLOSE_MAP

Prerequisite: Mapcheck file Open

CGDos Drawings

Before opening a CGDOS drawing you must choose the "setup" option to provide information needed for opening the PL1/PL2 files.

This feature allows you to import a CGDOS PL1/PL2 file and convert it to a standard CAD drawing. This is similar to a DXF conversion, but in addition to simple converting the graphics, this feature also retains the C&G data. That means that after the conversion is finished the drawing file is still referenced to the coordinate file. If you query a line it tells you what coordinate file the graphic was created from, the points that line is drawn from, the layer and line stop information just like query did in the CGDOS. This means you can continue working on the job after the conversion in a manner that is familiar to you as it was in CGDOS.

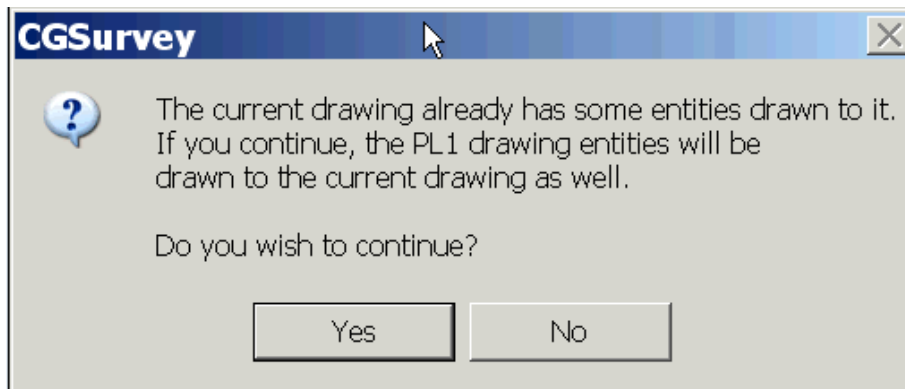

Pulldown Menu Location: CG-Survey > File

Keyboard Command: None

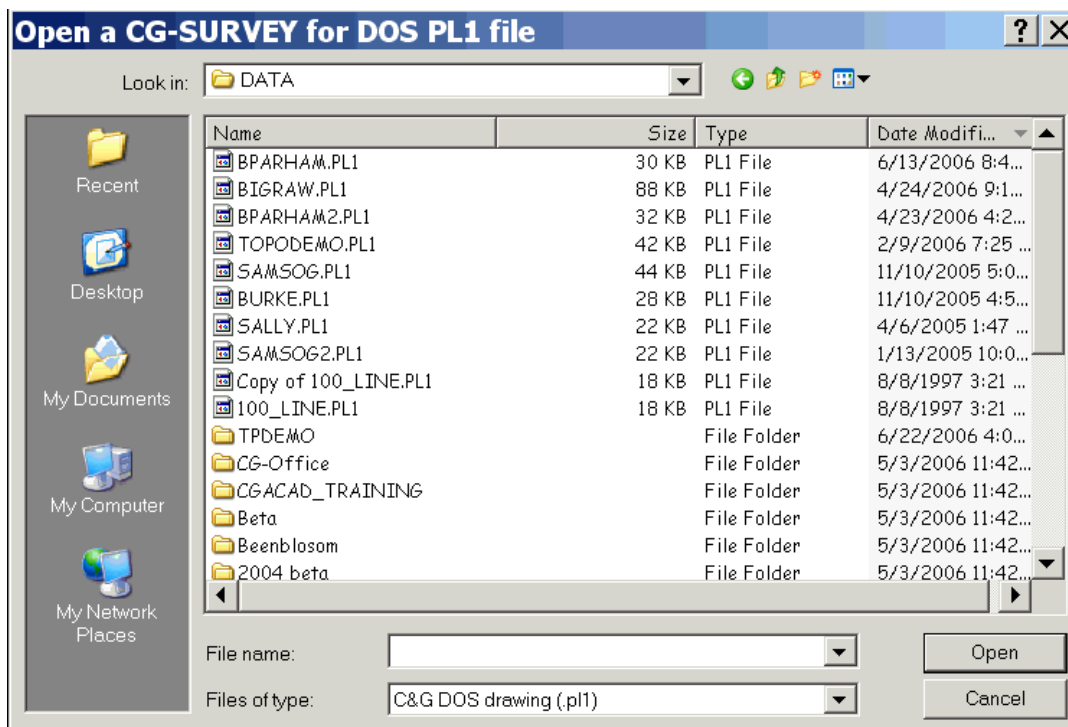

Prerequisite: CGDos Drawings>Setup

Open Dos Drawing

If the current drawing file you are in has any graphics the following dialog box will appear. This is meant to prevent you accidentally placing the PL1 drawing on top of another existing drawing file.

Selecting will bring up the following dialog box that will allow you to select the PL1 file to be converted to a standard CAD drawing.

After selecting the file to be converted, if you look at the command line you will see that the program is going through the PL1 file and converting the drawing entities one at a time to make them conform to the C&G format. This means all of the C&G data is maintained so the new drawing is still linked to the coordinate file it was created from. Also during this conversion process any of the CGDOS *.INS files (inserts) will be converted to standard CAD blocks and be added to the CG list of available inserts. Meaning all of the inserts you were accustomed to using in the CGDOS product will now be a part of the CG Survey program.

Prompts

Select a *.PL1 drawing file from browse file dialog box: Select file & click on OPEN button

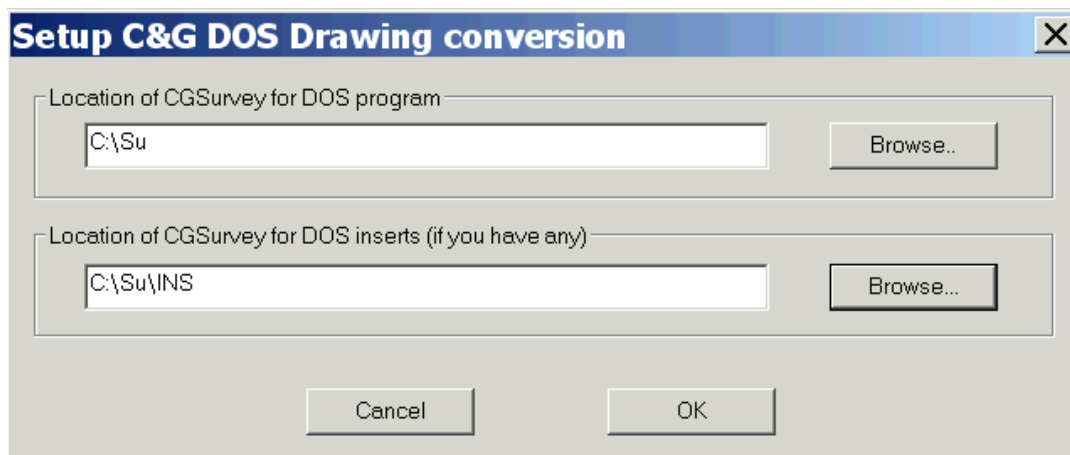

Pulldown Menu Location: CG-Survey > File

Keyboard Command: None

Prerequisite: CG-Survey > File > CGDos Drawings>Setup completed properly

Setup DOS Dwg

The first dialog asks you to give the path to the CGDOS Program Files and the path to CGDOS Inserts.

When this is set properly, any Insert used in the DOS PL1 file will be converted to a block and stored in the C&G symbols folder. These inserts will also be listed in the insert library when you go to: CGDraw > Drawing Settings > Active Symbol NOTE: Currently those inserts converted from the CGDOS PL1 files will not be shown graphically in the CGSurvey Active Point Symbol dialog box but they will appear in the symbols list and thus can be selected for use from the list.

Prompts

Select a Location for CGsurvey Program from browse file dialog box: Pick Browse button

Select a Location for Insert files from browse file dialog box: Pick Browse button

Pulldown Menu Location: CG-Survey > File

Keyboard Command: None

Prerequisite: None

Convert Old CG Dos Level File to New Format

This option converts old C&G DOS level files (files with a .LEV extension) to the new CGSurvey level file format (files with a .LEV extension).

Prompts

Select CGFile from the main menu.

Select Convert Old C&G DOS Level File to new Format from the pull-down menu.

From the file dialog box, select the file to convert:

Click the OPEN button to convert the file.

Pulldown Menu Location: CG-Survey > File

Keyboard Command: CVL, CG_CONVERT_DOS_LEVEL_FILE

Prerequisite: None

Convert Old CG Dos Raw File to New format

This option converts old C&G DOS raw files (files with a .RAW extension) to the new CGSurvey raw file format (files with a .CGR extension).

Prompts

Select CGFile from the menu bar.

Select Convert old C&G Raw File to new format from the pull-down menu.

From the file dialogue box, select the file to convert:

Click the OPEN button to convert the file.

Pulldown Menu Location: CGFILE

Keyboard Command: CVR, *CG_CONVERT_RAW

Prerequisite: None

Convert Old CG Dos Cross Section File to New Format

This option converts old C&G DOS Cross Section files (files with a .EW extension) to the new CGSurvey earthwork files format (files with a .CEW extension).

Prompts

Select CGFile from the menu bar.

Select Convert Old C&G Cross Section File to new format from the pull-down menu.

From the file dialog box, select the file to convert: Click the OPEN button to convert the file.

Pulldown Menu Location: CG-Survey > File

Keyboard Command: CVX, CG_EW_CONVERT_FILE

Prerequisite: None

Convert Old CG Dos Template File to New Format

This option converts old C&G DOS Template files (files with a .TPL extension) to the new CGSurvey earthwork files format (files with a .CTP extension).

Prompts

Select CGFile from the menu bar.

Select Convert Old C&G Cross Section File to new format from the pull-down menu.

From the file dialog box, select the file to convert:

Click the OPEN button to convert the file.

Pulldown Menu Location: CG-Survey > File

Keyboard Command: CVT, CG_EW_CONVERT_TEMPS

Prerequisite: None

Empty Print File

Choosing this menu item will remove all the text now in your print file.

You should empty the print file periodically so that it does not use too much of your disk space and become difficult to view and print.

Note: If user wishes to change the Printer.Txt file name or choose a different location. see CG-Survey > CG Options... - Output Tab

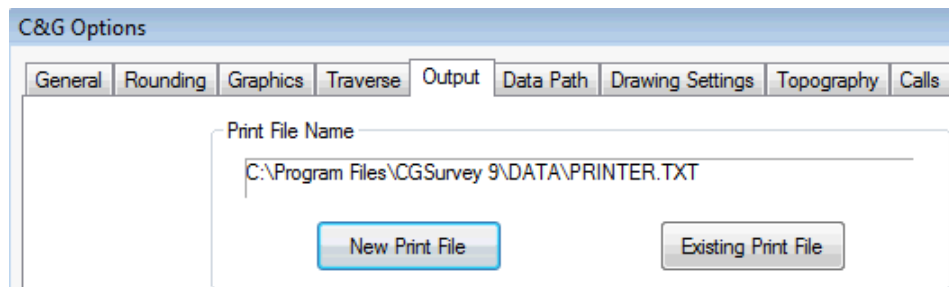

Pulldown menu Location: CG-Survey > File

Keyboard Command:EPF, cg_df

Prerequisite: Set print file name and path in CG-Survey > CG Options... - Output Tab

Print View Print File

While computations are taking place a Print File is being maintained showing all computations. This file is saved in the text file specified in the Output Options dialog box below

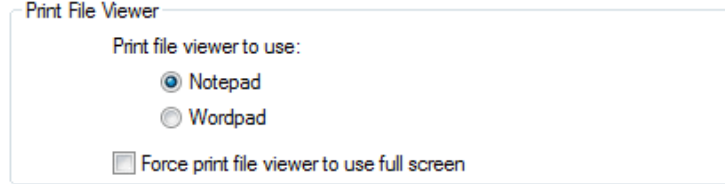

This text file may be edited, printed or viewed from any text editor or any word processor. (Note: For further explanation on Output Printing Settings please consult CGTools Menu)

After choosing the Print/View Print File menu item, the print file will be opened using the Windows text editor WordPad. To print the whole file, use the printer icon or the Print menu item on the WordPad File menu. To print a portion of the print file, you must highlight the portion you wish to print, then choose File > Print. On the General tab of the Print dialog box click the Selection radio button then click the Print button to print the highlighted text.

NOTE: Print Preview is also available on the WordPad File menu.

You can choose whether to use the Windows Notepad or Wordpad to view and print the print file by going to the CG-Survey > CG Options... menu and clicking the Output tab then clicking on either the Notepad or Wordpad radio buttons in the Print File Viewer section of the dialog (shown below).

Pulldown menu Location: CG-Survey > File

Keyboard Command:VPF, CG_VIEW_PRINT_FILE

Prerequisite: Set print file name and path in CG-Survey > CGOptions... - Output Tab

CGTrav

Quick Traverse

This feature allows you to utilize the keyboard and the mouse to perform a traverse using points and data found in the drawing and the coordinate file. There is no raw data entry associated with Quick Traverse. The Quick Traverse feature has no ability to adjust the resulting traverse. If you wish to adjust coordinates, you could create a raw data file using the CGEditor - on the CGTrav menu - then use the Reduce Traverse feature, also on the CGTrav menu.

NOTE: If you wish to check the closure of a plat from bearing and distance data, use the CGEditor to create a map check file, then use the Reduce Map Check File feature on the CGTrav menu.

Prompts

During the process of entering data for the Quick Traverse feature you will see the prompt:

[aZimuth/Bearing/Deflection/Side shot/cUrve/Closure/horiz. distaNces]

At this prompt you may:

Change the type of angular input between Horizontal Angle, Azimuth and Bearing modes at any time.

Change how distances are specified as either slope distance and vertical angle or horizontal distance and vertical distance.

Turn the vertical angle input on or off.

Traverse around tangent and non-tangent curves.

Switch from Traverse to Side shot mode.

Traverse mode: automatically occupy the foresight point.

Side shot mode: continue to occupy the current instrument point until you change to

Traverse mode: and thus occupy another point.

Note: There are several settings found in the C&G Options dialog box that should be set or checked prior using the Quick Traverse feature:

The default values for the initial traverse input modes are set in the Traverse Options.

If you wish to calculate or enter elevations, check the **Elevations** : ON checkbox and choose Enter Elev. Or Calculate Elev. as desired in the Global Options tab. If you are calculating elevations, make sure the Vertical Angles ON checkbox is checked on the Traverse Options tab.

Quick Traverse Example

In this example the mode is set to traverse and elevations are on and are to be calculated.

After choosing Quick Traverse from the CGTrav menu you will be asked to enter the following information:

Instrument point: for the example enter 1 (assuming that the currently open coordinate file has a point in it with a point ID of 1).

Backsight point: for the example enter 2.

[aZimuth/Bearing/Deflection/Side shot/cUrve/Closure/slope distaNces.]
Enter horizontal angle <0.0000>:

Since elevations are on and set to calculate so you will be prompted for the following:

If you selected H.I. as Plus-Up on the Traverse Options tab, the coordinates and elevation of the instrument point will be read from the file and you will be prompted for the instrument height (H.I).

If no elevation is found, you will be prompted to enter the ground elevation at the instrument point and then the H.I.

If you selected H.I. as Elevation in the Traverse Options dialog box, you will be asked to enter the actual elevation of the instrument scope.

Backsight Point: If you are turning angles or deflection angles instead you will be prompted for the back-sight point.

Rod Height: With Calculate Elevations on you are prompted to enter the prism height.
You will be prompted for the horizontal angle (or deflection angle)

If you need to change the prism height <esc> and you will be prompted for a new prism height, if you <esc> again you will be prompted for a new instrument point.

Angle data entry

Instrument point: 1

Back site: 2

aZimuth/Bearing/Deflection/Side shot/cUrve/Closure/slope distaNce.] S

Enter horizontal angle <0.0000>:

When you are entering Quick Traverse data you have the options to change the angular input method. To change the angular input mode, enter the upper case letter seen in the prompt for the method of entry you want to change to and press <Enter>. The prompt should then change to reflect your choice.

Note: You need not use the shift and type a capital letter to choose a command line option. For example, to change to Side shot mode you can type either s or S.

The method that is currently set will not be shown as an option in the command line prompts. For example,

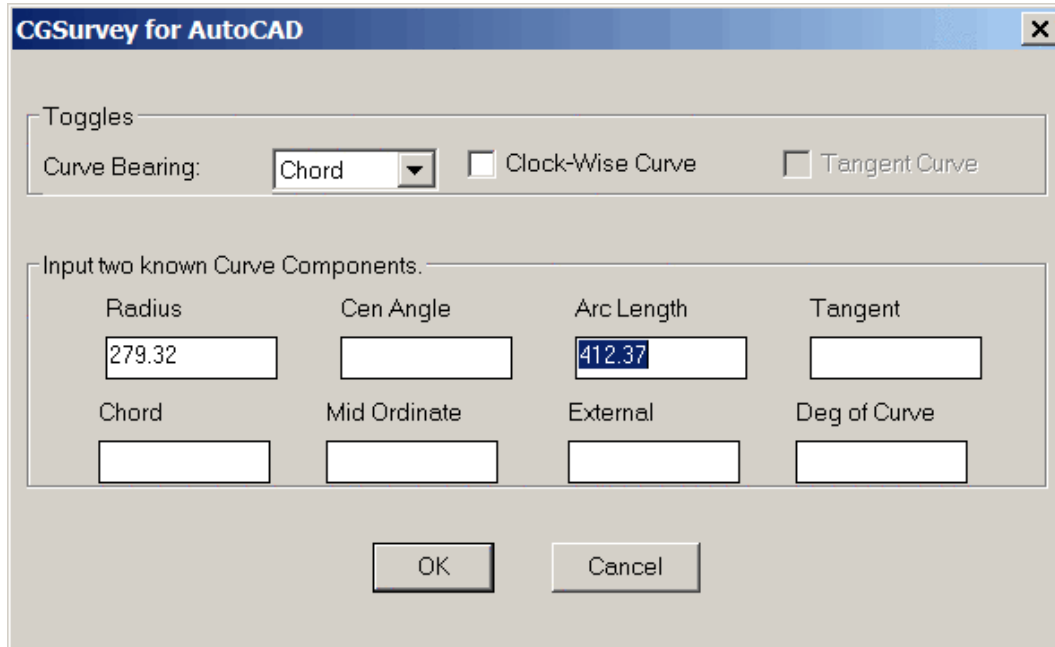

if you type s and <Enter> for Side shot mode, the prompt will change to include Traverse and Side shot will no longer be available since you have chosen it as the current mode.

Traversing a curve

The Traverse routine allows you to traverse both reverse and compound curves.

Note: You will not be allowed to traverse around a curve if calculate elevation is selected.

If you type U and <Enter> for cUrve, the following dialog box appears: U

The dialog box is titled "CGSurvey for AutoCAD" and contains the following elements:

- Toggles:**
 - Curve Bearing: Chord (dropdown menu)
 - Clock-Wise Curve
 - Tangent Curve
- Input two known Curve Components:**

Radius	Cent Angle	Arc Length	Tangent
279.32		412.37	
Chord	Mid Ordinate	External	Deg of Curve
- Buttons:** OK, Cancel

Enter any two of the curve components.

Identify the curve bearing as Chord if the angle, deflection, bearing or azimuth about to be entered is to the PT.

Identify the curve bearing as Radius if the angle, deflection, bearing or azimuth about to be entered is to the radius point.

Click the Clockwise box if the curve is clockwise. If this box is not checked, the curve is considered to be counterclockwise.

If there is a previous traverse leg, check the Tangent Curve checkbox if the curve is tangent to the previous leg. If this checkbox is not checked, the curve is assumed to be non-tangent.

When you have entered the required data: click the OK button.

The input multiplication factor is applied to the curve data you enter (radius, arc length, chord, etc.).

At the next prompt, if the curve is a non-tangent curve, enter the angle, deflection, bearing or azimuth from either the PC to the PT or the PC to the radius point (depending on whether you set Curve Bearing to Chord or Radius). If the curve is tangent to the previous traverse line you will not be asked for the angle and distance.

The curve data will be calculated and shown at the command line:

Bearing and distance from the PC point to the radius point.

Bearing and distance from the radius point to the PT point.

Bearing and distance from the PC point to the PT point.

Other curve information.

The radius and PT points will be stored in coordinate file using the STORING POINT prompt.

Closure

At the prompt: aZimuth/Bearing/Deflection/Side shot/cUrve/Closure/slope distaNce.]

Enter horizontal angle <0.0000>:

Type C and <Enter> to view closure information for the traverse to the current foresight.

Slope/Horizontal Distance Data Entry

If you have selected Slope Dist/Vert. Angle in the Traverse Options tab or switched to slope distances by typing N and <Enter> at the command line, enter the slope distance. Otherwise, enter the horizontal distance.

Note: The following steps are required only if Vertical Angles ON is checked on the Traverse Options tab or if Calculate Elev. was selected on the Global Settings tab.

For slope distance - vertical angle:

Enter the vertical angle.

Depending on the settings in the Traverse Options tab enter one of the following:

Zenith (zero up)

Nadir (zero down)

Transit (zero level)

Transit vertical angles can be full circle (0 - 360), or positive for up and negative for down.

For horizontal distance - vertical distance:

Enter the vertical distance.

Pulldown Menu Location: CGTrav

Keyboard Command: QTR, CG_QTRAV

Prerequisite: Open Coordinate File

Edit Raw File

The Edit Raw File feature allows you to use the CGEditor to create a new raw data file, append to an existing raw data file, or edit an existing raw data file. For further and complete information on using the Edit Raw File see the chapter on CGEditor in the Tools section.

CGEditor General Information

The CGEditor is an integral part of preparing files for use in C&G applications. The CGEditor is a very powerful tool. You can open multiple data files of any supported file type and edit the files as needed. The CGEditor has a full complement of tools for searching and replacing and navigating within a file. It will also allow you to cut or copy records from one file and paste them into another file in order to merge files, move data between phases of a job, etc.

The CGEditor can create and/or edit six types of data files used by C&G:

Raw Data Files

Raw data files contain information pertaining to a field traverse. Raw data files are typically downloaded from the data collector and converted to the C&G raw data file format. These files have the extension .CGR.

Map Check Files

Map Check files contain bearing, distance and curve information and are typically used to calculate the closure of a deed description. These files have the extension .CGM.

Cross Section Files

Cross Section files contain one or more cross sections identified by their station along the alignment. Each cross section record has the percent grade defined for its left and right slopes. Following the "Station" record are several "Point" records containing the elevations and offsets of the points along the cross section. Cross section files consist of a pair of files; the main data file has the extension .CEW and the index file has the extension .CEX.

Template Files

Template files are merely cross section files that represent a standard cross section and can be used to generate other cross section files. However, unlike cross section files, template files use an integer ID instead of a station to uniquely identify each template. Like cross section files, the percent grade is defined for the left and right slopes of each template and there are a set of "Point" records specifying the template elevation at a given offset. The centerline elevation at offset 0.00 is typically set to 0.00. Template files consist of a pair of files; the main data file has the extension .CTP and the index file has the extension .CTX.

Point Group Files

Point Group Files (formerly called batch point files) are simply a list of point numbers that can define a group of points, a lot/parcel of land, or an alignment. These are ASCII files and have a .PTS extension.

Coordinate Files

CGSurvey supports many different coordinate file formats:

C&G .CRD/.IDX - C&G numeric coordinate files

C&G .CGC/.CGX - C&G alpha-numeric coordinate files

Carlson .CRD - Carlson coordinate file format, numeric and alpha-numeric

Simplicity .ZAK - Simplicity coordinate file

LDT - MDB - Land Desk Top coordinate file

Pulldown Menu Location: CGTrav\Edit Raw File

Keyboard Command: ET, CG_EDIT_RAW

Prerequisite: Open Raw File

Data Collector Transfer

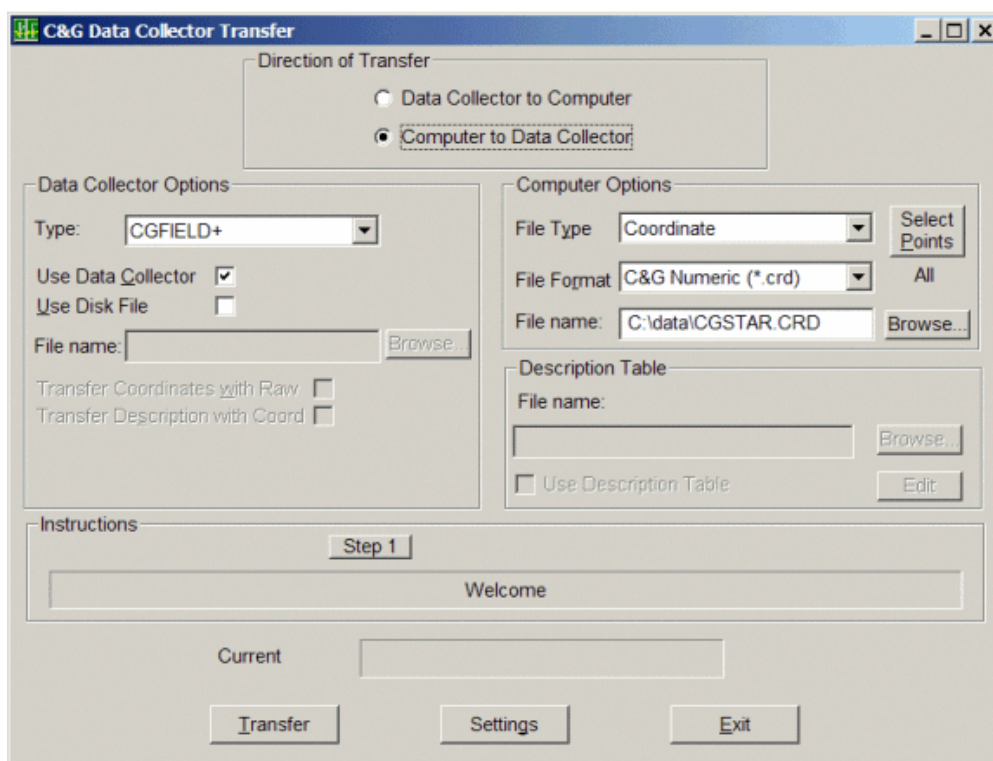

The Data Collector Transfer program allows transfer of data to and from the data collector. The program may also be used to convert raw data and coordinate files to the supported formats.

There are two variables that affect the interaction between your data collector and CGSurvey. One is the data collector itself and the other is the software you use in the data collector. This section provides information on the use of data collectors and software that will interact with CGSurvey.

NOTE: This manual is not a substitute for your data collector manual.

GENERAL INFORMATION ON USING DATA COLLECTORS

Before using the data collector program, make sure the correct data collector, communication port and communication parameters have been selected in the Settings dialog box.

Direction of Transfer:

Choose either "Data Collector to Computer" or "Computer to Data Collector".

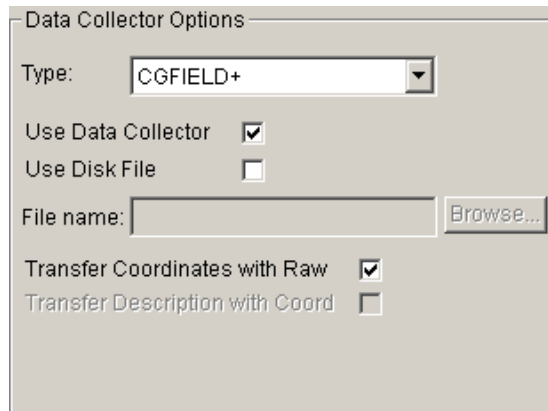

Data Collector and Computer Transfer Options

Instructions: Press the STEP 1 button. Depending on the type data collector, type file and direction of transfer, this option will give you step by step directions on how to proceed.

The Transfer dialog is divided into two sections, left and right. The left part of the dialog box pertains to "Data Collect Options" such as file source, file format and the file being transferred. The right part of the dialog box pertains to the Desk Top "Computer Options". Below are instructions for setting both.

Data Collector Options

Pressing the triangle to the right of the edit box will bring up the list of data collectors to choose. From the list select the type of data collector being used.

Use Data Collector:

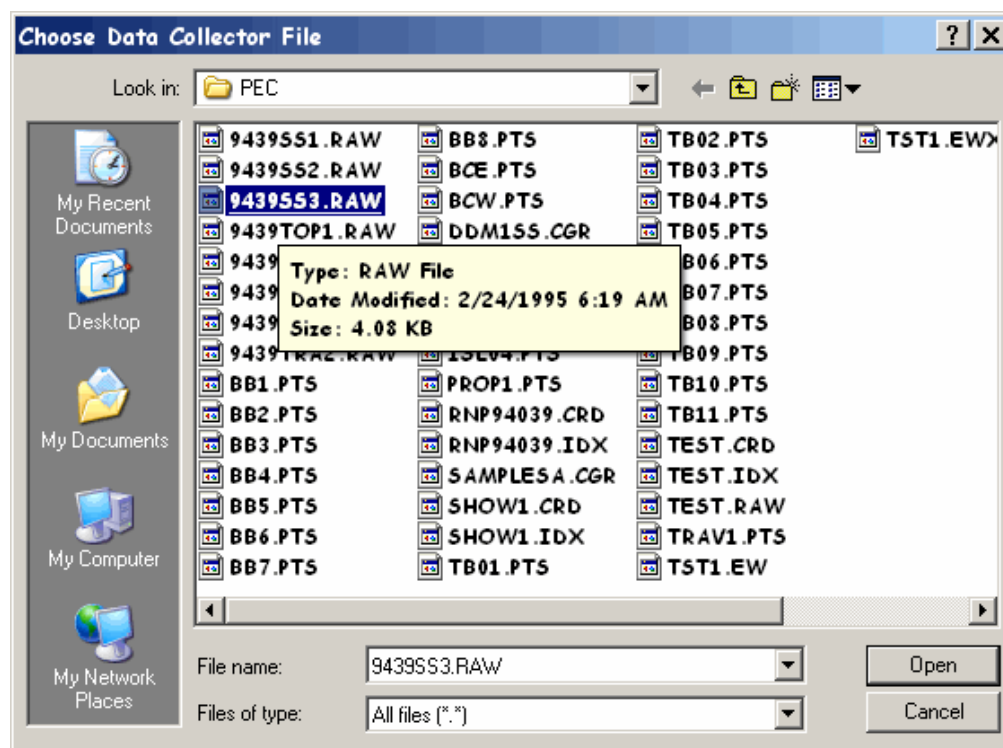

Check this box to transfer data to/from the data collector. You can also transfer to/from a file in the selected data collectors format.

Use Disk File:

Check this box if the data is in computer file. The data file must be formatted for the data collector selected.

File Name:

If you are importing from a file, or exporting to a file, or are connecting to a data collector that requires a file name for transfer, the File Name edit field will be active. To select the file path click on browse. In the file dialog box specify the path and file name of the file to be opened. select or enter the path and file name of the file desired file.

Transfer Coordinates with Raw:

Some field software allows unadjusted coordinates to be carried in the raw file as the field data is collected. This checkbox gives you the option to transfer this data or not. If you do not want approximate coordinates that were calculated in the field to be confused with control when processing the raw data, leave this box unchecked.

Computer Options

File type: Choose the file type you are transferring/converting. Example: Raw Data, Coordinate, ASCII, etc.

File Format: C&G will import and export several types of file formats for both Raw and Coordinate files.

Supported Raw Data File Formats:

New CGR *.cgr
 Old C&G *.raw
 OBS.....*.obs
 Geolab *.iob
 StarNet *.dat
 SDR2x *.dat
 SDR33 *.dat

Supported Coordinate File Formats:

C&G AlphaNumeric*.cgc / cgi
 C&G *.crd / idx
 Carlson AlphaNumeric *.crd
 Carlson Numeric *.crd
 ASCII *.nez
 ASCII *.asc
 Geolab *.neo
 StarNet..... *.pts
 SDR2x *.dat
 SDR33*.dat
 Simplicity..... *.zak
 LDT..... *.mdb

Description Table:

To use a description table check "Use Description Table" box.

You have the ability to use multiple description tables. Examples of that might be:

- State DOT
- Boundary
- As-Built
- Topography

Each of these could have different codes and descriptions and this option would allow you to choose which description table to use for the reduction of this file. To change the description table click the "Browse" button and select the TBL file.

Below is an example of a description table:

When using a description table, any INTEGER numbers in the description field of the data coming from the data collector will be replaced by the description in the table. For example, if your description is "13 5", the description put in the coordinate or raw data file will be "CL CMP".

Transfer

Instructions: The instructions window will guide you step by step through the transfer routine. It will tell you what to do on the data collector, and in what order.

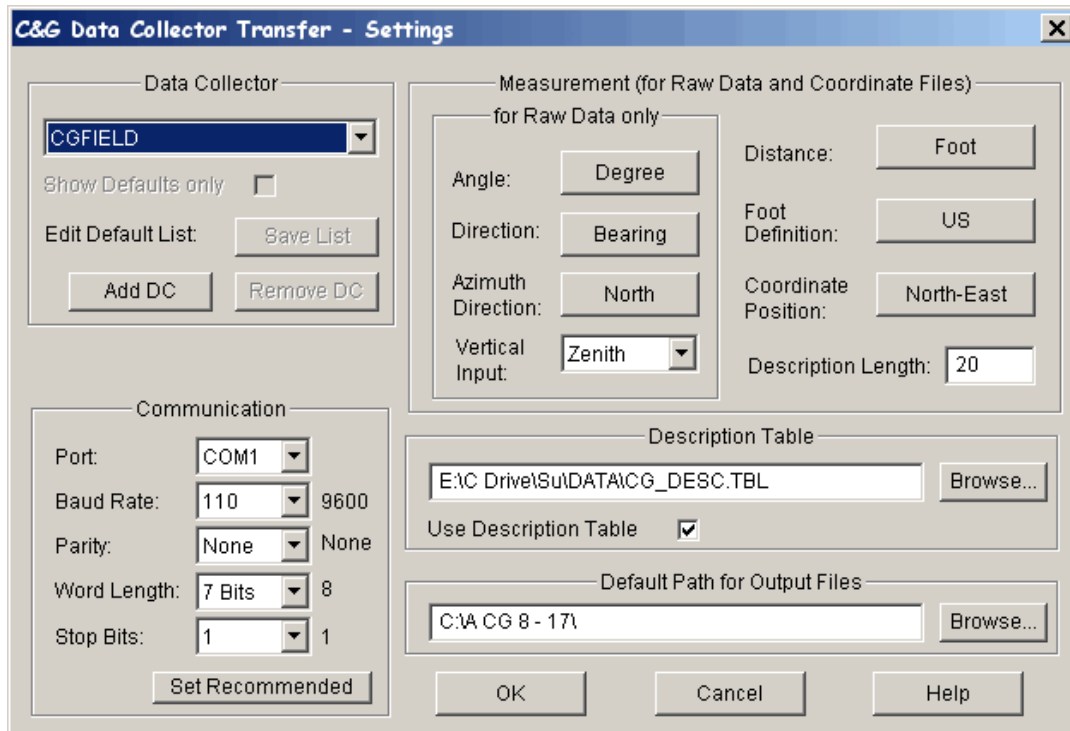

Transfer: Once all of the settings are set correct, clicking on the TRANSFER button will begin the transfer between the data collector/file and the desktop.

The **Current Status** window at the bottom of the Transfer Dialog will indicate the status of the transfer.

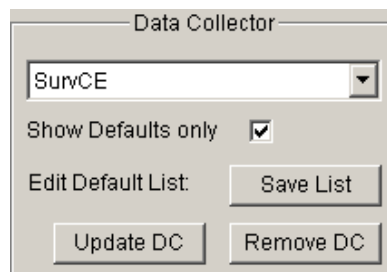

Settings

At the bottom middle of the main screen is the "Settings" button. The settings control communications, data units and output data path.

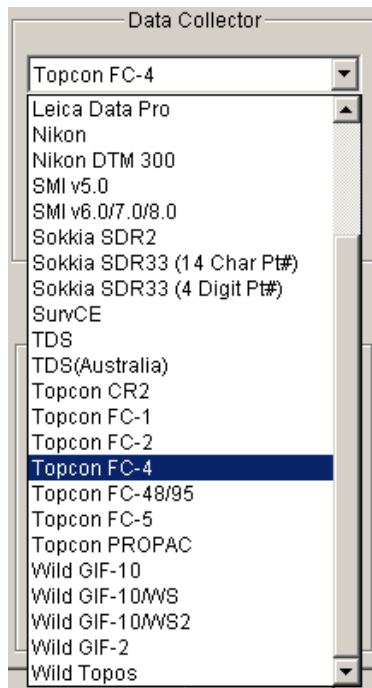

Data Collector

The Data Collector dialog box allows you to select a short-list of data collectors you are transferring to and/or from.

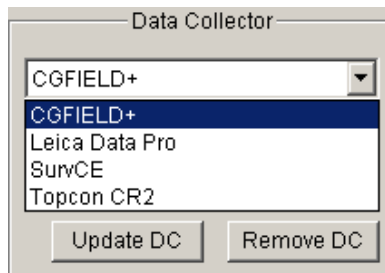

When you select the down button to the right of the data collector shown and the "Show Defaults only" box is unchecked, you will see the complete list of all the data collectors that C&G interfaces with.

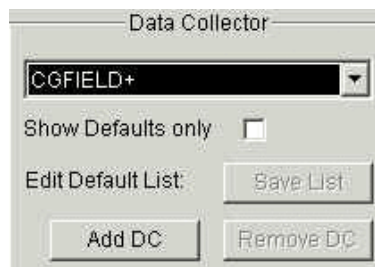

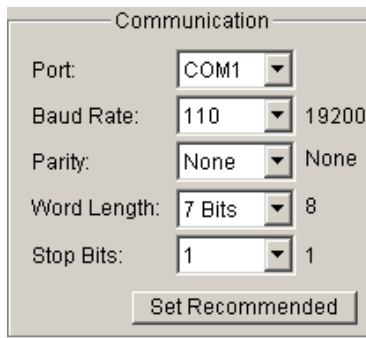

You also can create a Default List, This default list should consist of the various data collectors your company may have and/or interface with on a daily basis.

You can use the Show Defaults only check box to limit the data collectors which may be selected from the Data Collector list on the main Data Collector Transfer Screen. If this box is checked, only those data collectors you have specified for the default list will be show.

To add a data collector to the default data collector list:

First make sure the Show Defaults only box is unchecked. Next Select a data collector from the list by scrolling up and down the list using the arrow keys. When the new data collector is selected, make sure the communication parameters are correct to the data collector. Once the settings are correct, click Add DC button Now click the Save List to save the changes to the list.

When through setting all of the typical data collectors you may use, check the Show defaults only check box and only those instruments and settings will be displayed for your selection.

To remove a data collector from the default list:

Make sure the Show Defaults only is checked.

Highlight the data collector you which to remove from list

Click on the Remove DC

Click on the Save List button

Chose OK and verify that the data collector is no longer in the default listing.

Communications

The Communication box allows you to set the following parameters:

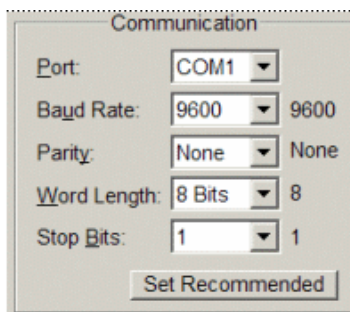

Port

Baud rate

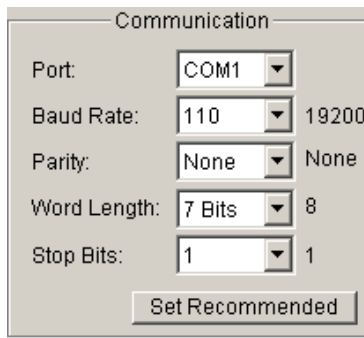

Parity

Word length

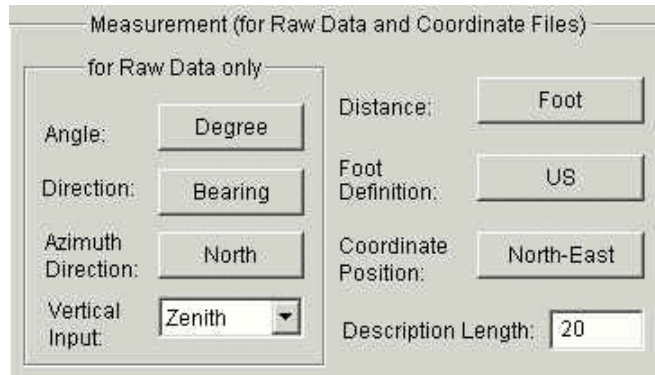

Stop bits

When a data collector is selected, C&G reads a list of default settings and compares it to the settings currently shown. If the current settings are different than those recommended the defaults will be displayed and a Set Recommended button will be displayed. This allows you to automatically set the recommended communication parameters for your data collector.

The **Measurement** portion of the Settings dialog box pertains to the units of Raw and Coordinate data input.

- Angle Mode..... Degrees or Grads
- Direction Mode..... Bearing or Azimuth
- Azimuth Direction:..... North or South
- Vertical Input..... Zenith, Nadir or Horizontal
- Distance.....Foot or Meter
- Foot Definition..... U.S. or International
- Coordinate Position..... North-East or East-North
- Description Length..... 1 to 100 characters

The **Description Table** portion of the Settings dialog allows you to select the default description table.

As mentioned earlier you can have multiple description tables, here is where you would select the description table to use.

The Use Description Table option, when checked , will replace any integer description found in the raw data file with corresponding description found on the description table. When this check box is not checked data will be transferred without translation.

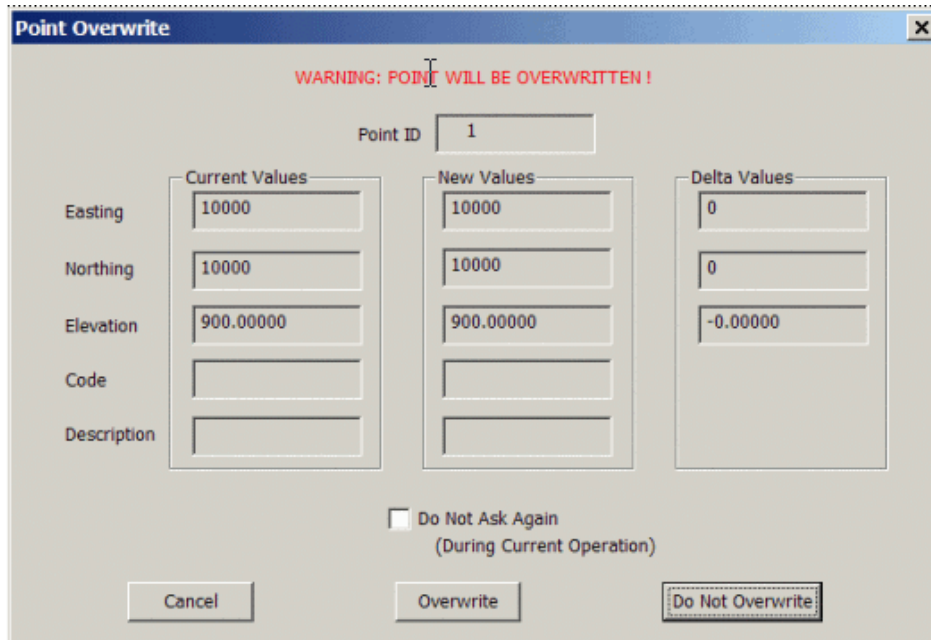

Default Path for Output Files

Allows you to set the default location for storing transferred files

Allows you to set the

Receiving Coordinates from Data Collectors:

There is a point protection feature in place when bring coordinates into an existing coordinate file from a data collector. If the point already exists, and if the coordinate values are different, you will see the following dialog box.

The image shows a 'Point Overwrite' dialog box with a warning message: 'WARNING: POINT WILL BE OVERWRITTEN!'. The dialog box contains a 'Point ID' field with the value '1'. Below this, there are three columns of input fields: 'Current Values', 'New Values', and 'Delta Values'. The 'Current Values' column has fields for Easting (10000), Northing (10000), Elevation (900.00000), Code, and Description. The 'New Values' column has fields for Easting (10000), Northing (10000), Elevation (900.00000), Code, and Description. The 'Delta Values' column has fields for Easting (0), Northing (0), and Elevation (-0.00000). At the bottom of the dialog box, there is a checkbox labeled 'Do Not Ask Again (During Current Operation)' which is currently unchecked. Below the checkbox are three buttons: 'Cancel', 'Overwrite', and 'Do Not Overwrite'.

You will have the following options:

Overwrite: overwrite existing point

Do Not Overwrite: skip point

Overwrite, Do Not Ask Again: Overwrite all existing points

Do Not Overwrite, Do Not Ask again: Bring in only new points

Transfer Options

Depending on the type of data collector that you are using, you will be able to perform some of the following functions:

- Receive raw data from the data collector or file.
- Send raw data to the data collector or file.
- Receive coordinates from the data collector or file.
- Send coordinates to the data collector or file.
- Send a program to the data collector.
- Execute a program on the data collector.
- Delete files on data collector
- View and/or Select files on data collector
- Format data area on the data collector

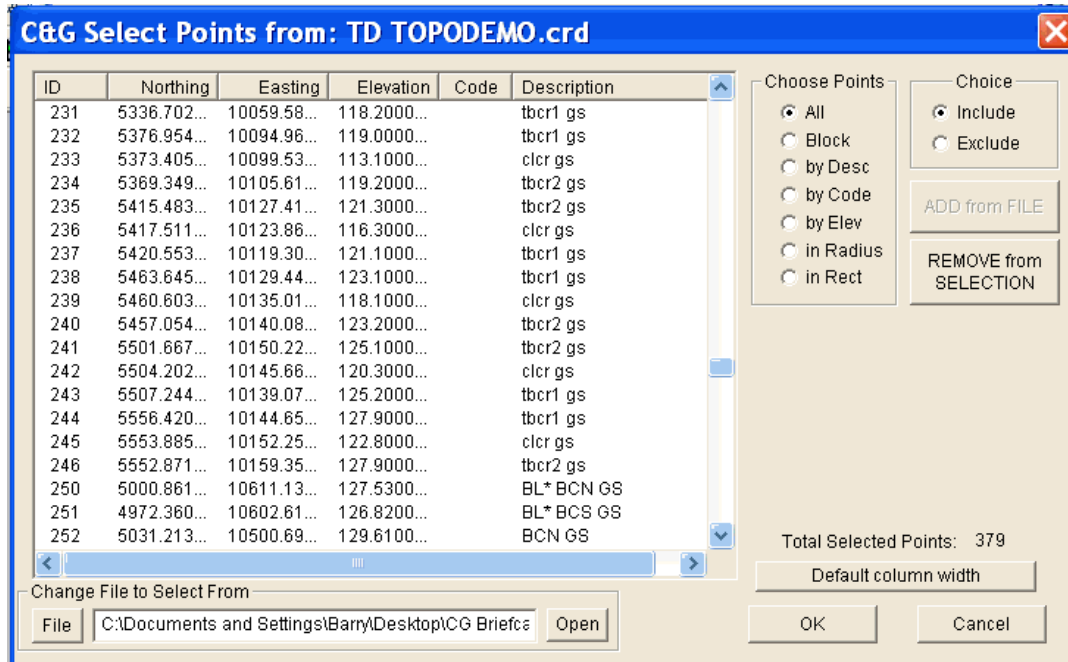

As data is received from a particular data collector or file, it is converted to a .CGR or .CRD file (or other supported format).

Data that is sent to the data collector is converted from the .CGR or .CRD format to the data collector format.

When data is received from a data collector, a read-only file in the data collectors native format is created and stored on the computer. If it is a raw data file, it has a .R\$\$ extension. If it is a coordinate file, it has a .C\$\$ extension.

Select Points

When transferring coordinates to the data collector you may choose which points are to be transferred. The default is ALL points. When you click on the Select Points button the following dialog box comes up.

Change file select from: Click the file button to select the coordinate file that you want transfer coordinates

from. **Choose Points:** This option allows you to select groups of points to be included from the file you have opened, using the C&G selection options.

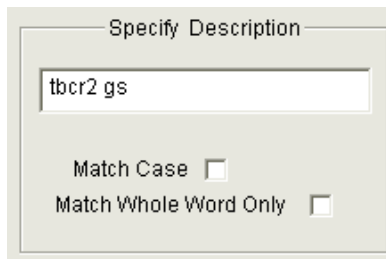

All Points: All Points in the file will be selected.

Block: select blocks of Points.

Desc: select points by their description.

Specify Description

tbcr2 gs

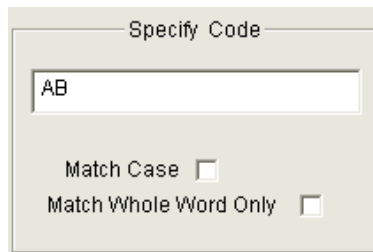

Match Case

Match Whole Word Only

Match Case: Case sensitive compare.

Match Whole Word Only: If your description is BOC this box is NOT checked, points with the descriptions BOC, BOC1, BOC2, etc. would all be included. If the box were checked, only points with the description BOC would be included.

Code: select points by Code

Specify Code

AB

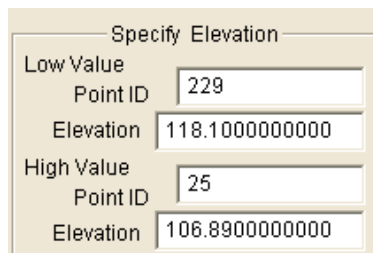

Match Case

Match Whole Word Only

Match Case: Match the case of the text

Match Whole Word Only: If checked, in the above example, only AB would be selected. Descriptions of AB1, ABC and ABB would not.

Elevation: select points by elevation

Specify Elevation

Low Value

Point ID

Elevation

High Value

Point ID

Elevation

Low Value:

Point ID: Point Number

Elevation: elevation at point

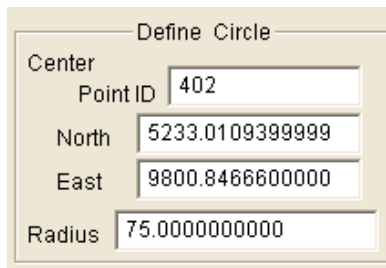

High Value:

Point ID: Point Number

Elevation: elevation at point

If a point number is entered in the point ID box the elevation for that point will be used for either the high or low elevation. You may however enter an elevation only.

In Radius: select all the points within a given radius.

Define Circle

Center
Point ID

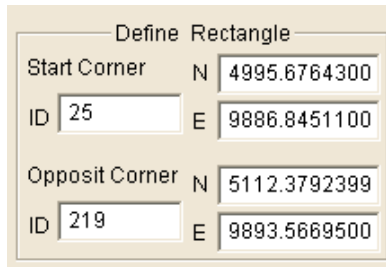

North

East

Radius

If a point number is entered in the point ID box, the northing and easting of that point will be used for the center of the search circle. To manually enter a northing and easting, leave the Point ID box empty and enter the values for the northing and easting of the circle. Enter the radius for the search circle.

In Rectangle: Select all the points within a given rectangle.

Define Rectangle

Start Corner N

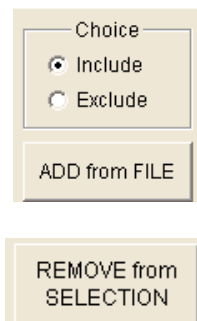

ID E

Opposit Corner N

ID E

If a point number is entered in the point ID box, the northing and easting of that point will be used for that corner of the rectangle. To manually enter a northing and easting, leave the Point ID box empty and the northing and easting values. The two points defined the diagonal corners of the rectangle.

Choice: This option allows you to choose to include or exclude points previously in the C&G select point dialog box. Example:

Choice

Include

Exclude

ADD from FILE

REMOVE from SELECTION

In the choose points dialog box: select by Desc

Then type: GS as the description

in the choice dialog box: select Exclude

Any point that has "GS" in the description field will be removed from the selection set.

Total selected Points: the total number of points selected is shown in the lower right hand corner of the dialog box.

Default Column Width: The columns have a default width. If you have changed the width of a column, say NOTHING, you may press this button to go back to the default widths.

The remainder of this section discusses specific data collectors and software.

CG-Field & FieldPlus Data Collectors

Establish a connection between the data collector and desktop computer with a standard 9-Pin serial cable, USB cable, Bluetooth, etc. Check the settings as shown above.

Download a Description Table

You can transfer the desktop description table directly to the CG-FieldPlus data collector. The table will be placed in the data collector's DC_DESC.TBL file. CG-Field will let you use codes without a description table. Simply delete the DC.CODES file from the data collector and use the code numbers to enter descriptions. When you transfer the file to the desk top, the codes will automatically be replaced with the appropriate description. (This allows you to combine codes.) For example, if you enter [1 20 30], in the description field on the data collector when the transfer takes place these numbers will be read from the desk top description table and converted to the corresponding description, such as [BL* TC SW].

Receiving Raw Data from CG-Field

NOTE: When uploading raw data from a data collector using CG-FieldPlus , a read-only file in the original CG-Field format is created on the computer (in the data directory) with a .R\$\$ extension.

On the desk top data collection transfer dialog box, set the following:

Set transfer method to Data Collector to Computer.

Data Collector Type; CGFIELD+

Use Data Collector:

Transfer Coordinates with raw: -yes or no (your choice)

File Type: Raw Data

File Format: C&G (*.cgr)

File Name: enter the path and name where the file is to be stored or click on the "Browse" button and select the path.

Description Table: enter the path where the Description Table is stored or click on the "Browse" button and select the path

Select Transfer when all settings are correct.

On the data collector Utils menu, select:

1:C&G Transfer

2:Send Raw Data

Enter or select the raw data file

The file will be transferred.

NOTE:CG-Field uses only 2-character point codes. If you have CGSurvey set for 4-character point codes, the CG-Field file will be converted to a 4-character format but it will still have the correct 2-character code. If you download the same file back to the data collector, the downloaded file will be correct if you did not add any codes that actually consist of 4 characters.

Receiving Coordinate File from CG-Field

On the desk top data collection transfer dialog box, set the following:

Transfer Data Collector to Computer

Data Collector:CGFIELD+

Use Data Collector:**File Type:** Coordinate**File Format:** C&G (*.crd) or C&G (*.cgc)**File Name:** enter the path where the file is to be stored or click on the "Browse" button and select the path.**Description Table:** enter the path where the Description Table is stored or click on the "Browse" button and select the path**Press Transfer when all settings are correct.****On the data collector Utils menu, select:****1:C&G Transfer****3:Send Coords****Select Points****All points****Blocks of points****From points file****The file will be transferred.**

NOTE: In any transfer routine it is important to prepare and have ready the device that will be receiving data first.

Sending Coordinate File to CG-Field

On the data collector Utils menu, select:

1:C&G Transfer**3:Receive Coords**

On the desk top data collection transfer dialog box, set the following:

Transfer: Computer TO Data Collector**Data Collector:** CGFIELD+**Use Data Collector:****File Type:** Coordinate**File Format:** C&G (*.crd) or C&G (*.cgc)**File Name:** enter the path where the file is to be stored or click on the "Browse" button and select the path.**Check the Select Points settings:**

This tool allows you to select what group or groups of coordinates are transferred to the data collector.

Press Transfer: when all settings are correct.

NOTE: You should not download a file containing a 4-character code to your data collector. You will be warned that the last 2 characters of the code will not be sent. This means that a code of 1584 will be received as 15.

Receiving ASCII File from CG-Field

On the desk top data collection transfer dialog box, set the following:

Transfer Data Collector to Computer**Data Collector:** CGFIELD+**Use Data Collector:****File Type:** ASCII**File Name:** enter the path where the file is to be stored or click on the "Browse" button and select the path.**Select Transfer when all settings are correct.**

On the data collector Utils menu, select:

1:C&G Transfer

6:Send ASCII
File Name With Extension
File:
Transfer Name:
*****.***
<Enter>

Sending ASCII File to CG-Field

On the data collector Utils menu, select:

1:C&G Transfer
5:Receive ASCII

On the desk top data collection transfer dialog box, set the following:

Transfer Computer to Data Collector

Data Collector: CGFIELD+

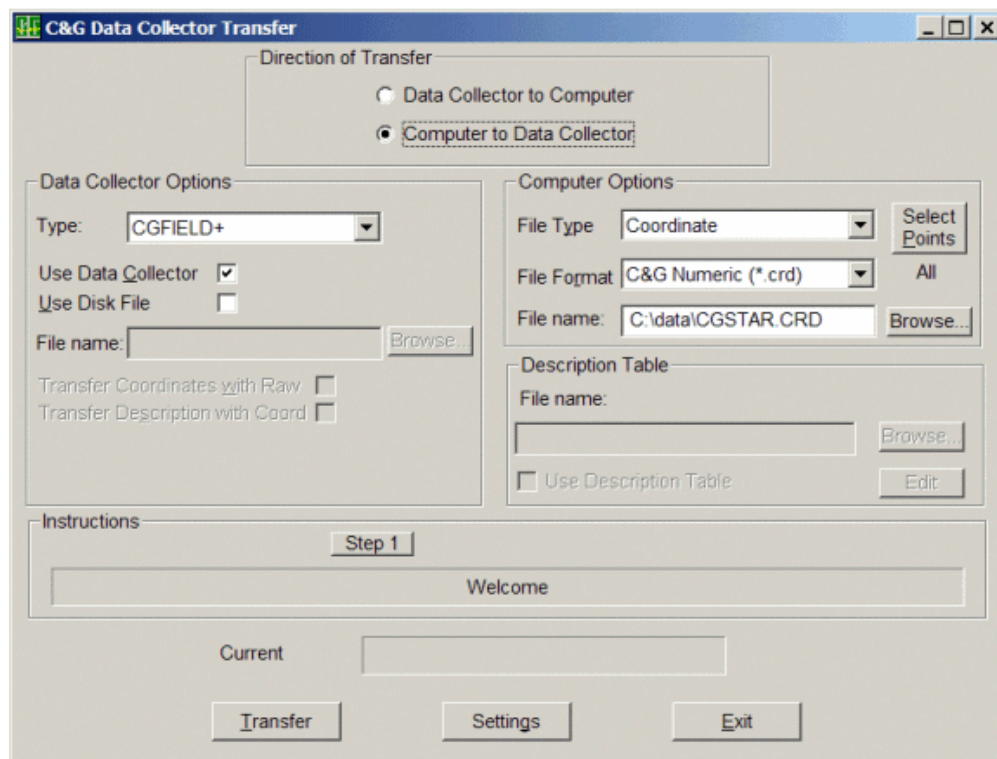

Use Data Collector:

File Type: ASCII

File Name: enter the path where the file is to be stored or click on the "Browse" button and select the path.

Select Transfer when all settings are correct.

The following are examples of typical data collection transfer settings. There will be cases with certain models or manufactures where special instructions will be required and C&G will provide those as needed.

There three different dialog boxes involved with data collection transfer:

C&G Data Collection Transfer (shown above)
Settings
Description Table Editor.

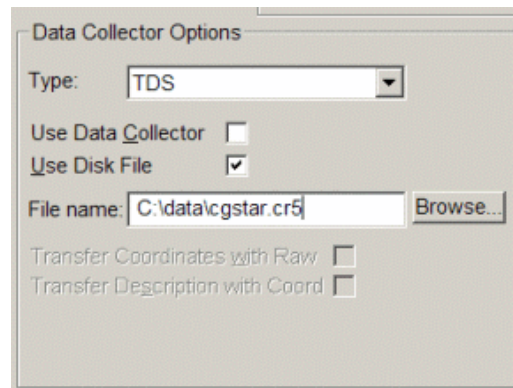

The function and settings for each of these is described in detail in the previous pages.

The examples shown on the following pages show transfers directly from and to data collectors. These same transfer routines will also work with files that have been downloaded to the desktop computer.

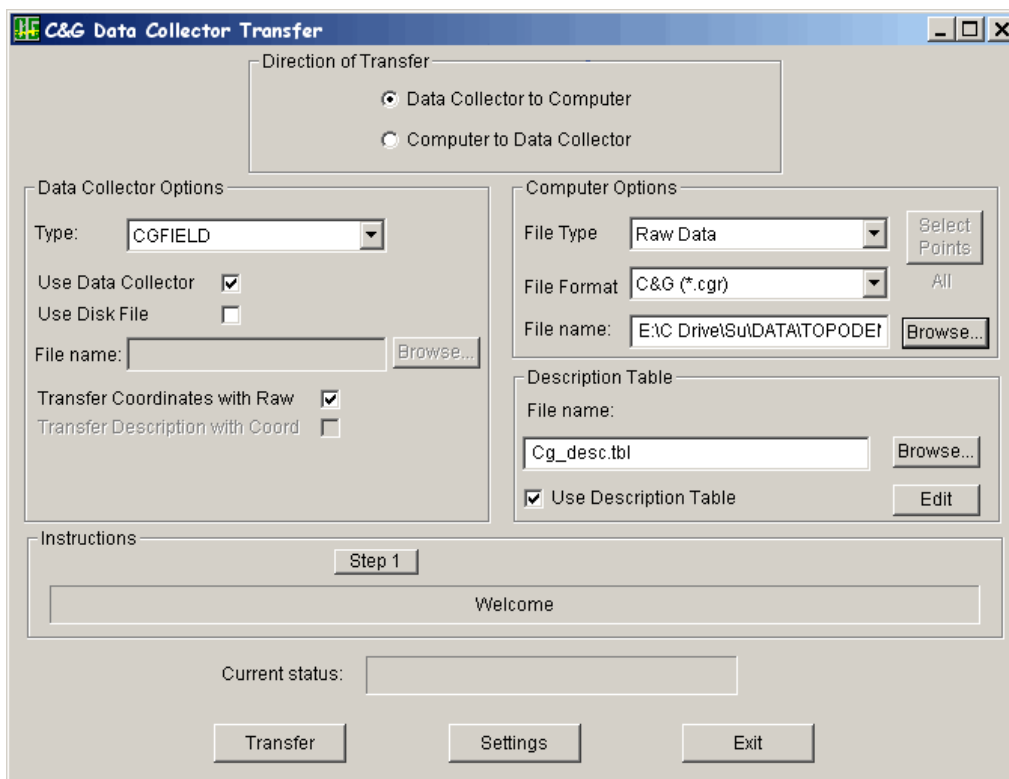

File Conversion Utility

To convert data from files check the Use Disc File box and either hand enter the path and name or click on "Browse" and search for the file location.

These files need to be in the correct data file format.

Receiving Raw Data

On the desk top data collection transfer dialog box, set the following:

Select Data Collector to Computer

Data Collector: (select data collector from list)

Check Use Data Collector:

Transfer Coordinates with raw: -yes or no (your choice)

File Type: Raw Data

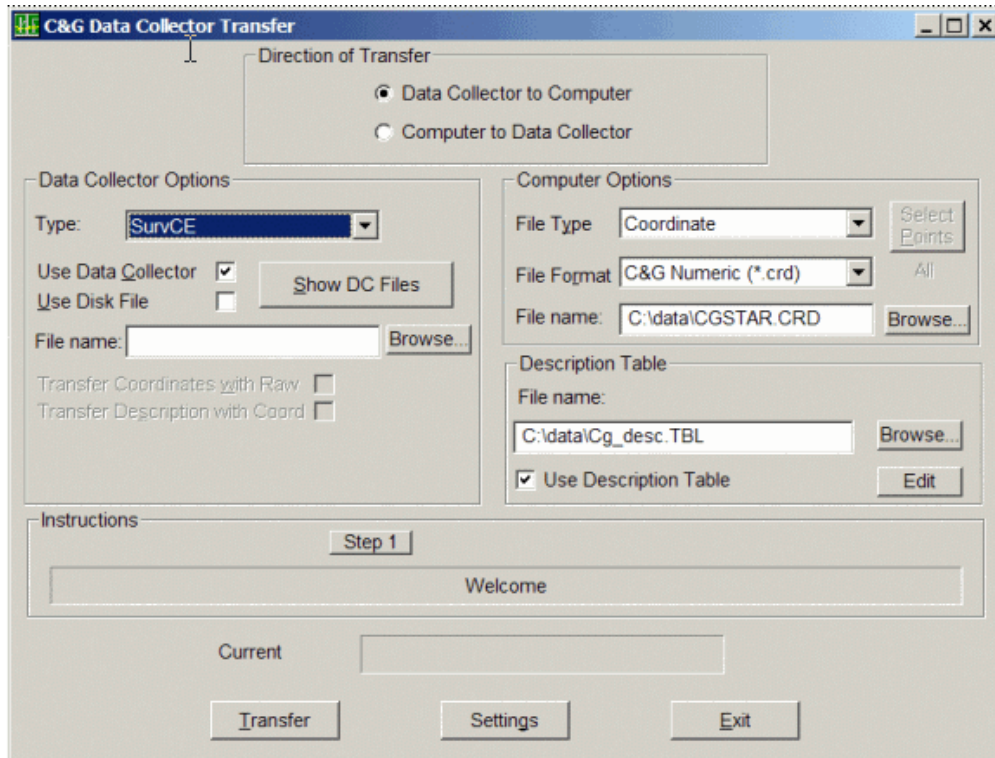

File Format: C&G (*.cgr)

File Name: enter the path where the file is to be stored or click on the "Browse" button and select the path.

Press Transfer: when all settings are correct.

Begin transfer from data collector

Receiving Coordinate Data

On the desk top data collection transfer dialog box, set the following:

Select Data Collector to Computer

Data Collector: (select data collector from list)

Use Data Collector:

File Type: Coordinate

File Format: C&G (*.crd) or C&G (*.cgc)

File: enter the path to store the file or click on the Browse button and select the path.

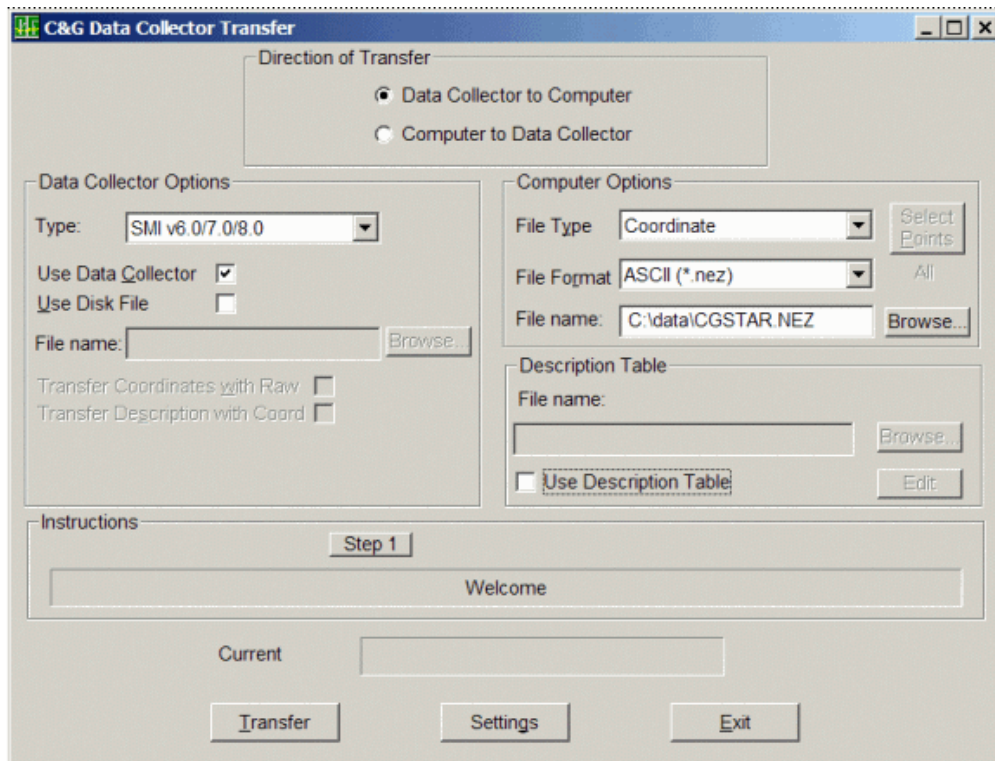

Description Table: enter the path where the Desc Table is located or click on the Browse button and select the path.

Press Transfer: when all settings are correct.

Begin transfer from data collector

NOTE: In any transfer routine it is important to prepare and have ready the device that will be receiving data first.

Receiving ASCII Data

On the desk top data collection transfer dialog box, set the following:

Select Data Collector to Computer

Data Collector: (select data collector from list)

Use Data Collector:

File Type: Coordinate

File Format: ASCII (*.nez)

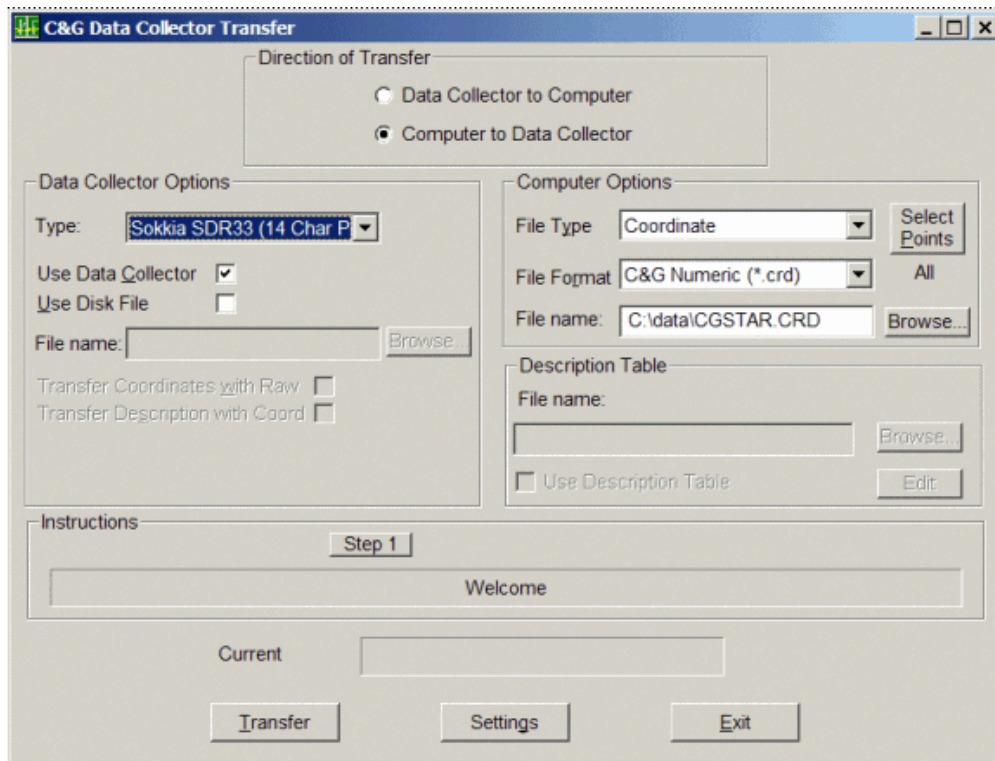

File: enter the path to store the file or click on the Browse button and select the path.

Description Table: enter the path where the Desc Table is stored or click on the File button and select the path.

Select Transfer: when all settings are correct.

Begin transfer from data collector

Sending Coordinate Data

Prepare Data collector to receive Coordinate file

On the desk top data collection transfer dialog box, set the following:

Select Computer to Data Collector

Data Collector: (select data collector from list)

Use Data Collector:

File Type: Coordinate

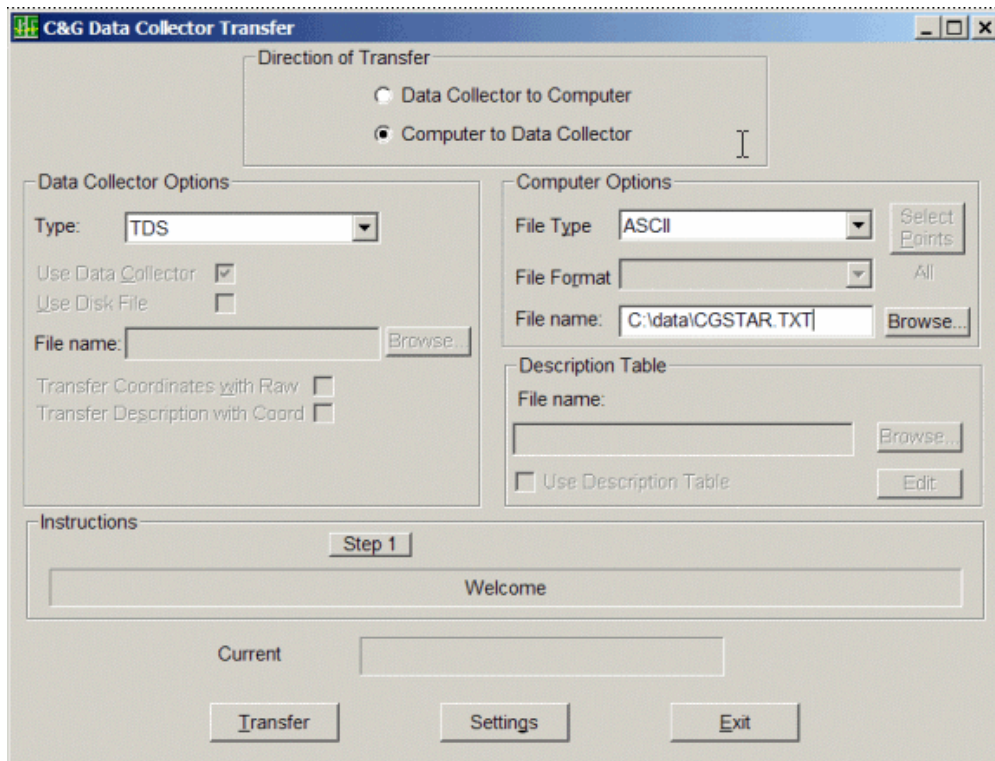

File Format: C&G (*.crd) or C&G (*.cgc)

File: enter the path to file or click on the Browse button and file

Check the Select Points setting:

Press Transfer: when all settings are correct.

Sending ASCII File

On the desk top data collection transfer dialog box, set the following:

Select Computer to Data Collector

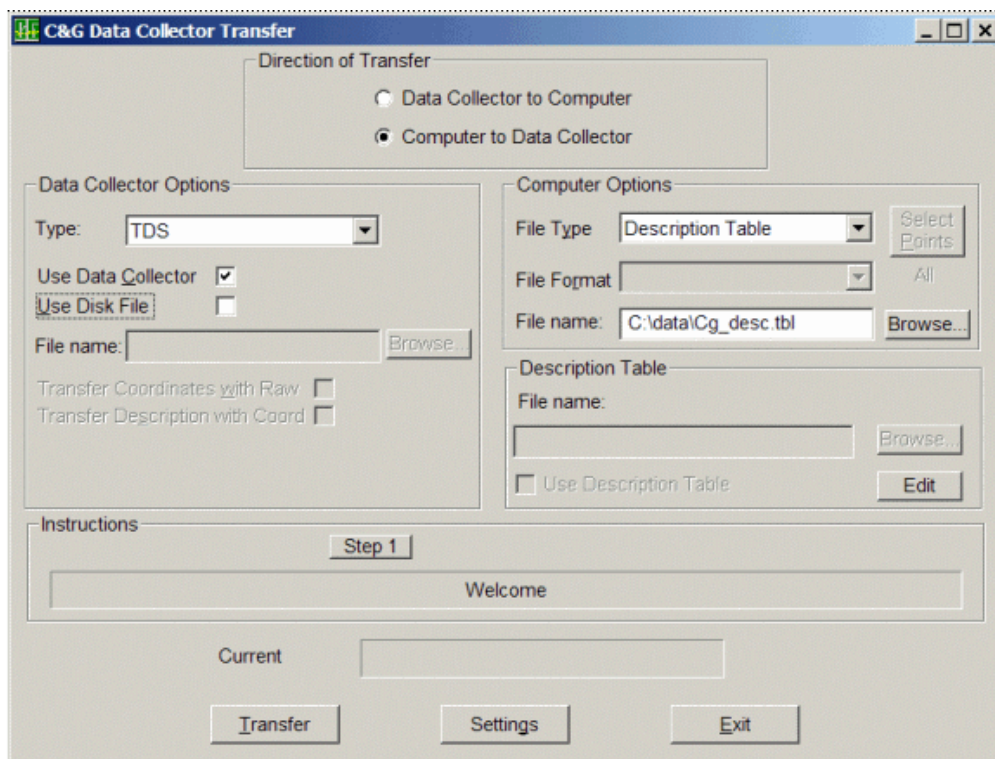

Data Collector: (select data collector from list)

File Type: ASCII

File: enter the path to store the file or click on the bROWSE button and select the path

Press Transfer: when all settings are correct.

Sending Description Table

On the desk top data collection transfer dialog box, set the following:

Select Computer to Data Collector

Data Collector: (select data collector from list)

File Type: Description Table

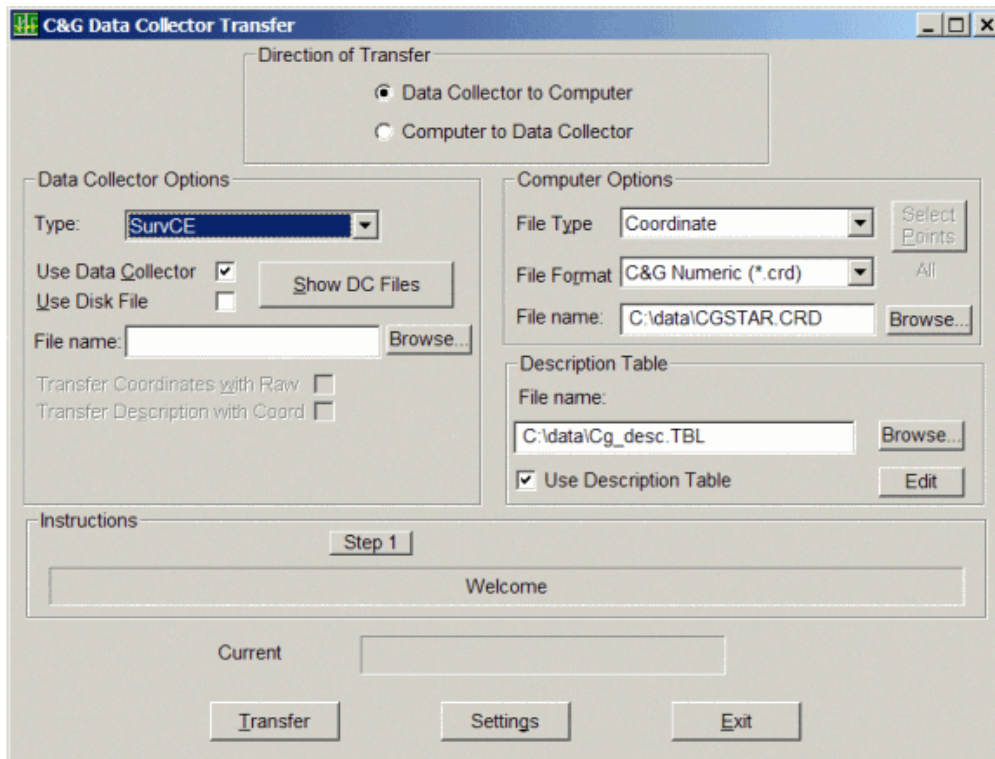

File: enter the path to store the file or click on the File button and select the path

Press Transfer: when all settings are correct.

SurvCE Data Collector

You can receive coordinates and raw data from the data collector, or send coordinates to the data collector. Make sure SurvCE is selected as the data collector.

Receive Coordinates from SurvCE

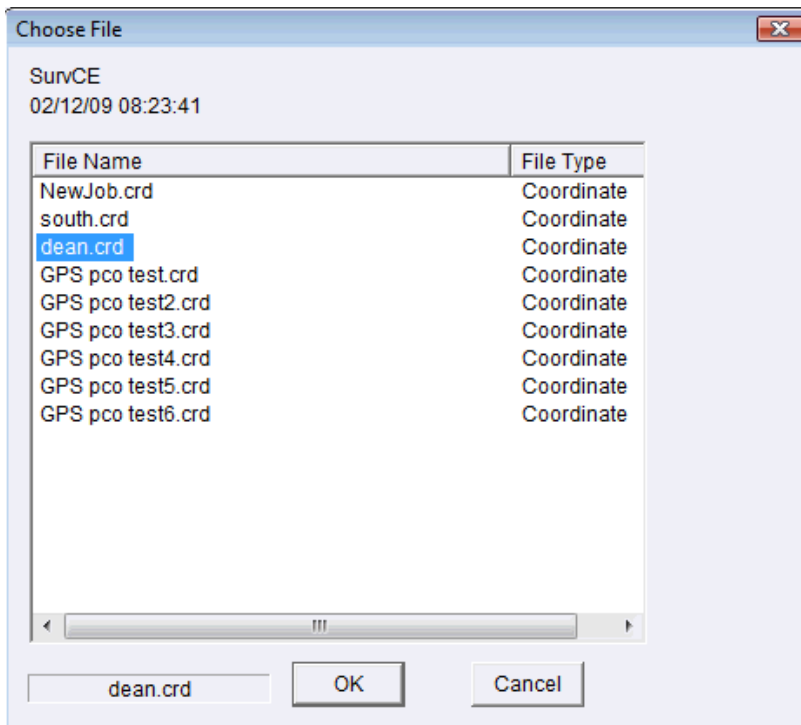

On the desktop, click on "Data collector to Computer": select SurvCE as the Type data collector.

Set FILE TYPE to Coordinate: and select the desired File Format.

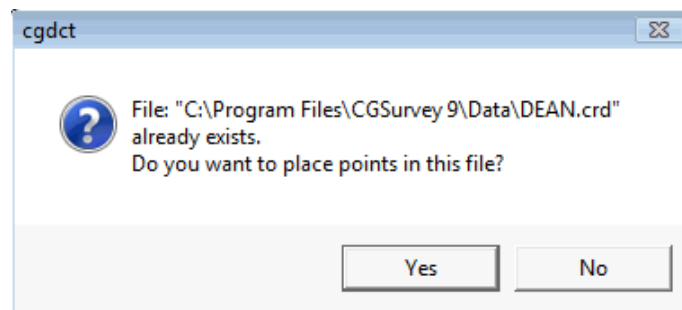

On the Data Collector, Select FILE >DATA TRANSFER: Choose Carlson/C&G Transfer.

On the desktop, select BROWSE button next to the FILENAME field: You will see the coordinate files that are on SurvCE.

Select the File you wish to download: and press OK.

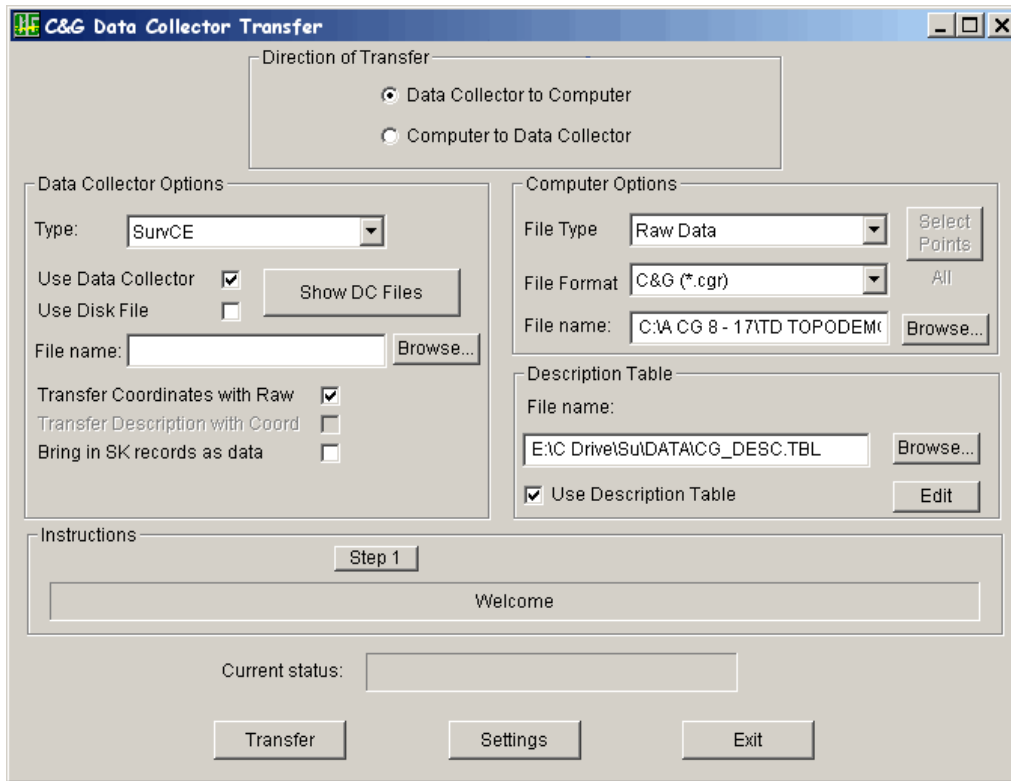

Press the Transfer button. If you do not have a destination FILE NAME selected, you will see the following dialog:

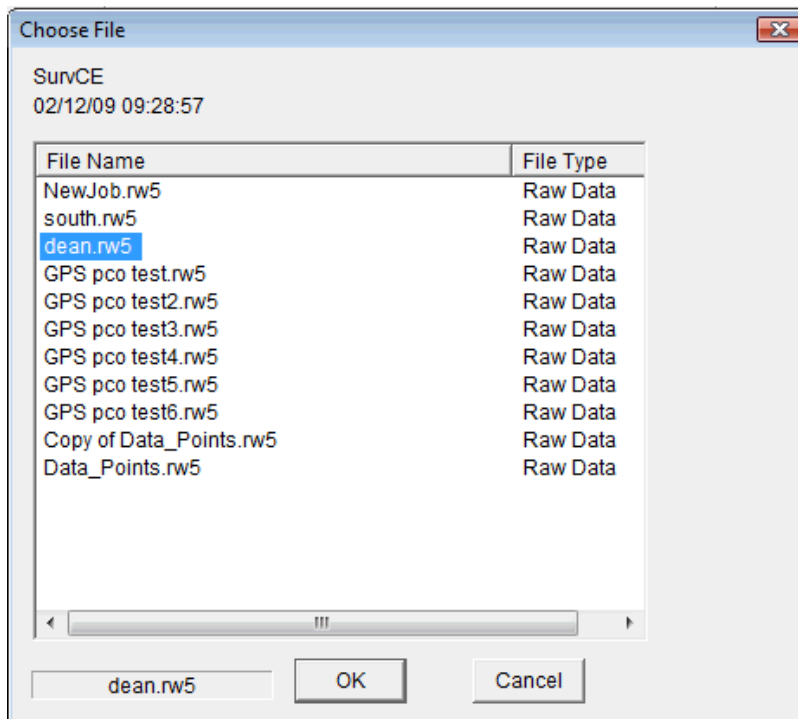

In this case, the file already exists, If you press OK the coordinates will be written to the existing file. Point Overwrite Protection will allow you to select which points you wish to bring in. You can decide individually whether you want to overwrite a point or not, or you can select overwrite ALL points, or you can select to bring in ONLY new points.

A file with the same name and a C\$\$ extension will also be created with the data that came directly from survCE in survCE's format. This file is read-only and can be archived for legal purposes.

Receive Raw Data from SurvCE

On the desktop, click on "Data collector to Computer": select SurvCE as the Type data collector.
Set FILE TYPE to Raw Data: and select the desired File Format.
On the Data Collector, Select FILE >DATA TRANSFER: Choose Carlson/C&G Transfer.
On the desktop, select BROWSE button next to the FILENAME field: You will see the raw data files that are on SurvCE.

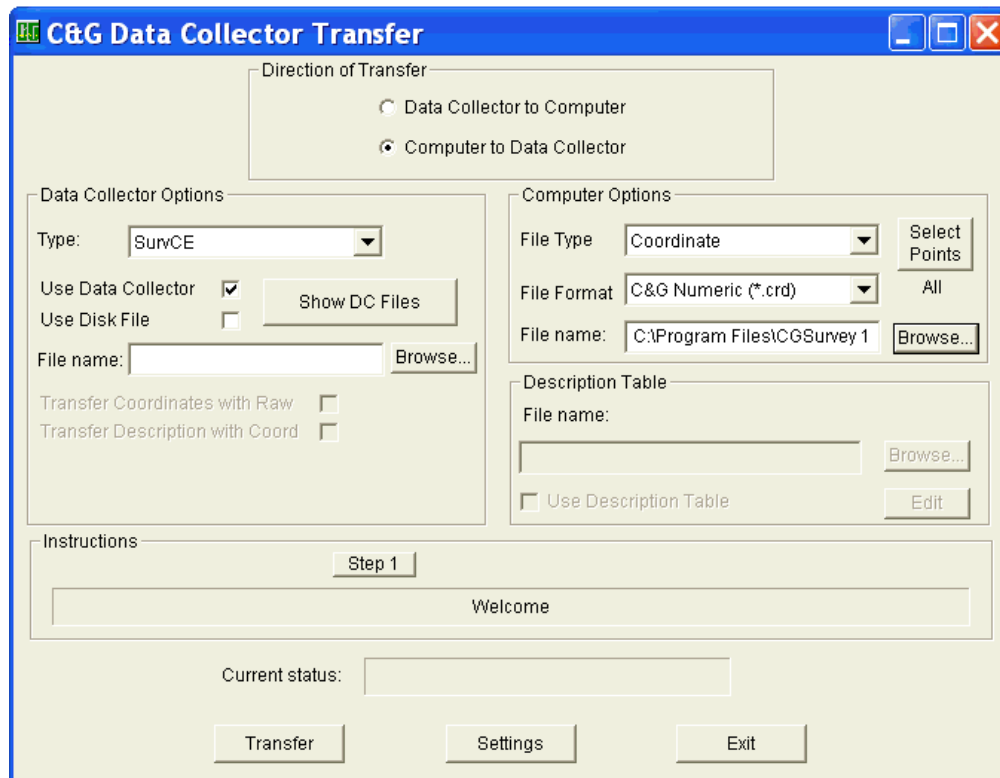

Select the File you wish to download: and press OK.

The selected raw data file will be transferred and converted to the selected format. A file with the same name and a R\$\$ extension will also be created with the data that came directly from survCE in SurvCE's format.

This file is read-only and can be archived for legal purposes.

Send Coordinates to SurvCE

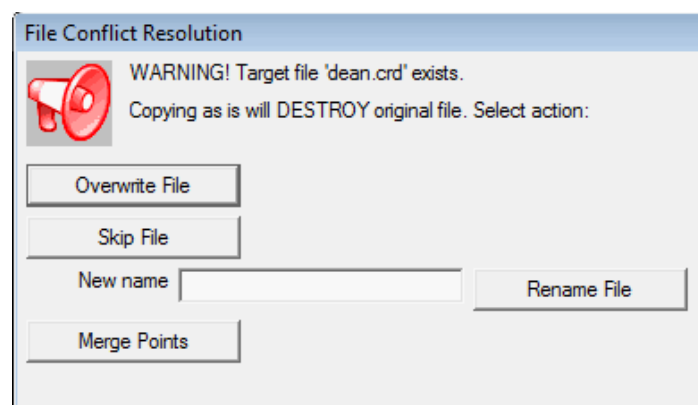

Select Computer to Data collector. Make sure the Data Collector TYPE is set to SurvCE: select the file to be set to SurvCE (N_DRUIDH.crd). If you do not select a destination name, it will be sent to the same named file as the source.

If you do not want to send ALL the points, but need to select specific point: press the SELECT POINTS button and choose the point to transfer.

On the data collector select FILE>DATA TRANSFER: Choose Carlson/C&G Transfer

On the Desktop, Press the TRANSFER BUTTON: The selected coordinates will be transferred.

If the file already exists on SurvCE, you will see the following dialog:

You have the following choices:

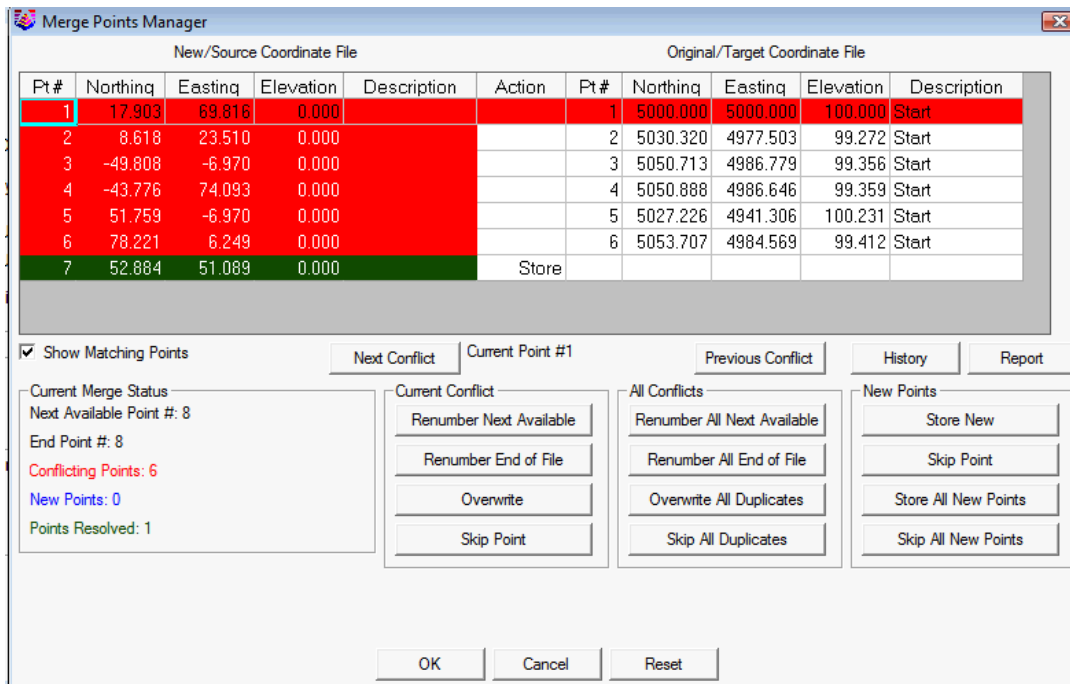

Overwrite the existing file

Skip the file (do nothing)

Rename the file

Merge the points.

If you select the Merge option, you will see Carlson's standard merge dialog:

This dialog allows you to fix all conflicts prior to transferring the points.

TOPCON DATA COLLECTORS

Use Topcon cable A-5 if your computer has a 25-pin serial port, or Topcon cable A-16 if your computer has a 9-pin serial port. When uploading raw data from a Topcon/TDS data collector, a read-only file in the original data collector format is created on the computer (in the data directory) with a .R\$\$ extension. When you send the description table to a Topcon/TDS data collector, only the first 999 descriptions will be sent.

FC1 DATA COLLECTOR

For the transfer program to be able to access any data in the FC1, it must be stored in the FC1 using the Program 2 supplied with the FC1 transfer software. First locate the necessary cables to connect the FC1 to your computer. (your dealer should be able to help you with this).

NOTE: Currently, the only programs that are supported are ET1 and GTS3, which are supplied with the system.

Follow these instructions:

Select either ET-1 or GTS-3 when prompted. Once you have loaded Program 2 into the FC1, you may enter your field data in either of two ways. The first way, is by connecting the FC1 to your total station and let the total station record angular and distance measurements for you by using the ET1 (GTS3) section of the FC1 program. The other way is to use the Manual Entry section of the program to store all of your field data directly through the FC1's keyboard.

Collecting Data using the FC1

(The following steps will be followed no matter which data entry method you use):

- 1) Set up data recording mode in the FC1.
- 2) Enter job information: job name, operator, instrument number, date, temperature, pressure.
- 3) Enter instrument point information: point number, H.I., backsight point, angle in instrument to backsight.
- 4) Enter foresight point information: point number, rod height, horizontal and vertical angles, distance.
- 5) If there are other foresights from the same instrument point, repeat step 4; or if you have another instrument setup, go to step 3; or if you are through, go to the end of the program.

NOTE: Never press the <skip> key when the FC1 is asking for data. Only use the <skip> key to by-pass "go to" options (see step 5 below).

Automatic Recording of Data

1) To set up the recording mode, have the FC1 connected to the ET1 (GTS3), and turned on. Wait until the left side of the display says READY.

If the right side of the display says PRG>2, then you are ready for step 1A.

Otherwise, press these keys: <func>, <#>, <Enter> and then go to step 1B below.

A) **Press the <F1> key.**

B) **When the display says GOTO 7 ET1-PROG? ("GOTO 7 GTS3-PRG")**, press the <Enter> key.

2) **Enter any name you want for the job-id:**

Enter the name of the operator.

Enter the instrument number.

Enter the date, temperature, and pressure.

3) **Sight the backsight point with the instrument:**

Enter the instrument point number.

Enter the instrument height (H.I.).

Enter the backsight point number.

Press <Enter> for the rod height.

Press <Enter> when the display says REC MODE 2 (REC V/H< MODE? on GTS3).

When the display says MODE>, press <2> and the ET1 should send angular information to the FC1.

4) **Turn to the foresight.**

Enter the foresight point number, and press <Enter>.

Enter a description for the foresight and press <Enter>.

Enter the foresight rod height and press <Enter>.

When the REC MD3-DR/2R (REC SD/V/HMODE?) message appears, press <Enter>, then choose mode 3 if you are entering a direct angle.

If this is your second angle to that foresight, then you may use mode 2 to record angles only.

5) **After step 4, then you should see this message in the display: GOTO 18 FS.PT#?.** If you wish to turn more angles from the current instrument point, **then press <Enter>**, and go back to step 4.

-or-

Press <Skip>. The next message will be GOTO 13 INST.PT? If you want to record another instrument set-up, then press <Enter>.

-or-

Press <Skip>. The next message is, GOTO 8 OPER.? To change operators, press <Enter>, and go to step 2.

-or-

Press <Skip>. The next message is, GOTO 53 END? To end input for this job, press <Enter>.

Steps on Manual Recording of Data

1) **To set up the recording mode, have the FC1 turned on. Wait until the left side of the display says READY. If the right side of the display, says PRG>2** then you are ready for step 1A.

Otherwise press these keys: <func>, <#>, <Enter> and go to step 1B.

A) Press the <F1> key.

B) When the display says GOTO 7 ET1-PROG? (GOTO 7 GTS3-PRG): press the <skip> key.

When the display says GOTO 30 MANUAL?: press the <Enter> key.

2) Enter any name you want for the job-id:

Enter the name of the operator:

Enter the instrument number:

Enter the date, temperature, and pressure:

3) Enter the instrument point number:

Enter the instrument height (H.I.).

Enter the backsight point number:

Enter the rod height if desired:

Enter the angle in the instrument: when the backsight was taken.

Enter the vertical angle and distance: if desired.

4) Turn to your foresight. Enter the foresight point number, and press <Enter>.

Enter a description for the foresight and press <Enter>.

Enter the foresight rod height and press <Enter>.

Enter the horizontal angle, slope distance, and vertical angle to the foresight.

5) After step 4, then you should see this message in the display: GOTO 43 FS. PT#?

If you wish to turn more angles from the current instrument point, then press <Enter>, and go back to Step 4.

-or-

Press <Skip>. The next message will be GOTO 36 INST.PT? If you want to record another instrument set-up, then press <Enter>.

-or-

Press <Skip>. The next message is GOTO 31 OPER.? To change operators, press <Enter>, and go to step 2.

-or-

Press <Skip>. The next message is GOTO 1 MENU? To go to the menu for another job, press <Enter>.

-or-

Press <Skip>. The next message is END. Press <Enter> to end entry for this session.

Receive Data from FC1

Once you have your data stored in the FC1, you must upload it to the computer.

Select the Receive Raw Data function. If you have already dumped the data stored on the FC1 to a computer file (in the Topcon format), you may choose to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file.

NOTE: To power your FC1 while sending data to the computer, you must plug the power cable into the signal port at the top of the FC1 and toggle the FC1's power switch to EXT.

TOPCON PROPAC DATA COLLECTOR

To enable the Propac to collect raw data in a format Suitable for CG-Survey's data transfer program the CG program must be installed on the 71B. To load the software: connect the Propac to the computer com port.

Follow the directions to download.

You may store the CG program in a freeport on the 71B. This has several advantages, the main one being it will not be lost if the batteries die.

Under the Propac options choose Load CG Program Into Propac.

On the 71B :

Type Freeport(.01) and key <Endline>.
Type COPY CG TO :PORT(.01) and key <Endline>.

For ROM Versions Prior to 1.75

Type DEF KEY 'f7',"USER @ RUNCG": and key <Endline>.

For ROM Versions 1.75 or Later

Type DEF KEY 'f7',"USER @ CONT PRGM2": and key <Endline>.

This will set up the raw data collection program to run on the Propac when the yellow function key and the <7> key are pressed. Unless something happens to the 71B, you should not need to reinstall the CG-Field program again.

Now delete the CG-Field program from the main memory of the Propac by typing PURGE CG:MAIN and key <Endline>. The program is still stored in the freeport.

To use the CG-RAW data program, turn the Propac on and type RUN PRO then key <Endline>. From the KEYS prompt press the yellow function key then the <7> key. This will start the CG program, then just follow the prompts.

The CG raw data program is the only one needed on the Propac other than the Propac options already available. If you are collecting coordinates and elevations instead of raw data, simply follow the Propac instructions.

To transfer the collected data to and from the computer, choose the Propac option you wish and follow the directions on the screen.

If you have already downloaded the data stored on the Propac to a computer file (in the Propac format), you may choose to receive the data directly from the file. Enter the file name that contains the data, and the file name for the .CGR file (raw data file) or .CRD file (coordinate file).

FC-4 DATA COLLECTOR

The C&G data collector transfer program can accept data that was collected from the FC-4 in either the traverse mode or topo mode. It can receive coordinates from the FC-4 and also send coordinates to the FC-4 for stakeout. The CG data collector transfer program supports most the valid methods of collecting data in the traverse or topo mode of the FC-4 (including the ability to collect direct and reverse angles). Refer to the FC-4 users manual to learn the different methods of data collection supported by the FC-4.

Special Features - When translating the FC-4 file to a raw data file using the C&G data collector transfer program:

- 1) If an FC-4 record is not used, the record will be placed in the raw data file as a comment with the message Not Used appended. No FC-4 record will be ignored. For example, *123 Not Used
- 2) Remarks ("R" records) will be placed in the raw data file as a comment record.
- 3) Coordinates will be placed in the raw data file as a coordinate record, (C 23 10000.0000 10000.0000 923.24 "TP).
- 4) When using the FC-4 Benchmark function, the following will be placed in the raw data file:
 - A) The benchmark coordinates.
 - B) The measurements to the benchmark as a foresight point.
- 5) When using the FC-4 Angle-Offset function the following will be placed in the raw data file:
 - A) A comment line saying the next line is an angle/offset and showing the 1st and 2nd angle recorded to the point.
 - B) A foresight record combining the first distance measurement and the 2nd angle measurement.
- 6) When using the FC-4 Distance-Offset function the following will be placed in the raw data file:

A) A comment line saying the next line is a distance/offset and showing the slope distance, vertical angle and offset distance measured to the base point.

B) A foresight record with a new slope distance and vertical angle calculated from the above information.

7) When using the FC-4 Perpendicular-Offset function the following will be placed in the raw data file:

A) The foresight record to the base point.

B) A comment line saying the next line is a perpendicular offset and showing the offset forward/backward, the offset left/right and the offset up/down.

C) A foresight record with a new horizontal angle, slope distance and vertical angle calculated from the above information.

NOTE: If there is no left/right offset, data will not convert correctly to a CG-SURVEY raw data record. For example, if the Perpendicular Offset routine is used to locate a point away from the instrument but on the same line, the resulting data record will use the wrong horizontal angle.

8) Backsight azimuths are transferred to the .CGR file as reference azimuths.

When a file is first created on the FC-4 the user will be prompted for some header information. When the data is transferred to the computer, the C&G data collection transfer program will use the job-id as the file name for the raw data file created on the computer.

To prepare the data collector and computer for data transfer, connect the A-5 or A-16 cable to the serial port of the FC-4 and to the appropriate serial port of the computer. Make sure the correct data collector comm port has been chosen in Settings Dialog.

Choose the appropriate menu option on the FC-4, then follow the instructions and answer the prompts as they appear on the screen. Once the raw data has been downloaded into the computer the raw data can be edited, reduced and printed out from the Traverse/Input Edit program.

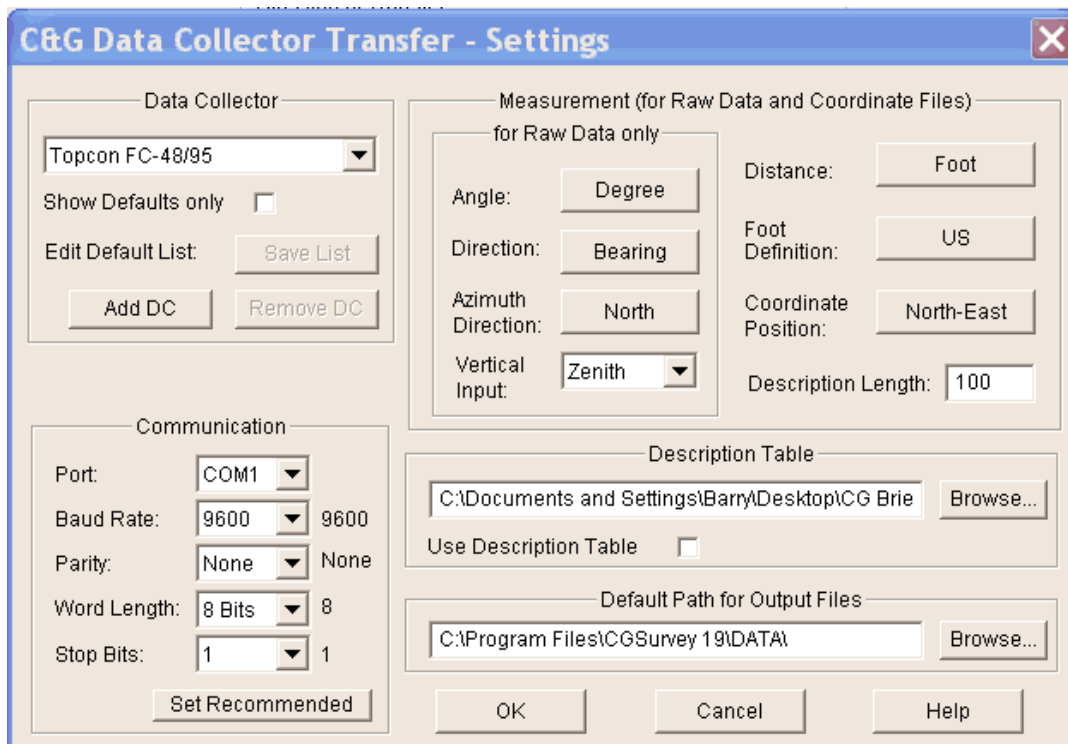

If you have already downloaded the data stored on the FC-4 to a file on the computer, you can transfer the data using the "Use Disc File" command

TOPCON and TDS

Transferring Data

On the C&G Data Collector Transfer screen set the data collector option to:
Check Settings to make sure all options are set correctly

Note: See opening section of this chapter for detailed instructions on the Settings dialog box and on sending and receiving files.

Sending Description Table to 48 When sending the description table (DC_CODES file) to the 48, the following occurs:

A new file (DESCRIPT.TXT) is created in the data directory on the computer.

The first 200 descriptions are duplicated from the DC_CODES file.

After that, the first 100 descriptions are reproduced 7 times with the following mapping codes preceding the descriptions:

- 201 - 300 BL*(DESC)
- 301 - 400 EL*(DESC)
- 401 - 500 CL*(DESC)
- 501 - 600 CF*(DESC)
- 601 - 700 OC*(DESC)
- 701 - 800 PC*(DESC)
- 801 - 900 PT*(DESC)

The DESCRIPT.TXT file is then sent to the 48.

TOPCON CR2 CARD READER

Data collected and stored using the Topcon Card Reader is in the same format as data on the FC-4. All data format rules for the FC-4 apply here.

Set-Up

Card Read Preparation. Before using the card reader it is necessary to set the two DIP switches on the bottom of the unit to the settings described below. The direction on the switch which is marked 'OFF' is really a '1'. You should read the attached label, not the switches.

The CR2 should be set as follows:

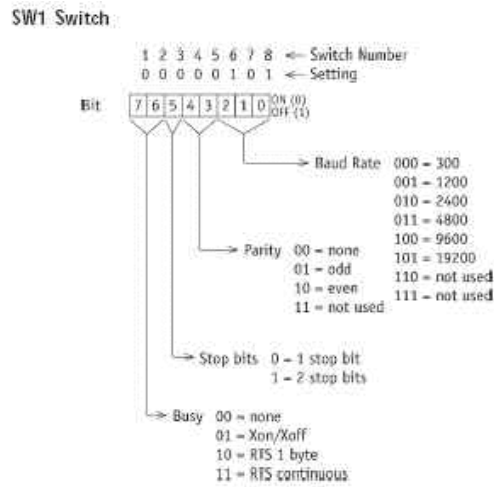

Baud: 19200

Parity: None

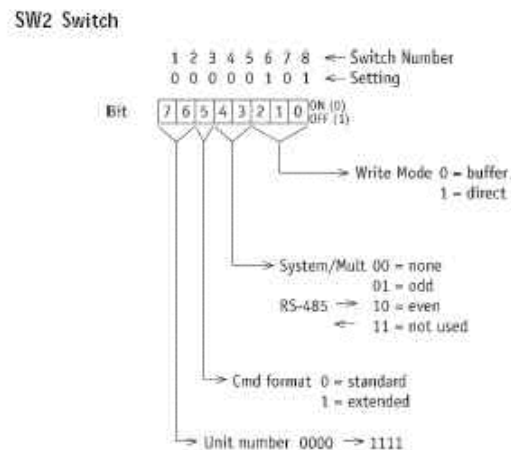

Stop Bits: 1

Word: 8

SW1 DIP Switch: Set the communication parameters

SW2 DIP Switch: Sets other parameters

Use the interface cable supplied with the CR2 unit and plug it into the comm port on the computer. Make sure you select the Topcon CR2 data collector and the correct comm port.

The Card Reader program allows:

- 1) Receive raw data from the CR2 or from a CR2 file.
- 2) Receive coordinates from the CR2 or a CR2 file.
- 3) Send coordinates to the CR2.
- 4) Send or receive a description table to CR2.
- 5) Receive description table.
- 6) Send or receive ASCII files from the CR2.
- 7) Send an executable (EXE) file to the CR2.
- 8) Catalog (or directory) of all files on CR2.
- 9) Delete files on the CR2.
- 10) Format cards for the CR2.

Receiving Data from the CR2

You may receive raw data files (.R), coordinate files (.N), ASCII files or description table from the CR2. All files on the CR2 of the type you wish to receive will be shown on the screen

Raw Data

Coordinates

ASCII

Description Table

Receiving Data from a CR2 File

If you have already downloaded the data stored on the CR2 to a file on the computer, you may choose to receive the data from the file.

Sending Data to the CR2

You may send coordinate (.CRD) files, ASCII files, EXE files or description table to the CR2. Select the file you wish to send. You may not send a file to the card reader that already exists on the CR2. You must delete the file first. The.CRD files will be converted to .N files. ASCII files will be transferred without conversion, (make sure the file you are transferring is a true ASCII file).

EXE files

Programs with .EXE extensions can be transferred to the CR2. These files will be transferred with a .X extension.

Note: See opening section of this chapter for detailed instructions on the Settings dialog box & information on sending and receiving files.

Catalog: The catalog function will show you all existing files on the Topcon Card Reader.

Deleting Files:All files on the CR2 will be shown on the screen. Select the file you wish to delete. Be careful, once the file is deleted it is gone forever.

Format: The format function will allow you to format a card, making it ready to accept (store) data. If the card is already formatted, you will be warned that all information on the card will be lost, be careful.

SOKKIA (LIETZ) SDR2 DATA COLLECTOR

General Information

Use the cable supplied with the SDR2 data collector to plug into your computers serial port.

When uploading or downloading to or from the computer, turn the switch on the cable toward the word PRINTER. If this does not work, turn the switch toward the word COMPUTER and try again. If you still have trouble please call us.

In order to use the Lietz SDR2 data collector with the transfer program, there are 4 areas that you must consider: (1) Entering data into the data collector in a format that can be sent to your computer, (2) the transfer program itself, (3) sending calculated coordinates back to the data collector, and (4) the data collector code conversion table which converts numeric codes for points into English-language descriptions as the data is sent to the computer.

Sokkia (Lietz) data collectors allow you to enter attribute data. To use attribute data with CG-SURVEY, it must be appended to the description records in the following format:

DESCRIPTION [attribute name] attribute

For example: PIPE [Diameter] 18"

Entering Data into the Data Collector

Note: that all of the following assume that you have a Getting Started book and Operator's Manual from the Lietz Company.

1) To begin a new job, press <clear> until Select operation appears in the display. Press the <Menu> key. When JOB appears in the display, press <Enter>, and enter the job name and scale factor.

2) To enter field data, press <clear> until Select operation appears in the display. Press the <Prog>. When Traverse appears in the display, press <Enter> and begin traversing.

2a) You may use the TOPO program rather than the Traverse program. If you use this program, you must use the R option when sending data to your computer. The "Transferring Field Data to the Computer" section of this contains more about this.

Note: The coordinates that you enter for the first instrument point are for the internal use of the SDR2, and can be changed when your field data gets to the computer.

Note: When recording your first backsight information, simply enter an azimuth from the instrument point to the backsight (0.0000 will do). The azimuth information is also only used internally in the SDR2. You can change all of that as you reduce your field notes on the computer.

Note: At each instrument setup, the first angle recorded must be to your backsight. Your instrument may be "zeroed" or not, but when the Traverse Reduction program runs, it will subtract the backsight angle from the foresight angles.

Transferring Field Data to the Computer

If you have already dumped the data stored on the SDR to a computer file (in the SDR format), you may choose option to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file (raw data file) or .CRD file (coordinate file).

Before data can be transferred in either direction between the computer and the SDR2, you must set up the transfer parameters in the SDR2. Once these have been set, they will not change, until you change them again. You do not have to set them each time. (The only parameter that you may wish to change is the baud rate.)

In our tests, the computer can receive data from the SDR2 at 4800 baud, its fastest speed, but the SDR2 could only receive points at 1200 baud. For fastest transmissions to and from the SDR2, you might wish to change this parameter in the SDR2.

The SDR-22 and SDR-24 data collectors will send to the computer at 9600 baud and receive data from the computer at 4800 baud.

1) Set up parameters by pressing <clear> until the message Select operation appears in the SDR2 display. Then, press <Menu>. Press the up or down arrow until Parameters appears in the display, then press <Enter>. You can then go from one parameter to the next by pressing the up or down arrows. When a parameter you wish to change shows on the display, press the <Edit> key, and change it. (See the SDR2 operator's manual.)

These parameters must be in effect:

Baud: 4800 (or 1200 for sending to the SDR2, see above discussion.)

Parity: not set
Word length: 8
Checksum: N
Coords: N-E-Elev

2) After the parameters have been set, simply connect the SDR2 to the computer, and select the transmission option. (On the Lietz transfer cable, there is a switch that must be set to DTE.)

3) Choose the same baud rate at the computer as you selected in the SDR2 parameters. When the computer says Waiting for data..., press <clear> on the SDR2 until Select operation shows in the display window. Press the <Menu> key. Press an up or down arrow key until Comms output shows in the display, then press <Enter> on the SDR2. Answer <N> if you do not wish to send all jobs. Then enter the job that you do wish to send. (See the SDR2 manual for a complete discussion of this process.)

4) The SDR2 should then send its information to the computer.

Note: As each job record is encountered in the computer will ask you for a file name to store the data in. You may press <Enter> to use the same name as was used in the SDR2 or enter another name. You must use a valid DOS name (all numbers and letters of 8 or less characters will be fine.)

Attribute data collected by the SDR (13AT records) is appended to the descriptions as follows: DESC[Attribute Name]Attribute

Example: PIPE[diameter]18"

Transferring Coordinates to the SDR2

Be careful of the units when transferring coordinates. For example, if the SDR2 is set to Metric Mode, the SDR2 will automatically convert the coordinates from feet to meters. Before you can transfer coordinates to the SDR2, you must first set up the transfer parameters in the SDR2. Refer to the first part of the previous section for details about how to do this. Then:

- 1) Ready the SDR2 by pressing <clear> until Select operation appears on the display. Press the <Menu> key. Then press the up or down arrows until Comms input appears on the menu. Press <Enter>.**
- 2) Select the Send Coordinates option and press Transfer.**
- 3) Select the coordinate file on the computer.**
- 4) Choose which coordinates to send.**

SOKKIA (LIETZ) SDR33 DATA COLLECTOR

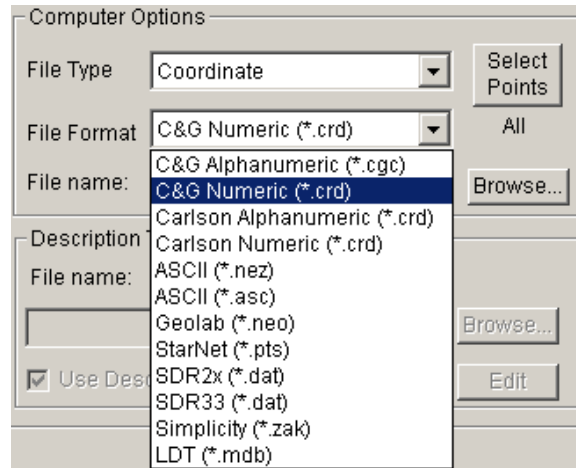

The SDR33 works the same as the SDR2. In Equipment Options there are two SDR33 choices, because when creating a new job on a SDR33 the format is determined by setting the Point ID field to Numeric (4) or Alpha (14).

SDR33 4-Pt

To transfer data to CG-SURVEY, select this setting if your SDR33 is set to Numeric (4). The highest point number allowed is 9,999.

SDR33 14-Pt

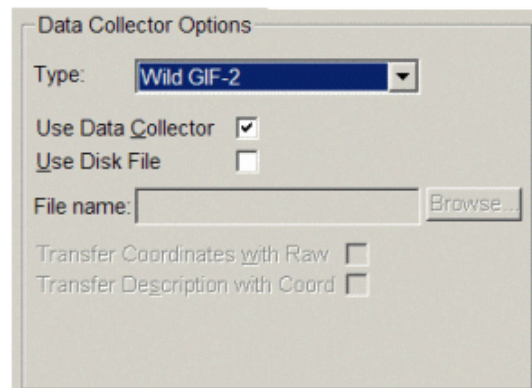

The C&G *.cgc files allow 10 character Alphanumeric point numbers. While C&G *.crd files allow only 5 digit numeric point numbers. To transfer a SDR33, set to Alpha (14), the file format setting must be set to *.cgc.

Note: See opening section of this chapter for detailed instructions on the settings dialog box and on sending and receiving files.

LEICA (WILD) GRE3/GRE4 AND GIF-2 INTERFACE

Set Up for GRE3/GRE4

Select the Wild: GIF-2 under Equipment Options. Before transferring data from the GRE3/4 to your computer, you must first set up the transfer parameters in the GRE3. To do this follow these steps on the GRE3/4:

- 1) <Set> <Mode> <7><0> <Run> <4><8><0><0> <Run> <Run>
(Sets the baud rate to 4800. If you wish, you may leave it at 2400, which is the rate the T2000 needs to communicate with the GRE3/4.)
- 2) <Set> <Mode> <7><1> <Run> <2> <Run> <Run>
(Sets even parity.)
- 3) <Set> <Mode> <7><2> <Run> <1> <Run> <Run>
(Use protocol.)
- 4) <Set> <Mode> <7><3> <Run> <0> <Run> <Run>
(<CR> only.)
- 5) <Set> <Mode> <7><4> <Run> <2> <Run> <Run>
(ACK/NAK + <CR>.)
- 6) <Set> <Mode> <4><0> <Run> <4> <Run> <Run>

(DDD.MMSS).

7) <Set> <Mode> <4><1> <Run> <1> <Run> <Run>

(Feet).

8) <Set> <Form> <.> <Run> <Rec>

(for the T2000)

-or-

<SET> <FORM> <+/-> <.> <RUN> <1> <1> <RUN> <REC>

(for the T1000)

Note: The above parameters do not "go away" when the GRE3/4 is switched off. They will stay the same until you change them or re-initialize everything.

Note: See opening section of this chapter for detailed instructions on the Settings dialog box & information on sending and receiving files.

Data Collection Format for GRE3, GRE4, GIF-10

The transfer program expects your data to be in a specific format. To get your data in this format, follow these steps.

1) To begin a new job enter a "CODE 1" block into the GRE3/4. Example:

RDY [CODE]

CODE [1]

I1 ? [RUN]

your job number (Example: 87001)

[RUN]

I2 ? job date (Example: 091687 for Sept. 16, 1987)

[RUN]

I3 ? [REC]

2) Define the first automatic point number for your first foresight. Example:

RDY [SET]

SET [NR0]

S NR [2] for point number 2 as first foresight.

[RUN]

3) At each instrument point, enter a "CODE 2" block into the GRE3/4. Example:

RDY [CODE]

CODE [2]

[RUN]

I1 ? [instrument point number] EX: [1] for instrument point 1.

[RUN]

I2 ? [instrument height] EX: [550] for 5.50 feet.

[RUN]

I3 ? [REC]

Note: Each instrument point "CODE 2" block must be followed by a measurement reading to your backsight. You will probably need to change the point number for the backsight by:

RDY [NR]

NR [point number] EX: 4 for backsighting point 4.

[RUN]

THEN:

RDY [MEAS]

REC [REC]

-or-

ALL on T1000 will store in GRE3/4

4) Record your foresights. If necessary, change the rod height and/or the description of the foresight.

Use "CODE 3" or "CODE 4" to do this. Both codes are essentially the same, but one asks for the description first and the other asks for the rod height first, allowing you to skip the second entry by pressing [REC] rather than entering a value (see the third example below). This step may be skipped if you do not wish to change either rod height or description from the previous entry.

Example 1:

RDY [CODE]

CODE [3] Code 3 = description, rod height

[RUN]

I1 ? [0][1] Description = 01 (must be 2 digits)

[RUN]

I2 ? [5][5][0] Rod height = 5.50 feet

[RUN]

I3 ? [REC]

See following section on Setting-up Description Codes.

Example 2:

RDY [CODE]

CODE [4] Code 4 = rod height, description

[RUN]

I1 ? [5][5][0] Rod height = 5.50 feet

[RUN]

I2 ? [1][0] Description = 10 (must be 2 digits)

[RUN]

I3 ? [REC]

Example 3:

RDY [CODE]

CODE [3] Code 3 = description, rod height

[RUN]

I1 ? [1][2] Description = 12 (must be 2 digits)

[RUN]

I2 ? [REC] (leave the rod height the same)

5) Take your measurement (make sure that the point number is correct first):

RDY [MEAS]

REC [REC]

6) Now, go to step 4 for another foresight or to step 3 for another instrument set-up:

Uploading from Data Collector to the Computer

If you have already dumped the data stored on the GIF-2 to a computer file you may choose to receive the data from the file. Enter the file name that contains the data. After you have collected your field data, connect the GRE3/4 to your computer. Then select the receive option on the computer. The baud rate in the computer must match the baud rate in the GRE3/4. After selecting the baud rate on the computer, follow the steps on the screen to initiate transmission.

Those steps are:

- 1) **Connect the GRE-3/4 to the computer, turn it on,** and wait for RDY to show on the display.
- 2) **Put the GRE-3/4 in upload mode by pressing <Data>** on the GRE-3/4.
- 3) **Press <GoTo>, press <Run>, and wait for the GRE-3/4 to display D CD.**
- 4) **Press <Send> and press <Run>** on the GRE-3/4.

After the computer detects the end of transmission, it will begin to format the data in a usable form. When each job record is encountered (CODE 1), you will be prompted to give the computer the name that you want to enter the file name for that job.

Sending Coordinates to the GRE-3/4

From the Menu, select the send coordinates option. The baud rate in the computer must match the baud rate in the GRE3/4. Initiate transmission on the GRE-3/4 by doing the following:

Note: See opening section of this chapter for detailed instructions on the Settings dialog box & information on sending and receiving files.

- 1) **On GRE-3/4, SET MODE 80 <Run> 2 <Run> <Run>** to select file 2.
- 2) **On GRE-3/4, SET MODE 81 <Run> <#blocks> <Run> <Run>** to dimension file 2.
- 3) **Press any key to continue:**
- 4) **Next, select the points you wish to send:** The transmission will begin.

LEICA (WILD) GIF-10 INTERFACE

Note: (Refer to data collection format GRE3 within this section)

Receiving Raw Data from GIF-10 Interface:

Select the receive raw data option on the computer. If you have already dumped the data stored on the GIF-10 to a computer file (in the Wild format), you may choose receive the data from the file. Enter the file name that contains the data.

The baud rate in the computer must match the baud rate in the GIF-10. Do the following on the GIF-10:

1) Set the comm parameters as follows:

Baud: (your choice)

Parity: EVEN

Protoc: ACK/NAK

Stop Bit: 2

End Mark: CR

Connected AS: DTE

2) Put the GIF-10 in upload mode by selecting <Send> on the GIF-10.

3) Press <Run> on the GIF-10 and select the file you wish to send.

4) Press <Run> on the GIF-10.

Sending Coordinates to the GIF-10 Interface:

Select the send coordinates option. The baud rate in the computer must match the baud rate in the GIF-10. Do the following on the GIF-10:

1) Create receive file in GIF-10 now.

2) Put the GIF-10 in download mode by selecting Receive on the GIF-10.

Select the points you wish to send. The transmission will begin.

Note: See opening section of this chapter for detailed instructions on the Settings dialog box & information on sending and receiving files.

LEICA (WILD) GIF-10/WS

This is a Wild GIF-10 interface that will accept data in the same format as WildSoft. You will be asked for the Observation Pattern when the file is transferred. This pattern can be either BS-FS-FS-BS or BS-FS-BS-FS. As with WildSoft, codes 101 and above will be treated as descriptor codes. Code 100 will be subtracted from the descriptor code and that description will be read from CG-SURVEY's description table. So 101 is description 1, 102 is description 2, and so forth.

The following table shows acceptable WildSoft data collection codes:

WildSoft Data Collection Codes

Code Function

1 Start Job

2 Occupy a Point

3 FS to Traverse Point

11 Assign Coordinates

13 Target Height

14 Add to Target Height

21 Occupy Saved Point
31 FS to Single Point
32 Radial Sideshots
33 Sets of Angles
63 Remark
101+ Descriptions

LEICA (WILD) GIF-10/WS2

This is the exact same interface as the GIF-10/WS except 100 is not subtracted from the descriptor code.

LEICA (WILD) GIF-10/TOPOS

This is a Wild GIF-10 interface that will accept data in the same format as the Canadian software TOPOS. To select this format, choose GIF-10/TOP from the data collector choices in the Equipment Options. The following information explains the format.

These six Wild codes are used:

Code	Field 1	Field 2	Field 3	Field 4	Rectype
91	Job Name	Date	Temperature	Pressure	New Job
10	Label #	HI	Instrument	Pt.	
20	Label #	RH	Backsight	Pt.	
30	Label #	RH	Trav.	Pt.	
40	Label #	RH	Side Shot	Pt.	
2	Label #	RH	Offset	Angle	SS

- 1) If RH (rod height) is 999 it will be considered no value (do not calculate elevation for this point).
- 2) The Label# (point description number) can contain up to eight characters. The first four and last four will be read as separate descriptions. For example, if Label# is 00210034, then description 21 will be pulled from the description table and description 34 will be pulled from the description table. If 21 is BL* and 34 is TC, then the resulting description will be BL* TC.
- 3) Point numbers are taken from measurement records. A measurement record will follow code 10, 20, 30, and 40 records. For example: In this example, there is a side-shot record (40), a point label description (71), a rod height (2.150), and a point number (332).
- 4) If an offset distance is placed in Field 3 of a side-shot record, the measured angle will be shown in a comment line prior to the data record with the newly calculated angle.
- 5) If a comment is placed in field 4 of a side-shot record, the comment will be appended to the point's description. example: If the label# is 25 and the comment is 150, description 25 (lets say TREE) will be pulled from the description table and the comment will be appended to the description, giving TREE 150 as the description.

Leica Data Pro:

You are allowed to read and write to the Leica Data Pro formatted GSI files. There is no communication directly with the Leica Total stations.

GEODAT 122/124 DATA COLLECTOR

In order to use the Geodat 122 or 124 data collector with the transfer program, there are three areas that you

must consider: (1) entering data into the data collector in a format that can be sent to your computer, (2) the transfer program itself, and (3) the data collector code conversion table which converts numeric codes to more readable descriptions when the data is sent to the computer. The following section describes how to enter your data into the data collector. The next section will then give you some information about how to transfer the data. The data collector code conversion table can be changed with menu selection E from the program menu.

Entering Data into the Data Collector

1) Each individual job stored in the Geodat's memory should begin with a job identifier. To enter a job identifier, follow these steps:

a) Press the <Info> key.

b) At the prompt "inFo=" enter a job number, like this: inFo=87001<Ent> (<Ent> means to press the <Ent> key.)

c) At the prompt "dAtA=" enter the date like this: Example: dAtA=050187<Ent> (for 05/01/87)

2) For each instrument location, you must enter an instrument point identifier.

Follow the following steps to do this:

a) Press the <Stn> key.

b) At the "Stn=" prompt enter you instrument point number like this: Stn=1<Ent> (for instrument point 1)

c) At the "iH=" prompt enter the instrument height, like this: iH=5.5<Ent> (for 5.5 feet)

d) Next the prompt "PCod=" will appear on the display. At this time, enter your backsight point, just like the foresights in the next step. You may enter "0" (zero) for all of the fields except:

"Pno=" (enter the backsight point number)

"Hor=" (enter the angle in your instrument when you take the backsight.)

3) Recording foresights. You are now ready to record a foresight:

a) At the "PCod=" prompt enter the point code for your foresight like this: PCod=10<Ent> (for point code 10)

Note: The point code will be used to assign a description to your foresight. The description that is associated with each code is up to you. Use the "Edit data collector code table" program to set up your codes before uploading your data to the computer.

b) At the "Pno=" prompt enter your foresight point number like this: Pno=2<Ent> (for point number 2)

c) At the "SH=" prompt enter the rod height of your foresight like this: SH=5.5<Ent> (for 5.5 feet)

The next three fields may be entered manually or may be automatically stored by your instrument.

d) At the "Hor=" prompt enter the horizontal angle to your foresight like this: Hor=65.1253<Ent> (for 65 degrees, 12 minutes, and 53 seconds.)

e) At the "ELE=" prompt enter the vertical angle to your foresight like this: ELE=90.1215<Ent> (for 90 degrees, 12 minutes and 15 seconds)

f) At the "diSt=" prompt enter the slope distance to your foresight like this: diSt=100.128<Ent> (for 100.128 feet)

Now, go to step 2 for a new instrument point, or step 3 for another sight from the current instrument point.

Note: If you have already dumped the data stored on the 122/124 to a computer file (in the 122/124 format), you may choose to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file.

Receive Data from Data Collector

Select the receive raw data option.

1) Before you upload your data, make sure that the description table is current.

2) Before you initiate the upload program, you must first define the upload parameters for the Geodat. To do this, follow the steps outlined below.

3) This should not have to be done each time. The values that you enter should stay the same until you change them.

a) Press the <f>, the <1>, the <0> and the <Ent> keys. (For function 10.)

b) Answer the baud rate question like this: bAud=1200<Ent> (for 1200 baud you can use 300 baud, but it will take longer to transfer your data.)

c) Make sure that "Eob=" looks like this: Eob=0123456789<Ent>

d) Make sure that the "StArt=" prompt looks like this: StArt=035<Ent>

e) Make sure that the "StoP=" prompt looks like this: StoP=000<Ent>

f) Make sure that the "ErrCodE=" prompt looks like this: ErrCodE=037<Ent>

g) Make sure that the "nuLLS=" prompt looks like this: nuLLS=000<Ent>

GEODAT 126, 400, 500 AND INTERNAL MEMORY THEODOLITES

These Geodat data collectors use the following data entry format:

Instrument Point Setup

Labels Explanation

*2 Instrument Point

3 Height of Instrument

*62 Backsight Point

21 Backsight Angle

6 Backsight Rod Height

7 Horizontal Angle to Backsight

8 Vertical Angle to Backsight

9 Slope Distance to Backsight

* Indicates required code

Note: Pcodes (label 4) cannot be used anywhere except in foresight records.

Note: The order of the instrument point setups is not important.

Foresight Points

Labels Explanation

*5 Foresight point

6 Backsight rod height

*7 Horizontal angle to backsight

*8 Vertical angle to backsight

*9 Slope distance to backsight

4 Pcode (Description)

* Indicates required code

Note: Foresight points must begin with either a Pcode (label) or a foresight point (code 5). The order of the remaining parameters is not important.

Label 4 (Pcodes) are placed in the description field of the raw data file. If you cannot get the entire point description into a single Pcode, we allow you to use multiple Pcodes for an individual point.

Example: 4 = Manhole,

4 = Inv. -10.23,

4 = 12" Conc.Pipe

The resulting point description is: Manhole, Inv. - 10.23, 12" Conc.Pipe If the Append Info Records to Pcode toggle is on, info records (label 0=) that directly follow a Pcode (label 4=) will be appended to the Pcode prior to being placed in the point description.

Example: 4 = Manhole,

0 = Inv. -10.23,

0 = 12" Conc.Pipe

The resulting point description is: Manhole, Inv. - 10.23, 12" Conc.Pipe

GEODAT 126 DATA COLLECTOR

I. The Cable

Your cable should be made as follows:

NC - No connection.

Geodat 126 (male)Computer 25 Pin

2 2 (TxD)
3 3 (RxD)
7 7 (S.GND)
5-NC ---5 (CTS) jumper 5-6-8-20
6-NC ---6 (DSR)
8-NC ---8 (CD)
20-NC ---20 (DTR)

Geodat 126 (male)Computer 9 Pin

2 3 (TxD)
3 2 (RxD)
7 5 (S.GND)
5-NC ---8 (CTS) jumper 8-6-1-4
6-NC ---6 (DSR)
8-NC ---1 (CD)
20-NC ---4 (DTR)

II. Set Protocol 2 and 5; Set Format 2

Be sure the INT./EXT. switch is set to INT. if you are not connected to an external power source. Be sure the on/off switch is in the on position.

Set protocol by using program 51 in the Geodat.

Protocol 2 Protocol 5

1: 9600 1: 9600
2: 2 2: 2
3: 7 3: 7
4: 2 4: 2
5: 10 5: 10
6: 0 6: 0
7: 0 7: 0
8: 0 8: 0
9: 0 9: 0
10: 0 10: 0
11: 0 11: 0

12: 0 12: 0
13: 0 13: 0
14: 1.13 14: 1.13
15: 0 15: 0
16: 3.371310 16: 3.371310

Set format by using program 50 in the Geodat.

Format 2

1: 1
2: 80
3: 13
4: 15

III. Data Storage in the Geodat 126

Raw data is gathered into job files using the pre-programmed UDS's in the Geodat 126. Call us if you wish to create others.

To use the existing programs, begin by choosing program #10. This sets up the header information and first instrument/back-sight points. For foresights, choose program #0 if you are carrying elevations or program #1 for horizontal locations only. Use program #11 to change instrument set-ups. These programs are explained on page 8:4 in the Geodat manual.

Coordinates are transferred from and into area files.

Special numeric point codes may be used. These codes are converted to alphanumeric descriptions as the data is received from the Geodat 126. The codes are defined in the description table.

IV. UDS Requirements

The initial testing of the Geodat 126 was done using the standard UDS's supplied with the Geodat 126. If you wish to try using your own, these rules apply:

- 1) A measurement must end with label 9. (See sample UDS's 0, 1, 2, 3.)
- 2) Each Job. No. file must begin (1st record) with ADM type data (see sample UDS 10). This sequence must end with label type 74 - Air Pressure.
- 3) Each instrument station sequence must end with Hz. Ref. (Label 21). See the UDS 11 in Geodat 126 manual for sample.

Select the receive/send option from the computer menu and follow the prompts. If you have already dumped the data stored on the DR-2 to a computer file (in the DR-2 format), you may choose to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file (raw data file) or .CRD file (coordinate file).

GEODAT 400 DATA COLLECTOR

Setting up the Geodat 400 for use with the transfer program:

- 1) Set protocol 0 (as shown below).
- 2) Set format 0 (as shown below).

Be sure the on/off switch is in the on position. Set protocol by using program 51 in the Geodat field instru-

ment.

Protocol 0

1: 9600
2: 0
3: 8
4: 1
5: 10
6: 0
7: 1
8: 17
9: 19
10: 0
11: 0
12: 0
13: 0
14: 1.13
15: 0
16: 1.04

Line 7 implements software handshaking between the 400 and the MS-DOS computer by using a value of 1. When the value of item 7 is 0, then no software handshaking is done.

Line 8 is given a value of 17 which is the Xon value used for the communication handshaking.

Line 9 is given a value of 19 which is the Xoff value used for the communication handshaking.

Set format by using program 50 in the Geodat field instrument.

Format 0

1: 1
2: 80
3: 324:
4 *

Note: It is important that the values above be set as we show them or our software can not communicate with the Geodat 400 Data Recorder.

If you have already dumped the data stored on the 400 to a computer file (in the 400 format), you may choose to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file (raw data file) or .CRD file (coordinate file).

Uploading Raw Data to the Computer

After you have collected your field data, connect the Geodat 400 to your computer. Select the receive raw data option. The baud rate in the computer must match the baud rate in the Geodat 400. Do the following:

- 1) **Connect the 400 to the computer, turn it off, then on.**
- 2) **Make certain that you have selected the correct protocol and format.**
- 3) **Enter name of Geodat job file.**

Download Coordinates into 400 Area File

Select the send coordinates option.

Select the points to send.

Ready the 400 with the following steps:

- 1) **Connect the 400 to the computer, turn it off, then on.**
- 2) **Make certain that you have selected the correct protocol and format.**
- 3) **Enter name of Geodat area file.**

The coordinates will be transferred.

Get Coordinates from 400 Area File

Receive coordinates from 400 Area File

The baud rate in the computer must match the baud rate in the 400. Do the following:

- 1) **Connect the 400 to the computer, turn it off, then on.**
- 2) **Make certain that you have selected the correct protocol and format.**
- 3) **Enter name of Geodat area file.**

The transmission will begin.

GEODAT 500 DATA COLLECTOR

Setting up the Geodat 500 for use with the transfer program:

- 1) Set protocol 0 (as shown below).
- 2) Set format 0 (as shown below).

Be sure the on/off switch is in the on position.

Set protocol by using program 51 in the Geodat field instrument.

Protocol 0

- 1: 9600
- 2: 0
- 3: 8
- 4: 1
- 5: 10
- 6: 0
- 7: 1
- 8: 17
- 9: 19
- 10: 0
- 11: 0
- 12: 0
- 13: 0
- 14: 1.13
- 15: 0
- 16: 1.04

Line 7 implements software handshaking between the 500 and the MS-DOS computer by using a value of 1. When the value of item 7 is 0, then no software handshaking is done.

Line 8 is given a value of 17 which is the Xon value used for the communication handshaking.

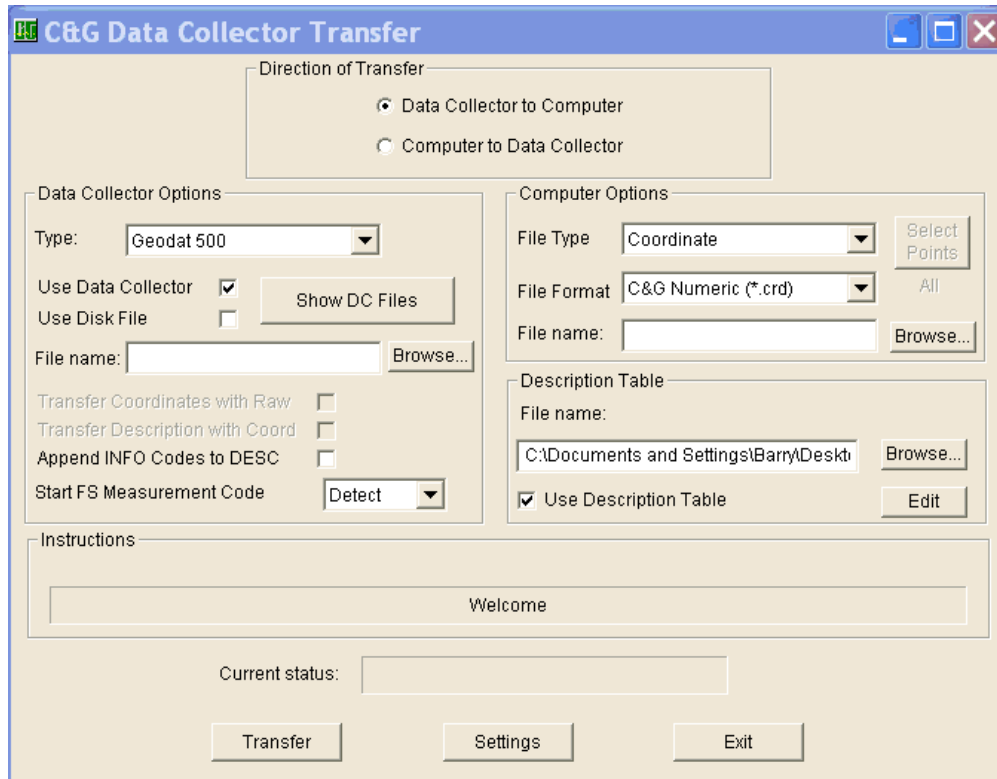

Line 9 is given a value of 19 which is the Xoff value used for the communication handshaking. Set format by using program 50 in the Geodat field instrument.

Format 0

- 1: 1
- 2: 80
- 3: 32
- 4: *

Note: It is important that the values above be set as we show them or our software can not communicate with the Geodat 500 Data Recorder.

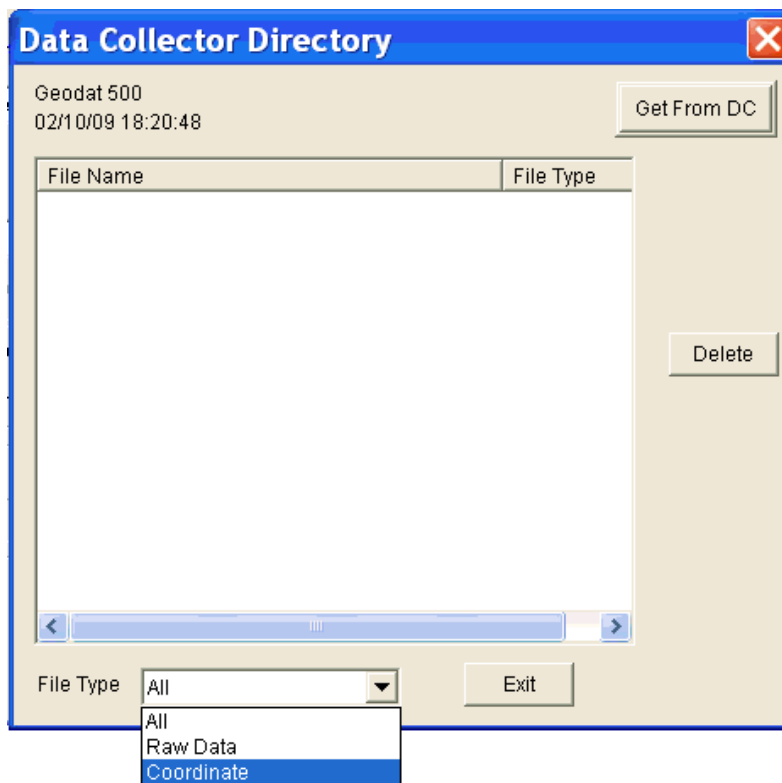

The C&G Data collector Transfer dialog box has an additional option for the GEODAT 500 collector, as shown below. the show DC files:

This Option actually reads and displays the data files on the GEODAT 500 data collector. From the display options you can select to view all files, just coordinate files or just raw files.

If you have already dumped the data stored on the 500 to a computer file (in the 500 format), you may choose to receive the data from the file. Enter the file name that contains the data, and the file name for the .CGR file (raw data file) or .CRD file (coordinate file).

You can also delete files from the GEODAT 500. Be careful, once the files is deleted it is gone forever. When you have the files selected, you want to transfer, select exit.

The Geodat 500 program allows:

- 1) Receive raw data from the Geo 500
- 2) Receive raw data from a file.
- 3) Receive coordinates from the Geo 500.
- 4) Receive coordinates from a file.
- 5) Send coordinates to the Geo 500.
- 6) Catalog (or directory) of all files on Geo 500.
- 7) Delete files on the Geo 500.

Receiving Data from the 500

You may receive raw data files (M=), or coordinate files (I=). All files on the 500 of the type you wish to receive will be shown on the screen (for example, all I= files for coordinate).

- 1) Select the file you wish to receive. Raw Data (Job Files)

- 2) After the raw data file is transferred, you will be asked to select the file name it will be stored under on the computer. The default value will be the same name with a .CGR extension. Coordinates (Area Files)

- 3) After the coordinate file is transferred, you will be asked to select the file name it will be stored under on the computer. The default value will be the same name with .CRD/.IDX extensions.

Sending Data to the 500

You may send coordinate (.CRD) files to the 500. All coordinate files on the computer will be shown on the screen. Select the file you wish to send.

- 1) You may select the only the coordinates that you wish to send (you do not have to send the entire file). Catalog
- 2) The catalog function will show you all existing files on the Geodat 500.

Deleting Files

All files on the 500 will be shown on the screen.

- 1) Select the file you wish to delete. Be careful, once the file is deleted it is gone forever.
- 2) Press <Esc> if you do not want to delete a file.

GEODIMETER TOTAL STATIONS WITH INTERNAL MEMORY

You can select Geodat 500 and interface directly with any Geodimeter that has internal memory. To transfer data from a Geodimeter Total Station with internal memory, do the following:

- 1) In Equipment Options, select Geodat 500 as the data collector and run data collection program.**
- 2) Use Geotronix cable #571136756. Connect RS232 on computer to RS232 on Geodimeter with cable.**
- 3) Power on Geodimeter and turn off compensator with Function 22 as follows:**

Key

<F> (Function)
<22>
<Ent> (Enter)
<0>
<Ent>

Then press <Ent> until P0 is displayed on Geodimeter screen.

- 4) Set the END character to 4 with Function 79 as follows:**

Key

<F> (Function)
<79>
<Ent> (Enter)
<4>
<Ent>

- 5) Initiate comm port on Geodimeter as follows:**

Key

<Mnu> (menu)
<4> (data com)
<1> (select device)
<2> (serial)
<Yes> (serial on)
<1.8.0.9600> (com=) skip if already set
<Ent> (enter)
<0> (table no=)
<Ent>
<No> (REG. key?)
<No> (Slave ?)

- 6) You may now select all options on the computer menu for data collection transfer with the Geodimeter. See Geodat 500 instructions for data transfer (disregard formatting procedures).**

SMI 48 ENHANCED DATA COLLECTOR

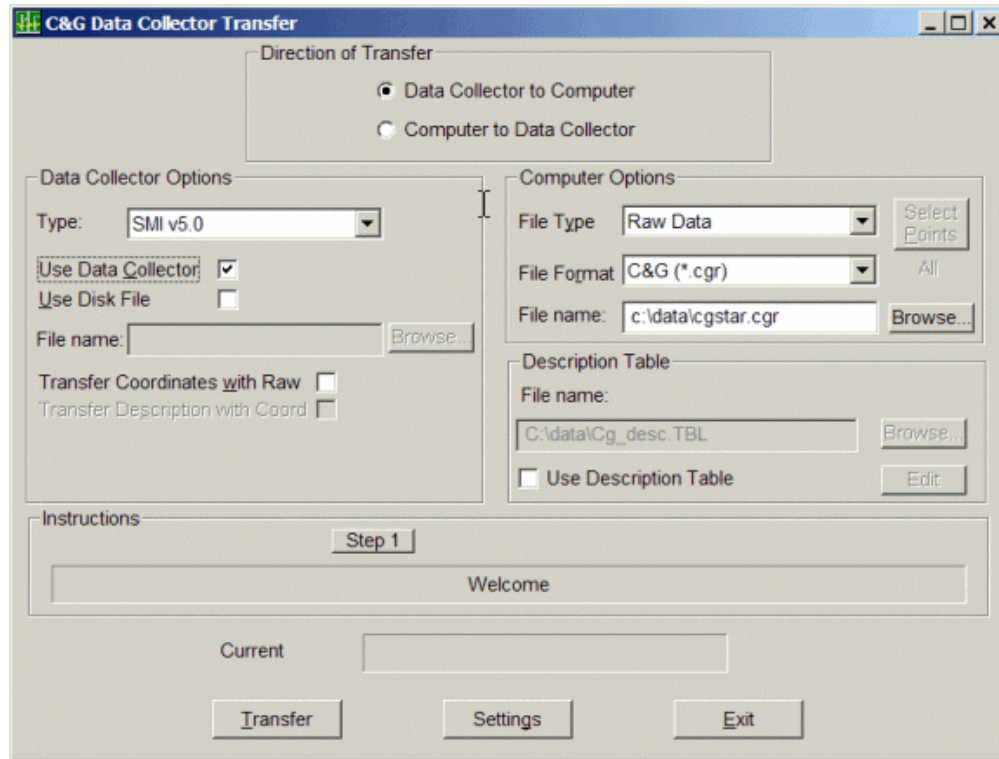

The SMI interface routine works only with SMI Enhanced Cards. Use the interface cable supplied with the SMI unit (plugs into the comm port on the computer).

SMI 48 transfer Versions 5

Receiving Data

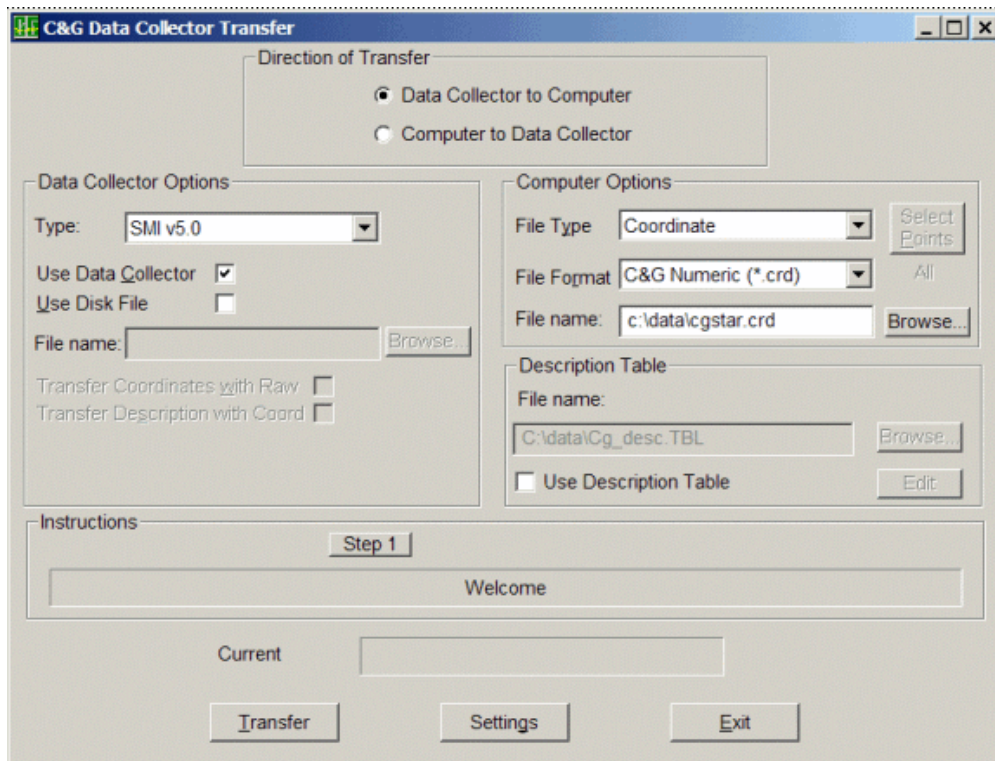

If you have already dumped the data stored on the SMI to a file on the computer, you may choose to receive the data from the file.

Receiving Raw Data from the SMI

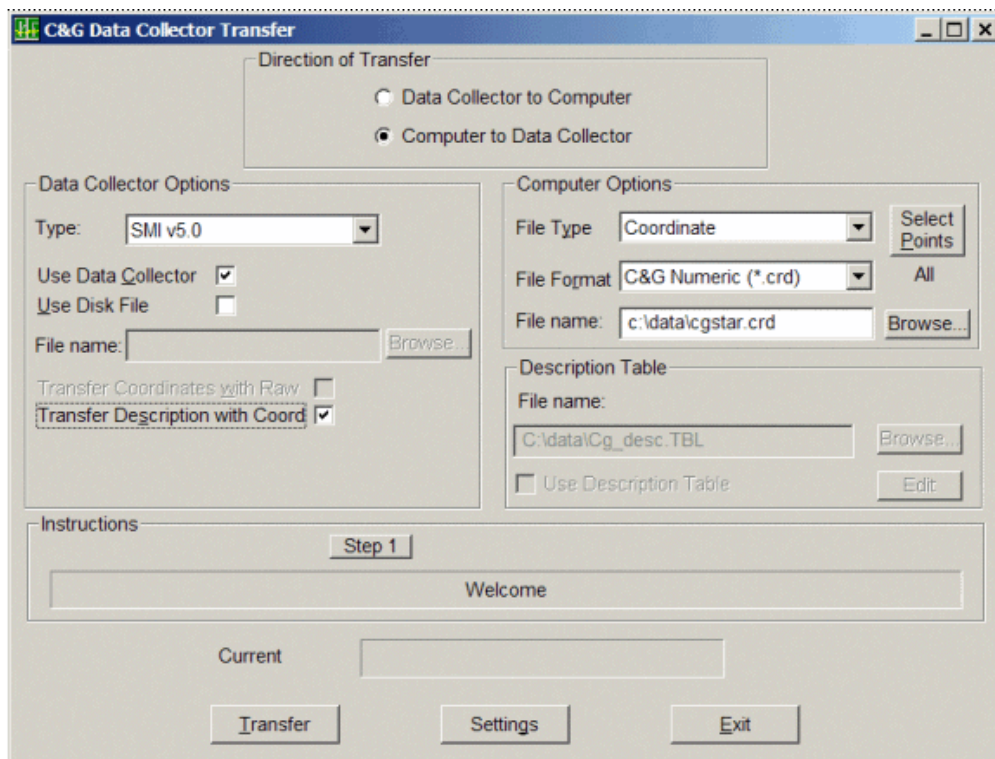

Select the Receive raw data option on the computer. On the SMI, select TOPC and then RAW. The transfer will begin. The file name will be shown on the screen after the transfer is complete. You may enter a new file name if you wish. Our reduction program does not allow a raw data file with mixed angle types (for example: azimuths, angles right, deflections, etc.). When you are collecting data on the SMI, stick to one angle type. You can mix distance types if you wish (slope/zenith, horizontal/vertical).

Receiving Coordinates from the SMI

- 1) Select the Receive Coordinates option on the computer: On the SMI select TOPC and then SMI.
- 2) On the SMI, enter the first and last point numbers you wish to send: The transfer will begin.

Sending Coordinates to the SMI

- 1) On the SMI select TD48 and the SMI.
- 2) Select the Send Coordinates option on the computer. You will be asked if you wish to send descriptions.

The answer to this question depends on whether the SMI coordinate file you are sending to is a 15 byte file (no descriptions) or a 30 byte file (descriptions).

3) **On the computer, select the points you wish to send. When the selection set is complete, press <T> for transmit.** The transfer will begin.

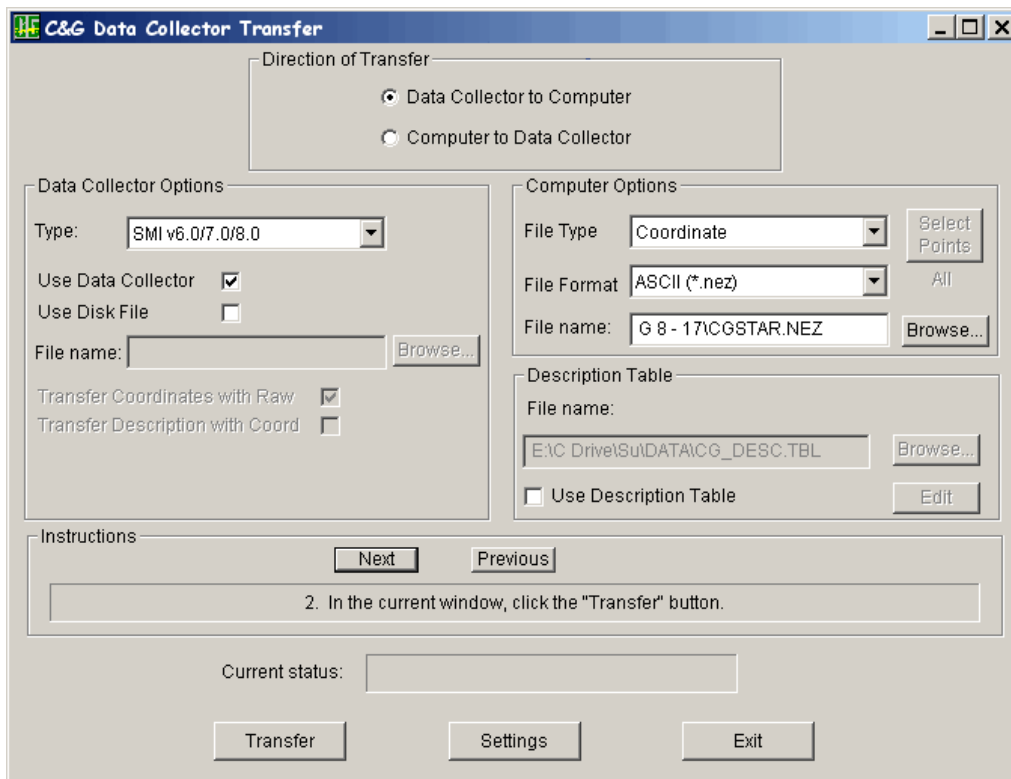

SMI 48 transfer Versions 6, 7 & 8

Receiving Raw Data from the SMI

1) **Get the C&G Transfer Program ready to receive raw data:** Press Transfer

2) **On the SMI data Collector select [PRINT]:** set the soft-key to [WIRE]

Receiving Coordinates from the SMI

1) **Get the C&G Transfer Program ready to receive raw data and Press Transfer**

2) **On the SMI data Collector select [JOB]. then [KERM]:** set the soft-key to [NE] and [COMM]. select [SEND] and then select the points to transfer.

Sending Coordinates to the SMI

1) **On the SMI data collector select [JOB] the [KERM]:** set the soft-key to [NE] and [COMM]. select [RECV].

2) **Configure the C&G Transfer Program to send Coordinates:** select the points to be sent and press TRANSFER

Nikon Data Collection Transfer

Receiving Raw Data from the Nikon Total Station:

- 1) **Get the C&G Transfer Program ready to receive raw data and Press Transfer**
- 2) **On the Nikon** select [MENU]. Select option [SET] and then option [COMM]. Set "Ext.Comm:" to Nikon. Set the communication parameters to match those in the C&G transfer program.
- 3) **From the Main Menu on the Nikon select "Comms" and "Download":** select format: NIKON and Data: RAW
- 4) Press ENTER to send.

Receiving Coordinates Data from the Nikon Total Station

- 1) **Get the C&G Transfer Program ready to receive raw data and Press Transfer**
- 2) **On the Nikon** select [MENU]. Select option [SET] and then option [COMM]. Set "Ext.Comm:" to Nikon. Set the communication parameters to match those in the C&G transfer program.
- 3) **From the Main Menu on the Nikon select "Comms" and "Download":** select format: NIKON and Data: COORD.
- 4) Press ENTER to send.

Sending Coordinates Data from the Nikon Total Station

- 1) **On the Nikon** select [MENU]. Select option [SET] and then option [COMM]. Set "Ext.Comm:" to Nikon. Set the communication parameters to match those in the C&G transfer program.
- 2) **From the Main Menu on the Nikon:** select "Comms" and "Upload Data". Press ENTER to receive.
- 3) **Configure the C&G Transfer Program to Send Coordinates:** select the points to be sent and press TRANSFER.

Pulldown Menu Location: CG-Survey>CGTrav>Data Collector Transfer

Keyboard Command:DC, CG_DATA_COLLECTOR

Prerequisite: Check Cable Connection & Communication Parameters

Reduce Traverse

The Reduce Traverse feature allows you to reduce a raw data file, with or without adjustment, and thus create a coordinate file or append to an existing coordinate file.

NOTE: Before you reduce a traverse, check the traverse settings on the Traverse Options tab of the C&G Options dialog.

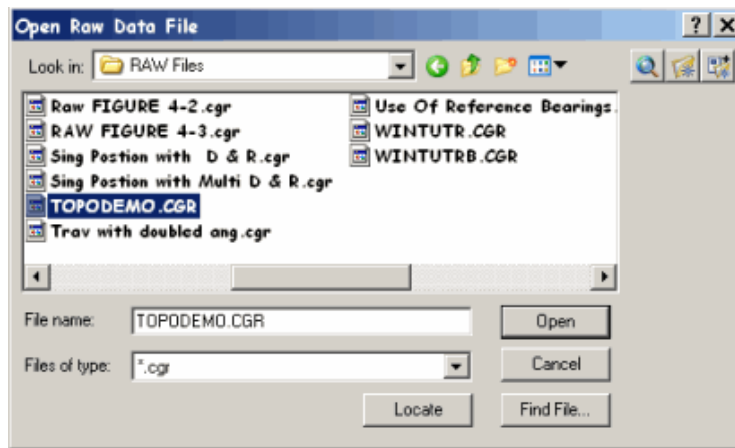

Select the type of adjustment to use: (Compass, Least Squares, etc..)

Adjust Angles: (off/on)

Balance Elevations: (off/on)

If you are adjusting a 3-D traverse, make sure Elevations are turned on: ON

Once the traverse options are set properly you can proceed with traverse reduction.

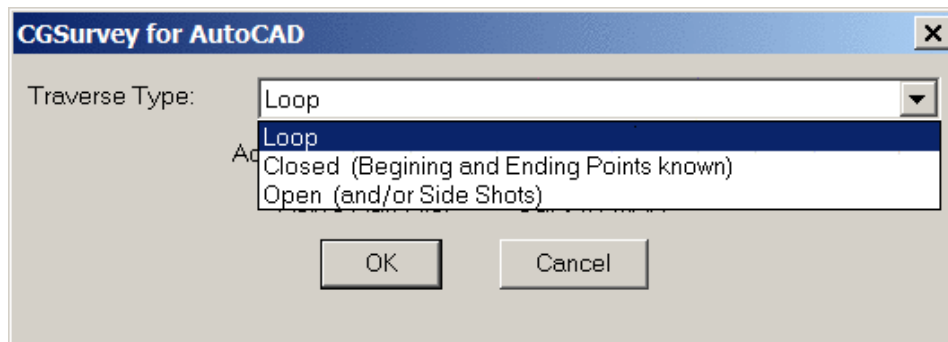

Select Reduce Traverse from the CGTrav menu.

If a raw data file is already open, it will be used. If not, a dialog box will appear prompting you to open a raw data file.

If a coordinate is already open it will be used. If one is not opened you will be prompted to open one. You can select an existing file or type in the name of a new file to create.

NOTE: One coordinate file may be used with many raw data files. For example, you may store the coordinates reduced from an initial boundary traverse (raw data file) in a newly created coordinate file. If you do additional location or traverse work with the control created by the original traverse, this additional work may be placed in new raw data files and reduced to the same coordinate file.

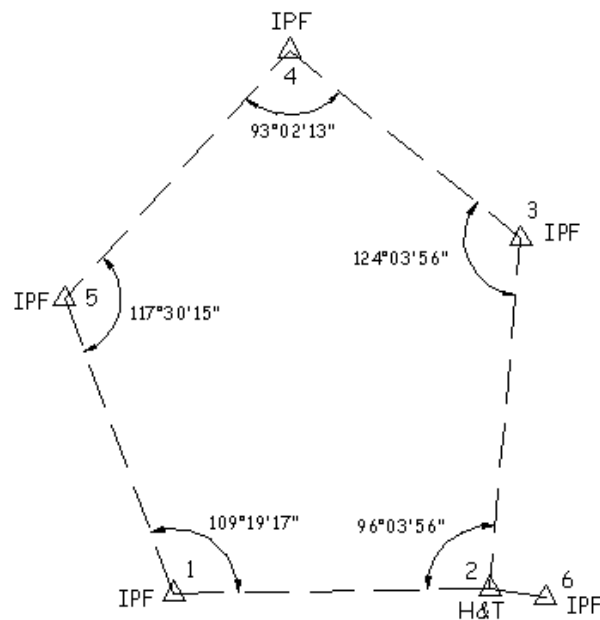

If the raw data file does not have traverse codes (*see the CGEditor chapter*) a dialog will appear asking you which type to use. There are three types of traverses that can be processed. These are shown in the following figure:

The following figures show examples of the three traverse types. The H.I. and rod height entries are optional (if Elevations are on). These are examples of a single distance/angle entry. Each type traverse may be placed in a separate raw data file and reduced into a single coordinate file. However, with the use of special codes you can combine traverses in a single raw data file (*See the CGEditor chapter*).

Traverse Reduction Types:

Closed Loop Traverse

CLOSED LOOP TRAVERSE

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist.	Vert.Angle	Foresight	Code	Description

Closed Loop Traverse Beginning and Ending at Ending at Known points

Shows above is closed traverse beginning on two known points (1 and 2) and ending on two known points (4 and 5). With this type of traverse, both a linear and angular closure can be calculated.

CLOSED LOOP TRAVERSE BEGINNING AND ENDING AT KNOWN POINTS

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist.	Vert.Angle	Foresight	Code	Description

FS				5.00000	87.23150			101		

Shown above is a traverse that begins on two known points, or a single known point and a back sight azimuth, and ends on one known point.

This situation sometimes occurs when you begin on two known points (or a single known point and a back sight azimuth) and end on one known point. In this case only a linear closure is possible.

In order to reduce this type of traverse you must use the CGEditor to enter data not gathered in the field.

Points 2 and 4 are the known beginning and ending points.

Points 100 and 101 do not exist.

We have entered a back sight reference bearing (N 25° 23' 25" E) from 2 to 100.

Line 8 is a dummy setup (we never setup on point 4 and back sighted point 8).

Line 9 shows a dummy angle to the dummy point 101.

Reduce the traverse as a closed Traverse Beginning and Ending on Known Points.

When the traverse is reduced you will have to enter one of the following:

The coordinates of point 101

The bearing from point 4 to 101. Or press <esc> for no angular closure.

If you choose no angular closure, the traverse will be reduced but will report only a linear closure. The adjustment will be made assuming no angular error.

Open Traverse

OPEN TRAVERSE - SIDESHOTS

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist	Vert.Angle	Foresight	Code	Description
IP	3	5.12	4		0.00000					
FS				5.00	113.19430	92.91000	89.15300	9	TP	H&T
IP	9	5.26	3		0.00000					
FS				5.00	284.01250	130.44000	91.15210	10	TP	IPF

An Open Traverse is either an open ended traverse which ties into no known points or a file containing only side shots. In both cases no adjustment is possible.

Note: The data shown in the CGEditor views accompanying the four illustrations include instrument height (HI) and rod height entries. However, if you have elevations turned off, these entries are optional. Also, the examples use single distance and angle entries but multiple measurements are allowed.

In these figures each traverse has been placed in a separate raw data file. However, with the use of special codes you can combine multiple traverses in a single raw data file.

Notes on Traverse Types and Reduction

Closed and Azimuth Traverses: If you are running azimuth traverses, the angle to the side shot is calculated and stored instead of the azimuth. After the traverse has been reduced and adjusted, the angles are used to calculate the side shot coordinates. Thus the side shots are always relative to the instrument point and backsight point used in their location. The first azimuth in the raw data file will be considered a reference azimuth and will be held.

Reducing Loop Traverses:

If there is at least one reference bearing in the raw data file being reduced you will not be asked for a starting bearing. If the instrument point coordinates at the first reference bearing exists, you will not be asked to enter the starting coordinates or elevation. The traverse reduction will begin from the first reference bearing in the raw data file, not necessarily the first instrument point.

If you have more than one reference bearing in the raw data file, the angular closure and adjustments will be from one reference bearing to the next. In other words, all reference bearings will be held as correct, and any angle adjustment will be done from one to the next. This feature was designed for those surveyors who perform

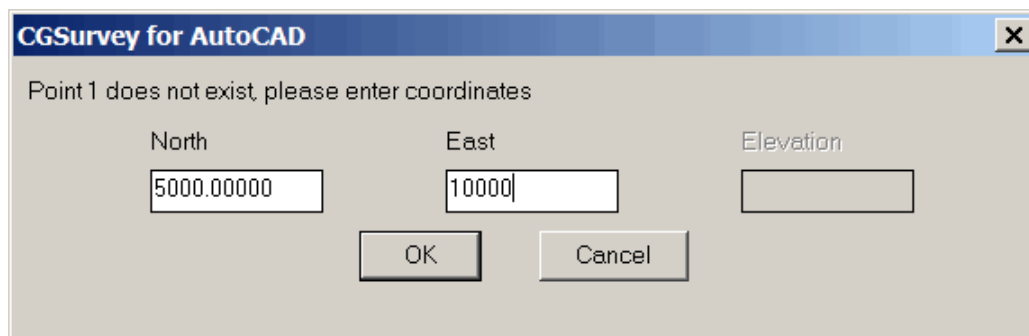

Solar or Polaris observations at intermediate traverse stations, and wish to hold the observed bearing at those stations (the bearings will of course change when the coordinates are adjusted, unless you use Crandall's Rule which does not change bearings)..

Reducing Open Traverse:

Any Reference Bearings found in the raw data file for an Open traverse will be ignored (except the starting reference bearing/azimuth to the back sight point).

Traverse Reduction: Closed Loop

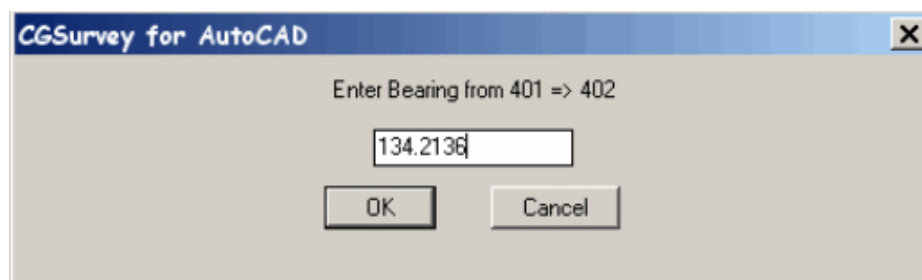

If the first instrument point in the raw data file does not exist, you will be asked to enter the coordinates for that point.

If the first back sight point in the raw data file does not exist and you do not have a reference bearing/ azimuth to the back sight point in the raw data file, you will be given the choice of entering one of the following:

Back sight point coordinates

Bearing from the first instrument point to the first back sight point

If you are processing a Closed Traverse that Begins and Ends on known points, and the last (tie) instrument point in the raw data file does not exist, you will be asked to enter the coordinates for that point. If the last foresight point in the raw data file does not exist and you do not have a reference bearing/azimuth to the foresight point in the raw data file, you will be given the choice of entering one of the following:

Foresight point coordinates

Bearing from the last instrument point to the last foresight point (the last instrument and foresight point are the tie points necessary for linear and angular closure calculations).

Note: The bearing from the first instrument point to the first back sight point, and the bearing from the last (or tie) instrument point to the last (or tie) foresight point will be treated as reference bearings (held fixed). These four points will not be adjusted. If there are any reference bearings in the raw data file, the angular closure and adjustments will be from one reference bearing to the next, just as in Loop Traverses.

Since you may have many foresights from the instrument tie point (side shots), you will be asked to enter which foresight point you will be tying into (unless there are no side shots at the last instrument point).

The traverse will begin by the coordinates found in the coordinate file for the first instrument point and backsight point (coordinate values can be placed directly into the raw data file). The traverse will then be calculated. When the traverse is finished, the coordinates for the last instrument point and foresight point in the raw data file will be read from the coordinate file (or raw data file) in order to calculate the angular, vertical and horizontal closure.

If Elevations are ON you will be shown the elevation control found in the Raw Data and Coordinate files that pertains to your traverse. If no elevation control is found none will be shown and you will have to ADD control. Your elevation control can be anywhere in the traverse. It does not have to be on the first point.

You will have the following option at the command line:

Point Elevation

1 500.00

[Add/Change/Delete/Go/aBort]: <G>g

Select Add to add points to elevation control: A

Select Change to change the elevation assigned to a point in the elevation control: C

Select Delete to remove a point from the elevation control: D

Select Go to calculate elevations: G

Select aBort to quit without calculating elevations B

Select the appropriate option and the elevations will be calculated based upon the supplied information.

At this point you will get two closure reports:

The first report is before angle adjustment:

***** Closure Report *****

Total angular error: -0°00'06"

Angular error per point: -0°00'01"

Correct Ending Coordinates, North: 5000.00000 East: 5000.00000

Ending Coordinates, North: 5000.04008 East: 5000.00421

Error, N: 0.04 E: 0.00 Total: 0.04 Brg: S 05°59'43"W

Distance Traversed: 2470.51 Closure: 61308

The Second Report is after angle adjustment:

***** Closure Report *****

Total angular error: 0°00'00"

Angular error per point: 0°00'00"
 Correct Ending Coordinates, North: 5000.00000 East: 5000.00000
 Ending Coordinates, North: 5000.04314 East: 5000.01593
 Error, N: 0.04 E: 0.02 Total: 0.05 Brg: S 20°16'08"W
 Distance Traversed: 2470.51 Closure: 53721

Following the angular adjustment the reduced traverse will be displayed:

Adjusted by Least Squares

***** Elevation Calculations - Elevations Adjusted *****
Elevations from Points: 1 -> 1
Vertical Err: -0.01, Distance Traversed: 2470.51

The calculate points will be stored in the coordinate file. There is an overwrite protection built into the software. If a point already exists in the coordinate file you will have the following options:

CANCEL: will terminate the process of storing coordinates.

OVERWRITE : will overwrite the existing point.

DO NO OVERWRITE: skip to the next point. If you have the "*Do Not Ask Again*" box checked, OVERWRITE will overwrite all points without asking,

DO NOT OVERWRITE: will only write NEW points to the coordinate file.

Traverse Reduction: Open Traverse/Side Shots

When reducing these types of traverses, no adjustments are possible. The coordinates for instrument points and back sight points will be pulled from the coordinate file (or raw data file) and used to calculate and store the foresights. This option allows you to occupy newly created points.

Coordinates of back sight points will be calculated only if a distance has been entered to the back sight point and the back sight point does not exist in the coordinate file.

If you are back sighting a point that does not exist in the coordinate file and the raw data file does not contain a reference bearing or azimuth to the back sight point, you will be given the choice of entering one of the following:

Coordinates of the back sight point

Bearing from the instrument point to the back sight point

If you choose to enter the bearing and there is no distance to the back sight point in the raw data file (thus making it impossible to calculate its coordinates), and you later occupy that point, you will be asked to enter the

real coordinates of the point.

If you are backsighting a point that does exist, and you have a distance measurement to the backsight point in the raw data file, we will show a warning if the inversed distance from the coordinate file does not match the measured distance within the tolerances set in the CGTools->Global Options->Traverse Options dialog.

A table will be printed containing the following:

Side Shots

Angle Distance Northing Easting Elevation Pt ID Code Description

Inst.Pt.: 1 Bs.Pt.: 10

148°15'53" 123.43 5058.01266 5108.95161 489.96 47 3 ipf1otp

97°53'24" 46.81 5045.85154 5009.40500 499.25 48 2 ip4rb

17°33'40" 96.60 5035.03240 4909.97367 506.27 49 2 ipf4rb

Angle Adjustments

If you have set Adjust Angles in the Traverse Options dialog box, all angles will receive equal adjustment. If there is more than one reference bearing, the angles will be adjusted equally between reference bearings. You will be shown the closures before and after the angle adjustment.

NOTE: If you are going to use the Least Squares Adjustment, you should not adjust the angles. Angular adjustment is part of the Least Squares Adjustment process.

Elevation Adjustment

If you have set Adjust Elevations in the Traverse Options dialog box, the elevations will be adjusted in proportion to the lengths of the lines (the longer the line, the more the adjustment).

Least Squares, Crandall's and Compass Rule

If you select any of these adjustment options the coordinates will be adjusted with the appropriate method.

Find Bad Angle

If you have a bad angular closure, select Find Bad Angle in the Traverse Options dialog box instead of an adjustment type. This function will not create or store any coordinate points.

NOTE: This option cannot be used with Azimuth Traverses.

You will see the following report:

Total angular error: 0°00'07"

Angular error per point: 0°00'01"

Correct Ending Coordinates, North: 10000.00000 East: 10000.00000

Ending Coordinates, North: 10000.05876 East: 9999.95840

Error, N: 0.05876 E: -0.04160 Total: 0.07200 Brg: S 35°17'49"E

Distance Traversed: 1492.10800 Closure: 20725

Instrument point: 1, Error: 0.07200, Closure: 20725

Instrument point: 2, Error: 0.08249, Closure: 18089

Instrument point: 3, Error: 0.08284, Closure: 18013

Instrument point: 4, Error: 0.07542, Closure: 19785

Instrument point: 5, Error: 0.06751, Closure: 22103

Worst Closure: 18013

Average Closure: 19620

Possible bad angle at instrument point: 5, Closure: 22103

In the above example, there were 5 traverse points. The traverse is reduced five times, beginning at each traverse point. The starting instrument point that produces the best closure is shown as having the bad angle. All closures are shown.

OTHER METHODS OF TRAVERSING

Every surveyor has his own unique methods when it comes to traversing. This section describes and shows examples of four additional entry methods.

Notice in the sample traverses there is a distance and vertical angle recorded for each foresight and back sight. This is optional, but you need at least one distance to each foresight.

Where both foresight and back sight distances are recorded, distances will be averaged when reduced

Side shots may be entered along with traverse information. You may turn more than one angle to side shots if you wish.

A description and/or code only needs to be entered once for a given foresight point.

Single Position with Direct and Reverse Angles

Perform this method as follows:

Shoot the back sight.

Turn to a foresight.

Record the angle and distance.

Plunge the instrument.

Take another reading (reversed) to the foresight. You may do this to traverse points and side shots.

Turn back to the back sight with the instrument reversed.

Record another angle to the back sight.

The final angle in each set for each instrument point must be a reverse reading to the back sight.

The angle in the instrument for the first back sight will be subtracted from the first angle to each foresight. The final (reverse) angle to the back sight will be subtracted from the second angle to each foresight. The two resulting angles will then be averaged to give you an angle to the foresight. All distances recorded will be averaged.

Single Positions with Multiple Direct and Reverse Angles

Entering multiple sets of direct and reverse angles is very much like the preceding example where 1 direct and reverse set was entered. The only thing to remember is that each direct and reverse pair is a set. When another set is entered, it begins with a back sight direct angle (recorded like a foresight), has direct angles and reverse angles to the foresights, and ends with a reverse angle to the back sight. Do not begin a new instrument point for the second set, merely record a new back sight angle and continue with the procedure through each foresight, and end with another reverse angle to your back sight.

Azimuth Traverses

Azimuths are entered into a file with the azimuth to each foresight entered in the Foresight data entry line at the azimuth column.

NOTE: If you are running a Closed Loop Traverse, a reference azimuth must be placed at the last instrument point if you wish to adjust the angular error.

The reference azimuth is the correct azimuth from the last instrument point in the raw data file to the first instrument point (or last foresight).

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Azimuth	^ Slope Dist.	^ Vert.Angle	Foresight	Code	Description

Each new instrument setup requires a 0 to the back sight. The first angle to the foresight is the single angle. This angle is locked into the gun and the back sight is retaken. The second angle to the foresight is the doubled angle. You can double angles to side shots.

Loop Traverse Beginning and Ending on External Reference Azimuths

This type of traverse occurs frequently. The example below shows a Loop Traverse that begins on an external reference azimuth and ends on an external reference azimuth. Even though this traverse closes on itself, it must be reduced as a Closed Traverse Beginning and Ending at Known Points.

Point 100 is a dummy point on the azimuth line. Line 3 shows a reference bearing from point 1 to 100 (negative means from ip to bs) of S00-00-00E.

Line 16 shows the same reference bearing.

Point number 100 need not exist in the coordinate file and will not be calculated, but a dummy backsight and foresight point number must be entered into the raw data file.

Use Of Reference Bearings and Azimuths

Reference Bearings and Azimuths are entered by Adding or Inserting a Reference Bearing data entry line. For example:

DR 1-2 123.4523

The direction from point 1 to point 2 is N23-45-23E.

Reference bearings and azimuths are optional (except for Closed Loop Azimuth Traverses). If a reference bearing is used, that direction will be held during the reduction process. More than one reference bearing may be used. The data below shows a raw data file using multiple reference bearings:

The previous data represents a loop traverse. If you choose to adjust angles, all angles will be adjusted from one reference bearing to the next (angles 1-5, 6-1). Angular closure information will also be shown from one reference bearing to the next. See the Reduction section of this chapter for more specific information on the use of reference bearings with different types of traverses.

Except for an initial reference bearing to the back sight point, reference bearings will be ignored for Open Traverses (no adjustments are available).

Multiple Traverse Codes in a Single File

This sample is of a raw data file that contains multiple traverse codes in a single file: ET end main loop traverse
Scale factors are placed after Instrument Point data entry lines. Any text following a LT, CT, OT or ET marker is

used for comments. Notice that the codes MUST precede the first instrument setup that begins the traverse. The Foresight Tie Point in the previous example is necessary because there is a side shot (point #25) at the end of the Closed Traverse. The reduction routine does not know whether you are tying into point 25 or point 2

Point	North	East	Elev	Code	Description

Pull Down Menu Location:CGTrav\ Reduce Traverse
Keyboard Command:RT, CG_REDUCE_RAW
Prerequisite:Open Raw file *.CGR

Edit Map Check File

The map check program is used to enter or edit deed and map information for checking closures and to assist with evaluating data from other sources for a job you are working on.

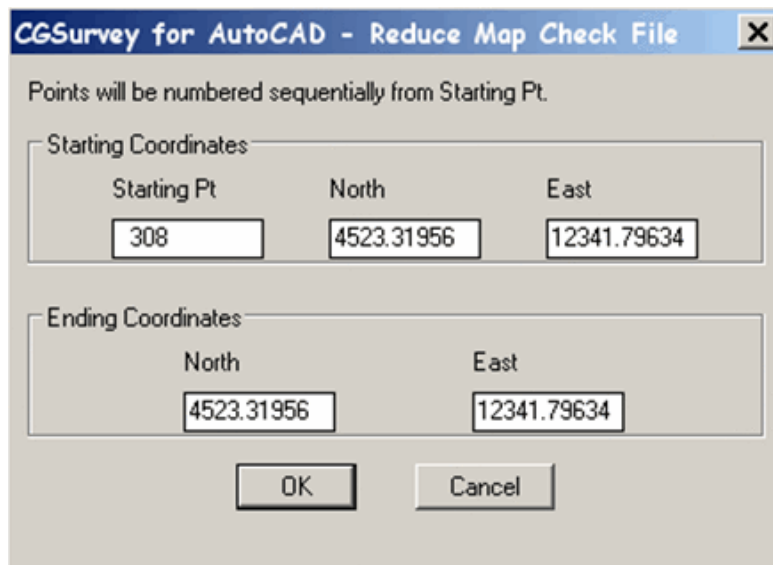

Note: for further and complete information on using the Mapcheck editor, see the chapter on CGEditor in the Tools section.

Pulldown Menu Location: CGTrav/Edit Mapcheck File
Keyboard Command: EM, CG_EDIT_MAP
Prerequisite: None

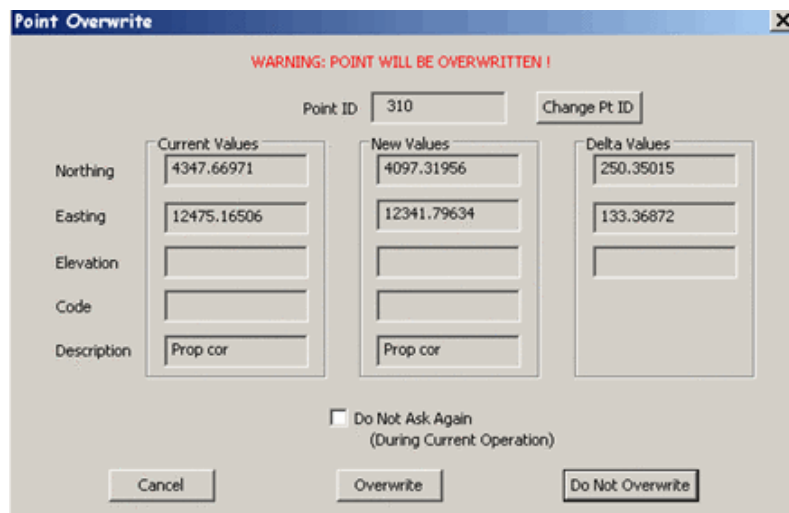

Reduce Map Check File

If a map check file is not open, a file dialogue box will appear, allowing you to open an existing map check file. If you wish the coordinates to be adjusted, select the type of adjustment in the Traverse Options dialog box. If a coordinate file is not open, a file dialog box will appear allowing you to open one. NOTE You may use the same coordinate file as often as you wish. Make sure the correct coordinate file is open.

Next Enter Point values: the starting Point number, Northing and Easting and the ending Northing and Easting:

The map data will then be reduced and the coordinates stored in the coordinate file. Overwrite protection is in place in case the points already exist in the coordinate file. If a point already exists in the coordinate file you will have the following options:

CANCEL: will terminate the process of storing coordinates.

OVERWRITE :will overwrite the existing point.

DO NO OVERWRITE: skip to the next point. If you have the "Do Not Ask Again" box checked.

Overwrite will overwrite all points without asking, and Do Not Overwrite will only write NEW points to the coordinate file.

The initial closure information will be shown. For example:

Correct Ending Coordinates, North: 5000.0000 East: 5000.0000

Ending Coordinates, North: 5071.8346 East: 4894.7441

Error, N: 71.83 E: -105.26 Total: 127.43 Brg: S 55°41'15"E

Distance Traversed: 1308.19 Closure: 10

A full report including acreage may be viewed by pressing the F2 key to view the CAD Text Window. You may also view/print the display file.

Visual Map Check

This routine allows you to graphically pick the Call Text (Bearings and Distance) from a drawing and perform a Map Check Closure.

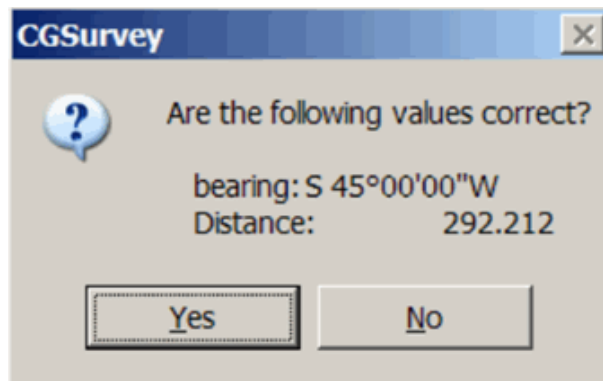

Prompts

First you will be asked: Pick Point of Beginning: You can enter the beginning point number, or graphically pick the point on the screen.

Next: Pick Bearing Text for Leg 1 (ask Reverse is ON) [Off/Done]<Done>: Graphically pick the text with the Bearing. If "ask Reverse" is turned ON, you will be allowed to reverse the direction of the bearing after it is selected:

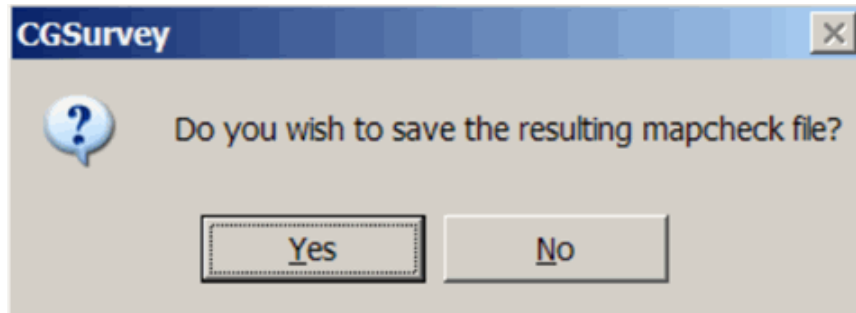

Next: Pick Distance Text for Leg 1: Graphically pick the text with the distance. You will see:

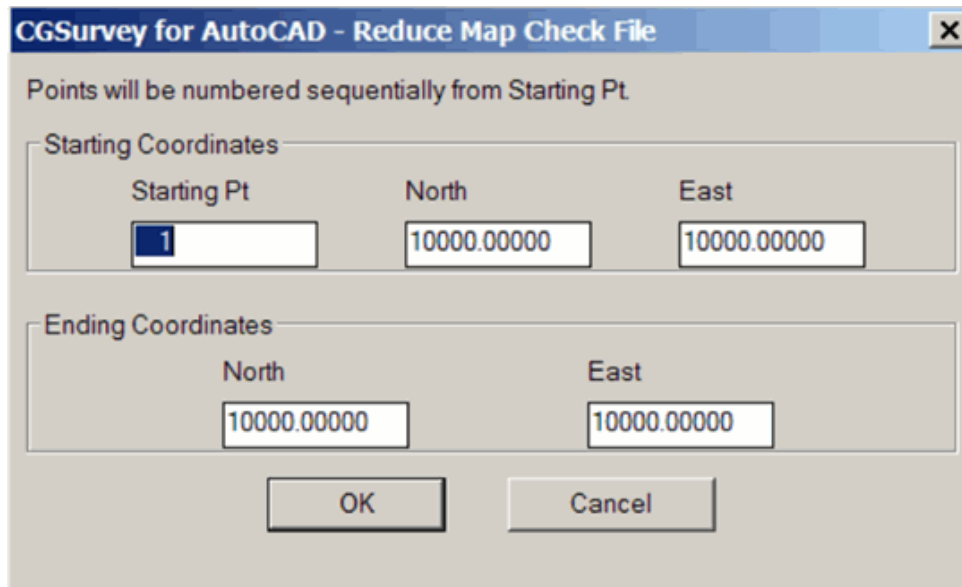

If you select YES, you will go to the next leg. If you select NO: you will be asked to pick the Bearing and distance for Leg 1 again.

After selecting all the Calls: press ENTER for DONE. You will have the option:

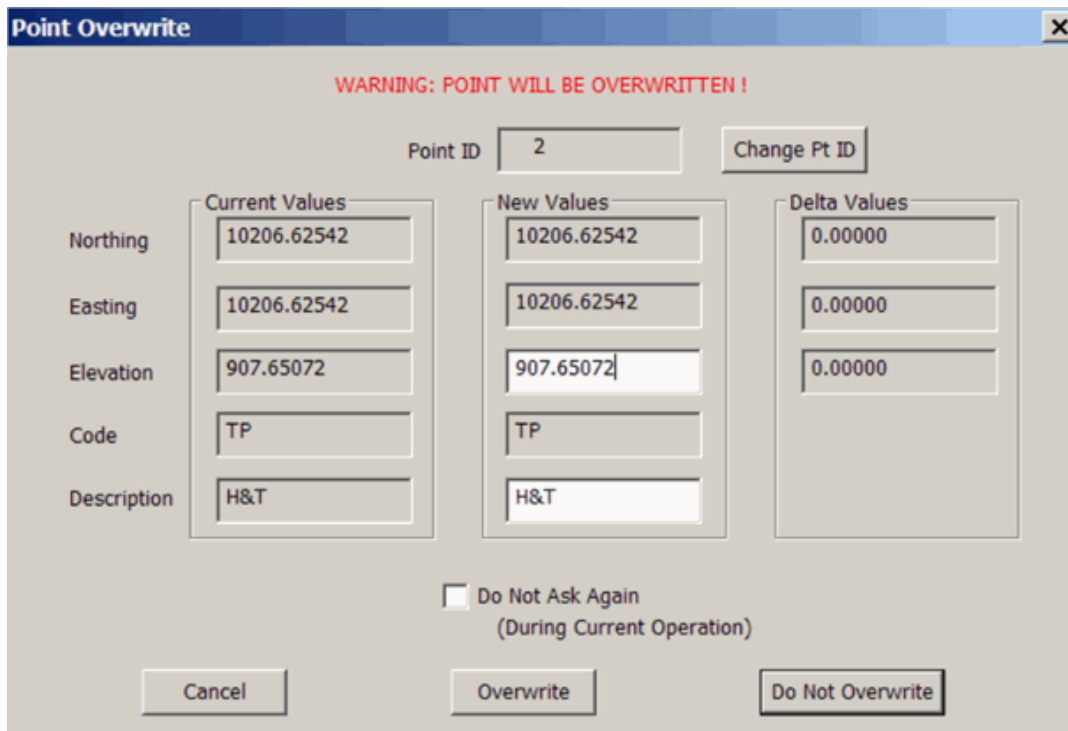

If you select YES, the information: you selected will be placed in a Map Check File. You will be asked to select the CGM file.

Next: Enter the starting and ending coordinates for the traverse.

The map data will then be reduced and the coordinates stored in the coordinate file. Overwrite protection is in place in case the points already exist in the coordinate file. If a point already exists in the coordinate file you will have the following options:

CANCEL: will terminate the process of storing coordinates.

OVERWRITE: will overwrite the existing point.

DO NO OVERWRITE: skip to the next point. If you have the "Do Not Ask Again" box checked, OVERWRITE will overwrite all points without asking, **DO NOT OVERWRITE:** will only write NEW points to the coordinate file.

Below is a sample Report:

Correct Ending Coordinates, North: 10000.00000 East: 10000.00000

Ending Coordinates, North: 9586.74896 East: 9586.74832

Keyboard Command: VM, cg_visual_mapcheck

Prerequisite: Call Text must be displayed to select

Create StarNet File

This option converts a raw data file to the Star*Net (.DAT) format. The raw data file will be preprocessed. During conversion, multiple distances and angles will be averaged and compared to the maximum ranges set in the Traverse Options dialog box. To use this option properly, you must know how Star*Net works. You should be familiar with all Star*Net codes and commands.

NOTE: This manual is not a substitute for the Star*Net manual.

Below is a sample raw data file that contains three different traverse types. This raw data file can be reduced using CG-SURVEY or written to a Star*Net file for reduction with Star*Net, both without any editing.

```

The coordinate formats (C code) are the same for Star*Net and CG-SURVEY; no translation is necessary.

If a comment line in the raw data file uses a valid Star*Net code or command, it will be used in its original form (as with coordinates); not as a comment. These codes are #, C, A, D, V, B, M, TB, T, TE, SS (followed by a space) and all dot commands. (example: .CURVE, .SCALE, etc...)

Multiplication factors are converted to the .Scale command. The original multiplication factor set in the Global Options dialog box will be placed at the beginning of the Star*Net file. Other multiplication factors will be placed as they occur in the raw data file.

NOTE: You cannot use a multiplication factor for meter/feet conversion in a 3-D traverse in Star*Net 3.2.

Reference bearings/azimuths are converted to the B format.

All traverse points are converted to the M format and side shots to the SS format. Only points used once (as a foresight point) will be considered a side shot. If a point is located from more than one instrument setup, or is used as an instrument point or backsight point, the point will be converted to a M format

The LT, ET, OT, FT and CT codes are converted to comments. Point codes are combined with descriptions.

If Elevations are on, the Star*Net file must be adjusted as a 3-D traverse. The following could occur:

If you input slope distances and vertical angles, all distances will first be reduced to their horizontal/vertical components. Multiple distances will be averaged and then a slope distance and vertical angle will be recomputed from the averaged horizontal/ vertical components. This is done so Star*Net can compute corrections for curvature and refraction and vertical divergence (can only be done if vertical angles are used in a 3-D traverse.) A ".Delta Off" command will be placed in the Star*Net file.

If Curvature and Refraction is on in the Options/Global Options dialog box, a Curve command will be placed in the Star*Net file.

If you input horizontal and vertical distances, a ".Delta On" command will be placed in the Star*Net file. No corrections for curvature and refraction or vertical divergence will be possible.

If Elevations are off in the Options/Global Options dialog box, the Star*Net file must be reduced as a 2-D traverse. The following will occur:

If you input slope distances and vertical angles, all distances will be reduced to their horizontal/vertical components and the vertical components will be thrown away. Multiple distances will be averaged.

No corrections for curvature and refraction or vertical divergence are allowed in a 2-D traverse with Star*Net version 3.2 or earlier.

Pulldown Menu Location: CGTrav

Keyboard Command:STN, CG_REDUCE.STARNET

Prerequisite: Open CG Raw file *.CGR

CGCogo

The Command Line:

Throughout CGSurvey the user will be prompted at the command line for input. Typically the command line is at the bottom of the CAD graphic screen, although the command line can be placed above the graphics screen. To enter a command at the command line use the key board, and press the <Enter> key when finished.

The F2 hot key can be used at any time to access a full text window that displays user input and history. As point numbers are typed in, or selected on the screen using the mouse, the point number entered is displayed at the command line. When the next point ID is requested the previous point ID is used as the starting point for the command.

For example, when inverting from 5 to 7. First you type 5 at the command line and press <Enter>.

Command:

[Point group/Reset/sNap on] (last point = <none>): 5

[cLockwise curve/ccW curve/Point group/Reset/sNap on] (last point = 5):

Note that 5 is now displayed as the "Last Point". This means that when 7 is entered at the command line the inverse will be calculated from point 5 to point 7.

To clear the last point enter R or "." and <Enter> for Reset. The last point will now be shown as <none>.

Inverse

This command allows you to determine the bearing and distance between the endpoints of a line or a curve by entering the points that define the line or curve.

After choosing the Inverse menu item you are asked to "Enter point sequence". A point sequence is a series of points that define the points being used to calculate the inverse. You may enter one point ID at a time to inverse from point to point. You may enter the two points separated by a dash (5-7), etc.

Enter point sequence

[Point group/Reset/sNap on] (last point = <none>): 5

[cLockwise curve/ccW curve/Point group/Reset/sNap on] (last point = 5): 7

Note that 5 is now displayed as the "Last Point". This means that when 7 is entered at the command line the inverse will be calculated from point 5 to point 7.

To "Reset" the last point enter R or "." and <Enter> for Reset. The last point will now be shown as <none>.

Inversing Around Curves Clockwise

To inverse around a clockwise curve (one curving to the right), enter the PC point ID then enter "L" or "+" to indicate a clockwise curve. Next enter the point ID of the radius point of the clockwise curve and follow with the PT point ID.

For Example:

First enter the PC of the curve. In this example type or pick point ID 2201

Enter point sequence

[cg-Point-group/Reset/turn-Snap-on] (last point = <none>): 2201

Now type L or "+" and <Enter> for a clockwise curve

Enter point sequence

[clockWise curve/Ccw curve/Point group/Reset] (last point = 2201):L

Next type or pick the radius point ID 2200

Enter radius point for curve [Reset/sNap on]: 2200

You may also use the mouse to pick a C&G Arc. In this case, the arc's radius point will be used

Next type or pick the PT point ID 2202

Enter point of tangency (PT) for curve [Reset/sNap]: 2202

Inversing Around Curves Counter Clockwise

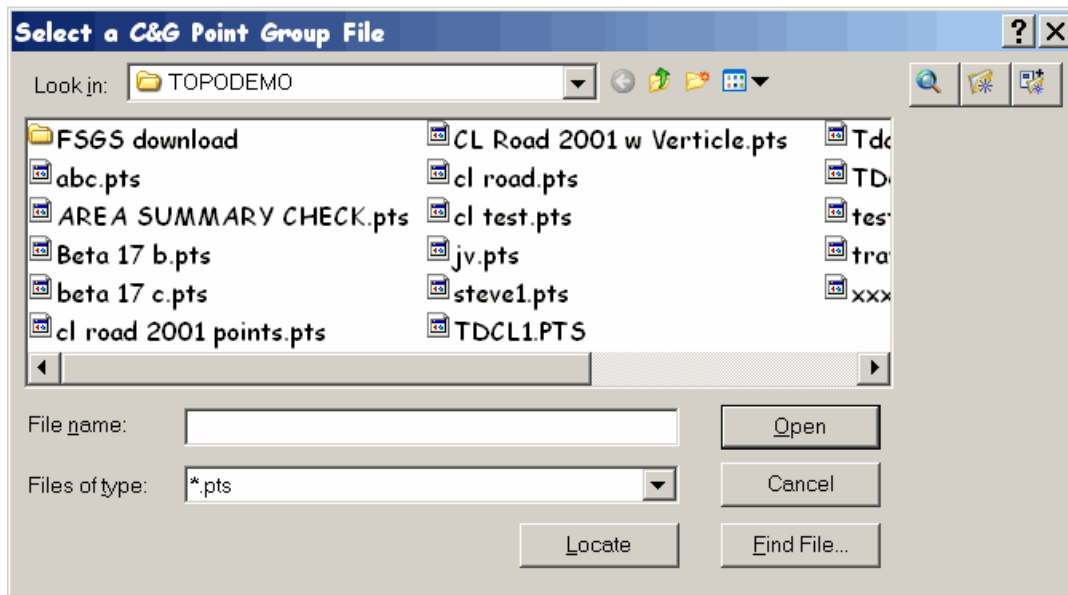

To inverse around a curve in a counter-clockwise direction (curving to the left) simply type W or "-" and <Enter> then proceed as with a clockwise curve.

Inversing between a series of points in the coordinate file

By entering 2 point numbers separated by a "+" you can inverse through successive point IDs in the order they are found in the coordinate file (either numeric or alphabetic order). For example, if you enter 3+6, inverses will be calculated and displayed from point 3 to 4, 4 to 5 and 5 to 6. You can use the <F2> key to view the information printed at the command line or you can view the print file (CGFile > Print/View Print File).

Inversing using Point Groups:

You can use a Point Group to inverse between a series of points specified by the point group. To specify a point group type a P or '*' and <Enter> at the command line. This will display a dialog box showing the Point Groups currently in the default directory.

Prompts

Enter point sequence

[Point group/Reset/sNap on] (last point = <none>): Enter or pick the first point on a line or the PC of a curve. Type "P" and Enter to use a point group to specify the inversing sequence. Type "R" and Enter to Reset the last point. Type "N" and Enter to turn on CAD snaps (these are turned off when the command starts).

[cLockwise curve/ccW curve/Point group/Reset/sNap on] (last point = 5): Enter or pick the next point ID to inverse to or type "L" and Enter or "W" and Enter to specify the radius point of a curve.

if you are entering a curve:

Enter radius point for curve [Reset/turn_Snap_on]: Enter or pick the radius point for the curve.

Enter point of tangency (PT) for curve [Reset/turn_Snap_on]: Enter or pick the PT point for the curve.

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg_inverse

Prerequisite: coordinate file

Intersects

This feature allows you to calculate intersections based on one of the following methods:

Bearing-bearing

The bearing-bearing intersect is calculated based on a line passing through a point on a given bearing intersecting another line passing through a second point on another specified bearing.

Bearing-distance

This is based on a line passing through a point at a given bearing intersecting a circle at a given distance (radius) from a second point. This intersection by result in 2 points of intersection.

Distance-distance

This is based on intersecting a circle at a given distance (radius) from a point with another circle at another given distance (radius) from a second point. This may also result in 2 points of intersection.

Perpendicular

This is based on calculating the perpendicular distance from a given point to a line that passes through another point

at a specified bearing.

Tangent

This is based on calculating the tangent points of a line drawn from a given point to a circle having a specified radius and radius point.

Command line input

After selecting the Intersects option on the CGCogo pull down menu and the Use Intersects Dialog menu item is not checked you will see the following prompt.

Intersection method: Brng-Brng/Brng-Dist/Dist-Dist/Perp/Tangent or offsets-on
[BB/BD/DD/Perp/Tangent/turn-Offsets-on]:

Bearing-Bearing Intersections:

Type "bb", then press <Enter>

At the Enter first Point: prompt type in or pick the point using the mouse

As an illustration, using the example shown in the figure: type or pick point 2203.

At the Enter first bearing: prompt there are 3 options available:

Type the bearing directly using the special C&G notation qddmss (quadrant, degrees, minutes and econds)
105.2316 (N 05° 23' 16"E)

Enter the two known C&G points that define the bearing either by typing the two points in with a dash between them or picking the two points one at a time using the mouse.

Or select a C&G line. When you select a line the bearing is computed by inverting between the two points that created the line. The bearing quadrant is based on traversing from the end point of the line farthest from the location where the line was picked to the end point of the line nearest to the point picked.

Enter second point: for the example type or pick point 2204

Enter second bearing: use any of the methods outlined for entering first bearing.

The intersection will then be calculated, the intersection point saved to the coordinate file and the results displayed at the command line.

When saving the intersection point, depending on your settings on the Global Settings tab of the C&G Options dialog, you may be asked to either enter or change the point ID, elevation, point code and description.

At each of the STORING POINT prompts there is an option to change settings [Settings]. Pressing S will bring up the Global Options tab of the C&G Options dialog box, allowing you to change settings prior to saving the point. (see the CGTools Chapter for a description of the CGOptions dialog box)

Bearing-Distance Intersection

Type bd to calculate the intersection of a circle with a line. Generally, the data is entered in the same fashion as for a bearing-bearing intersection.

Once the data is entered each of the two solutions will be displayed one at a time.

You will be asked if the solution shown is the correct solution.

Is this the correct solution [Yes/No/ESC]:

If the solution is the correct one press Y for <Yes>. If it is not the correct solution press N for <No> and the second solution will be displayed. If neither solution is correct press <Esc> to cancel and return to the previous prompt.

Distance-Distance Intersection

Type dd to calculate the intersection of two circles: with the distances being the radii of the circles
You will be prompted to enter the first radius point and distance (radius)
You will then be asked to enter the second radius point and distance (radius)
As with the bearing-distance intersection, the two possible solutions will be displayed and you will be asked to choose the correct one (see dialog below).

If you click the No button the other possible solution will be displayed. If you click the Yes button the intersection point will be stored. If you click Cancel the point will not be stored.

The routine will continue with additional DD Intersections prompts until you escape [ESC] the routine. The process will be repeated until the user presses <Esc> twice to end the command.

Perpendicular Intersection

Press P and <Enter> to calculate the point where the perpendicular constructed from a given point to a line intersects the line.

At the Enter first Point <>: prompt, type or pick a point on the line (in the example illustrated in the figure, type or pick point 2514)

At the Enter bearing: <>: prompt, type the bearing of the line or type or pick the two points defining the bearing (in the example, 2514-2513)

You will then be asked if you want to

Store Perp. Int. Pt. (Yes/No):

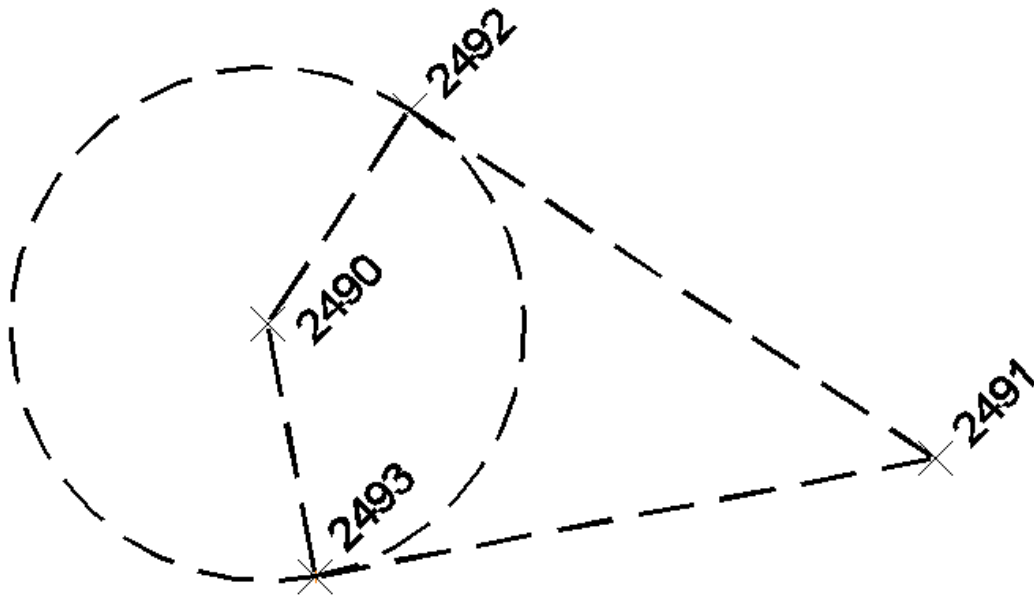

Choose whether to store the calculated point or simply view the data (you may not want to save the resulting intersection point).

Enter second point <>: Type the point ID, or use the mouse to pick the point from which the perpendicular to line is to be constructed (in the example, 2488).

The STORE POINT prompt will indicate the point being stored (in the example it will be 2489). Press <ESC> to cancel point storage.

To exit the Instrsects feature, the user must press <Esc> twice or the routine will repeat.

Tangent Intersection

Type T and <Enter> to calculate the points at which a line from a given point becomes tangent to a circle. You must choose a radius point for the circle, the radius of the circle, and the external point from which the tangent will start.

At the Enter radius point for circle: prompt, type or pick the center or radius point of the circle (in the example, 2490)

At the Enter radius of circle: prompt, type the radius or type or pick two points that define the radius distance (in this example, 2490-2492, or 69.92')

At the Second point: prompt, type or pick the point through which the tangent lines must pass (in the example, 2491)

As in some of the other intersection types, you must select the desired solution from the two possible solutions using the dialog shown for the distance-distance intersect.. If you click the Yes button, the intersection point will then be saved to the coordinate file and the results displayed at the command line.

To end the command, press <Esc> twice or the routine will repeat

Turn-Offsets-on:

Type O and <Enter> to turn the use of offsets on or off .

An example of an offset intersection would be the easement lines for a sewer line. This routine can calculate the offset intersection say for a 7.5' left offset and a 10' right offset, as shown.

For example:

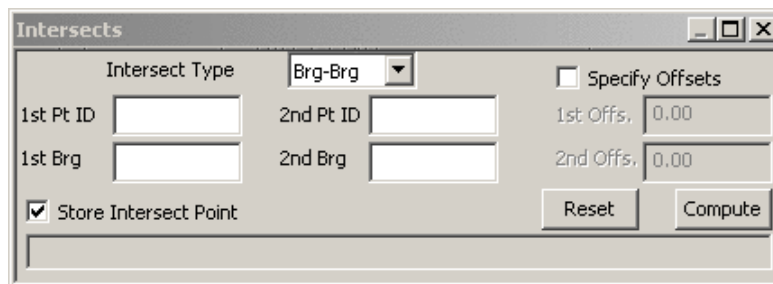

Enter first offset distance <>: -7.50

Enter Second offset distance <-7.50>: 10.00

The offset distances are positive if right of the line, as seen looking down the line in the direction of the defined bearing, negative if left of the line.

Intersects dialog

If the Use Intersects Dialog menu item is checked you will see the following dialog:

To use the Intersects dialog just set the Intersect Type drop down list to specify the type of intersect you wish to do.

Next click on the item you wish to specify. You may type in the information or you can move the cursor over the drawing area and you will be prompted for the information required for the edit box you were last in. To enter the next item, click on that edit box and type the information or, as before, move the cursor over the drawing and you

will be prompted for the necessary information for the last edit box you were in. Continue to do this until all information has been entered then click the Compute button to compute the intersection. The results will be printed

on the CAD command line and to the print file. If the Store Intersect Point check box is checked the intersection point will be stored in the coordinate file. You may specify offsets by checking the Specify Offsets checkbox and entering or picking the offset distance(s). Click the Reset button to remove all entered data from the dialog.

You may perform any other commands while the Intersects dialog is displayed - the data entered in the dialog will remain for use at any time.

Prompts

Not using Intersects Dialog:

Intersection method: Brng-Brng/Brng-Dist/Dist-Dist/Perp/Tangent or offsets-on

[BB/BD/DD/Perp/Tangent/turn-Offsets-on]: Type the 1 or 2 capitalized letters to specify the type of intersect to calculate or to turn offsets on.

point prompts

Enter point: Type a point ID or pick a point symbol on the screen.

Enter first point: Type a point ID or pick a point symbol on the screen.

Enter second point: Type a point ID or pick a point symbol on the screen.

Enter radius point for circle: Type a point ID or pick a point symbol on the screen.

Enter point on tangent line: Type a point ID or pick a point symbol on the screen.

bearing prompts:

Enter bearing <100.0000>: Type or pick the bearing.

Enter first bearing <100.0000>: Type or pick the bearing.

Enter second bearing <100.0000>: Type or pick the bearing.

distance prompts:

Enter distance <0.000000>: Type or pick the distance.

Enter 1st distance <0.000000>: Type or pick the distance.

Enter radius of circle <0.000000>: Type or pick the distance.

perpendicular intersect prompt:

Store perpendicular intersect point [Yes/No] <N>: Type "Y" or "N" and Enter.

Stopping to allow viewing of intersect point (red X) <Enter to continue> This prompt is displayed if you answered "N" to the previous prompt. Just press Enter to continue.

Intersects dialog: Type or pick the data into the appropriate edit boxes then click the Compute button to view the results and save the intersection point to the coordinate file.

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg.intersects

Prerequisite: coordinate file

Station Offset

In order to use the station offset functions, you must create a Point Group (formerly called a batch point file or point file) defining a centerline alignment. The Coordinate Management > Point Groups > Create section describes how you can create a Point Group.

To illustrate the use of point groups in the various station offset features, the following point group file will be used:

7.25+ (Slope in, 1st vert. Curve)

1.75- (Slope out, 1st vert. curve & slope in, 2nd vert. Curve)

200* (Vertical Curve Length curve 1)

/123.50 (PVI Elevation curve 1)

*1300 (PVI Station curve 1)

2.00- (Slope out of curve 2)

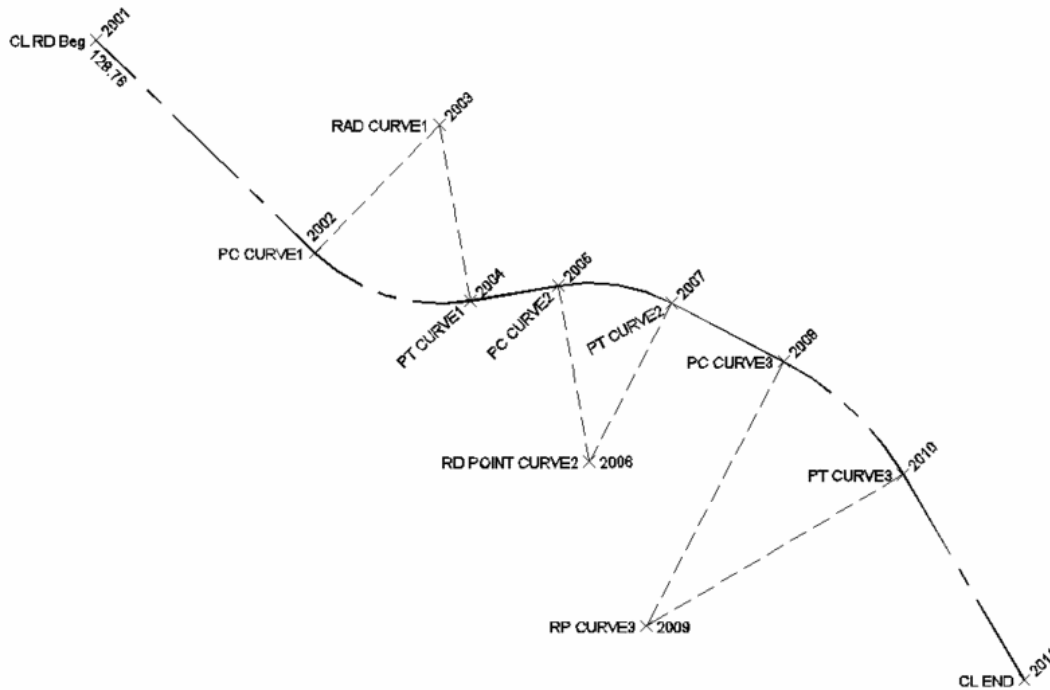

*1750 (PVI Station curve 2)

300* (Curve Length curve 2)

- 1000 (Subgroup name - also default beginning station)
- 2001 (Point ID at Sta. 10+00)
- 2002 (Point ID at PC of Curve)
- 2003 (Radius point ID, '-' indicates counter clockwise)
- 2004 (Point ID at PT of curve)
- 2005 (Point ID at PC of curve)
- +2006 (Radius point ID, '+' indicates clockwise curve)
- 2007 (Point ID of PT of curve)
- 2008 (Point ID of PC of curve)
- +2009 (Radius point ID, '+' indicates a clockwise curve)
- 2010 (Point ID of PT of curve - last entry in subgroup and in file)

NOTE: Information shown in parenthesis are comments used here for explanation and do not appear in the point group file itself.

Alignment used for examples

Coords From Station Offset

This feature allows you to calculate and store a coordinate point for any given station and offset along an alignment defined by a point group. Use the Select a C&G Point Group File dialog to open a point group file.

Enter Starting Station [Done] <0.0000> You can Press <Enter> to use the default station shown, or you can enter a new starting station. If you enter a "+" followed by a value, ex. "+50", all stations on a 50 foot interval will be calculated automatically.

Enter Offset <0.00000>: Enter the offset distance from the alignment.

The point ID, station, offset, northing, easting, elevation and description will be printed at the command line and written to the print file.

You may repeat the process until you have calculated all the desired stations or press D then <Enter> to exit the command.

Note: If Elevations are set to "Calculate" and Elevation is on, (See General tab of the C&G Options dialog) then you will be asked to "Enter constant elevation change for offset points". The constant elevation change will be added to or subtracted from the calculated elevation of each newly created point on the alignment. If there is vertical curve information contained in the point group, this information will be used to calculate the initial elevation of each point. If there is no vertical curve information, the elevation of each new point will be calculated by interpolation between the elevations of the points contained in the point group.

Prompts

Enter Starting Station [Done] <0.0000>: You can Press <Enter> to use the default station shown, or you can enter a new starting station.

Enter station [Interval] <0.000000>: Enter a station expressed as a decimal number. Type "I" and Enter to specify an interval or, alternatively, you can precede the station number with a "+". This will cause stations to be automatically calculated based on the value you specify.

If you choose Interval in the previous prompt:

Enter interval: Enter the desired interval for automatic generation of stations.

Enter offset (+ = right, - = left) <0.000000>: Enter the offset distance from the alignment.

Pulldown Menu Location: CG-Survey > Cogo > Station Offset

Keyboard Command: cg_crds_from_staoff

Prerequisite: coordinate file, point group file defining the alignment

Create Point Group From Station Offset

This feature allows you create a point group by locating all the points along a predefined alignment at a given offset. It then sorts the points by station and saves the points to a new Point Group.

Select Create Point Group from Station-Offset from the menu.

Use the Select a C&G Point Group File: to open the point group file specifying the points in the alignment.

At the Calculate new points on the control line [Yes/No] <Y> prompt,

If you answer no to this prompt, the points chosen by you in the previous step will be saved in station order to the new point group file.

If you answer yes to the prompt, a new point will be created exactly on the offset line for each point found in the coordinate file that lies within the given range. The elevation of the new point will be set to the elevation of the nearby existing point and the new point IDs will be written to the new point group file instead of the existing point IDs.

Repeat the above steps to specify another offset.

Press D for <Done> to exit.

Prompts

At the Enter Offset <0.00000>: Type an offset if desired or just press enter for no offset. Offsets to the left should be preceded by a "-".

At the Enter Maximum Range <0.0000>: Specify the tolerance for points not exactly on the alignment.

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: Use the various methods available to choose the points to be tested for being within the tolerance from the alignment.

Calculate new points on the control line [Yes/No] <Y>: Type "Y" and Enter or just Enter to create new points on the alignment for those points found to be near the alignment and place these new point IDs in the point group being created. Type "N" and Enter to place the existing points in the point group being created.

Pulldown Menu Location: CG-Survey > Cogo > Station Offset

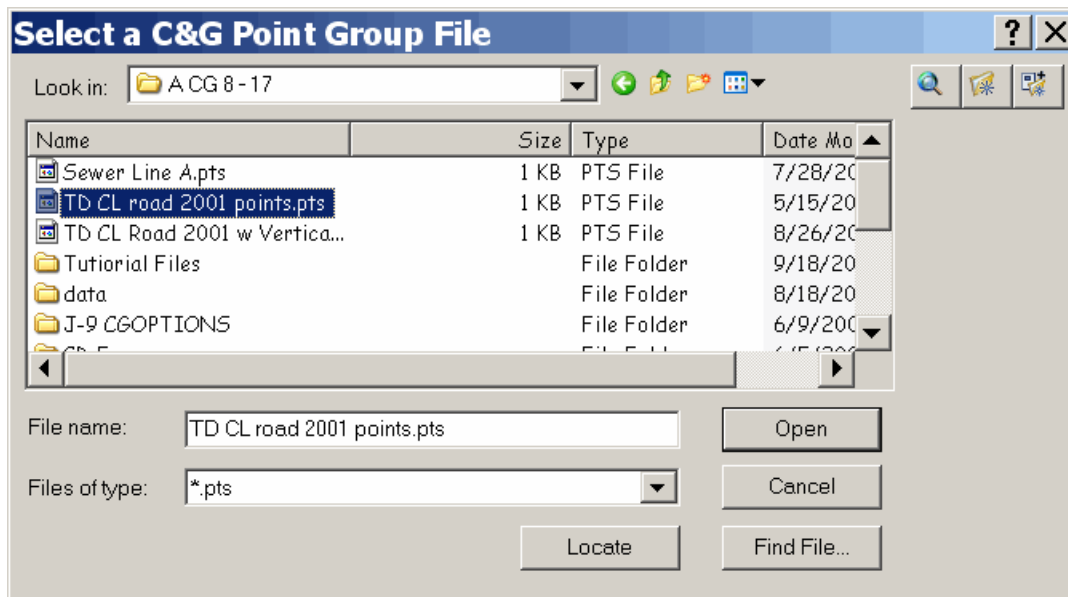

Keyboard Command: cg_bpf_from_sta

Prerequisite: coordinate file, point group containing the points in the alignment

Display Centerline Stations

This features allows you to view a list of the centerline stations for a given point group.

In the file dialog select the point group file that defines the alignment.

At the Enter Starting Station [Done] <1000>: prompt you will notice that the subgroup name is used to determine the starting station default value. To use the default value, press <Enter>. You may also enter a new starting station for the first point in the point group. For example, 24+34.12 is entered as 2434.12.

The centerline station information will be listed on the command line and written to the print file.

Point No.	Station	Offset	North	East	Elev.	Desc
2001	10+00.00	0.000	5524.47905	9768.66936	128.76	CL RD Beg
2002	12+55.95	0.000	5346.01086	9952.13553		PC CURVE1
2004	13+94.89	0.000	5305.76366	10082.50922		PT CURVE1
2005	14+69.89	0.000	5318.65419	10156.38943		PC CURVE2
2007	15+66.05	0.000	5303.94389	10251.42307		PT CURVE2
2008	16+72.04	0.000	5255.01123	10345.44075		PC CURVE3
2010	18+10.48	0.000	5160.36774	10445.29107		PT CURVE3
2011	20+10.67	0.000	4987.98790	10547.08317		CL END

The Enter Starting Station (Done) <0.00000>: prompt will again be displayed at the command line, at this point you can either enter another point group, or type in another starting elevation. When done entering data, type D and <Enter> for to end the command.

NOTE: The first line of the Point Group must be the beginning station of the alignment. In any routine that computes or requires stationing information the station numbers must be relative to the stationing in the Point Group file.

Prompts

At the Enter Starting Station [Done] <1000>: Enter the starting station for the alignment as a decimal number.

Pulldown Menu Location: CG-Survey > Cogo > Station Offset

Keyboard Command: cg_display_cl_sta

Prerequisite: coordinate file, point group file defining an alignment

Station Offset From Coords

This feature allows you to calculate the station and offset of selected points in the current coordinate file, based on the alignment as defined by the Point Group.

Select Station Offset from Coords from the menu.

You will first be asked to open the point group file that defines the alignment.

At the Enter Starting Station [Done] <0.00000>: prompt, enter the station of the first point in the point group. For example, if the first station is 24+34.12, enter it as 2434.12.

(As an example using the point group listed in the previous section, the starting station must be greater than 1000, the starting station in the point group, and less than 2016.05, the station of the last point in the point group. If not, no information will be displayed.)

Enter Maximum Range <0.00000>: The range identifies how far to look left and right of the alignment for points in the current coordinate file.

Next, you will be asked to select the points to be considered in computing the station offsets

Add points from coordinate file. (Enter when done) [All/Block/Code/Desc/Elev/Pt-group/Limit/Radius/Select]:

At the prompt type A and <Enter> for all the points in the current coordinate file or use the other options to choose a subset of the points. As indicated by the prompt, press <Enter> by itself to end point selection.

The station and offset information will be printed in order by station.

The Enter Start Station [Done] <0.0000>: prompt will appear again, you may enter the next starting station or type D and <Enter> to end the command.

Prompts

Enter Starting Station [Done] <0.00000>: Enter the starting station as a decimal number.

Enter Maximum Range <0.00000>: The range defines the distance tolerance left and right of the alignment for points selected from the current coordinate file.

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: Use the various methods to select points from the coordinate file to be searched for proximity to the alignment.

Pulldown Menu Location: CG-Survey > Cogo > Station Offset

Keyboard Command: cg_staoff_from_crds

Prerequisite: coordinate file, an existing point group file defining the alignment

Points on Line

This feature allows you to calculate and store points along a line at specified distances.

After choosing Points on Line from the menu and, if needed, opening a coordinate file, you will see following prompt:

Pts on line - specify No. of pts & dist., divide line, or place pts at interval [Number and dist/Divide/Interval]:

Choose one of the following:

Number and dist: Type N and <Enter> to specify a number of points at a given interval from the start point on a line.

Divide: Type D and <Enter> to select a line and indicate how many points you wish to create. The program then creates the specified number of points equally spaced along the length of the line.

Interval: Type I and <Enter> to create points at the specified interval along a line defined by 2 points.

Number and dist

This option allows you to calculate a given number of points at a fixed distance along a line. For example, you can set the corners for 3 lots at 150' intervals.

At the Enter start point: prompt, enter a point on the desired line by typing a point ID or picking a point with the mouse.

At the Enter bearing <100.0000>: prompt, use any one of the methods available to enter the bearing of the line on

which you wish the points to fall.

At the Enter distance <0.00000>: prompt, use any of the available methods to enter the distance between the points along the line.

Enter number of points: Enter the number of points you want created.

At the STORING POINT: prompt data required will vary depending on your current settings. You can enter a point number and its elevation, description, and code. This prompt will appear for each of the points created along the line

The Enter start point: prompt will repeat until you press <Esc>.

Pressing <Esc> again will allow you to create points on a line using one of the other methods.

Pressing <Esc> a third time to end command.

Divide

Choosing this method allows you to create points by dividing a line between two points into a specified number of divisions

Enter start point: Enter the first point defining the line by picking a point using the mouse or typing a point ID.

Enter end point: Enter the second point defining the line by picking a point using the mouse or typing a point ID.

Enter number of segments: Enter the number of points you want to create.

As the points are saved respond to the STORING POINT: prompt as required.

The Enter start point: will repeat unless you press <Esc>.

After pressing <Esc> once you may choose another method of creating points on a line or press <Esc> once more to end command.

Interval

This option allows you to create as many points as possible at a specified interval on a line between two points.

Enter start point: Enter the first point defining the line by picking a point using the mouse or typing a point ID.

Enter end point: Enter the second point defining the line by picking a point using the mouse or typing a point ID.

Enter Distance <0.0000>: Enter the desired distance between the points created along the line. Points will be created along the line at the given distance. As many points as will fit between the end points at the given spacing will be created.

No matter which method is used to create points, the Saving Point dialog (see below) will appear for each of the points created.

Click OK to save the point in the coordinate file.

Repeat from the Enter start point: prompt or press <Esc> to use another method to create points along a line. Press <Esc> once more to end the command.

Prompts

Specify: Number of points and distance, divide line or points at an interval

[Number and dist/Divide/Interval]: Type "N" and Enter to create a specified number of points along a line a specified distance apart. Type "D" and Enter to create a specified number of points between 2 points. Type "I" and Enter to create a point a specified distance from the starting point of a line specified by 2 points.

Enter start point: Enter the point ID or pick the point symbol for the starting point of the line.

for Number and Dist:

Enter bearing <100.0000>: Enter the bearing of the line along which the points are to be created.

Enter distance <0.000000>: Enter the distance between the points.

Enter number of points: Enter the number of points to be created.

for Divide:

Enter end point: Enter the point ID or pick the point symbol for the ending point of the line.

Enter number of segments: Specify the number of points to be created on the line between its end points.

for Interval:

Enter end point: Enter the point ID or pick the point symbol for the ending point of the line.

Enter distance <0.000000>: Enter or pick the distance along the line for creating the new point.

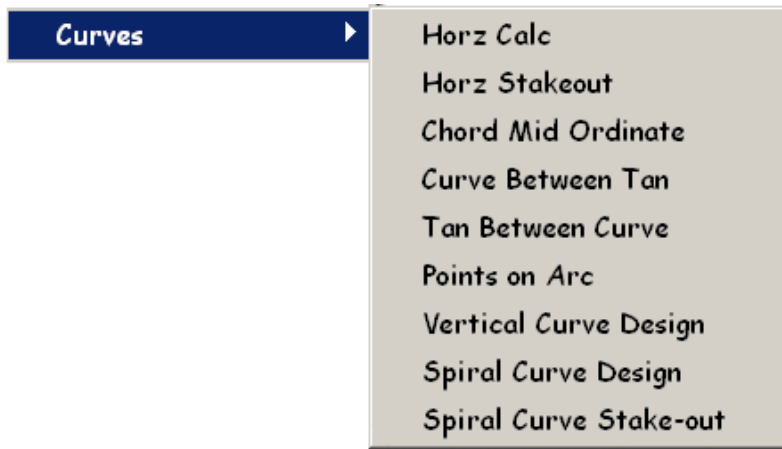

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg_pol

Prerequisite: coordinate file

Curves

There are several possible curve calculations available on the Curves submenu. The available options will be described in the following sections.

Calculate Horizontal

This feature allows you to calculate the components of a horizontal curve but does not save any points to the coordinate file.

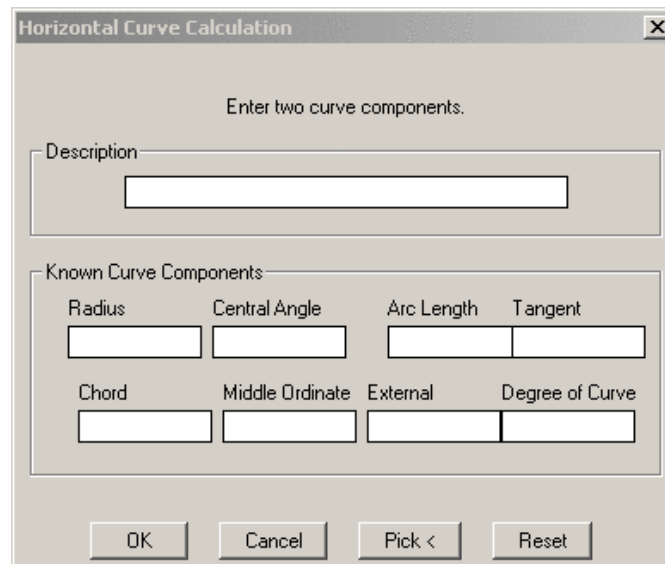

In the dialog enter any two curve components then press OK to calculate the other components.

To use the mouse to pick the two known components press the Pick button and pick the PC, PT and radius points or a C&G or non-C&G arc.

The description field is merely used to identify the curve in the printout.

The Reset button clears all fields.

When done, press the Cancel button to close the dialog.

A screenshot of a dialog box titled 'Horizontal Curve Calculation'. The dialog has a close button (X) in the top right corner. Inside, there is a text area labeled 'Description' with a text input field below it. Below that is a section titled 'Known Curve Components' containing two rows of input fields. The first row has four fields: 'Radius', 'Central Angle', 'Arc Length', and 'Tangent'. The second row has four fields: 'Chord', 'Middle Ordinate', 'External', and 'Degree of Curve'. At the bottom of the dialog are four buttons: 'OK', 'Cancel', 'Pick <', and 'Reset'.

Prompts

Horizontal Curve Calculation dialog: Enter any two curve components then press OK to calculate the other

components.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_horz_calc

Prerequisite: None

Curve Between Tangents

This feature allows you to calculate the curve components for a curve between two tangent lines given either the radius, the length of the tangent line or a point through which the arc passes.

At the Enter first point [Done]: prompt, enter or pick a point on one of the tangent lines. The point ID of the point selected will be displayed on the command line.

Enter first Bearing <100.000000>: use any of the available methods to enter the bearing from the point you just selected going toward to the point of intersection (P.I.) of the curve. The bearing entered will be displayed on the command line.

Enter second point: type or pick a point on the other tangent line.

Enter second bearing <100.000000>: enter the bearing of the other tangent.

Offset out <0.000000>: This is an optional entry. It allows you to calculate a point outside the curve (for example, on the right-of-way). Press <Enter> to use the default value or enter another offset. The offset used will be displayed on the command line.

Offset in <0.000000>: 50 This optional entry allows you to calculate a point inside the curve.

Enter point on arc [Radius mode/Tangent-Distance mode]:

At this prompt there are three options as to how to specify the location of the desired curve:

At this prompt you can type or pick a point on the arc,

Or you can type R and <Enter> to get the prompt:

Specify radius of curve [Tangent-mode/Point-on-arc-mode]:

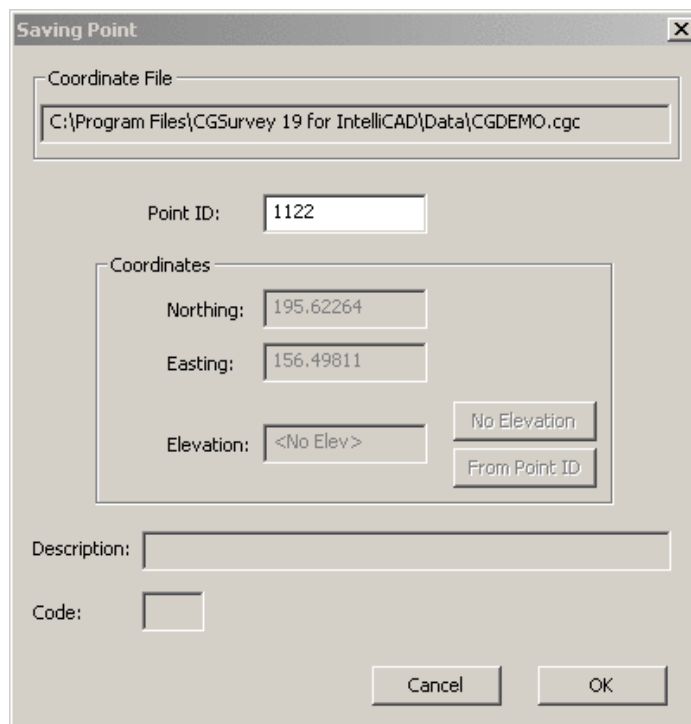

At this prompt specify the radius of the curve.

Or you can type T and <Enter> to get the prompt:

Specify tangent distance [Radius-mode/Point-on-arc-mode]:

At this prompt enter the distance from the PC or PT to the PI.

The locations of the PC, PI, PT, and radius point are calculated and the Saving Point dialog (see below) will appear once for each.

Depending on the Global Options settings, the calculated points may be drawn. If Auto Line Plot is on, the arc will be drawn as well. The coordinates of points that were created and the curve information will be displayed at the command line.

To end the command type D and <Enter> at the Specify an existing point on the first tangent line [Done]: prompt.

Prompts

Specify an existing point on the first tangent line [Done]: Enter or pick a point on one of the tangent lines.

Specify the bearing of the first tangent line <100.0000>: Enter the bearing or pick 2 points or a line to define the bearing.

Specify an existing point on the second tangent line: Enter or pick a point on the second tangent line.

Specify the bearing of the second tangent line <100.0000>: Enter or pick the bearing of the second tangent.

Offset out <0.000000>: This is an optional entry. It allows you to calculate a point outside the curve

Offset in <0.000000>: This optional entry allows you to calculate a point inside the curve.

Specify an existing point on the arc [Radius_mode/Tangent_distance_mode]: Enter or pick a point on the arc or change how you define the arc by entering "R" and Enter for the Radius method or "T" for the Tangent-distance method

Specify radius of curve [Tangent_distance_mode/Point_on_arc_mode]: Enter the radius or change the mode.

Specify tangent distance [Radius_mode/Point-on-arc-mode]: Enter the tangent distance or change the mode.

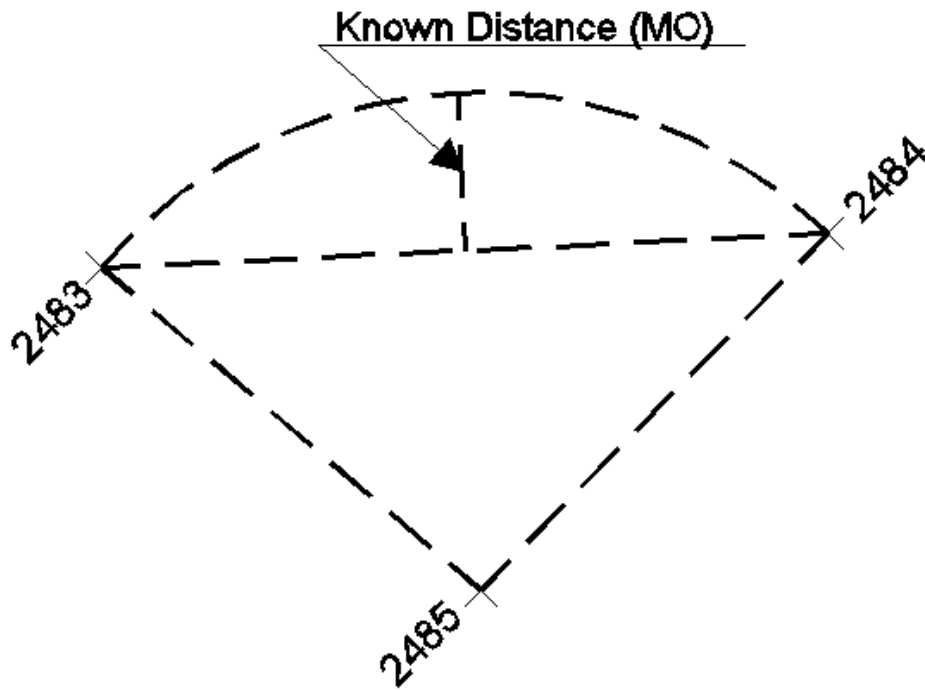

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_cbt

Prerequisite: coordinate file

Middle Ordinate Solution

Allows you to calculate the other curve elements when you can locate the chord and determine the middle ordinate distance in the field.

Prompts

Save coordinates [Yes/No] <Y>: press Enter or type "Y" and Enter if you want the calculated radius point to be stored in the coordinate file. If not type "N" and Enter. Press Esc key to end the command.

Enter P.C. point: specify the PC point by typing a point ID or picking a point on the screen.

Enter PT point: specify the PT point by typing a point ID or picking a point on the screen.

Middle ordinate: Type in the middle ordinant distance or pick it on the screen.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_chd_mo

Prerequisite: coordinate file

Points on Arc

This feature allows you to create points along an arc. The first point is set at a distance measured along the arc starting at the PC.

Enter PC point or pick a C&G Curve: enter or pick the PC point or pick a C&G curve.

If you picked a C&G Curve, the PC, Radius point, Pt point and arc length will be displayed at the command line. After picking a C&G Curve, skip the next 2 steps.

Enter PT point: Enter or pick the PT point.

Enter radius point [cLockwise/ccW]: For a clockwise curve either type L or '+' and <Enter> then pick or type a point ID or type a point ID preceded by a '+'. For a counter clockwise curve either type a W or a '-' and <Enter> then pick or type a point ID or type a point ID preceded by a '-' .

Enter arc length [Occupy/Multiple points] <0.000000>:

Occupy option

In occupy mode the points are located along the arc with the arc length being measured from the previous point. Thus the occupied point moves ahead to the last computed point as calculations proceed. When you type O and <Enter> the prompt becomes:

Enter arc length [do not Occupy/Multiple points] <0.000000>:

Specify the arc length at the prompt.

A point will be created and you will be prompted for the next arc length. Continue entering arc lengths until done then press <Esc> to return to the Enter PC point or pick a C&G Curve: prompt.

Multiple points option

This option allows you to compute multiple points along the arc at a given distance. The specified distance is used to set as many points along the arc as will fit between the PC and the PT. When you type M and <Enter> the prompt becomes:

Enter arc length [do not Occupy/Single point] <0.000000>:

Specify the arc length at the prompt.

As many points as can be fit between the PC and the PT will be created. You will then be prompted for the next arc length. Continue entering arc lengths until done then press <Esc> to return to the Enter PC point or pick a C&G Curve: prompt.

At the Enter PC point or pick a C&G Curve: prompt you can continue specifying curves or you can press <Esc> to end the command.

Prompts

Enter PC point or pick a C&G Curve: Enter a point ID or pick a point symbol or a C&G Arc on the screen. Press Esc to end the command.

Enter PT point: Enter or pick the PT point.

Enter radius point [cLockwise/ccW]: For a clockwise curve either type "L" (or a plus sign '+') and <Enter> then pick or type a point ID or type a point ID preceded by a '+'. For a counter clockwise curve either type a "W" (or a minus sign '-') and <Enter> then pick or type a point ID or type a point ID preceded by a '-' .

Enter arc length [Occupy/Multiple points] <0.000000>: Enter an arc length to create a single point on the arc. Enter "O" and Enter to "occupy" the calculated point so the next arc length is calculated from that point instead of the PC. Enter "M" and Enter to calculate multiple points along the arc at a specified distance.

Enter arc length [do not Occupy/Single point] <0.000000>: For multiple points enter the desired arc length or change input mode.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_poa

Prerequisite: coordinate file

Spiral Curve Design

This feature allows you to design a spiral curve. You will be prompted using standard spiral curve component nomenclature.

Follow the prompts described in the Prompts section below and the following Spiral curve data is calculated and displayed at the command line and written to the print file.

Point of Intersection of the spiral (PI for spiral)

Tangent point of the spiral (TS for spiral)

Point where spiral meets simple curve (SC for spiral)

Radius point of the simple curve

Point where simple curve meets outgoing spiral (CS for spiral)

Point where spiral meets tangent on outgoing side (TS for spiral)

For each of the points calculated the prompt

The Saving Point dialog (see below) will appear and allow you to specify the point ID.

The image shows a 'Saving Point' dialog box with the following fields and controls:

- Coordinate File:** C:\Program Files\CGSurvey 19 for IntelliCAD\Data\CGDEMO.cgc
- Point ID:** 1122
- Coordinates:**
 - Northing: 195.62264
 - Easting: 156.49811
 - Elevation: <No Elev>
- Buttons:** No Elevation, From Point ID
- Description:** (empty text box)
- Code:** (empty text box)
- Bottom Buttons:** Cancel, OK

Click OK to cause the point to be stored in the coordinate file.

At the Curve Description <enter if done>: prompt you can either enter the description for another curve or press <Enter> to end the command.

Prompts

Curve description <enter if none>: This description is optional but is used to identify the information in the results. Press Enter to end the command.

Enter the first point: Enter or pick a point on the tangent going into the spiral.

Enter first bearing <100.0000>: Enter or pick the bearing from first point to the P.I. of the spiral.

Enter second point: Enter or pick a point on the tangent going out of the spiral.

Enter second bearing <100.0000>: Enter the bearing from second point to the P.I.

Enter Radius [Degree.of.curve] <0.000000>: Enter or pick the radius or type "D" and Enter to change to degree of curve prompt.

or

Enter Degree of Curve [Radius]: Enter or pick the degree of curve or type "R" and Enter to change to radius prompt.

Enter spiral length in <0.00000>: Enter or pick the length of the spiral coming from the first tangent into the simple curve. Enter a zero for no spiral in.

Enter spiral length out <0.00000>: Enter the length of the spiral from the simple curve out to the second tangent. Enter a zero for no spiral out.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_scd

Prerequisite: coordinate file

Spiral Curve Stakeout

This feature allows you to calculate points along a spiral at a given interval and offset for use in staking out the curve in the field.

Curve Description <enter if done>: This text description is only used to identify the spiral curve data printed at the command line and written to the print file.

Enter the first point: Enter or pick a point on the tangent line going into the spiral.

Enter first bearing <100.000000>: Enter the bearing going toward the P.I. of the spiral from the first point.

Enter the second point: Enter or pick a point on the tangent line going out of the spiral.

Enter second bearing <100.0000>: Enter the bearing from the tangent point just defined to the P.I. for the spiral.

Enter Radius [Degree of Curve] <0.0000>:

Radius option: Entering the radius is the default option as indicated by the wording of the prompt.

Degree of Curve option: To change to entering the degree of curve type D and <Enter>.

Once you have chosen the type of data you wish to specify, type or pick the radius of the simple curve between the two tangents or the degree of curve.

Enter spiral length in <0.000000>: enter the length of the spiral from the TS (Tangent to Spiral) to the SC (Spiral to Curve). Enter zero for no spiral in.

Enter spiral length out <0.000000>: enter the length of the spiral from the CS (Curve to Spiral) to the ST (Spiral to Tangent). Enter zero for no spiral out.

Enter P.I. station <0.0000>: Enter the station of the P.I. For example: station 460+28.52 is entered as 46028.52

Enter station interval <0.0000>: Specify the interval at which you wish to stake the spiral. For example, enter 50 to stake every 50 units.

Enter offset from centerline <0.0000>: This can be a positive or negative number depending on whether you want to set points inside or outside the spiral. If you want to place points on the centerline, simply press <Enter> to use

the 0.00 default value.

Odd stations to be staked (6+34.22 as 634.22): You can stake as many odd station locations as needed. When done press <Enter> without entering a station value.

The points will be calculated and stored in the coordinate file. The station and offset will be placed in the description field.

The results will be printed at the command line and in the print file.

Continue to stake another spiral or press <Esc> or <Enter> at the Curve Description <enter if done>: prompt to end the command.

Prompts

Curve Description <enter if done>: This text description is optional and is used to identify the spiral curve in the output

Enter the first point: Enter or pick a point on the tangent line going into the spiral.

Enter first bearing <100.00000>: Enter the bearing going toward the P.I. of the spiral from the first point.

Enter the second point: Enter or pick a point on the tangent line going out of the spiral.

Enter second bearing <100.0000>: Enter or pick the bearing from the second tangent point to the P.I. for the spiral.

Enter Radius [Degree of Curve] <0.0000>: Enter or pick the radius. or, to change to entering the degree of curve, type "D" and Enter.

Enter spiral length in <0.000000>: enter the length of the spiral from the TS (Tangent to Spiral) to the SC (Spiral to Curve). Enter zero for no spiral in.

Enter spiral length out <0.000000>: enter the length of the spiral from the CS (Curve to Spiral) to the ST (Spiral to Tangent). Enter zero for no spiral out.

Enter P.I. station <0.0000>: Enter the station of the PI. For example: station 460+28.52 is entered as 46028.52

Odd stations to be staked (6+34.22 as 634.22): Enter as many odd stations as needed. When done press Enter.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_scs

Prerequisite: coordinate file

Stakeout Horizontal

This feature allows you to create points for field staking a horizontal curve.

After choosing the Horizontal Stakeout menu item, and opening a coordinate file you will be asked if you want to Save coordinates [Yes/No] <Y>.

If you respond Yes (or press enter), a new point will be saved to the coordinate file for each point to be staked along the curve. No matter how you answer this question, stakeout information will be generated and displayed.

Enter curve description: Enter a description that will allow you to identify the curve in the output.

P.C. station <0.000000>: Enter the station for the P.C. of the curve.

Station interval <0.000000>: Enter an interval for staking the points along the curve.

Odd stations to be staked (6+34.22 as 634.22) [Done]: Enter the station of any odd location along the curve to be staked. For example, you may wish to stake the point on the curve at which a pipe crosses or the point where the extension of a property line intersects the curve. You may enter as many odd stations as required. When done, press <Enter> at the prompt without entering a new odd station or press D and <Enter>.

Offset from C/L <0.000000>: enter a non-zero value here if you must stake points offset from the main alignment - for example: along a curb line, a barrier wall or along a property line.

If the distance is entered as a positive number, the distance will be added to the radius or staked outside the curve. If the number entered is negative, it will be subtracted from the radius or staked inside the curve. To stake the centerline, enter zero.

At the Enter PC point or pick a curve: prompt you can type a point ID for the P.C. or use the mouse to pick a point

or a C&G curve on the screen.

If you picked a C&G curve in the previous step, you need not enter the PT point or the radius point so skip the next 2 steps.

Enter PT point: type the point ID for the P.T. or click the point on the screen.

Enter radius point [cLockwise/ccW]: Use any of the available methods of specifying a radius point.

Type the radius point: If the curve is in a clockwise direction from the P.C. to the P.T., enter the point number preceded by a plus sign, e.g. +18. If the curve is in a counterclockwise direction from the P.C. to the P.T., the point ID preceded by a minus sign, e.g. -18.

Pick the radius point with the mouse: If the curve is in a clockwise direction from the P.C. to the P.T., type an L or a '+' and <Enter>, then use the mouse to pick the point on the screen. If the curve is in a counterclockwise direction from the P.C. to the P.T., type either a W or a '-' and <Enter>, then pick the point on the screen.

The report will be printed at the command line and written to the print file.

The command will repeat until you press <Esc> at the Save coordinates [Yes/No] <Y>: prompt to end command.

Prompts

Save coordinates [Yes/No] <Y>: Type "Y" and Enter or just Enter if you wish to save resulting points to coordinate file. Type "N" and Enter if not. Press Esc to end command.

Enter curve description: Enter a description that will allow you to identify the curve in the output.

P.C. station <0.000000>: Enter the station for the P.C. of the curve.

Station interval <0.000000>: Enter an interval for staking the points along the curve.

Odd stations to be staked (6+34.22 as 634.22) [Done]: Enter as many "odd" stations to be staked. Type Enter or "Done" and Enter when all odd stations have been entered.

Offset from C/L <0.000000>: If you wish to stake stations not on the centerline, enter the offset and press Enter or just press Enter to accept the default offset. Positive offset is outside the radius and negative is inside.

Enter PC point or pick a curve: Enter a point ID, pick a point symbol or pick a C&G arc.

if you did not pick a C&G arc:

Enter PT point: Enter or pick the PT point.

Enter radius point [cLockwise/ccW]: Enter "L" or "W" to choose the type of curve then Enter or pick the radius point. You may also enter "+" and Enter then enter or pick a point for the radius point of a clockwise curve or Enter a "-" and enter or pick a point for the radius point of a counter clockwise curve.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_hcso

Prerequisite: coordinate file

Tangent Between Curves

This feature allows you to calculate the end points of a tangent line joining two curves. This may be used, for example, to layout roads which do not have curve/tangent information.

Follow the prompts noted below and, if a solution is possible, the endpoints of the tangent between the two curves will be calculated. Point IDs will be assigned and coordinates stored for the points of tangency. Repeat or enter "D" when done.

NOTE: There are 4 tangent solutions for this problem. The solutions sets differ according to the sign preceding the radius or degree of curve.

Enter first radius point [Done]: Enter or pick the center point for one of the curves. Press Enter or type "D" and Enter when done.

Enter first radius <0.00000>: Enter the radius of the first curve. Use a "+" sign before the point ID to specify a clockwise curve or a "-" sign to specify a counter clockwise curve.

Enter second radius point: Enter or pick the center point for the second the curve.

Enter second radius <0.00000>: Enter the radius for the second curve. Use a "+" sign before the point ID to specify a clockwise curve or a "-" sign to specify a counter clockwise curve.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_tbc

Prerequisite: coordinate file

Vertical Curve Design

This feature prints a list of station and elevation information for stations along one or more vertical curves.

Use the Odd stations to be staked (6+34.22 as 634.22): prompt to enter any stations along the curve for which you wish elevation information. This permits you to calculate elevations over culverts or at other important locations.

The calculated station and elevation information . The station, tangent elevation, tangent offset and grade elevation will be printed at the command line and in the print file. The high or low point will be marked with an asterisk.

Repeat the process to design another vertical curve or press <Esc> at the Enter curve description: prompt to end the command.

Prompts

Enter curve description: Description is used to identify the curve in the output.

Enter slope in <0.00000>: The slope is entered as a percent. For example: enter -1.5 for a 1.5% downhill slope.

Enter slope out <0.00000>: Enter the slope as a percent.

Enter length of vertical curve <0.00000>: Enter the length of the vertical curve.

Enter PVI Station <0.000000>: Enter the PVI station. For example: Enter 1250.00 for station 12+50.00

Enter PVI Elevation <0.000000>: Enter the PVI elevation.

Enter station interval <0.000000>: Enter the station interval.

Odd stations to be staked (6+34.22 as 634.22): Enter any stations along the curve for which you wish elevation information.

Pulldown Menu Location: CG-Survey > Cogo > Curves

Keyboard Command: cg_vcd

Prerequisite: coordinate file

Area Summary

The Area Summary feature allows you to get information on the area and perimeter of one or more parcels and the tract that contains the parcels.

After choosing the Area Summary menu item and, if required, opening a coordinate file, you are asked to specify the type of Area Summary you want:

Type of Area Summary [Complete/Area only/Mapcheck] <C>:

Complete Area Summary

Complete summary allows you to get complete information on the area and perimeter of parcels and the tract that contains the parcels

Source of points defining area [Point group/Manual entry] <P>

If you have a Point Group, enter <P>. Enter <M> if you prefer to manually enter the points.

Once the overall area and parcels have been defined either by using a point group or manually entering the information, the Complete Area Summary is displayed at the command line.

The points used in defining the area are listed first. If there are any arcs involved in the area computation, all of the elements of the curve will be displayed as well. After listing the points defining the area, the area and perimeter summary are reported.

Area Only

The data input is the same as for the Complete Area Summary but the report produced contains only the area of each parcel and the accumulated area for the entire tract

Mapcheck Area

The data input is the same as for the Complete Area Summary as is the resulting report except that it also includes closure information. The closure information includes the correct ending coordinates; the actual ending coordinates; the northings, eastings, and bearing and distance of the error; the total distance traversed and the overall closure.

Prompts

Open Coordinate File dialog: If a coordinate file is not open, you will be asked to open one.

Type of Area Summary [Complete/Area only/Mapcheck] <C>: Press "C" and Enter or just Enter for Complete, "A" for Area only, or "M" for Mapcheck.

Source of points defining area [Point group/Manual entry] <P>: Type "P" and Enter or just Enter to use a point group to specify the points defining the tract. Type "M" and Enter to specify the points defining the tract by typing in point numbers or picking from the screen.

Pulldown Menu Location: CG-Survey > Cogo > Area

Keyboard Command: cg_asum

Prerequisite: coordinate file

Roadways

The roadways submenu contains 2 features: Right-of-Way/Easements and Intersections/Cul-de-Sacs and the Intersections/Cul-de-Sacs has a submenu containing several features for each type of intersection or cul-de-sac.

Right-of-Way Easements

The Right-of-Way/Easements feature allows you to compute offsets left and/or right of an alignment.

After the alignment points have been entered, offset points will be created to the left and right of each point you specified in the alignment. If Auto Point Numbering is on, the calculated points will be stored in the coordinate file. Depending on your settings for Auto Line Plot and Auto Point Plot in the Graphic tab of the C&G Options dialog, the new points and lines may also be drawn. If Auto Point Numbering is off, you will see the Saving Point dialog and can accept or change the default point number and other information associated with the point.

Prompts

Enter offset right<0.000000>: Enter the offset to the right of the alignment.

Enter offset left<0.000000>: Enter the offset to the left of the alignment.

Method for specifying center line points [Point group/Manual entry] <P>: To use a point group type "P" and Enter or just Enter and select the point group from a file dialog box. Type "M" and Enter to specify the alignment interactively.

Pulldown Menu Location: CG-Survey > Cogo > Roadways

Keyboard Command: cg_rw

Prerequisite: coordinate file containing points defining the alignment

Intersections/Cul-de-sacs

T Intersections

This feature allows you to calculate the right-of-way intersection points and/or the fillet points and fillet radius points (if fillets are used) at T type intersections. One or both of the roads may have arc centerlines.

The points defining the fillet points will be calculated and stored in the coordinate file. Repeat as needed or press <Esc> or <Enter> at the Enter C/L intersection point (Enter when done): prompt to end the command.

Prompts

Enter C/L intersection point (Enter when done): enter or pick the centerline intersection point.

Enter through road C/L bearing [Arc] <0.000000>: If the through road is a straight road, enter or pick the bearing for the road. Otherwise type A and <Enter> to switch to Arc mode and enter the radius point of the through road.

Enter through road width <0.000000>: Enter the width of the through road.

Enter 2nd road C/L bearing away from intersection [Arc] <0.000>: enter the 2nd bearing or press <A> for Arc and enter the radius point. The bearing is away from the intersection.

Enter 2nd road width <0.000>: Enter the 2nd road width.

Enter fillet radius <0.000>: If you do not want to have fillets, press <Enter> to use the 0.00 default value. Otherwise, enter the fillet radius.

Pulldown Menu Location: CG-Survey > Cogo > Roadways > Intersections/Cul-de-sacs

Keyboard Command: cg_tint

Prerequisite: coordinate file

X Intersections

The radius, PC and PT points for each fillet will be calculated and stored. If Auto Line Plot is on, the fillet arcs will be drawn. Repeat as needed then press Enter or Esc to end the command.

Prompts

Enter C/L intersection point (Enter when done): enter or pick the intersection point of the two road centerlines.

Enter 1st road C/L bearing [Arc]: If first road is straight, enter the 1st bearing. If it is an Arc, enter the 1st radius point.

Enter 1st road width: Enter 2nd road C/L bearing (Arc): If the intersection point for the first road centerline is on a straight segment, enter the bearing of the centerline. If it is on an arc, type A and <Enter> then enter the first road centerline's radius point.

Enter 2nd road width: Enter the second road width.

Enter 2nd road C/L bearing [Arc]: Enter the second road centerline bearing or type A and <Enter> and specify the centerline radius point for the second road.

Enter fillet radius: Enter the fillet radius or zero, if there are no fillets.

Pulldown Menu Location: CG-Survey > Cogo > Roadways > Intersections/Cul-de-sacs

Keyboard Command: cg_xint

Prerequisite: coordinate file

Y Intersections

The radius, PC and PT points for each fillet will be calculated and stored and if Auto Line Plot is on, the fillet arcs will be drawn. Repeat as necessary then press <Esc> or <Enter> to end command.

Prompts

Enter C/L intersection point (Enter when done): Enter or pick the intersection point for the three road centerlines.

Enter 1st road C/L bearing away from intersection point: Enter one of the road centerline bearings (going away from the intersection point).

Enter 1st road width: enter the first road width.

Enter 2nd road C/L bearing away from intersection point: Enter another of the road centerline bearings (going away from the intersection.)

Enter 2nd road width: Enter the width of the second road.

Enter 3rd road C/L bearing away from intersection point: Enter last of the road centerline bearings (going away from the intersection.)

Enter 3rd road width: Enter width of third road.

Enter fillet radius: Enter radius of fillets or zero for none.

Pulldown Menu Location: CG-Survey > Cogo > Roadways > Intersections/Cul-de-sacs

Keyboard Command: cg_yint

Prerequisite: coordinate file

Bubble Cul-de-Sac

This type of cul-de-sac is also called a fish-eye cul-de-sac. It is commonly used at sharp turns in roads in subdivisions.

Follow the prompts described below. When done the fillet points and radius points will be stored in the coordinate file. These points will be plotted and the fillet arcs will be drawn if the C&G settings call for it. You may repeat the process as necessary or press <Esc> to end command:

Prompts

Enter cul-de-sac radius point (Enter when done): type or pick the radius point.

Enter cul-de-sac radius <0.000>: Enter the radius of the cul-de-sac.

Enter 1st C/L bearing away from radius point <0.000>: Enter the bearing along the first roadway centerline away from the cul-de-sac radius point.

Enter 2nd C/L bearing away from radius point <0.000>: Enter the bearing along the second roadway centerline away from the cul-de-sac radius point

Enter road width <0.000>: Enter the roadway width.

Enter fillet radius <0.000>: Enter the fillet radius or zero for no fillets.

Pulldown Menu Location: CG-Survey > Cogo > Roadways > Intersections/Cul-de-sacs

Keyboard Command: cg_bcul

Prerequisite: coordinate file

Standard Cul-de-Sac

The standard cul-de-sac is a common feature of most subdivisions.

Enter cul-de-sac radius point (ENTER when done): type or pick the cul-de-sac radius point (in this example, point 2301).

Enter cul-de-sac radius <0.000000>: Enter or pick the radius of the cul-de-sac (60 units in the example).

Enter C/L bearing away from radius point [Arc] : In computing a straight cul-de-sac you must enter the bearing of the road centerline going away from the radius point. For the example the bearing is from point 2301 to point 2302.

Enter point on C/L (NOT radius point): This must be a C&G point on the centerline but cannot be the same as the cul-de-sac radius point. In this case we can use point 2302

Enter road width <0.000000>: enter the total width of the road right-of-way.

Enter fillet radius <0.000000>: Enter the fillet radius. Remember, you do not have to have a fillet radius, you may enter zero here.

The points needed to define the cul-de-sac and the fillets are calculated and stored in the coordinate file.

If Auto Line Plot is on the lines for the cul-de-sac and the fillets will be drawn automatically.

You may repeat the process as many times as necessary.

When done, press <Enter> at the

Enter cul-de-sac radius point (ENTER when done):

Standard Cul-de-Sac on ARC

The procedure for a cul-de-sac on arc is the same as it is for a straight cul-de-sac, except at the Enter C/L bearing away from radius point [Arc] : prompt, choose A for Arc, then enter the C/L radius point for the roadway, in this case point 2313.

Offset cul-de-sac:

The procedure for offset cul-de-sac is the same as a straight cul-de-sac except the radius point is the offset point. In the sketch, the point 2326 is the radius point. The bearing is from 2324 toward 2325 and the point on the C/L would be point 2325.

Prompts

Enter cul-de-sac radius point (ENTER when done): type or pick the cul-de-sac radius point. Press Enter when done.

Enter cul-de-sac radius <0.000000>: Enter or pick the radius of the cul-de-sac.

Enter C/L bearing away from radius point [Arc] : Enter or pick a point. For a straight cul-de-sac roadway, this must be a point on the centerline but cannot be the same as the cul-de-sac radius point. Type "A" and Enter to specify information for a cul-de-sac on a curved roadway.

if you chose a curved roadway:

Enter C/L radius point [Line]: Type a point ID or pick a point symbol or type "L" and Enter to switch back to a straight roadway.

Enter point on C/L (NOT radius point): Type a point ID or pick a point symbol.

Enter road width <0.000000>:

Enter fillet radius <0.000000>: Enter the fillet radius. You may enter 0.0 for no fillets.

Pulldown Menu Location: CG-Survey > Cogo > Roadways > Intersections/Cul-de-sac

Keyboard Command: cg_scul

Prerequisite: coordinate file

Stake-Out

The Stakeout feature allows you to calculate the required information for either a radial stakeout or staking out using angles right.

Angles Right

This feature is similar to the Radial Stakeout feature except it allows you select the foresight points one at a time.

If a coordinate file is not open, a file dialog will appear, allowing you to open an existing coordinate file.

After following the prompts outlined below, the angle from the backsight point, the distance, the foresight point ID, the azimuth and the description are printed at the command line and written to the print file.

You may press <F2> to view the complete listing of angles and distances.

Repeat the prompt sequence as many times as are required.

Press <Enter> or type D and <Enter> when done.

Prompts

Enter the instrument point. [Done]: Type or pick the instrument point.

Enter backsight point. [Done]: Type or pick the backsight point.

Enter foresight point. [Done]: Type or pick the foresight point.

Pulldown Menu Location: CG-Survey > Cogo > Stake-Out

Keyboard Command: cg_ar

Prerequisite: coordinate file

Radial Stake Out

This feature allows you to obtain the angles required to stakeout several foresight points from a single instrument point.

If a coordinate file is not open, a file dialog box will appear, allowing you to open an existing coordinate file.

After following the prompts outlined below, the angles right from the backsight point, the distances, the foresight point IDs, the azimuths and the descriptions for all the selected points will be printed at the command line and written to the print file.

You may press <F2> to view the complete listing of angles and distances.

Repeat as necessary for as many setups as are required.

When done, press <Enter> to end the command.

Prompts

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: Use one of several methods to specify the points in the coordinate file to be staked out.

Enter the Instrument point [Done]: Type or pick the instrument point.

Enter backsight point [Done]: Type or pick the backsight point.

Pulldown Menu Location: CG-Survey > Cogo > Stake-Out

Keyboard Command: cg_rso

Prerequisite: coordinate file

Best Fit

The best fit feature uses a least squares algorithm to compute the best fit line or circle for the points selected. The user can assign a weight to each point that is between 1 and 15, a point with a weight of 15 acts as if there are 15 of the points at the same location and thus skews the fit closer to that point. This is done to skew the result in favor of certain points. A weight of 0 means do not adjust this point or give it "infinite" weight.

When you choose Best Fit from the CGCogo menu you will see the following prompt:

Enter the type of best fit problem [Line/Arc/Tan-arc-tan] <L>:

Best Fit Line:

Press <Enter> for Line to calculate the best fit line through a series of points. In the example in the figure below, 2075 is an Iron Pin Found that we do not want adjusted, so the weight will be set to 0.

Enter a point ID or pick a point symbol on the line: for the example, type or pick 2075

Enter weight for point 2075 <1>: for the example type 0 (zero) and <Enter>

Enter a point ID or pick a point symbol on the line: for the example, type or pick 2076

Enter weight for point 2076 <1>: for the example, type 8 and <Enter>

Continue entering point ID - weight pairs until done then press <Enter> when asked for the next point ID.

The point locations and weights will be used to compute the best fit line .

The results, a list of the point IDs entered and their offsets from the best fit line and the bearing of the line, is printed at the command line and written to the print file.

Printed output for the line example

Pt.: 2075 Wt.: 0 Offset: 0.000 RT

Pt.: 2076 Wt.: 8 Offset: 5.360 LT

Pt.: 2077 Wt.: 3 Offset: 3.411 RT

Pt.: 2078 Wt.: 6 Offset: 1.915 RT

Pt.: 2079 Wt.: 2 Offset: 6.326 LT

Pt.: 2079 Wt.: 2 Offset: 6.326 LT

Pt.: 2080 Wt.: 4 Offset: 1.093 RT

Pt.: 2081 Wt.: 4 Offset: 0.986 RT

N: 6354.64727 E: 8112.07615 Dir: N 88°30'32"E

N: 6366.14982 E: 8553.96369 Dir: S 88°30'32"W

At the [Edit/Ok/Quit] <0>: prompt:

If you are satisfied with the results, press <Enter> for Ok and the endpoint coordinates will be computed and saved.

For each point saved, the Saving Point dialog (see below) will be shown.

Clicking OK will cause the point to be saved to the coordinate file.

If, on the other hand, you wish to edit the input data, type E and <Enter>. You see the following prompt:
[Add/Change/Delete/eXit]:

Add - add another point to the calculation

Change - change the weight of one of the points

Delete - remove one of the points from the calculation

eXit - when done editing.

If you wish to cancel the command without calculating the line type Q and <Enter>.

Best Fit ARC:

This option allows you to calculate the best fit arc through a series of points. As with the Line option, each point can be weighted from 0 (no adjustment) to 15.

At the Enter the type of best fit problem prompt, type A and <Enter> to choose the Arc option.

Enter the point ID - weight pairs as in the Line option.

When all the point ID - weight pairs have been entered press <Enter> at the Enter or Pick a C&G point on the line prompt.

A table of the results similar to that for the Line option will be displayed at the command line.

Output for the example in shown in the figure

Pt.: 2083 Offset: 2.862 OUT
Pt.: 2084 Offset: 3.699 IN
Pt.: 2085 Offset: 3.608 OUT
Pt.: 2086 Offset: 6.280 IN
Pt.: 2087 Offset: 5.584 OUT
Pt.: 2088 Offset: 1.393 IN
N: 6369.30690 E: 8269.70677 RAD: 237.282

The [Edit/Ok/Quit] <O>: prompt and its options for editing the input data are explained in the section on the Line option.

If you are satisfied with the results, press <Enter> for Ok and the PC, PT and radius point of the best fit arc will be saved to the coordinate file using the Saving Point dialog.

Tan-arc-tan:

This option allows you to calculate a combination of the best fit tangent line going into a curve, the best fit arc for the curve itself and the best fit tangent line out of the curve through a series of points defining two tangent lines and an arc.

The two tangent lines are calculated using a least squares solution and then the best fit arc is calculated. The method used to find the best fit arc is to calculate a radius and radius point for each point on the arc using a function that calculates a curve between tangents through a known point. Each radius and radius point is weighted based on the central angles between the PC, point-on-arc and PT points. The larger the central angles, the higher the resulting weight will be. All the calculated radii and radius points are then averaged. It is not necessary that you locate the actual PC or PT points in the field.

At the prompt

Enter the type of best fit problem [Line/Arc/Tan-arc-tan] <L>:

First you must enter the points on the 1st tangent line. At the series of prompts to:

Enter a point ID or pick a point symbol on 1st tangent:

and

Enter weight for point XXXXX <1>:

enter the point ID - weight pairs for the tangent going into the curve.

When done entering the tangent line points, press <Enter> when asked for the next point.

Next at the series of prompts:

Enter a point ID or pick a point symbol on the arc:

enter the points for the arc. Weights for these points are calculated by the program.

In the example shown in the figure, there are 2 points defining the first tangent, 3 points defining the arc and 2 points defining the tangent out.

Output for example shown in figure

Pt.: 2210 Wt.: 0 Offset: 0.000

Pt.: 2211 Wt.: 5 Offset: 0.000

N: 6512.07291 E: 8572.91824 Dir: N 45°00'00"E

N: 6567.12692 E: 8627.97226 Dir: S 45°00'00"W

Pt.: 2212 Wt.: 5 Offset: 0.000 LT

Pt.: 2213 Wt.: 1 Offset: 0.000 LT

N: 6585.04757 E: 8796.89599 Dir: S 45°00'49"E

N: 6505.88861 E: 8876.09255 Dir: N 45°00'49"W

Pt.: 2214 Offset: 1.736 OUT

Pt.: 2215 Offset: 3.232 IN

Pt.: 2216 Offset: 2.324 OUT

N: 6492.00101 E: 8721.39653 RAD: 119.183

The [Edit/Ok/Quit] <O>: prompt following the output is explained in the Line option.

If you are satisfied with the results press <Enter> for Ok.

The coordinates for the endpoints of the tangents and PC, PT and radius point of the curve are computed and saved to the coordinate file using the Saving Point dialog.

Prompts

Enter the type of best fit problem [Line/Arc/Tan-arc-tan] <L>: Type "L" and Enter or just Enter for a best fit line, "A" and Enter for a best fit arc or "T" and Enter for the best fit of a curve with two straight tangents in and out.

For a best fit line or arc:

Enter or Pick a C&G point on the line (or Arc): Type a point ID or pick a point symbol on the screen. Repeats until all points are entered and the user presses Enter at this prompt.

Enter weight for point <####> <1>: Enter a number between 0 and 15 (0 = infinite weight).

For best fit tan-arc-tan:

Enter a point ID or pick a point symbol on 1st tangent: Enter or pick as many points and weights as desired for the first tangent line.

Enter a point ID or pick a point symbol on the arc: Enter or pick as many points as desired for the arc (weights are determined by the program).

Enter a point ID or pick a point symbol on 2nd tangent: Enter or pick as many points and weights as desired for the second tangent line.

[Edit/Ok/Quit] <0>: Type "E" and Enter if you wish to change the weight of a point or add or delete points. Type "O" and Enter or just Enter to calculate the best fit line, arc or line-arc-line and store its defining points in the coordinate file. Type "Q" and Enter to quit without calculating the best fit points.

[Add/Change/Delete/eXit]: if you choose Edit then this prompt allows you to Add a point, Change a weight, or Delete a point. When done editing press "X" and Enter to return to the Edit/Ok/Quit prompt.

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg_bfit

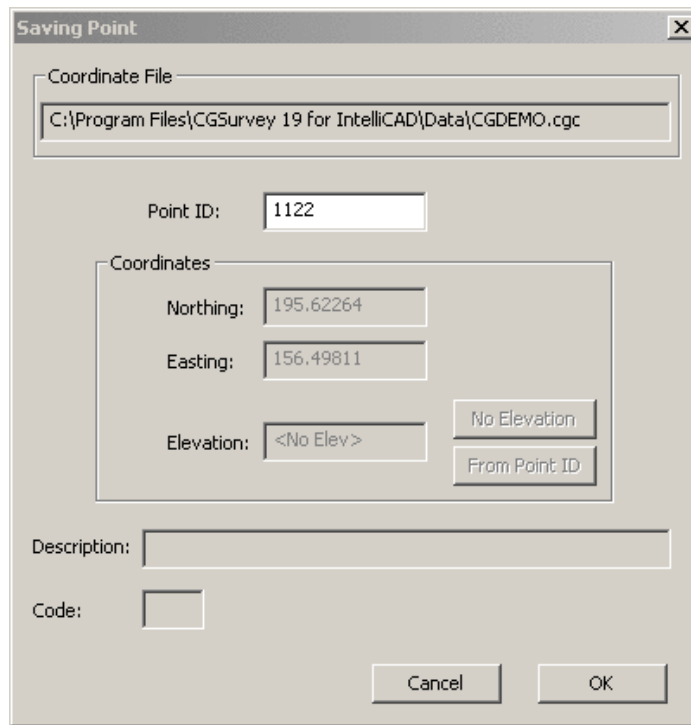

Prerequisite: Coordinate file.

Triangulation

This feature allows you to calculate the location of an unknown point given the angles at the 3 vertices of the triangle formed by the 2 known points and the unknown point.

Enter the point ID of the first known point then the point ID of the 2nd known point (the backsight) and the measured horizontal angle to the unknown point. Do the same for the 2nd known point backsighting the 1st known point. Next, if available, enter the angle between the 2 known points with the instrument at the unknown point. The standard deviation and other information for the calculation will be printed at the command line and written to the print file. The calculated point will be saved to the coordinate file using the Saving Point dialog (Shown Below).

Prompts

Enter first instrument point: Enter a point ID or pick a point symbol on the screen.

Enter first backsight point:: Enter a point ID or pick a point symbol on the screen.

Enter first horizontal angle to unknown point: Enter an angle.

Enter second instrument point: Enter a point ID or pick a point symbol on the screen.

Enter second backsight point: Enter a point ID or pick a point symbol on the screen.

Enter second horizontal angle to unknown point: Enter an angle.

Enter horizontal angle at unknown point or <skip> <0.00000>: Enter an angle if available or press Enter to skip.

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg_triangulation

Prerequisite: coordinate file

NAD83

This feature allows you to convert longitude and latitude to and from NAD83 state plane coordinate systems.

NOTE: Do not use this function for any other coordinate system, i.e. NAD 1927. Make sure the correct state is selected on the General tab of the C&G Options dialog box.

After choosing the NAD83 menu item from the CGCogo menu you will be prompted for the necessary data.

At the Enter zone prompt enter the letter for the appropriate zone for the area where the survey was performed. The zones allowed may vary by state.

[Coords to longitude-latitude/Longitude-latitude to coordinates] <C>:

Coords to longitude-latitude

Pressed <Enter> (or type C and <Enter>)

you will be asked to select the points.

After selecting points a table of longitude-latitude and related data for the points will be printed at the command line

Longitude-latitude to coordinates

Type L and <Enter>.

You will be asked to enter the longitude and latitude of the points you wish to calculate

When you have entered the final longitude-latitude pair press <Enter> when asked for the next latitude.

The computed points will be stored in the coordinate file using the Saving Point dialog shown below.

The image shows a 'Saving Point' dialog box. It has a title bar with 'Saving Point' and a close button. The main area contains a 'Coordinate File' field with the path 'C:\Program Files\CGSurvey 19 for IntelliCAD\Data\CGDEMO.cgc'. Below this is a 'Point ID' field with the value '1122'. A 'Coordinates' section contains three input fields: 'Northing' with '195.62264', 'Easting' with '156.49811', and 'Elevation' with '<No Elev>'. To the right of the 'Elevation' field are two buttons: 'No Elevation' and 'From Point ID'. At the bottom of the dialog are two more input fields: 'Description' and 'Code'. At the very bottom are 'Cancel' and 'OK' buttons.

Click OK to save the point to the coordinate file.

Repeat until done or press <Enter> to end the command.

Prompts

Enter zone (E, W): enter the letter for the appropriate zone for the area where the survey was performed. The letters allowed will vary depending on the state.

[Coords_to_longitude_latitude/Longitude_latitude_to_coords] <C>: Type "C" and Enter or just Enter to calculate coordinates given longitude and latitude. Type "L" and Enter to do the reverse.

if you chose Coords to longitude-latitude:

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: Use the various selection methods to choose the points for which you wish to calculate longitude and latitude

if you chose Longitude-latitude to Coords:

Enter latitude [<Enter> when done]: Enter the latitude angle for a longitude - latitude pair.

Enter longitude: Enter the longitude angle for a longitude - latitude pair.

Pulldown Menu Location: CG-Survey > Cogo

Keyboard Command: cg_nad83

Prerequisite: coordinate file

CGDraw

Drawing Settings

See **CG Options...** menu item in the **Tools** menu.

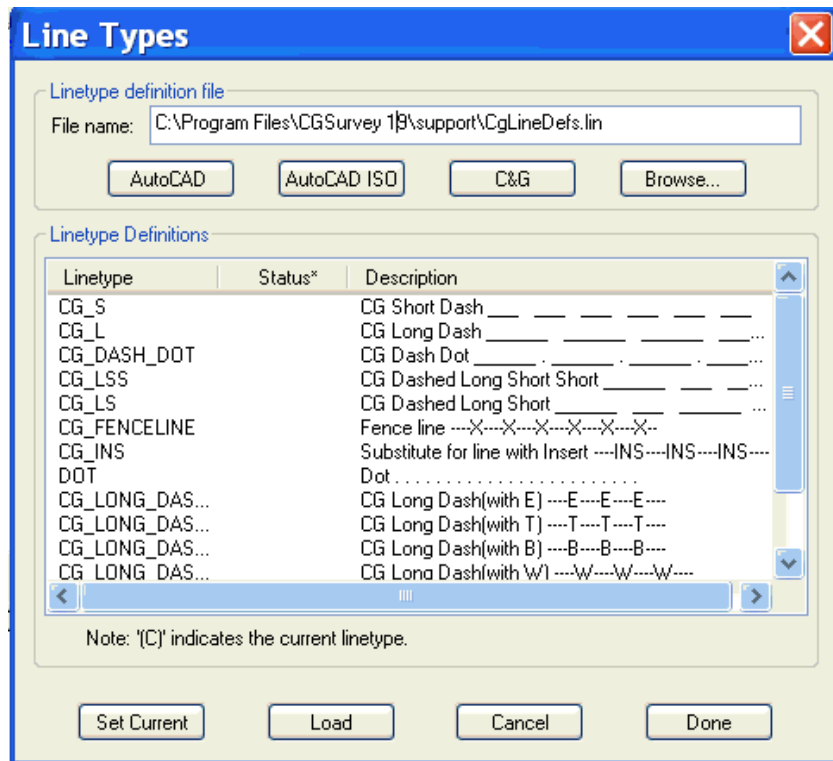

Pulldown Menu Location: CG-Survey > CGDraw>Drawing Settings

Keyboard Command: DSU, CG_DRAW_SETUP

Prerequisite: None

Set Line Type

To use a line type it must be loaded and it must be the current line type. The current line type will be used for any lines or polylines drawn. The Set Line Type feature allows you to load line types from any line type file (*.lin) and to specify the currently active line type. It gives you easy access to the most commonly use line type files while allowing you to access any line type file available to you.

Prompts

Clicking the Set Line Type menu item brings up the Line Types dialog: By default the dialog displays the acad.lin line type file contents (CgSu.lin in the standalone version of CGSurvey) .

By clicking the AutoCAD/IntelliCAD ISO button: you can view the acadiso.lin file line types (CgSu-iso.lin in the standalone version of CGSurvey).

By clicking the C&G button: you can view the custom line types created for CGSurvey (in CgLinedefs.lin). You may also use the Browse... button to view and load line types from other line type files.

To load a line type: pick the file the line type is in, highlight the desired line type, then click the Load button. Notice that the status column now indicates that the line type is "Loaded".

To make the highlighted line type current: click the Set Current button. The status column now reads "Loaded (C)", indicating that the line type is loaded and it is the currently active line type.

You can load a line type and make it current: by double-clicking it. If it is already loaded, double-clicking will make it current.

Cancel button: returns the current line type to what it was before the command was run.

Click the Done button: to close the dialog.

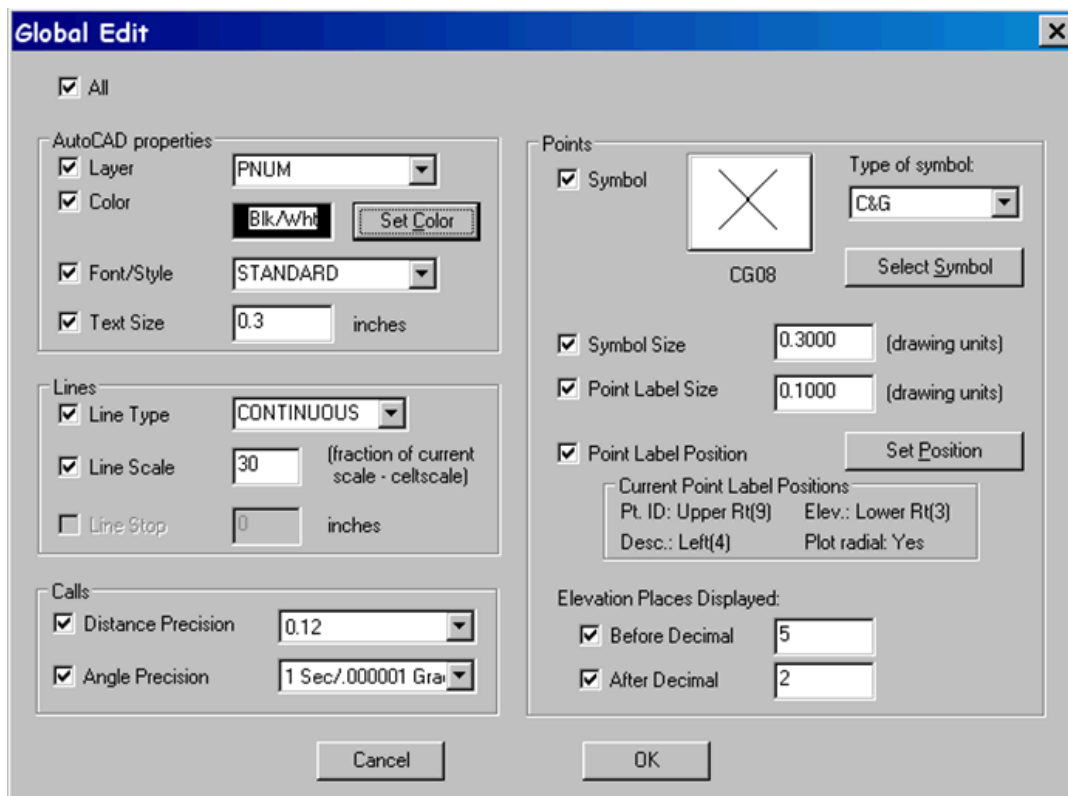

Pulldown Menu Location: CG-Survey > CGDraw>Set Line Type

Keyboard Command: SLT, CG_SET_LINE_TYPE

Prerequisite: None

Global Edit

Global Edit allows you to make several changes to one or more entities, in one operation.

Prompts

After selecting Global Edit from the CGDraw menu you will be asked to specify the method of entity selection at the command line:

Screen: This option allows you to use any of the standard mouse based CAD selection methods.

Points: Allows you to select C&G points using the standard C&G selection methods. Checking a given check box activates that section of the dialog box and allows you to make the desired changes.

Done: When finished selecting the entities enter "D" for done this will bring up the Dialog box.

There are five basic sections in this dialog.

All: checking this checkbox is just a fast way of checking all the checkboxes and thus allows you to edit all of the properties of the selected entities.

All of the editable items for the entities selected will have their checkboxes checked.

CAD properties

Layer: change the layer of the items selected

Color: Change the color of the items selected

Font/Style: Change the font style to a another existing font style.

Text Size: Change the current Text size (this setting is in inches)

Lines

Linetype: set the linetype for the lines selected. Pressing the down arrow will bring up a list of all of the available linetypes.

Line Scale: This allows you to set the length of the pattern.

Line Stop: This allows you to set the line stop. This item will only be activated if a C&G line was chosen.

Line stop is a C&G parameter that allows you to stop the line short of the point symbol plotted at the point location thus the line can be made to not go through the symbol. For example, if you were plotting 0.10 diameter circles for property corners, you could set the line stop to .10. This would cause a C&G line drawn to the property corner to end .05 plotted units short of the actual corner and thus not cross the property corner point symbol

Calls

Distance precision: From the pull down select the number of decimal places to be displayed.

Angle precision: From the pull down simple select the angle precision you need.

Points

This portion of the Global Edit dialog allows you to change various aspects of point symbols:

Symbol: from the pull down select the new symbol to use.

Symbol Size: set the symbol size (in inches or cm)

Point Label Size: Set the point label size (in inches or cm)

Point Label Position: Displays the point label configuration dialog box, set the options as needed.
Elevation Places Displayed: set the number of places to be displayed.

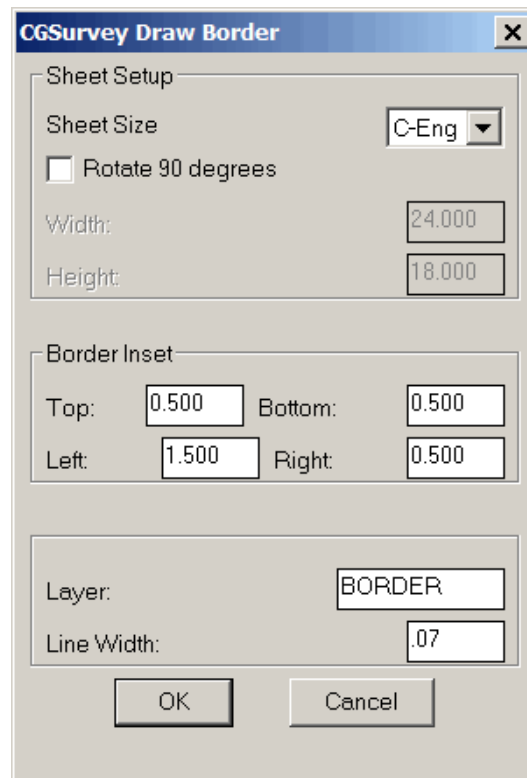

Pulldown Menu Location: CG-Survey > CGDraw>Global Edit

Keyboard Command: GE, CG_GLOBAL_EDIT

Prerequisite: Coordinate file

Border

This option allows you to place a border Polyline on your drawing with sheet sizes.

Prompts

Sheet Setup

Sheet Size: The letters A, B, C, etc. refer to ANSI sheet size standards. You also have the option of creating and naming custom sizes.

Rotate 90 Degrees: when checked will rotate the border 90 degrees.

Border Inset: specifies the inset distance for the border. Keep in mind this inset distance is measured from the edge of the plotable area of your plotter. Check the plotter manual for plotter specifications.

Layer: The layer the border will be drawn on.

Line Width: The thickness of the border line in inches (cm).

Press OK button when done and the border polyline will be drawn at the mouse cursor. You can move it to the correct location and left click to place it there.

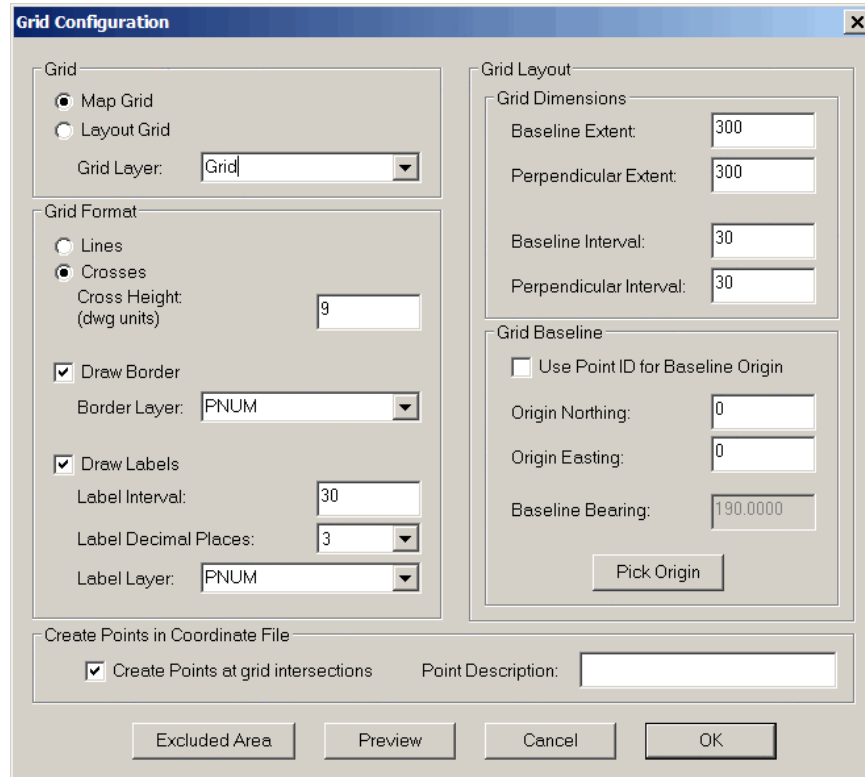

Pulldown Menu Location: CG-Survey >CGDraw>Border

Keyboard Command: DB, CG_DRAW_BORDER

Prerequisite: None

Coordinate Grid

Choosing the Coordinate Grid item in the CGDraw menu brings up the Grid Configuration dialog. The various areas of the dialog are described below:

Map Grid: is used to provide a visual reference grid to show northings and eastings on a map. A Map Grid can be labeled along its border to show the coordinate values of the grid lines. The Map Grid is oriented North-South East-West whereas a Layout Grid can be oriented at any specified bearing.

Layout Grid: is meant to be used to create points on a regular grid for laying out building columns, a topo grid, etc. A Layout Grid does not allow for a border nor for coordinate labels along the border.

Grid Layer: specify the layer the grid is to be created on. The layer does not need to exist prior to running this command.

Lines: If selected grid lines will be drawn for the full height and width of the grid dimensions.

Crosses: Only crosses will be drawn at the grid intersections for the full height and width of the grid dimensions.

Cross Height (drawing units): this defines the size of the crosses in drawing units. If your drawing scale is 40 feet and you wish to have crosses that are 0.25 inches when plotted, you must specify cross height as 10 feet.

Draw Border: If checked, a border will be drawn around the perimeter of the defined grid. You can choose a different layer for the border if you wish. This will allow you to set the color, line thickness and/or line type for the border (this option is not available for Layout Grid).

Draw Labels: Label the grid lines or crosses around the perimeter at the same interval as the Baseline and Perpendicular intervals (this option is not available for Layout Grid). If checked you must specify:

Label Interval: This number must be some even multiple of both the baseline and perpendicular intervals. The Label Interval CAN NOT be less than the base or perpendicular interval settings.

Label Decimal Places: Specify the number of decimal places used for the label text.

Label Layer: Specify the layer the labels are to be drawn on.

Grid Dimensions: Baseline Extent: This is the total width of the grid, East to West (or parallel to the baseline bearing in the case of a Layout Grid).

Perpendicular Extent: This is the total height of the grid perpendicular to the baseline.

Baseline Interval: This is the distance between the grid lines (or X's) drawn perpendicular to the baseline

Perpendicular Interval: This is the distance between the grid lines (or X's) drawn parallel to the baseline.

Grid Baseline:

Use Point ID for Baseline Origin: checking this box allows you to use an existing C&G coordinate for the **Grid Origin**. This is typically used for a Layout Grid.

Enter the point ID, or select the point from the screen.

Origin Northing/Origin Easting: manually enter the Northing and Easting value for the grid origin or pick it on the screen using the Pick Origin button.

Baseline Bearing: This is only used when you are drawing a Layout Grid. This is the bearing of the baseline. Use the standard C&G bearing input format qdd.mmss (e.g. 125.3527 for N25°35'27"E or 325.5405 for S25E54'04"W)

Pick Origin button: This option allows you to pick the origin graphically on the screen. You do not have to pick a C&G point.

Create Points at Grid Intersections:

Checking this box will cause the default C&G point to be plotted at each grid point or grid line intersection and a corresponding point to be stored in the currently open coordinate file. This is especially useful when creating a Layout Grid.

Point Description: enter a point description for the points saved to the coordinate file.

Exclude Area: This button allows you to graphically specify a horizontal window within which no grid is to be drawn. This can be used to guarantee that a title block, legend or other area is not obscured by the grid or its labels.

Preview: This button allows you to preview the grid as specified. Pressing <Enter> will return you to the Grid Configuration dialog allowing you to make changes if necessary.

Cancel : This button exits the command without drawing the grid.

OK: This button causes the grid to be drawn.

Pulldown Menu Location: CG-Survey > CGDraw>Coordinate Grid

Keyboard Command: GRD, CG_DRAW_GRID

Prerequisite: Coordinate file

Text on Arc

Create

Text on arc allows you to create text that follows an arc specified by you. Each word in the text is a separate block and can be moved later as needed.

Prompts

You will be prompted to Enter Text to place on arc:

Type the desired text then press <Enter>:

Enter center point for arc: using the mouse, select the center point of the arc the text is to follow, this can be a C&G point, or any point in the drawing. You need not actually have an arc drawn.

Enter Midpoint of text: select the midpoint of the text, this can be a C&G point, or any point in the drawing.

Move to desired location: The text will be drawn at the cursor. Move the cursor to the desired location and left click to place the text.

Pulldown Menu Location: CG-Survey > CGDraw>Text on Arc>Create

Keyboard Command: TOA, CG_TOA

Prerequisite: Coordinate file

Move

Allows you to move all the text associated with the selected text-on-arc entity.

Prompts

Select entities: select text

Entities in set: 1 item is found and selected

Select entities: press <Enter> to accept entry

Move Text to desired location: move text

Select entities: repeating the selection set

Press <ESC> or <Enter>: to end command

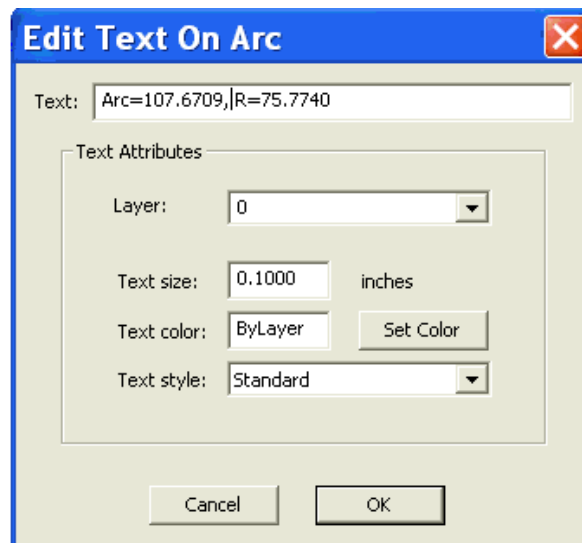

Pulldown Menu Location: CG-Survey > CGDraw>Text on Arc>Move

Keyboard Command: MTA, CG_MOVE_TOA

Prerequisite: Coordinate file

Edit

Allows you to edit the text associated with a text-on-arc entity.

Text: Arc=107.6709, R=75.7740 (Edit Text)

Text Attributes

Layer: 0 (current)

Text Size: 0.100 inches (Default)

Text color: Bylayer

Set Color Button: select a new color

Text style: Standard text style

Prompts

Select entities: select text

Entities in set: 1 item found and selected

Select entities: repeat selection set

Press <ESC> or <Enter >: to end command

Pulldown Menu Location: CG-Survey > CGDraw>Text on Arc>Edit

Keyboard Command: ETA, CG_EDIT_TOA

Prerequisite: Coordinate file

Delete

Allows you to delete all the text associated with a text-on-arc entity.

Prompts

Select entities: select text

Entities in set: 1 item found and selected

Select entities: repeat selection set

Press <Esc> or <Enter>: to end command

Pulldown Menu Location: CG-Survey > CGDraw>Text on Arc>Delete

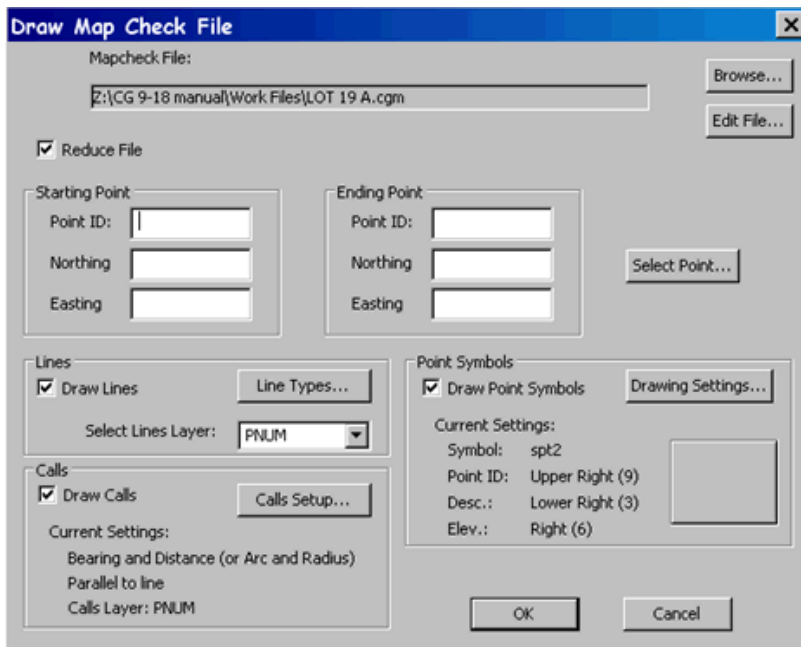

Keyboard Command: DTA, CG_DELETE_TOA

Prerequisite: Coordinate file

Draw Mapcheck

This routine will draw a mapcheck file. The settings allow you to plot points, draw lines, and place calls all at the same time.

If a mapcheck file is NOT currently open when you open the map check file routine a dialog box will prompt you to open a mapcheck file. Once a mapcheck file is open the following dialog box will open.

If the mapcheck file displayed at the top of the dialog box is not the file you want to draw you can use the browse button to search for another file.

You also have the option to edit the file which will take you to the mapcheck editor (CGEditor).

Reduce File: If this item is checked there will be a closure report written to the print file and the command line.

Starting/Ending Points: You have the option of entering an existing point number or manually entering the northing and easting. If you enter an existing point number the northing and easting values will be read from the coordinate file and placed in the appropriate edit boxes (see below).

If the starting and ending point are the same point, you need only enter the starting point values.

Clicking the **Select Point** button will cause the **Draw Mapcheck** dialog to be hidden thus allowing you to pick the starting and ending points from the screen or use the command prompt:

Select starting point for mapcheck:

or

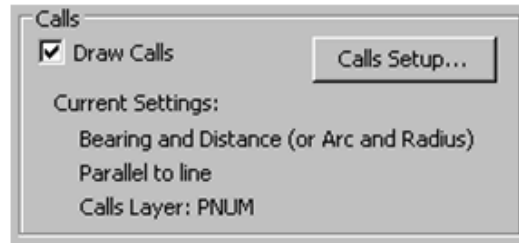

Select ending point for mapcheck:

rather than manually entering the point number or coordinate values in the edit boxes.

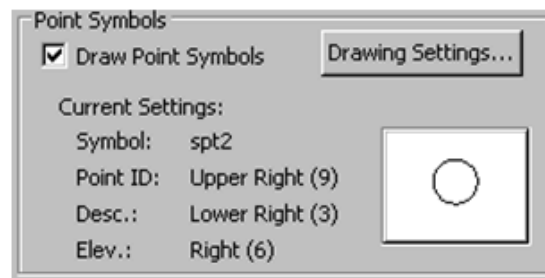

Lines: This portion of the dialog allows you to turn on or off the draw line command as well as select the linetype and layer where the line will be drawn

Calls: This section of the dialog allows you to turn on or off the draw calls command as well as edit the call setup options.

Point Symbols: This area of the dialog allows you to turn on or off the draw point symbols command as well as having a button that will take you to the drawing settings dialog. At the drawing settings dialog you can change the symbol, symbol size, label options and more.

OK: Selecting ok will cause the mapcheck file to be drawn, based on the current settings as described above.

Prompts

Select starting point for mapcheck: Select a point symbol or type a point number for the starting point.
or

Select ending point for mapcheck: Select a point symbol or type a point number for the ending point.

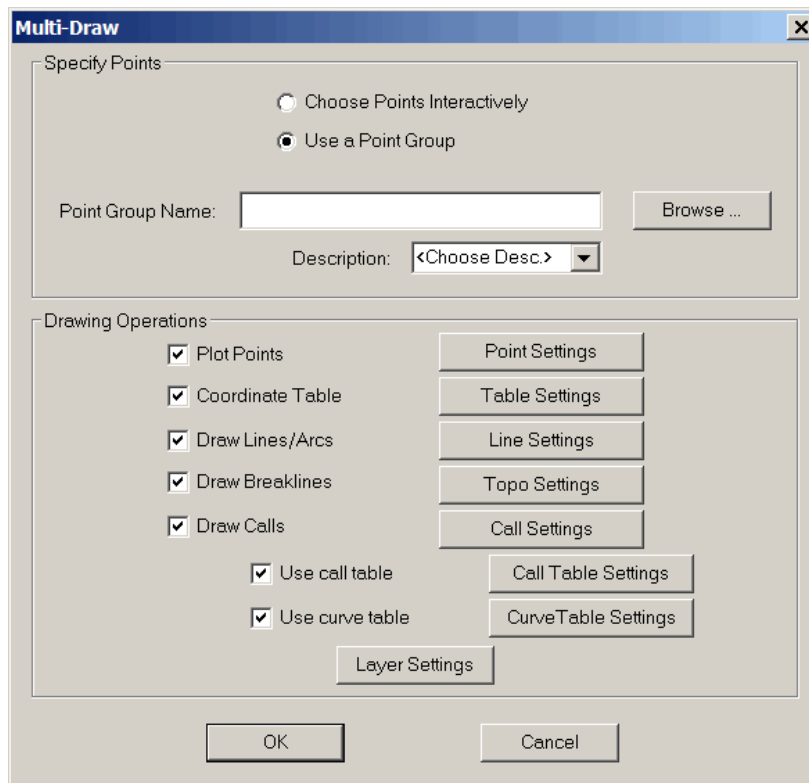

Pull-down Menu Location: CG-Survey > CGDraw>Draw Mapcheck

Keyboard Command: DMP, CG_DRAW_MAPCHECK

Prerequisite: Open Mapcheck file *.cgm

Multi-Draw

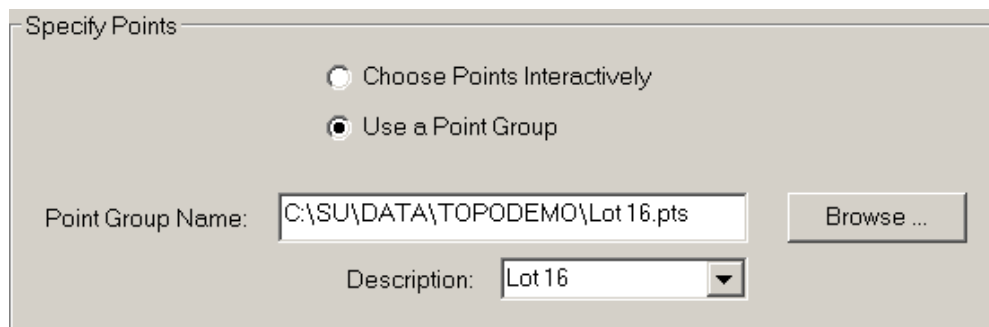

This feature allows you to complete several drawing operations at the same time. For example, in one operation you can plot points and generate a coordinate table for the points at the same time. Or you can draw lines by points and place calls on the resulting lines at the same time.

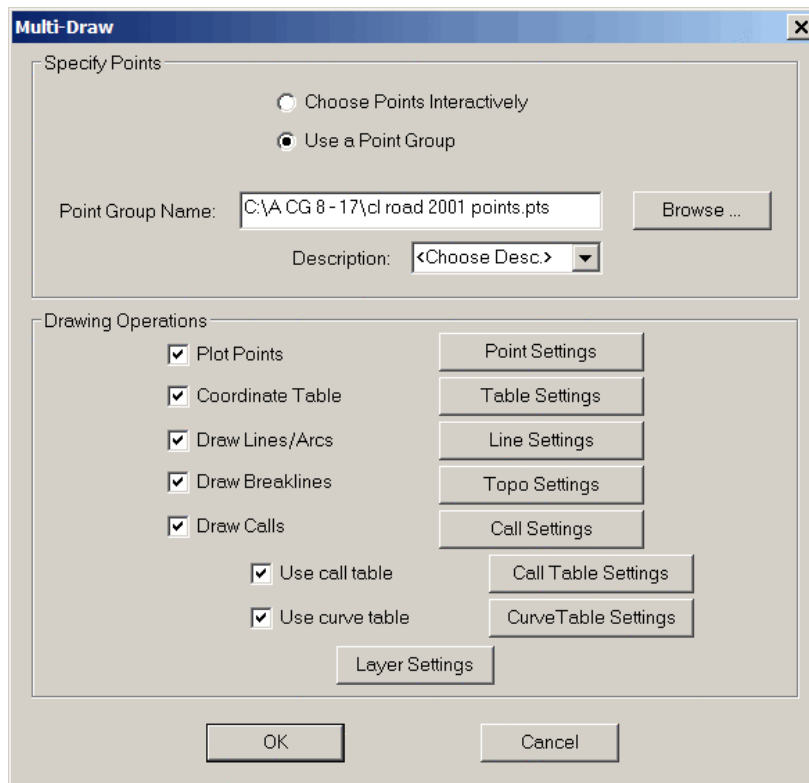

Prompts

When you choose Multi-Draw from the CGDraw menu, the Multi-Draw dialog box is displayed.

Specify Points

Use the radio buttons to indicate how you want to specify the points that will be used for the drawing operations. You can Choose Points Interactively using the standard C&G point sequence command line interface or you can Use Point Group.

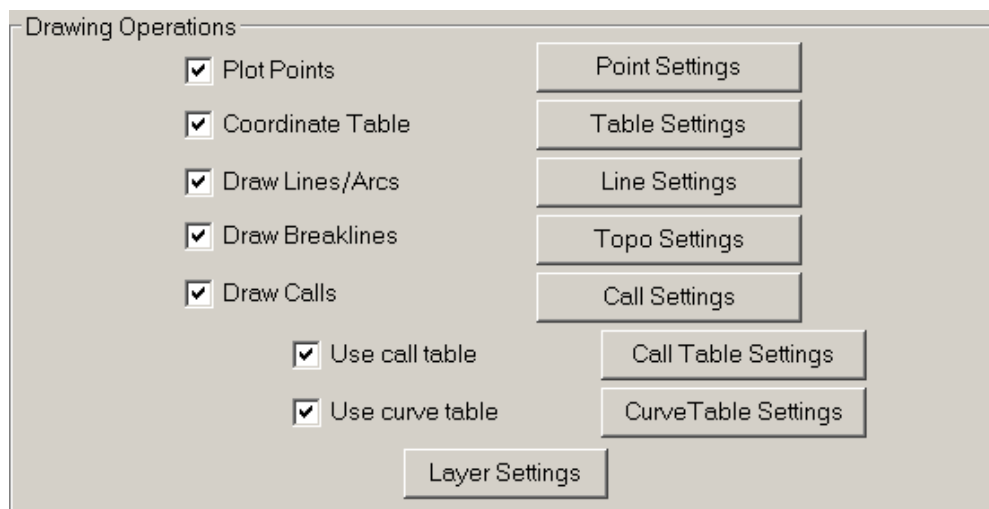

NOTE: If you Choose Points Interactively, you will not have the option of plotting points or creating a coordinate table.

If you click Use Point Group, you must specify a Point Group Name and the point group description for the points you wish to use. You can either type the full path (including the drive letter) to an existing point group file or you can click the Browse button and use the file dialog box to specify the Point Group file.

NOTE: In this context, Description refers to the Point Group description, NOT the description for the individual points as found in the coordinate file.

Drawing Operations

In this area of the dialog box you must specify which drawing operations to perform and, if needed, make the necessary settings changes required for the drawing operations. Any settings changes are saved to the drawing and thus remain in effect after this command is completed.

Plot Points: Checking this checkbox will cause the selected points to be plotted.

Point Settings button: selecting this button will bring up the Drawing Settings dialog box allowing you to make changes to the drawing settings.

Coordinate Table: Checking this checkbox causes a coordinate table to be created for the points selected.

Table Settings button: will bring up the Coordinate Table Settings dialog box allowing you to make changes to layer, text size and line spacing.

Draw Lines/Arcs: Checking this checkbox causes lines and or/arcs to be drawn between the points specified.

Line Settings button: Will bring up the Linetype Manager allowing you to select the linetype.

Draw Breaklines: Checking this checkbox causes breaklines to be drawn between the specified points. Breaklines are for use in topographic operations (see CGTopo).

Topo Settings button: displays the CGSurvey Auto Contouring settings dialog box allowing you to make changes to the current topo settings.

Draw Calls: When Draw Calls is checked, calls will be drawn between the points specified.

Call Settings button: will display the Call Settings dialog box allowing you to make changes.

If Use Call Table is checked: all call information will be placed in a call table, rather than along the line work. The Call Table Settings button displays the Call Table Settings dialog and allows you to set the layer calls will be placed on, the text size, the line spacing, the first course label, etc.

If Use Curve Table is checked: all curve information will be placed in a curve table, rather than along the line work. The Curve Table Settings button displays the Curve Table Settings dialog and allows you to specify: which components will be shown in the curve table, which layer the table will go on, the text size, the line spacing, the first course label, etc.

The Layer Settings button: displays the Layer Manager dialog. Here you can create any layers you need or set the current layer as required. When you are satisfied click OK.

If you choose Use Point Group: the drawing operations you have selected will be completed immediately.

If you have selected Choose Points Interactively: enter or pick the desired points at the following standard C&G point sequence command line prompt:

Note: When entering the points at the command line, some drawing operations may occur as you enter the points.

Placement of coordinate, call and or curve tables

No matter what point selection method you use, if you specified that any tables be drawn, the coordinate, call or curve table will be placed at the cursor and you will be asked to move the cursor to the desired location. Clicking the left mouse button will place the table in the drawing at the cursor location.

Pulldown Menu Location: CG-Survey > CGDraw>Mult-Draw

Keyboard Command: MD, CG_MULTIDRAW

Prerequisite: Coordinate File and/or Point Group

Plot Points and Symbols

Plot Points on Screen

Plot Points on Screen: This feature plots the selected points from a coordinate file on the screen.

Prompts

If a coordinate file is not open, a file dialog box will appear allowing you to open one.

You will then be asked to select the points to be plotted (for additional information, see Getting Started: Coordinate point selection sets).

Type the Capped Letter to initialize the selection Set

[All/Block/Code/Desc/Elev/Pt_group/Limits/radius/select]: A

Press <Enter>3x when done: The points will be plotted on the screen.

In which layer will the points be plotted?

If the Use Description Table for point plotting parameters checkbox is not checked in the Graphic Options tab in C&G Options dialog: then all points will be plotted on the current layer according to the Drawing Settings dialog.

If the Use Description Table for point plotting parameters checkbox is checked and the Default layer for codes or descriptions not found in description table is specified: point's will be plotted to the layers specified by the description table (for a discussion of description tables see the CGMngmt chapter).

Description matches a description found in the description table: the point and its labels will be plotted as specified in the description table. For a description to match it must be a whole word match, disregarding numbers.

For example:

Table Description Point Description Match

TC TC-.5 to Bc yes

SW SW1 yes

FH TOPFH no

If a point has several different descriptions found in the description table: then that point can be plotted in more than one layer. For example: If the point's description is TC WV, it will be plotted in the layer assigned to the description TC as well as the layer assigned to the description WV.

No match is found in description table: the point will be plotted in the default layer with point labels as specified for the active point symbol.

Pulldown Menu Location: CG-Survey > CGDraw>Plot Points and Symbols>Plot Points on Screen

Keyboard Command: PP, CG_PLOT_POINTS

Prerequisite: Coordinate file

Remove Points from Screen

This feature allows you to remove/erase specified points from the drawing.

Prompts

If a coordinate file is not open, a file dialog box will appear and allow you to open an existing coordinate file.

Using the standard C&G Select Points commands, select the points to be removed.

Type the Capped Letter to initialize the selection Set

[All/Block/Code/Desc/Elev/Pt_group/Limits/radius/select]: A

Press <Enter> 3X when done: The points will be removed from the screen.

Note: Remove Points from Screen does NOT delete points from the coordinate file.

Pulldown Menu Location: CG-Survey > CGDraw>Plot Points and Symbols

Keyboard Command: RP, CG_REMOVE_POINTS

Prerequisite: Coordinate file

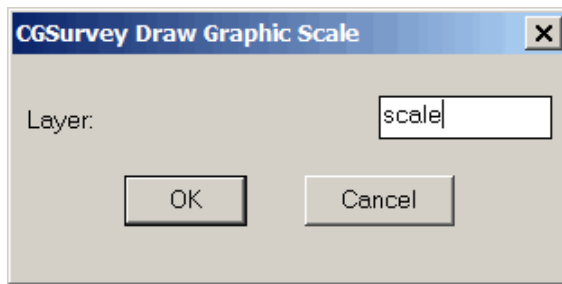

Graphic Scale

This feature allows you to draw a graphic scale. Make sure the correct scale has been specified in the Drawing Settings dialog box.

Prompts

In the CGSurvey Draw Graphic Scale dialog specify the layer for the graphic scale.

Layer: Scale

Once you have specified the layer: press the OK button.

The Graphic Scale symbol will then be drawn at the mouse cursor: You can move the cursor to position the graphic scale then press the left mouse button to place it at the cursor location.

Pulldown Menu Location: CG-Survey > CGDraw>Plot Points and symbols>Graphic Scale

Keyboard Command: GSC, CG_DRAW_GSCALE

Prerequisite: Coordinate file

Lines and Polylines

Lines by Point Number

This feature allows you to draw lines and/or arcs based on the points in the coordinate file.

Prompts

If you choose this option and a coordinate file is not open, you will be prompted to open one.

You will be prompted at the command line to enter the coordinate point IDs that define a line/arc or a series of lines/arcs. You may type the point IDs at the command line or pick points on the screen.

Enter Point Sequence

(point group/Reset/sNap on) (last point = <72>):

Once a point is selected the command line will change to a new group of options

(cLockwise curve/ccW curve/Point group/Reset/sNap on) (last point = <72>):

Once finished plotting points simply hit<Enter> and the command line will clear.

Point Input: When entering a point sequence specifying a line/arc the following input forms are acceptable:

34: Either specifies the starting point of a line or, if this is a continuing series of lines, draw a line from the previous end point to point 34 and occupy point 34.

6-9: Draw a line from point 6 to 9 and occupy point 9.

-4 : Draw a line from the previous end point to point 4 but remain at previous end point.

L: Specify a cLockwise curve. The previous end point is assumed to be the PC of the curve. The next point specified is the center or radius point of the curve and the next point entered is the PT of the curve.

W: Specify a counter clockWise curve. The data entry sequence is similar to a clockwise curve.

P: Use a Point group to specify the lines/arcs. You will be asked to pick the point group file using a file dialog box.

R: Reset the "last point" to none

N: Toggles the CAD snap command on or off

If you choose to use a point group file, lines will be drawn from point to point in the order specified in the point group file (see the CGMngmt chapter for information on point group files).

If you do not want to type in the point IDs to define the lines/arcs, you can select the points from points that are plotted on the screen using your mouse. (see Plot Points and Symbols).

Note: To specify an arc to be drawn pick the PC point of the curve then enter either **L** <Enter> for clockwise or **W** <Enter> for counter clockwise curve. When prompted, pick the radius point and then pick the PT.

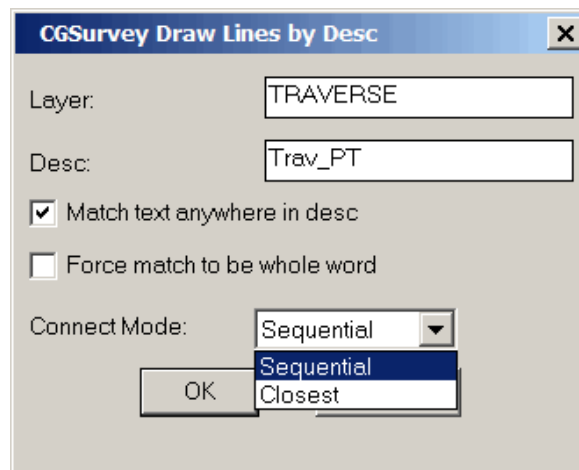

Pulldown Menu Location: CG-Survey > CGDraw>Lines and Polylines>Lines by Point Number

Keyboard Command: LBP, CG_LBP

Prerequisite: Coordinate file

Lines by Description

This feature allows you to connect lines between all the points in a coordinate file having a common description.

Prompts

After choosing the Lines by Description menu item you will see the CGSurvey Draw Lines by Desc dialog.

Layer: Specify the name of the layer the lines are to be drawn on.

Desc: Specify the description of the points you want to connect. Case is ignored and, unless the checkboxes described below are checked, only the leading characters of the point description are considered for a match.

Match text anywhere in desc: If this checkbox is checked, the entire point description field will be searched for the characters specified in the Desc: edit box. For example:

Input Description Point Description Match
MH SanMH Yes

Force match to be whole word: If this box is selected, the match must be a complete word in the point description, not just a portion of a word. For example:

Input Description Point Description Match
RD CL RD Yes (whole word)

RD CLRD No (not whole word)

Connect Mode

Sequential: Connects the points in point ID order.

Closest: Ignores point ID and connects to the closest point with named description.

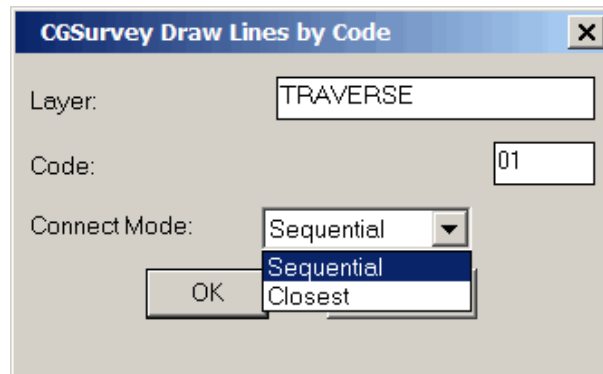

Pulldown Menu Location: CG-Survey >CGDraw>Lines and Polylines>Lines by Description

Keyboard Command: LBD, CG_LBD

Prerequisite: Coordinate file

Lines by Codes

This feature allows you to draw lines between the points in the coordinate file having a common point code. The point code is a two to four character field (depending on the type of coordinate file).

Prompts

Choosing the Lines by Code menu item brings up the CGSurvey Draw Lines by Code dialog.

With the exception of the Code: field, the items in this dialog are identical to those in the CGSurvey Draw Lines by Desc dialog.

Code: field specifies the code for the points you want to connect. Case is ignored.

Connect Mode

Sequential: connects line in point ID order

Closest: connect lines in Closet point with named description

Pulldown Menu Location: CG-Survey > CGDraw>Lines and Polylines

Keyboard Command: LBC, CG_LBC

Prerequisite: Coordinate file

Polylines by Point

This feature works very similar to the Lines by Point feature described in the previous pages. In Polyline by Points data entry is similar to Lines by Point except Reset does not apply to a polyline. The C&G Polyline allows you to treat road centerlines and other similar things that would normally be made up of several line segments, as one entity. You can use a C&G polyline to create a point group or you can place calls along it. You could also use a C&G polyline as the bounding polygon in the Fit Structure feature.

Pulldown Menu Location: CG-Survey > CGDraw>Lines and Polylines>Polylines by Point

Fit Polylines

This feature allows you to use a variety of best fit methods to smooth an existing polyline.

Prompts

First you must choose the method to use in fitting the selected polylines at the following prompt:

Type of fit to apply: [Decurve/Fit/Quadratic_spline/cUbic_spline/Cg_spline]<C>:

Next, select the polylines you wish to fit then press the <Enter> key or right mouse button to apply the fit to the selected polylines.

Decurve: This will decurve a previously smoothed polyline.

Fit: uses CAD fit - a series of interconnected circular arcs.

Quadratic spline: Uses a quadratic spline curve fitting algorithm.

Cubic spline: Uses a cubic spline curve fitting algorithm.

C&G Spline: Creates a smooth curve that passes through all vertices.

Pulldown Menu Location: CG-Survey >CGDraw>Lines and Polylines>Fit Polyline

Keyboard Command: FITP, CG_FIT_POLY

Prerequisite: Coordinate file

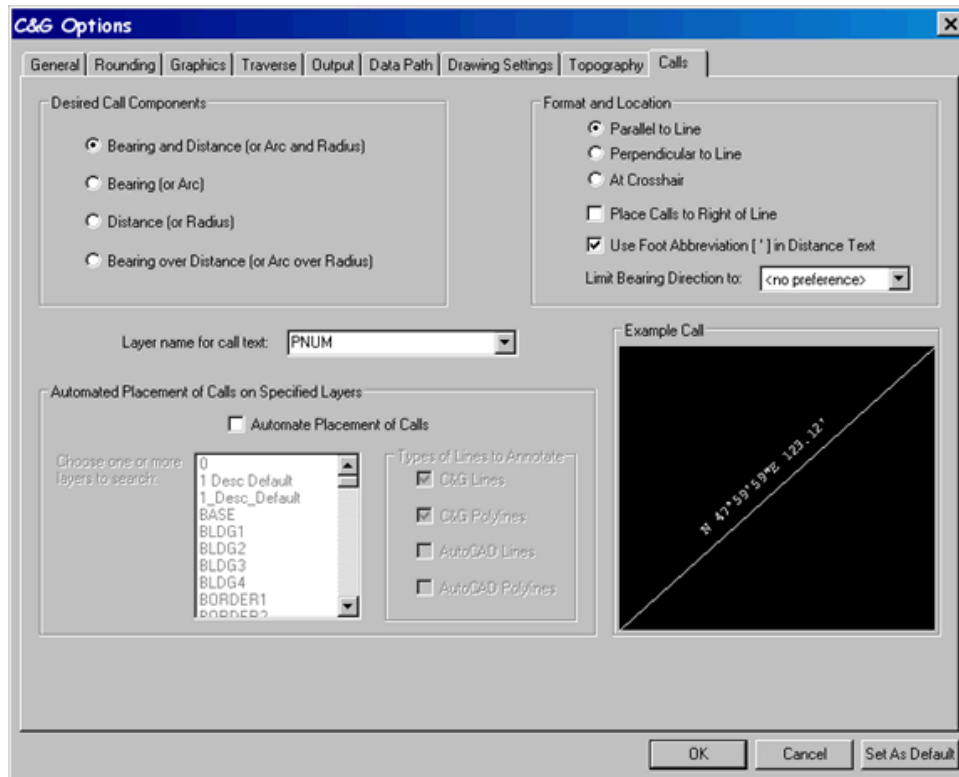

Calls

Place Calls

This feature allows you to annotate C&G and CAD lines, arcs and polylines.

Call Setup

Selecting Calls Setup will bring up the Call settings dialog box.

Desired Call Components: Specify the desired components for the call.

Bearing and Distance (or Arc and Radius)

Bearing (Arc)

Distance (Radius)

Bearing over Distance (Or Arc over Radius)

If you specify points to form a curve then the components shown in parentheses will be used to form the call text.

Format and location: Specify how you want the call placed relative to the line or arc:

Parallel: to the line or Arc

Perpendicular: to the line or arc

At Cursor: means the call text will be drawn horizontally at the cursor and you must move it to the desired location then left click to place it.

Place Call to Right of Line: If you are placing a call either parallel or perpendicular to a line or arc, select this box if you want the call placed to the right of the line or arc, assuming you are standing on the line and facing in the direction of the bearing. The call will be centered along the line or arc.

Use the Foot Abbreviation ['] in Distance Text: Checking this box will place the ['] mark after the distance (125.36'). Un-checking the box will remove the ['] mark (125.36).

Line Bearing Direction to:

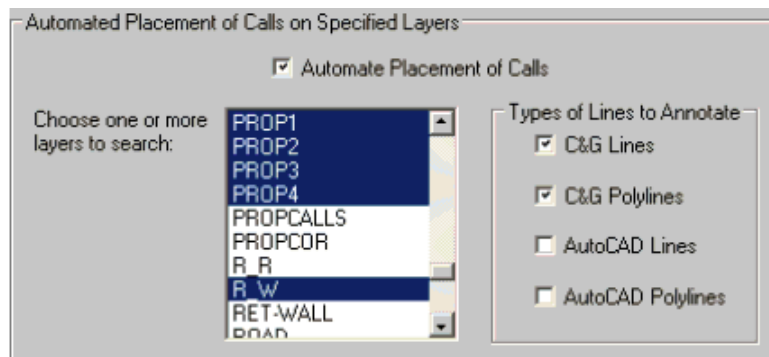

Selecting NW,NE: will force all calls to be shown only with NE and NW notation (N 428 35' 12" E or N 168 25' 31" W)

Selecting SW,SE :will force all calls to be shown only with NE and NW notation (S 428 35' 12" E or S 168 25' 31" W)

If < no preference >: is selected the software will define the bearing based on the direction of the points selected.

Layer Name for Call Text: Specify the layer where you want the calls placed.

Automated Placement of Calls on Specified Layers

Check the Automate Placement of Calls check box making the options in the dialog active. This routine allows you to select one or more layers to scan for the placement of calls. The scan will look for lines only in the layers you specify even though other layers may be currently displayed.

Choose one or more layers to search: this dialog will display the complete list of layers in the drawing file. You can scroll up and down the list and simple click with the mouse those layers you want to search for lines/polylines.

Types of Lines to Annotate:

C&G Lines and C&G Polylines: refer to lines that have been drawn using the CGDraw command, thus being based on the C&G coordinate file.

CAD lines and CAD Polylines: refer to lines that have been drawn using the CAD Draw command and are not based on the C&G coordinate files.

Example Cell: this display shows you the actual layout as it will appear on you drawing.

Prompts

When you choose the Place Calls menu item and a coordinate file is not already open, you will be asked to open a coordinate file. You will then see the following prompt at the command line:

Enter point sequence: [Point group/Reset/turn.sNap on/Setup/poLYline] (last point = <none>):

Point Group: If you press P and <Enter> you will be asked to enter a point group and it will be used to place calls automatically.

Reset: Press "R" resets the last point ID to <none>

sNap on or sNap off: Press "N" turns the CAD snaps on or off. When the command starts the AutoCAD snaps are off by default.

The Setup: Press "S" option brings up the Calls Setup dialog box.

polyline: if you Press "Y" and <Enter> you can then pick a C&G polyline and it will be annotated in the order that the vertices were specified when it was drawn.

Pulldown Menu Location: CG-Survey > CGDraw>Calls>Place Calls

Keyboard Command: CALL, CG_CALLS or CALS, CG_CALLS_SETUP

Prerequisite: Coordinate file

Move Calls

Allows you to move call text and once moved it will not go back to its original location when you use Refresh Screen to refresh calls. The calls will move or change if the point numbers that generated the call change but the position of the call relative to the end points will remain approximately the same.

Prompts

Select entities: Pick call on screen

Entities in set: 1

Select entities: Pick another call on screen

Move call to desired location.

Pulldown Menu Location: CG-Survey > CGDraw>Calls>Move Calls

Keyboard Command: MCL, CG_MOVE_CALLS

Prerequisite: Coordinate file

Reverse Calls

This feature allows you to reverse the bearing of the call.

Prompts

Pick a call to reverse: select call bearing on screen

Pick a call to reverse: select another call bearing on screen

Pick a call to reverse: select again if wish to continue or

Press <Esc>: to quit command

Pulldown Menu Location: CG-Survey > CGDraw>Calls>Reverse Calls

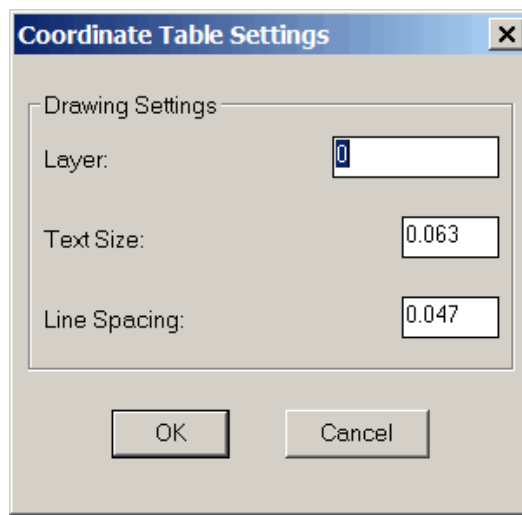

Keyboard Command: RCL, CG_REVERSE_CALLS

Prerequisite: Coordinate file

Tables

Coordinates

This feature allows you to draw a table containing information related to specified points in the coordinate file then place the table in the drawing by picking the desired location.

When you pick the Table > Coordinate menu item and a coordinate file is not already open, you will be asked to open one. Once a coordinate file is open, then the Coordinate Table Settings dialog will appear. Using this dialog you can configure the following settings:

Layer: Specify the layer on which you want the table drawn.

Text Size: Enter the text size in inches or centimeters. The text size is the size the text will appear when printed on a page.

Line Spacing: Enter the space you want between lines in inches or centimeters. The line spacing is the height of the spacing when the table is printed on a page.

Note Northings and Eastings will be rounded based on the values specified in the Rounding Options tab of the C&G Options dialog box.

Note The point ID, northing, and easting will always be part of the coordinate table. If you want elevations, codes and descriptions shown, make sure they are set to "On" on the Global Settings tab of the C&G Options dialog. Click OK to save the settings and continue the command, this will return the action to the command line. If you click Cancel the command will be canceled.

Selecting Points for the coordinate table:

Select the points that will be included in the table using the familiar C&G prompt.

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: A

Prompts

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: A

Expand base selection set: Choose more points from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select/Include/eXclude/View]:

Building Point Selection Set...

Press Enter 2 more times to end selection set: <Enter>

When done selecting points just press <Enter>:The table will be drawn at the cursor.

Move Coord Table to desired location: Drag the table to the desired location on the drawing and press the left mouse button to place the table.

Point	Northing	Easting	Elev.
1	311.54700	156.49600	806.000
2	195.62300	178.23400	800.000
3	179.32153	349.22200	804.000
4	88.75616	482.53484	784.000
5	89.62426	592.66286	774.000
6	278.84438	641.83001	806.000
7	384.00033	644.84340	797.000
8	451.01870	439.06257	792.000
9	369.50846	370.95736	792.000
10	431.09387	252.13509	812.000
11	398.49010	186.92788	810.000
12	277.07728	299.76590	796.000
13	301.70887	505.67938	804.000
14	221.32480	513.17644	780.000
15	273.50991	391.24427	803.000

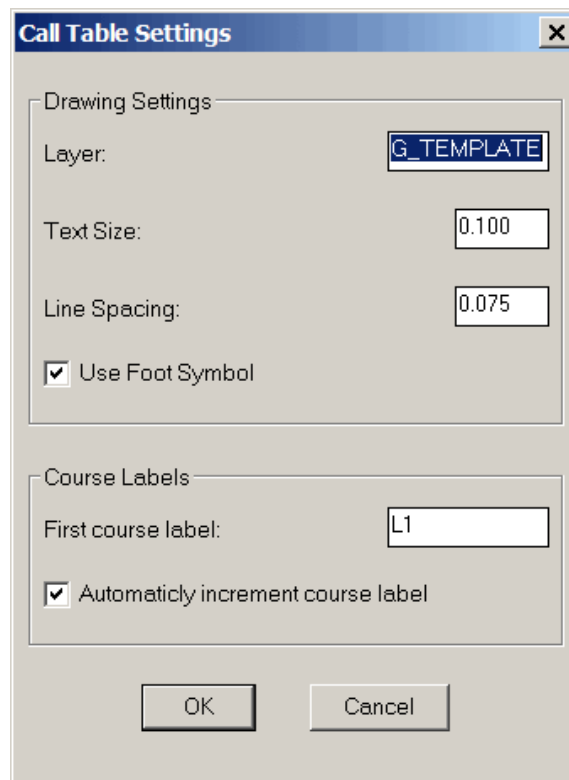

Pulldown Menu Location: CG-Survey > CGDraw>Tables>Coordinate

Keyboard Command: CRDT, CG_COORD_TABLE

Prerequisite: Coordinate file

Call Table

This feature allows you to place the bearings, distances, etc. in a table instead of along the lines and curves in the drawing. This is especially useful when space along the lines or curves is limited. When you use a call table only the course labels are placed along the line or curve to identify it in the table.

When you choose the Table > Call item from the menu the Call Table Settings dialog appears. As with the coordinate table, this dialog box allows you to enter: the layer, text size and line spacing for the call table.

Drawing Settings

Layer: CG_Template

Text size: 0.100

Line Spacing: 0.075

Use Foot symbol: Checked

This setting will place a Foot symbol < " > if desired.

Course labels

First course label: The course labels will be based on the First course label setting in the Call Table Settings dialog box. The course label will then be determined by incrementing the last character in the previous course label starting with the first course label.

For example: line1 increments to line2, line3, etc. whereas line_a increments to line_b, line_c, or as in the example above L1, L2 L3, etc.

Automatically increment course label: Check or Uncheck box

This setting will automate the process with selecting point sequence

After configuring the settings in the Call Table Settings dialog:

Ok Button : select OK

Prompts

You will be prompted at the command line to enter the point sequence.

Enter the point sequence by typing point IDs or by selecting C&G points and/or lines on the screen.

Enter point sequence: [cLockwise_curve/ccW_curve/Point_group/Reset/turn_Snap_on]

The Reset button: The ' R' resets the last point to <None>

When you are done entering calls: press <Enter>

This will end the input process and the call table will be drawn at the cursor.

Move Call Table to desired location: Drag the table and left-click the mouse button to place table on screen. The course description will be placed in the table and on the line or arc in the drawing.

Course	Bearing	Distance
L1	N 15°04'36" E	183.84'
L2	S 85°52'05" E	170.10'
L3	S 11°44'15" E	163.23'
L4	S 65°53'25" W	141.06'
L5	N 66°49'49" W	132.63'

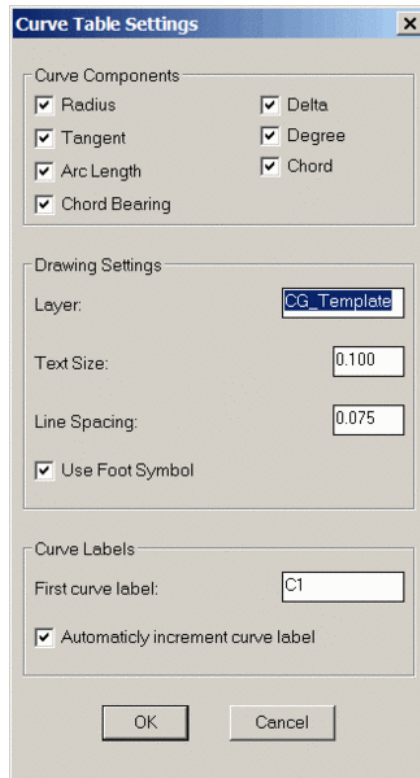

Pulldown Menu Location: CG-Survey > CGDraw>Tables>Call

Keyboard Command: CALT, CG_CALL_TABLE

Prerequisite: Coordinate file

Curve

This feature allows you to Draw a table containing curve information for specified curves.

You will be prompted to open a coordinate file if one is not already open. Once the coordinate file is open, the Curve Table Settings dialog box will appear. The Curve Table Settings dialog allows you to configure the following settings:

Curve Components

Check the checkboxes for the curve components that you wish to appear in the table, Radius, Tangent, Arc Length, Chord Bearing, Delta, Degree and Chord.

Drawing Settings

Enter the layer, text size and line spacing, and check or uncheck the Use Foot Symbol checkbox.

Layer: CG_Template

Text Size: 0.100

Line spacing: 0.075

Curve Labels

Enter the First Curve Label for the first curve

First Curve Label: C1

Automatically increment curve label: check or uncheck the Automatically increment curve label checkbox.

OK Button: When done, click OK to begin entering the curve data.

Prompts

You will be prompted at the command line to Enter point sequence

Picked C&G Point [1444]

Enter point sequence

[cLockwise_curve/ccW_curve/Reset/turn_Snap_on] (last point = 1444): L

Enter radius point for curve [Reset/turn_Snap_on]:

Picked C&G Point [1449]

Enter point of tangency (PT) for curve [Reset/turn_Snap_on]:

Picked C&G Point [1448]

Move Curve Table to desired location: Drag Table to desired location and Left-mouse click to place on the

Curve	Radius	Tangent	Length	Delta	Degree	Chord	Chord Bear.
C1	42.90'	48.07'	72.28'	98°30'20"	133°33'43"	64.01'	N 73°14'52" E

drawing.

Note: After entering the PT point for any curve, you can continue entering curve data. However, you should be aware that the PT point is shown as the last point.

If the PT point is not the PC of the next curve then you need to enter "R" for Reset. This allows you to begin the next curve at a new PC, then continue on to enter its radius point and PT.

Pulldown Menu Location: CG-Survey > CGDraw>Tables>Curves

Keyboard Command: CURT, CG_CURVE_TABLE

Prerequisite: Coordinate file

Auto Map

Map allows the user to automate the production of a drawing based on special "mapping codes" included in the descriptions found in the coordinate file. Using this feature can save a great deal of time. This allows the lines and points to be placed in the drawing based on mapping codes without user intervention.

Pulldown Menu Location: CG-Survey > CGDraw>Auto Map

Keyboard Command: MAP, CG_MAP_DRAW

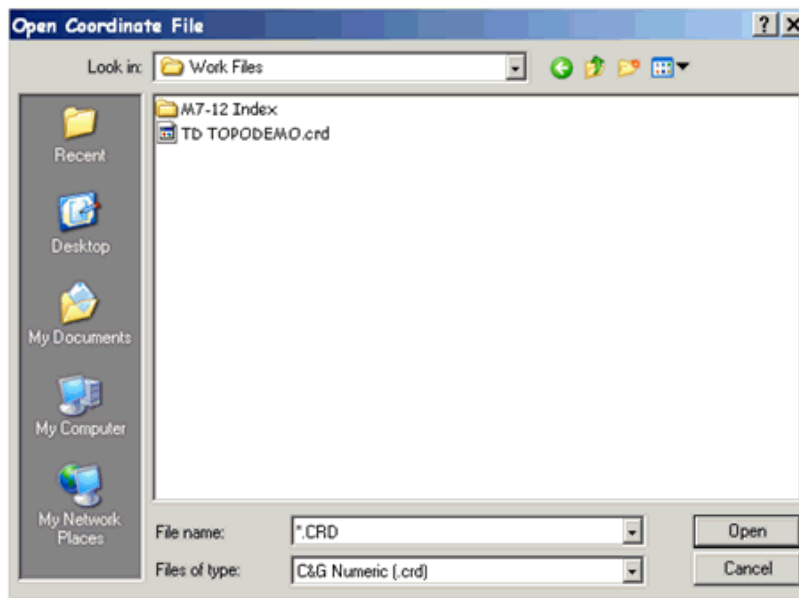

Prerequisite: Coordinate file

Draw

This feature automates the production of a drawing that can contain specific points, lines, arcs and curve fit lines. The draw option also acts as a Cogo function in that it will calculate the PC, PT and radius points of curves and has the ability to calculate points by traversing and intersection.

Prompts

After choosing the Draw command, if a coordinate file is not open, you will be asked to open one.

After opening the coordinate file, you will be asked to select the points you want to map:

Choose initial points for base selection set from coord. file: (Enter when done) [All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]:

Next, you will be asked whether you want to store elevations at calculated PC, PT, and radius points: When locating items like back of curb you may need to note the beginning and ending of curves. The points located are never exact as far as the beginning and ending of the curve, but when noted in the mapping routine the application will compute a PC, PT and Radius using the best fit routine and you can choose to store these points or not.

Note: If Auto Point Plot is ON as specified in the Graphic Options tab of the C&G Options dialog, points will be plotted and lines, arcs and/or curve fit lines are drawn when indicated by Mapping Codes found in the point descriptions.

Mapping Codes Used by the Draw feature

The map codes used by the Draw feature must be placed in the description field for each point in the coordinate file that is to be "Mapped".

Below is the list of map codes:

- BL - Begin Line
- EL - End Line (optional)
- CL - Close Figure
- PC - Begin Curve (tangent to previous line)
- OC - Point on Curve (begin/end non-tangent curve)
- PT - End Curve (tangent to next line)
- RP - Radius Point
- CF - Curve Fit (spline fit to irregular curves)
- CC - Compound Curve
- RC - Reverse Curve

Mapping Codes can be upper or lower case. The map code **MUST** be followed by an asterisk and a line description for the line that is being drawn. For example: BL*CURB1, where CURB1 is the line description for the line you are beginning. It is OK to have spaces between the code, asterisk and line description, but it is not necessary.

For example:

Point ID Description**5 BL* CURB1 BL*SW1 WV****6 CURB1****7 SW1 PP****8 PC* CURB1****9 FH****10 PT* CURB1****11 CURB1 SW1****12 OC* SW1****13 SW1****14 SW1****15 SW1****16 OC* SW1****17 CL* SW1****18 BL* CURB1**

Important Note: Mapped lines are connected in ascending order by point ID. The point ID's are always saved in the coordinate file in increasing order. Since the coordinate file is used to perform the Map Drawing and the point ID sequence is produced when the raw data is reduced, it follows that the order of field location of the points will determine point ID sequence order when the lines are mapped.

In the sample sequence above:

Point 5 begins two lines, **Curb1** and **SW1**. Curb1 and SW1 are line descriptions. A line description must be a whole word (no spaces). **WV** (water valve) is not the beginning of a line because an asterisk does not precede it.

For example:

5 BL*CURB1 BL*SW1 WV

The Curb1 line will be drawn from point 5 to point 6 to point 8. This begins a curve tangent to the line from 6 to 8 continuing to point 10. The curve is tangent to the line from 10 to 11. Since point 18 begins a new Curb1, point 11 is the end of the first Curb1 line (the EL code is not required in order to end a line).

A second line (SW1) will be drawn from 6 to 7 to 11 to 12. At point 12 a non-tangent circular curve begins and continues through points on the curve at 13, 14, and 15. The non-tangent curve ends at point 16 and lines continue from 16 to 17 to 1 (the CL code closes the figure). In creating the non-tangent curve from point 12 through point 16, points 13-15 are used by the Map Draw feature in the calculation of the best fit circular curve.

In addition to the lines drawn, the symbol specified for the WV description in the description table (see CGMngmt) will be placed at point 5 and, at point 7, the symbol specified in the description table for the description PP will be drawn.

As demonstrated in the above example, you may combine multiple codes and line descriptions within a single point description.

For example:

Point ID Description**20 BL*SW1 BL*CURB1 CURB2 EL*CURB3 CL*CURB4**

In this example point 20 begins the **SW1** line and the **CURB1** line. It continues the **CURB2** line. It ends the **CURB3** line and it closes the **CURB4** line.

The Begin Line Code:

All lines must start with a BL code. No lines will be connected to a point unless a word in the point description matches a BL* line name.

The Close Line Code: The close line code (CL) causes the Draw Map feature to connect the CL point to the BL point. You can also use the CL command to traverse. Thus you may place dimensions after a CL command. For example:

Point ID Description

20 *BL*BLD1

21 CL*BLD1+10.1+10.2-20.3+50.6 EL*SW1

Note: The FC-48 data collector does not allow '+' characters in description field. Because of this, the '/' character can be used instead of the '+' character in all the CL examples.

In the above example a line will be drawn from point 20 to point 21. The following points will then be calculated through a traverse sequence (assume the next point available is 100):

Occupied Pt BS Pt Angle Distance New Point

21 20 90 10.1 100

100 21 90 10.2 101

101 100 270 20.3 102

102 101 90 50.6 103

Point 103 will then be connected to point 20 to close the BLD1 line. Please note that point 21 is also the end of the SW1 line.

In a CL mapping code sequence, a negative dimension turns -90 degrees from the back azimuth and a positive dimension turns +90 degrees from the back azimuth. Both the '+' and '-' symbols are required but, as noted above, the '/' symbol can be substituted for the '+' where necessary.

This same figure could also be drawn using the following sequence:

Point ID Description

20 BL*BLD1

21 CL*BLD1+10.1+10.2-20.3+

Note that the closing distance was not included in the description sequence. See the following examples.

If you have located two corners of a rectangle, you may use the following short cut:

Point ID Description

20 BL*BLD1

21 CL*BLD1+50.6+

In the above example a line will be drawn from point 20 to point 21. The following points will then be calculated through a traverse sequence (assume the next point available is 100):

Occupied Pt BS Pt Angle Distance New Point

21 20 90 50.6 100

Point 101 will be calculated by a bearing-bearing intersection. Then point 101 will be connected to point 20. The first '+' sign determines the direction used to calculate point 100. The description ending in a '+' sign has the same effect as ending in a '-' sign: if there is no dimension after the last '+' or '-' sign, the last point will be calculated by a bearing-bearing intersect.

If you have located three corners of a rectangle, you may use the following short cut to define the lines to be drawn:

Point ID Description

20 BL*BLD1

21 BLD1

22 CL*BLD1+

In the above example lines will be drawn from point 20 to 21 to 22. The missing corner will be calculated using a bearing-bearing intersect and stored. As noted earlier, ending in a '-' sign instead of a '+' sign has the same end result.

Curve Codes

Anytime a circular curve is encountered, 3 new points may be calculated and stored in the coordinate file. These points are the PC, PT and radius point of the curve. It is necessary to calculate these points during automated mapping since the field points are only approximations of a perfect curve. They will automatically be assigned point numbers (regardless of the Auto Point Numbering setting). The points calculated during automated mapping of curves will begin with the coordinate files current high point number plus 1.

If the beginning of a line is also the beginning of a curve, one of the following formats must be used:

Point ID Description

10 BL*SW1 CF*SW1 (begin a curve-fit line)
or 10 BL*SW1 OC*SW1 (begin a non-tangent circular curve)
or 10 BL*SW1 PC*SW1 (begin a tangent circular curve)

Once a curve has begun, all matching line descriptions will be considered points on the curve until the curve is ended. A curve is ended with either a PT*, OC*, or CF* code.

For Example:

Point ID Correct Sequence Incorrect Sequence

10 OC*SW1 (Begin SW1)
11 SW1 OC*SW1 (will end SW1)
12 SW1 OC*SW1 (will end SW1)
13 SW1 OC*SW1 (will end SW1)
14 OC*SW1 (End SW1)

The first OC begins the curve. The next OC ends the curve. All the points between them are on the curve. The same is true for curve fit (CF*).

If a curve is either tangent (in), tangent (out) or tangent (in) & tangent (out), you only need two points to define the curve:

Point ID Sample 1 Sample 2 Sample 3

10 PC*CURB1 PC*CURB1 OC*CURB1
11 PT*CURB1 OC*CURB1 PT*CURB1

Otherwise you will need at least three points on a curve:

Point ID Description

12 CF*CURB1
13 CURB1
14 CF*CURB1

The RP Mapping Code

If you use the RP code (radius point), it will be used regardless of the number of points on the curve. The radius will be calculated by averaging all the distances from the radius point to the points on the curve.

Best Fit Circular Curve Calculations

If you have three or more points on a non-tangent curve, the best-fit curve solution is used to find the radius point.

If you have three or more points on a tangent curve (either tangent in, tangent out, or tangent in and out), the best-fit

curve solution is used to determine an approximate radius and radius point. A dummy point is then calculated on the curve and a curve is drawn that goes through the dummy point and meets the tangent criteria (the PC and PT points are shifted up/down the tangent lines as necessary). If only three points are located, PC, POC and PT, the curve will always go through the POC point.

If you have only two points (PC and PT) on a tangent curve, the tangent lines from the PC and PT will be intersected to find the PI of the curve. The distance from the PI to the PC and the distance from the PI to the PT will be averaged to obtain a tangent distance. A new PC and PT point will be calculated on the tangent line and the radius point will be calculated based on the tangent and central angle.

Non-Circular Curves

You may use the CF* code for a non-circular curve fit (splines). The CF code will start a curve fit line. The curve will continue until a second CF* code is encountered, example:

Point ID Description

11 CF*SW1

12 SW1

13 SW1

14 CF*SW1

Only use CF to start or end a curve. Notice points 12 and 13 do not have automated mapping codes.

A smooth curve will be drawn through points 11, 12, 13 and 14. No new coordinate points are generated with the CF code.

Layers and linetypes for mapped lines and curves

The description table determines the layer in which a mapped line will be drawn. For mapped lines and curves, only the description and layer fields in the description table are used. However, if the default layer is not set, no description table lookup is performed and the line is drawn on the current layer.

For example, assume that the default layer has been set and that the description table contains the following entry:

Desc. No. Description Layer Name

5 CURB Road

Since layer "Road" is specified for description "Curb", all lines with descriptions "Curb" will be placed in layer "Road". Numbers are not used in the comparisons: Curb1, Curb2, Curb10, etc. are considered a match for the description "Curb" and will therefore be placed in layer "Road".

If a matching description is not found in the description table, the line is drawn on the default layer (as set in the Graphic Options tab of the C&G Options dialog box).

Calculated Points

All coordinate points that are automatically calculated and stored during automated mapping are given a MP point code.

Note: Even though the point description field can contain Mapping Codes, the point code found in C&G coordinate files is separate and distinct from the point description field. All points already having an MP Code are ignored by automated mapping. This avoids re-mapping points that were generated during automated mapping and thus were not points actually located in the field.

Important Note: Consider the MP point code as a reserved code and do not use it for field data collection.

The description (e.g., CURB) used for calculated points is the same as the line description of the points the calculated point is associated with and reflects the type of calculated point that it is.

For Example:

Assuming the line description for the following points is "CURB1" and the points are the PC, PT and radius point of a curve, then the line descriptions will be:

New Point ID Point Code Description

100 MP PC CURB1

101 MP RAD.PT CURB1

102 MP PT CURB1

Plotting of Points

If Auto Plot Points is "On", all the selected points in the coordinate file will be plotted on the screen during the mapping process. If a default layer is set, Each point will be drawn on the layer specified in the description table. The points labels will be configured as specified in the description table. Any point that does not have a description match in the description table will either be drawn on the default layer.

Pulldown Menu Location: CG-Survey >Auto Map>Draw

Keyboard Command: MAP, CG_MAP_DRAW

Prerequisite: Coordinate file

Erase

The Map Erase feature will find all line, arc, curve fit and point entities created Using the Map Draw feature and delete them from the drawing. It will also delete any coordinate points from the coordinate file that where created with the using Map Draw (PC, PT, radius points and close line (CL) points or those points having the point code MP)

Pulldown Menu Location: CG-Survey >CGDraw>Auto Map>Erase

Keyboard Command: EMAP, CG_MAP_ERASE

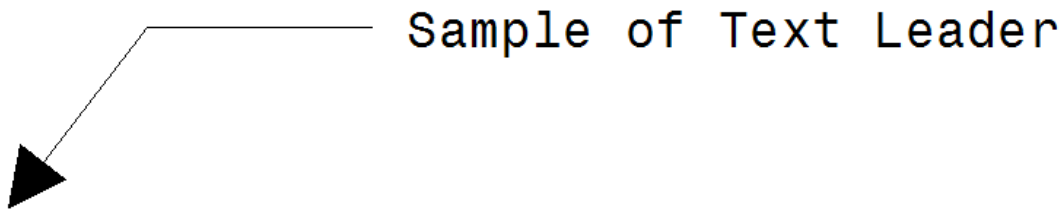

Prerequisite: Coordinate file

Leaders

Leaders are used to label features in the drawing. They consist of a line or series of connected line segments with an arrow at one end and a text label at the other end. The arrow size is determined by the symbol size as set in the Drawing Settings - Active Point Symbol dialog.

Text

A text leader allows you to draw a series of lines with an arrow at the starting point then specify the text that is to be drawn at the final endpoint of the leader.

Prompts

To draw a text leader:

Pick start of leader: Pick the starting position of the leader with the left mouse button:

Picked C&G Point [4]

To point (Enter to end): Move the cursor to the next point on the leader and press the left mouse button. The first segment of the leader will be drawn with an arrow placed at the first point picked

To point (Enter to end): As you pick succeeding points, lines will be drawn from the previous point to the current point.

To point (Enter to end): When you have picked the final point, press <Enter> or the right mouse button.

Enter Text for leader: At the command line, type the text to be placed on the leader and <Enter>.

Sample of Text Leader

Pick start of leader: repeats the command

Pulldown Menu Location: CG-Survey > CGDraw>Leaders>Text

Keyboard Command: TXTL, CG.TEXT_LEADER

Prerequisite: Coordinate file.

Coordinate Leader

This feature allows you to pick a point then draw a leader that is labeled with the coordinates of the point picked.

To draw a Coordinate Leader:

Prompts

Pick the starting point of the leader with the left mouse button: If you pick a C&G point, the coordinates will be read from the coordinate file, otherwise the graphic coordinates will be used.

Move the cursor to the next point for this segment of the leader and click the left mouse button: Repeat until all desired leader segments are drawn.

The coordinates of the first point picked will be drawn near the final point on the leader. The coordinates are rounded based on the rounding specifications in the Rounding Options Tab of the C&G Options dialog box.

Pulldown Menu Location: CG-Survey > CGDraw>Leaders>Coordinate Leader

Keyboard Command: CRDL, CG.COORD_LEADER

Prerequisite: Coordinate file

Point Label

This feature allows you to label a point using a leader instead of the normal point labels. This feature can only be used with C&G points. The leader will display the point ID and, if Elevation and/or Descriptions are "On", the elevation and description will be displayed as well.

Prompts

It is suggested that you first plot the points on the screen with the point labels turned off by setting their point label positions to 0 on the Drawing Settings - Point Label Position dialog. Thus only the symbols will be plotted. Next, in the Drawing Settings tab of the CGOptions dialog box: turn on the items you want to be displayed on the leader.

Now choose the Point Label Leader menu item:

Pick start of leader: Move the cursor to a C&G point and press the left mouse button. Picked C&G Point [3]

To point (Enter to end): Move the cursor to the end point of the next leader segment and press the left mouse button. An arrow will be drawn at the first point picked.

To point (Enter to end): When you have picked the end of the last segment of the leader, press <Enter> or the right mouse button.

To point (Enter to end): The point attributes will be placed near the last point picked for the leader.

(You may repeat the previous step as many times as is necessary)

When done press <Enter> when asked to pick the next C&G point, Press Enter

Pulldown Menu Location: CG-Survey > CGDraw>Leaders>Point Label

Keyboard Command: PTL, CG_POINT_LEADER

Prerequisite: Coordinate file

Station-Offset

This Leader feature allows you to label points along a predefined alignment with their station and offset.

Prompts

Prior to using this feature you must create a point group that defines the alignment.

Next you will be asked to open a point group file. In the Select a C&G Point Group File dialog box: select the point group file that defines the horizontal alignment you wish to use.

Enter starting station <0.00000>: 1000
10+00.00

Enter Starting station for the alignment as defined by the point group. If a station is specified for the first subgroup name in the point group file, it will be used as the default station (for more details on this, see the section on point group files in CGMngmt).

Pick the starting location of the leader: Picked C&G Point [3]

If a C&G point is not found at this location, the station and offset will be calculated using the drawing coordinates of the picked point. If a C&G point is found, the station and offset will be calculated from the coordinates read from the coordinate file. If a C&G point is found, the point ID will be printed at the command line.

To point (Enter to end): Move the cursor to the end point for this segment of the leader and press the left mouse button, An arrow will be placed at the first point picked. Repeat until all the segments of the leader have been specified.

To point (Enter to end): When you have picked the end point of the last segment of the leader, press the <Enter> key or right mouse button.

The station and offset label will be placed next to the end point of the leader.

To point (Enter to end): Enter

Pick start of leader: Repeats the command

Note: The station and offset values are rounded based on the values specified in the Rounding Options tab of the CGTools > CGOptions dialog box

Pulldown Menu Location: CG-Survey > CGDraw>Leaders>Station-Offset

Keyboard Command: STOL, CG_STA_OFF_LEADER

Prerequisite: Point group must be created

Query

Selecting Query and then selecting a drawing object will display information related to the following C&G entities:

Point symbols and labels
Lines

Arcs
Polylines
Calls
Structure Footprints
Coordinate, Call and Curve Tables

Prompts

Select entities: (Pick entity on screen) Entities in set: 1

Select entities: (item selected) C&G POLYLINE

Below is an example of a Query listing of a C&G Polyline:

Coordinate File: CGDEMO.CRD (C&G Numeric)

Plotted from Auto Mapping: No

Layer: Boundary

Points defining C&G Polyline: 11->9

Polyline is NOT CLOSED

Pulldown Menu Location: CG-Survey > CGDraw>Query

Keyboard Command: Q, CG_QUERY

Prerequisite: Coordinate file

Drop C&G Attributes

This feature allows you to strip the C&G attribute from any C&G entity. When the C&G attribute is dropped, the graphic entity becomes standard CAD entity and will no longer be affected by the Refresh Screen feature nor can they be used by C&G commands requiring C&G entities as input.

Prompts

Select entities: pick on graphic screen

Entities in set: 1

Select entities: pick again on screen

Entities in set: 4

Select entities: select another set of entities by window

Entities in set: 7

Select entities: Specify opposite corner: 8 total found,

Entities in set: 8

Pulldown Menu Location: CG-Survey > CGDraw>Drop C&G Attributes

Keyboard Command: DROP, CG_DROP

Prerequisite: Coordinate file

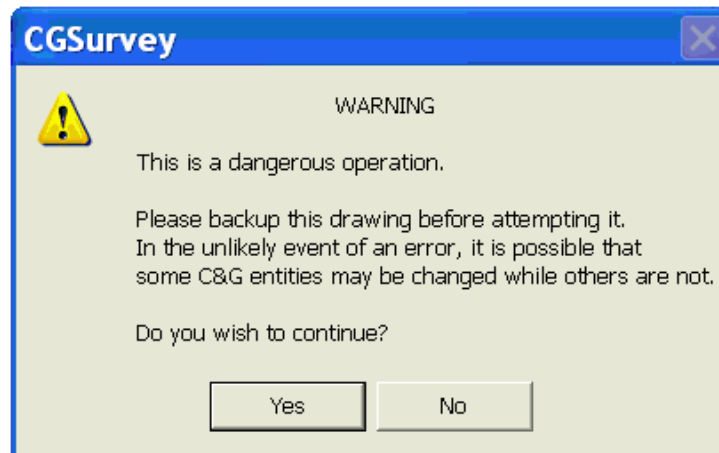

re-Associate Coord. file

This routine allows you to associate the current drawing file with different coordinate file than created the drawing file. An example of this could be a phase of a project. The overall project coordinate file might contain 10,000 to 15,000 coordinates, While working on a phase of the overall project a separate, smaller, coordinate file was created, easier to work with a 1000 points rather than 15,000. Now you want to re-associate this new drawing file with the

overall project coordinate file.

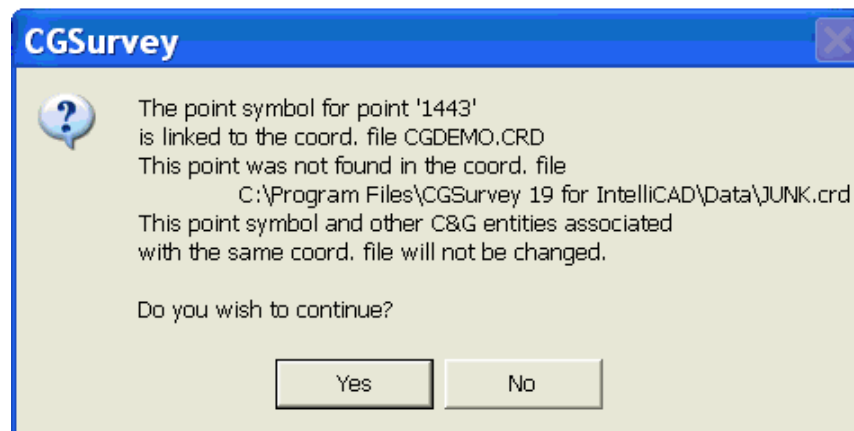

Prompts

After selecting the re-Associate command there will be displayed a Warning dialog box. This box recommends that you create a backup of your drawing file. The danger with using this application is if the coordinates are not managed carefully and the same point ID's were used in both the overall project file and the out parcel then the graphics will be incorrect. C&G graphics are based on the coordinate file and if the X/Y/Z values change so does the graphics.

Do you wish to Continue? Press <Y> button: Y

Re-associate only those C&G entities plotted using which coord. file [Any_file] <A>: A

An Additional Warning message may also appear indicating conflicts in linked crd files

Do you wish to Continue? Press <Y> button: Y

Pulldown Menu Location: CG-Survey > CGDraw>re-Associate Coord. file

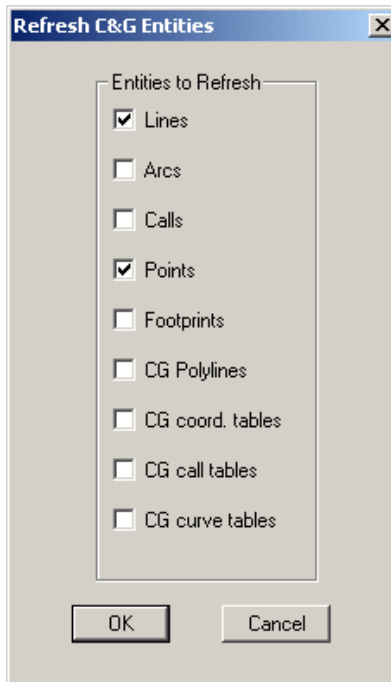

Keyboard Command: Not available

Prerequisite: Coordinate file

Refresh Screen

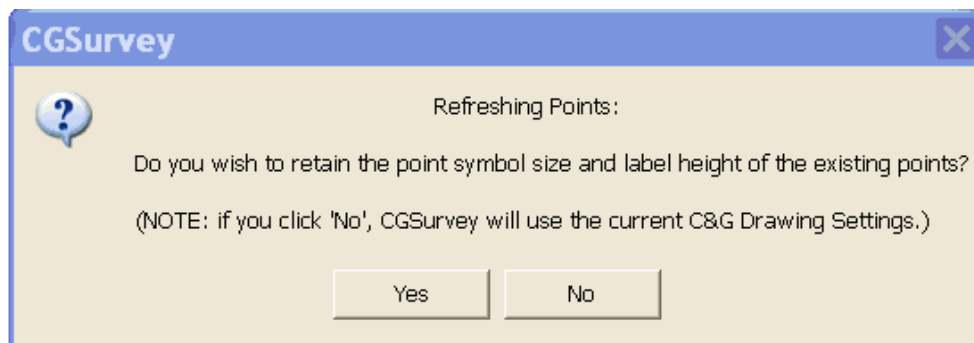

Many graphic entities created by CGSurvey contain attributes that tie them to the coordinate file (C&G points, lines, arcs, calls, etc.). Examples would be point numbers, elevations, and descriptions that are plotted with the node when you plot points. However, once an entity is drawn the user is free to move or edit it. Also, it may be necessary to change the coordinates of the point or points used to create the entity.

If C&G entities are edited or the coordinate values change, you refresh the drawing so that it reflects the current coordinate file values. You can use the Refresh Screen feature to find all C&G entities tied to the coordinate file and read the points from the coordinate file and redraw the entities based on the current coordinate values.

Prompts

Check the appropriate boxes in the list to refresh: Press Ok to continue

Do you wish to retain the point symbol size and Label height of the existing points?: Press <Y> button

Below is example of Refreshed screen entities:

Command: cg_refresh

24 Lines refreshed.

2 splines refreshed.
24 Calls refreshed.
24 Points refreshed.
There were 2 C&G polylines refreshed.

Pulldown Menu Location: CG-Survey > CGDraw>Refresh Screen

Keyboard Command: REF, CG_REFRESH

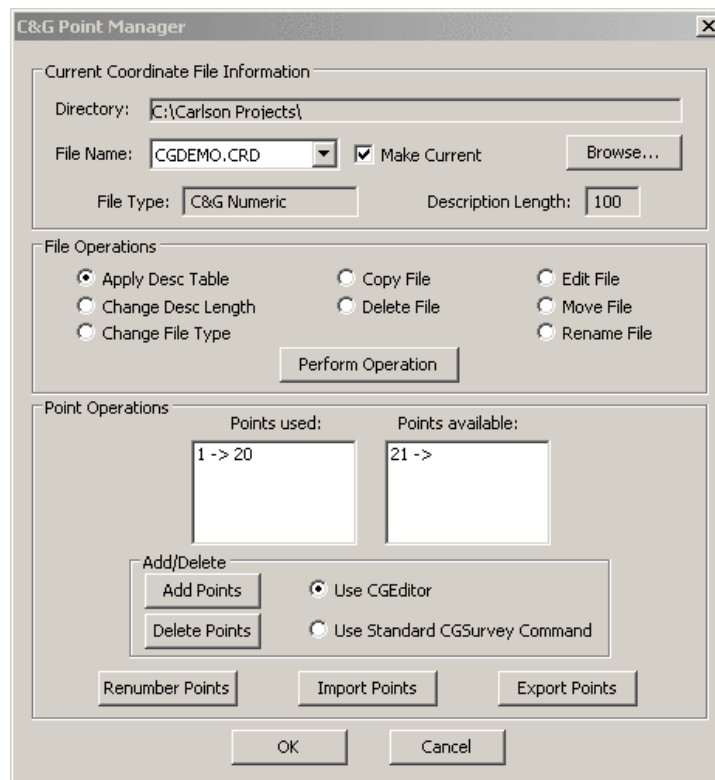

Prerequisite: Coordinate file

CGMngmt

Point Manager

The point manager allows the user to perform most of the normal coordinate file management functions. You can perform whole file operations such as renaming the file, copying or moving the file, etc. There are also point operations which allow the user to add, delete, or change individual points or groups of points in a coordinate file.

The **C&G Point Manager** dialog (shown below) is divided into three sections. These sections are described below.

Current Coordinate File Information

This section gives you basic information on the currently selected coordinate file. The **Directory** and **File Name** defaults to the currently active coordinate file but you can choose to perform operations on any one of the supported types of coordinate files by clicking the **Browse...** button. When you click the **Browse...** button you will see a file dialog allowing you to choose the coordinate file you wish to work on. The **Make Current** checkbox allows the user to make the specified file the current file. Thus, when the dialog closes, the file will be used for future commands requiring a coordinate file.

File Operations

This section of the dialog allows you to perform operations that effect the entire coordinate file.

There eight operations that can be performed using this section of the dialog (see descriptions listed below). To perform one of the operations on the file shown in the **Current Coordinate File Information** section, click on the radio button for the desired operation then click the **Perform Operation** button.

Apply Desc Table

This operation only applies to C&G coordinate files and will not be available for other file types. When you apply a description table to a coordinate file it translates the numeric codes found in the description field using a C&G description table. For each point in the coordinate file having an integer in the description field the program looks for that integer description number in the description table. If a matching description number is found in the description table, the description found in the description table is placed in the description field for that point and the description number is placed in the code field for that point. The point is then stored back to the coordinate file with the changed field values. If no match is found the point is not changed in any way.

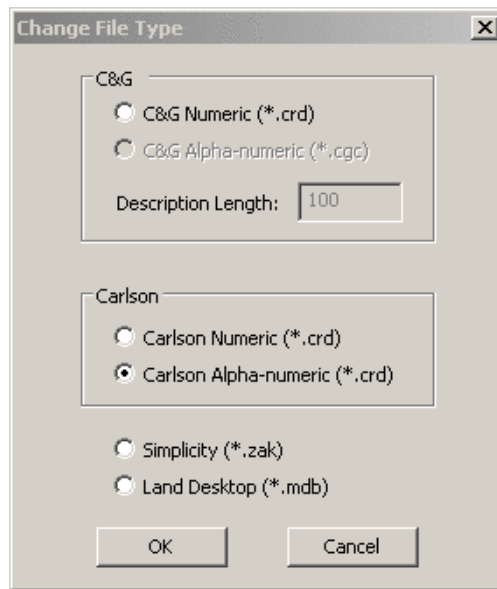

Change Desc Length

This operation only applies to C&G coordinate files and will not be available for other file types. When a C&G coordinate file is created, the user is allowed to specify the length of the description for a given point in the file. The description length may be between 1 and 100 characters. This operation allows the description length to be changed. It can be made smaller or larger. If an existing point in a coordinate file has a description that is longer than the new description length, the description will be truncated. When you click the **Perform Operation** button you will be asked to enter the desired description length (see dialog below).

Change File Type

This operation allows the use to convert among the supported types of coordinate files. The types supported are C&G numeric (*.crd) and alphanumeric (*.cgc), Carlson numeric (*.crd) and alphanumeric (*.crd), Simplicity (*.zak) and AutoCAD Land Desktop (*.mdb). When you select this operation and click the **Perform Operation** button you will see the **Change File Type** dialog:

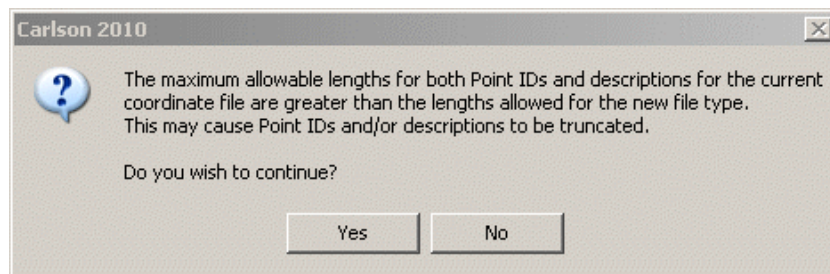

In the **Change File Type** dialog choose the type of file you want the current file to be converted into by clicking on the appropriate radio button.

Note: the radio button for the current file type is greyed out.

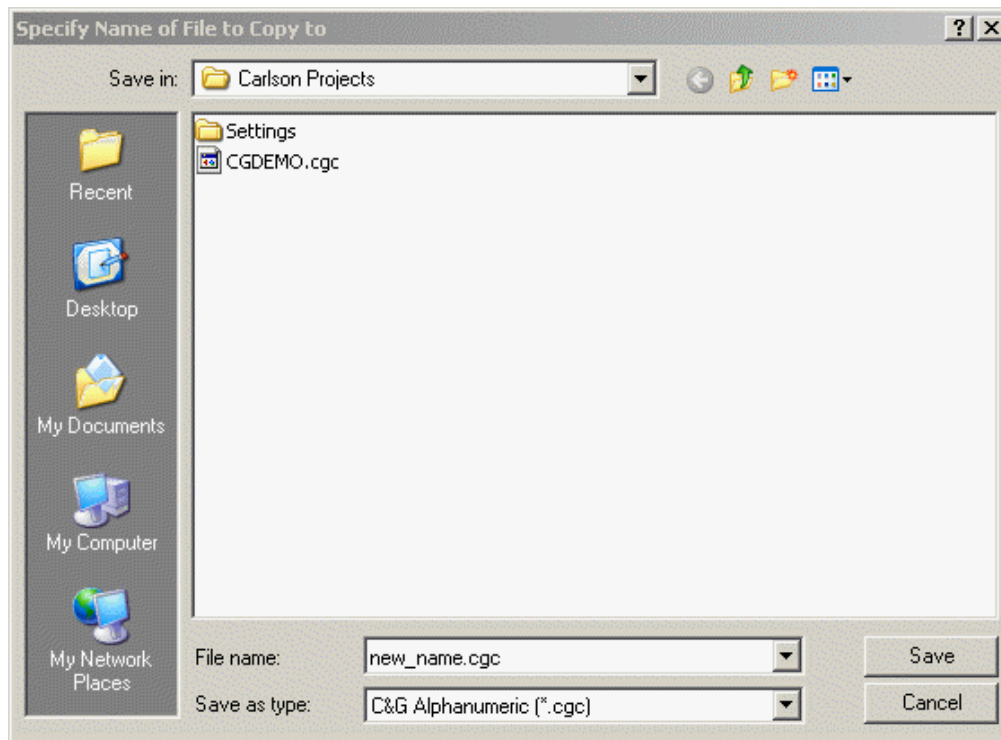

After choosing the file type click the **OK** button. Click **Cancel** to cancel the operation.

If you attempt to convert to a file type having point ID length or description length limits that are less than the limits for the file being converted, you will get the following warning:

Copy File

Performs a basic file copy. Must be to another directory and/or file name. When you click the **Perform Operation** button you will be asked to specify the copied file name and directory using a file dialog (see below).

Note: by changing the **Save as type:** this command can change the file type when it copies the file. However, if the type of file being copied has maximum allowable point IDs or descriptions that are greater than one or both of those for the file being copied to, you will receive a warning that point IDs and/or descriptions may be truncated (see Change File Type section above).

Delete File

Deletes the file listed in the **Current Coordinate File Information** area of the **C&G Point Manager** dialog along with any of its associated files. Before actually deleting the file you must click the **Yes** button in the following dialog.

Edit File

Allows the user to use the CGEditor to edit the coordinate file. You may add and delete points or edit any of the fields for an existing point (see the CGEditor section for more information on using the CGEditor)

CGEditor - CGDEMO.cgc

File Edit Add/Insert View Settings Tools Window Help

For Help, press F1

Row: 1

Move File

Moves the current file to a new location. You will use a file dialog to specify the new location of the file. When moving a coordinate file you may also change the file type by changing the **Save as type:** The same cautions with regard to possible point ID and description truncation apply here as they do any time you change the file type (see Change File Type section above).

Rename File

Simply renames the file to whatever name the user specifies. You will use a file dialog to specify the new name and location of the file. Thus this command may be used to change the file type and/or move the file to a different directory. To change the file type change the **Save as type:** in the file dialog when you specify its new name. The same cautions with regard to possible point ID and description truncation apply here as they do any time you change the file type (see Change File Type section above).

Point Operations

You may perform several operations that effect one or more of the points in the current coordinate file in this section of the **C&G Point Manager** dialog. Use the **Points used:** and **Points Available:** lists to help you determine which points or ranges of points you wish to work on.

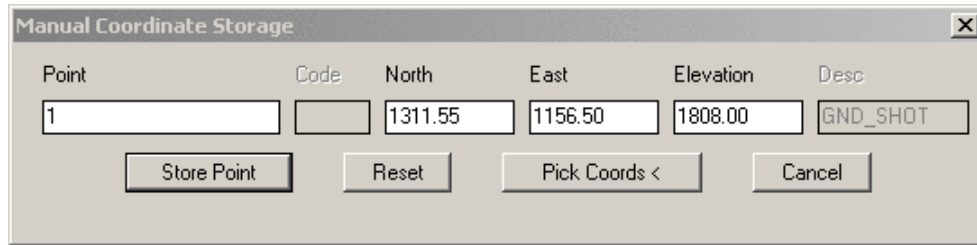

Add/Delete section

You may use the standard CGSurvey interface or the CGEditor to add or delete points. Choose which one to use using the radio buttons on the right side of the **Add/Delete** portion of the **Point Operations** area.

Add Points

If you chose to use the CGEditor, the CGEditor will come up (as shown above - see the CGEditor section for more information on using the CGEditor).

If you chose to Use the Standard CGSurvey Command, you will see the Manual Coordinate Storage dialog (see below). Fill in the edit boxes as described in **Management > Manual Storage**

The dialog box titled "Manual Coordinate Storage" contains a table with the following data:

Point	Code	North	East	Elevation	Desc
1		1311.55	1156.50	1808.00	GND_SHOT

Below the table are four buttons: "Store Point", "Reset", "Pick Coords <", and "Cancel".

Delete Points

If you chose to use the **CGEditor**, the **CGEditor** will come up (as shown above - see the **CGEditor** section for more information on using the **CGEditor**).

If you chose to **Use the Standard CGSurvey Command**, you will see the following prompt at the **Command:** line:

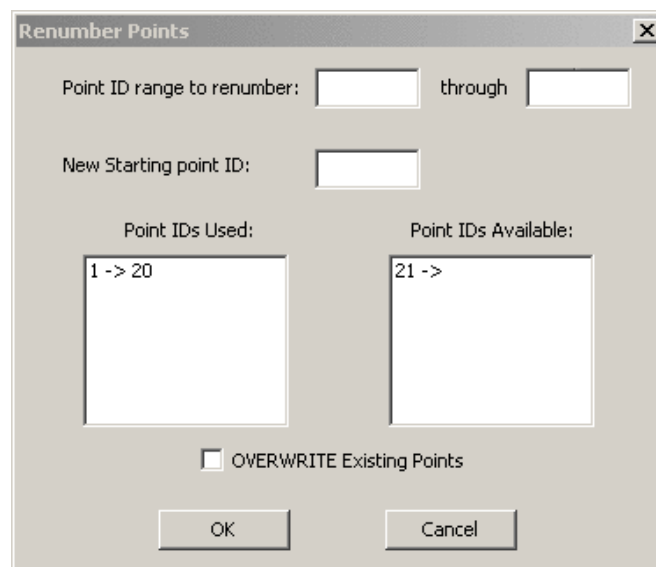

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: use one or more of the available methods to specify which points are to be deleted from the current coordinate file.

Buttons section

Renumber Points

If you click on the **Renumber Points** button you will see the **Renumber Points** dialog:

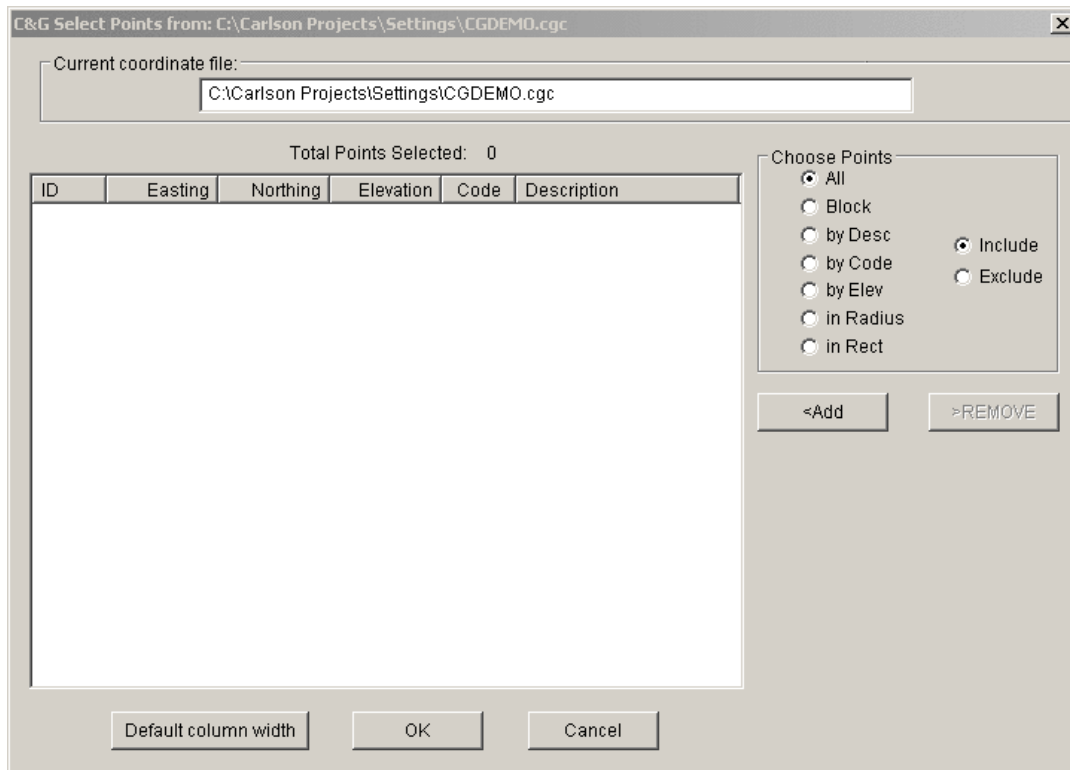

The dialog box titled "Renumber Points" contains the following fields and controls:

- Point ID range to renumber: [] through []
- New Starting point ID: []
- Point IDs Used: [1 -> 20]
- Point IDs Available: [21 ->]
- OVERWRITE Existing Points
- OK button
- Cancel button

Fill in the dialog (see the **Management > Renumber Points** section for more details) and click **OK** to renumber the specified range of points. If you check the **OVERWRITE Existing Points** checkbox, you will not be warned of any points that are overwritten during the renumbering process.

Import Points

You can use this to copy points from another coordinate file into the current coordinate file. If you click the **Import Points** button you will be asked to specify the coordinate file from which the points are to be imported. After specifying the import file name, you will use the **C&G Select Points from:** dialog to select which points are to be imported:

C&G Select Points from: <file name> dialog

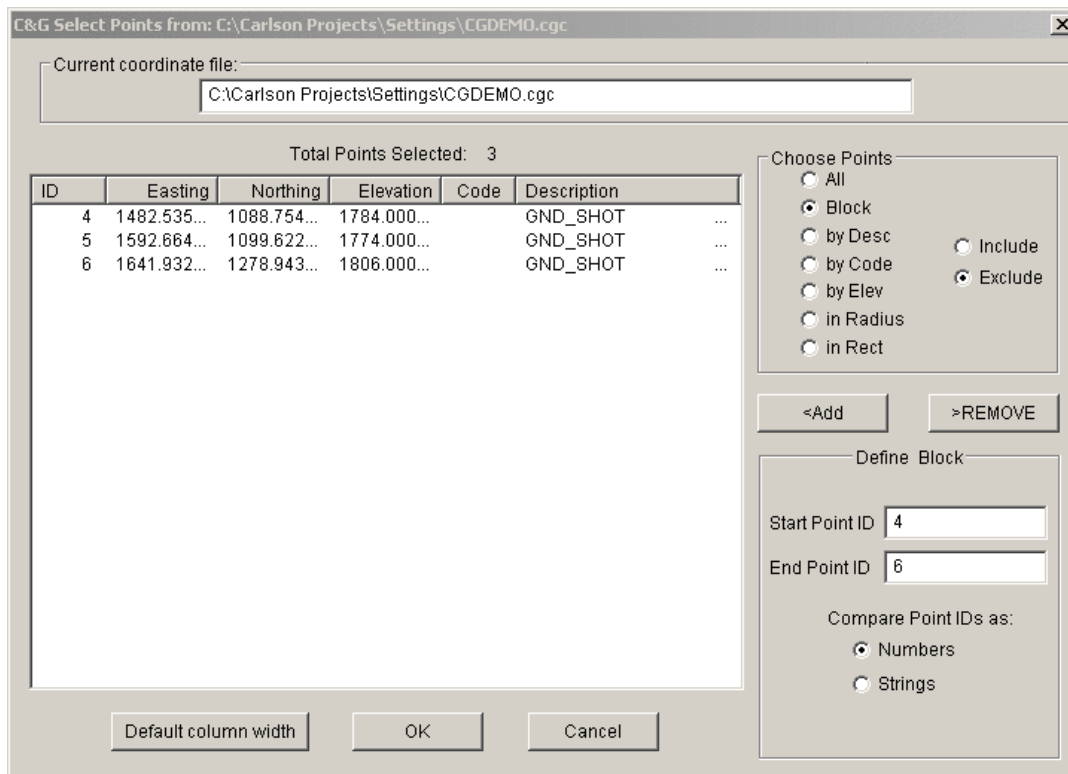

Choose Points section:

You can select any one of the methods you wish to use to choose the points by clicking one of the methods of point selection in the **Choose Points** section of the dialog. You may also specify whether you wish to **Include** or **Exclude** the points chosen. If you include the points, they will be added to the list from the coordinate file. If you exclude the points, the points chosen will be removed from the list of points previously **Included**. The method of choosing the points is very much like using the

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]:

prompt. For example, if you choose the **Include** radio button and the **All** radio button then click on the **<Add** button, all the points in the coordinate file will be shown in the list on the left side of the dialog. If you then choose the **Exclude** radio button and the **Block** radio button, fill in the block of points you wish to remain in the list, then all but these points will be excluded from the list when you click the **>Remove** button (see the example dialog below).

When the points you wish to import are all in the list on the left, click OK.

CAUTION: *If the points that are being imported exist in the current coordinate file, they will be overwritten without warning!*

Export Points - click the **Export Points** button to copy points from the current coordinate file into another coordinate file. You will be asked to specify the file to export the points into then, similar to importing points, use the **C&G Select Points from:** dialog to select the points to be exported. Click OK in the **C&G Select Points from:** dialog to export the points.

CAUTION: *If the points that are being exported exist in the file they are being exported to, they will be overwritten without warning!*

Prompts

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: use one or more of the available methods to specify which points are to be deleted from the current coordinate file. Note: this prompt is only used if you have the **Use the Standard CGSurvey Command** radio button set.

Pulldown Menu Location: CG-Survey > Management > Point Manager

Keyboard Command: cg_pt_mngr

Prerequisite: One or more Coordinate files

Edit Coordinates (CGEditor)

The user can use the CGEditor to edit an existing coordinate file or create a new one. You can add and/or delete points and edit existing points. The CGEditor has many sophisticated editing tools that make editing fast and relatively easy. Please refer to the CGEditor section of the Tools menu for a detailed explanation of how to use the CGEditor.

Pulldown Menu Location: CG-Survey > Management > Edit Coordinates (CGEditor)

Keyboard Command: EDC, CG_EDIT_COORDS

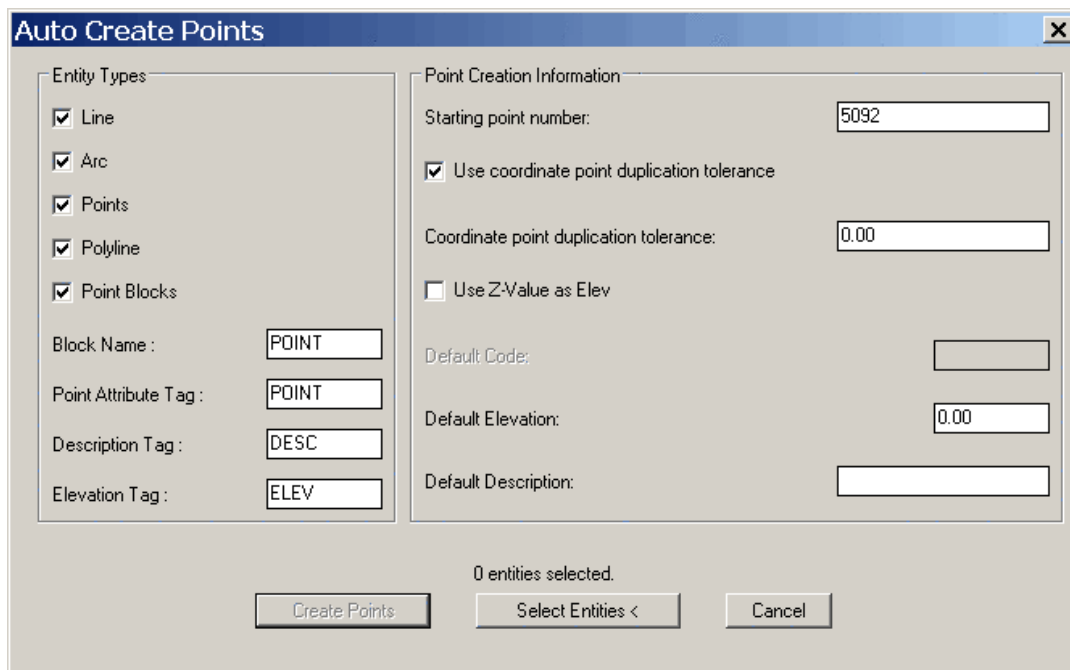

Prerequisite: None

Auto Create Points

The purpose of this feature is to create points in the current coordinate file and draw the associated point symbols using coordinate values extracted from existing drawing entities. These drawing entities may or may not have been created with CGSurvey. The user can automatically place C&G point symbols at the vertices, radius points, insertion points, etc. of selected lines, arcs, points, polylines, and point blocks. The coordinates of the newly created points are then saved in the currently open coordinate file.

Note: Unless point symbols are picked, the coordinates that are stored will be the coordinates of the CAD entity. In the case of point symbols, the point ID will be read and used to look up the proper coordinates in the current coordinate file.

After picking the Auto Create Points menu item, the Auto Create Points dialog box will appear:

Entity Types section

Select the entity types for which you wish to create C&G points. You can check any combination of the available entity types.

When you click the Select Entities button, specifying only certain entities allows you to window a large area but only have points created for the specified types of entities. You may also select individual entities or several groups of entities. After selecting the entities, click the Create Points button to create the points and save them to the current coordinate file.

Point Blocks

If you wish to have coordinates created for point blocks (or inserts) and you want the point ID, description and elevation to be set from information contained in the block, the block *must* have attributes that can be used to obtain

these values. When you choose Point Blocks, the following edit boxes in the dialog are activated and must be filled out:

Block Name: Specify the name of the blocks you wish to have points created for.

Point Attribute Tag: For the block entities chosen, specify the tag name for the attribute of the block contains the point ID. If no point ID attribute is found then the next sequential point ID will be used.

Description Tag: For the block entities chosen, specify which attribute of the block contains the description. If descriptions are ON and no description attribute is found then the default description will be used.

Elevation Tag: For the block entities chosen, specify which attribute of the block contains the elevation.

If elevations are ON and no elevation attribute is found: if the **Use Z-Value as Elev** is checked, then the Z value of the block insertion point will be used for the elevation of the newly created point; otherwise the specified default elevation will be used.

Point Creation Information section

Starting point number:

Use this to specify the starting point number. Specifying anything other than the next available point in the coordinate file as the starting point makes it possible that one or more existing points could be overwritten. However, whenever a situation arises that a point in the coordinate file may be overwritten, a dialog box will appear warning you of this and allowing you to decide whether to proceed with the overwrite or not.

Use coordinate point duplication factor:

If this box is checkbox Coordinate point duplication tolerance edit box is activated and you must enter a tolerance for determining coordinate point duplication. This is used to test if a new point that is about to be created is the same as a point already in the coordinate file. If the new point coordinates are within this tolerance the new point will not be created.

Use Z-Value as Elev

Select this box if the entities you select may have a Z value and you want that value used as the point's elevation.

Default Code

If point codes are turned ON, then this value is used as the default Code for all newly created points.

Default Elevation

If elevations are turned ON, then this value is used as the default Elevation for all newly created points.

Default Description

If descriptions are turned ON, then this value is used as the default Description for all newly created points.

Buttons

Select Entities <

Press this button to begin selecting the entities for which you wish to create coordinate points. The dialog box will disappear and you will be asked to use the normal entity selection methods to choose the entities to be used for point creation. Just press Enter at the Select Entities prompt when you are done. You will then be returned to the **Auto Create Points** dialog.

Create Points

After the entities have been selected, press this button to create coordinate points using the entities. Any existing C&G lines, arcs or polylines will be ignored since they already have points associated with them. Non-C&G lines, arcs and polylines will be converted to C&G lines, arcs and polylines.

Prompts

Fill in the dialog box as required (see above explanation).

Select Entities: use the normal entity selection methods to select the entities to use for creating points.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_acp

Prerequisite: Coordinate file.

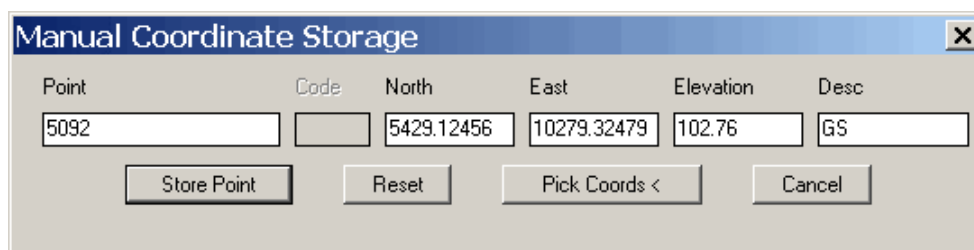

Manual Storage

This feature allows you to store points in a coordinate file by typing in the values for the point ID, code, northing, easting, elevation and/or description. You also have the option of using the mouse to pick the location coordinates on the screen.

When you choose the Manual Storage menu item:

If a coordinate file is not currently open, you will be prompted to open one.

Next, the following dialog box will appear:

Point	Code	North	East	Elevation	Desc
5092		5429.12456	10279.32479	102.76	GS

Buttons: Store Point, Reset, Pick Coords <, Cancel

Point

When the dialog box first appears, the point ID (**Point**) field defaults to the next available point ID as set on the General tab of the C&G Options dialog box. If you enter an existing point number in the point field and click on one of the other fields, the values associated with that point number will be retrieved from the current coordinate file and placed in the other fields. You may edit them if you wish.

Note: If you enter an existing point ID and alter any of the other fields associated with that point then save the point, **NO POINT OVERWRITE WARNING WILL BE GIVEN!**

North, East and Elevation

There are three different ways to enter coordinate values:

1. You can type in the coordinate values and elevation in the appropriate edit boxes.
2. You can duplicate a points values by entering a '+' sign and a point ID (example: +25) in the North field. When you click on another field, the coordinate values for the specified point will be automatically entered in the North, East and Elevation fields.
3. Or you can press the Pick Coords button. When you do this the dialog box disappears and you are prompted to pick a point on the screen. Once you have picked the desired point on the screen, the dialog box reappears with the coordinates of the selected point entered in the North and East fields.

Note: If you pick a C&G point, the coordinate values will be read from the coordinate file.

Note: The elevation field is only activated if Elevation is ON.

Code and Description

Enter the desired description in the description edit box.

Enter the point code in the edit box. The point code field is a 4 digit alpha or numeric code only used by

C&G. When present it can be used as a sorting tool in addition to the description table.

As an example: say that the description table number 25 is defined as 'Sanitary Manhole'. In addition to using 25 from the description table you also have used the code 'AB' for As-Built and 'DS' for design. Now you can build a selection set of all the description 25's, excluding all of the 'AB' codes and the selection set will contain only those points that are Design Sanitary Manholes.

Note: If descriptions are ON and **Get Description From Table** is checked, then if you enter an integer code in either the Code or Description field, that number will be used to lookup a description in the current description table. If a matching number is found it will be used for the code and the associated description will be used for the point's description. If there is no matching number found in the description table all fields will remain as entered.

Buttons

Store Point: When all the fields are entered, press the **Store Point** button to store the point in the coordinate file. If Auto Point Plot ON is checked on the Graphics tab in the C&G Options dialog, the point will be plotted as well.

Reset: This button clears all the fields in the dialog box and sets the point number to the next available point number.

Pick Coords <: click this button to use the mouse cursor to pick the point's coordinates on the screen.

Cancel: Press this button when done.

Prompts

Pick coordinates for point '<point ID>': use the mouse cursor to pick the coordinates for the point.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_man_coord_store

Prerequisite: Coordinate file

Delete

This feature allows the user to delete selected points from a coordinate file.

If a coordinate file is not open, you will be prompted to open one.

Select the points you wish to delete, either by picking with the mouse or entering the point sequence at the command line.

When point selection is complete, press Enter.

A dialog box will come up asking if you are sure you want to delete the points.

If you click OK, the points are deleted.

Note: Deleted points CANNOT BE RECOVERED unless point history is turned on. (See Carlson Configure)

Prompts

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt_group/Limits/Radius/Select]: Use any of the point ID selection methods to specify which points you wish to delete from the current coordinate file.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_delete_coords

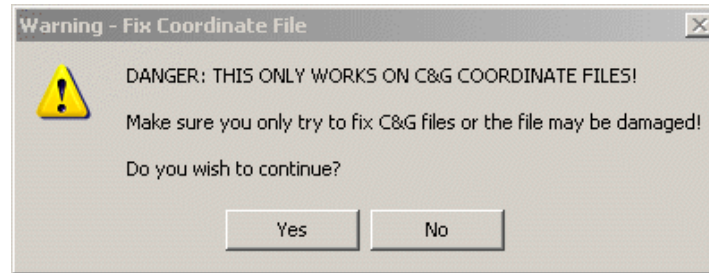

Prerequisite: Coordinate file.

Fix Coords

This feature should only be used if you wish to attempt to repair a damaged C&G coordinate file. A file can sometimes become damaged. when the computer is shut down prior to closing the file. It is wise to always keep a backup copy of your coordinate files in case a damaged one cannot be fixed.

Before running this command, try to open the file after closing any other C&G softer that may be running.

When you run this command you will first be warned that only C&G files should be fixed:

When the file dialog comes up, browse to the file you wish to attempt to repair.

If the fix is unsuccessful, you will get an error message otherwise the fix was successful.

Prompts

Use the file dialog to choose the file to be fixed.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_fix_coords

Prerequisite: Possibly damaged C&G Coordinate file

List

This feature allows the user to list all the information associated with selected points in the current coordinate file. If **Display at command line On** is checked on the Output tab of the C&G Options dialog box, the information for the selected points is displayed at the command line (press <F2> to view it). Otherwise the output is sent to the print file. If a coordinate file is not open, you will see a file dialog allowing you to open one.

Note: To print and/or view the print file after listing the coordinates, choose **Print/View Print File** from the CG-Survey > File menu. This will open a text editor with the print file as the current file. You may view the file or print it using the text editor.

Pulldown Menu Location: CG-Survey > Mngmt

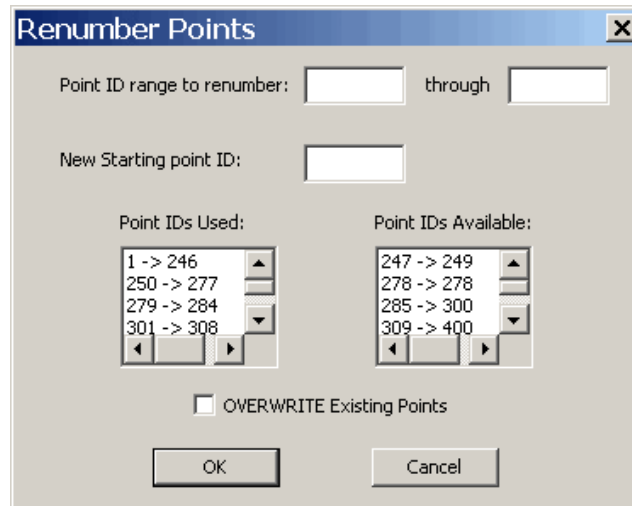

Keyboard Command: cg_list_coords

Prerequisite: Coordinate file.

Renumber Points

This feature allows you to renumber the point IDs of a range of points in the current coordinate file. The point IDs will be renumbered sequentially. If the renumbered points have been previously plotted to the drawing, the points will be redrawn to reflect the changed point IDs.

When you choose this menu item, the following dialog box appears:

Point ID range to renumber:

Specify the range of point IDs you wish to renumber. Use the Point IDs Used and Point IDs Available lists to help you determine the appropriate range.

New Starting point ID:

Specify the new starting point ID for the range specified. The specified range of points will be renumbered sequentially starting with the New Starting point ID.

OVERWRITE Existing Points

If you check this check box and, in the process of renumbering the points, the new point ID is the same as an existing point in the coordinate file, the point will be overwritten. However, if you do not check this checkbox and a possible overwrite is detected, you will be informed of the possible overwrite and required to check this checkbox before proceeding. If you do not wish to overwrite existing points, either re-specify the New Starting point ID or click the Cancel button.

To proceed with the renumbering click the **OK** button.

Note: this feature will only renumber points in a coordinate file in which all point IDs are numeric. Thus you can renumber the points in Carlson and C&G alphanumeric coordinate files only if all the point IDs are numeric.

Prompts

Fill in the dialog box as specified above.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_renumber_pts

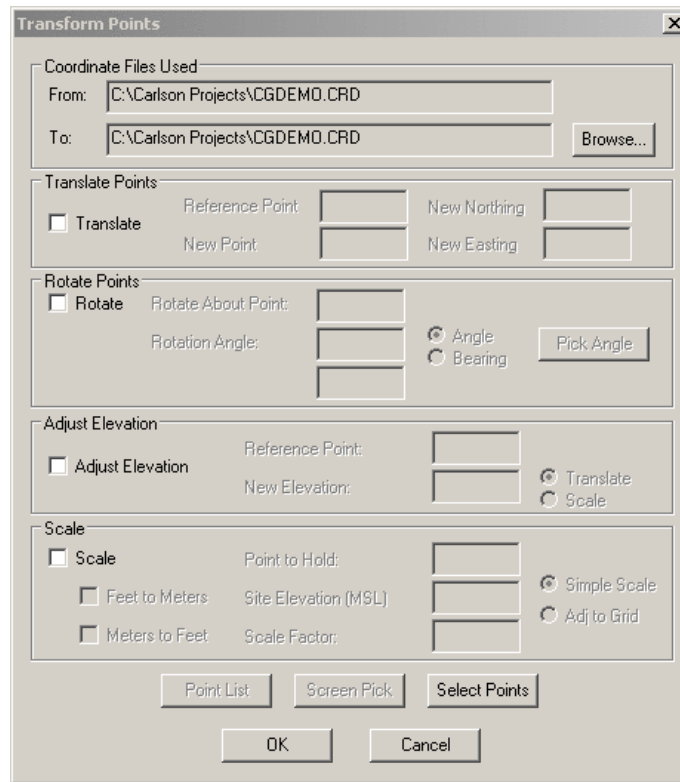

Prerequisite: Coordinate file

Transformations

Combined Transformations

The Combined Transformations feature allows the user to translate, rotate, adjust elevation and/or scale the selected points in a specified coordinate file. The user may also specify whether the transformed coordinates replace the values in the current coordinate file or are saved to another coordinate file.

The **Combined Transformations** menu item brings up the **Transform Points** dialog box. This dialog is used to configure the transformations that will be applied.

To begin the process, in the **Coordinate Files Used** area, choose the coordinate file into which the transformed points are to be stored. If you wish to store them in the current coordinate file, you can go on to the next step. However, if you wish to have the transformed points stored to a coordinate file other than current coordinate file, click the **Browse...** button and use the file dialog to choose the desired destination file.

Next, check the checkboxes for each of the transformations you wish to apply. Then, for each type of transformation to be applied, fill in each item of data in that area of the dialog.

Translate Points

To translate the points check the **Translate** checkbox, then fill in the data in the edit boxes in this section of the dialog.

The amount that the selected points are translated in the North and East directions is determined by the difference between the northing and easting of the Reference Point and the coordinates specified in the New Northing and

New Easting edit boxes.

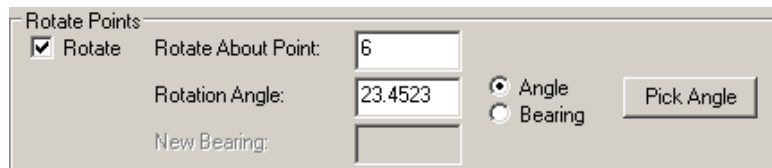

Reference Point specifies the point in the current coordinate file that is to be used as the reference point for the translation. All the selected points are translated in the same manner as the **Reference Point**. The reference point will be translated by the difference between its current coordinates and those specified in the **New Northing** and **New Easting** edit boxes. You can fill in the **New Northing** and **New Easting** edit boxes directly or you can enter a point ID in the **New Point** edit box. Assuming the point ID entered is found in the coordinate file, the coordinates read from the coordinate file will be placed in the **New Northing** and **New Easting** edit boxes. You can edit these coordinates or leave them as they are.

Rotate Points

If the **Rotate** check box is checked, the selected points will be rotated according to the specifications in the **Rotate Points** area. Rotation defaults to rotation by an angle but can be changed by merely clicking on the **Bearing** or **Angle** radio button.

Use the **Rotate About Point** edit box to specify the point in the current coordinate file about which the selected points will be rotated.

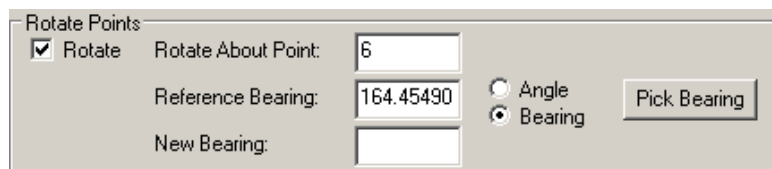

Rotating by an angle

The screenshot shows the 'Rotate Points' dialog box. The 'Rotate' checkbox is checked. The 'Rotate About Point' field contains the value '6'. The 'Rotation Angle' field contains '23.4523'. The 'Angle' radio button is selected, and the 'Bearing' radio button is unselected. A 'Pick Angle' button is visible on the right side of the dialog.

To rotate by an angle click the **Angle** radio button. Next, type in the appropriate angle in the **Rotation Angle** edit box or click the **Pick Angle** button and pick the desired angle on the screen.

Rotating by Bearing

The screenshot shows the 'Rotate Points' dialog box. The 'Rotate' checkbox is checked. The 'Rotate About Point' field contains the value '6'. The 'Reference Bearing' field contains '164.45490'. The 'Bearing' radio button is selected, and the 'Angle' radio button is unselected. A 'Pick Bearing' button is visible on the right side of the dialog.

To rotate by bearing, click the **Bearing** radio button then type in the appropriate values in the **Current Bearing** and **New Bearing** edit boxes or click the **Pick Bearing** button and pick the desired bearing on the screen.

Note: Bearings must be specified using qdd.mm.sss notation, where q is the quadrant (1 = NE, 2 = SE, 3 = SW, 4 = NW), dd is degrees, mm is minutes and sss is seconds. Seconds can be specified to 0.1 seconds if desired.

Adjust Elevation

If the **Adjust Elevation** box is checked, the elevations of the points will be adjusted according to the specifications in the **Adjust Elevation** area. The type of elevation adjustment can be specified by clicking on the **Translate** or **Scale** radio button.

To Translate elevations

The elevations of the selected points will be translated by the difference between the **Reference Point** elevation and the value entered in the **New Elevation** edit box. When you enter a point ID in the **Reference Point** edit box and click on another edit box the **New Elevation** edit box will be filled out with the current elevation of the reference point.

To Scale elevations

The elevations of the selected points will be scaled by the value entered in the **Multiplication Factor** edit box.

Scale

If the Scale check box is checked the northings and eastings of the selected points will be scaled according to the specifications in the Scale area of the dialog.

Meters to Feet and Feet to Meters

You can scale the coordinates to convert feet to meters or meters to feet by checking the appropriate check boxes. Using this form of scaling disables the other items in this section of the dialog box.

Other types of scaling:

The **Point to Hold** is a point in the current coordinate file that will be used to obtain the reference coordinates for the application of the specified scaling factor to the selected points.

Simple Scale - if you choose simple scaling it will calculate the scaled differences in northing and easting between the **Point to Hold** and each of the points selected for scaling. This scaled difference is found by calculating the difference between the coordinates of the **Point to Hold** and those of a given selected point and multiplying that times the specified **Scale Factor**. This scaled difference is then added back to the northing (easting) of the given selected point.

Adjust to Grid - this scaling method uses the **Site Elevation (MSL)** and the **Projection Table Factor** to adjust the northings and eastings of the selected points to grid coordinates

Scale

Scale Point to Hold:

Feet to Meters Site Elevation (MSL) Simple Scale

Meters to Feet Projection Table Factor: Adj to Grid

Methods of Specifying Point IDs for the Various Transformations

When specifying a point ID in the transformation data (for example to specify the **Reference Point** when the **Translate** checkbox is checked), you may select points using any one of the three options listed below:

1. Type the point ID directly into the edit box provided.
2. Point List: click the **Point List** button to bring up the **Choose Point Blocks** dialog. The left pane shows a listing of all the points found in the current coordinate file. Highlight the desired point in the **Points Available** list then click the **Add >** button and the point selected will be displayed in the **Points Chosen** list. In every case you are only allowed to choose a single point. Once you are satisfied with the point chosen click the **OK** button.

Choose Point Blocks

Coordinate file: C:\Carlson Projects\CGDEMO.CRD

Points Available:

Point Id	Northing	Easting
1	1311.55	1156.50
2	1195.62	1178.23
3	1179.32	1349.22
4	1088.75	1482.54
5	1099.62	1592.66
6	1278.94	1641.93
7	1384.00	1544.85
8	1451.02	1439.06
9	1369.51	1370.96
10	1431.09	1252.14
11	1398.49	1186.93
12	1277.08	1299.77
13	1301.71	1505.68
14	1221.32	1513.18

Add >

< Remove

Points Chosen:

Point Id	Rad	Seq ID	Northing
6		END	1278.94

OK Cancel

3. Screen Pick: when you click the **Screen Pick** button the **Transform Points** dialog disappears and **Choose a point:** prompt is displayed at the command line. You may type a point ID or pick a point symbol from the drawing.

Selecting Which Points Will be Transformed

At any time prior to clicking the **OK** button you may choose the points to be transformed. To do this click the **Select Points** button. The Transform Points dialog will disappear and you will be prompted to choose the points:

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: - use any of the available methods to specify the

points to be transformed. When done specifying the points press Enter until the Transform Points dialog reappears.

Transforming the points

To transform the selected points, click the OK button. The points will be transformed and saved to the specified coordinate file.

Prompts

Fill out the **Transform Points** as described above.

When the Select Points button is clicked the following prompt appears:

Choose initial points for base selection set from coord file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: - use any of the available methods to specify the points to be transformed. When done specifying the points press Enter until the Transform Points dialog reappears.

Pulldown Menu Location: CG-Survey > Management > Transformations

Keyboard Command: cg_transformations

Prerequisite: Coordinate file

Best Fit Transformation

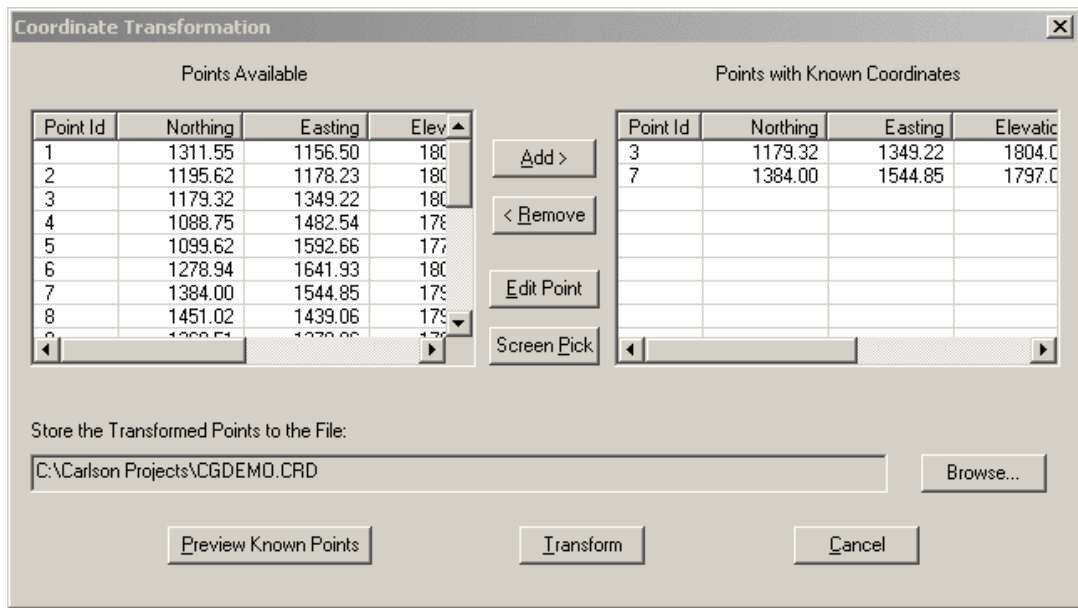

Best Fit Transformation is used to transform the coordinates in the current coordinate file using a "rubber sheet" method of transformation.

First the user must .

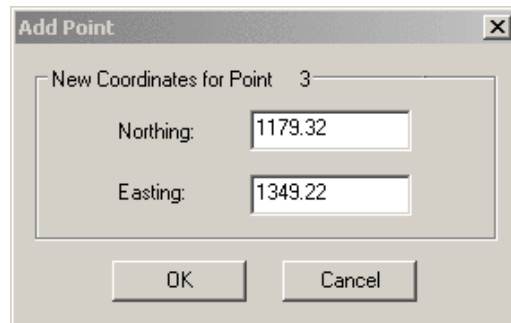

Add points from the coordinate file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: specify which points are to be transformed using one or more of the available selection methods.

Next, in the **Coordinate Transformation** dialog the user must choose at least 2 points in the coordinate file that are known (or "fixed") points

To specify a fixed point, highlight it in the **Points Available** list then press the **Add >** button to copy it to the **Points with Known Coordinates** list on the right. Or, if you wish, you can also specify a known point from the drawing by clicking the **Screen Pick** button and picking a point from the screen or typing a point ID at the command line. After choosing a known point, the following dialog will appear:

The **Add Point** dialog allows you to change the current coordinates of the known point or accept the current coordinates. When done specifying the coordinates of the known point, click the **OK** button

After a point has been placed in the **Points with Known Coordinates** list on the right, you can edit the values you entered by highlighting the incorrect point and clicking the **Edit Point** button. Or, if you wish, you can remove an incorrect point from the right hand **Points with Known Coordinates** list by highlighting it and clicking the **< Remove** button.

After specifying all the known points, you must specify which coordinate file will be used to store the transformed points. If you wish to use the current coordinate file you need do nothing. If you wish to write the transformed points to a different coordinate file than the one listed in the **Store the Transformed Points in the File:** edit box, click the **Browse...** button and use the file dialog (see below) to specify a new or existing coordinate file. When done choosing a coordinate file, click the **Open** button in the file dialog.

Click the **Transform** button in the **Coordinate Transformation** dialog to cause the transformed coordinates to be calculated and stored in the specified file

Prompts

Add points from the coordinate file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: specify which points are to be transformed using the typical C&G Selection method.

Follow the instructions above to fill out the **Coordinate Transformation** dialog box.

Pulldown Menu Location: CG-Survey > Mngmt > Transformations

Keyboard Command: cg_crd_trns

Prerequisite: Coordinate file

Copy Coordinates

This feature allows the user to copy a selected set of points from the current coordinate file to itself or to another coordinate file and, optionally, increase or decrease the point ID by a specified number.

First you must choose the points to be copied:

Add points from coordinate file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: use one of the available methods to specify the set of points to be copied.

Next, you must specify what value to add to or subtract from the point IDs to form the new point IDs. If you press <Enter> the default is to leave the IDs the same.

Value to add or subtract from point numbers <0>: press Enter to leave the point IDs as they are or enter a positive or negative number.

Next you must specify the coordinate file to which the points are to be copied.

Store coordinates in [Current-file/Existing-file/New-file] <C>: type "C" and Enter or just Enter to copy the specified points into the current coordinate file. Type "E" and Enter to choose an existing coordinate file into which to copy the points or Type "N" and Enter the copy the points to a new file. If you choose either an existing or new file you will use a file dialog to specify the file to use.

The selected points will then be copied to the specified file.

Prompts

Add points from coordinate file. (Enter when done)

[All/Block/Code/Desc/Elev/Pt-group/Limits/Radius/Select]: use one of the available methods to specify the set of points to be copied.

Value to add or subtract from point numbers <0>: press Enter to leave the point IDs as they are or enter a positive or negative number.

Store coordinates in [Current-file/Existing-file/New-file] <C>: type "C" and Enter or just Enter to copy the specified points into the current coordinate file. Type "E" and Enter to choose an existing coordinate file into which to copy the points or Type "N" and Enter the copy the points to a new file.

Pulldown Menu Location: CG-Survey > Management > Transformations

Keyboard Command: cg_move_coords

Prerequisite: Coordinate file

Description Tables

Description tables have several purposes. They can be used as a shortcut method of using point codes or numeric descriptions to automatically set point descriptions when points are saved to a coordinate file. (Descriptions have a similar functionality when used in conjunction with the CGEditor)

Note: the description table is only used in conjunction with saving points to the coordinate file if Descriptions are ON and **Get Description From Table** is checked on the General tab of the C&G Options dialog.

Description tables allow the user to specify many details regarding the appearance of a plotted point when using **Auto Map > Draw** or **Trav > Reduce**, or anytime points are being plotted.

Note: the description table is only used in conjunction with drawing points if Descriptions are ON and **Use description table for point plotting parameters** is checked on the Graphics tab of the C&G Options dialog.

A description number acts as an index into the description table.

When saving a point to the coordinate file and a number is used in a description field, the description table will be searched for that number. If that description number is found, the number in the description field will be replaced with the description in the description table. In the case of C&G coordinate files, the number will be moved to the point code field. If no match is found, the number will remain in the description field.

When plotting points, the description for the point being drawn is compared to the descriptions found in the description table. If a match is found then the point is plotted using the parameters specified in that description table entry.

The items in this menu allow you to create and manipulate description tables. You can create a new empty

description table and edit it. You can edit an existing description table. You can set or close the current description table and set a different default description table to be used in new drawings.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: None

Prerequisite: None

Create

This feature allows you to create a new description table. A dialog box will prompt you to name the description table to be created.

Once you have specified the description table to create, you will be allowed to edit the new, empty description table. See Description Table > Edit for a detailed description of how to edit a description table.

Prompts

Use a file dialog to specify the name and location of the new description table and the Edit Description Table dialog to create the table entries.

Pulldown Menu Location: CG-Survey > Mngmt > Description Tables

Keyboard Command: cg_create_desc_table

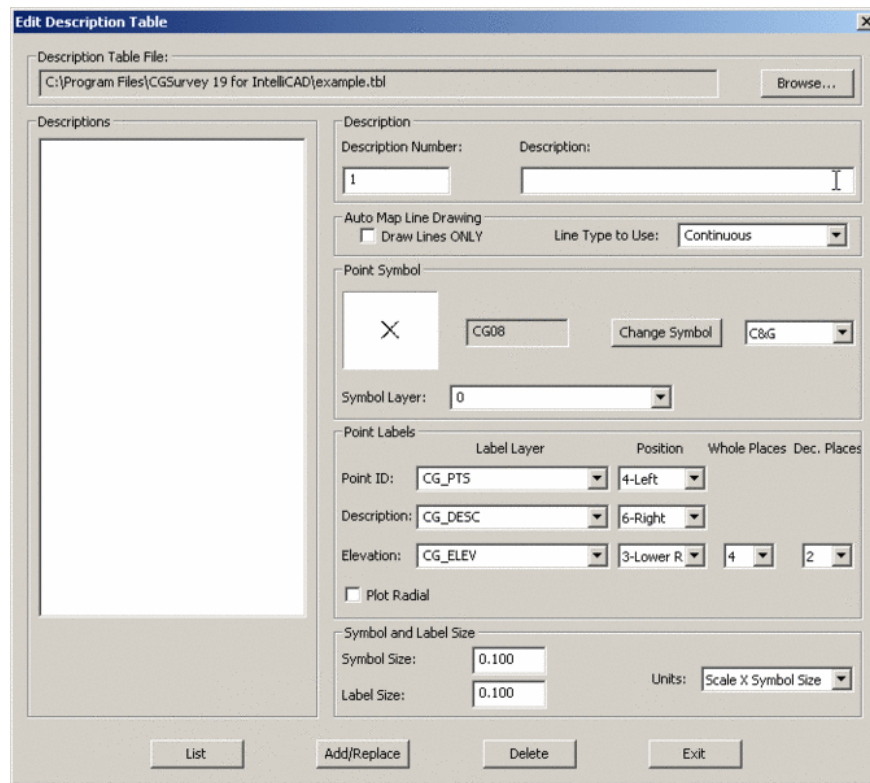

Prerequisite: None

Edit

This feature allows you to edit an existing description table. The following edit dialog box will appear:

Note: Editing a description table does not make it the current description table for the current drawing. To make a description table the current one you must choose the **Set Current** menu item in the **Description Table**.

Caution for CG-SURVEY for DOS users: You may open the older format CG-DOS Description Table. However, when opened, the CG-DOS description table will be converted to the current format and once converted, the description table cannot be converted back to or used by the CG-SURVEY for DOS program.

Description Table File:

Displays the name and location of the description table currently being edited. Pressing the **Browse** button brings up the **Choose a Description Table to Edit** file dialog box allowing you to select a description table to edit.

Note about the Browse button: If you are in the editor just after using the create menu item to create a new description table, you should not use the Browse button.

Descriptions list

This list contains a list of all the descriptions in the current description table. You may scroll through the list using the scroll bar on the right or use the scroll bar on the bottom to view the complete description. The list contains one description per line. By clicking on a description in the list its properties are displayed to the right of the list. The list itself contains some of the description's properties but you must click on the specific description you are interested in to view all its specifications. Each row in the list consists of first the description number then the description itself then the symbol and symbol and label height.

Description section

Description Number: This number acts as an index to the description table.

Description: The description you wish to set parameters for.

Auto Map Line Drawing section

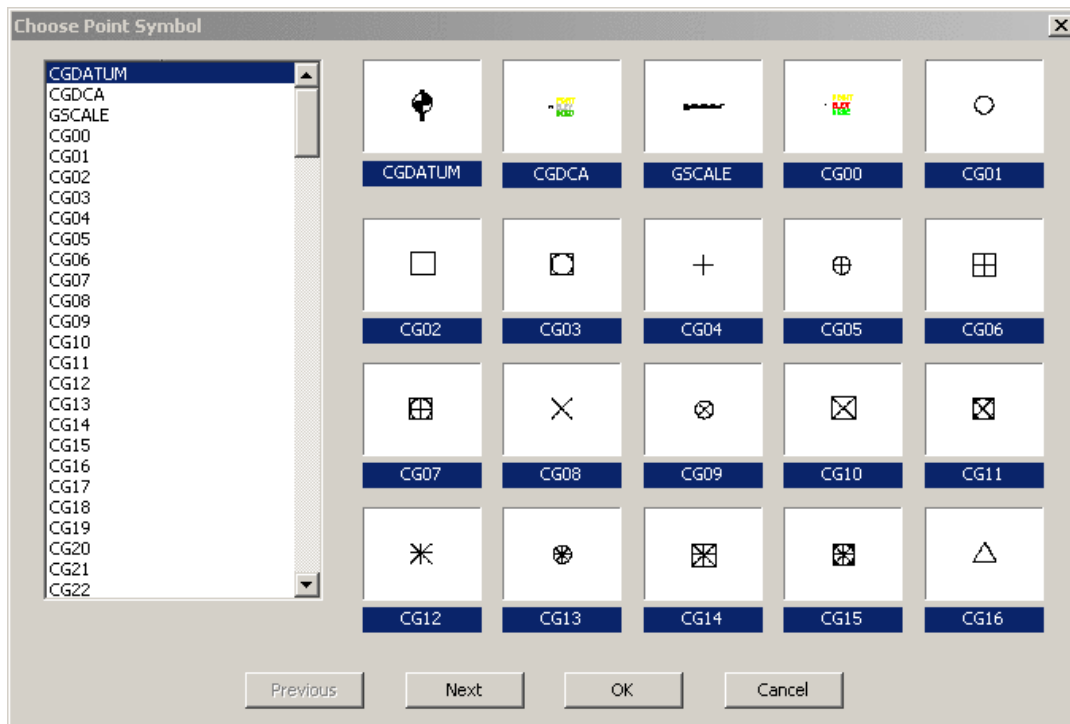

If you check the **Draw Lines ONLY** checkbox then during Auto Mapping (see Draw > Auto Map > Draw) points with this description will not have the point symbol drawn but will be connected by lines if the line drawing codes are used. The **Line Type to Use** drop down box allows you to choose one of the currently loaded line types for the

lines drawn between points having this description.

Point Symbol section

Symbol: The drawing in the box on the left side indicates which point symbol is currently specified for this description. The text next to the symbol drawing is the name of the symbol minus the .dwg ending. This is the symbol to be used when plotting a point having a description matching that specified in this description entry. You may specify any valid block name by first selecting the type of symbol you wish to use: either Carlson or C&G. You can specify any standard C&G or Carlson symbol supplied with the software or create your own custom point symbols. Custom point symbols must be located in either the users Sup directory with the Carlson symbols or with the C&G symbols in Sup\CGPTSYM generally found under C:\Documents and Settings\\Application Data\Carlson Software\\<CAD version> directory.

You may press the Change Symbol button to view and/or select the desired symbol.

Symbol Layer: The drawing layer that the point symbol will be plotted on for any point having a description matching that specified in this description table entry.

Point Labels section

Point Label Positions

The entries in this area refer to the plotting of Point ID, Description and Elevation labels around a point symbol.

Layer

The Point ID, Description and Elevation layer names can be specified. If none is specified then the current layer will be used.

Position

You can assign the Position of the point number, elevation and description labels in relation to the point symbol.

Valid positions are 0 through 9 based on the numeric keypad on your keyboard. Consider 5 as the location of the center of a point symbol. Labels can be placed around the point symbol just as the other numbers surround 5. You identify the location where you want the label to be placed around the point symbol by selecting the number on the numeric keypad that corresponds to that relative location. The relative positions are also indicated in the list and can be picked directly from the list.

Position 0 - indicates that you do not want the label to be plotted.

Position 5 - can only be used for the elevation label. (If you select position 5 for any other label it will be treated as Position 0). If you select position 5 for the elevation label the whole number portion of the elevation will be plotted to the left of the center of the symbol and the decimal portion of the elevation will be plotted to the right.

Whole Places - can be specified for the elevation label only.

Decimal Places - can be specified for the elevation label only.

Plot Radial

If Plot Radial is checked, the point labels will be plotted radially from the symbol's center at the Position specified.

If plot radial is not selected, point labels will be plotted horizontally.

Symbol and Label Size section

Symbol Size: The size of the symbol to be plotted for a point having a description matching that specified for this description table entry.

Label Size: The height of the point label text. This refers to labeling symbols with point number, elevation and description.

Units: Units can be set to **Scale X Symbol Size** or **Literal**.

Scale X Symbol Size indicates that the values for **Symbol Size** and **Label Size** will be multiplied by the drawing scale (Specified on the Drawing Settings tab of the C&G Options dialog) to determine the size of the symbol and/or label in actual drawing units.

Literal indicates that the specified **Symbol Size** is in actual drawing units and should not be scaled.

Note: If the **Units** for a given description is set to **Scale X Symbol Size**, then the symbol size and label height on the printed drawing are interpreted to be in inches if drawing units are set to FEET on the General tab of the C&G Options dialog and centimeters if drawing units are set to METERS or METRES.

Buttons

List: clicking this button causes the description table to be printed as a report on the command line and to the print file.

Add/Replace: click this button to save your changes when you complete a new description or edit an existing description.

Delete: click this button to delete the highlighted description. If you delete a description, it cannot be recovered and you will not be allowed to cancel the deletion.

Exit: When finished editing, click this button.

Prompts

Use the Edit Description Table dialog to enter or modify descriptions and their drawing parameters.

Pulldown Menu Location: CG-Survey > Mngmt > Description Tables

Keyboard Command: cg_edit_desc_codes

Prerequisite: An existing C&G description table or a newly created one (see Create)

Set Current

Allows the user to select the current description table using a file dialog. The selected description table will be active for the current drawing. When Set Current is used the description table name and location are saved with the drawing settings.

Prompts

Use a file dialog to choose the current file.

Pulldown Menu Location: CG-Survey > Description Tables

Keyboard Command: cg_set_desc_table

Prerequisite: Existing C&G Description table

Close Current

Closes the current description table. This is saved with the drawing as part of the CG_SETTINGS.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: cg_close_desc_table

Prerequisite: None

Set Default

Allows the user to select the default description table using a file dialog. The selected description table will be saved to the CGSURVEY.OPT file for the current user and used to set the default settings for any new C&G drawings created by the current user.

Prompts

Use a file dialog to choose the default file.

Pulldown Menu Location: CG-Survey > Description Tables

Keyboard Command: cg_set_default_desc_table

Prerequisite: Existing C&G Description table

Convert to SurvCE FCL file

This feature allows you to convert a C&G description table to a SurvCE feature code list or FCL file.

If you are using SurvCE and wish to import your C&G description table for use with SurvCE use this feature to create the FCL file then upload it to the SurvCE data collector FCL directory.

If a C&G description table is not currently open you will be asked to choose which file you wish to convert using a file dialog box.

Next, using file dialog, you will be asked to specify the name of the FCL file to create.

When you click OK after specifying the FCL file name, the conversion will take place.

Prompts

Use file dialog boxes to pick the C&G description table to convert and to specify the name of the FCL file to create.

Pulldown Menu Location: CG-Survey > Mngmt > Description Tables

Keyboard Command: CG_CONVERT_DESC_TO_SURVCE_FCL

Prerequisite: Existing C&G description table (*.tbl) and its index file (*.tbx).

Point Groups

Point groups were formerly called Batch Point Files or point files. These files are text files with the extension pts.

These features allow the user to create or edit a point group. A point group is simply an ASCII text file that contains a list of point IDs that are in a specific sequence. The points in a point group can describe a tract of land, a road centerline, a utility line, a group of lots in a subdivision, etc. - anything that can be defined by a series of points. Point groups can also contain the PC radius point and PT for horizontal curves as well as vertical curve information.

An example of a point group file:

If you view a point group file in a text editor like notepad you will see something like this example

Note: the text in square brackets does not appear in the file itself - it is only used to clarify this example:

```
LOT 1 [Subgroup description]
1 [Point 1]
23 [Point 23, PC]
+48 [Clockwise radius point 48]
49 [Point 49, PT]
50 [Point 52]
1 [Point 1, back to starting point]
LOT 2 [Subgroup description]
12 [Point 12]
24 [Point 24]
65 [Point 65]
70 [Point 70]
12 [Point 12, starting point]
```

The above example illustrates a point group with two subgroups. Each subgroup defines a lot. The last point in each subgroup is optional - you don't need to close the lot boundary by entering the starting point twice.

Pulldown Menu Location: CG-Survey > Mngmt

Keyboard Command: None

Prerequisite: Coordinate file

Create

There are two ways to create a new point group: you can use this command or you can use the CGEditor. Previous C&G users may prefer to use this command but the CGEditor allows the user the ability to view and edit the point group as it is being created.

If a coordinate file is not open, you will be prompted to open one using a file dialog.

Once the coordinate file is open, the point group file dialog can be used to specify the name of the point group file you wish to create.

Subgroup description <Enter when done>: Enter the subgroup description.

Specify points for subgroup <filename>:

[Block/Code/Desc/Elev/Indiv/liMits/Radius/Vertical_curve] <pick polyline>:

Use any of the available methods, including picking a polyline in the drawing, to specify the point IDs of the points in the subgroup. Remember that, within a given subgroup, you are defining a specific shape or line and thus the points need to be entered as an ordered sequence that properly defines the lot, alignment, etc.

Repeat the steps outlined above until all subgroups and their points have been entered.

To end the command and create the point group file, press Enter twice after specifying the last point in the last subgroup.

Using a Polyline to specify a group of points

If you pick a polyline, the coordinate file is searched for points having northings and eastings that match the x and y coordinates of the vertices of the polyline. If none of the points in the coordinate file match the polyline vertices, then no points are added to the points in the current subgroup. Any points that match are added to the subgroup points and you are prompted for the next point in the subgroup. You may continue using any of the methods of specifying points, including picking other polylines.

Entering a Curve

First type "I" and enter to enter individual points. As you are specifying the individual points in the subgroup you can specify a curve by entering the radius point ID immediately after entering the ID of the PC. The radius point must be indicated by preceding its point ID with a plus sign for a clockwise curve or a minus sign for a counterclockwise curve. The next point ID you enter is assumed to be the PT.

Vertical Curves

If you are creating a point group to define a road alignment, you may wish to enter vertical curve information so that both the horizontal and vertical alignments are defined.

Note: You may find it more convenient to use the CGEditor to enter vertical curve information.

To do this type "V" and Enter at the command prompt. You will see the following prompt:

Vertical Curve 1

[Next/slope-In/slope-Out/Length/pvi-Station/pvi-Elevation]:

For the first vertical curve you must enter five curve components. Enter these five components by typing the capitalized letter representing the component that you wish to specify, then press Enter. You will be prompted to

enter the component specified.

You must enter a value for each of the following five required fields:

The slope-In

slope-Out

Length of the vertical curve

pvi-Station

pvi-Elevation.

Entering succeeding vertical curves

After entering the information for the first vertical curve, enter <N> for Next. Since the slope in and PVI elevation are determined by the previous vertical curve information, so you need only specify three fields for any additional curves:

slope-Out

Length

pvi-Station

Use Previous and Next to enter and/or change the vertical curve information. You may enter as many as fifty vertical curves. You can press the F2 key at any time to view the prompt history screen, then use the scroll bar on the right to view the entire data entry sequence.

Multiple Subgroups

To place more than one subgroup in a single point group, press Enter when asked to select another point for the current subgroup. This ends input for the current subgroup.

At the **Subgroup description <Enter when done>**: prompt, enter the name of the next subgroup and go on to enter a new series of points, including both horizontal and vertical curve information as needed.

Continue to enter subgroups of points by repeating these steps until all subgroups have been entered.

When you have entered all the subgroups, press Enter until you get the Subgroup Description prompt.

Press Enter at the Subgroup Description prompt to end the command and create the point group file.

Prompts

Subgroup description <Enter when done>: Enter the subgroup description.

Specify points for subgroup <filename>:

[Block/Code/Desc/Elev/Indiv/liMits/Radius/Vertical_curve] <pick polyline>: use one or more of the available methods to specify points in the current subgroup.

Vertical Curve 1

[Next/slope-In/slope-Out/Length/pvi-Station/pvi-Elevation]: specify which element of the vertical curve you wish to enter or type "N" and Enter to begin entering the next vertical curve.

Vertical Curve ##

[Next/slope-Out/Length/pvi-Station]: after entering the data for the first vertical curve the following curves are controlled by the initial curve. Thus the prompt changes.

Pulldown Menu Location: CG-Survey > Mngmt > Point Groups

Keyboard Command: cg_create_bpf

Prerequisite: Coordinate file

Edit

The Edit Point Groups feature allows you to use the CGEditor to edit/create an existing point group file.

CGEditor General Information

The CGEditor is an integral part of preparing files for use in C&G applications. The CGEditor is a very powerful tool. You can open multiple data files of any supported file type and edit the files as needed. The CGEditor has a full complement of tools for searching and replacing and navigating within a file. It will also allow you to cut or copy records from one file and paste them into another file in order to merge files, move data between phases of a job, etc.

The CGEditor can create and/or edit six types of data files used by C&G:

Raw Data Files

Raw data files contain information pertaining to a field traverse. Raw data files are typically downloaded from the data collector and converted to the C&G raw data file format. These files have the extension .CGR.

Map Check Files

Map Check files contain bearing, distance and curve information and are typically used to calculate the closure of a deed description. These files have the extension .CGM.

Cross Section Files

Cross Section files contain one or more cross sections identified by their station along the alignment. Each cross section record has the percent grade defined for its left and right slopes. Following the "Station" record are several "Point" records containing the elevations and offsets of the points along the cross section. Cross section files consist of a pair of files; the main data file has the extension .CEW and the index file has the extension .CEX.

Template Files

Template files are merely cross section files that represent a standard cross section and can be used to generate other cross section files. However, unlike cross section files, template files use an integer ID instead of a station to uniquely identify each template. Like cross section files, the percent grade is defined for the left and right slopes of each template and there are a set of "Point" records specifying the template elevation at a given offset. The centerline elevation at offset 0.00 is typically set to 0.00. Template files consist of a pair of files; the main data file has the extension .CTP and the index file has the extension .CTX.

Point Group Files

Point Group Files are simply a list of point numbers that can define a group of points, a lot or parcel, or an alignment. These are ASCII files and have a .PTS extension.

Coordinate Files

CGSurvey supports many different coordinate file formats:

C&G .CRD/.IDX - C&G numeric coordinate files

C&G .CGC/.CGX - C&G alpha-numeric coordinate files
Carlson .CRD - Carlson coordinate file format, numeric and alpha-numeric
Simplicity .ZAK - Simplicity coordinate file
LDT - MDB - Land Desk Top coordinate file

Note: for further and complete information on using the Edit Raw File see the chapter on CGEditor in the Tools section.

Pulldown Menu Location: Management\Point Groups\Edit

Keyboard Command: BPF, CG_EDIT_BPF

Prerequisite: Open Raw File

CGTopo

Topographic Settings

Allows you to view or change the **Topographic Settings**. See the **Topography** tab section of the **CG Options..** menu item of the **Tools** menu.

Pulldown Menu Location: CG-Survey > Topo

Keyboard Command: cg_cont_setup

Prerequisite: None

Erase Surface from DWG

When you open a C&G surface (or TIN file, *.tin) it is shown on the screen as a graphic image overlaid on your drawing. You must use the **Write Surface to DWG** feature to actually create contour polylines, TIN lines, etc. If the surface changes due to changes in elevation or location of points you will want to erase the old surface and write the new surface to the drawing. However, once a surface is written to the drawing, it can be a difficult process to pick out all the surface entities in order to erase them from the drawing. This feature makes this an easy, one step operation.

You can use the items in this menu to erase the various topographic features: the TIN, Main Contours, Intermediate Contours, Break Lines, Include Boundaries, and/or Exclude Boundaries or All topo items.

Note: To erase contour labels use **CG-Survey > Topo > Label Contours > Delete Labels**

Pulldown Menu Location: CG-Survey > Topo

Tin

This feature erases all the C&G TIN entities found on the TIN layer specified on the **Topography** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Topo > Erase Surface from DWG

Keyboard Command: cg_erase_tin

Prerequisite: None

Main Contours

This feature erases all the C&G main contour polyline entities found on the main contour layer specified on the **Topography** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Topo > Erase Surface from DWG

Keyboard Command: cg_erase_main_cont

Prerequisite: None

Intermediate Contours

This feature erases all the C&G intermediate contour polyline entities found on the intermediate contour layer specified on the **Topography** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Topo > Erase Surface from DWG

Keyboard Command: cg_erase_interm_cont

Prerequisite: None

All topo items

This feature erases all the C&G topo entities found on any of the layers specified on the **Topography** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Topo > Erase Surface from DWG

Keyboard Command: cg_erase_all_topo

Prerequisite: None

Label Contours

The items in this submenu allow you to either label contour lines with appropriate elevations or remove previously placed contour labels.

Pulldown Menu Location: CG-Survey > Topo

Place Labels

This feature allows you to place the appropriate elevation labels at selected locations on C&G contour polylines. The label is a **TEXT** entity overlaying a **WIPEOUT** entity. The **WIPEOUT** entity serves to create a space between the label text and the contour line and to keep the contour line from showing through the text and obscuring it.

If you have not already done so, please review the contour labeling settings by choosing the **CG-Survey > Topo > Topographic Settings** menu item. The labels will be created on the **Main** and **Intermediate Contour Label Layers**. The **Labeling Interval** determines which contours are labeled. For example, if the **Labeling Interval** is set to 2.00, then every C&G contour polyline that you choose having an elevation evenly divisible by 2.00 will be labeled. The **Label-Contour Separation Distance:** is the space separating the contour line and the start and end of the label text.

Once you have verified the correct settings, choose the **Label Contours > Place Label** menu item.

At the prompt (see below) use the left mouse button to pick any point that is on one side of the contour line you wish to label.

Pass a line thru the contours to be labeled.

Pick first point on line. [<ENTER> to quit]:

Now, at the next prompt (see below), drag the rubber band line through one or more of the contours you wish to label and click the left mouse button a second time.

Pick second point [<ENTER> to quit]:

The labeling operation can be repeated as many times as needed, then press Enter to end the command.

Some Trouble Shooting Tips for Labeling Contours:

When a C&G surface is opened it is shown only as a graphic image overlying the drawing. Therefore, before you can place labels on the contour lines, the surface must be written to the drawing using the **CG-Survey > Topo > Write Surface to DWG** menu item..

If the labels do not appear on the contour lines you chose, verify the elevation on the contour using the **CAD LIST** command.

Also, try changing the **Labeling Interval** setting on the **Topography** tab of the **C&G Options** dialog.

If the labels still do not appear on the contour lines, look at **Drawing Settings** tab of the **C&G Options** dialog and verify that the **Text Size** is set to a value that is large enough to be seen when viewing the contours.

If the elevation labels are created with an incorrect number of decimal places, check the **Elevation Precision** on the **Rounding** tab of the **C&G Options** dialog under **Text in Drawing**. Use the **CAD UNDO** command to undo the previously placed labels and try again.

Prompts

Pass a line thru the contours to be labeled.

Pick first point on line. [<ENTER> to quit]: use the left mouse button to pick any point that is on one side of the contour line you wish to label.

Pick second point [<ENTER> to quit]: drag the rubber band line through one or more of the contours you wish to label and click the left mouse button a second time.

Pulldown Menu Location: CG-Survey > Topo > Label Contours

Keyboard Command: cg_label_contours

Prerequisite: C&G contour polyline entities in the drawing

Delete Labels

This feature allows you to delete previously placed C&G contour labels. C&G contour labels consist of two entities: a TEXT entity containing the elevation text and a WIPEOUT entity used to hide the contour polyline under the elevation text. While you can delete these using standard CAD commands, it requires several steps and can be tricky. This feature makes deleting these labels a one step operation.

After choosing the **CG-Survey > Topo > Label Contours > Delete Labels** menu item you will see the following prompt at the command line:

Select contour labels to delete:

Select objects: use the mouse to pick the label text for the labels to be deleted. Press Enter when done and the labels and their accompanying WIPOUT entities will be deleted.

Prompts

Select contour labels to delete:

Select objects: use the mouse to pick the label text for the labels to be deleted.

Pulldown Menu Location: CG-Survey > Topo > Label Contours

Keyboard Command: cg_del_cont_labels

Prerequisite: None

CGTools

CG Options

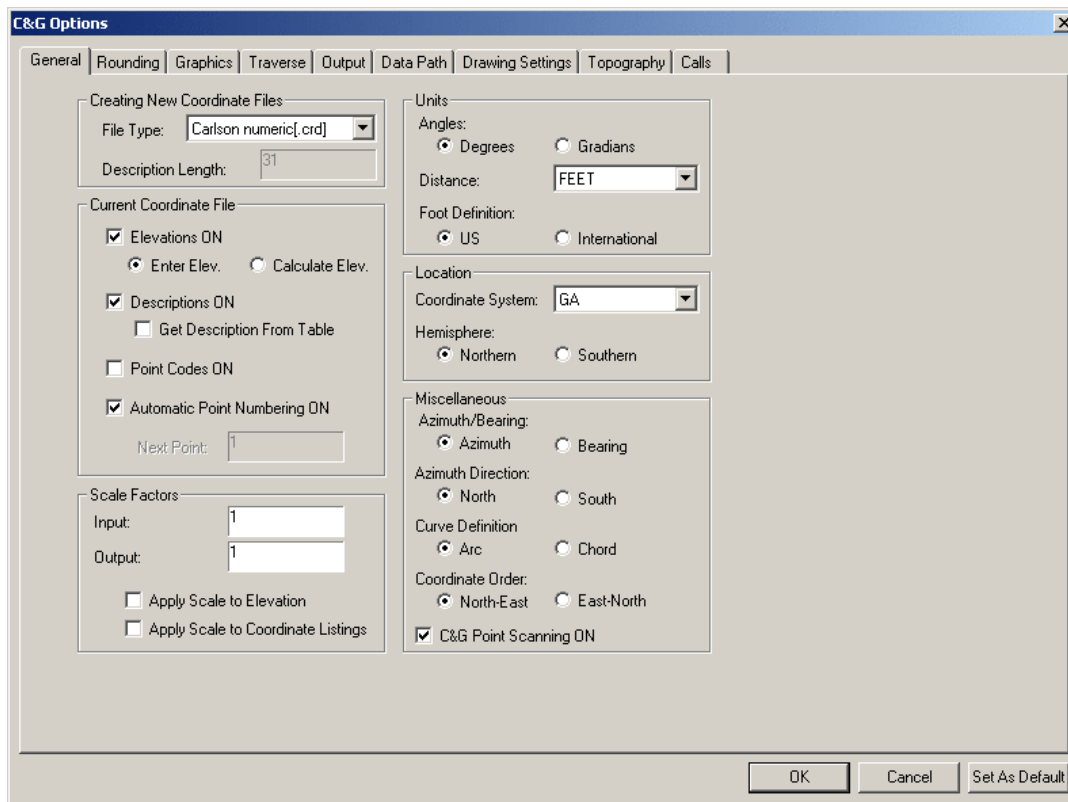

The **CG Options** menu item brings up the **C&G Options dialog**, allowing you to view or change various CGSurvey settings or save the currently configured settings to be used as the default settings for a newly created drawings.

There are nine tabs on the C&G Options dialog. Each tab pertains to a category of settings:

1. **General** tab - settings regarding the coordinate file type for new files, units, scale factors, and other general settings.
2. **Rounding** tab - number rounding settings used for the print file and for text placed in the drawing.
3. **Graphics** tab - specify when CGSurvey draws points and lines, format of bearings and other graphics related settings.
4. **Traverse** tab - settings used by all traverse related features.
5. **Output** tab - specify the name and layout of the print file and how the results of C&G features are displayed.
6. **Data Path** tab - specify the default path to your data files
7. **Drawing Settings** tab - specify drawing scale, text size, and details of how point symbols and their labels are to be drawn.
8. **Topography** tab - specify contouring parameters along with the layers used for the TIN, contour and other topographic entities.
9. **Calls** tab - specify the components, format and layer for calls (annotations).

Each of these tabs will be covered in the following sections.

This tab contains a wide variety of settings that apply to almost all of the features found in the CG-Survey menus. These are settings such as Next Point ID, Elevations, State, Arc Definition, Bearings/Azimuths, Coordinate order and more.

Creating New Coordinate Files section

File Type: You may select one of the following coordinate file types:

C&G numeric (*.crd)

- point ID can be an integer between 1 and 65,536
- description from 1 to 100 characters

C&G alphanumeric (*.cgc)

- point ID can contain up to 10 characters using any combination of letters and numbers.
- description from 1 to 100 characters

Carlson numeric (*.crd)

- point ID can be any integer containing up to 9 digits.
- description from 1 to 31 characters

Carlson alphanumeric (*.crd)

- point ID can contain up to 9 characters using any combination of letters and numbers.
- description from 1 to 31 characters

Simplicity (*.Zak)

- point ID can contain up to 8 characters using any combination of letters and numbers.
- description from 1 to 28 characters

Land Desktop Format (*.mdb)

- point ID can contain up to 255 characters using any combination of letters and numbers.
- description from 1 to 255 characters

Description Length: This value can only be set for C&G coordinate files. It becomes the default description length for new C&G coordinate and C&G raw data files. It can be set to from 1 to 100 characters.

Current Coordinate File section

Elevations ON If this checkbox is checked, elevations will be carried on all points computed and/or you will be able to enter an elevation when saving a point.

Enter Elev.: If this checkbox is checked, you will be prompted to manually enter elevations.

Calculate Elev.: If this checkbox is checked and an elevation can be computed from the data that has been entered during the command, it will be. Otherwise you will be asked.

Descriptions ON If the **Descriptions ON** checkbox is not checked, you will not be prompted to enter a description as points are created or edited.

If descriptions are ON, and **Get Description From Table** *IS NOT* checked, you will be prompted to manually enter a description for each coordinate point created. However, if Descriptions are on and **Get Description from Table** *IS* checked, when a point is stored and a description table *IS NOT* open, you will be prompted to select a description table. The description table will then be used to look up any integer number in the description in order to substitute the description in the table for the integer and move the integer to the Code files. (see help under CG-Survey > Management > Description Tables)

Point Codes ON If the **Point Codes ON** checkbox is checked, you will be allowed to enter a two to four character code depending on the number of characters in the code type you are using. This code can be used later to group points with the same code for plotting or listing points. When Point Codes are off, you will not be prompted to enter the point codes.

Automatic Point Numbering ON If the **Automatic Point Numbering ON** checkbox is checked, as points are created they will automatically be assigned the next available point ID in the current coordinate file. If Automatic Point Numbering is OFF, as points are created you will be prompted to enter their ID. If you enter a point number that already exists in the coordinate file, you will be asked if you want to overwrite the existing point or enter a new point ID.

Scale Factors section

Input: This allows you to set a scale factor that will be applied to all entered distances and coordinate values during any C&G feature.

Output: This allows you set a scale factor that will be applied to all output. For example, if this factor is set to 2.0 and the inversed distance between two points is 100.00, the output will show the distance as 200.00.

Apply Scale to Elevation If the **Apply Scale to Elevation** checkbox is checked, the Input and Output Scale Factors will be applied to elevation values.

Apply Scale to Coordinate Listings If the **Apply Scale to Coordinate Listings** checkbox is checked, the Input and Output Scale Factors will be applied to coordinates listed at the command line and in the print file using the C&G feature in menu item CG-Survey > Management > List.

Units section

Angles: Choose either the **Degrees** or **Gradians** radio buttons.

Distance: Choose Feet, Meters or Metres from the list.

Note: The only difference in the two metric choices is the spelling used for output.

Foot Definition: Choose either the **US** or **International** radio button.

Location section

State: specify the state in which the current survey was done.

This is only used in the following features:

Solar Observation

NAD83 (to and from longitude and latitude)

Hemisphere: Hemisphere can be set to **Northern** or **Southern**.

This is only used in the following features:

Solar Observation (Calculating the Convergency Angle)

NAD83 (to and from Longitude and Latitude - UTM only)

Miscellaneous section

Azimuth/Bearing: Allows you choose between **Bearing** and **Azimuth** for all direction input and output.

Azimuth Direction: This sets all azimuth input and output to either **North** or **South** azimuth.

Curve Definition The Curve Definition can be set to Arc or Chord.

Arc: the most commonly used definition in roadway design. When units are set to Feet, the degree of curve is the central angle of a 100 foot arc length.

Chord: is most commonly used in railroad work. When units are set to Feet, the degree of curve is the central angle of a 100 foot chord.

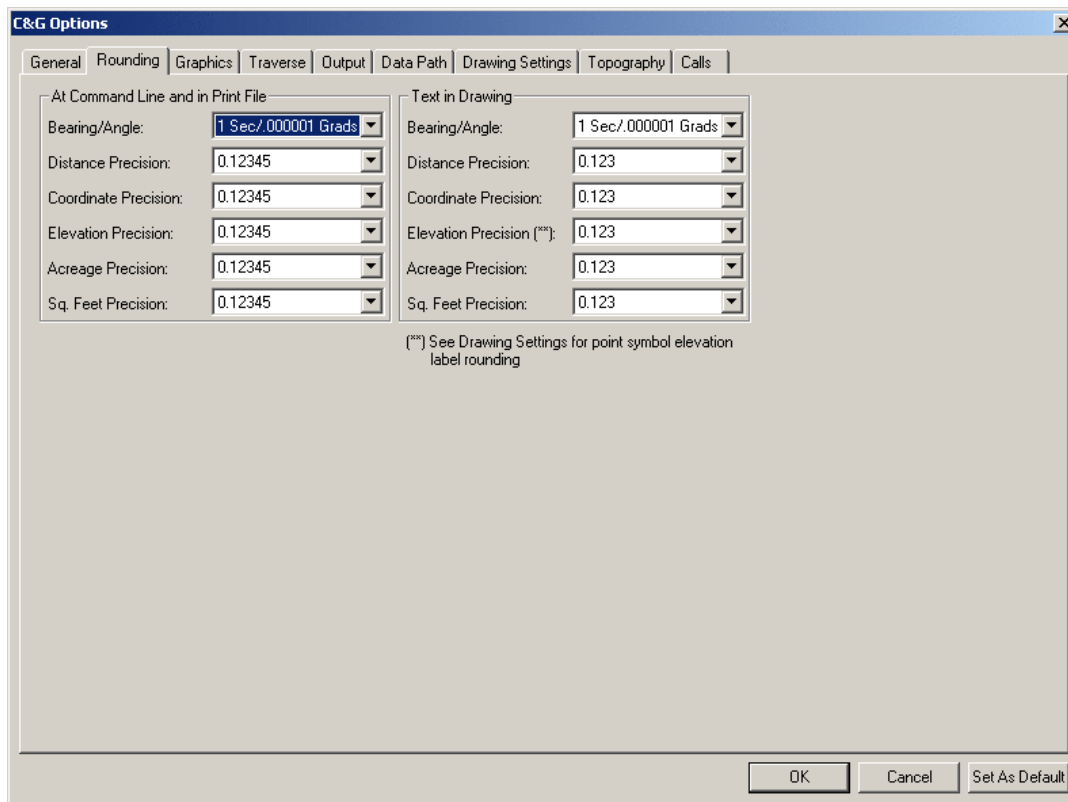

When a curve is added to a Curve Table or the results of calculations are listed at the command line and in the print file, the displayed information will reflect the **Curve Definition** setting.

Coordinate Order: Can be set to **North-East** or **East-North**. This sets the order in which coordinates are displayed and input.

Allows you to specify the rounding settings for various types of numbers for the print file text and for the drawing text.

Note: All internal calculations are performed with double precision accuracy. Only the output is rounded.

When you select the **Rounding** tab , you will see the following dialog:

The **Rounding** dialog has a section for **At Command Line and in Print File** rounding settings and a section for **Text in Drawing** rounding settings. Both sections have similar settings but they apply to different output. **At Command Line and in Print File** rounding settings effect all output to the command line and the print file. **Text in Drawing** rounding settings effect numeric text placed in the drawing.

Angular precision can be specified to the nearest:

Angles in Degrees or Angles in Grads

0.1 Second 0.000001 Grad

Second 0.00001 Grad

5 Seconds 0.0001 Grad

15 Seconds 0.001 Grad

30 Seconds 0.01 Grad

Minute 0.1 Grad

Distance precision can be specified to the nearest:

Foot (or Meter) 0 (no decimal places)

Tenth of Foot (or Meter) 0.1

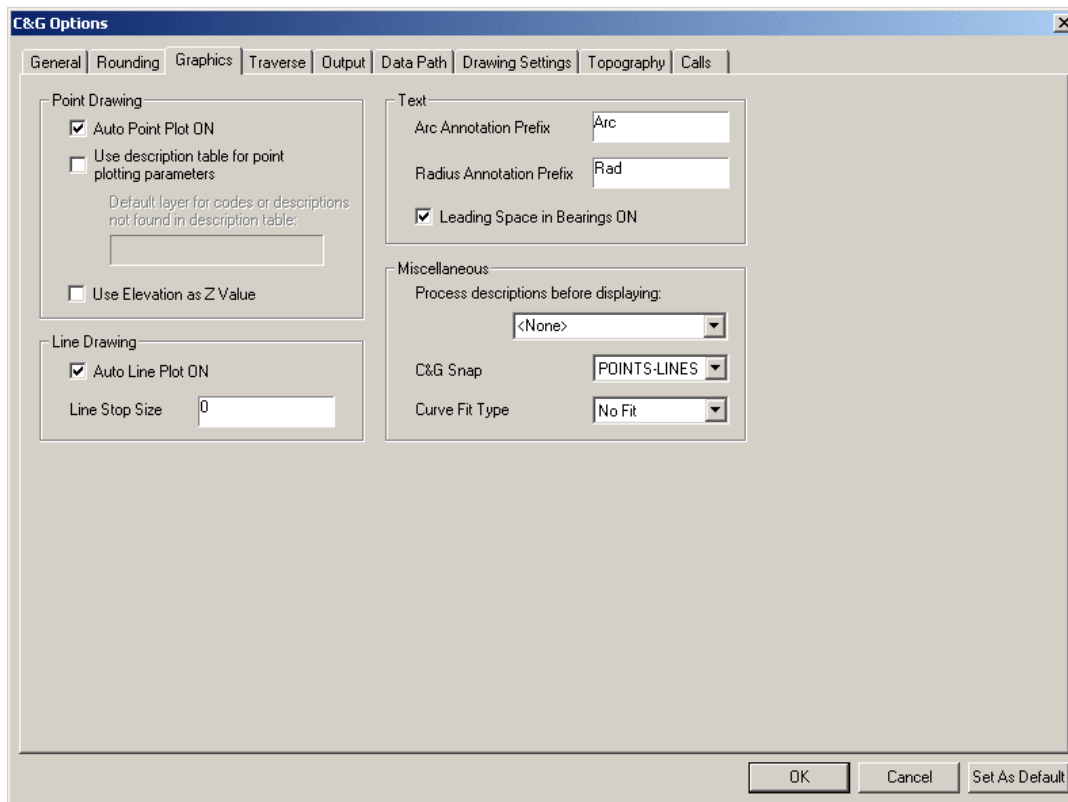

Hundredth Foot (or Meter) 0.12

Thousandth Foot (or Meter) 0.123

Ten Thousandth Foot (or Meter) 0.1234

Hundred Thousandth Foot (or Meter) 0.12345

The **Graphics** tab settings apply only to CGSurvey features that draw points, lines, etc. to the drawing. When you select the **Graphics** tab, the following dialog will appear:

Point Drawing section

Auto Point Plot ON If the **Auto Point Plot ON** checkbox is checked, points symbols will be drawn as they are calculated and saved to the coordinate file by the various C&G features.

Use Description table for point plotting parameters When this checkbox is checked the description(s) for a given point in the coordinate file will be matched with the descriptions in the description table. If a match is found then the description table information will be used to set the layer, symbol type, symbol size, and label positions of each point plotted. If no descriptions in the description table match then the layer will be set to the layer specified in the **Default layer for codes or descriptions not found in description table** edit box and the other settings specified in the **Drawing Settings** tab will be used (see below).

If the **Use Description table for point plotting parameters** checkbox is not checked, the points, symbols and labels will be plotted on the Current Layer as set in the CAD layer manager.

Default layer for codes or descriptions not found in description table: When the **Use description table for point plotting parameters** checkbox is checked, any points plotted that do not have a description or having a description that does not match any of those in the description table, will be plotted on the layer you have specified as the default layer in this edit box.

Use Elevation as Z Value: If this checkbox is checked, objects (lines/arcs/points) will be placed in 3-D space with the point elevation serving as the Z-value. C&G features, such as intersects and inverse, ignore the Z-value of lines and arcs. If you inverse a 3-D line, the 2-D distance between the points will be shown.

If the **Use Elevation as Z Value** checkbox is not checked, all objects will be placed at zero elevation.

Note: 3D lines can cause problems in trimming or editing using CAD functions. 3D lines do not intersect if their elevations are different. Thus two lines may appear to intersect in plan view but do not actually intersect in 3D space.

Line Drawing section

Auto Line Plot ON If the Auto Line Plot ON checkbox is checked, those features that create points that can be interpreted as a line will draw C&G lines.

The following features can draw lines and curves as the points are calculated:

Quick Traverse (not to side shots)

Curve Between Tangents and **Tangent Between Curves**

Bearing and **Hinge/Radial Area-Cut-Off**

Roadways (Right of Way/Easements and **Intersections/Cul-de-Sacs)**

Middle Ordinate Solution

Best Fit

Line Stop Size This allows you to terminate C&G lines at the edge of the point symbols plotted. If you are drawing lines and/or arcs with a C&G feature that draws lines and you want the line to end before crossing into the symbol, then set the **Line Stop Size** to the symbol size.

Note: If you set the line stop to something other than 0.0, the line that is drawn is shorter than the actual distance between the coordinate points. So if you wish to check the true distance of that line, use the **Query** command (on the Draw menu) rather than the CAD LIST command.

Text section

Arc Annotation Prefix

This is used when annotating arcs when drawing calls. This should be set to the desired prefix for arc length annotation.

Example:

"Arc =" annotation prefix results in the annotation being

Arc = 256.32

"A =" annotation prefix results in the annotation being

A = 256.32

Radius Annotation Prefix

This is used when annotating arcs when drawing calls. Similar to **Arc Annotation Prefix**, This should be set to the desired prefix for radius annotation.

Leading Space in Bearing

When the **Leading Space in Bearing** checkbox is checked the bearing text has a space between the N or S and the degrees text (eg, N 85°15'30"E). When left unchecked there is not space (eg, N85°15'30"E).

Miscellaneous section

Process Descriptions before Displaying:

This setting will allow you to specify how descriptions are processed prior to being displayed. It allows the removal of all underscores (_) and/or mapping codes. No change is made to the data in the coordinate file.

C&G Snap can be set to:

Off: No snap.

POINTS - Snap to C&G point symbols and labels.

LINES - Snap to C&G lines.

POINTS-LINES - Snap to C&G points and lines.

All C&G functions will use this setting when you are picking point symbols, point labels, lines, and arcs on the screen.

Curve Fit Type

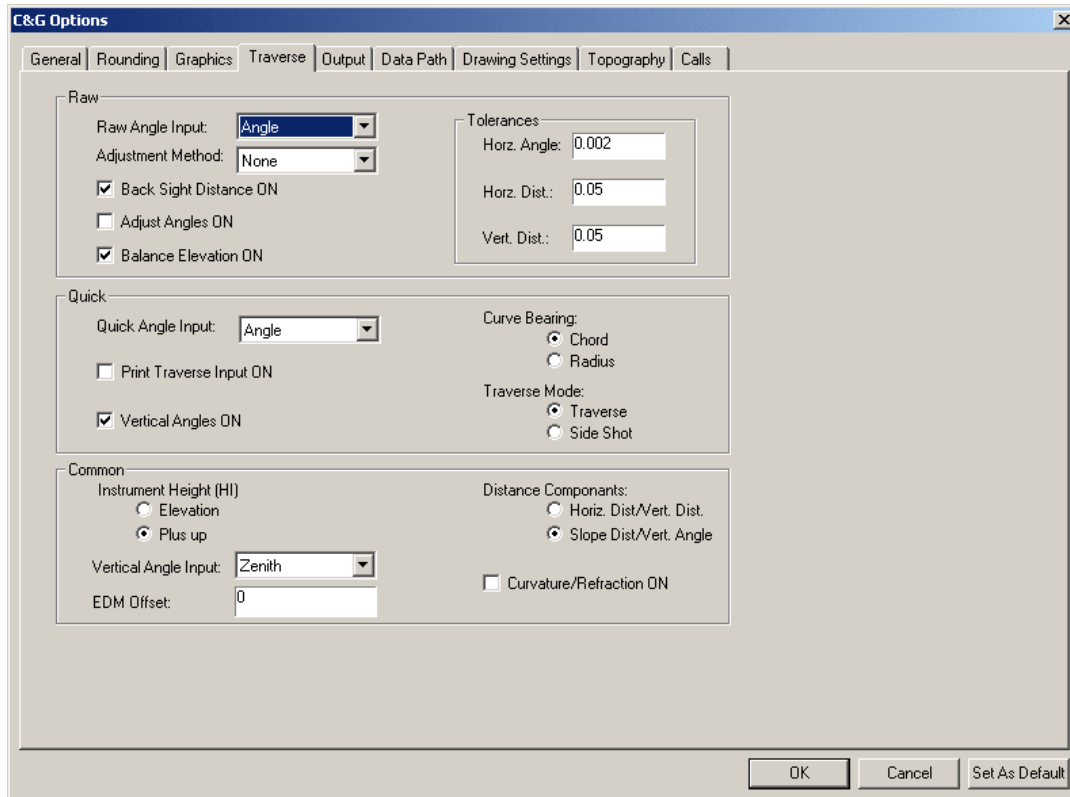

When contouring, the contour lines that are created can be smoothed using one of the following methods:

No Fit - Straight line segments between the points.

Fit - Use the CAD program's standard fit method. Contours may not pass through point symbols having the same elevation as the contour.

C&G Spline - Use the C&G Spline Fit algorithm. Contours are guaranteed to pass through point symbols having the same elevation as the contour.

These settings are specific to traverse raw data entry using the CGEditor and the traverse reduction and quick traverse features.

Raw section

Raw Angle Input

This allows you to specify how you want to specify angles when inputting raw traverse data. The options are: **Angle**, **Azimuth** or **Deflection** Angle.

Adjustment Method

You have the following choices for traverse adjustment:

None

Least Squares (NOT network least squares - see **SurvNET** for that)

Find Bad Angle

Compass

Transit

Crandall

Note: See the **Reduce Traverse** feature help section for more details on these methods.

If the **Backsight Distance ON** checkbox is checked and you entering raw traverse data, you must specify the distance to the backsight at each instrument point. These distances will then be used during the reduction process.

If the **Adjust Angles ON** checkbox is checked, angles will automatically be balanced prior to traverse adjustment. Angular error will be spread equally between all points. Closure information prior to and after balancing will be displayed at the command line.

If the **Balance Elevations ON** checkbox is checked, the elevations in a 3-D traverse will automatically be balanced during traverse adjustment. The elevations are adjusted proportional to the length of the traverse legs.

Tolerances section

Horz. Angle.

When comparing multiple angles for a given foresight point from a given instrument point and backsight point, this value will be used as the maximum acceptable angular error. If the difference between any two angles is greater than the acceptable limit, the reduction process will pause and showing the instrument point ID and angle measurements will be displayed at the command line.

Horz. Dist.

When comparing multiple horizontal distance components or measurements to a single foresight point, this value will be used as the maximum acceptable distance difference. If the difference between any two distances is greater than this limit, the reduction process will pause and the instrument point ID and the involved distances will be displayed at the command line.

The horizontal distance tolerance is also used as the maximum allowable difference between the two calculated curve radii at the curve end points. If the difference between the distances from the radius point to the PC point and the radius point to the PT point is greater than this value, the calculations will be terminated with an appropriate error message.

Note: for curves, if this value is set unreasonably low, many curves will produce this error message. If you change the setting to a larger, more reasonable value, the curve can be recalculated and generated without error.

Vert. Dist.

This value is the maximum acceptable elevation difference. It is used when comparing multiple vertical distance components/measurements to a given foresight point from a given instrument point. If the difference between the distances is greater than this limit, the reduction process will pause, showing you the instrument point ID and the involved distances. This only applies to the reduction of a 3-D traverse.

Quick section

Quick Angle Input

This specifies the default angle input mode for the Quick Traverse Feature. This can be changed when using the **Quick Traverse** feature.

The angle input modes are:

Angle

Deflection Angle

Azimuth

Bearing

If the **Print Traverse Input ON** checkbox is checked, all raw input data will be displayed along with the traverse output. If this checkbox is not checked, only the traverse output will be printed.

If the **Vertical Angles ON** checkbox is checked you will be asked to enter vertical angles with the traverse distances. This can be changed when using the **Quick Traverse** feature.

Curve Bearing

This defines how non-tangent curve bearings will be input and can be set to either **Chord** or **Radius** depending on how you wish to define the orientation of non-tangent curves.

When set to **Chord** and you are traversing around a non-tangent curve, you must enter the bearing or angle from the PC to the PT.

When set to **Radius** and you are traversing around a non-tangent curve, you must enter the bearing or angle from the PC to the radius point.

Curve Tables and printed calculations will reflect this setting.

Traverse Mode

Sets the default traverse mode for the **Quick Traverse** feature.

It can be set to **Traverse** or **Side Shot** mode .

Traverse mode: as a point is created the new point is occupied and backsight the previously occupied point.

Side Shot mode: as a point is created the currently occupied point and backsight will be held.

Common section

Instrument Height (HI)

The value entered for the HI can be either the actual instrument **Elevation** or the distance from the ground to the instrument (**Plus up**). In the latter case the elevation of the point the instrument is over is read from the coordinate file and the instrument height is added to it to determine the instrument elevation.

Vertical Angle Input - can be set to one of the following, depending on the type of instrument used:

Zenith: Zero angle up

Nadir: Zero angle down

Transit: Zero angle level

Note: If set to Transit, vertical can either be full circle (0 to 360 degrees; 0 to 400 grads) or positive angle up and negative angle down.

EDM Offset

Depending on where your EDM is mounted, enter the vertical difference between the center of the scope of the instrument and the center of the beam of the EDM (+ if EDM is above; - if EDM is below). Do not use an EDM Offset for scope mounted EDM's. This offset should only be applied to yoke or azimuth base mounted EDM's.

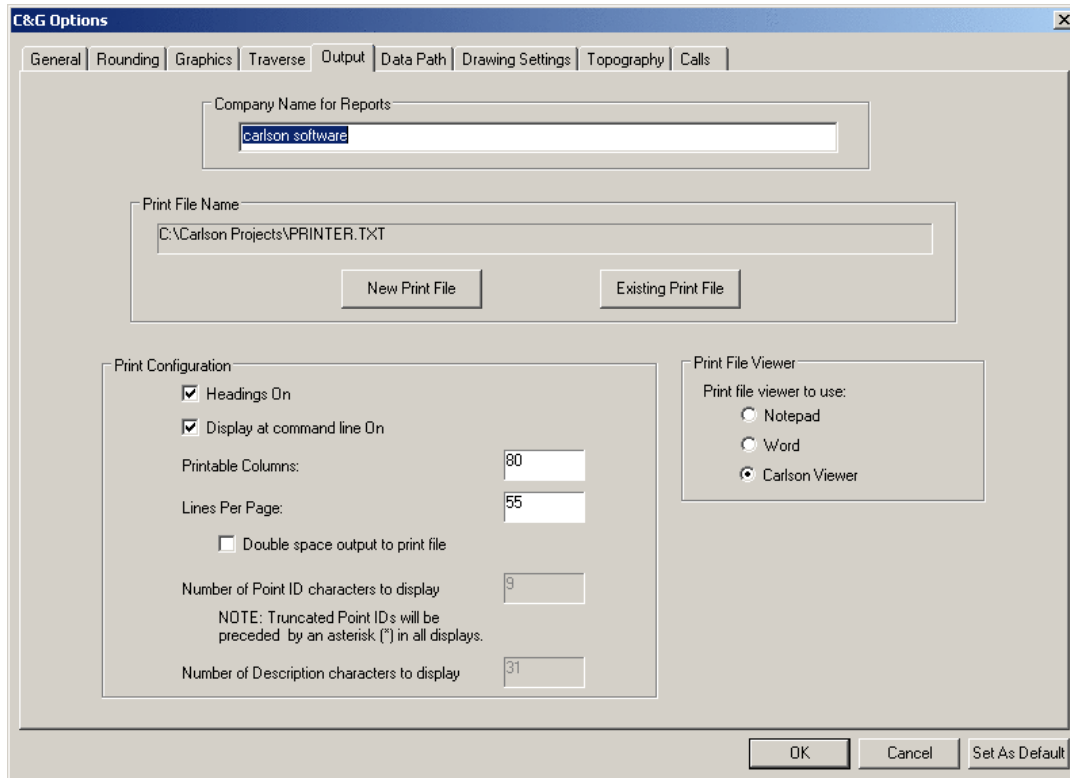

Note: Use of the EDM offset allows you to turn your vertical angles directly to the target. A correction will be applied to all distances and elevations computed from field entries in the Traverse and Quick Traverse routines. Most total stations today have the EDM coincident with the center line of instrument scope. In this case the EDM Offset should be set to zero.

Note: When an offset is entered, it is used on all distances in the traverse. If some distances are chained, the correction will also be applied. These shots should be reduced separately with no EDM Offset.

Distance Components - This option can be set to allow either **Slope Distance/Vertical Angle** or **Horizontal Distance/Vertical Distance** data entry.

If the **Curvature and Refraction ON** check box is checked, the horizontal and vertical components of all

slope distances are corrected for curvature and refraction. If your EDM does not already make this correction, it is recommended that this correction be used when carrying elevations using vertical angles and distances. This tab allows you to specify the name and format of the print file and how it is viewed.

Print File Name section

The final results of calculations and other actions performed during C&G command execution will always be printed to this ASCII text file. New information is always appended to this file and never overwritten. The default file name is PRINTER.TXT. It is recommended that you use a name that corresponds with the project you are working on. This way you will have a record of all calculations throughout the project. Use the **New Print File** button to specify a new print file to create. Use the **Existing Print File** button to specify an existing file.

Print File Viewer section

You can choose to use Microsoft Notepad or Wordpad when viewing or printing the print file. If you want the viewer to always come up full screen, check the **Force print file viewer to use full screen** checkbox.

Point Configuration section

If the **Headings On** checkbox is checked, a heading is printed to the command line and/or the print file any time multi-line output is generated by a C&G feature. The heading information contains date, time, feature name, coordinate file name and input and output scale factors. The header is repeated when the number of lines output by a function exceed the value set for **Lines Per Page**.

If the **Display On** checkbox is checked, the output from CGSurvey features is printed at the command line. Regardless of this setting, output is always sent to the print file.

Printable Columns

Use the edit box to specify the maximum number of characters per line to be written to the print file. This allows you to fit the text to the printed page given the font and paper you use. The acceptable values are 80 through 255.

Lines Per Page

This allows you to set the number of lines that will be placed on a page. If headings are on, a header will be printed to the print file and the command line each time this number of lines is exceeded.

On this tab you can specify the path to your data files. The data path is the default directory for file dialogs used in various C&G commands that open or save files.

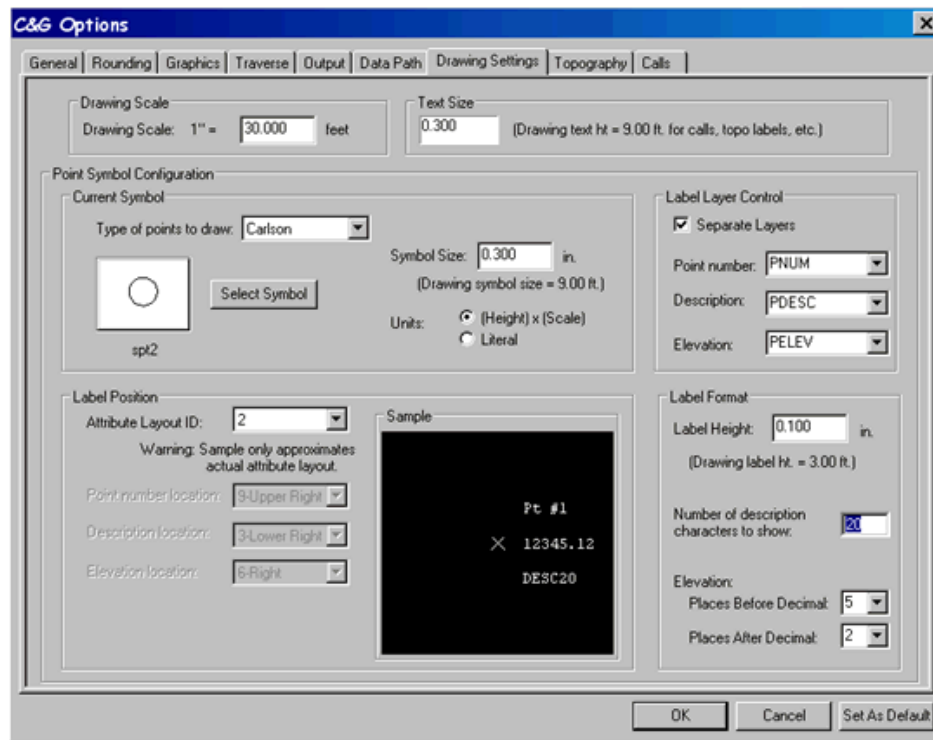

You can type the path in the **Data Path** edit box or you can use the **Browse...** button to use a file dialog to

specify the data path.

On this tab you can specify

drawing scale, text size, point symbol type and its format, and point symbol layers.

Drawing Scale section

This sets the horizontal scale. For example, if units are set to feet and you want a horizontal scale of 1" = 20' then type 20 in the Horizontal (ft/in) edit box. For metric units, if you want a scale of 1m = 500m then enter 500 in the Horizontal (m/m) edit box

Text Size section

Allows you to set the text size for any text drawn using a CGSurvey feature. The text size is the size of the text as measured on the plotted or printed page. It must be specified in inches if using feet or centimeters if using meters.

Point Symbol Configuration section

Current Symbol section

This section allows you to control the symbol, its size and how it is scaled (called units here).

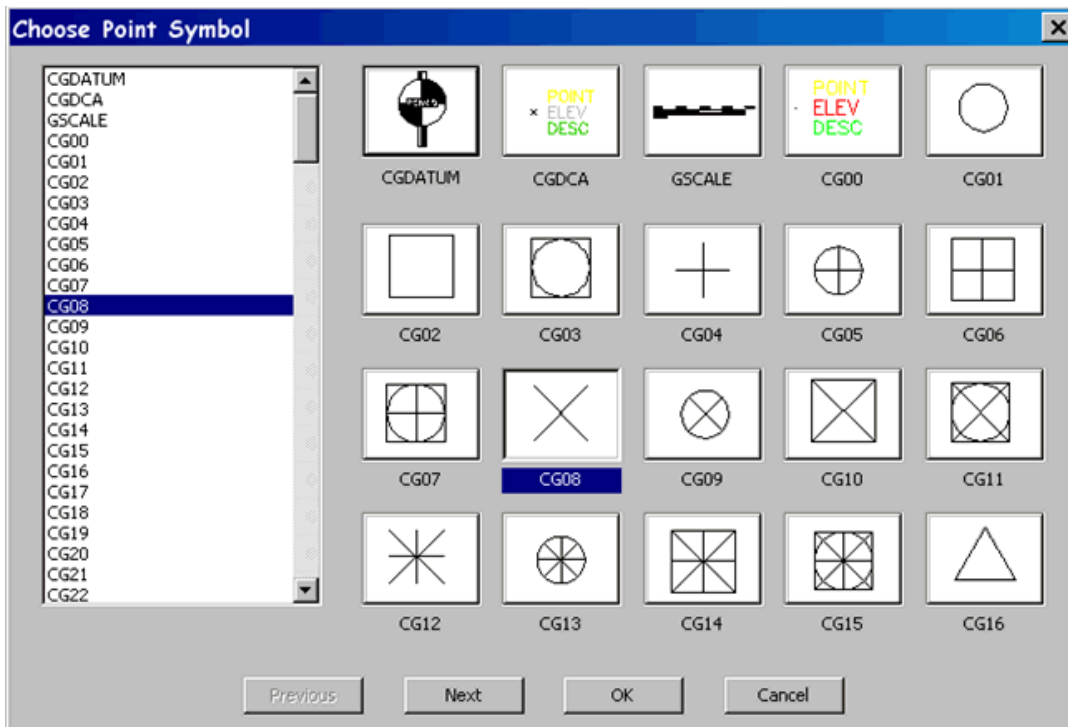

Type of Point to be Drawn: There are two point symbol libraries to select symbols from, the C&G and the Carlson symbol libraries.

Using symbols from either the C&G or Carlson symbol library both allow you to use all of the associated C&G features for plotting, sorting, line stops, attribute information, selection, etc. If you choose to use Carlson symbols the Label Position section of the dialog changes somewhat. This will be discussed later in this section.

Select Symbol button

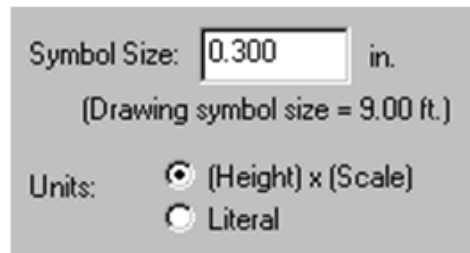

Choosing **Select Symbol** button will bring up the **Choose Point Symbol** dialog:

Use this dialog to choose the active point symbol. You do this by highlighting the symbol name in the list on the left or by clicking the symbol image on the right. Symbols CG00 and CGDCA are compatible with LDT/LDD points. The CGDCA symbol is the correct size for a true LDT/LDD point, and should be used if you are also using LDT/LDD.

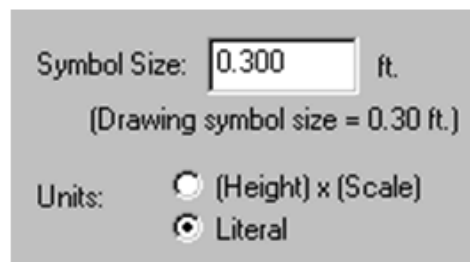

Symbol Size and Units

There are two options available for specifying symbol size: **(Height) X (Scale)** and **Literal**

Symbol Size: in.
(Drawing symbol size = 9.00 ft.)
Units: (Height) x (Scale)
 Literal

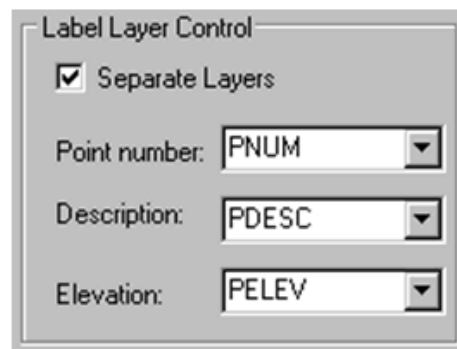

If **Units** are set to **(Height)x(Scale)**, then the symbol size entered here is specified as *plotted page units* (inches or centimeters - depending on whether feet or meters are being used). In this case, regardless of scale, the symbol will always be the same size when plotted. In example above, the symbol is set to .300". At 30 scale the symbol height will be 9 feet in the drawing itself, at 40 scale it would be 12 feet. Thus, in either case, its plotted size will be 0.3 inches.

Symbol Size: ft.
(Drawing symbol size = 0.30 ft.)
Units: (Height) x (Scale)
 Literal

If **Units** are set to **Literal** then the symbol will be drawn *in the drawing* at the size specified. This setting is often used for inserts such as title blocks, north arrows, company logos, standard notes, etc.

Label Layer Control section

Label Layer Control
 Separate Layers
Point number:
Description:
Elevation:

If you check the Separate Layers check box, you can assign each point label to a specific layer. This allows you to see only the labels you want by turning different layers on or off. If this checkbox is not checked, all the point labels will be drawn on the current layer.

Label Position section

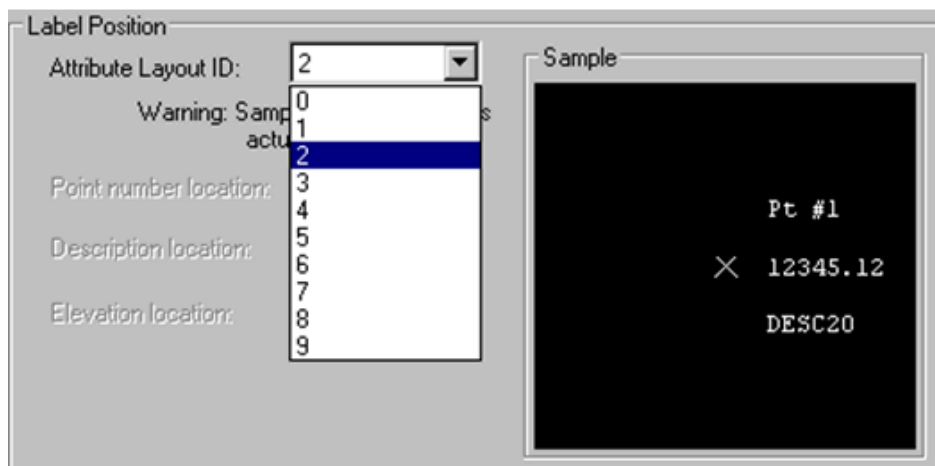

C&G Labels:

If the label location is set to **0 <Off>** that label will not be displayed when a point is plotted. Only the elevation is allowed to be at the **Center** position. If you select Center for the elevation label, the whole number portion of the elevation will be on the left side of the insertion point of the symbol and the decimal portion on the right side (example: the elevation 987.23 will be drawn as 987+23, where the plus sign represents the symbol).

If **Plot Radial** is checked, the point labels will be plotted radially from the symbol's center. If not selected, point labels will be plotted horizontally.

Label Position for Carlson Symbols

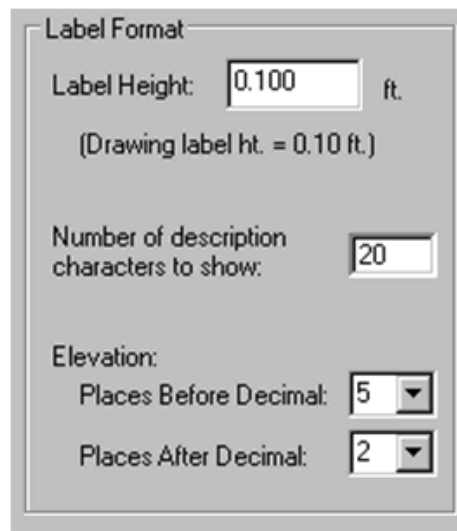

In the **Point Symbol Configuration** section of the dialog you have the option to plot C&G symbols or Carlson symbols. When the Carlson symbols are used, the **Label Position** portion of the dialog box changes to display the Carlson method for defining label positions (see below).

These "label positions" are actually pre-defined blocks with a predefined location and orientation for the attributes (or labels). There are ten blocks available. The available blocks are identified by the numbers 0 through 9.

Note: when Carlson point symbols are used, the Sample drawing is only approximate - the actual layout will look slightly different when drawn.

Label Format section

Label Height: this is the text size in inches/centimeters when **Units** are set to **(Height) x (Scale)** or feet/meters when **Units** are **Literal**. The **Label Height** is used for all three labels: point number, point description, and point elevation.

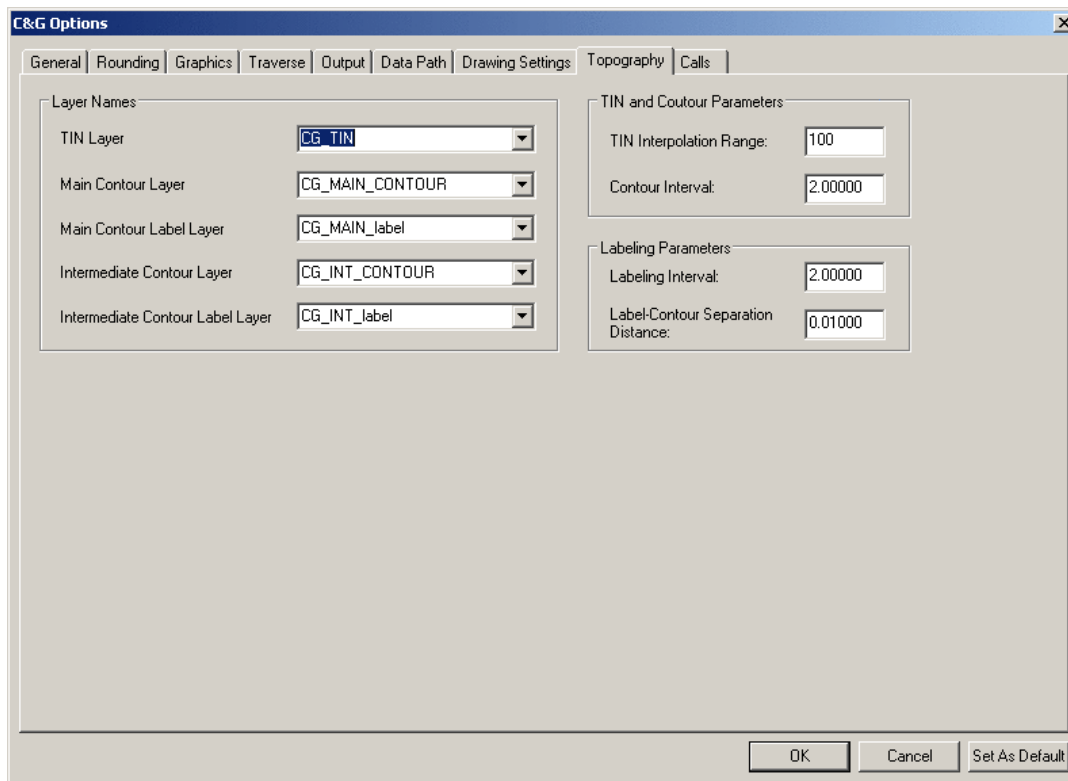

Number of description characters to show: Depending on the type of coordinate file being used, here may be as many as 255 characters in the description field. This option allows you to truncate the description at a given number of characters.

Elevation: This sets how many characters are displayed before and after the decimal point. On a flat piece of property 2 placed before the decimal may be enough information. On a steep mountain site 3 or 4 decimal places may be needed.

Topography tab

NOTE: The information on this tab is used for items on the CGTopo menu which has limited functionality and does not allow you to create a TIN. You must use the Carlson features to make, use and manipulate TINs (see Surface menu). These settings *may* be used when opening a CG-SURVEY for DOS drawing (*.PL1) when it has topo data in it.

The items on this tab allow you to specify contouring parameters and Tin, contour and other topographic entity layer specifications.

This dialog allows you to specify the drawing layers for the various topographic entities, as well as set various parameters for the creation of a new surface and placement of contour elevation labels.

Layer Names section

In this part of the dialog you can specify the layers for the various previously existing topographic entities found in the drawing. These allow you to label contours and, if necessary, remove contours and/or labels from the drawing.

TIN Layer: Specifies the layer on which triangulation network lines or TIN are found.

Main Contour Layer: Layer on which main contours are found.

Intermediate Contour Layer: Layer on which intermediate contours are found.

Main Contour Label Layer - Elevation labels for the main or index contour lines will be drawn on this layer.

Intermediate Contour Label Layer - Elevation labels for the intermediate contour lines will be drawn on this layer.

Note: The last two Contour Label Layer names will be used when labeling contours.

TIN and Contour Parameters section

TIN Interpolation Range: The interpolation range determines which points will be joined to form the triangles in the TIN. (MAY be used converting a CG-SURVEY for DOS PL1.)

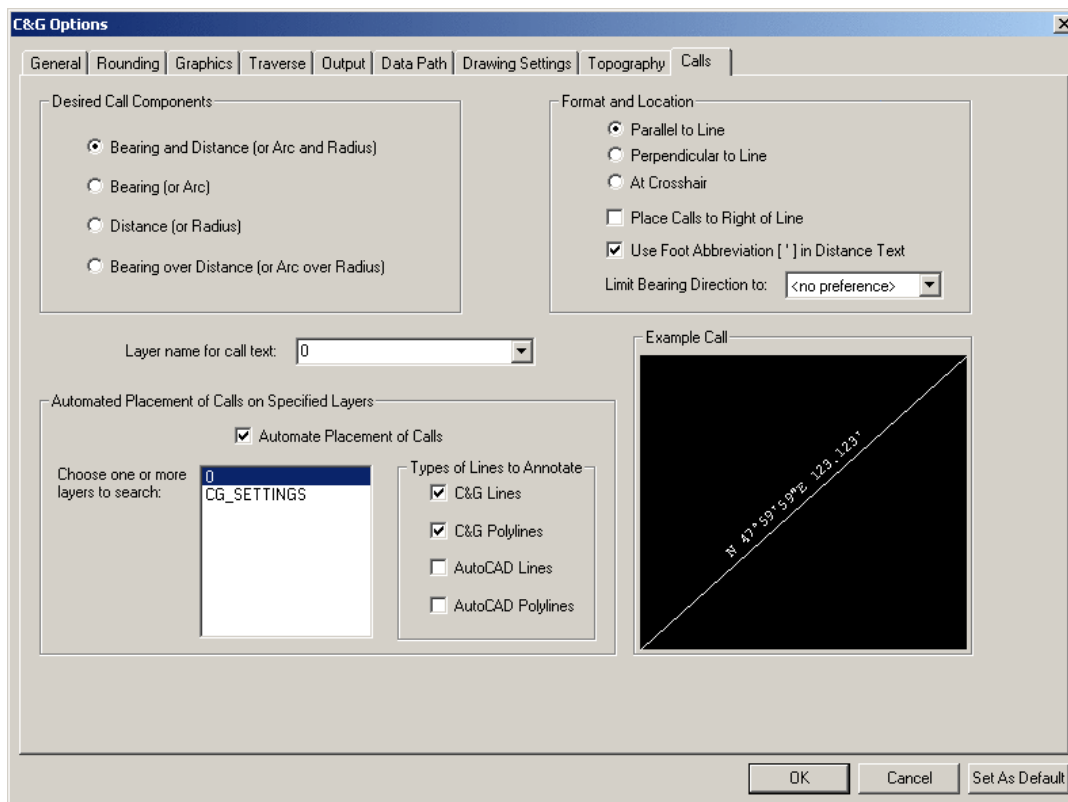

Contour Interval: (MAY be used converting a CG-SURVEY for DOS PL1.).

Labeling Parameters section

Label Interval: When labeling contours, only the contours falling on this interval will be labeled. For example, if you enter a 10' interval, only the contours at 900, 910, 920, etc will be labeled.

Label-Contour Separation Distance: This is the space between each end of the elevation label text and the contour line being labeled. A separation distance that is too small can make the elevation label hard to read, while a separation distance that is too large may not be visually pleasing.

This tab gives you several options for specifying the call or annotation format

Desired Components section

The of the dialog allows you to specify what you want displayed for a given call and whether the call text is stacked. The text in parentheses indicate the call items for a curve.

Format and Location section

The allows you to specify whether the call is placed **Parallel to Line**, **Perpendicular to Line** or requires the user to pick the location for horizontal call text (**At Crosshair**). If the **Place Calls to Right of Line** checkbox is checked the calls will be placed on the right side as determined by standing at the first point picked or the first point in a C&G line and looking toward the second point. You may also specify whether to use the foot symbol when units are feet. If bearings are being used, you may specify whether to limit bearing text to **NW,NE only** or **SW, SE only** or **<no preference>**.

Layer name for call text:

Specify the layer the call text is to be drawn on.

Automated Placement of Calls on Specified Layers section

This section of the dialog sets the parameters for a feature that allows you to place calls on C&G and/or CAD lines

and/or polylines found on specified layers. To use this option, check the **Automate Placement of Calls** checkbox. Choose one or more layer names from the list of layer names. You can specify multiple layers by holding the Ctrl key down while picking the layers to search.

In the **Types of Lines to Annotate** section, check the types of entities you wish to annotate.

Example Call section

The of the tab allows you to see a good approximation of how the call will look when drawn.

OK - click the **OK** button to save all the settings and close the dialog.

Cancel - click the **Cancel** button to close the dialog and discard any changes.

Set As Default

Click this button to save the settings to the CGSURVEY.OPT file. These settings will then be used whenever a new CGSurvey drawing is created.

Note: You can set the default settings and not affect any of the settings for the current drawing by clicking the **Cancel** button after clicking the **Set As Default** button.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_options

Prerequisite: None

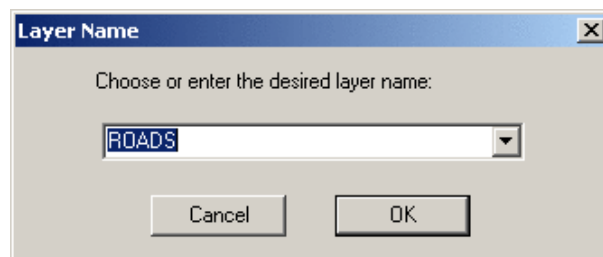

Copy Entity to Layer

This feature allows you to easily copy a single entity or group of entities from one layer to another.

Choose entities to copy:

Select entities: use the standard CAD selection methods to choose one or more entities to be copied. Once you have selected the entities press Enter.

Next use the **Layer Name** dialog to choose the layer to copy the entities to:

Prompts

Choose entities to copy:

Select entities: use the standard CAD selection methods to choose one or more entities to be copied.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_copyent

Prerequisite: None

Layer Control

These routines allow you to freeze, thaw, restore, turn on and off, and set the current layer without having to open the CAD layer manager.

Pick Layers to Freeze

This feature allows you to freeze layers by picking entities that are on layers you wish to freeze. You may pick as many entities as you wish.

Prompts

Select object on layer to FREEZE.

Select entities: choose objects on the layers you wish to freeze. Press Enter when done.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_lfreeze

Prerequisite: None

Pick Layers to Thaw

This feature allows you to thaw frozen layers by picking entities that are on a layer you wish to freeze. All frozen layers are turned on while you pick the entities. You may pick as many entities as you wish.

Prompts

Select object(s) on layers to keep THAWED.

Select entities: choose objects on layers you wish to thaw. Press Enter when done.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_lthaw

Prerequisite: None

Freeze ALL Layers

Choosing this menu item causes all layers, except the current layer, to be frozen.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_alfreeze

Prerequisite: None

Thaw ALL Layers

Choosing this menu item causes all layers to be thawed.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_althaw

Prerequisite: None

Pick Layers to turn Off

This feature allows you to turn off layers by picking entities that are on layers you wish to turn off. You may pick as many entities as you wish.

Prompts

Select object on layer to turn OFF. choose objects on layers you wish to turn off. Press Enter when done.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_loff

Prerequisite: None

Pick Layers to turn On

This feature allows you to turn on layers by picking entities that are on layers you wish to turn on. All layers will be turned on during the command to allow you to pick the desired entities. You may pick as many entities as you wish.

Prompts

Select object(s) on layers to keep ON.

Select entities: choose objects on layers you wish to turn on. Press Enter when done.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_lon

Prerequisite: None

Turn OFF ALL Layers

Choosing this menu item causes all layers, except the current layer, to be turned off.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_aloff

Prerequisite: None

Turn ON ALL Layers

Choosing this menu item causes all layers to be turned on.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_alon

Prerequisite: None

Pick Current Layer

This feature allows you to pick an entity that is on a layer you wish to make the current layer.

Prompts

Set Current Layer - Select entity on the desired layer: pick the entity which is on the layer you want to made the current layer.

Pulldown Menu Location: CG-Survey > Tools > Layer Control

Keyboard Command: cg_lset

Prerequisite: None

Elevations

If this menu item is checked, then point elevations are ON. If it is unchecked then point elevations are OFF.

When point elevations are ON and the **Enter Elev.** radio button is set on the **General** tab of the **C&G Options** dialog, you will be prompted to enter an elevation when new points are saved to the coordinate file. When point elevations are ON and the Calculate Elev. radio button is set you will not be prompted to enter an elevation. When point elevations are OFF, no elevation is stored when coordinate points are saved to the coordinate file.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_elev

Prerequisite: None

Descriptions

If this menu item is checked, then point descriptions are ON. If it is unchecked then point descriptions are OFF. Generally, when point descriptions are on, you will be prompted to enter a description when new points are saved to the coordinate file. Also, when descriptions are ON, the description field will be enabled when editing coordinate point values.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_desc

Prerequisite: None

Point Code

If this menu item is checked, then point codes are ON. If it is unchecked then point codes are OFF. Point codes are unique to C&G coordinate files that can be used to filter or group points in various C&G features.

When point codes are ON, you will be prompted to enter a point code when new points are saved to the coordinate file. When point codes are OFF, no code is stored when coordinate points are saved to the coordinate file.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_code

Prerequisite: None

Auto Point Number

If the **Auto Point Number** menu item is checked then automatic point numbering is ON. This means that, as points are created they will automatically be assigned the next available point ID in the current coordinate file and will be saved without any user interaction.

When auto point numbering is OFF, as points are created you will be asked to enter the point ID. If you enter a point ID that already exists in the coordinate file, you will be asked if you want to overwrite the existing point or enter a new point ID.

See also: **Automatic Point Numbering ON** checkbox on the **General** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_auto_num

Prerequisite: None

Auto Point Plot

If the **Auto Point Plot** menu item is checked, when a point is calculated and stored in the coordinate file it will be plotted in the drawing.

See also: the **Auto Point Plot ON** checkbox on the **Graphics** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_auto_pt_plot

Prerequisite: None

Auto Lines

If the **Auto Lines** menu item is checked, automatic line plotting is ON. When automatic line plotting is ON, the following COGO features will automatically draw lines and curves using the newly calculated points as they are saved to the coordinate file:

Quick Traverse - but lines will not be drawn to side-shots

Curve Between Tangents and **Tangent Between Curves**

Bearing Area Cut-Off

Hinge/Radial Area Cut-Off

Roadway (**Right-of-way** and all **Cul-de-Sacs** and **Intersections** features)

Middle Ordinate Solution for curves

Best Fit

See also: **Auto Line Plot ON** checkbox on the **Graphics** tab of the **C&G Options** dialog.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_tog_auto_lines

Prerequisite: None

CG Snap

C&G Snaps are object snaps that are active only during a C&G command. These snaps allow you to pick point symbols and/or C&G lines by clicking near them. They work similar to the CAD snaps but only snap to C&G entities. The C&G snaps work in conjunction with the normal CAD snaps but, when a C&G command is run, the CAD snaps are automatically turned off at the start of the command and the C&G snaps become active. In almost all C&G features you have the option of turning the CAD snaps back on if desired. When both the CAD and C&G snaps are on, the CAD snaps are applied first to determine the x and y screen coordinates of the point on the appropriate CAD entity; these coordinates are then passed to C&G and they are used to apply the C&G snaps and find the nearest appropriate C&G entity.

Note: If CAD snaps are turned on during a C&G command and if C&G snaps are also on, a double snapping process occurs. Because of this double snapping, it is recommended that when C&G Snaps are on, CAD snaps should be left off during C&G commands.

Note: If snapping is desired and C&G snaps are off, then the CAD snaps must be turned on each time a C&G command is run.

Pull-down Menu Location: CG-Survey > Tools

Keyboard Command: None

Prerequisite: None

Off

This turns off all C&G snaps.

Note: This setting applies ONLY to C&G features and is not directly supported by whatever CAD software you are using.

Pull-down Menu Location: CG-Survey > Tools

Keyboard Command: cg_snap_off

Prerequisite: None

Points

This allows you to pick near and snap to a C&G point symbol whenever a point ID is required for a C&G feature.

Note: This setting applies ONLY to C&G features and is not honored by whatever CAD software you are using.

Pull-down Menu Location: CG-Survey > Tools

Keyboard Command: cg_snap_points

Prerequisite: None

Lines

This allows you to pick near and snap to a C&G line whenever a bearing, distance, or pair of points is required for a C&G feature.

Note: This setting applies ONLY to C&G features and is not honored by whatever CAD software you are using.

Pull-down Menu Location: CG-Survey > Tools

Keyboard Command: cg_snap_lines

Prerequisite: None

Points and Lines

This allows you to pick near and snap to a C&G point or line whenever a point ID, bearing, distance, or pair of points is required for a C&G feature.

Note: This setting applies ONLY to C&G features and is not directly supported by whatever CAD software you are using.

Pull-down Menu Location: CG-Survey > Tools

Keyboard Command: cg_snap_points_lines

Prerequisite: None

Zoom to Point ID

This feature pans the drawing in order to place the location of the point ID you specify at the center of the screen. It is not necessary to plot the point symbol prior to using this feature.

Prompts

Point ID of point to zoom to: specify the point ID of a point in the current coordinate file.

The drawing will be panned to center the point and a "rubber band" line will extend from the point to your cursor.

Stopping to view point [View another/Done] <D>: Press "D" and Enter or just Enter to clear the rubber band line and return to the CAD command line. Press "V" and enter to specify another point ID.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: cg_zoom_pt

Prerequisite: coordinate file

Windows Calculator

Selecting this menu item will bring up the standard Microsoft Windows® calculator.

Pulldown Menu Location: CG-Survey > Tools

Keyboard Command: 'cg_cal

Prerequisite: None

CGEditor

The CGEditor is an integral part of preparing files for use for C&G applications. The CGEditor is a very powerful tool. You can open multiple data files of any supported file type and edit the files as needed. The CGEditor has a full complement of tools for searching and replacing and navigating within a file. It will also allow you to cut or copy records from one file and paste them into another file in order to merge files, move data between phases of a job, etc.

Types of data files supported

The CGEditor can create and/or edit four types of data files used by CGSurvey and Carlson.

Raw Data Files

Raw data files contain information pertaining to a field traverse. Raw data files are typically downloaded from the data collector and converted to the C&G raw data file format. These files have the extension .cgr.

Map Check Files

Map Check files contain bearing, distance and curve information and are typically used to calculate the closure of a deed description. These files have the extension .cgm.

Cross Section Files

Cross Section files contain one or more cross sections identified by their station along the alignment. Each cross section record has the percent grade defined for its left and right slopes. Following the "Station" record are several "Point" records containing the elevations and offsets of the points along the cross section. Cross section files consist

of a pair of files; the main data file has the extension .cew and the index file has the extension .cex.

Template Files

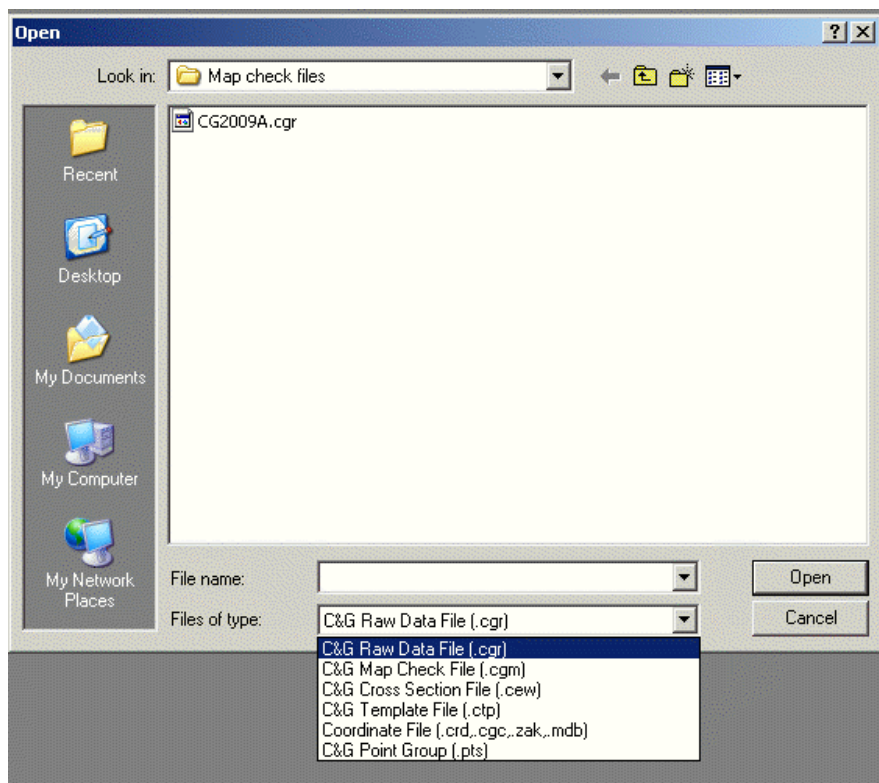

Template files are merely cross section files that represent a standard cross section and can be used to generate other cross section files. However, unlike cross section files, template files use an integer ID instead of a station to uniquely identify each template. Like cross section files, the percent grade is defined for the left and right slopes of each template and there are a set of "Point" records specifying the template elevation at a given offset. The centerline elevation at offset 0.00 is typically set to 0.00. Template files consist of a pair of files; the main data file has the extension .ctp and the index file has the extension .ctx.

NOTE: The CGEditor program sold as part of the standalone version of SurvNET can only be used to edit raw data files.

The CGEditor can be used to create new files or edit existing files. It uses a multi-document interface, so you can edit or view several files of several different types at the same time. The following sections will describe how to open and edit files.

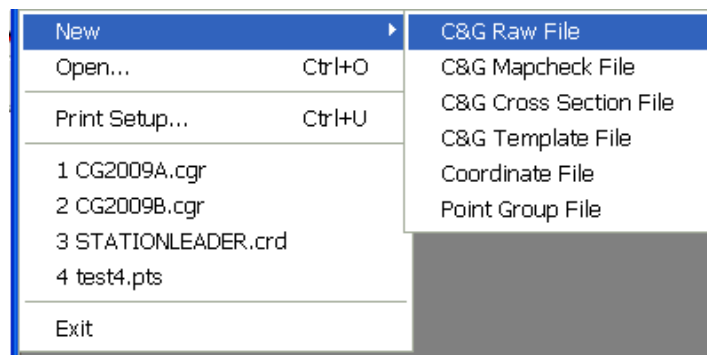

Opening Existing Files

To open an existing file, click on the **File** menu then choose **Open** in the submenu. You can then use the Open file dialog box to browse to the desired file. Check to make sure the **Files of Type:** is set correctly. Click on the desired file to highlight it, then click the **Open** button.

Creating Files

To create a new file, use the **File** menu and choose **New** and then click on the type of file you wish to create:

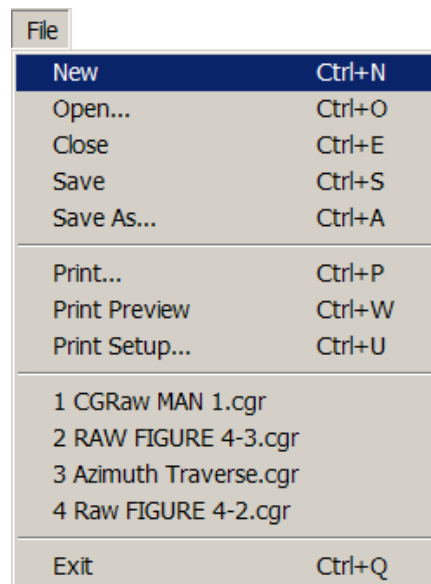

- C&G Raw File**
- C&G Mapcheck File**
- C&G Cross Section File**
- C&G Template File**
- Coordinate File**
- Point Group File**

After clicking the menu item for the type of new file you wish to create, a temporary file is created with no data in it and a spreadsheet-like window will open. At this point more menu items will be added to the main menu and, as you will see, the **Add** menu item will allow you to insert data rows (or records) where you can enter your data.

NOTE: The CGEditor program sold as part of the standalone version of SurvNET can only be used to edit raw data files.

The CGEditor Menus

File Menu

Many of the following File menu items will be familiar to experienced Windows users:

New: Allows you to create a new file.

Open (Ctrl + O): Brings up the Open File dialog box so you can select and edit an existing file.

Close (Ctrl + E): Closes the current data file. If more than one file is open, the file that is currently being worked on will be closed.

Save (Ctrl + S): Saves the current file.

Save As: Allows the user to save the current file to a file having a different name.

Print (Ctrl + P): Allows the user to print a copy of the currently active file.

Print Preview (Ctrl + W): Display a preview of the file about to be printed.

Print Setup (Ctrl + u): Printer selection as well as page size and layout.

Exit (Ctrl + Q): Exit the CGEditor application.

Edit Menu

As with the File menu, the Edit menu is typical of most Windows programs.

Most of the items in the Edit menu require that either a field within a record, or the entire record itself, be selected (highlighted) before clicking the menu item. To select a an individual data item (or field) in a data record simply click the field. To select a record (row) simply click in the first field (Type or Row#) for the desired record.

Undo (Ctrl + Z): Undoes the most recent editing action. (you need not have anything highlighted for this item)

Redo (Ctrl + Y): Reverses the most recent undo action. (you need not have anything highlighted for this item)

Cut (Ctrl + X): Cuts the currently highlighted cell or record. You may then use the paste command to put the cut cell or record in another location.

Copy (Ctrl + C): Copies the currently highlighted cell or record. You may then use the paste command to put the copied cell or record in another location.

Paste (Ctrl + V): Allows you to paste any previously cut or copied cell or record to the currently highlighted location.

If entire records are being pasted and only a field is currently highlighted, the pasted records will be inserted above the current record. However, if one or more entire records are currently highlighted, the pasted records will replace the highlighted records.

Delete (<Delete> key): Deletes the currently highlighted field or record.

Select All (Ctrl + A): Selects all the records in the current data file.

Clear (Ctrl + L): Removes the data from the selected field or record.

Add Menu

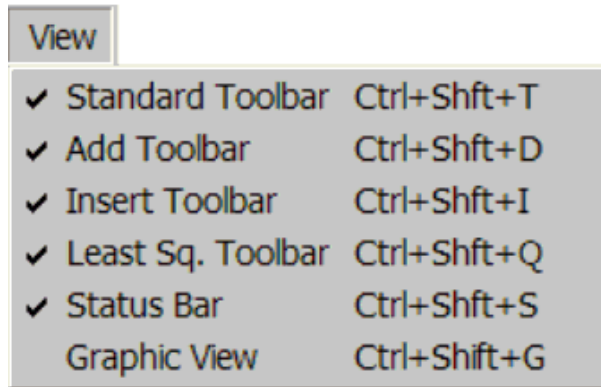

The Add menu allows you to add a record to the current file. The Add menu item appends the record to the end of the file. The types of records that can be added will depend on the type of file being edited, these record types will be described in more detail in later sections for each type of file you can editor.

Insert Menu

The Insert menu allows you to insert a record above the current record.

The types of records that can be inserted will depend on the type of file being edited, these record types will be described in more detail in later sections for each type of file you can edit.

View Menu

The View menu allows you to turn tool bars on or off. The items listed in the View menu will differ for different types of files. The individual tool bars will be discussed in the sections pertaining to the various types of files that can be edited.

Standard Tool Bar

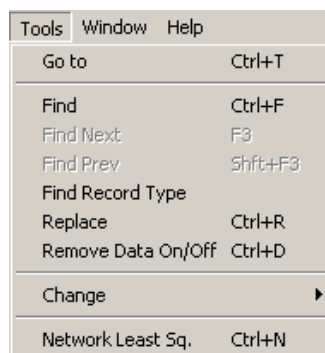

The above figure shows the standard tool bar. The Standard toolbar is the same for all types of files. It allows you to create all the various files that can be edited by the CGEditor. It allows you to open and save files. It allows you to cut, copy and paste and undo and redo as well as print the current file.

Settings

The Settings Menu will differ depending on the type of file being edited. But generally contains the settings for the file and the record colors.

Tools

The Tools Menu contains a variety of spread sheet tools, such as find, find next, find and replace etc. The menu will vary slightly for each type of data file and will be discussed in the sections pertaining to the various file types.

Windows

This menu contains many of the standard Window menu items found in other programs. It allows you to arrange the currently open windows in several configurations. It has the added functionality of the New Window command which allows you to have two or more views of a single file.

Traverse types

The raw data file can contain data pertaining to one or more traverses. If you will be using SurvNET to process the data, there is no need to delineate separate traverses in the raw data file. However, if you are using the old C&G traverse reduction program, and you want to combine more than one traverse in a raw data file, you will need to use the special traverse code records at the beginning and end of each traverse.

There are three basic types of traverses:

Closed Loop Traverse

Closed Traverse Beginning and Ending at Known Points

Open Traverse and Side Shots

Figures 1, 2, 3 and 4 show illustrations of each of these traverse types. Below each illustration you will also see the accompanying raw data as seen in the CGEditor.

Closed Loop

A closed loop begins and ends on the same two points as shown below in Figure 1

Figure 1

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist.	Vert.Angle	Foresight	Code	Description
IP	1	5.32000	5		0.00000					
FS				5.00000	109.19170	292.31000	88.35000	2	TP	H&T
IP	2	5.20000	1		0.00000					
FS				5.00000	96.03560	324.26000	88.51320	3	TP	IPF
FS				5.00000	190.32100	52.39000	90.32550	6	SS	IPF
IP	3	4.90000	2		0.00000					
FS				5.00000	124.03560	275.84000	92.22400	4	TP	IPF
IP	4	5.12000	3		0.00000					
FS				5.00000	93.02130	309.68000	89.13000	5	TP	IPF

FS				5.00000	117.30500	290.55000	90.00000	1	TP	IPF

Closed Loop beginning and ending on known points

Figure 2 shows a closed traverse beginning on two known points (1 and 2) and ending on two known points (4 and 5). With this type of traverse, both a linear and angular closure can be calculated

CLOSED LOOP TRAVERSE BEGINNING AND ENDING AT KNOWN POINTS

Figure 2

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist.	Vert.Angle	Foresight	Code	Description
IP	2	5.90000	1		0.00000					
FS				5.00000	50.11150	164.12000	88.20200	7	TP	H&T

IP	4	5.30000	8		0.00000					
FS				5.00000	62.55100			5		

Loop beginning on two known points and closing on an azimuth

Figure 3 illustrates a traverse that begins on two known points, or a single known point and a back sight azimuth, and ends on one known point. In this case it is only possible to calculate a linear closure.

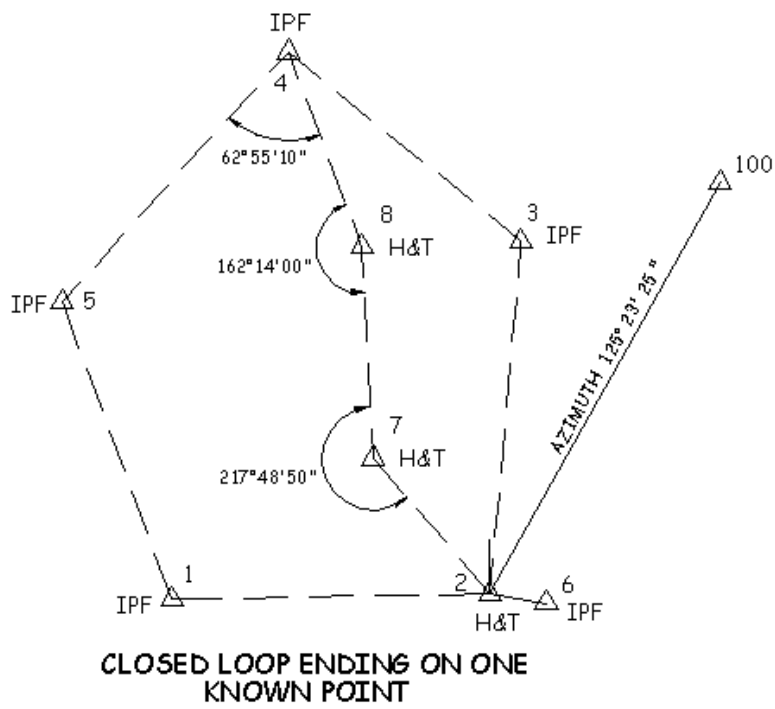

Figure 3

Set	From Point	To Point	Bearing							
DR	2	100	125.23240							
IP	2	4.90000	100		0.00000					
FS				5.00000	50.11150	164.12000	88.20200	7	TP	H&T

FS				5.00000	87.23150			101		

Open Traverse

Figure 4 shows an open traverse (side shots).

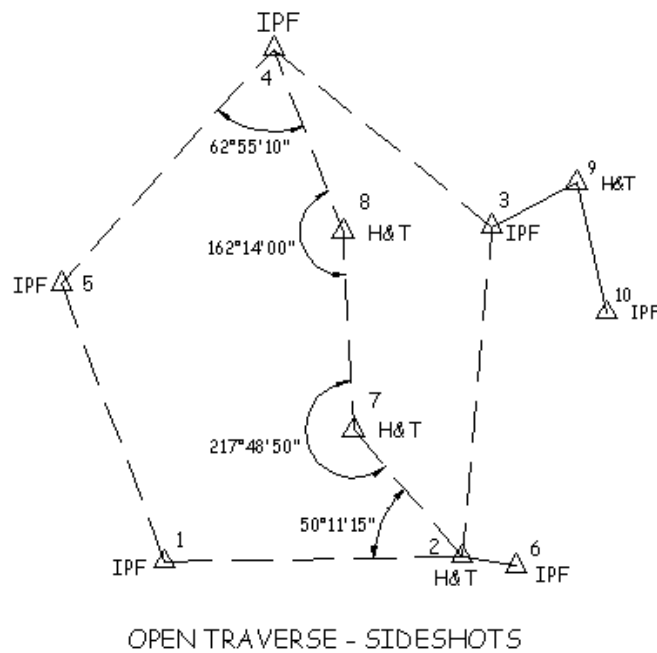

Figure 4

Set	Inst.Point	Inst.Height	Backsight	Rod Height	Horz.Angle	Slope Dist	Vert.Angle	Foresight	Code	Description
IP	3	5.12	4		0.00000					
FS				5.00	113.19430	92.91000	89.15300	9	TP	H&T
IP	9	5.26	3		0.00000					
FS				5.00	284.01250	130.44000	91.15210	10	TP	IPF

Note: The data shown in the CGEditor views accompanying the four illustrations include instrument height (HI) and rod height entries. However, if you have elevations turned off, these entries are optional. Also, the examples use single distance and angle entries but multiple measurements are allowed.

In these figures each traverse has been placed in a separate raw data file. However, with the use of special codes you can combine multiple traverses in a single raw data file.

Entering and Editing Traverse Data

In the CGEditor "Raw Data" refers to unadjusted field traverse data, typically downloaded to the PC from a data collector. C&G raw data files have the extension .CGR.

Creating or Opening a Raw Data File

To create a new file or open an existing file click on the **File** menu then either click on **New** or **Open**. If you click on **New**, another submenu will appear, pick **C&G Raw Data File**. In either case you will then see a file dialog. Browse to the directory where you wish to work and, if creating a new file, type in a file name, or, if opening an existing file, click on a raw data file (*.cgr). Next, click the **Save** button for a new file or the **Open** button for an existing file.

If you are creating a new file, an empty file will be shown in its own document window within the editor. If you are editing an existing file, the data from the file will appear in a similar document window. It is possible to have multiple documents open at the same time. So you could create a new file and open an existing file in the same editing session and each would appear in its own window in the editor. You can have as many new and/or existing

files open as your project demands.

Settings

Before entering any data you should check the current settings. Click the Settings menu item then click Raw Data File to review and/or change the current settings. (See Settings Menu section later in this section.)

Traverse Data Entry

A line or row in the raw data file is referred to as a record and each item of data in a record is referred to as a field. There are several types of records that you may use in a raw data file:

Instrument Point
Foresight
Foresight Tie
Reference Bearing
Coordinate Value
Standard Errors
Control
Measurement
Setup
Elevation
Scale
Loop Traverse
Closed Traverse
Open Traverse
End Traverse
Data on/off
Comment

The type of data required for each of these types of records varies. Some require no data entry and are only "flags" to signify the beginning or ending of a series of records, others require only one field to be filled out, while others require several fields of data.

Adding and Inserting new records

When creating a new file, to begin entering data you must select from the **Add** or **Insert** menus to create the first blank record and begin data entry. Depending on what type of record you are editing, when you press <Enter> for the last field in the record, the following record will be added automatically.

Note: If the **Add** and/or **Insert** toolbars are not showing, click on the View menu then click on the toolbar you want to turn on.

When you click on one of the **Add** menu items or toolbar icons, an empty record is added to the end of the file. If you click on one of the **Insert** menu items or toolbar icons, an empty record is inserted above the currently active record or field. To make a record the currently active record, just click on one of its fields.

Moving from field to field:

While entering data, to move to the next field, press the Enter or the Tab key. To move to the preceding field press the Esc key or both the Shift and Tab keys at the same time.

Insert and Add menus

Insert	
Instrument Point	Ctrl+Alt+P
Foresight	Ctrl+Alt+R
Foresight Tie	Ctrl+Alt+G
Reference Bearing	Ctrl+Alt+B
Coordinate Value	Ctrl+Alt+U
Coords From File	Ctrl+Alt+F
Standard Error	Ctrl+Alt+S
Elevation	Ctrl+Alt+I
Scale	Ctrl+Alt+C
Loop Traverse	Ctrl+Alt+L
Closed Traverse	Ctrl+Alt+D
Open Traverse	Ctrl+Alt+O
End of Traverse	Ctrl+Alt+N
Data On/Off	Ctrl+Alt+X
Comment	Ctrl+Alt+M

Instrument Point records

The first record of a raw data file is often an instrument point. Add or insert a blank record using the menus or toolbars. Fill in the following fields in the new instrument point record:

Inst. Point:

Enter the point ID of the instrument point.

Inst. Height (or HI):

Enter the instrument height. This may be either the distance from the IP on the ground ("Plus-up") or the actual elevation of the instrument, depending on how the data is to be reduced. This field will only be active if elevations are on. (See the Settings section in the Entering and Editing Traverse Data section of this chapter). If elevations are ON and you leave this field BLANK (zero is a valid height), all measurements taken at this setup will be considered 2D and no elevations will be calculated.

Backsight:

Enter the point ID for the backsight.

Rod Height:

Enter the rod height. This field will only be active if elevations are on. (See the Settings section in the Entering and Editing Traverse Data section of this chapter).

Horz. Angle:

Enter the instrument's initial horizontal angle reading at the backsight. When doing an azimuth traverse, no entry is required here.

Note: on doubled angles: Doubled angles require 2 Instrument Point records. Each new instrument setup requires a 0 to the back sight. The first angle to the foresight is the single angle. This angle is locked into the gun and the back sight is retaken. The second angle to the foresight is the doubled angle. You may also double angles to side shots.

Slope Distance and Vertical Angle or Horizontal Distance and Vertical Distance to the Back sight:

Enter the appropriate distance and/or angle. A blank is assumed to be a zero.

Note: When the **Slope Dist/Vert Angle** or **Horz. Dist/Vert. Dist.** column headings are preceded by a "^", it indicates that a record inserted before the current record (or added after the current record) will have the same type of distance entry mode. For example, if the heading shows Dist and Angle and you insert a record, the new record will be in the Slope Dist/Vert Angle distance entry mode. You can change this by clicking on one of the distance headings to remove or add the "^". If the "^" is not present it means that the inserted or added record will have the opposite distance entry mode than does the current record.

If, after entering the data in the last field of a given Instrument Point record, you press the Enter or Tab key, a **Foresight** record will automatically be created. If you want to change this newly created blank **Foresight** record into an **Instrument Point** record, press the Esc key. If you are at the end of the file, pressing Esc again to delete last blank record.

Foresight Point records

After entering the data for the last field in the **Instrument Point** record, press Enter. This will cause a **Foresight** record to be created below it. This record will contain the following columns (the explanations of several of these columns are as described for **Instrument Points**, only the differences will be noted here):

Rod Height:

This column is only active if elevations are on. If elevations are ON and this field is left BLANK, the point will be considered 2D and an elevation will not be calculated. **Horz. Angle:**

Enter the instrument's horizontal angle reading at the foresight point. Enter a positive value for a clockwise angle and a negative value for a counter-clockwise angle. This entry may be blank if you are entering only the distance readings to the foresight.

Slope Dist./Vert Angle or Horz. Dist/Vert. Dist.:

Enter the distance data for the foresight point.

Foresight:

Enter the Point ID for the foresight point.

Code:

Enter the code for the Foresight Point. This column is only active if Code is on. (See Settings in this section.)

Description:

Enter the description for the Foresight Point. The number of characters you are allowed to enter is set in the Settings under Description Length. If you enter an integer code here and the Translate Raw Descriptions Using Description Table is checked in the Settings and a matching description number is found in the description table, then the description from the table will replace the integer value you entered in the Description field. The integer value you entered will then be moved to the Code field.

Note: **Side shots** should be placed within the block of foresights immediately following the instrument point record for the instrument point from which they were shot. You may append side shots to the end of a traverse file, but they must be preceded by a begin open traverse record.

Foresight Tie records

In some cases, you will need to tie to an existing traverse. You use a **Foresight Tie** record to do this. This record is used in the reduction process to determine what known point you are tying into. It is necessary if there are side shots taken at the last setup along with the tie point.

In a closed traverse, you must end a traverse by occupying a known point and turning an angle to a second known point. The second known point is the tie point.

Reference Bearing

From Point

Enter the point ID of the from point.

To Point

Enter the point ID of the to point

Bearing (Azimuth)

Bearings must be entered in the form Qdd.mmsss where Q is the quadrant (1 = NE, 2 = SE, etc), d is whole degrees, m is minutes, and s is seconds (you can specify seconds to the nearest .1 seconds but when you do not wish to specify tenths of a second, a trailing zero is not required)

Azimuth is entered as ddd.mm.sss (when the leading d or the trailing s is zero, it is not required)

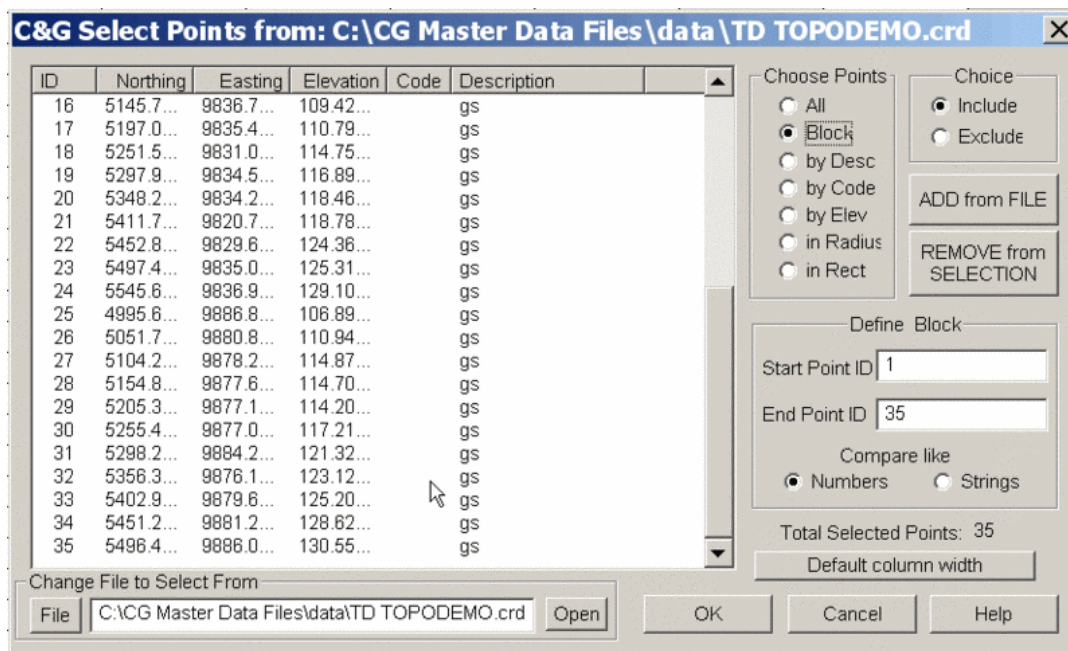

Coordinate Value record

You can use either the Add or Insert menus or toolbars to create a new coordinate record. You can then hand enter known coordinates for a point. Coordinates can be used as a reference point during the reduction process.

Entering Coordinate Value records from a Coordinate File

Instead of hand entering coordinate points, you can insert coordinate records from an existing coordinate file.

Click the Insert menu, then pick the Coords From File menu item.

Elevation

You can specify the elevation for a given point ID using an Elevation record.

Scale

You may specify a scale factor in a Scale record. A scale factor is a decimal number. You may enter as many scale factors as you wish. A scale factor will be used until another is encountered. Scale factors should be placed before an Instrument Point record.

Note: Multiple Traverses: If you are combining more than one traverse in a single raw data file, you must separate the traverses with special records. After inserting or adding a begin traverse record, you may type in a comment regarding the traverse in the Comment column. You may also specify the order in which the traverses are to be processed by using the first part of the Comment field. Please see Traverse reduction order below for more details.

Note: If you are processing the data with SurvNET, the Scale records are ignored. SurvNET calculates scale factors automatically when working on State Plane coordinates.

Beginning and/or ending a Traverse

Note: If you are processing the data with SurvNET, Traverse Records (LT, OT, CT, ET) are ignored. Since SurvNET adjusts all data simultaneously, it requires no traverse definitions.

Use **Loop Traverse**, **Open Traverse** and **Closed Traverse** records to delineate multiple traverses within a single file.

Traverse reduction order

The order in which the traverses appear in the raw data file is typically not important. Traverses are processed in the order in which they appear in the file. Traverses may be entered in a sequential order or you may embed one traverse within another. However, if the coordinates computed from one traverse are needed for the reduction of another traverse, then traverse order IS important. If this condition is true for a raw data file and the traverses have NOT been placed in the raw data file in the correct order, then you need to specify a **Traverse Order Number** for each traverse in the file.

Note: If you specify Traverse Order Numbers, the traverses in the file will be reduced in the order of their Traverse Order Numbers.

Traverse Order Numbers

Each **Loop Traverse**, **Open Traverse** or **Closed Traverse** comment field can contain a Traverse Order Number.

Note: The Traverse Order Number must be an integer and must appear as the first entry in the Comment field separated from the remainder of the comment by a space.

For example, the comment field of a **Loop Traverse** record having a **Traverse Order Number** of 3 should look like this:

3 this is a comment

If any one *Begin Traverse* record has a *Traverse Order Number*, then all *Begin Traverse* records MUST have a *Traverse Order Number*. Also, the *Traverse Order Numbers* in a given file must begin with 1 and continue sequentially. You may not duplicate a *Traverse Order Number* for any *Begin Traverse* record in a given file.

IMPORTANT NOTE: Reducing a raw data file having **Traverse Order Numbers** that violate any of the above specifications will have unpredictable results. Error messages during the reduction process may not reflect the fact that improper traverse order numbering is actually the root cause of the problem.

Loop Traverse

This record indicates the beginning of a loop traverse. A loop traverse begins and ends at the same point. If you wish to add a comment to identify the traverse in some way, just type it in the Comment column.

Closed Traverse

This record indicates the beginning of a closed traverse. A closed traverse ties into known points at both ends. If

you wish to add a comment to identify the traverse in some way, just type it in the Comment column.

Note: If you are running a Closed Traverse and tying into a single point, a reference azimuth must be placed at the last instrument point if you wish to adjust the angular error.

Open Traverse

This record indicates the beginning of an open traverse. An open traverse is a group of side shots. If you wish to add a comment to identify the traverse in some way, use the **Comment** column.

End Traverse

Signals the end of the data records for any of the traverse types.

Comment

Inserts a comment line above the current active line. Comment lines are ignored during processing.

Data On/Off

Data On/Off records surround a series of records that are to be ignored during processing by C&G or SurvNET. The first **Data On/Off** record encountered causes processing to skip to the next **Data On/Off** record. Processing continues beginning at the record after the second **Data On/Off** record. This can be used when trying to isolate errors in a traverse.

The Add and Insert Tool bars

ADD Tool Bar: add the various types of traverse records to the end of the current file.

Insert Tool Bar: insert one of the various types of traverse records above the current record.

Notice that the only difference between the appearance of the Add Toolbar and the Insert Toolbar above is the check mark in the lower right hand corner of each icon of the Insert Toolbar.

Toolbar Icon Explanation

IP Add/Insert an Instrument Point record

FS Add/Insert a Foresight record

FT Add/Insert a Foresight Tie record

DR Add/Insert a Reference Bearing record

S Add/Insert a Scale record

C Add/Insert a known Coordinate point record

E Add/Insert an Elevation benchmark record

LT Add/Insert a Loop Traverse record

OT Add/Insert a nOpen Traverse record

CT Add/Insert a Closed Traverse record

ET Add/Insert an End Traverse record

SE Add/Insert a Standard Error record for Network Least Squares Adjustment (SurvNET) program

Co Add/Insert a Comment record

The Least Squares Toolbar

The "network" icon:

Selecting this icon will start the **SurvNET** Network Least Squares program. If **SurvNET** has already been started, clicking this icon will bring it to the front so you can work with it. (See the **Tools** menu section and the **SurvNET** section for additional info.)

The "eyeball" icon:

This icon brings up a separate window displaying a scaled map of the current raw data file. (See Graphic View under the View menu section)

The "C" icon:

Clicking this icon hides all **Comment** records. The **Comment** records still remain in the raw file, they are just not shown on the screen. You will find that there are some actions you cannot perform when Comments are off.

The "No DO" icon:

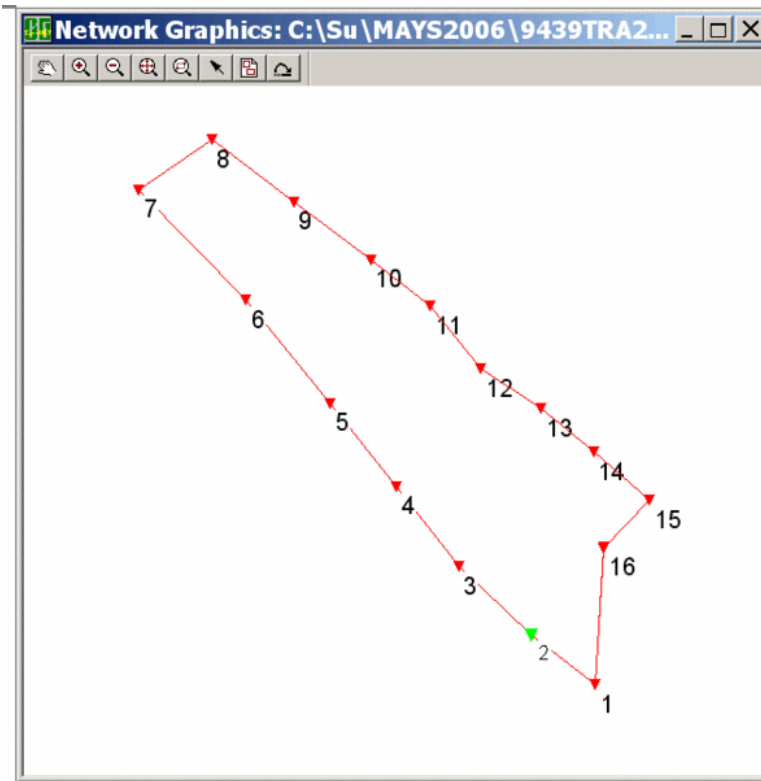

Clicking this icon removes all the **Data On/Off** records from the raw data file.

Status bar

When this menu item is checked, the status bar will display. The status bar is along the bottom border of the **CGEditor** window. On the left side of the status bar a brief help message is displayed when you hold the cursor over such things as menu items or toolbar icons. It also has indicators that tell you if Caps Lock or Num Lock are turned on and displays the Row/record number that is currently active.

Graphic View

Clicking on this menu item brings up a window containing a graphic representation of the traverse. The traverse lines and points are drawn to scale using the data from the current raw data file.

The Graphic View Window

The Graphic View window shows a scaled drawing of the current raw file traverse lines and points. The toolbar icons at the top of the window can be used to move around in the view and change its appearance. The icons will be discussed as they appear from left to right:

 **Pan:** This works very much like the CAD Pan command. When you click the hand icon the cursor changes to a hand. When you click on the graphic screen the first time you are "grabbing" the graphic. You can then move it to the proper view and click a second time to "put it down". You may repeat this as many times as you wish in order to move around the drawing. When done with the Pan command, click on the Pick Point icon.

 **Zoom In:** Clicking on this icon causes the graphic image to be enlarged a preset amount. The zoom factor cannot be configured. If you wish to see a certain area of the graphic image it is recommended that you click Zoom Extents then use Zoom Window to view the desired area.

 **Zoom Out:** As with Zoom In, Zoom Out reduces the image size a pre set amount. The zoom factor is not configurable.

 **Zoom Extents:** Zooms the image so all points and lines can be seen on the screen.

 **Zoom Window:** Allows you to click on two diagonal corners of the rectangular area that you wish to see.

 **Pick Point:** Use this icon to allow you to pick a point on the graphics screen in order to "zoom" to the first instance of the associated point ID found in the raw data editor window. This allows you to rapidly and conveniently locate a given point ID in the data file. This is especially useful in trouble shooting for errors or other problems in the data that may be more easily detected in the graphic image than when viewing the raw data. When you pick near a plotted point on the graphics screen its point ID is noted. The raw data file is then searched for that point ID. The active field in the editor window is then set to the first instance of that point ID. You can pick the same location several times to move to the next instance of the point ID in the file. If you have a large Pick Radius set (See Graphic Settings) or are zoomed out, picking a point may result in more than one point being found. If this occurs, a dialog box listing the nearby points will pop up. Using the list box in the dialog choose the desired point ID and press <Enter> or click OK to find the point in the data file.

Clicking this icon also allows you to turn off the Pan feature when you are done panning.  Brings up the **Graphic Settings** dialog:

The graphic settings dialog allows you to configure the appearance of the various items that may be seen on the graphics screen.

Note: The **Graphic Settings** dialog is also used for the **SurvNET** program and thus the items on the **Error Ellipses** and **GPS** tabs have no effect on the **CGEditor Graphic View**.

Points and Trav/SSs tabs

Control Points, Fixed Control Points and Floating Points and Traverse, Sideshots and Azimuths:

Specify whether the symbols, labels or lines for any of these should be shown. Also, if they are to be shown, specify symbol and/or line color, symbol type and point ID label size.

Symbol:

Choose to represent the various types of points as a Square, Triangle or Circle using the drop down list.

Color:

For symbol or line color you can choose Red, Green, Blue, Cyan, Magenta or Yellow from the drop down list.

Size:

Specify the point symbol size.

Pt. Num.

Text: Check the check box if you want the points labeled.

Size: If the points are to be labeled, specify the label height.

Pick Radius

When you pick near a point plotted on the graphics screen, the current field in the editor window moves to the first instance of that point in the current raw data file. Setting the pick radius allows you to specify how large an area around the pick point is to be searched for raw data points drawn in the Graphics View window.

Error Ellipses tab (Has no effect in CGEditor)

GPS tab (Has no effect in CGEditor)

 **Refresh Graphics:** Allows you to refresh the graphics to view recent changes in the raw data due to editing.

Important Note: For the **Refresh Graphics** to reflect recent changes in the raw data file, you must save the file itself prior to refreshing the graphics.

Settings Menu

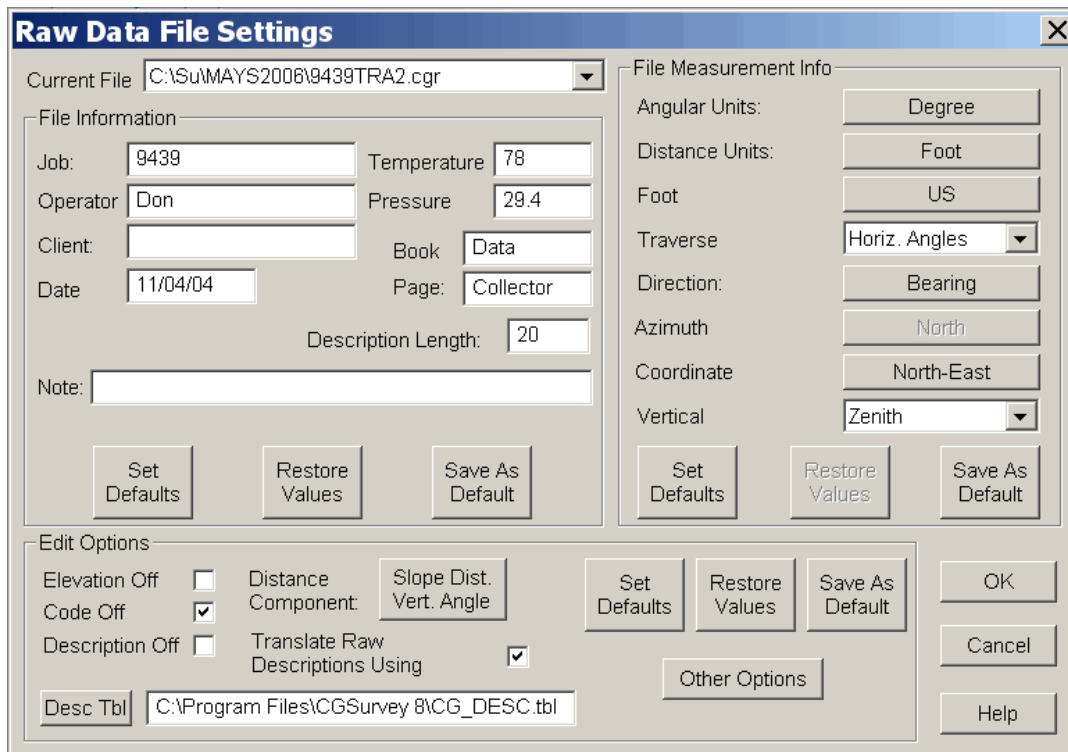

The items in the settings menu can be used to configure how the data in the raw data file will be interpreted and the appearance of that data as seen in the CGEditor.

Raw Data File Settings dialog

When you click on the **Raw Data File** menu item you will see a dialog box that allows you to specify many of the more important settings related to the currently open raw data files. You can also set up the defaults that will be used for newly created raw data files.

Note: See the More on Default Settings subsection at the end of the **Settings Menu** section.

The Raw Data File Settings dialog

Current File

To view and/or edit the settings for a given file, pick the file using the **Current File** list box. You can also view and/or edit the **DEFAULT** settings for newly created files.

File Information

This portion of the dialog allows the user to specify job or project specific information. Except for description length, these items are for your own information and do not affect processing of the raw data.

Job: Enter any name you wish to identify the job or project.

Operator: Enter the name of the person who led the field work.

Client: The name of the person or company for whom this work was done.

Date: Date in any format you wish to use.

Temperature: Temperature at the time the field work was done. For your reference only. May be Celsius or Fahrenheit.

Pressure: Atmospheric pressure at the time the field work was done. For your reference only. May be in any units.

Book: Field book number for the field work.

Page: Page number in the field book.

Description Length: Specify the length of the description field used in this file.

Set Defaults:

This button sets the items in the **File Information** portion of the dialog as the current default values. When a new raw data file is created, these default settings will be used. See the **More on Default Settings** heading at the end of the **Settings** section.

Restore Values:

This button allows you to set the values in the File Information portion of the dialog back to what they were when you opened the **Raw Data File Settings** dialog.

Save As Default:

Sets the default values for the **File Information** portion of the dialog. These values are used as the default settings when a new file is created. See the **More on Default Settings** heading at the end of the **Settings** section.

File Measurement Info

Angular Units: Clicking the button to the right changes the angular units from **Degrees** to **Grads** or vice versa.

Distance Units: Clicking the button to the right changes the distance units from **Foot** to **Meter** or vice versa.

Foot Definition: Clicking the button to the right changes the foot definition from **US** feet to **International** feet or vice versa. This button is only active when **Distance Units** are set to **Foot**.

Traverse Angles: Choose one of the items in the list to specify how the traverse angles were measured:

1. **Horiz. Angles**
2. **Azimuths**
3. **Deflection Angles**

Direction:

Specify what type of angle is used to define the direction of a line. Clicking the button to the right changes the direction from **Bearing** to **Azimuth** or vice versa.

Azimuth Direction:

Specify the reference direction for azimuths. Clicking the button to the right changes the azimuth direction from **North** to **South** or vice versa. This button is only active when **Direction** is set to **Azimuth**.

Coordinate Order: Clicking the button to the right changes the Coordinate Order from North-East to East-North or vice versa.

Vertical Reference: Pick one of the items from the list to the right to specify the reference orientation for measuring vertical angles:

1. **Zenith**
2. **Nadir**
3. **Horizontal**

Set Defaults:

This button sets the items in the **File Measurement Info** portion of the dialog to the current default values. See the **More on Default Settings** heading at the end of the **Settings** section.

Restore Values:

This button allows you to set the values in the **File Measurement Info** portion of the dialog back to what they were when you opened the **Raw Data File Settings** dialog.

Save As Default:

Sets the default values for the **File Measurement Info** portion of the dialog. These values are used as the default settings when a new file is created. See the **More on Default Settings** heading at the end of the Settings section.

Edit Options**Elevation Off:**

Check this check box to turn off the Elevation data entry column for this file. This makes data input more convenient since you do not have to enter any data in the Elevation column, nor do you have to tab through it. Turning off elevations does not cause any data to be deleted from the current file.

Code Off:

Check this check box to turn off the Code data entry column for this file. This makes data input more convenient since you will not have to enter any data in the Code column. Turning off codes does not cause any data to be deleted from the current file.

Description Off:

Check this check box to turn off the Description data entry column for this file. This makes data input more convenient since you will not have to enter any data in the Description column. Turning off descriptions does not cause any data to be deleted from the current file.

Note: You can turn the Elevation, Code and Description data entry columns on or off while editing a file by clicking on the column heading.

Distance Component:

Specify how distances are to be entered. Clicking the button to the right changes the Distance Component from Slope Dist-Vert Angle to Horiz. Dist-Vert. Dist. or vice versa.

Translate Raw Descriptions Using Description Table:

This check box is only active if descriptions are on. If you check this check box, integer codes entered in the Description field will be looked up in the specified description table (See the following item.). If a matching description number is found in the description table, the code will be moved to the Code field and the description found in the description table will be placed in the Description field. If no matching description number is found, the Description field remains as entered.

Desc Tbl:

Click on the Desc Tbl button use a file dialog to set or change the description table. The description table is used to set the Description field when an integer number is entered in the Description field. (See the previous item.) If you prefer, instead of clicking on the Desc Tbl button you can also type in the full file path in the edit box.

Set Defaults:

This button sets the items in the Edit Options portion of the dialog to the current default values. See the More on Default Settings heading at the end of the Settings section.

Restore Values:

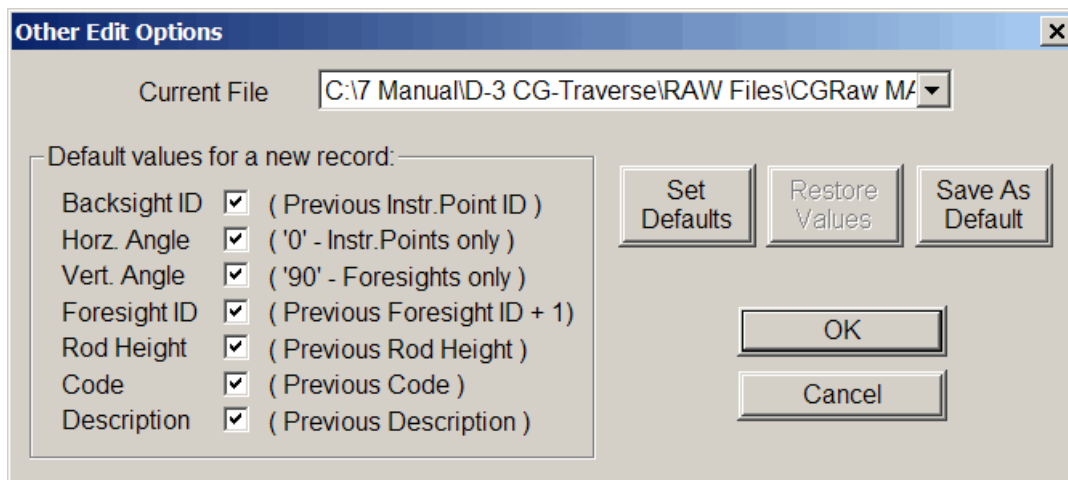

This button allows you to set the values in the Edit Options portion of the dialog back to what they were when you opened the Raw Data File Settings dialog.

Save As Default:

Sets the default values for the Edit Options portion of the dialog. These values are used as the default settings when a new file is created. See the More on Default Settings heading at the end of the Settings section.

Other Edit Options dialog

Click the **Other Options** button to bring up the Other Edit Options Dialog box.

Current File:

Click on the name of the file in the file list for which you wish to review and/or specify the settings. You can also choose to view or edit the DEFAULT settings.

Default values for new record:

Checking the check box for the following items causes CGEditor to "remember" the most recently entered value in the respective field. Thus when you insert or add a record containing one of the checked items, it will be filled in with a "default" value.

Backsight ID

Horz. Angle

Vert. Angle

Foresight ID

Rod Height

Code

Description

Note: The previously used field values are not "remembered" and thus will not be used to fill in new records the next time you open the **CGEditor**.

Set Defaults:

This button sets the items in the Other Edit Options dialog to the current default values. See More on Default Settings at the end of the Settings section.

Restore Values:

This button allows you to set the values in the Other Edit Options dialog back to what they were when you opened the Raw Data File Settings dialog.

Save As Default:

Sets the default values for the items found in the Other Edit Options dialog. These values are used as the default settings when a new file is created. See More on Default Settings at the end of the Settings section.

Click **OK** to close the **Other Edit Options** dialog.

Click **OK** to close the **Raw Data File Settings** dialog.

More on Default Settings:

When the CGEditor is started from CGSurvey, many of the initial default settings may not be those you had specified in a previous session. This is because many of the default settings you previously specified were overridden by the current CG Settings specified in CGSurvey. However, you may yourself override the default settings for the current session only by changing any of the settings and clicking the Save As Default button. If you wish to change the "default" settings for future editing sessions, you must change the CG Settings in CGSurvey.

Settings overridden by the settings on the various tabs in the CAD C&G Options dialog:

File Information: only **Description Length** is overridden by the settings in the CAD C&G Options dialog.

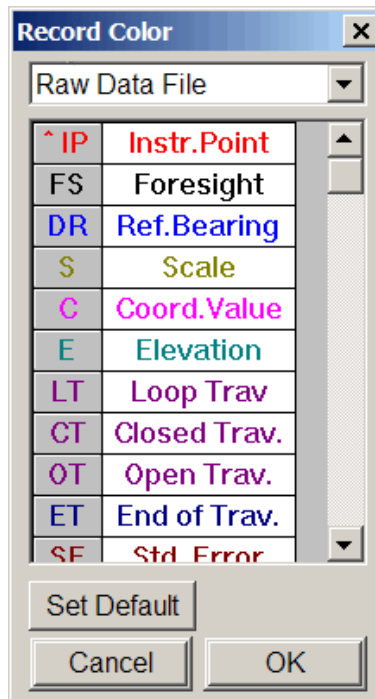

File Measurement Info: ALL items are overridden by the settings in the CAD C&G Options dialog.

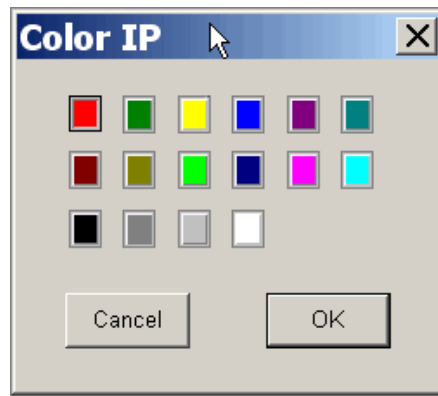

Edit Options: ALL items are overridden by the settings in the CAD C&G Options dialog.

Other Edit Options: NONE are overridden by the settings in the CAD C&G Options dialog.

Record Color

To set the color for a given record type click the **Record Color** menu item. Then, in the **Record Color** dialog, click on the record type and a color selection dialog will appear. Click on the color you want the that record type to have. If you click the **Set Defaults** button, the original program default colors are set. Click the **OK** button to save the color settings and close the dialog. Click the **Cancel** button to close the dialog without saving the changes.

Validate Records

If this menu item is checked, all the records in the file will be validated prior to saving the file. To change the Validate Record setting, just click the menu item. If an invalid record is encountered when saving a file with the Validate Records menu item checked, you are asked if you want to edit the invalid field, ignore the error or ignore all errors. If you decide to edit the offending field, the field will be highlighted and you can edit it and attempt to save again.

The Tools menu has several items that can be used to find and replace specific text in specific types of fields. It even allows you to apply simple mathematical functions to allow you to edit the data in a group of fields in a single step.

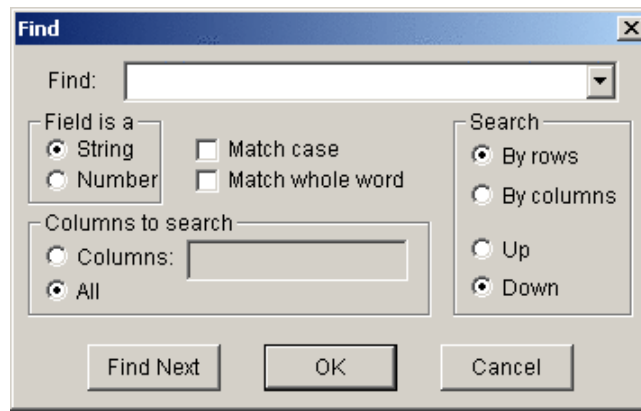

Goto (Ctrl + T):

Select this item to go to a certain row (or record) number. In the dialog box that comes up, type in the desired row number and click OK. The editor window will zoom to that record and set the current field to the first editable field in the record.

Find (Ctrl + f) menu item:

The **Find** dialog allows you to enter a value to find and set the detailed search criteria.

Find: Type in the string or number you are searching for in the edit box or pick a previous search string from the list.

Field is a: Choose what type of data is in the field you are looking for. Check appropriate checkbox for matching case and/or whole word.

Columns to search:

The default is to search **All** columns, but if you choose the **Columns** radio button, you can enter a comma separated list of column numbers. The column to the right of the TYPE column is column 1 and it is the first column in which you can search.

Search:

You can search **By Rows** or **By Columns** and you can choose to search **Up** or **Down** from the current field.

Once you have specified the parameters for the search, click the **Find Next** button to find the first instance of the search string. Continue to click the **Find Next** button to find the next instance of the string. To just find the next instance of a string and close the dialog box, you can click **OK**.

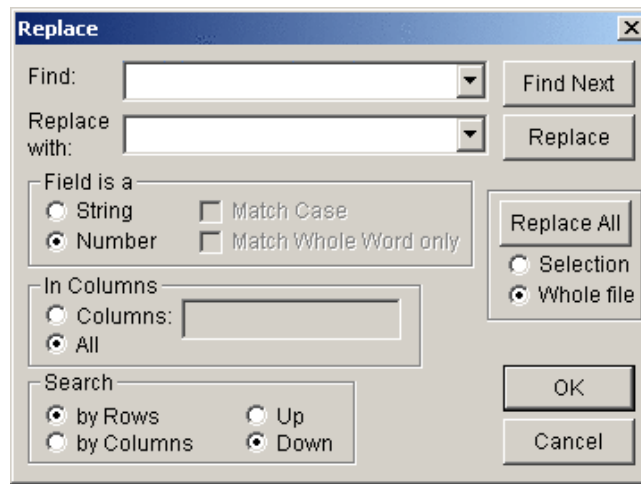

Find Next (F3) menu item: Finds to the next occurrence of the string previously specified in the **Find** dialog.

Find Prev (<Shift> + <F3>) menu item: Moves you to the previous occurrence of the string previously specified in the **Find** dialog.

Find Record Type menu item: Allows you to find the next record type of the type specified. The search starts at the current record. When you click this menu item, the **Find Record Type** dialog box is displayed. Choose the record type you wish to look for by picking from the list then specify the direction of search and click the **Find Next** button to find the record. Click **Cancel** when done.

Replace (<Ctrl> + r) menu item: When you click on this menu item, the **Replace** dialog appears.

The **Replace** dialog allows you to specify a **Find:** value and a **Replace with:** value. The other fields in the **Replace** dialog are the same as the **Find** dialog. You can view the **Find:** value one instance at a time by clicking the **Find Next** button, if you decide to replace a given value found just click the **Replace** button. Alternatively, you can allow the software to automatically replace all the instances of the **Find:** value encountered in the specified columns in the raw data file by clicking the **Replace All** button.

Note: Before clicking the **Replace All** button, be sure to specify whether you wish to replace matching fields in the highlighted **Selection** of fields/records or in all the fields in the **Whole File**.

Data On/Off (<Ctrl> + d) menu item:

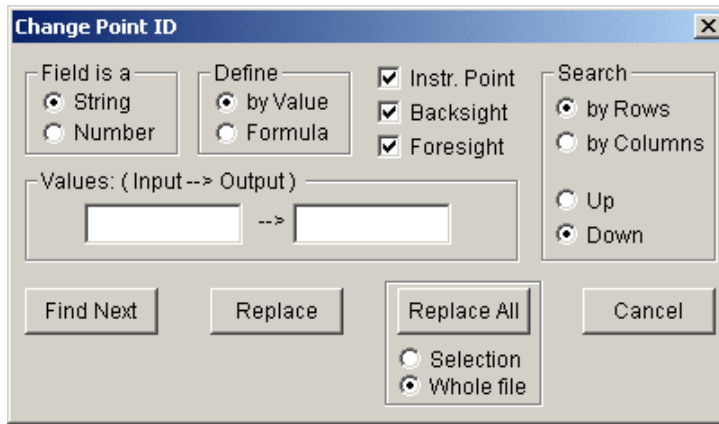

Selecting this menu item inserts a Data On/Off record above the current record. Records between pairs of Data On/Off records are ignored when the traverse is reduced. This can be useful when trying to find problems in a traverse.

Change

The items in this submenu allow you to change specific types of fields in the raw data file.

Point ID (<Ctrl> + I) menu item: This menu item allows you to change point IDs for instrument points, back sight points, or foresight points. You can change individual points one at a time or you can make a global change. You can specify a value to find and a value to replace it with. The **Change Point ID** dialog has several sections that are similar to the **Replace** dialog

Field is a: You must specify how you want to treat the point ID field. You can do this by clicking on the **String** or **Number** radio buttons.

Define: You must specify whether you wish to specify the replacement value **by Value** or **Formula**.

Note: The **Values: (Input -> Output)** section of the dialog changes its title to **Formula:** when you elect to **Define** by **Formula**. Also, the content of this portion of the dialog changes according to the field type (see **Values: or Formula:** section below).

Instr. Point, Backsight, and Foresight check boxes: Check the check boxes of the types of point IDs you wish to change.

Values: or Formula: section

When **Define** is set to **by Value** and **Field is a** is specified as either a **String** or a **Number** then the title of this section of the dialog becomes

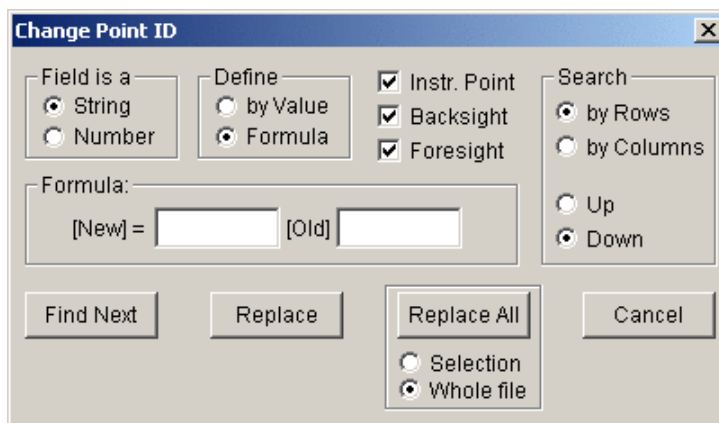

Values: (Input -> Output) (as shown in the dialog above). In this configuration the **Change Point ID** dialog functions like the **Replace** dialog except that it only searches the point ID fields specified.

Specify the value to search for in the edit box to the left of the "-->" and the value to replace it with in the edit box to the right of the "-->".

The **Find Next**, **Replace** and **Replace All** buttons act exactly the same as the **Find Next**, **Replace** and **Replace All** buttons in the **Replace** dialog.

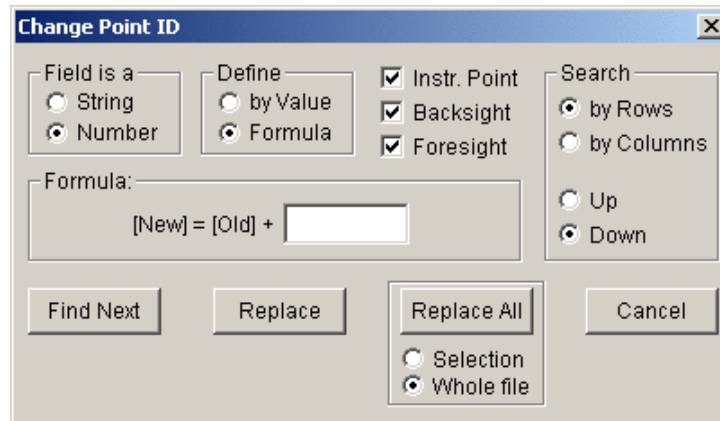

When **Define** is set to **Formula** the title of this section of the dialog becomes **Formula:**

If **Field is a** is specified as a **String**, the dialog is as shown below:

In this configuration the formula acts to add a prefix and/or a suffix to the existing point ID (represented by **[Old]**). Enter the prefix in the edit box to the left of **[Old]** and the suffix in the edit box to the right of **[Old]**. If you do not wish to add a prefix or you do not wish to add a suffix, you may leave either the left or right hand edit boxes empty.

If **Field is a** is specified as a **Number**, the dialog is as shown below:

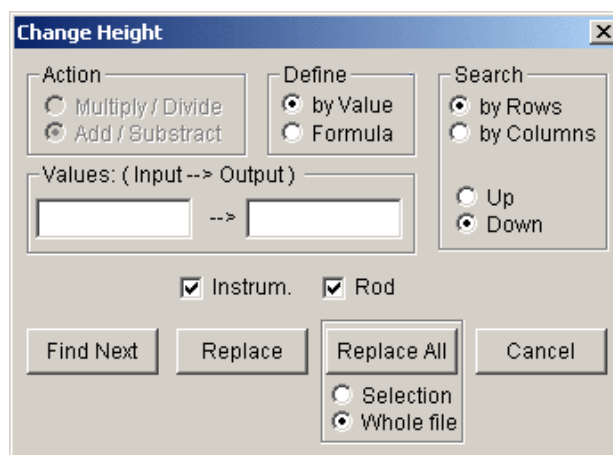

In this configuration the formula adds a specified number to a given point ID. Enter the positive or negative number in the edit box to the right of "[Old] +".

NOTE: When the **Field is a** is specified as a **Number** and a point ID containing non-numeric characters is encountered, it will be skipped and no change will be made to it.

Change Height (<Ctrl> + h)

Use this menu item to change the instrument height and/or rod height. Clicking this menu item brings up the **Change Height** dialog.

Action section of dialog

Use this section to determine how the height is to be changed when **Define** is set to **Formula**.

Multiply/Divide: Choose this if you wish to multiply or divide the height by a given number.

Add/Subtract: Choose this if you wish to add a specified number to the height or subtract a specified number from the height.

Define section of dialog by Value: If you choose by Value, this command becomes like the Replace command, except that it acts only on instrument heights and/or rod heights.

Formula: This allows you to specify a number to apply to the height by addition, subtraction, multiplication, or division. (See the **Action** and **Values:/Formula:** sections.)

Values:/Formula: section of dialog

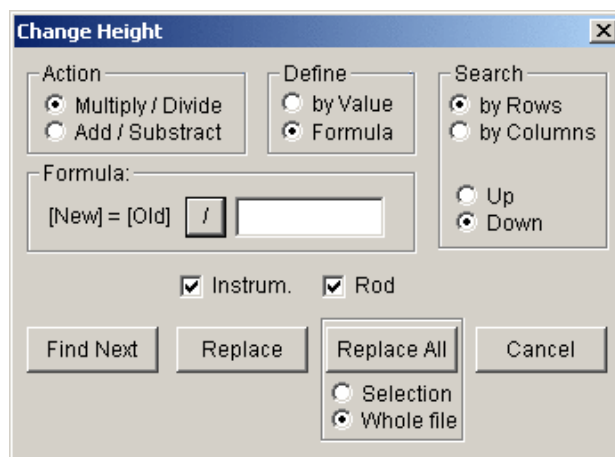

Depending on what you choose in the Action and Define sections there are several possibilities for this section of the dialog:

When **Define** is set to **by Value** the **Action** section of dialog is disabled and the title of this section becomes **Values: (Input->Output)**

In this configuration the feature functions like the **Replace** command, except that it acts only on instrument heights and/or rod heights.

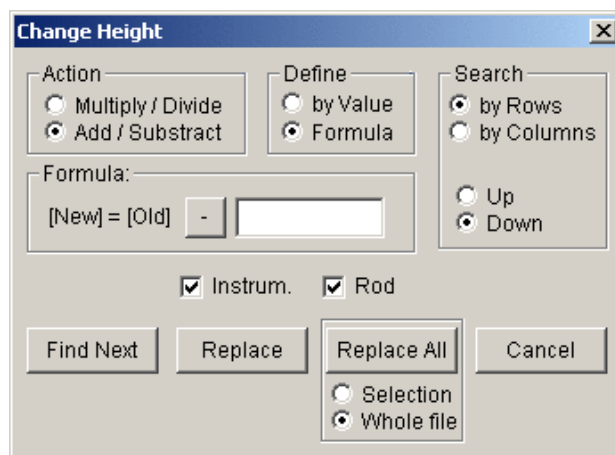

When **Define** is set to **Formula**, the **Action** section of dialog is enabled and the title of this section becomes **Formula:**

When the **Action** is set to **Multiply/Divide**, the **Formula:** section changes as seen below:

In this configuration you can multiply or divide the instrument height or rod height by the number specified in the edit box. To switch between multiply and divide, just click on the button with the multiply ("*") or divide ("/") symbol on it.

When **Action** is set to **Add/Subtract**, the **Formula:** section changes as seen below:

In this configuration you can add or subtract the number specified in the edit box to or from the instrument height or rod height. To switch between add and subtract, just click on the button with the add ("+") or subtract ("-") symbol

on it.

Search section of the dialog

Use this section of the dialog to specify how the records will be searched. The search begins at the currently active field.

Instrum. and **Rod** checkboxes: Check one or both of these check boxes to specify which types of heights are to be searched/changed.

Find Next button: Use this button to move to the next field that matches the specifications you entered.

Replace button: Use this button to replace the highlighted text that was found.

Change All button: Use this button to make the changes specified to all matching fields in the file. Be sure to specify whether to apply the changes to the highlighted **Selection** (records or fields) or to the **Whole file**.

Cancel button: Click the Cancel button to close the dialog.

Change Angle (<Ctrl> + g)

Choose this menu item to change vertical and/or horizontal angle fields. Clicking the **Change Angle** menu item brings up the **Change Angle** dialog: This dialog is almost identical to the **Change Height** dialog and will not be described in detail. The differences are: the **Multiply/Divide** action seen in the **Change Height** dialog is replaced by the **Make Opposite** action; you can check either the Vertical or Horizontal check boxes to specify the angles you wish to change; choosing **Formula** and **Make Opposite** disables the **Formula:** section of the dialog due to the fact that the action to be taken is merely to reverse the sign of the angle.

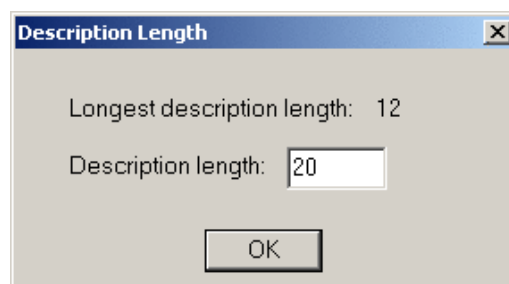

Change Distance (<Ctrl> + D)

The **Change Distance** dialog is almost identical to the **Change Height** dialog. The only difference is that you can choose to change the **Slope** distance and/or the **Horizontal** distance by checking the checkboxes.

Change DescLen (<Ctrl> + j)

This command allows you to set the description length for the current raw data file. It displays the **Longest description length:** that is found in the current records in the file. It allows you to specify a new **Description length:**.

Warning: If you specify a length less than the longest description found in the file, the descriptions that exceed that length will be truncated.

Network Least Sq. menu item

This menu item runs the **SurvNET Network Least Squares Adjustment** program. Please refer to the section on SurvNET for a detailed description of this very powerful traverse and level loop adjustment program.

Window menu

This menu contains many of the standard Window menu items found in other programs. It allows you to arrange the currently open windows in several configurations. It has the added functionality of the New Window command which allows you to have two or more views of a single file

Help

For information regarding the CGEditor program version click the About CGEditor... menu item.

Editing C&G Mapcheck Files

Mapcheck files are typically used to check the closure of a given parcel of land given the deed description of that parcel. A mapcheck file may contain straight line boundaries as well as boundaries described by both tangent and non-tangent curves.

Creating or Opening a Mapcheck File

To create a new file or open an existing file choose **File** on the main menu then either click **New** or **Open**.

If you choose **New** a submenu will appear, click the **C&G Mapcheck File** menu item.

In either case you will then see a file dialog. Browse to the directory where you wish to work and, if creating a new file, type in a file name, or, if opening an existing file, click on a mapcheck file (*.cgm). Next, click the **Save** button for a new file or the **Open** button for an existing file.

If you are creating a new file, an empty file will be shown in its own document window within the editor. If you are editing an existing file, the data from the file will appear in a similar document window. It is possible to have multiple documents open at the same time. So you could create a new file and open an existing file in the same editing session and each would appear in its own window in the editor. You can have as many new and/or existing files open as your project demands. You may also cut, copy and/or paste between files.

Settings: Before entering any data you should check the current settings. Click the **Settings** menu item then click **Map Check File** to review and/or change the current settings. (For more details, see the **Settings Menu** section of **Editing C&G Mapcheck Files**.)

Mapcheck Data Entry

Opening an existing template file or creating a new one is very similar to opening or creating a raw traverse data file. There are three types of records that you may use in a mapcheck file:

Straight line (identified as **Line** in the **Type** column)

Tangent Curve (identified as **TC** in the **Type** column)

Non-tangent Curve (identified as **NTC-C** or **NTC-R** in the **Type** column for Chord or Radius definition NTC records)

Adding and Inserting new records

To create a new record in the current file you must either use the **Add** or **Insert** menu item or the **Add** or **Insert** toolbar.

Note: If the **Add** and/or **Insert** toolbars are not showing, click the **View** menu then choose the menu item for the toolbar you want to turn show.

When you click on one of the **Add** menu items or toolbar icons, an empty record is added to the end of the file. If you click on one of the **Insert** menu items or toolbar icons, an empty record is inserted above the currently active record or field. To make a record the currently active record, just click on one of its fields.

Moving from field to field: While entering data, to move to the next field, press the Enter or Tab key. To move to the preceding field press the Esc key or the Shift and Tab keys at the same time.

Straight Lines

There are two fields to be filled out in a **Straight Line** (or **Line**) record:

Bearing or Azimuth: For a bearing, use the standard C&G bearing notation:

For Bearing: Qdd.mmsss

Where

q = quadrant (1 = NE, 2 = SE, 3 = SW, 4 = NW)

d = 2 digit bearing

m = minutes

s = seconds and tenths of seconds

For example: enter S 35° 22' 34.2" E as 235.22342

For Azimuth, use the notation: ddd.mmsss

Distance: Enter the length of the boundary in whatever units you have specified in the **Map Check File Settings**.

Code: Enter a code (optional).

Note: If **Code Off** is checked in the **Map Check File Settings** dialog, this field will not be active. However, clicking on the **Code** column title will turn it on.

Description: Enter a description (optional).

Note: If **Description Off** is checked in the **Map Check File Settings** dialog, this field will not be active. However, clicking on the **Description** column title will turn it on.

If **Translate Mapcheck Descriptions Using a Description Table** is checked in the **Map Check File Settings** dialog and you have entered an integer number description, then when you move to the next field, the description table will be searched for a description number matching the integer entered. If a matching description number is found, the description from the table will be placed in the **Description** field and the integer originally entered in the **Description** field will be placed in the **Code** field.

Tangent Curves

For a Tangent Curve record there are six possible fields to enter. Of the following six fields you must enter data for two of the first four:

Radius - decimal distance

Arc Length - decimal distance

Chord - decimal distance

Central Angle - angle specified as ddd.mmsss (degrees.minutes and seconds to nearest .1 sec.)

Code (optional - see Straight Lines above)

Description (optional - see Straight Lines above)

Non-Tangent Curves

The fields in a **Non-Tangent Curve** record vary according to whether it is defined using the chord bearing/azimuth or radius bearing/azimuth.

When using **Non-Tangent Curve** record it is necessary to specify whether the chord or radius definition will be used when specifying the curve . There are four ways to accomplish this:

1. Prior to Inserting or Adding the record, use the **Settings** menu then choose **Map Check File**. In the **Map Check File Settings** dialog set the **Curve Definition** in the **File Measurement Info** section of the dialog.
2. Prior to Inserting or Adding the record, use the **Settings** menu to check or uncheck the **Non-Tan Curves Use Chord** menu item. When the **Non-Tan Curves Use Chord** menu item is checked, newly created **Non-Tangent Curve** records will added or inserted that use the chord definition, otherwise they will use the radius definition.
3. Prior to Inserting or Adding the record, click the **C-R** toolbar icon. When the icon appears depressed, newly created **Non-Tangent Curve** records will use the chord definition, otherwise they will use the radius definition.
4. To change the type of curve definition for an existing **Non-Tangent Curve** record, use the Edit main menu and choose the Change Curve Def'n menu item. This changes the current record from what it is now to the opposite type of curve definition.

For both the **Chord** and **Radius** definitions the following fields are present in the record:

Chord or Radius Brg/Azimuth

used to orient the curve properly as it leaves the PC. As noted in the **Tangent Curves** section, bearings must be entered in the qdd.mmsss format and azimuths entered in the ddd.mmsss format. **Radius**

Arc Length

Chord

Central Ang

Code

Description

All but the first field has been discussed earlier in the **Tangent Curves** section and will not be described here.

Editing a Mapcheck File

Most of the menu items found in the mapcheck menus have been discussed in the **Editing Traverse Raw Data Files** section. Only the differences will be discussed here.

File Menu: The **File** menu when editing a mapcheck file is identical to the **File** menu discussed in the **Editing Traverse Raw Data Files** section.

Edit Menu: With the exception of the **Change Curve Def'n** menu item, the **Edit** menu is identical to the **Edit** menu discussed in the **Editing Traverse Raw Data Files** section. **Change Curve Def'n** was discussed above in the **Non-Tangent Curves** section

Add Menu: The Add menu allows you to add **Straight line**, **Tangent Curve** and **Non-Tangent Curve** records to the end of the file.

Insert Menu: The Insert menu allows you to insert **Straight line**, **Tangent Curve** and **Non-Tangent Curve** records above the current record.

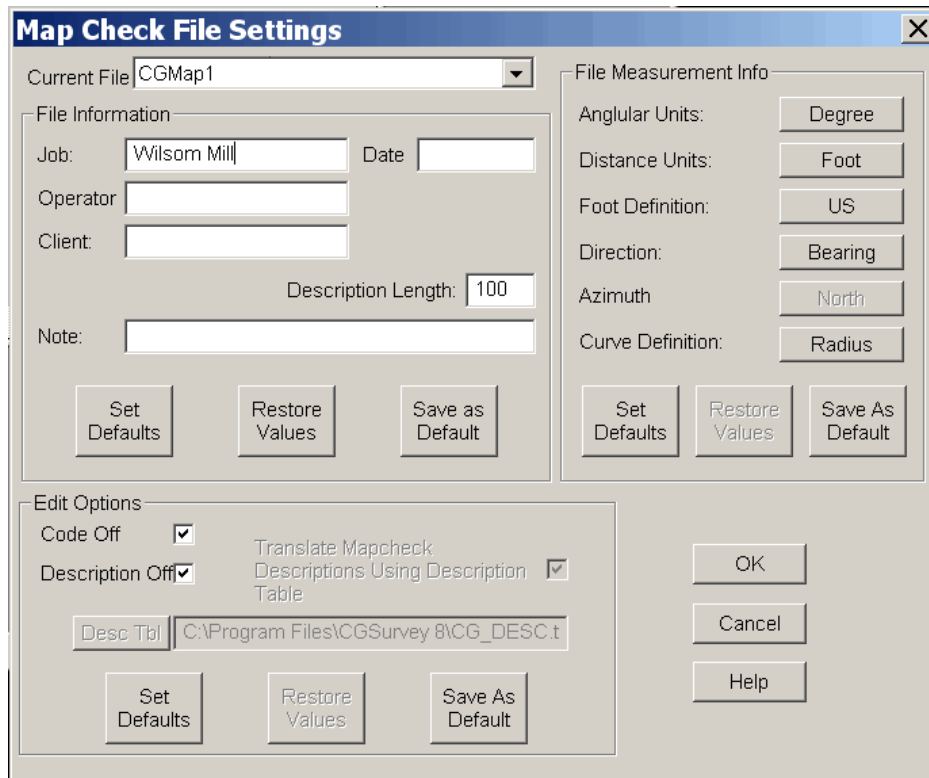

View Menu: Allows you to turn the toolbars on and off.

Settings Menu

The **Settings** menu contains items that allow you to specify the format of the data in a mapcheck file and how this data will appear in the **CGEditor**.

Map Check File settings menu item

The **Map Check File** menu item brings up the **Map Check File Settings** dialog (see below). This dialog allows you to specify settings for each of the mapcheck files currently open in the editor. It also allows you to specify the default settings for creating new map check files.

Current File: Use this list to choose a file you wish to set or view the settings for. You may also set or view the **DEFAULT** settings that are used for newly created files.

File Information and Edit Options:

The settings in the File Information and Edit Options sections have been discussed under the Settings Menu section of Editing a Raw Data File.

File Measurement Info:

Most of the settings in the File Measurement Info section have been discussed under the Settings Menu section of Editing a Raw Data File. However, a **Curve Definition** item has been added to this section for mapcheck files:

Curve Definition: click the **Curve Definition** button to change from Chord to Radius definitions and vice versa. **Curve Definition** only applies to the insertion or addition of **Non-Tangent Curve** records.

Record Color menu item

The **Record Color** menu item has been discussed under the **Settings Menu** section of **Editing Traverse Raw Data Files**. The only difference is that here you are setting the colors for the various types of mapcheck records instead of raw data records.

Validate Records

This menu item allows you to set whether records are validated prior to being saved. (See also, **Validate Records** in the **Settings Menu** section of **Editing Traverse Raw Data Files**.)

Non-Tan Curves Use Chord: Use this to switch which types of **Non-Tangent Curve** records are added or inserted.

Tools, Window and Help Menus the items in these menus have been discussed in the **Editing Traverse Raw Data Files** section

C&G Cross Section Files

Cross section files contain data which defines one or more topographic or design cross sections along an alignment. Any features using a cross section file assume that it is at right angles to the alignment. Each cross section is identified by its station along the alignment. Each cross section is defined by a **Station** record specifying a station on the alignment followed by a series of **Point** records specifying the offset and elevation of points on the cross section at that station. Cross sections can be used to visualize a site, specify design elevations and calculate volumes. Opening an existing cross section file or creating a new one is very similar to opening or creating a map check file.

Cross Section File Data Entry

Station Records: There are three fields to be filled out in a Station record:

Station: Specifies the station of this cross section along the alignment. For example: station 6+45.37 is indicated as 645.37.

Left Slope:

This field defines the slope at the left side of the cross section in feet per foot (or meters per meter if units are set to meters). This slope will be used to extend this cross section to meet any cross section it overlays.

Right Slope:

This field defines the slope at the right side of the cross section in feet/foot (meters/meter). This slope will be used to extend this cross section to meet any cross section it overlays.

Point Records

There are two fields in a Point record:

Offset: The **Offset** defines the perpendicular distance from the alignment to this point on the cross section.

Elevation: The Elevation specifies the elevation of this point on the cross section.

Cross Section File Data Editing

Adding and Inserting new records: To create a new record in the current file you must either use the **Add** or **Insert** menu or toolbars.

Note: If the toolbars are not showing, click on the **View** menu then click the item for the toolbar you want to turn on.

Settings Menu item

Record Color:

The **Record Color** menu item has been discussed under the **Settings Menu** section of **Editing Traverse Raw Data Files**. The only difference is that here you are setting the colors for the various types of cross section records instead of raw data records.

Validate Records: This menu item has been described in the **Settings Menu** section of **Editing Traverse Raw Data Files**

US Foot: If this menu item is checked units are US feet. If the **Meters** menu item is checked, this menu item is disabled.

International foot: If this menu item is checked units are International feet. If the **Meters** menu item is

checked, this menu item is disabled.

Feet: If this menu item is checked units are Feet.

Meters: If this menu item is checked units are meters.

Note: The settings for US Foot and International foot will be ignored if Meters is checked.

C&G Template Files

Template files contain data defining standard cross section templates that can be used to create a cross section file that represents the design cross sections for a proposed alignment. Cross section files created using templates can be overlaid on existing cross sections to allow the computation of cut and fill volumes and to visualize the design alignment. Opening an existing template file or creating a new one is very similar to opening or creating a map check file.

Entering and Editing Template Data

Entering and editing template data is analogous to that described in **Entering and Editing Cross Section Data** except that, instead of being identified by their station along the alignment, templates are identified by an integer template identifier. This identifier is used when building a cross section from templates in order to specify a template among the many that a template file may contain. Templates are placed along a proposed alignment at various stations and thus create a series of cross sections using the alignment elevation to set the elevation of the template points. When building cross sections along an alignment using templates, cross sections at stations between two template stations result in a series of cross sections being created to transition between the templates.

Template File Data Entry

Template Records: There are five fields to be filled out in a Template record:

Template: Template number for identifying the template

Left Slope:

Specifies the slope at the left side of the template in feet/foot (meters/meter). This slope will be used to extend this template generated cross section to meet any cross section it overlays. **Right Slope:**

Enter the slope at the right side of the template in feet per foot (or meters per meter units are set to meters). This slope will be used to extend this template generated cross section to meet any cross section it overlays. **Offset:**

The Offset defines the distance from the centerline of the template to this point on the cross section. The template centerline should be assigned a 0.0 offset. The 0.0 offset is placed on the alignment when cross sections are generated from templates.

Elevation:

The Elevation specifies the elevation of this point on the template. If the elevation of the centerline point is set to 0.0, then this elevation can be used to directly compute the elevation of the point based on the elevation of the alignment where the template is placed.

Editing a Template File: All template menu items and editing procedures are identical to those described for cross sections.

Editing Coordinate Files

Coordinate files contain data on the Point IDs, Northings, Eastings, Elevations, Descriptions and, for C&G files, Codes for various points located in the field and points created by calculations and/or by hand data entry. The coordinate file may have points from a single job, portions of a single job or many jobs. The Point ID must be a unique identifier for a given point. Typically Point IDs are integer numbers but may also be any combination of

letters and numbers depending on the format of the file.

The CGEditor can be used to edit six different types of coordinate files. All the supported coordinate file types have **Point ID**, **Northing**, **Easting**, **Elevation**, and **Description** fields. In all formats, any given point may have a blank **Description** field. The types of files supported and a brief description of their differences follows:

C&G Numeric (*.crd)

Point ID: any integer number between 1 and 65,536.

Description: The maximum description length for a given file can vary between 1 and 100 characters and is set when the file is created. A given point description entry may be blank.

Code: up to 4 characters long. Used to filter and sort points. The **Code** field may be blank.

C&G Alpha-numeric (*.cgc)

Point ID: up to 10 characters long and can contain any combination of alphabetic and numeric characters.

Description: The maximum description length for a given file can vary between 1 and 100 characters and is set when the file is created. A given point description entry may be blank.

Code: up to 4 characters long. Used to filter and sort points. The **Code** field may be blank.

Carlson Numeric (*.crd)

Point ID: any positive integer number containing 1 to 9 digits.

Description: entries can be from 0 to 31 characters long.

(the **Code** field is not supported.)

Carlson Alpha-numeric (*.crd)

Point ID: any a series of from 1 to 9 alphabetic or numeric characters.

Description: entries can be from 0 to 31 characters long.

(the **Code** field is not supported.)

Simplicity (*.zak)

Point ID: can be any positive integer number containing 1 to 8 digits.

Description: entries can be from 0 to 28 characters long.

(the **Code** field is not supported.)

Land Desktop (*.mdb)

Point ID: can be a series of from 1 to 255 alphabetic or numeric characters.

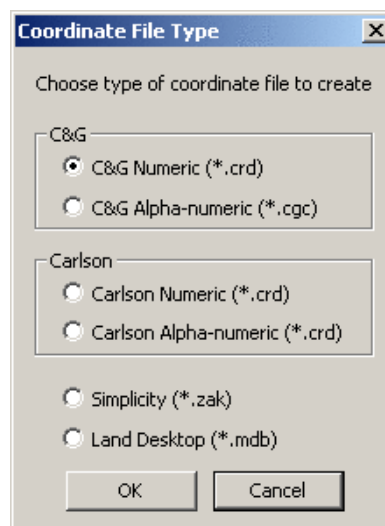

Description: entries can be from 0 to 255 characters long.

(the **Code** field is not supported.)

Creating or Opening a Coordinate File

To create a new file or open an existing file choose **File** on the main menu then either click **New** or **Open**.

If you choose **New** a submenu will appear, click the **Coordinate File** menu item or click on the "C" icon in the **Standard** toolbar. Next pick the type of coordinate file you wish to create using the **Coordinate File Type** dialog:

A new coordinate file with a temporary name will appear in its own document window in the CGEditor and will contain only a single blank coordinate **Point** record.

If you are opening an existing file using the **Open** menu item, you will be asked to choose the file using file dialog. Browse to the directory where you wish to work click on a coordinate file and click the **Open** button The coordinate records from the file will appear in a separate document window in the CGEditor.

It is possible to have multiple documents open at the same time. So you could create a new file and open an existing file in the same editing session and each would appear in its own window in the editor. You can have as many new and/or existing files open as your project demands. You may also cut, copy and/or paste between files.

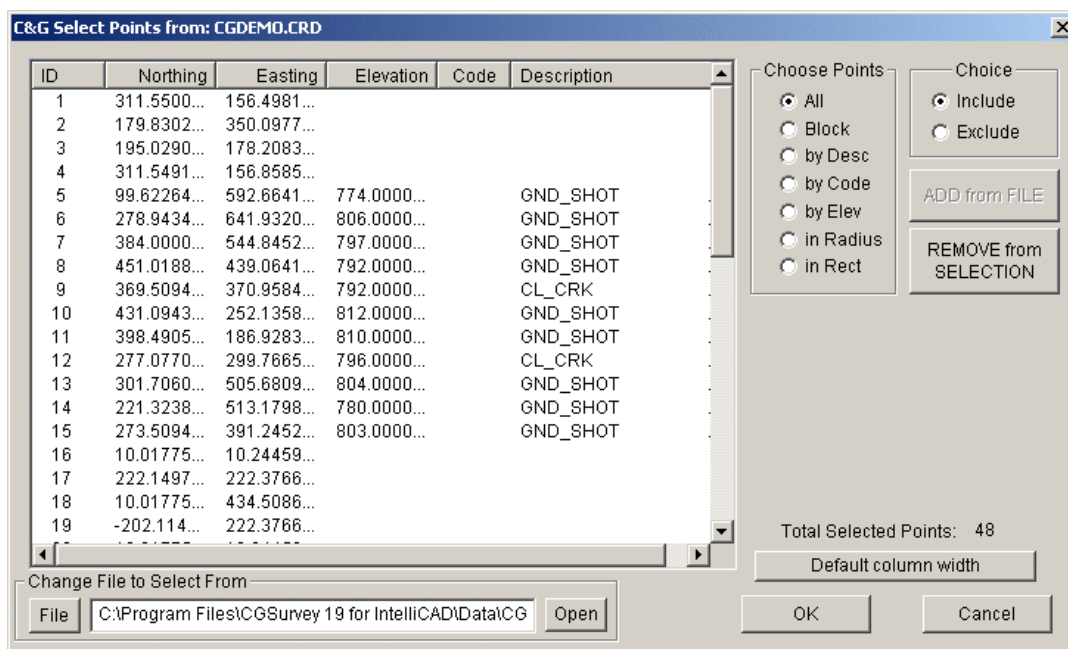

Settings: Before entering any data you should check the current settings. Click the **Settings** menu item then click **Coordinate File** to review and/or change the current settings. (For more details, see the **Settings Menu** section of **Editing Coordinate Files**.)

Entering and Editing Coordinate File Data

Once a coordinate file has been opened or created, you can edit any of the fields in any of the records. To create a new coordinate point you must use the Add/Insert main menu or toolbar. Both the Add/Insert menu and toolbar allow you to add or insert individual blank records or one or more records from an existing coordinate file. When you add a record or records, they are appended to the end of the file. When you Insert one or more records they are inserted just above the current record.

Insert and Adding Coordinate Records from an Existing Coordinate File

If you choose to either the Add or Insert Pts from File or the corresponding toolbar item, you will see the **C&G Select Points from:** dialog.

This dialog consists of a list of the points chosen so far from the file listed in the **Change File to Select From** edit box. Use the **File** button to set the file name and the **Open** button to open the file for use. When the dialog first comes the point list is empty.

Choose Points section

Choose one of the available methods you will use for choosing points. Different methods will cause data entry controls to appear below the **Choose Points section**.

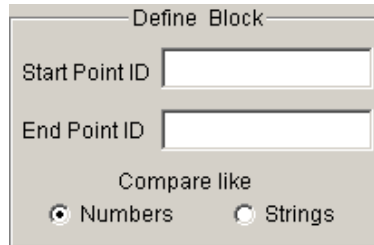

Note: Any time there are points in the list the REMOVE from SELECTION button will be enabled. Clicking this button will remove points from the list according to the current method being used to choose points.

All

If you choose all and not all of the points in the file are in the list, the **ADD from FILE** button will be enabled. Clicking the **ADD from FILE** button will add all the points from the file to the list.

Block

If you choose the **Block** method, the following **Define Block** section will appear below the **Choose Points section** of the dialog.

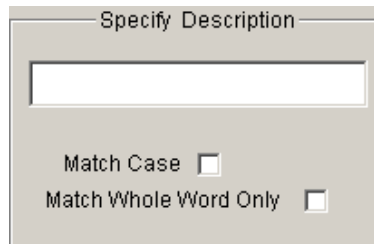

The 'Define Block' dialog box contains two text input fields: 'Start Point ID' and 'End Point ID'. Below these fields is a section labeled 'Compare like' with two radio buttons: 'Numbers' (which is selected) and 'Strings'.

Fill in the **Starting Point ID** and **End Point ID** then click the ADD from FILE button.

by Desc

If you choose the **by Desc** method, the following **Specify Description** section will appear below the **Choose Points section** of the dialog.

The 'Specify Description' dialog box features a large text input field at the top. Below it are two checkboxes: 'Match Case' and 'Match Whole Word Only', both of which are currently unchecked.

Fill in the description to look for and check the **Match Case** and **Match Whole Work Only** checkboxes as needed. Next click the **ADD from FILE** button

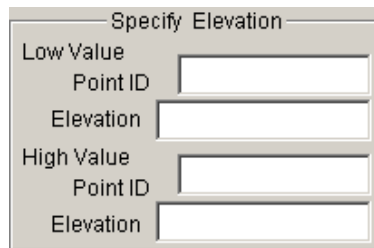

and any matching point records will be added to the list.

by Code

If you choose the **by Desc** method, the following **Specify Code** section will appear below the **Choose Points section** of the dialog. This section of the dialog looks and functions the same as the **Specify Description** section shown above except you must specify a code.

by Elev

If you choose the **by Desc** method, the following **Specify Elevation** section will appear below the **Choose Points section** of the dialog.

The image shows a dialog box titled "Specify Elevation". It contains two sections. The first section is labeled "Low Value" and has two input fields: "Point ID" and "Elevation". The second section is labeled "High Value" and also has two input fields: "Point ID" and "Elevation".

Specify the high and low elevation values. You can do this by directly entering the elevation values or you can type a point ID in the **Point ID** edit box then click on another edit box. When you do this the elevation of the point is written to the appropriate **Elevation** edit box. If you used a point ID to get the elevation, you can edit the value if necessary. Next click the **ADD from FILE** button to add the points to the list.

in Radius

in Rect

Coordinate File Data Entry

There is only one type of coordinate record called a **Point** record. This record has six fields:

Point ID: Point identifier must be unique. Its format varies according to the type of coordinate file.

Northing: Specifies the northing or Y coordinate of a point.

Easting: Specifies the easting or X coordinate of a point.

Elev: Specifies the elevation or Z coordinate of a point. (May be On or Off. To turn the column on click the column heading.)

Code (C&G coordinate files only):

a 4 character optional field used to group points. May be blank. (May be On or Off. To turn the column on click the column heading.)

Description:

Text describing the point. May be blank. Length limited by type of coordinate file. (May be On or Off. To turn the column on click the column heading.)

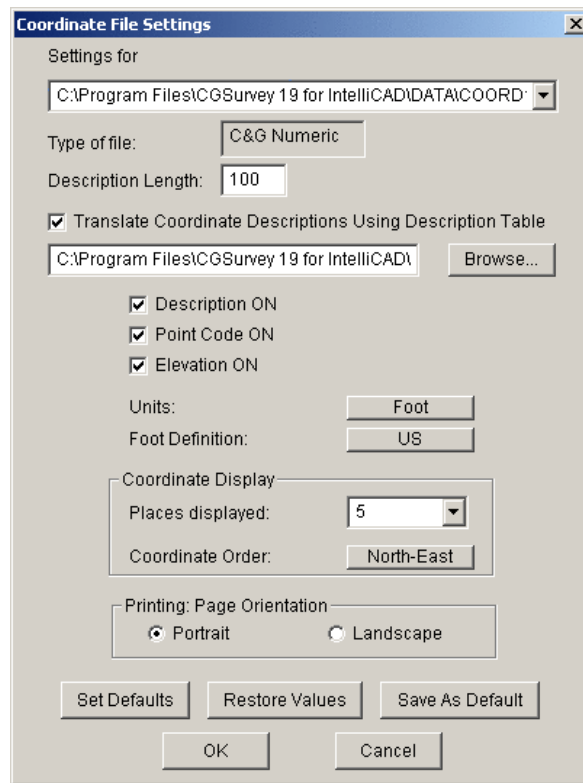

After adding or inserting a **Point** record, fill in the various fields as needed. Use the Tab or Enter keys to move from one field to the next. If you press Enter when in the last activated field in a record, a new blank record will be created just below the current record and the current field will be set to the **Point ID** field in the new record.

To replace the data in an existing record, just click once on the field you wish to replace and begin typing the new data. To edit the data in an existing record, click twice on the field you wish to edit and make any edits required in the existing data.

Settings Menu

Coordinate Files

Choosing this menu item brings up the Coordinate File Settings dialog

Settings for

drop down list box allows you to specify settings for any coordinate file currently open in the **CGEditor** as well as choose to set the **Default settings for new files you create.**

Type of File is only visible for the files currently open.

Description Length:

this edit box can be used to set a new description length for the file. If you choose to change the description length, any descriptions that already exist in the file will be truncated to the new length.

Translate Coordinate Descriptions Using Description Table checkbox

if this is checked then the description table file name edit box and the **Browse...** button will be enabled and you will be required to specify a description table to use.

Description ON checkbox - if this is checked then the **Description** column will be activated in the editor.

Point Code ON checkbox - if this is checked then the **Code** column will be activated in the editor. (Only applies to C&G coordinate files)

Elevation ON checkbox - if this is checked then the **Elevation** column will be activated in the editor.

Units: click the button to switch between **Foot** and **Meter.**

Foot Definition: click the button to switch between **US** and **International** feet. (Disabled if **Units** are set to **Meter**)

Coordinate Display section

Places displayed: drop down list - use to specify the number of decimal places displayed in the editor for northing, easting and elevation.

Note: the **Places displayed** setting does not affect the values actually stored in the coordinate file, only how they

are displayed in the editor window.

Coordinate Order: click button to switch between **North-East** and **East-North**.

Printing: Page Orientation section

choose **Portrait** or **Landscape**. You may wish to choose **Landscape** to avoid having the coordinate records with long descriptions causing each page to span 2 pages in width.

The **Set Defaults**, **Restore Values** and **Save As Default** have been covered elsewhere.

US Foot menu item

If this menu item is checked units are US feet. If the **Meters** menu item is checked, this menu item is disabled. The check will also be set or cleared by changes in the **Coordinate File Settings** dialog.

International foot menu item

If this menu item is checked units are International feet. If the **Meters** menu item is checked, this menu item is disabled. The check will also be set or cleared by changes in the **Coordinate File Settings** dialog.

Feet menu item: If this menu item is checked units are Feet. The check will also be set or cleared by changes in the **Coordinate File Settings** dialog.

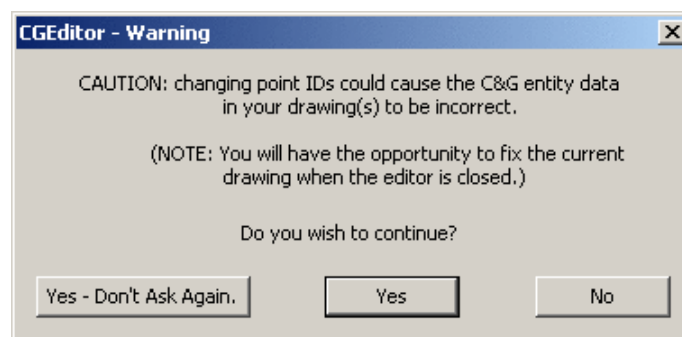

Meters menu item: If this menu item is checked units are meters. The check will also be set or cleared by changes in the **Coordinate File Settings** dialog. **Note:** The settings for US Foot and International foot will be ignored if Meters is checked.

Tools Menu

With the exception of **Renumber Points**, the items on the Tools menu are similar to those items already described for other file types.

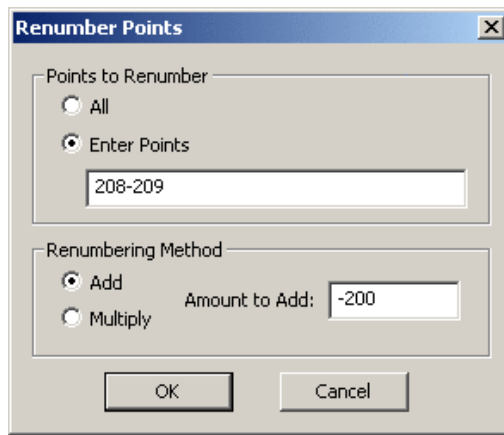

Renumber Points menu item

When you choose the **Renumber Points** menu item you will receive a warning regarding the problems that may be encountered in existing C&G drawings.

After considering the problems you may encounter due to point renumbering respond **Yes** or **Yes-Don't Ask Again** to continue with the renumbering operation, or **No** to cancel the operation.

If you choose to continue with the renumbering of points, you will see the **Renumber Points** dialog:

Renumber Points dialog

Points to Renumber section

First choose **All** or **Enter Points**.

If you choose **Enter Points** you must fill in the edit box specifying the points to renumber. The points to renumber can consist of single points or range(s) of points. Multiple entries of ranges and/or single points must be separated from the next entry by a comma (",") and ranges must be specified using a dash ("-")

Renumbering Method section

choose **Add** or **Multiply** then enter the **Amount to Add:** or **Multiply by:** in the edit box. You may specify a positive or negative whole number.

When done click **OK**. Click **Cancel** to end the command without changes to the coordinate file being edited.

Editing C&G Point Group Files

A C&G point group is essentially a list of points placed in a specially formatted text file (*.pts). It is possible to create and/or edit point group files using any plain text editor like Microsoft Notepad or Wordpad if you know the format of the file. Typically it is far easier to use the CGEditor to create and/or edit C&G point group files. Point groups have many uses in C&G commands: road alignments, property boundaries, define **Include** and **Exclude Boundaries** for **Topo** commands, etc. In the case of alignments, a point group can also include vertical curve information.

C&G point group files are organized into named subgroups. The subgroup name can be anything you wish to use to identify the points that follow. You may have several subgroups in a single point group file. For example, if you are defining subdivision lots, then you may choose the subgroup names to be lot 1, lot 2, etc. For an alignment you can make the subgroup name the starting station and C&G features will make this the default starting station when asking you for an alignment. Point groups can also be used to .

Creating and Opening Point Group Files

You may open and/or create as many files as are needed for your project.

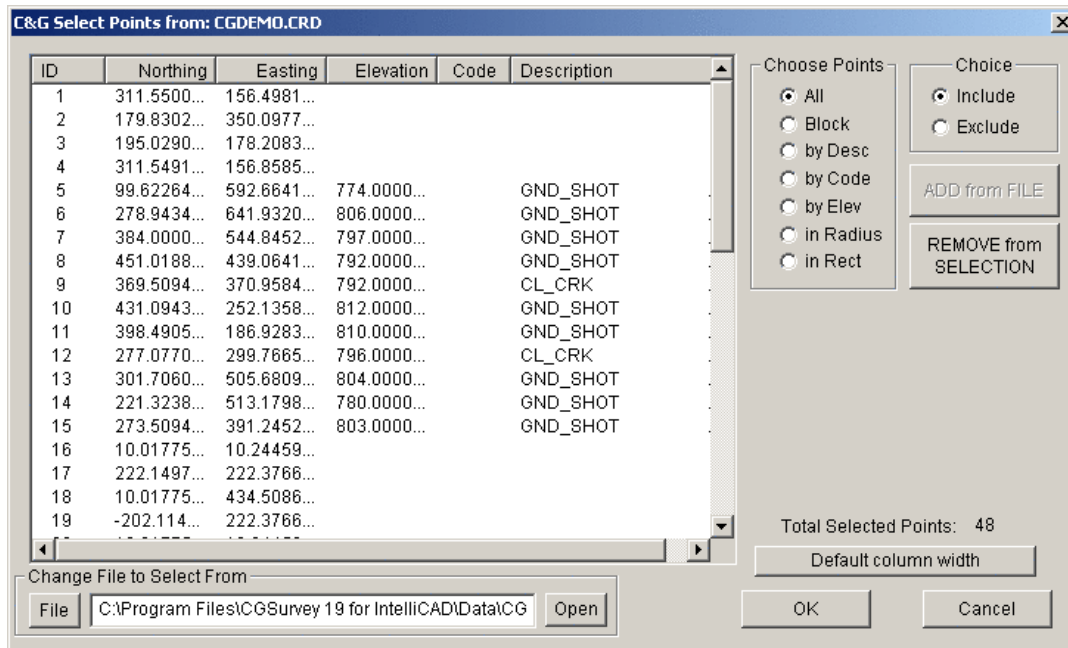

To create a new empty point group file choose the **File** menu then the **New** menu item then the **Point Group File** menu item or, more simply, just click the "P" toolbar icon on the **Standard** toolbar. In either case, a document window will appear within the main CGEditor window. This will have a single blank record or row for the **Subgroup** name - identified by **SGR** in the **Type** column.

To open an existing point group file, choose **File** then **Open...** Then, in the file dialog, browse to the directory where your point group file is located, highlight the desired file and click the **Open** button. The records will be read from the file and will be displayed in a separate document window

Entering and Editing Point Group File Data

If you do not have a subgroup name record, choose the **Add/Insert** main menu then, if you wish to place it at the end of the file, choose the **Add Subgroup** menu item or, if you wish to insert it above the current record, choose the **Insert Subgroup** menu item. After filling in the subgroup name, you can just press Enter to add a single Point record (identified by **PNT** in the **Type** column) below the subgroup name record. Alternatively, you can use the Add/Insert menu to add or insert a single point or you can choose to add or insert several points from a coordinate file. These same add and insert methods can be found on the **Add/Insert** Toolbar.

If you choose to **Add** or **Insert Pts from File** the following dialog comes up:

The use of this dialog to choose points has been described in detail under the section on **Editing Coordinate Files**. Please refer to that section for more details. After choosing the points you wish to add or insert into the point group using the **C&G Select Points from ...** dialog, click OK and the point records will be created in the point group file being edited.

Horizontal Curves

You may have noticed that the **Rad Pt Type** column is marked with **<None>** for the points you have inserted so far. However, if you wish to specify a curve in your alignment or lot boundary, you must designate the record as a radius point. If you click on the **Cw** toolbar icon (for clockwise) or the **Cc** toolbar icon (for counter clockwise) or choose similar items on the **Tools** menu, you will notice that the **Rad Pt Type** column for the point changes to **CW** or **CCW** to indicate that the point is a radius point. If a radius point is specified, the preceding point is assumed to be the PC and the following point is assumed to be the PT. If you wish to change the point back to not being a radius point, click the **Not Radius Pt** toolbar icon or use the **Tools** menu.

Vertical Curves

You may enter vertical curve information in a point group file. This allows you to not only specify the horizontal location of the alignment, but also its vertical alignment. A point group file that has vertical curves in it may not contain any subgroup records. If you attempt to place vertical curve data in a file having one or more subgroups, you will be given the following warning:

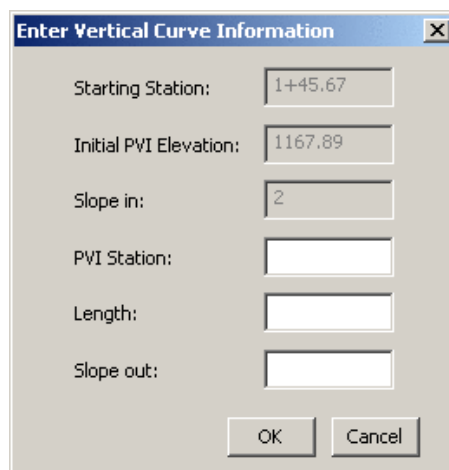

As indicated by the choices in the dialog, you may continue and place vertical curve info in a point group file containing subgroups, but it will not be usable in C&G commands.

If you have no subgroups (or if you do and answer "Yes" to the warning) and this is the first vertical curve in the file, the **Enter Vertical Curve Information** dialog will come up.

Enter the information in the dialog to specify the vertical curve. The **Starting Station** and the **PVI Station** should be entered as decimal numbers and when you click in another edit box the decimal station will be converted to standard station notation. The **Slope in** and the **Slope out** should be entered as a percent (For example, enter 2 or 2.0 for 2%). When you click **OK** the vertical curve records **VC1** and **VC** are added in the document window.

For the second and succeeding vertical curves, you can either **Add Vertical Curves** to the end of the vertical curve records or you can **Insert Vertical Curves** within the existing vertical curve records. For these vertical curve records, the dialog requires fewer entries:

This is a result of the fact that the initial vertical curve **Starting Station**, **Initial PVI Elevation** and **Slope in** control the overall vertical orientation of the succeeding vertical curves thus you need only enter the **PVI Station**, **Length** and **Slope out** for these vertical curves. When you click **OK**, another vertical curve record will be added to or

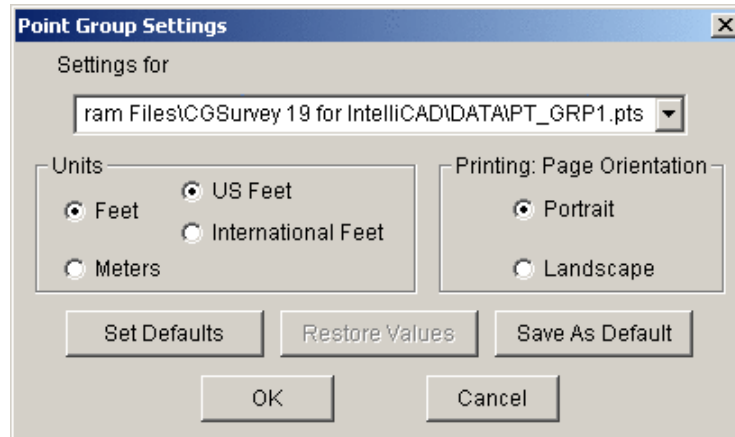

inserted into the document.

Once the vertical curve information has been specified you can go ahead and enter the points specifying the alignment.

Settings Menu

The Settings menu allows you to configure the point group file and the record appearance.

Choose the **Point Group Settings** menu item to bring up the **Point Group Settings** dialog:

In this dialog you can set the units and the page orientation for printing.

Note: the units setting only effects the display of stations in station notation.

Choose the **Record Color** menu item to bring up the **Record Color** dialog. Set the display color of the various records by clicking on the line for the record type. This brings up a color dialog that allows you to pick from the 16 available colors. Click **OK** when done.

Tools Menu

The items in the **Tools** menu are, for the most part, self-explanatory or have been covered in detail for other types of files.

Pulldown Menu Location: CG-Survey>Tools>CGEditor

Keyboard Command:eda, cg_edit_all

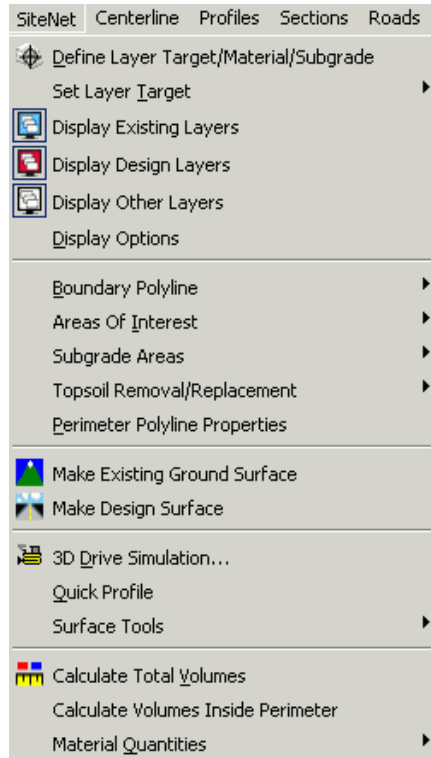

Prerequisite: May need existing C&G raw traverse data file (*.cgr), C&G Map Check file (*.cgm), C&G Cross Section file (*.cew), C&G Template file (*.ctp), coordinate files (*.crd, *.cgc, *.zak, *.mdb) and/or C&G Point Group files (*.pts)

Civil Module

5

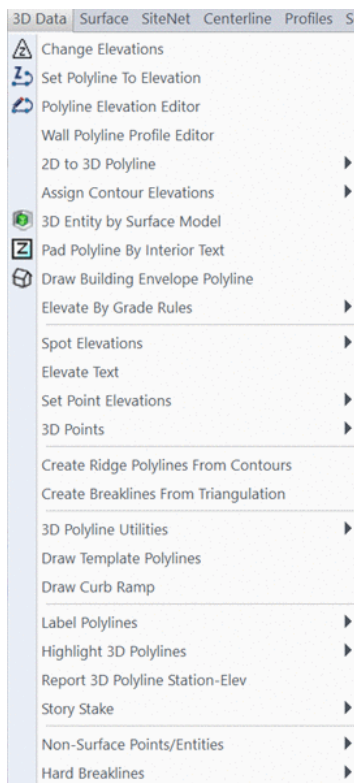

SiteNet Menu

The SiteNet programs build triangulation surfaces, apply surface adjustments, calculate volumes and report material quantities. Drawing layers are organized by target surfaces: design, existing or other. Polyline perimeters are used to define the site boundary, subgrade areas and topsoil areas. Once the layers and perimeters are setup, the surfaces are created by the Make Existing/Design Surface commands. Then there are commands to inspect the surfaces and report volumes and material quantities. See the Takeoff section of the Construction chapter of the manual for specifics on each command.

3D Data Menu

The 3D Data menu has commands for creating 3D entities to use for surface modeling. Several of these commands are shared in common with the Elevate menu of the Construction module.

Change Elevations

This command will change the elevation of selected entities. It can move the entity to a specified elevation from its current elevation (absolute) or do a differential change by adding or subtracting a value from its current elevation. If Carlson points are selected, their elevation attribute text and the elevation stored in the external coordinate file are changed. If the points are in the drawing at their real Z, this is also adjusted, however, if they are in the drawing at a fixed elevation, e.g. 0, the point blocks remain at that elevation.

There are options to move the changed objects to a new layer, and alternately to select a source object's elevation to supply the value of the elevation to change the selected object(s) to.

Prompts

Type of elevation change [<Absolute>/Differential**]:** *press A* to change to a specific (absolute) value, or *press D* to enter an amount of elevation change to apply to object's current elevation.

Change Layer for changed entities [Yes/No**]:** *press Enter* or *N* to keep on same layer, *press Y* to change layer of object after changing elevation.

Select/Enter Elevation **<100.0000>:** *125* By using the Absolute option all entities selected are changed to the elevation 125. You may simply *press Enter* to keep the value shown in brackets. *Press S* to select a source object's elevation for the new elevation to change the selected object(s) to.

Select objects: 1 found

Select objects: *press Enter* to conclude selection.

Tested 1 Entities

Carlson Software Points Changed > 1

Select/Input another Elevation (Enter to end): *press Enter*

Pulldown Menu Location: 3D Data

Keyboard Command: chgelev
Prerequisite: Something to change

Set Polyline To Elevation

This command allows you to assign elevations to one or more polylines. The command also affects lines, arcs, circles, inserts and points as well as polylines. The elevation can be assigned by entering the value or by picking an existing object or text entity that has the desired elevation. Note that this will change 3D objects to a single target elevation (making it a 2D object) as well as changing elevation values of 2D objects.

Note that this is the same command as **3D Entity to 2D** on the **Edit** menu.

Prompts

Enter/⟨Select text or linework of elevation⟩: *Press E to enter a value directly, or select text or linework of source value*

Linework Elevation: 440.000 (elevation of selected linework displays).

Select Lines, Arcs, Circles, Polylines, Inserts and Points for elevation change.

Select objects: 1 found

Select objects: 1 found, 2 total

Select objects: 1 found, 3 total

Select objects: *press Enter to conclude selection.*

LWPOLYLINE (indicates entity type)

LWPOLYLINE

3DPOLY to 2DPOLYLINE

Number of entities changed > 3

Pulldown Menu Location: 3D Data

Keyboard Command: 3dto2d

Prerequisite: A polyline and a target elevation to assign

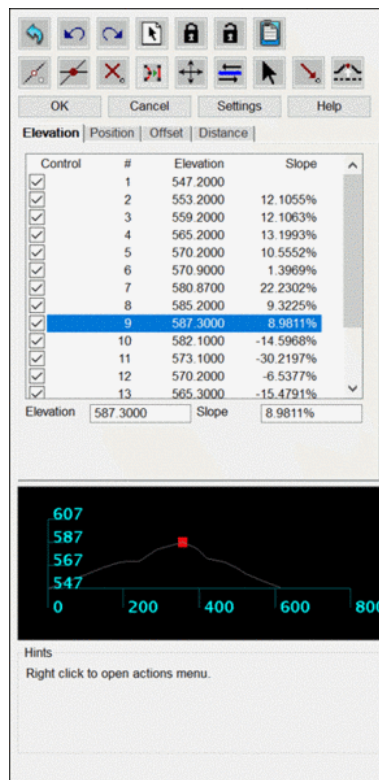

Polyline Elevation Editor

This command allows very precise control of 3D Polylines, specifically in the ability to edit vertex elevations, as well as add, delete, or move vertices. If these polylines are used in the creation of surfaces as breaklines, any editing you do may update the surface automatically. You can also control the location of Polyline vertices as defined by the station and offset of the vertices relative to a Centerline. Polyline vertices are designated as either control or free vertices. The elevation of control vertices are set and held, the elevations of free vertices are interpolated. In the drawing, control vertices are shown by default with red boxes, free vertices with blue boxes, but you may configure these using the Grip Color in the Settings.

Polyline Elevation Editor Dock Dialog:

When you run the Edit Assign Polyline Elevations routine, you are first prompted to select a Polyline to edit. After selecting a Polyline to edit, the following dock dialog appears on the left side of your screen. This dialog is "modeless" meaning that CAD commands and controls are still active while this dialog is active.

Tabs:

The four tabs in the panel provide access to control of Polyline vertex **Elevation, Position, Offset** and **Distance**.

- **Elevation:** This tab displays the vertices of the Polyline, each with a check box to set whether it is a control vertex or a free vertex (Control), its assigned number (#), its elevation (Elevation), and the slope from the previous vertex to that vertex (Slope). Selecting a vertex highlights its grip in the drawing. Once selected, you can enter an "elevation" or "slope" edits for that vertex. If multiple vertices are selected with varying elevation or slopes then "[multiple]" will be displayed in the "Elevation" and or "Slope" edits. When multiple vertices are selected, entering values in the "Elevation" or "Slope" edits will set all selected vertices based on the entered elevation or slope values.
- **Position:** The Position tab displays the Easting and Northing coordinates of each vertex. When one vertex is selected Northing and Easting can be entered in the "Northing" and "Easting" edits. When Multiple vertices are selected average Northing and average Easting are displayed in the "Average Northing" and "Average Easting" edits. When multiple vertices are selected entering values in the "Average Northing" and or the "Average Easting" edits will set all selected vertices Northing and or Easting values to based on the entered values.
- **Offset:** The Offset tab requires the selection of a Centerline to reference. Once a Centerline is designated, the Station and Offset of each vertex relative to the Centerline is displayed and can be edited.
- **Distance:** The Distance tab shows the horizontal distance for each Polyline segment. You can change a distance by highlighting the segment on the list and editing the value in the "Horz Dist" edit. If multiple vertices are selected "[multiple]" will be displayed in the "Horz Dist" edit. The user cannot set multiple segment's horizontal distances at once.

Toolbar Commands:

The toolbar provides access to several commands, some of which are tab specific.

Revert All: Reverts currently selected Polyline vertex positions and control information to vertex positions and control information when Polyline was initially selected. (Note: Selecting a new Polyline resets initial reversion location)

Undo: Undoes the most recent command line action. (Equivalent to ctrl+z)

Redo: Redoes the most recent command line action. (Equivalent to ctrl+y)

Select Polyline: Select Polyline to edit. (Note: if no Polyline is selected a Polyline can be selected using CAD selection)

Control Selected: Set selected vertices controlled, elevation will not be interpolated for control points. (This toolbar command is only available when elevation tab is active)

Free Selected: Set selected vertices free, elevation will be interpolated for free points. (This toolbar command is only available when elevation tab is active)

Output Report: Brings up Report Formatter dialog. Output reports can contain Easting, Northing, and or Elevation information for each vertex as well as whether or not each vertex is controlled or free.

 **Create Vertex:** Creates a vertex at the station nearest the mouse click position. Control/free state depends on the "Create Vertex Mode" setting (see Settings dialog).

 **Create Vertex At Crossing:** Prompts user to select crossing Polyline(s). If Polyline(s) selection is(are) applicable, crossing vertex point(s) are added at the elevation of the selected Polyline(s) at crossing. All created vertices are added as control points.

 **Delete Vertices:** Deletes currently selected vertices.

 **Reduce Vertices:** Prompts user to select an offset cutoff. Removes those vertices from the active Polyline that will not change the position of the Polyline at that vertex by more than offset cutoff. Will not removed controlled vertices.

 **Move Selected:** Move currently selected vertices based on drag offset. (Equivalent of click and drag)

 **Reverse Polyline:** Reverses indices of vertices. This will be reflected by reversing the vertices in the currently active list view.

 **Pick Elevation/Position From Screen:** Elevation- prompts user to pick an entity from screen. Will set elevation based on entity's elevation information. Vertex set controlled. Position-prompts user to pick position from screen sets Northing and Easting based on selected position. (This toolbar command is only available when elevation tab or position tab is active).

 **Pick Elevation From Surface:** Prompts user to select a surface model (tin;ft). Then prompts user to pick a direction point to run the slope from highlighted vertex. Elevation of highlighted point is determined from surface and slope is then applied along the line to the next control point. (This toolbar command is only available when elevation tab is active and one or more vertices is selected).

 **Pick Elevation With Slope:** Prompts user to pick a point or elevation text. Then prompts user to pick slope. An elevation is then calculated based on the run to the point selected at the slope the user input. Elevated vertices will be set controlled. (This toolbarcommand is only available when elevation tab is active).

 **Offset Selected Elevation:** Prompts user to input an offset amount. Adds(subtracts) offset amount from currently selected vertices. Offset vertices will be set controlled. (This toolbar command is only available when elevation tab is active)

 **Select Centerline:** Prompts user to select a Centerline or Polyline to apply Centerline information from screen. (This toolbar command is only available when Offset tab is active)

OK:

The "OK" button closes the Polyline Elevation Editor dialog, and saves the vertex position and control information of the currently selected Polyline.

Cancel:

The "Cancel" button closes the Polyline Elevation Editor dialog, and reverts the currently selected Polyline's vertex position and control information to the vertex position and control information when the Polyline was first selected.

Settings:

The "Settings" button provides control over various options pertaining to the use of the Polyline Elevation Editor routine.

- **Label Control Points:** Toggle on to display control vertices' numbers and elevations.
- **Label Non-Control Points:** Toggle on to display free vertices' numbers and elevations.
- **Hide Non-Control Points:** Toggle on to remove all free vertices' grips.
- **Auto-Center:** Toggle on to automatically center view such that all currently selected grips when they are selected.
- **Auto-Advance:** Toggle on to automatically advance the currently selected grip to the next available vertex (by vertex number).
- **Key "esc" key to Cancel button:** Toggle on to key "esc" to the Polyline Elevation Editors' dialog "Cancel" button. That is pressing the "esc" key will cancel and exit the Polyline Elevation Editor routine.
- **Base Elevation:** When toggled on the leading significant digits of the Base Elevation value will be added as a prefix to any elevation value entered. Base Elevation values must be whole numbers greater than or equal to zero. Typical use: (Base: 6000)+(User: 100)=(Elevation: 6100 displayed as 100).
 - *Conflicts:* Some user entered elevation values are ambiguous in terms of how to combine the Base Elevation, and the user entered elevation. These conflicts are dealt with as follows:
 - * *Significant Digit Conflicts:* In the case where a user entered value, and the Base Elevation value both contain significant digits in the same column(s), then the user entered value supersedes the Base Elevation value in that(those) column. Ex: (Base: 6500)+(User: 100)=(Elevation: 6100 displayed as 100).
 - * *Negative Value Conflicts:* Negative values are processed as values below the Base Elevation. However, adding a negative value can result in elevations that result in "Significant Digit Conflicts" with the Base Elevation. In this case the logic of the "Significant Digit Conflicts" applies. Ex: (Base: 6000)+(User: -100)=(Elevation: 5900 displayed as 5900).
- **Slope Mode:** Determines how slope at a vertex is displayed and interpreted.

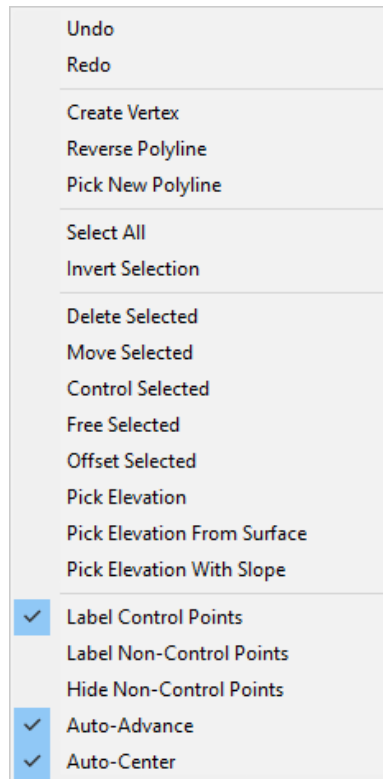

- *Slope Ratio*: Slope as a ratio of line length to line elevation [*run/rise*]
- *Slope Percent*: Slope as a percent [*rise/run*100*]
- *Slope Degree*: Slope as degree offset from 0° from -90° to 90° [*atan(rise/run)*180/PI*]
- **Allow Vertex Dragging**: Determines how dragging selected vertices functions.
 - *Never*: Never allow dragging.
 - *Prompt*: On completion of vertex dragging user is prompted on whether or not to accept the results of the dragging operation.
 - *Always*: Always allow dragging.
- **Create Vertex Mode**: Determines how elevation is calculated for vertices inserted using the Create Vertex toolbar command, double click on line, or right-click Create Vertex command.
 - *On Line*: Creates a vertex at the station nearest the pick point. Elevation is interpolated based on the equation [$elv=(InsertDistance2D/TotalDisatance2D)*(TotalElevationChange)$]. If no control points exist, then the elevation is set to the elevation of all other free vertices on the Polyline. Inserted vertex is a free point.
 - *At Pick*: Creates a vertex at pick point. Vertex is inserted in the Polyline after the vertex preceding the nearest station to the pick point. If the pick point is the result of a snap, the elevation of the new vertex is taken from the elevation of the snapped entity, and the created vertex is added as a control point. Otherwise, the created vertex is added as a free point.
- **Add Vertex Crossing Mode**: When running the function to add vertices at crossings with other linework, this option chooses whether to add intersection vertices on the crossing linework in addition to the current polyline.
- **Decimals**: Determines how many decimal places are displayed in Polyline Elevation Editor dialog. User can choose between 0 and 6 decimal places for display.
- **Label Alignment**: Determines where vertex index, and vertex elevation for all labeled vertices is drawn.
 - Right: Draw label to the "right" of vertex grip. Takes into account screen rotation.
 - Top: Draw label "above" vertex grip. Takes into account screen rotation.
- **Grip Selection**:
 - *Standard*: left-click to drag vertex, shift+left-click to select single grip vertex.
 - *Inverse*: shift+left-click to drag vertex, left-click to select single grip vertex. (legacy control)
- **Grip Border Width**: Allows user to set the relative size of the gripbox for all vertices based on the internal ACAD/ICAD GRIPSIZE variable. (Note: the values associated with each Grip Border Width choice represent the value that the internal ACAD/ICAD variable GRIPSIZE is set to for each Grip Border Width selection. If the current GRIPSIZE ACAD/ICAD variable is not one associated with any of the Grip Border Width choices ["Small," "Medium," "Large," "XLarge"] the Grip Border Width will be set to current ACAD/ICAD GRIPSIZE.)
- **Grip Color Settings**: Set the grip colors for easier editing of the vertices:
 - Hover Vertex
 - Control Vertex
 - Free Vertex
- **Profile View Settings**:
 - Drag Action: Choose between doing Zoom or Pan for click-n-drag in the profile view.
 - Axis Style: Set the profile grid display.
 - Vertical Exaggeration: Control the display for the profile vertical scale.

Help:

Display Carlson documentation for Polyline Elevation Editor.

Right-click Dialog:

There is a right-click menu available when the Polyline Elevation Editor routine is running which gives access to a variety of functions and settings. "Select All" and "Invert Selection" are the only commands unique to the right-click dialog. "Select All" selects all currently visible vertices. "Invert Selection" inverts all currently visible vertices. "Undo," "Redo," "Create Vertex," "Reverse Polyline," "Pick New Polyline," "Delete Selected," "Move Selected," "Control Selected," "Free Selected," "Offset Selected," "Pick Elevation," "Pick Elevation From Surface," "Pick Elevation With Slope," and "Pick Position" are equivalent to the Toolbar Command with the same name. "Label Control Points," "Label Non-Control Points," "Hide Non-Control Points," "Auto-Advance," and "Auto-Center" are equivalent to their settings dialog toggles with the same name.

Pulldown Menu Location: 3D Data

Keyboard Command: EDIT_PLINE.Z

Prerequisite: 3D Polylines with vertices

Wall Polyline Profile Editor

This command creates a retaining wall object using a polyline to define the alignment and attaching top and bottom profiles. This polyline is recognized by surface modeling commands like Triangulate and Contour as a retaining wall and the top and bottom profiles get built into the model. The wall polyline is also used in SiteNet and Takeoff for building the design surface including the subgrade surface for the base of the wall.

The polyline should be drawn so that the left side is the low side and the right side is high. Use the Reverse Polyline command in the Edit>Polyline Utilities menu if you need to switch the polyline direction.

The command prompts to select the polyline for the wall. If the polyline isn't already set as a wall polyline, the program prompts for a reference surface file which is used to define the initial top and bottom wall profiles. When the polyline is already set as a wall, the program loads the wall definition and goes directly to the profile editor.

The profile editor has a toggle to switch between editing the top and bottom profiles. Please see the Road Profile Editor command for a description on how to use the editor.

Surface View: Sets the color or texture of the wall for the 3D Viewer commands.

Layback Slope: Sets the slope from the top front to the bottom front of the wall.

Top Width: Sets the width of the wall at the top.

Bottom Width: Sets the width of the wall at the bottom.

Freeboard: Sets the height of the wall above the backfill surface on the back side of the wall.

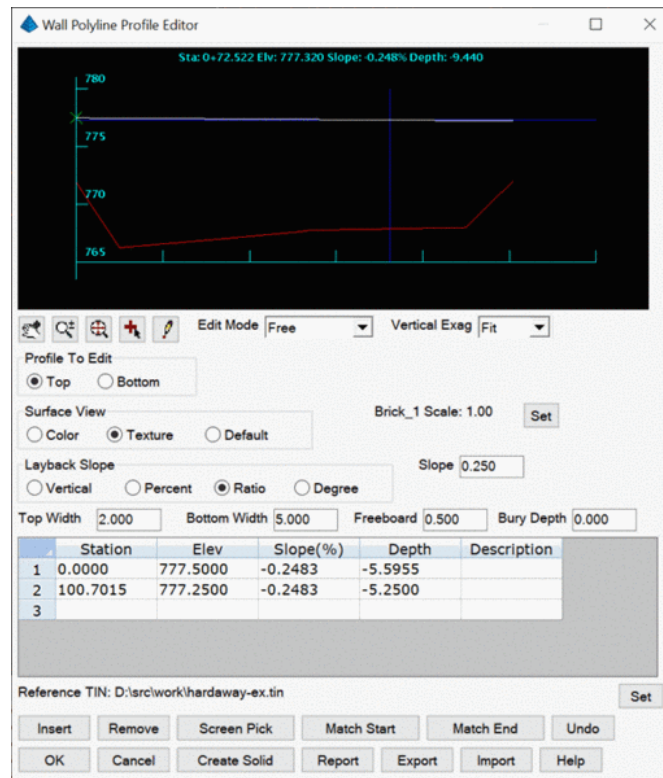

Bury Depth: Sets the depth of the wall below the surface at the front of the wall.

Match Start: Sets the top and bottom profiles to the same starting elevation.

Match End: Sets the top and bottom profiles to the same ending elevation.

Create Solid: Makes a solid model (.mdl) for the wall.

Report: Creates a report of the wall dimensions, profiles, volume, face area and backfill.

Prompts

Pick retaining wall polyline: *select polyline for wall*

Profile Editor dialog

Pulldown Menu Location: 3D Data

Keyboard Command: rwallpro

Prerequisite: polyline and surface file

2D to 3D Polyline by Surface Model

This command converts a 2D polyline into a 3D polyline by calculating 3D polyline vertices at all the intersects of the 2D polyline with the surface definition contained in the selected grid (.grd) or triangulation (.flt, .tin) surface file.

The command then interpolates elevations from these intersections at the original vertex locations. An application for this command is to "drape" linear features along a surface such as a 2D centerline. For example, a 2D centerline may be created in the drawing and then elevated to the target surface, thus providing a quick "profile" of the centerline which can then be offset for left and right edges, constructing a 3 dimensional model of the corridor alignment.

When you first run the command, a dialog pops up for selecting the desired surface file to use. Once selected, the following prompts appear:

Prompts

Loading edges...

Loaded 8788 points and 26097 edges

Created 17310 triangles

Select polylines to convert. *select one or more 2D polylines*

Select objects: 1 found

Select objects: *press Enter* to conclude selection.

Use current polyline elevations as vertical offset from surface [Yes/<No>]? *press Enter* to accept default.

Keep existing polylines [Yes/<No>]?

Set layer name for converted polylines [Yes/<No>]? *Press Y* to assign a new layer name or *press Enter*

Converting polylines ...

Elevated 1 polylines.

Pulldown Menu Location: 3D Data > 2D to 3D Polyline

Keyboard Command: 2dto3dpf

Prerequisite: polylines and a grid file or triangulation file.

2D to 3D Polyline by Screen Entities

This command converts a 2D polyline into a 3D polyline by calculating 3D polyline vertices at all the intersects of the 2D polyline with surface entities (contour polylines, triangulation lines) and by interpolating elevations from these intersections at the original vertices locations. An application for this command is to create breaklines. For example, a ridge or valley breakline could be generated from contour lines by drawing a 2D polyline along the ridge top or valley bottom, crossing the contours. Then the command would "grab" the contour line elevations along the polyline to make a ridge or valley breakline.

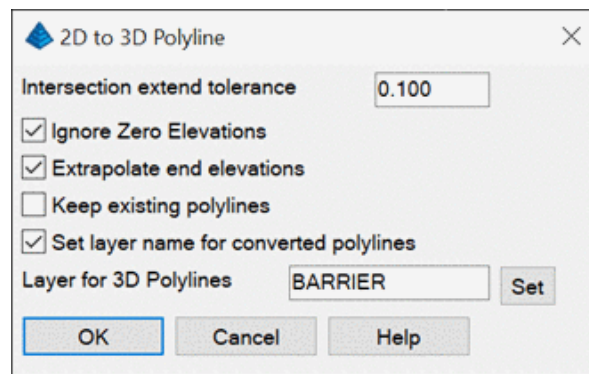

Intersection extend tolerance: Sets how far past the ends of the polyline to check for intersections.

Ignore Zero Elevations: Filters out any intersections at zero.

Extrapolate end elevations: Sets the start and end polyline elevations by extrapolating the last slope.

Keep existing polylines: Creates separate 3D polylines and leaves the original 2D polylines unchanged. Otherwise the original polylines are changed to 3D polylines.

Set layer name for converted polylines: Changes the layer name of the elevated polylines.

Prompts

2D to 3D Polyline dialog

Reading points ... 5353

Converted 1 polylines from 24 intersections.

Pulldown Menu Location: 3D Data > 2D to 3D Polyline

Keyboard Command: 2dto3dps

Prerequisite: Polylines and 3D surface entities

2D to 3D Polyline by Points

This command converts a 2D polyline into a 3D polyline by using the elevations of points. At each vertex of the polylines, the program looks for a point with elevation at the same x,y location. The points can be Carlson point blocks or POINT entities. This routine can be useful if the linework is created in 2D at zero elevation with commands like Draw 2D Polyline, and points with elevation are located along the linework. Then the linework can be converted into 3D polylines with this command. For example, a centerline polyline with arcs may need to be created in 2D for stationing because AutoCAD does not allow arcs on 3D polylines. To use this polyline as a breakline in surface modeling, this command can convert the polyline into a 3D polyline.

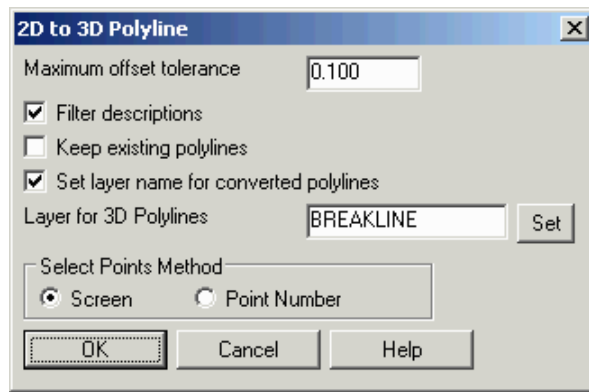

Maximum offset tolerance: points must be within this distance of the polyline vertices to get applied.

Filter descriptions: filters point by their description with ability for different vertical offsets by description.

Keep existing polylines: controls whether to erase for original 2D polylines.

Set layer name for converted polylines: assigns the layer name to the new 3D polylines.

Select Points Method: choose between screen picking the points or entering point number to process.

Prompts

2D to 3D Polyline dialog

Select polylines to convert.

Select points.

Select objects: *pick point entities*

Changed 1 polylines.

The routine will convert the 2D polyline into a 3D polyline and place it on the indicated layer.

Pulldown Menu Location: 3D Data > 2D to 3D Polyline

Keyboard Command: 2dto3dpt

Prerequisite: A polyline and points

2D to 3D Polyline by Slope From Reference

This command converts a 2D polyline into a 3D polyline using a slope from a reference 3D polyline or point. For example, this command can be used to elevate a bottom-of-bank polyline given an elevated top-of-bank polyline and bank slope. After selecting the polyline to elevate and the 3D reference, there is a prompt for the slope percent. Use negative for downhill. For each vertex on the 2D polyline, the program finds the nearest position on the 3D reference and assigns the vertex elevation using this reference position elevation plus the slope multiplied by the distance from the vertex to the reference.

Prompts Select polyline to assign elevations: *pick polyline to elevate*

Select reference 3D polyline: *pick reference polyline*

Enter slope percent: -25

Select polyline to assign elevations (Enter to end): *press Enter*

Pulldown Menu Location: 3D Data > 2D to 3D Polyline

Keyboard Command: elev_slope

Prerequisite: A 3D polyline or 3D points to reference

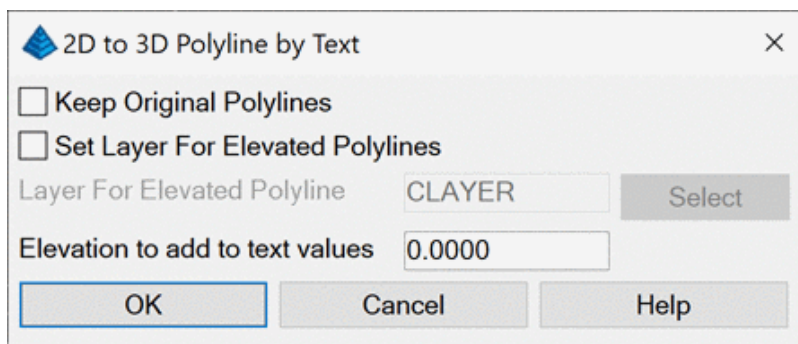

2D to 3D Polyline by Text

This command allows you to change 2D polylines to 3D polylines by elevation labels.

This command will prompt you for samples of the elevation labels and the polylines to convert. The program uses these samples to know the layer names for the labels and linework to process. Then select all the polylines with their labels you want to convert.

There is a dialog to enter in an elevation to add to label values. Often elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 539.97, 540.02, 540.11 sometimes, like in the example below, they are listed as 39.97, 40.02, 40.11. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing.

The dialog also has options to Keep Original Polylines which leaves the original 2D polylines. Otherwise the 2D polylines are replaced by the elevated polylines. The Set Layer For Elevated Polylines allows you to change the polyline layer for the elevated polylines.

This command will assign elevations from the labels to nearby vertices. If vertices do not have a nearby elevation label, then they will be interpolated from vertices that do have nearby elevation labels.

To decide how to apply the elevation text to the polyline, the routine computes the Center Point of the elevation text. Then the Nearest Vertex on the polyline to the elevation text Center Point is computed. Next the Center Point is projected onto the polyline to calculate the Projected Point. If the Center Pointer to Nearest Vertex distance is less than 2/3rd the Projected Point to Nearest Vertex distance then the Nearest Vertex is elevated base on the elevation text. Otherwise, a new vertex is inserted into the polyline at the Projected Point, and this new vertex is elevated based on the elevation text.

Prompts

Select sample of elevation text: *pick a text label*

Select sample of a polyline to convert: *pick a polyline*

Select polylines to convert and elevation labels.

Select objects: *select all the entities to process*

2D to 3D Polyline by Text With Leader

This command will assign elevations from the labels to the polylines by following the label leaders to their corresponding vertices on the polyline.

The command will prompt you for samples of the elevation labels, the leaders, and the polylines to convert. The program uses these samples to know the layer names for the labels and linework to process. Then select all the labels and leaders for the polylines you want to convert. Since you pre-specified the layers involved, you may safely window everything or type the keyword *ALL* and only those layers specified will be examined. You will then be prompted to enter an elevation to add to label values. Often, elevations are abbreviated to save time and space. For example, if every elevation in the drawing is in the 800s instead of labeling every elevation 817.85, 817.40, 817.30 sometimes, like in the above example, they are listed as 17.85, 17.40, 17.30 This option allows you to add a given amount, such as 800, to every label elevation to produce the correct elevation in the drawing.

The program searches for all leaders and gathers their associated text. If the program finds different labels in the elevation text, then this dialog box allows you to select the text you want to use to create the 3D polylines. In this example you might want to use elevations followed by TC. This dialog box allows you to select that text and exclude the other text which is not to be used in the elevations of the polyline, such as FS.

If you are creating 3D polylines from multiple elevation labels, then this dialog box will allow to offset certain labels by a given amount. In the above example you can offset an elevation labeled TC by -0.50 so that it matches vertices set by FS labeled elevations. **Note:** you must press *Enter* after setting the offset amount to assign it to the selected prefix in the list above.

Prompts

Options/Select sample of elevation text: *pick a text label* (Press *O* to set tolerance options).

Select sample of an annotation leader: *pick an annotation leader*

Select sample of a polyline to convert: *pick a polyline*

2D to 3D Polyline by Start/End Elevations

This command allows you to convert a 2D polyline to a 3D polyline by specifying the starting and ending elevations of the polyline. All intermediate polyline vertices elevations are linearly interpolated from these end point elevations.

Prompts

Select polyline to assign elevations:

Enter starting elevation: *109.85*

Percent/Ratio/<Enter ending elevation>: *112.16*

Select polyline to assign elevations (Enter to End): *press Enter*

Pulldown Menu Location: 3D Data > 2d to 3D Polyline

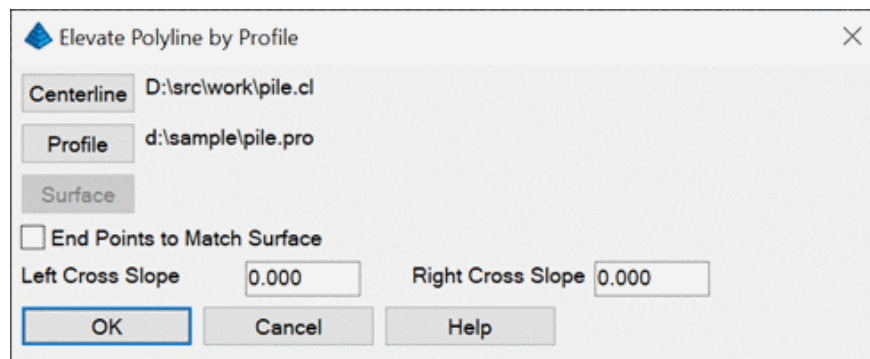

Keyboard Command: 2dto3dpl

Prerequisite: A polyline

2D to 3D Polyline by Profile

This command converts a 2D polyline into a 3D polyline by using a reference polyline, centerline and cross slope. For each vertex on the polyline, the program locates the station and offset from the centerline and then elevation on the profile for that station. Then the vertex elevation is set from that profile elevation plus the cross slope multiplied by the offset. For example, this command can be used to elevate a polyline for edge of pavement at a -2% cross slope from a centerline and profile for the road centerline. To elevate a polyline that is along the profile alignment without an offset, the Profile To 3D Polyline command is more direct method.

There is an option to use a surface to set the elevations at the start and end vertices of the polyline.

Assign Contour Elevations: Multiple in Series

This command can be used to quickly and accurately assign the elevation of series of polylines that have been converted from raster or digitized without correct elevations. The routine will automatically assign elevations to the polylines crossing the fence line selected by two points. At the same time the elevations are changed, the program can assign it a new layer, color, linetype, and polyline width. This process usually works best if contours are in a temporary (white) layer to start. When they are processed, they will take on the color of the new layers making it easy to distinguish which polylines have been processed.

Prompts

3D Entity By Surface Model

This command assigns the elevations of the selected points, inserts, lines and polylines to the elevations defined by the specified grid (.GRD) or triangulation (.FLT, .TIN) file. For lines and polylines, additional vertices are added to model the surface. 3D Polyines cannot have arcs, so any arcs in the original 2D polylines are converted to a series of chords. This command is useful to "drape" objects onto a surface and to easily update them if they are moved to a different location on the surface later by executing the command again.

Prompts

Choose Grid or Tmesh File to Process dialog

Select points, inserts, lines and polylines to convert.

Select objects: *pick the entities to convert*

Converting entities ...

Done.

Pulldown Menu Location: 3D Data

Keyboard Command: convert3d

Prerequisite: entities to be converted, grid or triangulation file

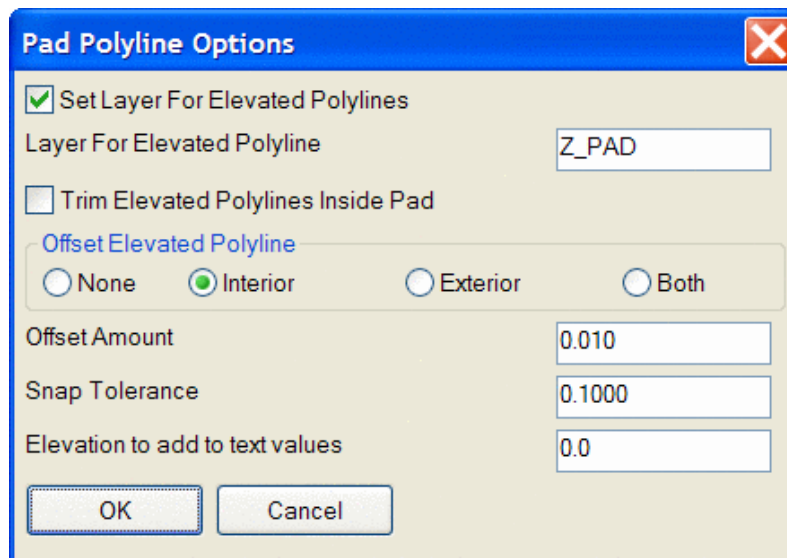

Pad Polyline By Interior Text

This command allows you to set one or more pad elevations using interior text labels.

In the Pad Polyline Options dialog box, you can choose whether to have the new geometry created on a new layer, and if so, specify the name for the layer. You also specify whether to trim any elevated polylines crossing through the new elevated pad. You also specify whether to horizontally offset the new polyline from the original geometry, and if so, whether to offset to the inside, outside, or both, and by how much.

The Snap Tolerance field joins linework which falls within the range you set to create a pad.

Elevation to add to text values adds to the values from the elevation labels. Often, elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 523.5, 543.3, 537.2 sometimes they are listed as simply 23.5, 43.3, 37.2. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing.

After completing the dialog box, click OK. You are prompted to select the layers you want to use for the text representing pad elevations and for the boundaries of the pads. You do this to tell the routine which layers to process once you are prompted to select objects to convert. Also, sometimes pads are drawn with linework from two different layers and Carlson Civil allows you to pick all the linework layers. If you chose to Trim Elevated Polylines Inside Pad, you are also prompted to identify by selection the layer(s) with the elevated polylines that you want trimmed. Finally, select all the pads, labels, and existing elevated polylines, press Enter, and the new polylines with elevations will be created.

Prompts

Draw Building Envelope Polyline

This command creates a rectangular polyline around selected linework. This can be used to give a building all one elevation.

In the Draw Building Envelope dialog box, set the layer for the new polyline and the desired offset value, (the above example is offset by 5 feet). Select whether or not to be prompted for specified offsets for each side, an elevation for the new polyline, and whether or not to trim existing linework that crosses the new polyline. Click OK. Select the entities that make up the building.

Prompts

Select building lines:

Select objects: *pick the building linework*

Draw another building envelope [**<Yes>/No**]?

Pulldown Menu Location: 3D Data

Keyboard Command: bldg_perim

Prerequisite: Building linework

Define Lot Edge Grade Rules

This command establishes grade rules for use in elevating lot edges with respect to a reference 3D polyline such as a road edge or other feature that must remain at its established elevations. Elevating lot edges will create 3D linework along selected lot edges in the drawing and set them at their designated elevations based on the rules established by this command (see *Elevate Lot Edges By Grade Rules* for a more detailed explanation).

This routine defines the actions to take when elevating lot edges by grade rules, establishing three categories of slopes to create (normal, minimum, and maximum) in the two possible conditions that will occur (cut or fill), for

the two edges of the lots being elevated (front edges and back edges). You may also establish intermediate grade breaks along the side lot lines by adding or editing additional grading rules in the middle windows. You define both cut and fill conditions in this routine, and the *Elevate Lot Edges By Grade Rules* command will use the appropriate condition based on whether the lot edge is in cut or fill at any given location with respect to a selected reference grade line such as a road edge or other feature.

Prompts

On execution, the routine prompts for a grade rules filename (.grr) to create if new, or select an existing .grr file. Once chosen, the following settings dialog will appear:

Options:

Slope Type: Choose which type of slope to define, either *percent*, *ratio*, or *vertical difference*.

Normal slope: Set the desired slope to use in initial lot line elevation. This is the slope that is applied whenever you first execute *Elevate Lot Lines By Grade Rules*. Note that positive slope values are from the reference grade line **up** to the front lot line, negative slope values are from the reference grade line **down**, and may be set either positive or negative for either cut or fill conditions. This is useful to force positive drainage toward a roadway, even where the reference grade line is in a fill condition.

Min/Max Slope: These slope values are the limits for automatic adjustment in balancing the final grading of the lots in the *RoadNET* routines. The lot lines' slopes are adjusted to values between these two limits to achieve balanced cut and fill, and if balance is not achieved within these limits, then the entire site is raised or lowered to reach a balanced condition.

Side Line Grade Breaks: The middle windows in the dialog allow you to add, edit, or remove additional grade breaks along the side lot lines and are established at a distance from the previous grade break (either the front line or the previously defined break point), at a given slope (again, defined using percent, ration, or vertical difference).

Back Slopes: These values are for establishing the back lot lines' slopes from the last encountered grade break (either the front line, or intermediate grade breaks).

Back Lot Edge At Existing Ground: Selecting this option will make the back line slopes portion unavailable, and

establish their elevations at the existing grade in their location. This will also prompt for selection of the existing surface model when executing the *Elevate Lot Lines By Grade Rules* routine to establish the required elevations along the back lot lines. Besides locating the back lot corners at the existing ground, this option will also drape the back lot edge on existing ground and add vertices into the back lot edge as needed to follow any undulations in the existing ground surface.

Pulldown Menu Location: 3D Data >> Elevate By Grade Rules

Keyboard Command: roadnet_grr

Prerequisite: None.

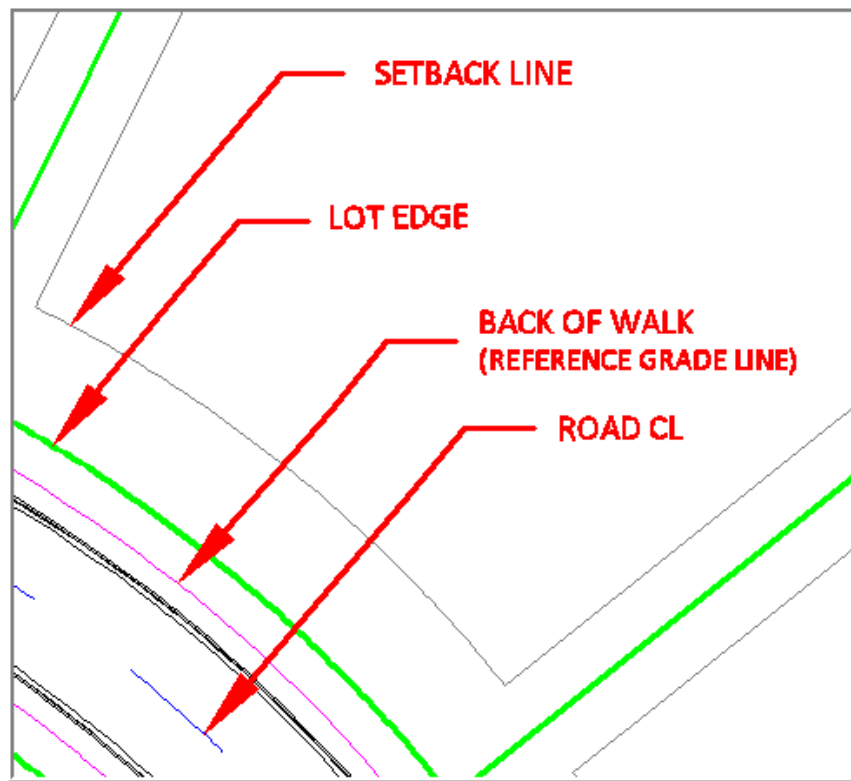

Elevate Lot Edges by Grade Rules

Elevating lot edges is useful to establish final grading for subdivisions or selected lot boundaries, and is also used in the *Road Network* routines by linking to the grade rule file. Once this final grade is established (by executing *Triangulate and Contour* selecting the elevated 3D lot lines as source objects), there are options to balance cut and fill by adjusting the lot lines' elevations based on the settings established in the grade rules (.grr) file. The initial elevation of lot lines will apply the **normal** slope, and the balancing routines will only adjust within the limits established by the **minimum** and **maximum** slope settings in the .grr file.

Consider the following example: you have a small subdivision with lot lines established using *LotNET* or other routine, and wish to elevate them with respect to the edge of the proposed roadway. Initially, the lot lines are at zero elevation. In this example, you will use the back edge of the sidewalk that is established as part of the roadway cross section template that creates all linework, at proposed grade based on the design profile of the roadway, and you wish to maintain this edge of walk at its design elevations.

Small Subdivision Design with Roads and Lots

Detail of roadway and lot edges

Execute the routine, and you will be prompted for some initial information:

Specify the distance away from the reference grade line to seek the front lot lines to elevate and establish the layer to place the elevated lot lines on. This retains the original 2D zero-elevation lot lines to use in annotation, etc. on their original layers.

Prompts

Keyboard Command: elevate_lots

Prerequisite: 3D reference grade line, lot lines to elevate

Elevate Pads by Grade Rules

This command sets the elevation of closed polylines at a specified slope from reference 3D polylines. For each closed polyline, the program finds the nearest offset to a reference polyline. Then the pad polyline is elevated using the reference polyline elevation at this nearest offset position and applying the vertical offset as the slope times the offset distance.

When the original pad polyline is 3D, the program maintains the original slopes of the 3D polyline and elevates by raising or lowering the 3D polyline instead of setting all the vertices to the same elevation. This method applies for a pad with varying elevations such as for an exposed basement.

The **Reference Elevation** has four methods. Elevation At Middle uses the middle position of the pad polyline segment that is on the frontage side of the pad and locates the station along the reference polyline that is at the perpendicular offset from this position. Highest Elevation takes the frontage segment of the pad polyline and checks the station range for this segment along the reference polyline to find the highest elevation within this range which is used as the elevation reference. Likewise, Lowest Elevation uses the lowest elevation on the reference polyline in front of the pad. The Reference Point method uses a point placed along the pad by the Tag Pad Reference Point command.

The program prompts for the existing surface triangulation file which is used to compare to the reference elevation and choose between using the specified cut or fill slope from the reference elevation to the pad. This feature allows you to have steeper slopes in cut than fill conditions to help with site balancing.

The **Min** and **Max Slopes** are stored with the pad polylines for use by the site balancing option in Calculate Total Volumes in SiteNet. These slopes are used as grading rules to make sure the pad stays within this slope range from the reference polyline when the pads are raised or lowered during the site balancing. The Min and Max Slopes are not used during the Elevate Pads By Grade Rules which only uses the **Cut/Fill Normal** slopes. Use the Grade Rules Editor command to edit these slopes and elevation reference info that is assigned to the pad polyline.

The **Vertical Offset** is added to the elevations of the pad polylines.

The **Assign New Layer** option changes the original layer to the specified layer for the elevated pad polylines. The **Retain Original Polyline** option creates new elevated polylines and leaves the original polylines unmodified.

The **Add Grade Breaks to Reference Polylines** adds break points to the side lot lines at the ends of the building pad as shown in this graphic.

The **Draw Swale Polyline** creates 3D breakline polylines to control storm water flow around the building pad. When the lot is sloping towards the street, the swale polyline is at the back of the pad as shown in the left graphic. When

the lot is sloping away from the street, the swale polyline is at the front of the pad as shown in the right graphic. The swale polyline elevation is set relative to the building pad elevation by the **Slope From Pad**, and the **Cross Slope** controls the swale elevations for connecting with the lot sides. The **Offset From Pad** sets the distance from the building pad to the swale polyline. The **Center Taper** controls how much the swale polyline bulges out in the middle and the **Edge Extend** sets the position of the swale polyline break points from the side lot lines.

Tag Pad Reference Point

This command creates points on building pads that are used by the Elevate Pads By Grade Rules command when using the Reference Elevation by Reference Point method. Each pad should have a single reference point. You set the symbol, layer and size for the reference points in the options dialog.

Prompts

Tag Pad Reference Point dialog

Pick pad reference point: *point a point*

Pick pad reference point (Enter to end): *press Enter*

Pulldown Menu Location: 3D Data > Elevate By Grade Rules

Keyboard Command: tag_pad_ref_pt

Prerequisite: None

Tag Inner Pads

This command assigns polylines to use as building pads within larger building pads such as a garage slab within a building. These inner pads are assigned a vertical offset from the main pad. The options dialog has a setting for the layer name of the main pad polyline. The Elevate Pads By Grade Rules command will process the inner pads to set the elevation by the vertical offset from the main pad.

Prompts

Tag Inner Pads dialog

Select inner pads for layer BLDG.

Select objects: *select pad polylines to tag*

Pulldown Menu Location: 3D Data > Elevate By Grade Rules

Keyboard Command: tag_inner_pad

Prerequisite: closed pad polyline

Grade Rules Editor

This command allows you to elevate other types of linework (besides lot edges and pads) with respect to a single reference elevation and offset point (or two single points if elevating a previously-elevated object using Lot Edge rules). This differs from the typical *Elevate Lot Edges By Grade Rules* in that instead of referencing the object to a reference line of constantly changing elevation, you will be setting a single point (or two single points) as a starting reference value.

You choose the linework you wish to elevate and establish for it a reference elevation and offset, if any. You may enter these values directly, or pick an object from the screen to establish the reference. If you leave the fields at their default of 0.000, you will elevate the selected object with respect to that zero reference elevation, so make sure that you have some valid reference data set in the fields. If you are elevating an object that has not previously been elevated using *Elevate Lot Edges By Grade Rules*, you will establish a single reference point/offset. If elevating a previous "Lot Edge Rules" object, you will establish two reference points/offsets, one for the front, and one for the back. You will also establish the grade rule for the back portion in addition to a single set of rules for a 2D object. (see dialogs below for differences).

The settings work much the same as the other grade rules (lot edges and pads) except that instead of elevating things based on a linear, changing reference elevation line, you are setting a single point of reference (or two single points) to elevate the selected object.

Prompts

Select grade polyline: *select the linework you wish to elevate*

If the selected object has not been previously elevated using *Elevate Lot Edges By Grade Rules*, you are then presented with the following dialog to establish the relationship of the selected linework to a reference elevation and offset. You may enter the values directly, or pick a point in the drawing and the values are calculated from the picked point.

Grade Z:	1487.341
Reference Z	1485.965
Reference Offset	27.514
Pick Reference Point	
Slope Type	Percent
Normal Slope	5.000
Min Slope	1.000
Max Slope	20.000

If selected object has been previously elevated using *Elevate Lot Edges By Grade Rules*, you will be presented with the next dialog, which illustrates the difference in the two cases:

Grade Z:	1511.230
Front Reference Z	1496.564
Front Reference Offset	27.500
Pick Front Reference Point	
Back Reference Z	1496.564
Back Reference Offset	55.030
Pick Back Reference Point	
Slope Type	Ratio
Front to Ref Max Offset	50.000
Front Normal Slope	1.875
Front Min Slope	25.000
Front Max Slope	3.000
Distance Vertical	50.000 25.517:1
Add Edit Remove	
<input type="checkbox"/> Back Lot Edge At Existing Ground	
Back Normal Slope	22.642
Back Min Slope	100.000
Back Max Slope	10.000

The fields and their values function the same as those in *Define Lot Edge Grade Rules*, so please refer to that command for more information.

Pick reference point: *<Osnap on> select a point in the drawing as a reference, and the values are calculated and populate the dialog fields for you.*

Select grade polyline (Enter to end): *select another, or press Enter to conclude selection*

Pulldown Menu Location: 3D Data >> Elevate By Grade Rules

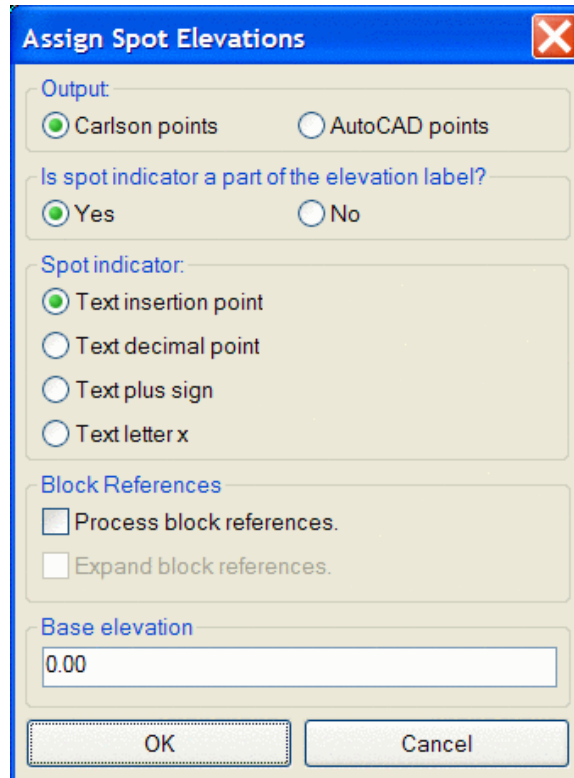

Keyboard Command: edit_grades

Prerequisite: linework to elevate

Convert Spot Elev To Points

This command takes spot elevation entities with zero elevations and assigns them elevations according to corresponding elevation labels.

This dialog box allows you to choose the format of the spot elevations entities that you want to convert.

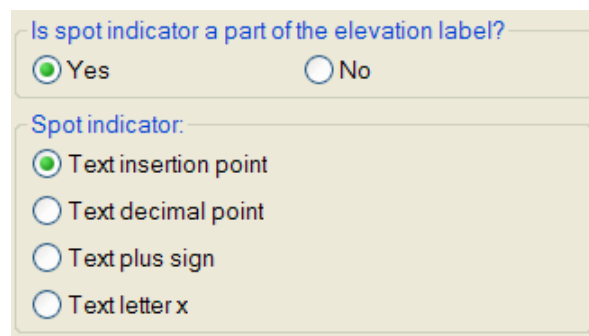

Output:

Carlson points: creates Carlson points at elevation of spot and stores them in coordinate file

AutoCAD points: creates AutoCAD point objects at elevation of spot

Is spot indicator a part of the elevation label?

If set to "Yes", four choices for Spot indicator are available to select from:

Text insertion point: uses the insertion point of the text for the location of the new point

Text decimal point: uses the decimal point in the text for the location of the new point

Text plus sign: uses the plus sign in the text for the location of the new point

Text letter x: uses the letter x in the text for the location of the new point

If set to "No", seven choices for Spot indicator are available to select from:

Is spot indicator a part of the elevation label?
 Yes No

Spot indicator:
 Linework leader
 Linework cross
 Text plus sign
 Text letter x
 AutoCAD point
 Circle or arc
 Closed linework

Linework leader: creates a data point at the end of a leader

Linework cross: creates a data point at the intersection of a linework cross

Text plus sign: creates a data point at the insertion point of a text plus sign

Text letter x: creates a data point at the middle of a text letter x

AutoCAD point: creates a data point at the node of an AutoCAD point

Circle or arc: creates a data point at the center of a circle or arc. If a circle is composed of two 180-degree arcs, however, it only creates 1 data point

Closed linework: creates a data point at the geometric center (centroid) of closed linework, such as a square or triangle shape

Block References:

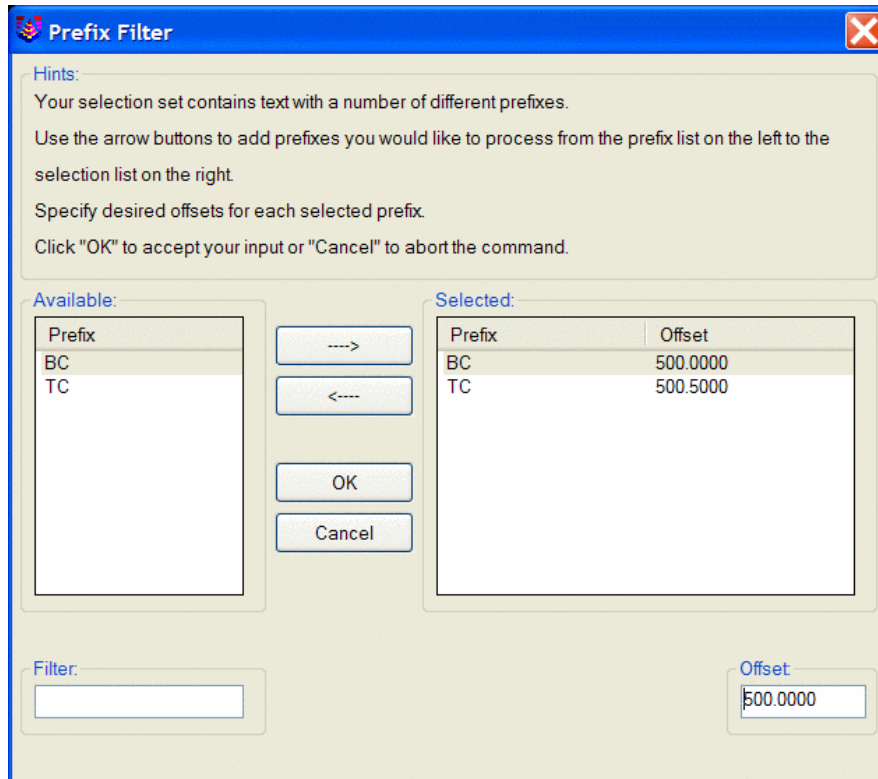

Process Block References: If check box is cleared, Carlson Civil searches only text entities for elevations, but if checked, Carlson Civil will search block references for elevations that are stored as attributes of a block. Use this option if the elevation is an attribute and the symbol designating the location of the spot elevation are both part of the block definition.

Expand Block References: Use this option to search block references when the elevation is stored as an attribute of a block, but the symbol designating the location of the spot elevation is a different block or even other geometry that is not defined within a block.

Base elevation: The value entered here is added to the existing spot elevations for all newly created points. Often, elevations are abbreviated to save time and space. If every elevation in a drawing is in the 500s instead of labeling every elevation 523.5, 543.3, 537.2 sometimes they are listed as simply 23.5, 43.3, 37.2. This command allows you to add a given amount, such as 500, to every label elevation to produce the correct elevation in the drawing. Note: The base elevation will not be added to any elevations that are closer to the base elevation value than they are to 0; e.g. if a base elevation of 500 is specified, 500 will be added to elevations like 23.4, 45.5, etc, but will not be added to elevations like 456.4 or 468.9.

Prefix Filter: Carlson Civil examines all selected spot elevations for prefixes or suffixes. If they are all the same, the command proceeds, but if there are different prefixes and/or suffixes found, the Prefix Filter dialog box is

invoked. This dialog box allows you to select which prefixes and/or suffixes to use to create spot elevations, and also allows you to use different offset values for each.

Prompts

Starting point number <1>: *press Enter*

Select TEXT, MTEXT spot elevations to process and any associated leader lines:

Select objects: *pick entities to process*

Pre-processing entity #40 of 40...

Processing elevation #40...

Converted 40 spot elevations.

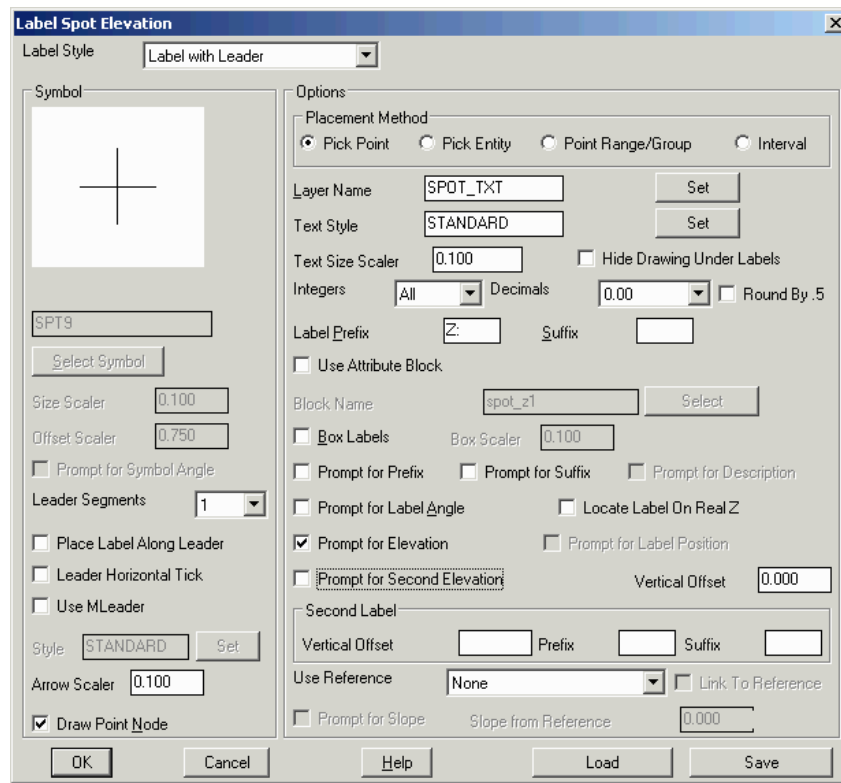

Pulldown Menu Location: 3D Data

Keyboard Command: spotelv2

Prerequisite: Spot elevations

Draw Spot Elevations

This command creates spot elevation labels based on user settings.

Label Style: This option at the top of the dialog determines which options are available in the rest of the dialog.

Label with Leader: This option draws a leader between the spot location and the label. The style of the leader is controlled by the current DIMSTYLE settings.

Label with Symbol: Draws the specified symbol at the spot with the label off to the side.

Carlson Point: This option creates a Carlson point entity with the point#, elevation, description attribute block and stores the point to the current coordinate file. When creating Carlson points, there is an option for **Prompt For Description** for entering descriptions for the points for the point entities and coordinate file.

Label Decimal on Point: Draws only the elevation label and positions the label so that the label decimal is on the spot.

Label Insertion on Point: Draws only the elevation label and uses the spot location for the insertion point of the label.

Label Only: Draws the label without any indicator of the exact reference point for the label.

Symbol: Specify the symbol to be used for the location of the spot elevation. If Draw with Leader is selected, the use of a symbol is automatically disabled. Along with the symbol name, you can also set the **Size Scaler** to size the symbol and the **Offset Scaler** to control the offset between the symbol and the label. The **Prompt For Symbol Angle** option allows you to rotate the symbol. Otherwise, the symbol is drawn horizontal to the current twist screen.

Leader Segments controls how many leader segments the program will prompt for. **Place Label Along Leader** draws the label along the leader instead of horizontal off the end of the leader. **Leader Horizontal > Tick** draws a short horizontal segment at the label end of the leader. **Leader Horizontal > Underline** draws a leader line under the label. **Draw Symbol with Leader** combines the symbol with the leader. **Arrow Scaler** controls the size of the arrowhead. The **Use MLeader** creates an mleader entity. Otherwise a regular leader and separate text entities are drawn.

Draw Point Node: Specify whether to create a node (point entity) at the spot.

Options: Under Options, there are settings to control the layer, text style, text size and prefix/suffix for the labels.

Box Labels controls whether to draw a box around the label and **Box Scaler** controls the size of the box and is applied as a factor of the text size.

Locate Label On Real Z sets whether the label and symbol are placed at the spot elevation or at zero elevation. There are several settings for fields to prompt for when placing each spot label including prefix, suffix, position and angle.

Use Attribute Block: This option uses a block with attributes to draw the spot elevations. This allows you more control of the label layout. There is one default spot elevation attribute block called `spot_z1.dwg` in the Carlson Support folder. To customize the layout, open the attribute block drawing, make your edits and then save the drawing. The attribute block uses three attribute definitions: Integers, Decimals, Suffix. Integers is for the elevation digits to the left of the decimal point. Decimals is for the digits to the right of the decimal point. Suffix is a text description.

Use MText: This option draws the labels as MText instead of regular Text.

Prefix/Suffix on New Line: This option labels the elevation value on a separate line from the prefix or suffix.

Placement Method:

Individual: Prompts the user for a screen pick or a point number to specify the location of the spot elevation.

Pick Entity: This method labels the elevation of the selected 3D entity. For 3D polylines, the elevation comes from the polyline at the location the polyline is selected.

Point Range/Group: Draw spot elevations at the specified point numbers or point group name from the current coordinate file.

Interval: Prompts the user to select an existing polyline and specify an interval distance to set spot labels along the polyline. It also prompts for number and interval for additional labels to be set at offset distances right and/or left of the polyline.

Use Reference:

Off: User is prompted to supply elevation for each new spot elevation.

Single Surface File: Prompts user to specify the triangulation or grid surface model file to read the elevations from. Spot elevations created with this method are automatically updated if the surface model elevation changes.

Two Surface Difference: Prompts user to specify an existing surface file and a design surface file, and labels the elevation difference between the two.

Slope Percent/Ratio From Point/Polyline: These methods allow you to set the spot elevation by a slope percent or ratio from a reference point/polyline. These methods have another option for whether to **Prompt for Slope** which will prompt for the slope from the reference for each spot. Otherwise, the **Slope From Reference** setting in the dialog is used. When using the Polyline reference method, the program finds the station-offset of the spot point along the polyline and uses the elevation of the polyline at that station for the reference.

Link To Reference applies to using a surface file or 3D polyline for the spot elevations. This link option will automatically update the labels when the reference surface file or 3D polyline change.

The **Hide Drawing Under Labels** option creates a wipeout under the spot label to hide any other drawing entities behind the label.

The **Integers** setting controls how many decimal places to the left of the decimal point to label and the **Decimals** settings controls how many decimal places to the right of the decimal point to label. The **Round By .5** option rounds the last digit to either 0 or 5.

Prompt for Prefix/Suffix: These options will prompt for the labels for each point which is useful when labeling different kinds of spots.

Prompt for Label Position: When using Label With Symbol style, this option will prompt for where to place the label for each spot.

Prompt for Elevation: Prompts to enter the elevation for each spot. Otherwise, the elevation of the picked point is used.

Prompt for Second Elevation: Prompts for a second elevation for each spot. This option applies when labeling two elevations at the same point such as top and bottom of curb when they have varying elevation differences between them. If the two elevation have a fixed elevation difference, then you can use the **Vertical Offset** for the **Second Label**.

Prompt for Label Angle: This option allows you to rotate the label for each spot. Otherwise, the label is drawn horizontal to the current twist screen.

Vertical Offset adjusts the elevation label by the specified amount.

Additional Label has separate settings for **Vertical Offset**, **Prefix** and **Suffix** which allows for labeling two elevations for the same spot such as labeling both bottom and top of curb.

$$+123.45 + \boxed{123.45} \quad \swarrow \quad 123.45 + 123.45$$

The **Save** and **Load** buttons write and recall the settings to a .LSE file so that you can store different label styles and share them.

Pulldown Menu Location: 3D Data

Keyboard Command: labspot

Prerequisite: None

Move Spot Elevations

This command allows you to reposition spot elevation label on the reference surface. The value of the label will update for the new position. In order for this command to run, the spot elevation labels must be created using the Draw Spot Elevations command with the Use Reference set to Single Surface File and the Link To Reference option turned on.

Prompts

Select spot elevation to move: *pick entity*

Pick new position: *pick a point*

Select spot elevation to move (Enter to end): *press Enter to end*

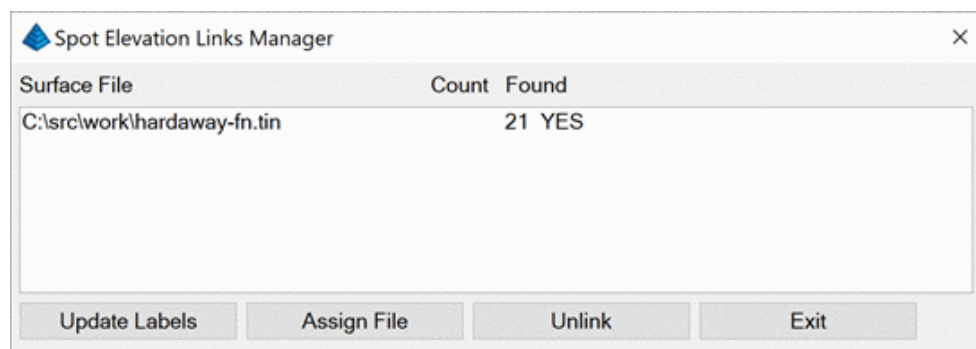

Pulldown Menu Location: 3D Data > Spot Elevations

Keyboard Command: movespot

Prerequisite: Spot Elevation labels drawn using Draw Spot Elevations command

Spot Elevation Links Manager

This command reports the number of spot elevations in the drawing created by the Draw Spot Elevations command and created with the Link To Reference option turned on. The report includes the name of the linked reference surface file and whether the file is found on the computer. The **Update Labels** function updates the spot elevations to match the current surface elevations in case the labels are out-of-sync. The **Assign File** function changes the reference surface file name for the spot elevations. The **Unlink** function removes the reference surface file link from the spot elevations.

Pulldown Menu Location: 3D Data

Keyboard Command: labspot_mgr

Prerequisite: Spot elevations

Adjust Elevation Labels

This command has several functions that allow you to modify spot elevation labels.

The **Remove Base Elevation** function removes the base elevation amount from the labels. For instance, often elevations are abbreviated to save space. If every elevation in a drawing is in the 500's instead of labeling every elevation 523.5, 543.3, 537.2 sometimes you may wish to have them displayed as simply 23.5, 43.3, 37.2. This command allows you to adjust the labels by a given amount, such as 500, to every label elevation. This does not affect the actual elevation of entities in the drawing or in the associated surface model file.

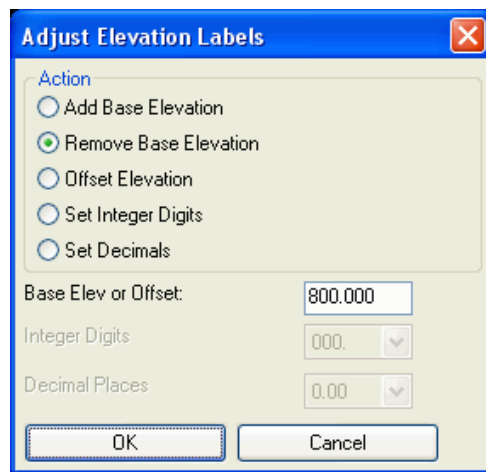

The **Add Base Elevation** function is the reverse of Remove and applies when the labels are missing the base elevation and you want to add this elevation into the labels.

The **Offset Elevation** function adds the specified offset amount to the elevation labels and applies when elevation labels need to be adjusted by a fixed vertical offset.

The **Set Integer Digits** function sets the number of digits to the left of the decimal point for the elevation labels.

The **Set Decimals** function sets the number of digits to the right of the decimal point for the elevation labels.

The **Elevation Block Attribute Tag** edit allows the user to specify the name of the tag in a block reference to apply elevation adjustment functions to. This settings does not apply to Carlson Coordinate Point block references for which the "ELEV2" tag attribute is always adjusted.

Prompts

Select a sample elevation label: *select single label to identify the source layer to process*

Select spot elevation labels to process.

Select objects: *select the text to process*

Pulldown Menu Location: 3D Data

Keyboard Command: adjust_elevation_labels

Prerequisite: Spot Elevation label text

Elevate Text

This command sets the elevation of text entities by reading the elevation value from the text label. For example, this command can elevate spot elevation labels. Having the text entities at real elevation instead of zero can be useful for viewing in 3D or using for surface modeling.

Prompts

Select text to elevate.

Select objects: *pick text entities*

Elevated 12 text entities.

Pull-down Menu Location: 3D Data

Keyboard Command: ztext

Prerequisite: None

Interpolate Points

This command divides the distance between two points and inserts one of the point symbols at the specified distances. It can also interpolate elevations. (To interpolate elevations the points picked must be at their real Z axis elevation.)

Prompts

Interpolate Elevations [<Yes>/No]? *press Enter*

Point w/elevation to calculate from?

Pick point or point number: *3*

2nd Point w/elevation?

Pick point or point number: *pick a point*

Number of Segments/Divisions: *5*

The command then locates 4 points.

Pull-down Menu Location: 3D Data > 3D Points

Keyboard Command: divlin

Prerequisite: Execute *Drawing Setup* to set defaults. Locate two points to divide between and if you want to interpolate elevation they should have a real Z axis elevation.

Elevation Between Points

This command interpolates new points between two reference points at a single elevation or elevation interval. The routine uses the elevations of the two reference points together with the target elevation to figure the interpolation distance. For example, with one reference point at 100, the other reference at 104 and the target at 101, then the new point will be created 1/4th the distance from the first reference point towards the second reference. The target elevations are used as elevations for the new points.

Prompts

Point to interpolate from.

Pick point or point number: *pick a point*

Point to interpolate to.

Pick point or point number: *pick a point*

Add single elevation or elevation interval [Single/<Interval>]? *press Enter*

Enter elevation interval: *1*

Pulldown Menu Location: 3D Data > 3D Points

Keyboard Command: addptz

Prerequisite: None

3 D Points - Interpolate Entity

This command divides the distance of a *LINE*, *ARC* or *PolyLINE* and locates points at the computed distances. It also interpolates elevations (To interpolate elevations the points picked must have an AutoCAD or real *Z*/elevation). The figure below shows a graphic example.

Prompts

Interpolate Elevations <Y>: *press Enter*

Point w/elevation to calculate from?

Pick point or point number: *1*

2nd Point w/elevation?

Pick point or point number: *2*

These points don't have to be on the entity selected to divide.

Select Entity to Divide: *pick point on entity*

Number of Segments/Divisions: *4*

The command then locates 3 points along the selected entity.

After selecting the points above (top), new points are located along the selected entity (above, bottom).

Pulldown Menu Location: 3D Data >> 3D Points

Keyboard Command: divent

Prerequisite: Two elevation points and the entity to divide between.

Points by Slope Ratio

This command allows you to locate points by defining a slope from a reference elevation. There is an options dialog where you can define the slope format as percent or ratio. Enter the slope as positive for up, negative for down. You can also choose to enter elevation difference (vertical) instead of a slope. Or match the slope between two other points.

There are several difference methods for defining the X,Y location for the points.

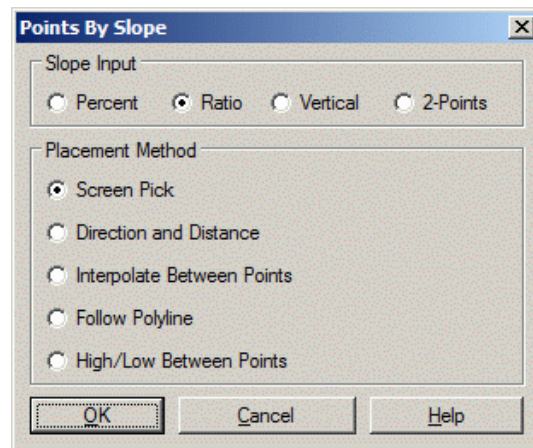

Screen Pick: Prompts for a reference starting point and then you screen pick the new points to create and enter the slope from the reference.

Direction and Distance: First pick the starting point. If the picked starting point is at zero elevation, the program will prompt for the reference elevation. Next pick a point for the direction. Then enter the slope and the horizontal distance.

Interpolate Between Points: First pick the starting point. If the picked starting point is at zero elevation, the program will prompt for the reference elevation. Next pick the second reference point. Then enter the slope and the number of points to create between the two reference points. This number of points will be evenly interpolated between the reference points.

Follow Polyline: This method is similar to Screen Pick except that instead of using the straight line distance between the reference and target points, you pick a polyline to get the distance. The program gets the distance by projecting the reference and target points onto the polyline and then following the polyline between these projected positions.

High/Low Between Points: With this method, you specify two reference points and two slopes. On the line between these two reference points, the program locates the point where the two slopes intersect.

Prompts

Slope ratio + for uphill - for downhill, Start point should be 3D.

Slope Ratio (? : 1) <2.0>: 1

Starting point ?

Pick point or point number: *screen pick a point*

Direction Point: *screen pick a point*

Enter Hz Distance or [I]nterpolate to Direction Point <I>: *press Enter*

Horizontal Dist: 214.94

Number of Points to Interpolate <2>: 5

Start Point Elevation: 0.0

End Point Elevation: 214.942

Difference in elevation: 214.942 Elevation add: 42.9884

Select/<Enter Point Elevation <42.99>>: press Enter

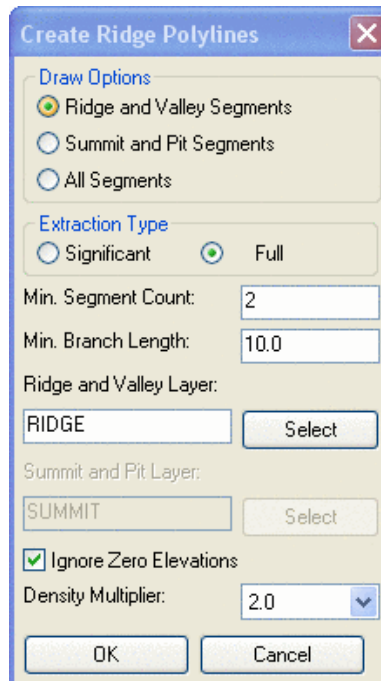

Pulldown Menu Location: 3D Data > 3D Points

Keyboard Command: SLP

Prerequisite: None

Create Ridge Polylines From Contours

This command creates 3D polylines along the tops of ridges and in the bottom of drainages for more accurate modeling of the surface.

Draw Options: Specify whether to draw Ridge/Valley segments, Summit/Pit segments, or all. Ridge/valley segments travel along the tops of ridges or bottom of valleys and are extracted from the contours lines by finding acute vertices and looking to the next adjacent contour for the corresponding acute vertex. Summit or pit segments model closed polyline contours and extend the trend either upward or downward to the peak or bottom point in the geometry.

Extraction Type (Significant and Full): Significant segments are those segments that fall into relatively flat areas of the triangulation (large open spaces between the contours). Use this setting to reduce the number of segments generated by this command. Full extraction will model all segments.

Minimum Segment Count and Branch Length: Use this setting to prevent small segment branches from being generated. This can reduce the occurrence of errors in the output.

Layer Selection: Specify the layer that the ridge/valley and summit/pit polylines will be drawn on. You may choose the select button to specify from the list of existing layers, or specify a new layer by simply typing the new layer name.

Density Multiplier: The quality of output produced by this command is directly proportional to vertex density of contour polylines. This multiplier can be used to temporarily increase contour vertex density for the duration of calculations at the cost of additional processing time. Setting this multiplier to higher values generally reduces occurrence of errors in the output.

Ignore Zero Elevations: select this to ignore linework set at zero elevation.

Pulldown Menu Location: 3D Data

Keyboard Command: cs_extract

Prerequisite: Contours with ridges and valleys

Create Breaklines From Triangulation

This command creates 3D polylines along the tops of ridges and in the bottom of drainages for more accurate modeling of the surface.

Threshold Angle: Specify the minimum angle between adjacent triangles in the surface model to generate a breakline in the drawing.

Layer: Specify the layer to draw the breaklines on. You may type a new or existing layer name, or press the Select button to choose from a list of existing layers.

Once you press *OK*, you will be asked to select the triangulation file to process. Once selected, the routine draws the breaklines on the indicated layer.

Pulldown Menu Location: 3D Data

Keyboard Command: draw_breaklines

Prerequisite: Triangulation file surface model

Offset 3D Polyline

This command allows you to offset a 3D polyline entity in both the horizontal and vertical directions. There are four offset methods. The *Interval* method applies one horizontal and one vertical offset to all the vertices of the polyline. The *Constant* method has a horizontal offset and sets the elevation of the polyline to one constant elevation. The *Variable* method allows you to specify each horizontal and vertical offset individually either by polyline segment or for each point. The vertical offset can be specified by actual vertical distance, percent slope or slope ratio.

Finally, the *Surface* method allows you to offset the 3D Polyline to intersect a target surface defined by a triangulation or grid file. This functions much like the **Design Pad Template** command on the **Surface** menu, but without creating side slope faces; only the intercept (or "daylight") line is created.

Prompts

Enter the offset method [<Interval>/Constant/Variable/Surface]: *press Enter*

Vertical/<Horizontal offset amount>: *15*

Percent/Ratio/Vertical offset amount <0>: *10*

Select a polyline to offset (Enter for none): *select a 3D poly*

Select side to offset: *pick a point*

Select a point on the graphics screen that is in the direction of the side of line to offset.

Select a polyline to offset (Enter for none): *press Enter*

Pulldown Menu Location: 3D Data

Keyboard Command: offset3d

Prerequisite: 3D polylines to use for selection; surface file for *Surface* method.

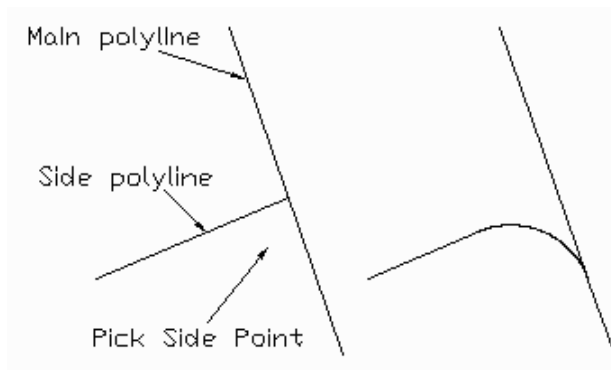

Fillet 3D Polyline

This command fillets two segments of a 3D polyline (or two un-joined 3D Polylines) with the given radius. AutoCAD's *FILLET* command does not support 3D Polyline entities. Since 3D polylines cannot have arcs, this command draws the fillet arc as a series of short chords. The elevations along the curve are interpolated from the 3D polyline.

There are two processing modes: corner and intersection. The corner mode works like the standard Fillet command except that it's in 3D. The intersection mode works at the intersection point between two 3D polylines. One polyline is set as the main polyline and the other as the side polyline. The main polyline is used for reference only and is not modified. The side polyline is modified to fit in the fillet radius. The intersection mode works for crossing and T intersections. An application of the intersection mode is for curb 3D polylines at road intersections.

Before and after fillet3d on the corner

Before and after fillet3d at intersection

Prompts

Fillet corner of a polyline or intersection of two polylines [*<Corner>/Intersection*]? *press Enter*

Enter fillet radius <10.00>: *press Enter*

Select a corner point on polyline: *pick 3D polyline near meeting point of two segments*

Select a corner point on polyline: *press Enter* (to end command)

Pulldown Menu Location: 3D Data > 3D Polyline Utilities

Keyboard Command: fillet3d

Prerequisite: 3D polyline

Join 3D Polyline

This command joins *3DPOLY* entities into a single 3D polyline entity. The routine requires that two endpoints be coincident, at the same elevation. A similar function is obtained with the **Join Nearest** command on the **Edit** menu, but will allow options to join across gaps and various options for treating the resulting common endpoint.

Prompts

Select the 3D polyline to join: *pick a 3D polyline*

Select the other 3D polyline to join: *pick a 3D polyline that has a common endpoint with the first 3 segments added to the polyline.*

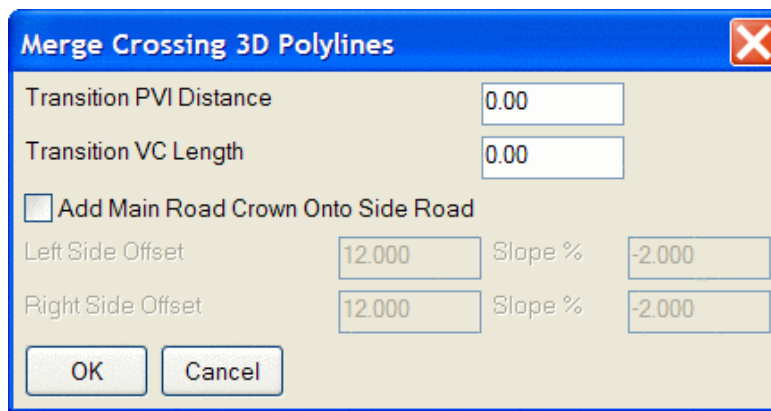

Pulldown Menu Location: 3D Data and Edit >> 3D Polyline Utilities

Keyboard Command: join3d

Prerequisite: 3D Polylines to use for selection

Merge Crossing 3D Polylines

This command works with 2 crossing 3D polylines, adding one or more vertices to one of them at the virtual point of intersection to match the elevation of the other. The 3D polyline that is vertically unchanged is referred to as the "Main 3D polyline", the 3D polyline that is edited is referred to as the "Side 3D polyline." The command uses the 2 vertices on the Main 3D polyline on either side of the virtual intersection to determine an interpolated elevation on the Main 3D polyline at the point of virtual intersection, and adds a vertex on the Main 3D polyline at that location with the calculated elevation, but the vertical characteristics of the Main 3D polyline are otherwise unchanged. The Side 3D polyline gets a new vertex at the virtual intersection with the same interpolated elevation, thereby changing it's vertical definition as much as necessary to match. The characteristics of the transition are controlled by the settings in the Merge Crossing 3D Polylines dialog box.

Transition PVI Distance: This option creates 2 additional vertices on the Side 3D polyline, each at the specified distance from the virtual intersection, and both with the same elevation as the vertex at the virtual intersection, essentially creating a flat section.

Transition VC length: This option creates a vertical curve for the transition, passing through the interpolated elevation at the virtual intersection. The start of the vertical curve is the specified value from the virtual intersection, as is the end, so the overall length of the entire vertical curve is actually twice the value specified in the dialog box.

Add Main Road Crown Onto Side Road: This option creates the transition by assuming the Main 3D polyline is a crowned roadway, and creates corresponding additional vertices on the Side 3D polyline.

Prompts

Select the Main 3D polyline: *pick the 3D polyline that will determine the crossing elevation, but will remain essentially unchanged*

Select the Side 3D polyline: *pick the 3D polyline that is to be changed to match the Main 3D polyline elevation at the virtual intersection*

Merge Crossing 3D Polylines dialog Adjust variables as desired in Merge Crossing 3D Polylines dialog box, pick OK.

Pulldown Menu Location: 3D Data

Keyboard Command: merge3d

Prerequisite: 2 crossing 3D polylines

3D Polyline by Slope on Surface

This command creates a 3D polyline at a user-specified slope. The user picks the starting point and then the polyline continues along the surface at the slope until it reaches a point where the maximum slope at the point is less than the design slope. The surface is defined by a grid or TIN file which must be created before running this routine. Applications for this command include designing haul roads or ditches.

Prompts

Enter the polyline layer <SLOPE_ROAD>: *press Enter*

Select the Grid File dialog

Reading row > 51

Extrapolate grid to full grid size (Yes/<No>)? *Y*

Limiting length for polyline (Enter for none):

Pick origin point of 3D polyline: *pick a starting point*

Direction of 3D Polyline (<Up>/<Down>)? *press Enter* The slope must go either uphill or downhill.

Direction of 3D Polyline facing up slope (<Left>/<Right>)? *R* Imagine facing uphill. Do you want the polyline to go to the left or right?

Enter the design slope: *10* This value is in percent slope.

Pulldown Menu Location: 3D Data

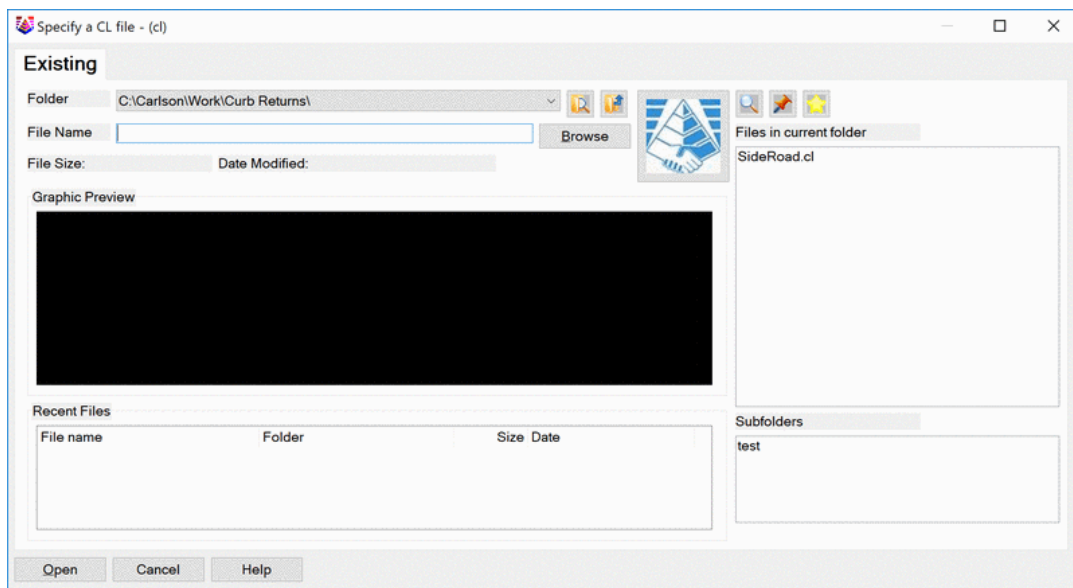

Keyboard Command: surfpl

Prerequisite: Existing surface file

Elevate Intersection Curb Return

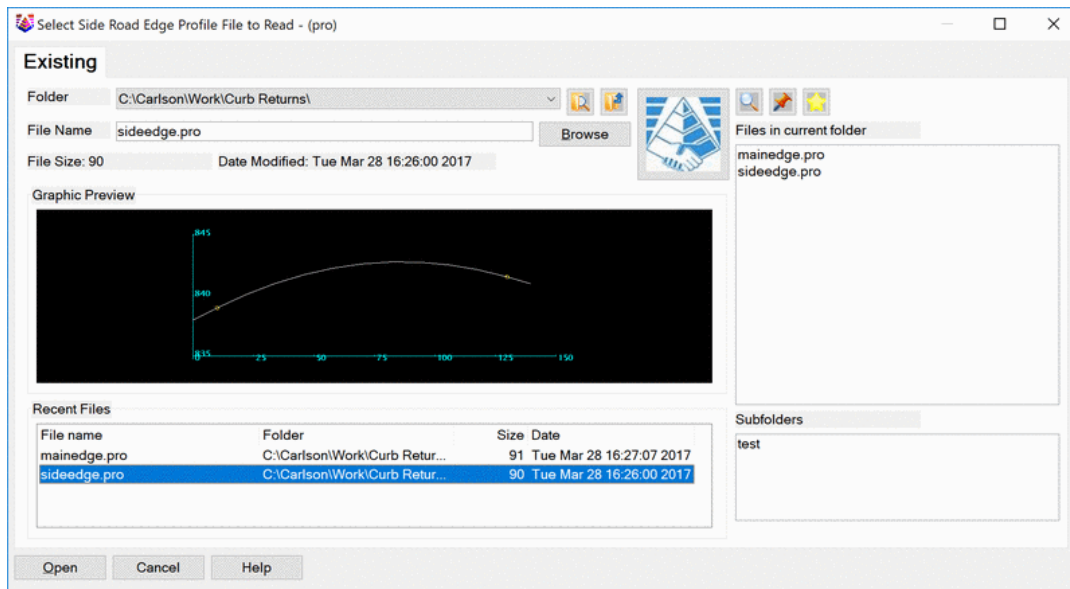

This command elevates an intersection curb return based on the distance along the side road in relationship to the curb return. Instead of an interpolation of the elevation this command will apply the interpolation from the side road to the curb return.

Side Road CL File/<Select polyline>: *select the side road's polyline or choose the centerline .CL file*

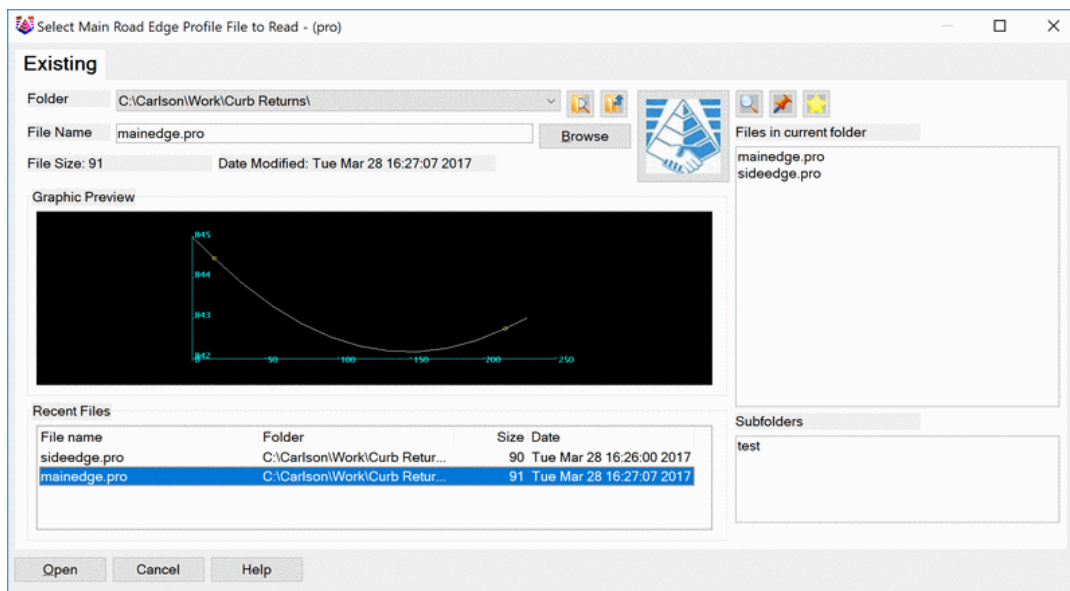

Select Side Road Edge polyline: *select the side road's edge polyline*

If the selection is not a 3D polyline, next you will be prompted to choose the Side Road Edge profile .PRO file

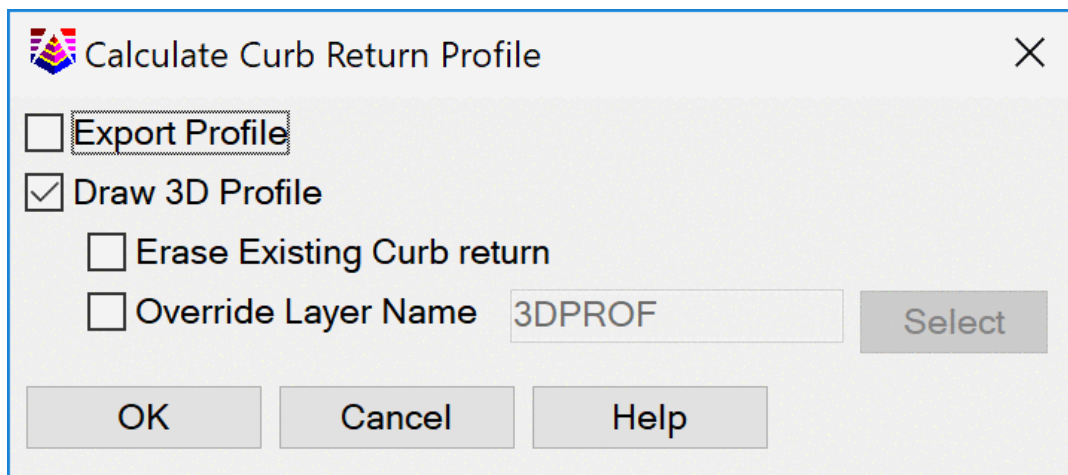

Select Main Road Edge polyline: *select the main road's edge polyline*

If the selection is not a 3D polyline, next you will be prompted to choose the Main Road Edge profile .PRO file

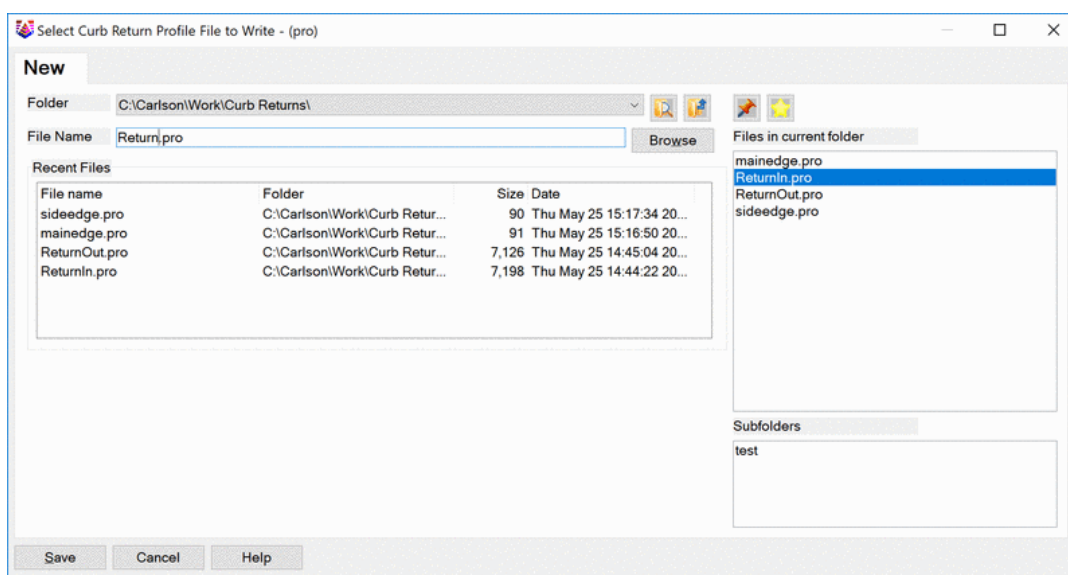

Select Curb Return polyline: *select the corresponding curb return edge polyline to create profile for*

Export Profile

Select the profile .PRO file to create for the curb return.

Draw 3D Profile

This will draw the profile as a 3D-Polyline on the original curb return's layer.

Erase Existing Curb Return

This will erase any already created 3D-Polyline drawn for the selected curb return.

Override Layer Name

This will override the original selected curb return's layer with the layer chosen.

Pull-down Menu Location: 3D Data - 3D Polyline Utilities

Keyboard Command: calcapron

Prerequisite: Existing profiles for Side and Main Road Edges

Min/Max Slopes 3D Polyline

This command checks 3D polylines to make sure slopes are within the specified range. For any segment that is outside the range, the program will set the elevation of the polyline vertex to put the segment within range. This routine could be used on a 3D polyline for a ditch to make sure the slope has a minimum grade. Also this routine applies to a 3D polyline for a road that has a maximum grade.

Prompts

All slopes up, down or either [Up/Down/<Either>]? U for up

Min slope percent: 1

Max slope percent: 9

Select polylines to process.

Select entities: *pick 3D polylines*

Changed 3 polylines.

Pull-down Menu Location: 3D Data > 3D Polyline Utilities

Keyboard Command: minmax3dp

Prerequisite: 3D polyline

Follow TIN Edges

This command creates a polyline by connecting edges in a triangulation to approximately follow the path of an existing polyline. One application is to create an inclusion or exclusion perimeter for carving out a portion of a triangulation surface. By having the polyline follow the triangulation edges, the polyline can be applied to the triangulation without trimming edges or adding points. Otherwise, when the polyline doesn't follow the triangulation edges, the program will embed the polyline into the triangulation by draping the polyline onto the triangulation.

Prompts

Enter the polyline layer <INCLUSION>: *PERIMETER*
 Select TIN File *Select a triangulation file*
 Select boundary polyline to follow: *pick a polyline*
 Loading edges...
 Done.

Pulldown Menu Location: Edit > 3D Polyline Utilities
Keyboard Command: tinline
Prerequisite: a polyline

Extend To Elevation

This command extends the end segment of a 3D polyline or line until the segment reaches the specified elevation. The slope for the extension is user-specified and defaults to the existing segment slope.

Prompts

Select line or polyline to extend: *pick a 3D line or polyline*
 End point elevation: **496.130**
 New elevation: *495*
 Slope to extend <-1.482>: *press Enter*
 Select line or polyline to extend (Enter to end): *press Enter*

Pulldown Menu Location: 3D Data
Keyboard Command: extend2z
Prerequisite: 3D linework

Break 3D Polyline by Surface

This command breaks 3D polylines against a surface. The surface is defined by a 3D grid or triangulated surface model which can be selected from a .grd, .flt or .tin file. Alternately, the user can select 3D entities on the screen from which the program internally calculates a 3D grid. This routine is one step in 3D polyline design. In this example, a valley fill is designed using 3D polylines as follows:

1. Draw 3D Polyline - draw a 3D polyline at elevation 1450 across valley
2. Offset 3D Polyline - offset the 3D polyline at 2:1 slope and 10:1 for benches and top
3. Break 3D Polyline by Surface - trims the 3D polylines by the valley sides
4. Draw 3D Polyline - with OSNAP endpoint, draw 3D polyline perimeter around 3D polylines ends
5. Make 3D Grid File - create 3D grid file of fill surface
6. Plot 3D Grid - draw the 3D grid using 3D polyline perimeter as inclusion polyline
7. Viewpoint 3D - creates the last figure view

Prompts

Source of surface model (File/<Screen>)? *press Enter* The *File* option allows you to choose the .grd, .flt, or .tin file that models the site. Otherwise, a grid will be calculated by picking the grid location and selecting surface entities on screen (e.g., contour polylines). Using the *File* option can be quicker because the surface is already calculated. Also the .grd file can be drawn to preview the existing surface.

Pick Lower Left limit of surface area: *pick a point*

Pick Upper Right limit of surface area: *pick a point*

Make GRiD Setting Dialog *OK*

Select polylines to clip.

Select objects: *pick the 3D polylines*

Select surface entities.

Select objects: *select objects that define the surface.*

Erase polyline below surface (<Yes>/No)? *press Enter* If you answer yes, the segments of the polylines below the surface will be erased from the intersection, if any, of the polyline with the surface. Otherwise the polylines will only be broken into separate polylines at the intersection.

Specify layer names (Yes/<No>)? *press Enter* If you answer yes, you will have the option to place the broken polylines into different layers.

Before Break 3D Polyline by Surface

After Break 3D Polyline by Surface

3D view of fill with grid mesh

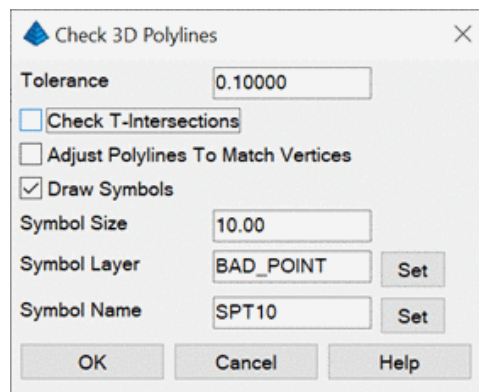

Pulldown Menu Location: 3D Data

Keyboard Command: surfbreak

Prerequisite: Plot the 3D Polylines to use for selection and entities that define a surface.

Check 3D Polylines Match Vertices

This command checks 3D polylines for vertices that match within the specified tolerance and for T-intersections. This command is a way to clean up 3D polylines to be used as breaklines in surface modeling. If the Triangulate & Contour routine reports a Data Problem Log with Vertical Edges or T-intersections, then this command can help clean up the polylines. This command can be used to identify the 3D polyline vertices within the tolerance. Besides creating a report of vertices, there is also an option to draw symbols at these vertices. Use the Adjust Polyline To Match Vertices to have the program modify the polyline vertices which will combine vertices within the tolerance into a single vertice.

Prompts

Check 3D Polylines dialog

Select 3D polylines to process.

Select objects: *select the polylines*

Check Report

Pulldown Menu Location: 3D Data > 3D Polyline Utilities

Keyboard Command: tin_pt_check

Prerequisite: 3D polylines

Add Points At Elevation

This command inserts vertices into a 3D Polyline at a specific elevation, or elevation interval, by interpolating between existing elevations in the polyline.

Prompts

Add single elevation or elevation interval [Single/<Interval>]? press Enter

Enter Elevation Interval: 50

Select 3D polylines to process. pick 3D polyline(s)

Select objects:

Processing polylines ...

Added 10 points to polylines.

Pulldown Menu Location: Edit > 3D Polyline Utilities

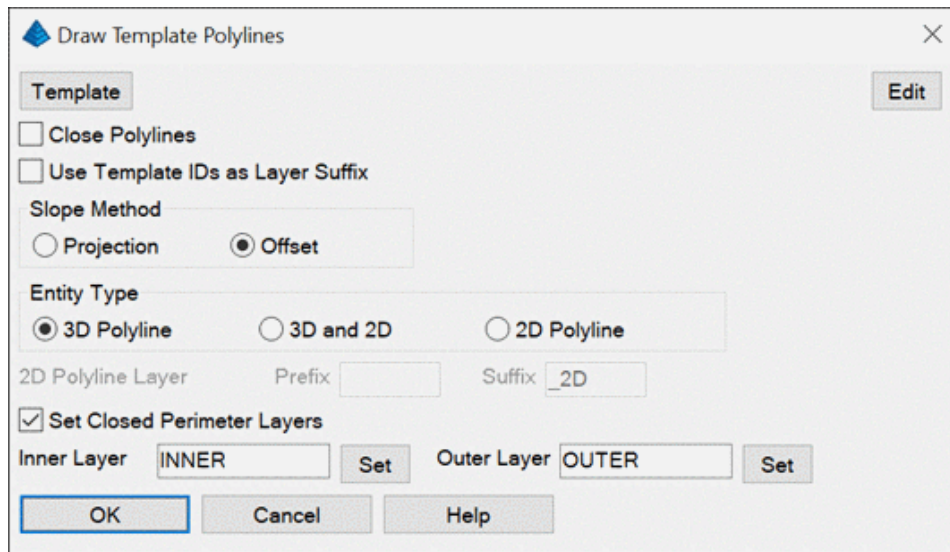

Keyboard Command: addplz

Prerequisite: 3D Polylines

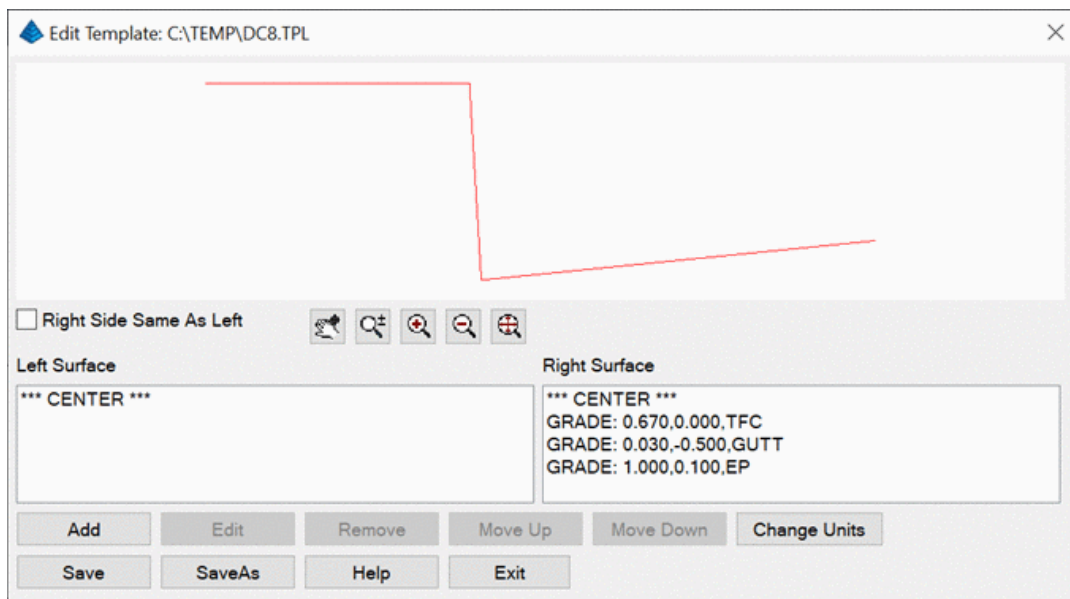

Draw Template Polylines

This command draws polylines that are offset parallel to an existing alignment polyline. A template file (TPL) from road design is used to define the offsets for the new polylines. This command can be used to turn 3D polylines into template polylines such as for curbs. The template 3D polylines can then be used for breaklines in surface modeling such as with the Triangulate & Contour routine.

In the dialog, pick the Template button to select a TPL file. Use the Edit button to edit the grades in the template. Each grade in the template is used to create a new template polyline. The grade distance is used for the horizontal offset and the grade slope is used for the vertical offset. The layer of the existing alignment polyline is used as the base layer for the template polylines. The Close Polyline option applies when the input polyline is unclosed. This option will when create a closed polyline using the farthest left and right template polylines. The Use Template IDs as Layer Suffix option adds the template ID to the layer name for each template polyline. The template polylines can be drawn as 3D polylines or as 2D polylines as zero elevation. For 2D polylines, there are layer prefix and suffix settings for creating separate layers for the 2D polylines. The Densify 3D Polyline option creates additional vertices at the specified interval. The Set Closed Perimeter Layers option uses the specified layers for the inner and outer template polylines.

Main dialog

Original alignment polylines

Template polylines created from curb template

Prompts

Draw Template Polylines dialog

Pick 3D polyline: *pick a polyline*

Pick side for template: *pick a polyline*

Pick 3D polyline (Enter to end): *press Enter*

Pulldown Menu Location: 3D Data > 3D Polyline Utilities

Keyboard Command: `tpl_3dp`

Prerequisite: 3D polyline

Draw Curb Ramp

This command modifies 3D curb polylines to fit in a ramp of the specified dimensions. For input, this command requires three 3D polylines that define the face of curb (bottom and top) and the back of curb. There is a dialog to enter the curb dimensions. For the **Pick Method**, the **Center** method places the ramp centered at the pick point. The **Sides** method prompts to pick two points on the curb polylines to define the left and right sides of the ramp. The **Driveway** method allows you to create multiple ramps at once by selecting closed polylines that represent driveways. These polylines must be closed polylines with two vertices on the curb polyline. The ramp is fit between these two vertices. The **Separate Pick Position Prompt** option prompts for the curb position point after selecting the curb polyline. Otherwise, the program uses the position that you select the curb polyline as the curb position. For the **Curb Method**, the **Curb Cut Only** modifies the three curb polylines and doesn't draw the ramp polylines. The **Elevate Driveway** option sets the elevation of the driveway polyline to match the curb polyline. For **Style**, the **Taper To End** option applies the **Front Taper** width to the back of the ramp as well as the front, the **Hold Fixed** option uses the full **Front Taper** width for the first ramp and then tapers, and the **Taper First Ramp** option applies the **Front Taper** only to the first ramp. The **Separate Curb Taper** is the distance the curb drop before the ramp. Leave this field blank to not use this curb taper. The **Direction Method** chooses between making the ramp perpendicular to the curb or having the program prompt for picking the ramp direction. The **Lip Method** controls the height between the bottom-of-curb and top-of-curb polylines at the bottom of the ramp. The **Ramp Slope** method sets the slope between these polylines to match the ramp slope and the **Height** method sets a fixed height. The **Slope Method** controls the ramp slope. The **Match Curb Height** method sets the slope so that the back of the ramp reaches the original height of the top-of-curb. The **Slope** method sets the ramp slope to the specified value. The **Second Ramp** and **Third Ramp** allow for additional ramps such as for a landing pad.

After the dialog, the program prompts to pick the curb 3D polylines to draw the ramp. The existing 3D curb polylines are modified to lower the curb for the ramp and new 3D polylines are drawn for the rest of the ramp. Also, the program updates other 3D linework that crosses the ramp such as sidewalks. These 3D polylines can then be used for breaklines in surface modeling such as with the Triangulate & Contour routine.

Pulldown Menu Location: 3D Data > 3D Polyline Utilities

Keyboard Command: curb_ramp

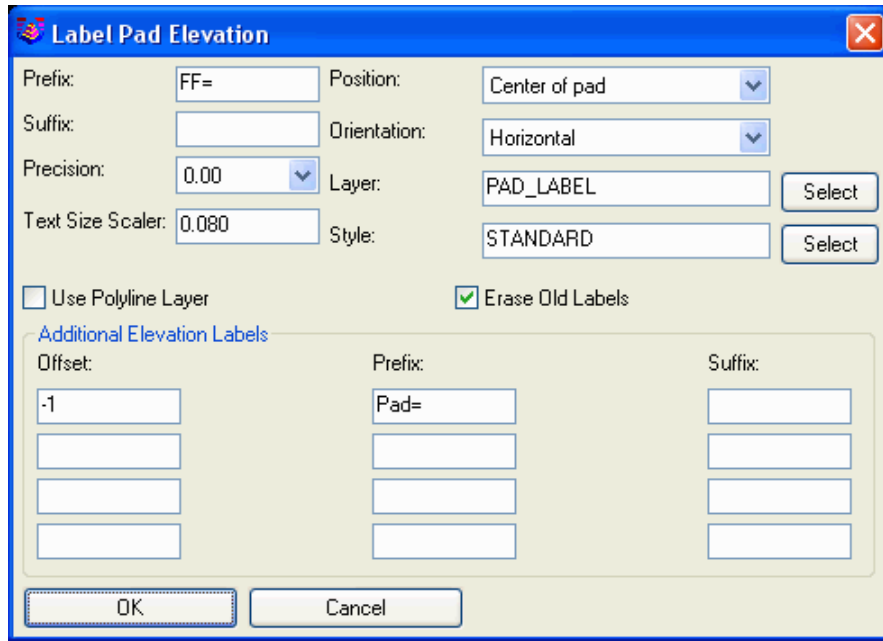

Prerequisite: 3D curb polylines

Label Pad Elevation

This command creates elevation labels inside closed polylines such as building pad polylines. The elevation value for the label comes from the elevation of the polyline. In the dialog, there are settings to control the label prefix, suffix, decimal place precision, text size position, orientation, layer and style for the labels. For **Position**, the Center of pad option creates the labels in the center of the polyline and the Edge of pad creates the label along the top segment of the polyline and draws a leader from the label to the polyline. For **Orientation**, the Horizontal option creates the label horizontal to the current twist screen and the Align With Pad option rotates the label to align with

the longest segment of the polyline. The **Use Polyline Layer** option will use the layer of the polyline for the label layer. The **Erase Old Labels** option erases previous labels when labeling the same polyline another time. The **Draw on Real Z Axis** creates the labels at the pad elevation instead of zero elevation. The **Additional Elevation Labels** are optional labels that are a fixed vertical offset from the polyline elevation. For example, you can use this option when the pad polyline elevation represents the finished floor elevation and you also want to label the basement elevation that is at a fixed offset.

If the Link Labels With Linework option is on in Carlson Configure > General Settings when the labels are created, then the labels will automatically update when the elevations of the polylines are changed.

Pulldown Menu Location: 3D Data > Label Polylines

Keyboard Command: labelpad

Prerequisite: Closed polyline with assigned elevation

Update Pad Elevation Labels

This command reads all previously created Pad Elevations, and updates their values if their associated Pad Polyline elevations have been changed.

Pulldown Menu Location: 3D Data >> Label Polylines

Keyboard Command: update_labelpad

Prerequisite: Previously created pad elevation(s)

Label Elevations Along Polyline

This command labels point elevations and aligns with a polyline based on settings shown in the dialog. These settings can be divided into five groups.

Label Settings: The **Source of Elevations** are read from Carlson points drawn on the screen, polyline vertices, elevations of grade break vertices and can also be picked on the screen. The **Side for Labels** is relative to the direction the polyline is drawn. Labels can be **aligned** horizontally, parallel or perpendicular to the polyline or according to the picked alignment. The **Offset distance scalar** offsets the label from the actual point.

Text Settings: The labels will be drawn on **Layer** with selected **Style**. The **Text size scalar** is relative to the current horizontal scale, which is set in *Drawing Setup*. These scalars are multiplied by the horizontal scale to obtain the actual drawing units. The number of **Integers** and **Decimals** can also be specified along with **Prefix** and **Suffix** for the main elevation label.

Leader Settings: The Leader Settings are used to **Draw Leader** with **Arrowhead** on the leader **Layer** with length of leader equal to **Leader Scaler**. The option **Draw text above leader** extends the leader tick to the length of the label.

Additional Settings: **Draw box around label** draws box around the elevation label. **Flip text for twist screen** changes the text direction if the text is drawn upside down. If the option **Ignore zero elevation** is on zero elevation labels will be ignored. The Carlson points or picked points are beyond **Maximum offset to use** will be ignored.

Additional Offset Settings: If the **Additional offset** is other than 0, it will be labeled with **Prefix** and **Suffix** using the other text settings on the next line of main elevation label.

The overlapping labels can be moved using Move Elevation Labels command to remove the overlap.

If the Link Labels With Linework option is on in Carlson Configure > General Settings when the labels are created, then the labels will automatically update when the elevations of the polylines are changed.

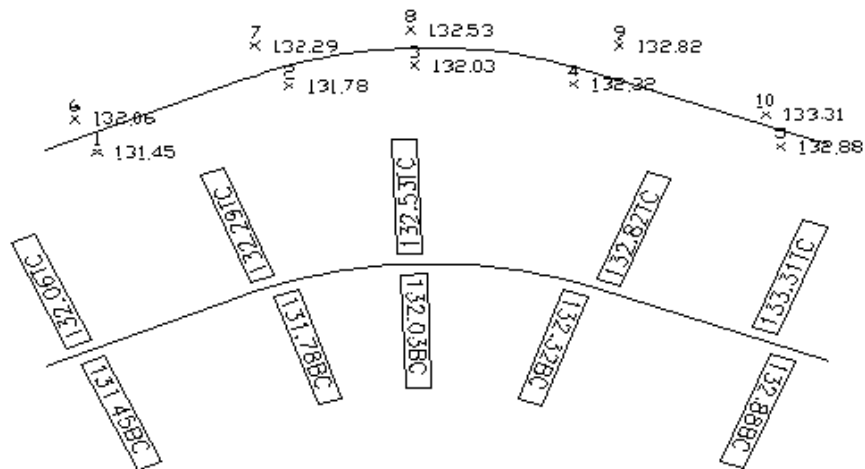

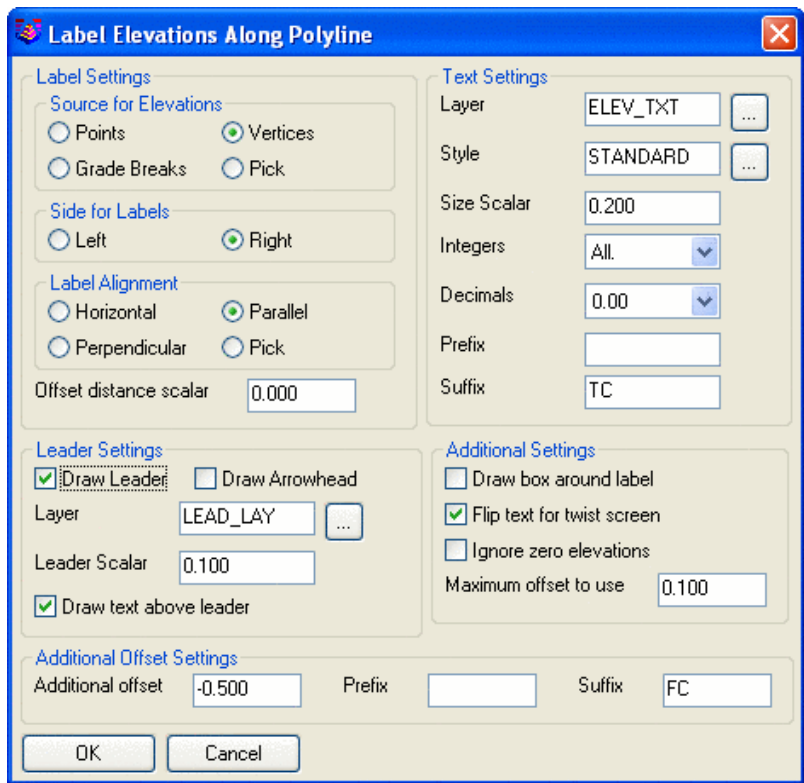

Prompts

Label Elevations Along Polyline dialog

Keyboard Command: elevlab
Prerequisite: Polyline and points

Move Elevation Labels

This command moves the selected elevation labels drawn using Label Elevations Along Polyline command with a leader. The purpose is to clean up label overlaps. To move a label, pick any one of the elevation labels text and the program will pick up all the other associated labels. Then pick the new location and while the pointer is moved, the program shows an outline of the label area. The program remembers the moved locations for each label so that when the elevation labels are redrawn, the moved locations are retained. The Restore function puts the labels back to their default position. The following graphics show the elevation labels before and after Move Elevation Labels was used to clean up the label overlaps.

Elevation Labels with Overlap

Move a label away

Elevation Labels without Overlap

Prompts

Select elevation label to move (R for Restore): *pick a elevation label text with leader*

Pick label position: *pick a point*

Select elevation label to move (R for Restore): *press Enter to end*

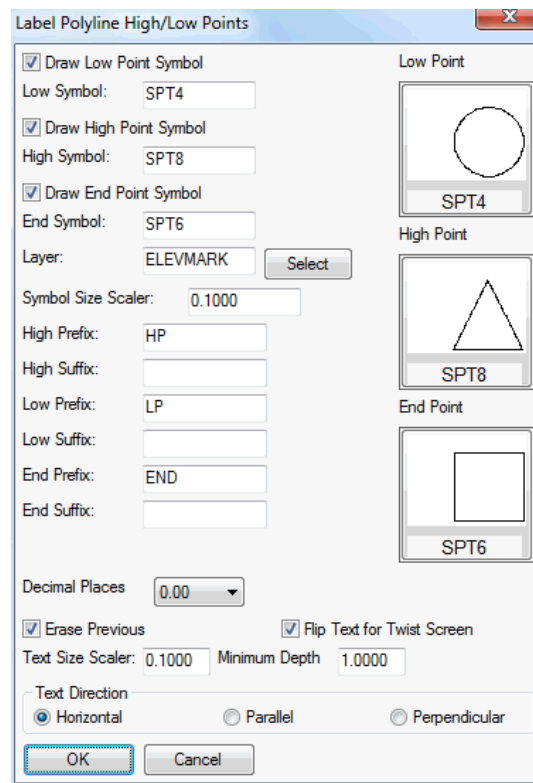

Pulldown Menu Location: 3D Data > Label Polylines

Keyboard Command: move_elevlab

Prerequisite: Elevation labels drawn using Label Elevations Along Polyline command

Label Polyline High/Low Points

This command finds and labels the high, low and end points of selected 3D Polylines. This is useful for drainage studies, finding low spots for placement of culverts or inlets, checking overhead clearances, etc. The **Erase Previous** option will erase labels created by this routine when running again on the same polyline. The **Flip Text for Twist Screen** option applies to text labels that would be upside-down in the current view depending on the polyline orientation. When a polyline has elevations that go up and down, multiple high and low points can be labeled for the different local highs and lows. The **Minimum Depth** setting controls how much elevation difference is needed to label a local high or low point.

Prompts

Keyboard Command: elevpl

Prerequisite: 3D polyline(s)

Label Polyline Segment

This command labels the distance and slope of 3D polyline segments, or between two picked points, in plan view.

In the dialog, choose the selection method; either the Entire polyline, Polyline segment, or Any two points. Then choose the location and/or visibility for the Horizontal distance, Slope distance, Slope %, and Slope ratio, enter any desired Prefixes and/or Suffixes, and the desired decimal Precision for each. Choose whether to Draw Slope Leaders, which are arrows pointing in the direction of the slope. The Slope Direction controls whether to draw the slope leaders in the direction of the polyline, always pointing uphill or always pointing downhill. Leader Position controls whether to draw the slope leaders alongside the slope label or above the label. Choose whether to Erase old annotations, and set the Text size scaler, Text offset scaler, and other related variables. Scalers are multiplied by the drawing scale to determine the actual sizes for the specified objects. Choose the Annotation layer from the drop list. Pick OK, and you are prompted to select the polyline or segment or two points to annotate.

	Location	Prefix	Suffix	Precision
Hz Distance	No annotation			0.00
Slope Distance	No annotation			0.00
Slope %	No annotation			0.00
Slope Ratio	No annotation			0.00

Text Size Scaler: 0.100 Label Layer: POLYLINE_LABEL Select

Text Offset Scaler: 0.025 Label Style: STANDARD Select

Arrow Size Scaler: 0.050

Draw Slope Leaders

Leader Position: Next to Label

Erase Old Annotations

OK Cancel

Prompts

Set up variables as desired in Annotate polyline dialog box, pick OK. Depending on your Selection method, the prompt will either read:

Select a polyline segment to annotate: *pick the segment*

or

Select a polyline to annotate: *pick the polyline*

or

Pick first point: *_nea to* For snap on.

Pick second point: *_nea to*

Press enter to return to the Annotate polyline dialog box, in the dialog box, pick Cancel to end.

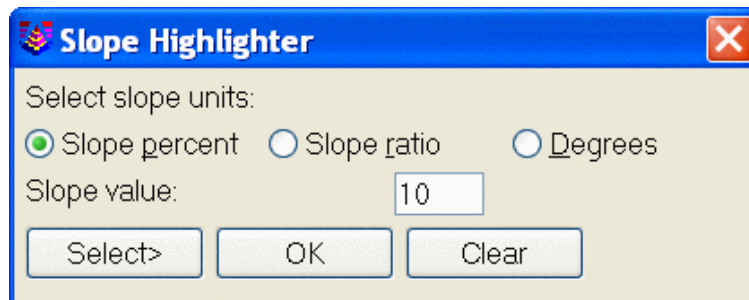

Pulldown Menu Location: Annotate

Keyboard Command: label3dp

Prerequisite: A 3D polyline

Highlight Segments by Slope

This routine highlights segments of a 3D polyline with slopes greater than the entered slope value. The RED segments are uphill, BLUE is downhill and BLACK/WHITE is for slopes less than the target slope. The slope can be entered as percent, ratio or degree. Choose Select to select the polyline and it is colored by slope.

Prompt

Select a polyline to highlight: *Select the 3D pline*

Pulldown Menu Location: 3D Data >> Highlight 3D Polylines

Keyboard Command: hlslope3dp

Prerequisite: 3D polylines

Highlight Crossing Breaklines

Breaklines are lines or polylines that are used in surface modeling to represent a feature such as a ridge, stream or curb. Breaklines force triangulation and interpolation to occur between the vertices of the breakline, which prevents any other triangulation line from crossing the breakline. It is important to avoid crossing breaklines in the surface model because the program cannot force triangulation along both since holding one will cross the other. Also the program cannot hold the interpolation along both because the elevation at the intersection point can be different for the two breaklines. For example, consider a breakline going from 101 to 105 and another going from 107 to 109. If these lines had an intersection at the midpoint, the elevation for one would be 103 and the other 108. This is an error that needs to be fixed by the user because those two breaklines are holding different elevations at the same point.

This command checks for intersections between the selected breaklines and then identifies any crossing breaklines by highlighting them. You can then edit these crossing breaklines before doing surface modeling such as Make 3D Grid or Triangulate & Contour.

Prompts

Ignore zero elevations [Yes/No]?

Reading points ...

Select surface entities to check.

Keyboard Command: xbar

Prerequisite: Polyline

Report 3D Polyline Station/Elevation

This command reports station or elevation information on a 3D polyline. If the station information is entered the program will return the elevation at the entered station. If the elevations are entered the program will determine and report the station at which the entered elevation occurred. If the elevation entered occurs at more than one location along the 3D polyline, all occurrences of the elevation are reported.

A prompt is provided allowing you to designate a starting station, or accept the default value of <0.0>. All entry and values are recorded and are displayed in the Carlson Standard Report Viewer upon completion.

Prompts

Select 3D polyline to report: pick a polyline

Starting Station <0.0>: press Enter

Enter elevation or station (<Elevation>/Station)? S

Enter Station to calculate elevation: 100

Station: 1+00.000 **Elevation:** 1052.262

Enter Station to calculate elevation (Enter to end): press Enter

Select 3D polyline to report: pick a polyline **Starting Station <0.0>:** press Enter

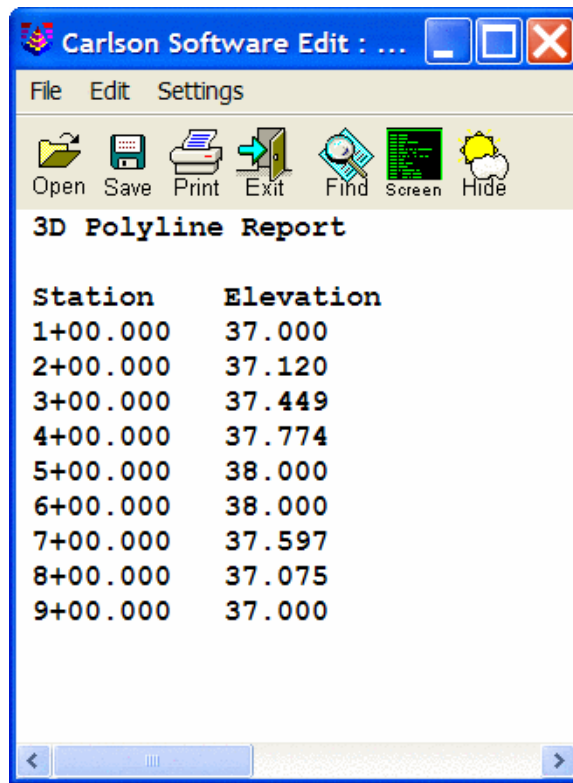

Enter elevation or station (<Elevation>/Station)? E

Enter Elevation to find stations: 2140

Enter Elevation to find stations: 2144

Enter Elevation to find stations: 2150

Enter Elevation to find stations (Enter to end): press Enter

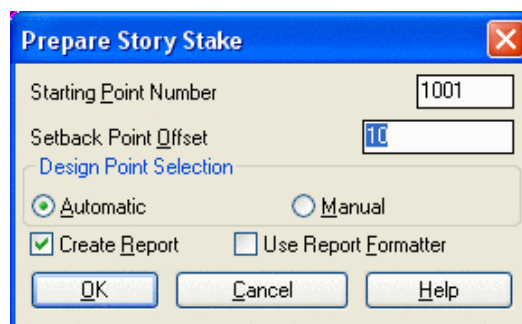

Pulldown Menu Location: 3D Data

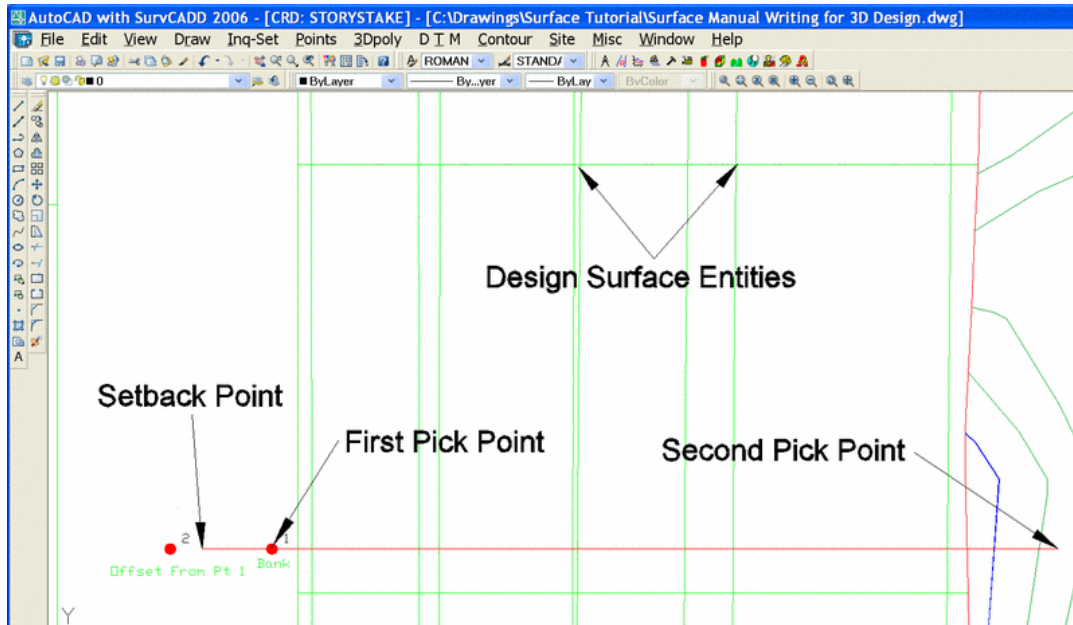

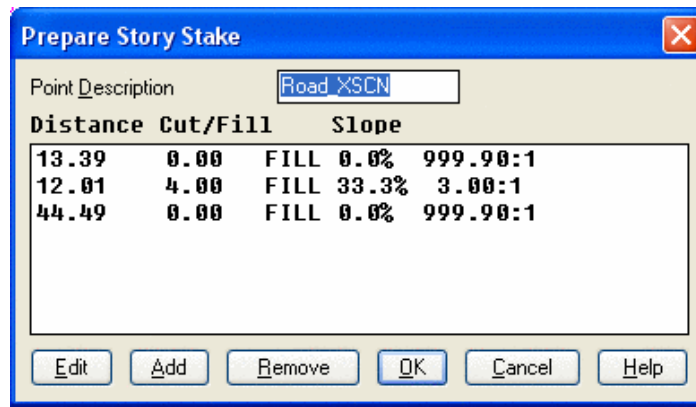

Keyboard Command: plreport3

Prerequisite: A 3D Polyline

Story Stake from Surface Entities

This command creates points with cut/fill information stored in the note fields for the points. Beginning at a point and facing a specified direction, the cut/fill information describes a design surface that is defined by contours and 3D polylines in the drawing. The program prompts you to pick the starting point followed by a direction point. Then the intersections for all the contours and 3D polylines between these two points are calculated and the resulting horizontal distances and slopes are shown in a dialog. In this dialog, you can edit, add or remove these slopes descriptions. The Point Description can also be specified. When OK is clicked, a point in the coordinate file is created at the starting point with this information stored in the note file. An offset point is also created at the specified offset distance back from the starting point. At the end of Story Stake from Surface Entities, a report of all the created points and the corresponding cut/fill data is shown if the Create Report option was set. Story Stake from Surface Entities does not draw the points in the drawing. These points can be drawn using the Draw-Locate Points command.

Prompts

Pick starting point: *pick the first point*

Pick direction point: *pick the second point to determine the direction*

Pick next starting point (Enter to end): *Enter if done*

Pulldown Menu Location: 3D Data >> Story Stake

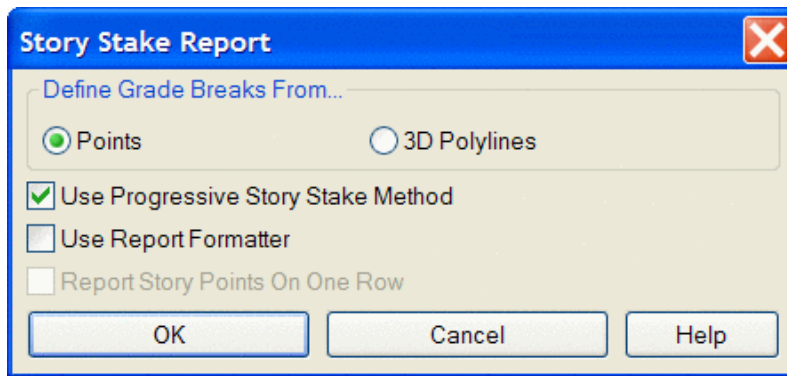

Keyboard Command: prepare_story

Prerequisite: Screen entities such as 3D polylines and contours

Story Stake By Points/Polyline

By Points

This option creates a report of cut/fill slopes and distances of a design surface from point to point. First you select the starting point. This starting position is shown as point 100 in the drawing below. Next you enter the subsequent point numbers to get the direction. The resulting horizontal distances and slopes are shown in a report dialog.

If the use Progressive Story Stake Method is turned off, the Cut/Fill, Distance and Slope is calculated from the first point to each point. The result is shown below. If it is turned ON, then it is point to point.

Tag Non-Surface Points

This command allows you to tag Carlson points in the drawing so that they will not be used when creating a surface. These could be points that are far from the site, such as off-site horizontal control, or points with elevations that are not on the ground, such as a TBM taken on the top of a fire hydrant. There are several methods available to select the points for tagging as non-surface points. One key to remember is that they must be present in the drawing to be tagged.

Range: This option allows you to specify a range of point numbers, or select ALL of the points currently in the drawing, or specify a Point Group, remembering, however, that only points that are currently in the drawing can be tagged. So if you select a Point Group, but only some of the points listed in the Point Group are currently present in the drawing, the whole Point Group will not be tagged

Area: This option allows you to utilize inclusion and/or exclusion polyline(s) to specify an area in the drawing within which any points currently in the drawing are tagged as non-surface points.

Selection Set: This option allows the manual selection of points within the drawing.

Description Match: This option allows the filtering of selected points by descriptions. For example, you could use a Range of ALL, but set the Description Match to TBM, and only the points with that description would be tagged.

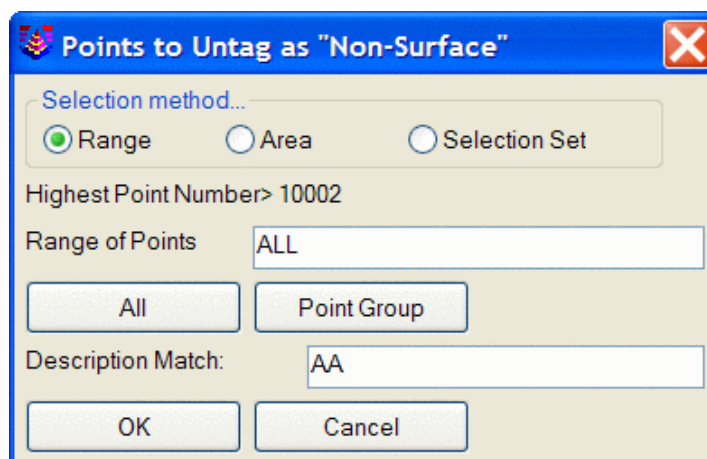

Pulldown Menu Location: 3D Data >> Non-Surface Points

Keyboard Command: tagns

Prerequisite: Carlson points in a drawing

Untag Non-Surface Points

This command allows you to Untag Carlson points in the drawing that have been tagged as non-surface points, so that they will again be used when creating a surface. As with tagging non-surface points, there are several methods available to select the points for untagging, and the points must be present in the drawing to be untagged.

Range: This option allows you to specify a range of point numbers, or select ALL of the points currently in the drawing, or specify a Point Group, remembering, however, that only points that are currently in the drawing can be tagged. So if you select a Point Group, but only some of the points listed in the Point Group are currently present in the drawing, the whole Point Group will not be tagged

Area: This option allows you to utilize inclusion and/or exclusion polyline(s) to specify an area in the drawing within which any points currently in the drawing are tagged as non-surface points.

Selection Set: This option allows the manual selection of points within the drawing.

Description Match: This option allows the filtering of selected points by descriptions. For example, you could use a Range of ALL, but set the Description Match to TBM, and only the points with that description would be tagged.

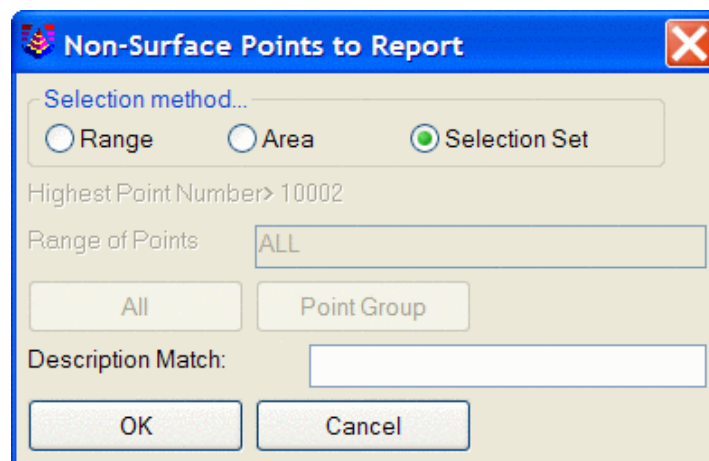

Pulldown Menu Location: 3D Data >> Non-Surface Points

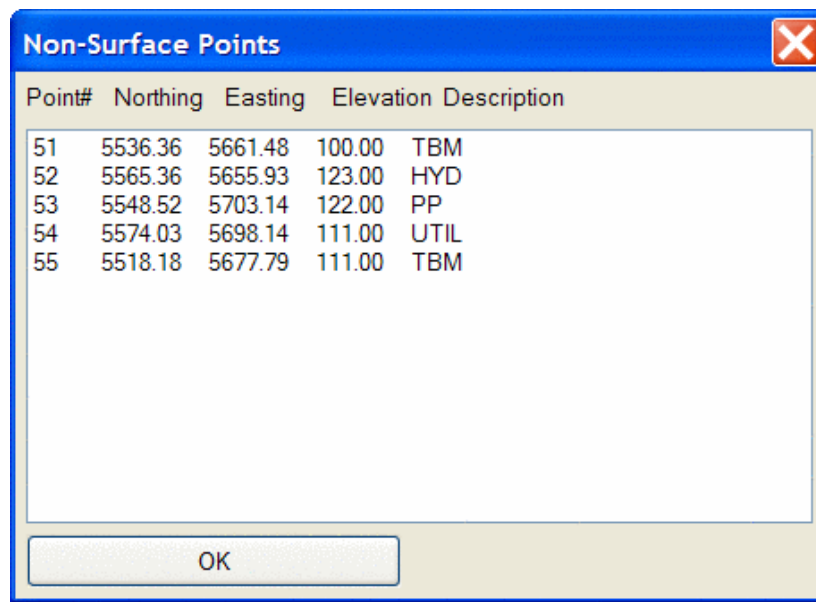

Keyboard Command: untagns

Prerequisite: Carlson points in a drawing

Report Non-Surface Points

This command allows you to generate a report of Carlson points in the drawing that have been tagged as non-surface points. As with tagging and untagging non-surface points, there are several methods available to select the points for the report, and again, the points must be present in the drawing to be included in the report.

Range: This option allows you to specify a range of point numbers, or select ALL of the points currently in the drawing, or specify a Point Group, remembering, however, that only points that are currently in the drawing can be tagged. So if you select a Point Group, but only some of the points listed in the Point Group are currently present in the drawing, the whole Point Group will not be tagged

Area: This option allows you to utilize inclusion and/or exclusion polyline(s) to specify an area in the drawing within which any points currently in the drawing are tagged as non-surface points.

Selection Set: This option allows the manual selection of points within the drawing.

Description Match: This option allows the filtering of selected points by descriptions. For example, you could use a Range of ALL, but set the Description Match to TBM, and only the points with that description would be tagged.

Pulldown Menu Location: 3D Data >> Non-Surface Points

Keyboard Command: tagns

Prerequisite: Carlson points in a drawing

Non-Surface Entities

This command tags selected entities in the drawing so that they will not be used when creating a surface in commands like Triangulate & Contour. For example, you could tag a 3D polyline for a building roof so that it's not used for modeling the ground surface. There are three commands to manage these tags:

Tag Non-Surface Entities: adds the non-surface tag to the selected entities

Untag Non-Surface Entities: removes any non-surface tag from the selected entities

Report Non-Surface Entities: reports the entity type and location for any selected entities that have active non-surface tags

Prompts

Select entities to tag as non-surface.

Select objects: *pick entities to tag*

Pulldown Menu Location: 3D Data >> Non-Surfaces Points/Entities

Keyboard Command: tagns_ent, untagns_ent, reportns_ent

Prerequisite: Entities in the drawing

Tag Hard Breakline Polylines

This command tags polylines with a description so that Triangulate & Contour can identify these polylines as hard breaklines. The tag is invisible and doesn't change the polyline. Triangulate & Contour will not smooth the contours as they cross these hard breaklines, even with contour smoothing turned on. For example you could tag 3D polylines that represent a wall or a curb so that the contours go straight across without smoothing curves. If contour smoothing is turned off, this tag had no effect.

Prompts

Select hard breakline polylines. (For no smoothing in Triangulate & Contour)

Select objects: *Select breaklines to tag*

Select objects: *press Enter* to conclude selection

Set 14 polylines as hard breaklines.

Pulldown Menu Location: 3D Data >> Hard Breaklines

Keyboard Command: hardbrk

Prerequisite: Polylines

Highlight Hard Breakline Polylines

This command visually highlights all polylines in the drawing that have been tagged as hard breaklines.

Pulldown Menu Location: 3D Data >> Hard Breaklines

Keyboard Command: highlight_hardbrk

Prerequisite: Polylines tagged as hard breaklines

Identify Hard Breakline Polylines

This command prompts to select polylines and reports to the command line whether they are tagged as hard breaklines or not.

Prompts

Select polyline: *select polyline*

Polyline is a hard breakline

Select polyline ([Enter] to End): *select polyline*

Not a hard breakline

Select polyline ([Enter] to End): *press Enter* to conclude.

Pulldown Menu Location: 3D Data >> Hard Breaklines

Keyboard Command: id_hardbrk

Prerequisite: Polylines, tagged or not as hard breaklines

Untag Hard Breakline Polylines

This command removes hard breakline description tags from polylines. These tags are used by Triangulate & Contour to identify polylines as hard breaklines. Contours are not smoothed as they cross these hard breaklines, even with contour smoothing turned on. This routine untags polylines so that contours are smoothed across them. If contour smoothing is turned off, hard breaklines have no effect.

Prompts

Select polylines to remove hard breakline tag from.

Select objects: *select polylines*

Pulldown Menu Location: 3D Data >> Hard Breaklines

Keyboard Command: softbrk

Prerequisite: Polylines with hard breakline tag

Extend 3D Polyline to Surface

This command extends 3D polylines to a surface. The 3D polyline is extended from the selected end of the polyline using the slope of the polyline end segment until this vector intersects the surface. The surface is defined by a 3D grid or triangulated surface model which can be selected from a .grd, .flt or .tin file.

Prompts

Select Surface File *Pick a triangulation or grid surface*

Pick polyline to extend: *pick a 3D polyline*

Pick polyline to extend (Enter to end): *press Enter*

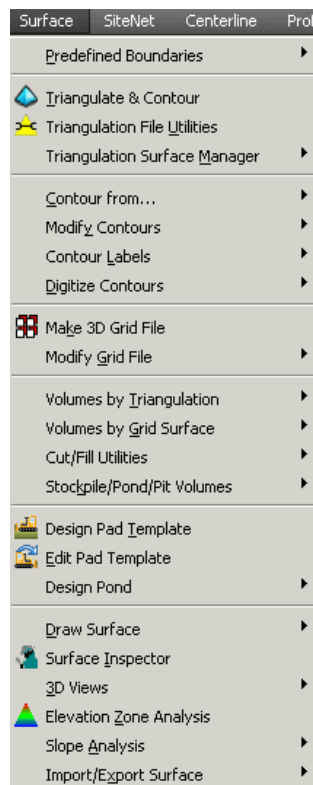

Pulldown Menu Location: 3D Data

Keyboard Command: surf_extend

Prerequisite: 3D Polylines and a surface model file

Surface Menu

The Surface menu has command for building and processing triangulation and grid surface models. The Survey and Hydrology modules have a subset of the surface commands. The Civil module has the full set of surface commands.

Tag Predefined Boundaries

This command allows you to identify closed polylines to be used as inclusion or exclusion boundaries. These boundaries are applied in Surface Menu commands such as *Two Surface Volumes* and *Triangulate & Contour*. Inclusion polylines limit processing to inside the polyline(s). For example, an inclusion polyline for volumes would be the limit of disturbed area. Exclusion polylines prevent processing inside the polyline(s). For example, a building perimeter or pond surface could be an exclusion polyline for contouring. *Tag Predefined Boundaries* assigns a site name to polylines and flags the polyline as either inclusion or exclusion.

Many Surface commands will prompt for inclusion and exclusion polylines. The advantage to Predefined Boundaries is that you don't have to select the boundary polylines each time that you run the Surface command. Instead, the program will recognize that the boundary is already specified and will prompt "Use predefined boundary Area 1 (<Yes>/No)?" This lets you simply press enter to use your predefined boundaries. If you want to pick different boundaries, you can type *N* for No and select them prior to processing. When you have more than one set of predefined boundaries, the routine lets you choose from a list of the boundary names as shown in the dialog.

Prompts

Boundary name <Site 1>: *Area 1*

Select Inclusion perimeter polylines.

Select objects: *pick the closed polylines or press Enter for none*

Select Exclusion perimeter polylines.

Select objects: *pick the closed polylines or press Enter for none*

Pulldown Menu Location: Surface >> Predefined Boundaries

Keyboard Command: plzone

Prerequisite: Closed polyline

Identify Predefined Boundaries

Identify Predefined Boundaries identifies any polylines in the drawing that have been previously tagged as *Predefined Boundaries*. The *Pick* option prompts to pick a polyline, and if it has been tagged as a Predefined Boundary, the Boundary Type and Boundary Name are presented at the command line. The *Search* option scans the entire drawing for Tagged Predefined Boundaries, highlights them in the drawing, and lists their location, layer, type and name at the command line.

Predefined Boundaries are applied in Surface commands such as *Two Surface Volumes* and *Triangulate & Contour*. Inclusion polylines limit processing to inside the polyline(s); e.g., an inclusion polyline for volumes would be the limit of disturbed area. Exclusion polylines prevent processing inside the polyline; e.g., a building perimeter or pond shoreline could be an exclusion polyline for contouring. Identifying polylines that have been previously tagged as Predefined Boundaries is often helpful during surface modeling.

Prompts

Pick polylines to check or search drawing [**<Pick>/Search**]: *press Enter for default pick method*

Select boundary polyline: *pick a polyline*

Inclusion boundary polyline for Site 1

Select boundary polyline (Enter to end): *press Enter*

Pulldown Menu Location: Surface >> Predefined Boundaries

Keyboard Command: plzoneid

Prerequisite: Assigned, predefined inclusion/exclusion closed polylines

Untag Predefined Boundaries

This command removes the previously tagged predefined boundary names from selected polylines. These polylines will no longer be automatically recognized as boundary polylines.

Prompts

Select polylines to remove boundary tag from.

Select objects: *pick the boundary polylines*

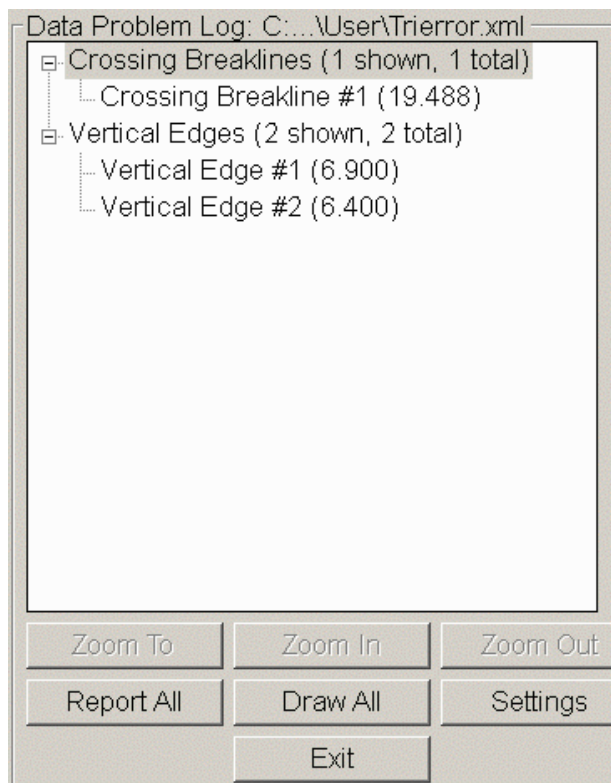

Pulldown Menu Location: Surface >> Predefined Boundaries

Keyboard Command: nozone

Prerequisite: predefined boundary polylines

Triangulation Data Check

This command checks 3D drawing entities for errors with being used to build a triangulation surface. For example, this routine checks for 3D polylines that cross and have different elevations at the crossing which is not allowed because a triangulation surface can't have different elevations at the same point. This command prompts to select the entities to check and then has a dialog to review any errors. See the Error Log section of the Triangulate and Contour topic of the manual for more information.

Pulldown Menu Location: Surface
Keyboard Command: tri_check_data
Prerequisite: Entities to check

Triangulate & Contour

At the heart of nearly every land design project is at least one terrain model. These models go by several names and one of the most common is that of a "TIN" or Triangulated Irregular Network; another common name is that of a "DTM" or Digital Terrain Model. Since accurate representations of a surface model are significantly important to most land development projects, having a thorough understanding of the Triangulate & Contour controls is very important.

Surface models are generally comprised of combinations of the following general data types:

- Points - Most surface models are comprised of points whose coordinates (x,y,z) contribute to the formation of triangular planes that connect three points that are in close proximity to one another. Within Carlson, most points come from the Draw Field to Finish command and/or the Draw-Locate Points command. Points can be selectively filtered from the triangulation engine through the use of the Tag Non-Surface Points command.
- Breaklines - Breaklines (or "fault lines") are used to control the connection sequence between four points which results in two triangles. Common uses of breaklines include ravines, ditches, berms and other areas where distinct grade discontinuity occurs. The "leg" of a triangle can travel along a breakline but cannot cross the breakline. Breaklines must be in the form of 3D polylines or simple lines whose vertices or endpoints define a valid "Z" elevation. A common problem related to breaklines is when two breaklines cross one another in 3D space. In these situations, an impasse results and will result in a "crossing breakline" report. Within Carlson, most breaklines come from the Draw Field to Finish command and/or the 3D Polyline command. Breaklines fall into one of two general categories:
 - "Soft" breaklines - Unless otherwise specified, all breaklines are considered "soft" breakline. The nature of soft breaklines allows a degree of contour smoothing across the breakline itself resulting in a "weathered-" or natural-looking contour.

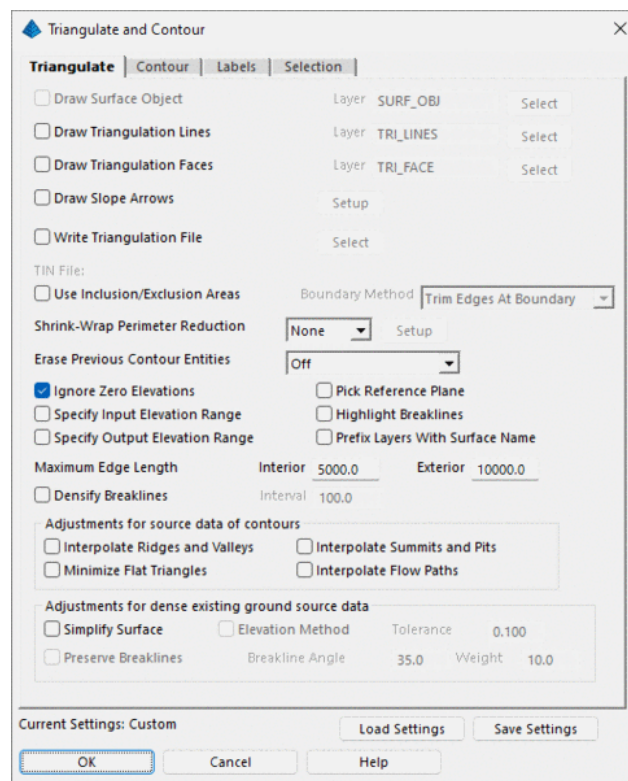

- "Hard" breaklines - Breaklines tagged as "hard" breaklines prevent contour smoothing through the breakline. Hard breaklines are generally used to represent man-made terrain breaks that commonly occur during excavation and construction. Breaklines can be changed to hard breaklines through the use of the Tag Hard Breaklines command.

Breaklines and other triangulate-able entities can be selectively filtered from the triangulation engine through the use of the Tag Non-Surface Entities command.

- Inclusions - Inclusions (or "boundaries") are used to identify the entities that can be used for triangulation and multiple inclusion regions can be selected for a given surface model. Entities that fall outside of an inclusion boundary and are not otherwise bound by a different inclusion boundary are ignored by the triangulation engine. Inclusion regions must be in the form of a closed 2D or 3D polylines. Within Carlson, most inclusion polylines come from the Shrinkwrap Entities command.
- Exclusions - Exclusions (or "void regions") are the antithesis of Inclusions and are used to prevent triangulation from occurring between points that are bound by an Inclusion region. Common uses of exclusion regions include building footprints and free-standing water limits (*e.g.* ponds). Entities that fall inside an exclusion region are ignored by the triangulation engine. Exclusion regions must be in the form of a closed 2D or 3D polylines. Within Carlson, most exclusion polylines come from the Boundary Polyline command and/or the 3D Polyline command.

Carlson provides a programming interface for these file types and also offers a third file type (*.GRD) for the representation of terrain data. See the Notes section for additional details.

The **Triangulate** tab provides options and settings that control the creation and analysis of the TIN itself.

Draw Surface Object: This option draws the triangulation faces as a Carlson Surface Object.

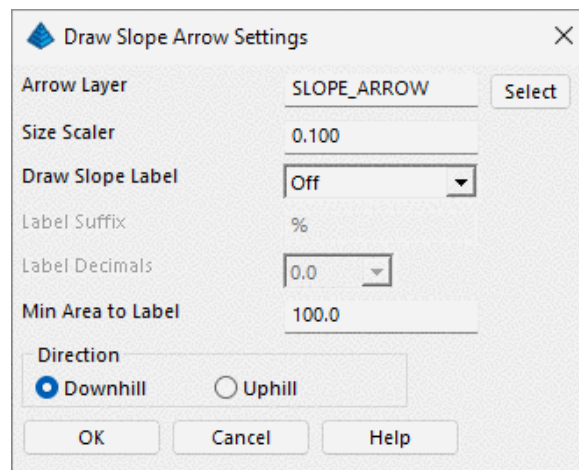

Draw Triangulation Lines: When enabled, the program will draw the triangulation using simple line entities at the appropriate elevation(s). Use the **Select** button or specify the layer for these lines.

Draw Triangulation Faces: When enabled, the program will draw the triangulation using a collection of 3D Face entities. These 3D Faces can then be used rendering routines such as *HIDE* and *SHADE* or in Carlson routines such as 3D Viewer Window, 3D Surface Fly-Over and Slope Zone Analysis. Use the **Select** button or specify the layer for these 3D Faces.

Draw Slope Arrows: When enabled, slope arrows are created within the triangles indicating the downhill dip direction as illustrated below.

Clicking the **Setup** button yields the Draw Slope Arrow Settings dialog box.

Arrow Layer: Indicate the layer to which the slope arrows are to be placed.

Size Scaler: Indicate a positive, non-zero value for the scale factor that should be applied to the slope arrows.

Draw Slope Label: When enabled, the slope value (expressed as a percentage or a ratio) of the triangle is labeled onto the slope arrow. Specify the desired unit suffix (*e.g.* "%") to apply to the end of the numerical value that is calculated from the TIN triangle(s).

Label Decimals: Indicate the amount of precision that is to be displayed on the slope label.

Min Area to Label: Indicate the smallest allowable triangle size that can be used for the slope percentage labels.

Write Triangulation File: When enabled (strongly suggested), an external surface model file is created which can subsequently be used for volume calculations, the creation of profiles, cross-sections and graded pads. Carlson

currently provides two file types to store the DTM data created by the Triangulate & Contour routine:

1. *.TIN - The TIN file format is the default and preferred file format due to its compact file size and organizational efficiency. The Carlson TIN format is governed by Carlson and is in a binary (non-human readable) format.
2. *.FLT - The FLT file format is a legacy ASCII-based (human-readable) file format and is used in some older machine control applications.

Use Inclusion/Exclusion Areas: When enabled, the program will prompt you for inclusion and exclusion polylines and prevents the use of the Shrink-Wrap Perimeter Reduction option. These are used to further control the area of activity for triangulation and contouring. The inclusion and exclusion polylines must be closed polylines and when used, must be drawn before using *Triangulate & Contour*. It is suggested that the height of the **Command:** line display must be set to show at least two lines so that the additional prompts can be easily viewed. Refer to the Notes section for additional information on Inclusion/Exclusion polyline selections.

Boundary Method: This option controls whether edges that cross the inclusion or exclusion perimeter are trimmed or removed. Use the Remove option if you don't want the triangulation to interpolate across the perimeters. Use the Trim option if you want the triangulation to fill the area up to the perimeter.

Shrink-Wrap Perimeter Reduction: This option produces an inferred Inclusion region around the data to be selected and mimics the results of the Shrinkwrap Entities command. Under the Setup, there is an option to draw the shrink-wrap perimeter polyline on a specified layer.

Erase Previous Contour Entities: In the event that a TIN needs to be recreated and Carlson-produced contours are in the drawing, three options exist that allow you to control whether or not the contour data should be removed from the drawing:

- Off - All existing Carlson-generated contours are left intact in the drawing. If these contours satisfy all of the triangulation requirements, they can be utilized by the Triangulation algorithm.
- Current Surface - Only the Carlson-generated contours that are associated with the active Triangulation file are removed from the drawing.
- All Contour Entities - All Carlson-generated contours are removed from the drawing, regardless of the surface model that created them.

Ignore Zero Elevations: When enabled, this option will filter out all data points and entities at an elevation of zero from the triangulation data set.

Pick Reference Plane: When enabled, this option allows you to contour an overhang or cliff by changing the reference plane to a side view. The reference plane can be specified by using the *View>Viewpoint 3D>View* command (see the AutoCAD/IntelliCAD Help menu for additional details) or by specifying three data points on the cliff (two along the bottom and one at the top).

Specify Input/Output Elevation Range: If you would like to manually set the range over which to contour, select either or both of the aforementioned toggles. One controls the triangulation of the source data and the other for the contour output. The program will automatically contour from the lowest elevation in the data set up to the highest at the increment specified in Contour Interval.

Highlight Breaklines: When enabled, this routine highlights breaklines in the triangulation network by drawing the triangulation lines along breaklines in yellow.

Prefix Layers With Surface Name: This option applies when using Write Triangulation File. The file name is added as a prefix to all the layers created during Triangulate and Contour as a way for layer management to organize all the contouring layers for a surface file.

Maximum Edge Length: Two bounds are provided to limit the length of the "legs" within a triangulation network. Based on the available data, if the edge length of a triangle exceeds the respective bound, the triangle will not be formed:

- **Exterior:** This value applies to triangulation lines around the perimeter of the triangulation area.
- **Interior:** This value applies all the other triangulation lines. Generally you would have the Exterior value larger than the Interior value.

Densify Breaklines: This option subdivides linework segments for the input data so that the maximum length of the segments is the specified Interval. This option is similar to the Densify Polyline Vertices command except that the entities are not modified in the drawing. Having shorter breakline segments is often helpful for holding the breaklines in the TIN and making more regularly sized triangles.

Minimize Flat Triangles: When enabled, this toggle instructs the triangulation "engine" to iterate through the triangulation permutations to minimize the occurrence of "flat" (or more precisely, horizontal) triangles. Flat triangles often occur when creating surface models from contour data. In this scenario, the often used Delaunay triangulation algorithm may produce unrealistic results. The Minimize Flat Triangle option will perform additional permutations of the triangulation network through the use of the Surface Manager > Swap Edge routine in an attempt to maximize the number of "sloped" triangles. Another option that produces similar results is the Interpolate Ridges and Valleys option.

Before: Surface made from an existing contour map with Minimize Flat Triangles disabled.

After: The same surface with Minimize Flat Triangles enabled. Note the better defined ravine and ridge definitions.

Difference: A Cut/Fill Color Map showing the regions of significant triangulation difference between the "Before" scenario and the "After" scenario of "Minimize Flat Triangles."

Interpolate Ridges and Valleys: The purpose of this option is to avoid flat areas by better defining surface ridges and valleys. When enabled, this option inserts breaklines into the drawing which are subsequently used in the triangulation process in an attempt to minimize flat, horizontal triangles.

Interpolate Summits and Pits: When enabled, this option creates additional triangulation in a summit or pit situation to more accurately represent existing ground conditions from a surface model created from contour entities. Since the tops of hills and the bottom of pits are often not shown on existing ground contour maps, this option often helps improve the accuracy of existing terrain conditions.

Interpolate Flow Paths: this function generates 3D data polylines from a contour map that approximate the downhill flow of water through valleys. These polylines are then used when creating a triangulation and can

improve the it in these valley regions by giving more definition to these areas. The polylines are created by looking for "sharp" or angled regions of the contours, and then connecting these regions with a smooth curve.

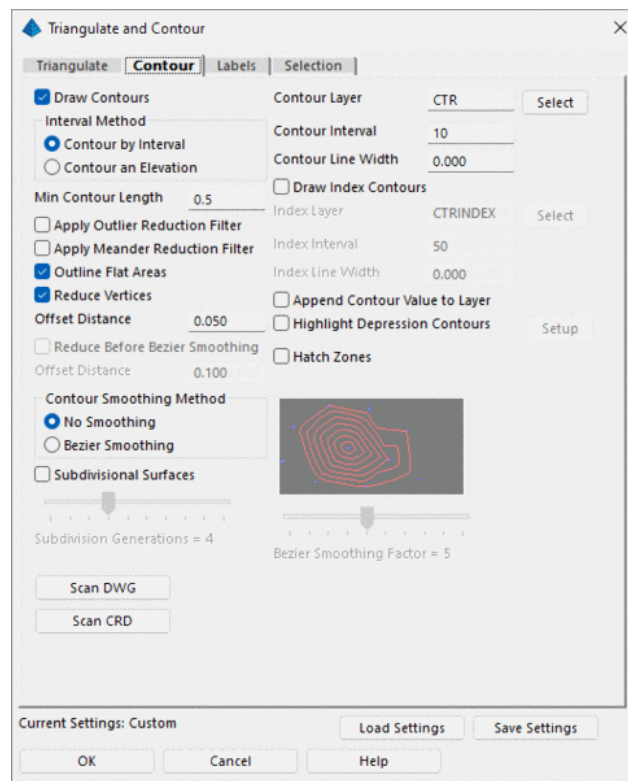

Simplify Surface: When enabled, this option reduces the digital size of a surface without significantly compromising the integrity or accuracy of the surface itself. The most common application to enable this option is when using very large datasets, such as smoothed contours. Its use is less applicable to design surfaces or surfaces based on surveyed points, but it can still be utilized.

Elevation Method: When enabled, this option reduces the size of the surface file by analyzing the difference in elevation between each vertex of the TIN and the vertices directly surrounding it, assigning a numerical weight or value to each vertex. If it is determined that the calculated weight for a particular vertex is less than the *Tolerance* factor, the vertex is a candidate for removal. The number of vertices removed is directly proportional to the *Tolerance* factor, so the higher the *Tolerance* factor, the more vertices are removed and vice versa.

Preserve Breaklines: When enabled, this option analyzes the TIN by focusing on the edges; calculating the angular difference between adjacent triangular faces. If the angular difference between edges is greater than the specified *Breakline Angle*, it is considered to be a breakline, and it is preserved. If its angular difference is determined to be below the *Breakline Angle*, it becomes a candidate for removal. In that case, the *Weight* factor is applied to the corresponding vertex, adjusting its original value. If the resulting value is still below the *Tolerance*, it is then removed. The number of vertices removed is inversely proportional to the *Weight* factor, so the greater the *Weight* factor. The fewer vertices that are removed, the lower the *Weight* factor, the more vertices that are removed.

A good rule-of-thumb that can be used when deciding whether or not to use these options is:

- If the surface contains no man-made features, use *Simplify Surface* option (with or without the *Elevation Method* option).
- If the surface contains man-made features, such as roads, use both *Simplify Surface* and *Preserve Breaklines*.

Draw Contours: When enabled, the program will draw contour lines using the designated settings after triangulation process is complete. Otherwise, only the designated Triangulation operations are performed. If this option is

disabled and contours are subsequently desired, use the Contours from TIN File command.

Interval Method: Indicate the desired elevation(s) for contours to be drawn:

- **Contour by Interval:** Specify the desired interval (*e.g.* every 2 feet) into the *Contour Interval* field.
- **Contour an Elevation:** Specify a desired elevation (*e.g.* a floodplain elevation or other unique elevation of interest) and set the desired value into the *Contour Interval* field.

Contour Layer/Index Layer: Specify the layer to which the contours/index contours are to be drawn.

Contour Interval/Index Interval: Specify the interval to which the contours/index contours are to be drawn. When contouring an elevation, you can enter multiple space-separated values to draw multiple contours. For example, entering "5 8 14" into this field would draw contours at elevations, 5, 8, and 14.

Contour Line Width/Index Line Width: Specify the line width to be applied to the contours/index contours.

Draw Index Contours: When enabled, index (or "major") contours will be created with independent characteristics from the regular contours.

Min Contour Length: Specify the minimum linear threshold that should be used to draw contours.

Apply Outlier Reduction Filter: When enabled, this option attempts to remove "the jaggies" which tend to occur along long, thin triangles.

Apply Meander Reduction Filter: This option smooths contours by removing back-tracking.

Outline Flat Areas: This option will outline flat areas of the surface. This is particularly useful for showing catch-benches that have been designed into a steeply angled portion of the surface. In the below image, a the 700' contour line is drawn on both sides of the catch bench. If the Outline Flat Areas option were disabled, only one side of the catch bench would be drawn.

Reduce Vertices: When enabled, this option removes extra vertices from the contours using the *Offset Distance* value. The Offset Distance is the maximum amount that the polyline can move horizontally when removing a point.

The result of this action is often a significant reduction in vertex locations along the contour resulting in a more efficiently-sized and compact drawing file.

Offset Distance: Specify the maximum allowable distance for shifting the original contour line in order to reduce vertices. The reduced contour will shift no more than this value, at any point, away from the original contour line. A lower value will decrease the number of vertices removed and keep the contour line closer to the original. A higher value will remove more vertices and allows the contour to shift further from the original location.

Reduce Before Bezier Smoothing: When enabled, this option removes extra vertices from the contours before they undergo Bezier Smoothing using the *Offset Distance* value. The Offset Distance is the maximum amount that the polyline can move horizontally when removing a point. Removing points before smoothing gives the Bezier smoothing more freedom to make the contour curvy.

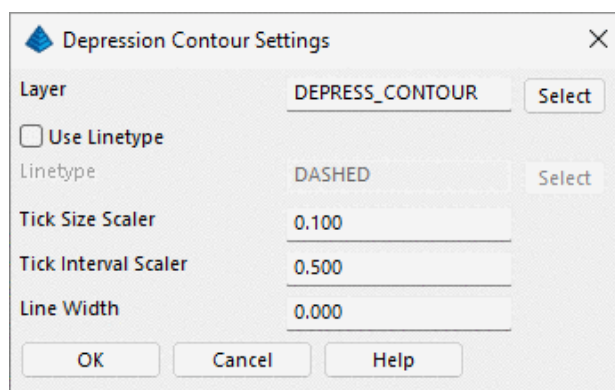

Contour Smoothing Method: Indicate the desired amount of smoothing (often used for existing, natural ground conditions to simulate a "weathered terrain" effect) that should be applied to the contours:

- **No Smoothing:** This option is often used for proposed, man-made surface considerations where the terrain has been shaped with earth-moving equipment. For applications where a "nature-emulated" man-made terrain is desired, refer to the Carlson Natural Regrade documentation.
- **Bezier Smoothing Factor:** This option holds all the contour points calculated from the triangulation and only smooths between the calculated points.
- **Polynomial Smoothing:** This option applies a fifth degree polynomial equation through the contour data points for a smooth transition between the triangulation faces.

Subdivisional Surfaces: When enabled, adjust the horizontal slider to indicate the degree of triangular subdivisions. This causes each triangle in the triangulation surface model to be subdivided into $(x + 1)^2$ triangles, where $x = \text{Subdivision Generations}$. The mathematically generated sub-triangle vertices are raised or lowered to provide smoother contours. More generations increase the smoothness of the contours but incur increased processing time. Although this algorithm does not produce "crossing contours," it can result in undesired contours in terrain scenarios such as where graded slopes abruptly transition to nearly horizontal slopes (*e.g.* the sides and bottom of a detention pond).

Bezier Smoothing Factor: Adjust the horizontal slider to obtain a preview of how much smoothing can be expected at each setting. Sliding the bar to the left results in a lower setting which have less looping or less freedom to curve between contour line points. Likewise, moving the slider to the right results in a setting that increases the looping effect. Note that too much smoothing applied in some situations can result in crossing contours.

Highlight Depression Contours: Depression contours are the lowest elevation closed contours that are surrounded by higher closed contours. This option highlights depression contours by either using a separate linetype or by drawing tick marks along the contour. Use the *Setup* button to get this dialog of settings for depression contours.

Linetype: Set the CAD linetype to use for depression contours.

Layer: Specify the layer to which the depression contours are to be drawn.

Tick Size Scaler: Indicate the relative scale factor that should be applied to the depression ticks.

Tick Interval Scaler: Indicate the desired interval scaler which controls the spacing of the depression ticks.

Line Width: Specify the line width to be applied to the depression contours.

Hatch Zones: When enabled, this option will create hatching between the contours based on elevation zones. The following dialog will open allowing the user to specify the hatch type and color for each elevation zone. The entire elevation range of selected data is displayed under Current Values.

Elevation	Range	Color	Pattern	Scale	Layer
500.000	<= 500.000	[Red]	SOLID	Set	zone1
510.000	500.00 to 510.00	[Orange]	SOLID	Set	zone2
520.000	510.00 to 520.00	[Yellow-Orange]	SOLID	Set	zone3
530.000	520.00 to 530.00	[Yellow]	SOLID	Set	zone4
540.000	530.00 to 540.00	[Light Yellow]	SOLID	Set	zone5
550.000	540.00 to 550.00	[Light Green]	SOLID	Set	zone6
560.000	550.00 to 560.00	[Green]	SOLID	Set	zone7
570.000	560.00 to 570.00	[Light Green]	SOLID	Set	zone8
580.000	570.00 to 580.00	[Green]	SOLID	Set	zone9
590.000	580.00 to 590.00	[Light Green]	SOLID	Set	zone10
600.000	590.00 to 600.00	[Green]	SOLID	Set	zone11
610.000	600.00 to 610.00	[Light Green]	SOLID	Set	zone12
620.000	610.00 to 620.00	[Cyan]	SOLID	Set	zone13
630.000	620.00 to 630.00	[Blue]	SOLID	Set	zone14

Auto: Opens the following dialog, allowing for automatic configuration of the range of elevations in each zone, assigning of colors and hatch patterns, and the scale.

Value Range
 Starting: 1
 Set Values
 Starting Value: 500.000
 Value Interval: 10.000

Pattern
 Set Pattern
 Pattern: 2X2BRIKC
 Select

Set Scale
 Scale: 1.000

Set Layer
 Layer: zone1
 Select

Color Setting
 Set Colors
 Starting Color#: 11
 Color: 10

Set Gradient Colors
 Low: 1
 Medium: 1
 High: 1

Starting Zone: Sets the zone with which to begin the application of the setting defined in this dialog. For Instance, if the Starting Zone was set to 10, the settings definitions applied here wouldn't affect Zones 1-9, but would start at

Zone 10.

Set Values: Enables the Starting Value and Value Interval fields, which allow the user to specify the starting elevation for the given zone and set the zone increment.

Starting Value: Sets the elevation of the beginning zone to define.

Value Interval: Sets the elevation increment for subsequent zones.

Set Pattern: Sets the hatch pattern for the defined zones.

Set Scale: Enables the Scale option.

Scale: Sets the scale for the selected hatch pattern.

Set Colors: Modifies the colors in the table using either Starting Color and Color Increment, or the Gradient option.

Starting Color: Sets the starting color number based on the standard CAD color chart.

Color Increment: Sets the color number to increase for subsequent zones. So if the increment was set to 5, and the starting color was 60, the next color would be 65, 70, and so on.

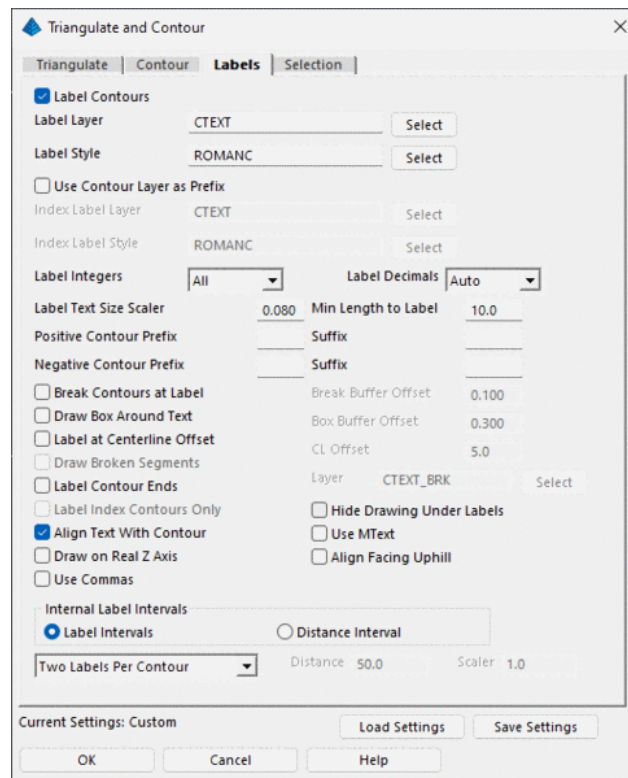

Set Gradient Colors: Sets the colors according to **Low**, **Medium**, and **High** colors. Note that the program will use the Index Colors (total of 256 color options) when setting gradients, which can result in duplicated colors if there are many entries in the table. This option is best used when there are only a small number of hatch zones.

Clear: Clears the all of the Elevation fields in the dialog.

Load: Loads previous settings from a saved .pat file.

Save: Saves the current setting configuration to a .pat file.

Scan DWG/Scan CRD : These buttons report the elevation range which can help with choosing the contour interval.

Label Contours: When enabled, contours will be labeled based on the settings below. If this option is disabled and further contour annotation is desired, utilize the Contour Elevation Label command.

Label Layer: Specify the layer name for intermediate contour labels. To only label index contours, enable the Label Index Contours Only option.

Label Style: Specify the text style that will be used for the contour label text.

Use Contour Layer as Prefix: This option adds the Contour Layer name to the Label Layer name.

Index Label Layer: Specify the layer name for index contour labels.

Index Label Style: Specify the text style that will be used for the index contour label text.

Label Integers controls how many digits to label to the left of the decimal. For example, if all contours are in the 5000's, then setting for three digits would label the 5280 contour as 280.

Label Decimals: Specify the amount of precision to display on the contour labels.

Label Text Size Scaler: Specify a relative text size scale factor to be applied to the label(s).

Min Length to Label: Specify the desired minimum length of contours that should be annotated. In other words, Contours whose length is less than the value will not be labeled.

Positive/Negative Contour Prefix: Indicate a desired string of prefix text (*e.g.* Elev=) that is to precede the positive and/or negative contour elevations, respectively.

Positive/Negative Contour Suffix: Indicate a desired string of suffix text that is to follow the positive and/or negative contour elevations, respectively.

Break Contours at Label: When enabled, the contour lines will be broken and trimmed at the label location for label visibility. As an alternative to physically placing a gap into the contour, consider using the Hide Drawing Under Labels option.

Break Buffer Offset: Specify the offset distance which determines the gap between the end of the trimmed contour line and the beginning or ending of the text.

Draw Box Around Text: When enabled, a rectangle is drawn around the contour elevation labels.

Box Buffer Offset: Specify the offset distance which determines the gap between the box and the beginning or ending of the text.

Label At Centerline Offset: When creating contours and subsequent plan sheets for roads, enable this option to position the labels at a fixed offset from a centerline. The program automatically uses any polylines in the drawing that are tagged as centerlines. To check whether a polyline is a centerline, use the Centerline ID command. To create a centerline polyline from a centerline file, use the Draw Centerline File command.

Draw Broken Segments: When enabled, the segments of contours that have been broken out for label visibility will be redrawn as independent segments. To join these segments back into the contour, use the Join Nearest command.

Layer: Specify the layer that is to receive the newly drawn broken segments.

Label Contour Ends: When enabled, the ends of "open" contours will be labeled.

Label Index Contours Only: When enabled, only the index contours are labeled. This option is active only when Draw Index Contours has been selected in the Contour tab.

Hide Drawing Under Labels: When enabled, a "Wipeout" entity is placed with the annotation label that will create the appearance of trimmed segments at the contour label, even though the contour line is still fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels yet the contour lines

themselves remain contiguous. This feature will also hide other entities that are in the immediate vicinity of the contour label.

Align Text with Contour: When enabled, the contour elevation labels will be rotated to align with their respective contour lines.

Use MText: When enabled, contour labels are created using the MText entity type. Otherwise, the standard DText entity type is used.

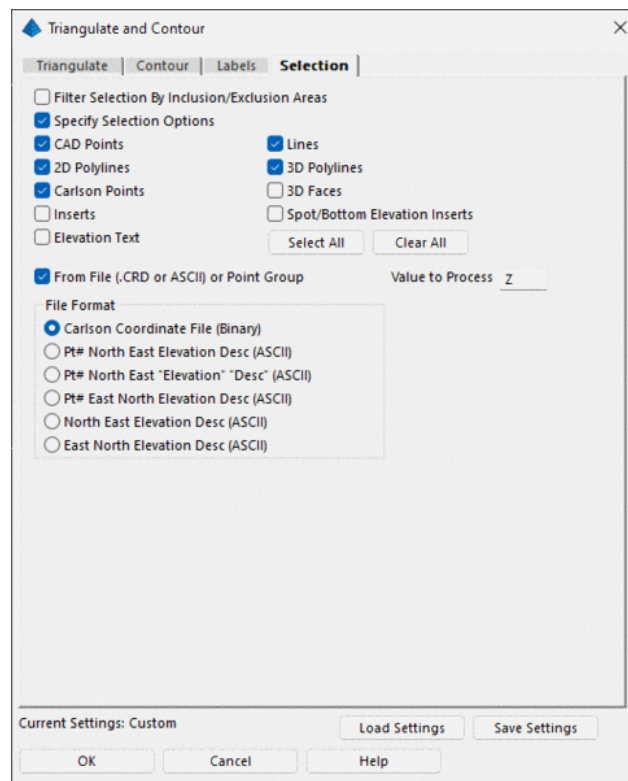

Draw On Real Z Axis: When enabled, the contour labels are placed at the same "Z" (elevation) value of the contour itself. When disabled, the contour labels are placed at a "Z" (elevation) value of 0 (zero).

Align Facing Uphill: When enabled, the contour elevation labels will still be rotated to align with their respective contour lines, but the labels will be placed in such a manner that the top of the text label will always be toward the uphill side of the contour.

Use Commas adds a comma into the labels for the thousands place such as "5,000" instead of "5000".

Internal Label Intervals: Indicate the desired method for contour labels within the contour itself:

- **Label Intervals:** This option will label each contour with a set number of labels.
- **Distance Interval:** This option allows you to specify an interval distance between labels. The distance can be set in drawing units or as a scaler that is multiplied by the drawing horizontal scale.

Filter Selection By Inclusion/Exclusion Areas: This option filters out selected entities from the triangulation that are outside the surface area defined by the inclusion/exclusion perimeter polylines. Otherwise, all the selected entities are used for triangulation and then the triangulation is trimmed at the inclusion/exclusion perimeters. Whether to prompt for inclusion/exclusion perimeters is specified on the Triangulate Tab.

Specify Selection Options: When enabled, indicate the type(s) of entities that are to be used during the triangulation process. This is an excellent method of "filtering out" unwanted entity types or enabling the use of desired entity

types.

CAD Points, Lines, 2D Polylines, 3D Polylines, 3DFaces, Elevation Text and Inserts (blocks) are standard CAD entities types.

Carlson Point Inserts refer to Carlson points (such as those placed with the Draw Field to Finish command or which utilize the Carlson "SRVPNO*" family of blocks with point number, elevation, and description attributes).

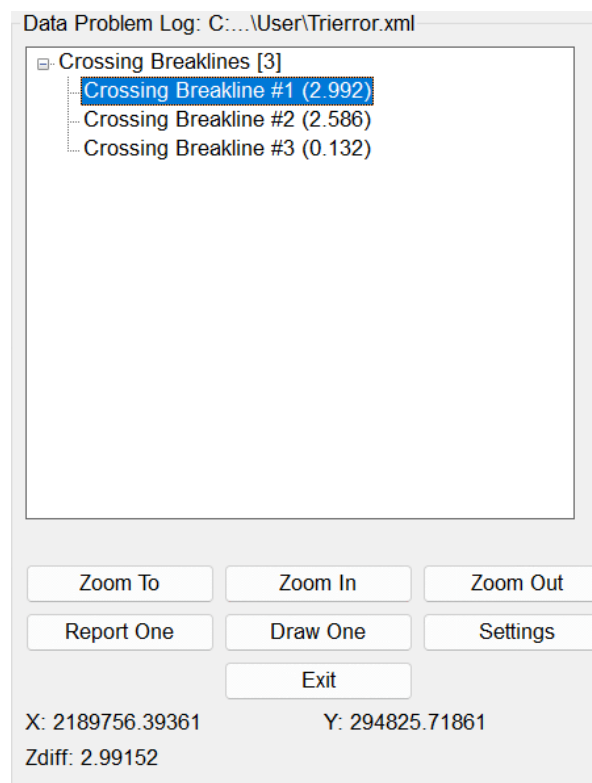

Spot/Bottom Elevation Inserts include text entities that start with 'X'.

From File: When enabled, allows you to triangulate from the points in an external coordinate (.CRD) or ASCII file. This option also provides access to the use of Point Groups as a data source.

An *Error Log* is generated if the triangulation routine finds vertical conflicts between breaklines or other surface entities and displays the conflicts in a "docked dialog box." Three types of conflicts are reported (each conflict type is listed into its own category):

1. Crossing Breaklines - Indicates the common X,Y location of two breaklines that do not share a common "Z" elevation.
2. Vertical Edges - Indicates that two entities or vertexes of differing elevations have the same x-y location, thus forming a vertical plane to another point.
3. Breakline T-Intersections - Indicates that a third entity is abutting another entity, but the second entity doesn't have a vertex at the point of intersection.

Click the "+" sign beside a category to display the individual conflicts within that category and click the "-" sign to collapse the list. When a line item error is selected, a highlighted arrow is temporarily placed in the drawing to indicate the exact location of the specific conflict. Zoom functionality allows the user to more closely inspect the specific problem area, and if needed a marker can be drawn or a report generated for an individual conflict or conflicts.

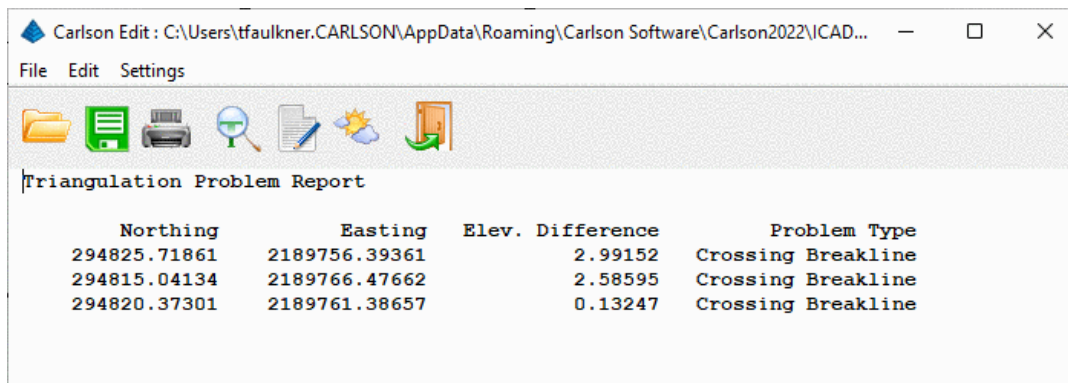

Zoom To: Centers the display on the location of the error without affecting the zoom resolution.

Zoom In: Increases the ability to see detail.

Zoom Out: Decreases the ability to see detail.

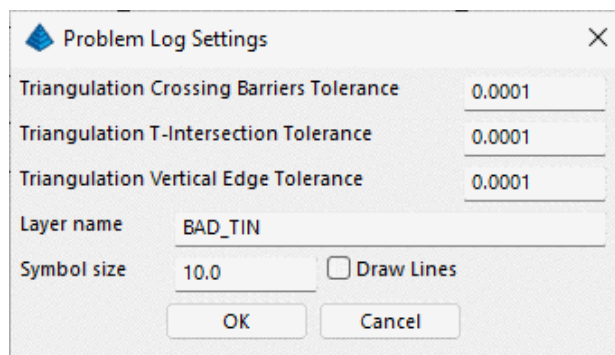

Report One/All: This option toggles between "One" and "All" depending whether a single line item conflict or an entire category is selected from the error log. An error report is generated listing the x-y position and the elevation difference of the entities in conflict.

Northing	Easting	Elev. Difference	Problem Type
294825.71861	2189756.39361	2.99152	Crossing Breakline
294815.04134	2189766.47662	2.58595	Crossing Breakline
294820.37301	2189761.38657	0.13247	Crossing Breakline

Draw One/All: This option toggles between One and All depending whether a single conflict or a category is selected from the list. This option draws an "X" symbol at each selected conflict.

Settings: Indicate the desired configuration settings for the error log:

Problem Log Settings

Triangulation Crossing Barriers Tolerance: 0.0001

Triangulation T-Intersection Tolerance: 0.0001

Triangulation Vertical Edge Tolerance: 0.0001

Layer name: BAD_TIN

Symbol size: 10.0 Draw Lines

OK Cancel

Tolerances: Indicate the lowest elevation difference threshold that should be reported for Crossing Breaklines, Vertical Edges and Breakline T-Intersections, respectively.

Layer Name: Specify the layer name for the "X" entities drawn with *Draw One/All* option. This also sets the layer name for the *Draw Lines* option.

In the case of crossing polylines, *Draw Lines* will trace over the polylines responsible for the conflict.

Symbol Size: Specify the size of the "X" symbol that is drawn to delineate the selected errors. This will determine the actual size of the symbol in the drawing. This value is not multiplied by the horizontal drawing scale.

Note:

- When selecting Inclusion/Exclusion polylines, you may select any number of Inclusion polylines and any number of Exclusion polylines. Selecting multiple Inclusion polylines results in "islands" of terrain data within a given TIN file.
- If *Triangulate & Contour* reports zero points found and fails to do anything when you're using Carlson points, then those points are probably located at zero elevation. To fix this problem, make sure that Carlson Point

Inserts is toggled on in the Selection tab. This will enable *Triangulate & Contour* to read the elevation from the elevation attribute of the point.

- For those experienced in programming, Carlson offers a DTM API (Application Programming Interface) which provides functions that can be used to access and manipulate information stored within a DTM file.
- In surface situations where a series of rectangular grid cells are desired, explore the Make 3D Grid File command.

Prompts

The following are the most often encountered prompts:

Select the Inclusion perimeter polylines or ENTER for none.

Select entities: Select the desired closed polylines that form the bounding inclusion area(s) of the surface model and press Enter when complete.

Select the Exclusion perimeter polylines or ENTER for none.

Select entities: Select the desired closed polylines that form the regions(s) of the surface model where triangulation should not occur and press Enter when complete.

Select the points and breaklines to Triangulate.

Select entities: Select the desired entities from CAD using standard CAD selection methods and press Enter when complete.

Pulldown Menu Location(s): Surface (Survey, Civil, Hydro, Construction, Field, Natural Regrade), Takeoff > Surface Tools

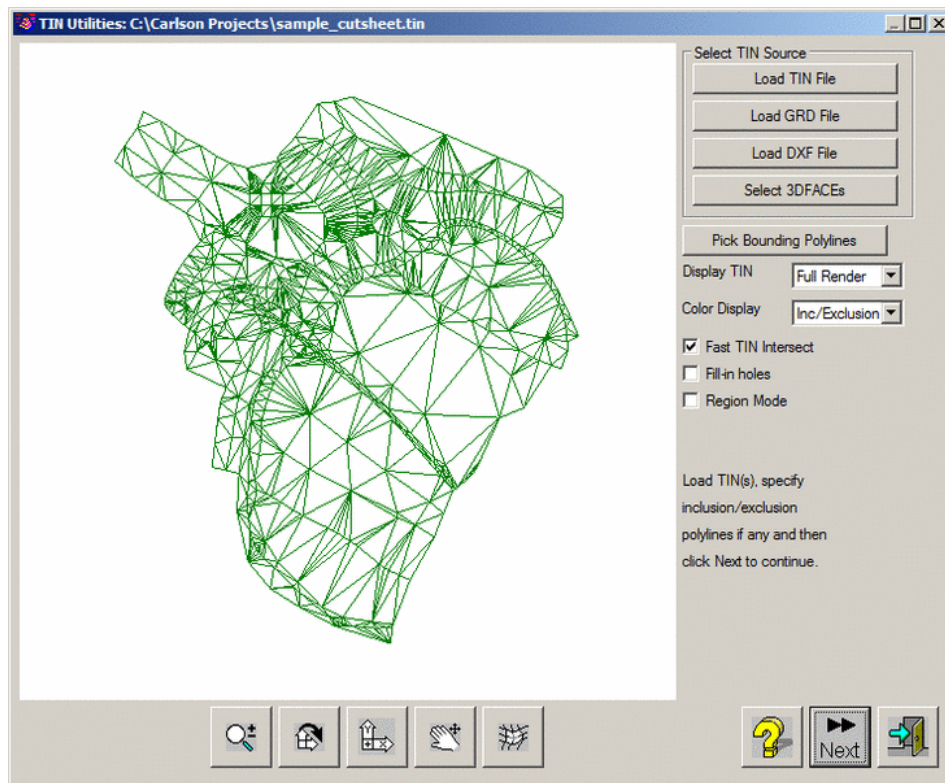

Keyboard Command: tri

Prerequisite: 3D entities in the drawing (defined by the Selection Tab) and/or an external point file

Triangulation File Utilities

This command allows you to modify TIN surfaces in a variety of different ways, then allows for 3D viewing and shading of the modified surface and finally for saving the file with a choice of output formats. The focus of the routine is to elevate or lower the TIN or selected areas within the TIN, merge TINs with other surfaces, or use data from other TIN files to apply to the current TIN.

Operations can be performed on the entire TIN or just on user selected Inclusion and/or Exclusion areas. The routine will automatically rework the TIN network for conformation to a selected boundary, say a building outline. In the case of said building, a value of 10 could be subtracted from the building outline. This will drop all of the triangulation within the outline by 10', thus creating a model of the excavated area for the building. The modified TIN can then be saved to a new file, which could be used to compute an excavation volume with Volumes by Triangulation. This routine does not allow for manual editing of individual portions of the TIN; refer to the editing options found under Surface Manager.

Load TIN File: Allows you to specify a triangulation (.flt or .tin) file to load.

Load GRD File: Allows you to specify a grid (.grd) file to load.

Load DXF File: Allows you to specify a DXF file to load. Only loads 3DFACE entities from the selected DXF file.

Select 3D Faces: Allows you to select 3DFACE entities from the current drawing. This also includes rectangular 3D faces from a plotted grid.

Pick Bounding Polylines: Allows you to select any inclusion/exclusion perimeter(s). When this button is selected, the user is taken back to the drawing and prompted to select the perimeters. Press *Enter* when the selections are finished to return back to the dialog.

Display TIN: Controls the detail level of the TIN in the graphic display. When the TIN is very large, the graphic display can cause delays. The Low Detail mode shows a simplified TIN graphic. The Outline Only mode shows only the TIN perimeter. The Full Render mode shows all the triangles.

Color Display: Displays the triangles based on whether or not they are part of the Inclusion/Exclusion set via the Pick Bounding Polylines option or colored based on the individual triangle color property.

Fast TIN Intersect: When checked, this command will perform a simple and fast check for overlapping triangles and is the preferred choice in most cases. However, if problems with the TIN are suspected, this option should be unchecked so a complete and thorough check and repair of the TIN is performed.

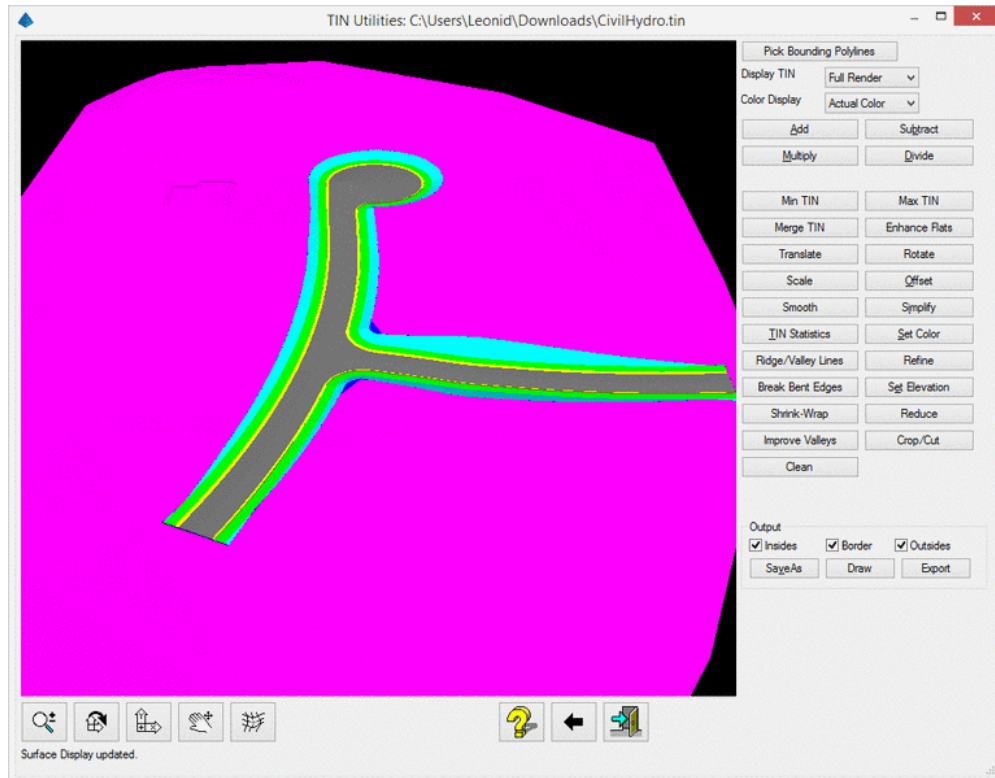

Fill-in-holes: When checked, any missing triangulation (or "gaps") in the surface will be automatically filled in with additional triangles. This option has to be set *before* loading the TIN file to take effect.

Region Mode: This option deals with nested or overlapping boundaries. When checked, "hatch pattern logic" is applied in which all nested boundaries are used in an alternating fashion, so that an Inclusion Boundary within an Exclusion Boundary is still recognized. If this option is not checked, everything within an Exclusion Boundary is ignored.

Next: Press this button to proceed to the next dialog after all selections have been made.

The next dialog allows you to perform mathematical operation(s) on the loaded TIN. Each operation is described below. Keep in mind that generally these operations are to be performed on an area inside your inclusion perimeter (but excluding anything inside your exclusion perimeters). If you do not specify any perimeters, the desired

operation(s) will be performed on the entire TIN.

Add: Adds to the TIN elevations using either a Value or another TIN. For Value, it prompts for a value to Add to the elevations of the subject area of the TIN. The TIN method raises the subject area of the current TIN by the elevation value from a second user-selected TIN file. This function is most applicable to applying a strata thickness (e.g. landfill cover) on top of a TIN to get a new target surface elevation.

Subtract: Subtracts from the TIN elevations using either a Value or another TIN. For Value, it prompts for a value to Subtract from the elevations of the subject area of the TIN. The TIN method lowers the subject area of the current TIN by the elevation value from a second user-selected TIN file.

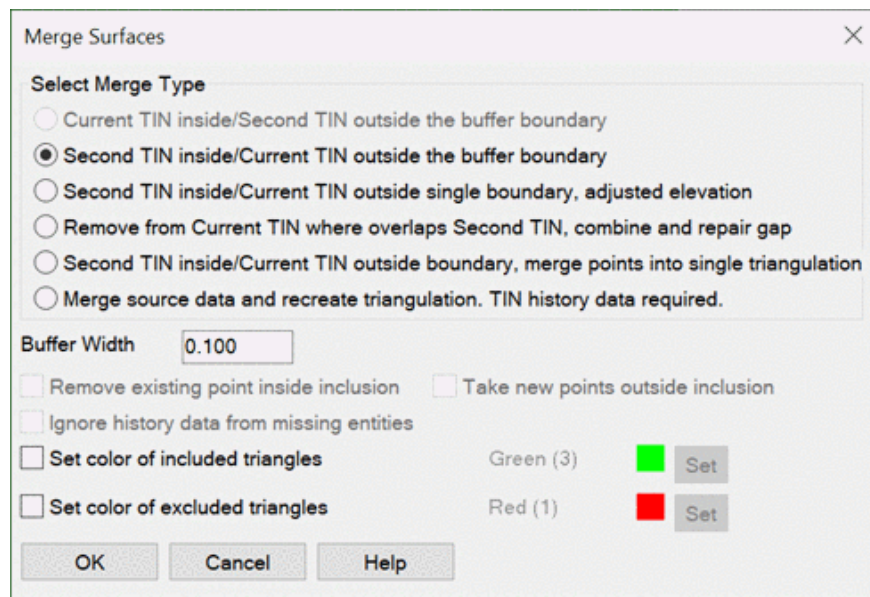

Multiply: Multiplies the TIN elevations by either a Value or another TIN. For Value, it prompts for a value to Multiply to the elevations of the subject area of the TIN.

Divide: Divides the TIN elevation by either a Value or another TIN. For Value, it prompts for a value to Divide into the elevations of the subject area of the TIN.

Min TIN: This does a comparison between the current TIN and a second user-selected TIN file and applies the lower value of the two TINs to the subject area.

Max TIN: This does a comparison between the current TIN and a second user-selected TIN file and applies the higher value of the two TINs to the subject area.

Merge TIN: Merges the current subject TIN into a second user-specified TIN file. There are six methods to merge tins. The methods for merging effect the way the gaps and elevation differences between the TINs are handled. If the two TINs being merged meet within a relatively close tolerance, the different methods will have little effect. In situations where the two surfaces being merged vary significantly, ie. an asbuilt of an area where the existing ground 'tie in points' are also disturbed, the method of merging will be more obvious.

1. **Current TIN inside/Second TIN outside the buffer boundary:** This method is only available when Bounding Polylines are selected in the first Triangulation File Utilities dialog. The current TIN will be used inside the boundary polylines and the second TIN is used everywhere else. Any gap or elevation difference between the two TINs are directly joined and interpolated within the confines of that gap. The current TIN file should be the smaller of the two surfaces since the subject file will be joined or merged into the second file. For example, to merge a pad design into existing ground with this method, choose the pad design as the current TIN, pick the pad perimeter as the bounding polyline and use existing ground as the second TIN. This method is effective if there is little difference between the two TINs.
2. **Second TIN inside/Current TIN outside the buffer boundary:** This method uses the second TIN inside the boundary and the current TIN everywhere else. The outline of the second TIN is used as the boundary if no bounding polylines were selected in the initial dialog. Any gap or elevation difference between the two TINs are directly joined and interpolated within the confines of that gap. For example, to merge a pad design into existing ground with this method, choose the existing ground as the current TIN and choose the pad design as the second TIN. This method is effective if there is little difference between the two TINs.
3. **Second TIN inside/Current TIN outside single boundary, adjusted elevation:** This method removes triangles from the current TIN for areas that overlap the second TIN and then adjusts the elevations to meet the second TIN edges. This method creates a smoother transition between the two TINs but will densify the triangles along the edges. For example when blending an As Built TIN into an previously surveyed area, choose the As Built TIN as second.
4. **Remove from Current TIN where overlaps Second TIN, combine and repair gap:** This method removes triangles from the current TIN for areas that overlap the second TIN. Then the second TIN is added into the current TIN surface and the gap between the current and second TINs is triangulated to stitch them together. This method is useful when the two TINs don't have matching elevations on their common boundary. This method will create a transition zone between the TINs but creates more distortion along the first TIN but will have less dense triangles than the *adjusted elevation* method.
5. **Second TIN inside/Current TIN outside boundary, merge points into single triangulation:** This method merges the two TINs by triangulating a new surface from the point data from each TIN, eliminating any overlapping areas. This method will create all new triangles for the entire surface so any previous edits (ie. swapped edges) will not be maintained.
6. **Merge source data and recreate triangulation. TIN history data required.** This method merges two TINs and recreates a new surface utilizing any edits made and recorded in the TIN history file. This is method

is effective for users who have performed particular edits to either TIN that may not be contained in the underlying data.

Set color of Included Triangles: When enabled, the color of triangles included in the merge are set as specified.

Set color of Excluded Triangles: When enabled, the color of triangles excluded from the merge are set as specified.

Enhance Flats: There are two methods:

1. **Interpolate Ridges, Valleys, Summits:** This routine eliminates flat triangles by adding a data point inside the triangle at a different elevation to subdivide the triangle. The elevation of this point is calculated based on the slopes of the neighboring triangles.

2. **Swap Edges to Minimize Flat Triangles:** This routine swaps edges of flat triangles when it can find a neighboring point with a different elevation and still maintain the triangulation.

Translate: This function has two methods:

1. **Delta:** This method moves the TIN points by the specified delta x, y and z.

2. **Geoid:** This method adjusts the elevations by the selected geoid. To use the Geoid method, the grid projection for the drawing must be defined in the Drawing Setup command.

Rotate: Rotates the TIN points by the specified rotation angle around a base point.

Scale: Scales the TIN points by the specified scale factor from a base point. The scale can be applied to just the x,y of the TIN points or the z, too. As an example, the Scale feature can be used to convert a TIN between Imperial and Metric units.

Offset: Performs a perpendicular offset (from the face/s) to the TIN surface by the specified amount. The routine offsets each point in the TIN vertically by looking at the slopes that connect to the point. For points at slope transition points such as at the bottom of a ditch, these corner points are effected by both slopes which means the program can't hold either exactly. To hold both slopes exactly would require changing the x/y position of the TIN points which this routine doesn't do to avoid more complications. So if the offset surface needs to exactly hold the slopes, then use another method like extracting Cross-sections from the Surface, offsetting these sections, creating 3D polylines from Sections and modeling the 3D polylines.

Smooth: There are three methods to smooth the triangulation surface.

1. **Moving Least Squares:** Smooths the surface by adjusting the elevations using a moving least squares method.

2. **Subdivide:** Performs a subdivision on the triangles within a TIN for the intent of developing a smoother rendition of the surface. This option is commonly used in scenarios where surface models are derived from man-made data (e.g. surfaces from contour maps, on-line sources, etc). The routine starts to subdivide each triangle "n" times with each iteration finding the centroid of the triangle. New triangles are formed using this centroid location and the process continues.

3. **Polynomial:** This option uses a polynomial interpolation in an effort to add additional points into the surface model in an effort to produce a more "rounded" (less man-made) surface.

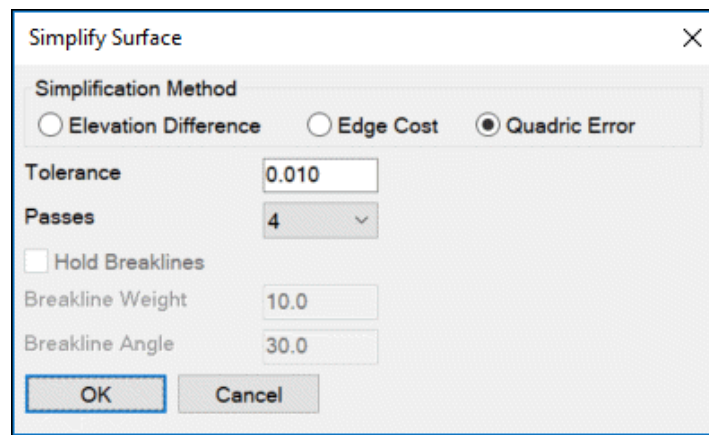

4. **Laplace:** This method uses the Laplacian method that adjusts each vertex using the positions of the neighboring vertices.

Simplify: Causes edges within the TIN mesh to be collapsed to reduce the number of triangles, edges, and points within the TIN while having a minimal impact on the overall shape of the TIN. There are three methods:

1. **Elevation Difference:** Looks at the effect of removing a point from the TIN. The point is removed if the elevation difference between the original point and the updated TIN is less than the tolerance.

2. **Edge Cost:** Looks at the effect of removing an edge from the TIN.

3. **Quadric Error:** Looks at vertex pairs and minimizes surface changes using quadric matrices.

Tolerance: This setting is used by both of the Simplification options described above. Specify the maximum average distance that any point can be moved outside of the plane of any triangle that connects to that point. Values might range from .01 to .1 for most purposes.

Passes: For the Elevation Difference option, this is the number of times the program will check through all the points.

Hold Breaklines: Further analyzes the TIN by focusing on the edges, calculating the angular difference between adjacent triangular faces. If the angular difference between edges is greater than the specified **Breakline Angle**, it is considered to be a breakline, and it is preserved. If its angular difference is determined to be below the **Breakline Angle**, it becomes a candidate for removal. In that case, the **Breakline Weight** factor is applied to the corresponding vertex, adjusting its original value. If the resulting value is still below the **Tolerance**, it is then removed. The number of vertices removed is inversely proportional to the **Breakline Weight** factor, so the greater the **Breakline Weight** factor, the fewer vertices that are removed, the lower the **Breakline Weight** factor, the more vertices that are removed.

TIN Statistics: Generates a report of the TIN statistics, including number of points, edges, and triangles, and minimum and maximum Z values.

Set Color: Assigns a selected color to the TIN triangles. The color is used when viewing the TIN file in the 3D viewer commands. To set the color within an inclusion perimeter, use the Pick Boundary Polyline option.

Ridge/Valley Lines: This option permits you to select previously drawn polylines that represent surface model breaklines to enhance the approximate appearance or effect of ridges and/or valleys within the surface model. A more precise procedure would be to first utilize the 3D Polyline routine and re-create the surface model by specifying the 3D polylines within the Triangulate & Contour routine.

Refine: This function adds points to the triangulation to make more uniform triangles and fewer skinny triangles. The Min Edge Length prevents adding points that result in an edge length below this minimum. The Iterations is how many passes the routine does through the triangulation.

Break Bent Edges: Used commonly in scenarios for a TIN created from contour entities, there is a likelihood of areas where horizontal triangles (also known as "flat triangles") adjoin sloped triangles. The routine will detect such edges, add an additional point on the horizontal triangles and assign its elevation representing the trend of the surface, by extrapolation, looking to restore presumed surface data that was lost in recreating the TIN from

contours. This methodology provides additional corrective options to that of the Minimize Flat Triangles option of the Triangulate & Contour routine.

Set Elevation: This button has four functions.

Set New Elev: Sets all TIN faces in the subject area to the elevation specified.

Set NULLs to Elev: Sets all NULL (empty) values in the subject area to the elevation specified.

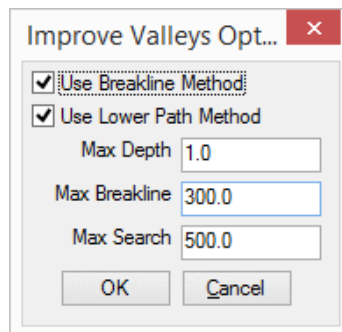

Set Elev to NULL: Sets all of the elevation values in the subject area to NULL (empty).

Set Elev by Surface: Sets all TIN faces within the subject area to the elevations from a second surface file within the same area. You will be prompted to select a second TIN file or grid file. Only areas common to both surfaces will be applied to the subject TIN.

Shrink-Wrap: This function removes skinny triangles around the perimeter without causing any triangulation points to become disconnected. There are three reduction levels: low, medium and high. The low removes the fewest triangles and high the most.

Reduce: This function removes triangulation points that are within the specified distance and then re-triangulates the surface.

Improve Valleys: The purpose of this function to clean up the bottom of the valley to permit unrestricted water flow for watershed analysis routines. The typical TIN may include small ridges, crossing the very bottom of the valley, obstructing the flow. There are two separate clean up methods in this function: the breakline method and the low path one.

Max search distance controls how far the program looks for another low point to try to connect the flow to.

- The **Breakline Method** improves TIN surface by inserting breakline segments between each eligible sink and the closest lower point to that sink such that the highest crest point between these two points is not higher than a given height tolerance (max depth) above the sink. Maximum breakline is a limit to the length of used breakline.
- The **Lower Path Method** works by finding optimal paths between neighboring sinks, and lowering the necessary points between them to allow water to run from one to the other. The maximum depth controls the maximum amount a point along the path can be lowered by.

Crop/Cut: This function removes the triangulation by a closed perimeter polyline. The routine embeds the polyline into the triangulation surface using the elevations of the triangulation. You can either remove the triangulation

inside the perimeter (Cut), or remove the triangulation outside the perimeter (Cut).

Clean: This function removes skinny and tiny triangles that have an edge less than the specified Distance Tolerance. The Spike Removal option removes steep V-shaped ditches or ridges in the surface. A Level of High removes more than Low.

Low Points: This function draws symbols at low points in the TIN which can be helpful for finding spots where rainfall will collect. There is a dialog with settings for the symbol to draw, size and layer.

Output Options

The following three options determine what part or parts of the TIN modifications that will be saved to the new TIN file. If the entire TIN is to be saved, all three options should be enabled.

- **Inside:** If this is the only option checked, only changes made to the TIN within the inclusion perimeter will be saved. TIN entities outside of the perimeter will not be saved to the named file.
- **Border:** When the routine re-works the TIN to fit around a perimeter, a small horizontal offset is automatically applied to prevent the formation of vertical faces. The Border function will save changes made to TIN in this offset area.
- **Outsides:** If this is the only option checked, TIN entities inside of the inclusion perimeter will not be saved to the named file. Everything outside of the perimeter will be saved.

Save: Saves the current TIN as an .flt or .tin file.

Draw: Draws the current TIN as 3D Faces in the current viewport. The Layer window is used to specify the layer that the faces will be created in.

Export: There are three export formats:

1. Export To Text (points only): Writes the TIN point locations to a user-specified ASCII-based coordinate file.
2. Export To Text (points and triangles): Outputs a text file of the points and triangle indexes.
3. Export To DXF: Saves the current TIN as a .dxf file. This format can be used by many other CAD programs.

Control

Action

Converts the left mouse button to a zoom function. Hold the button down and move the mouse up or down to zoom in and out.

Converts the left mouse button to a rotate function. Hold the button down to rotate the view in any X, Y or Z direction. When the XY appears in the window, the rotation will occur relative to the XY axis. When the mouse is moved toward the outer perimeter of the window, the XY will change to a Z. Holding the button down while the Z is visible will rotate the drawing on the Z axis.

Restores the graphics to plan view.

Converts the left mouse button to a pan function. Hold down on the button while moving the mouse to pan. Holding down the mouse wheel will also serve as a pan function in any of the above modes.

Toggles shading on and off.

Reverses the effects of all operations performed on the TIN and reverts it back to its original status.

This icon exits the routine. If the TIN has been modified, you will be prompted to save.

Usability Controls

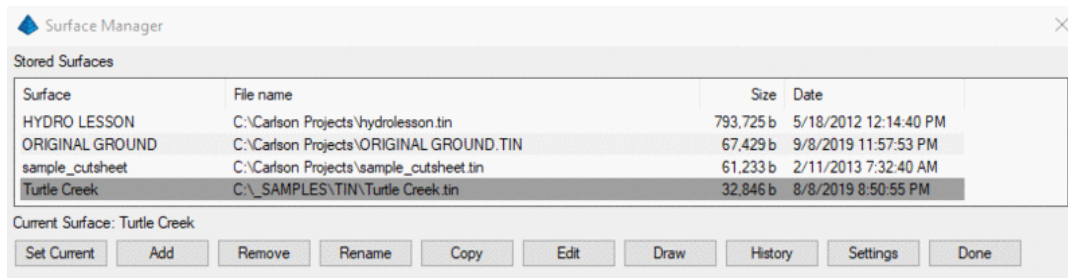

Pulldown Menu Location(s): Surface

Keyboard Command: tinutil

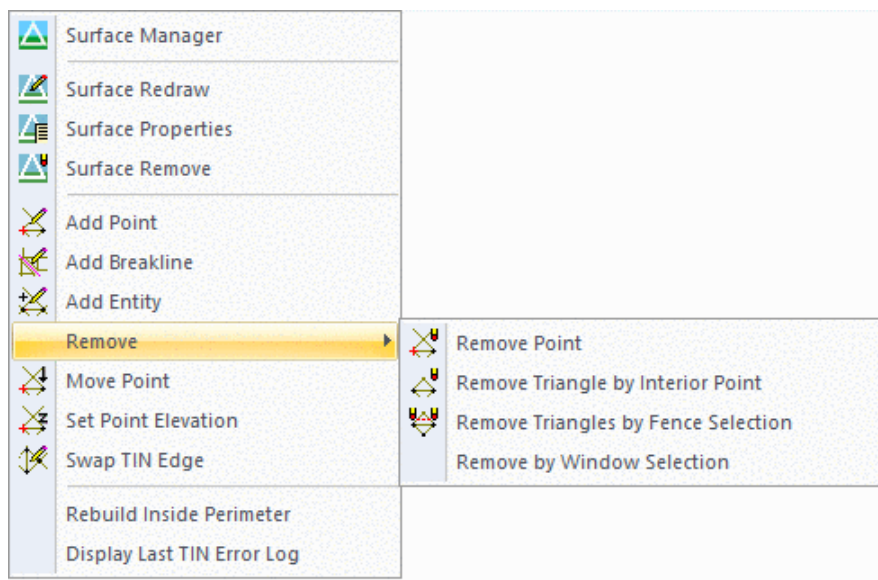

Prerequisite: 3D Faces, a TIN file or a DXF file containing 3DFACE entities.

Surface Manager

The Surface Manager toolkit allows you to modify pre-defined triangulated surfaces, making real-time modifications and updates to contours and associated TIN (Triangulated Irregular Network) definitions. Functionality includes swapping TIN lines, adding or removing (untagging) breaklines, adding or removing points by range or group, adjusting point elevations, removing TIN lines, drawing or removing contour lines and labels, re-contouring at a different interval or with different label settings, etc. Contour lines are automatically updated to reflect any changes made to the TIN. A surface must be named and saved by one of the surface modeling routines (in the Triangulate tab) as a prerequisite to using the Surface Manager.

All of the tools available in the Surface Manager are also available in the fly-out menu, as shown in this figure. Their functions are identical but require a surface to be set current. Changes made apply only to the current surface.

Set Current Designates a surface as current for editing with various surface tool functions, such as modifying TIN lines, setting a new contour interval, labeling contours, etc.

Add Allows you to add a surface by selecting a surface model file (.TIN or .FLT).

Remove Allows you to remove a surface from the list of stored surfaces.

Rename Allows you to rename a surface.

Copy Creates a copy of the TIN file and adds the copy as a new entry.

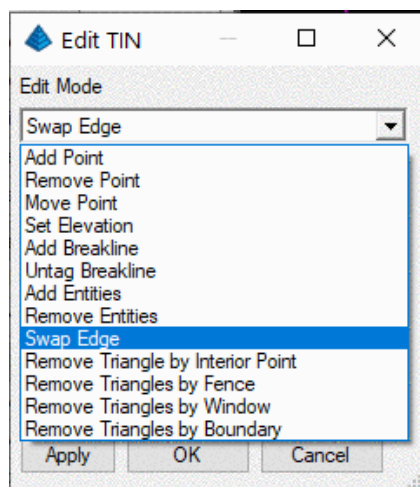

Edit Displays various edit tools. Clicking on any of these commands will activate the command line, where you will be prompted based on the Edit command selected.

Draw Allows you to alter the drawing display properties for TIN lines, contours and labels for the selected surface. Applicable dialogs from Triangulate and Contour are used to provide a full set of options. When accessed, settings for the current surface display configuration are set. To make a modification, simply specify the desired change and press ok. For instance, if Draw Triangulation Lines was checked on, unchecking the box and pressing ok will redraw the surface without the TIN lines. If the contours were drawn at 1 foot intervals, setting the interval value to 2 and pressing OK will redraw the contours at 2 foot intervals. Refer to the Triangulate and Contour section of the manual for a more detailed explanation of the options.

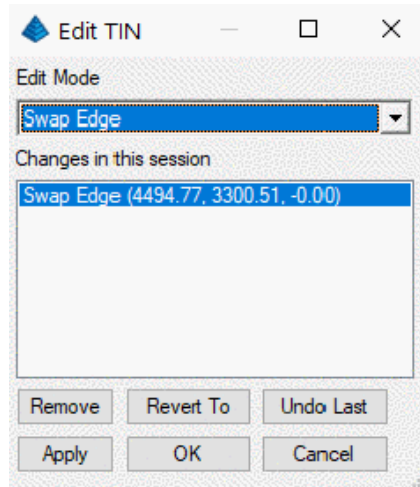

History The Triangulation History Editor displays all functions performed during the creation and editing of a TIN file. Each edit can then be eliminated from the process without recreating the TIN from scratch. In cases where the user does recreate the TIN, any edits previously performed can be recalled and re-implemented.

Settings Allows you to set the triangle edge and breakline Color and Transparency for easier editing. Many times the triangle edges or breaklines can get lost or match colors for say the contours and this allows you to better differentiate the items when editing.

The dialog for this function has the pulldown with the choice of the editing operation. You can pick it from the pull-down or type the corresponding keyword at the command line to switch.

As the operations are performed, they are recorded in the log.

Remove allows to remove any operation performed in this session. The TIN will be re-processed from the beginning of the session, skipping the edit being removed

Revert To removes all the edits following the edit selected. Allows the user to go back to last good edit and after re-processing continue editing

Undo Last removes the last edit and reprocesses TIN

Apply saves the current TIN as edited and continues editing

Operations:

Add Point (AP) prompts to pick point or point number to add [Group/Range]. This allows you to add triangulation point(s) to the network by either graphically picking points from the screen; typing a point number; or by adding an entire (R)ange or point (G)roup to the TIN. You can add points to the inside or the outside of the TIN. The elevation for graphically selected points is interpolated from the surrounding TIN network. This is a good method for adding additional triangulation to the surface in a sparse area. Also, a new elevation can be specified for the picked point. There is an option for whether to store the graphically selected point to the coordinate file. When 3D polylines are created by Field to Finish and you add point by range or point group that covers the point numbers used to make the 3D polylines, then the segments from these 3D polylines are used as breaklines in the TIN.

Remove Point (RP) removes an existing triangulation intersection from the TIN network. The affected triangulation re-adjusts to compensate for the missing intersection. Contours update accordingly.

Move Point (MP) is a combination of removing a point and adding it at a new location.

Set Elevation (SP) sets a new elevation for a specified TIN intersection. The affected TIN is adjusted and the contours are updated.

Add Breakline (AB) adds a breakline to the surface by picking beginning and ending points on the screen. The endpoint snap automatically turns on. Only one breakline can be created at a time. The TIN network will reconfigure to follow the new breakline and update the contours. This does not create 3d polylines in the drawing.

Untag Breakline (UB) removes breaklines from the TIN that were either added through Add Breakline Edit

command or through the initial selection of lines in the drawing.

Add Entities (AE) adds selected points and breaklines into the TIN by graphical selection of existing entities on screen.

Remove Entities (RE) removes selected points and breaklines from the TIN by graphical selection of entities used in its creation.

Swap Edge (SW) swaps common TIN edges to create two different triangles from the original triangle configuration. Contours automatically update to reflect changes made to the TIN. Some common edges may not be swapped because of the orientation of the two triangles.

Remove Triangle by Interior Point (RT) removes a TIN line from the surface by picking a TIN line or selecting an interior point. Contours are removed from the affected area.

Remove Triangles by Fence (RF) removes existing triangles that touch the fence as it is being drawn across the triangles.

Remove Triangles by Window (RW) removes existing triangles using a crossing-type window whereby any triangles that touch or are contained within the window when drawn will be removed.

Remove Triangles by Boundary (RB) removes existing triangles that touch or are contained within a selected closed boundary or polyline.

Add Pnt(AP), Move Pnt(MP), Set elev(SP), Add Breakline(AB), Untag Breakline (UB), Add Entities(AE), Swap edge(SW), ID Pnt(ID), Show/Hide Tris(ST), Remove Pnt(RP), Remove Tri(RT), Remove Entities(RE), Remove by Window(RW), Remove by Fence(RF), Remove by Boundary(RB), Update Tris(UT) Press Enter to end. Press Esc to cancel.

Add Pnt(AP)

Pick point or point number to add [Group/Range]: *Graphically pick points from the screen; type a point number; or add an entire (R)ange or point (G)roup to the TIN. When graphically selecting a point, you will be prompted for the elevation of the new point, and if you would like to add the new point to the current coordinate file.*

Move Pnt(MP)

Pick near point to move: *Graphically pick near a point to move. Carlson will take that point and place it in a new location when prompted.*

Set elev(SP)

Pick near point to set elevation: *Graphically pick near a point to change the elevation and you will be prompted for the new elevation.*

Add Breakline(AB)

Pick point or point number for 1st breakline point: *Graphically snap 2 points on the screen for the new breakline.*

Untag Breakline(UB)

Select an breakline edge to untag: *Graphically select a triangle edge that represents a breakline to remove.*

Add Entities(AE)

Select points and breaklines to add to triangulation. FILTER/Select entities: *Graphically select entities to add to the TIN by pick or window selection.*

SWap edge(SW)

Select an internal edge to swap: *Graphically pick near a Triangle Edge to swap. This will switch the direction of two triangles sharing the same edge.*

ID Pnt(ID)

(Prompt is from current edit command) *The coordinates of the nearest triangle vertex are displayed on the commandline (Point: x=, y=, z=).*

Show/Hide Tris(ST)

(Prompt is from current edit command) *Temporarily toggles the display of the triangles ON or OFF the screen for easier editing.*

Remove Point(RP)

Pick point to remove: *Graphically pick near a point you wish to remove from the TIN.*

Remove Tri(RT)

Removing Triangles, Pick point or enter keyword: *Graphically pick inside a triangle you wish to remove.*

Remove Entities(RE)

Select entities to remove from triangulation. FILTER/Select entities: Graphically remove breaklines, points, etc. that were used in the creation of the TIN that you want to remove from the TIN. This will reform the TIN without the selected entities.

Remove by Window(RW)

Pick 1st corner of area to remove: Graphically select 2 points of a window. Any TIN triangles inside or touching the window selection will be removed from the TIN.

Remove by Fence(RF)

Pick beginning of fence: Graphically select points on a screen to create a fence. Any TIN triangles touching the fence selection will be removed from the TIN.

Remove by Boundary(RB)

Select boundary polyline: Graphically select a closed polyline. Any TIN triangles inside or touching the polyline will be removed from the TIN.

Update Tris(UT)

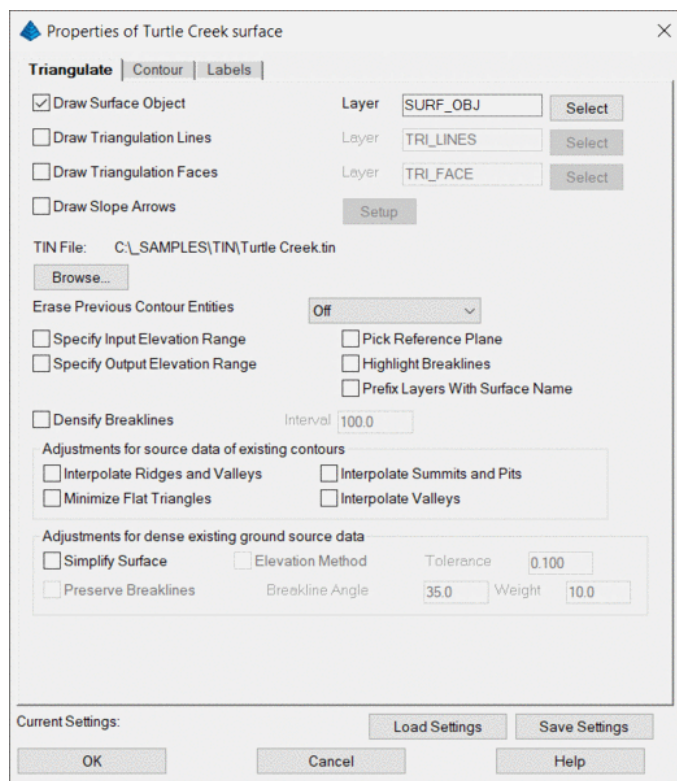

(Prompt is from current edit command) Refreshes the TIN drawn on the screen from the TIN file.

To conclude the Surface Edit mode, press Enter at the end of the internal command sequence. This will return to the Surface Manager dialog. If you press Escape key instead, the following dialog is displayed:

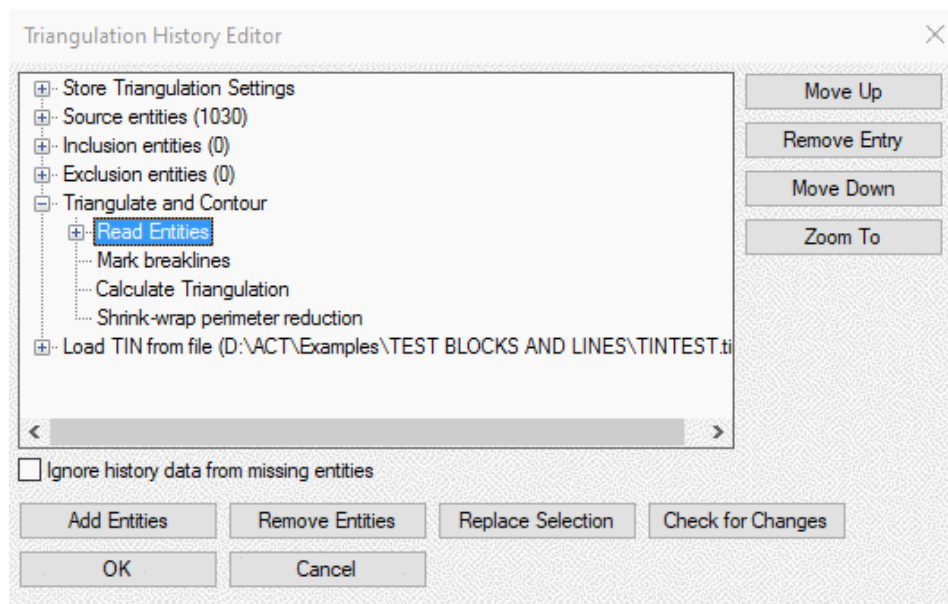

This prevents you from accidentally undoing all of your changes by unintentional pressing the ESC key.

(Draw) Properties allows you to draw the surface and control the properties for the TIN lines, contours and labels for the selected surface. Applicable dialogs from Triangulate and Contour are used to provide a full set of options. When accessed, settings for the current surface display configuration are set. To make a modification, simply specify the desired change and press ok. Refer to the Triangulate and Contour section of the manual for a more detailed explanation of the options.

The Triangulation History Editor displays all functions performed during the creation and editing of a TIN file. Each edit can then be eliminated from the process without recreating the TIN from scratch. In cases where the user does recreate the TIN, any edits previously performed can be recalled and re-implemented. For example, if you have added several breaklines and later decide that they were unnecessary, highlight the added breaklines and click Remove Entry. You can also change the order in which an edit appears, such as the application of an exclusion boundary toward the end of the list of edits.

Move Up / Move Down moves the selected edit up or down in the chronological list of edits.

Remove Entry removes an edit from the TIN.

Zoom To centers the CAD screen on the location of the selected edit.

Ignore history data from missing entities If toggled OFF, all history data in list will be used to process the TIN. If toggle ON, any entities not available will not be used to recreate the TIN, and therefore will be removed until the missing TIN entities are restored.

Add/Remove Entities allows you to select new items to add to the TIN or select existing items to remove from the TIN.

Replace Selection allows you to replace a TIN edit in the history with a new edit.

Check for Changes will read the TIN file and check to see if any changes have been made that are not currently reflected in the current TIN file.

Pulldown Menu Location: Surface

Keyboard Command: surface_mgr

Prerequisite: Need to have at least one TIN (.TIN/.FLT) file

Rebuild Inside Perimeter

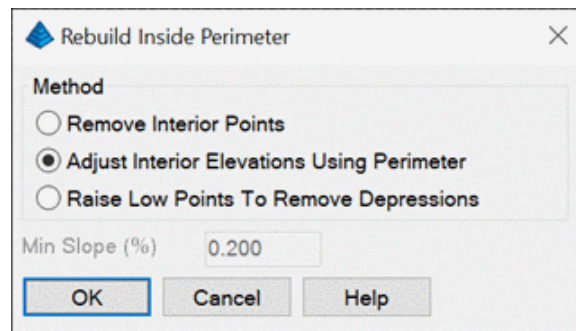

This command rebuilds a triangulation surface within a perimeter. One application of this command is to discard a problem area of the triangulation and rebuild this area using the good elevations around the perimeter of this area.

The perimeter is selected using a closed polyline. The command embeds the perimeter polyline into the triangulation using the elevations of the triangulation. There are three methods for adjusting the surface inside the perimeter:

Remove Interior Points: The surface points within the perimeter are removed. Then the area within this area is retriangulated using the elevations around the perimeter.

Adjust Interior Elevations: The elevations of the surface points within the perimeter are adjusted using a weighted average of the perimeter elevations.

Raise Low Points: The elevations of the surface points within the perimeter are raised to remove any points that are lower than the lowest perimeter elevation or make a slope lower than the specified Min Slope. This method can be used to make sure storm water drainage flows across this area.

Prompts

Select Triangulation File: Select file to load

Options dialog

Select perimeter polyline: *pick a closed polyline*

Output Triangulation File: Select file to write

Pulldown Menu Location: Surface > Triangulation Surface Manager

Keyboard Command: tin_rebuild

Prerequisite: A triangulation file and closed polyline

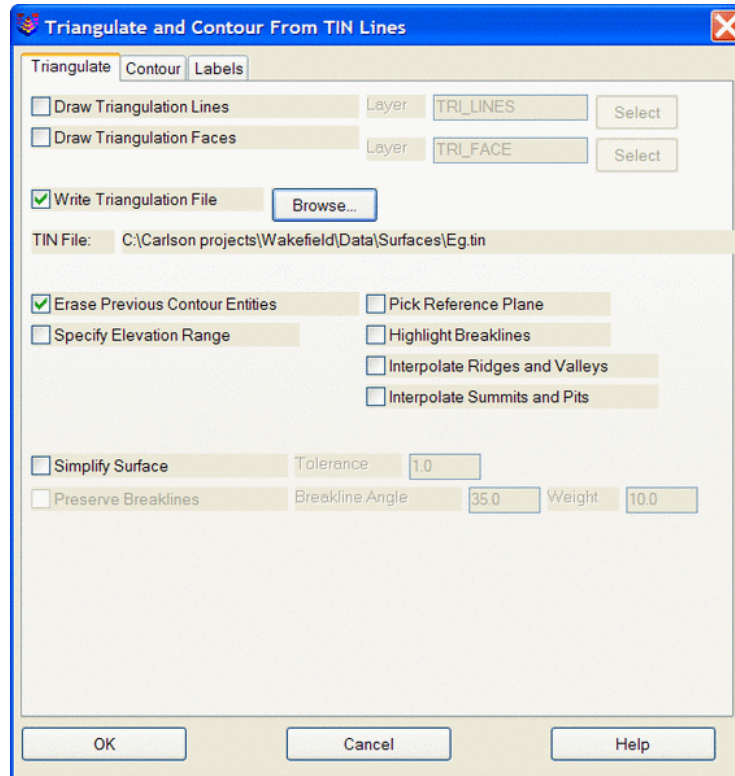

Contour from Triangular Mesh

This command creates contours directly from displayed Triangulated Irregular Network (TIN) surface features (triangles), optionally creating an external Triangulation File (.TIN) in the process. The user is prompted to pick a sample of the TIN to process. This will automatically filter out all other entities that don't reside on the layer of the displayed TIN faces. The triangles must be drawn on the screen as 3D Lines or 3D Faces. All of the settings for Triangulation, Contouring and Labeling, found in *Triangulate and Contour* are available. See the *Triangulate and Contour* section in the manual for a detailed description of each of these settings.

It is not recommended to use the "Subdivisional Surfaces" option in the Contour tab when using this routine. Use of this option with this routine may allow the internal reconfiguration of triangles that have been formed along breaklines.

Prompts

Triangulate and Contour From TIN Lines dialog box

Determining layer name for triangulation lines.

Select sample of triangulation line: *pick a tmesh line and press Enter*

Select all the triangulation lines to contour.

Select objects: *select the triangulation entities*

Reading points... 82

Contouring elevation 404

Inserted 1195 contour vertices.

The user may be prompted for additional information depending on settings used in the Triangulate and Contour dialog box.

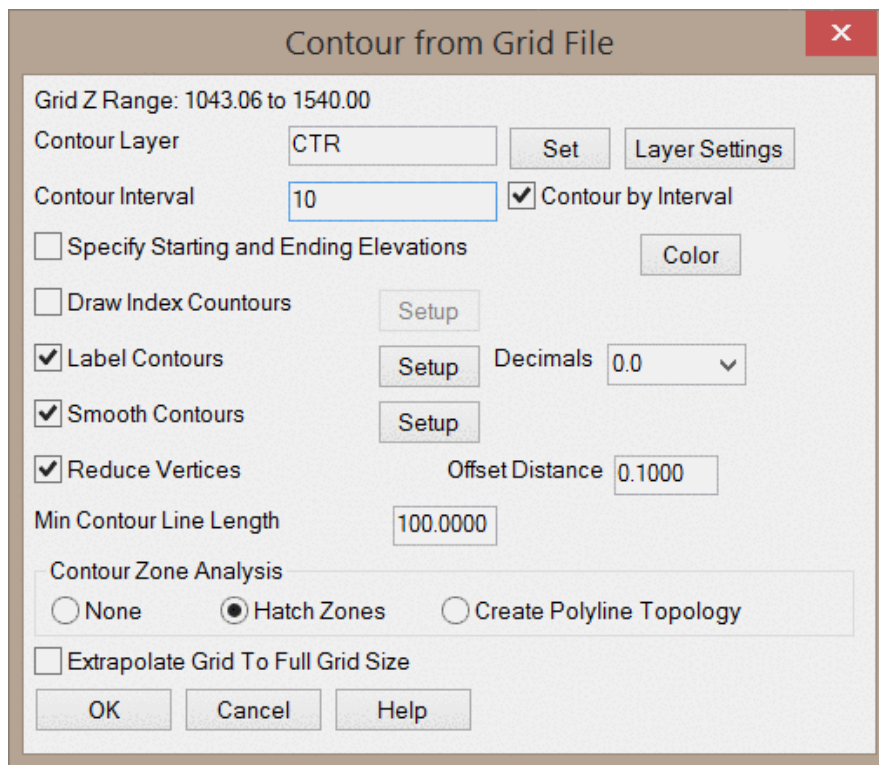

Pulldown Menu Location: Surface >> Contour from...

Keyboard Command: contour

Prerequisite: A triangulated irregular network drawn as lines or triangular 3D Faces.

Contours from Grid File

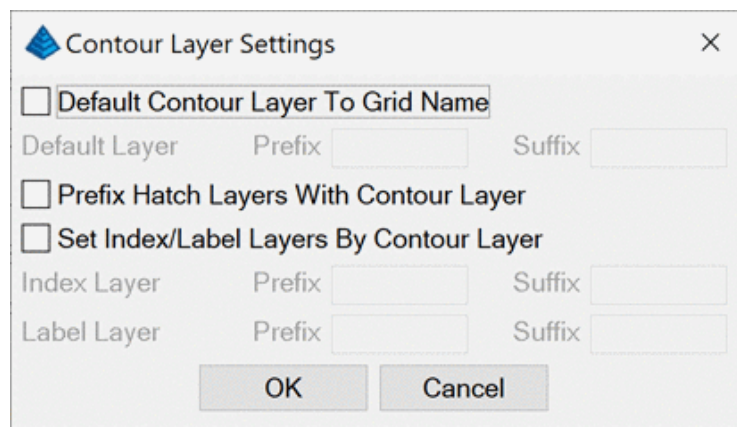

This command creates contours from a grid file. Contouring from a grid employs a different method than from a triangulation network and generally produces contours that loop more. The grid has data points at a regular interval while the triangulation has edges for every point and breakline in the surface. The smoothness of the contours depends a great deal upon the grid resolution. When the command is executed, you will be prompted to select inclusion/exclusion perimeter polylines to limit the contours to certain areas. If no perimeter polylines are selected, the entire grid will be contoured. After selecting a grid file to contour, the below dialog will appear.

Grid Z Range: This text displays the current range of Z values in the grid file to help you determine the optimal Contour Interval/Values.

Contour Layer: This sets the layer for the contours. You may select an existing layer by clicking the **Set** button.

Layer Settings: This button will open the below dialog, which controls default naming for layers of the various linework.

Default Contour Layer To Grid Name: When enabled, this toggle will automatically set the **Contour Layer** to match the grid name. For example, a grid named "Topo.grd" would default to draw contours on the "Topo" layer. The Prefix and Suffix are combined with the grid name. For example, a grid named "Topo.grd" with a prefix of "Contour" would create a layer of "Contour.Topo".

Prefix Hatch Layers With Contour Layer: When enabled, this toggle will use the **Contour Layer** as a prefix for all of the hatch layers. For example, if the first hatch zone is set to be drawn on the "Zone 1" layer and the Contour Layer is set to "CTR", the actual layer name of the hatch will be "CTR Zone 1".

Set Index/Label Layers by Contour Layer: When enabled, this option will automatically set the **Index Layer** and the **Text Layer** to be the same as the **Contour Layer**. However, you may also specify a prefix or suffix for each layer. For example, if the Contour Layer is set to "CTR" and the Index Layer Suffix is set to " Index", then the index contours will be drawn on the "CTR Index" layer. It is important to note that this option only sets these layer names when the command is first executed or when the above dialog is opened, meaning that you may still override these layer names if you wish.

Contour Interval/Values: This value is dependent on the **Contour by Interval** toggle.

When the toggle is enabled, this value will set the interval for the contours. For example a value of 2 will draw contours along the grid values of 2, 4, 6, 8, etc. The first value contoured will be the first value divisible by that contour value. For example, if an interval of 3 is selected for a grid that ranges from 5 to 20, the first contour will be drawn at a value of 6.

When the toggle is disabled, this value(s) will set the specific value(s) to contour. For example, if a value of 10 is selected, only one contour will be drawn where the grid has a value of 10. Multiple contours may be drawn by entering values separated by spaces. For example, entering "10 12 16" into this text box will draw contours at values of 10, 12, and 16.

Specify Starting and Ending Elevations: When enabled, this toggle will prompt you to enter the starting and ending values to contour. For example, if the grid ranges in values from 0 to 100, you can use this option to only draw contours for values ranging from 30 to 60.

Color: This button will open the color palette, where you can select the color for the contours. Please note that this does not set the color of index contours.

Draw Index Contours: When enabled, this option will draw some contours differently than the main contours. You can control the setup of the index contours by clicking the **Setup** button to the right of this toggle. When clicked, the below dialog will appear.

Index Layer: This sets the layer for the index contours. You may select an existing layer by clicking the **Select** button.

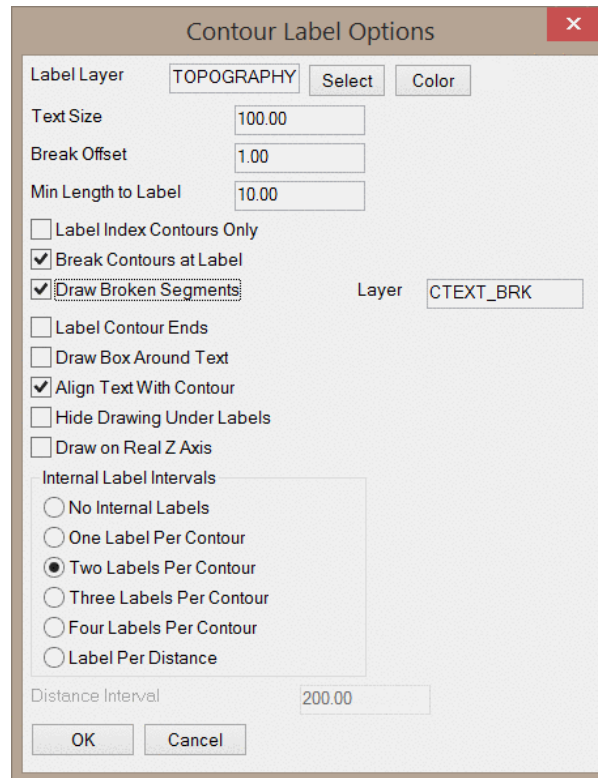

Color: This button will open the color palette, where you can select the color for the index contours. Please note that this does not set the color of non-index contours.

Index Interval: This value sets the interval of the index contours. This value will default to be the **Contour Interval** multiplied by 5.

Line Width: This value sets the width of the index contours. The non-index contours will have a line

width of 0 by default.

Label Contour Lines: When enabled, this toggle will add labels to the contours. The number of decimals in the labels is controlled by the **Decimals** dropdown list. You can control the setup of the labels by clicking the Setup button to the right of this toggle. When clicked, the below dialog will appear.

Label Layer: This sets the layer for the labels. You may select an existing layer by clicking the **Select** button.

Color: This button will open the color palette, where you can select the color for the index contours. Please note that this does not set the color of non-index contours.

Text Size: This value sets the height of the text in drawing units.

Break Offset: This value sets the distance between the end of the trimmed contour and the start/end of the text. This value is only used when the **Break Contours at Label** toggle is enabled.

Min Length to Label: This value sets the minimum length of contours to be labeled. For example, if this value is set to 10, a contour with a length of 5 will not be labeled.

Label Index Contours Only: When enabled, this toggle will only add labels to index contours.

Use MText: Sets whether to create the labels as Text or MText entities.

Break Contours at Label: When enabled, this toggle will break the contour line near the label, making it easier to read the labels.

Draw Broken Segments: When enabled, this toggle will draw the broken segments of the contour (the por-

tion of the contour under the labels). These segments will be drawn on the layer specified to the right of this toggle.

Label Contour Ends: When enabled, this toggle will draw additional labels at the ends of contours. This option will not draw additional labels on contours draw as closed polylines.

Draw Box Around Text: When enabled, this toggle will draw a box around the text labels.

Align Text with Contour: When enabled, this toggle will align the label with the contour itself. When disabled, labels will be aligned horizontally.

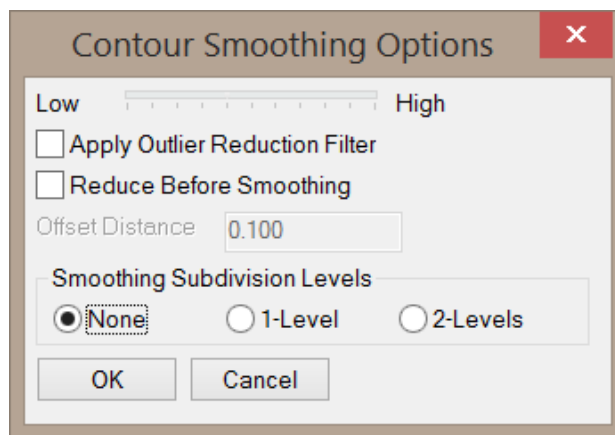

Hide Drawing Under Labels: When enabled, a WIPEOUT entity will be draw around the labels, hiding the contour and any other linework underneath it. This option has the same visual effect as breaking the contour at the label, but allows you to retain a continuous contour.

Draw on Real Z Axis: When enabled, labels will be drawn at the same elevation as the contour. When disabled, labels will be drawn at zero elevation.

--- **Labels Per Contour:** These radio buttons set the number of labels to draw on each contour.

Label Per Distance: This radio button will draw a contour label on a regular interval along the contour, set by the **Distance Interval** value.

Smooth Contours: When enabled, the contours will be smoothed to reduce sharp edges. You can control the smoothing options by clicking the **Setup** button to the right of this toggle. When clicked, the below dialog will appear.

Low-High Slider Bar: This slider bar controls the degree of smoothing. This is based on Bezier smoothing, which holds all the original points calculated from the grid and only smooths between the calculated points.

Apply Outlier Reduction Filter: When enabled, this toggle will remove spikes in the contours that don't follow the general trend direction.

Reduce Before Smoothing: When enabled, this toggle will apply the Reduce Vertices function to the contours before smoothing. The **Offset Distance** is the maximum distance the contour is allowed to move when removing vertices.

Smoothing Subdivision Levels: This option will internally subdivide the grid cells with a quadratic smoothing algorithm to help create smoother contours.

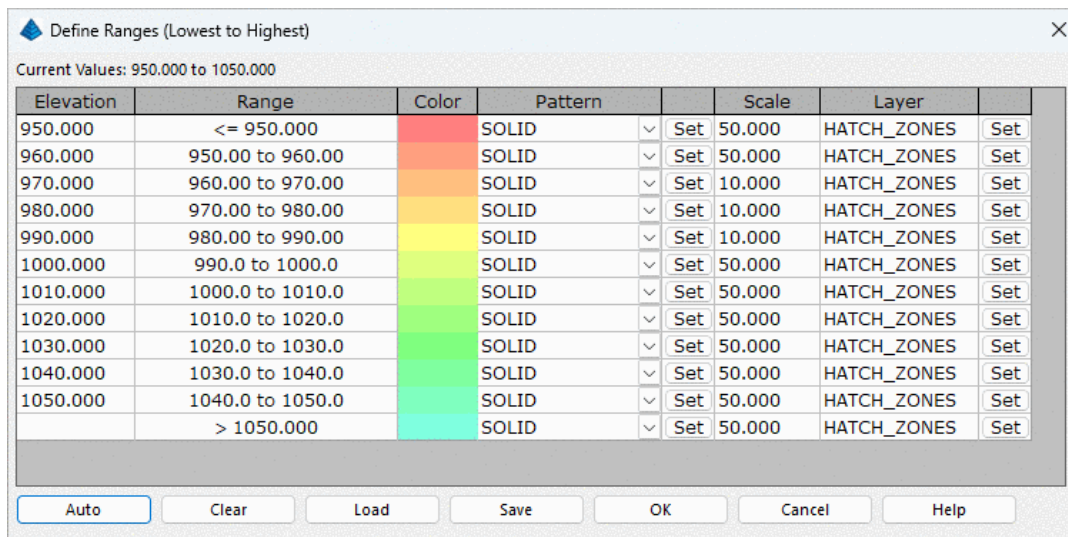

Reduce Vertices: When enabled, this toggle will apply the Reduce Vertices function to the contours. The **Offset Distance** is the maximum distance the contour is allowed to move when removing vertices.

Min Contour Line Length: This values sets the minimum length required for contours to be drawn. For example, if this value is set to 100, a contour with a length of 50 will not be drawn. This filter helps to prevent drawing relatively insignificant contours.

Contour Zone Analysis: This option controls how the contour zones will be drawn. A zone is simply the space between two contour lines.

None: The contour zone boundaries will not be drawn. Only the contours themselves will be drawn.

Hatch Zones: This option will draw the contour zone boundaries and hatch them according to the below dialog. When this option is selected, you will be prompted to pick a location to draw a legend. It is recommended that you select an inclusion boundary when using this option even if you are contouring the entire grid.

The above dialog controls the appearance of the hatch zones. A description of each column is given below. Note that you may need to scroll down to other pages to view all of the contour zones.

Elevation: Sets the maximum contour value for the zone.

Range: Displays the range of values included in the zone.

Color: Sets the hatch color for the zone.

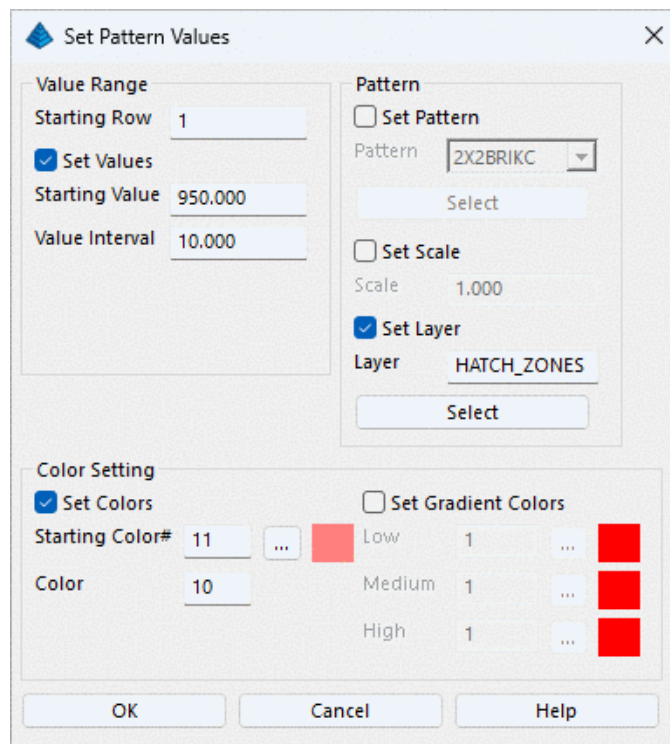

Pattern: Sets the hatch pattern for the zone.

Scale: Sets the hatch pattern scale for the zone.

Layer: Sets the layer for the hatch pattern.

Clear: This button will clear all settings in the dialog.

Auto: This button will display the below dialog, which will let you automatically populate each hatch zone with various properties.

Starting Zone: This value sets the first zone to be modified. If this value is set to 1, all zones in the dialog will be modified. You can toggle the various options on this dialog to only modify certain properties of each zone, however.

Set Values: When enabled, the values of each zone will be modified. The **Starting Value** sets the value of the first zone selected. That value will increment by the **Value Interval** value.

Set Colors: When enabled, the colors of each zone will be modified. There are two ways to set the colors of the zones, controlled by the **Set Gradient Colors** option.

When **Set Gradient Colors** is disabled, the colors for each zone will be defined by a **Starting Color #** and a **Color Increment**. The Starting Color # relates to a color in the CAD color palette. The Color Increment sets the color for the next zone. For example, if the Starting Color # is 10 and the Color Increment is 2, the second contour zone will use color 12. The default values of 10 and 10 will create a rainbow color gradient. Similarly, a Starting Color # of 11 and a Color Increment of 10 will produce a lighter shade of the rainbow gradient. It can be difficult to create other color gradients with this system, but the other method of setting color allows for easier selection of other gradients.

When **Set Gradient Colors** is enabled, you will be able to set color gradients by selecting a **Low**, **Medium**, and **High** color value. All intermediate colors will be selected automatically. It should be noted that this command can only use the colors from the CAD color palette, which includes 255 colors. As a result, attempting to use this option with a large number of hatch zones may result in some hatch zones using the same color.

Set Pattern: When enabled, the pattern for each zone will be set to the selected hatch pattern.

Set Scale: When enabled, the hatch pattern scale for each zone will be set to the **Scale** value.

Set Layer: When enabled, the layer for each zone will be set to the **Layer** value. You may select an existing layer by clicking the **Select** button.

Create Polyline Topology: This option will draw the contour zone boundaries, but will not hatch them. This option will add an extra label in the zone boundary to indicate the range of grid values in that zone. This can

be useful for GIS applications in other modules.

Extrapolate Grid to Full Grid Size: This option will extend the contour lines to the rectangular limits of the grid when values are left as null. Note that this will not modify the grid file itself.

Prompts

Select the Inclusion perimeter polylines or ENTER for none.

Select objects: *pick a closed polyline for the contour boundary if any*

Select the Exclusion perimeter polylines or ENTER for none.

Select objects: *pick a closed polyline for the area to exclude*

Grid File to Process dialog *select a .grd file*

Contour from Grid File options dialog

Extrapolate grid to full grid size (Yes/<No>)? *press Enter* This prompt appears if your grid extends beyond the limits of your data points in some areas.

Contours interpolated from GRID

Setting color ranges using "Hatch Zones" option

Pulldown Menu Location: Surface >> Contour from...

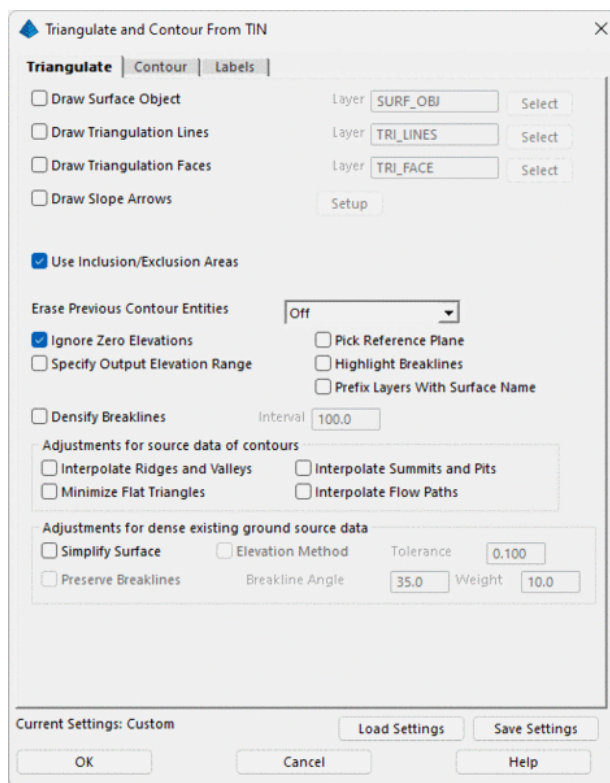

Keyboard Command: cntgrd

Prerequisite: A grid file

Contour from TIN File

This command creates contours directly from a TIN file (.flt or .tin) without the need to have the TIN drawn on the screen. The routine starts by opening the dialog for *Triangulate and Contour*, allowing the user to specify triangulation, contour and label settings. After pressing *OK* on the initial dialog, a second dialog opens, allowing for the selection of the TIN file from which to create the contours.

See the *Triangulate and Contour* section in the manual for a detailed description of each of the settings.

Prompts

Fill out the Triangulate and Contour Dialog information with the desired options. Select the desired TIN file and choose Open.

Loading edges...

Loaded 1994 points and 5944 edges

Created 3936 triangles

Removed 9 disconnected edges.

Reading points... 0

Contouring elevation 497

Inserted 1926 contour vertices.

The user may be prompted for additional information depending on settings used in the Triangulate and Contour dialog box.

Pulldown Menu Location: Surface >> Contour from...

Keyboard Command: cntrTIN

Prerequisite: A TIN file (.flt or .tin)

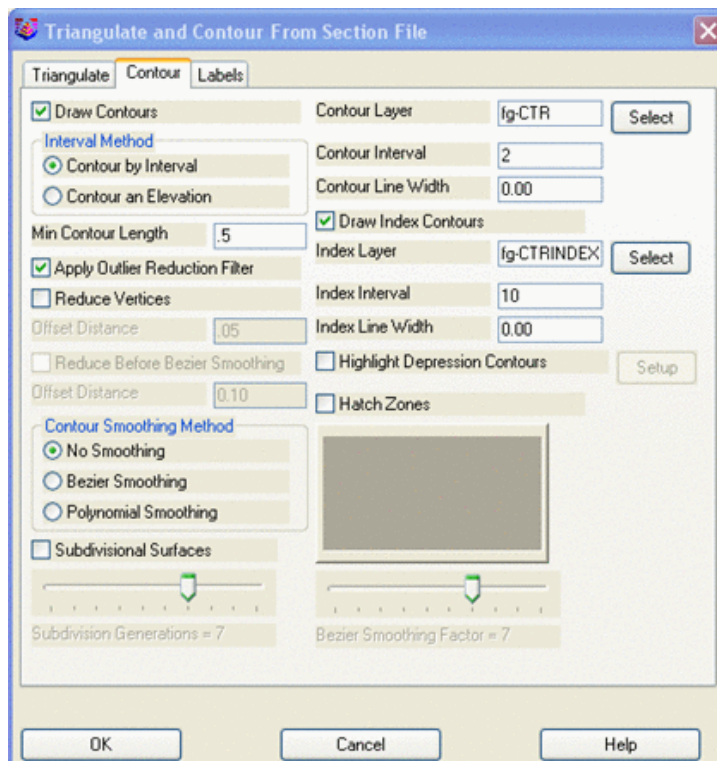

Contour From Section File

This command creates contours from an existing cross section file. Both a section file (.sct) and a centerline file (.cl) are required to generate contours. All of the settings for Triangulation, Contouring and Labeling, found in *Triangulate and Contour* are available.

See the *Triangulate and Contour* section in the manual for a detailed description of each of the settings.

Prompts

Triangulate and Contour dialog box

After pressing *OK*, the user will be prompted to select an existing section file (.sct) and a centerline file (.cl).

Reading points... 314

Inserted 314 points

Inserted 518 breakline segments

Contouring elevation 2016

Inserted 3091 contour vertices.

The user may be prompted for additional information depending on settings used in the Triangulate and Contour dialog box.

Pulldown Menu Location: Surface >> Contour from...

Keyboard Command: cntr_sct

Prerequisite: A section file (.sct) and a centerline file (.cl).

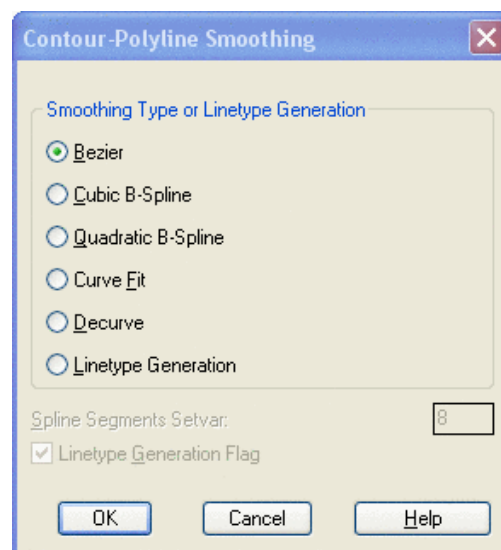

Smooth Contours

This command has options for applying smoothing to polylines. Select the radio button for the smoothing option you want to apply. If you use Quadratic B-Spline type smoothing or Cubic B-Spline type smoothing, the *Spline Segments* AutoCAD system variable is relevant. The Curve Fit option provides the least smoothing, and the Cubic B-Spline option applies the most. Another effective way of smoothing is by creating the contours from rectangular meshes using various grid resolutions. Increase the smoothing by lowering the grid resolution and decrease by raising the grid resolution. The Bezier option provides an incremental type of smoothing. The Linetype Generation option turns on the *Ltype Gen* flag for the selected polylines. For more information on this option and the spline smoothing options, look up the *PEDIT* command in the AutoCAD Reference Manual. After selecting the *OK*

button the routine will prompt for needed values.

Bezier smoothing is also embedded in many of the routines that create contours. Bezier smoothing applies the Bezier smoothing algorithm to polylines. This smoothing technique has two advantages over Spline or Curve Fit smoothing. One is that a Bezier smoothed polyline will pass through all of the vertices in the original polyline, while a Spline smoothed polyline only curves towards the original vertices and can pull away from vertices at sharp corners. Hitting all the original vertices can be an important feature in contour maps for maintaining the exact location of the contours. Another benefit of Bezier smoothing is the ability to control the looping and vertex factors. A higher looping factor increases the curving effect. Use this setting with some care, as too high a looping factor may cause nearby contour lines to cross after the smoothing has been applied.

Vertex reduction can also be applied along with the smoothing. This avoids having to create smoothed polylines with numerous vertices and then having to reduce these vertices in a second step. Be sure not to make the cutoff offset for reduction too high or you can negate or even reverse the smoothing effect. One disadvantage to Bezier smoothing is that it cannot be decurved like the other smoothing techniques.

Prompts

Enter the looping factor (1-10) <5>: *press Enter* This determines the extent of curving. 1- least curvy, 10 - most curvy.

Enter the offset cutoff <0.05>: *press Enter* This value is the maximum shift distance for vertices reduction. A higher value removes more vertices.

Select polylines to smooth.

Select objects: *pick polylines*

Before Smoothing

After Smoothing

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: Smooth

Prerequisite: Create Contour lines to smooth

Reduce Contour Vertices

Contouring and smoothing often creates an explosion in file size due to the many vertices it adds to the individual contour polylines. Fortunately, many of these vertices are very close together, some of which can be removed with no visible effect on the contour polylines themselves. *Reduce Contours Vertices* can reduce the total number of vertices up to 90%. This has the benefits of a smaller drawing file, faster drawing loading, and faster regens.

This command removes vertices in a polyline that are within a user specified offset cutoff. The algorithm looks at three vertices at a time, and calculates the distance between the second point and the line from the first to the third point. If this distance is less than the user specified cutoff, the second point is removed. In theory, reducing the polyline vertices should not shift the polyline more than the user's cutoff distance. The default for this cutoff is one tenth of a foot. Increasing the cutoff will remove more vertices while decreasing it will more closely preserve the original contour line. When combining vertex reduction with smoothing, it is suggested to smooth before reducing, although it can be done the other way around.

Prompts

Enter the offset cutoff <0.1>: .3

Select polylines to reduce. *select polylines*

Select objects: *press Enter* to conclude selection

Processed polylines: 1

Total number of vertices: 1125

Number of vertices removed: 939

Before Vertex Reduction

After Vertex Reduction

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: reduce

Prerequisite: Polylines (contours) with vertices to reduce

Edit Contours

This command revises a segment of a contour polyline. Begin by picking a point on the contour where you want to start editing. Then pick new points for the polyline. When finished picking new points, press Enter and then pick a point on the contour to connect with the new points. The polyline segment between the start and end points is then replaced with the new points.

If there is a triangulation file associated with the contours, then the command prompts for whether to update the triangulation surface file to match the contour edits. When this option is used, data points are added to the triangulation surface along the edited contour segment to make the triangulation surface match the contour line. Existing triangulation source data is retained. So the updated triangulation is the combination of the original source data and the additional points from Edit Contours. One way to get a triangulation surface associated with the contours is to use the Triangulate & Contour command with both Write Triangulation File and Draw Contours

options active.

Note: If the triangulation association is not used, then this routine has no effect on the actual triangulation or grid surface model file that the contours may have been drawn from. It only revises the drawn contour or polyline on the screen. If the contours are later regenerated from this file, the edits will be discarded.

Prompts

Select contour to edit: *pick the contour polyline at the place to start editing*

Pick intermediate point (Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *pick a point*

Pick intermediate point ('U' to Undo, Enter to End): *press Enter*

Pick reconnection point on contour: *pick the contour polyline at the place to join*

Edit this contour by picking new points

Contour with segment replaced with new points

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: editctr

Prerequisite: Polylines with elevation (contour polylines)

Contour ID

Contour ID reports the routine and source data used to generate the selected contour polyline.

Prompts

Select contour polyline to identify: *pick a polyline*

Surface Name: **Triangulate & Contour by screen entities**

Select contour polyline to identify (Enter to end): *press Enter*

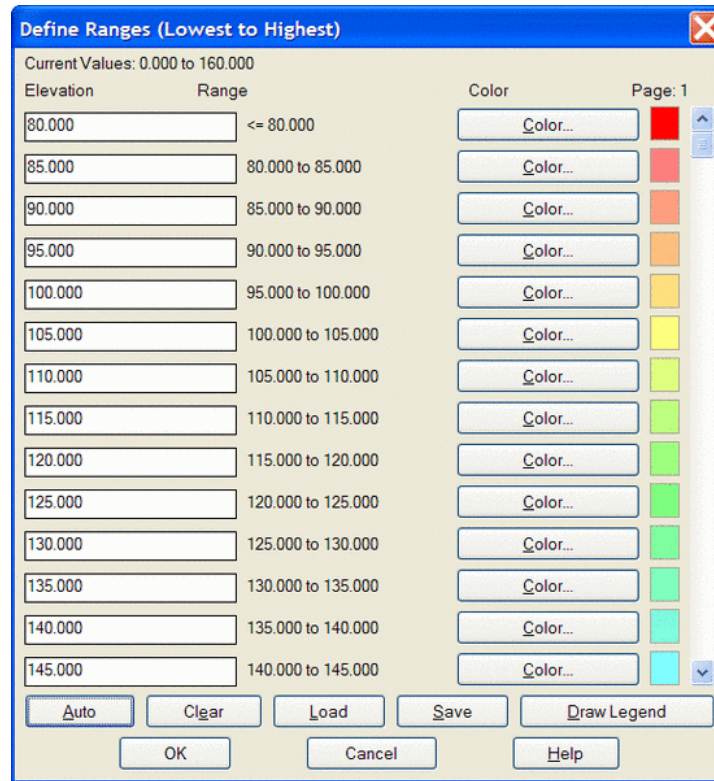

Pulldown Menu Location: Surface->Modify Contours

Keyboard Command: CTR_ID

Prerequisite: a contour polyline

Color Contours by Elevation

This command sets the color of the selected contour polylines and text based on elevation. The color to use is defined in elevation range table.

- **Auto** - This button opens the following dialog, allowing for automatic configuration of the range of elevations and colors.

- **Starting Zone #** - Sets the zone with which to begin the application of the settings defined in this dialog. For Instance, if the Starting Zone was set to 10, the settings definitions applied here wouldn't affect Zones 1-9, but would start at Zone 10.
- **Set Values** - Enables the Starting Value and Value Interval fields, which allow the user to specify the starting elevation for the given zone and set the zone increment.
- **Starting Value** - Sets the starting elevation value for the first zone.
- **Value Interval** - Sets the elevation increment for subsequent zones.
- **Set Colors** - Enables the Starting Color and Color Increment fields.
- **Starting Color #** - Sets the starting color number, based on the AutoCAD standard color chart.

- **Color Increment** - Sets the color number to increase for subsequent zones. So if the increment was set to 5, and the starting color was 60, the next color would be 65, 70, and so on.
 - **Note:** The Pattern, Scale, and Layer options do not apply to this command.
- **Clear** - Clears the all of the Elevation fields in the dialog
 - **Load** - Loads previous settings from a saved .pat file
 - **Save** - Saves the current setting configuration to a .pat file.

Prompts

Select polylines and text to color: *pick the entities*

Define Ranges Dialog

Pick point for color legend: *pick a point to a clear area of the drawing to place a legend or press Enter for no legend*

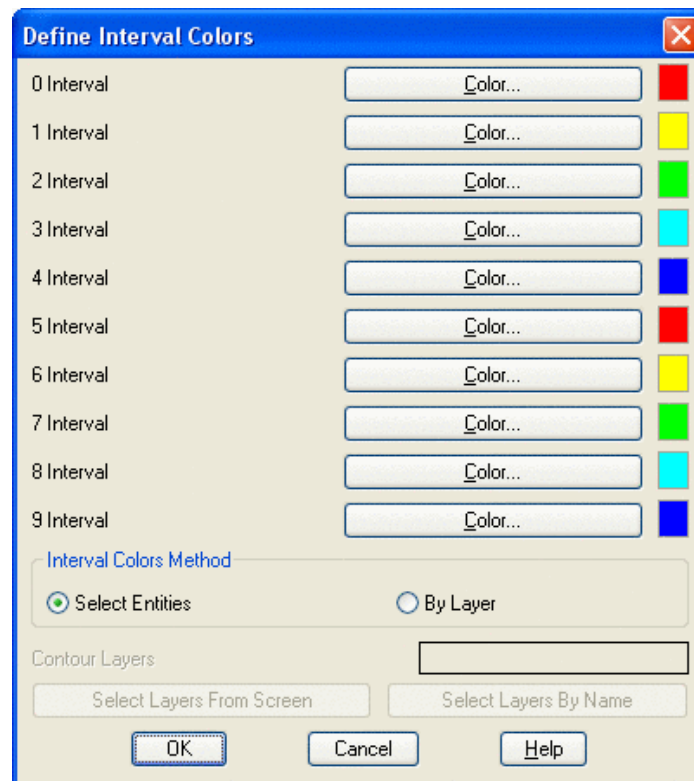

Pull-Down Menu Location: Surface >> Modify Contours >> Color Contours

Keyboard Command: ctrcolor

Prerequisite: Contours polylines

Color Contours by Interval

This command sets the color of the selected contour polylines based on the elevation interval values, which are essentially the number that the elevation ends with, so specific colors are assigned for elevations ending in 0, 1, 2, etc. The color assignments are defined in the Define Interval Colors dialog box.

Select Entities: User is prompted to select the contour polylines to change.

By Layer: Contour polylines are selected automatically by their layer.

Prompts

Define Interval Colors Dialog If Select Entities is set as Interval Colors Method, *pick OK*, and you are prompted to:

Select polylines and text to color: *pick the entities* If By Layer is set as Interval Colors Method, set the *layers by Screen* selection or *from a list by Name*, then *pick OK*.

Pull-Down Menu Location: Surface >> Modify Contours >> Color Contours

Keyboard Command: ctrcolor2

Prerequisite: Contours polylines

Highlight Index Contours

This command will move contours of a specified interval to another layer. This allows the user to change the color or width of a certain interval. This is useful if all the contours had been generated on a single layer, and you wish to display the index contours differently based on a new layer setting.

Prompts

Layer name of existing contours <CTR>: *press Enter*

Layer name for highlight contours <NCTR>: *press Enter*

Select Contours to Highlight.

Select objects: Select contours using any standard selection methods.

Select objects: *press Enter* to conclude selection. The program then sorts and displays the High and Low interval of the selected contours.

Contour increment to highlight: *10*

Starting Highlight at elevation <98.0>: *100*

Ending Highlight at elevation <152.0>: *150*

Assuming we had drawn 1 foot intervals, the above example would move the contours on elevations 100, 110, 120, 130, 140 and 150 to the layer NCTR.

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: indexctr

Prerequisite: Contours should be plotted and visible on the screen.

Highlight Depression Contours

This command highlights depression contours by changing their layer, color, and adding tick marks. A depression contour is a closed contour line that leads to a local minimum such that there are no contour lines with a higher elevation within the contour. This routine finds the depression contours out of the selected polylines. The depression contours are highlighted, and the user selects which ones to label.

Prompts

Layer name of existing contours <CTR>: *Enter*

Layer name for depression contours <DCTR>: *Enter*

Width for depression contours <1.0>: *Enter*

Tick Interval for depression contours <50.00>: *Enter*

Tick Size for depression contours <6.0>: *Enter*

Select the existing contours.

Select objects: *Select all the contour polylines*, even the contours that aren't depression contours.

Select objects: *press Enter* to conclude selection. The program then sorts and displays the high and low elevations

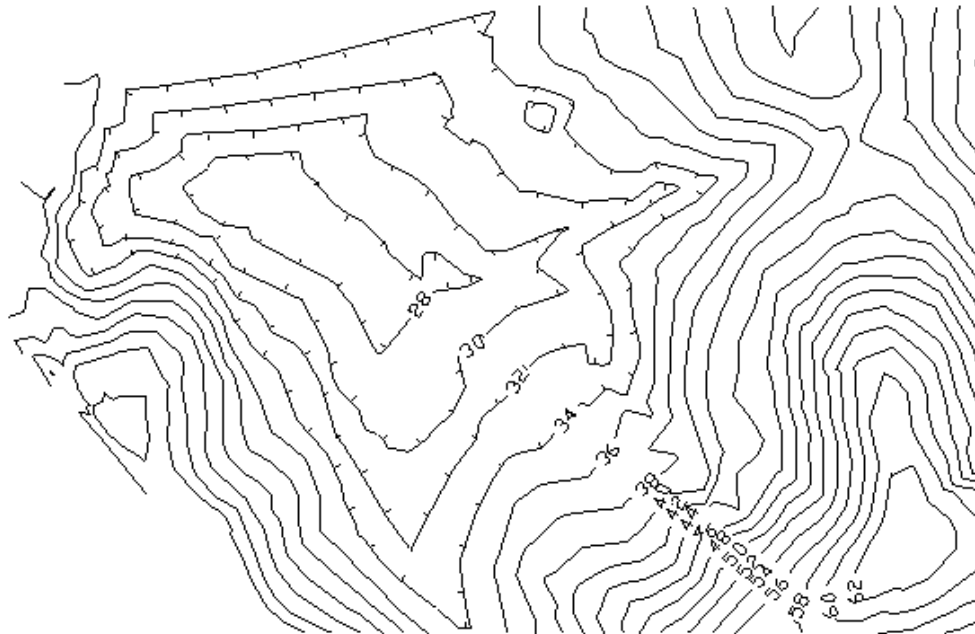

of the selected contours.

Reading the selection set ...

Locating the depression contours ...

Highlight all or selected depression contours [All/<Selected>]? A The "All" option changes all contours identified as depression contours to the specified layer and adds tick marks. The "Selected" option highlights all contours identified as depression contours and then user is prompted to select which ones to change to specified depression contour layer and add tick marks to.

Drawing the depression contours ...

Highlighted depression contours

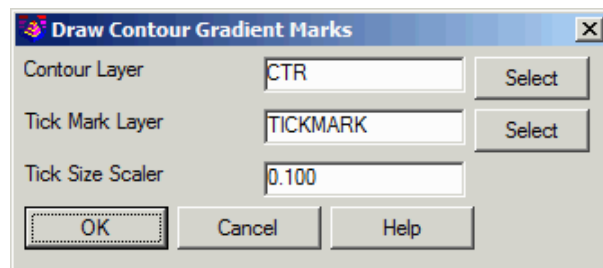

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: depress

Prerequisite: Contours should be plotted and visible on the screen.

Draw Contour Gradient Marks

This command draws lines perpendicular to contours to show the downhill slope direction. In the options dialog, set the layer for the existing contour polylines, the layer for the new gradient lines, and the size scaler for the new lines which is relative to the current scale from Drawing Setup. Next, the program prompts for the surface triangulation file which should be the same surface that the contours represent. The program uses this surface file to determine the direction for the gradient lines. Then the program prompts for where to draw the gradient marks. The Polyline option draws marks at each intersection of the selected polyline with the contours. The Point method prompts for two points and draws marks at the contour intersections with the line defined by these two points.

Prompts

Options Dialog

Select Surface File

Define a line which slices the contours at the place to label them.

Pick 1st point (P-Polyline, Enter to end): *pick point*

Pick 2nd point: *pick point*

Define a line which slices the contours at the place to label them.

Pick 1st point (P-Polyline, Enter to end): *press Enter*

Pulldown Menu Location: Surface > Modify Contours

Keyboard Command: ctr.grad

Prerequisite: contour polylines and surface file

Change Contour-Plines Width

This command allows the user to select a group of contours/plines and change their width for emphasis when plotting. Prior to running this command, the desired contours can be isolated to their own layer using the *Highlight Index Contours* command, or if already on a separate layer you may use *Isolate Layer* from the *View* menu.

An alternate to using this routine is to assign an AutoCAD *lineweight* to the layer that the contours or polylines are on and set the *Display Lineweight* toggle at the bottom of the screen. If using this routine to assign a polyline width, then this new width will display regardless of the lineweight toggle.

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: cwidth

Prerequisite: Contour polylines should be drawn and visible on the screen.

Trim Contour-Plines by Pline

This command can be used to trim a group of contour lines or polyline entities that cross a perimeter defined by a 2D polyline. The trim can be executed on the inside or the outside of the perimeter.

Prompts

Warning: All of the trim perimeter should be visible on the screen!

Select polyline which represents perimeter: *select trim perimeter*

Pick point on the side of perimeter to trim from: *pick a point* To trim contours on the inside of the perimeter, pick a point on the inside of the perimeter (this is useful for deleting contour lines that fall inside a building or some area that you want void of contours). To trim contours on the outside of the perimeter, pick a point outside of the perimeter.

Pulldown Menu Location: Surface >> Modify Contours

Keyboard Command: polytrim

Prerequisite: Draw a 2D closed polyline perimeter.

Contour Elevation Label

This command can be used to simultaneously create elevation labels on a group of contour polylines at elevation. First the command starts with a dialog with the label options. Then to place the labels, pick two points crossing the contour polylines at the desired label location. The program will find all the contour polylines that intersect the picked line (defined by the two picked points) and will place labels at the intersection point of each contour. A second crossing line can be initiated immediately, so multiple areas can be quickly labeled while remaining in the command. Alternatively, you can type P for Polyline at the Command prompt and select a polyline. Then the program finds all the intersections between the selected polyline and the contours and places labels at these intersections. The actual "z" elevation of the contour line determines the label value.

Label Layer specifies layer name for the contour labels that will be created.

Label Style specifies the text style to be used for labels.

Horizontal Scale is used in conjunction with the Text Size Scaler to determine unit height of the contour labels. **Text Size Scaler** is a scaler that will be multiplied by the horizontal scale to set the actual text height of the labels in AutoCAD units.

Integers controls how many digits to label to the left of the decimal. For example, if all contours are in the 5000's, then setting for three digits would label the 5280 contour as 280.

Decimals sets the decimal precision for the labels to be created.

Label Position determines the label position in relation to the contour polyline.

- **On Contour** centers the label on the contour line.
- **Above Contour** places the label above the contour line. If this option is used, the options for Break Contours at Label and Draw Broken Segments become inactive.

Ignore Zero Elevation Polylines enables the routine to filter out all entities with an elevation of zero.

Hide Drawing Under Labels activates a text wipeout feature that will create the appearance of trimmed segments at the contour label, even though the contour line is still fully intact. This feature provides the user with the best of both worlds; you have clean looking contour labels, yet the contour lines themselves remain contiguous. This feature will also hide other entities that are in the immediate vicinity of the contour label.

Align Facing Uphill makes the label parallel to the contour and flips the label so that it reads facing uphill. Otherwise, the labels are made to face up relative to the current screen view. When this option is on, the program prompts for a triangulation surface file that should match the surface the contours represent.

Use Commas adds a comma into the labels for the thousands place such as "5,000" instead of "5000".

When **Align Text with Contour** is checked, contour elevation labels will be rotated to align with their respective contour lines.

When **Break Contours at Label** is checked, the contour lines will be broken and trimmed at the label location for label visibility.

When **Draw Broken Segments** is checked, segments of contours that are broken out for label visibility will be redrawn as independent segments. Specify the layer for these broken segments in the box to the right of this toggle.

Label Contour Ends creates labels off the ends of the contours.

Label By Distance places the labels by distance along the contour. The user is not prompted for screen picks of contour crossing when this option is used.

- **Interval** sets the distance interval to be used between labels on each contour.

When **Draw Box Around Text** is checked, a rectangle will be drawn around the elevation labels. The Offset Scaler controls the size of the rectangle.

The **Draw On Real Z Axis** chooses between creating the text entities at the elevations of the contours or at zero elevation.

The **Use MText** chooses between creating MText and DText label entities.

Index Contours: Label All will label both index and intermediate contours with the same settings. Label Index Only labels only the index contours. Separate Index Layer will label both index and intermediate contours with the index labels on a different layer.

Prompts

Contour Label Options Dialog Opens Select the desired options and press OK.

Define a line which slices the contours at the desired label locations.

Pick 1st point (P-Polyline, Enter to end): *pick a point*

Pick 2nd point: *pick a point*

By selecting two points the contour lines that cross the line defined by the two points are labeled.

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: gclabel

Prerequisite: polylines with elevation (contour polylines)

Local Elevation Label

This command allows the user to place elevation labels on contour lines or other entities with elevation. The command prompts for two points to align the rotation angle of the label, centers the label between the picks, and then prompts for two break points which are used to erase/break the contour that runs through the elevation label. If a break is not required just press [Enter] at the break point prompts.

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: clabel

Prerequisite: polyline with elevation

Draw Contour Label Marker Line

This command draws lines that Triangulate and Contour looks for to control where to draw contour elevation labels. The labels are drawn where the contour polylines cross the marker lines. These marker lines can be drawn on a separate layer that can be turned off for plotting the drawing.

Prompts

Layer selection dialog

Pick start point: *pick a point*

Pick end point: *pick a point*

Pick start point (Enter to end): *press Enter*

Pulldown Menu Location: Surface > Contour Labels

Keyboard Command: mark_ctr_label

Prerequisite: None

Move Label Along Contour

This command slides an existing contour label along a contour, maintaining its alignment with the contour. After moving the label, you can type F for Flip at the Command prompt to rotate the label orientation by 180. The label must have originally been created with the *Break Contours at Label* option *Off*. If the option to *Hide Drawing Under Labels* was used when the label was created, the wipeout will move with the label when using this command.

In addition to moving a label, an existing label can be copied and placed at a new position along the contour by using the Copy option at the first prompt.

Prompts

Copy/<Select contour label to move>: *Pick label*

Pick new contour label position: *Move mouse to relocate label*

Flip last/<Select contour label to move (Enter to end)>: *press Enter*

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: move_ctr_label

Prerequisite: generated contour labels

Flip Contour Labels-Text

This command individually rotates each of the selected text entities by 180 degrees.

Pulldown Menu Location: Surface >> Contour Labels

Keyboard Command: fliptext

Prerequisite: Text labels on contours

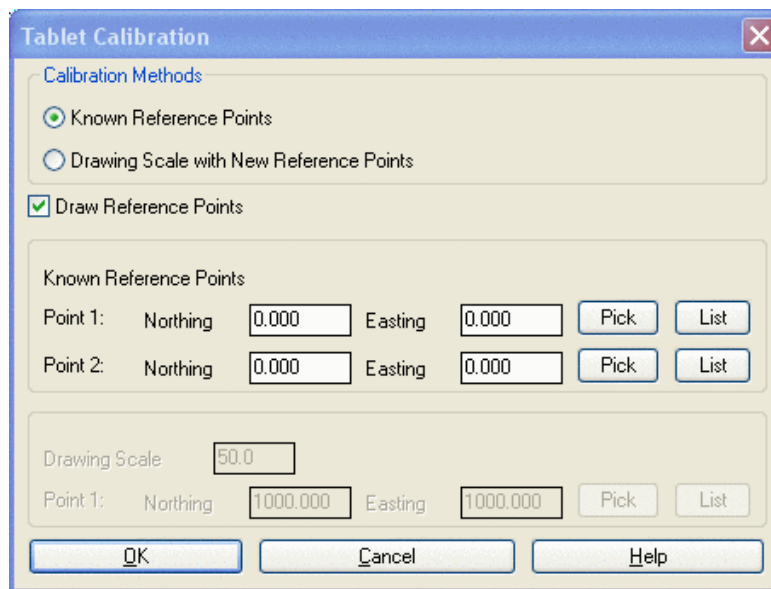

Tablet Calibrate

This command executes the routine to calibrate the digitizer tablet to a hardcopy drawing. There are two methods of calibration: *Known Reference Points*, and *Drawing Scale with New Reference Points*, which are explained in detail below. The Calibrate routine must be used prior to using the *Digitize Contours* command.

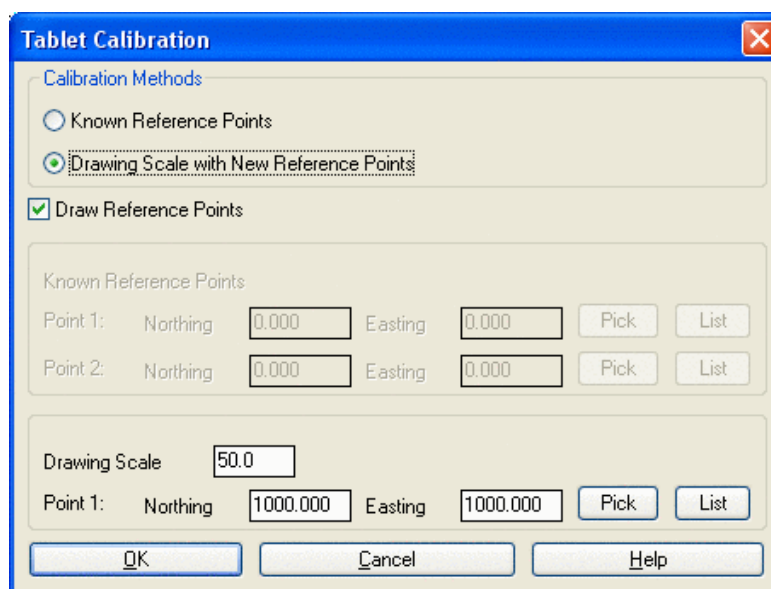

Please refer to Configure, General Settings and Digitizer Puck Layout for selection of the correct puck layout before proceeding.

Tablet Calibration

Known Reference Points uses two known coordinates for reference points on the hardcopy drawing. When this option is selected, the fields for coordinate information activate. Enter the known northing and easting values for the reference points from the information on the hardcopy drawing in the appropriate fields and select the *Pick* button. Pick the points from the hardcopy drawing using the tablet. Carlson Civil saves the coordinates of the two reference points for future calibrations and displays them on the *Tablet Calibration Dialog* the next time it is accessed, so if you are working on the same drawing, you can use the **Known Reference Points** method with the saved coordinates to calibrate to your previous coordinates. For greater calibration accuracy, choose two points that are farther apart rather than closer together.

Drawing Scale with New Reference Points is very convenient when you don't know the precise coordinates of the entities on your hardcopy drawing. You must specify the drawing scale from the plan. This method establishes a coordinate system relative to the position of the plan on the digitizer board. In addition to the drawing scale, you are required to enter a random coordinate for the first reference point, the default coordinate is (1000,1000). You then select the *Pick* button and pick the point on the hardcopy drawing to assign the specified coordinate to. The routine will compute the coordinate of the second reference point that you pick based on the first point. The coordinates of these two reference points would be saved and will be display in the *Tablet Calibration Dialog* as **Known Reference Points** the next time you calibrate the tablet, so you can digitize the previous coordinates if you are working on the same drawing, even though you may have moved or rotated your drawing on the digitizer tablet.

Prompts

Tablet Calibration Dialog

Specify the Calibration Methods. If you select *Drawing Scale* method, enter the drawing scale and the coordinate of the first reference point. Otherwise enter the exact coordinates of the first and second reference points.

Pick first reference point: *pick a point*

Pick second reference point: *pick another point*

Pulldown Menu Locations: Surface >> Digitize Contours

Keyboard Command: digsetup

Prerequisite: Affix a drawing to your digitizer tablet. Have a digitizer board and a puck connected to your computer, correctly configured, and have Wintab driver installed. Select the puck layout in Configure.

Digitize Contours (Polyline)

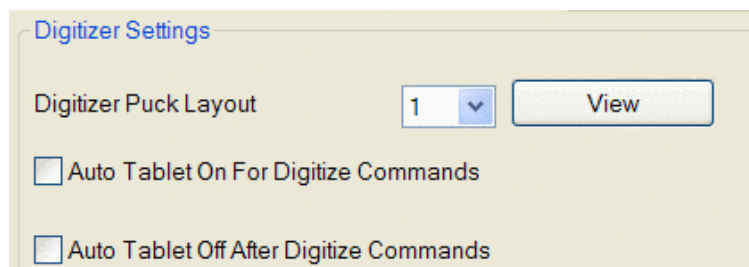

A contour is drawn as a polyline which consists of a series of connected points with a constant elevation. There are two ways to digitize contour lines: sketch mode or point mode. You can start digitizing a contour with one mode and switch to the other during digitizing the contour. Sketch mode uses more points than pick mode. In general, we recommend using pick mode to digitize the straight parts of lines because it reduces the number of points and speeds up calculations, but using sketch mode to digitize the curved parts because it is fast and accurate.

This command lets you digitize contours as polylines one at a time. The first time it prompts you with the *Digitize Contours Dialog*. Enter the layer name or select it from a list of existing layers. Look at your hardcopy plans and determine an elevation interval that is between most of the contours and enter it in the Elevation Interval field. You are able to modify both the value and the direction of the elevation interval between digitizing contour lines, using the buttons on the puck.

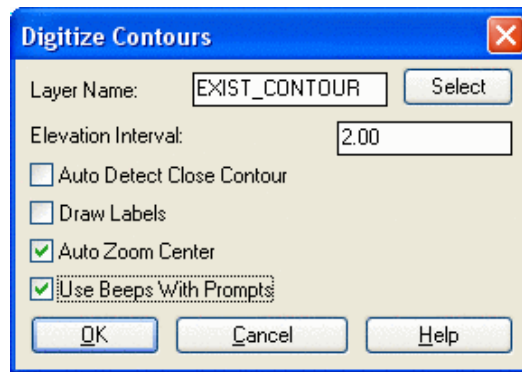

To have Carlson Civil automatically close contours whose beginning and ending points are within a specified range, check the *Auto Detect Close Contour*. *Draw Labels* will draw the elevation at the starting point of the contour. In Pick mode, if you want the program to automatically zoom the display to center around the last point when you get near the edge of the screen while picking points, check the *Auto Zoom Center*. Click *OK* to start digitizing.

If this is your first time digitizing a contour, you are defaulted to the Pick Mode digitizing, otherwise you will be defaulted to the previous digitizing mode. If you want to use the other digitizing mode, press *0* (the number "zero") on the puck or enter *0* from the keyboard. Place your cursor at one end of the contour line and begin digitizing the line. While digitizing a line, you can force a contour to close on itself by pressing *A* on the puck to end the contour and connect the last point to the first point, remove a mistake by pressing *B* on the puck, or switch to the other digitizing mode by pressing *0*. During Sketch Mode digitizing, you can stop digitizing by pressing the *Pick* or *Enter* button on the puck, take some rest or make edits, and start sketching again. At the end of the contour line, press *Enter* on your puck or keyboard. The contour is completed, and the elevation for the next contour is automatically incremented. You will be asked to digitize the next contour. If you press *A* on the puck or enter *Yes* on the keyboard, you can digitize another contour, or press *B* on the puck or enter *No* on the keyboard to end digitizing contours.

To digitize with a mouse instead of a digitizing tablet, go to the *Settings* menu, *Configure*, and *General Settings*. In the General Settings dialog box, under Digitizer Settings, clear the check box for *Auto Tablet On For Digitize Commands*.

This is the Digitize Contours dialog box.

Prompts

Digitize Contours Dialog

Increment(1.00)[A]/Direction(+)[B]/Elevation <573.00>: 450 Enter elevation or press Enter to accept current value.

Start Digitizing...

Sketch[0]/Pick the first point: *pick a point to start Pick Mode digitizing* Press 0 to switch to Sketch Mode.

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): 0 Press 0 on the puck or enter 0 on the keyboard to use Sketch Mode.

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): *pick and drag*

Drag to digitize (Pick or press Enter to stop sketching)... *pick or press Enter to stop sketching*

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): B Undo the last point.

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): B Undo the last point.

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): *pick and drag again*

Drag to digitize (Pick or press Enter to stop sketching)... *pick or press Enter to stop sketching*

Pick[0]/Close[A]/Undo[B]/Pick and drag (Enter to end): 0 Press 0 on the puck or enter 0 on the keyboard to use Pick Mode.

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *pick next point*

Sketch[0]/Close[A]/Undo[B]/Pick next point (Enter to end): *press Enter to finish digitizing*

Digitize Another Contour [<Yes(A)>/No(B)]? B Press B to finish digitizing.

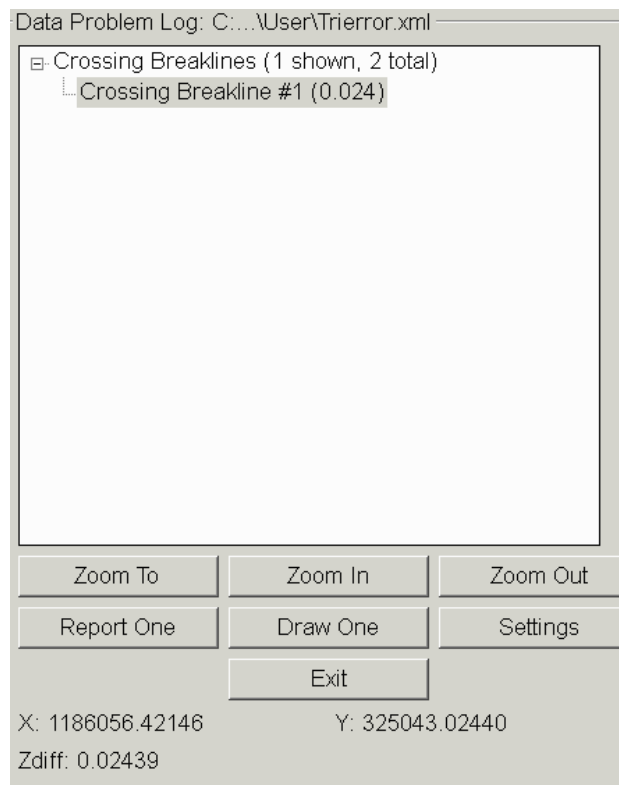

Pulldown Menu Location: Surface >> Digitize Contours

Keyboard Command: digcont

Prerequisite: Calibrate the tablet with the *Tablet Calibrate* menu option if contours are to be taken off an existing hardcopy drawing.

Display Last TIN Error Log

This command displays the data error log from the last run of Triangulate and Contour. The Triangulate and Contour command reports any errors in the source data such as crossing breaklines. If you exit this report during Triangulate and Contour, then you can bring up this report again using this command. See the Triangulate and Contour section of the manual for more information on this error report.

Pulldown Menu Location: Surface > Triangulation Surface Manager

Keyboard Command: tin_error_log

Prerequisite: data errors from Triangulate and Contour

Make 3D Grid File

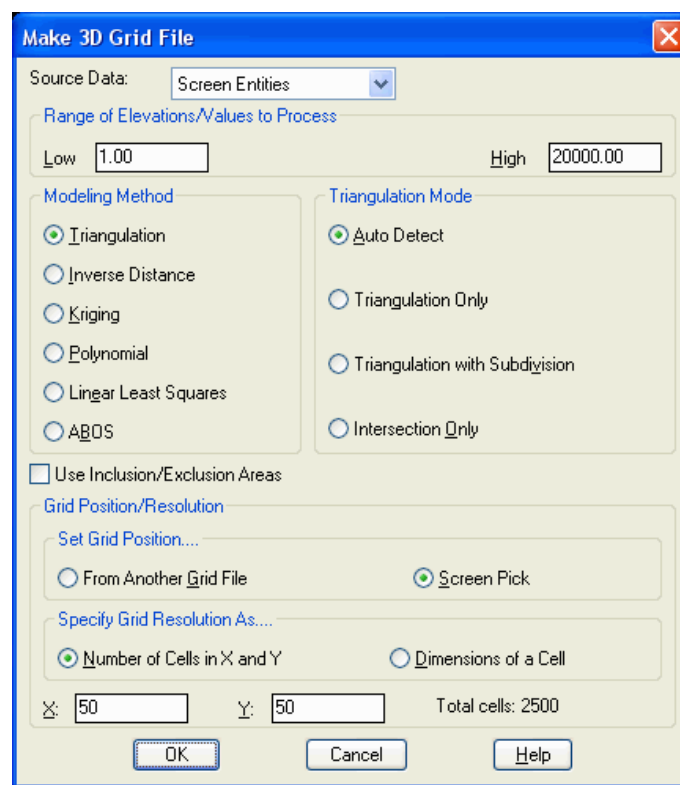

This command creates a grid (.GRD) file which serves as a surface model for use in many of the other Surface routines. The program internally makes a triangular network of the data points (if *Triangulation* is selected as the modeling method) and then interpolates the elevation values of a rectangular grid at the specified grid resolution. Data points can be either points, inserts, lines, or polylines. Lines and polylines are treated as breaklines in the triangulation.

Gridding as a means of modeling surface features is generally less favorable than triangulating as the surface is defined only at the intersection of the grid lines. This can lead to inaccuracies around local features such as ditches or curb lines, since the grid resolution must be small enough to adequately capture the changes in these local regions. Contrast this with Triangulated Networks which carry all this information at every point along the features. Gridding can, however, be useful for modeling large sites in general trends such as watershed analyses and large-scale volume computations.

Grid superimposed over triangulated features

The grid location is specified by first picking a lower left corner and then an upper right corner. The screen cannot be twisted when this is done because grids always run north-south and east-west.

The dialog box sets the range of elevations to process, modeling method and grid resolution. Each of these items is described below.

- **Source Data:** This option selects the type of data to use for gridding. The Screen Entities option processes selected 3D entities from the drawing including points, lines, polylines, 3D faces and inserts. The Coordinate File and Text File options read point data from the selected file. These methods are useful for large datasets that would take extra memory and time to draw as points in the drawing. For the Text File, the program will prompt for the order of the fields and the delimiter. The Triangulation File option will interpolate the grid elevations from the selected triangulation surface.
- **Range of Elevations/Values to Process:** Entities with elevations or values outside the range to process are ignored and will not be used for the gridding.
- **Modeling Method:** The modeling method almost always should be triangulation for surface topographic grid files. Polynomial, inverse distance, kriging and linear least squares apply to random data points for surfaces

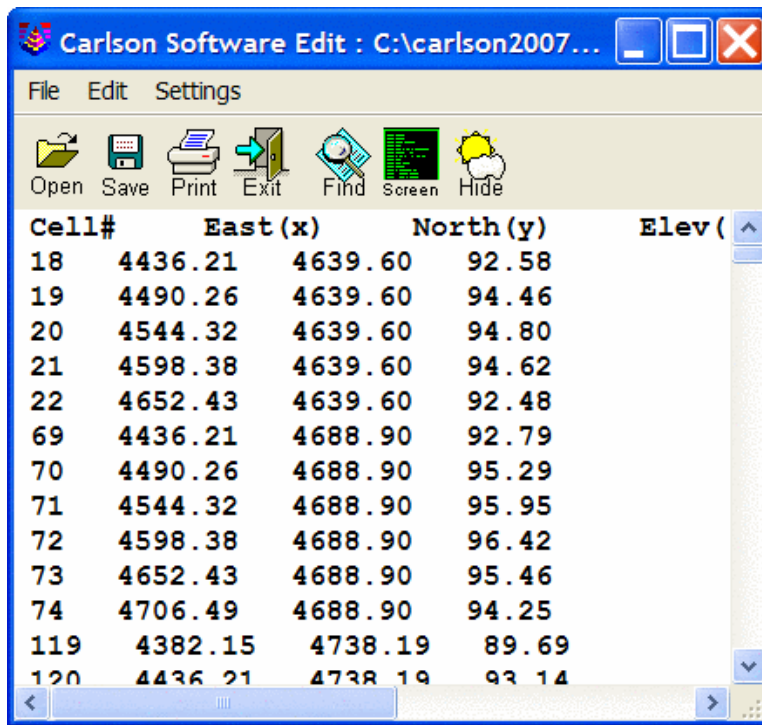

- like underground features, usually sourced by such methods as drillholes, data tables, etc.
- **Triangulation Mode:** When using Triangulation and Polynomial methods, There are four triangulation modes: AutoDetect, Triangulation Only, Intersection with Triangulation and Intersection Only.
 - **Auto Detect** method automatically chooses between the Triangulation Only and Intersection with Triangulation methods. If the selected surface entities are primarily made of polylines, then the Intersection with Triangulation method is used. Otherwise the Triangulation Only method is used.
 - **Triangulation Only** method builds a triangulation surface out of all the selected points, lines and polylines. All lines and polylines are treated as breaklines. Grid node elevations are calculated based on the triangulation.
 - **Triangulation with Subdivision** method uses the subdivisional surfaces modeling method. This option causes each triangle in the triangulation surface model to be subdivided into an average of three smaller triangles per subdivision generation. This gives a much smoother surface model, where instead of one triangle, there are now three or more.
 - **Intersection Only** method goes directly to the Steepest Intersection method using the selected lines and polylines. The Steepest Intersection method is used to assign the grid node elevations from the linework of the triangulation lines and the selected lines and polylines. The triangulation step is skipped and any selected point data is not used. This method can be used for making grids out of polylines such as a contour map as long as the surface is defined just by contour polylines without needing spot elevation points. Skipping the triangulation step makes this method a lot faster especially for large files.
 - **Use Inclusion/Exclusion Areas:** This option will prompt for inclusion and/or exclusion perimeter polylines and will only assign grid cell elevations within these areas and leave the rest of the grid cells as Null.
 - **Grid Resolution:** The grid resolution is specified by either the number of grid cells or by the size for each grid cell. It is usually best to set the Dimensions of a Cell to a known size, and the program will calculate the "number of cells in X and Y." While the program can handle really large grids with no limit, a general rule of thumb is to keep the total number of grids cells under 500,000 (about 700 by 700 cells) to limit the processing time. The grid location and resolution can also be specified by using the position/resolution from an existing grid file. In this case, the location and resolution of the new grid will match those of the selected grid file which is useful for routines that require two grid files with identical locations and resolutions.

No elevations are calculated on grid cells that extend beyond the extent of the data. The figure shows an example of how the grid is calculated to the limits of the data points. Extrapolation can be used to calculate elevations for the grid cells that are beyond the data limits. When there are grid cells with no elevation in a grid (.GRD) file, many routines will prompt *Extrapolate grid to full grid size?* Extrapolation fills in all the grid cells. The method to extrapolate uses a safe calculation that tends to average out or level the extrapolated values. So extrapolated grid areas are not as accurate as grid areas within the limits of the data. *Grid File Utilities* can be used to apply and save extrapolation to a grid file. The *Plot 3D Grid* command can then draw the grid file so that you can see the extrapolation.

A Carlson grid (.GRD) file has the following format:

Line 1 is the lower left Y coordinate
 Line 2 is the lower left X coordinate
 Line 3 is the upper right Y coordinate
 Line 4 is the upper right X coordinate
 Line 5 is the X direction grid resolution
 Line 6 is the Y direction grid resolution

The rest of the lines are the Z values of the grid intersects starting from the lower left moving in the left to right direction and ending at the upper right. If the intersect has no value, the letter 'N' is saved instead of the Z value for Null values. An example is shown in the Display-Edit Report dialog.

Cell#	East (x)	North (y)	Elev (z)
18	4436.21	4639.60	92.58
19	4490.26	4639.60	94.46
20	4544.32	4639.60	94.80
21	4598.38	4639.60	94.62
22	4652.43	4639.60	92.48
69	4436.21	4688.90	92.79
70	4490.26	4688.90	95.29
71	4544.32	4688.90	95.95
72	4598.38	4688.90	96.42
73	4652.43	4688.90	95.46
74	4706.49	4688.90	94.25
119	4382.15	4738.19	89.69
120	4436.21	4738.19	93.14

Gridding from Contour Maps

A grid file can be created from contours represented as polylines with elevation. The program calculates the elevation of each grid corner by looking for contour intersections in eight directions (N, S, E, W, NE, SE, SW, NW) and then interpolating the elevation between the two steepest intersections.

To accurately model the surface, it might be necessary to add entities in addition to the contour polylines. For one, spot elevation points can be added for the high and low points. Otherwise the grid model might plateau at the last contour. Also 3D breaklines need to be added on long narrow ridge and valley contours because in these areas the program will find the same contour when it looks for intersections in the eight directions. When all eight intersections are the same contour, the interpolated grid elevation equals the contour elevation instead of rising up the ridge or dipping in the valley. The 3D breaklines force interpolation along the ridge or valley. To draw these polylines, set the OSNAP to *Nearest* and run the *3D Polyline* command. Then draw the polyline by picking the contour polylines where the breakline crosses them. Another way to quickly create breaklines is to first draw 2D polylines. Then convert these polylines into 3D polylines with the *Screen* option in the *2D to 3D Polyline by Surface Model* command found on the 3Dpoly menu. There is also an automatic way to draw these breaklines. Under 3D Data, use the command: *Create Ridge polylines from Contours*.

Prompts

Grid File to Create File Selection Dialog

Enter a name for the grid file.

Use position from another file or pick grid position [<Pick>/File]?

Pick Lower Left grid corner <8111.88,3985.08>: pick a point for the lower left limit of the grid

Pick Upper Right grid corner <8366.88,4195.08>: pick a point

Make Grid File dialog box

In this dialog, you specify the grid resolution and whether or not to include data points with zero elevations. You can specify the resolution by entering the number of grid cells in the X and Y directions. By the Dimensions option, you to set the X and Y size for each grid cell.

Grid File Utilities

This command is used to modify and create grid files. The modifications can be done manually on a single grid, on multiple grids in a batch mode, or saved and rerun using the grid macros created with the macro editor. To modify manually, start by picking the Select Grid(s) button. There is an option to use inclusion and exclusion polylines to only modify the grid within/outside these perimeters. With this option active, the program will prompt for inclusion and exclusion polylines when a function is selected. Only grid cells inside the inclusion polylines will be modified. Grid cells inside the exclusion polylines will not be modified. If no inclusion and exclusion polylines are selected, then the entire grid will be modified. Each function is described below.

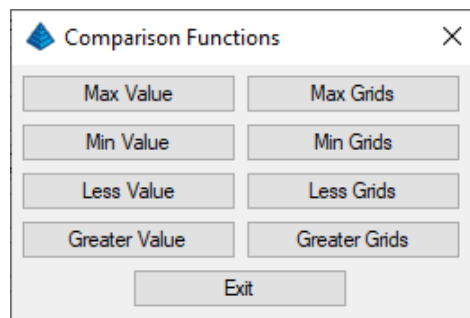

- **Select Grid(s):** This is the first step to load a grid. Usually a grid needs to be loaded before running a function. If Batch Process Grids is turned on, then multiple grids may be selected while holding down the Shift or CTRL buttons.

- **Auto Extrapolate On Load:** This will extrapolate values for any null or empty values in the grid as the grid is loaded.
- **Use Inclusion/Exclusion Areas:** If this is turned on, then the GFU function will only be applied within the selected inclusion polyline and outside the selected exclusion polyline.
- **Batch Process Grids:** When this option is turned on, GFU functions can be executed on many grids at once. It is recommended to move the grids to a backup directory, or create a copy of them, as the grids are over-written with the same name. The functions that cannot be batched are: Plot Grid, Merge Grid, List Grid, Import Grid, and Spreadsheet.
- **Math Functions:**

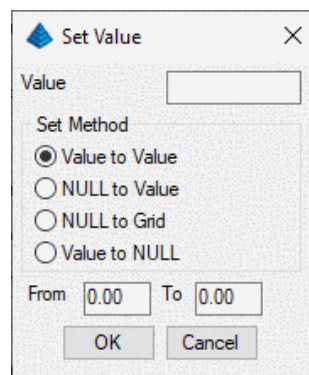

- **Add Value:** Adds an entered value to the grid values. ($\text{GridA} + X$)
- **Add Grid:** Adds one grid to another grid. ($\text{GridA} + \text{GridB}$)
- **Subtract Value:** Subtracts an entered value from the grid values. ($\text{GridA} - X$)
- **Subtract Grid:** Subtracts one grid from another grid. ($\text{GridA} - \text{GridB}$)
- **Multiply Value:** Multiplies the grid values by an entered value. ($\text{GridA} * X$)
- **Multiply Grid:** Multiplies the grid values by another grid. ($\text{GridA} * \text{GridB}$)
- **Divide Value:** Divides the grid values by an entered value. (GridA / X)
- **Divide Grid:** Divides the grid values by another grid. ($\text{GridA} / \text{GridB}$)
- **Power Value:** Raises the grid values to the specified power. ($\text{GridA} ^X$)
- **Power Grid:** Raises the grid values to another grid for the "power". ($\text{GridA} ^\text{GridB}$)
- **Offset Value:** Offsets the grid elevations perpendicular to the grid surface. Use a negative value to offset down.
- **Tan(), Sin() and Cos():** Applies these functions to the grid values which need to be in decimal degrees. ($\tan(\text{GridA})$, $\sin(\text{GridA})$, $\cos(\text{GridA})$)

- **Comparison Functions:**

- **Max Value:** Compares a grid and a value and takes the Maximum value of either. This is a way to stop a grid from going negative, below zero.
 - **Max Grids:** Compares a grid with another grid and takes the Maximum (higher) value of either.
 - **Min Value:** Compares a grid and a value and takes the Minimum value of either. This is a good way to cap a grid off at a certain value so it never goes higher than the specified value.
 - **Min Grids:** Compares a grid with another grid and takes the Minimum (lesser) value of either.
 - **Less Value:** Asks for a value to compare and a value to assign and uses the following logic:
If $\text{GridA} < \text{compare_value}$ then $\text{GridA} = \text{assign_value}$, otherwise no change
 - **Less Grids:** Asks for a grid to compare and a grid to assign and uses the following logic:
If $\text{GridA} < \text{compare_GridB}$ then $\text{GridA} = \text{GridC}$, otherwise no change
 - **Greater Value:** Asks for a value to compare and a value to assign and uses the following logic:
If $\text{GridA} > \text{compare_value}$ then $\text{GridA} = \text{assign_value}$, otherwise no change
 - **Greater Grids:** Asks for a grid to compare and a grid to assign and uses the following logic:
If $\text{GridA} > \text{compare_GridB}$ then $\text{GridA} = \text{GridC}$, otherwise no change
- **Set Value:** assigns the grid elevations to the user-specified value. Using inclusion and exclusion perimeters are usually required for this command. For example by using Set Value with the inclusion perimeter option, you could set the grid values to 0.0 within the inclusion polyline for a strata thickness grid. The four options are:
 - Value to Value will set all values to one value
 - Null to Value will set all Nulls to one value
 - Null to Grid will set all Nulls to another specified grid
 - Value to Null will set all values to Null.

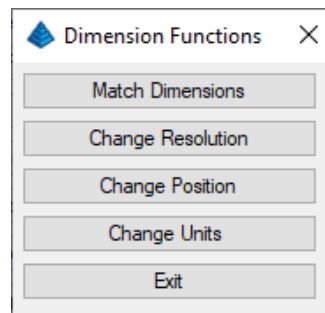

- **Extrapolate:** This function will assign values to null grid nodes by one of four methods.
 - Global Trend finds the average slope and slope direction from the existing grid elevations and applies this slope to calculate the missing elevations.
 - Average method calculates a grid elevation as the average of its nearest neighbors. This will create a very flat extrapolation.
 - Projected method extends the trend at the edge (as opposed to finding an average slope of the entire surface like the Global option).
 - Combined method uses a combination of both the Average and Projected methods.

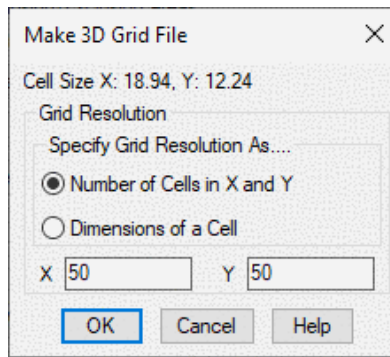

An example extrapolation of a surface using each method is shown below in 3D and in a profile view. The Original surface (brown color) is an example valley that only contains data in the center of the grid.

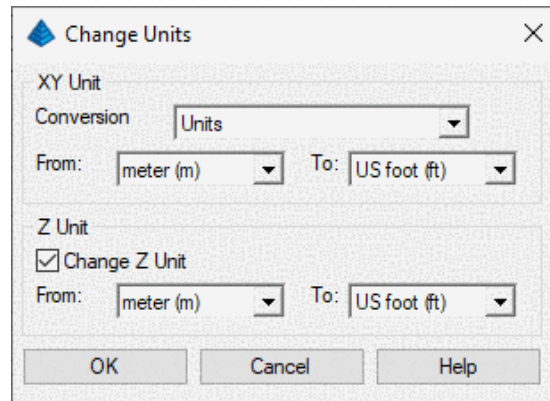

- **Dimension Functions:**

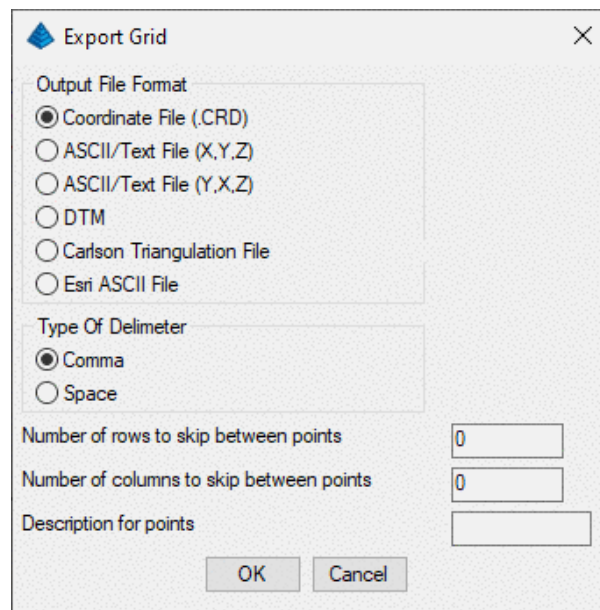

- **Match Dimensions:** Sets the grid position and resolution to match another grid file. The program will prompt for a grid file to get the position from. Certain commands require grids match position and resolution. Running this command will ensure grids will match.
- **Change Position:** This lets you change the lower left and upper right corners of the grid file. For example, you can use this routine to localize a grid file if you have a large grid for the entire site but are currently working on a smaller area. If the new position covers area outside the original position, any grid cells in this area will be assigned a null value. Otherwise the program uses the original grid values for the new grid position.
- **Change Resolution:** This changes the grid resolution (number or dimensions of grid cells). The program uses the original grid values for calculating the grid values at the new resolution. Enter a new value for X and Y number of cells or dimensions of cells.

- **Change Units:** Scales the grid X/Y and/or Z values to switch units such as meters to feet.

- **Apply Geoid:** Adjusts the grid elevations by the selected geoid. To use this function, the grid projection must be defined in the Settings > Drawing Setup command.
- **Slope Grid:** Converts a grid of elevations to a grid of slope values expressed as a percentage.
- **Smooth Grid:** This function has three smoothing method. The **Least-Squares** method applies a moving least-squares algorithm to adjust the grid elevations. The **Eliminate Spikes** method adjusts grid nodes with elevations too different (spikes) from neighbors within the **Search Radius**. The **Search Scaler** is used to identify spikes to adjust by using this scaler multiplied by the standard deviation of the grid values within the search radius. The **Interpolate Radius** is used to select the grid values for recalculating the grid value at the spike. **Quadratic Smoothing** uses neighboring nodes to adjust each grid node. This routine can be used to refine a grid so that the contours from the Contour from Grid routine appear smoother. Typically this adjustment is relatively small. To get more smoothing, run the routine more times.
- **Plot Grid:** This runs the Draw 3D Grid command.
- **Export Grid:** There are several choices for export options: Carlson Coordinate File (CRD), ASCII text as XYZ, ASCII text as YXZ, DTM, Digital Elevation Model (DEM), TIF, Carlson Triangulation (TIN) and Esri (ASC). There are two options for the ASCII delimiter, either a comma or a space. There is an option to skip a number of rows and columns between the exported points. When exporting into the Carlson CRD file, the description for the points is set at the bottom.

Export to DTM writes the current grid file to a DTM format text file. The format of this file is the following:

DTM 1.0 Header Line

test.dtm Name of file

51 Number of cells in X direction

51 Number of cells in Y direction

79442.4697 Lower left grid corner Y coordinate

14899.0326 Lower left grid corner X coordinate

0.0 Lower left grid corner Z coordinate

11.5618 Dimension of cell in X direction

7.0639 Dimension of cell in Y direction

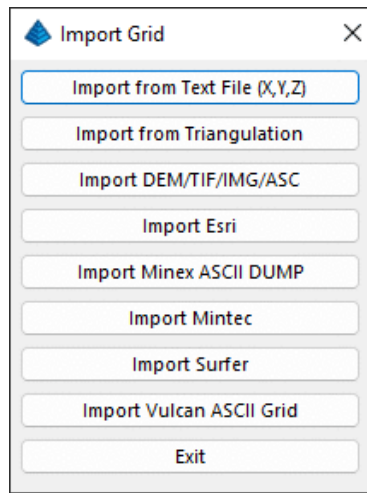

1581.2612 Grid cell values starting from lower left, moving from left to right

1580.8879

1580.3257

etc...

- **Merge Grids:** creates a grid file by merging together two existing grid files, grid1 and grid2. The current grid is grid1 and the program will prompt for a second grid. These two grids must overlap with the same location and resolution. The inclusion and exclusion perimeters apply to grid2 such that the merged grid will consist of grid2 cells within the inclusion perimeters and outside the exclusion perimeters and grid1 cells everywhere else. The result is stored in the current grid.
- **Import Grid:** There are several formats that may be imported.
 - Text File (ASCII): This function allows for various formats. The data can be comma or space separated or in fixed width columns.
 - Carlson Triangulation (TIN, FLT)
 - Digital Elevation Model (.DEM, .TIF .IMG or .ASC) such as from the USGS (US Geological Survey)
 - Esri (ADF)
 - Minex ASCII DUMP (ASC, CSV)
 - Mintec
 - Surfer (GRD both ASCII and Binary)
 - Vulcan ASCII Grid (ASC, CSV)

Import from Text File (X, Y, Z) creates a grid file from X Y Z data in any text file. There does not need to be a current grid file loaded since this routine will create a grid file. The text file should consist of one X Y Z coordinate per row with the first coordinate being the lower left grid corner and the last coordinate as the upper right grid corner. There are options for space or comma separated coordinates and for the order of the coordinates as either row (left to right) or column (bottom to top). The prompting will be as follows:

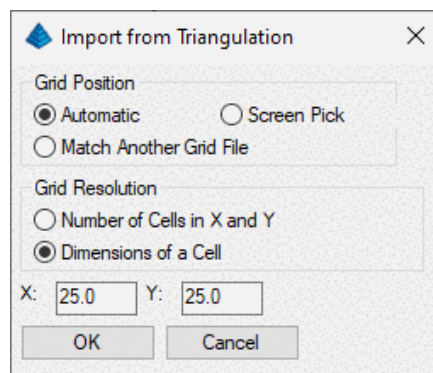

Separation type [<Space>/Comma/FixedWidth]?

Column number for X coordinate <1>:

Column number for Y coordinate <2>:

Column number for Z value <3>:

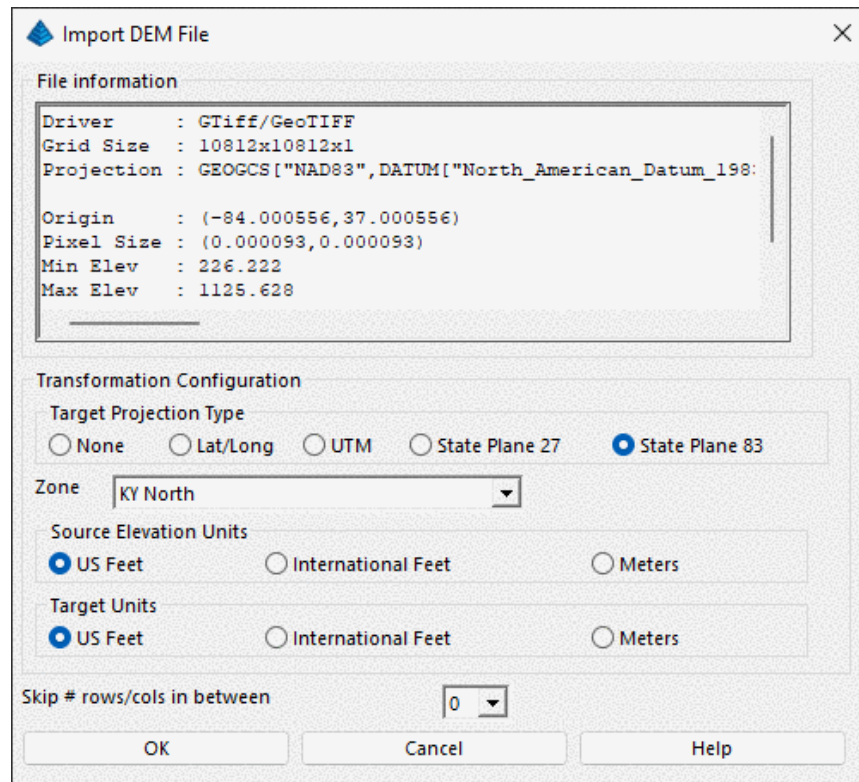

Import from Triangulation prompts user to select a tin or flt file and allows user to adjust grid position and resolution. The grid file is created with the same name in the same directory as the selected tin/flt file.

Import DEM/ESRI prompts the user to select a DEM, ADF, or ASCII ESRI grid file to be imported. The ESRI grid files can be created from ArcMap using the Raster To ASCII tool. If the file format is recognized, the program reads, and displays information about the source projection of the DEM/ADF/ESRI file, and allows the user to define a target projection for transforming the grid to a local coordinate system. the Source Elevation Units define the units of the Z values if they cannot be automatically detected. The Target Units will set the units for the X, Y, and Z values of the new grid. Note that if the Source Elevation Units and the Target Units use different units, the Z values will be scaled accordingly.

The "Skip every # rows/cols" option allows the user to reduce the size of the imported grid file. In the case of a DEM/ESRI files each pixel of elevation information of the DEM/ADF image data is interpreted as representing an elevated point located in the center of that pixel (not multiple points located on the edges of that pixel). In contrast, the "Import DEM/ADF File Dialog" will output the "Origin" of the DEM/ADF file in terms of the raster pixel extents. The output grid file is created with the same name in the same directory as selected DEM/ADF/ESRI

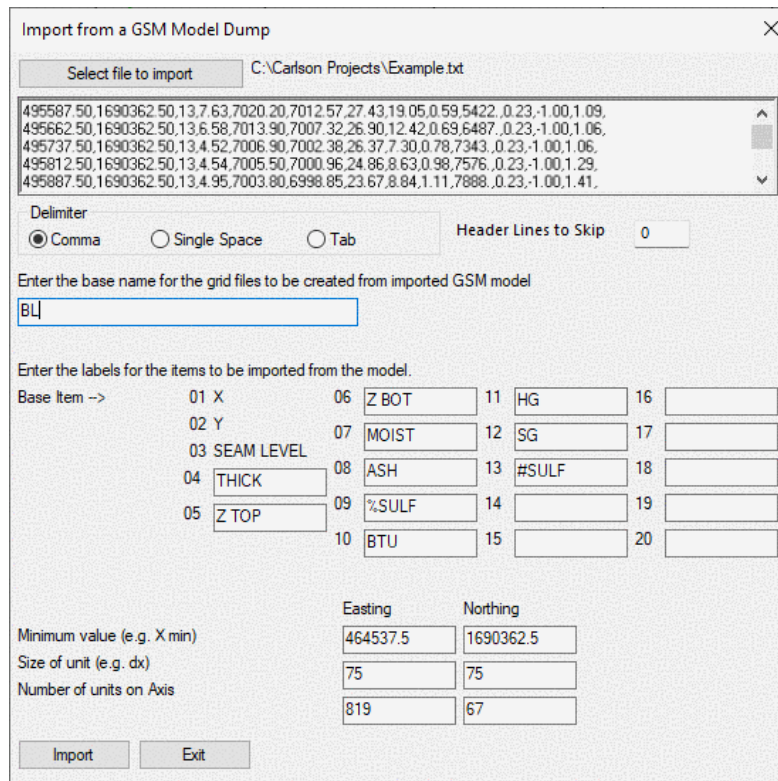

file.

Import Minex ASCII DUMP allows user to import multiple Minex ASCII grids from a single .asc or .csv file. The imported grids will be automatically named according to the header information in the .asc/.csv file. An example File Format is provided below.

```
; origin      3051045.00      952377.25
; extent      5375.50      4042.63
; mesh        15.00      15.00
; rotation    0 00 00
; x    1    12
; y    13    12
; SeamRoof    25 10
; SeamFloor   35 10
; SeamThick   45 10
3051052.50    953764.75      920.76
3051052.50    953779.75      922.01
3051052.50    953794.75      923.29
3051052.50    953809.75      924.60
3051052.50    953824.75      928.38      925.93
3051052.50    953839.75      940.24      927.30
3051052.50    953854.75      941.63      928.69
3051052.50    953869.75      943.06      930.11
3051052.50    953884.75      944.52      931.56
3051052.50    953899.75      946.01      933.04
3051052.50    953914.75      947.54      934.55
3051052.50    953929.75      949.10      936.10
```

Import Mintec allows user to import Mintec GSM Model Dump as grd files. User is prompted to select GSM Model Dump (txt) file, which is then processed to determine minimum northing, easting (lower left corner), resolution and size of the grid. First three columns of the GSM model dump must represent the X, Y and SEAM LEVEL respectively, a base name for the grid files is specified along with name of the quality that each column represents. User can define up to 17 qualities. When the import button is pressed all the imported grids are created with the name "BASE NAME-SEAM LEVEL-BASE ITEM.grd" in the same directory as source dump file.

Import Surfer prompts to select a grd file from Surfer program and creates a grd file.

- **List Grid:** displays a list of the northing, easting and elevation of each grid corner. There is an option to Include NULL values in the list. A grid node will have no value, or a Null value (listed as None) if the grid node was outside the limits of the data during Make 3D Grid File.

Carlson Software Edit : C:\Users\tfaulkner.CARLSON\...

File Edit Settings

- **Grid Info:** This function displays information about the grid file. It is a form of Grid Statistics. The items it

displays are shown in the report below:

Macro Editor: The Macro Command Recorder allows you to create a script for grid modification and save these steps to a .gfu file. These macros can be rerun to repeat grid modifications when the source grids are modified, thus saving time on tedious manipulation. Macros can also be reviewed for accuracy, whereas manual manipulation of grid files cannot be checked with as much detail. When writing a macro, you essentially perform the normal grid manipulations using the functions on the left of the dialog. Although the prompts will be slightly different than manual manipulation, the steps will be automatically added to the text window. You can then copy/paste the text as needed to speed up the macro-writing process.

Quick notes on the macro editor:

- You may enter the script manually (typing each variable, function, etc), or you may use the function buttons on the left. Some functions are more easily written manually compared to using the function dialogs on the left.
- Function templates may be inserted using the "Template to Insert" droplist on the left. Using these templates, you can see an example of the syntax for each function.
- You may add comments to the script to allow for easier review. Comments are simply preceded by a semi-colon (;). With the exception of the PERIM, INCLU, and EXCLU functions, any text following a semi-colon will be seen as a comment (the program will not attempt to read it upon execution of the script)
- Most all function follow a syntax of RESULT=FUNCTION. For example, to evaluate the result of adding Grids A and B together to create Grid C, the function would be written as C=A+B.
- When a variable is first defined, the variable will take on the grid dimensions (cell size and lateral extent) of the right side of the equal sign. For Example, consider an exmaple in which variable A is defined as a grid and B is not yet defined. If you write the equation B = A + 5, then variable B will cover the same lateral extent and will use the same grid cell size as variable A.

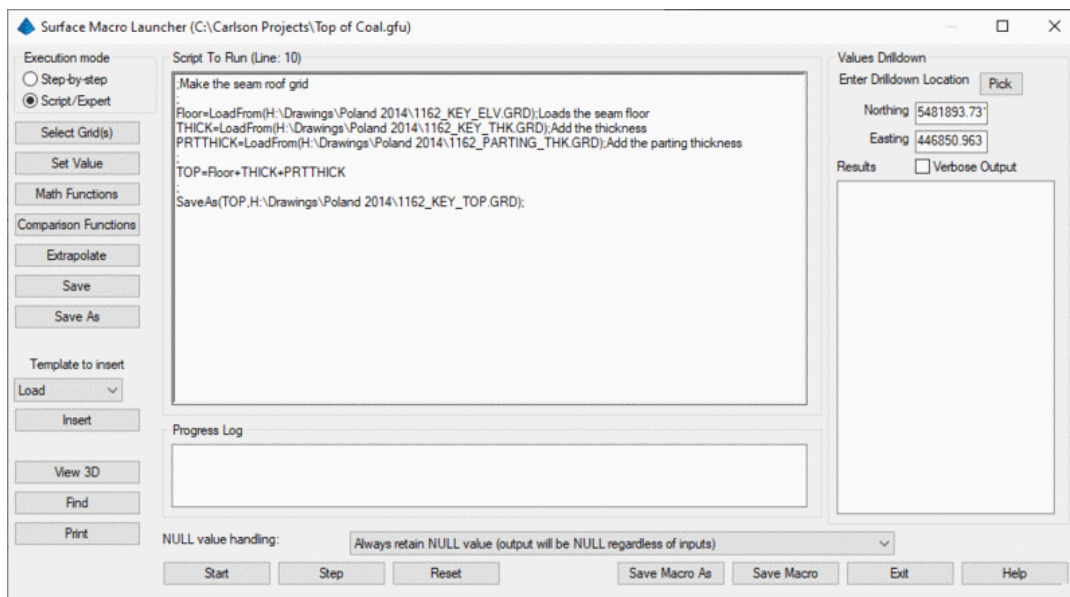

If two grid variables do not use the same grid dimensions, they can still be compared (note that this is not possible with manual manipulation of the grids). For example, if Grid A and Grid B cover only partially overlap, the equation B = A + 5 will allow Grid B to retain it's original dimensions, but it will only be updated where it overlaps A. In this way, you can avoid the intermediate step of settings grids to the same location/cell

size in order to compare them.

- When using the functions on the left side of the dialog (Math Functions, Comparison Functions, etc), you will sometimes be able to select existing grid variables from a dropdown list. In order for this list to be populated with the existing grid variables, you must first Start the macro, otherwise the program will not display the existing grid variables.
- When adding a step that involves another grid file, there are three options for storing this grid into the script. Use Grid Variable will use the grid assigned to the Grid Variable Name. Prompt for Grid File Name will bring up a grid file selection dialog each time the macro is run. Store the Grid File Name will save the specific grid file name into the macro.

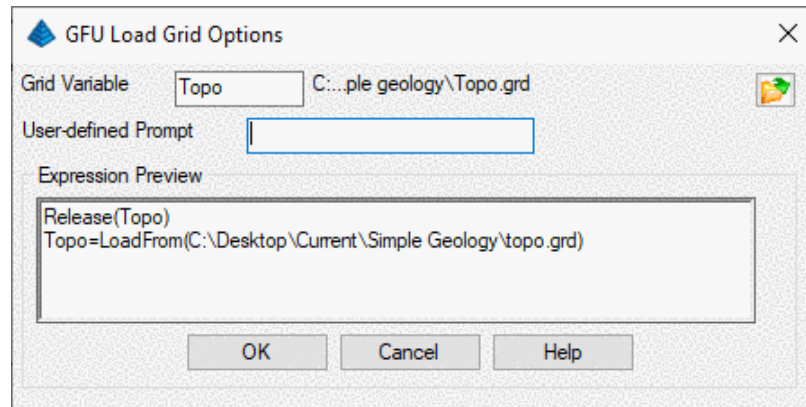

Surface Macro Launcher Details

The Surface Macro Launcher displays the GFU file name in the upper menu bar. This is an editor, and you can use basic functions like CTRL-X, CTRL-C & CTRL-V for cut, copy, & paste. GFU files also can be edited easily in any text editor, such as Notepad, WordPad or K-Edit. If there are any errors in the GFU during its execution, they will be displayed in the error log section when the macro runs. The Values Drilldown on the right side of the dialog allows you to inspect the calculations/grid variables at an actual Northing-Easting location, which is especially useful for checking that the results are correct. You may screen-pick a location by clicking the Pick button, or you may manually enter the Northing and Easting coordinates. As the macro runs, each variable will be display in the text readout below these options. If the Verbose Output option is disabled, only a summary of the grid variables will be displayed, with each variable updating as the macro runs. If the Verbose Output option is enabled, the results from each line of the macro will be displayed in the text readout.

- **Step-by-Step:** This execution mode is a simpler method and is intended to be executed immediately. It is similar to the previous windows simple "button pushing" to execute a function. These two modes have completely different dialogs when the functions are selected.
- **Script/Expert:** This mode stores the history and is a replayable history of the operations. It contains all of the higher level features and options, and is for the users who want to program it manually.

- **Select Grids:** In the Step-by-Step mode, the File Open dialog appears to select the file. In Script/Expert mode, the following dialog initially appears to add the expression to the macro for replaying. This function releases a variable if it is previously defined, and loads a grid file and assigns a variable to it. Another option is to enter an User-defined Prompt instructing the user on which grid to select at the time the macro is run. The dialog appears as shown. The preview shows how it will look when inserted into the macro.

- **Set Value:** This function sets the grid to new values based on the selected options. The Step-by-Step method has the following Set Functions shown in the first image below. The Expert method functions are shown in the second image. The expression #1 can either be set to a Value/Expression or to a New Grid file. The operation type contains four options of Set Value.

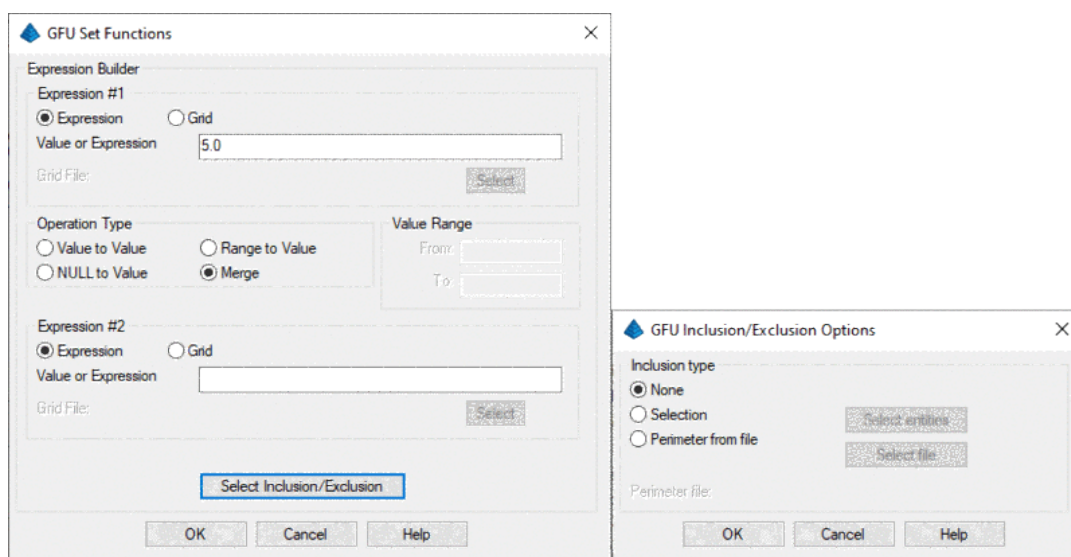

Value to Value (A=B for each point of A, sets the value to the value of B, Expr#1))

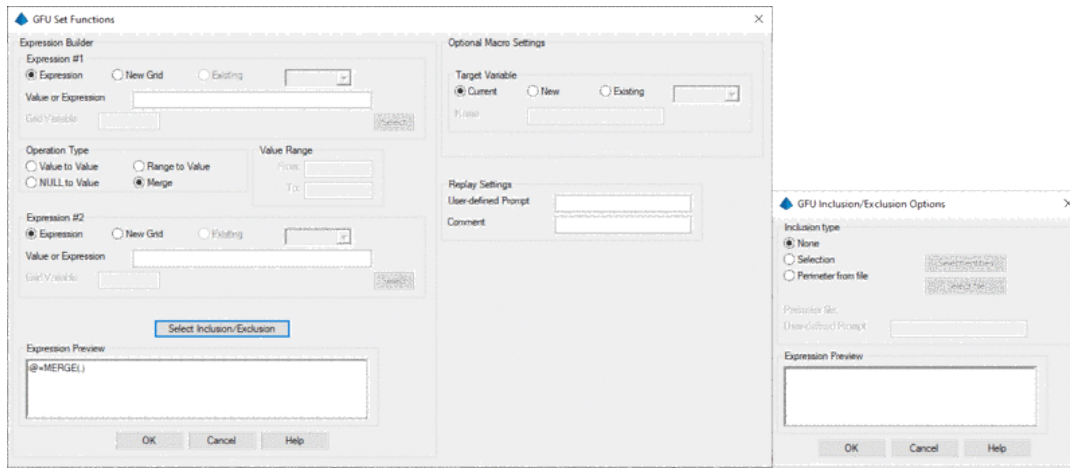

Null to Value (C=SET_NULL (A,B), For each point of C, sets the value to the value of A (Expr#1) if defined and the value of B (Expr#2) otherwise)

Range to Value (A=CHANGE_RANGE(B,C,D,E), for each point of A, if value of B (Expr#1) is between C and D, sets the value to value of E (Expr#2) or Null if not specified)

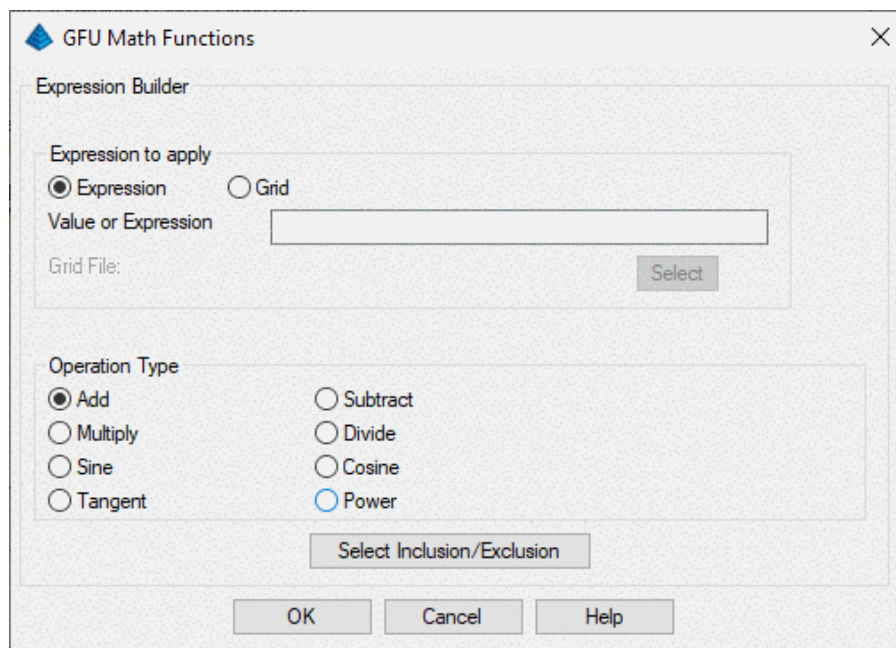

Merge (C=MERGE(A,B), for each point of C, sets the value to the value of B (Expr#2) if defined and the value of A (Expr#1) otherwise). Expression#2 is what the value will be set to, or to a new grid.

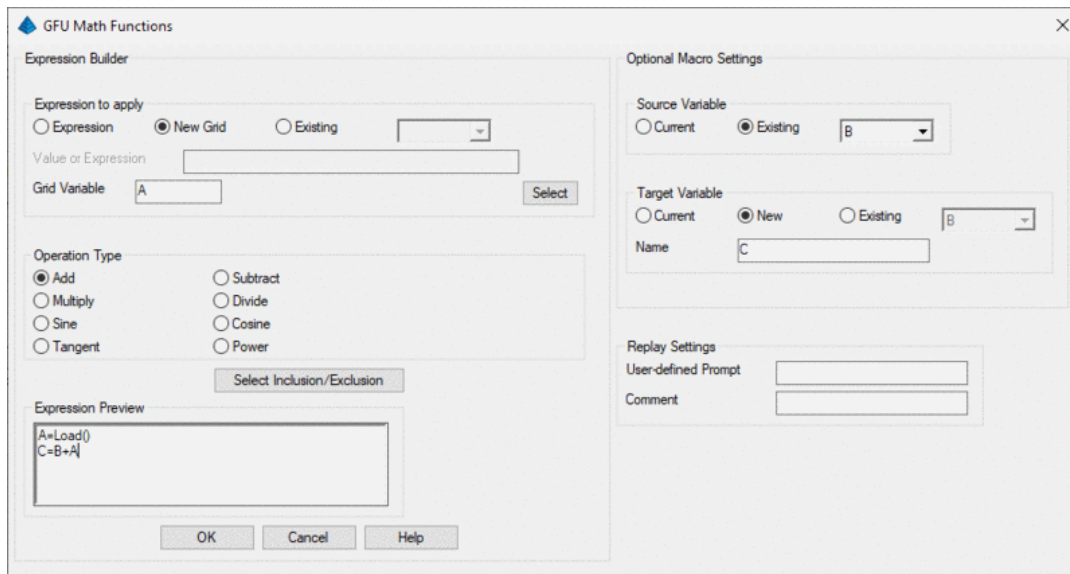

The Select Inclusion/Exclusion options can be set to None, Selection (manually select polyline), or a PLN polyline file. Note that PLN files may be created with the Export Polyline File command. The preview of the expression appears in the expert mode. These two modes appear the same in all the various functions. To set a grid to NULL, where the values fall within a range, use the following format: A=CHANGE_RANGE_VALUE(A,lowrange,highrange,NULL)

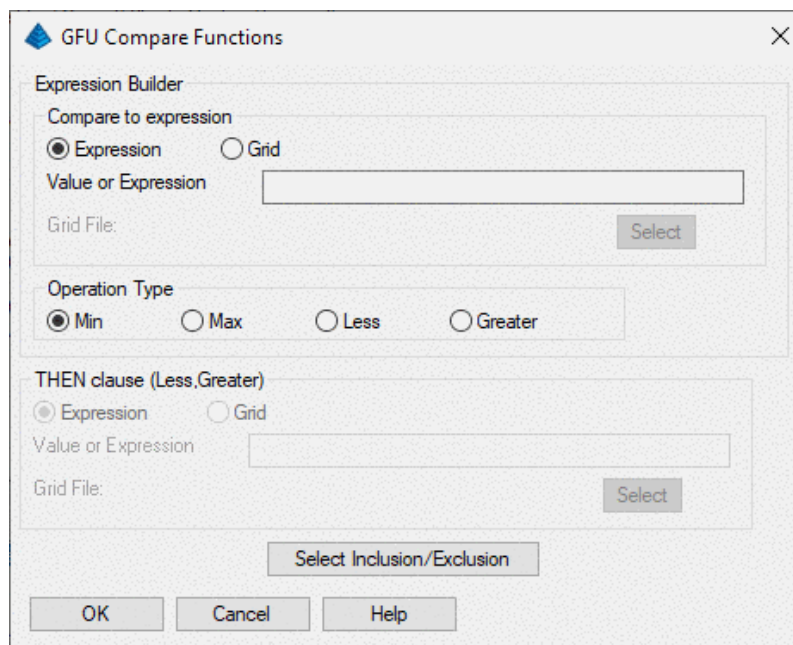

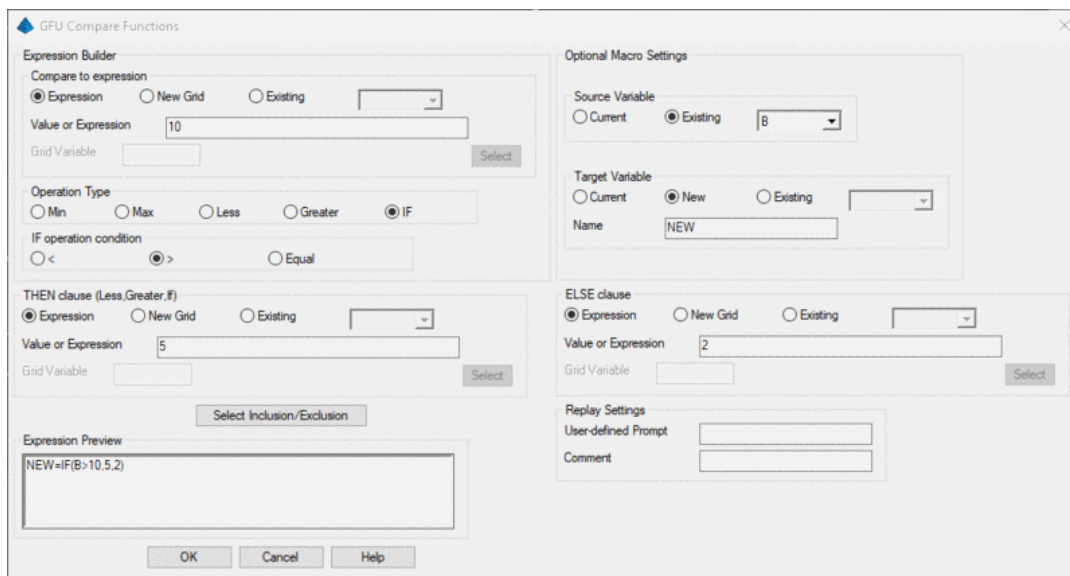

- Math Functions:** These functions apply the mathematical operations selected to the loaded grid. The Step-by-Step mode dialog is shown first, followed by the Script/Expert mode. The operations are Add, Subtract, Multiply, Divide, Sine, Cosine, and Power function.

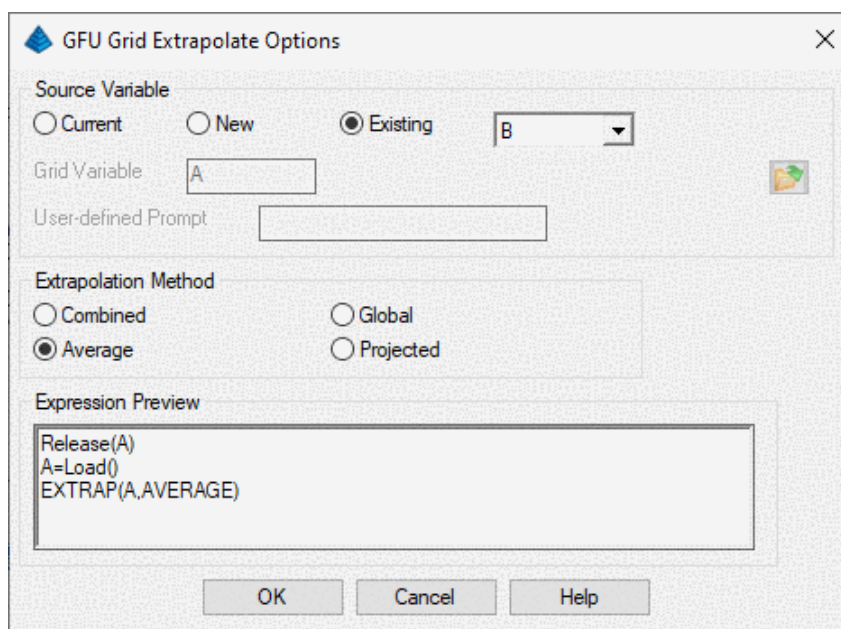

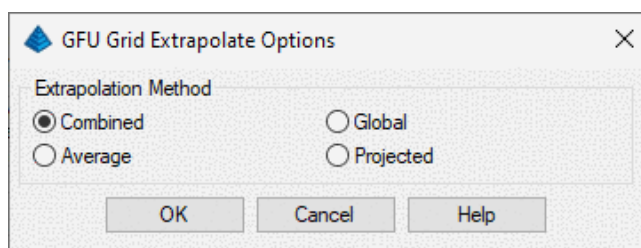

- Comparison Functions:** The Step-by-Step mode uses the Min, Max, Less, and Greater commands for grid editing. This is shown below in the first dialog. The second one shows the Script/Expert dialog that also contains the If Statement functions. The IF statement is the standard format of IF This, Then This, Else This. The Preview shows how it will appear in the GFU syntax.

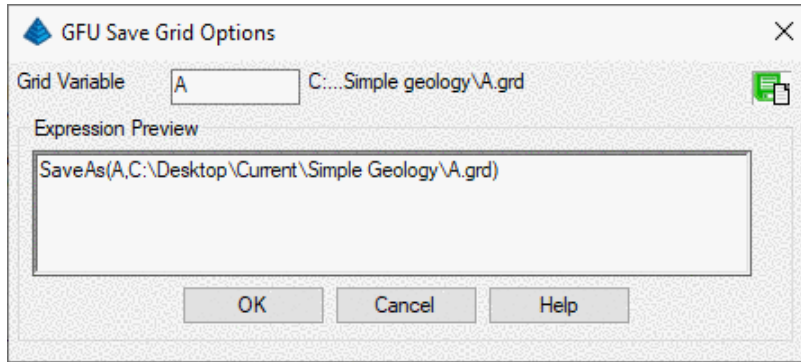

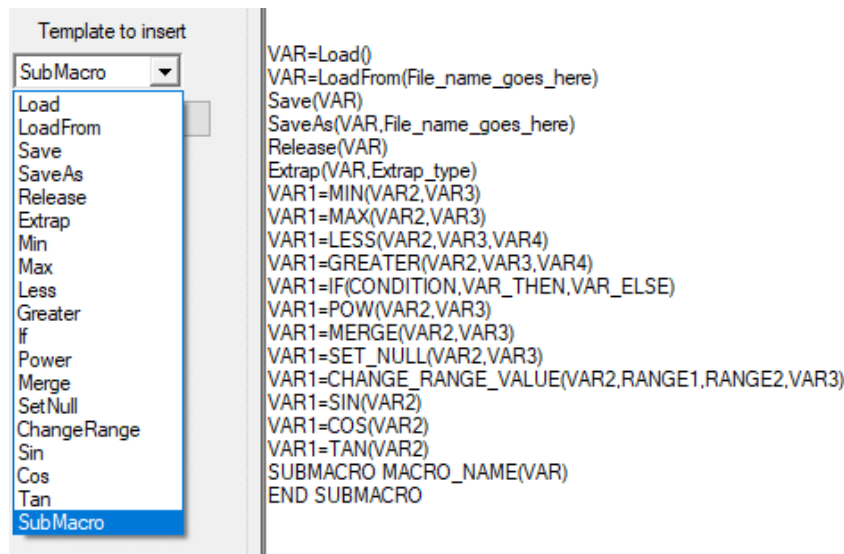

- **Extrapolate:** This function uses the four methods described above to extrapolate the grid to fill in any Null values. Details on each extrapolation method are provided above.

- **Save/Save As:** These commands add the syntax of saving to the macro. The variable can be the existing, or set to a new one here.

- **Template to insert:** This option allows for easy insertion of the syntax for the following functions.

- **Nested Submacros:** It is possible to define a macro for a certain function, and then call that macro and apply it to other variables in either the same macro, or in a different macro. Here are 3 examples of Submacros.

Submacro in the same macro that calls it. There are two submacros defined at the top, and then they are both called at the bottom, THICK2 and THICK.

```

SUBMACRO THICK()
A1=LOADFROM($PROJECTPATH\one.grd)
B1=LOADFROM($PROJECTPATH\two.grd)
C1=A1+B1;
SAVEAS(C1,$PROJECTPATH\three.grd)
END SUBMACRO
;
SUBMACRO THICK2(A,B,D)
C=A+B;
SAVEAS(C,D);
END SUBMACRO
;
A1=LOADFROM($PROJECTPATH\one.grd);
B1=LOADFROM($PROJECTPATH\two.grd);

```

```
THICK2(a1,B1,$PROJECTPATH\three_b.grd);
THICK()
```

Submacro in a different macro that calls it. The first step is to define the submacros in their own gfu, this one contains THICK and THICK2 and is saved as mymacros.gfu.

```
SUBMACRO THICK()
A1=LOADFROM(C:\downloads\one.grd);
B1=LOADFROM(C:\downloads\two.grd);
C1=A1+B1;
SAVEAS(C1,C:\downloads\three.grd);
END SUBMACRO;
;_____
SUBMACRO THICK2(A,B,D)
C=A+B;
SAVEAS(C,D);
END SUBMACRO;
```

INCLUDE: To include a previously defined macro in another macro, the INCLUDE function is used. Once mymacros.gfu is created, then it can be loaded (with INCLUDE) and referenced in another, separate GFU macro.

```
INCLUDE($PROJECTPATH\mymacros.gfu);

A1=LOADFROM($PROJECTPATH\one.grd);
B1=LOADFROM($PROJECTPATH\two.grd);
THICK2(a1,B1,$PROJECTPATH\three_b.grd);
THICK();
```

Here is an example, with comments, where the bottom elevation and the thickness are added together to get the roof, for 6 seams. The Submacro is defined by the equation just once. Then it is called and used 6 times at the bottom of the macro.

```
;Add the Floor and Thickness to get the seam Roof.
;Coal seams to apply this to are: C1,C2,C3,C4,C5,C6
;_____
;LOAD THE GRIDS INTO MEMORY
;
C1_KEY_ELV=LOADFROM(C:\Carlson Projects\C1_KEY_ELV.GRD)
C1_KEY_THK=LOADFROM(C:\Carlson Projects\C1_KEY_THK.GRD)
C2_KEY_ELV=LOADFROM(C:\Carlson Projects\C2_KEY_ELV.GRD)
C2_KEY_THK=LOADFROM(C:\Carlson Projects\C2_KEY_THK.GRD)
C3_KEY_ELV=LOADFROM(C:\Carlson Projects\C3_KEY_ELV.GRD)
C3_KEY_THK=LOADFROM(C:\Carlson Projects\C3_KEY_THK.GRD)
C4_KEY_ELV=LOADFROM(C:\Carlson Projects\C4_KEY_ELV.GRD)
C4_KEY_THK=LOADFROM(C:\Carlson Projects\C4_KEY_THK.GRD)
C5_KEY_ELV=LOADFROM(C:\Carlson Projects\C5_KEY_ELV.GRD)
C5_KEY_THK=LOADFROM(C:\Carlson Projects\C5_KEY_THK.GRD)
C6_KEY_ELV=LOADFROM(C:\Carlson Projects\C6_KEY_ELV.GRD)
C6_KEY_THK=LOADFROM(C:\Carlson Projects\C6_KEY_THK.GRD)
;_____
;DEFINE THE SUBMACRO EQUATION
;
```

SUBMACRO ROOF(X,Y,Z)

TOP=X+Y

SAVEAS(TOP,Z)

END SUBMACRO

;
;

ROOF(C1_KEY_ELV,C1_KEY_THK,C:\Carlson Projects\C1_KEY_TOP.grd)

ROOF(C2_KEY_ELV,C2_KEY_THK,C:\Carlson Projects\C2_KEY_TOP.grd)

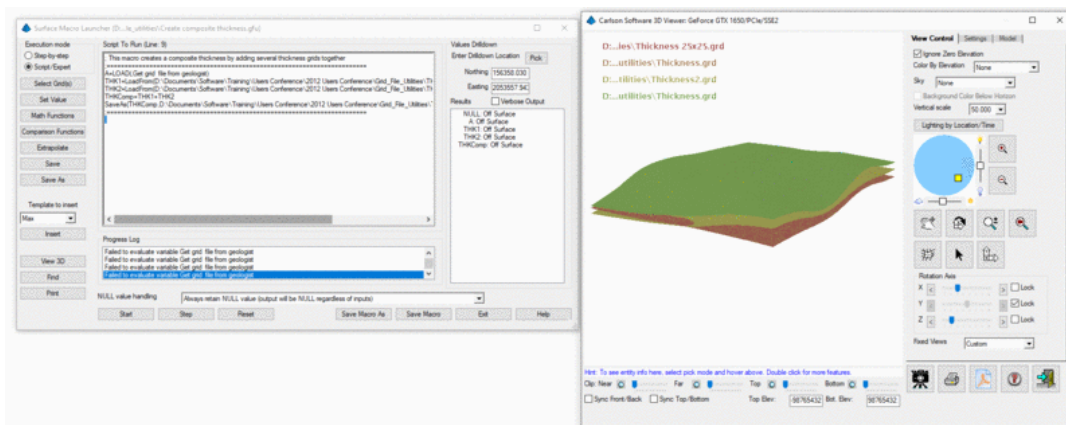

ROOF(C3_KEY_ELV,C3_KEY_THK,C:\Carlson Projects\C3_KEY_TOP.grd)

ROOF(C4_KEY_ELV,C4_KEY_THK,C:\Carlson Projects\C4_KEY_TOP.grd)

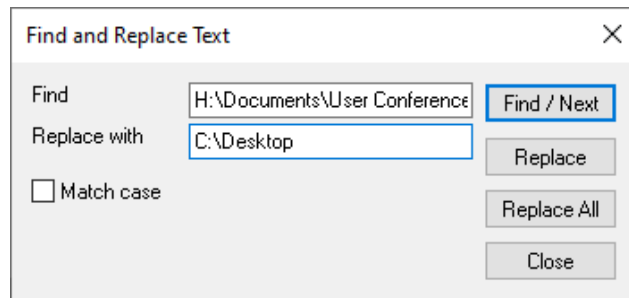

ROOF(C5_KEY_ELV,C5_KEY_THK,C:\Carlson Projects\C5_KEY_TOP.grd)

ROOF(C6_KEY_ELV,C6_KEY_THK,C:\Carlson Projects\C6_KEY_TOP.grd)

- **View 3D:** Using this option brings up the 3D Surface Viewer that steps through live all of the grids and displays them in 3D. This can be left open and moved to the side, or to another monitor to see all the surfaces and how they are modified, in a 3D view.

- **Find:** This is a Find, or Find and Replace to search the GFU text and make edits. It is useful if a file path has changed and all need to be reset to somewhere else.

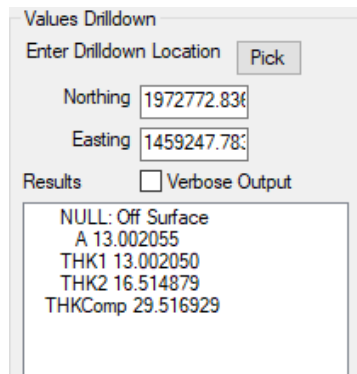

- **Print:** There are two options for printing. The Script Window prints out the entire GFU syntax. The Results Window prints out

- **NULL Value Handling:** This option determines how null values will be handled in the grid calculations. The "Always retain NULL Value (output will be NULL Regardless of inputs)" option will force any calculations with NULL inputs to create a NULL output. The "Treat NULL as 0.0 if one or more inputs are non-NULL";

Retain NULL if all inputs are NULL)" option will replace null values with zeros for calculations, but will retain null values in the output if all inputs are null.

- **Start/Step/Reset:** These buttons allow for individual stepping through the macro. It will advance only one line at a time with the Step. Start will run the entire macro. Reset will begin back at the beginning.
- **Save Macro As/Save Macro:** This saves the GFU macro either as its original name, or as a new name with Save As.
- **Values Drilldown:** The Values Drilldown is a good method for error checking on the macro. Use the Pick button to select a spot in plan view to fill in the Northing and Easting boxes. Then when the GFU is executed, the results of each line will be displayed. The Verbose Output will show the value of each line L1, L2, etc., instead of overwriting the variable each time it is encountered.

Variables

Variables in the GFU can be any keywords providing meaningful identification of the data loaded. A variable can be either just a value or constant; or most commonly a surface (Grid or TIN). Individual macro lines typically have one of the following forms:

Variable1=Variable2

Variable1=Expression

Variable1=Function(Expression1,Expression2)

Whenever new variable name is encountered on the left side of the equation, the new variable will be created. The program will use its knowledge of the right side of equation to define a type of the new variable. For example:

A=1.0 Variable A will be just a value

A=LoadFrom(abc.grd) Variable A is a grid loaded from file

B=A Variable B is same variable type as A

B=(1+C+A)/D Variable B will be 1+C+A, all divided by D. C and D will need to be defined somewhere before this line in the GFU.

Important!: Once a variable is defined, its type (like grid location and resolution) does not change. Therefore, for the existing variable A, the following expression:

A=Min(B,C)

is interpreted in the following way: for every point of the existing surface A calculate values of surface B and C and use the smaller of the two values to set new value of point elevation on surface A.

The following operators may be used in the expressions:

+, -, *, / - regular arithmetic operators

<, >, =, ! (not) - logic operators

— (or), & (and) - binary operators

Changing the scope of the equation

The scope of any line of the script can be modified by adding one of the following inclusion/exclusion operators:

A=Min(B,C);INCLU(handle_here) - will use AutoCAD entity with specified handle for the inclusion

A=Min(B,C);EXCLU(handle_here) - will use AutoCAD entity with specified handle for the exclusion

A=Min(B,C);PERIM() - will prompt for inclusion/exclusion at run-time

A=Min(B,C);PERIM(file_name) - will use specified file with inclusions/exclusions

Multiple inclusions or exclusions can be appended in this manner. Only points of target surface (A) passing inclusion/exclusion filter will be evaluated.

For custom, user define prompting, the following text should be used:

PERIM(,Prompt goes here) for user defined interactive inclusion and exclusion selection in CAD

The following script functions are currently defined:

Macro functions (performing operations on the entire surface at once)

- LOAD() Prompt user for the file to load. Returns a variable.
- LOAD(,Prompt goes here) for user defined prompting
- LOADFROM(string) Load surface from file. Grids (GRD) and TINs (FLT, TIN) are supported. Returns a variable.
- SAVE(Variable) Saves surface back to original file.
- SAVEAS(Variable,FileName) Saves surface into a file with given name.
- RELEASE(Variable) Releases memory used by a surface and undefines it for further use.
- EXTRAP(Variable[,Type])

Micro functions (taking effect on point by point basis as controlled by left side of the equation) Expressions can be complex ones with variables, value and functions

- MAX(Expression1,Expression2) Sets value to larger of two expressions evaluated.
- MIN(Expression1,Expression2) Sets value to smaller of two expressions evaluated.
- LESS(Expression1,Expression2,Expression3) If result of Expression1 is less than Expression2 then result is Expression3. Otherwise the source point is not changed. If Expression3 is not specified value is set to NULL.
- GREATER(Expression1,Expression2,Expression3) If result of Expression1 is greater than Expression2 then result is Expression3. Otherwise the source point is not changed. If Expression3 is not specified value is set to NULL.
- IF(Expression1,Expression2,Expression3) If Expression1 (can be logic expression like $(A+B)>C$ or $A=B$ or $A!B$ 'not equal') not 0 then result is Expression2, otherwise it is Expression3.
- POW(Expression1,Expression2) Result is value of Expression1 in power of Expression2
- MERGE(Expression1,Expression2) If Expression2 is valid at a point, then result is that value, otherwise it is value of Expression1
- SET_NULL(Expression1,Expression2) If Expression1 is valid at a point, then result is that value, otherwise it is value of Expression2
- CHANGE_RANGE_VALUE(Expression1, Range1, Range2, Expression2) If Expression1 is a valid point and its value is greater than equal to Range1 and less than equal to Range2, then result is Expression2. If Expression2 is not specified value is set to NULL.
- TIN_INTERSECT(Expression1,Expression2) Expects both Expression 1 and Expression 2 to be TIN's. This will add vertices to Expression 1 where Expression 2 has vertices. In this way, one TIN can be made to have vertices at the same XY locations as another TIN. Note that this function does not need to be preceded by "Variable=".

Here is an example of a complex IF statement used for coal recovery based on thickness of the seam:

```
COALTHK=LoadFrom(C:\Carlson Projects\Grids\C40_THK.GRD);
ROM_COAL=COALTHK
ROM_COAL=if((COALTHK<2)—(COALTHK=2),COALTHK - (COALTHK * 0.50),ROM_COAL)
ROM_COAL=if(((COALTHK<4)—(COALTHK=4))&(COALTHK>2),COALTHK      -      (COALTHK      *
0.10),ROM_COAL)
ROM_COAL=if((COALTHK<7)&(COALTHK>4),COALTHK - (COALTHK * 0.075),COALTHK - (COALTHK
* 0.05))
SaveAs(ROM_COAL, C:\Carlson Projects\Grids\C40_ROM_THK.GRD)
```

Pulldown Menu Location: Surface and Grids

Keyboard Command: GFU

Prerequisite: Make a grid (.GRD) file with the *Make 3D Grid File* command.

Edit 3D Grid

This command edits the elevation of a grid node by graphically picking the grid corner and entering a new elevation. The grid is a surface model that is represented by a rectangular mesh of grid cells. Each grid cell has four corners with elevation. This command modifies the elevation of one of these grid corners. After picking the grid node to edit, the program draws a temporary X marker on the selected point and shows the current elevation for the point. Before running this routine, a grid (.GRD) file must be created with the *Make 3D Grid File* command. Also the grid must be drawn on the screen using the *Draw Surface >> Draw 3D Grid File* command. Besides updating the elevation of the grid in the drawing, the grid file may also be updated. Whether to update the grid file is specified at the first prompt in the program.

Prompts

Update drawing only (Yes/<No>)? *press Enter* Choose between modifying the grid drawing or both the grid drawing and file.

Select Grid node to edit: *pick a grid cell corner*

Enter new Grid node elevation <305.519>: *press Enter*

Select Grid node to edit: *press Enter to end*

Pulldown Menu Location: Surface > Modify Grid File

Keyboard Command: editgrid

Prerequisite: A .GRD File and drawn grid 3D Faces

Merge Grid Files

This command creates a grid file by merging together two existing grid files, grid1 and grid2. The current grid is grid1 and the program will prompt for a second grid. These two grids must overlap with the same location and resolution. The inclusion and exclusion perimeters apply to grid2 such that the merged grid will consist of grid2 cells within the inclusion perimeters and outside the exclusion perimeters and grid1 cells everywhere else. The result is stored in the current grid.

No elevations are calculated on grid cells that extend beyond the extent of the data. Extrapolation can be used to calculate elevations for the grid cells that are beyond the data limits. The prompt *Extrapolate grid to full grid size?* shows when there are grid cells with no elevation in a grid (.GRD) file. Extrapolation fills in all the grid cells. The method to extrapolate uses a safe calculation that tends to average out or level the extrapolated values. So

extrapolated grid areas are not as accurate as grid areas within the limits of the data.

Merged Grid File to Write Dialog(*new file select dialog*)

Pulldown Menu Location: Surface >> Modify Grid File

Keyboard Command: mergegrd

Prerequisite: Two grid (.GRD) files

One Triangulation Surface Volumes

This command calculates and reports the volume between a triangulation surface (.tin, .flt) file and a reference. The reference can be either an elevation or the TIN perimeter. The elevation method applies to cases like having a triangulation surface for the bottom of a pond and calculating the water volume to a water elevation. The TIN perimeter method creates a second surface by triangulating the perimeter points of the TIN. This method applies to cases like stockpile volumes where the base of the stockpile is not level and is covered so that the perimeter is the only data available to model the base.

In the Volume Report Options, the Cut and Fill Swell Factors are multiplied by the Cut and Fill volumes for the report. The Report Tons option multiplies the volumes by the specified density to report tons. The Write TIN Difference option creates a new TIN surface of the elevation difference between the triangulation and reference surfaces.

Note: The volume comparison of this routine uses the triangulation surface file as the *base* surface, and the reference as the *fnal* surface. So be aware that if your reference is set primarily below the surface defined by the triangulation file, it will report as cut, when in reality you may be filling above the reference to reach the defined surface.

Pulldown Menu Location: Surface > Volumes By Triangulation

Keyboard Command: trivoll

Prerequisite: Triangulation (.flt or .tin) file

Two Triangulation Surface Volumes

Volumes By Triangulation is a volume method that compares two triangulation networks. This method is different from the grid based volume routines (*Volumes By Layer*, *One Surface Volumes*, *Two Surface Volumes*, *Stockpile Volumes*, etc.) and the cross section volume routine (*Calculate Section Volume*). Volumes by Triangulation calculates faster in most cases than the other methods, and it is the most accurate because it uses true TIN to TIN prismatic volumes. This added accuracy in general is very small. The grid resolution is usually sufficient to model the surface for the grid based volumes. The Volume By Triangulation accuracy applies well when there is a feature like a 5 foot wide ditch. Then the grid resolution would need to be less than 5 feet to model the ditch which might be difficult on a large site.

When multiple inclusion polylines are selected, there is an option to Report Multiple Perimeters Separately which reports the volumes for each inclusion separately. Otherwise the total volumes from all the inclusions is reported. For the separate inclusions report, the report will include the names assigned to the polylines by either the Tag Predefined Boundaries, Tag Area Descriptions, Tag Area Of Interest or Name Pit Polylines commands.

The disadvantage to this routine is that it lacks the output options that help the analysis of the volume such as Difference Contours. Also Volumes by Triangulation does no extrapolation and stops calculating volume at the perimeter of the smaller of the two triangulation networks. Volumes By Triangulation is better when used with point data instead of contour data because contour data requires triangulating all the contour polylines as breaklines which creates a large triangulation network and is slower.

The triangulation networks to compare are defined in .tin or .flt files that are created by *Triangulate & Contour* with the Write Triangulation File option. Note that while both file formats are supported, the newer binary triangulation file format (.tin) is twice as fast to load and save, and half the size, of the .flt triangulation file format. For this reason, the .tin file format is recommended. Before using this command, run *Triangulate & Contour* twice to create an triangulation (.TIN or .FLT) file for each surface. The volume calculation is limited by either the extent of the triangulation networks or by an inclusion/exclusion perimeter(s). These perimeters must be closed polylines.

Output data includes area, tons by density, average thickness, shrink and swell, ratio, and total volume.

Shrink/Swell Factors

An optional aspect of the Volumes by Triangulation routine is the ability to supply either a *Cut "Swell" Factor* and/or a *Fill "Shrink" Factor* to the results of the volume calculation. Having a solid understanding on the ramifications of each factor is important for determining how (and when) the values should be used for earthwork considerations.

The factors are commonly expressed as decimal differences from the "factor neutral" value of 1.00. In most cases, surface models are representations of what currently exists in the field or what is desired to exist after construction. Consider the following examples:

Excavating a Pit

Suppose you are given the task of designing a below ground storage pit. Based on your design surface model, the amount of Cut has been determined to be 1,000

C.Y.Cut Swell Factor > 1 (example 1.15)

Supplying a Cut Swell Factor greater than 1 would usually be taken to mean "How much volume will my 1,000 C.Y. of material occupy when it comes out of the ground?" With a 15% swell factor (1.15) applied, the 1000 C.Y. of excavated material would now occupy 1,150 C.Y. of space.

Cut Swell Factor < 1 (example 0.85)

Supplying a Cut Swell Factor less than 1 would usually be taken to mean "How much volume will 1,000 C.Y. of material occupy in this hole when it has been compacted?" With a 15% compaction factor (0.85) applied, the 1000 C.Y. of material getting compacted would now occupy 850 C.Y. of the hole space.

Working with a Stockpile

Suppose you have a stockpile of material that is suitable for building purposes. Based on your design surface model, the amount of material has been determined to be 1,000 C.Y.

Fill Shrink Factor > 1 (example 1.10)

Supplying a Fill Shrink Factor greater than 1 (see NOTE below) would usually be taken to mean "How much volume would this 1,000 C.Y. of material occupy if it were picked up and deposited elsewhere?" With a 10% swell factor (1.10) applied, the 1000 C.Y. of stockpile material would occupy 1100 C.Y. of space.

Fill Shrink Factor < 1 (example 0.90)

Supplying a Fill Shrink Factor less than 1 would usually be taken to mean "How much volume will 1,000 C.Y. of stockpile material occupy when it has been compacted?" With a 10% compaction factor (0.90) applied, the 1000 C.Y. of material getting compacted would now occupy 900 C.Y. of the hole space.

Note:

- In a design Fill scenario (such as a berm), often it is desired to know how much material would need to be brought in at a given compaction factor to occupy the design fill. To determine this value, use the following equation:

$$\text{Fill Factor} = 100.0 / (100.0 - \text{shrink_percentage}), \text{ using } 15\% \text{ shrink as an example,}$$
$$\text{Fill Factor} = 100.0 / (100.0 - 15.0) = 1.17647$$

Prompts

Select EXISTING Surface Triangulation File *Choose an .flt or .tin file*

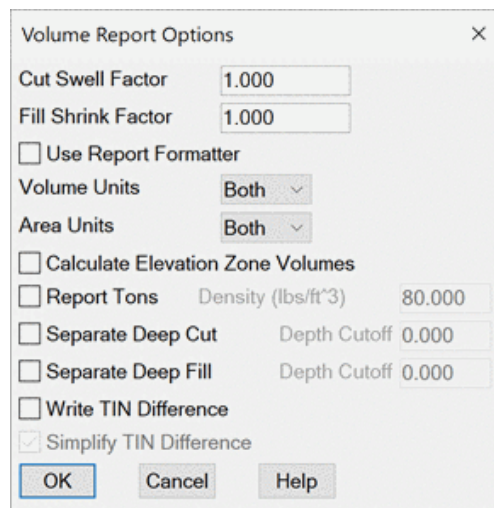

Select FINAL Surface Triangulation File *Choose an .flt or .tin file*

Select Inclusion polylines.

Select objects: *select objects* that form a perimeter around the area of study

Select Exclusion polylines.

Select objects: *select objects* that form an exclusion area within the area of study

Cut Swell Factor: Supply an appropriate factor by which the calculated Cut volume should be multiplied.

Fill Shrink Factor: Supply an appropriate factor by which the calculated Fill volume should be multiplied.

Use Report Formatter: Choose between customizing the report and using the standard report.

Volume Units and Area Units: Choose the units to include in the report.

Calculate Elevation Zone Volumes: This option calculates cut/fill volumes within elevation ranges. The ranges use a specified elevation interval and can start from the top or bottom.

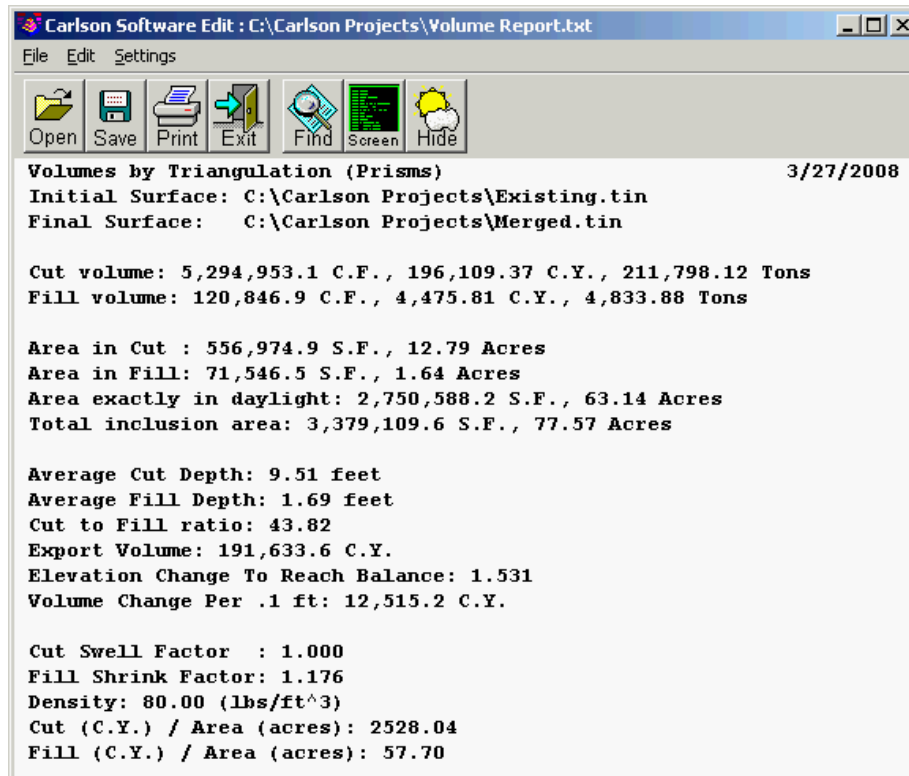

Report Tons: Enable this option to report the tonnage of Cut material and Fill material based on the material density.

Density: Specify the average material density for calculating the tons.

Separate Deep Cut/Fill: These options report the amount of cut/fill that is deeper than the specified Depth Cutoff.

Write TIN Difference: Enable this option to create a TIN based on the elevation difference between the EXISTING surface and the FINAL surface.

Simplify TIN Difference: Combining TINs to make the difference TIN can result in many small triangles. This option reduces the small triangles in this difference TIN.

Overexcavate area: 3,363,077.2 S.F., 77.21 Acres

The amount of Cut into the Strata surface is reported, as well as Other Cut, Total Cut and Total Fill. The Areas for the same are also reported. The volume and area of Overexcavation is also reported.

Pulldown Menu Location: Surface >> Volumes By Triangulation

Keyboard Command: trivol3

Prerequisite: 3 Surface Files (.FLT or .TIN)

One Grid Surface Volumes

This command calculates the cut and fill volumes between the surface modeled by one grid (.GRD) file and a constant elevation or value. This is the same as *Two Grid Surface Volumes* except that the second surface is a flat plane at a constant elevation instead of a 3D grid surface. Please refer to that section for additional details. If the grid contains grid cells that have no elevations, you have the option to extrapolate elevations from the grid cells with elevations. When you choose not to extrapolate, no volume is calculated for these grid cells. There are also options to specify inclusion and exclusion areas. When inclusion areas are specified, only the volume within this inclusion area is calculated. Volumes within an exclusion area are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to using this command.

Note: the volume comparison of this routine uses the selected grid file as the *base* surface, and the target elevation plane as the *fnal* surface, so be aware that if your target elevation is set primarily below the surface defined by the grid file, it will report as cut, when in reality you may be filling above the target elevation plane to reach the defined surface.

Extrapolate grid to full grid size (Yes/<No>)? *press Enter* If you enter Yes to this prompt, surface elevations will be computed for any grid cells that have null elevations.

Enter the base elevation: *1500* This defines the second surface.

Volume Report Options Dialog

Pulldown Menu Location: Surface >> Volumes By Grid Surfaces

Keyboard Command: volcalc1

Prerequisite: A grid (.GRD) file

Two Grid Surface Volumes

Two Grid Surface Volumes calculates the cut and fill volumes between two surfaces modeled by grid (.GRD) files. These two grid files must have the same location and resolution. To create the grid files, use the *Make 3D Grid File* routine. When creating the second grid file, choose *Use position of another file* and select the first grid file. Using the position of the first grid file sets the location and resolution of second grid to match the first.

There are several other routines that calculate volumes based on grid files. Grid based volumes can be calculated by *One Grid Surface Volumes*, *Volumes by Layer*, *Stockpile Volumes*, and *Pond/Pit Volumes*. These routines have special prompting and calculate the grid surfaces and volume in one step.

Volumes by Two Surface Volumes has three steps:

1. Creating the first grid file with *Make 3D Grid File*
2. Creating the second grid file with *Make 3D Grid File*
3. Running *Two Grid Surface Volumes*

One advantage to this command is that you have more output options to help analyze volumes.

Besides grid based volumes, volumes can also be calculated between triangulation surfaces using the *Volumes by Triangulation* commands. Cross section end area is another volume method that is used by the *Calculate Sections Volume* command in the Civil Design module.

There are also options to specify inclusion and exclusion areas. When inclusion areas are specified, only the volume within this inclusion area is calculated. **Important:** Whenever possible you should use a polyline that represents the limits of disturbed area as the inclusion perimeter. Volumes within an exclusion area are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to calling this routine.

If the grid contains grid cells that have no elevations, you have the option to extrapolate elevations from the grid cells with elevations. When you choose not to extrapolate, no volume is calculated for the grid cells left without elevations. In general, extrapolation is not very accurate and should be avoided whenever possible. Sometimes you may get small amounts of cut in stockpiles that should only be fill, or small amounts of fill in pits that should only

be cut. These extraneous quantities are due to extrapolation at the border and should be small enough to be ignored. When inclusion or exclusion polylines are used, the program will automatically extrapolate the grids. In addition to writing a volume report to the file, printer or screen, there are several volume report options.

Write Difference Grid File creates a grid (.GRD) file of the elevation difference of the two grid files.

Draw Difference Contours creates a contour map of the difference or depth between the two grid files.

Draw Elevation Difference in Each Cell plots the elevation difference at the grid corners which is the same as the Elevation Difference routine.

Draw Volume in Each Cell plots the calculated volume for each grid cell and is an excellent way to verify the volume calculation. If a cell contains both cut and fill, both values will be plotted.

Calculate Elevation Zone Volumes calculates the cut and fill between different elevation ranges.

Draw Cut/Fill Color Map fills each grid cell with different shades based on the average cut or fill in the cell. Red shades are used for cut and blue for fill. There is an option to draw a color legend. You can subdivide the grid cells at zone transitions. Also, there is an option to control the zone intervals and range.

Use Report Formatter allows you to customize the report by choosing the fields to report and their order. Also the report formatter can be used to output the report data to Microsoft® Excel or Microsoft® Access.

Process Another Area with Current Grids runs Two Surface Volumes again using the same grid files but different inclusion/exclusion polylines. This option saves the step of reloading the grid files to calculate volumes from the same grids for multiple areas.

The **Cut Swell Factor** value is multiplied by the cut volume in the report.

The **Fill Swell Factor** value is multiplied by the fill volume in the report.

Report Tons allows you to enter the material density and the program will report the cut and fill tons in addition to volume.

Given two accurate grid (.GRD) files, this routine will calculate accurate volumes. To verify the volume calculation, it is a good idea to check the grid (.GRD) files either by drawing them with *Draw Surface >> Draw 3D Grid File* and viewing them with *the 3D Viewer* or by contouring the grids with the *Contour Grid File* command.

Existing surface

Final surface contours with a closed polyline

Contours from the Draw Depth/Difference Contours option. Cut contours are red, fill contours are blue, daylight contours are green. This is a good way to check that both surfaces are modeled correctly and to verify the volumes.

This shows a grid drawn by *Plot 3D Grid File* and volume values drawn by the Draw Volume in Each Cell option of the Two Surface Volumes routine. Cut appears as negative and fill as positive. Notice that cells bordering cut and fill regions contain a little of both.

Pulldown Menu Location: Surface >> Volumes By Grid Surfaces

Keyboard Command: volcalc2

Prerequisite: Two grid files

Volumes By Layer

This is the easiest yet still equally accurate method for calculating volumes. For this command, volumes are calculated in one step by a simple window of the area, selecting the items, and *calculate*.

First, you must specify the grid location and resolution. The grid location should enclose the area for volume calculations. Next the program asks for the layer names of the entities for the base and final surfaces. You designate the layers to use for each surface either by typing the layer names or by picking from the screen, then during the routine you select the entities to use. You may safely use the keyword *ALL* to select the entities, since you have pre-defined the layers to use, and all those entities not on the specified layers will be filtered out. These entities, for use in modeling the surfaces, can be points, lines (such as triangulation lines), 2D polylines (such as contours), and 3D polylines (such as breaklines).

Inclusion and exclusion perimeters may optionally be specified to limit the volume calculation area on the grid. An inclusion perimeter should be used if there is a closed polyline for the limit of the disturbed area. Then the program internally generates grids of the surfaces from the entities on the corresponding layers and then calculates and reports the volume. The main disadvantage to this routine is that it doesn't have the special output options of *Two Grid Surface Volumes* such as Depth Contours.

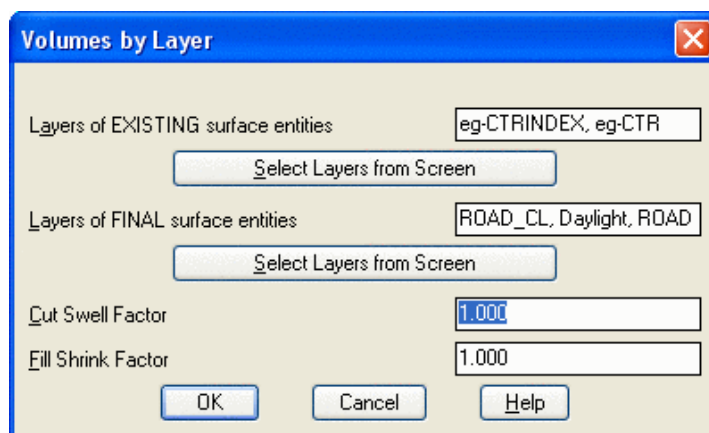

Prompts

Command: *layervol*

Pick Lower Left limit of surface area: *pick lower left corner of grid*

Pick Upper Right limit of surface area: *pick upper right corner of grid*

You are then prompted to designate layers:

Cut/Fill Report

This command reports the cut/fill between two surfaces at an interval. The existing and design surfaces can be either triangulation (TIN) or grid (GRD). After selecting the surfaces, the program prompts for optional inclusion and exclusion polylines to control the report area. Then there is an options dialog. The report works with the Report Formatter for choosing which fields to show including cut/fill, existing elevation, design elevation, northing and easting.

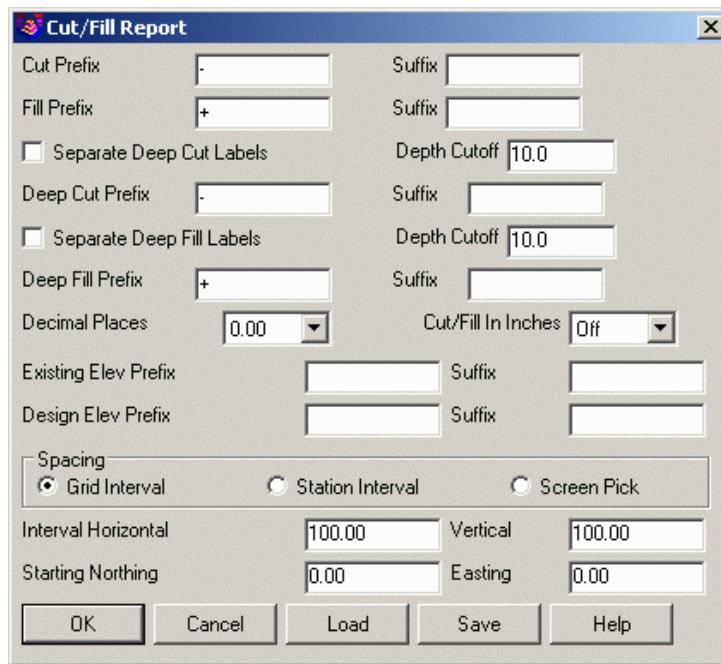

In the options dialog, you can customize the Cut/Fill labels. Text can be added either before or after the Cut/Fill amount, the Existing elevation, and the Design elevation with the Prefix and Suffix fields. Decimal Places sets to how many decimal places the labels will report. The Cut/Fill In Inches labels in feet and inches to the specified precision. The Separate Deep Cut/Fill Labels settings allow for highlighting deep areas by changing prefix/suffix labels.

The Spacing methods include:

Grid Interval: Places the labels at the specified Horizontal and Vertical Intervals starting with the specified Northing and Easting coordinate.

Station Interval: Uses a centerline polyline and places the labels at a station interval along this alignment.

Screen Pick: Prompts for each label position.

Pulldown Menu Location: Surface > Cut/Fill Utilities

Keyboard Command: cfreport

Prerequisite: Existing and design surfaces

Cut/Fill Labels

This command displays the design elevation, the existing elevation, and the amount to either cut or fill directly on the screen. The design and existing elevations can be defined by triangulation files, grid files or points.

In the Elevation Difference Label Options dialog, you can customize the Cut/Fill labels. Text can be added either before or after the Cut/Fill amount, the Existing elevation, and the Design elevation with the Prefix and Suffix fields. You can also choose whether or not to display the Existing Surface elevations and the Design Surface elevations. The Draw Marker Symbol option draws the specified symbol block at each label point. The Hide Drawing Under Labels option creates Wipeout entities around the labels so that you can read the labels clearly. Text Size chooses the text size for each line of the label. Text Style allows you change the Font Style displayed in the labels. Decimal Places sets to how many decimal places the labels will report. The Cut/Fill In Inches labels in feet and inches to the specified precision. The Separate Deep Cut/Fill Labels settings allow for highlighting deep areas by making them a darker color or adding prefix/suffix labels. The Label Cut and Label Fill toggles allow you to turn off cut or fill and label only the other.

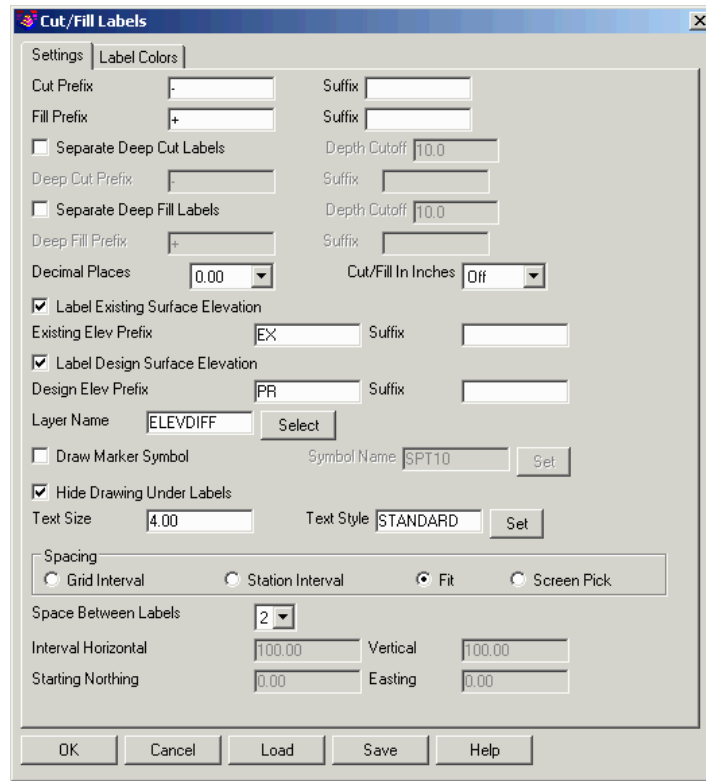

The Spacing Methods include:

Fit: Uses an inclusion perimeter and the size of the labels to make a series of rows and columns of labels that fit within the perimeter. The Space Between Labels sets the buffer around labels. The size of each space is determined by the Text Size.

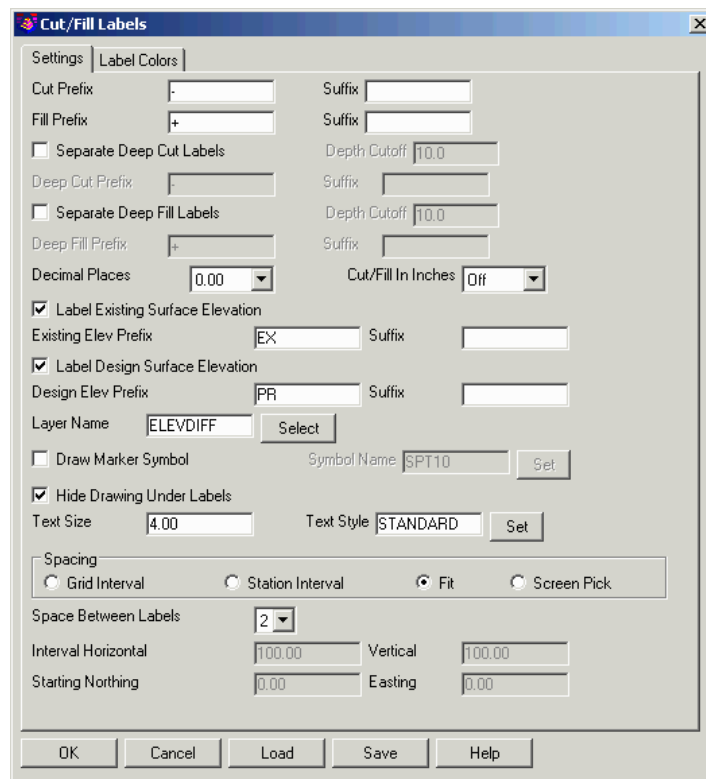

Grid Interval: Places the labels at the specified Horizontal and Vertical Intervals starting with the specified Northing and Easting coordinate.

Station Interval: Uses a centerline polyline and places the labels at a station interval along this alignment.

Screen Pick: Prompts for each label position.

On the Label Colors tab, the Automatic Coloring options choose a color scheme for the Cut-Daylight-Fill colors. The program will use a gradient color for the labels depending on the cut/fill value for the label. The deeper cut/fill values will have a deeper color. The Max Depth sets the value for the deepest color. You can also choose None for the Automatic Coloring and then set fixed colors for the cut and fill. The Custom method lets you specify all the colors and depth ranges.

The following image shows the main dialog box for setting the labeling options. The labeling created with these options looks like this:

PR117.00 EX129.59 -12.59	PR117.00 EX129.00 -12.00
PR117.00 EX127.40 -10.40	PR117.00 EX127.31 -10.31

The distribution of the labels on the site looks like this:

Pulldown Menu Location: Surface > Cut/Fill Utilities

Keyboard Command: elevdiff

Prerequisite: Existing and design surfaces

Cut/Fill Color Map

This command creates a cut/fill color map typically in red and blue in order to show the difference between grid or triangulation surfaces. In the options dialog, the ranges of the cut and fill zones are set along with the colors. The Automatic Colors has several colors styles to choose from for the cut to daylight to fill colors. When not using the Automatic Colors, the Cut/Fill Transition color is used for the zone between the smallest cut and smallest fill. For triangulation surfaces, the Map Subdivisions is how many times the surfaces will be divided in the X and Y directions to make cells for coloring. For example, Map Subdivisions of 50 makes 2500 colors cells from 50x50. The Limit Cut/Fill Map Range option is a way to draw the color map only for a specified range such as only showing the deep cut. The Auto Set function fills out the cut/fill ranges based on the current two surfaces. The Set By Interval function fills out the cut/fill ranges by a user-specified depth interval.

For analyzing using the grid option, you need to already have two existing grid files. If the grids are not visible in plan view, you may want to have them display on-screen using the *Draw 3D Grid File* command. The grids should overlap with the same location and resolution. The resulting red/blue map with legend is shown below.

No coloring is done on tin or grid cells that extend beyond the extent of the data. Extrapolation can be used to calculate elevations for the grid cells that are beyond the data limits. The prompt *Extrapolate grid to full grid size?* shows when there are grid cells with no elevation in a grid (.GRD) file. Extrapolation fills in all the grid cells. The method to extrapolate uses a safe calculation that tends to average out or level the extrapolated values. So extrapolated grid areas are not as accurate as grid areas within the limits of the data.

Prompts

For a color map showing differences between two grids:

Type of surface model source [Tin/<Grid>]? *press T* for a Triangulation (.TIN) file, or *press Enter* to accept default choice in brackets.

Select Base Grid File Dialog Select an existing .grd file.

Select Final Grid File Dialog Select a second existing .grd file.

Select Inclusion polyline: *pick a closed inclusion perimeter*

Select Exclusion polylines (Enter for none).

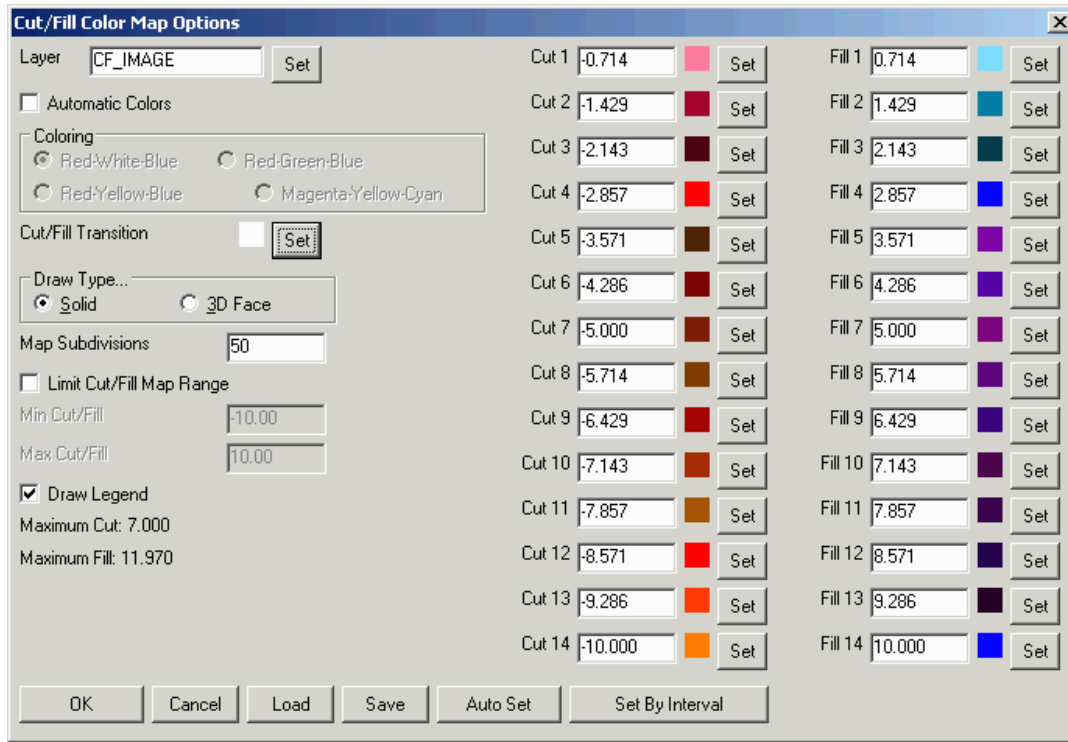

Select objects: *pick exclusion polylines or press Enter*

Cut/Fill Color Map Options Dialog

Select point for color legend: *pick a point*

Legend size <10.0>: *press Enter*

Label all zones or summary [All/<Summary>]?: *press Enter*

Pulldown Menu Location: Surface >> Cut/Fill Utilities

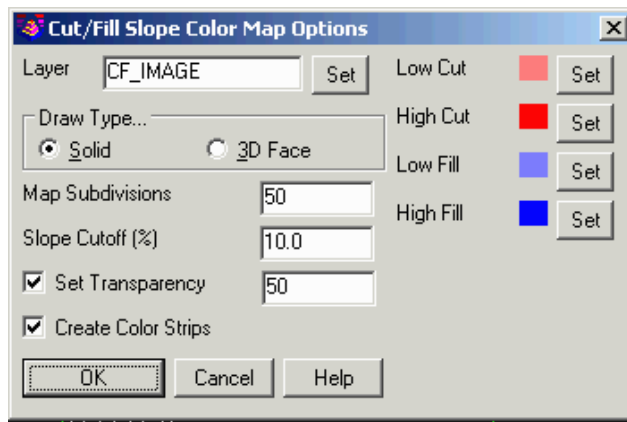

Keyboard Command: cf_map

Prerequisite: Two grid (.GRD), triangulation mesh (.FLT) or tin (.TIN) files

Cut/Fill Slope Color Map

This command creates color map like the Cut/Fill Color Map routine except instead of coloring by the amount of depth, this map uses different colors based on the amount of slope of the design surface. In the options, the Slope Cutoff sets the slope amount for using the specified low and high colors. Areas of cut that have a design surface slope below the cutoff are drawn with the Low Cut color and areas of cut over use the High Cut color. Likewise, areas of fill with a design surface slope below the cutoff use the Low Fill color and areas of fill over use the High Fill color.

The options dialog has settings for the color map properties including layer, entity type and transparency. The Map Subdivisions controls the resolution of the color map cells. A higher number makes more cells for higher resolution. The Create Color Strips option combines neighboring cells with the same color which speeds up the routine and makes for a smaller dwg size.

Prompts

For a color map showing differences between two grids:

Type of surface model source [Tin/<Grid>]? *press T* for a Triangulation (.TIN) file, or *press Enter* to accept default choice in brackets.

Select Base Triangulation File Dialog

Select Design Triangulation File Dialog

Select Inclusion polyline: *pick a closed inclusion perimeter*

Select Exclusion polylines (Enter for none).

Select objects: *pick exclusion polylines or press Enter*

Cut/Fill Color Slope Map Options Dialog

Pulldown Menu Location: Surface > Cut/Fill Utilities

Keyboard Command: cf_slope_map

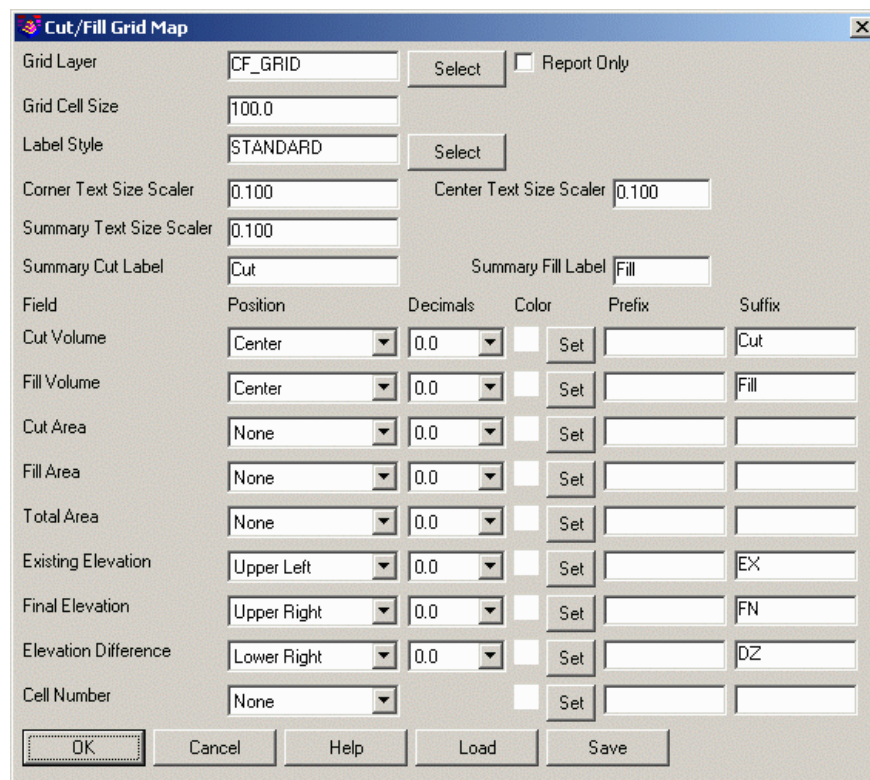

Prerequisite: Two triangulation surfaces

Cut/Fill Grid Map

This command labels cut/fill quantities and creates a report at a grid interval over the site. The grid cells are square at a specified size. The cut/fill quantities are calculated separately within each grid cell. The options dialog controls which cut/fill fields to label and the label position within the grid cell. There is a summary row at the bottom of the grid with the overall totals and sub-totals for each column.

After the options dialog, the program prompts for the corners for the area to grid. These corners should create a window around the site.

Then after drawing the grids and labels, the Report Formatter shows the cut/fill quantities for the grid cells. You can choose which fields to include in the report.

Prompts

Select Existing Triangulation File

Select Design Triangulation File

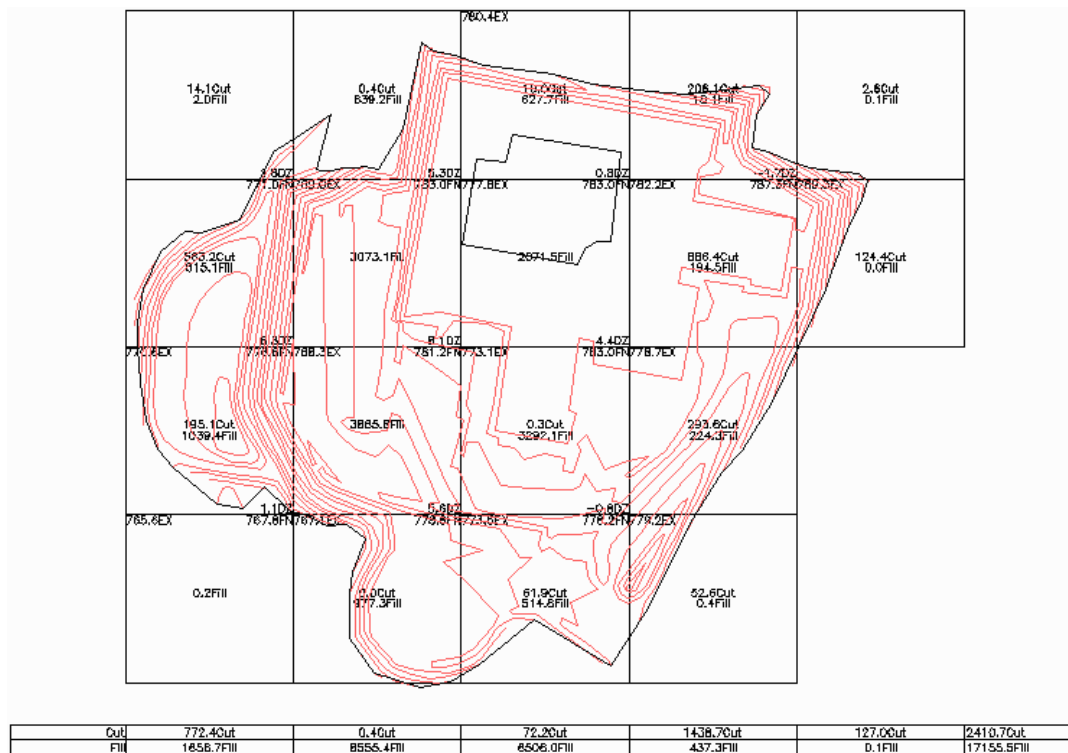

Select Inclusion polyline (Enter for none): *select polyline*

Select Exclusion polylines (Enter for none): *press Enter*

Cut/Fill Grid Map dialog

Pick first grid corner: *pick a point*

Pick second grid corner: *pick a point*

Sample Report:

Cell	Cut (C.Y.)	Fill (C.Y.)	Cut Area	Fill Area	Total Area
1	14.1	2.0	505.3	113.7	674.0
2	0.4	639.2	45.2	4693.4	4739.4

Pulldown Menu Location: Surface >> Cut/Fill Utilities

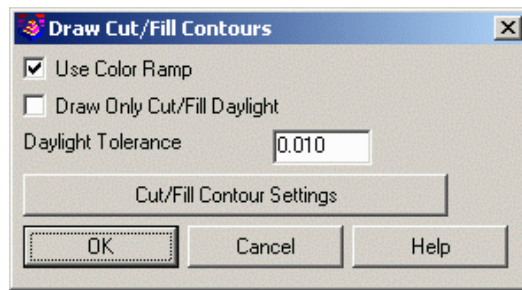

Keyboard Command: cf_grid

Prerequisite: Existing and design surfaces

Cut/Fill Contours

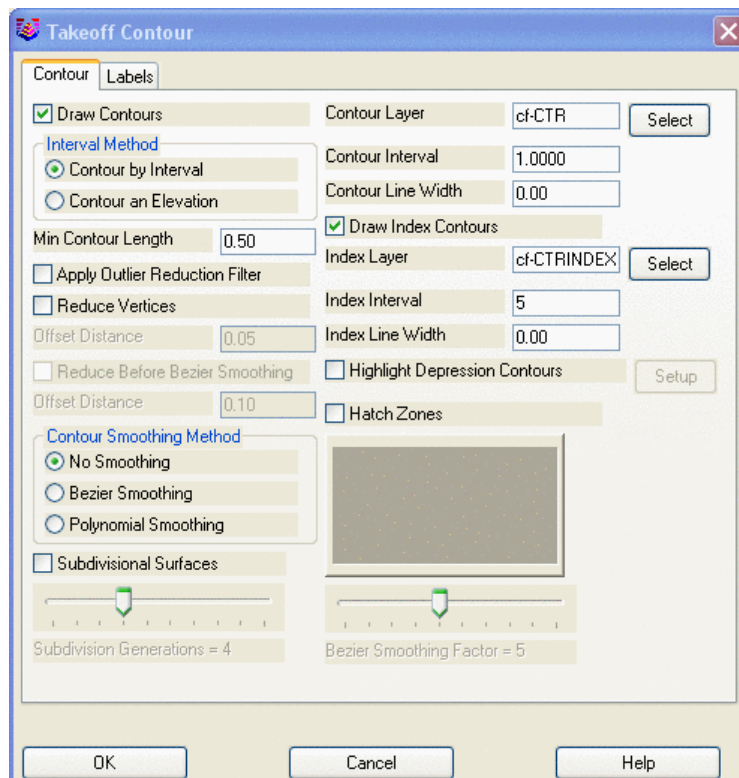

This command displays the amounts of cut and fill between two surfaces by computing and displaying cut/fill contour lines representing the amount of cut or fill along that line. Cut contours are displayed in red (with negative values), fill in blue (positive values), while the lines of zero cut (the "daylight" lines) are displayed in green ("0" labels).

The **Use Color Ramp** option changes the color of the contours to be darker as the cut and fill get deeper. Use the **Draw Only Cut/Fill Daylight** option to draw only the daylight lines, indicating the areas where the two surfaces intersect. The **Daylight Tolerance** setting controls which contours are drawn in green.

Cut/Fill Contour Settings:

You set the contour settings in the opening dialog by selecting the *Cut/Fill Contour Settings* button, which is comprised of the *Contour* and *Labels* tabs identical to those in *Triangulate and Contour*. Please refer to that command for details on the dialog options. You may wish to designate alternate layer names for these sets of contours to avoid overwriting previous contours on surface layers, and generally you will set the contouring interval to 1 foot.

Prompts

Draw Cut/Fill Contours dialog

Select Base Surface File

Cut/Fill Slope Lines

This command draws cut/fill slope lines with slope direction arrows. The arrowhead points in the downward direction of the slope. The cut/fill slopes are defined by selecting a 3D polyline for the top of slope and another 3D polyline for the toe of slope.

In the options dialog, the Style chooses the type of symbol to draw: arrow, Y, V, 3-line, Middle Dot, End Dot, 4-line or line. The Interval sets the spacing of the slope lines along the top of slope polyline. The Continuous method makes pattern repeat without interval spacing. There are settings for the arrowhead size and the color and layer for the slope lines. The Auto Size option adjusts the symbol size relative to the length of the cut/fill line. The Solid Cut Arrows option allows for different style arrowheads for cut and fill slopes. The Hatch Settings control whether to hatch the area between the top and toe 3D polylines and the hatch properties to use. The Perpendicular method draws the lines perpendicular from the top polyline to intersect with the toe polyline. The Proportional method draws the lines from the top polyline to a relative proportion position on the toe polyline. For example, when the top polyline position is 25% along the top polyline, then the toe position will be 25% along the toe polyline.

Arrow style slope lines

Y style with solid hatch in yellow

3 line style with hatch in blue

4 line style

Zigzag style

Pick top of slope polyline: *pick a 3D polyline*

Pick toe of slope polyline: *pick a 3D polyline*

Pulldown Menu Location: Surface > Cut/Fill Utilities

Keyboard Command: slope_lines

Prerequisite: 3D polylines for top and toe of slope

Cut/Fill Movement

This command optimizes earth movement from cut to fill between existing and design surfaces. The earth movement is reported separately by haul ranges which is useful when using different types of earth movers such as dozers and truck/shovel.

Select inclusion and exclusion boundaries:

If an exclusion or inclusion boundary needs to be set for the existing/design tins used in Cut/Fill Movement, first draw either the existing or design tin to screen using the Draw Triangular Mesh command, then select boundaries from the screen when prompted. If no exclusion or inclusion boundaries are selected, Cut/Fill Movement will process the entire existing/design tin (though other options such as **auto size grid limits** still apply).

The screenshot shows the 'Cut/Fill Movement' dialog box with the following settings:

- Grid Cell Size X: 100.0
- Grid Cell Size Y: 100.0
- Min Truck And Shovel Distance: 0.0
- Cut Swell factor: 1.000
- Fill Shrink factor: 1.000
- Auto Size Grid Limits
- Report Details
- Draw Grid
- Grid Layer: Draw_Grid (Set button)
- Draw Transport Paths
- Scale Path Width Relative To Volume
- Path Layer: CF_Movement (Set button)
- Label Volumes (Text Size: 8.000)
- Label Layer: FENCE (Set button)

Buttons: OK, Cancel, Help

Cut/Fill Dialog options:

Grid Cell Size X: Determines the x value (width) of generated cut/fill grid cells.

Grid Cell Size Y: Determines the y value (height) of generated cut/fill grid cells.

Min Truck and Shovel Distance: Defines the truck and shovel cutoff, see *Report Details*.

Cut Swell factor: The cut volume is multiplied by this factor.

Fill Shrink factor: The fill volume is multiplied by this factor.

Auto Size Grid Limits:

Toggle on: The X and Y limits of the existing/design surfaces are calculated then subdivided into grid cells according to Grid Cell X and Y sizes.

Toggle off: User is prompted to window a section of the existing/design surfaces. This windowed area is then subdivided into grid cells according to Grid Cell X and Y sizes.

Report Details:

Toggle on: Total Work, Average distance moved, total fill, and total in-cell movement volume is reported. In addition – for each cell – net fill, a breakdown of cut and fill, easting and northing cell center locations is reported. Finally a breakdown of transported cut is reported by From and To region, Total Volume transported, and Distance cut is moved (excluding internal transport).

Toggle off: Cut fill movement report reports total work average distance moved, total fill and total in-cell movement volume.

*Note: If a *minimum truck and shovel distance* greater than 0.0 is set the report will also include the Truck and Shovel cut off as well as volume moved less that cutoff, volume moved more than cut off and the average distance moved for both of these values.

Draw Grid: Draws a grid on "Grid Layer" (can be set using Draw Grid Layer Name edit box) representing grid cells as defined by Grid Cell Size X, Grid Cell Size Y and the Auto Size Grid Limits toggle.

Draw Transport Paths: Arrows representing the transportation of cut from its initial cut cell to its destination fill cell are drawn to screen according to the "Path Layer" (can be set using Path Layer Name edit box). The Arrows can be scaled to show the relative amount of transported cut by using the "Scale Path Width Relative To Volume" toggle.

Label Volumes: Draws text of the volume for each cut/fill area using the specified layer and text size.

Example: Detailed report

Cuts					
Index	Net Cut	Cut/Fill		Easting	Northing

Pulldown Menu Location: Surface > Cut/Fill Utilities

Keyboard Command: cf_move

Prerequisite: Two surface models

Cut/Fill Centroids

This command finds the centroids for each cut and fill area between two triangulation surfaces (.flt or .tin files), with options to draw centroid boundaries, label centroid amounts (in cubic yards for English units), and hatch the areas. Included is a routine to find the optimum movement of the cut to fill volumes which minimizes the total haul distance moved. This routine finds all the areas of cut and fill, and locates the centroid for each area.

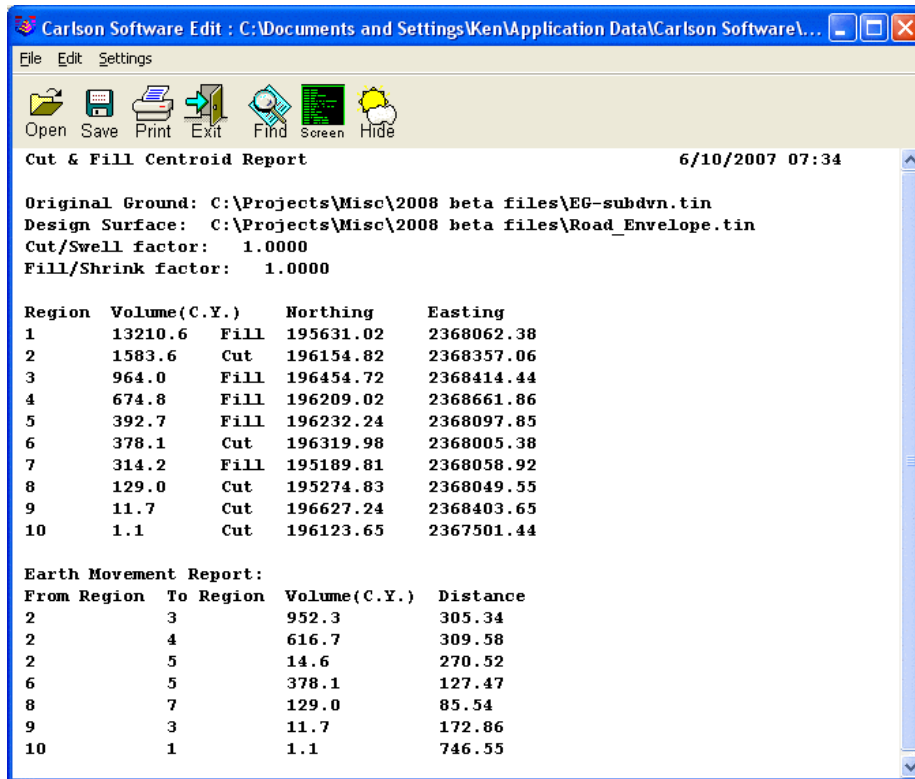

Prompts

Cut & Fill Centroid Locator Dialog

Select Original Ground Surface Dialog *Select an existing surface (.tin, .flt) file*

Select Design Surface Dialog *Select an existing surface (.tin, .flt) file*

Pulldown Menu Location: Surface >> Cut/Fill Utilities

Keyboard Command: cutfillc

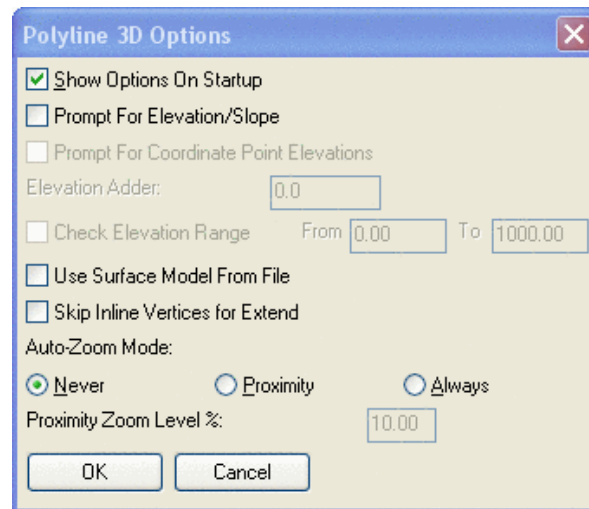

Prerequisite: Two triangulation files, (.flt or .tin)

Draw 3DPoly Perimeter

This command draws a 3D polyline on the PERIMETER layer. This is one way to generate the polyline that is required by the *Calculate Stockpile Volume* and *Calculate Pond/Pit Volume* routines. In these routines, this polyline is used as the inclusion perimeter for volumes. If you are using Carlson points to define the polyline, make sure they are present in the drawing at their real Z elevation, and then set your Object Snap to Insert prior to running this routine. Alternately, you can use point numbers from the current coordinate (.CRD) file. A third option is to obtain the elevations of picked points from a specified surface model. You have a further option to be prompted for each elevation, thus overriding the values found from the included points.

Prompts

If set to display, the 3D Poly options dialog will appear, and then you will be prompted for points to use to draw the 3DPoly Perimeter. Standard Carlson point number input or screen picks using selection methods are valid.

Dialog Options

Prompt for Elevation/Slope: Using the .XY filter allows the user to pick the X and Y coordinate from the screen and type in the elevation. If you use the No response then the Z coordinate of the point picked will be applied.

Use surface model from file: With this option, a surface file is specified, and then with each screen pick, the surface elevation is determined. If Prompt for elevations is set to No, the surface elevation is applied to the polyline vertex. If set to Yes, the surface elevation is displayed as the default, and can be accepted by pressing Enter, or a different elevation can be typed in instead.

Pick point or point number: *pick a point or type a point number*

Arc/Close/Undo/Pick point or point number: *15* This is a point number from the current coordinate (.CRD) file.

Note that if the response to Use Surface model from file is *Yes*, the elevation used is not the point elevation from the coordinate file (.CRD), but the elevation interpolated from the surface.

Arc/Close/Undo/Pick point or point number: *press Enter*

Draw another 3D polyline [Yes/<No>]? *press Enter* Pressing Enter ends the command.

Pulldown Menu Location: Surface >> Stockpile/Pond/Pit Volumes

Keyboard Command: 3dperim

Prerequisite: None

Draw 3DPoly Base Breakline

This command draws a 3D polyline in the BASE_BREAKLINE layer. This polyline is used by the *Calculate Stockpile Volume* and *Calculate Pond/Pit Volume* routines to model the base surface. You may want to set your Object Snap prior to running this routine so that you obtain the elevations of existing points while creating the 3D polyline. Besides picking and entering the points, you can also use point numbers from the current coordinate (.CRD) file.

This routine functions identically to the *Draw 3DPoly Perimeter* command, only placing the resulting 3D polyline on a different layer.

Pulldown Menu Location: Surface > Stockpile/Pond/Pit Volumes

Keyboard Command: 3dbase

Prerequisite: None

Calculate Stockpile Volume

This command is a customized and simplified method for calculating volumes in a situation in which the entire volume to be calculated is above the perimeter elevation, such as in the case of a stockpile of material. The complimentary command, *Calculate Pond/Pit Volume*, is for the opposite situation, in which the entire volume to be calculated is below the elevation of the perimeter.

The program internally computes BASE and FINAL grid surfaces from drawing geometry. The base surface is calculated from a 3D polyline representing the perimeter of the area being analyzed. If that 3D polyline is drawn on the PERIMETER layer, the command will automatically detect and use it. If no 3D polyline is found on that layer, you have an opportunity to manually select another 3D polyline to use. The 3D polyline perimeter can be drawn with the *Draw 3D Polyline Perimeter* command before using this routine.

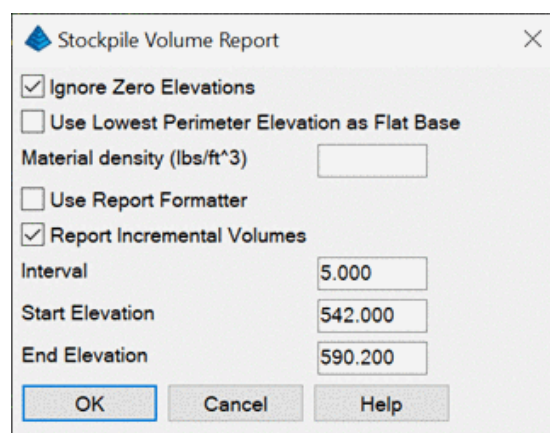

The 3D polyline perimeter is also used as the inclusion perimeter for the volume calculation.

Additional 3D polylines can also be specified to more precisely define the BASE surface. These must be on the BASE_BREAKLINE layer to be used for this purpose. These can be generated by the *Draw 3DPoly Base Breakline* routine.

The FINAL surface is calculated from all of the other selected drawing entities such as points, line, inserts, and polylines, along with the perimeter polyline, **but not including the BASE_BREAKLINE polylines**. These features are used only in computing the BASE surface.

You have the option of setting the resolution of the grids. There is also an option to report the fill volume in stages at an elevation interval.

The *Make 3D Grid File* and *Two Grid Surface Volumes* commands, used in combination, are an alternative to this command, and in any situation in which there are cut and fill volumes between the surfaces, that combination must be used to generate accurate results.

Option	Value
Ignore Zero Elevations	<input checked="" type="checkbox"/>
Use Lowest Perimeter Elevation as Flat Base	<input type="checkbox"/>
Material density (lbs/ft ³)	<input type="text"/>
Use Report Formatter	<input type="checkbox"/>
Report Incremental Volumes	<input checked="" type="checkbox"/>
Interval	5.000
Start Elevation	542.000
End Elevation	590.200

In the options dialog, the **Ignore Zero Elevations** filters out entities at zero elevation. The **Use Lowest Perimeter Elevation as Flat Base** models the base surface at a fixed level using the lowest elevation in the perimeter polyline. The **Material Density** is used to report tons and can be blank to skip the tons report. The **Use Report Formatter** option is for creating custom reports. The **Report Increment Volumes** option reports the volumes in stages.

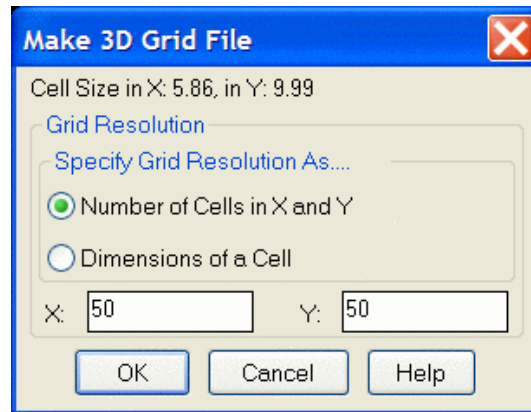

Prompts

Select stockpile entities and perimeter.

Select objects: *pick the objects that define the stockpile and the 3D polyline perimeter*

Stockpile Volume Report dialog

Select stockpile perimeter polyline: *pick the closed 3D perimeter polyline.* If the program didn't find a closed 3D perimeter polyline in the initial selection set, it prompts for this polyline.

Make Grid File dialog Set the resolution and then click OK.

Window these objects to obtain the volume report

Pulldown Menu Location: Surface >> Stockpile/Pond/Pit Volumes

Keyboard Command: stockvol

Prerequisite: Data representing the stockpile surface and a 3D polyline representing the perimeter of the stockpile.

Calculate Pond/Pit Volume

This command is a customized and simplified method for calculating volumes in a situation in which the entire volume to be calculated is below the perimeter elevation, such as in the case of a pond or pit. The complimentary command, *Calculate Stockpile Volume*, is for the opposite situation, in which the entire volume to be calculated is above the elevation of the perimeter.

The program internally computes BASE and FINAL grid surfaces from drawing geometry. The base surface is calculated from a 3D polyline representing the perimeter of the area being analyzed. If that 3D polyline is drawn on the PERIMETER layer, the command will automatically detect and use it. If no 3D polyline is found on that layer, you have an opportunity to manually select the 3D polyline to use. The 3D polyline perimeter can be drawn with the *Draw 3D Polyline Perimeter* command before using this routine.

The 3D polyline perimeter is also used as the inclusion perimeter for the volume calculation.

Additional 3D polylines can also be specified to more precisely define the BASE surface. These must be on the BASE_BREAKLINE layer to be used for this purpose. These can be generated by the *Draw 3DPoly Base Breakline* routine.

The FINAL surface is calculated from all of the other selected drawing entities such as points, line, inserts, and polylines, along with the perimeter polyline, **but not including the BASE_BREAKLINE polylines**. These features are used only in computing the BASE surface.

You have the option of setting the resolution of the grids.

Besides reporting the entire volume between the two surfaces, the report also includes the volumes at an elevation interval from the bottom to the top. These stage-storage volumes can also be stored to a capacity file (.cap) that can be used with the Hydrology module. In addition to the stage-storage volumes, the *Report Incremental Volumes* option reports the storage within an elevation range instead of relative to the surface.

The *Make 3D Grid File* and *Two Grid Surface Volumes* commands, used in combination, are an alternative to this command, and in any situation in which there are both cut and fill volumes between the surfaces, that combination must be used to generate accurate results.

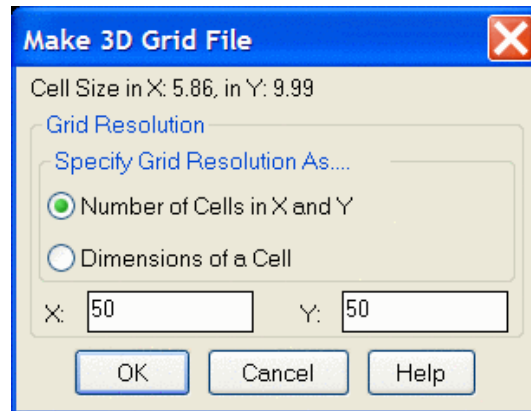

Prompts

Ignore Zero Elevations [<Yes>/No]? *press Enter*

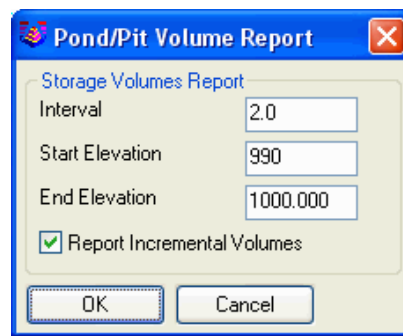

Select Pond/Pit entities and perimeter.

Select objects: *pick the objects that define the surface and the 3D polyline perimeter*

Select Pond/Pit perimeter polyline: *pick the polyline*

Make Grid File dialog Set the resolution and then click OK.

Pulldown Menu Location: Surface >> Stockpile/Pond/Pit Volumes

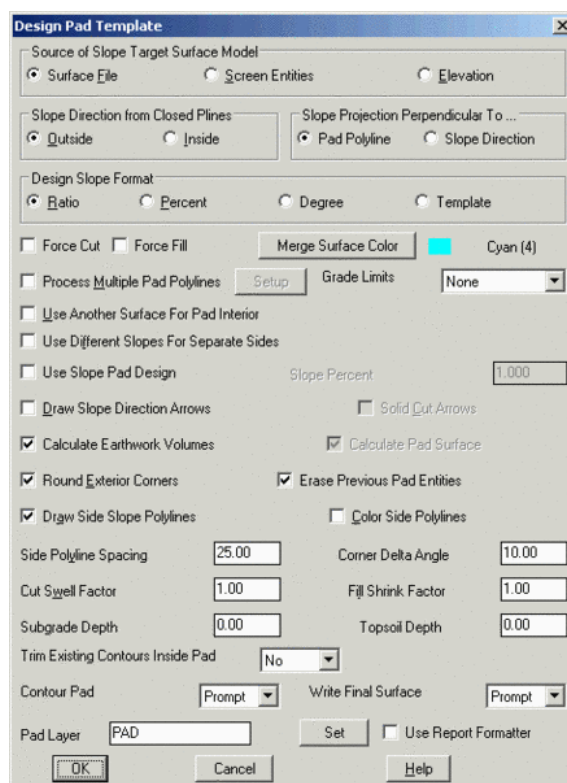

Keyboard Command: pitvol

Prerequisite: Data representing the pond/pit surface and a 3D polyline representing the perimeter of the pond/pit.

Design Pad Template

This command creates design slopes from a perimeter polyline at specified cut/fill slopes to reach existing ground. This routine can be used to design building pads, pits, roads, ditches, stockpiles, etc. The design is drawn as 3D polylines for the cut/fill slopes and for the daylight perimeter where the design meets existing ground.

Before beginning this routine, you must have drawn the polyline representing the outside edge of the feature to model. The edge is drawn as a polyline which can be either a 2D or 3D closed or open polyline. For a 2D polyline, the program will prompt for an elevation for the pad perimeter. With a 3D polyline, the pad perimeter is set to the elevations of the 3D polyline. For an open polyline, the program will prompt for the side for the design. With a closed polyline, the program designs the slopes either outward or inward depending on the settings in the dialog.

Under **Source of Slope Target Surface Model**, choose between a Surface File (.GRD, .FLT, .TIN), Screen Entities, or a specific Elevation. If using Screen Entities, the routine internally calculates a gridded model, the limits of which are specified by screen picks. Make sure that the grid area covers the entire area for the pad including room for the

cut/fill slopes.

For closed pad perimeters, there is a **Slope Direction from Closed Plines** option to draw the slopes inward or outward from the perimeter. The outward method starts the slopes at the design elevation of the perimeter and projects out to intersect the existing surface. The inward method projects the slopes inside to reach the grid surface or a set elevation. Outward sloping would be used for such things as building pads, parking lots, etc. where the interior remains as a defined surface. Inward sloping would be used for such things as the top edge of an excavated pit or pond where the interior side slopes project downward at the specified slopes until reaching the original ground surface.

The **Slope Projection Perpendicular To** option applies to sloping pad perimeters. The Pad Polyline method creates the user-specified slope perpendicular to the pad perimeter. The Slope Direction method accounts for the slope of the pad perimeter and makes the final surface to match the user-specified slope. For example, if the pad perimeter is at a 10% slope and the fill slope is at 2:1, then the Pad Polyline method would create fill slopes that are 2:1 perpendicular to the pad while slightly steeper (1.96:1) for the actual slope that goes in the slope direction with the effect of the sloping pad perimeter. For the same case except with the Slope Direction method, the resulting slope perpendicular to the pad is less steep (2.04:1) while the actual slope in the slope direction is exactly 2:1.

Under **Design Slope Format**, choose between *Ratio*, *Percent*, *Degree* or *Template*. The use of a Template allows for complex slopes to be applied, and is also an alternative approach to road design. The template (.TPL) file is created in the *Design Template* routine in the Roads menu. When using a template, the pad perimeter represents the centerline. One way to create the pad perimeter for the template is to use the *Profile to 3D Polyline* command which converts a 2D centerline to a 3D polyline using a design profile. With a template, the program uses not only the cut and fill slopes from the template file but also draws all the template grade points such as edge of road, curb and ditch. The subgrade, superelevation and template transition options of the template file are not used in this command. These options are only applied in the *Process Road Design* command. The grade points are drawn as 3D polylines parallel with the centerline. Cross section 3D polylines that include the grade points are also drawn at the specified interval.

The **Force Cut** option will try the cut slope to find a catch point even when the pad perimeter starts out in fill. This is possible when the existing ground is rising faster than the cut slope. Likewise the **Force Fill** option will try the fill slope to find a catch point when the pad starts out in cut.

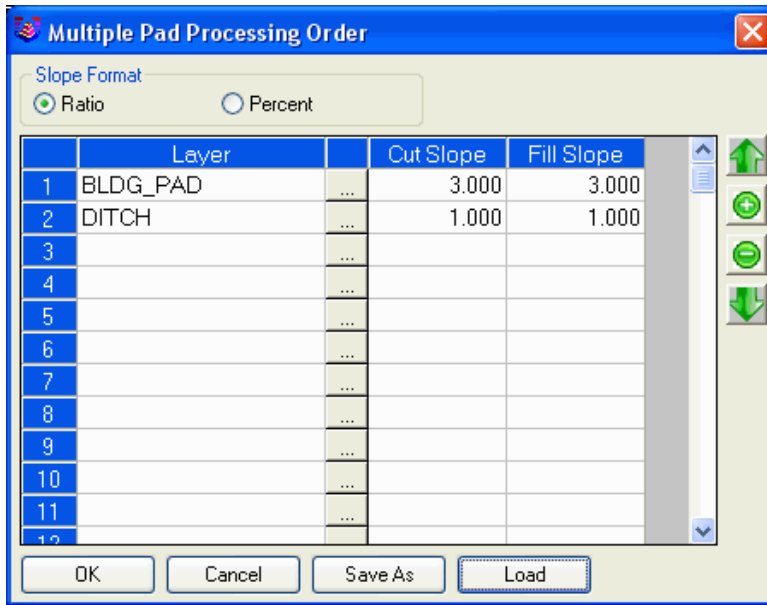

The **Grade Limits** option makes the cut/fill slopes fit within the grade limits either by making the slopes steeper or by putting in a vertical retaining wall. The retaining wall can be placed at the grade limit or at the pad perimeter. When this option is on, the program prompts to select a closed polyline to set the grade limits.

The **Min Cut/Fill Height** setting creates no tie slope when the cut/fill is less than a minimum. To always draw the tie slope, set this value to zero.

The **Merge Surface Color** is used to set the color of the triangles within the pad when using a triangulation surface as the target surface and updating this surface with the pad design. The triangle colors are shown in the 3D Viewer graphics.

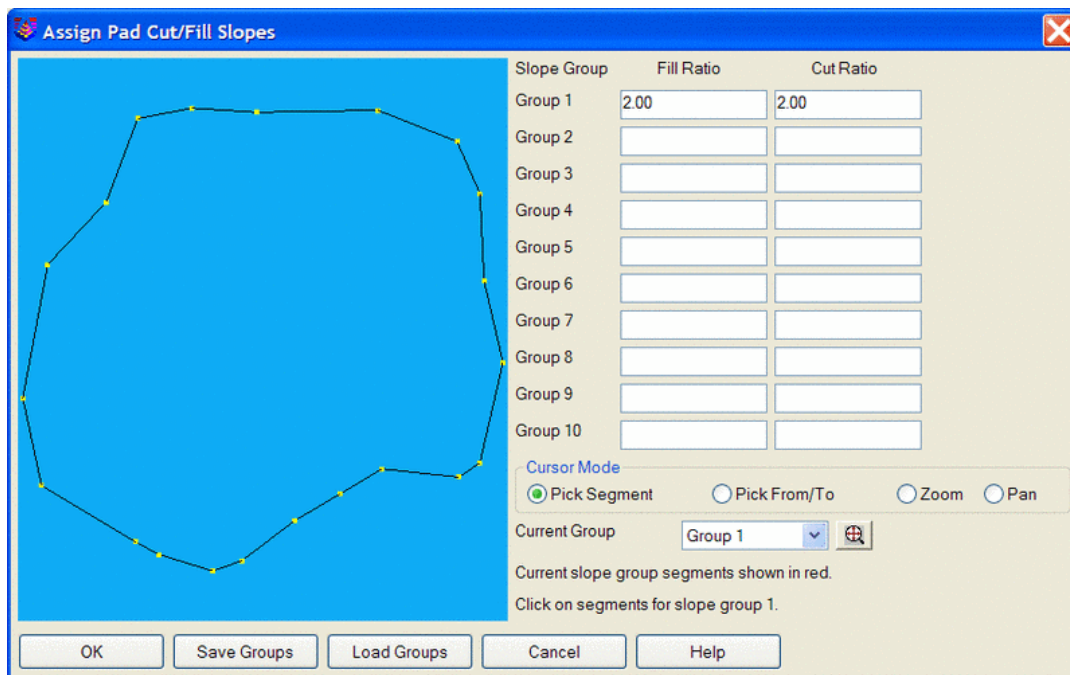

The **Process Multiple Pad Polylines** option allows you to process multiple pad perimeter polylines at a time instead of a single pad perimeter. The program will prompt for a selection set of pad perimeter polylines and then cycle through and run the design on each one. There will be one final report for the earthworks for all the pads. The Setup function allows you to specify different cut/fill slopes by layer and also to set the processing order by layer. For example, in the case of processing both building pads with a shallow slope and ditch polylines at a steeper slope, you could set up the processing order to do the building pad first and the ditch last so that the ditch cut slopes will carve out any overlap with the building fill slopes. These pad layer slope and order assignments can be saved

and loaded from a .PAD file.

Use Another Surface for Pad Interior will bring up a prompt for another Surface file (.GRD, .FLT, .TIN) to use for the design surface within the starting pad perimeter. Otherwise the program will model the pad interior by straight interpolation from the starting pad perimeter elevations. For example, if a building pad has a starting pad perimeter at a set elevation and the pad is supposed to be flat, then this option is not needed. This option is needed in a case where you are designing a pit and the starting pad perimeter is a 3D polyline that follows an undulating pit bottom surface. The pad design will model the pit side slopes. In order to model the undulating bottom of the pit, you need the Use Another Surface for Pad Interior option to select a surface that models the pit bottom.

Use Different Slopes for Separate Sides allows you to specify different slopes for different sides of your pad polyline. If this is toggled ON, the Assign Pad Cut/Fill Slopes dialog is invoked, where you can create multiple Slope Groups along the Pad Template polyline and set the Cut and Fill design ratios for each.

Use Slope Pad Design allows you to set a cross slope amount for the top of the pad. You will be prompted to

screen pick two points that designate the slope direction. For automatic balancing of cut/fill quantities, you will be prompted to find the optimal slope and slope direction.

Draw Slope Direction Arrows draws an arrow on the outslopes that points in the downhill direction. Arrows on fill slopes are drawn as solid filled.

Solid Cut Arrows allows you to choose between drawing the cut arrows as solid filled or as wire frame.

Round Exterior Corners holds the outslopes around the corners. Otherwise the side outslopes stay straight until they meet at the corners as shown in the figure.

Erase Previous Pad Entities erases drawing geometry created with this command previously.

When **Draw Side Slope Polylines** is ON, Design Pad Template will draw 3D polylines perpendicular to the pad perimeter from the pad to the catch point.

Color Side Polylines assigns different colors to Cut and Fill Side Polylines to make them easier to distinguish.

Example of pit design for option of Use Another Grid for Pad Interior

Pad corner without round corners option

Pad corner with round corners option

Side Polyline Spacing specifies the interval at which to draw the Side Slope Polylines. Besides at the interval, side slope polylines are also drawn at grid corners.

Corner Delta Angle is the delta angle in degrees between side slope polylines to span the delta angle around exterior corners.

The **Subgrade Depth** is applied to lower the design surface within the pad for the volumes calculations. The volumes are from the existing surface to the base of the subgrade. The effect of the subgrade is to increase cut and decrease fill.

The **Topsoil Depth** is used to report the topsoil removal volume by removing this depth within the pad disturbed area.

Cut volume is multiplied by the **Cut Swell Factor** in the final volume report.

Fill volume is multiplied by the **Fill Shrink Factor** in the final volume report.

The **Contour Pad** option draws contours on the pad. At the end routine, a dialog lets you set the contouring options. Usually you should specify a new contour layer and turn off smoothing.

The **Write Final Surface** option creates a surface model of the pad using the elevations of the pad within the disturbed area polyline and using the original ground surface everywhere else. At the end of the routine, the program will prompt for the surface file name to create.

The **Trim Existing Contours Inside Pad** option trims existing contours inside the disturbed limits of the pad.

You must specify the **Pad Layer Name** that the pad 3D polylines will be drawn on.

The **Use Report Formatter** option allows for making a customized report and outputs to various formats.

There is an option to calculate volumes for the pad design. The volumes are calculated by comparing the existing surface with the pad design. The inclusion perimeter for the volume calculation is the daylight perimeter polyline which represents the limits of disturbed area. The existing surface model is defined by the existing surface file (.GRD, .FLT, .TIN) or screen entities selected at the beginning of the command. The pad design surface is calculated by making a surface from the pad 3D polylines including the starting pad perimeter, the side polylines and the daylight perimeter.

Besides calculating the volumes in the *Design Pad Template* routine, you can also calculate the volumes with the *Two Surface Volumes* command, or the *Volumes by Triangulation* command. Two Surface Volumes works with two grid files, Volumes by Triangulation works with two TIN files. The design surface for Two Surface Volumes can be the final output surface from Design Pad or you can create a design surface with *Make 3D Grid File* using the 3D

polylines created in *Design Pad*. You could also create a TIN surface of the design surface using *Triangulate and Contour*. Some of the reasons to use either the Two Surface Volumes command or the Volumes by Triangulation command are that these volume routines have more output options (cut/fill color maps, etc.) and you can check the volumes by plotting or contouring the surface files. Also, you can combine several pads and other final surfaces by running *Make 3D Grid File* or *Triangulate and Contour* and then use these volume commands to calculate the overall site volumes.

The design is drawn as 3D polylines and the earthwork volumes are calculated. Before ending, the program allows you to adjust the design by changing the pad elevation, slopes and offset. The program can find the cut/fill balance by automatically adjusting the pad elevation. If adjustments are specified, the pad polylines are redrawn and the volumes recalculated.

A few key notes:

1. If the Source of Slope Target Surface Model is set to a Surface File, and the surface file used is a grid file, then the surface produced from the designed pad will be a grid surface and a grid file (.GRD).
2. If the Source of Slope Target Surface Model is set to a Surface File, and the surface file used is a TIN file, then the surface produced from the designed pad will be a triangulated surface and a TIN file (.TIN).
3. If the Surface used as a Target Surface is listed in the Surface Manager, the prompt seen in the Design Pad Template command is whether or not to Update the Surface, which is the Target Surface, so if you say "Yes," your Existing Ground Surface will now essentially contain the designed pad. So if you want to maintain an unedited version of Existing Ground, you may want to start with a copy of the Existing Ground Surface.
4. If the Surface used as a Target Surface is not listed in the Surface Manager, the prompt seen in the *Design Pad Template* command is whether or not to create a new surface of the combined surfaces.
5. If you respond "Yes" to the prompt about whether to contour the designed pad, the contouring dialog box has an option of whether to write the designed pad as a new surface, which will be only the area within the limits of the new design, not the entire Target Surface and design pad surface combined.

Prompts

First you are presented with the Design Pad Template dialog box.

If the Source of Slope Target Surface Model is set to a Surface File, you will first be asked to:

Pick the top of pad polyline: *select perimeter polyline*

Then the Select Slope Target Surface dialog box is presented. Choose the Slope Target Surface file, pick Open. You then proceed to enter the slope parameters of the pad...

If the Source of Slope Target Surface Model is set to a Screen Entities, you will first be asked to:

Pick Lower Left limit of pad disturbed area: *pick lower left* These prompts appear for the Screen Entities surface model method.

Pick Upper Right limit of pad disturbed area: *pick upper right* Be sure to pick these limits well beyond the area of the top of pad polyline in order to make room for the outslopes.

Make Grid File Dialog After selecting the limits of the disturbed area the program will generate a 3D grid that represents the surface. Specify the grid resolution desired and select OK.

Then,

Pick the top of pad polyline: *select perimeter polyline*

Then proceed to enter the slope parameters of the pad...

Enter the fill outslope ratio <2.0>: 2.5

Enter the cut outslope ratio <2.0>: 2.5 After entering outslopes slope ratios, a range of elevations along the pad

top will be noted.

Enter the pad elevation <29.54>: 39

Calculate earthwork volumes (<Yes>/No)? *press Enter*

Report Viewer Reports cut/fill volume.

Adjust parameters and redesign pond (Yes/<No>)? *press Enter*

Write final surface to grid file (Yes/<No>)? *press Enter*

Trim existing contours inside pad perimeter (Yes/<No>)? *press Enter*

Contour the pad (<Yes>/No)? *press Enter*

Existing contours with top of pad perimeter polyline

Pad template with contours

3D view of pad with DTM of surface and triangulation faces of pad

Template to apply in Design Pad Template

Existing surface with 3D polyline centerline

Result of Design Pad Template showing template grade polylines, cross section polylines, cut/fill slopes, and final contours

Viewpoint 3D view of Design Pad Template

Design Pad Template can also handle self-intersecting side slopes

Viewpoint 3D view of intersecting side slopes

Pulldown Menu Location: Surface

Keyboard Command: pad

Prerequisite: A pad perimeter polyline and surface entities or a surface file for an intercept target.

Edit Pad Template

This command is used in conjunction with *Design Pad Template*. It allows the user to modify an existing pad design that has been generated with *Design Pad Template*. The original design criteria of the pad can be modified and the routine will automatically re-calculate volumes, re-draw contours, disturbed limits, tin lines, etc. Possible modifications to the pad include cut/fill slopes, pad elevation, x-y position (the pad can be moved to a new location), horizontal offset, a single pad vertex can be moved to a new location, a new target surface can be specified, and finally, the pad and all of its elements can be deleted. Once the new design parameters are set, the routine will regenerate the pad based on the new parameters. The standard report viewer opens to display the new volume calculation and other design info.

Edit Pad Template requires a target surface to project to, which is typically the surface designated as the Source of Slope Target Surface Model in the Design Pad Template command. In Design Pad Template, when prompted to "Update Surface File" select *Yes*.

First the user is prompted to pick the pad polyline, which must be the original polyline used with *Design Pad Template* command. Subsequent edits to the Pad Template must also be initiated with the selection of that polyline. The Editing functions are displayed in an interactive docked sidebar dialog.

<input type="checkbox"/> Use Slope Groups	Set
Fill Slope	1.00
Cut Slope	1.00
Pad Elevation	1010.0000
Pad Volume	
Fill 9496.0 C.Y.	
Cut 1773.9 C.Y.	
Surface SIMO2	Set
Move Pad	Move Vertex
Add Vertex	Remove Vertex
Offset	Edit Vertex Z
Balance	Rotate Pad
Report	Delete
Write TIN	Exit Help
Process	

Use Slope Groups allows the assignment of varied slopes along the length of the Pad Template. Select the checkbox, and pick the Set button to access the Assign Pad Cut/Fill Slopes dialog box.

Fill Slope: displays the original fill slope criteria, *select* to edit to a new value.

Cut Slope: displays the original cut slope criteria, *select* to edit to a new value.

Elevation Delta: *enter a value* to adjust the elevation of the entire pad template.

Pad Volume: displays the cut/fill volume generated with the last use of either *Design Pad Template* or *Edit Pad Template*.

Surface: displays the target surface, *pick Set button* to change.

Move Pad: *Pick* to move the Pad Template to a new location on the site. The user is prompted at the command line to "Pick start point for translation" and then "Pick end point for translation." The pad is moved to the new location, with contours, tin lines, disturbed area and volumes regenerated on the fly.

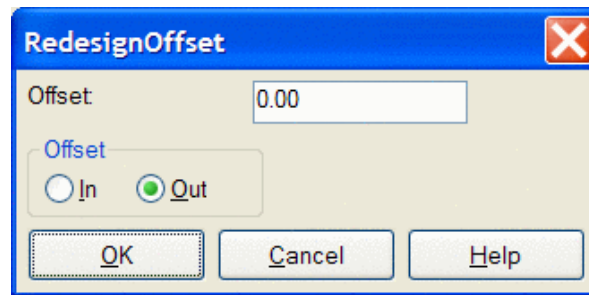

Move Vertex: *Pick* to move a vertex on the Pad Template. The user is prompted to screen select any vertex within the pad and place it in a new location. The pad vertex is moved to the new location, with contours, tin lines, disturbed area and volumes regenerated on the fly.

Add Vertex: *Pick* the position for a new point to add into the pad perimeter.

Remove Vertex: Select a point on the pad perimeter to remove.

Offset: *Pick* to apply a horizontal offset of the pad perimeter polyline. Enter the amount of offset desired in the field and then specify whether it is to go in or out.

Note: For subsequent operations of *Edit Pad Template*, the original pad polyline must be selected when prompted. The offset pad polyline is not eligible for selection.

Edit Vertex Z: Select a point on the pad perimeter to change the elevation. This function applies for 3D pad perimeters.

Rotate Pad: *Pick* to rotate the Pad Template.

Balance: *Pick* to automatically adjust the Pad Template elevation to balance the cut and fill volumes.

Delete: removes all of the pad design entities that were generated with *Design Pad Template* or *Edit Pad Template*.

Report: *Pick* to generate a cut/fill volume report.

Write TIN: Saves a TIN surface file of the pad surface.

Process: proceeds with the re-design of the pad using the current criteria.

Pulldown Menu Location: Surface

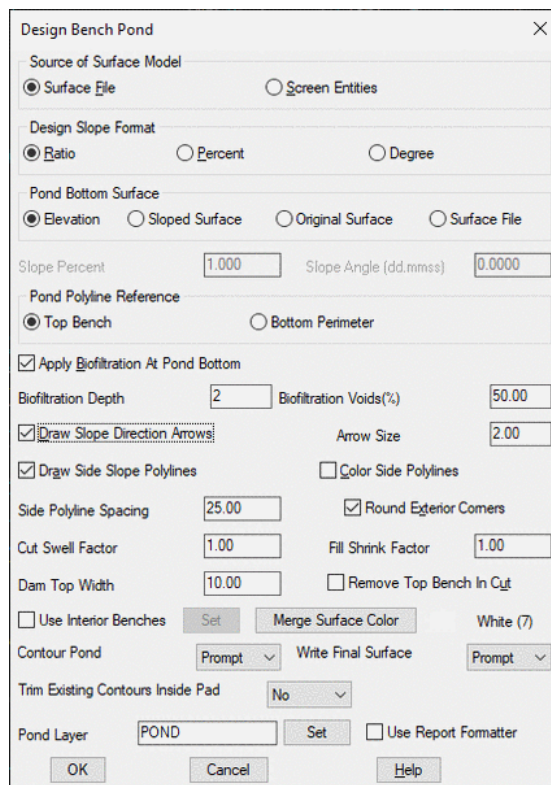

Keyboard Command: repad

Prerequisite: A Pad Template generated with the *Design Pad Template* command, and the surface model file used as a target surface.

Design Bench Pond

This feature will design a pond from a closed 2D polyline that defines the top dam perimeter of the pond. Before beginning this routine, you must have surface entities or surface files and a closed polyline that represents the top of the dam. The command creates a top of dam of the specified width, and then projects inward to model the pond, and outward to model the slopes to match to the target surface. Besides drawing the bench pond in 3D, the command also reports the earthwork to build the pond and the stage-storage data. There is also an option to output the stage-storage data to a .CAP file to use with Draw Stage-Storage or for hydrograph routing. After creating the pond and reporting the earthwork and stage-storage, the program prompts whether to adjust the design. There are three types of adjustment. One adjustment is to balance the earthwork cut/fill by adjusting the design elevation. Another adjustment is to resize to meet a specified stage-storage. The target storage adjustment can be done by either changing the pond bottom elevation or by offsetting the pond perimeter in or out. The third type of adjustment is to manually change one of the design parameters such as slopes or elevations.

This command starts with the dialog shown here.

Source of Surface Model: The existing surface may be defined by a 3D rectangular grid mesh (.grd file), a triangulation file (.flt or .tin file), or by screen entities. If the "Screen Entities" option is chosen, a grid file representing the existing surface will be internally created by using the user selected screen entities that depict the surface (Contours, Tri-Mesh, 3D Polys).

Design Slope Formula: Choose how you want to specify the slopes, either by ratio, percent or degree.

Pond Bottom Surface: Choose how to specify the pond bottom surface by either the original surface, sloped surface, surface file, or use a fixed set elevation. The Slope Surface has settings for the slope amount and direction that the program will use to build the bottom of pond surface. The Surface File method will prompt for a separate TIN surface file to use for the bottom of the pond. This method is useful for building a pond with bottom features like a V-ditch or specific low point. For this method, the bottom surface must be built using Triangulate & Contour before running Design Bench Pond.

Pond Polyline Reference: The program will prompt for you to select a pond perimeter polyline from the drawing. With this option, you can choose between using a perimeter polyline that represents the pond top bench or the pond bottom perimeter.

Apply Biofiltration At Pond Bottom: this option provides a storage at the bottom of the pond that isn't 100% water capacity. The depth is from the bottom of the pond, and the void is smaller than 100%, in the example below it is 50%. The Biofiltration is calculated in the storage and shown in the stage-storage report.

Draw Slope Direction Arrows: This option draws an arrow on the outslopes that points in the downhill direction. Arrows on fill slopes are drawn as solid filled.

Arrow Size: Specify the size for the slope direction arrows.

Draw Side Slope Polylines: This option draws 3D polylines from the pond top bench to the outside catch perimeter and inside to the pond bottom.

Color Side Polylines: This option will color the side slope polylines as red/blue for cut/fill.

Side Polyline Spacing: Defines the interval along the top of pond perimeter to draw 3D lines from the top of pond to the tie at the outslope.

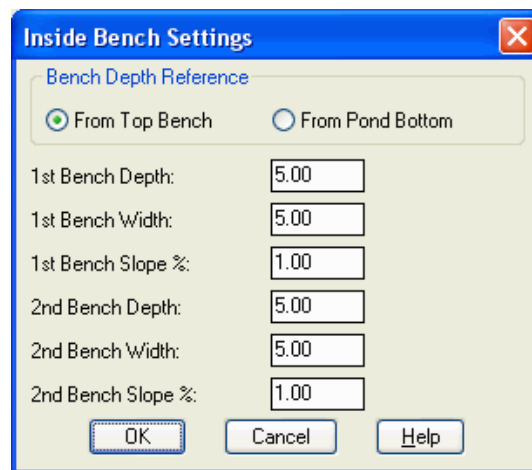

Cut Swell Factor: This value is multiplied by the earthwork cut volume for the report.

Fill Shrink Factor: This value is multiplied by the earthwork fill volume for the report.

Dam Top Width: Specify the width for the top of the dam.

Remove Top Bench in Cut: If this option is checked ON and the top of dam is in cut, then the bench will be removed.

Use Interior Benches: This option puts in up to two safety benches on the pond interior slope. The depth for the benches can be specified from either the top or from the bottom of the pond. If you only have one bench, then the fields for the second bench should be set blank.

Pond Layer Name: Specify the layer for the pond entities.

The design is drawn as 3D polylines with an option to draw contours on the pond, and the earthwork volumes and stage-storage volumes are calculated.

Prompts

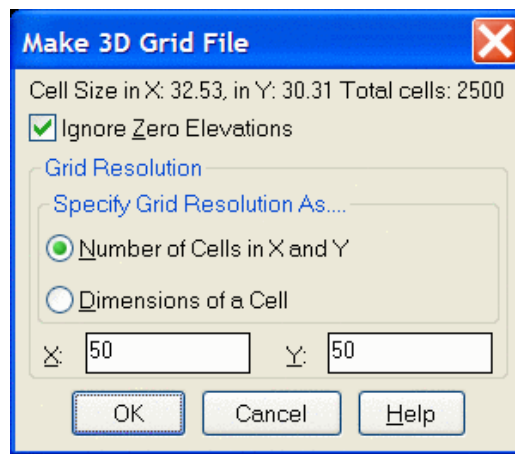

First the Design Bench Pond dialog box is presented.

If the Source of Surface Model is set to Screen Entities, when you pick OK you are prompted to:

Pick Lower Left limit of pond disturbed area: *Pick lower left*

Pick Upper Right limit of pond disturbed area: *Pick upper right* Be sure to pick these limits well beyond the area of the top of dam polyline in order to make room for the outslopes.

Make Grid File Dialog: Specify the grid resolution desired and select OK. Carlson Civil generates a 3D grid that represents the existing surface, using the drawing entities that fall within the specified area.

You are then prompted to:

Pick the top of dam polyline: *Select closed polyline*

Then proceed to design the pond...

If the Source of Surface Model is set to Surface File, when you pick OK, you are prompted to:

Pick the top of dam polyline: *Select closed polyline*

Then select the Existing Ground Surface Model file to use. Then proceed to design the pond...

Enter the fill outslope ratio <2.0>: *Enter*

Enter the cut outslope ratio <2.0>: *Enter*

Enter the fill interior slope ratio <2.0>: *Enter*

Enter the cut interior slope ratio <2.0>: *Enter*

TOP OF DAM POLYLINE

Existing contours with top of dam polyline

Bench Pond showing Slope Direction Arrows and complete with contours

Range of existing elevations along dam top: 2033.75 to 2041.81

Enter the top of bank elevation <2033.75>: *press Enter to accept the default which is the lowest surface elevation along the perimeter*

Enter the pond bottom elevation: 2012.55

Method to specify storage elevations [<Automatic>/Interval/Manual]? *press Enter* If manual is selected the user can specify the elevation(s) to calculate.

Pond Report viewer that shows the earthwork volumes and stage-storage data

Adjust parameters and redesign pond [Yes/<No>]? *Y*

If yes is chosen for adjust, the following 7 prompts appear along with the report again:

Balance cut/fill [Yes/<No>]? *press Enter for No. Yes will adjust the pond elevation to balance the cut/fill earthwork.*

Enter the fill outslope ratio <2.00>: *2.5*

Enter the cut outslope ratio <2.00>: *2.5*

Enter the interior slope ratio <2.00>: *2.5*

Enter the top of dam width <10.00>: *press Enter*

Enter the top of bank elevation <2033.75>: *press Enter*

Enter the pond bottom elevation <2012.55>: *press Enter*

Offset top of dam polyline [Yes/<No>]? *Y*

If yes is chosen for offset, the following 2 prompts appear:

Offset inwards or outwards [<In>/Out]? *press Enter*

Enter the amount to offset: *5*

Method to specify storage elevations [<Automatic>/Interval/Manual]? *press Enter*

Pond Report viewer that shows the earthwork volumes and stage-storage data

Adjust parameters and redesign pond [Yes/<No>]? *N*

Write stage-storage file (Yes/<No>)? *press Enter.* This option creates a .cap file to use with Draw Stage-Storage Curve and to use for hydrograph routing.

Update target surface file [Yes/<No>]? **press Enter.** This option is available when the target surface is a triangulation file. The bench pond design will be merged into the target surface to update the triangulation file.

Write final surface to grid file [Yes/<No>]? *press Enter*

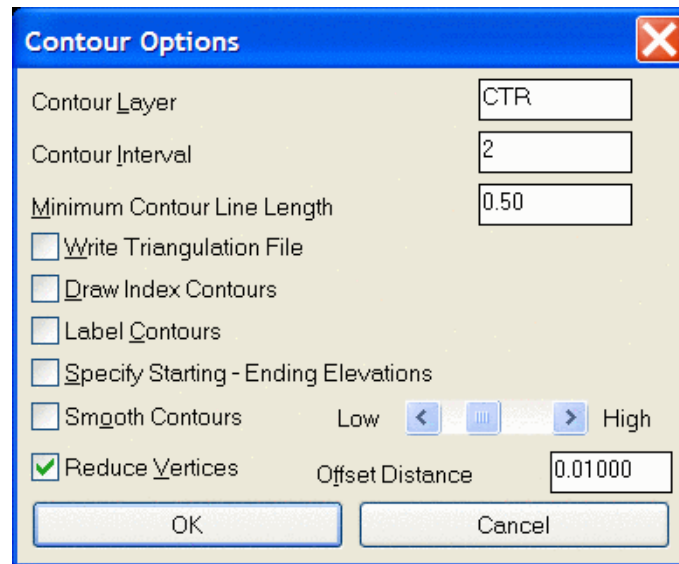

Trim existing contours inside pond perimeter [Yes/<No>]? *Y*

If yes is chosen, the following 2 prompts appear:

Retain trimmed polyline segments [Yes/<No>]? *Y*

Specify layer name for trimmed segments [Yes/<No>]? *press Enter*

Contour the pond [**<Yes>/No**]? *press Enter*

Refer to *Triangulate & Contour* section of the manual for a full explanation of Contour Options settings.

Bench Pond Design Report

3D view of Bench Pond

Pulldown Menu Location: Surface > Design Pond in Civil, Structure in Hydro

Keyboard Command: bpond

Prerequisite: Closed polyline that defines top of dam and surface entities

Edit Bench Pond

This command is used in conjunction with *Design Bench Pond*. It allows you to modify an existing pond design that has been generated with Design Bench Pond. The original design criteria of the pond can be modified and the routine will automatically re-calculate volumes, re-draw contours, disturbed limits, tin lines, etc. Possible modifications to the pond include cut/fill slopes, pond elevations, x-y position (the pond can be moved to a new location), horizontal offset, a single pond vertex can be moved to a new location, a new target surface can be specified, and finally, the pond and all of its elements can be deleted. Once the new design parameters are set, the routine will regenerate the pond based on the new parameters when the Process button is selected. The standard report viewer opens to display the new volume calculation and other design info.

Edit Bench Pond requires a target surface to project to, which is typically the surface designated as the Source of Slope Target Surface Model in the Design Bench Pond command. In Design Bench Pond, when prompted to "Update Surface File" select Yes.

The Edit Bench Pond command starts with a prompt to pick a pond polyline which can be any of the side slope or perimeter polylines created by the Design Bench Pond command. Another way to start Edit Bench Pond is to double-click on one of the pond polylines.

When the command starts, a dialog is docked on the left side of the drawing window. This dialog allows you to edit the pond while still being able to run other commands.

Fill Out Slope:	<input type="text" value="2.00"/>
Cut Out Slope:	<input type="text" value="2.00"/>
Fill Interior Slope:	<input type="text" value="2.00"/>
Cut Interior Slope:	<input type="text" value="2.00"/>
Top Elevation:	<input type="text" value="1040.0000"/>
Bottom Elevation:	<input type="text" value="1020.0000"/>

Fill Out Slope: displays the original fill slope criteria, select to edit to a new value.

Cut Out Slope: displays the original cut slope criteria, select to edit to a new value.

Fill Interior Slope: displays the pond interior slope for fill condition, select to edit to a new value.

Cut Interior Slope: displays the pond interior slope for cut condition, select to edit to a new value.

Top Elevation: enter the top elevation of the pond.

Bottom Elevation: enter the bottom elevation of the pond.

Pond Earthworks: displays the cut/fill earthworks and storage volume calculated with the last use of either Design Bench Pond or Edit Bench Pond.

Surface: Displays the target surface, pick Set button to change.

Move Pond: Pick to move the pond a new location on the site. The user is prompted at the command line to "Pick start point for translation" and then "Pick end point for translation". The pond is moved to the new location, with contours, tin lines, disturbed area and volumes regenerated on the fly.

Move Vertex: Pick to move a vertex on the top of pond perimeter. The user is prompted to screen select the vertex to edit and place it in a new location.

Add Vertex: Pick the position for a new point to add into the pond perimeter.

Remove Vertex: Select a point on the pond perimeter to remove. **Offset:** Pick to apply a horizontal offset of the top of pond perimeter polyline. Enter the amount of offset desired in the field and then specify whether it is to go in

or out.

Rotate Pond: Pick to rotate the pond.

Balance: Pick to automatically adjust the pond elevation to balance the cut and fill volumes.

Delete: removes all of the pond design entities.

Set Storage: prompts for a target elevation and storage, and then resizes the pond to fit.

Stage-Storage: write a stage-storage .cap file for the current design.

Report: Pick to generate a cut/fill volume and stage-storage report.

Process: proceeds with the re-design of the pond using the current criteria.

Pulldown Menu Location: Surface->Design Pond

Keyboard Command: edit_bpond

Prerequisite: A Bench Pond generated with the *Design Bench Pond* command, and the surface model file used as a target surface.

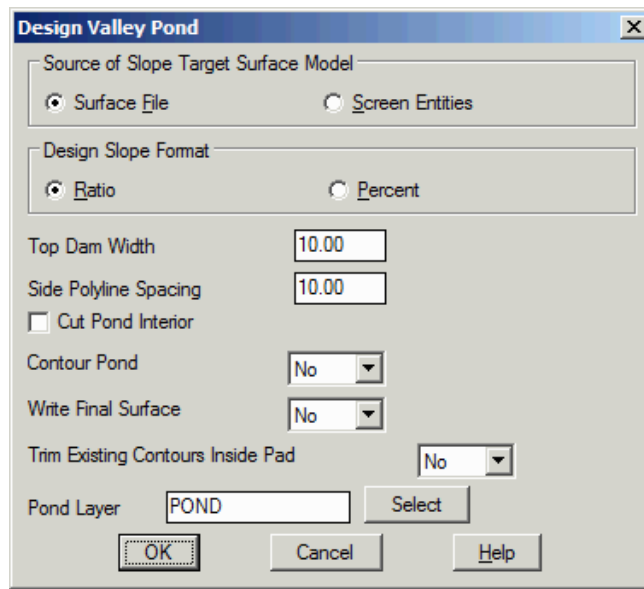

Design Valley Pond

This feature will design a valley pond, essentially by creating a dam across a low area, beginning with a surface model file (.GRD, .TIN, .FLT), or screen entities representing the surface, and a 2D polyline that defines the top of dam. These components must be present before starting. If Screen Entities are used, the program internally creates a grid mesh from the surface entities (Contours, Tri-Mesh, 3D polys) found by doing a crossing selection of the grid limit.

The design is drawn as 3D polylines with an option to drawn contours on the pond, and the earthwork volumes and stage-storage volumes are calculated.

The Cut Pond Interior option has two methods for cutting volume from the pond interior. This cut will create more water storage. The trace method prompts you to define a 3D polyline by picking points starting at the dam and going around the pond counterclockwise. At each point you enter an elevation. The default is the current ground elevation and typically you would enter a lower elevation. Then you enter a cut slope and the program will cut from this perimeter polyline at the entered slope. The polyline method requires a pre-drawn closed polyline inside the pond. The program will ask for a depth to cut and a cut slope. Polyline is set to the current ground elevation minus the cut depth. Then the program cuts out from the polyline to the original ground at the cut slope.

Prompts

For Screen Entities method:

Pick Lower Left limit of pond disturbed area: *pick lower left*

Pick Upper Right limit of pond disturbed area: *pick upper right* Be sure to pick these limits well beyond the area of the top of dam polyline in order to make room for the outslopes.

Make 3D Grid File Dialog

After selecting the limits of the disturbed area the program will generate a 3D grid that represents the surface. Specify the grid resolution desired and select OK.

Pick the top of dam polyline: *select a 2D polyline*

Pick a point within the pond: *pick a point*

Enter the fill outslope ratio <2.0>: *2.5 Enter*

Enter the cut outslope ratio <2.0>: *2.5 Enter*

Enter the top of dam elevation: *90 Enter*

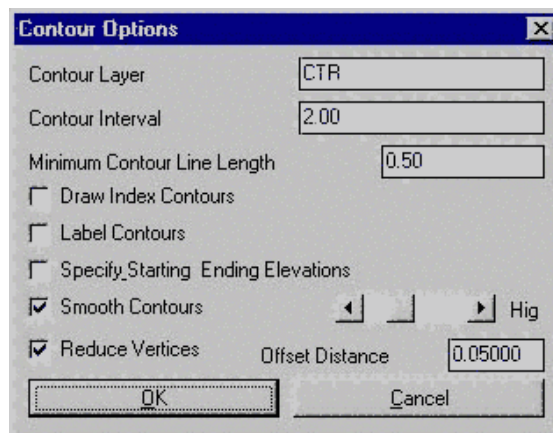

Existing contours with top of dam polyline

Valley Pond showing Emergency Spillway

Choose method to specify storage elevations (<Automatic>/Manual)? *Enter* If manual is selected the user can specify the elevation(s) to calculate.

Adjust parameters and redesign pond (Yes/<No>)? *Enter* If yes, the user will be able to enter new slope ratios and dam widths etc...

Valley Pond Design complete with contours

3D view of Valley Pond

Pulldown Menu Location: Surface > Design Pond in Civil, Structure in Hydro

Keyboard Command: vpond

Prerequisite: Polyline that defines top of dam

Draw Triangular Mesh

This command draws a triangulation (.flt or .tin) file as either Surface Object, 3D LINES or 3DFACEs. Since 3DFACE entities can be shaded within the *3D Viewer Window* or *3D Surface FlyOver*, or with the AutoCAD *3D Orbit* command, this is an excellent tool for visual surface inspection. 3D Lines cannot be shaded.

The Surface Object is a custom object for displaying the TIN in the drawing. This custom object also supports the EndPoint snap. The main advantage of the Surface Object is with displaying large TIN files because the Surface Object is more efficient than drawing individual 3D Faces or Lines. The Surface Object requires Carlson to be loaded to display.

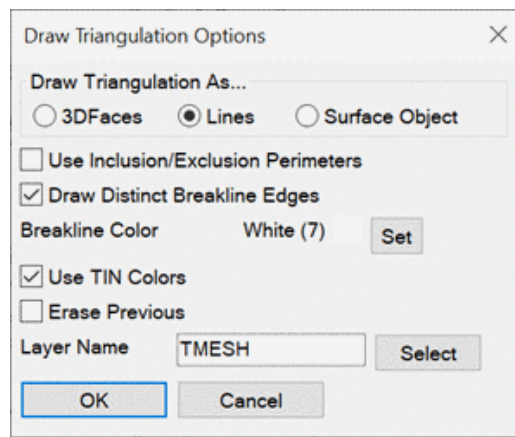

In the options dialog, choose the method for how to draw. The Use Inclusion/Exclusion Perimeters will prompt for selecting closed polylines to limit the area where to draw. The Use TIN Colors will color the entities using the colors for triangles stored in the TIN file. Colors can be stored in the TIN files using commands like Triangulation File Utilities, Road Network and Color Surface By Layer. The Erase Previous will erase the existing entities in case the TIN file has already been drawn. For Lines, there is an option to use a different colors for edges in the TIN that are from breaklines.

Triangulation (.flt or .tin) files can be created by routines such as *Triangulate & Contour*.

Prompts

Select Triangulation File to Draw

Choose a triangulation (.flt or .tin) file from the file selection dialog. You are then prompted for options:

If using Inclusion/Exclusion Perimeters, you will be prompted to select them as the routine executes.

Loading edges...

Loaded 198 points and 234 edges

This Triangulation mesh was drawn as 3DFaces with the Draw Triangular Mesh command, and then colored by elevation within 3D Viewer Window

Pulldown Menu Location: Surface >> Draw Surface

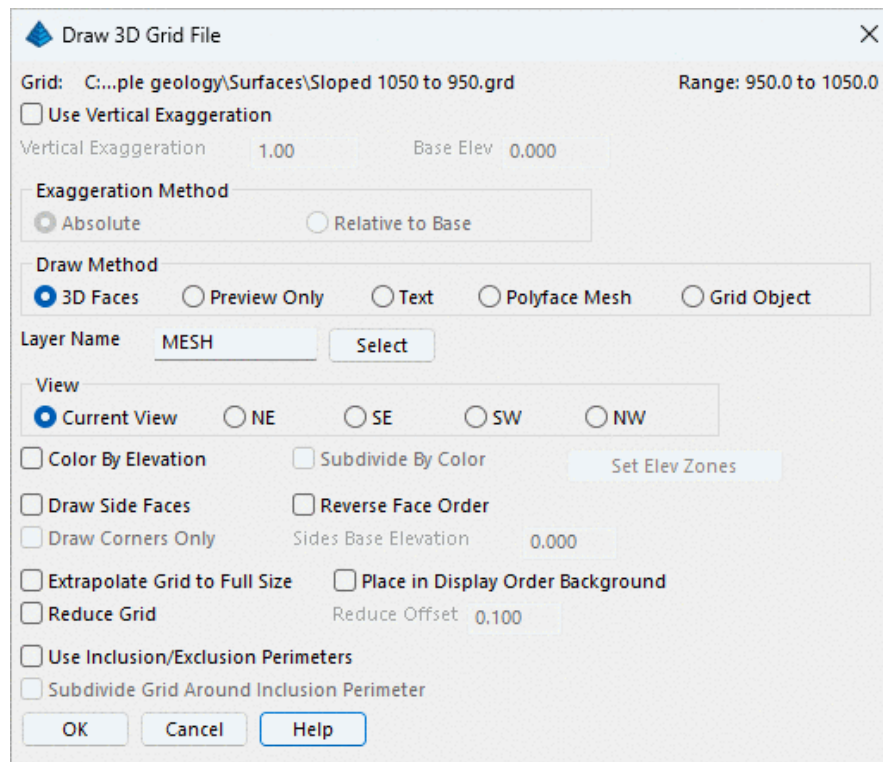

Keyboard Command: drawtri

Prerequisite: A triangulation (.flt or .tin) file

Draw 3D Grid File

This command draws the 3D grid mesh of the chosen grid (.GRD) file. Each grid cell can be drawn as a Surface Object, 3D Face entities, Polyface mesh, Text or temporary lines. 3D Faces and Polyface Meshes can be viewed/used in the following commands: *3D Viewer Window*, *Viewpoint 3D*, *Hide*, *Shade*, *3D Surface FlyOver*, and

The Surface Object is a custom object for displaying the grid in the drawing. This custom object also supports the EndPoint snap. The main advantage of the Surface Object is with displaying large grid files because the Surface Object is more efficient than drawing individual 3D Faces. The Surface Object requires Carlson to be loaded to display.

If **Use Vertical Exaggeration** is checked, grid elevations are multiplied by the value specified.

Exaggeration Method specifies whether to use an *Absolute* exaggeration method or *Relative to Base*, which uses the specified base elevation.

Specify the type of entities to draw in **Draw Method**. 3D Faces are described above. The Preview Only option draws the grid using temporary vectors. This method provides a much faster way to view the grid. However these temporary vectors are erased when the viewport is modified. This means as soon as you execute zoom, redraw, regen or plot, this grid will disappear. You can quickly redraw the grid by typing in VG for View Grid at the command prompt. Polyface Mesh is similar to 3D Faces except it is a single entity. The Text option will label the grid elevation at the grid corner. The text is placed center justified over the grid corner. To reduce clutter, there is an option to skip rows and columns.

Specify the layer for the grid entities in **Layer Name**.

Specify the initial viewing direction in **View**.

When **Color by Elevation** is checked, the grid will be colored based on a table of user-defined elevation ranges and the assigned colors. There is also an option to subdivide the grid cells at the color zone transitions, similar to the Elevation Zone Analysis command. Click the Set Elev Zones button to define ranges and colors.

When **Draw Side Faces** is checked, the program will draw vertical faces around the perimeter of the grid. The side

faces will be drawn vertically from the grid perimeter to the Sides Base Elevation. You may optionally specify the Sides Base Elevation, it defaults to 0.00.

When checked, **Reverse Face Order** changes the direction of the points for a grid cell from clockwise to counter-clockwise. The order applies to shading the grid cell in 3D render viewers such as the *3D Viewer Window* command. The grid cell will only appear shaded when viewing the grid cell from the clockwise side. Viewing from the other side will show a wire frame. The default is to show the shaded side from the top-down view. This option allows you to draw the grid so that the underside of the grid is shaded.

When checked, **Draw Corners Only** will draw the side lines only at the grid corners. Otherwise side lines are drawn down each perimeter grid cell.

When checked, **Extrapolate Grid to Full Size** draws the entire rectangular surface of the grid.

When **Use Inclusion/Exclusion Perimeters** is checked, it allows you to select inclusion and exclusion areas. Only grid cells inside the inclusion polylines will be drawn. Grid cells inside the exclusion polylines will not be drawn.

When checked, **Subdivide Grid Around Inclusion Perimeter** subdivides grid cells that are partially inside and outside the perimeter into smaller resolution grid cells.

Drawn grid file using inclusion perimeter and side faces option
viewed with Viewpoint 3D

Pulldown Menu Location: Surface >> Draw Surface

Keyboard Command: plotgrid

Prerequisite: a grid (.GRD) File

Quick Draw Surface

This command draws lines for the edges of a selected triangulation model. The purpose of this routine is to quickly get a picture of the triangulation connections. The lines are drawn as temporary graphics that get cleared when the display is redrawn. To create triangulation entities, use other routines such as Draw Triangular Mesh.

Prompts

Select Triangulation File

Choose the surface to draw

Pulldown Menu Location: Surface > Draw Surface

Keyboard Command: quicksurf

Prerequisite: a surface file (.TIN, .FLT)

Quick Contours

This command draws contours for a selected triangulation model at a given contour interval. The purpose of this routine is to quickly get a picture of the surface model from the contours. The contours are drawn as temporary graphics that get cleared when the display is redrawn. To create contour entities, use other routines such as Contour From TIN File or Triangulate & Contour.

Prompts

Select Triangulation File

Choose the surface to contour

Contour interval <5.00>: *press Enter*

Pulldown Menu Location: Surface > Draw Surface

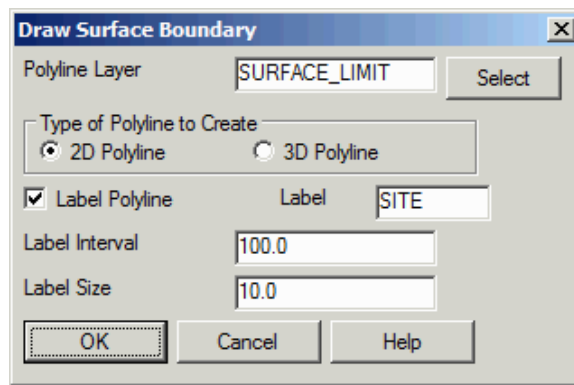

Keyboard Command: quickctr

Prerequisite: a surface file (.TIN, .FLT)

Draw Surface Boundary

This command draws the exterior perimeter of a triangulation or grid surface as a polyline. This is a simple way to show the size, shape and location of a surface without adding a lot of drawing entities and file size to the drawing.

The program prompts for the layer of the polyline to create and the type of polyline. A 2D polyline is drawn at zero elevation. A 3D polyline uses the surface elevations. There is an option for Label Polyline which adds text labels along the polyline with the specified name, size and interval. This label can be helpful to identify different surface boundaries.

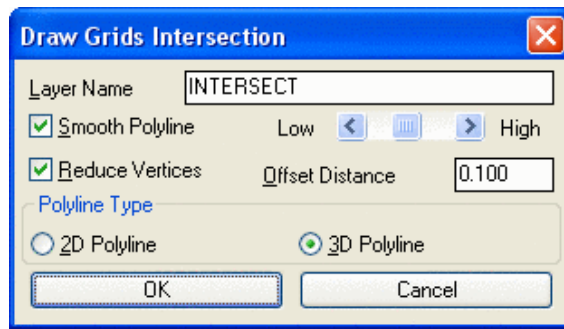

Pulldown Menu Location: Surface >> Draw Surface

Keyboard Command: grdlimit

Prerequisite: a surface file (.GRD, .TIN, .FLT)

Draw Surface Intersection

This command draws a 2D or 3D polyline at the intersection of two surfaces. In addition to this choice, the dialog also allows for the specification of the layer to draw the polylines on, whether or not to smooth them, and whether or not to reduce vertices.

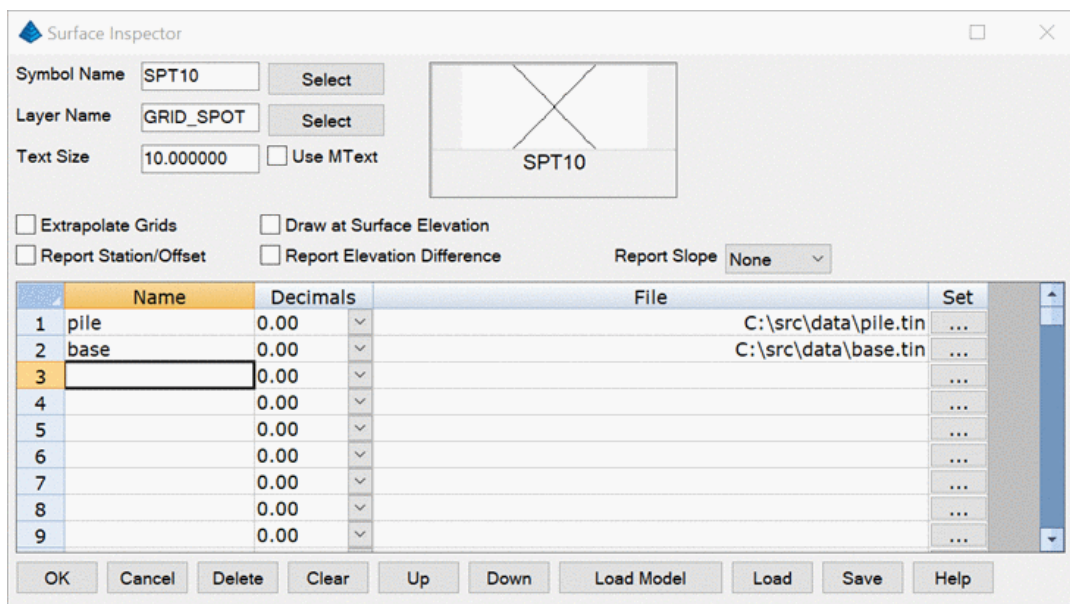

Pulldown Menu Location: Surface >> Draw Surface

Keyboard Command: grdcross

Prerequisite: two surface files (.GRD, .TIN, .FLT)

Surface Inspector

This command allows you to report and optionally label elevations for selected surface files. You can simultaneously analyze multiple surface files. Surface files can be either triangulation (.flt or .tin) files, grid (.grd) files, or any combination thereof. The following dialog opens when the command is initiated.

Symbol Name sets the symbol name to be plotted. Click **Select** to select the symbol from the symbol library.

Layer Name set the layer to use for the text labels.

Text Size sets the actual size (not scale factor) of the text label placed in the drawing. The **Use MText** controls whether to create the labels as MText or regular Text entities.

Turn the **Draw at Surface Elevation** toggle ON if you want the symbol to be located at the actual elevation of the surface.

The **Extrapolate Grids** option automatically extrapolates any unassigned grid nodes for grid surfaces.

Report Slope displays the slope of the surface along with the elevation.

Report Station/Offset prompts for a centerline and reports the station and offset in addition to the surface elevations.

When there are two surface files, the **Report Elevation Difference** option will add a third report field for the cut/fill between these two surfaces.

Name denotes the name that will be plotted when you label the elevation. The default value is the same as the name of the surface file, but you can change it.

Decimals individually sets the decimal elevation precision for each selected surface.

For **File**, either type in the surface name to use or press the **Select** button to choose the surface file from a browse window.

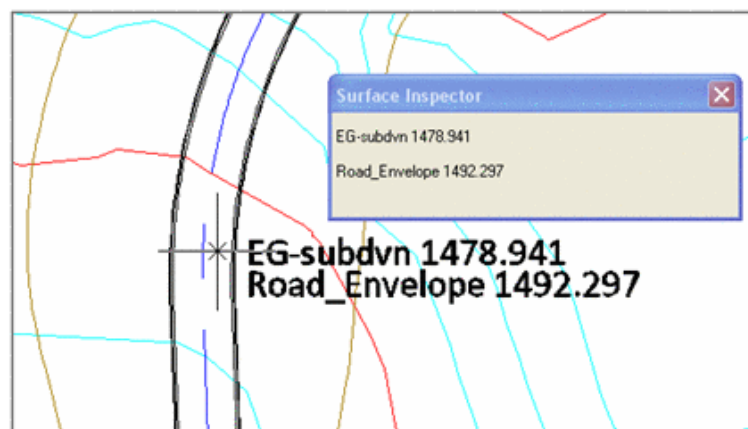

Load Model allows you to select grid files from a list of grids stored in a Geologic or Mining Model file. These files can be created in the Carlson Mining module.

Clear: Clears all values.

Load: Loads a Surface Inspector File (.SIF).

Save: Saves all settings to a Surface Inspector File (.SIF).

After you fill out the dialog box, click OK. Surface Inspector will load the surfaces and begin showing you real-time elevations for each surface as you move the cursor on the screen. If you pick a point or enter coordinates, the elevation will be labeled along with the surface name and selected symbol as shown below.

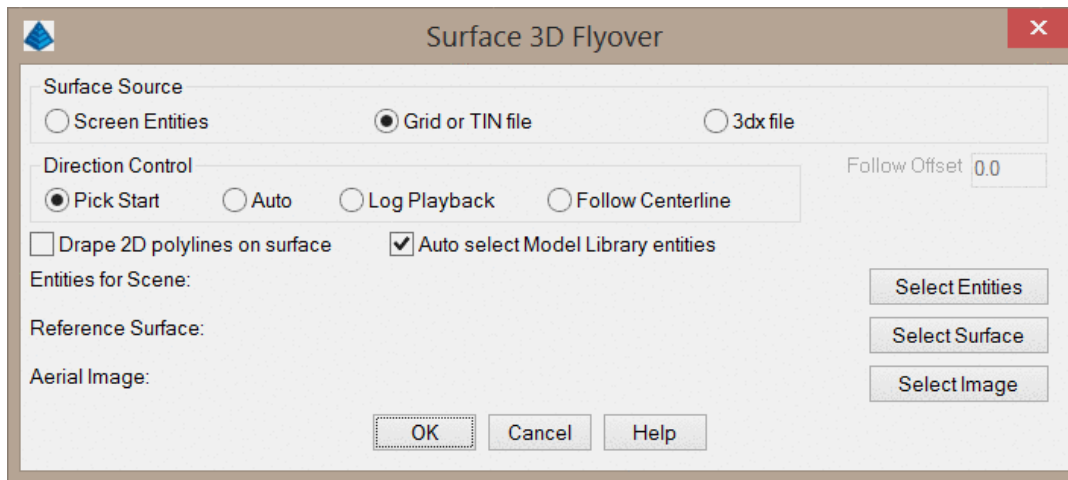

Pull-down Menu Location: Surface

Keyboard Command: surfvals

Prerequisite: Surface Model(s)

Surface 3D FlyOver

This command allows you to view a 3D surface in a simulated drive- or fly-over mode. You have the option of following a predefined path such as a road centerline or using a user-guided path (free flight). The surface to view can be defined with either screen entities, surface files, or both. The routine offers options for different types of surface shading, direction of travel, viewpoints, vehicles, reference surfaces, light position, color schemes, vertical exaggeration and more.

Surface Source: This option sets the source of the surface to view.

Screen Entities: With this option enabled, a surface will be generated from the selected 3D Faces. Other entities such as polylines will only be shown for reference. To select the screen entities, press the Select Entities button.

Grid or TIN file: With this option enabled, the surface is defined by either a triangulation file (.FLT or .TIN) or a grid file (.GRD). In addition to the surface file, screen entities may also be selected to be displayed. You will be prompted to select the surface after clicking OK.

3DX File: This method loads the scene from a 3DX file which can be saved from a previous run of Surface 3D FlyOver. Other 3D viewer commands such as the 3D Viewer Window can also save the scene to a 3DX file.

Direction Control: This option controls the method of movement through the 3D view.

Pick Start: This option allows the user to randomly navigate the site, but a starting direction must be defined by picking two points on the screen. Once travel starts, the direction can be controlled with the arrow keys on the keyboard.

Auto: This option also allows the user to randomly navigate the site, but a start point is automatically selected.

Log Playback: This option uses vehicle log files from Carlson Machine Control to animate the position of vehicles in the scene and show the surface updates.

Follow Centerline: This method prompts for a centerline file (.CL) or alignment polyline to follow. The camera position of the animation will be limited to follow this alignment. The **Follow Offset** value shifts the view position to the right (positive value) or left (negative value) of the centerline to simulate driving down one lane of the road.

Drape 2D polylines on surface: This option will drape 2D polylines onto the surface regardless of their original elevation.

Auto select Model Library entities: When enabled, this option will automatically detect 2D symbols in the drawing and display them as 3D symbols as specified in the 3D Viewer/Model Library command.

Select Entities: This button allows you to select drawing entities to display in the 3D window.

Select Surface (Reference Surface): This button allows you to select a reference surface file. This will allow you to report the cut/fill difference between the given surfaces at the current position. This option is only available when the Surface Source is set to Grid or TIN file. Note that this reference surface will not actually be displayed in the viewer.

Select Image (Aerial Image): This button allows you to drape an aerial image on the surface. This image must be a geo-referenced TIF image that overlaps the area of the surface model. See the Create World File by Image in Drawing for additional information.

After clicking OK, the 3D graphics window will appear.

The 3D window has several mouse and keyboard controls that can assist with navigating the scene. These are listed below:

- Hold left-mouse button: Rotates/pans/zooms the scene based on the current mode. You can change the mode by clicking one of the control icons.
- Hold right-mouse button: Zooms in/out on the scene
- Hold middle-mouse button: Pans the scene
- W key: Zooms in
- S key: Zooms out

- A key: Pans left
- D key: Pans right
- Q key: Pans up
- Z key: Pans down
- E key: rotates down
- C key: rotates up
- X key: rotates left
- V key: rotates right

View Direction: This option determines the direction that you look "out of" the vehicle based on the direction of travel. This setting does not change the direction of travel. There are six different view directions: Front, Back, Left, Right, Free Rotate and Detached. For Free Rotate, you can use the view controls to position the view relative to the vehicle and hold this position relative to the vehicle when you Run the animation. For the Detached mode, the view is not connected to the vehicle during the animation run which allows you to control the view point independently as the vehicle runs.

View Position: This option determines the position of the viewpoint relative to the vehicle. There are three different view positions:

1. Driver - The Driver position puts you inside of the simulated vehicle. **NOTE:** The Vehicle Icon option is not available when Driver is used.
2. Pedestrian - The Pedestrian position puts you behind and above the vehicle when view direction is set to front, above and to the left when the view direction is right, and so on.
3. Bird - The Bird position puts you further behind and higher above the selected vehicle.

Vehicle Icon: This option determines the type of vehicle to be used in the display. There are many options available, including dozers, sport-utility vehicles, emergency vehicles and others as setup in the 3D Model Library command. You may turn off the vehicle icon on the Settings tab.

Shading: This option determines the type of shading to be applied to the surface when the surface source is from a file. This option is not active when the surface is defined by screen entities. There are several shading options, including:

- None - Does not produce shading.
- Flat - Uses one color per 3D Face.
- Smooth - Blends colors together.
- Elevation - Generates colors based on the vertical position of the surface entities.
- Normal - 3D Faces are colored according the slope and slope direction of the surface.
- Cut/Fill - Generates colors based on depth of cut or height of fill between two surfaces. This option is only available when the Surface Source is defined by a File and a Reference Surface has been specified.
 - Cut is denoted by hues of red.
 - Fill is denoted by hues of blue.

Surface Transparency: This slider bar controls the transparency of the surface. Dragging the slider to the left will make the surface more transparent.

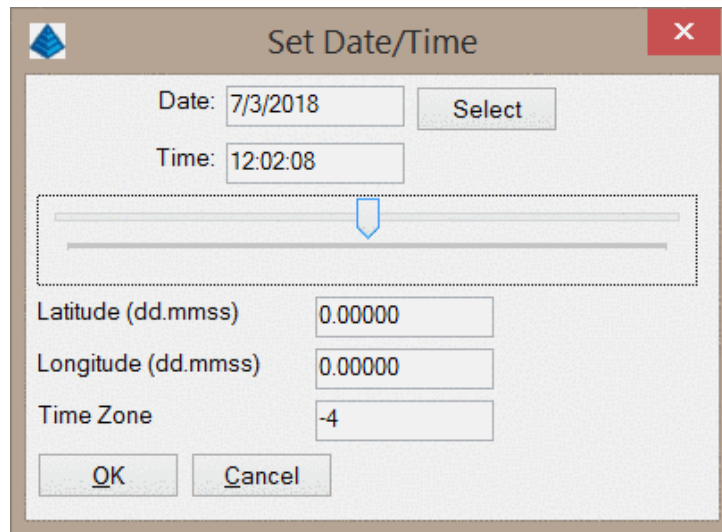

Vertical Scale: This option allows the user to specify a vertical exaggeration factor to aid in viewing relatively flat surfaces.

Elev: This value determines the height of the viewer vantage point above the surface. Clicking the up arrow will elevate further from the surface; clicking the down arrow will take you closer to the surface.

Distance: This value determines the horizontal distance from the viewers vantage point (behind) to the actual focal point on the surface. Clicking the Up arrow beside the control will increase the distance from the focal point; clicking the Down arrow will decrease the distance.

Speed: This value determines the rate of travel across the surface in miles per hour. Clicking the Up arrow beside the control will increase speed; clicking the Down arrow will decrease speed.

Lighting by Location/Time: This button will display the below dialog, which allows you to set the lighting as it would appear at a specific location at a specific time.

Date/Time: These values set the date and time for the lighting. The **Select** button will allow you to pick the date from a calendar. The horizontal slider below the time will allow you to set the time of day.

Latitude/Longitude: These values set the location of the viewpoint

Time Zone: This value adjusts for the various time zones. Values should be integers representing GMT adjustments. For example, the Eastern Standard Time (EST) in the USA will use a value of -5.

Control

Action

This control represents the position of the sun in plan view. If the yellow square is in the center of the blue circle, the sun is in a zenith. If the yellow square is near the edge of the circle, the sun is near the horizon. To move the yellow square, simply drag it to a new location, or click on the new location. The slider bars on the sides control the intensity and brightness of the display.

Switches to Pick Mode.

Switch to Dynamic Zoom mode. Click and drag to zoom in and out.

Switches to Rotation mode. When the cursor is placed near the outer edge of the view, a "Z" cursor is presented that permits rotation around the Z-axis. When the cursor is placed further into the interior of the view, an "X,Y" cursor is presented that permits the tilt angle of the view to be adjusted.

Switches to Pan mode. Click and drag to pan.

Starts (or "runs") the animation in the main window. While running, this button becomes the Stop button.

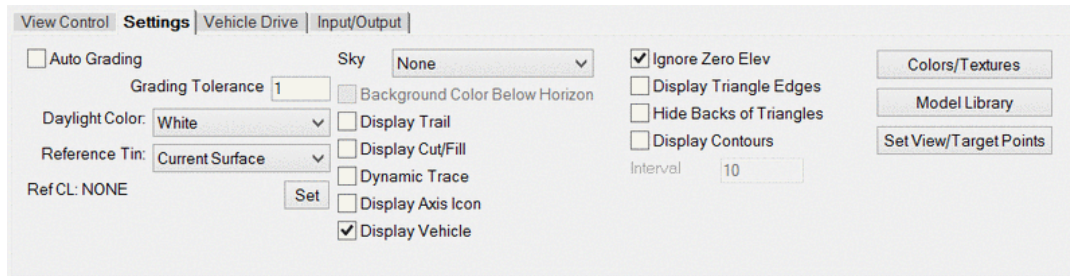

Stops the animation. When stopped, this button becomes the Run button.

Opens the help document you are currently reading.

Exits the command.

Auto Grading: This option automatically sets the Grading Tolerance based on the elevation difference with the reference TIN.

Grading Tolerance: When the cut/fill is less than this amount, the surface will be colored by the Daylight Color.

Daylight Color: The surface color for areas with cut/fill less than the Grading Tolerance.

Reference TIN: When using a Reference TIN from the first dialog, this option controls the direction of the cut to fill.

Ref CL: When a reference centerline has been selected, the current view position is reported beneath the main viewer window indicating the station/offset relative to the centerline.

Sky: This option controls the background image for the 3D viewer. By default, no background image will be displayed. When a background image is displayed, you can toggle the **Background Color Below Horizon** checkbox to hide the bottom half of the background image.

Display Trail: Displays the traveled route on the surface as a line.

Display Cut/Fill: This displays the amount of cut or fill at the location of the vehicle. This option is only available when a Reference TIN is used in the first setup dialog.

Dynamic Trace: When enabled, a position marker of the current view point is also displayed in the CAD/DWG window.

Display Axis Icon: Shows an x/y/z axis icon in the scene to help visualize the view angles.

Display Vehicle: This option toggles the visibility of the Vehicle in the 3D view.

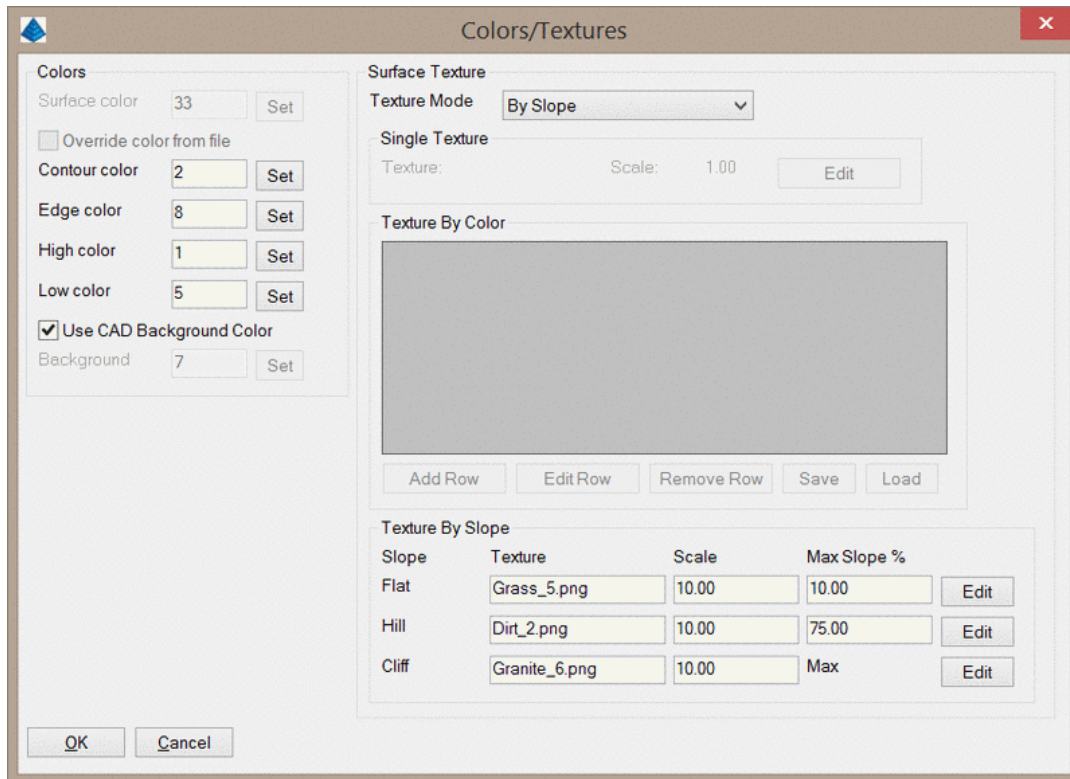

Ignore Zero Elevation: Ignores zero elevation entities in the scene.

Display Triangle Edges: Shows lines along the triangle edges in the scene.

Hide Backs of Triangles: This option toggles the display of the backs of 3D Faces. When enabled, even the edges of the triangles will be hidden.

Display Contours: Shows contours for the surface using the specified **Interval**.

Colors/Textures: This button opens the below dialog, which controls the colors and textures applied to the surface.

Surface Color: This setting will determine the color of surface entities when the shading mode is set to either flat or smooth. The color functions are only available when the Surface Source is defined by a File. If the Surface Source is defined by screen entities, color is determined by the properties of the screen entities.

Override color from file: When enabled, this option will override any color assignments and display the entire surface as a single color.

Contour/Edge color: These colors control the coloring for contours and triangle edges. Note that this does not affect the coloring of contour polylines that are loaded into the viewer, but only contours that are generated within the viewer.

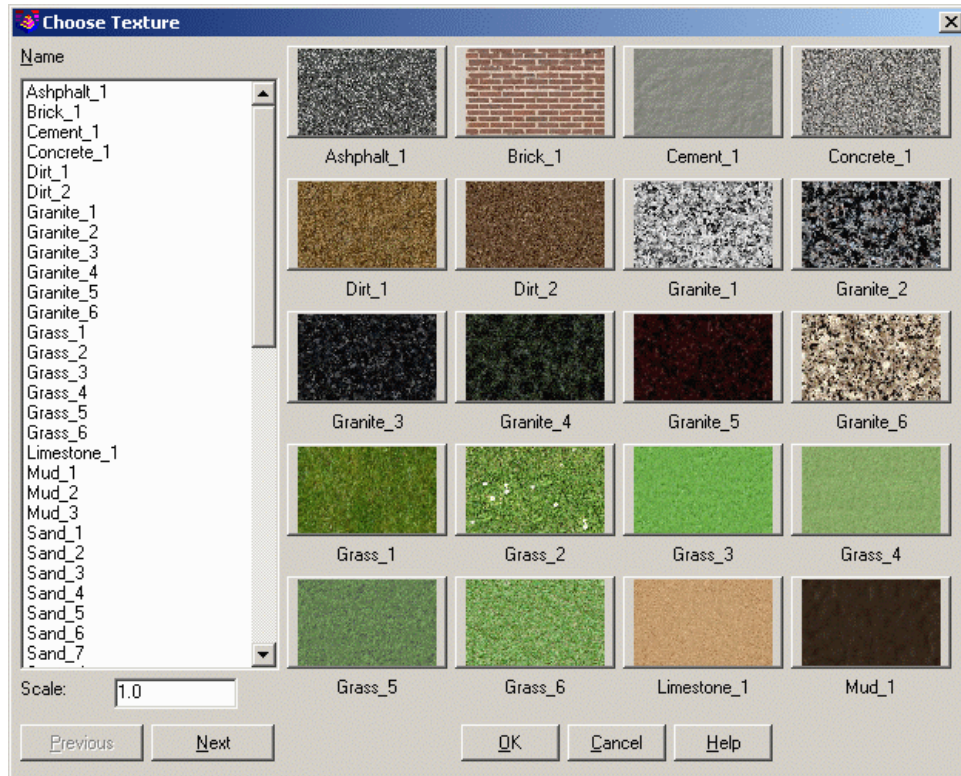

High/Low Color: When using the "Elevation" mode of shading, these values set the color gradient of surface entities that are in the higher elevation ranges of the surface.

Use CAD Background Color: When enabled, the background color of the 3D viewer will match the CAD background color. If this option is disabled, you can set a different background color.

Surface Texture: This function controls the texture for the surface. There are five Texture Modes.

None: No textures will be used.

Single Texture: Sets one texture for the entire surface. Clicking the **Edit** button will display the below dialog, allowing you to select a texture and a scale for the image.

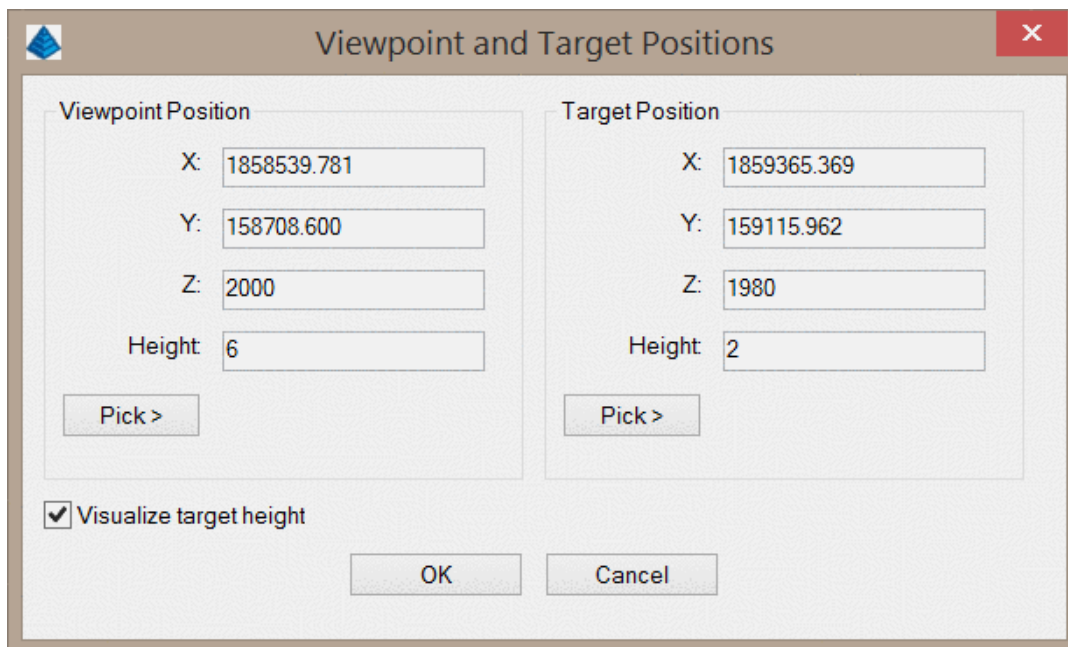

By Color: Sets a texture for each different color in the surface. The TIN file can have different colors for different areas by using the Road Network output TIN options to color by grade or by using Triangulation File Utilities. When this option is used, you will be able to add colors to the Texture by Color table.

By Color, Single as Default: This is the same as the By Color option except the Single Texture is used for any TIN colors not set in the lookup list.

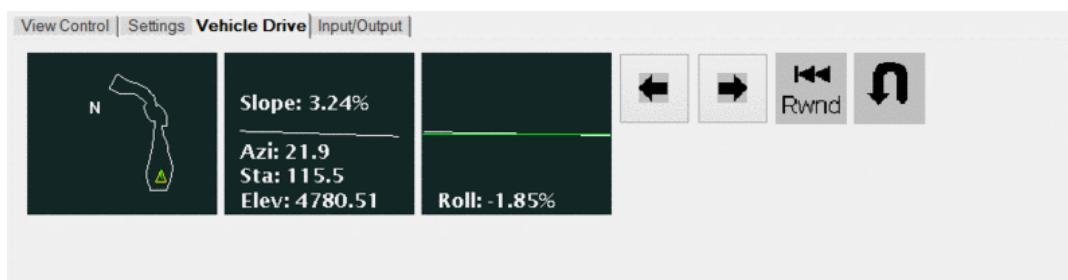

By Slope: This option sets the texture of the surface according to the slope of the surface. The cutoffs for the three slope groups are set with the **Max Slope %** value for that field. The textures for each slope group may be set by clicking the **Edit** button.

Model Library: This button opens the 3D Model Library.

Set View/Target Points: This button opens the below dialog, which lets you set the view position and target position by specifying the coordinates of each.

The positions can be entered in the edit boxes or you can use the respective **Pick >** button to pick a point in the drawing. The program will pick up the elevation of the surface for picked points and then the height above the position can be entered. For example, to check sight distance the view position could be a point on a road at the driver's eye height and the target position could be the object to check.

The window on the left shows the overall plan view and the location of the vehicle of the surface. The middle window displays the current station (when a polyline is used for direction control), elevation, slope (in relation to the direction of travel) and azimuth. The right window indicates the amount of roll or cross slope (in relation to the direction of travel) at your current position.

Control

Action

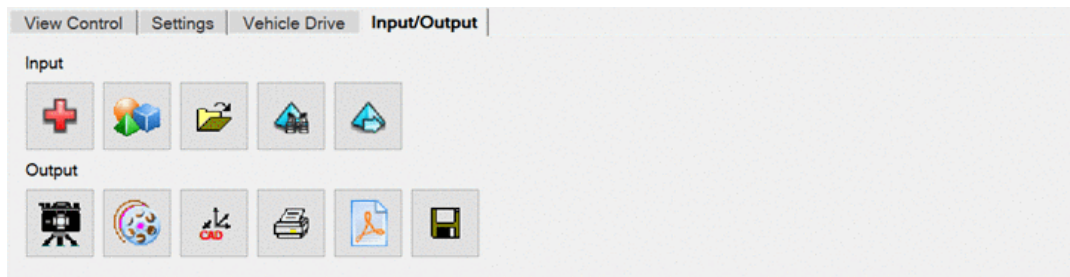

When using "Free Flight", this icon turns the direction of travel to the left.

When using "Free Flight", this icon turns the direction of travel to the right.

When using a 3D polyline for the travel direction, this button returns you back to the original starting position. The simulation must be in the Stopped mode for this to be active.

When using a 3D polyline for the travel direction, this button will reverse the direction of travel at the current position. The simulation must be in the Stopped mode for this to be active.

Additional Visualization Controls

Control

Action

Adds a 3D Model to the viewer.

Loads an MDL solid file.

Loads a 3DX file.

Sets the 3D Viewer viewpoint to match the current CAD viewpoint.

Reloads the data in the 3D Viewer.

Save a screenshot of the 3D Viewer.

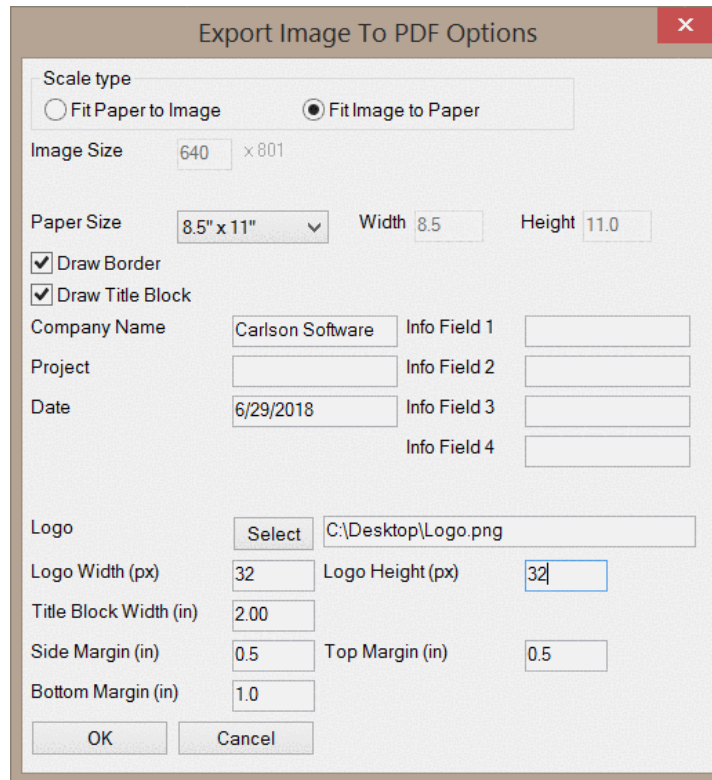

Records a movie of the 3D Viewer. The video will be saved to a .avi format. You will also be able to select from a variety of compression methods. After clicking OK, the recording will begin. You may click the icon again to stop the recording.

Sets the CAD viewpoint to match the current viewpoint of the 3D Viewer window.

Exports the 3D Viewer to a PDF report with project information. The default project information is set under Carlson Configure > General Settings. The dialog that appears for this command is shown below.

Exports the 3D Viewer to a 3D PDF. This function is further described in the to the 3D Viewer to 3D PDF help article. Note that you must have access to the CADNET module in order to use this command.

Save the entities in the 3D Viewer to a 3DX file.

Scale Type: This option controls how the image and the paper will be scaled to match one another. When the *Fit Paper to Image* option is selected, you will be able to manually set the **Image Size**.

Paper Size: This option sets the size of the PDF.

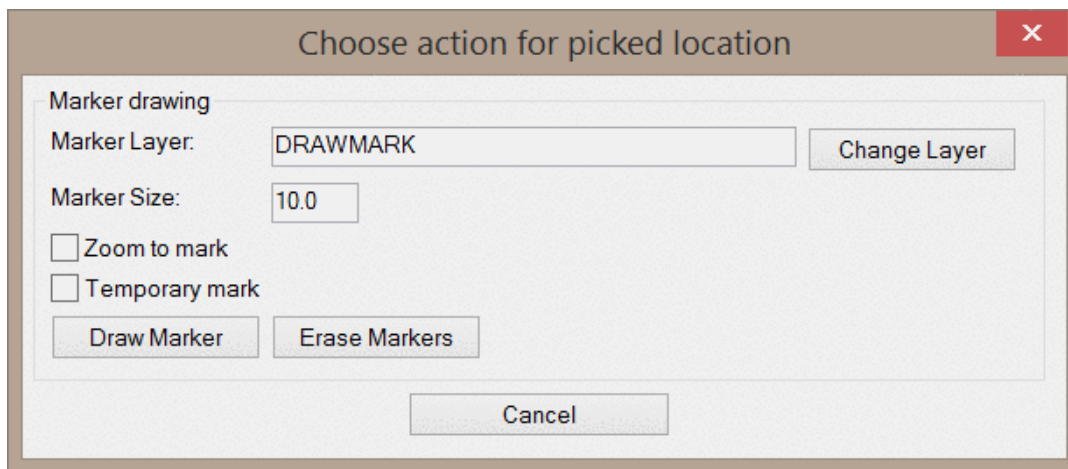

Draw Border: This option toggles the addition of a border around the PDF.

Draw Title Block: This option toggles the addition of a title block in the PDF. Information such as the **Company Name**, **Project**, **Date**, and **Logo** will be included in the title block. The logo may be selected by clicking the **Select** button and the dimensions may be specified in pixel dimensions.

Top/Side/Bottom Margin: These values set the margins around the PDF in inches.

This tab shows a project tree of the types of items in the scene. Right-click on items in the project tree to change the display properties.

When a location is "picked" through a double-click while in pick mode, the following dialog box displays with additional controls about how the location should be processed:

Marker Layer: Indicate a desired layer name or use the Change Layer button to select an existing layer for the position of an eventual marker.

Marker Size: Indicate the desired radius of a circle that will serve as the marker location.

Zoom to Mark: When enabled, the DWG will be zoomed to the location of the marker so it can be quickly found in the drawing.

Temporary Mark: When enabled, the marker will only be displayed in the drawing while the display remains static. As soon as a display update is summoned (via REDRAW, REGEN, ZOOM or PAN), the marker will no longer display on the screen. Disabling this toggle commits a CIRCLE entity into the drawing.

Draw Marker: Draws a marker into the drawing at the coordinates of the picked location and with the display characteristics defined by the Temporary Mark toggle.

Erase Markers: Erases any markers previously placed with the Draw Marker command.

- To entities within the DWG file (and optionally, Carlson surface files), use the 3D Viewer Window command.
- To quickly view just a surface file, use the Surface 3D Viewer command.

Pulldown Menu Location(s): Civil > Surface > 3D Views, Construction > Takeoff

Keyboard Command: flyby,(tk_flyby, tk_flyby2)

Prerequisite: A Carlson surface model (screen entities or file) and optionally a 3D polyline

Surface 3D Viewer

This command is identical to the 3D Viewer Window, except that this one loads a Carlson Grid GRD, TIN or FLT file. After the surface file is selected, the 3D viewer is shown.

On the Settings tab, there is an option to show contours.

On View Control, the larger pointer button puts the viewer in TIN edit mode. In this mode, the TIN Edit function list is enabled.

Swap TIN Edge: Double-click on a TIN edge to swap the connection points between two triangles.

Add Breakline: Double-click on a TIN point to set the first breakline point and then double-click on the second TIN point to create a breakline in the TIN.

Remove Point: Double-click on a TIN point to remove it from the surface.

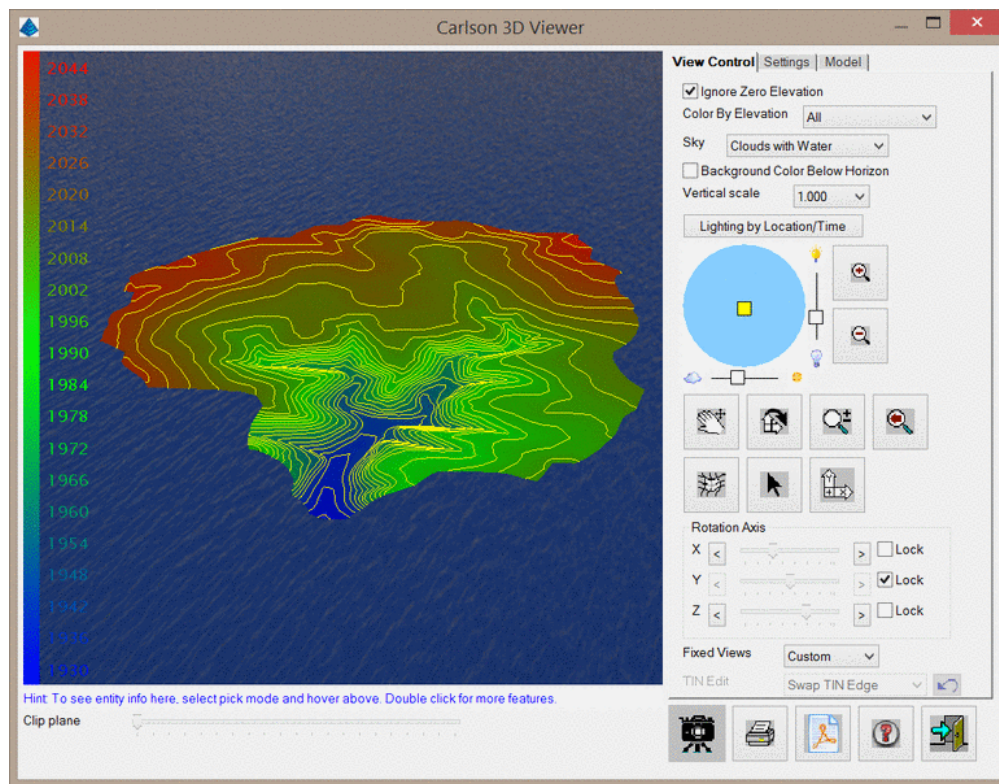

Remove Triangle: Double-click inside a triangle to remove it from the surface.

Set Point Elevation: Double-click on a TIN point and the program will prompt to enter the elevation.

Undo: The undo button next to the TIN Edit command list allows for undoing the last TIN edit.

When the TIN is edited, the program will prompt for whether to save the TIN when you exit the viewer.

The rest of the functions in this viewer are the same as documented in the 3D Viewer Window command.

- To entities within the DWG file (and optionally, Carlson surface files), use the 3D Viewer Window command.
- To visualize a site with animated vehicle controls, use the Surface 3D Fly-Over command.

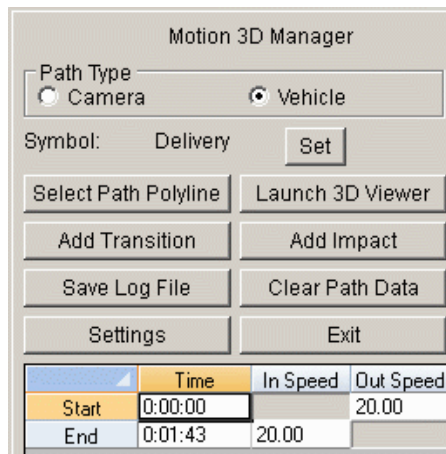

Pulldown Menu Location(s): View, Civil > Surface > 3D Views

Keyboard Command: cube_surface

Prerequisite: Carlson surface (TIN, FLT, GRD) to display

Motion 3D Viewer

This command creates moving vehicles for the Surface 3D FlyOver viewer. The vehicle paths are set by assigning a vehicle icon and speed to polylines. This command docks a dialog on the left of the drawing.

Use the Select Path Polyline function to tag a polyline as a path polyline. After selecting the polyline from the drawing, the dialog shows a spreadsheet of the transition points along the polyline. The speed is set at each point. When running the animation, the vehicle speed will be interpolated between these transition points as the vehicle moves along the polyline. At a minimum, there are two transition points for the start and end of the polyline.

The direction of the polyline in the drawing controls the direction of the movement in the viewer. When the polyline is 3D, the viewer will use the polyline elevations. When the polyline is 2D, the viewer will drape the polyline on the surface to set the elevations.

When the path polyline is selected, the Path Type chooses whether to use the polyline for the camera view position in the viewer or for drawing a vehicle icon.

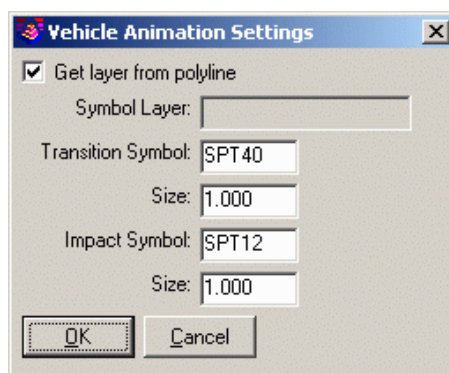

Use the Set button to select a Symbol for the vehicle icon. The list of available symbols comes from the 3D Model Library command.

Use the Add Transition function to add a speed transition point on the polyline path. The Add Impact creates a special transition point that represents where a vehicle had a collision. For this impact transition point, there is both a speed in and out to represent the sudden change in speed.

The Save Log File option creates a log playback file (.pos) which can be used by Surface 3D FlyOver.

The Clear Path Data function untags the path data from the selected polylines.

The Settings function show a dialog with settings for the temporary symbols that are shown in the drawing to indicate the transition points along the polyline.

When the path polylines are all set, use the Launch 3D Viewer command to display the scene with the vehicle

animation. The view controls are the same as the Surface 3D FlyOver command. Pick the Run button to put the vehicles in motion.

Pulldown Menu Location: Surface > 3D Views

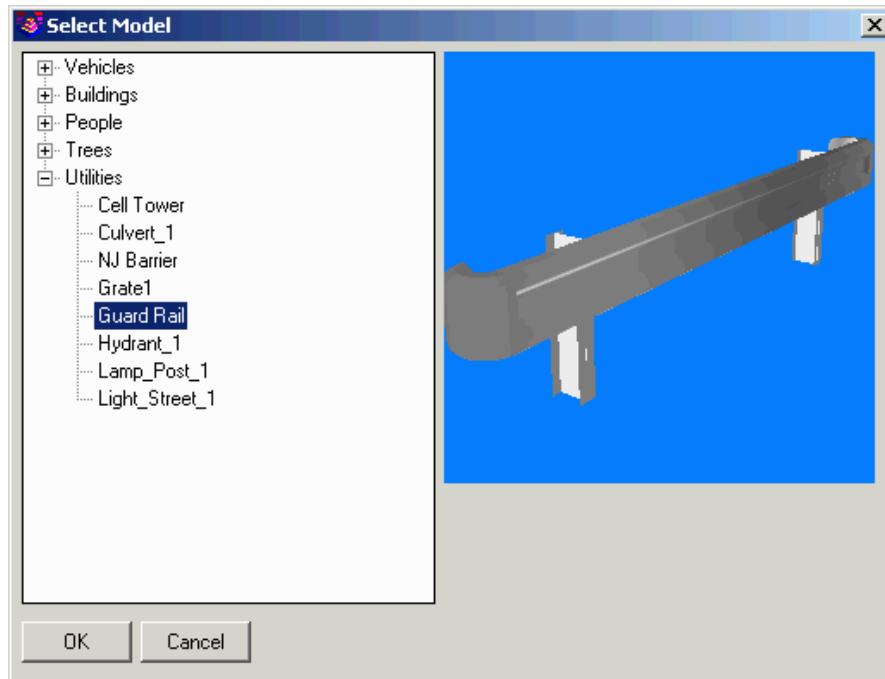

Keyboard Command: cube_motion

Prerequisite: Polyline

Linear 3D Object Polylines

These commands manage alignment polylines for 3D linear features such as fences or guard rails. These 3D features are used in the scene for 3D viewer commands such as Surface 3D FlyOver. When the polylines are 3D, the 3D viewer will use the polyline elevations. When the polylines are 2D, the 3D viewer will use the surface model to elevate the 3D objects.

This command assigns a 3D object to the selected polylines. This command prompts to select the polylines to assign and then prompts for the 3D object and Symbol Gap which controls the spacing of the 3D objects along the polyline. This gap is useful for 3D objects that occur at an interval such as street lights. For continuous objects like a fence, this gap should be set to zero. The available 3D objects to select from are defined in the 3D Model Library command.

This command creates a report of all the polylines in the drawing that are tagged as Linear 3D Object Polylines. The report includes the name of the 3D object, polyline layer and polyline starting coordinate. This report is useful to see how many and where these polylines are located in the drawing.

This command removes the 3D object assignments from the selected polylines.

Pulldown Menu Location: Surface > 3D Views

Keyboard Command: tag_linear3d, report_linear3d, untag_linear3d

Prerequisite: Polylines

Render, Shade, and Hide Commands

The *Render*, *Shade*, and *Hide* commands located under the Surface >> 3D Views menu simply execute the appropriate standard AutoCAD commands.

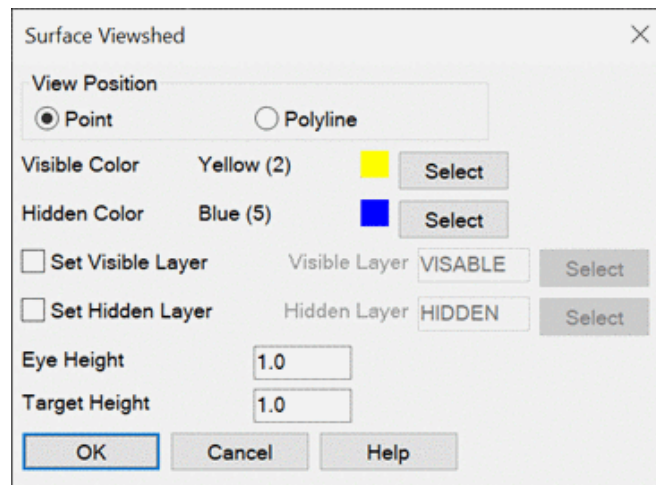

Pulldown Menu Location: Surface > 3D Views

Keyboard Command: render, shade, or hide

Prerequisite: none

Line of Sight Viewshed

This command colors 3D faces for a surface for whether the 3D face is either visible or hidden from a specified view point. The 3D faces need to be already drawn before running this command. The 3D faces can come from either a grid or triangulation surface. The colors for visible and hidden are set in the dialog. There are also options to change the layer of the 3D faces for visible or hidden status. The Eye Height is added to the elevation at the View Point to set the elevation of the viewer. The Target Height sets how high of an object the viewer can see for the visible areas. The View Position by Point prompts for a single 3D point to calculate the viewshed from. The Polyline method prompts for a 3D polyline and checks multiple view positions at an interval along the polyline.

Graphic shows position of view point, surface contours and 3D faces colored with yellow for visible surface and blue for hidden surface.

Prompts

Pick view point: *pick point*

Select 3D Faces to Analyze...

Select objects: *pick 3D faces*

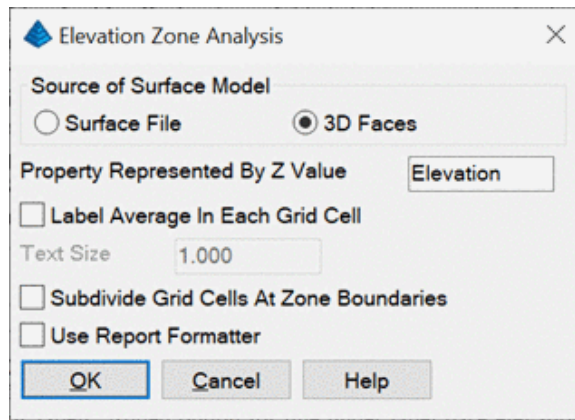

Pulldown Menu Location: Surface

Keyboard Command: viewshed

Prerequisite: 3D faces

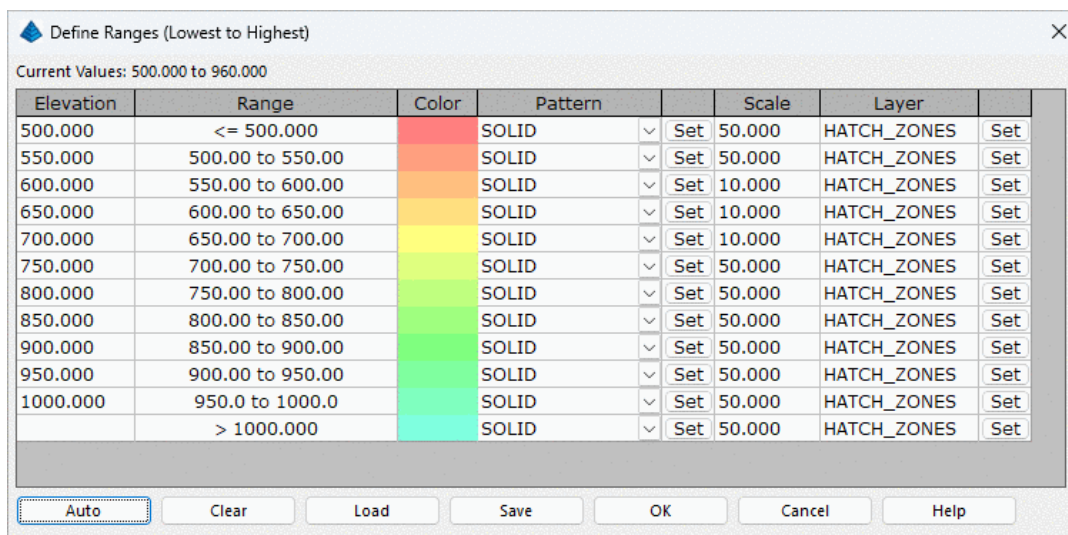

Elevation Zone Analysis

This command can be used to calculate the surface area of a surface in different elevation zone ranges and to analyze a surface by ranges or "zones" of elevation. The program requires either a triangulation surface file (TIN) or 3D Face entities. The 3D Face entities can be generated by the *Draw 3D Grid File* or *Draw Triangular Mesh* commands. The *Draw Triangulation Faces* option in *Triangulate & Contour* can also be used to create triangular 3D Faces. For each elevation zone, the 3D Faces can be hatched with a hatching pattern, solid filled with the SOLID pattern, or left empty with the NONE pattern. The 3D Faces are also placed in a separate layer for each zone. When using a surface file for input, the TIN file colors are set to the elevation zone colors which can then be rendered in the 3D Viewer commands.

In the options dialog, the **Property Represented By Z Value** sets the name used in the reports for the type of surface model. **Label Average In Each Grid Cell** creates text labels in the center of each 3D Face of the surface with the average surface value. **Subdivide Grid Cells at Zone Boundaries** gives higher resolution at the transition between zones. **Use Report Formatter** allows for customized report and different output formats.

There are also options to specify inclusion and exclusion areas. When inclusion areas are specified, only the area within the inclusion polyline is calculated. Areas within an exclusion polyline are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to calling this routine. Without inclusion and exclusion polylines, all the area of each selected 3D Face is used.

Prompts

Elevation Zone Analysis dialog

Select 3D Faces to Analyze...

Select objects: *pick the 3D Faces to process*

Define Ranges (Lowest to Highest) Dialog

Specify the elevation ranges, colors and patterns.

Select the Inclusion perimeter polylines or ENTER for none:

Select objects: *pick a closed polyline for the limits of disturbed area*

Select objects: *press Enter*

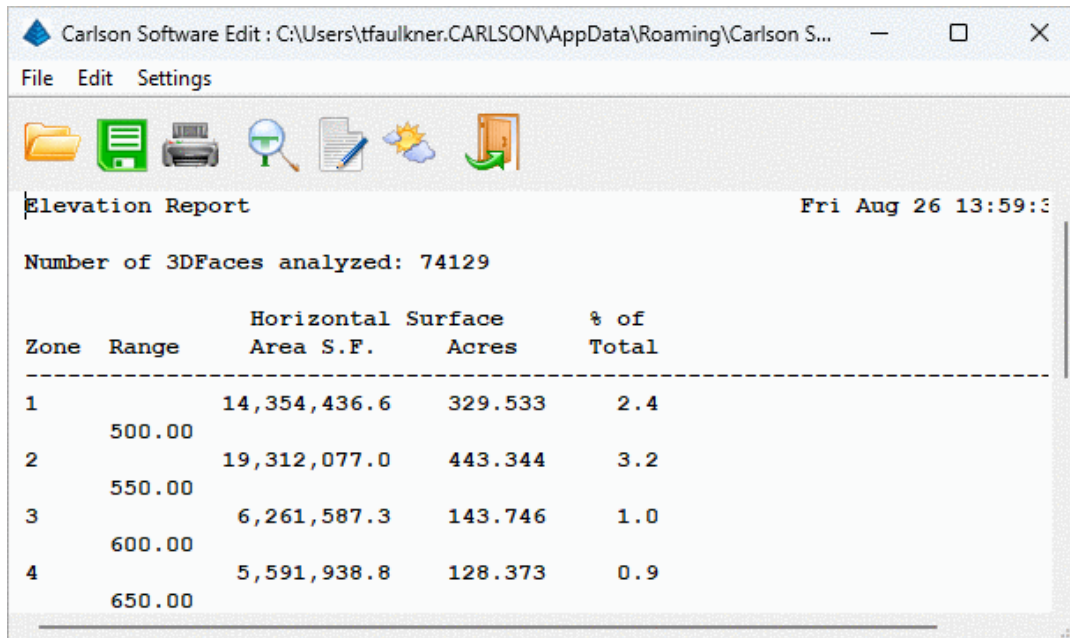

Select the Exclusion perimeter polylines or ENTER for none:

Select objects: *press Enter*

Select point for color legend (Enter for none): *pick a point*

If a point is picked, a legend showing the color of each range is drawn. The legend is drawn aligned to the current view *UCS*. For this reason it is best to have the mesh at the *Vpoint* at which it will be plotted before executing the analysis program.

A report is also generated in the standard report viewer.

Zone	Range	Horizontal Surface Area S.F.	Acres	% of Total
1	500.00	14,354,436.6	329.533	2.4
2	550.00	19,312,077.0	443.344	3.2
3	600.00	6,261,587.3	143.746	1.0
4	650.00	5,591,938.8	128.373	0.9

Result of Elevation Zone Analysis viewed in 3D and shaded

Pulldown Menu Location: Surface

Keyboard Command: elvzone

Prerequisite: displayed 3D Face entities.

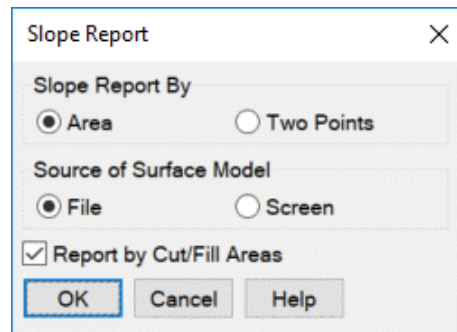

Slope Report

This command calculates the sloped surface area, average slope and average elevation on a site. The surface can be defined by a surface model file, (.GRD, .TIN or .FLT), or generated from 3D entities on the screen. Sloped area information is useful to compute seeding quantities for hillsides, for example.

For the screen method, the surface is modeled from the user-selected entities such as contour polylines. Besides the surface entities, a perimeter polyline is used as the inclusion area for the slope report. If the perimeter polyline is on the PERIMETER layer, the command will locate it automatically.

For area reports, there are options to specify inclusion and exclusion perimeters. When inclusion perimeters are specified, only the area within the inclusion perimeters is calculated. The area within exclusion perimeters is not included in the calculations. Inclusion and exclusion perimeters are represented by closed polylines and must be drawn prior to running this routine.

The option to Report by Cut/Fill Areas will report the slope areas separately for cut and fill areas. When this option is on, the program prompts for a second surface to use as a reference to determine the cut/fill areas.

Prompts

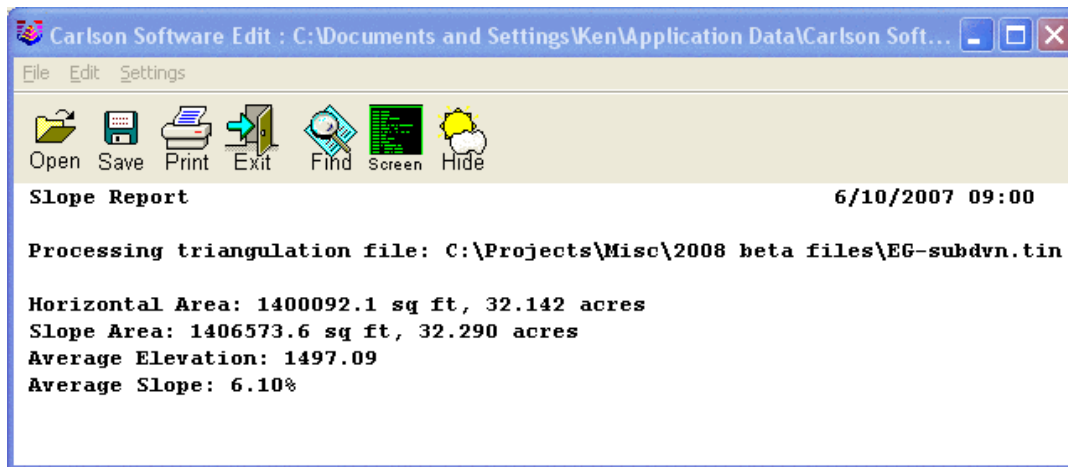

For Area report using a File:

Select surface model file.

Select the Inclusion perimeter polylines or ENTER for none: *pick any inclusion polylines*

Select the Exclusion perimeter polylines or ENTER for none: *pick any exclusion polylines*

Note: If the surface model file is a grid file (.GRD), you are prompted whether to extrapolate the grid to full grid size.

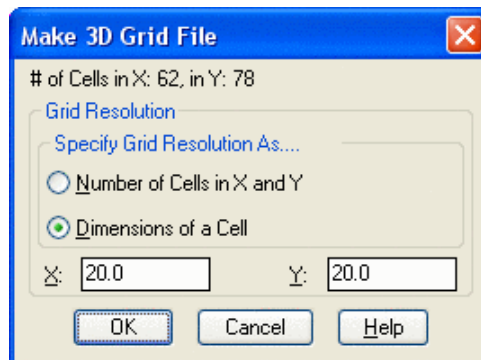

For Area report by *Screen* method:

Ignore zero elevations (<Yes>/No)? *press Enter*

Select surface entities and perimeter.

Select objects: *pick the objects*

If no polyline is found on layer PERIMETER, you are prompted to: Select Pond/Pit perimeter polyline. The Make 3D Grid File dialog is presented. Pick *OK*.

Select the Inclusion perimeter polylines or ENTER for none: *pick any inclusion polylines*

Select the Exclusion perimeter polylines or ENTER for none: *pick any exclusion polylines*

For *Points* method:

Select surface model file.

Pick first point:

Pick Second point:

The slope report is displayed on the command line for the 3D vector, projected on the surface, defined by those 2 picks.

Point 1: 5119.646,5640.322,98.979

Point 2: 4951.964,6022.419,135.546

Horiz Dist: 417.27 Slope Dist: 418.87 Elv Diff: 36.57

Slope: 8.76 Ratio: 11.41:1

Pulldown Menu Location: Surface >> Slope Analysis

Keyboard Command: sarea

Prerequisite: A surface file or screen entities of the surface.

Slope At Points

This command reports and labels the slope between two points or at points on a surface model (triangulation or grid). The **Input Method** for **Points** prompts you to pick two points and calculates the slope between these points. The points can be either picked in the drawing or entered by point number from the current coordinate file. The Input Method for **Surface Triangles** creates a label at center of each triangle face in the surface which can work well on grid files but is typically too much information for triangulated surface files. The Input Method for **Pick on Surface** prompts to pick the points where to calculate the slope. For the Pick method, the Define Slope setting allows a couple ways to pick. The **At Single Point** option calculates the slope from the surface model at the point. The **Between Two Points** method calculates the slope using the surface model elevations at two picked points and the horizontal distance between these points. As the crosshairs are moved across the surface, the slope at the current position is displayed in a floating dialog box.

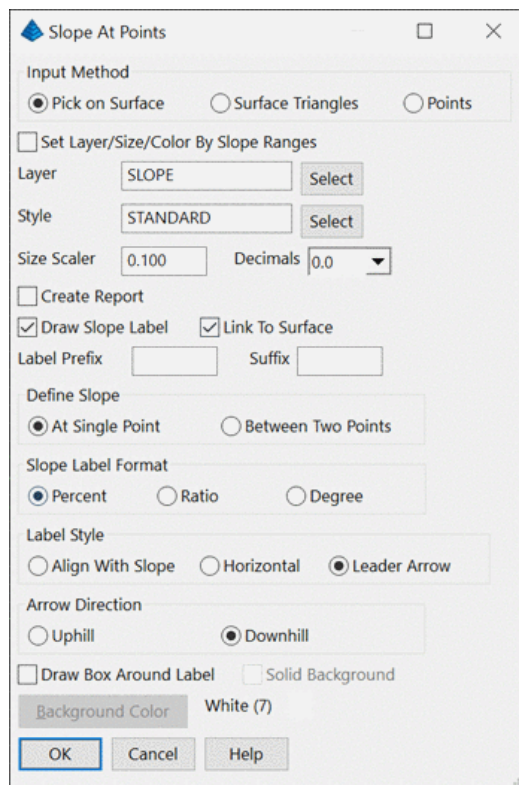

For the slope labels, the dialog has settings for the **Layer, Style, Prefix, Suffix, Decimals, Slope Label Format** and **Size Scaler**. The **Size Scaler** is multiplied by the drawing horizontal scale to calculate the text size in drawing units. The Create Report option uses the **Report Formatter** to make a report of the coordinates, slope amount and slope direction.

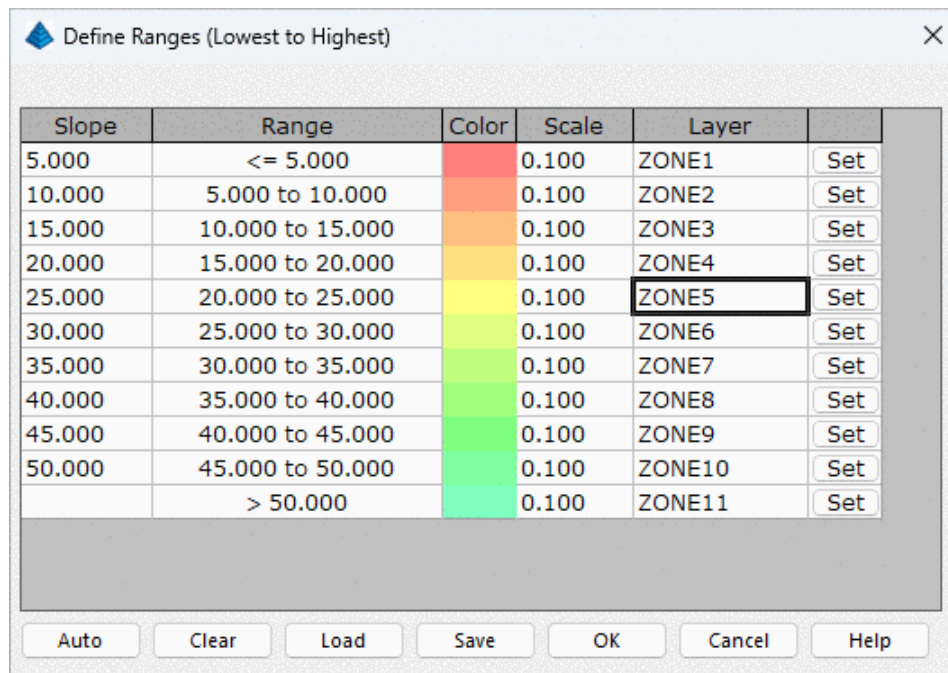

The **Label Style** of **Align With Slope** rotates the slope label in the slope direction. The **Horizontal** option creates a horizontal label. The Leader Arrow rotates the slope label in the slope direction and draws a leader arrow for the slope direction either facing uphill or downhill depending on the **Arrow Direction** option.

The **Link To Surface** option will update the slope label when the triangulation surface model is modified.

The **Draw Box Around Label** option draws a polyline box around the slope labels and the **Solid Background** option fills in this box with the specified color.

The **Set Layer/Size/Color By Slope Ranges** option invokes the Define Ranges dialog box. Enter slope values in the first column of boxes to set the Ranges.

Prompts

Slope At Points dialog box

Adjust settings as desired. Pick OK.

Select Surface Model.

Pick Points to label slope.

Draw grid file and Slope At Point labels using Surface Points

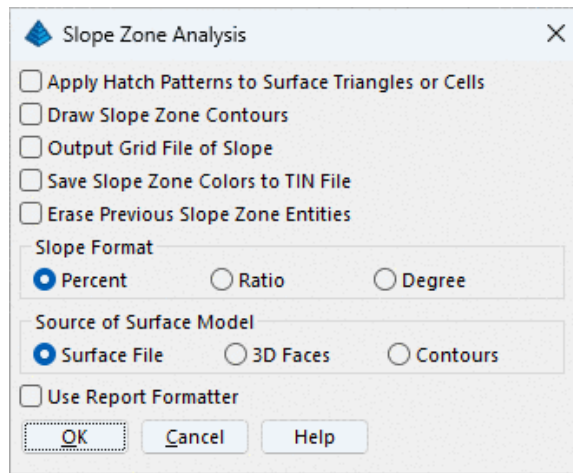

Pulldown Menu Location: Surface >> Slope Analysis

Keyboard Command: ptslope

Prerequisite: A surface model file (.TIN, .GRD, or .FLT)

Slope Zone Analysis

This command calculates the surface area of a site in different slope zone ranges. This command can use either a surface model file, (.TIN, .GRD, or .FLT), contour polylines, or 3D Face drawing entities which can be generated by the *Plot 3D Grid File* command, the *Draw Triangular Mesh* command, or the *Draw Triangulation Faces* option of *Triangulate & Contour*. For each slope zone, the 3D Faces can be hatched with any hatch pattern, including the SOLID pattern, or left empty with the NONE pattern. The command reports the area for each slope zone. When using a triangulation surface file, the *Save Slope Zone Colors* option sets the triangle colors in the TIN file for the slope zones. Then commands like *3D Viewer Surface File* can visualize the colored surface. When using the *Contours* method, the program prompts to select the contour polylines along with optional points to picking up high and low points. Using the *Contours* method along with the option to *Draw Slope Zone Contours with Hatch Slope Zones*, the hatch zone boundaries will follow the contours. The *Use Report Formatter* option allows for customized reports and different output formats.

The Draw Slope Zone Contours option generates contours of the slope zones based on the calculated slope at each point of the 3D Faces. The Output Grid File of Slope option creates a grid file of the slope values.

There are also options to specify inclusion and exclusion areas. When inclusion areas are specified, only the slope area within the inclusion polyline is calculated. Slope area within an exclusion polyline are not included in the calculations. Inclusion and exclusion areas are represented by closed polylines and must be drawn prior to calling this routine. Without inclusion and exclusion polylines, all the slope area of each selected 3D Face is used.

Prompts

Slope Zone Options dialog box. Choose whether to Draw Slope Zone Contours, whether to Output Grid File of Slope, and Slope Format. Pick *OK*

Select surface model file.

Define Ranges dialog. Specify the slope zones, colors and patterns from lowest to highest. Pick *OK*.

Select the Inclusion perimeter polylines or ENTER for none: *select perimeter(s) or press Enter*

Select the Exclusion perimeter polylines or ENTER for none: *select perimeter(s) or press Enter*

Report is generated.

Slope Report

Surface File: C:\scdev\data\SIMO2.grd

Average Slope: 21.6%

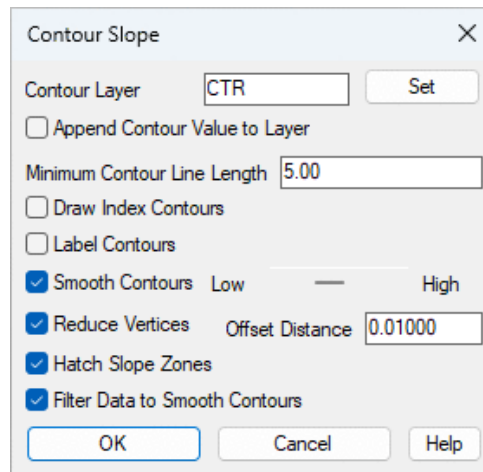

Minimum Slope: 0.0%

Maximum Slope: 81.7%

Zone	Range	Horizontal Surface Area S.F.	Acres	Slope Surface Area S.F.	Acres	% of Total	Average Slope %
1	20.00%	769,137.1	17.657	775,379.4	17.800	51.8	11.8
2	40.00%	583,761.4	13.401	607,257.9	13.941	39.3	28.2
3	60.00%	113,978.1	2.617	125,967.2	2.892	7.7	46.8
4		18,494.6	0.425	22,407.7	0.514	1.2	68.3
Total		1,485,371.1	34.099	1,531,012.2	35.147		

If you choose to draw Slope Zone Contours, the Contour Options dialog box is presented. There are settings for the contour layer and whether to label, smooth and reduce the contours. The Hatch Slope Zones option fills in the slope zone areas with colored hatching. The Filter Data to Smooth Contours option applies a filtering algorithm that reduces the noise. The slopes can vary greatly between neighboring points. When contoured directly, these slope

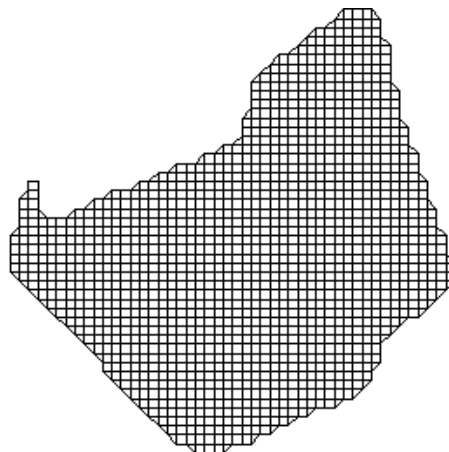

data points can produce incoherent contours with the smoothing.

Note: If you choose to use Screen entities instead of a surface model file, you are prompted whether to: **Freeze grid layer after processing [Yes/<No>]?**

Surface contours

3D Faces from a grid surface model

Original Contours

Surface Colored by Slope Direction

Pulldown Menu Location: Surface >> Slope Analysis

Keyboard Command: dzone

Prerequisite: 3D Face entities

Convert LDD Contours

This command allows you to convert Autodesk Land Desktop contours (known as AECC_CONTOUR objects) into polylines. You must have the AEC Object Enabler installed before using this command. If you do not have the object enabler installed, download the latest version from <http://www.autodesk.com>.

Note: If no object enabler is installed, opening a Land Desktop drawing with contours will display large boxes for each contour, essentially outlining the extents of each one. In this case you will need to download the object enabler. If the object enabler is installed, contours will appear normally, and you can use this command to convert them to standard lwpolylines or you can use the *Explode* command. The Carlson *Convert LDD Contours* command is preferable only in the fact that it will search the drawing for AECC_CONTOUR objects and convert only those, while an *Explode* command could inadvertently explode other entities that you do not wish to be exploded.

You can use the *List* command to determine if contours are polylines or AECC_Contour objects. Here is an example listing:

AECC_CONTOUR Layer: "CONT-MJR"

Space: Model space

Handle = 429

Major Contour Interval

Elevation: 1005.00

Smoothing: None

Number of Vertices: 48

Open

Length: 560.25

Constant width: 0.00

Style Name: Standard

Prompts

Select AEC Contours to convert

Select objects: *pick the AEC contour entities*

Pulldown Menu Location: Surface >> Import/Export

Keyboard Command: aec_cntr

Prerequisite: AEC Contours to convert

Convert LDT/Civil3D Surface Drawing

This command allows you to convert Autodesk Civil3D or Land Desktop custom surface objects into standard AutoCAD entities. For example, this command will convert AECC_CONTOUR objects into polylines with elevation. The conversion is done on the currently opened drawing. Besides converting the drawing entities, the routine checks for triangulation surface definitions within the drawing and prompts whether to save these surfaces to Carlson .TIN files. The conversion routine was developed in cooperation with the Open Design Alliance (ODA) and does not use object enablers from Autodesk.

If you have Civil 3D, another way to make a drawing with standard AutoCAD entities is to use the aectoacad command in Civil 3D which converts the custom objects into standard entities.

Pulldown Menu Location: Surface >> Import/Export

Keyboard Command: c3d_tin

Prerequisite: AEC surface objects to convert

Import NASA World Elevation Dataset

This command creates a grid surface file (.GRD) using a world elevation dataset from the NASA Space Shuttle program. The data covers all land areas up to latitude 60. The data was recorded in 2000 by the Shuttle Radar Topography Mission (SRTM). The data is at an interval of 1 arc-second or about 100 feet.

Before running this command, the grid coordinate system must be setup in Settings > Drawing Setup. The program first prompts to pick a window in the drawing for the surface area. The first time that you access data in an area, the program will download source data from the Carlson Software server.

Prompts

Pick first corner of bounding box: Identify one corner of a drawing window for the surface area

Pick second corner of bounding box: *Identify the opposite corner*

Surface File To Write

Pulldown Menu Location: Civil > Surface > Import/Export Surface, Survey > Surface > Import/Export Surface, Construction > Import/Export

Keyboard Command: nasa_grd

Prerequisite: Coordinate projection system, Internet connection

Import National Elevation Dataset

This command creates a grid or triangulation surface file (GRD or TIN) using the National Elevation Dataset (NED) from the USGS. The NED source data is at a resolution of 1/3 arc second. Before running this command, the grid coordinate system must be setup in Settings > Drawing Setup. The program first prompts to pick a window in the drawing for the surface area. Then there is a dialog to set the number of sample points. Currently the NED service is slow. So the number of samples is limited to 50 in X and Y directions. Also the NED data has limited grid resolution and does not interpolate. So if your sample spacing is smaller than the NED resolution, then samples within the same NED grid cell will have the same elevation.

Prompts

Pick first corner of bounding box: Identify one corner of a drawing window for the surface area

Pick second corner of bounding box: *Identify the opposite corner*

Options dialog

Surface File To Write

Pulldown Menu Location: Civil > Surface > Import/Export Surface, Survey > Surface > Import/Export Surface, Construction > Import/Export

Keyboard Command: getneddata

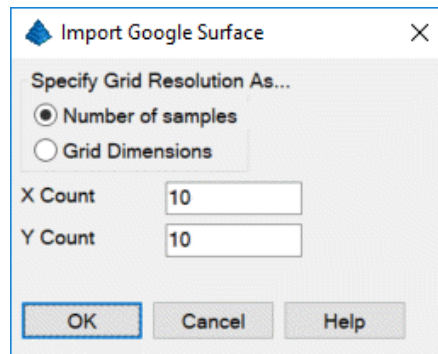

Prerequisite:Coordinate projection system, Internet connection

Import Google Earth Surface

This command creates a Carlson Triangulation file (TIN) by downloading surface data from Google Earth. While the elevation accuracy of the Google Earth surface should be considered coarse, it might be suitable for large-scale watershed modeling studies, preliminary land-planning studies or "proof-of-concept" preliminary designs.

Before running this command, the grid projection system for the drawing must be defined in Settings > Drawing Setup.

After selecting the TIN file to output, the program prompts to pick the rectangular area in the drawing for where to create the surface file. Then there is a dialog to set the grid resolution of the data points. You can either specify the number of rows and columns for the grid or define the size of the grid cells.

Note:

- In an effort to protect their servers from abuse, Google limits the number of data points.
- The Import Google Earth Surface routine fetches terrain data in real-time from the Google servers and requires an Internet connection to proceed.
- It bears repeating that the terrain data returned by Google Earth should only be used for illustrative or proof-of-concept purposes only!
- To import a Google Earth image into your drawing, use the Place Google Earth Image command.
- To import KML content into your drawing, use the Import Google Earth File command.
- To export content from your drawing to a KML file, use the Export Google Earth File command.

Prompts

Select Output File: *Choose a TIN file to create.*

Pick first corner of bounding box: *Identify one corner of a drawing window that should be used to set the Google Earth display*

Pick second corner of bounding box: *Identify the opposite corner of a drawing window that should be used to set the Google Earth display*

Import Google Surface dialog

Pulldown Menu Location: Civil > Surface > Import/Export Surface, Survey > Surface > Import/Export Surface, Takeoff > Tools > Import/Export, Construction > Import/Export

Keyboard Command: gesurface

Prerequisite: Coordinate projection system defined in Drawing Setup and Internet connection

Import/Export Trimble TTM File

These commands convert between Trimble TTM format triangulation files and Carlson format. First you select the source file to read and then the destination file to write.

Pulldown Menu Location: Surface->Import/Export Surface

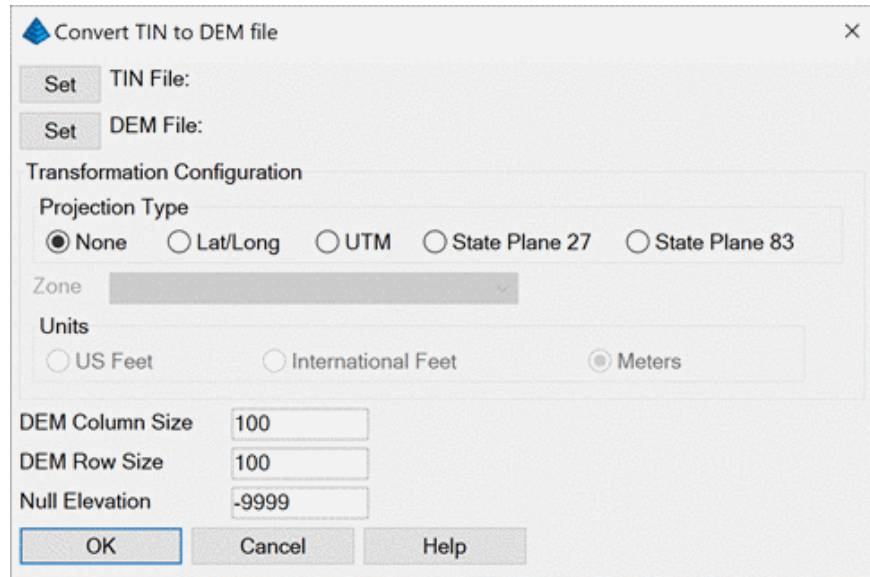

Keyboard Command: ttm2tin, tin2ttm

Prerequisite: File to convert

Export DEM TIF File

This command creates a GeoTIFF DEM (Digital Elevation Model) file from a TIN file. The GeoTIFF DEM file is a geolocated TIFF file with one raster band representing elevation. The GeoTIFF DEM file is created by first creating a grid of "DEM Column Size" columns and "DEM Row Size" rows across the extents of the TIN (based on the TIN's x,y bounds). The center of each grid cell is sampled, and the elevation of the TIN at that sample location is used to produce a corresponding pixel in the output GeoTIFF DEM file. Geolocation information for the output GeoTIFF DEM file is based on the extents of the input TIN file projected according to the "Transformation Configuration" options.

Convert TIN to DEM file dialog:

Input/Output Options: The "TIN File" "Set" button allows the user to select the input TIN file. The "DEM File" "Set" button allows the user to select the output GeoTIFF DEM file.

Transformation Configuration: This column provides options for setting the projection that will be applied when geolocating the output GeoTIFF DEM file. This projection specifies how to interpret the extents of the TIN file.

- **Projection Type:** Specifies how to interpret/project the extents of the TIN when geolocating the output GeoTIFF DEM file.
 - **None:** No projection. The extents of the TIN will be used to geolocate the output GeoTIFF DEM file with no projection.
 - **Lat/Lon:** Use Lat/Long projection. The extents of the TIN will be interpreted as Lat/Long values.
 - **UTM:** Use Universal Trans Mercator (UTM) projection. The extents of the TIN will be interpreted as UTM values. UTM Zone can be set from the "Zone" pop list.
 - **State Plane 27:** Use State Plane 27 projection. The extents of the TIN will be interpreted as State Plane 27 values. State Plane 27 Zone can be set from the "Zone" pop list.
 - **State Plane 83:** Use State Plane 83 projection. The extents of the TIN will be interpreted as State Plane 83 values. State Plane 83 Zone can be set from the "Zone" pop list.
- **Zone:** Specifies the UTM, State Plane 27, or State Plane 83 zone depending on "Projection Type" settings.
- **Units:** Specifies the units for the output GeoTIFF DEM file.

Elevation Sampling Options:

The "DEM Column Size," "DEM Row Size," and "Null Elevation" options specify how the "Export DEM TIF File" routine should go about sampling the input TIN file.

- **DEM Column Size:** Specifies the number of columns that will be included in the sampling grid.
- **DEM Row Size:** Specifies the number of rows that will be included in the sampling grid.
- **Null Elevation:** Specifies the pixel value to be used in the output GeoTIFF DEM file if no elevation information exists at a geolocated pixel's sampling position on the TIN.

Pulldown Menu Location: Surface > Import/Export Surface

Keyboard Command: tin2dem

Prerequisite: A triangulation file

Export Topcon TIN File

The Export Topcon TIN File command writes a Topcon TIN file (.TN3) from a Carlson triangulation file (.TIN, .FLT). The routine first prompts for the Carlson file and then the Topcon file.

The Import Topcon TIN File command creates a Carlson Tin file (.TIN, .FLT) from a Topcon triangulation file (.TN3). The routine first prompts for the Topcon file and then the Carlson file.

The units (Feet or Meters) for the triangulation file are the current units set in Drawing Setup.

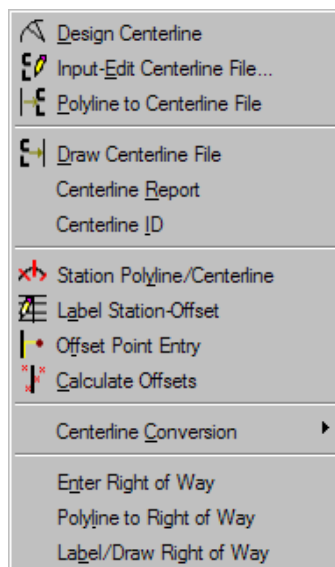

Pulldown Menu Location: Surface > Import/Export Surface

Keyboard Command: topcon_tin, tn3_to_tin

Prerequisite: A triangulation file

Centerline Menu

The Centerline menu provides commands for designing and editing centerlines and centerline files. Tools for stationing, labeling and offsetting centerlines, along with Right of Way features, are also provided in this menu. Additionally, there are many import and export conversion options to select from when you pick *Centerline Conversion*.

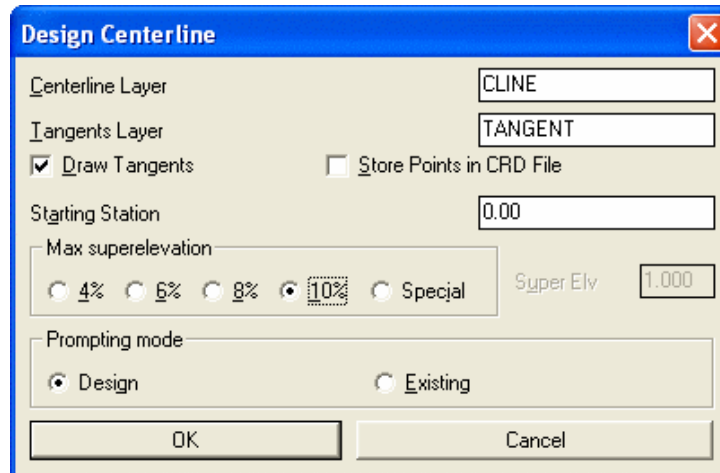

Design Centerline

This command draws a centerline polyline and writes the centerline data in a centerline file. The first step is to specify a centerline (.CL) file name. Next in the Design Centerline dialog you can specify several options. Centerline Layer is the layer name for the polyline. Tangents Layer is the layer name for the tangent lines drawn

from the centerline to the curve center. Max superelevation is used for determining the minimum recommended radius. Setting the Prompting mode to Existing skips design questions such as design speed.

After the Design Centerline dialog, the program cycles through curve prompting until End is selected. There are PC and PI modes for curve entry. In PC mode the arc's PC points are entered followed by the curve data. The PC points can be specified by either picking the point, entering a distance or entering a station. In PI mode, the arc's PI points are entered. Once the PI points determine two tangents, the program prompts for curve data for the previous PI. Spirals can only be entered in PI mode. You can switch between arc and PI mode between curves on the polyline. The arc curvature can be specified by degree of curve or radius. The minimum recommend radius is based on AASHTO. The arc length can be specified by PT station, tangent length or arc length.

The Store Points in CRD File will create points in the current coordinate file for each design point on the centerline. This option is also used for creating the SMI chain file within Centerline Utilities, since the SMI chain file requires point numbers. To specify the coordinate file, choose *Set Coordinate File* in the Points menu.

Prompts

Centerline file to design Enter the .CL file name to create.

Design Centerline Dialog Choose your options and click OK.

Pick Point or Point number: *pick a starting point or enter the starting point coordinates*

For PC mode design:

Pulldown Menu Location: Centerline

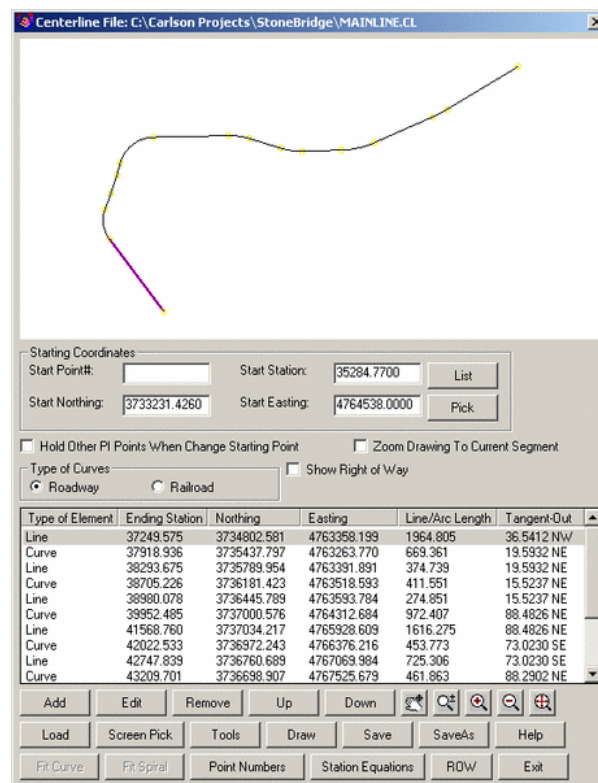

Keyboard Command: centerln

Prerequisite: None

Centerline Editor

This command can be used to input a new centerline or edit an existing centerline (.CL) file. It is a dialog-based alternative to Design Centerline and has the advantage of accepting whatever information you have on your centerlines (coordinates, stationing, length of tangents and arcs, *etc*). For creating a new centerline, it is ideal for entering data straight from highway design plans. For editing, this command allows you to change any of the geometric properties of any of the elements of the centerline (lines, curves, spiral-only and symmetrical spiral-curve-spiral elements), including the starting coordinates and station.

Starting this command launches the Centerline Editor main dialog box. To edit an existing Centerline, you can either pick the Load button and pick the .CL file, or pick the Screen Pick button and pick the polyline in the drawing that represents the Centerline. The Centerline is then displayed in the graphics window of the dialog box. The highlighted segment in the text window is also highlighted in the graphics window.

Drag Action (Zoom and Pan): In the graphics window, hold the left mouse button down and move mouse to Pan, roll the wheel to Zoom.

Zoom Drawing To Current Segment: This option zooms the drawing graphics to center on the centerline segment currently highlighted in the dialog.

Hold Other PI Points When Change Starting Point: With this option active, all the existing PI's are held when the starting coordinate is moved. Otherwise, all the PI's are moved by the same amount that the starting point is moved.

Show Right of Way: This option shows any ROW's defined in the centerline in the graphic preview window.

Type of Curves: This setting chooses between roadway and railroad definitions for curve lengths.

Add: Adds a new element after the highlighted element. Prompts you for the type of the element to be added, Line, Curve, Spiral-Only or Spiral-Curve-Spiral.

Edit: Allows you to edit the highlighted segment.

Remove: Removes the highlighted element from the centerline.

Up/Down: Moves elements in the table Up and Down in the list. For example, if this centerline ended with a tangential line from the last curve, then was followed by a non-tangential line at 45d NE, moving the last element up would create a line at 45d after the curve (non-tangential), and the formerly tangential line will remain tangential and therefore continue at NE 45d.

Load: Loads an existing centerline (.CL) file for review or editing. After loading a centerline, the listbox in the dialog shows a list of all the elements in the centerline, identifying them as either a line, curve, spiral only or full spiral-curve-spiral element and reporting the ending station, northing and easting of the element.

Screen Pick: Allows user to pick a CL off the screen in the drawing to load into the editor.

Tools > Reverse: Reverses direction of Centerline.

Tools > Rotate: Rotates the centerline by the specified rotation angle and around the specified pivot point.

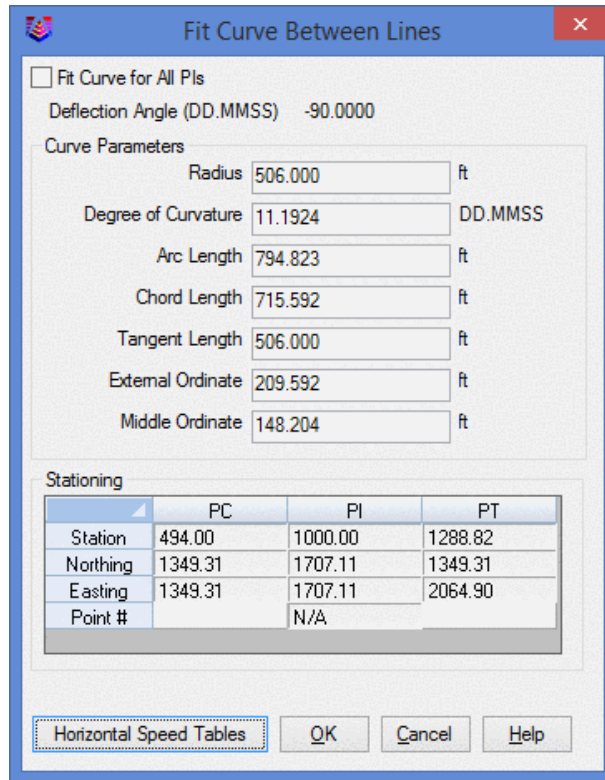

Tools > Scale: Scales the centerline which can be used for changing units between metric and English.

Draw: This button draws the centerline in the drawing on the specified layer.

Save: Saves the currently loaded centerline to a file, or will prompt you for a name if no name has been set.

SaveAs: Prompts you for a file name for the saved file.

Fit Curve: Fits a circular curve element into the centerline after the line element that is currently selected. When all the elements are lines, the program allows you to fit curve for all PIs. The program checks if the radius fits all PIs and will prompt the maximum radius that works for all PIs if the current radius is too big. The Horizontal Speed Tables allows you to pick a speed and a super elevation rate to the minimum radius.

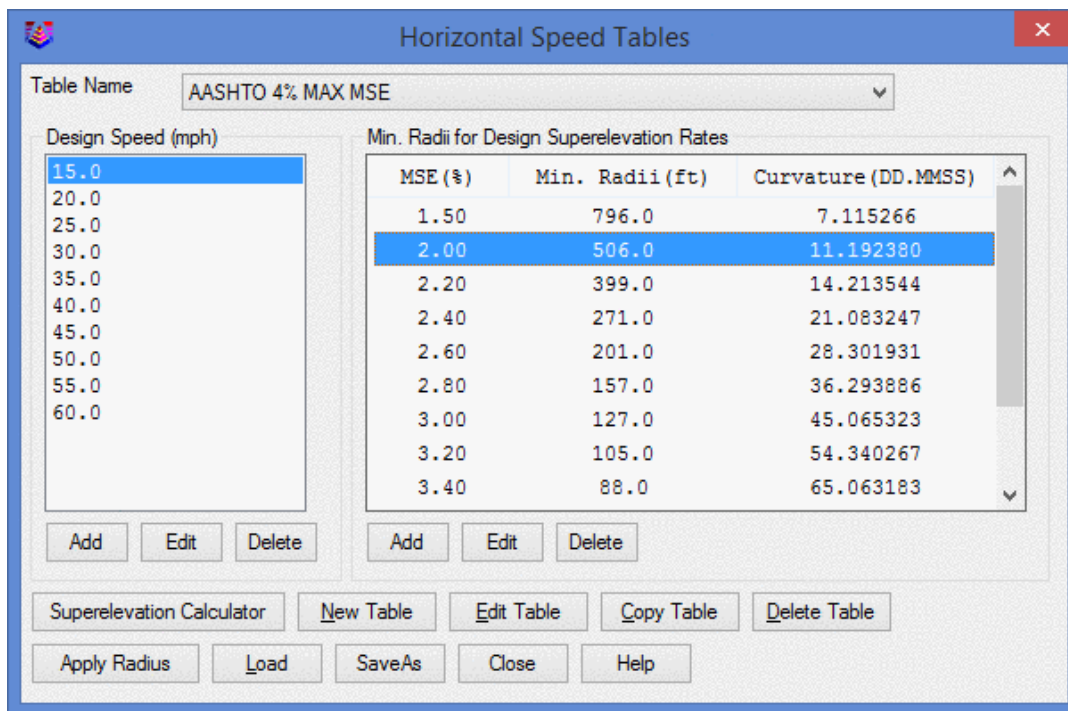

The dialog box titled "Fit Curve Between Lines" contains the following elements:

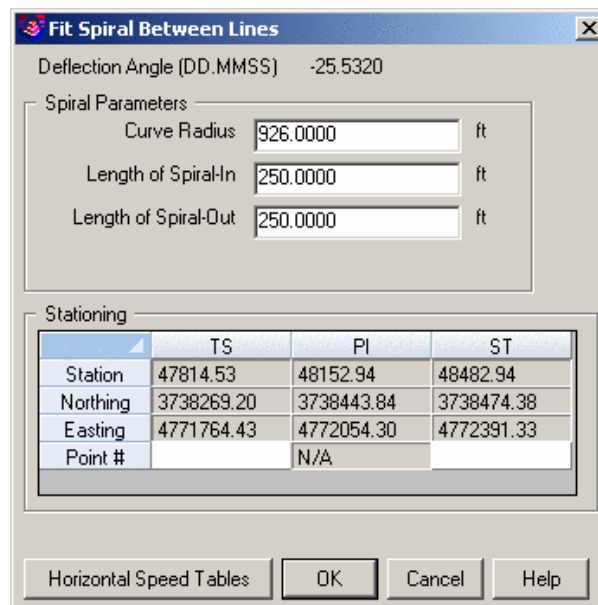

- Fit Curve for All PIs
- Deflection Angle (DD.MMSS) -90.0000
- Curve Parameters section with input fields:
 - Radius: 506.000 ft
 - Degree of Curvature: 11.1924 DD.MMSS
 - Arc Length: 794.823 ft
 - Chord Length: 715.592 ft
 - Tangent Length: 506.000 ft
 - External Ordinate: 209.592 ft
 - Middle Ordinate: 148.204 ft
- Stationing table:

	PC	PI	PT
Station	494.00	1000.00	1288.82
Northing	1349.31	1707.11	1349.31
Easting	1349.31	1707.11	2064.90
Point #		N/A	

Buttons at the bottom: Horizontal Speed Tables, OK, Cancel, Help.

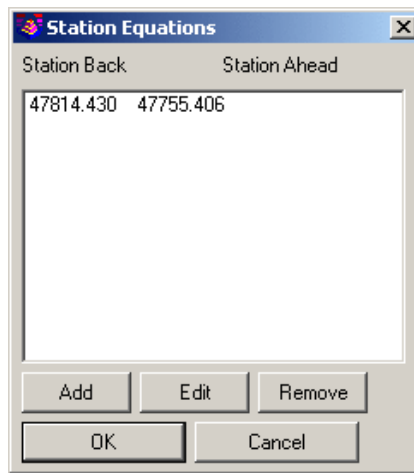

Fit Spiral: Fits a spiral curve element into the centerline after the line element that is currently selected.

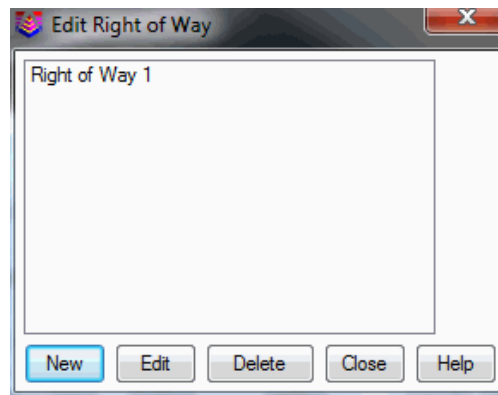

Point Numbers: This will create Carlson points along the elements of the centerline and store them to the current CRD file. The new points will be numbered in sequence beginning with the first available point number in the CRD file.

Station Equations: At any number of locations on a centerline, you can set the back station and forward station for the re-stationing of the centerline. The station equation dialog appears below:

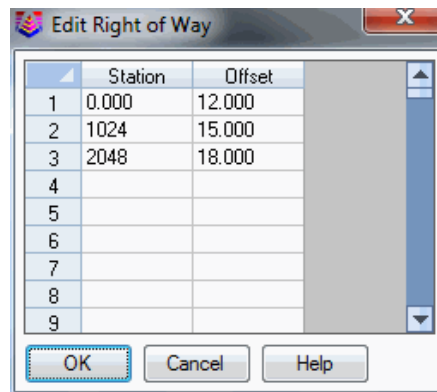

If the Station Back is lower than the Station Ahead, then a "gap" is inserted in the centerline, where the stations jump forward. If the Station Ahead is less than the Station Back, then an overlap occurs, where the common station range is repeated.

ROW: This function edits the right-of-way definitions associated with the centerline. There can be multiple ROW's assigned to the centerline for left and right sides as well as multiple on the same side. The function first shows a list of ROW's for the centerline where you can add, edit or delete.

When you add or edit a ROW, there is a second dialog for entering the stations and offsets that define the ROW relative to the centerline. Use negative offsets for left and positive for right.

Alternatively, the **Enter Right of Way** and **Polyline to Right of Way** commands are other ways to define the ROW's for a centerline.

Exit: Exits this routine, prompting to save changes if necessary.

The dialog for every type of element shows the point ID, the northing, easting and station of the start point of the

element. It then allows the user to modify or define the parameters specific to the type of element. The following are some of the things to remember about data entry in the centerline editor. These are valid for lines, curves and spirals.

- Wherever length of the element is to be entered, entering an expression of the type $123.5 - 93.7$ would evaluate the difference of the values. This is particularly convenient where only the stations of the start and end points of the element are known.
- When the station is specified, the program takes the length of the element as the difference between the station of the start point of the element and the station specified.
- All bearings should be specified by entering the angle between 0 and 90 degrees (in dd.mmss format) and selecting the quadrant.
- When entering the delta angle of a curve, only the absolute value (between 0 and 360 degrees) is to be entered. The direction of the curve is to be explicitly set as right or left, the default being left. All angles are entered in (dd.mmss) format.
- Point numbers, when used, access their coordinates in the current .CRD file. If the point number specified has no coordinates stored in the coordinate file, the point number is remembered for that particular location (say the radius point of a curve or the SC point of a spiral). Then, when the .CL file is saved, the program creates points for that location and stores them to the .CRD file with the specified point number.

The dialog for a Line allows the user to specify the line primarily by its length or station and its bearing. The line can also be defined by its end point number or its coordinates. The bearing of a line can be changed if the Tangential to the Previous Element toggle is not checked. By default, any line which follows a curve element is defaulted to be tangential to it. To use a bearing different than that of the previous element, uncheck this toggle and enter the bearing.

The dialog for the Curve allows the user to define the curve primarily by its radius and delta angle or arc length. The other parameters of the curve that can be edited are the bearing of tangent-out and the "Station to", which also defines the arc length. The curve can also be specified by entering the coordinates or point numbers of its end point (PT) and the radius point. Another way to specify the curve would be to enter the chord length or PT point station and chord bearing. If the central PI point and a point on the forward tangent are known, then the curve can be defined by entering both of these points and at least one other property of the curve (like radius, arc length, delta angle). The point on the forward tangent can be any point that defines the tangent out direction including the next PI point. If only the central PI point is known, then the tangent-out can be entered by bearing instead of by forward tangent point. Central PI and forward tangent points are not displayed from the .CL file. They have to be entered by the user and are valid only for that particular edit session; that is, they are not remembered the next time the file is loaded. Curves are assumed to be tangent to the last element unless the Tangential to the Previous Element checkbox is cleared.

The Curve Edit Mode option defines how the curve is accepted in the centerline. If the Hold PC point is checked on, the radius is taken as fixed and the delta angle of the curve is calculated based on some additional parameter. Hence, the extent of the curve is unlimited. However, if the Hold PI points option is checked on, the bearing of tangent-out of the curve is taken as fixed and the radius is calculated based on some other parameter. In this case, the curve is completely restricted within the central PI point and the bearing of tangent out. Hence, when the Hold PI points option is checked on, the above parameters should also be defined to carry out the calculations.

The dialog for the Spiral-Curve-Spiral element allows the user to define the spiral by entering either the various parameters of the spiral (like the angles and lengths) or the coordinates or point numbers of its defining points: the TS (Tangent-to-Spiral), SC (Spiral-to-Curve), Radius point, CS (Curve-to-Spiral), ST (Spiral-to-Tangent) and end point (optional). While defining the spiral by its geometric properties, the program will accept the data even if the information for the simple curve is given with zero spiral lengths. In this method, however, the central PI point of the spiral MUST be specified (that is, it is always in Hold PI Points mode). The tangent out can be defined by entering bearing or by specifying a point on the forward tangent. This forward tangent point can be the next PI coordinates. The direction of the spiral-in and spiral-out elements would be the same as the direction of the simple curve (left or right). The Spiral Definition setting chooses between Arc definition for clothoid spirals and Chord for 10-chord spirals.

The spiral can be defined by several different parameters and the order that you enter data into the spiral dialog can

be important. There are two main sequences for entering data. The method to use depends on the spiral data that you have. The first method is to enter the radius of the simple curve, the spiral in and out lengths, the tangent bearing out and the PI station. The second method is to make a Line segment coming up to the TS (tangent to spiral) point. This Line segment should be added before creating the Spiral element. Then with the Spiral In point set to the TS point, enter the radius of the simple curve, the spiral in and out lengths, the curve direction (left or right) and the arc length of the simple curve. Then the rest of the spiral points will be calculated.

The Spiral Only element allows for flexible transitions from curve to spiral to curve or line to spiral to curve or between any combination of curve and line elements. The Spiral-Curve-Spiral element, for example, can be entered as Line, Spiral Only, Curve, Spiral Only and Line, producing the same results. You can spiral from tangent to curve, curve to tangent and curve of one radius to curve of another radius. You can also spiral from one endpoint to another endpoint. To define the spiral by sweep angle, use the Delta Angle field. To define the spiral by length, use the Spiral Length field. To define the spiral by end point, fill in the min and max radius fields and then enter either the End Point Pnt# or coordinates and the program will calculate the radius and spiral length to fit that point.

The screenshot shows the 'Spiral-Only Element' dialog box with the following values and settings:

- Spiral-In Northing: 682243.3051
- Spiral-In Easting: 2054761.0326
- Spiral-In Station: 1337.1826
- Spiral Length: 175.0000
- Delta (Sweep) Angle (DD.MMSS): 6.160021
- Spiral Direction: Left, Right
- Element At Spiral Out: Line, Curve
- Curve Radius At Spiral Out: 800.000
- Min. Radius: 600
- Max. Radius: 1100
- End Point#:
 - Pnt#: (empty)
 - Northing: 682308.5742
 - Easting: 2054598.7600
- Tangential to Previous Element
- Angle Format: NE, SE, SW, NW, AZ, Gon
- Bearing(dd.mmss): 66.000139
- Deflection Angle(DD.MMSS): 0.000000

Once all the elements of the centerline are defined, the file can be saved and then plotted using the *Draw Centerline File* command.

Here is an example of a highway interchange ramp that involves a starting tangent and a spiral curve that goes abruptly into a simple curve and then a final tangent. Start by entering a starting Northing and Easting and starting Station. The Start Point# is optional. Then the concept is that you click Add to add each subsequent element (line, curve, spiral-curve-spiral or spiral only):

Pulldown Menu Location(s): Centerline (Survey, Civil), Roads (Construction, Takeoff)

Keyboard Command: cledit

Prerequisite: None

Polyline to Centerline File

This command writes a centerline (.CL) file from a polyline in the direction the polyline was drawn. The Northing and Easting for each vertex of the polyline is written to the centerline file and each arc in the polyline becomes a circular curve. After selecting the polyline, the program shows the direction by drawing temporary arrows along the polyline. To reverse the direction of the polyline, there is a keyword option R for Reverse at the Command line. Also, the Reverse Polyline command can be used to switch the direction of a polyline.

For stationing the centerline, there is a Command line prompt for entering the station at the beginning of the polyline and then using the polyline segment lengths for the rest of the centerline stations. Alternatively, there is a keyword option E for Ending to specify the station at the end of the polyline and then back calculating the centerline stations to the beginning using the polyline lengths. Also, the keyword P for Point prompts to pick a reference point along the polyline and enter the station at this reference point.

In addition to being used as roadway/corridor "baselines," a .CL file can also be used as the horizontal control for a Template Point Centerline.

Note: To convert lines and/or arcs into a polyline, use the Entities to Polylines command or the Join Nearest command

Prompts

Centerline file to Write dialog *Enter the .CL file name to create*

Select polyline that represents centerline: *Pick the polyline that represents your centerline*

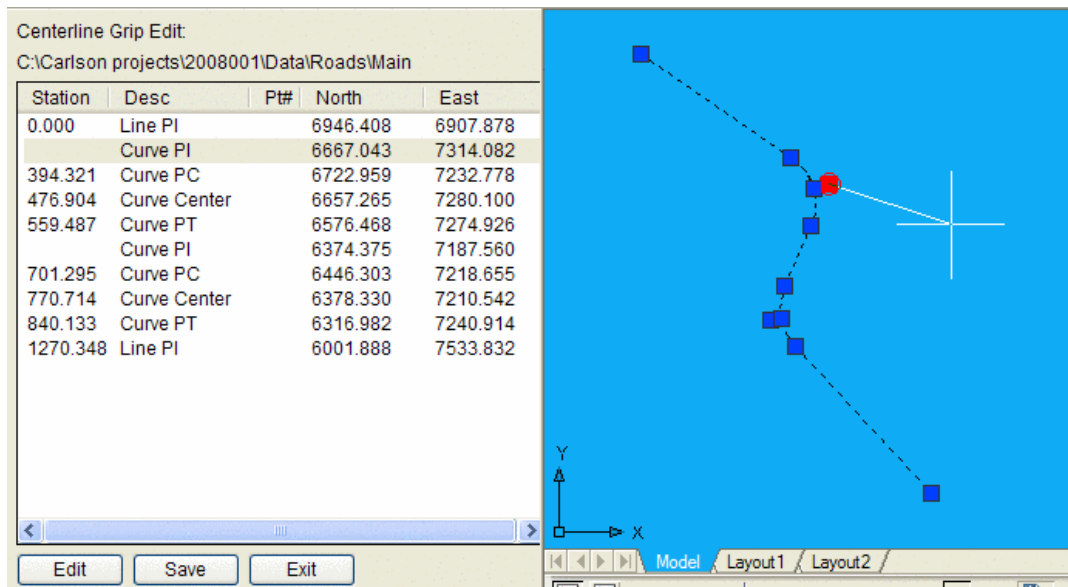

Pulldown Menu Location(s): Civil > Centerline, Survey > Centerline, Field > Roads

Keyboard Command: cpline

Prerequisite: A polyline drawn in the direction of increasing station values

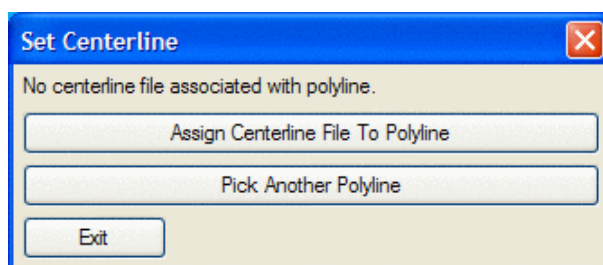

Edit Centerline On-Screen

This command allows the graphical editing of a centerline on the screen through a combination of grip editing and data editing in a docked dialog.

The command initially prompts you to select a polyline on the screen.

If you select a polyline that is not yet associated with a centerline file (.CL), you are prompted to assign a centerline file (.CL) to the polyline or to select another polyline.

Once the docked dialog appears, any component of the centerline geometry can be selected in the list and its data edited with the Edit button. However, the key points on the centerline can also simply be grip edited in the drawing, resulting in changes in the tabular data displayed in the docked dialog. Tangency between centerline components is maintained.

Pulldown Menu Location: Centerline

Keyboard Command: clgrip

Prerequisite: A polyline on the screen, which can either be already associated with a centerline file (.CL) or associated after picking

Draw Centerline File

This command reads a centerline (.CL) file and plots it as a 2D polyline in the drawing at the proper coordinates.

Centerline Layer is the layer name for the polyline to be drawn upon. The **Set** button can be used if you desire to select an existing layer from the current active drawing.

Draw PI Lines draws the straight line segments entering and exiting the PI. The length of the lines is controlled by entering a numerical value in the **PI Lines Length** option.

Label Centerline option draws station labels using a .STA settings file created by the Save Settings function in the Station Polyline/Centerline command.

Clear clears the current .STA file selection

When you click **<OK>**, you are prompted for the file name of the centerline(s) to plot. You can select single centerline (.cl) files individually or, by holding down the **Shift** or **Ctrl** keys, select multiple files at once. All centerline files are drawn with the same settings entered in the above dialog box.

The .CL file can be made with the following commands on the Design menu: *Polyline to CL File*, *Centerline Editor* or *Design Centerline*. Drawing the centerline file is a way to check the .CL file data graphically for correctness. If a spiral exists in the .CL file, the spiral will be represented by polyline segments.

Prompts

Draw Centerline Options dialog

Centerline File to Draw file selection dialog Select the .CL file name(s) to read and plot. Use the CTRL and/or SHIFT keys to select multiple Centerline file(s).

Pulldown Menu Location: Centerline

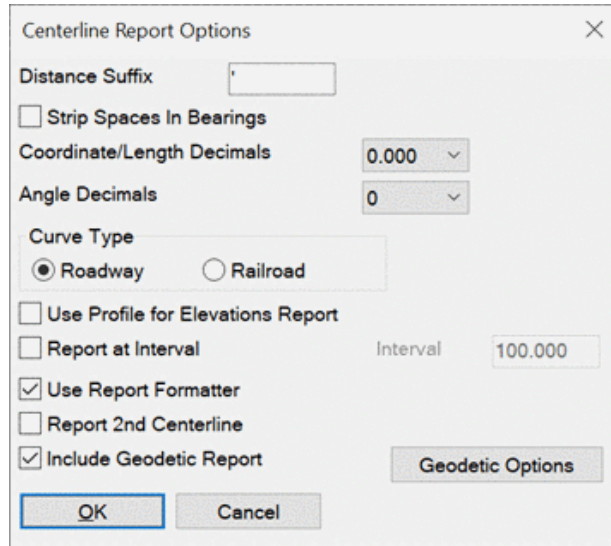

Keyboard Command: c12pline

Prerequisite: a centerline file

Centerline Report

This command reads a centerline file and creates a report in the standard report viewer which can be written to a file, a printer, or to your drawing. If the centerline file contains point numbers, then the report will include these

point numbers. If station equations are found, they are noted at the top of the report. The options dialog has settings for the report format and type of the centerline. The Use Profile for Elevations Report option will prompt you for a profile (.pro) file to add elevations to the report. The Report At Interval option will report stations, northing and easting at the specified station interval. The Use Report Formatter option lets you choose the report format and has output options for Excel. Also, the Report Formatter enables an expanded report with options for Report 2nd Centerline and Include Geodetic Report. The Report 2nd Centerline uses the second centerline for reporting offsets. The Geodetic Report adds geodetic distances and bearings to the report. It requires the grid projection to be defined in Drawing Setup.

Here is an example report:

```

```

Pulldown Menu Location: Centerline
Keyboard Command: clreport
Prerequisite: A centerline (.CL) file

Centerline ID

Centerline ID reports the centerline file name and location that is associated with an alignment polyline. The subject polyline must have been created with either Design Centerline, Input/Edit Centerline, or Polyline to Centerline File.

When the routine is initiated and an alignment polyline is selected, the file associated with that polyline is reported at the command line. Additional alignment polylines may be selected without re-entering the command, or Enter may be pressed to exit the command.

Prompts

Select centerline polyline to identify: *pick the polyline*

Centerline Name: D:\SAMPLE.CL

Select centerline polyline to identify (Enter to end): *press Enter*

Pulldown Menu Location: Centerline

Keyboard Command: CL_ID

Prerequisite: A polyline created from a Design Centerline, Input/Edit Centerline, Polyline to Centerline File, or Centerline File to Polyline.

Station Polyline/Centerline

This command will station a polyline or centerline file at a given interval distance. The options for this command are set in the dialog shown below. After setting the options, click OK on the dialog and then pick the polyline or select the centerline file. All settings can be saved as (.STA) files and loaded for reuse, and for storing multiple stationing schemes. Polyline/Centerline station labels are also dynamic, and so will update when changes are made in the geometry.

Station Polyline/Centerline dialog box showing various settings for stationing, including Distance For Stations (100.000), Distance For Intermediate Stations (50.000), Beginning Station (0.000), and options for Locate, Label Station Text, and Station Type.

Distance for Stations is the primary interval for stationing. On Curve allows for a different interval for curve segments versus line segments.

Distance for Intermediate Stations is the intermediate interval for stationing. On Curve allows for a different interval for curve segments versus line segments.

Beginning Station is the beginning station of the centerline for stationing.

Locate Even Stations labels the stations at the distance interval (i.e. 2+00, 3+00, etc.).

Locate Odd Stations labels the non-interval stations at the polyline/centerline end points and PC and PT points.

Locate User-Entered prompts you for individual stations to label.

Locate Start/End Stations labels the Start and End Station as specified when the option Specify Start/End Stations is enabled.

Without the **Increment Station Labels from Beginning** Station option, the program increments the station labels from zero. For example, if the station interval is 100 and the polyline starting station is 145, then the program will label 2+00, 3+00, etc. With this option active, the station labels are incremented from the starting station. In this example, the program would then label 2+45, 3+45, etc.

Label Deflection Angles adds deflection angles to centerlines without arcs. Settings for this are specified in the **Label Deflections Setup**, accessed by the Deflections Setup button.

The screenshot shows the 'Label Deflections Setup' dialog box. It features a title bar with a close button. The main area contains the following controls:

- Include Station:** A dropdown menu currently set to 'Off'.
- Station Prefix:** An empty text box.
- Suffix:** An empty text box.
- Use MText:** A checked checkbox.
- Fields on separate rows:** An unchecked checkbox.
- Label North/East:** An unchecked checkbox.
- Northing Prefix:** A text box containing 'NORTH:'.
- Northing Suffix:** An empty text box.
- Easting Prefix:** A text box containing 'EAST:'.
- Easting Suffix:** An empty text box.
- Use Symbol for Delta Angle Label:** An unchecked checkbox.
- Deflection Left Prefix:** A text box containing 'DL='.
- Deflection Right Prefix:** A text box containing 'DR='.
- Suffix (for both DL and DR):** Two empty text boxes.
- Deflection Label Position:** A group box containing three radio buttons: 'Perpendicular' (selected), 'Horizontal', and 'Parallel'.
- Deflection Angle Precision:** A dropdown menu set to 'ddd.mmss'.

At the bottom of the dialog are 'OK' and 'Cancel' buttons.

Include Station sets the station name as None, Prefix or Suffix to the deflection angle.

Station Prefix and **Suffix** are added to the Station Label.

Use MText option will create the deflection angle labels as Mtext.

Fields on separate rows will place each line of text on a separate layer.

Label North/East option adds a Northing and Easting coordinate to the PI location.

Use Symbol for Delta Angle Label adds a triangular shaped symbol as a prefix to the deflection angle.

Deflection Label Position controls the position of the label as Perpendicular, Horizontal or Parallel.

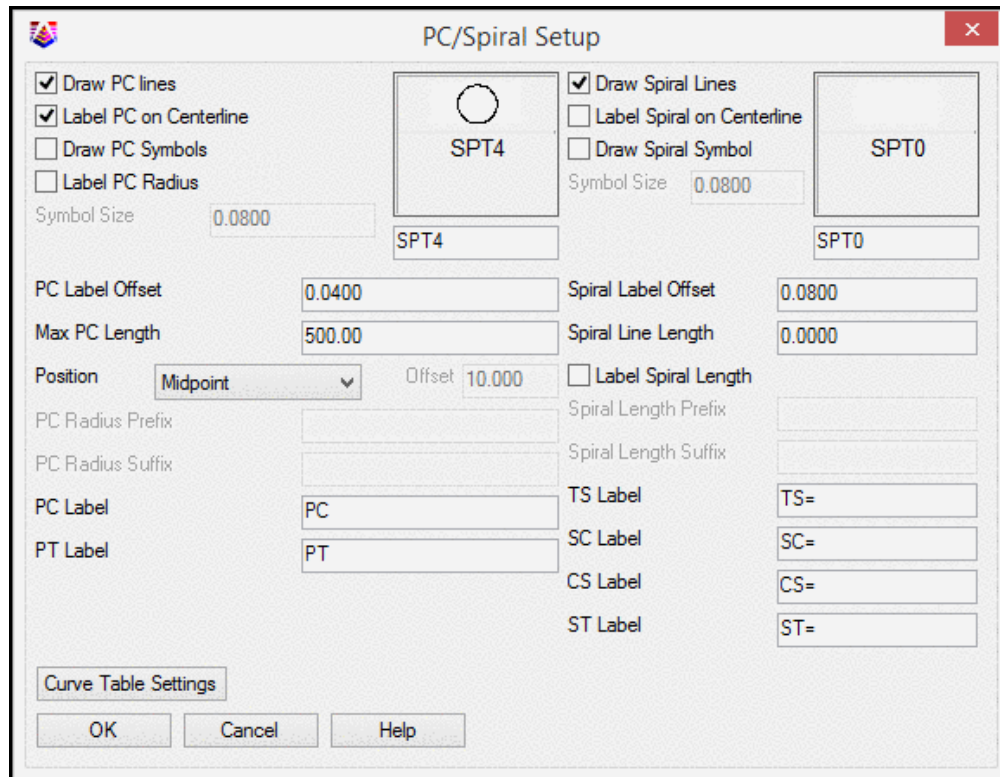

Deflection Label Alignment sets the text justification for the labels.

Deflection Angle Precision controls the format of the angle.

When **Specify Start/End Stations** is checked, only the stations between and including the specified starting and ending stations will be labeled. If locate centerline points and offset points are toggled on, only points within the specified stations will be located.

When **Erase Previous Station Labels** is checked, previous station labels are erased when new ones are generated.

The **PC/Spiral Setup PC** button accesses the **PC/Spiral Setup** dialog, where settings are controlled for lines and/or symbols and/or labels at the starting and ending (PC and PT) stations of an arc of the centerline as well as for the spiral special stations (TS, SC, CS, ST).

Label on Radial Lines controls whether to draw a perpendicular line and label the station.

Label On Centerline when checked, the station of the PC and PT will be labeled on the centerline as well as the PC and PT lines. When not checked only the PC and PT lines will be labeled.

Draw PC Symbols controls whether symbols are placed at these locations. If checked, the desired symbol is selected by picking on the symbol box.

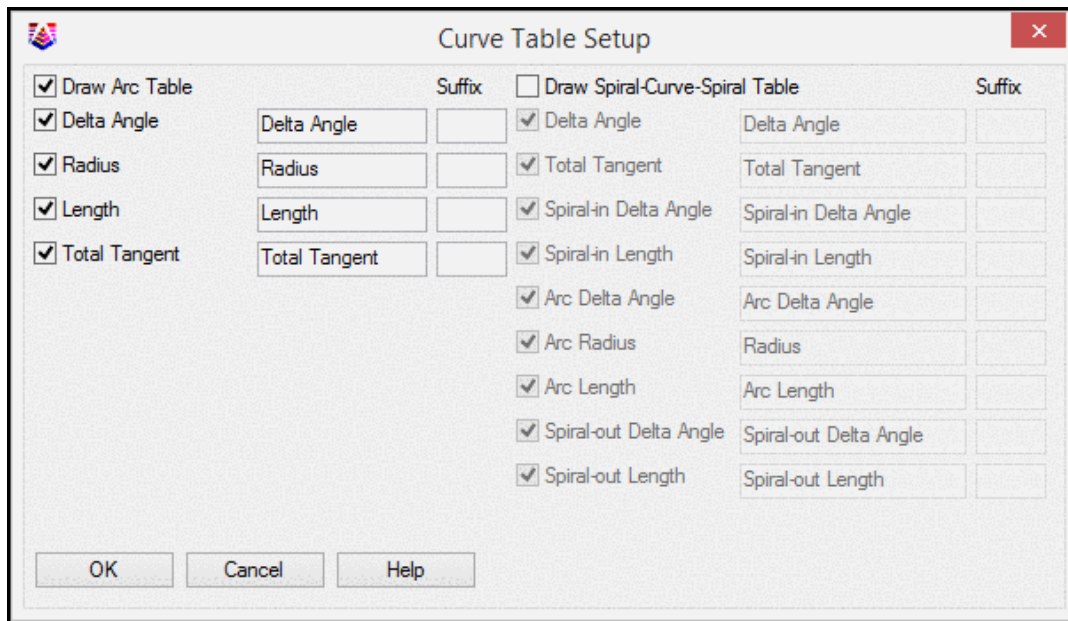

Label PC Radius controls whether this point is labeled.

Max PC Length controls the maximum length for the PC lines to be drawn described above.

Position controls the placement of the PC and PT labels as either the midpoint of the PC line or at a user defined offset from the centerline.

Prefix/Suffix: Each special station has a prefix/suffix string that can be added to the station label.

Curve Table Settings controls which elements will be labeled or placed in a data table for both arcs and spirals as shown in the **Curve Table Setup** dialog box.

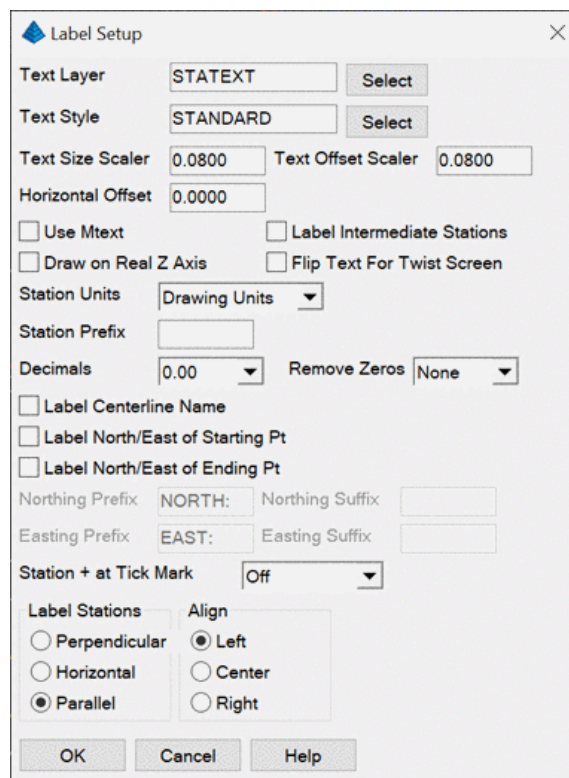

Draw Arc Table when enabled, creates and draws a table containing the arc information selected. **Delta Angle**, **Radius**, **Length** and **Total Tangent**.

When **Label PI Stations** is checked, the PI station is labeled at the PI point.

When **Locate PI Points** is checked a point will be created at the PI of a horizontal curve graphically and written to the active coordinate file.

When **Label Station Text** is checked, this command places station text along the polyline at the angle of the corresponding segment. After toggling this option on, the Label Setup button will become available for selection.

The **Label Setup** controls the placement, precision, font and size of station labels along the centerline.

Text Layer is the user-specified layer for text labels to be drawn on.

Text Style is the user-specified text style for labels.

Text Size Scaler determines the size of the station labels. This value multiplied by the horizontal scale setting in Drawing Setup results in the size of the label. For example, if the horizontal scale is set to 100 and the text size scaler is set to 0.10, the station labels will be 10 units.

Text Offset Scaler works like text size scaler above controlling the distance the text labels will be offset from the centerline.

Station + at Tick Mark labels the station text along the polyline with the '+' of the station text at the station's location on the polyline. See Marker Set up for marker size manipulation settings. The **On With +** option draws the label with the "+". The **On Without +** option draws the label without the "+".

Horizontal Offset shifts the station label along the centerline.

Use **MText** controls whether to create the labels as MText or regular Text entities.

Draw on Real Z Axis creates the labels and tick marks at elevation when using a 3D Polyline for the centerline.

Label Intermediate Stations: If the intermediate distance is the same as the station distance then no intermediate station ticks or labels will be drawn. For example, with the above entries and 0+00 for the first station the stations will be labeled with descriptions as follows: 0+00 0+50 1+00 1+50, etc.

If the **Flip Text For Twist Screen** setting is checked and the drawing has been twisted using the twist screen command, the label text will be flipped to read in the proper direction of the stationing.

Station Units when set to Miles divides the station values by 5280 for creating the station labels. When set to Kilometers, it divides the station values by 1000 for the labels.

Station Prefix adds to the front of the station labels.

Remove Zeros removes the specified number of least significant digits from the station label if these digits are all zero.

Label Centerline Name creates a label of the centerline name at the start of the centerline when using a CL file as the input.

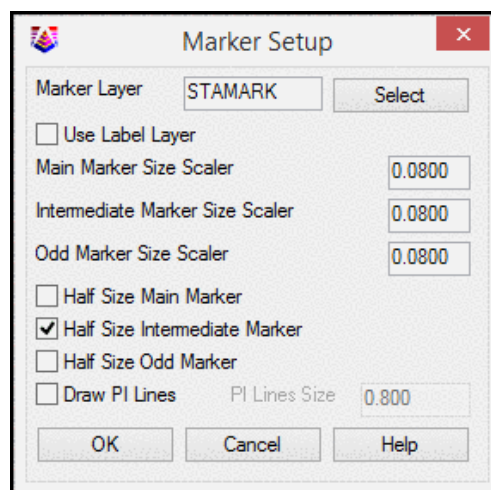

Label Northing/Easting toggles add coordinate labels at the start and/or end of the centerline including prefixes and suffixes as specified.

Decimals determines the number of decimal places of the stationing labels to be drawn for the odd stations and user entered stations only.

Use **Label Stations** to specify whether to label the stations perpendicular or parallel to the centerline.

Align determines the alignment of the station label, either left or centerline, centered along the centerline or to the right of the centerline. This option is only available when using the perpendicular option for station labels.

The **Marker Setup** options control the size of markers for different station types as well as the layer the markers will be drawn on.

The **Marker Layer** specifies which layer the station marks will be placed.

Use **Label Layer** option sets the label for the markers to be the same as that of the labels as set above.

The **Half Size Main Marker**, **Half Size Intermediate Marker** and **Half Size Odd Marker** options draw a perpendicular tick mark on only one side of the centerline. Otherwise a full marker is drawn that goes on both sides of the centerline.

Draw PI Lines option will draw a line in the direction of both tangents, in and out of the PI at the size designated in the **PI Lines Size**.

Specify whether to define the **Centerline By** picking a 2D polyline or 3D polyline in the drawing or selecting a centerline (.CL) file.

- Using a **2D Polyline** will result in horizontal distance stationing along the polyline.
- Using a **3D Polyline** will result in the slope distance stationing along the polyline.
- Using a **CL File** will result in horizontal distance stations as with the 2D Polyline option only a prompt for the centerline to use will display.

Use **Station Type** to specify the stationing format to use.

Use **Type of Curves** to specify whether you are labeling a roadway curve (arc definition) or railroad curve (chord definition).

Locate Centerline Points will locate points and store them in the current CoORDinate file.

Locate Radius Points will locate the radius points of any arc segments.

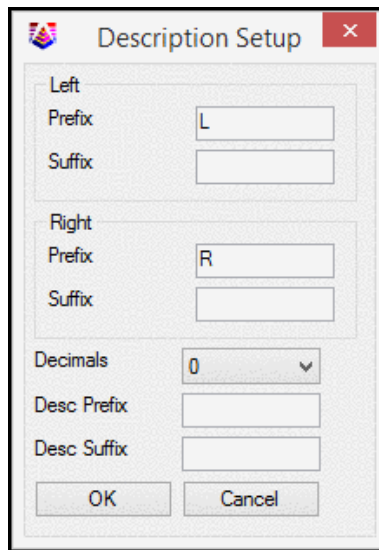

Starting Point Number determines the starting point number for the points to be located.

Vertical Exaggeration applies to Profile Polyline mode. This factor is the ratio between the horizontal and vertical scales on the profile grid.

There are two ways to **Set Elevations** for the centerline points and offset points to be created.

- The **3D Polyline** option gets the elevation of the point from a specified 3D Polyline within the drawing.
- The **Profile** option will determine the elevation of the point based upon the same station in the profile file. You will be prompted for the profile file to read for the elevation reference.
- With the **None** option selected, no elevations will be determined for the points.

When **Include Station in Description** is checked, the station along the centerline will be included in the resulting offset point description field.

Left Prefix or Suffix is added to the left offset label

Right Prefix or Suffix is added to the right offset label

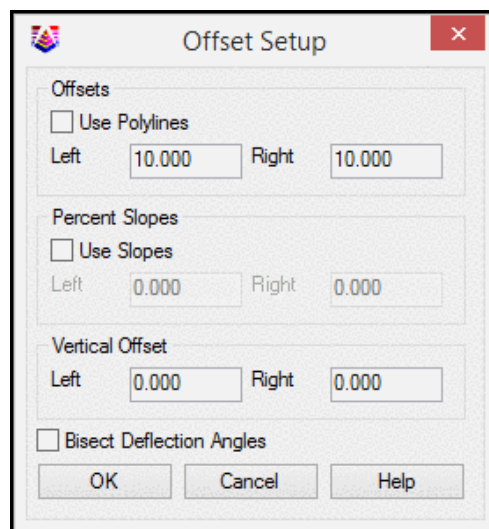

Decimals controls the label precision

Description Prefix is an optional user-specified prefix to be added to the point description.

Description Suffix is an optional user-specified suffix to be added to the point description.

When **Label Sta Equations** is checked on any station equation, contained in a centerline (*.cl) file will be labeled. This option is only available when stationing a centerline file (*.cl).

Locate Offset Points will create points at the specified left and right offset distances from the centerline. Options for setting the elevations and descriptions of the points are available from the Offset Setup dialog.

Use Polylines allows you to select an offset reference polyline.

Locate Odd creates offset points at vertices of reference offset polylines.

Left and **Right** offsets allow a user defined offset amount.

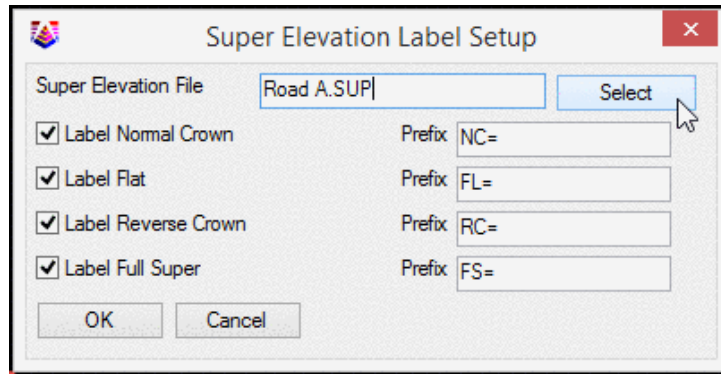

Percent Slopes allows you to project an offset grade based on a slope from the corresponding centerline points.

Vertical Offset allows you to define a separate vertical offset for the left and right horizontal offsets.

Bisect Deflection Angles controls how the offsets are located at angle points. When enabled, two offset points both

90 degrees from their respect centerlines are located.

Label Super Elevation: This option labels the super elevation transition stations as defined in the specified .SUP file. You can choose which types of the transition stations to label and set the prefix for each type.

Use **Select** to select a super elevation file (.SUP). This file is created as part of the Roads Menu contained in the Civil Module.

Labels using Centerline By 3D Polyline (Slope Station)

Pulldown Menu Location: Centerline

Keyboard Command: stapl

Prerequisite: A polyline or CL file

Label Station-Offset

This command will compute and label the stations, offsets and elevations of selected points or entities. Additional labels for the names of the reference alignments and point data (point name, northing, easting, latitude, longitude, description) can also be specified and placed.

A common usage for using dual alignments and profiles typically involves the alignment and profile of a road coupled with the alignment and profile of a pipe/utility.

1st/2nd Alignment: Specify the criteria for either one or two alignments that will be used for the label(s) that will be placed into the drawing.

Use 2nd Alignment: Enable this toggle if multiple alignments are to be used for the label(s) that will be placed into the drawing.

Name: Supply a label-friendly value for the name of the alignment (*e.g.* "King Street" or "Water Main"). The value(s) specified get assigned to the **Alignment** Label Field.

Centerline: Indicate the source (Polyline or Centerline File) for the reference alignment. If the Polyline option is selected, you will be prompted to select the polyline(s) after the OK button is pressed. If CL File option is selected, supply a valid path and file name for the centerline file or navigate to the file using the "File Picker" button. The Beginning Station will be determined from the selected Centerline File.

Beginning Station: Specify the beginning station of the centerline. The polyline should be drawn in the order of increasing stations. This control is not used when you use a centerline (.CL) file to define the centerline as the starting station of the centerline is stored in the .CL file.

Vertical Reference: Indicate the source (3D Polyline, Profile File, Road Network or Surface File) for the reference elevation. With a Vertical Reference, there are label fields to label the Elevation Reference and Cut/Fill. With 3D Polyline, there will be an additional Slope Station available under the Label Fields in addition to the regular

horizontal distance station. If the Profile option is selected, supply a valid path and filename for the profile file or navigate to the file using the "File Picker" button shown above. For the Road Network, specify the road network (.rdn) file with the "File Picker". With the Road Network method, the program will find the road design surface elevation for the specified points using all the road network design files including profiles, templates and transitions. For Surface File, the program will prompt for selecting a triangulation or grid surface model.

Cross Slope (%): Indicate the slope as a percentage to "travel" from the **Vertical Reference**. A value of 0 (zero) will not apply any cross slope from the reference elevation. Positive values will decrease the calculated elevation(s) and negative values will increase the calculated elevation(s).

Vertical Adjustment: Indicate the desired amount of vertical displacement that should applied to the calculated elevation. This is useful when deriving elevations for back or face of curb.

Label Alignment: Specify whether the labels should be Horizontal on the screen, Vertical on the screen, Parallel to the Centerline, Perpendicular to the Centerline, or user-specified by Picking.

Label Brackets: Options to draw brackets around the labels with different styles including Square, Parenthesis, Arrow and Curly. The Single, Double and Triple options are for how many brackets to draw.

Text Placement Options: Controls how the leader is drawn with the label. The Above/Below Leader method draws the leader along the label. The After Leader draws the leader up to the label.

Above/Below Leader

After Leader with Tick

After Leader No Tick

Text Size Scaler: Determines the size of the labels. This value multiplied by the horizontal scale setting in *Drawing Setup* results in the size of the label. For example, if the horizontal scale is set to 100 and the text size scalar is set to 0.10, the labels will be 10 units.

Text Offset Scaler: Controls the distance between the leader and the label.

Text Offset Scaler: Determines the scalar to offset top, and or bottom label(s) from the label line base point (i.e. the end of the leader line). This value is multiplied by the horizontal scale setting in *Drawing Setup* to determine the on screen label(s)' text offset up/down. (NOTE: Only available when top, and or bottom label(s) text is offset up, and or down. Not available when drawing labels as MLeader objects)

Text Style: Specify the desired text style for the label.

Use MLeader: Creates an MLeader which combines the leader with the label.

Leader Segments: Specify the desired number of leader segments that should be allowed when constructing the label.

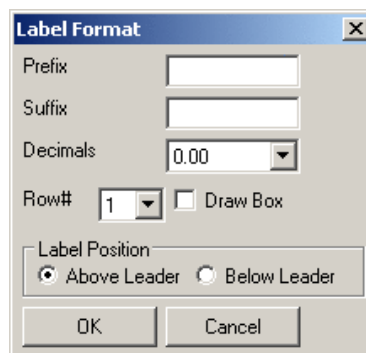

Use Relative Leader: Indicate whether successive labels placed into the drawing should re-use the geometry of the initial leader placed with the command.

Draw Leader Arrow: Indicate whether to draw an arrowhead on the leaders.

Draw Line From Centerline: This option draws a perpendicular line between the point and the centerline. The Setback Offset option shortens the line and makes gaps at the centerline and point ends. The Set Label Adjacent option places the label along this line instead of at the leader endpoint.

Draw At Fixed Position: After you pick the first label position, the rest of the labels will be placed at this same level. This option applies to the Vertical and Horizontal Label Alignment methods.

Label Fields: Use the green arrow buttons to specify the items that are to appear in the labels. As labels are "moved" from Available to Used, a Label Format dialog box particular to the label will appear that will allow for more precise display control. To subsequently edit each item, use the Format Editor button as shown below.

Note:

- The Row Number value is specified as the row starting closest to the leader with subsequent rows moving further from the leader as shown in the figure below. Row 2 below the leader has been illustrated with the Draw Box option enabled.

Layers: Specify the layer of each item that comprises the label.

Max Offset to Calc: Specify the maximum offset to calculate.

Truncate Station at +: Removes the digits before the + in the station labels.

Station Type: Specify the stationing format to use.

Station Units: When set to Miles divides the station values by 5280 for creating the station labels. When set to Kilometers, it divides the station values by 1000 for the labels.

Add to Existing Point Description: When picking points to label by point #, this option appends the label to point description instead of creating a text label. The description is updated both in the coordinate file and for the point description attribute in the drawing.

Flip Text for Twist Screen: When this option is enabled, the label(s) text will be flipped as necessary to adjust for the use of Twist Screen. When this option is disabled the normal, and forward direction of the Centerline will be used to determine an up direction for drawing the label(s) text. Applicable to Perpendicular, Parallel, and Pick Label Alignment.

Offset Tolerance: For points with an offset greater than the specified tolerance, this option puts the labels in a separate layer. This option is a way to highlight points with offsets more than the tolerance. The separate Offset Tolerance layer can be setup to use a different color.

Type of Curve: Specify whether the centerline is for a roadway or railroad. Stationing for Roadway Curves is measured along the curve length itself whereas stationing for Railroad Curves is measured along chord segments.

Save: Allows the current settings to be saved to a Station-Offset Settings (*.sos) file.

Load: Allows settings from a previously saved Station-Offset Settings (*.sos) file to be recalled for use.

Prompts

Real-time display of Station and Offset as you move the cursor.

A sample label with a 2-segment leader.

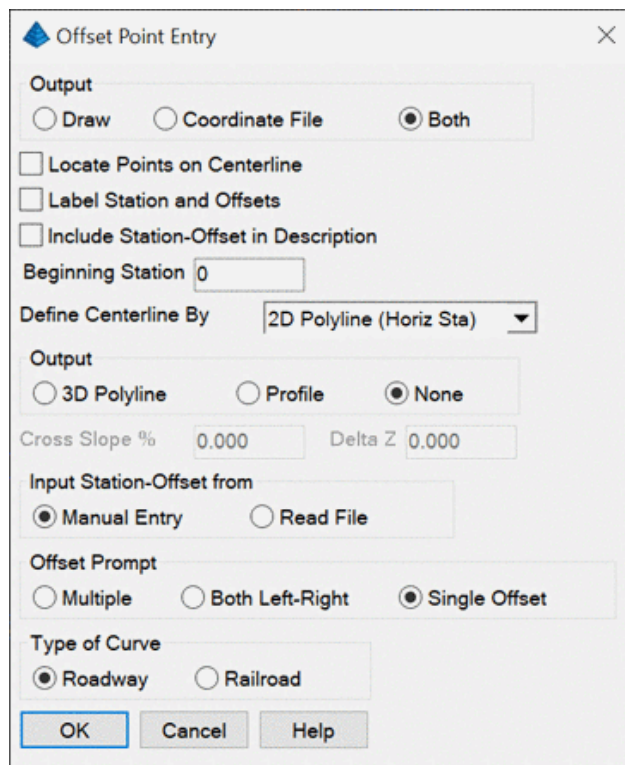

Pulldown Menu Location: Centerline

Keyboard Command: offsta

Prerequisite: A polyline or centerline file

Offset Point Entry

This command creates points along a centerline at specified stations and left and right offsets. The centerline can be defined by a polyline, centerline (.CL) file or two points.

The **Output** option to **Coordinate File** will store any points the current coordinate (.CRD) file. This includes centerline points and offset points. The option to **Draw** will draw the new points using the settings from Points > Point Defaults.

When **Locate Points on Centerline** is checked, the program will locate points along the centerline, otherwise just the offset points will be created.

When **Label Stations & Offsets** is checked, the program will label the station-offset as the point description attribute.

The **Include Station-Offset In Description** option will add the station and offset of the point into the point description.

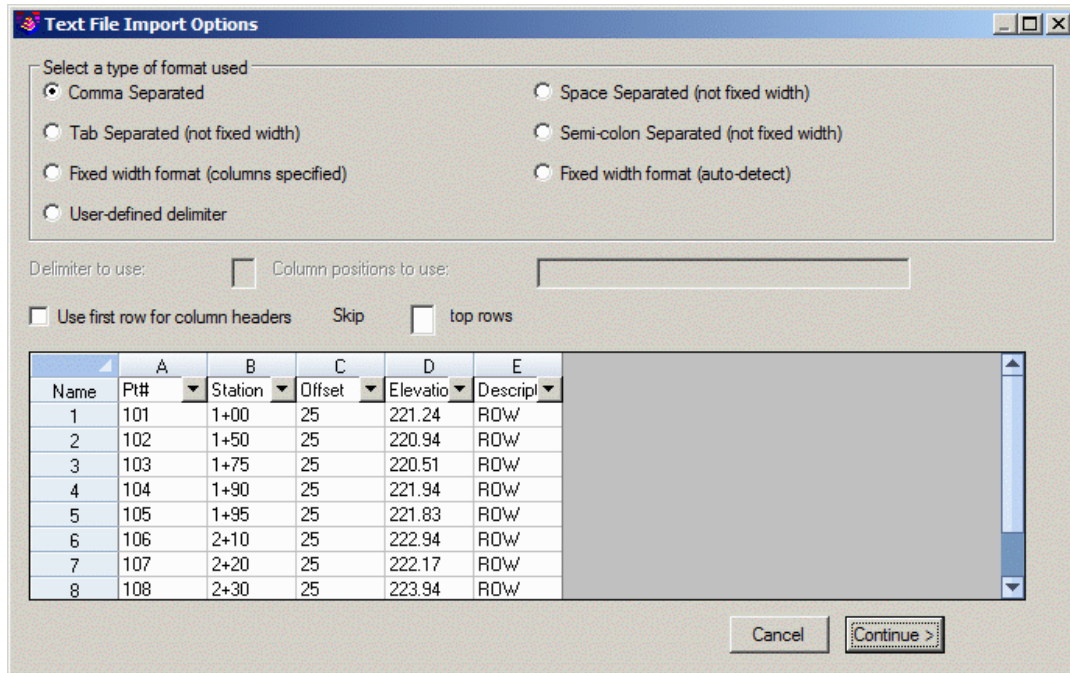

Beginning Station: Enter the Beginning Station of the Centerline.

Use **Define Centerline By** to specify whether to define the centerline by picking a polyline in the drawing, selecting a centerline (.CL) file, or using 2 points. For polylines, the 2D Polyline method works with horizontal distance stations and ignores any polyline elevations, and the 3D Polyline method works with slope distance stations using the polyline elevations.

Use **Reference Elevation** to assign elevations to the points created when locating points on the centerline of offset points. When using a 3D Polyline for the elevation reference, points will be created at the station entered and the offsets specified with the elevation of the same station along the 3D polyline. The Profile option will do the same as the 3D Polyline option only it will use a profile file for the elevation reference. You will be prompted for the profile to use for the elevation reference. None simply creates 2d point data on elevation zero. The Reference Elevation option is good for creating points along the centerline for final grade elevation points. *Profile to 3D polyline* can be used to transfer the profile data to the polyline before calculating the final grade points.

Cross Slope %: This option is used to alter the elevations of the new points by applying either a Cross Slope calculation or a Delta Z variable.

The Manual Entry option in **Input Station-Offset from** will prompt for the station and offset distances. The **Read File** option will read the stations and offsets from a text file. The text file format with point number, station, offset, elevation and description. The program handles station formats with or without the '+' (i.e. either 250 or 2+50). The elevation and description are optional. The Read File option is a quick routine to convert a station-offset data file into coordinates. The delimiter for the text file and the order of the fields are set in the dialog shown here.

When **Offset Prompt** is set to Both Left-Right, the program will prompt for left and right offsets. If you respond to an offset prompt with zero (0), no offset point is created. The Single Offset option will prompt for one offset per station. Enter a right offset with a positive value and a left offset as a negative value. The Multiple option keeps prompting for offsets at the current station until you enter a blank offset. This option applies when you have more than one offset to create on the left or right side.

Use **Station Type** to specify the stationing format to use.

Use **Type of Curve** to specify whether the curves are for a roadway or railroad.

Keyboard Command: offpts

Prerequisite: A centerline (.CL) file, polyline, or two points

Calculate Offsets

This command calculates the station and offsets of point coordinates relative to a centerline. The points to calculate can be stored in a coordinate (.CRD) file or picked on the screen. As the crosshairs are moved, the station and offset of the current position are displayed in real-time in a small window (see example). After entering the points to calculate, the program prompts for selecting another centerline which is optional in case you want a report for multiple centerlines.

Beginning Station: Specify the beginning station of the centerline. The polyline should be drawn in the order of increasing stations. Not available when you use a centerline (.CL) file to define the centerline.

Maximum Offset to Calc: This is the maximum distance from the Centerline for which offsets are calculated.

Report Offsets Ahead/Behind Centerline: When checked, this option shows offsets for points or picked points located before the beginning station and after the ending station of the centerline.

Label Station and Offsets: When checked, the station offsets will be labeled in the drawing.

Label Cut/Fill: When using a reference elevation from the Report Grade Elevation setting, this option labels the cut/fill between the reference elevation and the points.

Cut/Fill In Inches: Sets the precision for reporting cut/fill when using inches or whether to report in decimals.

Sort Report by Stations: When checked, this option will report the station-offsets in station order no matter what order the points were calculated.

Report Point Coordinates: When checked, this option will include the point northing and easting in the report.

Report Point Notes: When checked point notes will be included on the calculate offset report.

Create Point Notes: When checked, the station and offset of the offset point will be created as notes and written to a note file (*.not). This note file will have the same name as the crd file.

Use Report Formatter: When checked, the output of this command is directed to the Report Formatter which allows you to customize the layout of the report fields and can be used to output the data to Microsoft Excel or Microsoft Access. You must check this option on in order to use the Report Grade Elevation From option.

Round Stations: When checked, this option will round the stations for the selected points on the report to the Rounding Interval specified. For example if an offset point is located at station 1+01, and the rounding interval is set to 10, then the report will show the offset point at station 1+00.

Left/Right Prefix/Suffix: These settings are used with the offset label.

Store Station Text to CRD File: When checked, the station offset text is appended to point numbers that are selected.

Report Grade Elevation From: When checked, this option will calculate an elevation for each point from a 3D polyline, grid file (.grd) or triangulation (.flt) file. To Use this option, the *Report Formatter* must be toggled on. The grade elevation is reported and compared with the point elevation to report the cut/fill. For the 3D polyline option, the grade elevation is calculated by finding the elevation at the point on the 3D polyline that is the nearest perpendicular position from the offset point. The 3D polyline that is used for elevations does not need to be the same polyline that is used as the centerline for the station-offset calculations.

Define Centerline by: Specify whether to define the centerline by picking a polyline in the drawing, selecting a centerline (.CL) file, by a point and direction angle, or using 2 points. The polyline mode can be either 2D or 3D for horizontal or slope distance stationing.

Station Type: Specify the stationing format to use.

Decimals: Specify the display precision for the stations and offsets.

Type of Curve: Specify whether the curves are for a roadway or railroad.

Centerline Conversions

There are many import routines available under Centerline Conversion to convert other applications' centerline files to Carlson centerline files (.CL), and many export routines to convert Carlson centerline files (.CL) to other applications' formats. Each Import option prompts for the file to convert and the name of the new .CL file to create. Each Export option prompts for .CL file to convert and a file name for the new file. The import formats include C&G Point Group .PTS, InRoads .ASC, Geodimeter .ARE/.GEO/.RAW, GeoPak .OSD, Leica .GSI, MOSS .INP, Novapoint .TIT, SDMS .ALI/.PRJ, Softdesk, Sokkia .SDR, ISPOL .ALI, CLIP .PLA, TDS .RD5 and Terramodel .RLN/.ALN. The export formats include C&G Point Group .PTS, Leica .GSI, SMI .CH, Softdesk, Sokkia .SDR, Topcon .RD3, Trimble .DC, TDS .RD5 and TDS .PL5.

For the TDS RD5, there is an option to include a profile along with the centerline. Also, there is an option to include sections. When sections are included, the station data is included in the RD5 and the section grades are output to TP5 files where each station has a separate file for the left and right sides. The TP5 files are created in the same folder as the RD5.

For the Trimble DC, there are options to include a profile and sections along with the centerline.

For Civil 3D, the import works differently because the centerline definitions are stored within the drawing instead of external file. So this import does not prompt for a file but looks for Civil 3D centerlines in the current drawing. The Civil 3D centerline custom objects are converted to standard AutoCAD entities and there are prompts to save the centerline definitions to Carlson .CL files.

Horizontal Speed Table

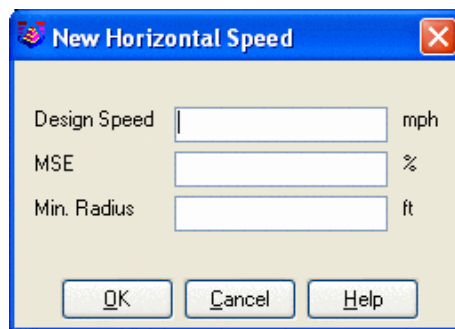

In the design of curve and spiral-curve-spiral centerlines, it's very important to determine the curve radii and superelevation rates, which can significantly affect the design speed of roads. The Horizontal Speed Table function provides a few of speed tables, which utilize AASHTO's speed table data and offer the recommendations for design speeds and curve parameters. Please refer to AASHTO A Policy on Geometric Design of Highways and Streets 2004 (pp 167-174) for details.

The Horizontal Speed Table function is integrated into the Centerline Editor command. To access the speed tables, in the curve or spiral centerline design dialogs, click on the Horizontal Speed Table button to open the speed table dialog shown as below. The Table Name list contains the names of all speed tables that has been defined. There are five default speed tables: AASHTO 4% MAX MSE, AASHTO 6% MAX MSE, AASHTO 8% MAX MSE, AASHTO 10% MAX MSE and AASHTO 12% MAX MSE. You can add, edit and delete any speed tables. On the left of the dialog, the Design Speed box lists all design speeds. On the right there is a table that lists all the curve and superelevation data of the highlighted speed. The curve and superelevation data table will change when you highlight different speeds. All speed table files are in the ...\\USER folder and are available for all projects.

Horizontal Speed Table

There are three buttons under the Design Speed list. Add button adds a new design speed to the current speed table. The New Speed dialog opens for you to enter the Design Speed, and MSE and Minimum Radius for the speed. Edit button allows you to edit the highlighted design speed. Delete button will delete the highlighted speed and all the curve and superelevation data associate to the speed.

New Design Speed

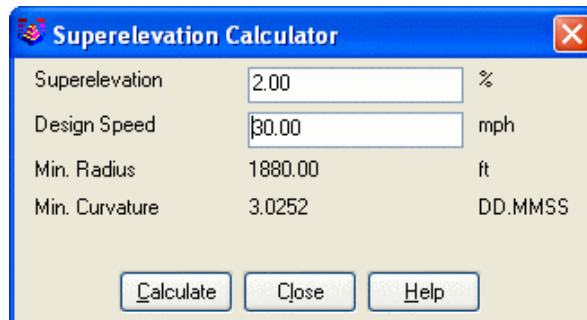

Edit Design Speed

Under the table of the curve and superelevation data, there are Add, Edit and Delete buttons which allow you to add, edit and delete the data entry for the highlighted design speed.

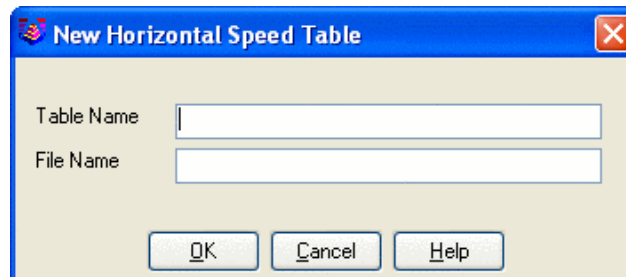

New Curve and Superelevation Data

If you have a special design speed or superelevation rate that is different than any data entry in the speed table, or if you don't want to look up the tables for a curve data, the Superelevation Calculator button is here to help you to get the curve data. Click on the button to open the Superelevation Calculator dialog. Enter the values in the Superelevation and Design Speed boxes, the Minimum Radius and Curvature will be calculated and displayed.

Superelevation Calculator

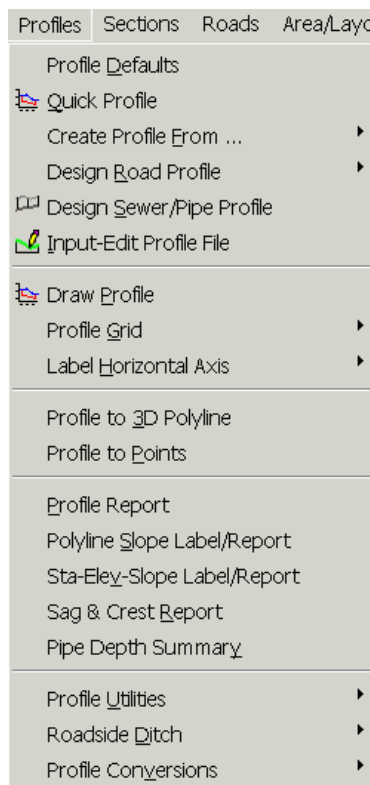

New Table button creates a new speed table, Edit Table button is used to modify the name of current table or the file that stores the speed data, Duplicate Table button makes a new speed table that contains the same data as current table, and Delete Table button removes current table completely.

New Horizontal Speed Table

Profile Menu

The Profile menu shown below has commands for creating, drawing and reporting profiles.

Quick Profile

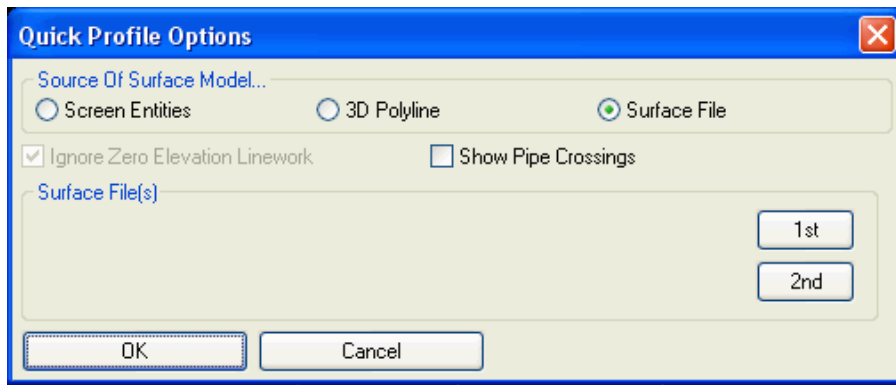

This command allows you to create a profile in one step. The alignment for the profile can be defined using picked points, a centerline file or a polyline. The surface for the profile can be defined by 3D screen entities, 3D polyline or surface files (grid or triangulation).

Screen Entities: The program creates the profile by finding the intersections of the centerline with 3D linework entities in the drawing. There's an option for whether to ignore entities at zero elevation.

3D Polyline: Creates a profile using a selected 3D polyline. The polyline vertex elevations are used for the profile elevations and the profile stations are from the lengths of the polyline segments.

Surface File: This option allows you to use one or two grid or triangulation surfaces. There's also an option to Show Pipe Crossings which will find and display pipe crossings from sewer networks and 3D polylines tagged as pipes. The sewer network can be created in the Hydrology module. To tag a 3D polyline as a pipe, use the Assign Pipe Data To Polyline command.

Since picked points are the default for the horizontal alignment, the command is as quick as select surface type (screen or file), then *Pick, Pick, Enter* and view. The resulting profile is displayed in a graphic dialog box with real time data reporting. As the crosshairs are moved across the profile in the window, the station, elevation and slope data corresponding to the current crosshair location appear in the lower right of the window. A second crosshair on the plan view corresponds to crosshair movement along the profile so the user knows exactly where the current profile point is on the plan view. Also the Adjust Alignment function allows you to drag a horizontal alignment point and update the profile in real-time.

Vertical Exaggeration: Determines the amount of vertical exaggeration for the profile in the window.

Drag Action: Determines whether the right mouse button functions as "Zoom" or "Pan" in the profile window.

Grid Ticks Only: Instead of the full graph as shown above, Grid Ticks only plots only ticks along the horizontal and vertical axis near the station and elevation text.

Colors: Set the profile colors for the graph.

Adjust Alignment: Allows you to pick a horizontal alignment point and while moving it, the profiles are updated in real-time. You can also select a horizontal alignment segment and move the whole alignment position. The Adjust Alignment function is only available when surface files are used as the source of the surface model. When you adjust the alignment, the program prompts on exit whether to save the adjusted alignment to a centerline file (CL).

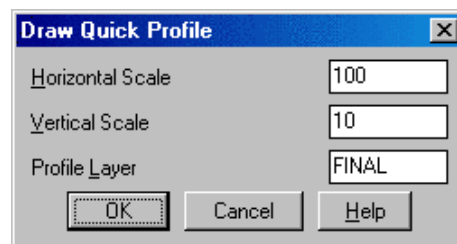

Save: Writes the current profile data to a .PRO file.

Draw: This draws the profile with grid in the drawing. The user has options for horizontal and vertical scales and the layer of the profile. The Draw Profile command includes more options for drawing the profile. In order to use this command, you must first create a .PRO file using the Save command described above.

Print: This makes a graphic report of the profile in either PDF or DWF format as selected under Settings->Configure.

Exit: Exits this command.

Help: Opens on-line help.

Note that the Draw option will exit the Quick Profile command after the drawing is complete. A typical completed drawing, in this case with two surfaces, is shown below. Note also that the horizontal stationing text offset follows the setting in the Draw Profile command itself.

Prompts

Pick starting point (CL-Centerline, P-Polyline): *screen pick alignment points for profile*

Pick second point: *pick next point*

Pick next point (Enter to end): *press enter to end*

Tested 58 of 58 Entities Intersects found > 33

Dialog Box

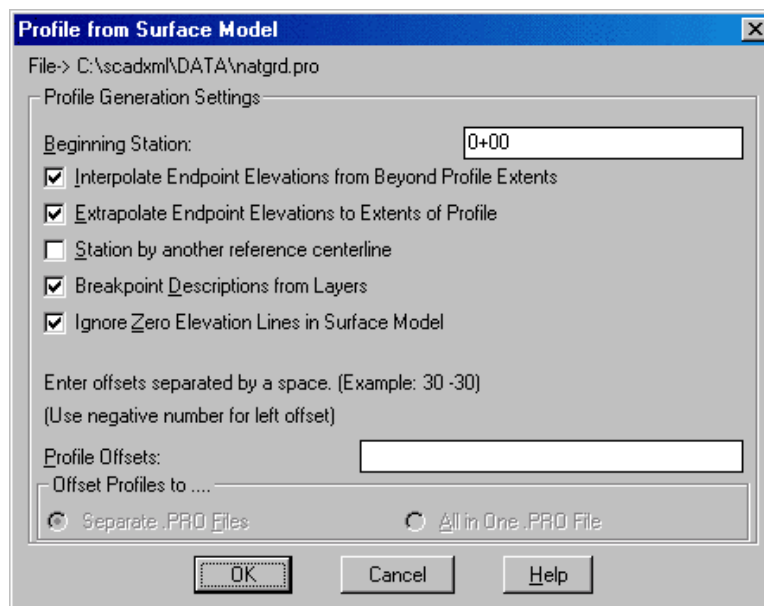

Pulldown Menu Location: Profiles

Keyboard Command: quickpro

Prerequisite: 3D screen entities or surface file

Profile from Surface Entities

Profile from Surface Entities creates a profile from contours, triangular mesh, and other 3D drawing entities. The method is to draw a polyline as the profile centerline. Then the profile is derived from the intersections of this polyline with the 3D entities. For added accuracy in pulling the profile, include the triangular mesh as well as the contours.

File: Displays the name of profile to be created.

Beginning Station: Specify the beginning station for the profile.

Interpolate Endpoint Elevations from Beyond Profile Extents: When checked, the program will look past the ends of the centerline for additional intersections with 3D entities. These additional intersections will then be used to interpolate the elevation at the starting and ending station of the centerline.

Extrapolate Endpoint Elevations to Extents of Profile: This option uses the slope of the last two elevation points of the profile and calculates the elevation of the endpoint from this slope.

Station by another reference centerline: When checked, the program will prompt you to pick another centerline polyline. The intersection points along the first centerline are then projected onto the second centerline. The profile then stores the elevation of the intersection with the station along the second centerline.

Breakpoint Descriptions from Layers: When checked, breakpoint descriptions are assigned based on layer name of surface entities. These descriptions are used in routines such as *Profile Editor* and *Profile Report*.

Ignore Zero Elevation Lines in Surface Model: When checked, any zero elevations selected in the surface model are ignored.

Profile Offsets: Specify optional offset profiles. Enter offsets separated by a space. Example: 30 -30 (to create 30' left and 30' right offset profiles). After entering the offset values, press TAB to select file options described below.

Offset Profiles to: Specify whether offsets profiles should be created as separate profile (.PRO) files, or included in a single profile (.PRO) file. Only available if you specify Profile Offsets above. Offset profiles are automatically named by combining the profile name and the offset. For example, if the profile is named NATGRD.PRO and you create a 30' right offset profile, it will be named NATGRD30.PRO.

Prompts

Profile File to Write dialog Specify a new profile file (.PRO) name to create.

Profile from Surface Model dialog Make choices, click OK.

Polyline should be drawn in direction of increasing stations.

CL File/<select polyline which represents the profile centerline>: *pick the centerline* (Do not press Enter.)

Select Lines, PLines, and/or 3DFaces that define the surface for profiling.

Select objects: *C* (for crossing and window everything the centerline crosses) or *All* (to select all objects on the drawing)

Keyboard Command: prosm

Prerequisite: A polyline centerline and surface lines and polylines.

Profile from Grid or Triangulation Surface

This command creates a profile (.PRO file) from a centerline polyline and a surface model stored in a 3D grid file (.GRD) or triangulation file (.TIN or .FLT). The polyline defines the alignment of the profile and the grid defines the surface.

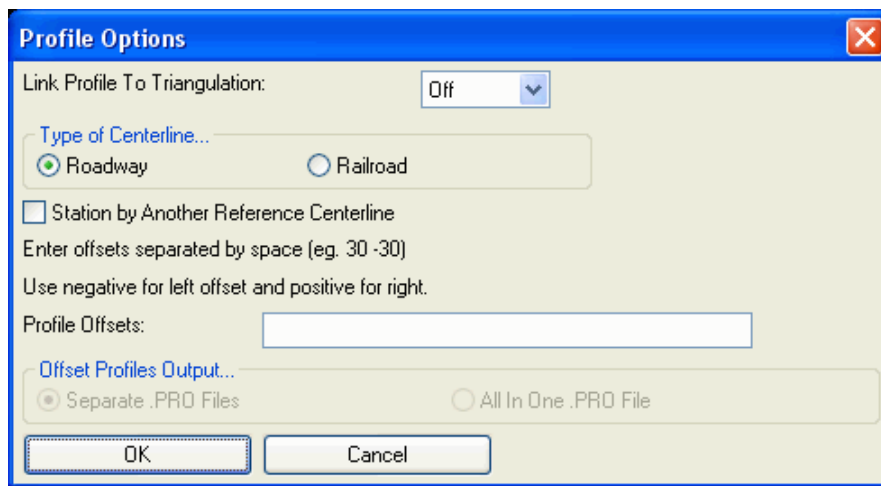

After selecting the reference surface file, there is a Profile Options dialog with these options:

Link Profile To Triangulation: This option will update the profile whenever the reference triangulation is modified.

Type of Centerline: This setting chooses the type of stationing for centerline curves.

Station by Another Reference Centerline: This option uses a second reference centerline for the stationing of the profile. The main centerline is used to find the elevations on the surface and then these main centerline positions are projected onto the reference centerline to get the stationing. The reference centerline needs to extend along the full range of the picked polyline in order to project correctly and capture offsets along the entire length of the picked centerline.

Profile Offsets: In addition to creating the profile along the centerline, you can also create profiles offset left and right.

Prompts

Choose Grid or Triangulation file to process Select existing .GRD, .TIN, or .FLT file.

Profile Options dialog.

Choose PROfile file to Write dialog Enter a profile file (.PRO) name to write.

Pulldown Menu Location: Profiles > Create Profile From ...

Keyboard Command: progrid

Prerequisite: A .GRD grid file, .TIN, or .FLT tmesh file

Profile from 3D Polyline

To create a profile (.PRO), Profile from 3D Polyline uses X-Y distances between the points of a 3D polyline for sequential stations and the Z values at these points for profile elevations. In the options dialog, Profile Name is an optional description for the profile. The Prompt For Elevations option will prompt for the elevation at each polyline vertex to use for the profile instead of using the polyline elevations. The Station By Another Reference Centerline method locates the station for each polyline vertex along a reference centerline and uses this reference station instead of the polyline distance for the profile stationing. The reference centerline can be defined by another polyline or centerline file (.CL). When using the reference centerline, the Combine Multiple Polylines Into Profile option allows you to select multiple 3D polylines and put the data into a single profile. For example, you can use these two options to create a profile of curb elevations with road centerline stationing by selecting multiple 3D curb polylines and the road centerline as the stationing reference.

After the options dialog, the program prompts for the .PRO file to create and then the 3D polyline to process.

Prompts

Created 72 data points for profile C:\sample\abc.pro

The new profile is then stored.

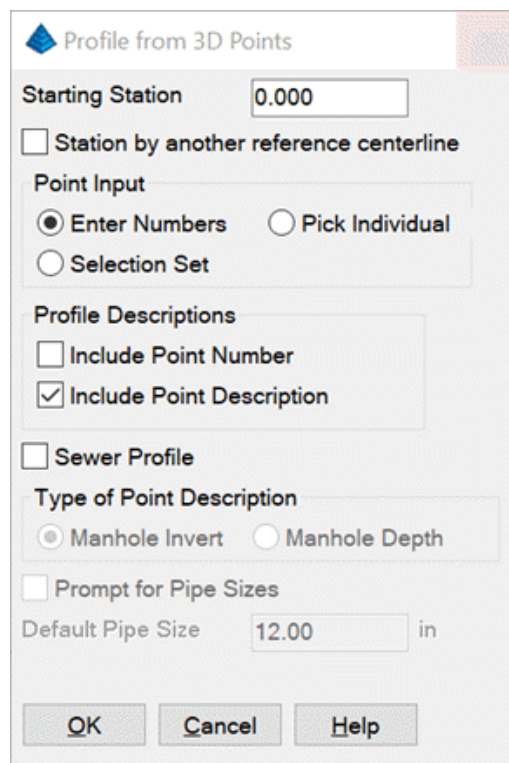

Pulldown Menu Location: Profiles

Keyboard Command: pro3dpl

Prerequisite: A 3D polyline

Profile from 3D Points

This command creates a .PRO file using the X-Y distances between user-specified points for sequential stations and the Z values at these points for profile elevations. Unlike many of the Carlson profile routines, this routine does not require a horizontal alignment. The points can be specified by point numbers from the current coordinate file or by picking Carlson points on the screen.

The Starting Station sets the profile station for the first point. The Station By Another Reference Centerline option

projects the points onto a separate centerline to calculate the stations for the profile. The Profile Description options allow storing the point number and description to the profile descriptions. The Sewer Profile option applies when the points are at manholes. In this mode, the program creates a sewer type profile and prompts for pipe sizes.

Prompts

In this graphic showing the points 34, 94 and 195. Note that the "+" in front of elevations higher than 0 is an option within Draw-Locate Points.

Pulldown Menu Location: Profiles > Create Profile From

Keyboard Command: pro3dpt

Prerequisite: Plot points with real Z axis elevations or a coordinate file.

Profile from Section File

This command creates a .PRO file from user-specified offsets or from specified descriptions on cross sections contained in a .SCT file. The elevations of the profile are derived from the elevations of the cross sections at the offset and the stationing for the profile matches the stations of the cross sections. There is an option to extend cross section elevations to reach the offset for the profile when necessary. If, for example, a road design has "SH" at some offset on each cross section, both left side and right side, you can pull the profile from the "SH" descriptions by specifying left or right side. So you can profile the shoulder, or the "TIE" point to existing ground, etc. Alternately, if the sections extend from offset 100 left to offset 100 right, you can pull a profile at offset -30, or 30, in which case the program will create a profile by interpolating the elevation from the sections for each station in the cross section file.

Prompts

Choose SCT file to read dialog

Select the existing cross section file.

Profile of offset or template description [<Offset>/Desc]? *press Enter*

Enter the offset to profile (left offsets as negative) <0.0>: *press Enter*

Extrapolate sections to this offset (<Yes>/No)? *press Enter* This prompt appears if the program detects that

some or all sections do not extend to the requested offset to profile.

If you chose Desc above, one of the advantages of the new file loading dialog is that you can review the ASCII descriptions in the section file, as shown below:

Enter description to profile: *EP*

Template side to process [Left/<Right>]? *L*

PROfile file to Write dialog box Enter a profile file name to write.

Create another profile (Yes/<No>)? *press Enter*

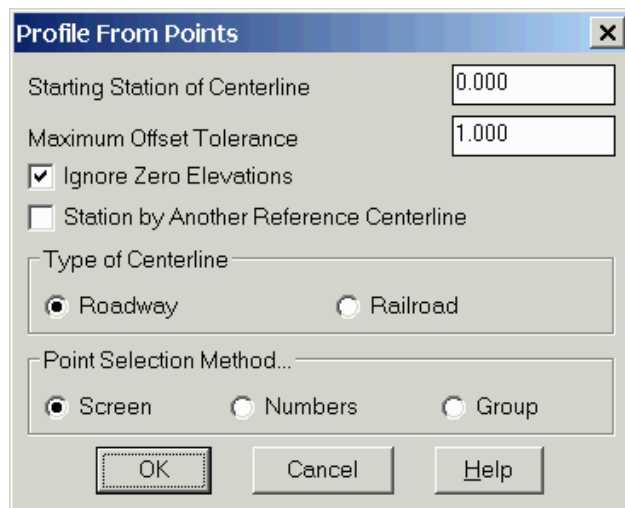

Pulldown Menu Location: Profiles > Profile from ...

Keyboard Command: profsct

Prerequisite: Cross sections in a .SCT file

Profile from Points on Centerline

This command creates a .PRO file from points and a centerline that is represented by a polyline or centerline file. The elevations of the profile are derived from the elevation of the points and the stationing for these profile points is calculated from the distance along the centerline. The points must be within the offset distance from the polyline in order to be included in the profile. The profile is created by projecting the points perpendicular onto the alignment to determine the station and the elevation comes from the point elevation. The polyline or centerline should be drawn (or defined) in the direction of increasing stations. The points can be selected from point entities in the drawing (Screen), by point numbers from the current coordinate file (Numbers), or by point group as defined by the Point Group Manager (Group).

Prompts

PROfile file to Write dialog box: Enter a new profile file name to write.

CL File/<Select polyline that represents centerline>: *pick a polyline or choose C for Centerline*

Select Centerline file if Centerline option is used. If the desired points are further from the centerline, enter a larger maximum offset tolerance.

Note: for all selected points, the points should be located on the real Z axis.

Select the Carlson points along the centerline.

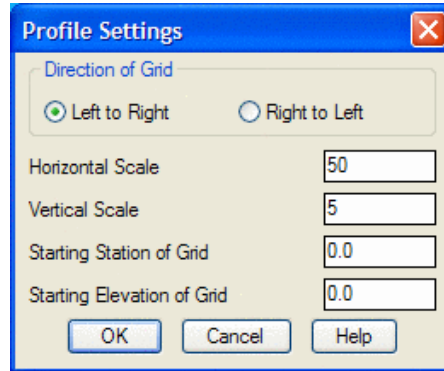

Select objects: Select the point entities.

Keyboard Command: profpts

Prerequisite: A polyline centerline and points

Profile from Polyline on Profile Grid

This command allows you to convert a polyline that is drawn on a profile grid into a profile (.PRO) file. The polyline must be drawn in the direction of stationing. Vertical curves, which are typically parabolas, will be captured as a series of vertices. The polyline can either be used to create a new profile (.PRO) file, or can be appended to an existing profile (.PRO) file. When the profile grid has equal horizontal and vertical scale for a vertical exaggeration scale of 1, and the polyline contains arcs, then the program creates a profile with circular curves.

Prompts

File Selection Dialog Box Specify the profile (.PRO) file to create, or an existing profile (.PRO) file to append to.

Profile Settings Dialog Set these parameters to match the dimensions of the grid for the profile plot.

Pick Lower Left Grid Corner: *pick the grid corner* Endpoint snap is set on.

Profile number <1>: *press Enter* This is an optional profile name used for multiple profiles.

Select the polyline to write profile from:

Select object: *pick the 2D polyline in the grid*

A station and elevation report is produced.

Pulldown Menu Location: Profiles > Create Profile From...

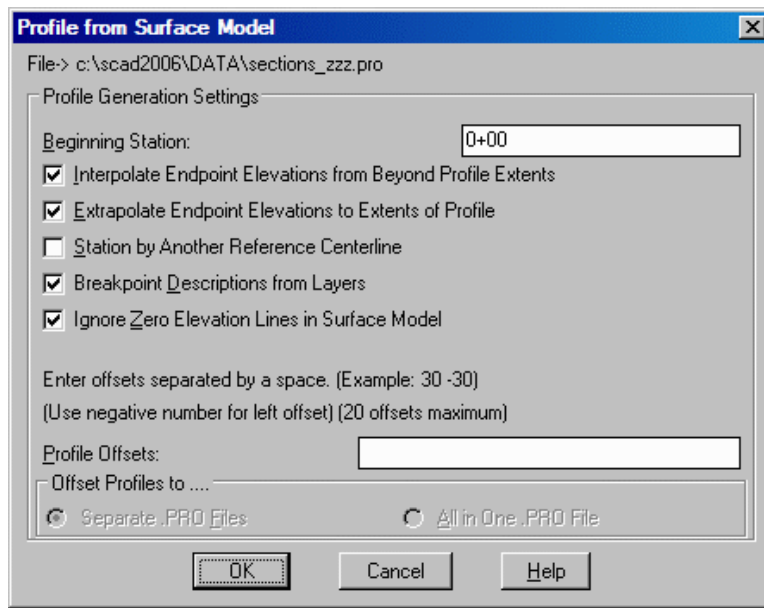

Keyboard Command: pro2dpl

Prerequisite: Drawn polyline which represents profile, existing drawn profile grid

Profile from Layers

This command creates a profile from surface entities with one of the specified layers. The surface entities can be contours, triangular mesh, and other 3D drawing entities. This command is the same as Profile from Surface Entities with the addition of the layer filtering. The method is to draw a polyline as the profile centerline. Then run Profile by Layers and specify the layer names of the surface entities to include in the profile. For example, the layer names CTR and TMESH could be entered to use only the contour polylines and triangulation mesh on these layers. Entities on all other layers would be ignored. The profile is derived from the intersections of this polyline with the 3D entities on the specified layers.

Prompts

Specify Layers Names Dialog Specify layers, click OK

Profile File to Write Dialog Specify a profile file name (.PRO) to create

Profile from Surface Model dialog box

Polyline should be drawn in direction of increasing stations.

CL File/<select polyline which represents the profile centerline>: *Pick the centerline*

Select surface entities on corresponding layers.

Select objects: *C* For crossing and window everything the centerline crosses.

Pulldown Menu Location: Profiles > Profile from ...

Keyboard Command: prolayer

Prerequisite: A polyline centerline and surface lines and polylines.

Profile from Pipe Polylines

This command creates a profile that contains the station, elevation and pipe width of pipes that cross the centerline. This type of profile is called a Crossing profile and Draw Profile treats it differently. Instead of connecting the station-elevation points with a polyline, Draw Profile draws each station-elevation as a circle with a radius of the pipe width. When there is vertical exaggeration in the drawn profile, the pipe circles are drawn as ellipses.

This routine uses a polyline that represents the centerline. The pipe polylines are 3D polylines with an assigned pipe width. One way to create them is to use the command *Draw Pipe 3D Polyline* in the Profile Utilities sub-menu. To attach the pipe width value to a polyline, use the *Assign Pipe Width to Pline* command also in the Profile Utilities sub-menu. The program then finds the intersections of the polyline centerline with the pipe polylines and stores the station of the intersection along the centerline with the elevation and pipe width of the pipe polyline. There is also a prompt to whether the pipe position is at the top, bottom or middle of the 3D pipe polylines.

Prompts

Profile File to Write Dialog Enter new .PRO file name.

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: *pick a polyline*

Enter the starting station <0.0>: *press Enter*

Select the pipe polylines crossing the centerline.

Select objects: *pick pipe polylines*

Position of pipe polylines on pipe [Top/Center/<Bottom>]? press Enter

Found 2 crossing pipe polylines.

The command Draw Profile would then interpret this profile as a pipe profile, and plot it as needed.

Pulldown Menu Location: Profiles > Profile from ...

Keyboard Command: propipe

Prerequisite: A polyline centerline and pipe polylines

Profile from 3D Solids

This command creates a profile of slices through 3D solids. The alignment for the profile can be defined either by centerline file or by a polyline. The solid model can be defined either by a Carlson 3D model file (MDL) or by 3D Solid entities in the drawing.

Prompts

Profile Solid dialog

Profile to Write *Specify a file name*

Select entities for model.

FILter/<Select entities>: *pick 3D solids*

Select polyline centerline: *pick a polyline*

Pulldown Menu Location: Profiles > Create Profile From

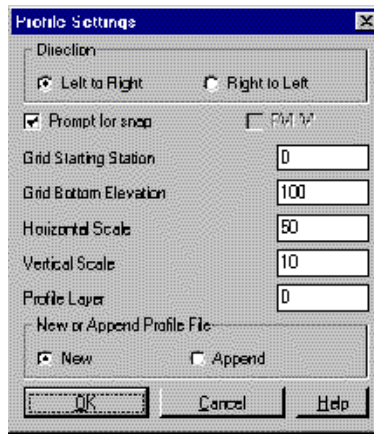

Keyboard Command: pro_solid

Prerequisite: CL file or polyline alignment, and 3D Solid or MDL file

Enter Profile On-Screen

This command allows you to create profile files and is similar to *Design Road Profile*. The only difference is that Enter Existing Profile does not ask for vertical curves. The procedure is to first specify the on-screen grid and then enter or pick the stations and elevations. The profile is drawn as it is entered.

Notice that the station, elevation, and slope at the current position of your cursor crosshairs is displayed at the bottom of the side-bar menu. These values will update whenever the crosshairs move except after selecting either the side-bar or top menu.

Prompts

Profile Settings dialog

Profile File to Write dialog Specify a profile file (.PRO) to create.

Station of first PVI or pick a point: 0

Elevation of PVI: 565

Second station or pick a point (U, E, D, Help): 200 'U' is undo, 'E' ends the routine, 'D' is incremental distance to the next station, 'H' brings up an explanation of these items on-screen.

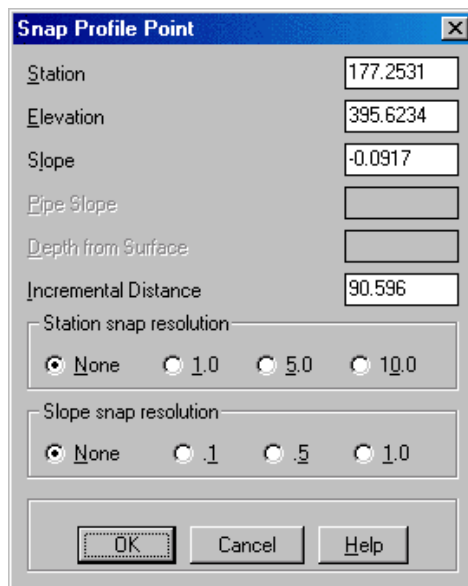

Percent grade entry/Ratio/<Elevation of PVI>: 575

Station of next PVI or pick a point ('U' to Undo, Enter to End): *pick a point*

Snap PVI dialog

This dialog box appears when you pick a point and the Prompt for Snap option in the Profile Settings dialog is selected. The station and slope may be changed to the nearest snap value. The elevation is the free variable and it will change to compensate for any snap. To change the elevation, select the elevation edit box and enter the new value.

Station of next PVI or pick a point ('U' to Undo, Enter to End): *press Enter*

Pulldown Menu Location: Profiles

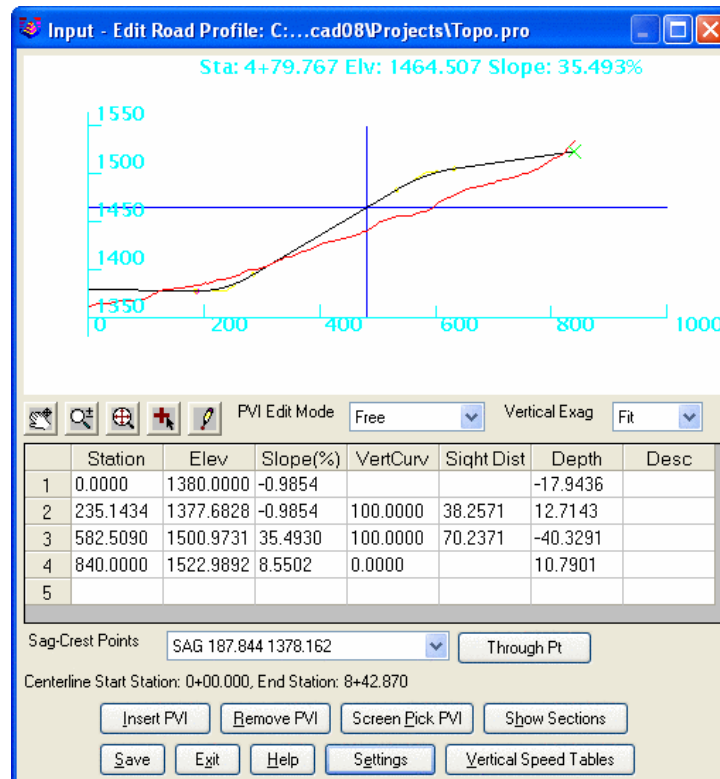

Keyboard Command: makeprof

Prerequisite: A profile grid drawn on-screen

Road Profile Editor

This command opens the Road Profile Editor dialog, showing the profile graph and a spreadsheet table containing the profile data. With this dialog, you can enter and edit road profile files (.PRO), not only by specifying the values in the spreadsheet, but also by editing the PVI points on the profile graph directly. The updates in the spreadsheet and the graphic box are synchronized.

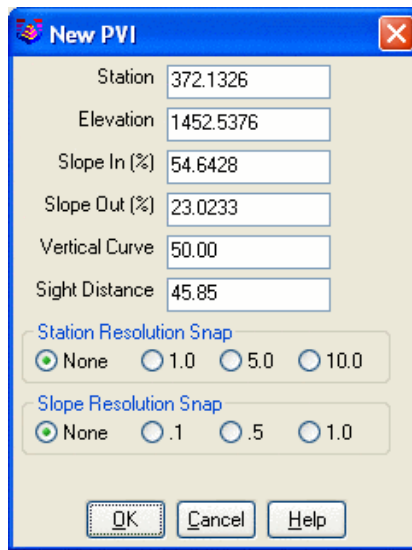

From the Profile menu in the Civil Design Module, choose Road Profile Editor. The program reads a road profile file (.PRO), a road centerline file (.CL) and a surface file (.TIN or .FLT). If you design a new road profile, just enter the new road profile file name. If you open an existing profile to edit, the profile graph is shown in the graphic box on the top, and the spreadsheet is filled with profile data. The buttons and lists between the graphic box and the spreadsheet provides the abilities to input and edit the road profile in graphic.

Road Profile Editor

1. Functions Editing Profile in Graphic:

Switch to pan mode button: Switch the cursor to PAN mode. **Switch to dynamic zoom mode button:** Switch the cursor to ZOOM mode. **Zoom Extents button:** Zoom the graphic window to show the complete graph. **Add PVI button:** Allow you to add a new PVI point by picking at any locations inside the graphic box. The program will extract the station and elevation of the point and display them in the New PVI dialog, from where you can modify the station and elevation directly in the Station and Elevation boxes, or by modifying the Slope In and Slope Out values. You can also specify the vertical curve length or sight distance to define the vertical curve of current PVI. The resolution snap for the station and slope round up the station and slope values. Click on OK button to save the new PVI data. Below is an example of the dialog.

New PVI dialog

Edit PVI button: Pick an existing PVI point on the profile graph and drag it around to change the station and elevation.

PVI Edit Mode list: This list has five options: Free, Hold Slope In, Hold Slope Out, Hold Station and Hold Elevation, which controls the movement of the PVI that is being edited by the Edit PVI button command.

Vertical list: This list determines the vertical exaggeration of the profile graph.

2. Spreadsheet Editor:

The spreadsheet editor allows you to enter and modify data cell by cell. The profile graph will be updated automatically after any changes of the profile data. **Insert PVI** button inserts a row in front of the highlighted row to create a new PVI, **Remove PVI** button deletes the highlighted row as well as the corresponding PVI, and **Screen Pick PVI** button allows you to pick a point on screen and insert it into the spreadsheet. In the **Sag-Crest Points** list, the coordinates of all Sag and Crest Points are listed.

3. Settings Dialog

Click on the Settings button, the settings dialog displays.

Hold Current Elevation: When you change a PVI's station or elevation, if this toggle is on, its slope out will be changed and the elevation of the next PVI is held, otherwise its slope out is held and the elevation of the next PVI will be changed.

User K-Value: Toggles between displaying K-Value and Sight Distance in the fifth column of the spreadsheet.

Grid Ticks Only: Toggles between displaying the grid and grid ticks in the graphic box.

Show Slope When Zoom In: This option allows to display the slopes on the long enough profile segments when zoom in.

Show Reference Surface: An option to show the reference surface profile along with the road profile in the graphic box.

Show Reference Surface At Left Offset: An option to show the reference surface profile at a user-specified left offset of the road centerline.

Show Reference Surface At Right Offset: An option to show the reference surface profile at a user-specified right offset of the road centerline.

Show Centerline Special Stations: When this toggle is on, the points at centerline special stations such as PC, SC, ST, TS and SP are shown in the graphic box.

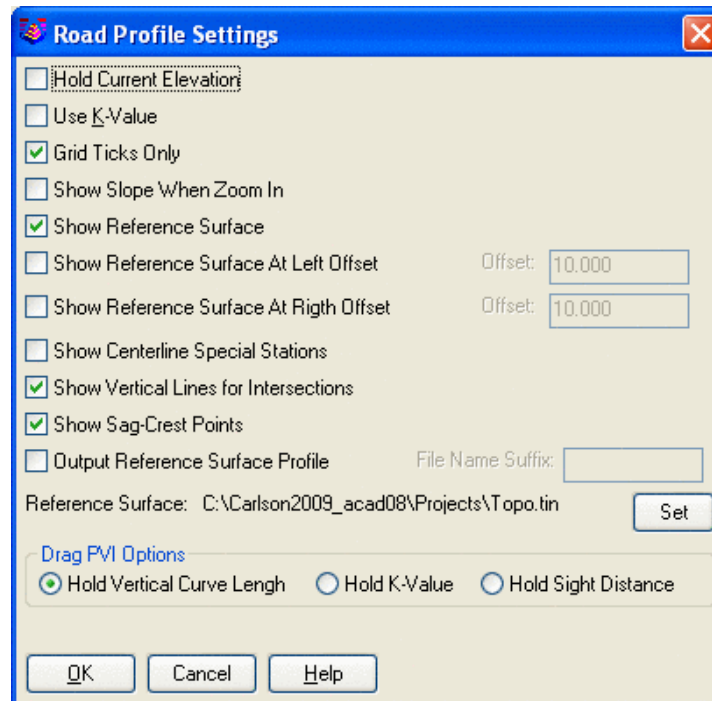

Show Vertical Lines for Intersections: When this toggle is on, vertical lines represent intersections of two road profiles are shown.

Show Sag-Crest Points: An option to draw the sag and crest points in the graphic box.

Output Reference Surface Profile: An option to output the surface profile to a file whose name has a suffix of the current road profile file name.

Set button: Set the current Reference Surface file to another one.

Drag PVI Options: When pick an existing PVI point on the profile graph and drag it around, you may choose to hold either the vertical curve length, or the K-value, or the sight distance.

Road Profile Settings

4. Show Sections

This function applies the design template at the road profile to get the road section file, computes the outslopes and earthworks relative to the reference surface section file, and displays both road and surface sections in a graphic dialog box. Click on the **Show Sections** button, the Road Design Templates dialog displays. The last 4 input items are strictly optional design files.

Design Template: Specify a template file (.TPL) or template series file (.TSF) that defines the final grade offsets and elevations and the cut/fill slopes.

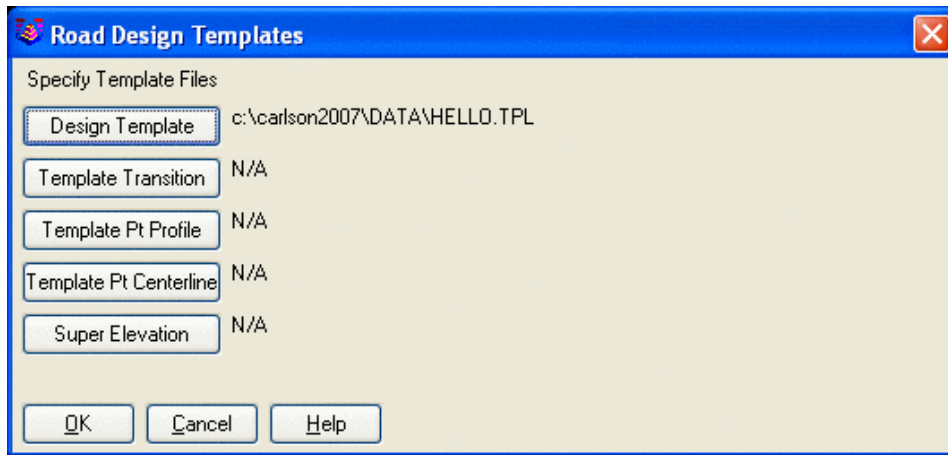

Template Transition: Specify a .TPT file, which allows modified template files to be applied at different ranges of stations on a project.

Template Point Profile: This option lets you have separate profiles for template points that are independent of the centerline file.

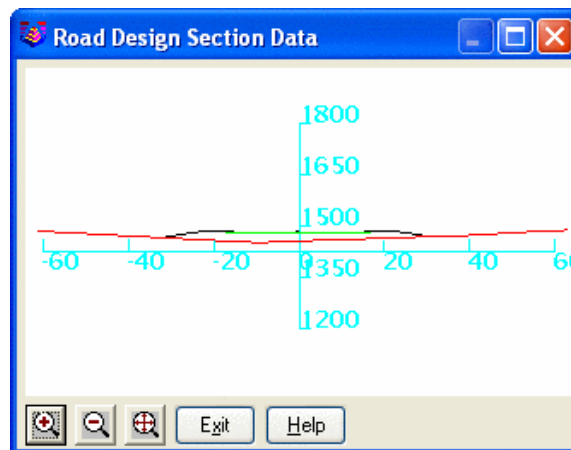

Template Point Centerline: This option lets you have separate centerlines for template points that are independent of the main centerline.

Super Elevation: This option is used to specify a super elevation file (.SUP) that defines the super elevation transition stations on a project.

After specifying the design template file(s), click on OK button to display the section graph. In the section dialog, the graph is automatically updated when you move your cursor along the road profile graph to change stations.

Show Sections: Choose Templates

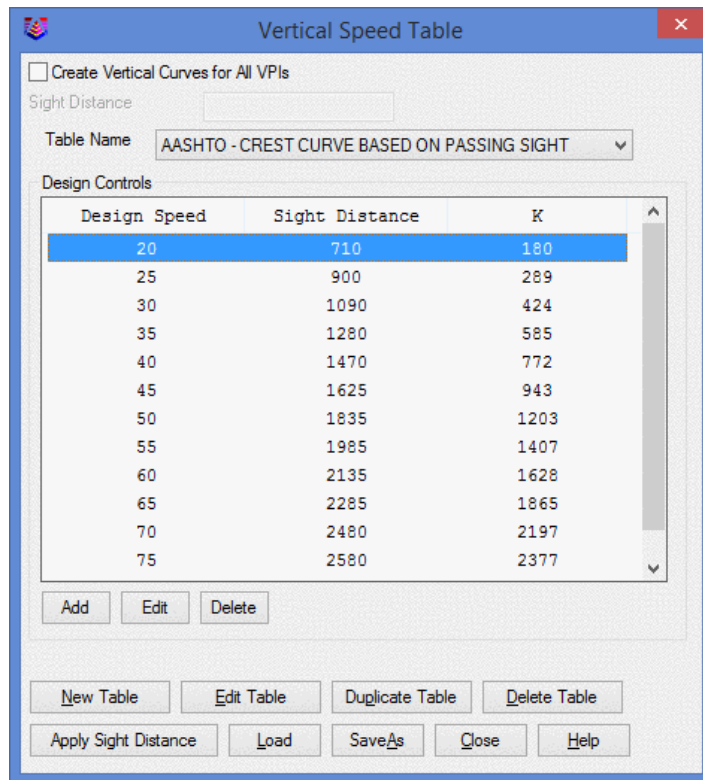

Road Design Section Dialog

5. Vertical Speed Tables

The Vertical Speed Table function provides a few of speed tables, which utilize AASHTO's speed table data and offer the recommendations for design speeds and curve parameters. Please refer to AASHTO A Policy on Geometric Design of Highways and Streets 2004 (pp 265-280) for details.

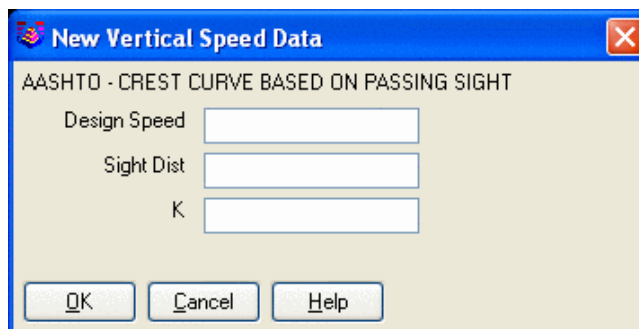

Click on the Vertical Speed Tables button to open the speed table dialog shown as below. The **Table Name** list contains the names of all speed tables that have been defined. There are five default speed tables: AASHTO - Crest Curve Based On Passing Sight, AASHTO - Crest Curve Based On Stopping Sight, AASHTO - Sag Curve Based On Stopping Sight, METRIC- AASHTO - Crest Curve Based On Passing Sight, METRIC- AASHTO - Crest Curve Based On Stopping Sight and METRIC- AASHTO - Sag Curve Based On Stopping Sight. You can add, edit and delete any speed tables. All speed table files are in the ... \USER folder and are available for all projects.

After highlighting a Design Speed and click Apply Sight Distance button, the Sight Distance value will be applied and the Vertical Curve is calculated and filled in the spreadsheet. When there's no vertical curve, you are allowed to create Vertical Curves for all VPIs and the program will check if the vertical curve value fits all the VPIs.

Vertical Speed Table

Click on the Add button, the New Vertical Speed Data dialog displays. Enter values in the Design Speed, Sight Distance and K boxes. Click on OK button to commit the new speed entry. Edit button allows you to modify design speed, sight distance and K values of the highlighted speed entry, and Delete button deletes the highlighted entry from current table. New Table button creates a new speed table, Edit Table button is used to modify the name of current table, Duplicate Table button makes a new speed table that contains the same data as current table, and Delete Table button removes current table completely.

New Speed Entry

New Vertical Speed Table

Prompts

Road Profile Editor dialog: Fill in values.

Pulldown Menu Location: Profiles > Design Road Profile

Keyboard Command: roadpro

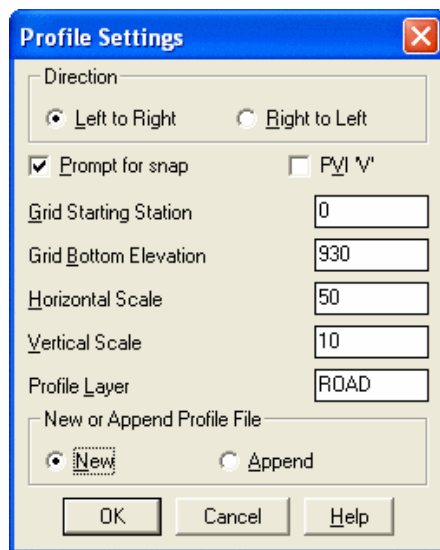

Prerequisite: a road profile file (.PRO), a road centerline file (.CL), a surface file (.TIN, .FLT)

Design Road Profile

This command is for simultaneously creating a .pro file and drawing the road profile. It is typically used when designing a road profile on top of a plotted existing grade profile, where the goal is to minimize cut and fill and keep to a minimum the number for vertical curves and avoid excessively steep grades. It is often necessary to match the starting and ending elevations of existing roads or features. For example, a side road will contact the main road at a fixed, given elevation. One concept to remember is that it may be best to favor a little more fill than cut in the design profile, because if your design template for the road involves ditches, a little bit of cut can lead to significant extra cut volumes due to the ditch placements. The *Design Road Profile* command works fine when overlaying on profile plots with either matching horizontal and vertical scales or exaggerated vertical scales (e.g. 50 H and 5 V). Just be sure to specify the correct scale settings in the Profile Settings dialog. The procedure is to first specify the on-screen grid and then enter or pick the stations and elevations.

Once two segments have been entered, you will be prompted for the vertical curve length. The vertical curve is a parabola, the typical form used in the United States. If you don't want a vertical curve, enter 0. Otherwise you can directly enter the vertical curve, or enter the sight distance or the K-value from which the vertical curve is calculated. The vertical curve can also be specified to pass through a point or do a best fit through multiple points. This through point option would be useful for hitting an existing feature such as a driveway on the vertical curve. Unequal vertical curves is another option where the vertical curve length going into the PVI differs from the length leaving the PVI. Before using your entry, the vertical curve, sight distance, and K-value are displayed. Object height and eye height are two variables that effect the vertical curve. Their values can be set using the command *Profile Defaults*.

Notice that the station, elevation and slope at the current position of your cursor crosshairs are displayed in real-time in a small dialog.

Prompts

Profile Settings dialog

Profile to Write Dialog Note that you can choose to append to an existing road profile, which allows you to continue design work in different work sessions. If Append is selected, the cursor will default to the end point of the selected profile, which will be treated as a 'PVI' point, so that you will be prompted for a vertical curve length after your very next picked point.

Pick Lower Left Grid Corner <5000.08,3211.24>[endp on]: Pick a lower left corner for the plotted grid on the screen. If you have just finished plotting the existing profile, the program will remember your lower left coordinates, and you just hit Enter to accept the default values.

Enter station or pick a point (Enter to End): 0

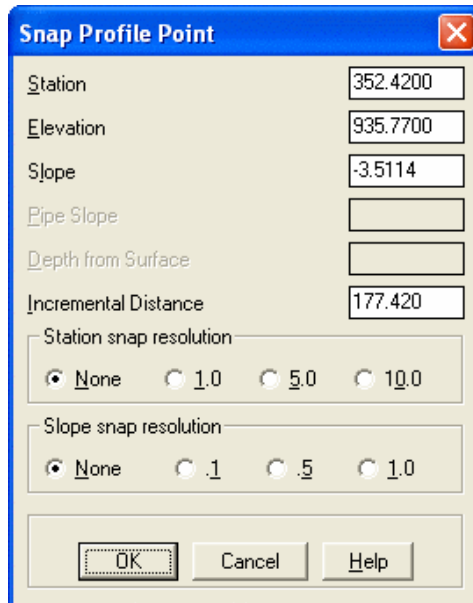

Elevation of PVI: 932.5

Station of second PVI or pick a point (U,E,D,Help): 175

Percent grade entry/Ratio/<Elevation of PVI>: 942

Station of next PVI or pick a point ('U' to Undo, Enter to End): *pick a point*

Snap PVI dialog

The Snap Profile Point dialog box is a standard Windows-style window with a blue title bar and a close button (X) in the top right corner. It contains several input fields and two groups of radio buttons. The fields are: Station (352.4200), Elevation (935.7700), Slope (-3.5114), Pipe Slope (empty), Depth from Surface (empty), and Incremental Distance (177.420). The Station snap resolution group has radio buttons for None (selected), 1.0, 5.0, and 10.0. The Slope snap resolution group has radio buttons for None (selected), .1, .5, and 1.0. At the bottom are three buttons: OK, Cancel, and Help.

The Snap PVI dialog box appears when you pick a point (if the Prompt for Snap option in the Profile Settings dialog is selected). The station and slope may be changed to the nearest snap value. The elevation is the free variable and it will change to compensate for any snap. To change the elevation, select the elevation edit box and enter the new value. In this example, you might choose a slope snap of 0.1 and if the station was flexible (not fixed, such as the end of the road), you could choose a station snap of 10.

View Table/Unequal/Through pt/Sight Distance/K-value/<Length of Vertical Curve>: 100

For Crest with Sight Distance>VC and Vertical Curve => 100.00

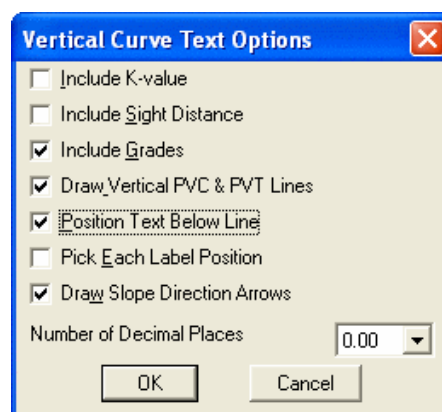

Sight Distance => 124.43, **K-value =>** 11.2

Use these values (<Y>/N)? *press Enter*

Station of next PVI or pick a point ('U' to Undo, Enter to End): *press Enter*

Vertical Curve Text Options dialog box

Pick vertical position for VC text: *Pick a position above the profile grid.* The final plot is shown below:

The Vertical Curve Text Options dialog box is a standard Windows-style window with a blue title bar and a close button (X) in the top right corner. It contains a list of checkboxes and a dropdown menu. The checkboxes are: Include K-value (unchecked), Include Sight Distance (unchecked), Include Grades (checked), Draw Vertical PVC & PVT Lines (checked), Position Text Below Line (checked), Pick Each Label Position (unchecked), and Draw Slope Direction Arrows (checked). The Number of Decimal Places dropdown menu is set to 0.00. At the bottom are two buttons: OK and Cancel.

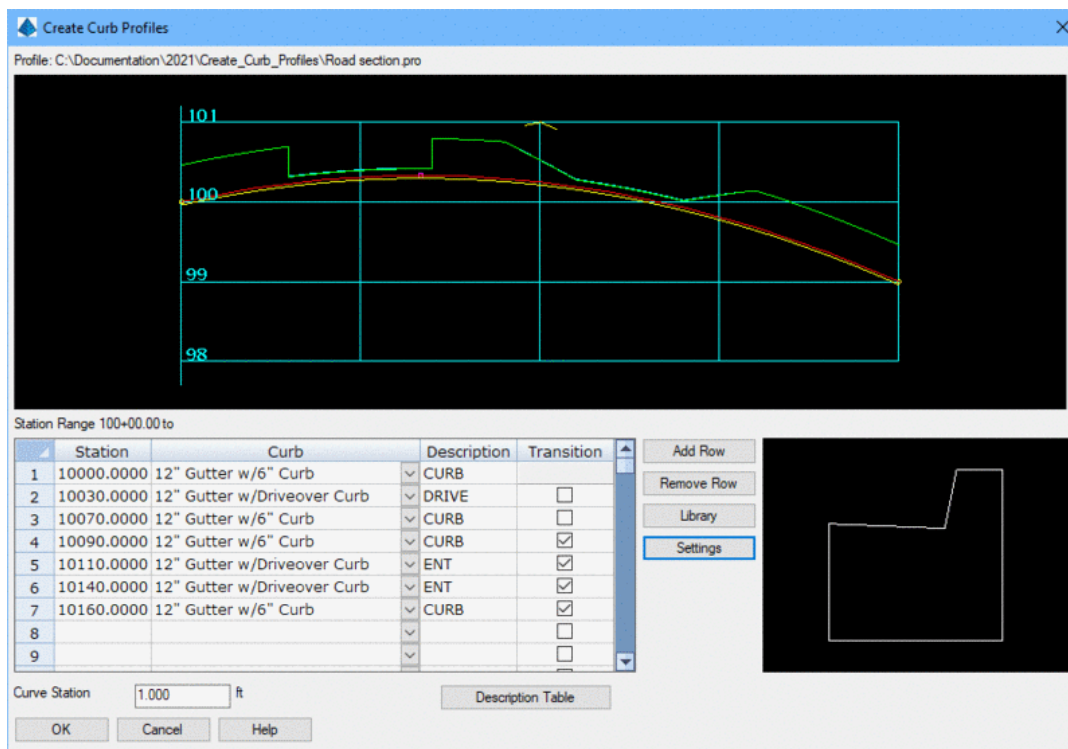

Pulldown Menu Location: Profiles

Keyboard Command: road

Prerequisite: A profile grid

Create Curb Profiles

This command allows you to build separate profiles (*.PRO) representing each daylighting portion of a curb section such as edge of pavement, gutter, face of curb and back of curb. These can then be drawn and plotted along side other profiles such as edge of pavement, centerline, ditch and sewer profiles.

Station determines which Curb Section is applied.

Curb displays Curb Section to be applied at station.

Description Used to a place label along profile if Description matches Description from the Description Table.

Transition determines if Curb Section will hold Curb Section geometry or perform a linear transition to next Curb Section station.

Add Row adds a Curb Section to the list of stations.

Remove Row deletes the highlighted Curb Section from the list of stations.

Library allows you to select a Curb Section already defined by Carlson or one you have created in a previous project using the Curb Section Library.

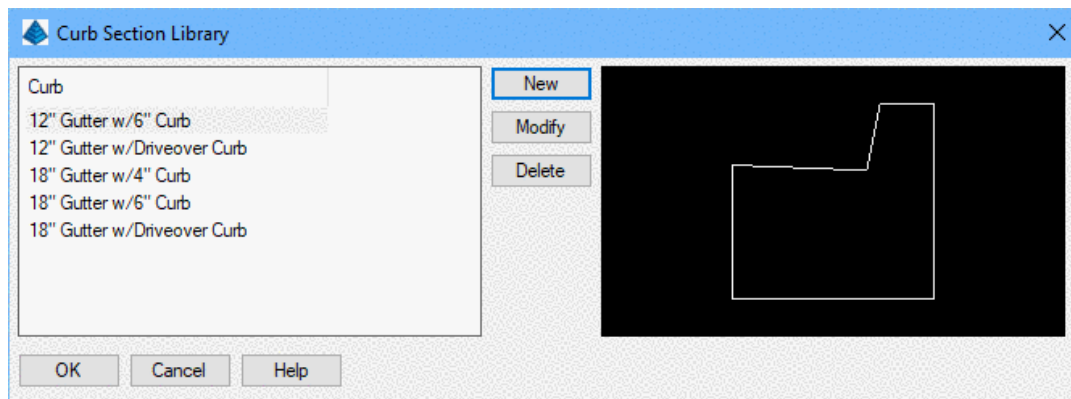

Settings to help you specify which of the profiles are created; the prefix that is applied; the color in the dialog box and whether or not these profiles are linked to the road profile.

Curve Station specifies an interval or 'densification' along vertical curves for each curb profile such that they appear curved.

Description Table allows you to automatically label the curb profiles. Enter a Description for the curb section and enter the same description in the Description Table and the desired label to be placed along the profile. You can also specify a symbol to be placed at that location.

Curb Section Library

Select a curb already defined by Carlson or one you have created in a previous project using the Curb Section Library.

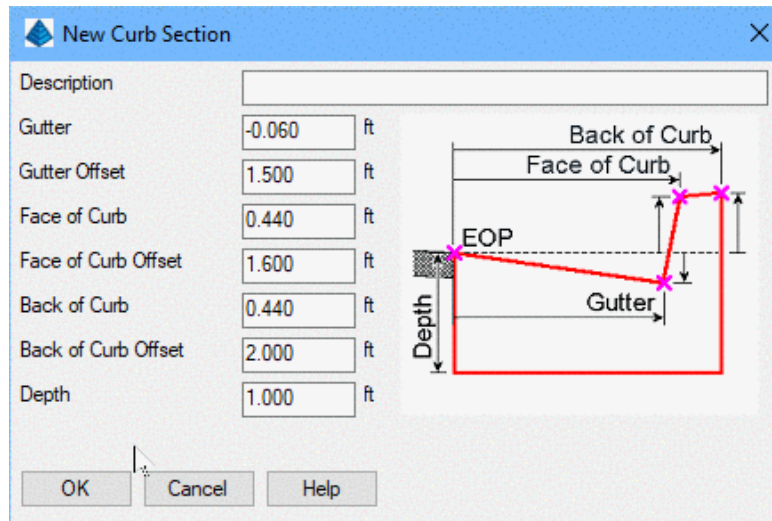

New Curb Section creates a new Curb Section.

Modify Curb Section modifies the highlighted Curb Section.

Delete Curb Section removes Curb Section from the Library.

New / Modify Curb Section

Create or modify a new curb section calculating profiles. Using the illustration as a guide on the New/Modify dialog boxes, enter the dimensions of the curb section using the Edge of Pavement (EOP) as the 'origin' or baseline for entering horizontal (Offsets) and vertical dimensions. For example, use positive offset values for the Gutter Offset; Face of Curb Offset and Back of Curb Offset as measured from the EOP toward the right. For heights above the edge of pavement such as Face of Curb and Back of Curb, use positive values above the Edge of pavement, and negative for Gutter if below the EOP. For the initial Depth of the Curb at the EOP, enter a positive value for the Depth even though this is below the EOP. NOTE: The Description entered here appears under the Curb heading on the main Curb Profiles dialog box and is not used for the purposes of labelling using the Description Table.

Description used to identify the Curb Section in the Library.

Gutter is the depth of gutter from the EOP, usually displayed as a negative value.

Gutter Offset is the bottom of gutter measured horizontally from the EOP.

Face of Curb is the height of the face of curb measured above the EOP.

Face of Curb Offset is measured horizontally from the EOP.

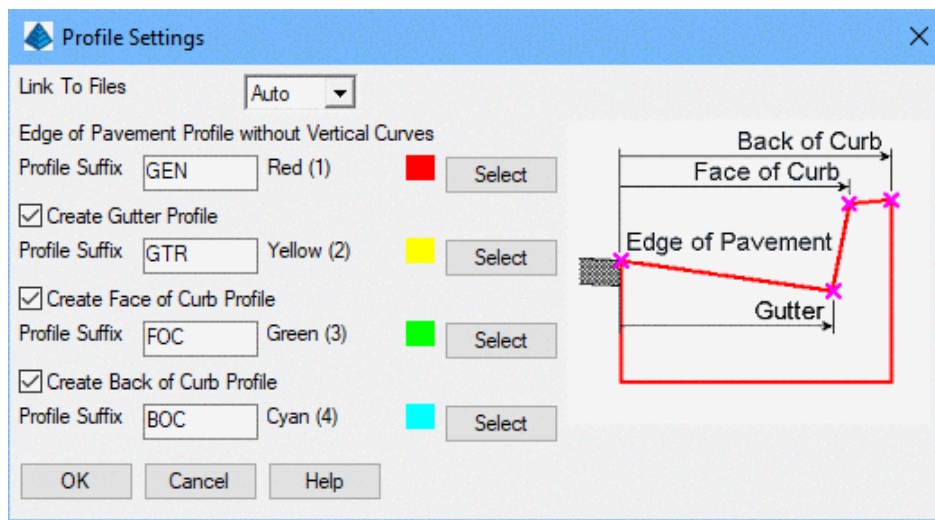

Back of Curb is the height of the back of curb measured above the EOP.

Back of Curb Offset is measured horizontally from the EOP.

Depth displays the depth of Curb Section at the EOP and entered as a positive value.

Settings

Specify which of the profiles are created; the prefix that is applied; the color in the dialog box and whether or not these profiles are linked to the road profile.

Link To Files determines how changes to the main road profile file affect curb profiles.

- **Off** indicates no changes to the curb profiles once initially created until Curb Profiles is run again.
- **Prompt** indicates changes to the road profile file trigger a prompt to the drawn curb profiles should they be updated.
- **Auto** indicates changes to the road profile file result in an automatic change to the drawn curb profiles.

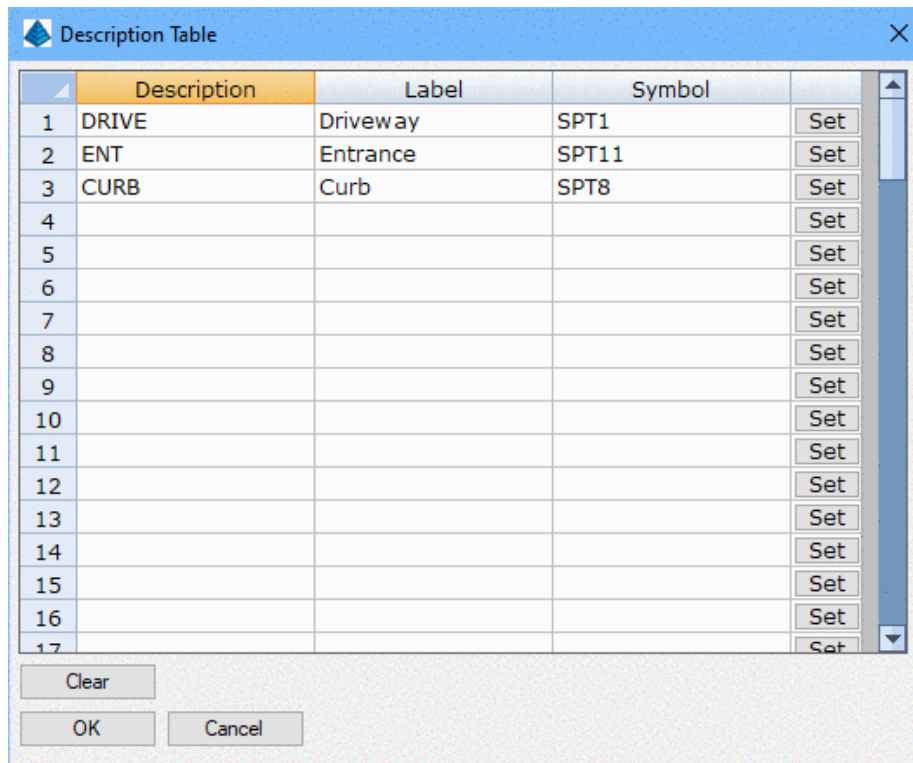

Profile Suffix is the suffix applied to the named curb profile (*.PRO) of the EOP, Gutter, Face and Back of Curb profiles.

Select allows you to set the color of the profile as displayed in the Curb Profiles dialog box. NOTE: This does not affect the color of the drawn profile in CAD.

Create toggles which profiles you are creating for all the curb profiles.

Description Table

Automatically label the curb profiles based on the Draw Stacked Labels using the Draw Profile command. The label is selected based on the description of the curb station. Additionally you can specify a symbol to be placed at the desired curb profile station.

Description matches the description of the Curb Section station. Used to determine what label and/or symbol can be drawn along the profile.

Label text placed at the profile station. You can use this in conjunction with the Draw Profile > Stacked Label to identify the Curb Section.

Symbol draws a symbol along the profile at the Curb Section station.

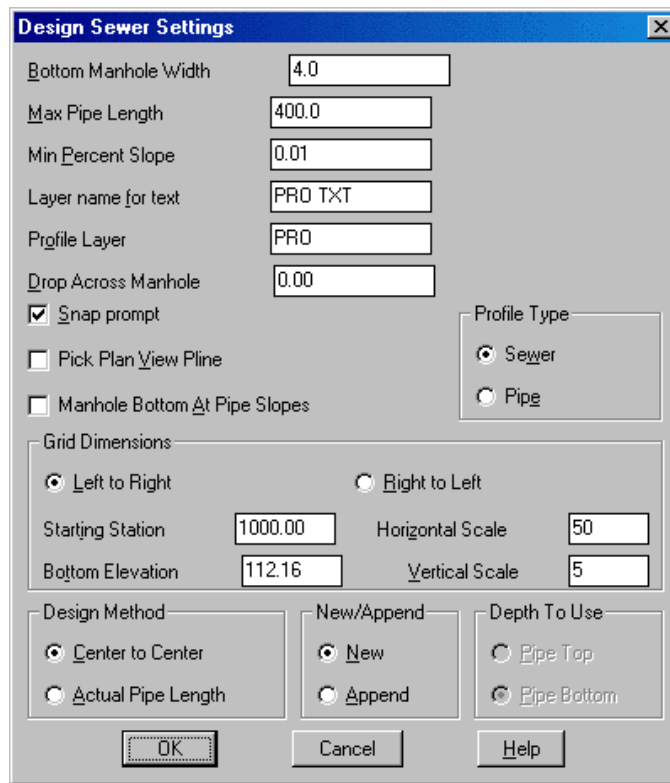

Pulldown Menu Location: Profiles > Design Road Profile

Keyboard Command: CURBPROF

Prerequisite: Design profile

Design Sewer/Pipe Profile

This command creates a sewer profile (.PRO) file with manholes, or will create a pipe profile (no manholes, no manhole width), and draws it on the screen. It requires that a grid is already drawn. It begins with the Design Sewer Settings dialog box.

Bottom Manhole Width: Specify the size for the bottom of manholes. Not available when Profile Type is set to pipe.

Max Pipe Length: Specify the maximum limit for the distance between manholes.

Min Percent Slope: Specify the minimum slope (absolute value) between manholes.

Layer name for text: Specify the layer name for annotation. If you enter a layer that does not exist, it will be created.

Profile Layer: Specify the layer name for pipes and manholes. If you enter a layer that does not exist, it will be created.

Drop Across Manhole: Specify the amount the elevation drop across the manhole in the direction of the profile. Will accept a negative a value. Not available when Profile Type is set to pipe.

Snap Prompt: Activates the PVI Snap dialog box. See below for description.

Pick Plan View Polyline: Allows you to select a polyline from plan view that represents the sewer centerline. This leads to the plotting of manhole symbols on the plan view and also creates default manhole-to-manhole stations.

Manhole Bottom At Pipe Slopes: When checked, the manhole bottom will be drawn level with the pipe slope.

Profile Type: Choose between Sewer profile or Pipe profile. Pipe profile do not include manholes.

Grid Dimensions: Specify the grid dimensions on which the sewer will be designed.

Design Method: Choose whether distances specified are center or manhole to center of manhole or actual pipe length. Not available when Profile Type is set to pipe.

New/Append: Choose between creating a new profile (.PRO) file or appending an existing file.

Depth to Use: Choose between specifying pipe top or pipe bottom elevations. Not available when Profile Type is set to sewer.

Prompts

File Selection dialog

Choose a new profile file name to create.

Pick Lower Left Grid Corner <5000.0,5000.0>[endp on]: *pick the corner*

Select existing ground polyline or ENTER for none: You may optionally pick a polyline to use for calculating the depth from the surface as the sewer stations are entered.

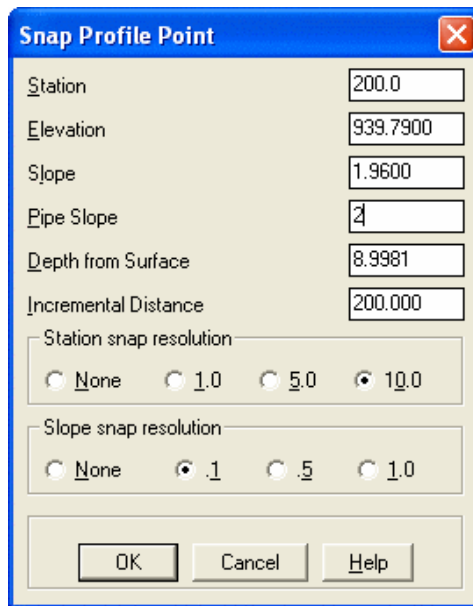

Enter station or pick a point (Enter to End): 0

Depth from Surface/<Elevation of manhole>: 935.7

Enter the step up/down in feet <0.00>: *press Enter*

Station of second MH or pick point (U,E,D,Help): *pick a point*

If the Pick Plan View Polyline option has been chosen, the program will default to the station of the next vertex in the selected polyline. If the Prompt for Snap option was selected in the main dialog, then the Snap Profile Point dialog appears here. The station and slope may be changed to the nearest snap value. The elevation is the free variable and it will change to compensate for any snap. To change the elevation, select the elevation edit box and enter the new value.

The image shows a dialog box titled "Snap Profile Point" with a close button (X) in the top right corner. The dialog contains several input fields and two groups of radio buttons. The fields are: Station (200.0), Elevation (939.7900), Slope (1.9600), Pipe Slope (2), Depth from Surface (8.9981), and Incremental Distance (200.000). The "Station snap resolution" group has radio buttons for None, 1.0, 5.0, and 10.0, with 10.0 selected. The "Slope snap resolution" group has radio buttons for None, .1, .5, and 1.0, with .1 selected. At the bottom are three buttons: OK, Cancel, and Help.

Enter the step up/down in feet <0.00>: *press Enter* Enter 0.1 if pipe drops one tenth into manhole and you are designing in upstream direction.

If you enter a station for the next manhole rather than picking a point on the screen, then you will be prompted as follows:

Depth/Percent grade/Min grade/<Elevation of manhole>: 939.79

Size of pipe in inches <10.0>: 8.0

Station of next manhole or pick a point (U,E,D,Help): *press Enter*

If you picked a plan view polyline, you will be asked:

Draw manholes on centerline [Yes/<No>]?: Y Then you will be prompted for the default manhole symbol to use.

Profile Sewer Settings dialog

Sewer Label Options dialog

Sewer Annotation Options dialog (Displayed by pressing the Annotation Options button.)

Select existing ground polyline: *pick a polyline or press Enter to be prompted for each manhole surface elevation*

This prompt only appears if no ground polyline was selected above.

Manhole No. 1 label [MH #1]: *press Enter*

Manhole No. 2 label [MH #2]: *press Enter*

Pulldown Menu Location: Profiles

Keyboard Command: sewer

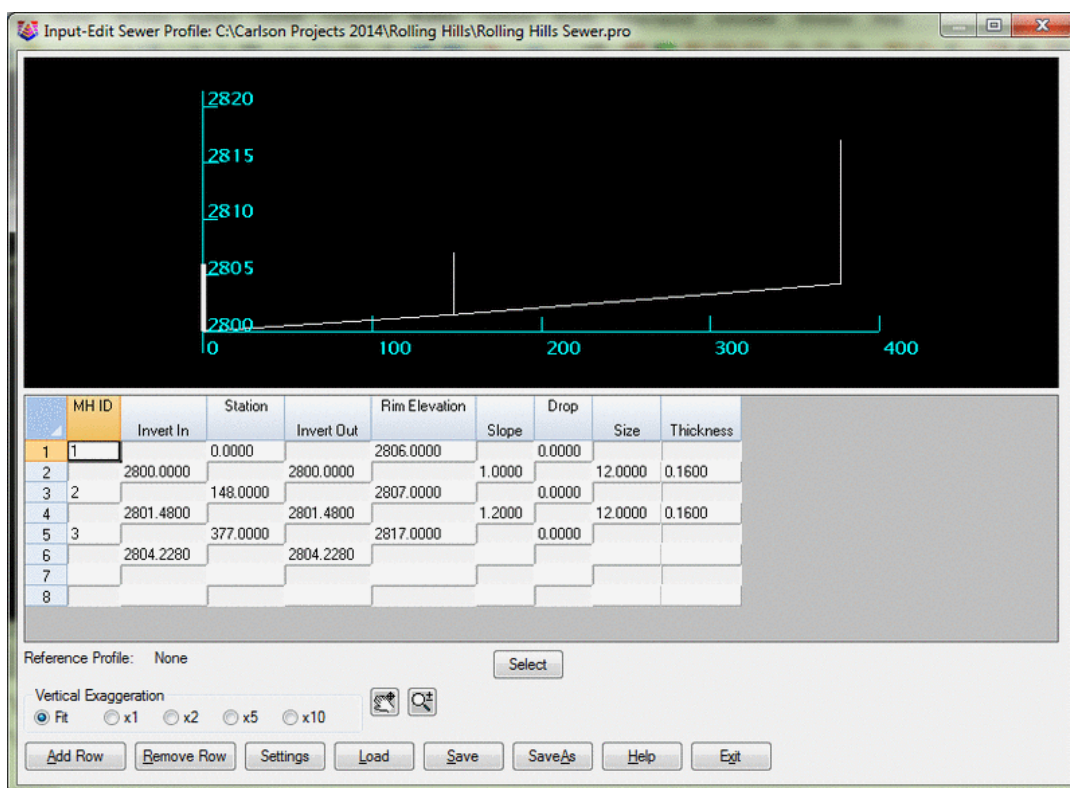

Prerequisite: A profile grid

Sewer/Pipe Profile Editor

This command allows for a way to enter and edit sewer profiles in a spreadsheet type editor formatted specifically for this purpose. In order to start a new profile must be created or an existing profile selected.

The dialog is staggered to make it clear how the sewer profile is structured. It provides for the ability to specify inverts in and out, rim elevations, slopes of the pipes, drops across the manhole and sizes and thicknesses for the pipes. The preview pane has standard controls for panning, zooming and setting the exaggeration for easy viewing.

Reference Profile: To show a reference profile choose the Select button and select a profile to use.

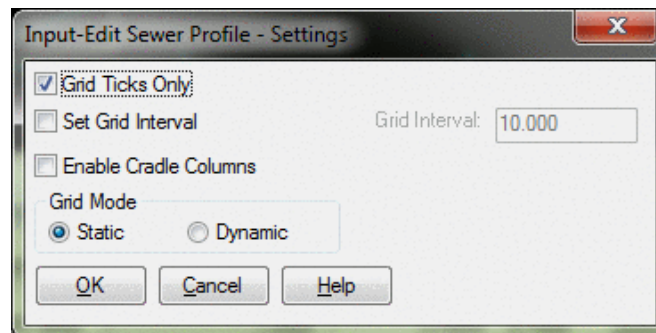

Vertical Exaggeration: Use the toggles here to fit or set the horizontal versus vertical exaggeration.

Pan and Zoom: Use the Pan and Zoom buttons to change the operation of the mouse in the preview window.

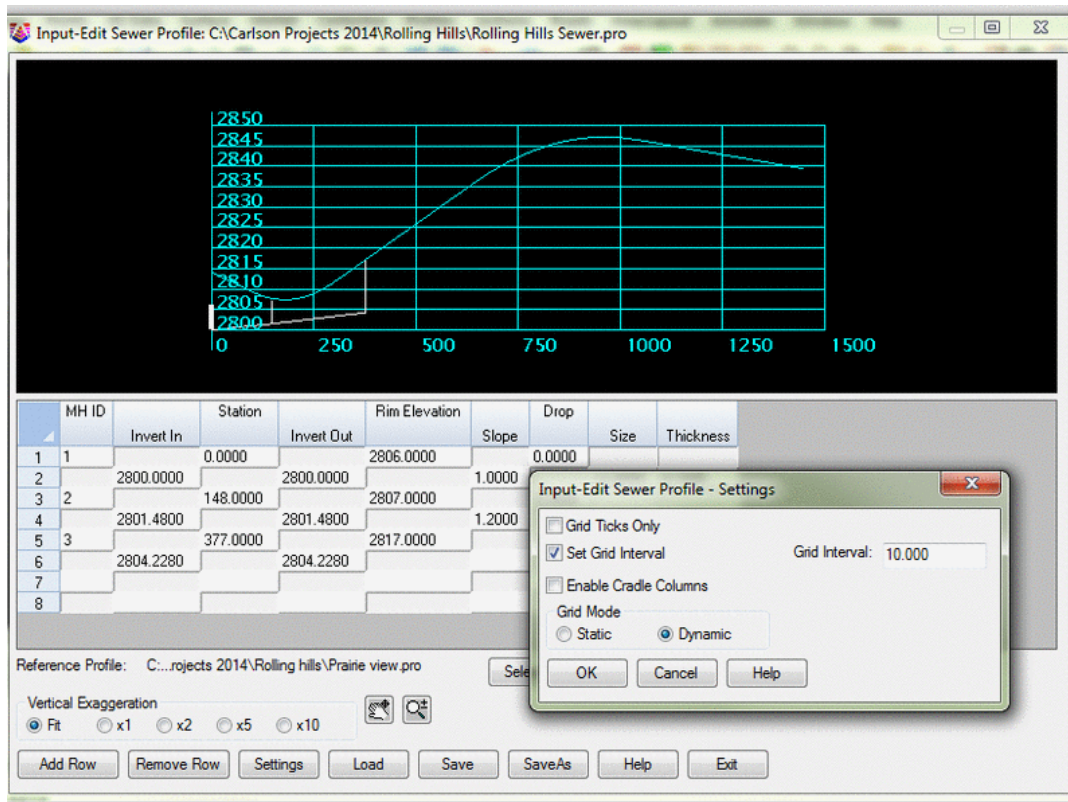

Add Row: Use the Add Row button to add a row. Highlight a row and then choose the Add Row button.

Remove Row: Select the row to remove and then select the Remove Row button.

Settings: Choose either Grid Ticks only or Set Grid Interval to change the preview display of the grid. Choose Enable Cradle Columns to add input for Cradles. Set static or dynamic to change the horizontal spacing of the grid lines.

Results of altered settings and a reference profile:

Load: Use the Load button to load a different profile.

Save: Use the Save button to save the profile.

SaveAs: The SaveAs button allows the saving of the profile with a different name.

Help: Launch help for this command with the Help button.

Exit: Use the Exit button to exit the command a prompt may ask for saving or not saving changes.

Pulldown Menu Location: Profiles

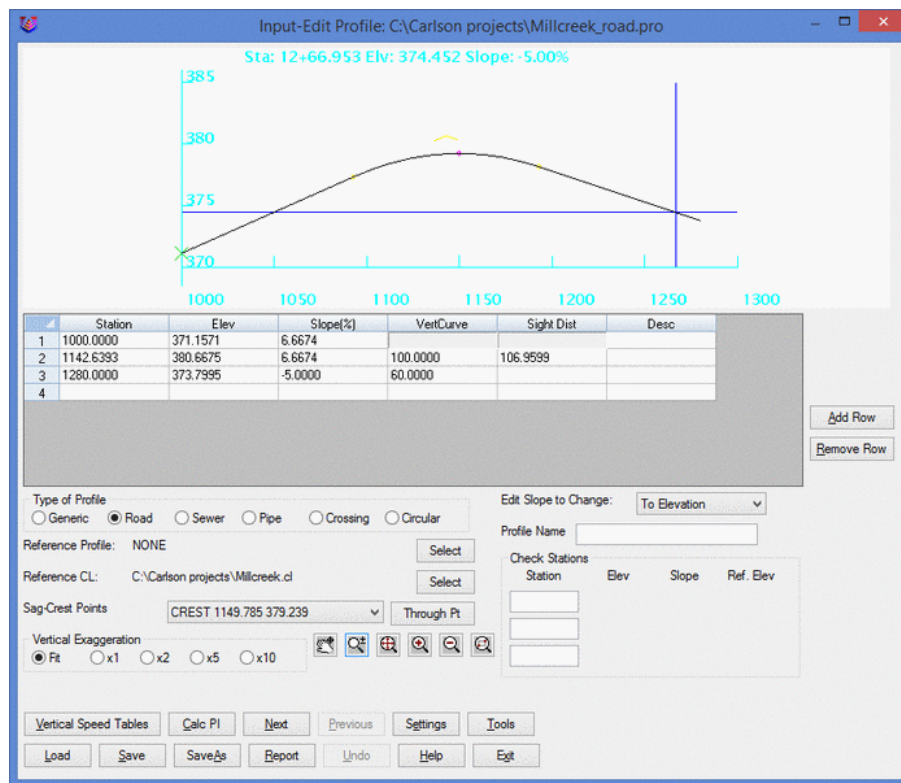

Keyboard Command: swrprofedit

Profile Editor

Similar to the Road Profile Editor command, this command features a spreadsheet type editor and handles a variety of profile (.PRO) configurations. Besides editing a profile, this routine can be used to just view the contents of a profile.

The command starts by prompting for the profile file to edit. Alternately, you can run Profile Editor by double-clicking on a profile polyline that is drawn on a profile grid.

The opening dialog below shows the layout of this editor. At the top of the dialog, you can dynamically see the profile and vary its appearance by using zoom and pan. The station, elevation and slopes are also shown at the lower left of the dialog which update/track with the movement of the cursor. There are between five and nine possible data fields in a profile depending on the type of profile that has been selected.

Profile Name: This name is optional and often used when multiple profiles are stored in a profile (.PRO) file and graphically generated using the Draw Profile command.

Add Row: Adds a new row into the profile after the current row.

Remove Row: Removes the current row.

Type of Profile: There are 6 types of .pro files and the spreadsheet columns will change to match the data fields for the selected profile type:

- *Generic* - Generic profiles have station, elevation and description fields.
- *Road* - Road profiles include the Generic controls and adds a vertical curve field. For an asymmetrical vertical curve, enter the left and right side values separated by a dash in the spreadsheet cell. For example, a 200' vertical curve with 50' to the left of PVI and 150' to the right would be entered as "50-150".
- *Sewer* - Sewer profiles include the Generic controls and adds step up, pipe size, pipe thickness, manhole elevation and manhole ID fields.
- *Pipe* - Pipe profiles include the Generic controls and adds a pipe size field.
- *Crossing* - Crossing profiles are for pipe crossings along the centerline. Besides station and elevation, the crossing data points also have the pipe size. The crossing elevation is for the bottom elevation of the pipe. The crossing profile data points are not connected.
- *Circular* - Circular profiles are the same as Road profiles except the vertical curve is circular instead of parabolic.

Edit Slope To Change: This setting controls which field to update when the slope is modified in the spreadsheet.

Reference Profile: Selects a reference profile and displays it in the profile graphic view. Also a Depth column is added to the spreadsheet which you can edit to set the profile elevation by depth from the reference profile.

Reference CL: Selects a reference centerline which is used for station equations.

Sag-Crest Points: When editing a road profile, its sag/crest points are shown here.

Through Pt: This button lets user to make the road profile pass through a certain point.

Vertical Exaggeration: Changes the look of the profile.

Edit Slope to Change: When edit the slope value, you can choose a value to change from the following selection: the next elevation, the previous elevation, the next station or the previous station.

Check Stations: Reports profile information at the specified stations. The Check Stations are not stored in the profile; they are merely used as a design/analysis tool for viewing the elevations at certain stations while adjusting the profile data. The **Offset** and **Slope** adjust the profile elevation and report the elevation at the offset.

Speed Tables: This button is enabled only when you edit a road profile. Please refer to the documentation on Road Profile Editor for the information on Vertical Speed Tables.

Next: Used for navigation when editing a .PRO file containing multiple profiles, loads the next profile.

Previous: Used for navigation when editing a .PRO file containing multiple profiles, loads the previous profile.

Load: Used for loading another, existing .PRO file for editing.

Save: Saves the profile using the current profile file name. The current profile file name is displayed in the top title bar of the dialog box.

SaveAs: Allows you to save the profile under a different profile file name.

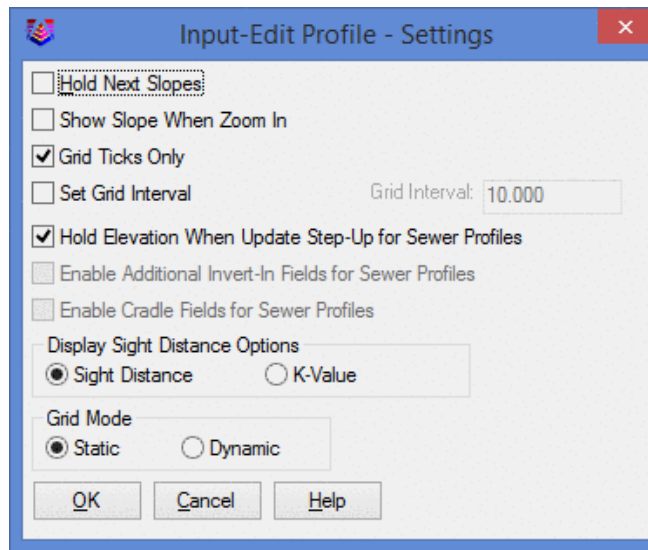

Calc PI: This function calculates a station/elevation point given two existing station/elevation points and slopes from them. The values are entered in this dialog. When you pick Calculate, the program finds the intersection of the grade lines. Then pick OK and the calculated PVI is added to the profile.

Calculate Intersection Point	
Intersection at Station: 1630.000 Elevation: 997.200	
Starting Station	790
Starting Elevation	993
Forward Station	1850
Forward Elevation	999.4
Slope From Starting Position to PI (percent)	0.5
Slope From Forward Position to PI (percent)	-1.0
[Calculate] [OK] [Cancel]	

Report: Creates a report of current profile.

Undo: Reverts the last action in the editor.

Settings: Opens the settings dialog.

Hold Next Slopes: When editing a profile elevation, this option will maintain all the slopes after the edit point by adjusting the elevations. Otherwise, the elevations for the rest of the profile points are held and the slope from the edit profile point to the next profile point is adjusted.

Show Slope When Zoom In: This option allows to display the slopes on the long enough profile segments when zoom in.

Grid Ticks Only: Toggles between displaying the grid and grid ticks in the graphic box.

Set Grid Interval: This option allows you to control the elevation grid spacing in the graphic preview. When this option is off, the program automatically figures the elevation grid interval.

Hold Elevation When Update Step-Up for Sewer Profiles: Toggles between holding the elevation or the pipe slope

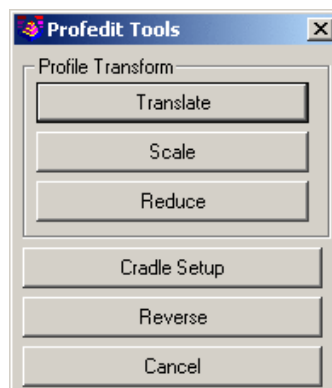

Enable Additional Invert-In Fields for Sewer Profiles: When editing a sewer profile, this option allows you to display an extra invert-in column for in-coming pipes. The invert-in elevations are separated by commas.

Enable Cradle Fields for Sewer Profiles: When editing a sewer profile, this option allows to display cradle above and cradle below columns.

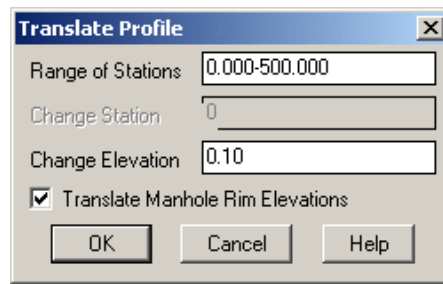

Display Sight Distance Options: Display either K-Value or Sight Distance in the fifth column for road profiles.

Grid Mode: The **Dynamic** option will update the grid interval labels when you zoom in or out of the profile image. The **Static** option will keep the grid interval labels static.

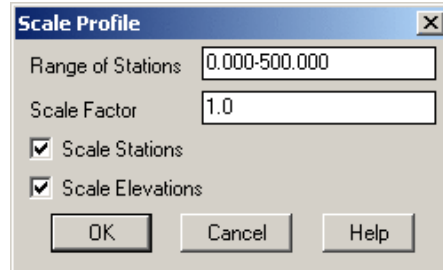

Tools: Opens the Tools dialog.

Translate: Globally adds or subtracts value to stations and/or elevations within the specified range of stations. while Scale will apply the specified scale factor to stations and/or elevations within the specified range of stations.

Scale: Applies the specified scale factor to stations and/or elevations within the specified range of stations.

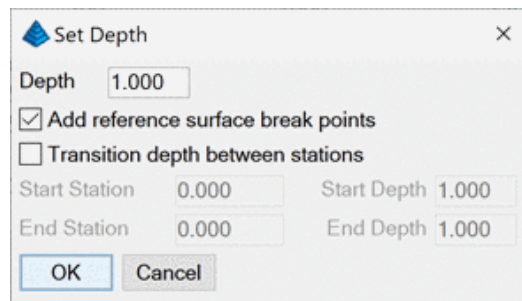

Reduce: Reduces the profile points by the Offset Cutoff value.

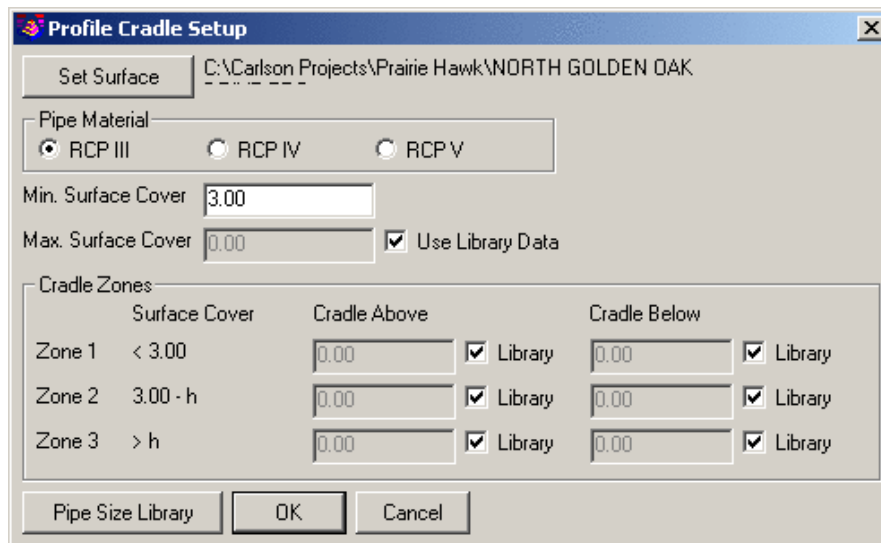

Reverse: Reverses the direction of the stationing for the profile.

Set Depth: When using a Reference Profile, this function sets the profile elevations by a specified depth from the reference profile.

Cradle Setup: Sets up the cradles for sewer profiles. The cradle parameters are different with different pipe sizes and are defined in the Pipe Size Library. You can either use library data or specify new values here.

Pulldown Menu Location: Profiles

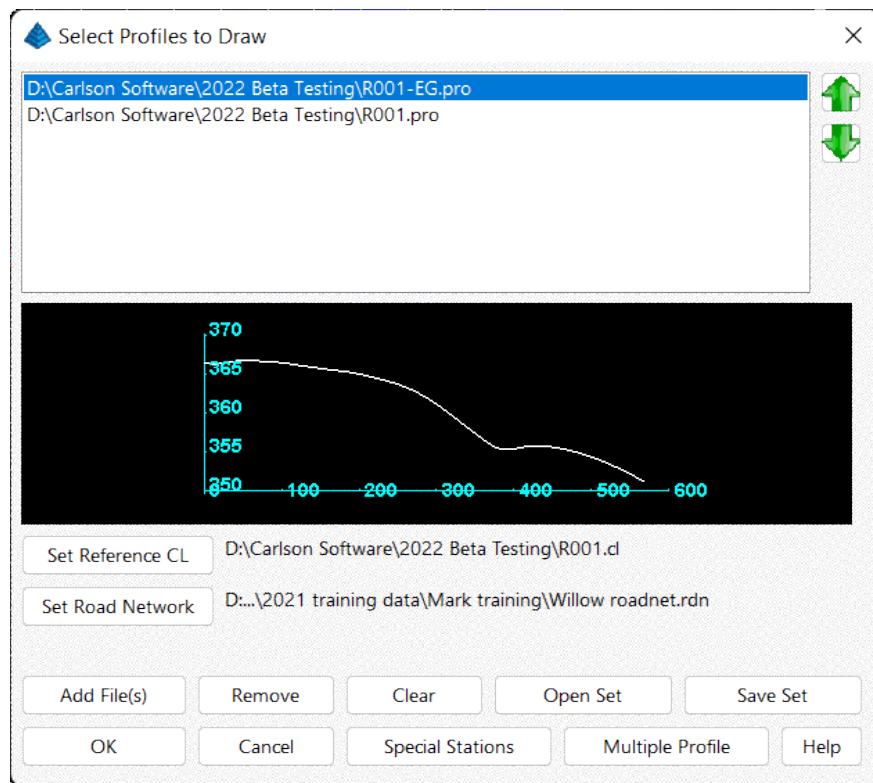

Keyboard Command: profedit

Prerequisite: None

Draw Profile

Draw Profile is a flexible routine for drawing a profile anywhere in the drawing. The profile can be placed in a layout tab or in the model space of the drawing. It may be drawn with or without a grid or with just tick marks. The vertical curve annotations for a road profile and manhole annotations for a sewer profile, may also be drawn. Draw Profile uses the profile information that is stored in .PRO files. It is also able to use a reference centerline stored in a .CL file. Once the profile is drawn using Draw Profile, the design and labeling routines of the Profiles dropdown are applicable to the profile. Please note, several of the options presented in the following dialogs will depend on the type of unit system being used, metric or English. Options such as text sizes, sheet dimensions, and scaling factors may vary from the examples shown here.

Select Profiles to Draw

Reference CL: When using Draw Profile to create Plan & Profile Sheets, a reference centerline will be needed to properly establish the "Plan" portion of the sheet. Use the **Set** button to locate and specify the desired Reference Centerline.

Set Road Network: Use this to set the current Road Network File (.RDN)

Add File(s): Use this option to add desired Profile (*.PRO) files one at a time into the dialog box.

Remove: Use this option to remove the currently selected profile the dialog box.

Clear: Use this option to remove all profiles from the dialog box.

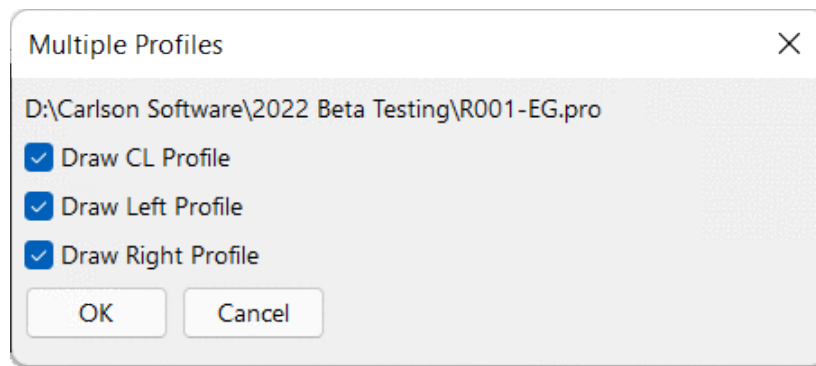

Open Set: Opens/loads a previously saved set of Profile files as stored in a *.PST file.

Save Set: Permits the current collection of profiles to be saved to a *.PST file for later recall.

Special Stations: Use this option to to label stations that are significant for the project.

Multiple Profiles: Use this option to add desired Profile (*.PRO) files (one or several at a time via standard Windows Shift+click and/or Ctrl+click functionality) into the dialog box.

Multiple Profile: For *.PRO files that have multiple profiles within the same file (*e.g.* those produced by the Profile Editor command that might have profile data at the centerline and also at offsets of -12 and +12), use this button to select which of the profiles to draw:

Another type of multiple profile is a profile with breaks such as a curb profile with breaks across intersections. This is built-in to Road Network (*aka* RoadNet). In RoadNet Settings (specifically, the Output Options tab), there's **Output EOP Profiles**. RoadNet will then create profiles with descriptions at the intersections and Draw Profile will break the profile across the intersections. You can also manually put in these descriptions in Profile Editor to set the breaks. Use **EP_FL:@E** to stop the profile and **EP_FL:@S** to resume the profile.

When the Select Profiles To Draw dialog has been set up, select the OK button to move on to the *Draw Profile* dialog box.

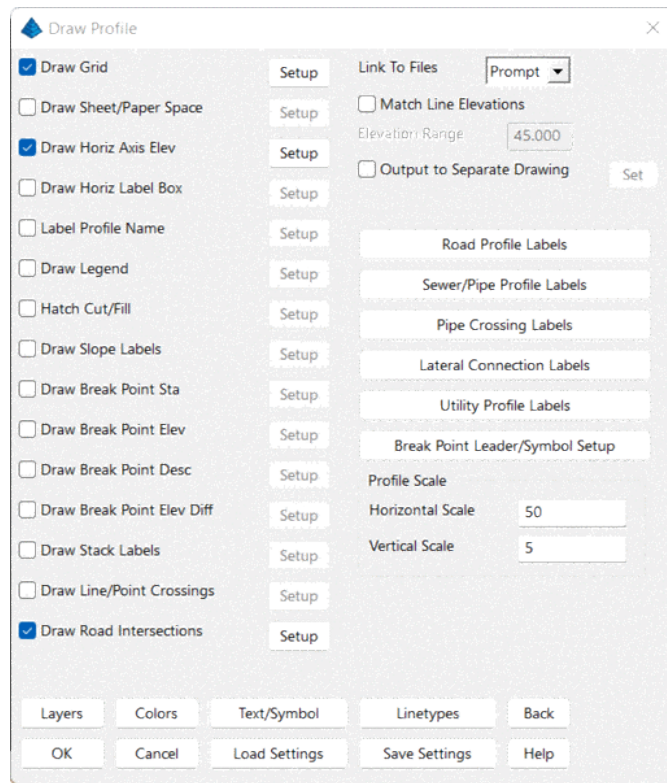

Draw Profile

Within the Draw Profile dialog box are numerous sub-commands that permit great flexibility in how the resulting profile(s) are drawn. Use the table below to access additional information about each of these sub-commands:

Draw Grid	Draw Sheet/Paper Space Label Profile Name	Draw Horiz Axis Elev
Draw Horiz Label Box		Draw Legend
Hatch Cut/Fill	Draw Slope Labels	Draw Break Point Sta
Draw Break Point Elev	Draw Break Point Desc	Draw Break Point Elev Diff
Draw Stack Labels	Draw Line/Point Crossings	Draw Road Intersections
Road Profile Labels	Sewer/Pipe Profile Labels	Pipe Crossing Labels
Lateral Connection Labels	Utility Profile Labels	
Layers/Colors	Text/Symbol	Draw Break Leader/Symbol Setup Linetypes

Draw Profile "Sub-Commands"

For each of the sub-commands above that have a check-box toggle, enable the toggle and use the appropriate Setup button to further access the option.

Link To Files: This setting controls the linkage of the plotted profile(s) to the actual profile file(s) (.PRO), determining how changes to the file affect the plotted profile(s):

- **Off:** Changes to an underlying profile file do not trigger a change to its drawn profile.
- **Prompt:** Changes to an underlying profile file trigger a prompt if its drawn profile should be updated.
- **Auto:** Changes to an underlying profile file result in an automatic change to its drawn profile.

Match Line Elevations: For high relief profiles that might otherwise exceed the profile limits of the sheet (typically dependent on the Vertical Scale), the Match Line Elevations option can be used to "break" (or vertically split) the profile and redraw the remaining portion (again, shifted vertically) to remain in the profile portion of the sheet.

Elevation Range: This is the range of elevations that is used in conjunction with the Match Line Elevations option. If the range is exceeded (that is, if the range is greater than 80), the program will break the profile and draw the remainder with a separate vertical axis range.

Output to Separate Drawing: When enabled, this option draws the profile(s) to a separate drawing. Use the **Set** button to specify the name/location of the external drawing. Suggested uses for this feature are when profile-only sheets need to be generated and provided to others for detailing or construction purposes.

Horizontal Scale: Indicate a real-world distance that should be used within the span of a horizontal grid cell.

Vertical Scale: Indicate a real-world elevation amount that should be used within the span of a vertical grid cell.

Layers

The Layers button permits layer names to be associated with items including the profiles, profile grid and general labels.

Sewer Label Layer Use Profile Layer option sets the profile layer name as a prefix or suffix to the sewer profiles and text layers

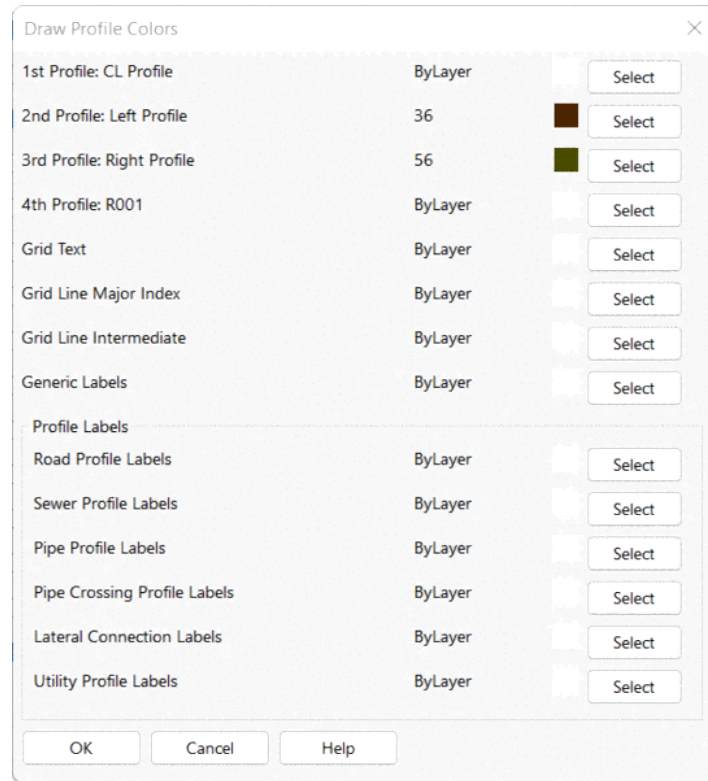

Set Level by Reference CL sets the level of the profile entities based on the name of the profile which can be seen in the Level Manager under the View menu.

The Prefix and Suffix options allow the user to add a prefix or suffix in various ways to the default layer names shown above.

Profile Line Layers displays the names of the profiles selected and allow the user to control which layer each profile will be placed on. If more profiles are selected, they will be displayed.

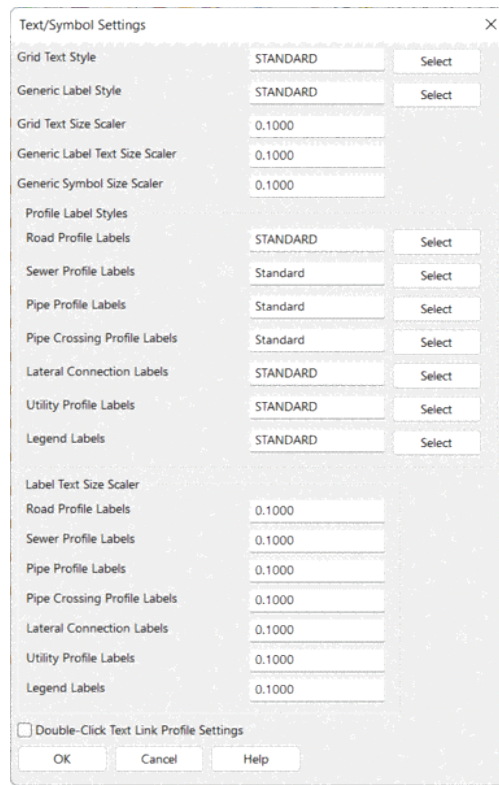

Colors

The Colors button provides the ability to control the color associated for items such as the profiles, profile grid and general labels. Any color selected will override the default ByLayer.

Text/Symbol Settings

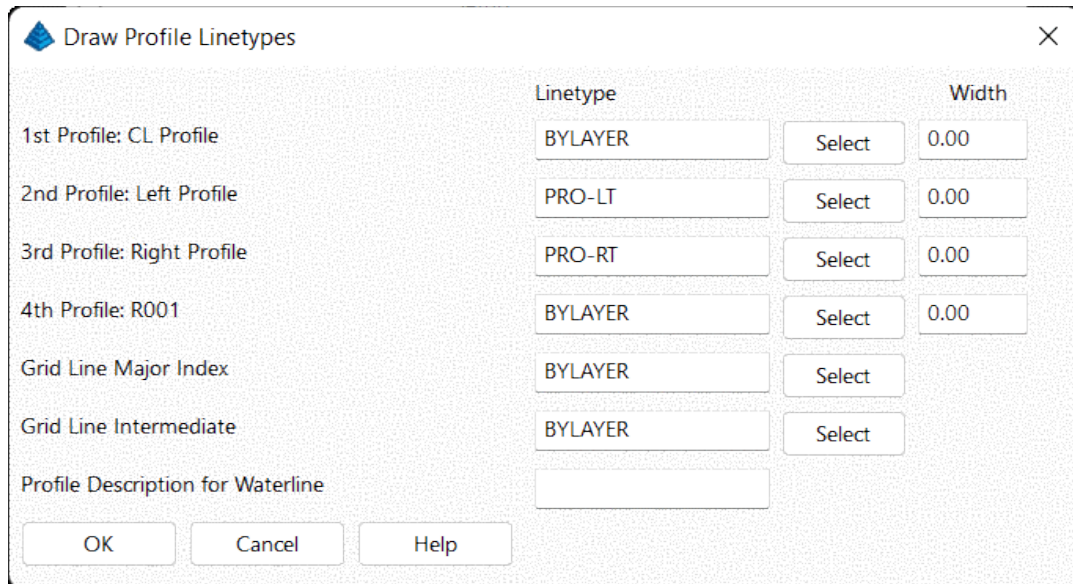

The Text/Symbol button has the text style and size scalars for profile grid and general labels. The size scalars are multiplied by the profile Horizontal Scale to determine the text size in drawing units.

Double-Click Text Link Profile Settings: When enabled, double-clicking a drawn profile text item launches the Draw Profile Settings for that text item. When disabled, double-clicking the text item launches the native CAD command (*e.g.* Edit Text).

Linetypes

The Linetypes button has lincotype settings for the profile line and profile grid. There are also settings for drawing a profile legend of the profile lines.

Label Profile Name on Profiles adds the name of the profile on the profile in a user defined location.

Profile Description for Waterline will draw a horizontal blue line at the profile elevation for the profile point with a description that matches this setting.

Draw Legend when enabled, will draw a legend of linetypes on the sheet(s) created when the **Draw Sheet** option is selected.

Draw Border with Wipeout places a wipeout component under the legend.

Line Length defines the length of the box that is drawn around the legend.

The **Horizontal** and **Vertical Offsets** control the placement of the legend relative to the sheet border.

Back: Allows you to return to the previous dialog box to alter or adjust the information it provides.

Load Settings: Loads a saved collection of Draw Profile settings, saved in a (.PFS) file.

Save Settings: Saves all Draw Profile settings in a (.PFS) file. Use this to be able to use all the settings on a future project.

Draw Grid

The Draw Grid option controls whether or not the grid and axis elevations for the profile are drawn. The **Setup** button launches the Grid Setup dialog. Here you can control numerous settings for how the grid, general text and stationing are drawn.

The screenshot shows the 'Grid Setup' dialog box with the following settings:

- Intervals:** Horizontal Grid: 25, Vertical Grid: 1, Horizontal Major Grid: 50, Vertical Major Grid: 5, Station Text: 50, Elevation Text: 5.
- Vertical Grid Adder:** Top: 10,000, Bottom: 15,000.
- Horizontal Grid Adder:** Left: 50,000, Right: 50,000.
- Grid Style:** Grid Lines, Grid Direction: Left to Right.
- Draw Vertical Bar on Right:** unchecked, Draw Vertical Bar separately: unchecked, Offset: 0,500.
- Tick Size:** Major, Minor.
- Label Stations:** checked, Label Station Equations: checked, Label Base Elev: unchecked, Label Scale: checked.
- Grid Title:** unchecked.
- Station Type:** 1+00.
- Station Text Orientation:** Horizontal, Station Text Position: Bottom.
- Draw Grid Line at PC/PT Station:** unchecked, Use Partial Labels for Intermediate Stations: checked, Increment Station Text from Beginning Station: unchecked.
- Label Elevations:** checked, Suffix: , Elev Text Vertical Justify: Bottom.
- Draw Elevation Labels Only On Left Side:** unchecked, Draw Grid Line Under Elevation Labels: unchecked.
- Elevation Text Offset Left:** Offset Scale: 0,100, Pick.
- Elevation Text Offset Right:** Offset Scale: 0,100, Pick.
- Offset Station Text:** checked, Offset Scale: 0,800, Pick.
- Stack Profile Grids:** unchecked, Setup.
- Draw Elevation Bar:** unchecked, Skip Grid Range Dialog: unchecked.

Horizontal Grid: Enter a value of how often grid lines should be displayed to coincide with the station values along the horizontal axis of the grid.

Horizontal Major Grid: Enter a value of how often major (or "heavy") grid lines should be displayed to coincide with the station values along the horizontal axis of the grid.

Station Text: Indicate how often station text labels should appear along the horizontal axis of the grid.

Vertical Grid: Enter a value of how often grid lines should be displayed to coincide with the elevation values along the vertical axis of the grid.

Vertical Major Grid: Enter a value of how often major (or "heavy") grid lines should be displayed to coincide with the elevation values along the vertical axis of the grid.

Elevation Text: Indicate how often elevation text labels should appear along the vertical axis of the grid.

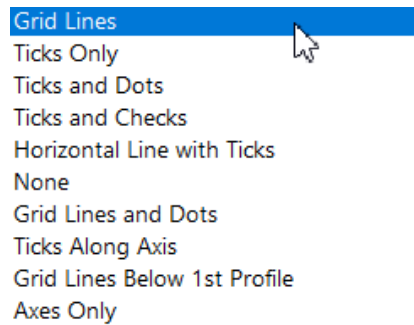

Vertical Grid Adder to Top: This adds the specified amount of grid to the top of the profile.

Vertical Grid Adder Bottom: This adds the specified amount of grid to the bottom of the profile.

Horizontal Grid Adder to Left: This adds the specified amount of grid to the left of the profile.

Horizontal Grid Adder to Right: This adds the specified amount of grid to the right of the profile.

Grid Style: This selects the type of Grid to generate. The choices are Grid Lines, Ticks Only, Ticks and Dots, Ticks and Checks, Horizontal Lines with Ticks, None, Grid Lines and Dots, Ticks Along Axis, and Grid Lines Below 1st Profile

Grid Direction: Profiles can be drawn Left to Right (the default) or Right to Left. Although most profiles are drawn left to right, if you have a road that runs East to West and you wish to draw the profile stationing beneath the actual road stationing, then choosing a Right to Left profile may be appropriate.

Draw Vertical Bar on Right: This option places the vertical label bar on the right of the grid, as opposed to the left.

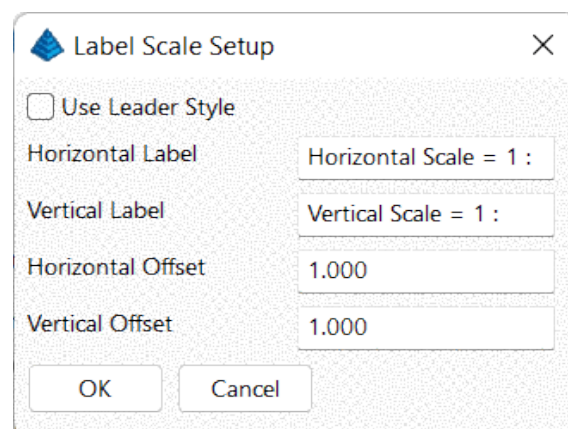

Draw Vertical Bar Separately: Draws a vertical bar with elevation labels separate from the profile grid. The **Offset** value controls how far away from the grid it will be drawn.

Label Stations: Disable this option if you do not want station labels to be placed along the grid.

Label Station Equations: Disable this option if you do not want station equation labels to be placed along the grid.

Label Base Elevation: Labels the low elevation on the sheet. The setup dialog allows for prefix and suffix for the text, size of text, layer and number of decimals to display.

Label Scale: Click on this option and you obtain a scale drawn at the lower left corner of the profile. Click the **Setup** button to establish the desired Scale labels and placement values.

Grid Title: Click on this option to place a Grid Title. Specify from the available items such as Horizontal Scale, Vertical Scale, Base Elevation and Profile Name. Configure the layer, text style, text scale and location offset.

The screenshot shows the 'Grid Title Setup' dialog box. It features a title bar with a blue diamond icon and the text 'Grid Title Setup' and a close button. The dialog contains several input fields: 'Layer' with 'PROTXT' and a 'Select' button; 'Text Style' with 'STANDARD' and a 'Select' button; 'Text Scale' with '0.100'; and 'Location Offset' with '0.100'. Below these are two list boxes: 'Available' containing 'Horizontal Scale', 'Vertical Scale', and 'Base Elevation'; and 'Used' containing 'Profile Name'. Between the lists are buttons for 'Add >>', '<< Remove', and 'Edit'. To the right of the 'Used' list are two green arrow buttons (up and down). At the bottom are 'OK', 'Cancel', and 'Help' buttons.

Station Type: Indicated the preferred style of station formatting.

Station Text Orientation: This option allows you to specify the orientation of the station text Horizontal or Vertical shown along the profile.

Station Text Position: Indicate if the station text should appear along the top of the profile grid or along the bottom of the profile grid.

Draw Grid Line at PC/PT Station: Places a separate grid line on PC and PT stations of curves from the reference centerline.

Use Partial Labels for Intermediate Stations: Enable this toggle if the "full station" content to the left of the "+" symbol should be omitted at intermediate stations. This is useful for large station values where intermediate station labels are desired. When enabled (assuming 100' station values), an intermediate station such as 1023+50 would simply be annotated as +50.

Increment Station Text from Beginning Station: Enable this option if you wish to have the station text labels be relative to the starting station value. For example, if the starting station value is 0+23.68 and the *Station Text* interval is 50, station labels of 0+73.68, 1+23.68, 1+73.68, *etc.*, would be generated.

Label Elevations: Disable this option if you do not want elevation labels to be placed along the grid.

Elev Text Vertical Justify: Indicate vertical justification for the elevation labels.

Draw Elevation Labels Only On Left Side: Enabling this option eliminates elevation labels on the right side of the profile.

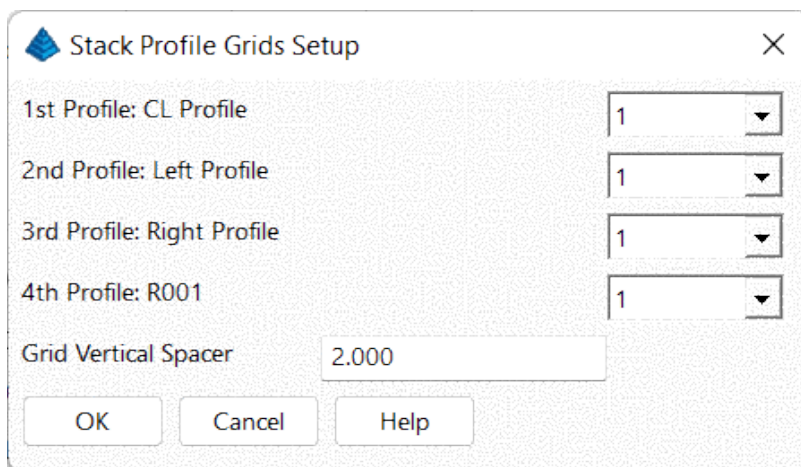

Draw Grid Line Under Elevation Labels: Enabling this option extends the grid lines underneath the elevation labels.

Offset Elevation Text: This option offsets the left-side vertical axis text using the specified Offset Scale.

Offset Station Text: This option offsets the horizontal axis Station text by the specified Offset Scale, allowing the insertion of elevation or other information above the stationing. It is often used in conjunction with the Label Horizontal Axis options.

Stack Profile Grids: This option allows you to stack profile grids for multiple profiles. In the **Setup** dialog, all profiles in the Multiple Profile file are listed and you can choose which one goes to the first grid, which one is second, and so on.

Grid Vertical Spacer: Indicate the amount of vertical space between successive grids.

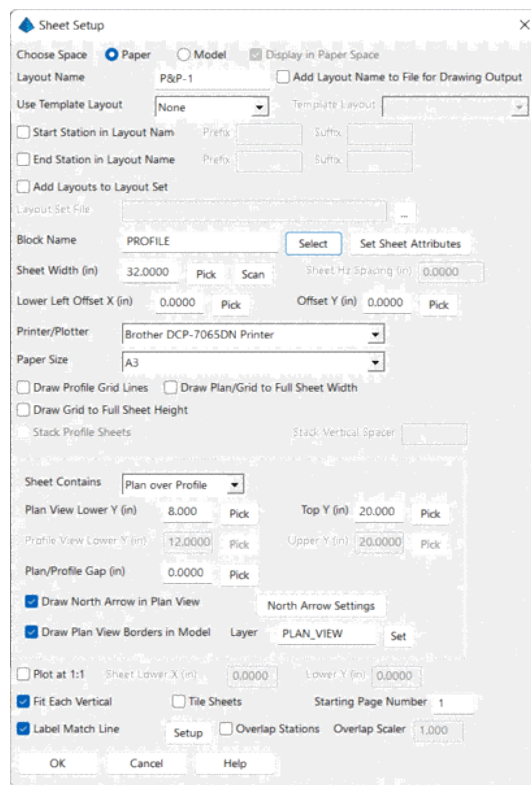

Draw Elevation Bar: Click on this option if you desire to have a vertical barscale displayed. It will run up and along the left-most vertical grid line of the profile, unless the Draw Vertical Bar on Right option is selected.

Skip Grid Range Dialog: This option automatically uses the calculated grid station and elevation ranges after picking OK from the main dialog instead of showing the dialog to set these ranges.

Draw Sheet/Paper Space

Plan Only, Profile Only, or Plan and Profile sheets can be created. The options within Sheet Setup become available when this toggle is checked on. Select Setup to access the Sheet Setup dialog.

Choose Space: Indicate whether sheets are to be drawn to **Paper** Space (also known as a Layout) or to **Model** Space. When the Model Space option is selected a toggle for how the sheets are created is enabled. They can be displayed in Paper Space or Model Space. If the Paper Space toggle is used the sheet will be drawn in Model Space but with Paper Space units.

Layout Name: Enter a name for the paper space "tabs" to be assigned to each layout for each sheet. The program will automatically divide the plan view and the profile view into sheet layouts, and if the length of the profile extends beyond a single sheet, then multiple layouts are created, with the layout name ID incremented by 1.

Note:

- The "Tile Sheets" toggle needs to be disabled for the auto-incrementing functionality.
- If either the *Start Station in Layout Name* or the *End Station in Layout Name* options are enabled, the Layout Name field will be disabled as the Layouts will get named automatically.

If you enter "ms" to go to model space within a Layout tab, you can pan to alter the plan view position. However, it is best to zoom in/out and edit within the Model tab. The Layout tabs appear at the bottom of the screen, along with the "Model space" tab to go back to standard plan view:

Add Layout Name to File for Drawing Output: When the option to Output To Separate Drawing is on, this option will create a separate DWG file for each layout by adding the layout name to the main DWG file name.

Use Template Layout: This option allows you to use a layout that exists in the current drawing as the template for layouts created by the command. This option only works for paper space sheet creation.

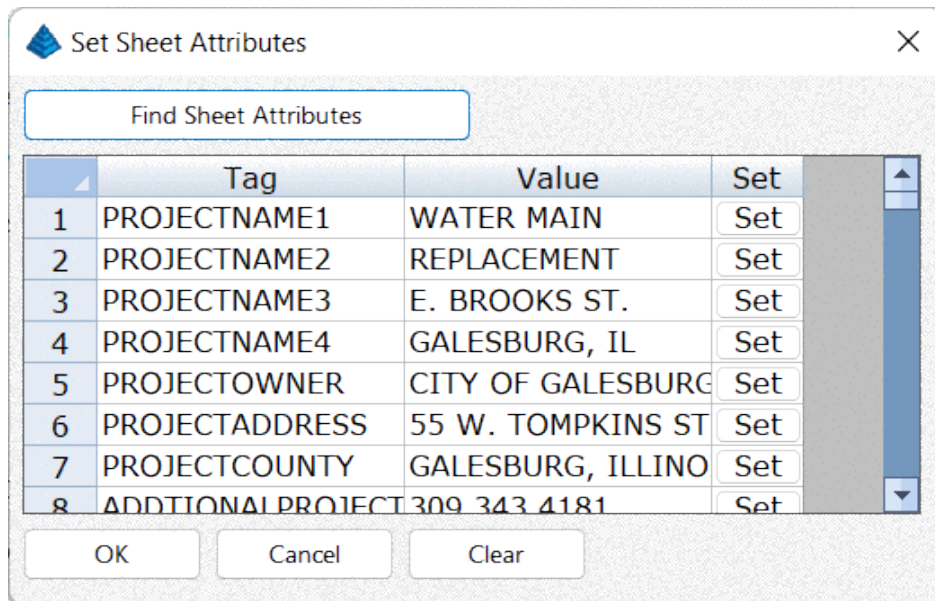

Start/End Station in Layout Name: These options allow you to include starting and ending station in the Layout Names.

Add Layouts to Layout Set: This option allows you to add the layouts created to an existing layout set that was previously generated using the Layout Set Manager. You will need to specify the name of the layout set.

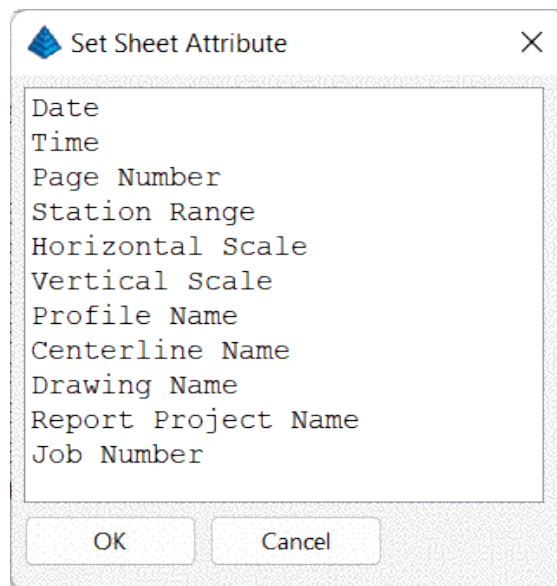

Block Name: This is the drawing name for the plan and profile sheet to be inserted. The Set button can be used to change the block name. Carlson provides a standard plan and profile border in the form of profile.dwg located in the working folder of %AppData%\Carlson Software\...\Sup\. You may wish to revise profile.dwg and add your company logo, and re-save it as profile1.dwg. Alternatively, you could add your own complete version of a Plan

and Profile sheet block/border. Be aware that the *Draw Right to Left* option in Draw Grid is superseded when Draw Sheet is enabled. Note that the Sheet mode will re-orient the centerline left to right, which may cause text (such as the stationing) to plot upside down, until you use the Flip Text command.

Set Sheet Attributes: This button allows you to specify the values used by any attribute definitions associated with the sheet Block Name. These can be entered manually in the Set Sheet Attributes dialog.

You can use the Set button to the right of any field to set that field to a preset value pulled from the drawing information.

Sheet Width: This is the profile width in the units specified on the sheet.

Lower Left Offset X/Y: Indicate the offset value(s) for the insertion point of the sheet in CAD units. This option allows user-defined Block Names to be properly positioned relative to the remainder of entities placed through the Draw Profile command.

Printer/Plotter: Indicate the desired output device.

Paper Size: Indicate the desired paper size.

Draw Profile Grid Lines: Enable this option if your Block Name does not contain profile grid lines and if you want profile grid lines to appear on the sheet.

Draw Plan/Grid to Full Sheet Width: Enable this option if you want to have what would otherwise be "partial" sheets (typically found at the end of a Plan & Profile Sheet run) occupy the full width of the sheet.

Draw Grid to Full Sheet Height: Enable this option if you want to have the profile grid drawn to the height of the sheet.

Stack Profile Sheets: When enabled (and when the Choose Space option is set to **Model**), this option permits the profiles to be stacked on top of one another.

Stack Vertical Spacer: Specify the amount of space that should be utilized when **Stack Profile Sheets** is enabled.

Sheet Contains: This drop list allows the selection of which type of sheet to generate.

Plan View Lower Y: This sets the lower position of the paper space window for the plan view.

Top Y: This sets the upper limit for the plan view window.

Profile View Lower Y: This sets the lower position of the paper space window for the profile view.

Upper Y: This sets the upper limit for the profile view window.

Plan/Profile Gap: Indicate the amount of vertical separation between the Plan portion of the sheet and the Profile portion of the sheet.

Draw North Arrow in Plan View: This draws a North Arrow in plan view. Click the **North Arrow Settings** button to establish the desired North arrow and placement information.

Draw Plan View Borders in Model Space: This draws the borders in Model Space which can be useful for orienting text and other labels to the orientation of the sheet. When this option is selected, use the Layer text box or Set button to choose the layer on which the borders will be drawn.

Plot at 1:1: With this clicked on, the sheet will be paper size, designed to be plotted at 1:1. A 30-inch profile sheet will measure 30 units, even though the centerline and profile may be 1500 feet in length. If the Scale 1:1 option is turned on, then you cannot check the distances of features using commands such as Bearing and Distance on the Inquiry menu, because the distances will be scaled down by a factor equal to the drawing scale (for example, at 1"=50', the reduction in scale factor is 1/50 or 0.02). You can set the absolute starting coordinate for the 1:1 scaled plot by setting the **Sheet Lower X** and **Sheet Lower Y** values. With this clicked off, the profile will draw full size, with a 1500-foot profile measuring 1500 feet.

Fit Each Vertical: With this option turned on, the program will size the profile grid to fit within the vertical space on the profile sheet. With this option off, the profile grid is sized to fit the elevation range of the profile.

Tile Sheets: If clicked on, only one Layout is created in paper space, and all sheets appear in this single Layout as tiles of individual sheets, much like the tiles mode of viewing files within Windows Explorer.

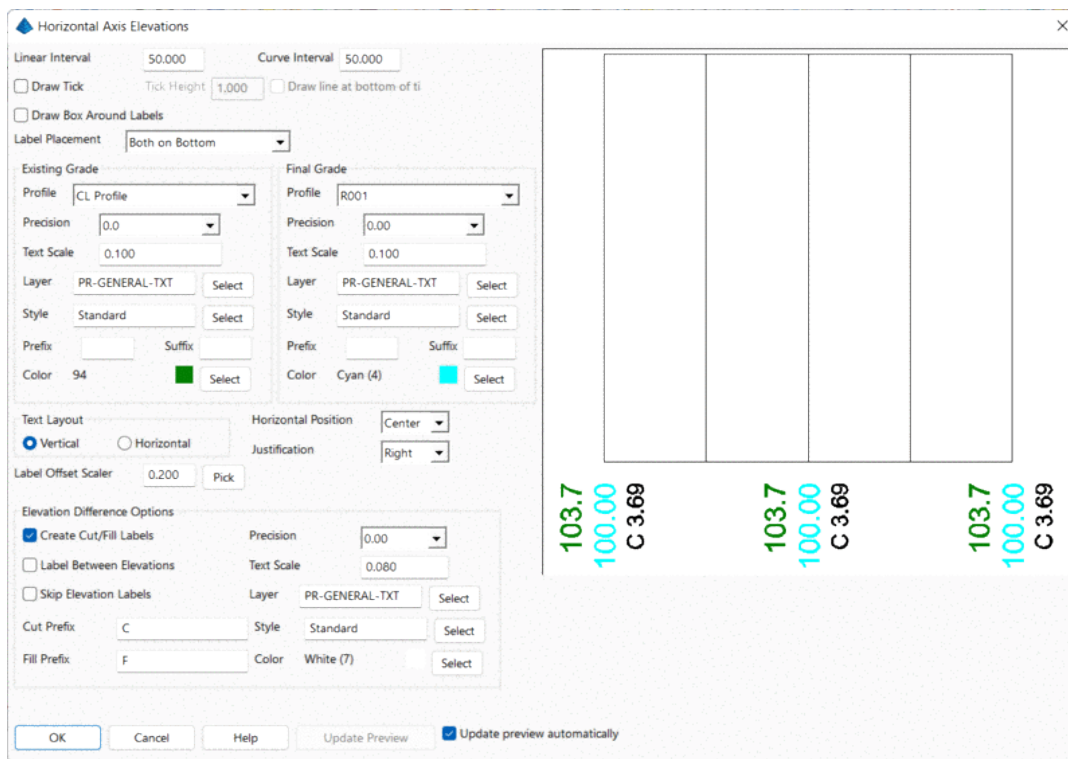

Starting Page Number: Specify the desired page number for the sheet(s) about to be cut. This is commonly used with the Set Sheet Attributes option.

Label Match Line: When clicked on and multiple sheets are plotted with plan view option on, a match line will plot in the plan view.

Overlap Stations: In multiple plan and profile sheet plotting, after the first sheet, all subsequent sheets will have the first 2 stations in common with the last 2 stations on the previous sheet, if the Overlap Station option is turned on. For example, if the last 2 stations are 3+10 and 3+20 on sheet 1, then sheet 2 will start with 3+10, then 3+20, with this option turned on. With this option turned off, if the first sheet ends with 3+20, then the second sheet would begin with 3+20.

Draw Horizontal Axis Elevations

This option creates elevation labels along the horizontal axis. Pick **Setup** to access the Horizontal Axis Elevations settings dialog. A preview of the labels will be shown to the right of the settings. If the preview does not match the settings, click the Update Preview button.

Linear and Curve Interval: Indicate how often the profile elevation labels should be placed along the horizontal axis of the sheet. The Curve Interval applies within vertical curves and the linear applies everywhere else.

Draw Tick and Tick Height: This option draws a line at the specified height at each station for the elevation labels.

Draw Box Below the Labels: When enabled, a box is drawn around the labels.

Place Existing Grade Profile Elevation on Top: When enabled, places the existing grades above the profile grid as opposed to below.

Existing/Final Grade: Indicate the appropriate profile, precision, text scale, layer, style, prefix, suffix and color for the text labels.

Text Layout: Indicate whether the text labels should be oriented vertically or horizontally.

Label Offset Scale: Indicate the distance from the horizontal axis for the labels. If the value is negative, the labels are placed above the horizontal axis.

Justification: Allows you to justify the elevation text about the left, center, or right side of the interval insertion.

Elevation Difference Options: If both existing grade and final grade are to be drawn, you may choose to also label the Cut/Fill depth values with the appropriate precision, text scale, layer, style, prefix, suffix and color for the text labels that separates the existing and final profiles at each station.

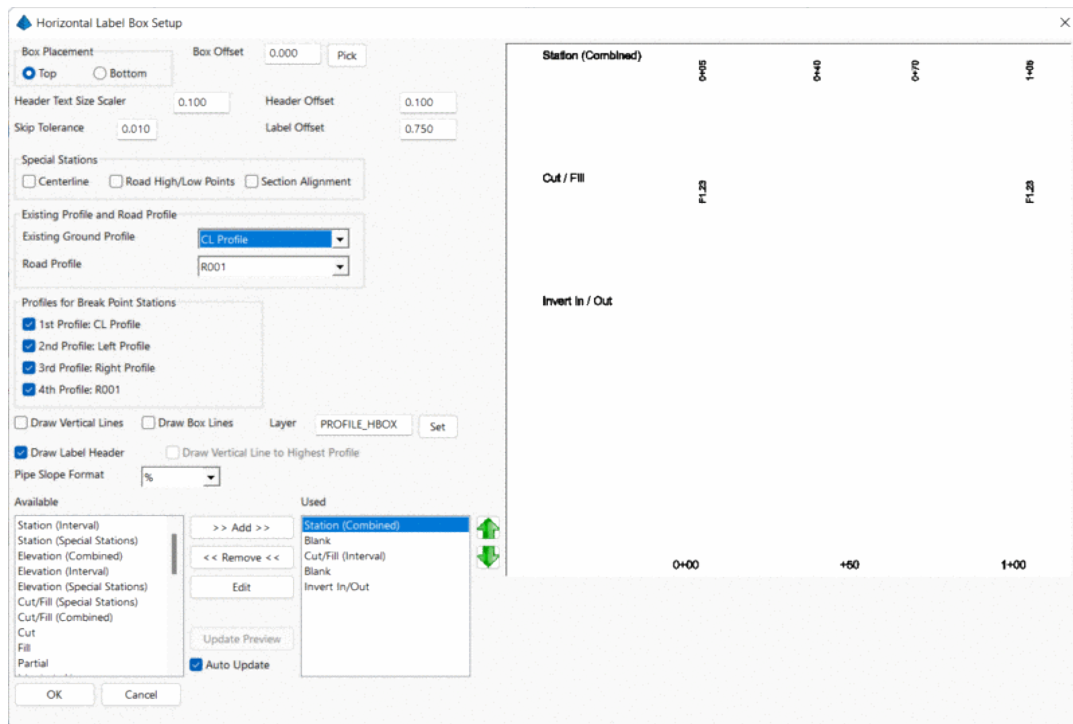

Label Between Elevations: When enabled (and for a **Text Layout** of Vertical), the label is centered on the various elevations and Cut/Fill Difference label.

Skip Elevation Labels: When enabled, only the Cut/Fill Difference label is generated.

Draw Horizontal Label Box

This option draws a boxed area either above or below the profile. It is best used in standard Draw Grid mode, with Draw Sheets clicked off. Pick Setup to access the Horizontal Label Box Setup dialog which has a list of available

fields to label. To label a field, highlight the field from the Available list and pick the Add button. Then use the Up/Down buttons to order the fields in the used list.

Box Placement: Set this to either Top or Bottom.

Box Offset: This controls how far to offset the box from the profile.

Header Text Size Scaler: Indicate a relative scale size for the header text values. This value is a scaler that is multiplied by the profile horizontal scale.

Header/Label Offset: This controls how far to offset the Header Text/Label Text box from the profile.

Skip Tolerance: Indicate a threshold in which labels should not be placed in an effort to reduce annotation clutter.

Special Stations: This controls whether special stations on the Centerline, high and low points on the profile and odd stations that exist in a Section Alignment are labelled.

Existing and Road Profile: Set which profile is existing and which is the finished road.

Profiles for Break Point Stations: Toggle on which profiles should be used for break point stations.

Draw Vertical Lines: This option draws lines from the data point on the profile to the label in the box.

Draw Box Lines: This option draws the row and column lines for the label box.

Layer: Set the layer for the elements to be drawn on.

Draw Label Header: Indicate whether or not the label header(s) should be drawn.

Draw Vertical Line to Highest Profile: This option is only available when the Draw Vertical Lines toggle is on. When on the vertical lines will be drawn to the highest profile.

Pipe Slope Format: Use this drop down to set the slope format between unit per unit or expressed as a percent.

Pipe Distance Format: Use this drop down to set whether the pipe length is shown as the horizontal distance or the slope distance.

Add and Remove: Use the >>Add>> button to add items to the list for annotation. Use the <<Remove<< to remove items from the list.

Edit: Use the Edit button to set parameters for the label in the box. The Label 2nd Row option creates another row for the field. You can also edit a blank row and specify the row height scaler.

Station (Combined) Label Box Fi... X

Label: Station (Combined)

Label 2nd Row:

Decimals: 0.00

OK Cancel

Use the Update Preview to see the results of your changes before committing them to a sheet. An example of the resulting plot is shown here:

Station (Combined)	0+00	0+05	0+40	0+70
Elev.	105.00	102.00	108.00	
Cut / Fill	F1.23	F1.23	F1.23	

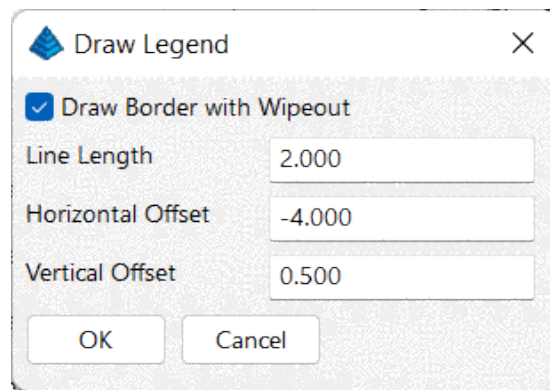

Label Profile Name

Use the Label Profile Names to place the profile names on the grid. Specify the Layer, Text Style, Text Size, Profile Prefix as well as the Label Location and the offset.

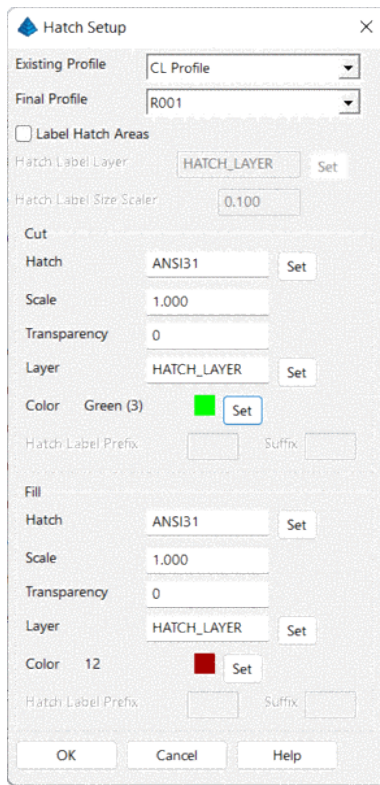

Draw Legend

Use the Draw Profile Legend setup to place a legend on the grid. Choose the line length, offset and if there is a wipeout placed under the legend.

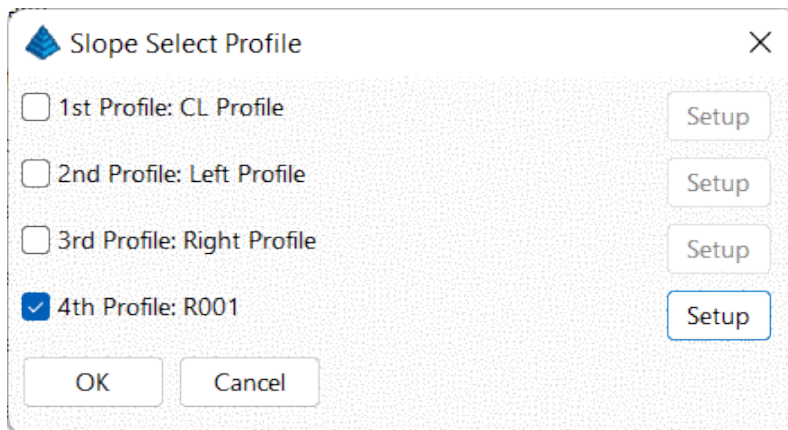

Hatch Cut / Fill

Use the Hatch Cut/Fill toggle to enable Hatch Setup. Choose the hatch pattern you would like to use for Cut and Fill as well as the scale, layer, transparency and color for each. There is an option to label the hatch areas with separate prefix/suffix labels for cut/fill.

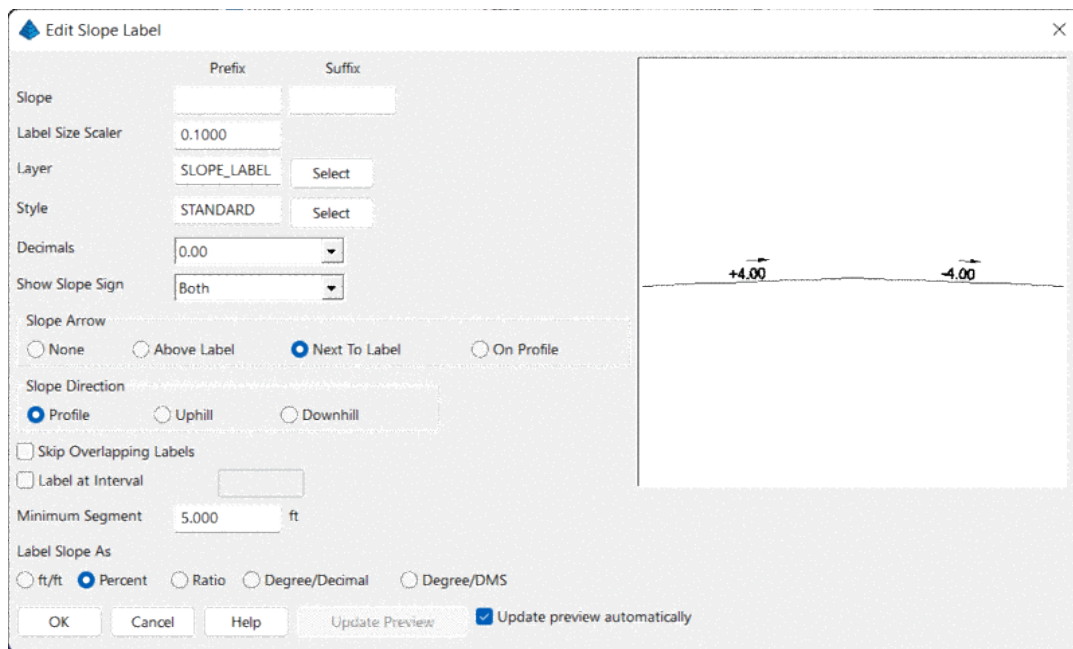

Draw Slope Labels

When enabled, this option allows you to detail additional slope information onto selected profiles.

Indicate the desired profile(s) whose slope annotation you'd like to control and click on the Setup button for expanded criteria.

Prefix/Suffix: Enter a prefix or suffix on the slopes as desired. Be aware that you may want to add spaces after the prefix or before the suffix.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Layer and Style: Set the layer and style for the text.

Decimals: Set the number of decimal places for the annotation.

Show Slope Sign: Indicate the preferred method for distinguishing positive *vs.* negative slopes.

Slope Arrow: If you would like a slope arrow to help understand the direction of slope, use one of the radio buttons for Above, Next to or On the profile.

Skip Overlapping Labels: If the labels would overlap and you do not want that to happen, use the Skip Overlapping Labels toggle.

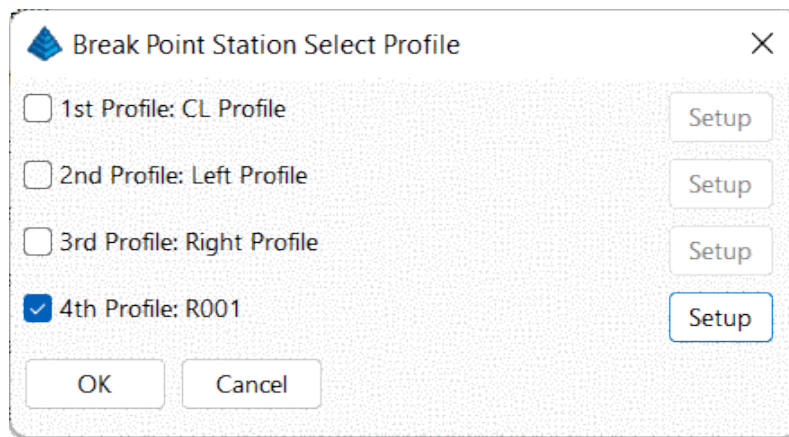

Label at Interval: Draws slope labels at the specified station interval.

Minimum Segment Size: You may not want to annotate shorter segments. If not, set a minimum segment size.

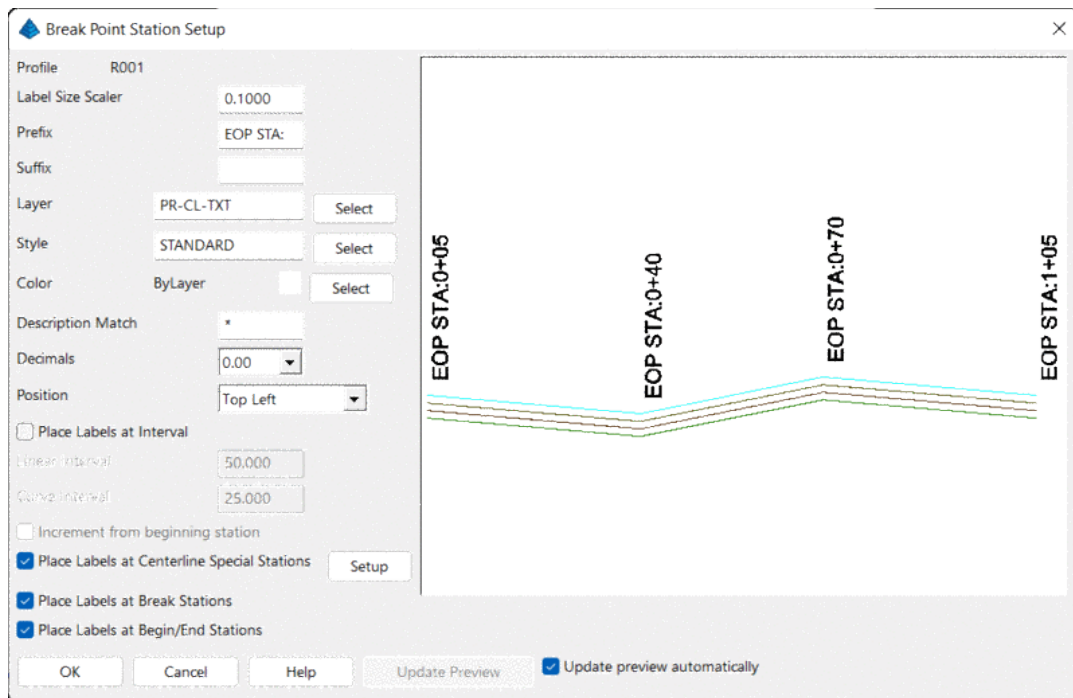

Label Slope As: You have the option of labeling the slope express as unit per unit, as a percent or as a ratio.

Update Preview: Use the update Preview button to see what your changes would look like before committing them to sheets.

Draw Break Point Station

When enabled, this option will label station values along the profile line above each break point in the profile. Pick **Setup** to access the **Break Point Station Setup** dialog.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Prefix / Suffix: Enter a prefix or suffix on the slopes as desired. Be aware that you may want to add spaces after the prefix or before the suffix.

Layer, Style and Color: Set the layer, style and color for the text.

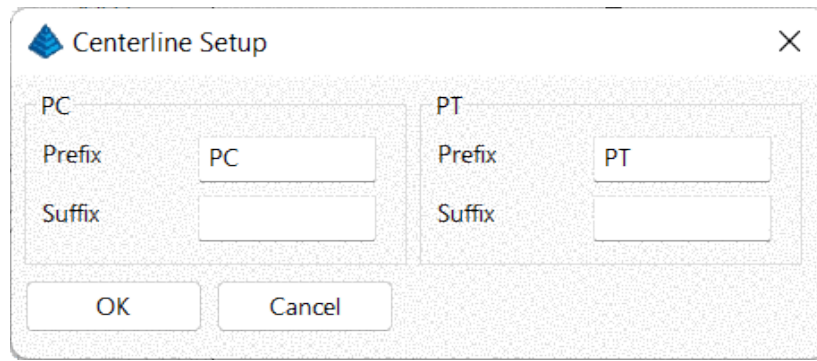

Description Match: Set the description you are looking to match.

Decimals: Set the number of decimal places for the annotation.

Position: Set the position for the text top or bottom and left, center or right.

Place Labels at Interval: Set up linear and curve intervals for the text.

Place Labels at Centerline Special Stations: Turn the toggle on and select the Setup button to change the settings.

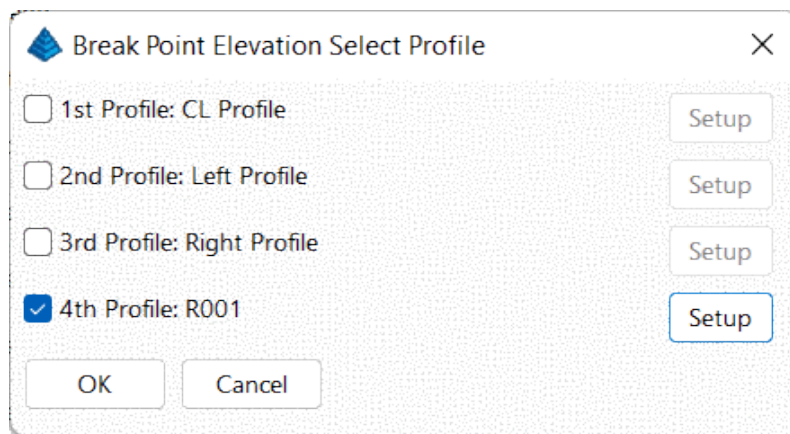

Place Labels at Break Stations: Toggle this on to place labels at break stations.

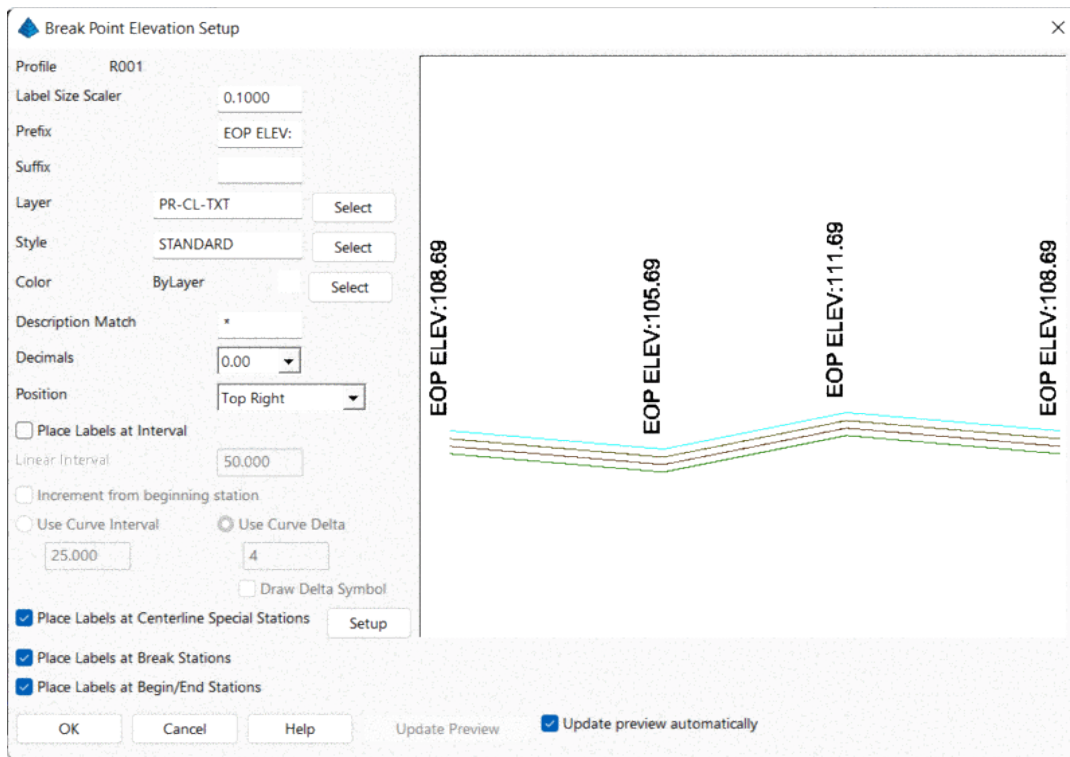

Place Labels at Begin/End Stations: Toggle this on to place labels at the beginning and ending stations.

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

Draw Break Point Elevation

When enabled, this option will label elevation values along the profile line at each break point in the profile. Pick **Setup** to access the Break Point Elevation Setup dialog.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Prefix / Suffix: Enter a prefix or suffix on the slopes as desired. Be aware that you may want to add spaces after the prefix or before the suffix.

Layer, Style and Color: Set the layer, style and color for the text.

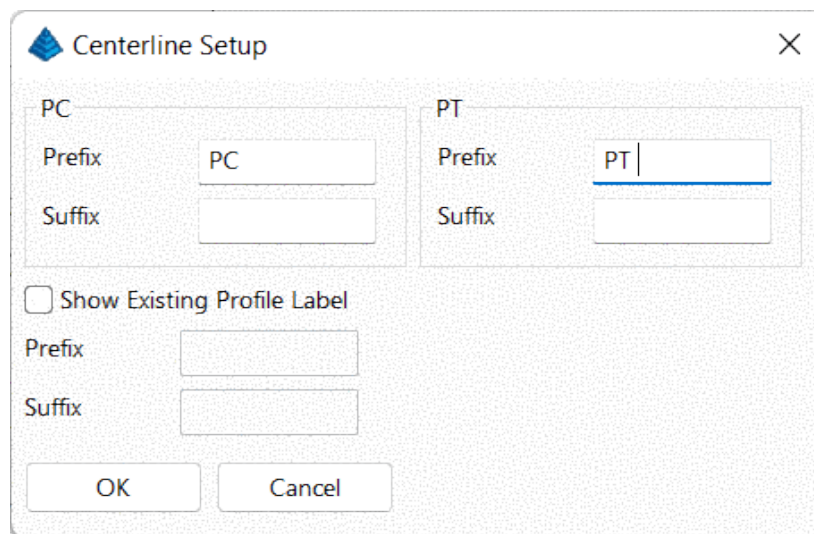

Description Match: Set the description you are looking to match.

Decimals: Set the number of decimal places for the annotation.

Position: Set the position for the text top or bottom and left, center or right.

Place Labels at Interval: Set up linear and curve intervals for the text.

Place Labels at Centerline Special Stations: Turn the toggle on and select the Setup button to change the settings.

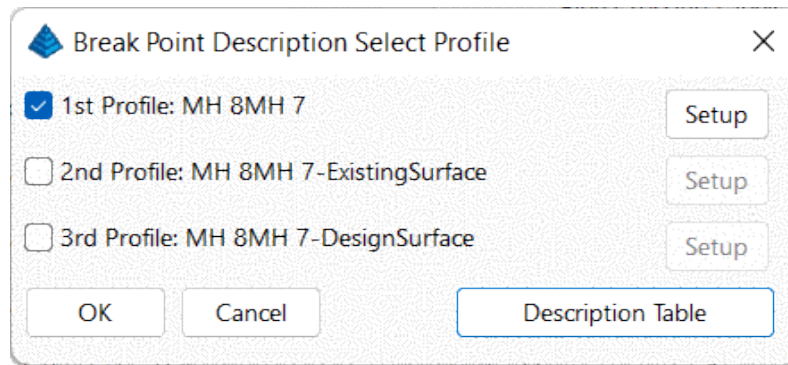

Place Labels at Break Stations: Toggle this on to place labels at break stations.

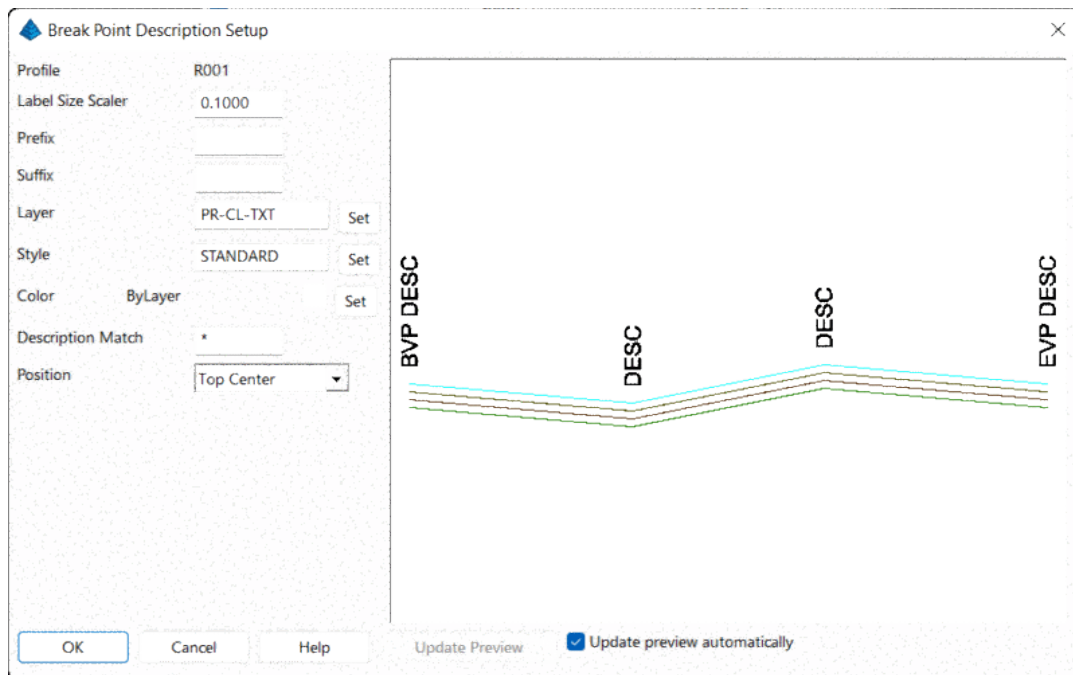

Place Labels at Begin/End Stations: Toggle this on to place labels at the beginning and ending stations.

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

Draw Break Point Description

When enabled, this option will label descriptions along the profile line at each break point in the profile. Pick Setup to access the Break Point Description Setup dialog.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Prefix / Suffix: Enter a prefix or suffix on the slopes as desired. Be aware that you may want to add spaces after the prefix or before the suffix.

Layer, Style and Color: Set the layer, style and color for the text.

Description Match: Set the description you are looking to match.

Position: Set the position for the text top or bottom and left, center or right.

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

The **Description Table** button on the Select Profile dialog for Draw Break Point Desc brings up the spreadsheet

dialog shown below. This table sets up translations of profile descriptions into labels and symbols to draw. For example, for a profile description of "WL", you can label the profile as "WATERLINE" and draw a symbol at this point. If you only want to change the label, then only fill out the label and leave the symbol blank.

	Description	Label	Symbol	
1	WL	WATERLINE	SPT7	Set

Draw Break Point Elevation Difference

Break Point Elevation Difference Select Profile

1st Profile: CL Profile Setup

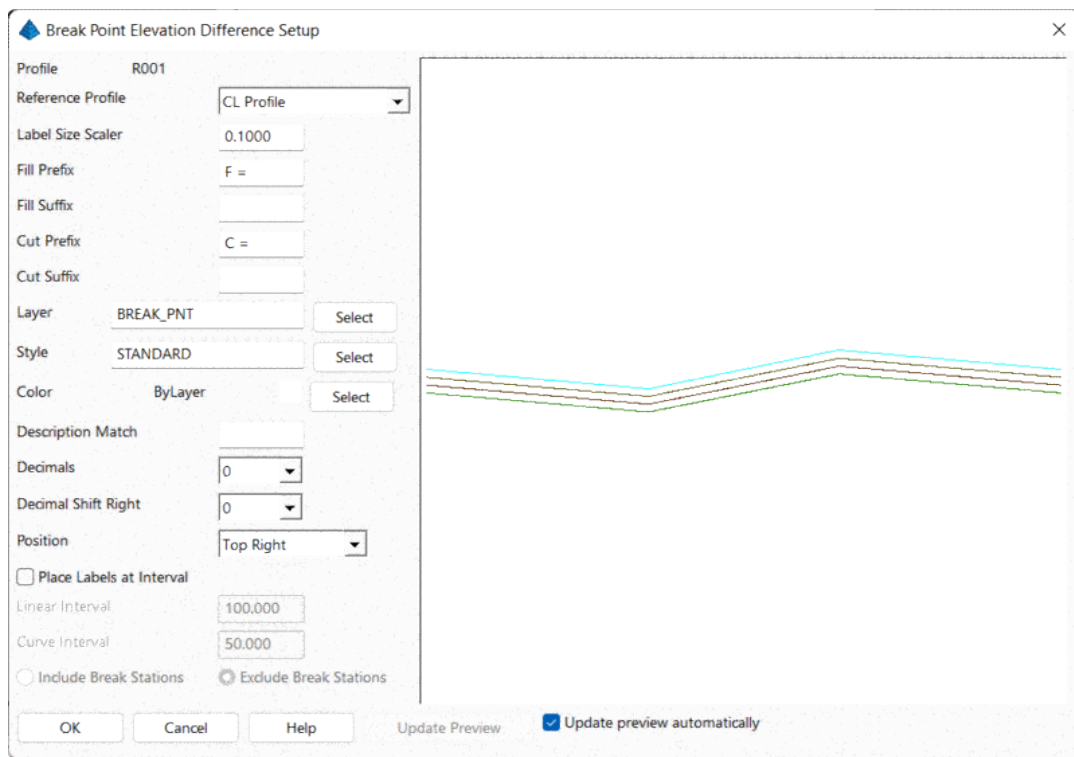

2nd Profile: Left Profile Setup

3rd Profile: Right Profile Setup

4th Profile: R001 Setup

OK Cancel

When enabled, this option will label elevation difference values along the profile line at each break point in the profile relative to a reference profile (*e.g.* existing grade). Pick **Setup** to access the Break Point Elevation Difference Setup dialog.

Reference Profile: Indicate the profile that should be used as the point of comparison for the break point locations.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Prefix/Suffix: Enter a prefix or suffix on the slopes as desired. Be aware that you may want to add spaces after the prefix or before the suffix.

Layer, Style and Color: Set the layer, style and color for the text.

Description Match: Set the description you are looking to match.

Decimals: Set the number of decimal places for the annotation.

Decimal Shift Right: Indicate the number of places to shift the decimal point to the right. For example, if a traditional elevation difference was calculated to be 1.234 and the Decimal Right Shift value is set to 1 (a factor of 10), the reported elevation difference would be shown as 12.34.

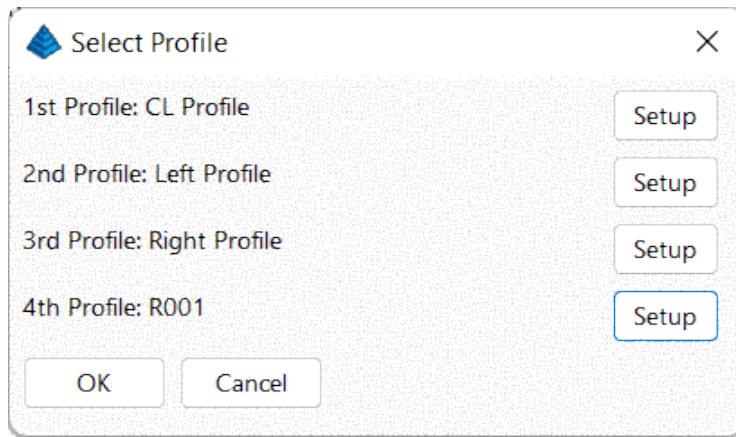

Position: Set the position for the text top or bottom and left, center or right.

Place Labels at Interval: Set up linear and curve intervals for the text.

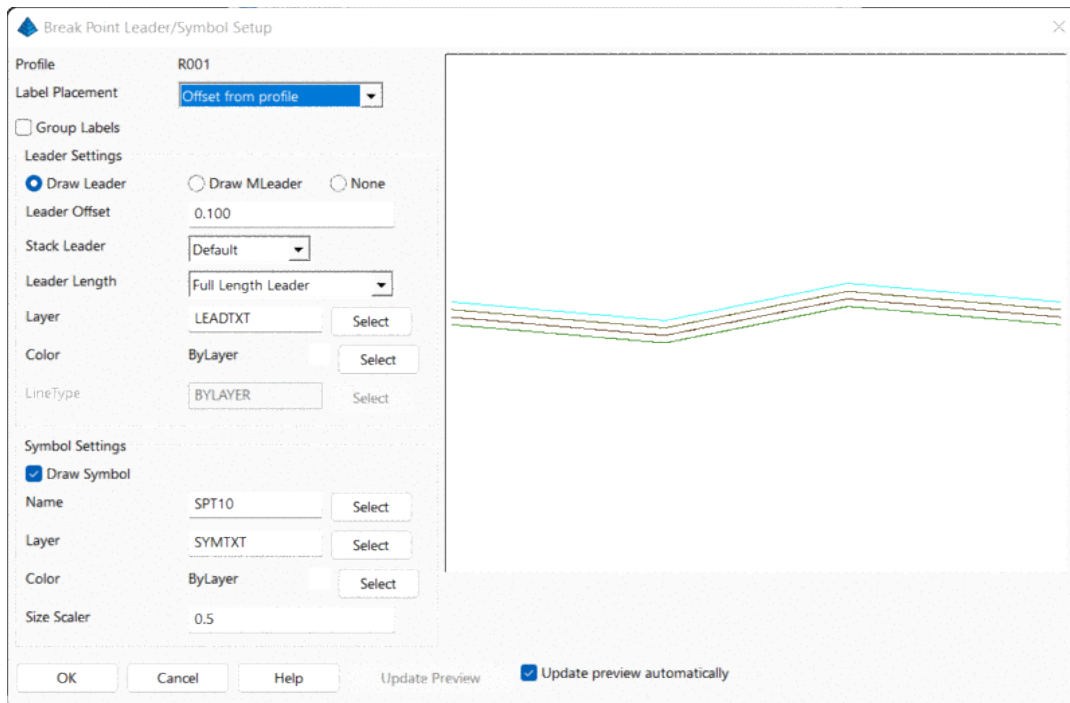

Include / Exclude Break Stations: Use the radio buttons to toggle between including or excluding break stations.

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

Break Point Leader / Symbol Setup

Click this button to establish if it desirable to have a leader and/or break point symbol used in conjunction with the Draw Break Point Sta and/or Draw Break Point Elev options.

Label Placement: Use the label placement settings to control where this annotation will be placed.

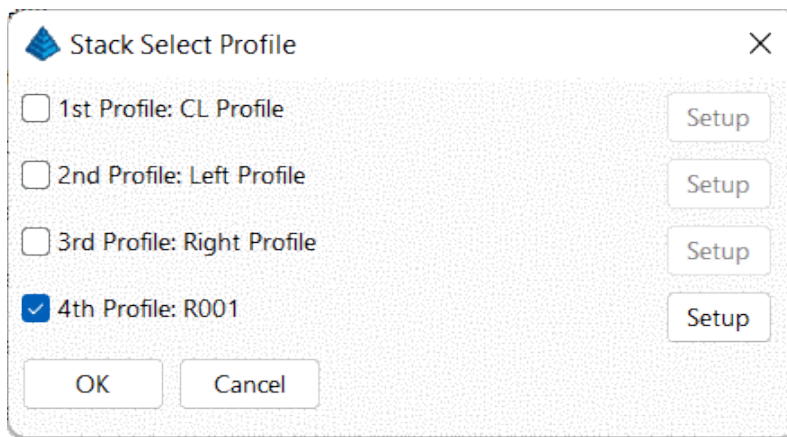

Offset Scaler: Set the label size scaler appropriate to your sheet setup.

Leader Settings: Set one of the two options for how the leader is drawn.

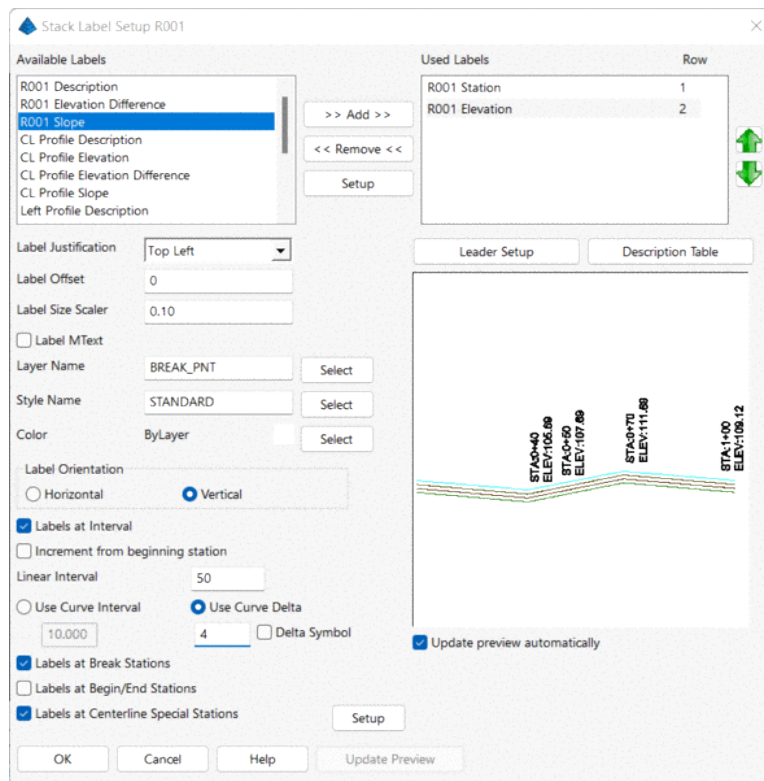

Symbol Settings: Set and select the symbol, layer, color and scaler for the symbol.

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

Draw Stack Labels

When enabled, this option will label station values, elevation and elevation differences along the profile line at breaks, fixed intervals along curves/tangents, begin/end station, and Special Centerline stations along the profile. Pick Setup to access the **Stack Label Setup** dialog.

Add and Remove: Use the >>Add>> button to add items to the list of used labels to annotate. Use the <<Remove<< to remove items from the list of used labels.

Setup: Highlight a Used Label and then click the Setup button to set parameters for the label in the box. The Label on New Row option creates another row for the label.

Label Justification: Specify the justification location of the label (Top or bottom left, center or right).

Label Offset: Set the label offset from the profile line in paper units.

Label Size Scaler: Set the label size scaler appropriate to your sheet setup.

Label MText: Creates MTEXT entity when toggled ON.

Layer Name: Set the label layer.

Style Name: Set the label text style.

Color: Set the label color.

Label Orientation: Label may be oriented horizontally or vertically along the profile.

Labels at Interval: Toggle this ON to place the stacked labels at regular intervals. You can specify the starting station and identify different intervals along vertical curves.

Increment from beginning station: Set the station from which to begin the interval.

Linear Interval: Set the distance along the profile to place the stacked labels.

Use Curve Interval: Set the distance interval along curves to place the stacked labels. This is addition to the linear interval already specified.

Use Curve Delta: Specify the number of segments along a given curve portions to place the stacked labels. Short and long curves will have the same number of stacked labels using this option. You may also place the Delta symbol at those locations.

Labels at Break Stations: Places a stacked label at every change in grade along the profile.

Labels at Begin/End Stations: Places a stacked label at the beginning and ending of the profile.

Label at Centerline Special Stations: Places a stacked label at the PC/PT from the referenced horizontal centerline file along the profile.

Leader Setup: Displays the Breakpoint Leader/Symbol setup.

Description Table: Displays the current Description Table.

Draw Line / Point Crossings

This option draws labels for linework that crosses the reference centerline. The reference centerline is set in the first Draw Profile dialog where the profiles to draw are selected. The **Setup** dialog has a list of layers. The program will find intersections between the reference centerline and linework on these specified layers. For each layer, there is a Description which is used for the label on the profile. Besides labeling these descriptions for the crossings, the program includes the station along the reference centerline at the crossing. In the options dialog, there are settings to control the layer, style, color, size, decimal places for the station label, label position and whether to draw a vertical line from the label to the profile.

Draw Road Intersections

When enabled, this option will label the location(s) of any road(s) from an identified Road Network that intersect the main road.

Size Scaler: Set the label size scaler appropriate to your sheet setup.

Decimals: Set the number of decimal places for the annotation.

Layer, Style and Color: Set the layer, style and color for the text.

Label Position: Use the label placement settings to control where this annotation will be placed.

Draw Road Name Label, Draw Main Station Label, Draw Side Station Label, Draw Elevation Label: Toggle on to draw the this annotation and set the location.

Leader Settings: Indicate the type of leader to be drawn.

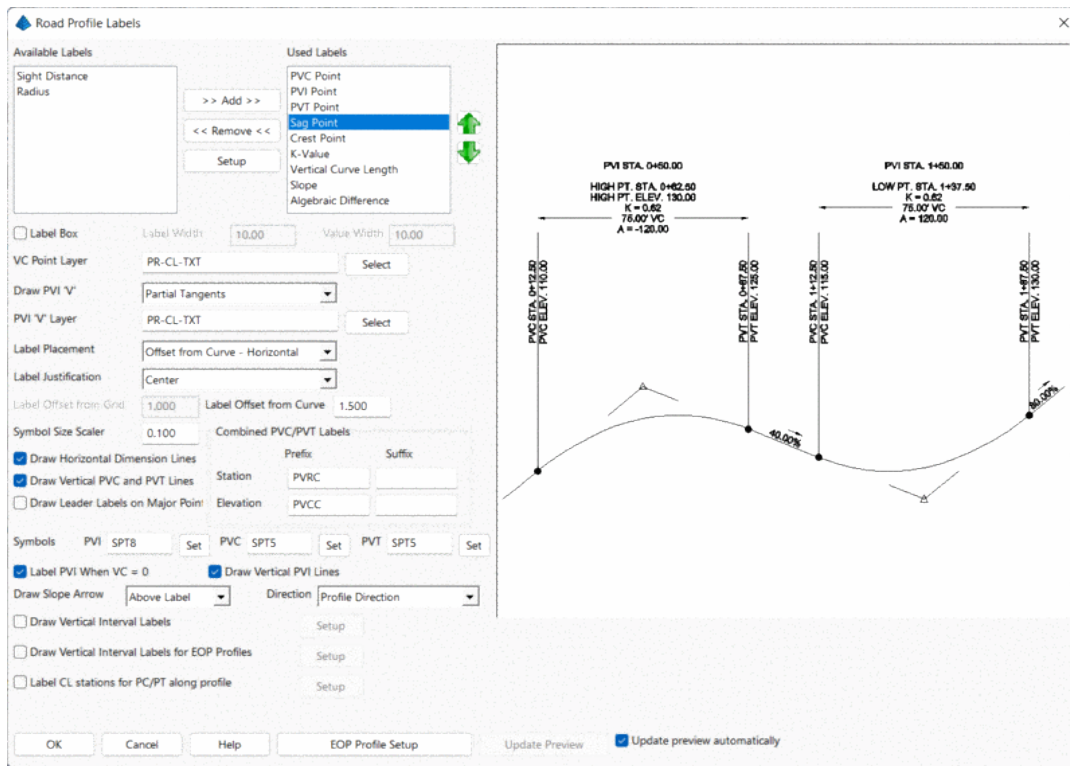

Offset Scaler: Indicate the plotted distance between the symbol and the text label(s) to establish the length of the leader.

Draw Symbol: Toggle this on to set a symbol and the size of the symbol.

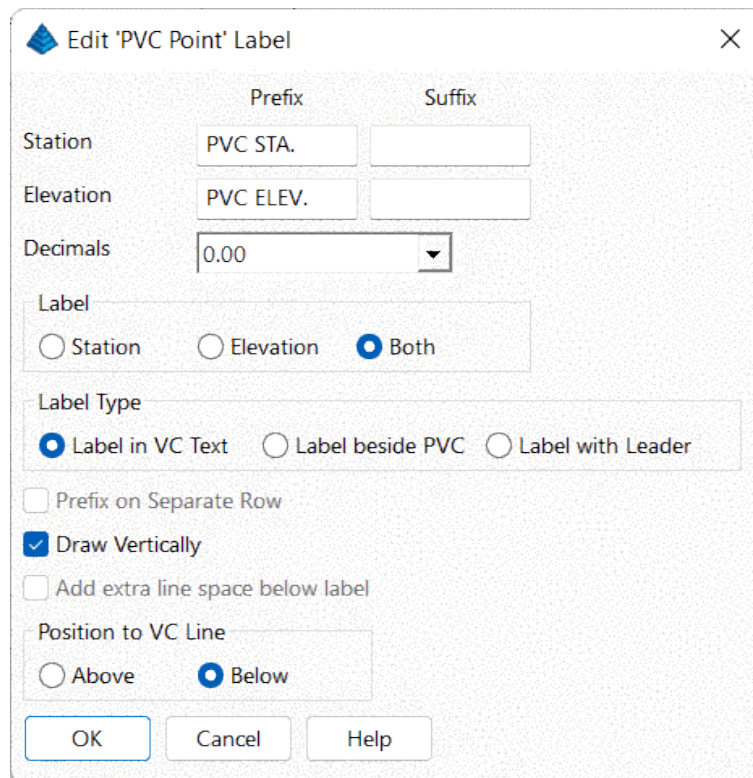

Update Preview: Use the update preview button to check your changes before committing them to a drawing.

Road Labels

This button opens Vertical/Circular Curve Settings dialog. From a wide variety of available labels, you are able to create your own label selections very conveniently.

Each label can be edited individually through the **Setup** button. You can specify the prefix, suffix, symbol style, decimal places, text orientation and position, *etc.*, in the Edit Label dialog. For the PVC/PVI/PVT labels, the **Label Beside** option applies when the Draw Horizontal Dimension Lines is off and it controls whether to place the labels along the profile at the station, or grouped with the rest of the road labels.

VC Point Layer sets the layer for the the point symbols on the vertical curve.

Draw PVI 'V': You can choose to draw either a full tangents style PVI 'V' point, or a partial tangents style, or nothing.

PVI "V" Layer specifies the layer that the tangent lines will be drawn on

Label Placement: This setting determines where to place the vertical curve labels. There are six options: Pick Single Row, Pick Individual Position, Auto Place Above Highest PVI Point, Specify Offset from Grid Top, Offset from Curve - Aligned, Offset from Curve - Horizontal.

Label Justification sets the text justification to Left or Center

Label Offset from Grid/Curve: Indicate the distance from the Grid or Curve when the **Label Placement** option is set to *Offset from Grid Top* or *Offset from Curve*, respectively.

Symbol Size Scaler sets the size for the symbols at the vertical curve points

Draw Horizontal Dimension Lines: This option draws horizontal lines connecting the PVC and PVT of all vertical curves.

Draw Vertical PVC & PVT Lines: This option draws vertical lines emanating from the PVC and PVT of all vertical curves.

Combined PVC/PVT Labels: sets the prefix and suffix for the stations and elevations of the vertical curve components

Symbols: for the PVI, PVC and PVT can all be selected from the symbol library.

Label PVI When VC=0: When vertical curve length is 0, no label is created unless you choose this option and then the PVI label would be shown.

Draw Slope Direction Arrow: Draws an arrow to indicate slope direction.

Arrow Direction: You can choose from Profile Direction, Uphill Slope Direction and Downhill Slope Direction.

Draw Vertical Interval Labels: This option labels the intervals of the vertical curve section. In its setup dialog, you can specify the intervals, distance from the vertical curve to put the labels, decimal places to display the interval stations and elevations, symbol settings and label settings.

Vertical Interval Labels [X]

Here is an example of a road profile.

EOP Profile Setup

This button allows you to establish the criteria for drawing and labeling Edge of Pavement (EOP) profiles:

Begin/End Front Curb Return: Enter a description for the front curb return.

Begin/End Back Curb Return: Enter a description for the back curb return.

Include Road Name: Enable this control if you'd like the road name included with the edge of pavement profile.

Draw VC Labels for EOP Profiles: When enabled, this option will label vertical curves found in edge of pavement profiles.

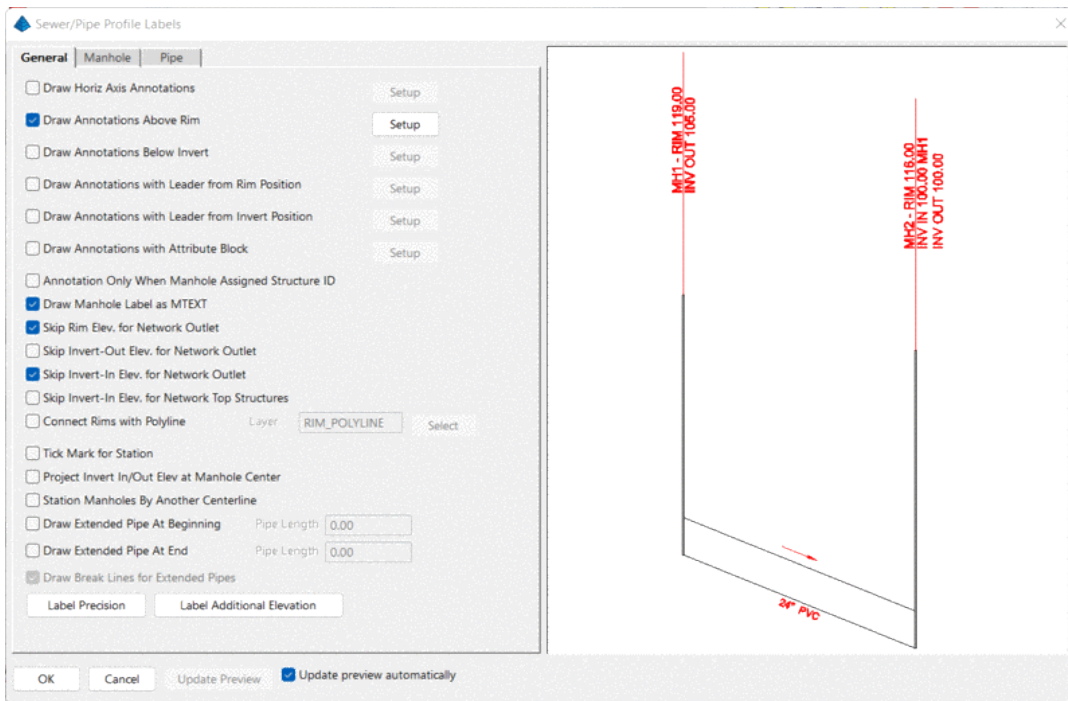

Draw Curb Return Length Label: When enabled, this option will label the length of curb returns. Use the **Setup** button to specify and control the display settings.

Draw Curb Return Elevation Labels: When enabled, this option will label the elevations of curb returns. Use the **Setup** button to specify and control the placement and display settings.

Sewer/Pipe Labels

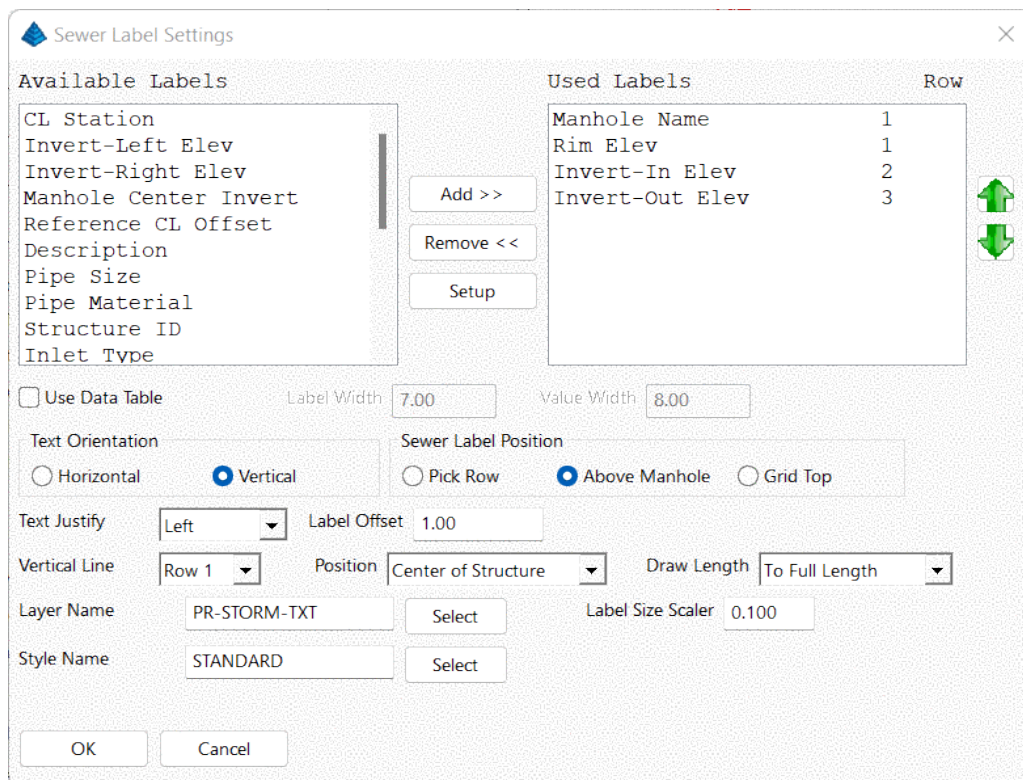

This button opens Draw Sewer/Pipe Options dialog.

General Tab

Each style has a **Setup** dialog to specify which labels are to be created and in what order. For labels with leaders, you can setup the leader styles

Example of Settings for Draw Annotations above Rim

Note:

In addition to the numerous annotation options found on the General Tab, many of the options will also contain an **Equation** option that permits user-defined equations using numbers and/or Rim, Invert Out or Step Up for even additional control. For example, to label rims with 2 elevations for 2 datums, one might specify an equation of **[RIM] + 1.0** (or similar).

Draw Horiz Axis Annotations: Labels structure or pipe profile along the horizontal axis.

Draw Annotations Above Rim: Creates structure or pipe profile labels above the rim of manholes.

Draw Annotations Below Invert: Creates structure or pipe profile labels below the rim of manholes.

Draw Annotations with Leader from Rim Position: Creates structure or pipe profile labels with a leader from manhole's rim position.

The screenshot shows the "Sewer Label Settings" dialog box. It is divided into two main sections: "Available Labels" and "Used Labels".

Available Labels: A list of labels that can be added to the project. The labels are: Invert-Left Elev, Invert-Right Elev, Manhole Center Invert, Reference CL Offset, Manhole Name, Description, Pipe Size, Pipe Material, Structure ID, and Inlet Type.

Used Labels: A table showing the labels currently in use, with a "Row" column indicating their order. The labels and their rows are: CL Station (1), Invert-In Elev (2), Invert-Out Elev (3), and Rim Elev (4). There are green up and down arrow buttons to the right of this table for reordering.

Buttons: Between the two lists are "Add >>", "Remove <<", and "Setup" buttons. At the bottom left are "OK" and "Cancel" buttons. At the bottom right are "Leader Setup", "Layer Name" (with a "Select" button), "Style Name" (with a "Select" button), "Label Size Scaler" (set to 0.100), and "Label Offset" (set to 0.500).

The screenshot shows the "Leader Settings" dialog box. It contains several settings for leader lines:

- Leader Style:** A dropdown menu set to "Horizontal".
- Text Placement:** A dropdown menu set to "After the Leader".
- Leader Line:** A dropdown menu set to "ALL Above Leader".
- Leader Offset:** A text input field set to "1.000".
- Linetype:** A text input field set to "BYLAYER" with a "Select" button next to it.
- Draw Arrow Head:** A checked checkbox.
- Arrow Size:** A text input field set to "0.120".

At the bottom are "OK", "Cancel", and "Help" buttons.

Leader Styles

Text Placement

Draw Annotations with Leader from Rim Position Example

Note: Using the the Network > Sewer Labels > Move Profile Pipe Label will allow for movements of labels and will hold the text in new location if redraw of the profile is required.

Draw Annotations with Leader from Invert Position: Creates structure or pipe profile labels with a leader from manhole's invert position.

Draw Annotations with Attribute Block: Inserts blocks with attributes for the structure or pipe labels.

Draw Manhole Label as MTEXT: When enabled, the manhole label will be placed as an MTEXT entity.

Skip Rim Elevation/Invert Out Elevation/Invert In Elevation for Outlet: When enabled, the cited component(s) will not be placed for the special Outlet structures.

Connect Rims with Polyline: When enabled, a polyline representing the average grade between each pair of rim elevations will be drawn to the specified layer.

Tick Mark for Station: Draws a tick mark at every station.

Project Invert In/Out Elev at Manhole Center: The Invert In/Out elevations are not the actual values, but are projected elevations to the manhole center.

Station Manholes by Another Centerline: This option will make new station for each manhole by referencing the profile to another centerline, for example a road centerline.

Draw Sump: When enabled, specify the height of the sump to be drawn into the sewer profile.

Draw Base: When enabled, specify the base height to be drawn into the sewer profile.

Draw Extended Pipe At Beginning/End: Draws the pipe beyond the beginning or the end by a specified length.

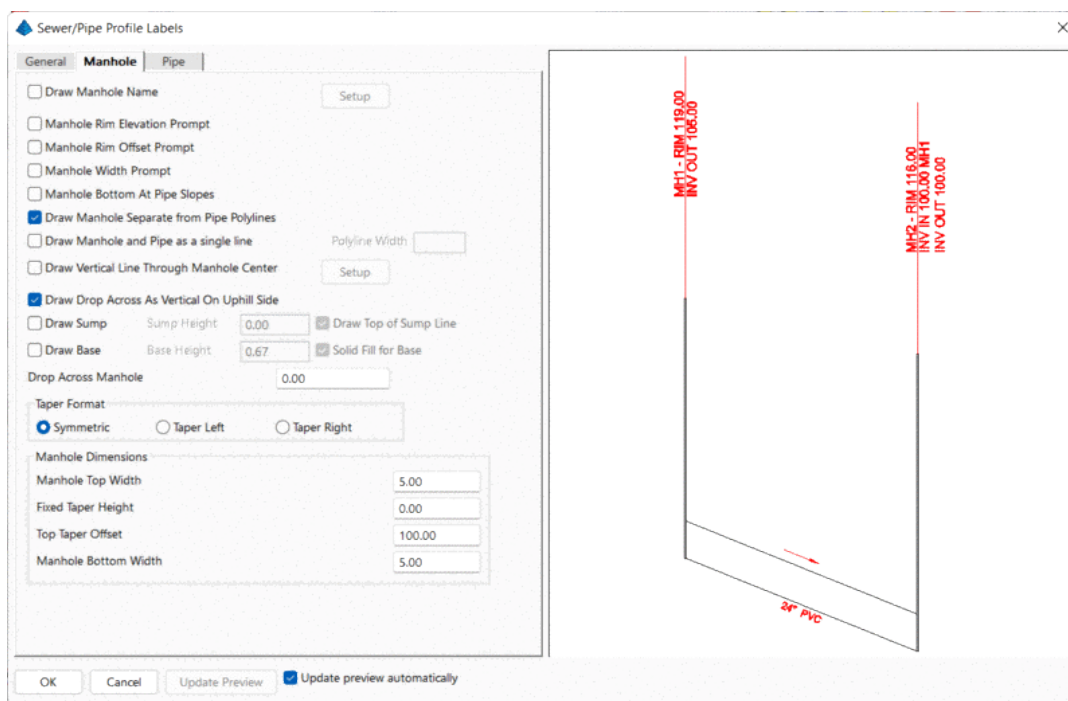

Draw Break Lines for Extended Pipes: When enabled (and requires either **Draw Extended Pipe At Beginning** or **Draw Extended Pipe At End** to be enabled), a "squiggle" is drawn at the end of the extended pipe to indicate that it is a partial pipe. Otherwise, the pipe end is left "open".

Label Precision: Click on the Label Precision button to set the amount of precision used for sewer station, elevation, length and slope labels.

Label Additional Elevation: This option may be utilized to apply a scale factor (*e.g.* Imperial Units to SI Metric Units) for plans that require alternate units to be cited.

Manhole Tab

On this tab, you are able to specify how to label the manhole name and how to draw the manholes.

Draw Manhole Name: Enable this option and select the desired geometric shape that shall circumscribe the manhole name. If selected, enter any desired prefix or suffix for the labels.

Manhole Name Setup

Symbol: Hexagon

Layer: MANHOLE_LABEL [Select]

Text Style: STANDARD [Select]

Text Size Scaler: 0.1000

Label Position: Above Manhole [Offset: 1.0000]

Prefix: [] Prefix on a new row

Suffix: [] Suffix on a new row

Draw Manhole Name as MText

OK Cancel Help

Draw Manhole Sides Down To Invert: Closes the manhole at pipes.

Manhole Rim Elevation Prompt: Ignores the manhole's rim elevation and prompts to enter new values.

Manhole Rim Offset Prompt: Prompts to enter the offset value and adds the offset to the manhole's rim elevation.

Manhole Width Prompt: Enable this option to prompt for the top width of the manhole.

Manhole Bottom at Pipe Slopes: Enable this option to prompt for the bottom width of the manhole.

Draw Manhole Separate from Pipe Polyline: Enable this option to draw the shape of the manhole as a separate polyline from that of the pipe.

Draw Vertical Line Through Manhole Center: Draws a vertical line through the manhole center from rim to bottom of profile grid.

Draw Drop Across As Vertical On Uphill Side: If a step up is used, draws this as a vertical line on the higher side of the structure.

Draw Sump: When enabled, specify the height of the sump to be drawn into the sewer profile.

Draw Base: When enabled, specify the base height to be drawn into the sewer profile.

Drop Across Manhole: Adds a step up to the invert-in elevation.

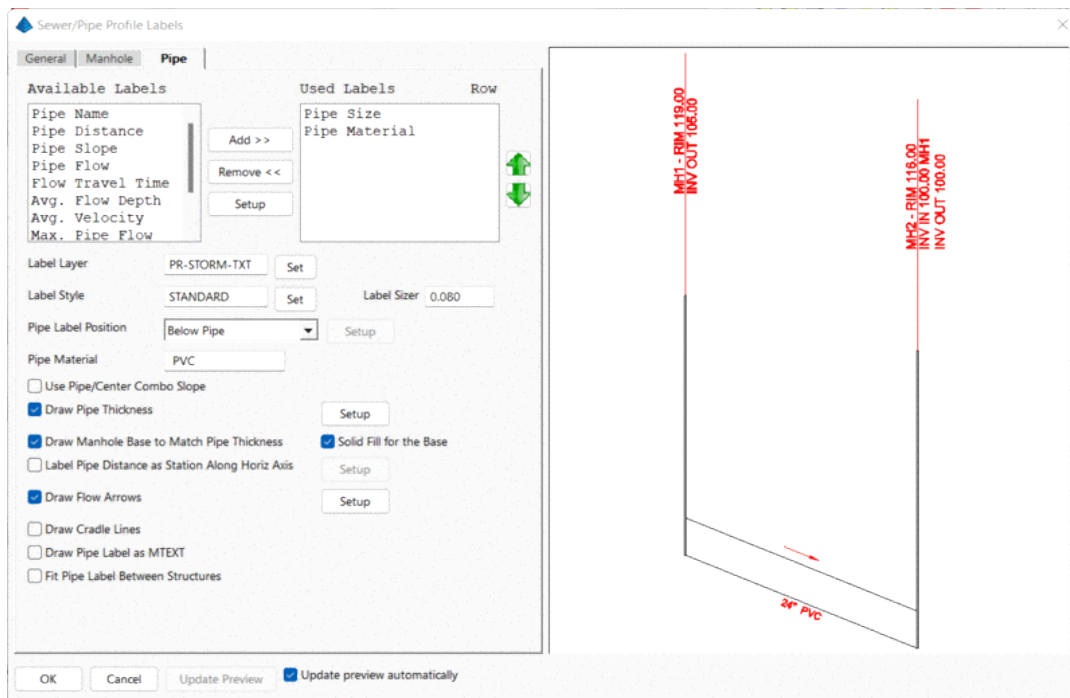

Taper Format, Manhole Dimensions: When drawing from a profile file created with the Design Sewer/Pipe Profile command, these parameters are used to define the manhole shape and dimension. When drawing from a profile created from Network in the Hydrology module with commands such as Export to Profiles, these Draw Profile settings are ignored and the dimensions come from the Network instead. The taper settings are used for transitioning between different manhole top and bottom widths. The Top Taper Offset sets the distance from the top of the manhole to the point that the taper will end. The Fixed Taper Height determines the overall length of the tapered section.

In this example image, all the manholes have Top Width of 2 and Bottom Width of 4. Manhole #1 has Top Taper Offset of 2 and Fixed Taper Height of 0. Manhole #2 has Top Taper Offset of 100 and Fixed Taper Height of 0. This large Top Taper Offset is greater than the manhole depth so that the taper runs the full length of the manhole. Manhole #3 has Top Taper Offset of 3 and Fixed Taper Height of 1.

Pipe Tab

Here you can choose to label pipe in a very flexible order. Each label has a setup function which specifies the label prefix and suffix, decimal places, row number and *etc.*

Label Layer: Set the layer for the labels.

Label Style: Set the text style and size of the text.

Pipe Distance Method: Label either the center to center distance or the actual distance of the pipe.

Pipe Slope Method: Choose from three common methods of calculating pipe slope.

Pipe Label Position: Choose from along the pipe, along the axis or inside the pipe.

Pipe Material: Indicate the type of material used for the pipe.

Draw Pipe Thickness: When selected, draws pipes in profile as double lines indicating the thickness of the pipe. This option also allows for cross hatching of the double lines.

Draw Manhole Base to Match Pipe Thickness: When selected, this option draws the base of the manhole to the same depth relative to the pipe thickness.

Label Pipe Distance as Station Along Horiz Axis: This option creates pipe distance labels as the station style along the horizontal axis. Click the **Setup** button to access the labeling method and style.

Label Pipe Distance as Station

Label Direction

Downstream to Upstream Upstream to Downstream

Layer Name: PIPE_LEN [Select]

Label Style: STANDARD [Select]

Label Offset: 0.10

Marker Height: 1.00

Label Decimals: 0.00

OK Cancel Help

Draw Flow Arrows: Indicate if arrows should be drawn illustrating the direction of flow.

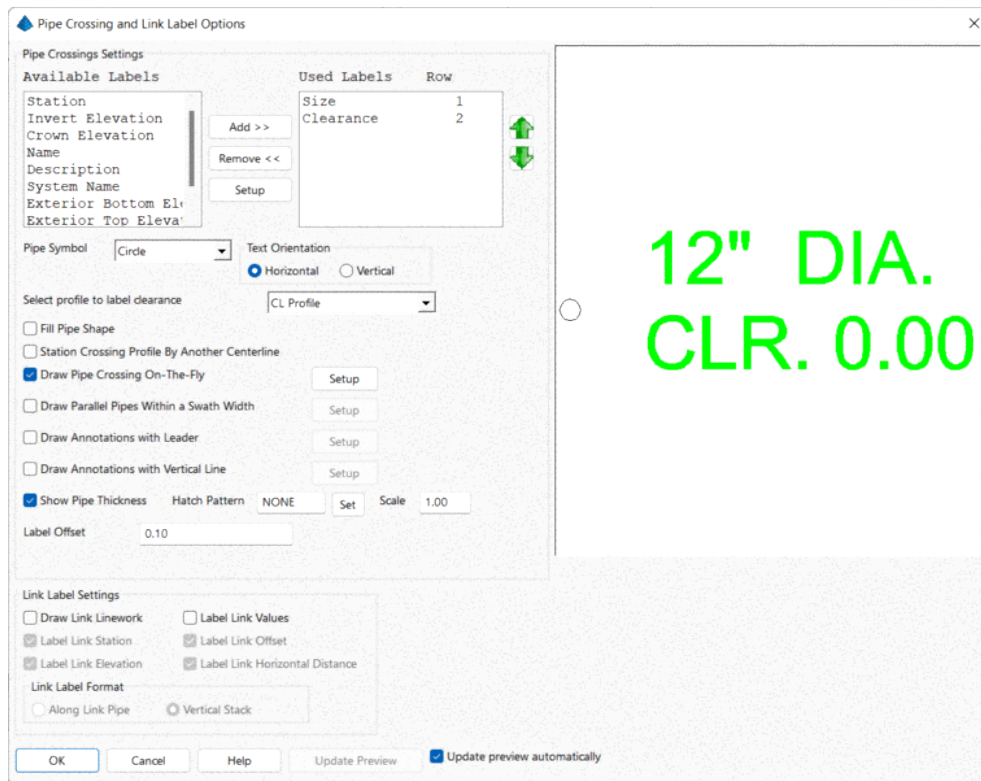

Draw Cradle Lines: If the sewer profile contains cradle data, this option would draw cradle lines above and below the pipe segments.

Draw Pipe Label as MTEXT: When enabled, text labels will be drawn as a *multiline text* (MTEXT) entity.

Fit Pipe Label Between Structures: When enabled, this option will ensure that pipe labels will fall within a structure-to-structure distance.

Pipe Crossing Labels

This button opens Pipe Crossing and Link Label Options dialog, which contains all the settings for drawing a pipe crossing type or profile, or the pipe crossings when pipes or sewer networks in the drawing are intercepted by a profile to be drawn.

(Setup) Label Prefix/Suffix: Indicate labels that should precede and/or follow the pipe information.

(Setup) Label Precision: Decimal places of the labels.

(Setup) Label Station/Elevation/Size/Name/System Name: Options to label the parameters or not.

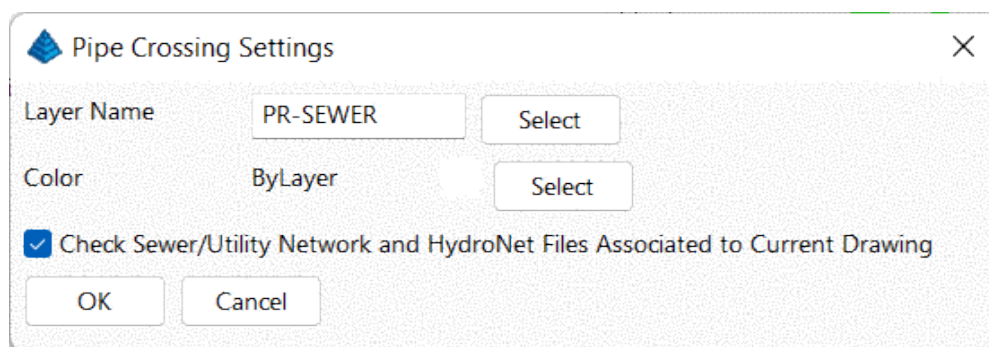

Pipe Symbol: Options to show pipe crossing in circle, square, or based on the pipe shape.

Text Rotation: Labels can be drawn either horizontally or vertically. This option becomes disabled when the *Draw Annotations with Leader* option is enabled.

Fill Pipe Shape: When enabled, the cross-section area of crossing pipes will be hatched for visual distinction.

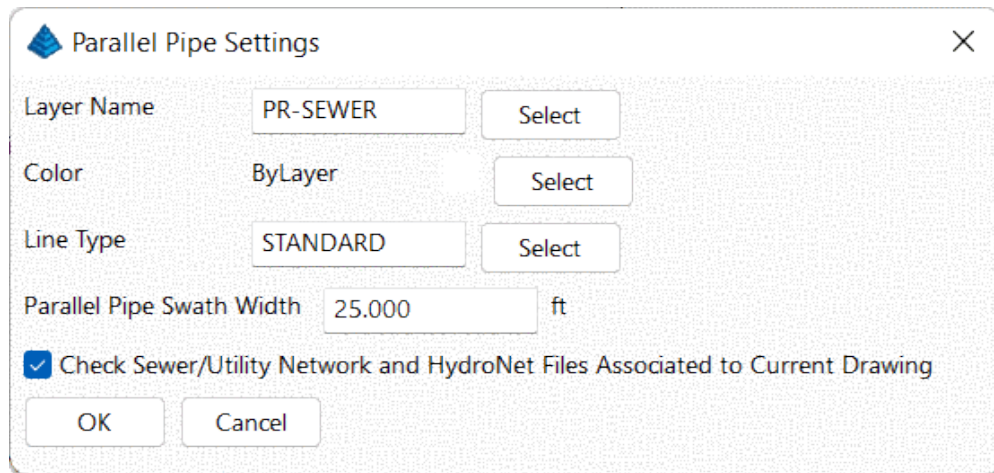

Station Crossing Profile By Another Centerline: This option will make new stations by referencing the profile to another centerline, for example a road centerline.

Draw Pipe Crossing On-The-Fly: When this option is chosen and there are pipes or sewer networks drawn in the drawing, the program will prompt to select a reference centerline that represents one of the profiles to be drawn to detect the pipe crossings. Any pipe crossings found would be drawn with other profiles.

Draw Parallel Pipes Within a Swath Width: When this option is chosen and there are pipes or sewer networks drawn in the drawing, the program will prompt to select a reference centerline that represents one of the profiles to

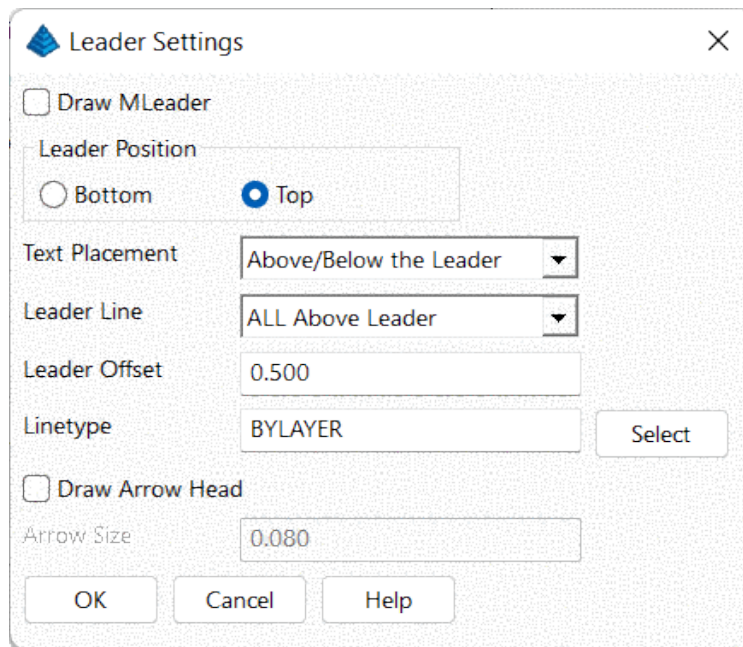

be drawn to detect if there's any pipe segments that are within a swath width along the profile. Any pipe segments found would be drawn with other profiles.

The screenshot shows the 'Parallel Pipe Settings' dialog box. It has a title bar with a blue diamond icon and a close button (X). The settings are as follows:

- Layer Name: PR-SEWER (with a 'Select' button)
- Color: ByLayer (with a 'Select' button)
- Line Type: STANDARD (with a 'Select' button)
- Parallel Pipe Swath Width: 25.000 ft
- Check Sewer/Utility Network and HydroNet Files Associated to Current Drawing
- Buttons: OK, Cancel

Draw Annotations with Leader: When enabled, this uses a leader in conjunction with pipe labels.

The screenshot shows the 'Leader Settings' dialog box. It has a title bar with a blue diamond icon and a close button (X). The settings are as follows:

- Draw MLeader
- Leader Position: Bottom, Top
- Text Placement: Above/Below the Leader (dropdown menu)
- Leader Line: ALL Above Leader (dropdown menu)
- Leader Offset: 0.500
- Linetype: BYLAYER (with a 'Select' button)
- Draw Arrow Head
- Arrow Size: 0.080
- Buttons: OK, Cancel, Help

Draw Annotations with Vertical Line: When enabled, this uses a vertical line and orientation to indicate the location of the pipe crossing being labeled.

Vertical Line Settings [X]

Layer Name: XPIPE_PROFILE [Select]

Color: ByLayer [Select]

Line Type: STANDARD [Select]

Line Position: Row 1 [v]

Line Location: Grid Bottom [v]

[OK] [Cancel]

Show Pipe Thickness: When enabled, this draws the pipes in profile using double lines to indicate the thickness of the pipe. The area between the lines can be cross-hatched.

Link Label Settings: Settings to determine how to draw link labels.

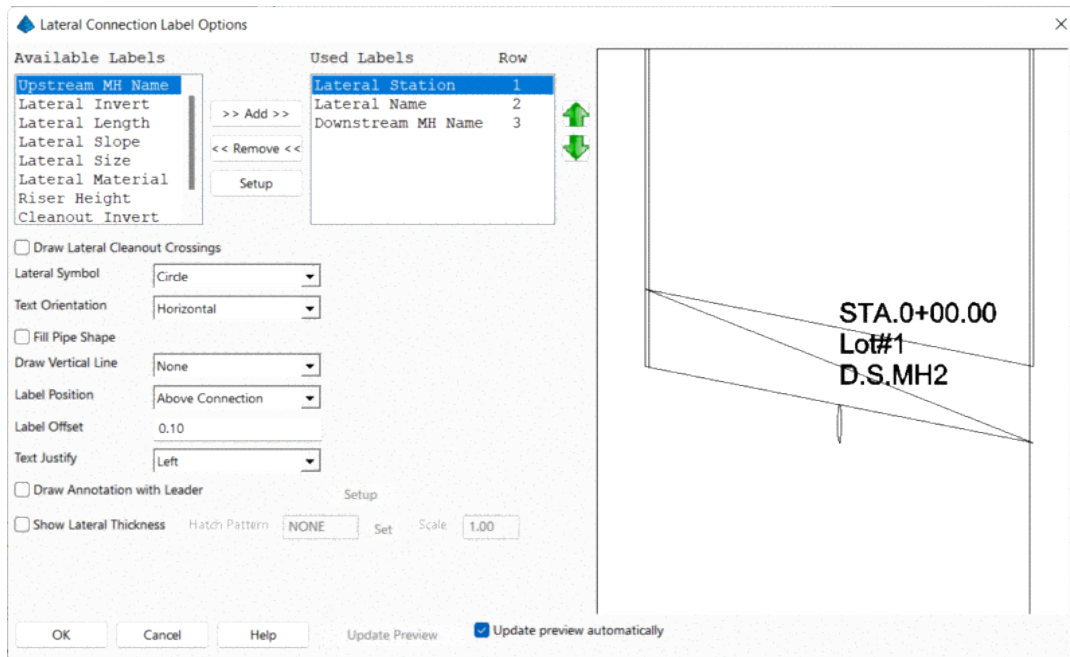

An Example of Pipe Crossings On-The-Fly (Showned in Green)

An Example of Parallel Pipes Within a Swath Width (Shown in Green)

Lateral Connection Labels

These settings apply for profiles create from a Sewer Network from the Hydrology module that contains lateral structures. There are several lateral data fields available for labeling. Use the Add/Remove buttons to make the list of fields to label. Use the Setup button to set the prefix and suffix for each field, and control whether the field is labeled on a separate row. There are settings to choose the symbol on the pipe at the lateral station, the text orientation, whether to draw a vertical line at the lateral station, set the label position and offset, set the text justification and whether to draw a leader from the pipe to the label.

Lateral Symbol: Set this to circle, square or pipe shape as appropriate.

Text Orientation: Use this to control whether the text is oriented horizontally or vertically.

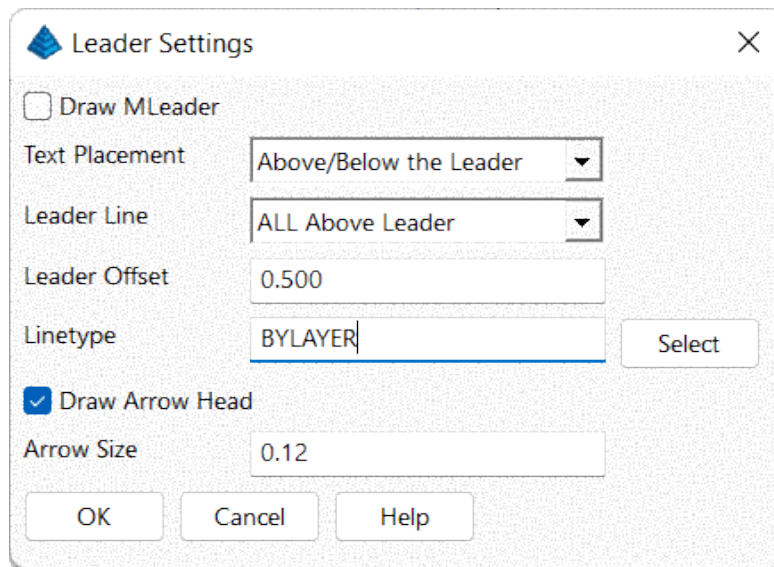

Draw Vertical Line: Set the vertical line to none or a number of rows.

Label Position: Use this to set the label position relative to the Right-of-Way, Connection or Mainline.

Label Offset: Set the offset of the label relative to its reference point.

Text Justify: Use this to justify the text either center, left or right.

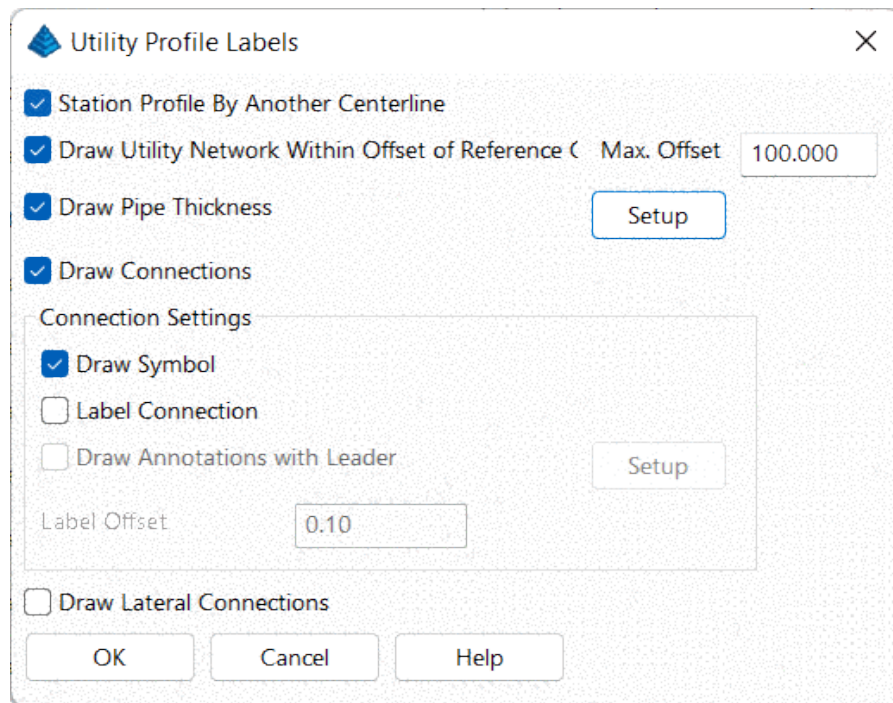

Draw Annotation with Leader: If you want to use a leader, enable this option.

Show Lateral Thickness: Use this setting to show the thickness of a lateral.

Update Preview: Use this button to update the preview window and review your changes before committing them to a drawing.

Utility Profile Labels

Station Profile By Another Centerline: This option will derive stations by referencing the utility to another centerline, for example a road centerline.

Draw Utility Network Within Offset of Reference: Set the Max. Offset for utility networks to draw.

Draw Pipe Thickness: If a pipe size thickness is specified within the Pipe Size Library the program will also draw wall thickness.

Draw Connection: When enabled, and for Utility Networks that have been assigned Connections, the connection point(s) is (are) drawn into the profile.

Label Connection: When enabled, and for Utility Networks that have been assigned Connections, the label(s) for the connection point(s) is (are) drawn into the profile.

Draw Annotations with Leader: This option will permit the Utility label to be placed with a leader with further control via the **Setup** option.

Label Offset: Indicate the plotted distance the Utility label should be drawn away from the Utility entity.

Prompts (may vary based on Settings)

Profile Grid Range

Profile Station Range: 0+00.00 to 5+68.19

Profile Elevation Range: 349.25 to 368.04

Grid Starting Station: -50.000

Grid Ending Station: 625.000

Grid Top Elevation: 380.000

Grid Bottom Elevation: 330.000

Use Fixed Grid Top/Bottom Elevations

Fixed Grid Top Elevation: 385.000

Fixed Grid Bottom Elevation: 305.000

OK Cancel

Grid Starting Station: Indicate the desired starting station for the profile grid.

Grid Ending Station: Indicate the desired ending station for the profile grid.

Grid Top Elevation: Indicate the bounding upper elevation for the profile.

Grid Bottom Elevation: Indicate the bounding lower elevation for the profile.

Use Fixed Grid Top / Bottom Elevations: Allows user to set fixed parameters for profile top and bottom elevations for all profiles.

Polyline should be drawn in direction of increasing stations.

CL File/ <Select pipe crossings on-the-fly or parallel pipes centerline>: Pick a polyline upon which to base the stationing or *Type C to select an existing Centerline .CL file and then press Enter*

Centerline Starting Station <0.0>: *Press Enter to accept the default station value specified or Type in the beginning station then press Enter*

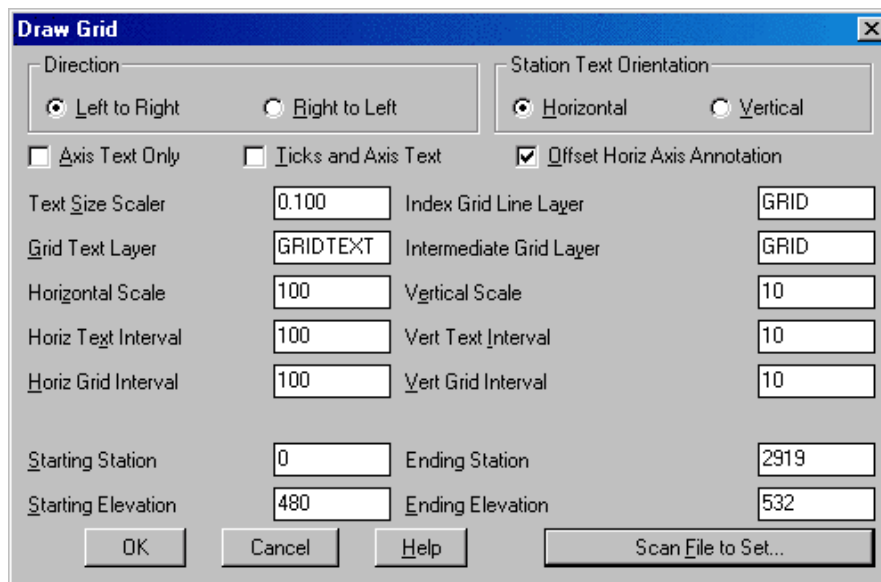

Pulldown Menu Location(s): Civil > Profiles, Survey > Surface, Hydrology > Network, Construction/Takeoff > Roads, Field > Roads

Keyboard Command: drawprof

Prerequisite: A profile .PRO file

Draw Profile Grid

This command plots a grid and labels the grid lines with stations and elevations. Profile grids can also be plotted along with the profile when using the command *Draw Profile*. Use this command to draw only the grid. The following dialog box appears:

Direction: Choose grid direction, either left to right or right to left.

Station Text Orientation: Specify whether the station text should be plotted horizontal or vertical.

Axis Text Only: When checked, grid lines are not drawn.

Ticks and Axis Text: When checked, one horizontal and vertical grid line as well as the annotations will be drawn.

Offset Horizontal Axis Annotation: When checked, additional space is added between the bottom horizontal grid line and the station labels in order to leave room for Horizontal Axis Elevations and sewer profile annotations.

Text Size Scaler: This sets the size of text used for annotation. This value is multiplied by the horizontal scale to obtain actual text size.

Index Grid Line Layer: Specify the layer name for index grid lines.

Grid Text Layer: Specify the layer name for text annotation along the horizontal and vertical axis.

Intermediate Grid Layer: Specify the layer name for intermediate grid lines.

Horizontal Scale: This sets the horizontal scale for the profile grid.

Vertical Scale: This scale sets the vertical exaggeration of the profile grid.

Horiz. Text Interval: This sets the spacing of the stationing text that appears along the horizontal axis. If you use a large Text Size Scaler such as 0.2 in English units, it is best to set the horizontal text interval to twice the horizontal scale, so that the larger text will not overlap along the horizontal axis.

Vert. Text Interval: This sets the spacing of the elevation text that appears along the vertical axes.

Horiz. Grid Interval: This sets the spacing of the grids that run vertically from the horizontal scale.

Vert. Grid Interval: This sets the spacing of the grids that run horizontally between the vertical axes on the left and right side of the profile.

Scan File to Set: Prompts to select a profile (.PRO) file which it reads to set the values for starting and ending stations and elevations.

Draw Grid with Station Text Vertical and no Offset Horizontal Axis

Prompts

Pick Starting Point for Grid <0.0 , 500.0>: *pick a point*

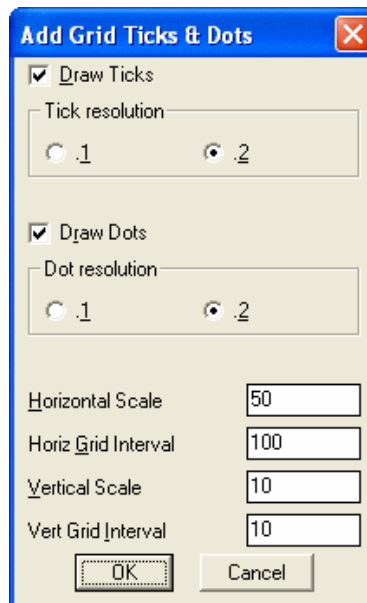

Pulldown Menu Location: Profiles > Profile Grid

Keyboard Command: drawgrid

Prerequisite: None

Add Grid Ticks and Dots

This routine draws ticks on the axis and/or interval dots on an existing grid.

Prompts

Add Grid Ticks & Dots dialog

Specify whether to draw the ticks and/or dots, and choose their resolutions (.1 or .2). Also, make sure the grid

parameters match the grid that you're working on.

Pick Lower Left Corner of Grid: *pick the corner* (endpoint snap is on)

Pick Upper Right Corner of Grid: *pick the corner* (endpoint snap is on)

Grid ticks and dots with metric stationing (no '+') as set in Profile Defaults

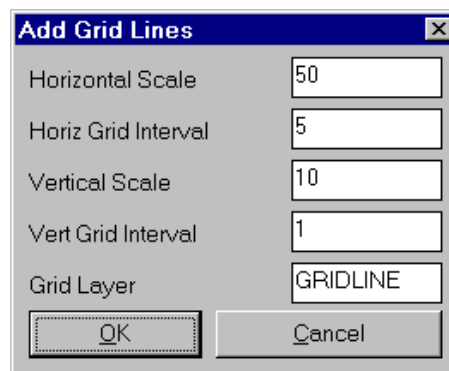

Pulldown Menu Location: Profiles > Profile Grid

Keyboard Command: tickdot

Prerequisite: A profile grid

Add Grid Lines

This routine draws grid lines at the specified scale and interval between the picked lower left and upper right grid corners.

Prompts

Add Grid Lines dialog

Make sure the grid parameters match the grid that you're working on.

Pick Lower Left Corner of Grid: *pick the corner* (endpoint snap is on)

Pick Upper Right Corner of Grid: *pick the corner* (endpoint snap is on)

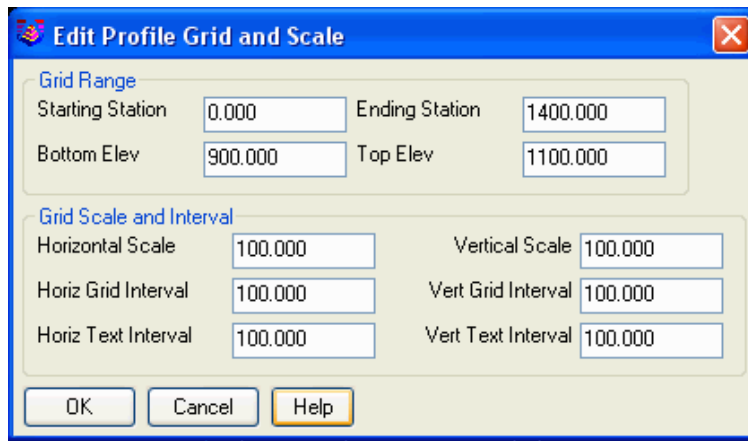

Pulldown Menu Location: Profiles > Profile Grid

Keyboard Command: gridline

Prerequisite: A profile grid

Adjust Profile Grid

This command allows you to modify the profile grid parameters for a profile that is already drawn. First you pick on any entity that is part of a drawn profile. Then change any of the settings in the dialog shown here and the program will update the profile.

Prompts

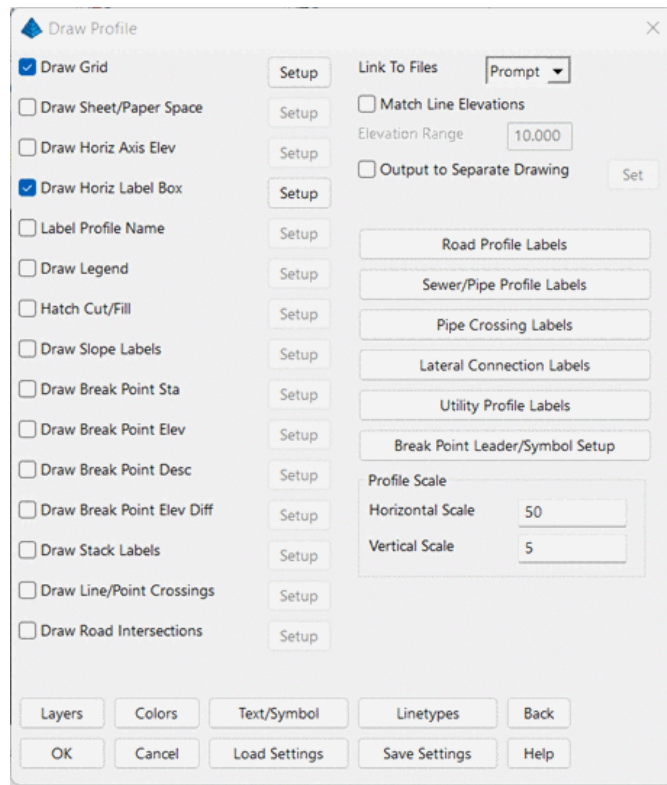

Pick profile to edit: *pick any entity from a drawn profile*
Edit Profile Grid and Scale dialog

Pulldown Menu Location: Profiles > Profile Grid/Sheet
Keyboard Command: edit_drawprof
Prerequisite: A drawn profile

Adjust Draw Profile Settings

This command allows changes to be made to an existing profile, either on the Model tab or on a layout tab. These changes include all of the options that were used to create the profile originally using the Draw Profile command.

The first step in Adjust Draw Profile Settings is to choose the profile you want to change by picking any entity on the profile drawing. Once you have selected a profile in the drawing, the **Draw Profile** dialog box appears, and contains all of the settings for creating the profile. Please see the Draw Profile section of this manual for a description of these settings.

When OK is clicked at the base of the dialog box, the profile is updated in its current location.

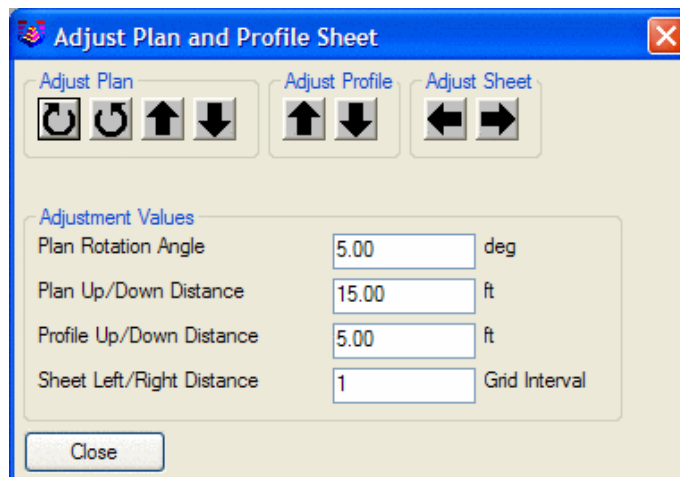

Pulldown Menu Location: Profile Grid/Sheet > Adjust Draw Profile Settings

Keyboard Command: reset_drawprof

Prerequisite: A profile in the drawing

Adjust Plan/Profile Sheet

This command is used on a Plan & Profile sheet generated by the Draw Profile command with the Draw Sheet option selected. Adjustments can be made to the plan view, profile, or sheet itself. The command is run entirely from the Adjust Plan and Profile Sheet dialog box. Adjustment settings are defined, and then all adjustments are accomplished simply by picking the appropriate icons.

Pulldown Menu Location: Profiles > Profile Grid/Sheet

Keyboard Command: ppsheet

Prerequisite: A Plan & Profile paper space layout generated with Draw Profile command

Move Sewer Profile Labels

This command moves the selected stack profile labels and sewer profile labels with a leader. The purpose is to clean up label overlaps. To move a label, pick any one of the text labels and the program will pick up all the other associated labels. Then pick the new location and while the pointer is moved, the program shows an outline of the label area. The program remembers the moved locations for each label so that when the sewer profile labels are redrawn, the moved locations are retained. The Restore function puts the labels back to their default position. The following graphics show the sewer profile labels before and after Move Sewer Profile Labels was used to clean up the label overlaps.

Sewer Profile Labels with Overlap

Move a label away

Sewer Profile Labels without Overlap

Prompts

Select sewer profile label to move (R for Restore): *Pick a sewer profile label text with leader entity*

Pick label position: *pick a point*

Select sewer profile label to move (R for Restore, Enter to end): *press Enter to end*

Pulldown Menu Location: Profiles > Profile Grid/Sheet

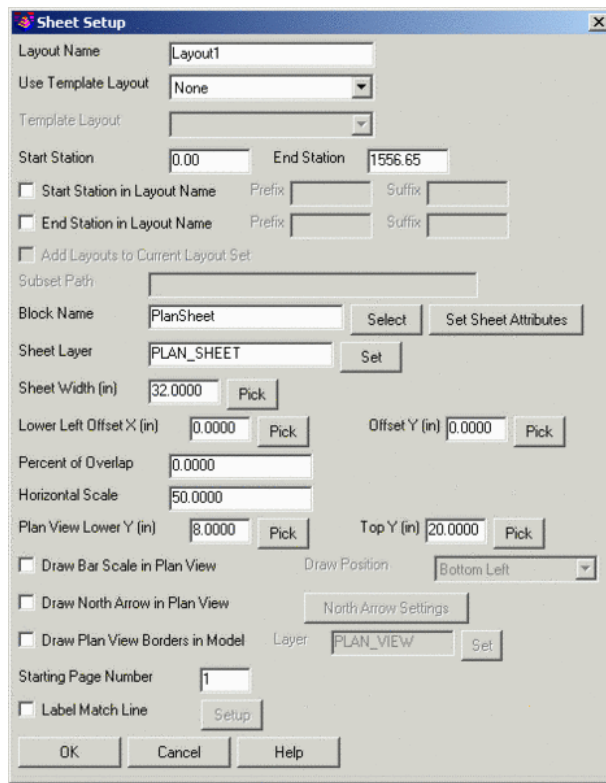

Keyboard Command: move_swrprof_label

Prerequisite: sewer profile labels with leader

Draw Plan View Sheets

Draw Plan View Sheets creates layout tabs with viewports for plotting an existing centerline. These plan view sheets are sized and oriented automatically based on the centerline design.

The first step in Draw Plan View Sheets is to choose the centerline to be plotted. This may be selected from the drawing, or you may select an existing centerline (.CL) file. Once you have selected a centerline, the **Sheet Setup** dialog box appears, and contains all of the settings for creating the layout tabs and sheets.

Layout Name: Enter a name for the paper space "tabs" to be assigned to each layout for each sheet. The program will automatically divide the centerline plan view sheet layouts, and if the length of the centerline extends beyond a single sheet, then multiple layouts are created, with the layout name ID incremented by 1.

Note:

- If either the *Start Station in Layout Name* or the *End Station in Layout Name* options are enabled, the Layout Name field will be disabled as the Layouts will get named automatically.

If you enter "ms" to go to model space within a Layout tab, you can pan to alter the plan view position. However, it is best to zoom in/out and edit within the Model tab. The Layout tabs appear at the bottom of the screen, along with the "Model space" tab to go back to standard plan view:

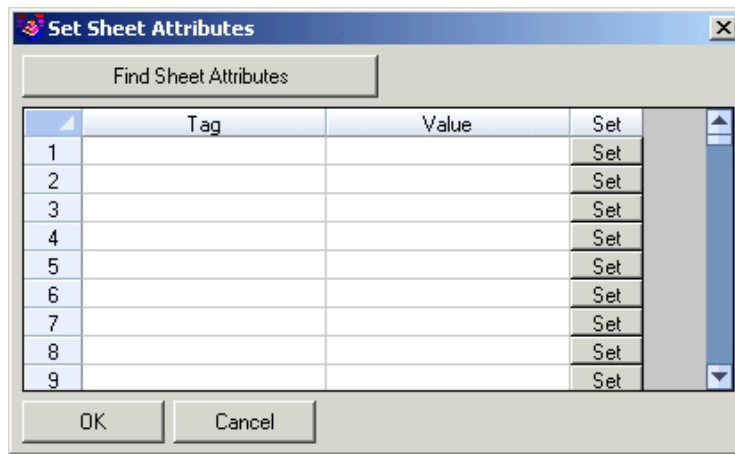

Start/End Stations: These values control the station range to draw.

Start/End Station in Layout Name: These options allow you to include starting and ending station in the Layout Names.

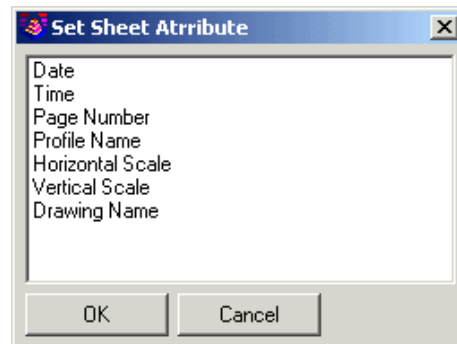

Add Layouts to Current Layout Set: This option allows you to add the layouts created to an existing layout set that was previously generated using the Layout Set Manager. You will need to specify the name of the layout set.

Block Name: This is the drawing name for the sheet to be inserted. The Set button can be used to change the block name. Carlson provides a standard plan and profile border in the form of profile.dwg located in the working folder of %AppData%\Carlson Software\...\Sup\. You may wish to revise profile.dwg to remove the grid, resize the plan viewport, and add your company logo, and re-save it as plan.dwg. Alternatively, you could add your own complete version of a sheet block/border.

Set Sheet Attributes: This button allows you to specify the values used by any attributes associated with the sheet block. These can be entered manually in the Set Sheet Attributes dialog.

You can use the Set button to the right of any field to set that field to a preset value pulled from the drawing information.

Sheet Width: This is the profile width, in inches, on the sheet.

Lower Left Offset X/Y: Indicate the offset value(s) for the insertion point of the sheet in CAD units. This option allows user-defined Block Names to be properly positioned relative to the remainder of entities placed through the Draw Profile command.

Percent of Overlap: Use this to set the amount of centerline shown beyond the match line on each sheet. This can make it easier to piece together sections of the centerline on separate sheets.

Horizontal/Vertical Scale: Set the scales to be used for the new viewport(s).

Plan View Lower Y: This sets the lower position of the paper space window for the plan view. With Lower Y set to 9 (inches above the base of the sheet) and Top Y set to 21, there is a 12 inch vertical window, running the full Sheet Width (typically 30 to 32). This window for the plan view can be expanded or reduced with these settings.

Top Y: This sets the top vertical limit for the plan view window, measured in inches from the bottom of the plan and profile sheet.

Draw Scale Bar in Plan View: Adds a scale bar to the finished sheet. If this option is selected, the scale bar can be placed in any corner of the sheet using the Draw Position drop down.

Draw North Arrow in Plan View: This draws a North Arrow in plan view. Click the **North Arrow Settings** button to establish the desired North arrow and placement information.

Draw Plan View Borders in Model Space: This draws the borders in Model Space which can be useful for orienting text and other labels to the orientation of the sheet. When this option is selected, use the Layer text box or Set button to choose the layer on which the borders will be drawn.

Label Match Line: When clicked on and multiple sheets are plotted with plan view option on, a match line will plot in the plan view.

When OK is clicked at the base of the dialog box, the layout tabs are created if necessary, and the sheets are drawn.

Pulldown Menu Location: Profiles

Keyboard Command: plansh

Prerequisite: None

Horizontal Axis Elevations

This command labels the elevations of a profile along the bottom horizontal axis at a user-specified interval. It requires an existing grid and profile. The profile can be read from either a .PRO file or from a profile polyline on the grid. This polyline must be drawn in the direction of the grid. There are more labeling options when using the screen polyline method.

In the dialog, you can set the layer name, style, size, color and decimal places for the labels. Two profiles can be labeled at once to handle existing and final profiles in one step (see graphic). When labeling two profiles with the "File" method (recalling a profile), use the "L" justification for the first set of horizontal axis elevations, and use the "R" justification for the second set. One convention is to label the existing profile to one decimal place and the final profile to two decimal places. When labeling only one profile, use the center justification. When using two profiles from the "Screen" selection method, there is an option to also label the elevation difference between the profiles. The Label Between Elevations option chooses between labeling the values in the order of existing elevation, cut/fill and final elevation or in the order of existing elevation, final elevation then cut/fill. The Skip Elevation Labels option will label only the cut/fill and not the elevations. The Save and Load functions are to save and recall settings from this dialog using a .HOR file.

Prompts

Read Profile from a File or from the Screen (File/<Screen>): *press Enter*

Plot Elevations on Horiz Axis dialog

Make sure the grid starting station and elevation match the grid that you're working on.

Pick the existing grade (Enter for none): *pick a profile polyline on the grid*

Pick the final grade (Enter for none): *press Enter*

Alignment of text (<Left>/Center/Right)? *C* This prompt occurs only in the "File" selection method.

Pick Lower Left Grid Corner: *pick the corner* (endpoint snap is on)

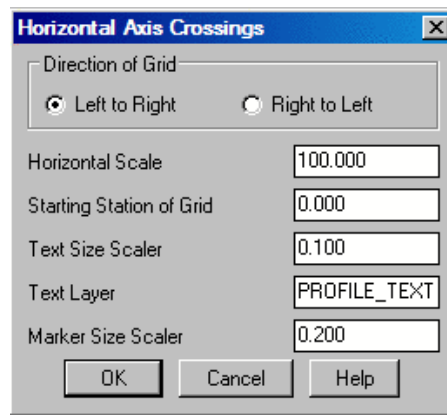

Pulldown Menu Location: Profiles > Label Horizontal Axis

Keyboard Command: horelev

Prerequisite: Profile grid with a profile polyline

Horizontal Axis Crossings

This purpose of this command is to draw ticks on the horizontal axis of the profile at station locations where the centerline intersects selected plan view polylines. It requires a grid, profile and an existing CL file, as well as user-specified values entered into the dialog. The profile can be read from either a .PRO file or from a profile polyline on the grid. This polyline must be drawn in the direction of the grid. In the dialog, you can set the direction of the grid, the horizontal scale and the starting station of the grid. You can also determine the Text Size Scaler, Text Layer name and the Marker Size Scaler. The command line offers the option to choose the existing centerline (.CL) file. You enter "C" and a dialog appears where you may select the file.

Prompts

Horizontal Axis Crossings dialog Fill in values.

Polyline should have been drawn in direction of increasing stations.

CL File/ <Select polyline that represents centerline>: *pick polyline*

Plan view showing crossing

Pulldown Menu Location: Profiles > Label Horizontal Axis

Keyboard Command: horcross

Prerequisite: Profile, profile centerline polyline and a .CL file

Profile to 3D Polyline

This command converts a 2D polyline centerline into a 3D polyline that follows the elevations of the profile. Horizontal and vertical curves are represented as a series of polyline segments since 3D polylines cannot contain arcs. Profile to 3D Polyline can be combined with other commands for plan-view road design as follows:

1. Draw 2D polyline centerline.
2. Profile from Surface Model - to create existing surface profile.
3. Design Road Profile - to design the final profile with vertical curves.
4. Profile to 3D Polyline - create a 3D polyline of the road centerline.
5. Offset 3D Polyline - offset the 3D polyline centerline left and right by the horizontal and vertical distances.
6. Design Pad Template - run twice for left and right polylines of road to tie into surface at specified cut and fill slopes. This creates the limits of the disturbed area. Or use Join Nearest, Direct Connect Endpoints, to create a closed loop pad with one run of Design Pad Template for simple ramps, driveways and access roads.
7. Triangulate & Contour - draw final contours using road 3D polylines.
8. Volumes - use any of the volumes commands to calculate cut and fill volumes.

Prompts

Layer Name for 3D Polyline <3DPROF>: *press Enter*

Select profile centerline polyline: *pick a polyline*

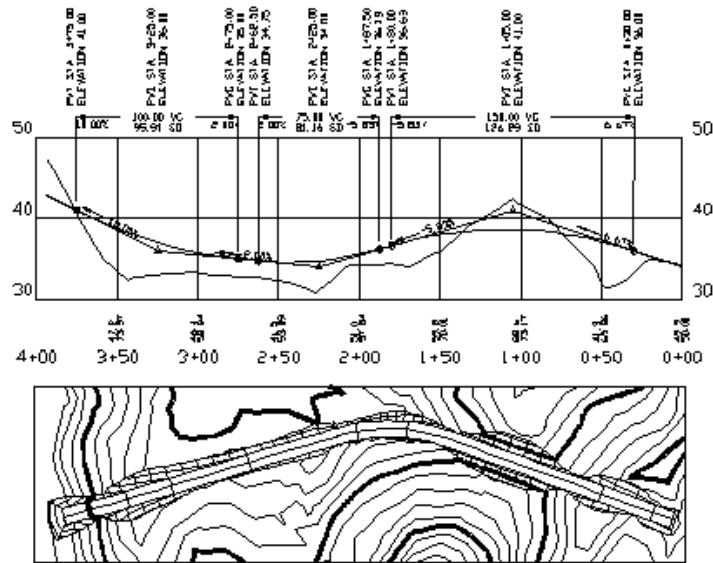

Station by another reference centerline [Yes/<No>]? *N* for no. This option will prompt for a second centerline to use for stationing.

Enter the starting station <0.0>: *press Enter*

Select Profile File

Starting station of centerline <0.0>: *press Enter*

Erase centerline (Yes/<No>)? *Y* This option will erase the original 2D polyline centerline.

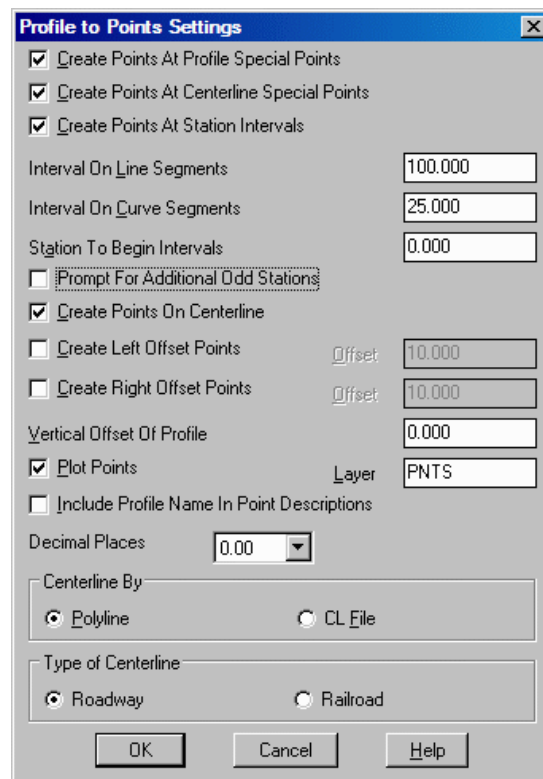

Example of road design in plan-view with Profile to 3D Polyline

Keyboard Command: proto3dp

Prerequisite: A .PRO file and a centerline polyline

Profile To Points

This command creates Carlson points along a horizontal alignment polyline using a profile file to compute the point elevations. The created points are stored in a coordinate (.CRD) file and can also be drawn on screen in the layer specified by the user. Station text, profile name, and special points (vertical and horizontal PC's and PT's) can be stored in the point description depending on user settings.

Create points at Profile special points: Includes vertical PC and PT points.

Create points at Centerline special points: Includes horizontal PC and PT points.

Create points at Station Intervals: Allows you to specify intervals for point creation.

Interval On Line Segments: Specify station interval for line segments.

Interval On Curve Segments: Specify station interval for curve segments.

Station to Begin Intervals: Specify station to start intervals.

Prompt For Additional Odd Stations: Any station can be entered to create additional points with elevations derived from the profile.

Create Points on Centerline: When checked, points will be created on the centerline.

Create Left Offset Points: When checked, left offset points will be created. Specify the offset in the edit box.

Create Right Offset Points: When checked, right offset points will be created. Specify the offset in the edit box.

Vertical Offset of Profile: Specify the vertical offset. Enter zero for no vertical offset.

Plot Points: When checked, points will be plotted in the drawing, otherwise points are only added to the current coordinate (.CRD) file.

Include profile name in point descriptions: When checked, the profile name will be used as the prefix on the point description. For example, if the profile name is DESIGN.PRO, then the point description might be DESIGN 0+63.37.

Decimal Places: Specify the display precision for points that are plotted in the drawing. This setting does not affect the coordinates stored in the CRD file.

Centerline by: Click either Polyline or CL File.

Type of Centerline: Click either Roadway or Railroad.

OK: Specify files.

Prompts

Select Coordinate File to Process

If the current coordinate is set, it is used automatically without this prompt.

Select profile centerline polyline: *pick a polyline*

Starting station of centerline <0.0>: *press Enter*

Station by another reference centerline [Yes/<No>]? *N for no.* This option will prompt for a second centerline to use for stationing. With this option, the first centerline is used for locating the points and the second reference centerline is used for locating the profile stations. So the first centerline represents where the points are created (ie. the edge of pavement) and the second centerline represents the profile location (ie. the road CL).

Choose Profile to Process dialog Specify a profile name.

Starting point number <1>: *press Enter* This defaults to the point number after the highest one currently in the CRD file.

Station for additional point (ENTER to end): *press Enter* This option will create a point at the specified station. Prompt occurs only if option is specified in dialog.

Points created along profile centerline using elevations from the above road profile

Keyboard Command: pro2pts

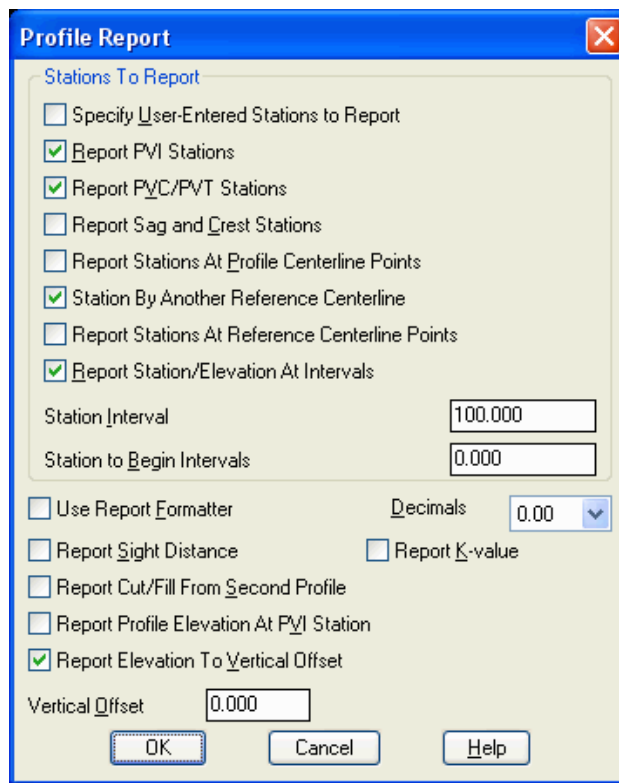

Prerequisite: A .PRO file and a centerline polyline

Profile Report

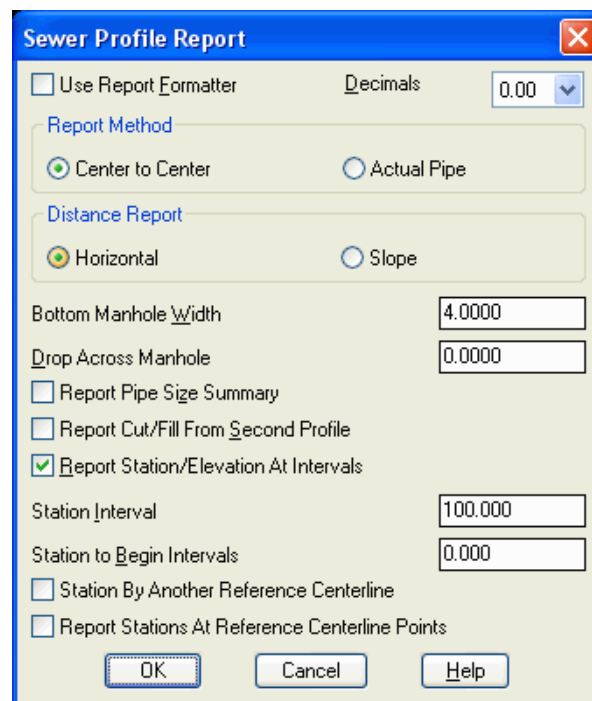

This command creates a summary report of generic, road, crossing, pipe and sewer profiles using a profile file (.PRO file). The report is generated in the standard report viewer which can print the report, save it to a file or draw it on the screen. The different types of profiles have different report options.

To report stations adjusted by station equations, first run Centerline Editor and enter the station equations. Then run Profile Editor and assign the centerline as the Reference Centerline for the profile.

For roadway profiles, Report Sag and Crest Stations will calculate and report sag and crest stations and elevations. Report Stations at Centerline Points will prompt the user for a centerline file (.cl file) and report stations and elevations at horizontal PC and PT points. Report Cut/Fill from Second Profile will compute and report the elevation difference between the subject profile and a second reference profile. Report Min/Max Cut/Fill reports the stations and amounts for the min and max cut and fill between the road and reference profiles. Report Station/Elevation at Interval will calculate and report stations at the specified interval in addition to other points. Report Elevation to Vertical Offset creates an additional elevation column in the report. The differential amount for this column is specified by the user in the Vertical Offset window. The Use Report Formatter option runs the report through the report formatter where you can choose which fields to report and the report order as well as output to Excel or databases.

For sewer profiles, the Report Method chooses between reporting the slopes and pipe distances between manhole centers or from the outside manhole edges for the actual pipe dimensions. The Report Pipe Size Summary option reports the total pipe length for each different pipe size. The Station By Another Reference Centerline option reports the sewer stations using a reference alignment besides the sewer alignment. For example, this option can be used to report the sewer stations based on the road centerline. When this option is on, the program will prompt for both the sewer centerline and the reference centerline. The program first finds the position of the sewer station along the sewer centerline and then finds the station of the nearest perpendicular offset along the reference centerline.

Prompts

Specify a Profile File dialog Choose the .PRO file.

Profile Report dialog Make selections, click OK.

If a vertical offset is entered, a second column of elevations is reported.

Sample Profile Report:

```

Polyline Slope Report

This command calculates the slope and distance of a line, polyline segment, an entire polyline, or pair of points, as drawn on a profile. There are options to label the slope and distance. If the labels are turned off, this command can be used to just report the profile slope and distance. The distance is the horizontal distance between the profile stations.

Horizontal Scale: Specify the horizontal scale of the profile grid.

Vertical Scale: Specify the vertical scale of the profile grid.

Text Size Scaler: Specify the text size scaler which is multiplied by the Horizontal Scale.

Symbol Size Scaler: Specify the symbol size scaler which is multiplied by the Horizontal Scale.

Layer: Layer name for the labels.

Style: Text style for the labels.

Slope and Distance Decimals: Specify the display precision for the slope labels and distance labels.

Label Symbol: When checked, the degree symbol or percent sign will be used in the label.

Label Arrow: When checked, a slope direction arrow will be included.

Arrow Scaler: Specify the arrowhead size scaler which is multiplied by the Horizontal Scale.

Label Minus Sign: Will label a minus sign on negative slopes.

Slope Prefix/Suffix: Strings to add to the slope value for the slope label.

Distance Prefix/Suffix: Strings to add to the distance value for the distance label.

Label Format: Choose whether to label slope and distance.

Slope Format: Specify how to label the profile slopes. The automatic settings means to use a percent label for any slope less than 10%. and a ratio for any slope greater than 10%.

Label Method: Choose to label the entire profile at once or to pick individual segments.

Reduce Profile Points: When checked, the number of labels created on the profile will be reduced based on the Offset Distance value. Applies only to the Entire Polyline selection option..

Offset Distance: Specify maximum offset between profile vertices. Only available when Reduce Profile Points toggle is checked on.

Prompts

Station-Elevation-Slope Report

This command calculates the elevation and slope along a profile at user specified stations or intervals. The routine allows three types of **Reference Profile** input options: Profile File (an existing .PRO file), Screen Profile (existing grid and polyline profile), or None (allows you to specify station-elevation points without referencing a profile). If the Screen Profile option is used, the profile polyline direction must match that of the stationing on the grid.

There are two **Output Options**: Report and Label Profile. The Report option will send the output data to the standard report viewer, which can then be printed, saved to a file or plotted in the drawing. The Label Profile option will create text on the existing grid and polyline profile. With either option, the user will be prompted to enter or pick the station to report unless the **Report at Interval** option is checked on. In this case, the reporting will be done automatically at the interval specified. With the Label Profile option, the user has the additional options for defining the data to be labeled(Station, Elevation, Both or None), the slope format and the vertical position of the text on the

grid. The **Label Orientation** choose between horizontal and vertical labels.

This command can also be used as a profile inspector. As you move the cursor around, the station, elevation and profile grade are displayed in a real-time window, unless you specify the more automatic "report at interval" method. If Prompt for snap is set on (available in non-interval mode), then when a point on the profile is picked, you have the opportunity to snap to an even 1, 5 or 10 stations.

Prompts

Pipe Depth Summary

This command reports the horizontal distances for the range of depths comparing a surface profile to a trench, pipe or sewer profile. There is an option to use two surface profiles and the program will use the minimum of the two depths. In addition to the report, the depth ranges can be labeled along the profile in the drawing.

The simplest of applications of this command, comparing a sewer profile to a surface profile and reporting the depth summary according to the specified Depth Zones, is shown below.

Use Trench Template for Volumes: Trench templates are made using the command Trench Template Editor within the Profile Utilities "flyout". Trench earthwork volumes are then computed.

Report Backfill Volumes: Available if trench templates is clicked on.

Use Rock Strata Profile: If clicked on, the Rock Profile can be entered in the lower portion of the dialog, and if the pipe invert is below rock surfaces along any segment, rock linear feet will be reported, in the same depth categories as used for trench depths. In the example shown below, if rock depth is uniformly 5 feet below surface elevation, in the form of a rock profile, rock quantities are 348 feet of 0-2 feet depth of rock trenching.

Use 2nd Surface Profile to Minimize Cut: If the final grade is below existing grade, in those areas, it saves trenching work to first do the cut to final grade, prior to filling over existing grade in areas of fill. Then trench depths are minimized. This option, if clicked on, computes trench depths to the minimum of the two specified surfaces, and activates the 2nd Surface Profile option in the lower portion of the dialog.

Extend Shorter Profile to Longer Profile: This option will extrapolate the starting and ending stations of the shorter profile to match the longer profile.

Draw Zone Dimensions on Profile: The depth zones will be annotated along the horizontal axis of a profile drawing with this option.

Report Manhole Depth Summary: This leads to the depth summary report.

Depth Zones: These zones are for reporting the pipe range of depth. The depths should be entered in lowest to highest order. Use the Next and Back buttons to move between the 20 possible depth values.

Prompts

Prerequisite: Two profiles, one for the surface and one for the pipe invert elevation

Label Profile On Centerline

This command labels a road profile on a centerline in the plan view. First you are asked to select a road profile and a centerline. Then on the Label Profile On Centerline Settings dialog, you need to choose which labels to draw. The left list shows the available labels to draw, the right list shows the label that have been chosen to draw. **Add** button moves the highlighted label on the left list to the right list, **Remove** button moves the highlighted label on the right list to the left list, and **Setup** button allows you to edit the options of how to display the highlighted label in the plan view.

The available labels include:

PVC, PVI, PVT, High and Low Points: To label the station and/or elevation of the profile at these points.

Slope: To label each different slope in the profile.

Station At Interval: To label the stations along the centerline at a station interval.

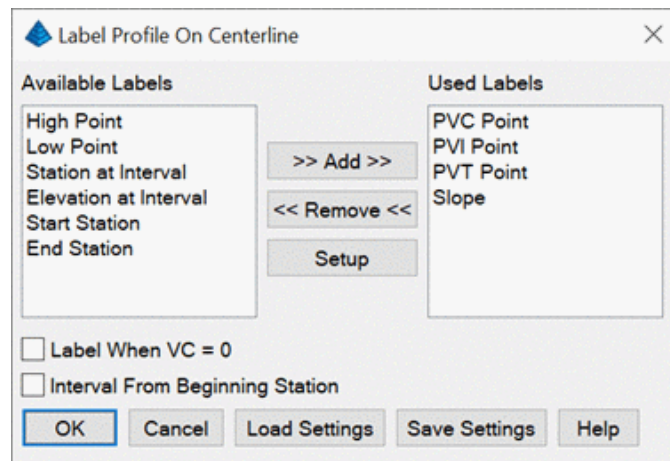

Elevation At Interval: To label the profile elevations at a station interval.

Start Station: To label the profile starting station.

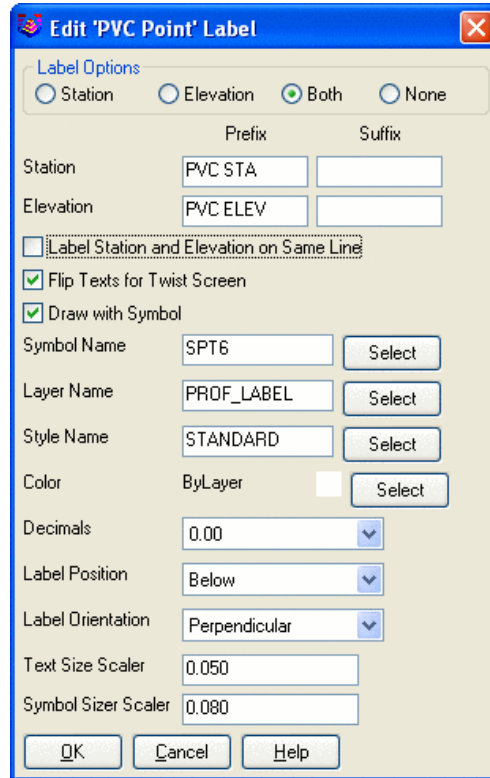

End Station: To label the profile ending station.

On the point label edit dialog, you may choose to display either the station or elevation, or both, or neither of them, and specify their prefix or suffix. If you choose to label both the station and the elevation, the labels are drawn in two lines by default, unless you elect the option to **Label Station and Elevation on Same Line**. When the screen is twisted, some of the labels would possibly be drawn upside down, the **Flip Texts for Twist Screen** option flips the text to the proper direction. **Draw with Symbol** setting draws a symbol at the position of the label. Next, you would select from a list the **Symbol Name**, **Layer Name**, **Style Name** and **Color** for displaying the label. The **Label Position** can be set to **Above** or **Below** the centerline or to the **Left** or **Right** of the centerline. There are three **Label Orientation** settings: **Horizontal**, **Parallel** and **Perpendicular**. **Text Size Scaler** and **Symbol Size Scaler** determine the size of the text label and symbol label respectively in plan view. The **Interval From Beginning Station** setting controls whether the station interval increments from the starting station of the centerline or from zero. The **Label When VC = 0** option will label profile stations that have a vertical curve of zero.

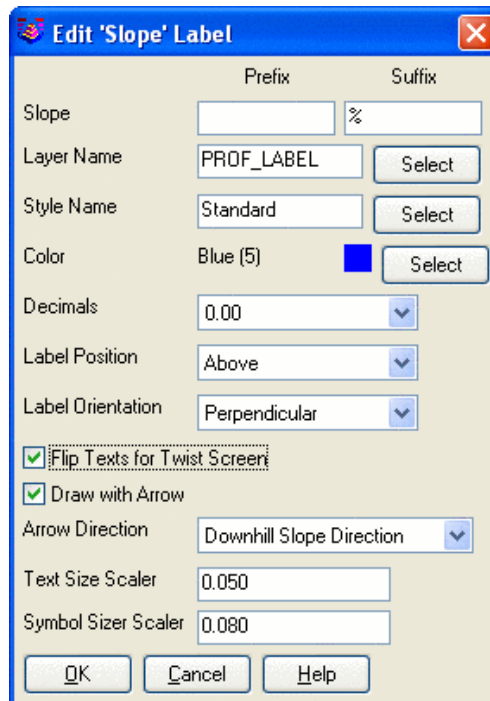

The slope label edit dialog is very similar to the point label edit dialog, the big difference is the **Arrow Direction**. There are four arrow directions: **Centerline Direction**, **Uphill Slope Direction**, **Downhill Slope Direction** and **Away from PVI**.

Label profile On Centerline Settings Dialog

An example dialog for editing PVC Point Label

An example dialog for editing Slope Label

Here's a site design example shown below, where a profile is labeled on the centerline. The PVI labels are above and parallel to the centerline, the PVC and PVT labels are below and perpendicular to the centerline, and the slopes are above and perpendicular to the centerline, their arrows are in the downhill slope direction.

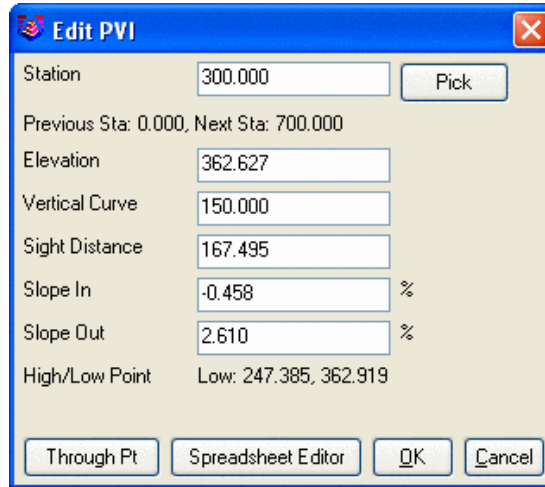

Site Design Example

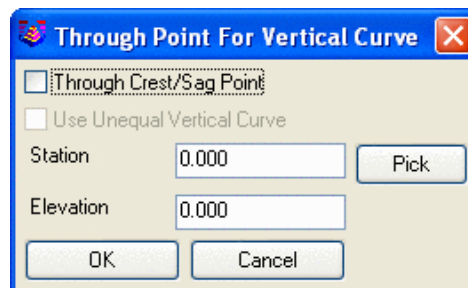

A closer look of profile labels

If the road profile is modified by a Carlson program, the profile labels will be updated automatically. When you double-click on one of the labels, a dialog of the labeled PVI section will pop up for editing. In the sample dialog show below, you can modify the station, elevation, and other parameters of the PVI point. **Pick** button allows you to pick on the screen to get the station. **Through Pt** button opens a dialog where you can define a point on the profile to pass through the fixed station and elevation. When click on **Spreadsheet Editor** button, the road profile editor is opened for you to edit road profile.

Edit PVI Dialog

Through Point Dialog

Pulldown Menu Location: Profiles > Label Profile On Centerline

Keyboard Command: proflabel

Prerequisite: a road profile file (.PRO), a centerline in the plan view or a centerline file (.CL)

Profile ID

This command reports the profile file name, horizontal scale and vertical scale that was used to draw the selected drawing entity. Simply pick a profile entity in the drawing and the profile file name is reported in the command text window. The profile must be drawn in Carlson by completing the Draw Profile command (without aborting the command by pressing Esc).

Prompts

Select profile entity to identify: *pick an entity*

Horizontal Scale: 50.0 **Vertical Scale:** 10.0

Profile Name: sewer.pro

Select profile entity to identify: *press Enter to end*

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: profid

Prerequisite: Profiles drawn on the screen

Review Profile Links

This command shows a list of all the profile links that the program knows about in the current drawing. These links are between the profile files and the drawn profiles in the drawing. You can use the Remove button to remove links for any obsolete profiles or if you don't want to link a certain profile.

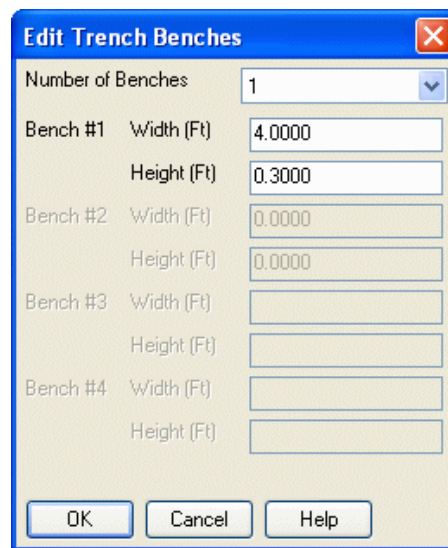

Pulldown Menu Location: Profile->Profile Utilities

Keyboard Command: profdict

Prerequisite: None

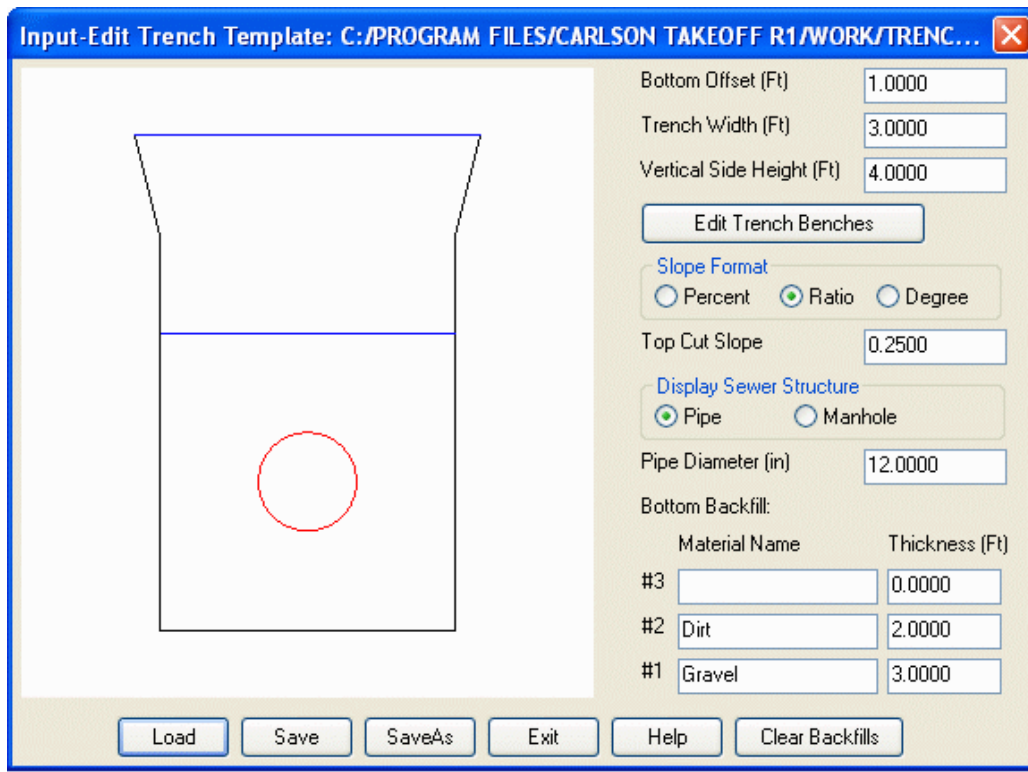

Trench Template Editor

This command lets you create a new trench template or modify an existing trench template. It prompts you the **Trench Template Editor Dialog**. If you are modifying a trench template, click the **Load** button on the dialog to open a trench template file and display the template data on the dialog. Enter the dimensions of the trench: bottom offset, trench width and vertical side height. The Edit Trench Benches button will bring up the below dialog, and allows you to enter in up to four benches into your trench.

Number of Benches		1
Bench #1	Width (Ft)	4.0000
	Height (Ft)	0.3000
Bench #2	Width (Ft)	0.0000
	Height (Ft)	0.0000
Bench #3	Width (Ft)	
	Height (Ft)	
Bench #4	Width (Ft)	
	Height (Ft)	

There are three methods for entering the cut slope, Percent, Ratio and Degree. Choose one of the methods and enter the slope value. There are three trench bottom backfill layers that can be defined. Enter the layer label in the material name field, the depth of the layer in the thickness field. Click Save or SaveAs to save the template information in a .tch file, and Click Exit to quit this command.

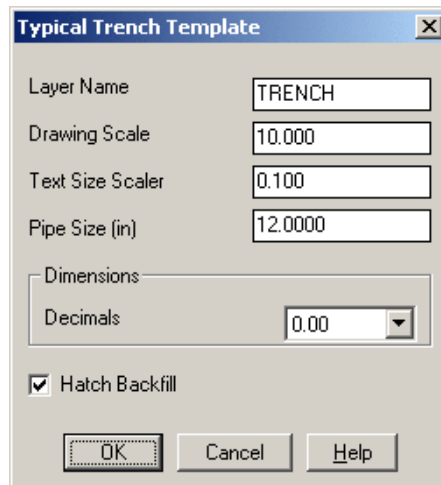

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: make_trench_tpl

Prerequisite: None

Draw Typical Trench Template

This command draws a trench template on the screen. After you select a trench template file (.tch) to draw, a **Typical Trench Template Dialog** is prompted for entering the layer name, drawing scale, text size scalar, pipe size and selecting how many decimal points you want. You can also hatch the backfill on the drawing. Click OK to draw the template at the position that you pick on the screen.

Prompts

Pick position to draw template: *pick a position on the screen*

Pulldown Menu Location: Profiles > Profile Utilities

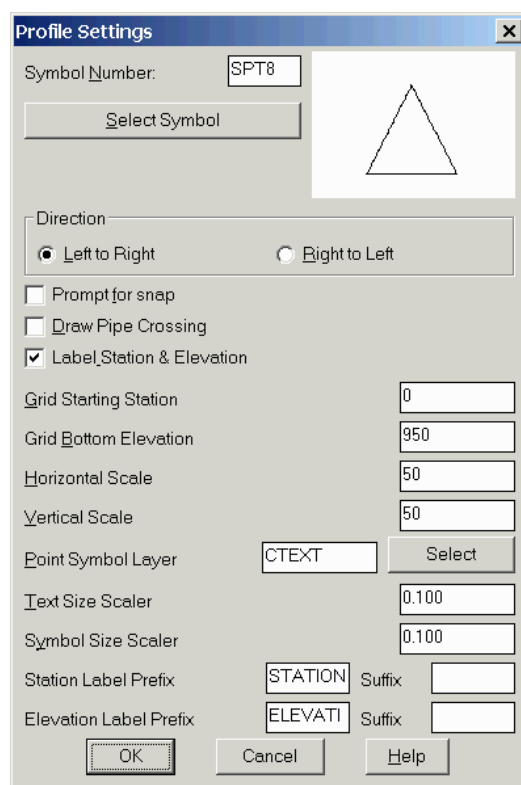

Keyboard Command: draw_trench_tpl

Prerequisite: None

Point Placement on Profile

This command has two methods for placing points on a profile. One method places symbols on an existing profile at picked points or at entered stations and elevations. The station and elevation of the current position of the crosshairs is displayed in the lower right of the screen menu. The symbols can be any of the point symbols or a special pipe crossing circle that will become an ellipse to represent any vertical exaggeration.

The other method will draw an entirely new profile based on points that are defined in a coordinate (.CRD) file. The elevations of the profile come from the elevation of the points and the stations come from the station value in the description field of the point. Points without the station value in the description field and points with a zero elevation are ignored. The station text in the point descriptions can be generated with the *Calculate Offsets* command in the Centerline menu. Using SurvCE, the Carlson data collection program, you can gather points in the field and store their station as the beginning of the description, and these points would then plot as a profile using this command.

Prompts

Place points from CRD file or pick points (File/<Points>)? *pick*

Restricted Grade Design

This command draws a retaining wall symbol in profile view and draws the excavation tie slopes from the base of the wall to the ground profile.

The program first prompts to select the retaining wall section symbol. To add custom symbols, create a wallXX.dwg in the Carlson SUP folder where XX is the wall number. For example, create a drawing wall3.dwg in the %appdata%\Carlson Software\Carlson2014\r18.2_x64\sup folder. This dwg should have one polyline drawn left to right to outline the wall section. The polyline should be open along the bottom. The wall1.dwg and wall2.dwg are examples of how to draw the wall section polyline.

After selecting the wall section, the program prompts for the tie slope and the base placement offset which is the offset from the base of the retaining wall to the bottom of the tie slope. Next there are prompts for the horizontal and vertical scales of the profiles which set the vertical exaggeration for the drawing. Then the program prompts for the insertion point for the base of the wall. Finally there is a prompt for selecting a ground polyline on the profile to intersect with the tie slopes.

Prompts

Tie slope ratio <1.000>: *press Enter*

Base placement offset <1.000>: *press Enter*

Horizontal Scale <50>: *press Enter*

Vertical Scale <50>: *press Enter*

Select ground polyline (ENTER for None): *pick polyline*

Total Wall Area: 12.00, Above Ground: 0.22, Below Ground: 11.78

Do another retaining wall [*<Yes>/No*]? *No*

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: rwallsym

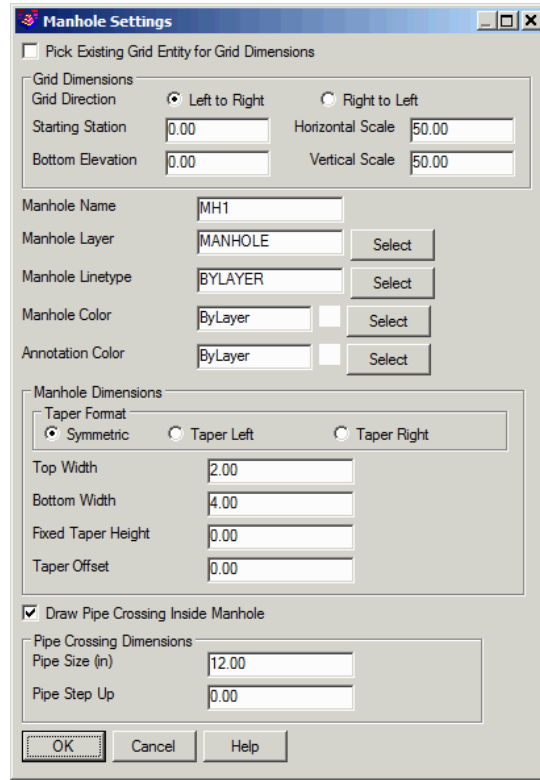

Prerequisite: None

Draw Single Manhole

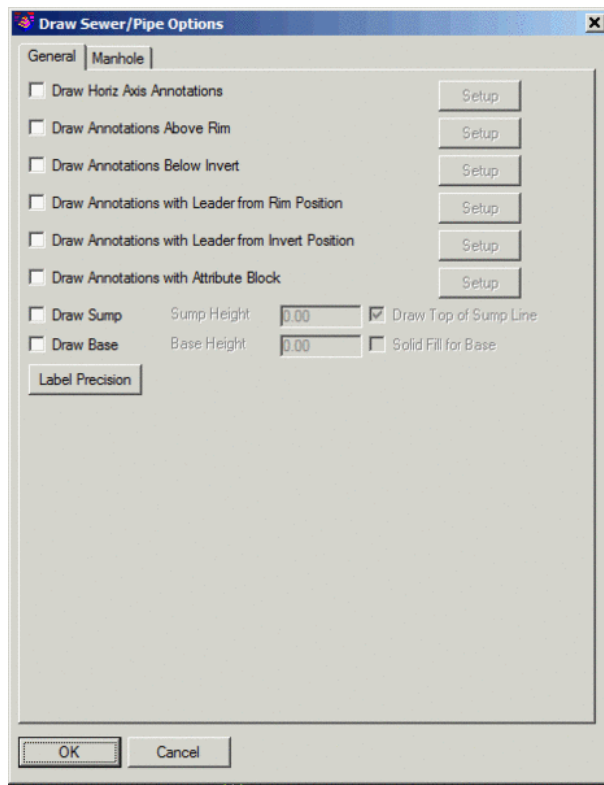

This command draws and labels a single manhole on a profile grid from user selected points at the desired bottom and top locations of the manhole. The user specifies the horizontal and vertical scales, layer and drop across manhole. Other options include the manhole top and bottom width, top taper offset and the fixed taper height. The Top Taper

Offset sets the distance from the top of the manhole to the point that the taper will end. A 2-foot offset on a 7-foot manhole is shown below. The Fixed Taper Height determines the overall length of the tapered section.

The manhole station, manhole elevation and rim elevation can be screen picked points on the profile or these values can be typed in at the command line. When using screen picks, the program shows the values of the picked positions in a dialog which allows for rounding or editing of the values.

The first dialog has the settings for the profile grid and the manhole parameters.

The second dialog has the label settings. These settings are the same as Draw Profile. See the Draw Profile topic in the manual for information on these settings.

Prompts

Enter manhole rim elevation or pick a point (Enter to End): *pick the surface point*

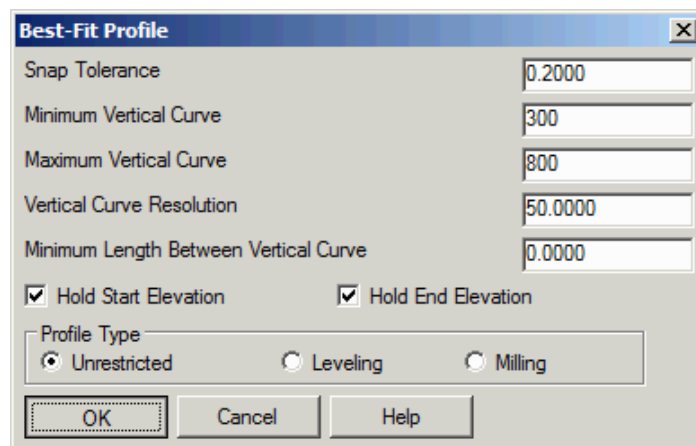

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: manhole

Prerequisite: Profile grid in drawing

Best Fit Profile

This command processes an input profile that has data points at an interval and creates a best-fit profile with tangents and vertical curves. Each tangent segment in the profile is calculated by the best-fit line least-squares method and each vertical curve is determined by calculating vertical curve lengths between the specified Minimum and Maximum Vertical Curves at the Vertical Curve Resolution and choosing the length with the smallest residuals. The input profile represents the surveyed of the existing profile. One method to create this input profile from survey point data is to use Triangulate & Contour to make a TIN surface from the points and then use Create Profile From Triangulation Surface.

In the process options dialog, the Snap Tolerance is the max offset from the point to the profile which is used for finding the best-fit tangent segments. The Minimum and Maximum Vertical Curve values control the range of possible vertical curve lengths. The Vertical Curve Resolution is used to round the resulting length to this value. The Hold Start and End Elevation options keep the original profile elevations for matching an existing road. For Profile Type, Leveling keeps the best-fit profile from going any lower than the original profile, and Milling keeps the best-fit profile from going any higher than the original profile.

The residual for each point is the elevation difference from the point to the best-fit profile. The results are shown in a dialog and you can toggle each point for whether to include in the calculations. Points that are toggled off are not used for calculating the profile but are still used in the residual report. The Remove function removes the point from both calculation and residual reporting. After picking OK on the results dialog, the program prompts for the profile to create with the best-fit results.

Station	Elevation	Residual	Process
732+58.955	927.519	0.026	Yes
732+74.094	927.528	0.023	Yes
732+84.984	927.509	-0.005	Yes
733+12.021	927.528	-0.006	Yes
733+24.312	927.579	0.035	Yes
733+30.257	927.525	-0.024	Yes
733+38.175	927.570	0.015	Yes
733+47.014	927.534	-0.028	Yes
733+72.478	927.558	-0.024	Yes
733+82.343	927.599	0.009	Yes
733+94.652	927.591	-0.009	Yes

This example Draw Profile shows the input profile and the best-fit profile along with elevation difference labels between the input profile break points and the best-fit profile.

Prerequisite: Two profiles

Average Profiles

This command averages up to four profiles and stores the resulting profile into a user-specified file name. Profiles that don't share the exact profile range will be projected to match the low and high stations in the selected profiles, after which the averaging will be computed.

Prompts

1st Profile file to Average dialog Specify a profile file.

2nd Profile file to Average dialog Specify a profile file.

3rd Profile file to Average dialog Hit Cancel to stop selecting profiles.

Choose Profile to Write Specify a profile file.

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: avgpro

Prerequisite: Two or more profile files

Draw Pipe 3D Polyline

This command creates a 3D polyline that represents a pipe. The points can be either picked on screen or specified by point number in the current coordinate file. This command is a convenient way to make 3D polylines that can become "pipe polylines" used for capturing their profile positions, leading to circular or elliptical or even square plots of the pipes or culverts within Draw Profile. However, this command is not required nor sufficient to make a pipe polyline useful in the *Draw Profile* command. Pipe polylines are made only by converting 3D polylines into pipe polylines using the adjacent command, *Assign Pipe Width to Pline*.

Prompts

Layer Name for 3DPoly <PIPE>: *press Enter*

Prompt for elevations (.XY filter) (Yes/<No>)? *Y for yes*

Undo/<Pick point or point numbers>: *pick a point*

Elevation <0.0>: *554.12*

Undo/<Pick point or point numbers>: *pick a point*

Percent slope/Ratio slope/Elevation <0.0>: *553.72*

Undo/Close/<Pick point or point numbers>: *press Enter*

Draw another 3D polyline (Yes/<No>)? *press Enter*

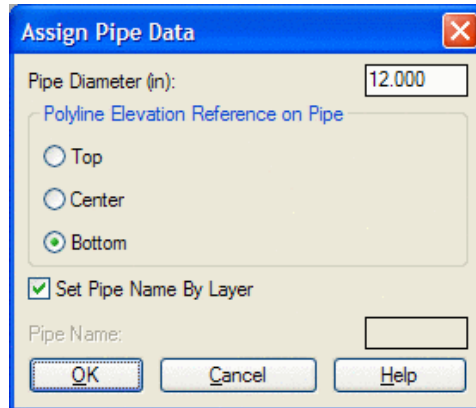

Pulldown Menu Location: Profile->Profile Utilities

Keyboard Command: drwpipe

Prerequisite: None

Assign Pipe Width to Polyline

This command attaches a pipe width to one or more polylines. Any polyline can be used, but it should be a 3D polyline that represents the elevations of the pipe. Pipe width is used in commands such as *Profile from Pipe Polylines* and *Section Points from Pipes* commands.

Prompts

Select polyline: *pick a polyline*

Enter pipe width (in): 18

Set pipe width for 1 polylines.

Select polyline (Enter to End): *press Enter*

Pulldown Menu Location: Profile->Profile Utilities

Keyboard Command: plwidth

Prerequisite: A polyline

Identify Pipe Polylines

This command reports pipe data tagged to polylines by the Draw Pipe 3D Polyline or Assign Pipe Data To Polyline commands. There are two methods. The Pick method prompts to select a polyline and reports its data. The Search method checks all the polylines in the current drawing and reports all the pipe data from the drawing and highlights the pipe polylines.

Prompts

Pick polylines to check or search drawing [<Pick>/Search]? *press Enter*

Select pipe polyline: *pick a polyline*

Polyline is set as pipe. Size: 12.0" Reference: Bottom

Select pipe polyline (Enter to end): *press Enter*

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: id_pl_pipe

Prerequisite: Pipe polylines

Label Pipe Polylines

This command labels pipe values in plan view for 3D polylines that are tagged with pipe data. See the Plan View Label Settings command in Hydrology > Network for information on the label settings.

	Position	Prefix	Suffix	Sequence
<input checked="" type="checkbox"/> Label Pipe Length	Above Pipe			1
<input checked="" type="checkbox"/> Label Pipe Size	Below Pipe		"	1
<input checked="" type="checkbox"/> Label Pipe Slope	Above Pipe		%	1
<input checked="" type="checkbox"/> Label Pipe Name	Above Pipe			1

Slope Format
 Percent Ft/Ft

Pipe Direction Label: Arrow On Pipe

Slope Decimals: 0.00 Length Decimals: 0.00

Text Size Scaler: 0.100 Arrow Size Scaler: 0.100

Label Layer: SWRNET Set Label Style: ROMANS Set

OK Cancel Load Save Help

Prompts

Label Pipe dialog

Select pipe lines to label.

Select objects: pick 3D polylines with pipe data

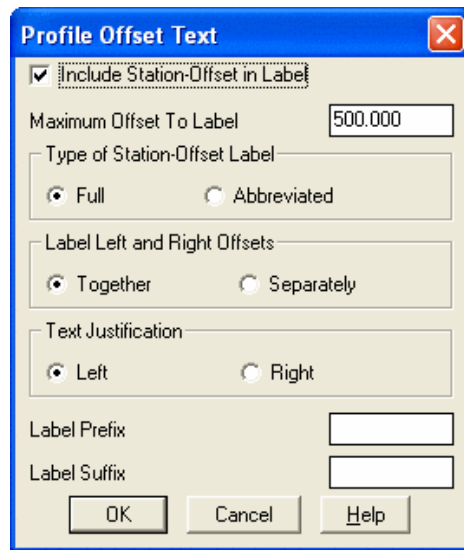

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: labpipe

Prerequisite: 3D polyline with pipe data

Profile Offset Text

This command draws station/offset and description text for points along a centerline polyline at a picked vertical position on the screen. It works well when used on combined Plan and Profile sheets, where the offset text can be plotted in the profile portion. The text is drawn vertically and is positioned horizontally at the station of the centerline. The station and offset of the point can optionally be included in the text. The points can either be picked or specified by point number. After picking the point, a text editor allows you to type in additional text for the label. For centerlines that are not roughly East-West, use Twist Screen under the View pulldown to re-orient the centerline to a near horizontal position on the screen. Only the "pick point or point number" option will display the edit box for the description.

Include station-offset in label: When clicked on, the calculated station and offset text is plotted.

Full or Abbreviated: The abbreviated form leaves off the even 100 feet in front of the stationing, and saves some space. Station 14+50.23 would plot as +50.23.

Label Left and Right Offsets (Together or Separately): The "Separately" option will ask for a horizontal alignment point for left and another for right offsets. Otherwise offsets will be labeled along one horizontal alignment based on one pick.

Text justification (Left or Right): Left plots down the screen and right will plot up the screen.

Label Prefix: Will place this prefix in front of the station and offset or entered text for the picked position. For example, the word "Sta." could be added as a prefix, leading to a plot such as Sta. 14+50.23.

Label Suffix: Will append this suffix to all text for each picked position.

Prompts

Profile Offset Text Dialog *make choices, click OK*

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: *pick the centerline*

Starting station of centerline <0.0>: *press Enter*

Pick horizontal alignment for text: *pick a point*

Pick point or point number (SS for Selection Set, Enter to End): *pick a point*

Profile Offset Text dialog

Pick point or point number (Enter to End): *press Enter*

Profile Offset Text along a centerline

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: protext

Prerequisite: A centerline polyline

Label Profile Differentials

This command labels the elevation difference between two profiles at specified stations. The text label is drawn along the polyline centerline in plan view. Cut is labeled as negative and fill as positive.

Prompts

Existing Ground Profile dialog Specify a profile file to read.

Final Surface Profile dialog Specify an existing profile file to read.

Select centerline polyline: Pick a polyline. This represents the centerline and should be drawn in the direction of increasing stations.

Starting station of polyline <0.0>: *press Enter*

Label all polyline vertices (<Yes>/<No>)? *press Enter* This option will label the elevation difference at the stations of each point on the polyline centerline.

Pick points to label (Yes/<No>)? *press Enter* This option allows you to pick points along the centerline to label.

Prompt for text position (Yes/<No>)? *press Enter* This option allows you to pick the position of each elevation difference label. Otherwise the text is automatically centered at the point on the polyline.

Text size <4.00>: *press Enter*

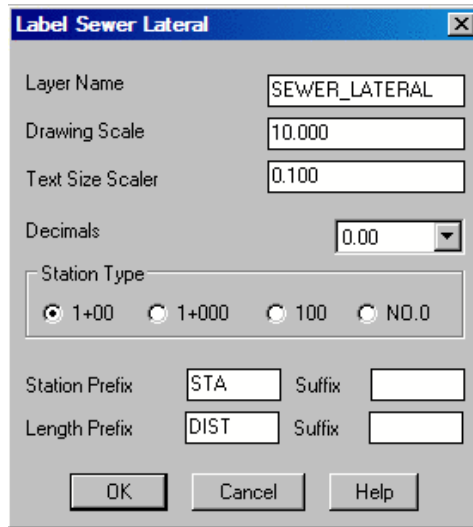

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: prodiff

Prerequisite: Two profile files

Label Sewer Laterals

This is a command to label, in plan view, the sewer laterals in linear feet. This includes a station distance from a known starting station on the main line, as well as the length of the lateral itself from the main sewer line to the property. You may optionally include a prefix and/or suffix for both the station and lateral labels.

Prompts

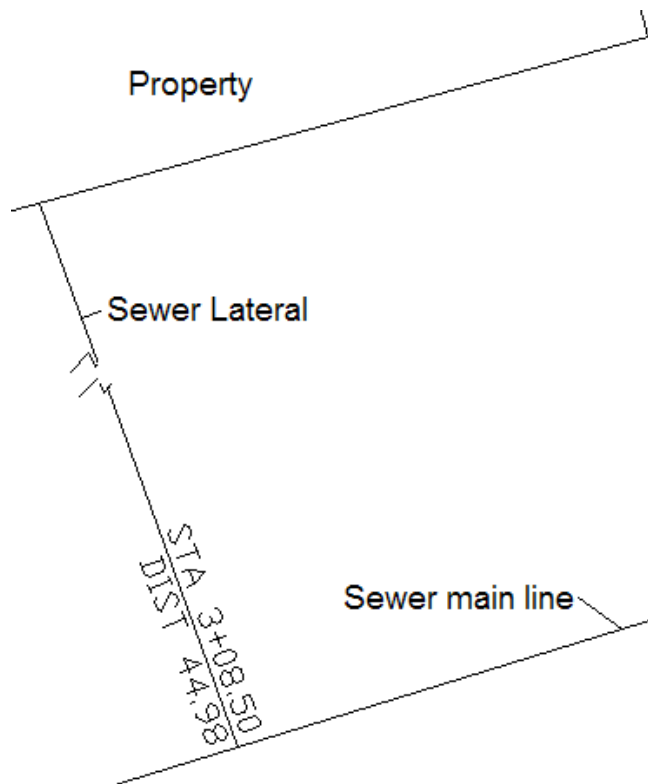

Label Sewer Lateral dialog Specify your preferred values.

Pick centerline/polyline that represents a sewer: *pick an entity*

Starting Station of the sewer <0.0>: *press Enter*

Pick a lateral intersection point (Enter to end): *pick an intersection point*

Pick a lateral to label: *pick entity*

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: label_sewer_lateral

Prerequisite: Sewer line with lateral(s)

International Roughness Index

This command calculates and reports the international roughness index for a profile. The command starts by prompting for the profile .PRO file.

The dialog box 'Calculate International Roughness Index' contains the following fields and buttons:

- Profile: C:\Carlson\Work\Manatts\E-49 Tama.pro (Set button)
- Reference CL: C:\Carlson\work\Manatts\E-49 Tama CL.cl (Set button)
- Profile Offset: 3 ft (Draw button)
- Starting Station: 1407+50.00
- Ending Station: 1688+00.00
- Overall IRI: 6.24 in/mi
- Overall Length: 27842.13 ft
- Interval: 528.00 ft (Calculate button)

Starting Station	Ending Station	IRI (in/mi)	Classification
1407+50.00	1412+78.00	7.76	Extreme
1412+78.00	1418+06.00	7.85	Extreme
1418+06.00	1423+34.00	3.43	Rough
1423+34.00	1428+62.00	17.20	Extreme
1428+62.00	1433+90.00	15.12	Extreme
1433+90.00	1439+18.00	8.42	Extreme
1439+18.00	1444+46.00	0.98	Medium
1444+46.00	1449+74.00	2.53	Rough
1449+74.00	1455+02.00	8.91	Extreme
1455+02.00	1460+30.00	2.81	Rough
1460+30.00	1465+58.00	4.89	Rough

Buttons: Setup Classification, Report, OK, Cancel, Help

The command opens to the Calculate International Roughness Index dialog and is initially set to the Starting and Ending Station values of the selected profile .PRO file. The profile .PRO file can be edited with the edit control or selected by pressing the Set button. The Starting and Ending Stations can be adjusted to isolate a specific area of interest along the profile. The IRI is calculated and output for the length of profile's station range. An Interval can be applied to calculate the IRI on an interval along the profile's station range. Use the Interval toggle to supply the interval distance and then press the Calculate button to run the calculation on the interval.

Additionally, a Reference Centerline can be set by pressing the Reference CL Set button. When a reference centerline is supplied, there is additional ability to output the International Roughness Index classifications to the drawing. Use the Profile Offset to supply the track that the profile is offset from the centerline and press the Draw button to output the classifications to the drawing.

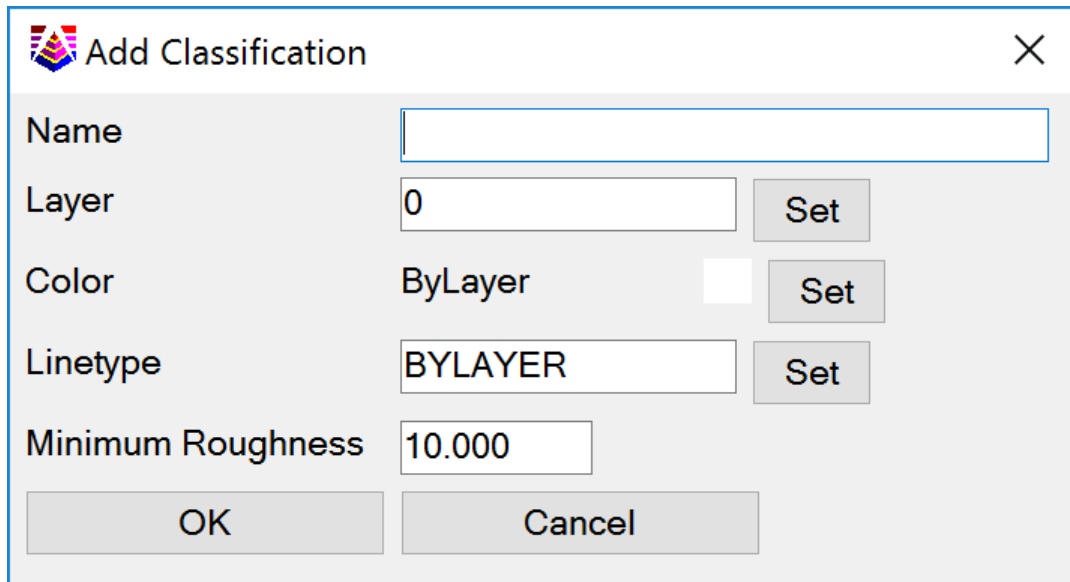

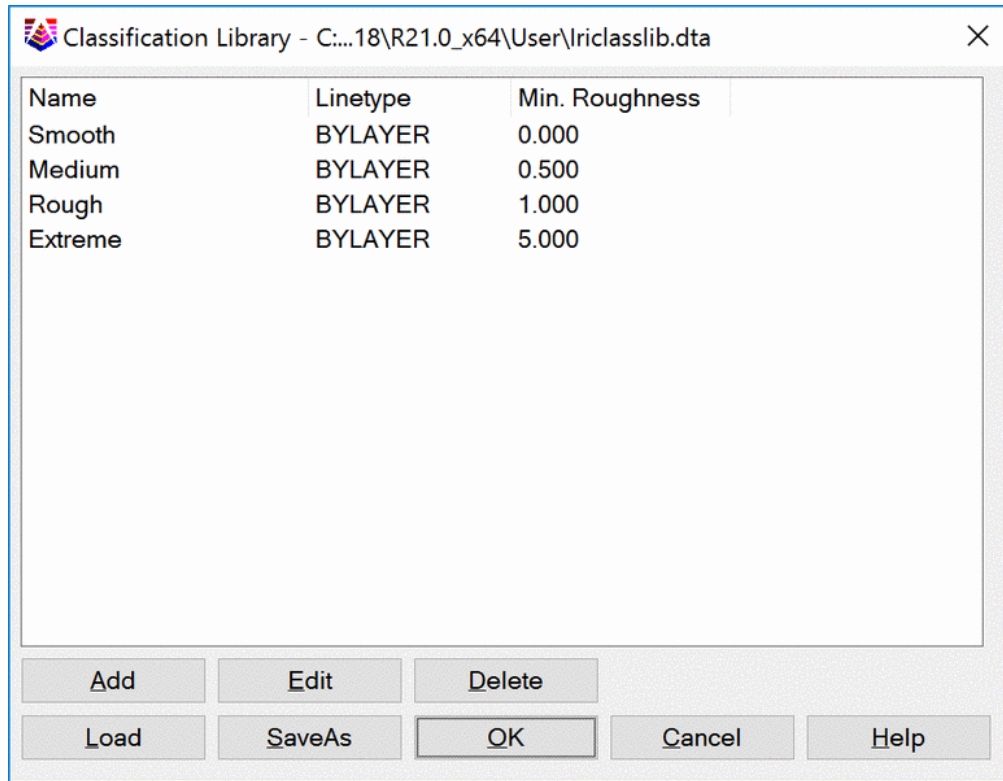

Setup Classification

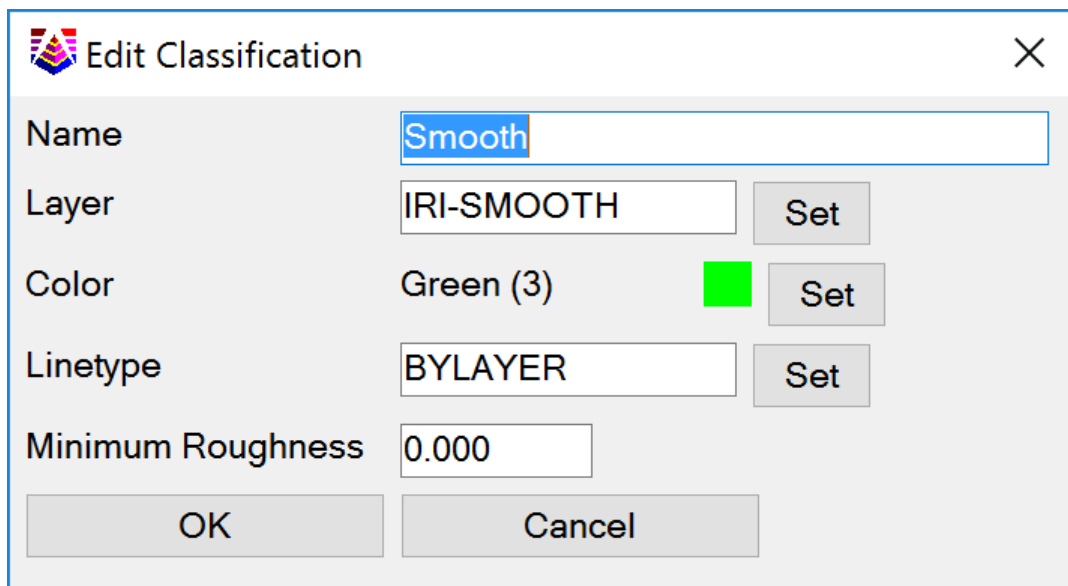

This defines a collection of roughness classifications. Each classification has a Name for a description, Layer, Color, Linetype and Minimum Roughness. Use the Add, Edit and Delete buttons to manage the list of classifications.

When the classifications are defined in the library, use the Draw Profile Offset to create the classifications in the drawing.

The current Classification Library is stored in the current USER folder under Documents & Settings in a file called

iriclasslib.dta. The Load and SaveAs functions can be used to store and recall the classification library to a .IRL file for archiving or sharing.

Report

Use the Report button to customize or "user define" the reporting options. The Report Formatter Options dialog box offers a variety of output options. You can choose the fields to report from the Available list and put them in report order under the Used list.

Selecting the Display option shows the report in the standard Carlson report viewer. Reports can be exported to an Excel spreadsheet as well.

Pulldown Menu Location: Profile > Profile Utilities

Keyboard Command: calciri

Prerequisite: .pro file

Restricted Grade Design

This command calculates the length of vertical curve required if the grade change is restricted to a rate of change per 100 feet/units.

Prompts

Percent of Grade + for uphill - for downhill.

Line select/<Percent of grade in <2.0>>: L

[nea on] select Line that defines grade in: *pick the line*

Slope Distance> 900.89 Horizontal Distance> 900.00

Elevation Difference: -40.00 Slope Ratio: -22.50:1 Slope Percent: -4.44

Line select/<Percent of grade out <-2.0>>: 2.5

Percent of grade change restriction per 100 linear units <2.0>: *press Enter*

Required length of vertical curve> 347.22

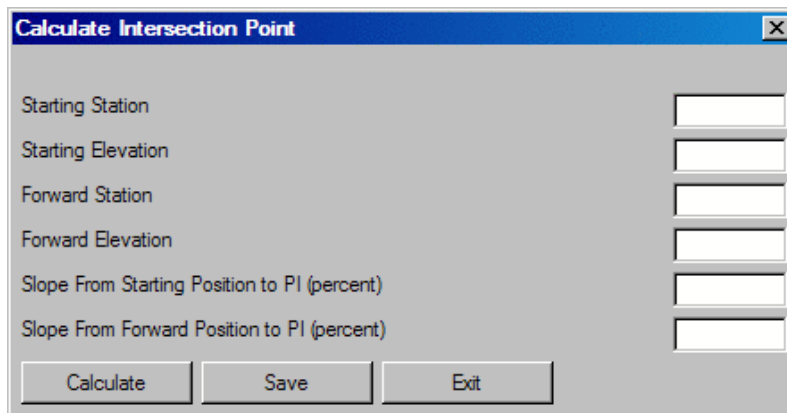

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: vcrj

Prerequisite: None

Calculate Intersection Point

This command is a profile utility that is used to find the intersection from two points and given slopes.

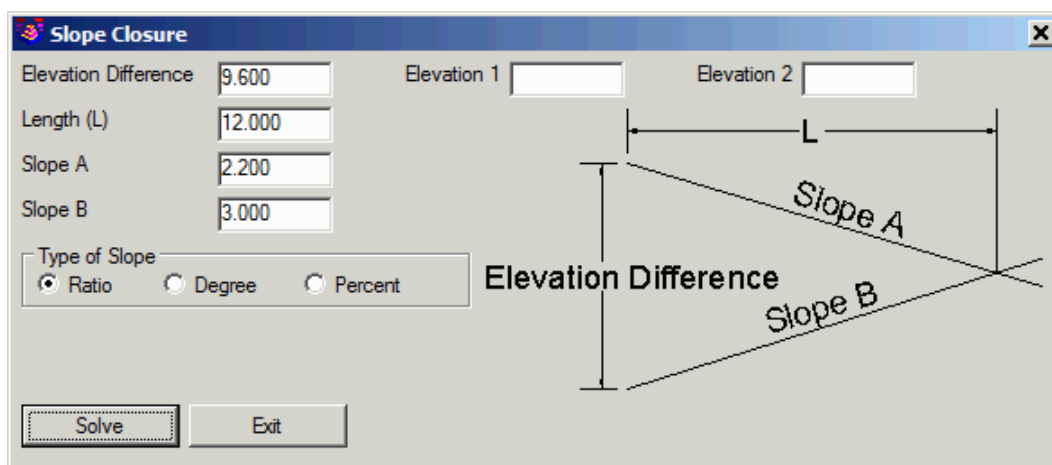

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: calc_pro_pi

Prerequisite: None

Slope/Length/Elevation Calculator

This command calculates length given two slopes and elevation difference or elevation difference given two slopes and length. The elevation difference can be entered directly or enter two elevations to have the program calculate the elevation difference. To run, fill in the input values and pick the Solve button.

Pulldown Menu Location: Profiles > Profile Utilities

Keyboard Command: slope_calc

Prerequisite: None

Sight Distance Design

This command computes the length of vertical curve required for a user-specified sight distance, grade in, and grade out. The object height and eye height may be set using the Settings > Carlson Configure > Section-Profile Settings command.

Prompts

Percent of Grade + for uphill - for downhill.

Line select/<Percent of grade in <2.0>>: L

Select Line that defines grade in: *pick the line*
Slope Distance> 600.33 Horizontal Distance> 600.00
Elevation Difference: 20.00 Slope Ratio: 30.00:1 Slope Percent: 3.33

View Table/K value/Sight distance/<Length of Vertical Curve <450.000>>: 350
With SD<VC Length, Crest Sight Distance> 289.37 K Value>63.00

Pull-down Menu Location: Profiles > Profile Utilities

Keyboard Command: vctan

Prerequisite: None

Enter Roadside Ditch

With this command you enter station and elevation profile data and pipe data which is stored in a file and can then be used by Draw Roadside Ditch. The roadside ditch consists of ditch, pipe and road profiles for the left and right side of a road centerline.

The program first asks whether to read an existing file. This option allows you to add data to an existing file so that you don't have to enter all the data in one run. Before entering the profile data, the program asks for the names for the profiles on the left and right side such as shoulder and edge of road. There can be any number of named profiles. Ditch and pipe profiles do not need to be named because the program always includes these. Along with the profile name, the program also asks for a layer name to use with each profile. The layer name is used in Draw Roadside Ditch to put the profiles in different layers that can give the profiles different colors and linetypes.

Then the program begins a cycle of asking for stations and elevations. First you need to specify whether the next data is for the left or right side by entering *L* or *R*. Then enter the station followed by the profile type (either Ditch, Pipe or Roads). The ditch profile type prompts for the ditch elevation. The pipe profile type prompts for pipe elevation, ending pipe station and elevation, pipe size, pipe type, and data about what the pipe is going under. The roads profile type prompts for the elevations for each of the named profiles. If there is no elevation for one of them, just press Enter. Once all the station and elevation information is entered, enter *End* at the next station prompt. Then specify a file to save the roadside ditch data. The file has a .RDS extension and is a text file that can be edited if necessary.

Prompts

Add to existing roadside file (Yes/<No>)? *press Enter*
Left profile name or Enter for none: *EDGE OF ROAD*
Layer name for EDGE OF ROAD <ROAD1>: *press Enter*
Additional Left profile name or Enter to continue: *LT. SD. SHLDR.*
Layer name for LT. SD. SHLDR. <ROAD2>: *press Enter*
Additional Left profile name or Enter to continue: *press Enter*
Right profile name or Enter for none: *CL OF ROAD*
Layer name for CL OF ROAD <ROAD1>: *CLINE*
Additional Right profile name or Enter to continue: *EDGE OF ROAD*
Layer name for EDGE OF ROAD <ROAD2>: *ROAD1*
Additional Right profile name or Enter to continue: *RT. SD. SHLDR.*
Layer name for RT. SD. SHLDR. <ROAD3>: *ROAD2*
Additional Right profile name or Enter to continue: *press Enter*
Right/Enter Left station <0.00>: *1305*
Assign (<Ditch>/Pipe/Road)? *R*
EDGE OF ROAD elevation or Enter for none: *31.2*
LT. SD. SHLDR. elevation or Enter for none: *30.8*
End/Undo/Right/Enter Left station <1305.00>: *press Enter*
Assign (<Ditch>/Pipe/Road)? *press Enter*
Enter ditch elevation: *29.2*
End/Undo/Right/Enter Left station <1305.00>: *1307*
Assign (<Ditch>/Pipe/Road)? *P*
Enter pipe elevation: *28.48*
Enter ending pipe station: *1318*
Enter ending pipe elevation: *28.45*
Pipe size in inches <15.0>: *press Enter*
Pipe name <RCP>: *press Enter*
Enter flare width: *2*
Enter flare length: *10*
Drive type <TOP CONC. DWY.>: *press Enter*
Drive id <100>: *211*

Drive ending station <1318.00>: *press Enter*
End/Undo/Right/Enter Left station <1307.00>: *R*
End/Undo/Left/Enter Right station <1307.00>: *1321*
Assign profile (<Ditch>/Pipe/Road)? *press Enter*
Enter ditch elevation: *30.2*
End/Undo/Left/Enter Right station <1321.00>: *E*
Dialog to Specify a File to save the entered data.
Pulldown Menu Location: Profiles > Profile Utilities
Keyboard Command: rside1
Prerequisite: None

Draw Roadside Ditch

This command draws the left and right side profiles for a road as entered and stored in a file made by Enter Roadside Ditch. The profiles are drawn on a special profile sheet. To customize this profile sheet, use AutoCAD to modify the drawing ROADSIDE.DWG in the Carlson\SUP directory.

Prompts

Choose a Roadside Ditch file to draw

Horizontal scale <10.0>: 5
Vertical scale <1.0>: *press Enter*
Grid horizontal label interval <50.0>: *press Enter*
Starting station to draw <1026.00>: *press Enter*
Ending station to draw <1320.00>: *press Enter*
Pick grid location: *pick a point*

Pulldown Menu Location: Profiles > Profile Utilities
Keyboard Command: rside2
Prerequisite: A Roadside Ditch file (.RDS)

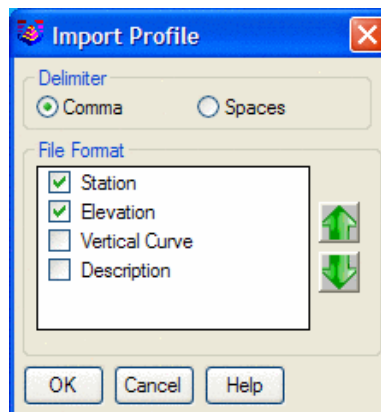

Profile Conversions

There are eleven Profile Conversion commands, all of which are listed below. The first nine in the list are Import Profile commands. These commands allow you to convert a single profile file from their respective program to the Carlson profile (.PRO) format. For each, you are prompted to select the file to be imported, then provide a Carlson profile file name. Underneath each of the nine brief descriptions shown are, in bold, the prompts that you see in dialog box form and/or on the command line.

The last two commands listed below are Export Profile commands. They allow you to convert a single Carlson profile (.PRO) file to Softdesk (.TXT) format, or a single Carlson profile (.PRO) file to Leica (.GSI) format. You are prompted to select the Carlson profile file, then provide a name for the Softdesk or Leica file.

Import Columnar Text

Allows you to Import a comma or space delimited text file to create a profile (.PRO) file.

Import CAiCE Profile

Allows you to convert a single CAiCE (.KCP) profile file to the Carlson profile (.PRO) format. You are prompted to select the CAiCE file, then provide a Carlson profile file name.

Pulldown Menu Location: Profiles > Profile Conversions
Keyboard Command: caice2pro

Import Leica Profile

Allows you to convert a single Leica profile (.GSI) file to the Carlson profile (.PRO) format. You are prompted to select the Leica file then provide a Carlson profile file name.

Choose Leica/Wild File to Read dialog Select existing file.
Choose Profile to Write dialog Select file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: wildpro2

Import MOSS Profile

Allows you to convert a single MOSS profile (.INP) file to the Carlson profile (.PRO) format. You are prompted to select the MOSS file then provide a Carlson profile file name.

Choose MOSS Profile File to Read dialog Select existing file.

Choose Profile to Write dialog Select file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: moss2pro

Import Novapoint Profile

Allows you to convert a Novapoint profile (.NYL) file to the Carlson profile (.PRO) format. You are prompted to select the Novapoint file then provide a Carlson profile file name.

Choose Novapoint Profile File to Read dialog Select existing file.

Choose Profile to Write dialog Select file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: nova2pro

Import Softdesk Profile

Allows you to convert a single Softdesk profile (.TXT) file to the Carlson profile (.PRO) format. You are prompted to select the Softdesk file then provide a Carlson profile file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: dcapro2

Import Sokkia/SDR Profile

Allows you to convert a single Sokkia/SDR (.SDR or .RAW) profile file to the Carlson profile (.PRO) format. You are prompted to select the Sokkia/SDR file, then provide a Carlson profile file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: sdr2pro

Import Spanish ALZ Profile

Allows you to convert a single Spanish ALZ profile (.INP) file to the Carlson profile (.PRO) format. You are prompted to select the Spanish ALZ file and then provide a Carlson profile file name.

Choose CLIP File to Read dialog Select existing .ALZ file.

Choose Profile to Write dialog Select file name.

Pull-down Menu Location: Profiles > Profile Conversions

Keyboard Command: alz_to_pro

Import Spanish RAS Profile

Allows you to convert a single Spanish RAS profile (.RAS) file to the Carlson profile (.PRO) format. You are prompted to select the Spanish RAS file and then provide a Carlson profile file name.

ISPOL File to Read dialog Select existing .RAS file.

Choose Profile to Write dialog Select file name.

Pulldown Menu Location: Profiles > Profile Conversions

Keyboard Command: ras_to_pro

Import Terramodel Profile

Allows you to convert a single Terramodel (.RLN) profile file to the Carlson profile (.PRO) format. You are prompted to select the Terramodel file, then provide a Carlson profile file name.

Pulldown Menu Location: Profiles > Profile Conversions

Keyboard Command: tm2pro

Export Softdesk Profile

Choose Profile File to Read dialog Select existing .PRO file.

Choose Softdesk File to Write dialog Enter new Softdesk file name.

Pulldown Menu Location: Profiles > Profile Conversions

Keyboard Command: dcapro1

Export Leica Profile

Choose Profile File to Read dialog Select existing .PRO file.

Choose Wild File to Write dialog Enter new .GSI file name.

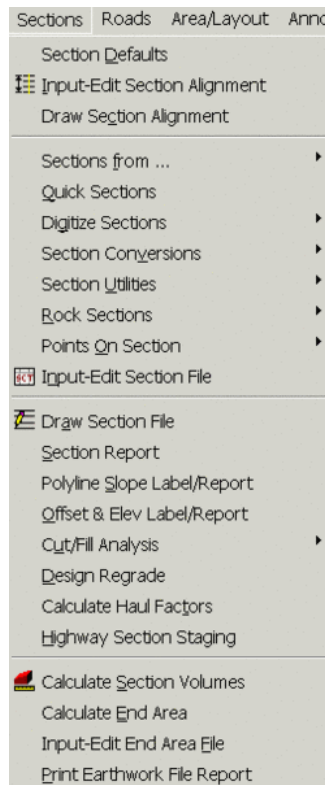

GSI file format [<8>/16]? *press Enter*

Pulldown Menu Location: Profiles > Profile Conversions

Keyboard Command: wildpro1

Section Menu

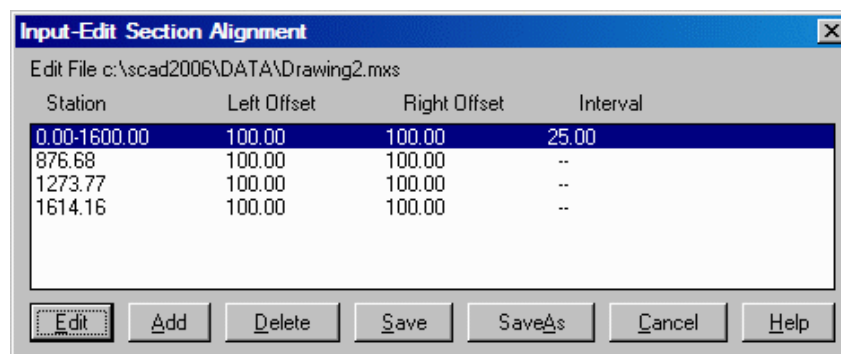

The Sections menu shown below has commands for creating, drawing and reporting sections. All commands are described in this section except for Polyline Slope Label/Report which is described under the Profiles section.

Section Alignment Editor

This command will create or append to a section alignment file which is stored as a Multiple Cross Sections (.MXS) file. This file contains the coordinates that define the center and endpoints of section lines and is a requirement of many section commands such as *Sections from Surface Entities* and *Sections to 3D Polyline*. The section alignment defines the stations along a centerline and how far left and right to create cross sections. This routine starts by asking for a new or existing .MXS file name. Then the centerline is specified by either by choosing a centerline file (.CL file) or selecting a polyline that represents the centerline. Next, the program prompts for the starting station of the centerline. If this is a new section alignment, the Make MXS File Settings dialog appears.

The Section Alignment Editor dialog lists all the section stations and offsets in the alignment of an existing .MXS file.

Dialog if using an existing .MXS file

Edit: Allows you to edit the currently highlighted row.

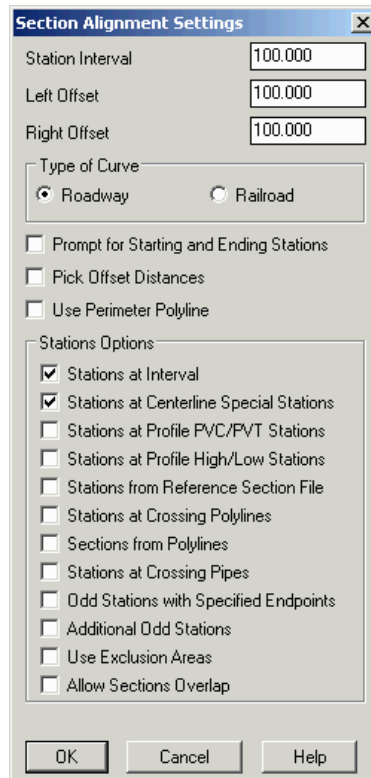

Add: Allows you to add more sections by displaying the Make MXS File Settings dialog (shown below).

Delete: Deletes the currently highlighted row.

Save: Saves the MXS file, exits this dialog and draws the section alignment on the screen using temporary vectors

(yellow for left offsets, magenta for right offsets). Any viewport change such as *Redraw* or *Zoom* will cause these vectors to disappear. The draw the section lines with Line entities, use the *Draw Section Alignment* command.

SaveAs: Saves a new MXS file with a user-specified name.

Dialog used for a new section alignment

Station Interval: Enter the station interval for sections.

Right Offset: Enter the width for the sections, right of the centerline. Not available if Pick Offset Distances is checked.

Left Offset: Enter the width for the sections, left of the centerline. Not available if Pick Offset Distances is checked.

Type of Curve: Specify either Roadway or Railroad curve to account for the differences in stationing curves.

Prompt for Starting and Ending Stations: This option allows you to specify the range of stations to process. Otherwise the program will use the full station range of the centerline.

Pick Offset Distances: Allows you to specify the offsets by using the distance between two picked points in the drawing.

Use Perimeter Polyline: Allows you to specify a closed polyline that will be used as the limit of the cross sections. The offsets will be contained within this closed polyline.

Station By Another Reference Centerline: Prompts for a separate CL to use for stationing. The program sets for station to store for the section alignment by locating the position of the original station on the section alignment centerline and then finding the station of this position along the reference centerline.

Stations at Interval: Creates cross sections at the specified interval such as every 25 feet. If the Prompt for Starting and Ending Stations is on, then the program will apply the station interval to the user-specified range of stations. Otherwise the station interval is used along the entire centerline.

Stations at Centerline Special Stations: Creates cross sections at every transition point in the centerline such as the PC, PT, spiral points and end points.

Stations at Profile PVC/PVT Stations: Creates cross sections at profile vertical curve transitions stations. When active, the program will prompt for the profile to process.

Stations at Profile High/Low Stations: Creates cross sections at profile vertical curve high and/or low stations. When active, the program will prompt for the profile to process.

Stations from Reference Section File: Creates cross sections at stations contained in the reference section file.

When active, the program will prompt for the section file to process.

Stations at Crossing Polyline: Allows you to select polylines that cross the centerline and creates cross sections at the intersections of these polylines with the centerline.

Sections from Polyline: This method prompts to select polylines that define the section alignments. This method is handy when the section alignments have multiple bends such as for HEC-RAS.

Stations at Crossing Pipes: This method creates cross sections at the stations where pipes intersect.

Odd Stations with Specified Endpoints: Creates cross sections at stations that are entered or at picked points along the centerline. This option also allows you to pick the left and right offset points which do not have to be perpendicular to the centerline.

Additional Odd Stations: Creates cross sections at the specified stations but the offsets are always perpendicular to the centerline with the user-defined default offset distances.

Use Exclusion Areas: This option prompts for selecting closed polylines to use as exclusion areas which are areas to skip for the section surface. The stations and offsets for the exclusion areas are stored in the section alignment file. Then routines like Calculate Section Volumes and Draw Sections will skip over these areas and not calculate volumes or draw section lines in these areas.

Allow Sections Overlap: On the inside of a centerline curve, section lines will cross when the section length is longer than the radius. This option controls whether to shorten the section lines on the inside of the curve or to keep the regular length and let the section lines cross.

Prompts

Specify an MXS file dialog Choose new or existing.

Polyline should have been drawn in direction of increasing stations.

CL File/<Select polyline that represents centerline>: *pick centerline*

Enter Beginning Station of Alignment <0.00>: *press Enter*

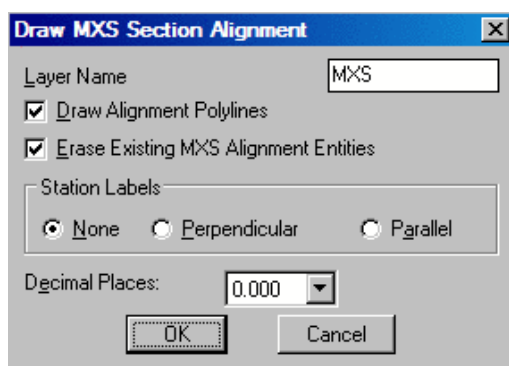

Pulldown Menu Location: Sections

Keyboard Command: editmxs

Prerequisite: A polyline centerline or a centerline .CL file

Draw Section Alignment

This command will draw the location of the cross sections contained in an existing .MXS file. The cross sections stations can also be labeled Perpendicular or Parallel. The main purpose of this routine is to allow you to graphically view the location of the cross sections.

A drawn .MXS file along with the centerline

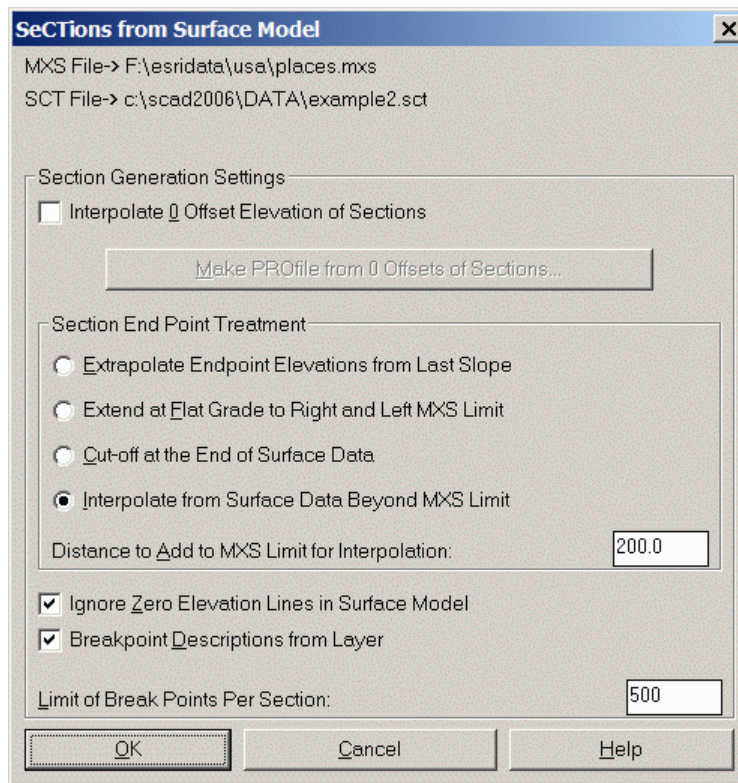

Pulldown Menu Location: Sections

Keyboard Command: drawmxs

Prerequisite: An existing .MXS file

Sections from Surface Entities

This command allows you to create cross sections from a surface model. The stations for the sections, and the left and right offset distances, are defined in the MXS file. This file must be created before running this routine by using the *Section Alignment Editor* command. The surface model is defined by lines or polylines with elevation. The polylines with elevation could be a contour drawing file from a photogrammetry firm, or it can be created from survey points with the *Triangulate & Contour* command. When using *Triangulate & Contour* it is useful to use the Draw Triangulation Lines option because the 3D triangulation lines represent all the breaklines in the surface which increases the accuracy of the cross section verses just using the contours. Breaklines or 3D polylines can also be used to represent ridges and valleys. The program samples the selected lines, polylines and 3DFace entities and calculates the intersections of these segments with any of the cross sections. The station, offset and elevation of these intersections make up the data in the section file. This section (.SCT) file can be reviewed or edited with the *Section File Editor* command. Also, the section file can be plotted with the *Draw Section File* command or used in the by the *Process Road Design* command to calculate volumes.

Interpolate 0 Offset Elevation of Sections: When checked, this option will add a data point at offset zero for every station with an elevation that is interpolated from existing offsets.

Make Profile from 0 Offsets of Sections: Allows you to specify a .PRO file name to create from the 0 offsets of the sections.

Section End Point Treatment: The section end points are the left and right furthest offsets such as left and right 100 feet. When calculating sections based on the intersections with surface entities, there usually isn't an intersection exactly at the end points. For example, there could be contours at offsets right 87.31 and 105.43 but no intersection exactly at 100. There are four methods for determining the elevation for these end points.

Extrapolate Endpoint Elevation from Last Slope: This option calculates the slope from the last two offset-elevation points and calculates the elevation at the endpoint from this slope. For example, given offsets at 80 with elevation 100, and 90 with elevation 101, the elevation at offset 100 would be 102.

Extend at Flat Grade to Right and Left MXS Limit: This option uses the last offset elevation as the end point elevation. For example, if the last offset were 85 with elevation 102, the program would add an offset at 100 with elevation 102.

Cut-off at the End of Surface Data: This option does not add offsets at the end points. The sections will end at the last offset found in the surface model.

Interpolate from Surface Data Beyond MXS Limit: This option looks beyond the offset limit for more intersections with surface entities. The endpoint elevation is then interpolated between the offsets above and below the endpoint. For example, given offsets at 90 with elevation 101, and at 110 with elevation 103, the endpoint offset at 100 would have elevation 102. If this option is selected, the Distance to Add to MXS Limit for Interpolation field becomes available.

Distance to Add to MXS Limit for Interpolation: Enter distance.

Ignore Zero Elevation Lines in Surface Model: When checked, all zero elevations will be ignored.

Breakpoint Descriptions from Layer: When checked, this option will store the layer name of the surface entity as the description for the offset-elevation point in the section file.

Limit of Break Points Per Section: Specify the maximum number of break points per section. Default value can be set using the *Section Defaults* command.

Prompts

MXS File to Process *Select the section alignment .MXS file*

Section File to Write *Specify the .SCT file*

New or Append *Choose whether to create a new .SCT section file, or add to an existing .SCT section file*

Sections from Surface Model dialog *Make selections*

Select Lines, PLines, and/or 3DFaces that define the surface.

Select objects: *Pick the surface entities*

Pulldown Menu Location: Sections

Keyboard Command: setsm

Prerequisite: Constructed surface model (.MXS file) to be sampled

Sections from Grid or Triangulation Surface

This command creates a cross section file (.SCT file) from a surface model that is defined by a 3D rectangular grid file (.GRD file) or a triangulation file (.FLT, .TIN). The grid file can be created in the Civil Design module with the *Make 3D Grid File* routine. The triangulation file can be created with the Write Triangulation File option in the *Triangulate & Contour* command. This command also requires a Section Alignment (.MXS) file to define the alignment and stations of the sections. The number of section points created is displayed at the end of the routine.

When using a triangulation file, there is an option for whether to link the sections to the triangulation. With the link, the section file will get updated in case the triangulation file is updated. When the link option is set to Auto, the update is done automatically. When the link option is set to Prompt, the program will prompt with a dialog for whether to update the sections when a triangulation change is detected.

Prompts

Choose Grid or Triangulation File to process *choose existing .GRD, .FLT, or .TIN file*

Choose MXS File to Process *choose existing .MXS*

Choose Section file to write *enter new file name*

Found 1410 section points.

Pulldown Menu Location: Sections

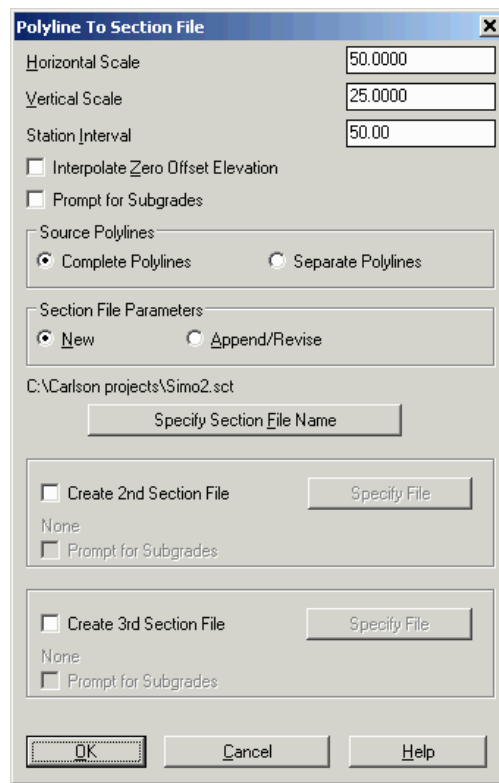

Keyboard Command: setgrid

Prerequisite: Grid (.GRD) or triangulation (.FLT or .TIN) file, and a cross sections .MXS alignment file

Sections from Polylines

This command allows the user to select a polyline that represents a section in cross section view and writes it to a .SCT file. This can be useful for revising sections or for defining a new one. For example, let's say you have extracted

sections from a surface model of the existing ground on a site, and have plotted them using the *Draw Section File* command. Next, the *Polyline by Slope Ratio* command is used to draw the proposed or final grade sections. Now use this command to send the sections to a Section file and compute the earthworks using the *Calculate Sections Volume* command. After selecting the command, the Polyline to Section File dialog appears.

The first time this command is selected, the output Section file is set to the same name as the current drawing. Select the Specify Section File Name button to specify a different name. The Station Interval edit box allows you to specify the amount that the default station number will be incremented as the station prompt shown below appears. The Interpolate Zero Offset toggle, if on, causes the program to output the elevation of the zero offset to the output .SCT file. A second and a third section file can be specified to process three sections at a time for each station. This allows you to handle both existing and final grades at once. The Prompt for Subgrades option will prompt for selecting subgrade polylines after the surface polyline for that section. For Source Polylines, the Complete Polylines method works with a single polyline that completely define the section for the station. The Separate Polylines methods allows you to select multiple polylines per section in case the section polylines are broken up into separate polyline entities. After selecting the OK button, the prompts below appear.

Prompts

Exit/Pick text/ <Station <0.00>>: *press Enter*

Exit/Pick text/ <Starting elevation of grid <100.00>> *440* This supplies the drawing coordinate to translate the grid from.

[int on] Pick point at starting elevation and zero offset of section ([Enter] for none): *press Enter*

Select station 0.00 1st section polyline: *select a polyline*

Select station 0.00 2nd section polyline: *select another polyline*

Exit/Pick text/ <Station <0.00>>: *E*

Pulldown Menu Location: Sections

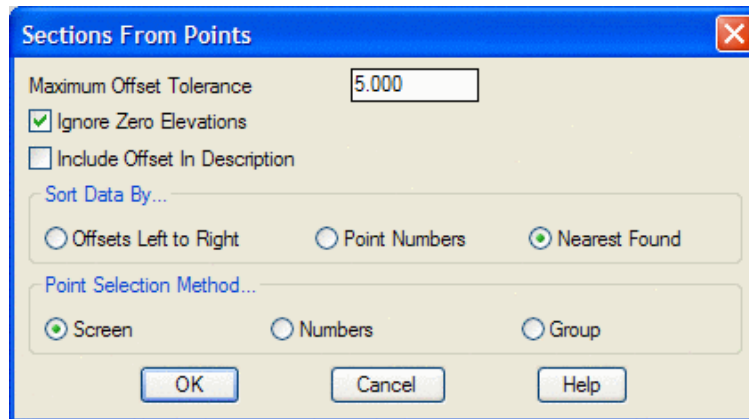

Keyboard Command: sctfpl

Prerequisite: Plot the section or profile to write to the .SCT file.

Sections from Points

This command creates an .SCT file from Carlson points in the drawing. An .MXS file is needed to define the centerline and the stations of the cross sections. The offsets for the cross section points are derived from the perpendicular distance between the centerline and the Carlson points. The cross section elevations come directly from the elevations of the points. In order to be included in a cross section, a Carlson point must be within the offset tolerance distance of the cross section line.

The order that the points within the Offset Tolerance at each station are used will of course determine the shape of the cross section. There are three ways for the collected points to be sorted. The Offsets Left to Right option sorts by the distance of each point from the CL. The Point Numbers option ignores that data, and instead sorts the points by their numbers. The Nearest Found option ignores both distance from the CL and point numbers and instead checks the horizontal and vertical proximity of the points to each other and sorts them based on this data. A powerful application of this method would be a survey of a tunnel where the points collected at each station were collected in a random order.

Prompts

Choose MXS File to Process *select file*

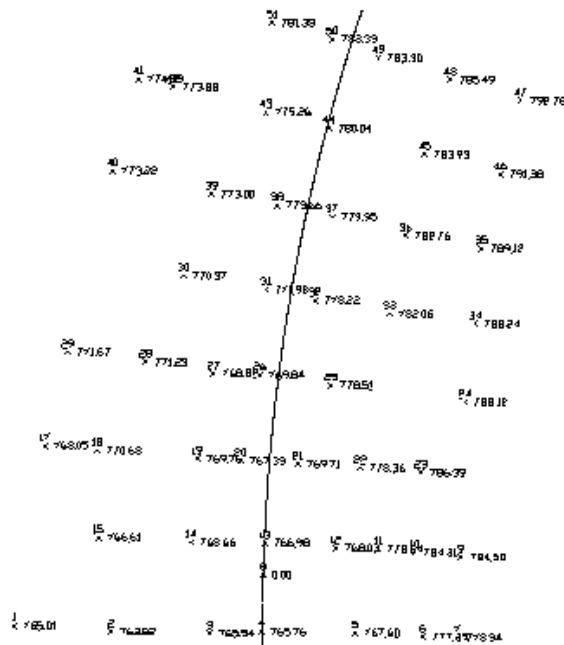

Choose SCT file to Append/Write *select file*

Enter the maximum offset tolerance <1.0>: *press Enter*

Ignore Zero Elevations (<Yes>/No)? *press Enter* This option filters out all Carlson points that have a zero elevation.

Select points along the sections.

Select objects: *pick the Carlson points*

Carlson points for use in creating Section file

Pulldown Menu Location: Sections

Keyboard Command: scpts

Prerequisite: Carlson points and an .MXS file

Sections from 3D Polylines

This command creates a cross section file (.SCT) from 3D polylines. The 3D polylines should be drawn perpendicular to the centerline. A section alignment file (.MXS) from the Section Alignment Editor command is needed to define the centerline and the stations of the cross sections.

The elevations for the cross section points come from the 3D polyline vertice elevations. The offsets for the cross section points are derived from the perpendicular distance between the centerline and the polyline vertices. In order to be included in a cross section, a polyline vertice must be within the **Maximum Offset Tolerance** distance of the cross section line.

When using 3D Polylines drawn in cross section, they should be drawn from left to right across the centerline. Use the Reverse Polyline command if needed to change the 3D polyline direction.

Prompts

Choose MXS File to Process *select file*

Choose SCT file to Append/Write *select file*

Sections From 3D Polylines dialog

Select polylines for sections.

Select objects: *pick polylines*

Pulldown Menu Location: Sections

Keyboard Command: sct3dp

Prerequisite: 3D Polylines and section alignment file (.MXS)

Sections from Coordinate File

This command will read a Carlson coordinate file, and, if the proper point descriptions are found, convert it to a .SCT file (stations, offsets, & elevations). This command offers great utility when combined with an electronic data collector. Sections can be surveyed and then compiled directly to cross sections, without having to extract them from a triangular mesh surface model. In other words, from the same file we can derive both plan and cross section views from one survey file. The .CRD file should have a point with a centerline description, followed by points that describe left and right offset points. For example, lets say we have a .CRD file with the following data in it.

Prompts

Coordinate File to Process dialog *choose the .CRD file*

Section File to Write *choose the .SCT file to create*

Sections From Coordinate File dialog *put in range*

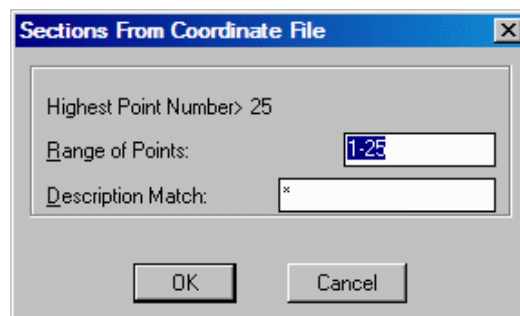

Station Center Point Description <SC>: *press Enter* You can use any set of characters that you want to use as the zero offset description code, although SC is recommended because it is the default.

Station Left Point Description <SL>: *press Enter* You can use any set of characters that you want to use as the left offset description code, although SL is recommended because it is the default.

Station Right Point Description <SR>: *press Enter* You can use any set of characters that you want to use as the right offset description code, although SR is recommended because it is the default.

Point#	North	East	Elevation	Description	
1	1000	1000	1050	CL/SC1+50	(centerline descriptor)
2	1007	1000	1049	EP/SL1+50	(left offset descriptor)
3	1008	1000	1048.2	ES/SL1+50	
4	1010	1000	1048	TD/SL1+50	
5	1012	1000	1046	BD/SL1+50	
6	1014	1000	1047.6	TD/SL1+50	
7	1016	1002	1047.8	PP	(would be ignored and not used in *.SCT file)
8	993	1000	1049	EP/SR1+50	(right offset descriptor)
9	992	1000	1048.2	ES/SR1+50	
10	990	1000	1048	TD/SR1+50	
11	988	1000	1046	BD/SR1+50	
12	986	1000	1047.6	TD/SR1+50	

Notice that SC is the zero offset/centerline description code, SL is the offset left description, and SR is the offset right description. The station number should immediately follow and be the last characters in the description field. The station number may or may not contain a plus sign. This example would produce an .SCT file that contains the station number 150 and 10 offsets and elevations.

Pulldown Menu Location: Sections

Keyboard Command: textstc

Prerequisite: A coordinate file with the correct descriptions.

Sections from Profile

This command creates or adds data to a .SCT file from the station-elevation data in a profile file (.PRO). For every matching station in the profile and section file, the profile elevation is applied to a specified offset in the section file. For example, consider a profile for the edge of pavement that is a constant 12 to the right side of the centerline. The elevations from this profile could be added to offset 12 in the section file. The program will assign the elevation at station 1+00 from the profile to the elevation at station 1+00 and offset 12 in the section file. When creating a new section file, an .MXS file is needed to define the station interval.

Prompts

Section offset of profile <0.0>: *enter the offset Negative for left, positive for right.*

Choose SCT File to Append/Write dialog *choose new or append existing .SCT file*

Choose MXS file to process dialog *choose existing*

Choose Profile file to process dialog *choose existing .PRO file*

Created 11 section points.

Pulldown Menu Location: Sections

Keyboard Command: pro2sct

Prerequisite: A profile .PRO file and .MXS file

Sections from Layers

This command creates cross sections from surface entities on one of the specified layers. The surface entities can be contours, triangular mesh, and other 3D drawing entities. This command is the same as *Sections from Surface Entities* with the addition of the layer filtering. Specify the layer names of the surface entities to include in the sections. For example, the layer names CTR and TMESH could be entered to use only the contour polylines and triangulation mesh on these layers. Entities on all other layers would be ignored. See *Sections from Surface Entities* for more details

Prompts

Specify Layer Names Dialog *pick Select Layers from Screen button, choose, then OK*

MXS File to Process dialog *choose existing .MXS alignment file*

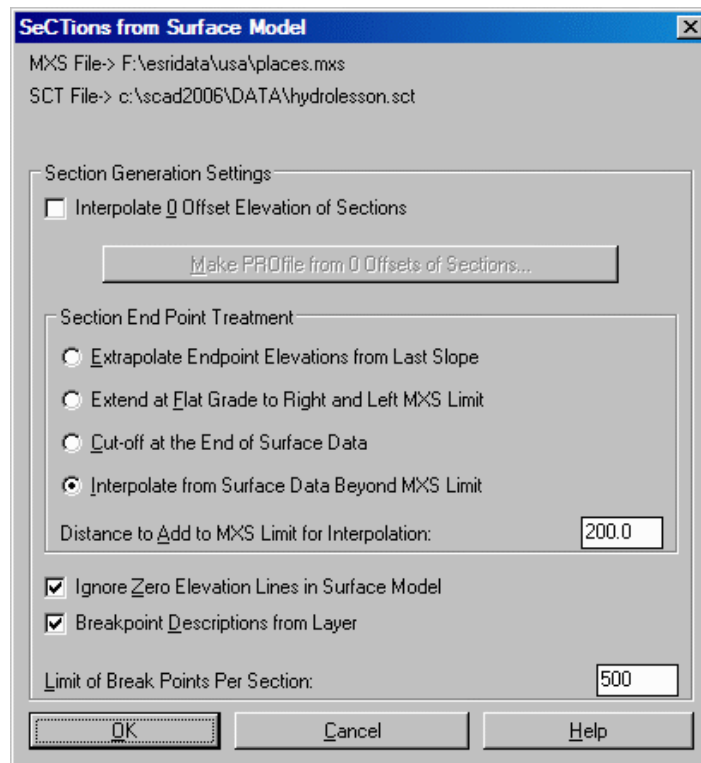

Section File to Write dialog *specify a new .SCT section file to create or append existing*

Sections from Surface Model dialog *Make selections*

Select surface entities on corresponding layers.

Select objects: *pick the linework to process*

Pulldown Menu Location: Sections

Keyboard Command: sctlayer

Prerequisite: A cross sections alignment file (.MXS file), surface lines and polylines.

Sections Points from Surface Entities

This command creates a section .SCT file in a similar way as *Sections from Surface Entities*. The difference is that these section points are not connected by a polyline as a surface in *Draw Section File*. Instead, a point symbol is drawn for each offset-elevation point. First this command prompts for the symbol to use. Next the program asks for the section alignment (.MXS) file to use, then the section (.SCT) file to make or append. Then you select polylines to create the section points from. The intersections of these polylines with the cross sections are calculated and the resulting station-offset-elevations are stored in the section file. The description field for these section points identify them as individual points instead of a surface. The description starts with POINT- followed by the symbol name (e.g. POINT-SPT5).

Prompts

Select Symbol dialog

MXS File to Process Select an existing section alignment .MXS file

Section File to Write dialog

New or Append Choose between creating a new .SCT file or add to an existing section file

Select surface polylines.

Select objects: *pick the polylines*

Added 21 points to section file.

Writing section file> C:\scad2006\data\horn.sct

Pulldown Menu Location: Sections > Points on Section

Keyboard Command: sctpts2

Prerequisite: Surface polylines and an MXS file

Sections Points from Right of Way

This command is the same as *Sections Points from Surface Entities* except that the symbol for the right of way is automatically drawn as a downward pointing arrow. The description field for these section points identify them as right of way points. The description is POINT-ROW. A new .SCT file is created or an existing one appended to.

Prompts

MXS File to Process Select a section alignment file

Section File to Write dialog

New or Append Choose between creating a new .SCT file or add to an existing file.

Select right of way polylines.

Select objects: *pick the polylines*

Added 21 right of way points to section file.

Writing section file> C:\scad2006\data\horn.sct

Pulldown Menu Location: Sections > Points on Section

Keyboard Command: sctrow

Prerequisite: Right of way polylines and an MXS file

Sections Points from Pipes

This command is the same as *Section Points from Surface Entities*, except that the symbols for the pipes are automatically drawn as a circles with a radius set to the pipe width. The profile equivalent of this command is *Profile from Pipe Polyines*. When *Draw Section File* has vertical exaggeration, the pipe is drawn as an ellipse. The description field for these section points identify them as pipe points. The description is POINT-PIPE followed by the pipe size in feet (e.g. POINT-PIPE-1.500). The pipe polyines used to derive the pipe section points can be created with the *Draw Pipe 3D Polyline* and *Assign Pipe Width to Pline* commands in the Sections->Section Utilities menu. Also, the position of the pipe polyines on the pipe can be selected. The choices are Top, Center and Bottom.

Prompts

MXS File to Process Select a section alignment file

Section File to Write

New or Append Choose between creating a new .SCT file or add to an existing file.

Select pipe polylines.

Select objects: *pick the polylines*

Position of pipe polyines on pipe [Top/Center/<Bottom>]? Enter

Added 46 pipe points to section file.

Writing section file> C:\scad2006\data\pipe.sct

Pulldown Menu Location: Sections > Points on Section

Keyboard Command: sctpipe

Prerequisite: Right of way polylines and an .MXS file

Quick Section

This command creates section files in one step. The horizontal alignment for the sections can be defined by using picked points, a centerline file or a polyline. A section alignment (.MXS) file is not required for this routine. 3D screen entities or surface files (.GRD, .FLT, or .TIN) are used to define the vertical alignment.

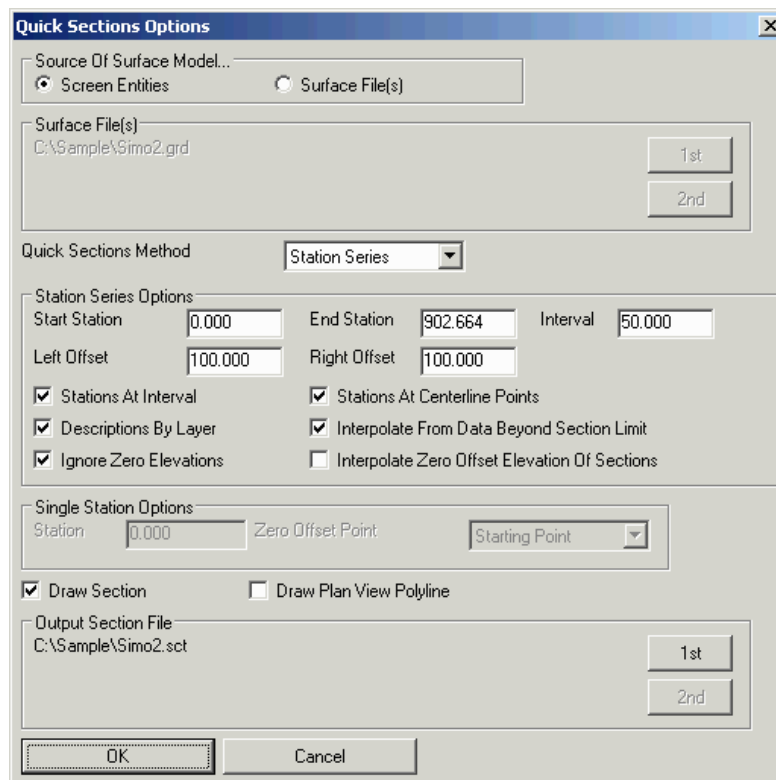

There are two options under Quick Section Methods. The Station Series method creates sections perpendicular from the horizontal alignment at a station interval. In this case, the horizontal alignment represents the centerline. The Single Station method creates one section along the horizontal alignment appends this section to the output section file. In this case, the horizontal alignment represents the alignment of the section.

For the Station Series method, there are settings for the Start Station of the horizontal alignment, the End Station to stop creating sections, the Interval for the stations, and the Left and Right Offsets to define the section width. There are also options to control the section stations to create. The Stations At Interval option will create sections at the specified station interval. The Stations At Centerline Points option will create sections at the special stations of the centerline for the centerline transitions such as PC, PT points

For the Single Station method, the Station value is assigned to this section. The Zero Offset Point chooses between using the starting point of the horizontal alignment as the zero offset or selecting a point along the alignment as the zero offset.

With the Source Of Surface Model set to Surface Files, the program prompts for up to two surface files so that up to two section files can be generated at a time. When the Surface Model is set to Screen Entities, only one section file is created from the screen entities. With Screen Entities, there are a few more options. The Descriptions By Layer option will use the layers of the screen entities as the descriptions for the section points. The Interpolate From Data Beyond Section Limit will check for intersections with the section line and the screen entities beyond the left/right offsets to interpolate the elevations at the left/right offset extents. The Ignore Zero Elevations will filter out screen entities that are at zero elevation. The Interpolate Zero Offset Elevation Of Sections will create a section point at offset zero by interpolating between the nearest section points.

The program requires an output section file to store the results. There is an output option to draw the sections which calls the Draw Section File command. Finally, the option to Draw Plan View Polyline will draw the horizontal alignment as a polyline which is especially useful if the method to define the alignment by picked points was used.

Prompts

Pick starting point (CL-Centerline,P-Polyline): *select a point*

Pick second point: *select second point*

Pick next point (Enter to end): *press Enter*

Quick Section Options dialog

Choose Source of Surface Model, Screen Entities or Surface File, and make other selections. Click OK.

Keyboard Command: quickset

Prerequisite: 3D Screen entities or surface files

Tablet Calibrate

This command executes the routine to perform calibration of the digitizer tablet to the drawing. There are two methods of calibration: Known Reference Points, and Drawing Scale with New Reference Points, which are explained in detail below. The Calibrate routine must be used prior to using the Digitize Contours command.

Please refer to Configure , General Settings and Digitizer Puck Layout for selection of the correct puck layout before proceeding.

Tablet Calibration

Known Reference Points uses two known coordinates for reference points on the drawing. When this option is selected, the fields for coordinate info activate. Enter the known northing and easting values for the reference points from the info on the drawings in the appropriate fields and press ok. The command line will prompt for the selection of each point from the drawing on the tablet. Furthermore, Carlson saves the coordinates of the two reference points for future calibrations and displays them on the **Tablet Calibration Dialog** the next time it is accessed, so if you are working in the same drawing, you can use the **Known Reference Points** method with the saved coordinates to digitize back to your previous coordinates. For greater calibration accuracy, choose two points that are farther apart rather than closer together.

Tablet Calibration

Calibration Methods

Known Reference Points

Drawing Scale with New Reference Points

Draw Reference Points

Known Reference Points

Point 1: Northing Easting

Point 2: Northing Easting

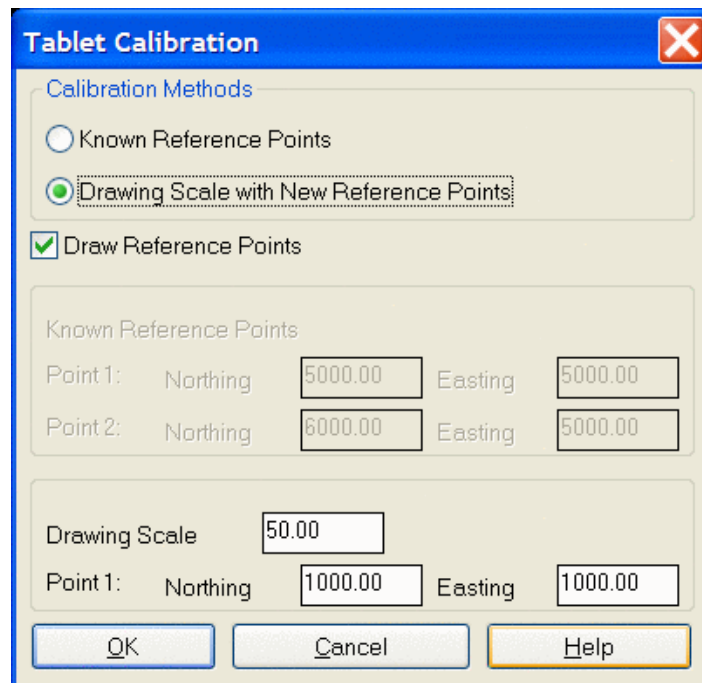

Drawing Scale

Point 1: Northing Easting

OK Cancel Help

Drawing Scale with New Reference Points is very convenient when you don't know the precise coordinates of the entities on your drawing. The user must specify the drawing scale from your plan, this method can establish a coordinate system relative to the position of the plan on the digitizer board. In addition to the drawing scale, you

are required to enter a random coordinate for the first reference point, the default coordinate is (1000,1000). Takeoff would computer the coordinate of the second reference point that you pick based on the first point. The coordinates of these two reference points would be saved and will be display on the **Tablet Calibration Dialog** next time when you calibrate the tablet, so you can digitize back to the previous coordinates using **Know Reference Points** method if you are working on the same drawing, though you might have moved or rotated your drawing on the digitize board option allows the user to specify the drawing scale of the plans be digitized and to assign an assumed northing and easting for a base point. When selected, Drawing Scale and Northing and Easting for Point 1 activate. Press ok. The command line will prompt for a pick of the first point.

Prompts

Tablet Calibration Dialog

Specify the Calibration Methods. If you select Drawing Scale method, enter the drawing scale and the coordinate of the first reference point. Otherwise enter the exact coordinates of the first and second reference points.

Pick first reference point: *pick a point*

Pick second reference point: *pick another point*

Pulldown Menu Locations: Contour in Civil Design, Sections in Civil Design, Digitize in Takeoff

Keyboard Command: digsetup

Prerequisite: Affix a drawing to your digitizer tablet. Have a digitizer board and a puck connected to your computer, and have Wintab driver installed. The digitizer has been correctly set up. Select the puck layout in Configure .

Digitize Sections Plan

This command allows you to digitize cross sections from a contour map. This is useful for pulling cross sections and earthworks from existing contour maps made by aerial photography, USGS or other engineering firms.

Prompts

Use **TABLET CALibrate** command to set scale prior to using this routine.

Contour Increment <1>: 2 The contour increment/interval of the map to be digitized.

Pick Zero Offset Station point: *pick a point*

Zero Offset Elevation: 1122.56

Starting Contour elevation <1122>: 1124 This is the elevation of the first contour to digitize.

Next Point Up Right: *pick a point*

If the first contour line is moving up in elevation and to the right of the zero offset point, then pick a point on the first line with elevation 1124. If this is not the case, then review the options below to change the prompt mode.

Press digitizer/mouse buttons:

- 1 - To pick next point on contour line
- 2 - To change to UP mode
- 3 - To change to DOWN mode
- 4 - Prompt for new elevation (this elevation is applied to the next point picked)
- 5 - To change to RIGHT mode
- 6 - To change to LEFT mode

or Press Keys:

- [X] - To end point prompting
- [U] - To change to UP mode
- [D] - To change to DOWN mode
- [N] - Prompt for new elevation (this elevation is applied to the next point picked)
- [E] - Erase/Delete the last point picked
- [R] or [+] - To change to RIGHT mode
- [L] or [-] - To change to LEFT mode

Press one of the keys, buttons or select from the side bar screen menu to change prompt to appropriate mode. When you have finished picking points press the [X] key to end the point prompting. The program then prompts:

Send Section to a file (Y/N) <Y>: *press Enter*

Name of Section File to write </sc/data/example.sct>: *press Enter* If the file already exists the user is asked to Overwrite or Append to the file.

Section Station Number: 100 The station, offsets and elevations are then written to the section (.SCT) file.

Pulldown Menu Location: Sections > Digitize Sections

Keyboard Command: digsec

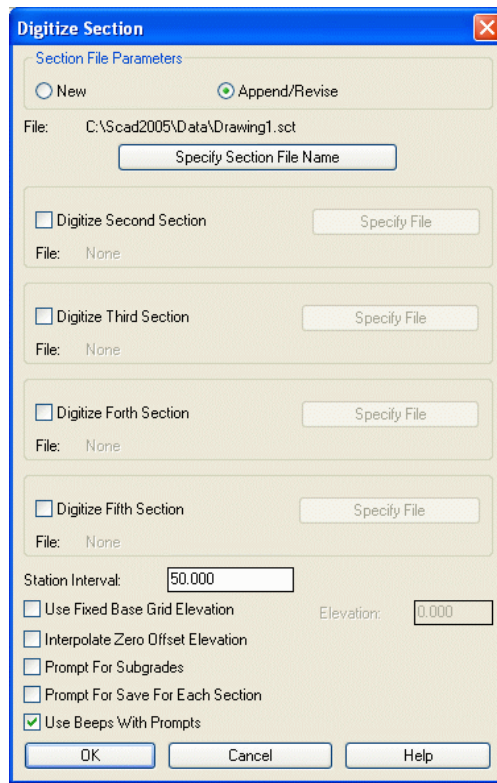

Prerequisite: An existing plan view contour drawing on screen or digitizing tablet. If digitizing a map on your tablet use the *Tablet Calibrate* command to calibrate your digitizer tablet to the scale of the drawing.

Digitize Sections XSec

This command creates a section file (.sct) by digitizing a section drawing. The command starts with the dialog shown below where you specify the section file name to create. The station interval is used to automatically default to the next station value when digitizing a series of stations. The Interpolate Zero Offset option will interpolate an elevation at the exact zero offset.

After the dialog, the program will prompt to pick three reference points on the section. These points should have known offsets and elevations. Additional sections can be aligned by a single point. Corners on the section grid can be used for these reference points. The reference points and the user-entered offset and elevations for them sets up the program for the section. Now you can start picking the section grade points.

You can also digitize existing and final surfaces back to back, and there is an undo function that will allow undo while digitizing points. As the section is digitized, it is shown in a real-time graphics window. Holding down the right mouse button acts as a zoom function, while holding down the mouse scroll button acts as a pan. The puck keys can be used to enter all the input data.

Prompts

 Digitize another station [<Yes>/No]? *N*

Pulldown Menu Location: Sections > Digitize Sections
Keyboard Command: digxsec
Prerequisite: Affix cross section on digitizing tablet

Digitize End Areas

This command writes an earthwork (.EW) file that can be used by the *Print Earthwork File Report* command and print an earthworks and volumes report. It is the users responsibility to record the sections in the proper consecutive sequence. The earthwork (.EW) file written by this command can be edited in any ASCII text editor.

Prompts

Datum elevation <0.0>: *100* Enter the datum elevation that you calibrated the tablet with.
Horizontal Scale <20.0>: *press Enter*
Vertical Scale <20.0>: *10*
Digitize cut area (Enter to end): *pick a point* Starting at either end of the section, digitize break points of cut area.
Digitize cut area (Enter to end): *pick a point*
Digitize cut area (Enter to end): *pick a point*
Digitize cut area (Enter to end): *press Enter* Press Enter to end prompting of break points. The end area is then displayed.
More cut areas (Y/N) <N>: **[Enter]**
 Respond with Y if you have more cut areas.
Digitize fill area (Enter to end): *pick a point*
Digitize fill area (Enter to end): *pick a point*
Digitize fill area (Enter to end): *pick a point* Press Enter to end prompting of break points.
More fill areas (Y/N) <N>: *press Enter* Respond with Y if you have more fill areas.
Send data to file (Yes No) <Y>: *press Enter* If you made no errors respond with Y to save data in the file.

End Area File to write <c:\scad2006\data\quan.ew>: *press Enter*

Station Number: 150 This would enter a station of 1+50.

Pulldown Menu Location: Sections > Digitize Sections

Keyboard Command: digendar

Prerequisite: An existing cross section on digitizing tablet. If digitizing a map on your tablet use the Tablet Calibrate command to calibrate your digitizer tablet to the scale of the drawing.

Section Conversions

All Import commands in this submenu are designed to convert other section file formats to the Carlson section (.SCT) file format. The Import Columnar Text has some options to make the program match the import data. This routine can be used for section text files that have station, offset, elevation and optionally description separated by spaces or commas. All the other Import routines read specific formats from other software. The Export commands are designed to convert the Carlson section (.SCT) file format to other section file formats. You will be prompted to specify the file name to convert, then specify a section (.SCT) file name.

Note: The Import/Export LandXML Files routine in the File menu supports section data as well as other survey and civil data types.

Another Note: The Section Report routine can be used to Export section data from Carlson and this command includes an option to use the Report Formatter which allows you to select the fields to export and their order. Plus the Section Report report formatter has functions to export to Excel and databases.

Prompts

Prompts and commands vary for importing and exporting section file data.

Importing:

Import Columnar Text

Type of delimiter [<Space>/<Comma>]? *C for comma.* Choose the type of separator between fields in the import file.

Section data contains description field [Yes/<No>]? *N for no.* This option specifies whether the import file contains descriptions for the section points.

Add description to section data [Yes/<No>]? *Y for yes.* This option will assign a specified description to the section points.

Description for section data: *TOPO*

Import Agtek Reads .ROG and .RDS format section files (ASCII only).

Import Arkansas DOT Imports Level Note File

Import C&G Reads C&G .CEW section files.

Import CAICE Earthworks Reads .ERP files.

Import Ceal Reads CEAL section files.

Import EMXS Reads section data from .XNG files.

Import GEOPAK Reads .XRS, .XSR, and .TXT format section files (ASCII only).

Import Georgia DOT Reads .END files.

Import IGRDS Reads .LIS, .RDS, and .TXT files.

Import InRoads Reads .TXT files.

Import MicroStation Reads InRoads .GEN files.

Import Moss Reads MOSS section files.

Import NC DOT Reads .ORI and .TXT files.

Import Pizer Reads .TXT files.

Import RoadCalc Reads RoadCalc (Eagle Point) sections files.

Import SMI Reads .CUT format section files (ASCII only).
Import Softdesk Reads .SEC format section files (ASCII only).
Import Spanish SC1 Reads ISPOL .SC1 section files.
Import Spanish TRV Reads CLIP .TRV section files.
Import TDS Reads .RD5 and .TP5 files.
Import Terramodel Reads .XSC files.

Exporting:

Export C&G Converts Carlson .SCT file to .CEW format.
Export GEOPAK Converts Carlson .SCT files to .TXT format.
Export IGRDS Converts Carlson .SCT files to .RDS format. Prompts for section surface type - original ground or final surface.
Export RoadCalc Converts Carlson .SCT files to RoadCalc (Eagle Point) format.
Export Topcon Converts Carlson .SCT files to .RD3 format.

Pulldown Menu Location: Sections > Section Conversion

Keyboard Commands xsecread, agtek, level, ceal, geopak2sct, gadot2sct, igrds2sct, moss, ncdot2sct, pizer2sct, inroadcalc, smisct, softsct, sc1_to_sct, trv_to_sct, tm2sct, sct2geopak, sct2igrds, outroadcalc, gen2sct

Prerequisite: Sections files; formats vary by command

Create Overshoot Section File

This command allows the user to create an overshoot section file using an existing .SCT section file and an existing rock section file. The existing .SCT file must be read, then an existing rock section file (.SCT) needs to be chosen. The new overshoot section file and file name will then be written. An overshoot drop depth is the key prompt in this command, along with the values for the beginning and the final stations. This will begin the processing of this routine and create the new data.

Prompts

Existing Section File to Read *select SCT file*

Rock Section File to Read *select SCT file*

Section File to Write *enter new SCT file name*

Enter the overshoot drop depth: 5

Range of stations: 0.00 to 150.00

Enter beginning station to process <0.00>:

Enter final station to process <150.00>: 1000

Last station to average <1614.160>: *press Enter*

Section File to Write Select a SCT file name and folder.

Pulldown Menu Location: Sections > Rock Sections

Keyboard Command: rockover

Prerequisite: A .SCT file

Draw SectionTemplate DWG

This command is step one in the Point on Section procedure. It inserts a section or template drawing to scale on a standard section sheet. The section or template must be an existing, separate drawing (.DWG) file. Prior to running this command, the scale and text size should be set with the *Drawing Setup* command found on the Settings menu.

Prompts

Enter the horizontal scale <1.0>: *press Enter*

Enter the vertical scale <1.0>: *press Enter*

Three file selection dialogs follow.

Choose Standard Section Sheet: *pick existing .DWG file* The standard section sheet is a drawing created at 1'=1' with its insertion point coordinates 0,0 at the lower left gridline.

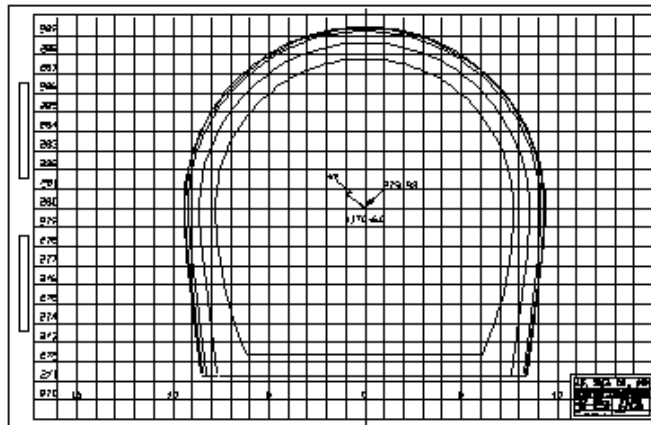

Choose Profile File: *pick existing .PRO file* The profile (.PRO) file for the vertical alignment defines the insertion elevation for the template insertion point.

Choose Tunnel Template: *pick existing .DWG file* The tunnel or section template is a drawing created at 1'=1' with the insertion point for the template at coordinates 0,0.

Enter profile station for section/template: 117060

Enter or pick section/template insertion point *pick a point or press Enter for none*

The standard section sheet with template in the center of sheet at the input horizontal and vertical scales is plotted.

Section sheet with template

Pulldown Menu Location: Sections > Points On Section

Keyboard Command: tunnel

Prerequisite: Vertical alignment in .PRO file, template or section drawings, and section sheet drawing.

Point Placement on Section

This command is step two in the Points on Section procedure. Before running this routine, the section or template sheet must be drawn on screen and there must be an existing coordinate (.CRD) file to read, with station and offset data in the description fields, as described under Points on Section. Station location points may also be picked on screen with the Points option. This command draws points on the section template from the coordinate (.CRD) file or via the Points method. If the Point option is selected, a Section Settings dialog appears, followed by a Snap Point dialog. The point elevation and the offset data in the description field are used to locate the point on the section.

Prompts

Place points from .CRD file or pick points [File/<Points>]? F

Enter the horizontal scale <1.0>: *press Enter*

Enter the vertical scale <1.0>: *press Enter*

Layer for points <PNTS>: *press Enter*

Select Coordinate File to Read Dialog *pick a file* You select the crd file to process.

Range of Point Numbers to use (A for All) <A>: *press Enter for all points to process*

Wildcard match of point description <*>: *press Enter for all points with or without descriptions*

Plot Full or Abbreviated text (Full/<Abbrev>)? F Here we used F for full description.

Range of stations: 117060.000 to 117090.000

Enter station to process: 117060

Enter search zone <1.0>: Search zone applies to survey data collected in an approximate range plus or minus a small distance on a known station.

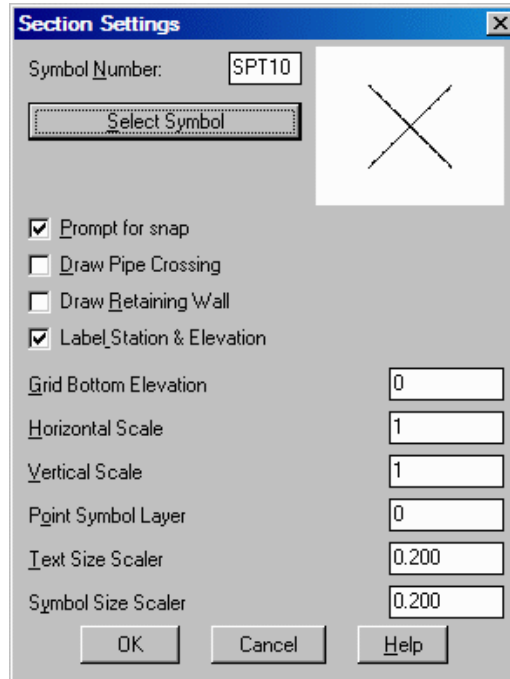

Pick Center of Grid [int on]:

Pick a known elevation on the centerline and on the next prompt enter that elevation.

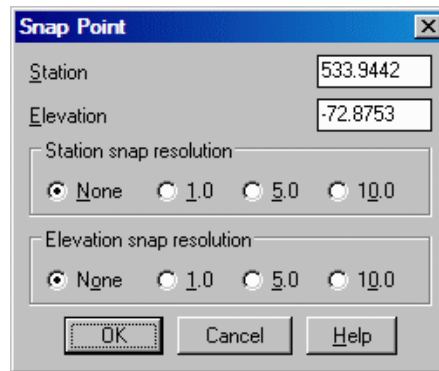

Enter base elevation of grid: 278

Enter station to process: *Enter next station or press Enter to end*

The points plot on the template or cross-section.

Point option dialog

Points plotted on template or cross-section

Pulldown Menu Location: Sections > Points On Section

Keyboard Command: ptsct

Prerequisite: Drawn section sheet and .CRD file with station and offset description field data

Point Offset Report/Plot

This command, which is step 3 in the Points on Section procedure, labels the tight/clear distances between points and a polyline on the section. Tight points are inside or to the right of the polyline while clear points are outside or to the left of the polyline. The polyline should be drawn in a clockwise direction. The points can be picked on the section or located from a .CRD file with the station and offset data in the description fields as described under Points on Section.

Prompts

Enter the horizontal scale <1.0>: *press Enter*

Enter the vertical scale <1.0>: *press Enter*

Coordinate File to Process Dialog Box *pick a file* Select the coordinate file for clear/tight report.

Write report to file (Yes/<No>)? *Y*

Enter the report file name to write: *117060.XS*

Write report to printer (Yes/<No>)? *Y* Make sure the printer is on-line and connected to the printer port.

Press Enter to continue *press Enter*

Write report into drawing (Yes/<No>)? *Y*

Enter the report title <Tight/Clear Report>: *press Enter*

Pick location for report: *pick starting location for Tight/Clear report*

Use manual or automatic label placement (Manual/<Automatic>)? *press Enter* Automatic draws the arrow leader lines perpendicular a set distance prompted next. Manual allows picking each leader lines location.

Label offset distance <1.00>: *press Enter*

Enter station to process: *117060*

Enter search zone <1.0>: Search zone applies to survey data collected in an approximate range plus or minus a small distance for a known station.

Pick Center of Grid [int on]: Pick a known elevation on the centerline and on the next prompt enter that elevation.

Enter base elevation of grid: *278*

Select polyline: *pick template polyline*

Number/<Pick Point>: *N* You can pick offsets or use point numbers.

Pick point/<point number or range>: *8-13*

Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	L9.20	282.38	8	443246.7039	785285.7725	+0.11	
Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	L9.15	271.98	9	443246.7118	785285.7231	+0.57	
Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	L1.10	289.28	10	443247.9877	785277.7749	-0.04	
Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	R4.30	288.13	11	443248.8436	785272.4431	-0.19	
Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	R9.00	281.18	12	443249.5886	785267.8025	-0.32	
Station	Offset	Elev	Pt#	North	East	TIGHT	CLEAR
1170+60.00	R9.30	272.48	13	443249.6361	785267.5063	+0.66	

Pick point/<point number or range>: *press Enter*

Enter more point numbers or pick more offsets or press return for no more.

Enter station to process (Enter to End): Enter next station or press Enter to end.

With Point Offset Report/Plot completed the finished product with points plotted on the cross section can be plotted to a printer or plotter with Tight/Clear or Cut/Fill report included as shown.

Pull-down Menu Location: Sections > Points on Section

Keyboard Command: sctoffset

Prerequisite: Drawn section sheet

Section File Editor

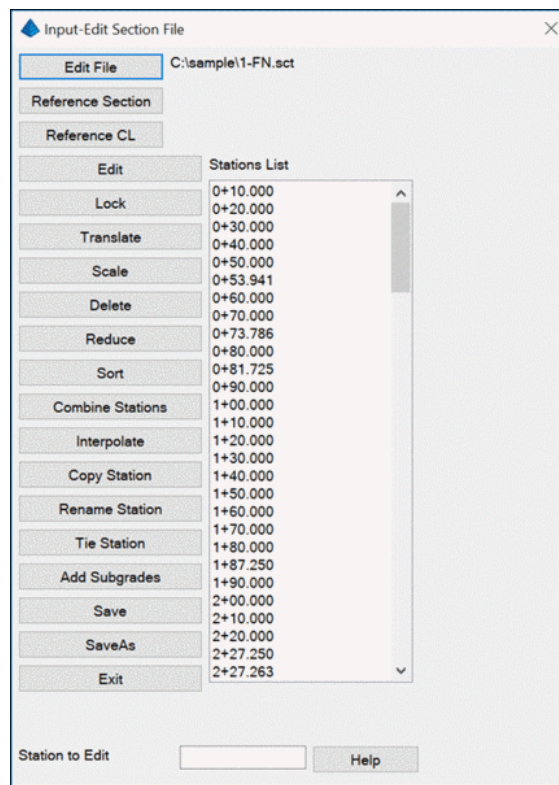

This program can be used to enter or edit data stored in a section file (.SCT file), including a real-time graphic window in the Edit mode. The section data consists of stations, offsets, elevations and descriptions. This command also has utilities for translating the offsets and elevations, deleting stations from the file, intersecting the out-slopes of one section file with another, combining multiple occurrences of the same station and sorting the stations, offsets and elevations.

While editing the section file, a second section file can be used as reference. To choose this file, pick the **Reference Section** button. For example, when editing the proposed section file, you can reference and view the ground section file as the second file. Besides showing the reference section in the graphic preview, the program also reports the end areas while editing a section station. Also, the reference section can be used to tie to the catch point. Another option is to set a **Reference CL** which is used to adjust the stations when the centerline has station equations.

The program begins by prompting for a New or Existing section .SCT file to process. The Section file to process dialog appears, allowing you to specify the file that you want to operate on. Use the New option to create a new file. Use the Existing option to edit the offsets and elevations for station/sections that you have already created, or append new stations to a file. The program defaults to a section file with the same name as the drawing or a name that you specified using another section command. You also can choose a 2nd existing .SCT file to reference. After specifying the file name(s), the program displays any stations currently in the file, in the Stations List of the Section File dialog box.

Alternately, when sections are drawn in the drawing, you can double-click on a section polyline to launch Section File for the .SCT file associated with the section polyline.

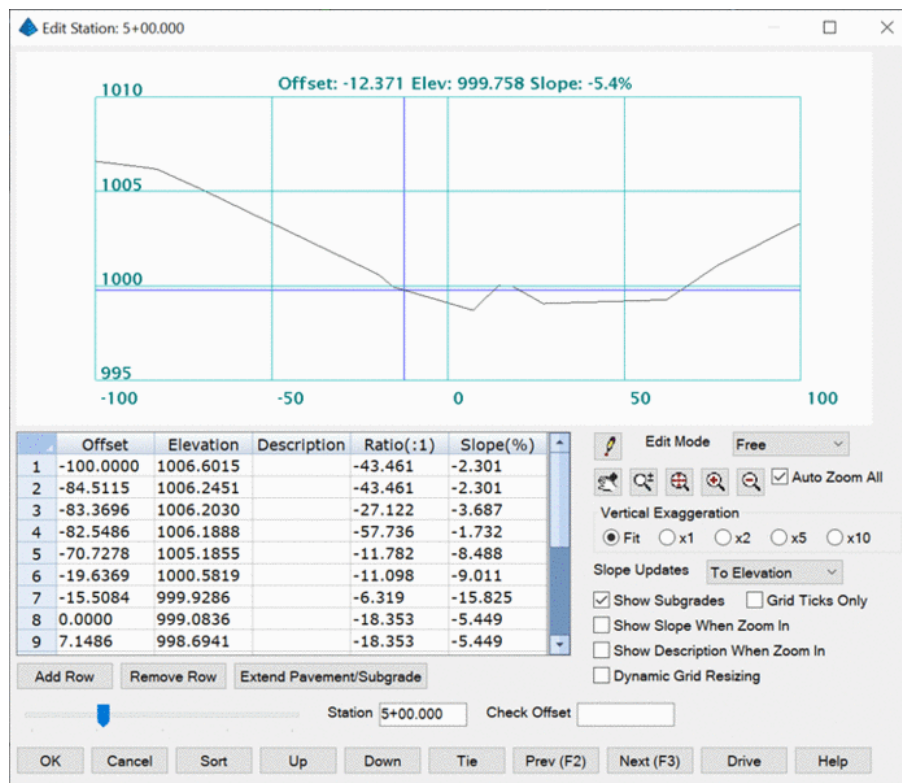

If you specified a new file, the Stations List box will be blank. To edit and display the offset and elevation data at a station, you can double click on the station in the Stations List box, or input the station in the Station to Edit edit box at the bottom of the dialog. To add a station to a new file or existing file, you must enter the station in the Station to Edit edit box. Stations will present in accordance with the Section-Profile settings in Configure under the Settings pull-down menu (eg. 10+00, 1+000, 1000).

Edit: Opens the Edit Station dialog which shows a graphic of the section on top, a list of the offset-elevation points in the middle, and the function buttons on the bottom. To add an offset point, type in the offset, elevation and optional description in the spreadsheet. Left offsets are entered as negative numbers. You can enter the slope or ratio from the last point and the program will calculate the elevation. To edit an offset point, highlight the point from the list and then edit the values in the Offset, Elev and Desc columns. The highlighted point will be marked by an X in the graphic screen. The Sort button will sort the list of offsets from lowest to highest, left to right. It is recommended that you Sort offsets before doing the Tie command, so that the left-most and right-most offsets appear first and last in the offset list. The Up button will move the highlighted offset point up in the list. Likewise the Down button moves the highlighted offset point down in the list. Prev (F2) and Next (F3) buttons move through the stations and allow you to review and edit stations in forward or reverse order. The scroll bar can also be used to quickly move through stations and then zero in with Prev (F2) or Next (F3). When you edit a slope value in the spreadsheet, then the Slope Updates setting controls which elevation value to update for the section segment.

The section data can be edited directly in the spreadsheet or graphically by picking the Edit Point button with the pencil icon.  To edit graphically, use the click-n-drag method. Start by picking the Edit Point button and then pick the section point to edit in the graphic preview and hold the mouse button down and then drag the mouse to the new position and then release the mouse button. The **Edit Mode** setting governs the click-n-drag operation. The **Free** mode allows the section point to be moved anywhere. There **Hold Slope** modes maintain the slope and moves the point along these slopes. The **Hold Offset** allows changing the section point elevation only. The **Hold Elevation** allows changing the point offset only.

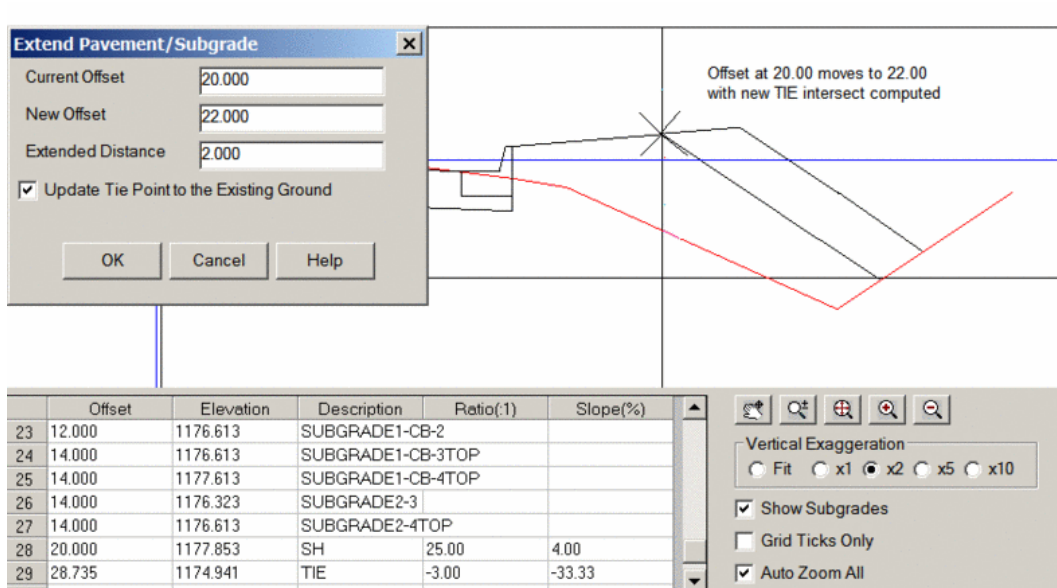

When a Reference Section is set in the main dialog, the Edit Station spreadsheet has a column for Depth. This Depth is the elevation different to the reference section. You can edit the depths to change the elevations for the section.

The **Add Row** button inserts an offset line above the currently highlighted row. The **Remove Row** button erases the highlighted offset and elevation from the list. After inputting or editing press the **OK** button to return to the Stations List dialog and keep any changes you have made. Select the **Cancel** button if you want to cancel changes made to the current station.

A real-time report of offset-elevation-slope now displays in the top of the graphic as you move the cursor across the section in the graphic window. The screen defaults to zoom mode where holding down the right-mouse button zooms in and out. You can also switch to pan mode. There are buttons for zoom extents, zoom in and zoom out. If your mouse has a scroll button, you can hold it down to pan and scroll it to zoom in and out. You can also set the **Vertical Exaggeration** ranging from 1X to 10X and including "Fit". **Show Subgrades** has the ability to tie a subgrade into the surface. **Grid Ticks Only** just shows the left and bottom axis lines of the grid with grid tick marks along the axes. With **Auto Zoom All** turned off, you can hold the same view position as you click **Next** and **Previous** and move through the list of stations. The **Description** is used in Draw Section File command to label under the station value and used in the Section Report command. The **Check Offset** field calculates an elevation based on an entered offset.

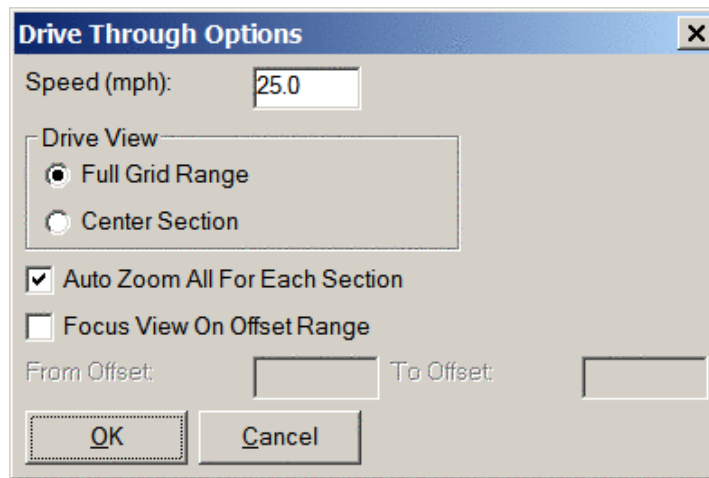

Extend Pavement/Subgrade allows you to move a surface point and shift, in parallel, the associated subgrades and tie points. One application, shown below, is to extend a shoulder point and re-computer the TIE point, all in one clean operation:

Another application of Extend Pavement/Subgrade is to move the curb position and all associated subgrades. The "inside" curb point is at 12.00 units from centerline. If the pavement is extended from 12 to 15 at this station, use of this feature will extend the subgrades, maintain all slopes and re-compute the TIE point, as shown below:

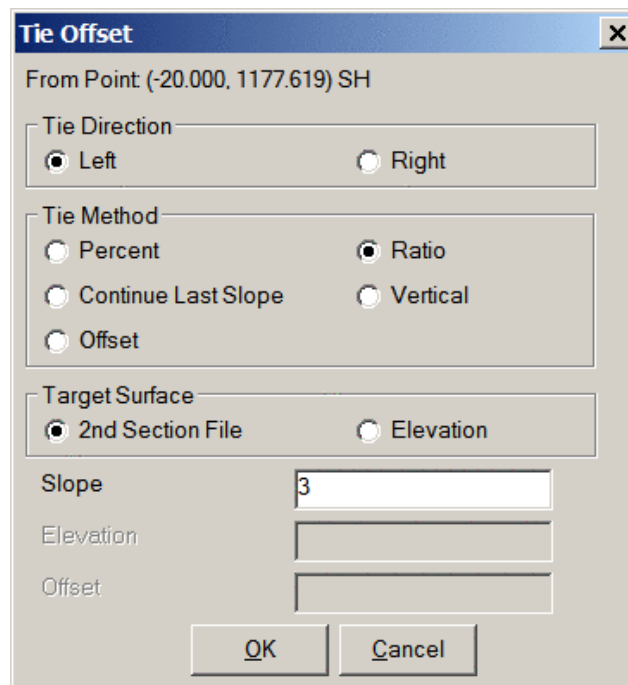

Drive (Edit Station): This function scrolls through the sections at the rate of speed specified by the user in the Speed window. The Drive View options determine whether the sections are displayed using the full width of the graphic window or centered in the window. The combination of Full Grid Range and Auto Zoom All allows the sections to rise and fall with the centerline elevations, as if you were driving an actual road. With Auto Zoom All off, and Full Grid Range on, the grid itself moves up and down at the current position of the first section, as you drive. Focus View On Offset Range allows the user to set the left and right viewing limits of the sections. Section data beyond the specified limits is not displayed.

Elevation Field (Edit Station): Equations (+, -, *, /) can be entered to calculate or adjust an elevation. For instance, to subtract 1.25' from elevation 1926.18, simply enter 1926.18-1.25 and press enter. The new elevation will be calculated and displayed in the viewer window.

Tie (Edit Station): The Tie button allows you to tie the left and right surface points of the 1st section file into the 2nd section file. It is used for classic outslope intersects from final grade to existing grade. The dialog layout includes an option to tie the section to a specified elevation, in addition to a surface (second section file). A left or right tie direction can also be selected. If a point has been tied in from SH for shoulder at offset -20 at 3:1, a new offset with the description "TIE" is created. If you try another outslope such as 4:1 from the same SH shoulder point, a new "TIE" point is created and the old TIE point is removed automatically.

Lock: This function will tag the section file as locked so that no routine can automatically overwrite this file. If a routine attempts to overwrite this section file, the program will stop, report that the file is locked and prompt whether to override the lock.

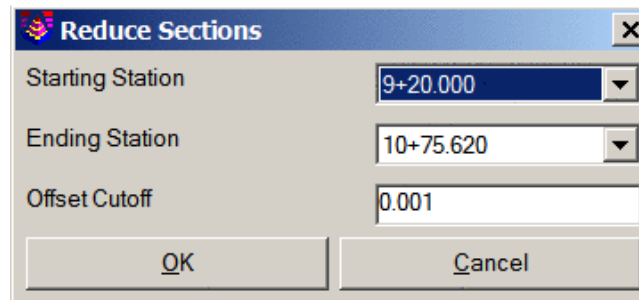

Translate: Allows you to add or subtract a distance from the offsets to adjust or shift the centerline. You can also adjust the elevations up or down. When using this option, you can choose the range of stations to operate on (starting and ending stations) and the values to adjust the offsets and elevations. If, for example, you want to shift the centerline, but not the elevations, enter the plus or minus amount you want to translate, and when prompted

for the elevation enter zero. The Station Equation function removes the station equation adjustments to the station values in order to set the station values to the true centerline distances. To use the Station Equation function, a Reference CL must be set on the main dialog. For elevations, there is an option to use a profile to define the amount of elevation change as the difference between the profile elevation and the section elevation at the zero offset.

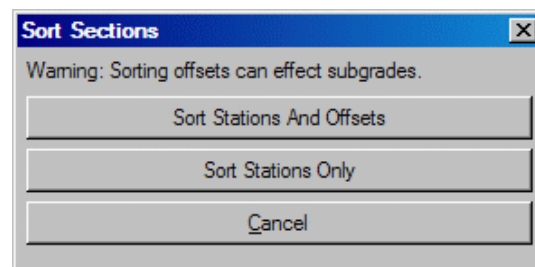

Scale: Allows you to scale the station, offsets and/or elevations by the specified scale factor. This function can be used to convert between English and metric units.

Delete: Allows you to remove a station or range of stations from the Stations List. You can delete a range of stations or an individual station. Also there are options to delete all the data for the selected stations or filter to delete only data that is outside an offset or elevation range. Since the station editor data is stored in memory, if you accidentally delete a range, Quit the editor without saving the stations to disk. Then recall the original file.

Reduce: Allows you to remove offsets from a range of stations by removing vertices in the offsets that are virtually in a straight line. Using an offset cutoff, meaning no offset and elevation moves more than the entered amount (eg. 0.01), excessive numbers of vertices can be eliminated. The command is similar to Reduce Vertices when applied to the plan view.

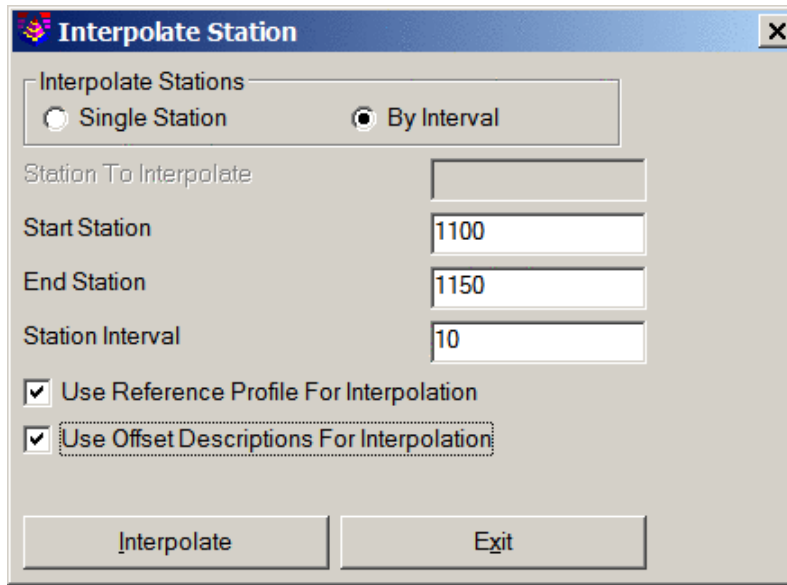

Sort: Allows you to sort the station numbers into ascending order, and sort the offsets and elevations in the individual station records (offsets are sorted from left to right). When sections are derived from the *Sections from Surface Entities* command they are already sorted, but when sections are digitized or input manually they occur in the order that you digitized them. So, for proper plotting and earthworks, you may want to run the Sort option before processing.

Combine Stations: Used to bring together in one record slot multiple occurrences of the same station number. This can occur when using the Digitize Sections (XSec) command and the section that you are digitizing has match/break lines which forces you to digitize the station in two or more parts.

Interpolate: Allows you to add or overwrite a station between two stations or projecting forward from two stations. You can choose to interpolate a single station or an interval of stations. Specify the two known stations in the Start Station and End Station edit boxes, as well as the interval if using the interval method. The program will do straight line, mathematical interpolations, adding offsets to the interpolated stations to match the totality of offsets in the starting and ending stations. However, if the offsets have descriptions, you can choose to interpolate by description and the program will interpolate by description (eg. EP at 12 on Station 1100 and EP at 15 at station 1150 would lead to EP at 12.6 at 1110). There is also an option to reference a profile, so if station 1100 and 1150 were on either side of a high point at 1125, the interpolated offsets would respect the profile as well as the starting and ending station. Use of this command is often critical to creating accurate digital terrain models of sites for machine control. Select the OK button to execute the function with the current settings or select the Cancel button to abort the process.

Copy Station: Allows you to copy a station that already exists to a new or existing station number. Choose the existing From Station using the edit pulldown box, then enter the new station number in the To Station edit box. Select the OK button to execute the function with the current settings, or select the Cancel button to abort the process.

Rename Station: Allows you to change the value of a station. In the dialog, select the existing station from the list and enter in the new station value.

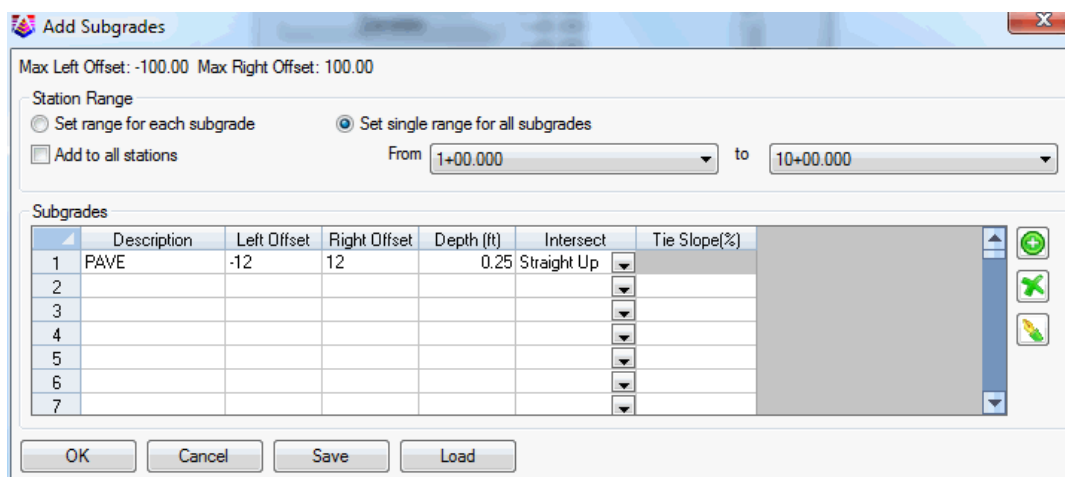

Tie Station: Allows you to tie the outslopes into the reference second section file. This routine first brings up a dialog to specify the range of stations to process. It includes a line to set the slope to tie with. The program will start from the left most offset and use this slope to find the intersection with the reference section file. Then the intersection from the right most offset is calculated with this slope. These intersection points are the tie points. The slope can be defined by percent, ratio, continue the last slope, and vertical.

Add Subgrades: Adds subgrades to the sections with specified depths and offsets. You can add multiple subgrades at a time by filling in the spreadsheet. Each row of the spreadsheet is for a separate subgrade. Each subgrade definition takes a description, left and right offsets, depth and intersection method of either straight up or at a specified slope. The subgrades are added by referencing the existing surface elevation and dropping down the specified depth. The center of the subgrade always drops down vertically. The outside of the subgrade ties in by the specified intersection method. The station range to add the subgrades can be the same of all the subgrades or

specified separately for each subgrade.

Save: Saves the currently loaded section file.

SaveAs: Allows you to save the currently loaded section file as a different file.

Exit: Allows you to exit from the section editor and return to the drawing editor. The program will warn you to save to a file if you have made changes.

Pulldown Menu Location: Sections

Keyboard Command: scted

Prerequisite: None

Draw Section File

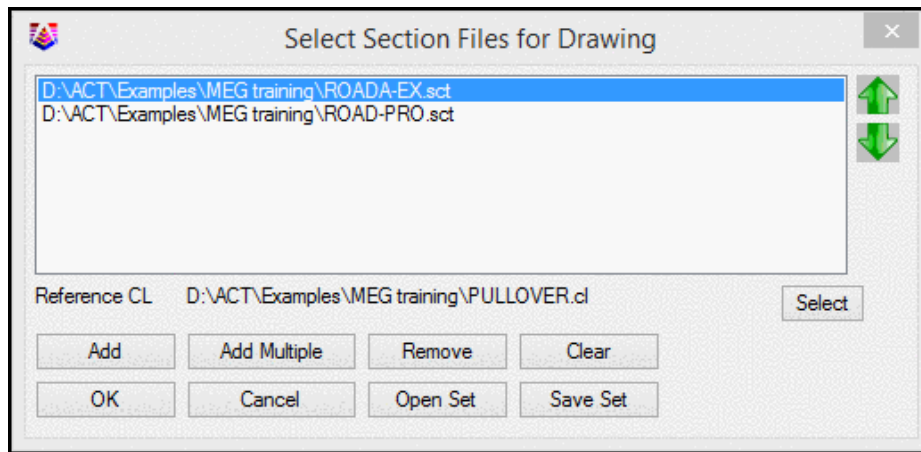

This command generates plots of cross-section data which can be used to further iterate the corridor design or used for construction documentation. The Section files drawn with this command can be created by several methods including the Section File Editor, Digitize Sections, any commands under the Create Sections from... menu, Process Road Design or Road Network commands.

For metric-based projects, please refer to the Drawing Metric Section Sheets section of this document.

The Draw Section File routine will call two primary dialog boxes:

- The first is the Section Files for Drawing dialog box that allows you to specify the Section files (.sct) to be drawn and some general sheet and layer settings.
- The second is the Draw Section File dialog box that allows you to specify various scale, layout and labeling settings.

If the *Type of Plot* option in the Draw Section File dialog box is set to "Sheet," a third Section File Sheet Drafting Parameters dialog will be displayed which provides detailed sheet layout settings.

Add: Specify an unlimited number of Section (.sct) files to plot

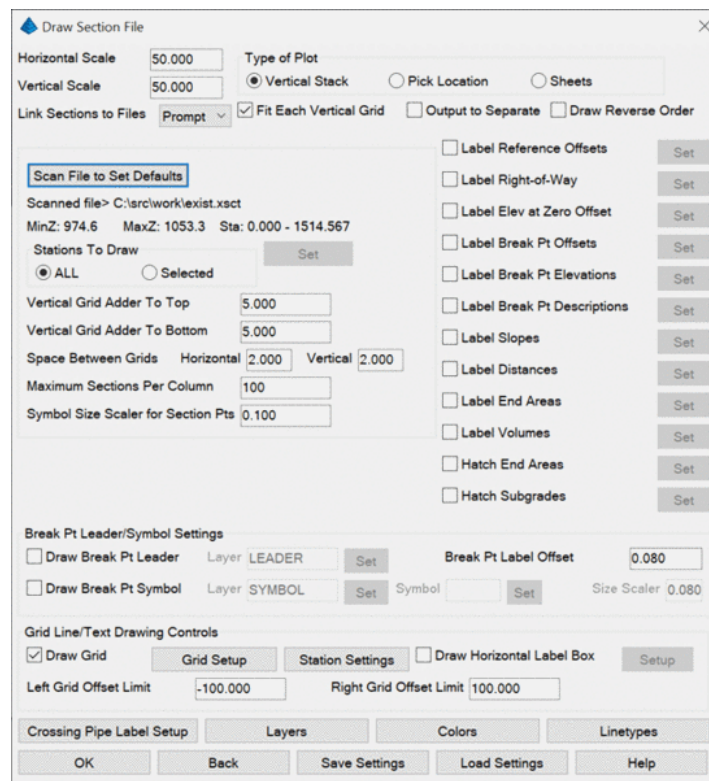

Add Multiple: Add multiple files to plot with a single selection

Remove: Highlight and remove any section file from the selection set

Clear: Clear the selection set (remove all files).

Open Set: Open a preset selection of cross sections(.XST file)

Save Set: Save the current selection set as an .XST file

After specifying the Section Files (.sct) the Draw Section File dialog box opens:

Horizontal Scale: Specify the horizontal scale.

Vertical Scale: Specify the vertical scale. The vertical scale relative to the horizontal scale determines the vertical exaggeration factor.

Link Sections to Files: This setting controls the linkage of the plotted sections to the actual section (.sct) file(s), determining how changes to the file affect the plotted sections.

Type of Plot: Specify the type of Plot you wish to create.

- **Vertical Stack:** Stacks all the cross sections in a vertical row or rows. The cross sections will be drawn in model space and will automatically stack with regard to the parameters set.
- **Pick Location:** allows the user to manually select a location in model space for each individual section.
- **Sheets:** draws the cross sections in either model space or paper space with regard to the settings in the Section File Sheet Drafting Parameters dialog box. When you pick OK on this main dialog, the Sheet Drafting Parameters dialog box appears allowing you to specify all the settings for sheet plotting.

Section File Sheet Drafting Parameters

Choose Space: Indicate whether sheets are to be drawn to **Paper** Space (also known as a Layout) or to **Model** Space. When drawing to Model Space, the Display In Paper Space option will draw the sections in model space and then create layouts with viewports to show the sections.

Layout Name: Indicate the name of the layout to which the first sheet should be drawn.

Use Template Layout: This option allows you to use a layout that exists in the current drawing as the template for layouts created by the command. This option only works for paper space sheet creation.

Add Layout Name To File For Drawing Output: When the Output To Separate Drawing option is active from the

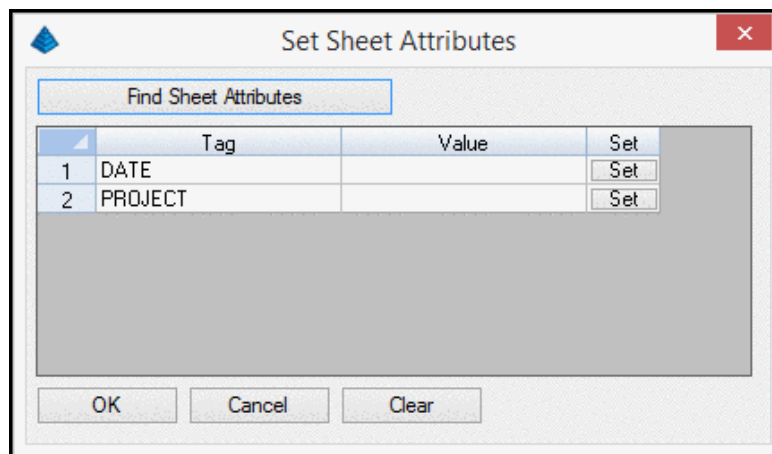

main settings dialog, this option creates separate drawing files for each sheet by appending the layout name to the drawing name.

Tile Sheets: Enabling this option places all sheets in the specified Layout Name. The result is a vertical stack of sheets in the layout. Disabling this option allows additional layouts to be created each containing one sheet. As additional layouts are created, the name of each successive layout is incremented by a value of 1.

Plot at 1:1: Enabling this option draws the sections so that one unit horizontally in the section is equivalent to one plotted unit. The ratio of the Horizontal Scale:Vertical Scale determines the amount of vertical exaggeration.

Block Name: Specify the drawing name that will be inserted for each sheet. The default is SCTSHT1 which is included with Carlson Software and is located in the `%AppData%\Carlson Software\...\Sup\` folder. You can use this or use a sheet block of your own design. The block should be drawn at a 1:1 scale since the program inserts it using the Horizontal Scale setting from the previous dialog. Click the **Set** button to browse/navigate to an alternate drawing file.

Set Sheet Attributes: For grid sheet block names that utilize attributes (useful for items such as sheet numbers, drawn date, drawn by, job name, *etc*), use this command to provide attribute values that will be placed for each sheet block:

Find Sheet Attributes: This routine will scan the Block Name for any attribute definitions and return them to the dialog box so values can be established for each attribute.

Starting Page #: Indicate the starting page number to be applied to the plots through the use of the Set Sheet Attributes command.

Scan Block for Width/Height: Use this routine to scan the specified Block Name for its width and height. These values are populated into the Sheet Width and Sheet Height controls.

Sheet Grid Interval: Indicate the spacing between the grid lines in the sheet block. The routine will not draw the grid lines and uses this information to control the placement of each section onto the sheet.

Vertical Space Between Sheets: Indicate the amount of space that should be placed between sheets when the Tile Sheets option is enabled.

Rows of Sections

Per Sheet: Specify the maximum number of sections that can be stacked on top of each other on a sheet.

Space Between: Specify how much space will be placed between the top of the last section plotted and the bottom of the next section. For U.S. Customary based units, a value of 1 would be a good starting value.

Columns of Sections

Per Sheet: Specify how many columns of sections can be placed on each sheet.

Space Between: Specify the distance between the left edge of one section column edge and the right edge of the next column. This will generally be the area where elevation labels and station circle annotation will be placed. For U.S. Customary based units, a value of 2 would be a good starting value.

Label Grid Zero Offset: Enable this toggle if the zero offset location of each section should be labeled on each section.

Column Order: Controls the station order of the sections for going top to bottom, or bottom to top.

Offset for 1st Section

Horizontal Offset: Specify how far from left edge of the sheet the first section will be placed on to the section sheet. The block SCTSHT1 has a 1" left margin.

Vertical Offset: Specify how far from bottom edge of the sheet the first section will be placed on to the section sheet. The block SCTSHT1 has a 1/2" bottom margin.

Preview: This button allows you to get an approximate idea of what the initial sheet will look like based on the current settings.

Back: This button allows you to return focus to the main dialog and make changes to any previous settings or cancel the routine.

Save Settings: This button allows you to save all the parameters settings to a file so you can easily recall them for another project.

- **Off:** A linkage between the SCT file and the graphical section entities is not formed; you will need to manually re-create section sheets after section design changes.
- **Prompt:** You will be asked whether or not to update the plotted sections when the underlying SCT file is changed.
- **Auto:** The plotted sections will automatically update when the underlying SCT file changes.

Fit Each Vertical Grid: When checked, the grid bottom elevation and grid height are set automatically and you may specify values to add to the top and bottom of each grid (see Vertical Grid Adder to Top and Vertical Grid Adder to Bottom). When not checked, you specify the elevation of the grid bottom and the grid height through the Grid Bottom Elevation and Grid Vertical Height controls, respectively.

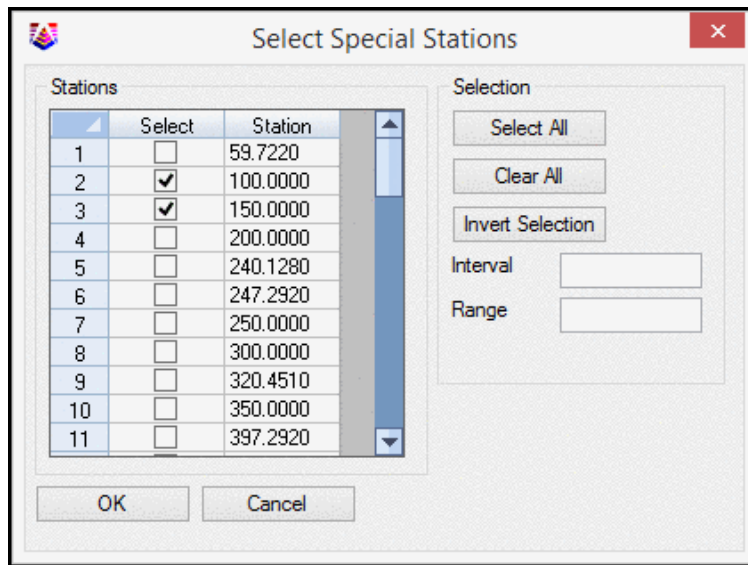

Output to Separate Drawing: When checked, this option will prompt for a New drawing name and location into which all cross sections will be drawn. When using the Vertical Stack method, the program will prompt for whether to output all the sections to the same drawing or create a separate drawing for each station.

Draw Reverse Order: When checked, this option will draw the cross sections in the order of the highest numbered station to the lowest.

Scan File to Set Defaults: This button allows the program to set the minimum and maximum parameters. If you choose this option, the program will automatically set the range of stations, vertical spacing distance, right and left grid distances and starting/datum elevation. This option writes a file called "sectsort.tmp" that is read and used to set the defaults the next time you use the program. Therefore, if you are selecting a different .SCT file to plot you should use this option to update the .TMP file.

Stations to Draw: Select eight All or Selected to specify the range of stations from the file which will be drawn.

- **All:** When selected the program will draw all of the stations in the file.
- **Selected:** This option will allow the user to specify exactly which stations will be drawn via the Set dialog box.

Interval: Specify the interval of stations to draw. For example, perhaps you sampled every 25 feet with the Sections from Surface Model command for more accurate quantities but only want to plot 50 foot stations. ALL is the default value for this field.

Range: Specify a range of stations to include

Vertical Grid Adder to Top: Specify the distance that will be added to the highest elevation of the section for the sheets and pick location options. This option is only available when Fit Each Vertical Grid is checked ON.

Vertical Grid Adder to Bottom: Specify the distance that will be subtracted from the lowest elevation of the section for the sheets and pick location options. This option is only available when Fit Each Vertical Grid is checked ON.

Grid Bottom Elevation: Specify actual bottom elevation for each section grid. This option is only available when Fit Each Vertical Grid is checked OFF.

Vertical Grid Height: Specify actual grid height for each section grid. This option is only available when Fit Each Vertical Grid is checked OFF.

Space Between Grids: Specify the **Horizontal** and **Vertical** distance between the sections when they are drawn when the Vertical Stack option is specified.

Maximum Sections Per Column: Sets the maximum number of sections allowed per column when the Vertical Stack option is specified.

Symbol Size Scaler for Section Pts: Sets the scale as a multiplier of the overall drawing scale for the section points to be drawn.

Label Reference Offsets: When enabled, the offset from selected break points of one section file relative to the position(s) of selected points from another section file can be labeled onto the plots.

Specify which section(s) to draw

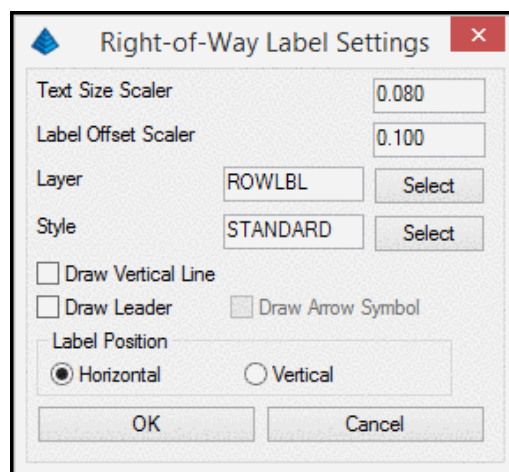

Set: Opens the dialog box for to set the display precision, text size scaler, layer, text style, color, prefix, suffix, position and draw order for these labels.

From Break Points: allows a user based filter to specify break points

To Reference Points: allows the user to control which offsets to label by specifying the reference points from a template (TPL) file.

Label Right of Way: When enabled, this option will label Right of Way points as defined using the Section Points from Right of Way command. Press the **Set** button to the right of this toggle to set the text size and label offset scalers, layer and text style settings.

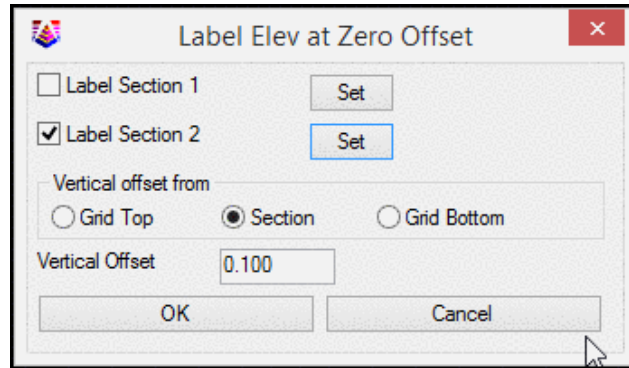

Draw Vertical Line: Places a vertical line, from top to bottom, through the Right-of-Way point.

Draw Leader/Draw Arrow Symbol: When enabled, a short vertical line is drawn, with or without, the arrowhead through the Right-of-Way point.

Label Position: Indicate the desired orientation of the "ROW" text label.

Label Elev at Zero Offset: Will label the section elevation at offset zero.

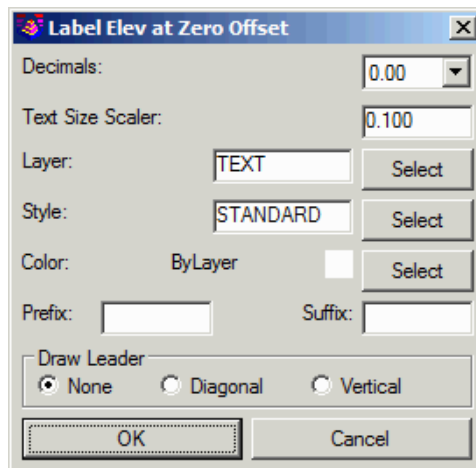

Specify which section(s) to draw

Vertical Offset from: sets the location of the Label relative to the grid or section.

Vertical Offset: controls the offset distance for the label.

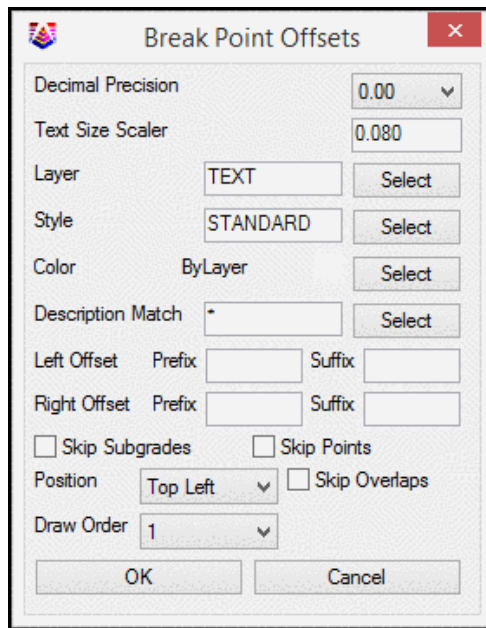

Set: opens the dialog box for to set the display precision, text size scaler, prefix, suffix, color and layer for these labels. The Draw Leader option can be set to None, Diagonal or Vertical.

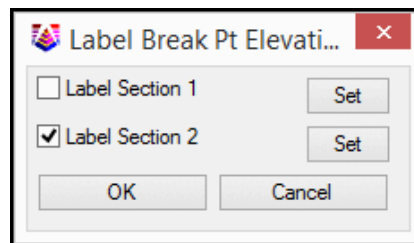

Label Break Pt Offsets: Select the Section(s) to be included in the labeling parameters

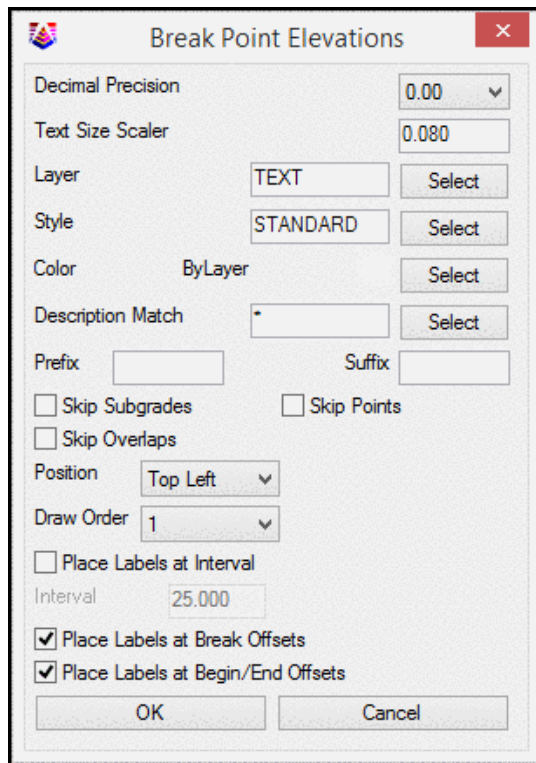

Set: Opens the dialog box for to set the display precision, text size scaler, layer, text style, color, prefix, suffix, and position for these labels. In addition the label position and draw order can be selected.

Label Break Pt Elevations: Select the Section(s) to be included in the labeling parameters.

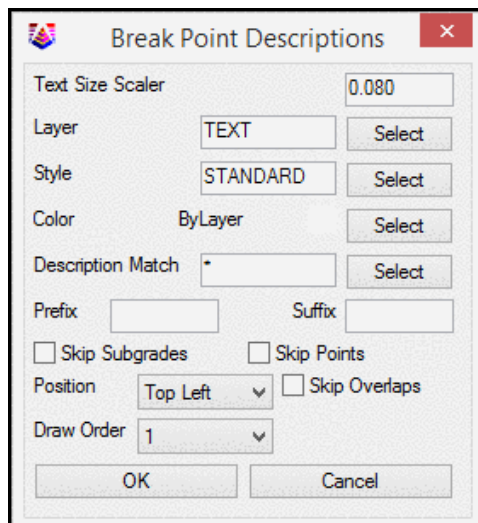

Set: Opens the dialog box to set display precision, text size scaler, Layer, style, color, prefix, suffix, position and draw order for these labels. The Description Match is a way to filter which section points to label. There are also options to toggle whether or not to place labels at the break offsets or Beginning and ending offsets.

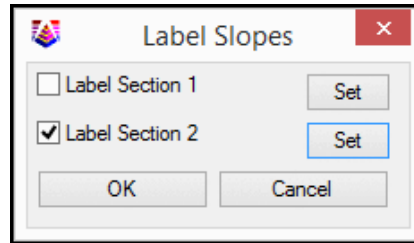

Label Break Pt Descriptions: Select the Section(s) to be included in the labeling parameters.

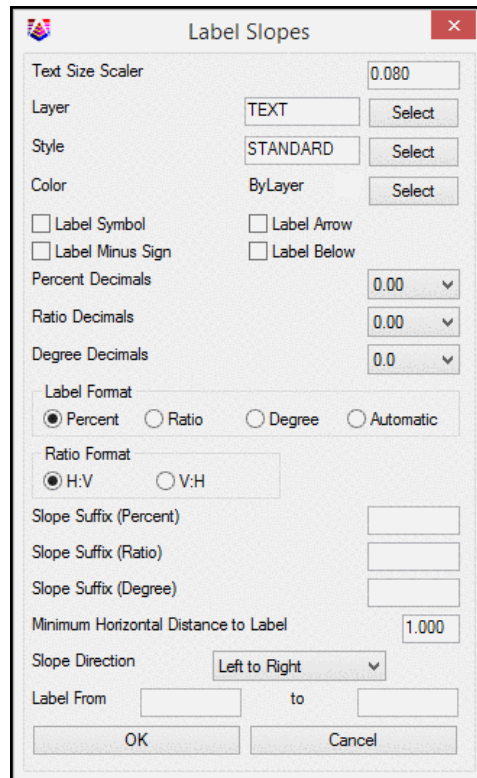

Set: opens the dialog box to set the text size scaler, layer, style, color, prefix, suffix, position and draw order for these labels. The Description Match is a way to filter which section points to label.

Label Slopes: Select the Section(s) to be included in the labeling parameters.

Set: Opens the dialog box to set the text size scaler, layer, style and color for these labels.

Label Symbol: places the % symbol after the slope label

Label Arrow: draws a slope direction arrow next to the label.

Label Minus Sign: places a - in front of negative slope values.

Label Below: places the label below the section line.

Label Format: controls which format the slopes will be labeled in.

Ration Format: Sets either *horizontal to vertical* or *vertical to horizontal* format

Slope suffix (Percent): creates a suffix to the slope label when using the Percent Label Format.

Slope suffix (Ratio): creates a suffix to the slope label when using the Ratio Label Format.

Slope suffix (Degree): creates a suffix to the slope label when using the Degree Label Format.

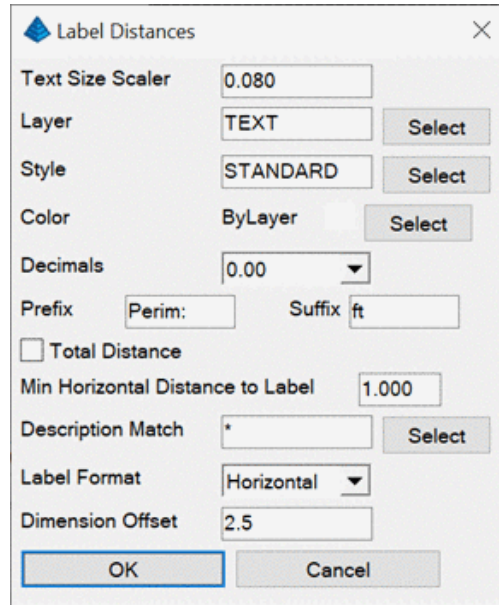

Minimum Horizontal Distance to Label: sets the minimum value of a segment length to label.

Slope Direction: can either be set *left to right* or *right to left*.

Label From: specifies the portions of the section to label a slope. for example, you could specify to only label the

slope between the SW (sidewalk) and SH (shoulder) ID points as defined in the Template file (.tpl) that was used to generate your Section file (.sct).

Label Distances: This option labels the horizontal distances between offset points. There are separate Label Distances settings for each section file. On the first dialog, toggle which section file you want to label distances. Choose the Set button to control the settings for that station. The settings dialog has settings for the distance label size, layer, style, color, decimals and suffix. The **Total Distance** option chooses between labeling just the total distance of the section or individual section segments. The **Description Match** is a way to control which section offset points to label. The **Min Horizontal Distance To Label** setting is a way to filter out short section segments and only label the longer segments. The **Label Format** sets whether to label the distances as a CAD dimension or as regular text rotated by the section slope or horizontal. The **Dimension Offset** controls the vertical distance between the section segment and the label.

Label End Areas: Will label cut and fill end areas on each section. The end areas are either between two sections (existing and design) or with a single section that creates a closed loop like for a tunnel. This dialog box sets the Decimal Precision, text size scaler, layer, style and color of the labels.

The dialog box 'End Area Settings' contains the following fields and options:

- Decimal Precision: 0.0
- Text Size Scaler: 0.080
- Layer: ENDAREA (with Select button)
- Style: STANDARD (with Select button)
- Color: ByLayer (with Select button)
- Cut: Prefix Cut, Suffix
- Fill: Prefix Fill, Suffix
- Skip Zero Labels
- Auto-Center On Section
- Offset: Horizontal 0.000, Vertical 0.000
- Vertical offset from: Top, Bottom
- Use Table
- Title Header: End Areas, Append Station
- Name Header: Material, Value Header: SF
- Include Elevation
- Ground Header: Ground, Final Header: Final
- Include Subgrades
- Subgrade 1: Asphalt, Subgrade 2: Gravel
- Subgrade 3: , Subgrade 4:
- Subgrade 5: , Subgrade 6:
- Buttons: OK, Cancel

Use Table: this option will create a table of the cut/fill values on each section.

Title Header: labels the table with this header. **Append Station** adds the station to the title header.

Cut and Fill label prefix and suffix: allows user defined prefix and suffix added to the label

Auto-Center On Section: this option will center the table or label next to the drawn cross section.

Skip Zero Labels: this option will not label cut or fill values of zero.

Include Elevation: this option will include the centerline elevations in the table. The Ground and Final Headers are user defined.

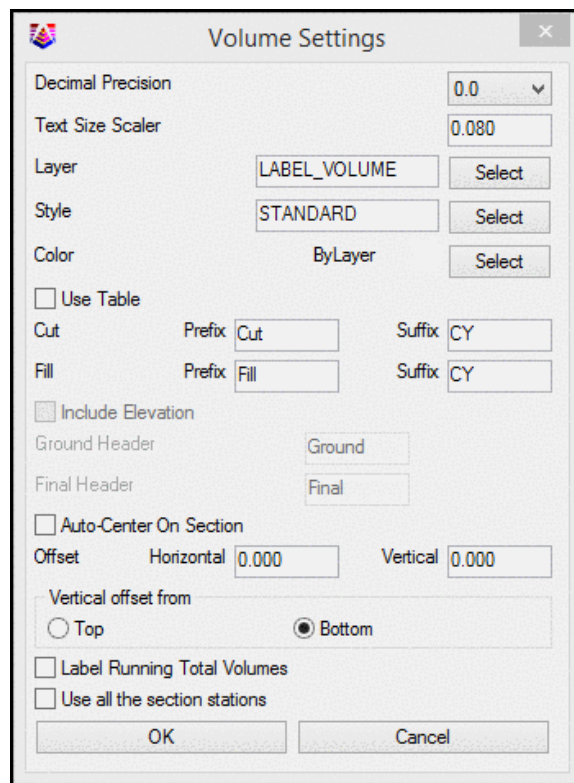

Include Subgrades: labels the end areas of the subgrades with settings for the names of up to 6 subgrades.

Offset Horizontal and Vertical: manually controls the placement of the table or label.

Vertical offset from: specifies where the offset dimensions are to be referenced to.

End Areas	
Material	SF
Cut	387.5
Fill	0.0
Asphalt	2.4
Gravel	8.0
Stone	6.7

Label Volumes: Will label cut and fill volumes on each section. The volumes are measured between the current station and previous station. There are settings to control the format and placement of the labels. This dialog box sets the Decimal Precision, text size scaler, layer, style and color of the labels.

Use Table: option will create a table of the cut/fill values on each section.

Cut and Fill label prefix and suffix: allows user defined prefix and suffix added to the label.

Include elevation: when enabled, this option will include the centerline elevations in the table. The Ground and Final Headers are user defined.

Auto-Center On Section: this option will center the table or label next to the drawn cross section.

Offset Horizontal and Vertical: manually controls the placement of the table or label.

Vertical offset from: specifies where the offset dimensions are to be referenced to.

Label Running total Volumes: will label the accumulative total volumes with each station.

Use all the section stations: chooses between using all the section stations to calculate volumes or only the stations being drawn.

Hatch Subgrades: This option hatches the subgrade areas of design section using the section points with descriptions starting with SUBGRADE. There are settings for up to four different hatch patterns.

Hatch End Areas: This option hatches the cut/fill areas between the first and second section files. The program treats the first section as existing and the second as design for determining cut verses fill. There are separate hatch pattern, color and scale settings for cut and fill.

Draw Break Pt Leader: Enable this option to include a leader with the Label Break Pt Offsets, Label Break Pt Elevations or Label Break Pt Descriptions options. Click the **Set** button to specify the desired layer for the leader.

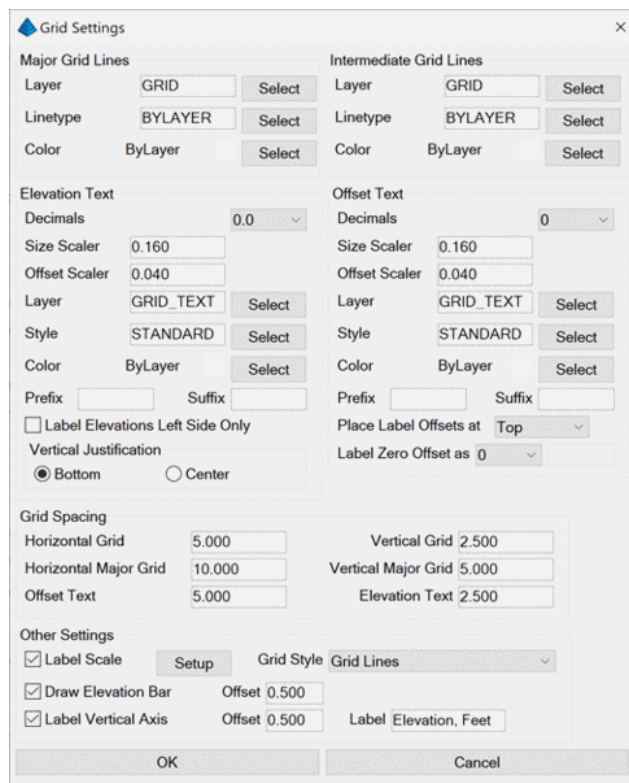

Note:

- When redrawing sections, the program retains any custom edits to label and leader positions.

Draw Break Pt Symbol: Enable this option to include a symbol with the Label Break Pt Offsets, Label Break Pt Elevations or Label Break Pt Descriptions options. Click the **Set** button (to the immediate right of the Layer control) to specify the desired layer for the symbol. Click the **Set** button (to the immediate right of the Symbol control) to specify the desired symbol and indicated the desired Size Scalar.

Break Pt Label Offset: Indicate the desired offset amount from the surface break point to its label.

Draw Grid: When enabled each cross section is drawn on a grid. The **Grid Setup** is used to customize how the grid will be drawn.

Main Grid Lines: Sets the Layer, Linetype and Color for the Major Grid Lines as set below

Intermediate Grid Lines: Sets the Layer, Linetype and Color for the Intermediate Grid Lines. (Those not defined as major)

Elevation Text: this section contains controls for setting the elevation Precision, text Size Scaler, Offset Scaler, Layer, text Style, and color, prefix and suffix for the elevation labels.

Offset Text: this section contains controls for setting the offset Precision, text Size Scaler, Offset Scaler, Layer, text Style, and color, prefix and suffix for the offset labels.

Label Elevations Left Side Only: when enabled, elevations will be labeled on the left side of the sections only.

Vertical Justification: this sets the justification of the elevation text.

Place Label Offsets: **Top** will place the labels at the top of the grid, **Bottom** will place along the bottom of the grid and **None** skips drawing the offset labels.

Grid Spacing: sets the horizontal and vertical spacing for the grid lines as well as the horizontal and vertical Major Grid lines the offset text (grid spacing) and the elevation text.

Label Scale: when enabled will label the horizontal and vertical scale.

Grid Style: sets the type of grid lines to be drawn. Grid Lines, Ticks Only, Ticks and Dots, Ticks and Checks, Text Only, Grid Lines and Dots, or Grid Lines Below 1st Section. This last option trims the grid lines by the first section so that the grid lines are drawn only below the section.

Draw Elevation Bar: places the elevations on a bar offset from the grid at a user defined location.

Label Vertical Axis: draws a label vertically along the vertical axis.

The **Station Settings** button displays another dialog box for the station label settings including decimal places, size, layer, style, color, prefix, suffix, format type and position. When the section file has descriptions assigned to the sections, the descriptions are labeled under the station position value. The **Circle Station** option will draw a circle around the station label.

Draw Horizontal Label Box: Enabling this option will draw a table with desired labeling above or below each cross-section. By picking the **Set** button to the right, you can choose the data to be placed in the table. The Elevation, Offset and Description of each point on the cross section can be added to the table. If more than one Section file (.sct) is being drawn on the cross-section, you will also have the option of displaying the elevation difference between sections.

Box Placement: Chooses between drawing the label box above or below the section grid.

Draw Vertical Line: Sets drawing a vertical line from the section data point to the specified row in horizontal label box.

Title Box Width: Sets the size for the field name in the label box.

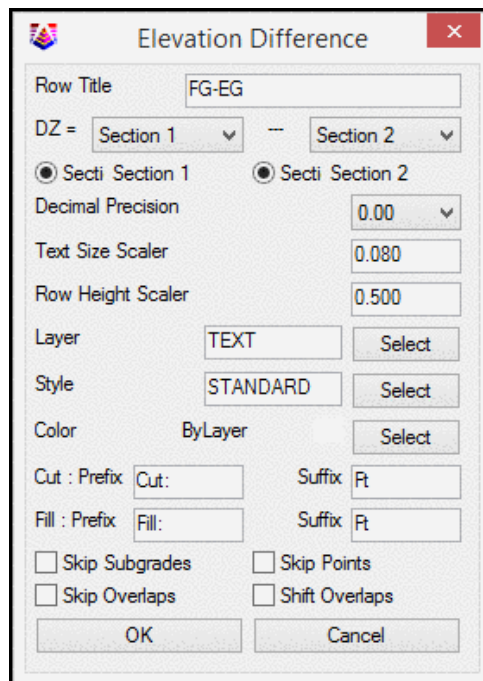

Offset From Grid: Controls the separation distance between the section grid and the label box.

Overlap Transition Distance: When drawing vertical lines and the labels are shifted to prevent overlap, this setting controls the length of the line for shifting over.

Label Elevation at Interval of Top Section: When labeling multiple values such as elevations for different sections, this option uses the stations from the section points of the top section as the stations to label for all the sections.

In the *Draw Horizontal Label Box* dialog, select from the **Available Fields** in the list on the left to populate the list of **Used Fields** on the right side. Once an item has been moved to the list of **Used Fields**, you can double-click on the Field to change settings and format for each Field. An example of the **Elevation Difference** option is shown below:

The **Row Title** for each field can be edited from the default to show a descriptive title. The **DZ** value in the Elevation Difference settings dialog allows you to specify which Section's elevations are to be subtracted from the other. This setting is critical to return the correct cut and fill depth values. In all field settings boxes, you have the ability to skip surface points in order to make the data more legible.

Place Labels at Interval: This option creates labels at the specified offset interval.

Place Labels at Break Offsets: This option creates labels at each section point.

Skip Subgrades: Enable this option to skip all subgrades as may have been defined in Design Template files (.tpl).

Skip Points: Enable this option to skip points in the Section file (.sct) that were created using any of the **Create Section Points...** commands.

Skip Overlaps: Enabling this option will cause any overlapping text in the table to be skipped. Having this option enabled will disable the Shift Overlaps option.

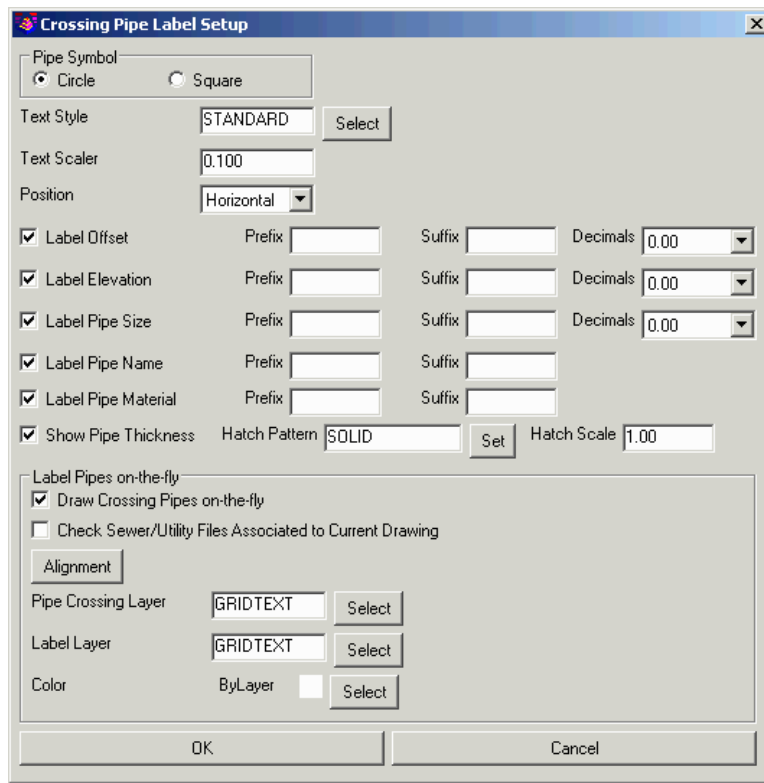

Shift Overlaps: Enabling this option will shift any text in the table to the right so that it does not overlap preceding text.

A sample cross-section with **Horizontal Label Box** is shown below:

EG : Elevation	284.92	285.42	285.48	285.08	284.70	284.42	283.37	283.07	282.70
EG : Offset	-100.00	-66.78	-58.61	-36.29	-1.24	21.45	55.51	72.66	100.00

Crossing Pipe Label Setup

Pipe Symbol: Choose whether to show the Pipe Crossing symbol as a circle or a square. When the sections are drawn with vertical exaggeration by different horizontal and vertical scales, then the circles or squares will be stretched into ellipses or rectangles.

Text Style and Text Scaler: Specify the text style and size of Pipe Crossing labels.

Position: Chooses between creating horizontal or vertical labels.

Label Offset, Label Elevation, Label Pipe Size, Label Pipe Name, Label Pipe Material: Enable any or all of these options to label the distance left or right off the alignment (Label Offset), the invert elevation, pipe size and pipe name of each crossing pipe. Use the optional settings for specifying "Prefix" or "Suffix" text and use Decimals to set precision for each label.

Show Pipe Thickness draws the pipe thickness around the crossing symbols using the specified hatch.

Draw Pipe Crossings on-the-fly: Enable this option to have Crossing Pipes that have been created using a Sewer Network file (.sew) or Draw Pipe 3D Polyline command drawn in cross sections. It is not necessary to enable this option if Pipe Crossings have been saved to a Section file (.sct) using the Section Points from Pipes command.

Check Sewer/Utility Files Associated to Current Drawing: This option looks for crossings with the pipes in .sew and .util files for the current drawing. To review and edit which files are in the current drawing, use the File > Drawing Explorer command. The program will show a list of files to choose from for checking.

Alignment: Pick this button to select either a Centerline file (.cl) or Section Alignment file (.mxs) to scan for Crossing Pipes.

Layer and Color: These settings specify the layer and color of the Pipe Crossing symbol.

Prompts

If the Pick Location option was specified, the program scans the station data and determines the minimum and maximum elevations, and proposes a datum elevation. If you have pre-plotted a grid sheet and want to reference another local grid coordinate, then change the datum elevation appropriately. The Pick Location type of plotting has the following prompts:

Station> 25.000 Min Elev> 1055.301 Max Elev> 1057.068

Change datum elev/<Select point that represents 0 offset elev 1050.0>: Pick a point

Station> 50.000 Min Elev> 1055.557 Max Elev> 1057.324

Change datum elev/<Select point that represents 0 offset elev 1050.0>: Pick a point

The program continues to prompt until the last station in the range specified is drawn. You can use the Cancel function (the *Esc* key) to stop plotting, if necessary.

If the Sheets option was specified with Model space as the destination, you can choose where to insert the sheet(s):

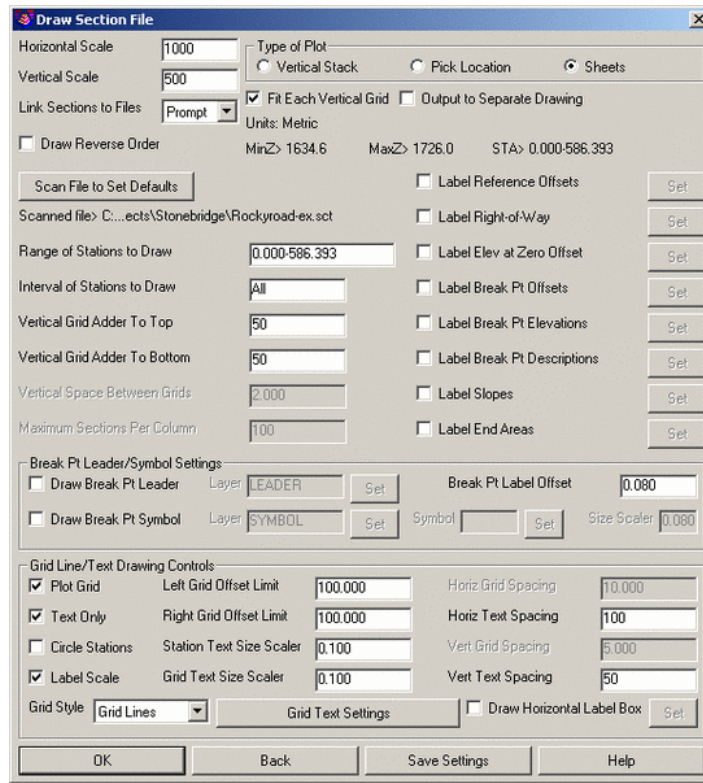

Select Starting Point for Row of Sheets <0.0,0.0>: Pick a point or press Enter to accept the default value specified

Sheet Sample

Drawing Metric Section Sheets

First, be sure that you are set to metric mode in Drawing Setup under the Settings menu. For our example, assume a 1:1000 horizontal scale. Once set, issue the Draw Section File command and click OK to reach the second dialog. There is a different block name for metric sections called schsht2.dwg which is located in the **%App-Data%\Carlson Software\...\Sup** folder. Begin by setting the parameters for the second dialog as shown.

Second dialog with metric settings

Third dialog with metric settings

Adjust settings as needed to achieve the desired look/layout.

For sections that make a closed loop such as for tunnels, the Label Volumes, Label End Areas and Hatch End Areas will use the difference between the sections. When you have one section for the tunnel design and another section

for the actual, these features will show the over cut and under cut amounts.

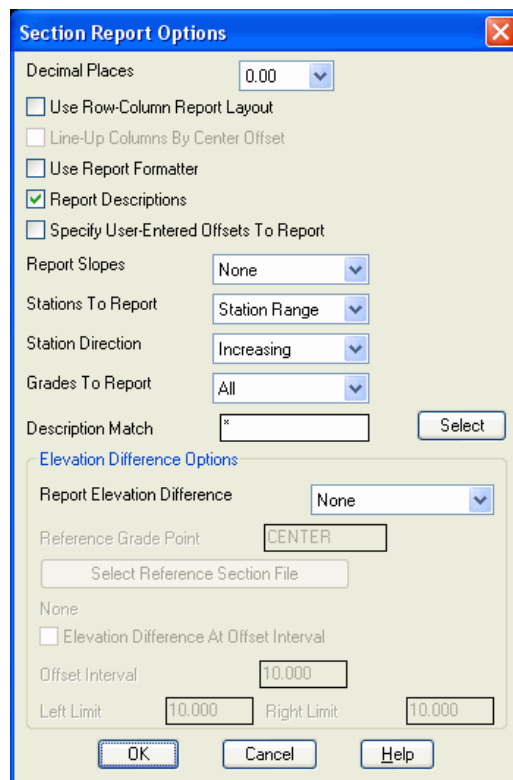

Pulldown Menu Location(s): Civil > Sections, Field > Roads

Keyboard Command: drawsct

Prerequisite: A Section (.sct) file

Section Report

This command generates a report of a section file for the specified stations. The information contained in the report is determined by the settings in the Section Report Options dialog box.

Decimal Places: Specify the display precision for stations and elevations.

Use Row-Column Report Layout: When checked, offsets are reported in columns. Example reports showing the difference are shown below. Also when active, there is an option to **Line-Up Columns By Center Offset** which makes the zero offset column line up. Otherwise, the columns are lined up by the left most offset.

Use Report Formatter: Report output is directed to the Report Formatter which allows for custom reports, as well as being able to export the report to Microsoft Excel or Access.

Report Descriptions: Controls whether the descriptions for each section point are reported.

Specify User-Entered Offsets To Report: After choosing OK from this dialog, the program will prompt for additional offsets to report with interpolated elevations. These are for offsets that don't already exist as section points in the section file.

Report Slopes: Will report the slope between section points. Specify how to report the slopes, either none, percent, ratio, or auto format. Auto format means that slopes less than 10% are reported in percent, while greater slopes are reported as ratios.

Stations to Report: Specify either a range and interval of stations to report or enter each station one at a time.

Station Direction: This setting controls the order of the stations for the report.

Grades to Report: This applies to section files that contain subgrades. For these section files, you can choose which grades to report (top surface or subgrades). All is also an option.

Description Match: This field can be used to filter the section points by their description.

Report Elevation Difference: Reports section elevations by Reference Grade Point, Section File or Surface File. The Surface File method works with a triangulation file (TIN) and can be used to compare a 3D TIN model with the design sections.

Reference Grade Point: Specify the reference grade ID. Only available if Grade Point option is selected, as mentioned above.

Select Reference Section File: Specify a reference file. Only available if Section File is chosen, as mentioned above.

Elevation Difference at Offset Interval: Used if there is an elevation difference.
The next three options only available if Elevation Difference at Offset Interval is clicked.

Offset Interval: Value required.

Left Limit/Right Limit: Values required.

Sample Report

Pulldown Menu Location: Sections

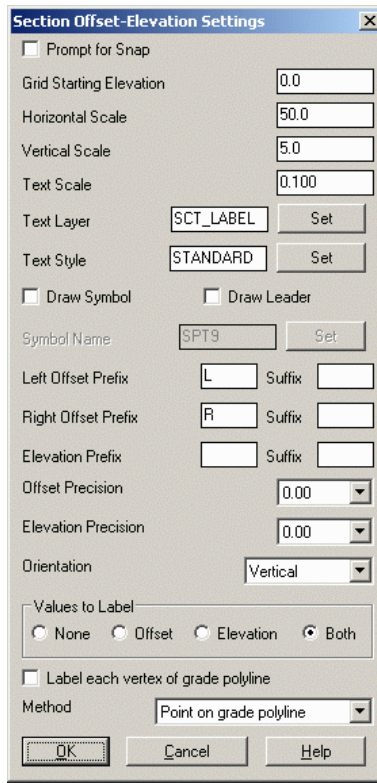

Keyboard Command: sctprnt

Prerequisite: A section file (.sct)

Offset & Elevation Report/Plot

This command calculates the offset and elevation at points along a polyline on a section grid. The results can be drawn on the grid or just displayed on the text screen. The Method setting controls whether the offset and elevation are either calculated for each vertex of the polyline, at picked points along the polyline or at user specified points on the grid. This command can also be used as a section inspector. As you move the cursor across the section, the offset, elevation and slope are reported in real-time in a pop-up window.

The Prompt For Snap toggle controls whether the command will present the snap dialog as you pick points to figure the offset and elevation at. The Grid Starting Elevation edit box allows you to input the beginning elevation of the local grid that you are designing in. Use the Scale edit boxes to set the proper horizontal and vertical scales for your design environment. The Label each vertex of grade polyline option will draw the offset-elevation label above each point in the selected polyline. There are also settings to control the layer, size, style, orientation, prefix, suffix and decimal precision for all the labels.

Prompts

Keyboard Command: offelev

Prerequisite: Must plot the polyline that represents the grade

Elevation Zone Section Volumes

This command calculates section volumes between two section files and reports the volumes broken out by elevation zone. After selecting the bottom and top section files, there's a dialog to set the starting elevation for the zones and the elevation interval. There is also the option to supply additional section files for reporting volumes for additional materials.

Station	Material	LTW	Area (S.F.)
0+000	Coastal	8200-8200	0
0+000	Coastal	8200-8200	237
0+000	Coastal	8200-8200	591

Draw Mass Diagram

This command draws a mass diagram uses data from a .MAS file created by commands such as Process Road Design, Calculate Section Volumes or Edit-Process End Areas. The diagram options are set in the dialog shown here. The Mass Diagram method of Instantaneous graphs the difference in cut/fill at each station, and the Accumulative method graphs the running total cut/fill difference starting from the first station. The other settings are a subset of the settings in the Draw Profile command. Please see the Draw Profile section of the manual for a description of these settings.

Mass Haul Report

This command reports the mass haul amounts and stations of balance. Before running this command, the mass haul data file must be created with another routine such as Process Road Design, Calculate Section Volumes or Mass Haul Analysis. The mass haul data file is a profile (.pro) format with stations and mass haul volume instead of the stations and elevation of the typical profile.

The Mass Haul Report has the stations and accumulated cut/fill volume balance up to the stations. The Report Balance Stations Only option makes a report for the stations where the cut/fill is balanced.

Mass Haul Report

Station Balance

0+09.226 0.000

1+53.409 0.000

7+04.560 0.000

11+97.656 0.000

Pulldown Menu Location: Sections > Cut/Fill Analysis

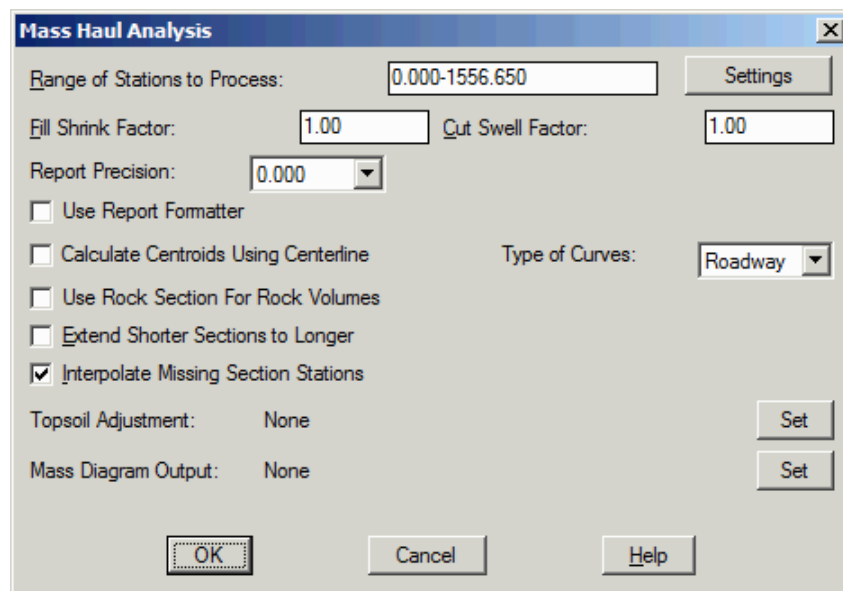

Prerequisite: Mass haul data file (.pro)

Keyboard Command: mhreport

Mass Haul Analysis

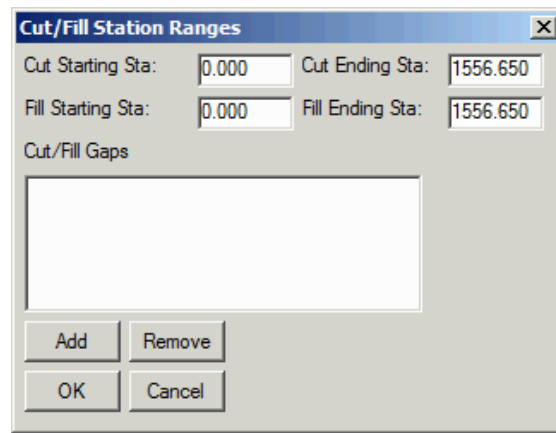

This command will determine the volume and haul distance for each group of net cut and net fill station ranges along a road. The program calculates the optimized cut to fill movements so that the total volume-distance moved is minimized.

You will first be prompted to select the Existing Ground section file and the Design Surface section file or on End Area (.ew) file. These files will be used to determine the Mass Haul quantities. If you do not have either of these files, you can create them using the different Create Sections commands under Roads. After you selected your section (.sct) files or (.ew) file, the following dialog will appear.

Range of Stations: The program will pick up the range of stations determined by your section files. In this field, you can modify the range of stations to process. The Settings button brings up another dialog with more station

options:

Cut/Fill Starting/Ending Stations: The Cut and Fill Starting and Ending Stations are for tapering the end areas at the start and end of the section range down to zero beyond the station range.

Cut/Fill Gaps: Use the Add and Remove buttons to define a series of station ranges for cut/fill gaps where the program will not calculate any volumes.

Shrink/Swell Factors: The Shrink Factor is multiplied by the fill quantities and the Swell Factor is multiplied by the cut quantities.

Report Precision: This setting controls the number of decimal places to use in the report.

Use Report Formatter: The Report Formatter will allow you to customize the information reported by the Mass Haul Analysis.

Calculate Centroids Using Centerline: This option will find the center offset for each Cut/Fill area and use a centerline to adjust the station interval along curve segments for the end area volumes.

Use Rock Section For Rock Volumes: This option will use a third section file for reporting rock cut quantities.

Extend Shorter Sections to Longer: This option will find your longest section and match the length of all your other sections to it.

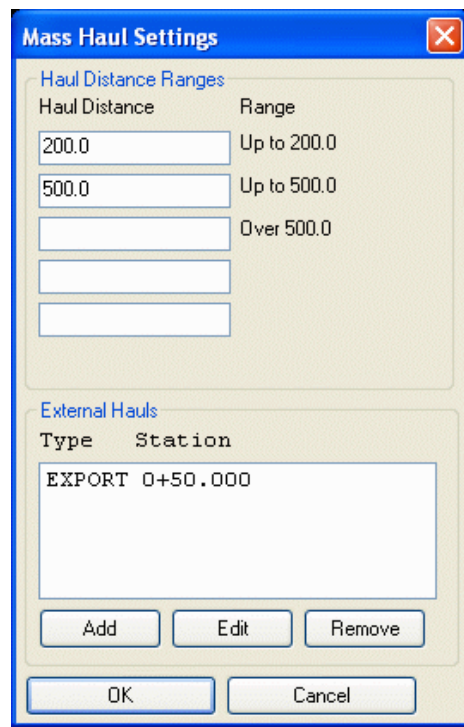

Interpolate Missing Section Stations: Toggle this on to interpolate any missing stations so that the Mass Haul report can use all the stations.

Topsoil Adjustment: This will apply a Topsoil Removal/Replacement definition from the Template Adjustments to adjust the sections.

Mass Diagram: This will create a Mass Diagram of the cut/fill balance by station. This data is stored in a profile file (.pro) format file, and you can use Draw Profile to draw it.

Mass Haul Settings

The Haul Distance ranges are for reporting the cut to fill volume movements by the different haul distance ranges. For each range of stations with a net cut volume, the report has a row for the net fill station range the cut was moved to, the amount of cut/fill, the volumes per haul distance range, the average haul distance per range and the overall haul distance average. The In Station Volume is the amount of cut and fill that occurred at the same station and doesn't have to be hauled to another station. The purpose is to evaluate how far the cut has to be moved, and the haul distance ranges can be used to separate the distances for different types of equipment.

The image shows a 'Mass Haul Settings' dialog box with a blue title bar and a close button. It is divided into two main sections: 'Haul Distance Ranges' and 'External Hauls'.

Haul Distance Ranges

Haul Distance	Range
200.0	Up to 200.0
500.0	Up to 500.0
	Over 500.0

External Hauls

Type	Station
EXPORT	0+50.000

Buttons: Add, Edit, Remove, OK, Cancel

The External Hauls can be used to specify the stations along the road for borrow pits or dump piles. The program will use volume from these external hauls when the cut/fill of the road does not balance.

When dealing with multiple external hauls, the program will automatically minimize earth movement based on the haul distances and the available import/export (determined by "Set Volume Limit") of each haul. "Distance" sets how far a borrow pit or dump pile is from the entry station. "Road Conditions" is a multiplier against the specified distance. For example, if road conditions are twice as poor along an 2,700ft entry road as the main road, then a "Road Conditions" of 2.0 should be used. The program will then use a distance of 5,400ft (2,700x2) for that external haul when calculating optimized movement along the road.

Cut/Fill Width Analysis

This command generates a report of the horizontal width of cut and fill areas between two cross sections. The report generated can take into account the cut, the fill or both. For example, the Process option for Cut only will report only the grinding areas as the cut end areas. The options for this command are set in the dialog shown. The **Report Width At Interval** option reports the width of each area is reported at different elevations set by the **Elevation Interval**. For the **Report Elevation At Width** option, the elevation is calculated for where the area has the **Target Width**. For the **Report Average Width/Height** option, the average width and height is calculated for each area. The **Report Tie Points** option reports the intersection points between the original ground and design sections. The **Use Report Formatter** option allows for customized reports and output to Excel and databases.

Cut Sheet

This command compared a base grade section (.SCT) file with a final grade section (.SCT) file. It then reports the cut or fill values between these two sections files. The cut and fills are calculated at offsets in a specified range of stations. The offsets can be entered either as values (ie. 10) or by grade IDs (ie. "EP") when the section has descriptions on the section points. The report shows a column of cut and fill values for each offset as shown below. The two section .SCT files should have matching stations, because the program compares the offsets and elevations of a station in the first section file with the offsets and elevations of the same station in the second section file. The Report Formatter option allows for customized reports and output to different formats such as Excel. Otherwise the standard report shown here is generated.

Design Regrade

This command allows you to create final sections and have the offset, grades, and end area dynamically displayed and calculated while in the design process. This command works on a section grid that has an existing grade polyline which is used as the reference for the cut/fill calculations. The final section points can be entered as offset-elevation or picked on the screen. As you move the crosshairs on the graphics screen, the offset, elevation, slope percent, slope ratio, and end areas are displayed in a real-time pop-up window. When picking design points, you can use this real-time window to check the slope and other values and get these values close to the desired amounts. Then after the point is picked, a snap dialog appears (if the snap option is active) which allows you to set a slope or other value to a fixed amount (i.e. set the slope to 2.00% from 1.97%).

There are several options when specifying the final section points. The 'T' (Tie) option goes from the last final section point to intersect the existing grade at the specified slope. The 'F' (Force grade) option prompts for a slope percent or ratio that is used to set the slope between the last two regrade points. The program expects the final section points to be entered from left to right, but you can reverse the entry order by using the 'S' (Switch Direction) option. The 'P' (Pick existing) will use a point on the existing grade that is closest to the picked point. This is the same as the object snap *nearest*. The 'M' (Modify) option allows you to change an already placed regrade point. The program will prompt you to pick which regrade point to change. You can then pick a new position for it. This option allows the adjusting of already placed regrade points to help balance the cut/fill.

The command starts with a settings dialog. The Prompt for Snap toggle controls whether the command will present the snap dialog for each section point that is picked on the screen. The Grid Starting Elevation edit box allows you to input the beginning elevation of the local grid that you are designing in. Use the Horizontal and Vertical Scale edit boxes to set the proper horizontal and vertical scales for your design environment. The Text Scale value is multiplied by the horizontal scale to set the text size of the cut/fill end area labels. The regrade can be saved in a .sct file with the Output Regrade to Section File option. The Output Regrade to Earthworks File option stores the cut and fill values of the regrade to an earthwork (.EW) file that can be used in the *Print Earthwork File Report* command.

The **Bench Design at Fixed Slope** creates a regrade between top and bottom bench elevations. Besides the bench elevations, this method also takes input for the slope between the benches. Then the program calculates the position for the regrade by side shifting the regrade surface until the cut and fill areas balance.

Prompts

Design Regrade Settings dialog Make choices and click OK.

Pick Center Point of Grid [int on]: *pick a point* Pick the point where the local grid lines intersect at the 0 offset and datum elevation.

Select the existing grade polyline: *select polyline*

First offset or pick a point (P,Help): *pick a point* If you have the snap prompting on then each time you pick a point from the screen the dialog below will appear.

Second offset or pick a point (U,S,T,P,M,Help): *pick a point* If you make a mistake on one of the points you select than use the U option to undo or delete your last entry.

Next offset or pick a point (U,F,S,T,P,M,Help): *F* If you want to type in a specific grade use the Force grade option.

Calculate Haul Factors

After creating a regrade polyline with *Design Regrade*, this command will calculate how far and how much earth must be hauled in order to obtain the regrade from the existing grade. Areas from cut will be moved into areas of fill. In order to be optimal, this command expects even amounts of cut and fill. Haul factors measure the amount of earth moved times the distance. There is also an option to label the cut and fill areas.

Keyboard Command: haulfact

Prerequisite: Existing and final grade polylines

Sections to 3D Polylines

This command creates 3D polylines from a section (.SCT) file. Besides the section file, a centerline polyline, centerline file or section alignment (.MXS) file must be specified to define the plan view location of the 3D polylines. The elevations for the 3D polylines come from the section file. These 3D polylines can then be used by other Carlson routines to create surface models.

In the options, dialog set the range of stations to draw and the Layer Name for the 3D polylines.

The **Draw Method** has four options:

Cross Section: The 3D polylines are drawn as cross-sections perpendicular to the centerline at each station.

Offsets By Description: The 3D polylines are drawn parallel to the centerline by connecting section points when the same description. To use this method, the SCT file must have descriptions on the section points. For example, if the section file has descriptions for each section point then you can draw 3D polylines for EP, SHD, TIE, etc.

Offsets By Value: The 3D polylines are drawn parallel to the centerline at a specified offset value.

Offsets By Sequence: The 3D polylines are drawn parallel to the centerline by connecting section points by their sequence in the section file. For example, a 3D polyline will connect all the 1st section points, another 3D polyline will connect all the 2nd section points, etc. This method requires the sections to have the same number of data points for each station.

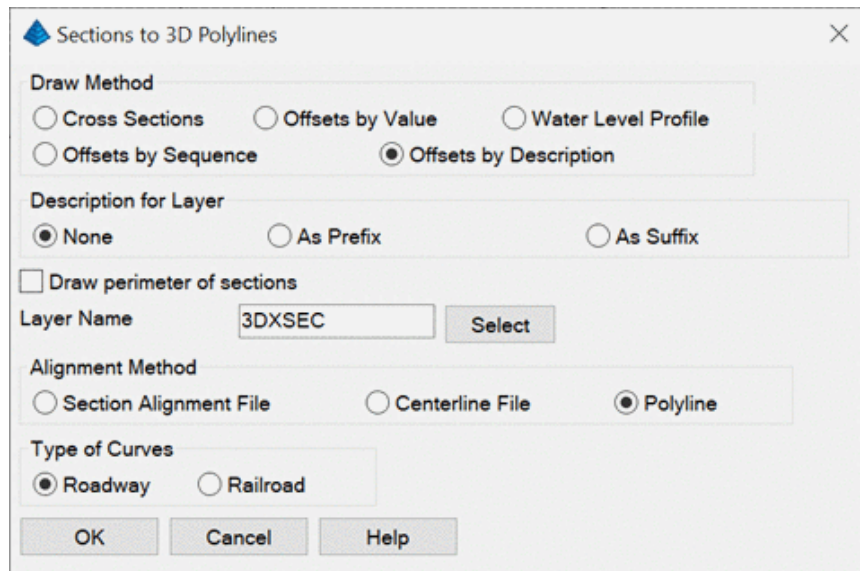

Water Level Profile: This method draws two 3D polylines for the left and right banks of a waterway. The section file represents the cross sections of the waterway. The program also prompts for a profile of the water level. At each section, the program gets the water elevation at that station from the water profile and finds the offset on the section for the left and right banks.

Description for Layer: This option uses the section point descriptions in the layer names for the 3D polylines when using the Offsets By Description method.

Draw perimeter of sections: This option will connect all the left most offsets and right most offsets together with a 3D polyline.

Alignment Method: Chooses how to define the horizontal alignment.

Type of Curves: This option chooses between roadway and railroad methods for stationing along curves.

Prompts

Choose Section File to Process Select the .sct file

Sections to 3D Polylines dialog Choose your settings

Select centerline polyline: *pick the polyline*

Enter the centerline starting station <0.0>: *press Enter*

Use reference profile to interpolate between sections [<Yes>/No]? *N for no.* This option will prompt for a profile to use for interpolating elevations along the 3D polylines between the section stations. This improves the accuracy when the profile goes through vertical curves. Without the profile, the 3D polyline elevations will be straightline interpolated between the sections.

Draw all template ids or specific ids and offsets [All/<Specific>]? *press Enter for Specific*

Enter Offset or Description to draw: *EP*

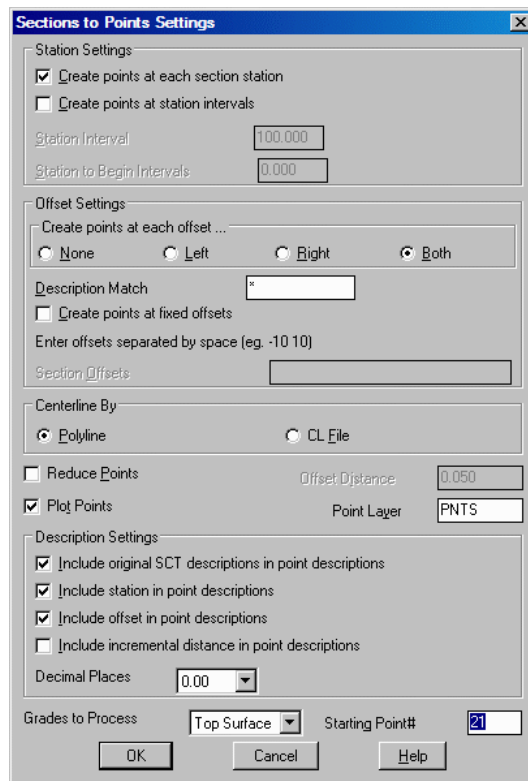

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: scto3dp

Prerequisite: A section (.SCT) file

Sections to Points

This command creates Carlson points using a section (.SCT) file to define the point elevations. The x,y position of the points are calculated based on the station and offset along a centerline polyline. These points are stored in the current coordinate (.CRD) file and can also be plotted in the drawing. Points can be created at each station in the section file or at a set station interval. The range of stations to process can also be set. The Description Match field can be used to filter the offsets and only create points with matching descriptions (e.g. only "EOP" offsets). The Create points at fixed offsets option can be used to make points at user-specified offset distances. The program will interpolate the elevations for these points by interpolating from the neighboring offsets. This is both a Centerline by Polyline or by CL File option. The CL File option will prompt for an existing centerline (.CL) file. The Reduce Points option will skip creating points for the same offset between stations if the x,y position and elevation change is less than the offset tolerance. Essentially, when a series of offsets are on a straight line (no vertical and no horizontal curve) then only the starting and ending points are needed and all the intermediate points can be skipped. For example, the Reduce Points routine will look at the left side EOP offset points at stations 1+00, 1+05 and 1+10 and if these three points make a straight line then the point for station 1+05 can be reduced. The Offset Distance is the tolerance that Reduce Points uses for testing whether the middle point (offset point at station 1+05) can be reduced. The distance for the middle point is calculated as the perpendicular distance from the middle point to the line between the two end points. Both the horizontal and vertical distances are checked.

Design Section Staging

This command takes a design cross section and splits it into two stages for cases when the design surface will be built in stages. There are two staging methods.

The Offset method splits the design section at a specified offset with the left side as one stage and the right side as the other stage. This method applies to the situation of designing a partly completed road or regrade. For example, if a four lane road will be built two lanes at a time, then the offset method can be used to split the design section with two lanes on the left side of the offset and the other two lanes on the right side. Using an existing and a final grade section file, the program will create four new sections files for the finished existing sections, finished final sections, remaining existing sections, and remaining final sections. The source existing and final section files should have matching stations. There is an option to process a range of the possible stations from the section files. The complete part of the road can be either on the left or right side. The pivot point is a cross section offset where the

completed part ends. From this point, the final grade will connect to the existing grade by a line at the specified slope.

The Description method uses a specified description from the existing ground section file plus an offset from this description. Then the existing section is overlaid onto the design section for the offset zone around this description. This method applies when a portion of the existing ground stays intact when the first stage of design is built and then this remaining portion of the design is done as the second stage. For example, this applies to improving railroads where the existing track is left undisturbed while the work for the new bed is prepared. In this case, the existing section file should have a description for the offset position of the existing track centerline. Then you specify the buffer offset around this centerline. From the resulting left and right offsets, the program ties the existing section into the design at a specified slope.

Prompts

For Offset Method:

Select Existing Sections File Choose the cross sections file.

Select Final Sections File Choose the cross sections file.

Enter slope as percent grade or slope ratio [Percent/<Ratio>]? *press Enter*

Enter the fill slope ratio <2.0>: *press Enter*

Draw Pipe 3D Polyline

This command creates a 3D polyline that represents a pipe. The points can be either picked on screen or specified by point number in the current coordinate file. This command is a convenient way to make 3D polylines that can become "pipe polylines" used for capturing their profile positions, leading to circular or elliptical or even square plots of the pipes or culverts within Draw Profile. However, this command is not required nor sufficient to make a pipe polyline useful in the *Draw Profile* command. Pipe polylines are made only by converting 3D polylines into pipe polylines using the adjacent command, *Assign Pipe Width to Pline*.

Keyboard Command: drwpipe

Prerequisite: None

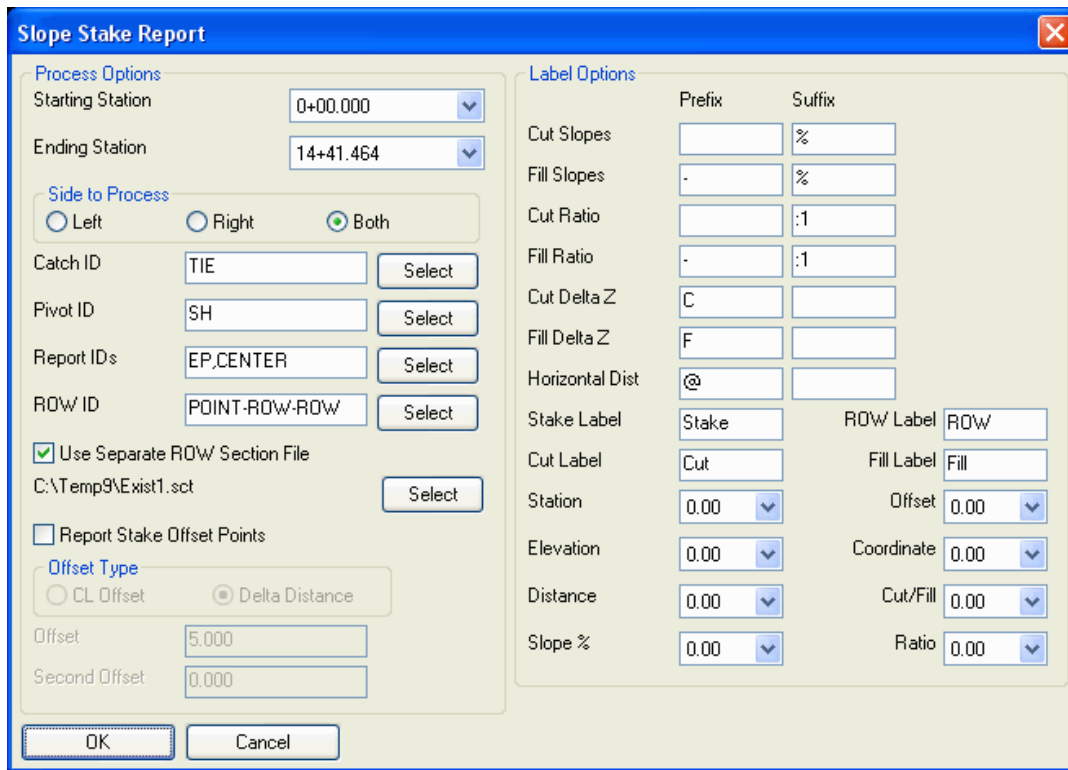

Assign Pipe Width to Polyline

This command is described in the Profiles Menu section of Help, under Profile Utilities.

Slope Stake Report

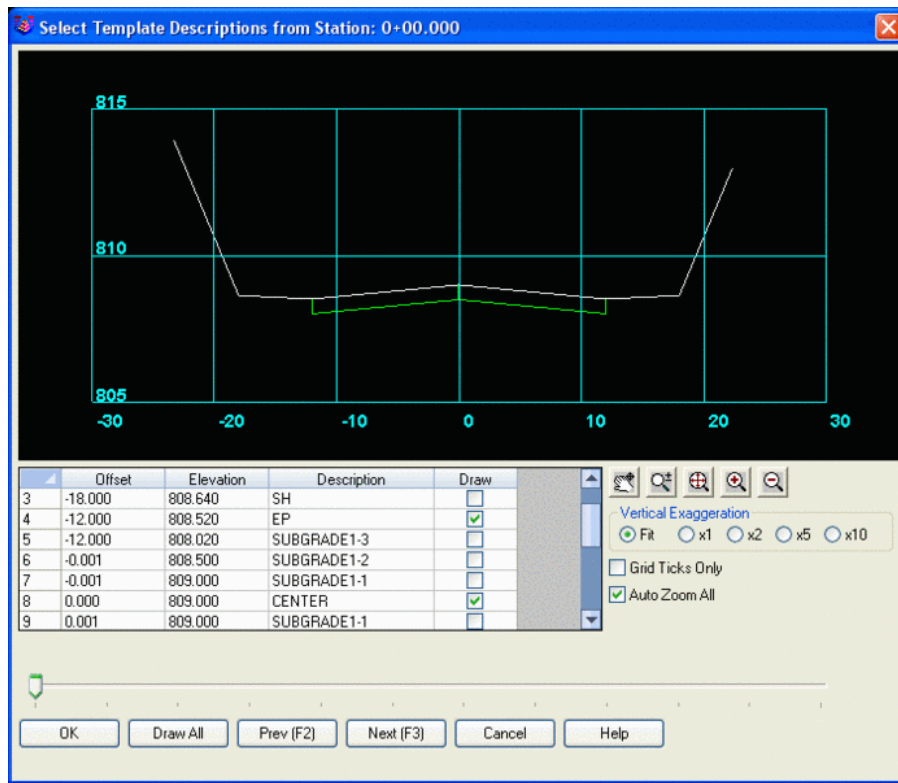

This command creates a slope stake report using cross section data with stations, offsets, elevations and descriptions. The program uses the data point descriptions to identify and catch and pivot points and other data points to report.

Besides processing a section file (.sct), the program also uses a centerline file (.cl) for reporting coordinates for the data points.

After selecting these files, there is a dialog for the report options. The Starting and Ending Stations control the range of stations to report. The Side To Process option selects whether to report the slope stake for the left or right of the centerline or both sides. The Catch ID is the section data point description for where the section ties into existing ground. The Pivot ID is the description for the hinge point at the beginning of the cut/fill slope. The Catch and Pivot ID's are required for the report. The Report ID's are optional additional section break points to include in the report. They should be entered in outside template to inside order. The Select button shows a graphic of the section data with toggles to select which section points to report. You can pick any combination of surface or subgrade points. Don't include the Catch ID or Pivot ID in the Report IDs because those IDs are already reported. The ROW ID is optional for including the ROW in the report. Typically, the ROW data is in the existing surface sections instead of the final sections. In this case, the Use Separate ROW Section File option can be used to specify the section file with the ROW data. The Report Stake Offset Points option adds an offset point that can be used for stakeout. The offset amount can be relative to the catch point or to the centerline. A second offset can be used for orientation with the first offset. The program reports the distance from the offset point to the catch point.

The Label Options section has prefix and suffix settings to add to the report values. There are also settings for the labels to use for the Stake, ROW and Cut/Fill names. There are also controls for the decimal places for the report values.

After specifying the options, the program uses the Report Formatter to generate the report. The available fields are point name, station, offset, northing, easting, elevation, cut/fill label, horizontal distance, vertical distance, slope percent and slope ratio. You can select which fields to report and their order. The field labels and decimal precision is controlled by the Report Formatter. The report can be output to the Report Viewer or Excel.

Prerequisite: Drawn Section File and SurvCE Slope Stake File

Extend Sections to Offset Limits

This command extends the offsets to the left and right limits for each station in a section file. The left and right offset limits are defined in the section alignment (.MXS) file. The elevations for the extended offsets can be extrapolated from the last slope from the existing offsets or the elevations can be carried flat from the last offset elevation. For example, consider section station with a left most offset of -192.5 and a right most offset of 197.3. If the MXS file had offset limits of 200 for left and right, then this routine would assign offsets with elevations at offsets -200 and 200. The resulting section file can be saved to a separate section (.SCT) file or overwrite the original SCT file.

Prompts

Select Section Alignment File *select .MXS file*

Section File to Read *select .SCT file*

Extend last slope or use last elevation [<Slope>/Flat]? *press Enter*

Choose SCT file to Write *specify new .SCT file name*

Pull-down Menu Location: Sections > Section Utilities

Keyboard Command: extendsct

Prerequisite: .SCT file and .MXS file

Extend Progress Sections

This command extends cross sections that partially cover the design sections to make the sections reach the full extents of the design. This routine applies to a design that is being built in stages. The purpose is to build sections for the surface at a progress stage during construction. The input progress sections for this command are updated and saved back to the progress section file. The progress sections can then be used in Calculate Sections Volumes to calculate progress volumes.

The progress sections will not go beyond the design so that extra volumes are not counted as part of the progress. For example, if a design is in fill and the input progress sections go above the design, then the output progress sections will be brought down to match the top of the design.

Besides prompting for the design sections and input progress sections, the program also prompts for the existing ground sections which are used to limit the progress sections to avoid any extra volumes. For example, if a design is in fill and the input progress sections go below the existing ground, then the output progress sections will be brought up to match the existing ground.

An example application is for road design where the progress is surveyed during construction using GPS to gather points along the road. These points are then used to create a progress section which cover a portion of the road surface but don't tie into the final design. Then this Extend Progress Sections command takes the progress sections from the points and extends the sections to tie into the design.

Input Sections

Resulting update of progress section

Prompts

Original Surface Section File *select .SCT file*

Design Surface Section File *select .SCT file*

Progress Survey Section File *select .SCT file*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sctprogress

Prerequisite: Existing, Design and Progress .SCT files

Section Area Report

This command reports the surface area from a cross section surface. Either the horizontal or slope area is reported. There are also prompts to limit the area report to a station range or offset range. The program prompts for the section file to process. There is an option to use a second section file for a cut/fill reference. When this reference section file is used, the program reports the area broken out by cut and fill areas.

Section Area

Section File: final.sct
Starting Station: 0+75.000
Ending Station: 15+50.000

Horizontal Area(SF)
127322.1

Prompts

Section File to Process *select .SCT file*

Use Another Section For Cut/Fill Reference dialog

Report slope or horizontal area [<Horizontal>/Slope]? *press Enter*

Starting station to process <75.000>: *press Enter*

Ending station to process <1550.000>: *press Enter*

Limit offsets to process [Yes/<No>]? *press Enter*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sctarea

Prerequisite: .SCT file

Slope Zone Section Analysis

This command reports the areas of the surface within different slope ranges. The surface is defined by a cross section file (SCT). The option to **Use Another Section For Cut/Fill Reference** reports the cut/fill areas and volumes within given ranges of slopes.

Prompts

Select Section to Process *Select .SCT file*

Select Slope Zone dialog

Report slope or horizontal area [<Horizontal>/Slope]? *S*

Slope format [<Percent>/Ratio]? *press Enter*

Greatest slope % of zone 1: *10*

Greatest slope % of zone 2: *press Enter*

Starting station to process <0.000>: *press Enter*

Ending station to process <1514.567>: *press Enter*

The Standard Report Viewer creates a report called Section Slope Zone Analysis Report.

Section Slope Zone Analysis

Section File: C:\src\work\output.xsct

Starting Station: 0+00.000

Ending Station: 15+14.567

Slope % Area(SF) % of Total

0.0 to 10.0 78757.5 61.3

> 10.0 49617.0 38.7

Total: 128374.5

Pulldown Menu Location: Sections

Keyboard Command: sctzone

Prerequisite: .SCT file

Color 3D Lines By Slope

This command sets the color of 3D lines by slope range. The slope ranges are defined in percent slope for up to ten ranges. There is an option to draw a legend of the slope colors.

Slope %	Range	Color	
5.000	<= 5.000	170	Set
10.000	5.000 to 10.000	150	Set
20.000	10.000 to 20.000	130	Set
30.000	20.000 to 30.000	110	Set
40.000	30.000 to 40.000	90	Set
50.000	40.000 to 50.000	70	Set
75.000	50.000 to 75.000	50	Set
100.000	75.000 to 100.000	30	Set
	> 100.000	10	Set

Prompts

Define Slope Ranges Dialog

Select 3D lines to color.

Select objects: *pick the entities*

Draw Legend [**<Yes>/No**]? Y

Legend size <5.000>: *press Enter*

Pick point for legend: *pick a point*

Pull-Down Menu Location: Surface > Slope Analysis

Keyboard Command: color3dline

Prerequisite: 3D Lines

Regrade Fill Slope

This command is used on stockpile projects to regrade the fill slopes of the cross sections with less steep slopes while maintaining the same end areas. The slope portion of the cross section to regrade is identified by entering the section descriptions for the top and bottom points.

Prompts

Select existing section file Pick a section file to read

Specify new section file to Output Enter a section file to create

Target Slope Percent: 80

Top of Slope Offset Description: TB

Bottom of Slope Offset Description: BB

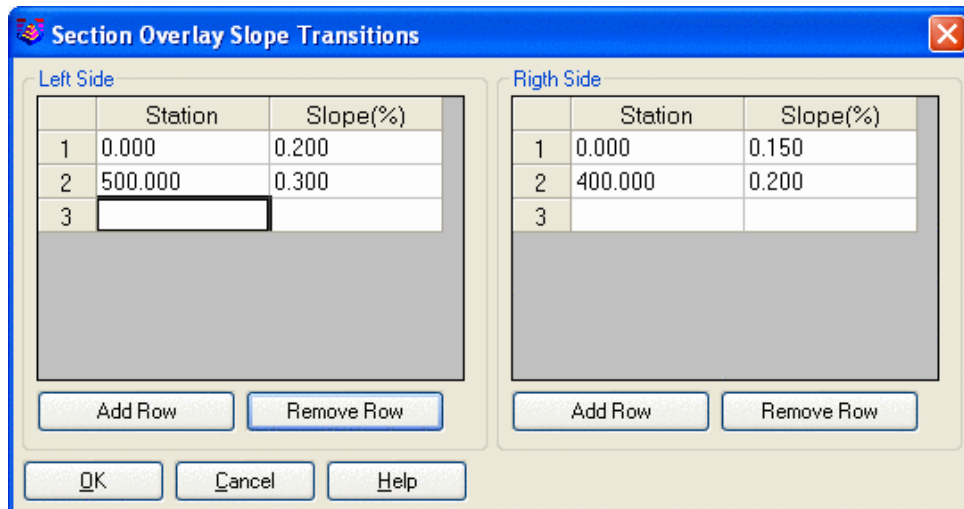

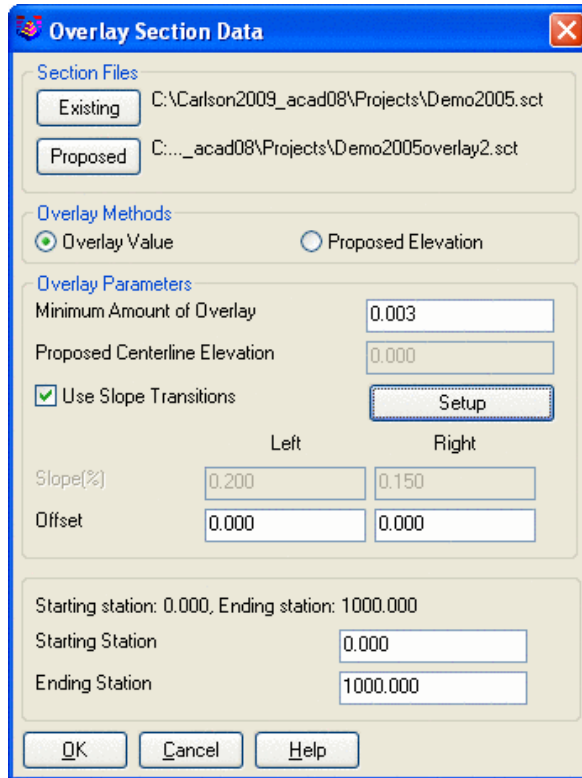

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: regrade_slope

Prerequisite: A section (.SCT) file

Overlay Section File

This command will create a section file at given cross slopes and minimum overlay from a reference section file. An existing and a proposed .SCT file must be selected, along with additional section information. A choice between Overlay Value or Proposed Elevation must be made. When the Overlay Value option is chosen, a Minimum Amount of Overlay must be entered, and the Slope values must be defined. You are allowed to set up slope transition values for certain station ranges. When the Proposed Elevation option is chosen, a Proposed Centerline Elevation value must be entered.

Prompts

Overlay Section Data dialog *Select file names and options, click OK*
 Report viewer creates a proposed section file report.

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sct_overlay

Prerequisite: A .SCT file

Average Section Files

This command will average a section file for a given station range. A source file to process must be selected to get things started. A starting station to average and a last station to average must then be entered. A new .SCT file will

be created as a result.

Prompts

Select Source Section File to Process Select a SCT file.

Starting station to average <0.000>: *press Enter*

Last station to average <1614.160>: *press Enter*

Section File to Write Select a SCT file name and folder.

Pulldown Menu Location: Sections, Section Utilities >

Keyboard Command: avgscct

Prerequisite: A .SCT file

Merge Sections

This command combines a range of stations of one section and a range of stations of a second section. The stations, offsets and elevations in these two ranges can be stored in a new file or they can overwrite an existing profile. Two .SCT files are required.

Prompts

First Section File to Merge *select an existing .SCT section file*

Starting station to merge <0.000>: *press Enter*

Last station to merge <1614.160>: *press Enter*

Second Section File *select another existing .SCT file*

Starting station to merge <0.000>: *press Enter*

Last station to merge <1310.050>: *press Enter*

Section File to Write *Enter a new .SCT file name and choose folder*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: mergesct

Prerequisite: Two section files

Compare Section Files

This command will report the differences between two section files. The report includes differences in offsets or elevations for the section data points. Also, the report includes stations that exist in one file and not the other. Here is a sample report.

Compare Section Files

1st Section File: C:\sample\final1.sct

2nd Section File: C:\sample\final2.sct

	1st Section File			2nd Section File		
Station	Offset	Elevation	Description	Offset	Elevation	Description
6+00.000	10.000	1007.873	EP	10.000	1008.003	EP
6+00.000	22.799	995.074	TIE	22.914	995.089	TIE
6+50.000	10.000	1008.906	EP	10.000	1009.208	EP
6+50.000	21.735	997.170	TIE	22.062	997.145	TIE

Pulldown Menu Location: Sections, Section Utilities >

Keyboard Command: comparesct

Prerequisite: A .SCT file

Move Section Leader Labels

This command custom positions section labels together with leaders. The section labels must be created with the Draw Break Point Leader option with the Draw Section File command. When the sections are redrawn, any custom positions done by this command are retained.

Before and after of Move Section Leader Labels to clean up label overlaps with grid lines

Prompts

Select section label to move: *pick a text label*

Pick label position: *pick a new position for the label*

Select section label to move (Enter to end): *press Enter*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sctmove

Prerequisite: section labels with leaders

Update Sections from Polylines

This command is used to update section (.SCT) files from manual changes made to polylines originally created by Draw Section.

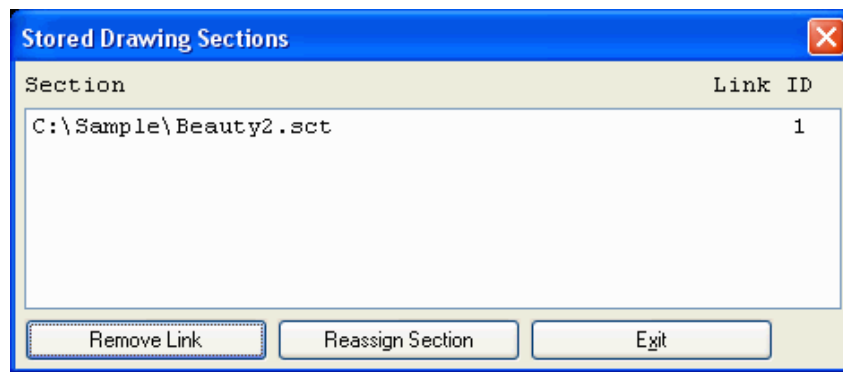

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: update_sct_from_dwg

Prerequisite: Drawn Sections

Review Section Links

This command shows a list of all the section links that the program knows about in the current drawing. These links are between the section files and the drawn sections in the drawing. These links are created by the Draw Sections command. You can use the Remove button to remove links for any obsolete sections or if you don't want to link a certain section. You can also reassign a link in case the location of the section file has changed.

Pulldown Menu Location: Sections->Section Utilities

Keyboard Command: sctdict

Prerequisite: none

Section ID

This command is used to pick a section drawing entity and then report the source section file name.

Prompts

Select section entity to identify: *select entity*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sctid

Prerequisite: A .SCT file

Set Descriptions By Offset

This command assigns descriptions to existing section points in a section file at specified offsets. Besides the specified offsets, the description can be set for the section point with the farthest left or farthest right offset.

Prompts

Set description for left most offset [Yes/<No>]? *Y*

Description: *TIE*

Set description for right most offset [Yes/<No>]? *Y*

Description: *TIE*

Offset to set description (Enter to end): *12*

Description: *EP*

Offset to set description (Enter to end): *press Enter*

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sct_desc_offset

Prerequisite: A section file

Set Descriptions By Polyline

This command assigns descriptions to existing section points in an SCT file using plan view polylines. For example, you can enter a description of "EP" and then selection the edge of pavement polyline. For each station, the program calculates the offset of the selected polyline and then sets the description at that offset in the SCT file if there is a section point with the matching offset.

Prompts

Choose Section File to Process Select the .sct file

Select centerline polyline: *pick the polyline for the zero offset position of the SCT file*

Enter the centerline starting station <0.0>: *press Enter*

Description for section: *EP*

Select EP polylines.

Select objects: *pick the polylines for EP*

Description for another section (Enter to end): *press Enter*

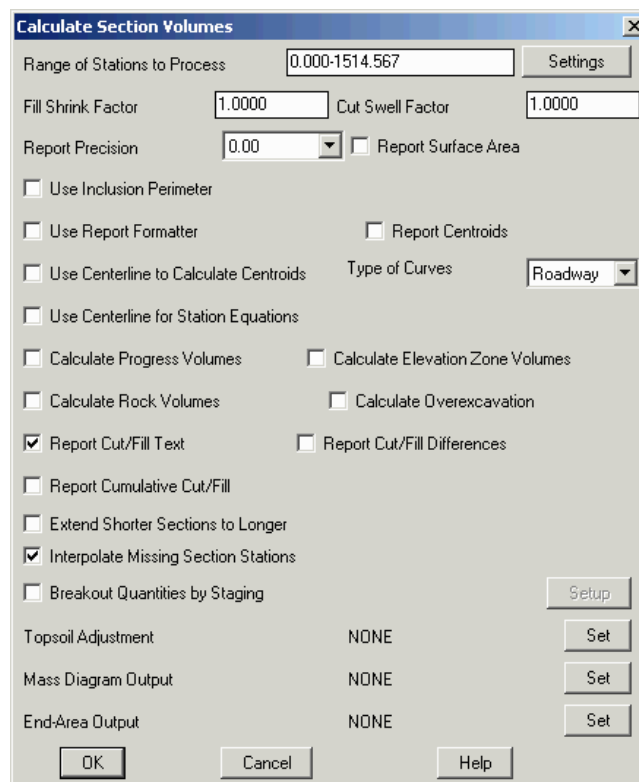

Pulldown Menu Location: Sections > Section Utilities

Keyboard Command: sct_desc_pl

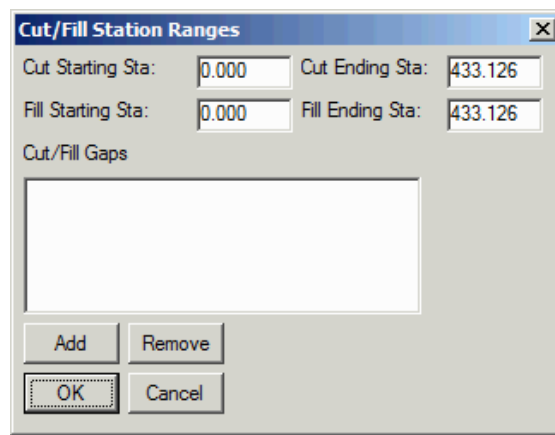

Prerequisite: A section (.SCT) file and polylines

Calculate Section Volumes

This command will read two section files and compute the cut and fill end areas and volumes. It computes the sections volume in the order they appear in the file. If you need to sort the stations in sequential order use the *Section File Editor* command. Begin by selecting the base section file then the final section file. After specifying the input files the Calculate Section Volumes dialog appears. The settings can then be chosen and customized to match your reporting needs. There is an option to apply topsoil removal/replacement adjustments, as well as support for processing sections with subgrades.

Range of Stations to Process: Specify the range of stations to process. Separate stations with a hyphen as shown. The Settings button brings up another dialog with more station options:

Cut/Fill Starting/Ending Sta.: Volumes are calculated using end areas between the range of stations. Instead of cutting off the volumes exactly at this range, the Ending and Starting Stations for Cut and Fill can be used to have the volume taper from zero at the specified Starting Station to the volume at the first station in the range. Likewise, the Ending Stations can be used to taper the volume from the last station in the range to zero at the specified Ending Station.

Cut/Fill Gaps: Use the Add and Remove buttons to define a series of station ranges for cut/fill gaps where the program will not calculate any volumes.

Fill Shrink/Cut Swell Factor: Allows you to specify a value that the volume calculated will be multiplied by.

Report Precision: Specify the decimal precision for the report.

Use Centerline to Calculate Centroids: When checked, the program will calculate the centroids using a centerline (.CL) file. You will be prompted to select the centerline file.

Use Centerline for Station Equations: This option applies to section files with stations numbered using station equations. This option will use the station equations defined in a centerline file to remove the station equations from the section file stations for calculating the true end area distances. You will be prompted to select the centerline file.

Use Inclusion Perimeter: This option prompts for a closed polyline in plan view for the limits of volumes. Without this inclusion perimeter, volumes are calculated to the extents of the sections.

Use Report Formatter: This option allows for customized report layout and contents. Otherwise a standard report is displayed.

Report Centroids: Specify whether or not to report centroids.

Calculate Rock Volumes: When checked, you will be prompted to select a third section (.SCT) file that will be used to calculate rock quantities.

Calculate Progress Volumes: This option prompts for a third section file that represents a stage of progress between the existing and design surfaces. The includes both the total cut/fill quantities and the subset of progress cut/fill quantities. The progress volumes are limited to be within the volumes between existing ground and design in order to avoid any extra cut or fill.

Calculate Elevation Zone Volumes: This option reports the amount of cut and fill for elevation zones. With this option, the program prompts for a starting station and elevation interval. Then starting at this elevation, the program calculates the amount of cut and fill between the section surfaces up to the next elevation. This elevation zone calculation is repeat until the highest elevation in the section files is reached.

Calculate Overexcavation: When checked, calculates volume of overexcavation. See diagram.

Report Cut/Fill Text: Specify whether or not to report cut/fill at each station.

Report Cut/Fill Differences: Adds a running total of the cut to fill balance at each station to the report.

Report Cumulative Cut/Fill: Adds a running total of the cut/fill at each station to the report.

Extend Shorter Sections to Longer: If checked, shorter sections are lengthened to the same left and right offset extents as the corresponding longer sections.

Interpolate Missing Section Stations: If checked, the missing stations are accounted for in the calculations.

Breakout Quantities by Staging: This option breaks out the cut and fill end areas and volumes according to user defined offsets along the road. The "Slope Format" determines how each stage will tie back into the road.

Breakout Quantities by Staging

Slope Format
 Ratio Percent Vertical

Cut Slope: 1.000 Fill Slope: 1.000

	Stage Name	Left Side	Offset	Right Side	Offset
1	Leftside	Left Edge		Offset Right	0
2	Right1	Offset Left	0	Offset Right	10
3	Right2	Offset Right	10	Offset Right	20
4					
5					
6					
7					
8					
9					
10					
11					
12					

Last Stage Name: Right SH

OK Cancel

In the example above, volumes will be reported separately for the left side of the road, the inside right lane (offset 0-10), the outside right lane (offset 10-20), and then the remainder right side of the road will automatically be reported as the "Last Stage".

Topsoil Adjustment File: This optional input file applies topsoil removal and replacement for the calculations. See the Topsoil Removal/Replacement command for more details on the .TOP file.

Mass Diagram Output File: Specify an optional (.MAS) file for mass haul data output for the Draw Mass Diagram and Mass Diagram Report commands.

End-Area Output File: Specify an optional end-area (.EW) file for output that can be used in the Edit-Process End

Area File command.

Prompts

Section File (Existing Ground) to Read *choose existing .SCT file*

Section File (Final Ground) to Read *choose the other existing .SCT file*

Calculate Sections Volume dialog Make selections.

Pulldown Menu Location: Sections

Keyboard Command: calcsct

Prerequisite: Two section (.SCT) files

Calculate End Area

This command allows the user to select two polylines representing an existing grade section and a final grade section, and calculate the end area. Or you can also specify and define cut/fill end areas by picking interior points. The area calculated can be drawn at a user specified point. Optionally, the command writes the stations cut and fill to an earthwork (.EW) file that can be printed/displayed by the *Edit-Process End Area File* command. This command starts with the Calculate End Area dialog.

Horizontal Scale: Specify the horizontal scale of the existing cross section.

Vertical Scale: Specify the vertical scale of the existing cross section.

Station Interval: Only available if *Write Results to EW File* is toggled on. Allows you to specify the station interval that the station prompting will default to as you select the polyline/sections for computation.

Extend Shorter Ends to Longer: Click or leave blank.

Calculate Unsuitable Areas: When checked, the user will be prompted for polyline(s) or interior point(s) that represent unsuitable material. The areas and/or volumes for the unsuitable material is reported out separately from the overall cut and fill areas and/or volumes for overexcavation consideration.

Define end areas by chooses between picking two polylines or picking inside each end area.

Text Scale: Specify the text size scaler, this value is multiplied by the horizontal scale to determine the final text

height.

Decimal Places: Controls the decimals for the cut/fill area labels.

Cut/Fill Prefix/Suffix: Specify prefix and suffix for the cut, fill, and unsuitable labels.

Label Layer: Specify the layer for the cut/fill area labels.

Write Results to EW File: When checked, the results will be written to an earthwork (.EW) file. You may create a new file or choose to append/revise an existing file.

Prompts

Calculate End Area dialog *make choices*

Specify Earthworks File (ew) dialog *specify new or existing file* This box appears if *Write Results to EW File* is clicked.

Select existing grade polyline (ENTER to end): *select polyline*

Select final grade polyline: *select polyline*

Calculating End Area...

Cut: 12002.965 Fill: 660.272

Pick Point for Label (Enter for none): *pick point*

Enter the station <0.00> *press Enter* Pressing Enter selects the default station 0+00. If the station does not exist in the file it will be added. If it does it will be revised.

Select existing polyline: *press Enter*

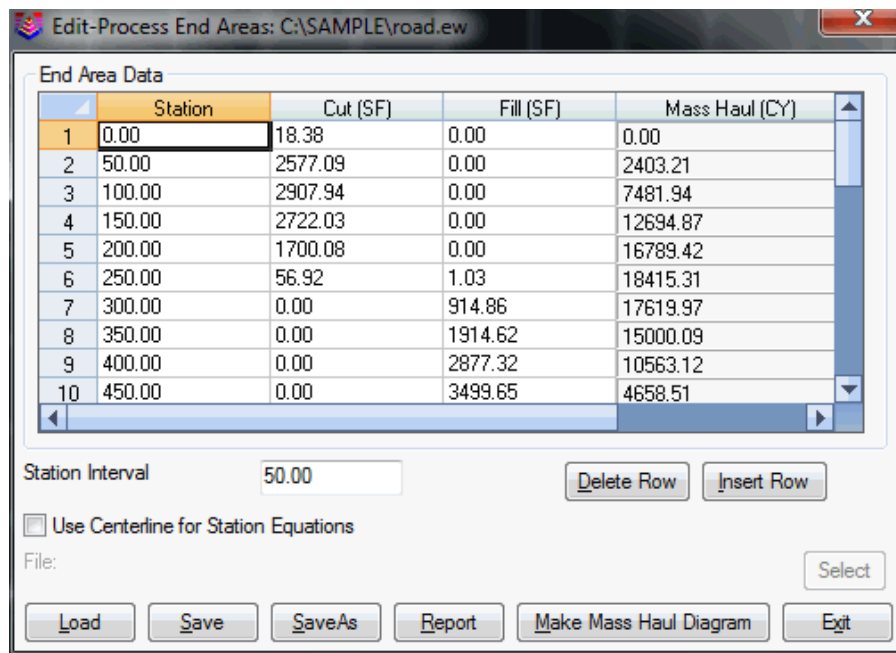

Continue moving along automatically to the next station interval and select polylines. Or enter the station values randomly. The command sorts the .EW file regardless. As a result of this sort feature, the user can select stations in any order and they will be arranged in ascending order for proper volume computation.

Keyboard Command: endarea

Prerequisite: Plot the existing grade and final grade polyline/section

Edit Process End Area File

This command opens an End Area (.EW) file for editing and processing. Data can be entered directly into the spreadsheet. The Calculate Section Volumes command has an option to create an .EW file. The accumulative volume is displayed in the right side column of the spreadsheet. The Report function outputs a report of the stations, intervals, cut and fill. The Make Mass Haul Diagram function makes a .MAS file that can be used by the Draw Mass Diagram and Mass Diagram Report commands. The Use Centerline for Station Equations option applies to end area data with stations numbered using station equations. This option will use the station equations defined in a centerline file to remove the station equations from the end area stations for calculating the true distances for the volume calculations. You will be prompted to select the centerline file.

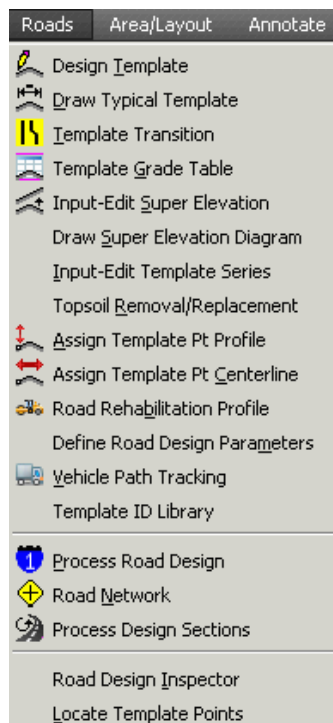

Pulldown Menu Location: Sections

Keyboard Command: ewedit

Prerequisite: None

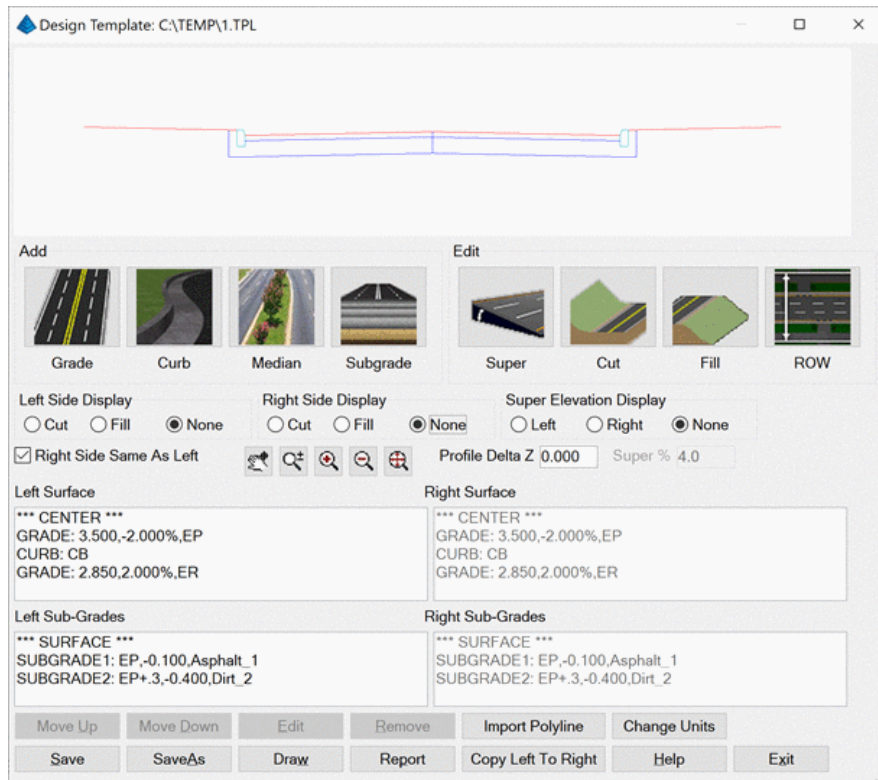

Roads Menu

The Roads menu commands covers template, transitions and processing road designs. The Roads menu is part of the Civil, Construction and Field modules.

Design Template

This command creates a template definition file (.TPL file) used primarily for modeling roadway, railway and other types of corridor designs.

Template files can then be applied through a variety of commands including (but not necessarily limited to):

- Process Road Design
- Road Network
- Draw Typical Template
- Locate Template Points
- Design Pad Template
- Draw Field-to-Finish

In the lower portion of the dialog box are four "list boxes" that list the elements of the template. The Surface elements are listed in order starting from the center of the template moving outward. The Subgrades are listed from top to bottom order. To add a template element, highlight the position in the list above where to insert the element. There is no limit to the number of Surface or Subgrade elements. The following types of objects can be utilized to create a template:

Button

Description

Grades - Typically, linear segments that defined paved surfaces such as roadway pavement, sidewalks and other linear surfaces that are "exposed to daylight."

Curb - Typically, "formed" shapes that help control storm-water run-off.

Median - Typically, "free-form" features such as "roll-over" medians or other types of traffic barricades.

Subgrade - Subsurface material(s) that are used to derive "pavement" volumes (e.g. bituminous asphalt, aggregate base course, etc).

Superelevation (Super) - Parameters that indicate how (and where) the template "grades" should elevate within curves or other areas of superelevation.

Cut Slopes (Cut) - Specialized "grade" slopes that are used to "tie" the template to an existing surface when the elevation of the outermost point of the template is below ground.

Fill Slopes (Fill) - Specialized "grade" slopes that are used to "tie" the template to an existing surface when the elevation of the outermost point of the template is above ground.

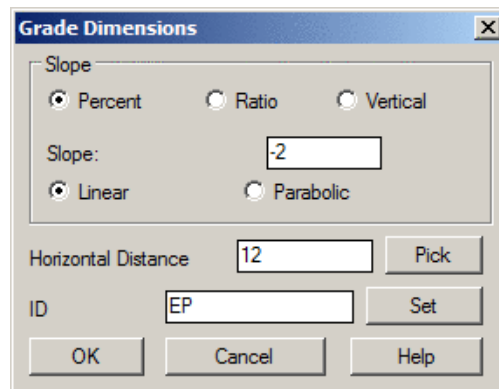

Rights-of-Way (ROW) - Additional constraints utilized by the template in an effort to minimize the "footprint" of the disturbed limits of a cross-section relative to the right-of-way based on a given centerline.

Template Components

Additional categories of functionality include:

- View Controls
- Data Tools

Grades

Percent: Specify this option when the "s" vertical displacement amount of a slope is specified relative to 100 horizontal units of measure.

Ratio: Specify this option when the "s" horizontal amount of a slope is relative to 1 units of measure vertically.

Vertical: Specify this option for an "undefined" (vertical) slope ("s") in which there is no horizontal component.

Slope: Indicate the "s" value relative to the type of slope selected above. Positive slope values indicate an increase in elevation along the grade segment; negative slope values indicate a decrease in elevation along the grade segment.

Linear: Specifies a constant slope along the grade segment.

Parabolic: Specifies a varied slope that gets steeper across the grade until it reaches the full specified slope at the end of the grade.

Horizontal Distance: Specify the horizontal distance component (positive values only) of the grade segment.

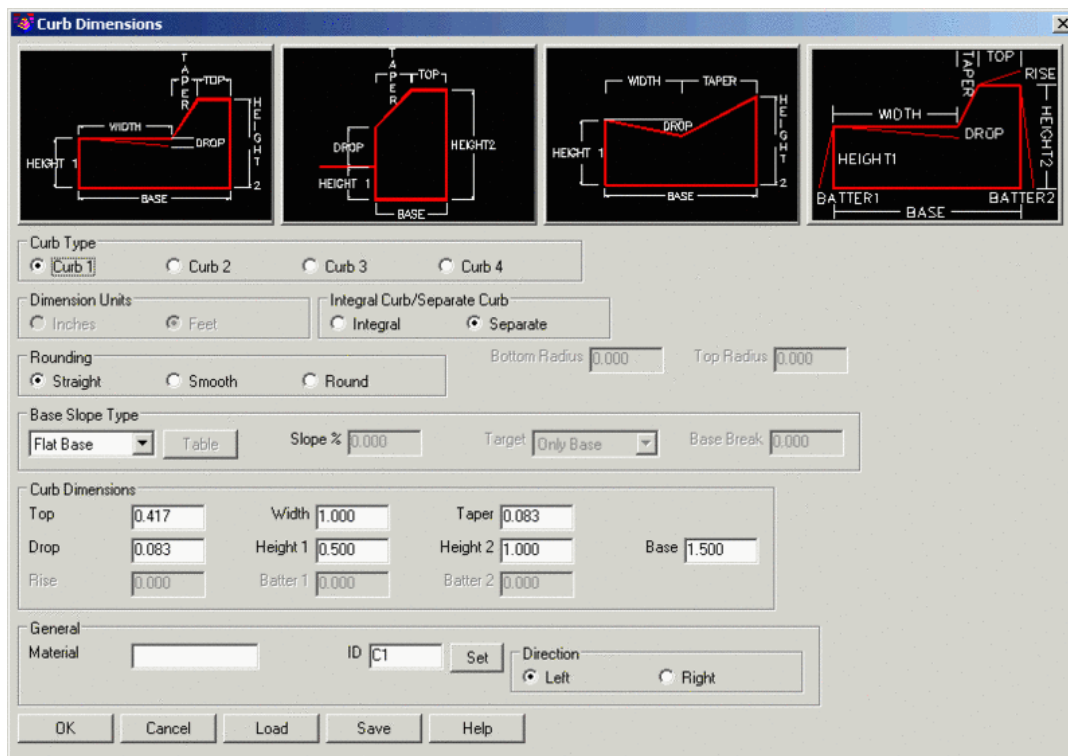

Pick: Prompts to select a linework segment or two points from the drawing to define the grade slope and distance.

ID: The ID (typically a two- or three-character identifier) serves four purposes:

1. The ID will be applied as a description to all final template points generated in the form of a coordinate file.
2. The ID can be used as a parametric design point for subgrade offsets and distances (*e.g.* EP+0.5).
3. Points of common ID may be connected by 3D polylines as an output option of Process Road Design.
4. Quantities can be generated with reference to the ID and material (gravel, concrete, *etc*) entered elsewhere within this command.

Set: Displays a list of grade ID's from the current Template ID Library.

Curb

Curb Type: Select the general shape of the curb "plate" that best matches the curb you wish to define. If your curb does not conform to one of these shapes, you can also utilize the Median component.

Dimension Units: Indicate the desired units for the Curb Dimensions (*e.g.* feet, inches or meters in metric mode).

Integral Curb/Separate Curb: Indicate whether to draw the front line of the curb to separate the curb from the subgrade. For example, fully concrete pavements that contain a curb would be drawn with the "integral" curb option:

Rounding: Indicate the type (or amount) of "smoothness" that should be applied between curb faces.

- Straight - no smoothing occurs between curb faces.

- Smooth - this option will smooth the surface of the curb which only shows when the template is applied in commands such as Process Road Design.
- Round - this option fillet a curve at the bottom and top of the *Taper* segment using the specified Bottom and Top Radius.

Straight

Base Slope Type: The Base Slope Type of the curb can either be flat, set to the slope of the incoming grade or set to a user-specified slope. For the Match Crown method, you can use the Table option to define a lookup table of different curb slopes for different crown grades. For cases with part of the curb at a slope and part flat, you can use the Base Break Offset to set the transition position between sloped and flat. The Target setting for the slope controls which parts of the curb are sloped.

Curb Dimensions: Indicate the various dimensions (in units defined by Dimension Units) of the curb components.

Material: Indicate the name of the material for the curb for reporting purposes from commands such as Process Road Design.

ID: The ID (typically a two- or three-character identifier) serves four purposes as discussed in this ID discussion.

Set: Displays a list of grade ID's from the current Template ID Library.

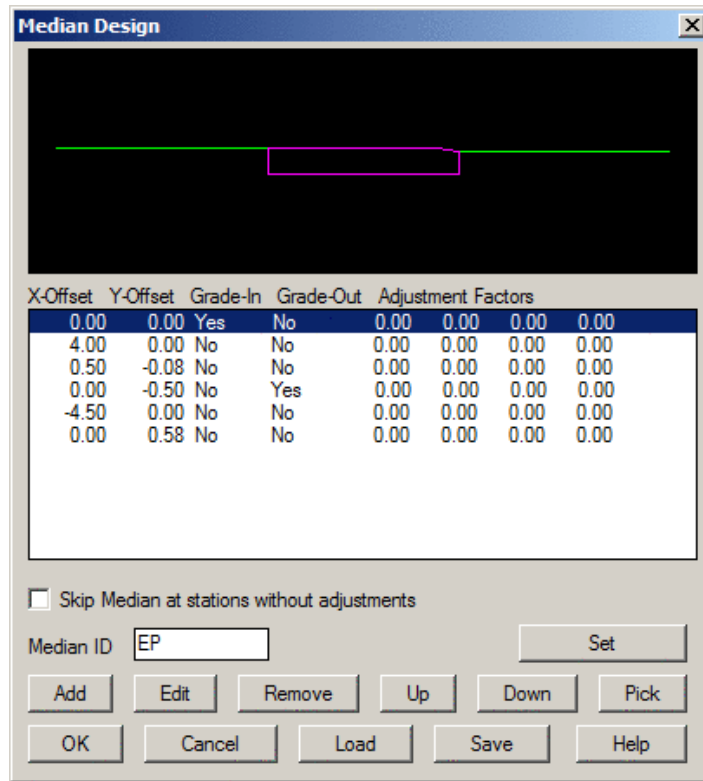

Direction: This option controls which way the curb faces and is needed for divided roadway templates that have curbs facing both ways on either side of the road.

Load: Allows a previously saved curb (*.crb) "plate" to be opened for editing.

Save: Commits the current curb "plate" to a named curb (*.crb) file.

Median

The Median is a flexible, closed figure defined in a clockwise direction. Each median point consists of an X and Y offset. The median must be closed and the program will automatically create the closing segment. The display shows the median in magenta and the grade lines in and out in green. For the display the grade in comes from the left and the grade out goes to the right. The median must define the Grade In point which is the point that ties into the incoming surface grade. Also the Grade Out point must be specified for where the surface grade continues out from the median. These Grade In and Grade Out points emanate from the starting or "from" position in the coordinate dialog where they are specified. Since a single median must be placed on the left or right side (and is typically not used symmetrically with right side same as left), you will need to offset the template centerline one-half the median width within the command Process Road Design in order to center the median. You will also have to move the "C/L" designation, to obtain centering, when using Draw Typical Template.

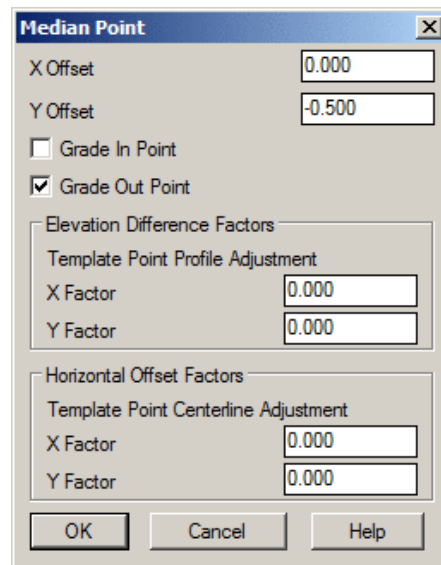

Skip Median at Stations without Adjustments: When enabled, this option creates the median only in the station ranges of a Template Point Profile and/or Template Point Centerline transitions.

Median ID: The ID (typically a two- or three-character identifier) serves four purposes as discussed in this ID discussion.

Set: Displays a list of grade ID's from the current Template ID Library.

Add (Edit): To enter the dimensions of the median, use the Add or Edit button to display a dialog box similar to that below:

X/Y Offset: Provide the X/Y displacement of the median segment relative to the end of the previous median segment.

Grade In/Grade Out Point: Indicate if the median point is the position that accepts the incoming grade and/or generates the location for the out-going grade segment of the template.

Elevation Difference Factors: Controls how to apply Template Point Profiles. For Template Point Profiles, the program figures the amount of vertical adjustment between the transition profile and the normal profile. The amount of this vertical adjustment is multiplied by the adjustment factor and then added to the X/Y Offsets of the median point.

Horizontal Offset Factors: Controls how to apply Template Point Centerlines. For Template Point Centerlines, the program figures the horizontal adjustment between the transition centerline and normal centerline for Template Point Centerlines and applies this adjustment by the factors to the offsets.

NOTE: These adjustment factors allow for dynamic medians. For example, the height of a retaining wall could be controlled using a Template Point Profile and the median points for the vertical sides would have a Y Factor set to 1 to pick up the full vertical adjustment and the median points for the top and bottom edges would have a Y Factor of 0 keep those edges the same.

Remove: Deletes the highlighted X/Y Offset record in the list.

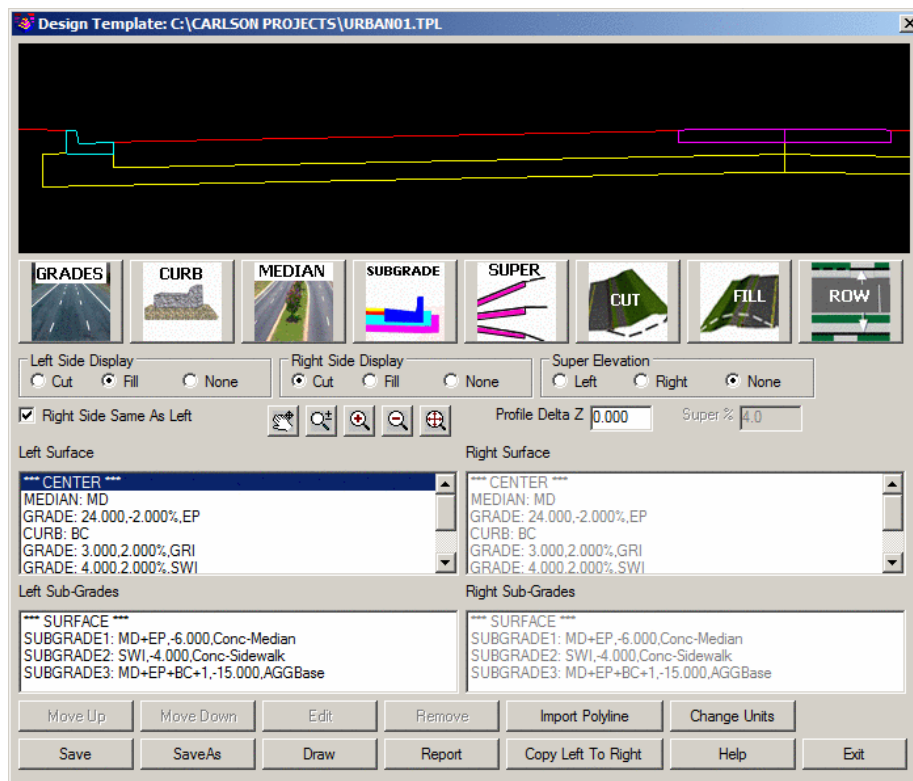

Up (Down): Changes the order of the highlighted X/Y Offset record in the list.

Pick: The Pick button prompts to pick a closed polyline from the drawing to define the median geometry.

Load: Allows a previously saved median (*.mdn) to be opened for editing.

Save: Commits the current median to a named median (*.mdn) file.

You can design a median for "mirroring" to create a centered effect, as illustrated in a paved "rumble strip" section as shown below. The only negative to this method is the appearance of a vertical line in the median plot.

Subgrade

Clicking the Subgrade button displays the dialog box below that permits you to establish "design" materials used to build the design project. Subgrade entries are displayed below the Grade entries and there can be any number of subgrades stacked below one another or side by side.

NOTE: The subgrade values for Horizontal Offset, Distance and Pivot Offset can be specified by *Template ID* points (consider using the Template ID Library to create a consistent set of template ID codes). For example, *EP* could be used in Distance to have the subgrade assume (and be controlled by) the width of the "EP" grade. Additionally, expressions can be used such as *EP+BC* to adopt the distance of the EP segment plus the distance of the BC segment. This is especially useful for template transitions so that if the width of the EP grade varies, the subgrade width will automatically adjust.

Subgrade Type: Chooses where to apply the subgrade. The roadway is the default for subgrades under the road grades. The Cut and Fill Slopes are for subgrades between the pivot (hinge) point at the end of the road grades and the catch (tie) point.

Slope Type: Indicate if the "bottom" of the subgrade surface should match the slope of the grade surface above it or if the subgrade slope should travel at a special slope value. Remember, a positive slope value increases in elevation further from the centerline while a negative slope value decreases in elevation further from the centerline.

Distance Direction: Indicate if the bottom of the subgrade moves away from (Out) or toward (In) the center of the template.

Intersect Surface: Indicate how the subgrade surface should "tie" into another component of the template to form a closed region:

- **Continue Slope:** Specify this option when the subgrade surface should continue along the slope as specified in the Slope Type control. Common uses of this intersect method is for aggregate surfaces used in rural design scenarios and/or railway ballast scenarios. When set to Continue Slope and the subgrade can't find an intersection because the subgrade is too low, then the **Tie Undershoot Vertically At Hinge** option can be used to make the subgrade switch to Straight Up method at the pivot point offset.
- **Straight Up:** Specify this option when the slope is to tie vertically to the surface above it. Common uses of this intersect method are for "rigid" shapes such as concrete roadways or sidewalks and for bituminous asphalt abutting Curb & Gutter.

- **Wrap Around:** Specify this option when the subgrade material is to extend beyond the limit of a previous component (typically, a curb) and then return toward the center of a driving lane to form a closed region as illustrated below:

When enabled, the **Wrap Height** control will become enabled that allows the wrap height (units of feet or meters) to be specified.

- **Tie Slope:** Specify this option when the subgrade is to tie into a previous element with a desired slope value. This slope type is commonly used when a subgrade region is being excavated with a "lay-back" slope. When enabled, the **Tie Slope** control will become enabled that permits the desired tie slope value (*e.g.* a 100% slope = a 1H/1V or 1:1 slope).

Horizontal Offset: Indicate the distance (by numerical or para-metrical equation) from the template centerline where the subgrade should start. The subgrade moves straight down from this location the depth specified in the *Vertical Offset*.

Vertical Offset: Indicate the *cumulative* depth from the elevation of the specified *Horizontal Offset* plus the desired thickness of the subgrade material. For example, if 6" of a pavement subgrade has been defined and 8" of aggregate subgrade is desired upon which the pavement is built, the vertical offset of the aggregate would be specified as 14". The **Match Existing Surface** option adjusts the subgrade depth to match the existing surface which applies for road rehabilitation when the subgrade is overlaying the existing surface.

Units: If applicable, specify the desired units of measure for the *Vertical Offset* control described above.

Distance: Indicate the distance (by numerical or para-metrical equation) of the desired width of the subgrade to the point where the Intersect Slope should start.

Material: Indicate the name of the material for the curb for reporting purposes from commands such as Process Road Design.

Coatings/Notes: This optional description is used in reporting and for labeling in Draw Typical Template.

Superelevation Settings: Indicate if special superelevation pivot points will be used:

Pivot Offset: Indicate the distance (by numerical or para-metrical equation) of the desired superelevation pivot point. This location allows the subgrade slope to break in superelevation independently from where the surface grade breaks. The subgrade will follow the superelevation slope from the centerline to the Pivot Offset. After the Pivot Offset, alternative slope factors govern.

Max Slope After Pivot: Indicate the maximum allowable slope for the subgrade once the Pivot Offset has been reached.

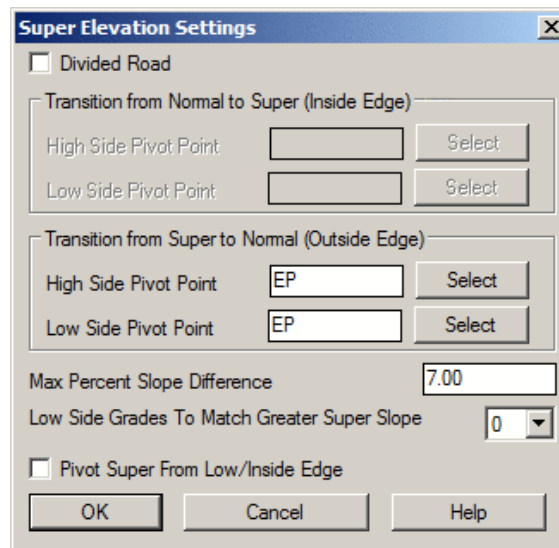

Slope Type After Pivot: Indicate how the slope of the subgrade after the Pivot Offset should be governed:

- **Normal:** This option sets the slope the same as the non-superelevation state.
- **Special:** This option can be used to set the slope to a specific value.
 - **Standard Slope Percent:** Indicate the default slope that should be attempted.

- **Minimum Slope Percent:** Indicate the minimum allowable subgrade slope.

Superelevation (Super)

Clicking on the "Super" (superelevation) button provides an interface of how the template should behave in zones of superelevation via the Superelevation Editor command.

Divided Road: When enabled, the *Transition from Normal to Super (Inside Edge)* controls will be enabled.

Transition from Normal to Super (Inside Edge): When enabled, identify (by Template ID point or para-metrical equation, *e.g.* EPI+2 or EPI-2) where superelevation pivot points (typically, inside edge of pavement) should occur for the High and/or Low locations of the Pivot Points for a Divided Roadway template.

Transition from Super to Normal (Outside Edge): Identify (by Template ID point or para-metrical equation, *e.g.* EP+2 or EP-2) where superelevation pivot points should occur for the High and/or Low locations of the Pivot Point for an Undivided Roadway template.

Max Percent Slope Difference: Indicate the maximum allowable grade difference between the segments on either side of the Pivot Point. Once this maximum allowable slope difference is achieved, template segments outside of the pivot point will elevate as a unit relative to the grade segment inside the Pivot Point.

Low Side Grades to Match Greater Super Slope: This option applies to the template grades that are outside the superelevation pivot point. When the superelevation slope becomes steeper than these outside grades, then these grades are adjusted to match the same super slope. You can adjust up to two additional grades past the superelevation pivot point. For example, consider a template where the superelevation pivot point is the EP grade and the next grade is a shoulder (SH) and you desire this first segment to adjust with the EP grade. Set the "Low Side Grades..." control to "1". If the regular SH slope is -4%, the SH will stay at -4% through the superelevation until the superelevation rate becomes greater than 4% (at this point, the SH crown has been removed). If the superelevation rate of the EP segment continues to 6%, the SH segment will steepen to -6% to keep the SH crown removed.

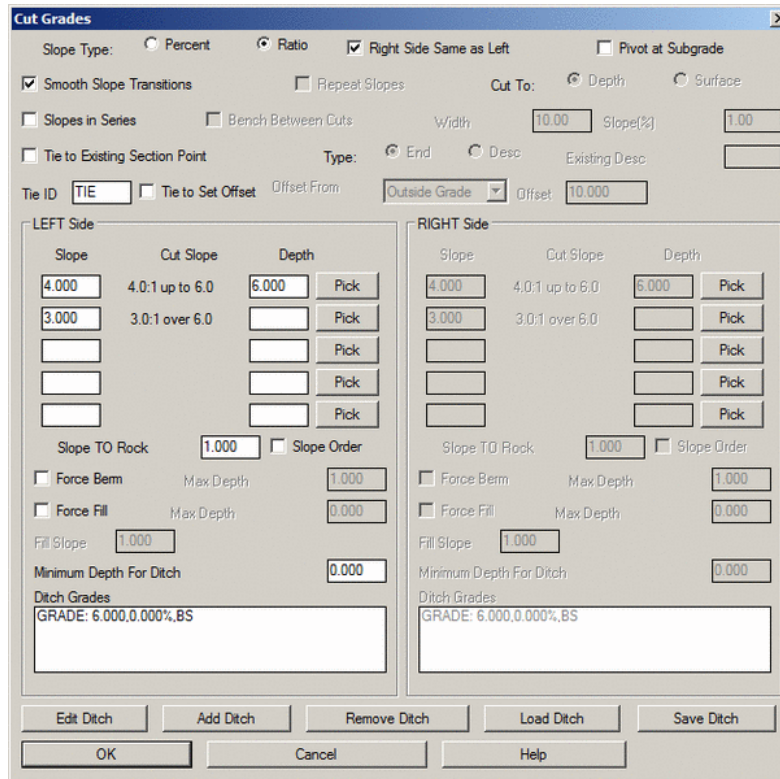

Pivot Super From Low/Inside Edge: Commonly used in Divided Roadway scenarios, when this option is enabled the elevation of the Inside Pivot Point relative to the design profile elevation is held fixed and segments outside of the Low/Inside Pivot Point are raised. There is an edit box to enter in the grade ID for this pivot super point which defaults to the Low Side Pivot Point if this is left blank.

Cut Slopes (Cut)

Use the Cut button to define cut-slope treatments when the outermost point of the template is below existing ground.

Slope Type: Indicate the type of slope unit used for the actual Cut Slope(s)/Fill Slope(s).

Right Side Same as Left: When enabled, the cut-slope treatments of the Left side of the template will also be used for the Right side of the template.

Pivot at Subgrade: This option will position the cut pivot point where the bottom subgrade intersects the template grade. The ditch or up-slope conditions will then occur from this special subgrade "daylight" pivot point, instead of from the outer grade pivot point.

Smooth Slope Transitions: When enabled, this option will gradually transition the slopes from one range to the next. In the Cut Grades dialog box example above, if the depth is 6 feet the slope will be in transition between 4:1 and 3:1.

Slopes in Series: When disabled, a single slope is used based on the depth of the Cut Pivot Point. When enabled, each slope is used to its target depth until an intersection with the ground is reached. Each successive slope in the series starts from where the previous slope ended.

Repeat Slopes: When enabled, the pattern of Cut slopes will repeat until the sequence of slopes "daylight" with existing ground.

Cut To: In addition to bench cut slopes to specific **Depths**, the Cut To option can be used to have each bench cut slope intersect a surface such as a rock section file. With Cut To set to **Surface**, the Process Road Design command will prompt for the cut slope surface for each bench. The bench surface can be either a cross section file, triangulation surface or user-specified fixed elevation. It is important to note that when cutting to a surface, you must specify a Slope and a Depth, even though the depths will not be used. In the below image, a slope of 3:1 is being used up to the first bench, a slope of 2:1 is being used between the first and second bench, and a slope of 1.5:1 is being used between the second bench and the topography.

LEFT Side			
Slope	Cut Slope	Depth	
3	3.0:1 up to 10.0	10.000	Pick
2	2.0:1 up to 20.0	20.000	Pick
1.5	1.5:1 over 20.0		Pick
			Pick

Bench Between Cuts: This option allows you to enter a "bench" pattern consisting of a width at a percent slope to be inserted between each cut slope. This option is commonly used in deep rock cuts as a means to help protect vehicles from loose/falling debris in the rock-cut areas.

Tie to Existing Section Point: When enabled, this option will tie the cut slope from the cut pivot point to either:

- **End:** The outer-most offset-elevation from the Existing Section file.
- **Desc:** The offset-elevation point with a specified description from the Existing Section file. This method is used when survey crews collect sections and designate the specific slope tie points.

Tie ID: Indicate the desired identification where the slope intersects the Existing Surface. This is the same setting as under the Fill Grades dialog.

Tie to Set Offset: When enabled, this option forces the cut slope catch point to a specified fixed offset. This offset can be relative to the:

- **Outside Grade:** The offset is determined from the outer-most Grade of the template.
- **Centerline:** The offset is determined from the Centerline and can be used when you want the slope to always tie into existing ground at a fixed Right-of-Way offset.

Cut Slope(s): There is room to specify up to five cut slopes that can be applied at specific depths. In a simple case of a single cut slope, supply the Slope value and leave the Depth and remaining Slope/Depth boxes blank.

Pick: These buttons prompt to select two points or a linework segment from the drawing to define the cut slope:

Slope to Rock: Indicate the slope that should be used when using a rock section file within Process Road Design.

Slope Order: Enable/Disable this toggle to switch between the two Slope Order modes for rock slopes:

1. **Slope TO Rock:** The cut slope will be the Slope To Rock up to the rock surface. After reaching the top of the rock surface, the regular cut slopes apply.
2. **Slope FROM Rock:** The regular cut slopes apply up to the rock surface. Then the slope from the Slope From Rock applies from the top of the rock surface to the ground surface.

Force Berm: This option will apply the Berm (defined using the Fill icon) in cut up to the **Max Depth** of cut. The **At Top of Cut** controls whether to place the berm at the pivot point from the road, or at the tie point where the cut slope intersects the ground.

Force Fill: When enabled, this option will make the template attempt to find a catch point with a specified **Fill Slope** even when the pivot point is in cut to a **Max Depth** in cut.

Minimum Depth for Ditch: When the Cut Pivot Point is shallower than this value, the ditch grade(s) will not be applied. To always apply the ditch grade(s) when in cut, specify a value of 0.

Ditch Grade(s) can be inserted between the Cut Pivot Point and the Cut Slope(s) as a means to further control and channel storm-water run-off. Ditch Grades are essentially identical to the Grades option used in the regular template. The location of the Cut Pivot Point is based on the outer-most Grade or Median segment. Consider one of the following scenarios:

- Cut Pivot Point is "Shoulder Point" - In this scenario, the last grade segment is taken to be a shoulder point. You could use:
 1. One ditch grade to create a "V-bottom" ditch (the single ditch grade emanates from the shoulder and forms one segment of the ditch with the cut slope comprising the other segment, or,
 2. Two ditch grades to create a "trapezoidal" ditch (the first ditch grade emanates from the shoulder with the second ditch grade forming the trapezoidal ditch bottom with the cut slope comprising the final segment.
- Cut Pivot Point is a "Toe of Foreslope" - In this scenario, the last grade segment is taken to be an additional slope (typically downward) from the shoulder point that is placed regardless of Cut vs. Fill. You could use:
 1. No ditch grades to create a "V-bottom" ditch. The last grade of the template and the cut slope comprise the V-bottom, or,
 2. One ditch grade to create a "trapezoidal" ditch (the single ditch grade forming the trapezoidal ditch bottom).

The option you use is ultimately governed by how/where the Cut Pivot Point should be defined.

Edit Ditch: Highlight a desired ditch grade and use this option (or simply double-click on the ditch segment) to adjust its value(s).

Add Ditch: Use this option to add any number of ditch grades. See the Grades for information pertaining to the various controls.

Remove Ditch: Highlight a desired ditch grade and use this option to remove it from the ditch grade list.

Load Ditch: Recalls a previously saved ditch (*.DIT) file.

Save Ditch: Saves the current ditch geometry to a ditch (*.DIT) file.

Fill Slopes (Fill)

Use the Fill button to define fill-slope treatments when the outermost point of the template is above existing ground. The options for Fill Slopes treatment are similar to those used for Cut and any difference(s) are noted below.

Slope Type: Refer to Cut – Slope Type for information.

Right Side Same as Left: Refer to Cut – Right Side Same as Left for information.

Pivot at Subgrade: Refer to Cut – Pivot at Subgrade for information.

Smooth Slope Transitions: Refer to Cut – Smooth Slope Transitions for information.

Slopes in Series: Refer to Cut – Slopes in Series for information.

Repeat Slopes: Refer to Cut – Repeat Slopes for information.

Fill To: In addition to bench fill slopes to specific **Depths**, the Fill To option can be used to have each bench fill slope intersect a surface. With Fill To set to **Surface**, the Process Road Design command will prompt for the fill slope surface for each bench. The bench surface can be either a cross section file, triangulation surface or user-specified fixed elevation.

Bench Between Fills: Refer to Cut – Bench Between Cuts for information.

Tie to Existing Section Point: Refer to Cut – Tie to Existing Section Point for information.

Tie ID: Refer to Cut – Tie ID for information.

Tie to Set Offset: Refer to Cut – Tie to Set Offset for information.

Fill Slope(s): Refer to Cut – Cut Slope(s) for information.

Pick: Refer to Cut – Pick for information.

Force Cut: When enabled, this option will make the template attempt to find a catch point with a specified slope even when the Pivot Point is in Fill. You can specify the Cut Slope to use and the **Max(imum) Depth** for the slope.

Force Ditch: When enabled, this option has two different methods to apply the Ditch Grades from the Cut definition when the **Max(imum) Depth** of fill has not been exceeded:

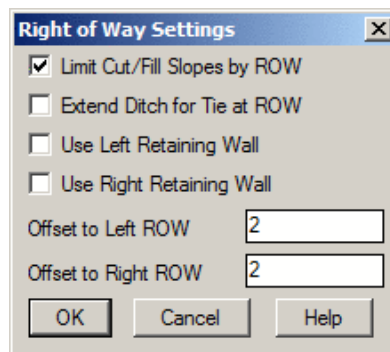

1. **At Base Of Fill: (enabled)** When enabled, the Force Ditch method creates the ditch where the Fill slope intersects existing ground. The **Uphill Only** option creates this base of fill ditch only when the existing ground goes uphill from the tie point.
2. **At Base Of Fill: (disabled)** When disabled, the Force Ditch method applies the ditch grades from the template pivot point.

Use Guardrail: When enabled, this option will extend the last template surface Grade the specified **SHD Extension** distance when the Fill is greater than the Min(imum) Depth.

Use Berm: Berm Grades are the fill equivalent to Ditch Grades. The **Minimum Depth** for Berm Grades will only draw the Berm Grades when the Fill depth is greater than the specified value.

Rights-of-Way (ROW)

The ROW (Right of Way) icon brings up the dialog shown which provides several methods that help govern how/where Cut and Fill slopes intersect existing ground. Right-of-Way data is stored in a Centerline (.CL) file as stations and offsets for the left and right sides of a centerline.

Limit Cut/Fill Slopes by ROW: When enabled, the Cut or Fill slope will become steeper in order to tie into the ground at the Right-of-Way offset. For example, if the Cut slope is 4:1 but this slope ties into the ground past the Right-of-Way, the slope will be modified to something steeper such as 3:1.

Extend Ditch for Tie at ROW: When enabled, this option allows you to tie the catch-slope into the original ground at the Right-of-Way offset by widening the lowest ditch slope along its slope until the Row-of-Way limit is attained. Common practice for the utilization of this option is to obtain additional fill material and/or for the placement of linear fences along the catch-slope (Right-of-Way).

Use Left/Right Retaining Wall: When enabled, the Cut or Fill slope will be applied until the Right-of-Way offset and will then tie into the ground via a vertical slope.

Offset to Left/Right ROW: Specify an additional "buffer" amount (if any) inside the Right-of-Way that is to serve as the desired Right-of-Way catch-point.

Left/Right Side Display: Choose the type of catch-slope treatment (*e.g.* **Cut**, **Fill** or **None**) that should be *displayed* in the dialog box *preview* of the template.

NOTE: The appropriate Cut/Fill slope will be applied to the cross-sections regardless of the Display setting.

Super Elevation: Choose the type of superelevation (*e.g.* **Right**, **Left** or **None**) that should be *displayed* in the dialog box *preview* of the template relative to the specified **Super %** amount.

NOTE: The appropriate superelevation will be applied to the cross-sections regardless of the Display setting.

Right Side Same As Left: When enabled, template geometry specified for the left-side of the template will be mirrored to the right-side of the template to create a symmetrical template. For unique geometry on either side of the template, disable this option and click/highlight in the desired side (Left *vs.* Right, Surface *vs.* Subgrade) to establish the desired geometry.

Profile Delta Z: This option applies a vertical offset to the profile when the template is processed. This vertical offset applies to a template that has an element at the profile position that makes the template different than the

profile grade. For example, when the profile grade is along the centerline at the pavement level and the template has a curb or median that is 0.5 above the pavement, then set the Profile Delta Z to 0.5 so that the template matches the pavement grade after coming down from the 0.5 curb or median.

Button

Action

"Pans" the Preview display of the template (same as a press/hold of the middle-button of a 3-button mouse).

"Dynamic zoom" of the Preview display of the template (same as a "wheel roll" of a wheel-button mouse).

Incremental "zoom in" of the Preview display of the template.

Incremental "zoom out" of the Preview display of the template.

"Zoom extents" of the Preview display of the template that fits/restores the content of the template into the Preview display.

Zoom/Pan Controls

Move Up/Down: Highlight an element whose position you want to change and click the appropriate button to move the template element up or down through the other Surface or Subgrade items.

Edit: Highlight an element whose data you want to modify. Alternatively, double-click on the item to edit it.

Remove: Removes the highlighted element from the list.

Import Polyline: This routine adds Grade element(s) to the template from a selected polyline. The polyline can either be drawn in cross section or in 3D. For the cross section polyline, the delta X of each polyline segment is used for the grade distance and the delta Y is used for the grade slope. For a 3D polyline, the horizontal distance of each polyline segment is used for the grade distance and the polyline elevations are used for the grade slope. After selecting the polyline, the routine prompts for the centerline point along the polyline which is the reference point for the template zero offset position.

Change Units: This option allows you to apply a scale factor to the distances in the template which can be used to convert between English- and Metric-based templates.

Save: Saves the current change(s) to the template (*.TPL) file.

Save As: Description of Control.

Draw: Refer to the Draw Typical Template documentation for information pertaining to this command.

Report: This option provides two different report formats:

1. **Detail Report:** This report provides all of the dimensions and their IDs of the template elements.
2. **IDs Report:** This report provides just the ID's of the template elements.

Copy Left to Right: This action is essentially the same as the Right Side Same As Left in that it clones the current elements on the left side of the template to the right side of the template.

Prompts

Draw Typical Template

This command draws a template and labels the slopes and distances. The cut and fill treatment can be shown on the left and/or right sides. All the cut/fill slopes are shown for the different depths when multiple slopes are defined. There are options to draw the normal template, super elevation or details of different sections.

You will be prompted to select the template (.TPL) file first, then the Typical Section dialog appears. Specify the parameters and press the Draw button.

Template Transition

This command creates a template transition file (.TPT file) that can be used for the commands *Locate Template Points* and *Process Road Design*. The template transition is associated with a typical template (.TPL) file. The

template transition file defines changes in grade distances or slopes for a specific template ID through a specified range of stations. Lane widths, for example, can be made to expand and contract. You can only modify existing template grades. Template Transition does not allow curbs, medians, subgrades or cut/fill treatment to be modified. Also new template elements cannot be added and existing elements cannot be removed. For this reason, lanes of road that "emerge" and slope distinctly from standard road lanes would need to be entered as small (0.001 in width) segments in the original template, available for expansion using Template Transition. Template Transition offers one of 3 ways to change template widths and slopes. Another way involves use of Template Point Profile and Template Point Centerline, where a particular template ID can be directed to follow a specific profile and centerline of its own. The third method is template-to-template transitions using Template Series Editor, where distinct templates transition one to another. All three methods require that template IDs "pre-exist" in order to be expanded, or to follow profiles and centerlines, or to transition between template files. So the technique of making very short phantom segments for emerging and disappearing "lanes" or roads with distinct grades is universal. If special slopes are not involved, lanes can expand and contract without creation of phantom segments in the original template. Only clever use of Template Series Editor, where templates with no curbs could "end" and templates with curbs can begin at specified stations, can effectively make "new" features like curbs and medians materialize.

Reviewing the below plan view, when you are given stations and offsets that define a template position like edge-of-pavement (above), you can use Template Transition effectively.

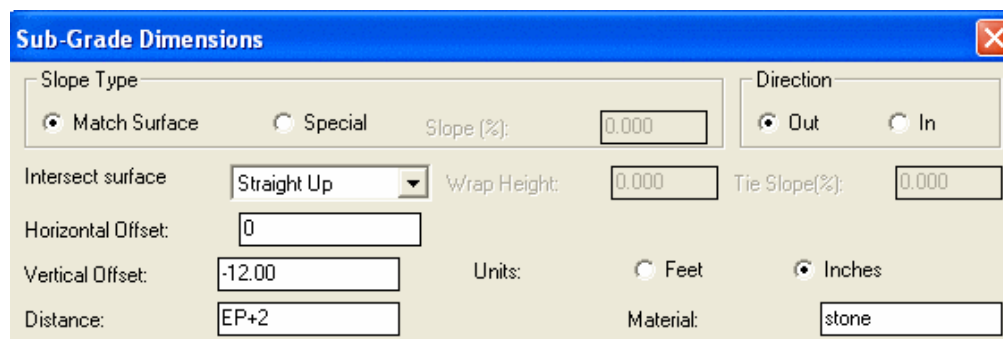

The first Template Transition dialog shows a list of the transitions, covering the above right-lane variable width. To add a transition, click the Add button. This brings up the second Template Transition dialog which shows the transition template for the second segment. The middle sections list the template grades that can be changed. To modify a grade, highlight the grade and click the Edit button. The Report function creates a report of the template transition data.

The Begin Transition Station is where the normal template begins to transition to the modified template. The Begin Full Template Station is where the modified template is used entirely. The End Full Template Station is where the template starts to transition back to normal. The End Transition Station is where the template has returned to normal. This method is designed for elements like passing lanes which expand from normal then contract back to normal. But you can also use this method for roads that start off or end expanded or altered. For example, to start off the road at a 40' edge-of-pavement dimension, it is necessary to transition up from 12.5' (normal dimension). If you need to have 40' at station 0, then enter station -0.01 as the "Begin Transition Station", and enter station 0 as the "Begin Full Template Station". Select the EP grade in the dialog, and change it to 40'. Then click "Link to next transition". The Link to Next Transition option joins the current transition to the next transition without returning to the normal template. This takes you to the second dialog, shown above. You sustain the 40' width from Begin

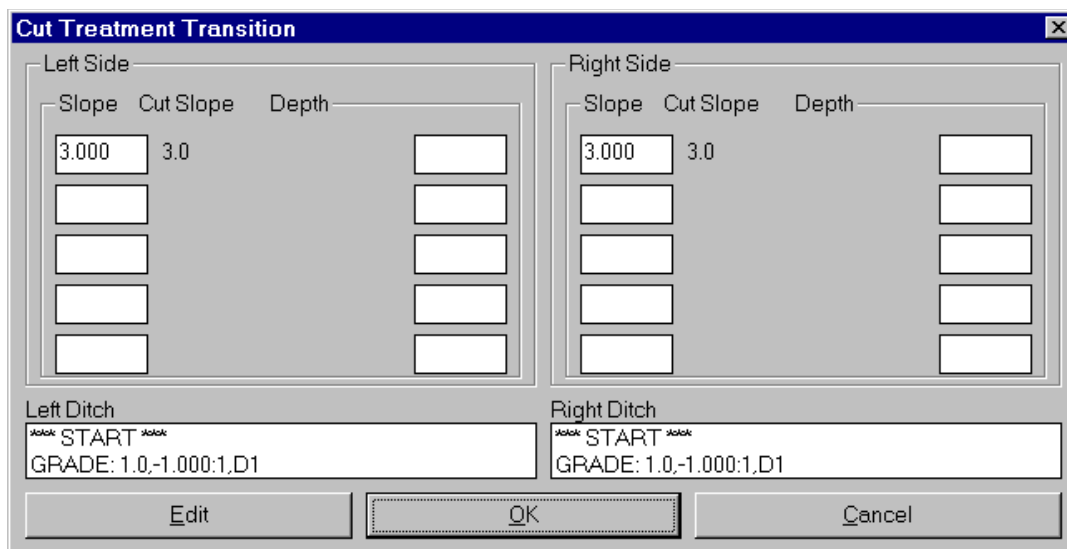

Transition Station 125.29 and transition at station 215.08 to a 24.23' dimension. Then quickly end the transition at station 215.081 for the "End Full Template Station". Finally, transition back to normal 12.5' by entering 335.51 for "End Transition Station".

The Series # setting is for grouping a sequence of transitions separately from other transitions. This Series # allows for independent transitions over the same station range. All transition changes that are part of the same transition should be given the same Series #. For example, when a grade on the right side of the road transitions separately from a grade on the left side of the road, all the transitions for the right side grade could be assigned as Series #1 and all transitions for the left side grade could be assigned as Series #2.

There is another "trick" to using Template Transition with templates that include subgrades. The subgrades will not automatically extend and follow the expanded grade IDs such as EP for "edge-of-pavement", unless the subgrades are defined in terms of the IDs themselves within Design Template. Subgrades that expand "at slope" to intersect a curb, for example, can expand naturally as the curb position moves outward on the right side. But subgrades that go "straight up" at back of curb at offset 14.5' in this example will stay at 14.5', unless defined as shown below by referencing the "EP ID":

Cut and Fill slopes can also be transitioned by picking the Cut and Fill buttons. Ditch and Berm grades can also be modified here.

Transitions can also be applied to the left, right or both sides. This allows you to have separate overlapping transitions for the left and right sides.

Template Transition dialog

Pulldown Menu Location: Roads

Keyboard Command: tpltrans

Prerequisite: A template .TPT file

Template Grade Table

This command creates a Template Grade Table file (.TGT), which is a lookup file for slopes and distances at stations for grade points within a template. Each side of the template is controlled independently. This user interface provides a simple and easy way to handle complex transitions. A similar result could be produced using a Template Series, or a combination of Template Grade Centerline for horizontal control and Template Grade Profile for vertical control. The advantage of Template Grade Table is that it provides a simpler solution. Besides handling transitions like lane widening, it can also be used to specify superelevation control.

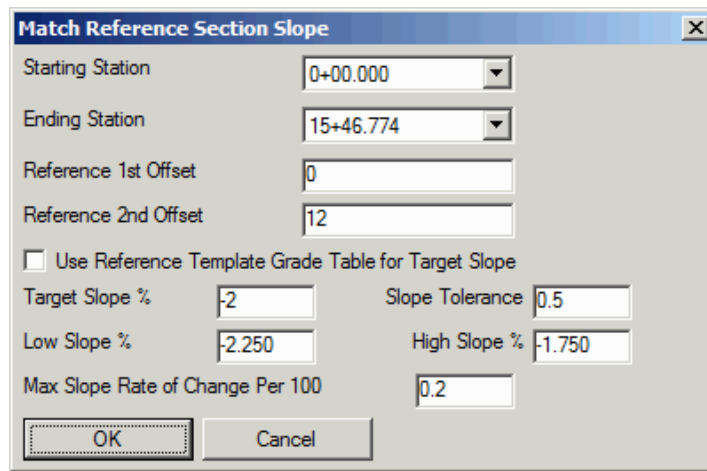

The way that Template Grade Table works is that you select a grade to modify on the left or right side. Then the program has a spreadsheet to define the sequence of transitions for the slope and distance of the selected grade. The grade will use the slope and distance defined in the template file (TPL) until the first station specified. Then the program uses the specified slope and distance going forward. When there is another transition station, the program interpolates the slope and distance between the transitions. For the example dialog below, the grade distance will be 14 at station 50 and will be 16 for all stations after 100. The slope and distance transitions are independent of each other. If one changes and the other doesn't at a station, you only need to enter a value for the one that changes. In the example dialog below, the distance doesn't change after station 100. So only the slope changes are entered after station 100.

A Template Grade Table can be used on a single road with Process Road Design command, or specified for specific roads within a Road Network.

The Template Grade Table is associated with a design template (.TPL) file which is used to set which grades are in the table.

Besides the grades in the template, the table also has the cut and fill slopes. Only the first cut and fill slopes are available. If the template has more complicated cut and fill conditions with multiple cut and fill slopes based on depth, then use the Template Series Files or Template Transition commands to transition these complex cut and fill conditions.

The **Match Slope** function assigns slopes to the grade table using cross slopes from a reference section file. This function can be used to match the template slopes to existing slopes such as for road rehabilitation to match the new road cross slopes to the existing. After selecting the reference section file, there is a dialog to set the range of stations to process and the offsets of the sections to get the cross slope from. The second offset is optional. When only one offset is specified, the program uses the existing slope at the offset. When both offsets are set, the slope is calculated between the two offset points on the existing surface. The Lowest and Highest Slope % settings are optional restrictions on the transition slopes. The Low/High Slope range can also be set by entering the Target Slope and Slope Tolerance. The Use Reference Template Grade Table for Target Slope option is a method to match the slope within the Slope Tolerance to a variable slope. For example, this option applies when matching an existing road that is transitioning through superelevation. When active, this option will make the program prompt for a separate Template Grade Table to use for the slope reference. The Max Slope Rate of Change Per 100 is an optional restriction on how quickly the slopes can change between stations. If you don't want to use a restriction, you can leave the field blank or set a high value.

The **Report** function shows all of the slope and distance changes for all of the template grades.

The **Import** function reads in transition data to the currently highlighted grade in the list. The data can come from either a text file, polyline, superelevation graph or superelevation file. For the text file, the format should have station, slope% and distance separated by a delimiter such as a comma. For the polyline method, the program prompts to select a polyline for the template grade and then prompts for the centerline alignment. There is an option to use another reference alignment for when the template grade is not the first grade from the centerline. Then the grade distances are set using the polyline location. If the reference alignment is selected and is a 3D polyline with elevations, then the import also assigns the grade slopes. For the superelevation graph, the import reads a polyline on a superelevation diagram grid to set the transition slopes. For superelevation file method, the import reads the transition slopes from a .sup file.

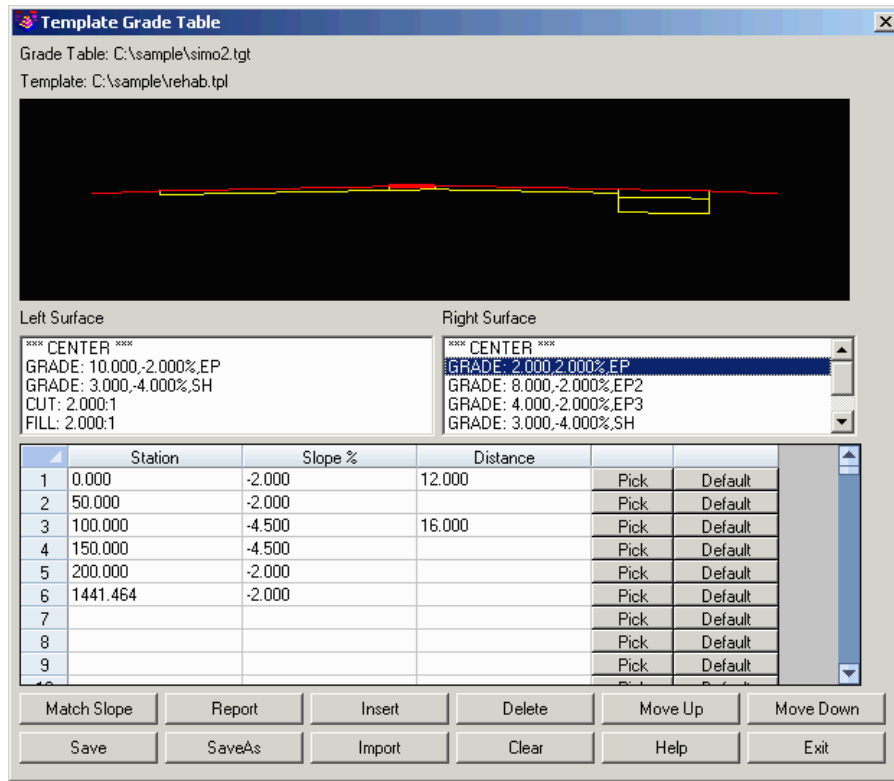

The **Insert**, **Delete**, **Move Up**, **Move Down** and **Clear** functions work on the data in the spreadsheet. The **Pick** button in the spreadsheet lets you screen pick a point to set the station for that row. The **Default** button sets the slope and distance to the values for the grade as defined in the template file (TPL).

Prompts

Template Grade Table to Edit/Create Choose New to create a new Template Grade Table, or Edit to modify an existing one.

Template File to Process: When creating a new Template Grade Table, an existing Template file must be selected to be used with it. When editing an existing .TGT, the Template previously associated with it will be automatically loaded with it.

Template Grade Table dialog

Pulldown Menu Location: Roads

Keyboard Command: tpltbl

Prerequisite: A template .TPL file

Super Elevation Editor

This command is an editor for super elevation stationing. The super elevation data is stored in new or existing super elevation (.SUP) files. When creating a new super elevation file, there is an option to read a centerline file and build the super elevation stationing based on the curves and spirals in the centerline using AASHTO-based stationing or optionally, the Virginia DOT method. The AASHTO calculations are based on the equations in chapter 3 of the 2004 Green Book titled Geometric Design of Highway and Streets. The length of the transition from normal crown to superelevation will be automatically computed by the program using either method based on the design speed and other settings. You can control the amount of this transition that occurs in the tangent leading up to the curve or in the curve itself by either a fixed distance or percentage of the transition. Use the **Transition Part in Tangent By Distance** for the distance method. Otherwise the percentage method is used. The **Include Runout** option sets the transition distance from the transition beginning station to the full super including the crown runoff. Otherwise the transition distance is from the super run-in station (flat outside lane) to the full super. The **Use Transition Curves** option enables fields for the transition curves at each super elevation grade break. For example, if a normal grade is -2% and it starts changing at station 1+00 to reach 4% as station 2+00, then you could have a transition at 1+00 to go from the constant -2% to the rate of change of 6% over 100'. This transition curve will show up in the Draw Superelevation Diagram similar to a vertical curve in Draw Profile.

Superelevation dialog box settings:

- Use Transition Curves:
- Use Reference Centerline:
- Method: AASHTO, Virginia DOT
- Normal Crown Percent Slope: 2.00
- Number of Lanes: 2.0
- Lane Width: 12.0
- Design Speed (mph): 30.0
- Transition Part in Tangent by Distance: Transition Distance in Tangent: 0.0
- Transition Part in Tangent(%): 50.0 Curve(%): 50.0 Include Runout
- Speed Table: AASHTO 4% MAX MSE
-

The main superelevation dialog displays a list of each super elevation transition. These entries should be sequentially entered from lowest to highest stations. To edit the super elevation stationing, highlight the entry line and click **Edit**. The **Add** button creates a new entry below the current highlighted row or at the top of the list if no row is highlighted. The **Delete** button removes the highlighted row from the list. The Report button creates a text report of the super elevation data. The **Calculate** button uses the current Speed Table and Design Speed in the dialog to set the transition stations. The **Save** button saves the super elevation file. To exit the program without saving, click the **Cancel** button.

The **Import** button brings in super elevation data from a delimited text file. Each row of the text file needs to have all the data for one super transitions including the beginning and ending stations. The Import function brings up another dialog for setting the data types for each field in the file. Here are the minimum fields for the import file:

Super Slope, Begin Transition, Begin Full Super, End Full Super, End Transition

For example:

5.0,576.610,806.398,882.794,1112.581

Superelevation dialog box showing a table of transition data:

Begin Transition	Begin Full	End Full	End Transition	Reverse
134+56.299	136+09.633	154+93.813	156+47.146	NO
167+99.492	169+52.825	188+49.357	190+02.690	NO
216+25.447	217+58.780	233+39.638	234+72.971	NO
245+22.847	246+39.514	259+56.086	260+72.753	NO
263+95.966	265+12.633	277+88.099	279+04.766	NO
301+96.686	303+13.353	312+33.060	313+49.727	NO
314+69.343	316+22.676	327+78.579	329+31.913	NO
338+36.688	339+53.354	348+56.227	349+72.894	NO
355+39.324	356+55.991	359+33.854	360+50.521	NO
367+72.865	369+26.199	386+84.897	388+38.231	NO

Speed Table: AASHTO 4% MAX MSE Design Speed: 45.0

The super elevation stationing is entered in the Input/Edit Superelevation dialog. The View Table button shows a table of the super elevation slope for the delta angle and radius at different design speeds. The Calc Super button calculates the slope of full super given the design speed. The station entries are defined as follows:

The screenshot shows the 'Input-Edit Superelevation' dialog box with the following fields and values:

- Station to begin Transition (TS OR PC-1/2 TRANS.):*
- Station to begin super run-in (flat outside lane):
- Station for super at Reverse Crown rate in:
- Normal Grade Slope (%): Design Speed:
- Percent Slope of Full Super (e):*
- Station to begin Full Super (SC OR PC+1/2 TRANS.):*
- Station to end Full Super (CS OR PT-1/2 TRANS.):*
- Compound Curve Percent Slope of 2nd Full Super:
- Station to begin 2nd Full Super:
- Station to end 2nd Full Super:
- Station for super at Reverse Crown rate out:
- Reverse Curve
- Station to end super run-off (flat outside lane):
- Station to end Transition (ST or PT+1/2 Trans.):*

Buttons: View Table, Calc Super, OK, Cancel, Calculate Stations.

Station to begin transition: where normal crown rate begins to transition

Station to begin super run-in: where slope becomes flat

Station for super at normal crown rate in: where slope equals negative of normal crown rate

Station to begin full super: where slope reaches full super slope

Station to end full super: where slopes begins to transition from full super back to normal

Station for super at normal crown rate out: where slope equals negative of normal crown

Station to end super runoff: where slope becomes flat

Station to end transition: where slope returns to normal crown rate

Given these various Station settings, an unequal rate of change can occur between any two stations. However, the program can calculate the stations to set an even rate of transition, as long as it knows the max superelevation, the normal crown slope and the station to start transition, start full super, end full super and end transition. The Calculate Stations button therefore calculates the stations for begin run-in, normal crown rate in, normal crown rate out and end super run-out. To calculate these stations the values with an "*" must be entered.

The Compound Curve option allows you to specify a second superelevation slope for a compound curve. In addition to specifying the second slope, the starting and ending stations for this slope must also be entered. The Reverse Curve option is similar to the Compound Curve option. A typical Reverse Curve is shown below in plan view and as it would appear in the summary dialog:

Begin Transition	Begin Full	End Full	End Transition	Reverse
389+00.000	390+50.000	396+12.000	421+49.000	YES
	399+00.000	417+96.671		NO

Speed Table: AASHTO 4% MAX MSE | Design Speed: 55.0

Buttons: Edit, Add, Delete, Report, Import, Save, SaveAs, Calculate, Cancel, Help

Station 399+00 is the "pivot" where superelevation left flattens and turns into superelevation right.

New or Existing Super Elevation File dialog

Superelevation File to Process Specify a superelevation file.

Superelevation Editor dialog

Pulldown Menu Location: Roads

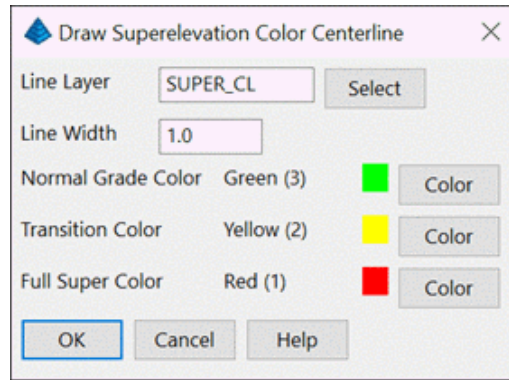

Keyboard Command: super

Prerequisite: None

Draw Super Elevation Color Centerline

This command draws the centerline as a polyline with colors for the super elevation transition zones. The program prompts for a super elevation file (.sup) that defines the transition stations and a centerline file (.cl) that defines the

horizontal alignment. Then there is a dialog to set the colors for the normal grade, transition and full super station ranges. The Line Width sets the width of the polyline.

Pulldown Menu Location: Roads

Keyboard Command: superdrawcl

Prerequisite: Super Elevation file (.sup) and Centerline file (.cl)

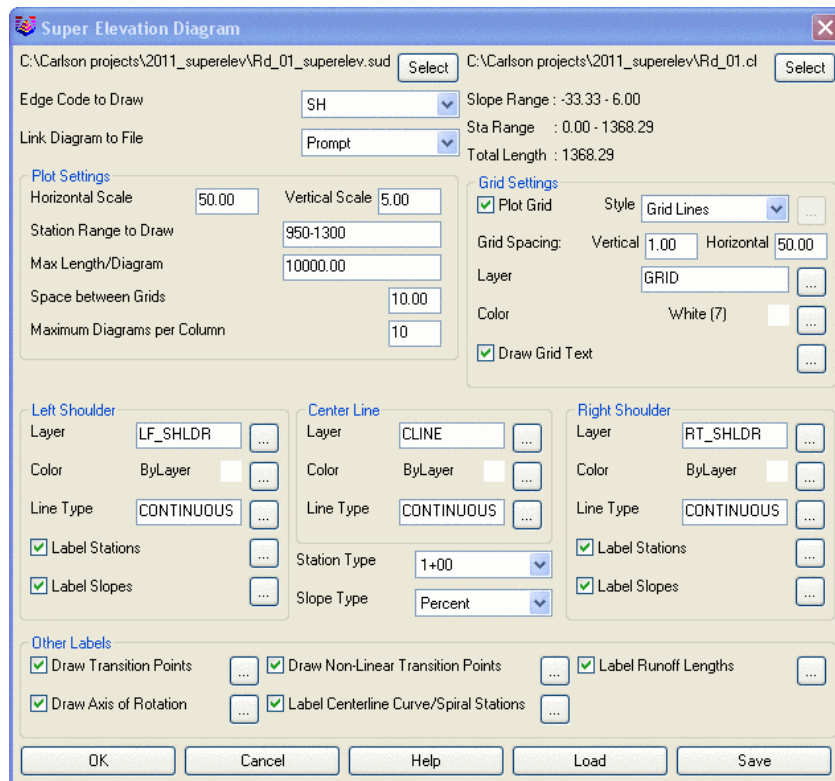

Draw Super Elevation Diagram

This command draws the station and slope diagram for a template grade ID from data in a Template Grade Table (TGT), for the slopes from a super elevation file (SUP), or for Super Elevation Diagram (SUD) file. The Super Elevation Diagram (.SUD) file can be created with the Process Road Design or the Road Network commands.

The Super Elevation Diagram is a graphical representation of the change in cross-slope between the centerline and the left and right shoulders of a roadway. The diagram is typically drawn on a grid, similar to a profile, where the horizontal component represents the stationing of the roadway and the vertical component shows the cross-slope.

Super Elevation Diagram

Draw Super Elevation Diagram Dialog Box

Select: Use this button (at the top-left of the dialog) to browse to and select the Super Elevation Diagram file (.sud) to be drawn.

Edge Code to Draw: Use this dropdown box to select the Template ID to be represented in the Super Elevation Diagram.

Link Diagram to File: This setting has 3 options: *Off*, *Prompt* and *Auto*:

Off: This option will not re-draw the Diagram in the drawing if and when the Super Elevation Diagram (.SUD) file changes.

Prompt: This option will notify the user that the Super Elevation Diagram (.SUD) file has changed and give the option of re-drawing the Diagram in the drawing.

Auto: This option automatically re-draws the Diagram when the Super Elevation Diagram (.SUD) file changes.

Ref CL: Use the **Select** button to associate the Super Elevation Diagram (.SUD) file with a Centerline (.CL) file.

After the (.SUD) file has been selected, various details about the file such as "Slope Range", "Station Range" and "Total Length" are displayed below the **Ref CL:** setting.

Plot Settings

Horizontal Scale: Set as needed.

Vertical Scale: Set as needed.

Station Range to Draw: Enter "ALL" to draw the entire length of roadway or specify a range of stations.

Max Length/Diagram: Specify the maximum length of each diagram. If the "Station Range to Draw" is longer than the "Max Length/Diagram", additional diagrams will be stacked vertically above the first.

Space Between Grids: If the total length of the Diagram requires stacking of multiple Diagrams, this value specifies the distance between Diagram Grids.

Maximum Diagrams per Column: When multiple Diagrams are stacked, this number sets the maximum number of Diagrams per Column. If this number is reached, a second column will be created.

Grid Settings

Plot Grid: Select this option to have centerline and shoulder diagrams drawn on a grid.

Style: Select the Grid Style from several options. *Grid Lines* is the default setting. Other options are:

Ticks Only: This setting draws tick marks for both the station increments along the bottom and the slope increments along the left edge of the diagram.

Ticks and Dots: This setting draws tick marks for both the station increments along the bottom and the slope increments along the left edge of the diagram and draws a series of "dots" in a grid pattern across the rest of the diagram.

Ticks and Checks: This setting draws tick marks for both the station increments along the bottom and the slope increments along the left edge of the diagram and draws a series of "+"-signs in a grid pattern across the rest of the diagram.

Grid Spacing: Set Vertical and Horizontal Grid Spacing as needed.

Layer : Enter the name of the Layer for grid lines, ticks, dots and checks or use the button to select the Layer from a list.

Color: Enter the Color for grid lines, ticks, dots and checks or use the button to select the Color from a list.

Draw Grid Text: Select this option to draw Grid Text for stationing and cross-slopes. Use the button to specify Grid Text settings such as precision, text size scaler, layer, text style, color and vertical/horizontal spacing.

Left Shoulder & Right Shoulder Settings

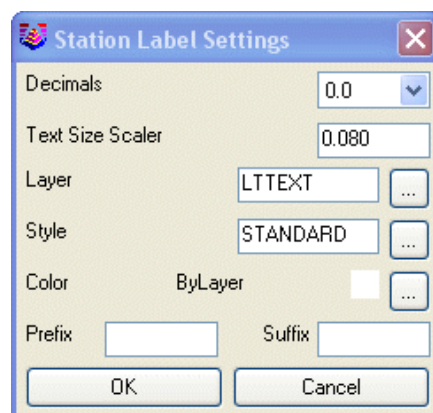

Layer: Enter the name of the Layer for the Left or Right Shoulder or use the button to select the Layer from a list.

Color: Enter the Color for the Left or Right Shoulder or use the button to select the Color from a list.

Linetype: Enter the Linetype for the Left or Right Shoulder or use the button to select the Linetype from a list.

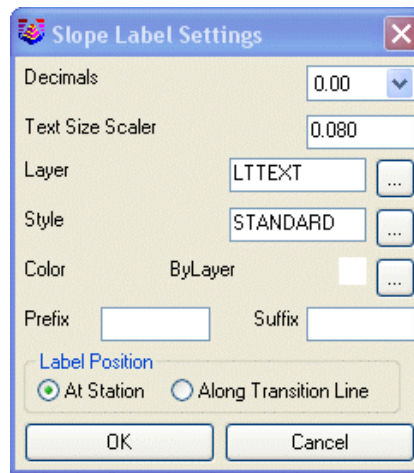

Label Stations: Select this option to label the Station value at each slope change along the Left or Right Shoulder.

Use the button to specify Shoulder Station Label settings such as precision, text size scaler, layer, text style, color and prefix or suffix.

Left & Right Shoulder: Station Label Settings

Label Slopes: Select this option to label the Slopes along the Left or Right Shoulder. Use the button to specify Shoulder Slope Label settings such as precision, text size scaler, layer, text style, color and prefix or suffix. The user also has the option of positioning the Slope label at the station of the Slope change or along the transition line.

Left & Right Shoulder: Slope Label Settings

Center Line Settings

Layer: Enter the name of the Layer for the Centerline or use the [...] button to select the Layer from a list.

Color: Enter the Color for the Centerline or use the [...] button to select the Color from a list.

Linetype: Enter the Linetype for the Centerline or use the [...] button to select the Linetype from a list.

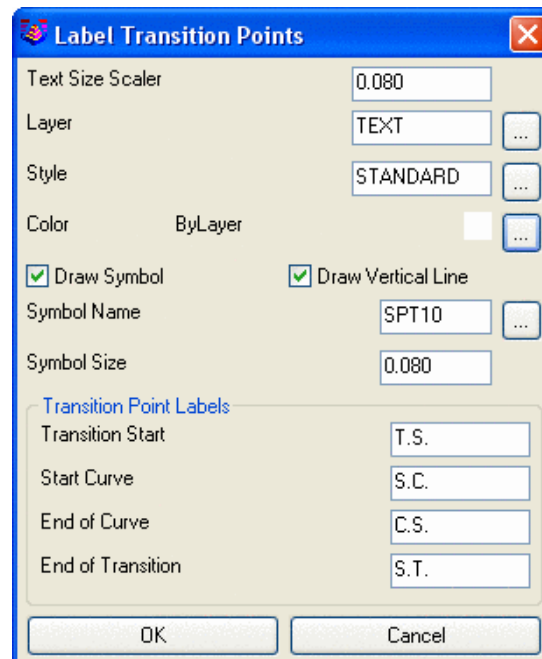

Station and Slope Type Settings

Station Type: Select the desired format for Station. The options are: *Percent* or *Ft/Ft*.

Slope Type: Select the desired format for Slope. The options are: *1+00*, *1+000* or *100..*

Other Labels

Draw Transition Points: Enable this option and use the [...] button to configure and format the labels for *Transition Start*, *Start Curve*, *End of Curve* and *End of Transition*.

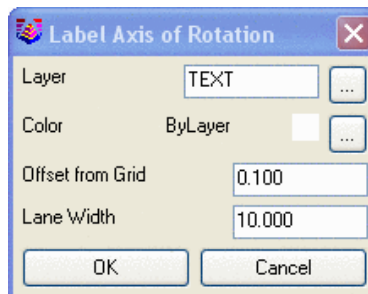

Label Transition Points Dialog Box

Draw Axis of Rotation: Enable this option and use the  button to configure and format the labels for the **Axis of Rotation**. The **Axis of Rotation** is a small icon displayed at the bottom of the grid at critical Super Elevation Points. The icon shows a cross-section view of the pavement slopes and a "+"-sign indicating the point of rotation for the Super Elevation.

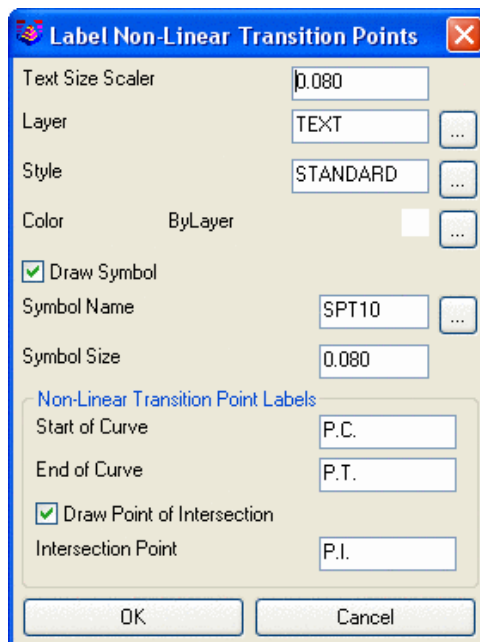

Axis of Rotation

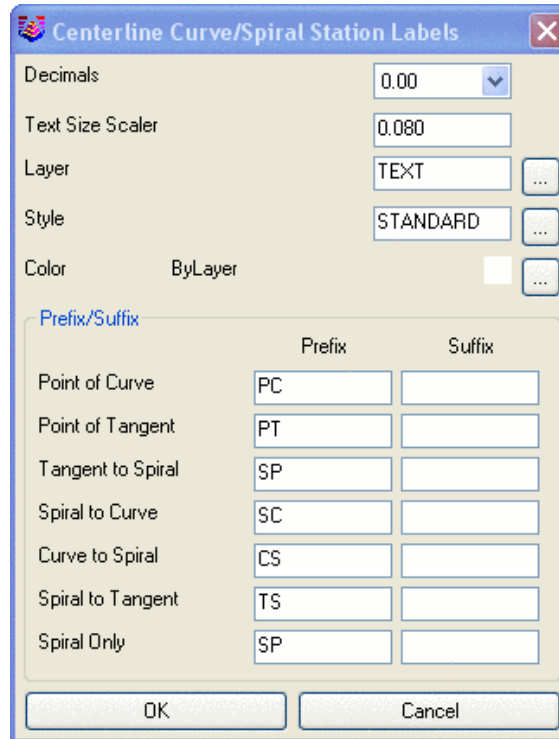

Label Axis of Rotation Dialog Box

Draw Non-Linear Transition Points: Non-linear transition points are drawn when the rate of change of elevation is not constant at the point where the Super Elevation starts or ends. Enable this option and use the  button to configure and format the labels for *Start of Curve*, *End of Curve* and *Point of Intersection*.

Label Non-Linear Transition Points

Label Centerline Curve/Spiral Stations: Enable this option and use the  button to configure and format the labels for *Point of Curve*, *Point of Tangent*, *Tangent to Spiral*, *Spiral to Curve*, *Curve to Spiral*, *Spiral to Tangent* and *Spiral Only*.

The dialog box titled "Centerline Curve/Spiral Station Labels" contains the following settings:

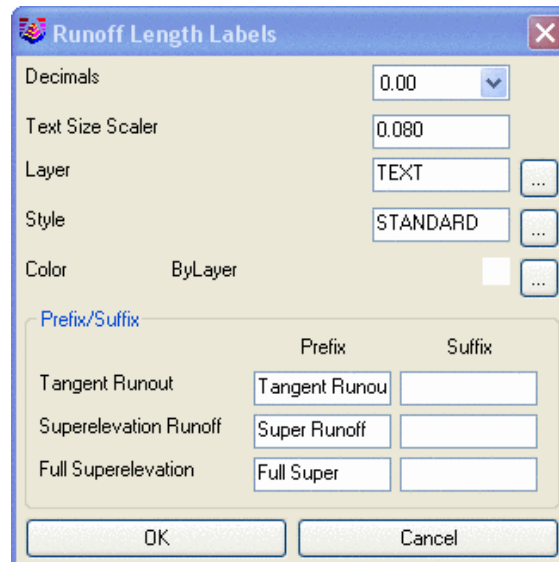

- Decimals: 0.00
- Text Size Scaler: 0.080
- Layer: TEXT
- Style: STANDARD
- Color: ByLayer (unchecked)

	Prefix	Suffix
Point of Curve	PC	
Point of Tangent	PT	
Tangent to Spiral	SP	
Spiral to Curve	SC	
Curve to Spiral	CS	
Spiral to Tangent	TS	
Spiral Only	SP	

Buttons: OK, Cancel

Label Centerline Curve/Spiral Stations

Label Runoff Lengths: Enable this option and use the  button to configure and format the labels for *Tangent Runout*, *Super Elevation Runoff* and *Full Super*. These distances are displayed as linear dimensions above the Diagram Grid.

The dialog box titled "Runoff Length Labels" contains the following settings:

- Decimals: 0.00
- Text Size Scaler: 0.080
- Layer: TEXT
- Style: STANDARD
- Color: ByLayer (unchecked)

	Prefix	Suffix
Tangent Runout	Tangent Runou	
Superelevation Runoff	Super Runoff	
Full Superelevation	Full Super	

Buttons: OK, Cancel

Label Runoff Lengths

Prerequisite: Super Elevation Diagram file (.sud), Template Grade Table file (.tgt), or Super Elevation file (.sup)

Template Series Editor

Template Series is another method of widening lanes or causing templates to change: direct template-to-template transitioning. Using this command, you specify the station where one template "ends" and the station where another template "begins", and the program auto-transitions between templates.

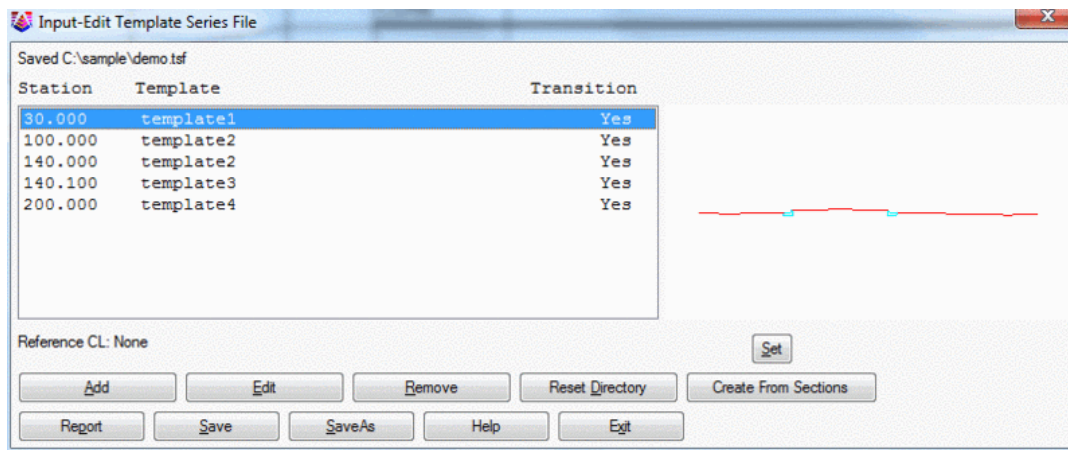

The Template Series is stored in a .TSF file and consists of a sequence of template file names (.TPL) with stationing. The Design Template command is used to create the .TPL files. The Template Series can be used in commands like Process Road Design and Road Network. In these commands, the template selection can be either a regular template (.TPL) or the template series (.TSF).

For the transition to work optimally, the templates should share the same IDs so that the program can connect the template 3D polylines and transition between templates. If the templates are distinct with separate, unrelated IDs, then by ending template1 at station 500 (for example) and starting template2 at station 500.01, a very abrupt transition can be accomplished.

For a design with transitioning templates, the Template Series method is an alternative to the Template Transition method, a third method of Template Grade Table, and to a fourth method of using Template Point Profiles and Template Point Centerlines, where a template ID "follows" a particular centerline and profile. One advantage of the Template Series approach is that it can be used to link different templates together, like non-curb and curb templates, as shown here in plan view:

For the above example, Template 1 applies from station 0+00 to 0+30, then transitions to Template 2 at 1+00 which has a wider EOP distance. This transition occurs between stations 0+30 and 1+00. Then the full Template 2 continues until station 1+40. Then Template 3 starts with a curb replacing a standard EOP/Ditch combination on the left side. So Template 3 would be set to begin at 1+40.1, a short distance past 1+40. This template transitions into Template 4 at station 2+00. Template 4 has a shorter middle grade on the left side. You do not need to enter start and ending templates at station 0+00 or after station 2+00. Therefore, the dialog for this example might look as follows:

Note that you can run Process Road Design to review the design results in plan view, with entry of only the Design Template/Series, the Profile and the Centerline (items 1, 2 and 4 within Process Road Design). You do not need existing cross sections to use Process Road Design. If you process at an interval such as 10 over any desired station range, you can output the Template Polylines and verify the result in plan view. If no sections are found, the program will process from edge of shoulder left to edge of shoulder right, and omit cut and fill slopes. With the correct templates, this would reproduce the plan view shown above.

Template Series Editor is also an effective way to accomplish superelevation, and even simultaneous superelevation and lane widening. Consider the "stages" of pivoting into superelevation of 3%. The first template might be called "Normal Crown" (the lower template). The second template might be called "Reverse Crown" (+2% cross slope). The third template might be called "Full Super" and would be the +3% template. You need the second template because you need to "restrain" the left-hand side of the road from pivoting until the continuous +2% cross slope is reached. If you only used the "Normal Crown" template, say, at station 4+00 and then the "Full Super" template at station 6+00, then at station 5+00, where 1/2 of the transition occurs, the left side cross slope would be -2.5% (transitioning halfway). In reality, the left side should not pivot until station 5+60. If the rate of pivoting is less from normal crown to flat outside lane, and the rate changes after that point, then you would need a fourth template to direct how the road transitions to full superelevation.

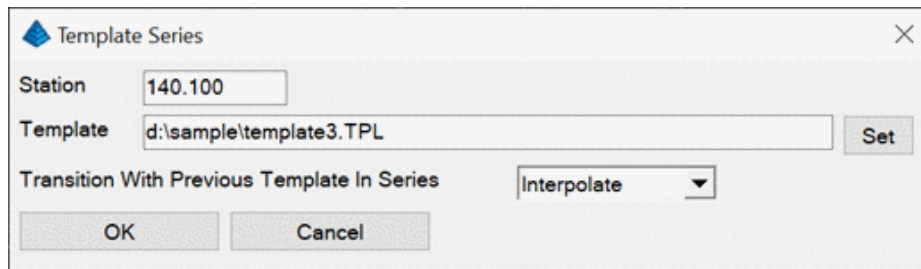

The Reference CL is optional. When it is set, then screen pick is an option for specifying the template transition stations.

The Report function has options for either a summary report of the stations and template, or a detailed report that adds the template dimensions.

The Reset Direction function applies when the folder for the template files (.TPL) has changed and you need to set a new location.

The Create From Sections function reads a section file for a design and creates templates at each change and fills in the template series with these templates. The section file must have descriptions on the section points (ie "EOP").

Here is the dialog for adding and editing templates for the series where you set the template name and station to apply. The Transition With Previous Template In Series as Interpolate will match any common template ID's with the previous template and linear interpolate any changes in distance or slope for the stations between the templates. For the Midway setting, the template dimensions are held unmodified up to the midway station between the templates where the switch occurs. For the None setting, the template switches over at the station in the dialog.

Pulldown Menu Location: Roads

Keyboard Command: tplsseries

Prerequisite: Template Files

Topsoil Removal/Replacement

This command creates a topsoil definition (.TOP) file which defines topsoil removal and replacement zones to be used in the *Process Road Design* command. You can have different topsoil adjustments for different station ranges. These adjustments are applied to the existing ground section in the *Process Road Design* command and will affect the cut and fill volumes. *Process Road Design* will also report the amounts of topsoil removal and replacement.

The command starts by displaying a list of the topsoil stations in the dialog shown below. To add a topsoil adjustment, pick the Add button which brings up a second dialog. You can have different amounts of topsoil removal and replacement for areas in cut and areas in fill. Subsoil is another category of removal that will be combined with any topsoil removal. The Subsoil removal volume is reported separately from topsoil removal by Process Road Design. Subsoil is automatically removed from the site and not used in fill or as a replacement quantity. Therefore, the subsoil element applies only to unsuitable materials that need to be removed. In the example below, we are only removing topsoil in cut (where cutting must take place in any case), and in the cut, we are removing 2' of subsoil which will be hauled off site (since subsoil is not re-used). The removed 0.5' of topsoil in cut will then be replaced in both cut and fill zones of the road within the limits specified by the "Replacement Limit ID". (No topsoil will be replaced on paved surfaces!)

Station	Topsoil Cut	Subsoil Cut	Topsoil Fill	Subsoil Fill	Replace Cut	Replace Fill
0.0-450.0	0.5	2.0	0.0	0.0	0.5	0.5

The Replacement Limit ID is an option to limit the replacement to occur only within the template left offset Limit ID and the right offset Limit ID. If this Limit ID is left blank, then the program will apply the replacement between the left catch point and the right catch point. Topsoil removal is always applied between the catch points. The Limit ID corresponds to a template ID as set in the Design Template routine. Typically, you would use an ID like SH for shoulder and replace topsoil only from the far left and right tie/catch points to the SH or shoulder point. If you use a curb and want to replace topsoil to back of curb, keep in mind that the program takes the basic code "CB" and creates 3 curb points typically, so the back of curb would become CB3 in most L-shaped curbs.

If the Topsoil (".TOP") file is selected within Process Road Design, all quantities of topsoil removal and replacement and subsoil removal are reported, as shown below:

Processing 0+00.00 to 4+42.10

Total Topsoil Removed: 5219.22 C.F., 193.30 C.Y.

Total Subsoil Removed: 20876.89 C.F., 773.22 C.Y.

Total Topsoil Replaced: 5309.57 C.F., 196.65 C.Y.

Hauled-In Topsoil: 90.35 C.F., 3.35 C.Y.

Total Cut : 9106.52 C.F., 337.28 C.Y.

Total Fill: 16402.56 C.F., 607.50 C.Y.

Total SUBGRADE1 - asphalt: 2763.36 C.F., 102.35 C.Y.

Total SUBGRADE2 - stone: 9209.44 C.F., 341.09 C.Y.

Total CURB - concrete: 1078.37 C.F., 39.94 C.Y.

The cut reported in Process Road Design would be the remaining cut after topsoil and subsoil removal, and the fill would be the fill necessary to bring the grade to base of topsoil replacement, on top of which the topsoil is added. The removal of topsoil and subsoil usually creates less cut and more fill, as some of the cut is accomplished by the topsoil/subsoil removal, and in terms of fill, the grade must be brought up to replace the "cavity" created by the topsoil and subsoil removal. Topsoil removal depths and replacement depths can have a dramatic impact on cut and fill quantities, particularly on smaller scale projects like subdivision roads. In this example, every extra 0.1' of topsoil removal produces approximately 100 c.y. of net fill.

Topsoil File to Read Specify a topsoil file.

Topsoil dialog Choose your options.

Keyboard Command: topsoil

Prerequisite: None

Assign Template Point Profile

This command assigns profile (.PRO) files to template point ID's like EP (edge of pavement), SH (shoulder) or DL (ditch line), storing this information in a template point profile (.TPP) file which can be used by the *Process Road Design* and *Road Network* commands. The purpose of the profile assignments is to allow separate profiles for template points that are independent of the centerline profile. For example, a ditch grade could have a different profile than the centerline. Multiple template point profiles can be assigned so the amount of control is unlimited. The Template Point Description corresponds to the name set in the *Design Template* command.

If you want the template ID point to follow a special slope or vertical alignment, use Assign Template Point Profile. The combination of using template point centerlines and profiles applied to particular template ID points is a design method sometimes referred to as "strings", where template elements string along special horizontal and vertical

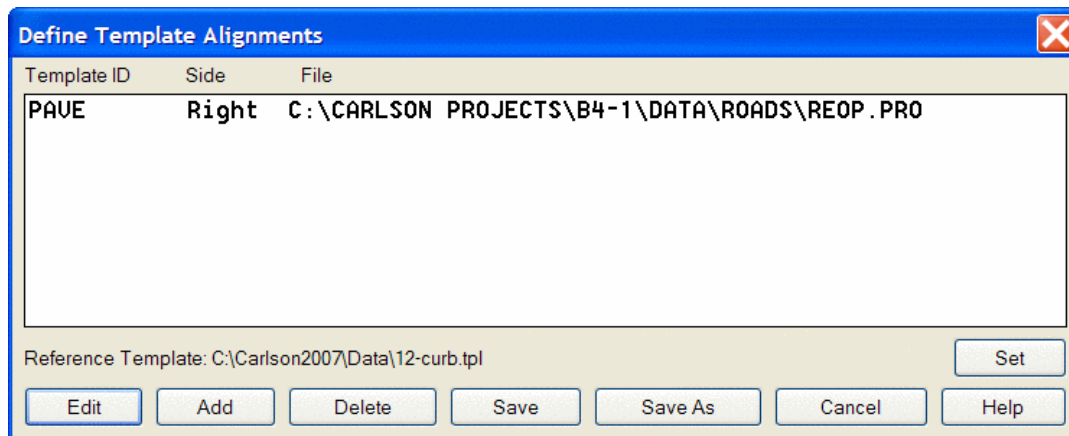

alignments. The rules of the template in terms of distances and slopes to the next point in the template will resume after the template point centerline and profiles are applied.

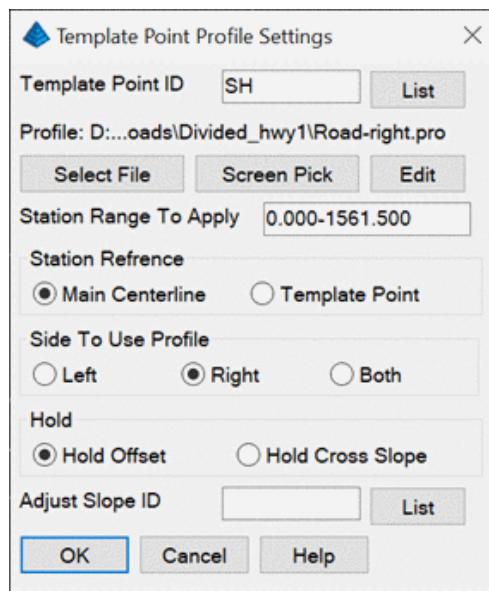

Prompts

First you are prompted to create a new Template Point Profile (.TPP), or edit an existing one.

Next the Define Template Alignments dialog is presented, showing a list of existing Template ID-Profile assignments. To add a new assignment, first pick the Set button to set the Reference Template file (.TPL), then pick the Add button. This brings up the Template Point Profile Settings dialog. First, pick a Template Point Description from the List, which is derived from the components defined in the Template. Next, pick the **Specify File** button, to choose the file (.PRO) to assign to the Template Point ID. Alternatively, instead of picking a profile, you can use the **Screen Pick** button to select a 3D polyline from the drawing which the program will use to generate a profile. Next, enter the Station Range To Apply the assignment. The **Station Reference** sets whether the template profile stationing uses the same stationing as the main CL or uses the template grade stationing. The template grade stationing applies when the template grade is also using a Template Point Centerline so that the template grade has a different length than the main CL. The **Side To Use Profile** specifies if this profile is for the Left, Right, or both sides of the main centerline. The **Hold** setting controls how to apply the profile. Since the template profile can change the relative position of the template ID from the centerline, you have two options for how to fit in the template ID profile: Hold Offset or Hold Slope. Hold Offset will keep the same offset for the template ID and adjust the slope to the template ID. The Hold Cross Slope will keep the same slope to the template ID and adjust the offset to reach the template ID profile elevation. Use Hold Offset when Template Point Profile is used in conjunction with Template Point Centerline, where a single template ID is defined to follow both a special and distinct horizontal alignment (centerline) and vertical alignment (profile). The Adjust Slope ID specifies another grade to apply the change in slope to which can be used for divided highway designs.

Pick OK. Back in the Define Template Alignments dialog, pick Add to add another assignment, Edit to edit an existing assignment, Report to create a report of the template point profile data, Delete to delete a defined assignment, or Save to Exit.

Now Process the road design employing the newly defined Template Point Profile assignment. In the Process Road Design main dialog, pick the Template Point Profile button to select the new file (.TPP). You could also create a new Template Point Profile file directly from this dialog box by picking the Edit button and specifying a new file name.

Pulldown Menu Location: Roads

Keyboard Command: tppset

Prerequisite: Profile file (.PRO) or 3D polyline

Assign Template Point Centerline

In roadway design situations involving varying pavement widths, Assign Template Point Centerline is an effective way to control the edge of pavement horizontal alignment as well as any other element in the template. This command assigns centerline (.CL) files to template ID points, independent of the main centerline, thereby controlling the horizontal location. Besides controlling the template grades, you can also control the tie point where the cut/fill slope intersects the existing ground by entering TIE for the Template Point ID.

The assignment of Template ID points to centerline files (.CL) is stored in Template Point Centerline files (.TPC). These files are then used by the *Process Road Design* and *Road Network* commands. The slope to these template points is based on the parameters defined in *Design Template*. Subgrades can be made to follow template IDs if their offset distances are defined not by distance but by reference to the template ID. For example, with a grade ID of EOP and a subgrade that goes one foot past this grade, the subgrade distance can be defined as EP+1 so that the subgrade follows the template point centerline adjustments.

The commands that process Template Point Centerlines such as Road Network will make the template grades follow the template point centerlines including along their curves for the output of the template 3D polylines and road TIN surface. This way Template Point Centerlines can be used to create rounded medians and edge-of-pavements that follow alignments that are independent of the main centerline as shown here.

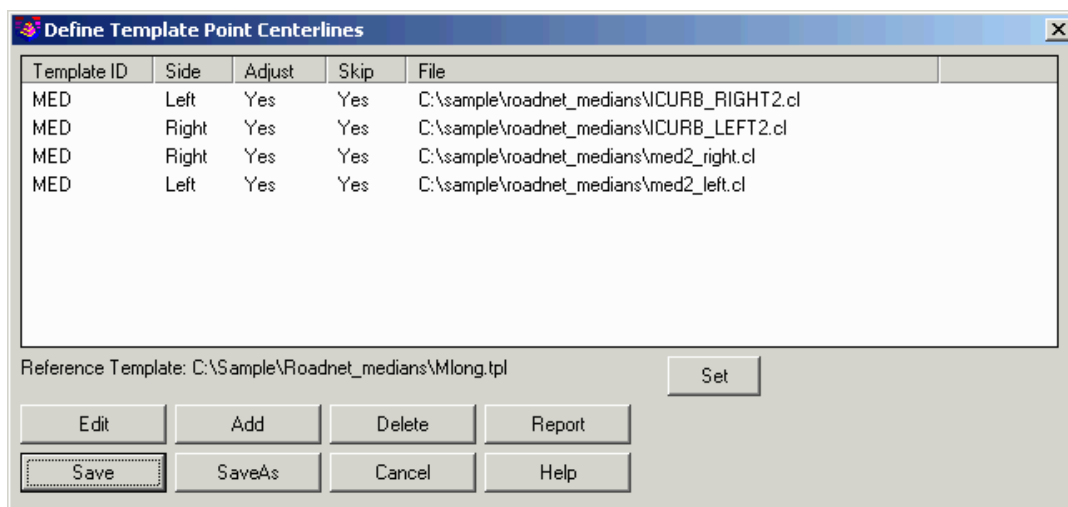

There are a few key settings to a road design with medians as shown here.

- Use Template Point Centerlines to control the alignments of the median and curbs. The Adjust Next Outside Grade Distance option should be ON.
- In the Design Template command, for a template (TPL) with a median crossing the centerline, use the Profile Delta Z set to the height of the median.
- Use the Template Series File command to define the sequence and station ranges of templates (TPL) switching between templates with and without medians. Turn OFF the option to Transition With Previous Template In Series.

Prompts

First you are prompted to create a new Template Point Centerline file (.TPC) or edit an existing one.

Next the Define Template Alignments dialog is presented, showing a list of existing Template ID-Centerline assignments. Use the Add, Edit and Delete buttons to manage the list of template point centerlines. The Report function creates a report of the template point centerlines in the standard report viewer. The Reference Template is optional for setting the road template (TPL) to use for selecting the template point description from a lookup list.

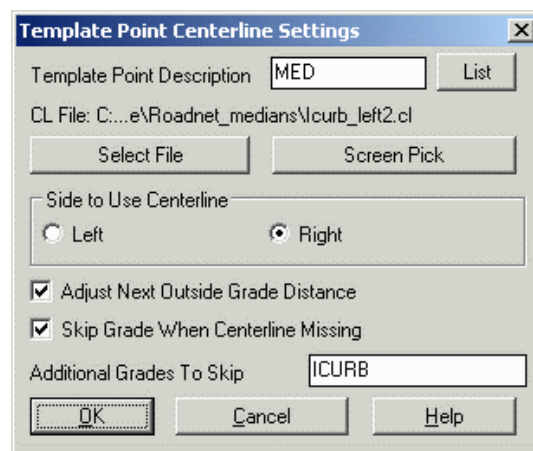

The Add and Edit buttons bring up the Template Point Centerline Settings dialog. First, set the Template Point Description which refers to the Template ID for an element in the Template (TPL) defined by the Design Template command. Next, pick the Specify Centerline File button, to choose the file (.CL) to assign to the Template Point ID. Alternatively, you can use the Screen Pick button to select a polyline from the drawing that the program will use to generate a centerline. Specify if this assignment is for the Left or Right side of the main centerline.

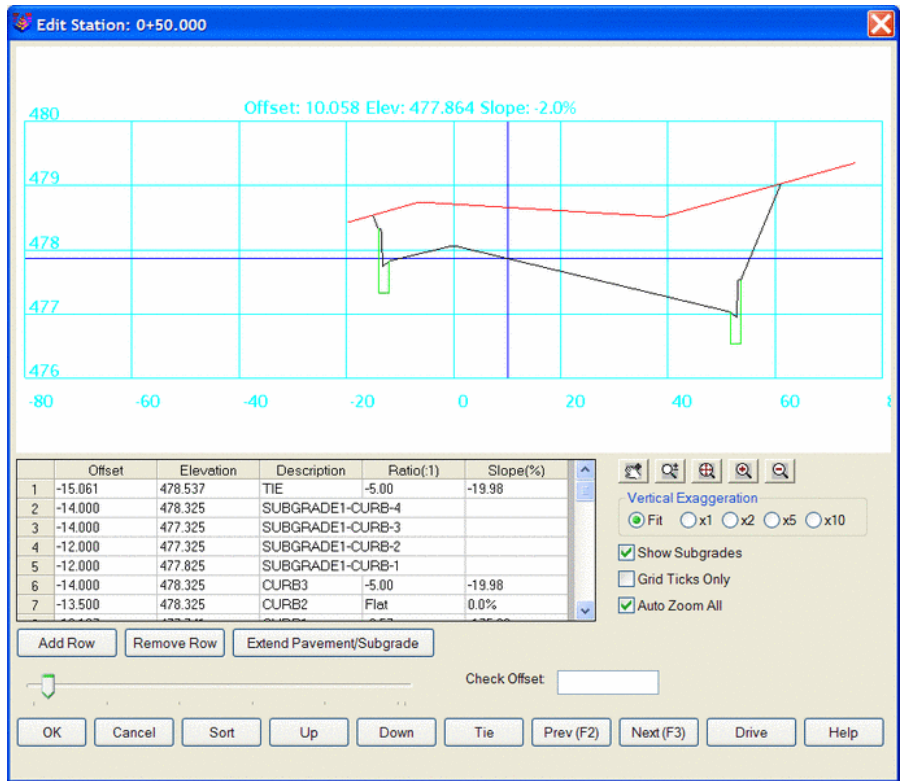

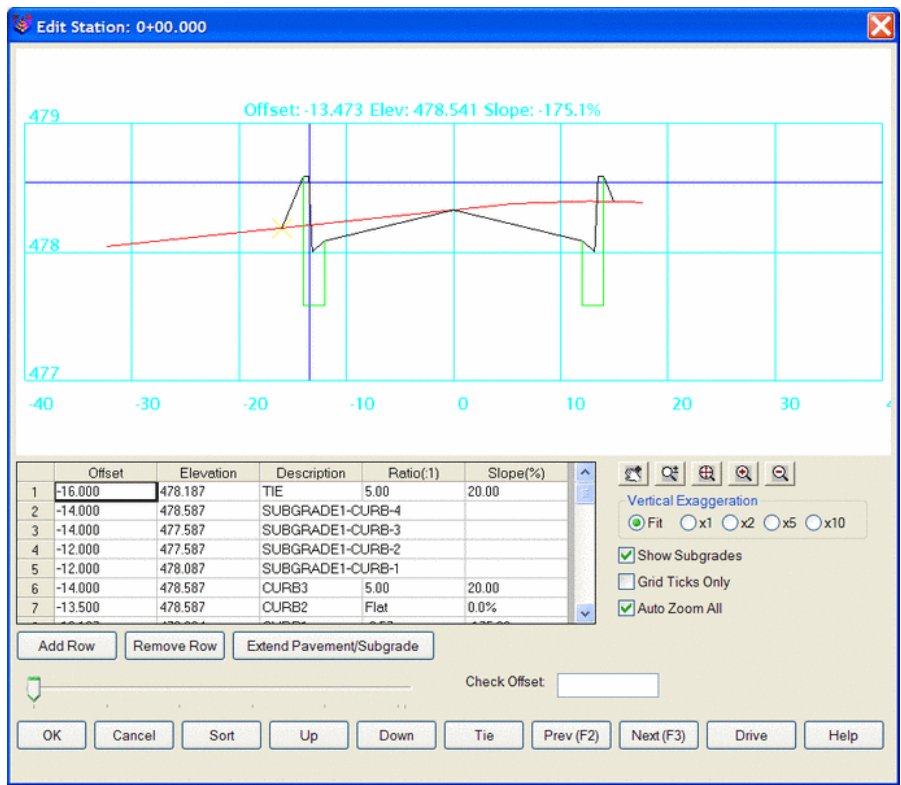

The **Adjust Next Outside Grade Distance** controls how template elements are affected that are outside from the current Template Point Description. This option controls whether to hold the grade distance or grade offset from the main centerline for the outside template elements. When this option is on, the outside grade distances are adjusted by the same amount that the template point centerline adjusts the horizontal alignment. When this option is off, the outside grade distances remain set by their distance defined in the template. For example, consider a template that has an inside median grade (MED) followed by an edge-of-pavement (EP) and the MED has a template point centerline. When this option is on and the template point centerline shifts the MED out 2 feet, then the EP grade is reduced by 2 feet so that the EP offset from the main centerline isn't affected. When this option is off and the MED is shifted out 2 feet, then EP grade distance doesn't change and the EP offset from the main centerline is shifted out 2 feet.

The **Skip Travel Lane for Parallel Grades** applies to a grade for a travel lane that is outside a grade being adjusted by a template point centerline. This option controls whether this outside grade is adjusted to by parallel with the template point centerline or the road main centerline.

The **Skip Grade When Centerline Missing** means that the template will only contain the element at stations that have a template point centerline for it. The Additional Grades To Skip specifies other related template elements to skip in this case. The option applies to template elements like intermittent medians that you only want included in the template for stations where they have a template point centerline defined.

Here are two sections along the roadway, illustrating the varying lane widths on the right side of the main centerline. These sections are created by *Process Road Design* with the TPC set in the input files and these sections are viewed with the *Section File Editor* command.

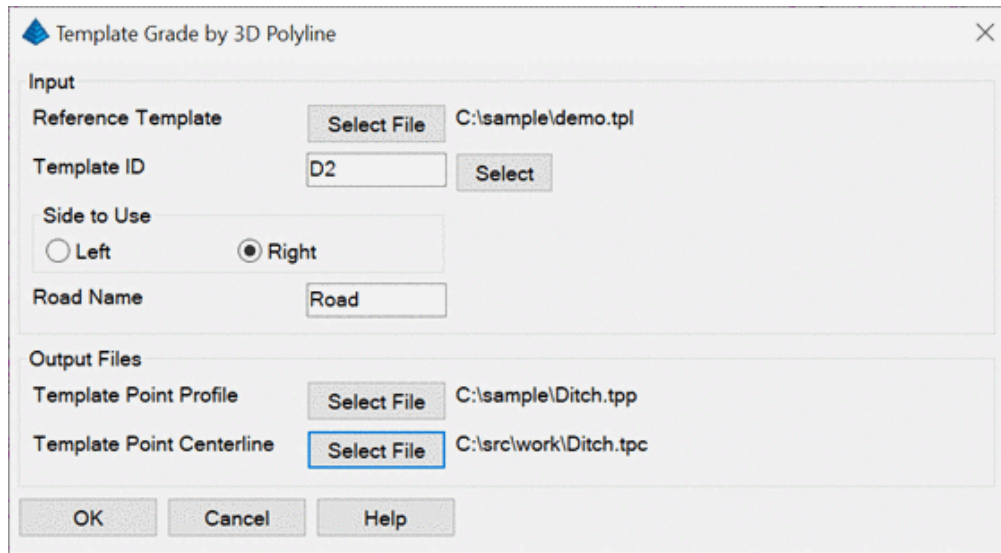

Pulldown Menu Location: Roads
Keyboard Command: tpcset
Prerequisite: Centerline file or polyline

Template Grade By 3D Polyline

This command uses a 3D polyline to define Template Point Profile and Template Point Centerline files which can then be used in Process Road Design and Road Network to have a template grade follow that 3D polyline. For example, the 3D polyline could define the bottom of a ditch and this routine will create the road design files needed to adjust the road template to follow the 3D polyline for the ditch.

After selecting the 3D polyline, there is a dialog with the input and output settings. The Template ID identifies the template element to match to the 3D polyline. The Side To Use tells whether the 3D polyline is for the left or right side of the centerline. The Road Name is used for naming the centerline (CL) and profile (PRO) files which are automatically named and placed in the same folder as the Output Files. The Output Files define the names of the Template Point Profile and Centerline files to create.

Prompts

Select grade 3D polyline: *pick a 3D polyline*
Template Grade by 3D Polyline dialog

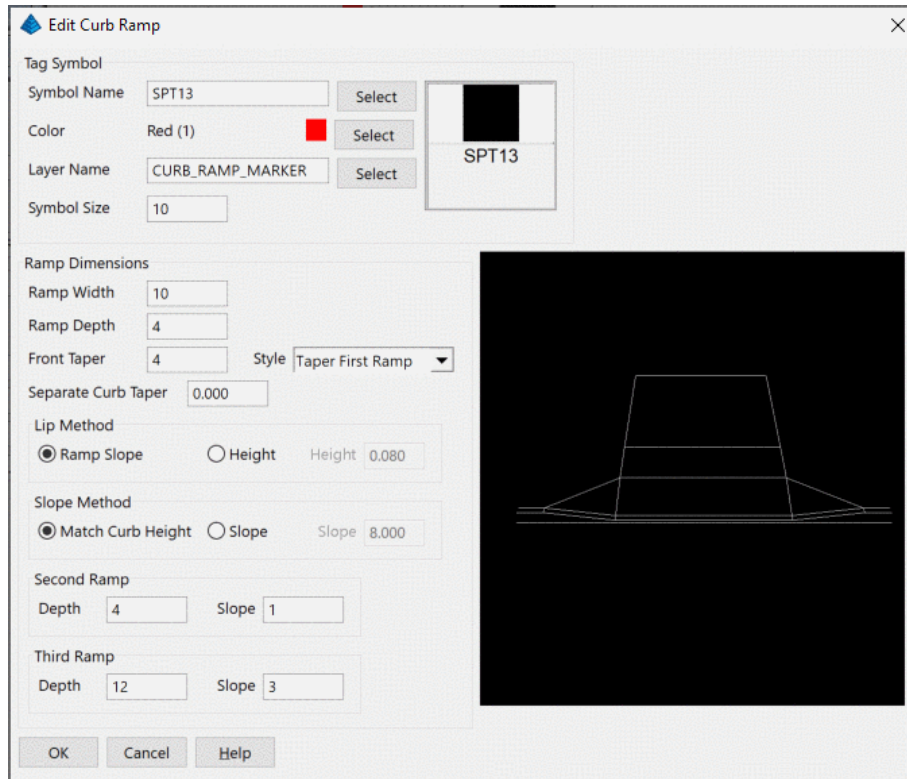

Pulldown Menu Location: Roads
Keyboard Command: prep_tpl_3dp
Prerequisite: 3D polyline

Edit Curb Ramps

This command edits previously drawn symbols for curb ramps.

In the options dialog, select a symbol to use for the curb ramp location markers. The dialog also has the ramp parameters which are described in the Draw Curb Ramp topic in this manual. After the dialog, pick points along the curb polylines for the ramps. The ramp marker should be placed on the curb polyline at the center of the ramp.

To process the curb ramps, run Process Road Design or Road Network and these commands will automatically find the symbol markers and create the curb ramps.

Prompts

Edit Curb Ramps dialog

Select curb ramp: *select existing tagged curb ramp*

Update curb ramp position: **<Exit>** *pick new position or press Enter*

Pulldown Menu Location: Roads

Keyboard Command: curb_ramp_edit

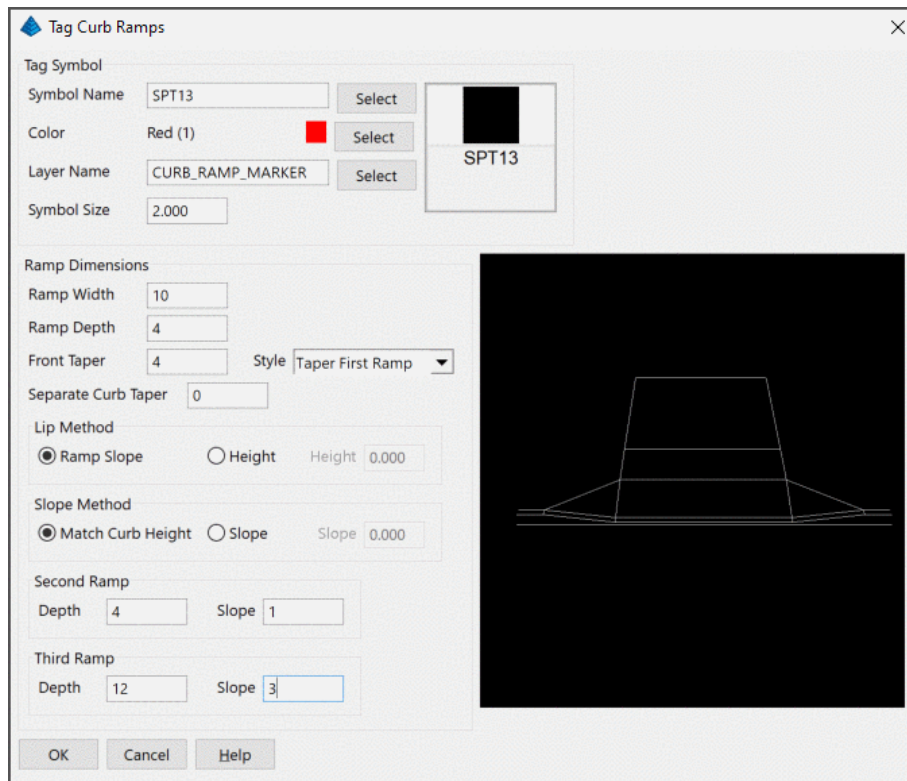

Prerequisite: tagged curb ramp

Tag Crub Ramps

This command draws symbols for where to create curb ramps in Process Road Design and Road Network. The curb ramps are drawn by adjusting the 3D polylines for the top-of-curb and back-of-curb to lower the curb for the ramp. Also, a 3D polyline of the ramp outline is created for each ramp. These curb ramps can be used for sidewalk handicap ramps and for driveways.

In the options dialog, select a symbol to use for the curb ramp location markers. The dialog also has the ramp parameters which are described in the Draw Curb Ramp topic in this manual. After the dialog, pick points along the curb polylines for the ramps. The ramp marker should be placed on the curb polyline at the center of the ramp.

To process the curb ramps, run Process Road Design or Road Network and these commands will automatically find the symbol markers and create the curb ramps.

Prompts

Tag Curb Ramps dialog

Pick curb ramp position: *pick a point along a curb*

Pick curb ramp position (Enter to end): *press Enter*

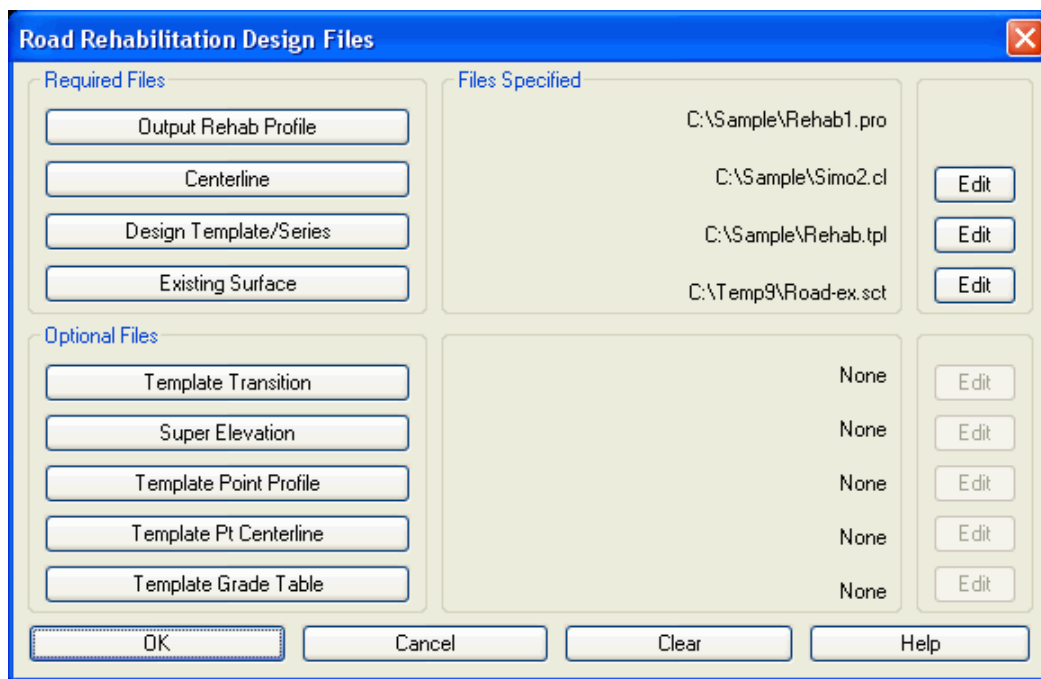

Pulldown Menu Location: Roads

Keyboard Command: tag_curb_ramp

Prerequisite: curb polylines

Road Rehabilitation Profile

This command creates a profile that sets a road design at an elevation to meet the specified overlay thickness along with leveling or milling thickness. The rehabilitation profile created by this command can then be used in Process Road Design to create the rehabilitation design including the rehabilitation surface, sections, quantities and linework.

The first dialog specifies the road design files. All these settings are the same as in Process Road Design except for the Output Rehab Profile. This profile is the output result for this command. The difference with Process Road Design is that the profile is an output instead of an input. Please see the Process Road Design section of the manual for a description of the other input files.

The second dialog has processing options. Again, many of these parameters are the same as Process Road Design. The settings specific to this command are the following:

Rehabilitation Method: This chooses between adding a leveling layer to the existing road or stripping the existing road by milling or grinding.

Minimum Leveling Thickness: This is the minimum fill thickness between the existing road and the bottom of the overlay subgrade of the new road.

Minimum Milling Thickness: This is the minimum cut thickness between the existing road and the bottom of the overlay subgrade of the new road.

Overlay Thickness: This is the depth of the overlay subgrade of the new road. This value should match the subgrade thickness defined in the template.

Template IDs to Rehab: These are the grade IDs from the template definition to process for the overlay. The Select button can be used to graphically pick the template IDs. Multiple IDs can be specified by entering the IDs separated by commas. For example, if a road has two lanes with two grades for overlay and the template IDs are LANE1 and EP, then enter "LANE1,EP" in the dialog.

Example 1: Milling

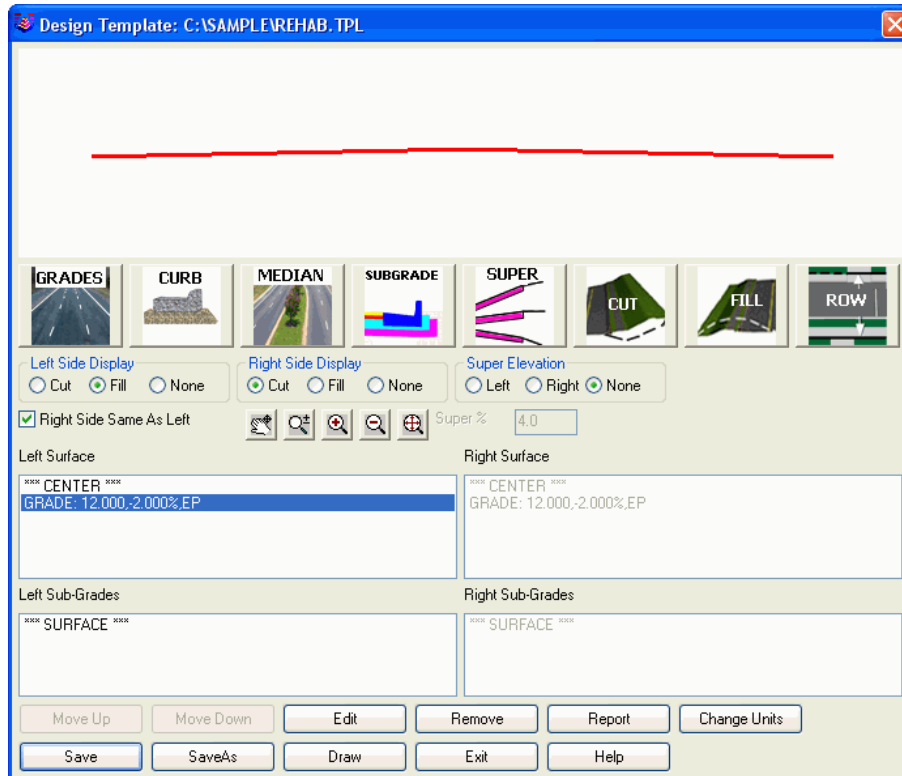

In this case, the existing road will be trimmed by the specified milling thickness.

Step 1: Define Centerline

Use a routine from the Centerline menu to create the .CL file. For example, for entering design plans, use Centerline Editor. For using the geometry of a polyline, use Polyline To Centerline File.

Step 2: Define Template

Run Design Template to create a .TPL file. In this case, the template will be a two lane road with 12' lanes and -2% cross slopes. That's the minimum that needs to be defined for the rehabilitation design. The cut/fill slopes are not required.

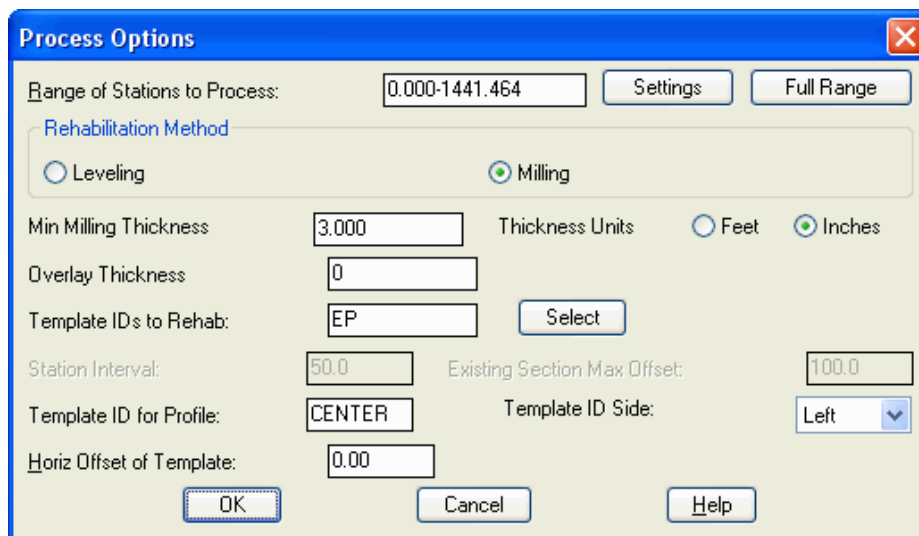

Step 3: Existing Surface

The existing surface can be either a triangulation model or cross sections of the existing road. To create a triangulation surface, you need 3D data for the existing road (points and breaklines) and then run Triangulate & Contour to create a .TIN file. To create cross sections, use the routines in the Sections menu for Section Alignment Editor to set the section intervals and then run one of the Create Section routines to make a .SCT file.

Step 4: Road Rehabilitation Profile

Run this command and specify the 3 files created in steps 1-3. Also set the output profile to create the .PRO file. On the second dialog, choose the Milling method. Set the Milling Thickness to 3 inches. Set the Overlay Thickness to zero since the template doesn't have a subgrade. Set the Template ID to EP to match the grade from the template.

Step 5: Process Road Design

Run this command and specify the 4 files created in steps 1-4. Also set the output Design Section file to create a .SCT file for the rehabilitation design.

Output:

The report includes the total cut and cuts per station which is the quantity of the milling.

```
Process Road Design
Template File> C:\sample\rehab.tpl
Profile File> C:\sample\rehab1.pro
Existing Surface File> C:\sample\road-ex.sct
Centerline File> C:\sample\simo2.cl
Design Section Output File> C:\sample\rehab1.sct

Processing 0+00.000 to 14+41.464
Total Cut : 9203.469 C.F., 340.869 C.Y.
Total Fill: 0.000 C.F., 0.000 C.Y.
```

Use Section File Editor or Draw Section File to view the design and existing sections.

Example 2: Milling with Overlay

This example adds an overlay thickness to the design from example 1. The steps are the same except for the following:

Repeat Step 2: Design Template

Add a subgrade below the EP grade with a depth of 6 inches.

Sub-Grade Dimensions

Slope Type: Match Surface Special Slope (%): 0.000 Direction: Out In

Intersect surface: Straight Up Wrap Height: 0.000 Tie Slope(%): 0.000

Horizontal Offset: 0.0 Vertical Offset: -6 Units: Feet Inches

Distance: EP Material: Asphalt

Super Elevation Settings

Low Side

Pivot Offset: Max Slope After Pivot (%): Slope Type After Pivot: Normal Special

Standard Slope Percent: 0.000 Minimum Slope Percent: 0.000

High Side

Pivot Offset: Max Slope After Pivot (%): Slope Type After Pivot: Normal Special

Standard Slope Percent: 0.000 Minimum Slope Percent: 0.000

OK Cancel Help

Repeat Step 4: Road Rehabilitation Profile

Use the same settings as example 1 except set the Overlay Thickness to 6 inches.

Repeat Step 5: Process Road Design

Run this command again with the updated Template and Profile.

Output:

The report includes the updated milling cut quantities along with the overlay subgrade volumes. Since the Milling Thickness stayed at 3 inches, the cut quantities stayed the same as example 1. The Overlay Thickness being thicker at 6 inches leads to more subgrade quantities and raises the new road above the existing in areas.

Process Road Design

```
Template File> C:\sample\rehab.tpl
Profile File> C:\sample\rehab1.pro
Existing Surface File> C:\sample\road-ex.sct
Centerline File> C:\sample\simo2.cl

```

```
Processing 0+00.000 to 14+41.464
Total Cut : 9203.673 C.F., 340.877 C.Y.
Total Fill: 0.172 C.F., 0.006 C.Y.
```

```
Total Subgrade1 - Asphalt: 17295.031 C.F., 640.557 C.Y., 34592.253 S.F., 3843.584 S.Y.
```

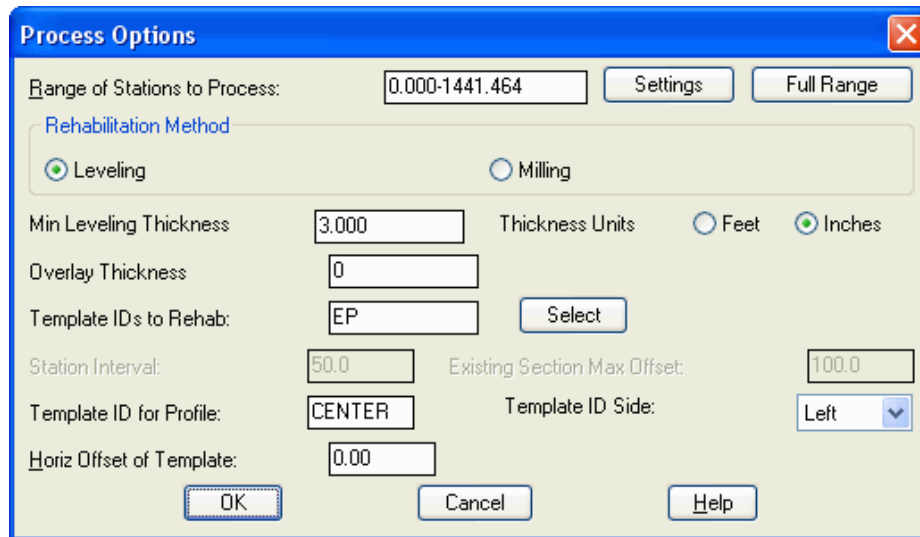

Example 3: Leveling

This example applies leveling to an existing road. The steps are the same as example 1 except for the following:

Repeat Step 4: Road Rehabilitation Profile

On the first dialog, use the same data files as example 1. On the second dialog, choose the Leveling method. Set the Leveling Thickness to 3 inches. Set the Overlay Thickness to zero since the template doesn't have a subgrade. Set the Template ID to EP to match the grade from the template.

Repeat Step 5: Process Road Design

Run this command with the same settings as example 1. The only difference is that the profile is set for leveling instead of milling.

Output:

The report includes the total fill and fills per station which is the quantity of the leveling.

Process Road Design

```
Template File> C:\sample\rehab.tpl
Profile File> C:\sample\rehab1.pro
Existing Surface File> C:\sample\road-ex.sct
Centerline File> C:\sample\simo2.cl
Design Section Output File> C:\sample\rehab1.sct
```

```
Processing 0+00.000 to 14+41.464
Total Cut : 0.000 C.F., 0.000 C.Y.
Total Fill: 8994.509 C.F., 333.130 C.Y.
```

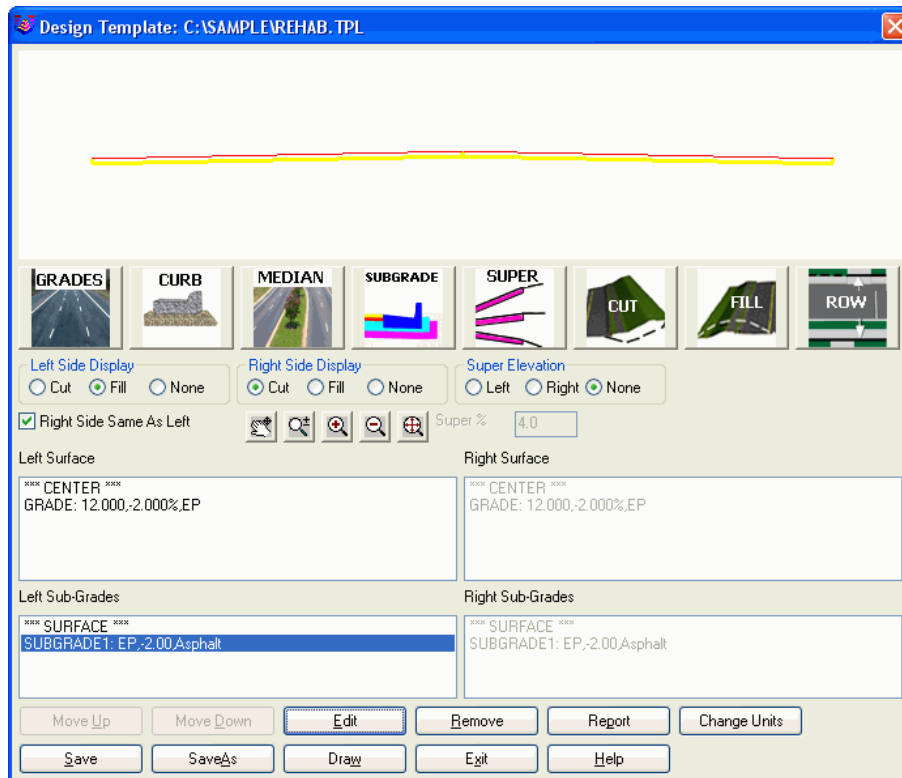

Example 4: Leveling with Overlay

This example adds an overlay thickness with a minimum of 4 inches to the design from example 3. Part of the overlay will be in the subgrade of the template and the rest will be in the Min Leveling Thickness setting. The steps

are the same as example 3 except for the following:

Repeat Step 2: Design Template

Add a subgrade below the EP grade with a depth of 2 inches.

Repeat Step 4: Road Rehabilitation Profile

Use the same settings as example 3 except set the Overlay Thickness to 2 inches and set the Min Leveling Thickness to 2 inches.

Repeat Step 5: Process Road Design

Run this command again with the updated Template and Profile.

Output:

The report includes the updated leveling fill quantities along with the overlay subgrade volumes.

Process Road Design

```
Template File> C:\sample\rehab.tpl
Profile File> C:\sample\rehab1.pro
Existing Surface File> C:\sample\road-ex.sct
Centerline File> C:\sample\simo2.cl

```

```
Processing 0+00.000 to 14+41.464
Total Cut : 0.000 C.F., 0.000 C.Y.
Total Fill: 3228.086 C.F., 119.559 C.Y.
Total Subgrade1 - Asphalt: 5765.356 C.F., 213.532 C.Y., 34592.253 S.F., 3843.584 S.Y.
```

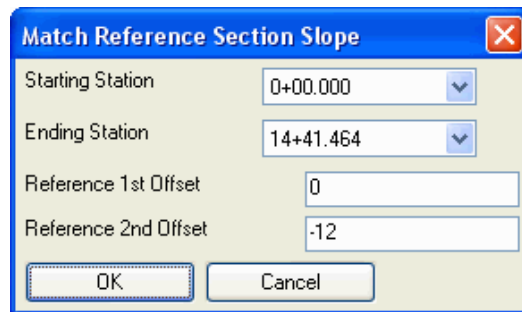

Example 5: Leveling with Overlay and Match Slopes

This example modifies example 4 to have the new road cross slopes match the existing cross slopes instead of being at a fixed design of -2%. The steps are the same as example 4 except for the following:

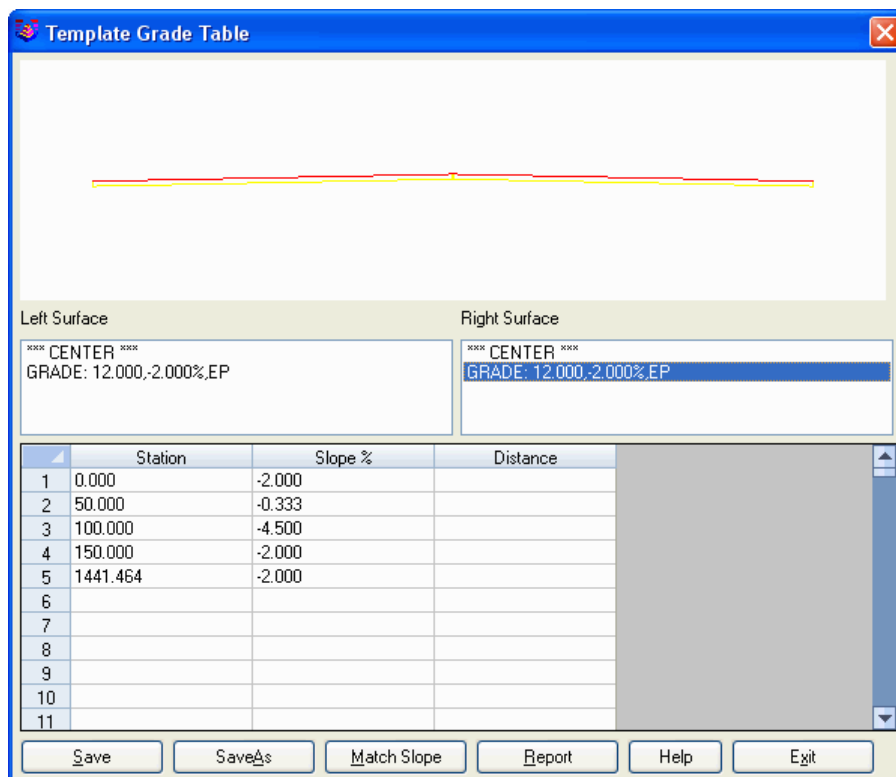

Step 2: Define Template

There are several methods to modify the template for transitions. For this example, the Template Grade Table command is used. This command defines slope and distance transitions for template grades. In this example, we will only use the slope transitions to make the design slopes match the existing road.

Run the Template Grade Table command and create a new .TGT file. Select the rehab template that was used in example 4 as the template to process. In the dialog, highlight the EP grade from the list for the Left Surface. Then pick the Match Slope button. Select the section file for the existing road. Next there is a dialog to set the range of stations to process and the reference offset points which are used to sample the existing surface to get the slope between these offsets. In this example, the full station range is used and the offsets are 0 for the center and -12 for the left EP.

Next, highlight the EP grade from the list for the Right Surface. Then pick Match Slope and select the existing section file. For the offsets, use 0 and 12.

Then back on the main dialog, pick the Save button.

Repeat Step 4: Road Rehabilitation Profile

Use the same settings as example 4 except set the Template Grade Table on the first dialog.

Repeat Step 5: Process Road Design

Run this command again with the updated Template and Profile.

Output:

The report includes the leveling fill quantities along with the overlay subgrade volumes.

Process Road Design

```
Template File> C:\sample\rehab.tpl
Profile File> C:\sample\rehab1.pro
Existing Surface File> C:\sample\road-ex.sct
Centerline File> C:\sample\simo2.cl
Template Grade Table File> C:\sample\simo2.tgt
Design Section Output File> C:\sample\rehab1.sct
```

Processing 0+00.000 to 14+41.464

Total Cut : 0.000 C.F., 0.000 C.Y.

Total Fill: 5765.382 C.F., 213.533 C.Y.

Total Left Subgrade1 - Asphalt: 2882.684 C.F., 106.766 C.Y., 17296.127 S.F., 1921.792 S.Y.

Total Right Subgrade1 - Asphalt: 2882.681 C.F., 106.766 C.Y., 17296.127 S.F., 1921.792 S.Y.

Example 6: Leveling with Overlay and SuperElevation plus Lane Widening

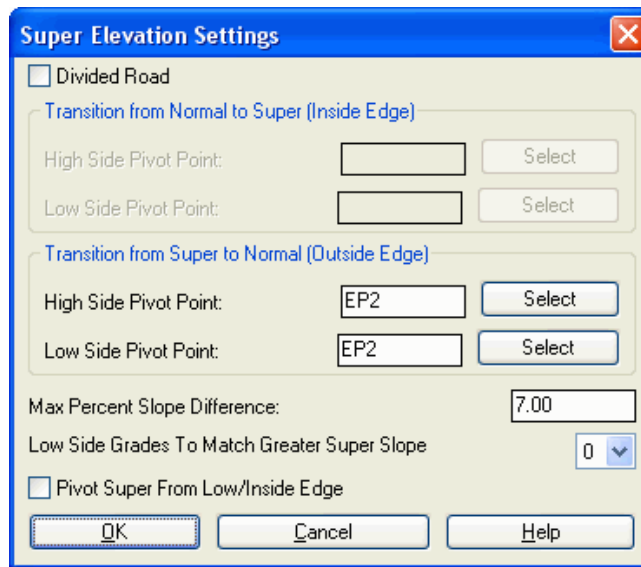

In this variation, the new road has both overlay and new design changes of applying new superelevation and widening a lane. The steps that are different than example 4 are described here.

Step 2: Define Template

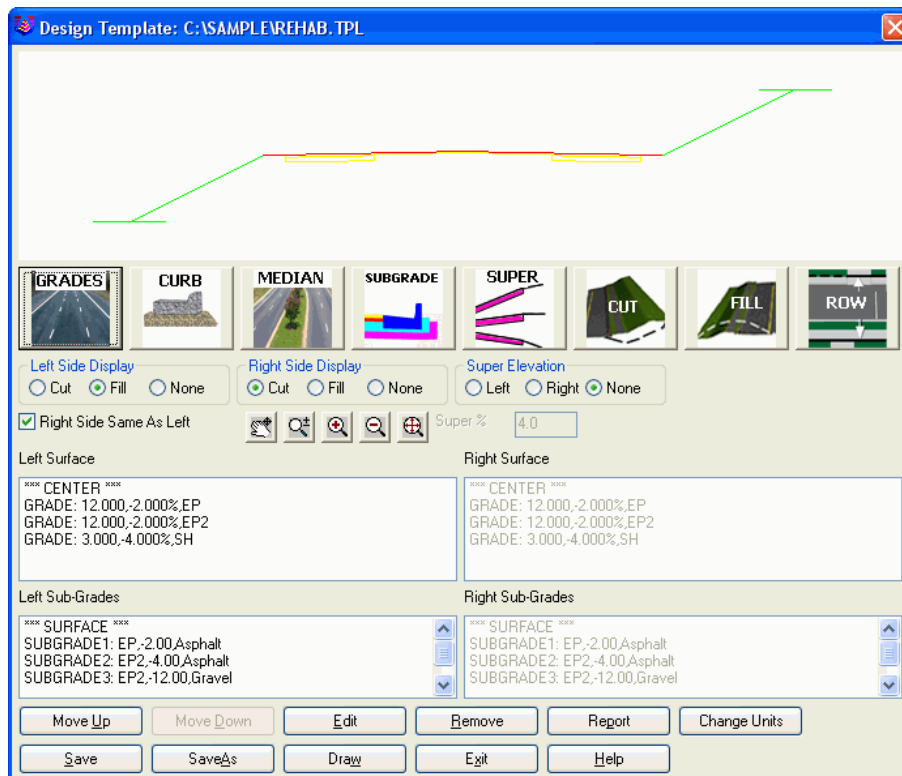

For this example, the template has additional design elements besides the overlay grades. Run the Design Template command to add the new elements.

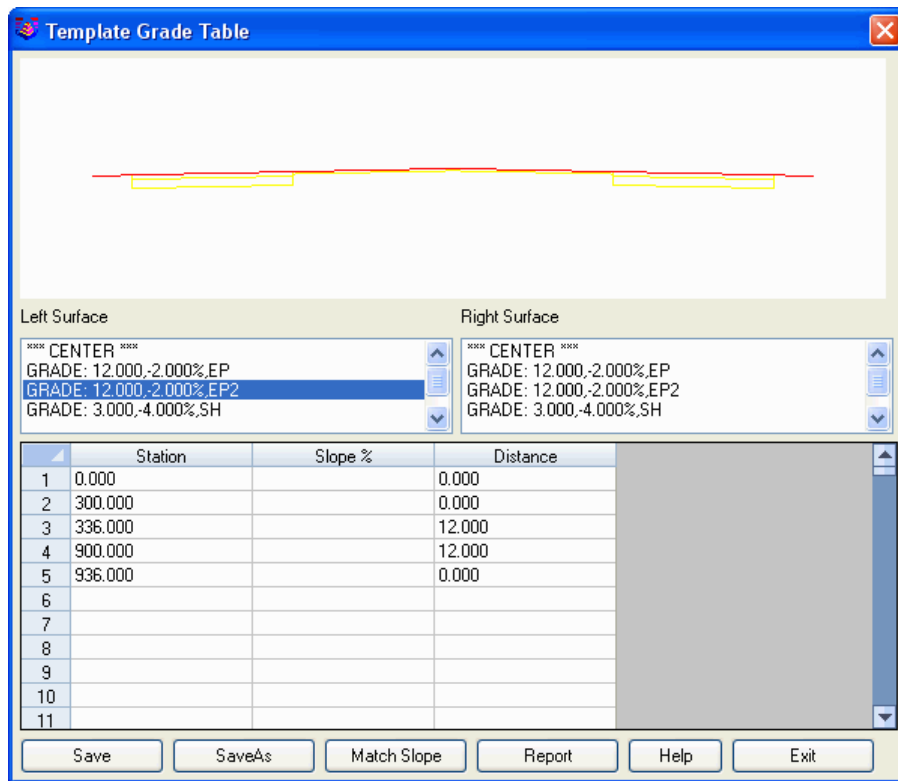

First, pick the Grades button to add a new grade for the new lane using a slope of -2%, distance of 12 and ID of EP2. Then add a new grade for a shoulder with slope of -4%, distance of 3 and ID of SH. Next, subgrades are needed for the new lane since this isn't over the existing road. Add a subgrade of 4 inches of asphalt under the new lane and another subgrade of 8 inches of gravel. Next pick the Cut button and set the cut slope to 2:1 and pick the Fill button and set the fill to 2:1. The cut/fill slopes are needed to tie the new road design elements to the existing surface.

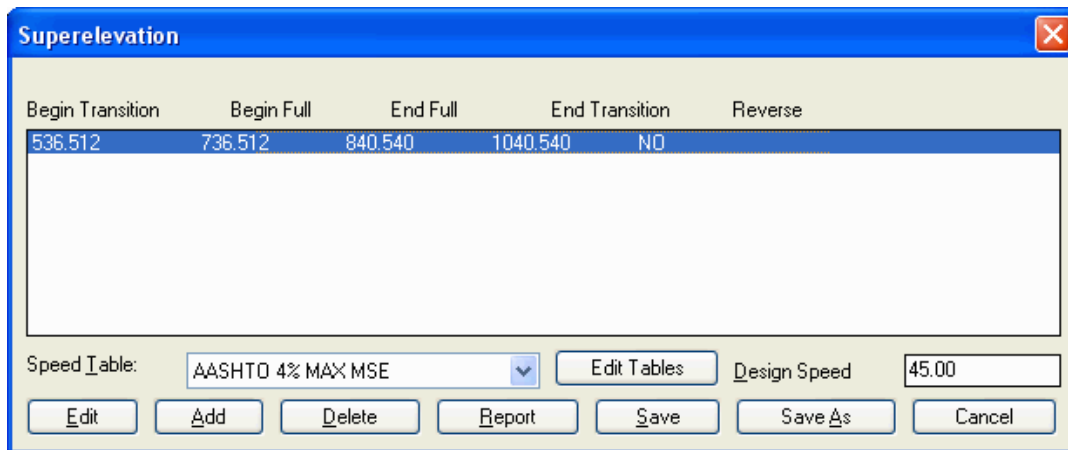

Finally, pick the Super button to set the superelevation transition ID's as EP2 so that the shoulder stays outside the super. Then pick the Save button.

Even though the template has the new lane EP2 defined for both sides, let's actually only apply this new lane for a range of stations on the left side. Run the Template Grade Table command and make a new .TGT file. Select the template file that was just created. Then pick EP2 on the Right Surface list. In the table, fill in the first row with station 0 and a distance of 0. This will eliminate EP2 on the right side. Then pick on EP2 from the Left Surface list. Fill out the table as shown to make the new lane start at station 3+00, reach full size at 3+36, start transitioning back at station 9+00 and return to zero at station 9+36.

Another template transition definition to create is the superelevation. Run the Super Elevation Editor command and create a new .SUP file. Use the option to select a centerline and specify the speed table to have the program set the transition stations. Or use the Add function to manually enter the transition stations and full super slope.

Repeat Step 4: Road Rehabilitation Profile

Use the same settings as example 4 except use the new template (TPL), template grade table (TGT) and superelevation (SUP) created in step 2.

Repeat Step 5: Process Road Design

Run this command again with the new template, profile, template grade table and superelevation.

Output:

The report includes the leveling fill quantities along with the overlay subgrade and the quantities for the new road elements.

```

Process Road Design

```

These sections show the road at a station before the new lane and superelevation and at a station with t

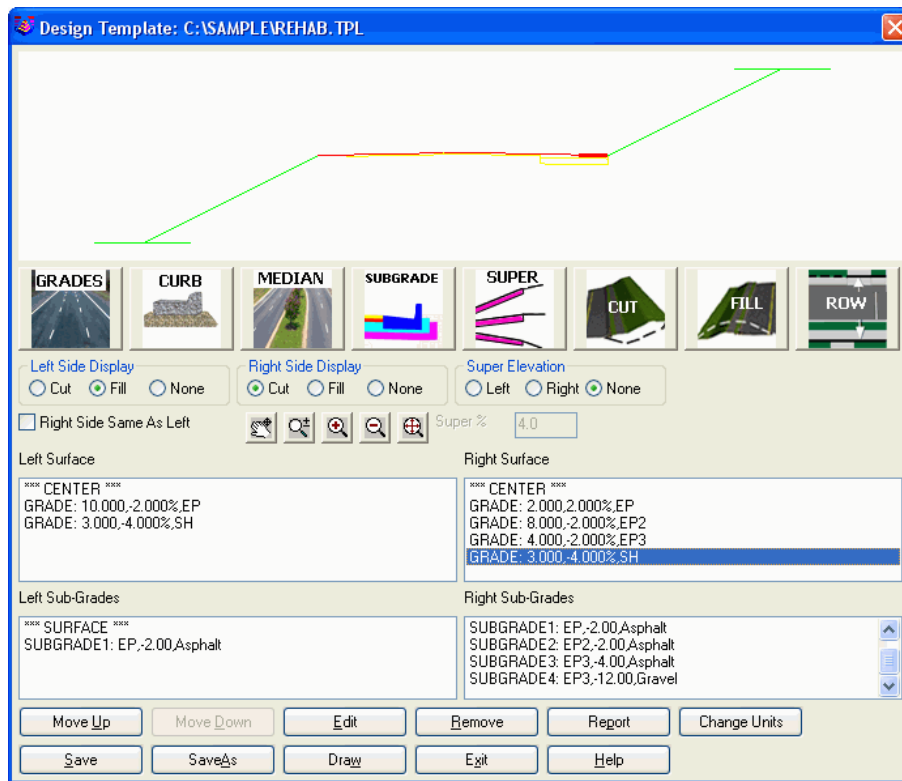

Example 7: Leveling with Overlay with Lane Widening at New Crown position

In this variation, the existing road has two 10' lanes that are being expanded to 12' lanes. The left EP is staying fixed and the extra 4' is added to the right side. So the crown is shifting 2' to the right. The steps are the same as example 4 except for the changes to the template definition.

Step 2: Define Template

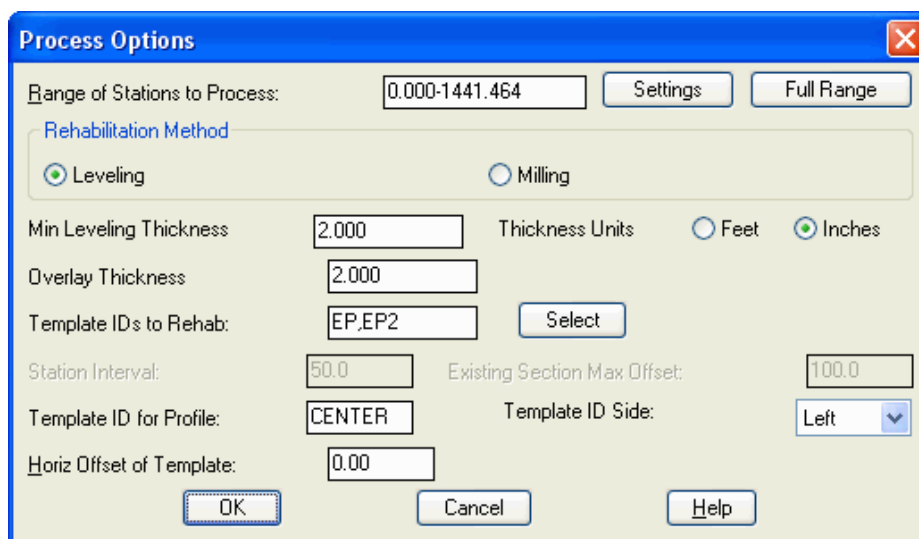

Use the Define Template command to make the template overlay and widening grades. For this example, there is one 10' grade on the left side for the overlay plus a 3' shoulder. On the right side, there are four grades. The first right side grade is 2' for the portion of the overlay that is shifting the crown over. The second grade is 8' for the remainder of the right side overlay. The third grade is 4' for the widening. The fourth grade is a 3' shoulder. The template has subgrades of 2" for the overlay grades and has two subgrades of 4" of asphalt and 8" of gravel for the widening grade. Since this template is asymmetrical, uncheck the toggle for Right Side Same As Left.

Next pick the Cut button and set the cut slope to 2:1 and pick the Fill button and set the fill to 2:1. The cut/fill slopes are needed to tie the new road design elements to the existing surface.

Repeat Step 4: Road Rehabilitation Profile

For the input files, use the template created in step 2, the centerline and existing surface. For the process options, choose the Leveling method and enter 2 inches for the Leveling and Overlay thicknesses. For the Template IDs, specify both EP and EP2 since both of these are overlay grades.

Repeat Step 5: Process Road Design

Run this command with the new template and profile.

Output:

The report includes the leveling fill quantities along with the overlay subgrade and the quantities for the new road elements.

Process Road Design

Pulldown Menu Location: Roads

Keyboard Command: rdrehab

Prerequisites: Centerline, template and surface files

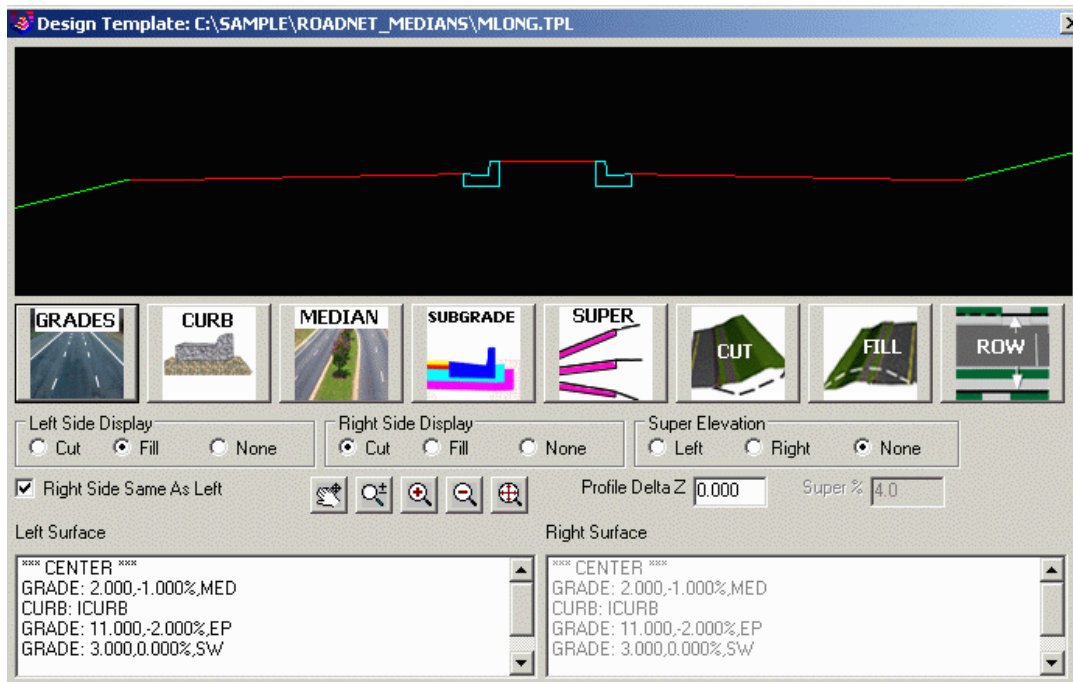

Define Median Adjustments

This command prepares a road design for median transitions by picking a plan view polyline for the median alignment and then creating the road design files for a median for the Template Point Centerline (.tpc) and Template Series File (.tsf).

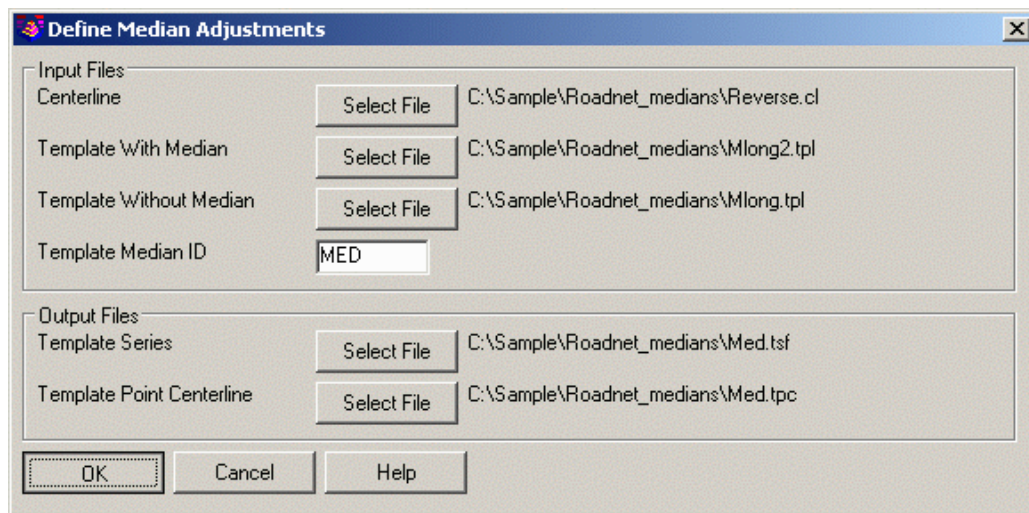

Before running this command, draw a polyline for the median in plan view. The road centerline must cross through the median as shown here.

Also before running this command, use Design Template to make two template files (TPL) where one template has the median and the other is without the median. In the example shown here, this template has the median with the grade of MED and the curb. The template without the median in this example does not have the MED grade and curb.

In the dialog for this command, select the input files for the centerline and template with and without the median. Also set the grade ID from the template for the median.

Finally, after the dialog the program prompts to select the median polyline from the drawing. Then the output Template Series File will assign the median and non-median templates based on where the centerline crosses the median polyline. The output Template Point Centerline will assign centerlines for the median using the median polyline.

To apply the median design, run Process Road Design or Road Network and use the Template Series File (TSF) and Template Point Centerline (TPC) for the road design input.

Pulldown Menu Location: Roads

Keyboard Command: prep_median

Prerequisite: Centerline, templates and median polyline

Define Road Design Parameters

This command defines design parameters that can be checked against a road design with the Process Road Design and Road Network commands. Only fill in the parameters to have checked. If you leave a parameter blank, then that parameter is not checked. You can have a different set of parameters for different stations along the road in case road conditions change such as different speed limits. The different sets of parameters are listed by station on the left of the dialog. Use the Add button to add a new parameter set and use the Remove button to remove the set highlighted in the station list. To view a parameter set, pick the station in the Stations list. If you don't need different sets of parameters, then leave the Starting Station as zero and don't add other stations.

Curve Radius	Max Slope%	Range
600.0	6.0	<= 600.0
999.0	5.0	600.0 to 999.0
1499.0	4.0	999.0 to 1499.0
1999.0	3.0	1499.0 to 1999.0
6999.0	2.0	1999.0 to 6999.0
	0.0	> 6999.0

Starting Station: This is the station to begin using the current set of design parameters.

Max Slope: This is the maximum profile slope percent that is allowed.

Max Distance at Max Slope: This is the maximum continuous distance that the profile can be at the max slope.

Min Slope: This is the minimum profile slope percent that is allowed.

Min Curve Radius: This is the minimum horizontal curve radius for the centerline.

Min Curve Radius for Delta Angle Range: This is the minimum horizontal curve radius for the centerline for curves with a delta angle in the specified range. Enter the delta angles in decimals degrees from low to high.

Min Sight Distance: This is the minimum sight distance for the profile.

Min K-Value: This is the minimum k-value for the profile.

Max Slope at Intersection: This is the maximum profile slope at an intersection with another road. The **Setback** is the distance along the profile from the intersection point that this max slope applies. This option only applies to Road Network.

Max Percent of Road over Slope: This is the maximum percent of the road that can be over the specified **Slope**.

Min Vertical Curve Length for Delta Slope over: This is the minimum vertical curve length for PVI's with an algebraic grade difference greater than the specified Delta Slope. The Delta Slope units are in percent slope.

Min Vertical Curve Length for Delta Slope between: This is the minimum vertical curve length for PVI's with an algebraic grade difference between than the specified Delta Slopes. Enter the delta slopes in percent slope format from low to high.

Max SuperElev Rate of Change Per 100: This is the maximum rate of change in the superelevation for the cross slope. The rate units are in percent slope per 100 feet or meters depending on your drawing units.

Check for Tangential Centerline: This option checks the horizontal alignment to make sure all the segments are tangential.

Check for Flat Areas: This option checks the superelevation at the Run-In and Run-Out stations where the outside lane is flat and warns if the profile is also flat at those stations.

Max SuperElevation: This is the maximum superelevation cross slope at full super for different curve radii. A lookup table of curve radius and max slope is used. The curve radii should be entered from low to high.

The **Horizontal** and **Vertical Speed Tables** are for referencing values to fill in for the design parameters.

Pulldown Menu Location: Roads

Keyboard Command: rdparam

Prerequisite: None

Vehicle Path Tracking Profile

This command traces the vertical paths for vehicle dimensions along a profile. The profile is defined by a profile drawing which must be created before running this command. The center of the front axle, the center between the rear axle(s) and if selected the center of the trailer axle(s) follow the profile.

Select profile polyline: *select a profile polyline from a Profile Drawing*

After selecting the profile, the program will display the Vehicle Path Tracking Profile dialog. The Vehicle Path

Tracking Profile dialog has three tabs; Vehicle, Trailer and Profile. Each tab contains data for the corresponding component.

The diagram shows a top-down view of a trailer with various dimensions and components labeled. The 'Trailer Height' is the vertical distance from the ground to the top of the trailer. The 'Trailer Length' is the horizontal distance from the front to the rear. The 'Front to King Pin' is the distance from the front of the trailer to the king pin. The 'Front to Landing Gear' is the distance from the front of the trailer to the landing gear. The 'Rear Overhang' is the distance from the landing gear to the rear of the trailer. The 'Ride Height' is the vertical distance from the ground to the bottom of the trailer. The 'Landing Gear Clearance' is the vertical distance from the ground to the landing gear. The 'Bumper Clearance' is the vertical distance from the ground to the bumper. The 'Front to Landing Gear' and 'Rear Overhang' are also labeled with arrows pointing to the respective dimensions.

Use Trailer: Use this toggle to setup the trailer data and choose profiles to draw.

Trailer Height: Height of trailer from the ground.

Trailer Length: Overall length of trailer.

Ride Height: Height of the bottom of the trailer from the ground.

Front to King Pin: Distance from the front of the trailer to the King Pin (Hitch Point).

Front to Landing Gear: Distance from the front of the trailer to the landing gear.

Rear Overhang: Distance from rear axis to the back of the trailer.

Landing Gear Clearance: Distance from ground to landing gear.

Bumper Clearance: Distance from ground to the bottom of the trailer bumper.

Tire Diameter: Diameter of trailer tires.

Axle Count: Number of trailer axles.

Axle Offset: Distance between trailer axles.

Draw Top Front: Draws the profile of the front high point of the trailer.

Draw Top Rear: Draws the profile of the rear high point of the trailer.

Draw Top: Draws the profile of the highest point of the trailer between the front and rear.

Draw Landing Gear: Draws the profile of the trailer landing gear.

Draw Bumper: Draws the profile of the trailer bumper.

Draw Minimum Clearance: Draws the profile of the lowest point between the landing gear and the axle axis.

Top Front Layer: Layer to draw the profile of the top front point of the trailer on.

Top Rear Layer: Layer to draw the profile of the top rear point of the trailer on.

Top Layer: Layer to draw the profile of the top of trailer between front and rear on.

Landing Gear Layer: Layer to draw the profile of the trailer landing gear on.

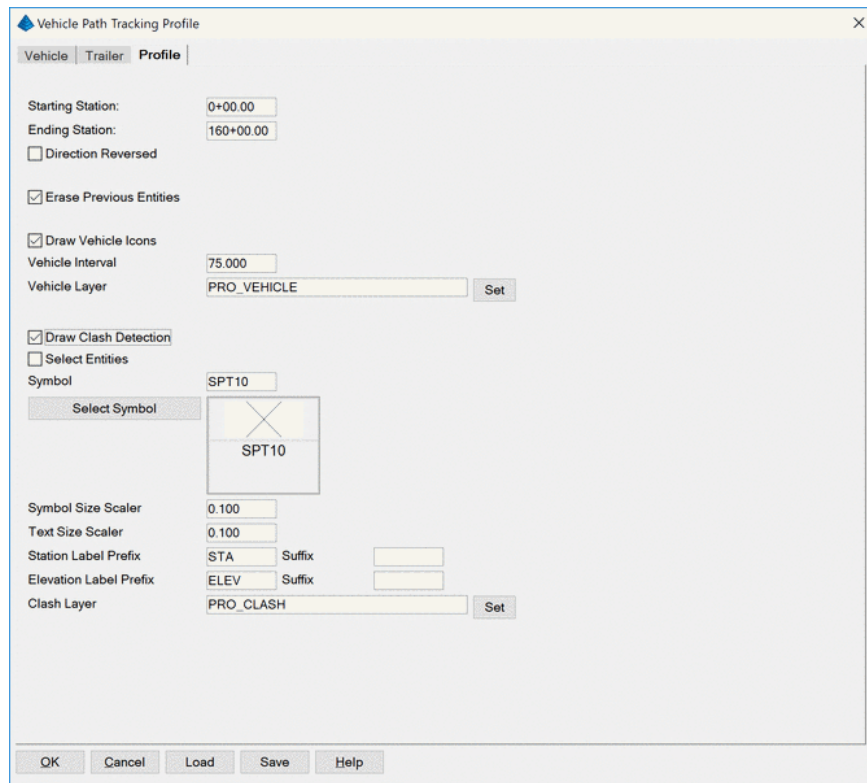

Bumper Layer: Layer to draw the profile of the trailer bumper on.

Minimum Clearance Layer: Layer to draw the profile of the lowest point of the trailer between the landing gear and the axle axis on.

Set: Select the corresponding trailer layer from list.

Profile

Starting Station: Starting station for vehicle and if selected trailer profiles to be calculated.

Ending Station: Ending station for vehicle and if selected trailer profiles to be calculated.

Direction Reversed: Draws the profiles from ending toward starting stations.

Erase Previous Profile Entities: Removes previously drawn profiles for selected profile.

Draw Vehicle Icons: Draws the vehicle and if selected trailer icons.

Vehicle Interval: Interval distance between icons.

Vehicle Layer: Layer to draw the icons on.

Set: Select the icon layer from list.

Draw Clash Detection: This option will detect locations where the profile paths conflict with the selected Profile.

Select Entities: This option allows for additional CAD objects to be selected and checked for conflicts with profile paths.

Symbol: Symbol to place at the detected clash locations.

Select Symbol: Select symbol from the symbol library.

Symbol Size Scaler: Sets the size for the symbols at the detected clash locations.

Text Size Scaler: Set the size of the labels for the detected clash locations.

Station Label Prefix / Suffix: Prefix and Suffix for all station labels placed at detected clash locations.

Elevation Label Prefix / Suffix: Prefix and Suffix for all elevation labels placed at detected clash locations.

Clash Layer: Layer to draw the detected clash icons and labels.

Set: Select the clash layer from list.

The **Save** and **Load** buttons save and recall the vehicle dimensions to a .VTV file.

Pulldown Menu Location: Roads > Vehicle Path Tracking

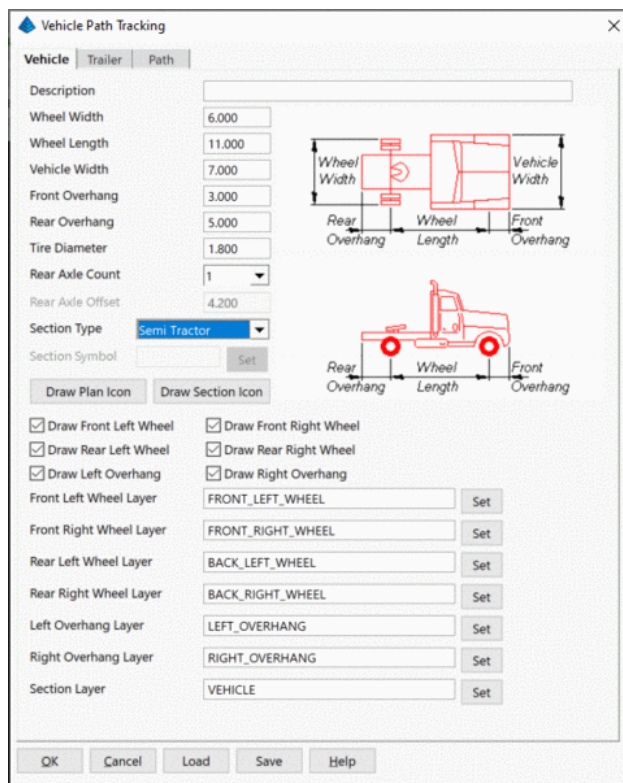

Keyboard Command: auto_track_pro

Prerequisite: Profile Drawing

Vehicle Path Tracking

This command traces the wheel paths for vehicle dimensions along a centerline. The centerline is defined by a polyline which must be created before running this command. The front axle follows this centerline based on the path settings from the Path tab. After specifying the vehicle dimensions and draw options in the command dialog, the program prompts for the centerline polyline and then draws the paths.

For the vehicle settings, pick on the Vehicle Tab. These are the set of dimensions for the vehicle and separate layers for the vehicle points to track.

Description: Description of the Vehicle Path Tracking command settings if saved. (Optional)

Wheel Width: Distance along the wheel axis to the outside of the tires.

Wheel Length: Distance between the front axle and rear axis.

Vehicle Width: Outside width dimension of the vehicle body.

Front Overhang: Distance from front axle to front of vehicle body.

Rear Overhang: Distance from rear axis to the back of the vehicle body.

Tire Diameter: Outside diameter of the vehicle tires.

Rear Axle Count: Number of rear axles.

Rear Axle Offset: Distance between rear axles.

Section Type: Section List for Vehicle types.

Section Symbol: Symbol to represent the vehicle.

Set: Select the corresponding vehicle symbol.

Draw Plan Icon Select location and places plan view detail of Vehicle in CAD.

Draw Section Icon Select location and places section view detail of Vehicle in CAD.

Draw Front Left Wheel: Draws the front left wheel path.

Draw Front Right Wheel: Draws the front right wheel path.

Draw Rear Left Wheel: Draws the rear left wheel path.

Draw Rear Right Wheel: Draws the rear right wheel path.

Draw Left Overhang: Draws the left overhang of the vehicle path.

Draw Right Overhang: Draws the right overhang of the vehicle path.

Front Left Wheel Layer: Layer to draw the front left wheel path on.

Front Right Wheel Layer: Layer to draw the front right wheel path on.

Rear Left Wheel Layer: Layer to draw the rear left wheel path on.

Rear Right Wheel Layer: Layer to draw the rear right wheel path on.

Left Overhang Layer: Layer to draw the left overhang of the vehicle path on.

Right Overhang Layer: Layer to draw the right overhang of the vehicle path on.

Section Layer: Layer to draw the details of the vehicle on.

Set: Select the corresponding vehicle layer from list.

Interstate Semi-Trailer [WB-20/65]

Tire Diameter: FEET
3.33

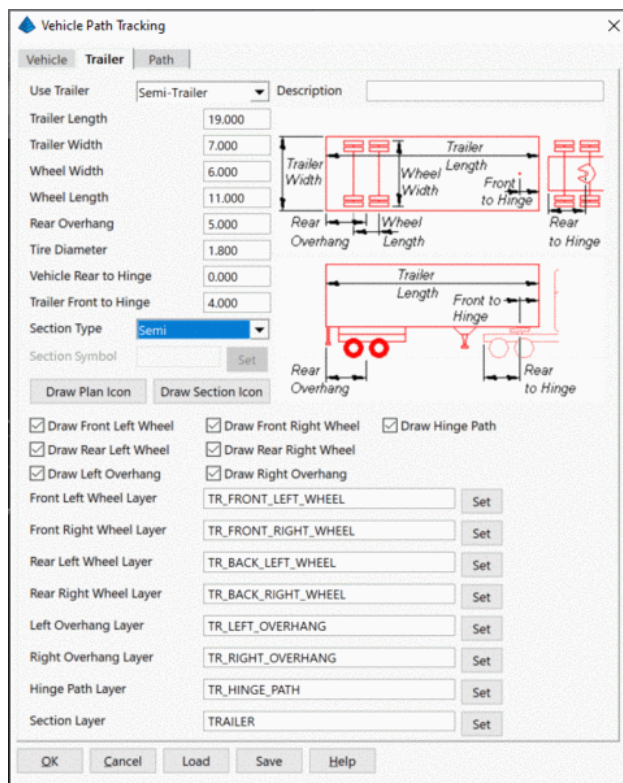

Interstate Semi-Trailer [WB-20/65]

Vehicle Width: FEET
8.5
Wheel Width: 8.5
Tire Diameter: 3.33

For the hinged vehicle settings, pick on the Trailer Tab. These are the set of dimensions for the trailer and separate layers for the trailer points to track.

Use Trailer: Use this list to setup the trailer data and choose paths to draw. Choose None or between Tow and Semi-Trailer to change the values for easier input based on semi-trailers or tow trailers.

Description: Description of the Trailer if saved. (Optional)

Trailer Length: Outside length dimension of the trailer.

Trailer Width: Outside width dimension of the trailer body.

Wheel Width: Distance along the wheel axis to the outside of the tires.

Wheel Length: Distance between the front axle and rear axle.

Rear Overhang: Distance from rear axis to the back of the trailer body.

Tire Diameter: Outside diameter of the trailer tires.

Vehicle Rear to Hinge: Distance from the rear of the vehicle and the hinge location.

Trailer Front to Hinge: Distance from the front of the trailer to the hinge location.

Section Type: Section List for Trailer types.

Section Symbol: Symbol to represent the trailer.

Set: Select the corresponding trailer symbol.

Draw Plan Icon Select location and places plan view detail of Trailer in CAD.

Draw Section Icon Select location and places section view detail of Trailer in CAD.

Draw Hinge Path: Draws the hinge path.

Draw Front Left Wheel: Draws the front left wheel path.

Draw Front Right Wheel: Draws the front right wheel path.

Draw Rear Left Wheel: Draws the rear left wheel path.

Draw Rear Right Wheel: Draws the rear right wheel path.

Draw Left Overhang: Draws the left overhang of the trailer path.

Draw Right Overhang: Draws the right overhang of the trailer path.

Front Left Wheel Layer: Layer to draw the front left wheel path on.

Front Right Wheel Layer: Layer to draw the front right wheel path on.

Rear Left Wheel Layer: Layer to draw the rear left wheel path on.

Rear Right Wheel Layer: Layer to draw the rear right wheel path on.

Left Overhang Layer: Layer to draw the left overhang of the trailer path on.

Right Overhang Layer: Layer to draw the right overhang of the trailer path on.

Hinge Path Layer: Layer to draw the hinge path on.

Section Layer: Layer to draw the details of the trailer on.

Set: Select the corresponding trailer layer from list.

Interstate Semi-Trailer [WB-20/65]

Tire Diameter: FEET
3.33

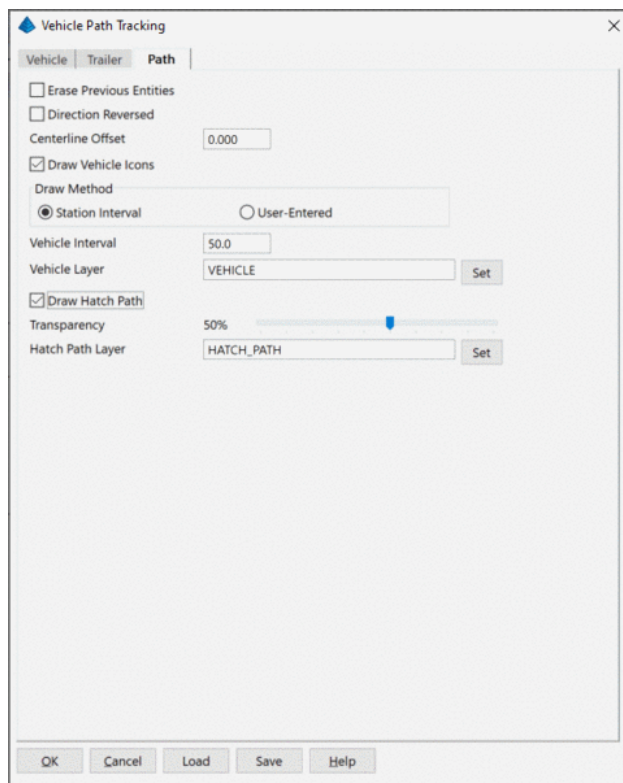

Interstate Semi-Trailer [WB-20/65]

Trailer Width: FEET
8.5
Wheel Width: FEET
8.5
Tire Diameter: FEET
3.33

For the path settings, pick on the Path Tab.

Erase Previous Entities: Removes previously drawn paths for selected centerline.

Direction Reversed: Processes the centerline from the end to the start.

Centerline Offset: Distance from the centerline for the front axle to follow.

Draw Vehicle Icons: Draws the vehicle and trailer symbols with the specified dimensions.

Draw Method Choose between placing vehicle symbols at the specified Station Interval along the centerline or User-Entered for prompting to pick points along the centerline to place the vehicle symbols.

Vehicle Interval: Interval distance between vehicle symbols.

Vehicle Layer: Layer to draw the vehicle and trailer symbols on.

Draw Hatch Path: Hatches the entire path of the vehicle and trailer along the centerline.

Transparency: Transparency applied to the hatch drawn.

Hatch Path Layer: Layer to draw the hatched path on.

Set: Select the corresponding layer from list.

The **Save** and **Load** buttons save and recall the vehicle and trailer dimensions to a .VTP file.

Prerequisite: Centerline polyline

Template ID Library

This command defines template ID's along with associated descriptions. The ID's can be selected in Design Template when adding grades, curbs or medians. The descriptions are only for identification during the ID selection. In Design Template, there are Set buttons next to the ID edit fields that select from the list of ID's defined in the Template ID Library. The purpose of the Template ID Library is to help with consistent naming of template elements.

The current Template ID Library is stored in the current USER folder under Documents & Settings in a file called tplidlib.dta. The Load and SaveAs functions can be used to store and recall ID settings to a .TID file.

Pulldown Menu Location: Roads

Keyboard Command: tplid.lib

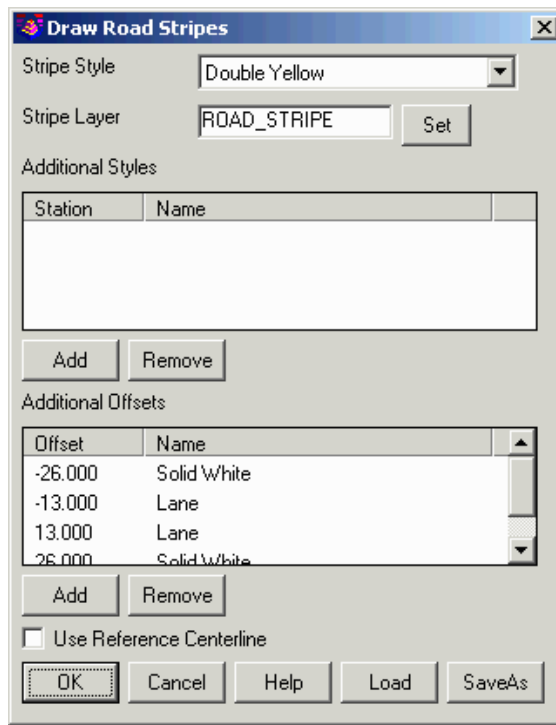

Prerequisite: None

Draw Road Stripes

This command draws polylines for stripe styles defined in Road Stripe Library. After selecting the Stripe Style from the dialog, the program prompts for the horizontal alignment which can be either a centerline file (.CL) or a polyline. Then the polylines for the stripe are drawn.

In the options dialog, the Stripe Style is selected from a list of names defined in the Road Stripe Library. The Stripe Layer is used for all the stripe polylines that are created. The Additional Styles list can be used for using different stripe styles along the alignment such as for a centerline that switches between double yellow to dashed yellow for a passing zone. The Additional Offsets list allows for drawing several road lines at a time based on offsets from the centerline such as drawing the white lane dashes and outside solid white lines along with the center double yellow lines. The Use Reference Centerline applies for dashed stripe styles that you want to control the dash spacing from the main centerline.

The Load and SaveAs buttons can be used to store and recall the stripe settings to a .RST file for archiving or sharing. The .RST file can also be used in Road Network for drawing the road stripes during that command.

Prompts

Draw Road Stripes dialog

CL File/<Select stripe polyline>: *pick polyline*

Pulldown Menu Location: Roads

Keyboard Command: road_stripe

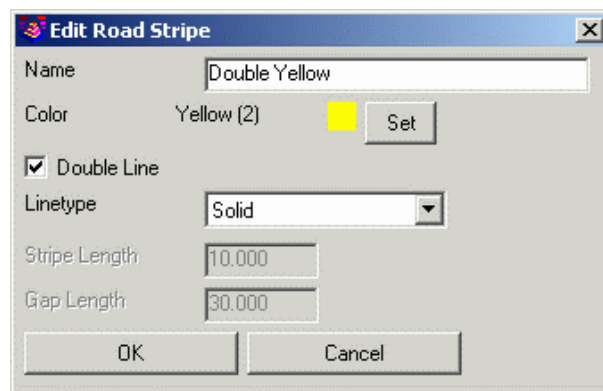

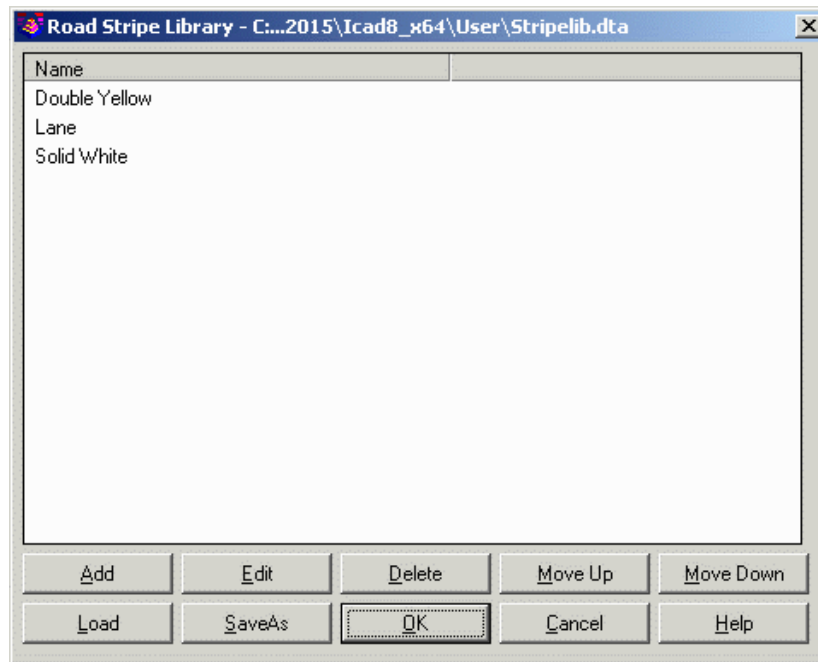

Prerequisite: None

Road Stripe Library

This command defines a collection of line styles. Each line style has a Name for a description, Color and Linetype. The Double Line option is for line styles of two parallel lines. The Linetype can be Solid for continuous line styles or Dash. For Double Lines, the Linetype can also be a solid on one side and dashed on the other such as for passing zones on the center double yellow line. For Dash Linetypes, the Stripe Length and Gap Length control the length of the dash and spacing between the dashes. Use the Add, Edit, Delete and Move Up/Down buttons to manage the list of line styles.

When the line styles are defined in the library, use the Draw Road Stripes command to create the line styles in the drawing.

The current Road Stripe Library is stored in the current USER folder under Documents & Settings in a file called stripelib.dta. The Load and SaveAs functions can be used to store and recall the stripe library to a .RSL file for archiving or sharing.

Pulldown Menu Location: Roads

Keyboard Command: stripe.lib

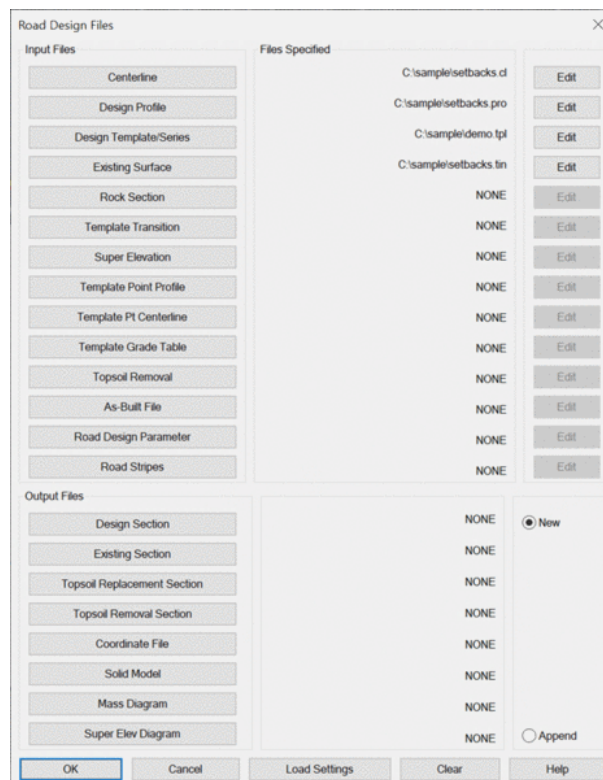

Prerequisite: None

Process Road Design

The primary function of this command is to assemble all of the components for a road design and process them together. While all of the Input Files can be created prior to accessing the Process Road Design command, all

can be edited from the Road Design Files dialog, and many files can actually be created from the Road Design Files dialog itself. The actual processing of the Road Design essentially applies the design template at the design profile elevation along the specified centerline and computing the out slopes and earthworks relative to the existing ground surface. The earthworks report can be shown in the standard report viewer or customized with the Report Formatter option. Secondary functions include creating a final grade section file for plotting with the *Draw Section File* command, creating final grade points in a coordinate file, creating a final surface/contour model, and drawing the road as 3D polylines. You can also output a mass haul diagram profile. The program also has options for applying a superelevation file, template transition file, template point profile, template point centerline, rock section file, an as-built existing section file and a topsoil removal file. *Process Road Design* can be used not just for final road design computations but for levees, channels and any template-based application.

This command begins with the dialog shown below. The top section contains input Files. In a typical implementation of this command, you will have already defined a horizontal centerline for the design to follow, however, you could actually pick the Centerline button, pick the New tab, name the new centerline file (.CL), pick Open, and then back in the main Road Design Files dialog, pick the Edit button and layout the centerline design. The only component that you must have already created before running Process Road Design is an Existing Surface file. As long as there is an Existing Ground Surface, the command will generate the Existing Ground Profile automatically, and the Proposed Finish Grade Profile can be created with the Edit button. Even a Design Template can be created right from here as well. Ultimately, the top 3 Input items (Centerline, Design Profile, and Design Template/Series) are required to Process a Road Design, leading to final sections and full contouring and 3D viewing. The Existing Surface is needed as well to process with earthwork calculations and tie slopes.

The rest of the input files are optional design files. It should be pointed out that Template Point Profile and Template Point Centerline enable template IDs to follow any defined centerline or profile and provide total flexibility of design. Lane widening, matching existing curb lines, special ditches, etc. can be easily accomplished with these two options. The template IDs simply "string along" or follow these pre-defined alignments, and the rules of the template apply to all other template ID points.

The Output Files section allows you to specify files to store the processing results. The Section File creates a final grade section file that can be drawn with *Draw Section File*. The Topsoil Section File creates the modified existing ground section file if Topsoil Removal is set in the input. This "post-topsoil removal" section file can be used for earthworks calculations to compare any stage of work, using *Calculate Sections Volume* under the

Section pulldown menu. The Coordinate File creates a coordinate file containing every break point in the final grade. The point descriptions include the station, offset and template ID. Whether to include the subgrade points as well as the final surface points is determined by the Include SubGrade Points in Output CRD File option on the next dialog. To the right of the Output Files is the option to create new output files or append to existing output files. If you extend the road, or revise a portion of the project, you can simply "Append" rather than overwrite. The first time that you run this command for stations 0-1000, you would set Output Files to New. Then you could run this command again, possibly with new inputs, for stations 1000-2000 and set Output Files to Append.

On the next dialog, there is a Save Settings button to store all the settings from the first and second dialogs into a specified Road Design File with an (.RDF) file extension. Recorded (.RDF) files can be recalled later using the Load Settings option.

Centerline

Specify the name of the Centerline file with this option. The (.CL) file contains the horizontal alignment geometry for a project. This parameter file must be specified if you want to have earthworks centroid corrections computed, generate final coordinates, Disturbed Area Polyline, and/or use Triangulate & Contour. The centerline file can be created by the *Design Centerline* or *Polyline to Centerline* commands in the Design pulldown menu.

Example Centerline

Design Profile

Specify the design profile (.PRO) file to derive the centerline elevations when the template is applied. This file defines the vertical alignment and is always required. The profile can be created with any of the profile creation routines in the Profile menu, but typically you would use *Design Road Profile* or *Input Edit Profile*.

Example Design Profile

Design Template/Series

Specify a template definition (.TPL) file or template series (.TSF) file that defines the final grade offsets and elevations and the cut/fill slopes. The template file is created by the *Design Template* command and the template series file (a set of templates ordered by range of stations) is created using *Template Series Editor*. A single template

file or a template series file is required to run *Process Road Design*.

Example Design Template

Existing Surface

Specify the surface model which will be treated as the existing ground for cut and fill volumes and to calculate the outslope intersections when the template is applied at the profile elevations. This Existing Surface can be defined by either a section file or triangulation. The section file can be created with commands such as *Sections from Surface Entities*, *Input/Edit Section File*, *Sections from Points* or one of the *Digitize Sections* commands on the Section menu. The triangulation file can be created with the *Triangulate & Contour* command.

Example Existing Sections

Rock Section File

This option specifies an optional rock section file that is used as an additional surface. When in cut, a special cut slope is used up to the intersection of the rock surface. After this intersection, the normal cut slopes apply. The special rock cut slope is specified in Design Template under the cut options. If the "pivot point" in cut is below the rock line, then the special rock cut slope will be applied. Note that rock sections can be derived from borings to rock, as modeled, or can be created quickly by using the "translate" command within *Section File Editor* to translate the existing ground sections by a vertical offset (e.g. -6) to an approximate top of rock.

Detail of rock cut slope

Template Transition File

Specify a .TPT file with this option. The Template Transition file allows modified template files to be applied at different ranges of stations on a project. In this way, template IDs can be made to widen (as for passing lanes) and contract. Use the *Template Transition* command under the Design menu to create a template transition file.

Super Elevation File

This option is used to specify a super elevation file (.sup file) that defines the super elevation transition stations on a project. The super elevation file can be created with the *Super Elevation Editor* command.

Template Point Profile

This option lets you have separate profiles for template points that are independent of the centerline profile. This design file is created with the *Assign Template Point Profile* command.

Template Point Centerline

This option lets you have separate centerlines for template points that are independent of the main centerline. This design file is created with the *Assign Template Point Centerline* command.

Template Grade Table

This input file is optional. The Template Grade Table is a method for template transitions that uses a lookup table of distance and slopes at transition stations for each template ID. This design file is created with the *Template Grade Table* command.

Topsoil Removal

This option applies topsoil removal and/or replacement to the existing ground section file. This design file is created with the *Topsoil Removal/Replacement* command.

As-Built File

The As-Built File is a cross section file used to match existing grade and retain as-built portions of a road improvement project. The final cross sections will conform to the as-built cross sections for those template IDs specified in the second dialog. Beyond the specified set of offsets in the as-built cross section file, the design road files will be applied.

Road Design Parameter

This input file is optional for running checks on the road design for parameters such as min sight distance and max grades. This .RDP file is created with the *Define Road Design Parameters* command.

Road Stripes

This option draws road markings such as double yellow lines along the centerline. The types of markings are defined in the *Road Stripe Library* command. The *Draw Road Stripes* command creates a .RST file for using with Process Road Design. The file sets which markings to draw and sets the centerline offsets.

Output Design Section File

Specify the name of the file to output the final grade sections calculated by applying the template file at profile elevations and calculating the outslope intersection with the existing ground cross sections. This file can then be plotted by using the *Draw Section File* command. After plotting the final sections overlaid on the existing sections, revisions can be made graphically with commands like *PEDIT* and *Polyline by Slope Ratio*. The data output to the file can also be edited and reviewed with the *Section File Editor* command. If the final sections are edited graphically, the revised section data can be updated in the .SCT file with the *Polyline to Section File* command.

Output Section File drawn with Existing Section File by the *Draw Section File* command

Output Existing Section File

This option creates a section file of existing ground. This applies when the existing surface is a triangulation file. The station intervals for the existing section file will match the stations from the design section file.

Output Topsoil Replacement Section File

This option writes out a modified existing ground section adjusted by the topsoil replacement. This option only applies when a Topsoil Removal file is being used.

Output Topsoil Removal Section File

This option writes out a modified existing ground section adjusted by the topsoil removal. This option only applies when a Topsoil Removal file is being used.

Output Coordinate File

This option creates a coordinate file containing every break point in the final grade for the range of processed stations. Using the second dialog, there are additional options to output subgrade and ditch/berm points. The point descriptions include the station, offset and template ID. The station interval is set by the stations in the Existing Section File.

Output Solid Model

This option creates a solid model file (MDL) for all the subgrades.

Output Mass Diagram File

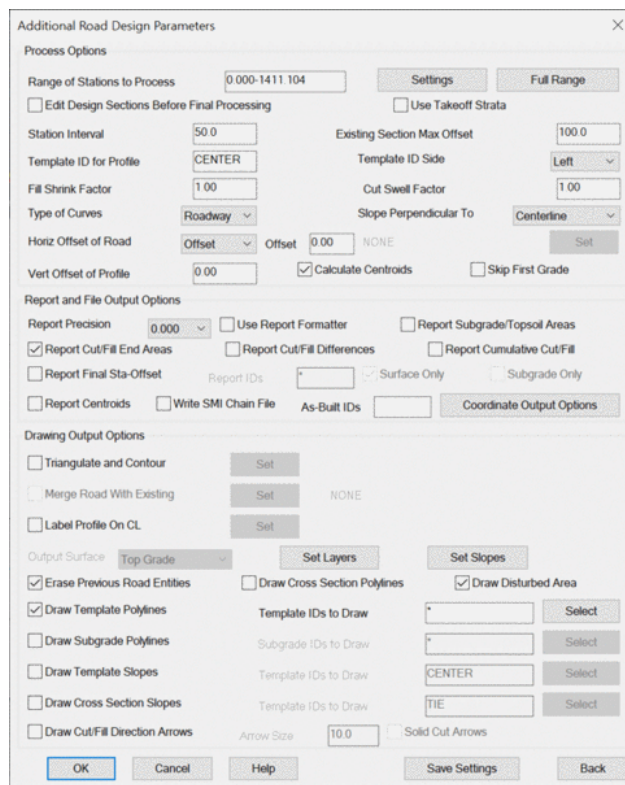

The mass haul diagram can be output as a profile file and shows the cumulative cut and fill along the selected range of stations. Cut and fill is balanced between points on the mass haul profile that cross the Z-axis. Because of the typically large values of cut and fill associated with road and earthwork projects, the vertical scale for the profile may need to be set to 10 times the horizontal scale, or more. The profile preview screen which appears when you select profile for loading will show the elevation range and help suggest an appropriate vertical scale.

Output Super Elevation Diagram File

This option writes out a super elevation transition file (.SUD) that can be used with the Draw Super Elevation Diagram routine. This file contains the template cross slopes and the transition stations.

Running the Road Design Job

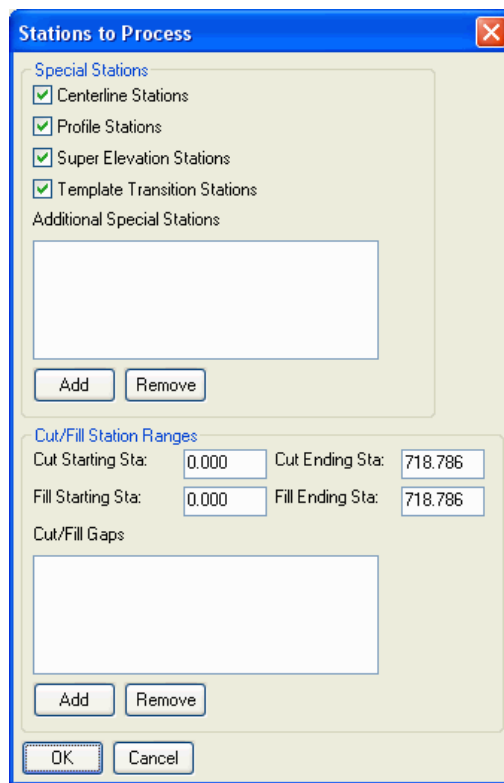

After setting up the files and options in the first dialog click the OK button. The next dialog shown below has processing options.

In the **Process Options** section, the *Range of Stations to Process* field sets the range of station that you want to calculate. Each time you use this command, the existing grade (.SCT) file is scanned and the range in the edit box is set to the minimum and maximum stations in the file. If you change the station range, you can click the *Full Range* button to restore the default full range of stations.

The *Settings* button will interpolate additional existing cross sections (internally) and create final cross sections at special stations like profile high and low points, profile transition stations for PVC and PVT, key centerline points like PC's and PT's, and superelevation and template transition points and any user-defined special stations. These additional station improve volume calculations.

Volumes are calculated using end areas between the range of stations. Also under the *Settings* button, there are controls for the cut/fill starting and ending stations. Instead of cutting off the volumes exactly at this range, the Ending and Starting Stations for Cut and Fill can be used to have the volume taper from zero at the specified Starting Station to the volume at the first station in the range. Likewise the Ending Stations can be used to taper the volume from the last station in the range to zero at the specified Ending Station. You can also specify cut/fill gaps to stop the end area volume calculations over the station range of that gap. This applies in cases like a bridge.

The *Edit Design Sections Before Final Processing* does just that. You can review and edit the final sections in the spreadsheet with graphic view editor similar to the Section File Editor command. For example, you can change the tie slope as selected stations. After making these changes, the modified final sections are used for the rest of the road design process including earthworks and drawing output.

The *Station Interval* and *Existing Section Max Offset* buttons are ghosted if the existing surface is a set of cross sections. If there is no existing surface, or the existing surface is a grid, TIN or FLT file, then you must enter the Station Interval to generate sections along the centerline. Besides the stations at interval, sections can be created at special stations as specified under the Settings button. The *Existing Section Max Offset* controls the max left and right offsets for generating the existing sections when the Existing Surface is defined by a triangulation file. This offset needs to be set far enough for the final sections out slopes to tie into existing. On the other hand, keeping this offset fairly close to the tie point will help make processing run faster.

The *Calculate Centroid* option applies to centerlines containing curves. The centroids of the cuts and fills will be computed, and the radius to these centroids will be calculated. Then the effective interval will be computed between cut and fill centroids. In this way, in a tight curve where fill is concentrated to the outside of the curve and cut is concentrated to the inside of the curve, fill will be increased and cut will be reduced. This also increases the accuracy of volume calculations.

The *Use Takeoff Strata* option uses the strata surfaces created in the Takeoff module to report the strata cut volumes both for the total strata volumes and the strata end areas per station. This method allows for unlimited strata definitions with advanced modeling techniques including Kriging and Inverse Distance to model strata surfaces. In Takeoff, the Drillhole/Strata Settings command is where you define the strata names and modeling methods. Next, the Place Drillhole command creates the drillholes. Once the drillholes are entered, use the Make Strata Surfaces command to build the strata surfaces which are stored as TIN files and associated with the current drawing.

The *Template ID for Profile* allows the profile grade to be applied to another template ID point other than the centerline. This feature might apply, for example, to a 2-lane road that will eventually be part of a 4-lane road being built in stages. The first-stage, 2-lane road would be fully symmetrical and designed around the crown of the road, but the template profile might be one of the edge of pavements. You can specify the template ID (e.g. EP), and

whether the left or right side ID should be used to apply the profile grade.

The *Shrink and Swell Factor* edit boxes allow you to specify a value that the volume calculated will be multiplied by. If you specify any number other than one an additional report showing accumulated adjusted volumes and differences will be produced.

The *Vertical Offset of Profile* edit box will place the template at the profile grade as raised or lowered by the entered offset.

The *Horizontal Offset of Road* will shift the template left or right on the centerline by the specified amount. Use a positive value to offset to the right and use a negative value to offset left. This option is useful, for example, when one side of a divided highway is built before the other side is to be started. In this case, you could define a normal template with a crown in the middle, but would enter a horizontal offset from the crown of the road to the actual centerline of the divided highway. In case the offset is variable instead of a fixed offset, there is an option to specify a centerline file (.CL) for the offset. This method applies for a divided highway where each side of the road follows its own alignment. In this case, the main centerline from the first dialog can be for the centerline along the median between the roads and this main centerline is used for the stationing in the reports and output sections. To process both sides of the divided highway, run Process Road Design twice, once for each side.

The *Slope Perpendicular To* option defines the slope projection method. The centerline method creates the template cut/fill slopes perpendicular to the centerline. The Slope Direction method accounts for the slope of the profile and makes the final surface to match the template cut/fill slope. For example, if the profile is at a 10% slope and the fill slope is at 2:1, then the Centerline method would create fill slopes that are 2:1 perpendicular to the centerline while slightly steeper (1.96:1) for the actual slope that goes in the slope direction with the effect of the profile. For the same case except with the Slope Direction method, the resulting slope perpendicular to the centerline is less steep (2.04:1) while the actual slope in the slope direction is exactly 2:1.

The *Skip First Grade* option skips the first template grade. This option applies when the road design is adding onto an existing road. In this case, the first grade in the template can cover to the edge where the existing road is being kept. Then Process Road Design will skip over the existing road and start the design from the second template grade.

The **Report and File Output Options** include settings for reporting final coordinates (if specified in the previous file output dialog), as well as special features.

To report tons and costs for the subgrade materials, set the material names in Design Template for the .TPL file. Also, in Define Materials Library in the Takeoff menu of the Construction menu, specify the density and cost parameters for the material names. Then the Process Road Design report will include the tons and costs for the subgrade materials.

The *Report Precision* controls the number of decimal places.

The *Use Report Formatter* option allows you to customize the fields to report and their order. It also can output the report to MS Excel or databases.

The *Report Subgrade Areas* option will include an additional line in the report for the end area of each subgrade material.

The *Report Centroids* toggle controls whether the shift in the cut or fill centroid radius shift will be included in the earthworks report.

The *Report Cut/Fill Text* option greatly expands the size of the report by presenting the cut and fill end areas at each station. A sample of the cut/fill text report is shown below. Volumes by end area method are presented between

each line containing station and end areas of cut, fill and optionally rock.

Station	Cut (sf)	Fill (sf)	Rock (sf)	Interval	Cut (cy)	Fill (cy)	Rock (cy)
3+00.00	0.00	101.07	0.00				
				50.00	313.78	93.58	0.00
3+50.00	338.88	0.00	0.00				
				6.09	80.93	0.00	0.00
3+56.09	379.10	0.00	0.03				
				43.91	824.60	0.00	31.84
4+00.00	634.92	0.00	39.12				

The *Report Cut/Fill Differences* option will report the cut/fill ratio and balance at each station.

The *Report Cumulative Cut/Fill Differences* option will report the running totals of cut/fill at each station.

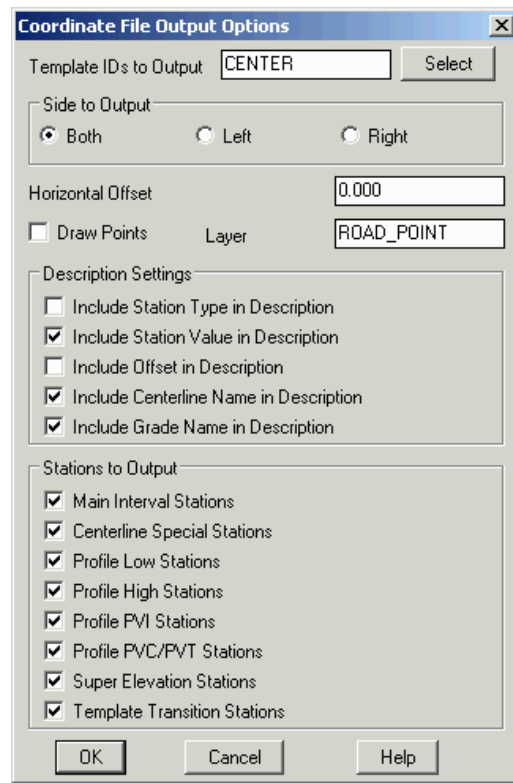

The *Report Final Station-Offset* option will create a report of the final section offset-elevation data in row-column format. The station and profile grade are shown on the left followed by columns of offset and elevation for each data point. There are options to report the surface points only, the subgrade points only or filter the points by ID.

Write SMI Chain File creates a chain (.CH) file that contains the centerline, profile and template data for SMI Construction V.

The *As-Built IDs to Use* option applies only if you have specified an as-built section file as one of the inputs in the previous dialog. Consider a normal road template with 20 feet to edge of pavement (EP) and 10 feet more to shoulder (SH). Going further, assume that when you run this template, it does a fill condition on the right and creates a TIE point. If you wanted to conform the template to match a wider section of road at certain stations, you could edit the output file of a normal run (using Section File Editor) and create new offsets and subgrade points for widening and even force a trapezoidal ditch in cut, as shown in the entries below:

	Offset	Elevation	Description	Ratio(:1)	Slope(%)
12	21.330	1996.950	EP	-50.00	-2.00
13	21.330	1995.920	SUBGRADE1-3		
14	31.500	1996.544	SH	-25.00	-4.00
15	21.330	1996.950	SUBGRADE1-4		
16	38.600	1992.994	BD	-2.00	-50.00
17	40.000	1992.994	BD2	Flat	0.0%
18	46.000	1995.994	TIE	2.00	50.00

Because all the other offsets to the left match by default, this editing will force the template to conform from offsets 21.33 right to the tie at 46 right. As you try different design template or other changes in *Process Road Design*, this as-built information would hold for the specified station. Alternately, you could edit the final cross section directly in *Section File Editor*. Note that you can use distinct, new ID points like BD2 which are not found in the template file, and they will be created if part of the as-built cross section file, and if referenced as *As-Built IDs to Use*. This As-Built method works best when inserting controlled section defined from TIE left to TIE right, which get inserted as completed sections in a run of Process Road Design.

The *Coordinate Output Options* apply when a Output Coordinate File is specified in the first dialog. The *Template IDs to Output* allows you to output any combination of template surface, subgrade, ditch and berm points. The *Side to Output* controls whether to create points on the left, right or both sides of the centerline. The *Horizontal Offset* shifts the points away from the centerline. The *Draw Points* option draws the points in addition to storing the points to the coordinate file. The *Description Settings* control the contents for the point descriptions. The *Stations to Output* control at which stations to create points. Here are example coordinates for station 0+90:

PtNo.	North (y)	East (x)	Elev (z)	Description
122	189497.42	611730.32	90.01	TIE 0+90.00L53.65
123	189461.43	611733.72	108.09	SHD 0+90.00L17.50
124	189457.45	611734.09	107.93	CURB3 0+90.00L13.50
125	189456.95	611734.14	107.93	CURB2 0+90.00L13.00
126	189456.95	611734.14	107.09	CURB1 0+90.00L13.00
127	189455.96	611734.23	107.09	EP 0+90.00L12.00
128	189444.01	611735.36	107.33	CENTER 0+90.00R0.00
129	189432.06	611736.49	107.09	EP 0+90.00R12.00
130	189431.07	611736.58	107.09	CURB1 0+90.00R13.00
131	189431.07	611736.58	107.93	CURB2 0+90.00R13.00
132	189430.57	611736.63	107.93	CURB3 0+90.00R13.50
133	189426.59	611737.00	108.09	SHD 0+90.00R17.50
134	189412.18	611738.36	100.85	TIE 0+90.00R31.97

The **Drawing Output Options** bottom section of the Additional Earthworks Parameters dialog contains output options which are only available when a centerline file is specified.

The *Triangulate & Contour* option will automatically run this command after Process Road Design is done to create the final contours. Triangulate & Contour uses the template 3D polylines to model the final surface, and the disturbed area polyline is used as the inclusion perimeter for the contours. With Triangulate & Contour clicked on, the *Setup* button becomes active. Picking Setup brings up the Triangulate & Contour settings including the contour interval and whether to draw 3D Faces. Also under Setup, there are controls for the colors of the 3D Faces for each template break point. With Triangulate & Contour active, Draw Template Polylines and Draw Disturbed Area Polyline are automatically turned on. The *Merge Road With Existing* option combines the road design triangulation with the existing ground surface and stores the resulting triangulation in the file specified with the Set button. This option is available when the Existing Surface is a triangulation file and the Triangulate & Contour option is active.

The Output Surface chooses between Triangulate & Contour building a surface for the top of the road template or the bottom subgrade.

The *Erase Previous Road Entities* option will erase any entities from the drawing that were created in a previous run of Process Road Design using the same design files. This option allows you to easily re-run Process Road Design and update the drawing entities after changing one of the road design files.

The *Draw Cross Section Polylines* option will create 3D polylines perpendicular to the centerline with each template break point. The interval of these cross section polylines is determined by the station interval of the Existing Sections.

The *Draw Template Polylines* option will create 3D polylines parallel to the centerline by connecting common template point IDs. For example, a template ID could be EP which this option would use to create 3D polylines for EP on the left and right of the centerline. Which template point IDs to connect in set under *Template IDs to Draw*. Setting this to an asterisk (*) will plot all the template break points. The *Select* button shows cross sections of the final templates for graphical selection of the ID's to draw.

Likewise, the *Draw Subgrade Polylines* option will create 3D polylines parallel to the centerline for the specified subgrade breakpoints.

The *Draw Disturbed Area Polyline* option will create a polyline perimeter that represents where the cut/fill slopes tie into the existing ground.

Draw Template Slopes creates slope arrows parallel to the centerline at the specified template ID's. For example, this option can be used to show the slope direction and amounts along the template flowline. The style of the slope arrows is set under the *Set Slopes* button at the bottom of the dialog.

Draw Cross Section Slopes create slope arrows perpendicular to the centerline at the specified template ID's. For example, use this option to show the cross section slope of the pavement lanes. The cross section interval is controlled by the station interval under Process Options. The style of the slope arrows is set under the *Set Slopes* button at the bottom of the dialog.

Label Profile On Centerline creates labels in plan view for the profile stations, elevations and slopes as well as high and low points. This option has the same functionality as the command by the same name in the Profiles menu.

The *Draw Cut/Fill Direction Arrows* option will draw arrow indicators for cut or fill slope direction. The arrows are drawn in plan view and usually are drawn together with the Draw Disturbed Area and Draw Cross Section Plines options. Cut arrows start from the disturbed area limit and point towards the centerline. Fill arrows start from the base of the fill slope and point away from the centerline. The *Solid Cut Arrows* option chooses between solid fill or wire-frame cut arrows. These arrows, especially when drawn as solid cut arrows, help distinguish cut and fill at a glance, when in plan view. In the example below, fill from a berm is shown at the left and cut down to a ditch is shown at the right. The arrows will only draw if there is enough dimension in the cut and fill to fit the entire arrow. So the cut and fill arrows reveal the deeper cut and fill zones.

Prompts

Road Design Files dialog: Choose the design files

Additional Road Design Parameters

Road Design Report dialog

Trim existing contours inside disturbed area (Yes/<No>)? *Y* This prompt appears if Triangulate & Contour is on. This option will trim polylines with elevation that cross the disturbed area perimeter for the road.

Join final contours with existing (<Yes>/No)? *Y* This prompt appears if Triangulate & Contour is on. This option will join the final contours with the existing contours where they join at the disturbed area perimeter.

Existing Contours and Centerline

3D template polylines, disturbed area perimeter polyline and final contours

Review of 3 Methods of Transitioning Templates using Process Road Design

The 3 methods of template transitions and super elevation are:

- (1) Template Transition and/or Super Elevation Files
- (2) Template Point Profile and Template Point Centerline files
- (3) Template Series file which transitions between multiple, named templates.

Road widening and lane transitions can be handled by all 3 methods. Special ditches are best handled by method (2), Template Point Profile and Template Point Centerline, especially since Template Transition files only work with lanes or portions of roads defined by the Grade button in Design Template. Template Transition files do not apply to cut and fill segments, unless they are designed as fixed features using the Grade button. Super elevation can often be handled by method (1) or method (3). Bear in mind that new lanes or template elements that emerge and then disappear need to exist as template ID points in all referenced templates, using all 3 methods. These template ID points can be set to 0.001 units from adjacent template points, then "told" to emerge and widen as new lanes with distinct slopes appear. The program will not transition templates that don't share common template ID points.

This deceptively easy looking example below might be approached by a combination of methods 1 and 2. For method 1 to apply (template transition), the slopes of the pavement lanes must be maintained according to the template definition from centerline to outside lane. The ditch portion will be handled by method 2 (template point centerline).

Assume Spouts Springs Road is a hillside road with a ditch cut on the left side and fill on the right side. The trapezoidal ditch is shown. We will design only from station 4+00 to station 6+94 where the intersection begins. The standard template of 10' left lane and 10' right lane might appear as shown below:

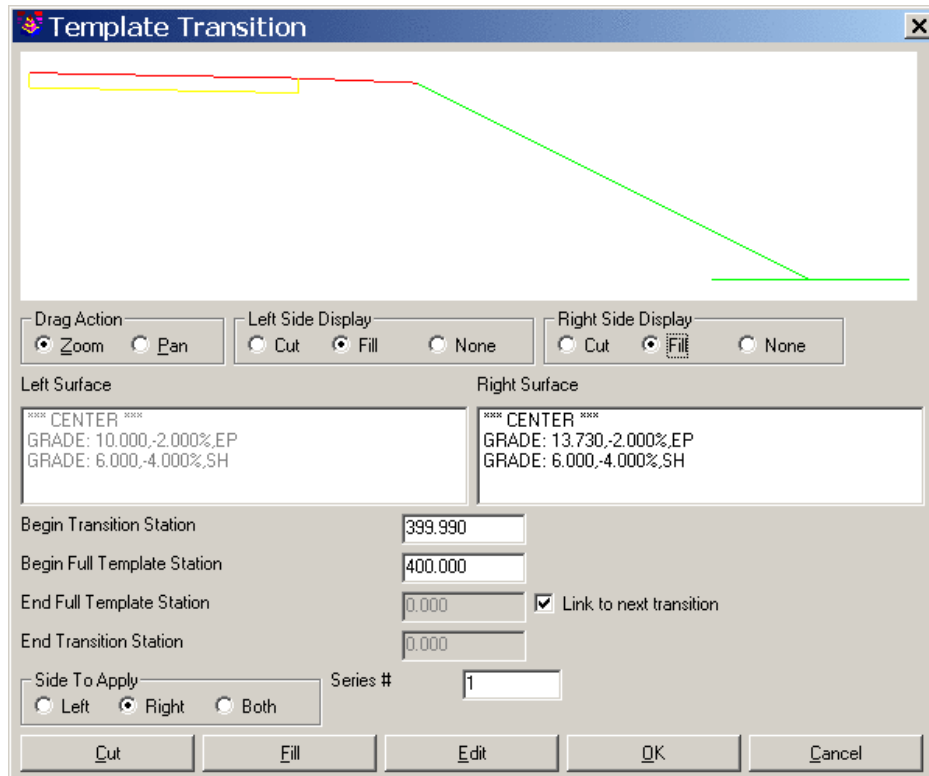

Note that if lanes are designed to expand, its important that the subgrade (9" of paving, shown above) be defined as following the ID, and should not be set to a fixed distance. The "EP" ID is used in the dialog below (top of subgrade

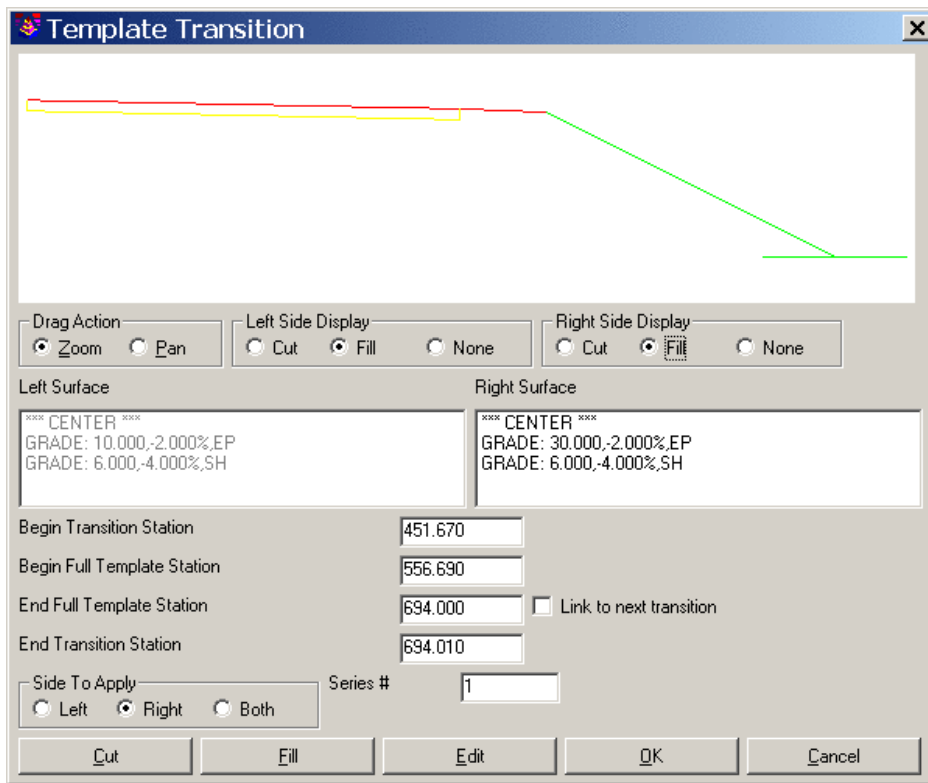

dialog within Design Template) for this example.

The right hand portion of this example would be entered as follows:

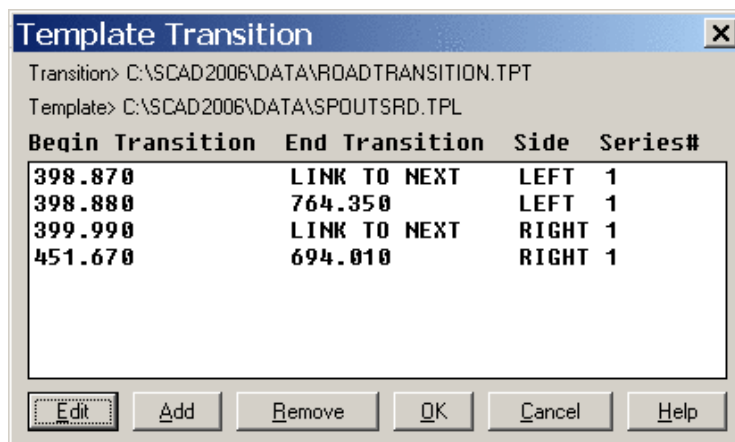

When you click "Add" within the Template Transition main dialog, you are presented with the above screen. Template transitions require that you specify the correct side of the road in the lower left, then click the Grade or lane to alter, which is the first lane on the right, which is set to 13.73 according to the plans. To make sure the lane is fully expanded from the standard 12 to the 13.73 at station 400, it is necessary to set the "Begin Transition Station" to something less than 400, as shown. Then if this "expanded" lane width does not transition back to standard 12 width, but changes again, you must click on "Link to next transition" and leave the "End Full Template" and "End Transition" stations blank. Then you click "Add" again for the final segment, which would be entered as shown:

First, you specify "Side to Apply" as "Right", then click the pavement lane and edit it to 30', as shown above. Referencing the plan view drawing for Spouts Road shown above, you transition from station 451.67 to the new 30' road lane width at station 556.69 and hold that to the "End Full Template Station", which is 694.00. Then you can enter an "End Transition Station" just past the end of the key station range, which internally would transition the template back to a standard width of 12' at 694.01 (a moot point as the end of the project is station 694 for this exercise). The key to template transition is that it is designed to transition from normal to expanded or reduced dimension, then transition back to normal. It is ideal for use in passing lanes that appear and then transition back, but requires use of "Link to next transition" to handle a sequence of lane width changes as above. Therefore, where lane widths change often, and don't transition back to the normal template lane width, it is often best to use Template Point Centerline as the method of lane transitioning. We will apply that below to the ditch line.

When the template transition process is repeated for the left driving lane, you obtain a final Template Transition dialog as shown here:

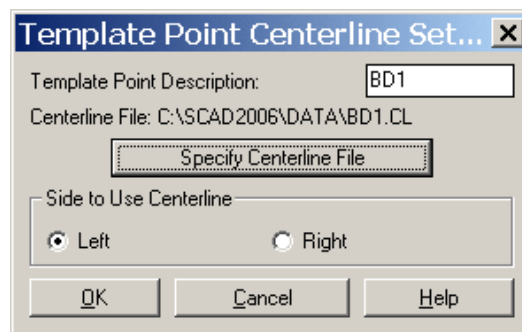

For the left side, the first screen just starts things up by establishing 10.28 as starting left side dimension, then the "Link to next transition" option is used, and the width of 18 is entered, transitioning to 18 at station 554.21 and holding that to an end station of 764.34, transitioning "back" to 12 at the fictitious 764.35, well beyond the 400 to 694 station range of interest. When this template transition file is run in Process Road Design and Triangulate &

Contour is turned on within Process Road Design, the output clearly shows that the lane transitions have followed the lane expansions correctly:

However, it is easy to see that the "design ditch" on the left side of the road, at 2' wide, did not conform to the special ditch which hugs the shoulder at station 7+00 but transitions to further off of the shoulder at 4+00. This special ditch is best handled with Template Point Centerline. To complete the special ditch design, use Polyline to Centerline File on both ditch polylines, calling the inside polyline BD1.CL and the outside polyline BD2.CL, as a reference to the ditch IDs, BD1 and BD2. You can give them a starting station of 0. The stationing of the ditch polyline does not matter, since only the coordinates of the centerline in the command Assign Template Point Centerline are used to determine the template ID position. Within Assign Template Point Centerline, Add each of the ditch sides as shown:

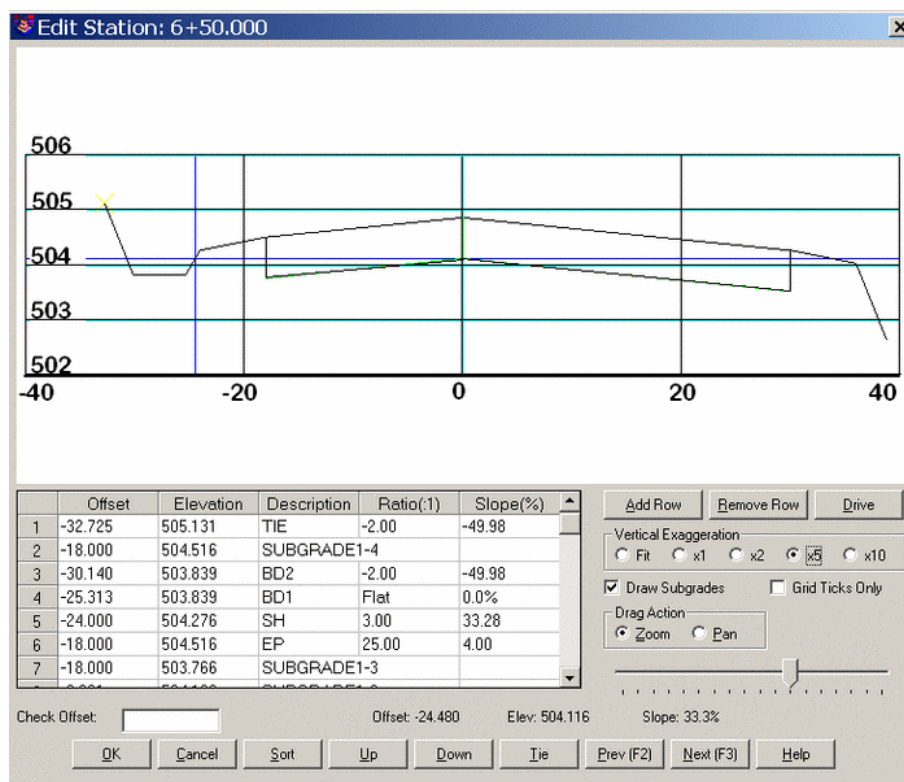

Note that if the ditch always exists on the left side, the ditch grades can be defined using the Grade button in Design Template, rather than using the Ditch feature within the Cut button. For final results, run the Process Road Design command using a combination of the Template Transition File and the Template Point Profile.

The end result is a final drawing that uses the Template Transition file to create the correct edge of pavement and uses the Template Point Centerline file to track along the correct ditch polylines. This is shown below in the final drawing of the 3D polylines generated by Process Road Design:

The actual slope to the ditch on the left is held at the design of 3:1, or whatever exists within the template from shoulder (SH) to base of ditch (BD1) in cut. Shown below in the Section File Editor screen editor is station 6+50, where the ditch is designed very close to the shoulder:

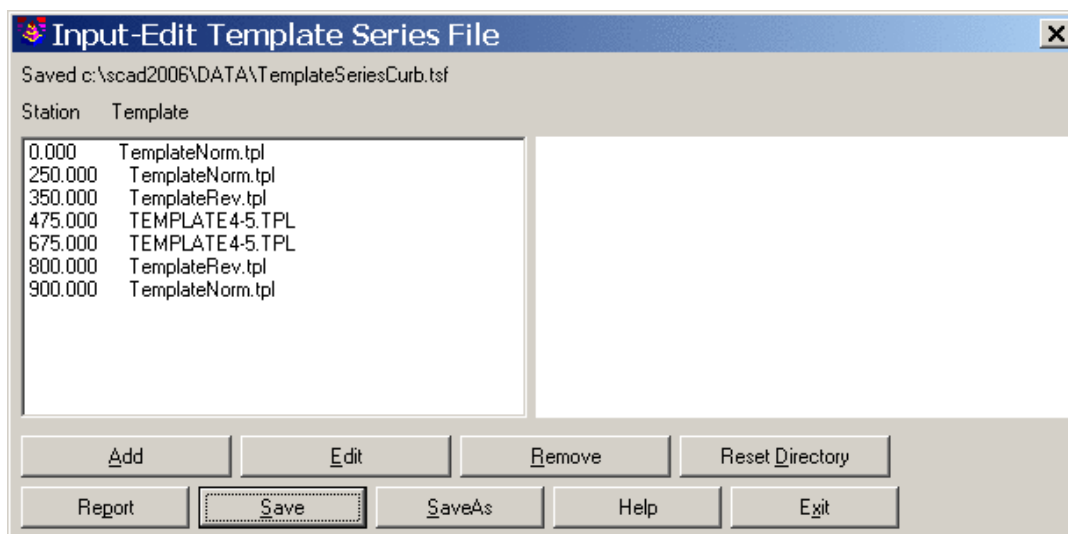

Note that the distance from BD1 to BD2 is irregular, based entirely on the plan view offset of the ditch polylines. Note also that BD1 to SH is 3:1, holding the defined slope. (The cursor position also can be used to verify slope of any portion of the section in "real-time".) Finally, note that the subgrade follows the widening and irregular position of the pavement lane EP for both left and right sides, since the subgrade offset from centerline was defined as EP.

Although superelevation can be handled by use of superelevation files, for most simple applications (2-lane roads in particular), a single curve with superelevation can be handled by a template series file, using only 3 templates: normal crown, reverse crown, full super. This is illustrated below, for a typical 2-lane road template:

The actual Template Series File will consist of 6 entries for one curve: Normal, Reverse, Begin Full Super, End Full Super, Reverse, Normal. You would only need to make one extra template, for simple roads, for every additional curve, for the full super condition, since normal and reverse crown remain the same. Note that the curbs, even on the high side, can be designed to slope downward and catch the shoulder drainage in Design Template by use of "special slope" of -1% in the curb design, or by entering a value for the added "Drop" across the gutter portion. Both methods create a downhill slope to the face of curb. So the above project might be designed as shown below in the Template Series Editor command:

Note that beginning and ending stations are not necessary. If station 0.00 was omitted, Process Road Design would use the normal template in any case from station 0 to 250. Similarly, Process Road Design will use the normal template going forward from station 900 automatically.

Review of 2 Methods of Matching Portions of Existing Roads

There are two main techniques for tying new template designs into existing roads, which may apply to road expansions, urban re-paving, grade improvements and other renovation projects. As more and more roadwork involves road improvement rather than new road development, these techniques become more useful and critical to master. The two techniques are: (1) Use of Template Point Profile and Template Point Centerline files to match existing conditions on portions of roads that do not change, and (2) Use of the "As-Built" cross section feature as one of the input files. An advantage of the As-Built method is that you can insert section points with special IDs for special features, whereas the Template Point Profile and Template Point Centerline methods must follow template IDs that

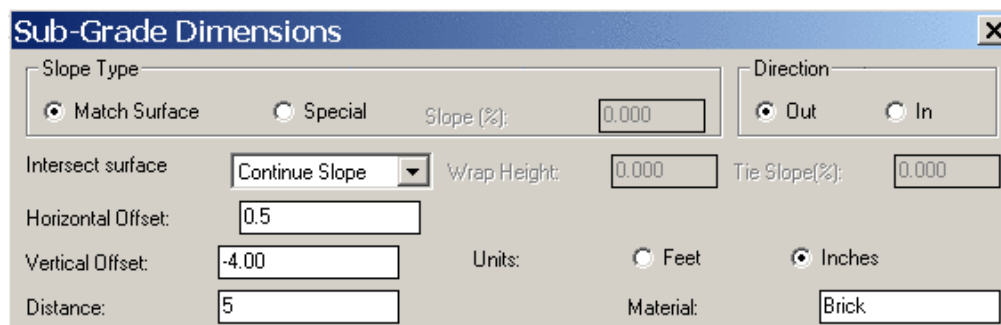

are found in the original, main template design file. But the Template Point or "string" method allows for calculating sections at any interval, while the As-Built section method will revise final sections only at stations found in the As-Built section file.

Consider this alley-way, which consists of a Belgian block style curb (no gutter) that is already in place. The plans are to remove a crowned asphalt alleyway and put in a bricked alleyway on sand, with a central, "depressed" rock drain of 1' width, to avoid water draining against buildings that abut the alley. But the design must match an existing "Belgian block" style curb on the right side of the road, which will not be removed.

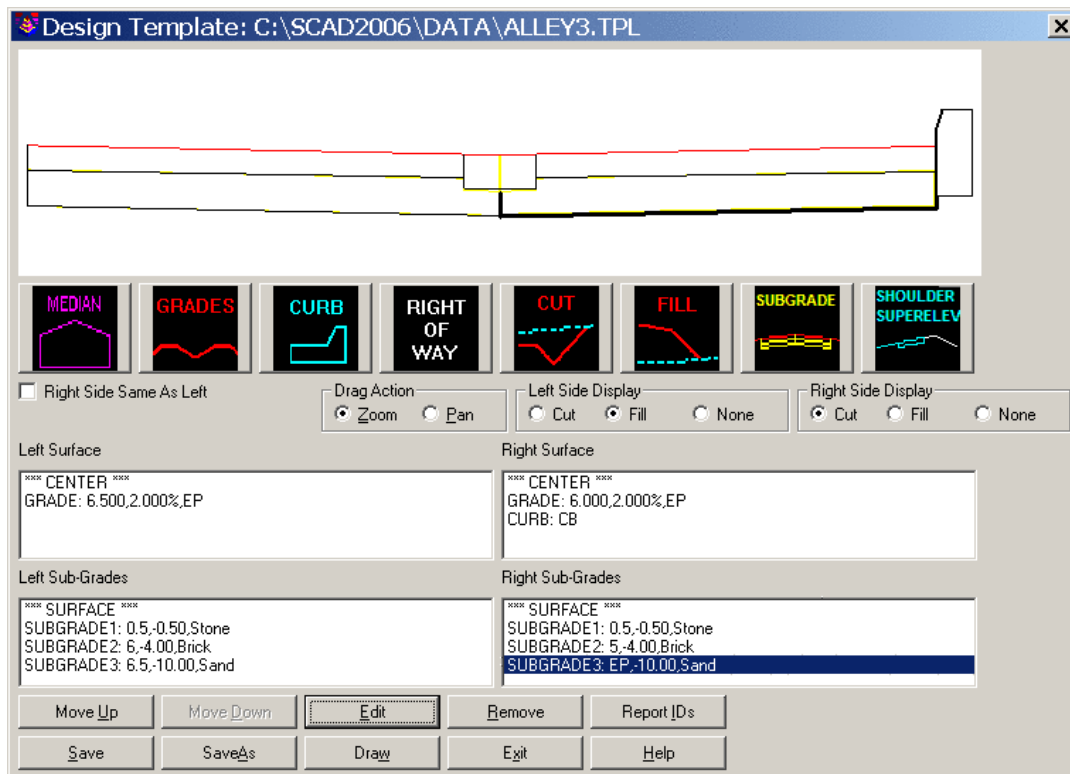

There is a new profile design involved, and a new template. However, the right side of the template will meet the exact grade and offset of the in-place curb, which has been surveyed as back of curb (CB3). Then the command Offset 3D Polyline was used to create the face of curb at EP=CB1, and to create the inside top of curb (CB2). Because of the symmetry and consistency of the curb, only the back of curb needed to be surveyed to hold the existing curb feature in place within Process Road Design. From that survey, the 3D Polyline for the EP is derived, which will be used for Template Point Centerline and Template Point Profile.

Features such as curbs and medians can be designed once within Design Template and then saved as curb or median files, then re-loaded and used in other templates, and applied to the left or right side of the template as desired. The central rock median of 1' total width can be constructed as two subgrades, one on the left side of 0.5' width and one on the right side of 0.5' width. The brick portion can be designed as a 4" thick subgrade as shown below. On the left side, you would need to use the "Straight Up" method of closing the subgrade surface. On the right side, you can use "Continue Slope". When using Continue Slope, it is best to underestimate the length needed to contact the next surface (the right curb), so continue can do an "extend" and find it. If you make the length too long (e.g. 6', which catches the curb which itself tilts back -2%), the program will not trim and will draw the subgrade to the back of the curb. Note that the vertical subgrade depth can be entered as 4 or -4. Both are accepted.

Be sure to define the sand subgrade on the right side (lowest subgrade) to have a distance of EP, a flexible distance

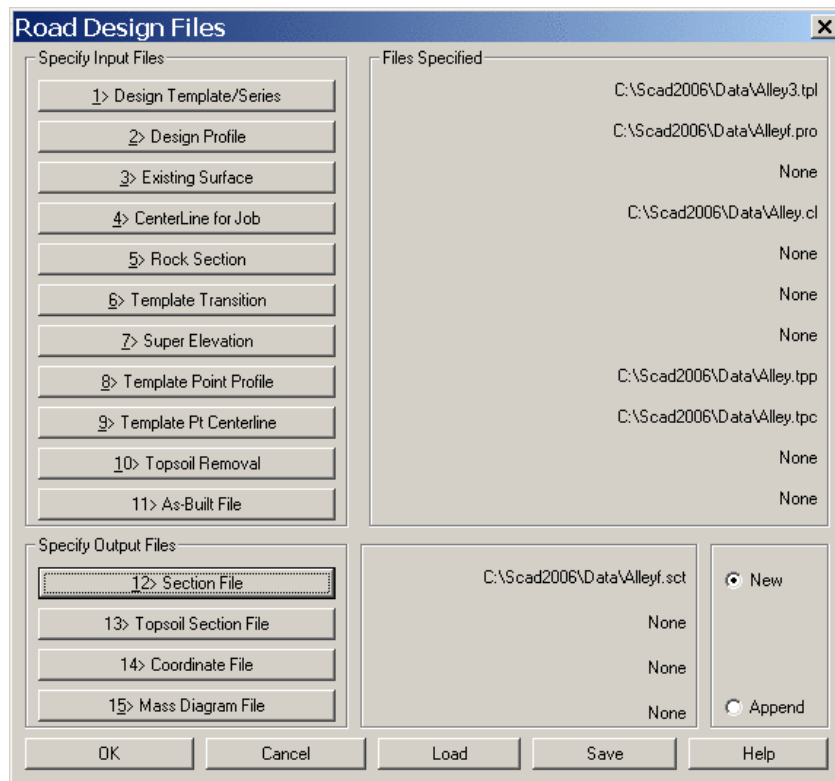

that follows the precise offset of the EP "ID", which will be assigned to follow the face of curb template point profile defined by CB1 above.

The next step is to set up the face of curb 3D polyline as a template point centerline and template point profile assigned to "EP". First you must do Polyline to Centerline File, pick the inner 3D polyline which is face of curb at proposed road level. Then you must do Profile from 3D Polyline and make a profile for the "EP". Then you assign this centerline and profile to the appropriate ID (EP) to force the curb to contact the correct curb position and elevation. The curb defined in the template matches the pattern of the in-place curb, so by setting EP to the correct template centerline and profile, the curb will "follow" at the correct position. The stationing used for the template point centerline is not critical to the calculation. However, the profile stationing much match and reference the centerline stationing. Therefore, when doing the command Profile from 3D Polyline, answer Yes to the question: "Station by another reference centerline [Yes/<No>]:". Making the Template Point Profile is always best accomplished by this method of Profile from 3D Polyline, referencing the design centerline. The Template Point Profile (and Template Point Centerline) would appear as shown here:

The files in Process Road Design would be set up as follows:

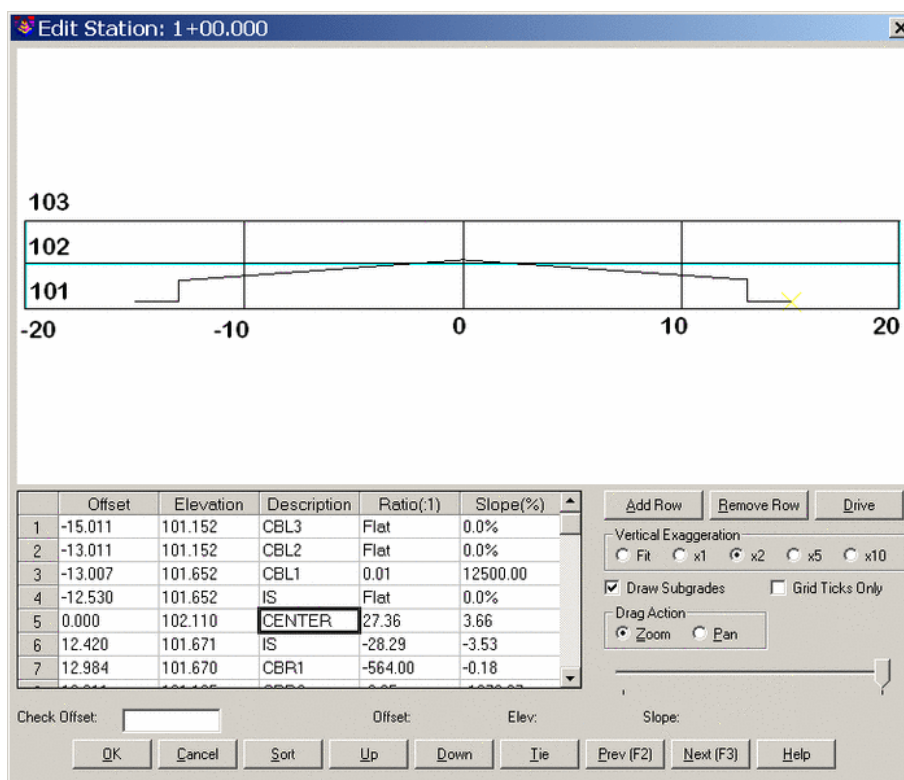

Note that no existing surface file is needed to compute final cross sections from as-built (straight wall on left of alley) to as-built (existing curb on right of alley). A final section is plotted below, showing the unique slope and lane distance determined by the as-built centerline and profile files that control the edge of pavement, and by extension, the curb, which continues with fixed dimensions from the edge of pavement.

A second method of doing as-built road design is to use the as-built cross section method. Whenever as-built cross sections are specified as part of the input files in Process Road Design, and then referenced for use on the Additional Road Design Parameters screen within Process Road, those offset IDs that are referenced will be held. Any matching IDs or new IDs found in the as-built cross sections will be substituted for the designed IDs within the final sections. In the example below, it might be proposed to redesign Edgemont Road from a roadside ditch road to one with a curb and gutter as well as sidewalks. However, the designer might want to keep the existing central median, already curb and gutter with plantings.

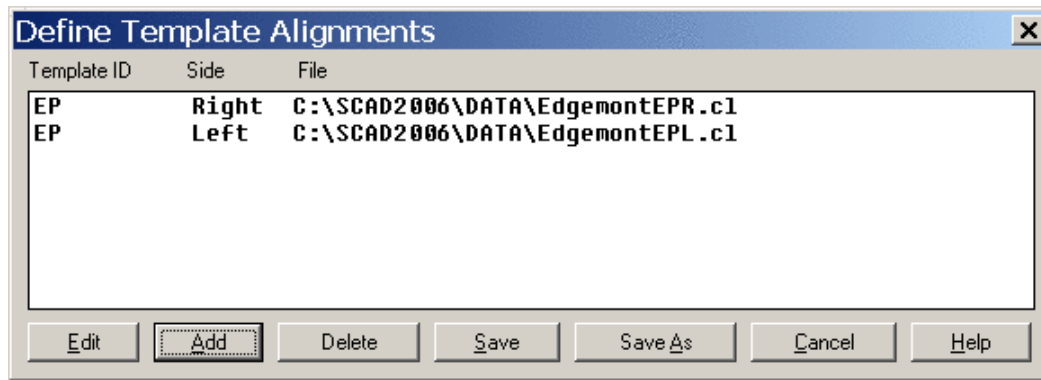

This example raises the challenging issue of inserting special interior points with new IDs into a set of design cross sections, through a length of about 125 feet of road. If a cross section of the island is taken through station 1+00, it might have the following ID points:

This cross section could then be part of an as-built cross section file (.SCT) which can be recorded at any desired station interval, the smaller the interval, the greater the accuracy. Now if the actual road template is defined as EP for edge of pavement and standard CB for curb, with CENTER for the centerline position, Process Road Design will substitute the As-Built File CENTER ID for the one calculated by the program, and will add in all the unique IDs from the cross section file, from -15.011 left to 15 right. Interestingly enough, this Edgemont Road example would also require a Template Point Centerline for the left and right edge of pavement, to pull the paving edge out to the expanded road dimension, which doesn't taper to normal until station 3+35.51. It would not require a Template Point Profile, so long as the road maintained a consistent design slope from centerline. When using Template Point Centerline, you need to turn the edge of pavement polylines into centerline files. Before doing so, test each polyline

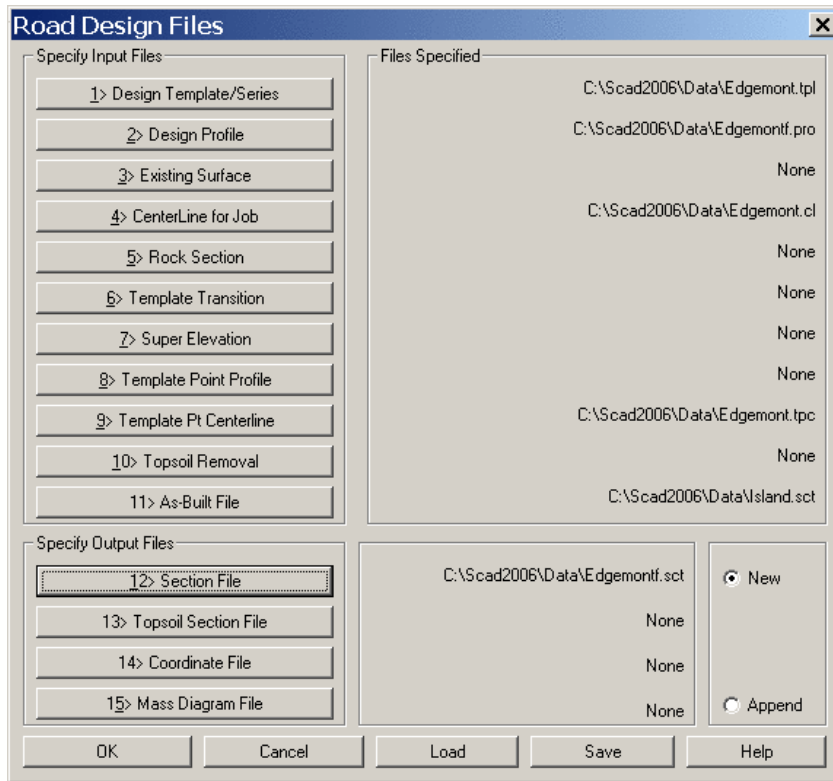

with the command Reverse Polyline (within Polyline Utilities under Edit) to verify that the polyline is drawn in the correct direction, as shown by the phantom arrows. The file Template Point Centerline elements might appear as shown:

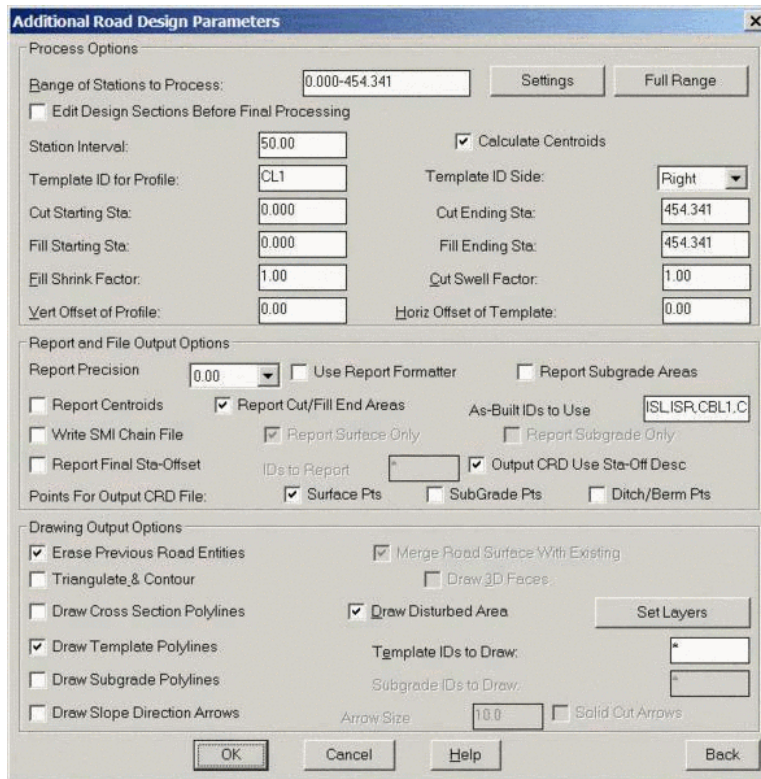

Be aware that a subgrade such as a concrete sidewalk, if it is to be placed behind the curb, must reference the curb or the edge of pavement ID for positioning, whenever the edge of pavement offset is changing based on use of a Template Point Centerline or As-Built cross section file containing duplicated IDs for edge of pavement. You can specify an offset for the sidewalk in the Subgrade option within Design Template, as shown below. The "2.52" offset was used to move past the tilting edge of the back-of-curb, which slightly exceeds 2.50.

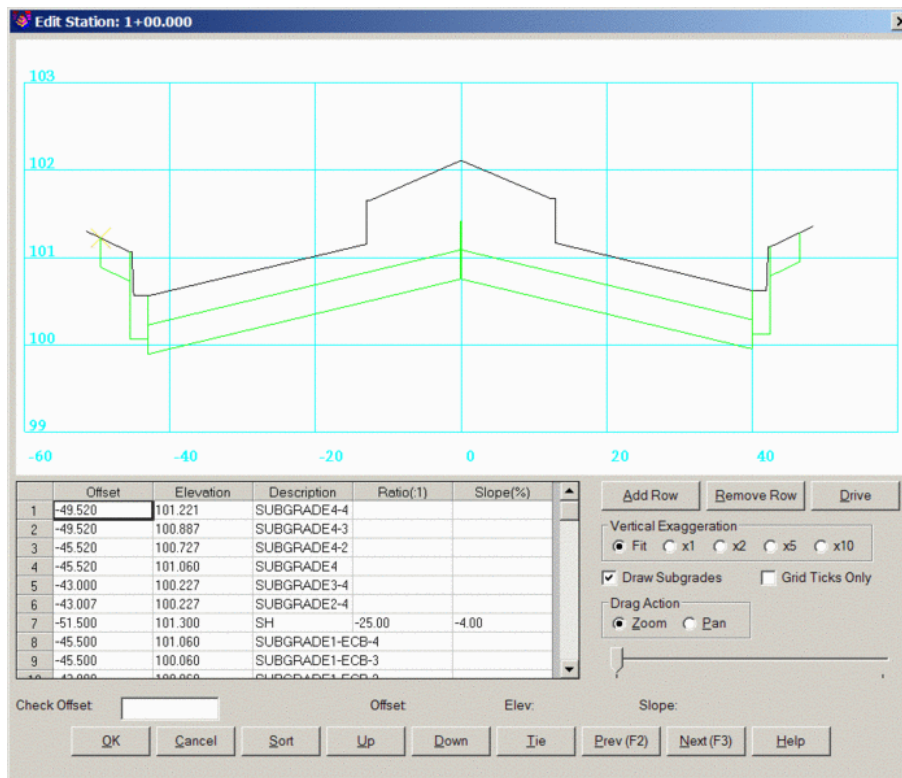

If the Island.sct file is the as-built cross sections, the entire input screen for the Edgemont Road project might appear as follows:

In the next dialog, fill in the descriptions for the section points in the As-Built IDs To Use field.

Here is the resulting output section file showing the combination of the design template with the as-built section points.

Example Divided Highway with Special Super Elevation Treatment

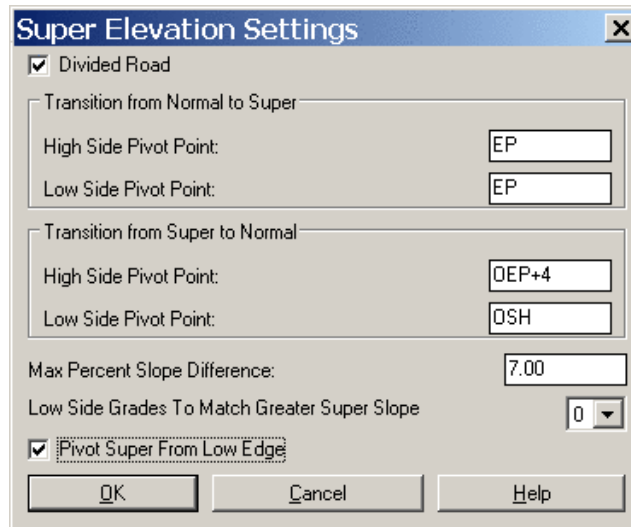

Divided highways such as 4-lane highways with a central depressed, grassy median are among the most challenging roads to define as templates, especially when accurate subgrade elevations and quantities are involved. Rules for superelevation and subgrade pivot points must be applied. And most divided highways do not use the centerline as the profile and require shifting the profile elevation to a specific template ID, like the inside edge of pavement or crown point for each side of the highway. This shifting occurs within Process Road Design. Furthermore, many highway departments have complicated rules for the profile grade. One such rule is that in superelevation, when the pivot lane reaches reverse crown, the profile moves from the crown of the road to the inside edge of pavement. Whatever the delta Z between the crown profile grade and inside edge of pavement profile grade is at reverse crown, this delta Z is subtracted from the profile grade and determines the profile of the inside edge of pavement from reverse crown through full super and back to reverse crown again. This typically improves drainage within the median portion, since a steep superelevation pivoting from the crown of the road can either reduce the median depth, or force the median too low. This is illustrated in the graphic below. Such challenging highways can be designed using special features within Design Template and Process Road Design.

The divided highway template itself can be quite complex. Let's review the requirements of our template below, first left side, then right side, in superelevation of 4.5%.

The main criteria for the design is that the pavement lanes are 12' wide, with 2% slope from the crown point in the middle (except in superelevation). On the interior high side of superelevation shown above, the grade breaks off at the EP or inside edge of pavement, and the maximum algebraic difference is 7%. So at 4.5% superelevation, the normal 4% downhill shoulder slopes instead at 7%-4.5%=2.5%, as shown. This part of the template behavior is controlled by the Superelevation Shoulder button within Design Template, with entries as shown here:

Note that the Super Elevation Settings dialog treats the "interior" of the road in the upper part, and the exterior of the entire road (like a 2-lane road) in the lower part. So the "Low Side Pivot Point" under the lower "Transition from Super to Normal" is where, walking from the middle of the road towards the left, super ends and normal slopes resume. That is set to OSH, or the outside shoulder position, the goal being to slope the full shoulder with the superelevation on the lower outside shoulder lane, then resume normal (non-super) slope at the 6:1 "recovery zone" slope. The entry of OSH as Low Side Pivot Point for Super to Normal controls that. In the upper part of the dialog, the inside "Transition from Normal to Super" sets the Low Side Pivot Point at EP. So at EP, walking from the template center left towards the left side of the road, normal ends at EP and superelevation begins. So the median upslope of 6:1 is normal, as is the shoulder, the super starts at EP. But because the 7% maximum percent slope difference is active, the shoulder can't remain at 4% but goes to 2.5% leading to the 4.5% superelevation. When super subsides to 3% or less, the shoulder would be normal at 4% as specified in the template design in this case.

Referring to the graphic above showing the left side of the divided highway, the gravel for the shoulder is shown running out to "daylight" on the outside recovery zone and on the inside median slope. However, to reduce quantities of stone, the stone runs at a uniform slope of -2% in normal crown, or matches superelevation, but pivots to 1% downhill at the outside OEP and 4' past the inside EP. This is accomplished through the subgrade entry dialog. First, the outside subgrade:

Note that the normal slope of the stone subgrade does not follow the surface but stays at the "special" slope of -2%, matching the surface always only beneath the asphalt portion within the pavement zone. For divided highways, it is always necessary to do at least 2 subgrades for each material: one from the crown or middle of the road "out" to the outslope (as above), and one from the crown or middle of the paved portion in to the interior. Since the crown of the road on each side of the highway is 32 feet left of the center depressed median position, the horizontal offset for the "out" position is 32. Enter the vertical offset as the entire distance from the horizontal offset down to subgrade bottom. In this way, any other thinner subgrades above are deducted from total subgrade quantities of the grade under consideration. If the goal is to "force" a -1% slope in both normal crown and superelevation, then set the Max Slope After Pivot(%) to -1%, and click "Special". Then set both Standard Slope and Minimum Slope Percent to -1%. This ensure that -1% will be used at the pivot offset of OEP, or as specified. Apply this to both subgrades ("in" and "out" from horizontal offset 32). If you simply entered -1% for the Max Slope After Pivot(%) and clicked Normal, slopes on the low side would break over to -1% but slopes on the higher side of each superelevation lane (beneath inside shoulder on the left, outside shoulder on the right) would continue on at the super slope and not break off. You must use the "Special" setting. The low side shoulder for the inside portion of the left side of the road is specified by the "In" subgrade, in this dialog:

Sub-Grade Dimensions

Slope Type: Match Surface Special Slope (%): Direction: Out In

Intersect surface: Wrap Height: Tie Slope(%):

Horizontal Offset: Vertical Offset: Units: Feet Inches

Distance: Material:

Super Elevation Settings

Low Side	High Side
Pivot Offset: <input type="text" value="ISH+4"/>	Pivot Offset: <input type="text" value="ISH"/>
Max Slope After Pivot (%): <input type="text" value="-1.000"/>	Max Slope After Pivot (%): <input type="text" value="-1.000"/>
Slope Type After Pivot: <input type="radio"/> Normal <input checked="" type="radio"/> Special	Slope Type After Pivot: <input type="radio"/> Normal <input checked="" type="radio"/> Special
Standard Slope Percent: <input type="text" value="-1.000"/>	Standard Slope Percent: <input type="text" value="-1.000"/>
Minimum Slope Percent: <input type="text" value="-1.000"/>	Minimum Slope Percent: <input type="text" value="-1.000"/>

OK Cancel Help

The pivot point for the subgrade on the inside left of the template is ISH+4, or 4 feet from inside shoulder to inside edge of pavement, the +4 being the direction walking out from the middle of the template in all cases. The right side of the template is shown next:

On the right side, the high-side subgrade pivot in the "out" direction, walking from the middle of the road outward, is OEP+4. On the right side, the high-side subgrade pivot in the "in" direction is simply ISH, as shown. So the controls exist to specify critical break points on subgrade and surface grades using Design Template. Whether this is the best design can be debated, but the controls are there to create surface and subgrade slope breaks and grade changes.

Referring to the Super Elevation Settings dialog above, the key to setting the superelevation of the divided highway to the inside edge of pavement at reverse crown (minus the 0.24 delta Z from profile grade to inside edge of pavement grade) is to click on the option, "Pivot Super From Low Edge".

Now you must run Process Road Design, using this template, to produce verifiable final cross sections. Set the Process Road "Additional Parameters" dialog such that "Crown" (or whatever ID is used for the center crown point on each side of the road) controls the profile grade.

Additional Road Design Parameters

Process Options

Range of Stations to Process: 0.000-1850.000

Station Interval: 50.00 Calculate Centroids

Template ID for Profile: CROWN Template ID Side: Left

Cut Starting Sta: 0.000 Cut Ending Sta: 1850.000

Fill Starting Sta: 0.000 Fill Ending Sta: 1850.000

Fill Shrink Factor: 1.00 Cut Swell Factor: 1.00

Vert Offset of Profile: 0.00 Horiz Offset of Template: 0.00

The final sections that are produced will shift the profile grade to the inside edge of pavement from reverse crown to reverse crown through superelevation, adjusted -0.24'. A final section is shown plotted below as drawn using Draw Section File:

Pulldown Menu Location: Roads

Keyboard Command: eworks

Prerequisite: Profile file and template file

Road Network

This command synthesizes road network design for subdivisions and commercial and industrial sites by enabling interactive 3D design of all road centerlines, profiles and templates, including cul-de-sacs. A docked dialog on the left of the screen identifying the existing DTM surface and all road files combines with an active CAD screen and command line. You can save drawings and run virtually any standard Autocad command while within the docked dialog. Once the user identifies all centerlines involved, the program detects intersections and end segments suitable for cul-de-sacs, and through user input of design parameters for cul-de-sac dimensions and intersection transitions, the program will process the complete 3D design, with output options including cross sections, 3D faces, TIN files and contours. The many roading files involved in a road network design are all saved to an "RDN" file that can be recalled, modified and re-processed.

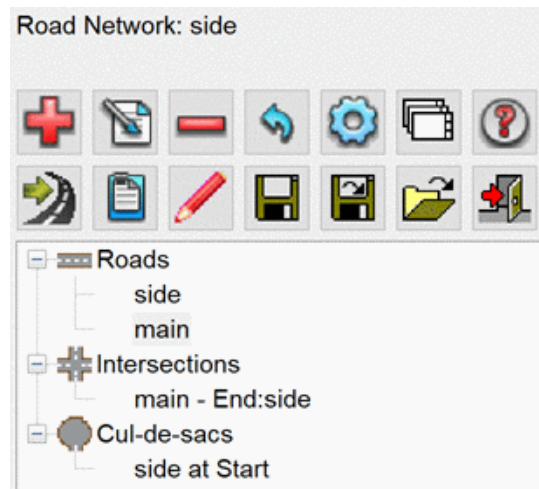

This **Road Network Help** document is divided into 7 parts: *Road Network Task Pane*, *Road Network Settings*, *Adding and Editing Roads*, *Road Network Road Profile Editor*, *Adding and Editing Intersections*, *Adding and Editing Cul de Sacs*, *Road Network Workflow Example #1* and *Road network Workflow Example #2*

When designing roads using Carlson's **Road Network** feature, all work is done through a **Task Pane** that docks along the left side of the drawing screen. Having the **Task Pane** open and active does not prohibit or interfere with normal Command: line or other CAD functionality.

All settings and files associated with a roadway design project are saved in the Road Network (.RDN) file. Upon starting the **Road Network** command, the user is prompted to open an existing or create a new Road Network

(.RDN) file in which to save the project data. Once loaded, the active Road Network filename is displayed at the top of the **Task Pane**.

Once Roads, Intersections and Cul-de-Sacs have been added to the Road Network, selecting any one of them in the project tree highlights the feature and centers it in the drawing screen. Highlighting and centering options may be changed in the **Display Options** tab of the **Road Network Settings** dialog box.

Road Network Task Pane

This area of the project tree lists the Roads defined as part of the Road Network. See **Road Network: Adding and Editing Roads** for additional assistance. The functions are accessed by right-click on the tree or by the icon buttons at the top of the dialog

Add: Pick this button to **Add** a Road to the Network. After adding the Road, the **Edit Road** dialog box is displayed allowing the user to manage and make changes to the **Input Files** and **Output Files** for the selected Road.

Edit: Pick this button to display the **Edit Road** dialog box to manage and make changes to the **Input Files** and **Output Files** for the selected Road.

Remove: Pick this button to delete the selected Road from the Road Network. After Removing the Road from the Network the design files associated with that Road will remain in the project folder.

This area of the project tree lists the Intersections within the Road Network. Intersections are created automatically as intersecting Roads are added to the Network. See **Road Network: Adding and Editing Intersections** for additional assistance.

Edit: Use this button to display the **Edit Intersection** dialog box and make changes to the **Input Data** and **Output Files** for the selected Intersection. Other changes that can be made to the Intersection design are:

- 1) Changing the Primary/Secondary status of the Roads creating the Intersection,
- 2) Making design changes that apply to the entire Intersection,
- 3) Making design changes that apply to one or more Corners of the Intersection.

Reset: Use this button to overwrite all design changes made to the selected Intersection and reset to the original Intersection design.

This area of the project tree lists the Cul-de-Sacs defined as part of the Road Network. See **Road Network: Adding and Editing Cul-de-Sacs** for additional assistance.

Add: Picking this button will display a list of Roads in the Network and prompt the user to "**Select Road**

for **Cul-de-Sac**".... After selecting the Road, the **Edit Cul-de-Sac** dialog box is displayed allowing the user to specify the **Input Data** and **Output Files** for the Cul-de-Sac.

Edit: Use this button to display the **Edit Cul-de-Sac** dialog box and make changes to the **input data** and **output files** for the selected Cul-de-Sac.

Remove: Use this button to **Remove** the selected Cul-de-Sac from the Road.

Process: Use this button to manually trigger the computation process for the Road Network and perform the tasks configured in the **Output Options** tab of the **Road Network Settings** dialog box.

Report: Use this button to Save or Print one of two Reports provided by the **Road Network** feature which are: the **Output Processing** report and the **Input Data Files** report. Default Report settings can be changed in the **Report Options** tab of the **Road Network Settings** dialog box.

The **Output Processing** Report displays the cut/fill and material quantities for each Road, Intersection and Cul-de-Sac of the Road Network.

```

Road Network Output Processing Report

The **Input Data Files** Report displays all of the user-specified design files associated with the Road Network. The user has the option of reporting only the filename or both the path and filename.

Road Network Input Data Files Report

Settings: This button displays the **Road Network Settings** dialog box which is the starting place for all projects designed using the **Road Network** feature. There are 5 tabs in the dialog box: **Process Options**, **Output Options**, **Report Options**, **Display Options** and **Transition Defaults**.

Draw: This function draws the profile or cross section for the selected road. First highlight the road name from the project tree and then pick this button. The program prompts whether to draw the design profile or output section. The draw functions call the Draw Profile and Draw Section File commands.

Save: Pick this button to **Save** the Road Network (.RDN) file.

SaveAs: Pick this button to Save the current Road Network (.RDN) file and give it a new path and/or filename.

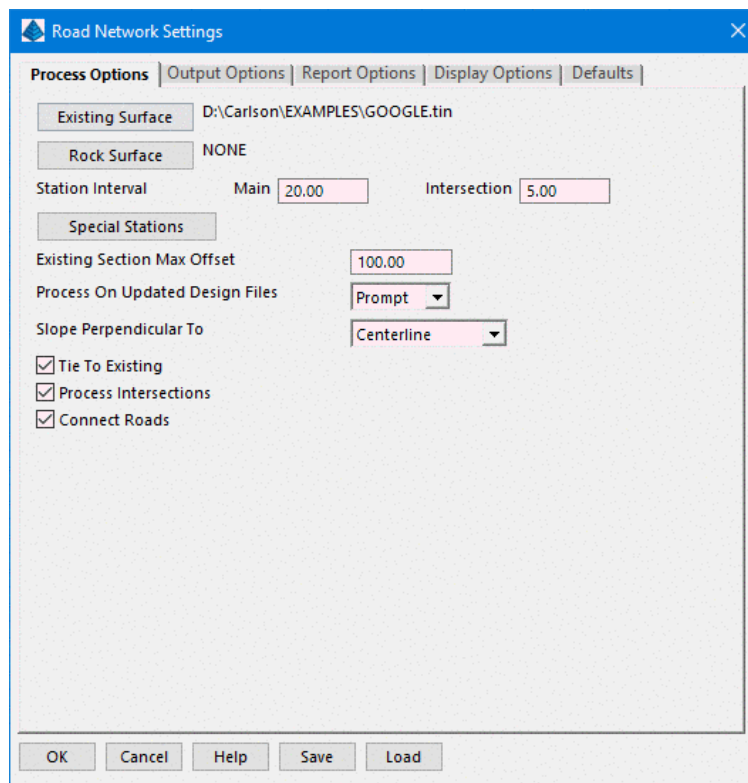

Load: Pick this button to **Load** an existing (.RDN) file.

New: Pick this button to start a **New** Road Network (.RDN) file.

Exit: Pick this button to **Exit** the Road Network command and close the **Task Pane**.

The **Road Network Settings** dialog box is accessible from the **Settings** button on the **Road Network: Task Pane**.

The **Road Network Settings** dialog box is the starting place for all projects designed using the **Road Network** feature. There are 5 tabs in the dialog box: **Process Options**, **Output Options**, **Report Options**, **Display Options** and **Transition Defaults**.

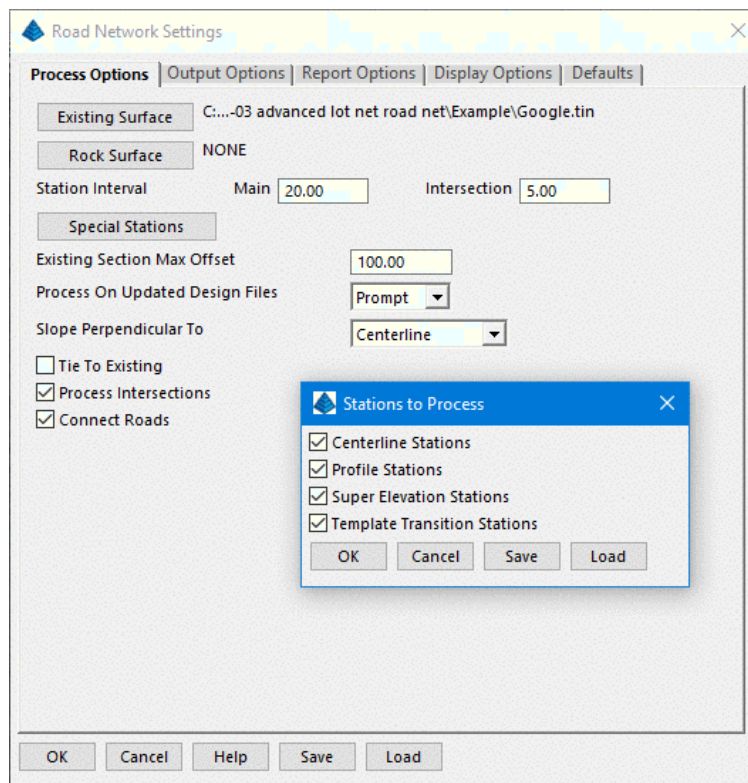

Existing Surface: Use this button to browse to and select the Existing Surface file to be used for the Road Network. Either a TIN or FLT triangulation file are accepted as valid surfaces, both of which can be made within the command Triangulate and Contour. For speed, it is recommended that the binary TIN file format be selected.

Rock Surface: Use this button to set the Rock Surface file to be used for the Road Network. This Rock Surface is optional. When the Rock surface is specified, the program will report rock quantities with the cut. Also, the cut definition in the road template file can have a separate slope to the rock surface.

Station Interval: These settings determine the distance between cross-section samples. The user has the option of specifying one sampling interval for the Intersection and another for the remainder of the Road.

Existing Section Max Offset: Use this setting to specify the furthest distance left and right of the Centerline that cross-sections are to be sampled.

Special Stations: This button displays the **Stations to Process** dialog box (shown above). This box allows the user to decide whether or not cross-sections are to be sampled at critical design points along each Centerline. **Special Stations** include critical points such as the PC & PT for Centerlines and the PVC, PVT, High Point and Low Point for Profiles. "Additional Special Stations" may be added by entering the station number. These settings apply to *all Roads* in the Road Network. To identify **Special Stations** for a particular Road, pick the **Special Stations** button in the **Edit Road** dialog box.

Process On Updated Design Files: This setting has 3 options: *Off*, *Prompt* and *Auto*:

Off: This option allows changes to the design files without triggering an automatic update to the entire Road Network.

Prompt: This option automatically prompts the user, "**Process Road Network?**" when design files are changed.

Auto: This option automatically updates the Road Network any time a design file is changed.

Prompt to Process Updated Road Network Design

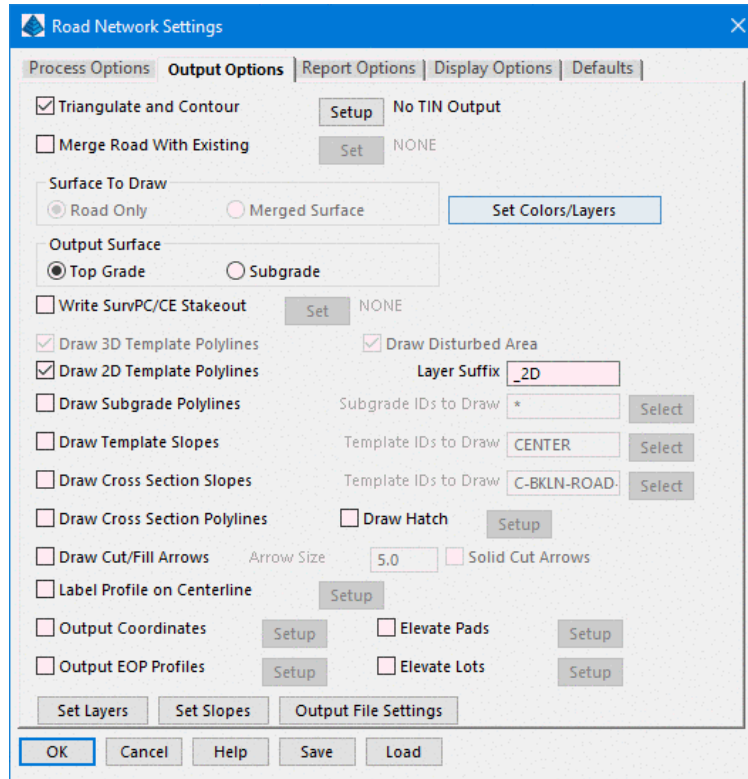

Slope Perpendicular To: This setting allows the user to specify the direction of cut and fill slope projection by selecting one of two options: *Centerline* and *Slope Direction*. The *Centerline* method projects the cut and fill slopes perpendicular to the Centerline of the Road without regard to the Profile of the Road. The *Slope Direction* method considers the Profile of the Road when projecting the specified cut and fill slopes. For example, projecting cut and fill slopes of 2:1, perpendicular to the Centerline, along a length of Road with a Profile slope of 10% would result in a slightly steeper slope (1.96:1) if measured along the top or toe of that slope. If the same conditions exist but the *Slope Direction* method is applied, the resulting slope (when measured perpendicular to the Centerline) is slightly less steep (2.04:1) but when measured along the top or toe of slope will be exactly 2:1.

Tie to Existing: If enabled and cut and fill slopes have been defined in the Template (.TPL) file, this setting will

project the specified slopes to the Existing Ground surface. If not enabled, the Road design will stop at the last **Template ID** preceding the cut and fill slopes.

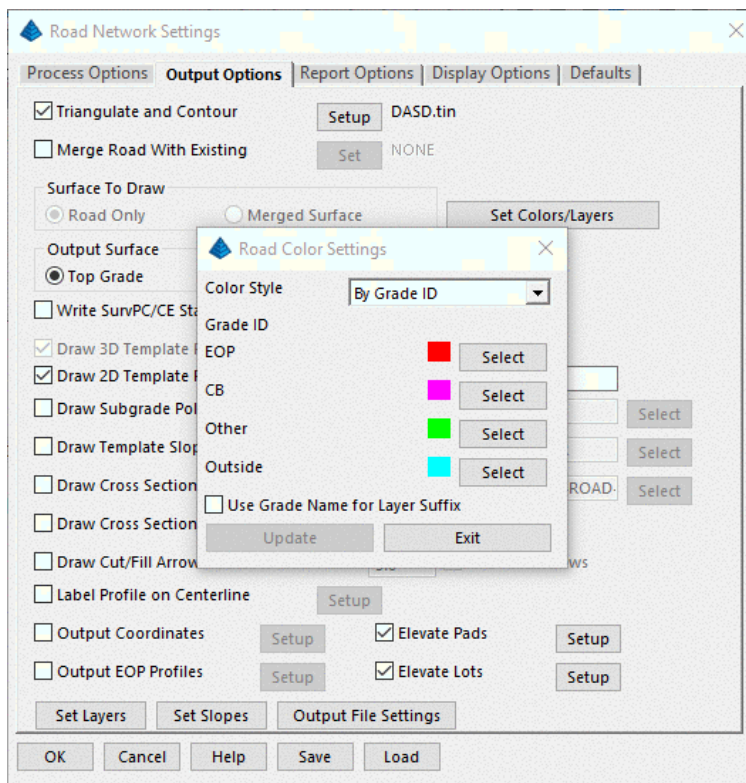

Process Intersections: If enabled this option will calculate all Roads and Intersections. If it is not enabled, each Road will be processed individually.

Connect Roads: This option applies to the 3D polylines/breaklines that are created when Processing the Road Network. If this option is enabled, the 3D polylines for different Roads will be combined around and through Intersections. If it is not enabled, the polylines will be drawn for each Road separately.

Output Options Tab

Set Road Colors: With **Triangulate and Contour** enabled, use the **Set Colors/Layers** button to display the **Road Color Settings** dialog box.

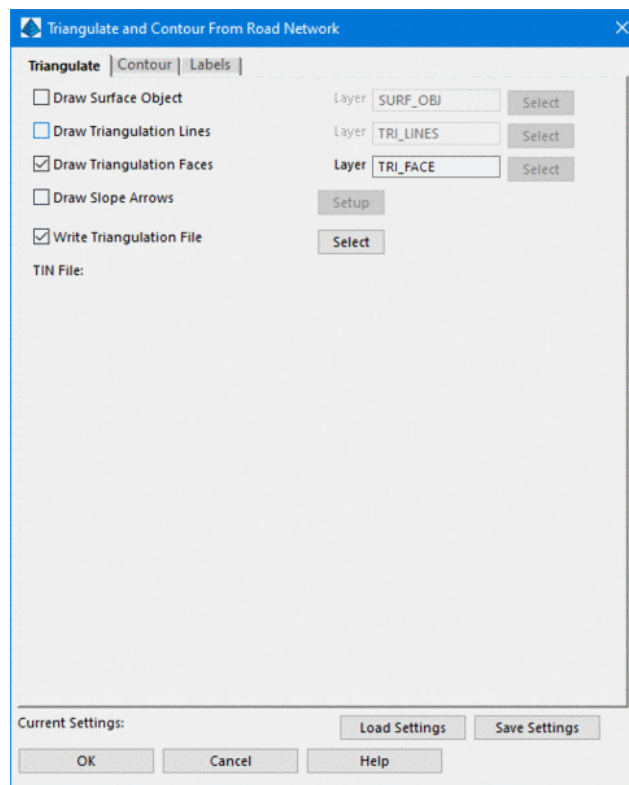

Triangulate and Contour: When enabled, use the **Setup** button to display the **Triangulate and Contour From Road Network** dialog box. Since this command is very similar to the **Surfaces** → **Triangulate and Contour** command, only those Settings and Options directly affecting the Road Network will be discussed here. Please refer to the **Help** files for that command if additional assistance is needed.

In the Triangulate and Contour From Road Network dialog box...

Triangulate tab

Draw Triangulation Faces: The **Road Network** version of this command provides additional controls (beyond those in the standard **Triangulate and Contour** command) for managing the color of the "Triangulation Faces". Once the "Triangulation Faces" option is enabled, the **Set Colors/Layers** button becomes active and, when picked, will display the **Road Color Settings** dialog box (shown below). The color of the faces can be set either by using the **Template IDs** defined in the Template (.TPL) file or using a color range based on the "Cut & Fill Depths" that uses a range of Reds and Blues to show areas and depths of Cut and Fill for the proposed Road Network. After the Road Network has been Processed, these shaded faces can be viewed using the **3D Viewer Window** command. Also within Triangulate & Contour, there is **Draw Slope Arrows** to create arrows in the drawing to show the direction of each triangular "plate" in the Road Network TIN. This can be helpful to visualize where water will be flowing.

Write Triangulation File: Once enabled, use the **Browse** button to specify the path and filename for the roadway design Surface (.TIN) file.

Contour and Labels tabs...

Use these tabs to define the settings for proposed contours and contour labels.

Output Options (Continued)

Merge Road with Existing: When enabled, use the **Set** button to specify the path and filename of a third Surface (.TIN) file to be created by merging the Existing and roadway design Surface (.TIN) files.

Surface To Draw: When creating both the road surface with Triangulate and Contour, and the combined road with existing ground using Merged Road, then this option is used to choose which surface to draw as 3D faces.

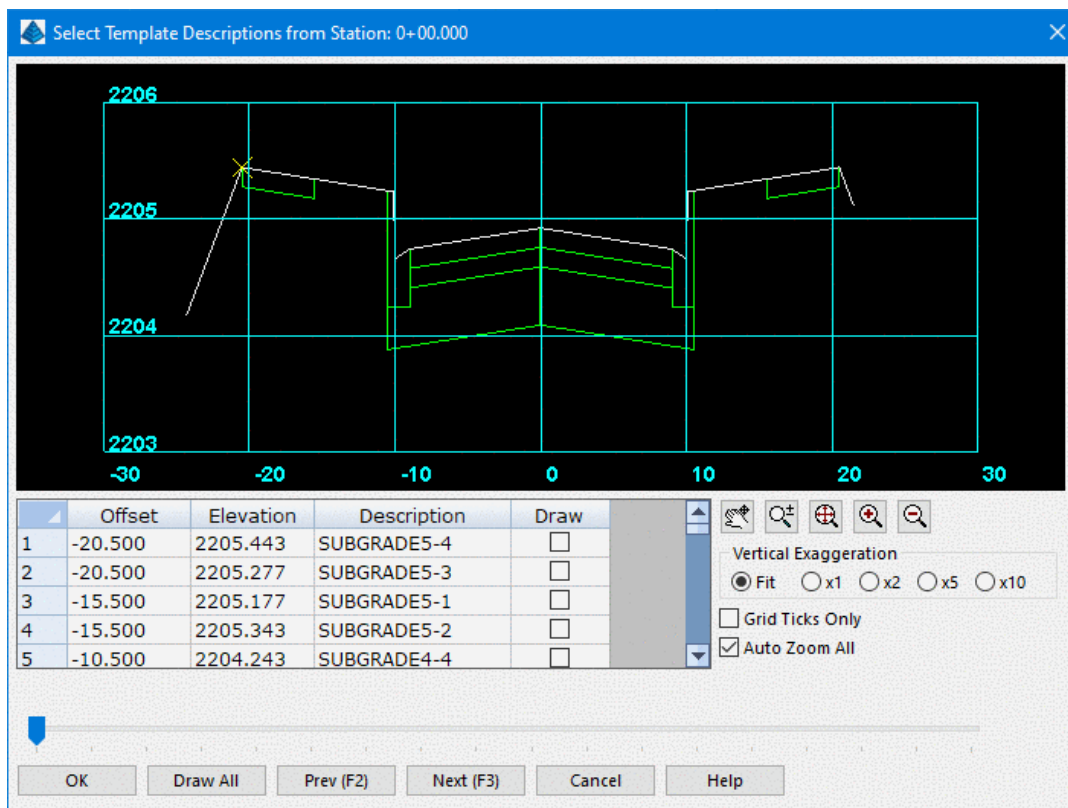

Write SurvCE Stakeout: When enabled, use the **Set** button to specify the path and filename of a SurvCE Stakeout (.RNF) file to be exported. This file can be directly loaded into data collectors using Carlson SurvCE for unlimited field stakeout of the Road Network.

Draw 3D Template Polylines: When enabled, this option will draw all 3D polylines used to generate the roadway design Surface. This option is automatically enabled when the **Triangulate and Contour** option is enabled. The layer for the polylines is set by picking the **Set Layers** button in **Output Options**.

Draw 2D Template Polylines: The 2D Template Polylines are the same as the 3D Template Polylines except that these polylines are created at zero elevation as lwpolyines. The layer names are the same except with the Layer Suffix added.

Draw Disturbed Area: When enabled, this option will draw a closed, zero-elevation polyline around the limits of disturbance of the roadway design Surface. The layer for the polyline is set by picking the **Set Layers** button in **Output Options**.

Draw Subgrade Polylines: When enabled, this option will draw all 3D polylines used to generate the roadway subgrade Surface(s). These polylines can be used to manually generate additional surfaces for modeling, stakeout or machine control purposes. Entering an asterisk (*) in the text box will draw polylines for all **Template IDs**. Once a Road has been added to the Network, the **Select** button will be activated. Picking the **Select** button displays a view of the Template (.TPL) file at the starting station and allows the user to **Draw** polylines for selected Subgrade IDs. If needed, the **Next** and **Previous** buttons at the bottom of the window allow the user to browse through the stations of the road design to find a particular Subgrade ID. The layer for the polylines is set by picking the **Set Layers** button in **Output Options**.

Pick Subgrade Polylines to Be Drawn

Draw Template Slopes: When enabled, this option will draw slope arrows parallel to the Centerline at the selected **Template IDs**. This option may be used to indicate direction and steepness of slope along the flowline of the gutter. Entering an asterisk (*) in the text box will draw slope arrows for all **Template IDs**. Once a Road has been added to the Network, the **Select** button will be activated. Picking the **Select** button displays a view of the Template (.TPL) file (similar to the one shown above) and allows the user to **Draw** polylines for selected **Template IDs**. If needed, the **Next** and **Previous** buttons at the bottom of the window allow the user to browse through the stations of the road design to find a particular **Template ID**. The layer for the slope arrows is set by picking the **Set Layers** button in **Output Options**. Other slope arrow settings are specified by picking the **Set Slopes** button in **Output Options**.

Draw Cross Section Polylines: When enabled, this option will draw a 3D polyline defining the roadway design surface cross-section at each sampled station along the Centerline. These polylines can be used to manually generate additional surfaces for modeling, stakeout or machine control purposes. The layer for the polylines is set by picking the **Set Layers** button in **Output Options**.

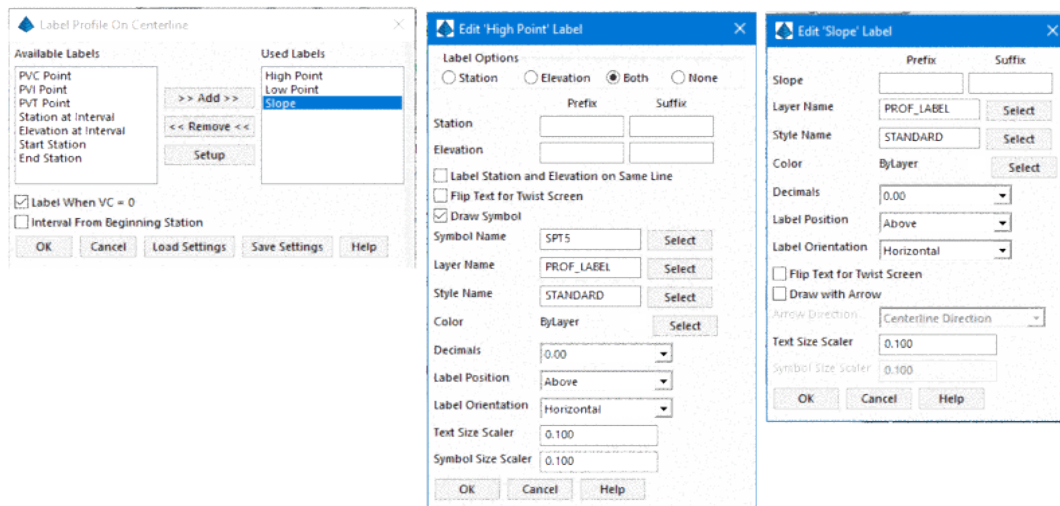

Draw Hatch: This option will hatch the grade areas. Pick the Setup button to define which hatch pattern to use for each Template Grade ID.

Draw Cut/Fill Arrows: When enabled, this option will draw arrows at each sampled cross-section station so that the arrow is pointing down-slope. The example shown below indicates a section of Cut slope transitioning to a section of Fill slope. Once enabled, the user has the ability to adjust the size of the arrows and specify whether or not the Cut/Fill Arrows should be solid.

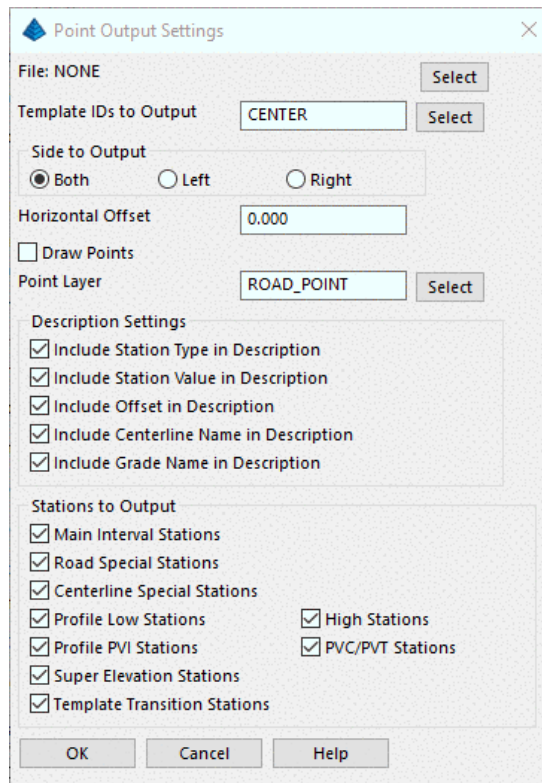

Cut/Fill Arrows On Slopes

Label Profile on Centerline: When enabled, this option labels Profile slopes and critical points such as PVC, PVT, High and Low Points in plan view along the Centerline. Once enabled, use the **Setup** button to open the **Label Profile on Centerline Settings** dialog. Then, from the list of "Available Labels", select the label(s) to be drawn and use the **Add** button to shift them to the list of "Used Labels". Selecting one of the "Used Labels" and then picking the **Setup** button allows the user to configure the label style and settings for each type of label.

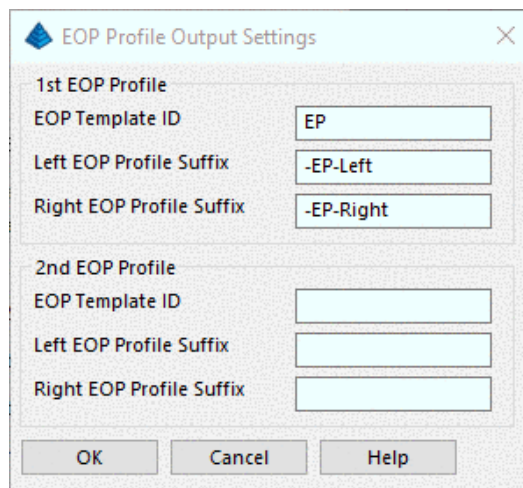

Label Profile on Centerline and Label Setup Dialog Boxes

Output Coordinates: When enabled, this option allows the user to export a Coordinate (.CRD) file containing all of the critical points for the Road Network. Once enabled, pick the **Setup** button to specify the path, file name and other criteria for the point file.

Point Output Settings Dialog Box

Output EOP Profiles: This option creates individual Profile (.PRO) files for the specified template grade such as the edge of pavement. The EOP profiles use the stations of the main centerline and the elevations from the template grade. You can create up to two EOP profiles such as for curb flow line and top-of-curb.

Output EOP Profiles Dialog Box

Elevate Pads: When enabled, this option adjusts the elevation of closed polylines within a specified proximity of the Road Network. Once enabled, use the **Setup** button to open the **Elevate Pad Settings** dialog box and configure the settings.

In the Elevate Pad Settings dialog box...

Reference Template ID: When determining the new pad elevation, all distances and elevation changes are based on the **Template ID** specified here. Type the **Template ID** in the text box or use the **Select** button to choose from a list.

Pad Layer: All original polylines found on this layer (and within the Max Offset of the Reference Template ID) will be elevated.

Max Offset: All original polylines within this distance of the Reference Template ID and on the specified "Pad Layer" will be elevated.

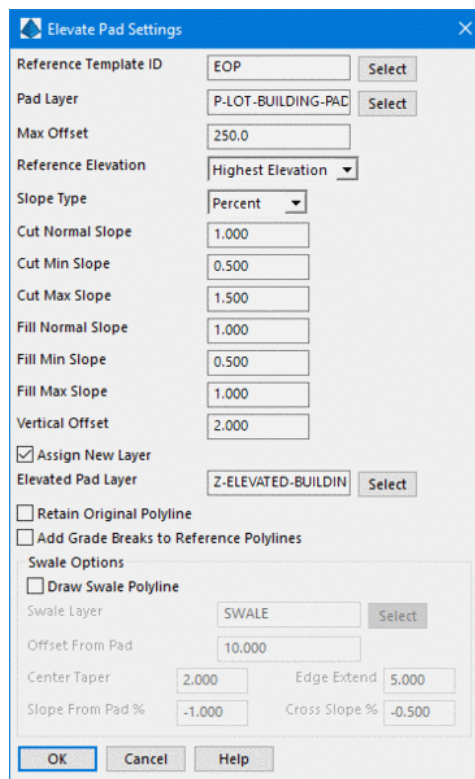

Reference Elevation: This setting has 3 options: "Highest Elevation", "Lowest Elevation" and "Elevation at Middle". Of the elevations found along the **Reference Template ID** that are adjacent to the pad polyline, the command will use either the highest, lowest or middle elevation found to set the new pad elevation.

Slope Type: This setting has 3 options: Percent (%), Ratio (x:y) and Vertical (change in elevation).

Cut/Fill, Normal/Min/Max Slopes: For future earthwork balancing adjustments, the settings in this dialog are used to specify the range of allowable slopes when in cut or fill conditions.

Assign New Layer: When enabled, this option allows the user to specify a new layer for the new, elevated pad polyline. Once enabled, either type the new layer name in the text box or use the **Select** button to choose the layer from a list.

Retain Original Polyline: This option is only available if the "Assign New Layer" option is enabled and will keep the original, zero-elevation polyline in addition to the new, elevated polyline. If this option is not enabled, the original polyline will be deleted from the drawing.

Elevate Pad Settings Dialog Box In the dialog shown here, all closed polylines on layer PAD that are within 100 feet of the road will have their elevations set based on a 2 percent grade up from the PAVE Template ID point, in either Cut or Fill conditions. In future earthwork balancing adjustments, the polyline can be adjusted a maximum of up to a 10 percent grade or down to a 1 percent grade from the Reference Template ID. The example below shows the results of elevating a pad so that it is 2.0' above (using Vertical option) the highest point along a Reference Template ID of "SH" (Shoulder) on the adjacent Road.

Elevate Pads - Example

Output Options (Continued)

Elevate Lots: When enabled, this option follows a logic similar to that of the **Elevate Pads** routine in that it elevates zero-elevation lot lines relative to a road design and based on a set of grading rules. Once the option is enabled, use the **Setup** button to display the **Elevate Lots Setup** dialog box.

In the Elevate Lots Setup dialog box...

Grading Rules: The necessity of a Grading Rules (.GRR) file is the key difference between elevating pads and elevating lots. If a Grading Rules (.GRR) file has already been prepared, use the **Select** button to browse to and select the file. To create a new file, pick the **Edit** button to open the **Define Grading Rules** dialog box and specify the desired settings. Then, pick the **SaveAs** button to **Save** a Grading Rules (.GRR) file. **Define Grading Rules** is a command that also exists outside of the **Road Network** feature. Please refer to the **Help** files for that command if additional assistance is needed.

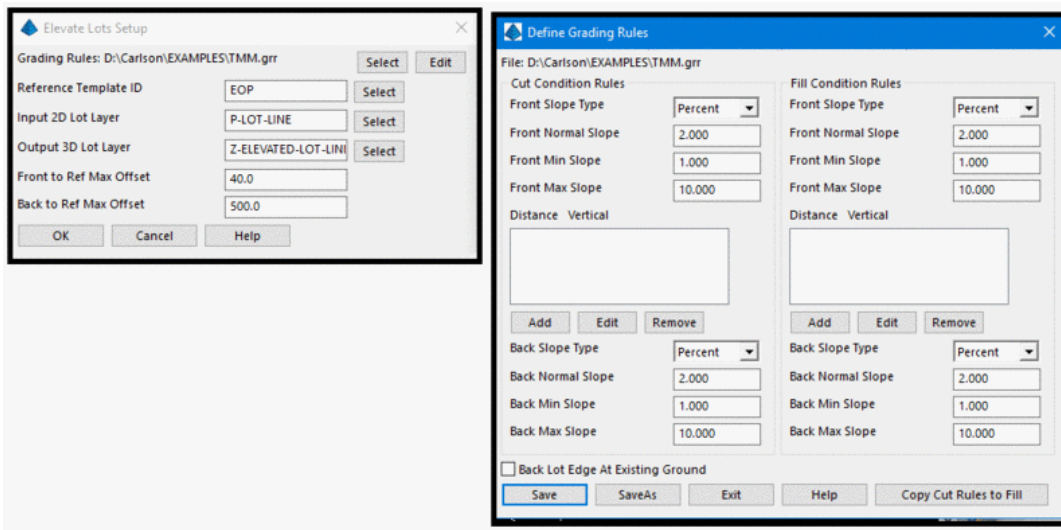

Reference Template ID: When determining the elevations for the new lot line, all distances and elevation changes are based on the **Template ID** specified here. Type the **Template ID** in the text box or use the **Select** button to choose from a list.

Input 2D Lot Layer: All original polylines found on this layer (and within the Max Offset of the Reference Template ID) will be elevated. Either type the layer name in the text box or use the **Select** button to choose the layer name.

Output 3D Lot Layer: This is the layer to which the newly elevated lot lines will be assigned. Either type the layer name in the text box or use the **Select** button to choose the layer name.

Front to Ref Max Offset: Use this setting to specify a distance from the **Reference Template ID** beyond which Lot Frontage polylines will not be elevated.

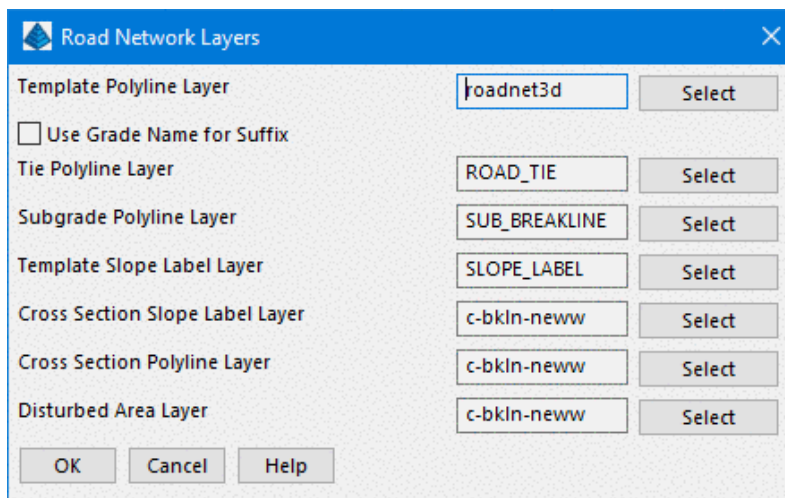

Back to Ref Max Offset: Use this setting to specify a distance from the **Reference Template ID** beyond which Back/Rear Lot polylines will not be elevated.

Elevate Lots and Define Grading Rules Dialog Boxes

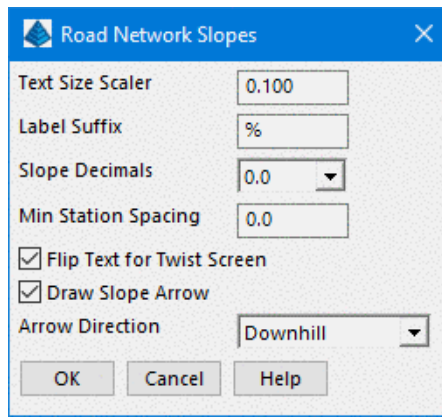

Output Options (Continued)

Set Layers: Pick this button to display the **Road Network Layers** dialog box.

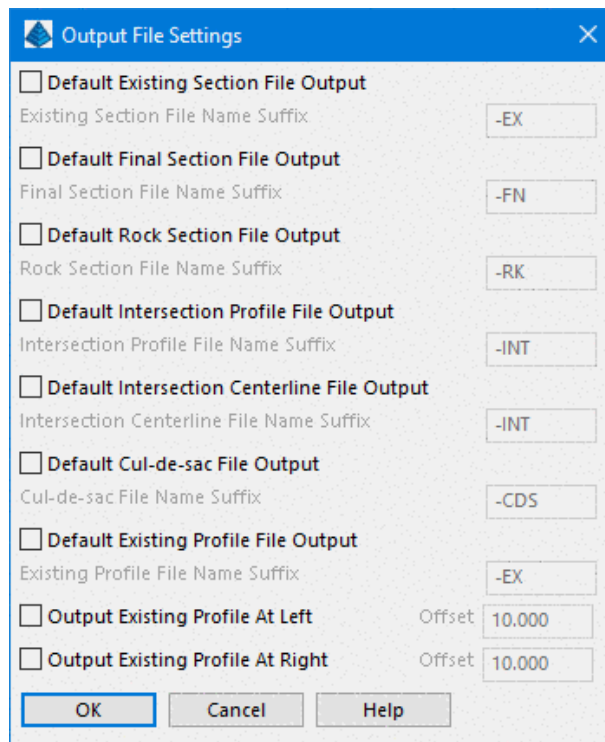

Road Network Layers Dialog Box

Set Slopes: Pick this button to display the **Road Network Slopes** dialog box and configure the settings for drawing slope arrows.

Road Network Slopes Dialog Box

Output File Defaults: Pick this button to specify default output file names for Centerline (.CL), Profile (.PRO) and Section (.SCT) files to be created when Processing the Road Network. Each item in the road design (Road, Intersection, Cul-de-sac) has its own output file names. The default options in this dialog apply to fill out default output file names when the item is first added to the road design. The Output Existing Profile At Left/Right options create offset profiles within the existing ground output profiles.

Output File Defaults Dialog Box

Settings on this tab allow the user to specify defaults for the Road Network **Report** feature. This feature is accessible from the **Report** button of the **Road Network: Task Pane**.

Report Precision: Specify the decimal precision for the report.

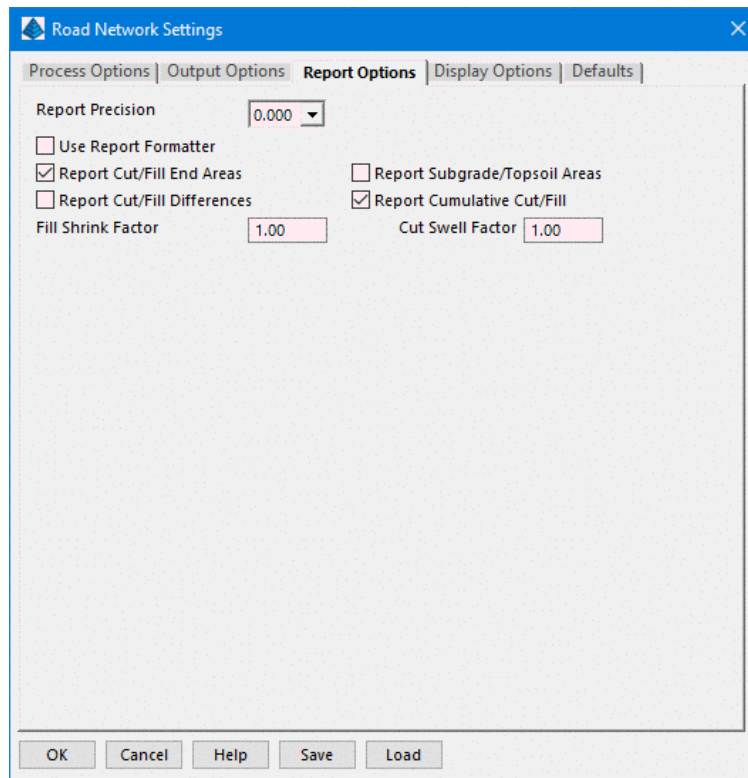

Use Report Formatter: This option allows for customized report layout and contents. Otherwise a standard report is displayed.

Report Cut/Fill End Areas: Specify whether or not to report cut/fill at each station.

Report Cut/Fill Differences: Adds a running total of the cut to fill balance at each station to the report.

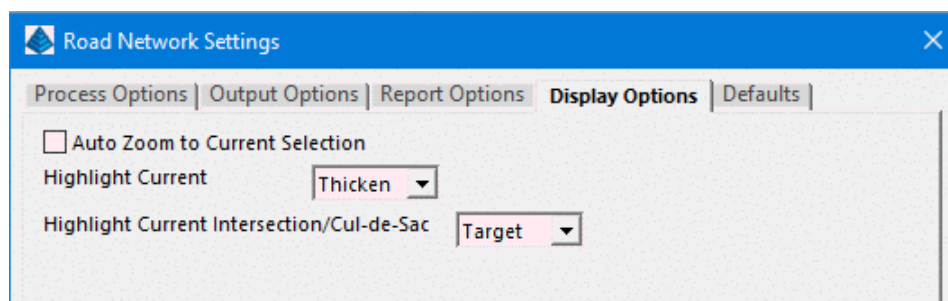

Report Cumulative Cut/Fill: Adds a running total of the cut/fill at each station to the report.

Fill Shrink/Cut Swell Factor: Allows you to specify a value that the volume calculated will be multiplied by.

Report Options Tab

Settings on this tab control how the drawing display updates when items are highlighted in the **Road Network: Task Pane**. The Auto Zoom option zooms the drawing to show the highlighted item. The **Highlight Current Centerline** chooses between no highlight, showing a thick centerline or showing a dashed centerline. The **Highlight Current Intersection/Cul-de-Sac** chooses between no highlight, drawing a pointer arrow or drawing a target circle symbol.

Display Options Tab

Settings in this tab allow the user to specify the default values used for transitioning from Road to Road, from Road to Intersection and from Road to Cul-de-Sac. There are also default dimensions and settings for new cul-de-sacs. You can also specify a default Road Design Parameter file to apply to new roads for checking parameters like max profile slope and min sight distance.

CL Intersections: Use this setting to define the default transition distance and vertical curve length for intersecting Centerlines. See **Road Network: Adding and Editing Intersections** for more.

Side Intersections: Use this setting to define the default vertical curve length for the Profile and the default radius for Corners at Intersections. See **Road Network: Adding and Editing Intersections** for more.

Surface Method: When calculating Intersections, there are two options for handling the cross-sections of the intersecting Roads: "Hold Main Crown", which honors the Primary Road Template through the Intersection, or "Radial from Curb", which grades between the Centerline Profile and the Profile of each Corner of the Intersection. The Profile for the Corner may be defined as the edge of pavement (EP), back of curb (BC) or other point on the cross-section by specifying the **Template ID** in the **Settings** tab of the **Edit Intersection** dialog box.

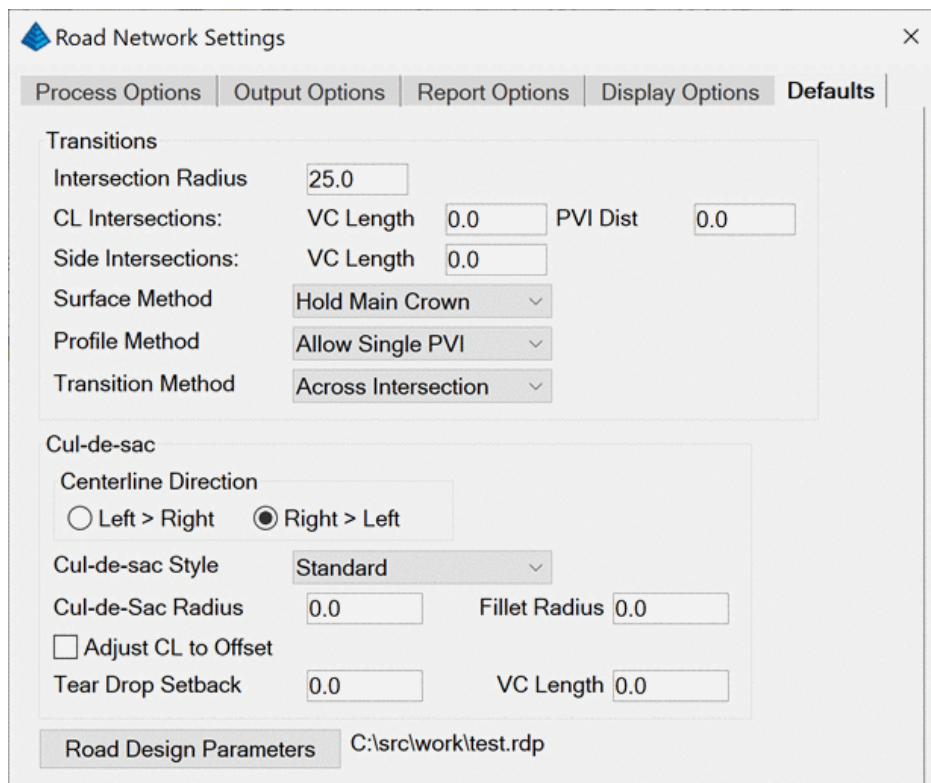

Surface Method: Radial From Curb

Surface Method: Hold Main Crown

Transition Method: This setting applies when a Road has a varying width through an Intersection. The "Across Intersection" option looks at the Primary Road (from start to end of the Intersection) to find the maximum offset distance between the Centerline and edge of pavement, and uses this distance to set the edge of pavement breakline across the Intersection with the Secondary Road. The "Mid Point" option simply finds the pavement width at the Intersection station and uses this distance to set the edge of pavement breakline across the Intersection.

Cul-de-Sac: Use this setting to define the default vertical curve length along the Cul-de-Sac Profile.

Defaults Tab

Roads in a Road Network are managed in the **Road Name** area of the **Road Network: Task Pane**.

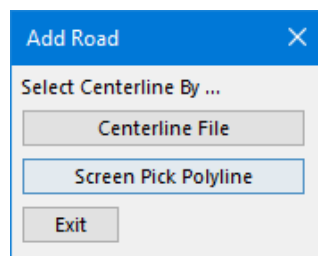

Add: Pick this button to **Add** a Road to the Network. After adding the Road, the **Edit Road** dialog box is displayed allowing the user to manage and make changes to the **Input Files** and **Output Files** for the selected Road.

Edit: Pick this button to display the **Edit Road** dialog box to manage and make changes to the **Input Files** and **Output Files** for the selected Road.

Remove: Pick this button to delete the selected Road from the Road Network. After Removing the Road from the Network the design files associated with that Road will remain in the project folder.

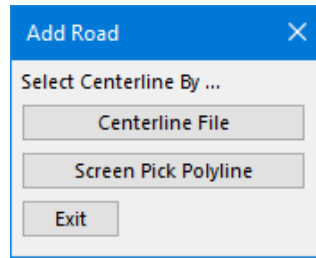

Adding a new Road may be done either by selecting a pre-defined Centerline (.CL) file or by screen-picking a 2D Polyline in the drawing and assigning a new Centerline (.CL) file to it.

Add: Use this button to **Add** a Road to the Road Network or right-click on Roads in the project tree and pick Add Road. After picking the **Add** button, the **Add Road** dialog box gives the user the option to "Select Centerline By..." **Centerline File** or **Screen Pick Polyline**. If the **Centerline File** option is chosen, the user is prompted to browse to and select the Centerline (.CL) file.

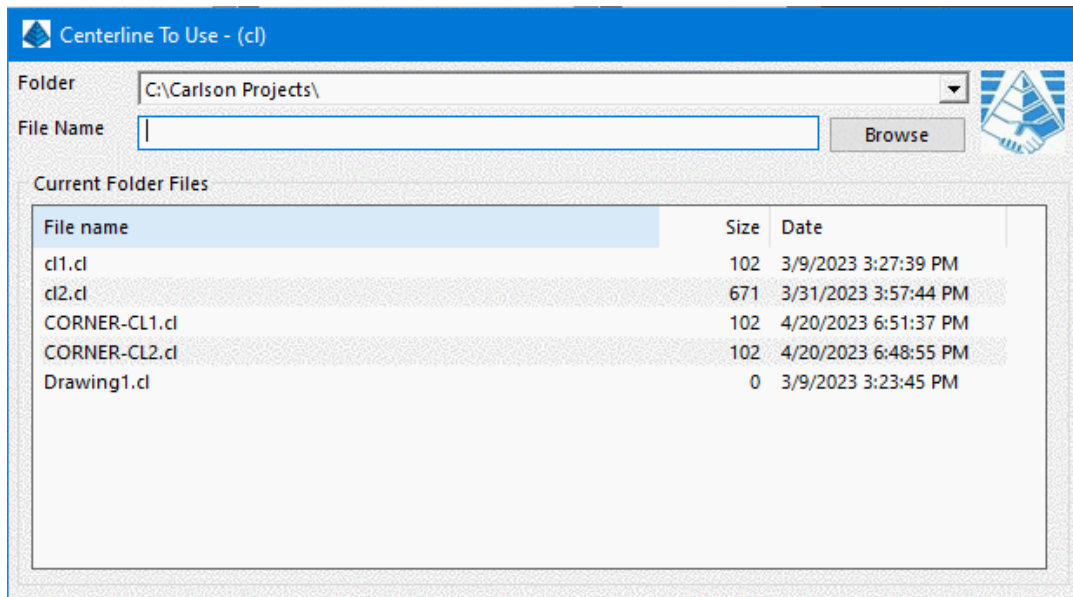

Specify Method to Use to Add Road

If the **Screen Pick Polyline** option is chosen, the user is prompted to select a polyline in the drawing. If an associated Centerline (.CL) file is not found in the project folder, the **Set Centerline** dialog notifies the user that, "No centerline file associated with polyline..." and the user must choose to either select another polyline or to **Assign Centerline File to Polyline**.

Set Centerline Dialog Box

After picking the **Assign Centerline File to Polyline** button, the **Centerline to Set** file dialog box prompts the user to assign a path and filename for the new Centerline (.CL) file.

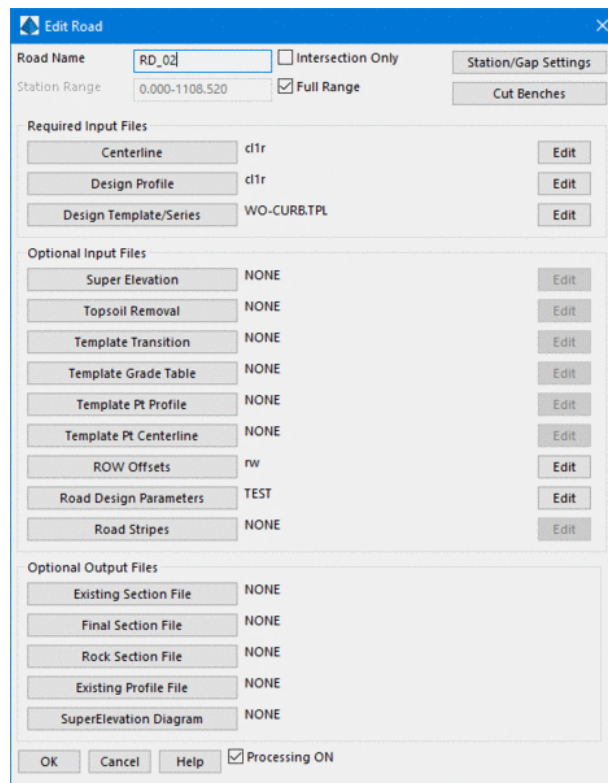

Centerline to Set File Dialog Box

Immediately upon defining the new Road, the **Profile to Use** file dialog box prompts the user to assign a path and filename for the proposed Profile (.PRO) file for the Road. By default, the new Profile (.PRO) file is named the same as the Centerline (.CL) file.

Profile to Use File Dialog Box

After specifying the Centerline (.CL) and Profile (.PRO) files for the Road, the **Edit Road** dialog box is displayed. This dialog serves as the "manager" for all files relating to the specific Road. The **Edit Road** dialog box allows the user to apply settings and associate various files that are specific to the Road - not the entire Road Network. The **Edit** button in the **Road Name** section of the **Road Network: Task Pane** also displays this dialog box.

Edit Road Dialog Box Intersection Only: If this option is enabled, Road Network will only consider the portions of this Road that intersect with other Roads when calculating the design.

Full Range: This option will process the full station range of the road. Otherwise, turn this option off and set the **Station Range** to process a subset of the road.

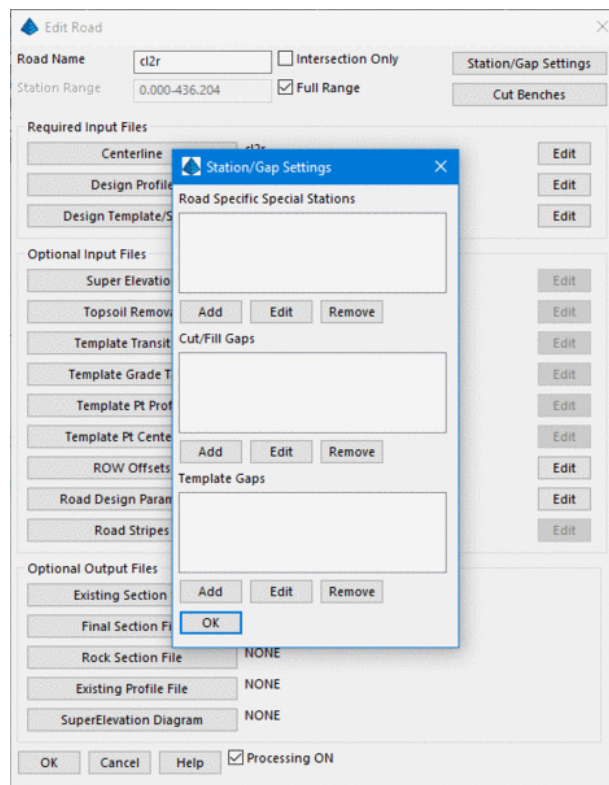

Cut Benches: Pick this button to specify up to 4 triangulation surface files to use when the "Slopes In Series" and "Cut to Surface" options are used in the Template (.TPL) file. In cut conditions, the program will look to intersect with these surfaces before it reaches the final target surface which is the Existing Surface set under Settings. The order of the Cut Bench Surfaces are from lowest to highest cut. So the Bench #1 is closest to the road and Bench #4 is furthest.

Station Settings: Pick this button to display for special stations and cut/fill gaps.

Special Stations: Enter one or more stations at which to sample cross-sections.

Cut/Fill Gaps: Use the Add and Remove buttons to define a series of station ranges for cut/fill gaps where the program will not calculate any volumes or apply the template cut/fill tie slopes. For example, these stations could be used across a bridge.

Template Gaps: These define station ranges to skip over and not create the road.

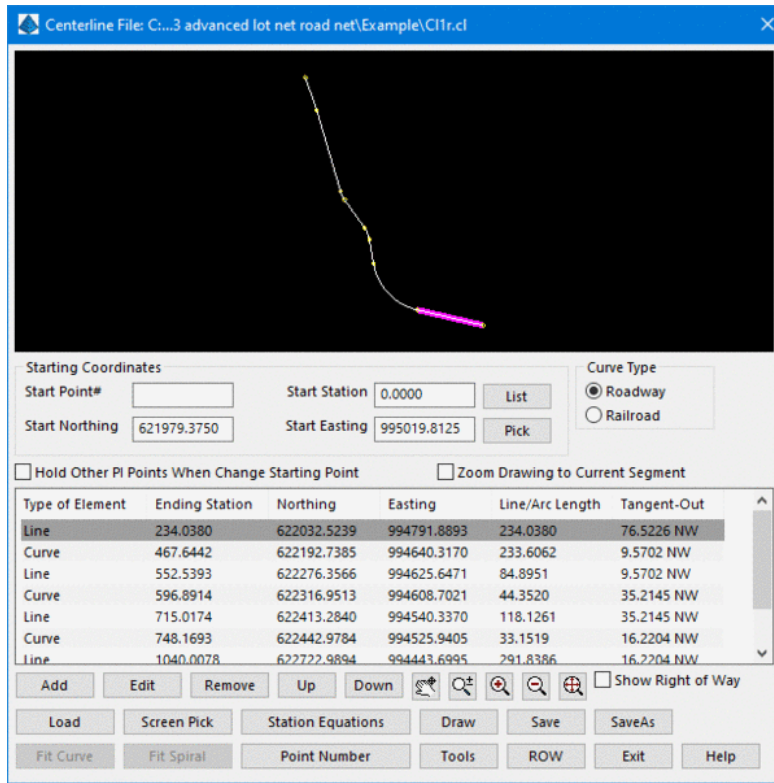

Add Road Specific Special Stations A Centerline (.CL) file, a Profile (.PRO) file and a Template (.TPL) File are **required** in order to process a roadway design using the **Road Network** feature. In addition, the **Road Network** feature accepts several additional files for designing Roads using specific criteria. In the **Edit Road** dialog box, picking the buttons on the left, that are labeled with the file type, will display a file dialog box prompting the user to select an existing or create a new file of that type. The corresponding **Edit** button to the right of each file type will display the editor for that file type.

Required Road Input Files

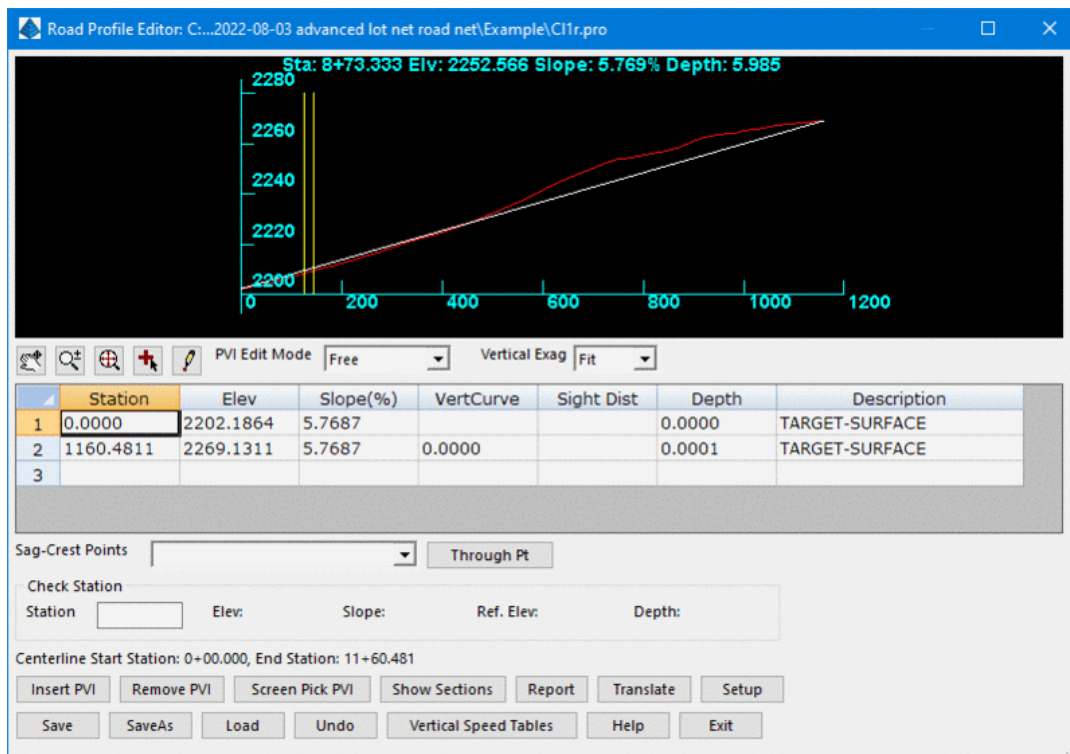

Processing On: This toggle controls whether Road Network processes this road. You may want to temporarily turn off this toggle for a road if Road Network processing isn't fully working and you want to isolate the roads having trouble.

Centerline: Pick this button to select an existing or create a new Centerline (.CL) file from which to define the horizontal alignment of the Road. The **Edit** button opens the **Centerline File** Editor. This Editor is the same as the one used for the **Centerline Editor** command. Please refer to the **Help** files for that command if additional assistance is needed.

Centerline File Editor

Profile: Pick this button to select an existing or create a new design Profile (.PRO) file for the Road. The **Edit** button opens the **Road Profile Editor**. The Editor provides the user with both a "profile-grid-view" and a "table-view" of the Profile (.PRO) file. See **Road Network: Road Profile Editor** for more.

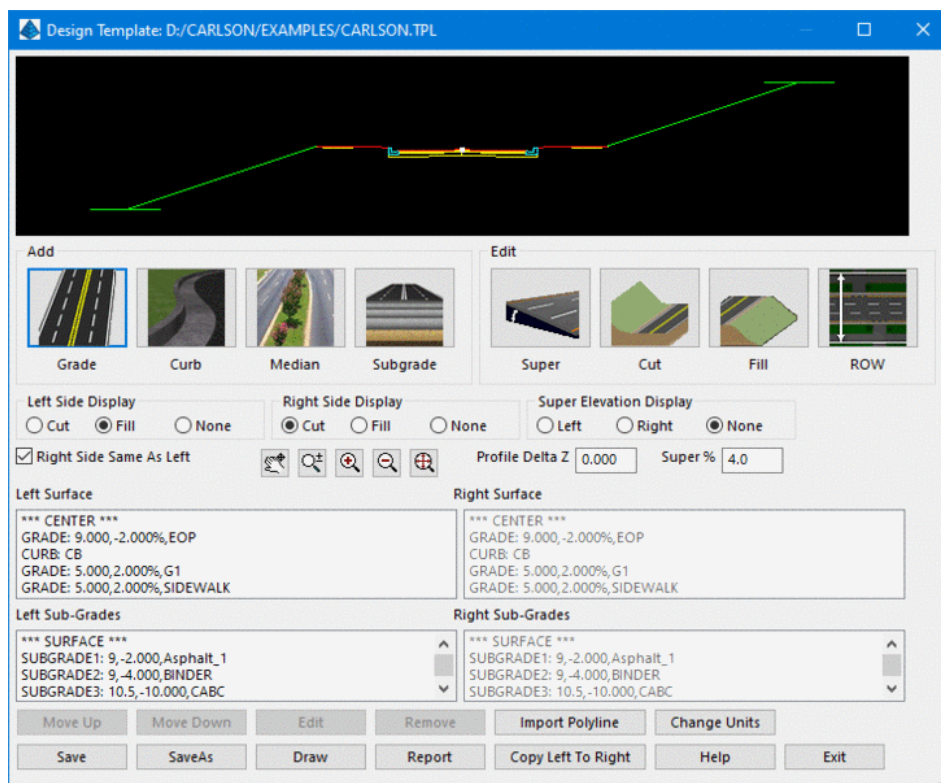

Road Profile Editor

Template: Pick this button to select an existing or create a new Template (.TPL) file or Template Series (.TSF) file for the Road.

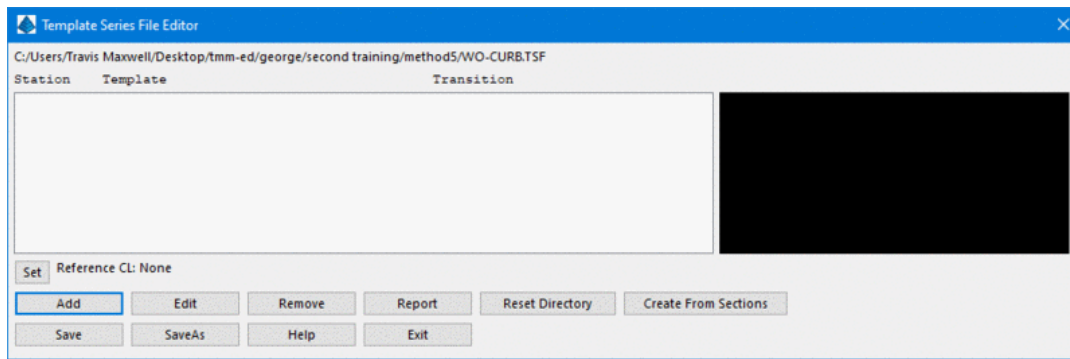

A Template (.TPL) file defines a typical roadway cross-section including pavement, curb, ditches, medians, super-elevations, subgrades, rights-of-way and cut/fill slopes. One of the most critical steps in defining a Road Template for use with the **Road Network** feature is the assigning of a **Template ID** to points on the Template. A **Template ID** is a unique name for each point on the Template and is used to transition from Road to Road, from Road to Intersection and Road to Cul-de-Sac. The **Template ID** serves 4 purposes: (1) the ID will be applied as a description to all final Template points generated in the form of a Coordinate (.CRD) file, (2) the ID can be used as a design point in the Template definition, as in EP+5 indicating 5 feet or meters right of edge of pavement, (3) points of common ID may be connected by 3D polylines in the **Output Options** tab of the **Road Network: Settings** dialog box and (4) Quantities can be generated with reference to the ID and material (gravel, concrete, etc.) also defined in the Template (.TPL) file.

A Template Series (.TSF) file references Template (.TPL) files for Template-to-Template transitioning and is one method used for widening and narrowing of Road sections.

Picking the **Edit** button will open the appropriate **Design Template** or **Template Series File Editor**. These Editors are the same as those used for the **Draw Typical Template** and **Template Transition** commands. Please refer to the **Help** files for those commands if additional assistance is needed.

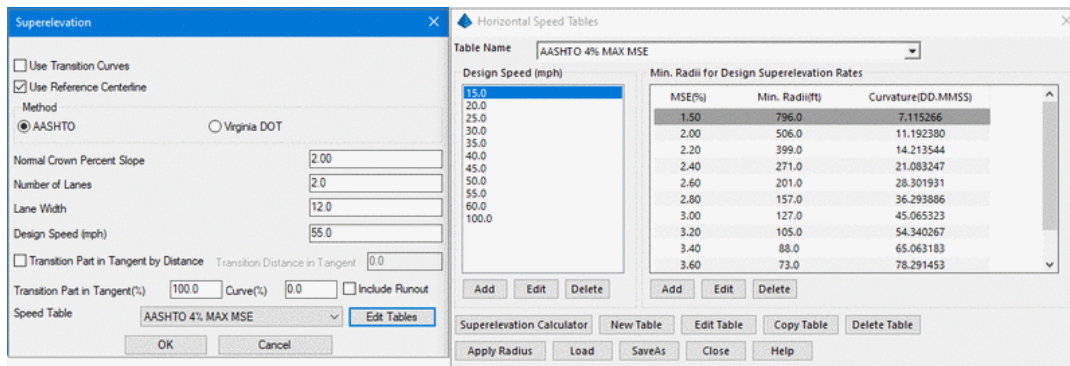

Design Template Editor

Template Series Editor

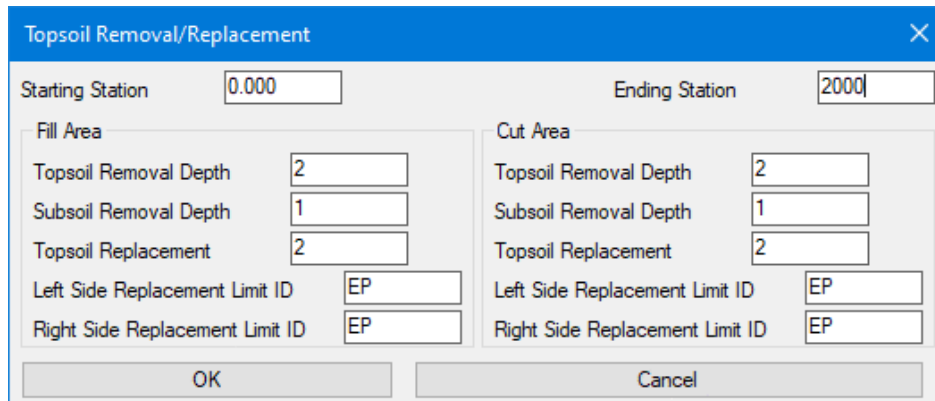

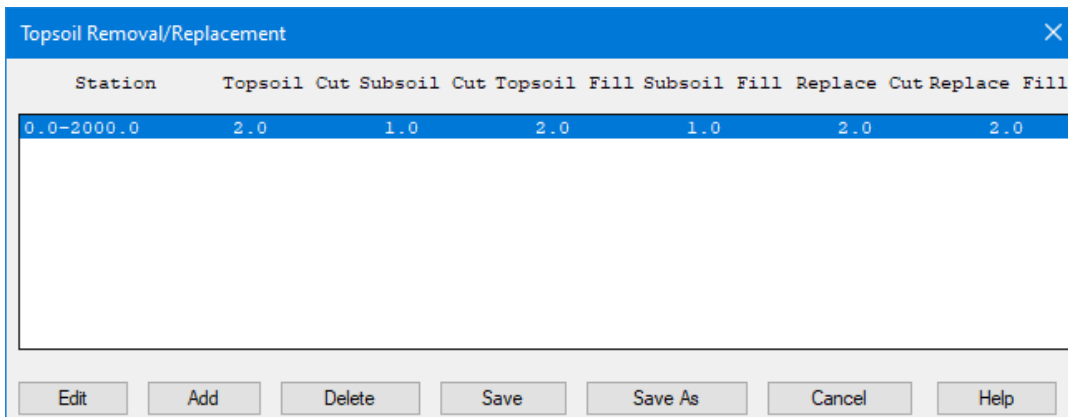

Optional Road Input Files

Super Elevation: Pick this button to select an existing or create a new SuperElevation (.SUP) file for the Road. The **Edit** button opens the **Super Elevation Editor**. This Editor is the same as the one used for the **Super Elevation Editor** command. Please refer to the **Help** files for that command if additional assistance is needed.

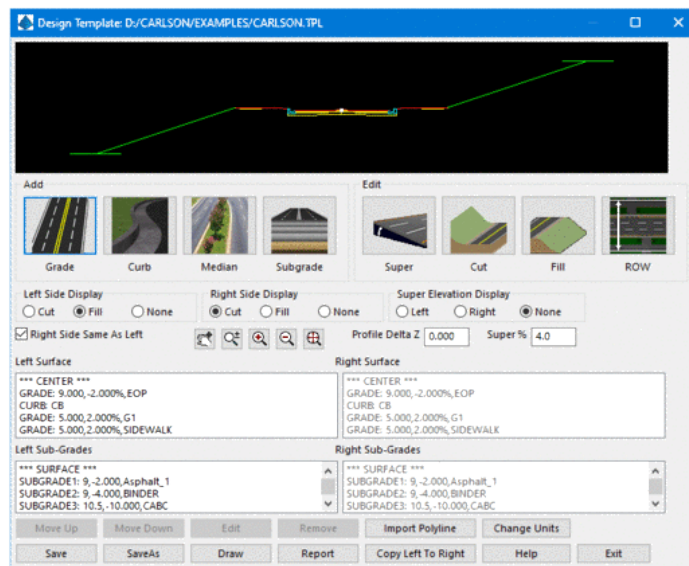

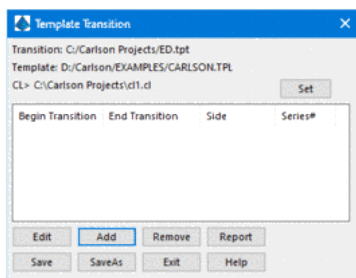

Super Elevation Editor

Topsoil Removal: Pick this button to select an existing or create a new Topsoil Removal (.TOP) file for the Road. This file allows the user to define topsoil removal and replacement zones to be used in the Road design. Different topsoil depths can be used for different station ranges and then are computed as part of the cut and fill volumes. The **Edit** button opens the **Topsoil File Editor**. This Editor is the same as the one used for the **Topsoil Removal/Replacement** command. Please refer to the **Help** files for that command if additional assistance is needed.

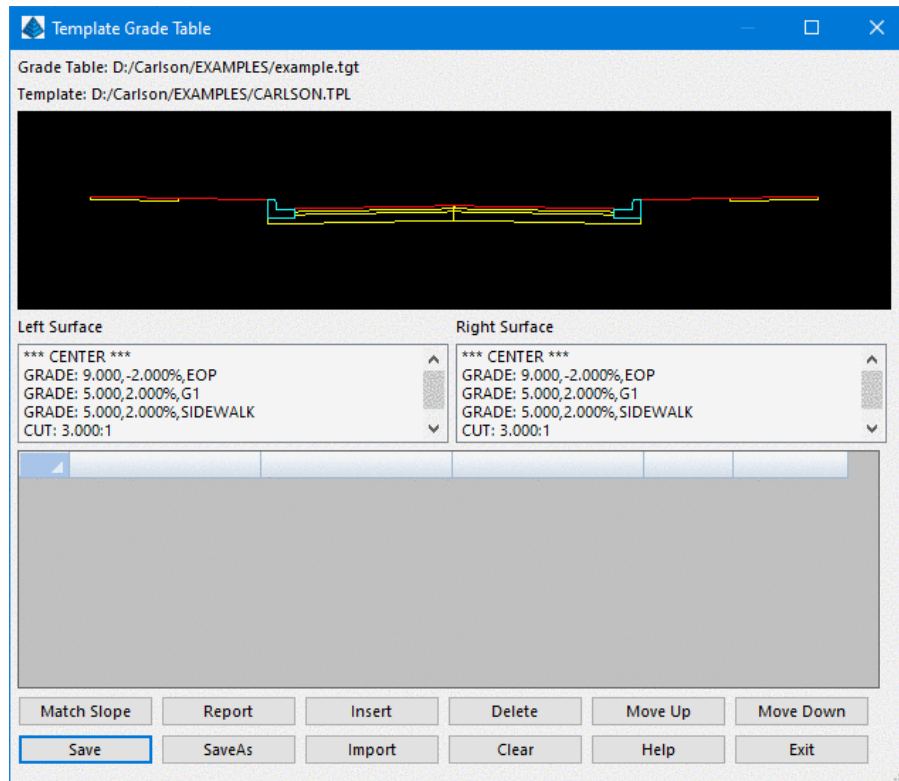

Topsoil Removal/Replacement Editor

Template Transition: Pick this button to select an existing or create a new Template Transition (.TPT) file for the Road. This file allows the user to define changes in grade distances or slopes for a specific Template ID through a range of stations and is another method of widening and narrowing Road sections. The **Edit** button opens the **Template Transition Editor**. This Editor is the same as the one used for the **Template Transition** command. Please refer to the **Help** files for that command if additional assistance is needed.

Template Transition Editor

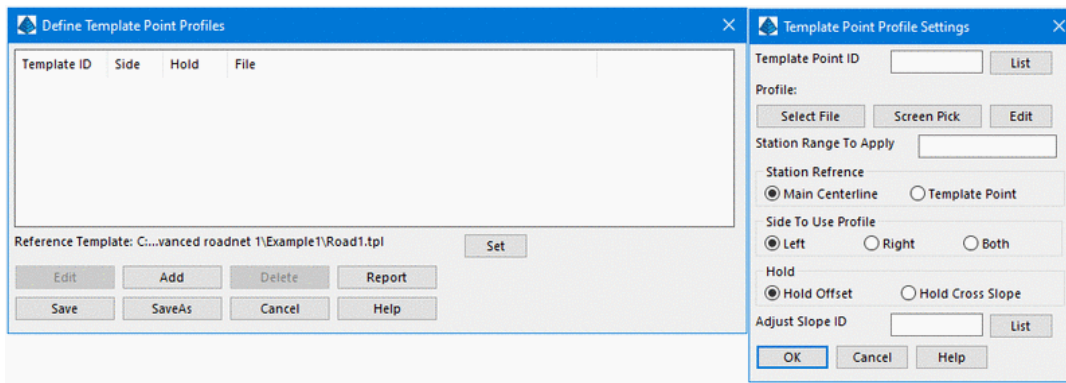

Template Grade Table: Pick this button to select an existing or create a new Template Grade Table (.TGT) file for the Road. This file allows the user to define specific slopes and distances for one or more Template IDs (and for left and right sides independently) that have been assigned in the Template (.TPL) file. The **Edit** button opens the **Template Grade Table Editor**. This Editor is the same as the one used for the **Template Grade Table** command. Please refer to the **Help** files for that command if additional assistance is needed.

Template Grade Table

Template Pt Profile: Pick this button to select an existing or create a new Template Point Profile (.TPP) file for the Road. This file allows the user to assign separate Profile (.PRO) files to specific Template IDs that have been defined in the Template (.TPL) file. This accommodates varying grade changes (for a ditch, for instance) independent of the Profile for the Centerline. The **Edit** button opens **Define Template Alignments** and then picking the **Add** button displays the **Template Point Profile Settings** dialog box. These dialog boxes are the same as the ones used for the **Assign Template Pt Profile** command. Please refer to the **Help** files for that command if additional assistance is needed.

Image error here

Assign Template Pt Profile Dialog Boxes

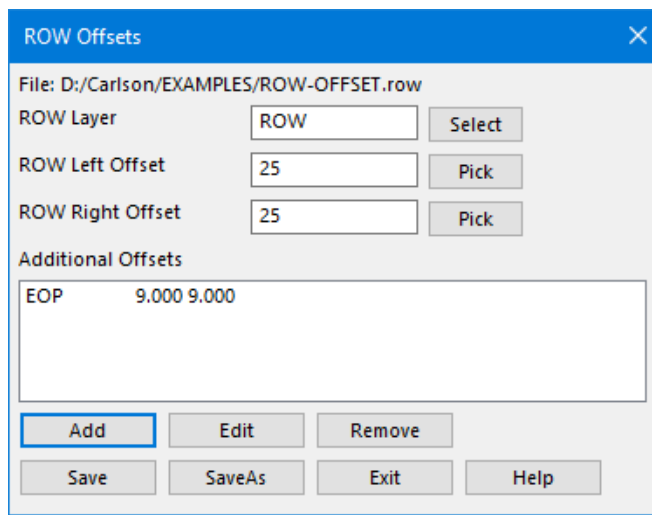

Template Pt Centerline: Pick this button to select an existing or create a new Template Point Centerline (.TPC) file for the Road. This file allows the user to assign separate Centerline (.CL) files to specific Template IDs that have been defined in the Template (.TPL) file. This accommodates varying widths for cross-section surfaces and provides an additional method of managing widening and narrowing of Roads. The **Edit** button opens **Define Template Alignments** and then picking the **Add** button displays the **Template Point Centerline Settings** dialog box. These boxes are the same as the ones used for the **Assign Template Pt Centerline** command. Please refer to the **Help** files for that command if additional assistance is needed.

Image error here

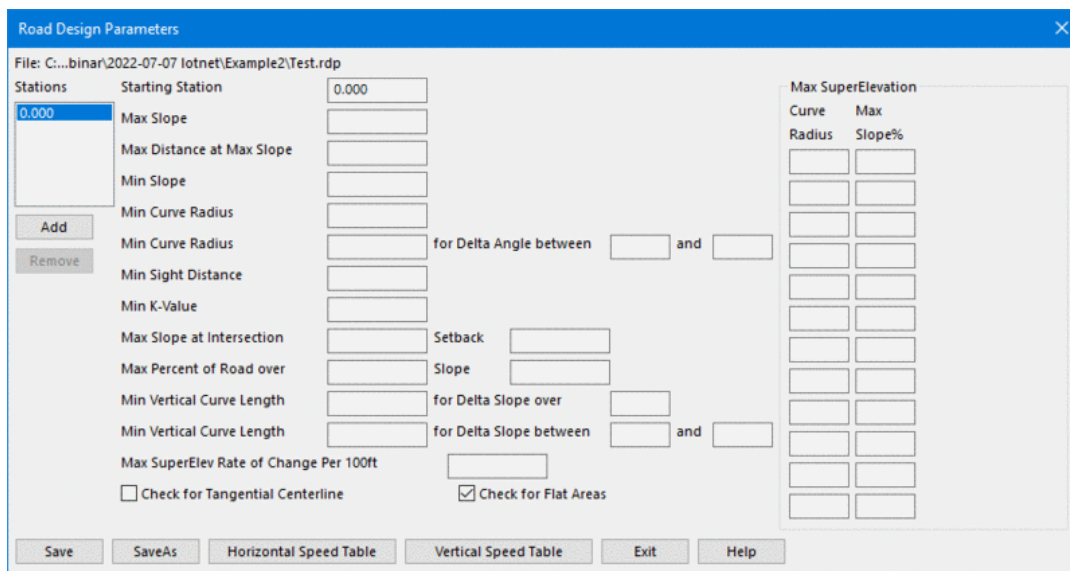

Assign Template Pt Centerline Dialog Boxes

ROW Offsets: The ROW feature draws 2D linework at specified offsets from the centerline. In the dialog, there are settings for the layer for the 2D polyline and the offsets left and right of the centerline. There is also a list of additional offsets to draw. Use the Add, Edit and Remove buttons to setup this list of offsets to draw. The names, offsets and layers for these 2D polylines is stored to a .ROW file.

Road Design Parameters: Pick this button to select an existing or create a new Road Design Parameters (.RDP) file for the Road. This file allows the user to define a set of Road design standards to compare against a roadway design. The Road Network Process function will report a warning when the design is out of compliance with these parameters. The Road Design Parameters can be specific to all stations along a Road or, in the event speed limit or other changes must be applied, a range of stations. The **Edit** button opens the **Road Design Parameters** dialog box. This box is the same as the one used for the **Define Road Design Parameters** command. Please refer to the **Help** files for that command if additional assistance is needed.

Road Design Parameters Dialog Box

Road Stripes: This option draws plan view polylines for road stripes such as double yellow lines along the centerline and dashed white lane lines. See the Draw Road Stripes command for a description of this feature.

Optional Road Output Files

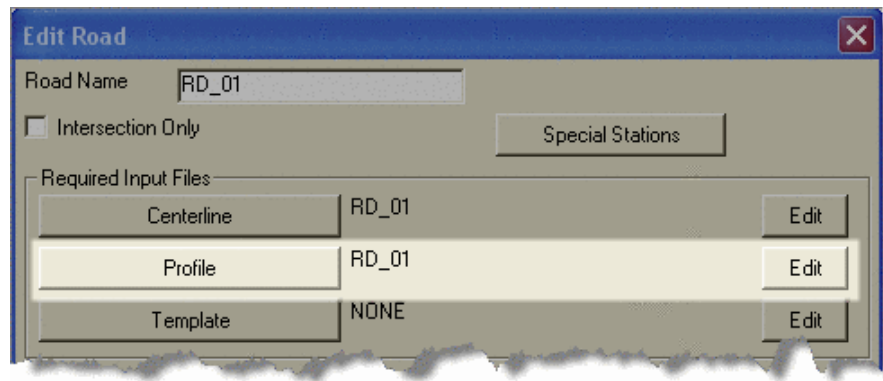

Existing Section File: Pick this button to specify the path and filename for the existing cross-section file to be written. The default filename is set by picking **Output File Defaults** button in the **Output Options** tab of the **Road**

Network Settings dialog box.

Final Section File: Pick this button to specify the path and filename for the final/design cross-section file to be written. The default filename is set by picking **Output File Defaults** button in the **Output Options** tab of the **Road Network Settings** dialog box.

SuperElevation Diagram: Pick this button to specify the path and filename for the SuperElevation Diagram (.SUD) file to be written.

The **Road Profile Editor** is accessible from the **Edit Road** Dialog box.

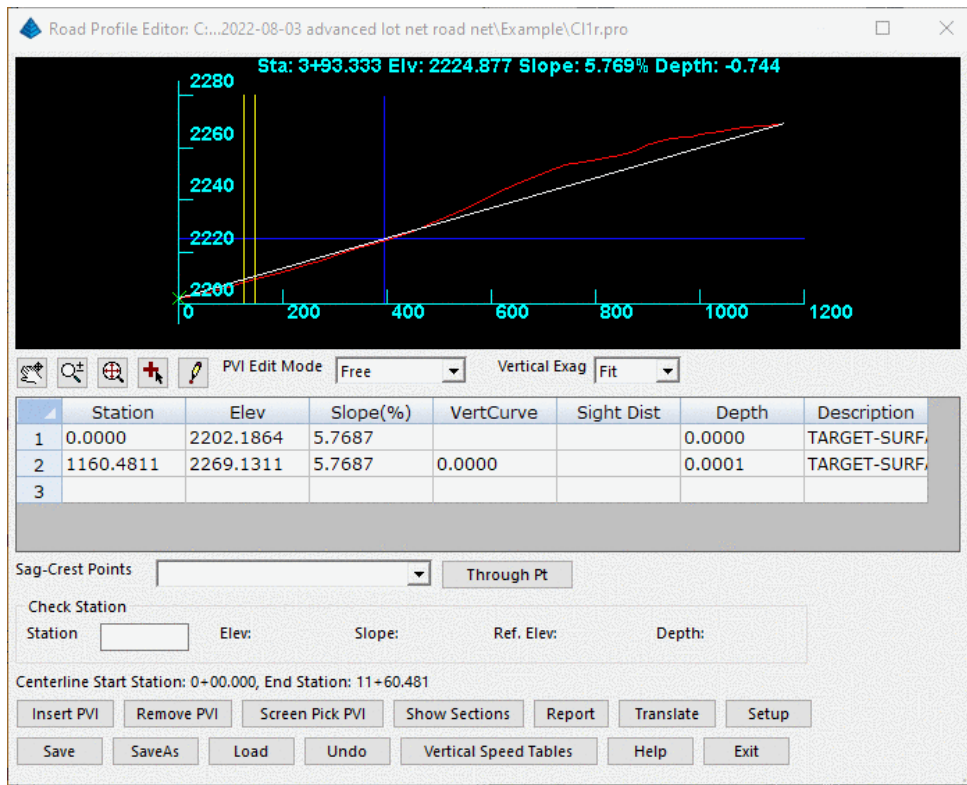

Pick "Edit" to Access the Road Profile Editor

In Carlson's **Road Network** feature, the initial design Profile is automatically generated and has only a starting and ending PVI - with the elevation at both ends tying into existing ground. The crosshairs are locked to the design Profile.

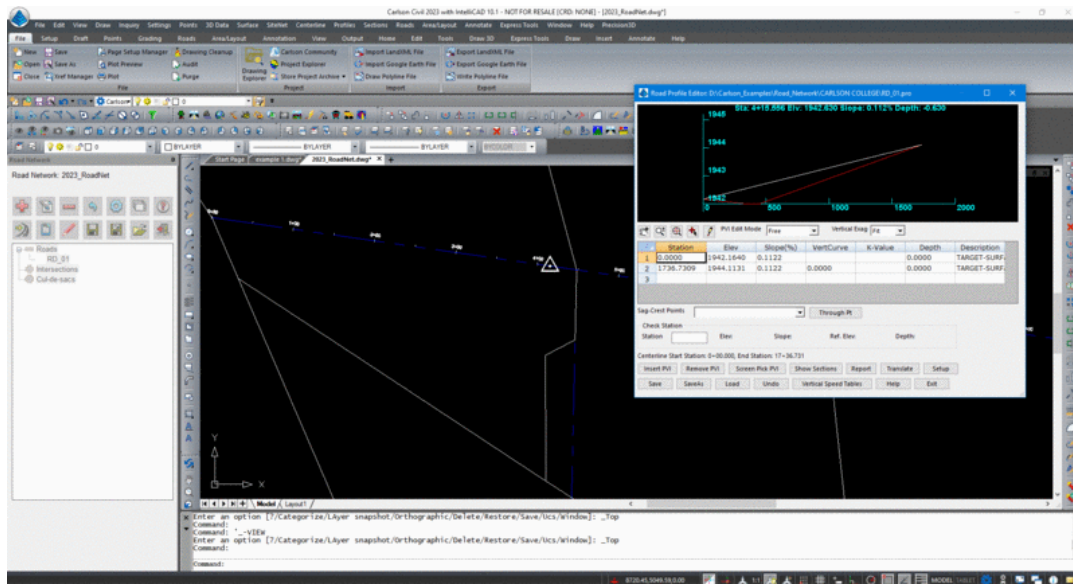

The initial PVIs can be seen in the profile-grid-view where the existing ground Profile is shown in red and the design Profile in white. The initial PVIs are shown in the table-view with the "PVI Description" indicating the PVI elevation is tied to the "TARGET-SURFACE" (existing ground).

The buttons and settings directly below the profile-grid-view allow the user to edit the Profile and adjust the Zoom and Scale factors of the profile-grid-view. The **Insert PVI**, **Remove PVI** and **Screen Pick PVI** buttons at the bottom of the dialog box allow the user to make changes to the Profile using the table-view.

Road Profile Editor

The profile-grid-view provides the user with a dynamic viewer and editor. As the crosshairs move along the design Profile, a "station" symbol on the drawing screen indicates the corresponding position/station along the Centerline. Also, as the crosshairs move along the Profile, the current Station, Elevation, Slope and Depth (between design and existing ground Profiles) are displayed and dynamically updated at the top of the window. The starting and ending stations for the Centerline are displayed above the buttons at the bottom of the window.

Road Profile Editor with Station Indicator in Drawing

Pan, Zoom and Zoom Extents: Use these buttons to change the Zoom factor in the profile-grid-view.

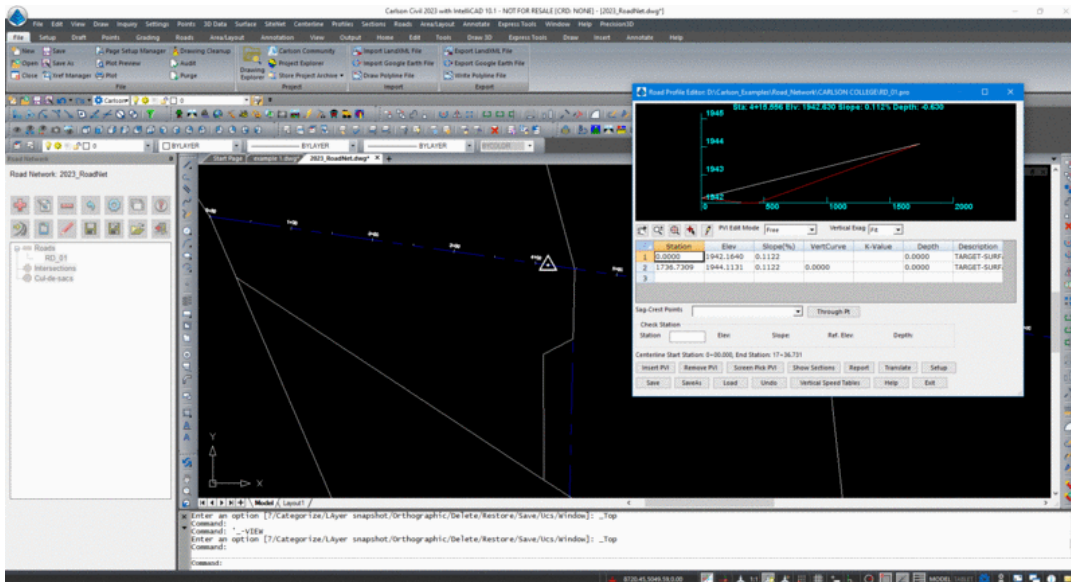

Add PVI: Use this button to "screen pick" the location for a new PVI in the profile-grid-view. After screen picking the new PVI location, the **New PVI** box prompts the user to provide additional design criteria to set the new PVI.

The 'New PVI' dialog box contains the following fields and options:

- Station: 75
- Elevation: 2213.6395
- Slope In (%): 9.5
- Slope Out (%): 100.0
- Vertical Curve: 0.00
- Sight Distance: (empty field)
- Station Resolution Snap: None 1.0 5.0 10.0
- Slope Resolution Snap: None .1 .5 1.0
- Buttons: OK, Cancel, Help

New PVI Dialog Box

Edit PVI and PVI Edit Mode: Use the **Edit PVI** button to change the elevation and station of a PVI in the profile-grid-view by dragging-and-dropping it to a new location. The default **PVI Edit Mode** is "Free" which allows 360-degree motion when dragging-and-dropping the PVI. Other **PVI Edit Mode** options are: **Hold Slope In**, **Hold Slope Out**, **Hold Station** and **Hold Elevation**. The user also can choose to **Hold Vertical Curve Length**, **Hold K-Value** or **Hold Sight Distance** when editing the PVI using drag-and-drop. This setting is controlled in the **Road Profile Settings** dialog box.

Vertical Exag: Use this setting to "Fit" the Profile into the profile-grid-view area of the window or use other pre-defined options such as "x1", "x2", "x5" and "x10" to exaggerate the vertical scale by 1-, 2-, 5- or 10-times.

Sag-Crest Points: After adding one or more vertical curves to the design Profile, a list of the "sag" and "crest" points along the Profile will be listed in the drop-down box.

Through Point: After selecting a PVI in the table-view, pick this button to force a sag or crest point to a specific station and elevation.

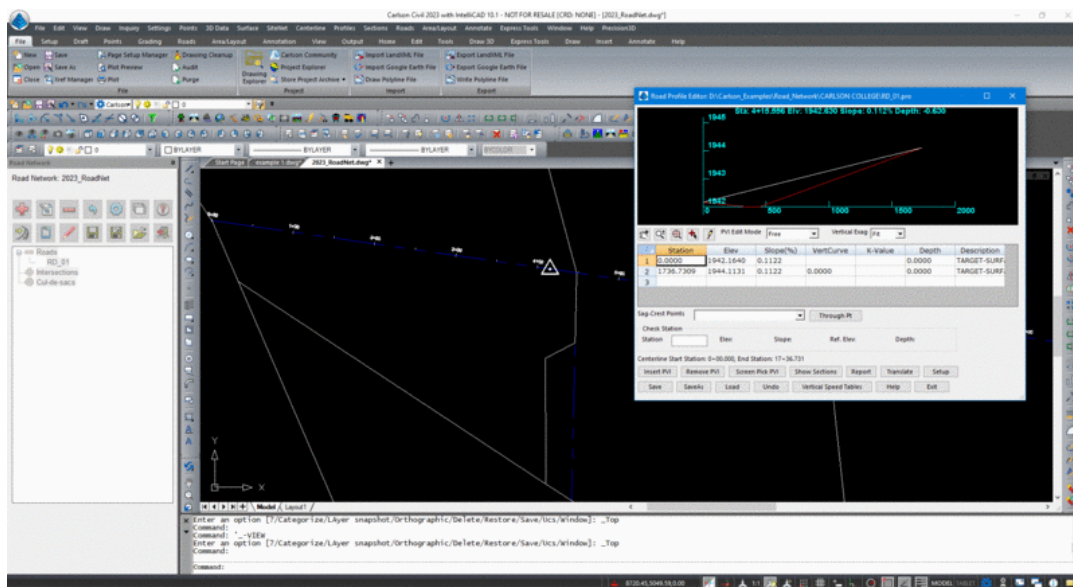

Check Station: To find the precise Elevation, Slope and Reference Elevation (existing ground) for a specific station, enter the station in the text box and *press Enter*.

Insert PVI: Before picking the **Insert PVI** button, the user must use the mouse to select/highlight a cell in the profile table-view. Then, picking the **Insert PVI** button will create a blank row, above the selected row, allowing the user to enter the information for the new PVI.

Remove PVI: Before picking the **Remove PVI** button, the user must use the mouse to select/highlight a cell in the row corresponding to the PVI to be removed. Then, picking the **Remove PVI** button will delete the selected row/PVI from the Profile.

Screen Pick PVI: Picking this button allows the user to change the station of a PVI by screen picking a location in the drawing. Before picking the **Screen Pick PVI** button, the user must use the mouse to select/highlight a cell in the corresponding row of the PVI to be changed. Then, picking the **Screen Pick PVI** button changes the user to the active drawing screen, prompting the user to "Pick PVI Point:" in the drawing area.

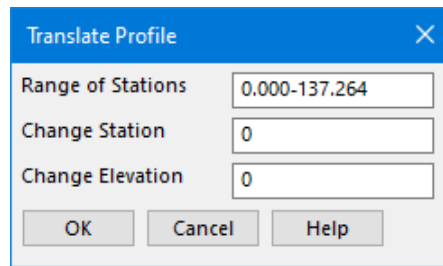

Show Sections: This option is only available if the Template (.TPL) file for the Road has already been specified in the **Edit Roads** dialog box. When picked, the **Show Sections** button will open a "Road Design Section Data" viewer window while keeping the "Road Profile" window open as well. This provides the user a dynamic design environment in which the plan-, profile- and section-views are visible at one time. Additionally, when the "Section" viewer window is open, the notes at the top of the profile-grid-view include the "Cut" and "Fill" end-area at the current station along with the "Cut" and "Fill" volume for the entire Road. These calculations are dynamic and will update if changes are made to the design Profile. Use the Specific Station to check the section at a station. Or move the cursor in the profile preview graphic to change the section station.

style="width: 800px;">

Road Profile View and Section Viewer with Station Indicator in Drawing

Translate: Picking this button will display the **Translate Profile** dialog box and allows the user to change the elevation of the entire Profile or a range of stations along the Profile.

Translate Profile dialog box

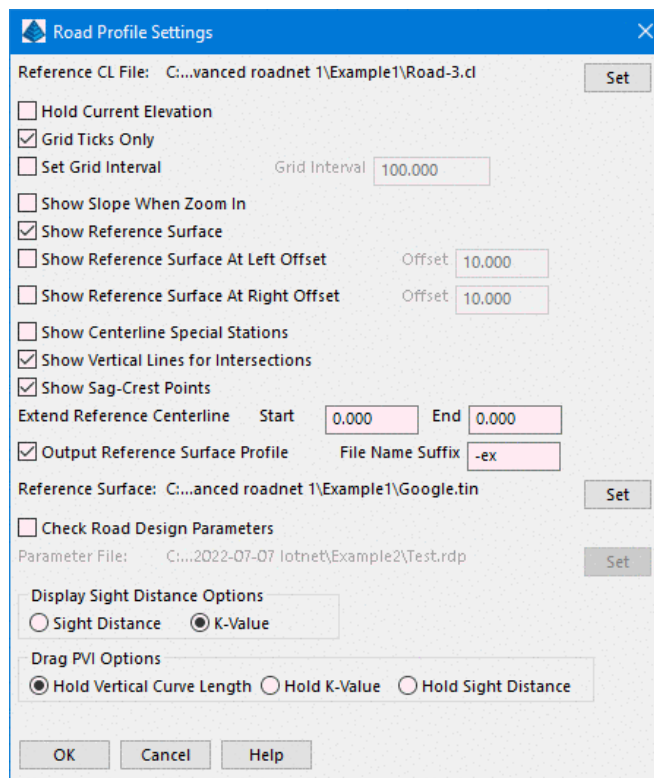

Save: This button saves changes to the Profile (.PRO) file.

Exit: This button exits the **Road Profile Editor** dialog box.

Undo: This button will undo the last change made to the Profile.

Setup: This button opens the **Road Profile Settings** dialog box. See below for more information.

Vertical Speed Tables: Use this button to specify the Vertical Curve Speed Table (.VST) files to use for the design of this Road.

Road Profile Settings Dialog Box

Reference CL File: In the **Road Network** feature, the "Reference CL File" is automatically set to the Centerline (.CL) file associated with the Road.

Hold Current Elevation: When enabled and the station and elevation of a PVI changes, the "Slope Out" of the adjusted PVI will change but the elevation of the next PVI will be left unchanged. Otherwise, if not enabled, the "Slope Out" of the adjusted PVI is held and the elevation of the next PVI is changed.

Grid Ticks Only: When enabled, only grid ticks will be shown in the profile-grid-view. Otherwise grid lines will be used.

Set Grid Interval: If enabled, this option allows the user to manually specify the grid- or grid-tick interval shown in the profile-grid-view.

Show Slope When Zoom In: When enabled, this option allows the user to display the slopes on those vertical

tangents that are long enough to display a slope label when Zoom-ing in closer to the Profile.

Show Reference Surface: When enabled, this option displays the Profile of a "Reference Surface" in addition to the design Profile. The "Reference Surface" is typically the original or existing ground Profile.

Show Reference Surface at Left Offset: When enabled, this option allows the user to see an additional Profile that is offset horizontally from the "Reference Centerline". The offset distance can be specified after the option is enabled.

Show Reference Surface at Right Offset: When enabled, this option allows the user to see an additional Profile that is offset horizontally from the "Reference Centerline". The offset distance can be specified after the option is enabled.

Show Centerline Special Stations: When enabled, critical Centerline stations such as PC, PT, SC, ST, TS and SP are shown in the profile-grid-view.

Show Vertical Lines for Intersections: When enabled, this option will display a vertical line representing the Centerline and Edge of Pavement stations for other Roads in the Road Network.

Show Sag-Crest Points: When enabled, this option displays a marker at the sag and crest points of each vertical curve.

Extend Reference Centerline: When enabled, the user may provide an extended range of stations so as to show Profile data beyond that generated along the associated Centerline (.CL) file. For instance, for a new Road tying into an existing Road (proposed CL file starts at the Intersection of the Centerline of the existing Road) an extended range of stations may be desired in order to see the Profile of the cross-slope, curb, ditch and slope across both sides the existing Road.

Output Reference Surface Profile and Suffix: When enabled, this option will generate an existing ground Profile (.PRO) file and allows the user to specify a suffix for the filename. The defaults for this option are set using the **Output File Defaults** button in the **Output Options** tab of the **Road Network Settings** dialog box.

Reference Surface: The "Reference Surface" is an additional surface Profile shown in the profile-grid-view alongside the design Profile. For the **Road Network** feature, the "Reference Surface" is the surface specified as "Existing Ground" in **Road Network Settings** dialog box.

Check Road Design Parameters: When enabled, this option will compare the current Road design to an established set of design parameters set in a Road Design Parameters (.RDP) file. Please refer to the **Help** files for the **Road Design Parameters** command if additional assistance is needed.

Display Sight Distance Options: Use this radio button to display either a "Sight Distance" or "K-Value" column in the profile-table-view.

Drag PVI Options: Use this radio button to specify the design criteria to "hold" when using the **Edit/Drag PVI** command in the profile-grid-view. The options are to "Hold Vertical Curve Length", "Hold K-Value" or "Hold Sight Distance".

Intersections are created automatically in the **Road Network** feature without any input from the user. Once Intersections are identified, they are listed and managed in the **Intersection** area of the **Road Network: Task Pane**.

Edit: Use this button or right-click on the intersection in the project tree and choose Edit Intersection to display the **Edit Intersection** dialog box and make changes to the **Input Data** and **Output Files** for the selected Intersection. Other changes that can be made to the Intersection design are:

- 1) Changing the Primary/Secondary status of the Roads creating the Intersection,
- 2) Making design changes that apply to the entire Intersection,
- 3) Making design changes that apply to one or more Corners of the Intersection.

Reset: Use this button to overwrite all design changes made to the selected Intersection and reset to the original Intersection design.

As stated above, Intersections are created automatically in the **Road Network** feature without any input from the user. Road Network recognizes and calculates the Intersection using the Centerline (.CL) files associated with the Roads in the Network. If two Roads are added to the Network and they share one or more common point, an Intersection is created and displayed as an Intersection in the **Road Network: Task Pane**.

For all Intersections, one of the two Roads creating the Intersection will be the "Primary" Road and the

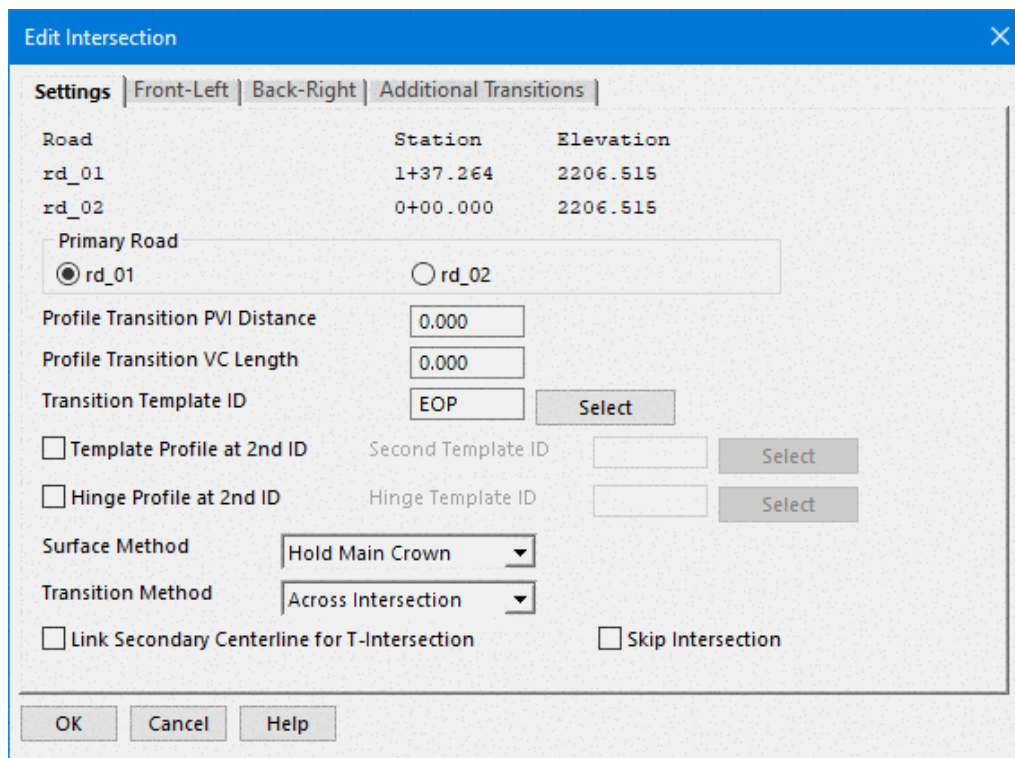

other will be the "Secondary" Road. When setting grade through an Intersection, the Primary Road's Template (.TPL) file takes priority and is used to define the cross-section. The grades of the Secondary Road will adjust to match the Primary Road. Additionally, changes to any of the Primary Road design files - such as the Profile (.PRO) file - will automatically update the affected file(s) of the Secondary Road.

Upon creation of an Intersection, the **Road Network** feature automatically designates one of the Roads as the Primary Road and the other as Secondary. For four-way Intersections, the first Road added to the Road Network will be deemed the Primary Road and the second Road will be Secondary. For T-Intersections, the Road going straight-through the Intersection will be deemed the Primary Road - even if it's added to the Network after the Road that stops at the Intersection. The user can change the Primary Road designation in the **Edit Intersection** dialog box.

Picking the **Edit** button displays the **Edit Intersection** dialog box which has a **Settings** tab and, depending on the type of Intersection, 2 or 4 additional tabs - each representing one **Corner** of the Intersection. The **Corner** tabs are labeled *Front-Right*, *Back-Right*, *Front-Left* or *Back Left*. T-Intersections will have 2 tabs and 4-way Intersections will have 4 tabs.

Intersection Settings

At the top of the **Settings** tab, the station and elevation of the Intersection is shown for all Roads.

The screenshot shows the 'Edit Intersection' dialog box with the 'Settings' tab selected. The dialog has a blue title bar with a close button (X) in the top right corner. Below the title bar, there are four tabs: 'Settings', 'Front-Left', 'Back-Right', and 'Additional Transitions'. The 'Settings' tab is active and contains the following controls:

Road	Station	Elevation
rd_01	1+37.264	2206.515
rd_02	0+00.000	2206.515

Below the table, there are two radio buttons for 'Primary Road': rd_01 and rd_02.

Other settings include:

- Profile Transition PVI Distance:
- Profile Transition VC Length:
- Transition Template ID:
- Template Profile at 2nd ID: Second Template ID
- Hinge Profile at 2nd ID: Hinge Template ID
- Surface Method:
- Transition Method:
- Link Secondary Centerline for T-Intersection
- Skip Intersection

At the bottom of the dialog are three buttons: , , and .

The Settings Tab of the Edit Intersection Dialog Box

Primary Road: Use the radio button to specify the Primary Road of the Intersection.

Profile Transition PVI Distance: This value represents the distance beyond the edge of pavement of the Primary Road (along the Secondary Road Centerline) that the cross-slope of the Primary Road will be extended.

Profile Transition VC Length: This setting allows the user to specify the length of vertical curve to be inserted at the PVI where the extension of the Primary Road's cross-slope and the Centerline of the Secondary Road meet.

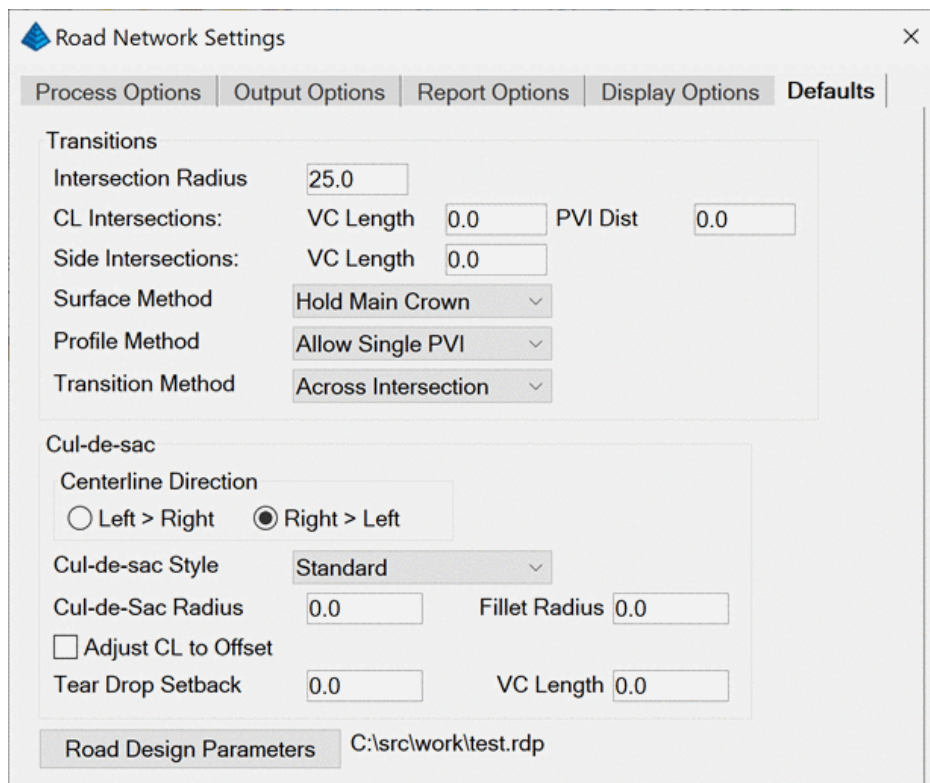

"Profile Transition PVI Distance" and "Profile Transition VC Length"

Template ID: This is the point on the cross-section used to define the horizontal (Centerline) and vertical (Profile) alignments around the Corners of the Intersection. Also, the profile for the side road will tie into this Template ID on the main road. The Template ID may be specified as any point on the cross-section - such as edge of pavement (EP) or the back of curb (BC) - as long as it has been defined as a **Template ID** in all of the Template (.TPL) files used to calculate the Intersection. Type the **Template ID** in the text box or use the **Select** button to choose from a list.

Template Profile at 2nd ID: This option sets the template ID for an additional template ID to control in the curb return besides the main ID. When this option is active, each curb return has a button to edit the template point profile for this additional ID. This option applies when the template is transitioning across the intersection on a grade ID besides the main ID.

Hinge Profile and 2nd ID: For the side road profile, this is an optional second point to match from the main road template.

Cross-section of main road showing side (alley) profile tying into single Template ID at flow line

Cross-section of main road showing side (alley) profile tying into Template ID at flow line as well as 2nd Hinge at Right-of-way of main road

Surface Method: See the Transition Defaults section above for details on this setting.

Transition Method: See the Transition Defaults section above for details on this setting.

Link Secondary Centerline for T-Intersection: When this option is enabled, changes to the Centerline (.CL) file of the Primary Road will, if necessary, force the Centerline of the Secondary Road to be extended or trimmed in order to keep the Intersection intact.

Skip Intersection: This option skips creating the curb returns for this intersection. This option applies for crossings like an overpass or railroad.

Note: The default value for several design criteria such as Intersection radius and length of vertical curve can be set in the **Transition Defaults** tab of the **Road Network: Settings** dialog box.

Corner tabs - *Front-Right, Back-Right, Front-Left, Back-Left*

Depending on the type of Intersection ("T" or 4-way), there will be either 2 or 4 additional tabs available in this dialog box. Each of these tabs represent a Corner of the Intersection and allows the user to specify horizontal and vertical **Input Data** and **Output Files** specifically for that Corner.

The screenshot shows the 'Edit Intersection' dialog box with the 'Front-Left' tab selected. The 'Input Data' section includes a 'Radius' field set to 25, a checked 'Tie To Existing' checkbox, an 'Edit Profile' button, a 'Reset' button, a 'VC Length' field set to 0.000, and an 'Edit 2nd Profile' button. Below this is an 'Edit Template Transition' button, a 'Profile Method' dropdown menu set to 'Allow Single PVI', a 'Template Grade Table' button, and the text 'NONE'. An 'Edit' button is located to the right of the 'Template Grade Table' section. The 'Output Files' section contains five rows, each with a button and the text 'NONE': 'Centerline', 'Profile', 'Existing Section File', 'Rock Section File', and 'Final Section File'. At the bottom of the dialog are 'OK', 'Cancel', and 'Help' buttons.

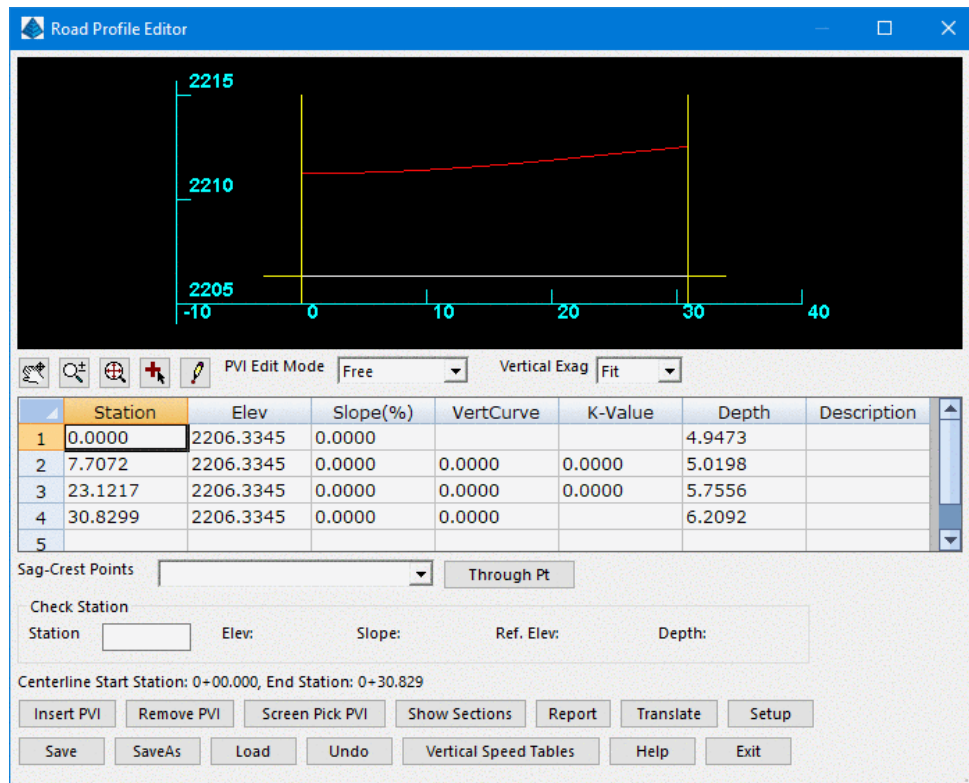

One of the "Corner" Tabs of the Edit Intersection Dialog Box

Intersection Input Data

Radius: Use this value to specify the radius of the curve for this Corner of the Intersection. The **Intersection Template ID** specified in the **Intersection Settings** tab of this dialog box determines the point on the cross-section being affected by this setting.

Tie to Existing: Enable this option to keep cut and fill slopes from projecting to the existing ground through the Intersection. In areas of steep cut or fill, this setting helps avoid overlapping Road and Intersection tie slopes.

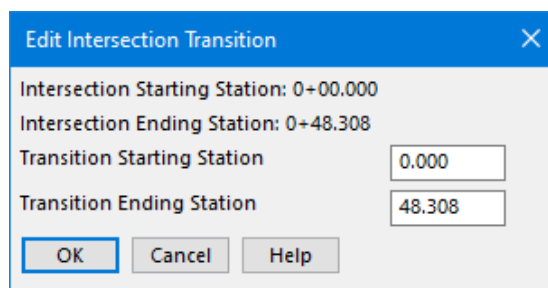

Edit Profile: Pick this button to open the **Road Profile Editor** and make changes to the Profile for this Corner of the Intersection. The **Intersection Template ID** specified in the **Intersection Settings** tab of this dialog box determines the point on the cross-section being represented in the Profile Editor. See **Road Network: Road Profile Editor** for more **Help** with this feature.

Edit Profile for a Corner of an Intersection

Reset: Use this button to overwrite all edits to the Profile of the Corner of the Intersection and reset to the original Profile.

Edit Template Transition: Pick this button to display the **Edit Intersection Transition** dialog box. This allows the user to control the stations for transitioning through the Intersection from a Template on one Road to a different Template on another Road. These Transition stations only apply when the Roads in an Intersection have been assigned different Template (.TPL) files.

Edit Intersection Transition Dialog Box

In the Intersection Transition Dialog Box... The Starting and Ending Stations of the Intersection transition are displayed at the top of the dialog box.

Transition Starting Station: This is the station at which the Primary Road Template ends.

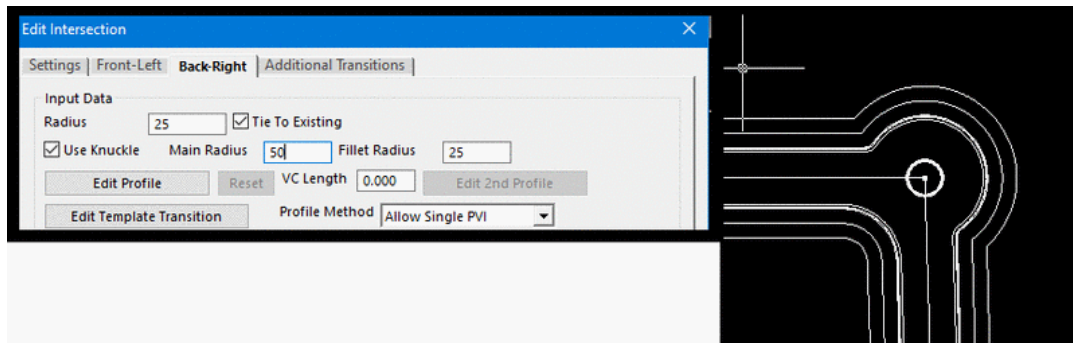

Transition Ending Station: This is the station at which the Secondary Road starts.

Profile Method: When the difference in grade at the Intersection between the Primary Road and the Secondary Road is too severe, two intermediate PVI's must be inserted into the Profile of the Corner of the Intersection in order to properly transition from one Road to another. In some cases, the transition is possible using only one

intermediate PVI in the Corner Profile. **Allow Single VC:** If this option is enabled and if the intersecting grades allow it, only one intermediate PVI will be inserted. **PVIs for Grades In/Out:** If this option is enabled, two intermediate PVIs will be inserted regardless of the intersecting grades. **No Automatic PVI:** This method make the program skip creating any PVI and the default profile will directly connect the starting and ending points of the profile.

Template Grade Table: Pick this button to select an existing or create a new Template Grade Table (.TGT) file defining the grades for the Corner of the Intersection. This file allows the user to define specific slopes and distances for one or more **Template IDs** that have been assigned in the Template (.TPL) file. The **Edit** button opens the **Template Grade Table Editor**. This Editor is the same as the one used for the **Template Grade Table** command. Please refer to the **Help** files for that command if additional assistance is needed.

"L" Intersection with Knuckle: When two centerlines connect at a right angle for an "L" intersection, there is a **Use Knuckle** option for the outside corner that can be used to make a knuckle bulb.

Intersection Output Files

Centerline: Pick this button to output a Centerline (.CL) file representing the horizontal alignment around this Corner of the Intersection. The **Intersection Template ID** specified in the **Intersection Settings** tab determines the point on the cross-section exported to the Centerline (.CL) file.

Profile: Pick this button to output a Profile (.PRO) file representing the vertical alignment around this Corner of the Intersection. The **Intersection Template ID** specified in the **Intersection Settings** tab determines the point on the cross-section exported to the Profile (.PRO) file.

Existing Section File: Pick this button to output an Existing Section (.SCT) file for this Corner of the Intersection.

Final Section File: Pick this button to output a Final Section (.SCT) file for this Corner of the Intersection.

Additional Transitions tab

Additional Profile Transition Distance: This option adjusts the transition PVI station on the side profile. The transition station starts as the offset of the Template ID on the main road. The cross slope of the main road is used up to the transition station. For example, if the Template ID is for edge of pavement up to the gutter pan at 11.67 and the side profile needs to match the main crown up the flow line at 13.00, then the Additional Transition Distance should be set to 1.33.
